UNIFIED FACILITIES CRITERIA (UFC)

WATER STORAGE AND DISTRIBUTION

UNIFIED FACILITIES CRITERIA (UFC)

WATER STORAGE AND DISTRIBUTION

U.S. ARMY CORPS OF ENGINEERS

NAVAL FACILITIES ENGINEERING COMMAND (Preparing Activity)

AIR FORCE CIVIL ENGINEER SUPPORT AGENCY

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	1 Oct. 2018	1. Updated reference to OEBGD in paragraph 1-3.2. 2. Added the word requirements in paragraph 2.1.1.1. 3. Updated UFC reference in paragraph 4-1.7.3. 4. Updated paragraph numbering in B-3.1.1. 5. Deleted the reference to the 10 State Standards in Appendix B.
2	1 May 2020	1. Updated paragraphs 5-3 and 5-3.6 to coordinate with revision of UFC 3-240-01. 2. Updated reference to UFC 1-200-01, DoD Building Code in paragraph 1-3.1. 3. Revised finished water storage criteria in paragraph 4-1.1 and 4-1.3. Added paragraph 4-1.2 for additional storage volume criteria to address a criteria change request in reference to overseas criteria. 4. Revised criteria for water distribution systems with a separate fire protection system in paragraphs 5-3.2.1, 5-3.5.2, 5-4.1, 5-5, and 5-5.3 to address a criteria change request in reference to water distribution systems without fire demand. 5. Added paragraphs 5-3.5.1.1, 5-3.5.1.2, 5-4.1.1, 5-4.1.2, 5-5.1, 5-5.2, and 5-5.3.1 to address a criteria change request in reference to water distribution systems without fire demand. 6. Revised fire protection criteria in paragraph 5-3.4 and used Designated Fire Protection Engineer. 7. Updated references in Appendix A.
3	1 July 2021	1. Updated CNICINST 5090.1A to CNICINST 5090.1B

		on the revision summary sheet, in paragraph 2-1.1.2 and Appendix A. 2. Revised pump redundancy requirements in paragraphs 3-3.1, 3-3.2 and 3-3.3. 3. Added equivalent in front of host nation standard in paragraphs 4-1.6, 4-1.7, 4-1.8, 4-1.8.1 and 5-2. 4. Revised separation distances in section 5-8. 5. Modified thrust restraint requirement in paragraph 5-7.4.

This UFC supersedes UFC 3-230-01 dated November 2012.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Title: UFC 3-230-01, *Water Storage and Distribution*

Superseding: UFC 3-230-1, Change 2, *Water Storage, Distribution and Transmission*.

Description: This revision provides updated technical content and includes the adoption of additional industry standards. It also addresses design order of precedence, cybersecurity, advanced metering, direct digital controls, and several criteria change requests.

Reasons for Document:

- This revised UFC provides requirements for the design of water distribution systems. It includes piping, storage and pumping requirements.
- Coordinates fire protection engineering, advanced meeting, direct digital controls and cybersecurity requirements.
- Establishes a design order of precedence for both foreign projects and projects in the United States.

Impact:

- This revision will have minimal impacts on design cost.

Unification Issues: This UFC includes Navy only requirements for overseas drinking water requirements in accordance with \3\ CNICINST 5090.1B /3/. This UFC also includes Navy only requirements for airfield lighting and marking requirements for water towers and other similar structures in NAVAIR 51-50AAA-2.

TABLE OF CONTENTS

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) provides requirements for typical storage, distribution systems for domestic water, fire protection and non-potable water for the Department of Defense (DoD). These minimum technical requirements are based on UFC 1-200-01. Where other statutory or regulatory requirements are referenced in the contract, the more stringent requirement must be met.

1-2 APPLICABILITY.

This UFC applies to service elements and contractors involved in the planning, design and construction of permanent DoD facilities worldwide. It is applicable to all methods of project delivery and levels of construction.

1-3 OTHER CRITERIA.

1-3.1 General Building Requirements.

Comply with UFC 1-200-01, DoD Building Code \2\ /2/. UFC 1-200-01 provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, physical security, cybersecurity, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFC and government criteria referenced therein.

1-3.2 Foreign Countries.

DoD 4715.05-G, Overseas Environmental Baseline Guidance Document \1\(OEBGD)/1/ applies when there are no FGSs in place. Therefore, in foreign countries this UFC will be used for DoD projects to the extent that it is allowed by and does not conflict with the applicable international agreements and the applicable FGS or OEBGD.

1-3.3 Safety.

All DoD facilities must comply with DoDI 6055.01 and applicable Occupational Safety and Health Administration (OSHA) safety and health standards.

The Designer of Record (DoR) must follow the concepts from ASSE Z590.3. By applying the concepts in ASSE Z590.3 occupational hazards and risks related to work premises, tools, equipment, machinery, substances, and work processes including their construction, use, maintenance, and ultimate disposal or reuse can be reduced. This standard also provides guidance for a life-cycle assessment and design model that balances environmental and occupational safety and health goals over the life span of a facility, process, or product.

1-3.4 Antiterrorism and Security.

Security must be an integral part of drinking water system design. Facility layout must consider critical system assets and the physical security of these assets. Planners, engineers, security and antiterrorism personnel must determine site specific threats to develop the antiterrorism and security protective measures for water storage and distribution systems. Use UFC 4-020-01 to establish protective measures for water storage and distribution systems. The engineering risk analysis, conducted as part of UFC 4-020-01, should be consistent with the terrorism risk analysis conducted by installation security or antiterrorism staff.

Refer to Best Practice documents, *Policy Statement On Infrastructure Security for Public Water Supplies*, found in the Policy Statements section of *Recommended Standards for Water Works* and ASCE 56-10/57-10, for guidelines on the protection of water utility systems.

1-3.5 Cybersecurity.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

Cybersecurity is implemented to mitigate vulnerabilities to all DoD real property facility-related control systems to a level that is acceptable to the System Owner and Authorizing Official. UFC 4-010-06 provides requirements for integrating cybersecurity into the design and construction of control systems.

1-3.6 Plumbing.

UFC 3-420-01 is a Core UFC which cites the use of the International Plumbing Code (IPC). Where the requirements in this UFC or UFGS 33 11 00 conflict with exterior plumbing components in the IPC use the requirements in this UFC or UFGS 33 11 00. Where the IPC will be used to provide the minimum requirement, the DoR must submit a list of the conflicts and proposed solutions to the Government Project Manager for review and approval prior to completing design.

1-4 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

1-5 BEST PRACTICES.

Appendix B identifies background information and practices for accomplishing certain water supply design and engineering services. The DoR is expected to review and interpret this guidance as it conforms to criteria and contract requirements, and apply the information according to the needs of the project. If a Best Practices document has guidelines or requirements that differ from the Unified Facilities Guide Specifications (UFGS) or UFC, the UFGS and the UFC must prevail. If a Best Practices document has guidelines or requirements that are not discussed in the Unified Facilities Guide specification (UFGS) or UFC, the DoR must submit a list of the guidelines or requirements being used for the project with sufficient documentation to the Government Project Manager for review and approval prior to completing design.

This Page Intentionally Left Blank

CHAPTER 2 GENERAL DESIGN REQUIREMENTS

2-1 DESIGN.

Use UFC 3-201-01 for topics such as surveying, site development, grading and storm drainage systems.

2-1.1 Design Criteria.

Design water supply systems to meet the potable water regulations and requirements of applicable federal, state and local government agencies or overseas equivalent.

2-1.1.1 Within The United States.

For projects located in the United States and its territories and possessions design the water supply system in accordance with the following criteria precedence:

1. State waterworks regulations or local regulations for the project location.
2. Utility provider's \1\requirements/1/.
3. *Recommended Standards for Water Works* (also known as the Ten State Standards) as noted herein.
4. Energy and sustainability: Use UFC 1-200-02.
5. Exceptions or additions to the above criteria as indicated in this UFC.
6. Refer to references in Appendix B for design guidance.

2-1.1.2 Foreign Countries.

For projects located outside of the United States and its territories and possessions design the water supply system in accordance with the following criteria precedence:

1. The Forward of this UFC (All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.)).
2. Final Governing Standards.
3. "DoD 4715.05-G, Overseas Environmental Baseline Guidance Document.
4. Navy Only: \3\ CNICINST 5090.1B /3/.
5. Utility provider's requirements.
6. Recommended Standards for Water Works, (also known as the Ten State Standards) as noted herein.

7. Energy and sustainability: Use UFC 1 200-02.

8. Exceptions or additions to the above criteria as indicated in this UFC.

9. Refer to references in Appendix B for design guidance.

2-1.2 Design Approval.

The DoR must identify, assist, and provide, as applicable, all permits, approvals, and fees required for the design and construction of the new project from Federal, state and local regulatory authorities or overseas equivalent. The Civil Engineering DoR must be a Professional Civil Engineer experienced and licensed. Licensure in the location of the project may be required to obtain permits and approvals. For new potable water supply systems, extensions to new areas, rehabilitation, or replacement of existing potable water supply systems, coordinate with the Safe Drinking Water Act primacy agency, as applicable, to determine primacy agency requirements. In the United States and its territories and possessions the Government will review permits for acceptability. In locations outside of the United States and its territories and possessions with Host nation agreements, follow permit approval procedure as directed in project scope and by the Government Project Manager. In locations outside of the United States and its territories and possessions without Host nation agreements, the Government will review and approve plans for compliance.

Consult with the Government Project Manager to determine the appropriate signatories for permit applications.

2-1.3 Planning for Non-War Emergencies.

Refer to Best Practices document AWWA M19, for non-war emergencies such as earthquakes, hurricanes, tornadoes, floods and vandalism.

2-2 PRELIMINARY SITE ANALYSIS.

Use UFC 3-201-01 for preliminary site analysis.

2-2.1 New Service Areas.

Utilize Installation's existing utility maps and planning documents to develop new service areas for present and future (minimum 5 year) conditions. Where adequate planning documents are not available, estimate future growth as described in UFC 3-230-03, Chapter titled *System Sources and Flows*.

2-2.2 Existing Conditions.

Use UFC 3-201-01 for geotechnical site investigation, surveying, and topographic surveying.

2-2.2.1 Geotechnical Site Investigation –Soil Corrosivity.

Require geotechnical evaluation for soil corrosivity when existing operating records, visual observations, inspections or testing indicate a need for corrosion control. Provide an evaluation of existing soils at the proposed depths and locations of the water piping in accordance with AWWA M27, Chapter titled *Evaluating the Potential for Corrosion* and provide recommendations on materials and positive corrosion protection systems.

2-3 SYSTEM SOURCES AND FLOWS.

Use UFC 3-230-03, Chapter titled *System Sources and Flows*.

This Page Intentionally Left Blank

CHAPTER 3 PUMPING FACILITIES

3-1 GENERAL.

Design pumping facilities in accordance with Chapter 2, paragraph titled *Design Criteria* and use *Recommended Standards for Water Works,* Chapter titled *Pumping Facilities*.

3-2 PUMPING STATIONS.

Pumps, piping and equipment must be protected from the weather. In cold climates pumps and piping must be protected from freezing temperatures. The pump station building must comply with 1-200-01, be constructed of noncombustible materials and meet applicable building standoff distances. Building layouts must be designed to accommodate the installation of new equipment, maintenance and future expansion. Equipment layouts must provide vertical and horizontal clearances for the repair or replacement of equipment without interrupting pump station operation. Provide personnel access and equipment access for maintenance and repair operations. Ensure pumping stations and equipment are easily accessible and not located in an OSHA defined permit required confined space. Provide a minimum of one double leaf door with a width of 6 feet (1.8 m) for maintenance and repair operations. Access points must be lockable and meet Installation security requirements. Use Best Practice document, Pumping Station Design for guidance on designing pump stations.

3-3 PUMPS.

Select pumps to supply varying demands and meet pressure requirements based on a hydraulic analysis. Pumps must be capable of providing the varying demands and minimum pressures for the full range of system flows. Investigate surge potential for all pumps. When investigation indicates the potential for flows or velocities that increase surge potential provide a surge analysis. A surge analysis is required for large pump stations (i.e., flows greater than 3,200 gpm (202 L/s).

3-3.1 Redundancy.

Provide a minimum of two pumps at each pump station. \3\ Pumping capacity must be able to discharge the peak flow with the largest pump out of service. /3/

3-3.2 Pumps With Elevated Storage.

Pumps for water storage are selected to meet the average day demand, maximum day demand and maximum day demand plus partial fire flow demand (i.e., fire flow demand not delivered by storage) as need to equalize system pressures. \3\ /3/

3-3.3 Pumps Without Storage.

Pumps are selected to meet flow, pressure, and efficiency requirements. Pumps must accommodate the maximum daily demand, the peak hourly rate plus fire flow demand, and the estimated minimum hourly rate. The location and required capacity of a water pumping system must be determined by a hydraulic analysis of the distribution system. \3\ /3/

3-3.4 Pump Drives.

The factors affecting selection of the type of power used to drive potable water pumps include dependability, availability and economic considerations. Provide emergency power operation, such as a dedicated standby emergency generator or a portable generator, in conformance with applicable regulatory and utility provider requirements.

3-3.5 Motor Capacity.

Motors must be selected with sufficient capacity to drive the pump under service required and to be non-overloading over the entire impeller curve without motor overload or failure. Provide motors in accordance with NEMA MG1 and NEMA MG2.

3-4 APPURTENANCES.

3-4.1 Controls.

Remote monitoring and control systems must meet the Installation's Information Technology security requirements and standards and UFC 4-010-06.

3-5 FIRE PUMPS.

Use UFC 3-600-01 paragraph titled *Fire Pumps*.

CHAPTER 4 FINISHED WATER STORAGE

4-1 GENERAL.

Design finished water storage in accordance with Chapter 2, paragraph titled *Design Criteria* and use *Recommended Standards for Water Works,* Chapter titled *Finished Water Storage*.

4-1.1 \2\ Objectives.

Finished water storage serves the following objectives:

- Supplies water required to meet demands in excess of production or delivery capabilities and equalize flow in water distribution piping;
- Helps maintain the design flow and system pressure in the distribution system;
- Eliminates interruptions caused by power outages; or
- Decreases or eliminates interruptions during water main repairs.

4-1.2 Storage Volume.

Finished water storage is a combination of treatment plant storage, equalization storage, fire demand storage, and emergency storage. Design finished water storage to provide the full range of domestic, industrial, fire, and emergency demands. The design must allow draining the storage facility for cleaning or maintenance without causing a loss of pressure in the system.

In addition to treatment plant storage, provide additional water storage when:

- The water distribution system relies on a single water supply source to maintain design flow and system pressure; or
- The water distribution system cannot maintain the design flow and system pressure.

Use UFC 3-230-03 to determine the minimum *Design Flow.*

Exceptions:

- When the water distribution system is served by more than one finished water storage source and upgrades to the distribution system are capable of providing the design flow and system pressure, additional water storage is not required;
- When design flow and system pressure can be maintained for all demands except fire demand and fire water storage is provided in accordance with UFC 3-600-01; or

- When design flow and system pressure can be maintained for all demands except fire demand and a separate fire water storage and distribution system is provided in accordance with UFC 3-600-01.

4-1.3 Sizing.

Water storage volume must be capable of providing the full range of domestic, industrial, fire, and emergency demands and reduces water usage to maintain drinking water quality. At a minimum, the volume of water storage required is the sum of the average total daily domestic requirements, plus any industrial demand that cannot be reduced during a fire period, and the required fire demand. Use a hydraulic analysis to determine the optimum number and size of finished water storage reservoirs. /2/

Compute fire demand in accordance with UFC 3-600-01.

4-1.4 System Storage.

Calculate water storage capacities based on the full operating levels of the water storage structure as measured to highest design water elevation of the system. The highest design water elevation of the system may not necessarily equal the effective volume available to the water system. Effective storage volume is equal to the total volume less any dead storage built into the system. For example, part of the system's capacity is typically designed as dead storage. Below this water surface elevation, the pressure delivered to the water distribution system falls below minimum pressure requirements. If a water system's source cannot deliver a design flow rate above a certain water surface elevation within the tank, this upper volume of the tank is considered unavailable to the water system and is not a part of the water storage volume.

Additional guidance to water storage may be found in Best Practices documents, AWWA *OPFLOW* and *Hydraulic Design of Water Distribution Storage Tanks*. These alternative approaches may be used if the water storage provided is greater than the minimum storage requirement. The storage required may be adjusted in accordance with UFC 3-600-01, Section titled *Facility On-Site Water Storage*.

4-1.5 Location of Reservoirs.

During the planning and preliminary design process determine the optimum location and type of storage. Use a hydraulic analysis to assist in determining the best type of storage reservoir and location for each system to ensure flow, pressure and water quality. Locate storage tanks to allow space for the types of vehicles and equipment required to operate and maintain the system.

Design of structures must be in accordance with UFC-3-220-01 and UFC 3-301-01.

4-1.5.1 Underground Storage Tanks.

Use elevated or above ground tanks before considering underground storage tanks. Underground storage tanks are the least preferred design option because of the high cost and limited technical advantages. Consider using underground storage tanks when:

- Elevated storage or above ground storage are impracticable.
- Where economy of construction result, such as, when architectural considerations make an aboveground tank very costly.
- Where protection against freezing is required.
- Where the area above the underground tank is to be utilized (e.g., a pedestrian plaza or park area).
- Where the hydraulic grade at a tank site requires the tank to be below grade.
- Where protection against sabotage and destruction warrant concealment.

4-1.6 Construction Materials.

Use materials for water storage structures that protect the quality of the stored water. For potable water storage select materials in accordance with Unified Facilities Guide Specifications, AWWA Standards and NSF 61 or \3\ equivalent /3/ host nation standard.

4-1.6.1 Concrete Tanks.

Provide concrete water tanks in accordance with AWWA D110, or AWWA D115.

4-1.6.2 Steel Tanks.

Provide steel tanks in accordance with AWWA D100 or AWWA D103.

4-1.6.3 Composite Tanks.

Provide elevated composite tanks in accordance with AWWA D107.

4-1.7 Freezing.

Equipment used for freeze protection that will come into contact with the potable water must meet NSF 61 or \3\ equivalent /3/ host nation standard.

4-1.8 Painting and Cathodic Protection.

Use paint systems that meet NSF 61 or \3\ equivalent /3/ host nation standard.

4-1.8.1 Interior Coatings.

Use AWWA D102 and AWWA M42 as applicable. Consult with local and state Health Departments or Host nation for lists of approved interior coating systems. Interior coating systems must comply with NSF 61 or \3\ equivalent /3/ host nation standard.

Use Best Practices document *Coatings for Potable Water Tank Interiors* by the Steel Structures Painting Council for design guidance.

4-1.8.2 Exterior Coatings.

Use AWWA D102, AWWA D103, AWWA M27 Chapter titled *Corrosion Control of Water Storage Tanks* and AWWA M42 as applicable.

4-1.8.3 Cathodic Protection.

Provide cathodic protection for all steel tanks and tanks containing structural steel components. \1\Use UFC 3-570-01 and AWWA D106 for a sacrificial anode cathodic protection systems. Use UFC 3-570-01 and AWWA D104 for an impressed current systems./1/

4-1.9 Disinfection.

Use AWWA C652 for disinfection requirements.

4-2 DISTRIBUTION SYSTEM STORAGE.

Remote monitoring and control systems must meet the Installation’s Information Technology security requirements and standards.

Instrumentation and control in foreign countries may have unique requirements. Coordinate with the Installation’s utility personnel to identify unique Installation practices or control requirements.

4-2.1 Drainage.

Design tank drainage area to minimize soil erosion when draining the tank for operations or maintenance.

4-2.2 Level Controls.

Provide instrumentation to monitor and control water storage volumes in the water system. Sequence pump operation (start and stop) controls to minimize water hammer. Use altitude valves or equivalent level controls to control water levels. Pump controls must be automated and turned on and off in response to signals corresponding to pressure or water levels in storage tanks. Use high and low level sensing switches corresponding to water levels in storage tanks for pump controls and alarm status monitoring. Select a level control system which allows pumps to accomplish the hydraulic requirements of the system but does not include additional control features that are not necessary for operation and monitoring.

Control and monitoring systems must have the capability to provide the range of flow rates, pressures and liquid levels. Select a control and monitoring system that will provide protection from pump and piping system damage and to serve as a tool to find system problems which may need operational adjustment, repair or maintenance.

4-2.2.1 Remote Monitoring.

Provide remote monitoring equipment for pump alarm conditions. Remote monitoring equipment must be able to relay power failure, pump failure (seal failure and start failure), and generator start failure at minimum. Remote monitoring equipment must transmit storage levels and alarms to a location where qualified personnel are available for surveillance on a 24-hour basis. A paging system may be used in locations where no 24-hour manning location exists.

4-2.2.2 Alarms.

Alarms must include high level, low level, and pump malfunctions. Provide for remote monitoring, such as telemetry, in conformance with applicable regulatory and utility provider requirements. If required, provide off site operation capability from a central location.

4-3 AIRFIELD REQUIREMENTS.

Comply with 14 CFR Part 77.

4-3.1 Airfield Notification.

Provide Federal Aviation Administration (FAA) notification in accordance with 14 CFR Part 77.9.

14 CFR Part 77.9 (February 1, 2018) provides the following notification requirements:

> If requested by the FAA, or if you propose any of the following types of construction or alteration, you must file notice with the FAA of:
>
> a) Any construction or alteration exceeding 200 feet above ground level at its site.
>
> b) Any construction or alteration that exceeds an imaginary surface extending outward and upward at any of the following slopes:
>
> (1) 100 to 1 for a horizontal distance of 20,000 ft. from the nearest point of the nearest runway of each airport described in 14 CFR 77.9 paragraph (d) of this section with its longest runway more than 3,200 ft. in actual length, excluding heliports.
>
> (2) 50 to 1 for a horizontal distance of 10,000 ft. from the nearest point of the nearest runway of each airport described in 14 CFR 77.9 paragraph (d) of this section with its longest runway no more than 3,200 ft. in actual length, excluding heliports.
>
> (3) 25 to 1 for a horizontal distance of 5,000 ft. from the nearest point of the nearest landing and takeoff area of each heliport described in paragraph (d) of this section.

c) Any highway, railroad, or other traverse way for mobile objects, of a height which, if adjusted upward 17 feet (5.2 m) for an Interstate Highway that is part of the National System of Military and Interstate Highways where overcrossings are designed for a minimum of 17 feet (5.2 m) vertical distance, 15 feet (4.6 m) for any other public roadway, 10 feet (3.0 m) or the height of the highest mobile object that would normally traverse the road, whichever is greater, for a private road, 23 feet (7.0 m) for a railroad, and for a waterway or any other traverse way not previously mentioned, an amount equal to the height of the highest mobile object that would normally traverse it, would exceed a standard of paragraph (a) or (b) of this section.

d) Any construction or alteration on any of the following airports and heliports:

(1) A public use airport listed in the Airport/Facility Directory, Alaska Supplement, or Pacific Chart Supplement of the U.S. Government Flight Information Publications;

(2) A military airport under construction, or an airport under construction that will be available for public use;

(3) An airport operated by a Federal agency or the DOD.

(4) An airport or heliport with at least one FAA-approved instrument approach procedure.

e) You do not need to file notice for construction or alteration of:

(1) Any object that will be shielded by existing structures of a permanent and substantial nature or by natural terrain or topographic features of equal or greater height, and will be located in the congested area of a city, town, or settlement where the shielded structure will not adversely affect safety in air navigation;

(2) Any air navigation facility, airport visual approach or landing aid, aircraft arresting device, or meteorological device meeting FAA-approved siting criteria or an appropriate military service siting criteria on military airports, the location and height of which are fixed by its functional purpose;

(3) Any construction or alteration for which notice is required by any other FAA regulation.

(4) Any antenna structure of 20 feet (6.1 m) or less in height, except one that would increase the height of another antenna structure.

4-3.2 Airfield Criteria Coordination.

4-3.2.1 Siting Coordination.

Coordinate with UFC 3-260-01.

4-3.2.2 Obstruction Lighting.

Coordinate with UFC 3-535-01.

4-3.2.3 Paint Markings.

Coordinate with UFC 3-260-01 for Army and Air Force and NAVAIR 51-50AAA-2 for Navy.

This Page Intentionally Left Blank

CHAPTER 5 DISTRIBUTION SYSTEM PIPING AND APPURTENANCES

5-1 GENERAL.

Design the distribution system in accordance with Chapter 2, paragraph titled *Design Criteria* and use *Recommended Standards for Water Works,* Chapter titled *Distribution System Piping and Appurtenances*.

5-2 MATERIALS.

Provide materials, equipment, components, manufactured units and appurtenances of the potable water system in accordance with Unified Facilities Guide Specifications and NSF 61 or \3\ equivalent /3/ host nation standard. Any part of the water piping system such as, valves, joining materials, gaskets or appurtenances that comes in contact or has the potential to come in contact with potable water is considered part of the potable water system. Provide components of the non-potable water system in accordance with AWWA standards or \3\ equivalent /3/ host nation standards.

5-2.1 Standards and Materials Selection.

Select materials and use of coatings to preserve high hydraulic efficiency to control tuberculation, slime formation and encrustations. During material and coating selection evaluate control potential, structural strength, field conditions, cost and maintenance requirements.

5-2.1.1 Exposed Pipe.

Exposed pipe may be placed on bridges for crossing streams or ravines, piers or pipe supports for crossing fault lines. Exposed nonmetallic pipe may only be used in climates not subject to freezing. Exposed iron or steel pipe subjected to freezing must be insulated or otherwise protected. Any pipe material subject to ultraviolet degradation must be protected.

5-2.1.2 Polyethylene Pressure Pipe.

Use TN-44 2015, and compute service life for potable water systems based on project conditions.

5-2.1.3 Fusible Pipe.

5-2.1.3.1 Fusible Polyethylene Pressure Pipe.

Use AWWA M55 to calculate safe pull and bending forces.

5-2.1.3.2 Fusible Polyvinyl Chloride Pressure Pipe.

Calculate safe pull and bending forces using a minimum factor of safety of 2.5.

5-3 SYSTEM DESIGN.

The distribution system must be designed to provide the design flow, in accordance with UFC 3-230-03 Section titled *Design Flow* and maintain the minimum system pressure. \2\ Use paragraph 2-2.1 to estimate future growth /2/. Use AWWA M31 and AWWA M32 in combination with UFC 3-600-01 for system analysis.

5-3.1 Calculations.

Provide calculations indicating the proposed design provides adequate flow and pressure and reduces or eliminates impacts to water quality. Manual calculations are acceptable for small projects that provide water to a single facility and where compliance with AWWA M32 and this UFC can be demonstrated.

5-3.2 Distribution System Pressure.

This maximum working pressure depends on new and existing piping materials and appurtenances. Specify piping materials and appurtenances with a pressure class that exceeds the maximum working pressure of the water distribution system plus surge pressure. The recommended maximum working pressure is 100 psi (689 kPa).

Higher pressures are required for fire sprinkler systems, ship berthing and drydock facilities in accordance with UFC 3-600-01, UFC 4-150-02 and UFC 4-213-12.

5-3.2.1 Without Fire Demand.

\2\Design /2/ the water distribution system to maintain a minimum pressure of 25 psi (172 kPa) or the minimum pressure required by UFC 3-420-01 for the design flow.

5-3.2.2 With Fire Demand.

Design the water distribution system to maintain a minimum residual pressure of 40 psi (276 kPa) at fire hydrants for the average day demand and 30 psi (207 kPa) during the design flow. Minimum residual pressures at fire hydrants must be at least 20 psi (138 kPa) while supplying fire flow and hose stream demand.

5-3.3 Diameter.

Where water distribution mains provide fire flow, the minimum pipe size is 6 inches (150 mm).

The minimum pipe size for distribution mains is 3 inches (75 mm). A hydraulic analysis and explicit authorization by the Government is required for distribution mains with a pipe size equal to or greater than 3 inches (75 mm) but less than 6 inches (150 mm).

5-3.3.1 Velocity.

Flow velocities should range from 2 to 5 feet per second (0.6 to 1.5 meters per second) in distribution mains for the design flow. The maximum velocity depends on new and existing piping materials and appurtenances. Ensure that the maximum pressure of the piping materials and appurtenances exceeds the maximum pressure of the system, including the potential for surge pressure.

5-3.4 Fire Protection.

Water distribution systems providing water and fire service must be capable of supplying the fire flow specified in UFC 3-600-01 plus any other demand that cannot be reduced during the fire period at the required residual pressure for the required duration. Analysis will determine whether the capacity of the system is fixed by the domestic, industrial, or fire demands, or some combination of the three demands. Compute fire demand in accordance with UFC 3-600-01. \2\ When the water distribution system is not capable of supporting the required fire flow, provide a cost benefit analysis. This analysis must compare design options, such as upgrades to the water distribution system or a separate fire water storage system to supply fire demand, and indicate the most cost effective solution. Consult with the Designated Fire Protection Engineer and consider appropriate design options.

Higher fire flow and pressure demands are required for aircraft hangers, storage facilities, unprotected facilities (buildings without fire sprinkler systems), and other high risk DoD facilities in accordance with UFC 3-600-01. /2/

5-3.5 System Layout.

The configuration of the water system is primarily determined by location of water demands, street patterns, location of water treatment facilities, water storage facilities and topography. Provide a pipe network with flow from two or more water sources and locate distribution piping to minimize connection costs. Reduce head loss and thrust restraint requirements by minimizing changes in direction and the number of bends. Do not connect fire hydrants to water mains not designed to carry fire flows (e.g., mains less than six inches). New underground pipelines must be at least 10 feet (3.0 m) from facility or building foundations, except for building service connections.

When flow demands or pressure requirements require upgrading segments of the distribution system, it is preferable that new pipelines parallel to existing pipelines be sized for the total capacity so that the existing pipeline may be properly abandoned.

5-3.5.1 Branch or Dead End Pattern.

The branch or dead end pattern evolves when distribution mains are extended along streets as the service area expands. Avoid dead ends and stagnant areas in the distribution system to the greatest extent possible.

5-3.5.1.1 \2\ Without Fire Demand.

Where dead ends are unavoidable, provide a flushing hydrant or blow-off assembly for flushing.

5-3.5.1.2 With Fire Demand.

Where dead ends are unavoidable, provide a fire hydrant or blow-off assembly for flushing./2/

5-3.5.2 Grid or Loop Pattern.

The grid or loop pattern has the hydraulic advantage of delivering water to any location from more than one direction, thereby avoiding dead ends. \2\ Provide a grid or loop pattern for water service to mission critical facilities, facilities with high water demands, or where the mission is dependent on potable water service for operation./2/

5-3.6 Capacity.

\2\ Use paragraph 2-2.1 to estimate future growth /2/. Refer to UFC 3-230-03, Chapter titled *System Sources and Flows* for additional criteria.

Evaluate effect of long detention time on decay of chlorine residual in accordance with latest EPA guidance.

5-3.7 Surge Analysis and Control.

Use the rules of thumb in AWWA M32 Chapter titled *Transient Analysis* to identify vulnerable systems and determine when a surge analysis may be required. Once a surge protection device or method is selected, complete an additional analysis to verify the adequacy of the proposed surge protection solution. Surges may be prevented by using water line appurtenances like shutoff valves, pressure relief valves, vacuum relief valves, check valves on pump discharge lines, and surge tanks. Provide appropriate devices to dampen or eliminate surge pressure.

5-3.8 Corrosion.

5-3.8.1 External Corrosion.

For corrosive soils, select materials, coatings, or cathodic protection systems to protect from external corrosion. Use AWWA M27; however, explicit approval by the Government is required prior to providing a cathodic protection system on a buried pipeline.

5-3.8.2 Internal Corrosion.

Use AWWA M58.

5-4 VALVES.

Refer to Appendix B for a general discussion of valves and their uses.

5-4.1 Shutoff Valves.

\2\ The spacing between shutoff valves must not exceed 5,000 feet (1,524 m) on long lines and 1,500 feet (457 m) on loops.

5-4.1.1 Without Fire Demand.

Provide shutoff valves capable of isolating piping sections during a single point failure and maintaining system demands in the distribution system. Locate shutoff valves at reasonable distances and limit the number of facilities without service during repair, maintenance and testing.

5-4.1.2 With Fire Demand.

Provide shutoff valves capable of isolating piping sections during a single point failure and maintaining fire demand and system demands in the distribution system. Use UFC 3-600-01 to locate shutoff valves or sectional valves required for fire protection. Locate additional shutoff valves at reasonable distances and limit the number of facilities without service during repair, maintenance and testing.

5-5 HYDRANTS.

5-5.1 Without Fire Demand.

Provide a minimum of one flushing hydrant or blow-off assembly for each isolated piping section. Use a minimum 2 inch (50 mm) flushing hydrant or blow-off assembly.

5-5.2 With Fire Demand.

Provide a minimum of one fire hydrant or blow-off assembly for each isolated piping section. Use a minimum 4 inch (100 mm) blow-off assembly.

5-5.3 Fire Hydrants.

Comply with the requirements of UFC 3-600-01, Section titled *Hydrants*.

5-5.3.1 Flushing Hydrants and Blow-Off Assemblies.

Locate flushing hydrants and blow-off assemblies in areas accessible to maintenance personnel and adjacent to paved areas. Install a shutoff valve located not more 20 feet (6.1 m) from each flushing hydrant or blow-off assembly. Laterals supplying flushing hydrants or blow-off assemblies must have a minimum diameter of 2 inches (50 mm). Grade to drain away from the flushing hydrants and blow-off assemblies, other facilities, roads, and parking areas. Ensure that the blow-off assembly does not drain into the vault in which it is placed./2/

5-6 AIR RELIEF VALVES.

5-6.1 Air-Valves: Air-Release, Air/Vacuum and Combination.

Use AWWA M51 for the design and selection of air-valves. Provide air-valves as required based on an analysis of the system. For flexible pipe, which might collapse under a vacuum, place vacuum release valves based on the analysis of the system, recommendations of the pipe manufacturer and adjacent to each shutoff valve on the uphill side.

5-7 INSTALLATION OF WATER MAINS.

5-7.1 Minimum Cover.

Minimum cover over pipes must be the most stringent of the following requirements:

a) Minimum required by the applicable AWWA Standard,

b) a minimum of 2.5 feet (750 mm),

c) greater than frost penetration according to UFC 3-301-01,

d) sufficient to support imposed dead and live loads for the pipe materials used.

Evaluate temporary conditions during construction and final conditions. Provide calculations for minimum cover.

5-7.2 Minimum Trench Width.

Provide a minimum trench width of 18 inches (450 mm) or the outside pipe diameter plus 12 inches (300 mm), whichever is greater.

5-7.3 Separation from Other Utilities.

Provide adequate horizontal and vertical separation between water pipelines and other utilities (e.g., electrical, telecommunications, natural gas) for installation, maintenance, and repair or replacement of utilities. The trench width may vary based on the soils encountered and depth. At a minimum, maintain the minimum trench width and bedding depth for the adjacent utilities. Based on site constraints and soil conditions, additional separation may be required to allow the replacement of one utility without impacting the adjacent utility.

5-7.3.1 Separation for Thrust Blocking.

Additional separation is required to ensure thrust blocking is not compromised. Use the following equation to compute length of separation.

$$L = D\tan(45° + \frac{\emptyset}{2})$$

L = separation length

D = depth of cover

∅= Frictional angle of soil

5-7.4 Thrust Restraint.

Use thrust blocks for thrust restraint \3\ in undisturbed, native soils /3/ before considering the use of restrained joints. Use DIPRA for design procedures. Provide calculations for thrust restraint using a minimum safety factor of 1.5. Use the geotechnical investigation report and consult with the Geotechnical Engineer to determine soil bearing capacity.

5-7.4.1 Connections to Existing Pipe.

Use thrust blocks when connecting to existing pipe. Where thrust blocking does not provide the required thrust restraint, require supplemental thrust restraint. Supplemental thrust restraint may include a combination of thrust blocks and restrained joints for the existing pipe. It may be necessary to expose the existing pipe to install the supplemental restrained joints.

5-7.4.2 Fusible Pipe.

Additional restraint may be necessary on fusible pipe at the connection to appurtenances or transitions to different pipe materials. Provide joint restraint as recommended by the fusible pipe manufacturer.

5-7.5 Testing.

Refer to AWWA C600 series for testing requirements for each type of pipe material. Require water mains and water service lines providing fire service or water and fire service to be pressure tested in accordance with NFPA 24.

5-7.6 Disinfection.

For disinfection testing requirements refer to AWWA Standard C651, *Disinfecting Water Mains*.

5-8 SEPARATION DISTANCES FROM CONTAMINATION SOURCES.

\3\Use IPC Section 603 for minimum separation distances for water service lines. Use the paragraphs below for minimum separation distances for water mains.

5-8.1 Parallel Installation.

Measure the separation distance from the closest sides of the two pipes, outside edge to outside edge or outside edge of sanitary sewer manhole, septic tank or subsoil treatment system.

5-8.1.1 Normal Condition.

Provide a minimum horizontal separation of 10 feet (3.0 m) between water mains and any gravity sanitary sewer, sanitary sewer force main, combined sewer overflow, sanitary sewer manhole, septic tank, or subsoil treatment system.

When local conditions prevent a horizontal separation of 10 feet (3.0 m), the water main must have a minimum vertical separation of 18 inches (450 mm) above any gravity sanitary sewer, sanitary sewer force main, or combined sewer overflow and be installed in a separate trench.

5-8.1.2 Unusual Condition.

Realign either the water main or the conflicting source of contamination to meet the required separation unless it is more cost effective to use the following alternative.

When local conditions prevent a horizontal separation of 10 feet (3.0 m) or a vertical separation of 18 inches (450 mm) above any gravity sanitary, or combined sewer overflow, construct the sanitary piping of AWWA approved pressure rated pipe material designed to withstand a minimum static pressure of 150 psi (1,034 kPa) and pressure test in place without leakage prior to backfill.

5-8.2 Crossings.

Measure the separation distance from the bottom of the top pipe to the top of the bottom pipe, outside edge to outside edge.

5-8.2.1 Normal Condition.

Provide a minimum vertical separation of 18 inches above the top (crown) of any gravity sanitary sewer, sanitary sewer force main or combined sewer overflow and the bottom of the water piping.

5-8.2.2 Unusual Condition.

Realign either the water main or the conflicting source of contamination to meet the required separation unless it is more cost effective to use the following alternative.

When local conditions prevent a vertical separation distance of 18 inches (450 mm) above any gravity sanitary sewer, sanitary sewer force main, or combined sewer overflow use the following:

a. Construct the sewer line of AWWA approved pressure rated pipe material designed to withstand a minimum static pressure of 150 psi (1,034 kPa), pressure tested in place without leakage prior to backfill;

b. Center the pressure rated pipe so that joints are 9 feet (2.7 m) to 10 feet (3.0 m) from the water main;

c. For water mains crossing over or under the conflicting source of contamination, maintain a minimum vertical separation of 6 inches (150 mm) between the water main and the sewer line; and

d. Provide adequate structural support to prevent settling and excessive deflection of the joints. /3/

5-9 CROSS-CONNECTIONS AND INTERCONNECTIONS.

5-9.1 Backflow Prevention and Cross Connection Control.

Use AWWA M14 for backflow prevention principles. Comply with the requirements of UFC 3-420-01. Comply with the requirements of UFC 3-600-01 for fire protection systems. Use AWWA C510 for double check valves and AWWA C511 for reduced-pressure principle backflow prevention.

5-10 WATER SERVICES AND PLUMBING.

Use AWWA M22 to size water service lines. Refer to AWWA C800 for underground service connection materials with a diameter of 2 inches (50 mm) or less. Use water distribution materials for services with a diameter greater than 2 inches (50 mm).

5-10.1 Fire Service.

Where the service lateral provides fire service or water and fire service use UFC 3-600-01. UFC 3-600-01 requires flow from two or more directions in the distribution system unless otherwise directed by the Government Civil Engineer or UFC 3-600-01, Chapter titled *Fire Protection Systems*.

5-10.2 Boosters.

Use UFC 3-420-01 for water service boosting systems and pumps.

5-10.3 Water Service Meters.

Use AWWA M6 and AWWA M22 for water meter selection and sizing. Locate meters after the fire service connection so that only non-fire building flows are metered. Meters are typically located near the curb line. Locate meters in grass areas to avoid exposure to vehicular traffic where feasible. In some cases, a meter may be located inside of a building. Locate meters no greater than 4 feet above the floor when inside a building. All meters must be easily accessible for manual reading, maintenance and repair.

5-10.3.1 Advanced Metering Infrastructure.

Comply with UFC 1-200-02 for advanced water meter requirements. Provide water meters compatible with the Installation's advanced metering infrastructure (AMI) systems. Connect the water meter signal to the AMI network. Coordinate advanced metering with UFC 3-520-01.

5-10.3.2 Remote Reading Systems.

Provide metering systems that are compatible with the Installation's remote water meter reading systems.

5-10.4 Sub-meters.

Sub-meters must conform to the same requirements as water service meters when used to comply with UFC 1-200-02.

APPENDIX B BEST PRACTICES

Appendix B identifies background information and practices for accomplishing certain water supply design and engineering services. The Civil Engineering Designer of Record (DoR) is expected to review and interpret this guidance and apply the information according to the needs of the project. If a Best Practices document has guidelines or requirements that differ from the UFGS or Unified Facilities Criteria, the UFGS and the UFC must prevail. If a Best Practices document has guidelines or requirements that are not discussed in the Unified Facilities Guide specification (UFGS) or UFC, the DoR must submit a list of the guidelines or requirements being used for the project with sufficient documentation to the Government Project Manager for review and approval prior to completing design.

B-1 WHOLE BUILDING DESIGN GUIDE.

The Whole Building Design Guide provides additional information and discussion on practice and facility design, including a holistic approach to integrated design of facilities.

The WBDG provides access to all Construction Criteria Base (CCB) criteria, standards and codes for the DoD Military Departments, National Aeronautics and Space Administration (NASA), and others. These include, Unified Facilities Criteria (UFC), Unified Facilities Guide Specifications (UFGS), Performance Technical Specifications (PTS), design manuals, and specifications. For approved Government employees, it also provides access to non-government standards.

B-2 WATER AUDITS AND LEAK LOSS CONTROL.

The loss of treated water can be a substantial economic loss to any water distribution system. Practice water audits and leak loss control following AWWA M36.

B-3 PUMPING FACILITIES.

B-3.1 Planning.

Pumping may be required to move stored water through the piping system to the customers. Planning factors include: availability of electric power, roadway access for maintenance and operation purposes, security and adverse impact to surrounding facilities. Refer to Table B-1 for additional planning factors.

B-3.1.1 Pumps.

The location of a pump station and intake structure, and the anticipated heads and capacities are the major factors in the selection of pumps. The function of a pump station in the overall distribution system operation can also affect the determination of capacities. Consider pump operating costs during pump selection.

Use Hydraulic Institute pump standards for guidelines on pump selection. Basic pump hydraulic terms, formulas, pump fundamentals, applications, instructions for installation, and operation and maintenance are given in the Hydraulic Institute pump standards.

Table B-1 Pumping Installation Planning

Category	Detailed Data and Information
Purpose of Service	Transmission of water from water source. Pumping in the distribution system. Pumping to elevated storage tank. Pumping for fire protection. Booster pumping. Pumping service at treatment plant. Other miscellaneous pumping.
Piping Layout	Length, sizes, fittings.
Demand Requirements	Maximum day demand: mgd or gpm. Average day demand: mgd or gpm. Minimum day demand: mgd or gpm. Peak hourly demand: gpm Variation in demand. Effect of storage on demand rates.
Static Lift Requirements	Static suction head or lift
Liquid Characteristics	Static discharge heads Specific gravity Temperature Vapor pressure Viscosity pH Chemical characteristics Solids content
Power Available	Type Characteristics

\1\/1/

B-3.1.1.1 Pump Drives.

Refer to Table B-2 for preferential choice and applications of various pump drive power systems.

B-3.1.1.2 Valves.

Valves used in pump station systems may include: gate valves, globe and angle valves, cone valves, butterfly valves, ball valves, check valves and relief valves.

B-3.1.2 Pump Station Layout.

Refer to Table B-3 for limitations of pumping arrangements.

Table B-2 Preferential Choice and Application of Pump Drive

Power	Choice	Drive	Application
Electricity	First	AC Motors	Primary power in stationary pumping
Diesel Oil	First	Internal combustion engines	In isolated area for stationary pumping. As emergency standby power source. Portable pumping source.
Natural Gas	Second	Gas turbine or internal combustion engine	In isolated area for stationary pumping. As emergency standby power source.
Air Compressor driven by motors or internal combustion engine	Second	Compressed air	At small installations for airlift pumps and for other pneumatic pumps.

Table B-3 Limitations of Pumping Arrangements

Type of Arrangement	Where to Use	Limitations
Bypassing the discharge (all or part)	Not used for normal operation in a large installation, but during emergency when other arrangements are inoperative	Waste of power
Multiple pumps operating in parallel	Use this arrangement as a normal installation	Requires multiple pumps, and possibly jockey pump to pressurize system at low demands
Intermittent pumping with elevated water storage	Use in areas where water pressure decreases due to either long runs or increases in elevation	May increase water pressure or require different pressure zones in areas with high water pressure or decreases in elevation
Intermittent pumping with ground water storage	Use when additional flow is required	Uses additional energy to run pumps and maintain water pressure
Manual or automatic speed variation to control pump discharge	Use in complex situations where multiple constant speed pumps would be more expensive.	Manual speed control will require personnel to monitor the system and make adjustments.

B-4 FINISHED WATER STORAGE.

B-4.1 Distribution System Storage.

In medium and large distribution systems, water storage is generally located near centers of heavy demand.

B-4.1.1 Ground Storage Tanks.

Ground storage is typically used to reduce treatment plant peak production rates, assist in supplying the design flow during periods of high usage and as a supplemental supply source for pumping to a higher pressure level. Ground storage for pumping is common in distribution systems covering a large area, because the outlying service areas are beyond the reasonable range of the primary pumping facilities.

Ground storage tanks will likely require the installation of variable speed pumps to meet frequent daily fluctuations in demand and eliminate the potential for water hammer.

B-4.1.2 Elevated Storage Tanks.

Elevated storage may be provided to help supply the design flow during periods of high usage and equalize system pressures. In general, elevated storage is more effective and economical than ground storage because of the reduced pumping requirements and the storage can also serve as a source of emergency supply since system pressure requirements can still be met temporarily when pumps are out of service.

B-4.1.2.1 Composite Tanks.

Elevated composite tanks are known to have lower maintenance costs because of the reduction in steel surfaces. In corrosive environments maintenance costs may be reduced by using composite tanks in lieu of steel tanks. Consider the use of composite tanks where corrosive environments are present, including areas like coastlines where saltwater environments increase corrosion potential.

B-4.2 Underground Storage Tanks.

The use of underground storage tanks should be avoided.

B-4.3 Level Controls.

Factors to be considered in selecting a system include cost, efficiency, reliability, structural requirements, ease of operation and degree of maintenance necessary. The ease of operation and degree of maintenance are critical at military installations where adequate personnel cannot always be provided.

B-4.3.1 Variable Speed Control.

In general, variable speed control devices are more expensive, less efficient, and require a higher degree of maintenance than constant speed controls. However, in some instances, variable speed pumping is the best approach. Consider variable speed drives when conditions are too complex for using multiple constant speed pumps and starting scenarios. Prior to installing variable speed pumps, coordinate with and get approval from the Installation’s utility provider.

B-5 DISTRIBUTION SYSTEM PIPING AND APPURTENANCES.

B-5.1 Materials.

B-5.1.1 Polyethylene Pressure Pipe.

Polyethylene (PE) pipe is subject to oxidative degradation by many variables including pH, the concentration and type of disinfectant, water temperature, installation procedure and conditions. Disinfectants like chlorine, chloramines, chlorine dioxide, ozone and others may create an Oxidation Reduction Potential (ORP) in PE Pipe.

B-5.1.2 Fusible Pipe.

Rapid crack propagation (RCP) can occur in many types of materials. Many variables including pipe damage during construction and air in the water line may cause rapid crack propagation (RCP). When RCP occurs in bell & spigot (B&S) pipe, the length of the failure is limited to the length of the pipe. Once pipes are fused together RCP can pass through the fused joints and may result in lengthy pipe failures. RCP has previously occurred in fusible PVC (fPVC) water piping on rare occasions. Ensuring air release valves are used where air may be trapped and pipe is adequately protected from damage during construction are two ways to help avoid RCP.

B-5.2 Distribution System Pressure.

Areas of excessively high or low pressures may be divided into multiple pressure zones. In some cases, the use of pressure reducing valves may be required to protect specific locations.

B-5.3 Valves.

See Tables B-4, B-5 and B-6 for the application of check valves, shutoff valves and gate valves.

B-5.4 Thrust Restraint.

Online thrust restraint calculators can assist in performing thrust restraint calculations. See EBAA IRON Restraint Length Calculator located at http://rcp.ebaa.com/ or the DIPRA Thrust Restraint Design for Ductile Iron Pipe located at https://www.dipra.org/ductile-iron-pipe-resources/calculators/thrust-restraint-of-ductile-iron-pipe. Consider the bearing surface of the fitting when designing thrust blocks. Compact fittings reduce the bearing surface of the thrust block.

B-5.5 Water Services and Plumbing.

Consider using the buildings internal water supply for building additions.

B-5.6 Meters.

Meters may serve multiple purposes. Billing, monitoring and diagnosing the health of the systems are and important operational functions. Metering data provides system operators with important information, such as where additional flow capacity is needed, where water quality may be a concern, and how the distribution system may be impacted from additional population growth. Properly designed meters that are installed using standard industry settings should find rather cost effective solutions exist for accurate metering. Properly sized meters can accurately measure the ranges of expected flows that it provides service to. Sub-metering can increase operational costs without increases in additional income.

Table B-4 Application of Check Valves

Check Valves	Application	Remarks
Swing Checks	All horizontal applications	Refer to AWWA C508
Ball Checks	On reciprocating pumps	Small diameter
Vertical Checks	All vertical applications	Refer to AWWA C507
Cone Checks	Surge relief	Requires automatic operator
Cushioned Checks	Surge relief	Slow closing
Foot Valves	Prevents loss of prime in suction lines	-
Flap Valves	At pipe outlets	-

Table B-5 Application of Shutoff Valves

Shutoff Valves	Application	Remarks
Gate Valves[a]	All applications	Refer to AWWA C500 and AWWA C509
Butterfly Valves	All applications	Largest size 72 in. Refer to AWWA C504
Plug Valves, Eccentric	All applications	Suitable for water containing solids and for three-way valves
Globe Valves	All applications	Small diameter
Needle Valves	All applications	Small diameter
Hydraulic Needle Valves	Reservoir outlets	Very large size requiring hydraulic operators
Mud Valves	Bottom drain opening of basins	-
[a] Except for low pressure, service gate valves 16 in (400 mm) -20 in (500 mm), and larger should be equipped with bypass. Refer to AWWA C500 and AWWA C509.		

Table B-6 Application of Gates

Gates	Application	Remarks
Radial Gates	Channel and reservoir outlets	-
Slide Gates	Channel and reservoir outlets	Low heads
Sluice Gates	Wall openings	Refer to AWWA C560
Shear Gates	Wall openings (low head)	Size up to 24 in. (600 mm)

APPENDIX C GLOSSARY

C-1 ACRONYMS.

AFCEC	Air Force Civil Engineering Center
AT&L	Acquisition, Technology, and Logistics
AWWA	American Water Works Association
B&S	Bell & Spigot
BIA	Bilateral Infrastructure Agreement
CCB	Construction Criteria Base
DDC	Direct Digital Controls
DoD	Department of Defense
DoR	Designer of Record
e.g.	*Exempli Gratia* (one or more possible examples)
EPA	Environmental Protection Agency
FAA	Federal Aviation Administration
FGS	Final Governing Standards
fPVC	Fusible Polyvinyl Chloride
HQUSACE	Headquarters, U.S. Army Corps of Engineers
HNFA	Host Nation Funded Construction Agreements
i.e.	*Id Est* (clarifies, more precisely)
IPC	International Plumbing Code
NASA	National Aeronautics and Space Administration
NAVAIR	Naval Air Systems Command
NAVFAC	Naval Facilities Engineering Command
NEMA	National Electrical Manufacturers Association
NEPA	National Environmental Policy Act

OEBGD	Overseas Environmental Baseline Guidance Document
ORP	Oxidation Reduction Potential
OSHA	Occupational Safety and Health Administration
PE	Polyethylene
PVC	Polyvinyl Chloride
SOFA	Status of Forces Agreements
UFC	Unified Facilities Criteria
UFGS	Unified Facilities Guide Specifications
U.S.	United States
WBDG	Whole Building Design Guide

C-2 DEFINITION OF TERMS.

Distribution Mains: All pipelines of the potable water distribution system, except the service lines (e.g., water, fire, irrigation).

Pipe Size: The nominal internal diameter of the pipe.

Surge pressure: The maximum hydraulic transient pressure increase (also known as water hammer) above the anticipated operating pressure in the system as the result of sudden changes in velocity of the water column. Two types of surge pressures are recurring (cyclic) surge pressure and occasional (emergency or transient) surge pressure.

Working pressure: The maximum sustained operating pressure applied to the pipe exclusive of surge pressures.

For additional definitions refer to the definitions given in the applicable standard.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	Date	Location
1	1 April 2021	1. Revised paragraph 2-5 to comply with America's Water Infrastructure Act and added a reference to Air Force AWIA ERP Checklist. 2. Revised paragraph 5-4.1.5 and Table 5-8 to clarify recommended maintenance frequencies. 3. Deleted paragraph 7-2.1.2, duplicate paragraph. 4. Revised paragraph 7-2.1.3 to clarify hydrant flushing procedure. 5. Changed AFI 32-1067 to AFMAN 32-1067 throughout UFC.
2	1 Nov. 2023	Modified backflow prevention testing requirements in Chapter 9.

This UFC supersedes UFC 3-230-02, *Operation and Maintenance: Water Supply Systems*, dated 10 July 2001.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA) and, in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies must contact the preparing Service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale must be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-230-02, *Operation and Maintenance: – Water Supply Systems*

Superseding: UFC 3-230-02, *Operation and Maintenance: Water Supply Systems* dated 10 July 2001.

Description: This document is to serve as a comprehensive operations and maintenance manual that on-site field and operations staff within the tri-service agencies can easily navigate through for operations and maintenance (O&M) of their water supply systems.

Reasons for Document:

- Provide updated O&M guidance that covers water supply systems of varying capacity and capabilities in a clear and concise manner for on-site hands on use by Department of Defense (DoD) field and operations staff.
- Provide relevant O&M features and details that clearly distinguish between “required elements” and “best practices.”
- Provide reference sources from both existing DoD-specific guidance documents as well as accepted industry standard guidelines.

Impact: Standardized guidance will assist operators in obtaining higher availability and design life from their systems.

Unification Issues:

Army:

- Technical Bulletin – Medical (TB MED) 576 to be additional standard for compliance with United Stated Environmental Protection Agency (EPA) Regulations for the Army.
- USA-CERL TR N-86/11 to be additional standard for emergency planning, natural disasters, manmade disasters, and vulnerability assessment for the Army.
- Public Works Technical Bulletin (PWTB) 200-1-46, 200-1-94, and 200-1-104 to be additional standards for water conservation for the Army.
- PWTB 200-1-86 to be additional standard for water availability determination for the Army.
- Preliminary Report: Field Test of Trash Rack Heating to Prevent Frazil Ice Blockage to be additional standard for intake maintenance for the Army.
- TB MED 575 to be additional standards for swimming pool maintenance for the Army.

Air Force:

- Air Force Instruction (AFI) 32-1064 to be additional standard for Safety for the Air Force.
- Air Force Guidance Memorandum (AFGM) 2017-32-01 to be additional standard for cybersecurity for the Air Force.
- AFI 32-2001 to be additional standard for fire protection for the Air Force.
- AF997 to be standard form for recording data for the Air Force.
- **\1** AFMAN 32-1067 **/1/** to be additional standard for administrative issues in cross-connection control for the Air Force.
- AFI 10-246 and QTP 4B071-15 to be additional standards for vulnerability assessment for the Air Force.
- AFI 48-144 to be additional standards for compliance with EPA regulations.
- Air Force Policy Directive (AFPD) 90-8 contains additional requirements for the Air Force for environment, safety, occupational health, and risk management.
- Air Force Water Conservation Guidebook contains additional requirements for water conservation for the Air force.
- **\1** Air Force AWIA ERP Checklist **/1/**

Navy:

- Bureau of Medicine and Surgery, BUMED Instruction, BUMEDINST 6240.10C, provides additional requirements for the Navy.
- Commander Navy Installations Command, CNIC Instruction, CNICINST 5090.1A, provides additional overseas water system requirements for the Navy.
- Office of the Chief of Naval Operations, OPNAV Instruction, OPNAVINST 5090.1E, provides additional environmental compliance requirements for the Navy.
- Headquarters United States Marine Corps, Marine Corps Order, MCO 5090.2, provides additional requirements for Marine Corps personnel and installations.
- Bureau of Medicine and Surgery, BUMED Publication, NAVMED P-5010-5, for additional water quality and operational requirements for the Navy.

EQUATIONS

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

This Unified Facilities Criteria (UFC) document updates the requirements of and replaces UFC 3-230-02 (10 July 2001).

1-2 PURPOSE AND SCOPE.

This UFC provides general technical guidance for operating and maintaining potable water systems that are fit for human consumption (FFHC), at fixed military installations. Since no two installations are exactly alike, this UFC is supplemental to site-specific operations and maintenance (O&M) manuals provided for each installation. An example of a user-friendly O&M manual template can be found on the State of Colorado's website: https://colorado.gov/pacific/cdphe/drinking-water-operations-and-maintenance-om-manual Use the best practice document *Small Water System Operation and Maintenance Manual,* as referenced in Appendix B for information on a manual template.

1-3 APPLICABILITY.

This UFC applies to fixed-base water systems and in some limited cases swimming pools. To provide military personnel with the most up-to-date information available, the UFC guides the reader to industry standards, manuals of practice, training guides, handbooks, and miscellaneous documents published by the American Water Works Association (AWWA) and other authorities in the water supply and treatment field.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government criteria for typical design disciplines and building systems as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4.1 International Plumbing Code (IPC).

IPC regulates the supply of potable water from public and individual sources to fixtures and outlets so that it remains FFHC. IPC also provides regulation on preventing backflow conditions.

1-5 SAFETY.

All DOD facilities must comply with DoDI 6055.01 and the applicable Occupational Safety and Health Administration (OSHA) safety and health standards. The portions that apply directly to O&M of water treatment plants is under Part 1910, Occupational Safety and Health Standards, and its associated subparts. Implementation of these OSHA standards at military installations is by way of specific service regulations. The service regulations are available through the installation's safety, occupational health, and fire department officers. Keep these regulations in the workplace and ensure they are available to all personnel. Use *DoDD 4715.1E* and follow the safety precautions included throughout this UFC and in applicable references. Specific instructions are included in the appropriate service regulations. Instruction manuals and other training aids are available through the library or training office.

General guidelines for safe work practices and techniques for a variety of water utility work situations can be found in the following best practice documents *AWWA M3*; *Water Treatment Plant Operation, Volumes 1 and 2*; *Work Practices for Asbestos-Cement Pipe;* and *ASCE 56-10*.

For the Air Force, see *Air Force Instruction (AFI) 32-1064. Air Force Policy Directive (AFPD) 90-8* contains additional requirements for safety and occupational health.

1-6 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

1-7 BEST PRACTICES.

Appendix B identifies supplemental information and practices for completing certain O&M tasks. This includes industry best practices documents and recommendations, and calculation examples. If a best practices document contains content or instructions that differ from UFGS or UFC, then UFGS and UFC shall prevail. An example of a user-friendly O&M manual template can be found on the State of Colorado's website: https://colorado.gov/pacific/cdphe/drinking-water-operations-and-maintenance-om-manual

1-8 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

CHAPTER 2 WATER SUPPLY SYSTEMS AND OPERATION

2-1 ORDER OF PRECEDENCE.

The operation of all fixed military installations' water systems must comply with specific regulatory and environmental requirements.

2-1.1 Foreign Countries.

DoD water supply systems must achieve, maintain, and monitor compliance with applicable environmental requirements and monitor these environmental requirements worldwide. DoD 4715.05-G, Overseas Environmental Baseline Guideline Document (OEBGD), applies when there are no FGS in place. Therefore, in foreign countries this UFC will be used for DoD projects to the extent that it is allowed by and does not conflict with the applicable international agreements and the applicable FGS or OEBGD.

For Army: Army regulations pertaining to the provision of drinking water apply to all Army installations and are found in AR 200-1, AR 420-1, AR 40-5, and TG 179. The Army regulations refer to guidance and procedures outlined in DA PAM 40-11; Technical Bulletin Medical (TB MED 575 and TB MED 576) as appropriate.

2-1.2 Water Quality Standards.

DoD water supply systems must achieve, maintain, and monitor compliance with applicable environmental requirements and monitor these environmental requirements worldwide.

2-1.2.1 Within the United States.

For Installations located in the United States and its territories and possessions the water supply system must comply with the following criteria precedence:

1. All applicable, state, and local drinking water regulations for the project location;

2. DoDI 4715.06, Environmental Compliance in the United States;

3. For Navy: BUMEDINST 6240.10C, OPNAVINST 5090.1E, NAVMED P-5010-5 and MCO 5090.2;

4. For Army: Technical Guide, (TG MED 179), US Army Public Health Command, April 2015; AR 200-1 (Environmental Protection and Enhancement), AR 420-1 (Facilities Management) and AR 40-5 (Preventive Medicine);

5. Utility provider's requirements;

6. Additions to the above criteria as indicated in this UFC; and

7. Refer to references in Appendix A for guidance.

2-1.2.2 Foreign Countries.

For Installations located outside of the United States and its territories and possessions the water supply system must comply with the following criteria precedence:

1. The Forward of this UFC (All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.));
2. Final Governing Standards (FGS);
3. DoDI 4715.05;
4. DoD 4715.05-G, OEBGD;
5. For Navy: BUMEDINST 6240.10C, OPNAVINST 5090.1E, CNICINST 5090.1A, NAVMED P-5010-5 and MCO 5090.2;
6. Army Only: TG MED 179;
7. Utility provider's requirements;
8. Additions to the above criteria as indicated in this UFC; and
9. Refer to Appendix B for guidance.

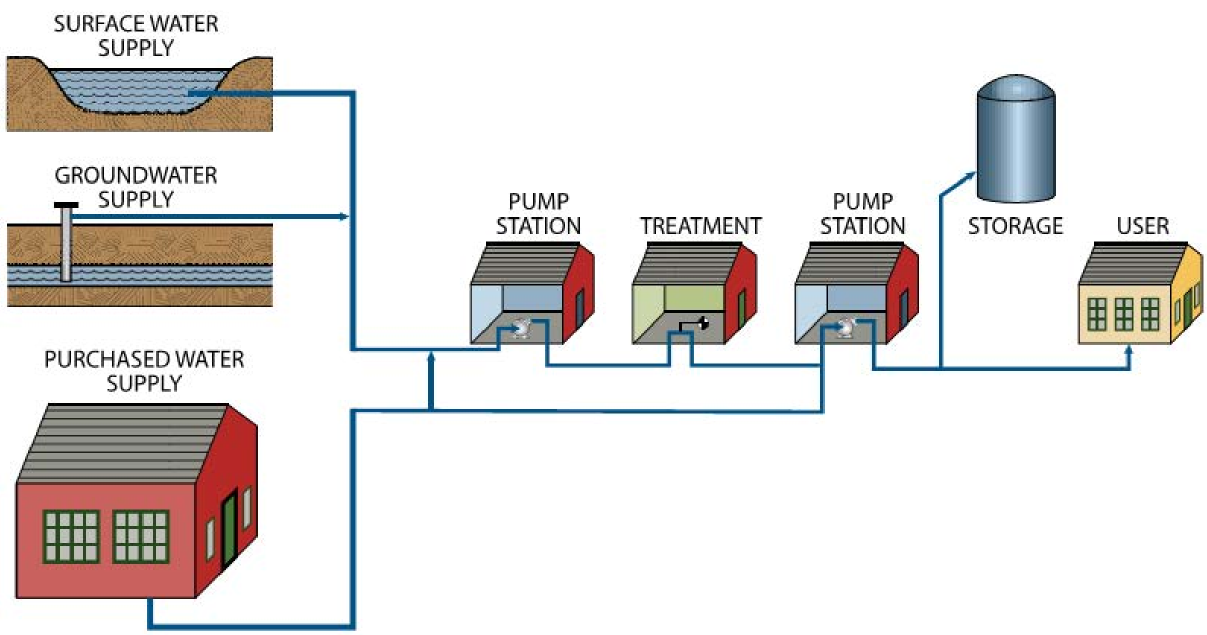
2-2 SYSTEM OVERVIEW.

All fixed military installations' water systems have a water supply source and facilities for distributing water to the point of use. At some installations, treatment and pumping facilities are also required. Figure 2-1 displays a typical water supply system configuration.

Minimum requirements for the operation of drinking water treatment plants and supply systems fall within the following categories:

- Compliance with regulatory requirements
- Operational management practices
- Plant-real property management and maintenance
- Water quality management

Figure 2-1 Water Supply System Configurations



Establish goals within each category, with the primary objective of maintaining the protection of public health. Maintain a consistent operation that satisfies the goals for each system. No changes should be made to the water system without first considering the compliance impacts or need for regulatory consultation and approval of any change. Starting, temporarily stopping, or ending operations of a water treatment plant or supply system must comply with the established goals and meet all regulatory requirements. Treatment plant production capacity should adequately meet system demands at all times. Operation and maintenance functions should be conducted in such a manner that plant site safety and water quality are not compromised.

2-2.1 Water Source.

The most common way to provide potable water at fixed military installations is to buy it from a nearby utility, either a municipality or a private water company. At installations where purchased water is not an option, obtain the water from surface water or groundwater sources such as rivers, lakes, reservoirs, or wells.

More detailed information on water supply is provided in Chapter 3.

2-2.2 Water Treatment.

Water treatment facilities vary from providing basic disinfection of groundwater supplies to sophisticated treatment plants using one or more of the following processes: coagulation, sedimentation, filtration, membrane technologies, carbon treatment, lime-soda softening, fluoridation, disinfection, and desalination. Depending on the quality of the source water and other pertaining factors, some water treatment facilities may only require chlorination.

More detailed information on water treatment is provided in Chapter 4.

2-2.3 Water Distribution.

The primary components of a water distribution system are pumps, pipes, and storage facilities. Well pumps are used to lift water from wells and may discharge directly to a distribution system, storage, or treatment plant. Low-lift pump stations move water from a surface supply to the intake of a non-pressure treatment plant. High-service pump stations transfer potable water from non-pressurized sources, such as storage reservoirs, directly to the distribution system. Pumps are installed in a pipeline or pressure zone of a distribution system to increase the pressure or meet peak demands. Pressure-reducing valves can be used to reduce the pressure for use in a lower pressure zone.

Pumps are included in Chapter 5. Information on water distribution and storage is provided in Chapter 6. Chapter 7 covers valves and hydrants.

2-3 WATER UTILITY STAFFING.

2-3.1 Certification.

Operator certification requirements of water supply facilities vary by regulatory jurisdiction. Just as the number of personnel required is determined by the needs of the facility, determine the numbers and grade levels of certified operators that are required at a given installation by analyzing the size and complexity of the facility installation. Regulatory agencies will also indicate the minimum licensed operator requirements to maintain compliance. For more information on certification, contact the Association of Boards of Certification for Operating Personnel in Water Utilities and Pollution Control Systems (ABC):

Executive Director, ABC
2805 SW Snyder Blvd., Suite 535
Ankeny, IA 50023
Web: http://www.abccert.org/

For more information on service-specific certification, contact the Operator Certification Office of the specific service.

2-3.2 Training.

Obtain operator training by attending technical schools, community colleges, short courses, and workshops and by successfully completing home study courses. Once certification is obtained, have continual training to maintain high standards of service; ensure safe, efficient operation; and stay informed of all current technical developments.

Additional information on training can be obtained either from ABC or *AWWA M52* and from the Operator Certification Office of the specific service.

2-4 INFORMATION MANAGEMENT.

Maintain records as evidence of conformity to requirements and system goals. Records are also necessary for planning purposes. The information management system's needs will vary by installation. The system, at the very least, should contain documented procedures defining the controls needed for identification, storage, protection, retrieval, retention time, and disposition of records. Update records, such as maps, routinely as changes are made to the installation and its surrounding area.

A computerized information management system is recommended for safe file storage. Maintain all records in accordance with service procedures. Example documentation to be maintained in the information management system includes the following compliance requirements:

- Monthly operating reports (MOR)
- Regulatory compliance records
- Monitoring plan and compliance test results
- Sample locations—frequency, low-residual sites, long travel-time sites
- Disinfectant residual results—maximum, minimum, average statistics
- Ammonia and heterotrophic plate count results
- Disinfection goals and residual results
- Disinfection byproduct results—maximum, minimum, averages
- Color, taste, and odor results
- Backflow prevention testing records
- Coliform testing results

Documents that can be considered best practice information that should be maintained in the information management system:

- Flushing program results
- Piping materials used
- Storage tank detention time, cleaning records, treatment evidence
- Leak detection and water loss calculations
- Main repair/replacement information
- Service line repair/replacement information
- Valve exercise goals and numbers

- Valve replacement goals and numbers
- Hydrant exercise goals and numbers
- Hydrant replacement goals and numbers
- Meter testing and replacement records
- Pressure records—maximum, minimum, averages
- Flow records—maximum, minimum, averages
- External corrosion—testing records
- Pump station operation and maintenance records
- Pipeline restoration and replacement records
- Pipeline disinfection records
- Corrosion monitoring results

2-4.1 Operating Records.

Maintain records, if applicable, for the following unit processes as listed below. Additional best practice information on these processes can be found in *Water Treatment Plant Operation, Volumes 1 and 2*:

- Activated carbon
- Aeration
- Chlorination
- Corrosion/scale control
- Filtration
- Fluoridation
- Ion-exchange
- Iron and manganese control
- Pre-sedimentation
- Reverse osmosis
- Screening
- Sedimentation
- Water softening
- Water weed control
- Ultraviolet (UV) disinfection

2-4.2 Logs.

Enter daily operating data in a daily log to provide a record of daily and average monthly operations. Record data from all aspects of treatment and operations, including routine duties, unusual conditions (operational and maintenance), accidents, complaints, and visitors.

Complete monthly and annual operating reports as assigned by site supervisors. Monthly operating reports permit technical review of current performance and comparison of performance over a long period of time. Accumulated monthly reports show variations caused by changes of seasons, methods of operation, and installation population. Annual reports include a description of the facilities, volume of water pumped/treated, quantity of chemicals consumed, capital costs, operating costs, and personnel status. Ensure annual reports are clear, concise, and informative. Keep the format consistent from year to year to facilitate comparison with past performance.

2-4.3 Water Supply System Maps and Records.

Prepare and maintain records of all installations and equipment for the water supply system. These records are to include an inventory listing of all locations and an individual record for each location. Complete or revise records when the components of the system are installed, replaced, repaired, or adjusted. Record locations using Geographic Information System (GIS). Where available, use prescribed forms for recording the data. GIS features include the following:

- GIS can store and display geographically referenced information that is represented through map display. GIS can store information that is useful for system analysis, including pipe assets, customer meter locations, land parcel data, aerial photography, street locations, digital elevation models (DEMs), digital terrain models (DTMs) and more. The usefulness of GIS pipe data is dependent on the way the information is collected and stored in GIS. GIS data may be used to build and, or, update distribution system models to create a detailed representation of the water distribution network.
- Distribution system modeling software data and results can be imported and exported to and from GIS. For utilities that have established a GIS, the added functionality of interfacing with a model can be valuable from enterprise, customer, and operational perspectives. Information in GIS is saved in file formats that most modeling software can access and can be translated into a format that can be imported into a model database. Beneficial data to be transferred between systems may pertain to demand allocation, topography extraction, and results presentation. GIS can be linked to various types of systems, including customer information systems, asset management systems, and common databases. GIS and other applications make building and maintaining models more efficient, valuable, and accurate, and they support various analysis and reporting

functions. Understand how GIS is used and use the system to maintain records for operating manuals, equipment lists, maintenance, repairs, and additional water supply system details, as needed.

For more information on GIS and modeling of water distribution systems, see *AWWA M32.*

2-4.4 Maintenance.

Keep maintenance records, including manufacturers' catalogs, brochures, and instruction manuals for all installed equipment. Use shop drawings and as-built drawings for equipment and facilities along with maintenance manuals to achieve efficient O&M of various systems. At a minimum, document when service was last performed and when it will be required again for each piece of equipment. To the extent possible, include a complete repair and cost history for all installed equipment.

2-4.5 Laboratory Reports.

Follow state and local requirements for reporting the results of water analysis. These requirements are at least as stringent as federal requirements, but specific requirements vary from state to state. Some general information that as a best practice might be recommended for inclusion in every report is covered in *Water Treatment Plant Operation, Volumes 1 and 2*.

2-4.6 Cost Accounting.

The waterworks supervisor should maintain records of operating costs in addition to those that are maintained by accounting personnel. Use these records to provide up-to-the-minute information on expenditures, predict yearly costs, and forecast budgets.

2-4.7 Data Analysis.

Establish an operating and maintenance procedure that documents the functionality of major pieces of mechanical equipment pertaining to water treatment and water supply systems. Record operational conditions and variables via operating logs or industrial control systems, such as supervisory control and data acquisition (SCADA) systems. Use feedback and results from SCADA systems, with additional software programs, to optimize control and operational planning. Develop the necessary graphics to assist in data analysis using Microsoft Excel or other useful software programs. Maintain water sampling details and analysis results and records using programs such as Microsoft Excel. Records should present historical data trends, changes in treatment patterns, or other changes that may affect water quality or plant efficiency. Analyze data trends and develop an action plan to respond to changes.

Maintain an adequate record-keeping system to allow for the continuous assessment of the water treatment and water supply systems. Establish a review cycle of the records to verify that operational control requirements pertaining to water quality, laboratory operations, and mechanical equipment are being satisfied. For more information on record-keeping, data management, and data review, see *AWWA G100 and AWWA G400.*

2-5 EMERGENCY PLANNING.

Develop procedures for water system protection, emergency operation, and ensuring an adequate water supply to protect public health and fire protection. **\1** Section 2013 of America's Water Infrastructure Act requires community drinking water systems serving more than 3,300 people to develop or update risk assessments and emergency response plans. The law specifies the components that the risk assessments and emergency response plans must address, such as:

1. Strategies and resources to improve the resilience of the system, including the physical security and cybersecurity of the system,
2. Plans and procedures that can be implemented, and identification of equipment that can be utilized, in the event of a malevolent act or natural hazard that threatens the ability of the community water system to deliver safe drinking water,
3. Actions, procedures, and equipment which can obviate or significantly lessen the impact of a malevolent act or natural hazard on the public health and the safety and supply of drinking water provided to communities and individuals, including the development of alternative source water options, relocation of water intakes, and construction of flood protection barriers, and
4. Strategies that can be used to aid in the detection of malevolent acts or natural hazards that threaten the security or resilience of the system. **/1/**

See publications *AWWA M5, AWWA M19, AWWA M52,* and AWWA (1994) handbook on Minimizing Earthquake Damage for more information on emergency planning.

For the Army, *USA-CERL TR N-86/11* contains further information on emergency planning.

\1 For the Air Force, AWIA ERP Checklist. **/1/**

2-5.1 Fire Protection.

Provide fire protection for two broad categories: general protection of installation facilities, and protection of the water supply and treatment facilities and equipment. For more best practice information on fire protection planning and procedures, see *AWWA M5* and *AWWA M31*.

For the Air Force, the Civil Engineer Operations Flight Chief is responsible for the inspection, testing, maintenance, and documentation associated with all fire detection, notification, suppression, water distribution systems, including fire pumps. For further information on the Air Force Fire Emergency Services Program, see *AFI 32-2001.*

2-5.2 Natural Disasters.

Address the effects and develop mitigation measures for natural disasters, including earthquakes, hurricanes, tornadoes, and floods. Discussions of the effects of natural disasters, and measures to mitigate them can be found in publications *AWWA M19, AWWA M60,* and AWWA (1994) handbook on Minimizing Earthquake Damage.

For the Army, *USA-CERL TR N-86/11* contains further information on natural disaster response.

2-5.3 Manmade Disasters.

Address the effects and develop mitigation measures for manmade disasters and include accidents, riots, strikes, hazardous material spills, vandalism, terrorism, and bomb blasts. Discussions of the effects of man-made disasters, and measures to mitigate them can be found in *AWWA M19.*

For the Army, *USA-CERL TR N-86/11* contains further information on manmade disaster response.

2-6 SECURITY AND RISK MANAGEMENT.

Each site has an explicit, easily communicated, and readily available security plan. Implement this plan as part of daily operations. Train all employees on the security plan and incorporate their security responsibilities into their job duties.

For the Air Force, *Air Force Guidance Memorandum (AFGM) 2017-32-01* contains further information on cybersecurity. *AFPD 90-8* contains requirements for risk management.

2-6.1 Vulnerability Assessment.

Perform an assessment to identify potential vulnerabilities in the security of the installation. Water system vulnerability assessment is required for compliance with the Bioterrorism Act of 2002. The assessment should include the following steps:

1. Asset characterization
2. Threat characterization
3. Consequence analysis
4. Vulnerability analysis
5. Threat likelihood analysis
6. Risk/Resilience likelihood
7. Risk/Resilience analysis

Identify resources required to maintain the security program and make necessary improvements. Review and update the risk assessment as new hazards and threats emerge. See *AWWA J100* for the full risk analysis and management for critical asset protection (RAMCAP) process. For a list of common water system components and how each component may be vulnerable to typical hazards, as well as an example of a vulnerability assessment, see *AWWA M19.* Do not share weaknesses in system security outside of the site security officer, department heads, and supervisors as determined by the site security plan.

For the Army, required information on vulnerability assessment can be found in *USA-CERL TR N-86/11.*

For the Air Force, required information on vulnerability assessment can be found in *AFI 10-246* and *QTP 4B071-15.*

2-7 REGULATIONS AFFECTING WATER SYSTEMS.

Congress passed the original Safe Drinking Water Act (SDWA) in 1974 (amended and reauthorized in 1986 and 1996) to ensure that the public drinking water system serving the U.S. population would meet established SDWA standards. These standards, known as the Primary Drinking Water Regulations and Secondary Drinking Water Regulations, set the numeric limits for drinking water quality. These regulations apply to all public water systems, defined as an entity that provides FFHC water through a distribution system to a minimum of 15 service connections or an average of 25 people for a minimum of 60 days a year. Most of the military installation water supplies are considered public water systems and are required to comply with local, state, and federal drinking water regulations, including public notification requirements.

Installations within the United States should comply with all state waterworks regulations or local regulations for the project location and the utility providers' requirements as applicable. Installations should check with the bio-environmental engineer and base environmental coordinator to assure compliance with the applicable regulations.

2-7.1 EPA Regulations.

SDWA and the 1986 and 1996 amendments to SDWA direct the United States Environmental Protection Agency (EPA) to promulgate regulations and guidance on maintaining drinking water quality to protect the public health. The 1996 amendments waived the sovereign immunity. All U.S. states have the primacy for the implementation of SDWA provisions, except for Wyoming and District of Columbia for which EPA requirements take precedence.

Individual states can establish additional required compliance requirements. For Installations located in the United States and its territories and possessions the water supply system must comply with the order of precedence criteria as outlined in 2-1.2.1 Within the United States.

For the Air Force, see *AFI 48-144* for guidance on compliance with EPA regulations.

For the Army, see *Technical Bulletin-Medical (TB MED)* 576 for guidance on compliance with EPA regulations.

2-7.2 Government Regulations for Overseas Installations.

For projects outside of the United States and its territories and possessions, the water supply system must follow the order of precedence criteria as outlined in 2-1.2.2 Foreign Countries.

2-8 WATER CONSERVATION.

Water conservation programs emphasize long-term improvements in water use efficiency and to manage drought planning. All U.S. states have the primacy for the implementation of SDWA provisions, except for Wyoming and District of Columbia for which EPA requirements take precedence. Individual states can establish additional required compliance requirements that include conservation, water allocation and unaccounted for water limits. Best practice information can be found in *AWWA M60*.Example water conservation practices can be found below.

- Efficient utilization of sources of supply.
- Leak detection and repair.

For the Army, see *Public Works Technical Bulletin (PWTB) 200-1-46, 200-1-94,* and *200-1-104.*

For the Air Force, see *Air Force Water Conservation Guidebook.*

CHAPTER 3 RAW WATER SUPPLY

3-1 CHAPTER OVERVIEW.

This chapter provides general information pertaining to raw water supply sources. Chapter 3 also presents specific information on the operation and maintenance of water wells, dams and reservoirs, and intake structures.

See publication *AWWA M21 and AWWA M50* for distinctions between source waters and an overview of hydraulic principles. Some best practice information can be found in *Water Treatment Plant Operation, Volumes 1 and 2*.

3-2 WATER USE.

Water use is for residential, commercial, and industrial purposes and for fire protection. The most important reason for maintaining continuity of service is to protect public health. To adequately supply all water requirements, water system operators need to know the magnitude and occurrence of peak flows, anticipated growth, and maximum projected water demand of the service area based on a 50-year drought.

A discussion of water use issues and emergency and alternative water sources can be found in *AWWA M21 and AWWA M50.* Some best practice information can be found in *Water Treatment Plant Operation, Volumes 1 and 2*.

For the Army, *PWTB 200-1-86* provides guidance for water availability determination.

3-3 GROUNDWATER SUPPLIES.

Detailed information on groundwater sources, water well terminology, well location and construction practices, and well types can be found in *AWWA M21,* and *AWWA A100.* Best practice information can be found in *Water Treatment Plant Operation, Volumes 1 and 2.*

3-3.1 Well Operation.

Groundwater sources are normally used to supplement surface-water sources. General engineering support in the form of well drilling by engineers is provided to the water collection and distribution process. Specific considerations necessitating well drilling are:

- When surface sources of water are not available in enough quantity or quality to support the force. This is likely to occur in arid terrain where the quantity of water required is high and surface sources are low. In arid environments, exploring and using groundwater can reduce the need to transport water to a desired location.
- If the distribution system is insufficient to support the force, haul distances may be significantly reduced by a well drilled close to the consumer.

- Chemical, biological, radiological, or nuclear or other type of contamination is expected that would render surface sources unusable.
- The mission is part of a humanitarian and civic assistance and, or, foreign humanitarian assistance mission. A major portion of the world's population lacks a readily available source of potable water. Providing a potable source by conducting well drilling operations may be the decisive operation in stability and, or, reconstruction operations and a critical part of the overall information operations campaign.

Follow all established operating procedures when installing and operating wells. Guidance on installing and operating wells is included in *NTRP 4-04.4.13/FM 3-34.469/AFMAN 32-1072, Water-Well Drilling Operations*.

3-3.1.1 Aquifer Performance.

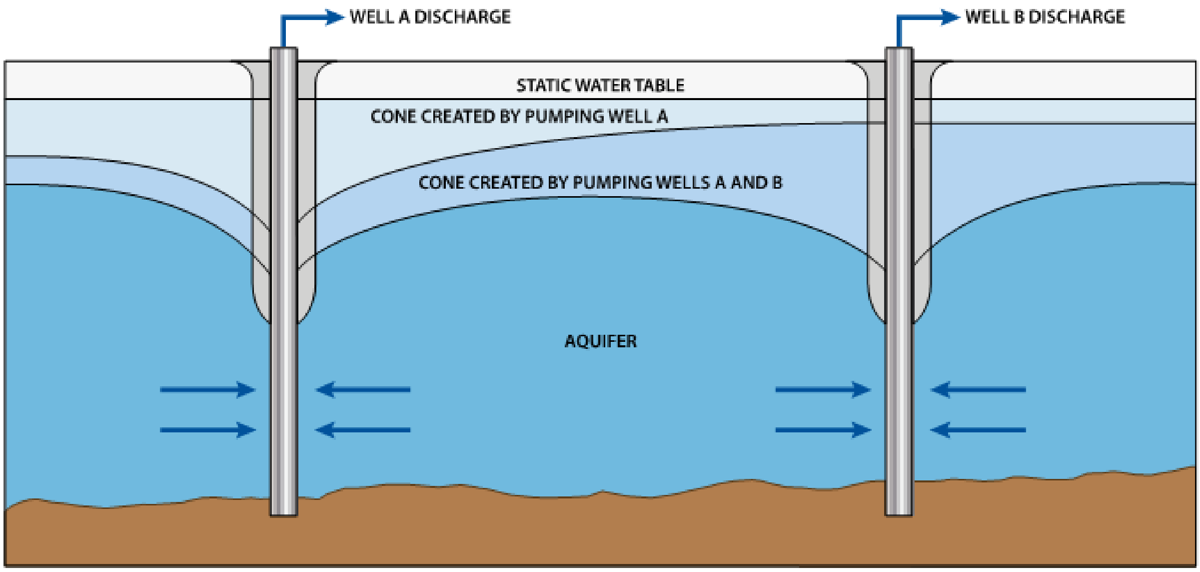
Analyze water well performance by calculating well yield, drawdown, and specific capacity. These calculations provide information for selecting appropriate pumping equipment and identifying any changes in the productive capacity of the well. Examples of such calculations are in Appendix B. Best Practice guidance from *Water Treatment Plant Operation, Volumes 1 and 2* can be used for further parameter definition and additional sample calculations.

3-3.1.2 Pump Schedule.

When water is pumped from a well, a depression is produced in the water table as drawdown occurs. When pumping stops, the water again rises to the static water level. The depth and lateral extent of the cone of depression depends on the pumping rate of the well. If two or more wells are located so closely together that their cones of depression overlap, the wells compete for the groundwater. As a result, each well produces less water than if it operated alone (Figure 3-1).

Place operating wells as far apart as possible to minimize the effect of overlapping cones of depression. Operate wells in rotation to equalize wear on pumping equipment.

Figure 3-1 Effects of Overlapping Field of Influence – Pumped Wells



3-3.1.3 Well Pump Operation.

Follow established operating procedures when pumping wells and keep pumping rates within the specified design range. Continuous operation generally is preferable to frequent starting and stopping, but the varying water demand and storage capacity usually require some combination of on and off time. Both over-pumping and frequent starting and stopping can damage the aquifer, resulting in reduced yield. In coastal areas, over-pumping may also cause saltwater intrusion. Frequent start/stop operations also shorten equipment life and consume more energy. It is usually preferable to limit pump starts to fewer than one per hour.

Follow the recommended operation guidelines below. Well pump information is included in *AWWA M21* and best practice *Small Water System Operation and Maintenance*.

- Always prime the pump with potable water.
- Disinfect the pump and drop pipe before installation and after any repair.
- Disinfect the equipment as it is lowered into the well, with special attention to the disinfection of the pump packing.
- Keep the drain from the pump base open and provide for the drain to be diverted away from the source.

3-3.1.4 Safe Pumping Yield.

Safe pumping yield is the amount of water that can be withdrawn from a well without producing an undesired effect on the well production. It is developed by comparing the measured drawdown to the maximum measured drawdown and how long it takes for the well to recover. This is further defined as the maximum amount of water that the well can produce over a certain period. Operate the well at a pumping rate that achieves 50% of the maximum drawdown to prolong the life of the well and decrease maintenance. Perform maintenance on the well to restore well yield if the desired yield cannot be obtained at this pumping rate.

3-3.1.5 Well Disinfection.

Disinfect wells, springs, infiltration galleries, and radial collectors as a normal maintenance procedure. Disinfect deep wells after original development, each time the pump is removed, each time the screen is cleaned using the surging method, and whenever regular bacteriological analyses indicate contamination is present. Well disinfection is required because well components are susceptible to contamination by pathogens before and during installation. *ANSI/AWWA C654-13* provides steps for the disinfection of wells and can be used as a guide for procedures in chlorination and bacteriological testing. Full disinfection procedures are available in *AWWA A100*, Chapter 11.

The available disinfectants are described below.

- Calcium Hypochlorite. Select a calcium hypochlorite conforming to AWWA B300 in granular or tablet form containing approximately 65% available chlorine by weight. Store the container in a cool, dark, dry environment to prevent deterioration. It is recommended that calcium hypochlorite not be used in water with high calcium hardness (greater than 100 milligrams per liter [mg/L]) unless it is dissolved in solution prior to well application.
- Sodium Hypochlorite. Select a sodium hypochlorite conforming to AWWA B300 that contains approximately 5 to 15% available chlorine. Special attention must be paid to control its length of storage and conditions to minimize deterioration.
- Liquid Chlorine. Liquid chlorine should only be used in combination with appropriate gas-flow chlorinators and injectors and under the direct supervision of an employee trained in its use and emergency procedures. Select chlorine conforming to AWWA B301 that contains 100% available chlorine and packaged in steel containers. See Table 3-1 for proper chlorine volumes. All chemical disinfectants must meet NSF/ANSI 60 certification requirements.

Table 3-1 Liquid Chlorine Volume per Water-Filled Well at 50 mg/L

Well Diameter		Volume per Water Depth	
in.	(mm)	gal/100ft	(L/m)
4	(101.6)	65.28	(8.1)
6	(152.4)	146.9	(18.2)
8	(203.2)	261.1	(32.4)
10	(254.0)	408.0	(50.7)
12	(304.8)	557.5	(73.0)
16	(406.4)	1,044.0	(129.7)
20	(508.0)	1,632.0	(202.7)
24	(609.6)	2,350.0	(291.9)
30	(762.0)	3,672.0	(456.0)
36	(914.4)	5,287.0	(656.7)
48	(1,219.2)	9,400.0	(1,167.5)
60	(1,524.0)	14,690.0	(1,824.1)

in. = inch; L = liter; mm = millimeter; m = meter

3-3.1.5.1 Well Disinfection Procedure.

Follow the below procedures for well disinfection.

a. Divert surface runoff, properly store equipment and components to prevent contamination, use drilling fluid additives that do not promote bacteriological growth, and cover the well between work periods

b. Select a disinfectant that is approved for use in potable water and the desired form: liquid chlorine, sodium hypochlorite solution, or calcium hypochlorite granules or tablets

c. Chlorination of Well after Equipment Installation. Treat water in the well casing to create a chlorine residual greater than or equal to 50 mg/L by using sodium or calcium hypochlorite. See Table 3-2 for proper chlorine application amount by well size. Surge the well three times and verify the chlorine residual of the water surged. Allow chlorinated water to rest in casing for a 12-hour minimum then pump to waste, testing the discharge water periodically for chlorine residual. When no residual is detected, pump the well to waste for 15 minutes and follow with bacteriological testing.

d. Bacteriological Testing. After the well has been chlorinated, 12 hours have passed, and it has pumped to waste for a minimum of 15 minutes with no detectable chlorine residual, at least two water samples shall be taken from the well while it is continuously pumped. Samples must be a minimum of 30 minutes apart. Test the samples for coliform in accordance with Standard Methods for the Examination of Water and Wastewater. If coliform testing is negative, the well may be placed into service. If samples test positive for coliform, perform one or more of the following procedures:

e. Pump the well to waste for a minimum of 15 minutes and repeat the sampling procedure.

f. Repeat well chlorination and testing.

g. Perform corrective action as directed by a qualified groundwater professional or engineer experienced in water well disinfection.

h. Disinfection of Flowing Wells. Perform bacteriological testing. If the samples test positive for coliform, apply chlorine at or below the lowest aquifer formation producing the artesian condition in an amount that will produce a chlorine concentration of a minimum of 25 mg/L in the flowing water. If samples still test positive for coliform, perform corrective action as directed by a qualified groundwater professional or engineer experienced in water well disinfection.

3-3.1.6 Well Records.

Maintain these well records:

- Well boring log
- Well construction record drawings
- Pump design details
- Maintenance records
- Water quality analyses
- Well discharge meter readings
- Schedule of well use (include duration of use)
- Pumping and static levels of well capacity tests
- Discharge pressure at various pumping rates
- Pump curve

Long-term records of rainfall and departures from normal rainfall amounts help show whether changes in the level of the water table and artesian pressure surface are caused by variations in long-term rainfall patterns.

For the Air Force, use form *AF997* to record well information.

3-3.2 Well Maintenance and Rehabilitation.

3-3.2.1 Cleaning Well Screens.

Decreasing yield is often caused by a clogged well screen or a clogged aquifer near the well bore. Clean the well screen to increase the yield if the specific capacity has dropped to 60% of the well's original specific capacity. Redevelop the well if the specific capacity has dropped to 40% of the well's original specific capacity. Basic methods for cleaning deep well screens in-place are described below. Refer to *AWWA M21* for best practice information. All well components need to meet *NSF/ANSI 61* requirements. Shallow well screens can be removed for cleaning.

3-3.2.1.1 Acid Treatment.

Calcium carbonate, calcium sulfate, and iron oxide deposits can cause screen encrustation. Corrosion may also cause encrustation. Screens can be cleaned with properly inhibited muriatic acid or sulfamic acid. Estimate the severity of encrustation from the records of changes in yield, specific capacity, and, or, drawdown. Use an experienced and qualified contractor to perform acid treatment. Unless otherwise directed by the utility manager, base personnel do not typically perform acid treatment operations. Do not pump nearby wells when acid treatment is in progress.

3-3.2.1.2 Chlorine Treatment.

Adding chlorine to a clogged well destroys bacterial slime growths. Follow the steps below for chlorine screen cleaning.

a. Prepare solutions of chlorine that produce 100 to 200 mg/L of chlorine when mixed with the water in the well (Table 3-2). Introduce the solution into the well carefully through a hose placed in the case with its discharge end at the level of the screen.

b. Allow the well to stand for 24 hours. Then pump water to waste until the chlorine residual reaches 0.1 mg/L. Surging during chlorine treatment is helpful (see 3-3.2.1.7).

c. Perform three or four successive treatments with chlorine. Alternating acid treatment with chlorine treatment can be effective. Complete the acid treatment first, followed by chlorine treatment after most of the acid has been pumped to waste. A second series of acid and chlorine treatments can be undertaken after the initial acid and chlorine treatments have been completed.

d. Remove the well pump during chlorine-soaking period. Chlorine and chloride will pit and damage iron and steel pump components as well as some stainless steels at levels of 50 mg/L and less.

Table 3-2 Materials Required for 100 Gallons (400 Liters) of Chlorine Solution

Desired Chlorine Strength	Chlorine		Dry Calcium Hypochlorite 70%		Quarts (L) of Bleach Per 100 Gallons (400 L) of Water		
	lbs	(g)	lbs	(g)	5%	7%	10%
50 ppm	0.05	(23)	0.07	(32)	0.4	0.3	0.2
100 ppm	0.10	(45)	0.14	(65)	0.8	0.6	0.4
150 ppm	0.15	(68)	0.20	(97)	1.2	0.9	0.6
200 ppm	0.20	(91)	0.30	(130)	1.6	1.2	0.8
300 ppm	0.25	(113)	0.40	(162)	2.4	1.7	1.2
400 ppm	0.35	(159)	0.50	(227)	3.2	2.3	1.6

g = gram; L = liter; lbs = pounds; ppm = parts per million

3-3.2.1.3 Phosphate Treatment.

The glassy phosphates (sodium hexametaphosphates) act as dispersing agents on such screen-plugging materials as amorphous silica, hydrated ferric oxide, iron carbonate, and calcium carbonate. Follow these treatment steps:

a. Dissolve 15 to 30 lbs (7 to 14 kilograms [kg]) of glassy phosphate in a minimum amount of water and add 1 lb (450 g) of calcium hypochlorite for each 100 gal (400 L) of water in the well casing (under static conditions). To dissolve the phosphate, suspend the chemical in a wire basket or burlap bag. Do not simply dump the phosphate in the dissolving tank or barrel. Add the solution to the well through a tremie-like pipe placed in the case with its discharge end at the level of the screen.

b. Allow the solution to remain in the well for 24 to 48 hours and surge approximately every 2 hours. If surging is not possible, allow the solution to stand in the well for 1 week.

c. Treatment with glassy phosphate for more than 1 week may cause the well yield to decrease. Phosphorus can be adsorbed to clays and become available to bacteria for metabolism and cell growth and development and subsequently increased clogging.

d. After treatment, pump the well to waste for 8 hours and test the output. Repeat the treatment until the output no longer improves. Analyze the phosphate content of the well water after final treatment and pumping to make sure it has been reduced to normal background levels. All treatment chemicals must meet NSF/ANSI 60 certification requirements.

3-3.2.1.4 Dry Ice Cleaning.

Use compressed carbon dioxide gas, or “dry ice,” to clean deep wells with high static levels. Follow these steps:

a. For wells measuring 6 to 10 in. (150 to 250 mm) in diameter, use 10 to 15 lbs (4.5 to 7 kg) of dry ice for light surging and 25 to 50 lbs (11 to 23 kg) for heavy surging. Drop pieces of broken dry ice of about 2 in. (5 centimeters [cm]) in diameter into the well casing until enough has been added to blow the water through the screen. The water will not freeze if there are 11 lbs (5 kg) or approximately 1.5 gal (5 L) of water in the well casing for each pound (450 g) of dry ice added.

b. Provide a pressure gauge on the well casing and seal the well to prevent loss of carbon dioxide. When the gas is released, it expands and creates a surging action that produces backpressure and backwashing of the screens. The escape of gas through the water-bearing strata will be evident from irregular movement of the pressure gauge needle. The particular conditions involved are different in practically all cases, and the exact procedure depends largely on the operator’s judgment.

Caution: Dry ice may cause “burns” if handled with bare hands. Use heavy gloves or tongs. Also, since high pressure may develop during dry ice treatment, provide for control and release of excessive pressure (150 pounds per square inch [psi] or 1,030 kiloPascals [kPa]). The gas is suffocating. Provide ample ventilation.

3-3.2.1.5 Jet Cleaning.

Clean a well from inside the well screen by horizontal jet cleaning. Figure 3-2 shows the jetting tool. The process requires only a relatively simple jetting tool with an attachment fitted with horizontal nozzle orifices, a high-pressure pump, a hose, a string of 2-in. (50-mm) pipe, and an adequate water supply. Follow these steps to jet clean a well screen:

a. Select a nozzle to match the output of the high-pressure pump used and the well pump (Table 3-3).

b. Attach the string of 2-in. (50-mm) pipe to a hose with a swivel connection at the top.

c. Lower the jetting tool into the screen. Turn on the high- pressure pump and slowly rotate the jetting tool while raising and lowering it. The forceful action of the high-velocity jets, working the water through the screen openings, breaks up the clog.

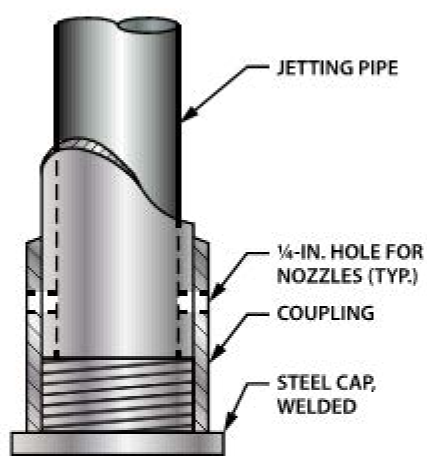
d. Pump the well lightly while the jetting is under way to remove the dislodged material. The well pump should pump out approximately 15% more water than is being added to the well by the jetting tool.

Table 3-3 Jetting Nozzle Discharge

Orifice		150 psi				200 psi				250 psi			
		1 Nozzle		2 Nozzles		1 Nozzle		2 Nozzles		1 Nozzle		2 Nozzles	
in.	(mm)	gpm	(Lps)	gpm	(Lps)	gpm	(Lps)	gpm	(Lps)	gpm	(Lps)	gpm	(Lps)
3/16	(5)	13	(0.8)	25	(1.6)	15	(0.9)	29	(1.8)	17	(1.1)	33	(2.1)
1/4	(6)	23	(1.5)	45	(2.8)	26	(1.6)	52	(3.3)	52	(3.3)	37	(2.3)
3/8	(10)	49	(3.1)	97	(6.1)	56	(3.5)	110	(6.9)	61	(3.8)	120	(7.6)

gpm = gallons per minute; Lps = liters per second. Nozzle discharge rates in Lps are approximate.

Figure 3-2 Jetting Tool for Well Screening



3-3.2.1.6 Sonic Process Cleaning.

Sonic process cleaning is performed by outside contractors by lowering a series of small, explosive charges on a wire into the well and detonating them by means of an electrical charge at the surface. The size of each charge depends on pipe size, thickness, grade, type, and condition. The charges are placed on a connecting wire at calculated distances and detonated in a special time-delay sequence. Each charge, lasting only a fraction of a second, creates an expanded gas bubble that produces a shock wave at its leading edge as it rushes down the well column. As the wave strikes the well casing, it causes strong vibrations that help loosen the clog. The expanding bubble also produces a surging action that helps clean the screen. This action is repeated with the detonation of each charge. Sonic processes are most effective in sandstone aquifers where clogging may only extend 1 to 2 in. into the aquifer. Do not use any other method of blasting for cleaning screens.

3-3.2.1.7 Surging.

Clean a well by surging if it is not desirable to pull the pump. Surging can be done by utility personnel or by seeking expert help. Follow the steps below to clean a well by surging.

a. Disconnect the discharge of the pump and alternately start and stop the pump. This operation raises the water in the pump casing and allows it to fall again. The greater the distance to the static water level, the more effective the operation. If the water level in the well stands at a high elevation, a surge pipe may be attached to the discharge of the pump.

b. Repeat the process of starting and stopping the pump at 3- to 5-minute intervals until the discharge runs clear. Water running back down the pump column just after the pump is stopped may cause the motor and impeller to turn in a reverse direction. Do not attempt to start pump during this reverse rotation.

3-3.2.1.8 Backwashing and Surging.

Backwash a well by allowing a large volume of water to rush down the casing if surging alone is not sufficient. Follow these steps:

a. Where bypass pump connections or wash-water lines are not included in the installation, remove the flap in the check valve.

b. Open the pump discharge valve and allow a full head of water from the storage tank to rush down the well casing. If the casing fills rapidly, it is because the screen is badly clogged. Caution: Before starting the backwash operation, be sure the pump and motor turn freely. Otherwise, the downrush of water may rotate the pump in the wrong direction and unscrew the pump shaft.

c. Allow the backwashing to continue for approximately 5 minutes then close the backwash valve, open the pump discharge valve, and start the pump. Run the discharge to waste until the water is clear. Repeat the operation. Check the results by measuring the water level and yield.

3-3.2.1.9 Backwashing and Backblowing.

Allow only experienced personnel to backwash with water and backblow with air only after pulling the well pump. The compressed air increases the surging action and provides air-lift pumping that removes dislodged sand. Follow these procedures:

a. Remove the well pump and insert a 4-in. eductor pipe to a depth according to Table 3-4. The arrangement of eductor pipe and airline is shown on Figure 3-3.

Table 3-4 Eductor Submergence Required for Various Well Depths

Depth of Well (ft)	Depth of Well (m)	Submergence of Eductor (percent of well depth)
10–50	(3.0–15.2)	70–66
51–100	(15.5–30.5)	65–55
101–200	(30.8–61.0)	54–50
201–300	(61.3–91.4)	49–43
301–400	(91.7–121.9)	42–40
401–500	(122.2–152.4)	39–33

m = meter

b. Cap the 4-in. (100-mm) eductor line with a tapped pipe plug through which the air line runs. Connect the air pipe by means of an air hose (or non-rigid system) to an air compressor having a minimum capacity of 110 cubic feet per minute (cfm) or 50 Lps.

c. With the eductor valve open, build up the air pressure until the water is discharged and pressure reaches a constant value. Pump the water until it runs clear.

d. Release the air pressure, close the 4-in. discharge valve, and apply air until static pressure is reached. At this point, air escapes from the bottom of the 4-in. eductor pipe and causes both air and water to surge through the screen and create movement in the sand and gravel.

e. Open the 4-in. (100-mm) valve and allow the air-lift to pump out the loosened sand and silt.

f. When the water is clear, repeat steps d and e above. Faster results can be obtained if water can be pumped into the well casing while the air is being added (step d above).

g. Check results after each series of operations. An increase in pumping pressure on the gage indicates increasing inflow into the well and less drawdown. Caution: When starting backblowing operations, do not start at maximum rates. Always keep the gravel chamber full to replace sand loss.

h. For this operation, provide excess air. The desirable amounts of excess air, with 50% submergence, are shown in Table 3-5.

Table 3-5 Air Requirements for Backwashing Well Screen with Air Lift

Lift		**Air Required per volume pumped**	
ft	**(m)**	**Cfm/gal**	**(Lps)**
100	(30.48)	0.5	(0.2)
200	(60.96)	0.7	(0.3)
400	(121.92)	1.0	(0.5)
500	(152.40)	1.5	(0.7)

cfm = cubic feet per minute; L = liters; min. = minute

3-3.2.2 Repairing Well Screens.

Check the wire windings, bail plug, and packer on all screens that are pulled. Replace damaged or corroded screens or return them to the factory for repair. It is not recommended to repair well screens in the field.

3-3.2.3 Abandonment of Wells.

Wells may be abandoned because of lowered water table, plugged screens, corroded casings that allow soil to enter the well, or objectionable sand pumping. For deep wells and driven wells, pull the casing and fill the hole with concrete. Securely cap the top of the well to prevent contamination of the aquifer and protect people or animals against falling into the well. Fill abandoned dug wells and springs as a safety measure.

3-3.2.4 Maintaining Specific Well Types.

In addition to the general maintenance items common to all wells, different types of wells require special care because of their construction or operation. Groundwater supply maintenance procedures are summarized in Table 3-6. The frequencies shown in Table 3-6 are suggested and may be modified by local command as individual installation conditions warrant.

Figure 3-3 Piping Arrangement for Backwashing and Backblowing

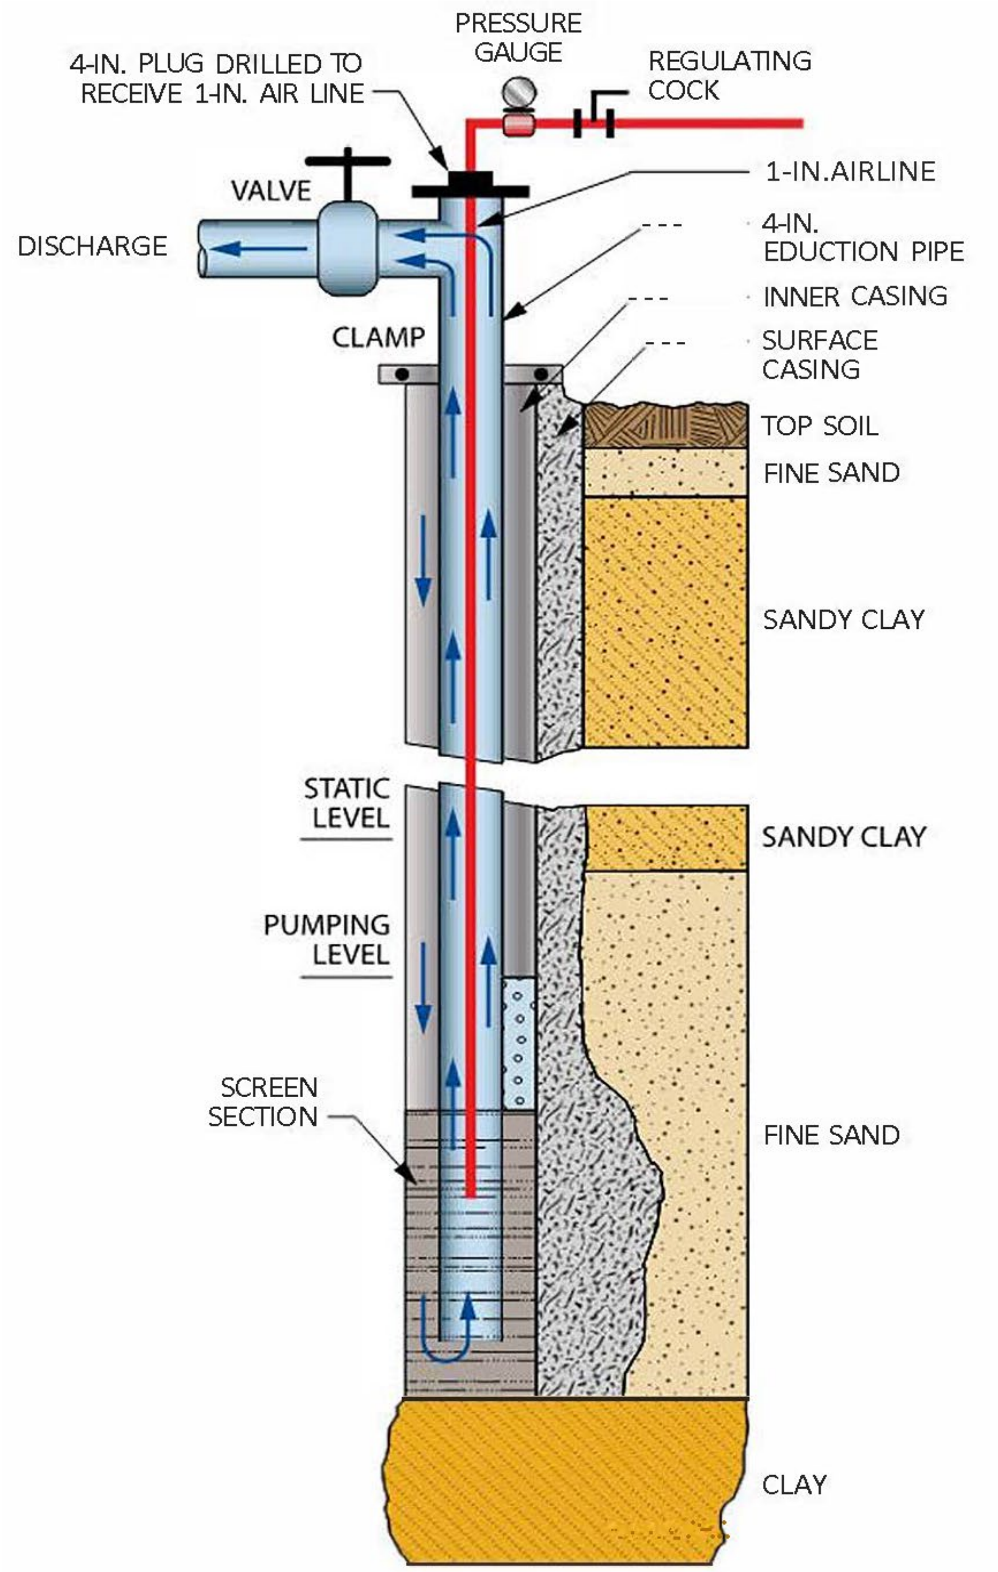


Table 3-6 Maintenance Checklist for Groundwater Supplies

Inspection	Action	Frequency
Operating record review	Ascertain changes in conditions since previous inspection and take necessary action.	Semi-annually
Sanitary conditions	Dig ditches to carry away standing water within 50 ft (15 m) of well, spring, or infiltration gallery.	Semi-annually
	Operator to ensure storm water flow does not flow across the well area. Divert storm water flow around well to prevent contamination.	Semi-annually
Pollution sources	Fence area to keep livestock at least 50 ft (15 m) from well or spring.	Semi-annually
	Remove cesspools, privies, or septic tanks; cover area with hypochlorite; fill any open excavations resulting from removal.	Semi-annually
Wells, springs, infiltration galleries, and silt	Remove accumulations of more than 1 ft (30 cm).	Variable
Concrete; cracks in housing; other watertight structures in wells, springs, infiltration galleries, and radial wells	Repair as necessary by making surface structure watertight.	Quarterly
	Shore up infiltration gallery wall structures.	Quarterly
Operating records and evidence of contamination	Disinfect wells, springs, and infiltration galleries, when indicated.	Variable
Well output loss and condition of well screen	Clean well screen by approved method.	Variable
Well equipment (well apron, top of casing, well	Repair as necessary to make all items watertight.	Semi-annually

Inspection	Action	Frequency
pits); cracks and possible leakage		
Well vents	Clean, repair, or replace if torn or clogged.	Monthly
Water use for equipment operation	Make certain water for bearing lubrication and pump priming are from a safe supply and that cooling water for engines and compressors is not returned to water system.	Semi-annually
Air intakes on compressors	Screen air intake if necessary, clean and replace air filters, and blow down air storage tanks to remove accumulated oil.	Monthly
Bored wells: casing failure	If water is turbid, the screen is defective; remove and replace.	Variable
Dug wells: silt accumulation; wall failure	Clean as necessary, repair cracked walls, and increase capacity if necessary by driving horizontal collector pipes.	Quarterly
Driven well: decrease in water yield; screen clogging	Try backwashing or pull the point and clean or replace.	Monthly
Gravel-packed wells: silt clogging of screen and gravel pack; gravel level	Clean as necessary; add new gravel as required to keep the level at proper elevation.	Monthly

3-3.2.4.1 Maintaining Bored Wells.

Casing failures and screen clogging are the primary causes of failure in bored wells. Clean or replace screens when experiencing high turbidity in the water.

3-3.2.4.2 Maintaining Dug Wells.

The masonry or concrete casings are subject to cracks and joint failure that can allow surface water into the well. Perform periodic removal of silt and sand accumulated at the well bottoms.

3-3.2.4.3 Maintaining Driven Wells.

Driving the well point may damage the screen or seal it off. If water yield decreases, suspect screen clogging and try backwashing. If this fails, pull the point and clean it or replace it with a new one.

3-3.2.4.4 Maintaining Drilled Wells.

Screens can become clogged and will require periodic cleaning. Inspecting or removing the screen requires a major effort. Cleaning the screen in place is the preferred method (see Chapter 3 paragraph titled Cleaning Well Screens). Alternatively, remove, clean, and replace the screen.

3-3.2.4.5 Maintaining Gravel-Packed Wells.

Both the gravel and screen may become clogged in a gravel-packed well. Add gravel periodically to keep the gravel level above the well screen.

3-3.2.5 Maintaining Springs.

Springs are subject to surface contamination. Inspect the area around the spring regularly to detect contamination and guide preventive measures for contamination control. If contamination is detected, thoroughly disinfect the spring before returning it to service.

3-3.2.6 Maintaining Infiltration Galleries.

In addition to silt accumulation, undermining of walls and failure of the wall structures may occur. Operating records on static level and drawdown will indicate whether the yield is being maintained. Perform maintenance functions such as cross bracing, adding sheet piles, and adding gravel to increase the service life of the structure. Consider driving wells in the bottom of galleries to increase the yield.

3-3.2.7 Maintaining Radial Wells.

Shallow radial water collectors may be subject to contamination from overlying ground pollution. Remove silt or sand that may accumulate in the caisson on a regular basis. Dewater the collector well and unite the surface if spalling of concrete walls is severe.

3-4 SURFACE WATER SUPPLIES.

General information on surface water supplies, water storage, intake structures, and low-lift pumping can be found in *AWWA M50*. Best practice reference information can also be found in *Water Treatment Plant Operation, Volumes 1 and 2*.

3-4.1 Operation.

Operating functions consist of surveying the watershed to locate possible contamination sources and controlling those sources as much as practical. Total ownership of the watershed is seldom possible, so agreements with others may be necessary to ensure a high-quality water source.

3-4.1.1 Intake Operation.

Many intakes are fitted with gates at various depths. Others have an adjustable suction pipe attached to a floating raft to draw water from the reservoir or lake at different levels. Experience will tell the operator which water intake depth yields the best water.

Damage by surface ice can be prevented by locating an intake below the ice level and placing lake intakes beyond the ice line of the lake. The intake structure, however, must be designed to withstand the pressure of the ice. If ice around an intake cannot be removed by scraping or other manual means, remove it by pumping water out of the intake (reverse flushing). If necessary, steam can be piped into the water to raise the temperature.

Table 3-7 provides inspection tasks and recommended frequencies. Actual frequencies may differ as determined by local command. Maintenance frequencies should follow best practice *Sacramento Course-Small Water System Operation and Maintenance*.

Table 3-7 Inspection and Maintenance Checklist for Surface Water Supplies

Inspection	Action	Frequency
Watershed area	Ensure that facilities are in working order for sewage disposal and garbage and trash removal. Remove debris.	Quarterly
Recreational facilities on watershed	Clean and repair facilities.	Monthly
Reservoirs	Remove vegetation in shallow water and vary water level a few inches for mosquito control.	Every 10 days (summer only)

Inspection	Action	Frequency
	Report algae blooms to operating staff.	Weekly (summer only)
	Dredge when there is extensive capacity loss by siltation; determine silting extent by comparing reservoir volume with the initial contour prior to sounding surveys and calculate storage capacities.	Annually
	Remove debris and extraneous vegetation from sides and bottom, if exposed. Grade sides to prevent erosion.	Weekly
Dams	Check for leakage and exposed surface conditions.	Monthly
	Verify that riprap on the upstream face is even and in good condition.	Annually
	Check for ice formations.	Daily (winter)
	Check spillway for trash, debris, and ice.	Daily (winter)
	Lubricate gates and appurtenances.	Monthly
Intake structures	Check for cracks, silt deposits, and ice clogging.	Weekly
	Check for material on screens not removable by regular operational procedures.	Weekly

3-4.2 Maintenance.

3-4.2.1 Intake Maintenance.

Intake stoppage may, in most cases, be cleared by backflushing the intake conduit or pipeline. When danger of intake stoppage exists, keep backflushing equipment readily available.

Maintenance operations on intakes in rivers, lakes, and impounded reservoirs involve the structures and their appurtenances.

- Inspect all structures periodically for cracks or structural defects.
- Measure the depth of the suction well to determine the accumulation of silt and sand. Dredge these accumulations as necessary.
- When ice conditions endanger the structure or clog the intake opening, take protective measures. Install log booms or bubble compressed air into the water at critical points to prevent freezing. Frazil ice can form in supercooled water and may cause complete blockage of intakes. Best practice information on frazil ice can be found in Water Treatment Plant Operation, Volumes 1 and 2.
- For the Army, see Preliminary Report: Field Test of Trash Rack Heating to Prevent Frazil Ice Blockage.
- Remove any material on screens that is not removable by ordinary operations. Lubricate and repair any accessory equipment to movable screens.

Table 3-8 Maintenance Checklist for Dams

Symptom	Possible Cause	Action
Excessive and, or, muddy seepage water exiting from a point	Water created an open pathway, channel, or pipe through the dam and is eroding and carrying embankment material.	Estimate or measure the outflow quantity. Determine whether it is increasing with time and if material transport by the flow is continuing.
		Lower the reservoir water level.
		Search for an opening on the upstream of the dam and plug it if possible.

Symptom	Possible Cause	Action
	Rodents, frost action, or poor construction allowed seepage water to create an open pathway.	Place filter sand at the seepage exit location to prevent material from being transported along with seepage. Place gravel initially, if needed, to slow the flow velocity and prevent the sand from washing away. Cover sand filter with gravel.
Seepage exiting from a point adjacent to the outlet pipe	A break or hole in the outlet pipe or poor compaction around the pipe allowed water to flow and create a pathway along the outside of the outlet pipe.	Determine if seepage is carrying soil particles (muddy water). Determine flow rate and if it is increasing with time. If flow increases or is carrying material, lower the reservoir level until seepage stops. Investigate the embankment along alignment of pipe to identify signs of settlement or sinkholes.
Seepage is exiting as a boil downstream from the dam	Part of the foundation material is supplying a path for reservoir seepage, possibly by sand or gravel layer in the foundation.	Examine the boil to see if foundation materials are being transported (typically expressed as a ring of material around the exit). If soil particles are building up at exist points, use sandbags or earth to create a dike around the boil. If the situation cannot be controlled with sandbags and soil materials are being carried by the flow, lower the reservoir water level.
		Measure outflow quantity and determine whether the seepage flows are

Symptom	Possible Cause	Action
		increasing with time and material is being transported.
		Lower the reservoir water level.
		Search for an opening on the upstream of the dam and plug it if possible.
Seepage water is existing at the abutment contact	Water flowing through pathways in the abutment or along embankment abutment contact resulted in erosion.	Place filter sand at the seepage exit location to prevent material from being transported along with seepage. Place gravel initially, if needed, to slow the flow velocity and prevent the sand from washing away. Cover sand filter with gravel.
		Check seepage and leakage outflows for muddy water.
		Inspect dam appurtenances for other anomalies (new seepage areas, depressions, cracks).
Sinkhole	Internal erosion (piping) or embankment materials or foundation.	Check seepage and leakage outflows for muddy water.
	Eroded cavern (cave-in).	Inspect dam appurtenances for other anomalies (new seepage areas, depressions, cracks).
	Small hole in the wall of an outlet pipe.	

Symptom	Possible Cause	Action
Slide, slump, or slip	Foundation movement or a too-steep slope caused earthfill to move along a slip plane.	Evaluate extent of the slide. Inspect for new or changed seepage conditions downstream of the slide area and for longitudinal and transverse cracks or scarps near the slide. Draw down the reservoir level.
Transverse cracking	Differential settlement between adjacent segments of the embankment.	Inspect the crack and record its location, length, width, depth, and other pertinent physical features. Stake out the crack limits.
		Under engineer's direction, excavate the crest along the crack to a point below the bottom of the crack. Backfill the excavation using suitable material and correct construction techniques. Visually monitor the crest routinely for evidence of future cracking.
Longitudinal cracking	Slope instability.	Inspect the crack and record its location, length, width, depth, and other pertinent physical features.
	Liquefaction of the foundation and, or, embankment materials after an earthquake.	Effectively seal the crack to prevent surface water infiltration.
	Differential settlement between zones or within embankment.	Visually monitor the crest routinely for evidence of future cracking.

Symptom	Possible Cause	Action
Rodent activity and animal impact	Cattail-filled areas and areas where trees are close to the reservoir provided an ideal habitat for animals.	Start a rodent control program.
	Overabundance of rodents increased the chances of burrowing, which created holes, tunnels, and caverns within the embankment dam.	Backfill existing rodent holes with suitable, well-compacted material.
		For large or deep holes, include a zone of filter material when backfilling.
Trees or obscuring vegetation	Natural vegetation obscured visual inspection and harbored animals.	Control vegetation that obscures visual inspection of the embankment.
	Large tree roots created seepage paths.	Under engineer's direction, remove all large, deep-rooted trees and shrubs on or near the embankment with care. Backfill voids promptly.
	Large trees blew over during a storm and damaged the dam.	Remove trees at the toe and groins of the dam to provide a 25- to 50-ft buffer. Monitor area for sinkholes and seepage paths after tree removal.
Surface erosion	Water from intense rainstorms or snowmelt carried surface materials down the slope and created continuous troughs, rills, and gullies.	If detected early, add protective grasses. Restore and protect eroded areas; add rock or riprap where appropriate.
	Upstream erosion from a face not protected with riprap.	Reestablish the normal slope. Place bedding material and properly sized riprap.

Symptom	Possible Cause	Action
Deteriorated or missing riprap	Poor quality riprap deteriorated.	Reestablish the normal slope. Place bedding material and properly sized riprap.
	Wave or ice action displaced riprap.	
	Riprap was improperly sized.	
Low area in dam crest	Excessive settlement of the embankment or internal erosion of embankment material.	Establish survey monuments or survey along the length of the crest from abutment to abutment to determine the exact amount, location, and extent of low spots on the crest. Use proper construction techniques to fill in the low area and reestablish the uniform elevation over the length of the crest. Routinely survey established monuments along the dam crest to detect any unusual settlement.
	Foundation spreading upstream and, or, downstream.	
	Prolonged wind erosion.	
	Improper final grading post-construction.	

3-5 WATER QUALITY.

Raw water supplies may be impacted by various materials, most of which are water soluble to some degree. Impurities and, or, contaminants can create undesirable qualities to water, pose a threat to humans, or cause no significant problems. The various water characteristics and contaminants that can impact water quality, are listed in Table 3-9.

Table 3-9 Water Quality Characteristics

Physical	Chemical	Biological	Radiological
Temperature	pH	Algae	Radionuclide contamination
Turbidity	Alkalinity	Bacteria	Industrial processes
Color	Hardness	Viruses	Medical processes
Taste	Calcium	Protozoa	
Odor	Stability	Macrophytes	
	Iron		
	Manganese		
	Dissolved oxygen (DO)		
	Fluoride		
	Organic chemicals		
	Inorganic chemicals		

CHAPTER 4 WATER TREATMENT

4-1 WATER TREATMENT.

Treatment consists of adding and, or, removing substances from water to bring about a desired change in quality. In general, treatment is provided to protect public health or improve the acceptability (aesthetic quality) of the finished product. This chapter is a guide to basic information on most of the common water treatment processes

4-2 TREATING WATER AT THE SOURCE.

Treatment of water supplies is generally done at a treatment plant where positive monitoring and control is possible. Sometimes, however, providing treatment at the source (in situ treatment) is more economical or practical. Treating reservoirs for algae or zebra mussel control is an example of in situ treatment. For detailed information on specific in situ treatment techniques, see *AWWA M7* and *AWWA M21.* For additional best practices use *Water Treatment Plant Operation, Volumes 1 and 2*.

4-3 UNIT TREATMENT PROCESSES.

See Chapter 10 for general maintenance routines and procedures for mechanical equipment associated with unit treatment processes.

4-4 TASTE AND ODOR CONTROL.

Controlling tastes and odors is one of the most troublesome problems in water treatment. Tastes and odors appear in both ground and surface water supplies. The main means of control are aeration, adsorption, and oxidation. Best practice information on taste and odor can be found in *Identification and Treatment of Tastes and Odors in Drinking Water*.

4-5 CONTROLLING ORGANIC CHEMICALS.

The SDWA regulates four categories of organic contaminants: pesticides, volatile organic compounds (VOCs), synthetic organic chemicals, and disinfection byproducts (DBPs). Effectively removing organic chemicals requires special treatment techniques. See Chapter 2 paragraph titled Regulations Affecting Water Systems for monitoring and reporting requirements.

4-5.1 Pesticides Group – Treatment.

Activated carbon adsorption is the most effective method available for removing pesticides. Some pesticide removal occurs during conventional treatment by coagulation, sedimentation, and filtration. However, removals are usually less than 10%. Chemical oxidation with chlorine, ozone, or potassium permanganate also removes less than 10% of pesticides.

Conventional water treatment followed by activated carbon adsorption effectively removes pesticides from drinking water. The effectiveness of carbon adsorption depends on the concentrations of absorbent and adsorbate, contact or residence time, competition for available adsorption sites, and the temperature and pH of the water. Dosage requirements can only be determined after sampling and by laboratory analysis or pilot plant operations.

- When adding powdered activated carbon (PAC), use multiple points of injection for maximum efficiency of the adsorbent and to maximize pesticide removal. A disadvantage of PAC is that the sludge formation after application requires further treatment.
- Provide continuous online operation when granular activated carbon (GAC) beds are used to protect against pesticide contamination. Demonstrations have shown that organic pesticides can be adsorbed with virgin or exhausted GAC used for odor control.

4-5.2 VOCs Group.

Volatile Organic Compounds (VOCs) are a group of organic chemicals that include any compounds of carbon that have photochemical reactivity in the atmosphere. These do not include carbon monoxide, carbon dioxide, carbonic acid, metallic carbides, carbonates and ammonium carbonate, or any carbon compound that has negligible photochemical activity, as designated by the EPA.

4-5.2.1 Sources of VOCs.

Water supplies derived from groundwater, as well as from surface water, may contain VOCs. Contamination is most common in urban or industrial areas and is generally believed to be from improper disposal of hazardous wastes and industrial discharges.

Many of the regulated VOCs are suspected carcinogens, and the others may damage the kidneys, liver, or nervous system. The presence of one of these compounds, even at a low level, is a concern because these are manufactured chemicals (not naturally occurring in the environment), and their presence indicates the potential for further contamination of that source water.

Groundwater is of concern in that these waters move slowly and do not have a rapid natural cleansing mechanism. Thus, once groundwaters are contaminated, they generally will remain so for many years or decades.

4-5.2.2 VOC Treatment.

Methods for removing VOCs include aeration and GAC. PAC treatment or conventional drinking water treatment (coagulation, sedimentation, and filtration) have not proven effective. Methods such as reverse osmosis and macromolecular resins eventually may prove useful in removing VOCs. Before implementing a VOC control strategy, check local environmental regulations and permit requirements. Aeration could cause a violation of air quality standards. Spent carbon from GAC adsorbers could be considered a hazardous waste.

4-5.3 DBPs Group.

4-5.3.1 Sources of DBPs.

Chlorine, when used for bacterial and viral disinfection of water supplies, interacts with organic precursors present in natural waters to form a variety of chlorinated organic compounds, collectively called disinfection byproducts. DBPs are associated with chronic health problems, including cancer. Because the natural organic precursors are more commonly found in surface waters, water taken from a surface source is more likely than groundwater (with some exceptions) to have high DBP levels after chlorination. Several DBPs have been targeted for regulation, including THMs and haloacetic acids. Other oxidants used for disinfection, i.e., ozone and chlorine dioxide, can also form DBPs (although not to the same extent as chlorine).

4-5.3.2 DBP Treatment.

4-5.3.2.1 Use treatment options available at the base to meet DBP standards by substituting new disinfectants for chlorine that do not generate or produce fewer DBPs; reduce organic precursor concentrations before chlorination; and remove DBPs after formation.

4-5.3.2.2 If available, select from the following alternate disinfectants: ozone, chlorine dioxide, and chloramine. Closely monitor the microbiological quality of the treated and distributed water during the transition period to an alternate disinfectant. Where the plant footprint allows, use UV disinfection as an alternate method to deactivate microorganisms without the production of DBPs.

4-5.3.2.3 To reduce precursor levels, use available treatment features such as offline raw water storage, aeration, improved coagulation, ion exchange resins, adsorption on PAC and GAC, ozone-enhanced biological activated carbon, and adjustment of the chlorine application point. Preform bench- and pilot-plant studies to determine which treatment process will most effectively reduce precursor levels.

- The air-water ratio required for aeration to effectively remove volatile organic precursors is higher than the air-water ratios needed for taste and odor control or iron and manganese removal. The high air-to-water ratio promotes the growth of aerobic organisms (such as algae) and can be a significant problem.
- Some organic precursors are removed during coagulation. These organics often adhere to the particulate matter that settles.
- High doses of PAC remove only a portion of the precursors. High costs and sludge problems limit the use of PAC for precursor control.

- GAC can adsorb a wide spectrum of organics. Frequently, GAC adsorbs enough precursor material so that chlorine disinfection can follow GAC treatment without forming excessive DBP precursors.
- One of the quickest and least expensive ways of maintaining low DBP levels in chlorine-treated water is to chlorinate the water with the lowest possible organic content. If water is filtered, the filter effluent is the water with the lowest possible organic content. However, contact tanks must be previously constructed to achieve the proper contact time for adequate disinfection of filter effluent. Chlorinating coagulated and settled water reduces but does not eliminate DBP formation potential in finished water because DBP precursors continue to form during distribution. Disinfection before filtration limits bacterial growth in the filters. The absence of a disinfectant at the beginning of treatment may cause problems because of the growth of algae, slime, and higher forms in the early part of water treatment plants. Monitor the use of pre-disinfection to prevent filter fouling versus the production of DBP precursors early in the process.

4-5.3.2.4 Technology available for DBP reduction includes PAC, ozonation, GAC, and aeration.

- High doses of PAC and ozone are required to get substantial (but not complete) DBP removal. These processes would be too expensive considering the removals obtained.
- GAC filters can effectively remove DBPs (as well as other organics) below contaminant levels.
- Locating the aeration process after chlorination will remove volatile DBPs from the finished water. However, organic precursors not removed in the water treatment process continue to react with the remaining chlorine residual after aeration to raise DBP levels in the distribution system. Therefore, removing volatile DBPs from finished water by aeration is not considered a viable control method.

4-5.3.3 State Approval of Treatment.

A facility must obtain state approval before significantly modifying its treatment process to comply with DBP requirements. The facility is required to submit a detailed plan of proposed modifications and safeguards it will implement to ensure that the bacteriological quality of the drinking water serviced is not decreased by such changes. Each system must comply with the provisions set forth in the state-approved plan.

4-6 TREATMENT PLANT INSTRUMENTATION AND CONTROL.

The references below include information on meters, recorders, alarms, and automatic control systems. SCADA should record all operation conditions of treatment plant systems. Instrumentation and control (I&C) is covered in Chapter 8. Specific information is provided on flow, pressure, and level measurement in *AWWA M2*, and *AWWA M33.*

Best practice information is contained in *Water Treatment Plant Operation, Volumes 1 and 2*.

4-7 CHEMICALS AND CHEMICAL APPLICATION.

Information about chemicals commonly used in the water works industry are listed in Table 4-1. For additional information on specific chemicals used in given unit processes—including application, storage, handling, and chemical safety—refer to the appropriate unit process heading in this section. The following manuals provide best practice guidance on water plant process control: *AWWA M4, AWWA M12, AWWA M20, AWWA M30, AWWA M37, AWWA M46, AWWA M56* and *AWWA M58*. Maintenance of mechanical equipment is covered in Chapter 10.

4-8 WATER TREATMENT PLANT RESIDUES.

The most common residues from water treatment processes are designated as either “slurries” or “sludges.” Slurry solids are usually spent activated carbon or waste diatomaceous earth from diatomaceous filters. Sludges may be mud-like, natural sediments; gelatinous aluminum, magnesium, or iron oxides and hydroxides; or calcium carbonate (lime sludge). Water treatment processes that produce these sludges are presedimentation of raw water; chemical coagulation, flocculation, and sedimentation; lime-soda ash softening; iron and manganese removal; and filter backwashing.

Other residues are surface water intake screenings; aqueous solutions of sodium, calcium, and magnesium chlorides that result from regeneration of cation exchange water softening resins; and reject stream from membrane processes.

Refer to the applicable paragraphs in this chapter for a discussion of the residue characteristics and appropriate solids concentration and dewatering techniques for the various water treatment processes.

4-8.1 Disposal Methods.

It is preferable to dispose of residues in a way that is both economically and environmentally acceptable. Recovery and disposal systems often require increasing the solids content of a residue by removing water. The required solids concentration (and the method of concentration) depends on the chemical recovery or final disposal alternatives used. Combining filter backwash and chemical clarification sludges is a cost-effective way to equalize the sludge and thicken it prior to disposal. Table 4-2 summarizes water treatment plant residue-handling systems currently in use.

Note: Do not discharge residue to a natural water course or public sewer without the approval of the applicable federal, state, and local authorities.

(1) For discharge to sanitary sewers, avoid cross connections and slug flow and always check possible damage to sewer system from residue discharge; effects of residues on liquid and solids treatment processes at the wastewater treatment plant; and hydraulic capacity of the wastewater treatment facilities.

(2) Sedimentation basins or solids contact reactions ahead of filters will generally remove 70-90% of total plant solids. The remainder of solids will appear in the filter wash water.

(3) Returning filter backwash and thickener overflow streams to plant influent may be viewed with disfavor by regulators because of the possibility of recycling pathogens. See US EPA's *Filter Backwash Recycling Rule* for information on recycle streams.

4-8.2 Recovery Processes.

Alum, ferric chloride, ferrous sulfate, magnesium carbonate, and lime can be recovered from waste sludge by various methods. However, recovery usually is not economical except at the largest municipal facilities and, thus, is not considered viable for military installations. However, manufacturers of alum and ferric coagulants will sometimes agree to accept waste sludges for reprocessing.

4-8.3 Ultimate Disposal.

Traditionally, water treatment plant wastes have been disposed of by discharge to rivers and lakes, either directly or by way of a storm sewer. Current environmental laws do not allow this because such discharge harms the receiving body of water (e.g., cloudy water, toxicity to aquatic life, formation of sludge banks). Following are alternative methods of ultimate sludge disposal, which, in some cases, may be economical and environmentally sound solutions.

4-8.3.1 Discharge to Sanitary Sewer.

In general, water treatment plant residues can be disposed of by discharge to a sanitary sewer without upsetting the wastewater treatment processes. However, problems can result if the amount of sludge is too great.

- The sewer can be overloaded hydraulically by large batch dumps of sludge. This problem can be handled by storing the sludge in a holding tank, then bleeding the sludge slowly into the sewer during periods of low wastewater flow (such as after midnight). However, sewer flow needs to be sufficient to prevent sludge solids from accumulating in the sewer since the solids may then clog the sewer.
- The water treatment sludge solids increase the amount of sludge to be disposed of at the sewage treatment plant. Therefore, the dewatering and disposal problems are not eliminated, but simply shifted elsewhere. Water treatment plant sludge is not affected by sludge digestion processes at the sewage treatment plant but does take up digester volume. In some cases, water plant sludges have been reported to clog digesters.

Table 4-1 Chemicals Used in Water Treatment

Chemical Name and Formula	Common or Trade Name	Shipping Containers	Suitable Handling Materials	Available Forms	Weight, lb/ft^3	Solubility, lb/gal	Commercial Strength	Characteristics	AWWA Standard
Coagulation									
Aluminum sulfate, $Al_2(SO_4)_3 \cdot 14H_20$	Alum, filter alum, sulfate of alumina	100-, 200-lb bags; 300-, 400-lb bbls.; bulk (carloads)	Dry—iron, steel; solution—lead-lined rubber, silicon, asphalt, 316 stainless steel	Ivory-colored: powder granule lump	38–45 60–63 62–67	4.2 (60 °F)	15–22% $A1_20_3$	pH of 1% solution, 3.4	B 403
	Liquid alum	Bulk; tank trucks, tank cars		Pale green liquid			8.3% $A1_20_3$ liquid	Crystallizes at 5 °F	
Ammonium aluminum sulfate, $A1_2(SO_4)_3(NH_4)_2SO_4 \cdot 24H_20$	Ammonia alum, crystal alum	Bags; bbls, bulk	Duriron, lead, rubber, silicon, iron, stoneware	Lump nut pea powdered	64–68 62 65 60	0.3 (32 °F), 8.3 (212 °F)	11% $A1_2O_3$	pH of 1% solution, 3.5	
Bentonite	Colloidal clay, volclay, wilkinite	100-lb bags; bulk	Iron, steel	Powder, pellet, mixed sizes	60	(Insoluble colloidal suspension used)			
Ferric chloride, (a) $FeCl_3$(35-45% solution)	“Ferrichlor,” chloride of iron	5-, 13-gal carboys; trucks; tank cars	Glass, rubber, stoneware, synthetic resins	Dark brown syrupy liquid		Complete	37–47% $FeCl_3$, 20–21% Fe		
(b) $FeC1_3 \cdot 6H_2O$	Crystal ferric chloride	300-lb bbls.		Yellow-brown lump			59–61% $FeCl_3$, 20–21% Fe	Hygroscopic (store lumps and powder in tight containers); no dry feed; optimum pH, 4.0–11.0	
(c) $FeC1_3$	Anhydrous ferric chloride	500-lb casks; 100-300-, 400-lb kegs		Green-black power			98% $FeCl_3$, 34% Fe		
Ferric sulfate $Fe_2(SO_4)_3 \cdot 9H_2O$	“Ferrifloc,” Ferrisul	100-, 175-lb bags; 400-425-lb drums	Ceramics, lead, plastic, rubber, 18-8 stainless steel	Red-brown powder 70 or granule 72		Soluble in 2-4 parts cold water	90-94% $Fe_2(SO_4)_3$, 25–26% Fe	Mildly hygroscopic; coagulant at pH 3.5–11.0	B 406
Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	Copperas, green vitriol	Bags; bbls.; bulk	Asphalt, concrete, lead, tin, wood	Green crystal granule, lump	63–66	0.5 (32 °F), 1.0 (68 °F), 1.4 (86 °F)	55% $FeSO_4$, 20% Fe	Hygroscopic; cakes in storage; optimum pH, 8.5–11.0	B 402

Chemical Name and Formula	Common or Trade Name	Shipping Containers	Suitable Handling Materials	Available Forms	Weight, lb/ft^3	Solubility, lb/gal	Commercial Strength	Characteristics	AWWA Standard
Potassium aluminum sulfate, $K_2SO_4Al_2(SO_4)_3 \cdot 24H_2O$	Potash alum	Bags, lead-lined; bulk (carloads)	Lead, lead-lined, rubber, stoneware	Lump Granule Powder	62–67 60–65 60	3.0 (68 °F), 3.3 (86 °F)	10–11% Al_2O_3	Low, even solubility; pH of 1% solution, 3.5	
Sodium aluminate, $Na_2OAl_2O_3$	Soda alum	100-, 150-lb bags; 250-, 440-lb drums; solution	Iron, plastics, rubber, steel	Brown powder, liquid (27 °Bé)	50–60	Complete	70–80% $Na_2Al_2O_4$, min. 32% $NA_2A1_2O_4$	Hopper agitation required for dry feed	B 405
Sodium silicate, Na_2OSiO_2	Water glass	Drums; bulk (tank trucks, tank cars)	Cast iron, rubber, steel	Opaque, viscous liquid			38–42 Bé	Variable ratio of Na_2O to SiO_2; pH of 1% solution, 12.3	B 404
Disinfection and Dechlorinating Agents									
Ammonium aluminum sulfate, $Al_2(SO_4)_3(NH_4)_2SO_4 \cdot 24H_2O$	Ammonia alum, crystal alum	Bags; bbls.; bulk	Duriron, lead, rubber, silicon, iron, stoneware	Lump Nut Pea Powdered	64–68 62 65 60	0.3 (32 °F), 8.3 (212°F)	11% Al_2O_3	pH of 1% solution, 3.5	
Ammonium sulfate, $(NH_4)_2SO_4$	Sulfate of ammonia	100-lb bags	Ceramics, plastics, rubber, iron (dry)	White or brown crystal		42.5	6.3 (68 °F)	Cakes in dry feed; add $CaSO_4$ for free flow	B 302
Anhydrous ammonia, NH_3	Ammonia	50-, 100-, 150-lb cylinders; in bulk (tank cars and trucks)	Glass, iron, monel metal, nickel, steel	Colorless gas		3.9 (32 °F) 3.1 (60 °F) 1.8 (125 °F)	99–100% NH_3		
Aqua ammonia, NH_4OH	Ammonia water, ammonium hydrate, ammonium hydroxide	Carboys; 750- lb drums; 8,000-gal tank cars or trucks	Glass, iron, monel metal, nickel, steel	Colorless liquid		Complete	29.4% NH_2 (26 °Bé)		
Calcium hypochlorite, $CaOCl_2 \cdot 4H_2O$	"HTH," Perchloron, "Pittchlor"	5-lb cans; 100- , 300-, 800-lb drums	Glass, rubber, stoneware, wood	White granule, powder	52.5		70% available Cl_2	1–3% available $C1_2$, solution used	B 300
Chlorinated lime, $CaO\ 2CaOC1_2 \cdot 3H_2O$	Bleaching power, chloride of lime	100-, 300-, 800-lb drums	Glass, rubber, stoneware, wood	White powder	48		25–37% available Cl_2	Deteriorates	

Chemical Name and Formula	Common or Trade Name	Shipping Containers	Suitable Handling Materials	Available Forms	Weight, lb/ft^3	Solubility, lb/gal	Commercial Strength	Characteristics	AWWA Standard
Chlorine, Cl_2	Chlorine gas, liquid chlorine	100-, 150-lb cylinders; 1-ton containers; 16- , 30-, 55-, 85-, and 90-ton tank cars; tank trucks (about 15-16 tons)	Dry-black iron, copper, steel; wet gas-glass, hard rubber, silver	Liquefied gas under pressure	91.7	0.07 (60 °F), 0.04 (100 °F)	99.8% Cl_2		B 301
Chlorine dioxide, ClO_2	Chlorine dioxide	Generated as used	Plastics, soft rubber (avoid hard rubber)	Yellow-red gas		0.02 (30 mm)	26.3% available Cl_2		
Ozone, O_3	Ozone	Generated at site of application	Aluminum, ceramics, iron, steel, wood	Colorless gas					
Pyrosodium sulfite $Na_2O_5S_2$	Sodium meta-bisulfite	Bags; drums; bbls.	Iron, steel, wood	White crystal-line powder		Complete in water	Dry, 67% SO_2; sol. 33.3% SO_2	Sulfurous odor	
Sodium chlorite, $NaClO_2$	Technical sodium chlorite	100-lb drums	Metals (avoid cellulose materials)	Light orange powder, flake			82% $NaClO_2$, 30% available Cl_2	Generates ClO_2 at pH 3.0	B 303
Sodium hypochlorite, NaOCl	Sodium hypo-chlorite	5-, 13-gal carboy; 1,300-2,000-gal tank trucks	Ceramics, glass, plastics, rubber	Light yellow liquid			12–15% available Cl_2		B 300
Sodium sulfite, Na_2SO_3	Sulfite	Bags; drums; bbls.	Iron, steel, wood	White crystal-line powder		Complete in water	23% SO_3	Sulfurous taste and odor	
Sulfur dioxide, SO_2	Sulfurous acid anhydride	Steel cylinders; ton containers; tank cars or trucks	Aluminum, brass, Durco D- 10, stainless steel 316	Colorless gas		20% at 32 °F, complete in water	99% SO_2	Irritating gas	
Fluoridation and Fluoride Adjustment									
Ammonium silico fluoride, $(NH_4)_2\ SiF_6$	Ammonium fluor-silicate	100- and 400-lb drums	Steel, iron, lead	White crystals		1.7 (63 °F)	100%	White, free-flowing solid	
Calcium fluoride, CaF_2	Fluorspar	Bags; drums; bbls.; hopper cars; trucks	Steel, iron, lead	Powder		Very slight	85% CaF_2, less than 5% SiO_2		

Chemical Name and Formula	Common or Trade Name	Shipping Containers	Suitable Handling Materials	Available Forms	Weight, lb/ft^3	Solubility, lb/gal	Commercial Strength	Characteristics	AWWA Standard
Hydro-fluosilicic acid, H_2SiF_6	Fluo-silicic acid	Rubber-lined drums; trucks; or R.R. tank cars	Rubber-lined steel, PVC	Liquid		Approx. 1.2 (68 °F)	Approx. 35%		B 703
Hydrogen fluoride, HF	Hydro-fluoric acid	Steel drums; tank cars	Steel	Liquid			70%	Below 60%, steel cannot be used	
Sodium fluoride NaF_6	Fluoride	Bags; bbls.; fiber; drums; kegs	Iron, lead, steel	Nile blue or white powder; light dense	50 75	0.35 (most temps.)	90–95% NaF	pH of 4% solution, 6.6	B 701
Sodium silicofluoride, Na_2SiF_6	Sodium silico-fluoride	Bags; bbls.; fiber; drums	Iron, lead, steel	Nile blue or yellowish-white powder	75	0.03 (2 °F), 0.06 (72 °F), 0.12 (140 °F)	99% Na_2SiF_6	pH of 1% solution, 5.3	B 702
Fluoride Adjustment									
Aluminum oxide, Al_2O_3	Activated alumina	Bags; drums	Iron, lead, steel	Powder, granules (up to 1-1/2-in. diam)	Variable	Insoluble	100%		
Bone charcoal C	“Fluo-Carb”	Bags; drums; bulk	Wood, iron, steel	Granules	Variable			Black; best used in beds for presolution	
Tricalcium phosphate $Ca_3O_8P_2$	“Fluorex”	Bags; drums; bulk; bbls.	Iron, steel	Granular technical	50–63	Insoluble		Also available as white powder	
High-magnesium lime $CaMgO_2$	Dolomitic lime	Bags; bbls; bulk	Wood, iron, steel	Lump, pebble, ground		Slakes slowly	58% CaO_2 40% MgO_2		
Stabilization and Corrosion Control									
Carbon dioxide, CO_2	Carbon dioxide gas, liquid carbon dioxide	20-, 50-lb cylinders. Bulk; tank trucks, tank cars			47.4 @ 70 °F				
Disodium phosphate, $Na_2HPO_4 \cdot 12H_2O$	Basic sodium phosphate, DSP, secondary sodium phosphate	125-lb kegs; 200-lb bags; 325-lb bbls.	Cast iron, steel	Crystal	60–64	0.4 (32 °F), 6.4 (86 °F)	19.5% P_2O_5	Precipitates Ca, Mg; pH of 1% solution, 9.1	

Chemical Name and Formula	Common or Trade Name	Shipping Containers	Suitable Handling Materials	Available Forms	Weight, lb/ft^3	Solubility, lb/gal	Commercial Strength	Characteristics	AWWA Standard
Sodium hexameta-phosphate, $(NaPO_3)_6$	"Calgon," glassy phosphate, vitreous phosphate	100-lb bags	Hard rubber, plastics, stainless steel	Crystal, flake, powder	47	1–4.2	66% P_2O_5 (unadjusted)	pH of 0.25% solution, 6.0–8.3	
Sodium hydroxide, NaOH	Caustic soda, soda lye	100-700-lb drums; bulk (trucks, tank cars)	Cast iron, rubber, steel	Flake Lump Liquid		2.4 (32 °F) 4.4 (68 °F), 4.8 (104 °F)	98.9% NaOH, 74–76% NaO_2	Solid; hygroscopic; pH of 1% solution, 12.9	
Sulfuric acid, H_2SO_4	Oil of vitriol, vitriol	Bottles; carboys; drums; trucks, tank cars	Concentrated—iron, steel; dilute— glass, lead, porcelain, rubber	Solution (60-66 °Bé)		Complete	77.7% H_2SO_4 (60 ° Bé); 93.2% H_2SO_4 (66 °Bé)	Approx. pH of 0.5% solution, 1.2	
Tetrasodium pyrophosphate, $Na_4P_2O_7$•$1OH_2O$	Alkaline sodium pyrophos-phate, TSPP	125-lb kegs; 200-lb bags; 300-lb bbls.	Cast iron, steel	White powder	68	0.6 (80 °F), 3.3 (212 °F)	53% P_2O_5	pH of 1% solution, 10.8	
Trisodium phosphate, Na_3PO_4•$12H_2O$	Normal sodium phosphate, tertiary sodium phosphate, TSP	125-lb kegs; 200-lb bags; 325-lb bbls.	Cast iron, steel	Crystal: coarse medium standard	56 58 61	0.1 (32 °F), 13.0 (158 °F)	19% P_2O_5	pH of 1% solution, 11.9	
Softening									
Calcium hydroxide, $Ca(OH)_2$	Hydrated lime, slaked lime	0-lb bags; 100- lb bbls.; bulk (carloads) trucks	Asphalt, cement, iron, rubber, steel	White powder: light dense		0.014 (68 °F) 0.012 (90 °F)	85–99% $Ca(OH)_2$ 63–73% CaO	Hopper agitation required for dry feed of light form	B 202
Calcium oxide, CaO	Burnt lime, chemical lime, quick-lime, unslaked lime	50-lb bags; 100-lb bbls; bulk (carloads	Asphalt, cement, iron, rubber, steel	Lump, pebble, granule		Slakes to form hydrated lime	75–99% CaO	pH of saturated solution, 12.4; detention time, temperature, amount of water all critical for effluent slaking	B 202

Chemical Name and Formula	Common or Trade Name	Shipping Containers	Suitable Handling Materials	Available Forms	Weight, lb/ft^3	Solubility, lb/gal	Commercial Strength	Characteristics	AWWA Standard
Sodium carbonate, Na_2CO_3	Soda ash	Bags; bbls.; bulk (carloads, trucks)	Iron, rubber, steel	White powder: extra-light light dense	23 35 65	1.5 (68 °F), 2.3 (86 °F)	99.4% Na_2CO_3, 58% Na_2O	Hopper agitation required for dry feed of light and extra-light forms; pH of 1% solution, 11.3	B 201
Sodium chloride, NaC1	Common salt, salt	Bags; bbls.; bulk (carloads)	Bronze, cement, rubber	Rock fine		2.9 (32 °F), 3.0 (68 °F), 86 °F	98% NaC1		B 200
Taste and Odor Control									
Activated carbon, C	"Aqua Nuchar," "Hydro-darco," "Norite"	Bags; bulk	Dry—iron, steel; wet—rubber, silicon, iron, stainless steel	Black granules power	15	Insoluble (suspension used)			B 600 & B 604
Chlorine, $C1_2$	Chlorine gas, liquid chlorine	100-150-lb cylinders; 1-ton tanks; 16- 30-55-ton tank cars	Dry—black iron, copper, steel; wet gas—glass, hard rubber, silver	Liquefied gas under pressure	91.7	0.07 (60 °F), 0.04 (100 °F)	99.8% $C1_2$		B 301
Chlorine dioxide, ClO_2	Chlorine dioxide	Generated as used	Plastics, soft rubber (avoid hard rubber)	Yellow-red gas		0.02 (30 mm)	26.3% available $C1_2$		
Copper sulfate, $CuSO_4$•$5H_2O$	Blue vitriol, blue stone	100-lb bags; 450-lb bbls.; drums	Asphalt, silicon, iron, stainless steel	Crystal Lump Power	75–90 73–80 60–64	1.6 (32 °F), 2.2 (68 °F), 2.6 (86 °F)	99% $CuSO_4$		B 602
Ozone O_3	Ozone	Generated at site of application	Aluminum, ceramics, glass	Colorless gas					
Potassium permanganate, $KMnO_4$	Purple salt	Bulk; bbls.; drums	Iron, steel, wood	Purple crystals		0.23 (32 °F) 0.54 (68 °F) 1.05 (104 °F)	100%	Danger of explosion on contact with organic matters	B 603

Table 4-2 Water Treatment Plant Residue Disposal Summary

Type of Waste	Quantities and Characteristics	Treatment Required	Disposal Possibilities
Screenings	Vary widely; evaluate particular water source; check other plants using same water source or other similar plants.	None	Return to watercourse if quantities are small.
			Truck to landfill along with other plant solid waste.
			Investigate disposal with wastewater treatment plant screenings.
Presedimentation Sludges	Vary widely; evaluate particular water source; check other plants using same water source or other similar plants.	Dewatering in lagoon, sand drying bed, or mechanical unit may be required.	Dredging or draglining and hauling to landfill; multiple, drainage basins make cleaning easier.
Chemical clarification sludges	Composed of raw water impurities and coagulation chemicals. Solids content - 0.1 to 2%; 75 to 90% of total is suspended; 20 to 40% of total is volatile. Dry unit weight 75 to 95 lbs/ft^3. Gelatinous.	Gravity thickening is often desirable, recycling supernatant to plant influent. (3)	Send concentrated sludge or continuously withdrawn sludge to wastewater treatment plant. (1)
		Sludge concentrations of 0.5 to 1.0% can be obtained.	Haul dried sludge, a minimum of 15% solids, off-site in accordance with state requirements and permit to a municipal landfill.
		In addition to gravity thickening, dewatering processes may also be used: Drying beds. Freeze/thaw treatment processes are effective for alum sludge dewatering but expensive except in climates where sludges can be	

Type of Waste	Quantities and Characteristics	Treatment Required	Disposal Possibilities
		placed in a lagoon and frozen naturally. Centrifuges and vacuum filters dewater sludges up to about 15% solids. Pre-coat vacuum filters dewater sludge up to 25% solids. Pressure filtration dewaters sludge to 25 to 40% solids, often requiring lime as conditioner.	
Filter wash water (2)	Normal wash generates about 150 gallons per square foot filter area. Chemically-precipitated raw water impurities and coagulation chemicals. For alum plants, total solids vary, with an average of 400 mg/L and a maximum of 1,000 mg/L. Plants removing iron and manganese may produce 4 times higher total solids.	Flow equalization and concentration through sedimentation and decanting.	Same as for coagulation sludges. Combine with coagulation sludge where applicable. Where no coagulation used, dispose as softening sludge. Gradually return entire flow to plant influent. (3)
Lime softening sludges	Assume 3 lb dry sludge solids per lb quicklime added.	Dewatering lime softening sludges is not particularly difficult. The following methods can be used following thickening:	Discharge to wastewater treatment plants (1)

Type of Waste	Quantities and Characteristics	Treatment Required	Disposal Possibilities
	Clarifier underflow	Lagooning (up to 50% solids). Vacuum filtration (40 to 50% solids). Centrifuging (50 to 60% solids). Return to water plant influent.	Dewatered sludge hauled to landfill (agricultural applications possible).
	Solids concentration generally is approximately 5% but may range from 2 to 30%. Non-gelatinous. Typically, 85 to 95% calcium carbonate, with some magnesium hydroxide.		Recalcining generally limited to large plants (>20 million gallons per day [mgd]) by economic considerations.
Diatomaceous earth sludges	See filter manufacturer's literature for quantities. Solids normally 60 to 70% diatomaceous earth; remainder raw water impurities; dry density about 10 lb/ft^3; specific gravity 2.	Lagooning, with supernatant recycled to plant influent.	Haul solids from lagoon to landfill.
Carbon slurries	Quantities and characteristics variable.	Granular carbon can be regenerated and recycled. Powdered carbon cannot be regenerated; dispose of powdered carbon following dewatering.	Haul solids to landfill. Incinerate dewatered solids (high heating value).
Cation exchange resin regeneration brines	See manufacturer's literature for quantities. Total dissolved solids up to 45,000 mg/L. Chlorides up to 112,000+mg/L. Almost no suspended solids.	Evaporation lagoons where concentration is desired and climate permits	Best solution is ocean disposal. Return to watercourse only if brine can be greatly diluted. Discharge to wastewater treatment plant only if greatly diluted. Disposal wells possible but suitability is site-specific.

4-8.3.2 Landfill.

Modern sanitary landfills are designed and operated to keep the amount of water leaching from the filled material to a minimum. For this reason, landfill regulations often require that sludges contain at least 20% dry solids and sometimes require as high as 50 to 60%. Wet sludges are not acceptable because they are difficult to mix well with other solid wastes before covering and because the large amount of water could percolate through the soil and pollute water supplies.

4-8.3.3 Lagoons.

Disposal lagoons are simply dewatering lagoons that are never cleaned out, thus, eliminating the main operating problem of drying lagoons. The main disadvantage is that large land areas are permanently committed for use as lagoons. For plants with small sludge quantities and plentiful land, lagoons can be practical for sludge disposal.

4-8.3.4 Land Spreading of Lime Sludge.

In many agricultural areas, particularly in the Midwest, farming practices require that lime or limestone be added to the fields periodically to control soil pH. Sludge from lime water softening processes can be used for this purpose if it is sufficiently dewatered to allow easy handling.

4-8.4 Laboratory Control Tests.

The main control tests involved in sludge handling and disposal are the solids tests (total solids and suspended solids) used to determine the effectiveness of dewatering processes. Some recycling processes require testing for hazardous materials. Ocean disposal may require bioassay testing to determine the effect on the aquatic environment.

4-8.5 Maintaining Records.

The dewatering and ultimate disposal of water plant sludges and other residues are expensive. To manage water treatment plant residues adequately, maintain records on residue quantities and characteristics, chemical quantities used for residue treatment processes, results of laboratory control tests, and operating notes.

4-9 DESALINATION.

Some geographic locations, including coastal areas, islands, and some inland regions, have little or no fresh water even though unlimited supplies of saline water are available.

When it is necessary to establish and maintain military installations in such areas, the water supply generally is derived by converting saline water into fresh water. Several methods are available, but they are expensive and complicated to use. These methods include distillation, ion exchange, electrodialysis, and reverse osmosis. Other methods (such as freezing, hydrate formations, solvent extractions, and solar evaporation) are not considered practical desalination methods.

For more information on desalination, see *USAID Desalination Manual*.

4-10 WATER SAMPLING AND ANALYSIS.

Sampling and analysis for plant quality control differs from testing conducted to monitor compliance with the SDWA. Process tests are generally conducted by treatment plant personnel, are used to enhance and control plant performance, and are not required by law. Applicable process control tests for each unit process are something that the actual Facilities O&M manual should discuss and provide to ensure the water treatment plan runs smoothly. Operators should refer to the O&M manual so that effective and efficient operations are maintained.

Process controls should include sampling for specific process parameters at various points in the treatment process. The various analysis is used to determine if the treatment is effective and optimized before there is a failure in the process that can lead to a regulatory violation. Sampling examples include parameters such as:

- pH of raw water and after addition of pretreatment chemicals
- pH of process water at midpoint in treatment to ensure adequate chemical dosing
- Turbidity readings prior to filtration to determine how effective pretreatment is

Complete sampling in accordance with *Standard Methods for the Examination of Water and Wastewater* per *AWWA G100.* Compliance monitoring is covered in Chapter 2 paragraph titled Regulations Affecting Water Systems. Required information on sampling and analysis can be found in *APHA/AWWA/ WEF Standard Methods for the Examination of Water and Wastewater*. Best practice info can be found in *Water Treatment Plant Operation, Volumes 1 and 2.*

This Page Intentionally Left Blank

CHAPTER 5 PUMPS AND DRIVERS

5-1 CHAPTER OVERVIEW.

This chapter covers the operation of pumps used in water supply facilities. It also covers the motors, engines, and accessories (together called pump drivers) that provide the mechanical source of energy to pumps.

5-2 PUMPS.

Velocity pumps and positive-displacement pumps are the two categories of pumps commonly used in water supply operations. Velocity pumps, which include centrifugal and vertical turbine pumps, are used for most distribution system applications. Positive-displacement pumps, which include rotary and reciprocating pumps, most commonly are used in water treatment plants for chemical metering and pumping sludge. Additional technical descriptions of the pump types commonly used in water supply systems, along with applications, operating characteristics, and a listing of general advantages and disadvantages, can be found in best practice *Water Treatment Plant Operation, Volumes 1 and 2*.

Specific information on vertical turbine pumps is contained in *AWWA E103*. Table 5-1 lists maximum capacity and discharge head values for several general pump types.

Table 5-1 Comparison of Pump Discharge and Head

Pump Type	Maximum Capacity		Maximum Discharge Head	
	gpm	(Lps)	feet of water	(kg/sq cm)
Air lift	3,000	(190)	700	(21)
Centrifugal				
Axial Flow (propeller)	200,000+	(12,600)	50	(2)
Diffuser	700	(45)	1,000	(30)
Mixed Flow	250,000+	(15,800)	100	(3)
Regenerative Turbine	100	(6)	600	(18)
Vertical Turbine	30,000	(1,890)	>1,500	(45)
Volute	40,000	(2,500)	500	(15)
Ejector (jet)	50	(3)	150	(5)

Pump Type	Maximum Capacity		Maximum Discharge Head	
	gpm	(Lps)	feet of water	(kg/sq cm)
Progressive Cavity (helical rotor)	1,200	(75)	2,300	(70)
Reciprocating Displacement Diaphragm	300	(20)	800	(25)
Piston	300	(20)	800	(25)
Plunger	300	(20)	800	(2)
Rotary Displacement	55	(3)	1,000	(30)

5-3 OPERATION OF PUMPS.

Operate all mechanical equipment, including pumps, in accordance with the manufacturer's instructions. General O&M information, including starting and stopping procedures, flow control, and performance monitoring. Some best practice information on this, can be found in *Water Treatment Plant Operation, Volumes 1 and 2*.

Pumps are occasionally installed to increase the pressure in a pipeline or in a specific zone of a distribution system to help meet peak demands such as fire flow and to supply water to elevated storage tanks. Pump stations are particularly suited for a distribution system located in hilly country where there are two or more pressure zones, or on the periphery of an overextended or overloaded distribution system. Pumping stations are usually automatically and remotely controlled from the main pumping station and are normally equipped with electrically driven centrifugal pumps.

For operator training assistance with calculating pumping rates, pump heads, horsepower and efficiency, and reading pump curves, see best practice *Water Treatment Plant Operation, Volumes 1 and 2*.

5-3.1 General Operating Instructions for Centrifugal Pumps.

A quick reference checklist for starting and stopping centrifugal pumps is provided in Table 5-2. Procedures may vary for different pump types and pump applications. Know what to expect when the equipment starts.

Table 5-2 Routine Operation-s Checklist for Centrifugal Pumps

Inspection	Action
Prestart Checks	
Valves	Open the valve in the cooling liquid supply to the bearing if the bearings are liquid cooled.
	Open the valve in the flushing water supply to the stuffing boxes if so equipped.
	Open the valve in the sealing liquid supply to the stuffing boxes or mechanical seals if so equipped.
	Open or close the discharge valves according to the manufacturer's manual.
Rotors	Check the rotor to see that it is free. If equipment is isolated correctly following proper lockout/tagout procedures, you should be able to turn the rotor shaft by hand. Do not start the pump until any difficulty is corrected.
	Prime centrifugal pumps before startup. The equipment will not pump water unless air in the pump and suction piping is replaced with water. In addition, the rotating element may seize from a lack of lubrication.
	Use one of the following methods to prime the pump, depending on operating conditions: positive suction head (1) or negative suction head (2).
Starting the Pump	Always start the pump according to the manufacturer's manual.
Equipment Area	Ensure that all personnel are clear of dangerous areas.
Valves	For pumps started with discharge valves closed, open valves slowly after pump approaches operating speed. Do not operate the pump with a closed discharge valve.

Inspection	Action
Stuffing Boxes and Packing	Observe leakage from the stuffing boxes and adjust the sealing liquid valve for proper flow to ensure packing lubrication. For new packing, allow pump to run for 10 to 15 minutes before tightening the stuffing box gland. Gradually tighten the stuffing box gland until leakage slows to a constant drip.
Pump and Driver	Check the general mechanical operation of the pump and driver. Ensure that working parts are free to move without damage.
Stopping the Pump	Always review instructions for disconnecting and securing drive and rotating equipment.
Valves	As a rule, there is a check valve in the discharge line close to the pump. In such cases, shut down the pump by stopping the driver according to the manufacturer's manual.
	Then close all valves, except the check valve, in this order: discharge, suction, pump cooling water supply, and other connections leading to the pump or system.
	In some instances, however, the use of a check valve is not feasible because the sudden closing of the valve under high discharge pressure might create pressure surges or water hammer. In such cases, close the discharge valve slowly to avoid water hammer.
Monitoring Operations Unusual Sounds	 Learn to recognize the normal sounds and conditions of a properly run pump. Listen to the sounds of the pump on regular inspection tours and investigate any abnormal sounds at once.
Bearings	Check bearing temperature and lubrication. Where petroleum-based lubricants are used, follow the manufacturer's manual and do not over lubricate.
Suction and Discharge Readings	Check these readings and compare with "normal" valves. Make sure valves are set as required. Check shaft packing. Check discharge rate. Check driving equipment.

(1) Positive Suction Head. When the intake (suction) side of the pump is under pressure, use the following priming sequence:

a. Open all suction valves to allow water to enter the suction pipe and pump casing.

b. Open all vents located on the highest point of the pump casing to allow trapped air to be released.

Note: The pump is properly primed when water flows from all open vents in a steady stream.

(2) Negative Suction Head. Two priming methods are available for a negative suction head condition—that is, when the pump lifts water to the intake (suction lift).

a. Vacuum Pump or Ejection Method. When steam, high-pressure water, or compressed air is available, prime the pump by attaching an ejector to the highest point in the pump casing for evacuating the air from the suction piping and casing. A vacuum may be substituted for the above equipment. Start the ejector or vacuum pump to exhaust the air from the pump casing and suction pipe. When water discharges from the ejector or vacuum pump, start the centrifugal pump, but continue priming until the centrifugal pump has reached operating speed.

b. Priming a Pump with a Foot Valve. A foot valve is used at the lowest point on the suction pipe. The foot valve retains water in the suction pipe and pump casing after the pump has been initially primed. To prime, open the suction valve, if one is installed. Open vent valves at the highest points on the pump casing. Fill the pump and suction line from an independent water supply. Allow to fill until a steady stream flows from the vent valves.

5-3.2 Troubleshooting Centrifugal Pumps.

Symptoms and possible causes of operating difficulties are listed in Table 5-3. For more troubleshooting help, see the specific pump vendor O&M manual. The *Water Treatment Plant Operation, Volumes 1 and 2 provides some general best practice information*.

See also Table 5-10, a troubleshooting checklist for vertical turbine well pumps, which are a class of centrifugal pump.

5-3.2.1 Cavitation Problems.

Cavitation is one of the most serious operational problems with centrifugal pumps. Cavitation occurs when cavities or bubbles of vapor form in the liquid. The bubbles collapse against the impeller, making a sound as though there were rocks in the pump. If left uncorrected, cavitation will seriously damage the pump.

Table 5-3 Troubleshooting Checklist for Centrifugal Pumps

Symptom	Possible Cause
Pump does not deliver water.	Pump not primed.
	Pump or suction pipe not completely filled with water.
	Suction lift too high.
	Air pocket in suction line.
	Inlet of suction pipe insufficiently submerged. Suction valve not open or partially open.
	Discharge valve not open. Speed too low.
	Wrong direction of rotation.
	Total head of system higher than design head of pump.
	Parallel operation of pumps unsuitable for existing conditions.
	Foreign matter in impeller.
Insufficient capacity delivered.	Pump or suction pipe not completely filled with water.
	Suction lift too high.
	Excessive amount of air or gas in water. Air pocket in suction line.
	Air leaks into suction line.
	Air leaks into pump through stuffing boxes. Foot valve too small.
	Foot valve partially clogged.
	Inlet of suction pipe insufficiently submerged.
	Suction valve only partially open. Discharge valve only partially open. Speed too low.

Symptom	Possible Cause
	Total head of system higher than design head of pump.
	Parallel operation of pumps unsuitable for such operation.
	Foreign matter in impeller. Wearing rings worn.
	Impeller damaged.
	Casing gasket defective, permitting internal leakage.
Insufficient pressure developed.	Excessive amount of air or gas in water. Speed too low.
	Wrong direction of rotation.
	Total head of system higher than design head of pump.
	Parallel operation of pumps unsuitable for existing conditions.
	Wearing rings worn. Impeller damaged.
	Casing gasket defective, permitting internal leakage.
Pump loses prime after starting.	Pump or suction pipe not completely filled with water.
	Suction lift too high.
	Excessive amount of air or gas in water. Air pocket in suction line.
	Air leaks into suction line.
	Air leaks into pump through stuffing boxes. Inlet of suction pipe insufficiently submerged. Water-seal pipe plugged.
	Seal cage improperly located in stuffing box, preventing sealing fluid from entering space to form the seal.

Symptom	Possible Cause
	Speed too high
Pump requires excessive power.	Wrong direction of rotation.
	Total head of system higher than design head of pump.
	Total head of system lower than pump design head.
	Foreign matter in impeller existing conditions.
	Misalignment.
	Shaft bent.
	Rotating part rubbing on stationary part. Wearing rings worn.
	Packing improperly installed.
	Incorrect type of packing for operating conditions.
	Gland too tight resulting in no flow of liquid to lubricate packing.
Stuffing box leaks excessively.	Seal cage improperly located in stuffing box, preventing sealing fluid entering space to form the seal.
	Misalignment. Shaft bent.
	Shaft or shaft sleeves worn or scored at the packing. Packing improperly installed.
	Incorrect type of packing for operating conditions.
	Shaft running off center because of worn bearings or misalignment.
	Rotor out of balance, resulting in vibration.

Symptom	Possible Cause
	Gland too tight, resulting in no flow of liquid to lubricate packing.
	Excessive clearance at bottom of stuffing box between shaft and casing, causing packing to be forced into pump interior.
	Dirt or grit in sealing liquid, leading to scoring of shaft or shaft sleeve.
Packing has short life.	Water-seal pipe plugged.
	Seal cage improperly located in stuffing box, preventing sealing fluid from entering space to form the seal.
	Misalignment. Shaft bent.
	Bearings worn.
	Shaft or shaft sleeves worn or scored at the packing.
	Packing improperly installed.
	Incorrect type of packing for operating conditions.
	Shaft running off center because of worn bearings or misalignment.
	Rotor out of balance, resulting in vibration.
	Gland too tight, resulting in no flow of liquid to lubricate packing.
	Failure to provide cooling liquid to water-cooled stuffing boxes.
	Excessive clearance at bottom of stuffing box between shaft and casing, causing packing to be forced into pump interior.

Symptom	Possible Cause
	Dirt or grit in sealing liquid, leading to scoring of shaft or shaft sleeve.
	Foundations not rigid. Shaft bent.
	Rotating part rubbing on stationary part. Bearings worn.
	Impeller damaged.
	Shaft running off center because of worn bearings or misalignment.
	Rotor out of balance, resulting in vibration.
	Dirt or grit in sealing liquid, leading to scoring of shaft or shaft sleeve.
	Excessive grease or oil in antifriction-bearing housing, or lack of cooling, causing excessive bearing temperature.
	Lack of lubrication.
	Improper installation of antifriction bearings (damage during assembly, incorrect assembly of stacked bearings, use of unmatched bearings as a pair, etc.).
	Dirt getting into bearings.
	Rusting of bearings because of water getting into housing.
	Excessive cooling of water-cooled bearing resulting in condensation in the bearing housing of moisture from the atmosphere.
Pump vibrates or is noisy.	Pump or suction pipe not completely filled with water.
	Suction lift too high. Foot valve too small.
	Foot valve partially clogged.

Symptom	Possible Cause
	Inlet of suction pipe insufficiently submerged.
	Operation at very low capacity.
	Foreign matter in impeller. Misalignment.
Bearings have short life.	Misalignment. Shaft bent.
	Rotating part rubbing on stationary part. Bearings worn.
	Shaft running off center because of worn bearings or misalignment.
	Rotor out of balance, resulting in vibration.
	Excessive thrust caused by a mechanical failure inside the pump or by the failure of the hydraulic balancing device, if any.
	Excessive grease or oil in antifriction-bearing housing or lack of cooling, causing excessive bearing temperature.
	Lack of lubrication.
	Improper installation of antifriction bearings (damage during assembly, incorrect assembly of stacked bearings, use of unmatched bearings as a pair, etc.).
	Dirt getting into bearings.
	Rusting of bearings because of water getting into housing.
	Excessive cooling of water-cooled bearing, resulting in condensation in the bearing housing of moisture from the temperature.
Pump overheats and seizes.	Pump not primed.
	Operation at very low capacity.

Symptom	Possible Cause
	Parallel operation of pumps unsuitable for existing conditions.
	Misalignment.
	Rotating part rubbing on stationary part. Bearings worn.
	Shaft running off center because of worn bearings or misalignment.
	Rotor out of balance, resulting in vibration.
	Excessive thrust caused by a mechanical failure inside the pump or by the failure of the hydraulic balancing device, if any.
	Lack of lubrication.

5-3.2.2 Causes of Cavitation.

Conditions that typically cause cavitation include operating the pump with too great a suction lift or an insufficiently submerged suction inlet. Cavitation develops when normal pump operating conditions have been exceeded. Noise, vibration, impeller erosion, and reduction in total head and efficiency result from cavitation. Cavitation in a centrifugal pump may be caused by any of the following:

- The impeller vane is traveling at higher revolutions per minutes than the liquid.
- Suction is restricted.
- Note: Do not throttle the suction of a centrifugal pump.
- The required net positive suction head (NPSH) is equal to or greater than the available NPSH.
- The specific pump speed is too high for the operating conditions.
- The liquid temperature is too high for the suction conditions

5-3.2.3 Water Hammer.

- Water hammer may occur when flowing water within a water system is abruptly stopped or a change in direction occurs, creating a pressure surge. The following are tips to reduce water hammer. Reduce sharp turns and elbows to reduce mechanical stresses.

- Calculate the amplitudes of water hammer on long lines. Provide the appropriate devices to dampen or eliminate any water hammer effects such as valves, valve controllers, or surge tanks.
- Utilize computer programs for water hammer analysis for large pumps stations.
- Install variable speed pumps for ground storage tanks to help eliminate the potential for water hammer.

5-3.3 Operating Instructions for Ejector (Jet) Pumps.

Jet pumps are a type of centrifugal pump. Because of their relatively low efficiency, they are rarely used for public water systems. However, jet pumps are inexpensive, require little maintenance, and may be used on wells supplying small, low-demand systems. The operating principle of these pumps is described in the specific pump vendor O&M manual. The *Water Treatment Plant Operation, Volumes 1 and 2* provides general operator information.

Note: All operating rules and troubleshooting checks that apply to centrifugal pumps apply to ejector pumps.

Start the pump and adjust the manual back pressure valve until the correct operating cycle is achieved. Do not change the adjustment after the pump is operating. If pump discharge decreases, check troubleshooting guides for centrifugal pumps. Also inspect the ejector nozzle and throat for deposits and check nozzle submergence.

5-3.4 Operating Instructions for Progressive Cavity Pumps.

Progressive or helical-rotor pumps are positive displacement pumps and not subject to the same problems as centrifugal pumps. Operate according to the manufacturer’s instructions.

Caution: Do not run dry.

Common operating problems encountered with progressive cavity pumps and possible causes are given in Table 5-4.

5-3.4.1 Operating Instructions for Rotary and Reciprocating Displacement Pumps.

A general description of positive displacement pumps is provided in the specific pump vendor O&M manual. The *Water Treatment Plant Operation, Volumes 1 and 2* provides general operator information.

5-3.4.2 Prestart.

Rotary- and reciprocating-displacement pumps do not usually require priming. However, when priming is necessary, follow priming procedures for centrifugal pumps.

Table 5-4 Troubleshooting Checklist for Progressive-Cavity Pumps

Symptom	Possible Cause
No water is delivered.	Broken or disconnected shaft.
	Excessive discharge head.
	Plugged or non-submerged suction.
Pump does not deliver rated capacity.	Speed too low.
	Suction lift excessive.
	Suction partially plugged.
	Mechanical defect.
Pressure is too low.	Discharge head too high.
	Speed too low.
	Pressure relief valve set too low.
	Mechanical defect.
Pump stops after starting to operate.	Bent column shaft.
	Clogged suction.

5-3.4.3 Starting and Operating.

Always start and operate rotary- and reciprocating-displacement pumps with both suction and discharge valves open to prevent motor overload and pump damage.

5-3.4.4 Operating Precautions.

- Rotary- and reciprocating-displacement pumps depend on clearances for efficiency. Keep grit or other abrasive material out of the liquid being pumped to prevent excessive wear and rapid loss of efficiency and self-priming ability.

- A pressure-relief valve that discharges back to the suction side of the pump is usually provided on the outlet piping. Adjust this valve for a relief pressure that does not overload the motor. Make sure the check valves seat properly at normal pressures. Otherwise, loss of efficiency and priming ability result.
- Use the manufacturer's manuals to develop a checklist for the rotary- or reciprocating-displacement pump being used.

5-4 PUMP MAINTENANCE.

Information contained in the following paragraphs is general and not intended to replace maintenance procedures provided by the equipment manufacturer and the specific pump vendor O&M manual. Additional general information on pump maintenance can be found in the publications listed in *Water Treatment Plant Operation, Volumes 1 and 2*, and *Centrifugal Pumps and Motors: Operation and Maintenance.*

5-4.1 Maintenance Procedures for Centrifugal Pumps.

The following paragraphs describe general maintenance procedures for all types of horizontal and vertical centrifugal pumps. For details of procedures that apply specifically to volute, diffuser, regenerative-turbine, split-case, and multistage design, consult the manufacturer's manuals.

5-4.1.1 Lubrication.

General lubrication instructions are provided in Chapter 10 paragraph titled Lubrication. Manufacturer's manuals cover lubrication frequency for special cases, but the following generally applies. Pump running times longer than 5 minutes will require increasing oiling rates.

Caution: Do not lubricate totally enclosed equipment or insufficiently guarded equipment while it is moving.

- To avoid errors, establish a marking system to make sure that the proper lubricant is used. Make sure the same product symbol and identifying color are marked on lubricant containers, lubricant applicators, and locations near lubrication points.
- Never over lubricate. Over lubrication causes antifriction bearings to overheat and may damage the grease seals. Over lubrication may also damage electric motor windings.
- For simplified operation, provide the same type of grease gun fitting (zerk) at all points using the same type of grease. The fewer the types of grease used, the fewer grease guns required and the less likelihood of improper grease being used.

- Table 5-5 provides a general lubrication schedule for centrifugal-type pumps. When hand oilers are used to lubricate the shaft bearings, check the settings daily and adjust them according to Table 5-6.

5-4.1.2 Packing.

Selection of packing is usually done in accordance with the manufacturer’s recommendations or assistance. For pumping water, packing types include non-reinforced woven or braided cotton asbestos, semi-metallic plastic, or a combination of the two. If you require the manufacturer’s assistance to select packing, supply detailed information to the manufacturer on the following items:

- Description of liquid handled, including percentage concentration, temperature, and impurities.
- Amount of abrasive present.
- Stuffing box dimensions (depth of box, outside diameter, and shaft or sleeve diameter) and stuffing box pressure and temperature.
- Shaft speeds.
- Sealing cage (lantern gland) location and width.
- Shaft or seal material and hardness.

A guide for stuffing box inspection is provided in Table 5-7.

Table 5-5 Lubrication Schedule for Centrifugal-Type Pumps

Lubrication Point	Action Required	Frequency
Antifriction bearing	Check temperature (with thermometer); if running hot, bearing is probably over lubricated; remove excess lubricant.	Monthly
	Drain lubricant; flush lubricant wells and bearings with kerosene; add clean fresh lubricant.	Quarterly
Ball-thrust bearing	Add fresh grease to grease cups, but do not attempt to keep grease from coming out around the collar seal.	Monthly
	Change the grease in the grease cup if the pump operates more than 50 times a day; otherwise, change yearly.	Quarterly

Lubrication Point	Action Required	Frequency
Bearing housing	Check oil level in oil housing; do not add oil with pump running; remove oil vent plug when adding oil.	Daily
	Open housing; flush with kerosene; add clean fresh lubricant.	Quarterly
Enclosed shaft-type bearing	Check oil cup; add lubricant as necessary.	Weekly
Grease-sealed packing gland	Check spring-loaded grease cup; refill as necessary; adjust spring tension to maintain grease discharge through packing at approximately 1 ounce per day.	Daily
Guide bearing	Add grease through fittings provided.	Monthly
Sealing water system	Check packing gland assembly; adjust packing if excessive seal-water leakage is noticed, allow 60 drops per minute with pump running.	Daily
	Check stuffing box for free movement of gland.	Semi-annually
Hand oiler	According to Table 15.	Each shift
Solenoid oiler	Check that leads are connected; check needle valve for clogging; adjust for 2 to 4 drops per minute; refill container as necessary.	Daily
Sleeve bearing	Check bearing temperature; if too hot, add lubricant.	Monthly
	Drain lubricant; wash wells and bearing with kerosene.	Quarterly
Universal joint coupling	Lubricate couplings and slip splines with fresh grease.	Semi-annually

Table 5-6 Hand Oiler Adjustment

Pump Operation Schedule (times per day)	Pump Running Time (minutes)	Oiler Rate
Maximum of 2	Not over 5 (a)	1 drop/15 min
3 to 12	Not over 5 (a)	1 drop/4 min
12 to 50	Not over 5 (a)	1 drop/2 min
More than 50		2 to 4 drops/min

5-4.1.3 Sealing Water Systems.

Make the daily checks for the sealing water system that are listed in Table 5-5. If the leakage cannot be adjusted properly, repack the stuffing box according to Chapter 5 paragraph titled Packing and Table 5-7. Confirm the frequencies in Table 5-7 with local command. Disassemble the sealing water lines and valves annually to verify that the water passages are open.

Table 5-7 Guide for Stuffing Box Inspection

Inspection/Procedure	Action	Frequency
Inspect stuffing box	Ensure that stuffing box glands are moving freely and that gland bolts and nuts are oiled.	Semi-annually
	Check for excessive leakage that cannot be reduced by gland adjustment; if found, proceed according to the steps below:	
Remove old packing	a. Remove old packing and clean box. If the box has a seal cage, make sure it is located opposite the sealing liquid inlet. b. Use packing recommended by manufacturer. c. Measure the depth of box and sealing liquid inlet tap. Place enough rings of packing in the bottom of the box that seal cage is in proper position once	Varies

Inspection/Procedure	Action	Frequency
	packing is compressed. Do not try to pack a pump by renewing only the last three or four rings.	
Check packing ring joints	a. Make sure the packing ring joints are staggered.	Varies
Add new packing	a. Cut the packing so that the joints are square after the packing is bent around the shaft. Cut packing about 1/16 in. longer than measured to be sure that the outside diameter of the ring hugs the stuffing box wall rather than the sleeve. Use care in cutting the rings. b. Except as detailed below, use the follower gland and a few convenient equal-length spacers to compress each ring firmly into place before inserting the next ring. c. Stagger the joints, and make sure that the lantern ring is centered under the water supply connection. d. After the last piece of packing has been placed, tighten the follower gland nuts until finger tight.	Varies
Woven or braided packing	a. Dip each ring of packing in oil before adding it to the stuffing box. b. Woven or braided packing does not have to be added one ring at a time. Fill the box half full. Then draw the rings up snug by taking up on the packing sleeves and gland. Release the follower, add the remainder of the packing, and draw up snug. Then back off the gland until finger tight.	
Plastic or metal packing	a. Plastic and metallic packing must be compressed individually. Dip each ring in oil, insert in the stuffing box,	

Inspection/Procedure	Action	Frequency
	and draw up tight by split-packing rings and gland. Hand turn the shaft a few times to gloss the packing. b. Always use metallic or jacketed rings next to the bottom of the box, bushings, seal cages, or glands because non-jacketed plastic rings will squeeze into the clearances provided at these locations.	
Combustion-type packing	a. Follow instructions supplied by the manufacturer when using combustion-type packing.	
Position lantern rings	a. If a lantern ring is used, be sure it is positioned correctly; if grease sealing is used, be sure the lantern ring is filled with grease before the remaining rings are put in place.	Varies
Run-in new packing	a. New packing has to be run-in. b. Start the pump with the stuffing box gland quite loose. Allow the pump to run 10 to 15 minutes. c. Gradually tighten the stuffing box gland until leakage is reduced to a constant drip. Packing that is too tight in the box causes undue friction, creates heat, glazes the packing, and may score the shaft sleeves. Packing must remain soft and pliable. d. Use drip leakage to ensure proper lubrication throughout the packing box.	Varies
Inspect packing gland	If the stuffing box leaks too much, tighten the gland. If this does not help, remove the packing and inspect the shaft sleeve.	Weekly

5-4.1.4 Rotary Seals.

If a pump has seals that do not have the conventional follower and pliable, replaceable packing, consult the manufacturer’s manual.

5-4.1.5 Shafts and Shaft Sleeves.

\1 When the pump is dismantled, examine the shaft carefully at the impeller hub, under the shaft sleeves, and at the bearings. **/1/**

- Shafts. The shaft may be damaged by rusting or pitting caused by leakage along the shaft at the impeller or shaft sleeves. If antifriction bearings are improperly fitted to the pump shaft, the inner race rotates on the pump shaft and damages the shaft. Excessive thermal stresses or corrosion may loosen the impeller on the shaft and subject the keyway to shock. Replace any shaft that is bent or distorted. After replacing the shaft, check it for possible runout. The maximum allowable is 0.002 in. (51 microns [µ]).
- Shaft Sleeves. Inspect shaft sleeves each year. They are subject to wear and may require replacement, depending on the severity of service. Replace the sleeve when it is appreciably worn, and the packing cannot be adjusted to prevent leakage. Otherwise, excessively grooved or scored sleeves will pare and score new packing as soon as it is inserted into the stuffing box.
- Bearings. Inspect the bearings and add lubricant according to the procedures described in Table 5-8. **\1** Maintenance frequencies are recommended and may vary based on manufacturer’s recommended maintenance frequency. Confirm maintenance frequencies with local command. **/1/**

Table 5-8 Maintenance Checklist for Bearings

Inspection	Action	Frequency
Check bearing temperature	Check with a standard thermometer. Antifriction bearings that are running too hot probably have too much lubricant.	Monthly
Change lubricant	Change lubricant according to Table 5-5. If lubricant change does not prevent overheating, disassemble and inspect the bearing. If nothing appears to be wrong, check the pump and motor alignment.	Quarterly
Check clearances	During the quarterly lubrication change, check the clearances. Recommended clearance is 0.002 in. (51 µ), plus 0.001 in. (25 µ) for each inch (25 mm) of the shaft-journal diameter.	Quarterly
Check bearing condition	Each year, when the pump is dismantled, check the condition of the bearings and the bearing race; replace as necessary.	Annually
	The preferred method in general use for mounting a bearing on a pump shaft is to heat the bearing to expand the inner race and shrink it on the shaft. The bearing is heated in an oil bath or electric oven to a uniform temperature of 200 to 250 °F (93 to 121 °C). When heated, quickly mount the bearing on the shaft.	
	An alternate method uses force exerted by an arbor press or hammer blows. In forcing a bearing onto a shaft, be sure that the race is never cocked during the operation. Firmly press the bearing position on the shaft against the shaft shoulder.	
	Check with a feeler gage.	

Sleeve bearings	Check with a standard thermometer. Sleeve bearings that are running too hot probably have too much lubricant.	Monthly
Change lubricant	Change lubricant according to Table 5-5. If lubricant change does not solve the overheating problem, disassemble and inspect the bearing. If the bearing is in good condition, check the pump and motor alignment.	Quarterly
Check clearances	During the quarterly lubrication change, check the clearances. Normal clearance is 0.002 in. (51 µ), plus 0.001 in. (25 µ) for each in. (25 mm) of the shaft-journal diameter. Make sure that the oil rings are free to turn with the shaft. Repair or replace oil rings when necessary.	Quarterly
Check bearing condition	**\1** When the pump is dismantled, check the condition of the bearings and the bearing race; replace as necessary. **/1/** Sleeve bearings are usually split-type and can be easily removed and installed. Rotation of the bearing is prevented by a pin in the top half of the bearing housing.	Annually

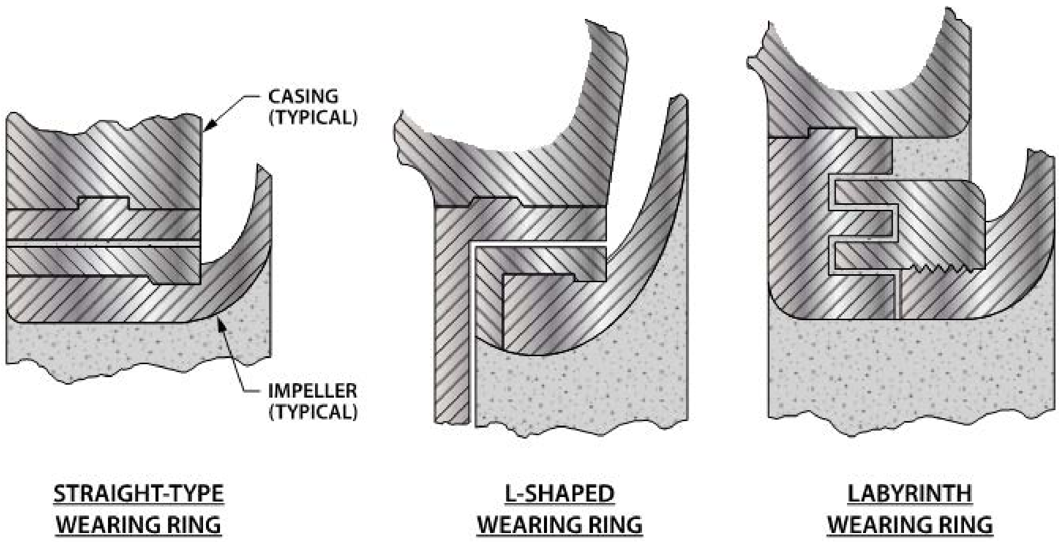
5-4.1.6 Wearing or Sealing Rings.

Each year inspect the wearing or sealing rings that seal the discharge water from suction water in rotating pumps. These are not perfect seals and do allow some leakage. Do not allow this leakage to become excessive because of worn rings or the pump efficiency will be impaired. Three types of wearing rings are shown on Figure 5-1.

- Proper wearing ring clearance is important. In the straight-type wearing ring - the most common type - the diametrical clearance need not be less than 0.025 in. (0.64 mm) and should not be greater than 0.050 in. (1.25 mm).
- In the L-shaped type, clearance in the space parallel to the shaft should be the same as for the straight-type. The clearance of the space at the right angle to the shaft is governed by the end-play tolerances in the bearing.

- For specification information on the L-shape and labyrinth-type rings, consult the manufacturer's manual.

Figure 5-1 Types of Wearing (Sealing) Ring



5-4.1.7 Impeller.

Each year remove the rotating element and inspect it thoroughly for wear (see Chapter 5, "Overhaul Procedures" for dismantling procedures).

- Remove any deposits or scaling.
- Check for erosion and cavitation effects. Cavitation causes severe pitting and a spongy appearance in the metal.
- If cavitation effects are severe, some changes in pump design or use may be necessary. Report the matter to the supervisor.

5-4.1.8 Casing Maintenance.

Keep the waterways clean and clear of rust. When the unit is dismantled, clean and paint the waterway with a suitable paint that will adhere firmly to the metal. A routine program of cleaning and repainting helps prevent complete erosion of the protective coat before replacement.

5-4.1.9 Pump Shutdown.

When a pump is shut down for an extended period, or for overhaul inspection and maintenance, the following procedures apply:

a. Shut off all valves on suction discharge, waterseal, and priming lines. Drain the pump completely by removing vent and drain plugs until the water has run off. This operation protects against corrosion, sedimentation, and freezing.

b. Disconnect the switch to the motor and remove the fuses.

c. Drain the bearing housing. If the shutdown is to be followed by an inactive period, purge all the old grease. Otherwise, refill with fresh grease. If an overhaul is scheduled, do not refill the oil or grease receptacles until the pump is reassembled.

5-4.1.10 Overhaul Procedures.

The frequency of complete overhaul depends on the hours of pump operation, the severity of service conditions, the construction material of the pump, and the care the pump receives during its operation. If the pump is not operated continuously, opening the pump for inspection is not necessary unless there is definite evidence that the capacity has fallen off excessively or if there is an indication of trouble inside the pump or in the bearings. In general, it is good practice to dismantle pumps in relatively continuous operation once a year. Because pump designs and construction vary from model to model, and from one manufacturer to another, there is no set of specific procedures for dismantling and reassembling. Rules (a) through (d) below are basic. For detailed procedures, consult the manufacturer’s manual.

a. Use extreme care in dismantling the pump to avoid damaging internal parts. For convenience in reassembly, lay out all parts in the order they are removed. Protect all machined faces against metal-to-metal contact and corrosion. Do not remove ball bearings unless absolutely necessary.

b. While the pump is dismantled, examine the foot and check valves to make sure they are seating and functioning properly.

c. To assemble the pump, reverse the dismantling procedure. Follow the manufacturer’s manual explicitly.

d. Check the pump and motor alignment after reassembly.

5-4.2 Rotary-Displacement Pumps.

There are numerous types of rotary displacement pumps and, therefore, it is not possible to set up detailed maintenance procedures that apply to all types. Establish individual maintenance procedures according to the manufacturer’s manual. Using the manual, set up procedures similar to those presented for a centrifugal-type pump. At annual intervals, disassemble the pumps and clean both exterior and interior surfaces.

5-4.2.1 Clearances.

Check clearances for tolerances listed in the manufacturer’s manual.

5-4.2.2 Packing.

Check the packing assembly and repack as needed.

5-4.2.3 Bearings and Alignment.

Check the bearings and the alignment of the pump and motor.

5-4.2.4 Checklist Items.

Check all items included in the checklist previously determined from the manufacturer's manual and the listings for centrifugal-type pumps.

5-4.2.5 Painting.

Paint exterior surfaces and interior surfaces subject to rust with a suitable underwater paint or effective protective coating.

5-4.3 Reciprocating-Displacement Pumps.

There are three types of reciprocating pumps: plunger, piston, and diaphragm. Consult the manufacturer's manual for each individual pump.

5-4.3.1 Calculations.

5-4.3.1.1 Slippage.

Calculate the delivery of piston and plunger pumps every year. The decrease in percent delivery from the volumetric displacement per pump stroke is termed "slippage." Excessive slippages indicate the need for maintenance and possible repair.

5-4.3.1.2 Volumetric Displacement.

Compute the volumetric displacement by multiplying the piston or plunger area by the length of stroke. Make proper allowance for double-action pumps.

5-4.3.1.3 Delivery.

Calculate the percent delivery from a comparison of the measured delivery per stroke and the computed volumetric displacement per stroke. If delivery is less than 90% of the volumetric displacement, check the valves, pistons, and packing for leakage. Make any necessary replacements to maintain the desired efficiency.

5-4.3.2 Pump Inspection.

Dismantle the pump and inspect thoroughly each year according to the following schedule:

a. Remove and examine all valves, valve seats, and springs. Reface valves and valve seats as necessary and replace worn or defective parts.

b. Remove all old packing and repack.

c. Check the pump and driver alignment.

d. Check the plunger or rod for scoring or grooving.

e. Clean the interior and exterior surfaces. Paint the interior with suitable underwater paint or protective coating. Paint the exterior.

5-4.4 Sludge Pumps.

Two types of sludge pumps, reciprocating and progressive cavity, are discussed here. Maintain centrifugal-type sludge pumps according to the procedures previously presented for centrifugal-type pumps. Modify the procedures listed to conform to manufacturers' manuals. For lubrication requirements of all sludge pumps, consult the manufacturer's manual.

5-4.4.1 Packing Procedures for Reciprocating Sludge Pumps.

Daily, or more frequently if necessary, check the sight-feed oil cup if one is provided for lubrication between the plunger and the stuffing box. Add a squirt of oil around the plunger as often as necessary.

At varying intervals, renew the packing when no take up is left on the packing-gland bolts.

a. Remove the old packing and clean the cylinder and piston walls. Place new packing in the cylinder and tamp each ring into place. Be sure that the packing ring joints are staggered.

b. To break the packing, run the pump for a few minutes with the sludge line closed and the valve covers open.

c. Turn down the gland nuts, no more than is necessary, to keep sludge from getting past the packing. Be sure all packing-gland nuts are tightened uniformly. When chevron-type packing is used, make sure that the nuts holding the packing gland are only finger tight to prevent ruining the packing and scoring the plunger.

Check the packing-gland adjustment each week to make sure that the gland is just tight enough to keep sludge from leaking through the gland, making sure that the piston walls are not being scored. Before operating a pump, especially after it has been standing idle, loosen all nuts on the packing gland.

5-4.4.2 Bearings and Gear Transmission for Reciprocating Sludge Pumps.

Daily (or once per shift), lubricate the bearings and the gear transmissions with a grease gun. If the pump runs continuously, grease more often than once a shift.

Check the gear transmission each month and keep it filled to the proper level with the proper oil. Open the drain to eliminate accumulated moisture.

Change the oil every 3 months to prevent excessive emulsification.

5-4.4.3 Shear Pins in Reciprocating Sludge Pumps.

a. Check the shear-pin adjustment each week. Set the eccentric by placing a shear pin through the proper hole in eccentric flanges to give the required stroke. Tighten the hexagonal nuts on the eccentric flanges just enough to take the spring out of the lock washers.

b. If shear pins fail, check for a solid object lodged under the piston, a clogged discharge line, or a stuck or wedged valve.

c. When a shear pin fails, the eccentric moves to the neutral position and prevents damage to the pump. Remove the cause of failure and insert a new shear pin.

5-4.4.4 Ball Valves in Reciprocating Sludge Pumps.

Perform an inspection of ball valves every 3 months. Replace valve balls that are worn small enough to jam into the valve chamber. A decrease in diameter of 1/2 in. (13 mm) is sufficient to cause this difficulty. Check the valve chamber gaskets and replace them when necessary.

5-4.4.5 Eccentrics in Reciprocating Sludge Pumps.

Each year, remove the brass shims from the eccentric strap to take up the Babbitt bearing. After removing the shims, operate the pump for 1 hour and check the eccentric to be sure it is not running hot.

5-4.4.6 Progressive Cavity Sludge Pumps.

5-4.4.6.1 Seals.

When grease seals are used instead of water seals, check the grease pressure in the seals daily.

a. For water seals, allow about 60 drops of leakage per minute when the pump is running.

b. If leakage is high, tighten the two gland nuts evenly a few turns, but do not draw the glands too tight. After adjusting the gland, turn the shaft by hand to make sure it turns freely.

5-4.4.6.2 Bearings.

Lubricate the sludge pump through the grease connections on the bearing housing each week. Flush out the bearing housing each year. Then refill with new grease.

5-4.4.6.3 Packing Glands.

Check the packing glands for leakage each week.

5-4.5 Well Pumps.

Well-pump types are centrifugal pumps, reciprocating (piston or plunger) pumps, and jet (ejector) pumps.

5-4.5.1 Centrifugal Well Pumps.

The turbine well pump is the most widely used type of well pump. Use the maintenance items listed for centrifugal-type pumps (Chapter 5 paragraph titled Maintenance Procedures for Centrifugal Pumps) and the manufacturer's manual to develop maintenance charts for turbine well pumps. In addition, check the following items:

5-4.5.1.1 Types of Lubrication.

5-4.5.1.1.1 Oil-Lubricated Pump and Bearings.

Make sure that the oil tubing and lubricators are filled each day. Check the solenoid oilers for proper operation and see that they are filled. Check the oil level in the sight gage lubricator for underwater bearings. Make sure that the oil feed is at an average rate of 3 to 4 drops per minute.

5-4.5.1.1.2 Water-Lubricated Pump and Bearings.

This type of design requires lubrication with clear water. Daily, make sure that the pre-lubrication tank is full when the pump is in use.

a. When filling the tank by pump, close the tank-filling valve when the tank is full. Open the lubrication valve to allow water to reach the bearings before the pump is started.

b. If the bearings are lubricated from main pressure, close the lubricating valve after the pump is started.

c. If the pump operates automatically and has a lubrication-delayed solenoid valve, wait 1 minute before checking the lubricating valve for proper operation. Check operation of the solenoid valve and check the packing for excessive leakage.

d. Check the pre-lubrication control on pumps that have safety controls to prevent starting before lubrication water is turned on. Make sure that this water flows to the bearings when the equipment is supposed to function.

e. Check the time-delay relay for proper functioning and compare with the manufacturer’s recommendation.

f. Clean and lubricate the guides and linkages.

5-4.5.1.2 Impeller Adjustment.

Every 3 months check the impeller for maximum efficiency setting and adjust if necessary. On hollow-shaft motors, the adjustment nut is on the top of the motor. Consult the manufacturer’s manual for the detailed adjustment procedure.

5-4.5.1.3 Impeller Fitting.

When the pump is pulled for inspection, note signs of pitting or wear on the impellers.

- **Cavitation.** Pitting in the lower stages may be from cavitation.
- **Sand Erosion.** Sand in the water erodes the impellers. If sand is the cause of difficulty, check the well screen and replace if necessary. Where the erosion effect is appreciable, repair or replace impellers that are not likely to last until the next inspection.
- **Clearances.** Repair or replace impellers, as necessary, to maintain the close clearance required for pump efficiency. See the manufacturer’s manual regarding pump clearances and efficiencies.

5-4.5.1.4 Bowls and Waterways.

When the pump is pulled for inspection, inspect the bowls and water passage for pitting, wear, and corrosion.

5-4.5.1.5 Overhaul Procedures.

5-4.5.1.5.1 Frequency.

As with the centrifugal pumps, the frequency of complete overhaul depends on the hours of operation and severity of operation, water quality and operating environment. Generally, however, a pump in continuous operation should be pulled for inspection and overhaul annually. Perform the overhaul under experienced supervision and in strict accordance with the manufacturer’s manual. Overhaul the pump if any of the following conditions exist regardless of scheduled maintenance frequency:

- The pump shaft does not turn freely because parts below the pump head are binding.
- The pump shows excessive vibration.

- A performance test shows a decrease of 25% in capacity under normal head and speed conditions.

5-4.5.1.5.2 Clearances.

When a pump is pulled, check the diametrical clearance of each bearing ring to make sure it is between 0.025 and 0.050 in. (0.64 and 1.25 mm). Allow a maximum diametrical clearance of 0.025 in. (0.64 mm) on oil-lubricated bearings. Maximum allowable clearances for water-lubricated cut-less rubber bearings are 0.040 in. (1.0 mm) for shaft diameters up to 1.5 in. (40 mm) and 0.070 in. (1.8 mm) for shaft diameters 1.5 to 4 in. (40 to 100 mm).

5-4.5.1.5.3 Dismantling and Reassembly.

Follow the same procedures listed for centrifugal-type pumps.

5-4.5.1.5.4 Alignment.

Check the pump and motor alignment each year.

5-4.5.1.5.5 Painting.

Annually, or when the pump is pulled, paint all iron parts with a good grade underwater paint or effective protective coating on the exterior of the pump and, if possible, on the interior parts subject to rust. Apply the paint only to surfaces that are clean and dry. Do not paint the data plate.

5-4.5.2 Reciprocating Well Pumps.

5-4.5.2.1 General Information.

Use the manufacturer’s manual to develop checklists for each reciprocating well pump.

5-4.5.2.2 Delivery.

Measure the pump output twice a year for a known number of strokes. Delivery per stroke should be at least 90% of the volumetric displacement of the pump (plunger area times stroke length). When the pump delivery drops to 50% or less, or when the pump delivery is between 50 and 90% but less than the installed water requirements, remove the pump from the well and check the valves and cup leathers. Before removing the pump, consult the manufacturer’s method for picking up the foot valve and for additional maintenance procedures.

5-4.5.2.3 Overhaul Procedures.

Inspect the pump jack for wear each year. Replace worn bearings and parts. Check the packing assembly and repack as necessary. If the pump delivery is satisfactory, do not overhaul the pump parts in the well. Paint the exterior of the pump as necessary.

5-4.5.3 Ejector Pumps.

5-4.5.3.1 Centrifugal Pump.

Maintain the centrifugal pump portion of the system according to the maintenance items listed for centrifugal pumps in Chapter 5 paragraph titled Maintenance Procedures for Centrifugal Pumps.

5-4.5.3.2 Ejector Assembly.

Each year, or as directed by the utility's manager, remove the ejector, the foot valve, and the screen from the well. Examine all parts for wear and corrosion and repair or replace any defective parts. Paint the exterior of the pump in accordance with *UFC 3-190-06*. If practical, paint interior iron with a good grade underwater paint or effective protective coating meeting *NSF/ANSI 61*.

5-4.5.4 Starting a New Well Pump.

Table 5-9 lists startup procedures for vertical turbine well pumps. While plant operators generally will not be responsible for performing these initial procedures, they may be charged with overseeing the contractors performing installation, and they should be familiar with the startup tasks. Figure 5-2 shows the necessary water-level checks. If problems occur, refer to the troubleshooting checklist provided in Table 5-10.

Table 5-9 Startup Checklist for Vertical Turbine Well Pumps

Inspection	Action
Prestart Inspection Well	Disinfect according to Chapter 3 paragraph titled Well Disinfection.
Pump equipment	Check alignment.
Valve and piping system	Check for proper operation. Check for leaks. Set valves so water pumped at startup does not feed into distribution system until bacteriological quality has been tested and clearance received.
Bearings	Pre-lubricate bearings on water-lubricated, line-shaft pumps with settings of more than 50 feet.
Electrical connections	Make sure that all electrical connections are correct and that terminals are tight.

Inspection	Action
Instrumentation	Make sure all instrumentation is hooked up according to the manufacturer's instructions.
Startup Inspection Pump	 Start pump. Check immediately for evidence of malfunction or excessive heat or vibration. Check operating power input.
Motor	Check for malfunction or excessive heat or vibration. Check rotation direction of motor. Check water or oil lubrication system.
Instrumentation	Observe how quickly motor comes up to operating speed; check final operation speed.
Bearings	Check for excessive heat or vibration.
Post-Startup Inspection Well	 Check for abrasive material (sand pumping) or the presence of gas within the well.
Water level	Make immediate check of water level and record data for future reference. Perform pumping and recovery water-level checks as shown in Figure 5-2.
Pressure tests	Check pump pressure and flow output. Determine the corresponding pumping level in the well. Compute the field head (1) and compare it to the pump curve supplied by the manufacturer (2).
Water quality	After pumping for 24 hours, collect a water sample for microbiological analysis to ensure water is free from disease-causing organisms.

(1) Field head is computed as follows: calculate the static and dynamic head losses being overcome by the pump. The total field head equals (a) the friction losses in the pump column and through the pump discharge elbow to the location of the pressure gage on the pump plus (b) the vertical distance from the pumping level in the well to the pressure gage plus (c) the pressure gage reading converted to feet of head.

(2) The manufacturer's pump curve should be a combined curve showing a composite assembly rating for multistage pumps, not a single-bowl-assembly curve used for a single-stage pump.

For additional help reading pump curves or calculating head losses, consult Chapter 2 paragraph titled Water Source. A sample field head calculation is provided in Appendix B.

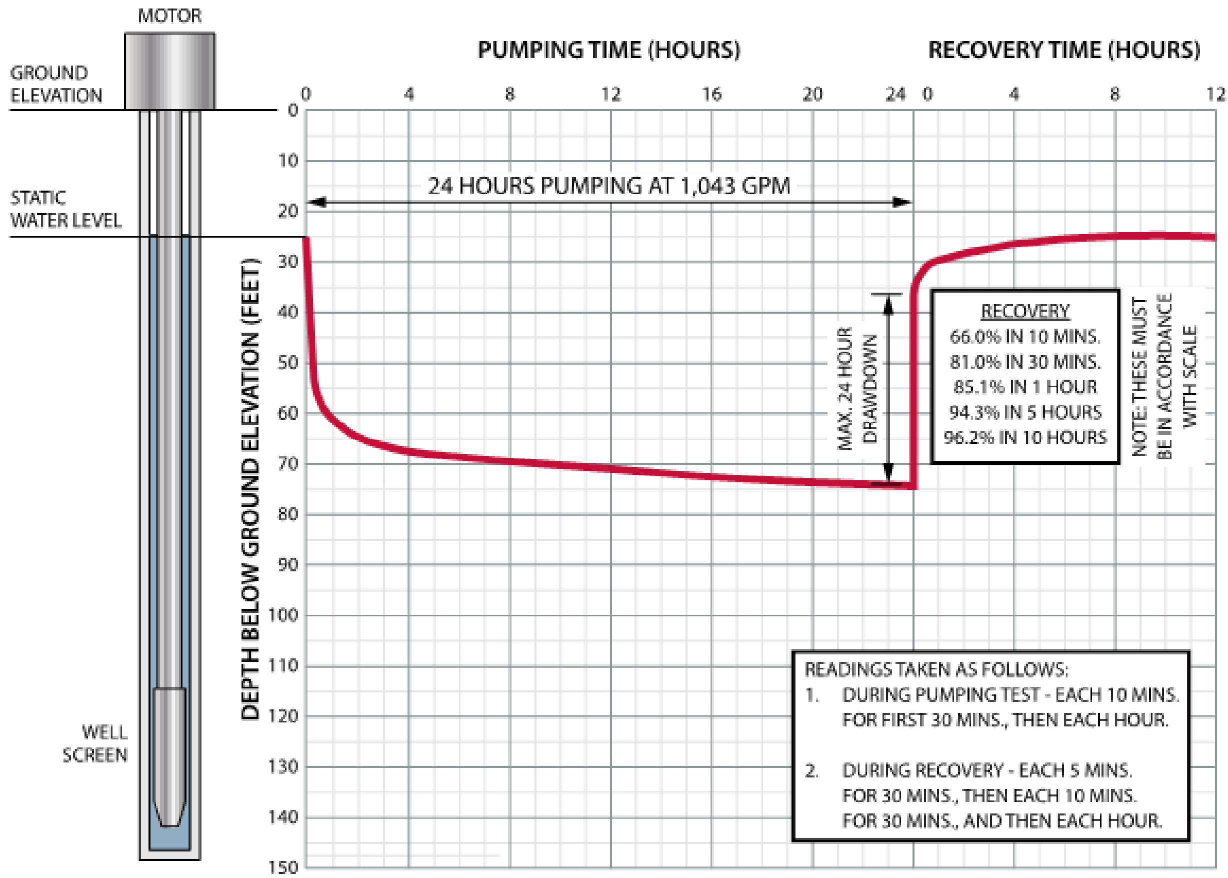
Table 5-10 Troubleshooting Checklist for Vertical Turbine Well Pumps

Symptom	Cause of Trouble	Remedy
Pump fails to start.	Bearing friction	Check tube tension nut for tightness; check for bent shaft and proper anchoring; check oil.
	Corrosion products or biological growth	Check, particularly on out-of-service pumps. Where necessary, flush with acid, chlorine, and, or, hexametaphosphate.
	Fuses burned out	Check voltages at each phase of motor terminals.
	Impeller locked	Check for sand; raise or lower impeller; backwash. Pull pump if necessary. Also check impeller adjustment; raise impeller to allow shaft to stretch for hydraulic thrust.
	Faulty driver	Disconnect from pump and check starting.
	Power not available	Check circuit breaker, fuse, and starter.
	Overload relay trip	Reset.
	Trash in casing	Check. If necessary, pull pump and clean.
	Low voltage	Check.
	Well cave-in	Check; pull pump; repair well.

Symptom	Cause of Trouble	Remedy
Pump does not deliver water.	Pump not primed	Check for proper pump submergence. Vent well to atmosphere to eliminate vacuum at pump suction.
	Discharge head too high	Check for closed discharge valves or stuck check valves.
	Pump parts failure	Check for broken shaft, broken bowl assembly, loose impellers, and loose column-pipe joints.
	Wrong direction of rotation	Check for switched power leads.
	Speed too low	Check power supply voltage and frequency. Check for bearing friction and impeller corrosion or obstruction.
	Suction clogged	Backwash or use chemical treatment to clean.
	Operating water level low	Check static level and drawdown. Lower pump, clean screen, and decrease pumping rate.
	Low speed	Check power supply voltage and frequency; check for excessive bearing friction and impeller corrosion or obstruction.
	Low water level in well	Check well vent. Check pump inlet for turbulence, vortexing, or eddies. Check well screen for sand, rust, or biological growth.
	Faulty instruments	Correct instrument readings.
Pump requires excessive power.	Impeller rub	Check adjustment of impeller height.
	Wrong lubricant	Compare manufacturer’s instructions with lubricant being used.
	Misalignment	Check for tight bearings; check for pump and casing vibration.

Symptom	Cause of Trouble	Remedy
	Packing too tight	Check for proper leakage to provide shaft lubrication.
	Pump selection wrong	Check capacity rating, etc.
	Wrong direction of rotation	Check power leads.
	Excessive speed	Check power frequency and voltage; check gear ratios.
Pump vibrates excessively.	Air entering pump	Check on over-pumping and water level drawdown; check leaks in well vent.
	Bearing trouble	Check for sand in water. Check lubricant (oil and grease) for proper grade.
	Rough operation	Check disconnected motor. Check for sand in impeller or bowl. Check for wear in rotating parts.

Figure 5-2 Typical Well Pumping and Recovery Test



5-5 PUMP DRIVERS.

Pump drivers provide the mechanical source of energy to pumps. The driver is usually an electric motor, gasoline, or diesel engine. More general operator training/knowledge-based information on pump drivers is provided in *Water Treatment Plant Operation, Volumes 1 and 2*.

5-5.1 Electric Motors.

Electric motors are the most common drive used in military water systems. Proper operation of an electric motor requires that the operator can recognize the normal sounds and conditions of a properly running motor. In general, investigate any change in the sound or operating condition detected during the regular inspection. Table 5-11 includes a list of routine operating checks for electric motors.

Table 5-11 Routine Operations Checklist for Electric Motors

Inspection	Action
Motor	Keep the motor free from dirt or moisture.
	Keep the operating space free from articles that may obstruct air circulation.
	Check the bearings for oil leakage.
Unusual Conditions Unusual noises in operation Motor fails to start or to come up to speed normally Motor or bearings feel or smell hot Continuous or excessive sparking at commutator Hot commutator Blackened commutator Sparking at brushes Fine dust under couplings with rubber buffers or pins Smoke, charred insulation, or solder whiskers extending from armature Excessive hum Regular clicking Rapid knocking Chattering brush Vibration	Check regularly for these unusual conditions. Report any irregularities to the plant superintendent for correction by the electrical shop.

5-5.1.1 Maintenance.

As a rule, the electrical shop is responsible for routine maintenance of electrical motors. Under some circumstances, the responsibility for cleaning and servicing antifriction bearings may be delegated to the operator. General guidance for routine maintenance of electrical equipment is provided in Chapter 10 paragraph titled Electrical Equipment and some best practice information is in *Water Treatment Plant Operation, Volumes 1 and 2*.

5-5.2 Gasoline and Diesel Engines.

Gasoline and diesel engines are commonly used for emergency, standby, and portable pumping units. The operator is usually responsible for performing operating checks. Table 5-12 lists items to check before, during, and after starting gasoline and diesel engines. Use this checklist as a general guide only. Obtain specific details from the manufacturer's manual for each unit, and perform any additional services specified in the manual.

Table 5-12 Operations Checklist for Gasoline and Diesel Engines

Inspection	Action
Prestart Checks Motor	Check equipment for signs of tampering or leaks.
Fire extinguisher	Ensure extinguisher is in working order.
Gages	Check all fuel, oil, and water levels.
Accessories and drives	Inspect according to manufacturer's instructions.
Battery	Check for cracks and leaks.
Air breather	Make sure breather is free of obstruction.
Startup/Warmup Checks Choke or primer	Check for proper operation.
Indicator lights	Ensure oil gage or indicator lights are in working order.
Other instruments	Check that ammeter, tachometer, fuel gage, voltmeter, and temperature gage are working.
Operating Checks Clutch	Ensure clutch is working properly.
Transmission and engine/controls	Check for unusual sounds, vibration, overheating, etc.

Inspection	Action
Instruments	Check that all instruments are registering readings.
Post-Shutdown Checks Gages	 Check fuel, oil, and water levels.
Instruments	Check indicators. Indicators should return to zero when engine is not running.
Battery and voltmeter	Check that battery has not run down and retains sufficient charge.
Accessories and belts	Check for signs of wear.
Electrical Wiring	Inspect wire integrity (no frayed or charred wires; no loose wires).
Air cleaner and breather caps	Look for obstructions or clogs.
Fuel filters	Be sure filters are not clogged or dirty. Change or clean as required or at regular intervals.
Engine controls	Controls should move freely. Check for binding, sticking, etc.
Leakage	Look for oil and coolant leaks.
Gear oil levels	Check level.

In addition to the checks listed in Table 5-12, perform the following tasks:

- **Unit Readiness Checks.** Operate all emergency and standby units at full load for the time specified by the equipment manufacturer. One hour each week is often recommended to ensure unit readiness.
- **Routine Maintenance.** Operators are generally responsible for operating checks and routine maintenance.

5-6 ACCESSORIES.

Accessories include belt drives, gear drives, variable speed drives, and couplings that connect the driver to the pump.

5-6.1 Belt Drives.

Two types of belts are used for belt drivers: V-belts and flat belts. Maintaining proper tension and alignment of belt drives ensures long life of belts and sheaves. Incorrect alignment causes poor operation and excessive belt wear. Inadequate tension reduces the belt grip and causes high belt loads, snapping, and unusual wear. Keep belts and sheaves clean and free of oil, which deteriorates belts. Replace belts as soon as they become frayed, worn, or cracked.

5-6.1.1 Installing Belts.

Before installing belts, replace worn or damaged sheaves. Check alignment with a straight edge or string and make the necessary corrections to keep the pulleys in line. Loosen the belt tensioning adjustment enough to remove and install belts without the use of force. Never use a screwdriver or other lever to force belts onto sheaves. Check multiple belts for matching size and length. It is not good practice to replace only one V-belt on a multiple belt assembly. Instead, replace the complete set with a set of matching belts. After belts are installed, adjust the tension. Recheck the tension after 8 hours of operation.

5-6.1.2 Checking Tension.

Check belt tension each week and adjust, as required, to prevent slipping or excessive wear on the belts.

5-6.2 Right-Angle Gear Drives.

O&M procedures for right-angle gear drives should follow manufacturer's recommendations. Immediately after starting a right-angle gear drive, remove the inspection plate and check for proper flow of lubricant. If there is no flow, stop the motion and check for mechanical defects. If no mechanical defect is found, it may be necessary to change the lubricant or drain and warm the old lubricant. Temperature or service conditions may require changing the lubricant type. To avoid detrimental effects of possible water-oil emulsion, drain old oil and refill with fresh recommended lubricant quarterly or about every 500 hours of operation, whichever is more frequent. The choice of lubricant depends on prevailing air temperatures and the manufacturer's recommendations.

5-6.3 O&M for Variable-Speed Drives.

5-6.3.1 Procedures.

Variable-speed drives are commonly used in water systems. Designs vary considerably from manufacturer to manufacturer. Therefore, consult the manufacturer's manual to determine O&M requirements. Items common to most variable-speed drives are listed below.

- Check for Normal Operation. Observe the drive each shift and note any abnormal conditions.
- Clean Discs. Remove grease, acid, and water from the disc face and thoroughly dry it. Use clear solvents that leave no residue.

- Check Speed-Change Mechanisms. Shift drive through the entire speed range to make sure that shafts and bearings are lubricated and discs move freely in a lateral direction on shafts.
- Check V-Belt. Make sure the belt runs level and true. If one side rides high, a disc is sticking on the shaft because of insufficient lubrication or the wrong lubricant. In that case, stop the drive, remove the V-belt, and clean the disc and shaft thoroughly with kerosene until the disc moves freely.
- Check Lubrication. Be sure to apply lubricant at all force-feed lubrication fittings and grease cup fittings. Refer to the manufacturer's manual for proper lubricants.

    a. Once every 10 to 14 days, add two or three strokes of grease through the force-feed fittings at the end of the shifting screw and variable shaft to lubricate the bearings of movable discs. Shift the drive from one extreme speed to the other to thoroughly distribute the lubricant over the disc-hub bearings.

    b. Every 60 days add two or three shots of grease through the force-feed fittings that lubricate the frame bearings on the variable-speed shaft.

    c. Every 60 days add grease to grease the cup that lubricates the thrust bearings on the constant-speed shaft.

    d. Every 60 days add two or three strokes of grease through the force-feed fittings on motor-frame bearings. Do not use hard grease or grease that contains graphite.

    e. Check the reducer oil level every 30 days and add oil when necessary. Drain and replace the oil according to the manufacturer's recommendations.

5-6.3.2 Remove Unit from Service.

If the drive will not be operated for 30 days or more, shift the unit to minimum speed. This places the springs on the variable-speed shaft on minimum tension and relieves the belt of excessive pressure and tension.

5-6.4 Couplings.

Unless couplings between the driving and driven elements of a pump or any other piece of equipment are kept properly aligned, breaking or excessive wear occurs in the coupling, the driving machinery, or the driver. Worn or broken couplings, burned out bearings, sprung or broken shafts, and excessively worn or ruined gears are some of the damages caused by misalignment. To prevent outages and the expense of installing replacement parts, check the alignment of the equipment before damage occurs.

5-6.4.1 Checking Coupling Alignment.

Excessive bearing and motor temperatures caused by overload, noticeable vibration, or unusual noises may all be warnings of misalignment. Realign when necessary, using a straight edge and thickness gage or wedge. To ensure satisfactory operation, level up the gap to within 1.5 in. (127×10^{-3} mm), as follows:

a. Remove coupling pins.

b. Rigidly tighten any driven equipment to its base. Slightly tighten the bolts holding the driver to its base.

c. To correct horizontal and vertical alignment, shift or shim the driver to bring coupling halves into position so no light can be seen under a straight edge laid across them. Lay the straight edge in at quarter points of the circumference, holding a light behind the straight edge to help ensure accuracy.

d. Check for angular misalignment with a thickness or feeler gage inserted at the same four places to make sure that the space between coupling halves is equal at all points.

e. If the equipment is properly aligned, coupling pins can be put in place easily (using only finger pressure). Do not hammer pins into place.

f. If the equipment is still misaligned, repeat the procedure.

5-6.4.2 Lubrication.

Use lubrication procedures and lubricants recommended by the manufacturer and in Chapter 10 paragraph titled Lubrication.

5-7 RECORDKEEPING.

Keep equipment and maintenance records for each pump and drive assembly. The method used is prescribed by local command. In general, records will contain entries for routine maintenance (lubrication and equipment checks, repacking, and cleaning), scheduled overhauls, and nonscheduled repairs. A description of the work done, the date, and the name of the person doing the work are minimum entries. Since a pump's condition is best evaluated by comparing its current performance to its original performance, a record of flow, pressure, pump speed, amperage, and other test data determined immediately following installation is recommended.

5-8 PUMP SAFETY.

Specific hazards related to operating and servicing pumps include rotating equipment, lifting heavy machinery, using hand tools, working with electrical devices, and fires.

Always stop machinery before it is cleaned, oiled, or adjusted. Lock out the controlling switchgear before any work begins so that the machinery cannot be started by another person. Post a conspicuous tag on or over the control panel, giving notice that the equipment is under repair and should not be restarted. Also note the name of the person who locked out the equipment.

Caution: Remove guards for maintenance only when the machinery is not in operation.

5-8.1 Motor and Engine Safety.

Follow special safety precautions when dealing with motors and engines. In addition to all the other safety concerns associated with water distribution (as discussed in other chapters), be cautious around electrical devices and be aware of fire safety guidelines.

5-8.2 Electrical Devices.

No safety tool can protect absolutely against electrical shock. Use plastic hard hats, rubber gloves, rubber floor mats, and insulated tools when working around electrical equipment. These insulating devices cannot guarantee protection, however, and no one using them should be lulled into a false sense of security.

Electrical shocks from sensors are possible in many facilities, such as pumping stations, because many instruments do not have a power switch disconnect. It is important to tag such an instrument with the number of its circuit breaker so that the breaker can be identified quickly. After the circuit breaker has been shut off, tag or lock the breaker so other personnel will not re-energize the circuit while repairs are being performed. Even after a circuit is disconnected, it is good practice to check the circuit with a voltmeter to be certain that all electrical power has been removed. Make sure switches are locked open and properly tagged when personnel are working on equipment. Use fully enclosed, shockproof panels when possible. Such equipment should be provided with interlocks so it cannot be opened while the power is on.

Use extreme care in working around transformer installations.

CHAPTER 6 DISTRIBUTION AND STORAGE

6-1 DISTRIBUTION SYSTEM DESIGN AND INSTALLATION.

Use UFC 3-230-01 for the design and installation of distribution systems.

6-2 DISTRIBUTION SYSTEM OPERATION.

Proper operation of the distribution system is required to maintain a dependable water distribution system, ensure water quality, provide adequate flows for protection against fire (fire flow), and maintain adequate pressure. Set and operate valves, keep records of water flows and levels, and correctly balance the system flow to maintain the desired pressure in all parts of the system. Records contain current system maps, maintenance records of all leaks and breaks, repair type, pipe condition, joint type, fire-flow tests, C-factor tests, pressure gauges, surrounding soil types, corrosion potential, and any hazardous material sites nearby. Implement a program for evaluating and upgrading existing portions of the distribution system as required. General information on system O&M can be found in *AWWA M31. Some best practice information is in Water Treatment Plant Operation, Volumes 1 and 2.*

6-2.1 Leak Inspection.

Leaking pipes waste water, reduce water pressure, and potentially create public safety hazards. Conduct leak detection surveys at the time of minimum water use. Shut off all valves, except those that will direct the water flow through the section under study.

Caution: Good practice requires that the firefighting authorities be notified before closing any section of the system.

Specific directions for leak detection and repair may be found in these publications; *AWWA M36*, and *AWWA M51, additional operational best practice information can be found in Water Treatment Plant Operation, Volumes 1 and 2*.

6-3 DISTRIBUTION SYSTEM MAINTENANCE.

Table 6-1 covers leak repair procedures for various distribution system problems.

Table 6-1 Checklist for Distribution System Maintenance

Problem Type	Repair Procedure
Joint leak	Caulk the joint (if caulk was used in the joint)
Cracked main	Cut out the section of cracked pipe and replace it with a stub of new pipe and mechanical couplings. Flush and disinfect.
Large section of corroded or leaking main in high-cost digging area	Hire outside professionals to perform slip lining, in situ formed-tube lining, cement-mortar lining, or other appropriate techniques.
Poor aesthetic water quality (taste, odor, color, turbidity)	Flush and disinfect the main. If the problem persists, modify chlorination procedures in the problem area or replace dead-ends or low points, if applicable.
Deposits or silt buildup in main	Flush and disinfect the main.
System flow below fire flow requirements	Hire outside professionals to mechanically clean mains. Line the mains post-cleaning or immediately begin chemical treatment.
Corrosive source water aggravating tuberculation	Stabilize water and increase pH. For more information on corrosion control, see Chapter 4.
Frozen pipes	Electrically or steam thaw pipes

6-3.1 Main Breaks.

If a break or leak is found, include the pipe location, material, size, type of leak or break, visual assessment of surrounding soil type, pipe depth, and assessment of saturation conditions of soil and proximity to water table in the maintenance record.

Establish procedures for water main repairs and ensure that personnel are trained to perform them. Perform the following tasks to eliminate delay in beginning the repairs:

- Post telephone numbers of key personnel conspicuously in the water plant.

- Keep the following items available and ready for use: valve keys, hand tools, digging tools, pavement breakers, trench-shoring material, a portable centrifugal pump, floodlights, an emergency chlorinator, and calcium hypochlorite.
- Keep a stock of split-sleeve and mechanical-joint repair fittings in sizes that fit critical mains.
- Make advance arrangements with a municipal utility, public works department, or an outside contractor for the use of large construction equipment (e.g., power shovels and cranes) that may be needed but are not normally stocked by the installation.

Select the proper leak repair technique. Understanding the methods of installation and the most advantageous use of each technique will help you make the proper selection for the repair.

6-3.1.1 Pipe Replacement.

Assess the physical condition of pipes. All materials used for pipe replacement shall conform to applicable AWWA and NSF/ANSI standards. The joints used in pipe replacement shall also meet AWWA standards. Mechanical joints shall have slip-on joints with rubber gaskets. Use transition joints between dissimilar piping materials.

6-3.2 Water Main Tapping Procedures.

Perform a wet tap of an existing water main where connection must be performed without turning off the water or interrupting service to existing customers. More detailed information on tapping valves and procedures may be obtained from the pipe manufacturer or from the publication listed in best practice *AWWA M44 Chapter 2*.

6-3.2.1 Pipe Lining.

Consider lining existing water mains as an alternative where high-cost digging is required, such as under pavements and in industrial areas. Lining a pipe can eliminate the need for frequent or continuous flushing. A smooth lining in a corroding pipe maximizes hydraulic carrying capacity and minimizes pumping costs. Additionally, linings can correct the structural failures, and bridge breaks and missing sections in corroded pipe, thus restoring service through a continuous pipeline. More information on cleaning and lining may be found in *AWWA M28. Additional operations best practices can be found in Water Treatment Plant Operation, Volumes 1 and 2*.

6-3.3 Flushing.

Remove matter deposited in the distribution system over time by annually flushing the system. Flushing and disinfection are required whenever mains are opened for repair in addition to annual flushing.

Flushing water mains near a nuisance, particularly at dead ends, may remove or reduce problems with taste, odor, color, or turbidity. If complaints about quality are received, investigate the possibility that stagnant water in dead-end lines may be the cause and take remedial action. Find and eliminate conditions that make repeated flushing necessary: a dead end or a low point in the main may allow sediment to accumulate, or growth of slime organisms may be caused by insufficient chlorination. Flushing is also helpful in clearing the non-potable part of the water system.

6-3.3.1 Water Age.

6-3.3.1.1 Pipe and storage is oversized for many installations based on overestimated fire hazard ratings and population. The oversized infrastructure leads to reduced turnover and therefore increased water age. Aggressive water conservation strategies have also decreased water turnover. Low density land-use planning strategies and outlying facilities located in far off dead-end zones can be designed with one pipe supply for both fire and potable use, which increases water age.

6-3.3.1.2 The amount of water turnover must be sufficient to remove old water and provide thorough mixing of the contents of the storage facility. It is generally recommended that a least 30% turnover be achieved daily. Maximize mixing and cycling in storage reservoirs and eliminate short-circuiting.

6-3.3.1.3 It is important to manage water age in the overall distribution and tank system as it relates to managing indicators of water quality problems, nitrification control, and DBP –TTHMs. Utilities are increasingly interested in modeling the water quality within a distribution system, particularly the decay of chlorine residual by using computer models to compute water age, track disinfectant residuals, and reduce disinfection by-products in a distribution system

6-3.3.1.4 Refer to *AWWA M32* and *AWWA M56* for best management information on water age management, modeling and nitrification prevention and control.

6-3.3.2 Flushing Procedure.

Start flushing at the supply source and continue to the ends of the distribution system. Do not start flushing at the ends of the system because accumulated debris must be drawn through the entire length of the system. For maximum scouring velocity, flush each section of pipe independently by closing off intersecting pipelines. This process directs the full flow through the section to be flushed. A velocity of 6 feet per second (fps) (1.8 meters per second [mps]) is recommended for flushing. Dechlorinate any water discharged to state waters. Table 6-2 gives the number of hydrant outlets required to flush various size water mains at the recommended pressure of 30 psi (207 kPa).

Table 6-2 Flow Rate and Number of Hydrant Outlets Required to Flush Water Mains with 30 psi (207 kPa) of Pressure

Pipe Diameter		Flow Required for 6 fps (1.8 mps) velocity		Number of 2.5-in. (65-mm) Hydrant Outlets	Number of 4-in. (100-mm) Hydrant Outlets
in.	(mm)	gpm	(m^3/hr)		
4	(100)	235	(50)	1	
6	(150)	525	(120)	1	
8	(200)	940	(210)	1	
10	(250)	1,970	(330)	2	1
12	(300)	2,010	(460)	2	1
16	(400)	3,750	(850)	3	2
18	(460)	4,750	(1,080)		2
24	(610)	8,450	(1,920)		3

6-3.3.2.2 Flushing Plan.

a. Using distribution maps, prepare a list of hydrants and blow-offs to be opened in an order that will flush the system from source to ends.

b. List, in correct order, valves to be closed and opened for each flushing point.

c. If service in any section will be disrupted by the plan, arrange to flush it at night. Notify heating plant and firefighting personnel in such sections.

6-3.3.2.3 Operating Guides.

a. Remove service meters from the section being flushed.

b. Flush each pipe section until water is reasonably clear.

c. Take care not to damage unpaved roads, walks, or improved grounds. If necessary, use a section of lightweight pipe to direct flows so that damage does not occur.

d. Place all valves in normal operating position before proceeding to the next flushing point.

e. To permit flushing dead ends, install a blow-off at the end of each end main. Paint the blow-off hydrants a different color than fire hydrants and prominently mark them as blow-off hydrants. Dead ends may need flushing more often than other sections of the system.

For information on hydrant flushing, see Chapter 7.

6-3.4 Cleaning.

Corrosion, scale, and deposited matter cannot normally be removed with simple flushing. When increased system head loss reduces system capacity below fire flow requirements, mechanical cleaning is necessary. As a rule, this work is done on a contract basis by firms specializing in main cleaning. After cleaning, the mains may be relined to restore original smoothness of the interior. If this is properly done, 95% or more of the original capacity can be restored. If the mains are not lined with a corrosion-resistant material after cleaning, start chemical treatment to prevent accelerated corrosion and red water. Best practice information on cleaning water mains can be found in *AWWA M28*, and *AWWA M51. Some operational best practices can be found in Water Treatment Plant Operation, Volumes 1 and 2*.

6-3.5 Electrical Thawing of Frozen Systems.

Pipes may freeze in temperate as well as frigid zones. In frigid climates, freezing presents a major problem to a water distribution system, and pipes are normally insulated and heated. In areas where the ground is permanently frozen, water pipes are placed in heated conduits. In temperate climates where freezing is only a seasonal problem, pipes are typically buried below frost penetration depth. It is also necessary to heat stored water in cold areas. Even with proper protection against freezing, pipes may freeze. When this happens, thaw pipes by electrical thawing. Perform electrical thawing by means of hot wire tape. The use of generator welding machines to thaw pipe is not acceptable.

Table 6-3 Current and Voltage Required to Thaw Wrought-Iron and Cast-Iron Pipe

	Pipe Size		Pipe Length		Approx. Volts	Approx. Amps
	Inches	(mm)	gpm	(Lps)		
Wrought iron	3/4	(20)	600	(180)	60	250
	1	(25)	600	(180)	60	300
	1-1/2	(40)	600	(180)	60	350
	2	(50)	500	(150)	55	400
	3	(75)	400	(120)	50	450
Cast iron	4	(100)	400	(120)	50	500
	6	(150)	400	(120)	50	600
	8	(200)	300	(90)	40	600

- Current and Voltage. Data concerning the current and voltage required to thaw various sizes of wrought-iron and cast-iron pipe are given in Table 6-3.
- Required Time. The time required for electrical thawing varies from 5 minutes to over 2 hours, depending on the pipe size and length, the intensity of freezing, and other factors. The best practice is to supply current until the water flows freely.
- Do not use a current higher than the one listed for the pipe size in Table 6-3. When in doubt, use a lower current for a longer period.
- Select contact points on the pipe as close as possible to the frozen section.
- Make sure contact points are free of rust, grease, or scale.
- Remove meters, electrical ground connections, and couplings to building plumbing from the line to be thawed.
- If pipe joints have gaskets or other insulation, thaw the pipe in sections between the joints or use copper jumpers to pass the current around the insulated joints.

6-3.6 Steam Thawing.

Steam thawing is slower than electrical thawing and used only when insulating material in pipe joints or couplings makes the use of electricity impractical. In steam thawing, a hose connected to a boiler is inserted through a disconnected fitting and gradually advanced as the steam melts the ice. Steam thawing is commonly used on fire hydrants.

6-3.7 Instrumentation, Control, and Information Management.

Information on these topics can be found in *AWWA M2*.

6-4 STORAGE FACILITY OPERATION.

Drain finished water to the ground and dechlorinate as necessary prior to introducing it into the storm sewer drains. Perform storage tank O&M in accordance with the facility's written inspection program and *AWWA G200* Section 4.3.1. Inspect tanks, regardless of tank material, by dry, underwater, or robotic inspection and in accordance with AWWA M42 Chapters 8 and 9 and AWWA C652 Section 4.4. Use dry inspection when possible to allow for the cleaning of the tank prior to inspection by trained technicians. Underwater evaluation is performed in accordance with AWWA M42 Chapter 9. Inspection by remotely operated vehicle (ROV) is performed in accordance with the requirements in AWWA C652 Forward II and AWWA M42 Chapter 9 Periodic Reinspection. Perform inspection in accordance with above standards, as indicated by the operating permit and by state or local requirements, whichever is more stringent.

6-5 STORAGE FACILITY MAINTENANCE.

Guidance on specific maintenance procedures and paint systems applicable to water storage facilities can be found in Chapter 10 paragraph titled Tanks and Reservoirs. Paint or coat exterior of tanks in accordance with *ANSI/AWWA D102.*

6-5.1 Safety.

Only trained and experienced operators are permitted to work on elevated and ground-level storage tanks and standpipes. This work is hazardous and dangerous for untrained workers. Special precautions are also needed for work on or in tanks. In these confined working areas, workers need to guard against slipping or falling from dangerous heights. Refer to *DoDD 4715.1E, OSHA Part 1910.146* and *AWWA M3*.

The following guidelines apply to working in and around storage facilities.

- Read, understand, and follow all applicable safety directives, including those pertaining to confined-space entry.
- Check the security of ladders frequently. Provide required safety cages or safety cable equipment.
- Provide workers with boots and clothing for working in wet and slippery conditions.
- Provide workers performing disinfection with special protective goggles and gloves.
- Install special fans or other ventilation equipment inside tanks while work is being done there.
- Provide adequate light inside tanks so that personnel can perform their work properly and safely. Take special care to use waterproof wiring and light units to prevent shocks in a wet environment.

CHAPTER 7 VALVES AND HYDRANTS

7-1 VALVES AND VALVE OPERATION.

Valves are used in water supply systems to start and stop flow, throttle or control the quantity of water, regulate pressures within the system, and prevent backflow. Valves typically are operated using manual, electrical, hydraulic, or pneumatic operators. Most valves used in water systems fall into one of the following general valve classifications: gate, globe, needle, pressure relief, air/vacuum relief, diaphragm, punch, and rotary. The type of valve and the method used to operate it depends on the use of the valve, its function in the water system, and the source of energy available.

7-1.1 Manual Operation.

Small valves or valves that are used infrequently generally are operated manually. Open manually-operated valves all the way, then close one-quarter turn of the handwheel. This prevents the valve from sticking in the open position. Open and close the valve slowly and at an even rate to reduce the hazard of a hammer. Open the valve by turning the handwheel or key counterclockwise or in the direction identified by the open arrow on the valve. Always consult the manufacturer’s instructions for operating a specific type of valve. It is good practice to operate (exercise) valves periodically.

7-1.2 Power Operation.

Only minimal attention is required for operating power-operated valves, except in the case of power failure. In this event, consult the manufacturer’s instructions for emergency manual operation. Most power-operated valves are equipped with safety devices to allow for emergency manual operation.

7-1.3 General Maintenance of Valves, Valve Boxes, and Accessories.

A general valve maintenance schedule is presented in Table 7-1. Specific maintenance procedures for various valve types and valve accessories are provided in literature supplied by the valve manufacturer. Maintain valve boxes on the same basis as the valve maintenance schedule in Table 7-1 or as directed by local command. Maintain a record of all valve physical, location, and operational characteristics along with the manufacturer, year installed, model, depth to operating nut, and any existing work orders.

Table 7-1 Valves and Accessories Maintenance Checklist

Inspection	Action	Frequency
Gate valves/ distribution system valves	Locate, check operation, lubricate stem packing; if packing leaks, dig up valve and tighten packing gland or replace packing; check stem alignment; check for broken stem or stripped stem or chewed nut.	Semi-annually
Valve bypass	Check for position, inspect, and lubricate.	Semi-annually
Gears	Check and lubricate; correct any deficiencies.	Semi-annually
Vault	Check condition, clean, and check masonry; make repairs as necessary.	Semi-annually
Treatment plant valves	Operate inactive valves.	Quarterly
	Lubricate as required (including gears).	Annually
	Replace or resurface leaking valve seats.	Variable
	Lubricate chain wheels.	Quarterly
Butterfly valves	Check valve stem for watertightness and adjust if necessary.	Semi-annually
	Check operation and inspect for tight closure.	Annually
Rotary valves/ cone valves/ ball valves	Operate; lubricate metal-to-metal contacts in pilot mechanism; lubricate packing glands; lubricate all parts of seating and rotating mechanisms.	Monthly
	Dismantle, remove corrosion products, wire brush plug and valve body; paint valves with corrosion-resistant paints.	Annually
Plug valves	Lubricate with lubricant stick.	Quarterly
	Operate all valves; check for corrosion and foreign matter between plug and seat; lubricate gearing.	Quarterly

Inspection	Action	Frequency
	Inspect; dismantle if necessary; clean, wire brush, re-machine plug and body or replace if condition is beyond re-machining.	Annually
Curb stops	Remove and replace whenever necessary.	Variable
Multiport valves	Lubricate with grease.	Semi-annually
Globe valves	Operate valve to prevent sticking; check for leakage, adjust packing nut, and replace packing if necessary.	Quarterly
	Check valve closure for tight shutoff; if valve does not hold, remove valve stem and disk and regrind seat and disk.	Semi-annually
Diaphragm valves	Operate valve; check valve stem and lubricate as necessary; check for tight closing.	Quarterly
	Check diaphragm for cracks; renew as necessary.	Annually
Sluice gates	Operate inactive gates; lubricate stem screws and gears.	Monthly
	Clean valve with wire brush and paint with corrosion-protective paint.	Annually
	Check seating wedges on valves seating against pressure.	Annually
Backflow preventers	Test tightness of unit if there is reduced pressure.	Monthly
Hydraulic cylinder	Check through one valve operation cycle.	Monthly
Piston rod and tell-tale rod	Oil packing; tighten packing gland if leakage exists; replace packing if necessary.	Monthly
Waste line discharge	Check for water flow when valve is wide open and shut; if leakage occurs, disassemble valve and piston, check leathers for wear and replace as necessary.	Monthly

Inspection	Action	Frequency
Cylinder and piston	Disassemble; inspect for scoring and corrosion; check cup leathers; polish any scored areas; remove corrosion products from piston surfaces and cylinder heads.	Annually
Pneumatic valve operators	Check packing and air hose; lubricate as necessary.	Monthly
	Check piston, cylinder, and leathers; polish any scored areas; remove corrosion products from piston surfaces and cylinder heads.	Annually
Motorized valve operators	Operate valve and check for tight closing.	Quarterly
	Change gear drive lubricant.	Quarterly or after 500 hours of operation, whichever is more frequent
	Maintain electric motors as described in Chapter 10 paragraph titled Electric Motors.	
Valve operator pilot controls	Check control through one full cycle of operation.	Monthly
	Lubricate pins, linkage, packing glands, and adjustment rod threads as necessary; remove corrosion products; check for leakage and repair.	Monthly
	Disassemble; inspect unit and clean strainers; examine diaphragm for failure; regrind or replace worn valve seats.	Annually
Air-release valves, valve unit	Remove valve from service; inspect float for leaks, and pins and linkage for corrosion; remove corrosion products; clean orifices.	Annually
Vault	Inspect for condition of masonry, steps, and manhole covers; repair as necessary.	Annually

Inspection	Action	Frequency
Altitude valve pilot controls	Inspect and lubricate.	Monthly
Valve unit and operator	Disassemble; inspect hydraulic cylinder and repair; inspect valve, repair, and paint, as necessary.	Annually
Check valves	Inspect the closure control mechanism (if any); clean and adjust as necessary; check pin wear if balanced disk type; check seating on ball type.	Annually
	Disassemble; clean, reseat, and repair as necessary.	Variable
Float valves	Inspect float; repair as necessary.	Monthly
	Inspect valve and valve operating mechanism.	Annually
Pressure-regulating valves	Inspect, clean, adjust, disassemble, and repair as necessary (see manufacturer's instructions).	Annually
Gear boxes	Lubricate gears (see manufacturer's instructions).	Monthly or weekly
	Check gear operation through full operating cycle and listen for undue noise, check for vibrations or any other restrictions to operation.	Semi-annually
	Check housing for corrosion; paint as necessary.	Annually
Valve boxes	Clean debris out of box; inspect for corrosion; check alignment and adjust as necessary.	Semi-annually
Floor stands	Lubricate stem and indicator collars.	Quarterly
	Inspect condition; clean and paint.	Annually
Post indicators	Lubricate.	Quarterly
Electric position indicators	Check contact points and wiring.	Annually

7-1.4 Distribution System Valves.

Distribution system valves are normally buried gate valves. These valves are usually equipped with a 2-in.-square (50-mm-square) operating nut, accessible through a valve box, that requires a valve key for operation. Common difficulties with distribution system valves are "lost" valves, inoperable valves, and valve boxes that have been covered by road work or filled with foreign matter.

7-1.4.1 Lost Valves.

The lost valve problem can be avoided by using an indexed valve record book in which all pertinent data are recorded, including all valve locations. Identify valves using geographic information system coordinates and save the coordinates in the valve record book. If a valve is lost, use a dip needle, miner's compass, or metal detector to locate the valve box. Once a lost valve is located, update the coordinates in the record book. A good valve record includes information on maintenance operations performed, tells whether the valve was opened or closed at the time of inspection, and lists any errors in location. Keep one copy of the valve record book with the maintenance crew and keep one on file.

7-1.4.2 Maintenance Procedures.

Distribution system valves are usually left open and operated only during emergencies. Establish a valve exercising program per best practice *AWWA M44 Chapter 5*. The program should include goals on how often each valve is exercised, measures to verify goals are met, and written procedures for follow-up and maintenance/replacement if goals are not met and should identify critical valves in the system to ensure they are exercised more frequently.

To check the operation of the valve, first close the valve completely and then open it completely. Back off on the valve about one turn to avoid locking the valve in an open position. If the valve does not operate properly, perform necessary maintenance and repair at once. Note all maintenance and repair in the valve record book. Guidelines for valve replacement and repair are available in further detail in *AWWA M44*. Turns-to-open should be recorded in the asset inventory and compared to the installation record to ensure full valve mobility. Table 7-2 lists potential valve issues and solutions.

Table 7-2 Distribution System Valve Maintenance Checklist

Item	Problem	Solution
Valve seating	Foreign matter lodged on the valve seat	Open valve slightly to give a high-velocity flow across the valve seat. Open a hydrant to increase flow, if necessary, to flush the foreign matter out of the valve seat.
Valve stem sealing	Packing is dry	Check and lubricate the valve-stem packaging. Dry packing will impede valve closure at all points of the stem movement. Lubricate dry packing by pouring a mixture of half kerosene and half lubricating oil down a ½-in. (13-mm) pipe to discharge the mixture onto the stem below the operating nut.
	Packing is leaking	Dig up the valve, tighten the packing gland, or replace the packing as necessary. To reduce leaking while replacing packing, open the valve as wide as possible.
	O-ring seals are leaking	If water is leaking around the stem, replace the O-rings (if applicable).
Valve stem	Valve stem is out of alignment, broken, or has stripped threads	If the valve stem is out of alignment, the valve operates easily near open or closed positions but not when the valve is partially closed. Replace the valve stem, following the manufacturer’s instructions. If the valve-stem nut is missing or damaged, replace it.
	Valve stem is broken	A broken or stripped stem permits unlimited turning of the stem without closing the valve. Replace the valve stem, following the manufacturer’s instructions. If the valve-stem nut is missing or damaged, replace it.
Valve seat refacing	Leaking gate valve seat	Follow manufacturer’s instructions to remove and reface the valve seat, including the following: remove the bonnet and inspect and clean all working parts; check all working parts for signs of wear or deterioration; remove old packing or O-rings; refinish working parts by grinding, sanding or polishing, and lapping; replace all parts

Item	Problem	Solution
		beyond repair; and replace the valve parts and repack and test the valve for proper operation.

7-2 HYDRANTS.

Fire hydrants are mainly used for fire protection. Other uses include flushing water mains and sewers and filling tank trucks for street washing and tree spraying. Hydrants may also be used as a temporary water source for construction jobs. General information related to types of hydrants, component parts, O&M, common operating problems, records, and hydrant safety is included in *PAWSOS: Water Transmission and Distribution* and *AWWA M51*. Keep maintenance and testing records and analyze them periodically to identify any long-term loss in distribution system carrying capacity.

7-2.1 Hydrant O&M.

Hydrants should maintain a minimum residual pressure of 20 psi when delivering fire flow. A hydrant maintenance and fire-flow testing program should be in-place. The program should include a goal for the hydrants to be inspected and tested annually, procedures for opening and closing the hydrants to minimize potential system damage, testing requirements, and a replacement goal for inoperable hydrants. Maintenance procedures for specific types of hydrants are provided in *AWWA M17*, including hydrant inspection and flow tests. Manufacturer-specific procedures should always be followed, including inspection frequency and lubrication. Use UFC 3-601-02 for technical guidance related to hydrant and flow testing. Additional details are provided below.

7-2.1.1 Hydrant Inspection.

Inspect hydrants annually and after each use at a minimum. Inspection crew should be equipped to repair hydrants at the time of their inspection. The hydrants should be tested by personnel familiar with the water system and coordinated by the fire marshal, according to command and field engineering office directives. Hydrants can usually be maintained by replacing all worn parts and seats through the top of the hydrant. The operator is generally responsible for ensuring that the proper tools are used. Specific inspection procedures, by hydrant type, are available in *AWWA M17*. Each year test the hydrant for tightness of joints and fittings in the following manner.

Remove one hydrant cap and replace it with a cap fitted with a pressure gauge. Open the valve slowly until it is wide open. Record the pressure. Check for leakage at the following points:

a. Hydrant Top. If a leak is found, remove the cover plate and tighten or repack the seal.

b. Nozzles Entering Barrel. For leaks here, caulk the connection with lead.

c. Nozzle Caps. If the nozzle caps are leaking, replace any defective gaskets.

d. Cracks in Barrel. For leaks from cracks in the barrel, install a new barrel or a new hydrant.

Table 7-3 Maintenance Checklist for Fire Hydrants

Inspection	Action	Frequency
Dry-barrel hydrants	Check drain valve to be sure it opens.	Annually
	Where ground water level rises into barrel, plug drain valve and dewater barrel by a pump.	Annually
Wet-barrel hydrants	Check packing glands and valve seats; repair as necessary,	Annually
Pit-type hydrants	Check for water accumulation; dewater as necessary.	Annually
Hydrants on dead-ends	Flush; check barrel after flushing.	Annually
Hydrants not on dead-ends	Flush; check barrel after flushing.	Annually
	Check water flow.	Annually
	Repair as necessary; if main shut down is required, notify public works and the fire department.	Variable
Drain valve	Inspect all places where leaks might occur; repair as necessary.	Monthly
Operating nut	Check for rounded corners; replace as necessary; lubricate.	Annually
Nozzle threads	Check for damage; replace as necessary.	Annually
Chains	Check for paint fouling; clean.	Annually

7-2.1.2 Hydrant-Flow Tests.

Flow tests are conducted to determine pressure and flow within the distribution system. They can also detect closed valves within the system, identify water available for firefighting, and determine the general condition of the system. Conduct flow tests on all parts of the distribution system every 5 years, at a minimum. Maintain records for each flow test performed.

During flow tests, the hydrant nozzle needs to be unobstructed, so the only way of protecting property is to choose the nozzle that will do the least damage. Provide barricades to divert traffic and take any other precautions necessary to minimize property damage and prevent personal injury. Conduct hydrant-flow testing in accordance with *AWWA M17, AWWA M31,* and *NFPA 291*. Best practice reference is *Water Treatment Plant Operation, Volumes 1 and 2*.

If a water system model exists for the facility, the operator should request that engineering public works provide a table listing all the fire hydrants in the model and project the flow at 20 psi residual for each hydrant. When the operator runs a hydrant test, this information for comparison would be useful. If the results are off any significant amount, it would be an indicator that some of the valves in the network are closed, partially closed, or damaged in some way.

7-2.1.3 Hydrant Flushing.

Flush hydrants to prevent sediment buildup in the hydrant and its connecting piping. Hydrant flushing should occur annually at a minimum and coincide with hydrant inspection. **\1** Take care to prevent damage to the hydrant main valve during flushing. To flush the hydrant, open the hydrant slowly by rotating the stem nut on top of the hydrant using a hydrant wrench. Open the hydrant gate valve to begin flowing water. High-pressure water cleaning should be conducted in accordance with the hydrant and hydrant pipe manufacturer’s recommendations. **/1/**

Water flow rates required for flushing water mains is given in *AWWA M31*. Before beginning the flushing, plan to divert flushing flow to prevent property damage. Use flow diffusers or a length of fire hose where necessary to direct the flow into a gutter or drainage ditch. Do not use a rigid pipe connected to a hydrant outlet and turned at an angle to divert flow down a gutter; the torque produced by the angular flow could be enough to twist or otherwise damage the hydrant.

7-2.2 Hydrant Safety.

In addition to the general safety precautions detailed in *AWWA M3*, special precautions must be taken to prevent injury and damage to private property during hydrant flushing. Divert the flow from traffic areas as necessary to prevent obstruction of traffic or freezing on road surfaces. If flow from the hydrant is diverted with a hose, the hose must be securely anchored. If the hose is inserted into a storm sewer, take care not to create a cross-connection.

CHAPTER 8 INSTRUMENTATION AND CONTROL AND WATER METERS

8-1 OVERVIEW.

This chapter contains information on primary instrumentation (sensors), secondary instrumentation (transmitters and recorders), and control systems as well as SCADA systems, which are relatively new tools for controlling and monitoring water treatment systems. Remote monitoring and control systems must meet the Installation's IT security requirements and standards. Special attention is given to O&M of water meters and other flow measuring devices, such as weirs and flumes.

8-2 INSTRUMENTATION AND CONTROL.

The term "instrumentation," as used in the water works industry, refers to a range of equipment used for observation, measurement, and control. Equipment types range from simple mechanical, direct-reading meters and gauges to complex electronic, automatic monitoring/control systems. All I&C systems have a sensing device. More complex systems will include one or more of the following elements: transmitter, indicator, and recorder. Modern I&C equipment allows an operator to monitor and control equipment, flow rates, pressures, levels, and processes not only at the water treatment plant but for all parts of the distribution network as well.

8-2.1 Water Meters.

The primary function of water meters is to measure and record the volume of water flowing in a line. Flow is the most important measurement made at water supply facilities. Flow data are used to account for the water treated and pumped to distribution, chemical flow pacing, and long-range planning. Various types of meters and flow measuring devices, including flumes and weirs, as well as installation, testing procedures and test equipment, recordkeeping, general maintenance, and repair of meters may be found in *AWWA G200, AWWA M6,* and *AWWA M33.*

8-2.2 Meter Reading.

Meters are generally furnished with registers that measure water flow in terms of flow rate or total volume. Water meter registers are typically of two general types: the straight-reading type and the circular-reading type. The straight-reading type is read like the odometer on a car. The meter register reports the number indicated by the counting wheels. Fixed zeroes to the right of the counting wheel window should be included in the meter reading. The circular reading dial is somewhat difficult to read and has been gradually replaced by straight registers on new meters. When a hand on any scale is between two numbers of a circular reading dial, the lower number is read. If the hand seems exactly on any figure, check the hand on the next lower scale. If that hand is on the left side of zero, read the figure on which the hand lies. Otherwise, read the next lower figure.

Because the registers are never reset while the meters are in service, the amounts recorded for any given period are determined by subtraction. To obtain the volume of water that passed through the meter since the previous reading, subtract the previously recorded reading from the present reading. The maximum amount that can be indicated on the usual line meter before it turns to all zeros and starts over again is 99,999 cubic feet, or 999,999 gallons. Thus, to get a current measurement when the reading is lower than the last previous one, add 100,000 to the present reading on a cubic feet meter or 1,000,000 to the present reading on a gallon meter. The small denomination scale giving fractions of 1 cubic foot or 10 gallons is used for testing purposes only and is disregarded in the regular reading.

Best practice information regarding direct meter readout and remote reading may be found in *AWWA M6*.

8-2.2.1 Automatic Meter Reading.

Automatic meter reading (AMR) is a technology where meters can send data directly from the meter to a remote reading device. AMR can be done by drive-by systems or by using a fixed network. One of the most common forms of AMR uses the drive-by gathering method. Data is transmitted from the meter to a mobile collection device or location at the water utility via telephone network, cable TV system, electrical power main, or radio frequency-based system, where the data can be received at a certain distance from the meter. Usually, the transmission from the meter can be picked up by an on-board recording device while driving by the residential or commercial buildings. The ease of gathering the data allows meter readings to be done more frequently. Another method used is a fixed network system. Data collectors are installed at points in the service area that collect meter data. This allows data to be collected as often as the utility desires and can give the utility and customer more accurate data about water usage. The real-time data gives customers more information and can be very helpful in resolving meter reading disputes. A combination of fixed network and drive-by may be the best AMR solution due to the varying degrees of population density.

One of the obvious benefits of both drive-by AMR and fixed network AMR is a decrease in meter reading costs. Without this technology, access to each meter or external encoder is required to get the meter reading. Additionally, an indoor meter may not be accessible if a customer is not at home. Since AMR readings are easier to get, readings can be done more frequently, and billing can be done monthly instead of quarterly, improving cash flow for the utility. Where meters are to be replaced, replace them with models that can easily be converted to AMR systems in the future. When qualifying and selecting meter manufacturers, investigate the compatibility of the meters offered by manufacturer with the existing or planned AMR infrastructure.

8-3 INSTRUMENTATION MAINTENANCE AND REPAIR.

The success of water instrument maintenance procedures is based on knowledge of the construction, operation, and adjustment of the equipment; availability of the necessary special tools; and stored spare parts and special instructions from manufacturers. For the special knowledge necessary, maintenance personnel are advised to consult the manufacturer’s instructions. Best practice information on maintaining water meters can be found in *AWWA M2*, *AWWA M6*, *AWWA M33*, and *AWWA M51*. Troubleshooting checklists and flowcharts for various I&C equipment can be found in *AWWA M2*.

8-3.1 Maintenance Schedules.

The design and intricacy of meters, instrumentation, and automatic control systems depend on the function to be performed and the manufacturer's particular equipment. Because there are many manufacturers of meters, instruments, and automatic controls, listing specific maintenance procedures that apply to all units is not possible. The procedures here are basic and the minimum required for the most common types of units. When developing maintenance schedules, personnel may adapt the procedures given here to specific directions Issued by the manufacturers.

8-3.2 Inspection and Maintenance Records.

Maintain a log of all inspection and maintenance actions. Use a card file for each piece of equipment, showing the type of equipment, the manufacturer's serial number, the date installed, the location, and the frequency of scheduled maintenance. Arrange cards chronologically so that the card will come to the attention of maintenance personnel at the proper time for the inspection to be made.

Where a computer system is used on the base, enter the service or meter history card information to establish a permanent record, and assign a control number for each service or meter. Include the following information in the record: meter size, make, model, type, serial number, date of purchase, current location, previous locations, repair history, and testing history. Future information concerning work on a service line or meter testing and repairs are to be entered for the appropriate control number. More information management guidance can be found in *AWWA M2*.

8-3.3 Sensor Maintenance.

Maintenance procedures for flow, pressure, and level-sensing devices are given in Table 8-1. Confirm frequency with local command.

Table 8-1 Maintenance Checklist for Flow, Pressure, and Level Sensors

Inspection	Action	Frequency
Flow Sensors		
Venturi-type devices		
Annular chamber	Flush and clean annular chamber, throat and inlet; purge trapped air from chamber and connecting piping; flush piezometer pressure taps.	Quarterly
Exterior	Clean and paint as necessary.	Annually
Interior	Check interior for corrosion; dismantle, clean, and restore smoothness of interior surfaces as necessary; for flanged joints, check possible intrusion of gasket into interior; replace if necessary.	Annually
Orifice plates	Remove plate, dress off roughness; flush sediment traps.	Annually
Pitot tube	On permanent installations, check tips and clean.	Quarterly
Flow tube	Check instrument taps; flush if necessary.	Quarterly
Pressure Sensors		
Diaphragm	Disassemble and check for condition and leaks; clean, adjust, repair, or renew as necessary; check calibration.	Annually
Bourdon tube	Check calibration, clean and adjust as necessary.	Annually
Manometer	Clean tubes and gage unit as necessary.	Semi-annually
	Check mercury level and add mercury if necessary; clean or replace mercury if necessary.	Annually or Variable

Inspection	Action	Frequency
Level Sensors		
Floats	Check for bent rod, binding, or other damage; correct undesirable conditions; apply light oil to moving parts; check alarm system.	Monthly
Bubble pipe	Check air discharge pipe for freeness; check air compressor system; clean, repair, or renew worn parts as necessary.	Quarterly
Probes	Check contacts, wiring, and electrical connections; repair as necessary.	Quarterly
	Check probe surface; check calibration; clean, repair, or renew as necessary.	Semi-annually

8-3.4 Transmission System Maintenance.

Information needs to be transmitted from the sensing device, which measures the variable, to the instruments that indicate, record, or total it. The transmission system may be mechanical, hydraulic, pneumatic, or electrical. Each system consists of two components—the transmitter and the transmission link. Maintenance procedures for transmission systems are summarized in Table 8-2. Confirm frequency with local command.

Table 8-2 Maintenance Checklist for Transmission Systems

Inspection	Action	Frequency
Mechanical	Direct links—make certain pulley, drums, cable, etc., work freely and are not corroded; clean, lubricate, and adjust.	Quarterly
Hydraulic	Pressure links-blow down pressure lines, make certain there are no restrictions; correct adverse conditions.	Semi-annually
Pneumatic		
Transmitter	Flush liquid side of air-relay units; clean; if necessary check diaphragm; check air-input orifice, clean, blow out moisture traps.	Daily
	Disassemble, repair, or renew as necessary.	Variable
Link	Check connecting tubing for condition; check nozzle system for leaks.	Semi-annually
Electrical		
Transmitter	Service transmitter; check signal interval length over instrument range.	Monthly
	Check mercury switch and magnet; adjust as necessary.	Quarterly
	Remove old lubricant, add new.	Semi-annually
Link	Check wires whenever necessary.	Variable
Indicators	Clean cover and glass of gauges.	Semi-annually
	Check zero setting and calibration	Annually
Mechanical transmission	Inspect and service as for transmitter.	Quarterly

Inspection	Action	Frequency
Hydraulic transmission	Vent air from mercury wells; check pulley shaft, chain, cam, stuffing box, and other parts.	Weekly
	Check mercury wells; add new mercury if necessary; clean or replace mercury if necessary.	Annually
Pneumatic transmission	Service on same schedule and in same manner as transmitter.	
Electrical transmission	Service generally on same schedule as transmitter.	
	Clean unit, especially dials.	Semi-annually
	Check operation, adjust and repair as necessary.	Annually
Recorders	Clean pen; check ink flow; check cam cycle and pulley freedom.	Bi-weekly
	Check zero position; adjust and lubricate.	Quarterly
	Check contact points, armature, clutch, clutch cups, etc.; clean, adjust, repair, or renew parts.	Semi-annually
	Renew modular unit if necessary.	Variable
	Renew illumination lamp as necessary.	Variable
Totalizers	Inspect, clean, adjust or repair on same schedule as recorders.	
Combination	Check, clean, adjust or repair on same schedule as individual components.	

8-3.5 Indicator, Register, and Recorder Maintenance.

Besides transmission devices, secondary instruments include indicators or gages (momentary indication of discrete information), recorders (chart record of information by time), and registers or totalizers (also termed “integrators”). The latter category expresses the total quantity of measured variable from start to current time. There are many styles and designs of each basic type, and various combinations of these types. Therefore, no detailed maintenance procedure can cover all types, designs, and combinations. Maintenance procedures depend not only on the type of receiver (indicator, recorder, or register) but also on the type of transmission system used. Maintenance personnel should study the manufacturer’s instructions for detailed procedures in addition to following the basic maintenance procedures for indicators, registers, and recorders summarized in Table 8-3. Confirm frequency with local command.

Table 8-3 Maintenance Checklist for Indicators, Registers, and Recorders

Inspection	Action	Frequency
Indicators l	Clean cover and glass of gages.	Semi-annually
	Check zero setting and calibration.	Annually
Mechanical transmission	Inspect and service as for transmitter.	Quarterly
Hydraulic transmission	Vent air from mercury wells; check pulley shaft, chain, cam, stuffing box, and other parts.	Weekly
	Check mercury wells; add new mercury if necessary; clean or replace mercury if necessary. Use caution when handling mercury to avoid spills – mercury fumes are poisonous.	Annually
Pneumatic transmission	Service on same schedule and in same manner as transmitter.	
Electrical transmission	Service generally on same schedule as transmitter.	
	Clean unit, especially dials.	Semi-annually
	Check operation; adjust and repair as necessary.	Annually
Recorders	Clean pen; check ink flow; check cam cycle and pulley freedom.	Bi-weekly

Inspection	Action	Frequency
	Check zero position; adjust and lubricate.	Quarterly
	Check contact points, armature, clutch, clutch cups, etc.; clean, adjust, repair, or renew parts.	Semi-annually
	Renew modular unit if necessary.	Variable
	Renew illumination lamp as necessary.	Variable
Totalizers	Inspect, clean, adjust or repair on same schedule as recorders.	
Combination	Check, clean, adjust or repair on same schedule as individual components.	

8-3.5.1 Recorders.

Recording instruments have all the fundamental elements of an indicator unit and contain a clock mechanism (spring or electrical), a chart, and a marking pen. Charts may be either circular or strip and are changed on schedule by operating personnel. Maintenance procedures depend on the type of transmission system employed, the design, and other factors. Consult the manufacturer's instructions for detailed procedures. General maintenance procedures are included in Table 8-3.

8-3.5.2 Totalizers or Registers.

This type of receiver has internal components similar to those in recorders. In addition, it contains an integrator mechanism that converts transmitted signals into a sum of the total quantity of material that has moved past the point of measurement from the beginning of the measured period to the time of observation. This total appears on a numerical register similar to an automobile odometer. Clean, service, and adjust registers according to the manufacturer's instructions on the same general schedule as recorders.

8-3.5.3 Combination Totalizer Indicator-Recorder.

There are various combinations, designs, and styles of instruments in this classification. There are also devices that sum totals from various individual totalizers or show ratios of one flow to another. In general, the maintenance procedures and schedules for this category are a combination of the procedures for the individual units above. Develop a maintenance schedule according to the manufacturer's instructions.

8-3.6 Water Meter Maintenance.

Maintenance procedures for water meters are summarized in Table 8-4. Further guidance on meter maintenance and repair is available in *AWWA M6*. The accuracy of cold water meters can be tested by the volumetric method, using volumetric tanks, or the gravimetric method, using weight scales. Various *AWWA C700*-series standards contain accuracy standards for new meters. See *AWWA M6* Table 5-2 for the recommended water meter testing intervals by state. Test rates for a variety of meter types are present in Table 5-3 of *AWWA M6*. All necessary testing equipment is also outlined in Chapter 5 of *AWWA M6*.

Table 8-4 Maintenance Checklist for Water Meters

Inspection	Action	Frequency
Volume meters	Check operation; check for noise.	Monthly
	Check mounting and alignment.	Annually
Velocity-type meters	Check operation; check for noise.	Monthly
Meter pit	Clean, remove water before freezing season.	Semi-annually
Exterior	Paint as necessary	Annually
Interior	Check for worn parts, repair or replace as necessary.	Variable
Proportional meters	Check on same program as velocity meters	Variable
Compound meters	Check large-flow component on same schedule as velocity-type meters	Monthly
Magnetic flow meters	Check electrical connections.	Annually
Meter pit	Check, clean, remove water to protect against freezing.	Annually (Fall)
Measuring unit	Check for possible hot water damage	Annually
Unit parts	Check for worn parts, repair or replace as necessary; clean and brighten.	Variable

8-3.7 Weir and Flume Maintenance.

All types of head-area meters are used for open-flow measurement, and their proper operation depends on the absence of any kind of interference at the discharge opening. Maintenance procedures for weirs and flumes are summarized in Table 8-5.

Table 8-5 Maintenance Checklist for Weirs and Flumes

Inspection	Action	Frequency
Weirs	Check weir edge to make certain it is clean.	Daily
	Check and open breather pipe, if any.	Monthly
	Drain weir to check evenness of water break- over; check for tuberculation or corrosion; dress-off rough spots	Annually
Parshall Flume	Check throat section to be sure it is clean and free of growths.	Monthly
	Clean stilling well and connecting pipes.	Quarterly

8-4 SAFETY.

General hazards connected with servicing I&C systems include use of hand tools, working in confined spaces, and electric shocks. Special attention should be given to prevent electrical shock that may be caused by improper grounding of building electrical systems onto the plumbing system. If residential water meters are not mounted on a yoke or if a permanent jumper wire is not provided across the meter connections, use a separate wire with large alligator clips as a temporary bridge between the pipes when meters are removed or installed.

CHAPTER 9 CROSS-CONNECTION CONTROL AND BACKFLOW PREVENTION

9-1 CROSS-CONNECTIONS AND BACKFLOW.

Cross-connections are the physical links through which contaminated materials can enter a potable water supply. The contaminant enters the potable water supply when the pressure of the polluted source exceeds the pressure of the potable source. The flow of contaminated water to the potable system is called "backflow." Backflow results from either back pressure or back siphonage. Backflow due to back pressure occurs when the user's water system is under higher pressure than the public water supply system. Back siphonage is caused by the development of negative or sub-atmospheric pressures in the water supply piping. This condition occurs when system pressure is lowered by pump malfunction or high fire flow.

Use UFC 3-230-01, UFC 3-420-01 and UFC 3-600-01 for backflow prevention and cross connection control.

For the Army, University of Southern California Foundation for Cross Connection Control and Hydraulic Research *Manual of Cross-Connection Control* shall be a requirement for backflow prevention devices.

9-2 \2\ DEGREE OF HAZARD /2/.

\2 Backflow hazards have been divided into two classes: low health hazard (non-health hazard) and high health hazard (heath hazard). ***/2/***

9-2.1 \2\ Low Hazard /2/.

\2 Refer to the IPC for a definition of pollution, also referred to as low hazard or low health hazard as defined by AWWA M14. ***/2/***

9-2.2 \2\ Not Used /2/.

\2\ /2/

9-2.3 \2\ High Hazard /2/.

\2 Refer to the IPC for a definition of contamination, also referred to as high hazard or high health hazard as defined by AWWA M14. ***/2/***

9-3 BACKFLOW PREVENTION.

Use UFC 3-230-01, UFC 3-420-01 and UFC 3-600-01 for the selection of backflow prevention devices and assemblies.

For the Army, for backflow prevention between potable water lines, irrigation systems, and for fire protection connections, use devices listed in IPC Chapter 6 and the University of Southern California Foundation for Cross Connection Control and

Hydraulic Research *Manual of Cross-Connection Control*. Find additional descriptions of backflow prevention devices in best practice *AWWA M14*. *Unified Facilities Guide Specifications Section 33 11 00 Water Utility Distribution Piping* shall be a requirement for backflow prevention devices and the *Manual of Cross-Connection Control*.

For the Air Force, **\1** *AFMAN 32-1067* **/1/** shall be a requirement for backflow prevention devices.

9-4 INSPECTION AND TESTING SCHEDULE.

\2 Conduct inspection and testing in accordance with UFC 3-420-01, state or local regulations, whichever is more stringent. **/2/**

9-4.1 Inspection.

\2 Inspect backflow prevention devices and air gaps installed in lieu of backflow prevention devices or assemblies. Ensure:

- Backflow prevention devices are in good condition, and
- An adequate air gap is maintained where an air gap is used in lieu of a backflow prevention device or assembly.

Keep the inspection in the recurring work program. Use a certified backflow inspector, third party to the contractor, or qualified installation personnel to perform inspections. **/2/**

9-4.2 Testing \2\ Backflow Prevention Assemblies /2/.

\2 Test backflow prevention assemblies using a certified backflow inspector, third party to the contractor, or qualified installation personnel. Repair and retest any assembly found to be defective until it passes. During testing ensure that backflow prevention assemblies are in good condition, are properly installed, and function without interference. **/2/**

9-5 MAINTENANCE OF BACKFLOW PREVENTERS.

\2 Backflow prevention devices and assemblies are mechanical and subject to breakdown. Backflow prevention assemblies will need to be isolated during testing and repair. If there is only one service line from the potable water system and if water service is required 100% of the time, install a second backflow preventer assembly of similar type to provide an uninterrupted supply of potable water. **/2/**

9-6 ADMINISTRATIVE.

Legislation, education, and licensing are discussed in the publication listed in *AWWA M14*.

For the Air Force, see **\1** *AFMAN 32-1067* **/1/.**

9-7 RECORDS OF INSPECTION \2\ AND TESTING /2/.

Develop and use an appropriate form to record data on all **\2** inspections and tests. Provide the location, degree of hazard, and description of protective device installed on the form. After each backflow preventer device inspection, record the date of inspection, observations, corrective action taken, and name of the inspector on the appropriate form. After each air gap inspection, record the date of inspection, observations, corrective action taken, and name of the inspector on the appropriate form. After each backflow preventer assembly test, record the date of test, test results, observations, corrective action taken, and name of the inspector on the appropriate form. **/2/**

This Page Intentionally Left Blank

CHAPTER 10 GENERAL MAINTENANCE

10-1 GENERAL.

Inspections and general maintenance services are required at military water supply systems. In addition, this chapter contains tables specifying tools and equipment, lubricants, and materials and supplies required to perform general and specific equipment maintenance tasks.

10-2 MAINTENANCE INSPECTIONS AND REPAIRS.

10-2.1 Types of Inspection and Repair.

10-2.1.1 Operator’s Inspection.

Regular inspection of equipment is part of an operator’s routine duties to ensure proper functioning of the system. Such inspection includes lubrication, minor adjustments, and renewal of parts that do not require major overhaul or repairs. The operator’s inspection also entails detecting and reporting (to the proper authority) any abnormal conditions (e.g., appearance, leaks, unusual noises).

10-2.1.2 Preventative Maintenance Inspection.

Cleaning, lubricating, adjusting, and renewing parts that do not require major overhaul and repairs, plus detecting and reporting (to the proper authority) any abnormal conditions (e.g., appearance, leaks, unusual noises) also comprise preventive maintenance inspection. Such inspections may be conducted by personnel who have been assigned specific areas of inspection responsibility or by personnel operating a particular piece of equipment or system.

10-2.1.3 Control Inspection.

Scheduled examinations or tests are made to determine the physical condition of utilities. These examinations are termed control inspections and performed jointly by engineering and operating personnel. Control inspection includes electrical, mechanical, and structural inspection.

10-2.1.4 Major Overhaul and Repairs.

As a rule, major overhaul and repairs are not made by operating personnel. This work is usually performed under contract.

10-2.2 Personnel.

Generally, well-trained personnel should perform inspections, repairs, and preventive maintenance tasks. Personnel assigned to these tasks should possess a thorough knowledge of the functions and operations of the equipment and the procedures for servicing it safely.

10-2.3 Maintenance Information.

Water supply system personnel need ready access to equipment O&M information. Keep this information on file and update it as necessary. The best sources of maintenance information are the manufacturers' instruction manuals provided with each piece of equipment. Include specific parameters such as model, serial number, warranty, map of equipment locations, and contact number for repairs. This material should be bound and organized according to equipment type and be kept in good order for quick reference. The following information typically is included in these manuals: descriptive literature (catalog cuts and data sheets); parts lists; instructions for installation, operation, maintenance, and repair; performance data (i.e., pump performance curves); electrical diagrams; and schedules of required lubricants and chemicals. It is normally recommended that operating personnel be familiar with each piece of equipment through careful examination of these instruction manuals.

The material contained in this UFC is designed as a general overview of maintenance requirements and may not contain answers for specific maintenance questions. Consult the manufacturers' instruction manuals for specific maintenance information. The specifications, shop drawings, and as-built drawings, which should be kept on file, show dimensions of each piece of equipment and provide information on pipe sizes and materials, valve types, and equipment types. They are available to plant personnel if the schematic drawings and valve and equipment schedules in this manual do not provide sufficient information.

10-2.4 Maintenance Management System.

Regularly scheduled preventive maintenance is essential for keeping equipment in good running order. Daily tasks may be incorporated into the sampling and laboratory testing routine to make the most efficient use of the operator's time. If possible, perform routine tasks on the same day of the week or month to avoid confusion about when they were last performed. For example, each Monday can be set aside for performing weekly tasks, and the first Tuesday of the month can be set aside for monthly tasks. Annual lubrication can be performed during January.

Since operating personnel cannot be expected to remember the service requirements for every piece of equipment, a system of preventive maintenance is essential. To ensure the system is successfully implemented and maintained, it should be relatively simple to operate, producing maximum output for minimum input. The following paragraphs describe the components of a good maintenance system. Best practice information on maintenance management systems can be found in *AWWA M5* and *G100-11*. Supplemental best practice information can be found in *Water Treatment Plant Operation, Volumes 1 and 2*.

10-2.4.1 Goals.

An effective maintenance management system is designed to achieve the following goals:

- Provide periodic, timely, standardized, and complete equipment maintenance.
- Prevent excessive maintenance, such as over greasing bearings.
- Increase system reliability by preventing or providing early detection of equipment malfunction.
- Improve the efficiency of equipment operation.
- Extend equipment life.
- Improve safety by reducing unexpected breakdowns and providing safety precautions along with maintenance and service procedures.
- Reduce overall maintenance costs.
- Provide a complete record system covering equipment history, maintenance costs, and workloads.
- Management system should keep records regarding whether the goals are being accomplished, have a periodic review, and take documented action if goals are not being achieved.

10-2.4.2 Components.

The following components are necessary for a maintenance management system:

- Complete equipment records and maintenance history
- Preventive maintenance scheduling
- Corrective maintenance cost reporting
- Standardized preventive maintenance procedures
- Management reports on maintenance costs, overdue tasks, and employee utilization
- Records management policies (document control) with examples of documentation/forms to be used
- Forecasting for future needs
- Mapping
- Evaluation of the actions taken for maintenance issues
- Technology, including decision models and tools and software as listed in AWWA G410

10-2.4.3 Maintenance Personnel.

Another component of an effective maintenance management system is efficient organization of maintenance personnel. This includes providing adequate staffing, developing job descriptions and an organizational chart, providing maintenance training programs, and holding periodic staff meetings. Continued training and scenario-based training should be scheduled for all personnel. Keep records of personnel training, skills, and experience.

Job descriptions often are developed for use in assessing the skill level required to perform particular tasks in a maintenance program. Depending on the size of the facility, complexity of equipment, and size of the maintenance department, various skill levels may be required (e.g., Operator I and II, Mechanic, Electrician). In many facilities, specialized equipment maintenance may require the use of outside contractors.

10-2.5 Spare Parts and Stock Control.

Keep sufficient types and quantities of materials and stock on hand to ensure practical, economical, and continuous service. This includes an inventory of spare and repair parts and equipment on-site. A review of the equipment and the manufacturers' recommendations will aid in determining which spare parts and miscellaneous supplies should be included in the inventory.

10-2.5.1 Expendable Stock.

Stock levels for expendable items used at a fairly uniform rate (such as pump packing, treatment chemicals, and laboratory reagents) are based on maintenance experience and operating reports. However, levels may be modified for reasons of economy. Thus, savings can sometimes result if treatment chemicals are bought in large quantities.

10-2.5.2 Standby Items.

Seldom-used materials needed to safeguard health, ensure uninterrupted operation of installation facilities, or prevent destruction of property are classed as standby items. Typical examples are chlorinator parts, such as a spare flowmeter, auxiliary chlorine valves, and cylinder connections. Hold materials to be stocked as standby items to a minimum, based on a detailed study of the water supply system. Consider these issues in setting up stocks of standby items.

- Non-critical parts immediately available from nearby installations, municipalities, or supply houses are not stocked. Critical parts are stocked.
- Much repair work at pumping stations and treatment plants can be anticipated, and parts for these repairs can be secured when needed.
- Only major sizes of pipe and fittings are stocked in large amounts.
- If the plant has several similar units, parts that are interchangeable need not be stocked for each unit.
- As soon as an item is drawn from standby stock, a replacement is ordered.

10-2.5.3 Supply of Material.

Watch stock levels closely and order essential materials far enough in advance to ensure continuous service. Supervisors should be familiar with normal and alternate sources of supply and the time each source usually needs to make delivery. Supervisors generally will follow up orders and help supply personnel find alternate supply sources if delivery is delayed. Supplies will be obtained according to normal supply procedures.

10-2.6 Removing Equipment from Service.

Provisions should be in place to mitigate the impact of less frequent equipment failures that cause equipment to be removed from service, which can have serious and immediate effects on the quality of water. These failures may be plant-specific or weather-related and can be identified through hazard analysis and planning. Develop redundancy plans for facilities that cannot be taken out of service for routine maintenance in accordance with *AWWA G410.*

10-2.6.1 Short Period.

Take precautions to prevent damage to equipment removed from service for a short time. Factors to be considered and precautions to be taken depend on the type of equipment and outside conditions. If the outage is likely to last more than 1 week, test operate the equipment once a week during that time.

10-2.6.2 Protracted Period.

Special precautions are necessary for equipment that is to be out of service for long periods. Failure to retire or adequately protect equipment may cause serious damage during idleness or on resumption of operation. When it is known that the outage will be protracted, dismantle the equipment, if practical, and protect it against corrosion and other damage with suitable greases, oils, and rust-preventative compounds or coverings.

10-2.7 Operating Under Winter Conditions.

Protecting operating and standby equipment against damage is especially important in cold climates. Make sure lubricants are changed to winter grades. Drain equipment that is temporarily out of use or on standby service or provide proper antifreeze coolant to prevent units (such as the housings of pumps, radiators, piping and similar items) from freezing or bursting.

Best practice information on operating equipment under winter conditions can be found in *Water Treatment Plant Operation, Volumes 1 and 2*.

10-3 ELECTRICAL EQUIPMENT.

The following maintenance instructions are general. Perform maintenance of individual pieces of equipment according to the recommendations of the manufacturer. Operating procedures and ambient conditions, such as dirt and vibration, may dictate maintenance schedules different from those recommended here.

10-3.1 General.

Major electrical equipment is best maintained by qualified, experienced electricians and in accordance with the manufacturer's recommendations. Water system personnel may perform some inspections, lubrication, and simple routine maintenance. In general, follow flash protection guidelines and do not open an electrical control panel unless properly trained and qualified to do it. De-energize electrical equipment at the motor control center and at the equipment itself before working on it. Always tag the open breaker and, if possible, lock it in the "open" position.

10-3.2 Routine Inspections.

Visually inspect electrical equipment every day. Keep area clean. Look for the source of any leaks or unusual heat, noise, or odors. On rotating equipment with sleeve bearings, check the oil level and see that oil rings turn with the shaft. On rotating equipment with slip rings or commutators, check for excessive sparking.

Inspect motors on rotating equipment weekly. Be sure that the shaft is free of oil and, or, grease from the bearings and start the motor to make sure it comes up to speed in normal time. Check the bearings for excessive heat or noise. Check slip rings and commutators for excessive sparking during starting.

Lubricate bearings according to the manufacturer's recommendations. Do not lubricate excessively; lubrication on insulating surfaces will deteriorate the insulation and gather dirt, which decreases the effectiveness of the insulation.

10-3.3 Switch Gear.

Perform the following work items in accordance with the manufacturer's instructions but not less than once per year. Perform the work more often if the equipment is exposed to excessive dirt or vibration.

These maintenance procedures apply to all electrical equipment that has contact-making devices (e.g., circuit breakers, contactors, switches, relays), electrical coils (e.g., transformers, reactors, solenoids), electrical terminations, insulators, or accessible electrical wiring or busses. Overall basic best practice information on motor control equipment can be found in *Water Treatment Plant Operation, Volumes 1 and 2*.

a. Open equipment panel and wipe insulators and busses with clean, soft, lint-free rags. Clean interior with soft brushes or a vacuum cleaner.

b. Check all accessible electrical terminations and connections, including terminations of power and control cables, bolted bus connections, and all accessible ground connections. Taped connections need not be checked. Check visually and tighten loose connections with a screwdriver or wrench.

c. Record the voltage at the secondary terminal of each power and distribution transformer, both loaded and unloaded. Compare this reading with previous readings. Change taps or contact the power company if the voltage is more than 5% high or low.

d. Inspect contacts on switches, contactors, circuit breakers, disconnects, and relays if the contacts are accessible. Dress or replace contacts if they are pitted or burned. Replace contacts in pairs, not singly.

10-3.4 Electric Motors.

Perform the following work items in accordance with the manufacturer's instructions but not less than once per year. Perform the work more often if the equipment is exposed to excessive dirt or vibration. Overall basic best practice information on motorized equipment can be found in *Water Treatment Plant Operation, Volumes 1 and 2*.

a. Blow dirt from the windings. Clean out magnetic particles that may be hanging on poles.

b. Drain, wash, and renew oil in sleeve bearings. Clean and renew grease in ball-and-roller bearings. Check air gaps. Inspect bearings for excessive wear.

c. Check end play. Under load, machines without thrust bearings should have the rotor within the end play. That is, the rotor should not be riding against the thrust collar of either bearing. This condition can cause heating and failure of the bearing; it can be corrected by shifting the rotor on the shaft or by shifting the laminations. Consult the manufacturer.

d. On rotating equipment with commutators or slip rings, check brush tension and brush wear. Make sure brushes are free in the brush holder. Replace brushes as required. Sand-in new brushes. Check commutators and slip rings for wear, scratches, or pitting. Dress as required.

e. Megger low-voltage rotating equipment using a 500-volt megger. Megger reading should be 1 megohm at minimum, but readings should be compared with previous readings because a decreasing megger reading indicates deteriorating insulation or excessive dirt or moisture.

f. Check foot bolts, end shield bolts, pulleys, couplings, gear and journal set screws, and keys. Ensure that all covers and guards for pulleys and couplings are in good condition and securely fastened. Observe operation during starting and running.

10-3.5 Standby Power Generators.

Operate emergency generators once a week, if possible, to ensure they will work properly when needed. Operate the generators in accordance with the manufacturer's instruction (operation at full load for at least 1 hour is commonly recommended). Normal power sources must be disconnected to operate standby power at full load. Engine generators should comply with all applicable regulations regarding exhaust emissions.

10-3.6 Instrumentation and Controls.

The following paragraphs address maintenance and calibration issues. Remote monitoring and control systems must meet the Installation's IT security requirements and standards. Additional information on instrumentation and controls, including general troubleshooting guidelines, can be found in Chapter 8. Some overall best practice information can be found in *Water Treatment Plant Operation, Volumes 1 and 2*.

10-3.6.1 Regular Maintenance.

If kept in the proper environment, modern electronic equipment requires only periodic cleanings. Every 3 months, instruments should be opened or withdrawn from their cases, inspected, and cleaned with a soft brush. Instruments with moving parts should be lightly lubricated in accordance with the manufacturers' instructions. Do not over-lubricate. Check for interferences between moving parts. Fill ink wells on recorders as needed. Look for source of unusual heat, sound, or odors.

10-3.6.2 Calibration.

Check calibration annually on instruments, gages, and pressure switches. If possible, calibrate equipment in place using the piping, wiring, and fluids of the processes and calibrate a whole subsystem at once. Since this method does not require removing the instrument, it avoids errors such as bad connections and leaks on reinstallation. The disadvantages are that in-place calibration may disrupt the process, and it may be difficult to get sufficient accuracy and range. Calibrate pressure gages and pressure switches by connecting them to a pressure header with a bleed valve and a pressure valve connected to an air tank. Use a gage of known accuracy and recent calibration for a reference. Check set points of pressure switches on increasing or decreasing pressure. Gages and pressure switches should be checked annually. Contract independent instrumentation companies to calibrate critical equipment meters annually to ensure accurate recording and independent verification.

10-3.7 Tools and Equipment.

To maintain, repair, and troubleshoot electrical equipment and circuits, the proper tools are required. In addition to a normal complement of small hand tools (see Chapter 10 paragraph titled Tools and Equipment), a voltage tester with sufficient range to measure the highest voltage expected, a clamp-on type ammeter, a megger (a device for checking the insulation resistance), and an ohmmeter or circuit tester are required.

10-4 MECHANICAL EQUIPMENT.

Operating logs or SCADA should record operational conditions for each piece of mechanical equipment within the system. The data should be used for identifying maintenance frequency, depending on the manufacturer recommendations. The following maintenance instructions are general. Maintain individual pieces of equipment according to the recommendations of the manufacturer. Operating procedures and ambient conditions, such as dirt and vibration, may dictate maintenance schedules different from those recommended here.

10-4.1 Aerators.

Maintenance frequencies for aeration equipment are summarized in Table 10-1.

Table 10-1 Maintenance Checklist for Aeration Equipment

Inspection	Action	Frequency
Waterfall type aerators (cascade)	Inspect aerator surfaces; remove algae; clean.	Daily
Waterfall type aerators (tray)	Clean and repair trays; clean coke or replace.	Semi-annually
Waterfall type aerators (cascade)	Repair or replace surfaces as necessary.	Annually
Packed tower aerators (strippers)	Inspect packing for scale buildup.	Weekly
Packed tower aerators (strippers)	Clean with acid. Caution: Handle acids very carefully. Do not pour water into sulfuric or chromic acid. These acids cause severe burns to skin and clothing. Perform acid treatment only on the approval of the officer in charge and under the supervision of a chemist or other qualified technician.	Biweekly or as required
Diffuser type aerators Porous ceramic plate or tube	Check discharge pressure. If clogging is evident, dewater tank and clean diffusers.	Variable

Inspection	Action	Frequency
Porous ceramic plate or tube	Drain aeration tank. Check for joint leaks, broken diffusers, and clogging. Note: Chlorine gas introduced into the air line at intervals between inspections helps hold down organic growths. Removable plates should be soaked in 50% nitric acid. Plates grouted in place cannot be treated with nitric acid, but instead with chromic acid (1g sodium dichromate to 50 mL sulfuric acid). Pour 2 fluid ounces on each plate on 2 succeeding days.	Semi-annually
Water side of ceramic diffusers	Clean with acid in place or remove and soak in acid. See Caution information in packed tower aerators (strippers).	Semi-annually
Air side of ceramic diffusers	If plates are clogged with iron oxide, treat with 30% HCl; if clogged with dust, soot, oil, etc., remove diffusers and burn off extraneous material in a furnace following the manufacturer's instructions.	Semi-annually
Porous saran-wound tube diffusers	Inspect and clean as required. As the component materials cannot be subjected to strong acid or heat, scrub the diffusers with a brush and detergent.	Semi-annually
Injection nozzles	Inspect and clean.	Semi-annually
Spray nozzle aerators Nozzles	Check for clogging. Clean, removing nozzles if necessary. Do not use a pipe wrench to remove the nozzles.	Weekly
Manifolds	Remove caps and clean out sediment. Check pipe supports and repair as necessary. Paint as necessary.	Quarterly
Spray fence	Paint.	Annually
Blowers and accessory equipment		

Inspection	Action	Frequency
Compressor or blower	Lubricate. Check output pressure for indications of clogging.	Daily
Air filters	Clean, repair, or replace.	Weekly
Compressor or blower	Open, inspect, clean, repair, and paint exterior surfaces.	Annually

10-4.2 Rapid-Mix Basins and Equipment.

Because rapid-mix devices revolve at great speed, do not attempt to check the rotation of the mixer paddles during operation, except by visual observation. When the mixing basin is empty, check the condition of the paddles, bearings, drive shaft, and motor. Then clean, lubricate, and paint as necessary. Table 10-2 presents a summary of maintenance procedures for rapid-mix basins.

Table 10-2 Maintenance Checklist for Rapid Mix, Flocculation, and Sedimentation Basins

Inspection	Action	Frequency
Rapid-mix basins	Drain, wash down walls, flush sediment to waste line. Do not allow cross-connections to the drinking water supply system.	Semi-annually
Baffled mixing chambers	Clean baffles and repair as necessary.	Semi-annually
Flocculator basins	Check paddle rotation to ascertain whether any flocculators are inoperative.	Monthly
	Clean and lubricate drive, bearings, gears, and other mechanical parts. Check underwater bearings for silt penetration. Replace scored bearings.	Semi-annually
Rapid (or flash) mixers	Check paddles. Clean bearings and drive shaft. Lubricate and paint as necessary.	Semi-annually
Revolving-sludge-collector basins	Drain tank. Check submerged parts.	Semi-annually

Inspection	Action	Frequency
Operating parts	Lubricate.	Daily or Weekly
Speed reducers and oil baths	Remove water and grit. Replace oil as necessary.	Weekly
Drive head	Lubricate (but do not over lubricate).	Daily
Worm gear	Check oil level.	Weekly
	Drain water from housing.	Monthly
Turntable bearings	Lubricate.	Monthly
	Change oil.	Semi-annually
Chains	Drain off water, add oil as necessary.	Monthly
	Change oil.	Semi-annually
Annular ball bearings	Lubricate.	Daily
	Inspect condition.	Monthly
Center bearings, shaft bearings, bushings, etc.	See manufacturer's instructions.	Variable
Tank equipment	Tighten bolts and nuts. Check for excessive wear. Flush and backblow sludge line. Check motors, couplings, and shear pins. Check rakes. Clean and paint equipment.	Annually
Conveyor type collector basins	See above and consult manufacturer's instructions.	Variable
Upflow or solids-contact clarifier	See manufacturer's instructions.	Variable

10-4.3 Flocculators.

Use Table 10-2 for flocculator maintenance.

10-4.4 Sedimentation Basins and Clarifiers.

All types of settling basins require the same basic maintenance (lubrication, cleaning, flushing, and painting). Maintain basins that incorporate proprietary mechanisms or devices according to the manufacturer's instructions. Basins with mechanical equipment for removing settled sludge usually clean themselves satisfactorily during normal operations. Table 10-2 presents a summary of maintenance procedures for sedimentation basins.

10-4.4.1 Non-Mechanically Cleaned Sedimentation Basins.

Clean non-mechanically cleaned sedimentation basins every 3 months, when an odor develops, or when rising floc particles indicate development of septic sludge conditions, whichever is more frequent. Drain the basin and clean the tank and mechanism with a high-pressure water hose.

10-4.4.2 Lubrication Requirements.

Regular lubrication is required when the basin is in continuous operation. Intermittent operation may allow an increase in the lubrication interval. If operating periods are intermittent and infrequent, operate the mechanism briefly between operating periods and lubricate accordingly. Devices subject to wide seasonal temperature variations will require seasonal changes in lubricant grades, especially when summer grade oils thicken at lower temperatures and reduce the flow capability. Daily or weekly lubrication of operating units is part of the operator's inspection. The choice of lubricant and its frequency of application are established by the manufacturer or by local command. Inspect the speed reducer each week to make sure that the oil is at the proper level, free of water and grit, and of a suitable viscosity. If a reducer runs hot during its operation, the oil level may be too high or too low. When the reducer is out of service for extended periods, make sure that it is filled completely to prevent seals from drying out. Replace oil when necessary.

10-4.4.3 Overload Alarm.

If the equipment has an overload alarm, check it for operation. If the alarm sounds at any time, shut off the equipment, locate the source of trouble, and rectify the situation. Disabling the alarm switch is not recommended. It is important that the alarm provide continuous operation under overload (high-torque) conditions. If the overload is caused by a sludge buildup leading to cut-out of the starter switch or pin shearing, drain the tank and flush out the sludge.

10-4.4.4 Upflow Clarifiers and Solids Contact Units.

These are all proprietary items; maintain them according to the manufacturer's instructions. Devices that use rotating parts have motors and gears that require maintenance.

10-4.4.4.1 Operator's Inspection.

Check for leaks in valves and piping each month. Make sure that sludge valves function properly. Also check time clock and other accessories that control sludge valve operation.

10-4.4.4.2 Cleaning Maintenance.

Drain unit, clean, and inspect wearing parts twice a year. Remove encrustation where it may interfere with operating parts; follow the manufacturer's instructions in this operation. Check chemical feed lines to make sure that they are not clogged and are in good condition.

10-4.5 Gravity Filters.

This paragraph deals with maintenance of conventional or rapid filters, formerly known as "rapid sand filters." Media commonly used in rapid filters include graded sand, crushed anthracite, GAC, and garnet or ilmenite. Media types may be used alone, as in traditional sand filters and deep-bed monomedia filters, or in combination, as in dual and tri- or mixed-media filters. The following maintenance procedures supplement (but do not substitute for) requirements established by the equipment manufacturers. Best practice information on filtration can be found in *AWWA M30* and *AWWA M37*. A quick reference guide to maintenance of gravity filters appears in Table 10-3.

Table 10-3 Maintenance Checklist for Gravity Filtration Equipment

Inspection	Action	Frequency
Filter media	Inspect surface for unevenness, sink holes, cracks, algae, mud balls or slime.	Monthly
	Dig out sand and gravel at craters of appreciable size.	Variable
	Locate and repair underdrain system breaks.	Variable
	Chlorinate to kill algae growths.	Quarterly
	Probe for hard spots and uneven gravel layers; if present, treat filter with acid.	Semi-annually
	Check wash water rise rate and sand expansion during backwashing.	Semi-annually
	Check sand condition for grain size growth; sample sand, determine weight loss on acid digestion, and run sieve test; acid-treat if necessary, or replace sand, if necessary.	Annually
Gravel	Check elevation of gravel surface.	Monthly
	Examine gravel for encrustation, cementation, alum penetration, or mud balls; if necessary, remove, clean, and re-lay gravel.	Semi-annually
Underdrain system	Remove sand from an area 10 feet square (1 sq m) and inspect an area of gravel 2 feet square (0.2 sq m) or larger. If underdrains are deteriorated, remove all sand and gravel, repair underdrains, and replace gravel and sand.	Annually
	If underdrain is porous and clogged by alum floc, treat with 2% NaOH solution for 12 to 16 hours.	Variable

Inspection	Action	Frequency
Wash water troughs	Check level and elevation; adjust.	Quarterly
	Check for corrosion; if present, dry troughs, wire brush, and paint.	Semi-annually
Operating tables	Clean table (console or panel) inside and out.	Weekly
Cables	Adjust tension	Variable
Hydraulic lines (or pneumatic)	Check for leakage, repair as required.	Variable
4-way transfer valves	Adjust, tighten packing glands or add new packing.	Monthly
	Lubricate with grease.	Monthly
	Adjust valve position indicator, if necessary.	Monthly
	Disassemble, clean, lubricate, and replace worn parts	Annually
Table	Paint inside.	Annually
Rate controllers Direct-acting General	Clean exterior, check diaphragm leakage, tighten packing, and check freedom of movement and zero differential.	Weekly
Diaphragm pot	Disassemble, clean, and replace.	Annually or Variable
Controller mechanism	Disassemble and service; clean venturi; paint surfaces needing protection.	Every 3 years

Inspection	Action	Frequency
Indirect-acting		
General	Clean outside; adjust packing; lubricate and tighten fittings; check knife edges; check piston travel; repack as necessary.	Weekly
Pilot valves	Disassemble, clean, and lubricate; check piston travel; clean piping and strainers; check for leaks in diaphragm.	Annually
Controller mechanism	Disassemble and service; clean venturi; clean hydraulic cylinders; paint as necessary.	Every 3 years
Mechanically operated loss-of-head gages	Check zero setting; adjust stop collars or cable; release air from float chamber.	Monthly
Mud leg	Flush out sediment.	Monthly
Float chamber	Remove float and clean, replace mercury if necessary, check pressure pipelines, paint interior and exterior.	Annually
Diaphragm-pendulum loss-of-head unit	Check zero setting; purge diaphragm cases of air; check cable at segment; remove dirt from knife edges; tighten cam hubs on shafts; drain mud from mud leg.	Monthly
Pipelines to diaphragm	Check for free flow and absence of encrustation.	Semi-annually
Diaphragm-pendulum unit	Check for leakage; disassemble unit, clean, and lubricate; check working parts and cables; repack stuffing box; check knife edges.	Annually
Mercury-float-type rate-of-flow gages	Check at zero differential; adjust indicator arm and recording pens; check stop collars on cables.	Monthly
	Check accuracy and percent error; if greater than ±3%, adjust.	Semi-annually

Inspection	Action	Frequency
Pressure lines	Check and clean as necessary.	Semi-annually
Float chamber	Clean float and check mercury; paint all parts requiring protection.	Annually
Piping and valves	Check for joint leaks; check pipe hangars and replace, if necessary; paint as necessary.	Monthly

10-4.5.1 Filter Media.

10-4.5.1.1 Monthly.

Drain the filter to the surface of the filter medium. Inspect the surface for unevenness, sinkholes, cracks, and evidence of algae, mud balls, or slime.

a. If depressions or craters on the surface area are of appreciable size, dig out the sand and gravel, and locate and repair any break in the underdrain system.

b. Remove mud balls manually or break them up with high-pressure sprays.

c. If severe algae growths exist on media or walls, remove the filter from service and treat it with a strong hypochlorite solution. Add enough hypochlorite to produce 2 to 4 mg/L of free residual chlorine in a volume of water 6 in. deep above the filter surface. Draw down the filter until the water level is just above the bed surface. Allow the filter to stand 6 to 8 hours, then backwash the surface. Follow this procedure with a complete backwashing. Repeat if necessary.

10-4.5.1.2 Quarterly

Probe the filter for hard spots and uneven gravel. Examine the sand below the surface by digging to gravel with the water drawn down to the gravel level. Clogs may appear because sand grains have cemented with mud balls or because grains have increased in size due to calcium carbonate deposit encrustation (e.g., in softening plants or where lime and ferrous sulfate are used for coagulation). If so, clean the sand by treating the idle filter with inhibited muriatic acid (hydrochloric acid to which a chemical has been added to reduce corrosion of metal) or sulfurous acid. It is good practice to notify the utility managers before these chemicals are used.

a. Add the inhibited muriatic acid at the surface and allow it to pass downward through the bed and out the filter drain or “rewash” line.

Alternatively, add it to an empty filter through a small tap on the bed side of the wash water supply line.

b. Use sulfurous acid as follows. Allow the sulfur dioxide gas from a cylinder to discharge into the filter wash water supply line while slowly filling the filter bed with wash water. Use one 150-lb cylinder with 6,000 gallons of water to produce a 0.3% solution. Allow solution to stand for 6 hours.

10-4.5.1.3 Twice a Year.

Usually when seasonal water temperature changes occur, determine any change in the rate of wash water rinse and check sand expansion as follows:

a. The flow rate of backwash water should be sufficient for cleaning the media but should not provide so much pressure that loss of media results. In general, the backwash flow rate should be at least 15 gallons per minute (min.) per square (sq) ft (10 liters per second per square meter [Lps/sq m]), which is equivalent to a rise rate of 2 ft per min. (600 mm/min.) as measured by a hook gage. Higher rates may be required for some types of filter media, but rapid sand filters typically backwash at a rise rate of about 2.0 to 2.5 ft per min. (600 to 750 mm/min.). The highest rate for each filter should be determined by actual experience at the plant. The rise rate is related to the backwash rate, as illustrated in the following calculation:

Equation 10-1. Backwash Flow Rate

$$\left(\frac{15gal}{\min * sf}\right)*\left(\frac{1cf}{7.48gal}\right)=\frac{2\,ft}{\min}$$

$$\left(\frac{10L}{\sec * m^2}\right)*\left(\frac{1m^3}{1000L}\right)=\frac{0.01m}{\sec}$$

$$\left(\frac{0.01m}{\sec}\right)*\left(\frac{60\sec}{\min}\right)*\left(\frac{1000mm}{m}\right)=\frac{600mm}{\min}$$

b. **Media Expansion.** Filter media should be expanded at least 20 to 25% for good cleaning action, although a greater expansion may be optimum in some cases. Higher expansions risk washing out some filter media along with the accumulated solids. The degree of expansion is affected by many variables associated with the filter media and the water. Filter media variables include size and gradation as well as shape and density. Water variables include viscosity and density which, in turn, vary with water temperature. Figure 10-1 relates media size and specific gravity to backwash rate and gives approximate temperature correction factors.

Media cleaning is also affected by interparticle abrasion, although the bulk of the cleaning action is due to the force of the rising backwash water. Expansion can be measured by attaching cups to a pole at suitable intervals, then dipping the pole into the backwashing filter bed; the highest cup that contains sand indicates the height of bed expansion. A waterproof flashlight attached to a pole works well to show the top of the sand but only after the backwash water becomes relatively clear.

c. **Hook Gage.** A multiple hook gage (Figure 10-2) is a series of vertical, sharp, pointed rods held in a frame that may be hung on the side of the filter. The tips of the sharp, pointed rods are set accurately at 2- or 3-in. (50- to 75-mm) spacings. The hook can be used to check the rate of filtration or backwashing, although its primary use is for measuring backwash flow rate. Hang the frame on the side of the filter and accurately record the time required for the water level to fall or rise between the points. The volume of water in the filter box between the gage points can easily be calculated. From the recorded time, the flow rate can be determined accurately.

10-4.5.1.4 Inspect the Media Twice a Year.

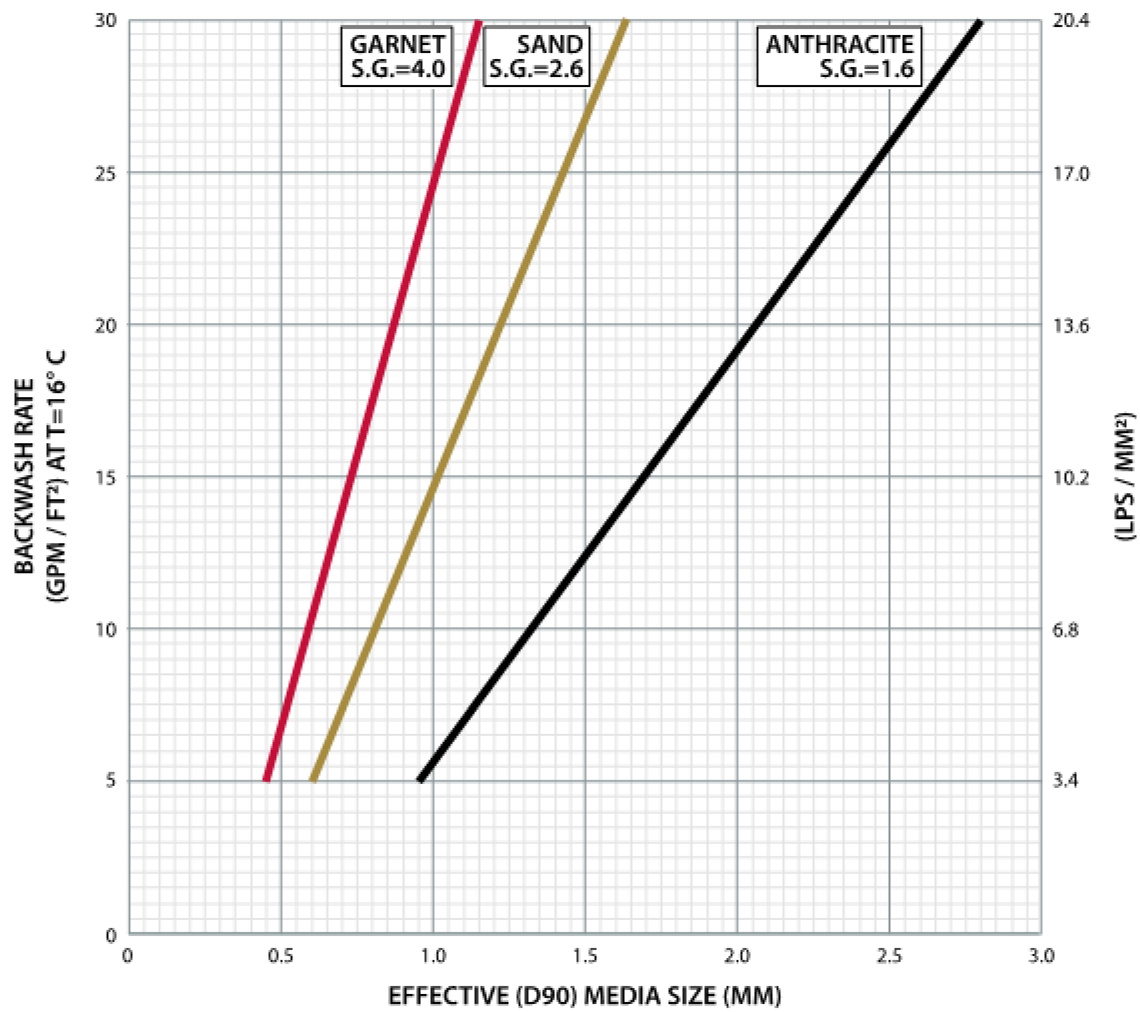
If visual inspection does not reveal the condition of the media, locate the elevation of the top of the bed to determine if the bed has “grown” in depth. Also, remove a media sample and analyze it as follows:

a. Make a sampling tube 12 in. (300 mm) square by 36 in. (1 m) deep. Force a tube into the gravel and drain the bed. Remove the sand from the tube. Collect several such samples from well-scattered locations on the filter bed, mix thoroughly, and reduce sample size by quartering until about 2 lb (1 kg) remain. Dry this sample and mix, quarter, and reduce it to a usable sample size.

b. Determine the loss of weight of a 10-g sample during acid treatment. Treat the sample with 10% hydrochloric acid in a Pyrex evaporating dish on a water bath for 24 hours. Replace acid loss during the treatment period. Wash, dry, and weigh the sand. Determine the weight loss and compare it to the previous analysis.

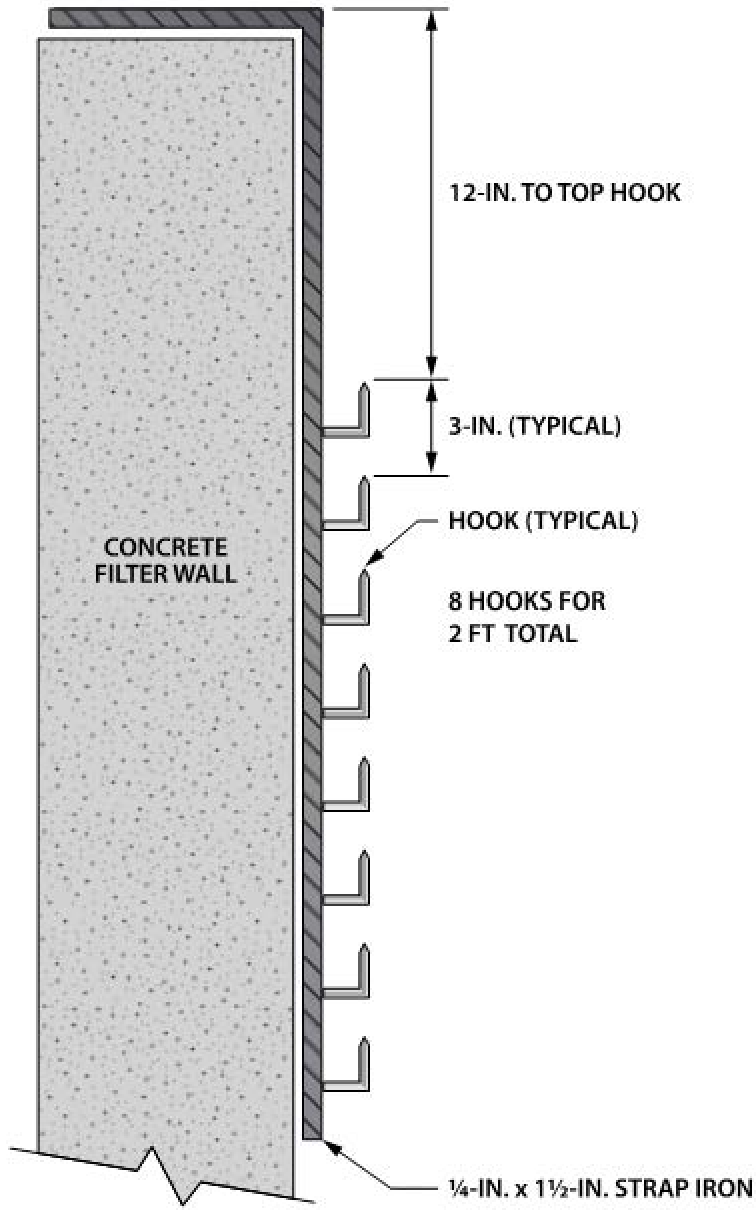
c. From the rest of the sand sample, remove 100 g and run a sieve test. Pass the sand through several standard sieve sizes, weighing the sand grains retained on each sieve. Compare the results to a previous test. Retention of greater amounts of sand on the larger sieve sizes indicates growth of the filter media.

Figure 10-1 Backwash Rate for Media Cleaning



TEMPERATURE CORRECTION: APPROXIMATE CORRECTION FACTORS TO BE APPLIED FOR TEMPERATURES OTHER THAN 16° C		
TEMPERATURE		MULTIPLY THE 16° C BACKWASH RATE BY
31° C	88° F	1.32
26° C	79° F	1.20
21° C	70° F	1.09
16° C	61° F	1.00
11° C	52° F	0.91
6° C	43° F	0.83

Figure 10-2 Multiple Hook Gauge



d. If visual inspection, weight loss, or sieve analysis shows growth of sand grains to a point that filtration efficiency is impaired, treat the sand as outlined in Chapter 10 paragraph titled Filter Media and adjust the water treatment process as necessary. If treatment is not effective, remove and replace the filter media.

10-4.5.2 Loss of Filter Media.

Media can be washed from the filter along with the backwash water or can filter through the gravel layer along with the product water. Losses of media in the backwash water can be kept to a minimum by controlling the backwash flow rate, maintaining level backwash troughs at the proper elevation above the media surface, and controlling hydraulic short circuiting because of clogged media or gravel. Losses through the filter gravel can be controlled by placing a layer of coarse garnet or ilmenite between the media and the gravel and controlling mounding of the filter gravel. Leakage of media can be detected by a small trap located in the effluent line from each filter. Many new filters leak sand for a period and then stop. Such leakage poses no real problem. However, if sand leakage increases over a period, it is probably an indication of mounded gravel.

10-4.5.3 Gravel Inspection.

Gravel inspection includes the procedures described in a. through c. below.

At monthly intervals, use a probe to check the gravel bed surface for unevenness. If ridges or sinkholes are indicated, the filter may need overhauling.

- **Probing a Filter During Backwash.** This method uses a metal rod long enough that the operator can reach the gravel layer while standing on the top of the filter. The rod has a heavy grade screen attached to the end so that it can penetrate the expanded filter media bed (the rod is stopped by the gravel layer). By probing every few feet along the filter, mounds or holes in the gravel layer can be discovered. A variation in the gravel level of over 2 in. (50 mm) indicates serious problems.
- **Probing a Filter at Rest.** The filter can be probed at rest using a metal rod of about 1/4-in. (6-mm) diameter that penetrates the sand layer but not the underlying gravel.
- Remove media from an area of about 3 sq ft (0.3 sq m) twice a year, taking care not to disturb the gravel. Examine the gravel by hand to determine whether it is cemented with encrustation or mud balls and whether it is layered improperly.
- If any undesirable conditions exist to a marked degree, remove the media and re-lay the filter gravel. If unevenness or layer mixing is caused by a faulty underdrain system, repair it; if it is caused by faulty backwashing, correct the backwashing procedure.

10-4.5.4 Filter Underdrain System.

Inspect the filter bottom as needed. Sand boils (during backwashing), sand craters on the surface, or marked unevenness of the gravel layers indicate trouble in the underdrain system. Inspection and treatment procedures are as follows:

a. To inspect the bottom, remove the media over an area of about 10 sq ft (1 sq m). Select an area where sand boils or other indications of trouble have been noticed. Place planking over the gravel to stand on and remove gravel from areas about 2 ft sq (0.2 sq m). Check underdrains for deterioration of any nature. If underdrains need repair, remove all sand and gravel, make repairs, and replace gravel and sand in proper layers.

b. Where underdrains are of the porous-plate type and clogged with alum floc penetration, flood the underdrain system with a 2% sodium hydroxide (caustic soda) solution for 12 to 16 hours.

10-4.5.5 Wash Water Troughs.

At quarterly intervals, check the level and elevation of troughs. Draw water below the trough weirs, crack the wash water valve, and observe any low points where water spills over the weir before the weir is covered completely.

a. Adjust the troughs as necessary to produce an even flow throughout their lengths on both sides.

b. Twice a year, inspect the metal troughs for corrosion. If corrosion exists, allow the troughs to dry, clean by wire brushing, and paint with an appropriate protective paint or coating.

10-4.5.6 Operating Console.

Operating controls for filter valves may be mounted on a console, panel, or table. The controls actuate filter valves that may be powered either by hydraulic or pneumatic means. The controls may be connected to the valve mechanism either by cable or chain and operated through electrical, hydraulic, or pneumatic connections.

Perform these maintenance operations each week:

a. Clean the table, console, or panel inside and out, using soap and water if necessary.

b. If the console is cable-operated, inspect it for leaks and stop any leakage; if it is pneumatically operated, check tubing for possible leakage.

Perform transfer-valve maintenance as follows:

a. Adjust 4-way transfer valves and handles each month to make sure that all filter valves open at the same rate. Tighten packing glands or add new packing as necessary.

b. Lubricate transfer valves with grease each month. Do not over lubricate the valves; one-half turn of the grease screw is generally sufficient.

c. Inspect the valve position indicator each month and adjust it to read correctly in all positions.

d. Disassemble the 4-way transfer valves in the table each year. Clean or replace any worn parts, seats, or washers.

Paint the inside of the table, console, or panel each year to protect against corrosion.

10-4.5.7 Rate Controllers.

Rate-of-flow controllers may be either direct-acting or indirect-acting. Maintenance procedures for both types follow.

10-4.5.7.1 Direct-Acting Controllers:

a. Each week, clean exterior, check for leakage through diaphragm pot, and lubricate or tighten packing to stop any existing leakage. Also, make sure that both the diaphragm and the control gate move freely between zero differential and the open and closed positions.

b. At regular intervals, remove and disassemble the diaphragm pot, including the rubber diaphragm. If the water does not cause tubercles, this operation may only need to be performed once every 3 to 5 years.

c. Every 3 years, disassemble and service the controller gate and mechanism. Inspect the venturi throat. Paint or apply protective coating as necessary.

10-4.5.7.2 Indirect-Acting Controllers:

a. Each week, clean the outside of the controller, adjust the packing, and lubricate or tighten the fittings as necessary to stop any leakage from the hydraulic cylinder, the controller valve, the piping, or the pilot valve. Make sure that the knife edges seat correctly and are free of paint and other foreign matter. Also, be sure that the piston has free vertical travel and does not bind. Replace the packing if necessary.

b. Each year, disassemble, clean, and lubricate the pilot valve. Remove foreign matter from the piston with a cloth. Do not use an abrasive to clean the piston. Make sure that the piston is moving freely. Disconnect and clean the pilot valve piping and strainers; make sure that no foreign matter enters the pilot valve during the cleaning operation. Check for leaks or cracks in the diaphragm.

10-4.5.8 Gauges.

Indicating and recording instruments mounted on the operating table or control panel may include a filter rate controller, loss-of-head gage, flow-rate gage, water level, backwash flow rate meter, wash water rise indicator, and summation gage for total filter output.

Mechanically Operated Loss-of-Head Gauge. The equipment that operates the indicator, or indicator recorder instrument, requires the maintenance operations described in the following paragraphs. The inspector should follow these instructions in general and consult the manufacturer’s instructions for detailed adjustments.

a. Each month check the zero setting in the following way. Open the equalizing valve on mercury float-type head gages and make certain that the indicator arm and the recording pen return to zero. Note the reason for any incorrect reading, and adjust the stop collar or wire cable, if necessary, to bring the indicator to the proper zero reading. On floats and float chambers that are so equipped, release the air. (On some models it is possible to release the air by jerking the wire cable lightly.)

b. Each month, remove the float from the float chamber, wash the float, and remove encrustations. Use care not to mar the float. Replace the mercury, if necessary, avoiding any spillage. When replacing the mercury, be sure that the amount is correct. Also, paint the interior and exterior of the float chamber and other parts each year to prevent corrosion. In addition, check the pressure pipelines to the float chamber and remove any encrustation.

Caution: Mercury fumes are poisonous. Handle mercury carefully since a spill creates a continuing health hazard and is difficult to clean up.

10-4.5.8.1 Diaphragm-Pendulum Unit Loss-of-Head Gauge.

When the actuating mechanism is of this type, the following general maintenance procedures apply. For a more detailed discussion of the procedures, consult the manufacturer’s instruction.

a. Each month purge the diaphragm cases of air and check the cable to be sure that it leaves the segment at a tangent to the lower end when the unit reads zero. Remove dirt from the knife edges; if necessary, tighten the cam hubs on their shafts. Drain mud from the mud leg as described in Chapter 10 paragraph titled Gauges above.

b. Check the pipelines to the diaphragm twice a year to make sure that they are open and free of encrustation.

c. Inspect the diaphragms each year for leakage. Replace if necessary.

Note: Spare diaphragms should be kept underwater.

d. Disassemble the unit to clean and lubricate it when necessary. Check the working parts and the cables (they should be free of knots, splices, or fraying). Repack the stuffing box if it is leaking. Make sure the knife edges rest solely on their edges when the pendulum is hung vertically and be sure all cable ends are knotted tightly.

10-4.5.8.2 Mercury-Float-Type Rate-of-Flow Gauges.

General maintenance procedures are outlined below. For more detailed procedures, consult the manufacturer’s instructions.

a. Once a month, check the unit by opening the equalizing valve to eliminate the differential pressure in the gauge. Adjust the indicator, the recording pens, and the register to zero. Check the position of the stop collars on the cables and inspect and clean the stops on the indicator and recording pen.

b. Every 6 months check the accuracy of the rate-of-flow gauges in the following way. Determine the exact time for the water to drop 1 ft (30 cm), using hook gauges. Determine the amount of water in this 1 ft (30 cm) depth (calculate, allowing for inlets, gullets, structural members, or measure the input, if possible, from the wash water rinse or the drop in the level of the wash water tank). During the period timed for the drop in the water level of 1 ft (30 cm), note and record the reading of the flow rate. Calculate the rate of flow and percent error, according to Equations 10-2 and 10-3.

c. Twice a year, check the pressure pipelines to the float chamber and clean and remove encrustation to allow for free flow.

d. Once a year, clean the float and check the mercury for replacement. If necessary, paint the interior and the exterior of the float chamber and other parts to protect against corrosion

Equation 10-2. Rate of Flow

$$Gpm = \frac{V * 60}{T}$$

Where:
V = volume in 1 ft depth of water (gallons or liters)
T = drop time (seconds)

Equation 10-3. Percent Error

$$Percent = \frac{F_1 - F_2}{F_2} * 100$$

Where:
Percent = percent of error
F_1 = indicated flow rate (gpm or L/min)
F_2 = measured flow rate (gpm or L/min)

Note: If the error is greater than ±3%, make the necessary adjustments.

10-4.5.9 Piping and Valves.

Each month check for leaks at the joints. Also check the pipe hangers and replace any that have deteriorated. Paint piping, valves, and hangers if necessary to prevent corrosion. See maintenance procedures for valves in Chapter 7.

10-4.5.10 Maintenance Schedule.

The maintenance operation frequency and schedule of inspections for filtration are presented in Table 10-3.

10-4.6 Pressure Filters.

Pressure filters need the same care and attention as gravity filters. Open these filters regularly and inspect them carefully. The following maintenance procedures apply:

Inspect piping and valves for leaks each week. Lubricate and repack valves if necessary.

Open the pressure shell and inspect the filter bed surface each month. Follow procedures described in (a) through (f).

a. Use a garden rake or probe during backwashing (while the manhole is open) to test for mud balls in the lower part of the filter bed and evenness of the gravel layer surface.

b. Determine whether the sand bed level has changed since the last inspection by comparing the bed surface elevation with some reference point.

c. If the filter does not have a surface wash system and shows evidence of mud balls, backwash it at the highest rate possible while jetting the surface with a stream of water from a high-pressure hose. Install a permanent surface wash system.

d. Open the filter each year and remove the sand from an area large enough to allow inspection of the gravel. If the sand or gravel distribution indicates non-uniform distribution of backwash water, the filter media and gravel may need to be removed and the underdrain system checked.

e. Clean and paint the exterior of the shell each year.

f. Every 3 years (or more often if necessary), remove the filter medium and gravel and check the underdrain system for wash water distribution. Repair if necessary. Clean the underdrain system and paint it or apply a protective coating to all parts subject to corrosion, including the inside of the shell. Replace the gravel and the filter media.

10-4.7 Precoat Filters.

In general, the maintenance procedures for cleaning the filter element are the same for both pressure- or vacuum-filter types. The following procedures apply.

Each month, or as often as operating conditions require, check the filter elements. The need for cleaning is evident when the precoat shows bare spots on the elements. Iron oxide deposits, manganese dioxide deposits, and algae growths cause element clogging.

For iron oxide removal, treat the elements with a 0.5% solution of oxalic acid. Information is available from the manufacturer on the amount of oxalic acid to use for units of different sizes. The following procedures are used:

a. Start with an empty filter after a regular washing.

b. Close the drain valve and the main outlet valve; open the recirculation valve.

c. Fill the tank to a level covering the top of the elements.

d. Add the proper quantity of oxalic acid and recirculate for 1 hour.

e. Drain and hose down the elements and the tank interior.

f. Close the drain valve; refill, circulate a few minutes, and then drain again. If the cleaning is not completely effective, repeat the procedure.

The procedure for manganese dioxide removal is the same as the procedure for iron oxide removal, except that anhydrous sodium bisulfite is added to the solution rather than oxalic acid (see the manufacturer's instructions for the correct amount).

To remove algae growths, add a 12.5% hypochlorite solution to the tank volume after filling the tank to the proper level (see the manufacturer's instructions for the proper amounts to use for units of different sizes).

Check the piping and valves and appurtenant equipment twice a year, including the body-feed equipment. Make any adjustments the manufacturer's instructions indicate are necessary. Clean and paint all exterior surfaces, if necessary.

Ion-exchange maintenance schedule is summarized in Table 10-4.

10-4.7.1 Operating Conditions.

Determine the operating condition of the softener each quarter. Refer to operating records and make such tests and meter readings as are necessary to determine the following information:

10-4.7.1.1 Flow Rate.

Natural ion exchangers can operate satisfactorily at a flow rate of 5 gpm/sq ft (3.5 Lps/sq m); synthetic resins operate at a rate of 6 to 7 gpm/sq ft (4 to 5 Lps/sq m). Rates higher than these cause undesirable head loss through the bed and bed packing. Adjust the controls of the flow rate each quarter.

Table 10-4 Maintenance Checklist for Ion-Exchange Softening Units

Inspection	Action	Frequency
Softener unit Shell	Clean and wire brush; paint.	Annually
Valves and fittings	Check for obstructions, corrosion, and fastness.	Quarterly
	Check for leaks; repack if necessary.	Semi-annually
Ion-exchange medium	Check bed surface for dirt, fines, and organic growths; remove foreign matter and add resin to desired level.	Quarterly
Gravel	Probe through resin to determine gravel surface; level gravel surface with rake during backwash flow; replace gravel when caked or if resin is being lost to effluent; wash and grade gravel and place in four separate layers; use new lime-free gravel at discretion of inspector.	Quarterly
Underdrains	Check pressure drop through underdrains; if necessary, remove manifold or plate underdrains; clean and replace.	Annually or Variable
Regeneration equipment Salt-storage unit	Clean tank as necessary to remove dirt.	Variable
Brine tank	Clean out dirt and insolubles; allow to dry; paint both exterior and interior surface.	Semi-annually

Inspection	Action	Frequency
Ejector	Clean, disassemble, check erosion and corrosion; clear clogged pipes; assemble and replace.	Annually
Operating conditions		
Flow rates	Check rate of flow through bed; adjust controls to optimum rate, depending on type of resin.	Quarterly
Backwash rates	Check rate and adjust controls to optimum rate.	Quarterly
Pressure	Check difference between inlet and outlet pressures; if undesirable changes in pressure drop have occurred, seek cause and remedy.	Quarterly
Efficiency	Compare total softening capacity with previous inspection; determine cause of decrease, if any, and remedy situation.	Quarterly
Out-of-service softeners	Drain; keep synthetic resins damp; do not regenerate before draining.	Variable
Demineralization equipment	Maintain according to manufacturer’s instructions.	Variable

10-4.7.1.2 Backwash Rate.

The rate of backwash should be 6 to 8 gpm/sq ft (4 to 6 Lps/sq m) of bed surface. Rates below this value do not clean the bed properly. Rates too high wash some of the resin out of the softener and reduce its softening capacity. Adjust the flow rate control to produce the best backwash rate each quarter.

10-4.7.1.3 Pressure.

Each quarter check operating records for any change in the difference between inlet and outlet pressure. Any change in head loss through the softener indicates a problem. A decrease in pressure drop may indicate improper valve closure or a channelized bed. An increase in pressure drop may indicate a valve not completely opened, a dirty bed, clogged gravel, or a clogged underdrain system.

10-4.7.1.4 Softening Efficiency.

Each quarter check the records to determine the softening capacity between the regeneration periods. Compare the current amount of hardness removal with that recorded when the ion-exchange resin bed was new, and calculate the efficiency based on the original capacity as 100%. A decrease in efficiency may be caused by a dirty bed, coated resin grains, loss of ion-exchange bed, or improper regeneration (either by weak brine solution or under-regeneration or over- regeneration). Replace resin bed if the efficiency has decreased by 25% and it cannot be almost completely restored by cleaning and using special procedures recommended by the manufacturer.

10-4.7.2 Demineralization Equipment.

Ion-exchange equipment used for demineralization is highly specialized. Maintain it according to the manufacturer's instructions.

10-4.8 Recarbonization Equipment.

10-4.8.1 Combustion Units.

Maintenance of combustion units depends on the equipment used, fuel impurities, effectiveness of the scrubber and drier, and construction materials. Consult the manufacturer's instructions for maintenance of the compressor or blower.

10-4.8.1.1 Operator's Inspection.

Each day, check burners, compressor, gages, and traps. Adjust the equipment to ensure top-level operation.

10-4.8.1.2 Drier, Scrubber, and Traps.

Each month check material in the drier and replace as necessary. Adjust the spray and clean out connecting piping; clean the gas traps.

10-4.8.1.3 Corrosion Inspection.

Every 6 months inspect all equipment for internal and external corrosion. Repair the equipment if necessary and paint it or use protective coatings.

10-4.8.2 Carbon Dioxide Gas Feeders and Evaporator Units.

Maintenance of carbon dioxide gas feeders and evaporator units generally will follow the procedures outlined in Chapter 10 paragraph titled Gas Chlorinators for vacuum-operated gas feed chlorinators and liquid chlorine evaporators. Consult the manufacturer's instruction for specific maintenance requirements.

10-4.9 Distillation Equipment.

Required maintenance for distillation equipment is presented in Table 10-5.

Table 10-5 Maintenance Checklist for Distillation Equipment

Inspection	Action	Frequency
Distillation equipment Multiple-effect evaporators Submerged tube/ Tubes or coils	Remove scale by cracking or acid wash (see manufacturer's instructions).	Variable
Zinc plates	Remove and replace when reduced to one-quarter of their original size.	Variable
Condenser or cooler tubes	Clean, as necessary, by wire brushing and flushing.	Variable
Flash-type evaporators Evaporator stages	Check for corrosion or encrustation; clean and repair as necessary.	Quarterly
Stream side of evaporator	Clean and repair.	Semi-annually
Entire unit	Check for signs of deterioration; repair or renew parts as necessary; paint exterior.	Annually
Vapor-compression distillation units Tubes in evaporator	Clean.	Every 200 to 400 hours
	Chemically.	Variable
	Mechanically.	Variable
Mechanical and electrical controls	Inspect, clean, and repair or replace worn parts.	Quarterly

Inspection	Action	Frequency
Engine, vapor compressors, vent condenser, heat exchanger, cooler system, etc.	Inspect, clean, repair, and adjust.	Semi-annually
Entire unit	Check, clean, repair, and paint as necessary.	Annually

10-4.9.1 Multiple-Effect Evaporators

These evaporators may be of two types:

10-4.9.1.1 Submerged-Tube Evaporators.

As a general practice, remove scale from the evaporator tubes as soon as it becomes 1/16 in. thick, regardless of the model or manufacturer.

Thermal Cracking of Scale. In the tube model, the scale may be cracked by suddenly flooding the shell with cold water after the tubes have been preheated with steam at the first effect coil steam pressure. This method of cracking is the most satisfactory when the scale is less than 1/16 in. thick.

Mechanical Cracking of Scale. Where thermal cracking is not effective, mechanical cracking may be used.

- Tube Model. Crack the scale by inserting a bar between the lines of tubes.
- Coil Model. Manually crack the scale by bouncing the coils on a hardwood block to crack the heavier coating, then wire brush the coils. Consult the manufacturer’s instructions for specific instructions.

Caution: Using a chipping hammer to remove the scale may seriously damage the coils.

Acid Cleaning. In the coil model, scale generally may be dissolved quickly by immersing the coil in a 20% solution of inhibited muriatic acid (commercial hydrochloric acid). Wash the coils thoroughly in water before reinstalling them in the evaporator.

Zinc Plate Replacement. Replace the zinc plates when they have been reduced to about one-quarter of their original size.

Condenser and Cooler Tube Cleaning. Clean these tubes (if used) by flushing, wire brushing or scraping, and flushing again before reinstalling them.

Shutdown Protection. If the plant is to be shut down for an indefinite period and is subject to freezing conditions, remove all water from all parts of the evaporator.

10-4.9.1.2 Flash-Type Evaporators.

Specific maintenance instructions are provided by the manufacturer. The following procedures are the recommended minimum:

- Check the evaporator stages for corrosion or encrustation each quarter; clean and repair the evaporator as necessary.
- Check the steam tube side of the evaporator twice a year and repair it if necessary.
- Each year, inspect all parts of the unit (both interior and exterior) for signs of deterioration and inspect the piping and valves. Repair or renew parts as necessary; paint interiors.

10-4.9.2 Vapor-Compression Distillation Units.

Detailed maintenance procedures are found in the manufacturer's instructions. The following procedures are the minimum required:

After 200 to 400 hours of operation, check the evaporator for corrosion or encrustation. If the tubes are encrusted, use either chemical or mechanical means for scale removal. Mechanical cleaning is used for hard scale that cannot be removed by chemical treatment.

- For chemical treatment, add sodium bisulfate directly, or in solution, to the evaporator. Sulfuric acid and inhibited muriatic acid are better than sodium bisulfate; however, in general they should be used only if approved by the utility managers. The amount of acid to be added varies, depending on the size and type of the unit. Consult the manufacturer's instructions. Generally, the acid cleaning is continued during a 2-hour recirculation period; methyl orange is used as the indicator to show when the acid is spent. After treatment, drain the unit, flush well, rinse with alkaline solution to neutralize any remaining acid, and return to service.
- The equipment needed to remove scale formation mechanically includes an electric drill with bit and wire brush attachments that fit the evaporator tubes. The tubes must be wet before the drilling is started. Water is fed through the drill bit during operation. Drill each tube and then wire brush. Remove scale from the evaporator shell or head by scraping; remove all dislodged particles of scale from the evaporator. Reassemble the evaporator and return it to service.
- Note: For safety, ground the electric drill used for removing scale and protect the operator from electrical shock resulting from using an electric drill in a wet environment.

- Check all mechanical controls, fuel lines, electrical connections, lubrication points, and valves each quarter.
- Check the engine, vapor compressors, vent condensers, heat exchanger, cooler system, and instrumentation twice a year. Clean, adjust, and repair this equipment as necessary.
- Check the entire system. Clean, repair each year, and paint as necessary.

10-4.9.3 Maintenance Procedure Schedule.

Maintenance operation frequencies and the schedule of inspection for distillation equipment are summarized in Table 11-5.

10-4.10 Electrodialysis Equipment.

When establishing maintenance procedures, follow the detailed instructions provided by the equipment manufacturer. General maintenance procedures for electrodialysis equipment can be found in best practice *AWWA M38*.

10-4.11 Reverse Osmosis Equipment.

Membrane equipment is specialized. Maintain it in accordance with the manufacturer’s instructions. General information on reverse osmosis equipment maintenance - including daily, weekly, and monthly monitoring; membrane cleaning; and troubleshooting procedures for a variety of operating problems - can be found in *AWWA M46* and *Reverse Osmosis: A Practical Guide for Industrial Users*.

10-4.12 Backflow Preventers.

See Chapter 9 paragraph titled Backflow Prevention Devices.

10-4.13 Valves.

See Chapter 7 paragraph titled Valves and Valve Operation.

10-4.14 Pumps.

See Chapter 5 paragraph titled Pump Maintenance.

10-4.15 Compressors.

Table 10-6 is a checklist of the procedures for maintaining compressors. Note that these procedures are general. Always read and follow the manufacturer’s instructions for mechanical equipment.

Table 10-6 Maintenance Checklist for Compressors

Inspection	Action	Frequency
Intake Filters	Inspect the compressor filter. Inspect more frequently (daily) in areas with severe dust. Never operate a compressor without the suction filter because dirt and foreign materials will collect on the rotors, pistons, or blades and cause excessive wear.	Monthly
	Clean or replace as indicated for each filter type.	Semi-annually
Impregnated paper filter	Replace when dirty.	
Cloth filter	Wash with soap and water, dry, and reinstall. Keep spare filter on hand for use when main filter is being washed.	
Wire mesh and oil-bath filter	Clean with a standard solvent; reoil or drain and refill oil bath; reuse.	
Bearings	Inspect bearings and lubricate if necessary. Most compressors have bearings that require oiling.	Daily
Crankcase reservoir	Examine the reservoir dipstick or sight glass for oil level. Keep reservoir full but do not overfill as excess oil can lock up or damage compressor. Heat from the compressor tends to break down oil quickly. Thus, most compressor manufacturers specify particular oils for their equipment and frequent oil changes are recommended. Heat from the compressor tends to break down oil quickly. Thus, most compressor manufacturers specify particular oils for their equipment and frequent oil changes are recommended.	Daily
	Change compressor oil when necessary. If there are filters in the oil system, change these regularly as well.	Quarterly

Inspection	Action	Frequency
Drip-feed oiler	Check drip rate.	Daily
Force-feed oiler	Check pressure.	Daily
Grease fittings	Ensure fittings are greased.	Quarterly
Cylinder or casing fins	Clean with compressed air or vacuum to ensure proper cooling of the compressor.	Weekly
Unloader	Check that compressor comes up to speed and that the unloader changes at start of the compression cycle. Listen for a change in sound. When the compressor stops, you will hear a small pop and the air bleeding off the cylinders. If the unloader is not functioning properly, the compressor will stall when starting, fail to start, or (if belt driven) burn off the belts.	Daily
Safety Valves	Test weekly. Do not change pre-set cutoff settings in high-pressure cutoff switches, low oil pressure switches, and high temperature cutoff switches. If any of these safety switches are not functioning properly, correct the problem before starting the compressor again. Record the safety switch settings and maintain record in the equipment file.	Weekly
Air receiver	Drain the condensate from the air receiver using the valve located at the bottom of the tank. If the air receiver is equipped with automatic drain valves, inspect periodically for proper functioning.	Daily
Belts	Inspect the belt tension by pressing the belt down approximately 3/4 in. between the two pulleys. Make sure the compressor is locked off before performing this test. Do not over tighten belts.	Semi-annually
Operating Controls	Examine regularly. Make sure compressor is stopping and starting at the proper settings. For dual installations, make sure compressors are alternating (if so	Quarterly

Inspection	Action	Frequency
	designed); inspect gage for accuracy. Compare readings with recorded startup values or other known, accurate readings.	
Tool oilers	If your compressor has a tool oiler on the receiver, check the reservoir and fill with rock drill oil when necessary.	Weekly
Entire unit	Clean all compressors thoroughly at least once a month. Dirt, oil, grease, and other materials should be cleaned off the compressor and surrounding area. Compressors tend to lose oil around piping, fittings, and shafts; therefore, diligent cleaning is required by the maintenance operator to ensure proper and safe operation.	Monthly

10-5 LUBRICATION.

Proper lubrication prevents damage to wearing surfaces, reduces the maintenance required, and cuts power costs and equipment outages. The instructions that follow list the recommended lubricants for various uses. Directions for lubricating specific equipment are presented in tabular form and, where desirable, are repeated in the text that applies to the specific equipment items. These instructions may be modified by the operator to meet individual situations, but in general, such modifications require the approval of the utility manager.

10-5.1 Types of Lubricants.

Oils, greases, and preservatives for waterworks are listed in Table 10-7. This list does not contain all the lubricants available under military specifications, but it has been developed to establish good lubrication practice for normal operating conditions with as few good lubricants as is feasible. Following Table 10-7 and Table 10-8 (a list of uses for oils and greases) does not relieve the operator from using lubricants that meet the requirements of the equipment manufacturer’s recommendations. The information in Table 10-7 should be familiar to all maintenance and operating personnel. This list is subject to modification at the judgment of maintenance personnel, providing the modification is approved by the utility manager.

Table 10-7 Lubricating Oils, Greases, and Preservatives

Product	Military Specification Number	Symbol	Approximate SAE Grade (a)	National Stock Number (b)	Temperature Range
Lubricating oil, general purpose	MIL-L-15016A	2075 2110(c) 2135 2190 2250 3050(c) 3065 3080 3150	20W 10W-75W 20W-75W 30W 40W 20W 30W-80W 40W-90W 140W	-- 9150-00-223-4137 9150-00-231-6664 9150-00-231-6639 -- 9150-00-223-4138 -- 9150-00-223-8890 9150-00-240-2258	10 °F (-23 °C) 0 °F (-18 °C) 0 °F (-18 °C) 35 °F (2 °C) 35 °F (2 °C) 0 °F (-18 °C) 5 °F (-15 °C) 15 °F (-9 °C) 25 °F (4 °C)
Lubricating oil, compounded	MIL-L-15019B	4065 6135 8190	40W 140W 30W	9150-00-243-3196 9150-00-231-6645 9150-00-231-9033	35 °F (2 °C) 60 °F (16 °C) 35 °F (2 °C)
Lubricating oil, mineral, cylinder	MIL-L-15018B	5190	140W	9150-00-240-2260	60 °F (16 °C)
Lubricating oil, stream turbine (noncorrosive)	MIL-L-17331B	2190TEP	30W	9150-00-235-9061	60 °F (16 °C)
Lubricating oil, internal combustion engine, subzero	MIL-L-10295A	OES	--	9150-00-242-7603	-65 to 0 °F (-54 to -18 °C)
Lubricating oil, instrument jewel-bearing, nonspreading low temperature	MIL-L-3918	OCW	--	9150-00-270-0063	-40 °F (-40 °C)
Lubricants; chain, exposed-gear and wire rope	VV-L-751A	CW-11B	--	9150-00-246-3276	All
Lubricating oil, internal combustion engine	MIL-L-2104A	OE-10 OE-30 OE-50	10W 30W 50W	9150-00-265-9425 9150-00-265-9433 9150-00-265-9440	-20 °F (-29 °C) 0 °F (-18 °C) 15 °F (-9 °C)

Product	Military Specification Number	Symbol	Approximate SAE Grade (a)	National Stock Number (b)	Temperature Range
Grease, automotive and artillery	MIL-G-10924A	GAA	--	9150-00-190-0907	-65 to 125 °F (-54 to 52 °C)
Grease, ball and roller bearing	MIL-G-18709	BR	--	9150-00-249-0908	125 to 200 °F (52 to 93 °C)
Grease, graphite	VV-G-671C	GG-1	--	9150-00-272-7652	125 °F max. (52 °C)
Lubricating oil, internal combustion, preservative	MIL-L-21260	PE-1	--	9150-00-111-0208	
Lubricating oil, preservative, medium	--	PL-MED	--	9150-00-231-2356	
Corrosion preventive, petroleum, hot application	MIL-G-11796A	CL-3	--	8030-00-231-2353	
Corrosion preventive, compound, solvent cutback, cold application	MIL-C-16173B	CT-1	--	8030-00-231-2362	

(a) SAE numbers 10W through 50W are for crankcase lubrication. SAE numbers 75W through 140W are for transmission lubrication.

(b) National stock numbers are for 5-gallon containers for lubricating oils and 35-pound containers for grease, except 1/2-ounce can for MIL-L-3918. For other containers see Federal Supply Catalog.

(c) Quenched.

10-5.2 Lubricant Uses.

Different authorities may make conflicting lube recommendations for essentially the same item; however, general reference material is available to help select the correct lubricant for a specific application.

Grease is graded on a number scale, or viscosity index, by the National Lubricating Grease Institute. For example, No. 0 is very soft; No. 6 is quite stiff. A typical grease for most treatment plant applications might be a No. 2 lithium or sodium compound grease, which is used for operating temperatures up to 250 degrees F (120 degrees C).

A list of uses for lubricants that are generally satisfactory when used on equipment operating under normal ranges of temperature, pressure, and corrosion is contained in Table 10-8. However, in view of the wide variation in characteristics of equipment and conditions of operation, the manufacturer's instructions for lubrication should be checked to make sure that listed lubricants meet the requirements of the manufacturer's recommended lubricants.

Table 10-8 Lubricating Oil and Grease Uses

Equipment	Oil or Grease Symbol
Air compressors Vertical with splash lubrication	 2110, 3050
Gage pressure less than 100 psi	2135, 2190, 3050
Gage pressure greater than 100 psi	2135, 2190, 3050
Horizontal External lubrication, sight feed, wick feed, hand oiling.	 2135, 2190, 3050
External lubrication, circulating system or splash type crankcase	2110, 2135, 3050
Cylinders Wet conditions	 8190
Dry conditions	2190. 2250, 3065
Bearings Ball, all temperatures to 200 °F (93 °C)	 BR
Ball, low-pitch line speed Operating temperature below 32 °F (0 °C)	 2075
Operating temperature 32 to 150 °F (0 to 66 °C)	2190, 2250, 3065

Equipment	Oil or Grease Symbol
Ball, medium-pitch line speed Operating temperature below 32 °F (0 °C)	2075
Operating temperature 32 to 150 °F (0 to 66 °C)	2135, 3050
Ball, high-pitch line speed Operating temperature below 32 °F (0 °C)	2075
Operating temperature 32 to 150 °F (0 to 66 °C)	2110, 3050
Ring-oiled, small, miscellaneous	2110
Kingsbury thrust bearing	2190 TEP
Thrust (other than Kingsbury, subject to water)	4065
Thrust (other than Kingsbury, not subject to water)	2135, 2190
Bronze guide	GAA
Countershaft	CG-1
Differential (enclosed)	3150, 5190, 6135

Roller (enclosed)	Winter 2075; Summer 3065

Equipment	Oil or Grease Symbol
Roller (semi-enclosed)	Winter 3080; Summer 6135
Slow-speed	CW-IIB
Medium-speed	5190
Chemical feeders	See manufacturer's instructions.
Clarifier equipment	Do
Couplings	6135
Drive jaw clutch	OE50
Gear case or gear head	Low temperature 3080; High temperature 5190
Gears Herringbone	 Winter 2075; Summer 3065
Helical	Do
Motor reducers	Winter 3050; Summer 2135
Open	5190
Planetary	Winter 2075, 2110; Summer 2135
Worm and pump transmission	Winter 3080; Summer 6135
Instruments	OCW
Motors	See manufacturer's instructions.
Packing, sludge pumps	4065, 6135
Pumps	See manufacturer's instructions.

Equipment	Oil or Grease Symbol
Seal packings	GAA
Shafting Large	 2190, 3065
Small	2110, 2135, 3050
Shear pins	WB
Sheaves	CG-1, GAA
Solenoid oilers	3050
Valve stems	GAA

10-5.3 Lubricating Precautions.

To avoid plant failures due to improper lubrication, take the following precautions:

- Do not over lubricate. Over lubrication causes antifriction bearings to heat and may damage grease seals; it may also cause damage to the windings in electric motors.
- Do not lubricate totally enclosed or insufficiently guarded equipment while the equipment is in motion.
- Temperature compatibility of grease and service duty required for equipment is critical. Equipment manuals must be specifically checked for proper lubricants as recommended and authorized by the equipment manufacturer.

10-5.3.1 Overfilling.

Every operator should be aware of the dangers of overfilling with either grease or oil. Overfilling can result in high pressures and temperatures, and ruined seals or other components. It has been observed that more antifriction bearings are ruined by over greasing than by neglect.

10-5.3.2 Temperature.

A thermometer can tell a great deal about the condition of a bearing. Ball bearings generally are in trouble above 180 degrees F (82 degrees C). Grease-packed bearings typically run 10 to 50 degrees F (5 to 30 degrees C) above ambient temperature

10-5.4 Lubricating Procedures.

Lubricate greased bearings as follows:

a. Shut off, lock out, tag, and block the unit if moving parts that might be a safety hazard are close to the grease fitting or drain plugs.

b. Remove the drain plug from the bearing housing.

c. Remove the grease fitting protective cap and wipe off the grease fitting. Be sure that you do not force dirt into the bearing housing along with the clean grease.

d. Pump in clean grease until the grease coming out of the drain hole is clean. Do not pump grease into a bearing with the drain plug in place. This could build up enough pressure to blow out the seals.

e. Put the protective cap back on the grease fitting.

f. With the drain plug still removed, put the unit back in service. As the bearing warms up, excess grease will be expelled from the drain hole. After the unit has been running for a few hours, the drain plug may be put back in place. Special drain plugs with spring-loaded check valves are recommended because they will protect against further buildup.

10-5.4.1 Flushing and Repacking.

Generally, the time between flushing and repacking for greased bearings should be divided by 2 for every 25 degrees F (14 degrees C) above 150 degrees F (65 degrees C) operating temperature. Also, generally, the time between lubrications should not be allowed to exceed 48 months because lube component separation and oxidation can become significant after this period of time, regardless of amount of use.

Another point worth noting is that grease is normally not suitable for moving elements with speeds exceeding 12,000 in. per min. (5 mps). Usually, oil lubricating systems are used for higher speeds. Lighter viscosity oils are recommended for high speeds, and, within the same speed and temperature range, a roller bearing normally will require one grade heavier viscosity than a ball bearing

10-5.4.2 Lubricant Storage and Use.

Keep lubricant containers tightly closed, except when in use, to prevent contamination of the lubricant by the entrance of dust, grit, and abrasives. Store lubricants in dust-free areas. Before using lubricant containers, wipe the spouts and lips; before using grease guns, wipe the gun and fitting to ensure the absence of foreign matter.

A good rule of thumb is to change and flush oil completely at the end of 600 hours of operation or 3 months, whichever occurs first. More specific procedures for flushing and changing lubricants are outlined by most equipment manufacturers.

10-5.4.3 Proper Lubricant System Inspection and Choices.

For clarifier drive units, which are almost always located outdoors, condensation presents a dangerous problem for the lubrication system. Most units of current design have a condensate bailing system to remove water from the gear housing by displacement. These units should be checked often for proper operation, particularly during seasons of wide air temperature fluctuation.

Pumps incorporate many types of seals and gaskets constructed of combinations of elastomers and metals. As for lubricants, conflicting advice can be obtained. A file containing data on general properties of materials used can help in the choice of lubricant.

10-5.5 Grease Fittings.

The same grease gun fitting should be provided on all lubrication points requiring the same grease. This practice reduces the number of grease guns required, keeps the use of improper lubricants to a minimum, and simplifies operation.

10-5.6 Identifying Lubricant Items.

The product symbol and identifying color should be marked on lubricant containers and grease guns and at or near all oil cups and grease fittings to ensure the choice of the proper lubricant for that location.

Best practice information on lubricants can be found in the publications listed in *Plant Engineering Magazine's Exclusive Guide to Interchangeable Industrial Lubricants* and *Plant Engineering Magazine's Exclusive Guide to Synthetic Lubricants*.

10-6 COMBUSTION ENGINES.

Few water system operators repair gasoline- or diesel-powered engines. However, several inspections and routine procedures are needed to ensure that these engines are well maintained. A checklist of these procedures can be found in the manufactures O&M manual for the equipment.

10-7 CHEMICAL STORAGE AND FEEDERS.

Different chemical feeders work on different principles. Each water treatment facility will require several chemical feeders to accurately control chemical application to the process. Some general information is provided in this chapter and in Chapter 4 under process headings that require use of chemical feeders. Always read and follow the manufacturer's instructions for mechanical equipment. DOD facilities must comply with

Fluoridation at DoD Owned or Operated Potable Water Treatment Plants. For best practice information, use *AWWA M4.*

10-7.1 Lime Slakers.

a. Clean the dust-removal and the vapor-removal equipment during every shift. Make sure that dust and moisture do not reach the chemical feeding mechanism and cause caking or corrosion. Remove clinkers or grit not removed by regular operations.

b. While the slaker is out of service each week, clean grit out of each compartment. Wipe off the outside of the slaker with an oily rag. (The thin film of oil prevents the adherence of moisture or lime solution and thus protects paint.) Clean the vapor-removal system and check the mechanism for proper functioning. Clean all appurtenances.

c. Each month, check agitators, stirrers, and heat exchangers; replace any impellers on baffles in front of the heat exchanger that show appreciable wear. Inspect and repair, or replace as necessary, all wiring defects or metal deteriorations. Tighten bolts, eliminate vibration, tighten belts, and paint the equipment where necessary. Every 1,000 to 1,500 hours, lubricate the support bearing-drive with grease (do not use oil).

d. Overhaul lime slakers each year. Drain and clean the slaker and dust-removal system. Check the slaker bottom and sides for wear and repair them as necessary. Paint the exterior and inside top edges of the slaker lids to protect them from corrosion. Check for leaks and scale in the heat exchanger. Clean the thermometers and check their accuracy. Clean and lubricate all bearings. Repair controls, floats, piping, screens, valves, and vapor-removal equipment. Paint all equipment where necessary

10-7.2 Gas Chlorinators.

The operator should be familiar with the equipment to be maintained. An instruction book is furnished with every chlorinator; consult it for specific steps to follow in servicing. Should the book be lost, the manufacturer can supply a duplicate (as long as the model and serial numbers are included with the request for replacement). Follow the manufacturer’s suggestions for O&M. This paragraph offers general maintenance procedures that apply to all gas chlorinators. A troubleshooting chart for solution-feed, vacuum-operated gas chlorinators is included as Table 10-9. General maintenance procedures for chlorination equipment are summarized in Table 10-10.

10-7.2.1 Inspect Chlorinator for Leaks.

Examine the chlorinator and all piping for chlorine or water leaks each day. All chlorine leaks are serious because they increase rapidly in size and cause extensive corrosion and damage. Red discoloration at gas header connections means a leak is corroding the fittings. Use an ammonia-water bottle to locate the chlorine gas leak. Do not pour ammonia water on the suspected leak. Rather, waft the open bottle near the suspected leak. If chlorine vapor is present, a dense white cloud will appear. Use litharge and glycerin cement or Teflon tape in making all metal-threaded pipe connections. Do not use grease or oil.

10-7.2.2 Operate the Chlorine Valves.

Open and close all chlorine valves each day to ensure proper and complete operation. Do not use force in closing a valve. Repair or replace any faulty valves at once.

10-7.2.3 Check the Water System.

Each month clean the water strainers and check the pressure-reducing valve for proper operation. Clean the injector nozzle and throat once a year. (Insufficient injector vacuum usually indicates that cleaning is required.) Muriatic acid may be used for cleaning mineral deposits from the injector nozzle and throat.

10-7.2.4 Check the Gas System.

Check all piping and parts carrying chlorine gas to verify they are operating properly. Check flexible connectors at the gas-supply containers. (To maintain a gas-tight seal, use a new lead gasket each time a valve or tube is connected, including each time an empty chlorine cylinder is replaced.) Remove and clean gas filters periodically. Check the heater each day to make sure it is warm. Verify that the metering devices, pressure-reducing and shutoff valves, hose lines, and gauges all work properly. Disassemble and clean when necessary to determine the cause of the fault. At the first sign of weakening, replace any faulty parts.

10-7.2.5 Clean the Cabinet and Critical Working Parts.

Thoroughly clean the chlorinator cabinet, glass parts, flowmeter, rate valve, vacuum regulator valve, and other parts in which dirt may interfere with operations or make equipment unsightly. Clean and cover unpainted metal that is subject to corrosion with a proper protective coating.

Table 10-9 Troubleshooting Checklist for Solution-Feed, Vacuum-Operated Gas Chlorinators

Symptom	Possible Cause
Flowmeter fails to indicate gas flow.	Gas supply valve closed.
	Gas supply cylinder(s) empty.
	Insufficient ejector vacuum.

Symptom	Possible Cause
	Filter in gas-inlet connection block dirty. Dirty flowmeter.
	Rate valve closed. Rate valve dirty.
	Air leakage in regulator stack.
	Vacuum regulator valve plug stuck in closed position.
Ejector vacuum is insufficient.	Ejector water supply valve closed. Solution line valve closed.
	Dirty strainer.
	Dirty ejector.
	Partially or fully blocked solution line.
	Ejector throat not full of water (applies only when ejector is mounted in horizontal position and back pressure is zero or less).
	Insufficient water supply flow rate and pressure for existing back pressure conditions. Drain valve leaking air.
	Insufficient pump discharge pressure.
Gas flow rate cannot be controlled.	Condensed gas vapor (liquid chlorine) in chlorinator. Dirty vacuum regulator valve.
	Air leakage in regulator stack.
	Insufficient ejector vacuum.
Maximum gas flow rate produces too low a residual in the treated process liquid	Chlorinator capacity too low.
	Air leakage caused by dirty sealing surfaces.

Symptom	Possible Cause
Minimum gas flow rate produces too high a residual in the treated process liquid.	Chlorinator capacity range too high.
Flowmeter continues to indicate flow when ejector water supply valve is closed.	Condensed gas vapors (liquid chemicals) in chlorinator.
	Vacuum regulator valve stuck in the open position.
	Solution line draining due to a back pressure of zero or less.
	Ball stuck in flowmeter.
Water leaks from ejector into gas line.	Diaphragm backflow check valve not seating properly.

Table 10-10 Maintenance Checklist for Chlorination Equipment

Inspection	Action	Frequency
Operation maintenance	Insert a new lead gasket in the chlorine valves or tubes to cylinders or equipment.	Variable
Condensation on chlorine cylinders	Ventilate.	Variable
Chlorine leak detection	Use an unstopped bottle of aqua-ammonia to detect leaks; repair immediately.	Daily
Gas system	Disassemble, clean, and replace faulty parts in piping, meters, valves, and tubing.	Daily
Chlorine valves	Open and close valves to assure that all are operable; check stuffing boxes and repair or replace faulty valves or packing.	Daily
Chlorine solution tubes	Look for location of potential leaks, and for iron and manganese deposits; if iron or manganese are present, treat with a solution of hexametaphosphate in makeup water.	Annually
Chlorine feeder water supply	Clean water strainers and pressure reducing valves; adjust float valves and ejector capacity.	Monthly

Inspection	Action	Frequency
Hard-rubber threads, valves and parts	Disassemble or operate; use graphite grease to prevent freezing; hand tighten only—do not use tools.	Quarterly
Vacuum relief	Clean out any obstruction.	Daily
Cabinet and working	Clean all parts where accumulation may interfere with proper operation.	Weekly
Overhaul	Disassemble and clean all parts thoroughly; paint cabinet inside and out; examine parts and repair or replace as needed; use care in choice of cleaning agents and lubricants.	Annually
Direct-feed chlorinators	Use same procedures as for solution-feed machine where they apply.	

10-7.3 Liquid Chlorine Evaporators.

The chlorine vessel on the inside of the evaporator and the water bath mechanism are the primary components requiring maintenance. The chlorine vessel is subject to internal corrosion from chlorine and external corrosion from the water bath. The chlorine vessel and the water bath are normally cleaned and inspected every 2 years or after evaporating 250 tons of chlorine, whichever occurs first. The sacrificial anodes in the cathodic protection system in the evaporator should be replaced when the evaporator is taken apart for cleaning and inspection. Follow these steps to clean the evaporator.

a. Dismantle and remove the chlorine vessel from the evaporator.

b. Flush the chlorine vessel with cold water to remove corrosion products from the inside.

c. Visually inspect the interior for pitting. If pitting is severe, replace the chlorine vessel.

d. Remove all flushing water and reassemble the evaporator.

e. Fill the water bath and heat it to 180 degrees F (82 degrees C). Attach an aspirator so that a vacuum can be exerted on the inside of the chlorine vessel. The vacuum should be about 25 in. (635 mm) of mercury and held for 24 hours with the water bath at 180 degrees F (82 degrees C) to make sure that all moisture is removed from the inside of the chlorine vessel.

10-7.4 Hypochlorite Solution Feeders.

a. Hypochlorite solutions are highly alkaline. The reaction of this alkaline material with the hardness in the makeup water results in carbonate scale deposits in the pump head and tubing and in the solution diffuser at the point of application. Dilute (5%) hydrochloric (muriatic) acid solution can be pumped through the hypochlorinator to remove this scale. Be sure to flush out the hypochlorite solution with water first.

b. The diaphragm continually flexes. Inspect it to make sure it operates properly.

c. Check valves and seats for corrosion, hardening, swelling, scale, or foreign material that might prevent proper seating.

10-7.5 Dry Chemical Feeders.

Maintenance procedures for dry chemical feeders are summarized in Table 10-11.

Table 10-11 Maintenance Checklist for Dry Chemical Feeders

Inspection	Action	Frequency
Dry feeders	Remove chemical dust accumulations; check feeder performance; check for loose bolts; clean solution tank of accumulated sediment; lubricate moving parts.	Daily
Drive mechanisms and moving parts	Service and lubricate.	Quarterly
Calibration	Check feed-rate accuracy and adjust, as necessary	Monthly
Overhaul feeders	Thoroughly clean feeder and feeding mechanism; paint; service and lubricate drive mechanisms and bearings; clean and paint solution tanks.	Annually
Feeders out of service	Clean; remove all chemicals from hopper and feeder mechanisms.	Variable
Disc feeders	Clean rotating disc and plow.	Variable
Oscillating feeders	Check and adjust mechanism and adjustable stroke rod.	Monthly
Rotary gate feeders	Clean pockets of star feeder and scraper.	Monthly
Belt-type feeders	Check vibratory mechanism, tare-balance, feeding gate, belt drive and belt; calibrate delivery.	Monthly
Loss-in-weight feeders	Check feeder scale sensitivity, tare-weight, and null balance.	Monthly
Screw feeders	Clean screw, check ratchet drive or variable speed drive.	Monthly
Dust collectors		
Motors	Lubricate motors	Variable
Filter bags	Check condition and attachment. Securely attach sound bags; replace damaged or torn bags.	Variable

10-7.6 Test Calibration.

Make monthly calibrations to check the accuracy of feed-rate and control mechanisms. Indicate or record feed rates and amounts. The test procedures in Table 10-12 apply to various feeders.

Table 10-12 Calibration Tests for Dry Chemical Feeders

Inspection	Action	Frequency
Volumetric dry feeders		
Test calibration and adjust feeder	Perform the test described below for your type of volumetric dry feeder (with or without scale) and repeat several times.	Weekly
	Average the data from several tests to compare with the rate setting, rate indicator, and recorder (if one is used). Take particular care in the timing and weighing operations.	
	Make any adjustments necessary to bring the feed rate within ± 5% by weight of the rate setting.	
Feeders not on a scale	Make at least three tests within the normal operating range of the feeder.	Weekly
	Use a pan or other container of known weight to catch the discharge of the feeder for a definite period. Weigh the discharged material, calculate the rate of feed per hour, and compare the results with the rate setting, rate indicator, and recorder (if one is used).	
Feeders on a platform scale	Balance the scale or record initial reading while the feeder is stopped; start the feeder and run for a definite period; rebalance the scale (i.e., record weight loss).	Weekly

Inspection	Action	Frequency
	From the difference in the two scale readings, calculate the amount fed in the measured time and then calculate the feeding rate in pounds per hour.	
Belt-type gravimetric feeders	Calibrate weekly or whenever the feeder is used for a different chemical.	Weekly or Variable
Clean belt and feeder	Clean according to manufacturer's instructions	Weekly or Variable
Set initial balance	Balance the scale and operate the feeder until the feeder scale beam is in full balance and indicates a proper load on the belt. If the feeder is proportionally paced, set the proportioning equipment on "manual control." Set the rate-of-feed at maximum and proceed with the following calibration test.	Weekly or Variable
	Stop the feeder and make sure the scale moves freely and is in exact balance.	
	Adjust the amount of chemical on the belts by adding or removing chemical at the rear of the belt, until an exact balance is obtained.	
	Zero the belt revolution counter or weight integrator, start the feeder, and run it until a definite weight of chemical has been discharged (about two-thirds of a belt load). Then stop the feeder.	

Inspection	Action	Frequency
Determine weight of material discharged	Rebalance the scale precisely.	Weekly or Variable
	The difference between this scale reading and the one taken during the test is the weight of material discharged.	
Compare balance and revolution counter; adjust poise if necessary	Check the calculated amount of material discharged against the number of pounds fed as indicated by the revolution counter. If the weight of the chemical delivered differs from that indicated by more than + 1%, adjust the poise on the scale beam and repeat the test. (Moving the poise to a lower value reduces the loading on the belt and vice versa.)	Weekly or Variable
	Repeat testing and adjustment until a belt loading is found that agrees with the amount fed, as indicated by the totalizer counter.	
	Note: Some belt type gravimetric feeders may be made to discharge into a container of known weight, in which the feed rate may be checked by actually weighing the amount discharged at a definite time.	
Loss-in-weight gravimetric feeder	Test calibration of this feeder is similar to the test calibration method used for the belt-type gravimetric feeder.	Weekly or Variable
	When the feeder is empty, check the tare weight to make sure that the scale shows 0 weight. All other determinations and adjustments are similar to the belt-type gravimetric feeder described above.	

10-7.7 Solution Feeders.

Maintenance procedures for solution feeders are summarized in Table 10-13.

Table 10-13 Maintenance Checklist for Solution Chemical Feeders

Inspection	Action	Frequency
Pot feeders		
Flow through pot	Determine amount of chemical fed to ascertain if flow through pot is effective.	Daily
Sediment trap	Clean trap and check needle valve.	Monthly
Chemical pot	Clean pot and orifice.	Semi-annually
Overhaul	Clean and paint pot feeder and appurtenances.	Annually
Differential solution feeders		
Chemical storage tank	Inspect and clean.	Semi-annually
Oil volume	Check and replenish.	Semi-annually
Pitot tubes and needle valve	Check and replace as necessary.	Annually
All equipment	Paint as necessary.	Variable
Decanter feeders		
Swing-pipe	Check to make sure it does not bind.	Monthly
Motor ratchet, pawl, reducing gears	Check and lubricate.	Semi-annually
Overhaul	Inspect, clean, repair, and paint all parts as necessary.	Annually or Variable
Rotating dipper feeders		
Motor	Follow manufacturer’s instructions	Variable
Transmission	Change oil after 100 hours of operation.	Every 100 hours
Shaft bearings	Lubricate.	Weekly

Inspection	Action	Frequency
Drive chain	Clean, check alignment; check sprocket teeth; lubricate chain and sprockets.	Monthly
Agitator	If used, clean and lubricate according to manufacturer's instructions.	Variable
Belt drives	Check alignment, tension, and inner cords of belt drives.	Monthly
Dipper and float valve	Check dipper clearance and adjust float valve setting	Semi-annually
Proportioning pumps Operator's inspection	Inspect sight feeders, rate of flow, piping, joints.	Daily
Feeder	Clean feeder.	Weekly
Solution tank	Clean	Monthly
Linings	If cracks occur, special linings should be repaired.	Annually
Overhaul	Disassemble, clean, and overhaul.	Annually

10-8 TANKS AND RESERVOIRS.

Water storage facilities are maintained according to the procedures listed in Table 10-14. The following paragraphs cover the activities involved in painting tanks: surface preparation, paint application methods, and paint selection. Best practice information on tank inspection, painting, and maintenance can be found in *AWWA M51*.

Table 10-14 Maintenance Checklist for Storage Facilities

Inspection	Action	Frequency
Complete inspection	Drain, clean, and examine interior surfaces. Repair as required. Disinfect before returning to service.	Every 3 to 5 years
Foundations, wood	Check for settlement, cracks, spalling, and exposed reinforcing; repair as necessary with 1 part cement to 1 part sand.	Semi-annually
Foundations, concrete	Check wood foundations and pads for checked, split, rotted or termite-infested members; also check for direct contact of untreated wood with soil. Repair or eliminate undesirable conditions as necessary.	Semi-annually
Concrete tanks (ground-level storage)	Check exterior for seepage; mark spots.	Semi-annually
Walls	Check exterior and interior for cracks, leaks, spalling, etc.	Annually (Spring)
	Remove loose, scaly, or crumbly concrete; patch with rich cement grout; paint grout with iron waterproofing compound.	Annually
	Chip out cracks and repair with cement slurry.	Annually
	For cracks in prestressed tanks, consult designing and, or, erecting company.	Annually
Expansion joints	Check for leakage; check for missing filler; clean and repair as necessary.	Semi-annually
Roofs	Check condition; check hatches; check screens on openings. Clean as necessary.	Semi-annually

Inspection	Action	Frequency
Earth embankments	Check for erosion, burrowing animals, improper drainage, and leakage through embankment. Repair as necessary. If leakage through the embankment exists, drain tank and look for cracks in tank walls or bottom.	Semi-annually
Concrete tanks (underground storage)	Check interior walls, roof, appurtenances and embankment; if leakage is evident, excavate and repair walls.	Semi-annually
Concrete tanks (elevated storage)	Check and repair.	Semi-annually or Annually
Steel tanks (ground-level storage)	Check for ice damage in spring; repair as necessary.	Annually
Walls and bottom	Examine exterior and interior for rust, corrosion products, loose scale, leaky seams, and rivets and for condition of paint.	Semi-annually
	Replace rivets or patch leaking areas, as necessary.	Variable
	Check painted surfaces for deterioration; paint as necessary.	Semi-annually
Roofs	Check condition, hatches, screens, manholes and paint; lock hatches; remove spider rods if corroded; repair, replace, or paint, as necessary.	Semi-annually
Steel tanks (standpipes)	If problem is noted during inspection, arrange for an outside contractor to repair the steel tank.	Semi-annually
Steel tanks (underground storage)	Check tank interior, roof, and appurtenances.	Semi-annually
Steel tanks (elevated storage)	If problem is noted during inspection, arrange for an outside contractor to repair the steel tank.	Semi-annually

Inspection	Action	Frequency
Tanks	Use contractor.	Semi-annually
Tower structures	Check for corrosion and for loose, missing, bowed, bent, or broken members; loose sway bracing; misalignment of tower legs; or evidence of instability. Repair as necessary.	Semi-annually
Roofs	Check obstruction and navigation lights, hoods, shields, receptacle, and fittings for missing or damaged parts or in operation; also check lightning rods, terminals, cables, and ground connections; repair, replace, or renew; paint as necessary.	Semi-annually
Risers and heating systems	Two months before freezing weather, check riser pipe insulation and repair as necessary; also check heating system operation.	Annually
	One month before freezing weather, operate heating system for 8 hours; repair or adjust defective parts.	Annually
Cathodic protection	Check flow of current; if absent, check fuses, anodes, ground wire connections and immersion of electrodes; adjust or repair as necessary. If current flow or amperage is above desired level, adjust as necessary; make certain that connections to rectifier are not reversed.	Variable
	Check anode condition; replace as necessary.	Variable
Wooden Tanks Towers	Check for loose, missing, twisted, bowed, cracked or split pieces; also check for termite infestation, misalignment of legs, and evidence of loose sway bracing; repair and eliminate undesirable conditions; paint as necessary.	Semi-annually

Inspection	Action	Frequency
Tanks	Check operating records to make certain tank is kept filled; also check structural condition of tank for soundness, evidence of leakage, and corrosion of steel bands. Check all appurtenances, ladders, roofs, screens, etc.; make any repairs or adjustments necessary.	Semi-annually
	Paint metal parts; paint timber only if necessary for appearance.	Annually
Pneumatic tanks	Inspect air pump and motor; check operating record of time cycle; check for air leaks, if time cycle is too short; check valve operations, particularly pressure relief valves.	Quarterly
	Check tank for signs of corrosion; take steps necessary to eliminate corrosion or protect against it.	Annually
Appurtenances	Check ladders, walkways, guardrails, handrails, stairways, and risers for rust, corrosion, poor anchorage, missing pieces, general deterioration or damage; replace or repair parts as necessary.	Semi-annually
Miscellaneous appurtenances	Check all electrical connections and conduits leading to tanks; make any repairs or adjustments necessary.	Semi-annually
Grounds	Check for accumulations of debris, trash, and foliage; clean the area.	Semi-annually

10-8.1 Paint Systems for Steel Storage Tanks.

10-8.1.1 Surface Preparation.

Good surface preparation is required to ensure adequate bonding of the paint to the metal to be protected. See Chapter 10 “Paint Application Methods.”

a. If the original surface preparation was poor and the mill scale was not removed when the tank was originally painted, blast cleaning is required before repainting. If the original surface preparation was adequate, but the old paint has completely broken down, blast cleaning of areas with loose or failing paint usually is warranted. If the old paint is still in good condition, only those areas with loose paint need to be removed by wire brushing or sanding.

b. All areas that have been cleaned of loose paint down to the bare metal need to be primed before rust has a chance to form. Follow Steel Structures Painting Council specifications.

10-8.1.2 Paint Application Methods.

Paint may be applied by several methods:

- Brushing
- Air spraying
- Airless spraying
- Roller application
- Special methods for applying heavy coatings.

The method best suited for application depends on the type of paint, degree of complexity of the surface being painted, paint viscosity, and other considerations, such as the amount of spray carryover with spray-painting techniques. The paint manufacturer and a professional painting contractor can advise installation personnel of the best application method for the tank being painted. Apply paint according to the instructions in *UFC 3-190-06*.

10-8.1.3 Paint Selection.

- Select protective coatings in accordance with *UFC 3-190-06*. It is normally recommended that only paints meeting *NSF/ANSI 61* be used on surfaces in contact with potable water. Environmental conditions affecting the exterior of the tank and water characteristics within the tank result in varying painting system requirements. A reputable paint manufacturer can provide valuable guidance in paint selection, based on laboratory testing results and experience with painting systems on similar tasks.
- Paint testing may be required on tanks for which a particular paint system has proven unsatisfactory. Various painting systems can be used on different areas of the tank to determine which system performs the best.
- The thickness of the dried paint film should be specified and measured after the painting has been completed. Various paints require varying dry film thickness for optimum life.

- In general, it is best to use paints that require similar surface preparation procedures for both the interior and exterior of the tank, since these procedures are usually conducted in a single operation.
- *AWWA D102* includes standards for several outside and inside paint systems. The standard gives general information on the suitability of the paint systems under varying conditions and information about surface preparation, paint film thickness, and procedures for applying paint. Paint systems used for painting tanks on military installations should meet or exceed the requirements established in this standard.

10-8.2 Cathodic Protection for Steel Tanks.

Design standards and specifications for cathodic and impressed current protection of steel water tanks may be found in *NACE SP0196* and *NACE SP0388*. For general information on corrosion of exposed and buried metals, refer to *AWWA M27*. Use *UFC 3-570-06* for the operation and maintenance of cathodic protection systems.

10-8.2.1 Limitations.

Cathodic protection is limited to structures in contact with an electrolyte, such as soil or water. In steel-elevated water storage tanks, only the inside surfaces of the riser and the submerged bowl can be protected. Protect the outside of the tank from atmospheric corrosion by some other means.

10-9 PIPELINES.

Although pipes are normally buried and out of sight, their maintenance should not be neglected. Components of a pipeline maintenance program include inspection, leak detection and repair, flushing, pigging, slip-lining, cement-mortar lining, wrapping, and cathodic protection. These and other aspects of pipeline maintenance are covered in *AWWA M51*, and *NACE SP0169*.

10-9.1 General Information.

The prevention of corrosion and surface deterioration is standard maintenance practice in waterworks. Protect all exposed surfaces, whether external or internal. Protective coatings and linings may be nonmetallic or metallic. The former includes paint, enamel, bitumen, cement, plastic, and rubber. Metallic coatings include zinc, aluminum, and lead. Other corrosion-control treatments are used on metal equipment surfaces that cannot be painted. Cathodic protection is used where electrolytic corrosion occurs.

10-9.2 Paint Protection.

Surface coating with paint is the most general method of corrosion prevention. Try to select paint to meet the existing conditions; the choice depends on if the equipment or structure is indoors or outdoors.

10-9.3 Paint Application.

Prepare and apply surface paints according to the procedures detailed in *UFC 3-190-06*.

10-9.3.1 Surface Preparation.

Before applying the paint, prepare all surfaces. Foreign substances on the surface interfere with the protective action of the coating. Therefore, remove loose scale, rust, dust, oil, or grease completely. For best results, paint only clean surfaces. Sandblast metal surfaces if required. Use sandpaper or a wire brush where required. Wipe off dust and clean greasy or oily surfaces with solvent cleaners. Take special precautions when removing lead-based paints. See *UFC 3-190-06*.

10-9.3.2 Preparation of Paint.

Paint should be mixed properly and screened, if necessary, to remove grit and film. Cover paint containers when not in use. Clean brushes, rollers, and spray applicators before and after use. For damp surfaces where drying temperatures are less than 40 degrees F (4 degrees C), specially prepared paints are normally used.

10-9.4 Corrosive-Preventative Compounds.

Corrosion-preventive compounds are used in pits, pump dry-wells, and damp areas. Paint does not serve this purpose. Table 10-7 shows two corrosion-preventive compounds commonly used in waterworks.

10-10 CHAIN DRIVE.

Chain drives may be designed for slow, medium, or high speeds. Follow these steps to maintain chain drives:

10-10.1 Check Operation.

Check general operating conditions during regular tours of duty.

10-10.2 Check Chain Slack.

The correct amount of slack is essential for proper chain drive operation. Unlike belts, chains should not be tight around the sprocket. When chains are tight, working parts carry a much heavier load than necessary. Too much slack is also harmful. A properly installed chain has a slight sag or looseness on the return run. All drive chains should have a tightener.

10-10.3 Check Alignment.

If sprockets are not in line or if shafts are not parallel, excessive sprocket and chain wear results. To check alignment, remove the chain and place a straight edge against sides of the sprocket where no wear has occurred. Replace sprockets and chain if they are excessively worn.

10-10.4 Lubricate.

Lubrication depends on the drive speeds. Refer to the manufacturer's manual and Chapter 10 "Types of Lubricants" for lubricant types. Lubrication for different types of drives includes the following methods:

10-10.4.1 Slow-Speed Drives.

Because slow-speed drives are not usually enclosed, adequate lubrication is difficult. Heavy oil applied to the outside of the chain seldom reaches the working parts; in addition, the oil catches dirt and grit and becomes abrasive. Soak exposed-type chains in a recommended lubricant to restore lubricating film. Remove excess lubricant by hanging the chains up to drain. Do not lubricate chains on elevators, conveyers, or feeders that handle dirty, gritty material. Dust and grit combine with lubricants to form a cutting compound that reduces chain life. Do not lubricate underwater chains that operate in contact with considerable grit. If the water is clean, lubricate the chain with the recommended lubricant with a brush while the chain is running.

10-10.4.2 Medium-Speed Drives.

Continuously lubricate medium-speed drives with a drip- or sight-feed oiler. The lubricant type depends on temperature conditions.

10-10.4.3 High-Speed Drives.

High-speed drives should be completely enclosed in an oil-type case and the oil maintained at proper level. Oil type depends on temperature conditions. Drain the oil and refill the case to the proper level according to the manufacturer's recommendations.

10-10.5 Clean and Inspect:

a. On enclosed types, flush the chain and enclosure with kerosene. On exposed types, remove the chain. Soak and wash it in kerosene. Clean the sprockets, install the chain, and adjust the tension.

b. Note and correct abnormal conditions before serious damage results. Do not put a new chain on old sprockets. Always replace old sprockets when replacing a chain. Old, out-of-pitch sprockets cause as much chain wear in a few hours as years of normal operation.

10-10.6 Troubleshooting.

A troubleshooting checklist for chain drives is included as Table 10-15.

Table 10-15 Troubleshooting Checklist for Chain Drives

Symptom	Cause of Trouble	Remedy
Broken pins or rollers.	Shock leads or chain speed too high for pitch.	If speed-pitch relation is cause, use chain of shorter pitch.
Chain climbs sprockets.	Poor fit or severe overload.	If sprockets fit poorly, renew; make sure tightener is installed in drive chain.
Chain clings to sprockets.	Possibly incorrect or worn sprockets or heavy tacky lubricants.	Renew or reverse sprockets or change to proper lubricant.
Chain gets stiff.	Poor alignment or excessive overload.	Correct alignment and eliminate overload.
Chain whips.	Too long centers; or high pulsating loads.	Correct either condition.
Noise.	Misalignment; improper slack, loose bolts.	Correct alignment; adjust slack; tighten bolts; reverse or renew worn chain.
Wear on chain side walls or sides of teeth.	Misalignment.	Remove chain and correct alignment.

10-11 TOOLS AND EQUIPMENT.

10-11.1 Tool Inventory.

Effective maintenance requires that the tools needed to service the facility properly be readily available. Table 10-16 provides a list of suggested tools to keep at the facility for general maintenance use. Authorization for specific tools is issued by individual services. Specialized equipment may require specific tools. Special test equipment may also be needed. Consult the manufacturer’s instructions for such equipment needs.

Table 10-16 Suggested Tools for Water Treatment Plants

Tools	
Axes, spare ax handles Awls Bars Crow Wrecking Bit brace and assortment of bits for wood and metal Blacksmith's anvil, tools, forge, and hand blower Bolt stock and dies Breast drill and assortment of drills Calipers Inside and outside Micrometer Caulking tools, water main type (assorted sizes and types) Chisels Assorted Bull point Cape Cold Diamond point Round nose Assorted, wood Assorted, for air hammer Hand Press, bench type Star drills of various sizes	"C" clamps, assorted Cotter pin puller Countersink, assorted for wood or metal Cutters, wire Cutters, 1/2-in. (10-mm) bolt Dies, assorted for bolt and pipe threading stocks Drills, assorted 1/2-in. (13-mm) electric, portable with drill press stand mount 3/8-in. (10-mm) electric, cordless, 12-voltDrills, assorted (continued) 1/4-in. hand drill, heavy duty 1/4-in. hand drill, heavy duty Drill bits Twist drills, high speed fractional set 1/16- to 1/2-in. x 64ths Twist drills, high speed metric set 1.0-mm to 13 mm x 0.5 mm Spade bits 1/4- to 1-1/2-in. by 1/8ths (6-mm to 40-mm) Masonry bits, carbide tip, for rotary drills 1/4-in. x 4-in., 5/16-in. x 4-in., 3/8-in. x 4-in., 1/2-in. x 6-in. (6-mm x 100-mm, 8-mm x 100-mm, 10-mm x 100-mm, 13-mm x 150-mm)

Tools	
Extractors, screw, various sizes Files Assorted sizes Flat Half round Round Taper (triangular) Wood rasp Fire pot, including metal foot and wrought steel ladle for use with B and S cast iron pipe Flanging tools, for use with copper pipe Flaring tools, for use with copper pipe Fuse puller Gages Set of shims Test for pressure and vacuum Glass cutter Grinder Electric or hand, bench type Wheels, coarse, fine, and wire brush Hacksaw, adjustable frame with extra blade	Hammers Ball peen, assorted sizes Blacksmith's type Claw Mason's Caulking Sledge-type, various sizes Hatchet Jacks, screw or hydraulic, various sizes Joint runner, asbestos, for use with lead joints Lathe Metal, 12-in. (300-mm) swing, 24-in. (600-mm) centers Tools and appurtenances Lead pot and ladles Levels Line Spirit, metal frame, 18-in. (500-mm) Line, Mason Manhole-cover lifting hooks Mattock Nail sets, various sizes Oil cans, several types and sizes as required

Tools	
Packing hooks Packing tools, assorted Pipe Cutter Pipe Cutter, wheels (spare) Pipe taps Pipe thread taps (combination), 1/4- to 2-in. (6- to 50-mm) Pipe threading stock with assorted dies Pipe tripod Plane, smooth, bench, 7-in. (180-mm) Pliers Assorted sizes Diagonal cutting Gas Combination slip joint Needlenose Wrench Plumb bob Puller, gear set Punches, assorted sizes, center, drift Putty knives Reamers, hand, taper, pipe expansion Rules, 6-foot folding	Saws, rip, crosscut, compass and keyhole Screwdrivers, various sizes Saw set Saw vise Scale platform Screw pitch gage Scribers Sharpening stone Shovels Square point, long and short handle Round point, long and short handle Snake, 25-foot (8-m) spiral Soldering iron and appurtenances Specific tools for specialized equipment Square, steel, large and small Stamping tools, steel, letters and numeral Straight edge, steel Tampers Tape, 50-foot (15-m) steel Tar pot Torch, blow and gasoline

Tools	
Trowels	Wrenches
Floats, steel, and cork assorted	Adjustable, various sizes
Pointing	Allen set screw
Valve resetting tool	Box wrench set
Vises, bench and pipe, portable chain vise and stand	Hydrant
	Monkey
Voltage tester	Open end, various sizes
	Ratchet, socket set
Wall scrapers	Socket, set of various sizes
Washer or gasket cutter for making own washers	Spanner
	Stillson, various sizes
Welding outfit with appurtenances, goggles and gloves	Torque
	Valve
Wire stripper	

10-11.1.1 Tool Care and Usage.

Tools have specific uses and in general should not be used for other purposes. When the proper tool is not available, try to obtain it.

10-11.1.2 Tool Storage.

For easy retrieval, keep tools on a tool board or in a toolbox. Keep the board or box clean and, if appropriate, paint it once a year. In general, tools not in their proper places should be in use; if not, find them and return them to their proper places.

10-11.1.3 Tool Inspection.

It is a good practice to inspect tools every month. Damaged or worn tools can be replaced and edged tools (chisels, planes) kept sharp if they are regularly checked. Clean and lubricate tools before returning them to storage.

10-11.1.4 Caution and Use.

Do not use a screwdriver as a chisel, pliers as a wrench, or a wrench as a hammer. Do not use toothed-jaw (Stillson-type) wrenches on hard rubber pipe, bolts, or nuts.

10-11.2 Equipment and Supplies.

In addition to proper tools, a water treatment plant should be adequately supplied with the equipment, implements, and supplies that are essential to proper maintenance. Good housekeeping is a part of maintaining buildings and grounds and a part of operating equipment. Thus, in-house equipment and materials usually include housekeeping and gardening tools, equipment, and supplies. Table 10-17 lists the suggested implements. Table 10-18 lists materials and supplies to keep at the facility.

Table 10-17 Suggested Equipment for Water Treatment Plants

Equipment	
Alemite or zerk grease guns for plant equipment	Paint sprayer
Block and tackle for 1/2- and 3/4-in. rope (10- to 20-mm)	Pick
Boots, rubber	Rope, 1/2-, 3/4-, 1-in., 10-, 20-, 25-mm) and sash cord.
Brooms, street, ordinary, industrial	Safety equipment:
Brushes, flue, paint and whitewash, scrubbing, wire	Barricades
Caulking gun for windows	Electric blankets
Chain hoist, 1-ton (1,000-kg) capacity	First aid equipment
Electric drop light, explosion-proof with 200-foot (60-m) extension cord	Gas detector
Electric torch light, 1-1/2 or 3-volt	Gas mask (chlorine)
Flashlights, hand	Harness (safety belt) with 25 feet (8 m) x of 3/4-in. (20-mm) rope
Gloves, rubber and canvas work	Respirator for paint spraying, dust, etc.
Hydrometers, battery and alcohol	Warning signals
Ladders, step, extension (20-foot)	Squeegees, floor and window
Lanterns, red and white globe	Torches, bomb-type
Leak detectors	Two-wheel hand trucks
Manhole lifter	Vacuum cleaner
Mop and handle	Valve key
	Waste cans
	Wheel barrow, rubber-tired
	Wringer buckets

Garden Implements	
Brush hooks	Lawn mower (hand or motor)
Garden trowel	Pruning shears
Hedge clippers	Rakes, wood, steel
Hoe	Scythe
Hose: Garden type (300-foot)	Sickle
Nozzle (Shut-off type)	Spade
Insect sprayer	Sprinklers
Lawn roller	

Table 10-18 Suggested Materials and Supplies for Water Treatment Plants

Materials	
Alcohol or antifreeze	Graphite
Assortment of bolts, nuts, washers, screws, cotterpins, rivets, lock washers, cap screws, stud bolt, etc., stored in jars or cans	Grease, for lubrication
Bricks, common	Hose, nipples, and clamps for garden hose, extra
Calcium chloride (for icy pavements) Caulking compound	Iron and boiler cement
Caulking compounds, Durolite or equal, for glass house windows	Kerosene
Caulking yarn	Lead and lead wool
Cement	Light bulbs
Cement, asbestos	Measures, oil, 1-quart and 1-pint
Chain, assorted sizes and lengths	Mops
Chamois skins	Nails, assorted sizes
Cleaning powders, assorted	Oakum
Cleaning solvents (kerosene, dry-cleaning solvent, wood alcohol)	Oil for lubrication
Cups, drinking	Oil, rust removing, penetrating
Cutter wheels, spare	Packing for pumps
Disinfectants	Paint remover
Emery cloth, assorted grades	Painter's drop-clothes
Fittings, brass or iron, assorted sizes	Paints, turpentine, linseed oil, thinners, etc.
Flashlight batteries	Pipe joint compound
Fuses, assorted Glass	Pipe stock, depending on system
	Plugs, rubber expansion

Materials	
Polish, brass Putty Rags, clean and sterilized Sand, stone or gravel Sandpaper, assorted grades Soap Solder Soldering paste Spare handles for hammers, hatches and axes Spare parts for all machines and apparatus	Sponges Steel wool Tape, friction and electrician's Thermometers, assorted Toilet paper Towels Valve grinding compound Waste, wiping Wicks, for torches and lanterns Wire, annealed No. 10 and No. 16

This Page Intentionally Left Blank

CHAPTER 11 SWIMMING POOL OPERATIONS

11-1 RESPONSIBILITIES.

Water system operators typically are not responsible for the operation, purification, and sanitation of swimming pools and spas at military installations. At some Army facilities they may be required to oversee the chemical balance, regulatory monitoring, and maintenance.

For the Army, follow *TB MED 575* and *TM 5-662.*

Responsibilities generally include monitoring water chemistry and maintaining pool equipment, including filters, pumps, and valves. In addition, operators may oversee emergency and accident procedures, administrative practices, and safety measures.

11-2 OPERATIONS.

Detailed best practice information about pool equipment and management can be found in *Pool-Spa Operators Handbook*. This reference guide covers the following topics:

- Types of pools
- Filters and filtration
- Pool circulation and recirculation equipment
- Pool water sanitizing, chemical balance, water testing, management, and maintenance
- Operational problems and chemical adjustments
- Care of seasonal pools
- Disease and accident prevention

Refer to *The Complete Swimming Pool Reference* for best practice information including the monthly operating checklist for swimming pool management in Table 11-1.

Table 11-1 Monthly Operating Checklist for Swimming Pools

Monthly Inspection	Specific Procedure/Requirement
Clean chemical feeders	Follow manufacturer's recommendations for cleaning feeders. Alternatively, follow the steps outlined below: a. Turn off the feeder. b. Remove the foot valve and strainer from the chemical solution being pumped. c. Place the assembly in fresh water and pump for 5 minutes to remove all chemicals. d. Place the foot and strainer in a 10% solution of muriatic acid. Turn on the pump. Run at least 1 pint of the acid through the unit. e. Remove the assembly from the acid solution and submerge in fresh water to remove all acid from the unit. Pump fresh water for at least 5 minutes to remove all acid before returning the unit to its original chemical solution.
Check gas chlorinators	See Chapter 10 paragraph titled Gas Chlorinators.
Check filter media	For sand filters: check for mud balls, channeling, or abnormalities; rake sand clean; add or replace sand if necessary.
	For D.E. filters: check filter septa for tears or holes; repair if necessary.
	For cartridge filters: soak in a cleaner to remove excess oils.
Check safety equipment and barriers	Inspect light fixtures, electronic surveillance equipment, GFIs, and fire extinguishers.
	Check integrity of all barriers, doors, locks and latches.

11-3 MAINTENANCE.

Refer to service-specific policy statements for guidance and direction regarding the responsibilities of operating personnel in providing O&M services at swimming pools and spas. If problems occur, refer to the troubleshooting checklist provided in Table 11-2. Do not perform troubleshooting of the pool water quality before ensuring that the pH is within the proper range.

Table 11-2 Troubleshooting Checklist for Swimming Pools

Symptom	Possible Cause of Trouble	Remedy
Cloudy water	Poor coagulation and filtration	Establish correct alum dosage; backwash filters and apply fresh floc to filters; maintain proper chlorine residual.
Cloudy water: greenish	Algae: chlorine too low	Maintain proper chlorine residual.
	Copper corrosion: pH low	Adjust pH by adding soda ash; maintain Langelier saturation index within recommended range.
Cloudy water: milky	pH low	Adjust pH by adding soda ash.
	PH high in hard waters	Adjust pH by adding sodium bisulfate or dilute hydrochloric acid. (Note: Use of these chemicals is for special cases only and requires permission of base medical officer.)
	Too much alum	Reduce alum dosage.
	Defective diatomaceous earth filter element	Repair or replace.
Cloudy water: rusty	Iron corrosion: pH low	Adjust by adding soda ash; maintain Langelier saturation index within recommended range.
	Iron in makeup: poor filtration	Establish correct alum dosage; backwash filters and apply fresh floc to filters; maintain proper chlorine residual. Ensure filters are in proper operational order by conducting required inspection and maintenance.

Symptom	Possible Cause of Trouble	Remedy
Discolored side walls or bottom: green	Algae: chlorine too low	Maintain proper chlorine residual. If adjustment of chlorine residual does not adequately remove the problem, drain pool and scrub walls and bottom with 5 mg/L chlorine solution. Rinse well before refilling pool.
	Copper corrosion: pH low	Adjust pH by adding soda ash; maintain Langelier saturation index within recommended range.
Discolored side walls or bottom: rusty	Iron corrosion: pH low	Adjust pH by adding soda ash; maintain Langelier saturation index within recommended range. If problem is severe, drain pool and scrub walls with strong soap solution. If soap fails to remove stain, scrub with 2 to 5% solution of muriatic acid. Rinse well and refill pool.
	Iron in makeup: poor filtration	Establish correct alum dosage; backwash filters and apply fresh floc to filters; maintain proper chlorine residual. Ensure filters are in proper operational order by conducting required inspection and maintenance. If problem is severe, drain pool and scrub with strong soap solution. If soap fails to remove stain, scrub with 2 to 5% solution of muriatic acid. Rinse well and refill pool.
Eye irritation	pH low Chlorine high	Adjust pH by adding soda ash. Adjust chlorinator to maintain proper chlorine residual.
	Chlorine low	Adjust chlorinator to maintain proper chlorine residual.

Symptom	Possible Cause of Trouble	Remedy
Inlet flow low	Pumps not operating	Look for clogged suction or discharge lines or air leaks in suction line. Check pump switches, valves, stuffing box, and internal parts. See pump maintenance procedures in Chapter 6 paragraph titled Storage Facility Maintenance.
	Hair catcher needs cleaning	Clean.
Filter runs short Skin irritation	Too much alum pH high	Reduce alum dosage. Adjust pH by adding sodium bisulfate or dilute hydrochloric acid. (Note: Use of these chemicals is for special cases only and requires permission of base medical officer.)
Slime on sides or bottom	Chlorine too low	Drain pool and scrub walls and bottom with 5 mg/L chlorine solution. Rinse well before refilling pool. Maintain proper chlorine residual.
Water feels slippery	pH high	Adjust pH by adding sodium bisulfate or dilute hydrochloric acid. (Note: Use of these chemicals is for special cases only and requires permission of base medical officer.)

This Page Intentionally Left Blank

APPENDIX A BEST PRACTICES

A-1 MEASURING WATER LEVELS AND DRAWDOWN.

Well tests are necessary to evaluate the performance of a well. These tests include measuring the static water level, pumping rate, pumping levels at various times after pumping has started, and the increasing water levels after pumping has stopped. Measure the static level, pumping level, and drawdown on each well as often as practical. If a daily measurement cannot be made owing to a large number of wells or difficulty in taking the measurements, measure the level in each well at least twice a month at as near the same time as possible. A sample calculation for static level, pumping level, and drawdown is included below.

Orifices, meters, and pitot tubes are used to measure flow rates described in *AWWA M2 and AWWA M33.* Measure water levels using the air-line method, electric sounders, wetted tape, or electrical depth gauges. The most common method of depth measurement is the air-line method, which is explained below and depicted on Figure B-1.

a. Place an air-line of known length in a well (unless one has been permanently attached) to a depth below the expected pumping level. Connect the surface end of the line to an air pump and connect a pressure gage to the line so that air pressure in the line can be read. Make all joints airtight.

b. With the well pump shut down, apply air pressure through the air pump until the gauge needle no longer registers any increase in pressure. The gage reading then shows the amount of pressure that was necessary to force the standing water out of the air line. This is directly proportional to the height of the water standing in the well above the bottom of the air line. Multiply the gage pressure in psi by 2.31 to determine the height in feet; multiply kiloPascals by 10.1973 to obtain centimeters of water.

c. Some gauges measure feet of water in addition to air pressure; if available, use a gage that indicates feet of water. To determine the distance below the air gage at which the water stands in the well, subtract the calculated height of water above the bottom of the air line from the known length of the air-line below the well top. This value is the static level.

d. Start the well pump and observe the air gauge until the reading no longer changes, pumping in additional air to make up for any leakage. Convert this pressure reading to feet. This measurement is the height at which water stands in the well above the bottom of the air line during pumping. Deduct this value from the length of the air pipe below the well top to get the pumping level. The drawdown is the difference between the static level and the pumping level.

- Maintain careful records of static level and drawdown correlated with the capacity or pumping rate. This information can help you anticipate difficulties and provide data for proper maintenance measures:
- A falling static level indicates gradual lowering of the water table or interference by other wells.
- An increased drawdown may indicate receding groundwater level, well interference, or leaky casing or delivery pipes. Increased drawdown may also suggest a clogged, scaled, or corroded well screen; a sand- or silt-packed gravel area and adjacent stratum; or a cave-in of the water-bearing stratum.

Take measurements periodically to develop a well chart like the one shown in Figure 5-2 (Chapter 5). The pumping rate can be kept constant using a valve in the discharge line. Start the test with the valve one-half to three-fourths open at the desired flow rate. Compare well charts with prior test results to detect changes that require attention.

A-2 5/3 RULE SAMPLE CALCULATION.

Working hours required per position per year. A work position entails a commitment of 8 work hours per work position per day.

Equation A-1 Work Hours per Work Position per Day

$$\frac{8 hours}{day} * \frac{365 days}{year} = \frac{2{,}920 hours}{year}$$

Equation A-2 Paid Hours per Work Year

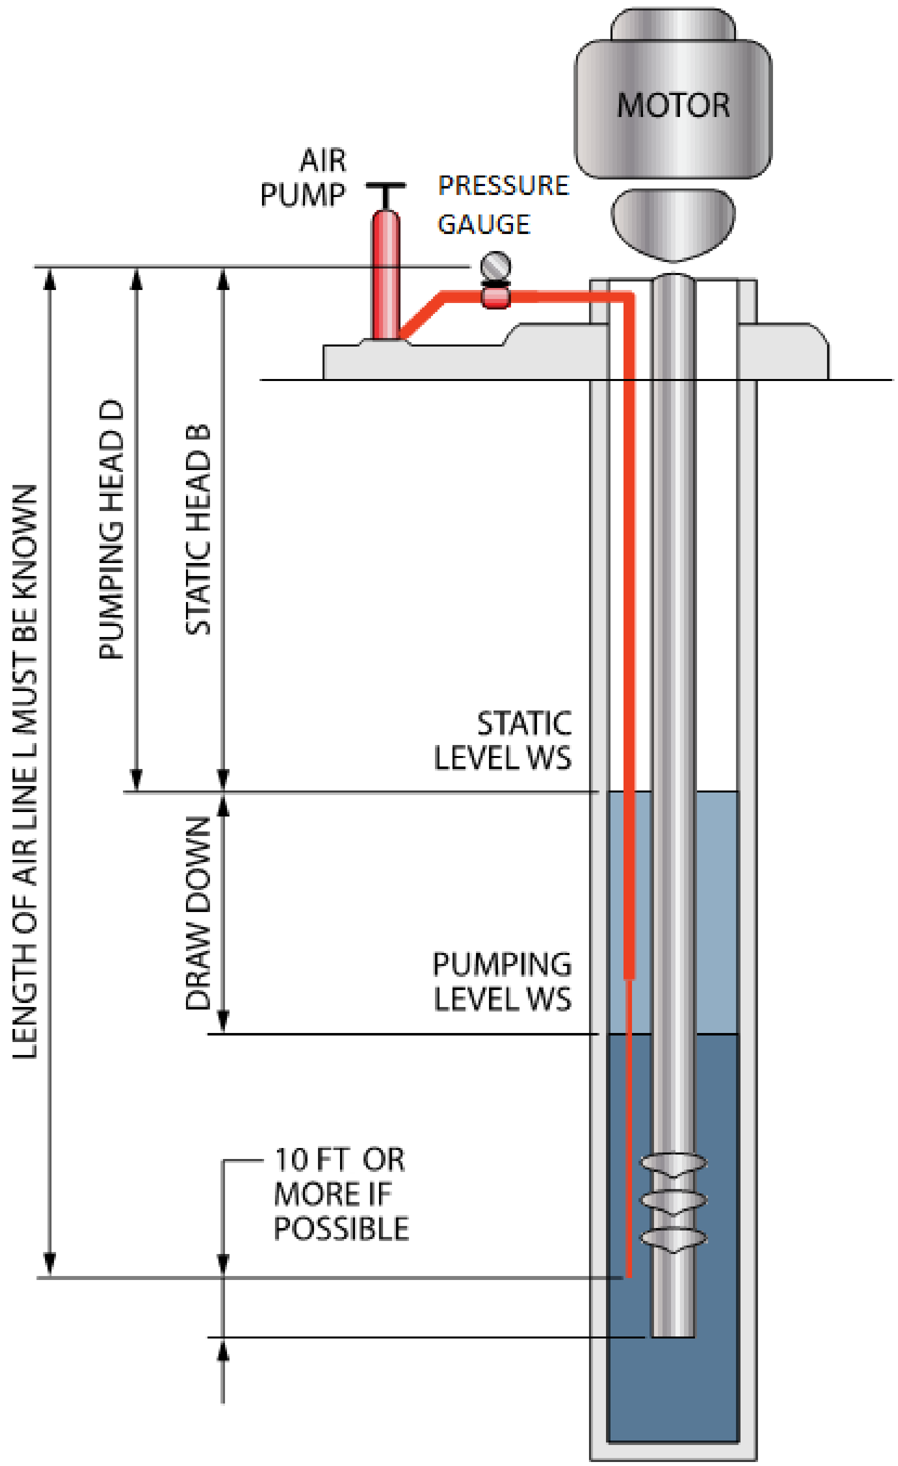
$$\frac{40 hours}{week} * \frac{52 weeks}{year} = \frac{2{,}080 hours}{year}$$

Non-productive hours typically vacation (160 hours), sick leave (40 hours), holiday (80 hours), training (48 hours): Approximately 328 hours total per year.

Equation A-3 Hours Worked per Year

$$\frac{2{,}080 hours}{year} - \frac{328 hours}{year} = \frac{1{,}752 hours}{year}$$

Figure A-1 Using Air Line to Find Depth of Water Level



Equation A-4 Number of Employees Required to Staff One Position per Shift

$$\frac{\frac{2{,}920 hours}{year}}{\frac{1{,}752 hours}{year}} = \frac{1.667 employees}{position / shift}$$

Equation A-5 Number of Employees Required to Staff One Position for Three Shifts

$$\frac{1.667 employees}{position / shift} * 3 shifts = \frac{5 employees}{position}$$

Labor Rate (actual cost to agency): Approximately $20.66 per hour.

Equation A-6 Agency Cost to Staff One Position

$$\frac{1.667 employees}{position} * \frac{2{,}080 hours}{year} * \frac{\$20.66}{hours} = \frac{\$71{,}636}{position}$$

A-3 STATIC LEVEL, PUMPING LEVEL, AND DRAWDOWN CALCULATION.

Assume a length of air line of 150 ft. Assume that the pressure gage reading before starting the pump is 25 psi. Assume that the gage reading during pumping is 18 psi.

Equation A-7 Static Water Level Calculation

$$B = L - \left(P_1 * 2.31 \frac{ft}{psi} \right)$$

Equation A-8 Pumping Level Calculation

$$D = L - \left(P_2 * 2.31 \frac{ft}{psi} \right)$$

Equation A-9 Drawdown Calculations

$$D - B = 108.4 - 92.3 = 16.1 ft$$

$$A - C = 57.7 - 41.6 = 16.1 ft$$

$$P_1 - P_2 = 25 - 18 = 7\,psi * 2.31 = 16.1\,ft$$

Where:
A = pressure before pump start expressed as ft of water
B = static water level (ft)
C = pressure during pump operation expressed as ft of water
D = pumping level (ft)
L = length of air line (ft)
P1 = pressure gauge before pump start (psi)
P_2 = pressure gauge during pump operation (psi)

A-4 METRIC STATIC LEVEL, PUMPING LEVEL, AND DRAWDOWN CALCULATION.

Assume a length of air line (L) of 45.7 m. Assume that the pressure gage reading (P1) before starting the pump is 172 kPa.

Convert pressure to meters of water (A) to determine the height of water above the bottom of the air line:

Equation A-10 Converting Pressure to Meters of Water (Metric)

$$kPa * \frac{4.0147 in.H_2O}{kPa} * \frac{0.0254m}{in.}$$

$$A = 172kPa * \frac{4.0147 in.H_2O}{kPa} * \frac{0.0254m}{in.} = 17.5m$$

Calculate the static water level (B) by subtracting the calculated height from the known airline length:

Equation A-11 Static Water Level (Metric)

$$B = L - A = 45.5 - 17.5 = 28.2m$$

Assume that the gage reading (P2) during pumping is 124 kPa. Convert this pressure to meters (C) using Equation B-10 to determine the height at which water stands in the well above the bottom of the air line during pumping:

$$C = 124kPa * \frac{4.0147 in.H_2O}{kPa} * \frac{0.0254m}{in.} = 12.6m$$

Calculate the pumping level (D) by subtracting (C) from the known length of air line using Equation B-12:

Equation A-12 Pumping Level Calculation (Metric)

$$D = L - C = 45.7 - 12.6 = 33.1m$$

Determine the drawdown using any of the following methods in Equation B-13:

Equation A-13 Drawdown Calculations (Metric)

$$D - B = 33.1 - 28.7 = 4.9m$$

$$A - C = 17.5 - 12.6 = 4.9m$$

$$P_1 - P_2 = (172 - 124) * 0.102 = 4.9m$$

Where:
A = pressure before pump start expressed as m of water
B = static water level (m)
C = pressure during pump operation expressed as m of water
D = pumping level (m)
L = length of air line (m)
P1 = pressure gauge before pump start (kPa)
P_2 = pressure gauge during pump operation (kPa)

A-5 FIELD HEAD CALCULATION.

Assume that a pressure gage located on the discharge of a well pump indicates a pressure of 35 psi for a discharge of 500 gpm. The corresponding pumping level in the well is 60 ft below the elevation of the pressure gage. The pump column is 8 in. in diameter and extends into the well 100 ft below the pump discharge.

The friction loss for 500 gpm of water through an 8-in. pipe, with a roughness coefficient (C) of 100, is 8.1 ft divided by 1,000 ft. The equivalent length of an 8-in.-long sweep elbow is 13 ft. Thus, the friction loss through the column and discharge elbow can be calculated as follows:

Equation A-14 Friction Loss Through Column and Discharge Elbow

$$113\,ft * \frac{8.1\,ft}{1{,}000\,ft} = 0.9\,ft$$

For help with head loss calculations, refer to best practice guidelines in *Water Treatment Plant Operation, Volumes 1 and 2*.

The vertical distance from the well pumping level to the pressure gage was given as 60 ft.

Equation A-15 Pressure Gage as Feet of Head

$$35\,psi * \frac{2.31\,ft}{psi} = 80.9\,ft$$

The total field head is the sum of the friction loss, vertical distance, and presence of ft of head:

Equation A-16 Total Field Head

$$0.9\,ft + 60\,ft + 80.9\,ft = 141.8\,ft$$

A-6 METRIC FIELD HEAD CALCULATION.

Assume that a pressure gage located on the discharge of a well pump indicates a pressure of 240 kPa for a discharge of 30 Lps. The corresponding pumping level in the well is 18 m below the elevation of the pressure gage. The pump column is 200 mm in diameter and extends into the well 30 m below the pump discharge.

The friction loss for 30 Lps of water through a 200-mm pipe, with a roughness coefficient (C) of 100, is 2.5 m divided by 300 m. The equivalent length of a 200-mm-long sweep elbow is 4 m. Thus, the friction loss through the column and discharge elbow can be calculated as follows:

Equation A-17 Friction Loss Through Column and Discharge Elbow (Metric)

$$34m * \frac{2.5m}{300m} = 0.3m$$

For help with head loss calculations, refer to best practice guidelines in *Water Treatment Plant Operation, Volumes 1 and 2*.

The vertical distance from the well pumping level to the pressure gage was given as 18.0 m.

Equation A-18 Pressure Gage as Feet of Head (Metric)

$$240kPa * \frac{0.1020m}{kPa} = 24.5m$$

Total field head is the sum of the friction loss, vertical distance, and pressure in feet of head:

Equation A-19 Total Field Head (Metric)

$$0.3m + 18.0m + 24.5m = 42.8m$$

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	Date	Location
1	1 May 2016	1. Updated information in 1-2, and 1-3.1. 2. Added reference to UFC 3-201-01 in paragraph 2-1. 3. Revised reference to DoD Instruction in paragraph 1-3.2. 4. Revised design requirements in paragraph 2-1.1. 5. Revised 2-1.2 and 3-1 to revise requirements and remove CONUS and OCONUS. 6. Revised AWWA reference in 2-1.3 and 3-5. 7. Revised requirements in paragraphs 2-1.1, 3-2, 3-3.1.1, 3-3.1.2, 3-3.2 and 3-4 to coordinate with changes to UFC 3-230-01. 8. Updated references in Appendixes A and B.
2	1 May 2020	1. Updated paragraphs 3-2 and 4-3.1 to coordinate with revision of UFC 3-240-01. 2. Updated reference to UFC 1-200-01, DoD Building Code in paragraph 1-3.1. 3. Updated references in Appendix A.

This UFC supersedes UFC 3-230-08A and UFC 3-230-12A, both dated 16 January 2004.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Center for Engineering and the Environment (AFCEE) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

JAMES C. DALTON, P.E. Chief, Engineering and Construction U.S. Army Corps of Engineers	JOSEPH E. GOTT, P.E. Chief Engineer Naval Facilities Engineering Command
TERRY G. EDWARDS, P.E. Director, Air Force Center for Engineering and the Environment Department of the Air Force	MICHAEL McANDREW Director, Facilities Investment and Management Office of the Deputy Under Secretary of Defense (Installations and Environment)

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Title: UFC 3-230-03, Water Treatment

Superseding: UFC 3-230-08A and UFC 3-230-12A.

Description: This new UFC 3-230-03 consolidates into one Tri-Service document the civil engineering criteria applicable to water treatment that were formerly in the superseded documents. This UFC – through succinct reference to industry and government standards, codes and references – makes possible the replacement and/or consolidation of numerous criteria documents.

The complete list of water engineering documents referenced in this UFC can be found in Appendices A and B.

Reasons for Document:

- The new UFC updates the guidance and requirements for water treatment contained in several existing engineering documents and efficiently consolidates them into a single UFC.
- The superseded UFC documents included requirements that were not consistent with industry standards or utilized different industry standards.

Impact:

This unification effort will result in the more effective use of DoD funds in the following ways:

- By significantly improving the design process for DoD projects and facilities, through a more efficient application of facilities criteria and enabling more efficient maintenance of facilities criteria.

- The consolidation of the UFC 3-230-03 will positively impact the project costs incurred, as a result of the following direct benefits:

  - Reduction in the number of civil references used for military construction provides more clear and efficient guidance for the design and construction of DoD facilities.
  - Improved clarity and convenience results in reduced time required for execution of project designs.
  - Reduction in ambiguity and the need for interpretation reduces the potential for design and construction conflicts.
  - The reduction in the number of documents and the use of industry standards improves the ease of updating and revising this reference document as better information becomes available.

Non Unified Issues: No major unification issues.

TABLE CONTENTS

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) provides requirements for typical water treatment systems for the Department of Defense (DoD). These minimum technical requirements are based on UFC 1-200-01. Where other statutory or regulatory requirements are referenced in the contract, the more stringent requirement must be met.

1-2 APPLICABILITY.

\1\This UFC applies to service elements and contractors involved in the planning, design and construction of permanent DoD facilities worldwide. It is applicable to all methods of project delivery and levels of construction.

1-2.1 Foreign Countries.

All design and construction outside of the United States and United States territories is governed by international agreements, such as the Status of Forces Agreements (SOFA), Host Nation-Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA), and country-specific Final Environmental Governing Standards (FGS) or the DoD *Overseas Environmental Baseline Guidance Document,* DoD 4715.05G. The OEBGD applies when there are no FGSs in place. Therefore, in foreign countries this UFC will be used for DoD projects to the extent that it is allowed by and does not conflict with the applicable international agreements and the applicable FGS or OEBGD./1/

1-3 OTHER CRITERIA.

1-3.1 General Building Requirements.

\1\Comply with UFC 1-200-01, DoD Building Code \2\ /2/./1/ UFC 1-200-01 provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, sustainability, low impact development (LID) and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-3.2 Safety.

All DoD facilities must comply with \1\DoDI 6055.01/1/ and applicable Occupational Safety and Health Administration (OSHA) safety and health standards.

1-3.3 Antiterrorism and Security.

Specific security concerns for Water Treatment Facilities are addressed in the “Policy Statement on Infrastructure Security for Public Water Supplies” of the *Ten State Standards*. Use Best Practices document, ASCE/AWWA Draft American National

Standard for Trial Use, *Guidelines for the Physical Security of Water Utilities*, for latest guidelines for protection of water utility systems.

1-4 REFERENCES.

Appendix A contains the list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-5 BEST PRACTICES.

Appendix B identifies background information and practices for accomplishing certain water treatment design and engineering services. The Designer of Record (DoR) is expected to review and interpret this guidance as it conforms to criteria and contract requirements, and apply the information according to the needs of the project. If a Best Practices document has guidelines or requirements that differ from the Unified Facilities Guide Specifications (UFGS) or UFC, the UFGS and the UFC must prevail. If a Best Practices document has guidelines or requirements that are not discussed in the Unified Facilities Guide specification (UFGS) or UFC, the DoR must submit a list of the guidelines or requirements being used for the project with sufficient documentation to the Government Project Manager for review and approval prior to completing design.

CHAPTER 2 GENERAL DESIGN REQUIREMENTS

2-1 DESIGN.

\1\Use UFC 3-201-01 for preliminary site analysis, site design, storm drainage systems, and pavements./1/

2-1.1 Design Criteria.

Design water treatment systems to meet the drinking water quality requirements of applicable federal, state and local government agencies or overseas equivalent.\1\

2-1.1.1 Within The United States.

Use UFC 3-230-01.

2-1.1.2 Foreign Countries.

Use UFC 3-230-01./1/

2-1.2 Design Approval.

\1\The DoR must identify, assist, and provide, as applicable, all permits, approvals, and fees required for the design and construction of the new project from Federal, state and local regulatory authorities or overseas equivalent. The Civil Engineering Designer of Record must be a Professional Civil Engineer experienced and licensed; licensure in the location of the project may be required to obtain permits and approvals. For new water treatment systems, rehabilitation or replacement of existing water treatment systems to water treatment systems, coordinate with the Safe Drinking Water Act primacy agency, as applicable, to determine primacy agency requirements. In the United States and its territories and possessions the Government will review plans for acceptability. In locations outside of the United States and its territories and possessions with Host Nation agreements, follow design approval procedure as directed in project scope and by Government Project Manager. In areas outside of the United States and its territories and possessions without Host Nation agreements, the Government will review and approve plans for compliance.

Consult with the Government Project Manager to determine the appropriate signatories for permit applications./1/

2-1.3 Planning for Non-War Emergencies.

Refer to Best Practices document \1\AWWA M19/1/, for non-war emergencies such as earthquakes, hurricanes, tornadoes, floods and vandalism.

This Page Intentionally Left Blank

CHAPTER 3 \1\SYSTEM/1/ SOURCES AND FLOWS

\1\The design capacity of the water treatment plant, including water system source and equalization storage, as indicated in UFC 3-230-01 chapter titled *Finished Water Storage*, must be able to accommodate the design flow./1/

3-1 \1\SYSTEM/1/ SOURCES.

Unless otherwise directed by the Government Project Manager, obtain potable water supply from a nearby public system. If this is not practical, sources must be developed for the Military activity.

The selection of a water supply source involves a review of the alternative sources available and their respective characteristics. Consider water quality and quantity data for the supply source over a significant period of time to sufficiently assess seasonal and long-term variability. Consider the following factors when selecting a water supply source:

- Safe yield
- Water quality
- Collection requirements (intake structure, wells, etc.)
- Treatment requirements (including the cost and feasibility of residue disposal)
- Transmission and distribution requirements

A complete discussion of water source selection and development is beyond the scope of this document. Refer to state waterworks regulations or overseas equivalent for the project location. \1\For areas outside of the United States and its territories and possessions/1/, evaluate all possible alternative sources, including cost, relations with the Host Nation, and antiterrorism considerations. Brackish or salt water must be used only when other sources are unavailable and must be converted to fresh water by a suitable process. Refer to AWWA's *Water Quality and Treatment*.

3-2 DESIGN POPULATION.

Refer to \2\ UFC 3-240-01, paragraph 3-1.1/2/.

3-3 \1\DESIGN FLOW.

The design flow is the greater of:

- peak hourly demand.

- maximum daily demand plus required fire flow.

When computing the design flow, account for other demands such as industrial demands./1/

3-3.1 Domestic \1\Demands/1/.

Domestic uses include drinking water, household uses and household lawn irrigation.

3-3.1.1 Per Capita Requirements.

\1\Use reliable water meter records to compute flows. If reliable water meter records are not available, use state regulations or overseas equivalent. Compute flows based/1/ on daily water consumption rates for the types of facilities included in state regulations or overseas equivalent. In locations where state regulations or overseas equivalent do not address types of facilities, obtain typical water demand from Table 3-1.

Table 3-1: Daily Domestic Consumption Rates [1]

Use Category [2]	**Flow Requirement** (gpcd) (m^3/cap/s)
Unaccompanied Personnel Housing [2]	110 (4.82×10^{-6})
Family Housing [2,3]	125 (5.48×10^{-6})
Nonresident Personnel and Civilian Employees (per 8 hr. shift)	30 (1.31×10^{-6})
Military Training Camps [2]	50 (2.19×10^{-6})

[1] Allowances do not include industrial \1\demands/1/.
[2] These values represent domestic \1\water rates/1/ for resident personnel averaged over the entire installation for a 24-hour period.
[3] In family housing areas, each housing unit must be assigned 3.6 residents for the purpose of calculating populations.

In addition to Table 3-1, other buildings and establishments normally found on military installations must be assigned typical daily water consumption rates obtained from the latest edition of Best Practices document, \1\MWH's/1/ *Water Treatment: Principles and Design*. Do not use these typical daily water consumption rates for contingency operations.

3-3.1.2 Controlling Demands.

The \1\Average Daily Demand/1/ must be calculated as follows:

Average \1\Daily/1/ Demand (gpd) (m^3/s) = (gpcd) (m^3/cap/s) x Design Population

Demand variations must be evaluated by the following:

Maximum Demand = \1\Average Daily/1/ Demand x K

\1\Compute Maximum Daily Demand and Maximum Peak Hourly Demand using the average daily demand and the coefficients indicated in Table 3-2. Use the greater of the computed demand or historical water meter records/1/.

Table 3-2: Demand Variations (Coefficient K)

Demand	Units of Demand	Coefficient K	
		Population < 5000	Population > 5000
Maximum \1\Daily Demand/1/	gpd (m^3/s)	2.25	2
\1\Peak Hourly Demand/1/	gpm (m^3/s)	4.0	3.5

The designer may make allowances in per capita demand, as deemed necessary, for small activities where all or nearly all demand occurs during working hours. Also account for a planned buildup or population decrease.

3-3.2 \1\Industrial Demands.

Use reliable water meter measurements to determine industrial demands. If reliable historical water records are not available, compute industrial demands based on actual conditions. Water meter records for similar types of facilities having similar uses to those anticipated may be used but must be adjusted to account for facility differences and regional conditions. When computing industrial demands consider processes such as cooling water systems, issues to ships, irrigation, swimming pools, shops, laundries, dining, processing, flushing, air conditioning, wash racks, rinse racks, and boiler makeup./1/ Confirm water characteristics required for industrial processes to determine appropriate treatment.

3-3.3 \1\Fire Demands.

Fire system demands must be derived from UFC 3-600-01./1/

3-4 \1\/1/

3-5 MATERIALS SELECTION.

Approach selection of equipment, piping, materials and coatings for water treatment systems in accordance with current AWWA standards. \1\Use AWWA M27 for the selection of materials, coatings, linings, and protective methods for specific pipe material, or a cathodic protection system to protect from external corrosion. Explicit approval by the Government is required prior to providing a cathodic protection system on a buried pipeline. Ensure compliance with NSF Standard 60 and NSF Standard 61./1/

This Page Intentionally Left Blank

CHAPTER 4 SITE SELECTION

4-1 LOCATION.

Water treatment plants must be located above the projected 100 year flood elevation according to UFC 3-201-01. Government approval is required for lower elevations to be considered even if it can be adequately shown that the proposed treatment plant can be protected from flooding.

Consider the following for a treatment plant site:

- Proximity to the source of raw water.
- Proximity to the area to be served.
- Potential for flooding of the site.
- Availability and reliability of electric power from more than one source of outside power.
- Geology and topography of the site.
- Size of the site, both for original and for anticipated expansions.
- Legal obligations or restrictions.
- Environmental considerations.
- Antiterrorism integrity.

4-2 ACCESS.

The site must be selected so that an all-weather road is available or can be provided for access to the plant. Consideration must be given, during layout of buildings, roads, fencing and appurtenances, to winter conditions, especially of snow drifting and removal.

4-3 FIELD INVESTIGATION.

4-3.1 Existing and Proposed Service Areas.

Utilize Installation's existing utility maps and proposed planning documents to develop existing and proposed service areas for present \1\and future conditions. Estimate future growth as required by \2\ Chapter 3 /2/./1/

4-3.2 Topographic Survey.

Provide a topographic survey of project area including locations of existing utilities in accordance with UFC 3-201-01.

4-3.3 Soils.

Evaluate geotechnical data on existing soils \1\for/1/ corrosivity, if existing operating records, visual observations, inspections or testing indicates a need for corrosion control. \1\When required by the contract/1/, provide an evaluation of existing soils at the proposed depths and locations of the water system components in accordance with

\1\AWWA M27, Chapter 3 entitled “Evaluating the Potential for Corrosion”/1/ and provide recommendations on materials and positive corrosion protection systems.

4-3.4 Environmental Considerations.

Contact the Installation’s Environmental Reviewer prior to design and evaluate site for environmental concerns and known contamination. Notify Government Project Manager of known environmental contamination to ensure adequate funding in current project.

CHAPTER 5 TREATMENT PROCESS SELECTION

The selection of treatment facilities must be determined by feasibility studies, considering all engineering, economic, energy and environmental factors. All legitimate alternatives must be identified and evaluated by life cycle cost analyses. Additionally, energy use between candidate processes must be considered. For the purpose of energy consumption, only the energy purchased or procured will be included in the usage evaluation. All treatment process systems must be compared with a basic treatment process system, which is that system accomplishing the required treatment at the lowest first cost. Pilot or laboratory analysis must be used in conjunction with published design data of similar existing plants to assure the optimal treatment. It is the responsibility of the Civil Engineering Designer of Record to ensure that the selected water treatment plant process complies with the National Primary Drinking Water Standards of the Safe Drinking Water Act or overseas equivalent, State and local regulations, whichever is more stringent.

5-1 PROCESS SELECTION FACTOR.

Consider the following factors in the choice of a water treatment process:

- Water supply source quality
- Desired finished water quality
- Reliability of process equipment
- Operational requirements and personnel capabilities
- Flexibility in dealing with changing water quality and equipment malfunctions
- Available space for construction and future expansion of treatment facilities
- Waste disposal constraints
- Capital and operating costs (including chemical availability)
- Process susceptibility to intentional contamination or disruption of operation

5-2 FLUORIDATION.

All designs of new DoD water treatment systems serving 3300 people or greater must include the ability to treat drinking water to the optimally adjusted concentrations of fluoride indicated in the latest Center for Disease Control's (CDC) National Guidelines For Fluoride Use found in *Recommendations for Using Fluoride to Prevent and Control Dental Caries in the United States*. All treatment systems serving less than 3300 people will be determined on a case by case basis.

5-3 CORROSION CONTROL TREATMENT.

Provide corrosion control treatment in accordance with AWWA M58, *Internal Corrosion of Water Distribution Systems* if there is evidence of internal corrosion of distribution system piping and building plumbing.

This Page Intentionally Left Blank

CHAPTER 6 SMALL WATER TREATMENT SYSTEMS

6-1 GENERAL DESIGN CRITERIA.

Design upgrades to existing treatment facilities and construction of new treatment facilities based on the criteria indicated in paragraph entitled "*Design Criteria*".

Design potable water systems treating less than 100,000 gallons per day (4.38 x 10^{-3} m^3/s) in accordance with EM 1110-2-503. Use Best Practices document, AWWA's *Design and Construction of Small Water Systems*, for design guidance.

If the Civil Engineering Designer of Record utilizes a particular water treatment system, technology, component or device, more than one manufacturer must be listed in the construction documents in accordance with the latest FAR regulations. The manufacturers' systems or components indicated must be currently approved for commercial use for the proposed application and project conditions in the State where the project is located. If the State does not maintain an approved water treatment system or components list or the project is in a location not subject to state water works regulations, then documentation must be provided to the Government indicating that each manufacturer's proposed water system or component is approved in at least one other state for commercial use for a similar application.

6-2 TYPICAL MILITARY APPLICATIONS.

Most small potable water systems on military installations that do not obtain water from a municipality use a groundwater source with limited or specialized treatment systems.

6-3 PACKAGED TREATMENT PLANTS.

Many small treatment systems on military installations are packaged treatment plants. These systems combine processes such as flocculation, aeration, sedimentation, and filtration in a single multicompartment tank. Typical types include demineralization, reverse osmosis, electrodeionization, and sea water desalination. Various processes may include proprietary components.

6-4 DISINFECTION.

Disinfection of the effluent must be provided as necessary to meet applicable drinking water quality standards.

Chlorine gas must not be used for disinfection for a small water treatment system.

6-5 RELIABILITY.

Multiple process units capable of independent operation must be provided for redundancy at all plants.

Provide for emergency power operation, such as a dedicated standby emergency generator or a portable generator, in conformance with applicable regulatory and utility provider requirements.

If the delivery of crucial chemical supplies is uncertain, larger than normal stores of these chemicals must be kept on hand, which will necessitate larger than normal chemical storage areas. Caution on the size of selected vessels and storage of chemicals must be exercised. The expected “shelf life” of chemicals and the operating environment must be taken into account. In addition, the procurement process for the facility must be understood before the finalization of any design project that requires ordering and storage of chemicals.

6-6 OPERATING CONSIDERATIONS.

To simplify plant operations, consider the following during the design stage:

Locate operations requiring frequent attention from plant operators reasonably close together. The most attention is generally required for operation of filters, flocculators and chemical feeding equipment.

Simplify chemical handling and feeding as much as possible. Locate unloading and storage areas for chemicals to be easily maintained and readily accessible and be close to the point of application of chemicals. Care must be exercised in the design of storage area ventilation system to ensure that normal and emergency discharges do not affect other areas or personnel.

Plants treating river water must provide the flexibility in treatment processes needed to cope with raw water quality changes such as high turbidity during rain/flood season.

Typically Operation and Maintenance Support Information (OMSI) manuals are required for treatment plants. OMSI manuals include preparation of the plant operating procedures and controls including a complete description of the treatment process flow.

6-7 ALTERNATIVE TECHNOLOGIES.

Consider technologies that can pre-condition water such that subsequent processing may be able to eliminate unit processes such that only simple technology or conventional treatment is required. Pilot testing to “prove” these assertions must be performed as appropriate.

CHAPTER 7 MEASUREMENT AND CONTROL

The primary purpose for instrumentation and control is to produce high quality aesthetic acceptable water compliant with regulatory primary drinking water standards and provide proactive alarms to treatment process malfunction.

7-1 MEASUREMENT OF PROCESS VARIABLES.

In order to determine the degree of effectiveness of the different treatment processes, several physical and chemical parameters associated with water treatment must be measured. After they are measured, the information must be evaluated so that necessary adjustments can be made in the treatment processes.

7-1.1 Minimum Analyses for Military Water Treatment Plants.

The type of water quality parameters and frequency of analysis to ensure drinking water is compliant with the National Primary Drinking Water Standards of the Safe Drinking Water Act or overseas equivalent are determined by the size of the system, treatment required, and water quality regulations. These requirements are typically set by state and local regulations. The frequency of analyses must also be adjusted locally to meet changing raw water characteristics. Minimum analyses frequencies and laboratory equipment requirements must comply with the more stringent requirements of individual state and local requirements. For locations outside the United States and United States territories refer to paragraph entitled "*Design Criteria*", for applicable requirements. Analyses conducted to determine compliance with drinking water regulations must be performed in an appropriately certified laboratory in accordance with the *Standard Methods for the Examination of Water and Wastewater* or approved alternative methods. Physical and chemical testing must be performed by trained and certified treatment plant operators or local laboratory personnel. Provide equipment to ensure proper process control must be required to be provided by the construction contractor or other suitable means prior to the plant coming online.

7-2 INSTRUMENTATION AND CONTROLS.

Provide for remote monitoring, such as telemetry, in conformance with applicable regulatory and utility provider requirements. If required, provide off site operation capability from a central location. Remote monitoring and control systems must meet the Installation's IT security requirements and standards.

Refer to AWWA's *Water Treatment Plant Design* for a detailed discussion of Process Instrumentation and Controls.

This Page Intentionally Left Blank

CHAPTER 8 CHEMICAL TREATMENT

8-1 CHEMICAL PROPERTIES AND STANDARDS.

All chemicals used in water treatment operation must meet the purity requirements of the AWWA standard specifications and comply with NSF Standard 60. Design must be based on the assumption that chemicals will be purchased in normal shipping containers (such as bags, drums, cylinders, or carboys) rather than bulk car or truckloads. Functions of various chemicals and chemical strengths are provided in AWWA's *Water Treatment Plant Design.* For remote locations where delivery is difficult, give priority to chemicals that are stable in storage and slow to degrade or lose potency.

8-2 CHEMICAL HANDLING, STORAGE AND APPLICATION.

Refer to AWWA's *Water Treatment Plant Design* and *Ten State Standards,* Part 5 for discussions of chemical handling, storage and application procedures.

This Page Intentionally Left Blank

CHAPTER 9 WATER TREATMENT WASTE RESIDUALS

9-1 QUANTITIES AND CHARACTERISTICS OF WASTE RESIDUALS.

In connection with water treatment plant location and design, the disposal of the wastes generated during the various treatment processes must receive careful consideration. Among these wastes are sludge from pre-sedimentation basins, coagulation and/or softening sludge, filter wash water, spent regenerant and rinse water from ion-exchange softeners, diatomite filter sludge and mineral wastes from desalination facilities. Ensure acceptable point of discharge for brine (mineral wastes) from desalination plants. Quantities of materials contained in the waste stream will be dependent on the type of treatment processes utilized and the quantity of water treated. A determination of the expected quantity of the various types of waste must be made and proper disposal methods identified during the design process.

9-2 WASTE MANAGEMENT.

For information regarding management and disposal of wastes generated by water treatment plants refer to AWWA's *Water Treatment Design*; AWWA's *Water Quality and Treatment*; and *Ten State Standards,* Part 9.

APPENDIX B BEST PRACTICES

Appendix B identifies background information and practices for accomplishing certain water treatment design and engineering services. The Civil Engineering Designer of Record (DoR) is expected to review and interpret this guidance and apply the information according to the needs of the project. If a Best Practices document has guidelines or requirements that differ from the UFGS or Unified Facilities Criteria, the UFGS and the UFC must prevail. If a Best Practices document has guidelines or requirements that are not discussed in the Unified Facilities Guide specification (UFGS) or UFC, the DoR must submit a list of the guidelines or requirements being used for the project with sufficient documentation to the Government Project Manager for review and approval prior to completing design.

B-1 WHOLE BUILDING DESIGN GUIDE.

The Whole Building Design Guide provides additional information and discussion on practice and facility design, including a holistic approach to integrated design of facilities.

The WBDG provides access to all Construction Criteria Base (CCB) criteria, standards and codes for the DoD Military Departments, National Aeronautics and Space Administration (NASA), and others. These include, Unified Facilities Criteria (UFC), Unified Facilities Guide Specifications (UFGS), Performance Technical Specifications (PTS), design manuals, and specifications. For approved Government employees, it also provides access to non-government standards.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Clearly defining water treatment requirements for industrial water continue to be critical to reduce maintenance cost and increase life expectancy on all equipment.

1-2 REISSUES AND CANCELS.

This UFC supersedes UFC-3-240-13FN Industrial Water Treatment Operation and Maintenance dated 25 May 2005.

1-3 PURPOSE AND SCOPE.

This UFC provides an overview of industrial water treatment operations and maintenance. As used in this UFC, the term “industrial water” refers to the water used in power generation, heating, air conditioning, refrigeration, cooling, processing and all other equipment and systems that require water for operation. This UFC covers Theory of Operation, cause and effect, prevention, and it provides specific performance criteria and minimally acceptable standards for water treatment programs as a whole.

1-4 APPLICABILITY.

This UFC applies to industrial water systems. Industrial water is not the same as potable water. Industrial water is never consumed or used under situations that require a high degree of sanitation. To provide DOD personnel with the most up-to-date information available, the UFC guides the reader to industry standards in the industrial water treatment of heating, cooling and ship to shore equipment.

1-5 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-6 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-7 GLOSSARY.

Appendix F contains acronyms, abbreviations, and terms.

1-8 REFERENCES.

Appendix G contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 INTRODUCTION TO INDUSTRIAL WATER TREATMENT

2-1 INDUSTRIAL WATER TREATMENT.

Industrial water is not the same as potable water. Industrial water is never consumed or used under situations that require a high degree of sanitation.

Industrial water requires water preparation or chemical treatment, or both, to avoid the problems described in paragraph 2-1.2. Water preparation and chemical treatment requirements are described in Chapters 3 through 6 according to the type of system in question. The shore-to-ship steam purity standards are described in Chapter 4. Examples of industrial water systems and their uses are:

- Steam Boiler Systems. (See Chapter 4.) Steam uses include space and hot water heating, sterilization, humidification, indirect food processing, and power generation.
- Cooling Water Systems. (See Chapter 5.) Cooling water is used in cooling towers, evaporative coolers, evaporative condensers, and once-through systems. Applications are broad, ranging from simple refrigeration to temperature regulation of nuclear reactors.
- Closed Water Systems. (See Chapter 6.) These include closed hot water, closed chilled water, and diesel jacket systems.

2-1.1 Fire Protection and Other Uses.

Fire protection systems such as dedicated fire water distribution systems and building fire sprinkler systems are not considered industrial water systems.

2-1.2 Problems Encountered in Industrial Water Systems.

Problems found in industrial water systems are attributable to reduced or restricted water flow or other changes in operational parameters, and often caused by corrosion, deposits, and biological growth. These problems result in reduced system efficiency (higher operating costs), increased equipment replacement costs, and reduced safety. At times they can be serious enough to cause complete system shutdown. The problems in industrial water systems fall into three main categories:

- Steam boiler water problems (corrosion, deposits, and carryover).
- Cooling water problems (corrosion, deposits, and biological).
- Closed loop problems (corrosion, deposits, and biological).

2-1.2.1 Deposits.

The term “deposits” refers to a broad categorization of residues. Deposits are composed of mineral scale, biological matter, and suspended or insoluble materials (for example, sludge, dirt, or corrosion byproducts). Deposits can be created by the attachment of deposit-forming materials to pipe or equipment surfaces, or by settling and accumulation.

2-1.2.2 Scale.

The term “scale” describes specific types of deposits caused when mineral salts, dissolved in water, are precipitated either because their solubility limits have been exceeded or as a result of reaction to water treatment chemicals. Scale adheres to pipe and equipment surfaces and its formation results in loss of heat transfer and restricted flow of water or steam. Many different types of scale reflect the quality and characteristics of the makeup water and the type of chemical treatment being applied.

2-1.2.3 Biological.

The term “biological” describes both macrobiological organisms (mollusks, clams, fish) and microbiological organisms (algae, fungi, bacteria). Algae are microscopic plants that may grow in various industrial water systems but most commonly appear on the distribution decks of cooling towers. Fungi are living organisms that may cause damage to the wooden parts of cooling towers by causing decay. Slimes are accumulations of these biological contaminants that foul and corrode the cooling water equipment. Macrobiological organisms can cause fouling problems in once-through cooling water systems if untreated (“raw”) water is used.

2-1.2.4 Suspended Solids (SS).

The term “suspended solids” refers to any materials present in the water stream that are not actually dissolved in the water. SS can result from the presence of dirt, silt, and sand in the makeup water or can be introduced into the water from air in a cooling tower system. These solids are caused by feedwater contamination, by internal chemical treatment precipitates, or by exceeding the solubility limits of otherwise soluble salts. Biological matter, both dead and living, can be a form of SS if carried in the water stream. Corrosion products, such as iron oxide, are forms of SS that often originate in the system piping.

2-1.2.5 Corrosion.

The term “corrosion” refers to metal deterioration resulting from a refined metal’s tendency to return to its original state (the ore from which the refined metal was produced). The process of corrosion involves a series of electrochemical reactions. Metals that contact water in any type of water system can corrode if there is no attempt to protect them.

2-1.3 Objectives of Industrial Water Treatment.

Industrial water is treated to achieve the following objectives with respect to the equipment in which it is used: maintaining its efficiency, prolonging its usable “life,” and reducing the frequency of repair or replacement (or both). These objectives can be achieved by treating the water to minimize scale and to control corrosion, fouling, and microbiological growth. To meet these objectives, an adequate and continuous supply of both properly conditioned makeup water and conditioned or chemically treated system water (water within the water-using system) is produced. The source for industrial water is often the installation's potable water distribution system; however, there is a growing trend to use recycled municipal wastewater for makeup to cooling tower systems. When this source of makeup water is used, additional steps can be taken to provide a backup water supply.

2-1.4 Water Conservation.

Make every effort to conserve water used in boilers, cooling towers, and other water-using equipment. This includes identifying and fixing leaks throughout the systems, reducing uncontrolled water losses (drift) from cooling towers, and operating the systems at the highest permissible cycles of concentration (COC) by using proper procedures for blowdown and chemical treatment. Water conservation (using less water) also reduces the amount of treatment chemicals required for the water treatment program. This, in turn, eases operation of wastewater treatment facilities, reduces the requirements for chemical handling, reduces the volume of chemical wastes generated, and reduces the cost of water treatment.

2-1.5 Responsibility for Treatment.

2-1.5.1 Office Responsible.

The office responsible for industrial water treatment exists at the base or facility level. This office is responsible for developing short-term and long-term strategies for acquiring the resources needed to execute an effective water treatment program that incorporates the principles, procedures, and programs provided in this manual.

2-1.5.2 Organizational Assignments.

The development and implementation of efficient and economical procedures for industrial water treatment and water testing processes requires the assignment of specific and appropriate organizational responsibilities. If the person assigned to perform the treatment and testing of industrial water is assigned additional duties, assignment of additional personnel may be required to ensure that adequate and continuous attention is given to industrial water treatment and testing. A system for the regular reporting of trends in test results and for the regular assessment of system performance can be established to keep the assigned personnel appropriately informed.

2-1.6 Unauthorized Non-Chemical Devices.

The military does not currently recognize using non-chemical treatment devices for comprehensive water treatment or trials. These situations are described in detail in Chapter 9.

2-1.7 Health and Safety.

Many of the chemicals used to treat industrial water may be harmful to the health of the system operator and other installation personnel unless they are properly handled and controlled. Handle water treatment chemicals and test reagents with care, following the guidance of Occupational Safety and Health Administration (OSHA) directives, manufacturers’ recommendations, and safety data sheets (SDS). To minimize chemical handling, use automated control and feed equipment. Chapter 8 describes chemical application processes.

2-1.7.1 Protection of Potable Water.

Protecting potable water supplies, as it applies to an industrial water system, involves preventing contamination of the potable water system. Eliminating cross-connections in the water system and using backflow prevention devices or air gaps to provide an interconnection barrier between the water systems are ways to achieve this prevention.

2-1.7.1.1 Cross-connections.

A cross-connection is a physical connection between a potable water supply system and a non-potable water system (such as an industrial water system) through which contaminated water can enter the potable water system.

Cross-connections are eliminated to maintain the safety of potable water supplies. Backflow prevention devices are installed to prevent cross-connections where potable water is supplied to industrial water systems.

2-1.7.1.2 Backflow Prevention Devices.

Class III backflow prevention devices (air gap or reduced pressure principle devices) are required when connecting a potable water supply system to an industrial water system that uses a source of non-potable water. They are also required when connecting a potable water supply system to an industrial water system to which chemicals have been added. Refer to UFC 3-420-01 Plumbing Systems for additional backflow prevention guidance.

2-1.7.1.3 Air Gaps.

If potable makeup water is supplied to a tank or other type of open system, provide an air gap between the water inlet and the maximum overflow level of the tank, device, or system.

2-1.8 Restrictions on Direct Steam Use.

Neutralizing amine chemicals, which are added to the steam to protect the condensate lines from corrosion, make the steam and condensate unfit for consumption or for other uses normally reserved for potable water. Treated steam should not come into direct contact with food and should not be used for heating food trays or for humidification. For these applications, steam-to-steam heat exchangers can be used to provide amine-free steam (see paragraph 4-2.7.6).

2-1.9 Record-Keeping Requirements.

Procedures for industrial water treatment and testing may vary from one installation to another based on differences in the characteristics and quality of the water, as well as on differences in the type and size of the systems. Water system specifications are developed to address local factors such as the installation's mission, geographic location, and climate. The data and information records and logs used to record the results of industrial water treatment and testing can be developed to reflect the minimum documentation requirements needed to verify adequate operation and control of the treatment program. Computer-generated logs require regularly scheduled backup. Chapter 7 provides recommended frequencies for sampling and testing various industrial water systems.

2-1.9.1 Control Charts.

Control charts can be developed to identify the following information: the treatment chemicals used; the chemical levels required to be maintained in the system; other required testing procedures (for example, conductivity, pH); and the information specific to the particular water system (especially for the larger boilers and cooling towers). Water treatment service companies commonly supply these control charts.

2-1.9.2 Operations Logs.

Operations logs can be maintained to establish trends for parameters and items identified in the program control charts. These logs are best maintained as computer-generated spreadsheets and graphs. Hardcopy records are also acceptable.

2-1.9.2.1 Large Boilers.

Maintain water treatment logs on-site in all plants operating above 15 pounds per square inch gauge (103 kilopascal (kpa)) steam or 30 pounds per square inch gauge (207 kpa) hot water, with an output capacity above 100 boiler horsepower or 1 megawatt (3.5 million British thermal units per hour (MMBTUH)). The logs should provide a record of the treatment and test results of boiler water, makeup water, and condensate water. One log can be maintained for each boiler and one for the plant makeup water data.

2-1.9.2.2 Cooling Towers.

Maintain operating logs on-site for all operating cooling towers, and those logs should contain results (including dates) of all chemical tests performed, COC, and the amount of chemicals added.

2-1.9.2.3 Other Systems.

Maintain operating logs on-site for low-pressure steam boilers, high-temperature hot water boilers, medium-temperature hot water boilers, low- temperature water boilers, and closed chilled water systems. These logs should contain results (including dates) of all chemical tests, amount of chemicals added, and the volume of blowdown water, where applicable.

2-1.9.3 Historical Records.

Information pertaining to the maintenance and history of industrial water treatment, other than that which can be entered on the log form or data accumulated for log form entries, can be maintained for each system in a computerized maintenance management system, a separate computer application, or as a hardcopy historical record book. Hardcopy records should be letter size 8.5 inches by 11 inches (216 millimeters x 279 millimeters) or larger, and can be entered into a bound book rather than a loose-leaf binder. Records should contain information (including dates) about system start-up and shut-down, occurrences of corrosion and scale, major maintenance activities performed on the system, replacement of piping and equipment, accidents, outages, changes in method of operation and treatment used, and other pertinent data, including equipment inspection results logs.

2-1.10 Support Available.

2-1.10.1 Boiler and Cooling Water Quality Assurance (QA) and Quality Control (QC) Program.

Submit heating or cooling system water samples to a laboratory for analysis in accordance with an appropriate water QA and QC program. The purpose of QA is to verify that applied treatment chemicals, control limits, and external treatment are appropriate. QA is used to assist operators and managers to achieve accurate in-plant chemical testing and control. The primary purpose for a QA and QC program is to ensure and verify that the in-plant test results represent accurately tested and reported concentrations of water treatment chemicals. If the QA and QC procedures are in error or are not followed, or if the test results are not accurate, the consequences are reduced safety, possible damage to the equipment, and wasted energy, chemicals, and water.

2-1.10.2 Other Support.

Matters pertaining to military policy, requests for technical staff visits to troubleshoot industrial water systems, training of water treatment personnel, and general technical questions can be addressed to the appropriate military office.

2-2 INDUSTRIAL WASTEWATER.

"Industrial wastewater" is a term that refers to any water discharged from an industrial water system. This term applies primarily to cooling tower and steam boiler blowdown; the term also applies to discharge industrial process water (like plating wastes).

2-2.1 Disposal Procedures.

Coordinate the treatment and disposal of liquid and solid (sludge) wastes from industrial systems with the installation environmental engineer.

2-2.1.1 Water Discharge Pretreatment.

Pretreatment of water discharge refers to a treatment procedure that is applied to water before it is discharged to the storm water system, the sanitary sewer system, or the base industrial wastewater treatment system. The installation environmental engineer is usually the individual responsible for determining when pretreatment is required and which methods will be used.

2-2.1.2 Water Discharge Restrictions.

The discharge of industrial water treatment system wastes may be regulated. All requirements can be established by working with the installation environmental engineer. The primary restriction is water quality. In addition to water quality restrictions, the discharge may be controlled in the following ways:

2-2.1.2.1 Discharge Location.

The location of the discharge can be determined by the configuration of both the water treatment system and the available sewers. Normal practice at the installation may include discharge into either the sanitary or industrial wastewater treatment system.

2-2.1.2.2 Discharge Rate.

The maximum rate of discharge to the designated sewer system may be a discharge requirement. Two factors are of importance in setting a maximum rate: the hydraulic capacity of the sewer and the strength (chemical concentration) of the waste.

2-2.1.2.3 Discharge Time Frame.

Discharge from a water treatment system unit may be allowed only at specified times.

2-2.1.2.4 Discharge Responsibilities.

The water treatment system operator is responsible for complying with the procedures and policies established at the installation, including directives on waste disposal that have been issued by the installation environmental engineer. The responsibilities of the installation environmental engineer include compliance of the installation's directives with government environmental regulations.

2-2.1.2.5 Review of Chemicals.

The installation environmental engineer should review the procedures for use of a new water treatment chemical to determine whether or not it can be safely disposed of using the existing procedures, or if new disposal procedures must be developed.

2-2.2 Environmental Regulations.

Numerous environmental regulations established by law may apply at the installation level. Contact the Installation environmental program staff for specific environmental requirements for the project location.

2-2.2.1 The Toxic Substances Control Act.

The Toxic Substances Control Act (TCSA) was amended by the Frank R. Lautenberg Chemical Safety for the 21st Century Act in which the TCSA authorizes the United States Environmental Protection Agency (EPA) to control all new and existing chemical substances that have been determined to pose a potential unreasonable risk to the public health or environment.

2-2.2.2 The Clean Water Act.

The Clean Water Act (CWA) incorporates the Federal Water Pollution Control Act and amendments. The CWA establishes limits for the discharge of pollutants to navigable waters, provides regulation of specific toxic pollutants in wastewater discharges, and provides requirements for the control of oil and hazardous substance discharges.

2-2.2.3 The Safe Drinking Water Act.

The Safe Drinking Water Act provides for protection of underground sources of drinking water and establishes primary and secondary drinking water standards. These standards are available from the installation environmental engineer.

2-2.2.4 The Federal Insecticide, Fungicide and Rodenticide Act.

The Federal Insecticide, Fungicide and Rodenticide Act requires that all pesticides be registered with the EPA. This requirement includes microbiocides used for cooling system treatment.

2-2.2.5 The Resource Conservation and Recovery Act.

The Resource Conservation and Recovery Act (RCRA) addresses the control of solid waste. Hazardous wastes are defined in the RCRA and are controlled by use of a complex manifest system that is designed to track waste from its generation to final disposal.

2-2.2.6 The Occupational Safety and Health Act.

The Occupational Safety and Health Act establishes health and safety requirements for the workplace, including handling and labeling requirements, safety precautions, and exposure limits to workplace contaminants.

2-2.2.7 The Comprehensive Environmental Response, Compensation and Liability Act.

The Comprehensive Environmental Response, Compensation and Liability Act, also commonly referred to as “Superfund,” establishes the responsibilities and procedures for the response to, and control of, existing uncontrolled hazardous waste sites.

2-2.3 Container Management Policy.

The Contractor should use containers that are either reusable or returnable. All containers remain the property of the contractor. All container systems are required to have secondary containment of the contents.

This Page Intentionally Left Blank

CHAPTER 3 TECHNICAL REQUIREMENTS MAKEUP WATER

3-1 MAKEUP WATER FOR INDUSTRIAL WATER SYSTEMS.

Industrial water systems at most United States Government installations use fresh water and, often, potable water. Makeup water, often referred to as "makeup," is fresh water that is added to an industrial water system to replace water lost by blowdown, evaporation, wind drift, leaks, steam, humidification, or withdrawal from these systems.

3-1.1 Sources of Makeup Water.

The usual source of makeup water is the installation's potable water supply. This source is water that has been conditioned and is usually of a very uniform quality from day to day. Other sources of makeup water could include groundwater obtained from shallow or deep wells, or surface water from streams or holding ponds. These sources are not treated to the extent that the potable water source is treated. Still another source is reuse water (for example water that is "used" and reclaimed and not rated as potable).

3-1.1.1 Groundwater.

The term "groundwater" refers to subsurface water, such as that obtained from wells or artesian springs. This water contains a high amount of dissolved minerals and is often consistent in quality, although it may vary with the seasons of the year and the conditions of the aquifer from which the water is drawn. Treating groundwater can improve its quality.

3-1.1.2 Surface Water.

The term "surface water" refers to water found in rivers or lakes. Surface water may vary in quality with the seasons of the year or local weather conditions, with higher turbidity and SS possible during rainy weather. Treating these waters prior to use can make the quality more uniform, depending on the type of treatment.

3-1.1.3 Reuse Water.

Reuse water is any water that has been previously used. Reuse water helps conserve the precious limited supply of fresh water since less fresh water is needed for an intended use. Treated municipal wastewater is a type of reuse water and can be a source of makeup. In addition to the natural impurities of a fresh water source, municipal wastewater usually contains ammonia, phosphate, and other byproducts of the waste treatment process. These impurities are factors that affect the usability of reuse water. Other examples of reuse water include cooling tower and boiler blowdown, softener rinse water, plating water effluent, condensate, and reverse osmosis (RO) reject water. Examine each type and source of reuse water and establish its suitability prior to use.

3-1.1.4 Source Selection Factors to Consider.

Industrial water systems will operate more effectively if the source for water is both reliable and (ideally) uniform in quality. A backup water source should be available for use in case of need.

3-1.2 Reasons and Criteria for Treating Makeup Water.

3-1.2.1 Reasons for Treating Makeup Water.

Makeup water is treated to remove or reduce the concentration of any unwanted impurity, including impurities that will cause corrosion, create a deposit or scale in the system, or otherwise interfere with the operation of the industrial water system or limit the use of the original water. The process of treating makeup water often results in water conservation, which minimizes the chemical treatments in terms of frequency and amount of use and the resulting cost.

3-1.2.2 Criteria for Treating Makeup Water.

3-1.2.2.1 Makeup Water for Cooling Tower Systems.

To allow the system to operate at a minimum of three COC, the makeup water needs to be of a minimum standard of quality. Pretreatment of makeup water for cooling towers is not required if the levels of impurities in the water are not excessive. Refer to Chapter 4 for factors limiting COC, including mineral limitations.

3-1.2.2.2 Makeup Water for Steam Boilers.

The quality requirement for makeup water often necessitates using water softeners (zeolite or ion-exchange units) to remove water hardness before use. Dealkalizers can be used to remove alkalinity. High-quality steam applications require demineralization or RO, or both.

3-1.2.2.3 Makeup Water for High-Temperature Hot Water Systems.

The makeup water for high-temperature 350° F (177° C), high-pressure hot water systems should be softened when its total hardness exceeds 10 parts per million (ppm) as calcium carbonate ($CaCO_3$). See Chapter 6 section 6-2 WATER TREATMENT FOR CLOSED SYSTEMS.

3-1.2.2.4 Other Systems.

Soften the makeup water for chilled water systems and for dual-purpose (hot and chilled) systems if its total hardness exceeds 250 ppm (as calcium carbonate [$CaCO_3$]). For hot water boilers, treat makeup water with sodium sulfite and caustic soda, and soften makeup water used for diesel jacket systems if the total hardness of the raw makeup water exceeds 50 ppm (as $CaCO_3$). See Chapter 6 section 6-2 WATER TREATMENT FOR CLOSED SYSTEMS.

3-1.2.3 Measurement of Makeup Water Rates.

Knowing the use rates of makeup water is essential for calculating proper operating data on cooling towers and steam boilers. You may estimate makeup water use rates by recording the time it takes to fill a container of known volume with water obtained from a blowdown line or, preferably, measured with an appropriately sized makeup meter to provide more accurate values. Filling a container is not a recommended method for measuring hot water streams such as boiler blowdown.

3-2 MAKEUP WATER TREATMENT METHODS.

Treatment of industrial makeup water is a process of external water treatment. External treatment involves the treatment, by various processes, of makeup water to remove or reduce hardness, alkalinity, dissolved gases, or other impurities before the water enters the water system (as in steam boiler, cooling tower, closed hot water system or chilled water system). This process of external treatment is often referred to as “pre-treatment.” In contrast, internal treatment involves the treatment of water directly within the water system. Both external and internal treatment methods may be used in a given system.

3-2.1 External Treatment.

External treatment equipment processes and water treatment chemicals reduce or remove impurities contained in the makeup water before the impurities in the water stream enter the internal system. The most effective way to protect the system, reduce boiler problems, and improve operating efficiency is to use a process of removing impurities before they enter a system, particularly a steam boiler. The required treatment methods and equipment are determined by the specific type and amount of impurities that must be reduced or removed from the makeup water. Table 3-1 lists the various external treatment methods that are available to remove the typical impurities found in makeup water. Figure 3-1 illustrates the effects of these treatment methods on raw water.

The treatment process may be applied to only a portion of the makeup water, in which case the treated water is then blended with raw (untreated) water to achieve a specific quality. Treatment involving this type of blending is known as “split-stream” treatment. Split-stream treatment may also involve the blending of two different treated waters to achieve a specific quality. Paragraphs 3-2.2 through 3-2.10 briefly describe external treatment methods. External water treatment is required only for steam boilers and high-temperature hot water systems, but its use may be justified for other industrial water systems as well. Although several types of treatment may be available, government installations most commonly use sodium zeolite softening (ion exchange) for treating makeup water. Table 3-2 provides a guide for selecting external treatment methods/equipment for steam boilers.

Table 3-1 Makeup Water Treatment Methods for Removing Impurities

Impurity	Removal/Reduction Method
Hardness (calcium & magnesium)	Sodium ion exchange Hydrogen ion exchange Lime-soda softening Evaporators RO Electrodialysis
Alkalinity (bicarbonate & carbonate)	Lime-soda softening Hydrogen ion exchange (followed by degasifying) Dealkalization (chloride ion exchange)
SS/turbidity	Filtration/clarification
Dissolved solids	Demineralization (deionization) Evaporators RO Electrodialysis
Dissolved iron	Aeration (converts to precipitated iron), then filtration Sodium ion exchange (iron will foul the resin)
Dissolved gases (carbon dioxide, hydrogen sulfide, methane)	Aeration Degasifying

Figure 3-1 **Effects of Treatment on Raw Water**

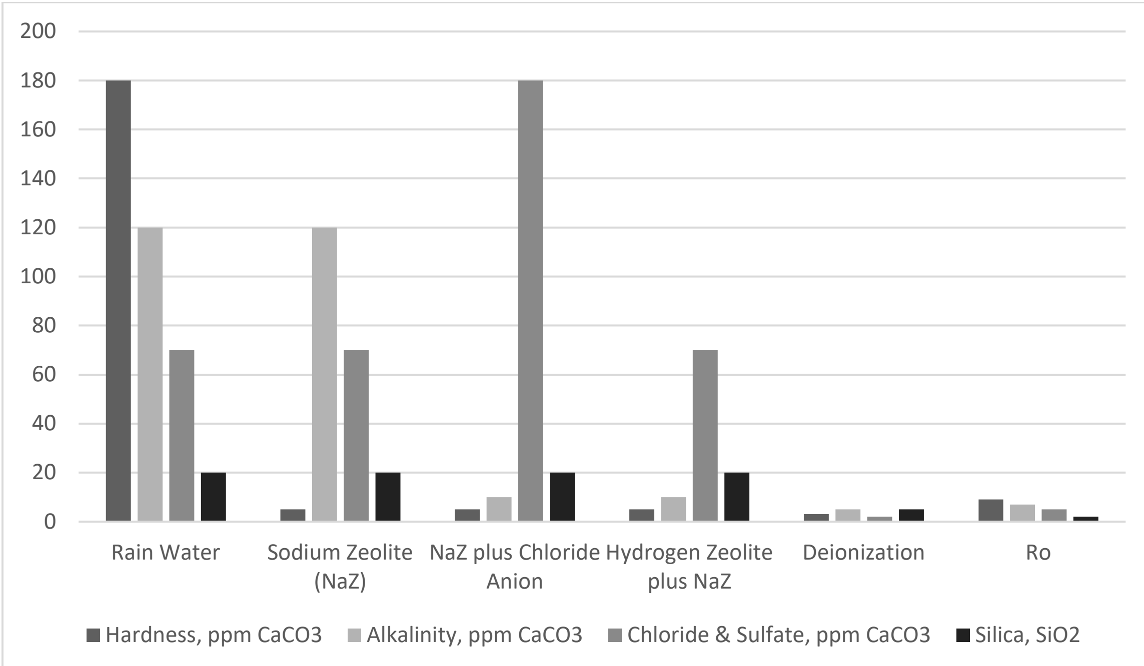

Table 3-2 External Treatment Equipment Selection Guide for Steam Boiler Makeup Water1

Makeup Rate l/sec (gpm)	Steam Pressure KPa (psig)	Alkalinity (ppm $CaCO_3$)	Turbidity	Recommended External Treatment Equipment
All	< 103 (< 15)	All	< 10	Normally internal treatment only
			> 10	Filtration plus internal treatment
< 6.3 (< 100)	103-138 (15-200)	< 75	< 10	Sodium zeolite
			> 10	Filtration plus sodium zeolite
		> 75	< 10	1. Sodium zeolite plus hydrogen zeolite 2. Sodium zeolite plus chloride/anion exchange 3. Hydrogen zeolite
			> 10	1. Filtration plus sodium zeolite plus hydrogen zeolite 2. Hydrogen zeolite
	138-448 (200-650)	< 35	< 10	Sodium zeolite
			> 10	Filtration plus sodium zeolite
		> 35	< 10	1. Sodium zeolite plus hydrogen zeolite 2. Demineralization
			> 10	1. Filtration plus sodium zeolite plus hydrogen zeolite 2. Filtration plus demineralization
> 6.3 (> 100)	103-138 (15-200)	< 75	< 10	Sodium zeolite
			> 10	1. Filtration plus sodium zeolite 2. Hot-lime soda
		> 75	< 10	Sodium zeolite plus hydrogen zeolite
			> 10	1. Filtration plus sodium zeolite plus hydrogen zeolite 2. Filtration plus demineralization Hot-lime hot-sodium zeolite
	138-448 (200-650)	All	< 10	1. Sodium zeolite plus hydrogen zeolite 2. Demineralization
			> 10	3. Filtration plus sodium zeolite plus hydrogen zeolite 4. Filtration plus demineralization Hot-lime hot-sodium zeolite
All	> 448 (> 650) (normally super-heated)	All	< 10	Demineralization
			10-400	Filtration plus demineralization
			> 400	Filtration plus demineralization RO Electrodialysis

1. See notes on following page.

NOTES:

1. Table 3-2 provides only general guidelines. The final choice of treatment system must be based upon complete raw water analysis, feed water requirements, and overall economics, including both external and internal treatment and blowdown. External treatment may be necessary to reach recommended levels of total dissolved solids (TDS) without exceeding other parameter limits for causticity, silica, or SS.
2. Separate deaeration is required for all boilers with pressure over 15 pounds per square inch gauge (0.103 megapascal), except where lime-soda softeners are designed to provide adequate deaeration as well as softening.
3. Degasification is required after hydrogen zeolite treatment.
4. The filtration process may require clarification and aeration.

3-2.2 Aeration.

Well water can contain high levels of dissolved iron (1 to 5 ppm). Although this quantity of dissolved iron may seem small, it can produce excessive precipitates when the iron comes in contact with air. If these precipitates are deposited in system lines, they will restrict flow and heat transfer. Soluble iron can be removed by filtration after contact with air (aeration), a process that causes the soluble iron to be converted by oxidation to insoluble iron, which then precipitates. Aerators are designed to mix air and makeup water in equipment that contains slats or trays to provide thorough mixing (aeration of the water). They are usually of the coke tray or wood slat design. Coke tray aerators consist of a series of coke-filled trays through which the water percolates. A forced-draft fan supplies air for aeration during the percolation process, with the water free falling from one tray to the next. Wood slat aerators are similar to small atmospheric cooling towers with staggered slats to break the free fall of the water and thereby increase the surface contact with air. Wood slat aerators can also be equipped with a forced-draft fan to increase efficiency. In addition to oxidizing iron, aeration can also strip or remove dissolved gases such as carbon dioxide, hydrogen sulfide, and methane. Aerators also contribute to a reduction in dissolved manganese by causing it to be oxidized to an insoluble salt.

3-2.3 Filters and Filtration.

A variety of filters can remove particles in a wide range of sizes, from course to very fine. These solids or particles may include soluble iron that has been precipitated, residual calcium carbonate particles, sand, dirt, debris, and some microbiological organisms.

3-2.3.1 Sand Filters.

3-2.3.1.1 Sand Filter Description.

A sand filter is a bed of sand (or anthracite coal) located below a set of distribution headers and resting on a support layer of coarse rock. The collection header, through which the clarified water is drawn, is situated below the sand filter. Water flows downward through the filter bed, either due to gravity or by applied pressure.

3-2.3.1.2 Method of Action.

The sand or anthracite acts as a support bed for a layer of SS laid down on top of the bed as a result of the filtering process. This layer of deposited solids, formerly SS, does most of the actual removal of solids from the water and is known as the filter cake.

3-2.3.1.3 Filter Cycle.

As the thickness of the filter cake builds up, the water flow decreases and the backpressure increases. When the flow rate becomes too low or the back-pressure too great, the water flow can be reversed, with the filter cake then being backwashed with the wash water to a waste collection point. The filter is then returned to service and the cycle is repeated.

Sand filtration rates are typically 3 gallons per minute per square foot (2 liters per second per square meter). Backwash rates are 12 to 15 gallons per minute per square foot (8.1 to 10.2 liters per second per square meter) for sand filters and 8 to 12 gallons per minute per square foot (5.4 to 8.1 liters per second per square meter) for anthracite filters. A variety of filter types are available.

3-2.3.2 Cartridge and Bag Filters.

Cartridge and bag filters are available in various mesh and pore sizes, which determine the size of the particles removed.

3-2.3.3 Centrifuge Separators.

Centrifuge separators represent still another way to remove suspended materials by passing water through a centrifuge chamber where particles are removed due to density instead of size. Using separators is limited to removing very small particulates. An advantage of separators is that they do not require back flushing or change-outs of filter cartridges or bags.

3-2.4 Lime-Soda Softening.

The lime-soda process is often used for treating large volumes of water 10,000 gallons per day (37,850 liters per day or higher) for potable and industrial uses. The process is used primarily to reduce the levels of hardness and alkalinity, but also to reduce the quantity of silica and SS. The process could be applicable to an entire base or facility; usually this process is not practical for individual small site locations. The process is labor intensive and can produce large amounts of sludge from the precipitated materials.

3-2.4.1 Method of Action.

The process involves adding hydrated lime (calcium hydroxide) and soda ash (sodium carbonate) to the water in an open reaction tank. The calcium and magnesium concentration is reduced by the resulting precipitation of solids. Bicarbonate and carbonate alkalinity is also reduced, as may be some silica. The sludge that is formed is allowed to settle for subsequent removal as a watery sludge. The treated water is filtered prior to use as makeup.

3-2.4.2 Cold and Hot Processes.

Adding lime and soda ash at ambient temperature is referred to as the "cold lime-soda process." When lime and soda ash are reacted with the water at temperatures greater than 212˚ F (100˚ C), the process is called the "hot lime-soda process". The hot process removes a greater amount of the hardness, alkalinity, and silica from the water than the cold process.

3-2.5 Ion Exchange Process.

Several types of ion exchange units are used at military installations. An ion exchange unit is an open or closed vessel containing an ion exchange material, also known as resin, which has been deposited on a gravel support bed. Most ion exchange units operate under pressure, but gravity flow units are also available. Flow rates vary with the type of equipment but are in the range of 6 to 8 gallons per minute per square foot of ion exchange material surface (4 to 5.4 liters per second per square meter). A backup ion exchange unit and a storage tank are typically included to permit an uninterrupted supply of treated water. The manufacturer's recommendations for proper equipment operation should be posted near the softening unit. A typical ion exchange hardness softener unit is illustrated in Figure 3-2. Figure 3-3 shows a typical duplex softener.

Figure 3-2 **Typical Ion Exchange Unit**

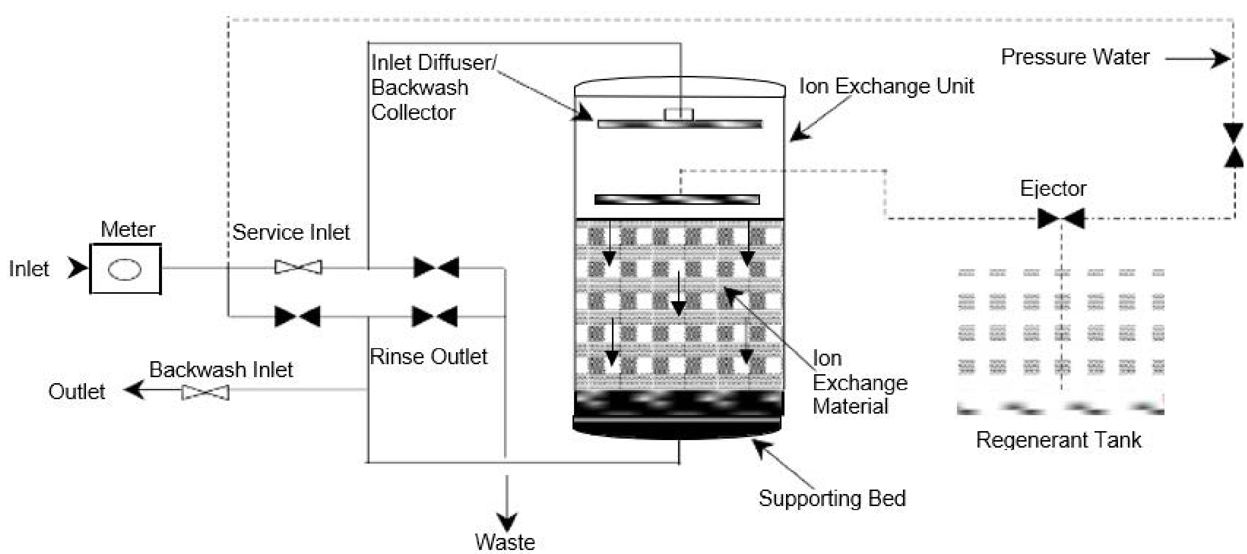

Figure 3-3 **Duplex Softener**

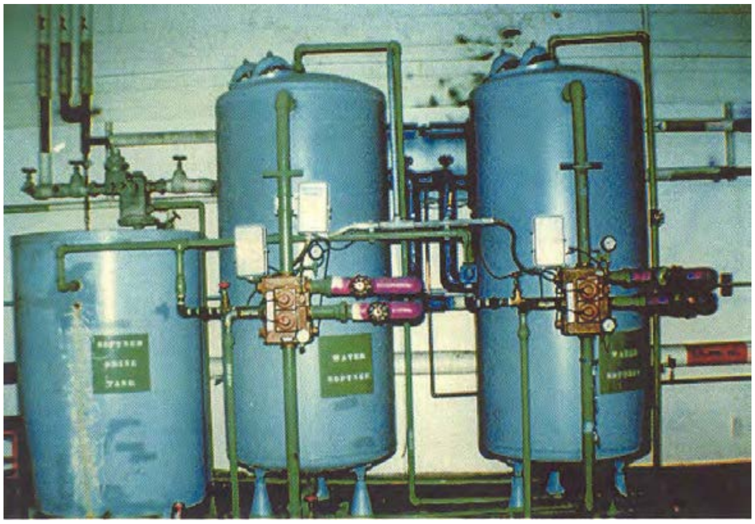


3-2.5.1 Sodium Ion Exchange.

3-2.5.1.1 Service Cycle.

The normal operating cycle during which hardness is removed from the makeup water flowing through the softener is determined by calculating the amount of water that can be softened by a given ion exchange material. The operator must consider several factors:

3-2.5.1.2 Sodium Ion Exchange Process.

The sodium ion exchange process depends upon the exchange of sodium ions in either the zeolite material or synthetic ion exchange resins (whichever is used) for calcium and magnesium ions in the makeup water, as shown below:

Calcium and Magnesium Hardness in Water	+	Sodium Zeolite	→	Calcium/Magnesium Zeolite ion exchange Resin	+	Sodium salts in water

3-2.5.1.3 Water Softener Capacity.

The softening capability or capacity of an ion exchange softener is usually given in units of grains (grams) of total hardness of calcium carbonate ($CaCO_3$). The operator needs to know how much water can be softened before regeneration is necessary. The volume of water that can be softened between regeneration cycles is determined by the softener capacity and the hardness in the water. See the example calculations below.

Equation 3-1. Water Softening

English Units:

The maximum capacity of the ion exchange softener is 2,000,000 grains. The water being treated has 257 ppm total hardness. If the softener regenerations cycle is set for maximum capacity, how many gallons of water can be softened before the softener must be regenerated?

$$Removal = \frac{Capacity, grains\ x\ 17.12}{\text{Total hardness, ppm, in raw water}}$$

$$= \frac{\text{2,000,000 grains x 17.12ppm 1}\ grain\ per\ gallon}{\text{257 ppm}}$$

$$= 133{,}230\ gallons$$

Metric Units:

2,000,000 grains x (1 pound/7,000 grains) x (453.6 grams/1 pound)

= 129,600 grams

$$Removal = \frac{\text{Capacity, grams x 1000 mg/gram}}{\text{Total hardness, ppm}\ (mg\ /\ liter)\text{, in raw water}}$$

$$= \frac{\text{129,600 grams x 1000 mg / gram}}{257\ ppm\ (mg\ /\ liter)}$$

$$= 504{,}280\ liters$$

Thus, for a softener with a rated capacity of 2,000,000 grains (129,600 grams), 133,230 gallons (504,280 liters) of water, with 257 ppm total hardness, can be softened between regeneration cycles.

3-2.5.1.4 Regeneration Cycle.

Regeneration of the ion exchange resin refers to replacement of the calcium/magnesium hardness that has accumulated on the ion exchange resin as a result of the exchange with sodium ions. The regeneration cycle is a process involving a number of steps during which the softener is taken off-line and backwashed. The resin is regenerated by treatment with a strong solution of salt (sodium chloride) and then rinsed.

When the exhausted ion exchange resin material is washed with a strong sodium chloride salt solution (brine), the resin is regenerated by the hardness (calcium and magnesium ions) being exchanged for sodium ions.

Hardness	Sodium	$\rightarrow$	Sodium	Hardness
Zeolite	Chloride		Zeolite	Chloride

The completeness of the regeneration is dependent upon the strength of the salt solution (brine) used and the length of time the solution is in contact with the resin. After the resin is regenerated, it can be used again and again (after regeneration) to continue to remove hardness from water. The following procedure is typical for an ion exchange resin regeneration process.

3-2.5.1.5 Backwash.

Before the exhausted resin bed is regenerated, it must be backwashed by flowing water from bottom to top. The flow rate must be adequate to remove any solids that have been caught on top of the bed. The resin bed volume will also be expanded by about 50 percent due to the backwash flow; the volume of expansion will be dependent upon the flow rate. The backwash flow rate should be controlled so that it will not sweep ion exchange resin out of the softener to the waste collection area. A backwash rate of 4 to 6 gallons per minute per square foot (2.72 to 4.07 liters per second per square meter) of bed surface for about 10 minutes is normal, but the manufacturer's recommendations should be followed.

3-2.5.1.6 Brining.

Next comes the addition of salt, a process known as “brining.” A 10 percent (by saturation) solution of sodium chloride salt brine is slowly added with a down- flow rate of 0.5 to 1 gallon per minute per cubic foot (1.11 to 2.22 liters per second per cubic meter) of bed volume for about 30 minutes. Rock salt is preferred to granulated salt as a brining salt because it is equally as effective, less expensive, and less prone to cake. Some installations may start with a solution of concentrated or saturated brine, which must be diluted before use in the brining step. The salt required and the capacity regenerated is shown for a typical resin in Table 3-3; however, the manufacturer's instructions should be followed, if available.

Table 3-3 Salt Required for Regeneration of a Commonly Used Cation Resin

Salt Use per lb/ft^3 of Ion Exchange Material (kg/m^3)	Capacity of Ion Exchange Material Hardness gr/ft^3 (m^3)
5.0 (80)	19,000 (43,450)
7.5 (120)	24,000 (55,130)
10.0 (160)	27,000 (61,615)
15.0 (240)*	32,000 (73,290)*

* Practical upper limit for exchange capacity. This upper limit and the actual dose per capacity relationship may vary with the resin; the manufacturer's instructions should be followed.

3-2.5.1.7 Slow Rinse.

A slow rinse follows the brining step and is performed at the same rate as the brining step. The rinse is performed with down flow through the softener. One to 3 bed volumes of fresh water are used to remove most of the excess sodium and hardness brine from the bed. The volume of fresh water is equal to 7.5 to 22.5 gallons per cubic foot (1000 to 3000 liters per cubic meter) of bed volume.

3-2.5.1.8 Fast Rinse.

In the last step, a fast rinse is used, also with down flow, to remove any traces of the sodium and hardness brines. This is done at a rate of 1.5 to 2 gallons per minute per cubic foot (200 to 270 liters per minute per cubic meter) of bed volume until the discharge is free of hardness; 35 to 100 gallons per cubic foot (4690 to 13,400 liters per cubic meter) of bed volume is required. The unit is now ready for another service cycle.

3-2.5.1.9 Testing and Record Keeping.

Influent water should be tested for hardness on a weekly basis. The softener effluent water should be tested for hardness on a daily basis, every shift (3 times a day), or as required for systems that require frequent (1 to 3 days) or less frequent regeneration. Accurate records should be kept of these tests, including recording the number of gallons (liters) of water that have been treated during each service cycle, and the amount of salt that was used during each regeneration cycle.

3-2.5.1.10 Operating Problems.

Several common problems are sometimes encountered during softener operation:

3-2.5.1.11 Resin Fouling.

A normal decrease in exchange capacity due to resin fouling is about 5 percent per year. Any decrease greater than this should be determined and corrective action taken.

3-2.5.1.12 Fouling Due to Iron.

A common cause of loss of capacity is resin fouling by iron salts. Soluble iron will exchange for sodium during the service cycle, but sodium will only be incompletely exchanged for iron during the regeneration cycle. There is a simple test to determine iron fouling: a pinch of iron-fouled ion exchange material added to a 10 percent hydrochloric acid solution in a test tube will cause the hydrochloric acid to turn yellow, indicating the presence of iron.

Iron-fouled resin can be returned to design capacity by cleaning with dilute hydrochloric acid, sodium bisulfite, or special resin cleaners. Specific procedures are required.

NOTE: The softener manufacturer's recommendations should be consulted before using this acid cleaning procedure, including those prohibiting acid procedures with a galvanized or unlined steel tank. To use acid procedures, the tank must be constructed of reinforced plastic or rubber, or must be plastic-lined with no breaks in the lining.

3-2.5.1.13 Improper Backwash.

Improper backwash is another common problem. A backwash rate that is too high can result in the ion exchange material being washed out of the unit. The bed depth can be measured by carefully probing to the underdrain support bed. Normal bed depth is usually 30 to 36 inches (0.75 to 1 meter). The bed volume in cubic feet (cubic meters) can be calculated by the following formula:

$$\text{Volume, m}^3 = (\text{Radius, m})^2 \times (\text{Depth, m}) \times 3.14$$

Check the bed depth at 10 points and use the average value. If there is much difference (15 percent or more) in the thickness of different points, channeling may be occurring. Channeling can be caused by too low a backwash rate.

If the calculated bed volume is less than the volume given by the manufacturer, material has been lost during the backwash step. The lost material should be replaced and the backwash rate carefully controlled to ensure material is not being washed out. If the cause of the unit's performance problem or deficiency cannot be determined, the manufacturer's service representative should be consulted.

3-2.5.1.14 Resin Replacement.

The resin in the ion exchanger should be replaced when either the resin capacity or the softening efficiency has decreased by 25 percent and cannot be restored by cleaning and by following the specific procedures recommended by the manufacturer. Based on a normal decrease of 1 to 5 percent per year, the typical ion exchange resin should last from 5 to 25 years. With good operation, the average service life is 8 to 10 years.

3-2.5.2 Hydrogen Ion Exchange.

The hydrogen ion exchange process is essentially the same as the sodium ion exchange process except that the regenerant chemical is an acid (sulfuric or hydrochloric) rather than a salt. The hydrogen ion exchange process will reduce both the amount of the total dissolved solids and the alkalinity of the treated water. During operation of the hydrogen cycle softener, it is necessary to check the outlet (softened) water at regular intervals. The hardness of the outlet water should always be less than 1 ppm. The ion exchange resin must be regenerated if the hardness exceeds 1 ppm. This check can be performed daily, once per shift, or as required depending on unit capacity.

3-2.5.2.1 Exchange Process.

Resins exchange calcium, magnesium, sodium and all cations with hydrogen ions.

Calcium/ Magnesium/ Sodium Salts	+	Hydrogen Zeolite	→	Calcium/ Magnesium/ Sodium Zeolite	+	Hydrogen Salts in Water

The hydrogen salts are acidic and will react with alkalinity to produce carbon dioxide and water. To provide for effective operation, the carbon dioxide must be removed after leaving the vessel by other means.

3-2.5.2.2 Regeneration Method.

The spent ion exchange material is regenerated by contact with dilute acid, such as sulfuric acid or hydrochloric acid.

Hardness and Sodium Salts	+	Sulfuric Acid	→	Hydrogen Zeolite	+	Hardness and Sodium Salt

Adding sulfuric acid in several steps of increasing strength, such as 2, 4, or 6 percent are required for sulfonated styrene resins if fouling of the exchange resin with calcium sulfate is to be avoided.

3-2.5.2.3 Equipment Requirements.

The hydrogen ion exchanger is much the same as the sodium ion exchanger, except that all equipment must be made of, or lined with, acid-resistant material.

3-2.5.2.4 Regeneration Cycle.

The regeneration cycle is much the same as that for the sodium ion exchanger, except that sulfuric acid is used instead of salt. To improve efficiency, regeneration of hydrogen ion exchangers is commonly done counter- currently. During operation of the hydrogen cycle softener, it is necessary to check the outlet (softened) water at regular intervals. The hardness of the outlet water should always be less than 1 ppm. The ion exchange resin must be regenerated if the hardness exceeds 1 ppm. This check can be performed daily, once per shift, or as required depending on unit capacity. Available information on safety and first aid should be reviewed before using sulfuric acid. Chemical handling and safety instructions should be posted near sulfuric acid equipment. Sulfuric acid is corrosive to skin, eyes, clothing, and other materials. Hydrochloric acid should be used with the same precautions. See section 8-4 for chemical safety information.

3-2.5.2.5 Troubleshooting.

Troubleshooting is much the same as for sodium ion exchange, although iron fouling does not occur in hydrogen ion exchangers since the acid removes iron from the resin.

3-2.5.2.6 Effluent Water Properties.

The hydrogen ion exchange effluent water is acidic and cannot be used directly. The water can be mixed with the outlet of a sodium ion exchanger with the result that the acid in the hydrogen ion exchange water will be neutralized to some degree and, at the same time, the degree of alkalinity in the sodium ion exchange water will be lessened. The proportion of the effluent waters to be mixed is dependent upon the analysis of the water being treated, but typically the proportion is approximately one-to-one (half-and-half). The testing of blended water should be done prior to blending to assure that the blended water is satisfactory for use in the boiler or cooling water system. If neutral (pH 7) water is required, a chemical (such as sodium hydroxide) must be added.

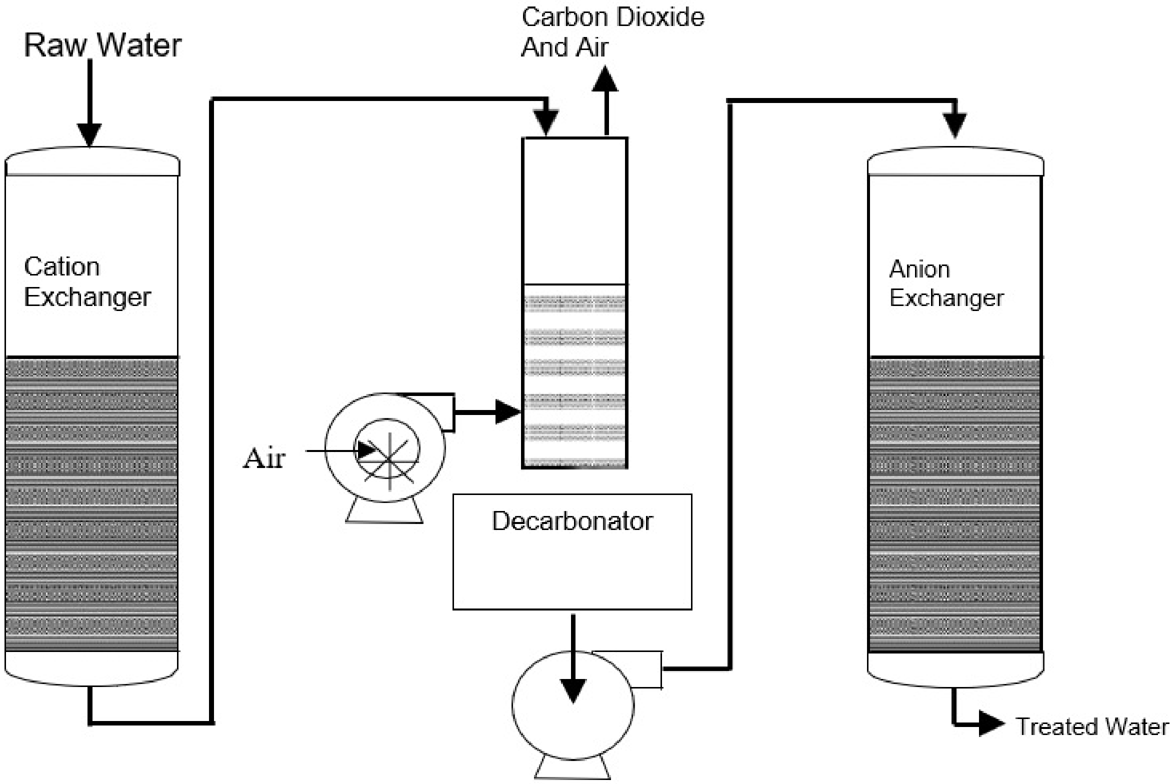
3-2.5.2.7 Carbon Dioxide Production.

Carbon dioxide is produced during the hydrogen ion exchange process and is also produced when the effluent water from hydrogen and sodium ion exchange is mixed. It is removed from the water in a decarbonator (degasifier or deaerator).

3-2.5.3 Demineralization.

Sodium and hydrogen ion exchangers remove only the positively charged ions (cation exchange - like calcium, magnesium, and sodium). Other ion exchange materials have been developed to remove negatively charged ions (anion exchange – such as sulfates, chlorides, and alkalinity). The process of demineralization uses both cation and anion exchange resins to remove all ions from the water, thus producing mineral-free water. A typical deionization (demineralizer) process is illustrated in Figure 3-4. During operation of the demineralizer, it is necessary to check the outlet water at regular intervals. The TDS of the outlet water should always be less than 1 ppm. The ion exchange resin must be regenerated if the TDS exceeds 1 ppm. This check can be performed daily, once per shift, or as required depending on unit capacity.

Figure 3-4 **Demineralization Process**



3-2.5.4 Anion Exchange Process.

The hydrogen ion exchange process is described in paragraph 3-2.5.2. The anion exchange process involves reactions of hydroxyl-regenerated zeolite with the effluent from the hydrogen ion exchanger:

Hydrogen and Anions+	Hydroxyl Zeolite	→	Water +	Sulfate/Chloride Zeolite

3-2.5.5 Anion Ion Exchange Regeneration Method.

The spent anion ion exchange material containing chlorides, sulfates, and other anions is regenerated with sodium hydroxide (caustic).

Sulfate Chloride Zeolite+	Sodium Hydroxide	→	Hydroxyl+	Sodium and Anions Zeolite

3-2.5.5.1 Exchange Process Result.

When the anion exchange process is combined with the hydrogen exchange process, the resulting final water will contain no minerals. It has become deionized (also referred to as demineralized) by exchanging all minerals to hydrogen hydroxide, HOH, commonly referred to as water and written as H_20.

3-2.5.5.2 Exchange Method.

The two reactions can take place in separate vessels (a “two-bed” deionizer), or the two ion exchange materials can be combined in a single vessel (a “mixed-bed” deionizer).

3-2.5.5.3 High Silica Waters.

Removal of silica and magnesium beyond what most demineralizers will provide is accomplished through pre-heating of caustic solution used for regeneration. Optimum temperature is 120 F (49 C) and should not exceed 140 F (60 C), as that temperature can damage the resin; however, few demineralizers are designed for this application.

3-2.5.5.4 Deionization Process Use.

The deionization process is not used at government installations. It is required mainly for high-pressure boilers or high-purity water use. The deionization process may also be used for shore plants providing steam or boiler feedwater to ships.

3-2.5.6 Dealkalization.

3-2.5.6.1 Anion Dealkalization.

It may be necessary to treat water having low hardness and high alkalinity to reduce the alkalinity (bicarbonate and carbonate). The anion exchange process called “anion dealkalization” will remove alkalinity and other anions (like sulfates and nitrates). In most cases, the anion dealkalizer is used following a hardness softener (it is located downline from the softener) because hardness, if not previously removed, can precipitate in the anion resin bed and cause plugging.

Bicarbonate and carbonate (anions) are exchanged for chloride (anion) as illustrated by the following reaction, where “Z” is the zeolite resin material:

NaHCO3 Sodium Bicarbonate	+	ZCl Chloride → Zeolite	NaCl Sodium Chloride	+	ZHCO3 Bicarbonate Zeolite

3-2.5.6.2 System Regeneration.

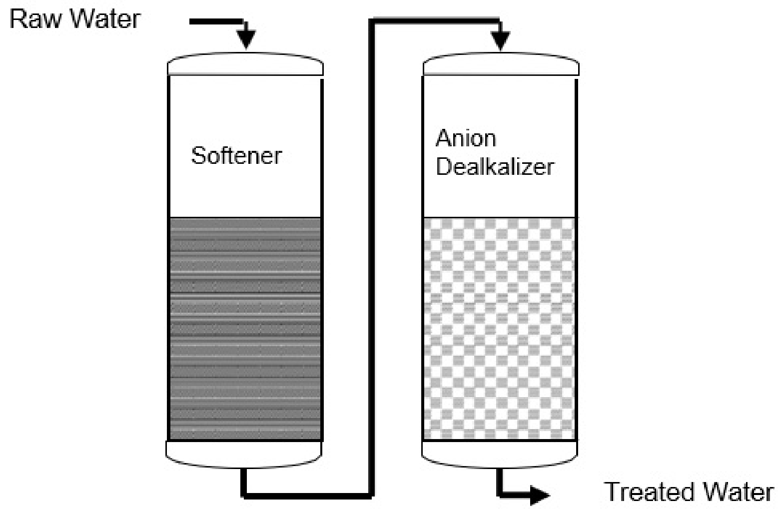
The system is regenerated with sodium chloride (salt) as shown below. The regeneration will be more efficient and effective if the brine used contains about 10 percent of the salt as caustic.

ZHCO3 Bicarbonate Zeolite	+	NaCl Sodium Chloride	→	ZCl Chloride + Zeolite	NaHCO3 Sodium Bicarbonate

3-2.5.6.3 Equipment and Operation.

The equipment and operation of such a system is much the same as for a sodium ion exchange material system described in the paragraph above. This process is illustrated in Figure 3-5.

Figure 3-5 **Anion Dealkalization Process**



3-2.5.6.4 Split-Stream Dealkalization.

In a split-stream dealkalization process, the water is split into two parallel streams with one stream passing through a strong acid cation exchanger (dealkalizer) and the other through a sodium zeolite softener. Blending of the two product streams produces a soft water that is low in alkalinity. The alkalinity reduction is described by the following equation, where "Z" is the zeolite resin material:

Ca(HCO3)2	+	2ZH	$\rightarrow$	Z2Ca	+	2H2CO3
Calcium Bicarbonate		Hydrogen Zeolite		Calcium Zeolite		Carbonic Acid

The carbonic acid dissociates into carbon dioxide (CO_2) and water (H^2O). The water is then passed into a decarbonator (degasifier or deaerator) to remove the CO_2.

3-2.5.6.5 Free Mineral Acid Production.

The strong acid cation exchange resin replaces the sodium, calcium, and magnesium ions with hydrogen ions. Thus, due to the presence of chlorides, sulfates, nitrates, and other anions, free mineral acids (FMA) (like hydrochloric and sulfuric) are produced. Adjustment of the pH level is necessary to balance alkalinity with acidity FMA and form neutral water.

3-2.5.6.6 System Regeneration.

The strong acid cation system is regenerated with sulfuric acid.

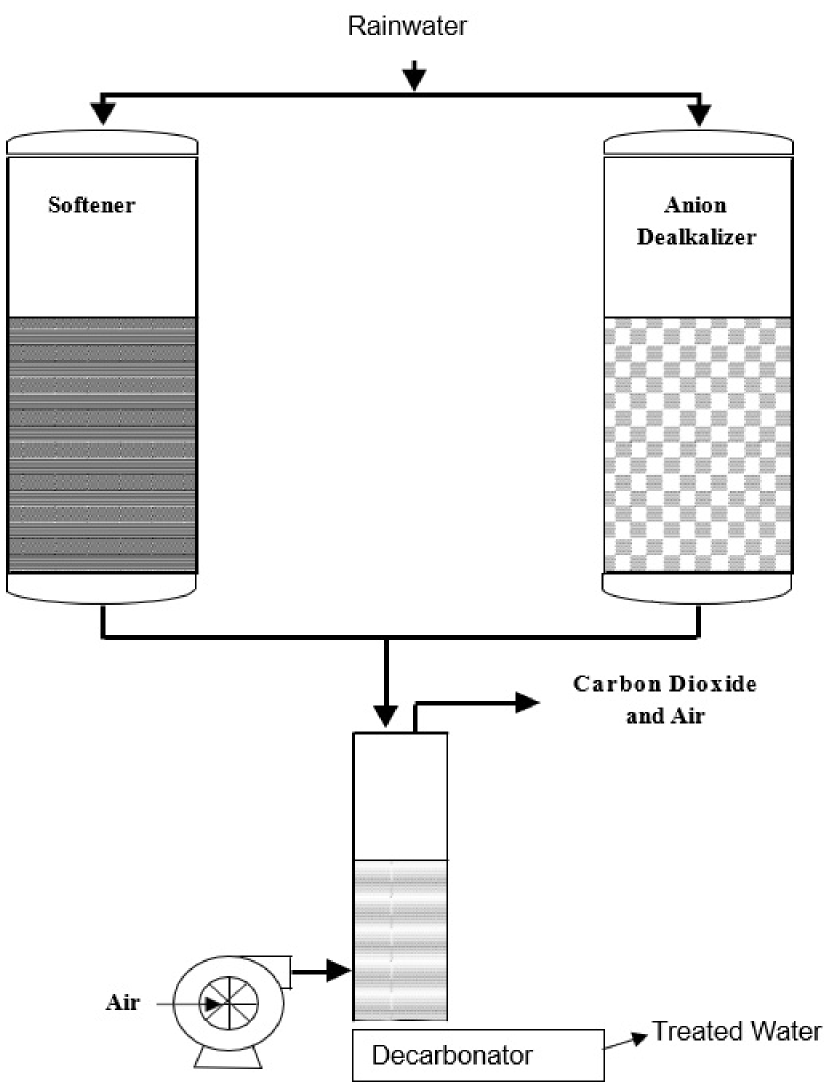
3-2.5.6.7 Equipment Requirements.

The acid exchanger tank must be made of, or lined with, an acid-resistant material.

3-2.5.6.8 Decarbonator Use.

Since blending the two split streams of finished water also produces CO_2, a decarbonator (degasifier or deaerator) is normally used to reduce the CO_2 concentration to 5 to 10 ppm or less. A typical split-stream process is shown in Figure 3-6.

Figure 3-6 **Split-Stream Dealkalizer**



3-2.5.7 Decarbonation.

Carbon dioxide is produced during hydrogen ion exchange and when the effluent waters from strong acid cation ion exchange and the sodium ion exchange are mixed. Carbon dioxide dissolved in water can cause corrosion in water lines, pump impellers, and vessels. As described in Chapter 4, the carbon dioxide concentration must be kept as low as possible in the boiler feed water and in the water entering steam condensate lines.

3-2.5.7.1 Methods of Decarbonation.

Free carbon dioxide is commonly removed in a degasifier or aerator (see paragraph 3-2.2). In steam systems and in high- temperature water systems, removal of CO_2 is usually achieved in the deaerator rather than with a separate degasifier unit, although steam systems can have degasifiers.

3-2.5.7.2 Analysis of Carbon Dioxide Content.

By analyzing the water for the hydrogen ion concentration (pH) and the total (M) alkalinity, the free carbon dioxide content can be calculated (see Table 3-4)

Table 3-4 Carbon Dioxide Content of Water vs. pH

pH	CO_2	pH	CO_2	pH	CO_2
5.4	4.4 M	6.6	0.45 M	7.3	0.099 M
6.0	1.9 M	6.7	0.38 M	7.4	0.079 M
6.1	1.5 M	6.8	0.31 M	7.5	0.062 M
6.2	1.23 M	6.9	0.24 M	7.6	0.050 M
6.3	0.92 M	7.0	0.19 M	7.7	0.040 M
6.4	0.75 M	7.1	0.15 M	7.8	0.033 M
6.5	0.62 M	7.2	0.12 M	7.9	0.026 M

NOTES:

1. At pH levels of 8.0 or higher, the free CO_2 content is negligible.
2. “M” is total alkalinity (as calcium carbonate [$CaCO_3$]).

EXAMPLE:

a. Total alkalinity (M) of an inlet water to a degasifier is 100 ppm and the pH is 6.8. CO_2 content = Value x M = 0.31 x 100 = 31 ppm

b. The outlet pH is 7.9, so the CO_2 content will be (let M = 80, since some alkalinity was removed as CO_2): CO_2 content = 0.026 x 80 = 2.1 ppm

c. The carbon dioxide removal is: 31 - 2.1 = 28.9 ppm

3-2.6 Evaporators.

In the evaporation process used in evaporators, water is heated to produce relatively pure water vapor that is then condensed to liquid water and used for boiler feed. Evaporators are of several different types. The simplest is a tank of water through which steam coils are passed to heat the water to the boiling point. To increase efficiency, the vapor from the first tank may pass through coils in a second tank of water to produce additional heating. Another type of evaporator operates under a partial vacuum, lowering the boiling point of water and enabling evaporation at lower temperatures. Following its production in the evaporator, water vapor is cooled and becomes liquid water that is essentially pure water, without any dissolved solids. Using evaporators may be economical where inexpensive steam is readily available as the source of heat. Evaporators also have an advantage over deionization units when the dissolved solids in the raw water are very high, such as on ocean-going vessels.

3-2.7 Reverse Osmosis (RO).

This process is the opposite of osmosis. It produces very pure water by separating dissolved minerals from the water. Water pressure is used to push water though a membrane. The membrane allows only pure water to pass through. Water thus produced is known as RO product water. All dissolved solids, organics, and gases that do not pass through the membrane are removed in the waste stream of RO reject water. Sufficient care must be taken to protect the membrane from deposits, which reduce efficiency or plug the membrane. This RO process is illustrated in Figure 3-7. An RO unit is shown in Figure 3-8.

Figure 3-7 **RO Schematic**

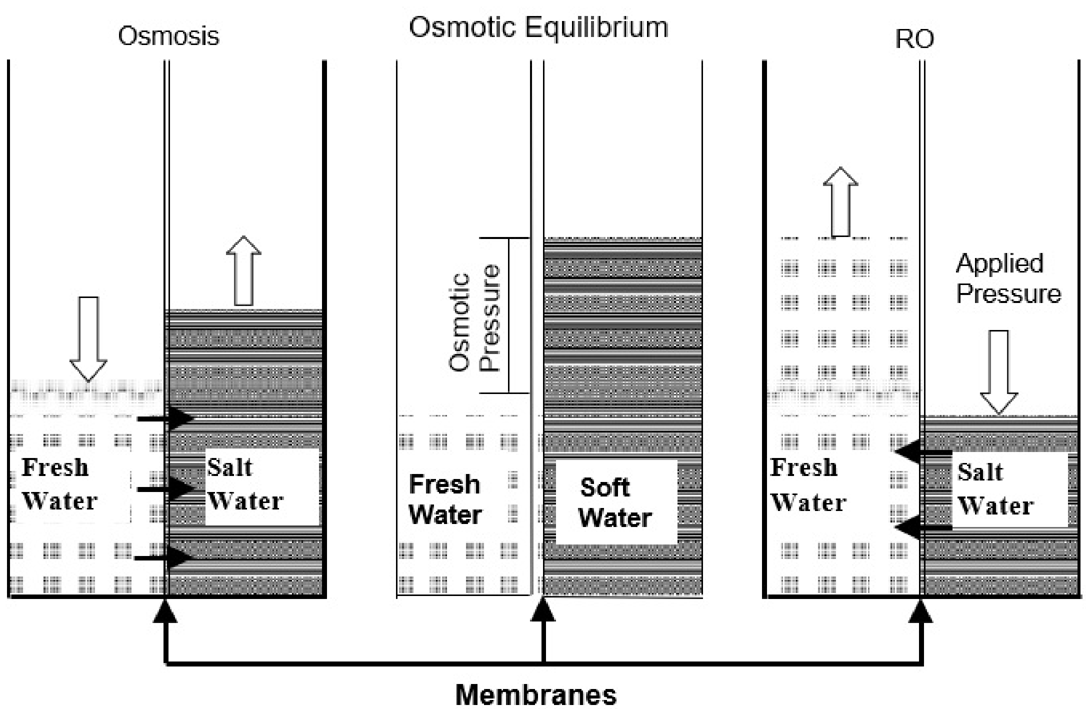


Figure 3-8 **RO Unit**

3-2.7.1 RO Pretreatment.

Material that can potentially foul (or plug) the membrane will interfere with the RO process and must be removed before the water contacts the membrane. Foulants include suspended and colloidal solids, iron, metal oxides, scale, and biological materials. It is important to determine a Silt Density Index (SDI), a measurement of suspended materials in the water, prior to using the water in the RO unit. Only water determined to be within the manufacturer's acceptable SDI range should be used. Pretreatment may be required to achieve an acceptable SDI.

3-2.7.1.1 SS Removal.

SS can be removed by filtration, usually using a sand filter followed by a cartridge filter. The addition of filter aids may be necessary to achieve acceptable filtration. In certain instances, coagulation and clarification may be required before the filtration step.

3-2.7.1.2 Iron Oxide Removal.

Iron oxides are the result of the oxidation of dissolved ferrous salts or corrosion of the equipment. The first process can be controlled by aerating the water prior to its being filtered, the second by threshold treatment with sodium hexametaphosphate before any aeration. For proper operation, these iron oxides must be removed prior to the water contacting the membrane.

3-2.7.1.3 Scale Prevention.

Scale-forming salts are concentrated as a result of the RO process just as they are during an evaporative process. To prevent scale, the water's pH is adjusted by adding either acid to produce a pH of between 5.0 and 6.5, or a scale inhibitor such as sodium hexametaphosphate or any of the phosphonates (PBTC (2-phosphonobutane-1,2,4-

tricarboxylic acid), HEDP (1-hydroxyethylidene 1,1- diphosphonic acid), or AMP (amino-tri (methylene) phosphonic acid)). The solubility of scale-forming salts controls the rejection rate of the water that cannot be processed through the RO unit (the amount of blowdown water produced). Specific guidelines should be obtained from the RO manufacturer.

3-2.7.1.4 Biological Fouling.

Biological fouling is a condition that must be prevented. Potentially, the RO unit membrane may be damaged when chlorine or other oxidants are used. For proper operation, the water must be dechlorinated with a reducing agent or with activated carbon before it contacts the RO membrane.

3-2.7.2 Membrane Configuration.

There are three basic membrane configurations: tubular, spiral-wound or scroll, and hollow fiber.

3-2.7.2.1 Tubular Configuration.

The tubular configuration is simply a porous tube supporting a membrane. Feedwater is introduced into the tube. Product water permeates the membrane going to the outside of the tube. The reject water exits from the far end of the tube.

3-2.7.2.2 Spiral Configuration.

The spiral configuration is a sheet membrane that is supported on each side by a porous material that provides flow distribution and rolled into a spiral or "jelly roll" configuration. The membrane is put in a pressure vessel so pressure can be maintained on its surface. This pressure forces the water through the membrane, separating it from the impurities. The membrane is laminated between porous sheets and sealed on three sides. The laminate is then attached on the fourth side to a porous tube and rolled around the tube into an element. Feed solution is forced into the element at one end, and the permeate works its way through the spiral to the axis tube where it emerges as purified product.

3-2.7.2.3 Hollow Configuration.

The hollow fiber configuration consists of small 3.3-inch (85-millimeter) diameter tubes whose outside wall is semi-permeable. A large number of these tubes are placed in a shell, similar to a heat exchanger. Water, under pressure, on the exterior of the tubes permeates the tubes and is collected from the tube interiors.

3-2.7.3 Sea Water.

RO technology is particularly useful when feedwater is high in dissolved solids or when the source is brackish water or seawater. When used ahead of a deionizer, the chemical requirements for the deionizers are greatly reduced, resin life is extended, and a smaller quantity of chemical regenerants is required.

3-2.8 Ultrafiltration.

The term “ultrafiltration” describes a pressurized membrane process in which particulate, colloidal, and high-molecular-weight dissolved materials are filtered from the water. Ultrafiltration is a process that is similar to RO in that a semi-permeable membrane is used to remove the filterable solids, except that the membrane is more porous, thus allowing some water-dissolved minerals to pass through with the product water. The feedwater flows through the inside of the fibers, permeates through the membrane, and is removed as product from the shell side. The filtered solids are continuously removed from the other end of the fiber in a reject stream that typically contains 5 to 10 percent of the feedwater dissolved solids.

3-2.9 Electrodialysis.

The term “electrodialysis” describes a process that separates all materials and minerals that are ionized from water by attracting the ions dissolved in the water through membranes that are oppositely charged. When the water is high in dissolved minerals, as in brackish water that contains more than 2500 ppm TDS, its use may be more economical than the ion exchange methods. Under some circumstances, it may remove enough minerals to make seawater usable in industrial water systems. This process does not remove un-ionized or poorly ionized materials such as some organics and soluble silica. As with RO, membranes must be kept clean.

3-2.10 Nanofiltration.

This is a process that, in terms of the size of materials removed, is intermediate between ultrafiltration and RO. The molecular weight cut-off properties of nanofiltration membranes are in the range of < 1 x 10-3 m (400 to 800 Daltons or 10 angstroms). Ionic rejections vary widely depending on the valence of the salts. Multivalent salts such as magnesium sulfate ($MgSO_4$) are rejected as much as 99 percent, while monovalent salts such as sodium chloride (NaCl) may have rejections as low as 20 percent.

CHAPTER 4 STEAM BOILER SYSTEMS

4-1 STEAM BOILER SYSTEM DEFINED.

A steam boiler is an enclosed vessel that holds water and is heated by an external source that converts the water to steam. All steam boilers contain tubes that separate the water from the heat source. Steam boilers are described in this Chapter; hot water boilers are addressed in Chapter 6. Operate boilers in accordance with UFC 3-430-07 and UFC 3-430-11.

4-1.1 Types of Steam Boilers.

Boilers are classified by two criteria*:* 1) operating pressure (the amount of internal pressure generated by the steam that is produced); and 2) the operational design (whether the water [water tube boiler] or the heat source [fire tube boiler]) passes through the inside of the tubes of the boiler vessel.

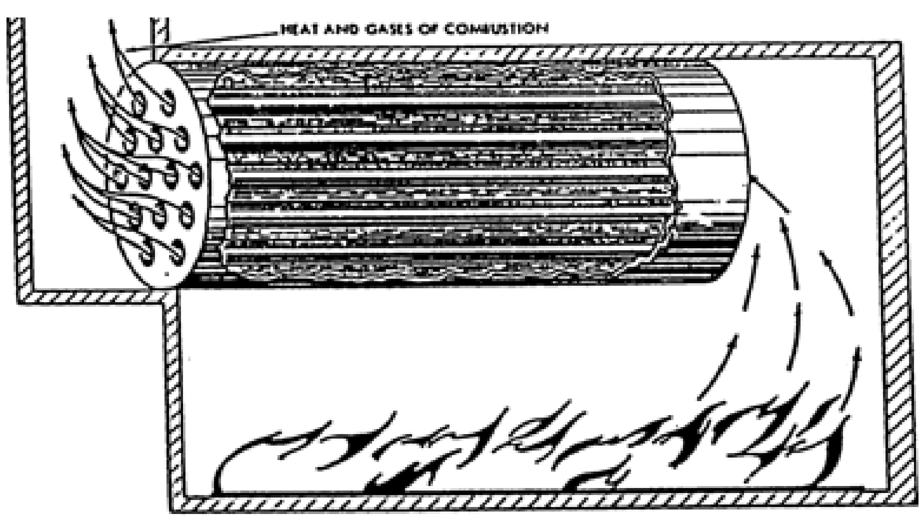
4-1.1.1 Pressure Classification.

A boiler that operates at pressures below 15 pounds per square inch gauge (103 kilopascals) is defined as a low-pressure boiler. A boiler operating pressure greater than 15 pounds per square inch gauge (103 kilopascals) is defined as high pressure. High-pressure boilers can operate at pressures reaching thousands of pounds per square inch gauge (thousands of kilopascals).

4-1.1.2 Fire Tube Boilers.

Fire tube boilers pass fire and hot combustion gas through the interior of the boiler tubes to heat the water that surrounds the tubes (see Figure 4-1). This type of boiler design is commonly used for factory-assembled (package) boilers, which are low pressure.

Figure 4-1 **Fire Tube Boiler**

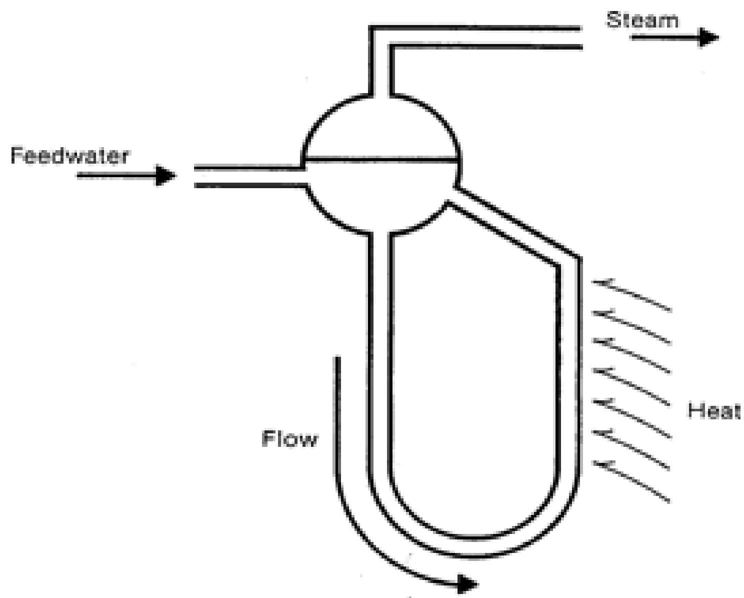


Fire tube boiler. The heat is inside the tubes.

4-1.1.3 Water Tube Boilers.

Water tube boilers pass water through the boiler tubes, with the fire and hot combustion gases contacting the exterior of the tubes (see Figure 4-2). Water tube boilers are used in high-pressure and very-high-pressure applications. Most military installations have a central boiler plant containing water tube boilers in addition to fire tube boilers that are located in, and serve, individual buildings.

Figure 4-2 **Water Tube Boiler**



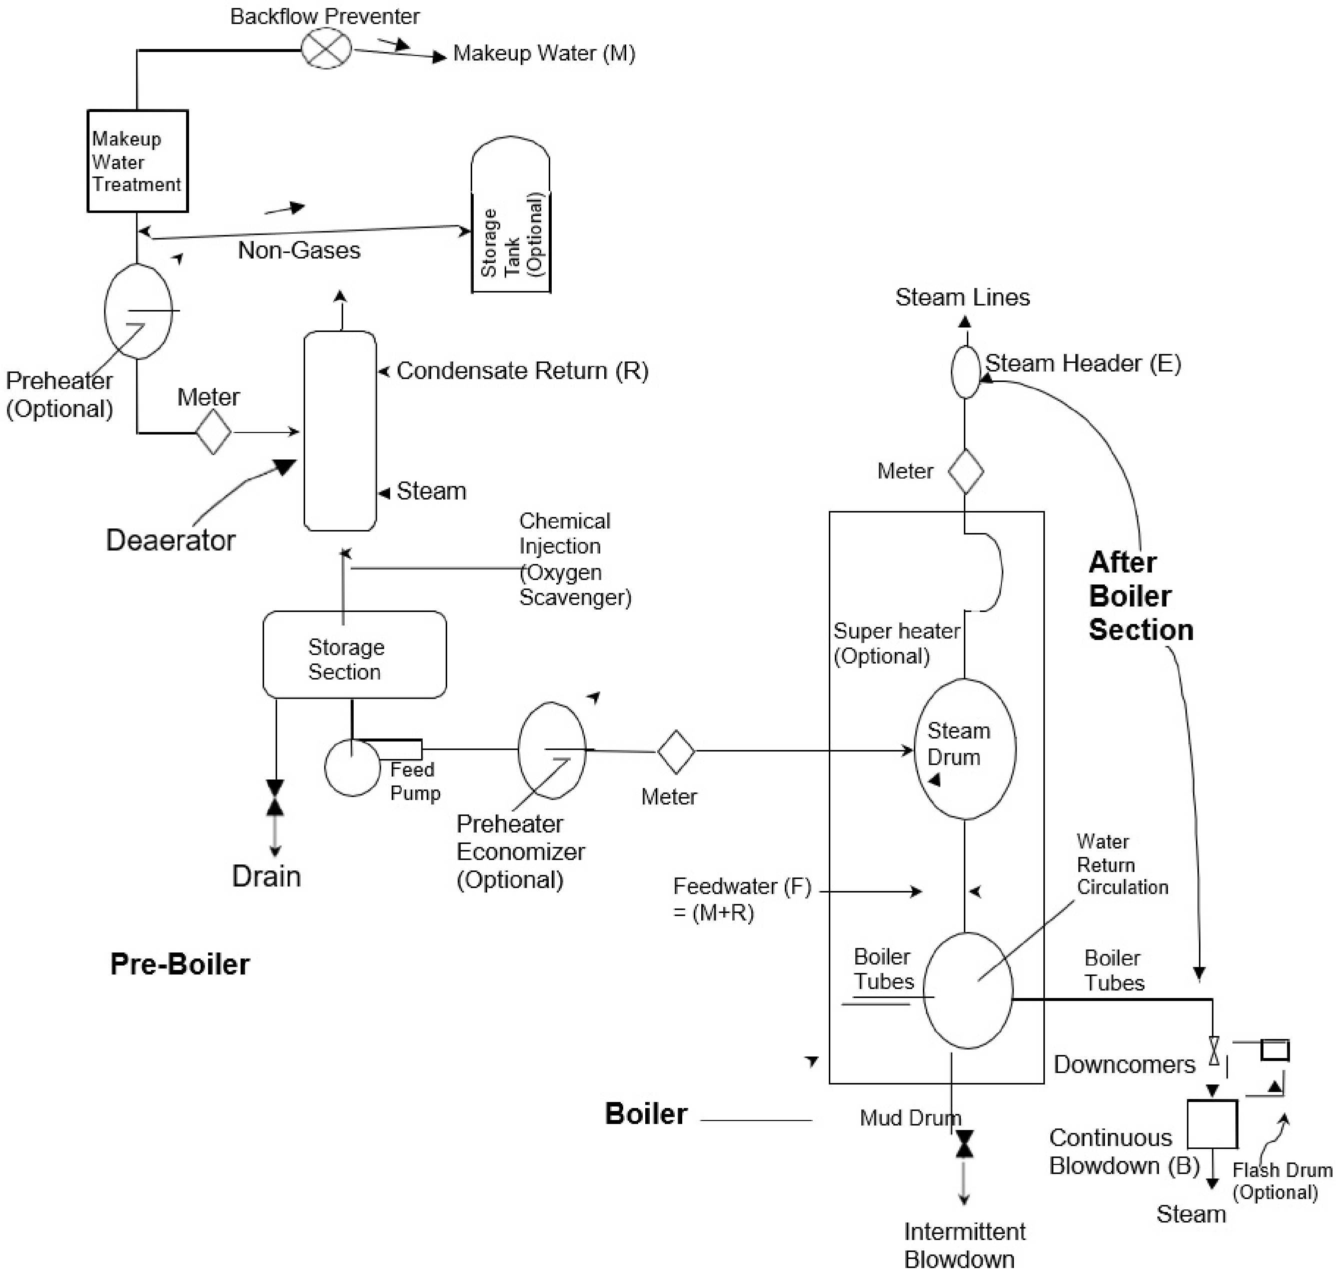
4-1.1.4 Boiler Capacity Rating.

Boiler capacity rating is given as units of either boiler horsepower, kilograms of steam per second (pounds per hour), or kilowatts (British thermal units (BTU) per hour), specifically: 1) one boiler horsepower unit reflects the energy to convert 34.5 pounds (15.7 kilograms) of water to steam from (and at) 100° C at sea level, which is equivalent to 9.812 kilowatts (33,479 BTU per hour); 2) kilogram of steam produced per second (pound of steam produced per hour) represents the number of kilograms of water used each second (pound per hour) to produce the steam; and 3) kilowatts (3,413 BTUs per hour) reflect the energy needed to evaporate the water (produce steam) each hour. The actual quantity of steam produced will vary depending on the boiler efficiency, boiler operating pressure, and altitude with respect to sea level.

4-1.2 Components of a Steam Boiler System.

The functional components of steam boiler systems vary from one system to another based on a variety of design, engineering and service requirements. The typical components that may be included in a specific unit are illustrated in Figure 4-3 and are briefly described in paragraphs 4-1.2.1 through 4-1.2.5.

Figure 4-3 **Components of a Simple Steam Boiler System**



4-1.2.1 Pre-Boiler.

The pre-boiler section of a steam boiler encompasses the boiler system's structural components that hold, move, and treat the water before the water enters the boiler. These pre-boiler system components include the integrated or supplementary water pre-treatment equipment used to process the boiler makeup water, the deaerator used to remove oxygen and other non-condensable gases, and the feed water heaters and pumps. The pre-boiler section may include a storage tank for the treated makeup water. The boiler feed water is usually composed of the makeup water combined with the condensed steam (condensate) that is returned from the distribution system (called the condensate return). The feed water, pre-heated or not, then enters the deaerator, which is used to remove (deaerate) oxygen and other volatile gases. See paragraphs 4-2.6.1 and 4-2.6.1.1 for more information on deaerators.

4-1.2.2 After-Boiler.

The after-boiler, or post-boiler, section of the boiler system encompasses all structural components of the boiler system that hold, move, and process the steam and water downstream from the actual boiler. The after-boiler includes steam piping, heat exchangers, steam traps, condensate piping, turbines, process equipment, and super heaters.

4-1.2.3 Boiler Components.

A fire tube boiler passes the hot combustion gases through the tubes, which are surrounded by the water to be converted to steam. A water tube boiler passes the hot combustion gases around the tubes, which contain the water to be converted to steam. In either type of boiler, the steam passes into a steam drum and then into the steam lines. The circulation of water in the water tube boiler may be accomplished by heating only, through a process of "natural circulation," which requires no external force or pumping. Alternatively, the water can be pumped through the heating circuit of the boiler by a process referred to as "forced circulation." Usually, a mud drum is provided at the lowest point in the water circulation section to allow the removal of any water-formed sludge. There will be at least two locations for the removal of boiler water blowdown*:* 1) for surface blowdown, sometimes referred to as a skimmer, located just below the operating water level of the steam drum; and 2) one or more bottom blowdown locations at the mud drum.

4-1.2.4 Steam Drum.

The feed water is added to the steam drum, where a mixture of steam and water is produced and where the steam is separated from the water. This separation process usually includes using mechanical devices to assist in removing any entrained boiler water from the steam. Chemicals used for internal boiler water treatment may be added (fed) to the water in the steam drum. A process of either continuous or intermittent surface blowdown is used to maintain the TDS of the boiler water and achieve the optimal operating conditions in the boiler. In some boiler systems, the blowdown water will be discharged to a flash tank, where a lower pressure steam is produced (possibly for use in the deaerator). Also, water from continuous blowdown may be used to preheat the makeup water by means of a heat exchanger. Steam from the drum may be discharged directly to the steam header or, in some boilers, heated further in a super heater to generate superheated steam.

4-1.2.5 Steam Header.

The steam generated by the boiler is discharged from the steam drum to a header. The steam header feeds the steam to the steam distribution system. The steam is consumed by process equipment, lost through leaks, lost from valves, fittings, or steam traps, or condensed for return to the deaerator and subsequently reused for additional steam production.

4-1.3 Measuring Equipment.

To develop an appropriate water treatment program for a steam boiler system, as well as to monitor the effectiveness of the on- going program, measure the quantities of steam, feed water, blowdown, makeup, and condensate into and from the system. As a minimum, install a flow meter in the makeup water line. Installing flow meters on the feed water line and in the steam header is also advisable, but due to cost considerations this practice is usually limited to large steam boilers. The rates and volumes for production of condensate and blowdown water can be calculated using the method described in paragraphs 4-1.5 and 4-1.6.

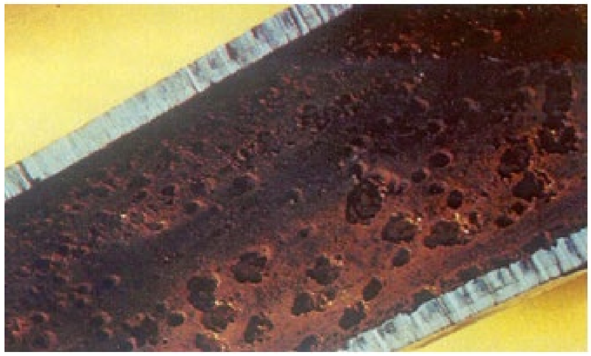
4-1.4 Common Boiler Problems.

Common water-related problems inside the entire boiler system are corrosion, deposition, and carryover.

4-1.4.1 Corrosion Problems.

Corrosion problems are the result of the action of oxygen and the effect of low or high pH on metal components, including the boiler tubes and drum, which are constructed of carbon steel. Corrosion can also occur from excessive alkalinity of excessive pH of the boiler water. This caustic attack is most likely to occur under scale or deposits, where very high local concentrations of hydroxide can build or in zones where insufficient cooling flows fails to sufficiently remove the heat input, leading to boiling, and thus steam blanketing occurs.” Corrosion can occur in the boiler, as well as in the pre-boiler and after-boiler sections, which can also be constructed of carbon steel. Corrosion can result in loss of metal volume or in a reduction of the integrity of the metal, situations that can lead to structural failure, particularly when metal loss is localized (see Figure 4-4). Corrosion is therefore also a safety concern. Corrosion in the steam lines, condensate lines located in the after-boiler section, and in the carbon steel piping can result in the production of system leaks leading to the loss of condensate, a situation which increases demands for energy, water, and chemicals.

Figure 4-4 **Boiler Tube Oxygen Pitting**



4-1.4.2 Deposition Problems.

Deposition problems result from the precipitation of minerals dissolved in the feed water, causing the formation of one or more types of scale on boiler system components. Deposition can occur by other mechanisms when corrosion products (rust) enter the boiler after being created in either the after-boiler or pre-boiler sections. These corrosion products can form iron-based scales. Using certain water treatment chemicals can also result in the formation of scale when the chemicals are not properly applied. All scales provide insulation to the transfer of heat between the water and the heated metal tubes (see Figure 4-5). Scale can occur in any section of the boiler system, resulting in a reduced capacity for heat transfer. Due to the resulting reduced heat transfer from the fireside of the tube to the water, the metal tubes operate at a higher temperature than if the scale were not providing insulation. Consequently, steam is produced inefficiently due to greater fuel demands, and fuel costs are increased. The greater the thickness of scale, the greater the insulating effect, and the higher the temperature of the tubes (see Figure 4-6). At sufficiently high metal temperatures, the tube can lose its tensile strength and rupture (see Figures 4-7, 4- 8, and 4-9).

Figure 4-5 **Scaled Boiler Tube**

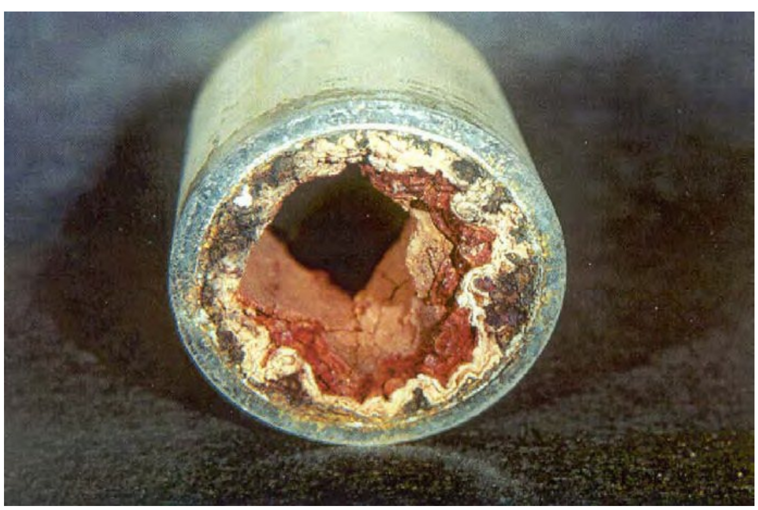


Figure 4-6 **Impact of Scale on Heat Transfer**

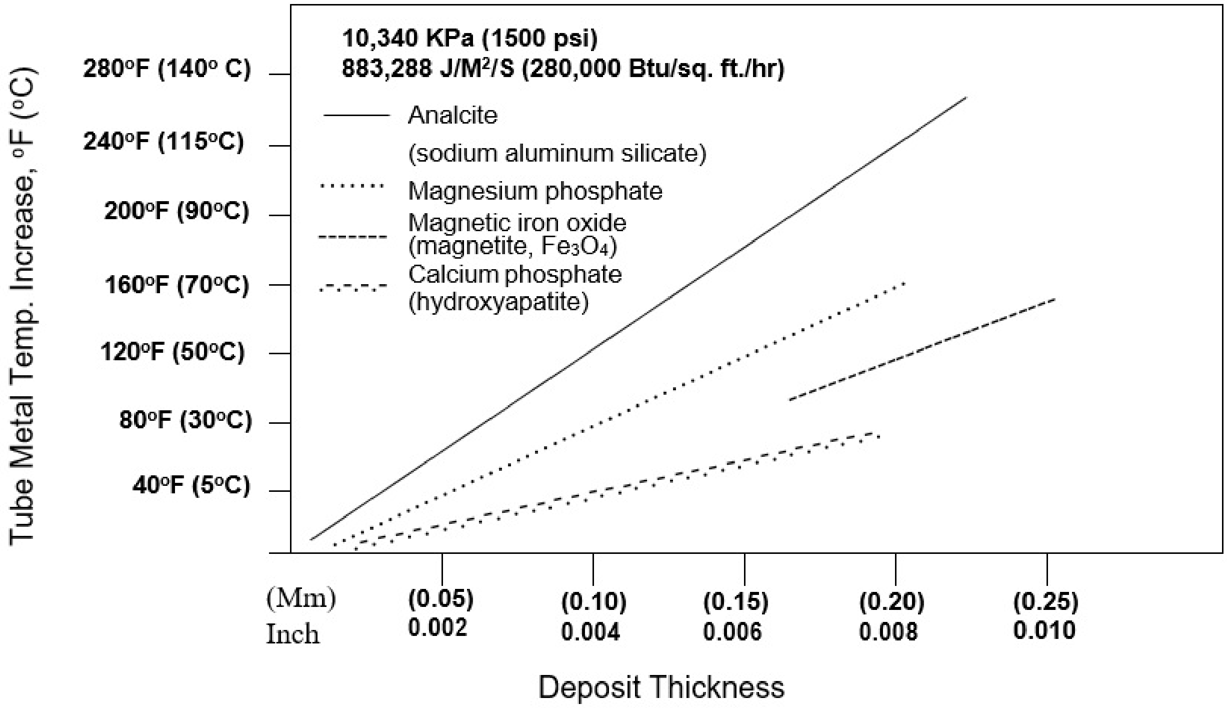

Figure 4-7 **Effect of Boiler Deposits on Boiler Tube**

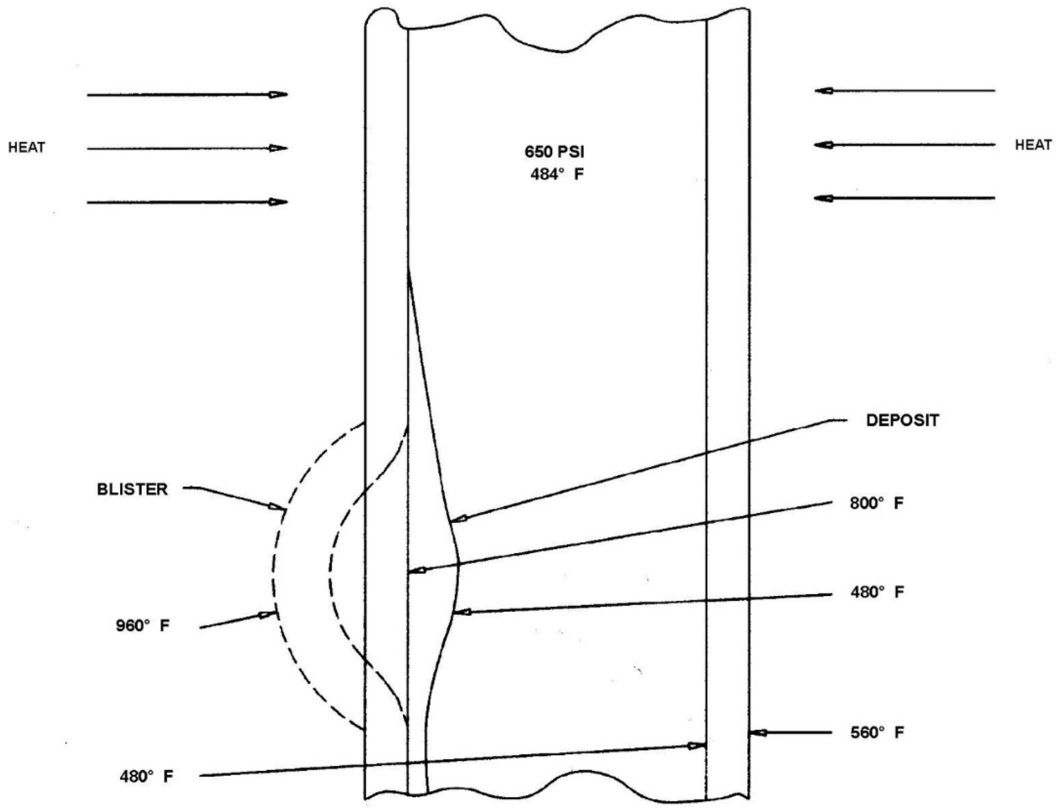

Figure 4-8 **Metal Fatigue on Boiler Tube**

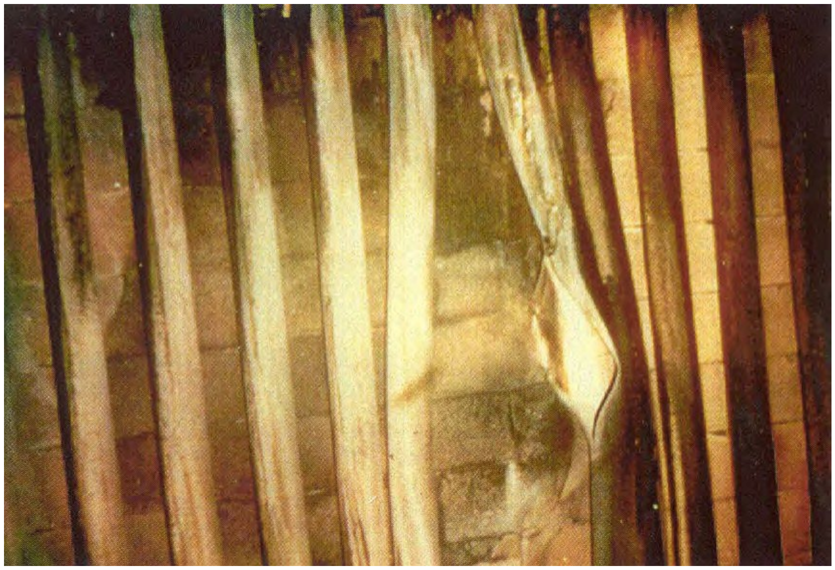
Figure 4-9 **Failed Boiler Tube**



4-1.4.3 Carryover Problems.

Carryover problems are caused by misting, foaming, priming, and silica carryover (see paragraph 4-2.8). Carryover is a process that results in impure steam quality. Dissolved solids contained in the carryover material can contribute to corrosion and deposition problems.

4-1.5 Calculations.

To understand and produce efficient boiler operations, boiler calculations are performed and the results applied correctly. Boiler calculations are the means for providing information used to determine optimal blowdown rates and to assess condensate return. The greatest efficiency of boiler operations can be achieved by optimizing the COC by adjusting the amount of blowdown to give the proper volume of water. Efficient boiler operations recover and return as much condensate as possible. The material balance or mass balance of an operating boiler system can be calculated from the results of water tests and the known (measured) value of a single boiler operational parameter such as steam production, makeup water usage, feed water usage, or blowdown. Steam table data can be used with mass balance information to calculate energy input and energy output for the boiler system. Chemical feed rates can be used with mass balance information to develop an estimation tool for the annual consumption of water treatment chemicals. Familiarity with these calculation procedures and their application to boiler system operations assessment is required of any base or facility engineer or section supervisor. This knowledge is also useful for boiler operators. Examples of boiler calculations are provided in paragraphs 4-1.5.3 through 4-1.6.3.

4-1.5.1 Cycles of Concentration (COC).

COC in a steam boiler is a term that refers to the number of times the minerals in the feed water have been concentrated in the boiler by its operation. As boiler water evaporates and steam is produced, minerals that were dissolved in the boiler water remain behind, increasing the mineral content of the remaining water. As steam is produced, additional mineral-laden feed water enters the boiler, resulting in additional minerals being introduced into the boiler and increasing the amount present in the boiler. Mineral content in an operating boiler water system can be limited only by blowdown.

4-1.5.2 Blowdown.

Blowdown consists of draining some of the boiler water with its accumulated solids, and replacing it with treated feed water before harmful levels of solids are reached. Dissolved solids tend to concentrate near the water surface in the steam drum. Therefore, surface blowdown is most effective in reducing the concentration of dissolved solids. Bottom blowdown is used to remove precipitated sludge from the boiler mud drum. However, blowdown results in the loss of heated water and treatment chemicals. Economical operation requires careful control of blowdown to maintain safe solids levels, while minimizing both heat and chemical additive losses.

4-1.5.3 Water Balance for Feed water, Evaporation, and Blowdown.

The total volume of the water (feed water) that is added to the boiler must equal the total volume of the water (steam plus boiler water blowdown) that is removed from the boiler. By convention, these water quantities are commonly expressed in kilograms per second (pounds per hour) in this equation for water balance:

Equation 4-1. Feedwater

$$F = E + B$$

Where:

F = feed water, lb/hr (kg/s)

E = steam generated, lb/hr (kg/s)

B = blowdown, lb/hr (kg/s)

4-1.5.4 Calculation of Feed water and Blowdown Water.

The feed water or blowdown water (or both) can be calculated in relation to the COC using these equations:

Equation 4-2. Calculation of feedwater & blowdown water

$$\mathrm{COC} = \mathrm{F} \div \mathrm{B} \text{ or } \mathrm{F} = \mathrm{B} \times \mathrm{COC} \text{ or } \mathrm{B} = \mathrm{F} \div \mathrm{COC}$$

Where:

COC= cycles of concentration, no units

F= feed water, lb/hr (kg/s)

B= blowdown, lb/hr (kg/s)

It is common to express blowdown as a percentage:

B = 100/COC

4-1.5.5 Relationship Between Feed water, Blowdown, Steam Generation, and COC.

Using the terms defined in paragraphs 4-1.5.3 and 4-1.5.4, the relationship between feed water, blowdown, steam generation, and COC is represented as:

a. F = B x COC, from COC, Equation 4-2 above

b. F = E + B, from COC, Equation 4-1 above

c. B x COC = E + B, replacing F in Equation 4-2 with Equation 4-1

d. B x COC - B = E, rearranging Equation c. above

e. B x (COC-1) = E, rearranging Equation d. above

f. B = E ÷ (COC-1), rearranging Equation a. above

4-1.5.6 Calculating Blowdown Rates.

The blowdown water volume is rarely measured by a meter. As shown below, it can be calculated if any two of the following parameters are known: 1) feed water; 2) COC; or 3) steam generation (E). Steam volume is usually measured in units of meters on large boilers. The COC can be calculated by measuring the conductivity or TDS in both the boiler water and the feed water. Note that the conductivity and quantity of TDS is the same for the boiler water and the blowdown water.

Equation 4-3. Calculating blowdown rates

$$COC = B_{TDS} / F_{TDS} \text{ or } B_{\mu mhos} / F_{\mu mhos3}$$

Where:

COC= cycles of concentration, no units B_{TDS}= blowdown TDS, ppm

F_{TD}= feed water TDS, ppm

$B_{\mu mhos}$= blowdown conductivity, micromhos $F_{\mu mhos}$= feed water conductivity, micromhos

4-1.5.7 Determining Feed water and Blowdown Rates.

The blowdown calculations in paragraph 4-1.5.6 can be used to determine the feed water rate in pounds per hour (units of kilograms per hour). Note that the term “feed water” refers to water that is fed to the boiler and includes the makeup water plus the condensate return and steam from the deaerator.

EXAMPLE:

a. 250-pound-per-square-inch-gauge (1720-kilopascal) boiler operates at a conductivity level of 5000 µmhos. The boiler feed water has a conductivity of 250 µmhos. The COC calculation is:

   COC = Bµmhos / Fµmhos or 5000 µmhos / 250 µmhos = 20 COC

b. The percent blowdown is:

   percent B = 100/COC or 100/20 = 5 percent

c. If the boiler is producing 40,000 pounds per hour (5 kilograms per second of steam), the blowdown must be:

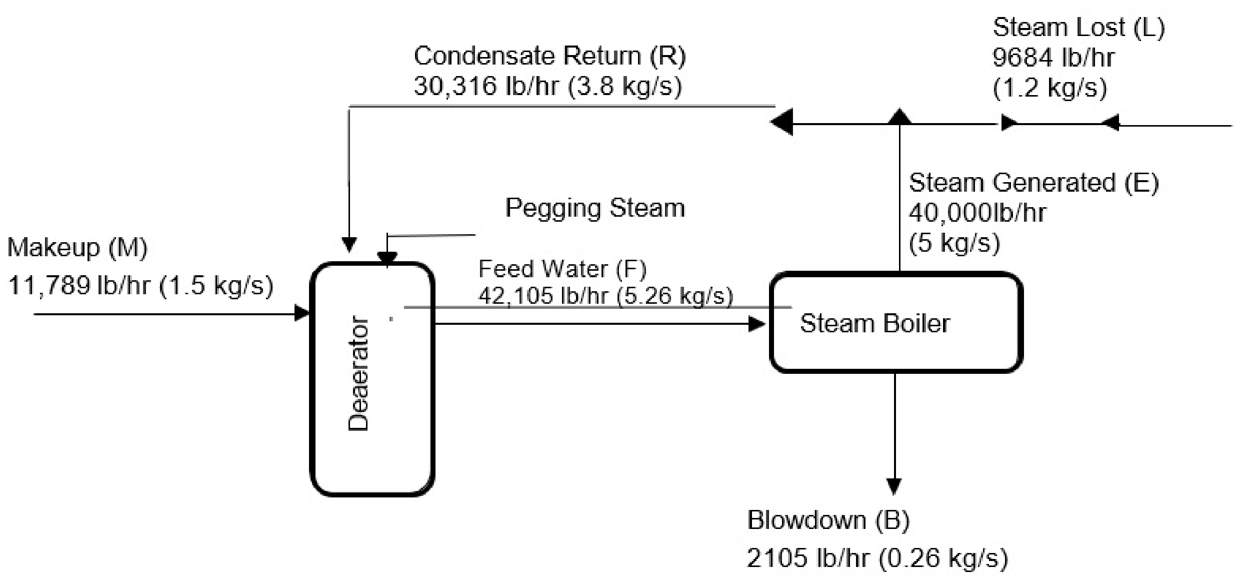
   B = E ÷ (COC - 1) = 5.0 ÷ (20 - 1) = 2105 lb/hr (0.26 kg/s)

d. The feed water is calculated to be:

   F = E + B = 5.0 + 0.26 = 42,105 lb/hr (5.26 kg/s)

This is equivalent to 5054 gallons per hour at 8.33 pounds per gallon (5.3 liters per second). This example is illustrated in Figure 4-10.

Figure 4-10 **Simplified Boiler System Water Balance**



4-1.5.8 Determining Makeup Water and Condensate Return Rates.

Makeup is the water from the external water treatment system added to the boiler system upstream of the deaerator. The amount, expressed as either volume or percentage, of makeup water required in a boiler is affected by blowdown, steam leaks, consumption of steam in process equipment, and loss of condensate by boiler system leakage. In a "tight" boiler system, where steam is not lost in process equipment, about 5 to 10 percent makeup is expected. Water balance is affected by condensate return; however, boilers that lose considerable condensate due to losses of steam or condensate can approach a requirement for 100 percent makeup, which is a very inefficient and costly condition. The calculations below can be used for determining makeup water needs and condensate return rates.

4-1.5.9 Makeup Water Rate.

Makeup is the difference between the volume of condensate return and the volume of feed water.

Equation 4-4. Makeup Water Rate

$$M = F - R$$

Where:

M = makeup, lb/hr (kg/s)

F = feedwater, lb/hr (kg/s)

R = condensate return, lb/hr (kg/s)

4-1.5.10 Condensate Return Rate.

Since the returned condensate usually does not contain any appreciable level of dissolved solids or conductivity, determination of percent makeup is calculated using the equation:

Equation 4-5. Condensate Return Rate

$$percent\ M = \left(1 - \frac{F\mu mho}{M\mu mho}\right) \times 100\ percent$$

Where:

percent M= percent makeup

Fµmho= feedwater conductivity, micromhos

Mµmho= makeup conductivity, micromhos

EXAMPLE 4-2:

a. Makeup water conductivity is 900 µmhos for the boiler water in this example. The percent makeup is calculated:

$$percent\ of\ M = \left(1 - \frac{F\mu mho}{M\mu mho}\right) \times 100\ percent\ or\ \left(1 - \frac{250}{900}\right) \times 100\ percent\ percent\ of\ M = 72\ percent$$

b. This means that the makeup water is 28 percent of the feedwater. The condensate return percent is calculated:

$$percent\ of\ R = 100 - percent\ of\ M = 100 - 28 = 72\ percent$$

c. The quantity of makeup water is calculated:

M = (percent of M/100) x F

or (28/100) X 42,105 lb/hr (5.3 kg/s)

M = 11,789 lb/hr (1.5 kg/s)

d. The quantity of condensate return is calculated:

R = F - M = 5.3 – 1.5 = 30,316 lb/hr (3.8 kg/s)

4-1.5.11 Difference Between Amount of Steam Produced and Amount of Condensate.

The difference between amount of steam produced and the amount of condensate returned represents the combined loss from the system of both steam and condensate. These losses may result from leakage of steam, consumption of steam by the process equipment, leakage of condensate, or deliberate discharge of contaminated condensate. The total water loss can be calculated:

Equation 4-6. Total Water Loss

$$L = E - R$$

Where:

L = total steam and condensate losses, lb/hr (kg/s)

E = steam generated, lb/hr (kg/s)

R = condensate return, lb/hr (kg/s)

EXAMPLE 4-3:

a. The steam losses from the boiler described in Examples 4-1 and 4-2can be calculated:

$L = E - R = 5.0 - 3.8 =$ 9684lb/hr (1.2kg/s)

b. This relationship and the information from the previous examples are presented in Figure 4-9.

4-1.5.12 Basis for Evaluating Boiler System Efficiency.

A good basis for evaluating boiler system efficiency can be developed by monitoring the system's water conductivity values, measuring the quantity of steam generated, and performing the required calculations after a regularly scheduled interval of time. An increase in steam loss may indicate a new leak, a size increase in existing leaks, a new consumption of steam, or condensate losses. Additionally, calculations of boiler system efficiency can provide a good basis for estimating savings in steam cost resulting from maintenance efforts to reduce steam and condensate losses.

4-2 BOILER WATER TREATMENT AND CONTROL.

References to boiler water treatment in the late nineteenth century relate that the process of removing the scale from a boiler required much less effort and time if the boiler operator had forgotten to remove cooked potatoes from the boiler water. It was determined that the starch in potatoes causes a soft sludge, rather than a hard scale, to be formed, and this sludge was easier to remove than hard scale. Other natural organics, including lignin and tannins from wood, plant matter, plant extracts, and even manure and coffee grounds, produced similar results. It was determined that addition of phosphate by itself produces a manageable sludge, although starch, lignins, and tannins have been used to supplement the phosphate. Phosphate is still very commonly combined with other water treatment chemicals. Early use of alkaline materials included lime, soda ash, and caustic soda. Oxygen scavengers, such as sodium sulfite, were found to be effective for preventing oxygen corrosion. Many of these materials are still used today. The wide range of water treatment chemicals that is currently available allows for development of a comprehensive approach to industrial boiler water treatment, including using specialty chemicals such as chelants, polymers, and amines.

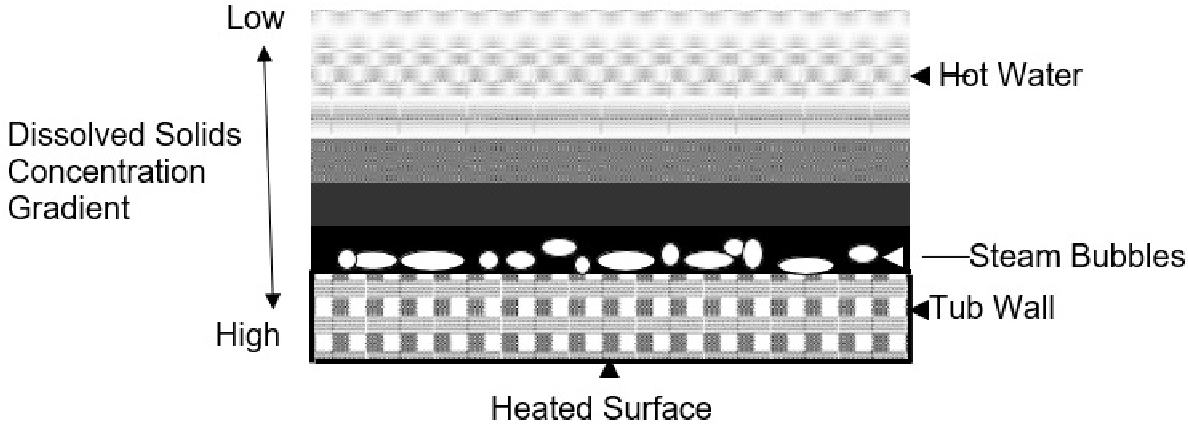
4-2.1 Boiler Deposit Formation.

Dissolved solids in boiler feed water become more concentrated in the boiler water as steam is generated. Some of the dissolved solids can come out of solution (precipitate) and form scale in the boiler tubes. Some dissolved solids can form sludge (mud) in the boiler and form adherent deposits on boiler tubes. These deposits reduce heat transfer.

4-2.1.1 Scale.

Scale can occur in isolated spots due to water evaporation, as illustrated in Figure 4-10. When a steam bubble forms on a heated surface, a thin film of water situated between the bubble and the tube wall becomes more concentrated with the dissolved materials. This thin layer can be as much as 30˚ F (17˚ C) hotter than the average boiler water temperature. These local conditions can cause precipitation of the dissolved solids and local formation of scale. See Figure 4-11.

Figure 4-11 **Localized Scale Formation Process**



4-2.1.2 Sludge Deposits.

Sludge deposits can form when the precipitated materials in the boiler water stick to the boiler tubes due to their hot surfaces as a result of the same phenomenon described in paragraph 4-2.1.1. Scale and sludge often form together.

4-2.1.3 Dissolved Solid Materials.

Some dissolved solid materials become less soluble as the water temperature increases. This situation occurs with most of the salts that constitute calcium and magnesium hardness ($CaCO_3$, $CaSO_4$, $MgCO_3$, $Mg[OH]_2$). As a result of this property, these materials tend to form scale in the hotter areas of the boiler because they remain soluble in the cooler areas of the boiler. By using an appropriate form of water treatment, these scaling agents can be removed from the boiler system water either before they enter the boiler (external treatment) or after (internal treatment), although it is often best to remove the dissolved magnesium and calcium minerals (hardness) before they enter the boiler (see paragraph 4-2). With the proper chemical treatment, they can be effectively controlled and treated internally in the boiler.

4-2.2 Common Scale Found in Boilers.

The most common scale materials consist of calcium and magnesium salts and iron oxide. Calcium and magnesium salt deposits are white or off-white. Iron oxide scales are red or black deposits. The type of scale can be identified accurately by deposit analysis. It is common to have more than one type of scale in boiler deposits.

4-2.2.1 Calcium Carbonate.

Calcium carbonate scale is white or off-white in color and is formed by the breakdown of calcium bicarbonate with heat. Calcium carbonate scale is formed in both untreated boilers and improperly treated boilers. A drop of a dilute acid solution on the deposit will cause bubbling on the calcium carbonate scale area as a result of the release of carbon dioxide. This procedure can be used to identify this type of scale. Calcium carbonate scale can result when there is calcium hardness in the boiler feed water due to improper softener operation and when there is an inadequate level of sludge or scale conditioner or dispersant.

4-2.2.2 Calcium Sulfate.

Calcium sulfate (gypsum) is off-white or tan in color and is formed in boilers that are using water of high hardness and low alkalinity without proper treatment. Addition of a strong acid will dissolve the calcium sulfate scale with no gas bubble formation or release of carbon dioxide. Calcium sulfate is much less common than calcium carbonate, but it can form when there is calcium hardness in the boiler feed water due to improper softener operation and when there is an inadequate level of sludge or scale conditioner or dispersant.

4-2.2.3 Calcium Phosphate.

Calcium phosphate is formed when the dissolved calcium in the feedwater reacts with phosphate treatment chemicals added to the boiler water. With proper treatment controls, calcium phosphate forms a sludge that will be removed in the blowdown. However, calcium phosphate can deposit as scale if the pH of the boiler water is below 11.0 and if a sludge conditioner is not used. Addition of a strong acid will dissolve this scale fairly easily with no gas bubble formation.

4-2.2.4 Magnesium Phosphate.

Magnesium phosphate scale is an off-white deposit formed by the reaction of magnesium salts from the feedwater with the phosphate used in the boiler water treatment. It will form only if both the hydroxide content and silica content of the boiler water are low. Addition of a strong acid will dissolve this scale fairly readily with no gas bubble formation.

4-2.2.5 Magnesium Silicate.

Magnesium silicate scale, an off-white deposit, is formed from the magnesium and silica in the feedwater when the pH is above 11.0 and the silica level is more than half that of the phosphate level in the boiler water. Normally, it forms as a sludge that will be removed in the blowdown, but it may form scale deposits on tubes if a sludge conditioner is not present. Most acids will not remove this deposit. Caustic or special chemicals are needed to remove the magnesium sulfate scale.

4-2.2.6 Iron Oxide and Iron Hydroxide.

Iron oxide scales and iron hydroxide scales are red/black deposits that are formed when the iron salts dissolved in the feedwater react with hydroxide found in the boiler water. Usually, the dissolved iron is introduced into the system from the condensate return due to corrosion. Iron oxide can be deposited as a scale on the boiler tubes if the proper type of sludge conditioner is not present. With proper water treatment, this deposit should form as sludge, rather than scale, and can be removed by blowdown. The presence of iron oxide on the internal boiler surfaces can be caused by oxygen corrosion of the boiler metal.

4-2.3 External Boiler Water Treatment.

Specific technologies for external treatment or pre-treatment are described in Chapter 3. The strategy for external treatment is to remove unwanted impurities in the makeup water before they can enter the boiler. Proper external treatment can eliminate, or at least minimize, scale- and corrosion-forming conditions and minimize the internal water treatment required to protect the boiler system components.

4-2.3.1 External Water Treatment for High-Pressure Boilers.

The higher the pressure of the boiler, the greater the need for high-purity feedwater. A 40,000-pound-per-hour (5-kilogram-per- second) water tube boiler operating at 900 pounds per square inch gauge (6205 kilopascals) requires deionized feedwater. External treatment options include RO followed by demineralization. Guidelines for feedwater purity are described in paragraph 4-3.4.

4-2.3.2 External Treatment for Low-Pressure Boilers.

Low-pressure boilers can operate with simple external treatment or sometimes no external treatment at all. A 3450-pound-per-hour (0.44-kilogram-per-second) (100 horsepower) fire tube boiler operating at less than 15 pounds per square inch gauge (103 kilopascals) may require using only a sodium zeolite softener for water treatment. A small heating boiler that is returning over 99 percent of the condensate may not require any external treatment, particularly if the makeup water is low in hardness and the condensate is not contaminated.

4-2.4 Internal Treatment of Boiler Water.

Internal treatment of boiler water is a process of adding chemicals to the boiler to control deposition and corrosion. Internal water treatment, together with proper blowdown control, controls the water impurities that have not been removed or reduced through external treatment.

4-2.4.1 Preventing Scale Formation.

Internal boiler water treatment for scale prevention can be performed using either a solubilizing chemical treatment program or a precipitating chemical treatment program. The solubilizing treatment program uses chemicals designed to keep scale-causing materials with hardness (mineral ions) in solution, whereas the precipitating treatment program uses chemicals designed to react with hardness-causing materials and precipitate them as a sludge that will not adhere to tube surfaces. Both the solubilizing approach and the precipitating approach require good blowdown control to keep hardness and sludge levels within chemical performance capabilities.

4-2.4.1.1 Low-Pressure Boilers.

Low-pressure steam boiler systems 15 pounds per square inch gauge (103 kilopascals and less) that use little or no makeup or blowdown are usually not chemically treated for scale control because, due to low makeup water demands, there is no continuous addition of scaling agents (present in the makeup water) to the boiler. If there are high makeup requirements (over 1 percent per month) or if the makeup water is over 300 ppm total hardness, a treatment program is required to protect the boiler system.

4-2.4.1.2 High-Pressure Boilers.

High-pressure boilers 15 to 900 pounds per square inch gauge (103 to 6205 kilopascals) must use either a precipitating-type water treatment chemical program or a solubilizing-type chemical treatment program.

4-2.4.1.3 Precipitating Water Treatment Programs.

A precipitating program often uses phosphate, which will react with calcium to form a calcium phosphate sludge called “hydroxyapatite” ($3Ca_3(PO4)_2 \bullet Ca(OH)_2$), and act as both as a sludge conditioner or dispersant. Magnesium reacts with hydroxide and silica to form a magnesium silicate sludge called “serpentine” ($2MgSiO_3 \bullet Mg(OH)_2 \bullet H_20$). Sufficient hydroxyl alkalinity (causticity) is required to allow the formation of the proper types of sludge. Sludge that is properly formed and conditioned is fluid enough to be removed through bottom blowdown of the boiler. Sodium hydroxide may be required to maintain the appropriate hydroxyl alkalinity (causticity). Phosphate precipitating agents are prepared as either orthophosphate (“ortho” means single phosphate) or as one of several forms of polyphosphate (“poly” means multiple phosphate molecules bonded together). Sodium hexametaphosphate, sodium tripolyphosphate, and sodium pyrophosphate are examples of polyphosphates. In the boiler, polyphosphate breaks down to the orthophosphate form due to the higher temperature. Polyphosphates can be added either to the feedwater or directly to the steam drum. Orthophosphate should only be fed into the steam drum, not to the feedwater, since it can react with the hardness (mineral ions) to form scale in the feedwater lines.

4-2.4.1.4 Solubilizing Water Treatment Programs.

A solubilizing program uses one or more of the following chemicals to keep scale-forming materials in solution: phosphonates (also known as organic phosphate), chelants, or polymers. Solubilizing agents, such as phosphonates (not to be confused with phosphate), chelants, and polymers are common chemicals used in boiler water treatment formulations. Chelants, such as ethylene diamine tetra-acetic acid (EDTA) or nitrilo-triacetic acid (NTA), bind (chelate) calcium, magnesium, and iron. Using phosphonates and chelants requires special injection systems and excellent feed control. Excess (free) phosphonate or chelant can attack metal surfaces, causing corrosion, although phosphonates are less aggressive than chelants. Water-treating polymers are long-chain, water-soluble compounds containing electrochemically active side branches that perform various functions such as solubilization, dispersion, agglomeration, and crystal distortion to prevent boiler deposits. Polymers do not attack metal surfaces and can be fed into the feedwater line or directly into the boiler steam drum with proper injection equipment.

4-2.4.1.5 Boiler-Specific Treatment Programs.

High-pressure boilers over 900 pounds per square inch gauge (6205 kilopascals) use high-quality feedwater that is produced by extensive external treatment; thus, scale-forming materials are not normally present in the water and cannot form scale in the boiler. These boilers often use water treatment programs designed specifically for that particular boiler. These programs require excellent control of water chemistry and involve applying coordinated phosphate, congruent phosphate, equilibrium phosphate, and all volatile treatment. Boiler pressures of this level are usually found in operations used to drive turbines for the generation of electrical power.

4-2.4.2 Determining Chemical Treatment Feed Rates.

Development of a chemical treatment program involves selecting the type of chemical to be used, selecting appropriate concentration levels for each chemical (when used in combination with other chemicals), and selecting the required chemical treatment (addition) scheme to ensure proper water treatment. Selection factors are described in paragraph 4-3. Blowdown discharge rates can be used to calculate the rate of chemical addition and the amount of chemical required to replace that lost in the blowdown and to meet the treatment objectives. In practice, chemical feed equipment is set up to deliver the chemicals on a “proportional-feed-on-demand” basis. The operator must keep treatment levels within prescribed control ranges by adjusting pumps and timers while controlling COC within the system. Selection of the type and quantity of required chemical treatment is an issue that involves both technical concerns and ancillary issues pertaining to institutional concerns in the areas of procurement, contracts, and budgets. This situation is described in Chapter 11.

Example illustrates phosphate demand. Similar approaches could be used for other treatment technologies. In the case of sulfite, the treatment requirement must first satisfy the demand due to oxygen in the feedwater. Additional sulfite is fed to attain a residual or excess amount in the boiler water to ensure adequate protection. The second part of Example 3-4 takes into account that the treatment chemical formulation is not composed of 100 percent active ingredients. Formulations are most often less than 50 percent active and can be as little as 10 percent active chemical, with the balance of the formulation usually being water.

EXAMPLE:

a. The boiler in Examples 4-1, 4-2, and 4-3 will be operated with a phosphate level of 60 ppm (as PO_4) in the boiler water. The blowdown has been determined to be 2105 pounds per hour (0.26 kilogram per second). The required phosphate addition on a daily basis must equal the phosphate that is discharged with the blowdown water, plus that used up in precipitating calcium phosphate. The amount of phosphate required to replace that lost in blowdown is calculated by this method:

Phosphate loss

= (B)(treatment ppm residual)/1,000,000

= 0.26 60 ppm (kg/s) x/1,000,000

= 0.13 lb/hr (0.000016 kg/s) or 1.38 kg/day

b. The treatment chemical selected is sodium hexametaphosphate (HMP) containing 90.5 percent phosphate as PO_4. This means there is 0.905 pound (0.905 kilogram) of phosphate (PO_4) per pound (kilogram) of chemical:

Chemical required

= phosphate loss ÷ 0.905

= 1.38 ÷ 0.905

= 3.35 lb/day (1.52 kg/day)

NOTE: This calculation does not incorporate any phosphate reaction and precipitation with hardness (see paragraph 4-2.4.3), so the practical amount of HMP needed would be slightly higher.

4-2.4.3 Preventing Sludge Deposits.

In either low-pressure or high-pressure boilers, the feedwater hardness (dissolved minerals) can precipitate in the boiler. To prevent the formation of adherent sludge deposits, natural or synthetic (or both) water- soluble organic chemicals are added to the boiler water. Organic chemicals help to create sludge by distorting the crystal structure of scale-forming compounds and preventing the formation of scale. Properly formed and conditioned sludge is fluid enough to be removed through bottom blowdown of the boiler mud drum. A typical natural organic compound, quebracho tannin, has been used traditionally with satisfactory results in military boilers, but its use is diminishing in favor of the new synthetic, water-soluble polymers. Tannin is effective for the control and minimization of sludge and contributes to corrosion control since it absorbs a small amount of dissolved oxygen and helps to form a protective film on mild steel surfaces. To be effective, tannin levels should be maintained at several hundred ppm (of active component) in the boiler water. Polymer materials are typically maintained between 5 to 20 ppm (of active component). The most recently developed synthetic water-soluble polymers have been shown to be more cost-effective than tannins. For example, polyacrylates or copolymers of methacrylate and sulfonated styrene are dispersants, sludge and scale inhibitors commonly used for minimizing the formation of deposits in boilers. Polymer treatments are commonly found in water treatment formulations available from vendors.

4-2.5 Corrosion in the Boiler.

Corrosion within the boiler results from an improper pH level (below 10.3), a situation that contributes to general (overall) corrosion, and from oxygen not being removed from the feedwater, a situation that causes pitting of the mild steel tubes and drums.

4-2.5.1 General Corrosion.

"General corrosion" is a term that refers to an overall uniform corrosion of metal surfaces. Adequate prevention of general corrosion is achieved by maintaining a proper pH, thus allowing the formation of a protective iron oxide coating known as magnetite. Magnetite is a self-limiting form of corrosion that forms in the outermost surface layers of, and that adheres to, the mild steel tube surfaces. Magnetite is composed of an iron oxide complex of $Fe_3O_4 + FeO + Fe_2O_3$.

4-2.5.1.1 Proper pH for Boilers up to 6205 Kilopascals.

The proper pH range for boilers up to 900 pounds per square inch gauge (6205 kilopascals) is between 10.3 and 12.0. Adjustment of the boiler water to within this pH range is achieved through cycling up the natural alkalinity contained in the feedwater and, if necessary, adding a chemical alkalinity agent such as sodium hydroxide (caustic soda), sodium carbonate (soda ash), or an alkaline phosphate treatment.

4-2.5.1.2 Proper pH for Boilers Over 6205 Kilopascals.

Proper pH adjustment for boilers over 900 pounds per square inch gauge (6205 kilopascals) is achieved by using water treatment chemicals, which are added because the demineralized feedwater is essentially unbuffered. The chemical treatment programs include coordinated phosphate, congruent phosphate, equilibrium phosphate, and all volatile treatment. Phosphate programs of this type are not used as conventional precipitating agents for hardness-causing materials but instead are used as buffering agents for pH control (see Table 4-1).

Table 4-1 Summary of Phosphate Treatment Programs

Program	PO_4	OH	Na:PO_4Ratio	pH
Conventional	30-60	20-350	N/A	11-12
Coordinated	5-25	Trace	2.85:1 to 3:1	9-10.5
Congruent	2-5	Zero	2.3 to 2.6:1	8.8-9.4
Equilibrium	<2.4	<1.0	N/A	9.3-9.6

4-2.5.2 Pitting Corrosion.

Pitting corrosion is a term that refers to a deep, localized corrosion usually caused by oxygen molecules on the metal surfaces in the boiler water. This process results in the formation of corrosion pits that can extend into the interior metal layers of metal boiler components. Corrosion pitting can be severe enough to lead to perforations of tube surfaces (see Figure 4-4).

4-2.5.3 Other Types of Corrosion.

Other types of corrosion can occur in high- pressure boilers over 900 pounds per square inch gauge (6205 kilopascals) for which the water treatment program includes coordinated, congruent, or equilibrium phosphate- type chemical treatment (not to be confused with standard phosphate precipitating programs). These other corrosion mechanisms include caustic attack, hydrogen embrittlement, and phosphate hideout.

4-2.6 Removing Oxygen from Feedwater.

A very corrosive liquid results when oxygen is dissolved in water. Oxygenated water is particularly corrosive to mild steel, which is almost always used to construct the main components of the boiler system. The corrosivity rate of oxygenated water doubles with every 18° F (10° C) increase in temperature. Oxygen corrosion can be recognized by the presence of pits found typically in the top of, or at the waterline of, the steam drum. Oxygen can be removed from feedwater by mechanical or chemical methods, or both; a combination of these methods is used commonly.

4-2.6.1 Mechanical Oxygen Removal.

Mechanical removal of oxygen from feedwater requires a deaerating heater in which both the makeup water and condensate return are in contact with live steam and mixed using trays, sprays, or both. This heating process literally strips most of the oxygen and other non-condensable gases out of the feedwater. The oxygen and other gases, along with a small amount of steam, are vented from the deaerator to the atmosphere.

4-2.6.1.1 Deaerator Operation.

Two key parameters associated with deaerator operation are controlled to maintain maximum oxygen removal. First, the deaerator vent is checked to verify that a plume of steam is always flowing out of the vent. Second, both the pressure within the deaerator and the temperature of the outlet water are controlled. Deaerators should operate at a pressure of 3 pounds per square inch gauge (20.68 kilopascals) or more. At any given pressure, the deaerator water outlet temperature should be within 2° F (1° C) of the water temperatures shown in Table 4-2, adjusted for the altitude of the installation. If the deaerator is operating with low or no steam flow or at a low water temperature, the deaerator is not being operated efficiently and is not removing the maximum amount of oxygen. Schematic diagrams of mechanical deaerators are shown in Figures 4-12 and 4-13.

Table 4-2 Deaerator Water Outlet Temperature for Boiler Systems at Various Sea Level Pressures

Deaerator Pressure psig (kPa)	Deaerator Water Outlet Temperature F (C)	Deaerator Pressure psig (kPa)	Deaerator Water Outlet Temperature F (C)
0 (0.00)	212.0 (100)	11 (75.84)	241.6 (116.4)
1 (6.89)	215.3 (101.8)	12 (82.74)	244.4 (118)
2 (13.79)	218.5 (103.6)	13 (89.63)	246.4 (119.1)
3 (20.68)	221.5 (105.3)	14 (96.53)	248.4 (120.2)
4 (27.58)	224.4 (106.9)	15 (103.42)	250.3 (121.3)
5 (34.47)	227.1 (108.4)	16 (110.32)	252.2 (122.3)
6 (41.37)	229.8 (109.9)	17 (117.21)	254.1 (123.4)
7 (48.26)	232.2 (111.2)	18 (124.11)	255.3 (124.1)
8 (55.16)	234.8 (112.7)	19 (131)	257.0 (125)
9 (62.05)	237.1 (113.9)	20 (137.90)	258.8 (126)
10 (68.95)	239.4 (115.2)	--	--

NOTE: For every 500 feet (152 meters) in elevation from sea level, subtract 1 F (0.5 C) from the listed temperature. A mechanical deaerator that is operating efficiently can reduce the oxygen content of feedwater from the saturation level to a fraction of a ppm. However, even a trace amount of oxygen can cause corrosion pitting in the boiler. The complete removal of oxygen requires the addition of a chemical agent called an "oxygen scavenger."

Figure 4-12 **Mechanical Deaerator Schematic (Spray Type)**

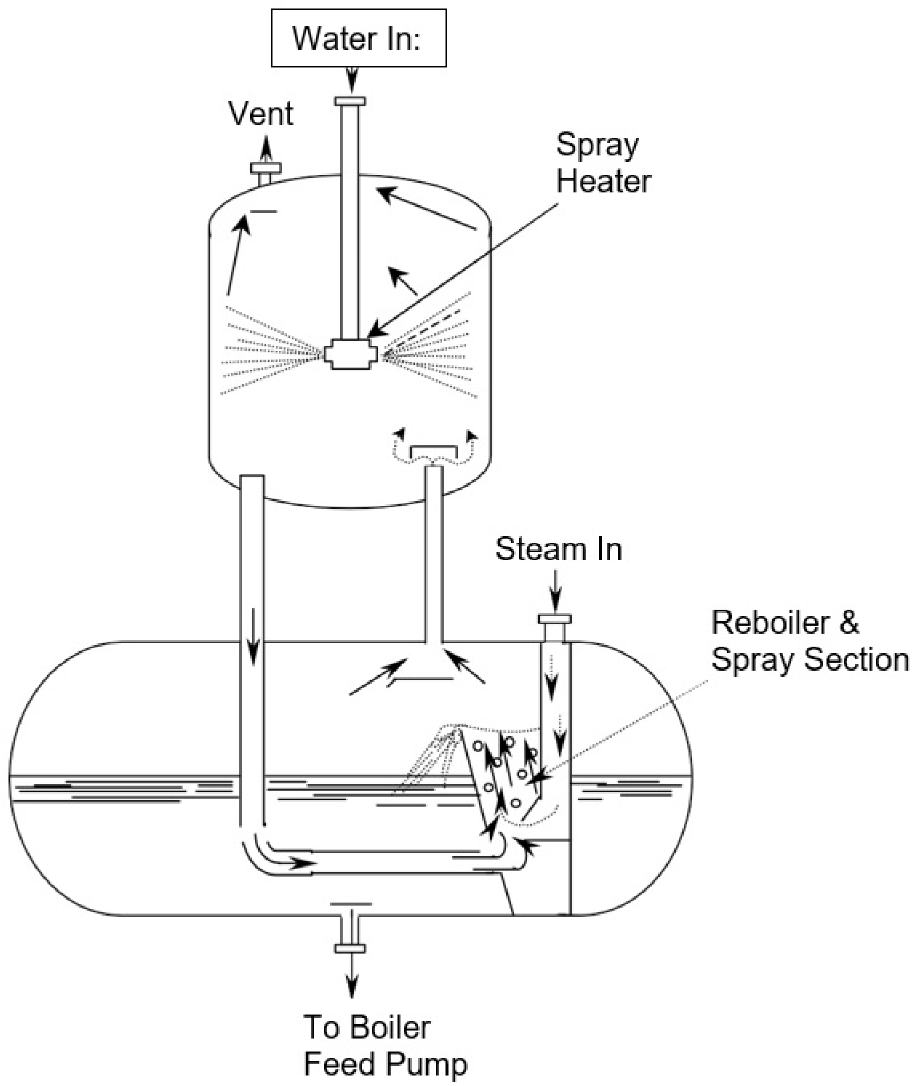


Figure 4-13 **Mechanical Deaerator Schematic (Tray Type)**

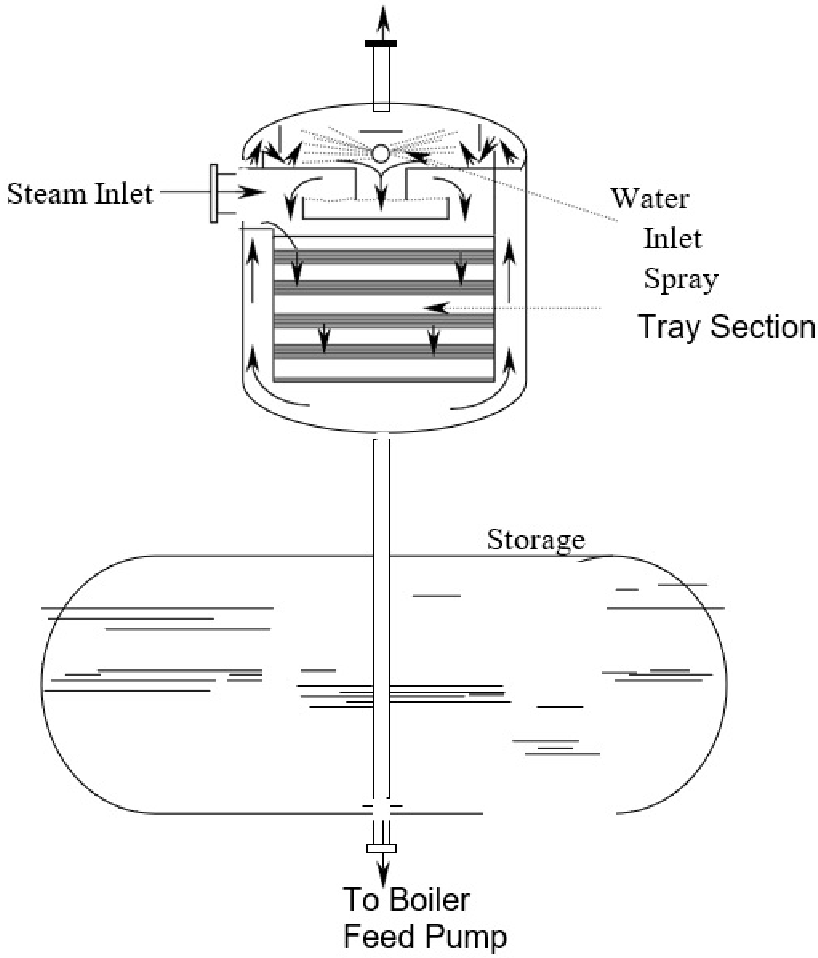


4-2.6.2 Chemical Removal of Free Oxygen.

Oxygen scavengers are chemicals that react with oxygen. Oxygen scavengers remove the oxygen from the boiler feedwater so it will not cause pitting corrosion.

4-2.6.2.1 Oxygen Scavengers for Boilers up to 6205 Kilopascals.

Oxygen scavengers for boilers up to 900 pounds per square inch gauge (6205 kilopascals) include catalyzed sodium sulfite and uncatalyzed sodium sulfite, both of which are oxygen scavengers and sources of sulfite. When a deaerator is used, any uncatalyzed oxygen scavenger will suffice and can be fed into the storage area of the deaerator. Use catalyzed sodium sulfite in systems without a deaerator. A cobalt sulfate salt, which is present in the catalyzed sodium sulfite material, is used as the catalyst. Catalyzed sulfite reacts more quickly with oxygen than does uncatalyzed sulfite. Both the sodium sulfite and the catalyst must be fed into the feedwater upstream from the boiler so oxygen can be scavenged before the feedwater enters the boiler. This addition scheme also serves to protect feedwater piping from corrosion. A sufficient amount of the oxygen scavenger must be fed to meet the demand for the oxygen initially present and provide an excess residual (reserve amount) for occasions when the oxygen level may increase unexpectedly, so that water testing will always indicate that an excess amount is present. (See Table 4-3 for typical sulfite levels in the boiler water.)

Table 4-3 Levels of Sulfite to be Carried in Boiler Water

Boiler Pressure psig (KPa)	Sulfite Residual (as ppm SO2)
0-15 (0-103)	20-40
16-149 (110-1020)	20-40
150-299 (1030-2060)	20-40
300-449 (2070-3100)	20-40
450-599 (3100-4130)	20-40
600-749 (4140-5160)	15-30
>750 (>5170)	15-30

4-2.6.2.2 Oxygen Scavengers for Boilers Over 900 PSI.

For boilers over 900 pounds per square inch gauge (6205 kilopascals), the list of oxygen scavengers includes specialty volatile treatments such as hydroxylamine, hydroquinone, carbohydrazide, hydrazine sulfate, and erythorbic acid. Hydrazine can no longer be used because it is a suspected carcinogen. Like hydrazine, these specialty volatile treatments not only scavenge oxygen but also passivate metal surfaces. These chemicals are normally maintained in the boiler water in the parts-per-billion (ppb) range. Sulfite-type oxygen scavengers are not used in boilers over 900 pounds per square inch gauge (6205 kilopascals) because of the potential for thermal decomposition producing sulfur dioxide and hydrogen sulfide, both of which can cause corrosion. The thermal decomposition reactions are:

Equation 4-7. Thermal Decomposition Reactions

$$\mathbf{Na2SO3 + H20 + Heat \rightarrow 2NaOH + SO2\uparrow}$$

$$\mathbf{or}$$

$$\mathbf{4Na2SO3 + 2H2O + Heat \rightarrow 3Na2SO4 + 2NaOH + H2S\uparrow}$$

These reactions have been shown to occur at boiler pressures as low as 600 pounds per square inch gauge (4140 kilopascals), although they do not usually create a serious problem until pressures exceed 900 pounds per square inch gauge (6205 kilopascals).

4-2.7 Condensate Corrosion and Control.

4-2.7.1 Causes of Condensate Corrosion.

Oxygen and carbon dioxide are common steam condensate impurities that promote condensate corrosion. Less common are process contaminants, each of which has corrosive properties dependent upon the nature of the contaminant and on the materials that may be corroded. The piping found in steam condensate systems is commonly constructed of mild steel, whereas heat exchangers are usually copper or mild steel.

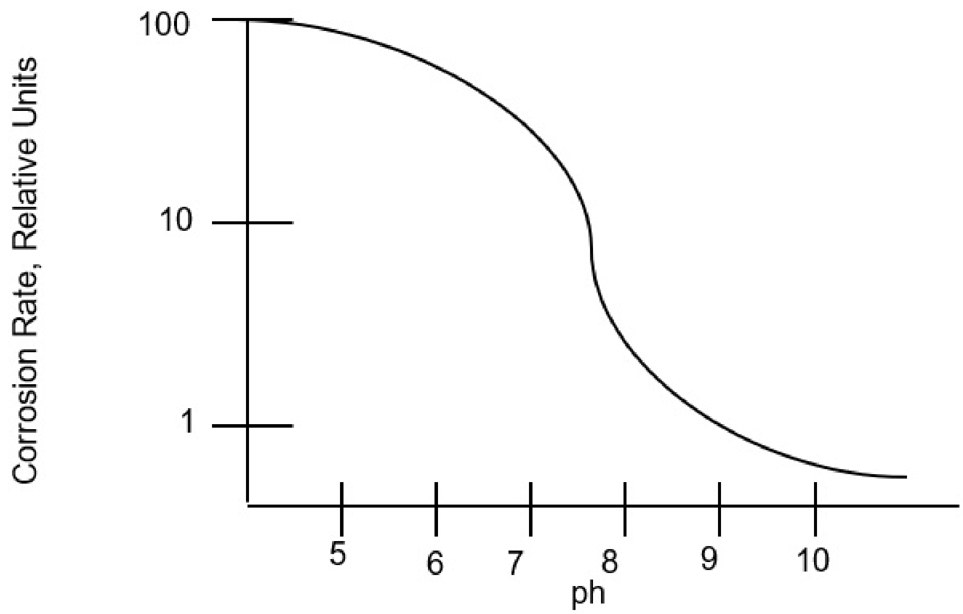
4-2.7.1.1 Air.

Air is the source of oxygen in a condensate system. Condensate lines that are used intermittently are particularly susceptible to condensate corrosion because the cooling of a heated condensate line creates a vacuum that can draw air into the system piping through valve seals or condensate sumps. Additionally, any dissolved oxygen in the feedwater that is not completely removed, either chemically or mechanically, can enter the boiler and pass with the steam into the condensate lines where it is consumed in a pitting corrosion attack on the metal surfaces. Oxygen corrosion in a condensate system is evidenced by pitting and by the presence of corrosion product deposits called "tubercles."

4-2.7.1.2 Carbon Dioxide.

Carbon dioxide (CO_2) can enter the boiler system if it is dissolved in the feedwater. However, CO_2 can be removed effectively through the deaerator. The most common source of carbon dioxide in steam condensate is the carbonate (CO^{2-}) and bicarbonate (HCO^{-}) ions (alkalinity) in the feedwater. Under the influence of heat and pressure in the boiler, the carbonate (CO^{2-}) and bicarbonate (HCO^{-}) ions (alkalinity) break down into hydroxyl (OH^-) ions (alkalinity) and CO gas. This free CO_2 is volatile and leaves the boiler with the steam. When the steam subsequently condenses, the CO_2 dissolves in the condensate and forms carbonic acid (H_2CO_3), which lowers the pH of the condensate and is corrosive to most metals, particularly to mild steel (see Figure 4-14). You can recognize carbon dioxide corrosion by the thinning of condensate line walls, particularly at the condensate liquid level within the pipe and at pipe threads where the condensate flows. Prevent corrosion in steam boiler systems by neutralizing the CO_2 with volatile amines.

Figure 4-14 **Effect of pH on Mild Steel and Copper Corrosion**



4-2.7.2 Estimating Carbon Dioxide in Steam.

Corrosion engineers find it useful to know the amount of carbon dioxide (CO_2) in steam when assessing the return on investment (cost savings from removing the CO_2 versus the cost for use of internal chemical treatment to remove the CO_2). Engineers and water treatment service companies need to estimate the amount of CO_2 to properly estimate the amount of neutralizing amine water treatment chemical that must be used. Example illustrates this estimation:

CO_2 levels in the steam can be estimated from the amount of bicarbonate and the carbonate alkalinity present in the feedwater as follows, where the “P” and “M” alkalinity measure these compounds. (See paragraph 7-6.1 for test methods.)

Equation 4-8. Estimating Carbon Dioxide in Steam

$$\mathbf{CO^2} = [\mathbf{bicarbonate\ x\ 0.79}] + [\mathbf{carbonate\ x\ 0.35}](\mathbf{18})\mathbf{CO^2} = [(\mathbf{M} - \mathbf{2P})\mathbf{x\ 0.79}] + [\mathbf{2P\ x\ 0.35}]$$

Where:

CO_2 = carbon dioxide estimate, ppm as CO_2

M = total (methyl orange) alkalinity, ppm as $CaCO_3$

P = phenolphthalein alkalinity, ppm as $CaCO_3$

EXAMPLE

a. Measured P = 2 ppm, M = 60 ppm

b. Bicarbonate CO_2 contribution (60 - (2 x 2)) x 0.79 = 44.2

c. Carbonate CO_2 contribution (2 x 2) x 0.35 = 1.4

d. Carbon dioxide estimate CO_2 = 44.2 + 1.4 = 45.6 ppm CO_2 in the steam

NOTE: This is a significant amount of CO_2 in steam due to the amounts of P and M alkalinity in the feedwater. There is some requirement to reduce alkalinity in this quality of feedwater.

4-2.7.3 Control of Carbon Dioxide by Neutralizing Amines.

Amines are organic compounds containing a nitrogen group similar to ammonia. They are referred to as “neutralizing amines” in boiler applications because they neutralize acidic (carbonic acid) conditions by raising the pH of the condensate. These amine compounds are volatile and escape the boiler with the steam and eventually dissolve in the steam condensate.

4-2.7.3.1 Control Limits.

Amines are added to maintain the pH between 7.5 to 9.0, ideally 7.5 to 8.5, in all parts of the condensate return system. The condensate pH level should not be allowed to fall below 7.5 anywhere within the entire condensate return system or corrosion will occur. For shore-to-ship steam, the requirement is 8.0 to 9.5 pH. (see Table 4-17). These amines are fed separately from other chemicals and are fed directly into the boiler steam drum where they vaporize and travel with the steam into the steam lines. Use continuous amine feed to maintain a constant, effective pH in the steam condensate.

4-2.7.3.2 Vapor-Liquid Distribution Ratios.

Morpholine, diethylamino-ethanol (DEAE), and cyclohexylamine are the three neutralizing amines approved for use in military boilers. Limitations of their use are described in paragraph 4-2.7.6. Physical and chemical properties of these amines are shown in Table 4-4. When steam condenses in a condensate return system that services multiple heat exchangers in different locations along the steam distribution system, some amines tend to “fall out” into condensate in legs close to the boiler while some amines tend to stay in the steam and come out in condensate toward the end of the steam distribution system. The degree to which this occurs is called the “vapor-liquid distribution ratio” and is expressed:

$$\text{Vapor-Liquid Distribution Ratio} = \frac{\text{Amine in steam phase}}{\text{Amine in condensate phase}}$$

Table 4-4 Physical and Chemical Properties of Neutralizing Amines

Property	Morpholine	DEAE	Cyclohexylamine
Boiling Point (100 percent amine)	264 F (129 C)	325 F (163 C)	273 F (134 C)
Boiling Point (amines/water azeotrope)	--	210 F (99 C)	205 F (96 C)
Decomposition temperature	644 F (340 C)	794 F (423 C)	205 F (96 C)
Vapor-Liquid Distribution Temperature	0.4	1.7	4.7
Specific Gravity (100 percent amine)	1.002	0.88	0.86
pH, 100 ppm solution	9.7	10.3	10.7
Amount of amine required to maintain pH of 8.0 in water	37 ppm	22 ppm	15 ppm

Amines have different vapor-liquid distribution ratios and will not work equally well in all systems. Depending on the particular amine, it can be effective in short-, medium-, or long-distance condensate lines. In complex condensate return systems, optimum results are obtained by choosing the appropriate amine or combination of amines on a system-by-system basis. A neutralizing amine selection chart is provided in Table 4-5. Often blends of different amines are used.

Table 4-5 Neutralizing Amine Selection Chart

Amine	Low Pressure (below 15 psig (103 KPa))	High Pressure Systems (above 15 psig (103 KPa))		
		Short System < 800 ft (<243 m)(2)	Medium System < 1 mile (<1.61 km)(2)	Long System > 1 mile (> 1.61 km)(2)
Morpholine		X		
DEAE	X		X	X
Cyclohexylamine	X			
Cyclohexylamine / morpholine mixture			X	X

NOTES:

1. Cyclohexylamine is not for use in systems having a feedwater alkalinity more than 75 ppm.
2. These system lengths are for classification only and are not absolute. For example, a medium-length system may have more of the characteristics of a long system if lines are poorly insulated or because of poor design. The characteristics of a condensate return system are best determined by a condensate pH survey.

4-2.7.3.3 Morpholine.

Morpholine has a low vapor-liquid distribution ratio and will drop out of steam quickly, making it suitable for protecting condensate return systems of short to moderate length. Morpholine is best suited for use in high-pressure systems (15 to 900 pounds per square inch gauge (103 to 6205 kilopascals)) because of its high boiling point. Very little morpholine is lost in deaerators from returning condensate.

4-2.7.3.4 DEAE.

DEAE has a vapor-liquid distribution ratio between that of morpholine and cyclohexylamine. This makes DEAE a good choice for protecting systems of moderate length where either morpholine or cyclohexylamine, if used separately, would not provide complete protection. The low boiling point of a mixture of DEAE and water makes DEAE suitable for use in both low-pressure boilers and high- pressure boilers.

4-2.7.3.5 Cyclohexylamine.

Cyclohexylamine has a high vapor-liquid distribution ratio and consequently is best suited for protecting extremely long systems. Cyclohexylamine can also be used in low-pressure systems. Cyclohexylamine is not used in systems when the feedwater alkalinity exceeds 75 ppm because of the low solubility of cyclohexylamine bicarbonate, which can be produced and form deposits. The likely areas for formation of these deposits are low-flow areas at the far end of the condensate return system. This deposition problem can be avoided by reducing feedwater alkalinity or by using DEAE. It is also necessary to treat long systems with morpholine to protect the early part of the system where steam is first condensed.

4-2.7.3.6 Amine Blends.

A mixture of morpholine, DEAE, or cyclohexylamine can be used to provide full protection in medium and large systems. The optimum blend of these amines is determined by measuring the actual pH of the condensate at various locations in the condensate return system. If samples from far sections have a lower pH than other samples, the cyclohexylamine in the mixture can be increased and vice versa. Another pH survey should be done when the blending ratio is changed. An initial blend of 1 part cyclohexylamine and 3 parts morpholine is a good starting point.

4-2.7.4 Control of Carbon Dioxide and Oxygen by Filming Amines.

Carbon dioxide corrosion can be controlled with 0.7 to 1.0 ppm of a filming amine such as octadecylamine. This chemical will coat the condensate pipe and prevent the carbon dioxide in the water from coming into contact with the pipe wall. Filming amines may also be appropriate for use if there is a high degree of air leakage (oxygen) because they coat the metal; however, you should not use them in condensate systems that have had corrosion problems in the past. Excess adsorption of the filming amine on the rust will occur and the amine can dislodge the rust and cause it to be returned to the deaerator or to the boiler. Adding filming amines continuously during operation and directly into the steam header through a quill, instead of into the steam drum, is essential. Addition of inadequate dosages can result in accelerated pitting-type corrosion due to incomplete surface coverage. You may need written authorization from the appropriate source before using filming amines in military boilers.

4-2.7.5 Control of Carbon Dioxide and Oxygen by Specialty Volatile Amines.

Some of the specialty oxygen scavengers described in paragraph 4-2.6.2.2 for boilers over 900 pounds per square inch gauge (6205 kilopascals) can be used for the purpose of control of both carbon dioxide and oxygen. The specialty volatile amines include hydroxylamine, hydroquinone, carbohydrazide, hydrazine sulfate, and erythorbic acid. They work by both raising the pH of condensate and by scavenging oxygen. They also passivate metal surfaces. Their use may not be appropriate and is restricted by the Food and Drug Administration (FDA). Note that these chemicals may not be needed for good operation of military boiler plants.

4-2.7.6 Amine Limitations and Indoor Air and Steam Quality Issues.

21 CFR Part 173.310 restricts using common neutralizing amines and filming amines to the limitations summarized in Table 4-6. Note that the limits shown in Table 4-6 are maximum allowable concentrations. Using amines may not always be advisable. If amine addition is not continuous, or if the boiler operation is cyclic (for instance shutting down the boiler for several hours each day), the maximum amine concentration may vary widely and exceed limits, even though the average concentration is within the limits.

Table 4-6 Amine Limits

Amine	Limitation
Cyclohexylamine	Not to be exceed 10 ppm in steam, and excluding steam in contact with milk and milk products.
DEAE	Not to exceed 15 ppm in steam, and excluding steam in contact with milk and milk products.
Hydrazine	Zero in steam.
Morpholine	Not to be exceed 10 ppm in steam, and excluding steam in contact with milk and milk products.
Octadecylamine	Not to be exceed 3 ppm in steam, and excluding steam in contact with milk and milk products.

4-2.7.6.2 Steam Used for Sterilization.

Some facilities, hospitals in particular, use steam in autoclaves for the purpose of sterilizing equipment such as surgical instruments. There is often concern that neutralizing amines may leave an amine contaminant on the equipment. Installing a dealkalizer to process the makeup water and thereby reduce the levels of bicarbonate and carbonate alkalinity is an alternative to using neutralizing amines. Using a dealkalizer effectively reduces, and may even eliminate, the need for neutralizing amines to reduce carbon dioxide corrosion. Steam- to-steam heat exchangers may be used to raise sterile steam.

4-2.7.6.3 Food Preparation.

The use of neutralizing amines or filming amines is prohibited if the steam contacts milk or milk products. In addition, to provide a margin of safety, the military prohibits any amines in steam used directly for cooking. This may be a sufficient reason to prevent using building steam in food preparation kitchens. In some cases, kitchens use steam to heat jacketed kettles in which food is heated. This application of steam as a heat source does not involve direct contact of the steam with foodstuffs. In other cases, direct contact between the steam and the foodstuffs is the method used to provide heating. There may be concerns that the amines will impart an amine taste or odor to the food. To alleviate this concern, use package steam generators to provide a source of steam that is independent of the building steam system. Another alternative is to use a steam-to-steam heat exchanger.

4-2.7.6.4 Humidification.

Steam is often used to humidify the air in buildings. The use of amines may raise a concern of contamination of the air in the building. To provide a margin of safety, the military prohibits using amines in steam that is used directly for humidification. Normally, the quantity of an amine in the air of a steam- humidified building is quite small, usually in the low ppb range; however, packaged steam generators can eliminate this concern.

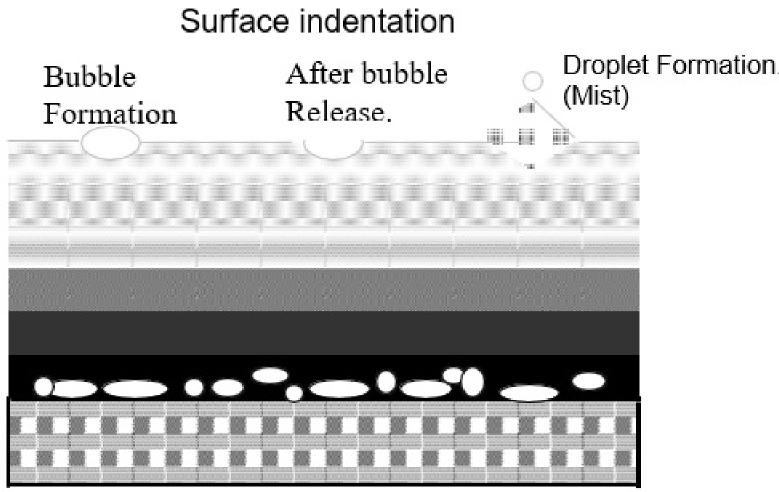
4-2.8 Water Carryover in Steam.

The steam that is produced from boiler water should not contain any liquid water. Common causes of water droplets or impurities being carried into the steam are misting, foaming, priming, and silica carryover.

4-2.8.1 Mist Carryover.

The term "misting" refers to a process in which a fine mist is produced as water boils. This 3-stage process is illustrated in Figure 4-15. In stage 1, a bubble of steam vapor reaches the water surface. In stage 2, the bubble bursts, leaving a dent in the water. In stage 3, the water rises to fill the dent. The center of the dent fills at a faster rate than the edges resulting in a small droplet of boiler water that is thrown off as a fine mist. Most, if not all, of the mist is removed in the mist eliminator section of the steam drum; however, any mist that is not removed will be entrained in the steam. These fine droplets will have the same level of dissolved solids as the boiler water and will contaminate the steam and the condensate.

Figure 4-15 **Water Boiler Mist Formation**



4-2.8.2 Foaming Carryover.

The term “foaming carryover” refers to boiler water foam and the carryover of foam into the steam. A variety of conditions can cause foam. Excessive levels of alkalinity, TDS, SS, and at times water treatment chemicals can interact to create foam in the boiler. Normally, maintaining the total alkalinity at less than 20 percent of the TDS and the total suspended solids (TSS) at less than 8 percent of the TDS can control foaming to a reasonable level. In addition, adding antifoam agents to the boiler water can control foaming. Polyamides and polyglycols are examples of antifoam agents.

4-2.8.3 Priming Carryover.

The term “priming” refers to boiler water in the steam when, due to liquid level variations and surges in the steam drum, water is mixed with the steam and is subsequently carried into the steam header. A mechanical problem or mechanical properties, such as oversensitive feedwater controls, large steam demands, or incorrect blowdown procedures, always cause priming. There is no chemical control method available, although the addition of antifoam chemicals may help reduce the extent of this occurrence. Boiler operations should be reviewed and modified if priming carryover is occurring.

4-2.8.4 Silica Carryover.

The term “silica carryover” refers to a situation that occurs when silica in the boiler water volatilizes and enters the steam independently of water carryover. The silica can then form a deposit in the condensate lines and in process equipment when the silica condenses from the steam. When steam turbines are used, silica deposition can be very serious, resulting in unbalancing of the steam turbine blades. Maintaining a low silica level in the boiler water can control silica carryover. The acceptable level is dependent upon the boiler operating pressure; Table 4-7 shows suggested limits.

Table 4-7 Silica Levels Allowed in Boiler Water

Boiler Pressure psig (KPa)	Allowable Silica ppm (as SiO_2)
0-15 (0-103)	150
16-149 (110-1027)	150
150-299 (1034-2062)	150
300-449 (2068-3096)	90
450-599 (3103-4130)	40
600-749 (4137-5164)	30
750 (5171)	20

4-2.8.5 Determining Water Carryover in Steam.

The best way to determine if any water carryover is occurring is to measure the conductivity of the steam or of the steam condensate. If you detect less than 25 micromhos conductivity in the condensate, then carryover is probably insignificant. If conductivity is greater than 25 micromhos, you should investigate to identify the cause.

4-2.8.5.1 Conductivity Measurement Implications.

A conductivity measurement above 25 micromhos in the steam condensate indicates that there is either carryover or leakage into the steam or condensate system. Accordingly, a test for hardness in the condensate must also be performed. If you find hardness, contamination of the condensate is likely due to raw water or leakage into the condensate system rather than boiler water carryover. If boiler water is at a very low hardness, then raw water may be the cause.

4-2.8.5.2 Deposit Analysis.

Any deposits found in the steam or condensate systems should be analyzed to determine the source. Deposits that are mostly magnetic iron oxide are due to corrosion of mild steel in the condensate system. Using neutralizing amines (as described in paragraphs 4-2.7.3 and 4-2.7.4) can control these deposits. If the deposits are mostly silica, increasing the blowdown or removing silica from the makeup water can reduce them. If the deposits are mostly sodium salts (sodium hydroxide, sodium carbonate, sodium chloride, sodium sulfate, and sodium phosphate), the cause is probably boiler water carryover from misting, priming, or foaming.

4-3 DEVELOPING A STEAM BOILER SYSTEM WATER TREATMENT PROGRAM.

A complete boiler water treatment program takes into account industry- developed guidelines for feedwater quality limits and boiler water quality limits. The water treatment industry recognizes the suggested water limits developed by the American Society of Mechanical Engineers (ASME), the American Boiler Manufacturers Association (ABMA), and USACE. The limits developed by these three organizations are not always identical; furthermore, the limits are actually only guidelines. In some cases these limits have been exceeded by boiler operations without unacceptable impacts; however, these limits should be considered as prudent, safe, and practical guidelines (see Tables 4-8 through 4-20).

4-3.1 Organizing a Treatment Program.

Once you have defined water treatment requirements, organize personnel to implement the program. The organization process consists of identifying a staff, training them to execute the program, and integrating the program into overall installation management.

4-3.2 Operator Training.

Operator training is essential to a water treatment program. Operators should understand the operation of their specific plant and reasons for specified procedures, including requirements of CFR Title 29, Part 1910.1200, *Hazard Communication*. An understanding of reasons for, and results of, chemical treatment is essential. Knowledge of thermodynamic and mechanical interactions of plant equipment is important. The operator should be particularly aware of safe operating procedures. Since internal chemical treatment of boiler water is a significant factor in achieving reliable and efficient plant operation, operators should have an understanding of the subject. Training should include the specifics of water treatment and related costs.

4-3.2.1 Pretreatment Training.

Pretreatment is necessary to ensure the quality of the water to be treated for industrial use and to prevent or reduce associated problems such as deposits and corrosion. Training might address these methods of pretreatment (depending on the type of plant):

- Chemical addition.
- Ion exchange.
- RO.
- Distillation.

4-3.2.2 Treatment Training.

Steam boilers, high-temperature water systems, and cooling water systems all require treatment of feed water to prevent or reduce deposits, scale, corrosion, and microorganisms.

4-3.2.2.1 Boiler Water Treatment.

The training related to boiler water treatment should address:

- Necessity for internal boiler water treatment.
- Deaeration and oxygen scavenging.
- Maintenance of concentration levels.
- Causes and effects of deposits, scale, and corrosion.
- Chemical treatment programs, such as phosphate, polymers, sulfite, hydrazine, and others.
- Where to feed chemicals.
- Effects of carryover and silica on steam purity.
- Prevailing ASME and internal standards.
- Corrosion in condensate returns from oxides of iron and copper.
- Effects of filming and neutralizing amines and hydrazine.
- Boiler layup procedures.
- Recognition of abnormal boiler water chemistry conditions.
- Taking prompt and effective corrective action for abnormal boiler water conditions.

4-3.2.2.2 Cooling Systems Treatment.

Training for treatment of cooling systems feedwater should address:

- Once-through cooling water systems.
- Recirculating cooling water systems.
- Need for and means of maintaining clean condensers.
- Chemicals and methods of treatment.
- COC.

4-3.2.2.3 Blowdown.

Blowdown is used in both cooling and steam systems to regulate COC of solids through dilution with makeup water. Training associated with blowdown procedures should include:

- Surface versus bottom.
- Internal provisions.
- Estimating blowdown.
- Continuous and intermittent.

- Controllers and COC.
- Heat recovery through flash tanks and heat exchangers for boilers.

4-3.2.3 Program Content.

Training should be provided in steps that are geared to operators' capabilities. Weekly sessions, with handouts, periodic reviews, and testing should be planned to assess trainees' retention and understanding of material and effectiveness of teaching methods. Training should include the following topics:

- Basic water chemistry.
- Chemistry concepts.
- Water chemistry fundamentals.
- Elementary water treatment.
- Water chemistry applications.
- Water treatment equipment.
- Boiler water treatment.
- Raw water treatment.
- Ion exchange.
- Cooling water treatment.

4-3.3 Equipment and Procedures.

Chapter 8 contains a description of water quality instrumentation and treatment equipment for various applications. Paragraph 8-3 describes procedures. The subject is also covered in Appendix D.

4-3.4 Feed water Quality Limits.

Tables 4-8 through 4-12 show feed water limits. The limits are specific for the type of boiler, operating pressure, and steam application. Since feed water is the combination of makeup water and condensate return, recovering as much uncontaminated condensate as possible is advisable, considering the cost of boiler water treatment and the benefits derived from both energy and water conservation. The high purity of uncontaminated condensate minimizes the requirement for treatment of makeup water and boiler water. The feed water parameters shown in Tables 4-8 through 4-12 do not specify levels for alkalinity and silica because it is assumed that these levels in the boiler water will be limited through blowdown. In higher pressure boilers using demineralized makeup water, alkalinity and silica will be very low or even absent. Although not specified, it can make sense to reduce feed water alkalinity and silica in boilers less than 900 pounds per square inch gauge (6205 kilopascals) to allow for an increase in COC and, consequently, to reduce chemical demand. The tables show limits for hardness, iron, and copper. Hardness and iron can be removed by softening the makeup water. Iron and copper may still be present in the feed water if they are present in the condensate due to corrosion. In many instances, these limits cannot be met for small heating boilers (such as oxygen content in feed water for boilers that lack a deaerator, or hardness levels in feed water for boilers that lack softeners). The only alternative is to chemically treat boiler water and control COC, as required.

Table 4-8 Suggested Feed water Limits for Industrial Water Tube Boiler 0–300 psig (0–2068 KPa)

Feedwater Property	ASME	ABMA	USACE
Dissolved oxygen ppm O_2 before chemical oxygen scavenger addition	< 0.007	Note 6	NS
Total iron ppm Fe (as Fe)	< 0.1	Note 6	NS
Total copper ppm Cu (as Cu)	< 0.05	Note 6	NS
Total hardness ppm (as $CaCO_3$)	< 0.5	Note 6	Softened
pH at 77 F (25 C)	8.3-10.5	Note 6	NS
Non-volatile TOC ppm (as O_2)	< 1	Note 6	NS
Oily matter ppm	< 1	Note 6	NS

NOTES:

1. Makeup water percentage: Up to 100 percent of feedwater.
2. Assumes existence of deaerator.
3. Conditions: no super heater, turbine drives, or process restriction on steam purity.
4. Steam purity: 1.0 ppm TDS maximum.
5. NS = not specified.
6. See ABMA Standard – Boiler 401

Table 4-9 Suggested Feedwater Limits for Industrial Water Tube Boiler 301-600 psig (2075-4137 KPa)

Feedwater Property	A SME	ABMA	USACE
Dissolved oxygen ppm O2 before chemical oxygen scavenger addition	<0.007	Note 6	NS
Total iron ppm Fe (as Fe)	<0.05	Note 6	NS
Total copper ppm Cu (as Cu)	<0.025	Note 6	NS
Total Hardness ppm (as CaCO3)	<0.3	Note 6	NS
pH at 77 F (25 C)	8.3-10.5	Note 6	NS
Non-volatile TOC ppm (as O2)	< 1	Note 6	NS
Oily Matter ppm	< 1	Note 6	NS

NOTES:

1. Makeup water percentage: Up to 100 percent of feedwater.
2. Assumes existence of deaerator.
3. Conditions: no super heater, turbine drives, or process restriction on steam purity.
4. Steam purity: 1.0 ppm TDS maximum.
5. NS = not specified.
6. See ABMA Standard – Boiler 401

Table 4-10 Suggested Feedwater Limits for Industrial Fire Tube Boiler 0–300 psig (0-2068 KPa)

Feedwater Property	Limit
Dissolved oxygen (ppm O2) before chemical oxygen scavenger addition	< 0.007
Total iron ppm Fe (as Fe)	< 0.1
Total copper ppm Cu (as Cu)	< 0.05
Total Hardness ppm (as $CaCO_3$)	< 1.0
Ph at 77 F (25 C)	8.3-10.5
Non-volatile TOC ppm (as O_2)	< 10
Oily matter ppm	< 1

NOTES:

1. Makeup water percentage: up to 100 percent of feedwater.
2. Assumes existence of deaerator.
3. Conditions: no super heater, turbine drives, or process restriction on steam purity.
4. Steam purity: 1.0 ppm TDS maximum

Table 4-11 ASME Feedwater Limits for Industrial Water Tube Boilers

Feedwater Property	0 - 300 psig (0 - 2068 KPa)	301-450 psig (2075-3103 KPa)	451 - 600 psig (3110 - 4137 KPa)	601 - 750 psig (4144 - 5171 KPa)	751 - 900 psig (5178 - 6205 KPa)	901 - 1000 psig (6212 - 6895 KPa)	1001 - 1500 psig (6902-10,342 KPa)	1501 - 2000 psig (10,349-13,790 KPa)
Dissolved oxygen (ppm O2) before adding chemical oxygen scavenger	< 0.007	< 0.007	< 0.007	< 0.007	< 0.007	< 0.007	< 0.007	< 0.007
Total iron ppm Fe (as Fe)	≤ 0.1	≤ 0.05	≤ 0.03	≤ 0.025	≤ 0.02	≤ 0.02	≤ 0.01	≤ 0.01
Total Copper ppm Cu (as Cu)	≤ 0.05	≤ 0.025	≤ 0.02	≤ 0.02	≤ 0.015	≤ 0.01	≤ 0.001	≤ 0.001
Total hardness ppm (as $CaCO_3$)	≤ 0.03	≤ 0.03	≤ 0.02	≤ 0.02	≤ 0.1	≤ 0.05	ND	ND
pH at 77 F (25 C)	8.3-10.0	8.3-10.0	8.3-10.0	8.3-10.0	8.3-10.0	8.3-9.6	8.3-9.6	8.3-9.6
Chemicals for pre-boiler system	NS	NS	NS	NS	NS	VAM	VAM	VAM
Non-volatile TOC ppm (as O_2)	< 1	< 1	< 0.5	< 0.5	< 0.5	< 0.2	< 0.2	< 0.2
Oily Matter ppm	< 1	< 1	< 0.5	< 0.5	< 0.5	< 0.2	< 0.2	< 0.2

NOTES:

1. Makeup water percentage: Up to 100 percent of feedwater.
2. Assumes existence of deaerator.
3. Conditions: Includes super heater, turbine drives, or process restriction on steam purity.
4. Saturated steam purity target as shown.
5. NS = not specified.
6. ND = not detectable.
7. VAM = Use only volatile alkaline materials upstream of a temporary water source.

Table 4-12 ASME Suggested Feedwater Limits for Marine Propulsion Water Tube Boiler

Feedwater Property	450-850 psig (3103-5861 KPa)	851-1250 psig (5867-8618 KPa)
Dissolved oxygen (ppm O_2) before chemical oxygen scavenger addition	< 0.007	< 0.007
Total iron ppm Fe (as Fe)	< 0.02	< 0.01
Total copper ppm Cu (as Cu)	< 0.01	< 0.005
Total hardness ppm (as $CaCO_3$)	< 0.1	< 0.05
pH at 77° F (25° C)	8.3–9.0	8.3–9.0
Chemicals for pre-boiler system	VAM	VAM
Oily matter ppm	< 0.05	< 0.05

NOTES:

1. Makeup water percentage: Up to 5 percent of feedwater.
2. External treatment: at sea, evaporator condensate; in port, evaporator condensate or water from shore facilities meeting feedwater quality guidelines.
3. Assumes existence of deaerator.
4. Saturated steam purity: 30 ppb TDS maximum, 10 ppb Na maximum, 20 ppb SiO2 maximum.
5. VAM = Use only volatile alkaline materials.

4-3.5 Boiler Water Chemistry Limits.

Tables 4-13 through 4-16 show boiler water chemistry limits. The limits are specific for the type of boiler, operating pressure, and steam application. There are two types of limits to recognize. The first comes from the presence of natural constituents in the feedwater (such as TDS or conductivity, silica, and alkalinity). These constituents can be the controlling factor for COC. Blowdown is ultimately required to keep their levels within limits. SS is the result of precipitation of minerals. These are kept within limits through bottom blowdown. The second type is treatment limits for chemicals added into the boiler (see Tables 4-17 and 4-18)

Table 4-13 ASME Suggested Boiler Water Limits for Industrial Water Tube Boiler

Boiler Water Property	0-300 psig (0-2068 KPa)	301-600 psig (2075-4137 KPa)
Silica (ppm SiO_2)	< 150	< 90
Total alkalinity	< 1000	< 850
Free OH alkalinity	NS	NS
Specific conductance (μmhos/cm) without neutralization	< 7000	< 5500

NOTES:

1. Makeup water percentage: Up to 100 percent of feedwater.
2. Assumes existence of deaerator.
3. Conditions: no super heater, turbine drives, or process restriction on steam purity.
4. Steam purity: 1.0 ppm TDS maximum.
5. NS = not specified.

Table 4-14 ASME Boiler Water Limits for Industrial Water Tube Boilers

Boiler Water Property	0 - 300 psig (0 - 2068 KPa)	301 - 450 psig (2075 - 3103 KPa)	451 - 600 psig (3110 - 4137 KPa)	601 - 750 psig (4144 - 5171 KPa)	751 - 900 psig (5178 - 6205 KPa)	901 - 1000 psig (6212 - 6895 KPa)	1001 - 1500 psig (6902 - 10342 KPa)	1501 - 2000 psig (10349 - 13790 KPa)
Silica (ppm SiO_2)	≤ 150	≤ 90	≤ 40	≤ 30	≤ 20	≤ 8	≤ 2	≤ 1
Total alkalinity	< 350	< 300	< 250	< 200	< 150	< 100	NS	NS
Free OH alkalinity	NS	NS	NS	NS	NS	NS	ND	ND
Specific conductance (μmhos/cm) without neutralization	5400-1100	4600-900	3800-800	1500-300	1200 -200	1000-200	≤150	≤80
TDS (maximum) ppm	1.0-0.2	1.0-0.2	1.0-0.2	0.5-0.1	0.5-0.1	0.5-0.1	0.1	0.1

NOTES:

1. Makeup water percentage: Up to 100 percent of feedwater.
2. Assumes existence of deaerator.
3. Conditions: Includes super heater, turbine drives, or process restriction on steam purity.
4. Saturated steam purity target as shown.
5. NS = Not specified.
6. ND = Not detectable

Table 4-15 ASME Boiler Water Limits for Industrial Fire Tube Boilers 0–300 psig (0-2068 KPa)

Boiler Water Property	Limit
Silica (ppm SiO_2)	< 150
Total alkalinity	< 700
Free OH alkalinity	NS
Specific conductance (μmhos/cm) without neutralization	< 7000

NOTES:

1. Makeup water percentage: Up to 100 percent of feedwater.
2. Assumes existence of deaerator.
3. Conditions: no super heater, turbine drives, or process restriction on steam purity.
4. Steam purity: 1.0 ppm TDS maximum.
5. NS = not specified

Table 4-16 ASME Suggested Boiler Water Limits for Marine Propulsion Water Tube Boiler

Boiler Water Property	450-850 psig (3103-5861 KPa)	851-1250 psig (5867-8618 KPa)
Silica (ppm SiO_2)	< 30	< 5
Total alkalinity	NS	NS
Free OH alkalinity	< 200	ND
Specific conductance (μmhos/cm) without neutralization	< 700	< 150

NOTES:

1. Makeup water percentage: Up to 5 percent of feedwater.
2. External treatment: at sea, evaporator condensate. In port, evaporator condensate or water from shore facilities meeting feedwater quality guidelines.
3. Assumes existence of deaerator.
4. Saturated steam purity: 30 ppb TDS maximum, 10 ppb Na maximum, 20 ppb SiO2 maximum.
5. NS = not specified.

6. ND = non detectable.
7. VAM = Use only volatile alkaline materials.

4-3.6 Shore-to-Ship Steam Quality.

Shore-to-ship steam purity is specified in NAVSEA S9086-GX-STM-020, Section 220, Volume 2, Boiler Water/Feedwater Test and Treatment.

Table 4-17 NAVSEASYSCOM Shore-To-Ship Steam Purity Requirements

Constituent Property	Requirement
pH	8.0 to 9.5
Conductivity	25µmho/cm max
Dissolved Silica	0.2 ppm max
Hardness	0.10 epm max
Total Suspended Solids	0.10 ppm max

4-3.7 Treatment Guidelines for Low-Pressure Steam.

Treatment guidelines for boilers operating at less than 15 pounds per square inch gauge (103 kilopascals) are determined by size and type, as described in Table 4-18. Cast iron boilers and boilers less than 334 watts (10 horsepower) are not treated. Boilers with greater than 95 percent condensate return can either be treated the same as a closed hot water boiler (see Chapter 6), or treated the same as boilers with less than 95 percent condensate return. The latter uses external treatment, usually softening, and internal chemical treatment that includes a scale inhibitor (precipitating type – phosphate) or solubilizing type (phosphonates and polymers) sulfite to control pitting due to oxygen, and a neutralizing amine to control pH in the condensate system. Sometimes raising pH in the boiler water requires a supplemental source of alkalinity. Usually this supplemental source is caustic soda, but it can also be sodium carbonate (soda ash).

Table 4-18 Treatment Guidelines for Low-Pressure Steam

Boiler	Guidelines
Cast iron	Not treated
Less than 334 W (10 hp)	Not treated
Boiler with 95 percent condensate return	1. External treatment: softening. 2. Internal treatment: precipitating or solubilizing scale inhibitor, sulfite, tannin derivatives, filming surfactant, caustic supplement if necessary, neutralizing amine. 3. See Tables 4-19 through 4-20. Or Treat same as closed hot water (see Chapter 6).
Boilers with less than 95 percent condensate return	1. External treatment: softening. 2. Internal treatment: precipitating or solubilizing scale inhibitor, sulfite, tannin derivatives, filming surfactant, caustic supplement if necessary, neutralizing amine. See Tables 4-19 and 4-20.

4-3.8 Treatment Guidelines for Medium- and High-Pressure Steam.

Treatment of medium- 16 to 299 pounds per square inch gauge (110 to 2062 kilopascals) and high-pressure 300 to 900 pounds per square inch gauge (2068 to 6205 kilopascals) boilers is similar and is described in Table 4-19. Treatment can include either a precipitating (phosphate) or a solubilizing (phosphonate or polymers) approach to scale control. Sulfite is used to control pitting due to oxygen, and a neutralizing amine is used to control pH in the condensate system. Sometimes raising pH in the boiler water requires a supplemental source of alkalinity. Usually this source is caustic soda, but it can also be sodium carbonate (soda ash). Boilers operating between 600 to 900 pounds per square inch gauge (4137 to 6205 kilopascals) will sometimes use erythorbic acid or specialty volatile oxygen scavengers or amines (such as hydrazine, DEHA, carbohydrazide, hydroquinone or methylethylketoxime) as oxygen scavengers in boiler water. The volatile compounds can also scavenge oxygen in a condensate system. Refer to paragraph 4-2.7 for a description of condensate corrosion control.

Table 4-19 Treatment Guidelines for Medium- and High-Pressure Steam

Parameter	Boiler Water Treatment Control
COC	Maximum of 100, per ASME
General corrosion	Maximum total alkalinity, per ASME guidelines, pH of 10.3–12.0. May require alkalinity builder.
Pitting corrosion	20-40 ppm sulfite for boilers up to 900 psig (6205 KPa). Specialty volatile oxygen scavengers optional for boilers 600-900 psig (4137-6205 KPa). Also, tannin derivatives and other organic-based oxygen scavengers
Condensate corrosion	Maintain pH of 7.5-9.3 using neutralizing amines or follow guidelines for filming surfactant chemistry. Specialty volatile oxygen scavengers optional.
Deposition control	1. Precipitating program using phosphate or carbonate with a polymer sludge conditioner. Or 2. Solubilizing program using chelants, phosphonates, or polymers. Or Tannin and lignin derivatives and phosphonates and/or polymers (including acrylate-styrenesulfonate co-polymers and polymethacrylates)
Carryover control due to foaming	Limit total alkalinity, per ASME guidelines, and treat with antifoam as required.

4-3.9 Condensate Corrosion and Control.

Oxygen and carbon dioxide are common steam condensate impurities that promote condensate corrosion. Less common are process contaminants, each of which has corrosive properties dependent upon the nature of the contaminant and the materials that may be corroded. The piping found in steam condensate systems is most commonly constructed of mild steel, whereas heat exchangers are usually copper or mild steel. (For more information, see paragraph 4-2.7.)

4-3.10 Treatment Guidelines for Very-High-Pressure Steam.

Treatment of very-high-pressure 900 pounds per square inch gauge (greater than 6205 kilopascals) boilers is different than for those of lower pressure. Because temperatures and pressures are much more extreme, the boilers can tolerate little in the way of boiler water impurities. Table 4-20 provides treatment guidelines.

Table 4-20 Treatment Guidelines for Very-High-Pressure Steam

Parameter	Boiler Water Treatment Control
COC	Maximum of 100, per ASME.
General corrosion control	Maintain pH, per ASME guidelines, using coordinated, congruent, or equilibrium phosphate, or with all volatile treatment.
Pitting corrosion control	Volatile hydrazine substitutes: hydroxylamine, hydroquinone, carbohydrazide, hydrazine sulfate, tannin derivatives, or erythorbic acid.
Condensate corrosion control	Maintain pH of 7.5-9.3 using specialty volatile oxygen scavengers listed for pitting control above.
Deposition control	External treatment to remove scaling agents. Example: RO with demineralization
Carryover control due to foaming	External treatment to remove alkalinity and other minerals. Example: RO with demineralization

4-3.11 Boiler Operator Duties.

Operators should keep feedwater quality, COC, and treatment levels within program control limits at all times. Operators must perform recordkeeping and assess trends in the results of system performance tests routinely (see paragraph 2-1.8). When changes in feedwater quality, TDS, or chemical treatment levels occur, the operator must investigate and resolve the reasons for these changes. Report to supervisor any unresolved abnormalities. Boiler operators need to understand their equipment and how it operates. Does it operate seasonally? Does it operate intermittently? Does the amount of condensate return vary? These conditions may require adjustments in chemical treatment.

Paragraphs 4-4 and 4-5 present some common problems.

4-4 CHEMICAL REQUIREMENTS FOR BOILER START-UP.

Start-up of a new or repaired boiler requires special water treatment procedures. The start-up of a boiler after a wet or dry layup period also requires special water treatment procedures.

4-4.1 Common Problems during Start-up of New Boilers.

A common problem that can occur during start-up of new boilers is corrosion of the boiler tubes due to improper initial conditioning of the water and boiler metal. Carryover of boiler water due to improper start-up can also occur, particularly with new boilers.

4-4.2 Start-up of New Boilers and Condensate Systems or Repaired Boilers.

As a result of the fabrication process, a new or repaired boiler that is erected in the field or shipped as a package unit will likely contain oils and greasy films, and perhaps rust, on the metal surfaces. The oils, grease, and rust can contribute to carryover and contaminate the steam and initiate corrosion of the boiler components. A pre-operational alkaline boil-out procedure is required to remove these materials. This pre-operational process is usually part of a new construction project and therefore may not be in the direct control of boiler operations personnel. Often, the contracting officer involved with the project can provide verification of the completion of this important step.

The following example of an alkaline boil-out procedure consists of four steps:

1. Inspect the inside of the boiler and remove all debris.
2. Add an alkaline boil-out chemical formulation to the boiler water. This should be roughly equivalent to the following formulation: 24 pounds (10.4 kilograms) of caustic soda, 24 pounds (10.4 kilograms) of disodium phosphate, 8 pounds (3.5 kilograms) of sodium nitrate, 0.5 pound (0.2 kilogram) non-ionic wetting agent (a low-foaming detergent) per each 1000 gallons (3785 liters) of boiler capacity.
3. Fill the boiler to the steam header and maintain at low fire for 1 to 2 days. For condensate systems, this formulation should be circulated for 3 to 4 days, drained completely, and the system dried completely by purging with dry air.
4. Drain and flush. Proceed immediately to operational treatment levels or to a layup status. Untreated water should never be allowed to remain in the boiler.

Table 4-21 Troubleshooting Boiler System Water

Problem	Recommended Solution/Possible Cause
Hardness in feedwater	1. Check softener Possible leak into condensate system
Change in overall treatment levels	1. Change in amount of condensate return 2. Change in blowdown control Change in overall chemical feed rate
Loss of alkalinity	1. Hardness incursion 2. Loss of caustic feed Excessive blowdown
Loss of scale prohibitor	1. Hardness incursion 2. Loss of chemical feed Excessive blowdown
Loss of sulfite	1. Loss of sulfite feed 2. Poor deaerator operation or influx of oxygen Excessive makeup and loss of condensate
High conductivity (>25 mhos) in steam	Carryover due to misting, foaming, or priming
Foaming carryover	Excessively high TDS, alkalinity, or chemical treatment
Priming carryover	Operational problem with excessive load demands, feedwater and level control problem, uneven firing patterns
Misting carryover	Defective mist eliminators

4-4.2.1 Start-up of Boiler from Wet Layup.

Boilers that have been properly laid up wet will already have adequate excess levels of sulfite and alkalinity (see paragraph 4-5.4). Upon adjusting the water level and firing up the boiler, feed all chemical treatments as normally added, except for sulfite and alkalinity supplement. There is no need to feed these treatments until blowdown results in reducing their levels. Then add chemicals in the amounts required to reach normal maintenance levels.

4-4.2.2 Start-up of Boiler from Dry Layup.

Boilers that have been properly laid up dry (see paragraph 4-5.3) can be filled with feedwater to their normal operating boiler water level. The start-up dosage of sulfite and alkalinity supplement (caustic or soda ash) can be fed along with the standard chemical treatment feed rates to obtain normal levels of water treatment chemicals. It is necessary to achieve proper sulfite and alkalinity levels in the boiler water to control corrosion while the COC is increased to normal operating levels. The sulfite concentration should be at least 20 ppm (SO_3), and the alkalinity level should result in a pH of about 11.0.

4-5 CHEMICAL REQUIREMENTS FOR BOILER LAYUP.

Boiler layup also requires special water treatment. Boilers that will be out of service for more than four calendar days require special water treatment to prevent internal corrosion. Boiler layup can be either dry or wet. The advantages of wet layup are that it often provides better corrosion protection and the boiler can be brought on-line much faster than when dry layup procedures are used.

4-5.1 Operational Considerations.

Operational considerations are important to consider when determining the proper boiler status. The terms “lead” and “lag” are used commonly for boilers that need to meet varying load demands. The lead boiler satisfies the base steam load. The lag boiler meets any extra steam demand that might be needed during hours of the evening or mornings or when (additional) process loads are required. Lag status does not apply to a cold boiler that is not required for duty for a few days. Such a boiler should be considered in layup condition and should be prepared accordingly.

4-5.2 Common Problems that Occur During Layup.

Common problems that occur during layup are: oxygen pitting of tubes and condensate piping, sometimes to the point of failure; general corrosion of tubes and condensate piping; and corrosion product contaminating feed water via the condensate system.

4-5.3 Dry Layup of Boilers.

Boilers with manholes may be laid up in one of two ways, depending on the length of storage and conditions in the boiler room: open dry layup, or moisture-absorbing material such as silica gel or lime, quicklime or silica gel layup.

4-5.3.1 Open Dry Layup Method.

The open dry layup method is recommended for short-term storage (30 to 150 days) where the boiler room is dry, has low humidity, and is well ventilated. It is important to keep the boiler dry. The recommended procedure consists of six basic steps:

1. Take the boiler out of service and drain it completely while still warm. Make sure the water walls and gauge columns are not overlooked.
2. Lock and tag out boiler in accordance with written procedures.
3. Break the feedwater and steam connections to the boiler and blank off connections if other boilers in the plant are operating.
4. The boiler may be opened and the inside washed of all loose scale and sediment by flushing with high-pressure water.
5. Use a stiff brush to clean all internal surfaces that can be reached.
6. Leave boiler open to the atmosphere. Should a humid atmosphere exist, the boiler must be closed up and the procedure specified in paragraph 4-5.3.2 used.

4-5.3.2 Quicklime or Silica Gel Layup Method.

This procedure is recommended for storage over 150 days or for less than 150 days when the boiler room and atmosphere is quite humid and not well ventilated. The recommended procedure consists of eight basic steps:

1. Take the boiler out of service and drain completely while still warm. Make sure that water walls and gauge columns are not overlooked.
2. Lock and tag out the boiler in accordance with written procedures.
3. Break the feedwater and steam connections to the boiler and blank off connections if other boilers in the plant are operating.
4. The boiler may be opened and the water-contacted inside surface washed to remove all loose scale and sediment by flushing thoroughly with high-pressure water.
5. Use a stiff brush to clean all internal surfaces that can be reached.
6. Place quicklime (not hydrated lime) or new, unused silica gel in one or more metal or fiber trays in the boiler. Place the trays on wood blocks so air can circulate under them. The amount of lime or silica gel required is about 50 pounds (22 kilograms) per 3000 pounds per hour (0.36 kilogram of steam per second) boiler capacity.
7. Seal the boiler to prevent any moist air from entering the boiler.
8. Open and inspect the boiler every 2 months. Replace any moist quicklime or silica gel with new material.
9. Carefully reseal immediately after the inspection and after the addition of new chemicals.

4-5.4 Wet Layup of Boilers.

This method means that the boiler is kept completely full of treated water. This method is easier to check and the boiler can be put back in service more quickly. This method should not be used if the boiler is subject to freezing temperatures.

4-5.4.1 Wet Layup without Draining (Operational Boilers).

This method is used most commonly when a boiler is to be shut down for 4 to 30 calendar days. Often the boiler must be maintained in a standby condition. Corrosion will most likely occur in the boiler unless both the water level in the steam drum and the chemicals in the boiler are increased. These procedures are recommended for wet layup of a boiler without draining or cleaning:

1. Approximately 4 hours before the boiler is to be shut down, add sufficient sodium hydroxide (caustic) to increase the hydroxyl alkalinity (causticity) to 10 to 20 percent higher than the upper limit given in Tables 4-19 and 4-20 for the pressure of the boiler to be laid up.

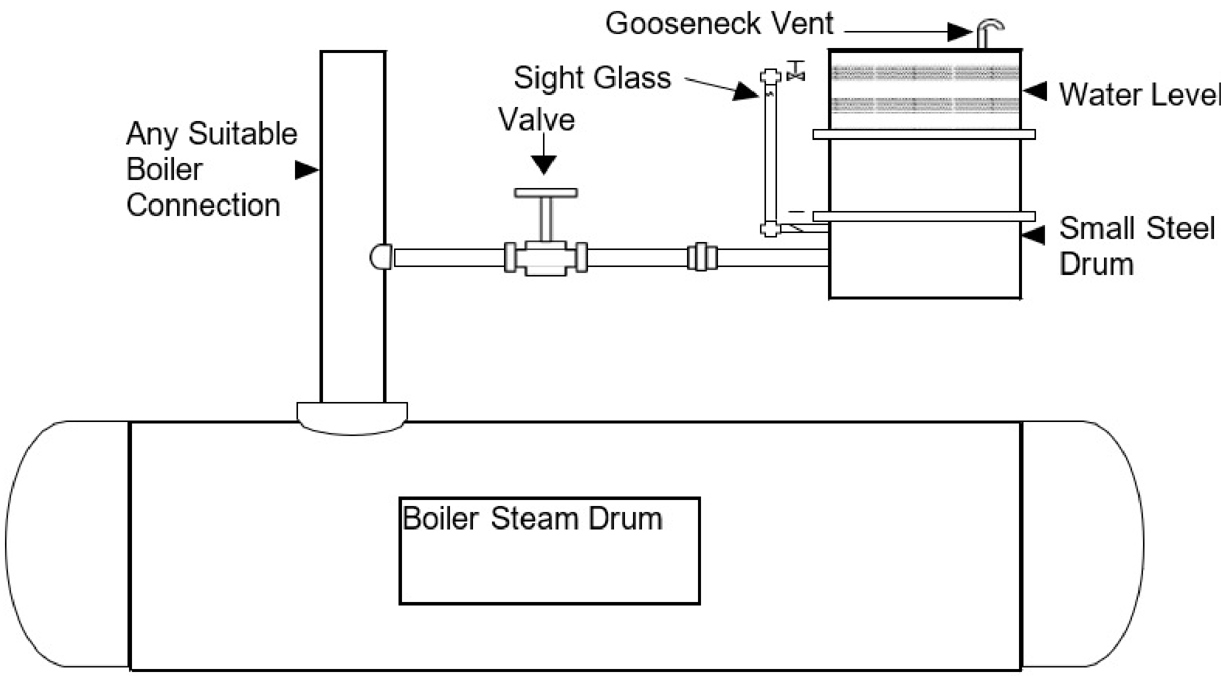
2. Add sufficient sodium sulfite to increase the sulfite residual to 200 ppm (as SO3).
3. Extinguish the fire to the boiler.
4. Add water to completely fill the entire boiler until the water runs out of the vent (safety) valve or air cock.
5. When the boiler is completely cool, add more water to ensure it is full.
6. Maintain a pressure of 5 to 10 pounds per square inch gauge (35 to 69 kilopascals) during layup and maintain the levels of alkalinity and sulfite.
7. Check the boiler frequently to make sure no water has leaked out.
8. Analyze the boiler water at least once per month to make sure the chemical residuals are being maintained.

4-5.4.2 Wet Layup of Drained Boilers.

These procedures are recommended for boilers that have been emptied for cleaning or repair before wet layup:

1. Drain the boiler completely and remove scale or deposits.
2. Remove connections to other active boilers, feedwater, and steam systems.
3. Fill the boiler with water (deaerated water if available) and add enough sodium hydroxide (caustic) to give a hydroxyl level of about 200 ppm (as OH).
4. Add sodium sulfite to give a sulfite residual of 200 ppm (as SO3).
5. Circulate chemicals in the boiler by careful boiling for 2 hours. Be sure to fill the boiler to replace any losses during this treatment.
6. Extinguish the fire to the boiler.
7. Add water to completely fill the entire boiler until the water runs out of the vent (safety) valve or air cock.
8. When the boiler is completely cool, add more water to ensure it is full. Maintain a pressure of 35 to 69 kilopascals during layup and maintain the levels of alkalinity and sulfite.
9. Inspect the boiler weekly and replace any water losses. To facilitate inspections, a small steel tank equipped with a gauge glass can be installed above the top of the boiler, as shown in Figure 4-16. Fill the tank with treated water and connect to a steam takeoff tap, vent, or safety valve connection. A glance at the water level in the small drum will quickly tell whether or not the boiler is completely filled.

Figure 4-16 **Inspection Gauge for Wet Boiler Layup**



4-5.5 Layup of Condensate Systems.

Layup of condensate systems is much more difficult than layup of boilers. As the system cools, oxygen will be drawn in, resulting in a situation that leads to corrosion. Purging the system with dry, inert gas can be effective, but the logistics can be nearly impossible and the hazards include the potential for suffocating people if the system is located in an unvented area. Application of a high dosage of a filming amine prior to shut down can be effective, but its use is restricted for many applications and is prohibited in military operations. Application of a high dosage of neutralizing amines (see paragraph 4-2.7.3) or of a specialty volatile oxygen scavenger (see paragraph 4-2.7.5) can be helpful. The application of any amine or specialty volatile oxygen scavenger can be limited where steam purity or FDA restrictions exist.

4-6 COMMONLY ASKED QUESTIONS AND ANSWERS ON BOILER WATER TREATMENT

Q1. What is meant by neutralized conductivity?

A1. Boiler water most often contains hydroxyl (OH^-) alkalinity. The OH^- contribution to conductivity is disproportionately large compared to other ion species. Furthermore, the OH^- contribution towards conductivity is not used in calculating TDS. The OH^- conductivity is therefore neutralized using an organic acid (gallic acid). Organic acids are used because they do not contribute to conductivity.

Q2. What is the relationship between conductivity and TDS?

A2. Conductivity is a measurement of electrical conductance of ionized species dissolved in water and is reported in units of micromhos or microsiemens per centimeter. TDS is the actual amount of mineral in solution measured in ppm. In boiler water, neutralized conductivity times 0.7 yields a good approximation to TDS. When tannin is used as a dispersant, the factor increases proportionally to the amount of tannin present.

Q3. Why are there different types of alkalinity to be concerned with?

A3. Alkalinity can exist as bicarbonate (HCO_3^-), a carbonate (CO_3^{2-}), or as hydroxyl (OH^-). Natural waters usually contain bicarbonate or carbonate alkalinity. Hydroxyl alkalinity is required in steam boilers below 900 pounds per square inch gauge (6205 kilopascals) and is either provided by addition of caustic or by the breakdown of bicarbonate and carbonate alkalinity in the boiler. The breakdown of bicarbonate and carbonate alkalinity also produces carbon dioxide, which forms carbonic acid in the condensate system.

Q4. How often should bottom blowdown be done?

A4. There is no absolute rule for frequency of bottom blowdown. It can vary between once per shift to once or twice a week. The required frequency depends on the boiler, the feed water quality and the type of chemical treatment program. A precipitating treatment program reacts with hardness in the feed water to form a sludge that must be removed through bottom blowdown. A solubilizing treatment program keeps hardness in solution and creates little in the way of sludge.

Q5. Where is the best location to feed sulfite?

A5. Sulfite, like any oxygen scavenger, should be fed into the storage section of a deaerator. This ensures the removal of oxygen before the feed water enters the boiler.

Q6. What is the difference between makeup water and feed water?

A6. Makeup water is water that comes from a source outside of the boiler system. Feed water is a combination of makeup water and condensate return.

Q7. How does one balance chemical treatment levels and COC?

A7. COC is controlled through blowdown. Blowdown is often measured by maintaining conductivity or TDS within a specific control range. Chemical treatment levels are controlled by the chemical feed rate into the boiler and by blowdown. It is best to maintain consistent control of COC first, followed by proper adjustment of chemical feed rates. If there is a sudden change in chemical treatment levels without any changes in blowdown or chemical feed rates, then there is likely to be a change in feedwater quality (change in condensate return rate, hardness excursion, poor deaerator operation).

Q8. Are boiler water treatment chemicals safe to work with?

A8. Yes, provided the directions on the SDS sheets are followed. The highest hazard is due to chemical burns from highly caustic substances.

Q9. Why is it impossible to get all the parameters (for example alkalinity, TDS) in the control range?

A9. It is not impossible as long as the control ranges are proper for a given boiler operation. The first parameter to control is COC. Maximum cycles are limited by some parameter (such as alkalinity, TDS, silica, carryover). Any one of these can be the limiting factor for COC. Once proper cycles are established, chemical treatment feed rates should be adjusted to keep levels within control ranges.

Q10. The softeners need to be regenerated more often than before. What could be the problem?

A10. The problem could be one of many things. It usually is due to higher demands for makeup water. It could, however, be due to an increase in makeup water hardness levels or a deficiency in regeneration. Deficiencies in regeneration can be due to insufficient brine strength, insufficient brine time, inadequate backwash resulting in channeling, lost or cracked resin, and heavily fouled resin due to iron.

CHAPTER 5 COOLING WATER SYSTEMS

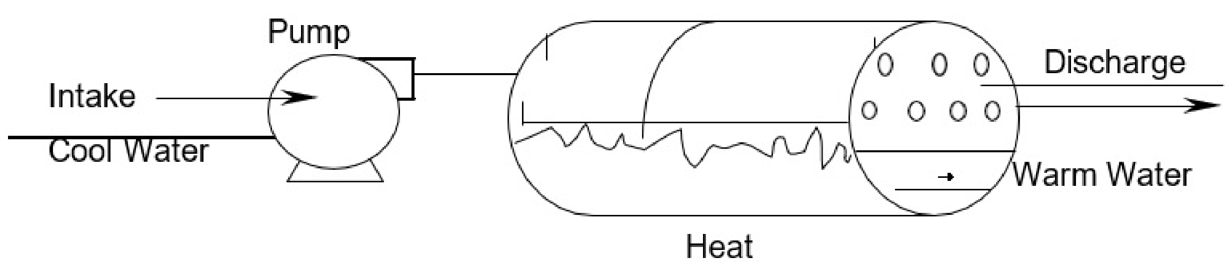
5-1 TYPES OF COOLING WATER SYSTEMS.

Cooling water systems remove heat generated from a variety of industrial processes. There are three basic types of cooling water systems: once-through, open recirculating, and closed recirculating cooling water systems. This Chapter describes once-through and open recirculating systems. Chapter 6 describes the closed recirculating system.

5-1.1 Once-Through Cooling Water Systems.

Once-through cooling water systems use cool water that circulates only once through the entire system before being discharged. This type of system is commonly found along rivers or coastlines where abundant water is available for use. The system contains heat exchange equipment and transfer piping, as shown in Figure 5-1. Power utility services often use this type of system.

Figure 5-1 **Once-Through Cooling Water System Diagram**



5-1.2 Open Recirculating Cooling Water Systems.

Open recirculating cooling water systems are open to the atmosphere and continuously recycle and reuse the cooling water. These systems are composed of an evaporator unit, a cooling tower, or an evaporative condenser. These units mix air and water and allow some of the water to evaporate, cooling the balance of the water volume. The cooled water is then circulated to heat exchangers or chillers, where heat is added to the cooling water thereby removing heat from the process flow stream. The warmed water is then circulated to the cooling tower, where the cycle is repeated. Water is lost from the system primarily through evaporation; however, a portion of the cooling water must be discharged as waste (blowdown) to maintain a suitable water quality within the system. All water lost from the system is replaced by makeup water. Recirculating cooling water systems are found in most air conditioning chiller operations, as well as many heat exchange operations. Evaporative fluid coolers and evaporative condensers are terms defining open recirculating cooling water systems that use evaporators, which are slightly different than a cooling tower and do not send the cooled water out of the evaporative unit itself. An evaporative cooler cools a circulating fluid that does not change phase (does not condense from a gas to a liquid). An evaporative condenser cools a circulating fluid from a gas into a liquid, such as a refrigerant. The hot fluid that is to be cooled is brought to the unit. Figure 5-2 shows a typical evaporative cooler and evaporative condenser diagram; Figure 5-3 shows a typical open recirculating cooling water system; and Figure 5-4 shows a typical cooling tower system.

Figure 5-2 **Evaporative Fluid Cooler and Evaporative Condenser Diagram**

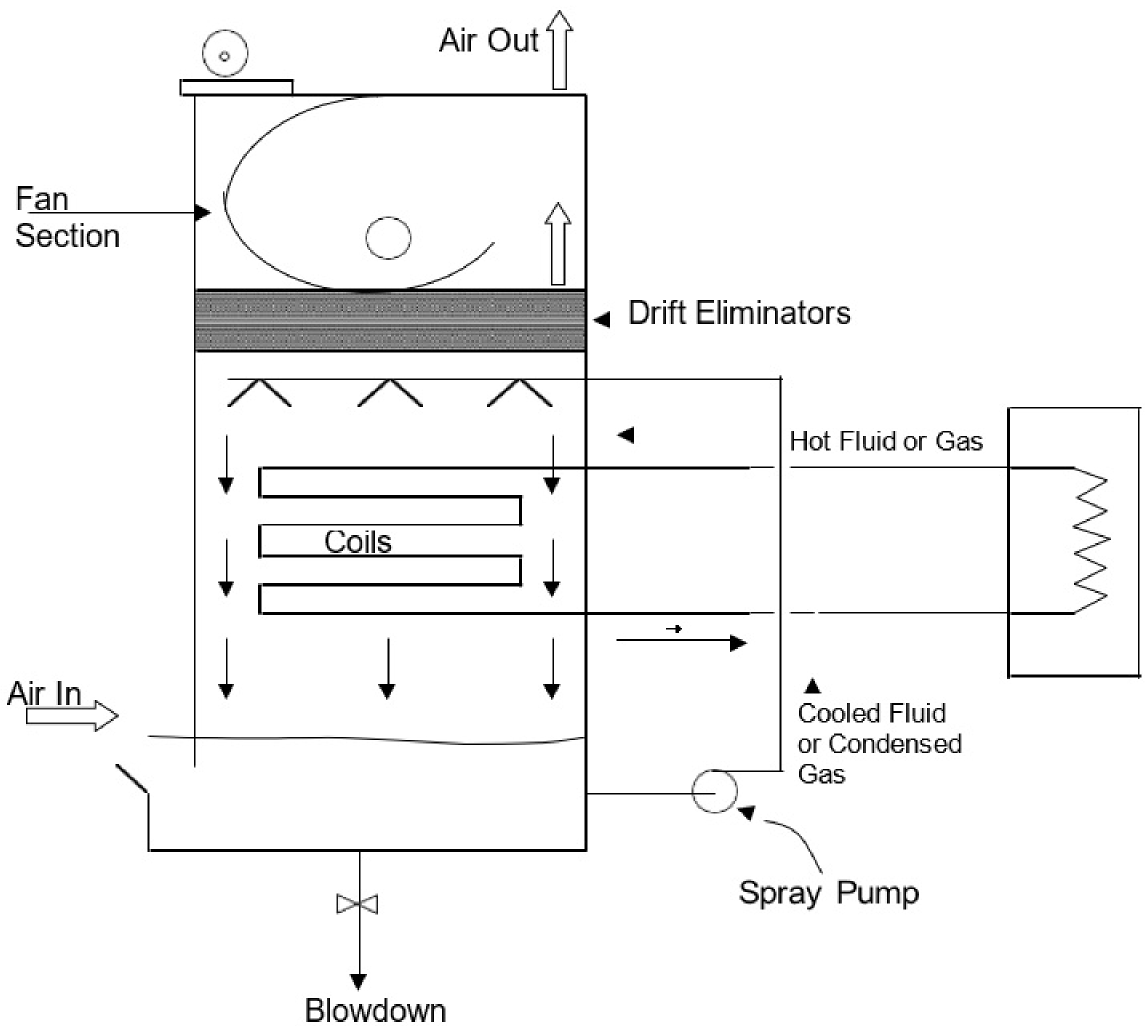


Figure 5-3 **Open Recirculating Cooling Tower Water System Diagram**

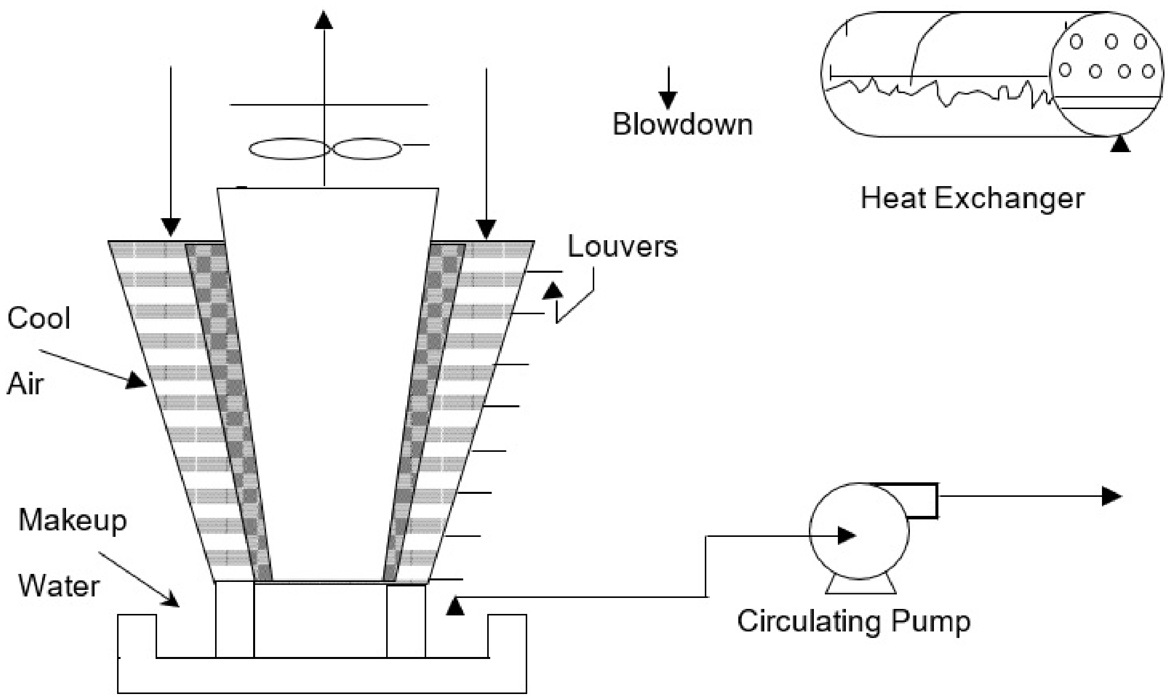

Figure 5-4 **Cooling Tower Water System**

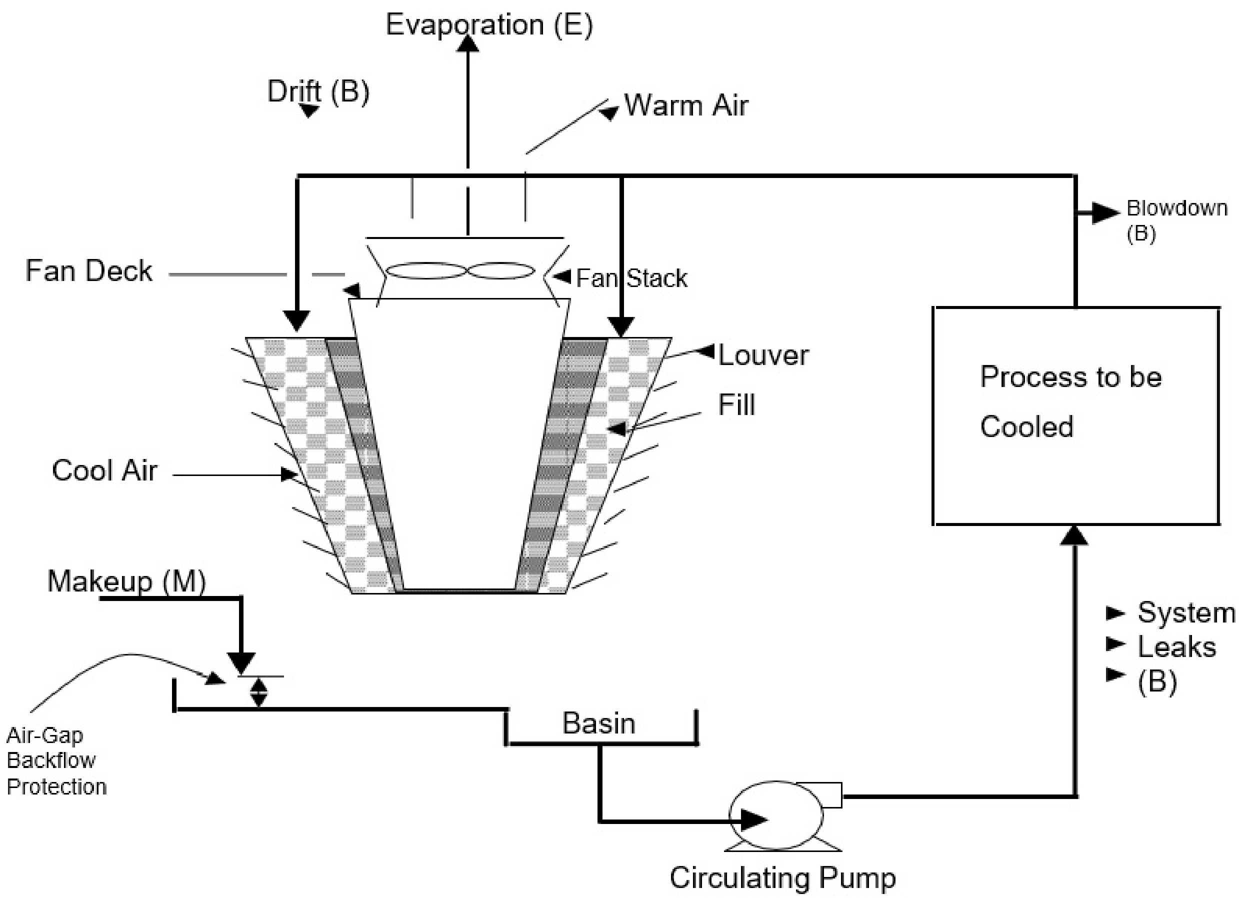

5-1.3 Types of Cooling Towers.

Types of cooling towers include natural draft, induced draft, and forced draft.

5-1.3.1 Natural-Draft Towers.

In natural-draft towers, airflow through the tower is achieved naturally (for example without any mechanical means such as fans). Air flows across the falling water and up through the cooling tower as a result of the differential density between the lighter, heated and humidified, air within the tower and the cooler and dryer outside air. Fitting the tower with spray nozzles, which create more mixing of air and water droplets and improve the evaporation efficiency, produces increased water- cooling rates. Large utility power plants use these large natural-draft cooling towers, which are called hyperbolic cooling towers due to their hyperbolic shape (see Figure 5- 5).

Figure 5-5 **Hyperbolic Natural-Draft Cooling Towers**

5-1.3.2 Forced-Draft Towers.

The term “forced draft” denotes that air is forced or blown by fans into the cooling tower and up through the flow of falling water in the cooling tower. Drift eliminators are installed to prevent water entrained in the air from leaving the system.

5-1.3.3 Induced-Draft Towers.

The term “induced draft” denotes that air is drawn by fans through the flow of falling water and up and out of the cooling tower. The airflow can be drawn either cross-flow or counter-flow with respect to the orientation of the falling water, resulting in either a cross-flow tower or a counter-flow tower. Drift eliminators are also present. (See Figures 5-6, 5-7, 5-8, and 5-9 for diagrams and photos of cross-flow and counter-flow cooling towers.)

Figure 5-6 **Cross-Flow Cooling Tower**

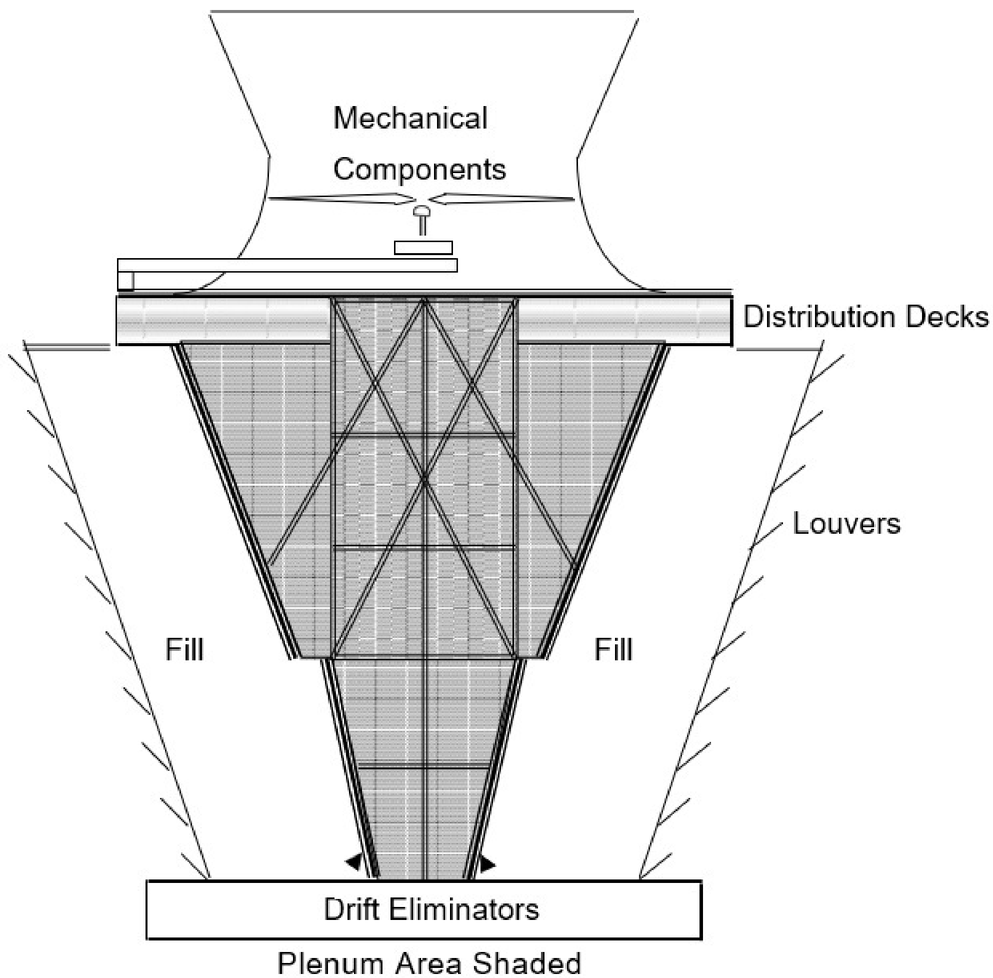

Figure 5-7 **Cross-Flow Cooling Tower**

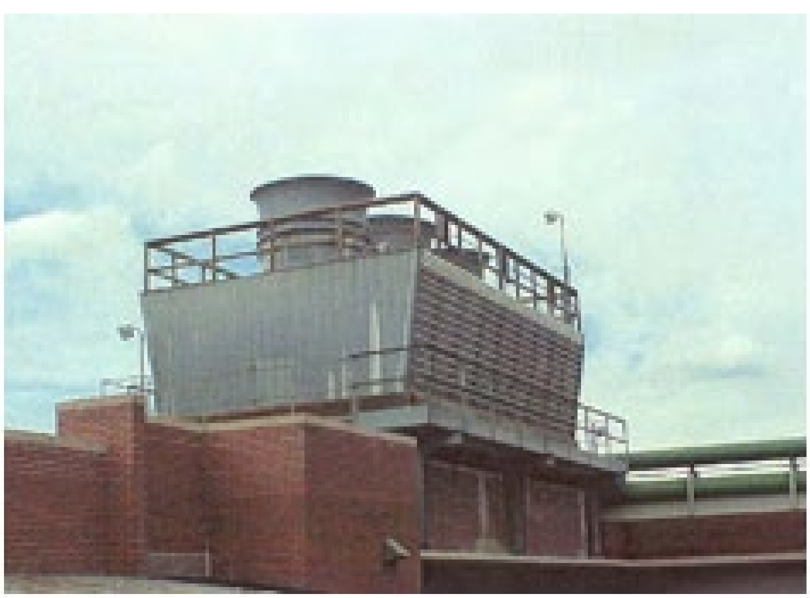

Figure 5-8 **Counter-Flow Cooling Tower Diagram**

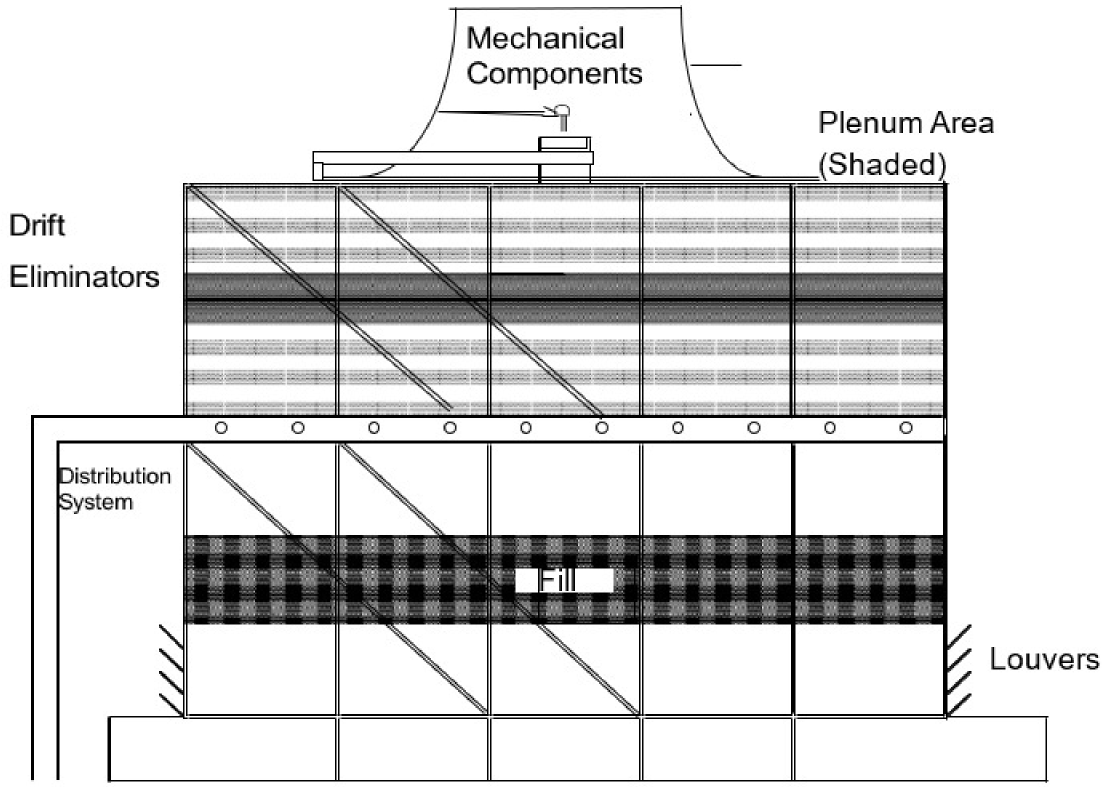

Figure 5-9 **Counter-Flow Cooling Tower**

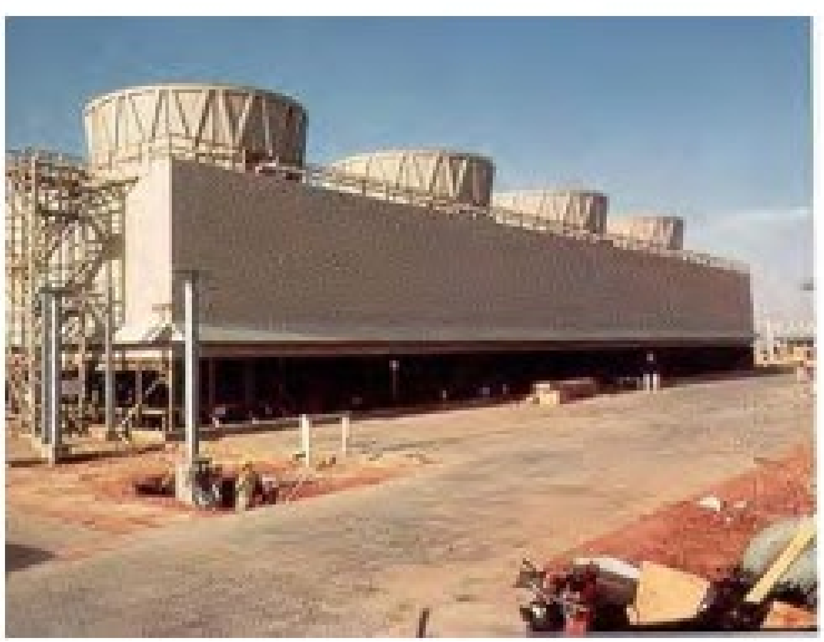


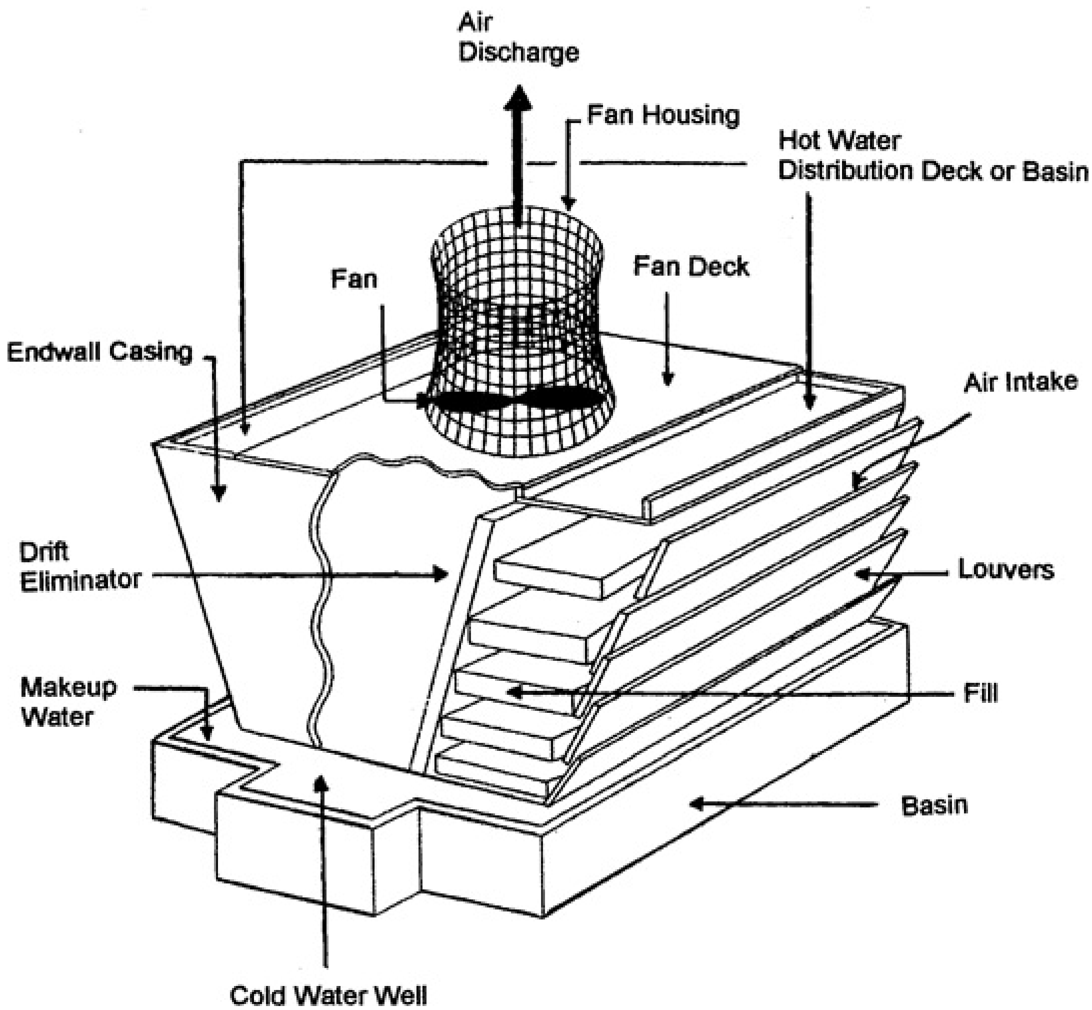
5-1.3.4 Typical Cooling Towers at Government Installations.

Cooling towers at military installations are commonly of the induced-draft, cross-flow variety, although counter-flow and forced-draft cooling towers are also represented. The cooling tower range in size from small to large capacity.

5-1.4 Components of a Cooling Tower.

Figure 5-10 shows a simple diagram of a 1-fan, induced-draft, cross-flow cooling tower. The major parts of the tower include the basin and cold well, louvers, fill, water distribution (and fan) deck, drift eliminators, fan and fan discharge, and the end wall casings.

Figure 5-10 **Induced-Draft Cross-Flow Cooling Tower Components**



5-1.4.1 Basin and Cold Well.

The basin is that portion of the cooling tower structure located under the tower that is used for collecting cooled water and which can be used as a location for adding makeup water. The cold well is a deepened portion of the basin that contains submerged water circulation pumps. The basin may be constructed of concrete, wood, metal, or fiberglass.

5-1.4.2 Louvers.

Louvers are flat or corrugated members constructed of wood, plastic, cement board, or fiberglass, and installed across (horizontally) the open side of a tower. The main function of louvers is to prevent water from splashing out of the cooling tower through the openings where air enters the tower. Louvers are usually set at an angle to the direction of airflow.

5-1.4.3 Fill.

Fill is the internal part of a tower where air and water are mixed. The fill intercepts the downward fall of water. The water is mixed with the air contained in the fill material and water is evaporated and cooled. There are two types of fill: splash fill and film fill. The falling water hits the splash fill, splashes, and breaks up into smaller water droplets, resulting in an increased rate of evaporation. The splash fill is made of wooden slats or bars, plastic, or ceramic tile. Film fill is a compact plastic material, similar to a honeycomb that causes water to flow over the fill material, creating a large wet surface that maximizes evaporation as air travels past the film surface (see Figure 5-11).

Figure 5-11 **High-Efficiency Cooling Tower Film Fill**

5-1.4.4 Drift Eliminators.

The drift eliminators efficiently remove water droplets from the air and return the recovered water to the cooling tower, thereby minimizing the loss of cooling tower water. They are located in areas that are situated after the fill and water sprays and just before the area where the air exits the cooling tower (see Figures 5-6 and 5-8). Drift eliminators are also known as “mist eliminators.”

5-1.4.5 Water Distribution and Fan Deck.

In a cross-flow cooling tower, the hot water basin is used to distribute the warm return water flow uniformly over the tower fill (see Figure 5-6). In a counter-flow cooling tower, water sprays are used to distribute the warm water (see Figure 5-8). The fan deck supports the motor and fan of the water spray system. The stack is the structure (typically a cylinder) that encloses the fan and directs warm, humid discharge air upward and out of the cooling tower.

5-1.4.6 Cell.

This is the smallest subdivision of a large cooling tower in which the fan can operate as an independent unit. A mid-wall casing must separate each end of the cell from the adjacent cells to ensure all air flow induced by the cell fan is drawn only through the cell fill and mist eliminator air path. Figure 5-7 illustrates a typical three-cell cross-flow cooling tower. Figure 5-9 illustrates a typical four-cell counter-flow cooling tower.

5-1.5 Common Cooling Water System Problems.

Water-related problems can cause system downtime, loss of equipment efficiency, the need for capital replacement of equipment, and can increase the risk of disease from pathogenic microorganisms. An open recirculating cooling tower system has a greater potential for these problems than does a once-through cooling water system, due to the air- and water-mixing design of the open recirculating system. These problems are associated with water-caused deposits, corrosion, or microbiological organisms, and occur for various reasons:

- The cooling tower is essentially a huge air scrubber that can introduce materials such as microorganisms, gases, dust, and dirt into the circulating water, which provides an excellent growth environment for pathogenic microorganisms. These materials can contribute to the formation of deposits and cause corrosion.
- If the water is not properly treated and its quality maintained, corrosion and scale and solids deposition can occur. The potential for these problems results from the nature of the cooling system design and the operating conditions, including water evaporation, mineral concentration, and water temperatures of up to 130° F (54° C).
- The constant addition of makeup water results in increased quantities of mineral constituents that can form scale, deposits, and corrosion.

Blowdown control and proper water treatment can minimize these problems.

- The film fill contains small water and air passages that can become plugged, thereby causing a reduction in cooling tower operational efficiency due to reduced water evaporation (see paragraph 5-1.4.3).
- Current designs for heat exchangers and cooling towers provide for more efficient operation than in the past, but unexpected water problems may occur. Some of the more prevalent potential problems are described in paragraphs 5-1.5.1 through 5-1.5.4.

5-1.5.1 Enhanced and Super-Enhanced Chiller Condenser Tubing.

Recent air conditioning chiller equipment designs incorporate enhanced and super-enhanced chiller condenser tubes. Previous designs have used smooth-bored waterside condenser tubing. The enhanced tube is machined with rifled grooves that provide an increased surface area and a resultant increase in heat transfer; however, the rifled grooves and ridges tend to entrap SS (such as dirt, silt, sand, and old corrosion products), which are deposited from the cooling water as it passes through the tube. This deposition of material on metal surfaces can create a type of localized corrosion called “under-deposit corrosion.” This situation has resulted in numerous cases of tube failure. The super-enhanced chiller tubes have even finer grooves and ridges, making this type of tubing even more susceptible to under-deposit corrosion. (See Figures 5-12 and 5- 13, which show photos of super-enhanced copper tubes.)

Figure 5-12 **Close-Up of Corrosion Pitting on Super-Enhanced Copper Tube**

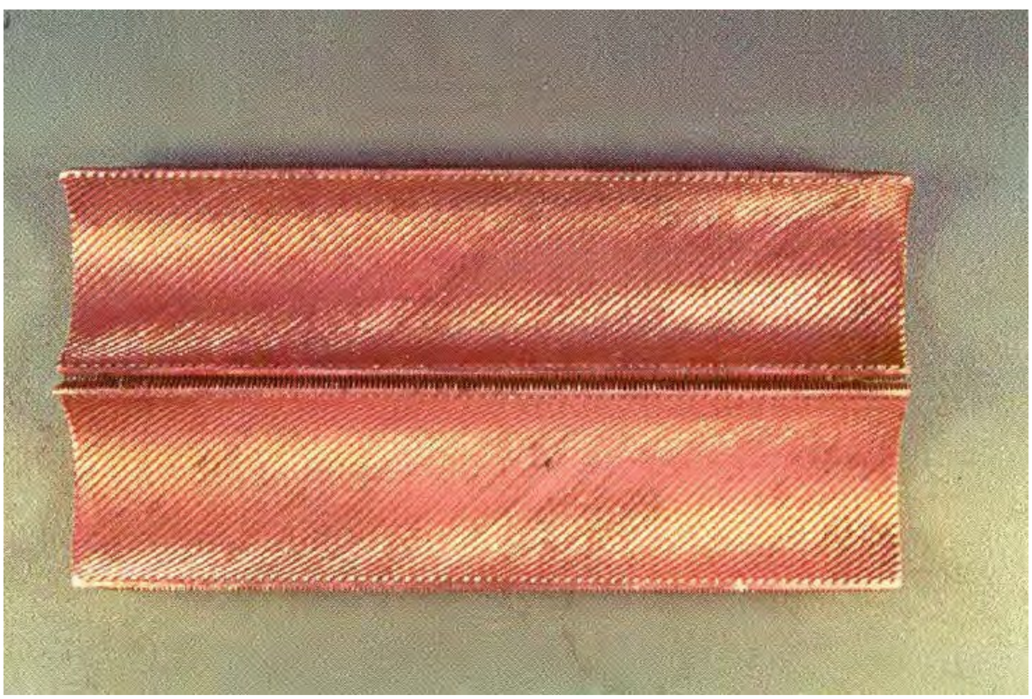


Figure 5-13 **Close-Up of Corrosion Pitting on Super-Enhanced Copper Tube**

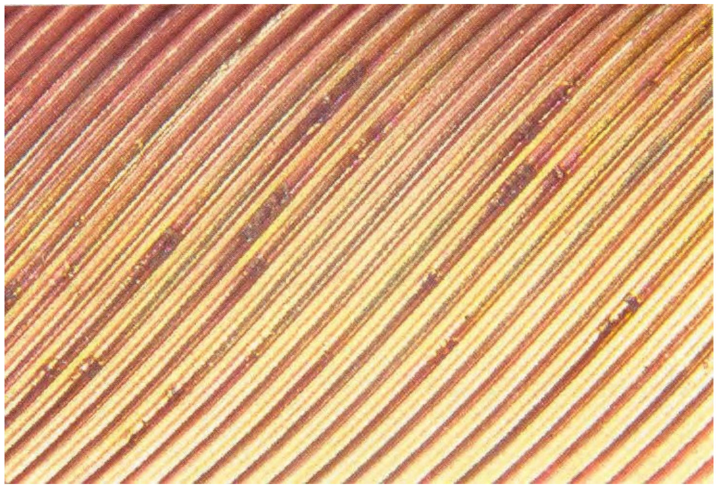


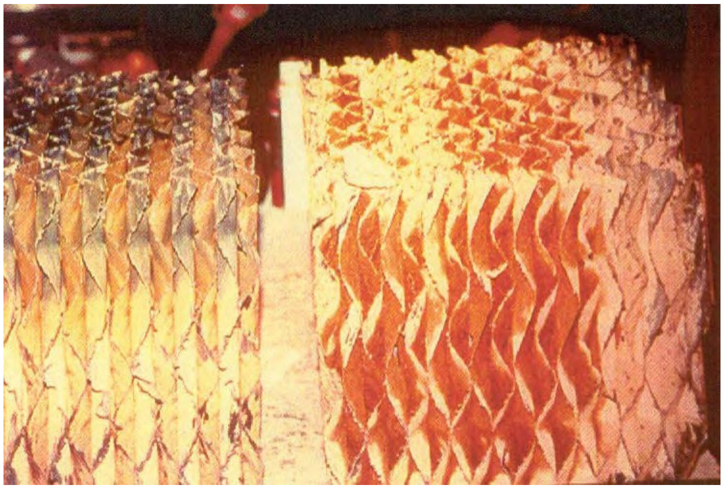
5-1.5.2 White Rust.

Some cooling towers are constructed with galvanized steel components and must not be exposed to conditions of high pH (high alkalinity). The galvanizing process deposits a protective zinc coating on a mild steel metal surface, resulting in increased resistance to corrosion. Failure to avoid such exposure can result in production of “white rust” due to the corrosion of the galvanizing coating. Eventually, this corrosion process exposes the mild steel underneath, which then starts to corrode. White rust failures have been a common occurrence throughout the country, mainly with newer cooling towers. Proper protection of the galvanizing material is necessary both during startup of a new cooling tower and during normal operations. Specific water treatment chemicals are needed to provide this protection. Examples include pretreatment with a high level of orthophosphate.

5-1.5.3 Cooling Tower Film Fill.

Small- and medium-sized cooling towers use film fill, which is a tightly packed media as compared to the splash-type fill used prevalently in the past (see paragraph 5-1.4.3 and Figure 5-11). Film fill has a higher potential for fouling (plugging) due to adherence and entrapment of biomass and of SS (such as dirt, silt, and sand). The cooling capacity of a cooling tower can be reduced if the film fill is extensively fouled (see Figure 5-14). Instances of severe fouling have resulted in the collapse of fill into the cooling tower basin. In addition, fouling deposits in the fill can harbor pathogenic microbiological organisms such as Legionnaires’ disease.

Figure 5-14 **Heavily Fouled Cooling Tower Film Fill**



5-1.5.4 Legionella Bacteria.

This type of bacteria is the cause of Legionnaires' disease. It can grow in cooling water systems even when a proper microbiological control program has been maintained. This bacterium can be discharged in the drift produced from all types of cooling tower systems. If a susceptible person inhales the bacteria, the disease could possibly develop. A number of outbreaks of Legionnaires' disease are reported throughout the country. See paragraph 5-4.7 for information on controlling Legionella.

5-2 COOLING TOWER WATER CALCULATIONS

5-2.1 Principles of Cooling Tower System Operations.

The function of a cooling tower is to dissipate heat from water-cooled refrigeration, air-conditioning and industrial process systems. Water is typically the heat transfer medium used to dissipate the heat. A cooling tower uses a combination of heat and mass transfer (evaporation) to cool the water flowing through the tower. Conductive heat transfer accounts for 20 to 30 percent of the total heat dissipated. The remaining 70 to 80 percent of total cooling is the result of evaporative cooling of about 1 to 2 percent of the recirculating water, depending on the decrease in temperature across the tower. It takes approximately 2,326,000 joules to evaporate 1000 BTU per 1 pound of water (1 kilogram of water). If this amount of heat is extracted from 1000 pounds (454 kilograms) of water, approximately 1 pound (0.45 kilogram) of water will be evaporated and the temperature will drop 1˚ F (0.55˚ C). If 10 pounds (4.5 kilograms) of water are evaporated, the water temperature will drop 10˚ F (5.5˚ C). The water lost by evaporation is replaced with makeup water. Water is also added to replace water lost through tower drift (loss of water from the tower as a fine mist), leaks in the system (unintentional blowdown), and water discharged as intentional blowdown. Water that is added to the cooling tower to replace all of these losses is known as cooling tower makeup water.

5-2.1.1 Relationship between Evaporation, Blowdown, and Makeup.

The operation of cooling towers can be described by the relationship between evaporation, blowdown, and makeup. Makeup water must equal blowdown water plus water evaporation to maintain a constant operating water level in the system:

Equation 5-1. Operation of Cooling Towers

$$M = B + E$$

Where:

M = makeup water, gpm (liters/sec)

B = blowdown, gpm (liters/sec) (all sources)

E = evaporation, gpm (liters/sec)

NOTE: Blowdown (B) includes discharge to sewer, drift loss, and any leaks from the system.

EXAMPLE:

M = 100 gpm (6.3 liters/sec)

B = 10 gpm (0.63 liters/sec)

E = 90 gpm (5.67 liters/sec)

5-2.1.2 Cycles of Concentration (COC).

One of the common terms used in describing the water use efficiency of cooling tower water systems is COC. COC represents the relationship between the makeup water quantity and blowdown quantity. COC is a measure of the total amount of minerals that is concentrated in the cooling tower water relative to the amount of minerals in the makeup water or to the volume of each type of water. The higher the COC, the greater the water use efficiency. Most cooling tower systems operate with a COC of 3 to 10, where 3 represents acceptable efficiency and 10 represents very good efficiency. It has been found that the range of 5 to 7 COC represents the most cost-effective situation.

5-2.1.2.1 Calculating COC by Volume.

If both makeup and blowdown water volumes are known, COC by volume can be calculated. The term is defined as:

Equation 5-2. COC by Volume

$$C = M \div B$$

Where:

C = COC, no units

M = makeup water, gpm (kg/hr)

B = blowdown losses, gpm (kg/hr)

EXAMPLE:

M = 100 gpm (6.3 liters/sec)

B = 10 gpm (0.63 liters/sec) C = M ÷ B = 10

5-2.1.2.2 Determining COC by Water Analyses.

To determine COC, you must know the mineral content of both makeup and blowdown water. For example, you must determine both the conductivity of the recirculating cooling tower water and the conductivity of the makeup water. (Note that the blowdown water will have the same conductivity as the recirculating water.) Conductivity is commonly measured in micromhos (μmhos). You can also estimate COC by using other water quality parameters such as chlorides, silica, or sulfates. The relationship is represented by this equation:

Equation 5-3. Determining COC by Water Analyses

$$c = \frac{\mathrm{B\mu mhos}}{\mathrm{M\mu mhos}} \; or \; \frac{\mathrm{B_{Cs}}}{\mathrm{M_C}}$$

Where:

C = COC, no units

Bμmhos = conductivity of blowdown (recirculating water), microμmhos (μmhos)

Mμmhos = conductivity of makeup water, μmhos Cl = chlorides in blowdown, ppm

Cl = chlorides in makeup water, ppm

EXAMPLE:

The measured conductivity of the blowdown (recirculating water) is 800 micromhos and the makeup is 300 micromhos.

The COC is:

$$c = \frac{\mu\text{mhos}}{\mu\text{mhos}}$$

$$\mathrm{C} = 800 \div 300 = 2.67$$

NOTE: The parameters of conductivity or chloride concentration are used commonly for such measurements. Other water quality parameters can be used, but sometimes with inaccurate results (calcium, magnesium, alkalinity, and silica can form deposits, meaning they drop out of solution). COC based on these parameters could be considerably less than that based on conductivity or chlorides. Similarly, chemical additions of sulfuric acid can yield higher sulfate levels than those species cycled up naturally.

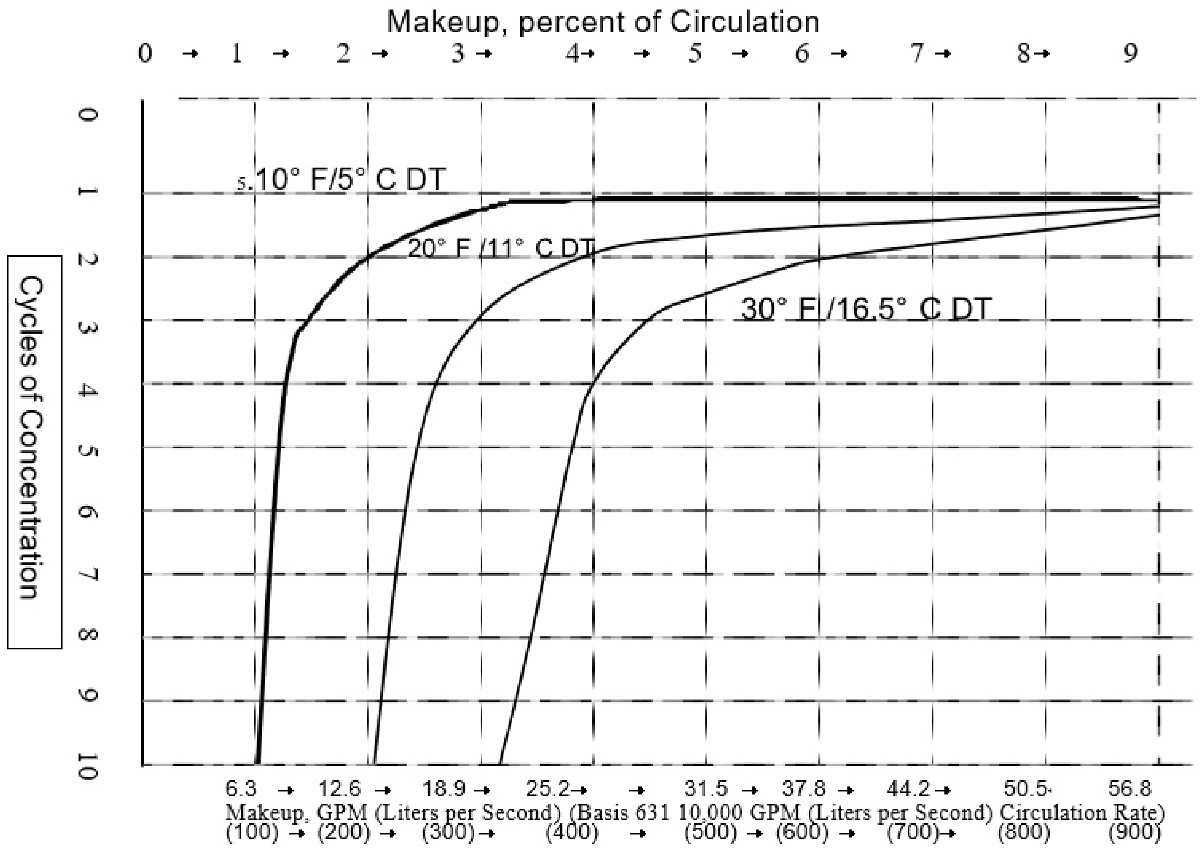
5-2.1.2.3 Controlling COC.

A simple, sometimes overlooked rule: To increase COC, decrease blowdown; to decrease COC, increase blowdown.

5-2.1.2.4 Relationship between COC and Makeup.

COC and makeup requirements are related to the temperature drop across a cooling tower and to the recirculating rate of the tower. As shown in Figure 5-15, for a recirculating tower with water temperature drops of 10° F (5.5° C), 20° F (11° C), and 30° F (16.5° C), the makeup water requirement decreases rapidly as COC is increased to about 4 or 5, with lower incremental reductions at higher COC; therefore, COC can be adjusted (increased) to allow for reductions in water use (water conservation) and for reductions in the amount of water treatment chemicals used.

Figure 5-15 **Effect of COC on Makeup Requirement**



5-2.1.3 Relationship between Blowdown, Evaporation, and COC.

You can use the cooling water evaporation loss to calculate the blowdown rate that must be maintained to operate at a selected COC. The relationship between blowdown, evaporation, and COC is represented with this equation:

Equation 5-4. **Relationship Between Blowdown, Evaporation, and COC**

$$\mathbf{B} = \mathbf{E} \div (\mathbf{C} - \mathbf{1})$$

Where:

B = blowdown, liters per day or liters per second (gpd or gpm)

E = evaporation, liters per day or liters per second (gpd or gpm)

C = COC, no units

EXAMPLE: A cooling tower evaporates 600 gallons per minute (37.8 liters per second) and operates at 4 COC:

$$\mathbf{B} = \mathbf{37.8\ l/sec\ (600\ gpm)} \div (\mathbf{4} - \mathbf{1}) = \mathbf{12.6\ l/sec\ (200\ gpm)}$$

a. This formula is derived using data from previously presented equations:

1. $M = B + E$ from paragraph 4-2.1.1
2. $C = M \div B$ from paragraph 4-2.1.2.1
3. $C = (B + E) \div B$ from equation (2) and (1) above
4. $C = 1 + (E \div B)$ rearranging equation
5. $(C - 1) = E \div B$ rearranging equation
6. $B = E \div (C - 1)$ rearranging equation

b. If you know the quantity of evaporation, you can calculate the blowdown required for a given value of COC. You can estimate the evaporation using simple "rule of thumb" estimates:

c. For a typical recirculating cooling tower water system, approximately 1 percent of the recirculating rate (R) of the cooling water is evaporated for every 10 F (5.5 C) temperature drop in the cooling water as it passes through the tower; therefore, you may calculate the evaporation rate (E) this way:

$$\mathbf{E(l/sec) = 0.01\ x\ R(l/sec)\ x\ \Delta T\ drop\ in}\ ℃ \div \mathbf{5.5}\ ℃$$

Since 0.01 ÷ 5.5 = 0.0018, this can be condensed to:

$$\mathbf{E = R\ x\ \Delta T\ x\ 0.0018}$$

or

$$\mathbf{E = R\ x\ \Delta T \div 550}$$

NOTE: Newer cooling towers can have 0.75 percent of the recirculation rate evaporated for every 10 F (5.5 C) drop.

EXAMPLE 4-2:

A cooling system operates at 5000 gallons per minute (315 liters per second). The temperature drop through the tower is 14 F (7.8 C). The evaporation estimate is represented by this equation:

$$\mathbf{E = 0.01\ x\ 315\frac{l}{sec}(5000\ gpm)x\ 14\ \ F(7.8\ \ C) \div 10\ \ F(5.5\ \ C) = 4.5\ l/sec\ (70\ gpm)}$$

or

$$\mathbf{E = 315\ x\ 7.8 \div 550 = 4.5\ l/sec\ (70\ gpm)}$$

d. For a cooling tower system serving air conditioner and chiller operations, the evaporation rate used depends on the type of chiller:

- Approximately 1.5 gallons per hour per ton (20 liters per hour per kilowatt) for centrifugal, reciprocating, and screw-type chillers.
- Approximately 3 gallons per hour per ton (40 liters per hour per kilowatt) for absorption-type chillers.

5-3 OBJECTIVES OF COOLING WATER TREATMENT.

The primary objectives of cooling water treatment are to maintain the operating efficiency of the cooling water system and to protect the equipment that contacts the cooling water. These objectives are accomplished by controlling or minimizing deposition, corrosion, and microbiological growth on the cooling water equipment. Treatment programs must also address requirements for environmental compliance, safety, water conservation, and limitation of chemical costs. This paragraph reviews the requirements for, and elements of, a water treatment program for cooling water systems.

5-3.1 Deposit Formation and Control.

Deposits that occur in cooling water systems are usually divided into two categories: scale and fouling. The presence of either type of deposit in the heat exchangers or in the film fill can interfere with heat transfer, thereby reducing the efficiency of operation. Deposits can also promote under- deposit corrosion. Scale and non-biological fouling are described in this paragraph. Biological fouling is described in paragraph 5-4.

5-3.2 Scale.

Scale is formed from minerals, formerly dissolved in water, that were deposited from the water onto heat transfer surfaces or in-flow water lines. As water is evaporated in a cooling tower, the concentration of dissolved solids becomes greater until the solubility of a particular scale-causing mineral salt is exceeded. When this situation occurs in an untreated cooling water system, the scale will form on any surface in contact with the water, especially on heat transfer surfaces. The most common scaling minerals are calcium carbonate, calcium phosphate, calcium sulfate, and silica, usually in that order. Formation of magnesium silicate scale is also possible under certain conditions. Most other salts, including silica, are more soluble in hot water than in cold water; however, most calcium and magnesium salts, including calcium phosphate and calcium carbonate, are more soluble in cold water than in hot water. This is called “reverse solubility.” The water temperature will increase as recirculating water passes through the cooling system. As a result, calcium and magnesium scales may form anywhere in the system, but most likely on heated surfaces such as heat exchangers or surface condensers. Silica will form in areas having the lowest water temperature, such as in the cooling tower fill.

5-3.2.1 Determining Scaling Potential.

The maximum solubility limit for specific dissolved minerals will determine the types of scale that can form under a given set of conditions. To minimize water blowdown, the amount of dissolved materials in the cooling water should be maintained as close as possible to the maximum solubility level. This water quality parameter, TDS, is controlled by maintaining COC in the system at a level that is equal to the lowest COC allowable for whichever salt has the lowest solubility. The salt of concern is often calcium carbonate or calcium phosphate, but it may be silica. The operating COC can be increased substantially with use of the cooling water treatment chemicals described in this paragraph.

5-3.2.2 Calcium Carbonate Scale.

Calcium carbonate scale results from the breakdown of calcium bicarbonate, a naturally occurring salt. The degree of scaling depends primarily on the calcium levels, bicarbonate alkalinity levels, and water temperature in the cooling water system. The most accurate prediction of scale can be developed using the Practical (Puckorius) Scaling Index (PSI) (see paragraph 5-3.4.2). A rough prediction of calcium carbonate scale potential can be developed using this formula:

Equation 5-5. Prediction of Calcium Carbonate Scale Potential

$$C = \sqrt{\frac{110000}{TA \ x \ M_{ca}}}$$

Where:

C = COC

TA = total (M) alkalinity (as $CaCO_3$) in makeup, ppm

M_{Ca} = calcium hardness (as $CaCO_3$) in makeup, ppm

5-3.2.3 Calcium Phosphate Scale.

Calcium phosphate scale results when calcium hardness reacts with phosphate. This will occur when more than 10 ppm of orthophosphate are present in the circulating water and when the calcium hardness is sufficiently high. The following formula can provide a very rough prediction of the potential for calcium phosphate scale:

Equation 5-6. Potential for Calcium Phosphate Scale

$$C = \frac{(105) \ x \ (9.8 - B_{pH})}{M_{ca}}$$

Where:

C = COC, no units

BpH = measured pH in blowdown, pH units

MCa = calcium hardness (as CaCO3) in makeup water, ppm

5-3.2.4 Calcium Sulfate Scale.

Calcium sulfate scale results when the calcium hardness reacts with the sulfate. The potential for calcium sulfate scale can be predicted using this formula:

Equation 5-7. Potential for Calcium Sulfate Scale

$$c = \sqrt{\frac{125000}{M_{ca} \, x \, M_{su}}}$$

Where:

C = COC, no units

M_{Ca} = calcium hardness (as $CaCO_3$) in makeup, ppm

M_{Su} = sulfate (as SO_4) in makeup, ppm

5-3.2.5 Silica Scale.

Silica scale can occur when the concentration of silica exceeds its maximum solubility limit in water. A safe, very conservative value to assume for the solubility limit is 150 ppm (as SiO_2); thus, the maximum COC can be calculated with this formula. However, silica solubility depends on pH and temperature and is in the range of approximately 150 to 180 ppm (as SiO_2) at the temperature range encountered in most cooling towers 80° F to 130° F (26° C to 54° C). As the pH increases in the cooling tower water, silica becomes more soluble; thus, if cooling tower water pH is 9.0, approximately 250 ppm silica (as SiO_2) is the maximum. Using 150 ppm as the upper limit, the allowable COC is represented by this equation:

Equation 5-8. Allowable COC

$$c = \frac{150}{M_{si}}$$

Where:

C = COC, no units

150 = assumed maximum solubility of silica, ppm

M_{Si} = silica (as SiO_2) in the makeup, ppm

5-3.3 Determining COC to Control Operations.

In cooling water systems, the lowest calculated COC allowable, as determined by the relationships for these salts, is the controlling factor for operations. This is because as the system operates, the material that has the lowest calculated COC will be the first to come out of solution (precipitate) and the most likely to form a scale deposit in the system. To prevent these materials from forming a deposit on cooling water equipment, you must keep the COC in the system at a level that is lower than the lowest COC calculated for calcium carbonate, calcium phosphate, calcium sulfate, and silica. Using appropriate water treatment chemicals will allow higher COC, depending on which chemical is used.

EXAMPLE 5-3:

a. A cooling tower makeup has the following composition:

Calcium hardness	100	ppm as $CaCO_3$
Total (M) alkalinity	60	ppm as $CaCO_3$
Phosphate	3	ppm as PO_4
Sulfate	60	ppm as SO_4
Silica	14	ppm as SiO_2
pH	7.2	

At what COC can the system operate scale free without water treatment? (Assume that the estimated pH in the blowdown water is 8.5.)

b. Based on calcium carbonate:

$$\boldsymbol{c = \sqrt{\frac{110000}{60 \times 100}} = 4.3}$$

c. Based on calcium sulfate:

$$\boldsymbol{c = \sqrt{\frac{125000}{100 \times 60}} = 14.4}$$

d. Based on silica:

$$\boldsymbol{coc = 150 \div 14 = 10.7}$$

The COC determined for calcium carbonate is lowest at 4.3, and this controls the system operation. If the system is operated without water treatment, scaling should not occur if the system is operated at less than 4.3 COC. Use of scale control treatment will allow the number of allowable COC (for calcium carbonate) to be increased; you can then determine the COC and blowdown by using a calculated scaling index.

5-3.4 Calcium Carbonate Scaling Indices.

The scale found most commonly in cooling tower water systems is calcium carbonate, present in the form of calcite ($CaCO_3$) (for example limestone). The solubility of calcium carbonate, which decreases with an increase in temperature, is a complex function of temperature, TDS, calcium hardness, total alkalinity, and pH. To predict if scale would form in the hotter sections of a cooling water system, researchers have developed several scaling indices. Paragraphs 5-3.4.1 and 5-3.4.2 describe the predictive indexes that are used most commonly for cooling water.

5-3.4.1 Langelier and Ryznar Indices.

W.F. Langelier derived a method to calculate the calcium carbonate scale-forming and scale-dissolving tendencies of drinking water. The method is based on determining the saturation pH (pH_s) at which calcium carbonate scale will start to precipitate out of solution. If the measured pH (pH_{actual}) of the water is greater than its pH_s, thus a positive value, the water has a scale-forming tendency. If the measured pH (pH_{actual}) of the water is less than its pH_s, thus a negative value, the water will have a scale-dissolving tendency. The pH_{actual} minus pH_s is known as the Langelier Index or Langelier Saturation Index (LSI) ($LSI = pH_{actual} – pH_s$). This index was originally designed to predict calcium carbonate scale in potable water. There are serious deficiencies in the accuracy of this index; consequently, it has lost its practical application for cooling water systems.

J.W. Ryznar later devised a more sensitive formula for predicting calcium carbonate scale. This formula is known as the Ryznar Index or Ryznar Stability Index (RSI). The formula is: $2pH_s – pH_{actual}$. A value of 6 indicates “stable” water, a value less than 6 indicates a scale-forming tendency, and a value greater than 6 indicates a scale-dissolving tendency. The indices have also been used to try to estimate the degree to which calcium carbonate scale will form in drinking water and in cooling water. The more positive the LSI value, the greater the scale formation; however, for the RSI, the smaller the index, the greater the scale formation. The LSI and RSI can give conflicting predictions based on the same water quality information.

5-3.4.2 Practical (Puckorius) Scaling Index (PSI).

Paul R. Puckorius and J. Maxey Brooke developed a modified version of the RSI that gives a more accurate and consistent indication of the calcium carbonate scaling potential of cooling water. Known as the Practical Scaling Index (PSI), and also known as the Puckorius Scaling Index, it takes into consideration the effect of the type of total alkalinity of the cooling water on the measured pH (pHactual) value. The measured pH does not always relate correctly to bicarbonate alkalinity because of the buffering effect of other ions. Rather than using the measured pH in calculating the PSI, an adjusted or equilibrium pH (pHeq) is used: PSI = 2pHs - pHeq. As with the RSI, a PSI value of 6 indicates stable water and a value lower than 6 indicates a scale-forming tendency. Without scale-control treatment, a cooling tower with a PSI of 6 to 7 should operate scale free. However, a PSI of greater than 6 indicates that scaling may occur. Information on calculating the PSI is provided in Appendix B. Use of the PSI is most applicable when cooling water pH is above 7.5.

5-3.5 Scale-Control Methods.

Three basic methods are used to prevent the formation of scale in cooling water systems:

a. Remove the water scaling ingredients from the water before use. This includes softening, RO, and other technologies described in Chapter 3.

b. Keep the scale-forming ingredients in solution. This is the most common scale-control method used for cooling water, and it can be achieved by use of either or both of the following two methods: adding acid, which lowers the pH of the recirculating water, or adding a scale inhibitor (phosphonate or specific polymer), which allows higher COC to be maintained without scaling. Acid neutralizes (destroys) mineral alkalinity, one of the constituents forming calcium carbonate scale; however, because of the hazards associated with handling strong acids and the potential damage from an acid spill, the use of acid in cooling towers is not recommended.

c. Allow the water-scaling ingredient to precipitate as sludge. Modern chemical treatment can distort or modify scale crystals such that they cannot adhere to each other to form a hard deposit; instead, they become a sludge that can be removed through filtration or blowdown. All three methods are authorized for use on military installations and can be used in combination with one another.

5-3.5.1 Calcium Carbonate Scale Control Using Solubilizing Chemicals.

Acids and phosphonates are chemicals that keep scale from forming. The use of acid in cooling towers may not be appropriate for use at military installations due to the associated risk of corrosion.

5-3.5.1.1 Acids.

The acid most commonly used is sulfuric acid used as a diluted solution (40 percent sulfuric acid in water). The use of acids requires adequate pH control.

5-3.5.1.2 Phosphonates.

The phosphonates used most frequently for calcium carbonate scale control in recirculating cooling water systems are AMP (amino-tri [methylene] phosphonic acid); HEDP (1-hydroxyethylidene 1,1-diphosphonic acid); and PBTC (2-phosphonobutane-1,2,4-tricarboxylic acid).

The chemical reaction of all phosphonates is similar; however, their stability varies greatly. The presence of chlorine or other oxidants in treated cooling water favors the use of PBTC, which is very resistant to decomposition, followed by HEDP, and finally AMP. An active dosage of 3 to 5 ppm of either AMP or HEDP, or 1.5 to 2.5 ppm PBTC, will increase the solubility of calcium carbonate by a factor of 3 or more relative to using no chemical treatment. Rather than operating at a PSI of 6.0 (stable water, no scale) in an untreated system, the cooling tower water can be used at a PSI of 4.0 without the occurrence of scale (see paragraph 5-3.4.2 and Appendix A); however, in the absence of calcium scaling conditions, phosphonates can increase the corrosion of both mild steel and copper.

5-3.5.2 Calcium Carbonate Scale Control Using Solubilizing Polymers.

Many different polymers are used in water treatment. For the most part, they have multi-faceted performance capability; they can inhibit various types of scale formation as well as disperse SS. Often water treatment products will include more than one type of polymer in the product formulation. For control of calcium carbonate, homopolymers such as polyacrylate, polymethacrylate, and polymaleate are used to keep calcium carbonate in solution. Dosages of 3 to 5 ppm of active polymer in the cooling tower water can control calcium carbonate scale formation to a PSI value as low as 4.5.

5-3.5.3 Calcium Carbonate Scale Control Using Sludge-Forming Polymers.

Certain homopolymers and copolymers act as crystal modifiers by distorting calcium carbonate crystals such that they do not attach themselves to heat exchange surfaces, but instead the crystals become SS that can be removed through filtration or blowdown. Usually dosages of 1 to 3 ppm of active polymer in the cooling tower water will control calcium carbonate scale. Due to formation of sludge, rather than the stabilization of carbonate in solution, the PSI is not meaningful under these conditions.

5-3.5.4 Calcium Phosphate Scale Control Using Solubilizing Inhibitors.

Often calcium phosphate scale is formed in cooling water systems treated with a phosphate- based corrosion inhibitor program or when phosphate is present in the makeup water (like potable or recycled water). Calcium phosphate is much less soluble in water than is calcium carbonate. If the calcium hardness is 500 ppm and the pH is above 7.0, without any polymer treatment calcium phosphate scale will likely form, even at the low level of 10 ppm phosphate (as PO_4) in the cooling water (see paragraph 5-3.3). Calcium phosphate solubility can be increased by a factor of a little less than 3 by the addition of 4-ppm phosphonate (HEDP/PBTC) or by the use of 6 to 8 ppm of a copolymer or terpolymer specific for calcium phosphate inhibition.

5-3.5.5 Calcium Sulfate Scale Control Using Solubilizing Polymers.

Calcium sulfate formation can result from high concentrations of calcium ions and sulfate ions in the recirculating water; however, calcium sulfate is the most soluble of the scale-forming calcium salts found in cooling tower waters having pH levels of greater than 8.0. This means that calcium sulfate scale will not form unless some calcium ions (hardness) remain in solution after the calcium reacts with all the carbonate and phosphate in the water. Calcium sulfate scale may occur when the recirculating water contains calcium hardness in the range of 500 to 700 ppm as $CaCO_3$ and sulfate in the range of 500 to 700 ppm SO_4. (See the predictive index in paragraph 5-3.4) The addition of 3 to 5 ppm of a copolymer of acrylate and acrylamide will allow calcium sulfate to remain in solution at a level almost 3 times the level allowed when using no treatment. Calcium sulfate scale rarely forms at pH levels above 8.0 in the cooling water.

5-3.5.6 Magnesium Silicate Scale Control.

Formation of magnesium silicate is possible in cooling systems, but only under certain rare conditions. Magnesium ions (hardness) first react with hydroxyl ions (OH-) to form magnesium hydroxide, which then reacts with (absorbs) dissolved or colloidal silica. A deposit analysis often reports this material as magnesium silicate. Since magnesium hydroxide solubility decreases at pH levels above 9.0, this scale will usually occur only at a pH level above 9.0 and when the magnesium hardness concentration is greater than 100 ppm.

5-3.5.7 Silica Scale Control.

Silica solubility is dependent upon temperature and pH. At pH levels greater than 8.5, silica remains soluble (no scale) at a concentration of 250 ppm as SiO2. At pH levels of 7.5 or below, maximum silica solubility is 150 ppm as SiO2. At maximum silica levels, silica will first deposit on the cooling tower slats rather than in the heat exchanger because silica is more soluble in hot water than in cold water. The slats will become coated with a white, sometimes sparkling, deposit. If this occurs, blowdown should be increased to decrease COC by at least 1 unit. This procedure should stop additional scale formation. If the concentration of silica in the makeup water is above 30 ppm, it will usually be the parameter that controls the adjustment of cooling water system COC. If the silica concentration is high, external treatment can reduce the level of silica in the makeup water (see Chapter 3). The introduction of water treatment chemicals based on new polymer technology may allow the solubility of silica to be increased above the old recognized limit of 150 ppm.

Table 5-1 Summary of Scale Control Methods

Scale	Control Method
Calcium carbonate	1. Solubilize using phophonates. 2. Solubilize using polymers (polyacrylate, polymethacrylate, polymaleate). 3. Form sludge using specialty polymers.
Calcium phosphate	1. Solubilize using phosphonates. 2. Solubilize using specialty copolymers or terpolymers.
Calcium sulfate	Solubilize using copolymers of acrylate and acrylamide.
Magnesium silicate	Maintain water chemistry of: pH < 9.0, magnesium hardness < 500 ppm, and silica < 100 ppm.
Silica	1. Maintain water chemistry with silica < 150 ppm. 2. Solubilize with silica-specific polymer.

5-3.6 Cooling Water Fouling.

The term “fouling” refers to the deposition of materials that are normally held in suspension in the cooling water: mud, silt, and other SS brought into the system with the makeup water; dust, dirt, and debris scrubbed out of the air passing through the tower; product leakage such as oils; corrosion products from the system; and biological organisms, both living and dead. Combinations of any or all of these materials can be present in the cooling water.

5-3.7 Fouling Control.

Fouling from mud, dirt, and corrosion products can be controlled by the addition of a water-soluble polymer dispersant, such as a polyacrylate. The addition of about 4 to 5 ppm of active polymer, together with sufficient water velocity (3.28 feet per second (1 meter per second)), can keep foulants in suspension and prevent them from being deposited on heat transfer surfaces. Higher dosages (5 to 20 ppm) of active polymer can be required for heavily fouled systems. It is best to reduce the loading of SS by mechanically removing them from the system through blowdown, filtration, and physical sump cleaning. Removing oil or oily materials requires a non-foaming surfactant. Paragraph 5-4 describes prevention of fouling by biological organisms. Table 5-2 summarizes foulant control methods.

Table 5-2 Summary of Foulant Control Methods

Foulant	Control Method
Mud, dirt, corrosion products	1. Disperse using polymers and maintain adequate flow. 2. Form sludge using specialty polymers.
Oily matter	Disperse using a non-foaming surfactant.

5-4 MICROBIOLOGICAL DEPOSITS AND CONTROL.

Microbiological organisms are composed of three classes: algae, bacteria, and fungus. Large biological organisms such as clams, snails, mussels, or similar species are referred to as macrobiological organisms. The presence of any biological growth can be detrimental to cooling tower operations. Problems include fouling, corrosion, and loss of efficiency.

These problems can lead to downtime, higher operating cost, and even premature replacement of equipment. Additionally, some bacteria are pathogenic and can pose a risk to human life.

5-4.1 Algae.

The term “algae” refers to algal, microbiological, tiny, stringy blue and blue-green plants, which are usually found growing in masses on top of and on sides of cooling towers.

Algae grow only in sunlit areas. They will slough off and become part of the suspended matter in the circulating water, a situation which may cause fouling and plugging of water sprays. Algae also provide a breeding place, and are a nutrient, for bacteria.

5-4.2 Bacteria.

The term “bacteria” refers to a large group of one-celled microorganisms. Bacteria can grow in either the absence or presence of sunlight. There are several ways to classify bacteria, including “aerobic,” meaning those living in the presence of oxygen, and “anaerobic,” meaning those living in the absence of oxygen. In a cooling water system, one can categorize bacteria as either “planktonic” or “sessile,” which are terms that describe whether the bacteria are, respectively, either free floating or found growing on surfaces (stickers). Categories of bacteria are described below. Table 5-3 shows types of bacteria and their growth conditions.

5-4.2.1 Planktonic Bacteria.

Planktonic bacteria are suspended in the water, sometimes referred to as “free floaters” or “swimmers,” and are aerobic bacteria that thrive in an oxygenated environment. They are not harmful to the cooling system since they do not cause deposits or corrosion, but they can provide nutrients for other microorganisms; in addition, some planktonic bacteria such as *Legionella Pneumophila* are pathogenic and can present a significant human health risk.

5-4.2.2 Sessile Bacteria.

Sessile bacteria are stickers, or non-swimming bacteria, and can cause deposits and corrosion. Sessile bacteria types include slime-formers and anaerobic (corrosive) bacteria. Slime-formers can grow and form gelatinous deposits on almost any surface in contact with the cooling water. These deposits can grow so large that they restrict water flow and interfere with heat transfer; they also may promote under-deposit corrosion. Feeling the sides of the cooling tower basin just below the water level is one way to detect the presence of slime-formers. Usually if there are slime formers in the system, you can feel deposits. Anaerobic bacteria thrive in oxygen- deprived environments and often establish colonies beneath slime deposits or under other types of deposits. One type of anaerobe is sulfate-reducing bacteria (SRB), which produce hydrogen sulfide, a chemical that is very corrosive to metals. This type of corrosion attack is much localized and can result in pipe and tube failures. The presence of SRB should be suspected in a water system if the underside of a slime layer is black or if you detect the odor of rotten eggs. Any type of microbiological corrosion is referred to as microbiologically influenced corrosion (MIC). Bacteria cause most of the MIC found in cooling water systems. Use surface microbiological measurements to monitor sessile bacteria.

Table 5-3 Bacterial Types and Problems Created

Bacteria Type	Technical Names and Examples	Conditions for Growth		Problems Created
		Temperature	pH	
Aerobic - capsulated	• Aerobacter aerogenes Flavobacterium • Proteus vulgaris • Pseudomonas aeruginosa • Serratia • Alcaligenes	68-104º F (20-40º C)	4-8 (7.4 optimum)	Aerobic - capsulated
Aerobic - spore forming	• Bacillus myocoides • Bacillus subtilis	68-104º F (20-40º C)	5-8	Aerobic - spore forming
Aerobic - sulfur	• Thiobacillus • thiooxidans	68-104º F (20-40º C)	0.6-6	Aerobic -sulfur
Anaerobic – sulfate reducing	• Desulfovibrio desulfuricans • Clostridium	68-104º F (20-40º C)	4-8	Anaerobic –sulfate reducing
Iron depositing	• Crenothrix • Leptothrix • Gallionella	68-104º F (20-40º C)	7.4-9.5	Iron depositing

5-4.3 Fungi.

The term “fungi” refers to classes of organisms made up of molds and yeasts, some of which attack and cause wood decay in cooling towers. The control of fungi requires special preservative treatment of wood. Fungi also produce deposits in cooling water equipment.

5-4.4 Microbiological Control.

The term “microbiological control” refers to techniques used to minimize the presence of microbiological organisms in cooling water. Chemical biocide treatment is the method used on government installations for microbiological control in cooling water. Biocides that are used to control microbiological growth fall into one of two broad categories: oxidizing and non-oxidizing microbiocides. A cost-effective approach for control involves the regular use of oxidizers as a primary biocide, augmented by selective use of non-oxidizing biocides. Important factors for the effectiveness of any biocide include using a proper dosage and allowing adequate contact time with the microbiological organisms. All microbiocides are toxic and must be handled safely and with caution; use the SDS for safety instructions.

5-4.4.1 Oxidizing Biocides.

“Oxidizing biocides” is a term describing microbiocides that oxidize or irreversibly “burn up” the bio-organisms. Oxidizing biocides also destroy nutrients that the microorganisms require for growth. Avoid addition of excess amounts (over-feeding) of oxidizing biocides because they are corrosive to metal and wood in the cooling system and have the potential to destroy some scale and corrosion inhibitors. The various oxidizing biocides are described below. Table 5-6 provides guidelines for selecting oxidizing microbiocides.

5-4.4.1.1 Chlorine and Chlorine Release Agents.

Chlorine (Cl2) compounds are the most effective industrial oxidizing biocides and the most widely used. Chlorine is available as a chlorine gas, dry calcium hypochlorite (HTH), liquid sodium hypochlorite (bleach), plus several other dry products that release chlorine. When chlorine is introduced into water, it hydrolyzes to form hypochlorite ion (OCl-) and hypochlorous acid (HOCl); it is the latter chemical that is the stronger oxidizing biocide. The presence of hypochlorous acid is greater, proportionate to hypochlorite ion, at low pH levels. At a pH of 5.0, hypochlorous acid exists almost exclusively. At a pH of 7.5, there are approximately equal amounts of hypochlorous acid and hypochlorite ion. Figure 5-16 shows this relationship. Chlorine is effective, but to a lesser degree, as a biocide at a pH of 7.5 or greater because the hypochlorite ion has about one-tenth the biocidal efficacy of hypochlorous acid. A pH range of 6.5 to 7.5 is considered optimal for chlorine or chlorine-based microbiological control programs. Above pH 7.5, relatively higher levels of chlorine are required to be effective. Military installations seldom use gaseous chlorine for treating cooling towers because of safety concerns, difficulty with controlling the feed of the gas, and increasing concern for the environmental effects of escaping residual chlorine gas. The most commonly used chlorine-based products are bleach and HTH.

Figure 5-16 **Halogen Species vs. pH in Water**

HOCl = hypochlorous acid
OCl^- = hypochlorite ion
HOBr = hydrobromous acid
Obr = hypobromite ion
Cl_2 = chlorine
Br_2 = bromine

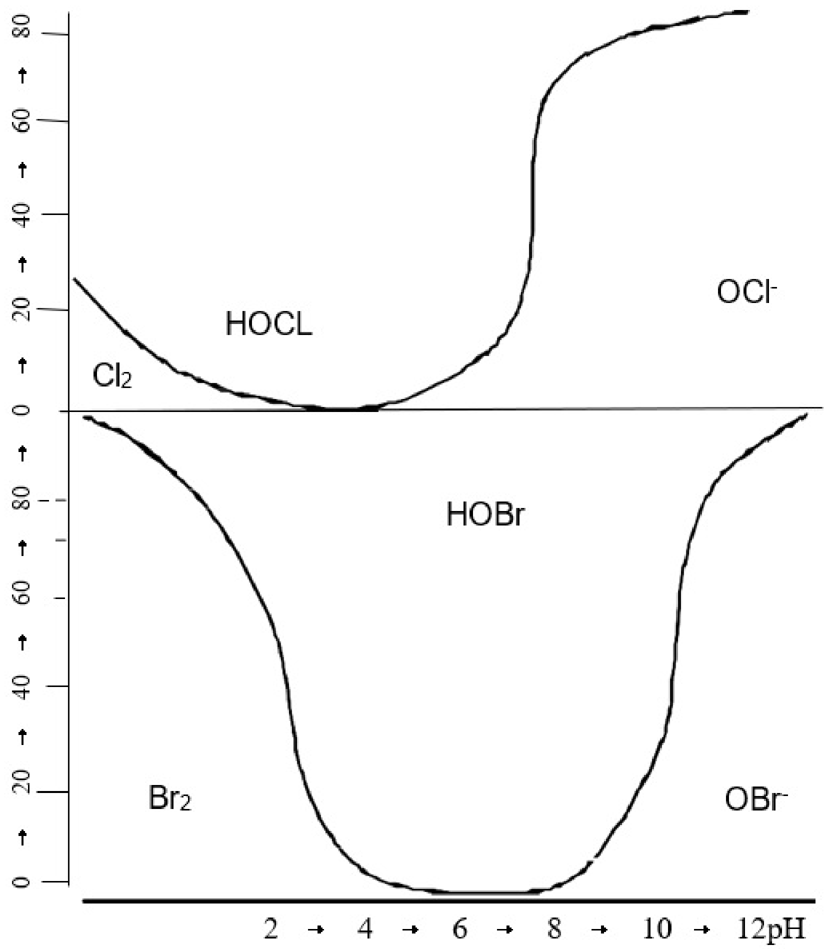


Table 5-4 Chlorine Release Agents

Release Agents	Comments
Sodium Hypochlorite 12 percent	Concentrated Liquid Bleach
Calcium Hypochlorite (HTH)	Dry product, releases chlorine
Chlorine Gas	Gaseous chlorine
Cloloisocyanurates	Dry organic chlorine compound, releases chlorine and cyanuric acid

5-4.4.1.2 Bromine Release Agents.

Bromine (Br2) compounds are very similar to chlorine compounds. Although more expensive than chlorine compounds, their main advantage is that bromine is more effective at higher pH ranges (7.5 or greater) than chlorine. Bromine has a lower vapor pressure than chlorine and is 6 times as soluble in water, making it less subject to vaporization loss from a cooling tower. When bromine is introduced to water, it hydrolyzes to form hypobromite ion (OBr-) and hypobromous acid (HOBr); Figure 5-16 shows this relationship. A pH range of 7.5 to 10.0 is considered optimal for the use of bromine. Bromine release agents include dry chemicals called hydantoins and bromine salts, such as sodium bromide. When a salt solution is mixed with an oxidizing agent, such as bleach, and a reaction occurs, bromine is produced. In water, bromine degrades more rapidly than chlorine. Recent developments in bromine chemistry have resulted in the production of a bromine solution (liquid). Table 5-5 shows examples of some bromine release agents. The most popular sources of bromine are the dry bromine release products.

Table 5-5 Bromine Release Agents

Release Agent	Comments
Bromo-chloro-dimethyl hydantoin	Dry product – releases bromine
Bromo-chloro-methyl-ethyl hydantoin	Dry product – releases bromine
Isocyanuric acid plus sodium bromide	Dry product – releases bromine
Chlorine plus sodium bromide	Produces bromine liquid
Peroxide plus sodium bromide	Produces bromine liquid
Ozone plus sodium bromide	Produces bromine liquid
Stabilized bromine	Hydrobromite liquid

5-4.4.1.3 Ozone.

Ozone (O_3) is a gas produced by passing dry air either through a strong electric field or near an ultraviolet light. If ozone is dissolved in water, the resulting solution can be added to cooling water. Ozone is a very strong oxidizing biocide that, if properly applied, can provide effective control of microorganisms in cooling tower systems; however, because of safety and operational problems associated with its manufacture and use, and the resulting high capital and operating costs, it is neither the most economical method nor the preferred method for microbiological control in cooling towers under normal operations. Ozone can increase metal corrosion and does not prevent scale (see paragraph 9-2.9.1).

5-4.4.1.4 Chlorine Dioxide.

Chlorine dioxide (ClO_2) is a gas generated by mixing several chemicals. The chlorine dioxide gas produced in this manner is subsequently dissolved in water, with the water containing the chlorine dioxide then added to the cooling water. Chlorine dioxide must be produced in close proximity to the point of use. It is not recommended for use on military installations due to the complexity of its production and safety concerns associated with its production and handling.

5-4.4.1.5 Hydrogen Peroxide.

Hydrogen peroxide (H_2O_2) is a liquid that is usually used at a concentration of 30 percent in water. Hydrogen peroxide is considered one of the most environmentally friendly oxidizing biocides because it degrades to water; however, concentrated hydrogen peroxide will react in a violent manner when it comes into contact with organic chemicals and materials.

Table 5-6 Guidelines for Oxidizing Microbiocide Effectiveness.

Microbiocide	Bacteria Types				Fungi	Algae	Comments
	Slime Forming		Iron Depositing	Corrosive			
	Spore Formers	Non-Spore Formers					
Chlorine	P	E	E	N	P	F	Dangerous to handle; corrosive to metal; available as dry, gas, or liquid; less effective higher pH (> 7.5)
Bromine	F	E	E	N	P	F	Can be produced from bromides; very effective at pH 6.0-10.0; very effective with ammonia; less volatile than chlorine
Ozone	E	E	E	F	G	P	Very volatile; can attack wood, PVC, copper, and gaskets
Chlorine dioxide	G	E	E	N	P	F	Must be produced onsite; very volatile; not sensitive to pH; does not react with ammonia and many organics
Chlorine	P	E	E	N	P	F	Dangerous to handle; corrosive to metal; available as dry, gas, or liquid; less effective higher pH (> 7.5)

E = Excellent G = Good F = Fair P = Poor N = Not effective

5-4.4.2 Non-Oxidizing Biocides.

Non-oxidizing biocides are microbiocides that act as “poisons;” they disrupt the metabolic or reproductive processes of micro- and macro-organisms and are therefore toxic. Non-oxidizing biocides are organic compounds that are very toxic to organisms, including human beings and animals. They are usually liquids, but some are available as dry products (such as pellets, solids). A major consideration for their use is their persistence with respect to the discharge limitations for water (effluent) containing these toxic substances. Also, when choosing and applying a non-oxidizing biocide, you must consider the cooling tower system’s operating parameters, such as pH and retention time. The applied dosages of microbiocides should never exceed EPA maximum limits, which are always printed on the container labels. The labels will also identify the active microbiocide ingredient, the percentage of each chemical that is present in the formulation, and the EPA registration number. Control programs often combine both oxidizing and non-oxidizing biocides. The most important aspect of bio-fouling control is to match the non-oxidizing biocide to the problem organism. Table 5-7 provides guidelines for non-oxidizing biocide effectiveness.

Table 5-7 Guidelines for Non-Oxidizing Microbiocide Selection.

Microbiocide	Bacteria Types				Fungi	Algae	Comments
	Slime Forming		Iron Depositing	Corrosive			
	Spore Formers	Non-spore Formers					
Quaternary ammonium salts	E	E	E	G	P	G	Effective pH 6.5-9.2; foaming potential; reacts with anionics
Organo tin plus quaternaries	E	E	E	G	P	G	Effective pH 6.5-9.2; foaming potential; reacts with anionics; tin compounds often restricted
Dibromo-nitrilo-propionamide	E	E	E	G	N	P	Effective pH 6.5-7.5; degrades quickly; uses glycol solvent
Methylene bis thiocynate	E	E	G	E	P	P	Effective pH < 7.5; deactivated with high pH
Isothiazolone	E	E	G	G	G	G	Effective pH 4.5-9.3; dangerous to humans
Dodecylguanidine	E	E	G	G	G	G	Effective pH 6.5-9.5
Glutaraldehyde	E	E	G	E	G	G	Effective pH 6-10
Terbutylazine	N	N	N	N	N	E	Very effective algaecide; blocks photosynthesis
Carbamates	E	E	G	G	G	F	Eff. pH 7-9; corrodes copper

E = Excellent G = Good F = Fair P = Poor N = Not effective

5-4.5 Algae Control.

Algae can be controlled by two techniques: chemical methods and physical methods. Since algae require sunlight to survive and grow, covering the upper hot water decks of cooling towers with plywood can often control algae deposits. Chemical methods consist of using oxidizing and non-oxidizing biocides, which can control algae to various degrees (see Tables 5-6 and 5-7). The effectiveness of oxidizers is considered only fair while that of several non-oxidizers is in the range of very good to excellent. One of the more effective biocides for algae is terbutylazine, a triazine product (see Table 5-7).

5-4.6 Bacterial Control.

Accepted industry practice for bacterial control is the use of oxidizing and non-oxidizing biocides that are specific for the type of bacteria. The most cost-effective microbiocide programs for medium and large cooling towers use an oxidizer as a primary biocide and one or more non-oxidizers selectively as a secondary biocide (see Tables 5-6 and 5-7). Smaller cooling systems often use one or more non- oxidizing biocides, although dry oxidizing biocides are also used commonly. The most overlooked aspect of bacterial control is maintaining a system kept clean of deposits and SS (such as dirt, silt, sand, corrosion products) through the use of filters and periodic wash-down procedures. Clean systems reduce the demand for chemical and microbiological control. Table 5-8 shows accepted industry guidelines for a bacterial control program with the use of a test kit.

Table 5-8 Guidelines for Bacterial Control in Cooling Towers.

Bacterium Type	Colony-Forming Units/ml
Total aerobic bacteria	$< 10^4$
Sulfate-reducing bacteria	Undetectable
Surface microbiological	$< 10^6$ – Undetectable

5-4.6.1 Bacterial Control with Oxidizing Biocides.

Bacterial control with oxidizing biocides can be accomplished by either continuous feed or slug feed of the oxidant. A continuous-feed process typically maintains 0.1 to 0.3 ppm of free halogen in the return water to the cooling tower. A typical slug-feed process adds treatment chemicals periodically to give 0.5 to 1.0 ppm of free halogen in the return water to the cooling tower for a period of 2 to 4 hours, 3 times per week. Halogen refers to the group of elements including chlorine and bromine. “Free” halogen refers to the measured residual of halogen available for disinfection. Stabilized Halogen technology is generally controlled on a total halogen residual. For continuous feed, control at 0.5 to 1 ppm total, and for slug feed control at 2.4 ppm for a period 2-4 hours, 3 times per week.

5-4.6.2 Bacterial Control with Non-Oxidizing Biocides.

Bacterial control with non-oxidizing biocides uses one or more biocides as shown in Table 5-7. Usually different non-oxidizers are added on an alternating schedule; they are slug-fed every other week for optimum effectiveness. Each time you use a non-oxidizing biocide, it is important to maintain an adequate dosage for 24 hours to enable sufficient contact time for maximum effectiveness.

5-4.7 Legionnaires’ disease.

Legionnaires’ disease (Legionellosis) is a respiratory disease (atypical pneumonia) that is caused by infection of susceptible individuals who have inhaled a fine water mist containing the bacterium known as *Legionella Pneumophila*. Water in a cooling tower can become infected with the bacterium if an inadequate microbiological control situation occurs. The presence and density of *Legionella Pneumophila* bacteria cannot be detected by standard microbiological testing methodologies. Instead, cooling water samples must be sent to a laboratory that has been certified to conduct the required tests. If the presence of the bacteria in cooling water is established, proper disinfection steps are required. A procedure known as the Wisconsin Protocol, developed by the

Wisconsin State Health Department, has proven effective. This protocol requires the addition of high dosages of chlorine (10 ppm free residual) at a pH of less than 7.5 for 24 hours, flushing the system, then repeating. Additional testing for Legionella is required to determine the effectiveness of the procedure. Maintaining a clean, microbiologically free cooling water system and using effective water treatment is preferable to dealing with remedial efforts. The Cooling Technology Institute (CTI) and the American Society of Heating, Refrigerating, and Air Conditioning Engineers (ASHRAE) have published position papers on the prevention of Legionella; these can be downloaded from their respective websites: https://www.cti.org/ and https://www.ashrae.org/. Refer to UFC 3-420-01 Plumbing Systems for additional guidance about Legionella.

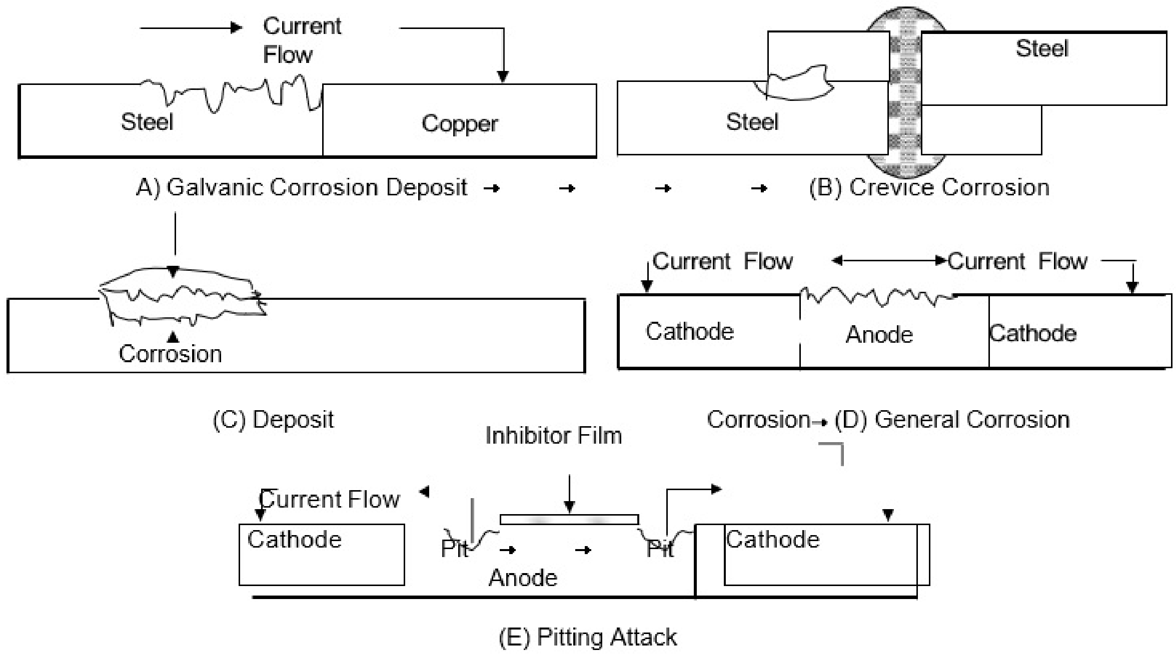
5-4.8 Macrobiological Control.

The term "macrobiological control" refers to control of larger biological organisms such as mussels, clams, and snails. They can exist in cooling systems that use seawater or river water as makeup. The first line of defense is using mechanical prevention with strainers and filters on the intake water to prevent infiltration into the cooling water system. Control methods within the cooling system include thermal shock and chemical treatment with oxidizing and non-oxidizing biocides.

5-5 CORROSION IN COOLING SYSTEMS.

The term "corrosion" (in a cooling water system) is defined as the electrochemical deterioration of a metal that is in contact with cooling water. Corrosion occurs when an electric current flows from one part of the metal (anode) through the water (electrolyte) to another part of the metal (cathode). Corrosion takes place at the anode only. The cathode is the driving force of the corrosion action. Forms of corrosion associated with industrial water systems are illustrated in Figure 5-17.

Figure 5-17 **Forms of Corrosion.**



5-5.1 Galvanic Corrosion.

See Figure 5-17 (A). This term refers to corrosion that occurs when two different metals are coupled together. The metal with the least resistance becomes the anode and will corrode due to the electrochemical reaction produced. One of the most common instances of galvanic corrosion occurring in cooling water systems results when mild steel and copper alloy metals are brought into contact with one another (like copper tubing attached to a mild steel tube sheet or brass valves connected to mild steel or galvanized piping). As a result of the electrochemical reaction, the copper is dissolved in the water and corrosion of copper alloy results. The copper can also plate out (stick) on mild steel surfaces, setting up additional galvanic cells. Another example is the electrochemical reaction that occurs when mild steel and zinc (galvanizing) are coupled together at temperatures normally found in cooling tower systems. The zinc becomes the anode and is corroded. Figure 5-18 shows the galvanic series. Any coupling of a metal that is higher in the galvanic series with a metal or alloy that is lower in the galvanic series results in electrochemical reaction in which the “higher” metal functions as the anode or active metal.

5-5.2 General Corrosion.

See Figure 5-17 (D). The term "general corrosion" refers to uniform corrosion of metal surfaces. A single piece of metal will have cathodic and anodic areas due to differences in impurities and stresses. These areas will change periodically, causing the metal to corrode over the entire surface at a more or less uniform rate.

5-5.3 Concentration Cell Corrosion.

When two pieces of the same metal are in a solution capable of acting as an electrolyte, and the electrolyte contains different substances or the same substance in different amounts, such as a salt or a mixture of salts, or oxygen, an electrical potential difference will develop between them.

5-5.3.1 Crevice Corrosion.

See Figure 5-17 (B). The term "crevice corrosion" refers to corrosion that occurs in a slight separation between two pieces of metal, such as at the contact point of two mild or stainless steel plates that have been bolted together. Water flow is restricted in a crevice and, as a result, oxygen is consumed faster than it can be replenished. The metal in the crevice functions as an anode and corrodes. This is a form of concentration cell corrosion, also called "differential oxygen cell" corrosion. Stainless steel is particularly susceptible to this type of corrosion, which results in localized or pitting attack.

5-5.3.2 Under-Deposit Corrosion.

See Figure 5-17 (C). The term "under-deposit corrosion" refers to corrosion occurring under any type of deposit. The underside of a deposit that has been caused by fouling, bacterial slime, or debris acts in much the same way as the inside of a crevice. The metal under the deposit becomes anodic and corrodes. This process is considered another form of concentration cell corrosion because oxygen cannot easily get under the deposit. All metals are susceptible to this type of corrosion, which results in localized or pitting attack.

5-5.3.2.1 Microbiologically Influenced Corrosion (MIC).

See Figure 5-17 (E). This term refers to metal corrosion associated with microbiological organisms whose presence contributes to the creation of, or maintenance of, a corrosive environment. MIC can be either eliminated or prevented to a large degree by the proper use of biocides.

5-5.4 Corrosion Rate.

The term "corrosion rate" refers to the rate at which the corrosion action proceeds. The rate is measured in units of mils per year (mpy). A mil is one-thousandth of an inch (0.0254 millimeter). The rate measurement is performed using corrosion coupons that have been exposed to cooling water for a short period of time (30 to 90 days). The weight of the coupon is measured before and after exposure to the water. The thickness of the metal lost due to corrosion over the testing period is then calculated using a measurement of the weight loss. This weight loss is extrapolated to give a rate for 1 year and a calculation of the thickness loss is then performed and the value is reported. Alternatively, this measurement can be taken using specialized instruments that rapidly measure corrosion rates. Table 5-9 shows the corrosion rates for corrosion coupons of different metals. Paragraph 7-5.2 provides detailed information on corrosion testing.

Table 5-9 Assessing Corrosion Rates in Cooling Water Systems: 90-Day Corrosion Coupon Test.

Metal	mpy	Comment
Mild steel piping	< 1	Excellent
	> 1 to 3	Good
	> 3 to 5	Fair
	> 5 to 10	Poor
	> 10	Unacceptable
Mild steel Hx tubing	< 0.2	Excellent
	> 0.2 to 0.5	Good
	> 0.5 to 1.0	Fair
	> 1.0 to 1.5	Poor
	> 1.5	Unacceptable
Copper and copper alloys	< 0.1	Excellent
	> 0.1 to 0.2	Good
	> 0.2 to 0.3	Fair
	> 0.3 to 0.5	Poor
	> 0.5	Unacceptable
Galvanized steel	< 2	Excellent
	> 2 to 4	Good
	> 4 to 8	Fair
	> 8 to 10	Poor
	> 10	Unacceptable
Stainless Steel	< 0.1	Acceptable
	> 0.1	Unacceptable

NOTE: Determine pitting on coupons by visual observation; any pitting is unacceptable.

5-5.5 Corrosion Control Methods.

In cooling water systems, two basic techniques are used to provide corrosion protection to the metals that the water contacts: use of chemical corrosion inhibitors, and raising the pH of the cooling water. Figure 5-19 illustrates the effect of pH on the corrosion rate of mild steel. Most military cooling water systems contain components fabricated primarily of copper alloy and mild steel. Galvanized steel is present in galvanized cooling towers and stainless steel may be present in piping. As the cooling water pH is increased (ideally to within the range of 8.0 to 9.5), copper and mild steel corrosion rates will decrease as shown in Figure 5-19, although very high pH levels are corrosive to copper. The increase in pH alone cannot always protect metals adequately, especially since cooling water is highly aerated (oxygen saturated). Chemical corrosion inhibitors are used to provide protection from corrosion of the metal components of cooling water systems. Table 5-10 shows criteria for the selection of corrosion inhibitors. The principal strategy for a cooling system corrosion protection program is to ensure protection of the metal in the heat exchanger (metal that is the thinnest metal in the system). The secondary goal is to provide protection from corrosion of the mild steel piping. When galvanized steel cooling towers are part of the cooling system, specialized corrosion inhibitors are the best control method. Galvanized steel is corroded at pH levels above 9.0 and below 6.0.

Figure 5-19 **Effect of pH on Corrosion Rate of Unprotected Mild Steel in Water.**

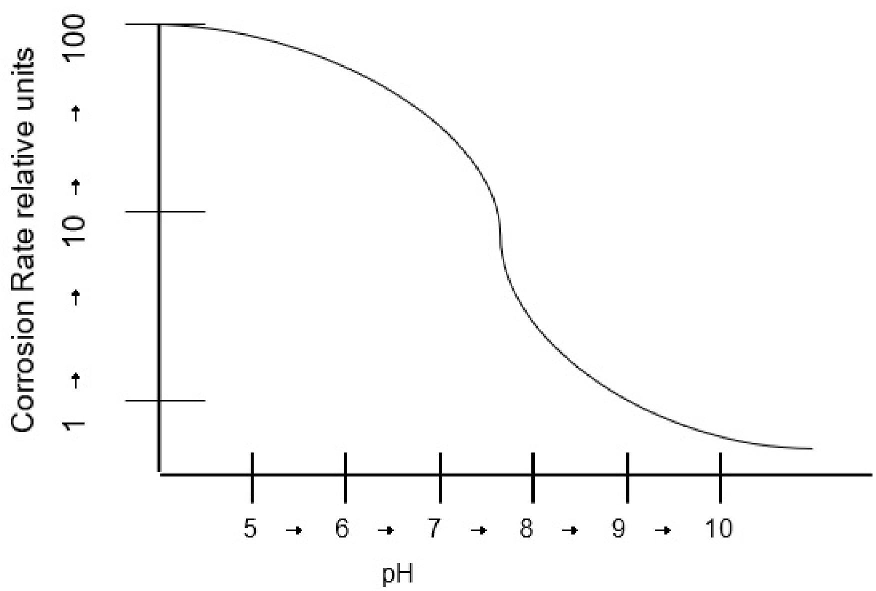

Table 5-10 Criteria for Corrosion Inhibitor Selection.

Corrosion Inhibitor	Metal			pH Range (ideal)
	Steel	Copper	Aluminum	
Cathodic Inhibitor				
Polyphosphate[1]	Excellent	Attacks	Attacks	6.5-8.5
Zinc salts[2]	Excellent	None	None	6.5-8.5
Polysilicate[3]	Excellent	Excellent	Excellent	7.5-10.0
Molybdate	Good	Fair	Fair	7.5-10.0
Anodic Inhibitor				
Orthophosphate[1]	Good	Attacks	Attacks	6.5-8.5
Orthosilicate[3]	Good	Good	Good	7.5-10.0
Copper Corrosion Inhibitor				
Azoles	Fair	Excellent	Fair	6.0-10.0

NOTES:

1. May require polymeric calcium phosphate dispersant.
2. Rarely used alone. Requires zinc solubilizer above pH 7.8.
3. Do not use if natural silica is 150 ppm or greater.

5-5.5.1 Effective Corrosion Control.

Effective corrosion control requires maintaining appropriate pH levels, plus adding maintenance dosages of chemical corrosion inhibitors. Chemical corrosion inhibitors form a protective film or barrier on the cooling system metal surfaces that have been cleaned prior to adding an initial high dosage of inhibitor. The initial high dosage of inhibitor passivates (protects) the metal. The appropriate dosage of corrosion inhibitor must be maintained continuously in the cooling water to ensure continuing protection. Table 5-11 shows examples of various passivation and maintenance dosage levels of corrosion inhibitors. Corrosion inhibitors are divided into three classes: cathodic, anodic, and general filmers. Corrosion inhibitors form a protective film on either the anode, the cathode, or over the entire metal surface. The types of corrosion inhibitors are described below.

5-5.5.1.1 Anodic Inhibitors.

Anodic inhibitors form a protective film coating on the anodic metal (where the metal is lost) and thus directly control corrosion by preventing the reaction that results in corrosion. Any unprotected areas will corrode at a much faster rate than the protected areas, a factor that could result in pitting or localized attack of the unprotected areas. Examples of anodic inhibitors include orthophosphate, nitrite, and orthosilicates. Under certain conditions, molybdate can function as an anodic inhibitor.

5-5.5.1.2 Cathodic Inhibitors.

Cathodic inhibitors form a protective film coating of the cathodic metal (where metal is not lost) and thus indirectly prevent corrosion by interfering with the current flow required for the electrochemical reaction to proceed between the cathodic and anodic metals. The corrosion reaction rate is governed by the size and type of the cathode relative to the anode. Even when cathodic areas are not completely covered by the protective film, corrosion will occur, but usually more slowly and uniformly than when using anodic inhibitors alone. The occurrence of localized corrosion or pitting attack is greatly reduced. Examples of cathodic inhibitors include zinc salts, polyphosphates, and polysilicates. Under most conditions, molybdate will function as a cathodic inhibitor.

5-5.5.1.3 General Inhibitors.

General inhibitors produce a protective film on the surfaces of all metals. These corrosion inhibitors are organic compounds, such as certain phosphonates, amines, and other nitrogen chemicals. They may be used in cooling water systems.

5-5.5.1.4 Corrosion Inhibitors for Specific Metals.

Some corrosion inhibitors provide corrosion control for specific metals. The protection of copper and copper alloys requires the use of azoles, such as tolyltriazole (TTA), benzotriazole (BZT), and butylbenzo-thiazole, which can be added to the system separately from, or as part of a blend of, other treatment chemicals.

5-5.5.1.5 Galvanic or Crevice Corrosion.

Control of galvanic or crevice corrosion is achieved primarily by engineering and mechanical design. These types of corrosion can also be partially controlled by physical and chemical considerations. A dielectric coupling (insulator), used to separate two different metallurgies, can help to prevent galvanic corrosion. From a chemical perspective, adjusting pH and using proper corrosion inhibitors will reduce corrosion.

5-5.5.1.6 Deposit Corrosion.

Control of deposit corrosion requires maintaining deposit-free metal surfaces. This applies to any form of deposit, such as scale, biomass, corrosion products, or foulants. The occurrence of most types of deposits is prevented by dispersants, scale inhibitors, or biocides, along with the maintenance of adequate flow velocities. Routine, adequate cleaning of filters and tower sumps will help reduce deposits.

5-5.5.1.7 MIC.

MIC is best prevented by stopping conditions that foster biological growth and by using an effective microbiological control program. A MIC prevention program includes adequate control (prevention) of deposits and fouling, avoidance of low-flow and dead-leg conditions, and implementation of a consistently effective microbiological program (see paragraph 5-4.4).

Table 5-11 Guidelines for Passive Film Formation and Subsequent Maintenance

Corrosion Inhibitor	Dosage (ppm)		Film-Formation Time (Days)
	Initial	Maintenance	
Cathodic Inhibitor			
Polyphosphate[1]	40-60 as PO_4	10-20 as PO_4	5-6
Zinc salts[2]	10-20 as Zn	3-5 as Zn	5-6
Polysilicate[3]	40-60 as SiO_2	10-20 as SiO_2	10-12
Molybdate	40-60 as Mo	5-20 as Mo	10-12
Anodic Inhibitor			
Orthophosphate[1]	40-60 as PO_4	15-20 as PO_4	5-6
Orthosilicate[3]	40-60 as SiO_2	10-15 as SiO_2	10-12
Copper Corrosion Inhibitor			
Tolyltriazole	10-20 as TTA	1-2 as TTA	5-6

Note: General: Maintenance dosage shifts to lower part of range as pH rises.

1. May require polymeric calcium phosphate dispersant.
2. Rarely used alone. Requires zinc solubilizer above pH 7.8.
3. Do not use if natural silica is 150 ppm or greater.

5-6 DEVELOPING AN EFFECTIVE COOLING WATER TREATMENT PROGRAM.

An effective and complete cooling water treatment program addresses many factors, including those associated with compliance and safety, protection of equipment, and cost. Compliance and safety considerations are mandatory components of the program. Achieving or exceeding minimally acceptable equipment protection at the lowest possible cost is an advisable outcome for a well-designed program. The overall cost of the treatment program includes not only the cost of chemical treatment, but also the costs of water, disposal, manpower, and equipment. Development of an appropriate cooling water treatment program is dependent upon knowledge of both the specific equipment to be protected and the quality of the water to be used (source water and system water).

5-6.1 Equipment.

Corrosion inhibitors are selected based on the metallurgy of individual pieces of cooling system equipment. Typical systems include equipment components of different metals. For example, systems may include smooth and enhanced copper tube bundles, mild steel transfer piping, and galvanized cooling tower components; therefore, to select the proper corrosion inhibitor, it is important to identify all metals contacted by the cooling water. (See Table 5-10 for corrosion inhibitor selection criteria.)

5-6.2 Operational Features and Parameters.

Operational features and parameters of the cooling water system must be known to select the proper scale and deposit inhibitors. This requirement refers to operational parameters such as maximum temperature, minimum velocities, usage patterns, and whether or not layup periods occur. The best chemical treatment programs cannot overcome the stresses of poorly operated systems. A good example of system stress is intermittent chiller operation that allows for SS accumulation (deposits) in chiller tube surfaces due to low flow or lack of flow. This situation creates a strong potential for under-deposit corrosion and for MIC that the chemical treatment may not be able to overcome completely. Stagnant water can also cause deposits and corrosion. High water temperatures can cause scale. The maximum water temperature should be known so that the proper scale-control method can be used.

5-6.3 Water Quality.

Water quality within the cooling water system is a critical consideration. The source may be potable or reuse or recycled water. The various water constituents must be known so appropriate water treatment chemicals can be selected for controlling specific water quality parameters.

5-6.4 Cooling Water Treatment Programs.

5-6.4.1 Categories.

For the purpose of developing a water treatment program, cooling tower recirculating water systems can be divided into three basic categories:

- Small-sized towers – capacity less than 25 tons (88 kilowatts)
- Medium-sized towers – 25 to 100 tons (88 to 352 kilowatts)
- Large-sized towers - greater than 100 tons (352 kilowatts)

The water treatment program selected for cooling tower systems will vary depending on the size of the tower (among other factors). Treatment program considerations are described in paragraphs 5-6.5 and 5-6.6 for small-, medium-, and large-sized towers, respectively.

5-6.4.2 Cycles of Concentration (COC).

The COC of small, medium, and large cooling towers may be controlled by blowdown, either automatic or manual, to avoid the high levels of silica and calcium salts that can lead to scale. If the cooling tower is not chemically treated, the COC should be adjusted to be slightly less than the lowest allowable COC value based on all scale-forming water ingredients (see paragraph 5- 3.3). The use of chemical treatment permits a higher

COC, which is usually limited by either the chemical effectiveness or the water treatment control.

EXAMPLE: An untreated cooling tower system can operate at 10 COC based on the level of silica without scale forming, but can operate at only 2 COC based on the level of calcium carbonate. Accordingly, the tower system should be operated at a maximum of 2 COC. The system can likely be operated at 5 to 6 COC when an effective chemical treatment is applied and maintained to control calcium carbonate.

5-6.5 Treatment Program for Small Cooling Towers.

Typically a small cooling tower will have a rating of less than 25 tons (88 kilowatts). The treatment program used for small towers should be designed to be simple to control and easy to apply, with very little operator attention required. This does not mean that no attention is required, only less than that required for medium-sized systems. The treatment program for small systems is shown in Table 5-12.

Table 5-12 Small Cooling Tower Treatment Program

Parameter	Method
COC	Do not exceed COC limits for untreated water
Scale and corrosion program	Dry, slowly soluble, phosphate compound
Microbiological program	Dry, slowly soluble, oxidizing biocide
SS	Filtration and periodic wash downs, as required

5-6.5.1 Treatment.

Small systems can be treated with a low dosage (5 to 10 ppm) of a slowly soluble phosphate chemical (sodium/calcium polyphosphate) by placing a nylon mesh bag containing the product into the cooling tower. The product, if applied in this manner, will usually provide adequate scale and corrosion control. Microbiological control can be obtained by use of a dry, pelletized, oxidizing biocide, such as bromo- chlorohydantoin or isocyanuric acid plus sodium bromide (see paragraph 5-4.4.1).

Either of these biocides can be fed continuously via a feeder or suspended in a mesh bag in the cooling tower water. The cooling tower sump should be kept clean of SS and other debris by use of a filter and periodic wash downs.

5-6.6 Treatment Program for Medium and Large Cooling Towers.

The chemical treatment program for these cooling tower systems (typically greater than 25 tons [88 kilowatts]) requires sufficient, regular testing as well as water and chemical control to protect the equipment in contact with the cooling water. Usually treatment includes control of scale, fouling, microbiological growth, and corrosion. The composition of an optimum chemical treatment program for cooling towers on a military installation depends on the quality of water available, the operating conditions of the cooling system, and the environmental constraints placed on treatment chemicals in the blowdown water (effluent discharge limitations). Conditions at a particular installation may require variation of the quantity or mix of the chemicals suggested in Table 5-13.

Table 5-13 Treatment Programs for Medium and Large Cooling Towers.

Parameter	Approach
COC	Target a minimum of 3 COC (ideally 5 COC) that the chemical treatment will allow.
Corrosion control	1. Use of cathodic corrosion, possibly supplemented with anodic inhibitors for mild steel. If a galvanized cooling tower is present, use a polysilicate or low-level phosphate while keeping pH in the range of 8 to 9. 2. Copper corrosion inhibitor should be used for all copper tubes and especially for enhanced and super-enhanced copper tubing.
Scale control	Phosphonate/polymer program, augmented by a phosphate dispersant if phosphate corrosion inhibitor is used.
SS	Polymer dispersant coupled with adequate flow. Avoid no- flow conditions in heat exchangers as much as possible. Mechanical filtration and routine physical sump cleaning recommended.
Microbiological control	1. Primary biocide: oxidizing biocide using continuous feed or slug feed as an alternate. 2. Secondary biocide: non-oxidizing biocide using slug feed, as required.

5-6.6.1 Treatment.

Medium and large cooling towers are usually, but not always, treated with a liquid formulation containing both scale inhibitors and corrosion inhibitors. These are often simply referred to as an "inhibitor.” Inhibitor products are usually fed on a continuous basis using automated control and feed equipment. The concentration of these formulated products varies greatly from vendor to vendor. Biocides are usually, but not always, liquid products. It is common to use an oxidizing biocide as a primary biocide and a non-oxidizing biocide as a secondary biocide, used as needed to control bacteria and other biological growth. Oxidizing biocides can either be fed continuously at a low level or dosed periodically at a higher level. Non-oxidizers are dosed as needed and only when oxidizing biocides are either ineffective or not used at all.

5-6.6.2 Testing.

Testing should be done regularly to insure that COC, chemical levels, and bacteria levels are within the targeted control range. This requirement could demand a testing frequency of three times per week, or even daily.

5-6.7 Cooling Tower Operator Duties.

If detected early, problems associated with scaling, corrosion and fouling in a cooling tower system can be minimized by corrective action. Some of the things the operator should look for when on-site are described below.

5-6.7.1 Cooling Tower Distribution Deck.

It is important to look for the presence of algae, debris, or anything that has plugged water distribution holes causing an uneven water flow through the tower, thus lowering tower efficiency. Clean plugged holes and replace damaged water distribution spray nozzles. In addition, look for the presence of algae deposits. If algae deposits are present, increase the level or frequency of biocide or algaecide treatment, and cover the deck if uncovered.

5-6.7.2 Cooling Tower Fill, Air Intake Slats, and Basin.

5-6.7.2.1 Scale Deposits on Cooling Tower Fill.

The presence of deposits, particularly on cooling tower fill, can be established by removing some fill to determine if partial plugging has occurred. Scale can range in color from white to gray or reddish depending on the scale composition. Scale formation on the cooling tower fill usually indicates a severe scaling situation. If possible, obtain a sample of the scale for analysis and, based on the result, select a scale inhibitor for that specific scale.

5-6.7.2.2 Scale Deposits on Air Intake Slats.

Scale can form on the air intake slats of a cooling tower. This buildup is due mostly to water splashing and evaporating, causing deposition of soluble salts or minerals. This situation does not indicate a serious problem. These deposits can be, and should be, washed off periodically, but ideally not into the cooling tower basin. Chemical treatment can provide some reduction in the occurrence deposits.

5-6.7.2.3 Slime Deposits.

Slime deposits (microbiological) can sometimes be detected by feeling below the water level on the distribution deck and on the walls of the cooling tower basin. Most microbiological growth will have a slimy feel. If slime deposits are present, increase biocide frequency or increase the dosage.

5-6.7.2.4 Suspended Solids.

The purpose of a dispersant is to keep particulate solids in suspension and to prevent them from settling or from adhering to heat transfer surfaces. Adequate water flow is required to prevent them from settling. Particulate solids in suspension are removed with the blowdown water. The tower water should be turbid if the dispersant is doing its job. Keep the cooling tower sump clean of SS by cleaning periodically and using a filter.

5-6.7.3 Corrosion Test Coupons.

When removing corrosion coupons, always note and record the visual appearance with regard to the presence of scale, rust, or biomass. Take photographs of the corrosion coupons. Submit (or evaluate) coupons for corrosion rate and for the type of corrosion that is occurring.

5-6.7.4 Inside Surface of Heat Exchanger Tubes.

To effectively examine the inside (water-contacted) surfaces of heat exchanger tubes, a boroscope is needed because only a few inches of the interior can be seen visually using a flashlight. Scale deposits, typically hard and tightly adhered to the tube surface, range in color from white to gray or reddish, depending on the composition of the scale. No scale should be present. It is important to inspect heat exchanger tubes at least once per year.

Fouling-type deposits may look similar to scale deposits. Unlike scale, these deposits usually adhere loosely to the tube surface. Biomass will appear slimy and feel slippery, and will usually adhere loosely.

5-6.7.5 Chiller Performance.

Degradation of chiller performance or chiller efficiency may be a strong indication of scale or fouling problems in the chiller. If a reduction in chiller capacity occurs while cooling water is being cooled efficiently and within design parameters, then the chiller condenser section should be opened and examined. The chiller evaporator section may not contain water material scale but may be fouled with corrosion products. You should open and examine the chiller evaporator if chilled water could possibly be inadequately treated.

5-6.7.6 Cooling Tower Surfaces.

Cooling towers made of galvanized steel should be examined for white rust or possible rusty surfaces that may indicate that the galvanizing is no longer present on the metal surfaces and the steel is rusting. Cooling towers constructed of wood should be examined for wood deterioration or decay.

5-7 COOLING WATER SYSTEM START-UP AND LAYUP REQUIREMENTS.

The startup of a new cooling water system requires special consideration. Proper cooling water system layup is also important, especially for chiller tube bundles or other heat exchange equipment. For a new cooling tower system, it is important to make sure that the equipment that contacts the cooling water is clean and properly protected from initial corrosion. Also, disinfection is needed to eliminate the presence of microbiological organisms that can cause corrosion, deposits, and growth of pathogenic organisms such as Legionella bacteria. Implementation of a proper layup process is critical to prevent corrosion and microbiological growth during stagnant water conditions.

5-7.1 Stand-by Conditions.

The term “stand-by” is often applied to a chiller that is in rotation with other chillers on-line. This stand-by period could be of varying duration, from a few days to a few weeks. Rotating chillers frequently is important for minimizing stagnant conditions that lead to under-deposit and MIC corrosion. It is good practice to run the recirculation pumps through a stand-by chiller for at least 15 minutes each day to minimize corrosion. A chiller that must be left on stand-by for an extended period of weeks without recirculation should be laid up wet or dry according to procedures described in paragraph 5-7.4.

5-7.2 Common Problems during Layup or Due to Improper Initial Start-up.

Common problems that occur during layup or due to improper initial start-up include corrosion of tubes and transfer piping (sometimes to the point of failure), micro-biological growth with potential for MIC corrosion, and growth of pathogenic microorganisms.

5-7.3 Start-up of New Cooling Water Tower Systems.

5-7.3.1 Initial Cleaning.

A new cooling water tower system will contain dirt, oils, greasy films, and rust located on the metal surfaces as a result of system fabrication. A pre-operational alkaline cleaning process is required to remove the dirt, oil, grease, and rust, and to prepare metal surfaces for initial corrosion control. When galvanized steel is involved, special care must be taken so that the pH does not exceed 8.5 during the cleaning and passivation process to avoid conditions that promote white rust. The cleaning and passivating procedure for a new cooling tower system is usually part of a new system construction project and, as such, is not in the direct control of the cooling system operations personnel. Verification of the completion of these important steps is obtained from the contracting officer involved with the project. A cleaning and passivation procedure for cooling tower systems with galvanized steel is provided below. The procedure is similar for systems that do not contain galvanized steel, except that the pH restriction does not apply.

5-7.3.2 Cleaning and Passivation Procedures.

In the startup of new cooling tower systems containing complex metallurgies that include galvanized steel, follow the cleaning and passivation procedures for cooling tower systems containing galvanized steel, stainless steel, mild steel, or copper. These procedures should not be used for cleaning and passivating aluminum. Conventional chemical cleaners and typical heating, ventilation, and air conditioning (HVAC) water treatment programs use highly alkaline, high-pH water, which can initiate white rust formation on galvanized surfaces and copper tubes. Galvanized steel can simply be passivated by exposure to highly aerated water and a phosphate or polysilicate treatment. This treatment forms a zinc corrosion inhibition layer, which is a natural, dense, adherent, and protective corrosion product film. High pH (above 8.5) produces unwanted white rust that is fragile and not protective against corrosion. The following procedures are recommended.

5-7.3.2.1 Hydrostatic Testing.

Perform hydrostatic testing:

a. Inspect and remove all debris.
b. Fill the system with treated water and circulate. This should include orthophosphate or hexametaphosphate (as PO_4) at 40 to 60 ppm, and tolyltriazole (active) at 10 to 20 ppm.

5-7.3.2.2 Pre-operational Cleaning Procedure.

If the system passes hydrostatic testing, proceed immediately to this pre-operational cleaning and passivation procedure. Do not allow untreated water to be added to the system.

a. Drain and flush any debris from hydrostatic testing.
b. Dose and circulate (for 24 hours) a sufficient amount of a cleaning formula based on the volume of the system. A formulation is provided below.
c. Drain and flush the system, and clean all strainers.
d. Fill the system with makeup water and circulate for 30 minutes.
e. Take a sample of system water while it is circulating. The sample should match the makeup water supply for clarity and SS; conductivity ±10 percent; and pH ±0.3 pH units from 7.5 to 8.5.

If necessary, repeat steps a) through e) until the system water matches this description. The system should now be clean and passivated.

5-7.3.2.3 Chemical Cleaning and Passivation Formulation.

Apply this chemical cleaning and passivation formulation when the water system pH is 7.5 to 8.5; adjust pH as required. Formulation limitations may require adding separate components to keep things in solution. Other formulations may be used.

- Orthophosphate (or) hexametaphosphate (as PO4): 60 ppm
- Polyacrylate (active): 20 ppm
- Tolyltriazole (active): 10 ppm
- Sodium gluconate: 50 ppm
- Pluronic L-61 (active) (non-ionic surfactant with antifoam): 400 ppm
- Phosphate scale inhibitor: 50 ppm

5-7.3.2.4 Passivation of the System.

Supplemental corrosion inhibitors may be used in conjunction with the phosphate but are not required. Maintain and circulate the levels for the time required. After passivation, proceed to operational readiness or layup as required. Tables 5-14 and 5-15 show chemical technology used for passivation.

5-7.3.2.5 Operational Readiness.

If system operation is not required for a period of a week or more, proceed to layup. For normal operation, allow corrosion inhibitor levels to subside to maintenance levels through normal blowdown. Proceed to maintenance water treatment program.

Table 5-14 Required Chemical Technology

Inhibitor	Dosage	pH	Film Formation
Polyphosphate	40-60 ppm as PO_4	6.5-7.9	14-21 days
Orthophosphate	20-30 days as PO_4	6.5-7.9	14-21 days
Tolytriazole	10-20 days as TTA	6.5-7.9	14-21 days

Table 5-15 Supplemental Chemical Technology

Inhibitor	Dosage	pH	Film Formation
Zinc	10-20 ppm as Zn	6.5-7.5	14-21 days
Polysilicate	40-50 ppm as SiO_2	7.5-8.5	14-21 days
Molybdate	40-60 ppm as Mo	7.5-8.5	14-21 days

5-7.4 Layup of Cooling Tower Systems.

5-7.4.1 Wet Layup of Cooling Water Systems and Equipment.

Systems and system equipment such as heat exchangers, chiller tube bundles and the like can be laid up wet, but first they require a physical cleaning to remove all suspended materials. Apply corrosion inhibitors at increased dosages, usually at a level of about 4 to 5 times the normal maintenance dosage. Apply an increased dosage (within EPA limits) of a non-oxidizing biocide that has a long half-life, such as glutaraldehyde or isothiazolone.

5-7.4.2 Dry Layup of Cooling Water Systems and Equipment.

Systems and equipment can be laid up dry, although dry layup is more appropriate for a single piece of equipment, such as a chiller's condenser tube bundle or other heat exchanger. All metal surfaces must be completely dry; residual moisture is not acceptable. In humid climates you should use a desiccant such as a quicklime gel or an equivalent. Place the desiccant in as many locations as necessary and replace as required.

CHAPTER 6 CLOSED INDUSTRIAL WATER SYSTEMS

6-1 DEFINITION.

The term “closed water system” refers to a water system that is used to provide heating, cooling, or both for industrial processes or facilities. The system is sealed (closed), sometimes under pressure, and is not open to the atmosphere. No evaporation takes place and, with good operation, water is lost only minimally from the system. In general, water treatment for closed systems is much easier than for open systems. Makeup water is needed only to replace seal leakage and other incidental leakage. Because of the small makeup water requirements of these systems, they require little chemical treatment, which can be added intermittently as needed. Once properly treated, the system water does not form scale and has little or no corrosion potential. Two main types of closed water systems are used at military installations: hot water closed heating systems and chilled water closed cooling systems.

6-1.1 Hot Water Heating Systems.

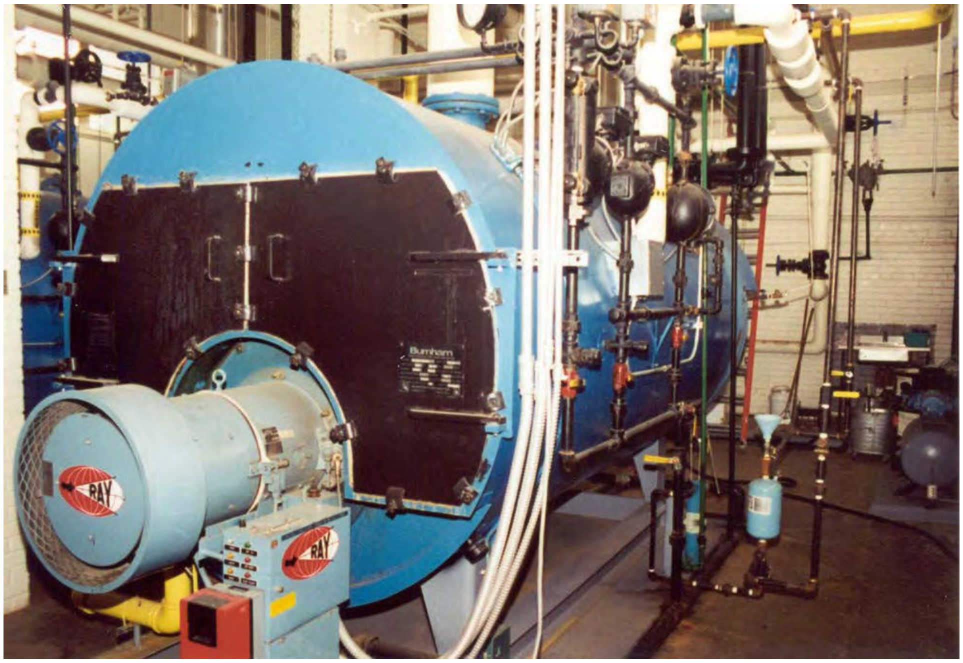
Hot water heating systems are designed to produce hot water, and although they are often referred to as hot water boilers, they are actually hot water heaters rather than boilers. For new construction, hot water heating systems are preferred over steam systems. Hot water heating systems, also known as hydronic heating systems, recirculate water to distribute heat in facilities. They operate at three temperature ranges:

- High-temperature water systems (pressurized systems with water temperatures higher than 350 F (177 C)) – no steam, only very hot water.
- Medium-temperature water systems (pressurized systems with water temperatures from 250 to 350 F (121 to 177 C)) – no steam, only quite hot water.
- Low-temperature water systems (water temperatures lower than 250 F (121 C))– no steam, only hot water.

6-1.1.1 Hot Water Boilers.

Hot water boilers can be either direct-fired (heated by combustion of gas, oil, or coal) or unfired (heat supplied by steam from a steam boiler, heated by hot water from a higher-temperature hot water system, or heated by a solar energy system). For many applications, hot water boilers are preferred over steam boilers because there are essentially no makeup water requirements and chemical treatment programs are less complex and easier to maintain. They require less manpower for operation, less maintenance, and have fewer water-related problems than steam boiler systems. Figure 6-1 shows a hot water boiler. Operate hot water boilers in accordance with UFC 3-430-07 and UFC 3-430-11.

Figure 6-1 **Hot Water Boiler**



6-1.1.2 Description of Hot Water Systems.

A typical hot water (hydronic) heating system is similar in composition to the closed cooling water system shown in Figure 6-2, except that a fired or non-fired heat exchanger is used rather than a chiller. Hot water boilers (fired and unfired) differ from steam boilers described in Chapter 4 because hot water boilers:

- Provide heated water but do not generate steam.
- Do not have deaerating heaters. (These are not required because there is essentially no makeup water requirement and thus very little air enters the system.)
- Require recirculating pumps to distribute the heated water to the processing equipment.
- Require expansion tanks that contain a cushion of steam or nitrogen.
- Do not contain a condensate return because there is no steam generated, but there is a return system.
- Do not require blowdown.
- Are fabricated with mild steel components, but also may contain copper heat exchanger tubes, particularly in unfired systems.

6-1.2 Closed Chilled Water Systems, Brine Systems, and Glycol Systems.

Closed chilled water systems, brine systems, and glycol systems supply cold or chilled water for cooling processes and air conditioning. They are water systems designed for minimal loss of water. These systems contain mild steel piping, copper heat exchangers and, in some systems, aluminum piping, stainless steel piping, cold rolled steel piping, and potentially other metals.

6-1.2.1 Closed Chilled Water Systems.

Closed chilled water systems circulate water that is cooled by refrigeration equipment. Water temperature ranges typically vary between 40 to 55° F (4 to 13° C). A typical chilled water system is depicted in Figure 6-2. Chilled water systems can have large storage capacity (1,000,000 gallons (3785 cubic meters) or higher). Chillers are shown in Figure 6-3.

Figure 6-2 **Typical Closed Chilled Water System Schematic**

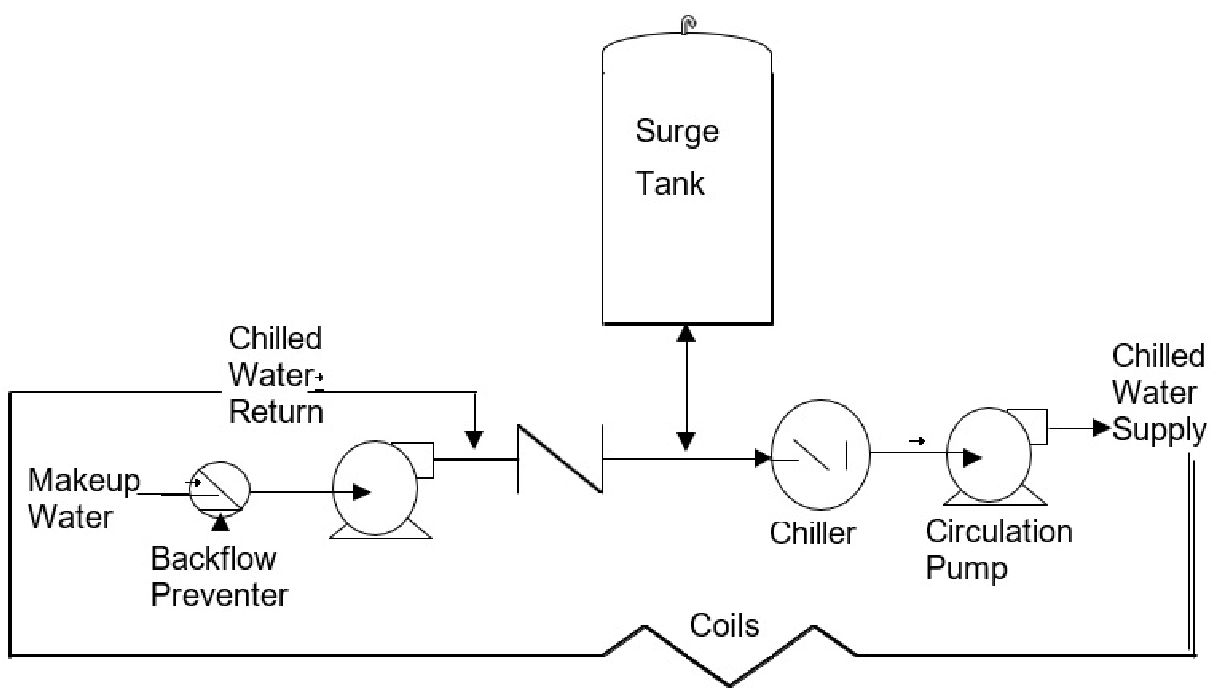


Figure 6-3 **Chillers**

6-1.2.2 Closed Brine Systems.

Closed brine systems are chilled water systems in which calcium chloride, sodium chloride, or a mixture of sodium chloride and calcium chloride has been added to the water to lower its freezing point sufficiently to maintain it as a liquid (ice-free) at temperatures of 30 to 50° F (-1 to 10° C). Brine systems have been largely replaced by glycol systems.

6-1.2.3 Closed Glycol Systems.

Closed glycol systems are chilled water systems that contain a mixture of water and glycol (ethylene or propylene) that will not freeze at the system operating temperature of 20 to 35° F (-7 to 2° C).

6-1.3 Combined Hot and Chilled Water Systems.

Some closed systems serve the dual purpose of producing circulating hot water during the cold season and chilled water during the hot season.

6-1.4 Diesel Engine Jacket Cooling Systems.

Diesel engine cooling systems are considered closed systems, even when surge tanks are open to the atmosphere.

The heat transfer from the circulating water is usually accomplished using a heat exchanger, not by evaporation. These systems have low water losses. Several of the metals used in these systems require good corrosion control. The three basic types of diesel engine cooling systems are described below.

6-1.4.1 Air-Cooled Diesel Cooling Systems.

Air-cooled diesel cooling systems are used on most small engines as well as some large engines. The jacket water is circulated through an air-cooled radiator. Antifreeze must be used in these systems when radiators are exposed to low-temperature atmospheric air or when the water temperature exceeds the boiling point (212° F (100° C))

6-1.4.2 Water-Cooled Diesel Engine Cooling Systems.

Water-cooled diesel engine cooling systems are used mainly on large engines. The jacket cooling water passes through a heat exchanger, rather than a radiator, where a separate cooling water loop removes the heat from the jacket cooling water. These systems commonly use antifreeze.

6-1.4.3 Vapor-Phase Diesel Engine Cooling Systems.

Vapor-phase diesel engine cooling systems, also called ebullient systems, use water that is heated to a temperature at the boiling point or above the boiling point for pressurized systems. Steam is formed from the cooling water as it removes heat from the system. The steam produced in this way can be recovered and used for space heating. This type of system requires significant amounts of makeup water and chemical treatment.

6-2 WATER TREATMENT FOR CLOSED SYSTEMS.

Water treatment programs for both closed hot water and closed chilled water systems are developed primarily to control corrosion, although the programs may also control deposition and microbiological organisms. If needed, scale deposition can be prevented by external treatment (as with ion exchange softening) or can be controlled with inhibitors as described in Chapter 4. Corrosion must be completely controlled by water treatment programs. If corrosion occurs, corrosion products will eventually plug the system, resulting in decreased operational efficiency and the need for cleaning. Microbiological growth is not a concern in hot water systems, but can occur in chilled water systems and should be controlled (see paragraph 6-2.3).

6-2.1 Makeup Water Requirements.

Makeup water requirements for closed systems are very small unless there are leaks in the system (see paragraph 6-2.4). Closed systems should not be drained or purged unless there is evidence that indicates the need to remove dirty water or sludge. For proper operation, makeup water in high- temperature and medium-temperature water systems is deaerated (de-oxygenated) using both mechanical and chemical methods and is also softened. Oxygen can be removed from low-temperature water systems either chemically or mechanically to prevent oxygen-induced corrosion. Chilled water systems can require partial softening if the makeup water exceeds 250 ppm total hardness (as $CaCO3$). The makeup water requirements are monitored carefully in systems of all types (see Table 6-1). If there is an increase in the quantity of makeup water required, the leak should be found and repaired quickly. After the repair, water treatment chemicals should be replenished immediately.

Table 6-1 Makeup Water Requirements for Closed Systems

System Type	Requirement
High-temperature hot water	Softened and deaerated
Medium-temperature hot water	Softened and deaerated
Low-temperature hot water	Less than 100 ppm total hardness as $CaCO_3$
Chilled, brine, glycol	Less than 250 ppm total hardness as $CaCO_3$
Diesel engine jacket	Less than 50 ppm hardness as $CaCO_3$ Demineralization when brackish water is used

6-2.2 Corrosion Control Programs.

Five basic water treatment programs are used in closed systems:

- Sulfite-caustic soda.
- Nitrite-azole.
- Molybdate-azole.
- Nitrite-molybdate-azole blend.
- Polysilicate-azole.

The choice of which chemical treatment system to use should be based primarily on the water temperature and the metals in the system as well as the relative cost of the treatment program at the specific installation. The various water treatment programs are listed in Table 6-2 for each type of closed water system. Table 6-3 provides microbiological control monitoring guidelines for closed water systems.

Table 6-2 Selection Guidelines for Closed System Treatment

System Type	Treatment Program
High-temperature hot water	Sulfite-caustic (1)
Medium-temperature hot water	Sulfite-caustic (1)
Low-temperature hot water	Sulfite-caustic (1) Nitrite-azole Molybdate-azole Nitrite-molybdate-azole
Chilled, brine, glycol	Nitrite-azole Molybdate-azole Nitrite-molybdate-azole
Diesel engine jacket	Polysilicate-azole

NOTES: (1) Or other oxygen scavenger-caustic.

Table 6-3 Microbiological Control Guidelines for Closed Water Systems

Bacterium Type	Colony-Forming Units/ml
Total aerobic bacteria	$< 10^3$
Sulfate-reducing bacteria	Undetectable
Surface microbiological	$< 10^6$ - Undetectable

6-2.2.1 Sulfite-Caustic (or other Oxygen Scavenger-Caustic) Treatment Program.

This program is required for high- and medium-temperature closed hot water systems. It is optional for low-temperature water systems. The water is treated with sodium hydroxide (caustic soda) and with sodium sulfite. This program is suitable for water systems having temperatures up to 550 F (288 C). This chemical program is not compatible with ethylene glycol nor propylene glycol. A recommended procedure for maintenance is described below.

1. Soften makeup water unless the total hardness in the makeup water supply is less than 10 ppm. The makeup water should be dealkalized if the makeup's total alkalinity is more than 200 ppm, as CaCO3.
2. Add sodium sulfite to maintain 50 to 100 ppm sulfite (as SO3).

Add the appropriate chemical to maintain a pH of 9.0 to 10.0. A pH lower than 9.0 can be raised by adding sodium hydroxide (caustic soda). A pH higher than 10.0 can be lowered by adding sodium bisulfite.

1. Test daily to maintain pH and sulfite levels within range.
2. Deaerator can be used to help reduce incoming oxygen in high make-up systems.

6-2.2.2 Nitrite-Azole Treatment Program.

This program is not recommended for systems having water temperatures exceeding 250 F (121 C), or for (CL + SO4) concentrations>800ppm. Also, avoid nitrate-based programs if (CL + SO4) concentrations is > 800ppm. It can be used in low-temperature water and chilled water systems. Water is treated with a nitrite-borax compound to a nitrite level of 1000 ppm (as NO2). This level will require about 1.7 to 1.8 pounds (0.77 to 0.81 kilogram) nitrite- borax per 100 gallons (0.38 cubic meters) of water in the system. Most water treatment service companies offer this treatment as a formulated product. There is also a generic nitrite-borax compound product that is a premixed blend containing approximately 68 percent sodium nitrite, 10 percent borax, 17 percent sodium carbonate (soda ash) and 5 percent copper corrosion inhibitor. Adjust to a pH of 9.0 to 9.5 with sodium carbonate (soda ash), if necessary. This chemical treatment program is compatible with ethylene glycol water mixtures used for freeze protection. A recommended procedure for maintenance is described below.

1. Soften makeup water if the hardness is over 250 ppm as $CaCO_3$.

2. Add sodium nitrite-borax-azole blend to maintain a nitrite level of 600 to 1000 ppm (as NO_2) in the system.
3. Add sodium carbonate, if necessary, to maintain a pH range of 8.5 to 9.5.
4. If copper is present, maintain a minimum of 10 ppm of tolyltriazole.
5. Test after chemical addition and then monthly for pH and nitrite levels.

6-2.2.3 Molybdate-Azole Treatment Program.

This program is not recommended for systems where water temperatures exceed 250 F (121 C). Most water treatment service companies offer this as a formulated product. There is also a generic molybdate-azole compound product that is a pre-mixed liquid containing approximately 10 percent sodium molybdate, 3 percent caustic soda, and 3 percent azole (copper corrosion inhibitor). Maintain a molybdate level of 125 ppm (as Mo) and adjust pH to the range of 8.5 to 9.5 with sodium hydroxide (caustic soda). NOTE: Some restrictions may pertain to discharge of water containing molybdate. This chemical treatment program is compatible with ethylene glycol or propylene glycol. A recommended procedure for maintenance of the system consists of five steps:

1. Soften makeup water if hardness is over 250 ppm as CaCO3 (calcium carbonate).
2. Control the molybdate-azole compound to maintain a molybdate level of 100 to 125 ppm (as Mo).
3. Add sodium hydroxide (caustic soda) to maintain a pH of 8.5 to 9.5. It is likely that a buffer will be needed for pH control in this range.
4. If copper is present, maintain a minimum of 10 ppm of tolyltriazole.
5. Test monthly for proper pH and molybdate levels.

6-2.2.4 Molybdate-Nitrite-Azole Treatment Program.

This program is not recommended for use in systems in which water temperatures exceed 250 F (121 C). An effective approach for corrosion control in these systems involves a program that combines elements of the molybdate program and the nitrite program. The targeted maintenance level for the combined addition of molybdate and nitrite is about half of what either would be for individual addition. Most water treatment service companies offer this chemical combination as a formulated product. This chemical treatment program is also compatible with ethylene glycol or propylene glycol. A recommended procedure for maintenance of the system consists of five steps:

1. Soften makeup water if hardness is over 250 ppm as $CaCO_3$ (calcium carbonate).
2. Control the nitrite-molybdate-azole compound to maintain a nitrite level of 300 to 400 ppm (as NO_2), a molybdate level of 50 to 75 ppm (as Mo). Avoid this program if (CL + S O_4) concentration exceeds [(NO_2 + MO)-100]ppm.

3. Add sodium hydroxide (caustic soda) to maintain a pH of 8.5 to 9.5. It is likely that a buffer will be needed for pH control in this range.
4. If copper is present, maintain a minimum of 10 ppm of tolyltriazole.
5. Test monthly for proper pH and treatment levels.

6-2.2.5 Polysilicate-Azole Treatment Program.

This program is not recommended for systems where water temperatures exceed 250 F (121 C). This program is especially beneficial when aluminum metal is present. Aluminum is rarely found in comfort heating and cooling systems, but is sometimes found in closed process cooling water loops or diesel engine jacket systems. Aluminum will corrode at high pH, so the pH of the system water must be closely monitored if aluminum is present. This chemical treatment program is also compatible with ethylene glycol or propylene glycol. A recommended procedure for maintenance of the system consists of five steps:

1. Soften makeup water if hardness is over 250 ppm as CaCO3 (calcium carbonate).
2. Control the treatment to maintain a polysilicate level of 80 to 100 ppm (as SiO2).Maintain a pH of 7.5 to 8.9. Adjust with dilute hydrochloric or caustic as necessary.
3. If copper is present, maintain a minimum of 10 ppm of tolyltriazole.
4. Test monthly for proper pH and treatment levels.

6-2.3 Treatment and Control of Microbiological Growth.

Treatment and control of microbiological growth is a concern in chilled or closed cooling water systems. It is a particular concern if a nitrite-based corrosion inhibitor is used. Nitrite can serve as a nutrient for some bacteria. Microbiocide selection must be compatible with the corrosion inhibitor program and the pH levels in the system water. Glutaraldehyde and isothiazolone are commonly used in chilled water systems. Oxidizing biocides should not be used since they are not compatible with nitrite water treatment.

6-2.4 Identifying Water Leaks.

The best way to check for leaks in a closed water system is to periodically read and record the water usage displayed by a totalizing water meter installed in the makeup water line or to use an inert, fluorescent material indicate a leak. The florescent material can also be used to help pinpoint leaks or do leak studies. If the system does not have a water meter, the existence of leaks can be checked by testing the inhibitor concentration in the circulating water. The inhibitor concentration should be measured once per month using molybdate, polysilicate, or azole, but not nitrite. Do not depend upon the nitrite test; nitrite can be lost due to bacteria action. If nitrite is measured and its concentration has decreased while the conductivity has remained constant, biological contamination is present. If the measured values for both parameters decrease, there is a leak in the system. Borate concentration would be the best indicator of leak detection.

When the inhibitor concentration has dropped to 98 percent of the original value, about 2 percent of the system water will have been lost. If the lapsed time for this 2 percent loss is less than 4 months, the system's loss of water is excessive and any leaks should be found and eliminated. Another convenient indication of water loss is the measurement over time of a drop in conductivity. If the system water conductivity equals that of the makeup, the treatment chemical is totally absent. Inert florescent material can be added to the system and used to help pinpoint leaks, or do leak studies. Loss of the fluorescent material can be monitored in real time; such loss indicates a leak.

NOTE: A 2 percent loss over 4 months equals 0.5 percent loss per month. The accuracy of this test is limited, so if the loss for any month exceeds 1 percent, the test should be repeated. If retesting confirms the water loss, the leaks should be found and eliminated.

EXAMPLE:

a. The initial recommended molybdate concentration in chilled water systems is 125 ppm. After 4 months, the concentration is 123 ppm. Is the water loss excessive?

$$\mathbf{Loss} = \left(\frac{[\mathbf{initial - final}]}{\mathbf{initial}}\right)\mathbf{x\ 100} = \left(\frac{[\mathbf{125 - 123}]}{\mathbf{125}}\right)\mathbf{x\ 100} = \mathbf{1.6\ percent\ after\ 4\ months}$$

b. The monthly loss based on the 4-month result is calculated:

$$\mathbf{1.6\ percent\ over\ 4\ months} = \mathbf{0.4\ percent\ per\ month}$$

This loss is less than 1 percent per month and not excessive.

c. If the concentration had dropped to 123 ppm after 1 month, the loss would be:

$$\mathbf{Loss} = \left(\frac{[\mathbf{125 - 123}]}{\mathbf{125}}\right)\mathbf{x\ 100} = \mathbf{1.6\ percent\ after\ 1\ month}$$

d. The monthly loss is calculated:

$$\mathbf{1.6\ percent\ over\ 1\ month} = \mathbf{1.6\ percent\ per\ month}$$

This loss is greater than 1 percent per month, and the system should be inspected for leaks.

6-2.5 Procedures for Layup of Hot and Chilled Water Systems.

Follow the procedure for wet layup of operational boilers described in paragraph 4-5.4. Note these additional recommendations:

- For hot water systems, completely fill the hot water generator and expansion tank. Where nitrogen pressurization is used for the system, the expansion tank should not be filled.

- For all steel systems using the sulfite-caustic soda program, increase the pH to 11.7 with sodium hydroxide (caustic soda). Add sodium sulfite to a level of 100 ppm (as SO3).
- Treat chilled water systems using the nitrite-borax or molybdate-caustic soda treatments with appropriate chemicals to maintain levels required for normal operation.

Test monthly for treatment chemicals and check water levels.

This Page Intentionally Left Blank

CHAPTER 7 WATER SAMPLING AND TESTING OF WATER SYSTEMS

7-1 WATER SAMPLING AND TESTING.

Water sampling and testing procedures provide information that can be used for the following purposes: to ensure the protection of the water system equipment; to prevent unexpected system failure; to provide information used to control water quality; and to verify that water treatment chemicals are maintained at the proper concentration within the system or, if not, to allow for adjustment of their concentration. Adequate chemical treatment of water systems requires that specific levels of specific chemicals be maintained in the water to provide the system with protection from corrosion and deposits. This requirement applies to both cooling and boiler water systems. The purpose of a sampling and analysis program for industrial water is to ensure and verify that the required levels of treatment chemicals are being maintained and that the water quality parameters are within the specified control ranges. The sampling and analysis program incorporates two levels of testing: in-plant routine testing used for operational purposes, and periodic independent (third-party) QA testing used for verification and oversight. When an analytical test indicates that the concentration of a given chemical is not within the limits required, the testing process must be evaluated to determine that the sampling and testing were performed properly and that the test result is valid. As part of an adequate QA/QC program, test methods, including the chemical reagents, must be checked on a yearly basis. A properly applied industrial water treatment program incorporates procedures that ensure that representative samples, which are samples that are representative of actual water system conditions, have been collected and analyzed. Safety considerations must be a priority when sampling any industrial water system (particularly boilers) and when conducting laboratory tests.

7-1.1 In-Plant Testing.

In-plant testing is used by water system operators to monitor and ensure both the proper operation of system equipment and the proper quality of the water in the equipment. Routine, appropriate, in-plant operational testing of the system waters is an essential component of a water treatment program. Routine testing of specific operational parameters and water quality criteria allows the operator to verify the adequacy of the water treatment program and to make necessary adjustments to avoid and prevent operational problems. When an analytical test indicates that the concentration of a given chemical is not within the limits required, the testing process must be evaluated to determine that the sampling and testing were performed properly and that the test result is valid. If testing data for the water quality analyses are inconsistent with that expected for the treatment method being used, the reasons must be determined. This determination can involve reanalysis and checking of the test reagents, as well as checking the accuracy of the in-plant testing results through independent QA analysis. Military installations are required to obtain water testing chemicals and equipment from commercial sources. Test procedures will be furnished with the test kits.

7-1.2 Independent QA Analysis.

To verify the accuracy of the in-plant testing, as well as to provide supplemental or additional analyses, independent (third-party) QA analytical services are incorporated as part of the plant's QA program. These services can be more complete than routine in-plant testing and can provide a more detailed analysis of the system conditions. Independent QA analysis is a useful tool for plant managers and operators to verify that their systems are being maintained properly, and is an especially important tool for government managers at sites where plant operations have been contracted out (outsourced).

7-2 COOLING TOWER WATER SAMPLING AND TESTING.

7-2.1 Cooling Water Testing Requirements.

Water samples from the recirculating cooling water systems should be tested for pH, conductivity, and inhibitor content. Calcium hardness and methyl orange (M) alkalinity may also be tested. In addition, follow the water testing requirements established by the supplier of the water treatment chemicals where appropriate. Testing parameters for the makeup water include, as a minimum, M alkalinity, conductivity, and calcium hardness. Appropriate water testing requirements and sampling frequency are summarized in Table 7-1. Periodic testing for chlorides in the recirculating water and makeup water may be required to calculate the most accurate COC in an operating system.

Table 7-1 Recommended Water Sample Frequency and Testing Requirements for Cooling Tower Systems

Water Tested	pH	M Alkalinity	Conductivity (or TDS)	Calcium Hardness	Inhibitor
Makeup water	--	1/W	1/W	1/W	--
Small CT < 25 tons (88 kW) water*	1/W	1/W	1/W	1/W	1/W
Medium CT 25-100 tons (88-352 kW) water*	2/W	2/W	2/W	2/W	2/W
Large CT > 100 tons (352 kW) water	1/D	1/D	1/D	1/D	1/D

NOTES:

C = Cooling tower.

W = Week (for example, 1/W = once per week).

D = Day (for example, 1/D = once per day).

* = Slowly soluble polyphosphate chemicals used in treatment of small and medium cooling towers should be checked at least weekly and replaced as necessary.

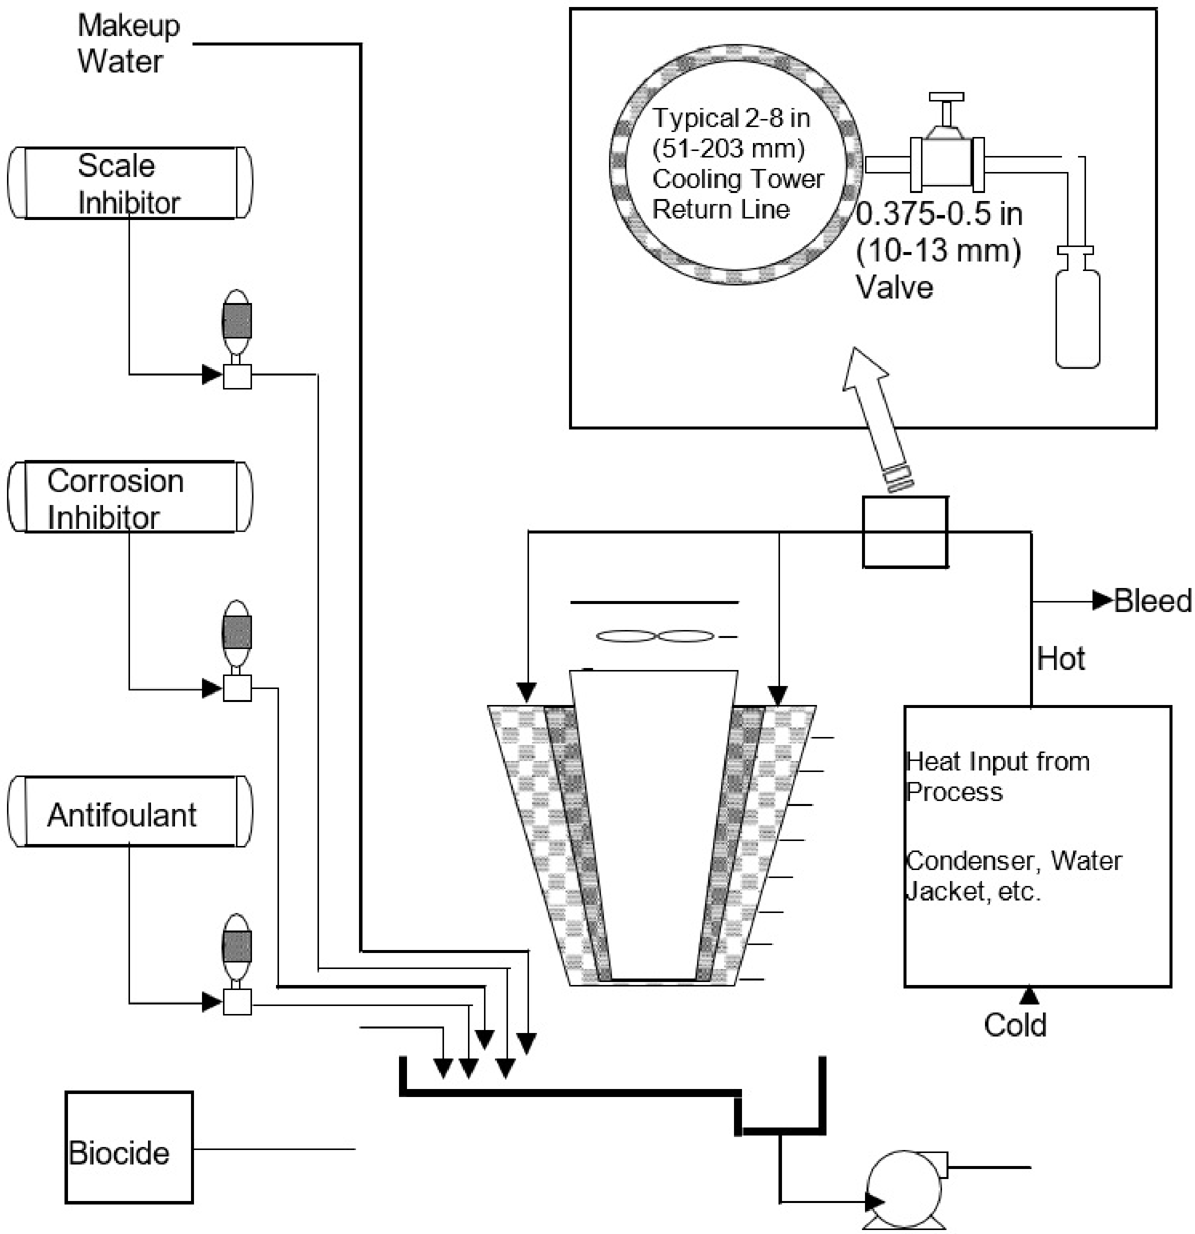
7-2.2 Frequency of Cooling Water Sampling and Testing.

Water samples of the recirculating water in small towers (less than 25 tons [88 kilowatts]) be sampled and tested at least once per week, those of medium-sized towers (88 to 25 to 100 tons (352 kilowatts)) at least 2 times per week, and those of large towers (more than 100 tons (352 kilowatts)) daily. You can establish a routine schedule that is designed to meet these goals for sampling and testing. For many cooling towers, the makeup water quality is quite consistent over time. Collection and analysis of 1 sample per week of the makeup source is usually an adequate frequency. If makeup water quality varies, increase the frequency to allow for sampling of makeup water at the same time as cooling water sampling. Always flush the water sample line prior to sampling.

7-2.3 Cooling Water Sampling.

Cooling tower water samples are collected in clean, 1-quart (1-liter) glass or plastic bottles. The bottle is capped (sealed) immediately and tested without delay (within 1 hour since some water quality will gradually change). The sample is not collected immediately after the addition of treatment chemicals but is collected after the chemicals have been allowed to mix thoroughly with the system water. Samples of the recirculating cooling water can be collected by dipping from the cold well, or can be collected from the recirculating pump discharge after the line has been flushed for 10 seconds or until no sediment remains. If these locations are inaccessible, another location may be used. Typical sampling points for an open recirculating system are shown in Figure 7-1. It is best to always collect the sample for each system in the same manner and from the same location for consistent results.

Figure 7-1 **Typical Water Sampling Points for an Open Recirculating Cooling Water System**



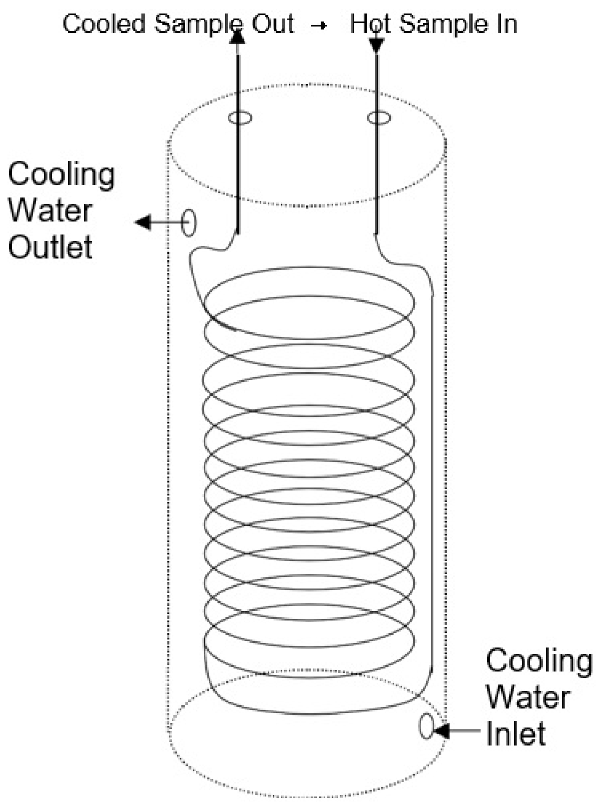
7-3 ROUTINE BOILER WATER SAMPLING AND TESTING.

Boiler water is very hot and under pressure. Caution should be exercised and appropriate safety procedures followed when collecting samples. If the boiler water is not cooled as it is sampled, part of the water will flash off as steam during the sampling process and the remaining sample will not be truly representative of the boiler water. The sample could contain a lower level of oxygen or carbon dioxide than the actual levels in the boiler water. Values of other sample constituents would be higher because less water would be present in the test sample due to the release of the steam. Use of the sample cooler described in paragraph 7-3.1 will greatly reduce the chance of the operator getting burned, and will allow a representative boiler water sample to be collected.

7-3.1 Boiler Water Sampling Cooler.

A commercially available boiler water sample cooler can be used when collecting a boiler water sample. If one is not available, then a 15 to 20 foot (4.6 to 6.1 meter) long coil of copper or stainless steel tubing 0.25 inch (76 millimeters) may be used to cool the sample. The coil can be immersed in a permanent cooling jacket as shown in Figure 7-2, or it may be immersed in a bucket of cold water, if this does not interfere with operation of the system or create a hazard. The flow of the boiler water sample through the coil must be slow enough so that the cooled boiler water sample is no more than just warm to the hand approximately 100° F (38° C).

Figure 7-2 **Boiler or Condensate Water Sample Cooling Coil.**



7-3.2 Boiler Water Sampling Procedures.

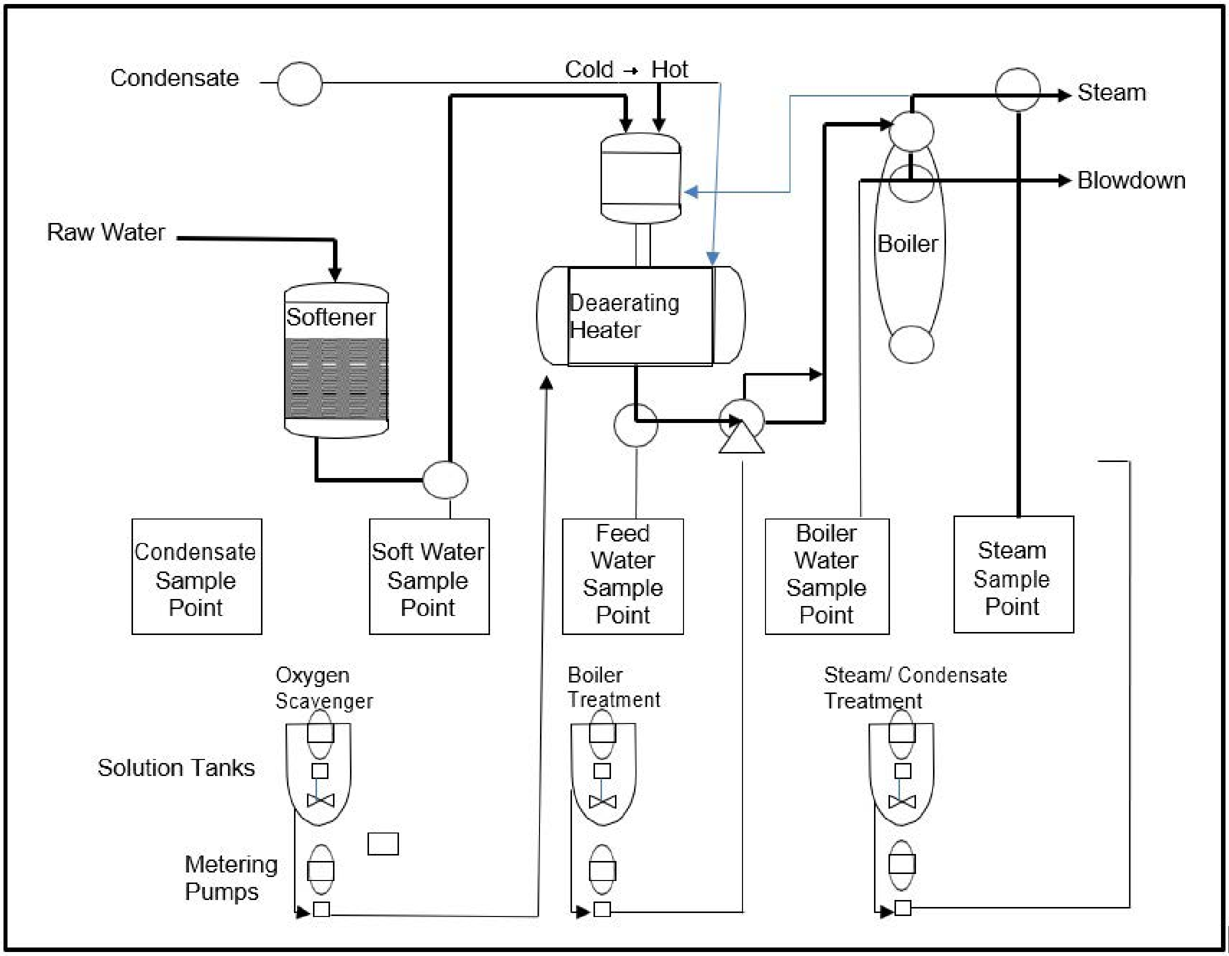
The cooling water to the jacket cooling coil is turned on before taking the boiler water sample and turned off after the sample has been collected. The coil with boiler water is flushed with several times its volume before collecting the sample to be tested. The cooled end of the boiler water sample coil is then extended to the bottom of the sample bottle and at least 1 volume of the bottle is allowed to overflow the container during the collection process. The sample collection bottle can be plastic or glass. Glass bottles are not used if the boiler is silica limited or if high silica is suspected.

7-3.3 Sampling Locations.

Typical locations for water sampling points in a steam boiler system are shown in Figure 7-3. Each sampling point has a separate cooling coil. Two or more sampling points are not connected by a single manifold to the same cooling coil because it is almost impossible to determine if one of the valves has a leak that might contaminate the sample being taken. Guidelines for sample collection are provided below.

- The makeup water sample does not have to be cooled. The sample location typically will be the output of an ion exchange unit or some other water-softening unit.
- The boiler feedwater sample is a combination of makeup and condensate return. An appropriate location for sample collection is from the discharge of the boiler feed pump. This will be a hot sample, so a cooling coil is used. Alternatively, sample collection for feedwater can be from the low-pressure deaerator outlet.
- The boiler water is very hot. Collect this sample from the continuous blowdown line between the boiler and the regulating valve if possible. You may collect it from a gauge-glass connection, if necessary. Use of a cooling coil is recommended.
- The steam condensate is hot. For small systems, collect this sample from a line that enters the deaerating heater if possible. For medium and large systems, you may need to collect condensate samples at two or more locations in the system to obtain sufficient data for calculation of the proper treatment level. When attempting to find a leak, you may need to collect condensate samples from various locations in the system. Use of a cooling coil is recommended.
- Steam is collected regularly for systems with high-quality steam requirements like those with turbines and those meeting NAVSEA steam quality requirements. Otherwise, steam samples are rarely collected. Refer to the ASME Performance Test Code (ASME PTC 19.11, Steam and Water Sampling, Conditioning and Analysis in the Power Cycle, for sampling procedures.

Figure 7-3 **Typical Locations for Water Sampling in a Steam Boiler Water System**



7-3.4 Frequency of Sampling and Testing.

The recommended sampling and testing frequency for steam boiler systems is summarized in Table 7-2.

Table 7-2 Water Sampling Frequency and Testing Requirements for Boiler Water Systems

Source of Sample	pH	Total Alkalinity* (M)	Hydroxyl Alkalinity (Causticity)	Calcium Hardness	TDS	Copper and Iron	Ortho-phosphate	Sulfite
Makeup water	--	1/W	--	1/W	1/W	--	--	--
Feedwater, small boilers (<25 hp [245 kW])	--	1/W	--	1/W	1/W	--	--	--
Feedwater, medium boilers (25-150 hp [245–1470 kW])	--	2/W	--	2/W	2/W	--	--	--
Feedwater, large boilers (>150 hp [1470 kW])	--	1/D	--	1/D	1/D	--	--	--
Boiler water, small boilers	1/W	--	1/W	--	1/W	--	1/W	1/W
Boiler water, medium boilers	2/W	--	2/W	--	2/W	--	2/W	2/W
Boiler water, large boilers	1/D	--	1/D	--	1/D	--	1/D	1/D
Condensate return (small boilers)	1/W	--	--	As needed	1/W	1/Q	--	--
Condensate return (medium boilers)	2/W	--	--	As needed	2/W	1/Q	--	--
Condensate return (large boilers)	1/D	--	--	As needed	1/D	1/Q	--	--

NOTES:

W = Week (for example, 1/W = once per week)

D = Day (for example, 1/D = once per day)

Q = Quarter (for example, 1/Q - once per 3 months)

* = Feedwater alkalinity only for boilers that use dealkalizers.

7-3.5 Boiler Feedwater Sample.

Boiler feedwater samples should be collected once per week for small boilers (less than 25 horsepower/245 kilowatts), at least 2 times per week for medium boilers (25 to 150 horsepower/1470 kilowatts), and daily for large boilers (greater than 150 horsepower/1470 kilowatts). The samples should be tested for M alkalinity, conductivity, and calcium hardness.

7-3.6 Condensate Water Sample.

Condensate water samples should be collected once per week for small boilers (less than 25 horsepower/245 kilowatts), at least 2 times a week for medium boilers (25 to 150 horsepower/1470 kilowatts), and daily for large boilers (greater than 150 horsepower/1470 kilowatts). The samples should be tested for pH and conductivity. If the conductivity is greater than 35 micromhos, the sample should be tested for calcium hardness. If applicable based on the metallurgy of the system, the condensate samples should be tested for iron and copper on a quarterly basis.

7-3.7 Boiler Blowdown Water Sample.

Boiler blowdown water samples should be collected for small boilers (less than 25 horsepower/245 kilowatts) once per week, for medium boilers (25 to 150 horsepower/1470 kilowatts) at least 2 times per week, and for large boilers (greater than 150 horsepower/1470 kilowatts) daily. The samples should be tested for hydroxyl (OH) alkalinity (causticity), neutralized conductivity, scale treatment chemicals (for example orthophosphate), and sulfite.

7-3.8 Boiler Water QA Analysis.

The components of a boiler water QA program are described in paragraph 2-1.10.1. Appropriate boiler water sampling requirements are described below.

- Each operating boiler plant equipped with hot water or steam boilers and having one or more boilers of 3.3 million BTU per hour or 100 horsepower (980 kilowatts) or greater capacity may submit a boiler water sample for QA once per month to an independent QA laboratory or to the contractor providing the service to the military. These QA contractors are independent experts in the field of boiler and cooling water treatment and interpretation of sample analysis data.
- Each operating boiler plant equipped with hot water or steam boilers of less than 100 horsepower (980 kilowatts) capacity submits a boiler water sample for QA once every 3 months to an independent QA laboratory or to the contractor providing the service to the military.
- For all high-pressure (greater than 15 pounds per square inch gauge (103 kilopascals)) boilers and for low- pressure boilers treated with caustic, phosphate, tannin, and sodium sulfite, the boiler water sample size is a 1-liter plastic bottle, or as required by the QA laboratory.
- For low-pressure boilers (less than 15 pounds per square inch gauge (103 kilopascals)) treated only with caustic, the boiler water sample size is a 0.12-liter (4-ounce) plastic bottle, although a 1-liter plastic bottle may be used.
- For hot water boilers, the boiler water sample size is a 1-liter plastic bottle, or as required by the contract laboratory.

- Boiler water sample shipping containers and bottles used for submitting boiler water check samples can be obtained by request to the contract laboratory. Shipping containers for high-pressure boiler water samples are designed for shipping a 1-liter plastic bottle. Shipping containers for water samples from low-pressure boilers treated with caustic soda are designed for shipping a 0.12-liter plastic bottle. Pack the bottle carefully so it will not leak during shipping. A completed information data sheet must be enclosed in each sample shipping container shipped to the laboratory.

7-4 WATER SAMPLING AND TESTING FOR CLOSED HOT AND CHILLED CIRCULATING WATER SYSTEMS.

The recommended testing frequency for these systems is summarized in Table 7-3, with additional information provided below.

Table 7-3 Water Sampling and Testing Requirements for Closed Hot and Chilled Circulating Water Systems

System	pH	Sulfite	Nitrite	Molybdate	Total Hardness	Total Alkalinity
HTW with caustic-sulfite treatment	1/day	1/day	--	--	--	--
Closed MTW & LTW hot water w/nitrite-borax treatment	1/mo	--	1/mo	--	--	--
Closed MTW & LTW hot water w/molybdate treatment	1/mo	--	--	1/mo	--	--
Chilled water & brine; w/molybdate treatment	1/mo	--	--	1/mo	--	--
Chilled water & brine w/nitrite-borax treatment	1/mo	--	1/mo	--	--	--
Diesel jackets w/molybdate treatment	1/mo	--	--	1/mo	--	--
Diesel jackets nitrite- borax	1/mo	--	1/mo	--	--	--
Ion exchange feedwater	--	--	--	--	1/week	--
Ion exchange outlet	--	--	--	--	3x/day	--
Dealkalizer feedwater	--	--	--	--	--	1/week
Dealkalizer outlet	--	--	--	--	--	3x/day

7-4.1 Sampling and Testing of Makeup Water.

The makeup water for boiler systems, chilled water systems, and diesel engine jacket water systems usually comes from an ion exchange unit or a dealkalizer.

The recirculating water from high-temperature water systems and from systems that use the sulfite-caustic soda treatment program is tested once per day for pH and sulfite (see paragraph 7-2.2.1).

Recirculating chilled water and hot water treated with the nitrite-borax or molybdate programs is tested once per month for either molybdate or nitrite, depending upon the chemical in use (see paragraph 7-2.2.2, 7-2.2.3 and 7-2.2.4). The system pH is tested once per month and on the day following chemical additions.

7-4.2 Ion Exchangers and Dealkalizer Water.

The recommended water testing frequencies for these systems are summarized in Table 7-3, with additional information provided below.

7-4.2.1 Influent Water Testing.

Ion exchange influent water is tested once per week for total hardness. Dealkalizer influent water is tested once per week for total (M) alkalinity.

7-4.2.2 Effluent Water Testing.

Effluent water from these systems is tested for total hardness either once per day or once per shift (3 times a day) depending on the frequency of regeneration; more frequently if the frequency of regeneration is excessive. The appropriate frequency (cycle length) will depend upon feedwater hardness, bed size, resin type, strength of regenerant, and flow rate.

7-4.2.3 Sampling Location.

The location of the water sample point is an important consideration for ensuring that a representative water sample is obtained. Care must be taken to avoid collecting a sample that is a mixture of influent and effluent water on ion exchange units that use automatic regeneration and multi-port valves.

7-4.2.4 Brine Testing.

The brine used for regeneration is sampled periodically and tested with a hydrometer to measure its strength. The sodium chloride brine should be as near 100 percent saturation as possible (approximately 28 percent by weight) for efficient softener regeneration.

7-5 WATER TESTING.

Routine and appropriate testing of the system water is an essential component of a water treatment program. Water testing provides information that can be used: to ensure the protection of the water system equipment; to prevent unexpected system failure; to provide information used to control water quality; and to verify that water treatment chemicals are maintained at the proper concentrations within the system or, if not, to allow for adjustment of their concentrations. An adequate testing program requires proper recordkeeping of the data that are used for assessing the effectiveness of the water treatment program. If testing data for the water quality analyses are inconsistent with that expected for the treatment method being used, determine the reasons. This determination can involve reanalysis and checking of the test reagents. If the test results are correct, the water quality and water treatment program must be re-evaluated and modified, if necessary. Paragraph 7-6 describes interpretation of water test results.

7-5.1 Water Sample Testing Methods.

Water tests are usually performed with test kits obtained from commercial sources. Test kits can be used to test for: alkalinity- phenolphthalein (P); alkalinity-methyl orange (M or total); alkalinity-hydroxyl (OH) or “causticity”; conductivity; tannin; pH; hardness (total and calcium, magnesium by difference); phosphate (ortho and total); sulfite; nitrite; chloride; molybdate; phosphonate; chlorine or bromine (total and free); total iron; and total copper.

7-5.2 Corrosion Testing.

Corrosion test specimens or corrosion testing instruments can be used to monitor the rate of corrosion. Corrosion test information can also be used to evaluate how well equipment is being protected from corrosion by the water treatment program. The degree of corrosion (if any) that is occurring in large or critical heating and cooling systems should be determined at all military installations.

Consider the following information when developing a program of corrosion testing:

7-5.2.1 Corrosion Test Coupons.

Corrosion test coupons are usually used as corrosion test specimens for open and closed cooling systems, closed hot water systems, and domestic water systems (see Appendix C).

7-5.2.2 Corrosion Pipe Inserts.

Corrosion pipe inserts are often used as corrosion test specimens in steam condensate return systems (see Appendix D).

7-5.2.3 Commercial Resources for Testing.

Corrosion test coupons and testing analysis services can be obtained from commercial sources. Corrosion pipe insert assemblies for steam condensate systems and analytical evaluation of the test inserts should be obtained from a QA laboratory or contractor under contract with the military. Guidance for corrosion testing is provided in Appendices C and D.

7-5.2.4 Corrosion Test Results.

Corrosion test results are usually determined as a rate of corrosion penetration into the metal and reported in mils metal loss per year (mpy). A one-thousandth [0.001] of an inch (mil is 2.5-thousandths of a centimeter); thus, the corrosion rate of 10 mpy means that the thickness of a piece of metal is reduced by 10 x 0.0025 = 0.025 centimeter per year (0.01 inch per year). If the metal coupon being studied is 0.1588 centimeter (0.0625 inch) thick, this means that it will be completely dissolved or corroded in just over 6 years. Corrosion rates may also be expressed in millimeters per year (mmpy) corrosion. The relationship between mpy and mmpy is: 1 mpy = 0.0254 mmpy; 1 mmpy = 39.4 mpy. Corrosion also may be given as a weight loss in milligrams per square decimeter per day (mdd). For mild steel, the relationship is: 1 mdd = 0.2 mpy or 1 mpy = 5 mdd.

7-5.2.5 Testing Instruments.

A variety of electronic instruments are available to monitor and record corrosion rates. These instruments are installed and maintained by individuals who have been adequately trained for these activities. The most commonly used instrument of this type is a linear polarization corrosion instrument that provides instantaneous corrosion measurement and is often used for troubleshooting.

7-5.2.6 Heat Transfer Corrosion Test Equipment.

Heat transfer corrosion test equipment is used to determine the corrosion rate under heat transfer conditions. This type of equipment can more accurately determine corrosion in chillers.

7-6 INTERPRETATION OF RESULTS FROM WATER TESTS.

Adequate chemical treatment of water systems requires that specific levels of specific chemicals be maintained in the water to provide the system with protection from corrosion and deposits. This requirement applies to both cooling and boiler water systems. When an analytical test indicates that the concentration of a given chemical is not within the required limits, the testing process must be evaluated to determine whether sampling and testing were performed properly and the test result is valid. As part of an adequate QA/QC program, test methods, including the chemical reagents, must be checked on a routine basis. Consider these guidelines when evaluating test results:

- When the (valid) test results indicate a treatment level that is too low, the chemical addition program should be evaluated and the appropriate adjustment made; this normally means increasing the chemical feed rate by 10 percent or less. If adjustments to the treatment program do not correct the situation, then the entire water system may need to be evaluated to determine the nature of the problem. You can obtain assistance through the military offices suggested in paragraph 2-1.10.2.

- When the (valid) test results indicate that a given level of treatment chemical is too high, the chemical addition program should be evaluated. Exercise caution when reducing chemical feed rates to adjust the level of a treatment chemical that exceeds the required limits. The chemical feed rate should not be reduced more than 5 to 10 percent at any one time.
- When the test results indicate that the level of hardness in the water is higher than the required level, the makeup water treatment system should be investigated and problems identified, including other possible incoming sources of water hardness into the system.

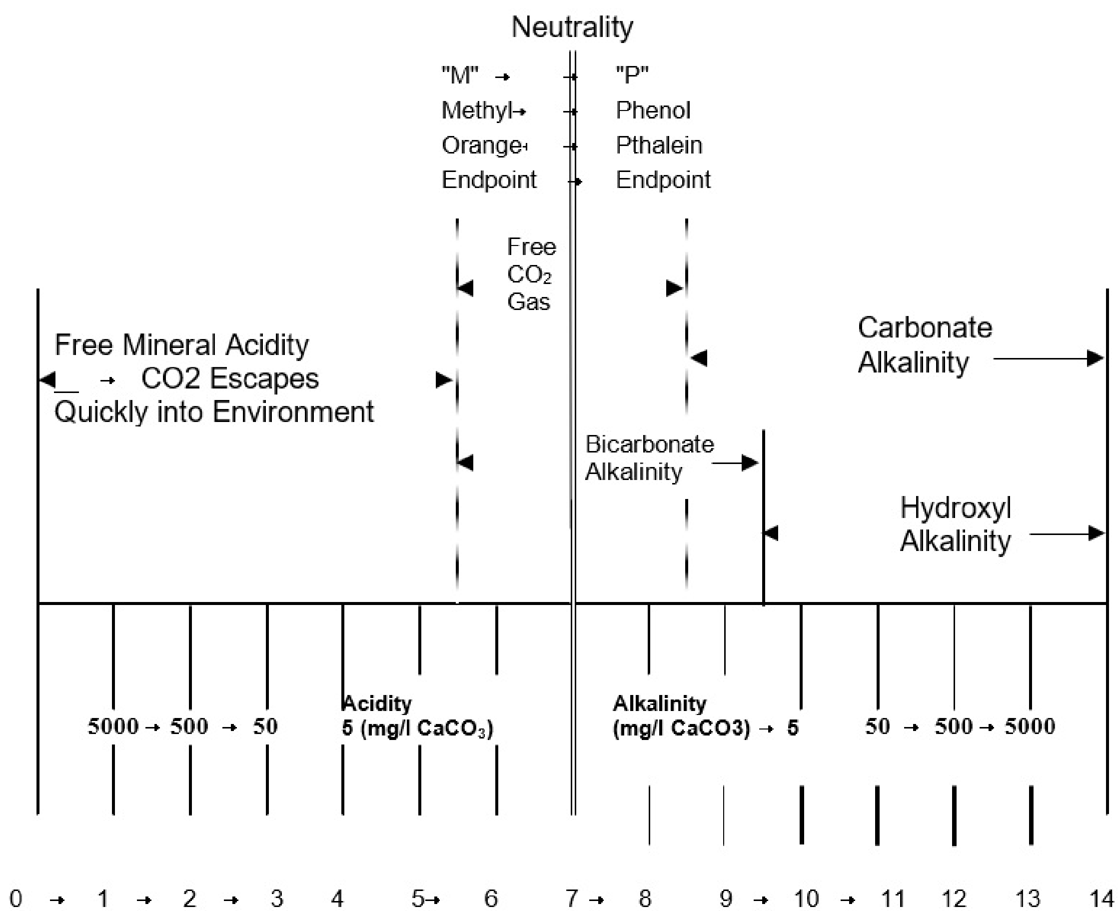
7-6.1 Alkalinity Test Relationships.

7-6.1.1 Sources of Alkalinity.

The three basic sources of alkalinity in water result from the bicarbonate ion (HCO $^{-}$), the carbonate ion (CO $^{-}$), and the hydroxyl ion (OH^{-}).

The amount of each of these ions in water can be determined by titration with an acid to specific pH levels (end points) using phenolphthalein (P alkalinity) or methyl orange (M alkalinity) indicators to their particular titration end-points. The relationship between pH and the various types of alkalinity is shown in Figure 7-4.

Figure 7-4 **Acidity, Alkalinity, and pH Ranges.**



7-6.1.2 Relationship of P, M, and OH Alkalinities.

Test procedures for determining P and M alkalinities are included in commercially available test kits. The OH^- alkalinity can be determined by a specific test or it can be estimated by knowing the P and M alkalinity values. The OH^- alkalinity is contributed by the hydroxyl ions (OH^-) in the water, and is also known as "caustic alkalinity" or "causticity." The relationship between the measured P and M alkalinity values and the level of hydroxyl, carbonate, and bicarbonate forms of alkalinity are shown in Table 7-4 and described below.

Table 7-4 Alkalinity Relationship Based on P and M Tests

Situation	Hydroxyl	Level of Alkalinity Contributed by Carbonate	Bicarbonate
P = M	M	0	0
P > ½M	2P – M	2 (M - P)	0
P = ½M	0	M	0
P < ½M	0	2P	M - 2P
P = 0	0	0	M

EXAMPLE:

If P = 86 ppm as CaCO3, and if M = 118 ppm as CaCO3 Then, situation 2 (from Table 7-4) exists (P > ½M)

or P is greater than ½ of M);

Hydroxyl = 2P - M = (2 x 86) - 118 = 54 ppm as CaCO3 Causticity = hydroxyl alkalinity as CaCO3 ÷ 3

= 54 ÷ 3 = 18 ppm as OH^-

Carbonate = 2(M – P) = 2 X (118 - 86)

= 64 ppm as CaCO3 Bicarbonate = 0 ppm as CaCO3

Check: Total = 54 + 64 + 0 =118 ppm M alkalinity as CaCO3

Review of each situation in Table 7-4 provides this information, with situation:

1. The tests for P alkalinity and M alkalinity are equal. This means that all of the alkalinity is due to hydroxyl ions. There is no carbonate or bicarbonate present. (This is rare but occurs when a caustic solution is not exposed to air.
2. The P alkalinity is greater than one-half of the M alkalinity. This indicates that there is hydroxyl and carbonate alkalinity, but no bicarbonate alkalinity.

3. The P alkalinity is equal to one-half of the M alkalinity. This indicates that all the alkalinity is due to carbonate. There is no bicarbonate alkalinity, and the hydroxyl alkalinity is insignificant.
4. The P alkalinity is less than one-half of the M alkalinity. This indicates that carbonates and bicarbonates are present.
5. The P alkalinity is zero. The M alkalinity is due to bicarbonates only. No hydroxyl or carbonate alkalinity are present.

7-6.2 pH (Hydrogen Ion Concentration).

7-6.2.1 Meaning of pH.

The pH (value) is a measure of the acidity or alkalinity of water. The test specifically measures the concentration of hydrogen ions in the water. Neutral water will have a pH of 7. Water with a value of less than pH 7 is considered acidic, while water with a value greater than pH 7 is considered alkaline. Examples are shown below.

- Common pH values for materials on the acid side include: spinach with a pH of approximately 5.5; orange juice and most soft drinks with a pH of approximately 3.5; lemon juice with a pH of approximately 2.2; and 0.1 normality (N) sulfuric acid with a pH of 1.2.
- Common pH values of materials on the alkaline side include: sodium bicarbonate with a pH of approximately 8.4; milk of magnesia with a pH of approximately 10.5; household ammonia with a pH of approximately 11.5; and 0.1 N sodium hydroxide with a pH of 13.0.

The pH scale is logarithmic. A pH of 4 is 10 times as acidic as a pH of 5 and 100 times as acidic as a pH of 6. This is important to consider when adding a strong acid to a system, because 0.1 N sulfuric acid will have more than 1 million times the acidity of neutral water.

7-6.2.2 Relationship to Causticity.

When the pH of water exceeds a value of 9.6 to 9.8, a measurable concentration of hydroxyl ions (OH^-) is present in the water. As the hydroxyl alkalinity (causticity) increases, the pH of the solution also increases. The relationship between causticity and pH is shown in Table 7-5.

Table 7-5 Relationship Between Causticity and pH

pH	Hydroxyl Alkalinity (ppm)	
	as $CaCO_3$	as OH
9.0	0.5	0.17
9.5	1.6	0.54
10.0	5	1.70
10.2	8	2.72
10.5	16	5.44
10.6	20	6.80
10.7	25	8.50
10.8	33	11.2
10.9	40	13.6
11.0	50	17.0
11.1	63	21.4
11.2	79	26.9
11.3	100	34.0
11.4	126	42.8
11.5	158	53.7
11.6	199	67.7
11.7	250	85.0
11.8	315	107
11.9	397	135
12.0	500	170

7-6.3 Conductivity and TDS.

Each of these water quality parameters is a measure of the amount of soluble minerals present in the water. Conductivity is measured with an electronic instrument based on the flow of an electrical current through the water sample. The measurement of TDS requires evaporation of a fixed amount of water to determine the weight of the remaining minerals (like the TDS in the water). The conductivity instrument may report the mineral content as micromohs or as dissolved solids. In neutral or alkaline waters, there is no consistent relationship between conductivity and TDS since each ion has its own specific conductivity. The hydroxyl ion has the highest conductivity of all the common ions found in boiler water. If alkaline boiler water is acidified to the phenolphthalein end-point with an organic acid, such as gallic acid, which neutralizes causticity but does not contribute to conductivity, the TDS is approximately equal to two-thirds of the neutralized conductivity in micromhos. This is known as “neutralized conductivity." In boiler water, a factor of 0.7 can be used for water treated with synthetic polymers as a sludge dispersant, and from 0.7 to 1.0 for water treated with Quebracho tannin, depending on the amount of tannin in the water. Conductivity and TDS are used to determine the COC and the potential for scale formation (see Chapter 4).

7-7 IN-PLANT LABORATORY WATER TESTING REQUIREMENTS.

The water tester should be provided with a separate working space to perform the required routine water control tests. This space can be a separate room having a suitable work bench, a sink and cabinet, a distilled or deionized water source, and adequate ventilation, heating, and cooling. Standard white fluorescent lighting at reading intensity can be provided. A record file for test results and references can be located in the test area.

7-7.1 Recommended Laboratory Equipment.

At each location, laboratory equipment should be selected so that all routine water tests can be performed. The equipment list can include standard glassware such as beakers, test tubes, graduated cylinders, and casseroles so the tests can be performed efficiently. The equipment required for each test can be included with the appropriate test kit.

7-7.2 Chemical Reagents.

A master list of chemical reagents can be maintained. The list includes testing reagents that are stocked, their reference number, the quantity of stock, and the test for which the reagent is used. The minimum stock level should be defined and the reagent ordered when that level is reached. The chemical reagents required for field tests will be included with the appropriate test kit. The supplier provides an SDS for each of the chemical reagents, and it should be kept in the vicinity of the test area in case of an emergency.

CHAPTER 8 WATER TREATMENT CHEMICAL FEED AND CONTROL

8-1 CHEMICAL FEED AND CONTROL SYSTEMS.

Chemical feed and control systems are designed primarily for dynamic industrial water systems that require regular use of chemicals and control of makeup water and blowdown. These systems consist of integrated components, including sensors, automatic valves, and chemical pumps. Some of the ancillary components include drum level sensors, alarms, and telecommunications for remote monitoring. Normally, a mechanical design engineer will develop the specifications for a chemical control and feed system.

8-1.1 Controller Types.

Water quality controllers are of two types. For cooling towers or boilers, a stand-alone type controller is the most commonly used and can be obtained from the manufacturer or from a water treatment service company. The other type of controller is an integrated component of a building management system. In many instances both types of controllers will be used for a given system, with one controller being used to augment the monitoring of the water system performance. This Chapter focuses on the stand-alone type controllers.

8-1.1.1 Cooling Tower Water Controllers.

Cooling tower water controllers control blowdown and chemical inhibitor feed, as a minimum. Inhibitor feed can be tied into blowdown; however, it is preferable to have inhibitor feed independent of blowdown to allow for adequate feed in cases in which excessive drift (uncontrolled blowdown) results in no requirement for controlled blowdown. Remote monitoring can also control biocide feed and pH control. The most desirable cooling water inhibitor feed control strategy incorporates real-time, continuous measurement of the inhibitor concentration in the recirculating system water. The controller should then make precise chemical feed adjustments based on the real-time measurement, so that treatment levels can be reliably maintained. The typical controllers used in cooling systems are listed in Table 8-1.

Table 8-1 Cooling System Controller Functions

Function	Type
Blowdown control	1. Conductivity 2. Timer
Chemical inhibitor feed	1. Water meter initiated 2. Function of blowdown 3. Continuous percent time 4. Calendar 5. Based on real-time, continuous measurement of the inhibitor concentration in the recirculating system water.
Biocide feed	1. Calendar 2. ORP (oxidation-reduction potential for oxidizing biocides)
pH control	pH electrode
Remote monitoring	1. Alarms 2. Telecommunications (wired, wireless, or internet)

8-1.1.2 Boiler Water Controllers.

Boiler water controllers control blowdown and chemical inhibitor feed, as a minimum. Chemical feed can be accomplished through any of several modes (continuous, water meter-initiated, blowdown, pH), depending on the requirement. Remote monitoring can also be established. The most desirable boiler water chemical feed control strategy incorporates real-time, continuous measurement of the chemical concentration in the water. The controller should then make precise chemical feed adjustments based on the real-time measurement, so that treatment levels can be reliably maintained. Typical controllers used in boiler water systems are listed in Table 8-2.

Table 8-2 Steam Boiler System Controller Functions

Function	Type
Blowdown control	1. Conductivity 2. Timer 3. Percent flow
Chemical inhibitor feed	1. Water meter initiated 2. Function of blowdown 3. Continuous percent time 4. Calendar 5. Based on real-time, continuous measurement of chemical concentration in the water
pH control	pH electrode
Remote monitoring	1. Alarms 2. Telecommunications (wired, wireless, or internet)

8-1.2 Chemical Pumps.

Chemical pumps are selected by the specific application for which they will be used, considering materials of construction, head pressure capacity, and volume capacity.

8-1.2.1 Feed Pumps.

Feed pumps tied to pulsing makeup meters or some other type of proportional feed system are recommended for most systems, especially large steam and cooling water systems and unmanned small systems. The most desirable feed method is to turn on the feed pumps when the continuous real-time measurement of the inhibitor indicator indicates that the inhibitor level is below the desired treatment level. Pumps that turn on in response to continuous real-time measurement can provide control to within 3 ppm of the desired treatment level.

8-1.2.2 Pumps of Various Types.

Pumps of various types can take suction from chemical solution tanks and inject a solution of a chemical into a line, a boiler drum, or a cooling tower basin. Pump types include piston pumps, spring-loaded diaphragm pumps, hydraulically actuated diaphragm pumps, peristaltic pumps, and gear pumps.

Piston pumps and, to a lesser degree, diaphragm pumps, have trouble with valves sticking or plugging if there are solids in the stream being pumped. Peristaltic pumps do not have this problem since they have no valves. They are especially recommended for feeding sulfuric acid, but they cannot pump against much pressure. Pumps configured for flooded suction produce a more reliable delivery than pumps that must hold a suction prime via a foot valve.

8-1.3 Water Meters, Automatic Valves, and Timers.

8-1.3.1 Water Meters.

Water meters are selected by the specific application for which they will be used, considering materials of construction, temperature rating, pressure rating, and volume capacity. Water meters fitted with an electrical contact head are used to send low-voltage signals to timers and pumps.

8-1.3.2 Automatic Valves.

Automatic valves are selected by the specific application for which they will be used, considering materials of construction, temperature rating, pressure rating, and volume capacity. Cooling towers normally use solenoid-actuated diaphragm valves. Boiler surface blowdown normally uses a motorized ball valve.

8-1.3.3 Timers.

Timers are selected by the specific application for which they will be used. The duty could be any of the following: signal timer, limit timer, percentage timer, or calendar program timer. They are often an integral piece of controller equipment but can also be stand-alone units.

8-1.4 Other Feed Devices.

8-1.4.1 Bypass Feeders.

The typical bypass pot feeder is used to feed a solid or dry product to a water stream. A bypass feeder will operate across an orifice plate, a partly closed valve, or any other restriction in the line. Bypass feeders are not recommended for steam boiler systems, cooling tower systems, or systems that require much makeup water.

8-1.4.2 Slowly Dissolving Dry Chemical Packages.

Nylon mesh bags containing slowly dissolving dry chemicals can be hung in the cold well of a cooling tower. This method of chemical addition is useful for small, remote cooling towers that require little attention.

8-1.4.3 Eductor Chemical Addition Systems.

The regenerant agent used for ion exchanger softeners is usually fed by an eductor, which is an enclosed unit having a feed rate set by the manufacturer. The sales representative should be contacted in case of an equipment malfunction.

8-1.4.4 Chemical Drip Pots.

Chemical drip pots are containers that contain treatment chemicals; they are mounted or hung in a cooling tower to feed chemical treatment, which drips into the cooling tower sump. These systems are not recommended for use, including those with a constant head.

8-2 CHEMICAL FEED METHODS.

For safety and manpower reasons, water treatment chemical feed should be accomplished using automated equipment when possible. In some situations manual feed is the most practical, or only, means available. Other situations require a combination of manual and automated chemical feed. Finally, some chemical feed systems are fully automated, thereby minimizing any direct handling of chemical treatment. The most desirable feed method is to feed product from pumps directly connected to base tanks. The base tanks are refilled by the water treatment supplier, thereby eliminating the handling of the products by the user. Pumps that turn on in response to continuous real-time measurement can provided control to within 3 ppm of the desired treatment level.

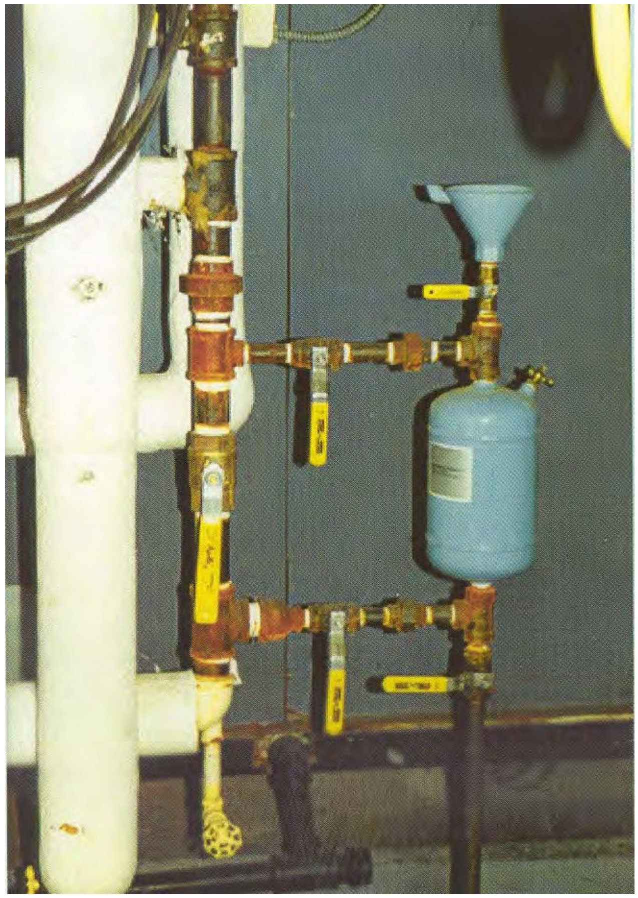
8-2.1 Manual Water Treatment Chemical Feed.

Manual water treatment chemical feed is commonly performed on closed systems, small cooling towers, and small steam boilers.

8-2.1.1 Chemical Pot Feeders.

Closed systems, such as chilled water, low- temperature hot water boilers, and even small steam boilers that return over 99 percent condensate, are usually fed manually via a chemical pot feeder (see Figure 8-1). Chemical pot feeders (also known as shot feeders) are plumbed into a system as a side stream using a three-valve bypass configuration. Feeders may have funnels or screw caps. The overall volume of a water treatment system should be considered when determining the proper size of a pot feeder. A 1-gallon (3.78-liter) pot feeder on a 20,000-gallon (75,700-liter) closed system can work, but is not practical. A larger 5-gallon (18.9- liter) pot feeder is more practical. Some pot feeders are designed to serve a dual purpose as a filter.

Figure 8-1 **Chemical Pot Feeder**



8-2.1.2 Dry Chemical Feeders.

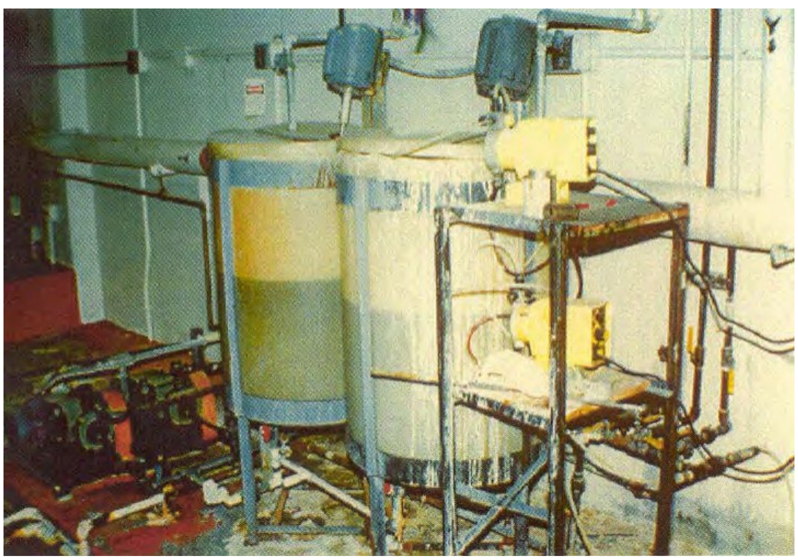
Small cooling towers often require a dry, granular, or pelletized product for control of scale, corrosion, or microbiological organisms. The dry chemical can be placed in a plastic mesh bag and hung in the cooling tower sump or put into a plastic container having small holes through which a stream of water can pass. Small cooling towers can be shock-fed with a liquid chemical agent, such as a biocide. This practice is not efficient and may be ineffective. The manual handling of biocides also raises safety concerns. A liquid chemical feed system may be more effective.

8-2.2 Automatic Chemical Feed with Manual Preparation.

This type of feed system is commonly found on steam boilers for which an operator must physically prepare a chemical mixture specific for that boiler operation. After preparation, the chemical mixture is automatically fed on demand using a chemical pump that is controlled by an external device or by tying into a feedwater or blowdown circuit. This type of setup can also be found on small cooling towers (see Figures 8-2 and 8-3).

Figure 8-2 **Manual Chemical Feed System**

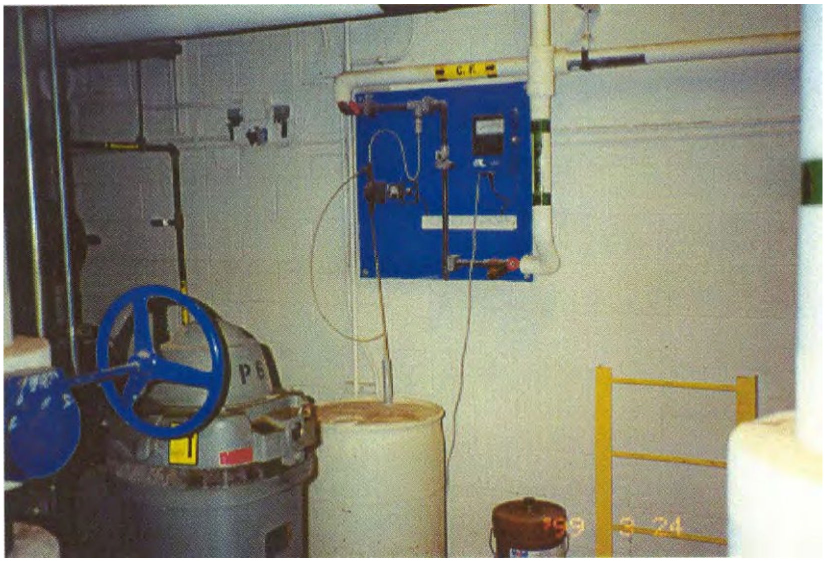
Figure 8-3 **Automatic Chemical Feed System**



8-2.3 Automatic Neat Chemical Feed.

The term “neat” refers to a concentrated chemical as received, with no dilution or mixing. An automatic chemical feed system must deliver the chemical proportionally (see Figure 8-4). Chemical pumps must be sized appropriately, and the system must have control equipment, which can consist of sensors, automatic valves, water meters, and timers. Once a system is properly connected to the chemical containers and adjusted, the only contact between the operator and the chemical containers results from maintenance of the chemical pumps, valves, and transfer lines. The most desirable chemical feed method is to feed product from pumps directly connected to base tanks. The base tanks are refilled by the water treatment supplier, thereby eliminating the handing of products by the user. The product is fed directly from pumps into the cooling or boiler water system.

Figure 8-4 **Automatic Neat Chemical Feed**



8-3 CHEMICAL CONTROL VERIFICATION.

To ensure that systems are being maintained within water treatment program control limits, it is necessary to verify that the proper water treatment chemical dosages are being used in treated water systems. Verification involves one or more of the various methods described below.

8-3.1 Continuous Testing.

Continuous water testing can be used in large systems where the service requirement justifies continuous control or the cost of the chemical feed warrants close control. This technique requires monitoring devices that are external to the system, which is equipped with probes and transmitters that send signals to the monitoring device. These systems are often linked directly to the chemical feed system to provide automatic control of the chemical feed.

8-3.2 Manual Testing.

Manual testing of the levels and dosages of water treatment chemicals is the most common method of testing. This technique is effective in systems in which the treatment chemical levels are not expected to vary widely in short periods of time, or in which the treatment chemical feed can be linked to the makeup water flow rate. Normally, the results of the manual testing are used to manually adjust the chemical feed rates. The testing frequency varies depending on the type and size of the water system. Critical systems require the most attention.

8-3.3 Little or No Testing.

Testing is necessary except in instances in which a chemical feed system does not require daily control monitoring or in which there is no treatment. This technique is used, for example, at remote cooling towers where a slowly soluble chemical is suspended in the cold well. Even for such systems an occasional test for treatment chemical level is recommended.

8-3.4 Calibrated Mass Balance.

Accurate chemical feed (rate and dosage) can be measured precisely and adjusted according to mass water balance. Some chemical delivery systems (pumps) use a calibration column to assure that chemicals are being fed. A measured volume of chemical is fed relative to makeup water or feedwater, then balanced by maintaining COC.

8-3.5 Automated Sensor Control.

This is a relatively advanced technology that automatically senses treatment level via an ion-specific electrode, such as might be used for pH control or spectro-analysis that senses chemical tracers. Chemical feed is adjusted automatically. The technology is effective as long as the sensing devices are calibrated and properly maintained. The technology for spectro-analysis control is relatively expensive. Another automated type of control is based on continuous monitoring and control of the inhibitor based on fluorescence technology. Chemical feed pumps are turned on when the continuous real-time measurement of the inhibitor indicates that the level is below the desired treatment level. Control can be reliably maintained within 3 ppm of the desired treatment levels in response to continuous real- time measurement. This type of control can be justified based on the reliability of proper treatment levels.

8-4 SAFETY AND GENERAL INFORMATION.

A water treatment program includes procedures for the feeding, handling, monitoring, storage, and disposal of treatment chemicals. General trends within the water treatment industry have been: to minimize or eliminate the physical handling of chemicals for reasons of safety and manpower; to provide container management systems to eliminate drum disposal problems; and to reduce or eliminate the need to store stockpiles of treatment chemicals.

8-4.1 Safety.

Chemicals used in water treatment, and in related maintenance activities, range from being highly toxic to mildly irritating to the persons handling them. All water treatment and testing chemicals are handled with caution, following any special instructions prescribed by the manufacturer. Areas where chemicals are handled or stored are kept clean and free of debris to minimize the chance of accidents. People who handle these chemicals can attend safety education classes, refer to the SDS for additional information, and use proper equipment for respiration and protection as recommended by the installation environmental or safety engineer.

8-4.1.1 Handling Acid.

When handling acid, avoid splashing the liquid. If acid does contact the eyes, skin, or even clothing, the affected area must be immediately flushed with water for 15 minutes. All cases of acid burns, especially to the eyes, are referred to a doctor. When acid is being diluted, water must never be added to acid because this may cause a violent reaction or splattering. NOTE: Acid is always poured into water; water is never poured into acid. When handling acid, goggles, face shield, rubber gloves, and a rubber apron must be worn. Safety equipment must be of a type approved by OSHA.

8-4.1.2 Handling Caustic Soda (Sodium Hydroxide).

Caustic soda is a strong alkali that can cause severe burns when contacted in either the liquid or solid form. If caustic soda does contact the eyes, skin, or clothing, immediately flush the affected area with water for at least 15 minutes. When water is added to caustic soda, a great deal of heat may be generated, which can cause the solution to splatter or boil. If inhaled, the dust or mist from dry caustic soda may cause injury to the upper respiratory tract. When handling caustic soda, wear close-fitting, OSHA-approved industrial goggles, rubber aprons and gloves, and coveralls that fit snugly at the neck and wrist.

8-4.1.3 Handling Other Chemicals.

Many of the other chemicals used in water treatment, including amines, soda ash, lime, sodium aluminate, sulfite, biocides, and algaecides may cause some irritation on contact with the skin. Handle all chemicals with caution, following the manufacturer's recommendations. For any contact of a chemical with skin, flush the skin immediately with water. Review the SDS that are available for the chemicals being handled for any special precautions that you should take.

Biocides and algaecides are toxic, and you should handle them only when observing special caution/precautions.

8-4.1.4 Chemical Spill Kits.

Each area where acids, caustic soda, or other hazardous materials are used or stored can be equipped with appropriate chemical spill kits. Kits for cleaning up acids, bases, and solvents are commercially available.

8-4.1.5 First Aid Information.

First aid information concerning a given chemical is listed on the SDS for that chemical.

8-4.1.6 Eyewash Fountain.

An eyewash fountain or a ready source of running tap water (a bubbler drinking fountain or hose with a soft flow of water) should be made readily available to wash out or flush the eyes. If even minute quantities of acid or caustic soda enter the eyes, immediately flush the eyes with large amounts of water for at least 15 minutes.

8-4.1.7 Safety Shower.

A readily accessible, well-marked, rapid-action safety shower should be located in the area where acid or caustic soda is being handled.

8-4.1.8 Safety Inspection.

All safety equipment should be regularly inspected to ensure it is in proper working condition. To prevent the accumulation of rust, the safety shower and eyewash equipment should be operated (checked) weekly. Clearly marked signs containing concise instructions on the use of the safety equipment should be placed near the emergency eyewash fountain and the safety shower.

8-4.2 Container Management.

The policy for container management is stated in paragraph 2-2.3 and is restated here. The military does not accept responsibility for disposal of chemical containers from water treatment suppliers or service companies. Any such company that has been contracted to provide chemicals must provide them in containers that are either reusable or returnable at the company’s cost. The containers remain the property of the contractor. All container systems should provide for secondary containment of the contents.

8-4.3 Chemical Storage.

Chemical storage procedures are required to follow OSHA directives, manufacturer’s recommendations, and the SDS. Identify products in storage areas by classifications of flammable, corrosive, oxidizers, reducers, and poisonous. Physically separate (store separately) the various classes of products as required by local codes. Because of the potential for chemical spills, storage areas for each class of products should have containment dikes. An alternate for container management is to use base tanks that are refilled by the water treatment service company, thereby eliminating the handling of the containers or products by the user.

This Page Intentionally Left Blank

CHAPTER 9 NON-CHEMICAL/NON-TRADITIONAL WATER TREATMENT DEVICES

9-1 POLICY.

Most non-chemical water treatment devices or equipment are not currently authorized for use on military installations, as stated in paragraph 3-1.5. The Air Force will allow their use only under an Energy Saving Performance Contract (ESPC) in which the contractor assumes all performance-based risk. The performance standards for system component protection must meet or exceed those that are achievable with chemical treatment.

9-1.1 Function.

Non-chemical devices for use in industrial water systems are designed to require little or no chemical treatment to solve or prevent one or more types of water-related problems, including scale, corrosion, slime, and odor. Some of the technologies are represented as non-chemical, when in fact they produce chemicals (such as ozone, and copper and silver ions). These technologies could be better described as non-traditional water treatment chemical devices. The various types of non-chemical devices are described in paragraph 9-2.

9-1.2 Acceptance.

To date, there has not been a general acceptance of most non-chemical devices. Manufacturer's representations as to their effectiveness and adequacy in performing the intended functions may not be supported by adequate performance data. Non-biased, independent verification of performance conducted by a third-party entity is an important component of the process that should be used to establish performance criteria of new technologies and equipment. This verification step has not always been performed for a given technology. Recognition of the adequacy of a non-chemical technology and acceptance of its use by professional societies such as ASHRAE, the National Association of Corrosion Engineers (NACE International), and CTI could provide an increased level of confidence that the technology does in fact work, at least on some basis and to some extent.

9-1.3 Performance Standards.

Traditional water treatment evaluation techniques and performance results provide the standard by which non-chemical devices should be measured. A complete water treatment program must address deposit control, corrosion control, microbiological control, and water conservation. These standards are described in Chapter 11. If a non-chemical water treatment device addresses only deposit control, but not corrosion or microbiological control, then it cannot make a claim to eliminate the need for all chemicals. The water treatment program would still require chemicals to control the problems that the non-chemical device cannot control.

9-2 TYPES OF NON-CHEMICAL WATER TREATMENT DEVICES.

Non-chemical devices for water treatment are hardware devices that do not use chemicals for the purpose of controlling or preventing corrosion, deposition, and biological growth in industrial water systems. This Chapter discusses the various types of non-chemical devices on the market. It is not intended to endorse or validate any of these technologies, nor to describe all types offered; however, the known effectiveness of these devices will be stated where performance results have been verified.

9-2.1 Electrical Impressed Current Devices.

Electrical impressed current devices are a proven corrosion control technology, known as cathodic protection that is used to protect lengths of underground outside surfaces of steel piping and mild steel heat exchanger water boxes. An electrical current is applied to offset the natural potential difference between an anode and a cathode. This technology does not prevent scale deposition or microbiological concerns and is mainly used to protect mild steel.

9-2.2 Grounded Wire Devices.

Grounded wire devices use a wire to ground a pipe or structure to prevent corrosion. This device is useful when stray currents (electrical) are causing corrosion. These devices have been touted as being able to prevent and remove scale. The principle of operation is uncertain, but it may be based on the fact that water impurities are charged ions and grounding affects the ions from forming scale. The scale control properties of this technology have not been conclusively and unambiguously verified.

9-2.3 Sacrificial Anodes.

The use of sacrificial anodes is a proven technology that uses blocks of metal that corrode (sacrifice) to protect the metal to which they are attached. A sacrificial anode is more anodic than the metal to which it is attached (see paragraph 5-5.1). This technology is actually a form of chemical corrosion protection. As an example, a zinc or magnesium metal sacrificial anode, when attached to a mild steel surface, becomes the anode in a corrosion reaction. The sacrificial anode is corroded preferentially while the mild steel is provided some localized corrosion protection. The action of sacrificial anodes is limited by the distance over which they can be effective; usually about 2 to 6 square feet (0.18 to 0.56 square meters) around the anode is protected, depending upon the water quality.

9-2.4 Filters.

Filters are a proven non-chemical method for removing SS in water. The removal of SS (dirt, silt, sand, corrosion products, and microbiological organisms) serves to minimize both the formation of deposits and the potential for under-deposit corrosion. Filtration affects biological control by reducing the presence of macro- and microbiological organisms in water. Removal of SS via filtration can improve the performance of all chemical control agents. This is comparable to a person washing a wound before applying a disinfectant. Filters do not address deposition due to scale nor do they control corrosion.

9-2.5 Magnetic Filters.

Magnetic filters are a proven method for removing magnetic iron oxides from a water stream. The most common application is the use of magnetic filters to remove iron oxide before the condensate is returned to the boiler in steam condensate systems. Magnetic filters usually are high capital costs.

9-2.6 Ultraviolet Light Generators.

Ultraviolet light generators are a proven method for microbiological disinfection of water. However, their effectiveness is limited to the distance through which the ultraviolet light can penetrate a water stream. This technology would not be effective for controlling (destroying) sessile bacteria that are already attached to a surface that the light cannot reach or for controlling (destroying) anaerobic bacteria that live underneath deposits that the light cannot penetrate. This technology has limited effectiveness with highly turbid water.

9-2.7 Magnetic and Electromagnetic Devices.

Magnetic and electromagnetic devices use an unproven technology based on the theory that magnetic fields change the physics of water and the water impurities. Water is a polar molecule. Most water impurities are positively or negatively charged ions. These are the physical properties that the magnetic fields are supposed to act on and to alter. The magnetic device is installed at a point where the water passes by, usually at a point where the water enters the system. A claim made commonly by the manufacturer of the device is that calcium carbonate scale, and possibly other scales, can be conditioned and often prevented.

Most of the literature fails to provide a performance envelope of various water qualities. Most manufacturers also fail to mention how corrosion or microbiological control is achieved or even addressed. Magnetic filters used to remove magnetic iron oxide have been shown to work, as described in paragraph 9-2.5.

9-2.8 Electrostatic Devices.

Electrostatic devices use an unproven technology based on the theory that an electric field changes the physics of water or the water impurities. Some manufacturers market their devices for scale control only. Other manufacturers state, without providing adequate verification data, that these devices address corrosion and microbiological concerns. Performance results are not included in the marketing literature.

9-2.9 Non-Traditional Water Treatment Chemical Devices.

9-2.9.1 Ozone.

Ozone (O_3) is a chemical gas consisting of three atoms of oxygen. It has been used in cooling tower water systems. Ozone is a very effective disinfectant for the control of aerobic bacteria and is somewhat effective for sessile bacteria. Ozone has been shown to have a limited and unpredictable effect on calcium carbonate scale. The scale that may form does not adhere to heat exchange equipment, but rather forms SS that can be removed with filtration. The performance envelope for prevention of calcium carbonate scale on heat exchange equipment is very limited and is much less than what is possible when using traditional chemical treatment. Ozone does not prevent corrosion of most metals. It provides some reduction of mild steel corrosion, but will increase the corrosion of copper at rates up to 10 times versus traditional chemical treatment. Ozone also attacks galvanized steel. Increasing the level of ozone in water increases the corrosiveness of the water. Levels of 0.1 mg/l or less are acceptable.

Ozone has a short half-life and must be generated on-site. Ozone-generating equipment can have high capital costs. It is difficult to maintain an effective residual of ozone throughout the entire cooling water system because of the extreme reactiveness of ozone. It is also very volatile and can be lost from the system as the water passes through the cooling water system, resulting in biomass within the tower fill.

9-2.9.2 Copper and Silver Ionizing Devices.

Copper and silver ionizing devices use copper and silver metal rods that are electrically corroded and thus put copper and silver ions in the cooling water. Copper and silver ions are known microbiocides. Both copper and silver ions are toxic to bacteria and algae. Performance envelopes are ambiguous. There is also a potential for the copper and silver ions to plate out on mild steel pipe, galvanized steel, and other metal surfaces, creating a galvanic corrosion cell and resulting in pitting corrosion.

CHAPTER 10 CHEMICAL CLEANING OF WATER SYSTEMS

10-1 GENERAL GUIDANCE.

Chemical cleaning of water systems can be divided into two classifications: pre-operational and remedial. Pre-operational cleaning is performed to prepare the water-contacted metal surfaces to receive chemical treatment, which provides protection from scale, corrosion, and microbiological growth. Remedial cleaning is performed to restore water systems that have been fouled with scale, corrosion products, and microbiological growth due to inadequate or ineffective water treatment. Cleaning, particularly remedial cleaning, is often performed by outside contractors familiar with cleaning procedures, techniques, and safety. It should be noted that if the water system is significantly scaled, the chemical treatment program was obviously inadequate and was not properly designed, set-up, controlled, or applied. After cleaning has been completed, the chemical treatment program and QC program must be improved so the same problem does not recur. Use of a well-designed QA program would have produced identification and notification of potential and developing problems before they became serious. Pre-operational cleaning is often performed by contractors responsible for the fabrication of the water system before turning it over to the military installation. Water system operations personnel must assess the effectiveness of any cleaning process that has been performed.

10-1.1 Pre-Operational Cleaning.

Pre-operational cleaning can be performed on all new systems or pieces of equipment installed in any existing system, including new boiler tubes or new chiller copper tube bundles. New piping and coils will usually be contaminated with materials such as mill scale, rust, oil, and grease resulting from the fabrication, storage, and installation of the equipment. Pre-operational cleaning is performed to remove these materials and prepare metal surfaces to receive corrosion protection from chemical treatment. Pre-operational cleaning agents that are used include detergents, wetting agents, rust removers, and dispersants. These cleaning agents have a pH in the range of 9 to 11. Water systems containing piping or components constructed of galvanized steel and aluminum should not be subjected to procedures that require high pH (greater than 8.5) because this would contribute to initiating corrosion of these surfaces.

The requirement for performing a pre-operational cleaning process is usually written into the specification for new construction of a water system that must be performed by a mechanical contractor. The mechanical contractor is required to perform the work as directed in the specifications; however, if the specifications are not appropriate for the specific system, including consideration of all system metallurgy, the cleaning process may contribute to corrosion to mild steel, galvanized steel, copper, or aluminum, or it may result in incomplete cleaning of dirty and corroded metal surfaces. The specifications should be reviewed by a qualified base inspector or qualified independent consultant to ensure that cleaning agents and procedures have been specified appropriately. A contracting officer or other individual responsible for QA should inspect the equipment after cleaning and document the effectiveness of the cleaning process.

10-1.2 Remedial Cleaning.

Remedial cleaning is performed to restore a water system that is fouled with scale, corrosion products, or microbiological biomass due to inadequate or ineffective water treatment. The problem could have resulted from using improper chemical technology, failure to maintain treatment levels within control parameters, or the failure of pre-treatment equipment. The cleaning agents used for remedial cleaning usually include acids, chelants, neutralizing agents, and specialty cleaning chemicals.

10-1.2.1 Safety and Environmental Issues.

Remedial cleaning may pose safety issues for personnel handling acids, caustics, and various chemicals. There could also be environmental concerns associated with chemical disposal. Inexperienced personnel should not perform the chemical cleaning of an industrial water system.

10-1.2.2 Contracting Cleaning Services.

For some cleaning jobs, such as large boilers and cooling towers, it may be advisable to engage a service company specializing in chemical cleaning. If the cleaning service is contracted, it is vital that adequate lines of communication be established, and that safety procedures employed by the service company comply with military regulations. An orientation meeting should be scheduled between military installation personnel and the service company representatives. At that time, the scope of the work can be defined, proper procedures initiated, and the nature of the hazards described thoroughly. The use of proprietary cleaning chemicals or chemical formulations may be involved; disclosure of the use and nature of these chemicals should be made at the orientation meeting. Military policies and restrictions can also be explained. The inspection of equipment after cleaning is usually the final step in the overall cleaning process.

10-1.3 Reasons for Cleaning.

Maintenance of an effective water treatment program is essential to minimize scale and corrosion problems in industrial water systems; however, scale and deposits that form will require remedial cleaning (descaling). If not removed, these scale and water-caused deposits may impact the safety of operations personnel, interfere with heat transfer, and cause excessive damage to, or destruction of, the water-using equipment. Cleaning is not appropriate for the removal of deposits when corrosion of the system has advanced to the point where a large number of leaks may result from the removal of the deposits.

10-1.4 Types of Deposits.

The deposits that occur in water systems can be inorganic mineral salts and corrosion products or organic (oily) or biological in nature. Deposits range in composition from very dense crystalline structures, to very porous and loosely bound materials, to gelatinous slimes. Most of the deposits formed from water constituents consist of corrosion products such as iron and copper oxides, mineral scales, or mixtures of these materials.

10-1.4.1 Waterside Deposits Located in Heat Exchangers.

Water deposits located in heat exchangers are usually carbonate-based scales, while steamside deposits may be a mixture of metallic oxides and organic residuals from lubricating oil, particularly where reciprocating-type engines are used. In steam systems, the oxides are usually iron and copper, resulting from aggressive condensate. Microbiological deposits may form in cooling systems from bacterial or algae growths, or from decomposition products of various microorganisms.

10-1.4.2 Boiler Deposits.

Boiler deposits may take various forms. In low-pressure boilers using a relatively hard feedwater, deposits are essentially calcium and magnesium, silicates, sulfates, carbonates, phosphates and hydroxides, plus some organics. Deposits may also contain considerable amounts of silica, iron, and copper. These deposits can be spongy or porous or relatively hard and glass-like. Deposits of the latter characteristic occur where silica is present in appreciable quantities in the boiler water. Deposits in medium-pressure to high-pressure boiler systems usually are mixtures of iron and copper oxides and phosphates. Dense deposits may tend to form in high-heat transfer areas. Considerable quantities of sludge-type accumulations may be found in downcomers, mud drums, waterwall headers, crossover tubes, and areas of low water circulation in the boiler.

10-2 REMEDIAL CLEANING PROCEDURES.

Cleaning procedure information and procedures presented in this Chapter are general in nature and must be modified to fit specific applications. Because contractors perform most cleanings, these procedures are provided only for general information (see paragraphs 10-1.1 and 10-1.2).

10-2.1 Cleaning Methods.

10-2.1.1 Mechanical Methods.

Mechanical methods are the oldest techniques used for removing deposits. To perform an adequate mechanical-type cleaning, the equipment to be cleaned may need to be partially or entirely dismantled. Even when equipment is dismantled, some areas may be extremely difficult to reach and clean. Chemical cleaning has largely replaced mechanical process equipment cleaning as the most satisfactory method of removing deposits; however, mechanical methods such as wire brushing, tumbling, scraping, and abrasive blasting with sand and grit are still employed in special applications.

10-2.1.2 Cleaning Agents.

Cleaning agents may be broadly classified as being acid, alkaline, organic, or solvent cleaners. There is no general or universal cleaner that removes all deposits. The selection of a solvent or cleaning agent is based on the material's ability to remove or dissolve the deposit, as well as on cost considerations, safety hazards, and the effect of the cleaning material on the metals involved.

10-2.1.3 General Guidance and Procedures for Preparing Cleaning Solutions.

General guidance and procedures for preparing cleaning solutions of inhibited hydrochloric (muriatic) acid and inhibited sulfamic acid are provided in paragraphs 10-2.2 and 10-2.3. Inhibited acid contains special chemical inhibitors that prevent the acid cleaner from attacking the base metal while allowing the acid to remove the unwanted corrosion product or scale deposit.

10-2.2 Hydrochloric (Muriatic) Acid.

Inhibited hydrochloric (muriatic) acid in strengths of 5 to 20 percent is very effective for removing calcium scale and iron oxide; however, for most applications, a 10 percent solution is adequate. The following formulation is for a 10 percent hydrochloric acid solution. It can be used for removing scale consisting primarily of carbonates with lesser amounts of phosphates, sulfates, and silicates. This type of scale is typically found in a steam boiler system containing copper alloys that has been treated with a phosphate-based program. Depending on the specific descaling application, some of these ingredients can be omitted from the formulation. For example, diethylthiourea is not needed if there is no copper in the system. It should be noted that if diethylthiourea is used, the waste material should be treated as a hazardous waste. Where there is only carbonate scale to be removed, ammonium bifluoride, which is used to remove silica-based scales, may be omitted. The addition of a wetting agent is preferable but not absolutely necessary.

10-2.2.1 Example Procedure for 10 Percent Solution.

The following is an example procedure that can be used to make 1000 gallons (3785 liters) of a 10 percent solution:

1. Add 285 gallons (1079 liters) concentrated (36 percent strength) hydrochloric acid, American Society for Testing and Materials (ASTM) E 1146, Specification for Muriatic Acid (Technical Grade Hydrochloric Acid), to approximately 600 gallons (2271 liters) of water.
2. Add the proper amount of a corrosion inhibitor, Military Specification MIL-I-17433, Inhibitor, Hydrochloric Acid, Descaling and Pickling, recommended by the manufacturer to the diluted acid solution. The inhibitor must be compatible with hydrochloric acid and must not precipitate under any condition during the cleaning operation.
3. In a separate tank containing about 75 gallons (284 liters) of water:
    a. Add 85 pounds (39 kilograms) of the chemical (1.3) diethylthiourea to complex any copper and keep it from depositing. Do not use the diethylthiourea as the corrosion inhibitor required in paragraph 9-2.2.1(step 2) above.
    b. Add 120 pounds (55 kilograms) of ammonium bifluoride, technical grade, to help dissolve certain iron and silica scales.

c. Add 1 gallon (3.79 liters) of wetting agent, Military Specification MIL-D-16791, Detergents, General Purpose (Liquid, Nonionic).

d. Add the dissolved diethylthiourea, ammonium bifluoride, and wetting agent to the diluted acid solution. Add sufficient water to obtain 1000 gallons (3785 liters).

10-2.2.2 Carbonate Deposits.

Carbonate deposits dissolve rapidly in hydrochloric acid, with evolution of free carbon dioxide. The escaping carbon dioxide tends to create some circulation or agitation of the acid, which ensures the continual contact of fresh acid with the scale. Once the carbonate has been dissolved from a mixed deposit, a loose, porous structure may be left behind. This residual material can be effectively removed from the equipment either mechanically or by washing with high-pressure water.

10-2.2.3 Phosphate Deposits.

The removal of phosphate deposits can usually be accomplished by using hydrochloric acid; however, phosphate deposits have a tendency to dissolve rather slowly. To minimize the total cleaning time, a temperature of 120° to 140 F (49° to 60 C) is usually necessary to remove a predominantly phosphate scale.

10-2.2.4 Metallic Oxides.

Most metallic oxides found in deposits can be removed with hydrochloric acid. The rate of dissolution is a function of temperature and solution velocity. If copper oxides are present on steel surfaces, special precautions are needed to prevent copper metal plate-out on the steel.

10-2.2.5 Silica and Sulfate Scale.

Heavy silica and sulfate scale is almost impossible to remove with hydrochloric acid. Special chemicals and procedures are required to remove this scale.

10-2.2.6 Hydrochloric Acid Limitations.

10-2.3 Sulfamic Acid.

Sulfamic acid is an odorless, white, crystalline solid organic acid that is readily soluble in water. An inhibited sulfamic acid compound, in a dry powder form, is available under Military Specification MIL-B-24155, Boiler Scale Removing Compound. A 5 to 20 percent solution (5 to 20 pounds to approximately 10 gallons of water (2 to 9 kilograms to approximately 38 liters of water)) is used for removing scale from metal surfaces. The following information pertaining to sulfamic acid should be considered:

- Carbonate deposits are dissolved in sulfamic acid in a similar manner as in hydrochloric acid. All the common sulfamate salts (including calcium) are very soluble in water.

- The dry powder form of sulfamic acid is safer to handle than a liquid solution of hydrochloric acid; however, aqueous solutions of sulfamic acid are much slower in action and require heating to remove scale. The sulfamic acid solution is heated to a temperature in the range of 130° to 160 F (54° to 71 C) to obtain the same fast cleaning time that is achieved by using hydrochloric acid at room temperature. Sulfamic acid is more effective on sulfate scale than hydrochloric acid.
- Inhibited sulfamic acid, used at temperatures up to 110 F (43 C), will not corrode galvanized steel. Its use is recommended for removing scale in cooling towers, evaporative condensers, and other equipment containing galvanized steel. In general, sulfamic acid can be applied to equipment while it is operating but should be drained from the system after a few hours, and the concentration of the normally used corrosion inhibitor should be increased several-fold to protect the metal surfaces.
- Commercially prepared descaling compounds consisting of concentrated or diluted inhibited acid (containing 7 to 28 percent of the acid and inhibitor) may be purchased under various trade names at prices 4 to 30 times the cost of the ingredients themselves if purchased as generic chemicals.
- Advertisements of some of these products may contain claims that cotton clothing and skin are not attacked by the acid. These claims are usually based on a very dilute solution of the acid that causes a minimal attack on clothes and skin; however, the cost of the cleaning process may be increased because a higher quantity of dilute product may be needed. Be aware that handling acid in any strength must be performed with considerable care, caution, and adherence to safety procedures.
- The cost of diluted acid is expensive; therefore, concentrated acid of government specifications should be purchased and diluted to usable strengths. The necessary corrosion inhibitors can be added to the dilute acid solution. Users of small quantities of acid cleaners (possibly less than 10 gallons (38 liters) of diluted acid per year) may not be able to justify purchasing undiluted acid and spending the time, cost, and effort to prepare the cleaning solution; therefore, consider the specific requirements before ordering.

10-2.4 Cleaning Preparation.

The unit to be cleaned must be isolated from other parts of the system. For systems that cannot be isolated by the closing of valves, isolation may be accomplished using rubber blankets, wooden bulkheads with seals, inflatable nylon or rubber bags, rubber sponge-covered plugs, or blind flanges and steel plates with rubber seals. Long lines may require auxiliary connections for chemical cleaning. The following information should be considered before the cleaning process is started:

- Decide whether to clean using a soaking process or by circulating the cleaning solution (see paragraph 10-2.5). In either case, temporary piping or hose lines will be required to connect the cleaning solution mixing tanks or trucks to the unit, with return lines to tanks or drains. Proper precautions and adequate provisions must be made to protect equipment, isolate control lines, replace liquid level sight glasses with expendable materials, and provide suitable points for checking temperatures. It may be necessary to remove selected system components if the cleaning process might damage them.
- The entire cleaning procedure/process must be developed in detail before starting chemical cleaning operations. Factors to be considered include: the methods for controlling temperatures; the means of mixing, heating, and circulating the chemical solution; proper venting of dangerous gases from equipment to a safe area; and means for draining, filling, and flushing under inert atmospheres. Sampling points, test procedures, and control limits should also be established.

10-2.5 Methods for Removing Scale.

Removing scale may be accomplished by circulating the inhibited acid solution through the equipment or by soaking the equipment in a tank of inhibited acid. Before starting any descaling process, check the acid to make sure it is properly inhibited. You may check the acid by placing a mild steel coupon into a beaker containing the prepared, diluted acid. You should notice no reaction around the coupon. If you observe a reaction generating hydrogen gas bubbles around the coupon, add more inhibitor.

10-2.5.1 Recirculating Cleaning Process for Boilers.

The following example is an appropriate procedure for cleaning small boilers or other systems using a hot recirculating inhibited acid solution:

1. Fill the boiler or system with preheated (160° to 170 F (71° to 77 C)) dilute inhibited acid solution.
2. Allow the dilute inhibited acid solution to remain in place for 8 hours. Circulate the acid solution for approximately 15 minutes each hour at a rate of about 50 gallons per minute (3.15 liters per second) to ensure good mixing.
3. Keep the temperature of the acid solution preheated at 160° to 170 F (71° to 77 C). Measure and record the temperature at least once every 30 minutes.
4. Check and record the acid strength at least every hour (see paragraph 10-2.6).
5. Drain the system by forcing the acid solution out using 40 to 50 pounds per square inch gauge (276 to 345 kilopascals) nitrogen; follow Federal Specification A-A-59503, Nitrogen, Technical, Class 1. If leaks develop

when the system is under nitrogen pressure, you must use an alternate method for removing the acid, such as pumping.

6. Fill the boiler with preheated (150° to 160 F (65° to 71 C°) water and soak at this temperature for 15 minutes.
7. Drain under nitrogen pressure of 40 to 50 pounds per square inch gauge (276 to 345 kilopascals).
8. Prepare this mild, acid-rinse solution: Add 2 gallons (7.57 liters) of hydrochloric acid (ASTM E 1146) for each 1000 gallons (3785 liters) of water. Also add corrosion inhibitor, Military Specification MIL-I-17433, in the amount recommended by the manufacturer.
9. Fill the boiler with the preheated (160° to 170 F (71° to 77 C)) mild acid-rinse solution and soak for 30 minutes.
10. Drain the mild acid-rinse solution under nitrogen pressure at 40 to 50 pounds per square inch gauge (276 to 345 kilopascals). Maintain a positive pressure of nitrogen in the boiler to prevent outside air from leaking inside.
11. Prepare this passivating solution: To each 1000 gallons (3785 liters) of distilled water (or other water with less than 50 ppm total hardness (as CaCO3)), add 80 pounds (36 kilograms) of passivation compound 0.5 percent by weight sodium nitrite and 0.25 percent by weight monosodium phosphate.
12. Fill the boiler with the passivating solution preheated to 150° to 160 F (65° to 71 C), circulate for 10 minutes, and hold in the boiler at 150° to 160 F (65° to 71 C) for an additional 30 minutes.
13. Drain and rinse boiler until the pH of the rinse water is pH 8 to 10.

10-2.5.2 Circulating Method without Heat.

The steps below describe a typical process for descaling smaller equipment, such as enclosed vessels or hot water heater coils, without heating the inhibited acid solution:

1. Note that an acid cleaning assembly may consist of a small cart on which is mounted a pump and a 5- to 50-gallon (18.9- to 189-liter) steel or polyethylene tank with a bottom outlet to the pump.
2. Install sill cocks at the bottom of the water inlet of the heat exchanger and the top of the water outlet so that a return line can be connected directly from the acid pump and from the heat exchanger to the acid tank.
3. Prepare an inhibited acid cleaning solution (see paragraphs 10-2.2 and 10-2.3).
4. Pump the acid solution into the heat exchanger through the hose connection. Continue circulation until the reaction is complete, as indicated by foam subsidence or acid depletion.
5. If the scale is not completely removed, check the acid strength in the system (see paragraph 10-2.6). If the acid strength is less than 3 percent,

add fresh acid solution and continue circulation until the remaining scale is removed. Usually an hour of circulation is adequate.

6. Drain the heat exchanger.
7. Neutralize remaining acid by circulating a 1 percent sodium carbonate (soda ash) solution (about 8 pounds per 100 gallons (3.6 kilograms per 38 liters)) for about 10 minutes.
8. Rinse thoroughly with water until the pH of the rinse water is pH 8 to 10.

10-2.5.3 Fill and Soak Method.

1. Prepare an inhibited dilute acid solution (see paragraphs 10-2.2 and 10-2.3) in a container of suitable size.
2. Depending on the item to be cleaned and the types of scale involved, you may want to place an agitator (mixer) in the tank or install a pump outside the tank to circulate the acid solution. A method to heat the acid may be required, such as a steam coil. All equipment must be explosion-proof and acid-resistant.
3. Immerse the item to be cleaned in the dilute acid solution. Continue soaking until the reaction is complete as indicated by foam subsidence or acid depletion.
4. If the scale is not completely removed, check the acid strength (see paragraph 10-2.6). If it is less than 3 percent, add additional acid and continue soaking the items until the remaining scale is dissolved. Usually 1 to 2 hours of soaking is adequate.
5. Remove item from tank.
6. To neutralize remaining acid, immerse the item in a 1 percent sodium carbonate (soda ash) solution (about 8 pounds per 100 gallons (3.6 kilograms per 38 liters)) for 2 to 3 minutes.
7. Rinse the item thoroughly with water.

10-2.6 Checking Acid Solution Strength.

The initial strength of the dilute inhibited acid will vary from 5 to 20 percent, although 10 percent is typical. As the acid is consumed by dissolving the scale, the strength of the acid decreases. The strength of the acid solution should be measured periodically during a cleaning operation. When the acid strength falls below 3 percent, the solution may be discarded since most of its scale-dissolving capability will have been used. Use the following procedure to check the acid strength:

Apparatus:

- Burette, 0.8 ounce (25 milliliters) automatic (for sodium hydroxide solution)
- Bottle, with dropper, 2 ounces (50 milliliters) (for phenolphthalein indicator solution)

- Graduated cylinder, 0.3 ounce (10 milliliters)
- Casserole, porcelain, heavy duty, 7.1-ounce (210-milliliter) capacity
  Stirring rod

Reagents:

- Sodium hydroxide solution, 1.0 normality (N)
- Phenolphthalein indicator solution, 0.5 percent

Method:

1. Measure 0.00264 gallons (10 milliliters) of acid solution accurately in the graduated cylinder.
2. Pour into the casserole.
3. Add 2 to 4 drops of phenolphthalein indicator solution to the casserole and stir.
4. Fill the automatic burette with the 1.0 N sodium hydroxide solution; allow the excess to drain back into the bottle.
5. While stirring the acid solution constantly, add sodium hydroxide solution from the burette to the casserole until color changes to a permanent faint pink. This is the endpoint. Read the burette to the nearest 0.003 ounce (0.1 milliliter).

Results:

1. For hydrochloric acid: Percent hydrochloric acid = milliliter of 1.0 N sodium hydroxide x 0.36
2. For sulfamic acid: Percent sulfamic acid = milliliter of 1.0 N sodium hydroxide x 0.97

CHAPTER 11 DEVELOPING A WATER TREATMENT PROGRAM

11-1 GENERAL INFORMATION.

Although each water treatment program may contain unique aspects, the strategic goals of every program are regulatory compliance and safety, protection of water-contacted equipment, and acceptable costs. Achieving these goals requires the cooperative efforts of personnel from several areas, including environmental protection, engineering, contracting, operations, and outside resources. Outside resources include water treatment services companies, equipment suppliers, and mechanical contractors. In some cases, military facilities may use outsourcing for procurement of all industrial water treatment chemicals and associated services. This Chapter addresses some of the options for developing both a water treatment program and performance standards that apply to implementation of a program.

Problems can occur when water treatment programs are not developed properly. Each water treatment program is designed to address regulatory compliance and safety requirements as well as water quality and equipment protection. A potential consequence of inadequate planning and design of a water treatment program is preparing inadequate scopes of work for use in procuring (contracting) for services. If equipment protection is not adequate, the cost attributed to this failure often far outweighs the cost of the water treatment chemical program. The most obvious problem is damage to, or the need for premature replacement of, the water-contacted equipment. Loss of operational efficiency is also a problem but is not always as apparent because it is rarely measured accurately; however, the additional operational costs due to operational inefficiency can be substantial. Specific types of equipment and system failures are described in Chapters 4, 5 and 6. When developing a water treatment program, you must give adequate effort and consideration to defining goals, devoting adequate resources to accomplish goals, and assessing performance.

11-2 OPTIONS FOR SETTING UP A WATER TREATMENT PROGRAM.

There are four methods for developing and implementing a water treatment program:

a. Generic Programs. In a generic water treatment program, facility operations personnel identify and use generic or commodity chemicals as part of the water treatment program that has been developed by facility personnel. Facility operations provide all services for chemical feed and control as well as monitoring and performance assessment. Facility personnel may be required to handle and mix generic chemicals. Alternatively, a contractor can develop the program for using generic chemicals, with services being provided by facility personnel.

Outsource Proprietary Chemicals Only. Procurement of proprietary water treatment chemicals is outsourced from a qualified water treatment contractor. Facility operations provide all services for chemical feed and control, and monitoring and performance assessment

a. Outsource Proprietary Chemicals and Some Basic Periodic Services. Proprietary water treatment chemicals, control and feed equipment, and periodic services are outsourced from a qualified water treatment contractor. Facility operations provide daily services for chemical feed and control, and monitoring and performance assessment.

b. Complete Outsourcing. All chemicals and services are outsourced to a contractor. The facility provides only maintenance of operating equipment (no water-treatment-related services).

11-2.1 Generic Chemical Water Treatment Programs.

Generic chemical water treatment programs have been implemented at military installations. The advantage of using this type of program is the cost savings generated by the use of generic chemicals relative to formulated products obtained from water treatment service companies. Generic chemicals are identified in Chapters 4 through 6. Generic chemical programs can be successful, but adequate planning and resources (including technical expertise) must be devoted to the implementation of the program. Generic chemicals and specifications are listed in Appendix E.

11-2.2 Chemicals and Services Outsourcing.

The General Services Administration (GSA) has developed standardized procedures and contracting arrangements for the outsourcing of: procurement of proprietary chemicals; procurement of proprietary chemicals with some periodic services; and procurement of total program services. The standard contracts have been designed to develop the most favorable pricing of water services received from contractors. GSA-listed proprietary products should not be purchased solely on a “price-per-pound” or “price-per-volume-of- product” basis. For purchases above $2500, make a “best value” determination after reviewing schedule price lists from at least three vendors. The “best value” determination must consider the price of products and the quality of services included with the products. It is usually necessary to obtain proposals from water treatment service companies and consider the details of the services to be provided as proposed, and the “cost per 1000 gallons (3785 liters) of makeup.” Proprietary products cost 5 to 20 times more than generic chemicals. These contracts only apply to GSA-listed products. Not all products on these GSA lists may be appropriate or approved for use in military industrial water systems. The contract-specified service requirements that are to be included with the GSA-listed products must be well defined; if not, a poorly monitored and poorly implemented program may result.

11-2.3 Contracts Based on Cost per Unit of Water.

A practical approach for obtaining cost-effective water treatment can be developed based on the bid price to treat a unit of water (1000 gallons (3785 liters) of water). Optimally, the contract scope of work will specify minimally acceptable performance standards as well as service requirements to be met by the contractor. Service requirements can vary from periodic consulting service to complete outsourcing.

11-3 DEVELOPING A SCOPE OF WORK (SOW) FOR INDUSTRIAL WATER TREATMENT.

This paragraph applies only to paragraph 11-2.1.3. A SOW (sometimes called a "statement of work" or a "statement of services to be provided") is developed for inclusion in the required procurement documents (request for proposal/bid (RFP/RFB) and contract). The SOW will identify the specific services, chemicals, and equipment that a contractor is to provide under the terms of the contract. The SOW will, at a minimum, specify or identify the following: SOW to be performed; qualifications of supplier; water characteristics of each system to be treated; description of industrial water systems and their operation; performance specification (results required); service requirements; equipment requirements for control, feed, monitoring, and sampling; requirements for chemicals and test equipment; and quotation for total chemical cost and usage. These issues are described below.

11-3.1 Qualifications.

The SOW specifies the minimum qualification requirements for contractors and contractor representatives. These requirements are developed to allow the participation of qualified contractors (water treatment chemical companies) having national, regional, and local operations. The SOW can specify the minimum number of years that the company has been in business and the minimum number of years and type of experience of contractor representatives, as well as required technical service capabilities.

11-3.2 Submittal Requirements and Format.

The SOW clearly specifies the type of response (submittal) that is required from an RFP or RFB. This is necessary to avoid receiving bid responses that are so different in their presentation that they cannot be easily or objectively compared. The evaluation process can be simplified by requiring bidders to provide a comprehensive acknowledgement that they understand and accept all requirements for compliance, qualifications, service requirements, and performance standards. The RFP/RFB should require a simple, generic, technical summary that lists the proposed chemical technology and treatment ranges for each type of system to be serviced under the procurement.

11-3.3 Water Quality.

The water supplied as makeup to industrial water systems is characterized in terms of its source, treatment, and quality, including seasonal and temporal variances. If external treatment is used on individual systems such as a steam boiler, this treatment is identified.

11-3.4 Description of Systems and Operations.

A description of the number, capacity, and types of systems to be serviced under the contract is a critically important element of a SOW. The metallurgy of all water-contacted surfaces is identified. Without this information, performance standards cannot be adequately defined. The condition of equipment is documented. Operational parameters, such as the equipment duty, load, and usage, are described so that water usage (preferably total water usage for each system) and chemical restrictions can be considered in developing the proposal.

11-3.5 Performance Specification.

Performance criteria are specified for protecting equipment against deposition, corrosion, and biological growths. Certain minimally acceptable standards for performance must be met. Recommended or example performance standards are listed in Chapters 4, 5 and 6 for the respective types of industrial water systems. Allowances are made for problems that cannot be totally controlled by chemical treatment alone. One example is SS accumulation in a cooling tower system. Chemical dispersants can aid in keeping SS from settling on metal surfaces, but it may require adequate flow and physical removal to maintain good control.

11-3.6 Service Requirements.

The SOW accurately describes the services to be provided by the contractor. Service includes the frequency of on-site visits, the duties to be performed, and the methods of reporting. The duties to be performed can include these activities: water testing; making log entries; training; maintaining automated chemical control and feed equipment; manual addition of chemicals to industrial water systems; inventory control; corrosion coupon studies; microbiological population determination; equipment inspections; laboratory support; quarterly reviews; and annual reviews.

11-3.7 Control, Feed, Monitoring and Sampling Equipment Requirements.

The SOW specifies what equipment, if any, is required to achieve consistent control of the makeup water treatment chemical program. Automated control and feed equipment is required on most medium and large cooling towers and on most steam boilers. Automated control and feed equipment helps limit the demand for service maintenance. To provide for the preparation of an appropriate SOW, engineering and facility maintenance personnel carefully evaluate their capabilities in the area of water treatment and water systems. Inadequate water treatment equipment can result in higher service requirements or inconsistent control of the chemical program. Descriptions of chemical applications can be found in Chapter 8.

11-3.8 Chemicals and Test Equipment.

The SOW specifies any restrictions on the use or discharge of chemicals. Examples of restrictions can include limitations on the use of acid, shipping container size limits, microbiocide selection criteria, and limitation on use of dry chemicals.

The SOW specifies how the cost of chemicals and services is being calculated and quoted. For example, quotations for chemical treatment can be based on the cost to treat 133.666 cubic feet (3.785 cubic meters) of water. Cost for services in the SOW can be required to be included in the cost of chemical treatment or quoted separately as line items, time, and materials. Contracts that require a "not-to- exceed" quotation supply bidders with a not-to-exceed water usage estimate.

11-4 REPORTS AND AUDITS.

Reports and audits are tools for documenting performance and cost effectiveness of any industrial water treatment program. Audits serve to verify results from the water treatment service company. Audits also serve to verify the cost-effectiveness of product being supplied by the water treatment service company. Audits are performed by qualified agencies within the military branch in question or by independent consultants contracted to perform such duties.

APPENDIX A PRACTICAL (PUCKORIUS) SCALING INDEX (PSI)

A-1 DEVELOPMENT OF PSI.

Have been used to predict the tendency of water to form or dissolve scale. Both the LSI and the RSI are based on the pH of saturation (pHs) for calcium carbonate under a specific water condition. Both indices use the measured pH of the cooling water.

1. LSI = (measured pH) - (pHs). A positive value indicates scale; a negative value indicates no scale.
2. RSI = (2 pHs) - (measured pH). A value below 6 means scale; above 6 means no scale.

A-1.1 PSI.

Use of LSI and RSI sometimes gave inconsistent or even conflicting results. Based on a long-term study relative to calcium carbonate scale formation when applying both the LSI and RSI, P.R. Puckorius and J.M. Brooke developed a new index that gives much better and more consistent indication of cooling water-scaling conditions. The new index, the Practical Scaling Index (PSI), sometimes called the Puckorius Scaling Index, is based on correcting the system pH to match the total alkalinity of the water being evaluated. This is necessary because the pH is often buffered, causing the pH to relate incorrectly to the bicarbonate alkalinity, one of the factors in the pH_s calculation.

A-2 CALCULATING PSI.

To calculate the PSI, the pH_s is determined in the same manner as for the LSI and RSI. An adjusted or equilibrium pH (pH_{eq}) is obtained from a total alkalinity/pH chart (Table A-7). The value of pH_{eq} rather than measured pH is used in the following formula:

$$\mathbf{PSI = (2\ pHs) - (pHeq)}$$

A value below 6 means scale; above 6 means no scale.

A-2.1 Calculating pHs.

The pHs can be determined from the relationship between various characteristics of water. The following factors and formula are used in determining the pHs:

a. Factors needed to calculate pHs :

A = TDS (ppm) (Table A-1)

B = Temperature (°F) (Table A-2)

C = Calcium hardness (ppm as $CaCO_3$) (Table A-3)

D = Total alkalinity (ppm as $CaCO_3$) (Tables A-5 and A-6)

Table A-1 Factor "A" for TDS

TDS (ppm)	Value of "A"
50	0.07
75	0.08
100	0.10
150	0.11
200	0.13
300	0.14
400	0.16
600	0.18
800	0.19

140	1.40	1.38	1.37	1.35	1.34
150	1.32	1.31	1.29	1.28	1.27
160	1.26	1.24	1.23	1.22	1.21
170	1.19	1.18	1.17	1.16	--

Find value of "B" in appropriate unit column.

Example: For water at 86° F, B = 1.88

a. pHs = 9.30 + A + B - (C + D)

b. EXAMPLE B-1:

Water from a cooling tower has a TDS of 1000 ppm, calcium hardness of 500 ppm (as $CaCO_3$), total alkalinity of 100 ppm (as $CaCO_3$) and measured pH of 8.2. The hottest temperature on the waterside of the heat exchanger is 120° F.

$pH_s = 9.30 + A + B - (C + D)$

$pH_s = 9.30 + 0.20 + 1.57 - (2.30 + 2.00) = 6.77$

A-2.2 Calculating pHeq.

a. Puckorius and Brooke developed the improved relationship between total alkalinity and pH after studying hundreds of cooling systems over some 20 years. The pH_{eq} values shown in Table A-7 for the total alkalinity measured in cooling water are used for calculating the PSI.

300	8.17	8.19	8.21	8.23	8.25	8.27	8.29	8.30	8.32	8.34
400	8.35	8.37	8.38	8.40	8.41	8.43	8.44	8.46	8.47	8.48
500	8.49	8.51	8.52	8.53	8.54	8.56	8.57	8.58	8.59	8.60
600	8.61	8.62	8.63	8.64	8.65	8.66	8.67	8.67	8.68	8.70
700	8.71	8.72	8.73	8.74	8.74	8.75	8.76	8.77	8.78	8.79
800	8.79	8.80	8.81	8.82	8.82	8.83	8.84	8.85	8.85	8.86
900	8.87	8.88	8.88	8.89	8.90	8.90	8.91	8.92	8.92	8.93

a. EXAMPLE A-2:

Water from a cooling tower has a total alkalinity of 100 ppm (as $CaCO_3$) and a measured pH of 8.2 (same as example A-1). From Table A-7, the pHeq is 7.47.

PSI = (2pHs) - (pHeq) = 2 (6.77) - 7.47

= 13.54 - 7.47 = 6.07

RSI = (2pHs) - (measured pH) = 13.54 - 8.2

= 5.34

LSI = (measured pH) - (pHs) = 8.2 - 6.77

= +1.43

b. The pHeq may also be calculated as follows:

pHeq = 1.485 log TA + 4.54

Where: TA denotes total alkalinity.

A-2.3 Scaling Severity Keyed to Indices.

a. Commonly accepted interpretation of the previously described indices is shown in Table A-8.

b. In Example A-2, the LSI predicted that the water would exhibit a severe to very severe scaling tendency. The RSI predicted that the water would exhibit a moderate to severe scaling tendency. The PSI predicted that the water is stable with no tendency to form or dissolve scale.

Table A-8 Scaling Indices vs. Condition

LSI	PSI/RSI	Condition
3.0	3.0	Extremely severe scaling
2.0	4.0	Very severe scaling
1.0	5.0	Severe scaling
0.5	5.5	Moderate scaling
0.2	5.8	Slight scaling
0.0	6.0	Stable water, no scaling, no tendency to dissolve scale
-0.2	6.5	No scaling, very slight tendency to dissolve scale
-0.5	7.0	No scaling, slight tendency to dissolve scale
-1.0	8.0	No scaling, moderate tendency to dissolve scale
-2.0	9.0	No scaling, strong tendency to dissolve scale
-3.0	10.0	No scaling, very strong tendency to dissolve scale

APPENDIX B CORROSION TESTING WITH COUPON-TYPE TEST SPECIMENS

B-1 PURPOSE.

Corrosion tests with metal coupon test specimens are used to determine how corrosive water is to a specific metal. Coupon test specimens are particularly useful in monitoring the effectiveness of chemical corrosion control programs. The extent of both general and localized corrosion can be determined. Also, examination of the specimens as they are removed from the system can provide information regarding deposit accumulation or microbiological slime growth. Corrosion test coupons are usually used as corrosion test specimens for open and closed cooling systems, closed hot water systems, and domestic water systems. See ASTM Standard Test Method: Corrosivity of Water in the Absence of Heat Transfer (Weight Loss Methods), D2688-15e1.

B-2 APPLICATION.

B-2.1 Description of Coupons.

The coupons are metal tags of various sizes. Generally, low-carbon steel specimens are used as the most susceptible metal to corrosion; however, copper, stainless steel, brass, and other metals are available for special studies. The specimens are prepared and cleaned to ensure uniformity and weighed. The general corrosion rate is determined after exposure. Coupons are cleaned and re-weighed. Corrosion rates are calculated based on the weight loss, time of exposure, and the area and specific gravity of the coupon, and are expressed in mils per year (MPY).

B-2.2 Test Conditions.

Since the goal of the corrosion testing program is to provide information regarding conditions within the system, the corrosion coupons should be exposed to conditions that reflect those in the system as a whole. Water velocity and temperature will significantly affect the corrosion rate. Corrosion rates can be significantly increased when velocity is either too low or too high. For best results, water velocity flowing by the test specimen should be 3 to 5 feet per second (0.90 to 1.5 meters per second), and both adjustable and measurable. Temperature also affects the rate of corrosion, with higher temperatures usually increasing corrosion; therefore, in cooling water systems both the cold supply water and the hot return water should be evaluated with corrosion coupons. When only one test rack can be installed, the warm water return at the tower should be used to provide an average hot water temperature.

B-2.3 Test Length.

Expose corrosion coupons for a minimum of 30 calendar days and a maximum of 90 calendar days, except for special tests. Although spot checks are useful, a regular schedule will determine trends and recognize changes within the system. When corrosion test specimens of different metals are installed in the same corrosion test rack, the more noble or resistant metal should be downstream of less resistant metals.

B-2.4 Receipt of Specimens.

Specimens are shipped in vapor-inhibited bags. Do not remove them from the bags until the specimen is to be installed. The vapor inhibited bags should be saved for returning exposed specimens. Do not handle specimens directly with fingers since fingerprints can initiate corrosion sites. Record on the appropriate form the exact location and date of installation.

B-2.5 Return of Specimens.

After the specimens have been exposed for the selected time (30, 60, or 90 calendar days), carefully remove, air dry without disturbing any deposits, and return them to the original vapor-inhibited bag. Record date of removal on the appropriate form. Then send the exposed specimens and completed forms to the supplier for evaluation. After evaluation, the results are presented and interpreted in a written report.

B-3 INSTALLATION OF COUPON-TYPE TEST SPECIMENS.

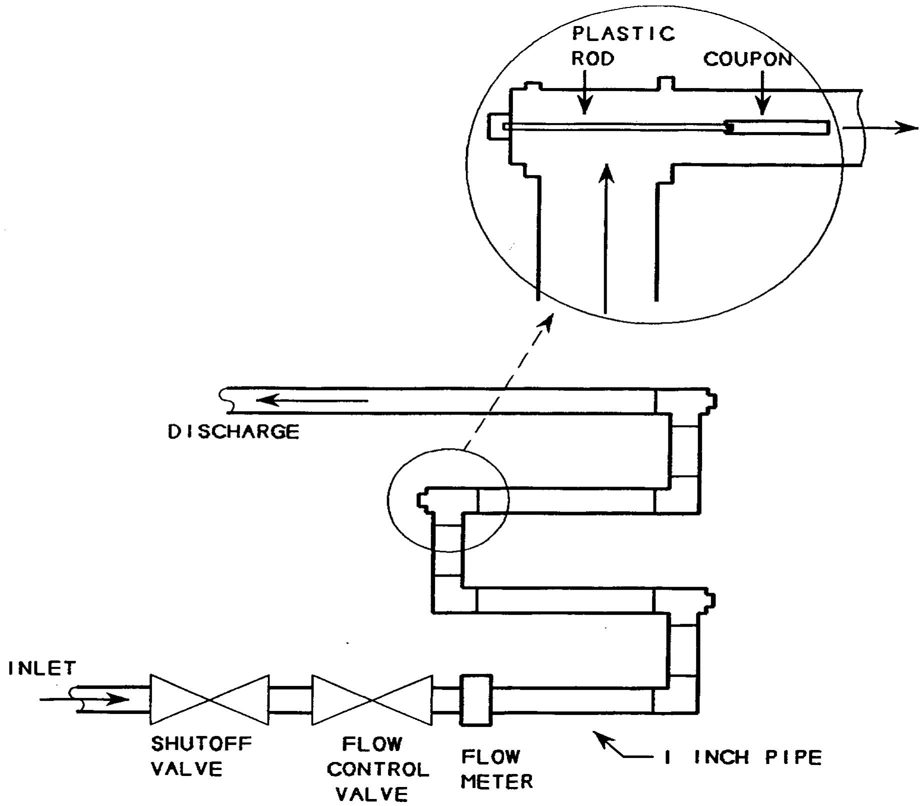
B-3.1 Method of Installation.

Coupons are usually installed in pipe "tees" by means of corrosion test racks which include a 1-inch (25-millimeter) pipe plug, drilled and tapped to accept a plastic or phenolic rod with a nylon nut and bolt for attaching the coupon to the rod. A bypass arrangement with 1-inch (25-millimeter) piping, as shown in Figure B-1, will facilitate installation and removal as well as allow the use of multiple specimens. Polyvinyl chloride (PVC) will eliminate electrical effects but cannot be used for hot condensate. A corrosion test rack may be purchased or constructed on site.

B-3.2 Placement of Coupons.

For steam and condensate return lines, install coupons in any convenient location where there are tees. When using a bypass arrangement, condensate from the outlet is piped back into the system. Bypasses should be constructed of iron pipe and fittings and installed only where there is sufficient pressure differential to ensure a continuous flow through the bypass. Direction of flow should be as shown in Figure B-1 to minimize turbulence around the corrosion test specimen and ensure that the test rack remains full of water.

Figure B-1 Bypass Piping for Corrosion Testing Cooling Water and Condensate Systems



B-3.3 Test Methods.

To ensure proper results, the following points should be checked:

1. Flow through the corrosion test rack must be continuous and measurable. Use flow meters for all installations. When a flow meter does not exist, flow must be measured by timing how long it takes to fill a container of known volume such as a 5- gallon (20-liter) pail.
2. Normally, water velocity through the corrosion test rack should be 3 to 5 feet per second (0.90 to 1.5 meters per second). The velocities in meters per second (feet per second) for given liters per second (gallons-per-minute) flows for various pipe sizes are shown in Table B-1

Table B-1 Flow Rate

Velocity ft/sec (m/s)	Line Size		
	1 in (25 mm)	1.25 in (32 mm)	1.5 in (38 mm)
3 (0.91)	8 gpm (0.5 l/sec)	14 gpm (0.9 l/sec)	19 gpm (1.2 l/sec)
5 (1.5)	13 gpm (0.8 l/sec)	23 gpm (1.5 l/sec)	30 gpm (1.9 l/sec)

NOTE: Corrosion coupons and coupon racks can be obtained from the following suppliers, among others:

1. Water treatment service companies.
2. Water treatment equipment companies.
3. Alabama Specialty Products Inc.
   152 Metals Samples Road
   Munford, Alabama 36268
   (205)358-4202
4. Advantage Controls, LLC
   4700 Harold Arbitz Drive
   Muskogee, Oklahoma 74403
   (800)743-7431

APPENDIX C CORROSION TESTING WITH TEST NIPPLE ASSEMBLY

C-1 PURPOSE.

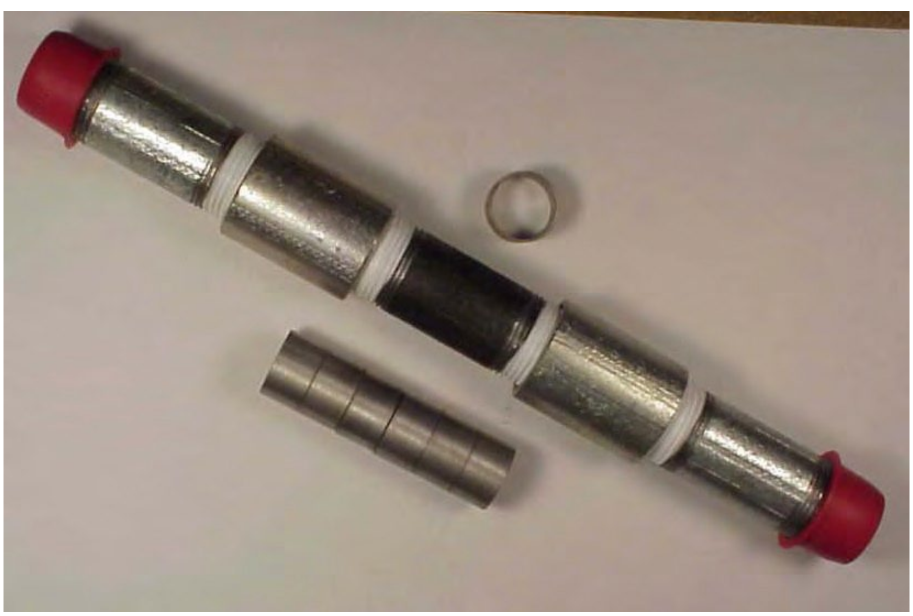
Corrosion tests with metal test specimens are used to determine how corrosive water is toward a specific metal. Although test nipple assemblies (referred to as "tester") can be used in many applications, they are used on military installations to evaluate corrosion problems in steam condensate return systems. See ASTM Standard Test Method: Corrosivity of Water in the Absence of Heat Transfer, D2688-15e1.

C-2 APPLICATION.

C-2.1 Tester Specifications.

The tester consists of three 3-inch by 0.75-inch (76 millimeter by 19- millimeter) National Pipe Thread (NPT) nipples, connected by two couplings (see Figure C-1). The center nipple contains short inserts machined from steel tubing similar to the steel pipe in the condensate system. The outside diameter of the inserts is approximately the same as the inside diameter of the center 0.75-inch (19-millimeter) machined coupling. The two end nipples of the tester are installed between two unions in such a manner that condensate will constantly flow through the tester. See paragraph C-3 for detailed installation instructions.

Figure C-1 Condensate Corrosion Tester



C-2.2 Likelihood of Corrosion.

Serious corrosion is more likely in large-area heating systems that have long return lines. More concentrated systems, such as laundries and low-pressure closed systems in which there is very little feed water makeup, generally experience much less condensate return line corrosion.

C-2.3 Scale of Testing.

If the test points are well chosen, information obtained from one or two condensate return systems on an installation or base is generally sufficient to serve as a survey of the entire facility. One or more testers would be installed in the largest area heating system and another in a smaller system. The testers should be installed at points where maintenance work has been required due to corrosion.

C-2.4 Receipt of Tester.

The supplier provides the tester complete and ready for installation. An appropriate data form is also provided with the tester. This form must be completed by the user for correct interpretation of corrosion that may occur on the tester inserts. The user is required to draw a picture to show how and where the tester was installed.

C-2.5 Removal of Tester.

At the end of the test period, the tester is removed. The tester is rinsed internally for several seconds with very hot water, drained, and immediately capped on both ends with the plastic caps that had been supplied with the tester.

C-2.6 Condensate Sample.

A condensate sample is collected from the area where the tester was installed and returned to the supplier at the same time as the tester.

C-2.7 Return of Tester.

The tester is packed in any convenient package, enclosing the completed data sheet, and returned to the supplier.

C-3 INSTALLATION OF TESTER.

C-3.1 Location of Tester.

Install the tester in a horizontal return line. If morpholine treatment is being used, install the tester in a building near the end of the steam main where the treatment would be expected to be least effective. If a mixture of morpholine and cyclohexylamine is used, install a tester at each end of the system.

C-3.2 Test Conditions.

Ensure representative sampling of the condensate by the tester. Do not install the tester to receive drips from steam mains. Drips may be less corrosive (less acidic) than the average condensate.

C-3.3 Placement of Tester.

Place the tester horizontally to receive the condensate from a hot water generator or space heater that is drained by a 0.75-inch (19- millimeter) trap. Do not install the tester downstream from a pump in the condensate line. Avoid bypasses and do not overload the tester with condensate from several traps. Enough condensate should flow to the tester to fill it at least halfway.

C-3.4 Method of Installation.

To install the tester, remove a section of the pipe from the condensate return system. Replace the section of pipe with the tester, unions, and any additional pipe needed to complete the installation.

C-3.5 Length of Test.

Leave the tester in place for about 90 days. Record the dates the tester was installed and removed.

This Page Intentionally Left Blank

APPENDIX D TESTING INDUSTRIAL WATER SYSTEM SAMPLES

D-1 PURPOSE.

Testing of industrial water is performed to determine the amount of treatment chemicals so dosage levels can be properly regulated. These tests are a means by which reliable water system operations are ensured, with respect to the impact of water quality on system equipment and operation. Testing may be conducted in a permanent field laboratory or at the plant or site location using portable test kits.

D-2 USE OF PORTABLE TEST KITS.

Portable test kits are primarily for use at the site location where the sample is taken when an immediate test result is needed. They can also be used in the permanent field laboratory. Test procedures are provided with the test kit. For tests that can be conducted either in the field laboratory or with a portable test kit, use field laboratory test procedures for best results. The water analyst should periodically check the results of the portable test kit against the field laboratory test on the same water sample (perform a check sample analysis). Portable test kits are available from a number of commercial sources.

D-3 LABORATORY PROCEDURES AND TESTING TECHNIQUES.

The achievement of accurate test results is dependent on the use of proper reagents and on following good, basic laboratory procedures and techniques.

D-3.1 Management of Reagents.

D-3.1.1 Supply.

The chemical reagents stored at each field laboratory should be specific for the tests that are performed. The amount on hand should be adjusted to ensure the supply is fresh. Reagent containers must be kept tightly closed when not in use and stored in a cool place. Except for reagents with a specified shorter shelf-life, liquid reagents should be consumed within one year and dry reagents consumed within 2 years. All reagents should be properly marked with appropriate warning labels, batch control numbers, and date packaged or discard date clearly marked.

D-3.1.2 Storage.

It is necessary to keep everything in good order at all times. Have a place for everything and keep everything in its place. Be sure all bottles are properly labeled and avoid mixing bottles. All bottles should be kept tightly closed. Keep any reserve stock of solutions and reagents in a cool, dark place.

D-3.2 Apparatus.

The apparatus are precision instruments capable of very fine measurements. Measure carefully, as the results will be "off" if improper sample amounts are taken, incorrect volumes of solution are added, the burette is not read correctly, or if the methods prescribed are not performed exactly as written. Each water analysis requires specific chemical apparatus. These are scientific instruments and are to be treated as such. The apparatus will last indefinitely if given proper care. All equipment and apparatus, especially glassware, should be kept clean. Unless this is done, the tests will not be reliable and errors will be introduced. Thoroughly rinse and air-dry all glassware immediately after use. If color apparatus is employed, do not expose to heat or direct sunlight. If any liquid is spilled on any of the equipment or apparatus, wipe off at once and dry.

D-3.3 Testing Procedures.

The suspended matter or sludge will generally settle to the bottom if the sample is allowed to stand before testing. The clear water can then be used for the tests, making it unnecessary to filter (except for specific tests). Theoretically, all water analyses should be made at 77° F (25° C); however, no appreciable error will be introduced if the test is made between 68 and 86° F (20° to 30° C). In general, the shorter the time between the collection and analysis of the sample, the more reliable the results will be.

When the water sample color interferes with the analysis, it may be necessary to filter the sample through activated charcoal. NOTE: This does not apply to the sulfite and nitrite tests.

APPENDIX E NONPROPRIETARY INDUSTRIAL WATER TREATMENT CHEMICALS

E-1 ANTIFOAM.

Polyamide or polyhydric alcohol

Use: Prevent foaming carryover in steam boilers

Federal Specification: None

Package/ National Stock Number (NSN): 5-gal can, NSN: 6850-01-181-016

E-2 ANTIFREEZE.

Inhibited, 87.6 percent ethylene glycol, 300˚ F (149° C) minimum boiling point, nonflammable, protection to –60˚ F (–51˚ C)

Use: Closed hot and chilled water systems

Federal Specification: A-A-52624, *Antifreeze, Multi-Engine Type*

Package/NSN: 1-gal can, NSN: 6850-00-181-7929

5-gal can, NSN: 6850-00-181-7933

55-gal drum, NSN: 6850-00-181-7940

E-3 BIOCIDE.

Active ingredient, methylenebis (thiocynate), 10 percent in water solution.

Use: Cooling towers with pH less than 7.5

Federal Specification: None

Package/NSN: 5-gal, NSN: 6850-01-191-5033

E-3.1 BIOCIDE.

Active ingredient 20 percent

2,2-Dibromo-3-nitrilopropionamide, 80 percent inert ingredients

Use: Cooling towers with pH less than 7.5

Federal Specification: None

Package/NSN: 5-gal can, NSN: 6850-01-191-5034

E-3.2 BIOCIDE.

Active ingredients 10 percent dodecylguanidine hydrochloride, 4 percent bis (tri-n-butyltin) oxide

Use: Cooling towers with and pH less than 7.5 Federal Specification: None

Package/NSN: 5-gal can, NSN: 6850-01-194-8306

E-3.3 BIOCIDE.

Active ingredients 20 percent

n-alkyldimethylbenzylammonium chloride, and 3 to 4 percent bis (tri-n-butyltin) oxide, pH greater than 10.5

Use: Cooling towers with pH greater than 7.5 Federal Specification: None

Package/NSN: 5-gal can, NSN: 6840-01-189-8139

E-3.4 BIOCIDE.

Active ingredient 60 percent poly (oxyethylene (dimethyliminio) ethylene-(dimethyliminio) ethylene dichloride)

Use: Cooling towers with pH greater than 7.5 Federal Specification: None

Package/NSN: 5-gal can, NSN: 6840-01-190-2551

E-3.5 BIOCIDE.

Active ingredients 60 percent consisting of 14 to 15 percent disodium cyanodithioimidocarbonate and 20 to 21 percent potassium n-methyldithiocarbamate

Use: Cooling towers with pH greater than 7.5

Federal Specification: None

Package/NSN: 5-gal can, NSN: 6840-01-198-7945

E-3.6 BIOCIDE.

Active ingredient 96 to 98 percent

1-bromo-3-chloro-5,5-dimethylhydantoin, granular

Use: Remote cooling towers with any pH

Federal Specification: None

Package/NSN: 35-lb can, NSN: 6840-01-185-7455

E-4 BORAX (SEE SODIUM NITRITE-BORAX BLEND, ITEM E-43).

E-5 CALCIUM HYDROXIDE.

(slaked lime) ($Ca[OH]_2$) technical, powder, 90 percent minimum by weight

Use: Lime-soda ash water softening

Federal Specification: A-A-55821, *Calcium Hydroxide, Technical*

Package/NSN: 50-lb bag, NSN: 6810-00-656-1091

E-6 CALCIUM HYPOCHLORITE.

($Ca[OCl]_2$) technical, granular, 65 percent chlorine by weight

Use: Algae control in cooling towers and disinfectant in treatment for Legionnaire's Disease

Federal Specification: ASTM-E1229

Package/NSN: 5-lb can, NSN: 6810-00-238-8115 100-lb drum,

NSN: 6810-00-255-0472

E-7 CAUSTIC SODA (SEE SODIUM HYDROXIDE, ITEM E-37).

E-8 CYCLOHEXYLAMINE.

Boiler feedwater compound, neutralizing amine, all drums to bear adequate caution labels to protect against fire, poison and caustic burn hazards

Use: Control corrosion by CO_2 in steam condensate lines Federal Specification: O-C-940, *Cyclohexylamine,* Technical Package/NSN:

60 percent, 400-lb drum, NSN: 6810-01-074-5201

60 percent, 15-gal drum, NSN: 6810-00-515-2235

98 percent, 15-gal drum, NSN: 6810-00-530-4695

98 percent, 55-gal drum, NSN: 6810-00-805-9798

E-9 DIETHYLAMINOETHANOL (DEAE).

100 percent solution

Use: Control corrosion by CO_2 in steam condensate lines

Federal Specification: None

Package/NSN: 55-gal drum, NSN: 6810-949-8331

E-10 DIPHOSPHONIC ACID (HEDP).

1-hydroxyethylidene 1,1-diphosphonic acid, active ingredient 58 to 62 percent, specific gravity 68˚ F/59˚ F (1.45 at 20˚ C/15˚ C), pH of 1 percent solution less than 2.0

Use: Inhibitor to prevent formation of calcium and magnesium scale in cooling water applications

Federal Specification: None

Package/NSN: 5-gal can, NSN: 6850-01-190-5509

55-gal drum, NSN: 6850-01-206-4601

E-11 ETHYLENE GLYCOL (SEE ANTIFREEZE, ITEM E-2).

E-12 HEDP (SEE DIPHOSPHONIC ACID, ITEM E-10).

E-13 HYDROCHLORIC ACID.

(muriatic), (HCl), technical, 31.45 percent minimum by weight, 20˚ Baumé (Bé)

Use: Iron-fouled ion exchange material regeneration applications

Federal Specification: ASTM E 1146, Specification for Muriatic Acid (Technical Grade Hydrochloric Acid)

Package/NSN: 96-oz, NSN: 6810-00-222-9641

5-gal can, NSN: 6810-00-236-5665

15-gal carboy, NSN: 6810-00-823-8010

E-14 MORPHOLINE.

Boiler feedwater compound, all drums to bear adequate caution labels to protect against fire, poison, and caustic burn hazards

Use: Control corrosion by CO_2 in steam condensate lines Federal Specification: A-A-59665, *Morpholine,* Technical Package/NSN:

40 percent 5-gal can, NSN: 6810-00-419-4298

40 percent 55-gal drum, NSN: 6810-00-559-9889

91 percent 55-gal drum, NSN: 6810-00-616-9437

98 percent 55-gal drum, NSN: 6810-00-559-9888

E-15 OCTADECYLAMINE.

Nontoxic, creamy white dispersion of octadecylamine, chemical formula $C_{18}H_{37}NH_2$, melting point of 114° F (45° C), boiling point of 697° F (369° C), filming amine

Use: Control corrosion by CO_2 in steam condensate lines Federal Specification: None

Package/NSN: 55-gal drum, NSN: None

E-16 PHOSPHATE COMPOUNDS (SEE ITEMS E-17 THROUGH E-26).

E-17 DISODIUM PHOSPHATE.

Anhydrous (Na_2HPO_4), 49 percent P_2O_5 minimum

Use: Remove hardness in boiler water

Federal Specification: MIL-DTL-32598, Sodium Phosphate, Dibasic, Anhydrous, Technical

Package/NSN: 100-lb bag, NSN: 6810-00-264-6630

E-18 DISODIUM PHOSPHATE.

Dodecahydrate (NA2HPO41•2H2O), 19 percent P2O5 minimum

Use: Remove hardness in boiler water

Federal Specification: None Package/NSN: 100-lb bag, NSN: None

E-19 POLYPHOSPHATE GLASS.

Slowly soluble, minimum P_2O_5 content 67 percent, solubility: 10 to 20 percent per month

Use: Treatment of cooling water in smaller cooling towers Federal Specification: None

Package/NSN: 100-lb drum, NSN: 6850-00-014-3442

E-20 SODIUM HEXAMETAPHOSPHATE.

$(NaPO_3)_6$ technical, type II, 66.5 percent P_2O_5, glassy form, beads or plates.

Use: Cathodic corrosion inhibitor in cooling towers and to remove hardness in boiler water

Federal Specification: O-S-635, *Sodium Polyphosphates, Technical*, Type II
Package/NSN: 100-lb bag, NSN: 6810-00-531-7805

E-21 SODIUM TRIPOLYPHOSPHATE.

Anhydrous ($Na_5P_3O_{10}$), white granular, 56 percent P_2O_5

Use: Remove hardness in boiler water

Federal Specification: O-S-635, *Sodium Polyphosphates, Technical*, Type III
Package/NSN: 100-lb bag, NSN: 6810-00-753-5053

100-lb bag, NSN: 6810-00-926-4836

E-22 SODIUM TRIPOLYPHOSPHATE.

Hexahydrate, ($Na_5P_3O_{10}$•$6H_2O$), granular or powder, 43 percent P_2O_5 minimum

Use: Remove hardness in boiler water

Federal Specification: None Package/NSN: 100-lb bag, NSN: None

E-23 TETRASODIUM PYROPHOSPHATE.

Anhydrous, ($Na_4P_2O_7$), granular, 53 percent P_2O_5, minimum

Use: Corrosion inhibitor in cooling towers and to remove hardness in boiler water

Federal Specification: None Package/NSN: 100-lb bag, NSN: 6810-00-249-8038

E-24 TETRASODIUM PYROPHOSPHATE.

Decahydrate, ($Na_4P_2O_7$•$10H_2O$), 31 percent P_2O_5 minimum

Use: Corrosion inhibitor in cooling towers and to remove hardness in boiler water

Federal Specification: None Package/NSN: 100-lb bag, NSN: None

E-25 TRISODIUM PHOSPHATE (TSP).

Monohydrate (Na_3PO_4•H_2O) technical, powder or granular, 36 percent P_2O_5 minimum

Use: Remove hardness in boiler water

Federal Specification: MIL-DTL-32594, Sodium Phosphate, Tribasic, Anhydrous; Dodecahydrate; and Monohydrate; Technical, Type III

Package/NSN: 100-lb bag, NSN: None.

E-26 TRISODIUM PHOSPHATE (TSP).

Dodecahydrate (Na_3PO_4•$12H_2O$) granular flake or crystalline, 16 percent P_2O_5 minimum

Use: Remove hardness in boiler water

Federal Specification: MIL-DTL-32594, Sodium Phosphate, Tribasic, Anhydrous; Dodecahydrate; and Monohydrate; Technical, Type II

Package/NSN: 100-lb drum, NSN: None

E-27 POLYACRYLATE.

Low molecular weight, water white to light amber color, total solids 45 to 65 percent, pH of 2.2 to 7.5, approximate molecular weight 2000 to 5000, specific gravity 77˚ F (1.1 to 1.23 at 25˚ C), viscosity 400 to 1400 at 77° F (25˚ C).

Use: Sludge dispersant in boilers

Federal Specification: None Package/NSN: None

E-28 POLYACRYLIC ACID.

Low molecular weight, water white to light amber color, total solids 45 to 65 ±2 percent, approximate molecular weight 1000 to 4000, specific gravity 1.1 to 1.3 at 77° (25˚ C), viscosity 200-1000 cps at 77° (25˚ C).

Use: Dispersant in cooling towers to prevent fouling by nonliving matter

Federal Specification: None

Package/NSN: 55-gal drum, NSN: 6850-01-194-6613

E-29 POLYMETHACRYLATE.

Low molecular weight, clear amber liquid, total solids 29 to 41 percent, pH of 6.0 to 10.5, approximate molecular weight 3800 to 10000, specific gravity 1.18 to 1.27 at 77° (25˚ C), viscosity 50 to 700 at 77° (25˚ C).

Use: Sludge dispersant in boilers

Federal Specification: None

Package/NSN: None

E-30 QUEBRACHO TANNIN EXTRACT.

Type I, powder Use: Sludge dispersant in boilers

Federal Specification: None

Package/NSN: 50-lb bag, NSN: 6810-00-891-5741

E-31 SALT (SEE SODIUM CHLORIDE, ITEM E-35).

E-32 SLAKED LIME (SEE CALCIUM HYDROXIDE, ITEM E-5).

E-33 SODA ASH (SEE SODIUM CARBONATE, ITEM E-34).

E-34 SODIUM CARBONATE.

(Soda ash) (Na_2CO_3), anhydrous technical, granular or powder form, 99.2 percent minimum by weight

Use: Remove calcium sulfate from water, increase alkalinity in boilers

Federal Specification: A-A-59563. “Sodium Carbonate, Anhydrous, Technical”
Package/NSN: 25-lb bag, NSN: 6810-00-262-0951

100-lb drum, NSN: 6810-00-233-1715

E-35 SODIUM CHLORIDE.

(Salt) (NaCl), technical mineral type, crude-sized form, type I, water soluble salt, 98.5 percent NaCl by weight

Use: Regenerate ion exchange resins

Federal Specification: A-A-694, Sodium Chloride, Technical (Water Conditioning Grade)

Package/NSN: 50-lb bag, NSN: 6810-01-026-0951, 80-lb bag, NSN: 6810-00-227-0437

E-36 SODIUM HYDROSULFIDE.

($NaSH \bullet 2H_2O$), technical grade, flake, 70 to 72 percent NaSH by weight

Use: Regenerate iron fouled ion exchange materials

Federal Specification: None

Package/NSN: 50-lb bag, NSN: None

E-37 SODIUM HYDROXIDE.

(Caustic soda) (NaOH), technical, type I, flake form particle size gradation A/A, 96 percent minimum assay as NaOH

Use: Regenerate ion exchange material, increase alkalinity in boilers and adjust pH in water

Federal Specification: None

Package/NSN: 100-lb drum, NSN: 6810-00-174-6581

E-38 SODIUM HYPOCHLORITE SOLUTION.

(NaOCl), clear, light-yellow liquid containing not less than 10 percent available chlorine by volume

Use: Disinfectant and treatment of Legionnaires‘ disease in cooling towers

Package/NSN: 5-gal can, NSN: 6810-00-169-5163

55-gal drum, NSN: 6810-00-214-8743

E-39 SODIUM MOLYBDATE.

Dihydrate ($Na_2MoO_4 \cdot 2H_2O$), white, free flowing odorless powder, soluble in water, commercial grade

Use: Corrosion inhibitor for open cooling systems

Federal Specification: None

Package/NSN: 200-lb lined fiber drum, NSN: None

E-40 SODIUM MOLYBDATE.

Solution, 35 percent as Na_2MoO_4, clear liquid, soluble in water

Use: Corrosion inhibitor for open cooling systems

Federal Specification: None Package/NSN: 55-gal drum, NSN: None

E-41 SODIUM MOLYBDATE BLEND.

Liquid, mixture of 10 to 12 percent sodium molybdate (Na_2MoO_4), 3 to 5 percent sodium hydroxide (NaOH), and 3 to 4 percent copper corrosion inhibitor

Use: Corrosion control in hot water systems, chilled and brine systems, combined hot and chilled water systems, and diesel engine jacket cooling systems; compatible with ethylene glycol antifreeze

Federal Specification: None

Package/NSN: 55-gal drum, NSN: 6850-01-185-1188

E-42 SODIUM NITRITE.

($NaNO_2$), granular, 97 percent NO_2 by weight, technical grade

Use: Corrosion control in hot water systems

Federal Specification: O-S-634, Sodium Nitrate, Technical (Nitrate of Soda)

Package/NSN: 100-lb drum, NSN: None

E-43 SODIUM NITRITE-BORAX BLEND.

Powdered or granular, a mixture of 65 to 70 percent sodium nitrite, 8 to 12 percent borax (sodium tetraborate), 4 to 5 percent copper corrosion inhibitor, and 15 to 20 percent sodium carbonate, free of excess foreign matter

Use: Corrosion control in closed hot water systems. Compatible with ethylene glycol antifreeze.

Federal Specification: None

Package/NSN: 30-gal can, NSN: 6850-01-185-1187

E-44 SODIUM SILICATE.

Relatively low alkalinity, 41° Bé, approximately 28.8 percent SiO_2, 6 to 7 percent Na_2O, not more than 0.5 percent suspended matter

Use: Cathodic corrosion inhibitor in cooling towers

Federal Specification: Canceled

Package/NSN: 5-gal can, NSN: 6810-00-247-0607

55-gal drum, NSN: 6810-00-247-0609

E-45 SODIUM SULFITE.

(Na_2SO_3), anhydrous, granular, 96 percent by weight minimum

Use: Remove oxygen from boiler feedwater and closed hot water systems (oxygen scavenger)

Federal Specification: A-A-5916B, Sodium Sulfite, Anhydrous, Technical

Package/NSN: 100-lb bag, NSN: 6810-00-782-2677

E-46 SODIUM SULFITE.

Catalyzed with cobalt, granular, 95 percent by weight minimum

Use: Remove oxygen from boiler feedwater (oxygen scavenger)

Federal Specification: None

Package/NSN: 50-lb bag, NSN: 6850-01-109-5604

E-47 SULFONATED STYRENE COPOLYMER.

Low molecular weight, clear amber color, total solids, 23 to 27 percent, pH of 6.8, molecular weight 5000 to 10,000, specific gravity 1.2 at 25° C, viscosity 10 to 40 at 25° C

Use: Sludge dispersant in boilers

Federal Specification: None Package/NSN: None

E-48 SULFURIC ACID.

(H_2SO_4), technical, class A, grade 2, 93 percent sulfuric acid concentration, 66° Bé

Use: Regenerate ion exchange resins, adjust pH in cooling towers

Federal Specification: None

Package/NSN: 13-gal carboy, NSN: 6810-00-975-0707 Bulk, NSN: 6810-00-251-8007

E-49 TOLYLTRIAZOLE (TTA).

Active ingredient 50 percent sodium tolyltriazole (43 percent TT)

Use: Corrosion inhibitor for copper alloys in cooling water systems

Federal Specification: None

Package/NSN: 5-gal can, NSN: 6850-01-189-9949

E-50 ZINC SULFATE.

Monohydrate ($ZnSO_4 \bullet H_2O$), white, free-flowing powder, soluble in water

Use: Cathodic corrosion inhibitor in cooling towers

Federal Specification: None

Package/NSN: 50-lb bag, NSN: 6810-01-198-3832

F-2 DEFINITION OF TERMS.

Acid: A compound, usually having a sour taste, which can neutralize an alkali or base; a substance that dissolves in water with a formation of hydrogen ions.

Aeration: Intimate contact between air and liquid by one of the following methods: spraying the liquid in the air; bubbling air through the liquid; or agitating the liquid to promote surface absorption of air.

Algae: Tiny plant life, usually microscopic, existing in water. They are mostly green, blue-green, or yellow-green, and are the cause of most tastes and odors in water. They create suspended solids (SS) when they grow in an industrial water system.

Alkalinity: (a) A term used to represent the content of carbonates, bicarbonates, hydroxides, and occasionally borates, silicates, and phosphates in water. (b) The capacity of water to react with hydrogen ions.

Alkalinity, total or mixed indicator (M): A measure of the total alkalinity of water. Measured by the quantity of 0.02 normality (N) sulfuric acid required to bring water to pH of 4.4, as indicated by the change in color of methyl orange or a mixed indicator. Results are expressed in parts per million (ppm) as calcium carbonate.

Alkalinity, Phenolphthalein (P): A measure of hydroxide ions (OH) plus one-half of the normal carbonates in water. Measured by the quantity of 0.02 normality (N) sulfuric acid required to bring the water to pH 8.2, as indicated by the de-colorization of phenolphthalein indicator. Results are expressed in parts per million (ppm) as calcium carbonate.

Alkalinity, Hydroxyl: A measure of hydroxyl ion (OH^-) contribution to the alkalinity. This is related to the system pH and also may be referred to as “causticity.”

Backwash: The reversal of flow through a filter or an ion exchanger to wash clogging material out of the filtering medium and reduce conditions causing loss of head.

Backflow preventer: A device for a water supply pipe to prevent the backflow of water into the water supply system from the system which it supplies.

Bacteria: Simple single-cell microscopic organisms generally free of pigment. They do not require light for their life processes.

Base: An alkali or hydroxide of alkali metals and ammonia. They can neutralize acids to form salts and water. A base will ionize to form hydroxyl ions (OH).

Biocides: Material typically used to destroy microorganisms (also called “microbiocides”).

Biological Deposits: Water-formed deposits of organisms or the products of their life processes. Biological deposits may be composed of microscopic organisms, as in slimes, or of macroscopic organisms such as barnacles or mussels.

Blowdown: Draining a portion of water from a system to reduce the concentration of dissolved solids or to discharge accumulations of materials carried by the water.

British Thermal Unit (BTU): The amount of heat necessary to raise the temperature of one pound of water one degree Fahrenheit (°F).

Brine: A saturated solution for ion exchange regeneration, refrigeration, or cooling processes. It is usually a sodium chloride water solution for ion exchange regeneration. It may be sodium chloride water solution or calcium chloride water solution for refrigeration.

Causticity: A common term that describes hydroxyl alkalinity or the alkalinity resulting from the presence of the hydroxyl ion (OH).

Concentration: A measure of the amount of dissolved substances contained per unit volume of solution. This may be expressed as grains per gallon, pounds per million gallons, milligrams per liter, ppm, or percent.

Condensate: The material formed when vapor returns to the liquid state. In steam heating systems, the water condensed from steam. In air conditioning, water extracted from air by condensation on the cooling coil of a refrigeration machine.

Conductivity, Specific Conductance: The reciprocal of the resistance in ohms measured between opposite faces of a centimeter cube of an aqueous solution at a specified temperature. Electrical conductivity is expressed in micromhos (µmhos), the reciprocal of megohms. This is used as a measure of total dissolved solids (TDS).

Corrosion: The destruction of a substance, usually a metal, or its properties because of a reaction with its (environmental) surroundings.

Cycles of Concentration (COC): In a system in which water lost through evaporation and blowdown is replaced with makeup water, COC is the ratio of the makeup quantity to the blowdown quantity (COC = M/B). It is the number of times the makeup water is concentrated in the system. The COC can also be calculated by dividing either the conductivity or the chloride content of the blowdown by the conductivity or chloride content of the makeup ($COC = Cond_{bd}/Cond_{mw}$).

Deaerator: Device for removing non-condensable gases from the boiler. It may operate on the principle of either heat or vacuum.

Dealkalization: Exchange of bicarbonate for chlorides in an ion exchange process.

Deionization: Complete removal of ions from water.

Demineralization: Reduction of the mineral content of water by a physical or chemical process; removal of salts.

Disinfection: The process of killing most (but not necessarily all) of the harmful and objectionable microorganisms in a fluid by various agents such as chemicals, heat, ultraviolet light, ultrasonic waves, or radiation.

Dissolved solids: (a) Solids, usually minerals, which are present in solution. (b) The dried residue from evaporation of the filtrate after separation of suspended solids (SS).

Distribution Ratio (D.R.): This is a measure of the vapor/liquid ratio for a given material. Extremely high and low values are generally unadvisable. A high D.R. results in either high amine losses at any vents or little availability of amine at points of initial condensation, or both. A low D.R. results in high amine losses in the blowdown.

Evaporation: The process by which water passes from a liquid state to a vapor. It is the main process by which heat is removed from a cooling tower and steam is produced in a boiler.

Feed water: Water being applied to the feed water heater or to the boiler, consisting of both makeup and condensate return.

Filming Amines: Chemicals that form an impervious barrier between metal and the steam condensate to prevent corrosion.

Foulants: Deposition of materials normally in suspension. This includes silt, air-scrubbed dust, microbiological residuals, reaction products from treatment, and corrosion products.

Generic Chemicals: A chemical identified and purchased by the recognized chemical name, such as the International Union of Pure and Applied Chemistry (IUPAC) designation. These generic chemicals may be blended or used separately. They are usually much less expensive than special chemical blends developed by manufacturers under a trade name.

Hardness: (a) A characteristic of water, chiefly due to the existence of carbonate and sulfate (and occasionally the nitrite and chloride) salts of calcium, iron, and magnesium. (b) Commonly computed from the amount of calcium and magnesium in the water and expressed as equivalent calcium carbonate. (c) Causes "curding" of water when soap is used, increased consumption of soap, deposition of scale in boilers, injurious effects in some industrial processes, and sometimes objectionable taste in the water.

Hardness, Carbonate: Hardness caused by the presence of carbonates and bicarbonates of calcium and magnesium in water. Such hardness may be removed to the limit of solubility by boiling the water. This is also called temporary hardness.

Hardness, Non-Carbonate: Hardness caused by calcium and magnesium sulfates and chlorides and compounds other than carbonates which cannot be reduced materially by boiling the water. (Also called "permanent hardness".)

Hardness, Total: The sum of carbonate and non-carbonate hardness.

Hydrogen Ion Concentration: Commonly expressed as the pH value that represents the logarithm of the reciprocal of the hydrogen ion concentration.

Inhibitor (applied to corrosion): A chemical substance or mixture that effectively decreases corrosion when added to a liquid (usually in small concentrations).

Ion: A particle, atom, or group of atoms, carrying either a positive or negative electrical charge, formed when an electrolyte is dissolved in water.

Ion Exchange: A process where water is passed through a granular material wherein ions on the granular material are replaced by ions contained in the water. For example, in the zeolite softening process, the sodium ions (Na^+) of the granular zeolite are replaced by the calcium ions (Ca^{++}) in the water to leave the water free of calcium (the cause of hardness), but with an increased amount of sodium.

Langelier Index (saturation index): An index based on the calcium hardness, total alkalinity, total dissolved solids (TDS), temperature, and pH. It is used to classify waters by their ability to either dissolve or deposit calcium carbonate. It is the algebraic difference between the actual pH and the calculated pH of saturation (pH_s) (LI = pH -

pH_s). A positive value indicates a scale-forming tendency, a negative value indicates a scale-dissolving tendency. It was one of the first indices developed for this purpose and was designed specifically for municipal water flowing in distribution lines.

Makeup Water: Water supplied to replace the loss in a system due to leaks, evaporation, wind drift, bleed-off, blowdown, or withdrawal.

Microbiocide: A material added to cooling tower water and chilled water to control the growth of microorganisms such as algae, bacteria, and fungi.

Micromho: An electrical unit of conductance (one-millionth of a mho), which is the reciprocal of electrical resistance.

Microorganism: A minute plant or animal in water or earth that is visible only through a microscope.

Milligrams per Liter (mg/l): A unit of the concentration of water or wastewater constituent. It is 0.001 gram of the constituent in 1000 milliliters (ml) of water.

Neutralizing Amines: Chemicals used to neutralize carbon dioxide in steam condensate to prevent corrosion.

Normality (N): The concentration of a solution in relation to a normal solution. Normality is a measure of the “strength” of a given solution. The normal solution contains a specific weight of a substance per liter based on the characteristics of the substance. Thus, a half-normal solution would be expressed as 0.5 N or N/2.

Oxygen Scavenger: A chemical used to remove final traces (trace amounts) of oxygen from boiler feedwater.

pH: Logarithmic measure of hydrogen ion concentration indicating degree of acidity or alkalinity of a solution. The pH range varies from 1 to 14. Values below 7.0 indicate acidity and above 7.0 indicate alkalinity (basicity).

pH_{eq}: The pH of equilibrium. The adjusted pH value of a water based on the empirical relationship between total alkalinity and pH developed from studies of hundreds of cooling systems. Development of an empirical relationship was necessary because pH in cooling waters is often buffered, a factor which affects the relationship between pH and bicarbonate alkalinity.

pH_s: The pH of saturation. It is the pH value below which a material will go into solution (dissolve) and above which it will precipitate. It is applied to calcium carbonate in the Langelier, Ryznar, and Practical Scaling Indices. It is a function of the calcium hardness, the total alkalinity, the total dissolved solids (TDS) and the temperature. It is determined with graphs, tables, or special slide rules. This equation is useful:

$$pH_s = 12.27 - 0.00915T - \log CaH - \log TA + (\log TDS)/10.$$

Phosphates: Chemicals used for corrosion control in cooling towers and deposit control in boilers. Commonly, these occur as orthophosphates or polyphosphates. The level of the active phosphate chemical is reported either as percent P_2O_5 (phosphorus pentoxide) or as PO_4 (phosphate), with these two oxides of phosphate being related by factor as follows: $PO_4 = 1.34 \times P_2O_5$.

ppm: Parts per million; one pound of material dissolved in one million pounds of water.

Precipitate: (a) To separate a dissolved substance in the solid form by its removal from a solution. (b) The substance in solid form that has been separated from solution.

Practical Scaling Index (PSI) — A modified scaling index developed by P.R. Puckorius and J.M. Brooke to provide a better and more consistent indication of scaling conditions of cooling water. It is based on using the pH of equilibrium (pH_{eq}) rather than the actual pH, and is calculated as follows:

$$PSI = 2\ pH_s - pH_{eq}.$$

As with the RSI, a value less than 6.0 in natural water indicates a scale-forming tendency. A value greater than 6.0 in natural water indicates a scale-dissolving tendency.

Regeneration: That part of the operating cycle of an ion exchange process in which a specific chemical solution is passed through the ion exchange bed to prepare it for a service run (return the ion exchange bed to its original composition).

Ryznar Index (stability index): An index classifying water as to its ability to dissolve or deposit calcium carbonate scale. It is calculated as twice the pH of saturation minus the actual pH ($RI = 2\ pH_s - pH$). Although in theory an RI of 7.0 should be neutral, experiments indicate that 6.0 is a better value. A value less than 6.0 in natural water indicates a scale-forming tendency. A value greater than 6.0 in natural water indicates a scale-dissolving tendency.

Scale: Deposition on a heat transfer surface of normally soluble salts. Scale is usually crystalline and dense, frequently laminated, and occasionally columnar in structure.

Shock Feed: The process of adding one or more water treatment chemicals in one application rather than gradually.

Slime: Biological growths that may accumulate to the extent that they foul equipment.

Sludge: A water-formed deposit that will settle, and may include all suspended solids (SS) carried by water. Sludge is commonly formed in boilers where it may be baked into place and become hard and adherent.

Softening Water: The process of removing from water the mineral substances that produce a condition called hardness. There are two softening processes in general use: chemical precipitation (lime and lime/soda softening) and the zeolite ion exchange process.

Solids, Suspended (SS): All matter in water that is not dissolved and can be removed with filtration.

Solids, Dissolved: The total concentration of all substances in a filtered solution which exist as solids after the liquid is completely evaporated from the solution.

Solids, Total: The sum of the suspended and dissolved matter (solids).

Zeolite: Natural minerals as well as synthetic resins used for ion exchange.

Change No.	**Date**	**Location**
1	1 Aug 2020	Corrected oil droplet sizes in section A-12.1.
2	1 Jan 2021	1. Changed heading 33.42 Minimum Flow Depths from [Replacement] to [Delete] and deleted the paragraph. 2. Deleted heading and paragraph for 34.11 Ladders [Addition] and replaced it with 34.11 Steps, Rungs and Ladders [Addition], revise the previous criteria for ladders and included new criteria for steps in manholes.
3	1 Mar 2024	Added the IPC as a modified standard in Chapter 1 and added modifications to the IPC in Chapter 3.
4	1 Oct 2024	Revised reference to 29 CFR 1910.23(d) for fixed ladder criteria in Chapter 3.

This UFC supersedes UFC 3-240-01 dated November 2012, UFC 3-240-02 dated November 2012 and UFC 4-832-01N dated January 2004.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineering Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-240-01 *Wastewater Collection and Treatment*

Superseding: UFC 3-240-01 dated 1 November 2012, with Change 1 dated 1 November 2014, UFC 3-240-02 dated 1 November 2012 with Change 2 dated 1 January 2019, and UFC 4-832-01N dated 16 January 2004.

Description: This revised UFC consolidates criteria for domestic wastewater collection, domestic wastewater treatment, industrial wastewater collection and industrial wastewater treatment into one UFC. The use of industry standards and federal codes aided in the consolidation of these criteria documents. This revision updates technical requirements, industry standards, and maximizes uniformity among Tri-Service requirements. Appendix C contains a complete list of referenced wastewater requirements and Appendix B contains a complete list of referenced best practices.

Reasons for Document:

- This revised UFC updates wastewater collection and treatment criteria that was previously contained in multiple criteria documents and efficiently consolidates them into a single UFC.
- Establishes technical requirements by maximizing the use of industry standards to meet DOD requirements.
- Reorganizes the content to align with industry standards.
- Coordinates criteria requirements in other core and specialty UFC criteria documents.

Impact:

- This revision will have minimal impacts on design cost.

Unification Issues:

- FC 1-300-09N is referenced for Navy design procedures.

TABLE OF CONTENTS

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

People have used different terminology to describe wastewater treatment facilities for many years. Today people use terms such as sewage treatment plant, wastewater treatment plant, wastewater treatment facility, or publicly owned treatment works to describe domestic wastewater treatment facilities. *Recommended Standards for Wastewater Facilities* uses the terms wastewater facilities or wastewater treatment facilities. The EPA generally uses the terms municipal wastewater treatment facilities and wastewater treatment facilities. In recent years, Water Environment Federation (WEF) started using the term water resource recovery facilities (WRRF) to describe domestic wastewater treatment facilities since the wastewater industry is becoming more focused on resource recovery. These terms apply only to domestic wastewater treatment. This terminology should not be used interchangeably with industrial wastewater treatment facilities.

1-2 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) provides requirements for domestic wastewater collection, domestic wastewater treatment, industrial wastewater collection and industrial wastewater treatment for the Department of Defense (DoD).

1-3 APPLICABILITY.

This UFC applies to service elements and contractors involved in the planning, design, and construction of permanent DoD facilities worldwide. It is applicable to all methods of project delivery and levels of construction. The contingency operation wastewater flows are applicable to facilities supporting military operations.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced herein.

1-5 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-6 NON-GOVERNMENT STANDARD MODIFICATIONS.

UFC 3-240-01 modifies Recommended Standards for Wastewater Facilities (known hereafter as the “10 States Standards”) for domestic wastewater collection treatment

\3 and the International Plumbing Code (IPC) in coordination with the modifications made by UFC 3-420-01. **/3/** Chapters 3 modifies **\3** the IPC and **/3/** Chapters 10, 20 and 30 of the 10 State Standards. Chapters 4 through 11 modify chapters 40 through 110 of the 10 States Standards. The 10 State Standards section modifications are one of four actions, according to the following legend:

[Addition] – Add new section, including new section number, not shown in 10 States Standards.

[Deletion] – Delete referenced 10 States Standards section.

[Replacement] – Delete referenced 10 States Standards section or noted portion and replace it with the narrative shown.

[Supplement] – Add narrative shown as a supplement to the narrative shown in the referenced section of 10 States Standards.

1-7 COMMENTARY.

Limited commentary has been added to the chapters. Section designations for such commentary are preceded by a "[C]" and the commentary narrative is highlighted with light gray.

1-8 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-9 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

1-10 BEST PRACTICES.

Appendix A provides guidance for accomplishing engineering services related to wastewater collection and treatment systems. The Designer of Record (DoR) is expected to review and interpret this guidance as it conforms to criteria and contract requirements and apply the information according to the needs of the project. If a Best Practices document has guidelines or requirements that differ from the Unified Facilities Guide Specifications (UFGS) or UFC, the UFGS and the UFC prevail. If a best practices document has guidelines or requirements that are not discussed in the UFGS or UFC, the DoR must submit a list of the guidelines or requirements being used for the project with sufficient documentation to the Authority Having Jurisdiction (AHJ) for review and approval before beginning design.

CHAPTER 2 PLANNING AND DESIGN

2-1 SAFETY.

Comply with DODINST 6055.01 and applicable Occupational Safety and Health Administration (OSHA) safety and health standards.

2-2 PLANNING.

Use UFC 3-201-01 for planning topics such as wetlands and flood hazard areas. Use the Installation's existing utility maps and planning documents to develop population estimates and plans for new service areas. Use WEF MOP 8, Chapter 2, *Principles of Integrated Design* for additional planning guidance.

2-2.1 Domestic Wastewater Collection.

In addition to population estimates, account for flow from industrial pretreatment, and ship to shore sources. Permits may be required for domestic wastewater collection systems.

2-2.2 Domestic Wastewater Treatment.

Plan the domestic wastewater treatment facility for current population and future population growth, minimum 5 years, using the Installation's master development plan. Account for seasonal fluctuations, low flow, peak flow, existing combined sewer flows, flow from industrial pretreatment, flow from ship to shore sources, receiving waterbody quality and discharge requirements. Plan for future expansion of new treatment components. Provide space for future expansion in the layout of new treatment components and processes. A life-cycle cost analysis should be conducted to account for future capacity issues, capital investment, operation and maintenance, and constructability. Applicable construction and operating permits are required for the treatment of domestic wastewater.

2-2.2.1 Pilot Testing.

Pilot testing should be performed as part of the planning effort because of the time required to perform tests. Evaluate the need for pilot testing using the 10 State Standards. Pilot testing can be used to verify performance predictions or determine the effectiveness of unit treatment processes needed for the design of a domestic wastewater treatment facility.

2-2.3 Industrial Wastewater Systems.

Plan the industrial wastewater treatment facility for the largest current and future peak flow, minimum 5 years, using the Installation's master development plan. Industrial wastewater may be discharged directly to a receiving waterbody when industrial wastewater effluent meets or exceeds receiving waterbody discharge requirements or indirectly to a domestic wastewater treatment facility when the industrial wastewater effluent meets or exceeds pretreatment requirements. Applicable construction and operating permits are required for the treatment or pretreatment of industrial wastewater. Refer to Figure 2-1 for an illustration of planning considerations. Use WEF MOP FD-3, Section 1, *Planning and Managing Industrial Wastewater Pretreatment Processes*.

Figure 2-1 Planning Considerations

Industrial Waste Characterization

- Identify industrial wastewater sources
- Identify types of pollutants
- Identify pollutant loads and flows
- Identify any variation in loads or flows
- Identify any existing treatment processes

↓

Regulatory Requirements and Treatment Criteria

- Define treatment objectives
- Identify discharge options, direct or indirect
- Identify categorical standards
- Identify permit requirements

2-2.3.1 Pilot Testing.

Pilot testing should be performed as part of the planning effort because of the time required to perform pilot testing. Pilot testing can be used to verify performance predictions or determine the effectiveness of unit treatment processes needed for design of industrial wastewater treatment facilities. Conduct pilot testing on the wastewater stream requiring treatment, when available, or on an equivalent wastewater stream.

2-2.4 Solids Management.

Use WEF MOP 8, Chapter 18 through 25 for guidance on solids or biosolids management.

Use *Solids Process Design and Management,* Chapter 2, *Considerations of Planning of Biosolids Management Projects,* for guidance on developing a biosolids management plan.

2-2.5 Planning For Non-War Emergencies.

Use *Emergency Planning, Response, and Recovery* for guidance when planning for non-war emergencies such as, earthquakes, hurricanes, tornadoes, and floods.

2-3 EXISTING CONDITIONS.

Use UFC 3-201-01 for preliminary site analysis, and evaluation of existing conditions such as geotechnical site investigation, environmental considerations, surveying, and topographic surveying.

2-3.1 Existing Sewers.

Use WEF MOP FD-6 for guidance when evaluating and rehabilitating existing sewers.

2-3.2 Modifications to Existing Wastewater Treatment Facilities.

Evaluate the effect of modifications on each individual wastewater treatment processes and notify the AHJ of any undersized treatment process or required upgrades to accommodate the modifications.

2-4 DESIGN.

Use UFC 3-201-01 for topics such as site development, grading, and storm drainage systems.

2-4.1 Design Criteria.

2-4.1.1 Within the United States.

For Installations located in the United States and its territories and possessions the wastewater system must comply with the following criteria precedence:

1. EPA or State as applicable and local regulations for the project location;
2. Utility provider’s requirements;
3. Criteria indicated in this UFC;
4. UFC 01-200-02 for energy and sustainability; and
5. Appendix A for design guidance.

2-4.1.2 Foreign Countries.

For Installations located outside of the United States and its territories and possessions, the wastewater system must comply with the following criteria precedence:

1. The Foreword of this UFC (All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation

Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA));

2. Final Governing Standards (FGS);
3. DoD 4715.05-G, Overseas Environmental Baseline Guidance Document (OEBGD);
4. Utility provider's requirements;
5. Criteria indicated in this UFC;
6. UFC 01-200-02 for energy and sustainability; and
7. Appendix A for design guidance.

DoD 4715.05-G, Overseas Environmental Baseline Guidance Document (OEBGD) applies when there are no FGSs in place. Therefore, in foreign countries this UFC will be used for DoD projects to the extent that it is allowed by and does not conflict with the applicable international agreements and the applicable FGS or OEBGD.

2-4.2 Design Approval.

The DoR must identify, assist, and provide, as applicable, all permits, approvals, and fees required for the design and construction of the new project from federal, state and local regulatory authorities or overseas equivalent. The DoR must be a Professional Engineer experienced and licensed. Licensure in the location of the project may be required to obtain permits and approvals. For new or rehabilitated sanitary sewer systems or facilities such as service extensions, domestic wastewater treatment, or industrial wastewater treatment, coordinate with the applicable primacy agency to determine permitting requirements. Consult with the Government Project Manager to determine the appropriate signatories for permit applications.

2-4.2.1 Within the United States.

In the United States and its territories and possessions, the Government will review permits for acceptability.

2-4.2.2 Foreign Countries.

In locations outside of the United States and its territories and possessions with host nation agreements, follow permit approval procedure as directed in project scope and by the Government Project Manager.

In locations outside of the United States and its territories and possessions without host nation agreements, the Government will review and approve plans for compliance.

2-5 FEDERAL DISCHARGE REQUIREMENTS.

In the United States and its territories and possessions, the EPA implements the Clean Water Act and regulates quality standards for surface waters. The Clean Water Act provides Federal regulations for the discharge of pollutants into the waters of the United States. The National Pollutant Discharge Elimination System (NPDES) 40 CFR 122 and the National Pretreatment Program 40 CFR 403.6 provide specific discharge standards and requirements for pollutants based on industry, pollutant, available technology and type of source. The EPA may delegate this authority to individual states territories or possessions.

2-6 CORROSION CONTROL.

Use AWWA M27, WEF MOP 8, Chapter 8, *Materials of Construction and Corrosion Control* and ASCE MOP 60, Chapter 4, *Corrosion Processes and Controls in Municipal Wastewater Collection Systems* for guidance on corrosion control.

2-6.1 Hydrogen Sulfide and Other Internally Corrosive Conditions.

In areas where high hydrogen sulfide concentrations, such as piping in wet wells or manholes, provide corrosion resistant materials, coatings or linings.

2-6.2 Materials Selection.

Approach selection of construction materials for corrosion control systems in accordance with the recommendations of WEF MOP 8, Chapter 8, Materials of Construction and Corrosion Control and AWWA M27. Corrosion control systems, such as, coatings, linings, polyethylene encasement or cathodic protection may be used to protect materials from corrosion. Explicit approval by the AHJ is required prior to providing a cathodic protection system on a buried pipeline. Use UFC 3-570-01 for the design of cathodic protection systems.

2-7 SECURITY.

Security must be an integral part of wastewater resource recovery system design. Planners, engineers, and security and antiterrorism personnel must determine site specific protective measures for wastewater systems. Use UFC 4-020-01 to establish protective measures. The engineering risk analysis, conducted as part of UFC 4-020-01, should be consistent with the terrorism risk analysis conducted by installation security or antiterrorism staff.

2-8 OPERATION AND MAINTENANCE.

Provide a design that:

- Minimizes operation and maintenance requirements, including additional training, higher level of operator certifications, or equipment that is not provided by the project. The AHJ must approve any operating equipment that is not provided by the project and required to maintain continuous operation of the wastewater treatment facility;

- Minimizes the number of operators required to operate the wastewater treatment facility. For new wastewater treatment facilities, the number of operators and level of training or operator certification required to operate the wastewater treatment facility must be approved by the AHJ. For existing wastewater treatment facilities, any increases to the number of operators, level of training, or operator certification required to operate the wastewater treatment facility must be approved by the AHJ. Give special consideration to minimizing operation and maintenance requirements in remote locations, including the limited availability of qualified operators available, technical support, and training opportunities;
- Includes operator training required to operate the wastewater treatment facility;
- Provides more than one piece of equipment, tank, or piping and isolation valves required to maintain continuous operation. Size equipment, tanks, and piping to maintain continuous operation with one piece of equipment or tank out of service.
- Provides space for the repair and removal of equipment without requiring the removal of equipment or pipe not in need of repair or replacement;
- Provides access, walkways, and space that complies with the applicable OSHA general industry and construction standards for operations, maintenance, and inspections;
- Provides tanks with isolation valves and drains to facilitate cleaning, inspection, and maintenance; and
- Provides drains with means of draining and containing pollutants that cannot be released to the environment.

2-8.2 Operation and Maintenance Manuals.

Prepare and furnish a site-specific operation and maintenance manual for wastewater pump stations and wastewater treatment systems, domestic or industrial. Operation and maintenance manual must include operating and maintenance procedures for the type of equipment specified or approved during construction, including any changes made during construction.

CHAPTER 3 – 10 STATES STANDARDS CHAPTERS 10, 20, AND 30

3-1 MODIFICATIONS TO CHAPTER 10 ENGINEERING REPORTS AND FACILITY PLANS.

For Navy: Use Chapter 10 except as modified by FC 1-300-09N.

3-1.1 SECTION 11 ENGINEERING REPORT OR FACILITY PLAN.

11.23 Population Projection and Planning Period [Replacement].

Use Chapter 2 to determine the minimum project planning period. Phased construction of wastewater facilities should be considered in rapid growth areas. Sewers and other facilities should be designed for the applicable Installation and project planning period.

11.23.1 Design Population [Addition].

Determine design population by the resident and nonresident populations. The effects of factors such as birth rates, death rates, and immigration are not applicable to military installations. The present and future populations may be obtained from the Installation's planning documents. Facilities that are not occupied and are included in the Installations current demotion plan should not be considered when determining resident and nonresident populations.

11.23.1.1 Resident Population [Addition].

Determine the resident population on full occupancy of all housing and quarters served. When the actual family population is unknown, the population of family housing units is typically estimated to be 3.6 residents per unit. Consider the number of National Guard, ROTC, reserve personnel, boarding schools, guesthouses, and any satellite functions such as service to a local community or other Federal agencies when estimating resident populations.

11.23.1.2 Non-resident Population [Addition].

Determine the non-resident population on full occupancy of all non-residential facilities. Consider the number of civil service personnel, contractor personnel, and daytime students when estimating non-resident populations.

11.242 Hydraulic Capacity for Wastewater Facilities to Serve Existing Collection Systems [Supplement].

When actual flow data is not available, use paragraph 11.243.

11.243 Hydraulic Capacity for Wastewater Facilities to Serve New Collection Systems [Replacement].

Hydraulic capacity for wastewater collection systems and wastewater facilities serving new collection systems.

a. Use Table 3-1 plus wastewater flow from industrial plants and major institutional and commercial facilities to compute the average daily flow unless water use data or other justification upon which to better estimate flow is provided.

b. When designing wastewater collection systems serving areas with wastewater generated by nonresidents or other short term uses, compute the average hourly flow rate based on the actual time period of waste generation.

c. Use the values in Table 3-1 and the peaking factors in Table 3-2 to compute peak flows. These peaking factors cover normal infiltration for wastewater collection systems built with modern construction techniques, refer to Chapter 30.

Table 3-1 Domestic Wastewater Allowances [1]

Permanent			
Type of Installation or Building	**Per Unit**	**gal/unit/day (L/unit/d)**	**Flow duration, Hours**
Single Family Housing [2,]	Per unit	300 (1136)	24
Multifamily Housing [2]	Per Unit	250 (946)	24
Type of Installation or Building	**Per Person**	**gal/cap/day (L/cap/d)**	**Flow duration, hours**
Military Installations	Per Person	100 (379)	24
Nonresident Personnel and Civilian Employees	Per Person	30 (114)	8
Military Training Camps	Per Person	50 (189)	24
BOQ and BEQ	Per Person	70 (265)	24
Barracks	Per Person	50 (189)	24
Temporary Host Nation Facilities			
Military Installations	Per Person	35 (132)	24
BOQ and BEQ	Per Person	20 (76)	24
Barracks	Per Person	15 (57)	24

1. Allowances do not include industrial or process wastes.
2. For the purpose of calculating populations in family housing areas, each housing unit is typically estimated to be 3.6 residents per unit.

Table 3-2 Minimum Peak Flow Factors

Population	Peak Factor
Greater than 500,000	2.5
Between 100,000 and 500,000	3.0
Less than 100,000	4.0

[C] 11.243 Hydraulic Capacity for Wastewater Facilities to Serve New Collection Systems [Replacement].

Peaking factors for military facilities are higher than most peaking factors to accommodate small populations, small service areas and unexpected operational changes.

d. Peak wastewater flow determined by total drainage fixture units may be used in lieu of estimated per capita peak flows if total drainage fixture unit flow is determined to be higher. Use UFC 3-420-01 and ASCE MOP 60 Chapter 3, titled *Quantity of Wastewater* to compute peak flow using total drainage fixture units.

[C] 11.243 Hydraulic Capacity for Wastewater Facilities to Serve New Collection Systems [Replacement].

Using total drainage fixture units to determine peak flow is not typically used by civil engineers to design wastewater collection systems. Using total drainage fixture units for facilities in which a large number of people may assemble in one place may be beneficial.

e. When actual flow data is not available and the condition of existing wastewater collection systems is unfavorable, an additional allowance for infiltration and inflow should be made.

f. When a new collection system serves existing facilities, evaluate the potential for infiltration and inflow from existing service lines or non-wastewater connections. Make an additional allowance for infiltration and inflow when infiltration and inflow from existing service lines is expected. Non-wastewater flows should be disconnect and rerouted or demolished.

11.244 Combined Sewer Interceptors [Replacement].

In addition to the above requirements, interceptors for existing combined sewers must have capacity to receive a sufficient quantity of combined wastewater for transport to treatment facilities to ensure attainment of the appropriate water quality standards.

11.244.1 Combined Sewers [Addition].

New combined sewers are not allowed. When an existing combined sewer is rehabilitated the stormwater interceptor should be separated from the wastewater collection system. Where stormwater interceptors are not separated from the wastewater collection system, rehabilitation of existing combined sewers may be approved when applicable regulations and permits allow rehabilitation of existing combined sewers.

11.245 Ship Chemical Holding Tank Discharges [Addition].

Use UFC 4-150-02 or contact the Government Project Manager for ship wastewater discharge capacities. Domestic wastewater discharges from ships have varying discharge capacities and high rates of flow.

11.246 Arctic Locations [Addition].

Wastewater systems in arctic locations practice water conservation. Water consumption is typically low, and infiltration is nil. If actual water consumption data are not available, base average daily wastewater flow for arctic locations on 80% of the flow determined for similar uses.

11.25 Organic Capacity [Supplement].

Pretreat normal laundry wastes when laundry flow exceeds 25% of the average daily wastewater flow.

11.250 Ship Chemical Holding Tank Discharges [Addition].

Ship wastewater discharges are more concentrated than typical domestic wastewater and may contain high concentrations of sodium from seawater use.

3-2 MODIFICATIONS TO CHAPTER 20 – ENGINEERING PLANS AND SPECIFICATIONS.

For Navy: Use Chapter 20 except as modified by FC 1-300-09N.

3-3 MODIFICATIONS TO CHAPTER 30 – DESIGN OF SEWERS.

3-3.1 SECTION 31 APPROVAL OF SEWERS [Supplement].

Use a gravity collection system unless justification is provided to and approved by the AHJ. A gravity sewer system is typically justified until the cost of the gravity system exceeds the cost of a pumped system by more than 10 percent.

31.1 Sewers for Collection of Ship Wastewater [Addition].

Use UFC 4-152-01 and UFC 4-150-02 for the design of piers, wharfs, and drydock wastewater collection facilities.

3-3.2 SECTION 33 DETAILS OF DESIGN AND CONSTRUCTION [SUPPLEMENT].

Design structural components of gravity sanitary sewer systems in accordance with UFC 1-200-01, ASCE MOP 60 Chapter 9, and the pipe manufacturer's recommendations. Provide appropriate seismic protection in areas subject to earthquakes. Use EPA 810-B-18-001 for seismic design guidance.

33.1.1 Building Connection [Addition].

\3 Use UFC 3-420-01 for building connections except as modified by this UFC.

[C] 33.1.1 Building Connection [Addition].

UFC 3-420-01 adopts and modifies the IPC. This section adopts and modifies Chapter 7 of the IPC which contains criteria for building sewer design. The building sewer is intended to begin 5 ft (1.5 m) from the building.

33.1.1.1 Modifications to the IPC.

701.3 Separate sewer connection. [Replacement].

Delete the last sentence and replace with the following:

Do not combine building sewers unless the connection is made in a manhole with a discharge pipe that is a minimum of 8 inches (200 mm) in diameter.

708.1.2 Building sewers. [Replacement].

Delete the first two sentences and replace with the following:

All building sewers must have a manhole located 5 ft (1.5 m) from the perimeter of the building or not more than 200 ft (61 m) from the connection to the building drain. Where a manhole is provided 5 ft (1.5 m) from the perimeter of the building, use the manhole to make the connection between the building drain and building sewer.

Where a manhole is not provided 5 ft (1.5 m) from the perimeter of the building, the junction of the building drain and the building sewer must be served by a cleanout that is located not more than 5 ft (1.5 m) from the perimeter of the building. When the length of the building sewer prior to the first manhole is greater than 100 ft (30.5 m), provide an additional cleanout so that either interval is not greater than 100 ft (30.5 m).

[C] 708.1.2 Building sewers.

Location and maximum spacing between manholes are covered in the 10 States Standards.

708.1.4 Changes in direction. [Replacement].

Where a manhole is not provided 5 ft (1.5 m) from the perimeter of the building and prior to the first manhole, provide cleanouts where the building sewer has a change of horizontal direction or a change of slope.

710.1 Maximum fixture unit load. [Supplement].

Add the following after the last sentence:

The minimum size for building sewers is 4 inches (100 mm) in diameter.

[C] 710.1 Maximum fixture unit load.

This supplement modifies Table 710.1(1) BUILDING DRAINS AND SEWERS and deletes pipes less than 4 inches (100 mm) in diameter from use as building sewers.

/3/

33.2 Depth [Supplement].

Minimum cover over sewer pipes must be the most stringent of the following requirements:

- 2 ft (0.61 m);
- 3 ft (0.91 m) for plastic pipe subject to traffic loading;
- greater than frost penetration according to UFC 3-301-01; or
- sufficient to support imposed dead and live loads for the pipe materials and pipe bedding used.

Evaluate temporary conditions during construction and final conditions. Provide calculations for minimum cover.

33.41 Recommended Minimum Slopes [Replacement].

Design and construct sewers with a diameter of 42 inches (1050 mm) or less to give minimum cleansing velocities, when flowing full, of not less than 2.0 feet per second (0.6 m/s), based on Manning's formula using an "n" value of 0.013. Minimum slopes for sewers with a diameter of 42 inches (1050 mm) or less are indicated in Table 3-3. Best

Practice: For sewer with a diameter of 42 inches or less, design sewers to provide a minimum velocity of 2.5 ft/sec (0.76 m/s), when flowing full.

Design and construct sewers with a diameter of 48 inches (1200 mm) or larger to give mean velocities, when flowing full, of not less than 3.0 feet per second (0.9 m/s), based on Manning's formula using an "n" value of 0.013.

33.42 \2\ Minimum Flow Depths [Delete] /2/.

Table 3-3 Minimum Slopes

Nominal Sewer Size	Minimum Slope in Feet Per 100 Feet (m/100 m)
8 inch (200 mm)	0.40
10 inch (250 mm)	0.28
12 inch (300 mm)	0.22
15 inch (375 mm)	0.15
18 inch (450 mm)	0.12
21 inch (525 mm)	0.10
24 inch (600 mm)	0.08
27 inch (675 mm)	0.067
30 inch (750 mm)	0.058
33 inch (825 mm)	0.052
36 inch (900 mm)	0.046
39 inch (975 mm)	0.041
42 inch (1050 mm)	0.037

33.43 Minimization of Solids Deposition [Replacement].

Select the pipe diameter and slope to minimize settling problems. Do not use oversized sewers to justify flatter slopes.

33.45 High Velocity Protection [Supplement].

Design gravity sewers to maintain subcritical flow conditions. Where steep slopes are unavoidable, use drop manholes to prevent supercritical flow conditions. Design downstream pipes to prevent hydraulic jumps and other flow disturbances.

33.47 Maximum Flow Depths [Addition].

Design sewer mains to carry the peak flow at a flow depth of no more than 0.9 d, where d is the sewer diameter.

33.5 Alignment [Replacement].

Use straight alignments between manholes.

Curvilinear alignment of sewers is not allowed.

33.7.1 Trenchless Technology [Addition].

Before beginning trenchless pipe design, obtain approval from the AHJ. Use UFC 3-230-01 for fusible pipe design.

3-3.3 SECTION 34 MANHOLES.

34.1 Location [Replacement].

Install manholes at the end of each line; all changes in grade, size, or alignment; at all intersections; at distances not greater than 400 ft (120 m) for sewers that are 15 inches (375 (mm) or less, and at 500 ft (150 m) for sewers that are 18 inches (450 mm) to 30 inches (750 mm). Distances of up to 600 ft (185 m) may be approved in cases where adequate modern cleaning equipment for such spacing is provided. Greater spacing may be permitted in larger sewers when approved by the AHJ.

34.1.1 Building Connections [Addition].

UFC 3-420-01 provides requirements for building sewers. These requirements include items such as making connections, changes in direction, location of cleanouts and for building connections larger than 8 in. (200 mm), and manhole location.

34.6 Watertightness [Supplement].

Watertight manhole frames and covers must be used when the manhole rim elevation is in the 100 year flood plain.

34.10 Frames and Covers [Addition].

Frames and covers must be sufficient to withstand impact from wheel loads where subject to vehicular or airfield traffic.

34.11 Steps, Rungs and Ladders [Addition].

\2 Provide steps or rungs in accordance with 29 CFR 1910.24(b) and ANSI A14.3 for manholes with a depth of 4 feet (1.2 m) or more above a lower level.

Provide a fixed ladder in accordance with **\4** 29 CFR 1910.23(d) **/4/** and ANSI A14.3 for manholes with a depth greater than 20 ft (6.1 m). ***/2/***

3-3.4 SECTION 35 INVERTED SIPHONS [SUPPLEMENT].

Depressed sewers must withstand internal pressures greater than atmospheric. Use pipe materials rated for force mains. Use inverted siphons only if no other option can be used.

3-3.5 SECTION 38 PROTECTION OF WATER SUPPLIES.

38.3 Relation to Water Mains [Replacement].

Use UFC 3-230-01 for horizontal and vertical separation distances from contaminated sources and wastewater sewer crossings.

38.31 Horizontal and Vertical Separation [Delete].

38.32 Crossings [Delete].

This Page Intentionally Left Blank

CHAPTER 4 – MODIFICATIONS TO CHAPTER 40 WASTEWATER PUMPING STATIONS

4-1 SECTION 41 GENERAL [SUPPLEMENT].

Use pumping stations only where specifically identified in the project scope of work or upon written approval from the AHJ. Obtain written approval before beginning design.

41.1 Flooding [Supplement].

Use UFC 3-201-01 for flood design.

41.2 Accessibility and Security [Replacement].

Provide pumping stations with adequate access for personnel and equipment maintenance and replacement. Access points must be lockable and meet Installation security requirements.

All pump stations must be readily accessible from an all-weather road. For stations that are not enclosed, provide access for direct maintenance from a truck equipped with hoist attachments. For enclosed stations, include provisions in the structure to facilitate access for repair and to provide a means for removal and loading of equipment.

41.4 Safety [Supplement].

Design the pump station to protect maintenance personnel from toxic, explosive, or otherwise hazardous atmospheres.

41.5 Site Selection [Addition].

Pumping facilities must not be constructed beneath buildings, streets, roadways, railroads, aircraft aprons or runways, or other major surface structures. Consider availability of utilities such as electric power, potable water, fire protection, gas, steam, and telephone service.

Maintain a minimum setback to buildings and other occupied facilities of 500 ft (152 m) for medium and large pumping stations, unless adequate measures are provided for odor and gas control. Small wastewater pumping stations are defined as having peak flows less than 500 gpm (31.5 L/s); medium wastewater pumping stations are defined as having peak flowrates of 500 gpm (31.5 L/s) to 3200 gpm (202 L/s); and large wastewater pumping stations are defined as having peak flows greater than 3200 gpm (202 L/s).

41.6 Architectural [Addition].

Design pump station buildings to be architecturally compatible with the surrounding buildings in accordance with the Installations Appearance Plan.

41.7 Upgrades to Existing Pumping Stations [Addition].

Existing pumping stations may be upgraded where a complete hydraulic analysis shows that the upgraded pumping station can operate at the proposed capacity in conformance with the jurisdictional requirements for a new pumping station of equal capacity. The hydraulic analysis must include effects on the existing force main to its point of discharge and, if networked, the effects on all other pumping stations connected to the system. This analysis is required whenever additional flow is added to a pump station, even if physical changes to the station are not proposed.

4-2 SECTION 42 DESIGN.

42.22 Equipment Removal [Supplement].

Provide space required to remove bolts from thrust harnesses of sleeve couplings and to slide couplings off joints. In the dry well or structure, provide a minimum clearance of 4 ft (1.2 m) between adjacent pump casings and a minimum of 3 ft (1.0 m) from each outboard pump to the closest wall. Maintain a 7 ft (2.1 m) minimum clearance between floor and overhead piping, where practicable.

42.3 Pumps [Supplement].

Evaluate the system characteristics and determine the requirements for the pumping systems, such as flow rates, system head-capacity curves, pump station location, area served and force main velocities when selecting pumps. To determine system requirements, develop a system head-capacity curve which includes minimum, average and peak flow rates for the design condition and, if applicable, any interim conditions. Select a minimum of three different pump manufactures or pump models capable of:

- Discharging the peak flow for the system with one pump out of service and simultaneous pump operation;
- Operating for the full range of wet well levels;
- Discharging to either a gravity sanitary sewer or force main as applicable; and
- Operating in the manufacturer’s recommended performance curve and maximizing pump efficiency for the design average and peak flow conditions.

Use WEF MOP FD-4 for guidance when developing system head-capacity curves and selecting pumps.

42.31 Multiple Units [Supplement].

A single pump may be used for a wastewater pumping stations serving extremely low flows, such as a remote gate house, when justification is provided to and approved by the AHJ.

42.35.1 Pump Motors [Addition].

Select a pump motor enclosure suitable for the pump location. Provide totally enclosed fan-cooled motors for dry well pump installations. Ensure submersible pumps have watertight motor enclosures. Ensure temperature ratings of motors installed outdoors are adjusted to suit ambient operating conditions. To prevent condensation in dry wells, provide heat for pump motors designed to operate on an intermittent basis. Use motors rated for hazardous locations. Use motor starter technology for large motors to limit inrush current and mitigate electrical transients on electrical supply.

42.35.2 Motor Horsepower [Addition].

Select the pump motor horsepower such that it will accommodate any variation in flow and head along the entire design impeller curve without motor overload or failure.

42.38 Pumping Rates [Supplement].

Use a computer program for water hammer analysis of large pump stations.

42.39 Cavitation [Addition].

Confirm net positive suction head available is greater than the manufacturer’s net positive suction head required at all anticipated operating conditions.

42.4.1 Adjustable Speed Drives [Addition].

Select the simplest system that allows pumps to accomplish the required hydraulic effects. Evaluate cost, efficiency, reliability, structural requirements, ease of operation, and degree of maintenance necessary. Operation and maintenance are critical at military installations where adequate personnel cannot always be provided. Coordinate with the electrical DoR when using adjustable speed drives for variable speed pump operation. In general, adjustable speed drives are more expensive, less efficient, and require a higher degree of maintenance than across-the-line full voltage motor starters. However, in some instances, adjustable speed drives may be the best approach.

42.4.2. Selection of Control Points [Addition].

Provide a minimum of 6 in. (150 mm) between pump control points used to start and stop successive pumps or to change pump speeds.

Set the high-water level in the wet well below the lowest incoming invert of the sewer and minimize the fall of wastewater releasing hydrogen sulfide.

42.62 Size [Supplement].

The minimum length, width, or diameter is 4 ft (1.2 m).

42.65 Pressure Gauges [Addition].

Provide pressure gages on discharge piping directly downstream of the pump in dry well pumping stations.

4-3 SECTION 46 ALARM SYSTEMS [SUPPLEMENT].

Provide alarms such as low level and high temperature when required by pump manufacturer to maintain the pump manufacturer's warranty.

Remote monitoring systems must meet the requirements in UFC 4-010-06. Use UFC 4-010-06 for cybersecurity Risk Management Framework (RMF).

4-4 SECTION 49 FORCE MAINS.

49.1 Velocity and Diameter [Replacement].

For grinder pumps use a minimum 1¼ in. (32 mm) diameter. For small non-clog submersible pumps and pneumatic ejectors use a minimum 4 in. (100 mm) diameter. Size force mains based on hydraulic calculations considering factors such as velocity, friction loss, and power requirements.

Flow velocities should range from 2 to 5 feet per second (0.6 to 1.5 meters per second) for the design flow. The maximum velocity depends on new and existing piping materials and appurtenances. Ensure that the maximum pressure of the piping materials and appurtenances exceeds the maximum pressure of the system, including the potential for surge pressure.

49.2 Air and Vacuum Release Valves [Supplement].

Use AWWA M51 for guidance on air and vacuum release valves.

49.4.1 Rigid Conduit [Addition].

For ductile iron force mains, use AWWA C150/ANSI A21.50 to calculate the required pressure class or special thickness class.

49.4.2 Flexible Conduit [Addition].

For PVC force mains use AWWA M23 and applicable AWWA and ASTM standards.

49.61 Friction Coefficient [Supplement].

Hazen-Williams Roughness: values lower than 80 are not allowed unless verified by flow and pressure tests; if verified, consider replacement.

49.10 Cover [Supplement].

Minimum cover over force mains must be the most stringent of the following requirements:

- 2 ft (0.61 m);
- 3 ft (0.91 m) for plastic pipe subject to traffic loading;
- greater than frost penetration according to UFC 3-301-01;
- greater than the depth required to install valve riser; or
- sufficient to support imposed dead and live loads for the pipe materials and pipe bedding used.

Evaluate temporary conditions during construction and final conditions. Provide calculations for minimum cover.

49.11 Thrust Restraint [Addition].

Use DIPRA for thrust restraint design procedures. Provide calculations for restrained joints using a minimum safety factor of 1.5. Use the geotechnical investigation report and consult with the Geotechnical Engineer to determine soil bearing capacity.

This Page Intentionally Left Blank

CHAPTER 5 – MODIFICATIONS TO CHAPTER 50 WASTEWATER TREATMENT FACILITIES

5-1 SECTION 51 PLANT LOCATION.

51.2 Flood Protection [Supplement].

Use UFC 3-201-01 for flood design and the minimum design flood elevation for flood design class 2. Provide wet proofing or dry proofing when station hatches are below the design flood elevation. Extend venting above the design flood elevation.

51.3 Location [Addition].

Maintain a minimum distance of 1,000 ft (305 m) between drinking water source and any wastewater treatment system.

For wastewater treatment facilities with a treatment capacity of 50,000 gpd (189 m^3/d) or less, maintain a minimum separation distance of 500 ft (152 m) from living quarters, working areas, and public use areas, when this minimum distance will not result in unacceptable noise or odor levels. Larger facilities, and wastewater treatment ponds regardless of size, must be more than one-quarter mile from living quarters, working areas, and public use areas.

51.3.1 Arctic and Cold Locations Outside the United States [Addition].

Exceptions to the 500 ft (152 m) restriction in paragraph 51.3 can be made for cold climate module complexes where the treatment system is a part of the module complex. Do not locate wastewater treatment equipment within the same module as living quarters.

5-2 SECTION 53 DESIGN.

53.1 Type of Treatment [Supplement].

The DoR must examine each unit operation in the proposed treatment system for potential problems caused by remote locations, limited availability of construction materials, available labor, time required for construction, cost of construction and operation and maintenance cost.

53.1.1 Arctic and Cold Locations Outside the United States [Addition].

For wastewater treatment unit operations in cold and arctic climates, the DoR must examine each unit operation in the proposed treatment system for potential problems caused by extreme cold, wind and snow, thermal stress on structures, frost heaving, and permafrost.

53.1.2 Tropic and Semiarid Locations Outside the United States [Addition].

For wastewater treatment unit operations in the tropics, the DoR must examine each unit operation in the proposed treatment system for potential problems caused by high temperature, torrential tropical rain, and variations in local wastewater characteristics.

53.2 Required Engineering Data for New Process and Application Evaluation [Supplement].

Provide three acceptable products when using a packaged wastewater treatment plant, equipment or component for approval. When approved by the AHJ, two acceptable products may be allowed. When only one suitable product is available, the DoR must submit a justification and authorization to the Government for approval. When a justification and authorization is approved by the Government Contracting Officer, one acceptable product will be allowed. Add the Government-approved product to the project specification.

53.2.1 Special Conditions for New Equipment Evaluation [Addition].

New equipment or components must be pre-approved for the proposed application and project conditions in the state or host nation where the project is located or approved by the applicable regulatory agencies. If the host nation does not maintain a pre-approved wastewater treatment equipment, equipment that is pre-approved for similar applications and project conditions by another state or host nation may be used when approved by the applicable regulatory authorities. Provide documentation indicating the location and conditions of the pre-approval and describe how the proposed application is similar to the project application.

5-3 SECTION 55 PLANT OUTFALLS.

55.1 Discharge Impact Control [Supplement].

A special study may be needed when effluent is discharged into a bay or similar area. Use ASCE MOP 60 for outfall studies and design guidance.

55.2 Protection and Maintenance [Supplement].

Anchor or pile support all sections of outfall pipelines subject to movement from the high water level to prevent movement.

Evaluate the low-water depth above the outfall pipe, ship and boat traffic, and use of anchors. Provide buoys, marking, or other means of warning as required.

55.4 Sizing and Capacity [Addition].

Design the minimum size of the outfall for peak hourly flow at the maximum anticipated stage of the receiving water. If the receiving water is tidal, evaluate both high and low conditions and tidal flow directions. If a diffuser is installed, use mixing models to select the port sizes and spacing. Ensure that port sizes are 2 in. (50 mm) in diameter or greater to avoid clogging by scaling or barnacles.

55.5 Outfall Depth [Addition].

Outfalls are typically a minimum of 8 ft (2.4 m) deep to provide mixing opportunity. Evaluate extending existing outfalls to deeper water. Factors for extending existing outfalls may include conditions such as, shallow water, shallow outfall depth, or permit compliance.

5-4 SECTION 57 SAFETY [SUPPLEMENT].

Ensure adequate safety by providing the following, as applicable:

- Continuous toxic gas monitors with alarms.
- Facility designs that eliminate the need to reach beyond safe limits.
- Facility designs that minimize the need for manual lifting.
- Directive, hazard-warning, and instructional signs, where appropriate.
- Equip pump and other equipment that handles corrosive solutions with spray or splash guards to protect the personnel working in the area.

57.2 Hazardous Chemical Handling [Supplement].

Include the following in a chemical handling area, as applicable:

- Easily accessible, clearly marked, well-lighted unloading stations.
- Guard posts to protect equipment and storage tanks from vehicle damage.
- A roofed platform or dock for unloading containerized chemicals.
- Mechanical devices to aid unloading and transporting chemicals to storage areas.
- Separate receiving and storage areas for chemicals that react violently when mixed together.
- Unique pipe configuration and valving for each chemical storage tank on-site to prevent the wrong chemical from being loaded into a tank.
- Dust control equipment for dry bulk and bagged chemicals.
- Protection of concrete against corrosive chemicals.
- Washdown and cleanup facilities for all chemical handling areas and separate drainage systems for noncompatible chemicals.
- A bulk tank level control system with a high-level alarm audible at the truck unloading station.

57.29 Eyewash Fountains and Safety Showers [Supplement].

Comply with the latest edition of ANSI Z358.1 for emergency eyewashes and shower equipment.

57.4 Chemical Storage [Addition].

Determine compatibility of all chemicals stored and store incompatible chemicals separately. Label all chemical storage areas. Follow the chemical manufacturer's recommendations regarding material compatibility and selection of system components in direct chemical contact. Include the following in a chemical storage areas, as applicable:

- Storage for peak demands.
- Light switches and ventilation controls located outside of the chemical storage rooms or areas.
- Automatic controls to actuate forced ventilation and lighting when chemical storage rooms are occupied.
- Protect exposed materials from the corrosive effects of stored chemicals.

57.4.1 Storage for Dry or Containerized Chemicals [Addition].

Provide the following:

- Dry rooms to store materials in original containers on boards or pallets.
- Adequate room to maneuver hand trucks, pallet jacks, or forklifts.
- Storage for dry chemicals at feed hopper inlet level or a platform capable of supporting a pallet of containers at the feed hopper inlet level.
- Signage indicating the safe load limits for floors, platforms and shelving.

57.4.2 Storage for Liquid Chemicals [Addition].

Provide the following:

- Containment of store volume plus a safety margin.
- Isolated containment for incompatible materials such as strong acids and strong bases.
- Capacity to hold the contents of one standard tank truck plus a sufficient reserve supply between shipments.
- Fire-rated storage facilities for flammable liquids.
- Freeze protection for exposed piping, valves, and bulk tanks.

5-5 SECTION 58 LABORATORY [SUPPLEMENT].

Do not locate administrative and laboratory buildings close to or downwind from primary treatment tanks, sludge drying beds ,or similar treatment processes that may cause unfavorable conditions.

CHAPTER 6 MODIFICATIONS TO CHAPTER 60 SCREENING, GRIT REMOVAL, AND FLOW EQUALIZATION

Use 10 State Standards Chapter 60.

This Page Intentionally Left Blank

CHAPTER 7 MODIFICATIONS TO CHAPTER 70 SETTLING

Use 10 State Standards Chapter 70.

This Page Intentionally Left Blank

CHAPTER 8 MODIFICATIONS TO CHAPTER 80 SLUDGE PROCESSING, STORAGE, AND DISPOSAL

8-1 SECTION 81 GENERAL. [ADDITION].

Comply with 40 CFR 501 and 40 CFR 503.

81.1 Domestic Wastewater and Septage [Addition].

For the disposal of sewage sludge generated during the treatment of domestic sewerage in a treatment works comply with:

40 CFR 258 for the disposal of sludge in a solid waste landfill; or

40 CFR 503 for land application, incineration, surface disposal and any other sludge use or disposal that may be regulated by 40 CFR 503. Refer to 40 CFR 503.6 for exclusions.

CHAPTER 9 MODIFICATIONS TO CHAPTER 90 BIOLOGICAL TREATMENT

Use 10 State Standards Chapter 90.

This Page Intentionally Left Blank

CHAPTER 10 MODIFICATIONS TO CHAPTER 100 DISINFECTION

10-1 SECTION 102 CHLORINE DISINFECTION.

102.1 Type [Supplement].

Do not use chlorine gas for disinfection in small treatment systems.

[C] 102.1 Type [Supplement].

Chlorine gas introduces additional safety concerns for both operators and others in close proximity. Operation of chlorine gas disinfection systems typically requires additional operator training.

This Page Intentionally Left Blank

CHAPTER 11 MODIFICATIONS TO CHAPTER 110 SUPPLEMENTAL TREATMENT PROCESSES

Use 10 State Standards Chapter 110.

This Page Intentionally Left Blank

CHAPTER 12 SMALL TREATMENT SYSTEMS

12-1 GENERAL.

Small treatment systems are defined as treatment systems and components with 10,000 or fewer people or an average wastewater flow of less than 1 mgd (3,785 m^3/d). Small treatment systems using conventional processes must comply with the 10 State Standards as modified by this UFC. Small treatment systems using innovative approaches to wastewater treatment may be allowed when approved by the AHJ. Use paragraph 53.2 for required engineering data and process evaluation for innovative approaches that do not conform to the 10 State Standards as modified by this UFC.

12-2 PACKAGED TREATMENT PLANT.

Packaged treatment plants are typically used for small treatment systems associated with military operations in remote locations. These systems combine processes such as aeration, settling, and solids treatment in a multi-compartment unit or units. Typical types of treatment include extended aeration (activated sludge), rotating biological contactors (RBC), and sequencing batch reactors (SBR). Various processes within the packaged treatment system may include proprietary components. The DoR is responsible for specifying performance requirements, construction quality control, testing and verification, providing operation and maintenance procedures, equipment startup and operator training. WEF MOP OM-7 provides operation and maintenance guidance for extended aeration systems.

This Page Intentionally Left Blank

CHAPTER 13 ON-SITE WASTEWATER TREATMENT AND DISPOSAL

13-1 GENERAL.

When a project is not served by a wastewater collection system, provide an on-site wastewater disposal system capable of handling the wastewater generated. Typical military applications include facilities such as remote training locations and remote entry control facilities. Use the IPSDC for on-site treatment systems.

13-2 ALTERNATIVE SEWER SYSTEMS.

Provide gravity collection systems when possible. Use the IPSDC for the design of alternative sewer systems.

13-3 HOLDING TANKS.

Holding tanks may be used when connecting to an approved wastewater collection system and constructing an on-site treatment system is not feasible. When a holding tank is used, the Installation must be able to demonstrate the means for regularly disposing of the sewage. Holding tank must be large enough to store peak flows for the Installation's disposal interval.

13-4 NONLIQUID SATURATED TREATMENT SYSTEMS.

Nonliquid saturated treatment systems, such as waterless toilets, may be used for composting human waste. Do not use a nonliquid saturated treatment system when a facility has a water supply source such as a potable water distribution system or potable well. Do not use non-potable water for handwashing or human consumption. Provide handwashing by waterless bacteriological hand cleaner and disposable hand towels or pre-moistened hand towels. Use the IPSDC for nonliquid saturated treatment systems.

This Page Intentionally Left Blank

CHAPTER 14 INDUSTRIAL WASTEWATER COLLECTION AND TREATMENT

14-1 INDUSTRIAL AND OILY WASTE CONTROL SYSTEMS.

This chapter provides design requirements for the collection and treatment of industrial and oily wastewater control systems. These requirements are intended to serve as a general guide to assist the DoR in determining all applicable requirements and include items such as permits, effluent discharge limits, and disposal of solids. The DoR must take into account new regulations, widely accepted practices and proven treatment technologies. More stringent state requirements may be applicable when the EPA has delegated their permitting authority to an approved state program or when the project is located outside of the jurisdiction of U.S. laws. The criteria provided does not eliminate, change or modify any statutory or regulatory requirement.

Collect and hold all fire suppression system discharge for offsite disposal. Do not collect fire suppression system discharge in domestic or industrial wastewater collection systems, combine with other industrial wastes, or provide industrial wastewater treatment for fire suppression system discharge. Use UFC 3-600-01 and UFC 4-211-01 for fire suppression system discharge collection and containment requirements.

14-2 SPILL PREVENTION, CONTROL, AND COUNTERMEASURE PLANS.

Use UFC 3-460-01 for spill prevention, control and countermeasures plan requirements associated with petroleum fuel facilities. 40 CFR 112.1 establishes the general applicability of the spill prevention, control and countermeasure rule. 40 CFR 112.1(d)(6) exempts wastewater treatment facilities or portions thereof that are used exclusively for wastewater treatment. This exemption does not apply to wastewater treatment devices such as oil water separators that are used to provide secondary containment under 40 CFR 112.8(c)(2) for oil storage containers. The exemption also does not apply to containers that are used to store recovered oil in an oily waste treatment process or facility. Refer to EPA 550-B-13-002 for additional guidance.

14-3 INDUSTRIAL DISCHARGE LIMITS.

Industrial wastewater may discharge wastewater either directly or indirectly. Indirect discharge is typically the most cost effective approach to treating industrial wastewater. For indirect discharge, effluent discharge limits are determined by pretreatment regulations and POTW requirements. For indirect discharge, the DoR must comply with pretreatment regulations, requirements set by the POTW and control mechanisms in the POTW’s NPDES permit. For direct discharge, effluent discharge limits are determined by direct discharge regulations and NPDES permits. For direct discharge, the DoR must obtain and comply with direct discharge regulations and the terms of the NPDES permit. EPA 833-R-12-001A provides industrial user permitting guidance.

14-4 GENERAL PRETREATMENT REGULATIONS FOR EXISTING AND NEW SOURCES OF POLLUTION (40 CFR 403).

The National Pretreatment Program, 40 CFR Part 403, provides the regulatory basis to require nondomestic dischargers to comply with pretreatment standards to ensure compliance with the Clean Water Act (CWA). The National Pretreatment Program controls toxic, conventional, and non-conventional pollutants from nondomestic sources that discharge into publically owned treatment works (POTW). EPA 833-B-11-001 provides federal pretreatment requirements and guidance.

14-4.1 Industrial Discharges.

Industrial discharges can fall into several different categories. Understanding and applying the requirements for industrial discharges is essential to understanding industrial wastewater treatment requirements and correctly applying responsibilities. 40 CFR 403.3 contains a complete list of definitions.

14-4.2 Industrial User (40 CFR 403.3(j)).

The National Pretreatment Program requires indirect discharges to obtain permits or other control mechanisms to discharge wastewater to the POTW. The permit may specify the effluent quality that necessitates that an industrial user pretreat or otherwise control pollutants in its wastewater before discharging it to a POTW.

14-4.3 Categorical Industrial User.

An industrial user subject to national categorical pretreatment standards.

14-4.4 Non-Significant Categorical Industrial User (40 CFR 403.3(v)(2)).

In general, non-significant industrial users never discharge more than 100 gallons per day of total categorical wastewater and some additional conditions apply including never discharging any untreated concentrated waste. Refer to 40 CFR 403.3(v)(2) for a definition and additional conditions.

14-4.5 Significant Industrial User (40 CFR 403.3(v)).

In general, significant industrial users are subject to categorical pretreatment standards and any other industrial user that discharges:

- An average of 25,000 gallons per day or more of process wastewater to the POTW,
- Contributes a process waste stream which makes up 5 percent or more of the average dry weather hydraulic or organic capacity of the POTW, or
- Is designated as such by the Control Authority on the basis that the industrial user has a reasonable potential for adversely affecting the

POTW's operation or for violating any Pretreatment Standard or requirement (in accordance with 40 CFR 403.8(f)(6)).

14-4.6 Middle-Tier Categorical Industrial User (40 CFR 403.12(e)(3)(i)-(iii)).

A classification that a POTW, in the case of a POTW with an approved pretreatment program, or the Approval Authority, in the case of a POTW without an approved pretreatment program may apply to certain industrial users if their discharge of categorical wastewater does not exceed certain conditions. Refer to 40 CFR 403.12(e)(3)(i)-(iii). In terms of discharge, the industrial user does not discharge more than 5,000 gallons per day.

14-4.7 National Pretreatment Standards: Prohibited Discharges (40 CFR 403.5).

40 CFR 403.5 identifies prohibited discharges for national pretreatment standards.

1. General prohibitions: 40 CFR 403.5(a)(1);
2. Specific prohibitions: 40 CFR 403.5(b);
3. When specific limits must be developed by POTW: 40 CFR 403.5(c);
4. Local limits: 40 CFR 403.5(d);
5. EPA enforcement actions under section 309(f) of the Clean Water Act: 40 CFR 403.5(e).

14-4.8 National Pretreatment Standards: Categorical standards (40 CFR 403.6).

Pretreatment standards are implemented through the National Pretreatment Program. Discharges from indirect dischargers are regulated through categorical standards. Existing and new categorical standards for specific industrial subcategories are included in 40 CFR 405 through 40 CFR 471.

14-5 DIRECT DISCHARGE (40 CFR 122).

A direct discharge is the discharge of any pollutant into waters of the United States from any point source. Refer to 40 CFR 122.1 for a complete list of regulatory requirements. Refer to 40 CFR 122.2 for a complete list of definitions. Unless covered by an exclusion, the NPDES Permit Program requires point source pollutant discharges to waters of the United States to obtain an NPDES permit. Refer to 40 CFR 122.3 for exclusions. For point sources that introduce pollutants through direct discharge, the EPA has promulgated effluent guidelines through the NPDES Permit Program and at the same time as pretreatment standards. Direct discharges are required to comply with the same categorical pretreatment standards as indirect discharges using effluent limitation guidelines established in the categorical pretreatment standards. Direct discharge usually requires extensive wastewater treatment to reduce pollutants and achieve effluent requirements. Refer to EPA 833-K-10-001 for direct discharge guidance.

14-6 INDIRECT DISCHARGE.

Once pretreatment effluent requirements have been met, industrial wastewater may be combined with domestic wastewater in the domestic wastewater collection system and conveyed to a POTW. Indirect discharge to a receiving water body occurs after the wastewater has passed through a POTW.

14-7 CONVENTIONAL POLLUTANTS (40 CFR 401.16).

Five conventional pollutants are defined in 40 CFR 401.16. Conventional pollutants are expected to be present in domestic wastewater. They are:

- Biochemical oxygen demand (BOD);
- Total suspended solids (TSS);
- Fecal coliform;
- pH;
- Oil and grease (O&G).

14-8 INDUSTRIAL POLLUTANTS.

Industrial wastewater may contain toxic or non-conventional pollutants in addition to conventional pollutants. POTW are not design to treat most toxic or non-conventional pollutants. When a POTW has the capability to remove toxic pollutants from industrial wastewater the pollutants can end up in the POTW’s sludge.

14-8.1 Toxic Pollutants (40 CFR 401.15).

40 CFR 401.15 provides a complete list of toxic pollutants. The list currently contains 65 toxic pollutants.

14-8.2 Priority Pollutants (40 CFR 423).

40 CFR 423, Appendix A to Part 423 - 126, provides a complete list of Priority Pollutants. The Priority Pollutants are a set of chemical pollutants that EPA regulates and for which EPA has published analytical test methods. The Priority Pollutant list is more practical than the list of toxic pollutants for testing and for regulation. Priority pollutants are described by their individual chemical names. In contrast, the list of toxic pollutants contains open-ended groups of pollutants. For example, chlorinated benzenes contain hundreds of compounds and there is no test for the group as a whole. The Clean Water Act, 33 USC 1317(a)(1), references the Toxic Pollutant List.

14-8.3 Nonconventional Pollutants.

Nonconventional pollutants are any pollutant not specified as a toxic pollutant or conventional pollutant. Nonconventional pollutants include parameters such as chlorine, ammonia, nitrogen, phosphorus, chemical oxygen demand (COD), and whole effluent toxicity (WET).

14-9 INDUSTRIAL WASTEWATER SURVEYS.

Identify all industrial wastewater sources and flows through field investigation and existing records to extent possible. The composition of industrials pollutants and flows can be variable and depend on the type and operation of the facility.

14-9.1 Physical Characteristics.

Use existing records to identify the physical characteristics of the industrial wastewater collection system. Determine the extent of available records such as existing maps or drawing files. Field verified all existing records to verify accuracy. Compile records and carefully review to see if they accurately represent the existing wastewater collection system.

14-9.2 Waste Stream Characteristics.

Being able to identify all pollutants and their concentrations is an important part of the industrial wastewater survey. North American Industry Classification System and Standard Industrial Classification codes may be helpful when determining the appropriate industrial category. Use existing records such as prior sampling results to identify pollutants and pollutant concentrations. If existing records are not available or are not sufficient to identify pollutant concentrations a field monitoring program should be established to verify and update existing records.

14-9.3 Waste Stream Flows.

Use existing records to identify waste stream flows to the extent possible. Most Installations meter water usage from water treatment facilities. Metered data may be used to perform a water balance evaluation. Add water obtained directly from other sources, such as wells.

14-10 PRELIMINARY DESIGN.

14-10.1 Facility Industrial Wastewater Survey.

Use WEF MOP FD-3, Chapter 4 *Industrial Wastewater Survey and Characterization* for industrial wastewater survey and waste stream characterization. The DoR must identify the physical characteristics, composition of industrials pollutants, flow characteristics for the facility type, and planned operation procedures.

14-10.1.1 Physical Characteristics.

If existing sewer maps are not available, they must be prepared. Show how the facility's industrial waste stream will connect to the existing industrial or domestic wastewater collection system and how the new connection will affect any existing industrial or domestic wastewater flows. Prepare a comprehensive schematic flow diagram of the facility's wastewater systems.

14-10.1.2 Waste Stream Characteristics.

For existing facilities, when existing records are not available or sufficient to identify pollutant concentrations identify wastewater characteristics through field investigation. Identify wastewater sources using typical industrial waste survey techniques such as identifying sources, establishing a sampling plan and dye tracer testing. Refer to EPA 833-K-10-001 for additional guidance.

14-10.1.3 Waste Stream Flows.

When existing flow records are not available, use actual measurement to establish flow rates or estimate flows from equipment ratings, process analysis, or other reliable methods. Identify variations in peak flow such as modes of occurrence (continuous or intermittent) and period of discharge. Correlate flowrates with process production rates and concentration variations.

14-11 DESIGN.

14-11.1 Process Changes.

Evaluate process changes that reduce waste stream volume, pollutant concentration, or treatment processes before proceeding on any industrial waste collection and treatment project. Process changes may include:

- Segregating or combining industrial waste streams based on waste stream characteristics;
- Changing cleanup operations from wet to zero discharge or dry methods;
- Product recovery;
- Using wastewater from one process as a source of water for another process (when the quality of the effluent from the first source meets or exceeds the required water quality of the following processes); or
- Recycling all or a portion of wastewaters.

Use WEF MOP FD-3, Chapter 7 *Management Strategies for Pollution Prevention and Minimization* for additional minimization practices.

14-11.1.1 Waste Stream Minimization.

Investigate waste stream minimization techniques to eliminate or reduce wastewater volume and pollutant concentrations. Reducing wastewater volume may be more economical than providing wastewater treatment. Evaluate process changes such as reducing waste stream volume, segregating waste streams, recycling treated effluent, and product recovery. Some pollutants have discharge limitations that require a zero discharge system. Segregate all industrial and domestic waste streams. Segregate stormwater drainage from all waste streams.

14-11.1.2 Separating Waste Stream Sources.

Isolate waste streams requiring different treatment processes, when pretreatment reduces downstream treatment requirements, containing recoverable materials, or with non-compatible or hazardous pollutants. The additional cost of source separation is typically offset by reducing treatment processes and operational cost.

14-11.1.3 Combining Waste Stream Sources.

Evaluate combining separate waste flows that are compatible for co-treatment, such as neutralization by combining acid and alkaline flows. Consider combining compatible waste streams when waste stream combination reduces the cost of treatment processes. Prohibit combining industrial and domestic wastewater.

14-11.2 Establishing the Design Flow.

Base design flow on the maximum flowrate to be treated, including any future expansions for the project planning period. Evaluate seasonal, daily and shift variations in determining peak flowrates. Where appropriate, establish production-based generation rates for projecting future flows. If unit wastewater generation rates from another facility are used, account for differences, including size, type of facility, and differences in operating procedures.

14-11.2.1 Peak Flows.

Design industrial wastewater collection systems for the peak industrial flow, as determined for the industrial process or activity involved. Peak hourly flows may be higher during a specific 8-hour shift during the day or for a specific day at single shift shops.

14-11.3 Industrial Wastewater Collection.

Collect industrial wastes in a manner that avoids unsafe conditions to personnel, equipment, and facilities. Select pipe materials, pumps, and appurtenances that are rated for the characteristics of the industrial waste stream. During the materials selection process, obtain and follow manufactures' recommendations. Obtain approval from the AHJ for any exceptions to manufactures' recommendations. Some waste streams may contain pollutants that can damage materials such as oily waste, solvents, high temperature, and unusual pH ranges. Some pipe materials are not rated for high-temperature waste streams. Use piping rated for the high-temperature of the wastewater being collected to prevent detrimental effects on the wastewater collection system. Use Chapters 2, 3, and 4 for the design of gravity sewer systems.

14-11.4 Industrial Wastewater Treatment.

Most POTW are not designed to treat industrial wastes that may contain toxic or non-conventional pollutants. Where pollution prevention techniques such as reducing or recycling industrial waste are not sufficient to reduce pollutants such as primary or toxic pollutants to the required regulatory levels, provide pretreatment for industrial wastewater sources in accordance with 40 CFR 403 or provide a separate industrial wastewater collection and treatment system. Document the industrial wastewater sources and the treatment or pretreatment strategies used for compliance.

Industrial wastewater treatment may include removal of fat, oil, and grease; organic or inorganic constituents; and pH control. Use Chapters 2 and 5 - 11 for the design of industrial wastewater treatment systems. Use WEF MOP FD-3 for industrial wastewater treatment and pretreatment guidance. Select industrial wastewater treatment processes based on the characteristics of the pollutants, the full range of industrial wastewater flows, permitted discharge limits, technical ability of personnel operating the industrial wastewater treatment facility, cost of construction, and operation and maintenance costs. Identify adverse effects from upstream treatment processes on subsequent treatment steps and methods of mitigating the adverse effects. For projects with wastewater flows from industrial sources, include evidence of adequate treatment or pretreatment strategies for review and approval by Installation EV staff and the AHJ.

14-11.4.1 Treatability.

Length and configuration of the collection system, liquid transport velocities, pumping, and associated appurtenances can significantly influence wastewater characteristics. Use WEF MOP FD-3 Chapter 5 *Wastewater Treatability Assessments* for treatability assessment guidance.

14-11.4.2 Pretreatment.

Use Chapter 2 and WEF MOP FD-3, Section 2, for design of pretreatment processes.

Identify daily and process-related variations in wastewater characteristics related to current and future production operations to develop control strategies. Evaluate combining separate waste flows that are compatible for co-treatment, such as neutralization by combining acid and alkaline flows.

14-11.5 Flow and Load Equalization.

Evaluate equalization on a large scale for compatible wastes received at a treatment facility, or on a smaller scale for specific process batch discharges. Processes with short duration and high flow and loading rates can adversely impact collection and treatment systems, evaluate at-the-source equalization to minimize hydraulic and pollutant load surges.

Evaluate the relative cost of constructing and implementing effective flow equalization, and the anticipated cost savings of reducing the size of downstream treatment processes. Determination of the need for flow equalization is based on the potential effects of peak hourly flow on pretreatment, industrial treatment facility, or POTW operating parameters such as flow rate, pH, BOD, COD, ammonia, toxicity, and variations in peak flow.

14-11.5.1 Basin Sizing.

Use peak flows for equalization, and as the basis for sizing treatment facilities.

The three basic types of equalization processes are alternating flow diversion, intermittent equalization, and completely mixed equalization. Completely mixed combined flow equalization is most common. Determine the minimum volume of a completely mixed combined flow equalization basin using the below formula.

$$V = (\Sigma f_i) T_e k$$

Where

V = equalization volume (m^3);

f_i = individual flowrates (m3/min);

T_e = equalization time (hours); and

k = conversion factor for units (min/hour)

For additional information and sizing information on alternating flow diversion or intermittent equalization processes and sizing using a cumulative flow curve, use WEF MOP FD-3, Chapter 8 *Flow and Load Equalization.*

14-11.5.2 Basin Construction.

Evaluate the need for liners based on frequency of basin use and solids deposition and clean-out. If required, provide a protective liner compatible with wastewater characteristics. Earth embankment lagoons are not allowed unless permitted by local regulatory agencies.

14-11.5.3 Mixing Conditions.

For biodegradable wastes provide minimum airflow rate of 4 ft^3/min/1000 gal (0.5 L/m^3 s) of basin volume to keep solids in suspension. Consult manufacturers as to circulation capacity of aeration or mixing equipment for manufacturer specific basin configuration.

14-11.6 Solids Removal.

Provide for removal of deposited solids from the basin, by either draining and cleaning during off-peak hours or by cleaning without draining. This can be through manways installed in steel tanks, depressed floor pits for solids accumulation and pumping, or by sloped floors in basins to collection pits.

14-11.6.1 Solids Separation and Handling.

Use WEF MOP FD-3 Chapter 9 *Solids Separation and Handling*. Remove suspended solids from industrial wastewater prior to discharge to a POTW. Concentrations greater than 500 mg/L can overload POTW systems and clog sewer lines and pumping station wet wells, and, if biodegradable, cause odors.

Classify solids by size and removal technique:

- Large solids – solids greater than 1 inch (25 mm)
- Grit – suspended matter that settles more rapidly than organic matter
- Settleable solids – particles with diameters between 1 µm and 25 mm that settle out of wastewater during a standard Imhoff cone test and may be organic or inorganic.
- Colloids – particles between 0.001 and 1 µm and may be organic or inorganic. Colloids are typically removed with chemical coagulation and flocculation.

14-11.6.2 Removal Methods.

Select methods based on the initial concentration of solids in the wastewater, the final concentration needed, and particle size and characteristics. For wastewater streams with TSS less than 1% (10,000 mg/L) the typical methods used include straining, gravity separation, and filtration. Use WEF MOP FD-3 Chapter 9, *Solids Separation and Handling*, and Chapters 6 and 7 of this UFC.

14-11.6.3 Solids Handling and Processing.

Industrial solids processing, particularly for industrial biological sludges, may be more difficult to dewater than domestic sludge. Solids conditioning, thickening, dewatering, and disposal are discussed in Chapter 8.

14-11.6.4 Disposal of Industrial Sludge.

Coordinate with Installation EV staff and industrial wastewater treatment operators to determine the optimal treatment strategy and waste disposal methods. All sludges resulting from industrial wastewater treatment processes must be evaluated as a potentially hazardous waste in accordance with 40 CFR 261; specifically 40 CFR 261.2 and 261.3. Treatment strategies, disposal methods and applicable exemptions or exclusions will be based on the results of that regulatory evaluation and must be approved by Installation EV staff and the AHJ.

14-11.7 pH Control.

Use WEF MOP FD-3 Chapter 11 *pH Control.* Adjust pH of wastewater if required prior to direct or indirect discharge. For direct discharge the effluent pH required is typically between 6 – 9 to protect receiving waters. POTW requirements will vary based on treatment processes, but typically will require 5.5 – 10 to protect collection systems and prevent process upset, and 6.5 – 8 if the POTW uses biological pretreatment processes.

Evaluate possible adverse chemical reactions due to acidity of wastewater such as reactions with cyanide and sulfides.

14-11.7.1 Acidity And Alkalinity.

Determine the wastewater's total acidity or alkalinity by performing a titration. Use the titration curve and flow variability to define reagent, dose, and process control characteristics.

Select neutralizing agents based on cost, reaction time, solids production, safety, maximum and minimum pH in overtreatment, ease of chemical handling, and availability. Solids produced during neutralization may require removal and processing.

14-11.8 Removal of Inorganic Constituents.

Refer to WEF MOP FD-3 Chapter 12 *Removal of Inorganic Constituents.* Inorganic constituents found in industrial wastewater include heavy metals, cyanide, sulfides, and nutrients (primarily nitrogen and phosphorus). Control heavy metals and other inorganic compounds present in some industrial wastes to avoid upset or pass-through problems to the POTW.

14-11.8.1 Treatment Strategies and Processes.

Inorganic pollutants may require treatment in individual rather than combined streams due to the variety of compounds and sources. Common treatment techniques include neutralization – precipitation, chemical reduction, oxidation, stripping, ion exchange, adsorption, membrane filtration, electrodialysis, and evaporation.

14-11.9 Removal of Organic Constituents.

Use WEF MOP FD-3 Chapter 12 *Removal of Organic Constituents.*

14-11.9.1 Biological Treatment Processes.

Use biological treatment processes for waste streams with a significant biodegradable fraction or to destroy hazardous organics by converting to more benign forms. Consider carbon source and nutrient and growth factors in design.

Conventional biological treatment systems can remove some organic compounds via biodegradation, volatilization (stripping) from aeration, and adsorption onto sludge, while others pass through. Actual removal performance depends on the operating characteristics (sludge age, mixed liquor suspended solids) of the treatment facility, the method of oxygenation, and the amount and nature of other compounds present in the wastewater.

14-11.9.2 Organic Treatment Approaches.

Evaluate reaction kinetics, bacterial growth and pollution removal rates, and process control parameters. One or more treatment technologies may be required to meet effluent limits. Treatment technologies include: activated sludge; sequencing batch reactors; facultative ponds; aerobic, anaerobic and combination ponds; fixed film technologies; trickling filters; and submerged media attached growth reactors.

Remove nitrogen via physical – chemical means or biological processes. If wastewater contains organic nitrogen, convert to ammonia by deamination followed by nitrification. Remove phosphorus by precipitation or biological processes.

CHAPTER 15 OILY WASTE TREATMENT

15-1 OILY WASTE SOURCES.

Oily waste originates in numerous locations on board ships and throughout shore facilities, including equipment washracks, vehicle maintenance, fueling and petroleum, oil and lubricant sources, metal products and machinery, floor drains, shipboard oily wastewater, and stormwater runoff. Design oil-water separators to handle anticipated maximum oily waste loads.

15-1.1 Oily Waste Characteristics.

The types and concentrations of pollutants in oily wastes will depend on the source of the oily wastewater and the source of the pollutants. Identify the source of the oily wastewater and the source of the pollutants to determine the appropriate treatment process. Oil, grease, and total suspended solids are the typically primary conventional pollutants found in oily waste. Oils may be present in the form of free, dispersed, emulsified, or dissolved oil. Other types of pollutants may include pollutants such as fuel, heavy metals, or solvents. Pollutants may be present individually or in combination with other pollutants.

15-1.2 Oily Waste Waste Oil.

Oily wastes and waste oils are byproducts of operating ocean-going vessels. Oily bilgewater is the mixture of water, oily fluids, lubricants and grease, cleaning fluids, and other wastes that accumulate in the lowest part of a vessel from a variety of sources including engines (and other parts of the propulsion system), piping, and other mechanical and operational sources found throughout the machinery spaces of a vessel. This type of oily waste is commonly referred to as oily waste waste oil (OWWO). Refer to Chapter 16 for additional OWWO criteria.

15-1.3 Sampling.

When the specific pollutant or combination of pollutants is unknown, develop a sampling plan for the type of activities performed at the facility. Analyze oily wastewater using approved EPA methods. The EPA publishes laboratory analytical methods, or test procedures that are used by industries and municipalities to analyze the chemical, physical ,and biological components of wastewater and other environmental samples that are required by the Clean Water Act. Most of these methods are published in 40 CFR 136. An American Society for Testing and Materials (ASTM) standard using an approved EPA method may be used. The completed analysis must identify the amounts of free, dispersed, emulsified, and dissolved oil fractions present. When pollutants other than only conventional pollutants may be present additional sampling and analysis will need to be included in the sampling plan. The additional sampling and analysis may include an analysis of volatile suspended solids (VSS) to determine the full range pollutants present. Refer to *Standard Methods for the Examination of Water and Wastewater* for guidance on sampling and analysis.

Sampling for facilities such as vehicle wash facilities will typically be limited to temperature, pH, total suspended solids and total oil and grease. Use grab samples to analyze for pH and total oil and grease. Use composite samples to analyze for total suspended solids. For composite samples, collect five grab samples evenly spaced over an 8-hour period or if the discharge is less than 8 hours, evenly spaced for the duration of the discharge.

15-2 IDENTIFICATION OF FLOWS.

Estimate the peak flow rate of the oily wastewater requiring treatment, including the addition of any future oily wastewaters. When determining peak flow rates, evaluate flow variations between shifts, daily operations and seasonal flow variations. Estimate peak flows by monitoring and measuring existing flows during peak operating periods for existing flows or by estimating peak flow based on the estimated peak flow of the water used at the facility for new flows. For example, the peak flow from a new aircraft washing facility may be estimated from the water used per aircraft multiplied by the maximum number of aircraft to be washed in a given period. Peak flow rates from a similar facility may be used when differing conditions are evaluated and accounted for, such as differences in the pressure of the water supplied, vehicle type and washing procedures.

15-3 OILY WASTE OIL COLLECTION.

Do not mix high flashpoint oil with low flashpoint oil, or halogenated solvents with non-halogenated oil. Evaluate segregation of oily wastewater streams based on the characteristics of the wastewater and the source of pollutants. Segregate oily wastewater and solvents at their source when possible. Do not mix oily wastewater with industrial wastewater such as wastewater containing metals and phenols.

Minimize the formation of chemical and physical emulsified oils. Avoid using emulsifying agents such as detergents and creating turbulent flow, such as pumping oily waste. Segregate oily wastewater containing emulsified oil from oily wastewater without emulsions when possible.

15-3.1 Waste Stream Minimization.

In addition to the waste stream minimization requirements indicated in Chapter 14, facilities such as washracks should be covered to prevent rainfall events from increasing the volume of oily waste requiring treatment. When cover is not provided, provide a waste collection system capable of segregating oily wastewater flows from stormwater runoff during periods when oily wastewater flows are not being generated.

15-3.2 Pumps.

Avoid pumping oily wastewater to a gravity or enhanced-gravity oil water separator. If pumping is required, use positive displacement pumps to prevent the formation of physical emulsions. When oily wastewater is pumped, an enhanced oil water separator should be used.

Manufacturers typically indicate peak influent flow capacity using gravity flow with no pumps upstream of the separator. When positive displacement pumps are used, de-rate the flow capacity of the oil water separator to account for non-quiescent conditions. When oily wastewater is pumped, the DoR must provide documentation from the specified manufacturers indicating the proposed oil water separator has been de-rated for the anticipated pump flowrates and is sized to meet effluent standards.

15-4 OILY WASTE TREATMENT.

Design the oily waste treatment system for the peak flow at the minimum expected operating temperature. Use the minimum operating temperature to determine the properties of the oil water mixture, such as density and absolute viscosity.

15-4.1 Oil Water Separators.

Use UFC 3-240-03 to evaluate the need for new or existing oil water separators. Coordinate with the Installation EV staff for direct discharge permitting requirements or POTW approval.

Design grit chambers and gravity separators located below grade for traffic loads. Use H-20 traffic loading as the minimum design load. When a gravity oil water separator is open to the atmosphere, the wall of the separator must extend a minimum of 6 in (150 mm) above the surrounding ground surface. Separators that are not designed for traffic loads must extend a minimum of 6 in (150 mm) above the surrounding ground surface.

15-4.1.1 Gravity Separators.

Separators that are open to the atmosphere may require removable grates or covers to prevent people from accidentally falling into the separator. Design grates or covers to be removable by no more than two people.

15-4.2 Conventional Pollutants.

Oily wastewater with pollutants limited to conventional pollutants typically includes facilities such as vehicle wash racks, aircraft washing, and vehicle maintenance facilities. When only conventional pollutants are present, gravity oil water separators are typically the most efficient type of treatment for free oil and in some cases, dispersed oil.

15-4.3 Emulsified Oils.

Gravity separators are not capable of removing emulsified oils without providing additional treatment processes. Do not use gravity separators as a single unit process for emulsified oil removal. Bench or pilot plant testing should be performed to determine an effective emulsion breaking method. An effective treatment process for emulsified oil treatment may include gravity separation to remove free oil followed by dissolved air flotation (DAF).

15-4.4 Dissolved Oils.

Treatment technologies for the treatment and direct discharge of dissolved oils are typically not performed on military installations. Dissolved oil may be removed through biological treatment processes employed by the downstream wastewater treatment plant or POTW.

15-4.5 Industrial Pollutants.

Oily wastewater containing pollutants other than conventional pollutants will typically require more than one treatment process. A single treatment process or commercial device is not typically capable of removing non-conventional pollutants and oil. Especially when oil is in the form of dispersed, emulsified or dissolved oil. A series of treatment processes or units is typically required to achieve the desired effluent quality. The treatment processes or devices provided must be able to meet the direct discharge or POTW discharge limits.

15-4.6 Pretreatment Techniques.

Provide pretreatment as close to the source as possible to help avoid emulsification. If flow is highly variable, flow equalization may be required to maintain quiescent conditions and ensure efficiency of the separator.

15-4.6.1 Grit Removal.

Provide a separate grit removal basin when the total suspended solids exceed 200 mg\l. Use a minimum detention time of 5 minutes for gravity separation. A grit removal basins will also assist with flow equalization.

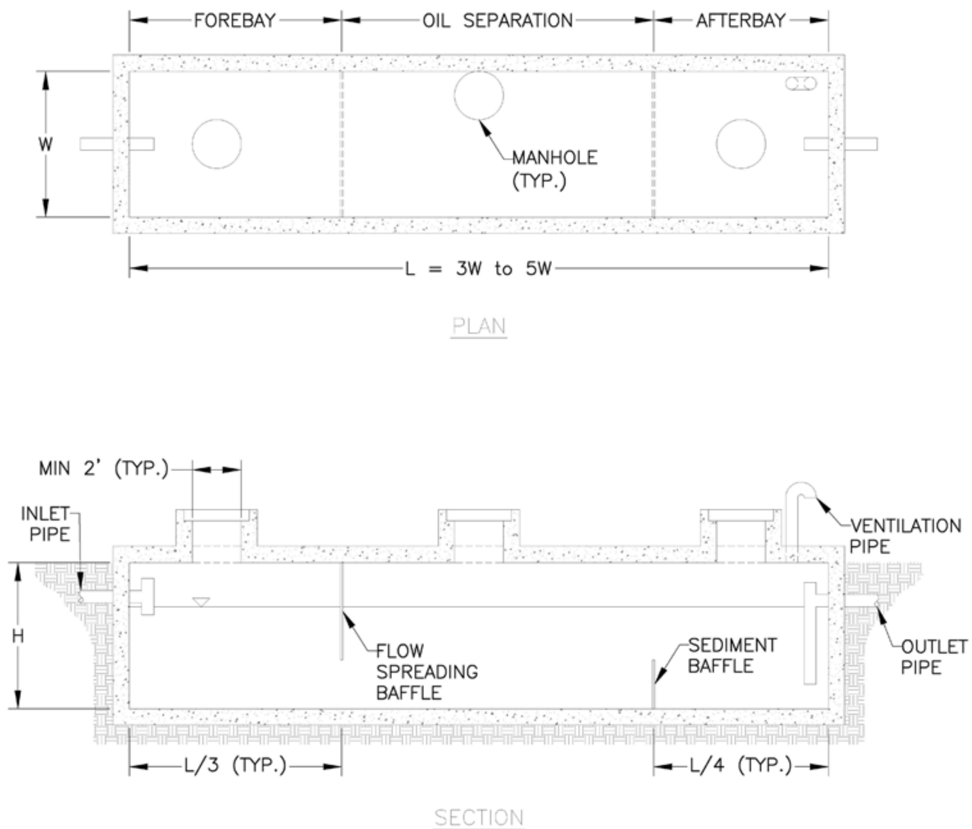
15-4.6.1.1 Maintenance.

Provide access for inspection and a truck with suction equipment to remove grit.

15-4.7 Gravity Separation.

Use gravity separation for the removal of free oil and settleable solids. Gravity separation of dispersed oil is typically more difficult and may require using parallel plate coalescing media to meet discharge requirements.

Figure 15-1 Gravity Oil Water Separator



15-4.7.2 Gravity Separator Sizing.

Use the following procedure to size a gravity oil water separator using the smallest oil droplet size to be removed:

1. Use stokes law to compute the rate of rise, V_t.

$V_t = [(g)(\rho_w - \rho_o)(d^2)] / [(18*\mu_w)]$

Where:
V_t = rise rate of the oil droplet (cm/s or ft/sec)
g = acceleration due to gravity (cm/s² or ft/s²)
ρ_w = density of water at the design temperature (g/cm³ or lbm/ft³)
ρ_o = density of oil at the design temperature (g/cm³ or lbm/ft³)
d = oil droplet diameter (cm or ft)
μ_w = absolute viscosity of the water at the minimum expected operating temperature (g/cm-s or lbm/ft-s)

2. Compute mean horizontal velocity, V_h or use a maximum value of 3 ft/min (0.91 m' min). Best practice; use a maximum value of 1 to 2 ft/min (0.3 to 0.61 m/min)

$V_h = 15 * V_t$

Where:
V_h = mean horizontal velocity (m/min or ft/min)
V_t = rise rate of the oil droplet (m/min or ft/min)

3. Compute the minimum vertical cross sectional area, Av.

$A_v = Q_{peak} / V_h$

Where:
A_v = minimum vertical cross sectional area (m^2 or ft^2)
Q_{peak} = peak flow rate (m^3/min or ft^3/min)
V_h = mean horizontal velocity (m/min or ft/min)

4. Select the depth, d. Use a minimum depth of 3 ft (0.9 m). Best practice; use a maximum depth of 8 ft (2.4 m). Additional depth may be required when mechanical sludge removal equipment is included.
5. Select the width, w. Best practice; use a minimum width of 6 ft and maximum width of 20 ft (6.1 m).
6. Compute the number of separators or separator channels, n.

n = Av / w * d

Where:
n = number of separators or separator channels
A_v = minimum vertical cross sectional area (ft^2 or $m^{2)}$
w = width of the separator (m or ft)
d = depth of the separator (m or ft)

7. Compute the depth to width ratio, d/w. Minimum depth to width ratio = 0.3 and maximum depth to width ratio = 0.5. If the depth to width ratio obtained is not in the acceptable range, repeat calculations until depth to width ratio is in the acceptable range.
8. Select the length, L. The minimum length should be 3 to 5 times the width. Best practice; use a minimum length equal to five times the width.
9. Compute the overflow rate, Vo.

$V_o = Q_{peak}/ L*w$

Where:
V_o = overflow rate (m/min or ft/min)
Q_{peak} = peak flow rate (m^3/min or ft^3/min)
L = length of the separator (m of ft)
W = width of the separator (m or ft)

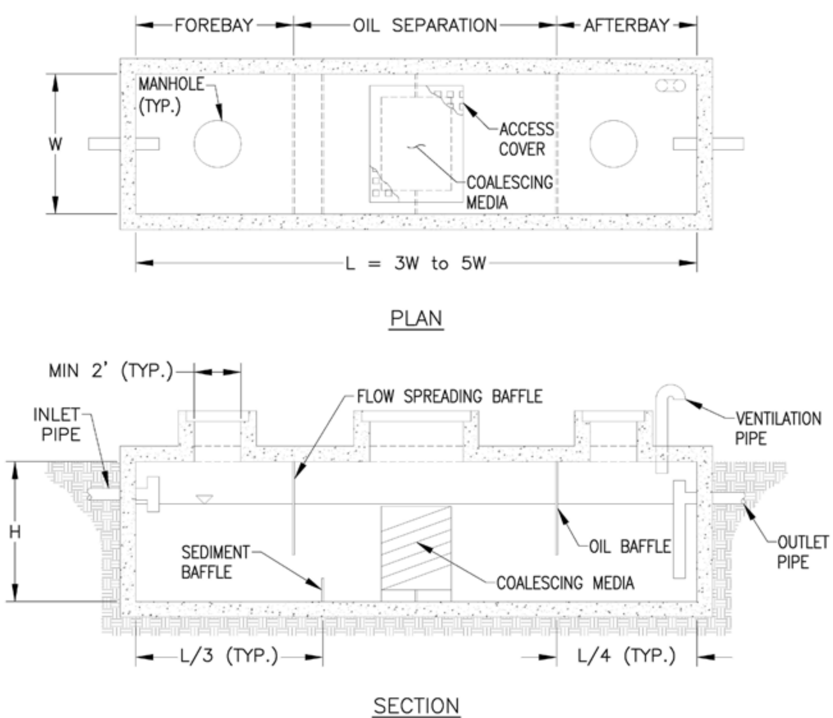
10. Verify that the oil droplet's rate of rise, Vt, equals or exceeds the over flow rate, Vo. When the oil droplet's rate of rise does not equal or exceed the overflow rate, repeat calculations until oil droplet's rate of rise equals or exceeds the over flow rate. When repeating calculations, try increasing the length of the separator first.
11. Select an appropriate freeboard based on fluctuations in peak flow and rainfall if the separator is not covered and has an open top. Use a minimum freeboard of 6 in (150 mm).

Removing oil with a droplet size smaller than 150 microns will significantly increase the size of the oil water separator. For example, an oil droplet size of 150 microns will rise nine times faster than a 50 micron oil droplet.

15-4.8 Enhanced Gravity Separation.

Coalescing media assists with gravity separation of oil droplets smaller than 150 microns. The coalescing media increases the surface area of the gravity separator and allows for efficient removal of oil droplets. Enhanced gravity separation can typically be used to treat oil droplets as small as 60 microns. Some more efficient enhanced separators may be able to treat oil droplets as small as 30 to 40 microns but successful removal will depend on many variables. When enhanced gravity separation is used to meet direct discharge limits, additional tertiary treatment may still be required to meet discharge limits indicated in the NPDES permit, especially for the removal of oil droplets in the 20 to 60 micron range. Discharges to a POTW typically do not require an enhanced gravity separator.

Figure 15-2 Enhanced Gravity Oil Water Separator



15-4.8.1 Enhanced Gravity Separator Sizing.

In general, the design of enhanced oil water separators is similar to gravity oil water separators with two general exceptions:

1. The surface area of the coalescing media reduces the surface area required for gravity oil water separator design.
2. The enhanced oil water separator can operate efficiently at higher horizontal velocities.

Most manufacturers have empirically derived design data that they use for enhanced oil water separator design. In these cases, the manufacturer is the best source of design data. For 60 micron oil droplets, the required horizontal surface area of parallel plates can be computed using the following equation:

$$A_h = Q_{peak}/V_t = Q_{peak} / (.00386) * ((S_w - S_o)/(\mu_w))$$

Where:
A_h = horizontal surface area of the plates (ft^2)
V_t = rise rate of the oil droplet (ft/min)
Q_{peak} = design flowrate (ft^3/min)
S_w = specific gravity of water at the design temperature
S_o = specific gravity of oil at the design temperature
μ_w = absolute viscosity of the water (poise)

Laminar flow through the coalescing media is required. Verify the Reynolds Number for flow through the coalescing media is less than 500.

15-4.9 Other Types of Treatment.

The degree of treatment required will be determined by the type of discharge, indirect or direct. For direct discharges, treatment requirements will also be identified in the NPDES permit. For indirect discharges, the POTW may identify additional treatment requirements. Sludge disposal requirements will be determined by the level of treatment provided and the characteristics of the sludge. Refer to WEF MOP FD-3 Chapter 10 *Removal of Fats, Oil and Grease,* for oily waste treatment guidance. Bench or pilot plant testing should be performed to determine the effectiveness of the treatment system.

15-4.10 Inspection and Maintenance.

Design oil water separators to be readily accessible for inspection by one person. Design each oil water separator bay or compartment to be readily accessible for inspection, maintenance and cleaning. Provide access for a truck with equipment capable of removing grit, oil or sludge from each oil water separator bay or compartment.

15-4.10.1 Enhanced Gravity Separators.

Enhanced gravity separators with coalescing media require a higher level of maintenance then gravity separators. Provide enhanced gravity separators with access for inspection and removal of the coalescing media units or packs. The coalescing media units or packs must capable of being removed as complete units or packs. Do not use coalescing media that requires disassembly in the separator prior to removal.

15-4.11 Redundancy.

Provide a minimum of two treatment units or channels when continuous operation is required. Two treatment units or channels will allow one channel to be taken out of service without bypassing the separator. The most cost effective design minimizes the number of treatment units or channels.

This Page Intentionally Left Blank

CHAPTER 16 OILY WASTE AND WASTE OIL COLLECTION AND TREATMENT.

16-1 SOURCES.

Most ships have oil water separators, waste oil tanks (WOT), oily waste holding tanks (OWHT), and oily waste transfer pumps (OWTP). A brief description of oily waste equipment is presented below:

1. OWHT can usually contain the oily waste generated in one-half day by a ship in auxiliary mode. It holds at least 1,000 gallons.
2. WOT can usually contain the oily waste separated during a 60-day mission.
3. OWTP is normally a segregated electric driven pump that pumps bilge water to the OWHT and waste oil or oily waste to shore facilities. Some older ships use rotary vane pumps, but the newer ones use sliding shoe pumps. Pumps discharge at least 10 psi at the lowest weather deck of the ship. These pumps normally have capacity of off-loading the OWHT in approximately 1- 2 hours. On aircraft carriers, the off-loading time may take up to 4 hours.

16-2 SHIP DISCHARGE VALUES.

Use UFC 4-150-02 or contact the Government Project Manager for ship oily waste discharge capacities.

16-3 SITE LAYOUT.

Use UFC 4-152-01 for the design of oily waste and waste oil (OWWO) collection systems serving piers, wharfs, and drydocks. Design the oily waste collection system to segregate oily and non-oily wastewater sources, minimize oil-water separator hydraulic loading, minimize emulsification, and maximize oil and grease concentration.

Include the following concepts when laying out a pier collection pipeline:

a. Ships of same class type often berth together.
b. Install valves at head of each pier to allow for isolation in case of pier pipeline damage.
c. Allow for minimum slope toward free discharge to prevent liquid stagnation and freezing.
d. Evaluate need for freeze protection.
e. Use a minimum fluid velocity that will prevent settling of suspended solids and minimize emulsification of oils.
f. Provide cleanouts at junctions, directional changes, end of pipe run and every 400 ft (122 m).

g. Provide single wall piping unless double-walled pipe or secondary containment is required by local regulations. Check local regulatory agencies for requirements.

h. Provide thrust support for OWWO pipeline. Use Chapter 4 for thrust restraint requirements.

i. Provide pipe supports or hangers spaced at intervals suitable for supporting the OWWO pipeline. Use MSS SP-58-2018 or pipe manufacturer's requirements, whichever are more stringent.

j. Use materials and coatings capable of withstanding marine environment conditions.

16-4 IDENTIFICATION OF FLOWS.

Ship bilge daily flow varies with the class of ship, shipboard operations, and condition of the ship's mechanical equipment. The three measures of oily waste discharge flow are average (Q_{ave}), peak (Q_{peak}), and additional oily waste discharge from compensating fuel tanks (Q_{comp}). These flows are used in various combinations (depending on facility size) to estimate the total daily oily waste flow (Q_{daily}) from a pier. Q_{comp} is determined based on the fueling capability of the facility. If no fuel capability exists on the pier, then this quantity is zero. Fuel capability may be in the form of piping, trucks or barges. If fueling capability exists, then this quantity is equal to the maximum fueling rate for one day. Q_{daily} is used to estimate ship utility discharges and shoreside oily waste treatment plant capacity, operating costs, and operating schedule. The size of the pier facility depends on the historical usage rates and pier berthing plan. Use UFC 4-150-02 or contact the Government Project Manager for ship oily waste discharge capacities. Use the following subparagraphs to estimate flows.

16-4.1 Facility Daily Flow.

Determine the number and classes of ships present during maximum holiday berthing and average daily berthing. Determine if the activity is a "small" or "large" facility. Determine the number and classes of ships present during maximum holiday berthing and average daily berthing. Compute Q_{daily} for small facilities. Compute Q_{daily} and $Q_{maximum}$ for large facilities.

16-4.1.1 Small Facilities.

Use the following equation for pier facilities with fewer than 15 vessels:

$$Q_{daily} = Q_{comp} + \sum_{n=1}^{N} Q_{peak}$$

Where:

Q_{daily} = design daily flow for facility in gpd (L/day)
Q_{comp} = maximum fueling flow per day from shore to ships in gpd (L/day)
N = number of ships at piers during maximum holiday berthing or special peacetime exercise
Q_{peak} = peak daily flow from each ship in gpd (L/day)

16-4.1.2 Large Facilities.

Use the following equation for pier facilities with 15 or more vessels:

$$Q_{daily} = Q_{comp} + \left(1.33 * \sum_{n=1}^{M} Q_{average}\right)$$

Where:

Q_{daily} = design daily flow for facility in gpd (L/day)
Q_{comp} = maximum fueling flow per day from shore to ships in gpd (L/day)
M = number of ships at piers during maximum holiday berthing or special peacetime exercise
$Q_{average}$ = average daily flow from each ship in gpd (L/day)

16-4.1.3 Maximum Daily Flow.

Use the following equation to determine maximum daily flow ($Q_{maximum}$) using the maximum number of ships berthed during special exercises or holiday operations:

$$Q_{maximum} = Q_{comp} + \sum_{n=1}^{N} Q_{average}$$

Where:

$Q_{maximum}$ = maximum daily flow during holiday berthing in gpd (L/day)
Q_{comp} = maximum fueling flow per day from shore to ships in gpd (L/day)
N = number of ships at piers during maximum holiday berthing or special exercises
$Q_{average}$ = average daily flow from each ship in gpd (L/day)

16-4.2 Design Flow For Pier Oily Waste.

Use the following equation to determine size of main and laterals, and pump station capacity:

$$Q_{main} = 0.31 \sum_{i=1}^{S} (n_i)\,(q_i)$$

Where:

Q_{main} = design daily flow in gpd (L/day)
S = maximum number of ships at piers, use ship mix that produces largest daily flow including holiday berthing
q_i = discharge rate from each OWTP (assume one pump per riser) in gpd (L/day)
n_i = total number of OWTP connected to the main, lateral or pump station

16-5 GRAVITY FLOW COLLECTION SYSTEM.

Compute the diameter of mains and laterals using Q_{main} as shown in the following subparagraph. Use a minimum design velocity of 2 fps (0.6 m/s) during discharge operations for collection mains. Use a minimum design velocity of 5 fps (1.5 m/s) during discharge operations for collection mains. The design velocity should be in the range of 5 to 7 fps (1.5 to 2.1 m/s).Compute maximum design velocity to prevent scour. Use pipe manufacturer data to compute scour velocity. The minimum slope must be capable of maintaining a full flow velocity of 2 fps (0.6 m/s) using manning's formula and a manning's n value 0.013.

Use a minimum 6 inch (150 mm) pressure main with a minimum 4 inch (100 mm) pressure laterals to main. Facilities berthing only submarines or MSO ships may use 3 inch (75 mm) lateral. Space laterals and pier riser at 150 feet (46 m). This relatively close spacing facilitates flexible berthing configurations, mission change and flexibility. Hose riser assemblies are not needed at the end of piers unless specifically required by the activity. Use dual hose receivers to provide capability for nesting ships. Nesting may occur during major exercises, holidays and during periods when nearby berths are down because of damage or repair. Provide containment according to 33 CFR 154.530.

16-5.1 Design Flow For Pier Oily Waste.

Use the following equation to determine size of main and laterals, and pump station capacity:

$$Q_{main} = 0.31 \sum_{i=1}^{S} (n_i)\,(q_i)$$

Where:

Q_{main} = design daily flow in gpd (L/day)
S = maximum number of ships at piers, use ship mix that produces largest daily flow including holiday berthing
q_i = discharge rate from each OWTP (assume one pump per riser) in gpd (L/day)
n_i = total number of OWTP connected to the main, lateral or pump station

16-5.1.1 Head Loss.

Since the ship's OWTP feeds the gravity collection system, head loss must be evaluated. Compute head loss at each main and lateral intersection and verify the discharge pressure from each ship's OWTP exceeds the estimated head loss at each main and lateral intersection. Determine deck riser elevation, ship discharge pressure and berthing plan, including nesting, for each ship class berthed at pier. If a ship's discharge pressure does not exceed the computed head loss, additional computations must be performed. Typically head loss can be reduced by increasing the main diameter first and then increasing lateral diameter if head loss still needs to be reduced. Evaluate the gravity collection system characteristics that contribute to head loss such as length of main, length of lateral, elevation of pier riser assembly, elevation of ship's deck riser, hose length and fittings. Evaluate maximum hose length for nested ship berthing.

16-6 PRESSURIZED PIER COLLECTION SYSTEM.

Only use pumps when gravity collection systems are not hydraulically feasible. Slope pressurized systems to prevent fluid stagnation, freezing, and for cleaning purposes. The minimum slope should be capable of maintaining a full flow velocity of 2 fps (0.6 m/s) using meanings formula and a manning's n value 0.013. Design requirements for pump systems:

a. Locate pumps as close to oily wastewater source as possible to maximize detention time between pumping and treatment and minimize impact of mechanical emulsification. Equalization tanks may be used as an alternative approach. If equalization is employed, avoid detention times that would likely result in odor and gas production. Use vapor controls as required by applicable environmental regulations.

b. Use reciprocating positive displacement or screw pumps to transfer oily wastewater to treatment unit or equalization facility. Maximize size of wet well and select a number of pumps and an operating schedule to minimize surge effect of pump off-on cycle times. Consider adjustable speed drives on transfer pumps.

c. If rotary displacement or centrifugal pump is used, design for low speed (≤900 rpm) to minimize mechanical emulsification.

d. Maximize size of wet well and select the number of pumps and an operating schedule to minimize surge effect of pump off-on cycle on downstream oil-water separators.

e. Consider the use of a pump control valve and a surge tank with control orifice to throttle discharge to oil water separator. Consider adjustable speed drives on transfer pumps.

16-7 PUMP STATIONS.

Design pump stations to handle the cumulative Q_{main} for piers served assuming that individual pier main flows occur simultaneously. Design requirements for pump stations:

a. Provide a protective wet well liner or protective coating capable of resisting oil, grease, and saltwater.

b. Provide continuous ventilation with complete air changeover every 2 minutes.

c. Provide basket or bar type inlet screens on a pump inlet which can be removed and cleaned from the ground surface without requiring confined space entry.

d. Determine pump capacity and operating cycle for peak flows. Use positive displacement pumps with pressure relief valve, rather than centrifugal pumps, to reduce mechanical formation of emulsion at oily waste treatment plants. Pumps should pass solids having a diameter 0.125 inches (3 mm).

e. Provide controls suitable for Class I, Division 1, Group D safety classification. Use float or sonic type mechanisms, not air bubblers, for pump control and alarm. Provide discharge pump control valve to minimize surge effect on equalization basins at oily waste treatment plants (not applicable for positive displacement pumps). Provide an alarm system for overflow or power failure. Provide manual override of pump controls but not of low level alarms.

f. Provide an accumulating flow meter, elapsed time meter for pumps, pump suction and discharge pressure gages with oil-filled diaphragm, and cutoff valves to monitor station activity.

16-8 OILY WASTE TREATMENT.

OWWO may contain free, dispersed, emulsified ,or dissolved oil. Gravity type oil water separators can typically provide complete treatment for free oil. A single treatment process or commercial device will not typically remove emulsified and dissolved oils in oil water mixtures. A series of treatment process units is typically required to remove emulsified and dissolved oils. The degree of treatment required will be determined by the type of discharge, indirect or direct. For direct discharges, treatment requirements will also be identified in the NPDES permit. For indirect discharges, the POTW may identify additional treatment requirements. Sludge disposal requirements will be determined by the level of treatment provided and the characteristics of the sludge. Refer to EPA 800-R-11-007 for OWWO guidance.

Design oily waste treatment systems to operate on a 40-hour workweek with emergency response for alarms outside of normal work hours unless the activity, state or local have extended operational requirements. Treatment systems should be sized for the following flows.

16-8.1 Equalization.

Use an equalization basin to equalize peak flows and store oily wastewater flows prior to oil-water separation. Equalization systems can be concrete or steel tanks. Equalization systems should be covered or under a roof in a rainy climate or where wildlife is present.

16-8.2 Primary Treatment.

Primary treatment is required. The extent to which receiving waters or treatment works are impacted by effluent determines whether additional treatment is required.

16-8.2.1 Gravity Separation.

Bench testing should be performed to determine time required for optimum gravity separation. During treatment, free oil floats to the surface. Skimmers may be used to collect and remove oils on the surface. Settleable solids, also referred to as sludge, sink to the bottom and can scraped into a hopper for withdrawal, additional treatment or disposal. Provide multiple LET to allow for continuous (fill and drawoff) operation of the facility.

16-8.2.2 Load Equalization Tank.

A load equalization tank (LET) is a batch operated, gravity oil-water separator. Oily wastes are discharged to the LET for a predetermined collection period. Wastes are settled, the oil skimmed off to storage, and sludge withdrawn for further processing and disposal. Clarified water is passed on for additional treatment or discharge. Batch treatment in a LET is recommended for treatment of OWWO. When a treatment method other than a LET is used, the alternate treatment method must be able to meet or exceed all LET requirements.

16-8.2.2.1 Load Equalization Tank Sizing.

Method 1: Use actual flow data to the extent possible.

Method 2: Estimate the type and number of berthed ships discharging to the pierside collection system including the number of ship waste oily barges and discharge frequency. Use historical records to the extent possible.

Method 3: Use Q_{daily}, $Q_{maximum}$, and Q_{peak} established for design of pierside collection systems.

16-8.2.2.2 Load Equalization Tank Design.

LET design requires multiple tanks for normal operation of the gravity separation process. At larger Installations subject to periodic surges in ship berthing, the capability to process sudden, abnormally high oily waste flows may warrant extra reserve capacity. At smaller Installations where available land area imposes layout restrictions, a minimum of three reduced volume LET may be necessary to provide operating flexibility for normal peak flow occurrences and for tank cleaning downtime. When oily waste generated from shore facilities will be treated in addition to OWWO additional LET may be required. Oily waste generated from shore facilities will typically have different oily waste characteristics and need to be segregated from OWWO for treatment. Each tank should have a minimum capacity equal to the average flow for 7 days. Determine the total number of tanks required using the maximum flow with one tank out of service. Longer LET operating periods or large volume upstream receiving tanks should not be used since they promote anaerobic conditions and hydrogen sulfide gas production. Hydrogen sulfide gas will corrode metal and concrete, cause odor problems, and create potential health hazards when hydrogen sulfide concentration exceeds 10 ppm. Design requirements for LET:

a. To the extent possible, use aboveground LET to facilitate gravity flow to downstream processes or the discharge point.

b. Provide mechanical oil skimming equipment.

c. Provide a separate oil containment tank for the oily waste collected from the surface of the LET.

d. Provide a sludge hopper on the inlet side of the LET to facilitate sludge removal.

e. Slope LET to facilitate the transport of settled solids to the sludge hopper.

f. Provide mechanical sludge collection for sludge removal and processing.

g. Provide mechanical efficiency and simplicity appropriate for the characteristics of the OWWO and sludge being treated.

h. Identify sampling requirements and provide sample taps or ports to facilitate sampling. Locate sample taps or ports in locations that are easily accessible or provide additional access to sampling taps or ports.

i. Provide multiple potable or non-potable water supply discharge points to facilitate tank cleaning, foam control, and general housekeeping. Space water supply discharge points to facilitate cleaning all LET for all possible operational procedures. Do not exceed 100 feet of tank length between water supply discharge points. Provide backflow prevention when potable water supply is used.

16-8.2.2.3 Circular Tanks.

At smaller Installations, where LET of less than 15,000 gallons (56,781 liters) are required, circular steel LET may be more cost effective than a rectangular concrete LET. Evaluate local availability and cost of materials. A circular tank may allow for more efficient use of available ground for system layouts on smaller parcels of land.

16-8.3 Secondary Treatment.

Secondary treatment may be required for direct discharges or discharges to a POTW. Dissolved air flotation (DAF) is recommended for secondary treatment. A DAF unit will remove significant amounts of residual OWWO and emulsified oils. Typical effluent discharges from a DAF unit may be as low as 10 to 15 mg/L. It may be necessary to add coagulating and emulsion breaking chemicals to the DAF influent to optimize removal of contaminants. Bench testing should be performed to size the secondary treatment system and determine optimum coagulant dose.

16-8.4 Tertiary Treatment.

To provide consistent direct discharge quality effluent, tertiary treatment may be required for direct discharge depending on permit requirements. The recommended process is multimedia filtration with relatively fine graded media followed by carbon adsorption. In certain situations, primarily where flows are higher and space limitations prevent installation of a sufficient number or size of multimedia filters, coalescing filtration units may be considered. Coalescing filters are mechanically complex, but they perform reliably if operated and maintained properly.

16-8.5 Redundancy.

Provide redundancy for OWWO treatment. It is important to avoid the loss of a key unit operation during maintenance, scheduled or unscheduled, for any piece of equipment. Provide redundancy for individual processes such as downstream polishing treatment units, transfer pumping equipment, and effluent monitoring instrumentation required for continuous operation.

16-8.6 Discharge to Publicly Owned Treatment Works.

For free oil removal, effluent discharge requirements may be achieved by batch treatment gravity separation processes. The oily waste is discharged into a short-term storage or separation tank referred to as a load equalization tank (LET). The typical effluent from a LET contains less than 50 ppm of oil and grease. Discharges to a POTW must be coordinated with and approved by the POTW.

16-8.7 Direct Discharge.

Effluent discharge requirements for direct discharge are more stringent. Additional treatment is required to remove oils, such as free oil or emulsified oil, remaining after

LET treatment. An NPDES permit would be required. Sulfide control and metals removal may also be necessary to meet effluent discharge requirements.

16-8.8 Emulsified Oil Treatment.

Unlike free oils, simple gravity settling is not effective for emulsified oils. Minimize the formation of chemical and physical oil emulsions. Avoid excessive turbulence such as pumping or turbulent flow and the use of detergents or emulsifying agents. Emulsions are usually complex, and bench or pilot plant testing is generally necessary to determine an effective method for emulsion breaking. Segregate emulsions or provide additional treatment for their removal from the waste stream. Use WEF MOP FD-3, Chapter 10 for emulsified oil treatment.

16-8.9 Hydrogen Sulfide Formation.

The presence of sulfides in oily wastewater is primarily due to biological reaction involving anaerobic bacteria that use hydrocarbons as their energy source and convert sulfates to sulfides. The pH of wastewater affects the distribution of sulfide species. If low pH oily wastewater is exposed to the atmosphere, hydrogen sulfide gas is released causing severe odors and corrosion problems. At alkaline pH, the sulfide species do not escape to the atmosphere. Exposure to small concentrations of hydrogen sulfide in the air is also a health hazard as it can affect the respiratory system.

The time gap between the generation and treatment and disposal of oily wastewater is a major factor for sulfide formation. During this time, oxygen is rapidly depleted causing a decrease in the ORP which favors the activity of sulfate reducing bacteria. This time should be kept at a minimum to limit sulfide production.

16-8.9.1 Control Techniques.

The principal physical and chemical methods for sulfite control at oily waste treatment plants include chemical oxidation, chemical precipitation, and wastewater aeration. Other techniques such as biological processes or adsorption have limited application due to cost and operational requirements of these processes.

16-8.10 Dissolved Metals Removal.

Oily wastewater may contain significant amounts of dissolved metals. The removal of dissolved metals may be necessary to meet comply with POTW requirements or direct discharge permit requirements. Metals such as iron, zinc, lead, copper, and nickel may be reduced to low levels by chemical precipitation.

16-8.10.1 Dissolved Metals Removal.

The removal of dissolved metals can typically be accomplished by raising the pH of the wastewater above 8 by using additives such as lime or sodium hydroxide. Most metals form highly insoluble precipitates at higher pH levels. The minimum solubility of different metals occur at different pH values. Therefore, a laboratory investigation is essential to determine the optimum pH level for removal of dissolved metals. For plants using sulfide control by chemical precipitation, additional treatment for metals removal may not be necessary. As alkaline solution is added for sulfide control, it will affect metals precipitation and metals will be co-precipitated as hydroxides and sulfides. The metal precipitates may be separated from wastewater in the oil-water separation equipment, such as DAF. For improved removal of these precipitates, addition of polyelectrolytes may be necessary. The laboratory investigation should be conducted to select the type and amount of polyelectrolyte for simultaneous suspended solids (metals precipitates) and emulsified oil removal from wastewater.

16-8.11 Sludge Disposal.

The characteristics of oily sludge are specific to the oily waste treatment facility and treatment process. Sludge may have toxic or hazardous characteristics. Evaluate the characteristics of the sludge to determine the appropriate method of disposal.

This Page Intentionally Left Blank.

APPENDIX A BEST PRACTICES

Appendix A provides design guidance.

A-1 WHOLE BUILDING DESIGN GUIDE.

The Whole Building Design Guide (WBDG) provides access to DoD criteria such as Unified Facilities Criteria (UFC), Unified Facilities Guide Specifications (UFGS), and for approved Government employees, access to non-government standards.

A-2 MATERIALS.

A-2.1 Rigid Conduit.

For concrete pipe use *Concrete Pipe Design Manual* for guidance. For ductile iron pipe use AWWA M41 for guidance. For cast iron soil pipe use *Cast Iron Soil Pipe and Fittings Handbook* for guidance.

A-2.2 Flexible Conduit.

For PVC pipe use the *Handbook of PVC Pipe Design and Construction* for guidance.

A-3 TRENCHLESS TECHNOLOGY.

Trenchless Technology Pipeline and Utility Design, Construction and Renewal and WEF MOP FD-6 provide guidance on trenchless renewal technology.

A-4 DOMESTIC WASTEWATER FLOWS.

Per capita rates should be determined using actual wastewater flow and load data, water usage rates or average daily per capita wastewater estimates for the specific facility type. For some facility types, it may be appropriate to use data from a similar facility type. When a similar facility type is used, differences in water conservation practices should be evaluated.

WEF MOP 8, Chapter 2, *Principals of Integrated Design* provides typical flowrates for commercial and institutional sources. Do not use these typical waste loading values for temporary host nation facilities.

A-4.1 Average Hourly Flow.

Example 1: 1,000 residents at 100 gal/cap/day (379 L/cap/day) will generate 100,000 gallons/day (379 m^3/day) in 24 hours for an average hourly flow rate of 4,167 gal/h (15.77 m^3/h).

Example 2: 1,000 nonresidents at 30 gal/cap/day (114 L/cap/day) will generate 30,000 gallons/day (114 m^3/day) in 8 hours for an average hourly flow rate of 3,750 gal/h (14.2 m^3/h). Note that the average daily flow is 30,000 gal/day (114 m^3/day), but the wastewater system must be designed to carry the 30,000 gallons (114 m3) in 8 hours not 24 hours.

A-5 WASTEWATER COLLECTION.

A-5.1 Pump Stations.

WEF FD-4 provides guidance for the design of wastewater pump stations.

A-5.2 Thrust Restraint for Force Mains.

Online thrust restraint calculators can assist in performing thrust restraint calculations. See EBAA IRON Restraint Length Calculator located at http://rcp.ebaa.com/ or DIPRA located at https://www.dipra.org/ductile-iron-pipe-resources/calculators/thrust-restraint-of-ductile-iron-pipe. Consider the bearing surface of the fitting when designing thrust blocks. Compact fittings reduce the bearing surface of the thrust block.

A-6 WASTEWATER TREATMENT FACILITIES.

A-6.1 Health and Safety.

WEF MOP 1 provides comprehensive guidance for health and safety at wastewater treatment facilities.

A-6.2 Security.

Water and Wastewater Systems Sector-Specific Plan, and Emergency Planning, Response and Recovery provide guidance for the protection of wastewater treatment facilities.

A-6.3 Operator Considerations.

Meetings with the wastewater treatment operator should held prior to development of the 35 percent design submittal. Operators can provide valuable input about problems with existing processes or operational lessons learned. Consider the experience and level of operator training when designing wastewater treatment systems.

A-6.4 Plant Location.

WEF MOP 8, Chapter 3, provides guidance for site selection.

A-6.4.1 Separation Distances.

Greater separation distances between occupied areas and the wastewater treatment facilities may be required to eliminate odors. Consider using greater separation distances when occupied areas are located on the leeward side of the wastewater treatment facilities, in areas subject to prolonged or frequent air stagnation, fog, or mist cover, at a lower elevations than the treatment works, or with surface and groundwater flow from the wastewater treatment facilities toward the occupied area.

A-6.5 Special Consideration for the Tropics and Semiarid Locations Outside of the United States.

Consider that brackish water may be used for washing, cooling, or cleaning; if it is allowed to enter the waste stream, the increased salinity will lower biological process efficiencies. Also, high dissolved solids concentrations have an effect on the treatment process efficiency. If gray water is separated from the waste stream and recycled or used directly for irrigation, washing, or cooling, wastewater flow will be low and much more concentrated. Loss of water by evaporation and from pipelines into the ground may further decrease flow to the POTW.

A-6.5.1 High-Temperature Parameters.

A major design parameter will be water temperature. Use of rooftop rain storage, cistern water, brackish water, and the ambient conditions will result in a very warm wastewater. The engineer should expect high salt content, including sulfate, chloride, phosphate, borate, and nitrate ions, and both alkali and alkaline earth cations. Oxygen levels will be very low and chalcogenides as well as dissolved hydrogen sulfide should be anticipated. The most dramatic effect of high temperature will be on biochemical reaction rates.

A-6.5.2 Unit Operations in the Tropics.

Although activated sludge, trickling filter, or rotating biological filter processes may be used in hot climates, strong sunlight and adequate space will make the use of wastewater treatment ponds advantageous. Temperature and sunlight intensity will control algal growth, which will be intense. The most useful type of pond will be the facultative pond. Pond retention time may be over 30 days; depth is typically between 5 and 10 ft (1.5 and 3.0 m).

For trickling filters and rotating biological disc filters, filter media volumes decrease proportional to temperature increases. Sludges dry much more rapidly in hot climates; but, in the humid tropics, covers may be required. Odor problems have been common in the sludges produced in hot climates, indicating that aerobic digestion or aerobic composting are potentially useful. Investigate anaerobic digestion and gas production because a hot climate encourages microbiological fermentation reactions.

A-6.6 Special Consideration for Cold and Arctic Locations Outside the United States.

Extreme low temperature is common: as low as -75° F (-59° C) in interior locations in northern Canada; below -100° F (-73° C) in Antarctica; and a month or more of subzero air temperature in the Arctic. Water, sewer, electric utilities, and steam lines are typically run in utilidors above ground to conserve their heat, allow for easy access, and conserve materials. Utilidors are kept insulated from the ground because the permafrost can be alternately melted and frozen if trenches are used.

A-6.6.1 Wind Protection.

Wind in the arctic zone produces a great heat loss problem, which is reflected in wind chill factors. Snow and wind loads on structures require careful consideration. Precipitation in northern climates is typically quite low, but the snow produces drifts and can cause severe problems in transportation and operation if the engineer fails to consider wind. Rotating biological equipment and other covered equipment should be well insulated, and designed to withstand thermal extremes, buffeting wind loads and wet spring snow.

A-6.6.2 Conservation Practices.

Because wastewater is transported above the ground surface or in well-insulated, well-constructed tunnels, fresh water use is almost the same as wastewater return. Design conditions can be expected to be about 300 ppm (300 mg/L) for BOD, BOD_5 at 60 to 80 gpd/cap (2.63 x 10-6 to 3.51 s 10-6 to 0.30 m^3/cap·s). Wastewater will typically be delivered to the facility at approximately 50° F (10° C).

A-6.6.3 Processes.

Chemical and biological processes are negatively affected by extreme cold. Chemical reaction rates are generally slower at low temperatures, and chemical solubilities are reduced. All chemical reactions, especially those involving partially soluble salts, should be recalculated to reflect the low solubility of chemicals in cold water. Each flocculent or deflocculant, each polymer, and each detergent or other organic chemical used should be tested for unanticipated interaction brought about by low temperatures.

The rates of biological reactions are also reduced greatly, which affects the sizing of biological treatment processes. The biological processes that have been used most successfully in cold climates include wastewater treatment ponds, either facultative or aerated; activated sludge with long solids retention times; and attached growth systems. Design biological processes such as lagoons and ponds to withstand the effect of ice and use submerged aeration systems. Attached growth systems such as trickling filters and RBCs should not be used unless they are adequately enclosed and protected from the cold. Suspended growth systems with short solids retention times such as conventional activated sludge should be avoided.

A-6.6.4 Modifications for Viscosity and Dissolved Oxygen Variations.

All operations where operation is viscosity dependent should be corrected for increased viscosity. This includes sedimentation tanks, filters, and wastewater treatment ponds. All processes that involve oxygen transfer will be aided by the increased solubility of oxygen at low temperatures; but, to overcome the deleterious effect of increased viscosity, more mixing may be required. An absorption process such as oxygen bubble-water transfer is enhanced by the lower temperature, but the lower viscosity reduces the rate of contact so that, overall, neither oxygen transfer nor absorption change in rate.

A-6.6.5 Insulation of Appurtenances.

Trash racks, bar screens, grit chambers, unit process tanks, biological reactors, aerators, gates, walkways, and instrumental sensing devices should be enclosed, covered, heated, insulated, redesigned to withstand icing and snowpack, or a combination.

A-6.7 Preliminary Treatment.

WEF MOP 8, Chapter 9, *Preliminary Treatment,* provides guidance for the design of preliminary treatment systems.

A-6.8 Primary Treatment.

WEF MOP 8, Chapter 10 *Primary Treatment,* provides guidance for the design of preliminary treatment systems.

A-6.9 Settling.

A-6.9.1 Primary Settling.

Table A-1 Best Practices for Primary Settling

Best Practices for Primary Settling					
Rectangular Tank	Minimum Length	Maximum Length	Minimum Width	Maximum Width	Maximum Depth
	50 ft (15 m)	300 ft (90 m)	10 ft (3 m)	80 ft (24m)	16 ft (4.9 m)
Circular Tank	Minimum Diameter	Maximum Diameter			Maximum Depth
	10 ft (3 m)	200 ft (60 m)			16 ft (4.9 m)
Best Practices for Secondary Settling					
Rectangular Tank	Minimum Length	Maximum Length	Minimum Width	Maximum Width	Maximum Depth
	100 ft (30 m)	200 ft (60 m)	20 ft (6 m)	33 ft (10m)	16 ft (4.9 m)
Circular Tank	Minimum Diameter	Maximum Diameter			Maximum Depth
	30 ft (9 m)	140 ft (43 m)			16 ft (4.9 m)

A-6.9.2 Surface Overflow Rates.

Table A-2 Surface Overflow Rates

Best Practices for Surface Overflow Rates				
	Design Average Flow		Design Peak Hourly Flow	
Primary Settling				
Tanks not receiving waste activated sludge	Minimum	Maximum	Minimum	Maximum
	800 gpd/ft^2 (33 m^3/m^2 d)	1000 gpd/ft^2 (41 m^3/m^2 d)	1000 gpd/ft^2 (41 m^3/m^2 d)	1500 gpd/ft^2 (61 m^3/m^2 d)
Tanks receiving waste activated sludge	550 gpd/ft^2 (22 m^3/m^2 d)	700 gpd/ft^2 (29 m^3/m^2 d)	800 gpd/ft^2 (33 m^3/m^2 d)	1200 gpd/ft^2 (49 m^3/m^2 d)

A-6.10 Biological Treatment.

A-6.10.1 Biofilms.

WEF MOP 8, Chapter 11 *Biofilm Reactor Technology and Design,* provides design guidance for biofilms and biofilm reactor systems.

A-6.10.2 Activated Sludge.

WEF MOP 8, Chapter 12: Suspended-Growth Treatment Processes, provides design guidance for aerobic activated sludge.

A-6.10.2.1 Solids Loading Rate.

The average solids loading rate is typically between 20 – 30 lb/d/ft^2 (98 – 146 kg/m2 d) and the peak solids loading rate is typically between 40 – 50 lb/d/ft^2 (195 – 244 kg/m2 d).

A-6.10.3 Integrated Biological Treatment

WEF MOP 8, Chapter 13: *Integrated Biological Treatment,* provides design guidance for fixed-biofilm treatment in series with suspended-growth treatment.

A-6.11 Support Systems for Wastewater Treatment Operations.

WEF MOP 8, Chapter 7 provide guidance on designing wastewater support systems such as instrumentation and control, chemical storage and chemical feed systems.

A-6.12 Advanced Wastewater Treatment.

WEF MOP 8 Chapter 14 *Physical and Chemical Processes for Advanced Wastewater Treatment* provides guidance for the design of advanced treatment systems. Advanced treatment systems include secondary effluent filtration, activated carbon adsorption, chemical treatment, membrane processes, air stripping, ammonia removal by breakpoint chlorination, and effluent reoxygenation.

A-6.13 Disinfection.

WEF MOP 8, Chapter 17 *Disinfection* provides guidance on disinfection design. Disinfection guidance includes chlorine disinfection, dichlorination, ultraviolet disinfection, ozone disinfection, and other disinfection methods.

A-7 SOLIDS PROCESS DESIGN AND MANAGEMENT.

Solids Process Design and Management provides guidance for processing sludge for disposal and sludge to biosolids.

A-8 NATURAL SYSTEMS.

WEF MOP 8, Chapter 16: *Natural Systems* and WEF MOP FD-16 provide design guidance for natural systems. Natural systems include infiltration, stabilization ponds, aquatic plants, and constructed wetlands.

A-8.1 Facultative Ponds.

A facultative pond is easy to maintain and has stable to flow and load variations. The facultative pond has low capital and operating costs. Organic loadings are generally much higher in summer than in winter. A facultative pond is applicable in climates where evaporative losses exceed the average annual rainfall. One disadvantage to facultative ponds is that they will require a larger amount of large land area to maintain area BOD_5 loadings in a suitable range.

A-8.2 Algae Control.

Algae present in pond effluent represents one of the most serious performance problems associated with facultative ponds. Refer to WEF MOP FD-16, Chapter 7, Section 22, for algae control.

A-8.3 Aerated Ponds.

The main advantage of aerated ponds compared with facultative lagoons is that they require less land area.

A-8.4 Aerobic Ponds.

Aerobic ponds, also referred to as high-rate aerobic ponds are not typically used and are typically limited to warm, sunny climates. The chief advantage of the high-rate aerobic pond is that it produces a stable effluent with low land and energy requirements and short detention times. Operation is more complex than for a facultative pond. Without an algae removal step d, the effluent will contain high suspended solids. Short detention times also mean that very little coliform die-off will result. Because of their shallow depths, these ponds need to paved or lined to prevent weed growth.

A-9 ON-SITE TREATMENT SYSTEMS.

A-9.1 Alternative Sewer Systems.

WEF MOP FD-12 provides design guidance for alternative sewer systems. Alternative sewer systems include pressure sewers systems, vacuum sewer systems, and effluent sewers.

A-10 BIOASSAY OF WASTEWATER.

Observed toxicity of effluent may be measured using bioassay procedures to determine the possible effects on the ecosystem of the receiving stream. Industrial process wastewater installations may contain toxic compounds that exhibit none of the generic pollutant parameters or cannot be disclosed for security reasons. Regulatory agencies may require bioassay monitoring of these effluents.

A-10.1 Standard Bioassay Procedures.

A bioassay measures the concentration of pollutant at which a designated percentage of selected test organisms exhibits an observable adverse effect. These require extensive equipment, time, and test procedures and do not provide a rapid assessment of effluent toxicity. The percentage is typically 50%, and the adverse effect is typically death or immobility. Concentrations (percent by volume) are expressed as LC50 for median lethal concentration and EC50 for median effective concentration.

- Test organisms—Effluent tests should be conducted with a sensitive species that is indigenous to the receiving water. The test organisms do not have to be taken from the receiving water. Refer to EPA 600/4-90-027F for a complete list of acceptable test organisms and temperatures.
- Methodology—refer to EPA 600/4-90-027F and S*tandard Methods for the Examination of Water and Wastewater* for a complete description of required test equipment, laboratory and test procedures, sampling and

analytical procedures, procedures for data gathering and reporting, and methods for data reduction and analysis to determine LC50 or EC50.

Regulatory bioassay requirements and LC50 or EC50 are typically based on 48- or 96-hour tests using fish or invertebrates (e.g., minnows or Daphnia, respectively).

A-10.2 Rapid Bioassay Procedures.

In lieu of standard procedures investigate the use of rapid bioassay procedures (RBPs). RBPs are useful tools in effluent monitoring, providing inexpensive yet reliable toxicity data quickly. Check with state or local regulatory agency for approval of RBPs before developing a test program.

A-11 INDUSTRIAL WASTEWATER TREATMENT

A-11.1 Biological Systems.

Control toxic substances such as heavy metals and certain organic compounds present in some industrial wastes to avoid upset or pass-through of biological systems. Use WEF MOP FD-3 Chapter 5 Wastewater Treatability Assessments to examine the degree and methods of removal of pollutants, including organic pollutants. Conventional biological treatment systems can remove some organic compounds via biodegradation, volatilization (stripping) from aeration, and adsorption onto sludge, while others pass through. Actual removal performance depends on the operating characteristics (sludge age, mixed liquor suspended solids) of the treatment facility, the method of oxygenation, and the amount and nature of other compounds present in the wastewater. Refer to WEF MOP FD-3 Chapter 6 *Industrial Wastewater Characteristics and Approach* to Wastewater Management for appropriate treatment options.

A-11.2 Nutrients.

Evaluate nutrient levels for separate and combined industrial waste treatment systems. Maintain minimum amounts of nutrients required for efficient biological treatment. Normal proportions needed for active microbiological growth are typically about 1 lb (0.45 kg) of phosphorus (as P) and 5 lb (2.25 kg) of nitrogen (as N) for each 100 lb (45 kg) of BOD removed (requirements are somewhat lower for lightly loaded systems). Evaluate mixing industrial wastes with domestic wastewater to avoid the need for supplemental nutrients as wastewater contains excess amounts. Mixing domestic wastewater with industrial waste may also affect disinfection requirements and increase disposal of waste solids from treatment because of human waste components in the solids.

A-11.3 Source Separation.

Examples of industrial wastewater to be separated are precipitation treatment of copper and lead (incompatible because optimum pH of precipitation of each metal is not equal) and acid reduction of hexavalent chrome in the presence of cyanide (hazardous because it produces toxic hydrogen cyanide gas).

A-12 OIL-WATER SEPARATORS.

Gravity oil-water separators and enhanced gravity separators with coalescing media should not be used to treat emulsified or dissolved oil.

A-12.1 Types of Oily Waste.

Oil is one of the most common types and highly visible forms of water pollution. Even small quantities **\1\ /1/** can cause harm to the aquatic environment.

A-12.1.1 Free Oil.

Oil droplets with a diameter of 150 microns and larger.

A-12.1.2 Dispersed Oil.

Oil droplets with a diameter **\1** greater than 20 microns and less than 150 microns. **/1/**.

A-12.1.3 Mechanically Emulsified Oil.

Oil droplets with a diameter **\1** less than 20 microns **/1/**.

A-12.1.4 Chemically Emulsified Oil.

Oil droplets with a diameter **\1** less than 20 microns with a chemical bond to other molecules **/1/**.

A-12.1.5 Dissolved Oil.

An oil-water mixture with oil in soluble form.

A-12.2 Field Investigation.

When possible, investigate existing operations and evaluate:

- Making process changes to reduce the amount of oily waste generated.
- Using spill prevention, control, and countermeasures such as minimizing leaks, avoiding spills, and using drip trays and dry absorbents to minimize the oily waste.
- The potential for toxic and hazardous materials in the waste stream.

A-12.3 Oily Waste Treatment.

The level of required treatment for oily wastewater depends on the method of discharge, POTW or direct discharge.

A-12.3.1 Discharge to POTW.

Effluent discharge limits to a POTW can range from 25 to 50 mg/l of oil and grease on the low end or as high as 100 mg/l to 200 mg/l of oil and grease for more efficient treatment works. Coordinate with the operator of the POTW to see what level of oily waste effluent they will be able to accept. Typical effluent quality requirements can be achieved by gravity oil-water separators.

A-12.3.2 Discharge to Navigable Water.

Effluent discharge limits for direct discharge depend on the water quality of the receiving water. Average oily waste effluent discharge limits typically range from 5 to 15 ppm (5 to 15 mg/l). Peak oily waste effluent discharge limits may be as high as 30 ppm (30 mg/l). Applicable permits, such as an NPDES permit, will need to obtained for direct discharges. As part of the permitting process, effluent limits for other types of contaminates such as pH and total suspended solids may also be required. Total suspended solids discharge limits are typically around 60 mg/l and pH discharge limits are typically a minimum of 6.0 to a maximum of 9.0.

Oily waste streams containing hazardous materials, metals, or other wastes with discharge should not be discharged to navigable waters without providing additional treatment.

A-12.4 Emulsions.

Minimize the formation of oil emulsions. Segregate emulsified oil for special treatment wherever possible.

A-12.4.1 Chemical Emulsions.

Using detergents increases emulsification and inhibits gravity oil-water separation.

A-12.4.2 Physical Emulsions.

Use of high-pressure water or centrifugal pumps cause emulsification of the oily waste. Physical emulsions are generally less detrimental to oil-water separation than the use of detergents.

A-12.5 Grit Removal.

Grit removal should be provided prior to entering the oil-water separator compartment for the removal of total suspended solids. When the suspended solids are minimal, the grit chamber may be included as the first oil-water separator compartment. For wastewaters with a high suspended solids concentration the design should include a separate grit chamber. A detention time of 5 minutes at the maximum rate of flow may be used to size the grit chamber. Settleable solids sink to the bottom of the chamber and will need to be removed and disposed of. Allow space for accumulated grit between for the expected grit removal maintenance cycle. Access should be provided for a truck with suction equipment to periodically remove grit.

A-12.6 Gravity Separators.

Gravity separators are used for the removal of free oil and in some cases dispersed oil. In gravity oil-water separators free oil floats to the surface where it can be separated from the clean effluent. Typical effluent depends on the flow rate through the oil-water separator and typically contains less than 50 ppm of oil and grease. Dispersed oil can be more difficult to remove as the micron size decreases. When removing dispersed oil the size of a gravity oil-water separator will need to need to be increased to improve the quality of the effluent. Using gravity separators to remove dispersed oil will typically require an oil-water separator that may be prohibitively large. Access should be provided for a truck with suction equipment to periodically remove the oil. Some gravity oil water separators are covered with steel grating that can be easily removed to provide access to the entire oil separation compartment.

A-12.7 Parallel Plate Separators.

Parallel plate coalescing media can enhance the performance of gravity separators and can typically remove the lower ranges of dispersed oil where gravity oil-water separators are ineffective or prohibitively large. The lower range of oil removal is typically in the range of 30 to 40 microns. Oil is removed by passing the wastewater at laminar velocity through the parallel plate coalescing media. Parallel plate coalescing media is inclined to aid in the removal of oil. Inclines typically range from 45 to 60 degrees. The plates may be made of oleophilic (oil-attracting) material to promote coalescence of oil droplets. For this reason, the units are sometimes referred to as coalescing plate separators. Coalescing plates are typically recommended where the facility is committed to the additional maintenance procedures required to periodically remove and clean the parallel plate coalescing media. Access should be provided for removing the parallel plate coalescing media unit without the need for entering the oil-water separator or disassembling the parallel plate coalescing media unit.

Some manufactures are starting to provide additional post-separation treatment capable of removing oil not typically removed by parallel plate separators. These additional treatment processes should be evaluated based on compliance with discharge limits, maintenance requirements and the cost associated with purchasing material required for maintenance.

A-12.8 Maintenance.

Lack of proper maintenance is one of the biggest causes of oil-water separator failure. Design oil-water separators with accessible chambers for monitoring and maintenance.

A-12.9 Emulsified Oil Treatment.

Emulsions are typically complex, and bench or pilot facility testing is generally necessary to determine an effective method for emulsion breaking. Common emulsion-breaking (demulsification) methods are a combination of physical and chemical processes. The most common approach to removing emulsified oils from wastewater is by the use of chemicals. Chemicals commonly used include alum, ferrous sulfate, ferric sulfate, ferric chloride, sodium hydroxide, sulfuric acid, lime, and polymers. The effectiveness of various chemicals in breaking emulsions can be determined by laboratory testing. Refer to *Standard Methods for the Examination of Water and Wastewater* (Method 5520 Oil and Grease and Method 2540 Solids) for the testing procedure.

A-12.9.1 Destabilization.

Treatment of oil emulsions is typically directed toward destabilizing the dispersed oil droplets, causing them to coalesce and form free oil. A typical process consists of rapidly mixing coagulant chemicals with the wastewater, followed by gentle mixing (flocculation). The agglomerated oil droplets may then be removed by gravity or flotation.

A-12.10 Oil and Oily Sludge Removal and Disposal.

Reliable oil removal is critical from the surface of the separation chamber for both commercially available units and custom-designed separators. Oil may be removed by suction or vacuum equipment. This equipment is sometimes referred to as a vacuum or truck and may also be used for cleaning catch basins.

Oils and oily sludges removed from the oil-water separator may be disposed of by sale by the Defense Logistics Agency, Disposition Service. Evaluate final disposal options with oil-water separation methods such as landfill, incineration or land disposal and associated environmental requirements to establish the most cost-effective total system. The sludge may require regulation as a toxic or hazardous waste if levels of pollutants exceed Resource Conservation and Recovery Act or state hazardous waste levels.

A-13 LOAD EQUALIZATION TANK SIZING.

Table A-3 Load Equalization Tanks

Sizing Guidance - 7 Day Capacity		
Let Volume	0.1 to 0.5 Mgal (379 to 1,893 m^3)	1.0 to 1.5 Mgal (3,785 to 5678 m^3)
Length to Width Ratio	3:1	5:1
Depth	10 ft (3.05 m)	20 ft (6.1 m)
Freeboard	1.5 ft (0.5 m)	1.5 ft (0.5 m)

Change No.	**Date**	**Location**
1	01 April 2024	Updated non-unified references and added sewer inspecting and cleaning guidance in Appendix A.

This UFC supersedes UFC 3-240-03N, dated January 2004.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-240-03, *Operation and Maintenance (O&M) Wastewater Treatment*

Superseding: UFC 3-240-03N, Wastewater Treatment System Augmenting Handbook Operation and Maintenance, dated January 2004

Description: UFC 3-240-03 provides technical requirements and guidance for the operation and maintenance of wastewater treatment systems.

Reasons for Document:

- The new UFC updates technical requirements and increases the use of industry standards.

- The majority of existing criteria was outdated and needed a major revision.

Impact:

- This update revises an existing Navy only UFC and unifies wastewater treatment operation and maintenance criteria across DoD. This operation and maintenance criteria will assist owners and operators with maintenance and operation of wastewater treatment systems and provide increased guidance.

Unification Issues:

AIR FORCE

- AFH 32-1290 provides additional requirements for cathodic protection systems.
- **\1** AFMAN 32-1062 provides additional requirements for electrical systems, power plants, and generators. **/1/**
- **\1\\ /1/**
- **\1** AFMAN 32-1067 provides further guidance water and fuel systems requirements and reporting. **/1/**
- **\1** AFMAN **/1/** 32-1068 provides further guidance on boiler personnel schedule requirements.
- **\1\\ /1/**
- AFI 32-7001 provides further guidance on reporting requirements.

ARMY

- AR 420-1 provides additional operating data requirements.

- PWTB 200-1-142 provides additional requirements for water reuse.
- TM 5-682 provides additional requirements for electrical facilities safety.
- TM 5-683 provides additional requirements for electrical interior facilities.
- TM 5-684 provides additional requirements for electrical exterior facilities.
- TM 5-685 provides additional requirements for operation, maintenance, and repair of auxiliary generators.
- PWTB 420-49-29 provides additional requirements for cathodic protection systems.
- TM 5-814-3 provides additional requirements for cold weather operation.

NAVY

- OPNAVINST 5090.1D provides Navy only requirements.
- OPNAVINST 5100.23G provides Navy only safety requirements.
- MCO P5090.2A provides Marine Corps only requirements.

This Page Intentionally Left Blank

TABLE OF CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides technical guidance and procedures for operations and maintenance (O&M) of wastewater treatment facilities.

1-2 APPLICABILITY.

This UFC applies to all service elements and contractors involved in the operation and maintenance of permanent DoD wastewater treatment plants worldwide.

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, DoD Building Code (General Building Requirements). UFC 1-200-01 provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-5 GLOSSARY.

Appendix B contains acronyms and definition of terms.

1-6 REFERENCES.

Appendix C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 REGULATORY COMPLIANCE AND MONITORING

2-1 OPERATION AND MAINTENANCE CRITERIA.

DoD wastewater systems must achieve, maintain, and monitor compliance with applicable environmental requirements and monitor these environmental requirements worldwide. Operate and maintain wastewater treatment systems in accordance with the requirements of applicable federal, state and local government agencies or overseas equivalent.

2-1.1 Within the United States.

For Installations located in the United States and its territories and possessions the wastewater system must comply with the following criteria precedence:

a. State wastewater or local regulations for the project location;

b. DoDI 4715.06;

c. Navy Only: OPNAVINST 5090.1D and MCO P5090.2A;

d. Additions to the above criteria as indicated in this UFC;

e. IPSDC;

f. WEF MOP 11; and

g. Refer to Appendix A for guidance.

2-1.2 Foreign Countries.

For Installations located outside of the United States and its territories and possessions the wastewater system must comply with the following criteria precedence:

a. The Forward of this UFC (All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA));

b. Final Governing Standards (FGS);

c. DoDI 4715.05 and DoD 4715.05-G, Overseas Environmental Baseline Guidance Document

d. Navy Only: OPNAVINST 5090.1D and MCO P5090.2A;

e. Additions to the above criteria as indicated in this UFC;

f. IPSDC;

g. WEF MOP 11; and

h. Refer to Appendix A for guidance.

2-2 FOREIGN COUNTRIES.

DoD 4715.05-G, *Overseas Environmental Baseline Guideline Document* (OEBGD), applies when there are no Final Governing Standards (FGS) in place. Therefore, in foreign countries this UFC will be used for DoD projects to the extent that it is allowed by and does not conflict with the applicable international agreements and the applicable FGS or OEBGD.

2-2.1 Wastewater Quality Standards.

DoD wastewater systems must achieve, maintain, and monitor compliance with applicable environmental requirements and monitor these environmental requirements worldwide.

2-3 SAFETY.

All DoD facilities must comply with DoDI 6055.1, DoDI 4715.1E, and applicable Occupational Safety and Health Administration safety and health standards.

For the Navy, also use OPNAVINST 5100.23G.

2-4 PLUMBING.

UFC 3-420-01 adopted the use of the International Plumbing Code (IPC) to comply with Public Law 104-113. Refer to UFC 3-420-01 for modifications to the IPC.

2-5 OPERATING REQUIREMENTS.

Wastewater treatment plant systems must operate within their approved permits and with federal, state, and local requirements or overseas equivalent. Operations and management staff at wastewater treatment plants (WWTP) are expected to understand, comply with these requirements and inform the Installation Environmental Program staff of any problems that may affect compliance.

2-5.1 Recordkeeping.

Equipment maintenance and repairs records are used for maintenance planning and scheduling to ensure that each piece of equipment is properly maintained to ensure it is reliable for the wastewater treatment process. All maintenance and repairs for each piece of equipment must be captured in a formal method to allow for an operator in the future to review the equipment history. The most common and effective way is to use a computerized maintenance management system.

The records for each piece of equipment can be used to make decisions on the repairs and replacement of the equipment. Such decisions look at the age of the equipment, the amount of time spent maintaining and repairing the equipment, and the cost of repairing and maintaining the equipment.

2-6 PERMITS.

Permits are issued for the construction, modification, discharge of treated effluent, discharge of stormwater runoff, and solids management practices. These permits may be issued by the Environmental Protection Agency (EPA), state, and local governments. In some cases, permits may be required from all three levels of government. Coordinate with the Installation Environmental Program staff during the permitting process.

2-6.1 Federal Permit Requirements.

Permits under Part 503.3(a), the requirements in Part 503 may be implemented through:

a. permits issued to treatment works treating domestic sewage by EPA or by states with an EPA approved solids management program; and

b. permits issued under Subtitle C of the Solid Waste Disposal Act; Part C of the Safe Drinking Water Act; the Marine Protection, Research, and Sanctuaries Act of 1972; or the Clean Air Act.

Treatment works treating domestic sewage submit a permit application to the approved state program, or, if there is no such program, to the EPA Regional Sludge Coordinator. Direct Enforceability under Part 503.3(b), the requirements of Part 503 automatically apply and are directly enforceable even when no permit has been issued.

2-6.2 National Pollutant Discharge Elimination System.

Code of Federal Regulations (CFR), Section 40, Part 122 describes the National Pollutant Discharge Elimination System (NPDES) permitting program. The NPDES permit program has separate regulations found in 40 CFR 125, 40 CFR 129, 40 CFR 133, 40 CFR 136, 40 CFR 400 through 460, and 40 CFR 503. When the EPA has designated authority to an individual state, Federal law allows these individual states to have more stringent requirements. WWTP owners or owner's designated representative needs to know if the EPA has delegated permitting authority to their state.

2-6.2.1 NPDES Permit Compliance.

Failing to comply with the NPDES permit may result in fines and other penalties. In some cases, it may even result in criminal prosecution. Since the NPDES program relies on self-reporting for implementation, EPA places special emphasis on timely and complete reporting. Enforcement actions are often swift and severe for being late with the monthly operating reports or for failing to report violations.

Exceedance of water quality limits will also draw regulatory attention and possible enforcement action. However, proactive planning prior to beginning the permit renewal process can reduce the likelihood of enforcement actions. In most states, the permitting agency may establish water parameters that the WWTP is not currently meeting. The permitting agency and WWTP owner or owner's designated representative should work together to determine a date when the parameter becomes effective in the future. This allows the WWTP time to upgrade or change the process to meet the parameters.

2-6.2.1.1 Negotiation of Effluent Limits.

Careful review by the discharger of the specific basis used for the water quality-based effluent limits is advisable. In many cases, the basis used in the development of the effluent limits is open to negotiation. Address effluent limits during the permit renewal process.

2-6.2.2 NPDES Permit Renewal.

NPDES permits require periodic renewal. The application and renewal of the permit is to be completed by the Installation as they may have different departments applying for permits. Permits may be modified by regulators prior to the normal permit renewal periods. Permit renewal applications need to be submitted 180 days (about 6 months) before the expiration date. If the existing permit is being violated regularly, the WWTP may need to develop a Wastewater Master Plan with a list of plant improvements and costs to bring the WWTP back into compliance with the discharge permit limits or as required by the permitting agency.

2-6.3 Operating NPDES Permit.

An operating NPDES permit is required before a WWTP can begin operating. An operating NPDES permit may include topics such as identifying the owner, describing the treatment process, describing the discharge location, frequency, and limits, and contain specific and general conditions. The owner is required to meet the discharge limits stated in the operating NPDES permit. The WWTP operator is responsible for keeping a copy of the permit on file at the WWTP. An operating NPDES permit is typically combined to contain the Federal, state, and local regulations and standards in a single document for the WWTP. In addition to treated wastewater, operating NPDES permits may address stormwater and other disposal options. When the EPA has designated authority, the state also may establish groundwater monitoring or discharge requirements. For example, disposal of treated effluent to the subsurface will require an Underground Injection Control permit from the state as required by the Safe Drinking Water Act.

Note: For the Army, AR 420-1 provides additional operating data requirements.

Note: For the Air Force, AFI 32-7001 and **\1** AFMAN **/1/** 32-1067 provide further guidance on reporting requirements.

2-6.3.1 Licensing and Staff Requirements.

The operating NPDES permit and applicable regulatory requirements determine the licensing and staffing requirements. Many states require that the chief operator be certified to complete the reports that are necessary to comply with state and federal water pollution control laws and regulations. Some facilities are required to have a certified operator on shift work when the chief operator is not on site. In some locations, all operators may require certification for the operation of a treatment plant. The EPA has stated that it would like to have all plants operated by qualified personnel; certification is a method of demonstrating an operator's level of qualification. Failure to have the correct number and level of certified operators can be considered a compliance violation.

2-6.3.2 WWTP Modifications.

An operating NPDES permit is not a construction permit. The EPA requires a modification to the operating NPDES permit when there is a significant change in the operation of the WWTP. In some states, an owner may construct or modify a facility, but it is a violation to place the modified facility in operation until a valid operating permit is obtained. Other states limit all construction activities until the changes or modifications are approved. Coordinate permit requirements with the Installation Environmental Program staff.

2-6.4 Disposal Permit Options.

Each Installation is responsible for disposal of waste such as solids, screenings, and grit in accordance with the approved WWTP permits. Treated effluent that is entirely disposed into the groundwater or onto land application sites does not need an operating NPDES permit from EPA to discharge, but it may be subject to NPDES permits for stormwater or solids.

2-6.5 Solids NPDES Permit.

Residual solids management has received special attention under 40 CFR 503. Solids management is typically addressed as part of the operating NPDES permit. However, a solids NPDES permit may still be required.

2-6.6 Stormwater NPDES Permit.

Each Installation is responsible for stormwater state management per the applicable permits. WWTPs that treat more than 1 million gallons per day (mgd) or are equal to or larger than 5 acres are included in the stormwater NPDES permitting program as a categorical industrial facility. Although stormwater could be included in the operating permit described above, many facilities obtain a general stormwater NPDES permit. This permit is maintained separately from the operating permit.

2-7 EMERGENCY REPORTING.

Emergency failures or spills typically require that the appropriate agencies be notified within 24 hours. Emergency reporting requirements should be included in the WWTP Operation and Maintenance Manual and displayed in obvious locations. Federal, State and Local governments may be involved with reporting emergency failures or spills.

2-7.1 Spill Prevention and Response Plan.

A stormwater NPDES permit typically requires best management practices and includes a spill prevention and response plan.

2-8 FACILITY OPERATION AND MAINTENANCE MANUAL.

The WWTP develops and updates the facility operations and maintenance manual. This manual includes a sapling and testing procedures required for day-to-day operations, reporting requirements, license requirements, and operating instructions (both normal operation and emergency operation). The operating instructions include single line drawings as applicable. Include maintenance and regulatory compliance requirements.

Retain shop drawings, catalogue cut sheets, and any other equipment information.

2-9 SAMPLING OF WASTEWATER.

A sampling and analysis program needs to be conducted as required by the NPDES operating permit. Typically, if a well-executed sampling plan is implemented, the process monitoring, and control program is more effective. Sampling is conducted for compliance with legal requirements, process monitoring and control, and historical data collection.

The NPDES operating permit's effluent limits are evaluated and monitored for compliance by sampling. Each permit specifies the sampling location, type, and frequency; analyses to be performed at each sample location; and frequency of reporting the results to the regulatory agency.

2-10 REPORTS.

The WWTP owner is responsible for ensuring all reporting requirements are completed by the chief operator or designated certified operator.

2-10.1 Capacity Analysis Report.

The Capacity Analysis Report documents the predicted future flows and loads within the treatment facility and evaluates the capacity of existing unit processes to reliably treat those loads for the next permitting cycle. The historical flows and the treatment performance of the preceding 5 years need to be analyzed. The carbonaceous biochemical oxygen demand (CBOD) and total suspended solids (TSS) loading (in pounds per day) also need to be verified. Population, flow, and load projections are then made to estimate what future loads will be, based on historical growth trends. The capacity of each unit process needs to be determined. These capacity assessments may already have been done for past renewals. However, the capacity rating of each process needs to be checked against the latest loadings and flow.

Use a 5-year period for future projections. Include future projects and realignment decisions when making future projections. If the plant is undersized, an expansion needs to be initiated and a Preliminary Engineering Report for improvements developed. Higher discharge rates also will precipitate additional permit application requirements to address anti-degradation issues.

2-10.2 Operation and Maintenance Report.

The Operation and Maintenance Report reviews plant operations data over the last permit cycle to evaluate needed improvements to the facility. Any upsets or spills need to be reviewed to determine the cause and possible solution. Some water quality exceedances may be a result of operation practices and need to be reviewed. The condition of the facilities is evaluated, such as the need for painting and other routine maintenance. Some needs may require changes to the process or construction approval. However, not every maintenance item needs to be reported to the agencies. Confirmation from the agency on which items need permitting is recommended after the Operation and Maintenance Report is completed.

2-10.3 Preliminary Engineering or Feasibility Report.

Use the Preliminary Engineering or Feasibility Report when modifications to the WWTP are required. This is a preliminary design study that will outline what changes are required to attain or maintain compliance. Typically, this report will contain a summary of the future flows and loads to be treated from the Capacity Analysis Report, a review of any alternative evaluations used to select the appropriate treatment technologies, and a conceptual-level design for upgraded facilities. A professional engineer sizes and plans for appropriate process changes. The Preliminary Engineering Report is submitted as part of the permit application renewal. Some states may require final construction drawings and specifications before approving the changes, whereas others may issue a construction permit based solely on the Preliminary Engineering Report.

2-11 REPORTING REQUIREMENTS FOR SEWAGE SOLIDS.

Reporting requirements for these solids are found in Part 503.18 for land application and Part 503.28 for surface disposal. These requirements apply to Class I solids management facilities and to WWTPs with a design flow rate equal to or greater than 1 mgd or that serve 10,000 or more people. Submit to the permitting authority the records they are required to keep as “preparers” of biosolids, owner of surface disposal sites. There are no reporting requirements associated with the use or disposal of domestic septage.

2-12 OPERATOR CERTIFICATION.

Operator certification is a process by which an individual is awarded a certificate from the state water quality regulatory agency for meeting specific criteria associated with the operation of wastewater treatment plants. Most states require that the responsible wastewater treatment plant operator possess a current state operator certification for the plant to meet the state's operating permit requirements. This certification process varies from state to state. Most states have different levels of certification that depend upon plant complexity and size or individual expertise. Certification requirements are usually contained in the permit or in state regulations. Certified operators demonstrate a specific level of proficiency in their selected field.

2-12.1 Training for Certification.

Additionally, operators may be required to attend classes or obtain a required amount of training prior to obtaining certification. Operators may contact state agencies to obtain specific information about training requirements for their certification.

Note: For the Air Force, **\1** AFMAN **/1/** 32-1067 provides additional requirements regarding operator training and certification.

2-12.2 Obtaining Certification.

Each state regulatory agency has a program for achieving certification. Operators should contact the state agency where the WWTP is located to obtain specific information about requirements and reciprocity programs. Although reciprocity exists between many states, certifications may not be transferable between some states. A certified operator may be able to apply for certification in other states that have reciprocity with the state issuing an operator certification. State regulatory agencies can help with reciprocity of certifications.

2-12.3 Training for Renewal of Certification.

States may require continual training by the operator to maintain their certification. Operators are required to review and complete the required amount of training to maintain their certification in the time periods set by their state regulations.

2-13 WASTEWATER REUSE.

Several states and communities are promoting the reuse of wastewater as a beneficial way of reducing both drinking water demands and wastewater discharge to the environment. The most common reuse projects involve using treated wastewater for irrigation purposes (e.g., golf courses). Other uses of water may include residential irrigation, fire protection, landscape features (e.g., ponds and fountains), and industrial supply. Generally, a project is only considered a reuse project if the reclaimed effluent replaces drinking water demand. Groundwater discharge is sometimes referred to as "groundwater recharge" and may be considered reuse if it is used to replenish the drinking water supply. However, contamination of the drinking water supply is a concern, and the discharge may have as many disincentives as incentives. Most land application projects that rely on groundwater infiltration for effluent disposal would be considered disposal projects, not reuse projects. Any disposal to natural surface waters will be considered an NPDES discharge and will be subject to all applicable rules.

2-13.1 Reuse Feasibility Study.

An engineering study is required to determine the actual water usage for a given reuse project. For example, an irrigator will not need water in wet periods or winter. The WWTP may therefore need to dispose of all its effluent for extended periods of time. The permit requirements need to be flexible to accommodate such seasonal effects. The objective of the engineering study is to determine a conceptual reuse system, including customers, available capacity, the size of the pipeline, pumps, and storage. This study is not a design-level project. Further design and permitting is required to implement a project.

2-13.2 Reuse Treatment Facilities.

Additional treatment processes may be needed to provide reuse-quality water. If there is a possibility of public contact with the water, provide high-level disinfection (<20 most probable number per 100 milliliters [mL]) for the effluent. Filtration before disinfection or discharge to an irrigation system also would be likely. If only a portion of the effluent flow is used for reuse, then these additional facilities would need to be sized accordingly and would treat only a side stream. An engineering feasibility study would need to determine the size and layout of these treatment facilities.

Note: For the Army, PWTB 200-1-142 provides additional requirements for water reuse.

2-13.3 Sludge Reuse.

Biosolids have beneficial plant nutrients and soil-conditioning properties. However, biosolids also may contain heavy metals, bacteria, viruses, protozoa, parasites, and other microorganisms that cause disease. If improperly treated and applied, they may also attract nuisance vectors such as insects and rodents. EPA actively promotes management practices that provide for the beneficial reuse of biosolids while maintaining or improving environmental quality and protecting human health. However, while the Part 503 regulations encourage the beneficial reuse of biosolids, they do not mandate it; traditional disposal methods, such as landfilling, may still be selected.

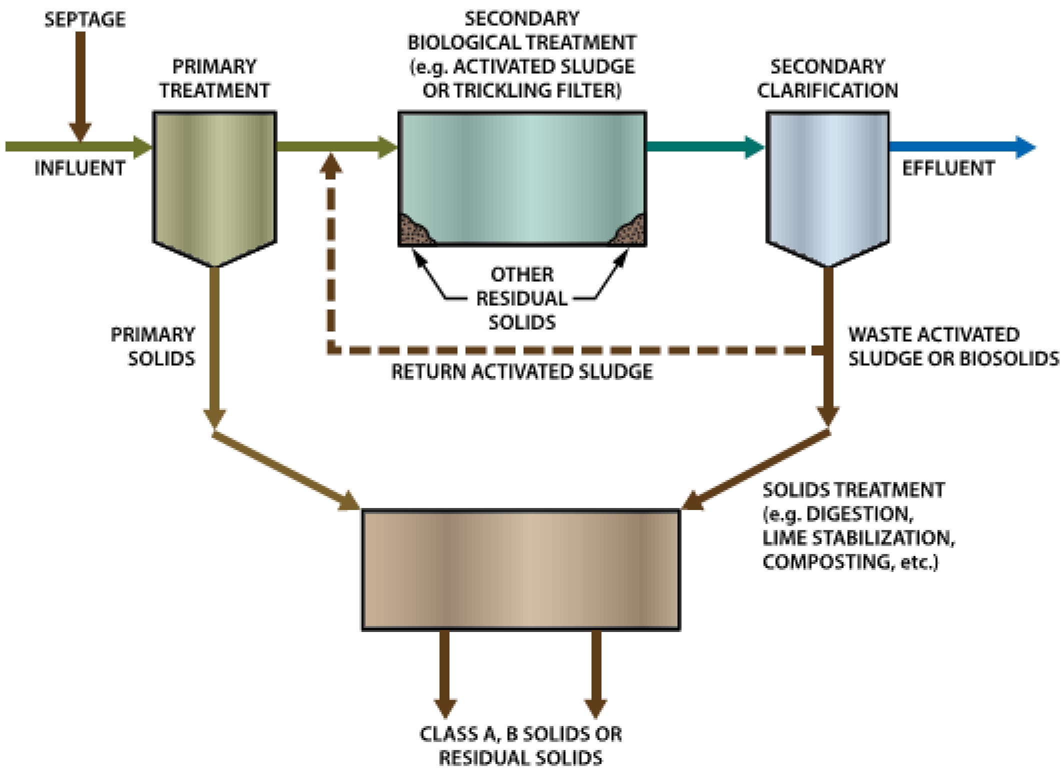
The use and disposal of biosolids, including domestic septage, are regulated under 40 CFR 503. This regulation, promulgated on February 19, 1993, was issued under the authority of the Clean Water Act, as amended in 1977, and the 1976 Resource Conservation and Recovery Act. For additional guidance on the Part 503 regulations, refer to EPA/625/R-92/013.

2-13.4 Solids Definition.

The Part 503 regulations promulgated the word “sludge” to describe a variety of solids residuals from wastewater treatment processes. The wastewater treatment industry and regulatory agencies have recently tried to minimize the use of the word “sludge” because the term is too general, and its negative connotations do not accurately reflect the industry’s goal: to promote the beneficial reuse of properly treated wastewater solids as useful soil amendments for agricultural users and the general population. In keeping with current industry practices, this document avoids the word sludge except when directly referred to in Part 503 regulations or a widely accepted process name, such as the “activated sludge process.” Figure 2-1 shows a secondary wastewater treatment plant and identifies the terminology used by industry and this document to replace the word sludge.

The primary solids referred to in Figure 2-1 are those derived from primary treatment processes. Solids drawn from the secondary treatment system are referred to as “waste activated sludge” or “biosolids.” The word biosolids refers to the residual treatment bacteria and inert solids contained in the biological treatment process. Solids that have undergone treatment for beneficial reuse generally are referred to as “residual solids” or classified according to their level of treatment, such as “Class A Solids.” In some cases, treatment facilities do not further treat primary or secondary solids and dispose of these in a permitted landfill; in this case, the residuals are referred to as “sludge,” meaning the product has not received treatment to reduce pathogens or vector attraction. The phrase “other residual solids” refers to the dense, grit-like solids that accumulate in process tanks and are removed when the tanks are periodically emptied and cleaned.

Figure 2-1 Residual Solids



2-14 PROTECTION OF PUBLIC HEALTH AND THE ENVIRONMENT.

In the judgment of the EPA administrator, Part 503 protects public health and the environment through requirements designed to reduce the potential for contact with the disease-bearing microorganisms (pathogens) and heavy metals in biosolids applied to the land or placed on a surface disposal site. These requirements are divided into the following categories:

- Requirements designed to control and reduce pathogens in solids
- Requirements designed to reduce the ability of the solids to attract vectors (rodents, birds, insects, and other living organisms that can transport solids pathogens away from the land application or surface disposal site)
- Requirements designed to limit the amount of heavy metals in solids applied to land or placed on a surface disposal site

Subpart D of Part 503 includes both performance- and technology-based requirements that aim to reduce pathogens and vector attraction. It is designed to provide a more flexible approach than Part 257, which required solids to be treated by specific listed or approved treatment technologies. Under Part 503, treatment works may continue to use the same processes they used under Part 257, but they can modify conditions and combine processes with each other if the treated solids meet the applicable requirements.

2-14.2 Pathogen and Vector Attraction Reduction.

Part 503.15 covers the applicability of the pathogen and vector attraction reduction requirements. The Subpart D requirements apply to solids (both bulk solids and solids that are sold or given away in a bag or other container for application to the land) and domestic septage applied to the land or placed on a surface disposal site. The regulated community includes anyone who generates or prepares solids for application to the land, as well as those who apply it to the land, including anyone who:

- Generates solids that are land-applied or placed on a surface disposal site
- Derives a material from solids
- Applies solids to the land
- Owns or operates a surface disposal site

2-15 LAND APPLICATION OR DISPOSAL.

Solids cannot be applied to land or placed on a surface disposal site unless they have met the two basic types of requirements in Subpart D: pathogen and vector attraction reduction requirements. These two types of requirements are separated in Part 503, which allows flexibility in how they are achieved. Demonstrate compliance with both types of requirements separately. Therefore, demonstration that a requirement for reduced vector attraction has been met does not imply that a pathogen reduction requirement also has been met, and vice versa.

2-16 PATHOGEN REDUCTION.

Sewage Sludge [503.32(a) and (b)]. The pathogen reduction requirements for sewage sludge are divided into two categories: Class A and Class B. These requirements use a combination of technological and microbiological requirements to ensure reduction of pathogens. The implicit goal of the Class A requirements is to reduce the pathogens in sewage sludge (including enteric viruses, pathogenic bacteria, and viable helminth ova) to below detectable levels. The implicit goal of the Class B requirements is to ensure that pathogens have been reduced to levels that are unlikely to pose a threat to public health and the environment under the specific-use conditions. For Class B solids that are applied to land, site restrictions are imposed to minimize the potential for human and animal contact for a period of time following land application until environmental factors have further reduced pathogens. Class B solids cannot be sold or given away in bags or other containers for application to the land. There are no site restrictions for Class A solids.

Domestic Septage [503.32(c)]. Domestic septage is a form of sewage sludge. Domestic septage is a liquid or solid material that is removed from a septic tank, cesspool, portable toilet, type III marine sanitation device, or similar system that only receives domestic septage (household, noncommercial, and non-industrial sewage). The requirements for domestic septage vary, depending on how it is used or disposed. Domestic septage applied to a public contact site, lawn, or home garden must meet the same requirements as other forms of sewage sludge. Separate, less complicated requirements for pathogen reduction apply to domestic septage applied to agricultural land, forests, or reclamation sites. These requirements include site restrictions to reduce the potential for human contact and to allow for environmental attenuation or pH adjustment with site restrictions only on harvesting crops. No pathogen requirements apply if domestic septage is placed on a surface disposal site.

2-17 VECTOR ATTRACTION REDUCTION.

Subpart D specifies 12 options to demonstrate reduced vector attraction. Eight of the options apply to sewage sludges that have been treated in some way to reduce vector attraction (e.g., aerobic or anaerobic digestion, composting, alkali addition, and drying). These options consist of operating conditions or tests to demonstrate that vector attraction has been reduced in the treated solids. Three options cover methods for injection or incorporating solids into the soil to reduce vector attraction.

One option is a requirement to demonstrate reduced vector attraction in domestic septage through elevated pH. This option applies only to domestic septage.

2-18 FREQUENCY OF MONITORING.

Sewage Sludge [503.16(a) and 503.26(a)]. The Class A and Class B pathogen requirements and the first eight vector attraction reduction options (the treatment-related methods) all involve some form of monitoring. The minimum frequency of monitoring for these requirements is given in Part 503.16(a) for land application and Part 503.26(a) for surface disposal. The frequency depends on the amount of solids used or disposed of annually. The larger the amount used or disposed of, the more frequently monitoring is required.

Domestic Septage [503.16(b) and 503.26(b)]. One of the options that can be used for demonstrating both pathogen reduction and vector attraction reduction in domestic septage is to elevate pH to >12 for 30 minutes without the addition of more alkali. When this option is used, monitor each container of domestic septage (e.g., each tank truck load) applied to the land or placed on a surface disposal site for pH.

2-19 RECORDKEEPING REQUIREMENTS.

Recordkeeping requirements are covered in Part 503.17 for land application and Part 503.27 for surface disposal. Records are required for both sewage sludge and domestic septage. Retain all records for 5 years except when the cumulative pollutant loading rates in Part 503 Subpart B (Land Application) are used. In that case, keep certain records indefinitely. Some records must be reported to the permitting authority.

- Land Application: Keep records to confirm that the solids meet the applicable pollutant limits, management practices, one of the pathogen requirements, one of the vector attraction reduction requirements, and where applicable, the site restrictions associated with land application of Class B biosolids. When bulk solids are applied to land, both the person preparing the solids for land application and the person applying them must keep records. The person applying solids that are sold or given away does not have to keep records.
- Surface Disposal: When solids are placed on a surface disposal site, the owner of the surface disposal site must keep records. In the case of domestic septage applied to agricultural land, forest, or a reclamation site or placed on a surface disposal site, the person applying the domestic septage. The owner of the surface disposal site may be subject to pathogen-related recordkeeping requirements, depending on which vector attraction reduction option was used.

Certification Statement: In every case, recordkeeping involves signing a certification statement that the requirement has been met. Parts 503.17 and 503.37 of the regulation contain the required certification language.

CHAPTER 3 WASTEWATER TREATMENT

3-1 INTRODUCTION.

For an operator to understand a wastewater treatment plant, it is important to have an accurate characterization of the wastewater influent. The wastewater characterization provides the operator with information to control the wastewater treatment processes. There are typically two types of influent water: domestic and industrial. Domestic wastewater comes from residential units such as single-family households, condominiums, apartments, cottages, or resorts. Industrial wastewater comes from non-residential sources such as institutional, commercial, or industrial facilities.

3-2 MAINTENANCE.

The maintenance requirements for preliminary treatment varies, depending on the type of equipment used. Recommended maintenance should be completed by operators and maintenance staff to maintain all warranties and performance guarantees. Refer to the equipment manufacturers operation manual and operate preliminary treatment equipment in accordance with manufacturers recommendations and all NPDES permits.

3-3 WASTEWATER INFLUENT CHARACTERISTICS.

Nonresidential sources vary, depending on the type of establishment. There are differences in waste-generating sources present, water usage rates, and other considerations. The characteristics for existing nonresidential buildings are characterized by sampling and metering the discharge wastewater. For new nonresidential establishments, use available characterization data from similar facilities. Refer to EPA/625/R-00/008 for typical loadings and concentrations.

Higher than typical ammonia influent levels may occur at some WWTPs because of water conservation programs. Higher than normal influent ammonia levels will require operational adjustments and additional process control monitoring.

3-4 PRELIMINARY TREATMENT METHODS.

The preliminary treatment processes are intended to remove large solids and abrasive material from the influent wastewater prior to damaging equipment or clogging piping. The failure of any of these units will affect downstream processes in the wastewater treatment plant. Therefore, it is important to keep the preliminary treatment units working as effectively as possible.

Refer to *Operation of Wastewater Treatment Plants*, Volume 1, Chapter 4 for additional guidance on preliminary treatment.

3-4.1 Preliminary Screening.

The screening system at a wastewater treatment plant is a system that is either machine run or a completely manual operation. The purpose of the screening system is to remove material that can damage equipment and clog piping in the wastewater treatment plant.

1-1.1.1 Screening Operation.

Manual bar screens and mechanical bars screens both operate in a manner to remove large material. Both come with different spacing between the screen's bars. The smaller the spacing between the screen bars the more material that will be captured by the screen.

3-4.1.1.1 Manual Bar Screens.

Inspect the manual bar screen for spacing between bars, damage to the bars, and any loose fasteners. Manual bar screens are manually cleaned with a tool that allows the operator to pull the captured material off the bar screen.

3-4.1.1.2 Mechanical Screens.

Mechanical screens normally operate in a fully automatic mode. Some newer designs of mechanical screens function with the differential level as the primary means of starting the mechanical screen with the timer as a backup. Determine the correct differential level for the mechanical screen and timers to prevent surging flow through the mechanical screen and wastewater treatment plant.

3-4.1.2 Screening Maintenance.

The maintenance for manual bar screens and mechanical screens are widely different due to the simplicity of manual bar screens and the complexity of mechanical screens.

3-4.1.2.1 Manual Bar Screens.

The maintenance requirements for manual bars screens is limited to periodic inspections of the bar screen with the channel drained and cleaned.

3-4.2 Grit Removal.

Wastewater flow contains material of fine, discrete, non-biodegradable particles called grit. The sources of grit include sand, cinders, rocks, coffee grounds, and cigarette filter tips. The purpose of a grit system is to remove material that can damage equipment and clog piping in the wastewater treatment plant. If grit is not removed during preliminary treatment the grit will accumulate in the bottom of aeration tanks, digesters, and sludge holding tanks which reduces the usable volume in the tanks. Typical grit parameters can be found in WEF MOP11, Table 18.1.

In an aerated grit removal system, the amount of air can also be changed. These changes impact the amount of grit that is removed. If the air to the aerated grit chamber is decreased, the amount of grit captured will increase, but the amount of organics captured also will increase.

3-4.2.1 Grit System Operation.

Grit is removed during preliminary treatment manually or by mechanical equipment. Perform periodic inspections of the grit removal system and inspect for wear and damage.

3-4.2.1.1 Manual Grit Removal.

Manual grit removal is the simplest form of grit removal. The manual grit removal system consists of one or more tanks. Multiple tanks allow a decrease in stream velocity so that grit particles may be allowed to settle out.

3-4.2.1.2 Mechanical Grit Removal Systems.

A mechanical grit removal system is a grit tank that includes a mechanical scrapper or a chain-flight system that pushes the grit to a sump. The grit is removed from the sump by a grit elevator or grit pumps where it is cleaned by a grit washer or grit classifier.

Normal operation is for the mechanical scrapper or chain-flight equipment to be operating continuously. To prevent clogging the grit pump suction or damaging the grit elevator, the operator determines the amount of time that the grit elevator or grit pump runs. The operator inspects the grit collected daily for the amount collected and the effectiveness of the grit washing.

3-4.2.1.3 Aerated Grit Removal Systems.

Aerated grit removal systems consist of one or more tanks that use compressed air to remove organics from the grit as it settles to the bottom of the grit tank. At the bottom of the tank, a longitudinal screw moves the grit to a sump where a grit pump takes suction and pumps the grit slurry to a grit classifier or grit washer to be cleaned. The grit also can be removed by a grit elevator that lifts the grit slurry to a grit classifier or grit washer.

Operators monitor the flow to ensure that the aerated grit removal system does not exceed its designed detention time. Normal operation is for the aerated grit chamber to have the aeration blower continuously running. To prevent clogging the grit pump suction or damaging the grit elevator, the operator determines the amount of time the grit elevator or grit pump runs. The operator inspects the grit collected daily for the amount collected and the effectiveness of the grit washing.

3-4.2.1.4 Vortex Grit Removal Systems.

Vortex grit removal systems spin the wastewater in a chamber to force the grit to be forced to the outer walls of the grit chamber. The grit then slides to the center of the grit chamber where it is removed by a grit pump. The grit slurry is pumped to a grit classifier or grit washer where it is cleaned and dried.

The vortex grit removal system requires the centrifugal force from the spinning of the wastewater to remove the grit. All the vortex grit removal systems have a minimum and maximum flow for which the system is designed. Ensure that the minimum and maximum flows are not exceeded in multiple vortex grit removal tanks. Some vortex grit removal systems have a mixer in the center to help induce the spinning action of the wastewater in the vortex grit chamber. Run the mixer continuously to ensure the vortex grit removal system is operating correctly. To prevent clogging the grit pump suction, the operator determines the amount of time that the grit pump runs. The operator inspects the grit collected daily for the amount collected and the effectiveness of the grit washing.

3-5 PRIMARY TREATMENT.

Primary treatment removes settleable and non-settleable materials. Settleable solids are typically inorganic materials such as grit. Non-settleable materials such as organic materials. The volume of settleable solids collected during primary treatment is typically reduced by the proper operation of the preliminary treatment system. The solids that are removed in the primary treatment process can reduce the treatment in the biological process by 25 to 30%.

Refer to *Operation of Wastewater Treatment Plants*, Volume 1, Chapter 5 for additional guidance on primary treatment.

3-5.1 Operation.

When a primary treatment tank is in operation, a mechanical scraper or a chain-flight system pushes the primary sludge to a sump. The sludge is removed from the sump by a pump and is then pumped to either a thickening process or a digester. In some cases, the primary treatment tank also acts as a gravity thickener for the primary sludge. The floatable material (known as scum) is pushed to a collection point. The scum is then removed from the primary treatment tank via a scum trough where the scum flows to a collection point where it is pumped to be removed from the wastewater treatment plant. In some WWTP processes, the scum is pumped to the digester for processing.

3-5.1.1 Process Control.

The various processes in the wastewater treatment plant vary based on wastewater flow and the environment in which the treatment plant operates. Adjust the number of primary treatment tanks in service to optimum detention time. The optimum detention time is 6 hours. Typically, there is minimal benefit with longer detention times.

The operator determines the best time to pump sludge out of the primary treatment tank, prevent sludge from going septic and maintain the required sludge thickness as required by downstream processes such as digesters and thickening. If the wastewater treatment plant sends WAS to the primary treatment process (co-settles), operators must ensure that the primary treatment pumping is enough to prevent denitrification from occurring in the primary treatment tanks and causing the sludge blanket from being carried into the biological treatment process.

3-5.1.1.1 Mean Cell Retention Time and Sludge Retention Time.

Determine a method of controlling the amount of mixed liquor (WAS) removed from the activated sludge system based on daily operating temperatures. The two common methods are mean cell residence time (MCRT) and Solids Retention Time (SRT_a). MCRT and SRT_a are similar, except for how they are calculated.

MCRT can be as low as 4 days during warm weather periods, and keep nitrification, but without any buffer to counteract an upset such as a slightly low pH. Wastewater treatment plants operation may vary between 4 days in warm weather and 10 days or more in cold weather.

Equation 3-1. Mean Cell Retention Time

$$MCRT = \frac{MLSS_{Total} + TSS_{Clarifier}}{TSS_{WAS} + TSS_{eff}}$$

Where:
MCRT = mean cell residence time (days)
$MLSS_{Total}$ = total activated sludge tanks mixed liquor (lb)
TSS_{WAS} = wasted mixed liquor (lb)
$TSS_{Clarifier}$ = clarifier total suspended solids (lb)
TSS_{Eff} = clarifier effluent total suspended solids (lb)

Equation 3-2. Aerobic Solids Retention Time

$$SRT_a = \frac{MLSS_a}{TSS_{WAS} + TSS_{eff}}$$

Where:
SRT_a = aerobic solids retention time (days)
$MLSS_a$ = aeration tank mixed liquor (lb)
TSS_{WAS} = wasted mixed liquor (lb)
TSS_{Eff} = clarifier effluent total suspended solids (lb)

3-5.1.1.2 Food to Mass Ratio.

Another item to consider when determining MCRT or SRT_a is the food to mass ratio (F:M). This is the ratio of the amount of BOD_5 to the mass of microorganisms in the total activated sludge tanks.

Equation 3-3. Food to Mass Ratio

$$F/M = \frac{BOD_{PE}}{MLSS_{Total}}$$

Where:
F:M = food to mass ratio
BOD_{PE} *= BOD_5 in primary effluent (lb)*
$MLSS_{Total}$ *= total activated sludge tanks mixed liquor (lb)*

Refer to WEF MOP 11, Table 20.1 for typical range of F:M parameters. Individual wastewater treatment plants may operate outside of the ranges listed below. Reference the F:M ratio as a check to see if it is relatively consistent. Investigate the F:M ratio if there are changes. This can indicate that the amount of WAS is incorrect or that there are significant changes to the wastewater flow constituents.

3-5.1.1.3 Alkalinity Adjustment.

Operators can adjust for alkalinity if the raw wastewater does not contain enough. Alkalinity is not lost in any process of the wastewater treatment plant unless coagulants are used to remove phosphorus. Monitor and adjust the alkalinity feed to maintain enough alkalinity in the wastewater to ensure complete nitrification is possible and to maintain at least a 75-mg/L residual in the effluent unless there is a required limit in the wastewater treatment plant NPDES permit.

3-6 BIOLOGICAL TREATMENT.

Most wastewater treatment occurs through biological treatment. Biological treatment occurs by creating an environment in the wastewater treatment tanks that allows a targeted type of bacteria to thrive and treat a specific constituent in the wastewater prior to the treated water being released to the environment. Constituents that are normally removed in the wastewater are biochemical oxygen demand (BOD_5) and CBOD, ammonia, nitrate, and phosphorus.

Refer to *Operation of Wastewater Treatment Plants*, Volume 1, Chapters 6, 7, 8, 9, and 10; *Operation of Wastewater Treatment Plants*, Volume 2, Chapter 11; *Advanced Waste Treatment*, Chapter 2 for additional guidance on biological treatment.

3-6.1 Biological Treatment Methods.

There are multiple methods of containing the bacteria (microbiology) in a space to treat the wastewater. These methods include activated sludge that uses large tanks, trickling filter which the wastewater flows through a tank with media, rotating biological contactors (RBCs), in which wastewater flows through a tank that contains a big wheel that rotates in the tank, and natural biological treatment (such as a lagoon). In all cases, there are biological-chemical reactions that occur. The most common biological-chemical reactions are nitrification (the conversion of ammonia to nitrates by bacteria) and denitrification (the conversion of nitrates to nitrogen gas by bacteria). Refer to *Advanced Waste Treatment* for various constituent removal requirements.

3-7 ACTIVATED SLUDGE.

The activated sludge process is a process in which wastewater treatment plants have one or more tanks filled with the microbiology in suspension with water. The bacteria water mixture is known as mixed liquor suspended solids (MLSS) and flows through the tanks to a clarifier, where it settles at the bottom and thickens slightly. The settled solids are then collected and pumped back to the biological process tanks. After the settled solids are pumped and returned to the process, its name is changed to return activated sludge (RAS). A portion of the settled solids is removed from the process and thickened or dewatered for disposal. The portion of the settled solids that is removed is called waste activated sludge (WAS).

Some treatment plants use two or more tanks in which all the activated sludge is processed. These tanks are called sequencing batch reactors (SBRs). SBRs allow a portion of the wastewater flow to enter them and then run all the activated sludge process on the single tank while another tank is filling. When the process is complete, the SBR drains the supernatant (treated water) before filling again to repeat the process.

3-7.1 Activated Sludge Operation.

The operation of the activated sludge process is complex and requires the most monitoring and adjustment in the wastewater treatment process. Any changes that are made in the activated sludge system take long periods of time (days to weeks) to see the full effect of any changes due to the growth rates of the microbiology in the activated sludge process. Operators must make small changes to the activated sludge system and wait some amount of time prior to making another change to see the effects of the change before making another. The amount of time that the operator will wait depends on the change made and hydraulic, organic, and nutrient loading. Changes, such as dissolved oxygen (DO) levels, can be seen within 1 hour of the change, whereas a change to the amount of WAS removed can take weeks to see the full effect of the change.

Refer to *Advanced Waste Treatment*, Chapters 5 and 6 for additional guidance on phosphorus and nitrogen removal.

3-7.2 Activated Sludge Process Control.

Process control in the activated sludge process is done to maintain and maximize the treatment of the wastewater to remove the various constituents as efficiently as possible. The removal of BOD_5 and nitrogen from the wastewater are only accomplished by the microbiology, whereas the phosphorus can be removed by both the microbiology and chemicals. Water temperature is an important factor to monitor and adjust in the wastewater treatment plant. As temperature decreases, the biological activity of the mixed liquor also decreases. Inversely, as the temperature increases, so does the biological activity of the mixed liquor. Nitrifying bacteria are only active between 4 and 40 ˚C.

3-7.2.1 SBR Process Control.

Review the timers for the process to ensure that the treatment goals are met. There may be adjustments that operators can make to the timers to improve the process, but this may affect the amount of wastewater that the facility can treat per day.

3-7.2.2 Chlorination.

It may become necessary to chlorinate the activated sludge to control unwanted microorganisms, such as filamentous organisms, and for sludge bulking events. In general, the range of dosage is 2 to 3 mg/L of chlorine per 1,000 mg/L of mixed liquor volatile suspended solids (MLVSS) in the aeration tanks. In severe cases, dosages up to 8 to 10 mg/L of chlorine per 1,000 mg/L of MLVSS in the aeration tanks have been required to be effective in controlling the bulking. The result of chlorination is often a turbid effluent since the nitrifiers are particularly affected by the chlorination. It is common for the chlorination of the activated sludge to last several weeks. Complete a daily microscopic exam during chlorination. Once the filamentous growth begins to decrease, gradually reduce the amount of chlorine feed to reduce the toxicity to the nitrifiers and re-establish the effluent quality.

3-7.2.3 Return Activated Sludge Pump.

Run the RAS pump (pump out of the clarifier) to keep the sludge blanket (thickened mixed liquor) between 1 and 2 feet in thickness in the clarifiers. This allows the RAS to be a thicker concentration. If the WAS is removed from the RAS, it reduces the amount of polymer needed for sludge thickening and keeps the sludge blanket low enough to prevent a hydraulic surge from washing it out in the effluent. The normal flow rate of the RAS pump is between 40 and 60% of influent flow on conventional activated sludge systems and 100 to 150% on extended aeration systems.

3-8 AEROBIC AND ANAEROBIC ZONE TREATMENT.

Every activated sludge wastewater treatment plant has an aerobic tank DO above 1.0 milligrams per liter [mg/L] in which oxygen is introduced by a mechanical aerator or a blower pushing air through air diffusers at the bottom of the tank. To remove BOD_5 and convert ammonia to nitrate, the DO level must be between 1.0 and 2.0 mg/L to ensure that enough oxygen is being provided to allow for the complete oxidation of the ammonia and BOD_5. This tank or portion of the tank is known to be “aerobic.” The size, detention time, temperature, and sludge age are the key factors in determining if an aerobic zone will oxidize BOD_5 and nitrify ammonia. If the wastewater treatment plant is designed to remove nitrogen, the plant will contain a pump near the end of the aerobic tank to pump MLSS that contains nitrates to the anoxic zone, which is normally at the beginning of the activated sludge process. In the portion of the tank where nitrate is being converted to nitrogen gas, the DO level must be below 0.5 mg/L, with sufficient BOD_5 and alkalinity available to complete the conversion. This tank or portion of the tank is known to be “anoxic.” In some wastewater treatment plants, there may be two anoxic zones. The first is where a majority of the denitrification occurs, but the second, which is after the aerobic zone, is used to remove any remaining nitrates to get to low total nitrogen levels. It is common to have to feed a supplemental carbon source into the second anoxic zone. This carbon source can be methanol, a glycerin product, or another preparatory substance. Review and understand the amount of BOD_5 that is in the carbon source and dose it appropriately to remove the nitrates without exceeding the operating NPDES permit requirements for BOD_5.

In some wastewater treatment plants, there is a tank or portion of a tank that is “anaerobic.” Anaerobic means that there are no nitrates in the portion of the tank and that DO is very close to 0.0 mg/L. In treatment plants that have an anaerobic zone, the activated sludge has certain bacteria in it that release phosphorus in the anaerobic zone but absorb more than they release in the aerobic zone. This allows for biological removal of phosphorus from the wastewater.

3-8.1 Mixer Operation.

In both the anoxic and anaerobic zones of the biological process, there are mixers that must be in operation at times to keep the MLSS from settling to the bottom of the tank. The mixers also allow the MLSS to move throughout the water, encountering various constituents and thus improving the biological process efficiency.

3-8.2 Clarifier Operation.

The MLSS flows out of the biological tanks into a clarifier. The clarifier is a tank that includes a continuously running mechanical scraper or chain-flight system that pushes the settled solids to a sump. The settled solids are continuously removed from the sump by the RAS pumps and pumped back to the biological tanks. The clarifiers also collect any remaining scum from the surface of the water. Collect and disposed of to prevent it from flowing out of the clarifier and into the clarifier’s effluent where it may cause an Operating NPDES permit violation by interfering with the disinfection process or by changing a water characteristic above the allowable limits. In some WWTP processes, the scum is sent to the digester for processing.

Periodically remove some of the settled solids from the process as WAS. By removing some of the mixed liquor from the biological tanks, the operator can promote growth in the biological tanks and remove old and unhealthy microbiology and any non-organic materials from biological process.

3-8.3 Nitrogen Removal Process.

In the clarifiers and the aerobic portion of the biological tank, there are pumps (internal recycle) that are used to help in the nitrogen removal process. These pumps and the

RAS pump return nitrates to the anoxic zone to allow denitrification to occur. Run the internal recycle pumps the design portion of the influent wastewater flow. A total recycle flow for denitrification of around 400% of influent provides the most denitrification with the lowest energy usage. After 400% recycle flow, the amount of nitrogen removed is significantly reduced.

3-8.4 Trickling Filters and Rotating Biological Contactors.

Trickling filters and RBCs operate similarly to each other to treat the wastewater. Trickling filters spray the wastewater over the surface of the media where the biological mass grows to treat the wastewater, whereas the RBC rotates large wheels of media with the biological mass on it into the wastewater flow to treat the wastewater. In trickling filters, the media can be either natural (such as stone or coal) or plastic, whereas the RBC media are always plastic. After either a trickling filter or RBC, a clarifier is used to capture any of the biological mass that is removed from the media.

Refer to *Operation of Wastewater Treatment Plants*, Volume 1, Chapters 6 and 7 for additional guidance.

3-8.4.1 Operation.

Trickling filters and RBCs are relatively simple in their operation. Run the trickling filters and RBCs at their design hydraulic and organics loading. Failure to do so will overload the trickling filter or RBC and cause the biomass to be scoured off the media and possibly cause an NPDES permit violation. The clarifiers that follow both the trickling filters and RBCs must periodically have the sludge pumped out for disposal.

Trickling filters do not normally have any mechanical equipment to make the distribution arm move as this is accomplished by the force of the wastewater exiting the distribution arm on to the media. To improve performance, trickling filters may have aeration blowers that either blow air into the bottom of the media or draw air through the top to aid in providing oxygen to the biomass.

3-8.4.1.1 Rotating Biological Contactor.

RBCs must always have their drive shaft running to turn the media to provide treatment to the wastewater. RBCs may have additional aeration to increase the efficiency of the wastewater treatment process.

3-8.4.2 Process Control.

There is little process control in trickling filters. RBCs have some adjustments that can be made to improve the treatment of the wastewater. RBCs can have their zone sizes changed, or wastewater can be step fed into different zones, which can allow increased treatment of the wastewater. RBCs also may be able to increase the speed and/or direction of the drive shaft to allow more oxygen to be introduced into the zones for increased treatment. Additional aeration can be used to increase the treatment efficiency of the units. The aeration system provides additional oxygen to the biomass to treat the wastewater.

3-9 NATURAL BIOLOGICAL SYSTEMS.

Natural biological systems include ponds (also known as lagoons) and land application. In both situations, the constituents in the wastewater are removed by natural occurring bacteria and require little to no operator intervention to maintain the treatment process.

Refer to *Operation of Wastewater Treatment Plants*, Volume 1, Chapter 9 for additional guidance.

3-9.1 Pond Operation.

Ponds have many factors that can affect their operation. Refer to *Operation of Wastewater Treatment Plants*, Volume I for additional guidance.

3-9.1.1 Oxygen Introduction.

Ponds use algae to provide oxygen to the bacteria in the pond through photosynthesis. Along with the algae, wind and waves also introduce oxygen to the pond to promote the growth of bacteria to treat the wastewater. In every pond, there are locations with little DO. Do not try to aerate every portion of a natural pond.

In some ponds, there is a mechanical method of providing the air to the pond, thus, increasing the amount of DO to the pond. Operate the aeration equipment as long as possible to achieve the best treatment results.

3-9.1.2 Operating Level and Testing.

Keep ponds at the same operating level to ensure that the level of treatment is adequate throughout the year. The level must be high enough to ensure that vegetation will only grow on the edge of the pond, typically 3 feet (900 mm). When allowing wastewater into ponds, the amount of water released into each pond in operation must be equal to ensure that no single pond is overloaded. If the pond is designed to work in a batch operation, the pond must be allowed to discharge only when it has the highest quality effluent.

Test the pond for DO, pH, and temperature at least twice per week to determine if any action is needed to improve the pond’s effectiveness and comply with operating NPDES permit requirements.

3-9.2 Land Application.

Land application of wastewater is a simple method of treating the wastewater with little operator action. The amount of wastewater pumped on the land is determined by the soil properties. Ensure that the amount of wastewater pumped on to the land does not exceed the permitted amount, as this may cause contamination of the groundwater.

3-10 DISINFECTION.

Provide disinfection of the treated effluent from wastewater treatment facilities to reduce the risk of human exposure to pathogens into receiving water bodies. Human pathogens of greatest concern are bacteria, viruses, and parasites. The most prevalent methods of disinfection include ultraviolet and chlorine disinfection. Additional methods, such as peracetic acid (PAA) and ozone addition, are used less frequently but are also discussed.

Refer to *Operation of Wastewater Treatment Plants*, Volume 1, Chapter 10 for additional guidance.

3-10.1 Disinfection Operation.

The operation of the disinfection system is to either kill or inactivate pathogens while minimizing cost and protecting the environment. The ultraviolet and chlorine disinfection systems operate very differently to achieve the disinfection of the treated water.

Evaluate bulk chemical purchases and onsite storage chlorine disinfection and dechlorination products for "shelf-life degradation" for the proper onsite storage size to be selected. This will optimize the expected shelf life of these types of products.

Maintain an adequate amount of chemicals in the storage tanks to ensure that pump suctions remain flooded. Order the bulk storage tanks chemicals in time to ensure that the bulk tanks are not drained before the delivery occurs. The amount of advanced time depends on delivery lead time and includes additional time for a short delay in delivery. Determine the chemical usage rate such that at the end of the season there is little chemical left and/or test the chemical prior to use to determine the actual concentration if using the chemical during the next season.

3-10.2 Ultraviolet.

The use of ultraviolet (UV) light for disinfection arose from concerns over the storage, handling, and water quality impacts of traditional chlorine disinfection. Ultraviolet light is a form of invisible light radiation. The use of UV light on pathogens in the wastewater stream will inactivate them, making it impossible to replicate. The intensity of the UV radiation is measured at a wavelength of 253.7 nanometers. The flow, UV transmittance (UVT), and UV intensity are continuously monitored to ensure that the correct dose is achieved.

Monitor process control parameters to ensure the effectiveness of the UV light disinfection, include UVT, design dose, wastewater quality, age of the UV lamps, and iron concentration. The UVT, which is impacted by both suspended and dissolved matter, is measured by the percentage of UV light intensity not absorbed after passing through 1 centimeter (cm) of water column. The lower the UVT, the lower the intensity of the light reaching the pathogens, which will result in less effective disinfection. The presence of suspended solids can negatively impact UVT as the solids can bind with the pathogens and provide a barrier between them and the UV light. Run the UV system in automatic control. This will allow the UV system to adjust the number of UV lamps and their intensity to account for changes in the wastewater flow and the changing UVT of the treated wastewater. The equation to determine the UV dose is shown below.

Equation 3-4. UV Dose

$$\boldsymbol{UV_{dose} = (I_{UV}) \times t}$$

Where:
UV_{dose} = UV dose (millijoules/cm^2)
I_{UV} = UV intensity ((milliwatts)/*cm^2)*
t = time (seconds [sec])

3-10.2.1 Impact of Ferrous Salts and UV Lamp Age.

The use of ferrous salts in wastewater treatment may also impact the performance of UV disinfection. Ferrous salts, which are often used for enhanced coagulation and sedimentation, can absorb invisible UV light, lessoning the effectiveness of UV disinfection. The age of the UV lamp has an influence on the intensity of the UV radiation. Monitor lamp output to determine lamp age. Store an adequate supply of backup lamps the facility if an older lamp needs to be changed out or in the case of lamp breakage.

3-10.3 Chlorination.

In chlorine disinfection, a chlorine solution is fed into the wastewater stream at a known flow rate. The solution is then mixed thoroughly for a predetermined contact time. The mechanism of disinfection through chlorination is the oxidation of the cellular material. Chlorination compounds include chlorine gas, liquid hypochlorites, and chlorine dioxide, which is used less commonly in wastewater applications.

These reactions are both temperature and pH dependent. The hypochlorite solutions form a weak hypochlorous acid, which dissociates to form an equilibrium of hypochlorous acid and hypochlorite ion. When pH is above 8.5, the equilibrium approaches 100% dissociation, and when the pH is below 6.0, the solution approaches 100% HOCl. Between pH of 2.0 and 6.0, chlorine exists predominately at HOCl. Chlorine gas is predominate in pH below 2.0. At pH above 7.8, hypochlorite ions persist.

3-10.3.1 Chlorine Dosing Equipment.

Run the chlorine dosing and dechlorination equipment in automatic control based on a desired free chlorine residual in the chlorine contact basin. This will allow the controls system to adjust the chlorine feed to maintain the setpoint based on changes in flow and water quality. Check the chemical feed pump's actual stroke volume against the displayed setting for volumetric accuracy.

3-10.3.2 Process Controls.

Important process controls that play an important role in any chlorination method include detention or contact time, chlorine residual, oxidation reduction potential, indicator bacteria results, and handling of the chlorine containers or cylinders. The actual amount of chlorine present in each chlorine disinfection solution will vary. Bulk delivery sodium hypochlorite is typically commercially available in a solution containing 15 grams per liter (g/L) (15%) as available chlorine. As sodium hypochlorite ages, its solution strength goes down and will stabilize at around 5 g/L (5%). Factors that affect the speed at which sodium hypochlorite degrades are sunlight, temperature, and atmospheric pressure. Due to this degrading property of sodium hypochlorite, operators must check the strength of the solution to determine the correct feed rate.

In systems that use sodium hypochlorite or calcium hypochlorite, operators must rotate pumps regularly to ensure pump operation and to remove any chlorine gas that has degassed from solution. As part of the pump operation, run the pumps at various speeds to ensure that the pumps are not gas bound.

3-10.3.3 Chlorine Residual.

Chlorine residual is comprised of free, combined, and total chlorine. Free and total chlorine are often the two parameters that are monitored in the effluent line. Combined chlorine consists of both chloramines as well as other chloro-organic compounds that form by the reaction of chlorine with ammonia and organic compounds present in the effluent. A chlorine demand exists in all wastewater effluent. The chlorine demand is defined by the amount of chlorine that is consumed or converted to other less active forms of chlorine by matter present in the wastewater. Examples of substances in wastewater that may consume chlorine include ammonia compounds, organic materials, ferrous iron and some sulfur compounds. Free chlorine residual is what exists after the breakpoint has been achieved. The total chlorine residual includes both the combined and free chlorine present in the effluent, but always test chlorine concentration for process quality assurance.

3-10.3.4 Dechlorination.

The presence of chlorine in high enough concentrations can be toxic to fish and other aquatic life. Common chemicals used for dechlorination include sulfur dioxide (SO_2), sodium metabisulfite ($Na_2S_2O_5$), and sodium bisulfite ($NaHSO_3$). Proper dosage is critical to produce a non- detectable chlorine residual. On a mass basis, 0.9 parts sulfur dioxide (or 1.46 parts $NaHSO_3$ or 1.34 parts $Na_2S_2O_5$) is required to dechlorinate 1.0 part residual chlorine. In practice, approximately a one- to-one ratio is used.

Three of the most important parameters that must be monitored and controlled for adequate dechlorination to occur are mixing efficiency, chlorine residual, and contact time. Mixing allows the chlorine to get mixed thoroughly into the water column to disinfect the water prior to discharge, whereas the contract time is required to provide adequate time to allow the chlorine to disinfect the water.

3-10.4 Ozone.

Ozone can be used to disinfect the treated wastewater. Ozone disinfects by destruction of the cell wall, reaction of radical byproducts of ozone decomposition, and damage to the nucleic acids inside the cells, thus, preventing cell replication. Ozone is provided in concentrations of 1 to 4% using dry air and 3 to 10% using pure oxygen. Ozone is created on site. Ozone has the same operating requirements as chlorine in that it requires mixing into the water column and detention time.

Collect ozone samples to determine the ozone percentage sufficient to treat the wastewater effluent. To prevent equipment damage, inspect the ozone cooling water system to ensure that it is operating correctly.

3-10.5 Bromine Chloride and Chlorine Dioxide.

Bromine chloride and chlorine dioxide can also be used for disinfection as they perform the disinfection in the same methods as ozone. The bromine chloride is fed as a gas into the wastewater, whereas the chlorine dioxide is created on site and fed into the treated wastewater flow as a liquid. Bromine chloride and chlorine dioxide have the same operating requirements as chlorine in that they require mixing into the water column and detention time.

3-10.6 Peracetic Acid.

PAA is a liquid solution of acetic acid and hydrogen peroxide. PAA is normally between 12 and 15% solution strength and has a long shelf life; therefore, it does not change solution strength as quickly as sodium hypochlorite. PAA is normally dosed under 4 mg/L, which meets most bacteria effluent limits and has a residual of less than 1 mg/L, which is the EPA established limit.

This Page Intentionally Left Blank

CHAPTER 4 SOLIDS MANAGEMENT

4-1 INTRODUCTION.

The treatment of wastewater creates sludge. This sludge contains organic material, inorganic material, and various types of bacteria, which when mixed are called solids. All this material is usually treated at the same location as the wastewater treatment plant. To aid, in the storage, transportation, and method of disposal wastewater treatment plants thicken, reduce the amount, and dewater the solids prior to being removed from the wastewater treatment plant.

Refer to *Operation of Wastewater Treatment Plants*, Volume 2, Chapter 12 for additional guidance.

4-2 MAINTENANCE.

The maintenance requirements for solids treatment varies, depending on the type of equipment used. Recommended maintenance should be completed by operators and maintenance staff to maintain all warranties and performance guarantees. Refer to the equipment manufacturers operation manual and operate solids treatment equipment in accordance with manufacturers recommendations and all NPDES permits.

4-3 DIGESTER OPERATING CHARACTERISTICS.

Refer to WEF MOP 11, Table 30.7 for typical characteristics of an aerobic digester. The values represent operating parameters that will be monitored at the plant. They will be able to monitor trends and predict potential digester upsets.

4-4 SLUDGE VOLUME REDUCTION.

Sludge volume reduction is intended to remove water from waste solids or biosolids and is also known as thickening or dewatering. It is desirable to thicken/dewater the sludge to reduce the process volume and therefore the costs associated with pumping, equipment sizes, and disposal.

4-4.1 Operation.

There are multiple methods to reduce the sludge volume, including, gravity thickening, mechanical thickening, mechanical dewatering, and natural dewatering. The difference between thickening and dewatering is the amount of water that is removed from the sludge. Thickened sludge normally contains between 1 and 8% solids, whereas dewatered sludge normally contains between 15 and 30% solids. Due to the variation in the different systems components and operations, operators must refer to the vendor equipment manual for proper operation of their system.

4-4.1.1 Gravity Thickening.

Sedimentation is the driving force for gravity thickeners through the acceleration of gravity. Gravity thickeners are typically circular but may also be rectangular. Depending on the solid being thickened, the nature of the flocculent and concentration of the solid will vary.

The rake or scraper mechanism is used to deposit the thickened sludge to the underflow. The drag is created between the thickened sludge and the rakes to generate a load on the raker drive. If this load becomes too high, an alarm notifies the operator of an overload caused by the sludge being too thick or a jam in the rake. The underflow rate is then increased to mitigate the problem, although this reduces the cake blanket.

4-4.1.1.1 Sludge Septicity.

A common potential problem with gravity thickeners is the sludge septicity. This is a problem if the sludge is floating, solids are being carried to the overflow, and/or there are foul odors and reduced sludge outflow concentrations. Sludge septicity is caused from storing the sludge too long in the thickener, either because the thickened sludge pumping rate is too low or the thickener overflow is too low. Depending on the cause of the problem, increase the pumping rate, increase the influent flow to the thickener, or incorporate dissolved oxygen via aeration. The addition of chlorine or hydrogen peroxide can temporarily solve septicity.

4-4.1.1.2 Sludge Pumping Rate.

Determine and monitor the pumping rate of the thickened sludge. If the wastewater treatment plant pumps WAS to the primary clarifiers and/or to the gravity thickeners, increase the amount of pumping to prevent the sludge from denitrifying in the gravity thickener or allowing it to stay in the gravity thickener so long as to allow for microorganisms to release phosphorus into the supernatant. If the sludge denitrifies in the gravity thickener, the nitrogen bubbles can cause the sludge blanket to rise to the surface and be washed out with the supernatant, which will cause an increased organic loading to the biological treatment system. If the sludge is allowed to settle in the gravity thickener and phosphorus is released, this can cause an increase phosphorus loading on the biological system and/or increase the amount of chemical usage to precipitate the phosphorus in the wastewater treatment plant. If either of these occur, it is possible the operating NPDES permit may be violated.

4-4.1.2 Mechanical Thickening.

Mechanical thickening systems include dissolved air flotation, gravity belt, centrifuge, and rotary drum thickening. These thickening methods require two or more pieces of equipment to accomplish the thickening process.

4-4.1.2.1 Dissolved Air Flotation Thickening.

Dissolved air flotation (DAF) thickeners are comprised of a flotation unit and a saturator. The flotation unit is utilized to divide the solid phase from the liquid phase and the saturator dissolves air into the compressed water. A reducing valve allows the pressure-saturated water to flow into the flotation unit and become supersaturated with the air. The wastewater feed is introduced downstream of the reducing valve. Small bubbles from the saturated feed are formed and attached to the wastewater particles, forming bubble-particle agglomerates. Then, mixing occurs to make sure chemical dispersion occurs. The buoyancy in the flotation unit causes the agglomerates to float and accumulate at the water level. The solids are removed by scrapping, and the solids concentration is increased from draining the interstitial water from the float.

Typically, DAF units are operated continuously but may be operated with short shutdown periods or only during certain hours of the day. When the units are not running continuously, a feed sludge holding and mixing tank can be utilized. Minimize the entrance velocity to the flotation unit to avoid shearing of flocculated sludge particles. The float skimmers are placed above the water level and the speed is set to maximize the solids concentration. Set the controlling pressure at the lowest value that allows optimal operation but not below 50 pounds per square inch (psi). There are three typical parameters that are monitored for DAF units: solids and hydraulic loading rates, air-to-solids ratio, and air volume and pressure.

- The solids loading rate is the weight of solids added (including recycle flow) to the unit divided by the flotation surface area. The efficiency of the DAF will decrease if the solids loading rate is exceeded. The typical values for WAS conditioned with polymer is 2 to 4 lb/square foot (ft^2) per hour (h). The hydraulic loading rate is the solids feed rate and recirculation rate divided by the flotation surface area. The rise rate, subnatant solids concentration, and overall efficiency are affected by the hydraulic loading rate. The peak hydraulic loading rate of WAS using polymer is 2.5 gallons per minute (gpm)/ft^2.
- The air-to-solids ratio is the mass of air divided by the mass of solids added to the DAF. As the air-to-solids rate increases, the float concentration increases. The typical range of air-to-solids ratio is 0.02 to 0.04 lb/lb.
- The air pressure in the DAF unit determines the size of air bubbles. The air pressure is an indicator of whether the DAF has good “float.” If the pressure is increased, the rise rate of solids decreases. An air flotation test can be conducted to monitor conditions in the DAF such as recycle rate, solids loading rate, air pressure and others.

4-4.1.2.2 Gravity Belt Thickeners.

Gravity belt thickeners take conditioned sludge and release additional water, utilizing gravity drainage on a porous belt that is typically horizontal. To separate the solids from the free water, chemical conditioning occurs, often by injecting the chemical through an injection ring into the sludge. The sludge is then collected in a retention tank where the velocity is reduced to allow solids to float to the top and flow by gravity to the moving belt. As the sludge moves along the belt, plows are used to turn over the solids and allow filtrate to drain. The sludge accumulates at the end of the belt before discharging to a dam or adjustable ramp, allowing further water removal. The belt is cleaned by a scrapper and high-pressure wash water spray system.

Many factors affect the functioning of the gravity belt thickeners. The proper polymer needs to be selected to achieve optimal thickening. The recommended solution range for polymers to condition sludge is 0.05 to 2% by weight for dry polymers, 0.1 to 0.5% by volume for emulsion/dispersion polymers, and 1 to 3% by volume for mannich polymers. If the concentration of polymer is above this range, it could cause the polymer to not mix properly and deteriorate the thickening process. Sludge that settles more easily (higher percent solids) will require less polymer. Only inject the minimum amount of polymer required to thicken the sludge because the extra will go out the drain. The retention time is the amount of time required for the polymer to react with the sludge and flocculate. The ideal retention time is ideally 15 to 20 seconds. If too much time is allowed, the flocs will be too large, and with a short time, the flocs will be too small. The belt speed can be adjusted to go slower or faster and adjusted in the field to reach the optimal speed. When the belt is traveling slower, there is more time for the cake to dry. When the belt is traveling faster, there is a larger amount of throughput or a quicker process time.

4-4.1.2.3 Centrifuge Thickening.

Centrifuges can thicken and dewater sludge through the same piece of equipment by only changing the weir setting. The solids are separated from the liquid through sedimentation because of the differences in density. The centrifuge generates thousands of times the acceleration of gravity through centrifugal force to separate the solids even further.

Centrifuges rely on constant feed to quality. This can be achieved by taking centrifuges on or offline as the production increases or decreases. Typical problems occur from varying primary and secondary sludge concentrations or septic feed. Centrifuges are designed for flow conditions of 25 to 1,500 gpm. The bowl speed is set by the manufacturer and rarely changed. The speed can be adjusted to determine if the set speed is operating optimally.

4-4.1.2.4 Rotary Drum Thickening.

Rotary drum thickening consists of drums of varying sizes with wedge wires, perforated holes, stainless steel fabric, or a combination of stainless steel and synthetic fabric to obtain the solids. The drum is rotated at 5 to 20 revolutions per minute by a variable-speed drive unit. Sludge enters the drum, and the water is drained through openings in the drum to an underdrain. The sludge is transported through the drum by a continuous internal screw or diverted angle to a discharge chute. The drum is periodically cleaned by wash water to ensure the high solids capture and dewatering efficiency.

Four process variables are utilized for effective thickening: sludge feed rate, polymer feed rate, pond depth, and drum speed. The pond depth is controlled by the angle of the drum, which can be adjusted to up to 6˚ from the horizontal. A typical starting range is between 2 to 3˚. If the incline increased, the solids are dryer but the capacity of the drum decreases. If the incline is decreased, the capacity increases but the solids are wetter.

4-4.1.3 Mechanical Dewatering.

Mechanical dewatering includes belt filter presses, centrifuges, and vacuum and pressure filters.

These processes may require polymer to enhance the dewatering of the solids from the liquid. The polymer dosage determines the amount of polymer needed per amount of feed solids. The polymer dosage equation is below.

Equation 4-1. Polymer Dosing

$$Dose_{polymer} = \frac{C_{polymer}}{C_{feed}} \times \frac{Q_{polymer}}{Q_{feed}} \times 2000\frac{lb}{ton}$$

Where:
$Dose_{polymer}$ = polymer dose (lb/ton)
$C_{polymer}$= polymer concentration (%)
C_{feed} = sludge feed solids concentration (%)
$Q_{polymer}$ = polymer feed rate (gpm)
Q_{feed} = sludge feed rate (gpm)

1-1.1.1.1 Belt Filter Press.

The operation of a belt filter press occurs in three zones: the gravity drainage zone, low-pressure zone, and high-pressure zone. The gravity drainage zone is where the sludge is thickened from the water draining out through movement on a porous belt. Then, low-pressure is applied to the feed to remove more water and create a biosolids matrix. This matrix is then passed through decreasing rollers to create a high-pressure zone to further filter the water.

The capture rate for the belt filter press must be 95% or higher and is therefore not a parameter that can be changed. Cake dryness, loading, and polymer dosage directly affect each other, and changing one variable affects the performance of the other. For example, if dryer cake is desired, the polymer dosage rate is increased, or the loading rate is decreased. Most belt filter presses have an inline mixing system to inject the polymer. The amount of polymer and intensity of mixing is adjusted based on the sludge and polymer being used.

4-4.1.3.2 Centrifuge Dewatering.

A dewatering centrifuge works like a thickening centrifuge. The capture rate for the centrifuges must be 95% or higher and is therefore not a parameter that can be changed. Cake dryness, loading, and polymer dosage directly affect each other, and changing one variable affects the performance of the other. For example, if dryer cake is desired, the polymer dosage rate is increased, or the loading rate is decreased. Centrifuges prefer warmer temperatures of up to 60 ˚F to operate most efficiently. The hydraulic loading rate is not as limited for centrifuges compared to filtration devices because thinner feed sludge does not impact the performance as much. The solids loading with more biosolids will have a lower residence time and wetter solids. The conveyor torque and speed, the bowl speed, the weir setting, and the polymer addition are additional mechanical variables that affect the operation. The conveyor differential speed is adjusted to control the cake removal rate. Decreasing the speed causes the cake to become dryer because the sludge blanket in the centrifuge builds up. Increasing the speed causes a lower height of the sludge blanket and increases the biosolids removal. The conveyor torque increases as the cake becomes drier because the viscosity increases. The speed is controlled automatically and keeps a constant torque value. The bowl speed is directly related to the process performance with an increase in speed equal to an increase in process performance. However, centrifuges are typically operated at lower speeds to avoid excessive wear, vibration, and noise. Evaluate the weir setting every 2 years to determine if it is still at the optimal setting.

4-4.1.3.3 Vacuum and Pressure Filters.

Vacuum and pressure filters utilize inorganic chemical conditioning with, most commonly, lime and ferric chloride. These chemicals are used to increase the ability to filter the sludge and remove the sludge from the filter media. Lime has a larger range of effective dosage than polymers. The solids capture rate is ideally 99% for a conventional filter press. The feed pressure falls between one of the two ranges: 95 to 130 psi or 200 to 250 psi. The filter media varies, depending on the application. Typically for dewatering organic biosolids, polypropylene filaments are used with 2.3 to 3.4 cubic meters (m^3)/min porosity. Refer to Appendix A for the typical conditioning doses of ferric chloride and lime.

The filter press needs to be checked periodically prior to initiation of the automatic filter cycle. Once sufficient feed stock has accumulated and the chemical solution is prepared, a high feed rate is initially required to completely fill in the press in a short time until the system reaches 55 psi. Then, only a small high-pressure pump is used to continue feeding to a maximum pressure of 95 to 130 psi. The cycle stops once a set cake concentration is obtained.

4-4.1.4 Natural Dewatering.

Natural dewatering occurs through air-drying by natural evaporation or induced drainage. Typically, anaerobic or aerobic digestions are utilized to stabilize the biosolids prior to air-drying. Air-drying may be more energy-efficient, and the systems are less complex compared to mechanical dewatering. Although, they can require a large amount of land and more labor to remove the cake. The natural systems are most common for small and rural treatment facilities where there is warm weather. There are multiple types of beds, including, reed beds, sand beds, vacuum-assisted beds, wedge-wire beds, and paved beds. They all have similar process variables such as being affected by the weather, chemical conditioning, feed solids, system design, and residence time. Since all depend on the weather, backup storage or treatment needs to be provided during low production. Multiple beds are required because cleaning requires the beds to be taken out of service.

4-5 SLUDGE DIGESTION.

Sludge digestion is a biological process intended to decompose organic solids into stable substances to reduce the amount of sludge and decrease the number of disease-causing microorganisms. Digester failure can make it harder to dewater the digested sludge and cause the plant to not meet sludge disposal requirements. Therefore, it is important to keep the sludge digestion processes functioning as effectively as possible.

4-5.1 Sludge Digestion Operations.

Sludge digestion at a wastewater treatment plant occurs by aerobic or anaerobic digestion. Both require a source of elemental oxygen, but anaerobic digesters prevent gaseous oxygen from entering the system.

4-5.1.1 Aerobic Digestion.

For effective operation, uniformity and consistency of the incoming sludge is important; otherwise, the digester performance may be inhibited and lead to foaming. It is ideal to feed the digester continuously, 24 hours per day, but if this is not possible, develop a consistent feeding plan.

4-5.1.1.1 Short Circuiting.

To prevent short circuiting, the withdrawal of solids occurs immediately after feeding raw sludge. Solids are withdrawn concurrently with the inflow if there is a surface overflow. At least once per day, withdraw solids from the digester to avoid a drop in the active microorganism population.

4-5.1.1.2 Mixing System.

Scum can accumulate on the digester liquid surface if the mixing system is not properly operating. A properly designed and operated mixing system keeps the scum mixed with the digester contents.

4-5.1.1.3 Addition of Oxygen.

Add oxygen to the digester while feeding and mixing the aerobic digester to promote the digestion process of the sludge. Target DO in the digester to a range of 0.3 to 3.0 mg/L.

The digestion process lowers the vector attraction of pathogens. EPA requires a 1.5 mg/L/g standard oxygen uptake rate at 20 ˚C for adequate vector reduction in vector attraction.

4-5.1.1.4 Temperature Requirements.

Aerobic digesters require warm weather to complete the digestion process. Normally, aerobic digesters are not provided heat from any other source other than the environment. If the digester temperature drops below 10 ˚C, digestion will not occur.

4-5.1.2 Anaerobic Digestion.

Anaerobic digestion works to stabilize organic material through a multistage biochemical process. The anaerobic digestion process requires mixing, heating, removing sludge, and feeding raw sludge. Proper mixing of the sludge will create the optimal environmental conditions. The mixing system typically runs continuously.

4-5.1.2.1 Digester Mixing.

There are two types of mixing systems: unmixed digestion and mixed digestion. In unmixed digesters, there is a top layer of scum on the liquid surface and bottom layer of stabilized biosolids and grit with a small area for mixing in between. Unmixed digestion is used for low-rate and standard-rate digesters at small facilities less than 1 mgd.

In mixed digestion, high rate digestion and higher loading rates are achieved by controlled mixing and heating, uniform feed rates, and thickening of digester feed. There are two common types of mixed digestion: mechanical and gas mixing systems. Mechanical mixing includes pumped and impeller-type mixing. Pumped mixing systems have pumps installed outside of the tank, and the mixing nozzles are installed inside the tank to create a flow pattern for complete mixing. Impeller mixing consists of a draft tube containing the impeller with a discharge nozzle into the tank at an angle to cause mixing of the sludge. An impeller, a drive shaft, and a drive are provided with the mixing systems. Most often, the drive shaft is reversible to allow for clearing blockages. Gas mixing systems consist of bottom diffusers, lances, bubble guns, and gas lifters. The central component is the compressor where the moisture and sediment from the gas needs to be removed upstream of the compressor. Flow-balancing manifolds may be required to evenly partition the flow to mixer inside the digester. To prevent a vacuum from being created in the digester when there is low pressure, monitor the pressure with a low-pressure regulator. When the compressor discharge surpasses a set level, the high-pressure regulating valves bypass gas to the suction of the compressor or to storage.

4-5.1.2.2 Digester Feeding.

It is ideal for digesters to be fed continuously 24 hours per day. If this is not possible, keep the feeding schedule continuous and uniform. Feed the digesters a mixture of feeds, such as waste activated sludge and primary sludge. To prevent short circuiting, the withdrawal of solids occurs immediately after feeding raw sludge. Solids are withdrawn concurrently with the inflow if there is a surface overflow. At least once per day, withdraw solids from the digester to avoid a drop in the active microorganism population.

4-5.1.2.3 Digester Covers.

Digester covers, specifically fixed covers, need to be monitored. When sludge is fed or withdrawn, and the tank is full, the inflow and outflow must be equal, or the tank could overpressure and push the cover from its mountings. If sludge is withdrawn without adding more sludge, a vacuum can be created. These obstacles can be prevented by installing safety relief valves, which often develop gas leaks.

4-5.1.2.4 Secondary Digesters.

Secondary digesters are typically utilized at medium and large wastewater plants. The primary digester is used to optimize digestion and is where most of the gas production occurs. The secondary digester may or may not be mixed and/or heated. It may be designed to be mixed and heated when the primary digester is out of service. Secondary digesters without heating can be used as a storage tank, standby primary tank, and a source of seed sludge. For storage vessels, floating or membrane covers work best because they allow for drawdown without creating a vacuum under the cover, which can damage the digester cover and tank walls.

4-5.1.2.5 Digestion Temperature Ranges.

Most anaerobic digestion occurs in mesophilic conditions (32 to 38 ˚C). The biochemical process occurs in one tank and typically as a high-rate process because it is more stable and has a shorter detention time. Volatile solids are reduced by 40% to 60% in the digester to create stable conditions.

Thermophilic digestion is operated at thermophilic temperatures (55 ˚C or higher) and conducted in one or more stages. The goal of thermophilic digestion is to reach greater pathogen destruction, which causes higher volatile solids destruction and lowers retention times. More energy is required compared to mesophilic digestion; therefore, it is important to utilize heat recovery techniques.

4-5.1.2.6 Volatile Solids Reduction.

The following equation can be used to calculation the volatile solids reduction based on the volatile solids in the feed and digester discharge:

Equation 4-2. Volatile Solids Reduction

$$\boldsymbol{VSR, percent = \left(\frac{VS_{feed} - VS_{digested\ sludge}}{VS_{feed}}\right) \times 100}$$

Where:
VSR = volatile solids reduction (%)
VS_{feed} = volatile solids in feed sludge (lb)

$VS_{digested\ sludge}$ = volatile solids in digested sludge (lb)

If the digesters do not have significant grit accumulation, the Van Kleeck equation may be used to calculate volatile solids reduction.

Equation 4-3. Van Kleeck

$$\boldsymbol{VSR, percent = \left(\frac{VS_{feed} - VS_{digested\ sludge}}{VS_{feed} - (VS_{feed} \times VS_{digested\ sludge})}\right) \times 100}$$

Where:
VSR = volatile solids reduction (%)
VS_{feed} = volatile solids in feed sludge (lb)
$VS_{digested\ sludge}$ = volatile solids in digested sludge (lb)

4-5.1.2.7 Digester Gas.

The gas from digesters can be utilized as it contains methane. The digester gas can be used by a boiler that is designed to use the digester gas after it has been conditioned (hydrogen sulfide removed) or on unconditioned digester gas. Digester gas can be used to create power through a turbine, but the gas must be conditioned to ensure that all impurities are removed from the digester gas to prevent damage to the turbines. The digester gas can also be directly burned to the atmosphere through a flare. In general, digester gas systems will always have a flare to ensure that the digester gas is properly disposed of, and it may have one or more other components to transform the digester gas into a useful energy source.

Note: For the Army, AR 420-1 provides further guidance on boiler operations.

Note: For the Air Force, **\1** AFMAN **/1/** 32-1068 provides further guidance on boiler personnel schedule requirements.

4-6 OTHER SLUDGE STABILIZATION METHODS.

In addition to anaerobic and aerobic digestion, there are other conventional ways to stabilize sludge such as composting, lime stabilization, thermal treatment, heat drying, and incineration. These methods are commonly used to reach Class A or Class B levels for beneficial reuse and disposal. These methods are critical to reduce odors or nuisances, reduce level of pathogens, and facilitate efficient disposal or reuse of the product.

4-6.1 Composting.

The most common use of composting is to stabilize raw sludge. Composting is also commonly used to further stabilize digested sludge. For compositing to work, the initial solids content must be between 40 and 50% solids. To obtain this solids level and to raise the carbon to nitrogen ratio, a bulking agent is normally added. The desired carbon to nitrogen ratio is between 26:1 and 31:1. Composting heats the compost pile to 50 to 70 ˚C to destroy most pathogenic organisms.

In a windrow system, the compost piles are turned over daily to aerate the compost pile. This occurs for at least 3 weeks, which must include 3 days at 55 ˚C after which the windrow is then considered ready for use as compost. In systems that the windrow is not turned over, a blower either pulls or pushes air through the windrow to provide oxygen to the interior portion of the windrow.

4-6.2 Lime Stabilization.

Lime stabilization is the process of adding lime to sludge to a pH of 12.0 or more for at least 2 hours. Lime stabilization destroys or inhibits pathogens and microorganisms in the sludge. Lime stabilization can occur on raw primary sludge, WAS, and anaerobically digested sludge. The lime can be added to the sludges either before or after dewatering, although before dewatering is more typical of lime addition. When shutting down the lime system, empty all lime to prevent issues during startup.

In addition to monitoring the pH, the operator must take biological samples every quarter or as required by the operating NPDES permit. Include the organisms as required on the operating NPDES permit for the samples. If none are stated, use indicator organisms, such as fecal coliforms and fecal streptococci.

4-6.3 Thermal Stabilization.

Thermal stabilization kills the microorganisms by breaking apart the cells and releasing the water inside of the cell. Thermal treatment uses heat and steam to raise the temperature and pressure of the sludge.

Note: For the Army, AR 420-1 provides further guidance on thermal processes for sludge.

4-6.4 Sludge Drying.

Sludge drying is used to reduce the volume of sludge being hauled and reduces the number of pathogenic organisms. The sludge is dried by exposing it to hot gases from a furnace. Variables that affect the sludge drying process are:

- Percent solids in the feed sludge
- Ratio of wet sludge to dry sludge
- System operating temperature
- Amount of hot gases that can be used for drying

Note: For the Army, AR 420-1 provides further guidance on thermal processes for sludge.

This Page Intentionally Left Blank

CHAPTER 5 CHEMICAL TREATMENT

5-1 INTRODUCTION.

Various chemicals are used at wastewater treatment plants. Chemicals range from sodium hypochlorite which is used for disinfection of the treated wastewater, to polymers, which are used for solids capture in a clarifier or for solids capture on a thickening or dewatering machine. Chemicals can come in gas form (such as chlorine), liquid form (such as sodium hydroxide), or solid form (such as soda ash). Operators must review their facility's O&M manual and the various equipment manuals to fully understand what each chemical is and how it is used at their wastewater treatment plant. Operators must also maintain and review the safety data sheet for each chemical used on site. The safety data sheet provides health and safety requirements for the specific chemical along with the chemical's physical properties and actions to complete if a spill occurs.

Degrees Baumé is used in the chemical industry to measure density of various liquids when ordering onsite chemicals. The Baumé scale is a pair of hydrometer scales with one for liquids with densities heavier than water and one for liquids with densities lighter than water. If the degrees Baumé of a chemical is known, the specific gravity can be calculated. Then, the specific gravity of the chemical can be used to find the actual chemical concentration.

5-2 MAINTENANCE.

The maintenance requirements for chemical treatment varies, depending on the type of chemicals and equipment used. Recommended maintenance should be completed by operators and maintenance staff to maintain all warranties and performance guarantees. Refer to the equipment manufacturers operation manual and operate solids treatment equipment in accordance with manufacturers recommendations and all NPDES permits.

5-3 OPERATIONAL REQUIREMENTS.

Store chemicals in accordance with UFC 3-600-01 and applicable National Fire Protection Association codes and standards. The operation of each chemical system is specific to the individual wastewater treatment plant. At some plants, a chemical, such as a polymer, can be delivered in a liquid ready for use, whereas at larger wastewater treatment plants, the polymer can be delivered in a dry powder, which requires the polymer to be added to water and mixed prior to use. Operators must review their facility's O&M manual and the various equipment manuals to understand how each piece of equipment works to add the chemical to the wastewater treatment process. Several industrial associations, including The Chlorine Institute, The National Lime Association, and The American Chemistry Council provide guidance for operators that can be used for the storage and use of the chemicals.

When loading bulk chemicals, follow the requirements in the spill control plan and applicable standard operating procedures to prevent spills and addition of the chemicals to the wrong chemical storage tank. Use the chemical usage rate and storage volume to determine the amount of the chemical remaining in storage and to see if there is any possible indication of a leak. Report any indications of leaks to the Installation Environmental Program staff. The chemical may be tested prior to use to determine the actual concentration. Chemical that has been stored for use during the next season should be tested to confirm chemical concentrations.

5-3.1 pH Adjustment.

Normally, at wastewater treatment plants, pH is not in need of adjustment for the biological process to occur. The high and low pH chemicals are used for cleaning items such as membranes, UV lamps, and for adjusting pH for chemical odor control systems. The common bulk pH-adjusting chemicals used at wastewater plants are citric acid and sodium hydroxide (caustic soda).

Citric acid can be delivered in either dry or liquid form. Normally, when citric acid is delivered in dry form, it is for small batches where the operator adds the dry acid to a tank to achieve a desired pH. Liquid citric acid is used to create large batch of low pH cleaning solutions. Sodium hydroxide is always delivered as liquid, but it can vary in solution strength of either 25 or 50%.

5-3.2 Indoor Chemical Storage.

Chemical storage rooms may have Heating, Ventilation, and Air Conditioning (HVAC) systems installed. Operators must ensure that all HVAC equipment is operating, to maintain a safe environment and preserve chemical quality. HVAC equipment may maintain temperature, humidity, and ventilation requirements for the chemicals being stored. HVAC systems can also be used to limit the amount of corrosion caused by the chemical vapors in the chemical storage room.

5-3.3 Outdoor Chemical Storage.

Outdoor chemical storage tanks may have tank heaters that are used to prevent freezing. Operators should inspect chemical storage heaters to ensure they are operating during cold weather to maintain the bulk chemical quality and prevent the chemicals from freezing in the storage tank.

Freezing of chemicals can damage equipment and piping, causing chemical leaks. A chemical of specific concern is a solution of 50% sodium hydroxide. The 50% sodium hydroxide solution will freeze at 59 ˚F (15 ˚C).

5-3.4 Cleaning Considerations.

After cleaning with an acid, do not add the low pH cleaning byproduct directly to the biological process as it will have a significant effect on the biological process. Neutralize the acid with a base (to a pH of around 7.0) or dilute the acid with water prior to disposing of it through the wastewater treatment plant. If neither option is possible, add the acidic solution to the wastewater flow slowly, taking long periods of time to add it, thus allowing the influent wastewater flow to dilute it prior to entering the biological process.

5-3.5 Alkalinity Adjustment.

Alkalinity adjustment is typical at wastewater treatment plants. The alkalinity is normally increased in the wastewater to support the nitrification of ammonia in the wastewater. Additionally, alkalinity may need to be adjusted to support the use of chemicals for phosphorus removal.

Alkalinity addition chemicals can come in liquid and dry powder form. The two liquid chemicals used are 50% sodium hydroxide and 62% magnesium hydroxide. Chemicals in solid form are typically dissolved in water to make a slurry. The slurry can then be pumped into the wastewater flow to increase its alkalinity. Lime and soda ash are the two most common chemicals.

5-3.5.1 Chemicals Used for Alkalinity.

Each chemical has specific operating procedures that operators must ensure are correct. The 50% sodium hydroxide solution must remain above 15 ˚C to prevent the chemical from freezing, which will damage equipment and piping. The location where the sodium hydroxide is stored must have its heating system checked regularly. If a tank heater and heat tracing are used on the piping, they must be checked for proper operation. Adjust the carrier water (motive water) to reduce the sodium hydroxide concentration in the carrier piping and to ensure that water velocity is fast enough to minimize the possibility of freezing.

Mix magnesium hydroxide and both soda ash and lime slurries. Magnesium hydroxide must remain constantly mixed to prevent the chemical pump suction from becoming clogged. Soda ash and lime must be mixed into the water to become a slurry.

5-3.6 Coagulants and Phosphorus Removal.

To remove phosphorus by chemical precipitation, various chemicals can be used. These chemicals can also be used to coagulate the suspended solids in the wastewater to increase the clarity of the water. The addition of these chemicals will increase the amount of sludge that is created at the wastewater treatment plant. The common chemicals that are used for phosphorus removal are aluminum and ferric salts.

Refer to *Advanced Waste Treatment*, Chapter 5 for additional guidance on phosphorus removal.

5-3.7 Aluminum Salts.

The aluminum salts come from three chemicals: aluminum sulfide (known as alum), aluminum chloride, and sodium aluminate. Sodium aluminate is the only aluminum salt that comes in a solid and must be dissolved on site. Alum consumes about 0.55 mg/L of alkalinity per every 1.0 mg/L of solution added, whereas aluminum chloride and sodium aluminate do not affect the water alkalinity. The theoretical amount of aluminum needed to remove phosphorus is 2:1 as a molar ratio. Below is the general equation for aluminum reaction to remove phosphorus.

Equation 5-1. Aluminum Phosphorus Removal

$$Al^{+3} + H_nPO_{-4}^{n+3} \leftrightarrow AlPO_4 + nH^+$$

5-3.8 Iron Salts.

The most common iron salt is ferric chloride (known as ferric), which is normally in a liquid form. Other ferrous salts can be used, but they require a pH higher than 8.5 or must be combined with chlorine to change the ferrous iron to ferric iron. Ferric consumes 0.93 mg/L of alkalinity per 1.0 mg/L of ferric added. The theoretical amount of iron ranges from 15 up to 30 mg/L (45 to 90 mg/L of ferric chloride) for every 1 mole of phosphorus. Below is the general equation for ferric reaction to remove phosphorus.

Equation 5-2. Ferric Phosphorus Removal

$$Fe^{+3} + H_nPO_{-4}^{n+3} \leftrightarrow FePO_4 + nH^+$$

On all the coagulants, they start to crystalize at 0 ˚C. Operators must check tank heaters and heat tracing on all the coagulant chemical system to ensure that no equipment damage occurs.

5-3.9 Polymers.

Polymers come in liquid and dry form. They are used for thickening and dewatering sludge but can be used to improve solids capture in a clarifier. Polymers range from cation (positive charge) to non-charge (neutral) and to anionic (negative charge). Some manufacturers also produce polymers that contain both cation and anion in the polymer. Keep liquid polymers in a cool dry location. Liquid polymer will degrade at temperatures higher than 50 ˚C. Keep dry polymers in a dry location to prevent clumping and clogging of piping after being introduced into the dilution water.

Conduct bench testing with a polymer manufacturer to determine the correct polymer and its dosing. As part of the bench testing, determine the correct solution strength to make the polymer, aging of the polymer, and mixing requirements of the polymer. In general, mix the dry polymer for at least 30 minutes at a low speed to allow the polymer to uncoil prior to use.

5-3.10 Oxidizers.

At wastewater treatment plants, oxidizers are used for odor control and control of hydrogen sulfide. The two most common oxidizers used are hydrogen peroxide and potassium permanganate. These chemicals normally are only used during warm weather to reduce odors and prevent the formation of hydrogen sulfide in the pipes and process of the wastewater treatment plant.

This Page Intentionally Left Blank

CHAPTER 6 ODOR CONTROL

6-1 MAINTENANCE.

The maintenance requirements for odor control systems varies depending on the type of chemical and biological odor control systems used. Recommended maintenance should be completed by operators and maintenance staff to maintain all warranties and performance guarantees. Refer to the equipment manufacturers operation manual and operate solids treatment equipment in accordance with manufacturers recommendations and all NPDES permits.

6-2 ODOR CONTROL SYSTEMS.

Wastewater, whether it is being collected, treated, or disposed, emits strong odors and potentially other air containments. Odor control is also implemented because of public concern for health and safety and/or intolerable odors. Odors can be treated with microbiology, which uses compounds in the odorous air for an energy source, or with chemicals, which react with the compounds in the odorous air and change the compounds into a non-odorous compound. Some compounds can be adsorbed into activated carbon as the air passes by it.

Refer to *Advanced Waste Treatment*, Chapter 1 for additional guidance on odor control.

6-3 OPERATION.

The operation of both chemical and biological odor control systems are different in their requirements. In both cases, sampling may be used to verify proper operation and verify performance to ensure that the treated air meets applicable permit requirements.

Record all operating data and evaluate any changes and trends in the data collected for each type of odor control system.

6-3.1 Chemical Odor Control Systems.

Operate chemical odor control equipment in accordance with the manufacturer's operation manual. Common setpoints may include pH, oxidation reduction potential, and free chlorine. Operators must ensure that the amount of makeup water supplied to the odor control system is enough to ensure proper operation of the odor control system without wasting a large amount of water. Refer to *Advanced Waste Treatment* for typical oxidant dosages for a chemical odor control system.

For an odor control system that contains activated carbon, monitor activated carbon performance. If the activated carbon shows signs of breakthrough, it must be replaced.

6-3.2 Biological Odor Control Systems.

Maintain the moisture content in the biological odor control media. The amount of water required to be applied to the media is dependent on the location of the biological odor control system and time of year. Times of dry weather and when the atmosphere contains dry air generally will require more water to be applied to the media than times of the year when there is precipitation and humidity in the air. Generally, biological odor control system media must be kept between 50 and 60% moisture content. Some biological odor control systems may have a system to increase the humidity in the odorous air prior to entering the media. Adjust the amount of water to raise the odorous air humidity to the manufacturers recommended humidity level.

Biological odor control system may have a nutrient addition system. Operate the nutrient addition system per the manufacturer requirements to ensure that the microorganisms have sufficient nutrients to allow them to grow and maintain treatment of the odorous air.

CHAPTER 7 COLD WEATHER OPERATION

7-1 INTRODUCTION.

Cold weather can affect every aspect of the wastewater treatment plant operation. Items to consider for cold weather operation for each process at the wastewater treatment plant follow.

7-2 MAINTENANCE.

Recommended maintenance should be completed by operators and maintenance staff to maintain all warranties and performance guarantees. Refer to the equipment manufacturers operation manual and operate equipment in accordance with manufacturers recommendations and all NPDES permits.

7-3 SCREENINGS.

Clean screens more frequently during cold weather, either automatically on timers or manually, because the screenings will freeze to the metal bars. Once this occurs, removing screenings from the bars is difficult. Mechanical mechanisms may also become jammed and inoperable. Weatherproofing or enclosing the area and providing heat may be desirable. Be aware of the potential for combustible materials entering with the wastewater. Provide proper ventilation and equipment to prevent explosive conditions.

Screenings may freeze to the sides and bottom of containers; prevent this from happening if possible. Grinders may bind because of ice if they are not run often enough. Consider operating the grinders continually or often enough to prevent ice buildup. Covering channels with rigid insulating materials may contain enough heat from the wastewater within the channel to prevent ice buildup on the grinder. Gear oil viscosity will be affected by freezing weather. Condensation also will occur in the gear boxes of this equipment, adversely affecting the gear oil. Check the oil routinely (twice monthly) in the winter.

7-4 GRIT REMOVAL.

Operation of grit-handling facilities may be difficult during extremely cold weather. The grit that is collected and transported will freeze easily in the equipment used to clean and move it to the holding container. Temporary enclosures may assist in keeping the process warm. If this process is to be enclosed, choose the materials carefully to prevent dangerous or explosive conditions. Heat-tracing the metal equipment may help prevent ice buildup. Heat-tracing involves wrapping an electrified wire loop around the equipment. Running warm water across cleaning areas also may prevent freezing, depending upon local conditions.

7-5 PRIMARY TREATMENT.

Clarifiers are affected in several ways by the decrease in seasonal temperatures. The density of water changes with temperature, and this change affects the settling characteristics of the solids. Materials at the surface of these quiescent basins will tend to freeze. Weirs and launders may also freeze, depending upon the ambient and wastewater temperature.

Settling characteristics change when temperatures lower; solids settle at a slower rate in colder (near freezing) waters. Stoke’s Law governs the physics of settling in primary clarifiers, and it is affected by temperature. For example, when the temperature drops from 68 ˚F (20 ˚C) to 38 ˚F (3 ˚C), the settling time for a particle increases 64%. Under these conditions, additional clarifiers may facilitate the process. The use of additional clarifiers may result in lower water temperatures and a higher risk of freezing. Evaluate the use of additional clarifiers and the risk of freezing. If the solids loading is high (above 2,000 mg/L), Stoke’s Law does not apply.

7-5.1 Inspection.

Inspect the aerobic digester for ice on the primary treatment surface and around the sludge flight and chain or the scum skimmer when cold weather occurs. If any ice is found, the operator must break up or remove the ice before it damages the primary treatment equipment.

7-5.2 Biological Treatment.

Cold weather affects the biological systems in the same way, in that the microbiology process slows down. But, the cold weather affects the mechanical equipment to each of the various types of biological system differently and thus each system is described below.

7-5.3 Activated Sludge.

Cold weather does not affect conventional activated sludge systems with a detention time of 4 to 6 hours as significantly as systems with longer detention times. Extended aeration systems having detention times of 10 to 24 hours will experience a temperature decrease that will affect the biological process Systems that use diffused air for oxygen transfer will add heat to the system in the air flow; conversely, mechanical mixing systems will have significant temperature decreases across the aeration basin as cold air is mixed into the activated sludge. Operators must take these temperature changes into consideration when selecting or changing aeration methods in a cold climate. Avoid ice buildup across the surface of the basins. The ice buildup will limit the oxygen transfer and may interfere with mixing equipment. Removing floating scum before winter will help prevent this extra material from freezing in the aeration basin.

7-5.3.1 Maintenance.

When a tank is offline and drained, protect equipment from cold weather and damage. Refer to the equipment manufacturers operating and storage instructions for storage and follow the recommended practices.

7-5.4 Biological Reaction Rates.

Biological reaction rates depend upon temperature. A reduction in temperature of 18 ˚F (10 ˚C) decreases the reaction rates by one-half. In cases where the temperature is affecting the process, changes to the process control are required. Process adjustments would include increases to the MCRT, aerobic Solids Retention Time (SRT_a), or a decrease in the food-to-microorganism ratio to maintain the same process performance and loading rates.

7-5.5 Aeration Equipment.

Ice buildup around mechanical aeration equipment will also affect safety and may overload equipment if it attaches to equipment surfaces. Continuous operation of mechanical mixers at low speed or intermittent operation will reduce the oxygen transfer and reduce ice buildup. Monitor oxygen concentration closely if this method is attempted. Heat tracing the components also may be helpful.

7-5.6 Clarifiers.

The most serious problems associated with clarifiers is freezing on the surface, surface scum, and ice buildup on the scum beach plate. These problems damage skimming mechanisms and may even cause the clarifier rake mechanism to jam or fail. Removing the skimming arm in winter may prevent this problem; however, the problems of scum freezing and removal remain. Hot water sprays, heat tape, and enclosed lamps may help in addressing these problems. Many times, ice must be carefully chopped off the surface of the tanks and removed to the launders. Covering clarifiers will typically help eliminate these potential problems. When designing covers, consider snow loads, weatherproofing of electrical controls, and the possibility of humidity within the covers. Torque limits on the rake mechanism need to be properly set to ensure proper operation if ice affects the collector.

7-5.6.1 Maintenance.

Routinely check torque limits on the rake mechanism and repair them if necessary.

7-5.7 Trickling Filters and Rotating Biological Contactors.

In trickling filter plants, the potential for icing is high. In the winter, turn off the draft in forced-draft systems unless a source of warm air is available to prevent ice from forming in the filter. The forced draft systems are used primarily when the outside air is less than 5 ˚F (3 ˚C) above or below the process liquid temperature. If ice forms within the unit, flood it to melt the ice. Take care when flooding the media and be cautious of structural loading as well as leaking and overloaded pumping systems, gates, and valves. Ice can form on the top of the media, which may affect the distributor arm. Covers are advised in extremely cold areas to prevent this situation. RBCs are usually covered to control odors but keep the covers in good condition to keep the heat within the wastewater. If the RBCs do not already have covers, install them to keep the media from freezing and affecting the shaft with additional loading and potential failure.

7-5.8 Natural Biological System.

Aerated lagoons will typically freeze during the winter. Remove mechanical mixers to prevent them from becoming covered with ice and turning over or sinking. Remove any baffles or be prepared to repair them in the spring. Because the ice will affect the depth of the lagoon, run winter operations at the highest liquid levels possible to increase lagoon volume. Because of the ice coverage, little to no algae activity will occur under the ice and snow. Adding the lower water temperature to the situation, lagoon performance in the winter may be marginal. With the rise in spring temperatures, the lagoons will have a liquid turnover, with a possible washout of solids.

7-5.9 Aerobic Digester.

While aerobic digesters are not normally in locations that experience long periods of cold weather, they can experience short spells of cold weather that can damage equipment. Inspect the aerobic digester for ice on the digester surface and around the mixing equipment when cold weather occurs. If any ice is found, the operator must break up or remove the ice before it damages the digester equipment. If an extended period of cold weather is experienced, consider building a temporary shelter around the digester to limit the amount of ice that forms on the digester.

Aerobic digesters operate at lower efficiencies. Longer detention times are required to obtain the needed levels of stabilization. Increase digester solids concentrations to accommodate these changes. Thus, decanting the digesters may take longer because of increases in viscosity.

7-5.10 Anaerobic Digester.

It will take more energy to keep the contents up to the processing temperature because of the lower feed temperature. Tank insulation (dome and sides) will need to be inspected in the fall of each year and repaired as needed.

7-6 ODOR CONTROL SYSTEM.

Both the chemical and biological odor control systems have heat traced and insulated water piping, which must remain full of water and is exposed to the cold weather. This will prevent freezing of the piping, which may cause equipment damage. Chemical piping in the chemical odor control system should be heat traced and insulated to prevent the chemicals from freezing or crystalizing in the piping.

To drain the biological odor control system, isolate the irrigation water system and drain to prevent equipment damage. To fully drain the system, consider using compressed air to remove all possible water. Inspect the odor control air duct for condensation in the interior piping by opening all water drain ports to remove water and then shutting them once all water has been drained out.

7-7 UTILITIES.

In electrical panels, frost may arc across some electrical circuits. A small warm-air fan in the vent of the electrical panel will keep the internal components warm and dry if this is a local issue.

\1\ /1/

Note: For the Army, TM 5-814-3 provides additional requirements for cold weather operation.

This Page Intentionally Left Blank

CHAPTER 8 WET WEATHER FLOW OPERATION.

Due to the infiltration of groundwater and use of combined sewers, the operation of a wastewater treatment plant must change when a large amount of precipitation is expected.

8-1 SCREENING PROCESS.

The increase in raw wastewater influent will increase the amount of material that it carries with it. Run mechanical screens more often by either reducing the differential level for the screen to start or reducing the timer to make the mechanical screen start. For manual bar screens, increase the number of times the screen is cleaned during a storm.

For both the mechanical screen and manual bar screen the increased removal of material will minimize the possibility of a sewer overflow in the collections system. The increased frequency of removing the materials also will minimize the surging of water flow through the wastewater treatment plant, thus, maintaining a high level of treatment for all water that flows through it.

8-2 GRIT REMOVAL PROCESS.

The increase in wastewater flow can increase the amount of grit that it contains due to velocity of the water flowing through the collection system. Prior to a wet weather event, it is recommended that the amount of time that the grit removal equipment runs to remove grit from the grit chamber be increased to remove the increased grit load.

8-3 BIOLOGICAL PROCESS.

Each of the biological systems are affected by wet weather. The increased flow can cause NPDES permit violations if operators do not take action. Below are recommended actions for the various biological process to maintain permit compliance during a wet weather event.

8-4 ACTIVATED SLUDGE.

When wet weather occurs, the constituent loading on the biological system may slightly increase, but the major increase will be the hydraulic loading on the activated sludge process. The increased flow will decrease detention times for treatment of the wastewater and settling of the mixed liquor in the clarifier. Prior to a major wet weather event, if possible, increase the amount of mixed liquor and increase the amount of tankage available to treat the wastewater. Additionally, increase the number of clarifiers in service to allow as much settling of the mixed liquor from the treated wastewater prior to it flowing out to the environment. Consider increasing how much RAS they return from each clarifier to minimize the possibility of washing out any mixed liquor from the bottom of the clarifiers.

8-5 TRICKLING FILTERS AND ROTATING BIOLOGICAL CONTACTORS.

As with activated sludge, the constituent loading on the biological system may slightly increase, but the major increase will be the hydraulic loading when a wet weather event occurs. If possible during a wet weather event, start up another trickling filter or RBC and increase the recirculation rate of the units. This will provide more time to allow treatment, and if the trickling filter and RBC do not have a biomass, the recirculation will seed the units to start growing the biomass on the media.

CHAPTER 9 UTILITIES.

A wastewater treatment plant cannot perform its function without the support of other utilities such as electrical distribution and natural gas. All the utilities have required operation and maintenance requirements that operators must be aware of and follow to ensure that proper treatment of wastewater continues without interruption to the treatment process.

9-1 ELECTRICAL DISTRIBUTION.

The electrical distribution system is typically required to have two independent power sources. Normally, the second power source is provided by emergency generators, but it can be provided by a second electrical power supply line that independent of the first electrical power supply. The electrical distribution system normally contains various voltages within it. These voltages are supplied by the power provider or emergency generators.

An electrical distribution has at least one power supply line that provides power the wastewater treatment plant. The power is then distributed to motor control centers, or to other power panel and lighting panels.

9-1.1 Operation and Maintenance.

Use UFC 3-540-07, UFC 3-550-07 and UFC 3-560-01 for additional operation and maintenance requirements. The operation of the electrical distribution system is limited to backup generators. Operators should inspect, test and store fuel in accordance with written standard operating procedures to maintain the operational integrity of backup generators. Any other operation of the electrical distribution must be completed by a qualified person to ensure personnel and equipment safety.

Note: For the Air Force, **\1** AFMAN **/1/** 32-1062 provides additional requirements for generators.

Note: For the Army, TM 5-682 provides additional requirements for electrical facilities safety. TM 5-683 provides additional requirements for electrical interior facilities, TM 5-684 provides additional requirements for electrical exterior facilities, and TM 5-685 and AR 420-1 provide additional requirements for operation, maintenance, and repair of auxiliary generators.

9-2 POTABLE WATER.

Potable water is used throughout the wastewater treatment plant for various uses. These uses include drinking water, seal water for pumps, chemical carrier water, fire protection, and equipment wash water.

9-2.1 Operational and Maintenance.

Use UFC 3-230-02 for operation and maintenance of water supply systems. Potable water supply systems are required to be protected from backflow by an approved backflow prevention device. Use UFC 3-230-01, UFC 3-420-01 and UFC 3-600-01 for backflow protection and cross control. Verify Installation specific requirements and testing frequency with the Installation Environmental Program staff.

Potable water may be piped to a hydropneumatic tank or a tank with an air gap to prevent any possibility of contaminating the potable water system with chemicals, sludge, or wastewater. Operate the hydropneumatic tanks per the manufacturer's operating instructions to prevent damage to the equipment and protect the potable water system.

Note: For the Air Force, **\1** AFMAN **/1/** 32-1067 provides additional requirements regarding potable water.

9-3 NATURAL GAS.

Natural gas may be used at wastewater treatment plants as a fuel source for a heating unit, a hot water heater, a sludge incinerator, or an emergency generator.

9-3.1 Operational and Maintenance.

Operators at a wastewater treatment plant typically do not have any operational requirements for the natural gas service up to and including the gas meter. Contact the natural gas utility provider for any emergency or service related questions. Post the natural gas service providers emergency contact information on-site.

Call the local utility marking service prior to any digging or excavation and obtain a permit or clearance to dig from the utility marking service.

9-4 CATHODIC PROTECTION.

Cathodic protection provides additional corrosion protection, supplementing the normal protection offered by protective coating systems. Use UFC 3-570-06 for operation and maintenance of cathodic protection systems.

Note: For the Army, PWTB 420-49-29 provides additional requirements for cathodic protection systems.

Note: For the Air Force, AFH 32-1290 provides additional requirements for cathodic protection systems.

9-5 HEATING, VENTILATION, AND AIR CONDITIONING.

The heating, ventilation, and air conditioning (HVAC) system is comprised of various pieces of equipment that are used to maintain the desired atmosphere inside a single room or the entire building. The atmosphere of the room or building includes temperature and humidity of the room or building.

The HVAC system is also used to maintain the number of air exchanges that occur in a room to reduce the potential for health effects on an operator when they enter the room and the potential hazard of fire or explosion from the accumulation of sewer gases. The HVAC system can also be used to maintain differential pressure in various locations in a building to prevent the migration of odors from sludge and other wastewater processes. The HVAC system may also work in conjunction with the odor control system to remove odors from a space or building.

9-5.1 Heating, Ventilation, and Air Conditioning Equipment.

The HVAC systems are comprised of some equipment that is simplistic in its function, whereas other pieces of equipment are complex and perform various functions for the HVAC system.

9-5.1.1 Heating Equipment.

The heating of air can be accomplished by various pieces of equipment. Unit heaters are industrial electric heaters, whereas gas unit heaters use natural gas to heat the air. Both unit and gas unit heaters are simple heaters that operate independently of any control system. Rooftop units can provide both heating and cooling of a space, but they require a control system to determine when the heat or cooling system of the rooftop unit will be used. The rooftop unit can use electricity or natural gas as its fuel source to heat the air.

9-5.1.2 Ventilating Equipment.

Ventilation is accomplished by fans and rooftop units. Fans can either supply air (push air into a space) or exhaust air (draw suction on a space). This method of supplying and exhausting the same amount of air is the simplest method of cooling a space, and it also can be used to provide air exchanges to maintain the atmosphere in the space. If the amount of air differs, then a pressure differential is created between the space and the outside atmosphere. Rooftop units normally provide air into a space; thus, if they are the only method of ventilation, the space will be pressurized, which will push out of the building into the outside atmosphere.

9-5.1.3 Air Conditioning Equipment.

Air conditioning of a space or building is accomplished by rooftop air conditioning units. These air conditioning units run to maintain the temperature setpoint in the control system. In addition, the air conditioning unit can run to maintain a humidity setpoint in the control system.

9-5.2 Operational Requirements.

The HVAC system must have all components operating as designed to maintain a safe environment. Operators must review all setpoints entered into the HVAC control system to ensure the temperature setpoints are correct and all times for occupancy are correct for the work day.

When entering a space, operators must turn on or ensure that the HVAC equipment is operating correctly. When operators exit a space, they must turn off the HVAC system if applicable.

Note: For the Army, AR 420-1 provides further guidance on boiler operations.

Note: For the Air Force, **\1** AFMAN **/1/** 32-1068 provides further guidance on boiler personnel schedule requirements.

9-6 FIRE PROTECTION SYSTEMS.

Use UFC 3-600-02 for the inspection, testing and maintenance of fire protection systems.

CHAPTER 10 SEPTIC SYSTEMS, GREASE TRAPS, AND OIL-WATER SEPARATORS

10-1 INTRODUCTION.

Septic sewer systems collect and treat wastewater where it is not feasible to provide a wastewater collection and treatment system. The majority of septic systems collect and treat domestic wastewater. Food-service operations typically use grease traps to prevent excessive discharge of grease and oil into the wastewater collection and treatment system. Refer to EPA/625/R-00/008 for additional guidance.

10-2 MAINTENANCE.

The maintenance requirements for septic system, grease traps and oil-water separators varies depending on user operating procedures and the type of equipment used. Recommended maintenance should be completed by operators and maintenance staff to maintain all warranties and performance guarantees. Refer to the equipment manufacturer's operation manual and operate equipment in accordance with manufacturer's recommendations and all NPDES permits.

10-3 SEPTIC TREATMENT AND DISPOSAL SYSTEM.

Septic systems are used when collection of wastewater by a centralized wastewater collection and treatment system cannot be provided. Septic systems collect domestic septage, provide treatment and dispose of the treated effluent on-site. A state or local permit may be required to construct, operate or modify a septic system.

Septic systems collect domestic wastewater flows from the building into the septic tank through a sewer pipe. In the tank, bacteria attack and digest organic matter by anaerobic digestion. The wastewater itself provides the bacteria for this process. The anaerobic digestion process changes the waste into gas, biosolids (residual organic and inorganic material), and treated effluent. The gas escapes into the air, the treated effluent is discharged to the leaching system, and the residual solids remain in the tank. The treated effluent is discharged into the soil through the perforated or open-jointed pipes in the drain field. Soil bacteria destroy remaining organic material in the effluent. Use IPSDC for septic treatment and disposal system requirements. Use EPA 932-F-99-068 and *Maintaining Your Septic System - A Guide for Homeowners*, for additional guidance on maintaining septic systems.

10-3.1 Domestic Wastewater Characteristics.

There are many factors that influence septage characteristics such as climate, user habits, septic tank size, design, pumping frequency, water supply characteristics, piping material, and use of water-conservation fixtures, garbage disposals, household chemicals, and water softeners. Refer to EPA 932-F-99-068 for domestic wastewater characteristics.

10-3.2 Monitoring Waste Discharged to System.

Because the septic tank treatment system is a biological process, it is particularly important that toxic or hazardous chemicals are not discharged into it. These chemicals would kill the bacteria used for treatment of the wastewater. Discharge of industrial wastewater to septic tanks violates the underground injection provisions of the SDWA. In addition, do not discharge grease and non-biodegradable into the system. The system is not designed to treat these products, and they can cause clogging in the system components. Use household cleaners, such as bleach, disinfectants, and drain and toilet bowl cleaners, in moderation and only in accordance with product labels. Overuse of these products can harm the septic tank system.

10-3.3 Water Conservation.

Water conservation is critical for proper operation of the drain field. Continual saturation of the soil in the drain field can significantly reduce the ability of the soil to naturally remove toxins, bacteria, viruses, and other pollutants from the wastewater. In addition to conserving water discharged to the septic tank and drain field, try to restrict water from roof drains, sump pumps, and other sources from draining into the area of the drain field.

10-3.4 Septic System Components.

10-3.4.1 Tank.

The size of the septic tank depends on the number of people using the building or the volume and type of waste. Figure 10-1 depicts a two-compartment septic tank system.

10-3.4.1.1 Septic Tank Maintenance.

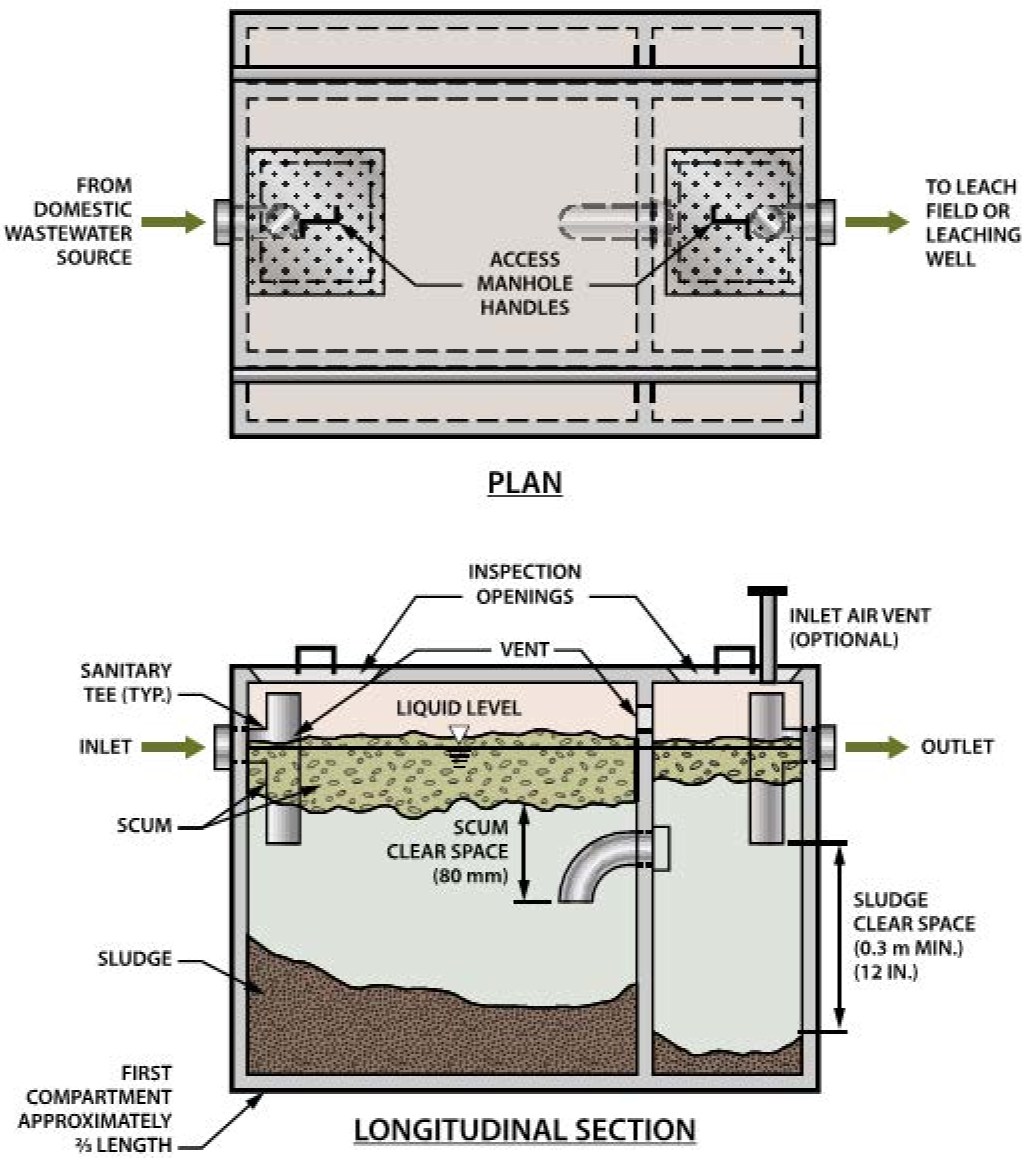
The primary maintenance requirement for the septic tank system is periodic removal of scum and settleable solids. It is not necessary to add yeast or bacteria to the system as a maintenance procedure. If human and kitchen wastes are being discharged to the system, there will be sufficient bacteria in the tank for treatment. Table 10-1 shows the estimated tank pumping frequencies, based on tank size and household size.

10-3.4.1.2 Inspecting the Septic Tank.

Inspect the septic tank every 1 to 5 years to determine if solids need to be removed. If garbage disposals discharge to the septic tank should be inspected annually.

Exercise extreme care when inspecting the septic tank as inhalation of toxic gases have been known to cause sickness or death. Never enter or inspect a septic tank alone. Toxic gases are produced by the natural treatment processes in septic tanks and special precautions need to be used to prevent inhaling these toxic gases. Contact the Installation Safety Officer to obtain a confined space permit if entry is required. Guidance on confined space entry requirements can found in *Operation of Wastewater Treatment Plants*, Volume 2, Chapter 14.

Figure 10-1 Typical Two-Compartment Septic Tank



10-3.4.1.3 Measuring Solids and Scum Inside the Tank.

There are two frequently used methods for measuring the scum layers inside the tank.

a. A hollow clear plastic tube is pushed through the different layers to the bottom of the tank. When the tube is brought back up it retains a sample showing a cross-section of the inside of the tank.

b. The layers can also be measured using a long stick. To measure the scum layer using a stick, a 3 in. (8 cm) piece of wood is attached across the end of the stick to form a "foot," and the stick is pushed down through the scum to the liquid layer. When the stick is moved up, the foot meets resistance on the bottom of the scum layer. The stick is marked at the top of the layer. The distance between the mark and the foot on the end of the stick can be measured to determine the total thickness of the scum layer.

The solids layer can be measured by wrapping cloth around the bottom of the stick and lowering it to the bottom of the tank. Insert the stick either through a hole in the scum layer or through the baffle or tee, if possible, avoid getting scum on the cloth. Estimate the solids depth by the length of solids sticking to the cloth.

Table 10-1 Estimated Septic Tank Pumping Frequencies in Years

	Household Size (number of people)					
Tank Size (gallons)	**1**	**2**	**3**	**4**	**5**	**6**
500	5.8	2.6	1.5	1.0	0.7	0.4
750	9.1	4.2	2.6	1.8	1.3	1.0
900	11.0	5.2	3.3	2.3	1.7	1.3
1,000	12.4	5.9	3.7	2.6	2.0	1.5
1,250	15.6	7.5	4.8	3.4	2.6	2.0
1,500	18.9	9.1	5.9	4.2	3.3	2.6
1,750	22.1	10.7	6.9	5.0	3.9	3.1
2,000	25.4	12.4	8.0	5.9	4.5	3.7
2,250	28.6	14.0	9.1	6.7	5.2	4.2
2,500	31.9	15.6	10.2	7.5	5.9	4.8

(1) These figures assume no garbage disposal is in use.

Source: *Maintaining Your Septic System - A Guide for Homeowners*

10-3.4.1.4 Removal of Settleable Solids.

Pump solids out of the tank when the depth of solids is one-third or more of the liquid depth. When pumping the tank, remove all contents, including scum, liquid, and solids. Use only the access ports on the tank for cleaning; do not pump out the tank through the distribution box. Do not use toxic or hazardous chemicals for cleaning the tank and do not use organic chemical solvents or petroleum products for degreasing or declogging the system. These chemicals and products are harmful to the system and to the groundwater near the system.

10-3.4.1.5 Removal of Scum.

The tee shaped outlet prevents the scum from leaving the tank. Pump the tank whenever the bottom of the floating scum layer is within 6 inches (150 mm) of the bottom of the outlet tee or the top of the floating scum layer is within 12 inches (300 mm) of the outlet tee.

10-3.4.2 Effluent Disposal Systems.

Soil absorption systems, pressure distribution systems, mound systems, and holding tanks are used to dispose or store treated effluent. Do not allow vehicles to drive over effluent disposal systems. Do not plant trees, shrubs, or similar plants over the effluent disposal systems.

10-3.4.2.1 Soil Absorption System.

A gravity effluent leaching system consists of a distribution box or header pipe and a drain field. The drain field is a system of open-jointed or perforated piping that allows the wastewater effluent to be evenly distributed into the soil. Where groundwater levels are high, the elevation may be insufficient for a soil absorption system and an alternative system is used to dispose of treated effluent.

10-3.4.2.2 Soil Absorption System Maintenance.

Replacement is the only remedy for a leachate system that is not functioning. There are no conclusive data to support the premise that enzymes and chemical treatment can revitalize a drain field.

10-3.4.2.3 Mound Systems

Mound systems are generally used in areas with high groundwater levels or a minimum soil depth to bedrock. Mound systems are prohibited in flood hazard areas. Mound systems require a pump to deliver the effluent to the elevated leaching system. Electric controls and a power supply are required to operate the pump.

10-3.4.3 Effluent Screens.

Effluent screens enhance solids removal and clarify the septic tank effluent. Typically, effluent screens are attached to the outlet pipe inside the septic tank. In some cases, effluent screens may be placed in a filter chamber located outside of the septic tank on the outlet side of the septic tank. Effluent screens can assist in preventing blockages that could damage the drain field. In some cases, a biolayer may build up on the screen. The biolayer can help with the removal of viruses and pathogens. Review the state requirements for your location to see if an effluent screen is required. Refer to EPA 832-F-03-023 for additional guidance on effluent screens.

10-3.4.3.1 Effluent Screen Maintenance.

Effluent screens require regular cleaning to keep them operating efficiently and to prevent plugging. The frequency of cleaning depends on many factors, such as, environmental conditions, the material entering the septic tank, and the size of the screen. Some states require the use effluent screens.

10-3.5 Septic System Failures.

Several warning signs can indicate that a septic tank system is failing and that more than cleaning of the system is necessary:

- Obnoxious odors around the system or inside the building
- Soft ground or low spots around the system
- Grass growing faster or greener around the system
- Gurgling sounds in the plumbing or plumbing backups
- Sluggishness in the toilet when flushed
- Plumbing backups
- Tests showing the presence of bacteria in nearby well water

Table 10-2 shows possible causes of septic tank system failures and suggests remedial procedures.

Note: For the Air Force, **\1** AFMAN **/1/** 32-1067 provides additional requirements for septic systems.

10-4 GREASE TRAPS.

If grease traps are not properly maintained, slug loads of grease will interfere with the performance of both the collection and treatment system. There are two general types of grease traps, with the largest being inground grease traps that are usually located outside the food-service establishment in an underground tank with ground-level access. The second type is an under-sink unit. The under-sink units can be either passive, which captures the grease and requires an operator to remove the grease periodically or an automatic system that removes the grease as set by a timer to a separate container that the operator must empty periodically. Under-sink units are not recommended because they generally do not provide adequate grease removal. Where under-sink units are used, proper maintenance is especially critical because of the higher potential for release of slug loads of grease into the wastewater system.

10-4.1 Configuration.

Grease traps usually consist of an underground, watertight concrete tank with inlet and outlet piping. The outlet pipe has a tee that allows the internal discharge to be located within 12 in. (300 mm) of the tank bottom. The size of the grease trap depends on the anticipated flow rate, water temperature, and grease concentration. Access to the tank is typically through one or two manhole rings and covers.

10-4.2 Location.

Grease traps are located outside food-service buildings in an accessible location for inspection and maintenance.

Table 10-2 Septic System Failures

Possible Causes of Failure	Possible Remedial Procedures
Underdesign	
• Tank size insufficient for wastewater flow quantity and/or characteristics • Drain field too small	• Replace septic tank or add additional septic tank(s) in parallel. • Replace septic tank or add additional septic tank(s) in parallel.
Faulty Drain Field Installation	
• Plugged pipes • Insufficient stone in trenches • Uneven grades	• For plugged pipes, insufficient stone, and uneven grades, install a new drain field on top of existing field.
Poor Soil Conditions	
• High groundwater • Insufficient distance below drain field to bedrock • Relatively impervious soils	• Improve surface drainage, install curtain drains, elevate field, and/or reduce water consumption. • Elevate drain field and/or reduce water consumption. • Elevate drain field and/or reduce water consumption.
Overload	
• Excessive wastewater loading • Poor stormwater drainage away from system • Leaking plumbing fixtures • Wastewater flow quantity and/or characteristics greater than anticipated in design due to changes in use of building, garbage grinders, etc.	• Increase tank size or reduce water consumption. • Improve surface drainage. • Repair plumbing fixtures. • Remove garbage grinders; increase drain field.

Possible Causes of Failure	Possible Remedial Procedures
Lack of Tank Maintenance	
• Septic tanks not pumped out at sufficient intervals, causing solids to be discharged to drain field	• Pump out tank, construct new drain field on top of existing drain field, relieve drain field by draining into a pit and pumping out, and let field rest for a month.

Source: Adapted from *Wastewater Engineering Design for Unsewered Areas*

10-4.3 Discharges to Grease Traps.

Grease traps do not perform effectively if they receive discharges with elevated temperatures or high solids concentrations. It is not recommended for grease traps to receive discharges from garbage grinders or produce -preparation sinks. Discharges from mechanical dishwashers are also not recommended. However, the preflush or prescraping sinks that serve mechanical dishwashers may be connected to the grease trap, provided no garbage grinders are used at these sinks.

10-4.4 Maintenance Procedures.

The critical maintenance procedure for all grease traps is periodic removal of accumulated waste. If the responsibility and procedures for cleaning grease traps are not clearly identified and implemented, the traps are ineffective. It is recommended that waste be pumped out of the grease traps rather than dissolved with solvents. Grease and solvents may have a negative impact on the wastewater collection and treatment system. Recovered oil and grease from food-service operations typically can be sold to a local recycling company. If proper maintenance cannot be maintained, consider removing the grease trap and having the user separate the grease before discharging wastewater to the sanitary system.

Note: For the Army, AR 420-1 provides further guidance on grease trap maintenance.

10-4.4.1 Pump-Out Frequency.

The recommended pump-out frequency ranges depending on the waste characteristics of the establishment and the size of the grease trap. The necessary pump-out frequency can be determined by checking the grease retention capacity in the grease trap. Remove grease and accumulated wastes as often as necessary to maintain at least 50% of the grease retention capacity.

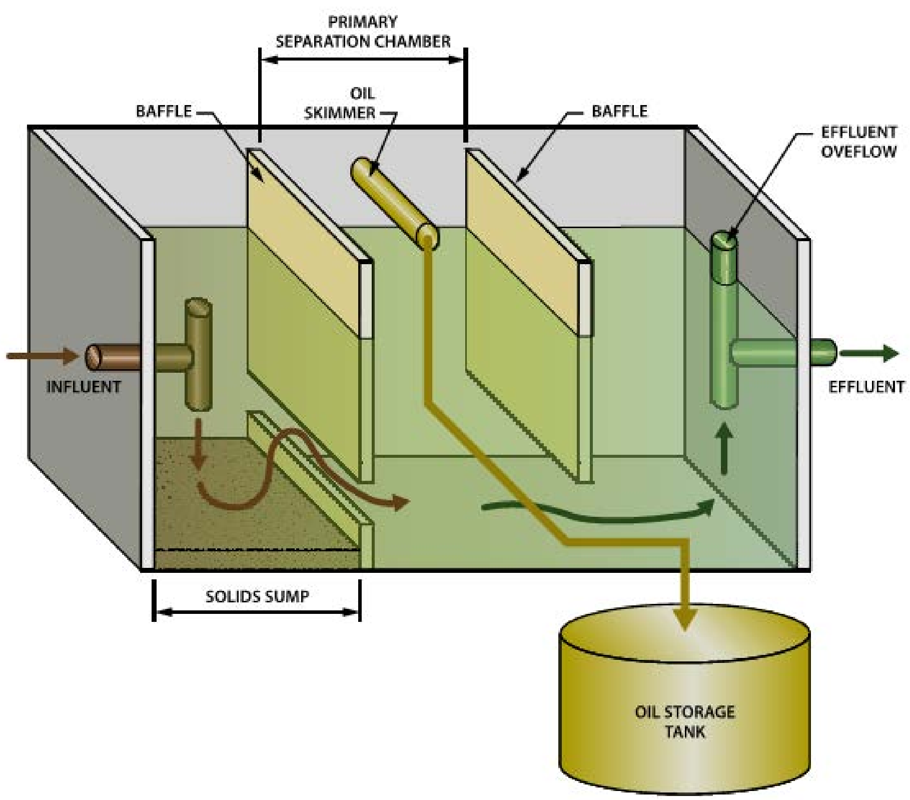
10-5 OIL/WATER SEPARATORS.

Oil-water separators are devices commonly used to separate oily waste products from wastewater streams. They are typically installed in industrial and maintenance areas to receive and separate oils at low concentrations from wastewater generated during industrial processes such as maintaining and washing aircrafts and vehicles. There are three predominant types of oil-water separators: conventional gravity separators, corrugated plate gravity separators, and flotation separators. Most oil-water separators used are conventional gravity separators. Most units, regardless of the type, are purchased as proprietary equipment from vendors.

10-5.1 Gravity Separators.

The process relies on the different densities of oil, water, and solids for successful operation. The wastewater is fed to a vessel sized to provide a quiescent zone of sufficient retention time to allow the oil to float to the top and the solids to settle to the bottom. Gravity oil-water separators come in two configurations: conventional gravity separators, such as those designed in accordance with guidelines established by the American Petroleum Institute (API) and corrugated plate interceptors (CPIs).

Conventional gravity separators are typically rectangular in-ground or above-ground tanks with maximum widths of 20 ft (6 m). A diagram of a typical conventional gravity separator is presented in Figure 10-3. Influent and effluent channels are normally located on opposite ends of the separator. The influent typically passes an inlet section that contains a slotted baffle to distribute influent evenly throughout the depth of the separator. For units without sludge collectors, there may also be a bottom baffle in the separator; this retains settled solids in the front part of the separator to reduce cleaning requirements. Other separators may have automatic sludge removal equipment that will rake accumulated sludge to a sludge hopper where it is pumped from the tank periodically.

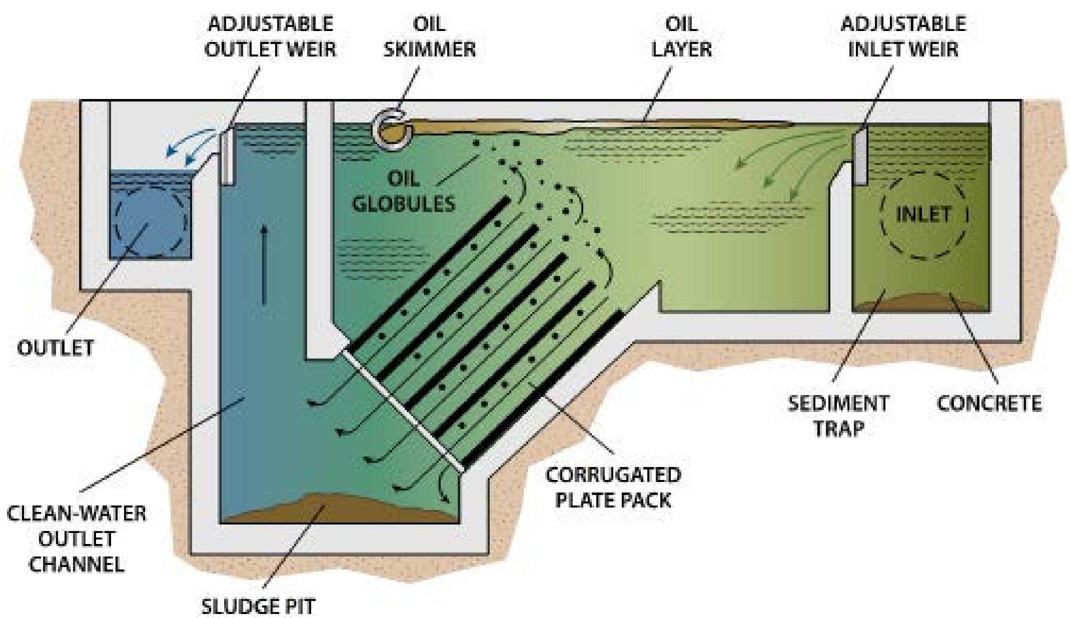


10-5.1.1 Sludge Level.

Monitor the sludge level routinely and remove sludge when it occupies 10% or more of the separator volume. All conventional gravity separators have a surface baffle at the Conventional Gravity Separator outlet end to retain floating oil and grease. The grease is removed by pumping or by activating a rotary drum or slotted pipe that allows the surface material to drain to a drum or oil holding tank. Regularly check the depth of the surface oil layer and conduct routine surface skimming. Experience gained from operating a conventional gravity separator in a specific application will indicate the required intervals for checking and skimming the oil layer. For example, although the oil layer might need to be checked and skimmed daily, this interval could range from several times per day to several times per month, depending on the rate of oil accumulation on the separator surface.

One criterion to use is monitoring the oil layer and skimming as often as necessary to prevent an excess amount of oil from being flushed through the separator by an unexpected hydraulic surge (e.g., rainfall). Thus, the frequency may also depend on the sensitivity of downstream processes to increased oil loading. The frequency will have to be determined by experience, but it likely will be such that the floating oil layer does not exceed about 2 in. (50 mm); some operators prefer that there be no floating oil layer on the separator.

Figure 10-2 Process Schematic of CPI Separator

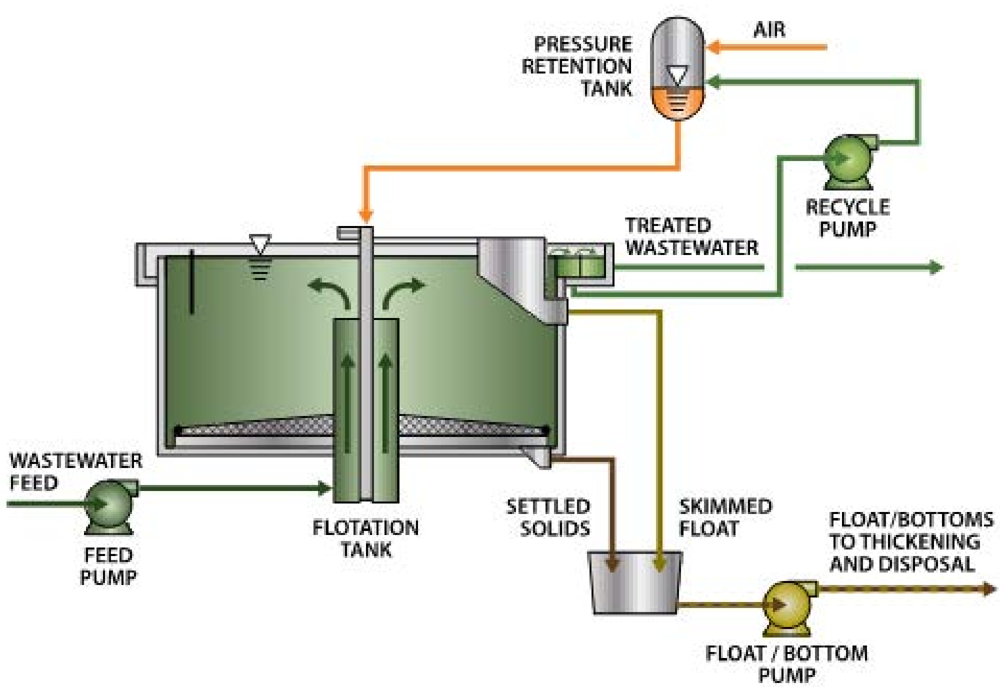


10-5.2 Corrugated Plate Interceptors.

CPIs are typically supplied by vendors and based on proprietary designs. A CPI consists of a tank containing parallel corrugated plates mounted from 0.8 to 1.6 in. (20 to 40 mm) apart and inclined at an angle to the horizontal. A diagram of a typical CPI is presented in Figure 10-4. Wastewater may flow either downward or upward between the plates. In the configuration shown, wastewater flows downward through the plates. As this happens, the oil droplets float upward and collect on the underside of adjacent plates where they coalesce. The coalesced oil droplets move up the plates and are retained in the separator to form a floating layer that is skimmed from the surface of the tank. Settled solids from the wastewater collect on the top side of adjacent plates, migrating down the plates and dropping into the bottom of the CPI vessel. In the diagram shown, treated water flows down through the plates and over a weir into an effluent flume. Some manufacturers use different configurations than the one shown.

CPI separators are smaller and easier to cover for controlling atmospheric emissions, and they may be less expensive than API-type separators. In practice, however, the smaller size has sometimes been a disadvantage because it may not provide sufficient volume to accommodate slugs of oil and it may not provide sufficient detention time for breaking emulsions. In some cases, the plate packs have become severely fouled. CPIs are usually drained and hosed down routinely to clean the plates. Operating experience over time will dictate how often this occurs, but a minimum interval of every 6 months is appropriate.

Figure 10-3 Process Schematic of Dissolved Air Flotation



10-5.3 Dissolved Air Flotation.

DAF is commonly used to remove oil, grease, and suspended solids from industrial wastewaters. A diagram of a typical DAF is presented on Figure 10-4. Typically, gravity oil-water separators are used in front of flotation units to remove the major fraction of free or floating oils; thus, flotation units usually are considered polishing units. The air bubbles can be added to the wastewater by a variety of means. Diffused air flotation and induced air flotation are the two most common types of DAF units. Both types incorporate a flotation vessel with a baffle to retain floated oil, an oil-skimming mechanism, and sometimes a bottom-scraping mechanism to remove heavy particles that do not float.

Significant mechanical equipment is associated with these systems and must be maintained according to manufacturer's directions. Flotation vessel surface skimming generally is continuous but settled sludge must be drawn off manually. The draw-off frequency will have to be determined by experience but could range from once daily to twice monthly, with weekly being a reasonable starting point.

10-5.4 Emulsified Oils.

The most common military applications seldom involve simple oil-and-water mixtures. Waste streams generated from military applications frequently contain significant quantities of dirt, cleaning aids (detergents, solvents), fuels, floatable debris, and various other items common to military equipment and activities. Oil-water separators are not designed to separate these other products. Improper use can result in oil passing through the oil-water separator. Misuse of these systems can upset treatment plants and exceed discharge requirements.

The following factors directly affect the efficiency, use, and management of oil-water separators: frequency and intensity of influent flow, design capacity, emulsifying agents, periodic maintenance practices, type of separator system, and other contaminants contained in the waste stream. Installation personnel must be familiar with these factors so they can operate and maintain these systems. A separator that is being used improperly must be reported to the environmental office.

10-5.4.1 Emulsifying Agents.

Emulsifying Agents, detergents, and soaps designed to remove oily grime from dirty weapon systems, vehicles, or other components can adversely affect oil-water separator operation. These agents are designed to increase solvency of oily grime in water. Hence, the oil droplets take longer to separate from water, reducing separation efficiency. Overzealous use of detergents can degrade efficiency by completely emulsifying oil in the wastewater stream, thus, allowing the oil to pass through an oil-water separator unaffected.

10-5.5 Frequency and Intensity of Flow.

The longer the residence time of the waste stream in the oil-water separator, the more efficient it will be at separating oil. Contaminated water enters a receiving chamber of the separator where the flow velocity of the wastewater is reduced, thereby allowing heavy solids to settle while larger oil droplets float to the top of the compartment. Further separation continues in a separation chamber where smaller droplets of oil separate from the water and join the larger droplets previously separated. The oil layer that has accumulated on the top of the water spills over an oil skimmer into a holding area; the wastewater then flows, or is pumped, to the stormwater or sanitary sewer system.

A longer separation time increases the efficiency of the oil-water separator by allowing a greater amount of oil to rise to the top of the wastewater. Therefore, restricting the wastewater to design flow rates will improve the efficiency of the separator.

10-5.6 Design Capacity.

An oil-water separator has a finite capacity for storing oils and sludges accumulated during its operation. Quite often, the oil-water separator holding compartments can become saturated or full of oils and sludges, allowing contamination to flow freely into the wastewater effluent exiting the separator system. Ensuring that the separator capacity meets the needs of the process will aid separation efficiency.

10-5.7 Operational Changes.

An oil-water separator designed and installed to a past mission requirement may not be suitable for a new mission. For example, a wash rack with an oil-water separator designed to capture contaminants from a small fighter aircraft will not handle larger wastewater volumes from a larger aircraft. Additionally, changes in mission can affect the effluent characteristics of the wastewater being discharged to an oil-water separator (i.e., wastewater with solvents or emulsions versus free floating oil). As missions evolve, the oil-water separator use must be re-evaluated to confirm continued suitability.

Mission conversions can necessitate modifying stormwater or wastewater drainage systems. Oil-water separators that do not have a stormwater diversion system can suffer from reduced removals from the hydraulic loading of stormwater that does not need to be treated. Thus, separator collection systems also must be reviewed for excessive stormwater flows.

10-5.8 Contaminants in Wastewater Stream.

Particulate heavy metals and solids in the wastewater will settle into the sludge at the bottom of the oil-water separator receiving compartments. The sludge could be regulated as a hazardous waste if levels exceed RCRA or state hazardous waste levels. Solvents or fuels also may be retained in oil-water separator sludge.

10-5.9 Evaluation of Need for Oil-Water Separators.

An oil-water separator may not be needed to meet pretreatment or discharge permit limits, coordinate with the Installation Environmental Program staff to see if the oil-water separator may be eliminated, see Figure 10-4. Operators should assist by knowing what is discharged to separators, educating others whose activities are generating the wastewater, and alerting Installation Environmental Program staff of any problems. Vehicle and equipment washrack wastewater typically contains oil and grease but have a relatively small amount of solids. Exterior washing of vehicles and equipment, particularly after field training exercises, can discharge large quantities of solids. At many installations, central vehicle wash racks are provided specifically for exterior washing.

Operators should assist Installation Environmental Program staff in evaluating the need for and effectiveness of existing oil-water separators. Consider the potential for emulsified oil. Example: Are high-pressure water or detergents being used. These practices increase emulsification and allow smaller oil droplets to pass through the oil-water separator.

10-5.10 Operation and Maintenance.

The ability of oil-water separators to function properly depends on the application of required routine service and maintenance.

Personnel using and maintaining the system are expected to understand the separation process and the components of the specific oil-water separator. Maintenance personnel are expected to be familiar with the piping and configuration of each separator for which they are responsible. Periodically inspect all parts of the separator and its draining system to prevent failures caused by operations, breaks, and mechanical settings. Items suggested for inspection and a recommended frequency for inspection are listed in Table 10-3. To determine requirements for periodic draining and cleaning, system users must be familiar with the capacity of the separator and holding tanks, uses of the system, and its potential misuses. Separator performance can be an important indicator of the mechanical condition of the device. Performance can be tracked by regular influent and effluent sampling and analysis.

Note: For the Air Force, **\1** AFMAN **/1/** 32-1067 provides additional requirements for oil-water separators.

Note: For the Army, PWTB 200-1-142 provides additional requirements for oil-water separators.

Figure 10-4 Decision Tree for Pretreatment of Oily Waste

b SOME SOLIDS CAN ALSO BE REMOVED BY OIL REMOVAL PROCESS

c IF HAZARDOUS WASTE IS FOUND IN THE PROCESS DISCHARGE, THE HAZARDOUS WASTE MUST BE REMOVED FROM THE WASTE STREAM

10-5.10.1 Periodic Maintenance Practices.

Sludges and oils that are not periodically pumped from separator holding tanks can render the separator inoperative. Additionally, leaks from oil-water separators can result in environmental pollution that could require investigative studies and extensive cleanup. Regular equipment inspections and a preventive maintenance plan can prevent contaminated discharges from the oil-water separator system. Depending on the wastewater characteristics (e.g., low pH), what material the separator is made of, and the age of the facility, perform visual equipment inspections from once per week to once per month. Conduct more rigorous inspections two to four times per year. Focus inspections on areas below the water line, equipment construction joints, piping connections and interfaces, and other areas prone to wear, spills, or leaks.

Table 10-3 Recommended Inspection Frequency for Oil-Water Separators

Item	Suggested Frequency
Conventional Gravity Separator	
Flight mechanism: flights, chains, sprockets, rails, drive	Visual weekly; detailed annually
Sludge hopper valves: open/close freely, close tight	Weekly
Oil skimmer mechanism: moves freely, level, not plugged	Weekly
Skimming pump(s)	Weekly
Sludge pump(s)	Weekly
CPI Separator	
Parallel plates: fouling	Weekly
Skimmer weir: level	Annually
Skimming pump(s)	Weekly
Sludge pump(s)	Weekly
Flotation	
Surface skimmer mechanism: drive, flight, roller, beach	Visual weekly; detailed annually
Bottom rake: flight	Annually
Pressurization pump and tank	Weekly
Back pressure valve: holds recommended back pressure	Weekly
Sludge valve: operates freely, closes tightly	Weekly
Skimming/bottoms pump(s)	Weekly

10-5.10.2 Parameters of Concern.

Parameters of concern are those that would be expected to be removed or reduced across the separator: oil, grease, and TSS. Data may be plotted to help identify trends showing both influent and effluent concentrations. Compare effluent concentrations with influent concentrations to detect performance deterioration and with discharge permit limits obtained from the Installation Environmental Program staff to assess permit compliance. Frequency of separator effluent sampling is as required by the discharge permit. Influent sample frequency must be the same as effluent sampling frequency. At a minimum, twice monthly is recommended.

APPENDIX A BEST PRACTICES

A-1 PERMITS.

Coordinate with the Installation Environmental Program staff for permit renewal or changes. NPDES permit forms will vary, depending upon the primary agency, EPA or state, and the characteristics of the discharge. The EPA delegates permits to states with approved permitting programs. State and local agencies may have more stringent requirements. Permit forms may require historical plant operation data and much of the same information required for the Capacity Analysis and Operation and Maintenance reports. There is no fee required from the federal government, but state and local agencies may assess fees to process applications.

As part of the operating NPDES permit, WWTPs may be required to periodically submit operating data to the agency that issued the permit, including data to verify the WWTP is operating in accordance with its operating NPDES permit. This may include providing nutrient results of the wastewater treatment plant, sludge sample results and other items such as various flow meter calibration.

A-2 STORMWATER NPDES PERMITS.

Stormwater NPDES permits typically involve developing a stormwater pollution prevention plan, and routinely inspecting the stormwater system, monitoring runoff, and maintaining records on site.

A-3 CURRENT TRENDS AFFECTING WWTP OPERATIONS.

The regulatory agencies responsible for the issuance of discharge permits are implementing more comprehensive programs to ensure protection of the water quality standards of the state’s streams.

A-3.1 Water Quality-Based Effluent Limits.

Effluent limits contained in operating NPDES permits are developed by the permit writer and based on state water quality standards for the receiving stream. These effluent limits are called water quality-based effluent limits. Each stream in the state is classified in the water quality standards according to its existing or potential uses. Specific and general standards apply to each classification.

The inclusion of water quality-based effluent limits in the permit is based on a review of the effluent characterization presented in the discharger’s operating NPDES permit application. This review, conducted by the permit writer, assesses the presence of compounds that have the potential to violate the water quality standards.

A-3.2 Waste Load Allocation.

Most operating NPDES permits include limits on oxygen-demanding substances (such as CBOD and ammonia). Development of these limits typically is based on a waste load allocation for the receiving stream. Stream modeling is used to assess the assimilative capacity of the stream based on the applicable dissolved oxygen standard. This capacity is then allocated among all the dischargers in the area. Generally, some portion of the stream's capacity is reserved for future dischargers.

Waste load allocation modeling typically consists of a desk-top effort for small discharges and a calibrated and verified model based on field measurements for larger discharges. Modeling is performed by the discharger or by the state agency. Regardless of who performs the modeling, the results receive a detailed review by both the state and EPA. Typically, these results are put out for public comment. In many cases, the public comment period is concurrent with the public notice for the NPDES permit.

A-3.3 Chemical-Specific Criteria.

Water quality-based effluent limits is based on chemical-specific criteria from the water quality standards (such as for metals or toxics) or on general narrative criteria. Specific criteria are used in the development of effluent limits, and in many cases, an allowance for dilution in the receiving stream is provided.

Typically, some portion of the 7Q10 low-flow for the receiving stream is used for dilution purposes. 7Q10 is a hydrogeological determination of the lowest average flow over 7 consecutive days with an average recurrence frequency of once in 10 years. Consider background concentrations in the receiving stream when performing dilution calculations. Where the 7Q10 low-flow is zero, the criteria will apply at the point of discharge, prior to any dilution.

A-3.4 Aquatic Life Criteria.

For aquatic life criteria, acute or chronic values apply. The application of acute versus chronic criteria is dependent on many items, including the use classification and the available dilution in the receiving stream. Generally, if the available dilution is greater than 100 to 1, then the acute criteria apply.

A-3.5 General Narrative Criteria.

To address these narrative criteria, most states apply a whole-effluent toxicity requirement in the permit. The whole-effluent approach to toxics control for the protection of aquatic life involves the use of acute and/or chronic toxicity tests to measure the toxicity of wastewaters. The acute test assesses the lethality of the wastewater to the test organisms and is conducted based on the regulatory agencies' requirements. The chronic test assesses growth and reproduction in addition to lethality and is conducted based on the regulatory agencies' requirements. Whole-effluent toxicity tests use standardized surrogate freshwater or marine plants, invertebrates, and vertebrates. The test is run at the same dilution as is allowed for the wastewater in the receiving stream. Failure to meet the criteria results in the need to conduct a toxicity reduction evaluation on the discharge. If the plant is not yet built, the effluent standards are determined by using effluent standards from a similar type of facility. Additionally, permits consider the standards of the receiving stream.

Example of general narrative criteria:

Toxic substances must not be present in receiving waters, after mixing, in such quantities as to be toxic to human, animal, plant, or aquatic life or to interfere with the normal propagation, growth, and survival of the indigenous aquatic biota.

A-4 COLD WEATHER OPERATION.

Consider Tables A-1 for treatment process components subject to freezing problems.

Table A-1 Treatment Process Components Subject to Freezing Problems

Preliminary Treatment	Clarifiers	Biological Reactors	Solids Management	Disinfection
Pumping	Primary	Activated sludge	Digestion	Chlorination
Screens	Secondary	Extended aeration	Dewatering	
Grinders	Polishing ponds	Oxidation ditches	Disposal	
Grit chamber	Air flotation	Trickling filters		
Flow measurement	Thickeners	Rotary biological contactors		
Flow equalization		Aerated lagoons		
		Facultative lagoons		

Source: SR 85-11.

Consider Table A-2 for winter problems associated with preliminary treatment.

Table A-2 Winter Problems with Preliminary Treatment

Problem	Solution
Ice buildup in headworks area	Keep building heated above 50 ˚F (10 ˚C).
Icing of bar racks	Cover inlet channel. Flush with warm water. Weather-strip channels to reduce cold air entry into building. Clean by hand frequently.
Septage pumping lines freeze	Use heat tape on lines and valves. Use proper flushing after pumping truck. Use manhole to directly dump into plant. Do not handle septage in winter. Drain all lines.
Septage freezing in truck	Pass engine exhaust through truck tank to prevent freezing. Drain truck tank pipings and valves.
Collected grit freezes	Store dumpsters in heated building before emptying. Store truck inside. Remove no grit in winter.
Icing of grit dewatering equipment	Duct kerosene heater into area.
Grit machine freezes	Enclose unit.
Screened rags freeze	Remove regularly by hand.
Spiral lift pumps freeze	Run water on ice to reduce buildup.
Screw pumps freeze	Install timer to “bump” screw once per hour.
Valves and hoses freeze	Drain lines. Keep hoses on.

Automatic sampler freezes	Place sampler inside building. Do not use in severe cold. Build insulated structure heated with light bulb. Insulate suction lines. Purge lines after sample taken. Move sampler location to decrease exposure. Install suction lines to give a straight fall.
Flow measurement device freezes	Use heat tape and glass fiber insulation on flow transmitter. Insulate chamber and heat with one light bulb. Put heat tape on Parshall flume linkage.
Float for flow measurement freezes	Heat with light bulb and insulate. Add antifreeze to float box.
Grit removal bypass channel freezes	Temporarily switch flow to bypass channel, 30 minutes/day or more often if needed.
Water freezing at comminutor	Build Plexiglas structure to keep influent warm.
Doors frozen shut on screening enclosure because of condensation	Put heat tape around door enclosure.
Stairs above screw pumps are slippery from icing condensation	Plant policy requires all operators to keep one hand free at all times to use rails.

Source: SR 85-11.

Consider Table A-3 for winter problems associated with clarifiers.

Table A-3 Winter Problems with Clarifiers

Problem	Solution
Scum line freezes	Flush out with hot water. Use sewer bag to free blockages. Install automatic flushing mechanism.
Scum trough freezes	Cover exterior trough. Break ice into pieces and remove by hand. Install automatic flushing mechanism.
Scum freezes on beaching plate	Flush off with hot water. Discontinue scum removal in winter. Shovel and hose down by hand. If adjustable, decrease exposed plate area.
Ice on beaching plate hangs up collector arm and damages mechanism	Remove skimmer during winter. Remove ice by hand.
Scum freezes on outside ring of peripheral feed clarifier	Cover clarifier.
Scum solidifies, will not flow	Use warm water to flush.
Scum freezes at center feed	Install a warm water sprayer to keep scum moving toward skimmer.
Surface icing	Remove secondary arms to prevent damage. Keep clarifiers on 24 hours/day. Remove thick ice with long- armed backhoe. Shorten detention times.
Icing in idle units	Pump units dry routinely.
Icing in gear units	Install heat tapes on drain line. Drain water in bullgear after rain and when temperature rises.

Hoses and hydrants freeze	Leave lines on. Drain lines after use.
Traveling bridge controls ice-up	Build enclosure over controls.
Icing of bus bar for bridges	Install heat guns or warm air blower.
Switches on monorakes freeze	Shut off units in snow and ice to prevent freezing.
Accumulation of snow on monorake rails stops wheels	Shut down rake during snowstorms and remove snow.
Automatic sampler freezes	Build insulated boxes heated with a 100-watt light bulb.
Waste activated sludge lines freeze	Locate lines deeper. Install proper drainage.

Source: SR 85-11.

Consider Table A-4 for winter problems associated with biological systems.

Table A-4 Winter Problems with Biological Systems

Problem	Solution
Ice buildup on surface area	Remove by hand. Run on high speed for 15 minutes. Turn off for ½ hour, allow mixed liquor to warm aerator, and turn on high speed. Steam ice off. Bump aerator on and off carefully.
Impeller icing causing ponding on fixed shroud	Remove shroud. Ice will still build up, but aerator will not be damaged.
Ice buildup on supporting columns causing rotating shroud to pond on columns	Shorten detention times; run aerators on timers.
Cooling of mixed liquor	Install timers on aerators. Use diffused air instead of surface aeration. Remove some aerator blades.
Icing in idle tank damaging structure	Fill tank 1 foot above baffle. Install small sump pump to keep surface free of ice. Exercise units regularly during sunny days. Care must be taken not to damage units. Use inner tubes to absorb ice expansion. Bubble air to prevent freezing.
Ice buildup on splash guard, electrical conduit, and walkways	Use good snow and ice removal procedures, salt. Plant policy requires operators to keep one hand free to hold railing.
Decreased removal efficiencies	Increase MCRT, decrease food-to-microorganism ratio.

Source: SR 85-11.

Consider Table A-5 for winter problems associated with disinfection problems.

Table A-5 Winter Disinfection Problems

Problem	Solution
Feed lines freeze	Enclose all storage and pumping facilities in a heated building.
Hypochlorite solution crystallizes in pumps and pipes	Keep in heated room above 65 ˚F (18 ˚C).
Surface contact chamber freezes	Cover and insulate tanks.

Source: SR 85-11.

A-5 ODOR CONTROL SYSTEMS.

Each of the odor control systems require maintenance that is based on the air flow, constituents in the odorous air streams, and site conditions. These individual factors have effect on the amount and type of maintenance that each system requires.

A-6 CHEMICAL ODOR CONTROL SYSTEM.

Based on the data collected on the operation of the chemical odor control system, cleaning the plastic media in the system may be required. The media may be replaced or acid washed. Seven to 10 years is the normal expected frequency of cleaning or replacing the media.

A-7 BIOLOGICAL ODOR CONTROL SYSTEM.

Based on the data collected on the operation of the biological odor control system, replacing media in the biological odor control system may be required. Depending on the type of media, the expected life will vary. If the media are made of natural items (e.g., soil, wood chips), the media will need to be replaced every 2 to 3 years. If the media are manmade products, the media are expected to last 7 to 10 years.

A-8 MAINTENANCE.

While maintenance requirements for all the equipment is be completed as detailed in the manufacturer's equipment manual, there are other tests and observations an operator can complete to identify problems or extend the periodicity of the maintenance requirements.

Consider Table A-6 for winter problems associated with solids management.

Table A-6 Winter Problems with Solids Management

Problem	Solution
Unable to use solids drying beds in winter; beds freeze	Cover beds.
Not able to apply solids to land in winter	Stockpile solids in winter months.
Aerobic digester freezes if blower is shut off to allow thickening by decanting	Cover tank. Decant smaller amounts more often.
Solids mixture freezes in tank	Run mechanical agitator overnight.
Ice forms on digesters	Insulate better.
Icing in gravity thickener	Run final effluent to keep hydraulic loading higher.
Solids holding tank freezes	Take offline during winter.
Solids freeze on truck	Use truck body heated with exhaust gases.
Solids lines freeze; valves freeze	Drain lines correctly. Dismantle and thaw valve. Put heat tape on lines. Increase return rates.
Holding tanks too small to last winter	Use spare clarifier of oxidation ditch.
Extensive heat loss from anaerobic digester	Improve insulation.
Operating temperature could not be reached in a new compost pile	Cover pile and insulate. Mix solids and wood chips with hot compost. Blow hot exhaust from working pile into new pile.

Source: SR 85-11.

A-8.1 Predictive Maintenance.

Predictive maintenance is maintenance completed on a periodic basis. The results of predictive maintenance are used to determine (predict) when a piece of equipment is going to fail or to discover a problem in a piece of equipment before a failure occurs. Most predictive maintenance requires that the piece of equipment be running at its design point before testing starts and during testing.

The periodicity will need to be determined by the operator based on the criticality of the component to the wastewater treatment process, ease of completing the test, treatment plant operations, and budget. As an example, an influent pump cannot have vibration testing and thermal imaging completed during the summer when the pump will not run at full deign speed for long periods of time.

A-8.2 Vibration Testing.

Vibration testing is conducted on mechanical equipment to determine bearing failure. Vibration testing is conducted on both the machine bearings and its motor bearings. The results of the test can provide operators with information on bearing wear and allow the operator to replace or repair bearings prior to the bearing failing. If the bearing were to fail, it may cause equipment damage and result in a violation to the NPDES permit. Conduct vibration testing by a qualified person to ensure that the results are accurate and the test is done consistently each time.

Measure vibration displacement in inches or millimeters. In all cases, the vibration is the measure of the amplitude of the motion from the piece of machinery. If one of the values is known, it can be converted to another using one of the two equations below:

Equation A-1. Vibration Velocity

$$v = 2 * \pi * f * d$$

Where:
v = peak velocity (m/sec or in/sec)
f = cycles per second (hertz)
d = peak displacement (mm or in.)

Equation A-2. Vibration Acceleration

$$a = 2 * \pi * f * v$$

Where:

a = acceleration (g [m/sec^2] or in./sec^2)
f = cycles per second (hertz)
v = peak velocity (m/sec or in./sec)

A-8.3 Lubrication and Wear Particle Analysis.

Lubrication and wear particle analysis is a test that provides information about the condition of the lubricant itself that is provided by a testing laboratory. The analysis provides information on the amount of chemical contamination of the lubricant, the state of the lubricant additives, the molecular condition of the lubricant, and the amount of dissolve elements in the lubricant. The analysis also provides the amount of, makeup, shape, and size of the particles in the lubricant that come from the wear of the internal machinery components being lubricated.

The results of the lubrication and wear particle analysis can help operators adjust their lubrication schedule from the manufacturer's recommendations.

A-8.4 Thermographic Imaging.

Thermographic imaging is the measure of either the temperature or the difference in temperature of both mechanical and electrical components. When thermographic imaging is used, the equipment being checked must be operated at its designed operating point. Thermographic imaging can identify poor lubrication practices on pieces of equipment and poor alignment of the equipment. In electrical equipment, thermographic imaging can identify when equipment is overloaded, there are loose electrical fittings or poor electrical connections, and other potential failures.

A-8.5 Ultrasonic Analysis.

Ultrasonic analysis is used on bearings to determine when it must be greased and how much grease to add. Ultrasonic analysis must be done several times on a piece of equipment with normal lubrication conditions to establish a baseline sound signature, which is measured in decibels (dB). When the bearings sound signature changes by more than 8 dB from its baseline signature, correct the bearing by adding grease to it. If the bearings sound signature changes by more than 12 dB, the bearing is showing an indication of deterioration.

A-8.6 Electrical Surge Testing.

Electrical surge testing is the only testing that can be done on a motor to determine if the motor is deteriorating and may possibly fail. The testing tests the motor's winding for weakness in the turn to turn, coil to coil, and phase to phase insulation. The electrical surge testing looks for faults in the motor windings themselves. A megohm test also known as "meggering" can be performed on the motor windings. The megohm test only examines the motor windings insulation quality.

A-8.7 Motor Current Signature Analysis.

Motor signature analysis is used to detect both mechanical and electrical issues in equipment. This test uses the electrical amperage draw of the motor as load changes over time to provide an early warning of equipment or motor deterioration. Start the motor current signature when the piece of equipment is new to allow for a baseline signature to be developed. Compare the motor current signature to the base line and trend to identify the deterioration of the piece of equipment.

A-8.8 Bearing Greasing.

Bearings are required to be greased on a regular basis and measure the amount of grease added in ounces or grams. Measure the grease to be pumped in as each grease gun dispenses different amounts of grease per pump. Some larger bearings require periodic cleaning out of the bearing and repacking it with grease based on the bearing manufacturer's requirements.

It is common for equipment manufacturers to direct the operator to grease the motor bearings at set intervals. Review the motor greasing frequency. Consider the following items to determine the frequency of motor greasing:

- Motor frame size
- Motor speed
- Severity of service

A-8.9 Severity of Service.

Factors that affect the severity of service are the motor's daily hours of operation, the ambient temperature of the atmosphere around the motor, and the amount of dust in the atmosphere around the motor. In general, motors that are in warmer and dustier locations require greasing more often than motors operating inside a clean and cool room.

A-8.10 Lubricants.

Lubricants come with different options and have different operating ranges. Use the lubricant that is specified in the manufacturer's equipment manual. If the operator decides to change the lubricant type, consult a lubrication engineer and the equipment manufacturer to ensure the equipment is properly lubricated to prevent equipment damage.

The viscosity of lubricating oils will change because of freezing temperatures. The operator can either change the oil to suit the expected temperature range or use heat tape or immersion-type heaters to maintain higher oil temperatures. Sometimes multi-viscosity year-round synthetic oils may be appropriate. Gear boxes tend to collect moisture and condensate, which may either degrade lubrication oil or cause corrosion.

A-8.11 Painting and Coatings.

Maintenance of coating systems in wastewater treatment plants depends upon a number of factors:

- Knowing the specific coating systems that currently exist within the plant
- Implementing an active inspection program
- Providing a good maintenance painting program

Maintenance painting operations are different than new construction painting operations. With a proper maintenance painting program, total recoating is generally atypical rather than normal. In saltwater or coastal environments, painting frequency may need to be increased.

A-8.11.1 Inspection.

Routinely inspect all coating surfaces and be observant for the first signs of coating breakdown such as rust staining and streaking, blistering of coating, peeling of coating, and other signs of deterioration. Coatings on steel substrates generally will show the first signs of failure at sharp edges such as edges of structural steel, adjacent to welds, and around threads of bolts and edges of nuts. Failures on flat surfaces take longer to develop.

In immersion service, coating failures also develop first at edges but can also develop on flat surfaces because of imperfection/s and defects. Linings in tanks and vessels are especially critical.

A-8.11.2 Chemical Storage Areas.

Most chemical storage areas will have concrete containment walls to contain potential spills of the tank. Coat containment surfaces with a suitable coating system capable of withstanding the spilled chemical. Most monolithic (bonded) coatings will mirror any cracks that may develop in the concrete. Visually inspect these areas to detect any leaks or spills through the concrete.

A-8.11.3 Material Selection.

Much of a typical wastewater treatment plant consists of cast-in-place concrete structures. With a few exceptions, concrete performs well in the environments associated with wastewater treatment plants. Other common construction materials also do well but require careful selection and maintenance to achieve long-term service life. The wastewater associated with the wastewater treatment plants is usually not extremely aggressive unless the facility receives wastewater from certain industrial operations.

Hydrogen sulfide is ever present and must be recognized, especially in the vapor areas above the wastewater surface. Where the wastewater is agitated or falls over weirs, hydrogen sulfide is released. Any condensate formed will be acidic and therefore aggressive to concrete and unprotected carbon steel.

A-8.12 Corrosion.

Perform regular inspection of the concrete and steel surfaces in these aggressive areas and take appropriate action when significant corrosion becomes evident. Corrosion of metal surfaces usually occurs faster than on concrete surfaces. Take corrective action as soon as possible.

UFC 3-190-06 contains requirements for painting and coating various components in a wastewater treatment plant.

A-8.13 Maintenance Scheduling.

Follow the manufacturer's maintenance requirements at the recommended periodicities; however, each Installation should review their periodicities and adjust based on specific Installation requirements, experiences, or other considerations such as predictive maintenance results. If the Installation cannot complete all maintenance items, consider a tiered approach in which designated higher tier maintenance items are completed first. A recommended tiered approach would include the following levels:

- Operator-level maintenance
- Tier I
- Tier II
- Tier III
- Tier IV

If a maintenance item is in a lower tier and not completed over multiple cycles, failure to complete the maintenance may cause the piece of equipment to fail. Over time, lack of completion of lower-tier maintenance items will require that those items move up on the tier list. Failure to reassign maintenance completion priority may result in the system not operating as required to meet the wastewater treatment plant's permit requirements.

A-8.13.1 Operator-Level Maintenance.

The operator-level maintenance tier comprises maintenance items that are non-intrusive and normally take little time to complete. Examples of operator-level maintenance include:

- Instrumentation cleaning
- Monitoring equipment for abnormal noise, vibration, and lubricant leakage
- Equipment performance testing

A-8.13.2 Tier I Maintenance.

Tier I maintenance includes maintenance items that must be completed as required by the various operating permits of the wastewater treatment plant. Examples of Tier I maintenance items include:

- Flow meter calibration
- Laboratory instrumentation calibration
- Maintenance items required by the NPDES permit, equipment and system warranties, and performance guarantees

A-8.13.3 Tier II Maintenance.

The Tier II maintenance level includes maintenance items that are completed to keep the equipment running or to check equipment health. Examples of Tier II maintenance items include:

- Checking or changing oil in gearboxes
- Predictive maintenance on equipment
- Changing air filters for HVAC units

A-8.13.4 Tier III Maintenance.

The Tier III maintenance level includes maintenance items that result in major changes to the wastewater treatment process or require a large amount of manpower to complete. Examples of Tier III maintenance items include:

- Cleaning aeration grid air diffusers
- Most electrical system maintenance
- Checking and replacing wear part clearances

A-8.13.5 Tier IV Maintenance.

Tier IV maintenance level includes maintenance items that are required to be completed at infrequent intervals of the equipment's operation life. Examples of Tier IV maintenance items include:

- Rebuilding a pump or blower
- Cleaning or replacing media in an odor control system
- Replacing clarifier scrappers **\1**

A-8.14 Wastewater Collection.

Cleaning and inspecting sewers assists in maintaining sewer capacity and identifying repairs that may be needed. A site-specific maintenance plan for cleaning and inspecting wastewater collection systems should be prepared to assist in maintaining sewers. Include options and procedures for cleaning and inspecting sewers in the maintenance plan. The Installation should determine cleaning and inspection schedules based on the age of the sewer, sewer condition and availability of funding. Use WEF MOP FD-6 and EPA 832-F-99-031 for sewer cleaning and inspection guidance. **/1/**

A-9 O&M GUIDANCE DOCUMENTS.

The Sacramento series are the primary technical guidance references for the operation and maintenance of wastewater treatment systems. These references provide valuable training, operating, maintenance and troubleshooting techniques. These best practice references should be available to personnel operating and maintaining the WWTP.

A-10 OPERATOR TRAINING.

There are various methods of obtaining training for certification. State regulatory agencies or Association of Boards of Certification can help. The required training can be obtained from the following locations:

- The California State University, Sacramento, has correspondence courses available that provide the basics for most state examinations and certification processes.
- Water Environment Federation has wastewater courses both in printed and computer CD-ROM formats.
- Local, state, and national trade shows may have forums that can help meet the required training for the operator certification.
- Local and state classes for operator certification
- College level classes
- Approved equipment manufactures operation and maintenance training
- Approved consultant provided training

A-11 OPERATIONS OF EQUIPMENT AND SYSTEMS.

Consider the following items as part of equipment and system operations.

A-11.1 Starting, Stopping, and Changing Equipment.

Starting, stopping, and changing equipment and wastewater treatment plant processes should be done using site-specific O&M manuals, equipment manufacturer O&M manuals, and standard operating procedures.

A-11.2 Emergency Operating Requirements.

Make emergency generators available and always fueled to above the 75% level. There needs to be enough pumps and tankage available to meet design flow. Complete repairs to equipment that prevent meeting design flow/loads as soon as possible.

There will be specific emergency operating requirements for individual WWTPs. These specific requirements should be identified in the site-specific O&M manual.

A-11.3 Equipment Calibration and Field Checking.

Conduct instrument calibration frequently to have accuracy across readings. Take measurements, flows, and concentrations twice to check the accuracy of the measuring device.

It is useful to have portable field equipment to double-check the values/readings from permanently mounted monitoring instruments as a quality check for data and treatment process control.

A-11.4 Sampling and Process Data Review.

Review sampling and process data to identify trends. These trends can be utilized by the operators to improve the operation of the WWTP. Review plant-operating parameters that includes but is not limited to DO, RAS flow, and influent flow.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA) and, in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies must contact the preparing Service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale must be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 3-240-11, *Landfills in Support of Military Operations*

Superseding: None

Description: This UFC provides guidance for planning, design, construction, and operation of landfills at contingency locations. This UFC describes appropriate practices for land disposal of non-hazardous solid waste. This UFC is applicable to contingency locations outside the United States.

Reasons for Document:

- This document provides guidance for military engineers to design and construct landfills at contingency locations or have the necessary landfill specifications available so a contracting officer can incorporate these specifications in contracts for landfill construction and operation during contingency operations.
- This document fills the need for UFC construction specifications for landfill facilities in support of contingency operations.

Impact:

- This document provides guidance that will protect force health by diverting solid waste from burn pits to landfills in contingency operations and avoid long-term health effects through best use of engineering principles.
- This document provides typical design specifications that can be tailored to fit site-specific needs and that will save repetitive costs for planning and designing landfills during contingency operations.
- This document provides guidance that will balance Service members' health and safety, environmental protection, and field-expedient practices.

Unification Issues: There are no unification issues.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

1-1.1 General.

This UFC describes waste streams generated during contingency operations in theater and provides design guidance on landfill construction. Solid waste disposal can be a significant problem. Proper planning for and management of solid waste is critical to protect the health of Service members and the environment. Improper handling and disposal of solid waste can create unhealthy working conditions and impact mission accomplishment. Generated waste, if not dealt with properly, can contaminate food and water sources, contribute to spread of disease, cause varying degrees of harm to the environment, and generate ill feelings with the host nation (HN). Experiences in Iraq and Afghanistan have demonstrated some of the consequences when waste generation is not considered early in the planning phase or when DoD does not effectively respond to problems related to waste generation or disposal. These include health concerns associated with trash burning and the residual negative environmental impacts related to base camp transfers and closures.

The extent to which the environment can directly affect military operations and the resulting need to consider environmental considerations in its plans and operations depends on the specifics of the operation, including the situation on the ground, the military objectives, and the ultimate goals of the operation. Some information on this topic is available in DoDI 4715.22, *Environmental Management Policy for Contingency Locations*. ATP 3-34.5, *Environmental Considerations*, can also help commanders make informed decisions about environmental issues during a contingency operation. The longer forces must remain in the theater of operations, the more complex environmental issues can become.

1-1.2 Future Operations.

Recent experience suggests that ongoing and future contingencies will feature large stability, security, transition, and reconstruction (SSTR) components, will involve longer stays in theater, and require forces to perform functions that have historically been managed by U.S. government agencies, international organizations, or non-governmental organizations (NGO). These factors elevate the importance of treating environmental issues more explicitly and systematically in planning, operations, and training[1].

Future operational environments will likely be complex. Local or HN waste recycling, disposal, or treatment facilities (or services) may be nonexistent or beyond reach due to proximity, security, or political considerations. Thus, the burden for waste management falls on DoD. Commanders must consider the various operational impacts of waste generation early in the planning phase and throughout each phase of the operation. Commanders must also protect their Service members from long-term exposure to

[1] Mosher et al. 2008

waste, pollution, and diseases, whether those exposures are from conditions in the base camp or from conditions endemic to the area of operations. Consequently, it will be necessary to consider more comprehensive solutions to base camp wastes, disease vectors, and health protection for all on the base camp.

1-1.3 Concurrence with Integrated Solid Waste Management (ISWM) Program.

An integrated solid waste management (ISWM) program assesses various aspects of waste management, including the collection, storage, and disposal of waste, source reduction, recycling and composting, facility management, and budgeting and financing. It identifies existing waste systems, assesses needs, and sets forth the ways to design, implement, and monitor a more effective and sustainable waste management program. (See TM 3-34.56, *Waste Management for Deployed Forces*, for more information on ISWM program development.)

Since all methods of waste disposal can affect the environment to some degree, waste minimization should be of primary importance within every operation. Commanders should continually seek to reuse and recycle waste materials. Composting is one identified option that can also reduce materials that go into the landfill. Also evaluate reducing the amount of packaging materials sent into theater. Disposal of solid waste in a landfill is an option in ISWM programs. Current UFC construction specifications for landfills are designed to meet standards in CONUS; therefore, this UFC was developed to provide the necessary guidance for landfill construction in theater operations.

1-2 PURPOSE AND SCOPE.

1-2.1 Purpose.

This UFC describes appropriate practices for land disposal of non-hazardous solid waste during contingency operations for base camps with temporary and semi-permanent construction levels. (See UFC 1-201-01, *Non-Permanent DoD Facilities in Support of Military Operations*, for construction levels.) The goal is to balance Service members' health and safety, environmental protection, and field-expedient practices. If the HN does not have adequate infrastructure for managing solid waste, it is recommended that a contingency landfill be considered when a camp population is projected to grow to more than 500, when there is potential that the life expectancy of the base camp will be two years or more, and when, depending on combatant command (CCMD) policy, there are site conditions, resources, and logistics available to construct a landfill.

1-2.2 Scope.

This UFC covers land disposal of:

- Non-hazardous solid waste as defined below
- Non-hazardous byproducts of other waste management processes

This UFC does not cover:

- Management and disposal of hazardous waste (HW)
- Management and disposal of medical waste

For the purpose of this UFC, a contingency landfill is a landfill that accepts less than 20 tons per day of waste. This quantity of waste would be the maximum expected from a camp of 2000 people. Contingency landfills will only be developed in regions that experience less than 64 centimeters (cm) (25 inches [in.]) of rainfall each year.

1-2.3 Additional Information.

Refer to TM 3-34.56 for additional information on waste management for deployed forces. Chapter 5 of the TM details information on HW and special waste. This chapter also provides information on the six-step process to develop an HW and special waste management plan. Chapter 6 of the TM provides an overview of medical waste and describes some unique requirements that must be considered in developing a plan for collecting, storing, transporting, and disposing of medical waste.

1-3 APPLICABILITY.

This UFC is applicable to contingency locations outside the United States when a landfill is required and where other alternatives such as incineration or local hauling are not feasible.

1-4 WASTE MANAGEMENT OPTIONS.

Generated waste places a significant demand on a unit’s resources. Municipal waste disposal or treatment facilities will likely be nonexistent, incapacitated, substandard, or beyond reach due to security or logistical considerations. DoD is responsible for the entire waste management process. To reduce the amount of waste generated, it is essential to employ the principles of “reduce, reuse and recycle,” i.e., to manage daily operations to reduce the amount of waste generated.

1-4.1 Open-Air Burn Pit.

A burn pit is an area designated for burning trash in open air while not using an incinerator. DoD policy prohibits the use of open-air burn pits during contingency operations except in circumstances in which no alternative disposal method is feasible (see DoDI 4715.19, *Use of Open-Air Burn Pits in Contingency Operations*). Incinerators, engineered landfills, or other accepted solid waste management practices must be used whenever feasible. When open-air burn pits are used, they will be operated in a manner that prevents or minimizes risks to human health and safety of DoD personnel and, where possible, harm to the environment.

For each contingency operation, the operational commander must develop and approve an ISWM plan. The use of open-air burn pits is not allowed unless included within this plan. For additional information on procedures and minimum requirements for an open-air burn pit, refer to Section 3 of DoDI 4715.19.

1-4.2 Incineration.

A solid waste incinerator is any DoD-approved furnace used to burn solid waste for the purpose of destruction of and reduction of the volume of waste. Incineration is a waste treatment process that involves the combustion of organic substances (e.g., paper, plastic, wood, food) in waste materials. Incineration and other high-temperature waste treatment systems can be described as "thermal treatment." Incineration of waste material converts the waste into ash, flu gas, and heat. Solid waste incinerators are maintained and operated in accordance with the manufacturer's specifications. The majority of solid waste typically incinerated includes wastes from dining and life support area facilities and other non-recyclable materials including office waste and packaging waste. Incinerator operators must maintain a daily log and, at minimum, record the time, date, and amount of waste incinerated and the primary and secondary chamber temperatures during incineration. Consult command environmental staff for current requirements on air monitoring.

1-4.3 Composting.

Composting is nature's process of recycling decomposed organic materials into a rich soil known as compost. A large percentage of solid waste is organic, like packaging materials (cardboard and paper) and waste food. Four tasks are central to the design of a solid waste composting facility: collection, contaminant separation, sizing and mixing, and biological decomposition. Composting reduces the amount of materials that must be collected, transported, and disposed of in a landfill. It will also reduce fuel costs associated with burning solid waste if wet wastes are removed from the burn pit or incinerator.

1-4.4 Recycling.

Recycling is the process of converting waste materials into reusable objects to prevent waste of potentially useful materials, reduce the consumption of fresh raw materials, and reduce energy usage by decreasing the need for conventional waste disposal. Recycling also brings economic advantages, i.e., costs associated with solid waste disposal can be reduced if recycled materials can be sold. Examples of materials that can be recycled include plastics, cardboard, wood, mixed paper, aluminum cans, other metals, glass bottles and jars, and milk and juice cartons. Materials that have been sorted for recycling need to be stored in a facility so they do not create a fire, health, or safety hazard. These materials should also be bundled or contained to avoid spillage. Since recycling relies on the local economy, options might be limited in contingency operations.

1-4.5 Landfill.

Landfills are engineered disposal sites, designed to protect health and the environment. They are permanent facilities that will be in place for a long time; they require maintenance and may require long-term monitoring. While landfills may be preferable to burn pits, they should only be constructed where no other alternative is feasible, such as incineration or local hauling.

1-5 LAWS, REGULATIONS, AND POLICY.

Regulatory compliance may not seem relevant in many contingency operations, where U.S. laws do not apply, HN laws may be minimal or nonexistent, and local environmental conditions may be degraded. It is the commander's and leaders' responsibility at each contingency location to ensure ISWM is incorporated throughout all operations to minimize the harmful effects of waste on human health, the environment, and the mission. Even though U.S. regulations do not apply to contingency operations, similar environmental considerations, as reflected in the contingency location environmental standards (CLES), on properly managing and disposing waste can be applied in the operational area, to the extent practical, without impacting the mission. In contrast, units stationed at permanent bases overseas must comply with established final governing standards (FGS) that respect local HN laws.

1-5.1 Treaties, if Applicable.

Another body of laws that affect U.S. military forces are international treaties that govern armed conflict, known collectively as Environmental Laws of War (ELOW). Various international treaties, federal policies, and U.S. military Service regulations provide direction on conducting operations by preventing certain operations (such as environmental modification as prohibited by the Convention on the Prohibition of Military or Any Other Hostile Use of Environmental Modification Techniques) and regulating others (such as cross-border movement of hazardous material regulated by the Basel Convention) (see ATP 3-34.5). According to the conventions, combatants are required to protect the natural environment against widespread, long-term, and severe damage during war.

1-5.2 DoDD 3000.10, Contingency Basing Outside the United States.

This directive establishes policy and assigns responsibilities for DoD contingency basing outside the United States. It states that it is DoD policy to pursue increased effectiveness and efficiency in contingency basing by promoting scalable interoperable capabilities that support joint, interagency, intergovernmental, and multinational partners. Use operational energy efficiently in accordance with DoD operational energy strategy and DoD directives, minimize waste, and conserve water and other resources. Minimize adverse impacts on local populations. Refer to Enclosure 2 of DoDD 3000.10 for an extensive list of responsibilities for various DoD organizations.

1-5.3 DoDI 4715.22, Environmental Management Policy for Contingency Locations.

This directive establishes policy, assigns responsibilities, and provides direction for environmental management at contingency locations in accordance with DoDD 4715.1E, *Environment, Safety, and Occupational Health (ESOH).* DoDI 4715.22 applies to all phases in the lifecycle of contingency locations, including planning and design, establishment, operation and management, and transition or closure. It establishes policy and provides oversight of a multi-DoD component work group to identify, develop, and revise the CLES as required. The CLES will include minimum environmental compliance standards and best management practices, including those that avoid or mitigate adverse effects.

1-5.4 Manuals.

For Army:

FM 3-34, *Engineer Operations*, provides overall doctrinal guidance and direction for conducting engineer activities. This FM provides information on engineer support to stability operations, which includes the task of constructing waste treatment and disposal facilities.

ATP 3-34.5, *Environmental Considerations*, serves as a guide for planners in identifying environmental-related issues as they pertain to operations and enables the integration of these issues into the operations planning process. Appendix B of this ATP provides information on international laws and treaties.

TM 3-34.56, *Waste Management for Deployed Forces*, gives guidance on planning and construction of waste management services and infrastructure. It covers expeditionary and large camps, and covers planning and roles and responsibilities.

1-5.5 DoDM 4715-05, Volumes 1–5, Overseas Environmental Baseline Guidance Document (OEBGD).

The primary purpose of DoD 4715-05G (OEBGD), composed of multiple volumes, is to provide standards to protect human health and the environment on enduring installations under DoD control outside the United States. The OEBGD is used by DoD lead environmental components (LEC) to establish and update FGS. The OEBGD establishes baseline environmental standards for installations in countries where an FGS is not required or has not been developed. While it does not technically apply to contingency locations, it still provides broad guidance on good environmental practices.

DoDM 4715.05, Volume 5, *Overseas Environmental Baseline Guidance Document: Waste*, contains definitions and criteria to ensure solid wastes are identified, classified, collected, transported, stored, treated, and disposed of safely and in a manner protective of human health and the environment. These criteria apply to residential and commercial solid waste generated at the installation level.

1-5.6 Summary.

Current policy regarding environmental issues impacts planning, design, construction, and operation and maintenance of contingency operations. DoDI 4715.22 establishes policy, assigns responsibilities, and provides direction for environmental management at contingency locations in accordance with DoDD 4715.1E and DoDD 3000.10. TM 3-34.56 provides guidance for conducting waste management operations while deployed on brigade level and below. In addition, standard operating procedures (SOP) are also available (e.g., Iraq, Afghanistan) that provide procedures for environmental compliance and guidance to the multi-national corps. These procedures are appropriate for use in the theater of operations.

1-6 GLOSSARY.

Appendix A contains acronyms, abbreviations, and terms.

1-7 REFERENCES.

Appendix B contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 PLANNING

2-1 WASTE REDUCTION.

Waste management operations involve collection, segregation, recycling, composting, reduction, transportation, and disposal of waste materials. Recycling and reuse programs should be initiated for plastics, cardboard, paper, batteries, tires, wood, aluminum cans, and other metals. This will require conducting source segregation, sorting, reuse, and a recycling program to make it effective. Sorting/source segregation of materials should be part of waste management from the beginning, even if the recycling program is not yet established. Especially sorting/segregation of demilitarized (DEMIL), HW, and medical waste must be in place from the very beginning as part of ISWM. Composting of food waste will also need to be considered, based on the size and volume of waste generated. Efforts should be made to reuse materials, such as construction materials, wood pallets, and packaging material, whenever possible. Reusable materials can be given away to locals at no cost, subject to the approval of the base commander or CCMD policy. Location of trash cans, recycle bins, and signs that explain separation of waste should be clear and simple to follow.

2-2 SOLID WASTE DISPOSAL DETERMINATION.

Following waste reduction measures, if disposal is required, determine if the HN has an existing landfill within reasonable distance with a capacity to accept additional solid waste. If the HN landfill can be used, an agreement must be developed for the terms, conditions, and requirements. If an HN landfill is not available and it is not possible to use an incinerator, identify a site that will host the new landfill. The site selection and planning processes will begin with a review of any existing environmental baseline survey (EBS) or environmental condition report (ECR); a review of local laws that might affect the construction of a landfill should also be conducted. Understanding the local geographic, geologic, hydrologic, environmental, and population conditions will significantly contribute to the planning process.

2-3 INTEGRATED SOLID WASTE MANAGEMENT PLAN

To achieve the best overall results, a camp should have an ISWM plan that identifies waste types and sources, recycling and recycling options, and safe treatment or disposal practices for all materials. At a minimum, this plan will describe the operation of the landfill, including procedures for excluding receipt of hazardous waste, PCBs, bulk liquid waste, and non-containerized liquids into the landfill.

2-4 ENVIRONMENTAL MANAGEMENT PLAN.

Develop a location-specific plan to identify potential environmental risks and associated resources needed to protect the environment and comply with applicable international agreements, DoD policy, and environmental compliance requirements, as appropriate.

2-5 DETERMINING SCOPE OF LANDFILL.

2-5.1 Primary Considerations.

There are five primary considerations when planning a landfill for in-theater operations.

- Feasibility
- Duration
- Capacity
- Sizing
- Future sizing

2-5.2 When to Construct a Landfill.

A decision by the lead Service or combatant commander to construct a landfill should be based on the definite advantages the landfill will bring to the deployed forces, whether those advantages are environmental, operational, or economical (i.e., cost-savings). Therefore, if the in-theater operations are expected to increase and a landfill is deemed necessary, a feasibility investigation should be conducted. Feasibility investigations assess projected future waste disposal demands and compare these demands with the current method of waste management. As stated in paragraph 1-6, it is recommended that a contingency landfill be considered when a camp population is projected to grow to more than 500, when there is a potential that the life expectancy of the base camp will be two years or more, and when, depending on CCMD policy, there are site conditions, resources, and logistics available to construct a landfill. The feasibility investigation should analyze and document existing conditions and final conditions; the topography at the proposed landfill site; surface drainage; quantity and location of cover material; supporting facility requirements; and recommended operational procedures. All of these aspects are outlined in this UFC.

The size of a landfill must be designed to accommodate the duration of the military operation and any future growth of the facilities it serves. The capacity of the landfill must meet the projected future demands of the base camp it is supporting. Capacity estimates should consider other waste management options such as recycling, volume reduction, and waste minimization. Equation 3-1 in Chapter 3 can be used to calculate the volume of a landfill; required area can be calculated once the landfill depth is determined based on site condition, including depth of groundwater table.

2-5.3 Waste Characteristics.

Data on the solid waste destined for disposal is needed for the accurate design of a landfill. That data includes the types of waste, amounts, and variations in delivery rates. For in-theater operations, that data can be estimated from an analysis of the population to be served and the operations conducted at a facility.

2-5.4 Mission Duration.

Consider the expected duration of the mission and nature of the operation. In addition, identify types and amounts of waste that will be generated (based on type, size, and function of units within the organization). The expected duration of the mission will determine appropriate design, performance, and construction standards. An analysis can be made of the population to be served and other major sources of solid waste.

2-5.5 Operational Methods.

The three most commonly used methods of operating a landfill are the area method, trench method, and ramp. Selecting the most appropriate method for a proposed landfill depends on local site conditions. Selection criteria, design, construction, and operation of all three methods are explained in Chapters 3, 4, and 5.

2-5.6 Operational Equipment.

Determine the types of operational equipment needed to collect, deliver, and operate the landfill. The equipment needed is determined by the projected types and estimated quantity of solid waste being disposed of in the proposed landfill. The capabilities of the equipment must be considered in evaluating factors such as access roads, grades, drainage, operation in severe climates, and feasibility of operation in a war zone. Generally, a waste-hauling truck, tracked or wheeled tractor with dozer, front-end loader, and trash blade are needed for daily operations of the landfill. A wheeled compactor and scraper also add value to the daily operations of a landfill. The specific equipment requirement will be mostly dictated by the site condition and availability of equipment in theater.

2-5.7 Closure.

Planning the closure of the landfill is a critical step when developing the design and operations of a landfill. This includes selecting the leachate collection and gas collection systems (if dictated) and final cover material as well as any maintenance that might need to be conducted after closure. Closure activities must begin soon after the last load of waste is received.

2-6 SITE SELECTION.

Landfills are site-specific and their design must take into consideration the unique environmental and land use qualities of a region. Additionally, the landfill site selection process should include careful planning that takes into account minimizing hauling distances while maximizing distances from bed-down areas and other inhabited locations in addition to locating the landfill away from living quarters, airfields, helipads, and access control points. Site selection should also consider the climate and environmental attributes of a location to ensure the landfill is properly designed to meet those conditions. The first stage in site selection is determining where a landfill should be optimally located. A landfill must be located downwind and downward from the bed-down area and dining facility. A safe distance must be maintained from all other activities of the base camp in accordance with a theater-specific SOP. In absence of theater-specific guidance, a distance of 400 meters (m) (1,312 feet [ft]) must be maintained downwind from the nearest bed-down area. Table 2-1 lists other landfill standoff distances that must be maintained[2]. No landfill should be constructed within a floodplain of major rivers, a 100-year floodplain area, or within 90 m (295 ft) of a navigable river or stream.

Table 2-1 Landfill Standoff Distances

Sensitive Areas	Distance m (ft)
Lake or pond	300 (984)
River	90 (295)
Highway	300 (984)
Public park	300 (984)
Water well	365 (1198)

2-6.2 Solid Waste Types and Quantities.

Estimate the types of waste and quantities expected for the life of the landfill operations. This estimate will determine the size of the landfill and scope of the operations.

2-6.3 Cover.

There should be a sufficient quantity of on-site soil suitable for use as cover material for the duration of landfill operations at the selected site.

2-6.4 Existing Site Utilities.

Sites with underground pipes or conduits (e.g., sewage, stormwater) must be rejected. If no other site is available, the underground infrastructure must be relocated before landfill construction.

2-6.5 Access.

Sites that can be directly accessed by existing all-weather roads are preferred. Direct routes to the landfill provide time and cost savings. Routes that use primary roads, go through residential areas, or cross major highways create safety hazards and should be avoided.

2-6.6 Agricultural Land.

If possible, locate landfills away from agricultural land.

[2] Bagchi, A. 1994

2-6.7 Airports.

All parts of a landfill complex must be located away from airports so the landfill does not pose a bird hazard to aircraft. A theater-specific SOP must be followed to identify a safe distance for the landfill site from the airports. If possible, follow UFC 3-260-01, *Airfield and Heliport Planning and Design*, which prescribes a lateral clearance zone of 152 m (500 ft) on both sides of the runway and a clear zone (CZ) of 915 m (3,000 ft) from the end of the runway with a 60-m (200-ft) approach/departure clearance. In general, for airports used by turbojet aircraft, the landfill must be 3 kilometers (km) (10,000 ft) from the end of the runway. For airports used only by piston-type aircraft, the landfill should not be closer than 1.5 km (5,000 ft) from the end of the runway. If a landfill site under consideration is within 8 km (5 miles) of any runway end, the commander or his/her representative must notify the affected airport authority.

2-6.8 Environmental Considerations.

The location of a landfill determines its level of environmental impact. Locations with features favorable to landfill design are more acceptable. Favorable features that might contribute to less-engineered landfill designs include naturally occurring clay soils, deep groundwater levels, remote or absent surface water sources, and limited surface run-off. Other environmental factors to consider are:

- Ground and surface water conditions
- Geology
- Soils
- Topographic features
- Floodplains
- Permafrost
- Cultural sites (Cultural property will be respected during armed conflict in accordance with the 1954 Hague Convention as ratified by the U.S. Senate in 2009.)
- Critical habitats of endangered species
- Aesthetic impacts

Environmentally sensitive areas such as wetlands, 100-year floodplains, permafrost areas, critical habitats of endangered species, and recharge zones of sole source aquifers should be classified as lowest-level priority for siting in-theater landfills.

2-6.8.1 Wetlands.

In theater, avoid all wetlands and wetlands buffer areas.

2-6.8.2 Unstable Areas.

Avoid karst terrain and other unstable areas.

2-7 CLIMATE.

The effects of heavy rains or snow should be considered and their effects on operations analyzed. Other factors to consider are litter problems and dust blowing from mounds of cover material. If the site is in an area where freezing temperatures will inhibit excavation, space for storing cover material needs to be incorporated into the facility. If adverse weather will disrupt operations, a landfill should not be constructed.

2-7.1 Cold Weather.

Extremely cold weather can greatly reduce the biological activity in a landfill. In areas where winter temperatures are lower than -34 °C (-30 °F), only minimal waste stabilization occurs. Frozen soil is another serious problem. In cold climates, excavate fill during the summer season and stockpile cover material to be used during the winter.

2-7.2 Hot Weather.

Extremely hot weather has no real adverse effects on landfill operations.

2-7.3 Wet Weather.

A major problem during wet weather is maintaining maneuverability of vehicles and equipment used to handle solid waste. Selecting a site that is well drained and has soil that provides adequate vehicle handling helps mitigate problems during wet weather. It may be necessary to import gravel to maintain roadways.

2-7.4 Dry Weather.

Dry weather does not cause operational problems at landfills although extremely dry weather limits the amount of biological activity taking place. Blowing refuse should be controlled by promptly covering waste materials and by erecting portable fences downwind of the working face, which is where waste is being dumped into the landfill and compaction and covering are ongoing.

CHAPTER 3 DESIGN GUIDELINES

3-1 GENERAL.

The proper design of a landfill that is adequate to the conditions in a theater environment is a challenging task because every site location is different and, in most cases, unfamiliar to the designer. An appropriate design that meets the site-specific need for disposal of solid waste generated at the contingency base while protecting human health and environment is the key. If needed, add additional protective measures, depending on site-specific requirements, topography, and geology and if required by the combatant commander. As a basis for the design of the landfill, review available information including, but not limited to, topographic maps, geological information, floodplain area, wetlands, faults, seismic impact zones, unstable areas, and surrounding area land use, including airports and helipads in the vicinity. In addition, verify the contingency operation cooperates with HN officials where applicable, to the extent possible in the ISWM planning process. Important factors to consider while designing the landfill are:

- Contingency operations
- Number of personnel
- Security of forces leaving the secured contingency operation
- Vehicles used for hauling waste
- Access road to the landfill
- Land area to be used for landfilling
- Landfilling method: area method, ramp method, or trench method, depending on the terrain
- Surface drainage to divert runoff water
- Protection of surface and groundwater
- Landfill gas and leachate

3-2 HEALTH AND SAFETY CONSIDERATIONS.

3-2.1 Landfill Workers.

Landfill workers face health and safety risks throughout the life of the landfill and even into closure. To minimize risks, depending on site-specific conditions, the design of the landfill will take into consideration the following hazards:

- Construction hazards
- Traffic accidents (e.g., rollovers during ramp or trenched operations)
- Heavy equipment operations during construction, operation, and closure
- Workers’ exposure to:

- ○ Waste material
- ○ Dangerous gases
- ○ Unknown chemicals
- ○ Disease vectors, including birds
- ○ Austere environment
- ○ Noise

Appropriate personal protective equipment (PPE) must be provided to landfill workers as the contingency situation permits, including clothing, steel-toe working boots, air-filtering headgear, and puncture-proof hand gloves.

3-2.2 Neighboring Inhabitants.

A landfill design that does not threaten the health and safety of nearby inhabitants in general precludes the following:

- Pollution of surface and groundwater from landfill-generated leachate
- Air pollution from dust or smoke
- Infestation by rats, flies, or other vermin
- Other nuisance factors, such as odors and noise
- Fires and combustion of refuse materials
- Explosives hazards from methane gas generated within the landfill
- FOD (foreign object debris) and bird strike hazard to aircraft
- Uncontrolled traffic from landfill construction/operation

3-3 SITE LAYOUT.

3-3.1 Road Access.

Although the siting of the landfill is influenced by many factors and in many cases will be dictated by the contingency location and mission type, the design must take into consideration the convenience and safety of the collection vehicles. The landfill must be easily accessible by an all-weather road with the shortest hauling distance possible considering other factors. The access road plan must also be aligned with existing terrain to minimize new construction and avoid the path of the natural drainage system.

3-3.2 Buffer Zones.

A buffer zone is the separation distance (both horizontal and vertical) between the landfill and any sensitive areas including, but not limited to, drinking water sources, Service members' bed-down areas, critical habitats, and historic and archeological sites. Buffer zones provide several benefits, including:

- Preventing migration of contamination off-site from accidental release
- Protecting drinking water sources
- Minimizing health effects on Service members and other contingency location residents

3-3.3 Fencing.

The landfill design may include a perimeter fence. The contingency location standard must be followed for type and height of the fence. In absence of a contingency standard, at a minimum, a 1.8-m (6-ft) -high chain link fence may be installed to catch blowing litter, prevent unauthorized landfill use, and maintain security.

3-4 LANDFILLING METHODS.

Generally, there are three methods used for solid waste landfilling—trench/cell method, area method, and ramp method—depending on site topography, geology, availability of land, groundwater level, availability of cover material, and any other site-specific condition.

3-4.1 Trench Method.

The trench or cell method is suited where the groundwater table is deeper and excavated soil can be used as cover material (Figures 3-1 and 3-2). Excavated trenches can be square or rectangular, depending on the site-specific condition and soil types, and will be constructed as mission requirements dictate to minimize earthwork. Trench cells should be separated by a 1- to 1.5-m (3- to 5-ft) path to ensure wall stability, surrounded by a movable fence to prevent littering caused by blowing waste. Table 3-1 lists recommended design criteria for trench cells. It is especially important in contingency operations to only dig as the mission requires to economize earthwork, considering the demand of solid waste generation.

Figure 3-1 Layout of a Trench Landfill

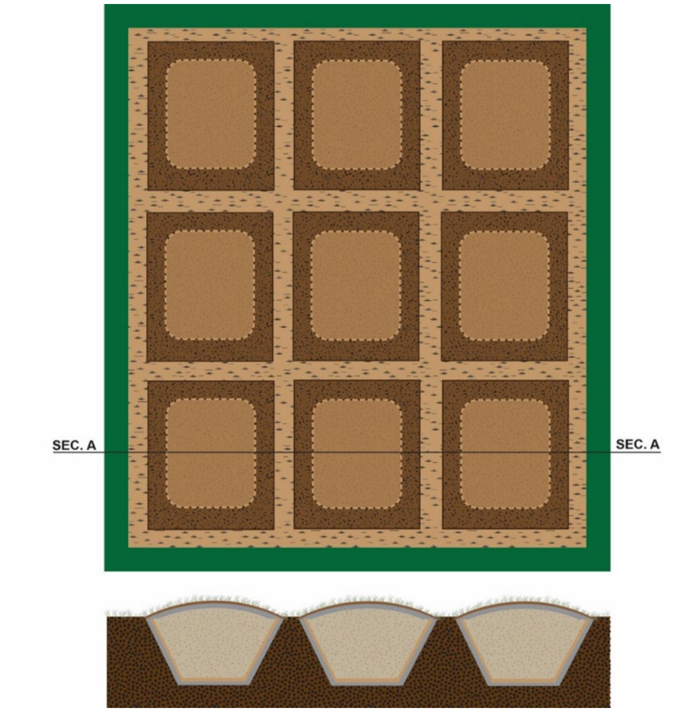

Figure 3-2 Trench Method of Burying Waste

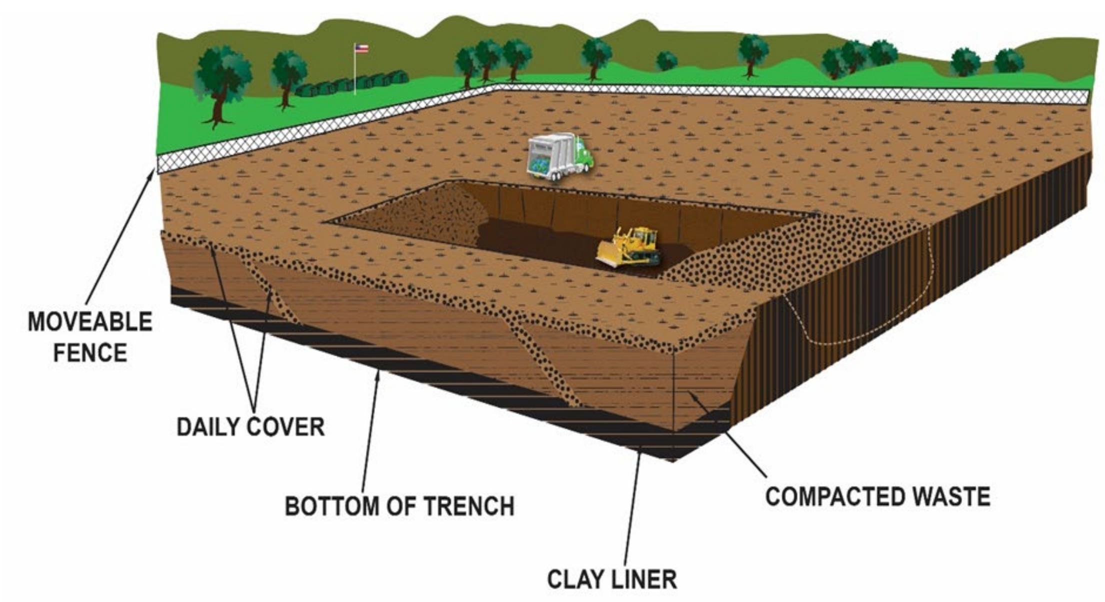

Table 3-1 Trench Landfill Design Factors

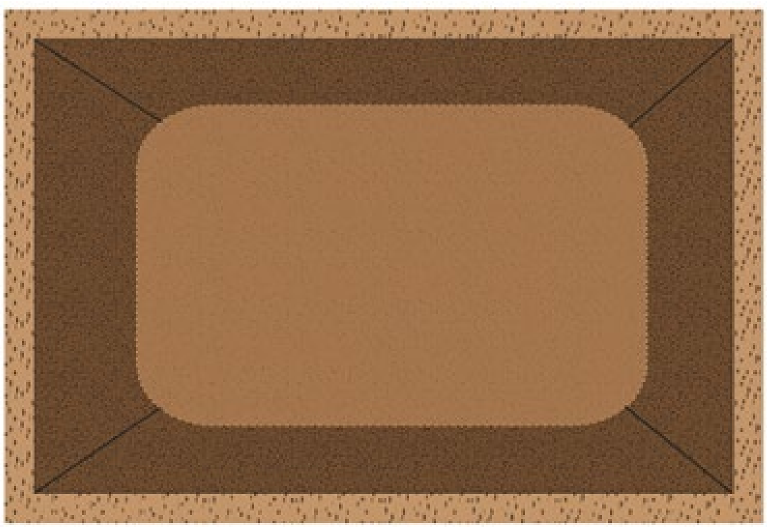
Parameter	Cell Criteria
Daily waste generation	7.2 kg (16 lb) per person[3]
Side slope	1.5 – 3:1
Depth (max)	6 m (20 ft)
Width (max)	6 m (20 ft)
Width (max)	As needed
Compaction	356 kg/m^3 (600 lb/yd^3)

Source: EM 1110-3-177

3-4.2 Area Method.

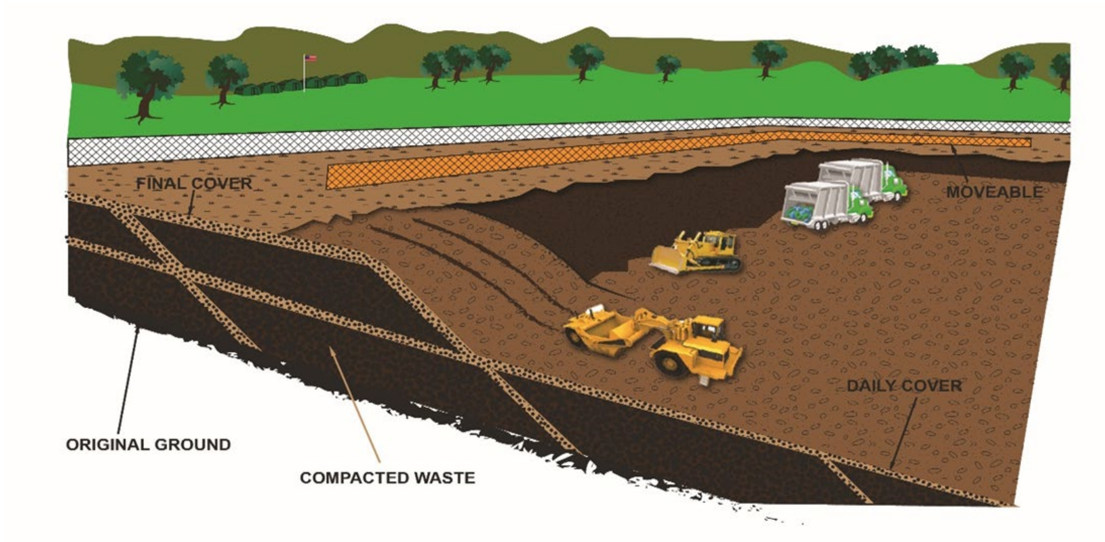
The area method is used where the terrain is not suitable for deep digging due to the presence of a high groundwater table or when encountering bedrock. Depending on the site-specific condition, the area method may or may not require excavation to meet the requirement to maintain a 150-cm (59-in.) buffer zone between the bottom of the landfill and highest seasonal groundwater level (Figures 3-3 and 3-4). However, the cover material may be hauled in or be collected from a nearby borrow pit. Using this method, the total area required for the landfill is estimated based on the current contingency population and the operational life of the landfill, based on the need to serve the current and projected contingency population.

Figure 3-3 Layout of the Area Method



[3] Cosper et al., 2013

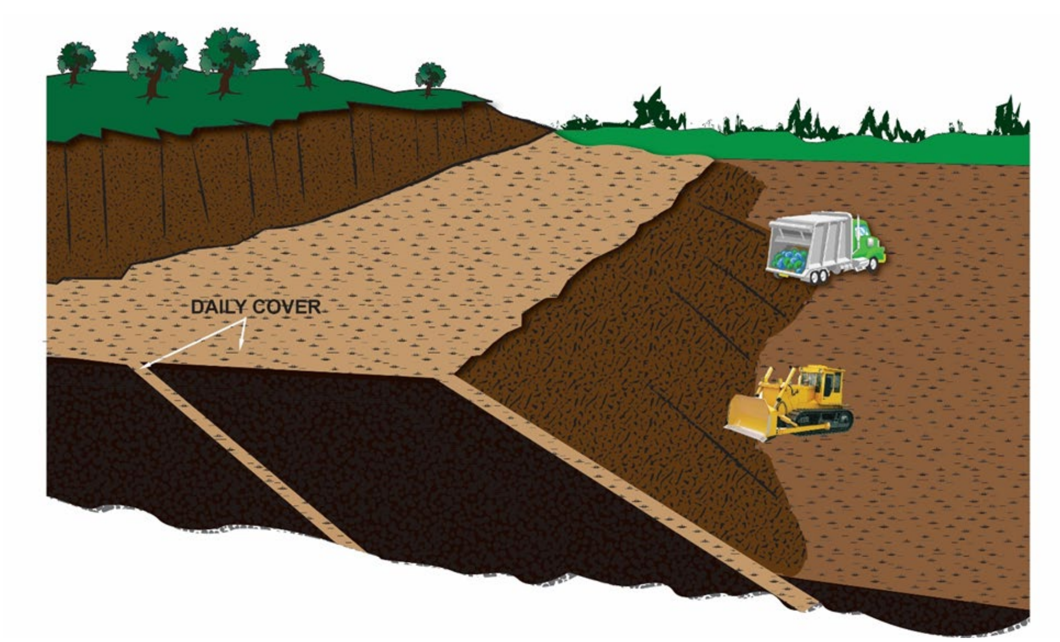
Figure 3-4 Area Method of Burying Waste



3-4.3 Ramp Method.

The ramp/canyons or ravines method is suitable for mountainous or hilly areas or rolling land with progressive slope. Old borrow pits/quarries also fit this category. When using this method, cover material is obtained from the daily working face and compacted. The procedures to place daily waste and compact it may vary, depending on the site condition. Site geology and hydrogeology and the need to control surface drainage, place leachate, and collect gas (if required) may further complicate site development in a contingency situation using the ramp method; therefore, landfilling using the ramp method is the least-preferable method in a contingency situation.

Figure 3-5 Ramp Method of Burying Waste



3-5 LANDFILL DESIGN.

3-5.1 Capacity.

Daily per capita solid waste generation must be known or estimated to calculate the required landfill volume. In current theaters, daily per capita solid waste generation varies from 4.5 to 9 kilograms (kg) (10 to 20 pounds [lb]), depending on contingency site locations and time of the year. However, for simplicity of the design for a contingency landfill, a total of 9 kg/day/capita (20 lb/day/capita) solid waste generation is recommended to be used as the planning factor to calculate the number of tons to be disposed of at a proposed landfill. Appropriate compacting equipment may not always be available in a contingency situation; therefore, a lower value of 240 kg (529 lb) of waste per cubic meter (m^3) (35 cubic feet [ft^3]) of density is recommended to calculate the total volume required for a landfill. The following equation can be used to calculate the required volume of landfill space for any size population.

Equation 3-1. Required Volume of Landfill Space

$$Q = Peck/d$$

Where:
Q = cubic meter (m^3)/year
P = population of the base (person)
e = ratio (cover material to compacted solid waste, 1.25)
c = per capita waste generation rate, kg/day/person
k = number of days in a year, 365 day/year
d = compacted waste density, kg/m^3

For example, a base with a population of 2,000, including Service members and contractors, will require a landfill space of about 34,000 m^3 (1,200,699 ft^3) per year.

P = 2,000
e = 1.25
c = 9 kg/day
k = 365 day/year
d = 240 kg/m^3
Q = (2,000 x 1.25 x 9 kg/day x 365 days/year)/240 kg/m^3 = 34,218 m^3/year

3-5.2 Landfill Liners.

Solid waste landfills require a lining system installed on the side slopes and floor of the landfill to provide a protective layer for the environment, including the soil and surface and groundwater. The selected lining system must be compatible not only with the expected waste to be disposed of but also the surrounding area. Typical lining systems are constructed of either compacted clay or a synthetic material such as high-density polyethylene (HDPE). If a locally sourced natural clay of low permeability is not available and a synthetic liner cannot be obtained and installed, landfilling should not be considered as an option for solid waste disposal.

3-5.2.1 Compacted Clay Liners

Constructing the landfill liner from a natural clay (i.e., clay, silty clay, clayey silt) is most economical and advantageous for contingency locations. This preferred option allows the use of locally available material for construction of the liner. Laboratory measurements, including particle size and Atterberg limits, should be conducted to investigate the suitability of the local soil as the liner material prior to constructing the liner. The constructed liner should have a hydraulic conductivity of less than or equal to 1×10^{-9} meters per second (m/s) (3.9×10^{-8} inches per second [in./s]). The total thickness of the liner should be no less than 1 m (3 ft), placed in 250-millimeter (mm) (10-in.) compacted lifts. Table 3-2 lists recommended design criteria and soil specifications.

Table 3-2 Specification for Clay Liners

Criteria	Value	Standard
Liner thickness	1 m (3 ft)	
Lift thickness	250 mm (10 in.)	
Hydraulic conductivity	1×10^{-9} m/s (3.9×10^{-8} in./s)	ASTM D5084
Soil specifications		
% passing No 200 sieve[4] Clay content	> 50% > 10%	ASTM D2487
Atterberg limits:[5] Plasticity index Liquid limit	 10% to 30% > = 30%	ASTM D4318

3-5.2.2 Synthetic Liners

If site conditions do not favor the use of a compacted clay liner, the use of a synthetic liner should be investigated. The manufacturer of the synthetic liner must be consulted regarding the compatibility of the liner to the waste, soil conditions, and the potential extreme weather conditions present in theater as well as the possibility for delivery and support of the installation of the liner at the site. It is recommended that the synthetic liner have a thickness of 1 to 2 mm (40 to 80 mil).

The subsurface of the soil will need to be carefully prepared and free from rocks to prevent damage to the liner. A leachate collection system will also be required for all synthetically lined landfills. Contact your Service-specific subject matter expert for support in leachate collection system design.

[4] Daniel and R. M. Koerner 1993 (EPA/600/R-93/182)
[5] Ibid.

3-5.3 Final Cover.

The final cover of the landfill consists of 45 cm (18 in.) of compacted earthen material with a hydraulic conductivity less than 10^{-7} centimeters per second (cm/s) (10^{-7} 3.937 in./s) with 15 cm (6 in.) of earthen material capable of sustaining native plant growth and be graded with 2 percent slope top to form a crown. The landfills must be kept as dry as possible to minimize leachate and gas formation. To minimize infiltration of rainwater into the landfill, the final cover must not be less permeable than the bottom liner. In accordance with EM 1110-3-177, *Sanitary Landfill - Mobilization Construction*, slopes longer than 7.5 m (25 ft) may require additional erosion-control measures, such as construction of horizontal terraces. The final soil cover on a completed landfill disposal facility must be seeded or otherwise vegetated to minimize erosion.

3-5.4 Ultimate Use of a Landfill Site.

It is up to the combatant commander (CCDR) to decide how the land of a closed landfill will be used once it is closed in accordance with the closure plan. Typically, a closed landfill is off limits to heavy vehicles. Also, other agreements with the HN like a SOFA may play a critical role in decisions regarding the ultimate use of a closed landfill site. A closure plan must be developed early in the life of the landfill—potentially during the design or site development phase.

3-5.5 Access Road.

An access road must lead to the main access control point of the landfill from the public road system. The road must be capable of carrying the load of the collection trucks in all weather conditions and should consist of a minimum of two lanes, 7.5 m (25-ft) wide, for two-way traffic. The slope of the road should be no more than the design specification of service vehicles or any other equipment that will use the road. The access road may also lead to the vicinity of the working area; however, the access road should not cross completed cells.

Secondary or branch roads are used to deliver wastes to the working face from the access road due to the fact that working faces are continuously changing. A secondary or branch road is temporary and will be used only until the area or cell is filled. Therefore, a secondary or branch road can be constructed by compacting natural soil and topping it with gravel, crushed stone, crushed concrete, or asphalt binder, depending on the site condition and availability of the material.

3-6 LEACHATE CONTROL.

3-6.1 General.

Landfill leachate is the liquid that percolates through the strata of solid waste deposited in the landfill. The source of water to form leachate comes from either infiltration of water through the refuse or groundwater movement through the landfill. Landfill refuse will absorb a certain amount of water and remaining water will percolate through the liner out to the environment. If the landfill is located on or near a drinking water source then management of leachate is critical to protect both surface and groundwater.

3-6.2 Composition of Leachate.

Table 3-3 lists characteristics of common leachate constituents from a typical municipal solid waste landfill[6]. The composition of the leachate can vary considerably based on the type of waste buried, amount of infiltration, and age of the landfill. The composition of the leachate varies from landfill to landfill and mostly depends on what type of waste is buried in the landfill. A non-hazardous solid waste landfill will produce leachate mostly consisting of organic content (carbon and hydrogen).

Table 3-3 Leachate Characteristics and Average Values of Common Constituents

Constituents (in mg/L except pH)	Average Concentration in Newer Landfills (in mg/L except pH)	Average Concentration in Older Landfills (in mg/L except pH)
pH	6	8
Biological oxygen demand (BOD_5)	13,000	180
Chemical oxygen demand (COD)	22,000	3,000
Calcium	1,200	60
Iron	780	15
Ammonia	740	740
Total phosphorus	6	6
Chloride	2120	2120

3-6.3 Leachate Collection.

A landfill carefully constructed using a clay liner should not require a leachate collection system. The landfill site should be carefully selected to ensure the bottom of the landfill is 1.5 m (5 ft) above the highest seasonal groundwater level and not located on top of a groundwater aquifer or nearby surface water that serves as a source of potable water for local inhabitants. Note that geotechnical expertise is required to make this determination.

3-6.4 Leachate Treatment.

When landfill leachate is collected, it should be treated onsite in a wastewater treatment lagoon or wastewater collection system. If onsite treatment is not available, offsite treatment of the collected leachate should be considered. In an arid region, build an evaporation bed for disposal of collected leachate. Excavate the top 7.5 cm (3 in.) of the evaporation bed quarterly and use as daily cover in the landfill. In other regions or in

[6] Kjeldsen et al. 2002

any other situation, discharge leachate to the local municipal wastewater plant, with prior approval. Final disposal of the leachate through a contractor should not be considered until all the options described above are evaluated.

3-7 METHANE GAS CONTROL.

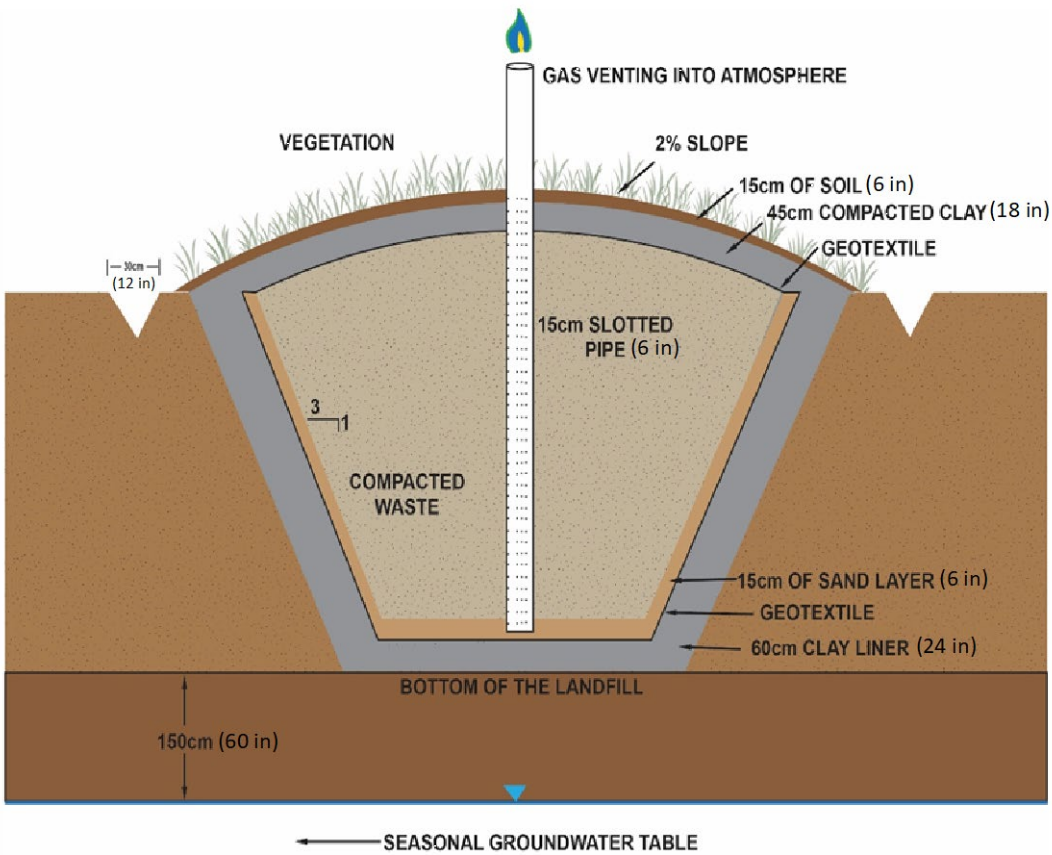
3-7.1 Production.

Methane gas production in a landfill is part of the natural process. Initially, the waste decomposes aerobically, depletes the available oxygen in the refuse, and produces carbon dioxide. Later in the process, in absence of oxygen, an anaerobic condition is created and methane gas is produced. Carbon dioxide and methane are two major gases produced from the decomposition of solid waste in landfills. The volume of gas generated depends on the quantity and quality of the waste disposed. Minimization of gas production must be the goal of the landfill designer. Gas reduction can be accomplished by controlling moisture in wastes. Anaerobic bacteria require nutrients and moisture to produce methane gas. Consider minimizing infiltration of runoff water into the solid waste through better compaction and slope, which will reduce gas generation. The drier the waste, the less amount of gas will be produced. Methane gas collection should not be the goal in a contingency situation unless otherwise directed by the CCDR.

3-7.2 Gas Disposal.

Consider a system to vent gas to the atmosphere through passive venting. Install a venting pipe with a perforated bottom through the waste depth at time of landfill closure up through the clay liner of the landfill to release gas into the atmosphere. One vent per 7,645 m^3 (10,000 cubic yards [yd^3]) of waste or approximately one vent for every 1,400 m^2 (⅓ acre) of land area may be needed to release gas into the environment. See Figure 3-6 for diagram. An observation monitor may be used at the landfill boundary to monitor methane concentration. The methane concentration should not exceed the lowest explosive limit (LEL) of 5 percent in facility structures on the landfill perimeter or at the landfill property boundary. The preventive medicine (PM) team should monitor LEL or any other health effects of landfill gas at least quarterly.

Figure 3-6 Design for Passive Gas Venting



3-8 STORMWATER CONTROL.

Controlling run-off water at a landfill site is critical to prevent environmental contamination and damage to the landfill structure. Specifically, runoff water can carry siltation to the working face of the landfill, add additional moisture to the refuse, and cause excessive leachate and increase gas generation. The landfill final cover must be compacted and sloped to the maximum extent to prevent infiltration of precipitation and minimize leachate and gas generation. The final soil cover on completed portions of the landfill must be seeded or otherwise vegetated to minimize erosion. A stormwater control system must be in place to prevent surface water run-on discharge into the working face of the landfill using berms, dikes, or ditches. Such structures must be designed to protect the landfill from a 24-hour, 25-year storm.

3-9 SUPPORT FACILITIES.

Support facilities required for support of landfill operations will vary, depending on contingency location, operation of the landfill, and availability of resources. The requirement will be different if a landfill is operated by Service members versus operated by a contractor. For example, if the landfill is contractor operated, a scale will be required if the contract is based upon the quantity of the disposed solid waste. The facilities described in the following sections may be required to operate and maintain a landfill.

3-9.1 Administration Facility.

A building or semi-portable containerized unit with a sanitary system will be required on the perimeter of the landfill to manage and run day-to-day operations of the landfill.

3-9.2 Control Facility.

A control facility should be located at the entrance of the landfill at a strategic location for truck inspection. Any unwanted materials should be denied entry at this point.

3-9.3 Sort and Separation Buildings.

All solid waste must be brought to a central location for manual sort and separation before going to the landfill. A manual sort and separation must be conducted to remove any sensitive materials such as ammunition even if the refuse is source separated.

3-9.4 Truck Scales (If Required).

If there is a need for the waste to be weighed, a truck scale must be located next to the control room.

3-9.5 Utilities.

Power, potable water, shower, and latrines are recommended for the landfill workers, as appropriate. A fire hydrant or other means of fire control should be available near the landfill.

3-9.6 Processing Equipment.

An equipment shed or facility should be centrally located for all equipment used for major operations involved in spreading waste after dumping, compacting waste, and spreading and compacting daily and final cover. Generally, a front-end loader, waste transportation truck, dozer, and compactor are needed for landfill operations. The dozer can serve as a compactor.

This Page Intentionally Left Blank

CHAPTER 4 CONSTRUCTION

4-1 GENERAL.

Engineering plans will be developed based on technical specifications following the design criteria in Chapter 3. The first cell and half of the second cell will be excavated at the outset of the project, which minimizes the amount of initial excavation. As one cell is filled with waste, the next cell will be partially excavated; the excavated soil will then be used to support construction of the cap system over the filled cells. This process will continue throughout the life of the landfill.

4-2 TRENCH METHOD.

Before excavation, the area for the landfill should be cleared of all trees, shrubs, and grass. The topsoil should be removed and stockpiled for future use. Excavation using heavy equipment will follow the specifications identified in the engineering plans. The landfill cell should be sufficiently over-excavated to accommodate the compacted clay liner. Throughout the excavation process, rocks, gravel, and other soil and materials not suitable for the landfill should be removed.

During the excavation process, soils should be segregated and stockpiled based on their properties, paying close attention to segregate the soil layer identified in the technical specifications to be used for the clay liner. Prior to the installation of the liner, clay, or synthetic, the subgrade should be free from large clods and soft spots.

Trenches should be aligned perpendicular to the prevailing wind; this orientation can greatly reduce the amount of blowing litter. Refer to Figure 3-1 for layout of the trench method and Figure 4-1 for construction and operation of the trench and area methods of landfill.

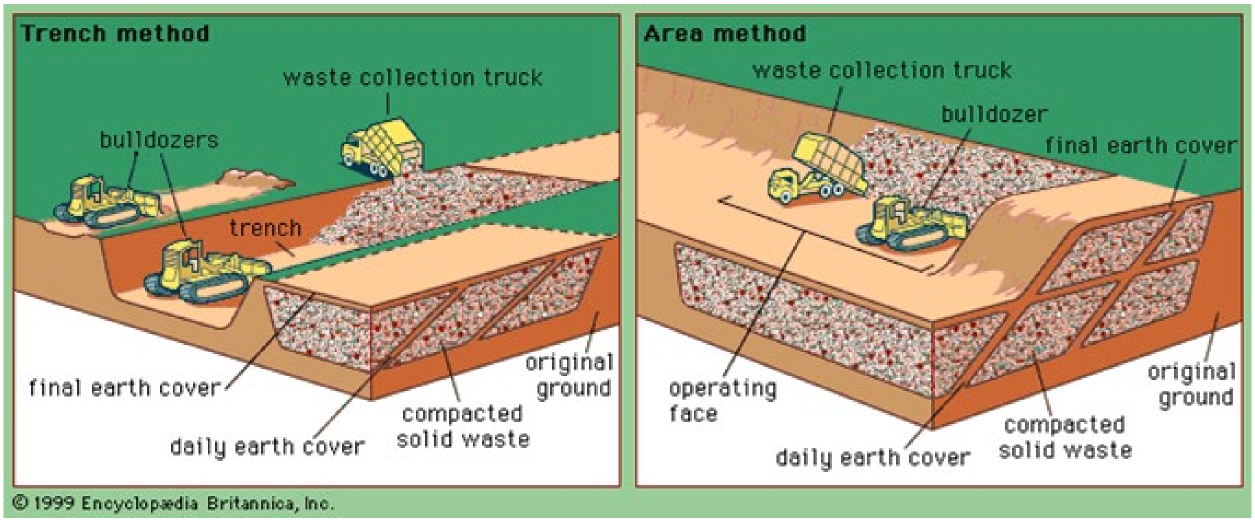
4-3 AREA METHOD.

The area method is used when the terrain is unsuitable for the excavation of trenches in which to place the solid waste and/or when the groundwater table is close to the ground surface. In this method, the waste is spread and compacted on the natural surface of the ground and cover material is spread and compacted over it. The area method is used on flat or gently sloping land and requires the least excavation. Daily cover soil may be available onsite or it may be hauled in and stockpiled from offsite sources. The filling operation is usually started by building an earthen levee against which wastes are placed in thin layers and compacted. The length of the uploading varies with site conditions and size of the operation. The width over which the wastes are compacted varies from 2.5 m to 6 m (8 ft to 20 ft), depending on the terrain (see TM 5-634, *Solid Waste Management*, paragraphs 4.2.7.2 and 4.2.7.3).

4-4 RAMP METHOD.

In this method, solid wastes are placed and compacted as described for the area method and partially or wholly covered with earth scraped from the base of the ramp. This technique makes a pit in which to place the next day’s waste. Additional soil must be hauled in as in the area method. Due to the increasing costs and problems associated with obtaining usable cover material, the use of the ramp method must be based on an economic feasibility study and may not be a suitable method for a contingency operation.

Figure 4-1 Trench and Area Methods



The designer of a landfill should prescribe the method of construction and the procedure to be followed for solid waste disposal, as there is no “best method” for all sites. The method selected depends on the physical conditions and the amount and type of solid waste to be handled.

The cell is the building block common to both the trench and the area method. All solid waste received is spread and compacted in layers within a confined area. The dimensions of the cell are determined by the volume of the compacted waste, which in turn depends on the density of the in-place solid waste. Cells should be divided by berms or other means and stormwater should be eliminated from the working portion of the landfill.

4-5 CONSTRUCTION PRACTICES.

There are several important things to consider during construction.

- Depending on site-specific conditions, compacted clay is recommended to use as liner material
- All soil and layers on waste must be pushed ahead of equipment as operations progress. Even foot traffic should be kept to a minimum on liners.
- A good access road must be provided and maintained in the trench, with additional subbase installed.
- Access roads must be designed to support the anticipated volume of truck traffic.

- Grades should not exceed equipment limitations.
- If membrane liners are used, it is noted that they are highly susceptible to expansion and contraction during temperature changes and must be laid in such a way as to avoid stress on the seams.
- Liners should be held in place by anchor trenches, sand bags, or soil cover.
- Anchor trenches are commonly used at the top of the side slopes but should not be firmly compacted.
- It is better for the liner to slip slightly than to cause stress.
- If it is anticipated that a liner will be excavated and extended to cover a new cell at a later date, a minimum of 1.5 m (5 ft) edge of liner material should be protected to provide a clean, smooth surface for future seaming.
- Seaming of wet membrane surfaces is not allowed.

4-6 CONSTRUCTION QUALITY ASSURANCE.

The construction quality assurance program should describe expected performance by the closure contractor, such as removal or demolition of onsite structures, installation of fencing, repair or construction of sediment ponds, litter pick-up, etc. All piping systems (if any) and compacted clay liner must be inspected. If a membrane liner is used, the construction contractor must be required to submit field installation directions for the flexible membrane liner, in addition to manufacturer quality control guidelines. In addition, the gas generated within the landfill should be monitored. The quantity of gas generated depends on waste volume, waste composition, and time since deposition of waste in the landfill. Gas pressure, stress on vegetation, and toxicity of the gas are some of the venting issues that should be considered. Passive or active venting systems can be installed, which consist of a series of isolated gas vents.

This Page Intentionally Left Blank

CHAPTER 5 OPERATION AND MAINTENANCE

5-1 LANDFILL OPERATIONS.

This chapter provides information to guide landfill construction and operation. Landfill operating procedures are determined by many site variables. The operational plan provides the landfill's technical details and procedures for constructing various engineered elements. The landfill could potentially be operated for months to years as needed during the contingency operation; therefore, personnel need to consult the plan to ensure long-term conformance. If necessary, methods can be used to extend the useful life of a landfill. Such methods include reducing the volume of materials before placing them in landfills and finding more efficient methods for depositing waste in landfills. Methods of operating a landfill could have an effect on landfill design; therefore, the desired method of operation should be reviewed before design commences.

5-1.1 Restrictions.

In general, only wastes for which the facility has been specifically designed will be accepted for disposal. Other waste types may be accepted if it has been demonstrated that they can be satisfactorily disposed of within the design capability of the landfill or after appropriate modifications have been made.

5-1.2 Cover Requirements.

Volume requirements for cover material depend on the surface area of waste to be covered and the thickness of soil needed to perform particular functions. Cell configuration can greatly affect the volume of cover material needed; therefore, the surface area needed should be kept to a minimum. Most soil materials can satisfy the purpose of cover soil. However, if minimization of infiltration is necessary, relatively low-permeability cover material should be used and placed at the steepest allowable grade to encourage runoff. Low-permeability soils will remain effective only if the soil has a low shrink-swell potential or if the soil moisture can be maintained to prevent cracks from shrinking and swelling. Design specifications in Chapter 3 should be followed for placing cover material. In addition, cells that will not have additional wastes placed on them for three months or more should be covered with 30 cm (12 in.) of cover material. Cover material minimizes fire hazards, reduces odors, controls blowing litter, and discourages scavenging. Covers also reduce exposure to birds, insects, and rodents, which can transmit human disease.

5-1.3 Working Face.

The working face is an area of active waste placement. The slope of the working face controls area to volume of the landfill and compaction of waste. The daily and intermittent cover should be obtained from the adjacent cell under construction. The waste should always be placed at the toe of the working face. Uncompacted waste will be spread in layers no more than 1 m (3 ft) thick before compacting. Once compacted, another layer of waste can be added and compacted so the waste cell will be several meters/feet thick before the daily soil cover is added. The working face should have a 20 percent to 30 percent slope and be as narrow as feasible to accommodate the number of trucks using the landfill.

Several layers may be compacted on top of one another. Each layer of waste may be spread with a thickness of no more than 0.5 m to 1 m (1.5 ft to 3 ft) and then compacted. The compacted waste occupies about one-quarter of its original loose volume. At the end of each day's operation, the waste is covered with a daily layer of 15 cm (6 in.) soil to eliminate windblown litter, odors, and insect or rodent problems. Thus, one cell contains a daily volume of compacted solid waste and soil cover. There are three basic methods of burying the waste: trench, area, and ramp. All three methods involve shaping one day's waste into a cell by spreading and compacting it in layers. Chapter 3 provides design specifications for these methods.

5-1.4 Entry Control.

Public access to landfills must be controlled by artificial and/or natural barriers to prevent unauthorized vehicular traffic and illegal waste dumping. A fence can be used to control or limit access. A wooden fence may be used to screen the operation from view. Litter fences or movable fences are used to control blowing paper in the immediate vicinity of the working face. Generally, trench operations require less litter fencing as the solid waste tends to be confined within the walls of the trench. At a windy trench site, a 1.5-m (5-ft) fence will usually suffice. When blowing paper is more of a problem in an area operation, higher litter fences are often needed. Gates that can be locked when the site is unsupervised will also control access.

5-1.5 Prohibited Items.

In general, only wastes for which the facility has been specifically designed should be accepted for disposal. Specific waste types that have chemical, biological, or physical characteristics that are not compatible with disposal site design, location, or operation; that pose an unacceptable environmental or health effect; or pose a threat to the safety of personnel or users of the facility should be prohibited from acceptance for disposal. A container holding liquid wastes cannot be placed in a landfill.

There must be a systematic process to exclude unauthorized wastes from the landfill. This will include:

- Random inspections of incoming loads
- Records of inspection
- Training for operators
- Notifying the chain of command if hazardous waste, PCBs, bulk liquids, or non-containerized liquids are discovered

5-1.6 Landfill Inspection Program.

One of the most important considerations is to design the system to facilitate inspection and maintenance. There should be access to all parts of the system to facilitate inspection. The landfill should be inspected for signs of erosion, cracking, or sloughing. The landfill should also be inspected for birds, insects, and rodents. Ensure entry roads are safe and provide all-weather access. Chapter 3 outlines procedures for operation and maintenance of leachate and landfill gas.

5-1.7 Groundwater Monitoring.

The groundwater around the perimeter of the landfill must be monitored, at least quarterly, to ensure the landfill is not leaking. It requires an expert to determine the number and location of groundwater wells to install and monitor. Table 3-3 lists some constituents that could signal the presence of leachate. Values must be compared to background groundwater levels.

5-2 OPERATING RECORDS AND CONTROLS.

The landfill operating record must be maintained and must include the types and amount of waste being buried, a topographical map, and documentation of the dimensions of the area being used for landfill.

This Page Intentionally Left Blank

CHAPTER 6 CLOSURE

6-1 FINAL COVER.

Installing the final cover is as important as installing the liner at the base of the landfill. The main purpose of the final cover is to minimize the infiltration of water from precipitation or surface runoff; therefore, the final cover should be installed in the shortest possible time. As outlined in paragraph 3-5, the final cover of the landfill consists of 45 cm (18 in.) of compacted clay with a hydraulic conductivity less than 10^{-7} cm/sec ($4x10^{-8}$ in/s) plus 15 cm (6 in.) of earthen material capable of sustaining native plant growth; the final cover must be graded with a 2 percent slope at the top to form a crown. The clay liner compaction should be done at optimum moisture with uniform distribution of moisture. A clay cover should be installed when each cell of the landfill is completed. Restrict the travel of heavy equipment over the closed landfill once the final cover installation is complete.

6-2 MAINTAIN FENCES.

A security fence should be maintained at the closed landfill to control or limit access and discourage vandalism and trespassing. Digging by unauthorized personnel may compromise the integrity of the landfill cover and may initiate erosion of the final cover.

6-3 SIGNS IN LOCAL LANGUAGE.

Warning signs must be posted at the perimeter in both English and the local language, with a letter size in compliance with the contingency location standards. At a minimum, the sign should say “Warning: Landfill - No Unauthorized Access.” In addition, the sign should state the landfill closure date if the landfill is closed.

6-4 POST-CLOSURE CARE.

A properly designed and constructed landfill should require minimal post-closure maintenance. It is important to periodically inspect the cap for integrity and erosion. A closure plan must be prepared outlining the necessary steps to close a landfill unit, especially the installation and maintenance of the final cover. The closure plan must ensure the site is not disturbed as long as the site is controlled by the United States. Also, the closure plan may be beneficial when handing the landfill over to the HN to give them a starting point along with an environmental condition report. The main objective of a closure plan is to ensure a closed landfill does not affect public health and the local environment. A closure plan should include instructions for post-closure care and maintenance, including a groundwater, leachate, and gas-monitoring program, instructions for maintaining the final cover, a point of contact for the closed landfill, and a description of post-closure use of the land. These inspections and monitoring must continue as long as the US controls the site. Once the landfill is closed, the site must be identified on a contingency area map and must be recorded in the closure document when the base camp is closed. As part of the SOFA or any other agreement with the HN, the post-closure care and maintenance plan may transfer to the HN.

A-2 DEFINITION OF TERMS.

A-2.1 Waste.

Any discarded material. Waste is generally categorized as nonhazardous solid waste, hazardous waste (HW), or medical waste. Nonhazardous solid waste includes items such as food waste, discarded paper, cardboard, plastic, wood, construction debris, and glass.

A-2.2 Hazardous Waste (HW).

Any solid waste listed under the Resource Conservation and Recovery Act (RCRA), 40 CFR 261, as hazardous waste or exhibits any of the four hazardous characteristics of toxicity, reactivity, ignitability, or corrosivity. HW items include used solvents, contaminated fuel, petroleum-contaminated soils, paint waste, and batteries. HW management and disposal is outside the scope of this UFC.

A-2.3 Medical Waste

Any waste that is generated in diagnosis, treatment, or immunization of human beings or animals, that is capable of causing disease, or that, if not handled properly, poses a risk to individuals or a community. Medical waste requires special precautions due to its unique characteristics and potential to cause infection. Management of medical waste is outside the scope of this UFC. Refer to Service public health staff and the following publications:

- U.S. Army Medical Command Regulation 40-35, *Management of Regulated Medical Waste (RMW)*, provides information on management of regulated medical waste.

- AFI 41-201, *Managing Clinical Engineering Programs*, gives basic guidance on appropriate handling of medical waste in paragraph 5.16.

- BUMEDINST 6280.1C, *Management of Regulated Medical Waste,* gives detailed instructions on medical waste handling and disposal.

This UFC supersedes UFC 3-250-01FA, dated January, 2004 and UFC 3-230-06A dated January 2004.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-250-01, *PAVEMENT DESIGN FOR ROADS AND PARKING AREAS*

Superseding: This UFC supersedes UFC 3-250-01FA, dated January, 2004 and UFC 3-230-06A dated January 2004.

Description: This revision provides pavement design procedures and requirements for the pavement design of roads and parking areas worldwide. It clarifies when State pavement design procedures may be used and when Pavement-Transportation Computer Assisted Structural Engineering (PCASE) is required.

Reasons for Document:

- This UFC updates the guidance and requirements for specialized pavement design and underdrain design in two existing criteria documents and efficiently consolidates them into a single UFC.

- Provides consistency in applying pavement design requirements for projects with standard vehicle types, particularly with regard to using State pavement design procedures.

Impact:

This unification effort will result in less cost to maintain DoD criteria and a more efficient pavement design in the following ways:

- By relying on State pavement design procedures for standard vehicle types that typically travel local roads.
- Reduction in the number of references used for military construction provides a clear and efficient guidance for the design and construction of DoD pavements.
- Reduction in ambiguity and the need for interpretation reduces the potential for design and construction conflicts.

Unification Issues:

None.

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides minimum criteria for the design procedures and requirements for the pavement design of roads and parking areas. It clarifies when State pavement design procedures may be used and when Pavement-Transportation Computer Assisted Structural Engineering (PCASE) is required. Pavement design engineers must use this minimum criteria when making decisions and determining an acceptable pavement design procedure.

1-2 APPLICABILITY.

This UFC applies to all military service elements and contractors involved in the planning, design, and construction of DoD facilities worldwide.

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-5 GLOSSARY.

Appendix C contains acronyms, Unified Soil Classification System (USCS) soil types, units of measure, definition of terms and referenced figures.

This Page Intentionally Left Blank

CHAPTER 2 PRELIMINARY SOIL INVESTIGATION

2-1 GENERAL.

Soil subgrades provide a foundation for supporting pavements. The strength and uniformity of the subgrade will affect the required pavement thickness and the performance of the pavement during its design life. Conduct a thorough investigation of the subgrade to determine soil characteristics. Soil uniformity and moisture conditions under the pavement are especially important with respect to frost action.

2-2 INVESTIGATION OF SITE.

Characteristics of subgrade soils must be known to predict pavement performance. Determine the general suitability of the subgrade soils based on classification of the soil, moisture-density relationship, degree to which the soil can be compacted, expansion characteristics, susceptibility to pumping, and susceptibility to detrimental frost action. Factors such as groundwater, surface infiltration, soil capillarity, topography, rainfall, and drainage conditions will also affect the future support rendered by the subgrade by increasing its moisture content and thereby reducing its strength.

2-2.1 Preliminary Site Analysis of Subgrade Conditions.

Before planning field explorations, conduct a general survey of the topographic and subsurface soil conditions at the site. Investigate previous performance of existing pavements, minimum of five years, on similar local subgrades to assist in evaluating subsurface conditions. Sources of data should include the landforms, soil conditions in ditches, and cuts and tests of representative soils in the site. Augment the survey with existing soil and geological maps. Sources of information include earlier subsurface investigations near the site, United States Geological Survey maps, and soil survey maps. Evaluate surface drainage at the site and subsurface drainage of the subgrade.

2-2.2 Subsurface Explorations.

Conduct subsurface explorations to test each type of soil identified in the preliminary site analysis. Test pits and soil borings may be used for subsurface investigations. The spacing of subsurface explorations along roadways depends on the variability of the existing soil conditions. When preliminary site analysis substantiates soil uniformity, use a maximum spacing of 400 ft (120 m). Make additional subsurface explorations when the preliminary site analysis indicates unusual or potentially troublesome subgrade conditions. When subsurface explorations have previously been conducted to the required depth and those subsurface explorations confirm soil uniformity, the spacing may be increased to a maximum of 1500 ft (450 m) as long as the subsurface explorations results continue to confirm soil uniformity.

The depth of subsurface explorations must extend beyond the frost penetration depth as determined from Chapter titled Seasonal Frost Conditions and be no less than 6 ft (2 m) below finished grade. Depth requirements stated above are measured from the pavement surface.

2-2.3 Dynamic Cone Penetrometer.

The Dynamic Cone Penetrometer (DCP) test can be used to determine design California Bearing Ratio (CBR) values. When using the DCP to determine CBR values in shallow pavement applications, perform test in accordance with ASTM D6951/D6951M.

2-2.4 Soil Classification.

Classify soil samples from the subsurface explorations according to the USCS in ASTM D2487.

2-2.5 Soil Evaluation

Use the subsurface exploration samples to compute soil properties, prepare soil profiles and to select soils for further testing. To help identify soft layers in the soil, evaluations must include moisture content.

2-3 BORROW AREAS.

Perform preliminary subsurface explorations in areas where material is to be borrowed from adjacent areas. Extend subsurface explorations to a minimum depth of 2 to 4 ft (0.6 to 1.2 m) below the anticipated depth of borrow. Use the preliminary samples to classify soils, compute moisture content, and determine compaction characteristics.

CHAPTER 3 TECHNICAL REQUIREMENTS

3-1 SELECTION OF PAVEMENT TYPE.

Use rigid pavements or composite pavements with a rigid overlay for the following areas:

- Vehicle Maintenance Areas.
- Pavements for All Vehicles with Non-pneumatic Tires.
- Open Storage Areas with Materials Having Non-pneumatic Loadings in Excess of 200 psi (1.38 MPa), covered or uncovered.
- Hardstands (Organizational Vehicle Parking Areas, Motor Pool, Unit's Equipment Parking).
- Pavements Supporting Tracked Vehicles.
- Vehicle Wash Racks.
- Vehicle Fueling Pads.

Exception: For architectural or special operational requirements design pavements based upon life-cycle cost analysis.

3-2 DESIGN VARIABLES.

The prime factor influencing the structural design of a pavement is the required load-carrying capacity. The thickness of pavement necessary to provide the desired load-carrying capacity is a function of the following variables:

- Vehicle gross loads and wheel configurations.
- Volume of traffic during the design life of pavement.
- Soil strength.
- Modulus of rupture (flexural strength).

3-3 RIGID PAVEMENTS.

The rigid pavement design procedures presented in this UFC are based upon the critical tensile stresses produced within the pavement by the vehicle loading. Correlation between theory, small-scale model studies, and full-scale accelerated traffic tests show that maximum tensile stresses in the pavement occur when the vehicle wheels are tangent to a free or unsupported edge of the pavement. Stresses for the condition of the vehicle wheels tangent to a longitudinal or transverse joint are less severe because of the use of load-transfer devices and aggregate interlock in these joints to transfer a portion of the load across the joint. Because of their cyclic nature, other stresses are, at times, additive to the vehicle load stresses. These other stresses include restraint stresses resulting from thermal expansion and contraction of the pavement and warping stresses resulting from moisture and temperature gradients within the pavement. Provision for those stresses not induced by wheel loads is included in design factors developed empirically from full-scale accelerated traffic tests and from the observed performance of pavements under actual service conditions.

3-4 FLEXIBLE PAVEMENTS.

The design procedure used by DoD to design flexible pavements for roads and parking areas is referred to as the Beta Criteria design procedure. This procedure requires that each layer be thick enough to distribute the stresses induced by traffic so that when such stresses reach the underlying layer they will not overstress the underlying layer causing excessive shear deformation. The Beta Criteria is used to sketch the design curves contained in Appendix E. Besides the determination of layer thicknesses, adequately compact each layer so that traffic does not induce excessive settlement. Use ASTM D1557 compaction effort procedures to design against consolidation under traffic.

3-5 MANDATORY USE OF PCASE.

PCASE is mandatory for the design of roads and parking areas trafficked by special military vehicles and for all vehicle types outside of the United States and its territories and possessions. Refer to UFC 3-201-01 for the types of vehicles characterized as special military vehicles.

PCASE is also mandatory for the design of organizational vehicle parking areas.

3-5.1 Pavement-Transportation Computer Assisted Structural Engineering.

PCASE is a computer program developed by the United States Army Corps of Engineers (USACE), Engineer Research and Development Center (ERDC), is available for use by the public. PCASE can be used to determine pavement thickness and compaction requirements. The computer program runs on the Microsoft Windows™ operating systems or Windows™ compatible systems. PCASE may be obtained electronically from the following:

- https://transportation.wes.army.mil/pcase or http://www.pcase.com
- A compact disk (CD) is also available from the U.S. Army Corps of Engineers, Transportation Systems Center, 1616 Capitol Avenue, Omaha, NE 68102-4901.

3-6 MATERIALS.

Materials for pavements designed in accordance with this UFC and PCASE must conform to requirements set forth in this and the Unified Facility Guide Specifications (UFGS). To the greatest practical extent, specify local materials that meet requirements of the Department of Transportation in the State in which the project is located, and are in accordance to UFC requirements. Only the materials should be changed in the UFGS, all other requirements such as general requirements, tolerances, and execution requirements should stay the same. The construction materials for pavements designed using state Department of Transportation (DoT) thickness design criteria must conform to the DoT material specifications. The construction execution procedure for physically determining acceptable conditions, preparation, installation, field quality control and inspection must conform to the UFGS.

3-7 DRAINAGE SYSTEMS.

Pavement subdrainage systems are covered in this UFC. Refer to UFC 3-201-01 for criteria on storm drainage systems (e.g. surface drainage, underground drainage systems, stormwater management facilities, erosion and sediment control). Refer to UFC 3-210-01 for criteria on low impact development.

This Page Intentionally Left Blank

CHAPTER 4 PAVEMENT DESIGN

For the design of pavements traveled by standard American Association of State Highway and Transportation Officials (AASHTO) vehicles or vehicles not characterized as special military vehicles in UFC 3-201-01, in the United States, the State pavement design procedure may be used, except that the use of keyed joint, if allowed by the State, must not be used on pavement thinner than 9 inches. When using the State pavement design procedure, use the pavement design criteria and procedures recognized by the Department of Transportation (DoT) in the state in which the project is located. Refer to UFC 3-201-01, paragraph titled “Design Traffic” to predict average daily traffic (ADT) when using a State pavement design procedure.

4-1 EFFECT OF VEHICULAR TRAFFIC ON PAVEMENT DESIGN.

Design pavement thickness to withstand the anticipated traffic, categorized by type and weight of vehicles, and number of passes of each type for the design life of the pavement. For most pavements, the magnitude of the axle load is of greater importance than the gross weight of pneumatic-tired vehicles because axle spacing is generally so large that there is little interaction between the wheel loads of one axle and the wheel loads of the other axles. Thus, for the case of pneumatic-tired vehicles having equal axle loads, the increased severity of loading imposed by conventional four or five axle trucks as compared with that imposed by two or three axle trucks is largely a fatigue effect resulting from an increased number of load repetitions per vehicle operation. For forklift trucks where the loading is concentrated largely on a single axle and for tracked vehicles where the loading is evenly divided between the two tracks, the severity of the vehicle loading is a function of the gross weight of the vehicle and the frequency of loading. Relations between load repetition and required rigid pavement thickness developed from accelerated traffic tests of full-scale pavements have shown that, for any given vehicle, increasing the gross weight by as little as 10 percent can be equivalent to increasing the volume of traffic by as much as 300 to 400 percent. Therefore, for rigid pavements, the magnitude of the vehicle loading must be used as a more significant factor in the design of pavements than the number of load repetitions.

4-2 EQUIVALENT SINGLE AXLE LOAD (ESAL).

The ESAL used in this UFC is not the ESAL as computed by the AASHTO Guide for Design of Pavement Structures. In PCASE, the equivalency used is based on mixed traffic and the CBR Beta design model. Direct comparison or equivalence between AASHTO and PCASE ESAL is not straightforward since the ESAL computation in each methodology derives from specific models, assumptions, and design procedures. The conversion of each vehicle to ESALs is based on research done by the USACE, ERDC.

4-3 PAVEMENT DESIGN.

Unless specified otherwise in the project specific requirements, design pavement based upon anticipated vehicles and loadings for a 25 year life; however, sections must not be less than the minimums indicated in UFC 3-201-01. Pavements design is based on loads and the total number of passes during the life of the pavement for the expected vehicles. Typically, traffic is counted in terms of ADT. This ADT value should take into consideration the type, numbers of passes, and load for each of the vehicles in the mix. The ADT in the daily traffic distribution is converted to total number of passes for the desired pavement design life.

For example, if a road is to be designed for an average of 10 passes per day of a 5 axle truck, then the total design passes for a 25 year life will be 10 passes/day × 365 days/year × 25 years = 91,250 total passes. Design charts have been prepared using PCASE and can be used in lieu of PCASE. These charts are for flexible and rigid pavements use required thickness and total number of passes for various vehicles and are provided in Appendix E, and Appendix F, respectively. When designing for a mix of vehicles (mixed traffic), the concept of an equivalent vehicle is used. In this procedure each vehicle is converted to a critical or controlling vehicle, which in turn represents the cumulative effect of all vehicles in the mix. This procedure is the same procedure used to convert mixed traffic to an equivalent number of passes of an 18,000 lb (8,200 kg) single-axle, dual load ESAL. Use the number of ESALs to compute the minimum pavement layer thicknesses and compaction requirements.

4-3.1 Vehicle Wander Width.

As vehicles travel down a road, there is a natural tendency for the vehicles to wander from side to side. This lateral wander determines the actual number of load or stress repetitions applied to a given point on the pavement. This effect is accounted for in pavement design by the wander width, which is defined as the total width of pavement over which the centerline of a vehicle is distributed 75 percent of the time symmetrically around the mean. Traffic studies have indicated that the wander width for roads is about 33 in (850 mm) assuming a statistical normal distribution of traffic. This means that a vehicle would deviate laterally from its centerline a maximum distance of 165 in (420 mm) from its line of travel. The pavement design charts presented in this UFC are based on these assumptions.

4-3.2 Location of Critical Loads.

In roads with 12 ft (4 m) wide lanes, the location where the maximum loads are applied is about 0 to 3 ft (0 to 1 m) from the pavement edge. If no mechanisms are provided to transfer tire load to the adjacent shoulders, a condition of zero load transfer occurs at the pavement edge. This has a marked impact on the stresses that a concrete slab will be subjected to. In rigid pavements, the Westergaard theoretical analysis for edge stresses is used to compute these critical stresses and no reduction due to load transfer is performed. In flexible pavements, the concept of cumulative damage associated with each vehicle is used to account for the lateral wander and vertical stress applied to the subgrade.

4-3.3 Mixed Traffic.

The examples included in Appendix G illustrate the procedure for handling mixed traffic for either flexible or rigid pavements. The mixed traffic procedure performs an equivalency between vehicles by calculating the thickness requirements of each vehicle for the specified number of passes and subgrade CBR. The vehicle with the largest required thickness then becomes the controlling vehicle and the other vehicles converted to it by the procedure described in the examples. The calculations are based on the thickness requirements of each individual vehicle; therefore the resulting controlling vehicle for flexible and rigid pavements may be different. Since subgrade conditions may vary along a road, mixed traffic calculations use a representative subgrade strength category instead of a specific value. These representative subgrade categories are shown in Table 4-1. However, when the final mixed traffic equivalency has been finished in terms of the equivalent passes of the controlling vehicle, the design CBR or k value will be used to obtain the required pavement thickness above the subgrade.

Table 4-1 Representative Subgrade Categories

Subgrade Category	Flexible Pavements, CBR Range	Representative CBR Value	Rigid Pavements k-value Range psi/in[1]	Representative k-value, psi/in[1]
A	CBR ≥ 13	15	k ≥ 442	552.6
B	8 < CBR <13	10	221 < k < 442	294.7
C	4 < CBR ≤ 8	6	92 < k ≤ 221	147.4
D	CBR ≤ 4	3	k ≤ 92	73.7
[1] kPa/mm = psi/in ÷ 0.271				

This Page Intentionally Left Blank

CHAPTER 5 FLEXIBLE PAVEMENT SUBGRADES

5-1 FACTORS TO BE CONSIDERED.

Consider the following primary factors regarding subgrades for flexible pavement design:

- The general characteristics of the subgrade soils (e.g. soil classification, limits).
- Depth to bed rock.
- Depth to groundwater table (including perched groundwater table).
- The attainable compaction in the subgrade and the adequacy of the existing density in the layers below the zone of compaction requirements
- The CBR that the compacted subgrade and un-compacted subgrade will have under local environmental conditions.
- The presence of weak soft layers in the subsoil.
- Susceptibility to detrimental frost action.
- Expansion potential

5-2 COMPACTION.

The natural density of the subgrade must be sufficient to resist densification under traffic or the subgrade must be compacted during construction to a depth where the natural density will resist densification under traffic. Table 5-1 shows the depth, measured from the pavement surface, at which a given percent compaction is required to prevent densification under traffic. Subgrades in cuts must have natural densities equal to or greater than the values shown in Table 5-1. Where such is not the case, compact the subgrade from the surface to meet the tabulated densities, or remove and replace the subgrade, in which case the requirements for fills apply. As another option, cover the subgrade with sufficient selected material, subbase, and base so that the un-compacted subgrade is at a depth where the in place densities are satisfactory. In fill areas, place cohesionless soils at no less than 95 percent of ASTM D1557 maximum density and cohesive fills at less than 90 percent of ASTM D1557 maximum density.

Table 5-1 Depth of Compaction for Select Materials and Subgrades (CBR[1] ≤ 20)

Equivalent Passes of an 18,000-lb (8,200-kg) ESAL		Depth of Compaction[2] or Percent Compaction Shown, in

[1] California Bearing Ratio (ASTM D4429).
[2] Depth of compaction is measured from pavement surface.

5-3 COMPACTION EXAMPLES.

Appendix G includes two examples illustrating the application of subgrade compaction requirements

5-4 SELECTION OF DESIGN CBR VALUES.

Flexible pavements may be designed using the laboratory soaked CBR, the field in-place CBR, the CBR from the Dynamic Cone Penetrometer as described in ASTM D6951/D6951M or the CBR from undisturbed samples as described in ASTM D1883 or ASTM D 4429. For the design of flexible pavements in areas where no previous experience regarding pavement performance is available, the laboratory soaked CBR is normally used. Where an existing pavement is available at the site that has a subgrade constructed to the same standards as the job being designed, in-place tests or tests on undisturbed samples may be used in selecting the design CBR value. In-place tests are used when the subgrade material is at the maximum water content expected in the prototype and frost is not expected to penetrate the subgrade. Contrarily, tests on undisturbed samples are used where the material is not at the maximum water content and thus soaking is required. Sampling involves considerably more work than in-place tests and undisturbed samples tend to be slightly disturbed. Therefore, in-place tests should be used where possible. Guides for determining when in-place tests can be used are given in details of the CBR test in ASTM D4429.

CHAPTER 6 FLEXIBLE PAVEMENT SELECT MATERIALS AND SUBBASE COURSES

6-1 GENERAL.

This UFC designates layers between the subgrade and base course as selected materials or subbases. Select materials are those with design CBR values equal to or less than 20; subbases are those with CBR values above 20. Minimum thicknesses of pavement and base have been established to eliminate the need for subbases with design CBR values above 50. Where the design CBR value of the subgrade without processing is in the range of 20 to 50, select materials and subbases may not be needed. However, the subgrade cannot be assigned design CBR values of 20 or higher unless it meets the gradation and plasticity requirements for subbases.

6-2 MATERIALS.

Use the soils investigations described in Chapter titled Preliminary Soils Investigation to determine the location and characteristics of suitable soils for select material and subbase construction.

6-2.1 Select Materials.

The subbase materials for each CBR value must conform to the quality and gradations requirements given in the guide specifications so that they will develop the needed strengths. Select materials are normally locally available coarse-grained soils (gravel: GW, GP, GM, GC, or sand: SW, SP, SM, SC), although fine-grained soils in the ML and CL groups may be used in certain cases. Consider limerock, coral, shell, ashes, cinders, caliche, disintegrated granite, and other such materials when they are economical. Recommended plasticity requirements are listed in Table 6-1. A maximum aggregate size of 3 in (80 mm) is suggested to aid in meeting grading requirements. Select material subbases are typically only used with subgrade CBR values less than 4 and large ESAL traffic volumes. Where frost is expected to penetrate the material, the subbase course must also meet the frost criteria in paragraph titled Free-Draining Material Directly Beneath Bound Base Or Surfacing Layer for free-draining material that contain 2.0 percent or less, by weight, of grains that can pass the No. 200 sieve.

6-2.2 Subbase Materials.

Subbase materials may consist of naturally occurring coarse-grained soils or blended and processed soils. Materials such as limerock, coral, shell, ashes, cinders, caliche, and disintegrated granite may be used as subbases when they meet the requirements described in Table 6-1. The existing subgrade may meet the requirements for a subbase course or it may be possible to treat the existing subgrade to produce a subbase. However, use native or processed materials only when the unmixed subgrade meets the liquid limit and plasticity index requirements for subbases. Do not “cut” plasticity by mixing subgrade. Material stabilized with commercial additives may be economical as a subbase. Portland cement, lime, fly ash, or bitumen and combinations thereof are commonly used for this purpose. Also, it may be possible to decrease the plasticity of some materials by use of lime or Portland cement in sufficient amounts to make them suitable as subbases. When using ash or cinders, the free lime content must be less than 5% and the material must be volumetrically stable.

6-3 COMPACTION.

Compaction of subbases will be 100 percent of ASTM D1557 density except where it is known that a higher density can be obtained, in which case the higher density should be required. Compaction of select materials and subgrades will be as shown in Table 5-1 except that in no case will cohesionless fill be placed at less than 95 percent or cohesive fill at less than 90 percent.

6-4 DRAINAGE.

Subbase drainage is an important aspect of design and is discussed in Chapter titled Design of Subsurface Pavement Drainage Systems.

6-5 SELECTION OF DESIGN CBR VALUES.

During the design phase where the materials have normally not been selected for construction, the design CBR values should be selected based on the gradations recommended in Table 6-1 and the cost of the materials available. The select material or subbase is generally uniform, and the problem of selecting a limiting condition, as described for the subgrade, does not ordinarily exist. Tests are usually made on remolded samples; however, where existing similar construction is available, CBR tests may be made in place on material when it has attained its maximum expected water content or on undisturbed soaked samples. The procedures for selecting CBR design values described for subgrades apply to select materials and subbases. CBR tests on gravelly materials in the laboratory tend to give CBR values higher than those obtained in the field. The difference is attributed to the processing necessary to test the sample in the 6 in (150 mm) mold, and to the confining effect of the mold. Therefore, the CBR test is supplemented by gradation and Atterberg limits requirements for subbases, as shown in Table 6-1. Suggested limits for select materials are also indicated. In addition to these requirements, the material must also show in the laboratory tests a CBR equal to or higher than the CBR assigned to the material for design purposes.

Table 6-1 Maximum Permissible Design Values for Subbases and Select Materials

Material	Design CBR	Size in	Gradation Requirements,* % passing		Liquid Limit	Plasticity Index
			No. 10	No. 200		
Subbase	50	3	50	15	25	5
Subbase	40	3	80	15	25	5
Subbase	30	3	100	15	25	5
Select material	20	*3	…	**25	**35	**12

* Cases may occur in which certain natural materials that do not meet the gradation requirements may develop satisfactory CBR values in the prototype. Exceptions to the gradation requirements are permissible when supported by adequate in-place CBR tests on construction that has been in service for several years. The CBR test is not applicable for use in evaluating materials stabilized with additives.
** Suggested limits.

This Page Intentionally Left Blank

CHAPTER 7 FLEXIBLE PAVEMENT BASE COURSES

7-1 MATERIALS.

Use high-quality materials in base courses of flexible pavements. These high-quality materials provide resistance to the high stresses that occur near the pavement surface. Guide specifications for graded crushed aggregate, limerock, and stabilized aggregate may be used without qualification for design of roads and parking areas. Guide specifications for dry- and water-bound macadam base courses may be used for design of pavements only when the cost of the dry- or water-bound macadam base does not exceed the cost of stabilized-aggregate base course, and the ability of probable bidders to construct pavements with dry- or water-bound macadam base to the required surface smoothness and grade tolerances has been proved by experience in the area.

7-2 COMPACTION.

Compact base courses for flexible pavements sections to the maximum density practicable, but never less than 100 percent of ASTM D1557 maximum density. Generally, the base course will be compacted to a minimum of 100 percent of ASTM D1557 maximum density.

7-3 DRAINAGE.

Drainage design for base courses is discussed in Chapter titled Design of Subsurface Pavement Drainage Systems.

7-4 SELECTION OF DESIGN CBR.

Because of the effects of processing samples for the laboratory CBR tests and because of the effects of the test mold, do not use the laboratory CBR test to determine CBR values of base courses. Instead, assign selected CBR ratings as shown in Table 7-1. These ratings have been based on service behavior records and, where pertinent, on in-place tests made on materials subjected to traffic. Materials must conform to the quality requirements given in the guide specifications to develop the needed strengths. To obtain an 80 CBR for No. 6 Aggregate Base Coarse, the material must have 50 percent crushed particles and be graded, but the No. 1 Graded-Crushed Aggregate Base Coarse material has a higher 90 percent of crushed material.

7-5 MINIMUM THICKNESS.

Refer to UFC 3-201-01 for minimum thickness requirements where the State pavement design procedure is used. Where the use of PCASE is mandatory, the minimum allowable thickness of base course is shown in Table 7-2. The total thickness of pavement plus base for roads and parking areas must not be less than 6 in (150 mm) or the frost penetration depth as determined from Chapter titled Seasonal Frost Conditions except where a surface treatment is applied. Where frost is expected to penetrate the base material, the base course must also meet the frost criteria in paragraph titled Free-Draining Material Directly Beneath Bound Base Or Surfacing Layer for free-draining material that contain 2.0 percent or less, by weight, of grains that can pass the No. 200

sieve. The drainage criteria in Chapter titled Design of Subsurface Pavement Drainage Systems, requires a minimum of 4 in (100 mm) of drainage layer and 4 in (100 mm) of subbase (separation) course for most pavements. When a pavement design requires 12 in (300 mm) or more of granular material above the subgrade, add base course. For pavements requiring less than 12 in (300 mm) of granular material above the subgrade, evaluate the drainage requirements in Chapter titled Design of Subsurface Pavement Drainage Systems to determine a cost effective system of granular materials. Placing an asphalt surface directly on a drainage layer (without a base course) can be accomplished under certain conditions.

Table 7-1 Design CBR Values

No.	Type	Design CBR
1	Graded crushed aggregate	100
2	Water-bound macadam	100
3	Dry-bound macadam	100
4	Bituminous binder and surface courses, central plant, hot mix	100
5	Limerock	80
6	Aggregate	80

Table 7-2 Minimum Thickness of Flexible Pavement Sections

Equivalent Passes of an 8,164-kg (18,000-lb) ESAL	Minimum Base Course CBR								
	100			80			50		
	Surface[1] in	Base in	Total in	Surface[1] in	Base in	Total in	Surface[1] in	Base in	Total in
≤ 20,000	ST[3]	4	4.5	MST[4]	4	4.5	2	4	6
20,001 to 150,000	2	4	6	2	4	6	2.5	4	6.5
150,001 to 500,000	2	4	6	2.5	4	6.5	3.5	4	7.5

Conversion Factor: millimeters = 25.4 × inches

Symbols: ≤ less than or equal to, < less than, > greater than, ≥ greater than or equal to

[1] Use a minimum surface pavement thickness of 3 in (75 mm) for any vehicle with a tire pressure ≥ 100 psi.

[2] 50-CBR base course is restricted to roads and parking areas with less than or equal to 500,000 ESALs.

[3] Bituminous surface treatments (spray application).

[4] Multiple bituminous surface treatments (spray application).

This Page Intentionally Left Blank

CHAPTER 8 BITUMINOUS PAVEMENT

8-1 GENERAL.

The bituminous materials used in paving are asphaltic or tar products as listed in UFC 3-250-03. Although asphalts and tars resemble each other in general appearance, they do not have the same physical or chemical characteristics. Tars are affected to a greater extent by temperature changes and weather conditions; however, they tend to have better adhesive and penetrating properties than asphalts. Generally, asphalt surface courses are preferred to tar surface courses. The selection of the type of bituminous material (asphalt or tar) should normally be based on economy.

8-2 CRITERIA FOR BITUMINOUS PAVEMENTS.

The basic criteria for selection and design of bituminous pavements are contained in UFC 3-250-03 which includes the following criteria:

- Selection of bitumen type;
- Selection of bitumen grade;
- Aggregate requirements;
- Quality requirements;
- Types of bituminous pavements.

8-3 MINIMUM THICKNESS.

Refer to UFC 3-201-01 for minimum thickness requirements where the State pavement design procedure is used. Where the use of PCASE is mandatory, the minimum thickness of bituminous materials varies with the strength of the underlying base course and is given in Table 7-2.

This Page Intentionally Left Blank

CHAPTER 9 FLEXIBLE PAVEMENT DESIGN

9-1 GENERAL.

Flexible pavement designs must provide the following:

- Sufficient compaction of the subgrade and of each layer during construction to prevent objectionable settlement under traffic.
- Adequate drainage of base course.
- Adequate thickness above the subgrade and above each layer together with adequate quality of the select material, subbase, and base courses to prevent detrimental shear deformation under traffic and, when frost conditions are a factor, to control or reduce to acceptable limits effects of frost heave or permafrost degradation.
- A stable, weather-resistant, wear-resistant waterproof, non-slippery pavement.

9-2 DESIGN PROCEDURE.

9-2.1 Conventional Flexible Pavements.

In designing conventional flexible pavement structures, apply the design values assigned to the various layers to the curves and criteria presented in this UFC. As several designs are generally possible for a specific site, select the most practical and economical design meeting the minimum design requirements. Since the decision on the practicability of a particular design may be largely a matter of judgment, include full particulars regarding the selection of the final design (including cost estimates) in the design analysis.

Refer to UFC 3-201-01 for permeable pavement criteria.

9-2.2 Stabilized Soil Layers.

Flexible pavements containing stabilized soil layers are designed through the use of equivalency factors. A conventional flexible pavement is first designed and the equivalency factors applied to the thickness of the layer to be stabilized. When stabilized materials meeting all gradation, durability, and strength requirements indicated in UFC 3-250-11, and Chapter titled Seasonal Frost Conditions are used in pavement structures, an appropriate equivalency factor may be applied. Soils which have been mixed with a stabilizing agent and which do not meet the requirements for a stabilized soil are considered modified and are designed as conventional pavement layers. When Portland cement is used to stabilize base course materials in DoD pavements, the treatment level must be maintained below about 4 percent by weight to minimize shrinkage cracking which will reflect through the bituminous concrete surface course. In this case, the base course will, in most instances, be modified rather than stabilized. In addition, when unbound granular layers are used between two bound layers (e.g., an unbound base course between an asphalt concrete (AC) surface course and a stabilized subbase course), provide adequate drainage to the unbound layer to prevent entrapment of excessive moisture in the layer. Additional criteria on soil stabilization may be obtained from UFC 3-250-11.

9-2.3 All-Bituminous Concrete.

All-bituminous concrete pavements are also designed using equivalency factors. See paragraph titled Equivalency Factors below. The procedure is the same as for stabilized soil layers discussed above.

9-3 DESIGN TRAFFIC.

The design of flexible pavements for roads and parking areas will be based on the actual traffic expected to use a flexible pavement during its service life and the procedures described in Chapter titled Vehicular Traffic. The designer is cautioned that in selecting the design traffic, consideration must be given to traffic which may use the pavement structure during various stages of construction and to other foreseeable exceptional use.

9-4 THICKNESS CRITERIA FOR CONVENTIONAL FLEXIBLE PAVEMENTS.

For roads and parking areas, obtain the required thickness of flexible pavements from the design charts presented in Appendix E. The charts in Appendix E were developed using thickness design requirements and are given in terms of subgrade CBR. If the design includes vehicles not covered Appendix E, PCASE must be used. Minimum thickness requirements are shown in Table 7-2. For frost condition design, thickness requirements will be determined from Chapter titled Seasonal Frost. In regions where the annual precipitation is less than 15 in (380 mm) and the groundwater table (including perched groundwater table) is at least 15 ft (4.6 m) below the finished pavement surface, the danger of high moisture content in the subgrade is reduced. Where in-place tests on similar construction in these regions indicate that the water content of the subgrade will not increase above the optimum, the total pavement thickness, as determined by CBR tests on soaked samples, may be reduced by as much as 20 percent. The minimum thickness of pavement and subbase must still be met; therefore the reduction will be affected in the subbase course immediately above the subgrade. When only limited rainfall records are available, or the annual precipitation is close to the 15 inch criterion, give careful consideration to the sensitivity of the subgrade to small increases in moisture content before any reduction in thickness is made.

Appendix G includes an example of thickness design for conventional flexible pavements.

9-5 THICKNESS CRITERIA-STABILIZED SOIL LAYERS.

9-5.1 Equivalency Factors.

The use of stabilized soil layers within a flexible pavement provides the opportunity to reduce the overall thickness of pavement structure required to support a given load. The design of pavement containing stabilized soil layers requires the application of equivalency factors to a layer or layers of a conventionally designed pavement. To qualify for application of equivalency factors, the stabilized layer must meet appropriate strength and durability requirements set forth in UFC 3-250-11. An equivalency factor represents the number of inches (millimeters) of a conventional base or subbase which can be replaced by 1 in (25 mm) of stabilized material. Equivalency factors for stabilized materials are determined as shown in Table 9-1. The cement content must be limited to 4 percent by weight or less to prevent excessive reflective cracking. Selection of an equivalency factor from the tabulation is dependent upon the classification of the soil to be stabilized.

Table 9-1 Equivalency Factors for Stabilized Material

Material	Equivalency Factors	
	Base	Subbase
Asphalt-stabilized		
All-bituminous concrete	1.15	2.30
GW, GP, GM, GC	1.00	2.00
SW, SP, SM, SC	*	1.50
Cement-stabilized		
GW, GP, SW, SP	1.15	2.30
GM, GC	1.00	2.00
ML, MH, CL, CH	*	1.70
SC, SM	*	1.50
Lime-stabilized		
ML, MH, CL, CH	*	1.00
SC, SM, GM, GC	*	1.10
Lime, Cement, Fly ash Stabilized		
ML, MH, CL, CH	*	1.30
SC, SM, GM, GC	*	1.40
Unbound crushed stone	1.00	2.00
Unbound aggregate	*	1.00
* Not used for base course material.		

9-5.2 Minimum Thickness.

Apply the minimum thickness requirements to the standard pavement before determining the stabilized layer thicknesses. However for pavements with stabilized layers, the minimum thickness requirement for the asphalt layer is the same as shown in Table 7-1 for conventional pavements.

9-6 EXAMPLE THICKNESS DESIGN-STABILIZED SOIL LAYERS.

The equivalency factors require that a conventional flexible pavement be designed to support the design load conditions. If it is desired to use a stabilized base or subbase course, divide the thickness of conventional base or subbase by the equivalency factor for the applicable stabilized soil. Two examples for the application of the equivalency factors are included in Appendix G.

9-7 SHOULDERS AND SIMILAR AREAS.

These areas are provided only for the purpose of minimizing damage to vehicles which use them accidentally or in emergencies; therefore, they are not considered normal vehicular traffic areas. Provide paved shoulders for high volume roads. Others will be surfaced with soils selected for their stability in wet weather and will be compacted as required. Dust and erosion control will be provided by vegetative cover, anchored mulch, coarse-graded aggregate or liquid palliatives UFC 3-260-17. Shoulders will not block base course drainage, particularly where frost conditions are a factor.

9-8 BITUMINOUS SIDEWALKS, CURBS, AND GUTTERS.

Refer to UFC 3-201-01 for criteria on bituminous sidewalks, curbs and gutters.

9-9 FLEXIBLE OVERLAY DESIGN.

For the design of flexible pavement overlays, see Chapter titled Pavement Overlays.

9-10 FLEXIBLE PAVEMENT DESIGN CURVES.

Appendix E contains the flexible pavement design curves of vehicles commonly included in the design traffic mix. If a design curve for a vehicle not included in Appendix E, the U.S. Army Corps of Engineers, Transportation Systems Center, 1616 Capitol Avenue, Omaha, NE 68102-4901 may be contacted.

CHAPTER 10 RIGID PAVEMENT DESIGN

10-1 SOIL CLASSIFICATION AND TESTS.

All soils should be classified according to the USCS as given in ASTM D2487. There have been instances in construction specifications where the use of such terms as "loam," "gumbo," "mud," and "muck" have resulted in misunderstandings. These terms are not specific and are subject to different interpretations throughout the United States. Such terms should not be used. Sufficient investigations should be performed at the proposed site to facilitate the description of all soils that will be used or removed during construction in accordance with ASTM D 2487; any additional descriptive information considered pertinent should also be included. If Atterberg limits are a required part of the description, as indicated by the classification tests, the test procedures and limits should be referenced in the construction specifications.

10-2 COMPACTION.

10-2.1 General.

Compaction improves the stability of the subgrade soils and provides a more uniform foundation for the pavement. The ASTM D1557 soil compaction test conducted at several moisture contents is used to determine the compaction characteristics of the subgrade soils. The range of maximum densities normally obtained in the compaction test on various soil types is listed in UFC 3-260-02. This test method should not be used if the soil contains particles that are easily broken under the blow of the tamper unless the field method of compaction will produce a similar degradation. Certain types of soil may require the use of a laboratory compaction control test other than the soil compaction test. The unit weight of some types of sands and gravels obtained using the compaction method above may be lower than the unit weight that can be obtained by field compaction; hence, the method may not be applicable. In those cases where a higher laboratory density is desired, compaction tests are usually made under some variation of the ASTM D1557 method, such as vibration or tamping (alone or in combination) with a type hammer or compaction effort different from that used in the test.

10-2.2 Requirements.

For all subgrade soil types, compact the subgrade under the pavement slab or base course to a minimum depth of 6 in (150 mm). If the densities of the natural subgrade materials are equal to or greater than 90 percent of the maximum density from ASTM D1557, no rolling is necessary other than that required to provide a smooth surface. Compaction requirements for cohesive soils (Liquid Limit (LL) > 25; Plasticity Index (PI) > 5) are 90 percent of maximum density for the top 6 in (150 mm) of cuts and the full depth of fills. Compaction requirements for cohesionless soils (LL<25: PI<5) are 95 percent for the top 6-in of cuts and the full depth of fills. Compaction of the top 6 in (150 mm) of cuts may require the subgrade to be scarified and dried or moistened as necessary and re-compacted to the desired density.

10-2.3 Special Soils.

Although compaction increases the stability and strength of most soils, some soil types show a marked decrease in stability when scarified, worked, and rolled. Also, expansive soils shrink excessively during dry periods and expand excessively when allowed to absorb moisture. When soils of these types are encountered, special treatment will usually be required. For nominally expansive soils, water content, compaction effort, and overburden should be determined to control swell. For highly expansive soils, replacement to depth of moisture equilibrium, raising grade, lime stabilization, pre-wetting, or other acceptable means of controlling swell should be considered.

10-3 TREATMENT OF UNSUITABLE SOILS.

Soils not suitable for subgrade use, as specified in UFC 3-260-02, should be removed and replaced, covered with soils which are suitable or treated. The depth to which such adverse soils should be removed, covered, or treated depends on the soil type, drainage conditions, and depth of freezing temperature penetration and should be determined by the engineer on the basis of judgment and previous experience, with due consideration of the traffic to be served and the costs involved. Where freezing temperatures penetrate a frost-susceptible subgrade, follow the design procedures outlined in Chapter titled Seasonal Frost Conditions. In some instances, unsuitable or adverse soils may be improved economically by stabilization with such materials as cement, fly ash, lime, or certain chemical additives, whereby the characteristics of the composite material become suitable for subgrade purposes. Criteria for soil stabilization are in UFC 3-250-11. However, subgrade stabilization should not be attempted unless the costs reflect corresponding savings in base course, pavement, or drainage facilities construction. Highly expansive subgrades are typically removed and replaced with suitable soil, compacted at a moisture content and unit weight that will minimize expansion, or chemically treated. Care should be taken when using calcium-based materials such as lime and Portland cement to chemically treat clay soils with soluble sulfates. The combination of calcium-based stabilizer, water, and clay with soluble sulfates will produce calcium-aluminate-sulfate-hydrate minerals with very large expansion potential. An adequate amount of water and mellowing time is required to allow formation of the expansive minerals before compaction.

10-4 DETERMINATION OF MODULUS OF SUBGRADE REACTION.

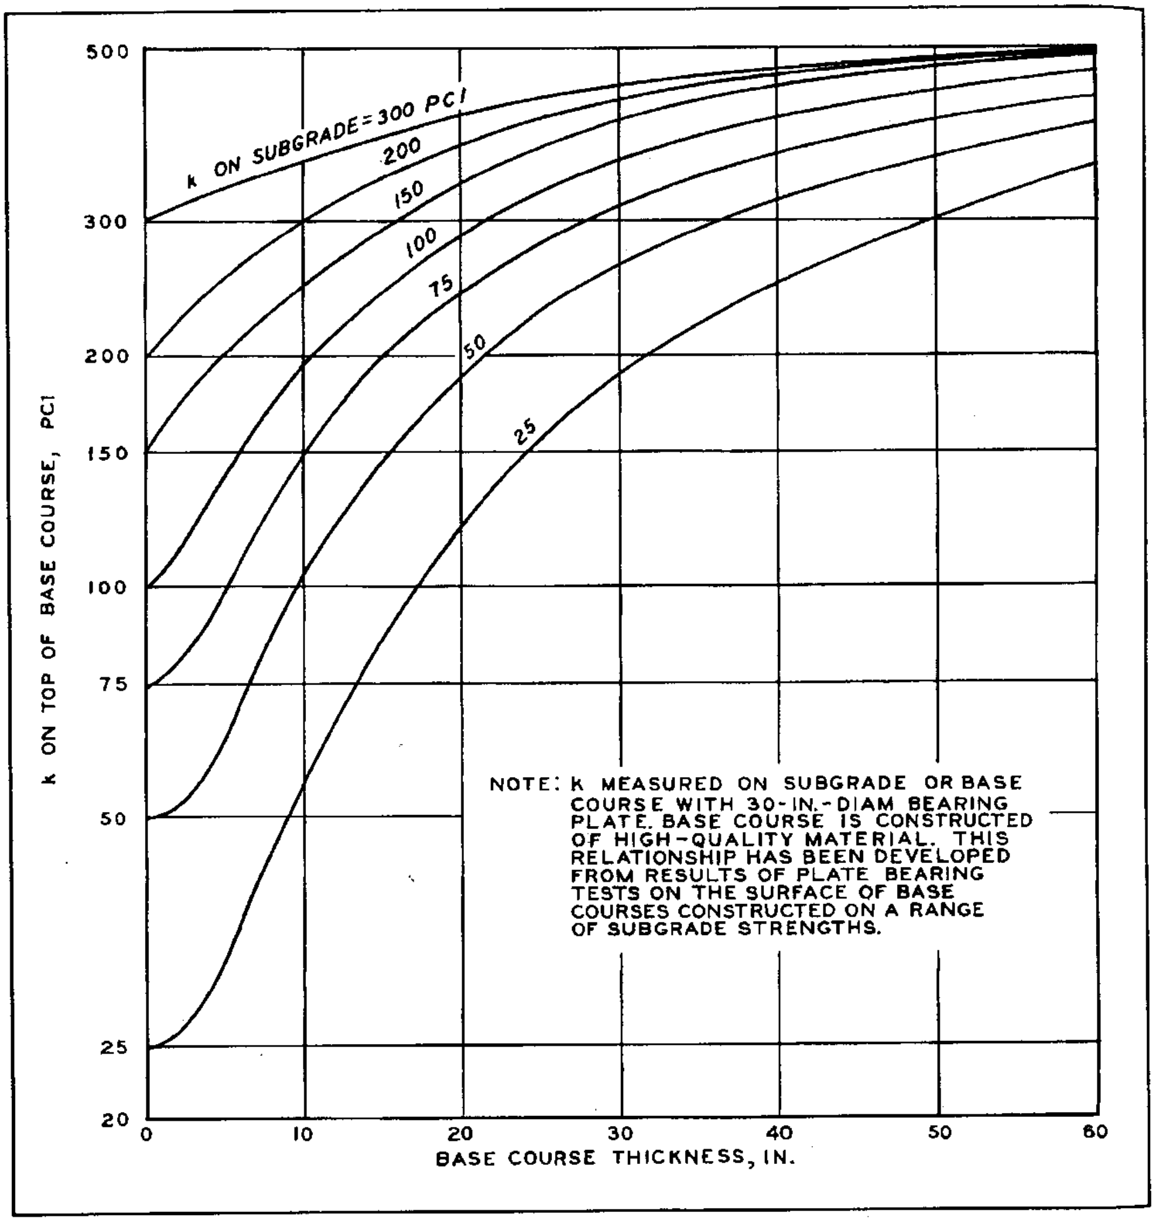
For the design of rigid pavements in those areas where no previous experience regarding pavement performance is available, determine the modulus of subgrade reaction **k** for design purposes by the field plate-bearing test. Where performance data from existing rigid pavements are available, adequate values for **k** can usually be determined on the basis of consideration of soil type, drainage conditions, and frost conditions that prevail at the proposed site. Table 10-1 presents typical values of **k** for various soil types and moisture conditions as a function of base course thickness. Consider these values as a guide only and their use in place of the field plate-bearing test, although not recommended, is left to the discretion of the engineer. Where a base course is used under the pavement, the **k** value on top of the base (also known as the effective k value) is used to determine the pavement thickness. The plate-bearing test may be run on top of the base, or Figure 10-1 may be used to determine the modulus of soil reaction on top of the base. It is good practice to confirm adequacy of the **k** on top of the base from Figure 10-1 by running a field plate-load test.

Table 10-1 Modulus of Soil Reaction (psi/in)*

Type of Material	Moisture Content Percentage							
	1 to 4	5 to 8	9 to 12	13 to 16	17 to 20	21 to 24	25 to 28	Over 28
Silts and clays, LL greater than 50 (OH, CH, MH)		175	150	125	100	75	50	25
Silts and clays, LL less than 50 (OL, CL, ML)		200	175	150	125	100	75	50
Silty and clayey sands (SM and SC)	300	250	225	200	150			
Sand and gravelly sands (SW and SP)	350	300	250					
Silty and clayey gravels (GM and GC)	400	350	300	250				
Gravel and sandy gravels (GW and GP)	500	450						

*Typical values of k in pounds per cubic inch for rigid pavement design.
Conversion factor: kPa/mm = psi/in ÷ 0.271.
Notes:
1. Values of k shown are typical for materials having dry densities equal to 90 to 95 percent of the maximum. For materials having dry densities less than 90 percent of the maximum, values should be reduced by 50 pounds per cubic inch (psi/inch), except that a k of 25 psi/inch will be the minimum used for design.
2. Values shown may be increased slightly if density is greater than 95 percent of the maximum, except that a k of 500 psi/in will be the maximum used for design.
3. Frost area k values are given in Chapter titled Seasonal Frost Conditions.

Figure 10-1 Effect of Base Course Thickness on Modulus of Soil Reaction for Non-frost Conditions



CHAPTER 11 RIGID PAVEMENT BASE COURSES

11-1 GENERAL REQUIREMENTS.

Base courses may be required under rigid pavements for replacing soft, highly compressible or expansive soils and for providing the following:

- Additional structural strength;
- More uniform bearing surface for the pavement;
- Protection for the subgrade against detrimental frost action;
- Drainage;
- Suitable surface for the operation of construction equipment, especially slip form pavers.

Use of base courses under a rigid pavement to provide structural benefit should be based on economy of construction. Thick base courses have often resulted in lower maintenance costs since the thick base course provides stronger foundation and therefore less slab movement. Provide a minimum base-course thickness of 4 in (100 mm) over subgrades that are classified as OH, CH, CL, MH, ML, and OL to provide protection against pumping. In certain cases of adverse moisture conditions (high groundwater table or poor drainage), SM and SC soils also may require base courses to prevent pumping. The designer is cautioned against the use of fine-grained material for leveling courses or choking open-graded base courses since this may create a pumping condition. Positive drainage should be provided for all base courses to ensure groundwater is not trapped directly beneath the pavement since saturation of these layers will cause the pumping condition that the base course is intended to prevent. The base course material and drains must meet the drainage criteria listed in Chapter titled Design of Subsurface Pavement Drainage Systems.

11-2 MATERIALS.

If conditions indicate that a base course is desirable under a rigid pavement, a thorough investigation should be made to determine the source, quantity, and characteristics of the available materials. A study should also be made to determine the most economical thickness of material for a base course that will meet the requirements. The base course may consist of natural, processed, or stabilized materials. The material selected should be the one that best accomplishes the intended purpose of the base course. In general, the base course material should be a well-graded, high-stability material. In this connection, all base courses to be placed beneath concrete pavements for roads and parking areas should conform to the following requirements:

- Percent passing No. 10 sieve: not more than 85.
- Percent passing No. 200 sieve: not more than 15.
- Plasticity index: not higher than 6.

- Where local experience indicates their desirability, other control limitations such as limited abrasion loss may be imposed to ensure a uniform high-quality base course.

11-3 COMPACTION.

Where base courses are used under rigid pavements, the base course material should be compacted to a minimum of 95 percent of the maximum density. The engineer is cautioned that it is difficult to compact thin base courses to high densities when they are placed on yielding subgrades.

11-4 FROST REQUIREMENTS.

In areas where subgrade soils are subjected to seasonal frost action detrimental to the performance of pavements, use the requirements for base course thickness and gradation outlined in Chapter titled Seasonal Frost Conditions.

CHAPTER 12 CONCRETE PAVEMENT

12-1 MIX PROPORTIONING AND CONTROL.

Proportioning of the concrete mix and control of the concrete for pavement construction is in accordance with UFC 3-250-04. Normally, a design flexural strength at a 28-day age is used for the pavement thickness determination. When it is necessary to use the pavements at an earlier age, consideration should be given to the use of a design flexural strength at the earlier age or to the use of high early strength cement, whichever is more economical. Fly ash gains strength more slowly than cement. If used it may be desirable to select a strength value at a period other than 28 days if time permits. Refer to UFC 3-201-01 for minimum flexural strength criteria.

12-2 TESTING.

The flexural strength of concrete and lean concrete base is determined in accordance with ASTM C78/C78M.

12-3 SPECIAL CONDITIONS.

Mix proportion or pavement thickness may require adjustment due to results of concrete tests. When tests results are less than predicted or a retrogression in strength, then the minimum pavement section must be increased. If the concrete strength is higher than predicted, then the thickness may be reduced. Rather than changing the thickness required as a result of tests on the concrete, the mix proportioning can be changed to increase or decrease the concrete strength, thereby not changing the thickness. If using the local state DoT specifications for the construction, verify that the specifications are compatible with lump sum bidding and that alkali-silica reaction (ASR) has adequately been addressed in your area.

CHAPTER 13 PLAIN CONCRETE PAVEMENT DESIGN

13-1 GENERAL.

Rigid pavements for roads and parking areas must be plain (non-reinforced) concrete except for those conditions listed in Chapter titled Reinforced Concrete Pavements or unless otherwise approved by the Government Civil Engineer. Non-reinforced pavement design requires a minimum of 0.05 percent steel in odd-shaped slabs and mismatched joints. Refer to UFC 3-201-01 for permeable pavement criteria.

13-2 ROLLER-COMPACTED CONCRETE PAVEMENTS.

Roller-compacted concrete pavements (RCCP) are plain concrete pavements constructed using a zero-slump Portland Cement Concrete (PCC) mixture that is placed with an AC paving machine and compacted with vibratory and rubber-tired rollers. The design of RCCP is presented in Chapter titled Roller-Compacted Concrete Pavements.

13-3 DESIGN PROCEDURE.

For roads and parking areas, obtain the required thickness of plain and roller-compacted concrete pavements from the design charts presented in Appendix F. Parking areas assume that only a few vehicles will apply loads close to the edge of pavement and therefore, the pavement is designed assuming 25 percent joint load transfer. Use Appendix F to determine the thickness of concrete in parking areas, divide the design concrete flexural strength by 0.75 (i.e., Flexural Strength ÷ 0.75). This is equivalent to reducing the edge stress (multiplying the edge stress by 0.75) to account for joint load transfer. For example, if a flexural strength of 600 psi is selected for the design of a parking area, then the flexural strength to be used in the design charts is 600 ÷ 0.75 = 800 psi. The net result is a thickness that is less than the road design. These design charts are graphical representations of the relationship between flexural strength, modulus of subgrade reaction *k*, pavement thickness, and repetitions of a vehicle. If the design includes vehicles not covered in Appendix F, PCASE must be used. These design charts are based on the theoretical stress analyses of Westergaard (New Formulas for Stresses in Concrete Pavements of Airfields, American Society of Civil Engineers Transactions), supplemented by empirical modifications determined from accelerated traffic tests and observations of pavement behavior under actual service conditions. Enter the design charts using the 28-day flexural strength of the concrete. Make a horizontal projection to the right to the design value for *k*. Make a vertical projection to the appropriate pass level line. Make a second horizontal projection to the right to intersect the scale of pavement thickness. The guidelines shown on the curves are an example of the correct usage of the curves. When the final pavement thickness obtained from the design curve indicates a fractional value, round up in 0.5 in (10 mm) increments. All plain concrete pavements must be uniform in cross-sectional thickness. Thickened edges are not normally required on roads since the design is for free edge stresses. Only use thickened edges where the road layout requires repeated wheel loads across the free edge of the pavement. The minimum thickness of plain concrete is 6 in (150 mm). These charts also assume that the vehicle loadings traverse very close to the edge of the pavement and there is very little load transfer between the road slabs and the shoulders. Consequently, the computed edge stress is not reduced before it is used to check for maximum allowable edge stress values.

13-4 DESIGN PROCEDURE FOR STABILIZED FOUNDATIONS.

The thickness requirements for a plain concrete pavement on a modified soil foundation must be designed as if the layer is unbound using the *k* value measured on top of the modified soil layer. For stabilized soil layers, consider the treated layer to be a low-strength base pavement and the thickness determined using the following modified partially bonded overlay pavement design equation:

$$h_o = \sqrt[1.4]{h_d^{1.4} - \left(0.0063 \sqrt[3]{E_f}\ h_s\right)^{1.4}} \quad \text{(eq. 13-1)}$$

Where:

h_o=thickness of plain concrete pavement overlay required over the stabilized layer, inches;

h_d=thickness of plain concrete pavement from design charts based on k value of unbound material, inches;

E_f=flexural modulus of elasticity of the stabilized soil. The modulus value for stabilized soils is determined according to the procedures in Appendix H;

h_s=thickness of stabilized layer, inches;

The coefficient 0.0063 derives from $\left(\frac{1}{\mathrm{E_c}}\right)^{\frac{1}{3}}$ where E_c represents the concrete modulus of elasticity, usually assumed being equal to 4,000,000 psi.

For additional information on stabilization and mix proportioning see UFC 3-250-11.

13-5 DESIGN EXAMPLES.

Appendix G contains two design examples of rigid pavement design

13-6 CONCRETE SIDEWALKS, CURBS AND GUTTERS.

Refer to UFC 3-201-01 for criteria on concrete sidewalks, curbs and gutters.

13-7 RIGID PAVEMENT DESIGN CURVES.

Appendix F contains the rigid pavement design curves of vehicles commonly included in the design traffic mix. If a design curve for a vehicle not included in Appendix F, the U.S. Army Corps of Engineers, Transportation Systems Center, 1616 Capitol Avenue, Omaha, NE 68102-4901 may be contacted.

CHAPTER 14 REINFORCED CONCRETE PAVEMENTS

14-1 APPLICATION.

Under certain conditions, concrete pavement slabs may be reinforced with welded wire fabric or formed bar mats arranged in a square or rectangular grid. The advantages of using steel reinforcement include a reduction in the required slab thickness, greater spacing between joints, and reduced differential settlement due to non-uniform support or frost heave. Figure C14-1, Figure C14-3, Figure C14-4, and Figure C14-5 show the typical details for the design and construction of reinforced concrete pavements.

14-1.1 Subgrade Conditions.

Reinforcement may reduce the damage resulting from cracked slabs. Cracking may occur in rigid pavements founded on subgrades where differential vertical movement is a definite potential. An example is a foundation with definite or borderline frost susceptibility that cannot feasibly be made to conform to conventional frost design requirements.

14-1.2 Economic Considerations.

In general, reinforced concrete pavements are not economically competitive with plain concrete pavements of equal load-carrying capacity, even though a reduction in pavement thickness is possible. Alternate bids, however, should be invited if reasonable doubt exists on this point.

14-1.3 Plain Concrete Pavements.

In plain concrete pavements, steel reinforcement should be used for the following conditions:

14-1.3.1 Odd-Shaped Slabs.

Odd-shaped slabs should be reinforced in two directions normal to each other using a minimum of 0.05 percent of steel in both directions. The entire area of the slab should be reinforced. An odd-shaped slab is one in which the longer dimension exceeds the shorter dimension by more than 25 percent or a slab which essentially is neither square nor rectangular, or has unmatched joints with an adjacent slab. Refer to Figure C14-1 (Appendix C).

Reinforcement of slabs is required where the joint patterns of abutting pavements or adjacent paving lanes do not match, unless the pavements are positively separated by an expansion joint or slip-type joint having not less than 0.25 in (6.4 mm) bond-breaking medium. The pavement slab directly opposite the mismatched joint should be reinforced with a minimum of 0.05 percent of steel in directions normal to each other for a distance of 3 ft (1 m) back from the juncture and for the full width or length of the slab in a direction normal to the mismatched joint. Mismatched joints normally occur at intersections of pavements or between pavement and fillet areas.

14-1.4 Other Uses.

Reinforced concrete pavements may be considered for reasons other than those described above provided that a report containing a justification of the need for reinforcement is prepared and submitted for approval to the Government Civil Engineer.

14-2 DESIGN PROCEDURE.

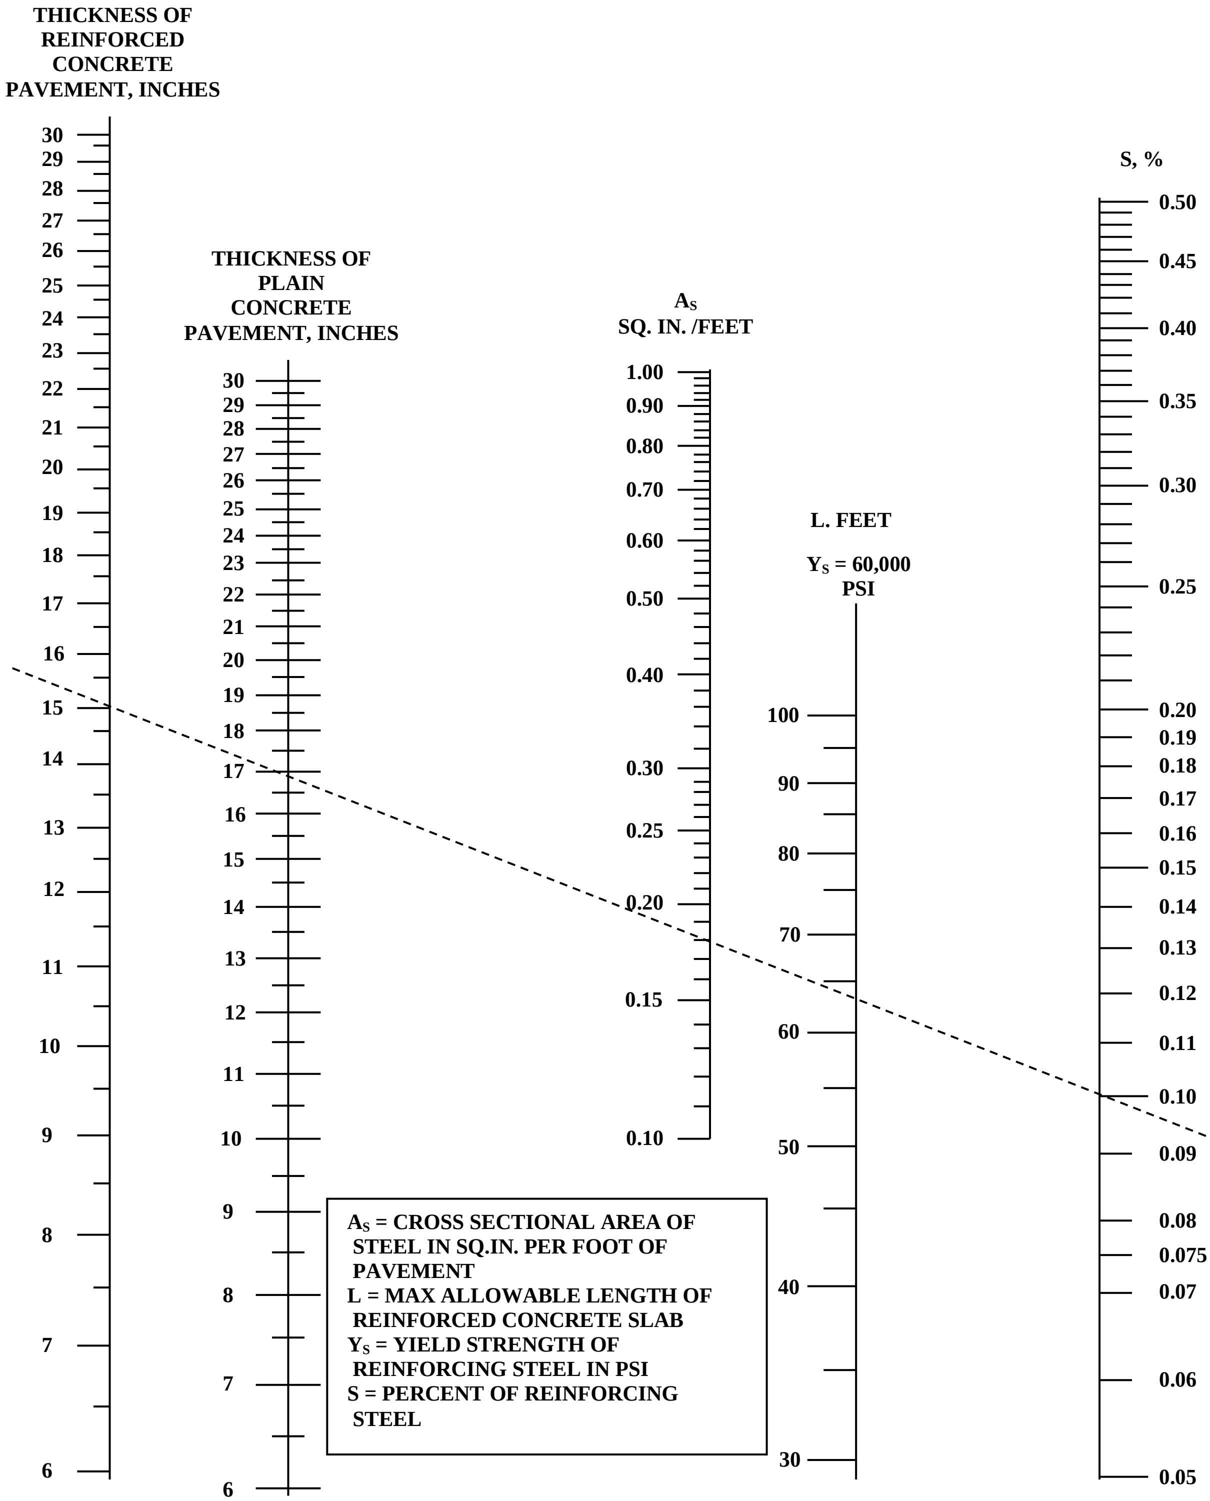
14-2.1 Thickness Design on Unbound Base or Subbase.

The design procedure for reinforced concrete pavements uses the principle of allowing a reduction in the required thickness of plain concrete pavement due to the presence of the steel reinforcing. The design procedure has been developed empirically from a limited number of prototype test pavements subjected to accelerated traffic testing. Although some cracking occurs in the pavement under the design traffic loadings, the steel reinforcing holds the cracks tightly closed. The reinforcing prevents spalling or faulting at the cracks and provides a serviceable pavement during the anticipated design life. Essentially, the design method consists of determining the percentage of steel required, the thickness of the reinforced concrete pavement, and the minimum allowable length of the slabs. Figure 14-1 presents a graphic solution for the design of reinforced concrete pavements. Since the thickness of a reinforced concrete pavement is a function of the percentage of steel reinforcing, the designer may determine either the required percentage of steel for a predetermined thickness of pavement or the required thickness of pavement for a predetermined percentage of steel. In either case, it is necessary first to determine the required thickness of plain concrete pavement by the method outlined previously in Chapter titled Plain Concrete Pavement Design. Enter the nomograph in Figure 14-1 using the plain concrete pavement thickness h_d (to the nearest 0.1 in (3 mm)). Then draw a straight line from the value of h_d to the value selected for either the reinforced concrete pavement thickness h_r or the percentage of reinforcing steel S. Note that the S value indicated by Figure 14-1 is the percentage to be used in the longitudinal direction only. For normal designs, the percentage of steel used in the transverse direction is one half of that used in the longitudinal direction. In fillets, the percent steel is the same in both directions. Once the h_r and S values have been determined, obtain the maximum allowable slab length L from the intersection of the straight line and the scale or L. Difficulties may be encountered in sealing joints between very long slabs because of large volumetric changes caused by temperature changes.

14-2.2 Thickness Design on Stabilized Base or Subgrade.

To determine the thickness requirements for reinforced concrete pavement on a stabilized foundation, first determine the thickness of plain concrete pavement required over the stabilized layer using procedures set forth in Chapter titled Plain Concrete Pavement Design. Then use this thickness of plain concrete with Figure 14-1 to design the reinforced concrete pavement in the same way discussed above for non-stabilized foundations.

Figure 14-1 Reinforced Rigid Pavement Design



14-3 LIMITATIONS.

The design criteria for reinforced concrete pavement for roads and parking areas are subject to the following limitations.

- No reduction in the required thickness of plain concrete pavement should be allowed for percentages of longitudinal steel less than 0.05 percent.
- No further reduction in the required thickness of plain concrete pavement should be allowed over that indicated in Figure 14-1 for 0.5 percent longitudinal steel, regardless of the percentage of steel used.
- The maximum length L of reinforced concrete pavement slabs should not exceed 75 ft (25 m) regardless of the percentage of longitudinal steel, yield strength of the steel, or thickness of the pavement. When long slabs are used, special consideration must be given to joint design and sealant requirements.
- The minimum thickness of reinforced concrete pavements should be 6 in (150 mm) and the minimum thickness for reinforced overlays over rigid pavements will be 4 in (100 mm).

14-4 DESIGN EXAMPLE.

Appendix G includes a design example for a reinforced concrete pavement.

14-5 TYPICAL DETAILS.

Figure C14-3, Figure C14-4 and Figure C14-5 (Appendix C) show typical details for a reinforced concrete pavement.

CHAPTER 15 PAVEMENT OVERLAYS

15-1 GENERAL.

Normally, overlays of existing pavements are used to increase the load-carrying capacity of an existing pavement or to correct a defective surface condition on the existing pavement. Of these reasons, the first requires a structural design procedure for determining the thickness of overlay; whereas the second requires only a thickness of overlay sufficient to correct the surface condition, and no increase in load-carrying capacity is considered. The design method for overlays included in this chapter determines the thickness required to increase load-carrying capacity. These methods have been developed from a series of full-scale accelerated traffic tests on various types of overlays and are, therefore, empirical. These methods determine the required thickness of overlay that, when placed on the existing pavement, will be equivalent in performance to the required design thickness of a new pavement placed on subgrade.

15-2 PREPARATION OF EXISTING PAVEMENT.

Exploration and tests of the existing pavement should be made to locate all areas of distress in the existing pavement and to determine the cause of the distress. Areas showing extensive and progressive cracking, rutting, and foundation failures should be repaired before the overlay. Such repair is especially needed in areas where excessive pumping, bleeding of groundwater at joints or cracks, excessive settlement in foundation, subgrade rutting, surface rutting, and slides have occurred. If testing of the existing pavement indicates the presence of voids beneath a rigid pavement, they should be filled by grouting before the overlay. The properties of the existing pavement and foundation such as the modulus of subgrade reaction, CBR, thickness, condition index, and flexural strength should be determined. The exact properties to be determined depend upon the type of overlay to be used. The surface of the existing pavement should be conditioned for the various types of overlays as follows.

15-2.1 Rigid Overlay.

Overlay thickness criteria are presented for three conditions of bond between the rigid overlay and existing rigid pavement: fully bonded, partially bonded, and non-bonded. The fully bonded condition exists when the concrete is cast directly on concrete and special efforts are made to obtain bond. The partially bonded condition exists when the concrete is cast directly on concrete with no special efforts to achieve or destroy bond. The non-bonded condition exists when the bond is prevented by an intervening layer of material. When using a fully bonded or partially bonded rigid overlay, clean the existing rigid pavement of all foreign matter (such as oil and paint), spalled concrete, extruded joint seal, bituminous patches, or anything else that would act as a bond-breaker between the overlay and existing rigid pavement. In addition, for the fully bonded overlay, prepare the surface of the existing pavement according to the recommendation in UFC 3-250-04. Apply a sand-cement grout or an epoxy grout to the cleaned surface immediately prior placement of the concrete overlay. When using a non-bonded rigid overlay, clean the existing rigid pavement of all loose particles and cover with a leveling or bond-breaking course of bituminous concrete, sand asphalt, heavy building paper, polyethylene, or other similar stable material. The bond-breaking medium generally should not exceed a thickness of about 1 in (25 mm) except in the case of leveling courses where greater thicknesses may be necessary. When applying a rigid overlay to an existing flexible pavement, clean the surface of the existing pavement of loose materials, and repair any potholing or unevenness exceeding about 1 in (25 mm) by cold planning, localized patching or the application of a leveling course using bituminous concrete, sand-asphalt, or a similar material.

15-2.2 Flexible Overlay.

When using a flexible overlay, no special treatment of the surface of the existing rigid pavement is required, other than the removal of loose material. When the flexible overlay is over bituminous concrete, clean the surface of the existing rigid pavement of all foreign matter, spalled concrete, fat spots in bituminous patches, and extruded soft or spongy joint seal material. Fill joints or cracks less than 1 in (25 mm) wide in the existing rigid with joint sealant. Clean joints or cracks that are 1 in (25 mm) or greater in width and fill with an acceptable bituminous mixture (such as sand asphalt) which is compatible with the overlay. Use leveling courses of bituminous concrete to bring the existing rigid pavement to the proper grade when required. Before placing the all-bituminous concrete, apply a tack coat to the surface of the existing pavement.

15-3 CONDITION OF EXISTING RIGID PAVEMENT.

15-3.1 General.

The support that the existing rigid pavement provides to an overlay is a function of its structural condition just before the overlay. In the overlay design equations, the structural condition of the existing rigid pavement is assessed by a condition factor C. Select the value of C based upon a condition survey of the existing rigid pavement. Use an interpolation of C values between those shown if it is considered necessary to define more accurately the existing structural condition.

15-3.2 Plain Concrete Overlay.

The following values of C are assigned for the following conditions of plain and reinforced concrete pavements.

15-3.2.1 Condition of Existing Plain Concrete Pavement:

C=1.00 - Pavements are in good condition with little or no structural cracking due to load.

C=0.75 - Pavements exhibit initial cracking due to load but no progressive cracking or faulting of joints or cracks.

C=0.35 - Pavements exhibit progressive cracking due to load accompanied by spalling, raveling, or faulting of cracks and joints.

15-3.2.2 Condition of Existing Reinforced Concrete Pavement.

C=1.00 - Pavements are in good condition with little or no short-spaced transverse 12 in (300 mm) to 24 in (600 mm) cracks, no longitudinal cracking, and little spalling or raveling along cracks.

C=0.75 - Pavements exhibit short-spaced transverse cracking but little or no interconnecting longitudinal cracking due to load and only moderate spalling or raveling along cracks.

C=0.35 - Pavements exhibit severe short-spaced transverse cracking and interconnecting longitudinal cracking due to load, severe spalling along cracks, and initial punch-out type failures.

15-3.3 Flexible Overlay.

The following values of C are assigned for the following conditions of plain and reinforced concrete pavement.

15-3.3.1 Condition of Existing Plain Concrete Pavements.

C=1.00 - Pavements are in good condition with some cracking due to load but little or no progressive-type cracking.

C=0.75 - Pavements exhibit progressive cracking due to load and spalling, raveling, and minor faulting at joints and cracks.

C=0.50 - Pavements exhibit multiple cracking along with raveling, spalling, and faulting at joints and cracks.

15-3.3.2 Condition of Existing Reinforced Concrete Pavement.

C=1.00 - Pavements are in good condition but exhibit some closely spaced load-induced transverse cracking, initial interconnecting longitudinal cracks, and moderate spalling or raveling of joints and cracks.

C=0.75 - Pavements in trafficked areas exhibit numerous closely spaced load-induced transverse and longitudinal cracks, rather severe spalling or raveling, or initial evidence of punch-out failures.

15-4 RIGID OVERLAY OF EXISTING RIGID PAVEMENT.

15-4.1 General.

There are three basic equations for the design of rigid overlays which depend upon the degree of bond that develops between the overlay and existing pavement: fully bonded, partially bonded, and non-bonded. Use the fully bonded overlay equation when special care is taken to provide bond between the overlay and the existing pavement. Use the partially bonded equation when the rigid overlay is to be placed directly on the existing pavement and no special care is taken to provide bond. Use a bond-breaking medium and the non-bonded equation when a plain concrete overlay is used to overlay an existing reinforced concrete pavement or an existing plain concrete pavement that has a condition factor $C \leq 0.35$. Also use these equations when matching joints in a plain concrete overlay with those in the existing plain concrete pavement causing undue construction difficulties or resulting in odd-shaped slabs.

15-4.2 Plain Concrete Overlay.

15-4.2.1 Thickness Determination.

The required thickness h_o of plain concrete overlay is determined from the following applicable equations:

Fully bonded

$$h_o = h_d - h_E \qquad \text{(eq. 15-1)}$$

Partially bonded

$$h_o = \sqrt[1.4]{h_d^{1.4} - C\left(\frac{h_d}{h_e} \times h_E\right)^{1.4}} \qquad \text{(eq. 15-2)}$$

Non-bonded

$$h_o = \sqrt{h_d^{2} - C\left(\frac{h_d}{h_e} \times h_E\right)^{2}} \qquad \text{(eq. 15-3)}$$

where h_d is the design thickness of plain concrete pavement determined from Appendix F using the design flexural strength of the overlay and h_e is the design thickness of plain concrete pavement using the measured flexural strength of the existing rigid pavement, the modulus of soil reaction **k** of the existing rigid pavement foundation, and the design traffic needed for overlay design. The use of fully bonded overlay is limited to existing pavements having a condition index of 1.0 and to overlay thickness of 2.0 in (50 mm) to 5.0 in (125 mm). The fully bonded overlay is used primarily to correct a surface problem such as scaling rather than as a structural upgrade. The factor h_E represents the thickness of the existing plain concrete pavement or the equivalent thickness of plain concrete pavement having the same load-carrying capacity as the existing pavement. If the existing pavement is reinforced concrete, h_E is determined from Figure 14-1 using the percent reinforcing steel S and design thickness h_e. The minimum thickness of plain concrete overlay is 2 in (50 mm) for a fully bonded overlay and 6 in (150 mm) for a partially bonded or non-bonded overlay. When the final pavement thickness obtained from the design curve indicates a fractional value, round up in 0.5 in (10 mm) increments. See paragraph titled Overlay Design Example for an example.

15-4.2.2 Jointing.

For all partially bonded and fully bonded plain concrete overlays, provide joints in the overlay to coincide with all joints in the existing rigid pavement. It is not necessary for joints in the overlay to be of the same type as joints in the existing pavement. When it is impractical to match the joints in the overlay to joints in the existing rigid pavement, either use a bond-breaking medium and design the overlay as a non-bonded overlay or reinforce the overlay over the mismatched joints. Should the mismatch of joints become severe, consider a reinforced concrete overlay design as an economic alternative to the use of a non-bonded plain concrete overlay. For non-bonded plain concrete overlays, the design and spacing of transverse contraction joints is in accordance with requirements for plain concrete pavements. For both partially bonded and non-bonded plain concrete overlays, dowel the longitudinal construction joints using the dowel size and spacing discussed in Chapter titled Rigid Overlay Of Existing Flexible Or Composite Pavements. Do not use dowels and load-transfer devices in fully bonded overlays. Joint sealing for plain concrete overlays must conform to the requirements for plain concrete pavements.

15-4.3 Reinforced Concrete Overlay.

A reinforced concrete overlay may be used to strengthen either, an existing plain concrete pavement, or an existing reinforced concrete pavement. Generally, the overlay will be designed as a partially bonded overlay. Use the non-bonded overlay design only when a leveling course is required over the existing pavement. Design the reinforcement steel for reinforced concrete overlays and place in accordance with reinforced concrete pavements.

15-4.3.1 Thickness Determination.

Determine the required thickness of reinforced concrete overlay using Figure 14-1 after determining the thickness of plain concrete overlay from the appropriate overlay equation. Then, using the value for the thickness of plain concrete overlay, select either the thickness of reinforced concrete overlay and determine the required percent steel or select the percent steel and determine the thickness of reinforced concrete overlay from Figure 14-1. The minimum thickness of reinforced concrete overlay must be 6 in (150 mm).

15-4.3.2 Jointing.

Whenever possible, the longitudinal construction joints in the overlay should match the longitudinal joints in the existing pavement. Dowel all longitudinal joints dowel size and spacing designated in Chapter titled Joints For Plain Concrete using the thickness of reinforced concrete overlay. It is not necessary for transverse joints in the overlay to match joints in the existing pavement; however, when practical, match the joints. Determine the maximum spacing of transverse contraction joints in accordance with equation 17-1, but do not exceed 75 ft (25 m) regardless of the thickness of the pavement or the percent steel used. Joint sealing for reinforced concrete pavements must conform to the requirements for plain concrete pavements.

15-5 RIGID OVERLAY OF EXISTING FLEXIBLE OR COMPOSITE PAVEMENTS.

15-5.1 Flexible Pavements.

Design a rigid overlay of an existing flexible pavement in the same way as a rigid pavement on grade. Determine a modulus of subgrade reaction **k** by a plate-bearing test performed on the surface of the existing flexible pavement. If it is not practical to determine **k** from a plate-bearing test, use Figure 10-1 to determine an approximate value. Figure 10-1 yields an effective **k** value at the surface of the flexible pavement as a function of the subgrade **k** and thickness of base and subbase above the subgrade. When using Figure 10-1, consider the bituminous concrete to be unbound base course material. Using this **k** value and the concrete flexural strength, determine the required thickness of plain concrete overlay from the charts in Appendix F. However, the following limitations should apply:

- In no case should a **k** value greater than 500 pci (140 KPa/mm) be used.
- Perform the plate-bearing test to determine the **k** value on the flexible pavement at a time when the temperature of the bituminous concrete is within five degrees of the ambient temperature of the hottest period of the year in the locality of the proposed construction.

15-5.2 Composite Base Pavements.

Two conditions of composite pavement are possible when considering a rigid overlay. When the composite pavement is composed of a rigid base pavement with less than 4 in (100 mm) of all-bituminous overlay, determine the required thickness of rigid overlay using the non-bonded overlay equation. If the composite pavement is composed of a rigid base pavement with 4 in (100 mm) or more of either all bituminous or bituminous with base course overlay, determine the required thickness of overlay by paragraph titled Flexible Pavements above. The same limitations for maximum **k** value and temperature of pavement during testing apply.

15-6 FLEXIBLE OVERLAY OF FLEXIBLE PAVEMENT.

Overlays are used for strengthening or rehabilitation of an existing pavement. Strengthening is required when heavier loads are introduced or when a pavement is no longer capable of supporting the loads for which it was designed. Rehabilitation may include sealing or resealing of cracks, patching, limited reconstruction before an overlay, restoration of the surface profile, improvement of skid resistance by a friction course, or improvement of the surface quality. When it has been determined that strengthening is required, design the overlay by designing a new pavement and comparing its thickness with the thickness of the existing pavement. The difference between these two pavements is the thickness of overlay required to satisfy design requirements. Overlays may be all-bituminous concrete or asphalt concrete and base course. The flexible pavement, after being overlaid, must meet all compaction requirements of a new pavement. Where the existing construction is complex, consisting of several layers, and especially where there are semi-rigid layers, such as soil cement, cement-stabilized soils, or badly cracked PCC, exercise careful judgment to evaluate the existing materials. UFC 3-260-03 provides criteria for evaluating existing construction.

15-7 FLEXIBLE OVERLAY OF RIGID BASE PAVEMENT.

15-7.1 Design Procedure.

The design procedure presented determines the thickness of flexible overlay necessary to increase the load-carrying capacity of existing rigid pavement. This method is limited to the design of the two types of flexible overlay, the all-bituminous and the bituminous with base course. The selection of the type of flexible overlay to be used for a given condition is dependent only on the required thickness of the overlay. Normally, use the bituminous with base course overlay when the required thickness of overlay is sufficient to incorporate a minimum 4 in (100 mm) compacted layer of high quality base course material plus the required thickness of bituminous concrete surface courses. For lesser thicknesses of flexible overlay, use the all-bituminous overlay. The method of design is referenced to the deficiency in thickness of the existing rigid base pavement and assumes that a controlled degree of cracking takes place in the rigid base pavement during the design life of the pavement.

15-7.2 Thickness Determination.

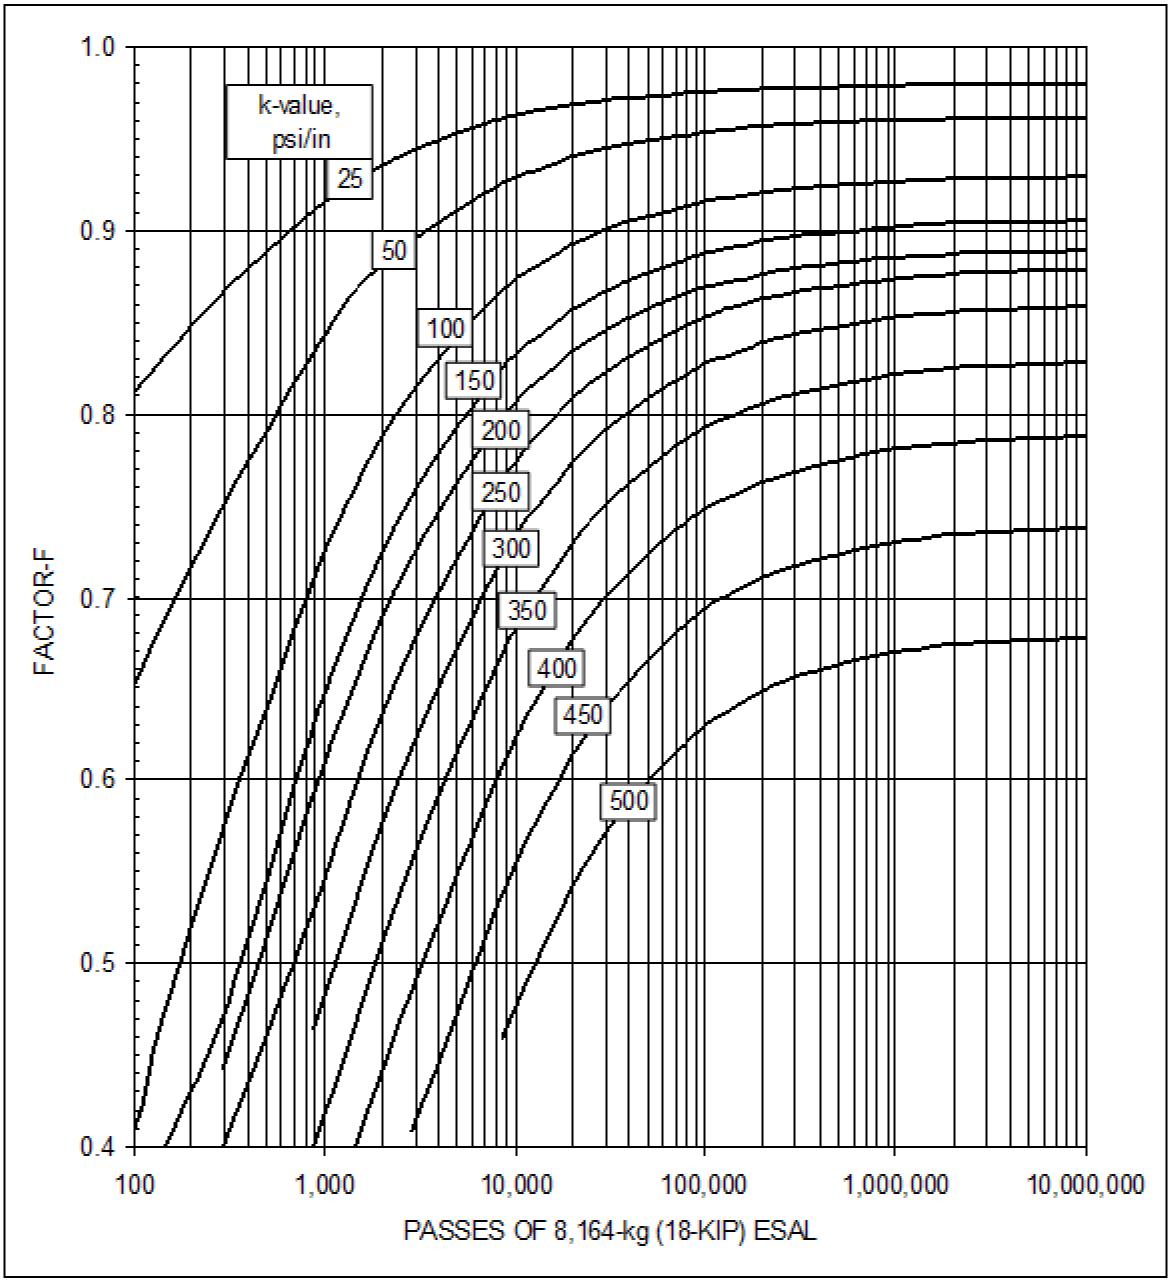
Regardless of the type of non-rigid overlay, determine the thickness by

$$t_o = 3.0\left(Fh_d - Ch_E\right) \text{(eq. 15-4)}$$

where h_d is the design thickness of plain concrete pavement from the charts in Appendix F; the factor h_e represents the thickness of plain concrete pavement equivalent in load-carrying capacity to the thickness of existing rigid pavement. If the existing rigid pavement is plain concrete, then the equivalent thickness equals the existing thickness. If the existing rigid pavement is reinforced concrete, determine the equivalent thickness from Figure 14-1. F is a factor, determined from Figure 15-1, that projects the cracking expected to occur in the base pavement during the design life of the overlay. C is a coefficient from paragraph titled Condition of Existing Pavement based upon the structural condition of the existing rigid pavement.

Round the computed overlay thickness up using 0.5 in (10 mm) increments. To reduce reflective cracking, the minimum thickness of all-bituminous overlay used for strengthening purposes will be 4 in (100 mm). No limitation is placed on the minimum thickness of an all-bituminous overlay when used for maintenance or to improve pavement surface smoothness. In certain instances, the flexible overlay design equation may indicate thickness requirements less (sometimes negative values) than the minimum values. In such cases use the minimum thickness requirement. When strengthening existing rigid pavements that exhibit low flexural strength (less than 500 psi (3.5 MPa)) or that are constructed on high-strength foundation (k exceeding 200 pci (50 kPa/mm)), it is possible that the flexible pavement design procedure in this UFC indicates a lesser required overlay thickness than the overlay design formula. For these conditions, determine the overlay thickness by both methods, and use the lesser thickness for design. For the flexible pavement design procedure, consider the existing rigid pavement an equivalent thickness of high quality crushed aggregate base (CBR = 100), and determine the total pavement thickness based upon the subgrade CBR. Consider any existing base or subbase layers as corresponding layers in the flexible pavement. The thickness of required overlay is then the difference between the required flexible pavement thickness and the combined thicknesses of existing rigid pavement and any base or subbase layers above the subgrade.

Figure 15-1 Factor for Projecting Cracking in a Flexible Pavement



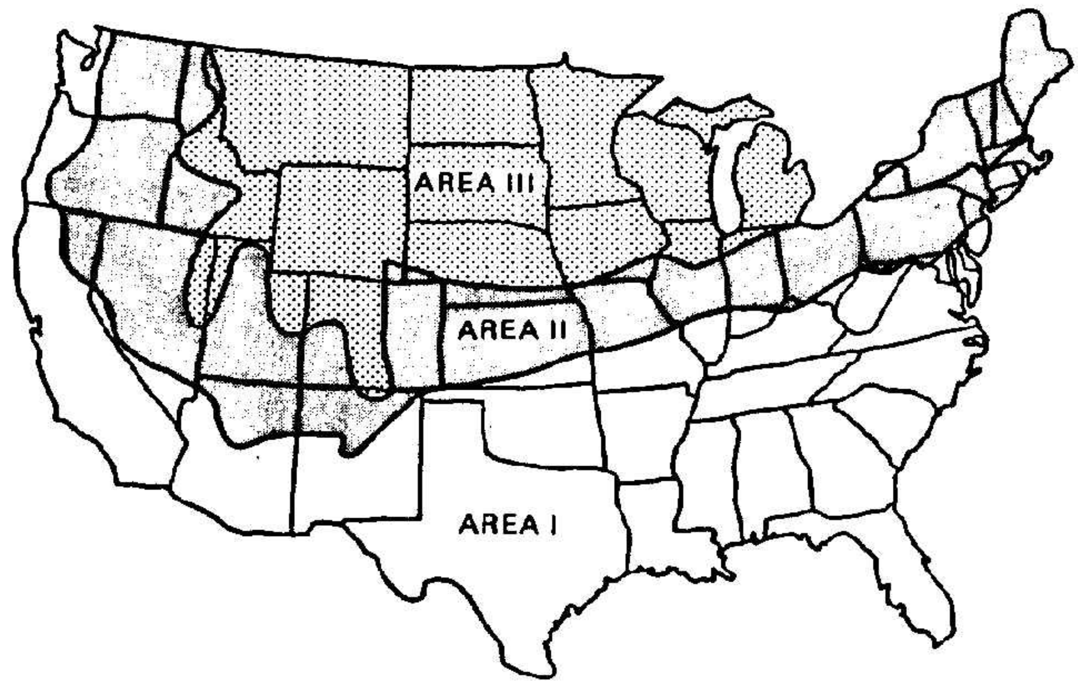
15-7.3 Jointing.

Normally, joints, other than those required for construction of a bituminous concrete pavement, are not required in flexible overlays of existing rigid pavements. It is good practice to try to layout paving lanes in the bituminous concrete to prevent joints in the overlay from coinciding with joints in the rigid base pavement. Movements of the existing rigid pavement, both from contraction and expansion and deflections due to applied loads, cause high concentrated stresses in the flexible overlay directly over joints and cracks in the existing rigid pavements. These stresses may result in cracking, often referred to as reflection cracks, in the overlay. The severity of this type of cracking depends, in part, upon the type of rigid pavement. For example, a plain concrete pavement normally has closely spaced joints and may result in reflection cracks over the joints, but the cracks are fairly tight and less likely to ravel. Nevertheless, reinforced concrete pavements normally have joints spaced farther apart, which in turn experience larger movements. The reflection cracks over these joints are more likely to ravel and spall. Likewise, either existing plain concrete or reinforced concrete pavements may have expansion joints that experience rather large movements, and consideration should be given to provide an expansion joint in the flexible overlay to coincide with the expansion joint in the existing pavement. No practical method has been developed to absolutely prevent reflective cracking in flexible overlays; however, experience shows that the degree of cracking is related to the thickness of the overlay, with the thinner overlays exhibiting the greater tendency to crack.

15-8 USE OF GEOTEXTILES TO RETARD REFLECTIVE CRACKING.

Geotextiles are effective in retarding reflective cracking in some areas of the United States, as shown in Figure 15-2. When using geotextiles under an asphalt concrete pavement, the existing pavement should be relatively smooth with all cracks larger than 0.25 in (6 mm) sealed. A leveling course is also recommended before application of the fabric to ensure a suitable surface. A tack coat is also required immediately before placement of the geotextile. The minimum overlay thickness is shown in Figure 15-2. When using geotextiles under a flexible pavement overlay, the geotextiles can be used as a membrane strip or a full-width application. The existing pavement should be stable with negligible movement under loads and all joints and cracks larger than 0.25 in (6 mm) sealed. With the strip method, apply the geotextile directly on the concrete joints and cracks and then overlay. With the full-width method, apply the geotextile directly to the existing pavement or place on a leveling course. In flexible overlays, the lower viscosity (or higher penetration grade) asphalts are less likely to experience reflective cracking. Therefore, use the lowest viscosity grade asphalt that provides sufficient stability during high temperatures.

Figure 15-2 Location Guide for the Use of Geotextiles in Retarding Reflective Cracking



AREA I – GEOTEXTILES ARE RECOMMENDED WITH MINIMUM OVERLAY THICKNESS OF 2 IN.
AREA II – ARE RECOMMENDED WITH OVERLAY THICKNESS OF 3-4 IN.
AREA III – GEOTEXTILES ARE NOT RECOMMENDED

15-9 OVERLAYS IN FROST REGIONS.

Whenever the subgrade is susceptible to differential heaving or weakening during the frost-melt period, the overlay design should meet the requirements for frost action as given in Chapter titled Seasonal Frost Conditions. When it is determined that distress in an existing pavement has been caused by differential heaving due to frost action, an overlay may not correct the condition unless the combined thickness of the pavement is sufficient to prevent substantial frost penetration into the underlying frost-susceptible material.

15-10 OVERLAY DESIGN EXAMPLE.

Appendix G includes examples of design for bonded, partially bonded, unbounded rigid overly and flexible overlay design.

CHAPTER 16 JOINTS FOR PLAIN CONCRETE

16-1 ROADWAYS

A typical layout and cross section of a roadway is presented in Figure C16-1 (Appendix C) and shows the location of various types of joints. Figure C16-2, Figure C16-3, Figure C16-4, Figure C16-5, and Figure C16-6 (Appendix C) show the associated details for the design and construction of plain concrete pavements. Figure C14-1 (Appendix C) presents a layout of joints at intersections of plain concrete pavements. Figure C16-2 (Appendix C) shows the layout of joints for plain concrete parking areas. Joints for roller compacted concrete pavements (RCCP) are discussed in Chapter 18.

16-2 JOINT TYPES AND USAGE.

Joints are provided to permit contraction and expansion of the concrete resulting from temperature and moisture changes, to relieve warping and curling stresses due to temperature and moisture differentials, to prevent unsightly irregular breaking of the pavement, and as a construction expedient, to separate sections or strips of concrete placed at different times. The three general types of joints are contraction, construction, and expansion and are shown in Figure C16-7 (Appendix C).

16-2.1 Contraction Joints.

Weakened-plane contraction joints control cracking in the concrete and limit curling or warping stresses resulting from drying shrinkage and contraction, and from temperature and moisture gradients in the pavement, respectively. Shrinkage and contraction of the concrete causes slight cracking and separation of the pavement at the weakened planes, which provides some relief from tensile forces resulting from foundation restraint and compressive forces caused by subsequent expansion. Contraction joints are required transversely and may be required longitudinally depending upon pavement thickness and spacing of construction joints. UFC 3-250-04 contains instructions for the use of sawcuts or preformed inserts to form the weakened plane.

16-2.1.1 Width and Depth of Weakened Plane Groove.

The width of the weakened plane groove must be a minimum of 1/8 in (3 mm) and a maximum equal to the width of the sealant reservoir. The depth of the weakened plane groove must be great enough to cause the concrete to crack under the tensile stresses resulting from the shrinkage and contraction of the concrete as it cures. Experience, supported by analyses, indicates that this depth should be at least one-fourth of the slab thickness for pavements 12 in (300 mm) or less, and 3 in (75 mm) for pavements greater than 12 in (300 mm) and less than 18 in (450 mm) in thickness. In no case is the depth of the groove less than the maximum nominal size of aggregate used. Concrete placement conditions may influence the fracturing of the concrete and dictate the depth of groove required. For example, concrete placed early in the day, when the air temperature is rising, may experience expansion rather than contraction during the early life of the concrete with subsequent contraction occurring several hours later as the air temperature drops. The concrete may have attained sufficient strength before the contraction occurs so that each successive weakened plane does not result in fracturing of the concrete. As a result, an excessive opening may result where fracturing does occur. To prevent such an opening, increase the depth of the groove to one-third of the slab thickness to assure the fracturing and proper functioning of each of the scheduled joints.

16-2.1.2 Width and Depth of Sealant Reservoir.

The dimensions of the sealant reservoir are critical to satisfactory performance of the joint sealing materials. The minimum width is 3/4-in (19 mm) and the minimum depth is 1.0 – 1.5 times the width.

16-2.1.3 Spacing of Transverse Contraction Joints.

Transverse contraction joints must be constructed across each paving lane perpendicular to the center line. The spacing between transvers contraction joints is generally 10 ft (3 m). If possible the slabs should be close to square or the joint spacing should equal the paving width. In regions where the design freezing index is 1,800 or more degree days the maximum spacing should be 20 ft (6 m). The joint spacing must be uniform throughout any major paved area, and each joint must be straight and continuous from edge to edge of the paving lane and across all paving lanes for the full width of the paved area. Staggering of joints in adjacent paving lanes can lead to sympathetic cracking and is not permitted unless reinforcement is used or separated by a thickened edge expansion joint. The maximum spacing of transverse joints that effectively control cracking varies appreciably depending on pavement thickness, thermal coefficient and other characteristics of the aggregate and concrete, climatic conditions, and foundation restraint. It is impractical to establish limits on joint spacing that are suitable for all conditions without making them unduly restrictive. The joint spacing in Table 16-1 give satisfactory control of transverse cracking in most instances, subject to modification based on available information regarding the performance of existing pavements in the vicinity or unusual properties of the concrete. Experience shows that oblong slabs, especially in thin pavements, tend to crack into smaller slabs of nearly equal dimensions under traffic. Therefore, it is desirable, insofar as practicable, to keep the length and width dimensions as nearly equal as possible. In no case should the length dimension (in the direction of paving) exceed the width dimension more than 25 percent. Use joint spacing as indicated in Table 16-1 or as approved by the Government Civil Engineer. Requests must indicate local conditions and justification for the proposed change in joint spacing.

Table 16-1 Allowable Spacing of Longitudinal and Transverse Contraction Joints

Pavement Thickness, in (mm)	Spacing of Joint, ft (m)
Less than 9 (225)	10 to 15 (3.0 to 4.6)
9 to 12 (225 to 300)	15 to 20 (4.6 to 6.1)
Over 12 (300)	20 (6.1)*
* The maximum spacing of transverse contraction joints for DoD pavements is 20 ft (6.1 m).	

16-2.1.4 Spacing of Longitudinal Contraction Joints.

Contraction joints must be placed along the centerline of paving lanes that have a width greater than the determined maximum spacing of transverse contraction joints in Table 16-1. These joints may also be required in the longitudinal direction for overlays, regardless of overlay thickness, to match joints existing in the base pavement unless a bond-breaking medium is used between the overlay and base pavement or the overlay pavement is reinforced. Normally, the contractor should be given the option to used construction joints in the longitudinal paving direction to permit smaller paving equipment to be used.

16-2.1.5 Doweled and Tied Contraction Joints.

16-2.1.5.1 Transverse Joints.

Dowels are required in transverse contraction joints for plain concrete pavements for roads and parking areas that use slab lengths greater than those in Table 16-1. Dowels are recommended in the last joint at ends of long paving lanes such as large storage and parking areas. Doweled transverse contraction joints in plain concrete pavement are required to ensure joint load transfer under heavy, repeated loads and reduce slab pumping and faulting. Doweled transverse contraction joints provide a smoother driving surface across the joint. Doweled transverse contraction joints in reinforced concrete pavements are required to ensure good joint transfer where conventional contraction joints may have inadequate load transfer because of excessive joint opening. Table 16-2 presents the size and spacing of dowels. Because of inadequate thermal expansion and contraction capability, not more than two consecutive joints must be constructed with tied bars. Smooth dowel must be used in every other joint.

Table 16-2 Dowel Size and Spacing for Construction, Contraction, and Expansion Joints

Pavement Thickness, in (mm)	Minimum Dowel Length, in (mm)	Max Dowel Spacing, in (mm)	Dowel Diameter and Type
Less than 8 (200)	16 (400)	12 (300)	.75 in (20 mm) bar
8 to 11 (200 to 275)	16 (400)	12 (300)	1 in (25 mm) bar
12 to 15 (300 to 380)	20 (510)	15 (375)	1 in (25 mm) to 1.25 in (32 mm) bar, or 1 in (25 mm) extra strength pipe*
* Extra strength pipe will be filled or plugged when used.			

16-2.1.5.2 Longitudinal Joints

For plain concrete pavements, deformed tie bars are required in longitudinal contraction joints that fall 15 ft (4.6 m) or less from the free edge of paved areas that are 100 ft (30.5 m) or greater in width. The deformed tie bars must be 30 in (750 mm) long, and spaced on 30 in (750 mm) centers. In addition, longitudinal contraction joints placed along the center line of paving lanes that have a width greater than the maximum spacing of transverse contraction joints must be tied using tie bars of the dimensions shown in Figure C16-3 (Appendix C).

16-2.2 Construction Joints.

Construction joints may be required in both the longitudinal and transverse directions. Longitudinal construction joints, generally spaced 10 to 25 ft (3.0 to 7.6 m) apart but which may reach 50 ft (15.2 m) apart, depending on construction equipment capability, must be provided to separate successively placed paving lanes. Transverse construction joints must be installed at the end of each day's paving operation and at other points within a paving lane where the placing of concrete is discontinued a sufficient length of time for the concrete to start to set. All transverse construction joints should be located in place of other regularly spaced transverse joints (contraction or expansion types). There are several types of construction joints available for use, as described below. The selection of the type of construction joint depends on such factors as the concrete placement procedure (formed or slip formed) and foundation conditions. Make longitudinal changes in grade at a joint if slip formed paving is permitted. Spacing between longitudinal joints in parking areas should be as uniform as possible to minimize contractor downtime required to adjust paver width.

16-2.2.1 Doweled Joint.

The doweled joint is the best joint for providing load transfer and maintaining slab alignment. It is a desirable joint for the most adverse conditions such as heavy loading, high traffic intensity, and lower strength foundations. However, because the alignment and placement of the dowel bars are critical to satisfactory performance, this type of joint is difficult to construct, especially for slip formed concrete. However, the doweled joint is required for all transverse construction joints in plain concrete pavements.

16-2.2.2 Thickened-Edge Joint.

Thickened-edge type joints may be used instead of other types of joints using load transfer devices. When the thickened-edge joint is constructed, the thickness of the concrete at the edge is increased to 125 percent of the design thickness. The thickness is then reduced by tapering from the free-edge thickness to the design thickness at a distance of 5 ft (1.5 m) from the longitudinal edge. For pavement thickness less than 12 in (300 mm), the taper distance can be reduced to 3 ft (0.9 m) at the designer’s option. The thickened-edge joint is considered adequate for the load-induced concrete stresses. However, the inclusion of a key in the thickened-edge joint Figure C16-4 (Appendix C) provides some degree of load transfer in the joint and helps to maintain slab alignment; although not required, it can be used for pavement constructed on low- to medium-strength foundations. The thickened-edge joint may be used at free edges of paved areas to accommodate future expansion of the facility or where wheel loadings may track the edge of the pavement. The use of this type joint is contingent upon adequate base course drainage meeting requirements of UFC 3-250-04.

16-2.2.3 Keyed Joint.

The keyed joint is the most economical method, from a construction standpoint, for providing load transfer in the joint. The key or keyway can be satisfactorily constructed using either formed or slip formed methods. The required dimensions of the joint can best be maintained by forming or slip forming the keyway rather than the key. The dimensions and location of the key are critical to its performance. Deviations exceeding the stated tolerances can result in failure in the joint. Keyed joints should not be used in rigid pavements that are less than 9 in (225 mm) in thickness. Tie bars in the keyed joint limit opening of the joint and provide some shear transfer that will improve the performance of the keyed joints. However, tying all joints in pavement widths of more than 75 ft (25 m) can result in excessive stresses and cracking in the concrete during contraction.

16-2.3 Expansion Joints.

Expansion joints must be used at all intersections of pavements with structures or with other concrete pavements where paving lanes are perpendicular to each other, and they may be required within the pavement features. The types of expansion joints are the thickened-edge joint, the thickened-edge slip joint, and the doweled type joint. Refer to Figure C16-5 and Figure C16-6 (Appendix C). Filler material for the thickened-edge and doweled type expansion joint must be a non-extruding type. The type and thickness of filler material and the way of its installation will depend upon the particular case. Usually, a preformed material of 3/4-in (19 mm) thickness is adequate; however, in some instances, a greater thickness of filler material may be required. Filler material for slip joints must be either a heavy coating of bituminous material not less than 1/16 in (1.5 mm) in thickness when joints match or a normal non-extruding-type material not less than 1/4 in (6 mm) in thickness when joints do not match. Where large expansions may have a detrimental effect on adjoining structures, such as at the juncture of rigid and flexible pavements, consider expansion joints in successive transverse joints back from the juncture. The depth, length, and position of each expansion joint must be sufficient to form a complete and uniform separation between the pavements or between the pavement and the structure concerned.

16-2.3.1 Between Pavement and Structures.

Expansion joints must be installed to surround, or to separate from the pavement, any structures that project through, into, or against the pavements, such as at the approaches to buildings or around drainage inlets. The thickened edge expansion joint is generally best suited for these places. Refer to Figure C16-5 (Appendix C).

16-2.3.2 Within Pavements and at Pavement Intersections.

Expansion joints within pavements are difficult to construct and maintain and often contribute to pavement failures. Keep their use to the absolute minimum necessary to prevent excessive stresses in the pavement from expansion of the concrete or to avoid distortion of a pavement through the expansion of an adjoining pavement. Determine the need for and spacing of expansion joints based upon pavement thickness, thermal properties of the concrete, prevailing temperatures in the area, temperatures during the construction period, and the experience with concrete pavements in the area. Unless needed to protect abutting structures, omit expansion joints in all pavements 10 in (250 mm) or more in thickness and also in pavements less than 10 in (250mm) thickness when the concrete is placed during warm weather since the initial volume of the concrete on hardening will be at or near the maximum. However, for concrete placed during cold weather, expansion joints may be used in pavements less than 10 in (250 mm) thick.

16-2.3.2.1 Longitudinal Joints

Longitudinal expansion joints within pavements must be of the thickened-edge type, refer to Figure C16-5 (Appendix C). Dowels are not permitted in longitudinal expansion joints because differential expansion and contraction parallel with the joints may develop undesirable localized strains and cause failure of the concrete, especially near the corners of slabs at transverse joints. Expansion joints are not required between two adjoining pavements where paving lanes of the two pavements are parallel.

16-2.3.2.2 Transverse Joints

Transverse expansion joints in roads are typically not needed since the initial volume of concrete hardening will be at or near the maximum. Transverse expansion joints in roads and parking areas can progressively close up over the years, allowing adjacent contraction joints to open more. The result is increased infiltration of fines and loss of load transfer in the adjacent contraction joints. Transverse expansion joints are required at bridge approach slabs. Thickened edge expansion joints may be used in roads and parking areas which do not require doweled contraction joints. Transverse expansion joints may be considered when pavement is constructed at low temperature or using materials that in the past have shown high expansion characteristics.

16-2.3.2.3 Slip Joints

A special expansion joint, the slip joint, is required at pavement intersections.

16-3 DOWELS.

The important functions of dowels or any other load-transfer device in concrete pavements are to help maintain the alignment of adjoining slabs and to transfer some stresses from loads to the adjacent slab, thereby limiting or reducing stresses in the loaded slab. Specify different sizes of dowels for different thicknesses of pavements as indicated in Table 16-2. When extra strength pipe is used for dowels, fill the pipe with either a stiff mixture of sand-asphalt or Portland cement mortar or plug the ends of the pipe. If the ends of the pipe are plugged, the plug must fit inside the pipe and be cut off flush with the end of the pipe so that there will be no protruding material to bond with the concrete and prevent free movement of the dowel. All dowels must be straight, smooth, and free from burrs at the ends. One end of the dowel will be painted and oiled to prevent bonding with the concrete. Dowels used at expansion joints must be capped at one end, in addition to being painted and oiled, to permit further penetration of the dowels into the concrete when the joints close.

16-4 SPECIAL PROVISIONS FOR SLIP FORM PAVING.

Make provisions for slip form pavers when there is a change in longitudinal joint configuration. The thickness may be varied without stopping the paving train, but the joint configuration cannot be varied without changing the side forms, which normally require stopping the paver and installing a header. The following requirements apply at a pavement transition area.

16-4.1 Header.

The header may be set on either side of the transition slab with the transverse construction joint doweled, as required. The dowel size and location in the transverse construction joint should be commensurate with the thickness of the pavement at the header.

16-4.2 Transition Between Different Joints.

When there is a transition between a doweled longitudinal construction joint and a keyed longitudinal construction joint, the longitudinal construction joint in the transition slab may be either keyed or doweled. The size and location of the dowels or keys in the transition slabs should be the same as those in the pavement with the doweled or keyed joint, respectively.

16-4.3 Transition Between Two Keyed Joints.

When there is a transition between two keyed joints with different dimensions, the size and location of the key in the transition slab should be based on the thickness of the thinner pavement.

16-5 JOINT SEALING.

All joints will be sealed to prevent infiltration of surface water and solid substances. Use a jet fuel resistant sealant, either poured or preformed, in the joints of hardstands, wash racks, and other paved areas where fuel or other lubricants may be spilled during the operation, parking, maintenance, and servicing of vehicles. Poured joint sealant must conform to UFGS 32 01 19 and preformed joint seals must conform to UFGS 32 13 73. Use sealants that are not fuel resistant in joints of all other pavements. Compress preformed sealants 45 to 85 percent of their original width. Base the selection of poured or preformed sealant upon economics. Compression-type preformed sealants are recommended when the joint spacing exceeds 25 ft (7.6 m). For many projects the cold applied (silicone) sealants have the best life-cycle cost.

16-6 SPECIAL JOINTS AND JUNCTURES.

Situations can develop where special joints or variations of the more standard type joints are needed to accommodate the movements that occur and to provide a satisfactory operational surface. Some of these special joints or junctures are as follows:

16-6.1 Slip-Type Joints.

At the juncture of two pavement facilities, expansion and contraction of the concrete may result in movements that occur in different directions. Such movements may create detrimental stresses within the concrete unless provision is made to allow the movements to occur. At such junctures, a thickened-edge slip joint must be used to permit the horizontal slippage to occur. The design of the thickened-edge slip joint is similar to the thickened-edge construction joint. Refer to Figure C16-6 (Appendix C). The bond-breaking medium must be either a heavy coating of bituminous material not less than 1/16 in (1.5 mm) in thickness when joints match or a normal non-extruding type expansion joint material not less than 1/4 in (6 mm) in thickness when joints do not match. The 1/16 in (1.5 mm) bituminous coating may be either a low penetration (60 to 70 grade asphalt) or a clay-type asphalt-base emulsion similar to that used for roof coating and must be applied to the face of the joint by hand brushing or spraying.

16-6.2 Joints Between New and Existing Pavements.

A special thickened-edge joint design, refer to Figure C16-4 (Appendix C), must be used at the juncture of new and existing pavements for the following conditions:

- When load-transfer devices (keyways or dowels) or a thickened edge are not provided at the free edge of the existing pavement.
- When load-transfer devices or a thickened edge is provided at the free edge of the existing pavement, but neither meet the design requirements for the new pavement.
- For transverse contraction joints, when removing and replacing slabs in an existing pavement.
- For longitudinal construction joints, when removing and replacing slabs in an existing pavement if the existing load-transfer devices are damaged during the pavement removal.
- Any other location where it is necessary to provide load transfer for the existing pavements. The special joint design may not be required if a new pavement joins an existing pavement that is grossly inadequate to carry the design load of the new pavement or if the existing pavement is in poor structural condition. If the existing pavement can carry a load that is 75 percent or less of the new pavement design load, special efforts to provide edge support for the existing pavement may be omitted and the alternate thickened-edge joint used as shown in Figure C16-4 (Appendix C); however, if omitted, the existing pavement may experience accelerated failures. Design the new pavement with a thickened edge at the juncture. Use any load-transfer devices in the existing pavement at the juncture to provide as much support as possible to the existing pavement. Consider drilling and grouting dowels in the existing pavement for edge support as an alternate to the special joint; however, use a thickened-edge design for the new pavement at the juncture.

CHAPTER 17 JOINTS FOR REINFORCED CONCRETE

17-1 REQUIREMENTS.

The exceptions for joint requirements and types of reinforced concrete pavements are the same as for plain concrete pavements except as listed below.

Figure C17-1, Figure C17-2 and Figure C17-3 (Appendix C) show the associated details for the design and construction of joints for reinforced concrete pavements.

17-1.1 Unscheduled Joints.

All joints falling at a point other than a regularly scheduled transverse contraction joint must be doweled with the exception of the thickened-edge type. One end of the dowel must be painted and oiled to permit movement at the joint.

17-1.2 Thickened-Edge-Type Joints.

Thickened-edge-type joints must not be doweled. Thicken the edge to 125 percent of the design thickness.

17-1.3 Transverse Construction Joint.

When a transverse construction joint is required within a reinforced concrete slab unit not at a regularly scheduled contraction joint location, carry the reinforcing steel through the joint. In addition, use dowels meeting the size and spacing requirements of Table 16-2 for the design thickness in the joint.

17-1.4 Transverse Contraction Joints.

Transverse contraction joints in reinforced concrete pavements should be constructed across each paving lane, perpendicular to the pavement center line, and at intervals of not less than 25 ft (7.6 m) nor more than 75 ft (25 m). The maximum allowable slab width or length for reinforced concrete pavements is a function of the effective frictional restraint developed at the interface between the slab and subgrade, the percentage of steel reinforcing used in the slab, and the yield strength of the steel reinforcing. Allowable slab widths or lengths can be determined directly from Figure 14-1 for yield strengths of 60,000 psi (410 MPa). If it is desired to use reinforcing steel having a yield strength other than this value, determine the maximum allowable slab width or length from the following equation:

Equation 17-1 $$L = \left[0.00047 \cdot h_r \cdot \left(f_s \cdot S\right)^2\right]^{\frac{1}{3}}$$

where

h_r=thickness of reinforced concrete pavement, in

f_s=yield strength of reinforcing steel, psi

S=percent of reinforcing steel

17-1.5 Two Traffic Lanes.

For reinforced concrete pavements where two traffic lanes are placed as a single paving lane, provide a longitudinal contraction joint at the center line of the paving lane to control cracking. In these joints, carry the reinforcing steel through the joint. Tie bars are not required.

17-1.6 Pavement Center Line.

Tied longitudinal contraction joints are also required at the center line of reinforced concrete pavements when the width of the pavement exceeds the allowable length of slab L for the percentage of steel reinforcement being used. When such joints are required, break the steel reinforcement at the joint, and use 5/8-in (16-mm) diameter tie bars 30 in (750 mm) long and spaced 30 in (750 mm) center to center.

17-2 JOINT SEALING.

Joint sealing for reinforced concrete pavements must be the same as for plain concrete pavements (see paragraph 15-5). Use preformed compression sealants when the joint spacing exceeds 50 ft (15.2 m).

CHAPTER 18 ROLLER-COMPACTED CONCRETE PAVEMENTS

18-1 INTRODUCTION.

RCCP is a zero-slump PCC mixture that is placed with an asphalt concrete paving machine and compacted with vibratory and rubber-tired rollers. Mixture proportions and most engineering properties of RCCP are similar to those of conventional plain concrete pavements. The mixture proportions of RCCP are not appreciably different than those used in conventional concrete; flexural strengths of beams taken from RCCP facilities and test sections routinely exceed 650 psi (4.5 MPa) at 28 days. Limited tests show that the fatigue characteristics of RCCP mixtures are similar to those of conventional concrete pavement mixtures. In Canada under moderately severe environmental and heavy loading conditions, RCCP hardstands have performed well for over 10 years alongside conventional concrete hardstands. Therefore, it may be assumed that the same rationale applied to the thickness design for plain non-reinforced concrete pavement thickness may also be applied to the design of RCCP.

18-2 LOAD TRANSFER.

A major difference exists in the assumptions of load transfer at joints made for plain concrete pavements and RCCP, which directly affects the design stress and therefore the thickness of the pavement. RCCP has typically been allowed to crack naturally, and spacing between these cracks is usually irregular, ranging from 40 to 70 ft (12 to 21 m) apart. Although, spacing between cracks have been reported much greater than and lower than this range. Consequently, the width of the crack opening will be greater and the load transfer developed from aggregate interlock at the cracks will be highly variable, if not totally lost. Limited tests at Fort Hood, TX and Fort Stewart, GA have revealed average load transfer at transverse contraction cracks of 18.6 percent (standard deviation of 6.7 percent) and longitudinal cracks of 16.7 percent (standard deviation of 5.9 percent), respectively. Tests on longitudinal and transverse cold (construction) joints revealed even less load transfer. Therefore, the assumption of 25 percent load transfer at joints constructed of plain concrete would not be valid for RCCP thickness design. Therefore, base the thickness design of RCCP on no load transfer at the joints, (i.e. assuming all joints and cracks to be a free edge condition).

18-3 THICKNESS DESIGN.

Use the thickness design curves shown in Appendix F to determine thickness requirements for RCCP. These curves are the same as used for plain concrete roads and parking areas.

18-4 MULTILIFT PAVEMENTS.

The maximum lift thickness that can be placed at an acceptable grade and smoothness and compacted to a uniform density is about 10 in (250 mm). Therefore, if the RCCP design thickness is greater than 10 in (250 mm), two or more lifts will be necessary to achieve the design thickness. If possible, the upper lift should be of minimal thickness, preferably one-third of the total pavement thickness (but no less than 4 in (100 mm)), to aid in creating a smoother surface finish. The type of bond achieved between the lifts is a function of the construction sequence and timing and will govern the method of thickness design used for multi-lift RCCP. The three types of bonding conditions to be considered in RCCP thickness design are full bond, partial bond, and no bond.

18-4.1 Full Bond.

Full bond may be assumed between adjacent lifts if they are placed and compacted within 1 hour of each other, or if a thin grout is placed between the upper and lower lifts. The surface of the lower lift must be kept clean and moist until the upper lift is placed and should not be rolled with the rubber-tired roller. If the full bond condition is achieved, the thickness should be determined as if a monolithic slab were used, with no consideration for the joint between lifts in the thickness design calculations.

18-4.2 Partial Bond.

Partial bond should be assumed between subsequent lifts if they are placed and compacted more than 1 hour apart. Keep the surface of the lower lift clean and moist until the upper lift is placed. The thickness should be designed as a rigid overlay of a rigid base pavement with partial bonding according to the guidance in Chapter titled Pavement Overlays.

18-4.3 No Bond.

Assume no bond between adjacent lifts if some type of bond breaker is used between the lifts, such as a curing compound or asphalt emulsion sprayed on the surface of the lower lift. Design the thickness as a rigid overlay of a rigid base pavement with no bond, according to the guidance in Chapter titled Pavement Overlays.

18-5 JOINT TYPES FOR RCCP.

18-5.1 Expansion Joints.

Expansion joints, within an area paved with RCCP, are not required except to protect facilities located within the paved area.

18-5.2 Contraction Joints.

Generally, longitudinal contraction joints are not required in RCCP. However, most RCCP pavement to date has been allowed to crack naturally in the transverse direction. These cracks usually occur randomly at 40 to 70 ft (12 to 21 m) spacings, and have performed well, with little raveling or faulting. The natural cracks are typically not sealed; however, it is recommended that all cracks be routed and sealed in areas where the pavement may be susceptible to frost damage. Sawing of contraction joints is recommended at spacing of 50 to 75 ft (15 to 23 m), providing the sawing can be accomplished in the first 24 hours without excessive raveling. Determine the optimum time for sawing and optimum transverse joint spacing during the test section construction. Depth of sawcut should be one-third of the pavement thickness. For multi-lift pavements, make the sawcut one-third the pavement depth if full bond conditions are used. If partial bond or no bond conditions are used, make the sawcuts in each lift in coinciding locations to one-third the lift thickness (the sawcuts in the lower lifts may be made 1 hour after compaction). The longitudinal and transverse cold joints for each lift should always coincide. Seal all sawed joints.

18-5.3 Construction Joints.

Currently, there are two types of construction joints in RCCP; fresh and cold. When fresh concrete can be placed and compacted against in-place concrete before initial set (usually within 90 min), consider the juncture or joint to be a fresh joint requiring no special treatment. For the construction of a fresh joint, the edge of the in-place concrete is left un-compacted and rolled after the adjoining concrete has been placed. When the in-place RCCP has stiffened significantly before the adjoining fresh concrete can be placed (usually around 90 min), consider the resulting juncture a cold construction joint. The in-place concrete must be fully compacted and then the edge trimmed back to solid concrete to form a near vertical face. If the required density or smoothness is not obtained, then remove the in-place concrete. Immediately before placement of the adjoining concrete, dampen the vertical edge. After placement of the fresh concrete, the excess which spills onto the compacted material should be pushed back to the edge of the fresh concrete before rolling. No effort will be made to achieve load transfer at the cold joint. Make every effort to keep cold longitudinal construction joints spaced at least 50 to 75 ft (15 to 23 m).

This Page Intentionally Left Blank

CHAPTER 19 SEASONAL FROST CONDITIONS

19-1 GENERAL.

This chapter presents criteria and procedures for the design and construction of pavements placed on subgrade or base course materials subject to seasonal frost action. The most prevalent modes of distress in pavements and their causes are listed in Table 19-1. The detrimental effects of frost action in subsurface materials are manifested by non-uniform heave of pavements during the winter and by loss of strength of affected soils during the ensuing thaw period. This is accompanied by a corresponding increase in damage accumulation and a more rapid rate of pavement deterioration during the period of weakening. Other related detrimental effects of frost and low temperatures are possible loss of compaction, development of permanent roughness, restriction of drainage by the frozen strata, and cracking and deterioration of the pavement surface. Hazardous operating conditions, excessive maintenance, or pavement destruction may result. Except when other criteria are specifically established, pavements should be designed so that there will be no interruption of traffic at any time due to differential heave or to reduction in load-supporting capacity. Pavements should also be designed so that the rate of deterioration during critical periods of thaw weakening and during cold periods causing low-temperature cracking will not be so high that the useful life of the pavements will be less than that assumed as the design objective.

19-2 FROST-SUSCEPTIBILITY CLASSIFICATION.

For frost design purposes, soils are divided into eight groups as shown in Table 19-2. The first four groups are generally suitable for base course and subbase course materials, and any of the eight groups may be encountered as subgrade soils. Soils are listed in approximate order of decreasing bearing capacity during periods of thaw. There is also a tendency for the order of the listing of groups to coincide with increasing order of susceptibility to frost heave, although the low coefficients of permeability of most clays restrict their heaving potential. The order of listing of subgroups under groups F3 and F4 does not necessarily indicate the order of susceptibility to frost heave of these subgroups. There is some overlapping of frost susceptibility between groups. Soils in group F4 are of especially high frost susceptibility.

19-2.1 S1 and S2 Groups.

The S1 group includes gravelly soils with very low to medium frost-susceptibility classifications that are considered suitable for subbase materials. They generally exhibit less frost heave and higher strength after freeze-thaw cycles than similar PI group subgrade soils. The S2 group includes sandy soils with very low to medium frost-susceptibility classifications that are considered suitable for subbase materials. Due to their lower percentages of finer than 0.02 mm grains than similar F2 groups subgrade soils, they generally exhibit less frost heave and higher strength after freeze-thaw cycles.

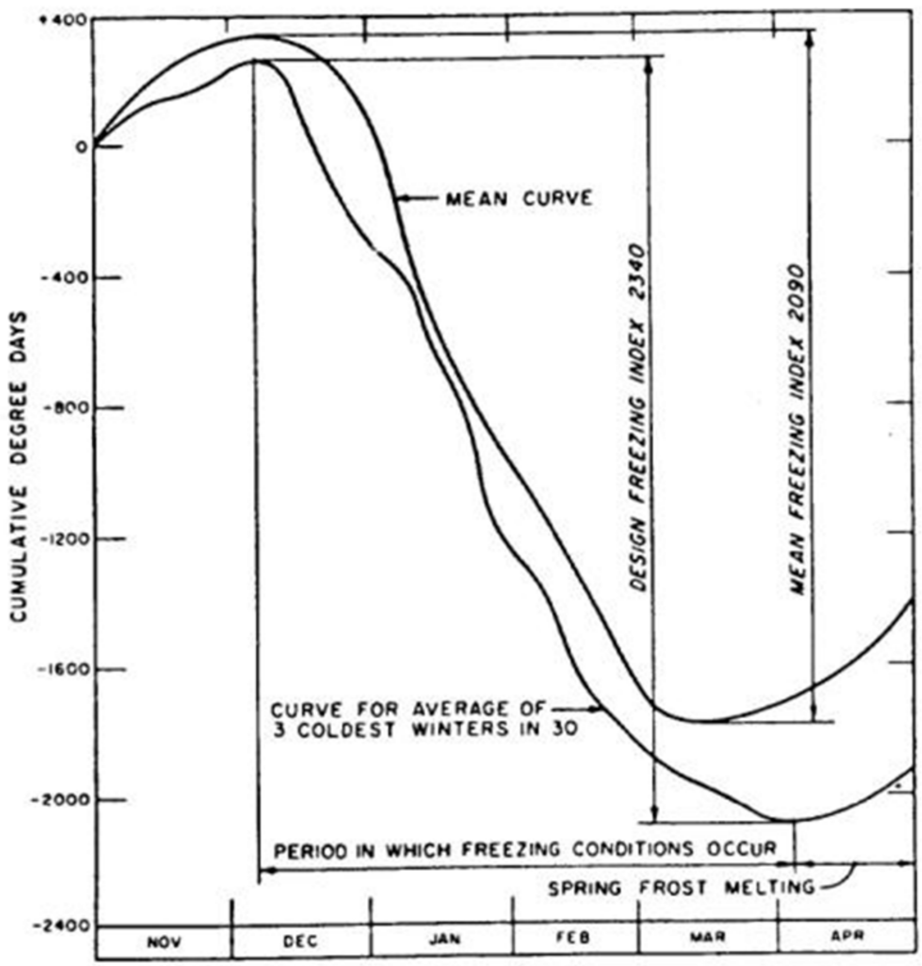
Table 19-1 Modes of Distress in Pavements

Distress Mode	General Cause	Specific Causative Factor
Cracking	Traffic-load associated	Repeated loading (fatigue) Slippage (resulting from braking stresses)
	Non-traffic-associated	Thermal changes Moisture changes Shrinkage of underlying materials (reflection cracking, which may also be accelerated by traffic loading)
Distortion (may also lead to cracking)	Traffic-load associated	Rutting, or pumping and faulting (from repetitive loading) Plastic flow or creep (from single or comparatively few excessive loads)
	Non-traffic-associated	Differential heave Swelling of expansive clays in subgrade Frost action in subgrades or bases Differential settlement Permanent, from long-term consolidation in subgrade Transient, from reconsolidation after heave (may be accelerated by traffic) Curling of rigid slabs, from moisture and temperature differentials
Disintegration	May be advanced stage of cracking mode of distress or may result from detrimental effects of certain materials contained within the layered system or from abrasion by traffic. May also be triggered by freeze-thaw effects.	

19-2.2 F1 and F2 Groups.

The F1 group includes frost-susceptible gravelly soils that in the normal unfrozen condition have traffic performance characteristics of GM, GW GM, and GP GM type materials with the noted percentage of fines. The F2 group includes frost-susceptible soils that in the normal unfrozen condition have traffic performance characteristics of GM, GW GM, GP GM, SM, SW SM, or SP SM type materials with fines within the stated limits. Occasionally, GC or SC materials may occur within the F2 group, although they normally fall into the F3 category. The basis for division between the F1 and F2 groups is that F1 materials are expected to show higher bearing capacity than F2 materials during thaw, even though both may have experienced equal ice segregation.

Figure 19-1 Determination of Freezing Index



19-2.3 Varved Clays.

Varved clays consisting of alternating layers of silts and clays are likely to combine the undesirable properties of both silts and clays. These and other stratified fine-grained sediments may be hard to classify for frost design. Since such soils are likely to heave and soften more readily than homogeneous soils with equal average water contents, the classification of the material of highest frost susceptibility should be adopted for design. Usually, this will place the overall deposit in the F4 category.

Table 19-2 Frost Design Soil Classification*

Frost Group	Kind of Soil		Percentage Finer than 0.02 mm by Weight*	Typical Soil Types Under Unified Soil Classification System
NFS**	(a)	Gravels	0-1.5	GW, GP

** Non-frost susceptible.
*** Possibly frost-susceptible, but requires laboratory test to determine frost design soils classification.

19-2.4 Special Conditions.

Under special conditions the frost group classification adopted for design may differ from that obtained by application of the above frost group definitions when the difference is not greater than one frost group and complete justification for the variation is presented and approved by the Government Civil Engineer. Such justification may take into account special conditions of subgrade moisture or soil uniformity, in addition to soil gradation and plasticity, and should include data on performance of existing pavements near those proposed to be constructed.

19-3 ALTERNATIVE METHODS OF THICKNESS DESIGN.

The thickness design process is the determination of the required thickness for each layer of a pavement system and of the combined thickness of all layers above the subgrade. Its objective is to determine the lowest-cost pavement system whose rate of deterioration under traffic loads and environmental conditions will be acceptably low. In seasonal frost areas, the thickness design process must include the effects of frost action. Two methods are prescribed for determining the thickness design of a pavement that will have adequate resistance to distortion by frost heave and cracking and distortion under traffic loads as affected by seasonal variation of supporting capacity, including possible severe weakening during frost-melting periods.

19-3.1 Limited Subgrade Frost Penetration Method.

The first method is directed specifically to the control of pavement distortion caused by frost heave. It requires a sufficient thickness of pavement, base, and subbase to limit the penetration of frost into the frost-susceptible subgrade to an acceptable amount. This method also includes a design approach to determine the thickness of pavement, base, and subbase necessary to prevent the penetration of frost into the subgrade. Prevention of frost penetration into the subgrade is nearly always uneconomical and unnecessary, and will not be used to design pavements to serve conventional traffic, except when approved by the Government Civil Engineer.

19-3.2 Reduced Subgrade Strength Method.

The second method does not seek to limit the penetration of frost into the subgrade, but it determines the thickness of pavement, base, and subbase that will adequately carry traffic loads over the design period of years, each of which includes one or more periods during which the subgrade supporting capacity is sharply reduced by frost melting. This approach relies on uniform subgrade conditions, adequate subgrade preparation techniques, and transitions for adequate control of pavement roughness resulting from differential frost heave.

19-4 SELECTION OF DESIGN METHOD.

In most cases the choice of the pavement design method will be the one that gives the lower cost. Exceptions dictating the choice of the limited subgrade frost penetration method, even at higher cost, include pavements in locations where subgrade soils are so extremely variable (as, for example, in some glaciated areas) that the required subgrade preparation techniques could not be expected to provide sufficient protection against differential frost heave. In other cases special operational demands on the pavement might dictate unusually severe restrictions on tolerable pavement roughness, requiring that subgrade frost penetration be strictly limited or even prevented. If the use of limited subgrade frost penetration method is not required, preliminary designs must be prepared by both methods for comparison of costs. A preliminary design must also be prepared following the NFS criteria, since the thickness requirements under NFS criteria must be met in addition to the frost design requirements.

19-5 LIMITED SUBGRADE FROST PENETRATION.

Use this method of design for seasonal frost conditions where it requires less thickness than the reduced subgrade strength method. Its use is likely to be economical only in regions of low design freezing index.

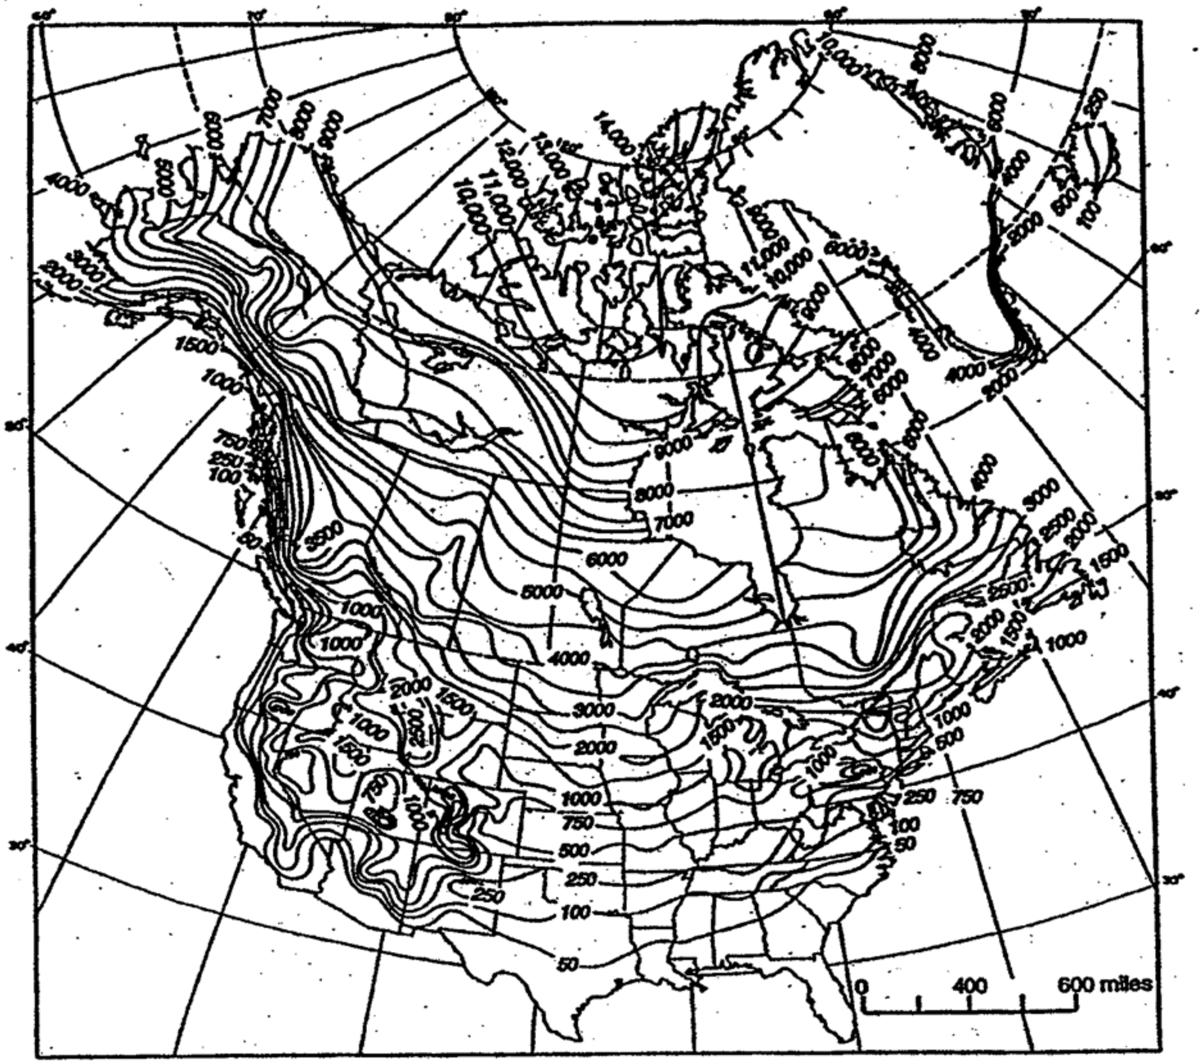
19-5.1 Air Freezing Index.

Air freezing index values should be based on actual air temperatures obtained from the meteorological station closest to the construction site. This is desirable because differences in elevation or topographical position, or nearness to bodies of water, cities, or other sources of heat may cause considerable variation in air freezing indexes over short distances. These variations are of greater relative importance in areas of design freezing index of less than 1,000 degree Fahrenheit days (i.e., mean air freezing index of less than about 500 degree Fahrenheit days) than they are in colder climates. The daily maximum, minimum, and mean monthly air temperature records for all stations that report to the U.S. National Weather Service are available from Weather Service Centers. One of these centers is generally located in each state. The mean air freezing index may be based on mean monthly air temperatures, but computation of values for the design freezing index may be limited to only the coldest years in the desired cycle. These years may be selected from the tabulation of average monthly temperatures for the nearest first-order weather station. A local climatological data summary containing this tabulation for the period of record is published annually by the National Weather Service for each of the about 350 U.S. first-order stations. If the temperature record of the station closest to the construction site is not long enough to determine the mean or design freezing index values, the available data should be related, for the same period, to that of the nearest station or stations of adequate record. Site air freezing index values can then be computed based on this established relation and the indexes for the more distant station or stations.

19-5.2 Design Freezing Index.

The design freezing index should be used in determining the combined thickness of pavement, base, and subbase required to limit subgrade frost penetration. As with any natural climatic phenomenon, winters that are colder than average occur with a frequency that decreases as the degree of departure from average becomes greater. A mean freezing index cannot be computed where temperatures in some of the winters do not fall below freezing. A design method has been adopted that uses the average air freezing index for the three coldest years in a 30 year period (or for the coldest winter in 10 year of record) as the design freezing index to determine the thickness of protection that will be provided. A distribution of design freezing indexes for North America and Northern Eurasia are shown in Figures 19-2 and 19-3 and are to be used as a guide only.

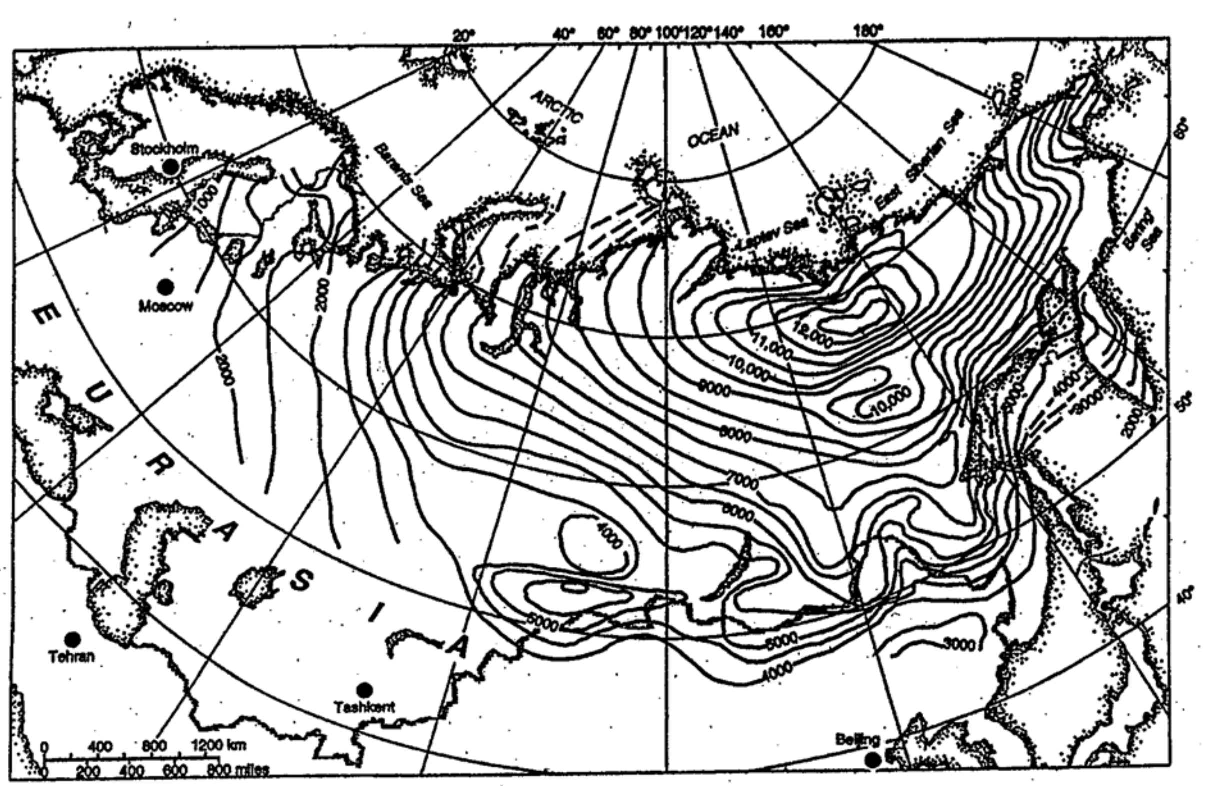
Figure 19-2 Distribution of Design Freezing Indexes in North America



CONVERSION FACTORS

°C - HOURS = 13.33 x °F DAYS

Figure 19-3 Distribution of Mean Freezing Indexes in Northern Eurasia



19-5.3 Design Method.

The design method permits a small amount of frost penetration into frost-susceptible subgrades for the design freezing index year. The procedure is described in the following subparagraphs.

Estimate average moisture contents in the base course and subgrade at start of freezing period, and estimate the dry unit weight of base. The moisture content of the base is generally affected by the moisture content of the subgrade, drainage, precipitation, and depth to groundwater table. As the base course may, in some cases, comprise successive layers containing substantially different fine contents, the average moisture content and dry unit weight should be weighted in proportion to the thickness of the various layers. Alternatively, if layers of bound base course and granular unbound base course are used in the pavement, the average may be assumed to be equal to the moisture content and dry unit weight of the material in the granular unbound base course.

From Figure 19-4, determine frost penetration depth (a). These frost penetration depths are based on modified Berggren formula and computational procedures. Frost penetration depths are measured from pavement surface. Depths are computed on a 12 in (300 mm.) rigid pavement kept free of snow and ice, and are good approximations for bituminous pavements over 6 to 9 in (150 to 225 mm.) of high-quality base. Computations also assume that all soil beneath pavements within depths of frost penetration are granular and NFS. It was assumed in computations that all soil moisture freezes at 32 degrees Fahrenheit (0 degrees Celsius). Use straight line interpolation where necessary. For rigid pavements greater than 12 in (300 mm) thick, deduct 10 degree s Fahrenheit days for each 1 in (25 mm) increment of pavement exceeding 12 in (300 mm) from the design freezing index before entering Figure 19-4 to determine frost penetration depth (a). Then add extra concrete pavement thickness to the determined frost penetration.

Compute thickness of unbound base C (Figure 19-5) required for zero frost penetration into the subgrade as follows:

$$C = a - p$$

Where

a = frost penetration depth

p = thickness of PCC or bituminous concrete

Compute ratio $$r = \frac{\text{water content of subgrade}}{\text{water content of base}}$$

Enter Figure 19-5 with C as the abscissa and, at the applicable value of r, find on the left scale the design base thickness b that will result in the allowable subgrade frost penetration shown on the right scale. If r is greater than 3.0 use 3.0.

19-5.4 Thickness.

The above procedure results in a thickness of material between the frost-susceptible subgrade and the pavement so that for average field conditions subgrade frost penetration of the amount s should not cause excessive differential heave of the pavement surface during the design freezing index year.

19-5.5 Controlling Thickness.

If the combined thickness of pavement and base required by the NFS criteria exceeds the thickness given by the limited subgrade frost penetration procedure of design, adopt the greater thickness given by the NFS criteria as the design thickness.

19-5.6 Effects of Non-frost Susceptible Criteria.

Rigorously follow the base course composition requirements of this chapter. The design base thickness is the total thickness of filter layers, granular unbound base and subbase, and any bound base. For flexible pavements, the thickness of the asphalt surfacing layer and of any bound base, as well as the CBR requirements of each layer of granular unbound base, must be determined using NFS criteria. The thickness of rigid pavement slab must also be determined from NFS criteria.

Figure 19-4A Frost Penetration Beneath Pavements

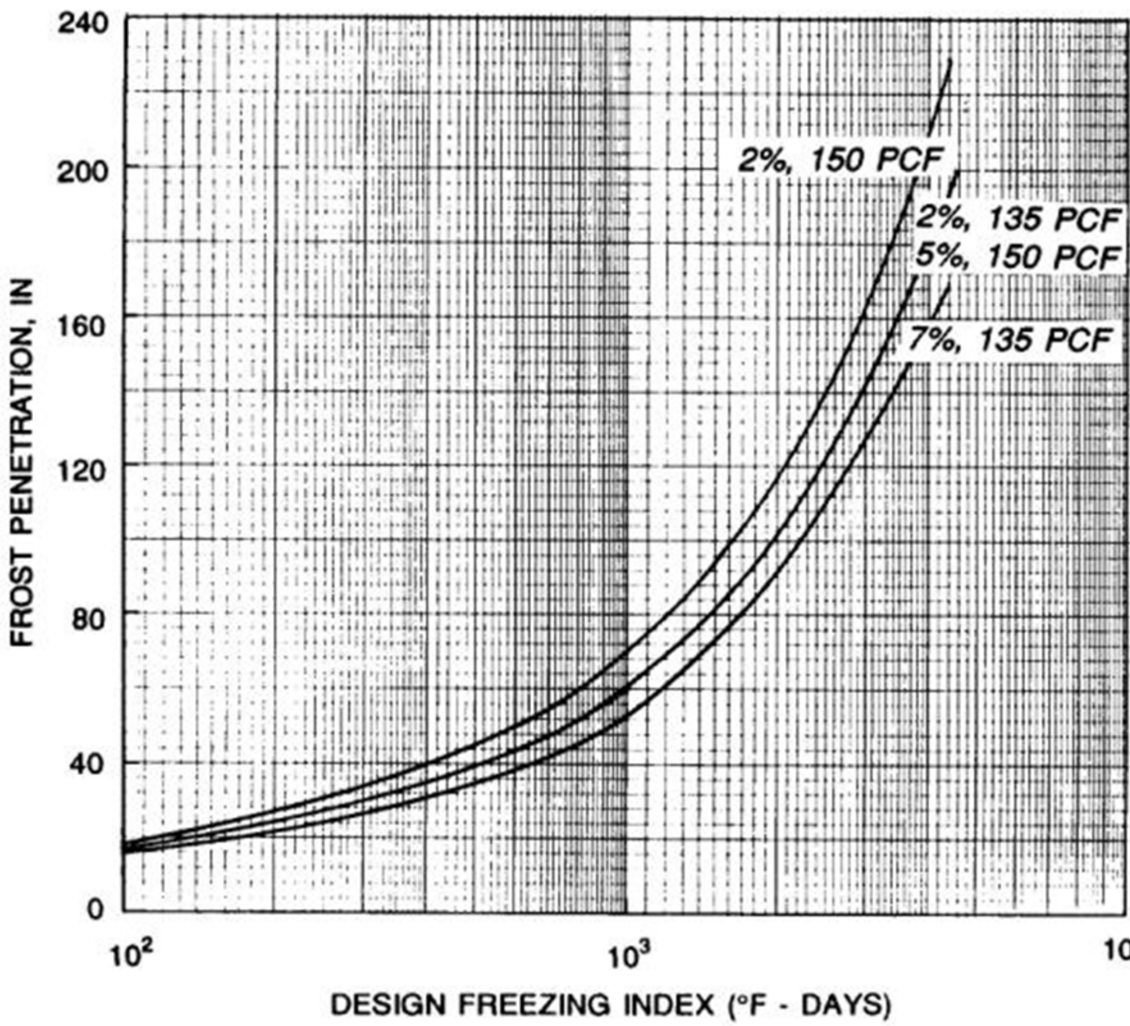


Figure 19-4B Frost Penetration Beneath Pavements

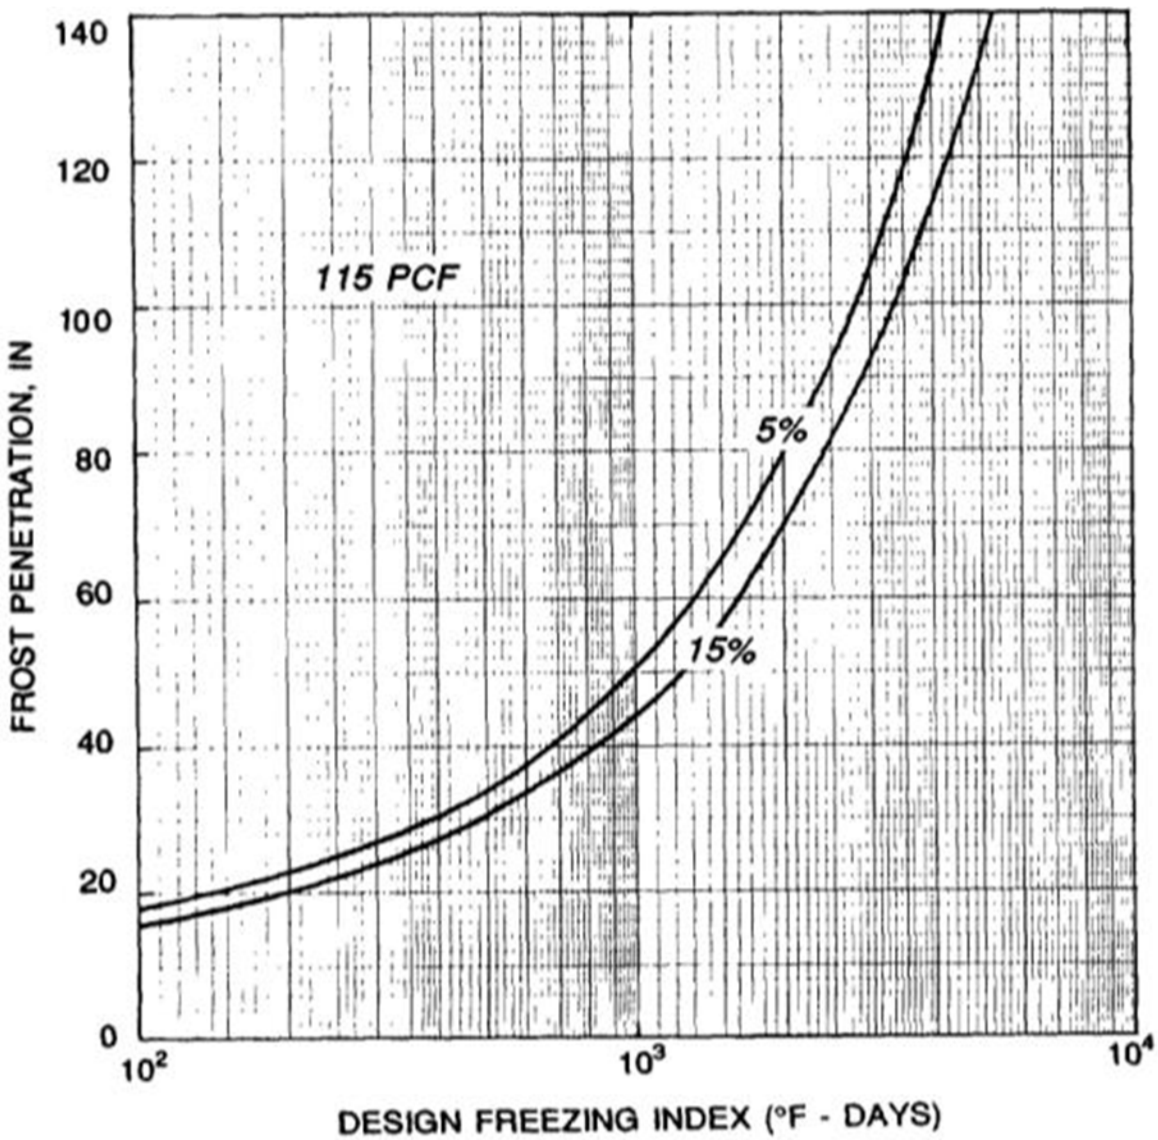

Figure 19-4C Frost Penetration Beneath Pavements

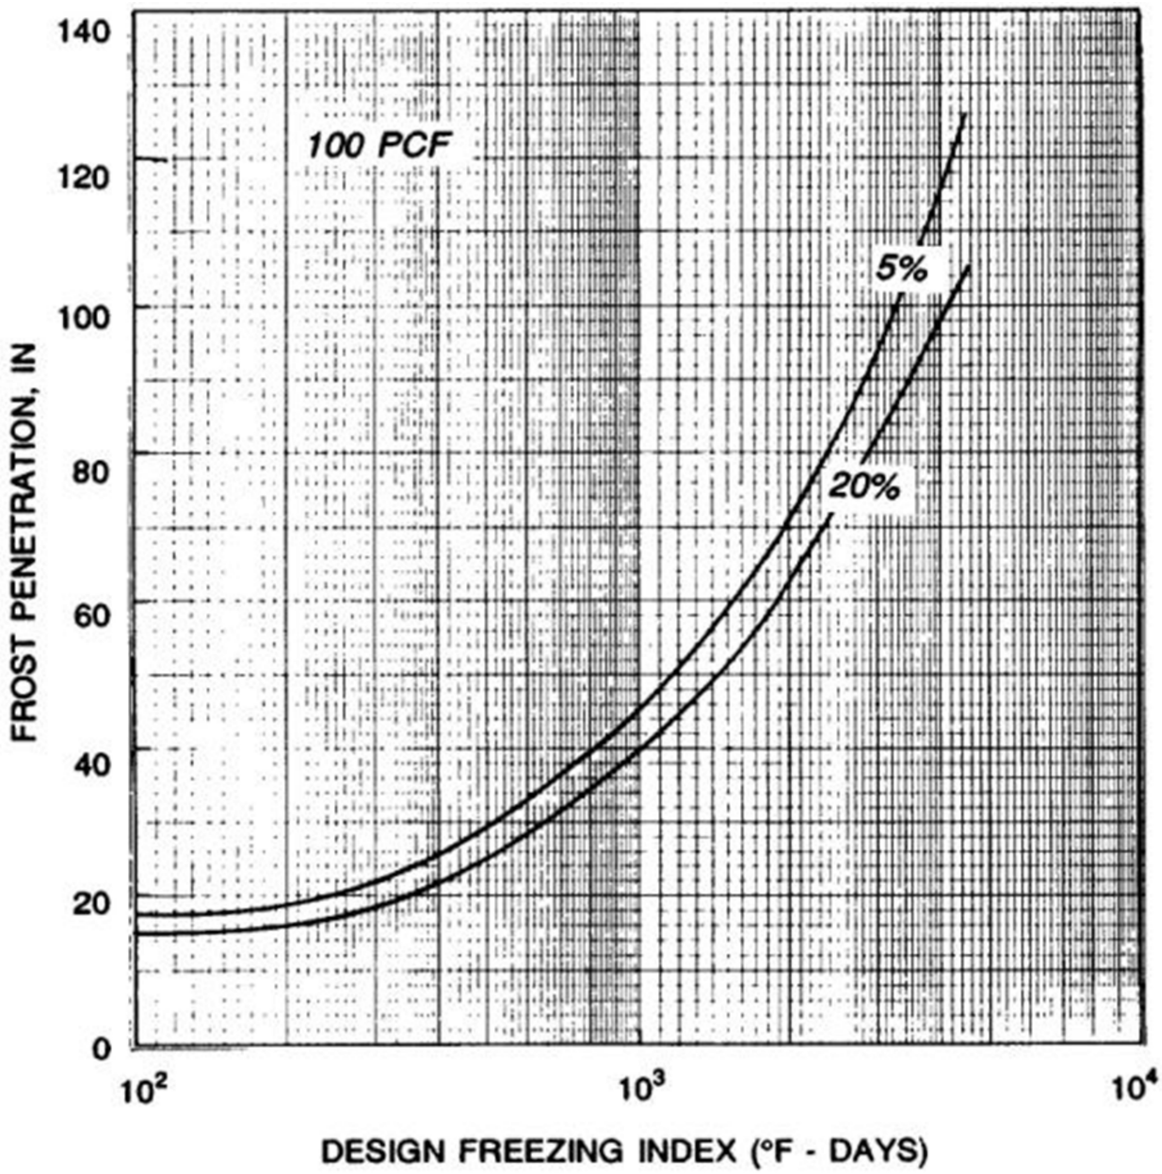

Figure 19-5 Design Depth of Non-frost Susceptible Base for Limited Subgrade Frost Penetration

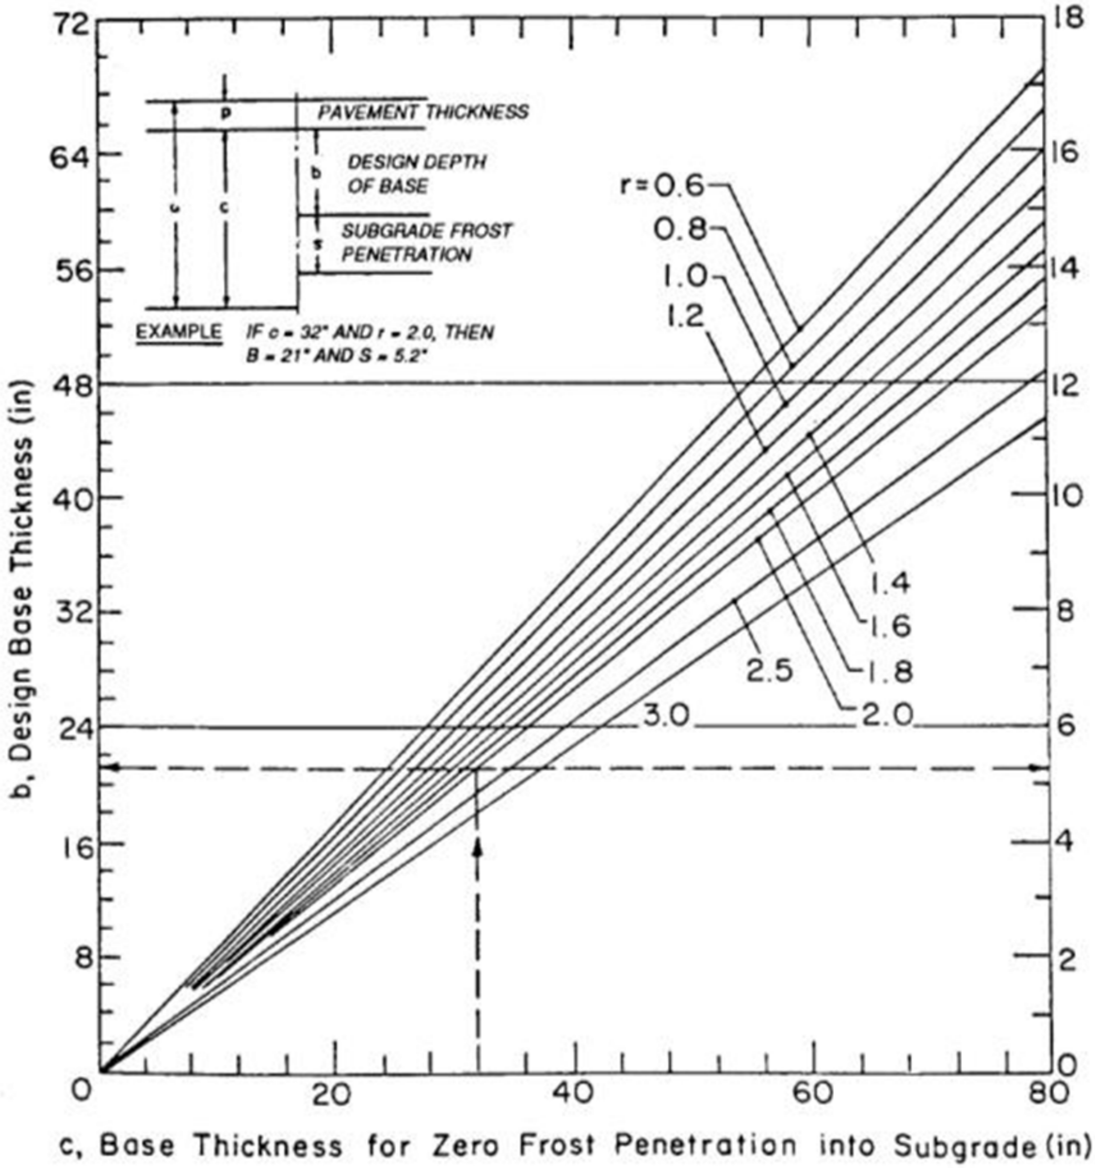


19-6 REDUCED SUBGRADE STRENGTH.

Thickness design may also be based on the seasonally varying subgrade support that includes sharply reduced values during thawing of soils that have been affected by frost action. Except for pavement projects that are located in regions of low design freezing index, this design procedure usually requires less thickness of pavement and base than that needed for limited subgrade frost penetration. The method may be used for both flexible and rigid pavements wherever the subgrade is reasonably uniform or can be made reasonably horizontally uniform by the required techniques of subgrade preparation. This will prevent or minimize significant or objectionable differential heaving and resultant cracking of pavements. When the reduced subgrade strength method is used for F4 subgrade soils, unusually rigorous control of subgrade preparation must be required. When a thickness determined by the reduced subgrade strength procedure exceeds that determined for limited subgrade frost penetration, the latter smaller value must be used, provided it is at least equal to the thickness required for NFS conditions. In situations where use of the reduced subgrade strength procedure might result in objectionable frost heave, but use of the greater thickness of base course indicated by the limited subgrade frost penetration design procedure is not considered necessary, intermediate design thickness may be used. However, these must be justified on the basis of frost heaving experience developed from existing pavements where climatic and soil conditions are comparable.

19-6.1 Thickness of Flexible Pavements.

In the reduced subgrade strength procedure for design, the design curves in Appendix E should be used for road, street, and parking area design. Do not enter the curves with subgrade CBR values determined by tests or estimates, but instead with the applicable frost-area soil support index from Table 19-3. Frost-area soil support indexes are used as if they were CBR values; the term CBR is not applied to them, however, because being weighted average values for an annual cycle, their value cannot be determined by CBR tests. The soil support index for S1 or S2 material meeting current specifications for base or subbase are determined by conventional CBR tests in the unfrozen state.

General field data and experience indicate that on the relatively narrow embankments of roads and parking areas, reduction in strength of subgrades during frost melting may be less in substantial fills than in cuts because of better drainage conditions and less intense ice segregation. If local field data and experience show this to be the case, then a reduction in combined thickness of pavement and base for frost conditions of up to 10 percent may be permitted for substantial fills.

Flexible pavement criteria for NFS design should also be used to determine the thickness of individual layers in the pavement system, and to ascertain whether it will be advantageous to include one or more layers of bound base in the system. The base course composition requirements set forth must be followed rigorously.

Table 19-3 Frost-Area Soil Support Indexes for Subgrade Soils for Flexible Pavement Design

Frost Group of Subgrade Soil	Frost-Area Soil Support Index
F1 and S1	9.0
F2 and S2	6.5
F3 and F4	3.5

19-6.2 Thickness of Rigid Pavements.

Where frost is expected to penetrate into a frost-susceptible subgrade beneath a rigid pavement, it is good practice to use a NFS base course at least equal in thickness to the slab. Experience has shown, however, that rigid pavements with only a 4 in (100 mm) base have performed well in cold environments with relatively uniform subgrade conditions. Accordingly, where subgrade soils can be made reasonably uniform by the required procedures of subgrade preparation, the minimum thickness of granular unbound base may be reduced to a minimum of 4 in (100 mm). The material must meet the requirements set forth below for free-draining material as well as the criteria for filter under pavement slab. If it does not also meet the criteria for filter over subgrade, a second 4 in (100 mm) layer meeting that criterion must be provided.

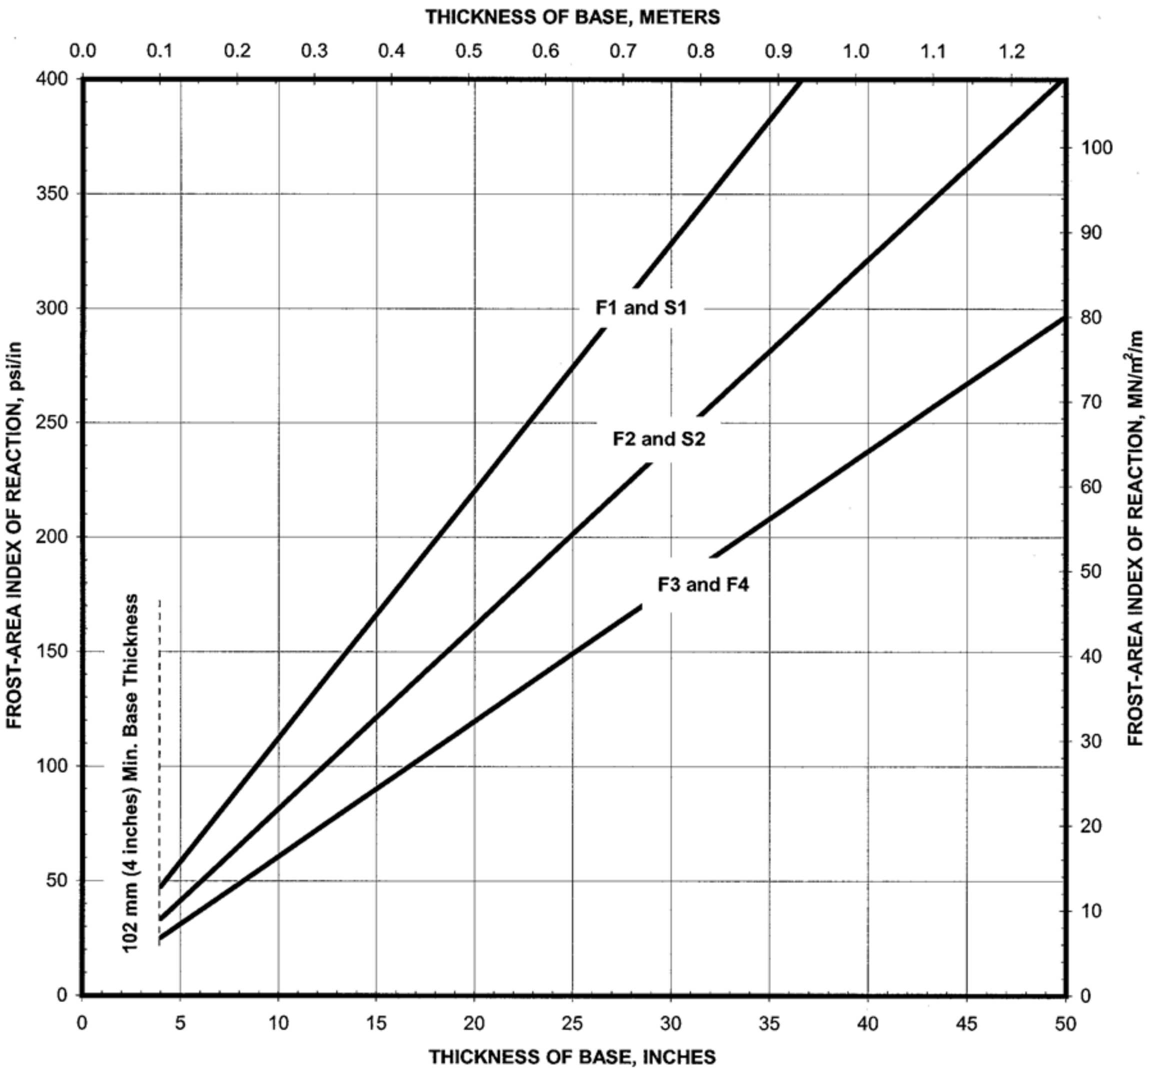
Additional granular unbound base course, giving a thickness greater than the minimum specified above, improves pavement performance, giving a higher frost-area index of reaction on the surface of the unbound base Figure 19-6 and permitting a pavement slab of less thickness. Bound base also has significant structural value, and may be used to effect a further reduction in the required thickness of rigid pavement slab. Criteria for determining the required thickness of rigid pavement slabs in combination with a bound base course are contained in Chapter titled Plain Concrete Pavement Design. The requirements for granular unbound base as drainage and filter layers are still applicable.

The thickness of concrete pavement must be determined in accordance with Chapter titled Plain Concrete Pavement Design, using the frost-area index of reaction determined from Figure 19-6. This figure shows the equivalent weighted average index of reaction values for an annual cycle that includes a period of thaw-weakening in relation to the thickness base. Frost-area indexes of reaction are used as if they were moduli of reaction, k, and have the same units. The term modulus of reaction is not applied to them because being weighted average values for an annual cycle, they cannot be determined by a plate-bearing test. If the modulus of reaction, k, determined from tests on the equivalent base course and subgrade, but without frost melting, is numerically smaller than the index of reaction obtained from Figure 19-6, the test value must govern the design.

19-7 FREE-DRAINING MATERIAL DIRECTLY BENEATH BOUND BASE OR SURFACING LAYER.

Base courses may consist of either granular unbound materials or bound base materials or a combination of the two. However, do not place cement or lime bound base directly beneath bituminous pavement unless approved by the Government Civil Engineer. Also, do not place an unbound course between two relatively impervious bound layers. If the combined thickness, in inches, of pavement and contiguous bound base courses is less than 0.09 multiplied by the design air freezing index (this calculation limits the design freezing index at the bottom of the bound base to about 20 degrees Fahrenheit days), not less than 4 in (100 mm) of free-draining material must be placed directly beneath the lower layer of bound base or, if there is no bound base, directly beneath the pavement slab or surface course. The free-draining material must contain 2.0 percent or less, by weight, of grains that can pass the No. 200 sieve, and to meet this requirement, it probably will have to be screened and washed. If the structural criteria for design of the pavement do not require granular unbound base other than the 4 in of free-draining material, then the material in the 4 in (100 mm) layer must be checked for conformance with the filter requirements below. If it fails the test for conformance, an additional layer meeting those requirements must be provided. When using a drainage layer, the drainage layer must extend to an open ditch or subdrain. Pavement drainage is discussed in Chapter titled Design Of Subsurface Pavement Drainage Systems.

Figure 19-6 Frost-Area Index of Reaction for Design of Rigid Roads and Parking Areas



19-8 SOIL STABILIZATION.

19-8.1 Bound Base.

Soils containing only lime as the stabilizer are generally unsuitable for use as base course layers in the upper layers of pavement systems in frost areas. Lime, cement, and a pozzolanic material such as fly ash may be used in some cases to produce a cemented material of high quality that is suitable for upper base course and that has adequate durability and resistance to freeze-thaw action. Soil stabilization mixture design will be based on the procedures set forth in UFC 3-250-11 with the additional requirement that the mixture, after freeze-thaw testing as set forth below, should meet the weight-loss criteria specified in UFC 3-250-11 for cement-stabilized soil. The procedures in ASTM D560/560M should be followed for freeze-thaw testing, except that the specimens should be compacted in a 6 in (150 mm) diameter mold in five layers with a 10 lb (4.5 kg) hammer having an 18 in (450 mm) drop, and that the preparation and curing of the specimens should follow the procedures indicated in UFC 3-250-11 for unconfined compression tests on lime-stabilized soil.

19-8.2 Stabilization with Lime.

If it is economical to use lime-stabilized or lime-modified soil in lower layers of a pavement system, a mixture of adequate durability and resistance to frost action is still necessary. In addition to the requirements for mixture design of lime-stabilized and lime-modified subbase and subgrade materials set forth in UFC 3-250-11, cured specimens should be subjected to the 12 freeze-thaw cycles in ASTM D560/560M (but omitting wire-brushing) or other applicable freeze-thaw procedures. This should be followed by determination of frost-design soil classification by standard laboratory freezing tests. For lime-stabilized or lime-modified soil used in lower layers of the base course, the frost susceptibility, determined after freeze-thaw cycling, should meet the requirements set forth for base course in Chapter titled Flexible Pavement Select Materials And Subbase Courses. If lime-stabilized or lime-modified soil is used as subgrade, its frost susceptibility, determined after freeze-thawing cycling, should be used as the basis of the pavement thickness design if the reduced subgrade strength design method is applied.

19-8.3 Stabilization with Portland Cement.

Cement-stabilized soil meeting the requirements set forth in UFC 3-250-11, including freeze-thaw effects tested under ASTM D560/560M, may be used in frost areas as base course or as stabilized subgrade. Cement-modified soil conforming with the requirements in UFC 3-250-11 also may be used in frost areas. However, in addition to the procedures for mixture design specified in UFC 3-250-11, cured specimens of cement-modified soil should be subjected to the 12 freeze-thaw cycles in ASTM D560/560M (but omitting wire-brushing) or other applicable freeze-thaw procedures. This should be followed by determination of frost design soil classification by standard laboratory freezing tests. For cement-modified soil used in the base course, the frost susceptibility, determined after freeze-thaw cycling, should meet the requirements set forth for base course in Chapter titled Flexible Pavement Select Materials And Subbase Courses. If cement-modified soil is used as subgrade, its frost susceptibility, determined after freeze-thaw cycling, should be used as the basis of the pavement thickness design if the reduced subgrade design method is applied.

19-8.4 Stabilization with Bitumen.

Many different types of soils and aggregates can be successfully stabilized to produce a high quality bound base with a variety of types of bituminous material. In frost areas the use of tar as a binder should be avoided because of its high temperature susceptibility. Asphalts are affected to a lesser extent by temperature changes, but a grade of asphalt suitable to the prevailing climatic conditions should be selected. Excepting these special conditions affecting the suitability of particular types of bitumen, the procedures for mixture design set forth in UFC 3-250-11 and UFC 3-250-03 will ensure that the asphalt-stabilized base will have adequate durability and resistance to moisture and freeze-thaw cycles.

19-9 SUBGRADE REQUIREMENTS.

It is a basic requirement for all pavements constructed in frost areas, that subgrades in which freezing will occur, must be prepared to achieve uniformity of soil conditions by mixing stratified soils, eliminating isolated pockets of soil of higher or lower frost susceptibility, and blending the various types of soils into a single, relatively homogeneous mass. It is not intended to eliminate from the subgrade those soils in which detrimental frost action will occur, but to produce a subgrade of uniform frost susceptibility and thus create conditions tending to make both surface heave and subgrade thaw-weakening as uniform as possible over the paved area. In fill sections the least frost-susceptible soils must be placed in the upper portion of the subgrade by temporarily stockpiling the better materials, cross-hauling, and selective grading. If the upper layers of fill contain frost-susceptible soils, then the finished fill section must be subjected to the subgrade preparation procedures required for cut sections. In cut sections the subgrade must be scarified and excavated to a prescribed depth, and the excavated material must be windrowed and bladed successively until thoroughly blended. The depth of subgrade preparation, measured downward from the top of the subgrade, must be 24 in (600 mm) or two-thirds of the frost penetration less the actual combined thickness of pavement, base course, and subbase course, whichever is less. The prepared subgrade must meet the designated compaction requirements for NFS areas. The construction inspection personnel should be alert to verify that the processing of the subgrade will yield uniform soil conditions throughout the section. To achieve uniformity in some cases, it will be necessary to remove highly frost susceptible soils or soils of low frost susceptibility. In that case, the pockets of soil to be removed should be excavated to the full depth of frost penetration and replaced with material surrounding the frost-susceptible soil being removed.

19-9.1 Exception Conditions.

Exceptions to the basic requirement for subgrade preparation are subgrades known to be NFS to the depth prescribed for subgrade preparation and known to contain no frost-susceptible layers or lenses, as demonstrated and verified by extensive and thorough subsurface investigations and by the performance of nearby existing pavements. Also, fine-grained subgrades containing moisture well in excess of the optimum for compaction, without drainage or other means for reducing the moisture content, and which consequently it is not possible to scarify and re-compacted, are also exceptions.

19-9.2 Treatment of Wet Fine-Grained Subgrades.

If wet fine-grained subgrades exist at the site, it is necessary to achieve frost protection with fill material. This may be done by raising the grade by an amount equal to the depth of subgrade preparation that otherwise would be prescribed, or by undercutting and replacing the wet fine-grained subgrade to that same depth. In either case the fill or backfill material may be NFS material or frost-susceptible material meeting specified requirements. If the fill or backfill material is frost susceptible, it should be subjected to the same subgrade preparation procedures prescribed above.

19-9.3 Cobbles or Boulders.

A critical condition requiring the attention of inspection personnel is the presence of cobbles or boulders in the subgrades. All stones larger than about 6 in (150 mm) in diameter should be removed from fill materials for the full depth of frost penetration, either at the source or as the material is spread in the embankments. Any such large stones exposed during the subgrade preparation work also must be removed, down to the full depth to which subgrade preparation is required. Failure to remove stones or large roots can result in increasingly severe pavement roughness as the stones or roots are heaved gradually upward toward the pavement surface. They eventually break through the surface in extreme cases, necessitating complete reconstruction.

19-9.4 Changes in Soil Conditions.

Abrupt changes in soil conditions must not be permitted. Where the subgrade changes from a cut to a fill section, a wedge of subgrade soil in the cut section with the dimensions shown in Figure C19-7 (Appendix C) should be removed and replaced with fill material. Tapered transitions also are needed at culverts beneath paved areas, but in such cases the transition material should be clean, NFS granular fill. Other pipes under pavement should be similarly treated, and perforated-pipe underdrains should be constructed. These and any other discontinuities in subgrade conditions require the most careful attention of construction inspection personnel, as failure to enforce strict compliance with the requirements for transitions may result in serious pavement distress.

19-9.5 Wet Areas.

Careful attention should be given to wet areas in the subgrade, and special drainage measures should be installed as required. The need for such measures arises most often in road construction, where it may be necessary to provide intercepting drains to prevent infiltration into the subgrade from higher ground adjacent to the road.

19-9.6 Rock Excavation.

In areas where rock excavation is required, consider the character of the rock and seepage conditions. In any case, the excavations should be made so that positive transverse drainage is provided, and no pockets are left on the rock surface that permit ponding of water within the depth of freezing. The irregular groundwater availability created by such conditions may result in markedly irregular heaving under freezing conditions. It may be necessary to fill drainage pockets with lean concrete. At intersections of fills with rock cuts, the tapered transitions mentioned above Figure C19-7 (Appendix C) are essential. Rock subgrades where large quantities of seepage are involved should be blanketed with a highly pervious material to permit the escape of groundwater. Often, the fractures and joints in the rock contain frost-susceptible soils. These materials should be cleaned out of the joints to the depth of frost penetration and replaced with NFS material. If this is impractical, it may be necessary to remove the rock to the full depth of frost penetration.

19-9.7 Rock Subgrades.

An alternative method for treatment of rock subgrades, in-place fragmentation, has been used effectively in road construction. Blast holes 3 to 6 ft (0.9 to 1.8 m) deep are commonly used. They are spaced suitably for achieving thorough fragmentation of the rock to permit effective drainage of groundwater through the shattered rock and out of the zone of freezing in the subgrade. A tapered transition should be provided between the shattered rock cut and the adjacent fill.

19-10 OTHER MEASURES TO REDUCE HEAVE.

Other possible measures to reduce the effects of heave are the use of insulation (Appendix D) to control depth of frost penetration and the use of steel reinforcement to improve the continuity of rigid pavements that may become distorted by frost heave. Reinforcement does not reduce heave nor prevent the cracking resulting from it, but it helps to hold cracks tightly closed and thus reduce pumping through these cracks. Transitions between cut and fill, culverts and drains change in character or stratification of subgrade soils. Subgrade preparation and boulder removal should also receive special attention in field construction control.

19-11 PAVEMENT CRACKING ASSOCIATED WITH FROST HEAVE.

One of the most detrimental effects of frost action on a pavement is surface distortion as the result of differential frost heave or differential loss of strength. These may also lead to random cracking. Deterioration and spalling of the edges of working cracks are causes of uneven surface conditions and sources of debris. Cracking may be reduced by control of such elements as base composition, uniformity and thickness, slab dimensions, subbase and subgrade materials, uniformity of subsurface moisture conditions, and, in special situations, by use of reinforcement and by limitation of pavement type. The importance of uniformity cannot be overemphasized. Where unavoidable discontinuities in subgrade conditions exist, gradual transitions are essential.

19-12 COMPACTION.

Subgrade, subbase, and base course materials must meet the applicable compaction requirements for NFS materials.

19-13 USE OF INSULATION MATERIALS IN PAVEMENTS.

The use of synthetic insulating material within a pavement cross section must have written approval by the Government Civil Engineer, which can also provide advice and assistance in regard to the structural analysis. Criteria for design of pavements containing insulating layers are contained in Appendix D.

19-14 DESIGN EXAMPLE HEAVILY TRAFFICKED ROAD.

Appendix G includes examples of design for flexible and rigid pavements in an environment subjected to seasonal frost.

19-15 ALTERNATIVE DESIGNS.

Besides the two methodologies in dealing with seasonal frost, investigate other design alternatives using stabilized layers, including aggregate base course pavements, to determine whether they are more economical than the designs presented above.

This Page Intentionally Left Blank

CHAPTER 20 DESIGN OF SUBSURFACE PAVEMENT DRAINAGE SYSTEMS

20-1 GENERAL.

In recent years subsurface drainage has received increasing attention, particularly in the area of highway design. A number of studies have been conducted by State Highway Agencies and by the Federal Highway Administration that have resulted in a large number of publications on the subject of subsurface drainage. Appendix A contains a list of publications which contain information pertaining to the design of subsurface drainage for pavements.

20-1.1 Effects of Water on Pavements and Subgrade.

Water has a detrimental effect on pavement performance, primarily by either weakening subsurface materials or erosion of material by free water movement. For flexible pavements the weakening of the base, subbase or subgrade when saturated with water is one of the main causes of pavement failures. In rigid pavement, free water trapped between the concrete surface and an impermeable layer directly beneath the concrete, moves due to pressure caused by loadings. This movement of water, referred to as pumping, erodes the subsurface material creating voids under the concrete surface. In frost areas water contributes to frost damage by heaving during freezing and loss of subgrade support during thawing. Poor subsurface drainage can also contribute to secondary damage such as ‘D’ cracking or swelling of subsurface materials.

20-1.2 Traffic Effects.

The type, speed and volume of traffic will influence the criteria used in the design of pavement drainage systems. For rigid pavements pumping is greatly increased as the volume and speed of the traffic increases. For flexible pavements the buildup of pore pressures as a result of high volume, high speed traffic is a primary cause of the weakening of the pavement structure.

20-1.3 Sources of Water.

The two sources of water to be considered are from infiltration and subterranean water. Infiltration is the most important source of water and is the source of most concern in this document. Subterranean water is important in frost areas and areas of very high groundwater table or areas of artesian water. In many areas, perched groundwater may develop under pavements due to a reduced rate of evaporation of the water from the surface. In frost areas, free water collects under the surface by freeze-thaw action.

20-1.3.1 Infiltration.

Infiltration is surface water which enters the pavement from the surface through cracks or joints in the pavement, through the joint between the pavement and shoulder, through pores in the pavement, and through shoulders and adjacent areas. Since surface infiltration is the principal source of water, it is the source needing greatest control measures.

20-1.3.2 Subterranean Groundwater.

Subterranean groundwater can be a source of water from a high groundwater table, capillary forces, artesian pressure, and freeze-thaw action. Groundwater tables rise and fall depending upon the relation between infiltration, absorption, evaporation and groundwater flow. Seasonal fluctuations are normal because of differences in the amount of precipitation and maybe relatively large in some localities. Prolonged drought or wet periods will cause large fluctuations in the groundwater level. Subterranean source of water is particularly important in areas of frost action when large volumes of water can be drawn into the pavement structure during the formation of ice lenses. For large paved areas the evaporation from the surface is greatly reduced which causes saturation of the pavement structure by capillary forces. Also, if impervious layers exist beneath the pavement, perched groundwater can be present or develop from water entering the pavement through infiltration. This perched groundwater then becomes a subterranean source of water. In general, the presence of near surface subterranean water must be identified during soil exploration and drainage facilities designed to mitigate the influence of subterranean water.

20-1.3.3 Freeze-Thaw.

Freeze-thaw action can result in large amounts of groundwater being drawn into the pavement structure. In freeze-thaw conditions, groundwater flows to the freeze front by capillary action. Repeated cycles of freeze-thaw result in the growth of ice lenses that can cause heave in the pavement structure. Heaves in soils as great as 60 percent are not uncommon and under laboratory conditions, heaves of as much as 300 percent have been recorded. The formation of ice lenses in the pavement structure affects the structural integrity of the pavement structure in two very detrimental ways. One effect is the formation of the ice lenses causes a loss of density of the pavement materials resulting in strength loss of the pavement materials. A second effect is thawing of the ice results in a large volume of free water that must be drained from the pavement. Because thawing usually occurs simultaneously from both the top and bottom of the pavement structure, the free water can be trapped within the pavement structural. Providing adequate drainage minimizes pumping and promotes the restoration of pavement strength. In the design of sub-drain systems in frost areas, free water in both the upper and lower sections of the pavement must be considered.

20-1.4 Classification of Subdrain Facilities

Subdrain facilities can be categorized into two functional categories, one to control infiltration, and one to control groundwater. An infiltration control system is designed to intercept and remove water that enters the pavement from precipitation or surface flow. An important function of this system is to keep water from being trapped between impermeable layers. A groundwater control system is designed to reduce water movement into subgrades and pavement sections by controlling the flow of groundwater or by lowering the water table. Often, subdrains are required to perform both functions, and the two subdrain functions can be combined into a single subdrain system. Figure C20-1 and Figure C20-2 (Appendix C) illustrate examples of infiltration and groundwater control systems.

20-1.5 Subsurface Drainage Requirements.

The determination of the subsurface soil properties and water condition is a prerequisite for the satisfactory design of a subsurface drainage system. Field explorations and borings made in connection with the project design should include the following investigations pertinent to subsurface drainage. A topographic map of the proposed area and the surrounding vicinity should be prepared indicating all streams, ditches, wells, and natural reservoirs. The analysis of aerial photographs of the areas selected for construction may furnish valuable information on general soil and groundwater conditions. An aerial photograph presents a graphic record of the extent, boundaries, and surface features of soil patterns occurring at the surface of the ground. The presence of vegetation, the slopes of a valley, the colorless monotony of sand plains, the farming patterns, the drainage pattern, gullies, eroded lands, and evidences of the works of man are revealed in detail by aerial photographs. The use of aerial photographs may supplement both the detail and knowledge gained in topographic survey and ground explorations. The sampling and exploratory work can be made more rapid and effective after analysis of aerial photographs has developed the general soil features. The location and depth of permanent and perched groundwater tables may be sufficiently shallow to influence the design. The season of the year and rainfall cycle will measurably affect the depth to the groundwater table. In many locations, information may be obtained from residents of the surrounding areas regarding the behavior of wells and springs and other evidences of surface or subsurface water. The soil properties investigated for other purposes in connection with the design will supply information that can be used for the design of the drainage system. It may be necessary to supplement these explorations at locations of subsurface drainage structures and in areas where soil information is incomplete for design of the drainage system.

20-1.6 Laboratory Tests.

The design of subsurface drainage structures requires knowledge of the following soil properties: strength, compressibility, swell and dispersion characteristics, the in situ and compacted unit dry weights, the coefficient of permeability, the in situ water content, specific gravity, grain-size distribution, and the effective void ratio. These soil properties may be satisfactorily determined by experienced soil technicians through laboratory tests. The final selected soil properties for design purposes may be expressed as a range, one extreme representing a maximum value and the other a minimum value. The true value should be between these two extremes, but it may approach or equal one or the other, depending upon the variation within a soil stratum.

20-1.7 Drainage of Water from Soil.

The quantity of water removed by a drain varies depending on the type of soil and location of the drain with respect to the groundwater table. All the water contained in a given specimen cannot be removed by gravity flow since water retained as thin films adhering to the soil particles and held in the voids by capillarity do not drain. Consequently, to determine the volume of water that can be removed from a soil in a given time, the effective porosity as well as the permeability must be known. Limited effective porosity test data for well-graded base course materials, such as bank-run sands and gravels, indicate a value for effective porosity of not more than 0.15. Uniformly graded soils such as medium coarse sands, may have an effective porosity of not more than 0.25. Open graded aggregate used for drainage layers will have an effective porosity of between 0.25 and 0.35.

20-2 PRINCIPLES OF PAVEMENT DRAINAGE.

20-2.1 Flow of Water Through Soils.

The flow of water through soils is expressed by Darcy's empirical law which states that the velocity of flow (v) is directly proportional to the hydraulic gradient (i). This law can be expressed as:

Equation 20-1 $$v = k \times i$$

Where k is the coefficient of proportionality known as the coefficient-of-permeability, Equation 20-1 can be expanded to obtain the rate of flow through an area of soil (A). The equation for the rate of flow (Q) is:

Equation 20-2 $$Q = k \times i \times A$$

According to Darcy's law, the velocity of flow and the quantity of discharge through a porous media are directly proportional to the hydraulic gradient. For this condition to be true, flow must be laminar or non-turbulent. Investigations have found that Darcy's law is valid for a wide range of soils and hydraulic gradients. However, in developing criteria for subsurface drainage, liberal margins have been applied to allow for turbulent flow. The criteria and uncertainty depend heavily on the permeability of the soils involved in the pavement structure. It is therefore useful to examine the influence of various factors on the permeability of soils. In examining permeability of soils in regard to pavement drainage, the materials of most concern are base and subbase aggregate and aggregate used as drainage layers.

20-2.2 Factors Affecting Permeability.

20-2.2.1 Coefficient of Permeability.

The value of permeability depends primarily on the characteristics of the permeable materials, but it is also a function of the properties of the fluid. An equation (after Taylor) demonstrating the influence of the soil and pore fluid properties on permeability was developed based on flow through porous media similar to flow through a bundle of capillary tubes. This equation is as follows:

Equation 20-3 $$k = D_s^2 \cdot C \cdot \left(\frac{\gamma \cdot e^3}{\mu \cdot (1-e)} \right)$$

where

k=the coefficient of permeability

D_s=Hazen's effective particle diameter

C=shape factor

γ=unit weight of pore fluid

μ=viscosity of pore fluid

e=void ratio

20-2.2.2 Effect of Pore Fluid and Temperature.

In the design of subsurface drainage systems for pavements, the primary pore fluid of concern is water. Therefore, when permeability is mentioned in this chapter, water is assumed to be the pore fluid. Equation 20-3 indicates that the permeability is directly proportional to the unit weight of water and inversely proportional to the viscosity. The unit weight of water is essentially constant, but the viscosity of water will vary with temperature. Over the widest range in temperatures ordinarily encountered in seepage problems, viscosity varies about 100 percent. Although this variation seems large, it can be insignificant when considered in the context of the variations which can occur with changes in material properties.

20-2.2.3 Effect of Grain Size and Void Ratio.

It is logical that the smaller the grain size the smaller the voids that constitute the flow channels, and hence the lower the permeability. Equation 20-3 suggests that permeability varies with the square of the effective particle diameter and the cube of the void ratio. Since the void ratio is, for the most part a function of the material gradation, the influence of effective particle diameter will be magnified. Consider that when the effective particle size increases from No. 200 (0.08 mm) to No. 16 (1.2 mm) the permeability, according to equation 20-3, would increase by a factor of about 250. Assuming the increase in effective particle size would result in an increase in the void ratio by a minimum of two times then the permeability due to the increase in void ratio would be by a factor of 8. Thus the total increase in permeability due to the increase in the effective particle size and increase in void ratio would be by a factor of about 2000. Also, the shape of the void spaces has a marked influence on the permeability. As a result, the relationships between grain size, void ratio and permeability are complex. Intuition and experimental test data suggest that the finer particles in a soil have the most influence on permeability. The coefficient of permeability of sand and gravel materials, graded between limits usually specified for pavement bases and subbases, depends principally upon the percentage by weight of particles passing the No. 200

sieve. Table 20-1 provides estimates of the permeability for these materials for various amounts of material finer than the No. 200 sieve.

Table 20-1 Coefficient of Permeability for Sand and Gravel Materials (Coefficient of 55)

Percent by Weight Passing No. 200 Sieve	Permeability for Remolded Samples	
	mm/sec	ft/min
3	5×10^{-1}	10^{-1}
5	5×10^{-2}	10^{-2}
10	5×10^{-3}	10^{-3}
15	5×10^{-4}	10^{-4}
20	5×10^{-5}	10^{-5}

The volume of water that a soil mass is capable of holding is directly related to the void ratio. Not all water contained in a soil can be drained by gravity flow since water retained as thin films adhering to the soil particles and held by capillarity do not drain. Consequently, to determine the volume of water that can be removed from a soil the effective porosity (n_e) must be known. The effective porosity is defined as the ratio of the volume of the voids that can be drained under gravity flow to the total volume of soil, and can be expressed mathematically as

Equation 20-4 $$n_e = 1 - \frac{\gamma_d}{G_S \times \gamma_W}\left(1 + G_S \times W_e\right)$$

where

γ_d=dry density of the soil

G_S=specific gravity of solids

γ_W=unit weight of water

W_e=effective water content (after the soil has drained) expressed as a decimal fraction relative to dry weight

Limited effective porosity test data for well-graded base course materials, such as bank-run sands and gravels, indicate a value for effective porosity of not more than 0.15. Uniformly graded medium or coarse sands, may have an effective porosity of not more than 0.25 while for a uniformly graded aggregate, such as would be used in a drainage layer, the effective porosity may be above 0.25.

20-2.2.4 Effect of Structure and Stratification.

Generally, in situ soils show a certain amount of stratification or a heterogeneous structure. Water deposited soils usually exhibit a series of horizontal layers that vary in grain-size distribution and permeability, and generally these deposits are more permeable in the horizontal than in the vertical direction. In pavement construction the subgrade, subbase, and base materials are placed and compacted in horizontal layers which result in having a different permeability in the vertical direction than in the horizontal direction. The vertical drainage of water from a pavement can be disrupted by a single relatively impermeable layer. For most pavements the subgrades have a very low permeability compared to the base and subbase materials. Therefore, water in the pavement structure can best be removed by horizontal flow. For a layered pavement system the effective horizontal permeability is obtained from a weighted average of the layer permeability by the formula.

Equation 20-5 $$k = \frac{(k_1 \times d_1 + k_2 \times d_2 + k_3 \times d_3 + ...)}{(d_1 + d_2 + d_3 + ...)}$$

Where:

k = the effective horizontal permeability

$k_1, k_2, k_3 ...$ = the coefficients of horizontal permeability of individual layers

$d_1, d_2, d_3 ...$ = thicknesses of the individual layers

When a drainage layer is used in the pavement section, the permeability of the drainage material will likely be several orders of magnitude greater than the other materials in the section. Since water flow is proportional to permeability, the flow of water from the pavement section can be computed based only on the characteristics of the drainage layer.

20-2.3 Quantity and Rate of Subsurface Flow.

20-2.3.1 General.

Water flowing from the pavement section may come from infiltration through the pavement surface, groundwater or both. Normally groundwater flows into collector drains from the subgrade and will be an insignificant flow compared to the flow coming from infiltration. The computation of the groundwater flow is beyond the scope of this UFC. The volume of surface water infiltration flowing into the pavement depends on factors such as type and condition of surface, length, intensity of rainfall, properties of the drainage layer, hydraulic gradient, time allowed for drainage and the drained area. Consider all these factors in the design of the subsurface drainage system.

20-2.3.2 Effects of Pavement Surface.

The type and condition of the pavement surface has considerable influence on the volume of water entering the pavement structure. In the design of surface drainage facilities, assume all rain falling on paved surfaces to be runoff. For new well designed and constructed pavements, the assumption of 90 percent runoff is probably a good conservative assumption for the design of surface drainage facilities. For design of the subsurface drainage facilities, the design should be based on the infiltration rate for a deteriorated pavement. Studies have shown that for badly deteriorated pavements well over 50 percent of the rainfall can flow through the pavement surface. Since it is almost impossible to completely maintain a pavement over its life and since water may also enter from the shoulders, the infiltration rate for a deteriorated pavement must be used.

20-2.3.3 Effects of Rainfall.

The volume of water entering the pavement is directly proportional to the intensity and length of the rainfall. Relatively low intensity rainfalls can be used for designing the subsurface drainage facilities because high intensity rainfalls do not greatly increase the adverse effect of water on pavement performance. The excess rainfall would, once the base and subbase are saturated, run off as surface drainage. For this reason a seemingly non-conservative design rainfall can be selected.

20-2.3.4 Capacity of Drainage Layers.

If water enters the pavement structure at a greater rate than the discharge rate, the pavement structure becomes saturated. The design of horizontal drainage layers for the pavement structure is based, in part, on the drainage layer serving as a reservoir for the excess water entering the pavement. The capacity of the drainage layer as a reservoir is a function of the storage capacity of the drainage layer plus the amount of water which drains from the layer during a rain event. The storage capacity of the drainage layer is a function of the effective porosity of the drainage material and the thickness of the drainage layer. The storage capacity of the drainage layer q_s in terms of depth of water per unit area is computed by:

Equation 20-6 $$q_s = n_e \times h$$

where

n_e=the effective porosity

h=the thickness of the drainage layer

In the equation the dimensions of the q_s will be the same as the dimensions of the h. If all the water does not drain from the drainage layer, then the storage capacity is reduced by the amount of water in the layer at the start of the rain event. The criterion for design of the drainage layer calls for 85 percent of the water to be drained from the drainage layer within 24 hours; therefore it is conservatively assumed that only 85 percent of the storage volume will be available at the beginning of a rain event. To account for the possibility of water in the layer at the beginning of a rain event, equation 20-6 is modified to be:

Equation 20-7 $$q_s = 0.85 \times n_e \times h$$

The amount of water (q_d) which will drain from the drainage layer during the rain event may be estimated using the equation

Equation 20-8 $$q_d = \frac{t \times k \times i \times h}{2 \times L}$$

Where:

t = duration of the rain event

L = length of the drain path

k = permeability of the drainage layer

i = slope of the drainage layer

h = thickness of the drainage layer

In these equations the dimensions of q_s, q_d, t, k, h and L should be consistent. The total capacity (q) of the drainage layer will be the sum of q_s and q_d resulting in the following equation for the capacity

Equation 20-9 $$q = (0.85 \cdot n_e \cdot h) + \left(\frac{t \cdot k \cdot i \cdot h}{2 \cdot L} \right)$$

Knowing the intensity of water entering the pavement, equation 20-9 can be used to estimate the thickness of the drainage layer such that the drainage layer will have the capacity for a given design rain event. For most situations the amount of water draining from the drainage layer is small compared to the storage capacity. Therefore, in most cases, equation 20-7 can be used in estimating the thickness required for the drainage layer. For most highway designs a 4 in (100 mm) thick drainage layer will be sufficient.

20-2.3.5 Time for Drainage.

It is desirable that the water be drained from the base and subbase layers as rapidly as possible. The time for drainage of these layers is a function of the effective porosity, length of the drainage path, thickness of the layers, slope of the drainage path, and permeability of the layers, refer to Figure C20-3 (Appendix C) for pavement geometry. Until 1994, criteria specified that the base and subbase obtain a degree of 50 percent drainage within 10 days. The equation for computing time for 50 percent drainage is:

Equation 20-10 $$T_{50} = \frac{\left(n_e \times D^2\right)}{\left(2 \times k \times H_o\right)}$$

Where:

T_{50} = time for 50 percent drainage

n_e = effective porosity of the soil

k = coefficient of permeability

D, H_o and H = base and subbase geometry dimensions as shown in Figure C20-3 (Appendix C).

The dimensions of time *k, H*

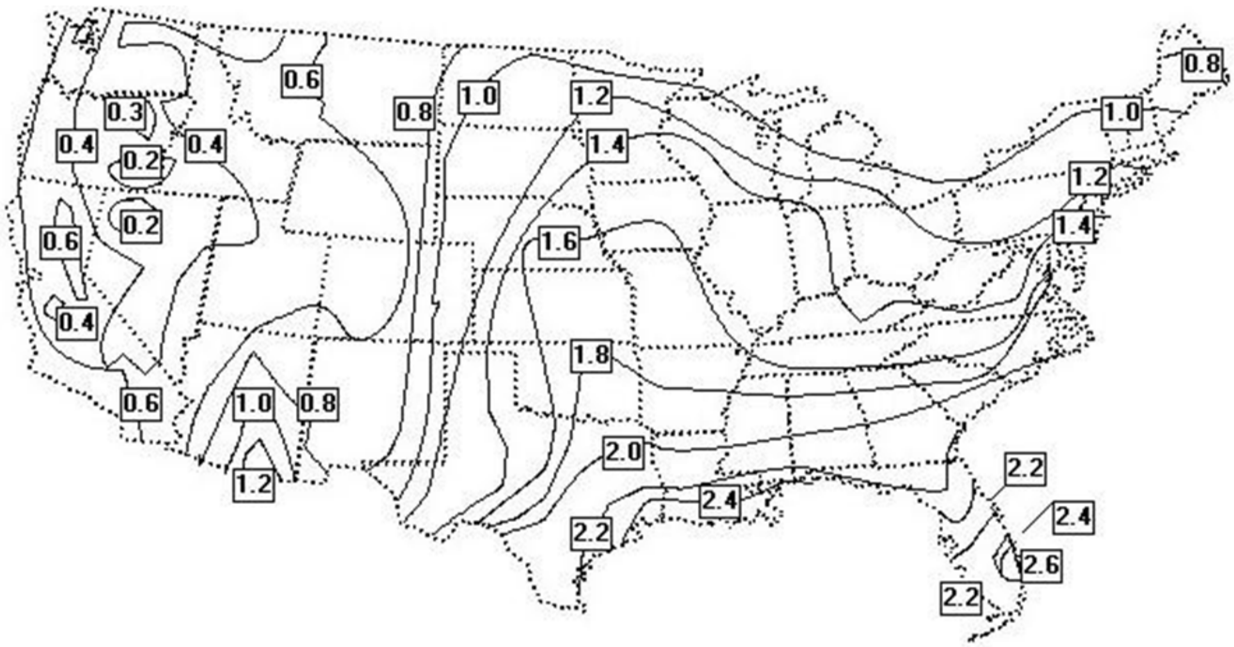
The dimensions of time k, H_o, H and D must be consistent. If In Figure C20-3 (Appendix C) the thickness of the drainage layer is small compared the length of the drainage path, the slope of the drainage path (i) can represent the value of $\left(\frac{H_o}{D}\right)$ therefore equation 20-10 can be written

Equation 20-11 $$T_{50} = \frac{n_e \times D}{2 \times i \times k}$$

Experience has shown that base and subbase materials, when compacted to densities required in pavement construction, seldom have sufficient permeability to meet the 10 day drainage criterion. In such pavements the base and subbase materials become saturated causing a reduced pavement life. When a drainage layer is incorporated into the pavement structure to improve pavement drainage, the criterion for design of the drainage layer must be that the drainage layer must reach a degree of drainage of 85 percent within 24 hr. The time for 85 percent drainage is about twice the time for 50 percent drainage. The time for 85 percent drainage (T_{85}) is computed by

Equation 20-12 $$T_{85} = \frac{n_e \times D}{i \times k}$$

Figure 20-1 Design Storm Index (in/hour), 1-hr Rainfall Intensity-Frequency Data for Continental United States Excluding Alaska



20-2.3.6 Length and Slope of the Drainage Path.

As can be seen in equation 20-10, the time for drainage is a function of the square of the length of drainage path. For this reason and the fact that for most pavement designs the length of the drainage path can be controlled, the drainage path length is an important parameter in the design of the drainage system. The length of the drainage path (L) may be computed from the following equation

Equation 20-13 $$L = \frac{L_t \times \sqrt{i_t^2 + i_e^2}}{i_t}$$

Where:

L_t = the length of the transverse slope of the drainage layer

i_t = the transverse slope of the drainage layer

i_e = the longitudinal slope of the drainage layer

The slope of the drainage path (i) is a function of the transverse slope and longitudinal slope of the drainage layer and is computed by the equation

Equation 20-14 $$i = \sqrt{i_t^2 + i_e^2}$$

20-2.3.7 Rate of Flow.

The edge drains for pavements having drainage layers must be designed to handle the maximum rate of flow from the drainage layer. This maximum rate of flow will be obtained when the drainage layer is flowing full and may be estimated using equation 20-2.

20-2.4 Use of Drainage Layers.

20-2.4.1 Purpose of Drainage Layers.

Special drainage layers may be used to promote horizontal drainage of water from pavements, prevent the buildup of hydrostatic water pressure, and facilitate the drainage of water generated by cycles of freeze-thaw.

20-2.4.2 Placement of Drainage Layers.

In rigid pavements the drainage layer will generally be placed directly beneath the concrete slab. In this location, the drainage layer will intercept surface water entering through cracks and joints, and permit rapid drainage of the water away from the bottom of the concrete slab. In flexible pavements the drainage layer will normally be placed beneath the base. In placing the drainage layer beneath the base the stresses on the drainage layer are reduced to an acceptable level and drainage is provided for the base course. Placement of the drainage layer in areas of frost penetration requires special consideration, in that, during the thaw it is likely that free water will be generated as the thaw front advances up from the bottom as well as down from the top. For frost areas it is possible that the drainage layer is best placed beneath any good draining NFS material. Another consideration in the design of subsurface drainage systems in frost areas is that it is possible for the drains to become blocked by snow and ice.

20-2.4.3 Permeability Requirements for the Drainage Layer.

The material for drainage layers in pavements must be of sufficient permeability to provide rapid drainage and rapidly dissipate water pressure and yet provide sufficient strength and stability to withstand load induced stresses. There is a trade-off between strength or stability and permeability; therefore the material for the drainage layers should have the minimum permeability for the required drainage application. For most applications a material (referred to as a rapid draining material) with a permeability of 1,000 ft/day (300 m/day) will provide sufficient drainage.

20-2.5 Use of Filters.

20-2.5.1 Purpose of Filters in Pavement Structures.

The purpose of filters in pavement structures is to prevent the movement of soil (piping) yet allow the flow of water from one material to another. The need for a filter is dictated by the existence of water flow from a fine grain material to a coarse gain material generating a potential for piping of the fine grain material. The principal location in the pavement structure where a flow from a fine grain material into a coarse grain material is water flowing from the base, subbase, or subgrade into the coarse aggregate surrounding the drain pipe. Thus, the principal use of a filter in a pavement system is to prevent piping into the drain pipe. Although rare, the possibility exists for hydrostatic head forcing a flow of water upward from the subbase or subgrade into the pavement drainage layer. For such a condition it is necessary to design a filter to separate the drainage layer from the finer material.

20-2.5.2 Piping Criteria.

The criteria for preventing movement of particles from the soil or granular material to be drained into the drainage material are:

$$\frac{\text{15 percent size of drainage or filter material}}{\text{85 percent size of material to be drained}} \leq 5$$

and

$$\frac{\text{50 percent size of drainage or filter material}}{\text{50 percent size of material to be drained}} \leq 25$$

The criteria given above are used when protecting all soils except clays without sand or silt particles. For these soils, the 15 percent size of drainage or filter material may be as great as 0.4 mm and the d_{50} criteria will be disregarded.

20-2.5.3 Permeability Requirements.

To assure that the filter material is sufficiently permeable to permit passage of water without hydrostatic pressure buildup, the following requirement should be met:

$$\frac{\text{15 percent size of filter material}}{\text{15 percent size of material to be drained}} \geq 5$$

20-2.6 Use of Separation Layers.

When drainage layers are used in pavement systems, the drainage layers must be separated from fine grain subgrade materials to prevent penetration of the drainage material into the subgrade or pumping of fines from the subgrade into the drainage layer. The separation layer is different from a filter in that there is no requirement, except during frost thaw, to protect against water flowing from the subgrade through the layer into the drainage layer.

20-2.6.1 Requirements for Separation Layers.

The main requirements of the separation layer are that the material for the separation layer have sufficient strength to prevent the coarse aggregate of the drainage layer from being pushed into the fine material of the subgrade and that the material have sufficient permeability to prevent buildup of hydrostatic pressure in the subgrade. To satisfy the strength requirements the material of the separation layer should have a minimum CBR of 50. To allow for release of hydrostatic pressure in the subgrade, the separation layer should have a higher permeability than that of the subgrade. This would not normally be a problem because the permeability of subgrades are orders of magnitude less than the permeability of a 50 CBR material but to ensure sufficient permeability the permeability requirements of a filter would apply.

20-2.7 Use of Geotextiles.

20-2.7.1 Purpose of Geotextiles.

Geotextiles (engineering fabrics) may be used to replace either the filter or the separation layer. The principal use of geotextiles is the filter around the pipe for the edge drain. Although geotextiles can be used as a replacement for the separation layer, geotextile adds no structure strength to the pavement; therefore this practice is not recommended.

20-2.7.2 Requirements of the Geotextiles for Filters.

When geotextiles are to serve as a filter lining the edge drain trench, the most important function of the filter is to keep fines from entering the edge drain system. For pavement systems having drainage layers there is little requirement for water flow through the fabric; therefore for most applications, it is better to have a heavier fabric than would normally be used as a filter. Since drainage layers have a very high permeability, geotextile fabric should never be placed between the drainage layer and the edge drain. The permeability of geotextiles is governed by the size of the openings in the fabric which is specified in terms of the apparent opening size (AOS) in millimeters. For use as a filter for the trench of the edge drain the AOS of the geotextile should always be equal to or less than 0.212 mm. For geotextiles used as filters with drains installed to intercept groundwater flow in subsurface aquifers the geotextile should be selected based on criteria similar to the criteria used to design a granular filter.

20-2.7.3 Requirements for Geotextiles Used for Separation.

Geotextiles used as separation layers beneath drainage layers should be selected based primarily on survivability of the geotextiles with somewhat less emphasis placed on the AOS. When used as a separation layer the geotextile survivability should be rated very high by the rating scheme given by AASHTO M 288. This ensures the survival of the geotextiles under the stress of traffic during the life of the pavement. To ensure that fines will not pump into the drainage layer yet allow water flow to prevent hydrostatic pressure the AOS of the geotextile must be equal to or less than 0.212 mm and also equal to or greater than 0.125 mm.

20-3 DESIGN OF THE PAVEMENT SUBSURFACE DRAINAGE SYSTEM.

20-3.1 General.

Provide a pavement subsurface drainage system for the rapid removal of surface water and water generated by freeze-thaw action. Although the primary emphasis will be on removing water from under the pavement, there may be occasions when the system will also serve as interceptor drain for groundwater.

20-3.2 Methods.

For most pavement structures, water is to be removed by the use of a special drainage layer which allows the rapid horizontal drainage of water. The drainage layer must be designed to handle surface infiltration from a design storm and withstand the stress of traffic. A separation layer must be provided to prevent intrusion of fines from the subgrade or subbase into the drainage layer and facilitate construction of the drainage layer. The drainage layers should feed into a collection system consisting of trenches with a drain pipe, backfill, and filter. The collection system must be designed to maintain progressively greater outflow capabilities in the direction of flow. The outlet for the subsurface drains should be properly located or protected to prevent backflow from the surface drainage system. Some pavements may not require a drainage system in that the subgrade may have sufficient permeability for the water to drain vertically into the subgrade. In addition, some pavements designed for very light traffic, may not justify the expense of a subsurface drain system. Even for the pavements designed for very light traffic care must be taken to insure that base and subbase material are free draining and that water will be not trapped in the pavement structure. For pavements not having collection systems the base and subbase must daylight at the shoulders.

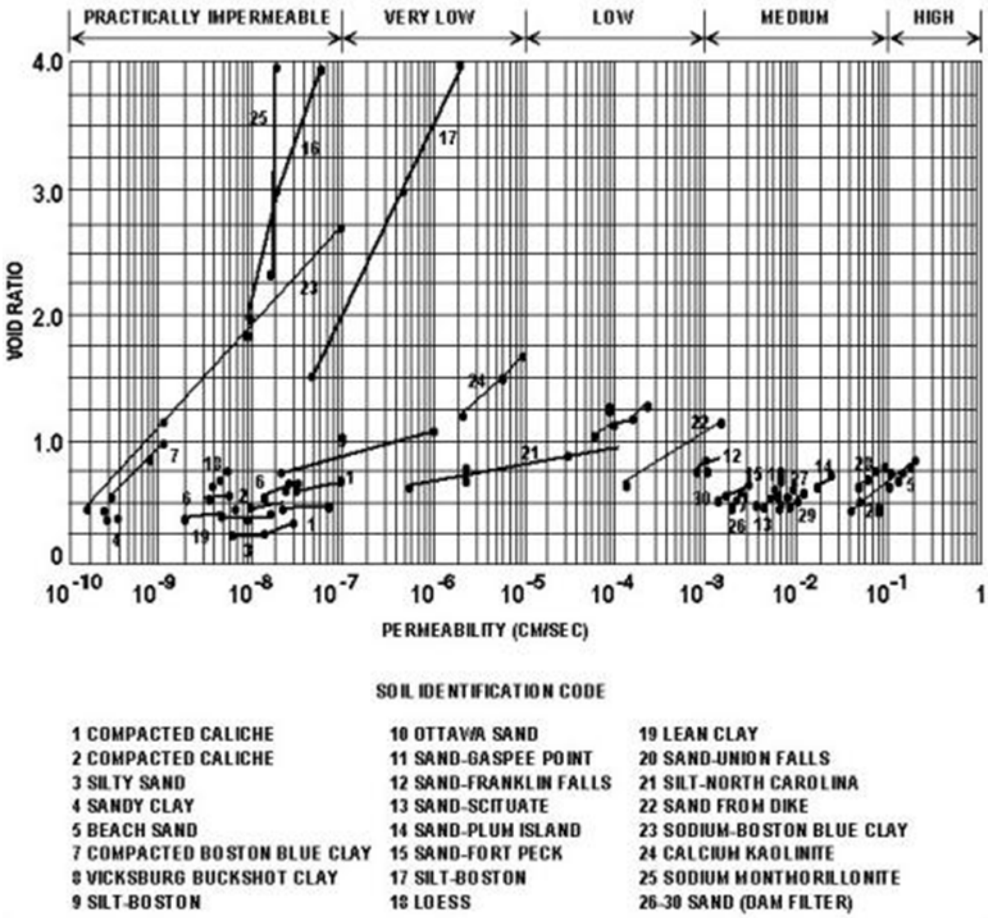
20-3.3 Design Prerequisites.

For the satisfactory design of a subsurface drainage system, the designer must have an understanding of environmental conditions, subsurface soil properties and groundwater conditions.

20-3.3.1 Environmental Conditions.

Temperature and rainfall data applicable to the local area should be obtained and studied. The depth of frost penetration is an important factor in the design of a subsurface drainage. For most areas the approximate depth of frost penetration can be determined by referring to UFC 3-260-02 or by using the computer program for frost analysis. Rainfall data are used to determine the volume of water to be handled by the subsurface drainage system. The data can be obtained from local weather stations or by the use of Figure 20-1.

Figure 20-2 Permeability Test Data (from Lambe and Whitman, With Permission)



20-3.3.2 Soil Properties.

In most cases the soil properties investigated for other purposes in connection with the pavement design will supply information that can be used for the design of the subsurface drainage system. The two properties of most interest are the coefficient of permeability and the frost susceptibility of the pavement materials.

20-3.3.3 Coefficient of Permeability.

The coefficient of permeability of the existing subsurface soils determines the need for special horizontal drainage layers in the pavement. For pavements having subgrades with a high coefficient of permeability the water entering the pavement will drain vertically and therefore horizontal drainage layers will not be required. For pavements having subgrades with a low coefficient of permeability the water entering the pavement must be drained horizontally to the collector system or to edge drains.

20-3.3.4 Frost Susceptible Soils.

Soils susceptible to frost action are those that have the potential of ice formation occurring when they are subjected to freezing conditions with water available. Ice formation takes place at successive levels as freezing temperatures penetrate into the ground. Soils having a high capillary rate and low cohesive nature act as a wick in feeding water to ice lenses. Soils are placed into groups according to the degree of frost susceptibility as shown in Table 20-2. Because a large volume of free water is generated during the thawing of ice lenses, horizontal drainage layers are required to permit the escape of the water from the pavement structure and thus facilitate the restoration of the pavement strength.

Table 20-2 Frost Susceptible Soils

Typical Soil			
Frost Group	**Type of Soil**	**Percent Finer than 0.02 mm by Weight**	**Types Under Unified Soil Classification System**
F1	Gravelly Soils	6-10	GW-GM, GP-GM, GW-GC, GP-GC
F2	(a) Gravelly Soils (b) Sands	10-20 6-15	GM, GC, GM-GC SM, SC, SW-SM, SP-SM, SW-SC, SP-SC, SM-SC
F3	(a) Gravelly Soils (b) Sands, except very fine silty sands (c) Clays (PI > 12)	> 20 > 15 --	GM, GC, GM-GC SM, SC, SM-SC CL, CH, ML-CL
F4	(a) Silts (b) Very fine sands (c) Clays (PI < 12) (d) Varved clays and other fine grained, with banded sediments	-- > 15 -- --	ML, MH, ML-CL SM, SC, SM-SC CL, ML-CL CL or CH layered ML, MH, SM, SC SM-SC or ML-CL

20-3.3.5 Sources for Data

The field explorations made in connection with the project design should include a topographic map of the proposed pavement facility and surrounding vicinity indicating all streams, ditches, wells, and natural reservoirs. An analysis of aerial photographs should be conducted for information on general soil and groundwater conditions. Borings taken during the soil exploration must provide depth to groundwater tables and subgrade soil types. Typical values of permeability for subgrade soils can be obtained from Figure 20-2. Although the value of permeability determined from Figure 20-2 must be considered only an estimate, the value should be sufficiently accurate to determine if subsurface drainage is required for the pavement.

For the permeability of granular materials, estimates of the permeability may be determined from the following equations:

Equation 20-15
$$k = \frac{217.5 \times (D_{10})^{1.478} \times (n)^{6.654}}{(P_{200})^{0.597}} \text{ (mm/sec)}$$

or

Equation 20-16
$$k = \frac{(6.214 \times 10^{5}) \times (D_{10})^{1.478} \times (n)^{6.654}}{(P_{200})^{0.597}} \text{ (ft/day)}$$

Where:

n = porosity $= 1 - \frac{\gamma_d}{\gamma_w \cdot G}$

G = specific gravity of solids (assumed 2.7)

γ_d = dry density of material

γ_w = density of water

D_{10} = effective grain size at 10 percent passing in millimeters

P_{200} = percent passing No. 200 (0.08 mm) sieve

For the most part the permeability needed for design of the drainage layer will be assigned based on the gradation of the drainage material. In some cases, laboratory permeability tests may be necessary, but it is cautioned that the permeability of very open granular materials is very sensitive to test methods, methods of compaction and gradation of the sample. Therefore, conservative drainage layer permeability values should be used for design.

20-3.4 Criteria for Subsurface Drain Systems.

Not all pavements require a subsurface drain system either because the subgrade is sufficiently permeable to allow vertical drainage of water into the subgrade or the pavement structure does not justify the expense of a subsurface drain system. For pavements having a subgrade with permeability greater than 20 ft/day (6 m/day), one can assume that the vertical drainage is sufficient to not require a drainage system. In addition to the above exemption for the requirement for drainage systems, flexible pavements having total thickness of structure above the subgrade of 8 in (200 mm) or less are not required to have a drainage system. All pavements not meeting the above criteria are required to have a subsurface drainage system. Even if a pavement meets the exemption requirements, a drainage analysis should be conducted for possible benefits for including the drainage system. For rigid pavements in particular, care should be taken to ensure water is drained rapidly from the bottom of the slab and that the material directly beneath the concrete slab is not susceptible to pumping.

20-3.4.1 Surface Water Inflow.

The subsurface drainage of the pavement is to be designed to handle surface water infiltrated from a design storm of 1 hour duration at an expected return frequency of 2 yr. The design storm index for different parts of the U.S. can be obtained from Figure 20-1. Determine the inflow by multiplying the design storm index (R) times an infiltration coefficient (F). The infiltration coefficient varies over the life of the pavement depending on the type of pavement, surface drainage, pavement maintenance, and structural condition of the pavement. Since the determination of a precise value of the infiltration coefficient for a particular pavement is very difficult, a value of 0.5 may be assumed for design.

20-3.4.2 Length and Slope of Drainage Path.

The length of the drainage path is measured along the slope of the drainage layer from the crest of the slope to where the water will exit the drainage layer. In simple terms, the length of the drainage path is the maximum distance water will travel in the drainage layer. The length of the drainage path (L) in feet (meters) is to be computed by equation 20-13, where and the slope (i) of the drainage path is to be computed by equation 20-14.

20-3.4.3 Thickness of Drainage Layer.

The thickness of the drainage layer is computed such that the capacity of the drainage layer is equal to or greater than the infiltration from the design storm. When the length of the drainage path (L) is in feet (meters), the design storm index (R) is in feet/hour (meters/hour), the permeability of the drainage layer (k) is in feet/hour (meters/hour), and the length of the design storm (t) is in hours, the equation for computing the thickness (H) in feet (meters) is

Equation 20-17
$$H = \frac{2 \times F \times R \times L \times t}{(1.7 \times n_e \times L) + (k \times i \times t)}$$

The effective porosity (n_e), the infiltration coefficient (F) and the slope of the drainage path (i) are non-dimensional. If the term ($k\ i\ t$) is small compared to the term ($1.7\ n_e\ L$) which would be the case for long drainage paths, i.e., for drainage paths longer than about 20 ft (6 m), then the required thickness of the drainage layer can be estimated by deleting the term ($k\ i\ t$) from equation 7-17 or

Equation 20-18
$$H = \frac{F \times R \times t}{0.85 \times n_e}$$

where the units are the same as in equation 20-17.

20-3.4.4 Drainage Criteria.

The subsurface drainage criteria for roadways require the drainage layer to become saturated. The drainage layer should be capable of attaining 85 percent drainage within 24 hours. For pavement areas receiving only low volume, low speed traffic the time for 85 percent drainage is 10 days. The time for 85 percent drainage is computed by the equation

Equation 20-19 $$T_{85} = \frac{n_e \times L}{i \times k}$$

where the dimensions of (T_{85}) will be in days when (L) is in feet (meters) and (k) is in feet/day (meters/day). The time of drainage may be adjusted by changing the drainage material, the length of the drainage path or the slope of the drainage path. Changing the drainage material changes both the effective porosity and the permeability but the effective porosity changes, at the most, by a factor of 3, whereas the permeability may change by several orders of magnitude. Thus, providing a more open drainage material decreases the time for drainage but more open materials are less stable and more susceptible to rutting. It is therefore desirable to keep the drainage material as dense as possible. The drainage layer of a pavement is usually placed parallel to the surface; therefore in most cases the slope of the drainage path is governed by the geometry of the pavement surface. For large paved areas such as vehicle parking areas, the time for drainage is best controlled by designing the collection system to minimize the length of the drainage path. For edge drains along roads and parking areas, it may be difficult to reduce the length of the drainage path without resorting to placing drains under the pavement. Pavements having long longitudinal slopes may require transverse collector drains to prevent long drainage paths. Thus, designing the subsurface drainage system to meet the criteria for time of drainage involves matching the type of drainage material with the drainage path length and slope.

20-3.5 Placement of Subsurface Drainage System.

20-3.5.1 Rigid Pavements.

In the case of rigid pavements the drainage layer, if required, must be placed directly beneath the concrete slab. In the structural design of the concrete slab the drainage layer along with any granular separation layer must be considered a base layer, and structural benefit may be realized from the layers.

20-3.5.2 Flexible Pavements.

In the case of flexible pavements the drainage layer should be placed either directly beneath the surface layer or beneath a graded crushed aggregate base course. If the required thickness of granular subbase is equal to or greater than the thickness of the drainage layer plus the thickness of the separation layer, the drainage layer is placed beneath the graded crushed aggregate base. Where the total thickness of pavement structure is less than 12 in (300 mm), the drainage layer may be placed directly beneath the surface layer and the drainage layer used as a base. When the drainage layer is placed beneath an unbound aggregate base, care must be taken to limit the material passing the No. 200 (0.08 mm) sieve in the aggregate base to 8 percent or less.

20-3.5.3 Separation Layer.

The drainage layer must be protected from contamination of fines from the underlying layers by a separation layer to be placed directly beneath the drainage layer. In most cases the separation layer should be a graded aggregate material meeting the requirements of a 50 CBR subbase and can be considered as part of the subbase. For design situations where a firm foundation already exists and thickness of the separation layer is not needed in the structure for protection of the subgrade, a filter fabric may be substituted for the granular separation layer. In frost areas the separation layer should be NFS.

20-3.6 Material Properties for Drainage Layers.

The material for a drainage layer should be a hard, durable crushed aggregate to withstand degradation under construction traffic as well as in service traffic. The gradation of the material should be such that the material has sufficient stability for the operation of construction equipment. While it is desirable for strength and stability to have the well-graded aggregate, the permeability of the material must be maintained. For most drainage layers, the drainage materials should have a minimum permeability of 1,000 ft/day (300 m/day). Two materials, a rapid draining material (RDM) and an open graded material (OGM), have been identified for use in drainage layers. The RDM is a material having a sufficiently high permeability (1,000 ft/day to 5,000 ft/day (1,500 m/day)) to serve as a drainage layer and will also have the stability to support construction equipment and the structural strength to serve as a base or a subbase. The OGM is a material having a very high permeability (greater than 5,000 ft/day) which can be used for a drainage layer. The OGM will normally require stabilization for construction stability and for structural strength to serve as a base in a flexible pavement. Gradation limits for the two materials are given in Table 20-3 and the design properties are given in Table 20-4. The gradations given in Table 20-3 provide very wide bands and it is possible to produce gradations within these bands that may not be sufficiently stable for construction without the use of chemical stabilization. Table 20-5 provides the gradation specifications for three aggregate materials each of which will meet the criteria for stability. These gradations were developed to produce the maximum density given maximum aggregate sizes of 1-1/2 in (38 mm), 1 in (25mm), and 3/4 in (19mm) and a maximum of 8 percent passing the number 16 sieve. For drainage layer thicknesses less than 6 in (150 mm). gradations number 1 or 2 may be used. For drainage layers 6 in. or more in thickness any of the three gradations may be used but the gradations having the larger size aggregates will produce the more stable aggregate. Each of the gradations would produce a drainage layer having a permeability of about 1000 ft/day.

20-3.6.1 Aggregate for Separation Layer.

The separation layer prevents fines from infiltrating or pumping into the drainage layer and provides a working platform for construction and compaction of the drainage layer. The material for the separation layer should be a graded aggregate meeting the requirements of a 50 CBR subbase as given in Chapter titled Flexible Pavement Select Materials and Subbase Courses except that the maximum aggregate size should not be greater than 1/4 the thickness of the separation layer. The permeability of the separation layer should be greater than the permeability of the subgrade, but the material should not be so open as to permit pumping of fines into the separation layer. To prevent pumping of fines the ratio of d_{15} of the separation layer to d_{85} of the subgrade must be equal to or less than 5. The material property requirements for the separation layer are given in Table 20-6.

Table 20-3 Gradations of Materials for Drainage Layers and Choke Stone

Drainage Layer Material			
Sieve Designation (in)	**Rapid Draining Material**	**Open Graded Material**	**Choke Stone**
1-1/2 in (38 mm)	100	100	100
1 in (25 mm)	70-100	95-100	100
3/4 in (19 mm)	55-100	--	100
1/2 in (13 mm)	40-80	25-80	100
3/8 in (10 mm)	30-65	--	80-100
No. 4 (5 mm)	10-50	0-10	10-100
No. 8 (2 mm)	0-25	0-5	5-40
No. 16 (1 mm)	0-5	--	0-10

Table 20-4 Properties of Materials for Drainage Layers

Property	Rapid Draining Material	Open Graded Material
Permeability in feet/day (m/sec)	1,000-5,000 (300-1,500)	> 5,000 (> 1,500)
Effective Porosity	0.25	0.32
Percent Fractured Faces (COE method)	90% for 80 CBR 75% for 50 CBR	90% for 80 CBR 75% for 50 CBR
C_v	> 3.5	--
LA Abrasion	< 40	< 40
Note: C_v is the uniformity coefficient = D60/D10.		

Table 20-5 Material Gradations for Drainage Layers

Sieve Size	Gradation No. 1 3/4 in (19 mm) max.		Gradation No. 2 1 in (25 mm) max.		Gradation No. 3 1-1/2 in (38 mm)max	
	Percent Passing	Tolerance	Percent Passing	Tolerance	Percent Passing	Tolerance
1-1/2 in (38 mm)					100	-5
1 in (25 mm)			100	-5	79	±8
3/4 in (19 mm)	100	-5	85	±8	66	±8
1/2 in (13 mm)	78	±8	65	±8	52	±8
3/8 in (10 mm)	63	±8	53	±8	42	±8
No. 4 (5 mm)	38	±8	32	±6	25	±6
No. 8 (2 mm)	19	±6	16	±6	12	±4
No. 16 (1 mm)	4	±4	4	±4	4	±4

Table 20-6 Criteria for Granular Separation Layer

Maximum Aggregate Size	Lesser of 2 in (50 mm) or 1/4 of layer thickness
Maximum CBR	50
Maximum Percent Passing No. 10 (2 mm)	50
Maximum Percent Passing No. 200 (0.08 mm)	15
Maximum Liquid Limit	25
Maximum Plasticity Index	5
d_{15} of Separation Layer to d_{85} of Subgrade	$\leq$ 5

20-3.6.2 Filter Fabric for Separation Layer.

Although filter fabric provides protection against pumping, it does not provide extra stability for compaction of the drainage layer. Therefore, fabric should be selected only when the subgrade provides adequate support for compaction of the drainage layer. The important characteristics of the fabric are strength for surviving construction and traffic loads, and AOS to prevent pumping of fines into the drainage layer. Filter fabric for separation must be a nonwoven needle punched fabric meeting the criteria given in Table 20-7.

Table 20-7 Criteria for Filter Fabric to be Used as a Separation Layer

	Criteria	ASTM Test Method
50 Percent or Less Passing No. 200 Sieve	AOS (mm) < 0.6 mm Greater than No. 30 sieve	D4751
Greater Than 50 Percent Passing No. 200 Sieve	AOS (mm) < 0.297 Greater than No. 50 sieve	D4751
Minimum Grab Strength in lb (kN) at 50% Elongation	0.8 (180)	D4632/D4632M
Minimum Puncture Strength in lb (kN)	0.35 (80)	D4833/D4833M

20-4 STABILIZATION OF DRAINAGE LAYER.

Stabilization of OGM is normally required for stability and strength, and to prevent degradation of the aggregate in handling and compaction. Stabilization may also be used when high quality crushed aggregate is not available and there may even be occasions when stabilization of RDM is necessary. Stabilization may be accomplished mechanically by use of a choke stone or by the use of a binder such as asphalt or Portland cement.

20-4.1 Choke Stone Stabilization.

A choke stone is a small size stone used to stabilize the surface of an OGM. The choke stone should be a hard, durable, crushed aggregate having 90 percent fractured faces. The ratio of d_{15} of the coarse aggregate to the d_{15} of the choke stone must be less than 5, and the ratio of the d_{50} of the coarse aggregate to d_{50} of the choke stone must be greater than 2. The gradation range for acceptable choke stone is given in Table 20-3.

20-4.2 Asphalt Stabilization.

Stabilize the drainage material with asphalt by using only enough asphalt to coat the aggregate. Take care to not fill the voids with excess asphalt. Asphalt grade used for stabilization should be AC20 or higher. For stabilization of OGM, 2 to 2-1/2 percent asphalt by weight should be sufficient to coat the aggregate. Higher rates of application may be necessary when stabilization of less open aggregate such as RDM is necessary.

20-4.3 Cement Stabilization.

As with asphalt stabilization, Portland cement stabilization should only use enough cement paste to coat the aggregate, and take care to not fill the voids with excess paste. The amount of Portland cement required should be about 2 bags/yd^3 (170 kilograms per cubic meter) depending on the gradation of the aggregate. The water-cement ratio should be just sufficient to provide a paste which will adequately coat the aggregate.

20-5 COLLECTOR DRAINS.

20-5.1 Design Flow.

Provide collector drains to collect and transport water from under the pavement. For pavements having drainage layers, provide the drainage layers with a means for water to drain either with a collector or ditches. The collector system should have the capacity to handle the water from the drainage layer plus water from other sources. The water entering the collector system from the drainage layer is computed assuming the drainage layer is flowing full. Thus, the volume of water (*Q*) in cubic feet per day per foot (cubic millimeters per second per meter) of length of collector pipe (assuming the drainage layer is only on one side of the collector) would be

Equation 20-20 $$Q = 1000 \times H \times i \times k \text{ in cubic mm per second per meter}$$

or

Equation 20-21 $$Q = H \times i \times k \text{ in cubic ft per day per foot}$$

where

H=thickness of the drainage layer, ft (mm)

i=slope of the drainage layer

k=permeability of the material in the drainage layer, ft/day (mm/sec)

If the collector system has water entering from both sides, the volume of water entering the collector would be twice that given by equation 20-20.

20-5.2 Design of Collector Drains.

20-5.2.1 Drain System Layout.

Normally, the collector drains are equally spaced along the shoulder of the pavement. The system consists of the drain pipe, flushing and observation risers, manholes, discharge laterals, filter fabric, and trench backfill. Since placement of subsurface drains under pavements may be a source of differential settlement or heave, this should be avoided when possible. The drainage system for large areas of pavement may require placement of subsurface drains under the pavement. For these cases the subsurface drains should be placed to avoid high traffic areas. In areas of extreme cold temperatures and heavy snow buildup laterals must be placed to reduce the probability of the laterals or outlets becoming clogged with ice or snow. Also in areas of extreme cold temperatures it may not be possible to place the collector drains below the depth of frost penetration therefore it is possible that the collector pipe may be filled with ice while thawing is occurring near the surface. For this case provisions must be made to drain the upper portion of the pavement either by day-lighting the drainage layer or providing special laterals to drain the drainage layer.

20-5.2.2 Collector Pipe.

The collector pipe may be perforated flexible, Acrylonitrile-Butadiene-Styrene, corrugated polyethylene (CPE) or smooth rigid polyvinyl chloride pipe (PVC). Pipe must conform to the appropriate AASHTO Specification. Most State Highway Agencies use either CPE or PVC. For CPE pipe, AASHTO specification M 252 “Corrugated Polyethylene Drainage Tubing” is suggested, while for PVC pipe, AASHTO Specification M 278, “Class PC 50 PVC Pipe,” is recommended. It is recommended that asphalt stabilized material not be used as backfill around pipe, but, if it is to be used, then the pipe should be PVC 90 degrees C electric plastic conduct, EPC40 or EPC80 conforming to the requirements of National Electrical Manufacturers Association Specification TC2. Geocomposite edge drains (strip drains) may be used in special situations but only with the approval of the Government Civil Engineer. Geocomposite edge drains should only be considered for pavements not having a drainage layer.

20-5.2.3 Pipe Size and Slopes.

The pipe must be sized, according to equations 20-22 or 20-23, to have a capacity sufficient to collect the peak flow from under the pavement. Equations 20-22 and 20-23 are Manning equations for computing the capacity of a full flowing circular drain. The equation for flow (*Q*) in cubic feet per second is:

Equation 20-22 $$Q = \frac{1.486}{n} \cdot (A) \cdot \left[\frac{d}{4}\right]^{2/3} \cdot \left(s^{1/2}\right)$$

where

n = coefficient of roughness for the pipe
A = area of the pipe, ft^2
d = pipe diameter, ft
s = slope of the pipe invert

For metric units the equation for flow in cubic meters per second is:

Equation 20-23 $$Q = \frac{1.0}{n} \cdot (A) \cdot \left[\frac{d}{4}\right]^{2/3} \cdot \left(s^{1/2}\right)$$

where

n and s are as defined in equation 20-22
A = pipe area, m^2
d = pipe diameter, m

The coefficient of roughness for different pipe types can be obtained from Table 20-8 Except for long intercepting lines and extremely severe groundwater conditions, 6 in (150 mm) diameter drains should be satisfactory for most subsurface drainage installations. The minimum size pipe recommended for all collector drains is a 6 in (150 mm) diameter pipe. The recommended minimum slope for subdrains is 0.15 percent.

Table 20-8 Coefficient of Roughness for Different Types of Pipe

Type of Pipe	Coefficient of Roughness, *n*
Clay, concrete, smooth-wall plastic, and Asbestos-cement	0.013
Bituminous-coated, non-coated corrugated metal pipe or corrugated metal pipe	0.024

20-5.3 Placement of the Drainage Layer and Collector Drains.

20-5.3.1 Design.

In general the drainage layer is placed below the concrete surface in the case of rigid pavement and below the base course for a flexible pavement as illustrated in Figure C20-7, Figure C20-8, and Figure C20-9 (Appendix C). In most cases the trench for the collector drains should be constructed of sufficient width to provide 6 in (150 mm) clearance on each side of the pipe. The depth of the trench must be sufficient to provide a minimum 12 in (300 mm) from the top of the pavement subgrade to the center of the pipe plus 3 in (75 mm) clearance beneath the pipe. In frost areas extra care must be used in placing subsurface drains. For F3 and F4 subgrades a collector pipe will always be placed such that there will be positive drainage for the drainage layer and any NFS fill. If possible the drains should be placed below the depth of frost penetration. For many locations it will not be economically possible to place drains below the depth of frost penetration and therefore the drains and backfill will be subject to freezing. In areas where the depth of frost penetration is greater than 4 ft (1.2 m) below the bottom of the drainage layer, the top of the pipe need not be located deeper than 4 ft (1.2 m) below the bottom of the drainage layer. In frost areas where differential heave will cause pavement problems, the sides of the trench must be sloped not steeper than 1 vertical on 10 horizontal for the depth of frost penetration. At the edge of the pavement, where the pavement will not be subjected to traffic, the sides of the trench may be sloped at a slope of 1 vertical on 4 horizontal. The sloping of the trench sides is not required for the parts of the trench in NFS materials or for F1 or S1 soils unless the pavement over the trench is subjected to high speed traffic. The placement of collector drains under the interior portion of a pavement in frost areas is a special case where the collector drain is not directly connected to the drainage layer by an OGM or a RDM. This case is illustrated in Figure C20-7, Figure C20-8, and Figure C20-9 (Appendix C). The interior designs are based on the premise that NFS fill will have sufficient permeability to allow vertical drainage of the drainage layer into the collector pipes. Another premise is that the filter fabric will have sufficient area as not to impede the flow of water from the NFS fill to the collector pipe. The exception to the minimum requirement for the depth of the collector pipe below the surface of the subgrade is the interior case in a frost area for an F3 or F4 subgrade when the collection pipe is in above the depth of frost penetration. For this case the depth of the pipe below the surface of the subgrade is to be kept to a minimum.

20-5.3.2 Backfill.

Backfill the trench with a permeable material to rapidly convey water to the drainage pipe. The backfill material may be OGM, RDM, or other uniform graded aggregate. Place a minimum of 3 in (75 mm) of aggregate beneath the drainage pipe. Proper compaction or chemical stabilization of the backfill is necessary to prevent settlement of the fill. In placing the backfill, compact the backfill in lifts not exceeding 6 in (150 mm). When geocomposites are used in place of pipe, place the geocomposites against the material to be drained and thus the backfill is not expected to convey water. For this reason the backfill for the geocomposites will not require the high permeability required for the backfill around the pipe drains. However, since the backfill for the geocomposites will be against the side of the trench, the backfill should meet the requirements of a granular filter.

20-5.3.3 Geotextiles in the Trench.

Provide the trench with a geotextile filter fabric. Place the filter fabric to separate the permeable backfill of the trench from the subgrade or subbase materials. The filter fabric must not be placed so as to impede the flow of water from the drainage layer to the drain pipe. The filter fabric must also protect from the infiltration of fines from any surface layer. This is particularly important for drains placed outside the pavement area where surface water can enter the drain through a soil surface. The filter fabric for the trench must be a nonwoven needle punched fabric meeting the criteria given in Table 20-9.

Table 20-9 Criteria for Fabrics Used in Trench Construction

	ASTM Test Method	Criteria
Soil With 50 Percent or Less Passing No. 200 Sieve	D 4751	AOS < Sieve No. 30 (0.6 mm)
Soil With Greater Than 50 Percent Passing No. 200 Sieve	D 4751	AOS < Sieve No. 50 (0.3 mm)
Minimum Grab Strength in lb (kN) at 50% Elongation	D4632/D4632M	130 (0.6)
Minimum Puncture Strength in lb (kN)	D4833/D4833M	55 (0.25)

20-5.3.4 Trench Cap.

Cap edge drains placed outside of a paved area with a layer of low permeability material, such as an asphalt stabilized surface, to reduce the infiltration of surface water into the subsurface drainage system. If the area above the edge drain is to be sod surfaced, a filter layer will be required between the drain layer and sod.

20-5.4 Lateral Outlet Pipe.

20-5.4.1 Design.

The lateral outlet pipe provides both a means of getting water out of the edge drains, and for cleaning and inspecting the system as illustrated in Figure C20-10 and Figure C20-12 (Appendix C). Provide edge drains with lateral outlet pipes spaced at intervals 300 to 500 ft (90 to 150 m) along the edge drains and at the low point of all vertical curves. To facilitate drain cleanout, the outlet pipes should be placed at about a 45 degrees angle from the direction of flow in the collector drain. The lateral pipe should be a non-perforated solid-walled pipe and should be equipped with an outlet structure. A three percent slope from the edge drain to the outlet structure is recommended. To reduce outlet maintenance, outlet pipes should, where possible, be connected to existing storm drains or inlets. For lateral pipe flowing to a ditch, the invert of the outlet pipe should be a minimum of 6 in (150 mm) above the 2-year design flow in the ditch. To prevent piping, the trench for the outlet pipes must be backfilled with a material of low permeability, or provided with a cutoff wall or diaphragm. Dual outlets with large radius bend are recommended for maintenance considerations, as shown in Figure C20-11 (Appendix C). The dual outlet system allows sections of collector drains to be flushed out to clear any debris material blocking the free flow of water. Other recommended design details for drainage outlets are as follows:

- For pipe drains, use the same diameter pipe as the collector drains. For prefabricated geocomposite drains, 4 in (100 mm) to 6 in (150 mm) diameter pipe should provide adequate hydraulic capacity. The flow capacity of the outlets must be greater than that of the collector drains. In general, because of the greater slope provided for outlet pipes, the hydraulic capacity is not a problem.
- The discharge end of the outlet pipe should be placed at least 6 in (150 mm) above the 2 year design flow in the drainage ditch. The same requirement applies even if the outlet is discharging into storm drain inlets.
- In frost areas, give special attention to the placement of the outlet pipes such that they do not become clogged with ice or snow.

20-5.4.2 Outfall for Outlet Pipe.

The outfall for the outlet pipe should be provided with a headwall to protect the outlet pipe from damage, prevent slope erosion, and facilitate the location of outlet pipes. Place headwalls flush with the slope so that mowing operations are not impaired. Easily removed rodent screens should be installed at the pipe outlet. The headwall may be pre-cast or cast-in-place.

20-5.4.3 Reference Markers.

Although not a requirement, reference markers are recommended for the outlets to facilitate maintenance and observation. A simple flexible marker post or marking on the shoulder will suffice to mark the outlet.

20-5.5 Cross Drains.

Cross drains may be required at locations where flow in the drainage layer is blocked, on steep longitudinal grades where the water needs to be intercepted to prevent long drainage paths, or at the bottom of vertical curves. For example, cross drains may be required where pavements abut building foundations, at bridge approach slabs, or where drainage layers abut impermeable bases.

20-5.6 Manholes and Observation.

Manholes, observation basins, and risers are installed on subsurface drainage systems for access to the system to observe its operation and to flush or rod the pipe for cleaning. Manholes on subgrade pipe drains should be located at intervals of not over 1,000 ft (300 m) with one flushing riser located between manholes and at dead ends. Manholes should be provided at principal junction points of several drains.

CHAPTER 21 DESIGN OF AGGREGATE SURFACES

21-1 GENERAL.

The thickness design of aggregate surfaced roads and parking areas is similar to the design of flexible pavement as described in Chapter titled Flexible Pavement Design. This procedure involves selecting a vehicle mix or traffic, as explained in Chapter titled Vehicular Traffic, a subgrade CBR, and using unsurfaced design criteria contained within the PCASE software. The procedure determines total thickness of material to be placed above the subgrade, as well as its required strength in relation to the CBR value. A computer program is available for determining pavement thickness and compaction requirements and may be obtained as described in paragraph titled Pavement-Transportation Computer Assisted Structural Engineering.

21-2 ENTRANCES, EXITS, AND SEGMENTS.

Special consideration should be given to the design of approach roads, exit roads, and other heavily trafficked areas. Early failure or poor performance may be expected in these areas due to the channelized traffic. Since these areas will almost certainly be subjected to more frequent and heavier loads than the road, the design should be based on vehicular loads and passes usually used for primary road designs. In the case of large hardstands having multiple use and multiple entrances and exits, consideration should be given to partitioning and using different design sections. The immediate benefits that would accrue include economy through elimination of overdesign in some areas and better organization of vehicles and equipment.

21-3 THICKNESS CRITERIA (NON-FROST AREAS).

Refer to UFC 3-201-01 for minimum thickness requirements. Thickness requirements for aggregate surfaced roads and parking areas are determined using the PCASE software for a given soil strength and design vehicles and pass levels. Since roads and parking areas are usually designed for equivalent 18-kip (8,200-kg) axles, the design chart in Figure 21-1 is provided for convenience. The computed design thickness may be constructed of compacted granular fill for the total depth over the natural subgrade or in a layered system of granular fill (including subbases) and compacted subgrade for the same total depth. The layered section should be checked to ensure that an adequate thickness of material is used to protect the underlying layer and if it also meets the minimum surface CBR required. The granular fill may consist of base and subbase material provided the top 6 in (150 mm) meet the gradation requirements in Table 21-1.

21-4 FROST AREA CONSIDERATIONS.

In areas where frost effects have an impact on the design of pavements, additional considerations concerning thicknesses and required layers in the pavement structure must be addressed. The specific areas where frost has an impact on the design are discussed in the following paragraphs; however, a more detailed discussion of frost effects is presented in Chapter titled Seasonal Frost Conditions. For frost design purposes, soils have been divided into groups as shown in Table 19-2. Only the NFS group is suitable for base course. NFS, S1, or S2 soils may be used for subbase course and any of the eight groups may be encountered as subgrade soils. Soils are listed in approximate order of decreasing bearing capability during periods of thaw.

Figure 21-1 Aggregate Surfaced Design Chart; 18-kip Axle (8,200-kg)

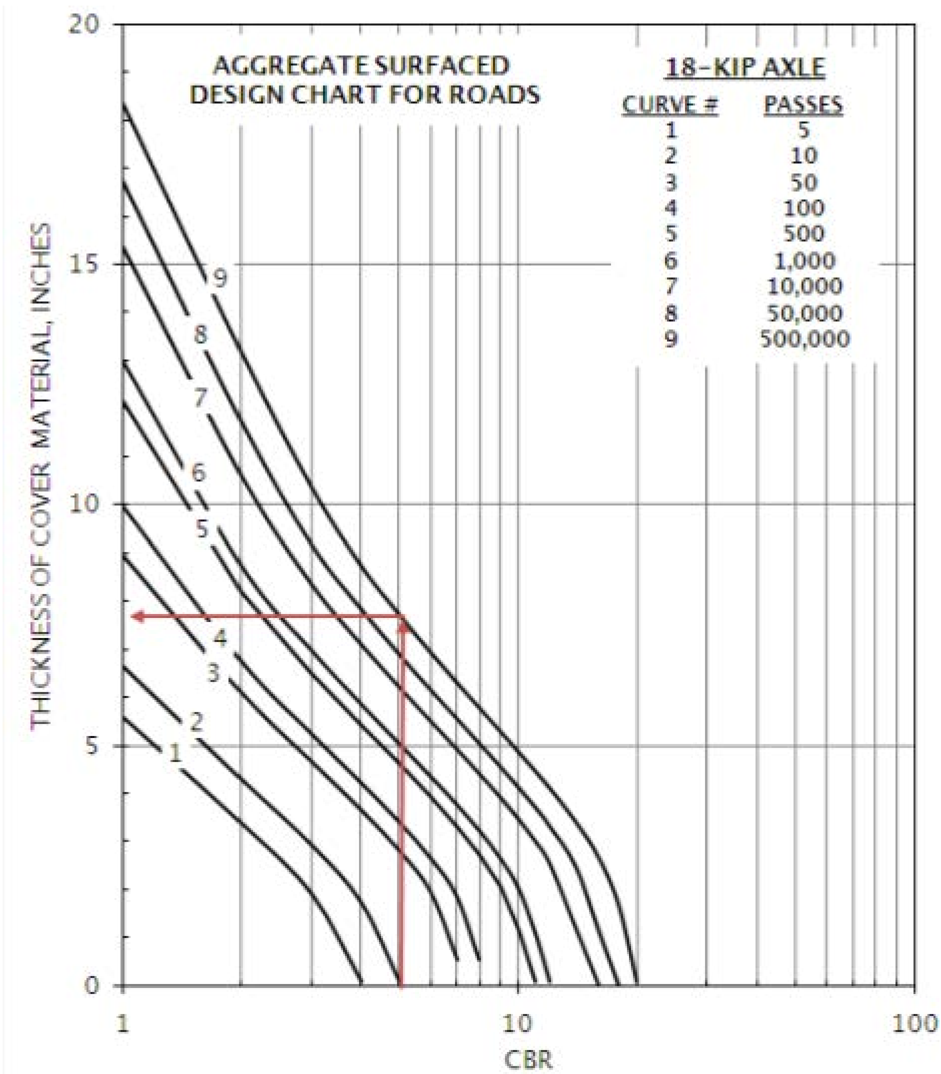


Table 21 1 Gradation for Aggregate Surface Courses

Sieve Designation	No. 1	No. 2	No. 3	No. 4
1 in (25 mm)	100	100	100	100
3/8 in (10 mm)	5-85	60-100	---	---
No. 4 (5 mm)	35-65	50-85	55-100	70-100
No. 10 (2 mm)	25-50	40-70	40-100	55-100
No. 40 (0.4 mm)	15-30	24-45	20-50	30-70
No. 200 (0.08 mm)	8-15	8-15	8-15	8-15
Note: The percent by weight finer than 0.02 mm must not exceed 3 percent.				

21-4.1 Required Thickness.

Where frost susceptible subgrades are encountered, determine the section thickness required according to the reduced subgrade strength method. The reduced subgrade strength method requires the use of frost area soil support indexes listed in Table 19-3. Frost-area soil support indexes are used as if they were CBR values; the term CBR is not applied to them, however, because, being weighted average values for an annual cycle, their values cannot be determined by CBR tests.

21-4.2 Required Layers in Pavement Section.

When frost is a consideration, it is recommended that the pavement section consist of a series of layers that will ensure the stability of the system, particularly during thaw periods. The layered system in the aggregate fill may consist of a wearing surface of fine crushed stone, a coarse-graded base course, a well-graded subbase of sand or gravelly sand. To ensure the stability of the wearing surface, the width of the base course and subbase should exceed the final desired surface width by a minimum of 12 in (300 mm) on each side.

21-4.3 Wearing Surface.

The wearing surface contains fines to provide stability in the aggregate surface. The presence of fines helps the layer's compaction characteristics and helps to provide a relatively smooth riding surface.

21-4.4 Base Course.

The coarse-graded base course is important in providing drainage of the granular fill. It is also important that this material be NFS so that it retains its strength during spring thaw periods.

21-4.5 Subbase.

The well-graded sand subbase is used for additional bearing capacity over the frost susceptible subgrade and as a filter layer between the coarse-graded base course and the subgrade to prevent the migration of the subgrade into the voids in the coarser material during periods of reduced subgrade strength. The material must therefore meet standard filter criteria. The sand subbase must be either NFS or of low frost susceptibility (S1 or S2). The filter layer may or may not be necessary depending upon the type of subgrade material. If the subgrade consists principally of gravel or sand, the filter layer may not be necessary and may be replaced by additional base course if the gradation of the base course is such that it meets filter criteria. However, for finer grained soils, the filter layer will be necessary. If a geotextile is used, the sand subbase or filter layer may be omitted as the fabric will be placed directly on the subgrade and will act as a filter.

21-4.6 Compaction.

Compact the subgrade to provide uniformity of conditions and a firm working platform for placement and compaction of subbase. Compaction of subgrade does not change its frost-area soil support index because frost action causes the subgrade to revert to a weaker state. Hence, in frost areas, the compacted subgrade is not considered part of the layered system of the road which is comprised of only the wearing, base, and subbase courses.

21-4.7 Thickness of Base Course and Filter Layer.

Relative thicknesses of the base course and filter layer are variable and should be based on the required cover and economic conditions.

21-4.8 Alternate Design.

The reduced subgrade strength design procedure provides the thickness of soil required above a frost-susceptible subgrade to minimize frost heave. To provide a more economical design, a frost susceptible select material or subbase may be used as a part of the total thickness above the frost susceptible subgrade. However, the thickness above the select material or subbase must be determined by using the Frost Area Soil Support Index (FASSI) of the select or subbase material. Where frost-susceptible soils are used as select materials or subbases, they must meet the requirements of current specifications except that the restriction on the allowable percent finer than 0.02 mm is waived.

21-5 SURFACE COURSE REQUIREMENTS.

The requirements for the various materials to be used in the construction of aggregate surfaced roads and parking areas are dependent upon whether or not frost is a consideration in the design.

21-5.1 Non-Frost Areas.

The material used for gravel surfaced roads and parking areas should be sufficiently cohesive to resist abrasive action. It should have a liquid limit no greater than 35 and a plasticity index between 4 and 9. It should also be graded for maximum density and minimum volume of voids to enhance optimum moisture retention while resisting excessive water intrusion. The gradation, therefore, should consist of the optimum combination of coarse and fine aggregates that will ensure minimum void ratios and maximum density. Such a material will then exhibit cohesive strength as well as inter-granular shear strength. Recommended gradations are as shown in Table 21-1. If the fine fraction of the material does not meet plasticity characteristics, modification by addition of chemicals might be required. Chloride products can, in some cases, enhance moisture retention, and lime can be used to reduce excessive plasticity.

21-5.2 Frost Areas.

As previously stated, where frost is a consideration in the design of roads and parking areas, a layered system should be used. The percentage of fines should be restricted in all the layers to facilitate drainage and reduce the loss of stability and strength during thaw periods. Gradation numbers 3 and 4 shown in Table 21-1 should be used with caution since they may be unstable in a freeze-thaw environment.

21-6 COMPACTION REQUIREMENTS.

Compaction requirements for the subgrade and granular layers are expressed as a percent of maximum density as determined by ASTM D1557. For the granular layers, the material must be compacted to 100 percent of the maximum ASTM D698 density. Select materials and subgrades in fills must have densities equal to or greater than the values shown in Table 21-2, except that fills will be placed at no less than 95 percent compaction for cohesionless soils (PI < 5; LL < 25) or 90 percent compaction for cohesive soils (PI > 5; LL > 25). Subgrades in cuts must have densities equal to or greater than the values shown in Table 21-2. Subgrades occurring in cut sections must be either compacted from the surface to meet the densities shown in Table 21-2, removed and replaced before applying the requirements for fills, or covered with sufficient material so that the un-compacted subgrade is at a depth where the in-place densities are satisfactory. The depths shown in Table 21-2 are measured from the surface of the aggregate road and not the surface of the subgrade.

Table 21-2 Compaction Depth Requirements for Aggregate Surfaces

Equivalent Passes of an 18,000-lb (8,200-kg) ESAL	Depth of Compaction or Percent Compaction Shown, in								
	Cohesive Soils PI > 5, LL > 25					Cohesionless Soils PI ≤ 5, LL ≤ 25

21-7 DRAINAGE REQUIREMENTS.

Adequate surface drainage should be provided to minimize moisture damage. Expeditious removal of surface water reduces the potential for absorption and ensures more consistent strength and reduced maintenance. Drainage, however, must be provided in a way to preclude damage to the aggregate surfaced road through erosion of fines or erosion of the entire surface layer. Also, care must be taken to ensure that the change in the overall drainage regime as a result of construction can be accommodated by the surrounding topography without damage to the environment or to the newly constructed road or airfield.

The surface geometry of a road should be designed so that drainage is provided at all points. Depending upon the surrounding terrain, surface drainage of the roadway can be achieved by a continual cross slope or by a series of two or more interconnecting cross slopes. The entire area should consist of one or more cross slopes having a gradient that meet the requirements of UFC 3-201-01. Judgment is required to arrange the cross slopes to remove water from the road at the nearest possible points while taking advantage of the natural surface geometry to the greatest extent possible.

Adequate drainage must be provided outside the road or airfield area to accommodate maximum possible drainage flow from the road. Ditches and culverts must be provided for this purpose. Culverts should be used sparingly and only in areas where adequate cover of granular fill is provided over the culvert. Additionally, adjacent areas and their drainage provisions should be evaluated to determine if rerouting is needed to prevent water from other areas flowing across the road or airfield.

Drainage is a critical factor in aggregate surface roads and parking area construction, and maintenance. Therefore, drainage should be considered before construction, and when necessary, serve as a basis for site selection.

21-7.1 Materials.

A wide selection of materials for dust control is available to the engineer. No one choice, however, can be singled out as being the most universally acceptable for all problem situations that may be encountered. However, several materials have been recommended for use and are discussed in UFC 3-260-17.

21-8 DESIGN EXAMPLES.

Appendix G contains two design examples of unsurfaced aggregate roads.

APPENDIX B BEST PRACTICES

B-1 CONSTRUCTION OF THE DRAINAGE LAYER.

B-1.1 Experience.

Construction of drainage layers can present problems in handling, placement, and compaction. If the drainage material does not have adequate stability, major problems can develop in the placement of the surface layer above the drainage layer. Experience with highly permeable bases (drainage layers) both by the Corps of Engineers and various State Departments of Transportation indicates that pavements containing such layers can be constructed without undue difficulties provided due precautions are taken. The real key to successful construction of the drainage layers is the training and experience of the construction personnel. Before start of construction, instruct the construction personnel in the handling and placing of the drainage material. The placement of test strips is recommended for training of the construction personnel.

B-1.2 Placement of Drainage Layer.

Place the material for the drainage layer in a manner to prevent segregation and to obtain a layer of uniform thickness. The materials for the drainage layer require extra care in stockpiling and handling. Placement of the RDM and OGM is best accomplished using an asphalt concrete paver. To ensure good compaction, the maximum lift thickness should be no greater than 6 in (150 mm). If choke stone is used to stabilize the surface of OGM, place the choke stone after compaction of the final lift of OGM. Spread the choke stone in a thin layer no thicker than 1/2 in (10 mm) using a spreader box or asphalt paver. Work the choke stone into the surface of the OGM by the use of a vibratory roller and by wetting. The choke stone remaining on the surface should not migrate into the OGM by the action of water or traffic.

B-1.3 Compaction.

Compaction is a key element in the successful construction of the drainage layer. Compaction control normally used in pavement construction is not appropriate for materials such as the RDM and OGM. It is therefore, necessary to specify compaction techniques and level of effort instead of the properties of the end product. It is important to place the drainage material in relatively thin lifts of 6 in (150 mm) or less and to have a good firm foundation beneath the drainage material. The recommended method of determining the required compaction effort is to construct a test section and closely monitor the aggregate during compaction to determine when crushing of the aggregate appears excessive. Experience indicates that sufficient compaction can be obtained by six passes or less of a vibratory roller loaded at about 10 short tons (9 metric tons). Material not being stabilized with asphalt or cement should be kept moist during compaction. Asphalt stabilized material for drainage layers must be compacted at a somewhat lower temperature than a dense-graded asphalt material. In most cases, it will be necessary to allow an asphalt stabilized material to cool to less than 200 degrees F (93 degrees C) before beginning compaction.

B-1.4 Protection after Compaction.

After compaction, protect the drainage layer from contamination by fines from construction traffic and from flow of surface water. It is recommended to place the surface layer as soon as possible after placement of the drainage layer. Take precautions to protect the drainage layer from disturbance by construction equipment. Only tracked asphalt pavers should be allowed for paving over any RDM or OGM that has not been stabilized. Drivers should avoid rapid acceleration, hard braking, or sharp turning on the finished drainage layer. Although curing of cement stabilized drainage layers is not critical, efforts should be made to protect cement stabilized drainage layers at curing until the surface layer is placed.

B-1.5 Proof Rolling.

Proof rolling is not normally required, but for roads and parking areas that are to be subjected to traffic of heavy vehicles, it is good practice to require proof rolling. In particular, proof rolling the separation layer before placement of a drainage layer is recommended. For flexible pavements constructed for heavy material handling equipment, it is recommended that the proof rolling be accomplished using a rubber-tired roller load to provide a minimum tire force of 20,000 lb (90 kN) and inflated to at least 90 psi (620 kPa). A minimum of six coverages should be applied, where a coverage is the application of one tire print over each point in the surface of the designated area. For rigid pavements and other flexible pavements, proof rolling of the separation layer may be accomplished using the rubber-tired roller described above or by using a truck having tandem axles with either dual tires or super single tires. The truck should be loaded to provide 20,000 lb per axle. During proof rolling, action of the separation layer must be monitored for any sign of excessive movement or pumping that would indicate soft spots in the separation layer or the subgrade. Since the successful placement of the drainage layer depends on the stability of the separation layer, all weak spots must be removed and replaced with stable material. All replaced material must be proof rolled as specified above.

B-2 CONSTRUCTION: SEASONAL FROST CONDITIONS

B-2.1 CONTROL OF SUBGRADE AND BASE COURSE CONSTRUCTION.

Personnel responsible for field control of pavement construction in areas of seasonal freezing should give specific consideration to conditions and materials that could result in detrimental frost action. In frost areas, the contract plans and specifications should require the subgrade preparation work as indicated in paragraph titled Subgrade Requirements. They also should provide for special treatments such as removal of unsuitable materials encountered with sufficient information included to identify those materials and specify necessary corrective measures. However, construction operations quite often expose frost-susceptible conditions at isolated locations of a degree and character not revealed by even the most thorough subsurface exploration program. It is essential, therefore, that personnel assigned to field construction control be alert to recognize situations that require special treatment, whether or not anticipated by the designing agency. They must also be aware of their responsibility for such recognition.

B-2.2 BASE COURSE CONSTRUCTION.

Where the available base course materials are well within the limiting percentages of fine material set forth above, the base course construction control should be in accordance with normal practice. In instances where the material selected for use in the top 50 percent of the total thickness of granular unbound base is borderline with respect to percentage of fine material passing the No. 200 sieve, or is of borderline frost susceptibility (usually materials having 1.5 to 3 percent of grains finer than 0.02 mm by weight), frequent gradation checks should be made to ensure that the materials meet the design criteria. If it is necessary for the contractor to be selective in the pit to obtain suitable materials, his operations should be inspected at the pit. It is more possible to reject unsuitable materials at the source when large volumes of base course are being placed. It may be desirable to stipulate thorough mixing at the pit and, if necessary, stockpiling, mixing in windrows, and spreading the material in compacted thin lifts to ensure uniformity. Finish surface stripping of pits should be enforced to prevent mixing of detrimental fine soil particles or lumps in the base material.

B-2.3 Gradation of Base Course Materials.

The gradation of base course materials after compaction should be determined often, particularly at the start of the job, to learn whether or not fines are being manufactured in the base under the passage of the compaction equipment. For base course materials exhibiting serious degradation characteristics, a test embankment may be needed to study the formation of fines by the proposed compaction process. Mixing of base course materials with frost susceptible subgrade soils should be avoided by making certain that the subgrade is properly graded and compacted before placement of base course, by ensuring that the first layer of base course filters out subgrade fines under traffic, and by eliminating the kneading caused by over compaction or insufficient thickness of the first layer of base course. Excessive rutting tends to cause mixing of subgrade and base materials. This can be greatly minimized by frequent rerouting of material-hauling equipment.

B-2.4 Visual Inspection.

After completion of each layer of base course, a careful visual inspection should be made before permitting additional material placement to ensure that areas with high percentages of fines are not present. In many instances these areas may be recognized both by examination of the materials and by observation of their action under compaction equipment, particularly when the materials are wet. The materials in any areas that do not meet the requirements of the specifications, which will reflect the requirements of this UFC, should be removed and replaced with suitable material. Do not use a leveling course of fine-grained material as a construction expedient to choke open-graded base courses, to establish fine grade, or to prevent overrun of concrete. Since the base course receives high stresses from traffic, this prohibition is essential to minimize weakening during the frost-melting period. Action should be taken to vary the base course thickness so as to provide transition, when this is necessary, to avoid abrupt changes in pavement supporting conditions.

B-3 MAINTENANCE OF SUBSURFACE DRAINAGE SYSTEMS.

B-3.1 Monitoring Program.

Commitment to maintenance is as important as providing subsurface drainage systems. In fact, an improperly maintained drainage system can cause more damage to the pavement structure than if no drainage were provided at all. Poor maintenance leads to clogged or silted outlets and edge-drain pipes, missing rodent screens, excessive growth of vegetation blocking outlet pipes and openings on day-lighted bases, and growth of vegetation in side ditches. These problems can potentially cause backing up of water within the pavement system, thereby defeating the purpose of providing the drainage system. Therefore, inspections and maintenance of subsurface drainage systems should be made an integral part of the policy of any agency installing these systems. The inspection process comprises of two parts: (a) visual inspection and (b) video inspection.

B-3.1.1 Visual Inspection.

The visual inspection process includes the following items:

(i) Evaluation of external drainage-related features, including measurement of ditch depths and checking for crushed outlets, excessive vegetative growth, clogged and debris-filled day-lighted openings, condition of headwalls, presence of erosion, and missing rodent screens. This operation should be performed at least once a year.

(ii) Pavement condition evaluation to check for moisture-related pavement distresses such as pumping, faulting, and D-cracking in PCC pavements and fatigue cracking and AC stripping in AC pavements. This operation could be either a full-scale Pavement Condition Index (PCI) survey or a brief overview survey, depending on agency needs. The recommended frequency for this activity is once every 2 years.

B-3.1.2 Video Inspection.

Video inspections play a vital role in monitoring in-service drainage systems. The video inspection process can be used to check for clogged drains due to silting and intrusion of surrounding soil, as well as any problems with the drainage system, such as ruptured pipes and broken connections. Video inspections should be carried out on an as-needed basis whenever there is evidence of drainage-related problems. A video inspection system typically consists of a camera head, long flexible probe mounted on a frame for inserting the camera head into the pipe, and a data acquisition unit fitted with a video screen and a video recorder. This system can be used to detect and correct any construction problems before a project is accepted. The construction-related problems that are easily detected using the video equipment include crushed or ruptured drainage pipes and improper connections between drainage pipes, as well as the connection between the outlet pipe and headwall.

B-3.2 Maintenance Guidelines.

B-3.2.1 Collector Drains and Outlets.

Flush the collector drains and outlets periodically with high-pressure water jets to loosen and remove any sediment that has built up within the system. The key to this operation is having the appropriate outlet details that facilitate the process, such as the dual headwall system shown in Figure C20-11 (Appendix C). Keep the area around the outlet pipes should be kept mowed to prevent any buildup of water. Repair or replace missing rodent screens and outlet markers, damaged pipes and headwalls need to be either repaired or replaced.

B-3.2.2 Day-lighted Systems.

Routine removal of roadside debris and vegetation clogging the day-lighted openings of a permeable or dense-graded base is very important for maintaining the functionality of these systems.

B-3.2.3 Drainage Ditches.

Mow the drainage ditches should be kept mowed to prevent excessive vegetative growth. Clean the bottom of the ditch of debris and silt deposited at the bottom of the ditch should be cleaned periodically to maintain the ditch line and to prevent water from backing up into the pavement system.

B-4 AGGREGATE ROADS

B-4.1 MAINTENANCE REQUIREMENTS.

The two primary causes of deterioration of aggregate surfaced roads and parking areas requiring frequent maintenance are environmental conditions and traffic. Rain or water flow wash fines from the aggregate surface and reduce cohesion, while traffic action causes displacement of surface materials. Maintenance should be performed at least every 6 months and more often if required. The frequency of maintenance will be high for the first few years of use but will decrease over time to a constant value. The majority of the maintenance will consist of periodic grading to remove the ruts and potholes that will inevitably be created by the environment and traffic and to replace fines. Occasionally during the lifetime of the road, the surface layer may have to be scarified, additional aggregate added to increase the thickness back to that originally required, and the wearing surface re-compacted to the specified density.

B-4.2 DUST CONTROL.

The primary objective of a dust palliative is to prevent soil particles from becoming airborne as a result of wind or traffic. Where dust palliatives are considered for traffic areas, they must withstand the abrasion of the wheels or tracks. An important factor limiting the applicability of the dust palliative in traffic areas is the extent of surface rutting or abrasion that will occur under traffic. Some palliatives will tolerate deformations better than others, but normally ruts in excess of 1/2 in (13 mm) will result in the virtual destruction of any thin layer or shallow-depth penetration dust palliative treatment. The abrasive action of tank tracks may be too severe for use of some dust palliatives in a traffic area.

C-2 DEFINITION OF TERMS

Apparent Opening Size (AOS): A measure of the opening size of a geotextile. AOS is the sieve number corresponding to the sieve size at which 95 percent of the single-size glass beads pass the geotextile (O95) when tested in accordance with ASTM D4751.

Average Daily Temperature: The average of the maximum and minimum temperatures for a day, or the average of several temperature readings taken at equal time intervals, generally hourly, during a day.

Base Course: Course containing all granular unbound, chemical- or bituminous-stabilized material between the pavement surfacing layer and the un-treated, chemical or bituminous stabilized subgrade.

Bound Base: Chemical-stabilized or bituminous-stabilized soil used in the base and subbase course, consisting of a mixture of mineral aggregates and soil with one or more commercial stabilizing additives. Bound base is characterized by a significant increase in compressive strength of the stabilized soil compared with the untreated soil. In frost areas bound base usually is placed directly beneath the pavement surfacing layer where its high strength and low deformability make possible a reduction in the required thickness of the pavement surfacing layer or the total thickness of pavement and base, or both. If the stabilizing additive is Portland cement, lime, or lime-cement-fly ash (LCF), the term bound base is applicable only if the mixture meets the requirements for cement-stabilized, lime-stabilized, or LCF-stabilized soil set forth within this UFC and in UFC 3-250-11.

Boulder Heave: The progressive upward migration of a large stone present within the frost zone in a frost-susceptible subgrade or base course. This is caused by adhesion of the stone to the frozen soil surrounding it while the frozen soil is undergoing frost heave. The stone will be kept from an equal, subsequent subsidence by soil that will have tumbled into the cavity formed beneath the stone. Boulders heaved toward the surface cause extreme pavement roughness and may eventually break through the surface, necessitating repair or reconstruction.

Coefficient of Permeability: A measure of the rate at which water passes through a unit area of material in a given amount of time under a unit hydraulic gradient.

Choke Stone: A small size stone used to stabilize the surface of an OGM. For a choke stone to be effective, the ratio of d15 of the coarse aggregate to the d15 of the choke stone must be less than 5, and the ratio of the d50 of the coarse aggregate to d50 of the choke stone must be greater than 2.

Composite Pavement: Existing pavement to be overlaid with rigid pavement is composed of an all-bituminous or flexible overlay on a rigid base pavement.

Cumulative Damage: The process by which each application of traffic load or each cycle of climatic change produces a certain irreversible damage to the pavement. The pavement deteriorates continuously under successive load applications or climatic cycles.

Degree-Days: The Fahrenheit degree-days for any given day equal to the difference between the average daily air temperature and 32 degrees Fahrenheit. The degree-days are minus when the average daily temperature is below 32 degrees Fahrenheit (freezing degree-days) and plus when above (thawing degree-days). Figure 19-1 shows sample curves obtained by plotting cumulative degree-days against time.

Design Freezing Index: The average air freezing index of the three coldest winters in the latest 30 year of record. If 30 years of record are not available, the air freezing index for the coldest winter in the latest 10 year period may be used. To avoid the necessity of adopting a new and only slightly different freezing index each year, the design freezing index at a site with continuing construction need not be changed more than once in 5 year unless the more recent temperature records indicate a significant change in thickness design requirements for frost. The design freezing index is illustrated in Figure 19-1.

Drainage Layer: A layer in the pavement structure that is specifically designed to allow rapid horizontal drainage of water from the pavement structure. The layer is also considered to be a structural component of the pavement and may serve as part of the base or subbase.

Effective Porosity: The effective porosity is defined as the ratio of the volume of voids that will drain under the influence of gravity to the total volume of a unit of aggregate. The difference between the porosity and the effective porosity is the amount of water that will be held by the aggregate. For materials such as the RDM and OGM, the water held by the aggregate will be small; thus, the difference between the porosity and effective porosity will be small (less than 10 percent). The effective porosity may be estimated by computing the porosity from the unit dry weight of the aggregate and the specific gravity of the solids which then should be reduced by 5 percent to allow for water retention on the aggregate.

Flexible Base Pavement: Existing pavement to be overlaid is composed of bituminous concrete, base, and subbase courses.

Flexible Overlay: A flexible pavement (either all-bituminous or bituminous with base course) used to strengthen an existing rigid or flexible pavement.

Freezing Index: The number of degree-days between the highest and lowest points on a curve of cumulative degree-days versus time for one freezing season. It is used as a measure of the combined duration and magnitude of below-freezing temperatures occurring during any given freezing season. The index determined for air temperature about 4.5 ft (1.4 m) above the ground is commonly designated as the air freezing index, while that determined for temperatures immediately below a surface is known as the surface freezing index.

Frost Action: The general term for freezing and thawing of moisture in materials and the resultant effects on these materials and on structures of which they are a part, or with which they are in contact.

Frost Boil: The breaking of a small section of a highway or airfield pavement under traffic with ejection of soft, semi-liquid subgrade soil. This is caused by the melting of the segregated ice formed by the frost action. This type of failure is limited to pavements with extreme deficiencies of total thickness of pavement and base over frost-susceptible subgrades, or pavements having a highly frost-susceptible base course.

Frost Heave: is the raising of a surface due to ice formation in the underlying soil.

Frost Melting Period: The interval of the year when the ice in the base, subbase, or subgrade materials is returning to a liquid state. It ends when all the ice in the ground has melted or when freezing is resumed. In some cases there may be only one frost-melting period, beginning during the general rise of air temperatures in the spring. However, one or more significant frost-melting intervals may occur during a winter season.

Frost Susceptible Soil: Soil in which significant detrimental ice segregation will occur when the requisite moisture and freezing conditions are present.

Geocomposite Edge Drain: A manufactured product using geotextiles, geogrids, geonets, or geomembranes in laminated or composite form, which can be used as an edge drain in place of trench-pipe construction.

Geotextile: A permeable textile used in geotechnical projects. For this UFC geotextile will refer to a nonwoven needle punch fabric that meets the requirements of the apparent opening size (AOS), grab strength and puncture strength specified for the particular application.

Granular Unbound Base Course: A base course containing no agents that impart higher cohesion by cementing action. Mixtures of granular soil with Portland cement, lime, or fly ash, in which the chemical agents have merely altered certain properties of the soil such as plasticity and gradation without imparting significant strength increase, also are classified as granular unbound base.

Ice Segmentation: The growth of ice as distinct lenses, layers, veins and masses in soils, commonly but not always oriented normal to the direction of heat loss.

Hardstand: An area for parking heavy vehicles, both wheeled and tracked, for significant periods of time. Hardstands are usually constructed of rigid concrete but may be constructed of compacted stone or compacted earth for short periods of time.

Hazen's Effective Particle Diameter: The Hazen's effective particle diameter is the particle size, in millimeters, which corresponds to 10 passing on the grain-size distribution curve. This parameter is one of the major parameters in determining the permeability of a soil.

Mean Daily Temperature: The mean of the average daily temperatures for a given day in each of several years.

Mean Freezing Index: The freezing index determined on the basis of mean temperatures. The period of record over which temperatures are averaged is usually a minimum of 10 year, preferably 30, and should be the latest available. The mean freezing index is illustrated in Figure 19-1.

Non-Frost Susceptible Materials: Cohesionless materials such as crushed rock, gravel, sand, slag, and cinders that do not experience significant detrimental ice segregation under normal freezing conditions. Non-Frost-susceptible materials also include cemented or otherwise stabilized materials that do not evidence detrimental ice segregation, loss of strength upon thawing, or freeze-thaw degradation.

Open Graded Material (OGM): A granular material having a very high permeability (greater than 5,000 ft/day (1,500 m/day)) which may be used for a drainage layer. Such a material will normally require stabilization for construction stability or for structural strength to serve as a base in a flexible pavement.

Open Storage Areas: Permanent exterior storage areas used by any type of wheeled vehicular traffic or having non-pneumatic loadings in excess of 200 psi (1.38 MPa), covered or uncovered, that are separate from the interior area of a building.

Overlay Pavement: A pavement constructed on an existing base pavement to increase load-carrying capacity or correct a surface defect.

Pavement Pumping: The ejection of water and soil through joints, cracks, and along edges of pavements caused by downward movements of sections of the pavement. This is actuated by the passage of heavy axle loads over the pavement after free water has accumulated beneath it.

Pavement Structure: Pavement structure is the combination of subbase, base, and surface layers constructed on a subgrade.

Period of Weakening: The interval of the year that starts at the beginning of a frost-melting period and ends when the subgrade strength has returned to normal summer values, or when the subgrade has again become frozen.

Permeable Base: An open-graded granular material with most of the fines removed (e.g., less than 10 percent passing the No. 16 sieve) to provide high permeability (1,000 ft/day or more) for use in a drainage layer.

Porosity: The amount of voids in a material, expressed as the ratio of the volume of voids to the total volume.

Rapid Draining Material (RDM): A granular material having a sufficiently high permeability 1,000 to 5,000 ft/day (300 to 1,500 m/day) to serve as a drainage layer and also having the stability to support construction equipment and the structural strength to serve as a base or a subbase.

Rigid Base Pavement: An existing rigid pavement is one on which an overlay is to be placed.

Rigid Overlay: A rigid pavement used to strengthen an existing flexible or rigid pavement.

Separation Layer: A layer provided directly beneath the drainage layer to prevent fines from infiltration or pumping into the drainage layer and to provide a working platform for construction and compaction of the drainage layer.

Stabilization: Stabilization refers to either mechanically or chemically stabilizing the drainage layer to increase the stability and strength to withstand construction traffic and design traffic. Mechanical stabilization is accomplished by the use of a choke stone and compaction. Chemical stabilization is accomplished by the use of either Portland cement or asphalt.

Subbase Course: The layer of supporting material between the base course and the subgrade.

Subsurface Drainage: The process of collecting and removing water from the pavement structure. Subsurface drainage systems are categorized into two functional categories: one for draining surface infiltration water, and the other for controlling groundwater.

C-3 TRI-SERVICE PAVEMENT DETAILS

The Pavements and Airfields Tri-Service Working Group has developed typical details for use during design. These details can be download at http://www.wbdg.org/ccb/browse_cat.php?o=29&c=248. Some of these details contain information that was provided in earlier versions of the superseded criteria documents.

When these details are changed, an updated version will be posted to the Whole Building Design Guide webpage. Updated details will be included in the document during the next change or revision. Refer to http://www.wbdg.org/ccb/browse_cat.php?o=29&c=248 for the most recent version.

APPENDIX D USE OF INSULATION MATERIALS IN PAVEMENTS

D-1 INSULATING MATERIALS AND INSULATED PAVEMENT SYSTEMS.

The only acceptable insulating material for use in roads is extruded polystyrene board stock. Results from laboratory and field tests have shown that extruded polystyrene does not absorb a significant volume of moisture and that it retains its thermal and mechanical properties for several years. The material is manufactured in board stock ranging from 1 in (25 mm) to 4 in (100 mm) thick. Approval from the Government Civil Engineer is required for use of insulating materials other than extruded polystyrene.

D-1.1 Synthetic Insulating Material.

The use of a synthetic insulating material within a pavement cross section is permissible with the written approval of the Government Civil Engineer. Experience has shown that surface icing may occur on insulated pavements at times when uninsulated pavements nearby are ice-free and vice versa. Surface icing creates possible hazards to fast-moving motor vehicles. Accordingly, in evaluating alternative pavement sections, the designer should select an insulated pavement only in special cases not sensitive to differential surface icing. Special attention should be given to the need for adequate transitions to pavements having greater or lesser protection against sub grade freezing.

D-1.2 Insulated Pavement System.

An insulated pavement system comprises conventional surfacing and base above an insulating material of suitable thickness to restrict or prevent the advance of subfreezing temperatures into a frost-susceptible subgrade. Unless the thickness of insulation and overlying layers is sufficient to stop subgrade freezing, additional layers of granular materials are placed between the insulation and the subgrade to contain a portion of the frost zone that extends below the insulation. In consideration of only the thermal efficiency of the insulated pavement system, 1 in (25 mm) of granular material placed below the insulating layer is much more effective than 1 in (25 mm) of the same material placed above the insulation. Hence, under the design procedure outlined below, the thickness of the pavement and base above the insulation is determined as the minimum that will meet structural requirements for adequate cover over the relatively weak insulating material. The determination of the thickness of insulation and of additional granular material is predicated on the placement of the latter beneath the insulation.

D-2 DETERMINATION OF THICKNESS OF COVER ABOVE INSULATION.

On a number of insulated pavements in the civilian sector, the thickness of material above the insulation has been established to limit the vertical stress on the insulation caused by dead loads and wheel loads to not more than one-third of the compressive strength of the insulating material. The Boussinesq equation should be used for this determination. If a major project incorporating insulation is planned, advice and assistance in regard to the structural analysis should be sought from the Government Civil Engineer.

D-3 DESIGN OF INSULATED PAVEMENT TO PREVENT SUBGRADE FREEZING.

Once the thickness of pavement and base above the insulation has been determined, it should be ascertained whether a reasonable thickness of insulation will keep subfreezing temperatures from penetrating through the insulation. Calculations for this purpose make use of the design air and surface freezing indexes and the mean annual soil temperature at the site. If the latter is unknown, it may be approximated by adding 7 degrees Fahrenheit to the mean annual air temperature. For paved surfaces kept free from snow and ice, an n-factor of 0.75 should be used. For calculating the required thickness of insulation, the design surface freezing index and the mean annual soil temperature are used with Figure D-1 to determine the surface temperature amplitude A. The initial temperature differential V_o is obtained by subtracting 32 degrees Fahrenheit from the mean annual soil temperature, or it also may be read directly from Figure D-1. The ratio V_o/A is then determined. Figure D-2 is then entered with the adopted thickness of pavement and base to obtain the thickness of extruded polystyrene insulation needed to prevent subgrade freezing beneath the insulation. If the required thickness is less than about 2 (50 mm) to 3 in (75 mm), it will usually be economical to adopt for design the thickness given by Figure D-2, and to place the insulation directly on the subgrade. If more than about 2 (50 mm) to 3 in (75 mm) of insulation is required to prevent subgrade freezing, it usually will be economical to use a lesser thickness of insulation, underlain by subbase material (S1 or S2). Alternative combinations of thicknesses of extruded polystyrene insulation and granular material base and subbase to contain completely the zone of freezing can be determined from Figure D-3, which shows the total depth of frost for various freezing indexes, thicknesses of extruded polystyrene insulation, and base courses. The thickness of subbase needed to contain the zone of freezing is the total depth of frost penetration less the total thickness of pavement, base, and insulation.

D-4 DESIGN OF INSULATED PAVEMENT FOR LIMITED SUB GRADE FREEZING.

It may be economically advantageous to permit some penetration of frost into the subgrade. Accordingly, the total depth of frost penetration given by Figure D-3 may be taken as the value in Figure 19-4, and a new combined thickness **b** of base, insulation, and subbase is determined that permits limited frost penetration, into the subgrade. The thickness of subbase needed beneath the insulation is obtained by subtracting the previously established thicknesses of base, determined from structural requirements, and of insulation, determined from Figure D-3. Not less than 4 in (100 mm) of subbase material meeting the requirements of Chapter titled Seasonal Frost Conditions should be placed between the insulation and the subgrade. If less than 4 in (100 mm) of subbase material is necessary, consideration should be given to decreasing the insulation thickness and repeating the process outlined above.

D-5 CONSTRUCTION PRACTICE.

While general practice has been to place insulation in two layers with staggered joints, this practice should be avoided at locations where subsurface moisture flow or a high groundwater table may be experienced. In the latter cases it is essential to provide means for passage of water through the insulation to avoid possible excess hydrostatic pressure in the soil on which the insulating material is placed. Free drainage may be provided by leaving the joints between insulating boards slightly open, or by drilling holes in the boards, or both. The Government Civil Engineer may be contacted for more detailed construction procedures.

APPENDIX G EXAMPLES

Solutions of the problems using PCASE software differ slightly from the solutions determined through the use of the pavement design charts. The difference is due to the higher level of numerical accuracy in the PCASE software. When using the pavement design charts, round the thickness up using 0.5 in (10 mm) increments.

G-1 MIXED TRAFFIC CALCULATION.

The mixed traffic calculations described by this example apply only to flexible pavements; a similar procedure can be followed for rigid pavements. The mixed traffic includes a truck with a single axle load of 18,000 lb (8,200 kg), passenger cars, 5-axle trucks, and 3-axle trucks. A design subgrade CBR of 4 was established from field tests. A CBR of 4 corresponds to a subgrade category D, as instructed in Table 4-1. Therefore, only for the purpose of traffic calculations, the representative CBR of 3 should be used. Table G-1 gives the corresponding design vehicle weights and total number of passes for the entire life of the pavement. It is assumed that the required thicknesses of cover material above the subgrade have already been determined from the procedures described in Chapter titled Flexible Pavement Design. Once the subgrade category has been established (Category D with a representative CBR = 3), the first step is to determine the total thickness of cover over the subgrade for each vehicle. This is accomplished by going to the design curves, shown in Appendix E, corresponding to each vehicle in the mix with a CBR = 3 and the assigned number of passes and reading the required thickness in Column 4 of Table G-1. The second step involves selecting the controlling vehicle based on the largest thickness requirement. In this example, the controlling vehicle is the 18-kip axle with a thickness of 16.4 in (420 mm). The third step is to determine the number of allowable passes of the other vehicles in the mix as if they were operating on pavement with a thickness of 16.4 in. This is determined using the same design charts, but working in reverse and reading the passes with the subgrade CBR = 3 and the controlling thickness of 16.4 in (420 mm). The fourth step is to determine the ratio of design passes in terms of the controlling vehicle. This is done by dividing the allowable passes for the thickness section (of the controlling vehicle) by the allowable passes of each vehicle (shown in Column 5). The corresponding fractions shown in Column 6 are then multiplied by the design passes (Column 3) to determine the equivalent passes in terms of the controlling vehicle. From Table G-1, 1,395,400 passes of the 18-kip axle operating at 18,000 lb (8200 kg) is equivalent or will have about the same thickness requirements as the traffic mix shown on Table G-1. From Figure E-1, an 18-kip axle loaded to a gross weight 18,000 lb (8200 kg), 1,395,400 passes and a design subgrade CBR equal to 4 will require a pavement thickness of 14 in (350 mm). It is actually not necessary to select the vehicle with the larger thickness requirements to perform a mixed traffic calculation. For example, the 5-axle truck could have been used as the controlling vehicle, but all the calculations would have to be referenced to the passes of this vehicle. These calculations are shown in Table G-2. This mixed traffic procedure, using the 18,000-lb (8200 kg) equivalent vehicle is used for PCASE to establish minimum pavement thicknesses and compaction requirements.

G-2 COMPACTION REQUIREMENTS.

Two examples illustrating the application of subgrade compaction requirements are as follows:

G-2.1 Example 1: Cohesionless Subgrade.

Assume clean cohesionless sand and a design CBR of 18, with a natural in-place density of 90 percent of maximum density to beyond the depth of exploration of 6 ft (1.8 m). From Table 5-1 for less than 5.7 million equivalent 18,000 lb (8,200 kg) single axle loads, it is found that 100 percent density must extend to a depth of 12 in (300 mm) below the pavement surface. Below this depth, fill sections must be compacted to 95 percent maximum density throughout, and cut sections to 95 percent of maximum density to a depth of 22 in (560 mm) below the pavement surface. The designer must decide from previous experience or from test pavement section data whether or not these percentages of compaction in cut sections can be obtained from the top of the subgrade. If they cannot, a part of the subgrade must be removed, the underlying layer compacted, and the material replaced, or the thickness of select material or subbase must be so increased that the densities in the un-compacted subgrade will be adequate.

Table G-1 Example of Mixed Traffic Calculations for a Flexible Pavement

(1) Vehicle	(2) Gross Weight, lb (kg)	(3) Design Total Passes	(4) Required[1] Thickness in (mm)	(5) Allowable Passes	(6)=1,000,000/(5) Ratio of Passes in Terms of Controlling Vehicle	(7)=(6)*(3) Equivalent Passes of Controlling Vehicle
18,000 lb (8,200 kg) ESAL	18,000 lb (8,200 kg)	1,000,000	16.4 (420)	1,000,000	1.000	1,000,000

3-Axle Truck	35,000 (16,000)	500,000	12.8 (325)	Unlimited	0.000	0
Equivalent Passes in Terms of 5-Axle Truck =						353,000
[1] Required thickness calculations for mixed traffic are based on CBR = 3 (Subgrade Category D)						

G-2.2 Example 2: Cohesive Subgrade.

Assume a lean clay, a design CBR of 7, and a natural in-place density of 83 percent of maximum density extending below the depth of exploration of 6 ft (1.8 m). Compaction of the subgrade from the surface would be impracticable with ordinary equipment beyond the 6 (150 mm) to 8 in (200 mm) depth that could be processed; therefore, the minimum depth of cut would be limited by the in-place density. From Table 5-1 for 5.7 million equivalent 18,000 lb (8,200 kg) axle loads, it is found that the 83 percent in-place natural density would be satisfactory below depths of about 25 in (625 mm) from the pavement surface. From CBR design curves (explained subsequently), the top of the subgrade will be 14 in (370 mm) below the pavement surface; therefore, a zone 11 in (275 mm) thick below the top of the subgrade requires treatment. The bottom 7 - 8 in (180 - 200 mm) of this can be processed in place; so about 4 in (100 mm) of material must be removed and replaced. Compaction to 95 percent of maximum density is required for all cohesive material that lies within 12 in (300 mm) of the pavement surface. Since the subgrade does not fall within this zone, compaction requirements in the replaced material should be 90 percent to conform to fill requirements, and the layer processed in place should be 85 percent of maximum density to conform to fill requirements.

G-3 THICKNESS DESIGN FOR CONVENTIONAL FLEXIBLE PAVEMENTS.

This example illustrates a design by the CBR method when the subgrade, subbase, or base course materials are not affected by frost. Assume that a design is to be prepared for a road that will support 200,000 passes per year of an equivalent 18,000 lb (8,200 kg) single axle dual-tire load for a period of 25 year (Total Design Passes = 200,000 ×

25 = 5,000,000). Further, assume that compaction requirements will necessitate an increase in subgrade density to a depth of 6 in (150 mm) below the subgrade surface and that a soft layer occurs within the subgrade 24 in (600 mm) below the subgrade surface. The CBR design values of the various subgrade layers and the materials available for subbase and base course construction are as follows:

Material	Soil Classification	Design CBR
Base	GM (limerock)	80
Subbase	GP	25
Compacted subgrade	CL	10
Natural subgrade	CL	7
Weak layer in subgrade	CH	4

The total pavement thickness and thicknesses of the various subbase and base layers are determined according the following procedure.

G-3.1 Total Thickness.

The total thickness of subbase, base, and bituminous surface will be governed by the CBR of the compacted subgrade. From the flexible pavement design curves shown in Figure E-1, the required total thickness above the compacted subgrade (CBR of 10) is 7.8 in (195 mm) to protect from 5,000,000 passes of 18,000 lb (8,200 kg) equivalent single axle. A check must be made of the adequacy of the strength of the natural subgrade and of the weak layer within the subgrade. From the curves in Figure E-1, the required cover for these two layers is 9.8 in and 14.5 in (245 mm and 370 mm), respectively. If the design thickness is 7.8 in (195 mm) and the subgrade is compacted to 6 in (150 mm) below the subgrade surface, the natural subgrade will be covered by a total of 7.8 in (195 mm) + 6 in (150 mm) = 13.8 in (345 mm) of higher strength material. Similarly, the soft layer occurring 24 in (600 mm) below the subgrade surface will be protected by 7.8 in (195 mm) + 24 in (600 mm) = 31.8 in (795 mm) of total cover. Thus, the cover is adequate in both cases.

G-3.2 Minimum Base and Pavement Thicknesses.

As indicated in Table 7-2 for 5,000,000 passes of an 18,000 lb (8,200 kg) equivalent single axle, dual-tire load, the minimum base thickness is 4 in (100 mm) and the pavement thickness is 3.5 in (89 mm).

G-3.3 Thickness of Subbase and Base Courses.

The design thickness of the base and subbase will depend upon the CBR design value of each material. The total thickness of subbase, base, and pavement, as determined above, is 7.8 in (195 mm). The thickness required above the subbase (CBR = 25), as determined from Figure E-1, is 3.4 in (83 mm); therefore, the required thickness of subbase is 7.8 in (195 mm) – 3.4 in (83 mm) = 4.4 in (112 mm). The 3.4 in (83 mm) layer required above the subbase will be composed of a base course and pavement; however, adjustments must be made in the thicknesses of the base and the pavement to comply with minimum thickness requirements, which is a combined thickness of pavement and base of 7.5 in (183) = 3.5 in (83 mm) of asphalt surface and 4 in (100 mm) of base. Therefore, the final design will consist of a 4 in (100 mm) subbase course, a 4 in (100 mm) base course, and a 3.5 in (83 mm) pavement.

G-4 THICKNESS DESIGN FOR STABILIZED SOIL LAYERS.

To use the equivalency factors requires that a conventional flexible pavement be designed to support the design load conditions. If it is desired to use a stabilized base or subbase course, the thickness of conventional base or subbase is divided by the equivalency factor for the applicable stabilized soil.

G-4.1 Example 1.

Assume a conventional flexible pavement has been designed which requires a total thickness of 16 in (410 mm) above the subgrade. The minimum thickness of AC and base is 2 and 4 in (50 and 100 mm), respectively, and the thickness of subbase is 10 in (250 mm). It is desired to replace the base and subbase with a cement-stabilized gravelly soil (GP) having an unconfined compressive strength of 890 psi (6.1 MPa). The material qualifies for application as base course since its strength is greater than 750 psi (5.2 MPa), as required by the UFC 3-250-11. From Table 9-1 the equivalency factor for a base is 1.15. Therefore, 4 in ÷ 1.15 = 3.5 in (100 mm ÷ 1.15 = 87 mm) of stabilized base course. Since the minimum required thickness is 4 in (100 mm), the excess of stabilized base course of 4 in – 3.5 in = 0.5 in (100 mm – 87 mm = 13 mm) is computed as equivalent thickness of non-stabilized subbase material, which is equal to 0.5 in. * 2.3 = 1.1 in (13 mm * 2.3 = 30 mm). This equivalent subbase thickness is accounted in the stabilized base; therefore the needed non-stabilized subbase is thinner than 10 in (250 mm) and equal to 10 in – 1.1 in = 8.9 in (250 mm - 30 mm = 220 mm). The next step includes the calculation of the equivalent thickness of subbase stabilized material, as 8.9 in ÷ 2.3 = 3.86 in (220 mm ÷ 2.3 = 96 mm). The required minimum thickness for stabilize subbase is 4 in (100 mm). Therefore, the total thickness of the cement-stabilized pavement is 2 in (50 mm) of AC, 4 (100 mm) in of cement-stabilized gravelly soil base, and 4 in (100 mm) of cement-stabilized gravelly soil subbase.

G-4.2 Example 2.

Assume a conventional flexible pavement has been designed which requires 3.5 in (89 mm) of AC surface, 4 in (100 mm) of crushed stone base, and 18 in (460 mm) of subbase. It is desired to construct bituminous pavement. The equivalency factor from Table 9-1 for a base course is 1.15 and for a subbase 2.30. The thickness of AC required to replace the base is 4 in. ÷ 1.15 = 3.5 in (100 mm ÷ 1.15 = 87 mm). Since the minimum required thickness is 4 in, the excess of stabilized base course of 4 in – 3.5 in = 0.5 in (100 mm – 87 mm = 13 mm) is computed as equivalent thickness of non-stabilized subbase material, which is equal to 0.5 in. * 2.3 = 1.1 in (13 mm * 2.3 = 30 mm). This equivalent subbase thickness is accounted in the stabilized base; therefore the needed non-stabilized subbase is thinner than 18 in (460 mm) and equal to 18 in – 1.1 in = 16.9 in) (460 mm – 30 mm = 440 mm) The next step computes the equivalent thickness of subbase stabilized material, as 16.9 in. ÷ 2.3 = 7.3 in (440 mm ÷ 2.3 = 190 mm). The total thickness of the ABC pavement is 3.5 in + 4 in + 7.3 in = 14.8 in~ 15 in (87 + 100 + 190 = 377 mm ~ 380 mm)

G-5 THICKNESS DESIGN FOR RIGID PAVEMENTS.

G-5.1 Example 1: Non-Stabilized.

A road is to be designed on a non-stabilized foundation for the following traffic and subgrade conditions:

Traffic:

Passenger Cars, 3,000 lb (1,400 kg) 2,400 passes/day

3-Axle Truck, 35,000 lb (16,000 kg) 120 passes/day

5-Axle Truck, 80,000 lb (27,000 kg) 80 passes/day

M1A2 Tank, 139,000 lb (63,000 kg) 16 passes/day

Subgrade:

k-value = 100 psi/in (27 kPa/mm)

Concrete:

28-day Flexural strength = 750 psi (5.2 MPa)

Modulus of Elasticity = 4,000,000 psi (27,600 MPa)

Design Life: 25 years

For these design conditions and using the mixed traffic procedures described in Chapter titled Vehicular Traffic with a subgrade category C (k-value equal to 147 psi/in (40 kPa/mm)), the equivalent passes in terms of the M1A2 tank are computed and are shown in Table G-3. From Figure F-5, 147,295 passes of an M1A2 tank results in a required thickness of 7.8 in (198 mm). Rounding up in 0.5 in (10 mm) increments to a final thickness will be 8 in (200 mm).

G-5.2 Example 2: Stabilized Soil.

A rigid pavement, functioning as road is to be designed over a 6 in (150 mm) stabilized soil having an E_f = 650,000 psi (4,500 MPa) for the following traffic and subgrade conditions:

Traffic:

M1A2 Tank, 139,000 lb (63,000 kg) 40 passes/day

M2A3 Tank, 58,200 lb (26,400 kg) 16 passes/day

M923 5-Ton, 32,500 lb (14,700 kg) 80 passes/day

M978 HEMMT, 59,000 lb (26,800 kg) 80 passes/day

M998 HMMWV, 7,900 lb (3,600 kg) 160 passes/day

Subgrade:

k-value = 100 psi/in (27 kPa/mm)

Concrete:

28-day Flexural strength = 750 psi (5.2 MPa)

Modulus of Elasticity = 4,000,000 psi (27,600 MPa)

Design Life: 25 years

Table G-3 Mixed Traffic with M1A2 Tank, 63,049 kg (139,000 lb) as Controlling Vehicle Non-Stabilized Foundation

(1) Vehicle	(2) Gross Weight, lb (kg)	(3) Design Total Passes	(4) Required[1] Thickness in (mm)	(5) Allowable Passes	(6)=146000/(5) Ratio of Passes in Terms of Controlling Vehicle	(7)=(6)*(3) Equivalent Passes of Controlling Vehicle
Passenger Car	3,000 (1,400)	21,900,000	2.6 (66)	Unlimited	0.000	0
3-Axle Truck	35,000 (16,000)	1,095,000	5.5 (140)	Unlimited	0.000	0
5-Axle Truck	80,000 (27,000)	730,000	6.5 (165)	8,230,570	0.001	1,295
M1A2 Tank	139,000 (63,000)	146,000	7.2 (183)	146,000	1.000	146,000
						147,295

[1] Required thickness based on k-value = 147 psi/in (40 kPa/mm) (Subgrade Category C).

For the design conditions stated, using the mixed traffic calculations shown in Table G-4, and disregarding the presence of the stabilized layer (which will be considered at a second step), this pavement is to be designed for 365,444 passes of an M1A2. From the design chart in Figure F-5, the required thickness would be 8.3 in (210 mm). For this example, if the plain concrete is to be placed on 6 in (150 mm) of cement stabilized soil having an E_f = 650,000 psi, then the thickness of plain concrete required would be as follows: using equation 13-1,

$$h_o = \sqrt[1.4]{h_d^{1.4} - \left(0.0063 \times \sqrt[3]{E_f}\ h_s\right)^{1.4}}$$

$$h_0 = \sqrt[1.4]{8.3^{1.4} - (0.0063\sqrt[3]{650000} * 6)^{1.4}}$$

This calculation results in a thickness h_o = 6.6 in., therefore use 7 in (180 mm) for design.

Table G-4 Mixed Traffic with M1A2, 63,049 kg (139,000 lb) as Controlling Vehicle Stabilized Foundation

(1) Vehicle	(2) Gross Weight, lb (kg)	(3) Design Total Passes	(4) Required[1] Thickness in (mm)	(5) Allowable Passes	(6)=365000/(5) Ratio of Passes in Terms of Controlling Vehicle	(7)=(6)*(3) Equivalent Passes of Controlling Vehicle
M1A2 Tank	139,000 (63,000)	365,000	7.6 (190)	365,000	1.000	365000
M2A3 Tank	58,200 (26,400)	146,000	5.7 (150)	Unlimited	0.00	0

						365,444
[1] Required thickness based on k-value = 147 psi/in (40 kPa/mm) (Subgrade Category C).						

G-6 REINFORCED CONCRETE PAVEMENTS.

A design example for a reinforced concrete pavement requires a plan concrete thickness of 7.9 in (200 mm) for given traffic and subgrade conditions. The percentage of longitudinal reinforcing steel ***S*** required to reduce the pavement thickness to 7 in (180) mm) is obtained from Figure 14-1 as 0.10 percent. Similarly, the percentage of longitudinal reinforcing steel required to reduce the pavement thickness to 6 in (150 mm) is 0.30 percent. From paragraph titled Thickness Design On Unbound Base Or Subbase, the percentage of transverse reinforcing steel would be either 0.05 for a design thickness of 7 in or 0.15 for a design thickness of 6 in. The choice of which percentage of steel reinforcement to use should be based on economic factors, foundation, and climatic conditions peculiar to the project area. If the yield strength of the steel is assumed to be 60,000 psi (410 MPa), the maximum allowable spacing of the transverse contraction joints would be 49 ft (15 m) for 0.10 percent longitudinal steel, and 97 ft (30 m) as the maximum spacing for 0.30 percent longitudinal steel. In the latter case, the maximum permissible spacing of 75 ft (25 m) would be used.

G-7 OVERLAY DESIGN.

Design an overlay for an existing road having a plain concrete thickness of 6 in (150 mm), a flexural strength of 650 psi (4.5 MPa), a subgrade **k** value of 100 pci (27 kPa/mm), and a projected design traffic of 20 million of an 18,000 lb (8,200 kg) ESAL. The concrete overlay will also have a flexural strength of 650 psi. The factor for projecting cracking in a flexible overlay is 0.93 from Figure 15-1. The existing pavement is in good condition with little or no structural cracking. The condition factor C is therefore equal to 1.0 for concrete and flexible overlay. From Figure F-1, h_d is 8.1 in

(206 mm.). Overlay thickness requirements for the various types of overlays are as follows:

G-7.1 Bonded Overlay

$h_o = h_d - h_E$

h_o = 8.1 – 6 in (206 - 150 mm)

h_o = 2.1 in (56 mm); round up in 0.5 in (10 mm) increments to 2.5 in. (60 mm)

G-7.2 Partially Bonded Overlay

$$h_o = \sqrt[1.4]{h_d^{1.4} - C\left(\frac{h_d}{h_e} \times h_E\right)^{1.4}}$$

$$h_o = \sqrt[1.4]{8.1^{1.4} - 1.0\left(\frac{8.1}{8.1} \times 6.0\right)^{1.4}}$$

h_o = 3.7 in. (94 mm); round up in 0.5 in (10 mm) increments to 4 in. (100 mm)

G-7.3 Un-bonded Overlay

$$h_o = \sqrt{h_d^2 - C\left(\frac{h_d}{h_e} \times h_E\right)^2}$$

$$h_o = \sqrt{8.1^2 - 1.0\left(\frac{8.1}{8.1} \times 6.0\right)^2}$$

h_o = 5.4 in. (137 mm); round up in 0.5 in (10 mm) increments to 5.5 in. (140 mm)

G-7.4 Flexible Overlay

$$t_o = 3 \times (F \times h_d - C \times h_E)$$

t_o = 3.0 (0.93 × 8.1- 1.0 × 6)

t_o = 4.6 in (117 mm); round up in 0.5 in (10 mm) increments to 5.0 in. (120 mm)

G-8 DESIGN FOR SEASONAL FROST CONDITIONS.

Design a flexible and a rigid pavement for the following conditions:

G-8.1 Site and Traffic Characteristics.

Class B (rolling terrain within the "built-up area").

Category III.

Design Traffic. 1,200,000 18-kip ESAL.

Design Freezing Index. 700 degrees Fahrenheit-days.

G-8.2 Subgrade Material.

Uniform sandy clay, CL

Plasticity index, 18

Frost group, F3

Water content, 20 percent (average) Normal-period CBR, 10

Normal-period modulus of subgrade reaction

k = 200 psi/in (54 kPa/mm) on subgrade and 325 psi/in (88 kPa/mm) on 22 in 560 mm) of base course.

G-8.3 Base Course Material.

Crushed gravel (GW), normal-period CBR = 80, 30 percent passing No. 10 sieve, 1 percent passing No. 200 sieve, and water content = 5%.

G-8.4 Subbase Course Material.

Coarse to fine silty sand (SP-SM), normal period CBR=20, 11 percent passing No. 200 sieve, 6 percent finer than 0.02 mm, frost classification 52, meets filter criteria for material in contact with subgrade.

G-8.5 Average Dry Unit Weight

(good quality base and subbase, 135 pounds per cubic feet (2160 kg/m^3))

G-8.6 Average Water Content after Drainage

(good quality base and subbase, 5 percent)

G-8.7 Highest Groundwater.

About 4 ft (1.2 m) below surface of subgrade.

G-8.8 Concrete Flexural Strength.

4.5 MPa (650 psi).

G-8.9 Flexible Pavement Design by Limited Subgrade Frost Penetration Method.

From Figure 19-4, the combined thickness ***a*** of pavement and base to prevent freezing of the subgrade in the design freezing index year is 45 in (1140 mm). According to criteria in Table 7-2, the minimum pavement thickness is 3.0 in (75 mm) over a CBR = 80 base course that must be at least 4 in (100 mm) thick. The base thickness for zero frost penetration is 45 - 3.0 = 42 in (1140 – 75 = 1065 mm). The ratio of subgrade to base water content is r = 20/5 =4. Since this is a highway pavement, the maximum allowable ***r*** of 3 is used in Figure 19-5 to obtain the required thickness of base b of 26 in (660 mm), which would allow about 6 in (150 mm) of frost penetration into the subgrade in the design year. Subgrade preparation would not be required since the combined thickness of pavement and base is more than one-half the thickness required for complete protection.

G-8.10 Flexible Pavement Design by Reduced Subgrade Strength Method.

From the REDUCED SUBGRADE STRENGTH section, paragraph titled Reduced Subgrade Strength, the frost-area soil support index is 3.5, which, from the design curve (Figure E-1) yields a required combined thickness of pavement and base of 16 in (410 mm). Since this is less than the limited subgrade frost penetration method required thickness of 29 in (740 mm), of which 3 in (75 mm) is the required AC layer and 26 in (665 mm.) is granular material,, the 16 in thickness would be used. The pavement structure could be composed of 3 in of AC, 6 in (150 mm) of crushed gravel (since the crushed gravel contains only 1 percent passing the No. 200 sieve, it also serves as the free-draining layer directly beneath the pavement), and 7 in (180 mm) of silty sand subbase material. Subgrade preparation would be required to a depth of 26 – 16 = 10 in (665 – 410 = 255 mm).

G-8.11 Rigid Pavement Design by Limited Subgrade Frost Penetration Method.

From Figure F-1, the required concrete slab thickness p, based on the normal period k = 325 psi per inch (88 kPa/mm), the concrete flexural strength of 650 psi (4.5 MPa) and 1,200,000 ESAL, is 6.3 in (use 6.5 in (165 mm)). From Figure 19-4, the combined thickness of pavement and base for zero frost penetration is 45 in (1140 mm), equivalent to that for the flexible pavement. By use of r = 3 and a thickness of base for zero frost penetration of 45 – 6.5 = 38.5 in (1140 – 165 = 975 mm) in Figure 19-5, the required thickness of base b is 22 in (560 mm), which would allow about 5.5 in (140 mm.) of frost penetration into the subgrade in the design year. No subgrade preparation would be required.

G-8.12 Rigid Pavement Design by the Reduced Subgrade Strength Method.

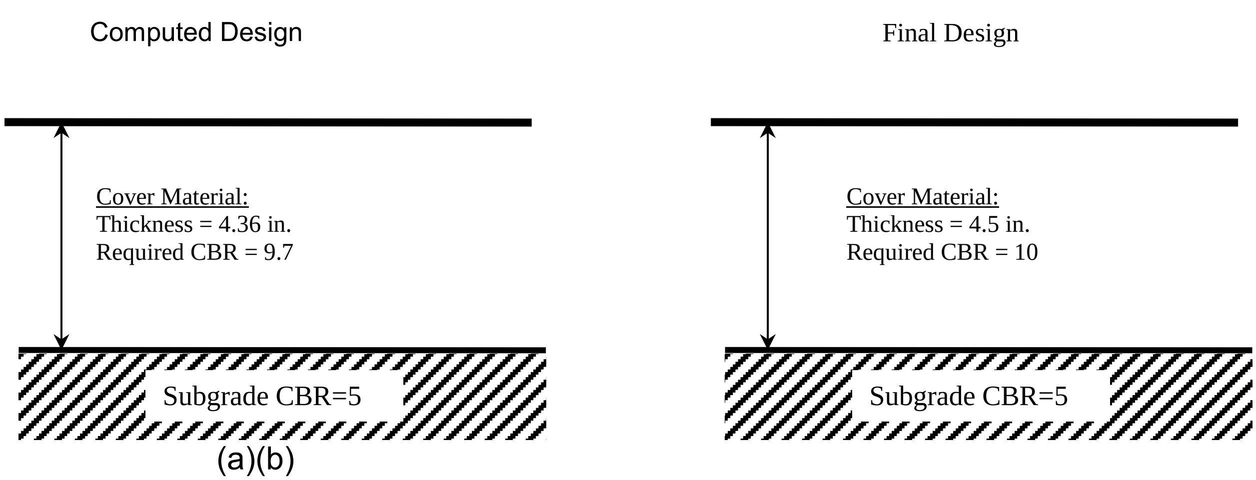
Since frost heave has not been a major problem, a minimum of 4 in (100 mm) of the free-draining base course material could be used, plus 4 in of the subbase that will serve as a filter material on the subgrade. For this case (8 in (200 mm) of base and subbase, from Figure F-1), the frost-area index of reaction would be 50 psi per inch (13.6 kPa/mm)) (Figure 19-6), requiring a pavement slab 8 in thick. As indicated in paragraph titled Subgrade Requirements, the depth of subgrade preparation must be 24 in (600 mm) or two-thirds of the frost penetration less the actual combined thickness of pavement, base course, and subbase course, whichever is less. Therefore, in this case, the required depth of subgrade preparation is 24 in (600mm) – 16 in (400 mm) = 8 in (200 mm).

G-9 DESIGN OF AGGREGATE SURFACED ROADS.

G-9.1 Example 1: Non-Frost Design.

An aggregate surfaced road is to be designed for 20,000 passes of a M923, 5-ton cargo truck 32,500 lb (14700 kg). The subgrade is cohesive material with a CBR equal to 5. Frost is not a consideration. Inputting these data into the PCASE design module results in the thickness and required CBR of cover material as shown in Figure G-1. The solution indicates that the cover material is to be built to a thickness of 4.36 in (111 mm.) and with a required CBR of 10 and it must meet the gradation and compaction requirements as dictated in Tables 21-1 and 21-2. The granular material should conform to the material requirements for NFS areas previously discussed.

Figure G-1 Results for Example 1-Non-frost design, M923, 5-Ton Cargo Truck (mm = 25.4 x inches)



G-9.2 Example 2: Frost Design.

An aggregate surfaced road is to be designed for 10,000 passes of a M977, 10-ton cargo truck 62,000 lb (28,100 kg) (or about 29.8 million ESAL). The subgrade is frost susceptible cohesive material classified as F3 with a natural CBR equal to 6. As specified in paragraph titled Frost Area Considerations, for areas where frost effects are expected, it is recommended that the pavement structure be built of a series of layers to ensure the stability of the pavement system. It is also recommended that the system be designed based on the reduced subgrade strength method using the frost area soil support indices FASSI values listed in Table 19-3 (for F3 soil FASSI is equal to 3.5). Therefore for construction purposes, the pavement structure will consist of:

- A wearing surface of fine-graded crushed rock

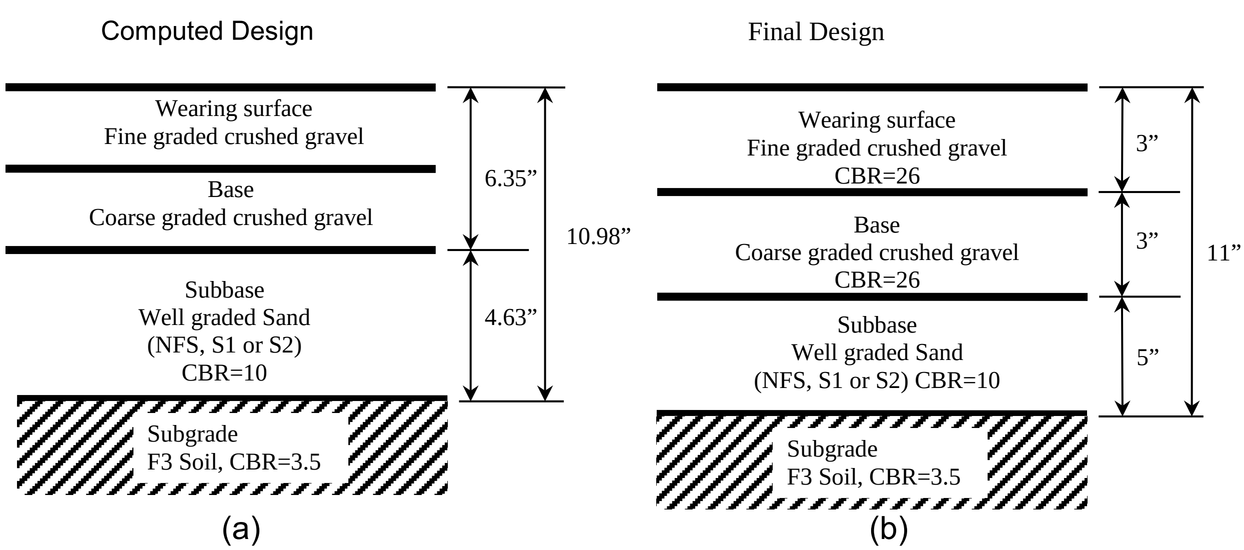
- A base course of coarse-graded crushed rock

- A subbase of well-graded sand (Frost group F1 and S2) with a CBR = 10

The wearing surface and the base course materials will be crushed aggregate with the same CBR value, then in PCASE these two layers can be treated as a unique layer.

The total required thickness of cover material above the subgrade, using a FASSI value of 3.5, is 10.98 in (279 mm) with a CBR of 21 for the top layers. The required thickness above the subbase (CBR equal to 10) is 6.35 in (161 mm); therefore the layers with CBR equal to 21 require a total thickness of 6.35 in. The subbase thickness is determined by subtracting the thickness required over the 10 CBR from total thickness required over the 3.5 CBR. The resulting subbase thickness is 4.63 in (116 mm). The layer thicknesses results are shown in Figure G-2. As mentioned, the top layer can be divided into two layers constituted of material with the same CBR but different characteristics. The resulting pavement structure may be proportioned by using the minimum of 3 in (75 mm) for wearing, base course, and sand subbase as shown in Figure G-2 (b). Again, each pavement layer must meet the gradation and compaction requirements dictated in Tables 21-1 and 21-2.

Figure G-2 Results for Example 2-Frost design, M977, HEMTT, 10-TON Cargo Truck (1 mm = 25.4 x inches)



APPENDIX H DETERMINATION OF FLEXURAL STRENGTH AND MODULUS OF ELASTICITY

H-1 FLEXURAL STRENGTH TEST PROCEDURE.

Use ASTM C78/78M to compute flexural strength.

H-1.1 CALCULATIONS.

H-1.1.1 Modulus of Rupture

Use modulus of rupture equation from ASTM C78/78M.

H-1.2 REPORT.

Provide a test report. Include report items in ASTM C78/78M.

H-2 MODULUS OF ELASTICITY TEST PROCEDURE

Soil stabilization is a method of improving soil properties by blending and mixing other materials. The modulus value for stabilized soils is determined according to the procedures in AASHTO MEPDG.

This UFC supersedes UFC 3-250-03, dated 15 May 2001, Air Force ETL 01-7, dated 5 June 2017, and Air Force ETL 01-9, dated 17 July 2001.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC is used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and is periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

REVISION SUMMARY SHEET

Document: UFC 3-250-03, *O&M Manual: Standard Practice For Flexible Pavements*

Superseding: UFC 3-250-03, *Standard Practice Manual for Flexible Pavements,* 15 May 2001; AF ETL 01-7, *Large Aggregate Asphalt Mixtures, 5 Jun 2017*; and AF ETL 01-9, *Procedures to Retard Reflective Cracking, 17 Jun 2001.*

Description: This UFC provides guidance for the preparation of drawings and specifications for road and airfield flexible pavements using asphalt cement materials. It also provides useful information for design engineers, laboratory personnel, and project managers concerning mix design, materials, production, and placement of the various asphalt mixtures.

Reasons for Document: This UFC provides engineers with current changes in technology to outline materials, equipment, techniques, and cautions required to produce a cost-effective and durable flexible asphalt pavement. Additionally, a number of editorial changes were needed to improve readability. Figures and tables were also improved.

Impact: Cost impact is negligible; improved guidance results in improved performance and reduced life cycle cost.

Unification Issues: None

CHAPTER 1 INTRODUCTION

1-1 PURPOSE.

This UFC provides guidance for the preparation of drawings and specifications for road and airfield flexible pavements using asphalt cement materials. The term "asphalt" is used herein instead of bitumen or bituminous (a generic term for both asphalt and tar materials) because asphalt is the material typically used in pavement construction. In the past, tar or coal tar was used only in instances where fuel resistance was required. Due to problems with emissions, tar is no longer used in flexible pavement construction except occasionally as a sealer. This UFC also provides useful information for design engineers, laboratory personnel, and project managers concerning mix design, materials, production, and placement of the various asphalt mixtures.

1-2 SCOPE.

This UFC prescribes materials, mix design procedures, and construction practices for flexible pavements.

1-3 REFERENCES.

Appendix A contains a list of references cited within this UFC.

1-4 UNITS OF MEASURE.

The primary system of measurement used in this UFC is the International System of Units (SI). In some cases, inch-pound (IP) measurements are the governing critical values because of applicable codes, accepted standards, industry practices, or other considerations where the IP measurements govern. The IP value is shown in parentheses following a comparable SI value.

1-5 SPECIAL TERMS.

Special terms used in this UFC are explained in Appendix C.

1-6 BACKGROUND.

Asphalt mixtures (hot-, cold-, and warm-mix asphalt and other asphalt surfaces) provide a resilient, relatively waterproof, load-distributing medium that protects the base course and underlying pavement structure from the harmful effects of water and abrasion from traffic. Asphalt pavements wear, weather, and deteriorate from aging; therefore, maintenance of these pavements extends pavement life. The flexibility of asphalt mixtures allows a pavement structure to adjust slightly to consolidation of underlying layers or deflection due to load without affecting pavement performance. Flexible pavements also allow stage construction and use a range of construction materials, often leading to substantial savings through the use of locally available materials. Additional pavement courses are placed on existing pavements to provide additional structural strength as total loads increase or as traffic intensity increases. Design and construct the economical pavement that satisfy the objective of long pavement life.

1-7 SAFETY CONSIDERATIONS.

Department of Defense's (DoD) objective is to construct pavements that provides traffic safety. A non-skid surface is essential, and grade control is required to provide rapid removal of surface water to minimize the potential for hydroplaning. All pavement surfaces normally exhibit a sufficiently coarse texture to provide skid resistance. Avoid aggregate types known to have a history of polishing because they are probably the greatest cause of low skid resistance, prevalent in surface treatments and seal coats. Avoid aggregates having friable particles, as these tend to break down and form foreign object debris (FOD). Construction techniques are important for surface treatments and seal coats to ensure good bond between the asphalt and aggregate, providing aggregate retention. Pavement surfacing such as sealers that do not include aggregate are not applied in areas of high-speed traffic.

CHAPTER 2 HOT-MIX ASPHALT

2-1 INTRODUCTION.

Hot-mix asphalt (HMA) is often used for high-performance pavements. Select the degree of performance required based on traffic conditions and the availability of materials. HMA mixtures consist of mineral aggregate and asphalt cement. These HMA mixtures are meet the design requirements for airfield pavements, roads and streets, and storage areas. In general, from 4 to 6.5 percent asphalt cement content is required for asphalt base, intermediate courses, and surface courses and 5 to 7 percent asphalt cement content for porous friction course (PFC) and stone matrix asphalt (SMA); however, determine the optimum asphalt content according to mix design procedures. The term “hot-mix asphalt” refers to any hot asphalt mixture produced in a hot-mix plant; however, unless referred to directly by a specific name, it refers to dense-graded HMA with aggregate gradations shown in Table 2-1. Much of the information discussed in this section is found in report AATP 05-01 developed by Auburn University.

2-1.1 Advantages.

The hot-mix method of preparing paving mixtures provides for thorough coating of the aggregates with a uniform film of asphalt cement and accurate control of aggregate sizes and quantity of asphalt cement. Hot-mix pavements require no curing period after being laid and are used as soon as the pavement has cooled. Roll the paving mixture to compact the mix while it is sufficiently hot because rolling is ineffective after the mixture has cooled, making the mix design density unachievable. Hot-mix asphalt pavements are constructed rapidly minimizing the probability of damage to the HMA due to weather conditions that occur immediately after construction is completed. Immediately after adequate rolling and a cooling period, the pavement has a high degree of stability from the interlocking of the coarse and fine aggregate and adhesion of the asphalt cement, as well as a high resistance to moisture penetration and frost damage.

2-1.2 Gradations and Layer Thickness.

Selection of a gradation from Table 2-1 is based on the layer thickness of the HMA to be placed and the need to limit aggregate segregation. Segregation occurs more quickly in mixes with coarser aggregates; therefore, do not use aggregate gradation No. 1 on the surface. Ensure the layer thickness for gradation No.1 is at least 57 millimeters (2.25 inches), the layer thickness for gradation No. 2 is at least 37.5 millimeters (1.5 inches), and the layer thickness for gradation No. 3 is at least 28.5 millimeters (1.1 inches). Use 25-millimeter- (1 inch) thick layers of HMA only in unusual situations, such as level courses, since these thin layers tend to cool quickly and are difficult to place and compact properly. The preferred thickness of the surface layer for an airfield pavement is 51 millimeters (2 inches). Design and/or construct underlying layers with a thickness no greater than 76 millimeters (3 inches). The thickness of underlying layers is determined by the total designed thickness of the asphalt mixture. Surface layers for airfields are not less than 37.5 millimeters (1.5 inches) thick.

Table 2-1 Aggregate Gradations for HMA Pavements

Sieve Size, mm	Gradation 1 19 mm Nominal Max Agg Size by Mass	Gradation 2 12.5 mm Nominal Max Agg Size by Mass	Gradation 3 9.5 mm Nominal Max Agg Size by Mass
25.0	100	–	–

No. 200	3–6	3–6	3–6

When a leveling course is applied, ensure layers are at least 37.5 millimeters (1.5 inches) thick except in areas where it is tapered to tie into the underlying layer. Ensure areas of leveling course that require tapering (it's better not to use tapering techniques) of the mix are at least 19 millimeters (0.75 inch) thick in the thinnest part of the taper to allow sufficient thickness for minimal compaction. Before overlaying, mill the asphalt surface to a grade resulting in no need for a leveling course. This allows each layer to be placed at a constant thickness throughout which is preferred.

Mixes with maximum aggregate size tend to have lower optimum asphalt content so these mixes are potentially a little cheaper for the contractor to produce but these mixes are more difficult to handle and compact and tend to segregate during handling. Use gradation 2 for all surface course mixtures for airfields unless the thickness is less than 37.5 millimeters (1.5 inches); in this case, use gradation 3. Provide good justification to use asphalt layer thicknesses less than 37.5 millimeters (1.5 inches). Use gradation 2 for intermediate layers as well unless the layer thickness exceeds 57 millimeters (2.25 inches); then gradation 1 is allowed to be used. Use gradation 3 for shoulders and for any layer that is constructed less than 37.5 millimeters (1.5 inches) thick.

2-1.3 Uses.

If properly designed, HMA paving mixtures are used for an asphalt base course, intermediate course, surface course, porous friction or stone matrix asphalt course. Wheel loads, wheel spacing, tire pressures, intensity of traffic, and subgrade strength (California Bearing Ratio (CBR)) dictate the thickness of the pavement (UFC 3-260-02). For airfield pavement applications, HMA is used for intermediate and surface courses on types A, B, C, and D traffic areas, blast areas, and any other areas (including non-traffic) where their use is economical. The four types of airfield traffic areas (A, B, C, and D) and their relationship to other methods of traffic area nomenclature are described in UFC 3-260-02. HMA is often used on any road or street, classification A through F. PFCs have been used in the past to prevent hydroplaning but have not been used in recent years on airfields primarily due to potential for raveling of the surface resulting in FOD. Gain approval from the Pavements Discipline Working Group (DWG) or their designated representative before using a PFC on an airfield. Grooving is used on runways in place of PFCs to facilitate removal of the water from the pavement surface. SMA is used in applications requiring a rut- and abrasion-resistant surfacing. SMA mixtures are more expensive than HMA, so they are not used. Areas subjected to fuel spills require an application of a fuel-resistant sealer to protect the HMA pavement or the use of a fuel resistant binder. When possible, investigate the use of a rigid pavement for areas with expected fuel spillage.

HMA is used for new construction and for rehabilitating existing pavements. For new construction it is important to ensure that the existing subgrade meets the strength requirements used for design. It is also essential that the quality of materials in the subbase and base courses meet the design requirements. Ensure a condition survey of existing pavements is made in order to develop a design for existing pavement repairs. During construction, it is essential that the design for materials and thicknesses be followed. Immediately address any construction issues prior to placement of material to avoid ultimately having to remove and replace such.

2-2 EQUIPMENT.

2-2.1 Plant Equipment.

The purpose of an asphalt plant is to produce the mixture using mix design proportions of aggregate materials and asphalt cement and mix the materials so that all aggregates are thoroughly coated and the mixture is uniform throughout. HMA is produced in both batch and drum mix asphalt plants. Drum mix plants are common in the U.S. Either type of asphalt plant is used to produce high quality HMA. Initiate asphalt mixture quality control at the aggregate stockpiles. Manage each aggregate stockpile to prevent segregation or mixing with adjacent stockpiles or contamination from other materials including underlying material.

2-2.1.1 Batch Plant.

The components of a batch plant are illustrated in Figure 2-1. Cold feed hoppers have individual feeders for each of the aggregates used in the mixture. Set feeders so that the desired percentage of each aggregate as specified in the job mix formula is fed into the plant. Rate of feed is controlled by the gate opening, belt speed, or other methods, depending on the type of cold feed. If aggregate feeders are not set as specified in the job mix formula, the following problems occur:

a. One of the aggregate hot bins overflows with material while another hot bin runs low on material.

b. The gradation of the aggregate in the mix being produced does not meet the design gradation.

c. The amount of natural sand varies from the design proportion and exceeds the amount allowed in the specifications.

2-2.1.1.1 Cold Feed Bins.

Before the start of a project, calibrate the cold feed bins so that each bin feeds the desired rate of material. The cold feed calibration involves feeding one aggregate at a time onto a belt that is common to all aggregates. Determine the speed of this belt prior to calibration of the feeders. One way to do this is to divide the belt length by the time required for one revolution. After the material is fed onto the belt, completely remove and weigh the material over a given length (for example; 2 meters (6.5 feet)). To convert the weight of the sample taken to kilograms per hour (pounds per hour) and later to metric tons (tons) per hour, use the following relationship:

$$R = \frac{3600\ WS}{L}$$

Where:
R = rate of feed, kilograms per hour (pounds per hour)
W = weight of sample, kilograms (pounds)
S = speed of belt, meters per second (feet per second)
L = length of belt sampled, meters (feet)

Feed each aggregate at four to five different feeder settings and determine the rate of feed for each setting. Develop a plot of this data showing the relationship between the rate of feed (kilograms or metric tons (pounds or tons) per hour) and the feeder setting (gate opening, feeder belt speed, or other method for setting the aggregate feeder) for each aggregate. Use these plots to set each cold feed bin to feed at the desired rate.

2-2.1.1.2 Dryer.

After the aggregate cold feed bins have been properly set, the aggregate feeders are set to provide the desired percentages, and the aggregate is fed up the cold elevator and through the dryer. The dryer removes the moisture from the aggregate down to less than 0.5% and heats the aggregate to the desired temperature for mixing and handling.

2-2.1.1.3 Dust Collector.

A dust collector collects the dust created in the dryer and at other plant locations and adds all or any portion of it back into the mix at the hot elevator. Ensure the plant has the capability to remove any desired portion of the collected dust or to return it back to the mixture.

2-2.1.1.4 Screens.

The aggregate exits the dryer and is carried, along with the returned dust, up the hot elevator, over the screening deck, and into the hot bins. Screen sizes are selected such that the oversize material is rejected and the remaining aggregates are separated into various sizes. Ideally, select the screen sizes so that the amount of material going into each hot bin is proportional to the relative volume of that hot bin. For example, suppose that hot bin No. 1 has a volume of 3 cubic meters (4 cubic yards), hot bin No. 2 has a volume of 1.5 cubic meters (2 cubic yards), and hot bin No. 3 has a volume of 1.5 cubic meters (2 cubic yards). Select screens so that 50 percent of the material goes into bin No. 1, 25 percent into bin No. 2, and 25 percent into bin No. 3. This is not done for each mix since it takes effort to change the screens and asphalt batch plants produce a range of mixes during a normal workday.

2-2.1.1.5 Hot Bins.

Determine the percentage of each hot bin to be used in the mixture. Take samples of each hot bin and the gradation for each sample determined. Select the percentage of each bin so that the gradation of the combined materials from the hot bins is equal to the gradation of the job-mix formula (JMF). Variations occur in the combined hot bin gradation and that sent through the drier due to possible aggregate degradation or loss of fines in the dust collection system; however, ensure the gradation of the blended aggregate is equal to that originally developed in the mix design.

2-2.1.1.6 Mixer.

After the cold feed and hot bins are properly set, the combined aggregate from the hot bins is mixed with the approved mix design amount of asphalt binder. Select the mixing time, 5 seconds for dry mixing and 25 to 40 seconds for wet mixing, so that all aggregate particles are coated. Ensure the plant produces a uniform asphalt mixture having approved mix design aggregate gradation, asphalt content, and temperature. The batch plant weighs in approved mix design percentage of the various nominal size aggregates stored in the hot bins and asphalt binder to produce a batch of material that is then mixed in a pugmill.

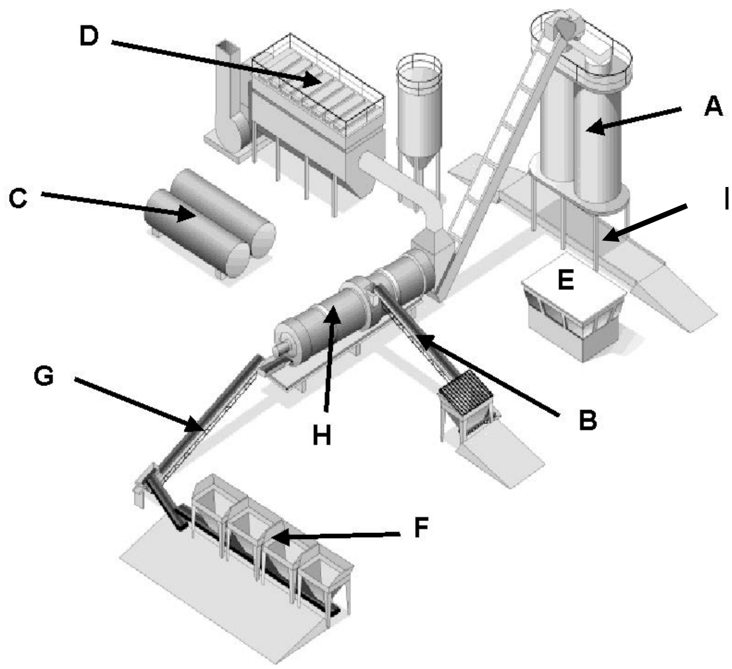
2-2.1.1.7 Storage Silo.

A storage silo is not required in a batch plant but almost all asphalt plants have one or more storage silos to temporarily store material during production. Ensure the storage silo in a batch plant meets the same requirements as that for a drum mix plant discussed below.

2-2.1.2 Drum Mix Plant.

The drum mix plant is illustrated in Figure 2-2. The drum mix plant is generally produces HMA at a higher production rate compared to a batch plant. When a drum mix plant is used, the gradation is completely controlled at the cold feed bins since no additional screening of the mixture occurs. The asphalt cement is either added to the aggregate while inside the drum or added to the aggregate immediately after passing through the drum. This plant type is used to readily produce HMA containing reclaimed asphalt pavement as well as HMA containing no reclaimed asphalt pavement.

Figure 2-2 Drum Mix Plant



A-Storage Silo

C-Binder Storage
D-Baghouse
E-Control House
F-Cold Feed Hopper
G-Cold Elevator
H-Dryer and Mixer
I- Truck Scales

(Courtesy of NAPA)

2-2.1.2.1 Cold Feed Bin

The cold feed bins in a drum mix plant are set up much the same way as for the batch plant, but the drum mix plant has a weight sensor on the aggregate feed belt that weighs the aggregate on the run prior to being fed into the dryer. Adjust this aggregate weight based on moisture content since there is moisture in the aggregate that is removed during the drying process. The asphalt pump adds binder based on the belt-measured weight of aggregate which is more asphalt binder than desired unless the aggregate weight is corrected based on the measure moisture content.

2-2.1.2.2 Dryer.

For the drum mix plant, the burner for the dryer is normally located on the high side (parallel flow) or the low side (counter flow) of the drum. In the parallel flow dryer, the aggregate enters the dryer on the high end of the drum and helps to shield the asphalt binder being added inside the drum from direct contact with the flame. The asphalt cement is added to the dryer at the midpoint to two-thirds the length to prevent close contact with the flame, which causes over-heating and damage to the asphalt binder. A counter-flow drum mix plant has the burner on the low end of the drum and is more energy efficient than a conventional drum mixer and produces less emissions during plant operations. With a counter flow plant, various techniques are used to protect the asphalt from the flame as it passes through the plant. Examples of techniques used include double barrels (where the aggregate is heated in the inner drum and the asphalt cement is added in the outside drum), coaters (where the asphalt cement is added to the aggregate after it passes through the dryer), and heat shields (shield the asphalt cement from the flame).

2-2.1.2.3 Dust Collector.

The dust collector in a drum mix plant operates similar to that in a batch plant.

2-2.1.3 Asphalt Mixture Storage Silo.

Asphalt storage silos are used to store HMA mixture before loading it onto trucks. Ensure the storage silo volume is maintained for the drum mix plants continuous flow production. The silos allow plants to run continuously even when there is a temporary shortage of trucks. Material is stored in silos for short periods of time, but if stored too long, the material cools excessively or oxidizes excessively, causing the asphalt binder to become hard and brittle. The asphalt binder has the potential to drain from the aggregate during long-term storage. This draindown is more likely to occur with mixes having high coarse aggregate content such as open-graded friction course and stone matrix asphalt. Hence for these mixture types storing the mixture in the silo for more than 30 minutes is not allowed.

Meet the stored mixture specification requirements when sampled and tested after storage. As a general rule, HMA dense-graded mixtures are not stored more than 3 hours in a non-insulated storage silo or for more than 8 hours in an insulated storage silo. If segregation of aggregate or draindown of asphalt binder occurs in the silo, disallow use of the silo or make changes in the equipment or process to prevent segregation and draindown.

2-2.2 Placement Equipment.

2-2.2.1 Asphalt Spreader (Paver).

2-2.2.1.1 Types of Spreaders.

An asphalt spreader is used to place mixture types, such as hot mix, cold mix, and base course material. Spreaders currently in use operate on either tracks or rubber tires, and have a vibrating screed to strike off and smooth the paving mixture. Spreaders use a tamping bar in conjunction with the screed, or an oscillating screed with a vibrating compactor, and others use a vibrating screed for both strike-off and initial compaction. Conventional paving machines are place HMA, provided these machines are maintained in good mechanical condition, kept adjusted, and operated by experienced personnel. Poor pavement surfaces result if the screed plates are worn or rusty or if the tamping bars (when used) are worn or not properly adjusted.

2-2.2.1.2 Automatic Grade Control.

Ensure asphalt spreaders have a means of automatically controlling the grade. In many cases the grade of the base course or underlying layers is controlled and the desired thickness of asphalt mixture is placed resulting in the desired grade on the surface. When directly controlling grade of an asphalt layer, grade control is used on both sides of the paver for the first pass. For additional passes, the existing edge is matched on one side of the paver while grade control is used on the opposite side of the paver. For roads, slope control in the paver is often used to control the desired grade. In this case one side of the paver matches the existing pavement and the opposite side is controlled by setting the screed of the paver to provide the desired slope. Controlling the grade by utilizing the transverse slope with the paving machine is not acceptable when multiple lanes are to be placed since the error using the transverse slope approach increases as the number of lanes placed is increased. Methods of grade control that have been used include stringline, laser, and Global Positioning System (GPS)/automation. The asphalt mixture is placed to a desired grade with the asphalt paver but after compaction the mix rolls down 20 to 25 percent of the loose thickness. Hence, if 63.5 millimeters (2.5 inches) of loose mix is placed, this results in 51 millimeters (2.0 inches) of mix after compaction. This results in the initial placement of the asphalt mixture being 13 millimeters (0.5 inch) higher than the desired grade after compaction.

2-2.2.2 Material Transfer Vehicle.

Segregation and lack of smoothness are problems that occur on many paving projects. The use of a material transfer vehicle (MTV) has been shown to minimize segregation and improve pavement smoothness. The MTV is used to transfer the HMA paving mixture from the transport truck to the hopper of the paver. These devices hold a substantial amount of paving mixture, allowing more freedom in mixture transport, and they remix the paving mixture to help reduce segregation that often occurs during placement. In addition to helping prevent segregation, the MTV improves pavement smoothness by allowing a paver to operate continuously (less stopping and starting) without having to be concerned with trucking operations. MTVs receive mixtures directly into a hopper from dump trucks. State's Department of Transportation (DOT) require that an MTV be used on critical projects, such as interstate highways, so MTVs are readily available. All MTVs are not the same. MTVs work better for reducing segregation and improving performance. As a minimum, specify an MTV that has an articulating arm and one that is self-propelled and operated independently from the paver. Ensure the MTV has remixing capability to minimize segregation. There are many machines that simply transfer the mix from the truck to the paver. Many of these do not remix the asphalt mixture. One method of remixing is to have an auger inside the MTV that has auger blades at varying spacing (closer together near the end and further apart near the middle of the auger where the material is fed to the paver) which results in mixing of the materials as they are being fed to the paver.

2-2.2.3 Joint Heaters.

Joint-heating devices that are attached to asphalt spreaders have been used on a number of HMA construction projects. The joint heaters are used to heat the edge of an adjacent pavement lane during placement so that a hot joint is obtained. The hot joint allows for higher compaction. Experience with joint heaters has shown that there is a danger of overheating the existing asphalt mixture. Accordingly, do not use joint heaters on airfields.

2-2.2.4 Asphalt Distributor.

Asphalt distributors are used to apply asphalt material evenly over a pavement surface. Clean the openings of all nozzles of any blockages. Ensure nozzles are the same size and turned at the same angle with reference to the spray bar to produce a uniform fan of bituminous material. The height of the spray bar above the surface being sprayed is important for uniform application. When the bar is too high or too low, a difference in application rate across the spray bar occurs, causing streaking. Adjust the height of the spray bar so that a double or triple overlap of the spray fan is obtained. The Asphalt Institute's Manual Series No. 19 (MS-19) offers guidance for calibrating and checking application equipment. American Society for Testing and Materials (ASTM) Standard D2995 (ASTM D2995) details a method for the determination of the application rate of asphalt (bituminous) distributors. Fully calibrate a distributor before being allowed to be used on a project.

2-2.2.5 Rollers.

A number of roller types are used for paving operations. Rollers used to compact asphalt mixtures are static steel-wheel, vibratory steel-wheel, and rubber-tired rollers. Occasionally rollers have a steel drum on one end of the roller and rubber tires on the other end of the roller. These types of rollers are not allowed for use on HMA because the rubber tires tend to pick up the asphalt mixture resulting in damage to the HMA surface.

2-2.2.5.1 Static Steel-Wheel Rollers.

Static steel-wheel rollers are available in two-wheel (tandem) and three-wheel (tricycle) versions. These two wheel tandem rollers are used for finish rolling but have been used for breakdown rolling as well. Static steel-wheel rollers leave a smooth finish on the pavement surface, but excessive rolling with steel wheel rollers results in lateral movement of the mixture as it’s being rolled, causing surface cracking and a general loss in density. Equip these rollers with a system for watering the drums and ensure they have scrapers to remove any material that sticks to the drums. The three-wheel rollers, tricycle rollers, are not used as often, partially due to their tendency to push and shove the asphalt mixture, which results in surface problems.

2-2.2.5.2 Vibratory Steel-Wheel Rollers.

Vibratory steel-wheel rollers are commonly used for breakdown and intermediate rolling of HMA mixtures. They consist of dual-drum vibration, single-drum vibration and single-drum static, or single-drum vibration and rubber tires on the rear axle; however, use of rubber tires on the vibratory steel wheel rollers for asphalt is not normally recommended due to the potential for pickup of the HMA. These vibratory steel wheel rollers are used for breakdown, intermediate, and finish rolling. Breakdown rolling is performed in either static or vibratory mode, although almost everyone now uses a vibratory roller for breakdown rolling. Intermediate rolling is almost always performed in the vibratory mode, while finish rolling is performed in the static mode. Limited data that indicates that excessive rolling with a vibratory roller results in bleeding of the asphalt surface resulting in excessive loss of friction. Therefore, limit the maximum number of passes to three in the vibratory mode. Ensure the vibratory roller has a watering system along with scrapers on the steel drums. Although the vibratory roller is used for intermediate rolling, it does not replace a rubber-tired roller.

2-2.2.5.3 Rubber-Tire Rollers.

Rubber-tired rollers are used commonly for intermediate rolling of HMA mixtures. They are also used as breakdown rollers when mixtures are excessively tender. Whether used as breakdown or intermediate rollers, these rollers provide for an increase in compaction and produce a watertight surface. Ensure a rubber-tired roller consisting of nine tires, four on one end of the roller and five on the end of the roller and with a minimum total mass load of 18,180 kilograms (40,000 pounds) or 2,020 kilograms (4,440 pounds) per tire and a minimum tire inflation pressure of 620 kilopascals (90 pounds per square inch (psi)), is available for construction of heavy-duty pavements on roads or airfields. Ensure the rubber-tired roller has a watering system for the tires and has scrapers and pads in good shape to prevent accumulation of materials on tires. Commercially available products are available that when applied to the rubber tires keep the HMA mixture from sticking to tires. An effective method for preventing pickup is to get the tires hot and keep them hot. In cold climates or in windy conditions, apply skirts to protect the tires from excessive cooling caused by wind. While roller types are not in the specifications, it is recommended that a rubber-tired roller be included in the train of rollers for compaction of all heavy-duty HMA pavements, and these rubber tire rollers have tires containing the minimum pressures and weights as described above. The rated weight for a rubber tire roller is the loaded weight for the roller. If the roller is not filled with ballast (sand and water), the weight is less than the rated weight. If the actual weight of the roller is needed, weigh it. Rubber tire rollers always yield the best results for longitudinal cold joints and transvers transition joints between asphalt and concrete vs. vibratory or non-vibratory steel rollers.

2-2.2.5.4 Operation of Rollers.

Operate rollers at or below a rate of 4.8 to 8 kilometers per hour (3 to 5 miles per hour) (fast walking speed). Ensure starts and stops are gradual to avoid damaging the freshly laid mixture. Quick turns or any turns that cause cracking on freshly laid mixture is not allowed.

2-3 MATERIALS.

2-3.1 Asphalt Materials.

Asphalt materials used in hot-mix paving operations include the products conforming to the specifications listed in Table 2-2. Asphalt cements for use in pavement design and construction are graded or classified in one of two ways. They are graded on the basis of penetration (ASTM D946) or by the performance grading system (ASTM D6373). Currently, in the continental United States (CONUS) and many other countries, the performance grading system is used; however, in many countries, penetration grades of asphalt are obtained more easily. If performance graded asphalt is available, specify it for any airfield project. In general, use the softest grade of asphalt cement consistent with traffic and climate. Base selecting a grade of asphalt cement on several considerations, such as climate, traffic conditions, economics of asphalt availability, and previous regional experiences. Traffic conditions and economic considerations vary from project to project, but environmental conditions and regional experiences are normally similar. For example, in warm and hot regions, primarily select a grade of asphalt cement to ensure that the mix is stable during the summer months, and in cold regions, primarily select a grade of asphalt cement to ensure that the mix is not prone to cracking during winter months. These requirements are discussed in the following subparagraphs.

Table 2-2 Specification References for Asphalt Materials

Bitumen Type	Specification
Asphalt cement (performance-graded asphalt binder)	ASTM D6373
Asphalt cement (penetration-graded)	ASTM D946
Cutback asphalt (slow-curing type)	ASTM D2026
Cutback asphalt (medium-curing type)	ASTM D2027
Cutback asphalt (rapid-curing type)	ASTM D2028
Asphalt, emulsified (anionic)	ASTM D977
Asphalt, emulsified (cationic)	ASTM D2397

2-3.1.2 Performance Graded (PG) Asphalt Cements.

The performance grading system (ASTM D6373) classifies asphalt binders using performance-related properties according to the upper and lower temperatures that are expected during the life of the pavement. American Association of State Highway and Transportation Officials (AASHTO) R29 provides information for grading or verifying the performance grade of asphalt cement. PG asphalts have replaced penetration- and viscosity-graded asphalts in the United States. Unlike the viscosity and penetration grading systems, the performance grading system is used to classify unmodified as well as polymer modified asphalt binders.

2-3.1.3 Classification Method for PG Graded Asphalt Cements.

Specify PG graded asphalt binders wherever available. Consider the same PG binder grade as that used by the state highway department in the specific geographic area as the base grade for the project (e.g., the PG grade specified in that specific location for dense-graded mixes on highways with design equivalent single axle loads (ESAL) less than 10 million). The exception is that grades with low temperature requirements higher than PG XX-22 are not to be used (e.g., PG XX-16 or PG XX-10), unless the engineer or the local DOT has had successful experience with these grades.

Rutting is not a problem on airport runways but there have been issues on taxiways where the traffic is slower moving. At airfields with a history of stacking on ends of runways and taxiway areas, rutting has occurred due to the slow speed of loading on the pavement. If there has been rutting on the project or if stacking occurs regularly during the design life of the project, then apply the following grade "bumping" for the top 125 millimeters (5 inches) of paving in the end of runway and taxiway areas: for aircraft tire pressure between 0.7 and 1.4 megapascals (100 and 200 psi), increase the high temperature grade by one grade; for aircraft tire pressure greater than 1.4 megapascals (200 psi), increase the high temperature grade by two grades. For those projects used by aircraft and missions intended to primarily support air operations on ships, a high temperature increase of two grades is required for all HMA projects.

PG grades are provided in 6 degree increments, for example PG 64-22, PG 70-22, PG 76-22 on the high temperature side and PG 64-22, PG 64-28 on the low temperature side. However, many state DOTs, in the southern climates, have selected a mid-range grade on the high end, PG 67-22, as the primary grade of asphalt binder to use. When in these states specify the mid-range grade, PG 67-22, unless the high temperature grade needs to be bumped to be more resistant to rutting.

Polymer-modified asphalt (PMA) has been shown to perform well for improving the resistance to rutting. Using PMA results in a bumped grade of asphalt binder. When bumping the high temperature grade, ensure the low temperature grade remains the same as that for the base grade asphalt. A rule of thumb is that any asphalt binder, having the sum of the high and low temperature grades exceeding 90, is likely to contain a polymer. For example a PG 64-22 has a sum of 86 and this is likely not modified; however, a PG 76-22 has a sum of 98 and this asphalt binder is almost certainly modified. Changing from a PG 64-22 to a PG 76-22 provide much improved resistance to rutting but substantially increase the cost of the asphalt mixture (by 15%, but this varies considerably).

2-3.1.3.1 Polymer Modification of Asphalts.

Many polymers greatly improve the stiffness and flow characteristics of asphalts at high temperatures and are being demonstrated in pavement applications to significantly reduce rutting where this has been a problem in the past. These modified mixtures are produced at higher mixing temperatures to facilitate mixing, placement, and compaction. Polymers improve the low temperature characteristics of an asphalt binder and improve the ability of the pavement to resist low temperature cracking.

Many agencies bump the grade of asphalt binder to provide a binder that is more resistant to rutting and to help ensure that the binder contains a polymer. This bumping results when the high temperature grade is increased. For example, the grade of asphalt binder to be used in a certain area is identified as PG 64-22. However, to minimize rutting potential and to help ensure that a polymer is used, the agency elects to bump the grade to a PG 76-22. This provides increased stiffness at high temperatures without increasing the stiffness at low temperatures thus producing a more rut resistant mixture without increasing the potential for cracking. When the PG grade is bumped, the agency desires that a polymer be used in the binder. However, the grade is bumped in other ways, such as air blowing, but the asphalt binder won't perform as well when a polymer is used to bump the binder grade.

Ensure that a polymer is used to bump the asphalt binder grade by modifying the binder specification. The modifications to the binder specifications that have been used include, but are not limited to, elastic recovery, forced ductility, phase angle requirement. This has resulted in agencies adopting different requirements thus creating a problem for asphalt binder producers. As a result there has been a lot of work to standardize the binder test to ensure polymer modification resulting in development of the multiple stress creep recovery (MSCR) test. This test is being finalized and is eventually a part of the binder specification requirements but is not yet included as part of the specifications. If the PG binder grade is bumped, it is recommended that additional PG binder requirements (PG plus) specified by the local state DOT be adopted as part of the binder specification. Once the MSCR test procedure is completed and adopted as a part of the ASTM binder specifications, it becomes part of the requirements.

2-3.1.4 Asphalt Cement Selection by Temperature Region.

2-3.1.4.1 Determining the Temperature Region.

Table 2-3 gives guidance for selecting penetration-graded and performance graded asphalt binder by temperature region. When local experience suggests a specific grade of asphalt binder be used, local experience controls. For example, in the U.S., the local state DOT has requirements for selecting the grade of asphalt binder to use. If local experience cannot be used, climatological data are required to provide input into the selection method. First, average monthly maximum temperature data are required to compute a pavement temperature index (PTI). When project locations have average monthly maximum temperatures above 23.9 degrees Celsius (C) (75 degrees Fahrenheit (F)), the PTI is defined as the sum of the monthly increments exceeding 23.9 degrees C (75 degrees F). Conversely, when no average monthly temperature exceeds 23.9 degrees C (75 degrees F), the PTI is defined as the difference between the highest average maximum temperature for the warmest month and 23.9 degrees C (75 degrees F).

Table 2-3 Asphalt Binder Base Grade Selection Criteria Based on Pavement Temperature Index*

Pavement Temperature Index, Cumulative °C (°F)	Temperature Region	Asphalt Cement Selection Criteria
< 16.7 (30)	Cold	120-150 penetration, PG (52,58)-xx**
16.7–44.4 (30–80)	Warm	85–100 penetration, PG 64-(22 or 28)
> 44.4 (80)	Hot	60–70 penetration, PG (64, 70 or 76)-22

*Use only if there is no local guidance on asphalt cement grade to use)

**Use cold region requirements described in paragraph 2-3.1.3.3 for low temperature grade.

2-3.1.4.2 Example of Calculations for PTI.

This example shows the method for calculating the PTI for two construction sites. The average monthly maximum temperature and the difference above 23.9 degrees C (75 degrees F) for Site A and Site B are provided in Table 2-4.

Table 2-4 Example PTI Data

	Site A		Site B	
Month	**Average Maximum Temperature °C (°F)**	**Difference Above 23.9 °C (75 °F)**	**Average Maximum Temperature °C (°F)**	**Difference Above 23.9 °C (75 °F)**
January	15.8 (60.4)	--	-1.2 (29.8)	--
February	20.3 (68.5)	--	-2.3 (27.9)	--
March	23.2 (73.8)	--	6.1 (43.0)	--
April	26.6 (79.9)	2.7 (4.9)	14.6 (58.3)	--
May	31.4 (88.5)	7.5 (13.5)	19.6 (67.3)	--
June	34.7 (94.5)	10.8 (19.5)	21.3 (70.3)	--
July	36.4 (97.5)	12.5 (22.5)	25.0 (77.0)	1.1 (2.0)
August	33.3 (91.9)	9.4 (16.9)	23.4 (74.1)	--
September	32.3 (90.1)	8.4 (15.1)	19.4 (66.9)	--
October	26.8 (80.2)	2.9 (5.2)	14.2 (57.6)	--
November	23.3 (73.9)	--	6.3 (43.3)	--
December	15.7 (60.3)	--	2.7 (36.9)	--
Cumulative Total		**54.2 (97.6)**		**1.1 (2.0)**

The temperature index at these sites is the sum of the increments of average monthly maximums above 23.9 degrees C (75 degrees F); therefore, these are the PTIs for each site:

Site A = 54.2, cumulative degrees Celsius (97.6 cumulative degrees Fahrenheit).
Site B = 1.1, cumulative degrees Celsius (2.0 cumulative degrees Fahrenheit).

Based on the criteria in Table 2-3, Site A is a hot region, and Site B is a cold region.

2-3.1.4.3 Cold Region Requirements -- Determining the Design Air-Freezing Index.

When it is determined that a project exist in a cold region, as defined in Table 2-3, additional climate data are required. For the project area under consideration, a design air-freezing index (DFI) is also required to meet cold region requirements. (Reference UFC 3-260-02 for determination of DFI.) DFIs are used to differentiate between climates in cold temperature regions. A DFI of 1,667 degree Celsius-days or 3,000 degree Fahrenheit-days (degree-days) is used as the delineation between moderately cold and severely cold (extremely cold) climates. Moderately cold climates have DFIs up to 1,667 degree-days, and severely cold climates have DFIs greater than 1,667 degree-days. After the DFI is determined, select the grade of asphalt from Table 2-5. The minimum pavement temperature is estimated as a function of DFI as shown in Figure 2-3. Knowing the minimum pavement temperature is helpful in selecting the best low temperature grade of the asphalt binder. Ensure the low temperature grade is lower than the estimated low temperature from the figure. For example if the estimated low pavement temperature is -26 degrees C (-14.8 degrees F) then the PG grade is -28 or lower.

2-3.1.4.4 Examples of Asphalt Cement Selection in the Three Regions.

a. **Asphalt cement selection in a hot region.** A parking lot is to be built in a region that has a PTI of 54.4, cumulative degrees Celsius (97.6, cumulative degrees Fahrenheit). Assume that the DOT requires a grade of PG 67-22 for routine traffic and PG 76-22 for heavy traffic such as an Interstate Highway. In this case select a PG 67-22 or select a PG 76-22 in areas of known potential rutting issues such as slow moving airfield traffic areas including taxiways and runway ends and roads with high volume and/or slow moving traffic.

If no local guidance is available use Table 2-3 for selecting the asphalt cement grade. An asphalt cement that is graded as a 60-70 penetration or use a PG (64, 70, 76)-22. If rutting has been a problem or if aircraft stacking is expected then PG 76-22 is preferred. However, if this is for shoulder or other areas with little or no traffic, select PG 64-22. A PG 70-22 works reasonably well in traffic or non-traffic areas.

b. **Asphalt cement selection in a warm region.** A street is to be constructed in a region that has a PTI of 23.3, cumulative degrees Celsius (42, cumulative degrees Fahrenheit). Based on Table 2-3, select 85-100 penetration asphalt cement or PG 64-(22, 28) unless local guidance suggests a different grade. The -28 is more resistant to cracking and the -22 is more economical.

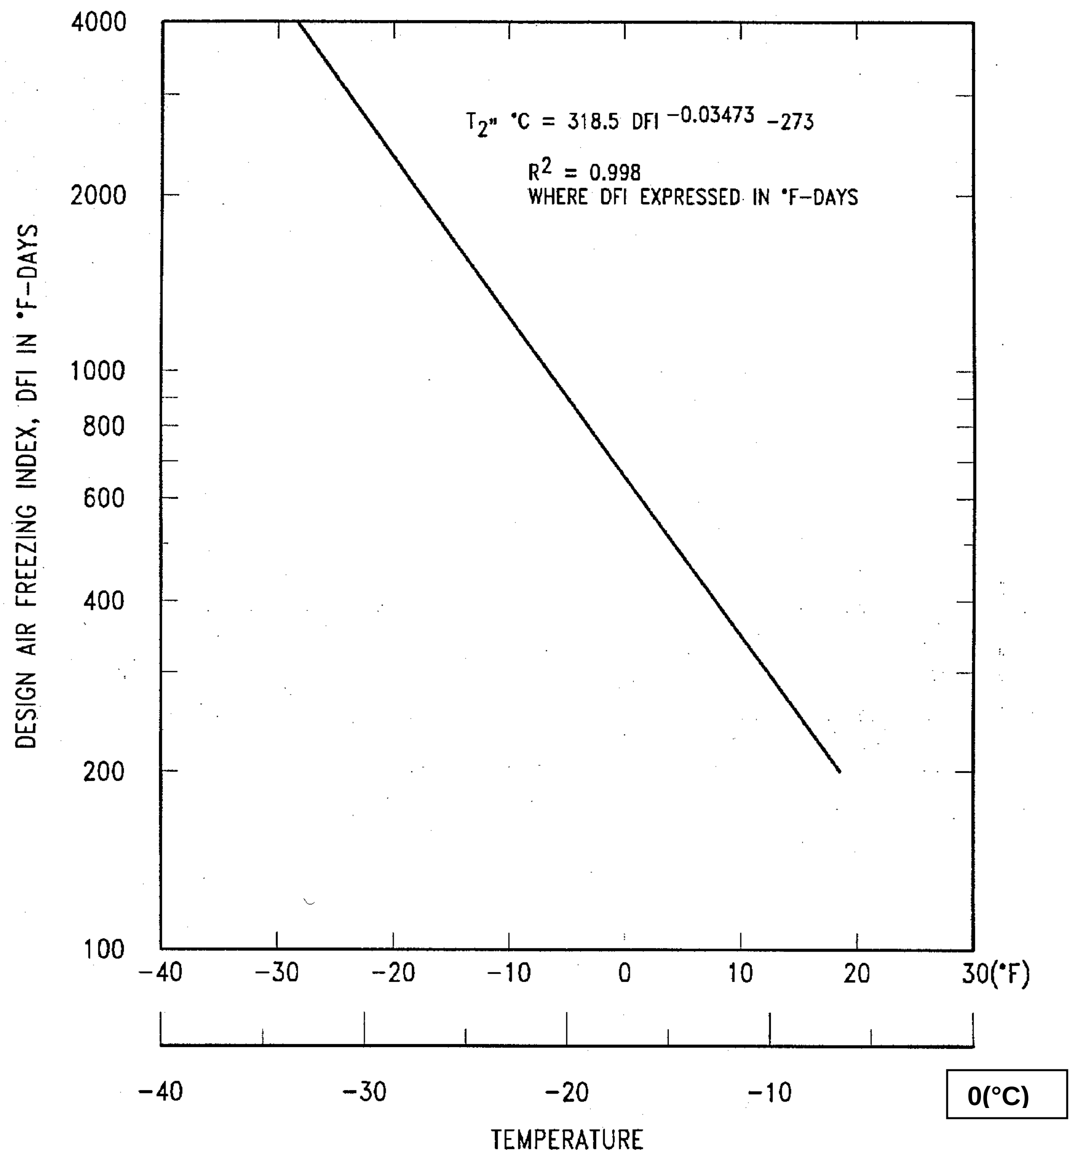
c. **Asphalt cement selection in a cold region. C**onstruct a heavy-duty open storage area (design index of 0) for use by 22,680-kilogram (50,000-pound) forklift trucks in a region with a PTI of 1.1, cumulative degrees Celsius (2, cumulative degrees Fahrenheit) and a DFI of 1,278 degree Celsius-days (2,300 degree Fahrenheit-days) calculated using UFC 3-260-02. Use penetration 120-150 if penetration graded asphalt is used or use PG (52, 58)-(28, 34) based on Tables 2-3 and 2-5. Again use local guidance for selecting grade of asphalt binder if available. Grade 58 is more resistant to rutting and Grade -34 is more resistant to cracking.

Table 2-5 Asphalt Cement Selection Criteria Based on Design Air-freezing Index*

Pavement Temperature Index, Cumulative °C (°F)	Temperature Region	Asphalt Cement Selection Criteria
< 1,667 (3,000)	Moderately Cold	PG (52, 58)-(28, 34)
> 1,667 (3,000)	Severely Cold	PG(52, 58)-(34, 40)

*Use only if there is no local guidance on asphalt cement grade to use)

Figure 2-3 Minimum Anticipated Pavement Temperature as a Function of DFI



2-3.2 Aggregates.

Use clean, hard, and durable aggregates for use in HMA. Angular aggregates provide more stable HMA mixtures than do rounded aggregates. Natural sands and gravels tend to be rounded and need to be limited or the gravel crushed to provide angular properties. Remove the fine aggregate from the source stone material before crushing to remove soft particles and potential clay balls that develop in the seams of the rock. Remove the fine aggregate from the gravel source before crushing to remove potential soft particles and clay balls, and to ensure that after crushing, particles are fractured and angular.

2-3.2.1 Sieve Analysis.

Subject aggregates to be used in a paving mix, as listed in Table 2-1, to a sieve analysis. From an aggregate's grading curve, an experienced engineer obtains information concerning the suitability of the aggregate for a paving mix, the quantity of asphalt cement required, and whether to add mineral filler. Conducted sieve analyses of fine and coarse aggregates according to ASTM C136. Washed sieve analysis are needed to get accurate measure of dust but for quality control (QC) testing during construction dry gradations are conducted to reduce test time. Use washed gradations for acceptance testing.

2-3.2.2 Specific Gravity.

Bulk specific gravity values for aggregates used in paving mixture are required in the computation of percent VMA. The method to determine the bulk specific gravity of aggregate is provided in ASTM C127 for coarse aggregate and ASTM C128 for fine aggregate.

2-3.2.3 Abrasion and Impact Resistance of Coarse Aggregate.

The determination of percent loss for coarse aggregates is not required if the aggregate has been found to meet the project mix design by previous tests or performance; however, test coarse aggregates obtained from new or doubtful deposits for resistance to degradation by evaluating the conformance to specification requirements for percent loss as measured using the Los Angeles Abrasion Machine (ASTM C131).

2-3.2.4 Soundness Test.

The soundness test is used where damage from freezing is a potential problem. Do not perform the soundness test on aggregate that has been found to meet the mix design by previous tests or performance data; however, aggregate obtained from new or doubtful deposits is tested for conformance to specification requirements using the sodium sulfate or magnesium sulfate solution tests (ASTM C88).

2-3.2.5 Percent Crushed Pieces.

Ensure the percentage of crushed pieces in both the coarse aggregate and fine aggregate fractions are sufficiently high to promote stability in the HMA mix design. Use

CRD-C 171 to determine the percentage of crushed aggregate particles for coarse aggregate (particles retained on a 4.75 millimeter (No. 4) sieve). Ensure a description for a crushed face and the required percentage of crushed aggregate particles is specified in the contract specifications. Natural gravels require crushing to produce the mix design percentage of fractured faces. Crushed stone, on the other hand, almost always meet the fractured face requirement.

2-3.2.6 Particle Shape.

The particle shape of crushed aggregates is required to be essentially cubical. Flat and elongated aggregate particles are susceptible to breakage under compaction and subsequent traffic. This breakdown of aggregate results in a change in volumetric properties of the mixture often resulting in a mix that does not meet the specification requirements. Determine the quantity of flat and elongated particles for conformance to specification requirements using ASTM D4791.

2-3.2.7 Clay Lumps and Friable Particles.

Some aggregates tend to have clay balls and soft particles. This test requirement (ASTM C142) evaluates the aggregate to ensure that aggregate containing clay balls or other friable particles that tend to breakdown during handling or during traffic is not allowed in the asphalt mixture. While these particles don’t normally result in disintegration of the pavement, they do result in blemishes that are unsightly and lead to FOD which is a significant problem for airfield pavements.

2-3.2.8 Sand Equivalent.

Some aggregates contain a significant amount of clay particles distributed throughout the aggregate. These particles that are not identified in the clay lumps and friable particles test present a problem. The sand equivalent test (ASTM D2419) evaluates a fine aggregate to determine the ratio between sand size and clay size particles. When a fine aggregate fails the sand equivalent test, it is not acceptable for use.

2-3.2.9 Natural Sand Content.

Natural sand is defined as any fine aggregate material that occurs naturally and has not been crushed. Natural sands tend to be rounded particles which, when used in excess, cause instability in the HMA mixture. The limit of 15 percent natural (uncrushed) sand in airfield mixtures assures a strong and stable pavement under aircraft. Natural sand also tends to have a smooth surface often resulting in poor bond between the asphalt binder and the sand particles. When reclaimed asphalt pavement (RAP) is used, determine the amount of natural sand in the RAP and included in the total amount of natural sand in the recycled mixture.

2-3.2.10 Fine Aggregate Angularity.

The fine aggregate angularity (FAA) test method (ASTM C1252, Method A) measures the uncompacted void content in the fine aggregate portion of a mix and is related to the angularity of the fine aggregate portion of the mixture. Generally crushed fine aggregates have an FAA value greater than 45 while natural sands have FAA values between the high 30s and the low 40s. The minimum specified value of FAA is 45 unless local experience indicates that aggregates with a lower value provide better performance. Occasionally, the FAA of a fine aggregate portion of the total aggregate is less than 45 even when it contains 100 percent crushed stone particles.

2-3.2.11 Voids in Mineral Aggregate (VMA).

The VMA is the volume of intergranular void space between the aggregate particles of a compacted paving mixture expressed as a percent of the total volume; it includes the air voids and the volume of the asphalt not absorbed into the aggregates. While VMA is not an aggregate property, it is a measure of the packing ability of an aggregate. The VMA is a function of bulk specific gravity of the aggregate, bulk specific gravity of the mix, asphalt content, and specific gravity of the asphalt binder. The VMA requirement is used to establish the minimum amount of asphalt binder added to the asphalt mix design. Without the VMA requirement, laboratories design asphalt mixes to have less asphalt binder to reduce mix cost. These low asphalt content mixes are difficult to place and compact and often result in reduced pavement durability. The VMA requirement indirectly controls the minimum asphalt content.

2-3.2.12 Combining Aggregates.

When asphalt mixtures are produced, combine aggregates from two or more sources. This UFC provides methods and procedures for determining the aggregate blend available and prescribes the asphalt content for the aggregate blend. Whenever an asphalt mixture does not meet established criteria, improve the gradation of the aggregate, use another aggregate, or make adjustments in the mix. Option choice is a matter of engineering judgment by the contractor and involves an analysis of the available aggregate supplies and costs.

2-3.3 Mineral Fillers.

Mineral filler refers to the material passing the 0.075 mm (No. 200) sieve. Most asphalt mixtures have enough mineral filler in the crushed aggregates and no additional filler is required. In fact, many mixtures have too much filler in the aggregates and procedures have to be used to waste some of the filler prior to or during the plant production operations. Some mineral fillers are more desirable to use in asphalt paving mixtures than others. For example, fine sands are less suitable fillers than limestone filler or some other by-product of crushed stone. Design asphalt pavement mixtures using commercial fillers that conform to ASTM D242.

2-3.3.1 Addition of Mineral Filler.

Additional filler is seldom needed in asphalt mixtures since the aggregates typically contain sufficient filler. The quantity of mineral filler to be added or removed depends on the amount of filler naturally present in the aggregate. In most cases the amount of filler in the aggregate produces a mixture meeting the specification requirements. With some aggregates, washing is performed to remove the excess filler in the aggregate before producing an asphalt mixture. High filler contents reduce the VMA in the mixture making it difficult to meet the specification requirements for VMA. The addition of satisfactory mineral filler, when needed, results in lower optimum asphalt content and increased stability of a paving mixture. Mixtures with low filler contents typically require additional asphalt binder to fill the voids resulting in a mixture that tends to be less stable if the filler is too low. Higher amounts of filler result in lower optimum asphalt content and reduced film thickness causing loss in mixture durability. Practical considerations and optimum performance usually dictate quantities of approximately 5-6 percent passing the 0.075 mm (No. 200) sieve for HMA and approximately 10 percent passing for sand-asphalt mixtures.

2-3.4 Antistrip Agents.

Several antistrip agents have been used successfully to reduce the probability of the asphalt stripping from the aggregate. Antistrip agents are added to the asphalt binder before it leaves the refinery, while others are added directly into the mixer as mineral filler. Hydrated lime is a commonly used antistrip agent and is one material with a history of success in preventing stripping. The liquid antistrip agents are easier to work with since these materials are mixed into the asphalt at the refinery and don’t require any extra effort by the contractor. When hydrated lime is added at the plant, have a silo to hold the lime and meter it into the mix thus requiring more effort by the contractor. Other available antistripping agents fall into these general groups: cationic surfactants, iron naphthenate, organosilane, and Portland cement. The tensile strength ratio (TSR) (ASTM D4867/D4867M) is used to evaluate the stripping property of a dense-graded asphalt mixture.

2-3.4.1 Recommended Antistrip Agent.

The recommended procedure for improving the resistance of an aggregate to stripping is to add 1 percent by weight hydrated lime to the mixture. Include this 1 percent lime in the determination of the aggregate gradation. Exact amounts are determined through trial and error on test specimens with various amounts of antistripping materials. Research has shown that lime provides better resistance to stripping than other materials. Some state DOTs are considered lime states and others are not. When in a state that does not use lime, local contractors are not set up to add lime increasing cost to set up equipment to store lime and feed it into the mix.

2-3.5 Antifoam Agents.

Silicone additives or modifiers reduce foaming of asphalt mixes when they come in contact with moisture. Silicone additives have been used successfully to suppress foaming of asphalt in asphalt plants. The silicone that has been used for this purpose is mixed at a rate of 1 milliliter per 640 liters (1 ounce per 5,000 gallons) of asphalt binder. The recommended range is also given as 1 to 2 parts per million. Silicones have been used to reduce the hardening of HMA while it is in storage silos. Silicone additives have successfully prevented slumping of mixes in trucks, which occurs when the hot-mix gradation is such that the mix traps escaping steam. In addition, silicones have provided better finishing qualities to pavement mixtures. These qualities include improved workability, reduced tearing during placement, and a reduction in the amount of effort required for compaction. Testing by several agencies has revealed no detrimental effects on the properties of asphalts when silicone is used in the recommended concentrations. Silicones are persistent materials, and their effects potentially carry over from one tank of asphalt to another. Mixing and control is best achieved by addition of the silicone at the refinery. (If silicone is added to the asphalt binder to prevent foaming, the asphalt binder cannot be used with the foaming process to produce warm mix asphalt).

2-4 DENSE-GRADED HMA.

Dense-graded HMA consists of a mixture of well-graded aggregate and asphalt cement. The HMA is produced at a central plant, laid to the desired grade with an asphalt spreader, and compacted with steel wheel and rubber tire rollers. HMA provides a high-strength, water resistant, smooth riding surface.

2-4.1.1 Aggregate Considerations.

Dense-graded HMA mixtures have several aggregate requirements and considerations. For airfield mixtures that support high-pressure tires, ensure the percentage of natural sand does not exceed 15 percent of the combined weight of the total aggregate. This percentage is 25 percent for roadway (low-pressure) mixtures, but needs to be validated with the mix design. The amount of filler that exists naturally in aggregates is sufficient to produce HMA meeting the mix design but needs to be validated. Usually, practical considerations and optimum performance dictate 5 to 6 percent filler, which is almost always available in the aggregates being used. Ensure the aggregates used meet the specification requirements for the aggregate properties discussed in paragraph 2.3.2.

2-4.2 Marshall Mix Design.

2-4.2.1 Contractor-provided Job Mix Formula (JMF).

Current practice is for the contractor to design the mixture and develop the JMF for the aggregates and asphalt used in the paving project. Supply a sufficient amount of aggregate and asphalt to the contracting officer or the contracting officer’s representative for possible verification tests. If verification tests are not performed, keep these material samples until the project is completed and accepted. Ensure the JMF supplied contains, as a minimum, the following information:

- Percent passing each sieve size for each aggregate and combined gradation.
- Optimum asphalt content.
- Percent of each aggregate and mineral filler to be used.
- Asphalt penetration grade, or performance grade.
- Number of blows of hammer per side of molded specimen (if Superpave is used, then show the number of gyrations).

- Laboratory mixing temperature.
- Lab compaction temperature.
- Temperature-viscosity relationship of the asphalt cement.
- Plot of the combined gradation on the 0.45 power gradation chart, stating the nominal maximum size.
- Graphical plots of stability, flow, air voids, VMA, and unit weight versus asphalt content.
- Bulk specific gravity and absorption of each aggregate.
- Percent natural sand.
- Coarse aggregate test results including: Los Angeles (LA) abrasion, sulfate soundness, percent fractured faces, flat and elongated particles, clay lumps and friable particles.
- Fine aggregate test results including: sand equivalent, uncompacted void content, clay lumps and friable particles.
- Tensile strength ratio and wet/dry specimen test results.
- Antistrip agent (if required) and amount.
- List of all modifiers and amounts.
- Percentage and properties (asphalt content, binder properties, and aggregate properties) of RAP in accordance with specifications when RAP is used.

The JMF likely needs to be adjusted based on plant-produced materials but only adjusted within the limits allowed in the specifications. Adjustments that exceed these specified limits are not be performed without a revised mixture design. Adjust the JMF only when changes in materials or procedures occur or to improve the JMF. It is common to adjust the mix design after construction of the test section and as needed during mixture production.

2-4.2.2 Procedure.

Laboratory tests are conducted on laboratory-compacted samples compacted with the effort identified in the specifications. These samples are tested to identify air voids, voids filled with asphalt, and VMA. Based on these properties (primarily air voids) the optimum asphalt content is selected. A final selection of aggregate blend and asphalt content is based on these data with due consideration to relative costs of the various mixes. The procedure set forth in paragraph 2-4.2.3 apply directly to all mixes containing not more than 10 percent by weight of total aggregate retained on the 25-millimeter (1-inch) sieve.

2-4.2.3 Preparation of Test Specimens.

Selection of materials for use in designing the paving mix is addressed in section 2-3. As an example, suppose that an aggregate gradation for a hot-mix design is required to meet the requirements of the 19-millimeter (3/4-inch) maximum (high-pressure) aggregate gradation band (gradation No. 2, 12.5 mm [1/2 inch] nominal) shown in Table 2-1. Design data are required on this blend. The initial mix design tests is usually conducted in a central testing laboratory on samples of stockpile materials taken by the laboratory. The procedure for proportioning stockpile samples to produce a blend of materials to meet a specified gradation is outlined in paragraphs 2-4.2.3.1 and 2-4.2.3.2 Adjustments to the mix design is based on samples taken from the asphalt plant and is usually conducted in a field laboratory near the plant.

2-4.2.3.1 Proportioning of Stockpile Samples.

As a preliminary step in mixture design and manufacture, determine the proportions of the different available stockpiled materials required to produce the mix design gradation of aggregate. This step is required to determine whether a blend is produced meeting the mix design and, if so, determine the proportion of each aggregate to be fed from the cold feeder bins into the dryer. Sieve analyses are conducted on material from each of the stockpiles, and the data are shown graphically in Figure 2-4. Another method of plotting or graphically illustrating the data is through the use of the 0.45 power curve. This was developed in the early 1960’s by the Federal Highway Administration (FHWA) using a formula developed in a study by Fuller and Thompson. The equation developed by Fuller is:

$$P = 100 \ (d/D)^n$$

where d is the opening of the sieve size in question, P is the total percent passing or finer than the sieve, D is the maximum size of the aggregate, and n is equal to 0.45. The FHWA recommends that this chart be used as part of the hot-mix design process. Combine the four aggregate fractions to produce the desired blend. The estimated percentage of each fraction needed to produce this blend is determined by trial-and-error calculations. Normally, two or three trials are required to obtain the desired blended gradation.

2-4.2.3.2 Proportioning of Bin Samples from Batch Plants.

Once it is demonstrated that a blend is prepared from the available materials, samples of these materials are processed through the asphalt plant for verification of the mix design or during construction of the test section. Conduct sieve analyses for each batch of processed aggregate. The data are shown graphically in Figure 2-5. Blend the hot-bin aggregates to produce the same gradation as that produced in the JMF. The percentage of each bin is estimated, and calculations are made to determine the gradation produced from these estimated percentages. The gradation of this recombined blend is then checked against the desired gradation. Two or three trials are usually sufficient to produce a combined mixture having a gradation equal to the job mix formula. This step is not needed when a drum mix plant is used since the aggregate is not rescreened in the plant.

Figure 2-4 Gradation Curves for Stockpile Samples

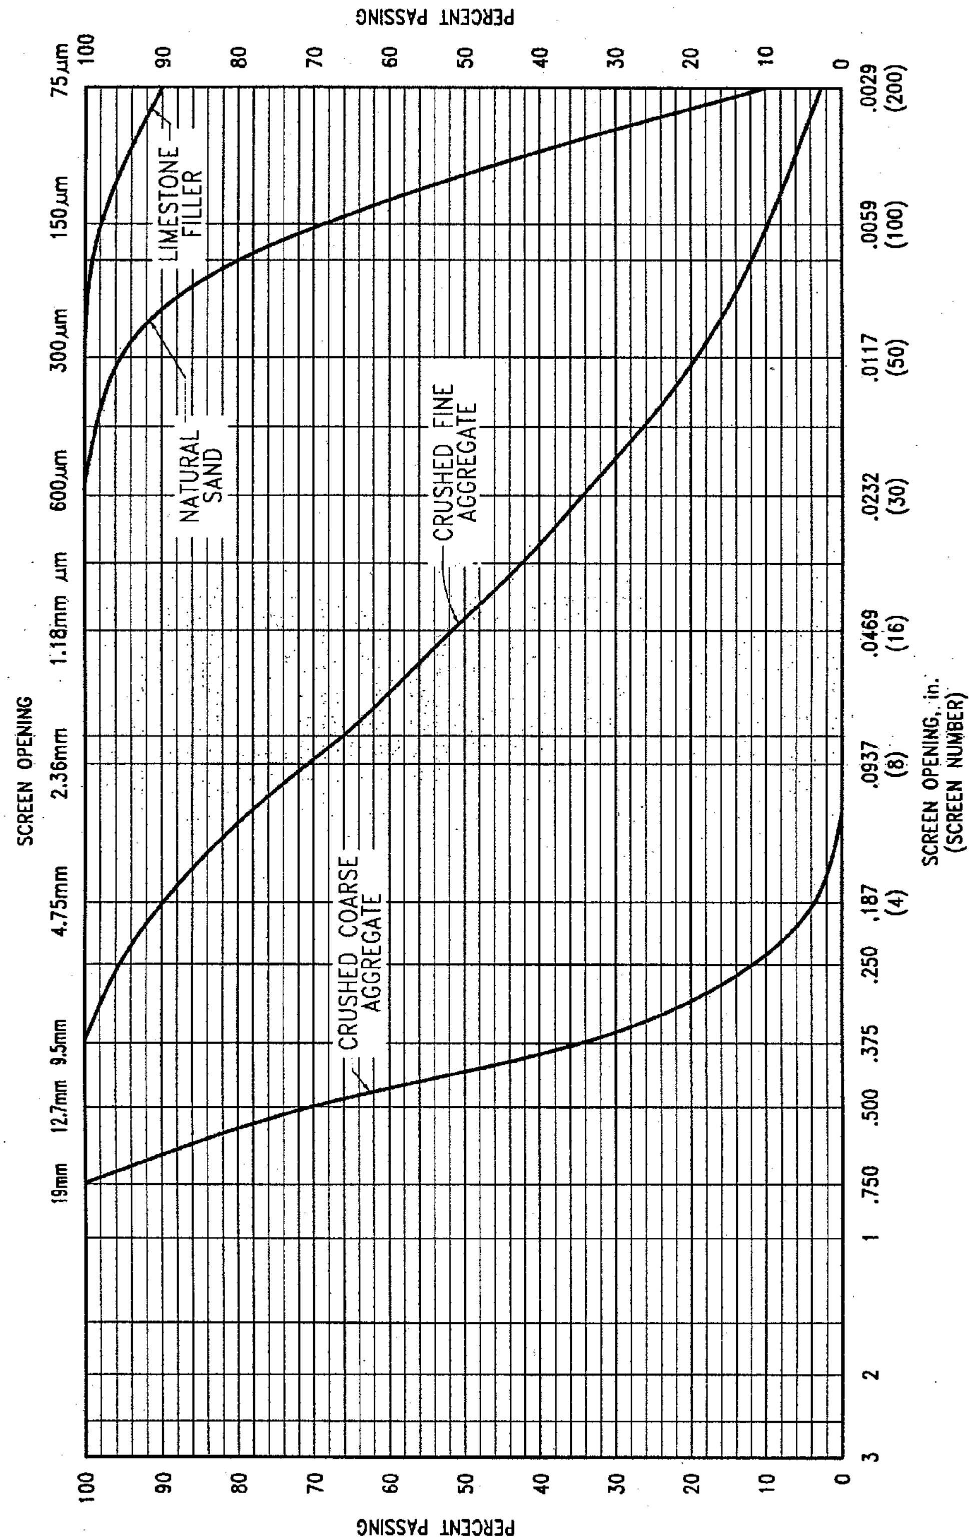


Figure 2-5 Gradation Curves for Bin Samples

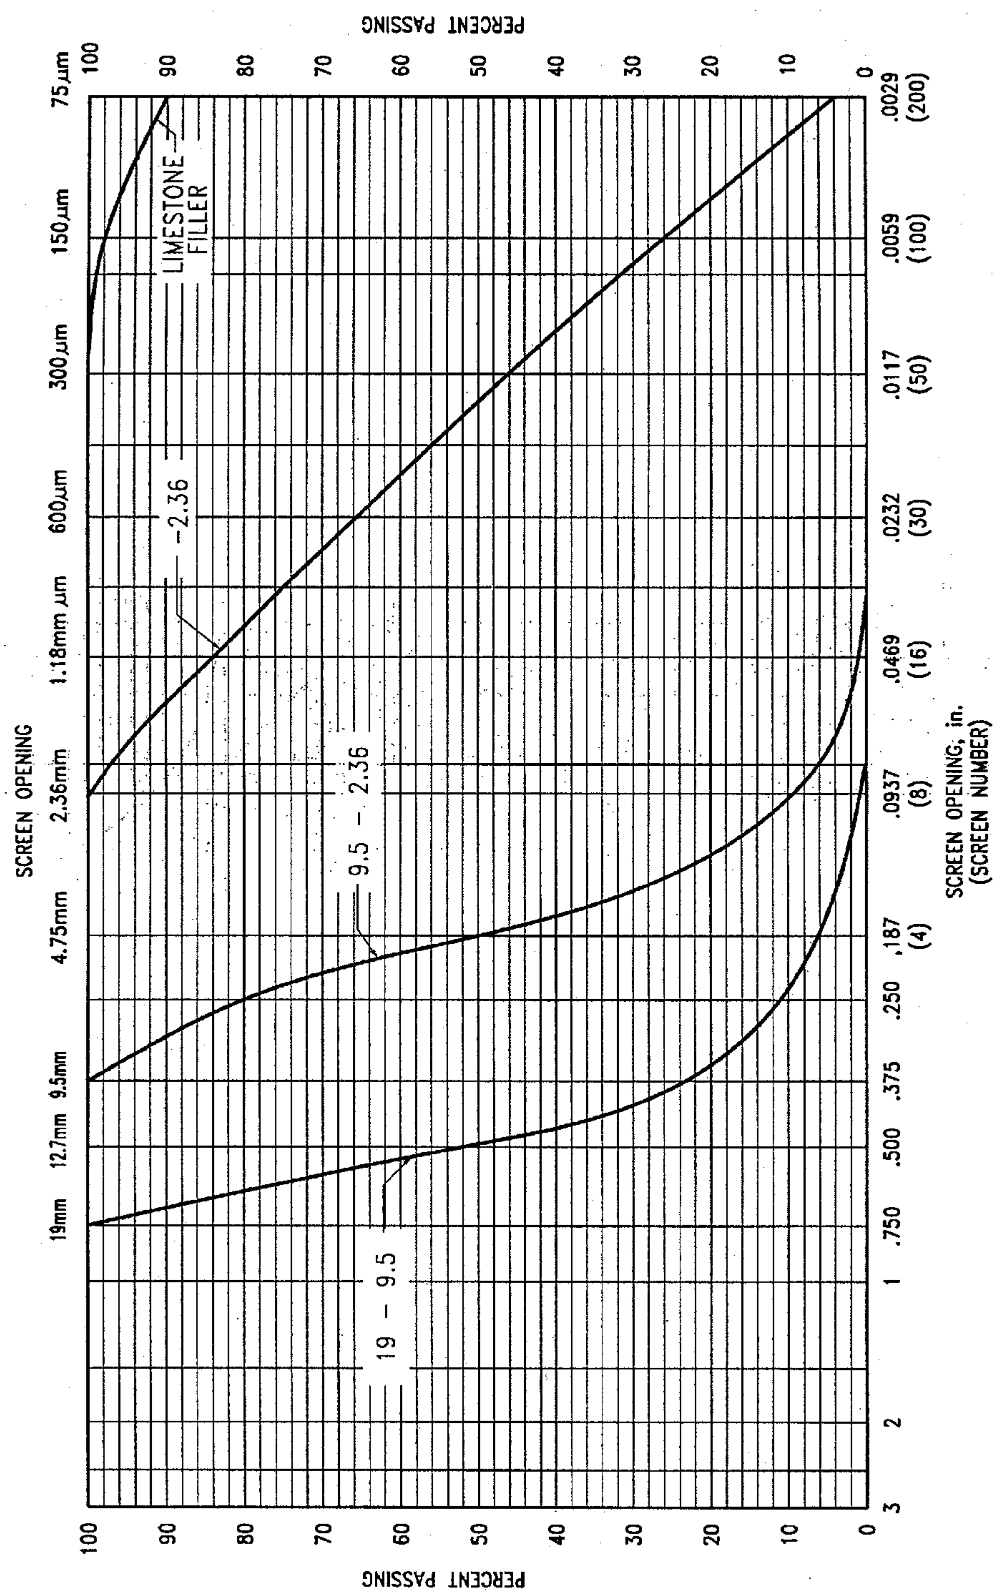

2-4.2.4 Asphalt Contents for Specimens.

The quantity of asphalt binder required for an aggregate is important to ensure performance. Procedures are described in paragraph 2-4.2.5. Normally, to start the laboratory tests, an estimate is made of the optimum amount of asphalt binder based on total weight of mix. Laboratory tests usually are conducted for a minimum of five asphalt contents: two above, two below, and one near the estimated optimum asphalt content. Incremental changes of 1 percent of asphalt are used for preliminary work, but increments of 0.5 percent are used for final design.

2-4.2.5 Selection of Design Compaction Method.

DoD use the Marshall mix design method. Specifications have also been prepared for using Superpave mix design procedures which use the Superpave Gyratory Compactor. Procedures for conducting the Marshall mix design tests are described in the Asphalt Institute's Manual Series No. 2 (MS-2) and CRD-C649. The primary difference between the Marshall method and the Superpave method is the method of compaction. A Marshall hammer is used for the Marshall method and a gyratory compactor is used for the Superpave method.

When using CRD-C649, establish the mixing temperature to provide the asphalt binder with a kinematic viscosity of 280±30 centistokes, determined according to the procedure provided in ASTM D2493. A manual hammer is required. When a mechanical hammer is used, calibrate it to provide the same specified density as that obtained with the effort with a manual hammer. It is easier to use a manual hammer for mix design and to use a mechanical hammer once full scale production begins. Compact samples produced at the asphalt plant using 50/75 blows as specified with a manual hammer and a variable number of blows with a mechanical hammer. Then select the number of blows required with the mechanical hammer to produce the specified density equal to that with the required number of blows with the manual hammer. Use this correlation only on the one project and not on additional projects since the correlation varies for different mixes. Verify the accuracy of the calibration weekly during the conduct of the project.

2-4.2.6 Tabulation of Data.

After selecting the laboratory design method and preparing test specimens, tabulate the data on forms similar to those shown in MS-2 or CRD-C649 and CRD-C650 for the Marshall procedure and for Superpave. Arranging data as shown in Table 2-6 facilitates tabulation of specimen test property data. Other material properties needed to make calculations include the bulk specific gravity of the aggregate, which is 2.700 (for this example), and the specific gravity of asphalt binder, which is 1.02 (for this example). Make plots of data from Table 2-6 for stability, flow, unit weight, percent voids total mix (VTM), percent VMA, and percent voids filled with asphalt (VFA) as shown in Figure 2-6(a-f). The desired values of VMA depend on the size of the aggregate particles in the mixture as shown in Table 2-6. The average actual specific gravity of the mixture is obtained for each set of test specimens, as shown in column G of Table 2-6. The unit weight values are determined in accordance with ASTM D2726 and provided in grams per cubic centimeter (g/cm^3) at 25 degrees C (77 degrees F). At this temperature, the average values are multiplied by 997 to convert to kilograms per cubic meter (kg/m^3)(62.24 to obtain the density conversion in pounds per cubic foot (lb/ft^3). Enter these data in column M. Plot the density conversion values as shown in Figure 2-6, and draw the best-fit smooth curve. The data from columns J, K, and L are used to plot curves for percent VTM, VMA, and VFA, respectively, in Figure 2-6. The corrected (converted) stability values in column O and the flow values in column P of Table 2-6 are plotted on Figure 2-6 to evaluate the stability and flow properties of the mixture. For Superpave, flow and stability are not used.

2-4.2.7 Relationship of Test Properties to Asphalt Cement Content.

Test property curves, plotted as described in paragraph 2-4.2.6, have been found to follow a reasonably consistent pattern for mixes made with non-modified grades of asphalt cement. Polymer-modified asphalt cements exhibit less consistent trends. Standard trends shown in Figures 2-6 (a-f) are noted in the following sub-paragraphs:

2-4.2.7.1 Flow.

The flow value increases at an increasing rate with increasing asphalt content. Flow is part of Marshall procedure but not used in Superpave.

2-4.2.7.2 Stability.

The Marshall stability increases with increasing asphalt content up to a point, after which it decreases. Stability is part of Marshall procedure but not used in Superpave.

2-4.2.7.3 Unit Weight.

The curve for unit weight of total mix is similar to the curve for stability, except that the peak of the unit-weight curve is normally at a slightly higher asphalt content than the peak of the stability curve.

2-4.2.7.4 VTM.

VTM decreases with increasing asphalt content. The void content of the compacted mix approaches a minimum void content as the asphalt content of the mix is increased.

2-4.2.7.5 VMA.

The VMA decreases with increasing asphalt content as the mixture becomes better lubricated and easier to compact. As the asphalt content continues to increase, the asphalt occupies space and begins to push apart aggregate particles, thereby increasing the VMA.

2-4.2.7.6 VFA.

The percent VFA increases with increasing asphalt content and approaches a maximum value in much the same manner as the VTM (above) approaches a minimum value.

2-4.2.8 Requirement for Additional Test Specimens.

The curves in Figure 2-6 are typical of those normally obtained when non-modified grades of asphalt cement are used with aggregate mixes. Some aggregate blends furnish erratic data that make plotting the typical curves difficult. In these cases, an increase in the number of specimens tested at each asphalt content normally results in data that plots as typical curves.

2-4.2.8.1 Equations Used for Calculation of Mixture Properties.

These are the mixture properties:

G_b = specific gravity of binder, ASTM D70
G_{sb} = bulk specific gravity of aggregate, ASTM C127 and C128
P_b = percent of total asphalt by weight
G_{mb} = bulk specific gravity of mixture, ASTM D2726
G_{mm} = theoretical maximum specific gravity of mixture, ASTM D2041
V_v = air voids in mixture, percent of total mixture
VMA = voids in mineral aggregate, percent of total mixture
VFA = voids filled with asphalt
W_{dry} = weight of sample after compaction in dry condition
$W_{submerged}$ = weight of sample submerged in water for 3 to 5 minutes
W_{SSD} = weight after removing from water and blotting dry, often called the saturated surface dry (SSD) weight

Determination of bulk specific gravity of mixture: $G_{mb} = \dfrac{Wdry}{W(SSD) - W(submerged)}$

Determination of air voids: $V_v = 100(1 - \dfrac{G_{mb}}{G_{mm}})$

Determination of VMA: $VMA = 100 - \left(\dfrac{G_{mb}(1-Pb)}{G_{sb}}\right)100$

Determination of VFA: $VFA = \dfrac{100(VMA - V_v)}{VMA}$

2-4.2.8.2 Determination of Stability and Flow

Stability and flow are determined by measuring the load and deformation of a sample at failure (ASTM D6927). The adjusted stability is needed to correct samples that are taller or shorter than 6.35 centimeters (2.5 inches) in height to get an equivalent stability to that of a 6.35 centimeters (2.5-inch)-tall sample. The stability is the load to failure, and the flow is the deformation at failure. The samples are corrected for height based on the height of the sample or the volume of the sample, which is determined when evaluating the volumetric properties of the mixture.

Example: Using the data for Specimen No. 1 at 5.0 percent asphalt in Table 2-6, the calculations are shown below for determining the mixture properties. The specific gravity of the binder is known to be 1.02. The bulk specific gravity of the aggregate is 2.70. A sample of the loose mix is obtained and the theoretical maximum density (TMD) is determined. For this example, the theoretical maximum density was determined to be 2.519. Samples of the remaining mixture are compacted using a specified effort and the mixture properties determined. After compaction, the sample is weighed dry, weighed while submerged in water, and weighed in a SSD condition after being removed from the water bath and the surface water blotted.

The sample volume is determined by:

$$Volume = Wssd - Wsubmerged = 1240.2 - 729.3 = 510.9\ cc$$

The bulk specific gravity of the sample is determined by:

$$G_{\mathrm{mb}} = \frac{Wdry}{W(SSD) - W(submerged)}$$

$$G_{mb} = \frac{1237.9}{1240.2 - 729.3}$$

$$G_{mb} = 2.423$$

Multiply this bulk specific gravity by 62.24 (since the test is conducted at 25 degrees C (77 degrees F)) to convert to pounds per cubic foot.

The VTM is determined to be:

$$V_{\mathrm{v}} = 100(1 - \frac{G_{mb})}{G_{mm}})$$

$$V_v = 100(1 - \frac{2.423}{2.519})$$

$$V_v = 3.8 \text{ percent}$$

The VMA is determined to be:

$$VMA = 100 - \left(\frac{G_{mb}(1-Pb)}{G_{sb}}\right)100$$

$$VMA = 100 - \frac{2.423(1-0.05)}{2.70}100$$

$$VMA = 14.8 \text{ percent}$$

The VFA is determined to be:

$$VFA = \frac{100(VMA - V_v)}{VMA}$$

$$VFA = \frac{14.7 - 3.8}{14.7}$$

$$VFA = 79.6 \text{ percent}$$

2-4.2.9 Importance of Asphalt Content.

Previous testing has indicated that optimum asphalt content is an important factor in meeting the specified design of an asphalt paving mixture. Extensive research has resulted in criteria for determining the optimum asphalt content for a given blend of aggregates. Criteria have also been established to determine whether the aggregate furnishes the design paving mix at the selected optimum asphalt content.

2-4.2.10 Determination Optimum Asphalt Content & Acceptability of Mix.

The data plotted in graphical form in Figure 2-6(a-f) is used to illustrate the determination of optimum asphalt content. In addition to the data from Figure 2-6, optimum asphalt content and acceptability of the mix are determined based on Table 2-8. Separate criteria are shown for use where specimens were prepared with 50- or 75-blow compactive efforts. As shown in Table 2-9, the optimum asphalt content is determined at 4 percent air voids for surface or intermediate mixtures and is determined to be 4.9 percent. Table 2-10 shows that at the optimum bitumen content of 4.9 percent, this mixture meets the minimum criteria for acceptability of the mix for a 75-blow compactive effort.

2-4.2.11 Dust/Asphalt Ratio

One check of the design mixture is the dust proportion. This is the ratio of the mass of the aggregate passing the 0.075 mm (No. 200) sieve, divided by the effective asphalt content, in percent of total mass of the mixture. The normal range is 0.8 to 1.2. The ratio is intended to ensure that dust is added to the mix to provide good stability but not so much that results in excessively low asphalt content and subsequent durability problems.

Table 2-8 Design Criteria

Percent[b] VTM	HMA surface or intermediate course	3–5 percent	3–5 percent	3-5 percent	3-5 percent
	Sand asphalt	5–7 percent	NA	5-7 percent	NA
Percent VMA	HMA surface or intermediate course	See Table 2-7	See Table 2-7	See Table 2-7	See Table 2-7
	Sand asphalt	NA	NA	NA	NA
Percent VFA	HMA surface or intermediate course	75–85 percent	70–80 percent	75-85 percent	70-80 percent
	Sand asphalt	65–75 percent	NA	65-75 percent	NA

[a] Sand asphalt is not to be used for pavements having traffic with tire pressures above 690 kPa (100 psi).
[b] The theoretical maximum specific gravity is determined by the use of ASTM D2041.

Table 2-9 Determination of Optimum Asphalt Content[1]

Criteria	Asphalt Content, Percent
Flow curve	NA
Stability curve	NA
Unit-weight curve	NA
4 percent air voids from VTM curve	4.9
VMA curve	NA
VFA curve	NA

[1] Based on data in Figure 2-6.

Table 2-10 Evaluation for Acceptability of Design Mix

Test Property	4.9 Percent Asphalt	Criteria for Acceptability
Flow 0.025 centimeters (0.01 inch)	10	< 16
Stability, kN (lbf)	9.0 (2,030)	> 8.0 (1,800)
Percent VTM	4.0	3–5 percent (HMA)
Percent VMA	14.8	14 min
Percent total VFA	78	70–80 percent (HMA)

2-4.2.12 Moisture Susceptibility.

The final evaluation of the design mixture involves a test for moisture susceptibility. The TSR of the mixture at the selected optimum is performed according to ASTM D4867. A TSR value of less than 75 percent requires the use of an antistrip additive in the mixture.

2-4.2.13 Superpave Mix Design.

Superpave mix design is acceptable for airfield pavements. UFGS 32 12 15.13 provides for use of Superpave mix design as an option for the designer. Marshall mix design and Superpave mix design share common guidance. The aggregate and asphalt binder requirements are the same whether Marshall or Superpave is used. A difference is the way samples are compacted. For Marshall, samples are compacted with a Marshall hammer. For Superpave, samples are compacted with a Superpave gyratory compactor. Samples for Marshall are 102 millimeters in diameter (4 inches) and 64 millimeters tall (2.5 inches). For Superpave, samples are 150 millimeters in diameter (6 inches) and 115 millimeters tall (4.6 inches); hence, sample material is larger for a Superpave mix design than for a Marshall mix design. For Superpave, the number of gyrations is set at 75 for high tire pressures greater than 1380 kPa (200 psi) and 50 for low tire pressures for less than 1380 kPa (200 psi).

The asphalt content is varied in 0.5 percent increments just as with Marshall mix design. Stability and flow tests are not conducted for Superpave designed mixes. Plots of the data that obtained with a Superpave mix design are provided in Figure 2-6, a-d. The quality of the mix is based on air voids, VMA, and voids filled with asphalt. The specification requirements for air voids, VMA, and voids filled with asphalt are the same for Superpave as for Marshall. These properties are determined for Superpave mixtures in the same way that they are determined for Marshall mixes. The optimum asphalt content is selected at 4 percent air voids. Moisture susceptibility testing is performed to ensure acceptability of the mixture, just like with Marshall.

Hence, the Superpave mix design and Marshall mix design procedures are almost identical except for the type of compactor used, the size of sample, and the fact that flow and stability are not part of the Superpave mix design procedure. The Superpave mix design compactive effort (number of gyrations) was selected to match that for Marshall (75 blows with Marshall hammer is equal to 75 gyrations with the Superpave gyratory machine and 50 blows with the Marshall hammer is equal to 50 gyrations with the Superpave gyratory machine). Hence for a specific aggregate, it is expected that the mix design provide the same results whether using Marshall or Superpave.

2-4.3 Mixture Control.

2-4.3.1 JMF Production at Asphalt Plant.

After the aggregate and asphalt binder qualities have been determined to meet the required mix design has been completed, the next step is to ensure that the JMF is produced at the asphalt plant. To evaluate the quality of the material produced and to ensure the required paving mixture is produced, a complete plant laboratory is required. Locate the laboratory at the plant site and ensure it contains the same equipment as that listed in MS-2 or CRD-C649 and CRD-C650. Because of the capacity of asphalt plants, assign at least two technicians to conduct control tests; otherwise, all testing cannot be completed in a timely manner.

2-4.3.2 Asphalt Plant Laboratory Burden.

The heaviest demands on plant laboratory facilities occur at the initiation of plant production. Feed aggregates and asphalt binder through the plant at a relatively constant rate and at the correct proportions. The gradation of the aggregate supplied by the plant often does not precisely reproduce the job mix formula developed in mix design. This often requires that the job mix formula be modified slightly. The specifications provide guidance on how much the mix is modified without requiring a new mix design. Feed the aggregates and asphalt binder through the plant at a constant rate to obtain efficient plant operation and to produce a mixture conforming to requirements.

2-4.3.3 Mix Adjustments.

The aggregates obtained from the hot bins of batch plants cannot be proportioned to exactly reproduce the gradation of the aggregate used in the laboratory design. Similarly, the gradation of the aggregates that have passed through a drum-mixer plant do not entirely duplicate the gradation used in the mixture design. This occurs because fines are generated during handling and production operations. Usually only slight adjustments are required to the original mix design and a completely new design is not required. If the change in gradation is substantial to prevent the contractor from meeting the mix design gradation (i.e., the gradation does not meet the job mix formula), it is necessary to adjust or redesign the mix using plant-produced aggregates. Specimens are prepared and tested for the new design in the same manner as for the original design tests. The optimum asphalt content and acceptability of the mix produced by the plant are determined. Perform sufficient additional tests to establish the optimum asphalt requirements and to ensure that the mix meets the applicable criteria.

2-4.3.4 Production & Laydown Quality Control & Quality Assurance.

Control several items routinely during the production and laydown operation to provide the specified pavement. As part of the quality control program, test for and control, at a minimum, asphalt content, aggregate gradation, temperatures, aggregate moisture, moisture in the asphalt mixture, laboratory air voids, VMA, stability, flow, in-place density, grade, and smoothness. As part of a quality assurance program, test mixture items including: aggregate gradation, asphalt content, voids, and VMA. The laydown items include density, smoothness, and final grade. Measure and analyze these items statistically. These items are air voids, density (mat and joint), and final grade. When these items do not meet the specified requirements, the contract unit price is reduced or the mixture is rejected. Projects of less than 1,000 metric tons (1,000 tons) of hot-mix are constructed without the pay reduction clause for economic reasons.

2-4.3.4.1 QA Methodology.

To evaluate the quality of a job, the work is divided into lots. Each lot is considered as a separate job and as such is evaluated solely on the test results for that lot. Ensure a lot does not exceed 2,000 metric tons (2,000 tons) of production or one normal day’s production. Subdivide the lot into four equal sublots, and take a random sample from each sublot for evaluation of air voids, asphalt content, and density. The random sublot sample for these properties includes one sample of uncompacted asphalt mixture, one field core from a pavement joint area, and one field core from the compacted HMA.

ASTM D3665 provides detailed information on how to determine sampling locations within a sublot. As an example, suppose that 1,000 metric tons (1,100 tons) (one lot) of HMA were placed in two adjacent lanes, one lane 2,000 meters (6,600 feet) long and the other 1,000 meters (3,300 feet) long. The width of each paving lane was 3 meters (10 feet). The joint length between the two lanes is 1,000 meters (3,300 feet); thus, one sample is taken at random for each 250 meters (825 feet) of joint length to evaluate joint density. The total length of the two lanes is 3,000 meters (9,900 feet); therefore, take one random sample from the mat for each 750 meters (2,475 feet) of HMA. Ensure the mat core samples are at least 0.3 meter (1 foot) away from any joint, the effective width of the paving lanes is 2.4 meters (8 feet). Obtain two random numbers and multiply the first one times the length and the second times the width to give the location for the core within the sublot. In this case, with random numbers of 0.108 and 0.485, the location of the core from the beginning of the sublot is 750 meters (2,500 feet)×0.108 = 81 meters (270 feet) and 2.7 meters (9 feet)×0.485 = 1.31 meters (4.3 feet) from 0.3 meter (1 foot) inside the designated left or right edge of the pavement. The random samples do not have to be precisely located, but it is important that the procedure being used to locate the sampling location is based on a standard form of measurement and is not affected by surface appearance.

2-4.3.4.2 QC Methodology.

The asphalt content and aggregate gradation is determined from samples of the asphalt mix taken between the production and the laydown operation. It is preferred that samples be taken from the back of loaded trucks before they leave the asphalt plant. It is also acceptable to take samples from other locations such as truck at laydown site or from behind the paver. Take samples from the paver hopper or at the paver auger during production. This is not acceptable since this practice is unsafe and it is extremely difficult to obtain a sample in this way. ASTM D979 and D3665 provide information needed for obtaining samples.

If a lot size equal to 1,000 metric tons (1,000 tons) is selected, ensure a sample of asphalt mix is taken for each 250 metric tons (250 tons) produced. Obtain a random number of each 250 metric tons (250 tons) produced. As an example, suppose that a random number is selected between 1 and 250 and is determined to be 200. This selection means that the 200th ton batched is sampled.

2-4.3.4.3 Air Void and Asphalt Content Deviations from JMF.

After the four asphalt contents and corresponding void values are determined for a lot, these results are compared with the JMF and the absolute difference is determined. Suppose the design air void content is 4.0 percent and the four air void contents of the sampled mixtures are determined to be 3.5, 3.0, 4.0, and 3.7. The mean absolute deviation from the JMF is determined to be:

$$\text{Mean absolute deviation} = (0.5+1.0+0.0+0.3)/4 = 0.45$$

The same procedure is used to determine the mean absolute deviation for asphalt content. After the mean absolute deviation is determined for the air void content and asphalt content for a lot, the maximum percent payment for that lot is determined from the tables provided in the specification requirements.

2-4.3.4.4 Density Measurements.

Determine density within the mat and at the joints between mats. Density measurements for acceptance is measured from cores taken from the pavement. Density gauges are not acceptable for acceptance testing. Obtain one sample in the mat and one in the joint for each sublot. The total linear length of joint constructed for a given lot is divided into quarters and one random sample taken for each sublot. These sample locations are determined in a similar way as that for aggregate gradation and asphalt content. Take all mat samples at least 0.3 meter (1 foot) from the edge of mat or joint. Use ASTM D3665 to determine sample locations in the mat and joint. ASTM D5361 provides information on obtaining the pavement sample.

The mat density and joint density for each sublot is expressed as a percentage of the theoretical maximum density (TMD) for that sublot. When a joint core sample is taken across two sublots, the density is determined using an average of the TMD for each of the two sublots. Suppose that the TMD for four consecutive sublots within a lot was 2,408 kilograms per cubic meter, 2,398 kilograms per cubic meter, 2,389 kilograms per cubic meter, and 2,421 kilograms per cubic meter, yielding an average TMD value of 2,404 kilograms per cubic meter. Further assume that the corresponding four sublot mat samples have individual densities of 2,324 kilograms per cubic meter, 2,356 kilograms per cubic meter, 2,348 kilograms per cubic meter, and 2,373 kilograms per cubic meter, and that the four corresponding sublot joint samples have individual densities of 2,311 kilograms per cubic meter, 2,324 kilograms per cubic meter, 2,343 kilograms per cubic meter, and 2,325 kilograms per cubic meter. Based on these results, the mat lot density is determined as:

$$\text{Mat density} = \frac{2{,}324 + 2{,}356 + 2{,}348 + 2{,}373}{4(2{,}404)} = 97.8\ \text{percent}$$

and the average joint density is:

$$\text{Joint density} = \frac{2{,}311 + 2{,}324 + 2{,}343 + 2{,}325}{4(2{,}404)} = 96.8\ \text{percent}.$$

The average density in the mat and the average density in the joint are used along with the tables in the specifications to determine the maximum percent payment for the lot of material being evaluated.

2-4.3.4.5 Evaluation of Grade and Smoothness.

The surface of the completed pavement is evaluated on a systematic basis to determine the acceptability of grade and smoothness. The results are compared with the specification requirements to determine the percent payment for grade and smoothness.

2-4.3.4.6 Quality Control Charts.

To properly evaluate the quality control of a mixture and maintain up-to-date records of test results, maintain control charts. It is recommended that the control charts be plotted for the critical sieves in the gradation requirements. The critical sieves include the 4.75 millimeters (No. 4) and 75 micrometers (No. 200) sieves. The plots are also to be made for asphalt content, laboratory density, stability, flow, VTM, VFA, mat density, and joint density. Make a plot of individual values and for the running average of four samples.

Subparagraphs a through c provide an example of the use of control charts. Assume that the density results shown in Table 2-11 were obtained from the in-place mat.

Table 2-11 Lot Density as a Percent of Laboratory Density

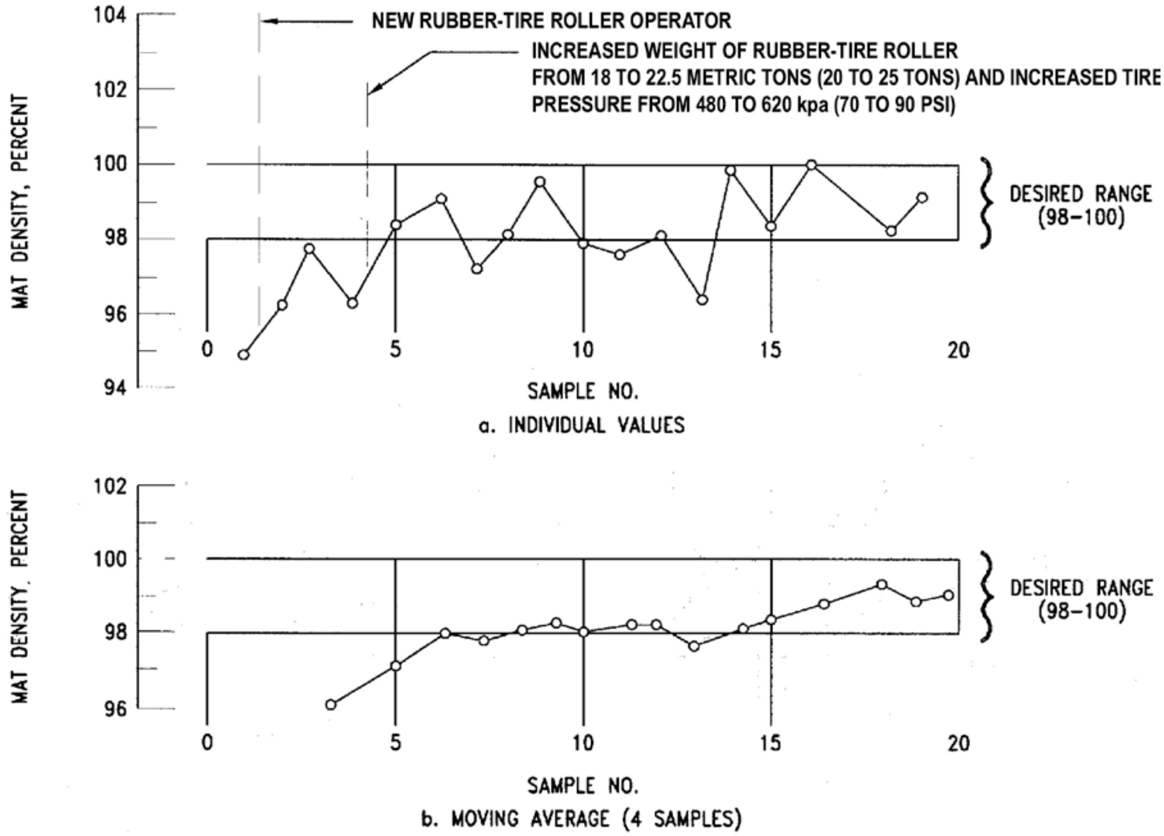
Lot 1	Lot 2	Lot 3	Lot 4	Lot 5
95.2	98.4	99.5	98.1	100.0
96.4	99.1	98.0	96.8	99.1
97.8	97.3	97.5	99.8	98.3
96.6	98.1	98.3	98.6	98.9
Average				
96.5	98.2	98.3	98.3	99.1

a. Figure 2-7 shows the control charts for mat density. The first test result obtained is plotted in Figure 2-7, a. Note that this measurement falls below the desired range. At this point, it is concluded that the process is out of control; thus, stop the operation until the cause of the deficiency is identified and corrected.

b. The second, third, and fourth samples are those obtained after corrections to the process, and they are higher but still below the desired range. At this point, the weight of the rubber-tired roller used to compact the mat was increased from 18 to 22.5 metric tons (18 to 22 tons), and the tire pressure was increased from 480 to 620 kilopascals (70 to 90 psi). After these changes, the density results were within the desired range.

c. The moving average is determined for the last four samples tested (Figure 2-7, b). Plotting the moving average smoothes out the plot of individual values and allows trends to be spotted more readily.

Figure 2-7 Mat Density Control Chart



2-4.4 Significance of Changes in Mixture Properties.

As a general rule, most of the QC test results (for example, air voids, VMA, asphalt content, gradation) are obtainable quickly and are reasonably reliable indicators of the consistency of the plant-produced mix. A measurable change in these properties or properties outside the specified limits indicates that there is a mixture problem. A review of the control charts normally indicates the problem. Adjust mix proportions whenever any test property consistently falls outside of the specified tolerances. In the case of batch plants, the use of faulty scales and the failure of the operator to accurately weigh the required proportions of materials are common causes for paving-mixture deficiencies. Improper weighing or faulty scales need to be detected readily and corrective measures taken by maintaining a close check of load weights. Figure 2-8 lists other probable causes of paving-mixture deficiencies. For drum mix plants, a mixture problem typically is an indication that the rate of feed of one or more of the materials into the plant is incorrect.

Figure 2-8 Types of HMA Deficiencies and Probable Causes

Probable Causes of Deficiencies in Hot Plant Mix Paving Mixtures / Types of Deficiencies That May Be Encountered in Producing Hot Plant Mix Paving Mixtures

Item	Probable Cause	Bitumen content fails to check job-mix formula	Gradation fails to check job-mix formula	Poorly mixed loads	Fat, rich mixtures	Lean or burned mixtures	Mixture temperature fails to check job mix	Smoking loads	Steaming loads	Overweight or underweight loads	Lack of uniformity of mixtures in loads
1	Aggregate scales out of adjustment	X	X		X	X					
2	Bridging of hot aggregate in bin		X							X	X
3	Bitumen scales out of adjustment	X			X	X				X	X
4	Lack of proper weighing by operator	X	X		X	X				X	X
5	Faulty pug mill dump gate	X	X	X	X	X				X	X
6	Bitumen temperature too high			X	X	X	X				X
7	Drum feed not uniform						X	X	X		
8	Improper dryer operation					X	X	X	X		
9	Too little bitumen	X				X					X
10	Too much bitumen	X			X						X
11	Sampling method not uniform	X	X		X	X					
12	Excessive moisture content of aggregate								X		X
13	Bin overflow pipes not functioning	X	X								X
14	Leaky bins	X	X		X	X					X
15	Segregation of aggregates in bins		X								X
16	Mixing time not uniform	X		X							X
17	Mineral filler feed not uniform	X	X		X						X
18	Aggregate temperature too high					X	X	X			
19	Temperature mechanism out of adjustment					X	X	X	X	X	X
20	Improper feed of aggregates to dryer	X	X		X	X		X	X		X
21	Overrated dryer capacity						X		X		X
22	Faulty screen operation		X								X
23	Overloaded pug mill			X							X
24	Improper set on pug mill	X	X	X							X
25	Bitumen and aggregate feed out of adjustment	X	X		X	X					X
26	Bitumen pump not functioning properly	X			X	X					
27	Not sufficient hot aggregate in storage bins	X	X								X
28	Aggregate gates not properly set	X	X		X	X					X

Items 6 to 23 are applicable to all types of plants. Items 1 to 5 and items 24 to 28 are applicable to batch plants and volumetric plants, respectively.

2-4.4.1 Hot-bin Gradations.

When batch plants are used, conduct the hot-bin gradation tests at least once daily during operation. Determine hot-bin gradations on all bins in conjunction with sampling of the pavement mixture. Determine washed sieve analyses initially.

2-4.4.2 Construction Control.

Well-designed mixes are compacted by adequate field rolling to about 98 percent or greater of the density obtained by compacting specimens with previously specified laboratory procedures (or at least 94 percent of theoretical maximum density). Roll asphalt intermediate, base course, or surface course mixes until the density specified is met.

2-4.4.3 Pavement Sampling.

Take samples for determining pavement density and thickness either with a coring machine (with a core barrel nominal diameter of at least 100 millimeters (4 inches)) or by cutting out a section of pavement at least 100 millimeters (4 inches) square with a concrete saw. When the compacted thickness of the pavement is less than 50 millimeters (2 inches), use a 150-millimeter (6-inch) -diameter core barrel to obtain the sample. Ensure these samples include the entire thickness of the layer of asphalt mixture being evaluated. Take density samples of each day’s production and have delivered to the project laboratory by noon of the following day, and make the density determinations by the end of the day. Any changes in placing technique to obtain the required density is made immediately prior to placing additional pavement.

2-4.4.4 Testing Pavement Samples.

Prepare pavement samples for testing by carefully removing all particles of base material or other foreign matter. Carefully trim broken or damaged edges of sawed samples for density tests carefully from the sample. Take thickness measurements before separating the sample into layers. Split a sample consisting of an intermediate course and surface course at the interface of these layers before testing. Usually these courses are separated with only a few blows of a sharp-edged chisel at the interface. When possible, use a concrete table saw to separate layers of pavement. This is true when the underlying surface was a milled layer or the asphalt was placed directly on a crushed stone base. Eliminating excess tack, uncoated aggregate, and voids from the bottom of a core sample greatly increase the accuracy of density measurements. Determine the density of the sawed samples by weighing them in air and in water and as described in paragraphs 2-4.2.6 and 2-4.2.8. Discard samples from which density measurements are desired if damage is apparent. Take additional samples from the same sublot.

Nuclear gauges and other nondestructive density tests are currently being used to check the density of HMA. These methods are fast, but the results are often questionable. Factors that affect the results of density measurements with the nondestructive gauges are the thickness of the asphalt mixture, the density of the material below the asphalt mixture, moisture, and smoothness at the test location. The nondestructive density gauges are useful for developing roller patterns, but conduct density tests for acceptance by removing samples from the pavement and weighing them in air and water to determine density.

2-4.4.5 Density Data.

Density data obtained from specimens in the manner described in paragraphs 2-4.2.6 and 2-4.2.8 is compared with the average laboratory density or theoretical maximum density for the same lot.

2-4.4.6 Pavement Imperfections and Probable Causes.

Pavement imperfections result from not following specified laying and rolling operations as well as not meeting specified mix designs or faulty plant operation. These imperfections are controlled only by inspection. Figure 2-9 presents these potential pavement imperfections result.

2-5 POROUS FRICTION COURSE.

A PFC is an open-graded, free-draining asphalt paving mixture that is placed on an existing pavement to minimize hydroplaning and to improve skid resistance in wet weather. PFC is just another name for open-graded friction course (OGFC) used by many state DOT agencies. Do not use this surface for low-speed applications or in areas subjected to tank traffic. The thickness of the finished course varies from approximately 19 millimeters (3/4 inch) to 25 millimeters (1 inch). A PFC has a coarse surface texture and is sufficiently porous to permit drainage of water internally as well as along the surface. A combination of water pressure relief through the internal and surface voids and the rough surface texture promotes tire-to-aggregate contact. PFC paving mixtures are produced in HMA plants and placed with conventional asphalt paving machines. Place them on pavements that are in good condition. Similar to Section 2-1.2, determine if a leveling course is required to achieve the desired surface conditions before construction of the PFC. Due to performance issues, FOD potential, PFCs have not been used on airfields in recent years.

2-5.1 Materials.

2-5.1.1 Aggregates.

High-quality aggregates are required for PFCs with a maximum Los Angeles (LA) abrasion loss (ASTM C131) of 25 percent and 40 percent for high and low tire pressure loadings, respectively. A crushed aggregate is required and has a minimum of 90 percent by total weight of aggregate with one crushed face and 70 percent with two crushed faces. Specify antistrip agents when required. Design, specify and use an antistripping agent not only in the PFC but also in the underlying HMA layer regardless of the results from the TSR test (ASTM D4867/D4867M). Table 2-12 presents the aggregate gradation requirements for PFCs.

Figure 2-9 Types of HMA Pavement Imperfections and Probable Causes

Probable Causes of Imperfections in Finished Pavements \ Types of Pavement Imperfections That My Be Encountered in Laying Hot Plant Mix Paving Mixtures	Bleeding	Brown, dead appearance	Poor surface texture	Rough uneven surface	Uneven joints	Roller marks	Shoving	Waves	Cracking	Honeycomb	Tearing of surface during laying
Excessive moisture in mixture		X					X				
Not cut back to uniform thickness					X						
Inadequate cross rolling				X		X					
Excess of bitumen in mixture	X						X				
Lack of bitumen in mixture		X							X		X
Mixture too coarse	X		X						X	X

Table 2-12 Aggregate Gradation for PFCs

Sieve Designation (Square Openings)	Percent Passing by Weight of Total Aggregates	
	Gradation "A" 19 mm (3/4-inch) Maximum (Compacted Nominal Thickness, 25 mm, 1 inch)	Gradation "B" 12.5 mm (1/2-inch) Maximum (Compacted Nominal Thickness, 19 mm, 3/4 inch)
19 mm (3/4 inch)	100	100
12.5 mm (1/2 inch)	70–100	100
9.5 mm (3/8 inch)	35–75	80–100
4.75 mm (No. 4)	25–40	25–40
2.36 mm (No. 8)	10–20	10–20
600 µm (No. 30)	3–10	3–10
75 µm (No. 200)	0–5	0–5

2-5.1.2 Asphalt Cement.

Test requirements for asphalt cements are outlined in specifications (ASTM D946, D3381, D6373, or AASHTO M320). Guidance on the selection of an asphalt type is provided in section 2-3.1. Historically, many PFCs were constructed using modified asphalt to improve the ability of the asphalt to hold the aggregate in place and reduce oxidation deterioration in the porous mat. When using PFC, specify polymer modified asphalt cement.

2-5.2 Mixture Design.

2-5.2.1 Proportioning of Aggregates.

For PFC use polymer modified asphalt and fibers. The modified asphalt and fibers help to reduce draindown when storing for a short period of time and during haul to the paving site. Select the aggregate gradation from Table 2-12.

2-5.2.2 Fiber Stabilizers.

Tables 2-13 and 2-14 provide the requirements and test procedures to be used with cellulose and mineral fibers, respectively. The dosage rates normally used for cellulose fibers is 0.3 percent by weight of the total mix and for mineral fibers is 0.4 percent by weight of the total mix. The recommended tolerance for the fibers is 10 percent of the required fiber weight.

Table 2-13 Properties of Cellulose Fibers (after NAPA 1999)

Properties	Requirement
Sieve Analysis Method A, Alpine Sieve[1] Analysis Fiber length Passing 150 μm (No. 100) sieve Method B, Mesh Screen[2] Analysis Fiber length Passing 850 μm (No. 20) sieve 425 μm (No. 40) sieve 106 μm (No. 140) sieve	 6 mm (0.25 in.) (max.) 70% (±10%) 6 mm (0.25 in.) (max.) 85% (±10%) 65% (±10%) 30% (±10%)
Ash Content[3]	18% (±5%) non-volatiles
pH[4]	7.5 (±1.0)
Oil Absorption[5]	5.0 (±1.0) (times fiber weight)
Moisture Content[6]	< 5% (by weight)

[1] Method A, Alpine Sieve Analysis. This test is performed using an Alpine air jet sieve (Type 200 LS). A representative 5-gram (0.18 oz) sample of fiber is sieved for 14 minutes at a controlled vacuum of 75 kPa (11 psi). The portion remaining on the screen is weighed.

[2] Method B, Mesh Screen Analysis. This test is performed using standard 850, 425, 250, 180, 150, 106 μm (No. 20, 40, 60, 80, 100, 140) sieves, nylon brushes, and a shaker. A representative 10-gram sample of fiber is sieved using a shaker and two nylon brushes on each screen. The amount retained on each sieve is weighed and the percentage passing calculated. Repeatability of this method is suspect and needs to be verified.

[3] Ash Content. A representative 2- to 3-gram (0.07 – 0.11 oz) sample of fiber is placed in a tared crucible and heated between 595 and 650 degrees C (1100 and 1200 degrees F) for not less than 2 hours. The crucible and ash are cooled in a desiccator and reweighed.

[4] pH Test. Five grams (0.18 oz) of fiber is added to 100 ml (0.106 quarts) of distilled water, stirred, and let sit for 30 minutes. The pH is determined with a probe calibrated with pH 7.0 buffer.

[5] Oil Absorption Test. Five grams(0.18 oz) of fiber is accurately weighed and suspended in an excess of mineral spirits for not less than 5 minutes to ensure total saturation. It is then placed in a screen mesh strainer (0.5 square millimeter [7.75×10^{-4} square inch] hole size) and shaken on a wrist action shaker for 10 minutes, 3.2 centimeter (1.25 inch) motion at 240 shakes per minute). The shaken mass is then transferred without touching, to a tared container and weighed. Results are reported as the amount (number of times its own weight) the fibers absorb.

[6] Moisture Content. Ten grams (0.35 oz) of fiber is weighed and placed in a 121 degrees C (250 degrees F) forced air oven for 2 hours. The sample is then reweighed immediately upon removal from the oven.

Table 2-14 Properties of Mineral Fibers[1] (after NAPA 1999)

	Properties	Requirement
Sieve Analysis	Fiber length[2]	6 mm (0.25 in.) max. mean text value
	Thickness[3]	5 μm (0.0002 in.) max. mean test value
Shot Content[4]	250 μm (No. 60) sieve	95 percent passing (min.)
	63 μm (No. 230)	65 percent passing (min.)

[1] The European experience and development of the above criteria are based on the use of basalt mineral fibers.

[2] The fiber length is determined according to the Bauer-McNett fractionation.

[3] The fiber diameter is determined by measuring at least 200 fibers in a phase contract microscope.

[4] Shot content is a measure of non-fibrous material. The shot content is determined on vibrating sieves. Two sieves, 250 μm (No. 60) and 63 μm (No. 230), are used; for additional information see ASTM C612.

2-5.2.3 Asphalt Content.

The asphalt content of PFCs is expressed as a percentage of the total mix by weight. A surface area constant, K_c, as described in the centrifuge kerosene equivalent (CKE) test (ASTM D5148), is used to determine the optimum asphalt content. The K_c value is used in the relation $2K_c+4.0$ to determine the estimate of asphalt (EOA). This asphalt content is valid for aggregates with an apparent specific gravity in the range of 2.60 to 2.80 and with a water absorption value less than 2.50 percent when tested by ASTM C127 for coarse aggregate and ASTM C128 for fine aggregate. A slight increase in asphalt content (up to 0.5 percent) is required when the absorption is greater than 2.50 percent. The EOA is inversely proportional to the specific gravity of the aggregate, ensure adjustments are made when the specific gravity is outside of the 2.60 to 2.80 range.

2-5.2.4 K_c Factor.

The K_c factor indicates the relative particle roughness and surface capacity based on the porosity of the aggregate to be used for the PFC. The K_c factor is determined from the percent of Society of Automotive Engineers (SAE) 10 oil retained, which represents the total effect of the coarse aggregate's absorptive properties and surface roughness. The K_c factor is determined from that portion of the aggregate sample that passes the 9.5-millimeter (3/8-inch) sieve and is retained on the 4.75-millimeter (No. 4) sieve using the procedure described in ASTM D5148. If the specific gravity for the aggregate is greater than 2.70 or less than 2.60, apply a correction to oil retained using the formula given in ASTM D5148. No correction need be applied for asphalt viscosity.

2-5.2.5 Mixing Temperature.

Mixing temperature to provide an asphalt viscosity of 275±25 centistokes is obtained by evaluating the temperature-viscosity relationship for the type of asphalt selected at a minimum of three temperatures (ASTM D2170 and ASTM D2171). ASTM D2493 provides details for plotting this information on a graph with temperature versus log viscosity. Plotting this information normally results in a straight-line relationship, and the temperature for the correct viscosity is chosen from the graph.

2-5.3 Plant Control.

2-5.3.1 Plant Laboratory.

A plant laboratory is needed to ensure that the aggregate is properly graded and the mix contains the prescribed percentage of asphalt binder. Locate the laboratory at the plant to minimize the time between production and testing.

2-5.3.2 Sieve Analysis.

Conduct all sieve analyses by the method described in ASTM C136. Recommended sieve sizes for plant sieve analysis are: 19 millimeter (3/4 inch), 12.5 millimeter (1/2 inch), 9.5 millimeter (3/8 inch), 4.75 millimeter (No. 4), 2.36 millimeter (No. 8), 600 micrometers (No. 30), and 75 micrometers (No. 200). For batch-mix plants, accomplish sieve analyses on material from each plant hot bin. Obtain samples for these sieve analyses after a few tons of aggregate have been processed through the dryer and screens so that the sample is representative. For drum mixers, make the sieve analysis directly from the cold feeds. Final mix proportions are determined on the basis of these analyses. For both types of plants, aggregate gradations will also be conducted on the aggregate recovered from the asphalt mixture.

2-5.3.3 Asphalt Content Tests.

Accomplish extraction tests in accordance with ASTM D2172. A nuclear gauge is used to determine the asphalt content, when tested in accordance with ASTM D4125, provided the gauge is calibrated. The asphalt content is also determined by the ignition method in accordance with ASTM D6307. Follow procedures specified in ASTM D5444 for sieve analysis. If the nuclear gauge is used to measure asphalt content, there is no way to recover the aggregate from the mixture for testing.

2-5.3.4 Mix Proportions.

Adjust mix proportions whenever tests indicate that specified tolerances are not being met. In the case of batch plants, common causes for mixture deficiencies are faulty scales and the failure of the operator to accurately weigh the required proportions of materials. Detect failure of accurate weighing or faulty scales and take corrective measures by maintaining a close check of load weights. Figure 2-8 presents other probable causes of mixture deficiencies due to plant operations.

2-5.3.5 Controlling Plant Production.

Normally the plant inspector obtains a sample of the PFC mix after the plant has been in production for 30 minutes. Test the sample as rapidly as possible for compliance with gradation and asphalt content requirements. If plant is too far from the construction site, draindown potentially occurs during haul due to the extended period of haul time.

2-5.4 Construction.

2-5.4.1 Pavement Control.

A PFC pavement has no density requirements. A characteristic of this overlay is its rapid cooling. If minimum asphalt drainage is desired, ensure the roller closely follows the paver to initially set the PFC so that asphalt drainage is minimized. If drainage in the truck or the paver causes a rich spot (excess asphalt cement) in the pavement, and warm weather conditions exist (high temperatures), rolling is delayed to allow the asphalt to drain into the PFC. Two passes with a 10-metric ton (10-ton) steel-wheel roller (in static mode if a vibratory roller) is required to properly seat the PFC mix.

2-5.4.2 Pavement Sampling.

Samples for determining thickness (ASTM D979) are taken either with a coring machine or by cutting out a sample of pavement at least 100 millimeters (4 inches) square with a concrete saw. Ensure the sample includes the entire thickness of the PFC.

2-5.4.3 Storage Silos.

Avoid storage of PFC mix whenever possible; the maximum allowable storage time under any circumstance is not to exceed 1 hour. Excessive storage time allows the asphalt to drain, causing segregation of the mixture. Coordination between the plant and the laydown operations eliminates the need for extended storage.

2-5.4.4 Pavement Operations under Normal Conditions.

Guide specifications do not permit placement of PFC when the surface temperature of the existing pavement is below 16 degrees C (60 degrees F). Ensure the contractor applies the specified rolling before the mixture becomes too cool to be properly seated. Generally, perform all rolling before the PFC mixture cools to 80 degrees C (175 degrees F). A PFC cools quickly because of the thin layer of material and high void content in the thin PFC layer.

2-6 STONE MATRIX ASPHALT.

SMA is a mixture of aggregate, mineral filler, asphalt cement, and a stabilizer (modified asphalt with or without the addition of cellulose or mineral fiber). SMA is designed to minimize rutting and abrasions even under high loads and high tire pressures. SMA mixtures depend on aggregate-to-aggregate contact to support traffic loads, therefore their mix design requires a higher percentage of coarse aggregate than HMA. Excess fine aggregate or too much mastic prevents the coarse aggregate particles from obtaining full contact and therefore lowers the mixture's resistance to rutting. The high void content of the mix is occupied by fine aggregate, mineral filler, asphalt cement, and a stabilizer (polymer, cellulose, or mineral fiber), which forms a mastic portion of the SMA mixture. This mastic stabilizes the coarse aggregate and reduces the final air voids in the SMA to 3 to 4 percent. SMA is comparable to HMA in regards to structural design, mix design, and construction. SMA originated in Europe and has recently been placed by state and federal agencies on projects throughout the country. The design and construction of SMA pavements are described in this chapter.

2-6.1 Materials.

2-6.1.1 Aggregates.

The gradation used for SMA is gap-graded for the coarse aggregate retained on the 4.75-millimeter (No. 4) sieve. This coarse aggregate makes up from 72 to 80 percent of the aggregate in the mix. Ensure 100 percent of the coarse aggregate passes the 19-millimeter (3/4-inch) sieve, and the amount of the fine material passing the 75-micrometer (No. 200) sieve is from 8 to 10 percent. Table 2-15 lists the gradation as recommended by the NAPA and FHWA. This gradation is based on the recommendations of a technical working group jointly representing NAPA and FHWA that reviewed the performance of SMA mixtures in place. Table 2-16 lists the recommended coarse and fine aggregate properties for SMA. Another test that is often used for airfield specs is ASTM C142, *Clay Lumps and Friable Particles*, which might be used in place of ASTM D3744, coarse and fine durability index.

2-6.1.2 Filler.

As presented in Table 2-15 for SMA mixtures, the recommended amount of aggregate filler (dust) passing the 75-micrometers (No. 200) sieve is 8 to 10 percent. This amount of filler in the SMA is higher than that usually found in dense-graded HMA. The amount of filler is important in obtaining the desired mixture air voids and in affecting the optimum asphalt content. The SMA asphalt content is sensitive to the aggregate fines and filler content. SMA mixtures commonly employ a filler-to-asphalt ratio of 1.5 and higher. In contrast, conventional dense-graded hot mix recommends a filler-to-asphalt ratio of less than 1.2. A well-graded filler with less than 20 percent of the total filler smaller than 20 micrometers (0.001 inch) is required. Commercial fillers are added by mineral filler feeder systems. Fly ash, limestone dust, and other types of rock dust have been used successfully as fillers for SMA applications.

2-6.1.3 Stabilizer.

There is a tendency for the asphalt binder to drain from the aggregate during storage, transportation, or placement because of the high asphalt content in the mix, the thick asphalt coating on the coarse aggregate, and the high voids in the aggregate skeleton. To reduce this drainage potential, stabilizers are used to stiffen the mastic or to increase the asphalt binder viscosity. These stabilizers are categorized into two groups: (1) either cellulose fibers or mineral fibers, and (2) polymers. When SMA has been placed with a combination of fibers and asphalt polymer, the fibers have been shown to perform better at reducing draindown than polymers.

Table 2-15 SMA Gradation Guideline (after NAPA 1999*)

Sieve Size	Percent Passing
19 mm (3/4 in.)	100
12.7 mm (1/2 in.)	85–95
9.5 mm (3/8 in.)	75 maximum
4.75 mm (No. 4)	20–28
2.36 mm (No. 8)	16–24
600 μm (No. 30)	12–16
300 μm (No. 50)	12–15
75 μm (No. 200)	8–10
*National Asphalt Pavement Association, publication QIP-122	

2-6.1.3.1 Fiber Stabilizers.

Tables 2-13 and 2-14 provide the requirements and test procedures to be used with cellulose and mineral fibers, respectively. The dosage rates normally used for cellulose fibers is 0.3 percent by weight of the total mix and for mineral fibers is 0.4 percent by weight of the total mix. The recommended tolerance for the fibers is 10 percent of the required fiber weight.

2-6.1.3.2 Asphalt-Polymer Stabilizers.

SMA mixtures have been placed using a polymer to modify the asphalt cement and stabilize the mixture so that fibers are not required. There have also been instances where a polymer and a fiber have been used in conjunction to stabilize SMA mixtures. Follow the manufacturer’s design and construction recommendations when the standard SMA guidelines are not applicable for asphalt-polymer stabilizers.

Table 2-16 Recommended SMA Coarse and Fine Aggregate Properties (after NAPA 1999)

Property	Specifications	Requirement
Coarse aggregate:		
LA abrasion, %	ASTM C131, AASHTO T96	30 max.
Flat and elongated, +No. 4 3 to 1 (length to thickness), % 5 to 1 (length to thickness), %	ASTM D4791	 20 max. 5 max.
Fractured faces, +No. 4 One fractured face, % Two fractured faces, %	CRD-C171	 100 min. 90 min.
Absorption, %	ASTM C127, AASHTO T85	2 max.
Coarse and fine durability index	ASTM D3744, AASHTO T210	40 min.
Sulfate soundness loss, 5 cycles Sodium sulfate, % or Magnesium sulfate, %	ASTM C88, AASHTO T104	 15 max. 20 max.
Fine aggregate:		
Crushed manufactured fines, %		100 min.
Sulfate soundness loss, 5 cycles Sodium sulfate, %		 15 max.
Liquid limit	ASTM D4318, AASHTO T89	25 max.

2-6.1.4 Asphalt.

Ensure the asphalt cement complies with the requirements of ASTM D946, ASTM D3381, or ASTM D6373, and the asphalt cement used is the grade normally used in the area by the local DOT or on previous Department of Defense (DoD) projects. When using ASTM D6373, the grade is normally bumped to be equal to that specified for heavy traffic. Ensure the temperature of the asphalt cement at the time of mixing is that required to achieve a viscosity of 170±20 centistokes. Where polymer modified asphalt cement is used, manufacturer’s recommendations for mixing temperature are to be followed.

2-6.2 Mixture Design.

Determine optimum asphalt content with procedures similar to those outlined in section 2-4.3. Table 2-17 contains the recommended mix design requirements for SMA, which are based on the requirements in AASHTO MP8.

Table 2-17. SMA Mix Design Requirements (after NAPA 1995)

Design Parameter	Value
Marshall[1]	
(1) VTM, percent[2]	3–4
(2) Asphalt content, percent[3]	6.0 min.
(3) VMA[4]	17 min.
(4) Stability, N (lbf)	6200 (1400) suggested minimum
(5) Flow, 0.25 mm (0.01 in.)	8–16
(6) Compaction, number of blows on each side of test specimen	50
(7) Draindown, percent[5]	0.3 max. (1 hour reading)

[1] Marshall procedures are in accordance with AASHTO T245 (ASTM D6927).
[2] VTM (voids in total mix or air voids) is based on AASHTO T166, T209 (ASTM D2041), and T269 (ASTM D3203). Maximum density is based on AASHTO T209 (ASTM D2041).
[3] Based on weight of total mix.
[4] VMA (see Asphalt Institute MS-2).
[5] ASTM D6390

2-6.2.1 SMA Draindown Test.

For the purpose of this test method (ASTM D6390), draindown is considered to be that portion of the asphalt cement that separates itself from a sample of uncompacted SMA mixture as a whole and is deposited outside the wire basket during the test. This test method is used to determine whether the amount of draindown measured for a given SMA mixture is within acceptable levels. This test method also provides an evaluation of the draindown potential of an SMA mixture produced in the field.

2-6.2.2 JMF Requirements.

It is the contractor's responsibility to ensure that, in addition to meeting the aggregate gradation requirements, the produced material provides an asphalt mixture that conforms to the applicable design parameters listed in Table 2-17. Submit in writing the proposed JMF in accordance with contract specifications, including:

a. The percentage (in units of 1 percent) of aggregate passing each specified sieve (except the 75-micrometer (No. 200) sieve), based on the total dry weight of aggregate as determined by ASTM C117 and C136.

b. The percentage (in units of 1/10th of 1 percent) of aggregate passing the 75-micrometer (No. 200) sieve, based on the dry weight of aggregate as determined by ASTM C117.

c. The percentage (in units of 1/10th of 1 percent) of aggregate finer than 0.020 millimeter (7.87×10^{-4} inch) in size, based on the dry weight of aggregate as determined by AASHTO T 88-13 (2017).

d. The percentage (in units of 1/10th of 1 percent) of asphalt material to be added based upon the total weight of mixture.

e. The proposed percentage of each stockpile to be used, the average gradation of each stockpile, and the proposed target value for each sieve size. Ensure the target values and the combined average gradation of all the stockpiles when combined in accordance with the contractor's recommended stockpile combinations are within the gradation ranges for the designated grading in Table 2-12.

f. The type and amount by weight of mix of stabilizer additive to be used.

g. Additional information required as part of the JMF includes:

(1) The material sources for all ingredients.

(2) The material properties, as listed, for all ingredients:

(a) The specific gravities of the individual aggregates and asphalt.

(b) The LA abrasion of the aggregates.

(c) The sand equivalent value of the combined aggregate.

(d) The flat and elongated percent of the coarse aggregate (3-to-1 and 5-to-1 ratios) retained above the 4.75 millimeter (No. 4) sieve.

(e) The plasticity index of the aggregate.

(f) The absorption of the aggregates.

(g) The asphalt temperature/viscosity curves.

(3) The mixing temperature.

(4) The mix design test property values and curves used to develop the job mix in accordance with those provided for HMA in this chapter and also in the Asphalt Institute's MS-2.

(5) The plot of the gradation on the FHWA 0.45 power gradation chart.

2-6.3 Mixing Plants.

SMA has been mixed in both batch and drum-mix plants. However, make required adaptations to meet the SMA components mix design.

2-6.3.1 Batch Plants.

The mineral filler is added directly into the weigh hopper. Batch plants have an existing mechanism for accomplishing this; however, attention is required to assure accurate proportioning of the amounts of filler required for SMA. The fiber is also added directly into the weigh hopper, which occurs when the hot aggregate is also being placed into the hopper. An alternative method of adding the fibers directly to the pugmill as the hot aggregates are added has also been used successfully.

2-6.3.2 Drum-Mix Plants.

The mineral filler is added directly into the drum mixer. Attention is required to assure accurate proportioning of the amounts of filler added. The fiber is also added directly into the drum mixer. A separate feeding system is usually employed, in the case of loose fibers. Ensure these fibers are added to the aggregates to avoid direct contact with the burner flame.

2-6.3.3 Mixing Time.

The time required to mix SMA is usually greater than that to mix dense-graded HMA. For batch plants, the dry-mixing time is increased from 5 to 15 seconds, and wet-mixing is increased at least 5 seconds for cellulose fibers and up to 5 seconds for mineral fibers.

2-6.3.4 Storage.

Temporary (less than 1 hour) storage of SMA in surge bins is used only for balanced production capacity. Limit storage in heated and insulated storage bins to 4 hours unless laboratory testing indicates that additional time is acceptable. Base acceptability on no adverse changes in binder properties and excessive draindown not occurring. Do not store mixture overnight.

2-6.4 Test Section.

The construction of a test section is important to allow examination of the contractor’s mixing and placement procedures. This is true if the contractor has not had experience in mixing or placing SMA.

2-6.5 Placement.

2-6.5.1 Equipment.

The trucks, pavers, distributors, and other general equipment are the same as those used for any asphalt concrete (AC) construction. Only steel-wheel rollers are used for SMA. Rubber-tire rollers are not used since they tend to pick up the rich mix excessively. Vibratory rollers are used, but take care to prevent breakdown (fracture) of the aggregate.

2-6.5.2 Surface Preparation.

Clean the surface of all loose or deleterious material. Apply a tack coat as described in section 3-3. A minimum atmospheric temperature of 7 degrees C (45 degrees F) and rising is required at the time of placement.

2-6.5.3 Paving.

Ensure the SMA mixture, when delivered to the paver, is at a temperature sufficiently high for good compaction but not so high as to damage the asphalt binder. Never exceed 177 degrees C (350 degrees F) for the mixture temperature.

2-6.5.4 Compaction.

Compact the SMA to a minimum of 94 percent of maximum theoretical density. Use steel-wheel rollers for rolling. Vibratory rollers are used provided that the aggregate is not excessively crushed. Rubber-tire rollers do not perform well with SMA due to the high amounts of asphalt cement in the mixture causing asphalt buildup on the wheels. Continue rolling until the required density is obtained. This is usually controlled through the use of a nuclear density gauge. Due to the amount of binder coating the aggregate particles, it is important that the roller drums be properly moistened with water containing small amounts of detergent to prevent adhesion. Ensure traffic remains off the SMA surface until it has cooled below a minimum of 60 degrees C (140 degrees F). One method that has been used to increase the rate of cooling to allow for earlier trafficking is flooding with water from a truck after the completion of all rolling.

2-7 WARM-MIX ASPHALT.

In recent years, processes that allow mixtures to be constructed at lower temperatures have been developed, and these lower temperature mixtures are referred to as warm-mix asphalt. A number of processes have been used, but specific processes are not discussed here. These processes allow the asphalt mixture to be mixed and placed at temperatures of 132 degrees C (270 degrees F) down to 110 degrees C (230 degrees F). The techniques involve using additives to change the viscosity of the asphalt at the higher temperatures or a foaming process. Generally, these warm mixes meets the requirements for HMA. While there has been little use on airfields, there has been significant use on highways. It is anticipated that use of warm-mix asphalt (WMA) increases significantly on airfields in future years. Early performance of WMA has been good. Use UFGS 32 12 15.13 as the guide specification for WMA. Prior to using WMA, contact the Pavements Discipline Working Group (DWG) or their designated representative.

The primary purpose of WMA is to reduce emissions during production. The additional cost for producing WMA is often offset by the savings in fuel cost. Hence, WMA potentially is a little lower cost than HMA or it might be a little higher depending on location and other factors. Besides reducing emissions, WMA also has other benefits including improved workability and ability to provide a mixture easier to compact during cooler weather. There have been a number of studies for roads and for airfields comparing the performance of WMA and HMA. So far, studies have shown that WMA and HMA have similar performance characteristics. One thing that has to be monitored, when WMA is used just as with HMA, is the moisture in the mix. Since mix temperatures are lower with WMA, the amount of moisture tends to be a little higher as specified in the mix design. So far, this has not been a significant problem but it is one that has to be monitored.

There are approximately 30 products/techniques for producing WMA. All of these have not been determined to be viable for airfields. UFGS 32 12 15.16 provides an approach for determining viable products. There are no significant differences in production, placement, and compaction of WMA and HMA.

This Page Intentionally Left Blank

CHAPTER 3 SPRAY APPLICATIONS

3-1 INTRODUCTION.

“Spray application” is a term used to describe many different types of asphalt applications. An economical maintenance and repair method for flexible pavements is accomplished using spray applications of an asphalt material. When properly constructed, asphalt spray applications are economical as well as long lasting and are beneficial in treating or improving the pavement condition and increasing the life of the pavement. Where additional thickness is needed to increase the structural strength of pavements, spray applications are not considered helpful because they don’t contribute the structural strength. The different types of spray applications to be discussed in detail in this chapter are prime coats, tack coats, and fog seals and rejuvenators.

Note: The main cause for concern with fog seals and rejuvenators is reduced skid resistance, which is discussed in detail in sections 3-4 and 3-5. The amount of application is greater in lower-trafficked areas, such as pavement shoulders, the outer edges of runway and taxi pavements, and parking areas. Application rates are greatest where traffic, such as high-speed traffic, is not expected to occur. Due to a possible decrease in skid resistance, obtain approval from the Pavements Discipline Working Group (DWG) or their designated representative prior to using fog seals and rejuvenators.

3-2 PRIME COAT.

Asphalt prime coat consists of a low-viscosity liquid asphalt material applied by a pressure distributor to an unbound base course before placement of a HMA pavement. The purposes of the prime coat are to prevent lateral movement of the unbound base during pavement construction, to waterproof during pavement construction, and to form a tight, tough base to which an asphalt pavement adheres. To accomplish these purposes, ensure the prime material penetrates into the unbound base and fills the void spaces. A completed unbound base is susceptible to serious damage from rain, wind, and traffic. A prime coat is insurance against this water and traffic damage. Apply prime coat material to a dust-free, unbound base as soon as the base has been thoroughly compacted and before construction or other traffic loosens surface material in the compacted base. For best penetration of emulsions, the application of water (saturation or ponding) improves the wetability of the emulsion and improves penetration. Allow sufficient time to permit prime material to penetrate thoroughly into the compacted base. In instances where construction of an asphalt layer is to follow in less than 7 days upon completion of base course compaction, the application of a prime coat is not mandatory if it improves construction scheduling, but the use of a prime coat is preferred. When construction of an asphalt layer does not occur for at least 7 days, the compacted base is primed. Whether the compacted base is primed or not, take steps to protect the surface from any damage (e.g., from water, traffic) until an asphalt layer is placed. Generally, it is required that a prime coat be allowed to cure for 48 hours to withstand construction traffic, and cool or wet weather further increases the required time. Construction traffic on an uncured or improperly cured prime coat causes base movement. Local conditions, local experience, the type of base material, and the type of prime coat material available are all to be considered when deciding on the application of a prime coat.

3-2.1 Materials.

3-2.1.1 Asphalt.

Use low-viscosity asphalt material as prime material, but ensure the selection of type and grade is given consideration. These following items are consider in selecting the priming material:

- Air temperature
- Humidity
- Void content of the base course
- Curing time of the prime material
- Environmental restrictions
- Available materials

3-2.1.2 Prime Coats.

Recommended priming materials include emulsified asphalts and cutback (liquid) asphalt. Table 3-1 shows the recommended types and grades.

Table 3-1 Prime Coat Materials

Type	Grade
Cutback	SC-70 SC-250 MC-30 MC-70 MC-250 RC-70 RC-250
Emulsion	SS-1 SS-1h CSS-1 CSS-1h

A prime coat works only if it penetrates into the base course. Open-textured (high void content) bases are primed easily, but a tight surface (low voids) cannot be penetrated readily. In cases of low voids, consider the less viscous cutbacks such as RC-70, MC-30, MC-70, and SC-70. If penetration does not occur, an asphalt film is left on the surface of the base, causing slippage of the bituminous surface during and after construction. Use caution in using RC-70 or RC-250 because the solvent in the cutback evaporates rapidly or is absorbed by the base course fines and leaves an asphalt film on the surface. Undiluted emulsions cause asphalt film problems if the base course surface is tight. When emulsions are used for prime coat it is recommended that the emulsion be diluted with 1 part water to 1 part emulsion. Generally, cutback asphalts penetrate better and are better prime coat materials than asphalt emulsions. However, many areas do not allow the use of cutback asphalts. Also, emulsions are specially formulated to improve their penetrating ability. So, many asphalt suppliers produce an asphalt emulsion that is specially formulated for prime coats.

3-2.1.2.1 Influence of Weather.

Weather influences the choice of the correct priming materials. Since emulsions are dependent on the evaporation of water for curing, low temperature or high humidity slow or stop the curing process. Cutbacks are not as dependent on weather conditions as emulsions. In cold weather, however, the rapid-curing cutbacks (RCs) cure quicker than the slower curing cutbacks (MCs and SCs).

3-2.1.2.2 Considerations for Use of Cutbacks.

Cutback materials are available in locations throughout the United States and the world. Environmental, safety, and cost considerations have led to increased use of emulsions as prime coat materials. Environmental restrictions, under certain conditions, have begun to limit the use of cutback prime coat materials. This plus concerns that flammability and the cost of cutbacks have led to an increased used of asphalt emulsion prime coats. Dilute asphalt emulsions with water before applying as a prime coat, and exercise handling and storage considerations to prevent freezing, settling, and breaking.

3-2.2 Application Rate.

Prime coats are usually applied in quantities of 0.45 to 1.13 liters per square meter (0.10 to 0.25 gallons per square yard) of residual asphalt. The optimum amount of prime is highly dependent on the plasticity index of the base material, the amount of fines in the base, the nature of the fines, the tightness of the surface, and the moisture content of the base; therefore, determine the optimum amount of prime required by field trial. Test sections at various application rates are recommended for determining the optimum amount of prime. After 48 hours of curing, if there is free or excess bitumen on the surface or if the base continues to appear shiny, the base is probably overprimed. Generally, the prime is absorbed into the base within 2 to 3 hours. When excessive prime is used, the surplus probably is absorbed into the overlying asphalt layers. In turn, the absorption of the excess contributes to pavement slippage or rutting. Where excessive prime is applied, blot the excess with an application of clean fine sand or mineral dust. The ideal end result is to obtain maximum penetration without leaving free prime on the surface.

3-2.3 Placement.

Lightly broom surfaces to be primed that contain appreciable amounts of loose material or are dusty. A dusty surface cause prime to “freckle,” that is, have areas with no prime and adjacent areas with drops of excess prime. A light application of water just before applying the prime aids in reducing freckles and getting good distribution of the prime. Ensure the primer is uniformly applied with a pressure distributor at the required application rate and at the specified temperature for the asphalt used. The minimum curing time varies according to the grade and type of asphalt being used, the nature of the base, the temperature, and the humidity, but curing takes place within 48 hours.

3-2.4 Control.

Since prime coat material is applied with a pressure distributor, calibrate and check the distributor for the specified application rate before applying the prime. ASTM D2995 offers a method for determining the application rate of bituminous distributors. In addition, ensure all nozzles are free and open, the same size, and to the same angle in reference to the spray bar to produce a uniform fan of prime. The height of the spray bar above the surface is important because a bar too high or too low gives an unequal application across the spray bar, causing streaking. Ensure the height of the spray bar is such that a double or triple lap of the spray fan is obtained.

3-3 TACK COAT.

A tack coat is a light application of asphalt material to an existing paved surface immediately prior to placing the next pavement layer or course. The purpose of the tack coat is to provide a bond between the two pavement layers. The tack coat is applied by pressure distributor to cleaned surfaces. Apply the tack coat in a light and uniform application.

3-3.1 Materials.

Emulsions are common types of asphalt material used as tack, but cutbacks and asphalt cements are also used. For tack coats, the asphalt emulsion is not to be diluted. Obtain the correct spraying viscosities (temperatures) for the type of material used. Recommended tack coat materials and spray application temperatures are shown in Table 3-2. Cutbacks and emulsions are sprayed at low temperatures, but asphalt cements require considerable heating to reach a viscosity for spraying. A tack coat is always to be used when adding an asphalt mixture on top of a bound layer such as HMA or Portland cement concrete (PCC).

In cold weather, cutbacks are used with less concern than with emulsions; however, concerns with cutbacks, as mentioned before for prime coats, make them unavailable. Use of an emulsion requires that consideration be given to weather conditions, storage and handling requirements, and curing time. Ensure all tack coats are completely cured before placing the new pavement layer.

3-3.2 Application Rate.

Tack coats are usually applied in quantities of 0.23 to 0.68 liter per square meter (0.05 to 0.15 gallon per square yard) of residual asphalt, but adjust the exact quantities to suit field conditions. Light applications are preferred since heavy applications cause serious pavement slippage and bleeding problems; however, failure to use any tack coat also causes pavement slippage problems.

Table 3-2 Tack Coat Materials and Spray Application Temperatures

Type	Grade	Application Temperature °C (°F)
Cutback	RC-70	49-93(120–200)
	RC-250	74-121(165–250)
Emulsion	RS-1	21-60(70–140)
	MS-1	21-71(70–160)
	HFMS-1	21-71(70–160)
	SS-1	21-71(70–160)
	SS-1h	21-71(70–160)
	CRS-1	52-85(125–185)
	CSS-1	21-71(70–160)
	CSS-1h	21-71(70–160)
Asphalt cement	200–300 pen	129(265)+
	120–150 pen	132(270)+
	85–100 pen	138(280)+
	AC-2.5	132(270)+
	AC-5	138(280)+
	AC-10	138(280)+
	AR-1000	135(275)+
	AR-2000	141(285)+
	AR-4000	143(290)+
	PG 58-22, 64-22	143(290)+

3-3.3 Placement.

Apply tack coats to clean, dust-free asphalt pavement courses prior to placement of the overlying pavement layer. Apply the tack coat immediately before placement of the overlay; therefore, unless an asphalt cement is used, allow the tack coat time to cure. A tack coat is required on a base course when the prime coat on that surface has been subjected to construction traffic or other traffic. User a pressure distributor to apply tack coats at an application temperature that produces a viscosity between 10 and 60 seconds, Saybolt Furol, or between 20 and 120 centistokes, kinematic viscosity. The suggested spray application temperatures in degrees Fahrenheit for tack coat materials are shown in Table 3-2. When an even or uniform coating is not obtained, an improved coverage is possible by making several passes over the freshly applied tack coat with a pneumatic-tired roller. However, take steps to ensure a uniform application from the asphalt distributor. Ensure the tack coat is completely cured (volatiles or water evaporated) before the overlying layer is placed. A properly cured surface feels tacky. Plan work so that the amount of tack coat placed on the surface is equal to the amount required for one day of operation. Keep all nonessential traffic off the tack coat so that dust, mud, or sand is not tracked onto the surface. There are tack coats that are tack free when cured. These products were developed to prevent tracking of the tack by the trucks to areas outside the work area. Guidance for using these products is provided in UFGS 32 12 13.

3-3.4 Control.

The control of tack coat application is the same as that for prime coat application, as discussed in paragraph 3-2.2.

3-4 FOG SEALS.

A fog seal is a light spray application of diluted emulsified asphalt to an existing asphalt pavement surface. Fog seals are used to maintain old pavements, reduce raveling, waterproof, and in general extend the life of existing pavements. Fog seals are good for treating pavements that carry little or no traffic; however, there are several considerations when using fog seals:

- The pavement skid resistance is possibly reduced.
- The pavement air voids or permeability is possibly reduced.
- Close the pavement to traffic for 12 to 24 hours to allow for curing of the seal material.

3-4.1 Materials

In the past, asphalt emulsions and cutbacks were used for fog seals, but in recent years, the materials used are emulsions and rejuvenators. The emulsions often used are SS-1, SS-1h, CSS-1, and CSS-1h. Use only slow-setting emulsions, to allow for maximum penetration of the asphalt into the pavement. Several products are marketed as rejuvenators; they are proprietary products and their use is discussed in section 3-5.

3-4.2 Application Rate.

The application and dilution rate for fog seal varies with the absorption characteristics of the existing pavement surface. Rates vary between 0.14 to 0.36 liters per square meter (0.03 to 0.08 gallons per square yard of residual asphalt). Place test sections on the pavement to determine the best application rate. Adjust the application rate so that the pavement does not become slick or unstable and does not have excess free material on the surface after curing 12 to 24 hours. Asphalt emulsion are applied at full strength or are diluted as much as 1 part emulsion to 5 parts or more of water; however, normal application dilution is 1 part emulsion to 1 part water. Evaluate the amount of dilution for each job using a test section similar to application rate.

3-4.3 Placement.

Use only a pressure distributor that has been calibrated to deliver the fog seal at the specified rate to apply the seal material. Clean all surfaces to which the seal is applied. Apply the fog seal when the ambient temperature is above 4.5 degrees C (40 degrees F), but warmer temperatures are preferable because the material breaks and cure faster. The seal material is applied to a damp pavement if the dilution material is water, but ensure the pavement is not be too wet or the seal does not break properly and does not penetrate into the pavement. Blot excess seal left on the surface with clean sand and broom.

3-5 REJUVENATION.

Rejuvenation is the spray application of a material on an asphalt surface for the purpose of rejuvenating an aged asphalt cement binder. This rejuvenation is intended to extend the life of the asphalt pavement by softening or rejuvenating the surface asphalt toward the properties it had shortly after construction. The application of a rejuvenator is effective when the pavement has not aged to the point at which block cracking or substantial raveling has occurred. Depending on the climatic conditions, pavement rejuvenation is required within 3 to 6 years after placement. Rejuvenators are spray applied to the pavement surface and allowed to penetrate into the pavement. Rejuvenators are not to be used on runways without fine aggregate cover due to their tendency to reduce the surface friction. Obtain approval from the Pavements Discipline Working Group (DWG) or their designated representative prior to the use of rejuvenators or rejuvenators-sealers on airfields.

3-5.1 Testing.

Test results have shown that the viscosity test is effective in determining a change in asphalt properties compared to a penetration test. The viscosity test identifies changes in asphalt properties regardless of amount of rejuvenator applied, while the penetration test potentially identifies no change in asphalt property. The dynamic shear rheometer (DSR) test method is also used to produce results for evaluation; however, while the test requires less asphalt than the other methods, current extraction methods normally recover the amount of material required to perform the preferred viscosity test. If the DSR test method is used, select the phase angle test parameter for comparison since it has been shown to be statistically consistent that the G* parameter.

3-5.2 Materials.

Rejuvenation materials are not currently specified by ASTM or any other organization. The various rejuvenators available are proprietary products. Available rejuvenator materials are classified into two major types according to their major components, either asphalt or coal tar bases. Ensure the rejuvenator selected for use has a proven record of performance; however, if performance data on a rejuvenator are not available, apply the rejuvenator to a test area on the pavement and evaluated to determine its potential performance. Fog spray applications of emulsified asphalt cannot be considered to act as a rejuvenator as they don't normally have significant penetration into the pavement surface.

3-5.3 Application Rate.

The rate of application varies greatly with the condition, dry, oxidized, and open-textured, of the pavement surface. Ensure the application rate of total liquid is within the range of 0.18 to 0.9 liters per square meter (0.04 to 0.2 gallons per square yard). The application rate is selected as the amount of material that is absorbed into the pavement surface within 12 to 24 hours of application depending on the trafficking needs of the rejuvenated pavement. Follow the manufacturer's recommendations concerning dilution and other factors. Depending on the amount of solids or residual material within the rejuvenator, as evidenced by materials remaining on the pavement surface after curing, sand-sized aggregate are used to provide initial skid resistance after placement. The rejuvenators that leave material on the surface to hold aggregate are also classified or referred to as rejuvenator-sealer because they rejuvenate the surface asphalt and also, at least temporarily, seal the pavement surface. Coal tar- and asphalt-based rejuvenator-sealers leave residue on the pavement surface to hold aggregate for at least a short time. The sand used is a fine-grained aggregate that passes the 1.18 mm (No. 16) and usually the 600 μm (No. 30) sieve. The amount of aggregate applied varies with the type of rejuvenator-sealer and the condition of the pavement surface, usually within the range of 0.27 to 0.54 kilogram per square meter (0.5 to 1.0 pound per square yard).

3-5.4 Placement.

Prior to placement of the rejuvenator, thoroughly clean all the lose material from the pavement surface. Rejuvenators are usually placed with an asphalt distributor truck or any other type of specially designed application spray vehicle. Manufacturers and contractors have added a feature to immediately apply aggregate directly on top of the rejuvenator (rejuvenator-sealer). Follow manufacturer recommendations concerning application temperature and dilution of the material. When a rejuvenator is applied to the pavement, ensure clean dry sand is available to blot areas that received too much rejuvenator. Spread the sand evenly over these areas, broom into a pile, and remove.

Rolling the pavement surface with a rubber tire roller 1 or 2 days after rejuvenator has been applied helps to knead and close hairline cracks. The minimum application temperature is normally 10 degrees C (50 degrees F); however, temperatures at or above 21 degrees C (70 degrees F) results in improved penetration and curing.

3-5.5 Control.

Calibrate the asphalt distributor and check all nozzles according to ASTM D2995. When a rejuvenator-sealer is applied, the aggregate distribution system is calibrated and checked according to ASTM D5624. Conduct test sections of the pavement to be rejuvenated to test various application rates and the function of the distribution equipment.

3-5.6 Skid Resistance.

Rejuvenators normally reduce the skid resistance of treated pavement surfaces. Any excess rejuvenator that is not removed reduces skid resistance. Rejuvenator materials, when applied in the correct amounts, have skid resistance values approaching pretreatment values within a few days. Rejuvenator-sealer materials, those leaving substantial amounts of material on the pavement surface, provide skid resistance values when the application of aggregate has been applied to them. As the rejuvenator-sealer cures and traffic is applied, this thin layer of sand is worn off along with the material, and the skid resistance approaches that of the untreated pavement.

This Page Intentionally Left Blank

CHAPTER 4 SEAL COATS

4-1 INTRODUCTION.

Seal coats are one of several types of applications that consist of a relatively thin layer of aggregate cemented together with an asphalt (bituminous) material. The types of seal coats addressed in this chapter include surface treatments, slurry seals, fuel-resistant sealers, and micro-surfacing. Seal coats are widely used because of their low cost and usefulness in light to medium traffic roadways and parking areas. These treatments are normally used to seal or waterproof the pavement, provide wear resistance, and increase skid resistance. All seal coats are relatively thin coatings of material and do not add structurally to the pavement. Contact Pavements Discipline Working Group (DWG) or their designated representative prior to using surface treatments on airfield pavements due to FOD potential. Surface treatments have a FOD potential in that they use aggregate particles that are 9.5 to 19 millimeters (3/8 to 3/4 inches) in diameter. Slurry seals and micro-surfacing use aggregates with maximum sized particles less than 4.75 millimeter (No. 4) in diameter and fuel-resistant sealers use sand sized particles less than 1.18 millimeter (No. 16) in diameter. The major FOD potential from slurry seals, micro-surfacing, and fuel-resistant sealers occur when sections of the seals were not completely bonded to the underlying HMA. The individual aggregate particles are too small (1.18 to 19 millimeters) to cause a potential FOD threat.

4-2 SINGLE AND DOUBLE BITUMINOUS SURFACE TREATMENTS.

A single bituminous surface treatment (SBST) consists of an application of bituminous material on a prepared surface followed immediately by a single layer of cover aggregate. “Chip seal” is a commonly used term for the same process. Double bituminous surface treatment (DBST) is similar to a SBST except that two applications of bitumen and cover aggregate are used. The first application of aggregate uses a coarser aggregate than the second application and usually determines the DBST thickness. The second application of aggregate partially fills the surface voids and keys into the aggregate in the first aggregate course. SBSTs and DBSTs are used on prepared base courses and on new or old pavements. The DBSTs with additional layers are used to provide greater wearing resistance and potential structural strengthening (minimal).

4-2.1 Materials.

4-2.1.1 Binder.

The functions of the asphalt binder are to hold the aggregate in place, bond it to the underlying surface, and seal the underlying surface to prevent the entrance of moisture and air. The binders specified for SBST and DBST are cutback asphalts, emulsified asphalts, and asphalt cements. The types and grades are shown in Table 4-1. ASTM D1369 also provides a list of binder materials based on aggregate size and expected temperatures at application.

Table 4-1 Surface Treatment Asphalt Materials

Type	Grade
Cutback (seldom used currently due to environmental issues)	RC-250
	RC-800
	RC-3000
Emulsion	RS-1
	RS-2
	CRS-1
	CRS-2
Asphalt cement	120–150 pen
	200–300 pen
	AC-2.5
	AC-5
	PG 58-22
	PG 64-22

4-2.1.1.1 Selecting Type and Grade.

Select the type and grade of binder carefully. Consider these factors:

- Climatic conditions.
- Curing time of the binder.
- Environmental restrictions.
- Available materials.
- Temperature of the surface.
- Condition of the surface.
- Condition of the aggregate.

4-2.1.1.2 Cutback Asphalts.

Historically, rapid-curing cutback asphalts were used for surface treatments. RC-250 was used when cooler temperatures were anticipated and RC-3000 when warmer temperatures were anticipated. Currently, environmental requirements limit the availability of cutback asphalts, and as a result, emulsified asphalt binders are widely used binders.

4-2.1.1.3 Emulsions.

Emulsions require handling and storage considerations to prevent freezing, settling, and premature breaking, but they are applied with little or no additional heating. In selecting the type of emulsion, consider the compatibility of the aggregate and emulsion. As a general rule, anionic emulsions adhere better to limestone and other aggregates composed of predominantly calcium minerals. Cationic emulsions adhere better to aggregates high in silica, such as chert and quartz gravels. Cationic and anionic emulsions both adhere well to damp aggregates.

4-2.1.1.4 Asphalt Cements.

Asphalt cements harden quickly so that the cover aggregate is held in place better than other binders provided the asphalt cement does not chill before the cover aggregate is applied. Chilling of the binder before applying the aggregate is one major disadvantage with asphalt cement binders. To ensure good bond, the aggregates are often heated when asphalt cements are used. Another disadvantage with the use of asphalt cements is the high amount of heat required for spraying. Because of the difficulties encountered with asphalt cements, carefully consider using cutbacks or emulsions instead of asphalt cement.

4-2.1.2 Aggregates.

The aggregate has an effect on the degree of wear resistance, riding quality, and skid resistance of the surface treatment. Use only clean, dry, aggregate fragments that are free from dust or dried films of harmful material. Ensure the aggregate has a single-size (uniform) gradation and is composed of hard, angular, polish-resistant material. Flat and elongated aggregate particles and wet or dusty aggregates are not used. Quantities of moisture up to 1 percent do not create a problem, in warm weather, but dust prevents the adhesion of the binder to the aggregate. When an emulsion is used as the binder, aggregate with up to 3 percent moisture are commonly used. ASTM D1139 offers additional physical requirements for aggregates to be used in surface treatments.

Tables 4-2 and 4-3 provide the recommended aggregate gradations for SBST and DBST, respectively. The correlating size number designation from ASTM D448 is also provided. For DBST, gradation Nos. 1 and 2 and gradation Nos. 3 and 4 from Table 4-3 is used in combination.

4-2.2 Design.

The type and amount of aggregate and bitumen to be used for surface treatments is determined in accordance with ASTM D1369. This standard provides guidance on typical rates of aggregate and bitumen for the various types of surface treatments, and cites other ASTM standards that are applicable for measuring both bituminous and aggregate quantities. D1369 lists recommended grades of various asphalt and tar materials for use with surface treatments. Similar guidance is also available in the Asphalt Institute’s Educational Series No. 11 (ES-11) and ES-12.

Table 4-2 Gradations for SBST

Sieve Size	Percent Passing by Weight, Gradation Designation		
	No. 1 (No. 6[1])	No. 2 (No. 7[1])	No. 3 (No. 8[1])
25 mm (1 in.)	100	--	--
19 mm (3/4 in.)	90–100	100	--

[1] Number size designation from ASTM D448.				

4-2.3 Construction.

Field construction practices determine the success or failure of a well-designed surface treatment; therefore, equipment, surface preparation, and construction techniques are important.

4-2.3.1 Equipment.

Among the equipment used in placing a surface treatment, the asphalt distributor and the aggregate spreader are important. Aggregate spreaders are used during the construction of bituminous surface treatments to apply the aggregate to the surface being treated. Design and calibrate the spreader to apply a predetermined amount of aggregate uniformly over the surface. Aggregate spreaders are self-propelled; others are propelled by the truck hauling the aggregate. The self-propelled aggregate spreaders are desirable because they allow for a uniform application of material and a smoother operation. Ensure calibration and operation of the distributor and aggregate spreader meet the specified results.

4-2.3.2 Surface Preparation.

Without surface preparation, the life expectancy of a pavement is reduced; therefore, repair all soft or failed areas and remove all loose material, dirt, and vegetation prior to placing the surface treatment. Also sand or remove a bleeding surface before construction of the surface treatment.

4-2.3.3 Application.

Give attention to the application rates of both binder and aggregate. Too much binder causes bleeding or low skid resistance, and too little binder results in the loss of cover aggregate. Apply 5 to 10 percent excess aggregate, although too much aggregate results in a waste of materials and damage to windshields.

Apply the aggregate immediately after the binder application to obtain a good bond between asphalt and aggregate. Rolling with a rubber-tired roller immediately after applying the aggregate seats the aggregate in the binder and improve the bond.

4-2.3.4 Control.

Since the distributor and aggregate spreader are important for the successful application of materials, calibrate and check them to ensure that the specified application rate is obtained. ASTM D2995 offers a method for determining the application rate of asphalt (bituminous) distributors. In addition, ensure all nozzles are free and open, the same size, and at the same angle with reference to the spray bar to produce a uniform fan of asphalt. The height of the spray bar above the surface is important. A bar too high or too low produces a variable application across the spray bar, causing streaking. Ensure the height of the spray bar is such that a double or triple lap of the spray fan is obtained. ASTM D5624 offers a method for determining the application rate of aggregate transversely across the width of the spreader.

A test section is another method to evaluate the construction techniques and the application rates required for surface treatment. Construct at least one test section before allowing surface treatment applications on a full scale.

4-3 SLURRY SEAL.

A slurry seal is a mixture of asphalt emulsion, well-graded fine aggregate, water, and mineral filler. These materials are combined in proportions to produce a homogeneous, fluid-like slurry. Ensure the consistency of the slurry is spreadable to be squeegeed over an existing pavement surface. A thick, sealed surface results after evaporation of the water and curing of the mix. When properly designed, constructed, and cured, the slurry seal improves the qualities of an existing pavement surface, but the structural strength of the pavement structure is not significantly improved. Slurry seals are used to protect worn, weathered, or cracked pavements from the adverse effects of weather conditions and traffic wear. With use of aggregates, the slurry seal is also used to reduce skid or slipperiness problems. Slurry seals have application to roads and streets, parking lots, and bridge decks. This type of seal coat is best suited for pavements that are not subjected to heavy traffic. Because aircraft normally causes a rapid deterioration of the slurry seal and there is a high potential for FOD, do not apply slurry seals to airfields.

4-3.1 Equipment.

Various types of equipment are needed on a slurry seal project, but the basic pieces of equipment required include a truck-mounted continuous-mix slurry machine, spreader box, power broom, front-end loader, distributor, and pneumatic-tired roller. The truck-mounted continuous-mix slurry machine, which serves as a portable mixing plant, is an important piece of equipment. It is the only type of mixing equipment recommended for mixing a slurry seal. A slurry seal machine is used to mix aggregate, filler, asphalt emulsion, and water in the correct proportions and to uniformly apply the material to the surface to be sealed. The slurry seal machine contains storage for the aggregate, filler, emulsion, and water. Before use, calibrate and set the machine to deliver the job materials in the correct proportions. The machine manufacturer's instructions usually offer the best guidance for calibrating the slurry machine; however, a calibration method based on a revolution counter is applicable to all machines. By attaching a revolution counter to any shaft that is mechanically interlocked with the emulsion pump, water pump, fines feeder, and aggregate conveyor, the relative quantities of each of these components per revolution is determined for various gate openings, metering valve openings, or sprocket sizes. The materials are mixed and deposited into a squeegee box, which applies the slurry seal onto the surface at a thickness equal to the maximum aggregate size.

4-3.2 Material Requirements.

4-3.2.1 Emulsion.

The binder used in a slurry seal is asphalt emulsion. The emulsion is often either slow-set anionic (SS-1 or SS-1h) or slow-set cationic (CSS-1 or CSS-1h). The slow-set emulsions are best suited for slurry seals, but quick-set emulsions are specifically designed for slurry seals. The use of quick-set emulsions requires that an experienced slurry seal contractor perform the job because of the amount of time available for handling the slurry seal before it cures. Slow-set cationic emulsions cure faster than slow-set anionic emulsions because the curing process is partly a chemical reaction that expels water from the mix. Anionic emulsions cure primarily by evaporation of the water from the mix; therefore, they are greatly influenced by weather conditions. Low temperatures, high humidity, or rain slows or stops the curing process. Emulsion break; that is, the asphalt separates from the water upon contact with certain types of aggregates. If a break occurs, change either the emulsion or aggregate type.

Aggregates have a slightly negative or positive charge. A cationic emulsion bonds better with a negatively charged aggregate and an anionic emulsion bonds better with a positively charged aggregate. Aggregates that have a minimum charge, and in this case, an anionic or cationic aggregate works.

4-3.2.2 Aggregate.

Give close attention to the aggregate as well as the emulsion used in a slurry seal. Clean all aggregates, and crush the particles to produce an angular shape. Do not use aggregates that contain plastic fines. These fines absorb excessive amounts of emulsion, not allowing the required amounts of binder to coat the remaining aggregate. The fines also promote low-wear characteristics and premature break of the emulsion. Better performance is expected from slurry seals that are produced using crushed aggregate. Natural sands such as dune, river, and beach sands and other rounded aggregates tend to have poor skid resistance and wear characteristics and therefore do not use these in slurry seal coatings.

4-3.2.2.1 Gradations for Aggregates.

Ensure the aggregates are dense-graded so that the particles lock themselves together. Table 4-4 shows the gradations for use with slurry seals. Gradation type 1 is normally used for filling and sealing cracks in a pavement surface, and it provides a thin wearing surface. Gradation type 2 is widely used, and is used to fill voids, correct moderate surface irregularities, seal cracks, and provide a wearing surface for traffic. Aggregate gradation type 3 assures a thicker seal and provides a coarser surface texture. This gradation might be used as the first course in a two-course slurry seal surface treatment.

4-3.2.3 Mineral Filler.

When stability or segregation problems occur, mineral filler at a rate of 0.5 to 4.0 percent by weight of the total mixture is used to solve the problem. When mineral filler is needed, Portland cement (PC) or hydrated lime (HL) is often used in slurry seals. The filler is used to improve the mix stability, that is, to suspend heavier aggregate particles throughout the slurry seal mixture, to reduce segregation of materials, and to meet gradation requirements. Take care to ensure that the fines content, including mineral filler, does not exceed the gradation limits. Excessive fines or mineral filler causes shrinkage cracking to occur in the seal coat.

4-3.2.4 Water.

Water controls the workability of the slurry seal mixture. Ensure the mixture contains the required amount of water to produce a smooth, creamy, homogeneous, fluid-like appearance. If more water is used than required, the resultant mixture is soupy, and segregation or bleeding of the mixture occurs. On the other hand, if less water is used than required, the slurry mixture is stiff and neither spreads smoothly nor performs. Use only potable water in a slurry seal mixture.

Table 4-4 Slurry Seal Aggregate Gradations

Sieve Size	Percent Passing		
	Type 1	Type 2	Type 3
9.5 mm (3/8 in.)	–	100	100
4.75 mm (No. 4)	100	90–100	70–90
2.36 mm (No. 8)	90–100	65–90	45–70
1.18 mm (No. 16)	65–90	45–70	28–50
600 µm (No. 30)	40–65	30–50	19–34
300 µm (No. 50)	25–42	18–30	12–25
150 µm (No. 100)	15–30	10–21	7–18
75 µm (No. 200)	10–20	5–15	5–15

4-3.3 Design.

The method of developing a JMF for slurry seals selects the optimum asphalt content based on a desired film thickness of asphalt and the absorption characteristics of the aggregate. The water and mineral filler content requirements are determined by a cone test, and the wear characteristics are determined by the wet track abrasion test (WTAT) as described in ASTM D3910. Appendix C contains a summary design method and an example problem for slurry seals. The method is intended to furnish a starting point for field application. Adjust the proportions of the mixture to field conditions; however, construct a field test section using the laboratory-developed JMF.

4-3.4 Factors Affecting Design.

Consider these important factors before using a slurry seal:

- The cost of placing a slurry seal is relatively small, but this mixture does not provide additional strength to the pavement and does wear rapidly under a high volume of traffic.
- Slurry seal fills and seals many surface cracks.
- Slurry seals are used to seal a pavement surface to retard oxidation and raveling or to provide a thin (6-millimeter (1/4-inch)) wearing surface.

- Skid resistance is improved if crushed aggregates are used in the mix.
- Uncured slurry seal is adversely affected by changes in weather conditions.
- Close treated pavement to traffic to allow the slurry seal to cure (sometimes as long as 24 hours, but usually 6 hours).
- Slurry seal is better suited for a pavement subjected to low or moderate traffic because heavy traffic causes a rapid deterioration of the thin layer.
- Only structurally sound pavements are suited for a slurry seal.
- Design and application are important for meeting job required job performance.
- Generally, slurry seals have a three- to five-year life.
- Slurry seals fills cracks and coats the surface of the pavement to a depth of 3 to 6 millimeters (1/8 to 1/4 inch).

4-3.5 Surface Preparation.

Without surface preparation, the life expectancy of a slurry seal surface is reduced. Remove all loose material (including loose or flaky paint), dirt, and vegetation. Treat cracks wider than 3 millimeters (1/8 inch) before applying the seal coat. After the surface is cleaned, apply a light tack coat to improve the bond and to reduce the asphalt absorption of the old surface.

4-3.6 Application.

The surface texture of the fresh slurry seal is affected by the condition of the flexible lining of the spreader box, fragments of cured slurry adhering to the edges of the lining or to the squeegee, and the condition of the burlap drag. Worn lining results in an uneven thickness of the seal coat. Fragments of cured slurry seal or aggregate particles caught in the lining produce gouges and streaks. Wash or replace the burlap drag as needed to ensure that accumulations or crusts of mix do not cause scars or streaks. Empty and clean the mesh basket screen that is hung at the end of the discharge chute. Check the slurry seal for lumps or balling, which is caused by inadequate mixing or premature break of the asphalt emulsion. Deviation of the mix from the specified gradation potentially results in a product not meeting required job performance.

4-3.6.1 Joints.

Whenever possible, make joints while the slurry seal mixture applied in the first pass is still semi-fluid and workable. If operations preclude fresh working joints, allow the previously laid pass to set and cure sufficiently to support the spreader box without scarring, tearing, or being scraped from the pavement surface.

4-3.6.2 Hand Application.

Give close attention to spreading of the slurry seal mixture by hand squeegee. Overworking causes partial breaking of the emulsion before the final spreading is completed, which results in a nonuniform material that has poor appearance and durability.

4-3.7 Curing.

Slurry seals, depending on the emulsion characteristics in relation to the aggregate with which the emulsion is used, cure primarily by evaporation of water from the surface, by deposition of asphalt on the aggregate that frees the water, or by a combination of both. If curing is from the surface downward, the surface presents a cured appearance, but the material below possibly is still uncured. Therefore, assure thorough curing of the slurry seal before traffic is permitted.

4-3.8 Rolling.

Rolling is advantageous in reducing voids in the slurry seal, smoothing out surface irregularities, and increasing the resistance to water. Begin rolling as soon as the slurry seal has cured to support the roller without any pickup of the slurry seal mixture. Use a rubber-tired roller for rolling the slurry seal mixture.

4-4 FUEL-RESISTANT SEALER.

Fuel-resistant sealer (FRS) material is a combination of coal-tar emulsion, fine aggregate, water, and occasionally other additives. These materials are mixed in batches and applied to HMA surfaces by hand, sprayer, or mechanical squeegee. Coal-tar emulsion binder provides a fuel-resistant surface, and the fine aggregate provides skid resistance. The FRS is placed in thin layers, usually 2 millimeters (1/16 inch) or less. Particle size affects the minimum thickness that is applied by squeegee. An FRS does not significantly enhance the structural strength of the pavement structure.

4-4.1 Areas of Application.

Apply FRS to any HMA surface subjected to fuel drippage or spillage. This includes vehicle maintenance and parking areas.

4-4.2 Considerations for Use.

Important factors to consider before using an FRS:

- Use FRS only where a fuel-resistant surface is required.
- FRSs do not have as long a service life as surface treatments with asphalt cement binder, but they last up to 4 years, depending on traffic and climate conditions.

- Parking areas with low vehicle turnover or low usage rates (therefore lower instances of fuel spillage) are better served with a single or double bituminous surface treatment or a slurry seal.
- FRSs provides a seal to protect the underlying HMA pavement to retard oxidation and weathering.
- Close the pavement to traffic during the curing of FRS layers (usually 4 to 8 hours).
- Uncured FRS is adversely affected by changes in weather conditions such as rain or freezing temperatures.
- Only structurally sound pavements are suited for an FRS.
- Mixture design and application are important for obtaining a required job performance.

4-4.3 Material Requirements.

4-4.3.1 Coal-tar Emulsion.

The binder material used in an FRS is a coal-tar emulsion. The coal-tar emulsion is usually specified as having to meet the requirements of ASTM D5727.

4-4.3.2 Aggregates.

Ensure aggregates are either natural or manufactured angular aggregate, are clean, free of organic and other objectionable material, and meet the gradation requirements in Table 4-5.

4-4.3.3 Water.

Use only potable water in an FRS mixture. Determine the amount of water required from laboratory testing prior to construction. Additional water normally is required under high temperature pavement conditions.

4-4.3.4 Additives.

Additives used in FRSs include various types of polymer and silicon materials. These materials are added to the FRS mixture in the field or added to the coal-tar emulsion during the emulsifying process. The polymer materials often used are latex combinations of acrylonitrile and butadiene. Ensure additives used are compatible with the coal-tar emulsion.

Table 4-5 FRS Minimum Application Rates and Corresponding Aggregate Gradations

Gradation Type		Coarse	Medium	Fine
Minimum Application Rate, L/m² (gal/yd²)		**1.35 (0.3)**	**1.0 (0.22)**	**0.72 (0.16)**
Sieve Size	1.18 mm (No. 16)	100	100	100
	850 µm (No. 20)	85–100	98–100	100
	600 µm (No. 30)	25–85	85–100	98–100
	425 µm (No. 40)	5–25	25–85	85–100
	300 µm (No. 50)	2–10	5–25	25–85
	212 µm (No. 70)	---	2–10	5–25
	150 µm (No. 100)	0–2	0–4	2–10
	106 µm (No. 140)	--	0–2	0–2

4-4.4 Design.

Historically, the design of FRS mixtures has been based on the selection of materials (sand, water, and additives) from an allowable range based on a gallon of coal-tar emulsion. The current guide specification requires that the final FRS mixture developed be required to meet two test requirements. These tests are curing time and resistance to kerosene.

4-4.4.1 Application Rate.

The rate of application of sealer depends, to a great extent, on the gradation of the aggregate used. The coarser the gradation, the thicker the application required. This ensures that the aggregate is embedded in the sealer and does not wear off under traffic. The rates given are for general guidance and vary depending on the final proportions (solids content) of the sealer that is applied. Recent research suggests that thinner coatings of FRS are not as susceptible to cracking with age; therefore, when possible, use the fine gradation (smaller size aggregate particle). This decreases the occurrence of cracking and increases the life span of the FRS.

4-4.4.2 Requirements.

The FRS mixture is required to meet the requirements provided in Table 4-6. Ensure the amount of sand added to the FRS mixture does not exceed 480 to 720 grams per liter (4 to 6 pounds per gallon) of coal-tar emulsion. Sand loads of greater amounts are not normally fuel resistant and fail the resistance to kerosene test.

Table 4-6 Physical Properties of Sealer Mixtures

Property	Requirement	Referenced ASTM Test Method
Curing time, firm set	8 hours maximum	D2939
Resistance to kerosene	No penetration or loss of adhesion	D2939

4-4.5 Equipment.

Various types of hand-held squeegees, brooms, and other non-mechanical equipment are needed on the typical FRS project. Depending on the job size, they are completed with only mixers sized to job size and hand-held squeegees; however, the basic equipment required for mechanical application on an FRS project includes a truck-mounted batch-mix machine, squeegee blades, power broom, and front-end loader or fork truck. The truck-mounted batch-mix machine is where the FRS mixtures are proportioned and mixed and then taken to the project site and applied to the pavement surface. FRS mixtures are always batch mixed and then applied, unlike slurry seals that are made in a continuous mix operation. The batch-mix machine usually has a manufacturer-supplied calibration sheet showing the number of gallons per depth in the tank. The depth is usually monitored with a marked dipstick. The squeegee blades apply the FRS material to the pavement surface. The power broom cleans the pavement surface prior to application. The front-end loader is used for aggregate handling; however, a forklift is often needed because bagged and manufactured aggregate is often used.

4-4.6 Surface Preparation.

Remove all loose material from the pavement surface prior to application of the FRS. Clean and seal cracks wider than 3 millimeters (1/8 inch) or with vegetation prior to application of the FRS.

4-4.7 Application.

After sufficient mixing, pour the FRS mixture directly on the pavement surface and squeegee across the pavement surface. In hot weather conditions where the pavement surface gets hot, applying a fog spray of water prior to application of the FRS material assists in bonding the FRS to the pavement surface. Use a minimum of two applications of the FRS material to eliminate the possibility of any continuous, full-depth voids in the FRS. When possible, make each additional application perpendicular to the previous one. Whenever possible, place consecutive lanes while the sealer mixture applied in the first lane is still semi-fluid and workable. If operations preclude fresh working joints, allow the previously laid pass to set and cure sufficiently so that it is not scarred, torn, or scraped from the pavement surface during the placement of the adjoining pass.

4-4.8 Curing.

FRSs cure by evaporation of the water from the sealed pavement surface. Sunlight and warmer temperatures increase the rate of curing. Curing time varies from 2 to 24 hours depending on the thickness of FRS applied and the existing climatic conditions. Ensure FRSs are not applied when freezing temperatures (<0 degrees C, <32 degrees F) are possible within the required curing time.

4-5 MICRO-SURFACING.

Micro-surfacing, also known as micro-texturing, macro-seal, or macro-pavement, is a latex-modified asphalt emulsion slurry paving system. This system was originally developed in West Germany in the 1970’s and has been used in the United States since 1980. The total system consists of a latex-modified asphalt emulsion, a chemical set control additive, high-quality crushed aggregate and mineral filler (usually Type 1 Portland cement), and water.

4-5.1 Equipment.

Some of the methods of mixing and application are similar to those of a slurry seal. Equipment such as brooms, loaders, and asphalt distributors are the same as for a slurry seal. However, other equipment required for mixing and application of micro-surfacing mixtures are different than those required for slurry seals. Mixing is accomplished in a multi-bladed, twin-shaft, pugmill mixer. Application equipment with constant agitation within the slurry box is required to achieve a uniform placement of slurry. Micro-surfacing mixtures are placed with self-propelled mixing and placement vehicles. These vehicles have bins and tanks to carry all the aggregate, filler, asphalt emulsion, water, and additives required to make the mixture. Two basic types of vehicles are used to place micro-surfacing -- those that do so with the help of nurse or resupply trucks and those that place and then leave for resupply. These vehicles have the ability to apply a fog spray of water to the pavement directly in front of the spreader box. The spreader box contains blades to continually agitate the slurry. On relatively smooth surfaces, the rear seal is rubber and acts as a strike-off (screed). On rough surfaces, normally a steel strike-off is used to form an intermediate leveling course, with another slurry then placed over the leveling course. Rut boxes are used to fill ruts in individual traffic lanes. These boxes are V-shaped, with the point of the V toward the rear of the box. They have two shafts with multiple blades on each side of the V to continuously agitate the slurry. The box is designed to push aggregate to the center and is equipped with two metal leveling plates and a rubber strike-off.

4-5.2 Material Requirements.

4-5.2.1 Emulsion.

The binder used in micro-surfacing is a latex-modified asphalt emulsion. The base asphalt emulsion used is normally a cationic slow-setting emulsion with a hard base asphalt (CSS-1H) as specified in ASTM D2397. The latex polymer is combined with the asphalt cement during the emulsifying process, at a rate of 3.0 percent by weight of residual material.

4-5.2.2 Additives.

Liquid additives are added during the field mixing process to provide control of the set properties of the micro-surface mixture. The amount of additive used increases with decreasing temperatures. This is because the additive acts to cause the emulsion to break or cure faster. Obtain these additives from the emulsion manufacturer to assure compatibility with all components of the mixture.

4-5.2.3 Aggregates.

Ensure the aggregate used is a high-quality, 100 percent crushed aggregate. Aggregates previously used for micro-texturing include granite, flint, slag, limestone, basalt, chert, and gravel. The aggregate is required to meet one of the gradation types listed in Table 4-7. The gradations used for micro-surfacing are the same as those of an asphalt slurry seal, except that type 1, the finest gradation used for a slurry seal (Table 4-4), is not used for micro-surfacing.

Table 4-7 Gradation Types for Micro-Surfacing

Sieve Size	Type 2 Percent Passing	Type 3 Percent Passing
9.5 mm (3/8 in.)	100	100
4.75 mm (No. 4)	90–100	70–90
2.36 mm (No. 8)	65–90	45–70
1.18 mm (No. 16)	45–70	28–50
600 μm (No. 30)	30–50	19–34
300 μm (No. 50)	18–30	12–25
150 μm (No. 100)	10–21	7–18
75 μm (No. 200)	5–15	5–15

Mineral filler is added to the mixture to obtain the desired dispersion (reduce segregation) and working characteristics (speed-up or slow-down the rate of cure of the system) of the micro-surfaced mixture. Determine the amount of mineral filler added from laboratory testing, normally not to exceed 3.0 percent of the weight of the aggregate. Mineral filler is non-air entrained Portland cement, hydrated lime, or another mineral additive.

4-5.2.4 Water.

Use potable water free of soluble salts or any other harmful materials. Limit the amount of water used to that required to produce a mixture of the desired consistency. The amount of water required increases slightly with increasing temperatures.

4-5.3 Design.

A method of mix design for military pavements has not been developed. Instead, procedures developed by the International Slurry Surfacing Association (ISSA) are recommended for use and are detailed here. These procedures are broken down into three parts. The first is the evaluation of materials to verify that they meet the requirements described in section 4-5.2. These materials include the aggregates and the polymer-modified asphalt cement. The second part involves testing the effects of mixing and application characteristics, water content, filler, and additives, and determining the optimum asphalt content through the preparation of trial mixes. The third part involves performance-related tests on the mixture to ensure good long-term performance. ASTM D6372 provides information on standard practices in the design, testing, and construction of micro-surfacing.

4-5.3.1 Mix Characteristics.

Trial mixes are used to determine if the emulsion and aggregate are compatible, if a mineral filler or field control additive is needed, and if used, the concentration and the range of water that produces homogeneous mixtures. Trial mixes are also prepared to determine the optimum filler content and the effects of mineral filler on wet cohesion. These mixes are prepared with constant asphalt emulsion contents and incremental changes in the amount of mineral filler, usually either hydrated lime or Portland cement. Once the desirable mineral filler content has been determined, trial mixes are again prepared, this time keeping the mineral filler content constant and making incremental changes in the asphalt emulsion content.

4-5.3.1.1 Cohesion Test (ISSA Technical Bulletin 139 (TB-139)).

The cohesion test is the method used to classify the set and traffic time of micro-surfacing systems. The cohesion tester is a power steering simulator that measures the torque required to tear apart a 6- or 8-millimeter-thick (0.236- or 0.315-inch-thick) by 60-millimeter (2.36-inch) in diameter specimen under the action of a 32-millimeter-diameter (1.26-inch-diameter) rubber foot loaded to 200 kilopascals (4,177 pounds per square foot). A system is defined as “quick set” if it develops a torque value of 12 to 13 kilograms per centimeter (67.1 to 72.6 pounds per inch) within 20 to 30 minutes. A torque of 12 to 13 kilograms per centimeter (67.1 to 72.6 pounds per inch) is considered the cohesion value at which the mixture is set, water-resistant, and cannot be remixed. A system is defined as "quick traffic" if the mixture develops 20 to 21 kilograms per centimeter (111.9 to 117.6 pounds per inch) torque within 60 minutes. At 20 to 21 kilograms per centimeter (111.9 to 117.6 pounds per inch), sufficient cohesion has developed to allow rolling traffic. Figure 4-1 provides a method to classify various slurry seals and micro-surfacing systems. All micro-surfacing mixtures are designed as quick set, quick traffic systems. Cohesion test results are also used to optimize mineral filler by the use of the “Benedict Curve” (see Figure 4-2), in which the effect of an incremental addition of mineral filler versus cohesion is plotted. The optimum filler content is the value that gives the highest cohesion value. The shape of the curve shows the sensitivity of the system to changes in mineral filler. This helps determine the range of mineral filler that give acceptable laboratory results.

Figure 4-1 Classification of Mix Systems by Cohesion Test Curves

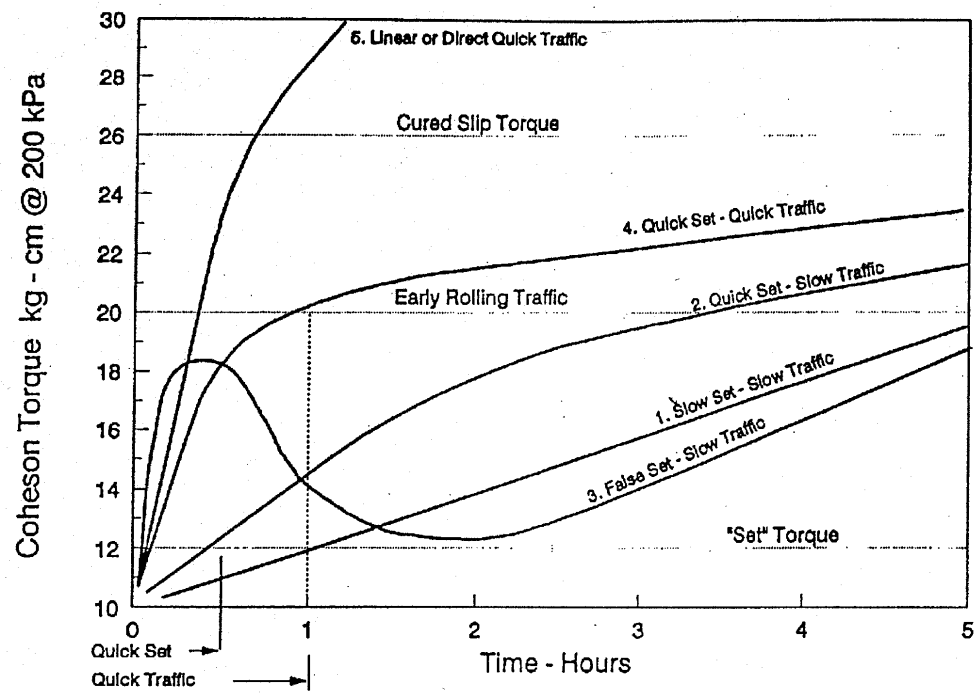

Figure 4-2 Mineral Filler Content Optimization "Benedict Curve"

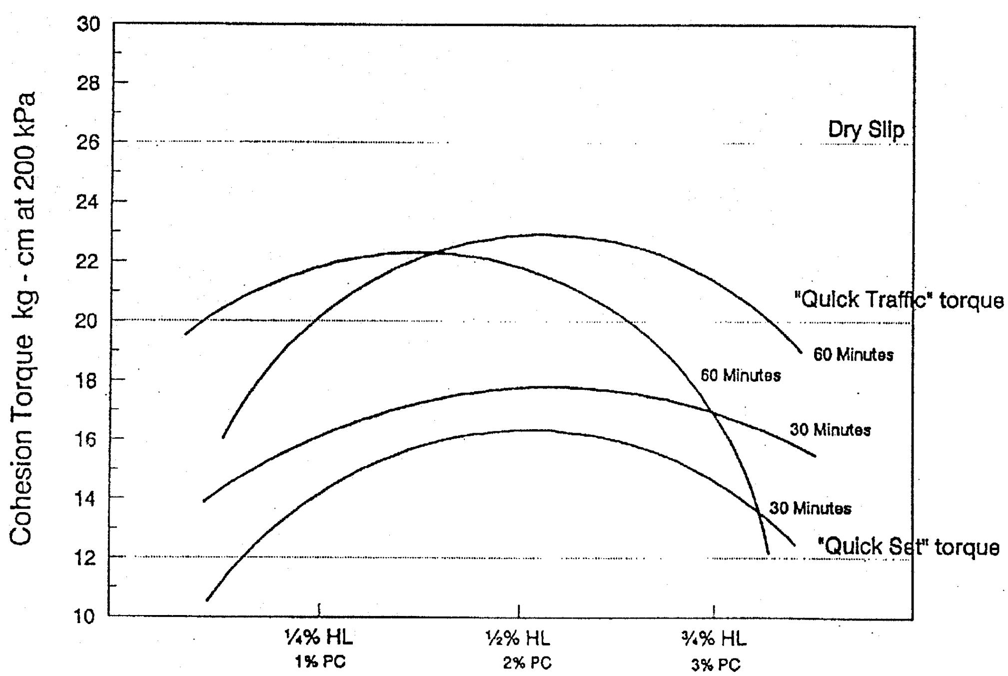

4-5.3.1.2 Stripping.

Two tests used to evaluate the potential for stripping are: the Wet Stripping Test (ISSA TB-114) and the Boiling Test (ISSA TB-149). The Wet Stripping Test is performed on 60 degrees C (140 degrees F) cured cohesion specimens that are boiled in water for 3 minutes to determine the asphalt adhesion to the aggregate. A coating retention of 90 percent or greater is considered meeting required specifications, with 75 to 90 percent being marginal and less than 75 percent not meeting required specifications. The Boiling Test is similar to the Wet Stripping Test. Either test is also used as an early compatibility indicator test.

4-5.3.2 Determination of Optimum Asphalt Content.

There are several ways to determine the optimum asphalt cement content. One way is to use ISSA test procedures, and another is to use a modified Marshall procedure. A few states also specify requirements for Hveem stability test.

4-5.3.2.1 ISSA Procedure.

The optimum asphalt content is determined from ISSA procedures by graphically combining the results of a WTAT and a loaded wheel test (LWT). Figure 4-3 (a, b, and c) shows how the optimum asphalt content along with an acceptable range is determined by graphically combining WTAT and LWT data. Ensure the minimum and maximum asphalt content falls within the range usually provided in the specification. The ISSA recommends that residual asphalt content be within a range of 5.5 to 9.5 percent.

a. **Wet Track Abrasion Test (ASTM D3910/ISSA TB-100).** This test determines the abrasion resistance of micro-surfacing mixture relative to asphalt content and is one of two ISSA tests used for determining optimum asphalt content. This test simulates wet abrasive conditions such as vehicle cornering and braking. A prepared and cured sample of mixture 6 millimeters (0.24 inch) thick by 280 millimeters (11.0 inches) in diameter that has been soaked for periods of either 1 hour or 6 days is immersed in a 25 degrees C (77 degrees F) water pan and is wet abraded by a rotating weighted (2.3-kilogram [5.1 pounds]) rubber hose for 5 minutes. The abraded specimen is dried to 60 degrees C (140 degrees F) and weighed. The maximum allowed weight losses for 1-hour and 6-day soaks are 0.54 kilogram per square meter (0.11 pound per square foot) and 0.8 kilogram per square meter (0.16 pound per square foot), respectively. Asphalt contents that result in these weight losses are considered the minimum asphalt contents. The WTAT on a 6-day soaked sample is not required; however, due to the increased severity of the 6-day soak, it is preferred by laboratories and user agencies for predicting the performance of the system.

b. **Loaded Wheel Test (ISSA TB-109).** This test is used to determine the maximum asphalt content to avoid asphalt flushing in micro-surfacing systems. This is accomplished by specifying and measuring fine sand that adheres to the sample subjected to simulated wheel loadings. The ISSA recommends a maximum sand adhesion value of 0.54 kilogram per square meter (0.11 pound per square foot) for heavy traffic loadings. If the sand adhesion is below this maximum value, mixture bleeding does not occur. In this test, a 50-millimeter-wide (1.97-inch-wide) by 375-millimeter-long (14.76-inch-long) specimen of desired thickness (25 percent thicker than the coarsest particle) is fastened to the mounting plate and is compacted with one thousand 57-kilogram (125.6-pound) cycles at 25 degrees C (77 degrees F). At the end of compaction, the specimen is washed, and then dried at 60 degrees C (140 degrees F) to a constant weight. A measured quantity of sand is then placed on the sample, and the LWT is repeated for a specified (usually 100) number of cycles. The specimen is then removed and weighed. The increase in weight due to sand adhesion is noted.
