Depressions are localized pavement surface areas having elevations slightly lower than those of the surrounding pavement. In many instances, light depressions are not noticeable until after a rain, when ponding water creates “birdbath” areas, but the depressions can also be located without rain because of stains created by ponding water. Depressions can be caused by settlement of the foundation soil or can be built up during construction. Depressions cause roughness and, when filled with water of sufficient depth, can cause hydroplaning of aircraft.

A-6.2 Severity Levels.

L Depression can be observed or located by stained areas, only slightly affects pavement riding quality, and may cause hydroplaning potential on runways (see measurement criteria below).

M Depression can be observed, moderately affects pavement riding quality, and causes hydroplaning potential on runways (see measurement criteria below).

H Depression can be readily observed, severely affects pavement riding quality, and causes definite hydroplaning potential (see measurement criteria below).

A-6.3 How to Measure.

Depressions are measured in square feet (square meters) of surface area. The maximum depth of the depression determines the level of severity. This depth can be measured by placing a 10-foot (3-meter) straightedge across the depressed area and measuring the maximum depth in inches (millimeters). Depressions larger than 10 feet (3 meters) across must be measured by either visual estimation or direct measurement when filled with water.

Table A-3 Maximum Depth of Depression

Severity	Runaways & High-Speed Taxiways	Taxiways & Aprons
L	0.125 to 0.5 in (3 to 13 mm)	0.5 to 1 inch (13 to 25 mm)
M	0.5 to 1 inch (13 to 25 mm)	1 to 2 inches (25 to 51 mm)
H	> 1 inch (> 25 mm)	> 2 inches (> 51 mm)

Figure A-16 Low-Severity Depression

Figure A-17 Medium-Severity Depression

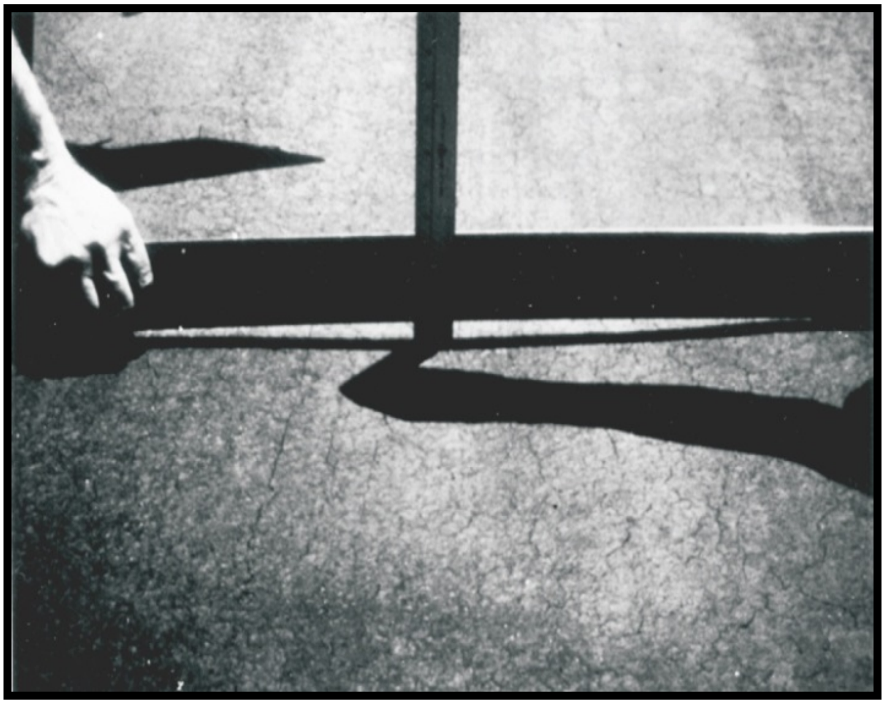

Figure A-18 High-Severity Depression

Figure A-19 High-Severity Depression

A-7 JET BLAST EROSION (46) {6}.

A-7.1 Description.

Jet blast erosion causes darkened areas on the pavement surface when bituminous binder has been burned or carbonized; localized burned areas may vary in depth up to approximately 0.5 inch (13 millimeters).

A-7.2 Severity Levels.

No degrees of severity are defined. It is sufficient to indicate that jet blast erosion exists.

A-7.3 How to Measure.

Jet blast erosion is measured in square feet (square meters) of surface area.

Figure A-20 Jet Blast Erosion

A-8 JOINT REFLECTION CRACKING FROM PCC (47) {7}.

A-8.1 Description.

This distress occurs only on pavements having an asphalt or tar surface over a PCC slab. This category does not include reflection cracking from any other type of base (i.e., cement stabilized, lime stabilized); such cracks are listed as L&T cracks. Joint reflection cracking is caused mainly by movement of the PCC slab beneath the AC surface because of thermal and moisture changes; it is not load-related. However, traffic loading may cause a breakdown of the AC near the crack, resulting in spalling and FOD potential. If the pavement is fragmented along a crack, the crack is said to be spalled. Knowledge of the slab dimensions beneath the AC surface will help identify these cracks.

A-8.2 Severity Levels.

L Cracks have only light spalling (little or no FOD potential) or no spalling and can be filled or non-filled. If non-filled, the cracks have a mean width of 0.25 inch (6 millimeters) or less. Filled cracks are of any width but their filler material is in satisfactory condition.

M One of these conditions exists: (1) cracks are moderately spalled (some FOD potential) and can be either filled or non-filled of any width; (2) filled cracks are not spalled or are only lightly spalled but the filler is in unsatisfactory condition; (3) non-filled cracks are not spalled or are only lightly spalled but the mean crack width is greater than 0.25 inch (6 millimeters); or (4) light random cracking exists near the crack or at the corner of intersecting cracks.

H Cracks are severely spalled (definite FOD potential) and can be either filled or non-filled of any width.

A-8.3 How to Measure.

Joint reflection cracking is measured in linear feet (linear meters). Identify and record the length and severity level of each crack. If the crack does not have the same severity level along its entire length, separately record each portion. For example, a crack that is 50 feet (15 meters) long may have 10 feet (3 meters) of high-severity cracking, 20 feet (6 meters) of medium-severity cracking, and 20 feet (6 meters) of low-severity cracking; these are recorded separately. If the different levels of severity in a portion of a crack cannot be easily divided, rate that portion at the highest severity present.

Figure A-21 Low-Severity Joint Reflection Cracking

Figure A-22 Medium-Severity Joint Reflection Cracking

Figure A-23 High-Severity Joint Reflection Cracking

A-9 LONGITUDINAL AND TRANSVERSE (L&T) CRACKING (48) {8} (NON-PCC JOINT REFLECTIVE).

A-9.1 Description.

Longitudinal cracks are parallel to the pavement's centerline or laydown direction. They may be caused by (1) a poorly constructed paving lane joint, (2) shrinkage of the AC surface due to low temperatures or hardening of the asphalt, or (3) a reflective crack caused by cracks beneath the surface course, including cracks in PCC slabs (but not at PCC joints). Transverse cracks extend across the pavement at approximately right angles to the pavement centerline or direction of laydown. They may be caused by items 2 or 3 above. These types of cracks are not usually load-associated. If the pavement is fragmented along a crack, the crack is said to be spalled.

A-9.2 Severity Levels.

L Cracks have either minor spalling (little or no FOD potential) or no spalling. The cracks can be filled or non-filled. Non-filled cracks have a mean width of 0.25 inch (6 millimeters) or less; filled cracks are of any width but their filler material is in satisfactory condition.

M One of these conditions exists: (1) cracks are moderately spalled (some FOD potential) and can be either filled or non-filled of any width; (2) filled cracks are not spalled or are only lightly spalled but the filler is in unsatisfactory condition; (3) non-filled cracks are not spalled or are only lightly spalled but the mean crack width is greater than 0.25 inch (6 millimeters); or (4) light random cracking exists near the crack or at the corners of intersecting cracks.

H Cracks are severely spalled, causing definite FOD potential. They can be either filled or non-filled of any width.

A-9.3 How to Measure.

L&T cracks are measured in linear feet (linear meters). Identify and record the length and severity of each crack. If the crack does not have the same severity level along its entire length, separately record each portion of the crack with a different severity level. For example, see the explanation of how to measure joint reflection cracking in paragraph A-8.3. If block cracking is recorded, L&T cracking are not recorded in the same area.

Figure A-24 Low-Severity L&T Cracking

Figure A-25 Medium-Severity L&T Cracking

Figure A-26 High-Severity L&T Cracking

A-9.4 Longitudinal and Transverse Cracking (Non-PCC Joint Reflective) in Porous Friction Courses (PFC): Severity Levels.

Note: These severity levels are in addition to the existing definitions.

L Cracks have either minor spalling (little or no FOD potential) or no spalling. The cracks can be filled or non-filled. Non-filled cracks have a mean width of 0.25 inch (6 millimeters) or less; filled cracks are of any width but their filler material is in satisfactory condition. Furthermore, the average raveled area (area with dislodged or missing coarse aggregate larger than 0.19 inch [4.75 millimeters]) around the crack is less than 0.25 inch (6 millimeters) wide.

M The average raveled area (area with dislodged or missing coarse aggregate larger than 0.19 inch [4.75 millimeters]) around the crack is 0.25 to 1 inch (6 to 25 millimeters) wide or one of these conditions exists: (1) cracks are moderately spalled (some FOD potential) and can be either filled or non-filled of any width; (2) filled cracks are not spalled or are only lightly spalled, but the filler is in unsatisfactory condition; (3) non-filled cracks are not spalled or are only lightly spalled but the mean crack width is greater than 0.25 inch (6 millimeters); or (4) light random cracking exists near the crack or at the corners of intersecting cracks.

H The average raveled area (area with dislodged or missing coarse aggregate larger than 0.19 inch [4.75 millimeters]) around the crack is greater than 1 inch (25 millimeters) wide or cracks are severely spalled, causing definite FOD potential. They can be either filled or non-filled of any width.

A-9.5 How to Measure.

L&T cracks are measured in linear feet (linear meters). Identify and record the length and severity of each crack. If the crack does not have the same severity level along its entire length, separately record each portion of the crack with a different severity level. For an example, see the explanation of how to measure joint reflection cracking in paragraph A-8.3. If block cracking is recorded, L&T cracking are not recorded in the same area.

Figure A-27 Low-Severity PFC L&T Cracking

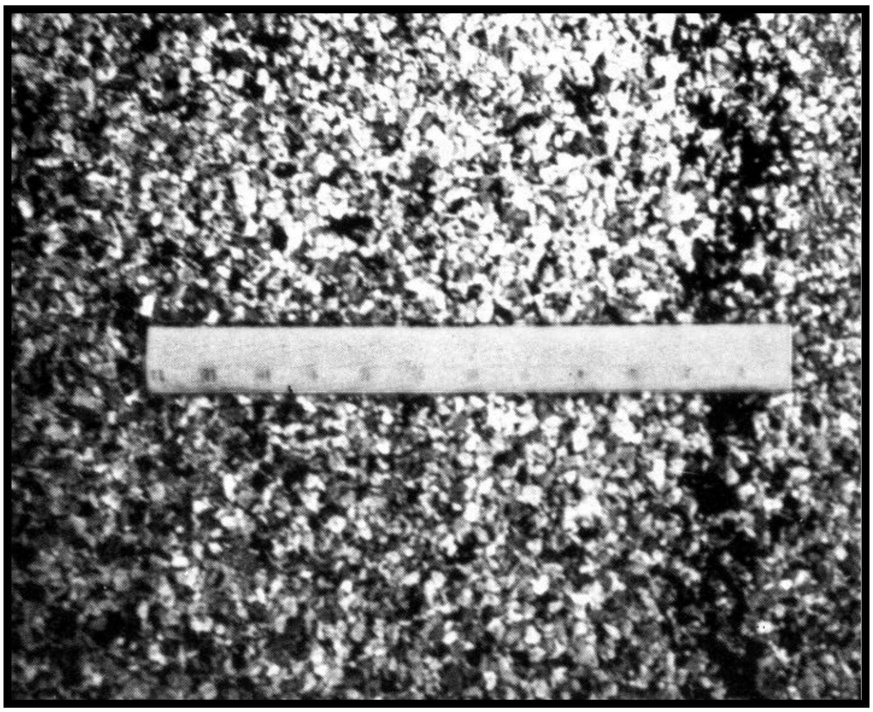

Figure A-28 Medium-Severity PFC L&T Cracking

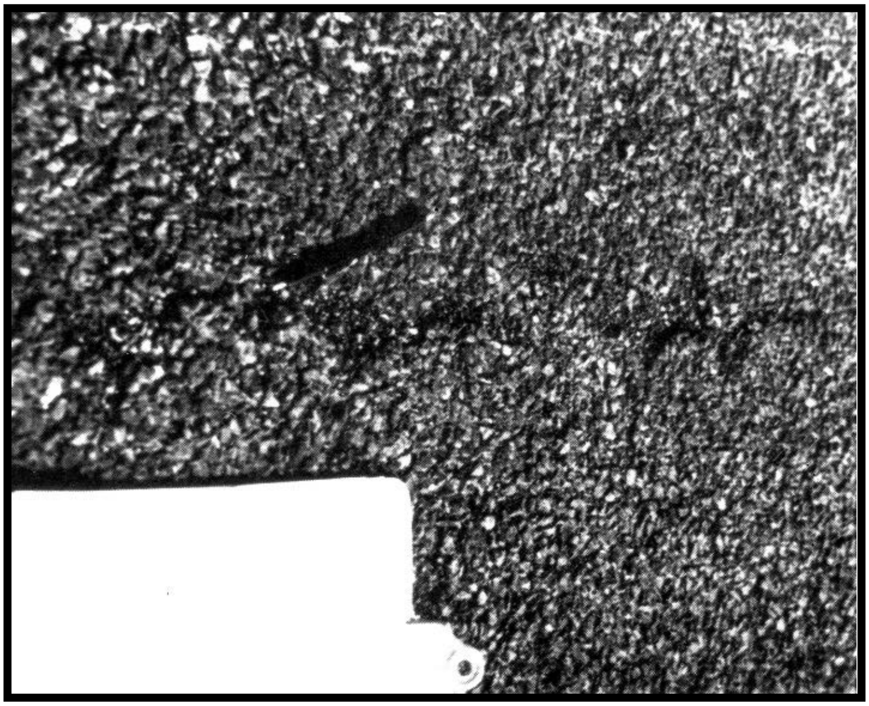

Figure A-29 Medium-Severity PFC L&T Cracking

Figure A-30 High-Severity PFC L&T Cracking

A-10 OIL SPILLAGE (49) {9}.

A-10.1 Description.

Oil spillage is the deterioration or softening of the pavement surface caused by the spilling of oil, fuel, or other solvents.

A-10.2 Severity Levels.

No degrees of severity are defined. It is sufficient to indicate that oil spillage exists.

A-10.3 How to Measure.

Oil spillage is measured in square feet (square meters) of surface area. A stain is not a distress unless material has been lost or the binder has been softened. If hardness is approximately the same as on surrounding pavement and if no material has been lost, do not record as a distress.

Figure A-31 Oil Spill

A-11 PATCHING AND UTILITY CUT PATCH (50) {10}.

A-11.1 Description.

A patch is considered a defect, regardless of how well it is performing.

A-11.2 Severity Levels.

L Patch is in good condition and performing satisfactorily; little or no FOD potential.

M Patch is somewhat deteriorated and affects riding quality to some extent; some FOD potential.

H Patch is badly deteriorated and affects riding quality significantly or has high FOD potential. Patch needs replacement.

The use of dense-graded AC patches on PCC surfaces causes a water-damming effect at the patch that contributes to differential skid resistance of the surface. Rate low-severity, dense-graded patches as medium-severity patches because of the differential friction problem. Medium- and high-severity patches are rated the same as above.

A-11.3 How to Measure.

Patching is measured in square feet (square meters) of surface area; however, if a single patch has areas of differing severity levels, measure and record these areas separately. For example, a 25-square-foot (2.5-square-meter) patch may have 10 square feet (1 square meter) of medium severity and 15 square feet (1.5 square meters) of low severity. Record these areas separately. Any distress found in a patched area is not recorded; however, its effects on the patch will be considered when determining the patch’s severity level.

A very large patch (area > 2,500 square feet [230 square meters]) or feathered-edge pavement may qualify as an additional sample unit or a separate section.

Figure A-32 Low-Severity Patching

Figure A-33 Medium-Severity Patching

Figure A-34 High-Severity Patching

A-12 POLISHED AGGREGATE (51) {11}.

A-12.1 Description.

Aggregate polishing is caused by repeated traffic applications. Polished aggregate is present when close examination of a pavement reveals that the portion of aggregate extending above the asphalt is either very small or there are no rough or angular aggregate particles to provide good skid resistance. Existence of this type of distress is also indicated when the number on a skid resistance rating test is low or has dropped significantly from previous ratings.

A-12.2 Severity Levels.

No degrees of severity are defined; however, when the degree of polishing is significant, polishing is included in the condition survey and rated as a defect.

A-12.3 How to Measure.

Polished aggregate is measured in square feet (square meters) of surface area. If bleeding is counted, polished aggregate is not counted in the same area.

Figure A-35 Polished Aggregate

A-13 RAVELING (52) {12}.

A-13.1 Description.

Raveling is the dislodging or loss of coarse aggregate particles (stone or rocks larger than 0.19 inch [4.75 millimeters]) from the pavement surface. This is characterized by aggregates larger than 0.19 inch (4.75 millimeters) missing or no longer bound to the surface.

A-13.2 Dense Mix Severity Levels.

As used herein, “coarse aggregate” refers to predominant coarse aggregate sizes of the asphalt mix. The term “aggregate clusters” refers to when more than one adjoining coarse aggregate piece is missing. If in doubt about a severity level, examine three representative areas of 1 square yard (1 square meter) each and count the number of missing coarse aggregate particles.

L One of these conditions exists: (1) in a 1-square-yard (1-square-meter) representative area, the number of coarse aggregate particles missing is between five and twenty; or (2) missing aggregate clusters are less than 2 percent of the examined 1-square-yard (1-square-meter) area. In low-severity raveling, there is little or no FOD potential.

M One of these conditions exists: (1) in a 1-square-yard (1-square-meter) representative area, the number of coarse aggregate particles missing is between 21 and 40; or (2) missing aggregate clusters are between 2 and 10 percent of the examined 1-square-yard (1-square-meter) area. In medium-severity raveling, there is some FOD potential.

H One of these conditions exists: (1) in a 1-square-yard (1-square-meter) representative area, the number of coarse aggregate particles missing is over 40; or (2) missing aggregate clusters are more than 10 percent of the examined 1-square-yard (1-square-meter) area. In high-severity raveling, there is significant FOD potential.

A-13.3 How to Measure.

Raveling is measured in square feet (square meters) of surface area. Mechanical damage caused by hook drags, tire rims, or snowplows is counted as areas of high-severity raveling.

Figure A-36 Low-Severity Raveling (Dense Mix)

Figure A-37 Medium-Severity Raveling (Dense Mix)

Figure A-38 High-Severity Raveling (Dense Mix)

A-13.4 Slurry Seal/Coal Tar Over Dense Mix Severity Levels.

L (1) The scaled area is less than 1 percent. (2) In the case of coal tar where pattern cracking has developed, the surface cracks are less than 0.25 inch (6 millimeters) wide.

M (1) The scaled area is between 1 and 10 percent. (2) In the case of coal tar where pattern cracking has developed, the cracks are 0.25 inch (6 millimeters) wide or greater.

H (1) The scaled area is over 10 percent. (2) In the case of coal tar, the surface is peeling off.

A-13.5 How to Measure.

Raveling is measured in square feet (square meters) of surface area. Mechanical damage caused by hook drags, tire rims, or snowplows is counted as areas of high-severity raveling.

Figure A-39 Low-Severity Raveling (Slurry Seal/Coal Tar Over Dense Mix)

Figure A-40 Medium-Severity Raveling (Slurry Seal/Coal Tar Over Dense Mix)

Figure A-41 High-Severity Raveling (Slurry Seal/Coal Tar Over Dense Mix)

A-13.6 Porous Friction Course (PFC) Severity Levels.

L In a 1-square-foot (0.1-square-meter) representative sample, the number of aggregate pieces missing is between five and twenty and/or the number of missing aggregate clusters does not exceed one.

M In a 1-square-foot (0.1-square-meter) representative sample, the number of aggregate pieces missing is between 21 and 40 and/or the number of missing aggregate clusters is greater than one but does not exceed 25 percent of the area.

H In a 1-square-foot (0.1-square-meter) representative sample, the number of aggregate pieces missing is over 40 and/or the number of missing aggregate clusters is greater than 25 percent of the area.

A-13.7 How to Measure.

Raveling is measured in square feet (square meters) of surface area. Mechanical damage caused by hook drags, tire rims, or snowplows is counted as areas of high-severity raveling.

Figure A-42 Low-Severity Raveling (PFC)

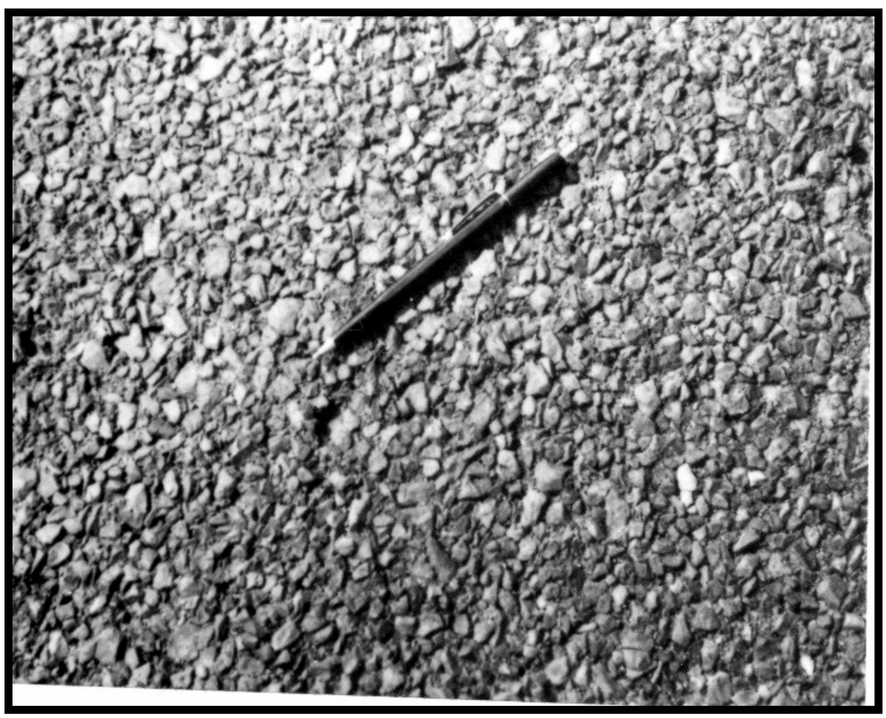

Figure A-43 Medium-Severity Raveling (PFC)

Figure A-44 Medium-Severity Raveling (PFC)

Figure A-45 High-Severity Raveling (PFC)

A-14 RUTTING (53) {13}.

A-14.1 Description.

A rut is a surface depression in the wheel path. Pavement uplift may occur along the sides of the rut; however, in many instances, ruts are noticeable only after a rainfall, when the wheel paths are filled with water. Rutting stems from a permanent deformation in any of the pavement layers or subgrade. It is usually caused by consolidation or lateral movement of the materials due to traffic loads. Significant rutting can lead to major structural failure of the pavement.

A-14.2 How to Measure.

Rutting is measured in square feet (square meters) of surface area and the severity is determined by the mean depth of the rut. The mean rut depth is calculated in inches (millimeters) by laying a straightedge across the rut, measuring the depth, then using measurements taken along the length of the rut to compute the mean.

Table A-4. Mean Rut Depth Criteria

Severity	All Pavement Sections
L	0.25 to 0.5 inch (6 to 13 mm)
M	0.5 to 1 inch (13 to 25 mm)
H	> 1 inch (> 25 mm)

Figure A-46 Rutting

A-15 SHOVING OF ASPHALT PAVEMENT BY PCC SLABS (54) {14}.

A-15.1 Description.

PCC pavements occasionally increase in length at ends where they adjoin flexible pavements (commonly referred to as “pavement growth”). This “growth” shoves the asphalt- or tar-surfaced pavements, causing them to swell and crack. The PCC slab growth is caused by a gradual opening of the joints as they are filled with incompressible materials that prevent them from reclosing.

A-15.2 Severity Levels.

As a guide, Table A-5 is used to determine the severity levels of shoving. At present, no significant research has been conducted to quantify levels of severity of shoving.

Table A-5. Shoving Criteria

Severity	Height Differential
L	< 0.75 inch (< 19 mm)
M	0.75 to 1.5 inch (19 mm to 38 mm)
H	> 1.5 inch (> 38 mm)

L A slight amount of shoving has occurred, with little effect on ride quality and no breakup of the asphalt pavement.

M A significant amount of shoving has occurred, causing moderate roughness or breakup of the asphalt pavement.

H A large amount of shoving has occurred, causing severe roughness or breakup of the asphalt pavement.

A-15.3 How to Measure.

Shoving is measured by determining the area in square feet (square meters) of the swell caused by shoving.

Figure A-47 Low-Severity Shoving

Figure A-48 Medium-Severity Shoving

Figure A-49 High-Severity Shoving

A-16 SLIPPAGE CRACKING (55) {15}.

A-16.1 Description.

Slippage cracks are crescent- or half-moon-shaped cracks having two ends pointed in the direction of traffic. They are produced when braking or turning wheels cause the pavement surface to slide and deform. This usually occurs when there is a low-strength surface mix or poor bond between the surface and next layer of pavement structure.

A-16.2 Severity Levels.

No degrees of severity are defined. It is sufficient to indicate that a slippage crack exists.

A-16.3 How to Measure.

Slippage cracking is measured in square feet (square meters) of surface area.

Figure A-50 Slippage Cracking

A-17 SWELL (56) {16}.

A-17.1 Description.

A swell is characterized by an upward bulge in the pavement's surface. A swell may occur sharply over a small area or as a longer, gradual wave. Either type of swell can be accompanied by surface cracking. A swell is usually caused by frost action in the subgrade or by swelling soil but a small swell can also occur on the surface of an asphalt overlay (over PCC) as a result of a blowup in the PCC slab.

A-17.2 Severity Levels.

L Swell is barely visible and has a minor effect on the pavement's ride quality as determined at the normal aircraft speed for the pavement section under consideration. (Low-severity swells are not always observable but their existence can be confirmed by driving a vehicle over the section at the normal aircraft speed. An upward acceleration will occur if the swell is present.)

M Swell can be observed without difficulty and has a significant effect on the pavement's ride quality as determined at the normal aircraft speed for the pavement section under consideration.

H Swell can be readily observed and severely affects the pavement's ride quality at the normal aircraft speed for the pavement section under consideration.

A-17.3 How to Measure.

The surface area of the swell is measured in square feet (square meters). Consider the type of pavement section (i.e., runway, taxiway, or apron) when determining the severity rating. For example, a swell of sufficient magnitude to cause considerable roughness on a runway at high speeds would be rated as more severe than the same swell located on the apron or taxiway where the normal aircraft operating speeds are much lower. The guidance in Table A-6 is provided for runways:

Table A-6. Swell Criteria

Severity	Height Differential
L	< 0.75 inch (< 19 mm)
M	0.75 to 1.5 inch (19 to 38 mm)
H	> 1.5 inch (> 38 mm)

Figure A-51 Low-Severity Swell

Figure A-52 Medium-Severity Swell

Figure A-53 High-Severity Swell

A-18 WEATHERING (SURFACE WEAR) – DENSE MIX ASPHALT (57) {17}.

A-18.1 Description.

Weathering is the wearing away of the asphalt binder and fine aggregate matrix from the pavement surface.

A-18.2 Severity Levels.

L Asphalt surface is beginning to show signs of aging that may be accelerated by climatic conditions. Loss of the fine aggregate matrix is noticeable and may be accompanied by fading of the asphalt color. Edges of the coarse aggregates are beginning to be exposed (less than 0.04 inch [1 millimeter]). Pavement may be relatively new (as new as six months old).

M Loss of fine aggregate matrix is noticeable and edges of coarse aggregate have been exposed up to one-fourth of the width (of the longest side) of the coarse aggregate due to the loss of fine aggregate matrix.

H Edges of coarse aggregate have been exposed greater than one-fourth of the width (of the longest side) of the coarse aggregate. There is considerable loss of fine aggregate matrix, leading to potential or some loss of coarse aggregate.

A-18.3 How to Measure.

Weathering (surface wear) is measured in square feet (square meters). Weathering (surface wear) is not recorded if medium- or high-severity raveling is recorded.

Figure A-54 Low-Severity Weathering

Figure A-55 Medium-Severity Weathering

Figure A-56 High-Severity Weathering

APPENDIX B DISTRESS DEFINITIONS -CONCRETE-SURFACED AIRFIELDS

B-1 INTRODUCTION.

This appendix contains distress definitions and measuring methods for concrete-surfaced airfields. This information is used to determine the pavement condition index (PCI).

Note: Each distress definition is followed by a number in parentheses, indicating the PAVER distress code, and a number in braces, indicating the ASTM D5340 distress code, i.e.,
"Distress (#) {#}." See Table 3-6.

Table B-1 Frequently Occurring Problems in Pavement Distress Identification

Situation	Action	Remarks
Low-severity scaling (i.e., crazing)	Count only if possible future scaling will occur within 2 to 3 years	
Joint seal damage	This is not counted on a slab-by-slab basis	A severity level based on the overall condition of the joint seal in the sample unit is assigned
Joint spall small enough to be filled during a joint seal repair	Do not record	
Medium- or high-severity intersecting crack (shattered slab)	Do not count any other distress	
Corner or joint spalling caused by "D" cracking	Record only "D" cracking	If spalls are caused by factors other than "D" cracking, record each factor separately
Crack repaired by a narrow patch (e.g., 4 to 10 in. [100 to 250 mm] wide)	Record only crack and not patch at appropriate severity level	
Original distress of patch more severe than patch itself	Record original distress type	If, for example, patch material is present on scaled area of slab, only the scaling is counted

Situation	Action	Remarks
Hairline cracks that are only a few feet (meters) long and do not extend across the entire slab	Rate as shrinkage cracks.	

B-2 BLOWUP (61) {1}.

B-2.1 Description.

Blowups occur in hot weather, usually at a transverse crack or joint that is not wide enough to permit expansion by the concrete slabs. The insufficient width is usually caused by infiltration of incompressible materials into the joint space. When expansion cannot relieve enough pressure, a localized upward movement of the slab edges (buckling) or shattering will occur in the vicinity of the joint. Blowups can also occur at utility cuts and drainage inlets. This type of distress is almost always repaired immediately because of the severe damage potential to aircraft. Blowups are included for reference when closed sections are being evaluated for reopening.

B-2.2 Severity Levels.

L Buckling or shattering has not rendered the pavement inoperative and only a slight amount of roughness exists.

M Buckling or shattering has not rendered the pavement inoperative but a significant amount of roughness exists.

H Buckling or shattering has rendered the pavement inoperative.

Note: For pavements to be considered operational, all foreign material from blowups must have been removed.

B-2.3 How to Count.

A blowup usually occurs at a transverse crack or joint. At a crack, a blowup is counted as being in one slab, but at a joint, two slabs are affected and the distress is recorded as occurring in two slabs.

Figure B-1 Low-Severity Blowup

Figure B-2 Low-Severity Blowup

Figure B-3 Medium-Severity Blowup

Figure B-4 High-Severity Blowup

B-3 CORNER BREAK (62) {2}.

B-3.1 Description.

A corner break is a crack that intersects the joints at a distance less than or equal to one-half the slab length on both sides, measured from the corner of the slab. For example, a slab that is 25 by 25 feet (7.5 by 7.5 meters) and has a crack intersecting the joint 5 feet (1.5 meters) from the corner on one side and 17 feet (5 meters) on the other side is not considered a corner break—it is a diagonal crack. However, a crack that intersects 7 feet (2 meters) on one side and 10 feet (3 meters) on the other is considered a corner break. A corner break differs from a corner spall in that the crack extends vertically through the entire slab thickness while a corner spall intersects the joint at an angle. Load repetition combined with loss of support and curling stresses causes corner breaks.

B-3.2 Severity Levels.

L Crack has either no spalling or minor spalling (no FOD potential). If non-filled, it has a mean width less than approximately 0.125 inch (3 millimeters); a filled crack can be of any width, but the filler material must be in satisfactory condition. The area between the corner break and the joints is not cracked.

M One of these conditions exists: (1) a filled or non-filled crack is moderately spalled (some FOD potential); (2) a non-filled crack has a mean width between 0.125 inch (3 millimeters) and 1 inch (25 millimeters); (3) a filled crack is not spalled or only lightly spalled but the filler is in unsatisfactory condition; or (4) the area between the corner break and the joints is lightly cracked. “Lightly cracked” means one low-severity crack dividing the corner into two pieces.

H One of these conditions exists: (1) a filled or non-filled crack is severely spalled, causing definite FOD potential; (2) a non-filled crack has a mean width greater than approximately 1 inch (25 millimeters), creating tire damage potential; or (3) the area between the corner break and the joints is severely cracked.

B-3.3 How to Count.

A distressed slab is recorded as one slab if it (1) contains a single corner break, (2) contains more than one break of a particular severity, or (3) contains two or more breaks of different severities. For two or more breaks, record the highest level of severity. For example, count as one slab with a medium-severity corner break a slab containing both low- and medium-severity corner breaks. Measure crack widths between vertical walls, not in spalled areas of the crack. If the corner break is faulted 0.125 inch (3 millimeters) or more, increase severity to the next higher level. If the corner is faulted more than 0.5 inch (13 millimeters), rate the corner break at high severity. If faulting in the corner is incidental to faulting in the slab, rate faulting separately. The angle of crack into the slab is usually not evident at low severity. Unless the crack angle can be determined, to differentiate between a corner break and corner spall, use these criteria: If the crack intersects both joints more than 2 feet (600 millimeters) from the corner, it is a corner break. If less than 2 feet (600 millimeters), unless you can verify the crack is vertical, it is a spall.

Figure B-5 Low-Severity Corner Break

Figure B-6 Medium-Severity Corner Break

Figure B-7 High-Severity Corner Break

B-4 LINEAR CRACKS (LONGITUDINAL, TRANSVERSE, AND DIAGONAL) (63) {3}.

B-4.1 Description.

These cracks, which divide the slab into two or three pieces, are usually caused by a combination of load repetition, curling stresses, and shrinkage stresses. (For slabs divided into four or more pieces, see shattered slab/intersecting cracks, paragraph B-13.) Low-severity cracks are usually warping- or friction-related and are not considered major structural distresses. Medium- or high-severity cracks are usually working cracks and are considered major structural distresses.

Hairline cracks that are only a few feet (meters) long and do not extend across the entire slab are rated as shrinkage cracks.

B-4.2 Non-reinforced PCC Severity Levels.

L Crack has no spalling or minor spalling (no FOD potential). If non-filled, it is less than 0.125 inch (3 millimeters) wide. A filled crack can be of any width but its filler material must be in satisfactory condition or the slab is divided into three pieces by low-severity cracks.

M One of these conditions exists: (1) a filled or non-filled crack is moderately spalled (some FOD potential); (2) a non-filled crack has a mean width between 0.125 inch (3 millimeters) and 1 inch (25 millimeters); (3) a filled crack has no spalling or minor spalling but the filler is in unsatisfactory condition; or (4) the slab is divided into three pieces by two or more cracks, one of which is at least medium severity.

H One of the following conditions exists: (1) a filled or non-filled crack is severely spalled (definite FOD potential); (2) a non-filled crack has a mean width approximately greater than 1 inch (25 millimeters), creating tire damage potential; or (3) the slab is divided into three pieces by two or more cracks, one of which is at least high severity.

B-4.3 How to Count.

Once the severity has been identified, the distress is recorded as one slab. If a crack is repaired by a narrow patch (e.g., 4 to 10 inches wide [100 to 250 millimeters]), record only the crack and not the patch at the appropriate severity level.

Cracks used to define and rate corner breaks, “D” cracks, patches, shrinkage cracks, and spalls are not recorded as longitudinal/transverse/diagonal cracks.

Figure B-8 Low-Severity Linear Cracks

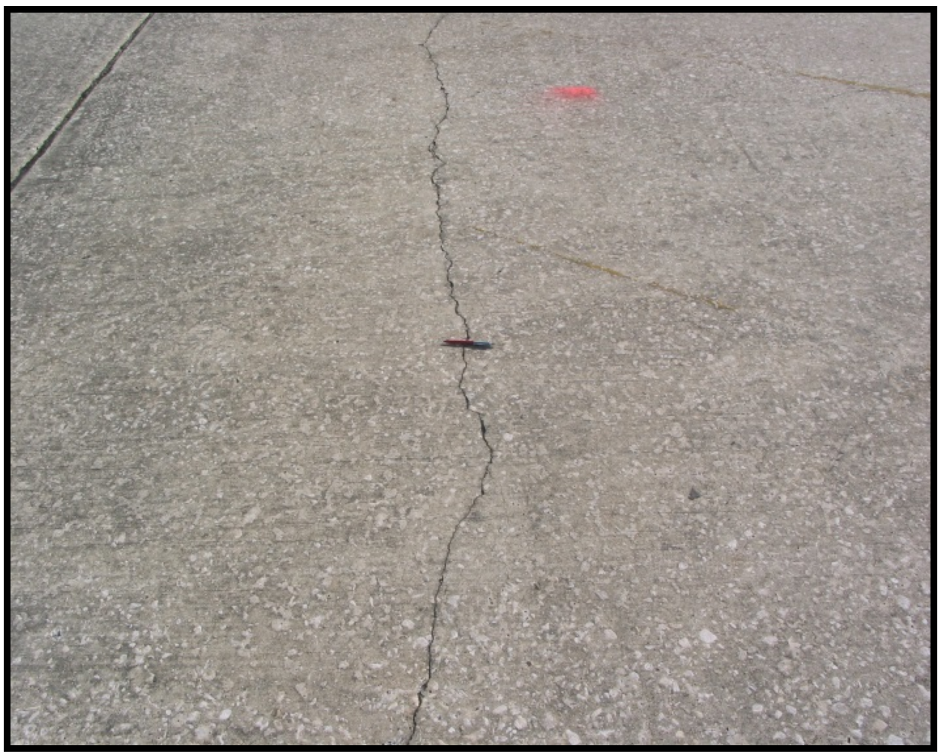

Figure B-9 Medium-Severity Linear Cracks

Figure B-10 High-Severity Linear Cracks

B-4.4 Reinforced Concrete Severity Levels.

L (1) Non-filled crack, 0.125 inch (3 millimeters) to 0.5 inch (13 millimeters) wide, with no faulting or spalling; (2) filled or non-filled cracks of any width < 0.5 inch (13 millimeters), with low-severity spalling; or (3) filled cracks of any width (filler satisfactory) with no faulting or spalling. **Note:** A crack less than 0.125 inch (3 millimeters) wide with no spalling or faulting is counted as shrinkage cracking.

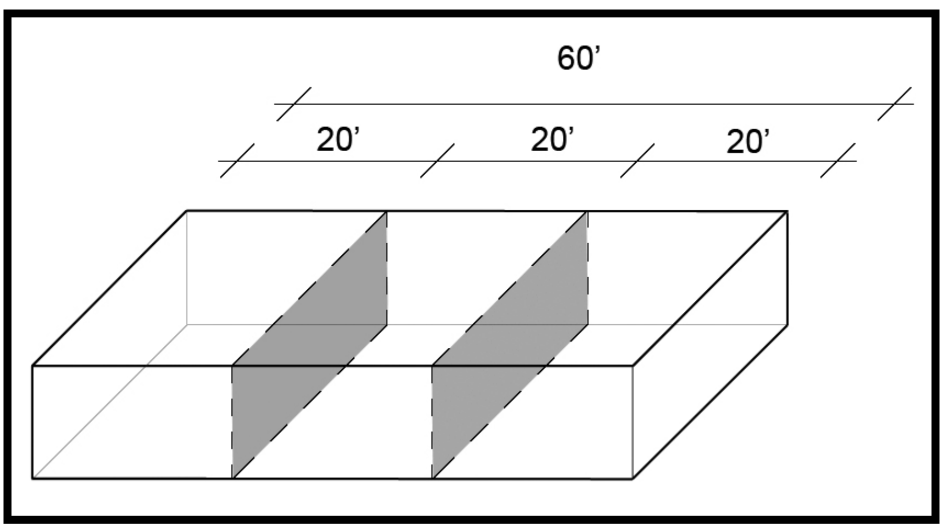
M (1) Non-filled cracks, 0.5 inch (13 millimeters) to 1 inch (25 millimeters) wide, with no faulting or spalling; (2) filled cracks of any width with faulting < 0.375 inch (10 millimeters) or medium-severity spalling; or (3) non-filled cracks of width < 1 inch (25 millimeters) with faulting < 0.375 inch (10 millimeters) or medium-severity spalling.

H (1) Non-filled cracks of width > 1 inch (25 millimeters); (2) non-filled cracks of any width with faulting > 0.375 inch (10 millimeters) or medium-severity spalling; or (3) filled cracks of any width with faulting > 0.375 inch (10 millimeters) or high-severity spalling.

B-4.5 How to Count.

Once the severity has been identified, the distress is recorded as one slab. If a crack is repaired by a narrow patch (e.g., 4 to 10 inches wide [100 to 250 millimeters]), only the crack and not the patch are recorded at the appropriate severity level. Slabs longer than 30 feet (9 meters) are divided into approximately equal length “slabs” having imaginary joints assumed to be in perfect condition.

Figure B-11 Cracks (Reinforced PCC)



B-5 DURABILITY (“D”) CRACKING (64) {4}.

B-5.1 Description.

Durability cracking is caused by the inability of the concrete to withstand environmental factors such as freeze-thaw cycles. It usually appears as a pattern of cracks running parallel to a joint or linear crack. A dark coloring is usually seen around the fine durability cracks. This type of cracking may eventually lead to disintegration of the concrete within 1 to 2 feet (0.3 to 0.6 meter) of the joint or crack.

B-5.2 Severity Levels.

L "D" cracking is defined by hairline cracks occurring in a limited area of the slab, such as one or two corners along one joint. Little or no disintegration has occurred. No FOD potential.

M (1) "D" cracking has developed over a considerable amount of slab area with little or no disintegration or FOD potential; or (2) "D" cracking has occurred in a limited area of the slab, such as in one or two corners or along one joint but pieces are missing and disintegration has occurred. Some FOD potential.

H "D" cracking has developed over a considerable amount of slab area with disintegration or FOD potential.

B-5.3 How to Count.

When the distress is located and rated at one severity, it is counted as one slab. If more than one severity level is found, the slab is counted as having the higher severity distress. If "D" cracking is counted, do not record scaling on the same slab.

Figure B-12 Low-Severity "D" Cracking

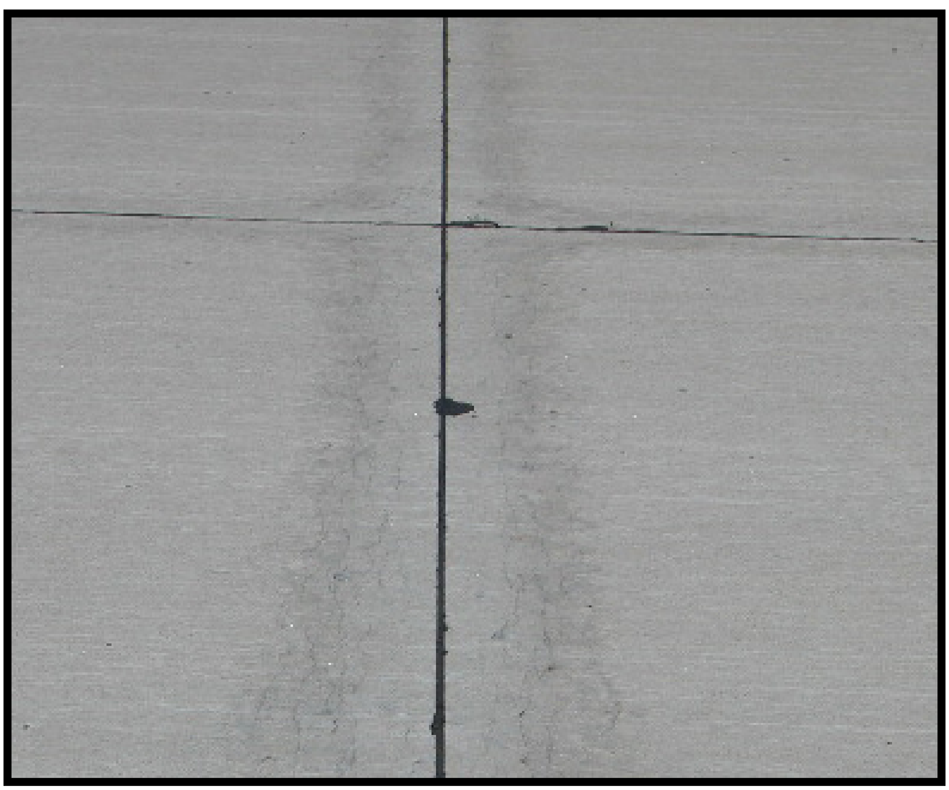


Figure B-13 Medium-Severity "D" Cracking

Figure B-14 High-Severity "D" Cracking

B-6 JOINT SEAL DAMAGE (65) {5}.

B-6.1 Description.

Joint seal damage is any condition that enables soil or rocks to accumulate in the joints or allows significant infiltration of water. Accumulation of incompressible materials prevents the slabs from expanding and may result in buckling, shattering, or spalling. Pliable joint filler bonded to the edges of the slabs protects the joints from accumulating materials and prevents water from seeping down and softening the foundation supporting the slab. Typical types of joint seal damage are (a) stripping of joint sealant, (b) extrusion of joint sealant, (c) weed growth, (d) hardening of the filler (oxidation), (e) loss of bond to the slab edges, and (f) lack or absence of sealant in the joint.

B-6.2 Severity Levels.

L Joint sealer is in generally good condition throughout the sample. Sealant is performing well, with only a minor amount of any of the above types of damage present. Joint seal damage is at low severity if a few of the joints have sealer that has debonded from, but is still in contact with, the joint edge. This condition exists if a knife blade can be inserted between the sealer and joint face without resistance.

M Joint sealer is in generally fair condition over the entire surveyed section, with one or more of the above types of damage occurring to a moderate degree. Sealant needs replacement within two years. Joint seal damage is at medium severity if a few of the joints have any of these conditions: (1) joint sealer is in place but water access is possible through visible openings no more than 0.125 inch (3 millimeters) wide. If a knife blade cannot be inserted easily between sealer and joint face, this condition does not exist; (2) pumping debris is evident at the joint; (3) joint sealer is oxidized and “lifeless” but pliable (like a rope) and generally fills the joint opening; or (4) vegetation in the joint is obvious but does not obscure the joint opening.

H Joint sealer is in generally poor condition over the entire surveyed section, with one or more of the above types of damage occurring to a severe degree. Sealant needs immediate replacement. Joint seal damage is at high severity if 10 percent or more of the joint sealer exceeds the limiting criteria listed above or if 10 percent or more of the sealer is missing.

B-6.3 How to Count.

Joint seal damage is not counted on a slab-by-slab basis but is rated based on the overall condition of the sealant in the sample unit. Joint sealer is in satisfactory condition if it prevents entry of water into the joint, has some elasticity, and if no vegetation is growing between the sealer and joint face. Premolded sealer is rated using the same criteria as above except as follows: (1) premolded sealer is elastic and is firmly pressed against the joint walls and (2) premolded sealer is below the joint edge. If the sealer extends above the surface, it can be caught by moving equipment such as snow plows or brooms and pulled out of the joint. Premolded sealer is recorded at low severity if any part is visible above the joint edge. It is at medium severity if 10 percent or more of the length is above the joint edge or if any part is more than 0.5 inch (13 millimeters) above the joint edge. It is at high severity if 20 percent or more is above the joint edge, if any part is more than 1 inch (25 millimeters) above the joint edge, or if 10 percent or more is missing. Rate joint sealer by joint segment. Sample unit rating is the same as the most severe rating held by at least 20 percent of the segments rated. In rating oxidation, do not rate on appearance, rate on resilience. Some joint sealer will have a very dull surface and may even show surface cracks in the oxidized layer. If the sealer is performing satisfactorily and has good characteristics beneath the surface, it is satisfactory.

Figure B-15 Low-Severity Joint Seal Damage

Figure B-16 Medium-Severity Joint Seal Damage

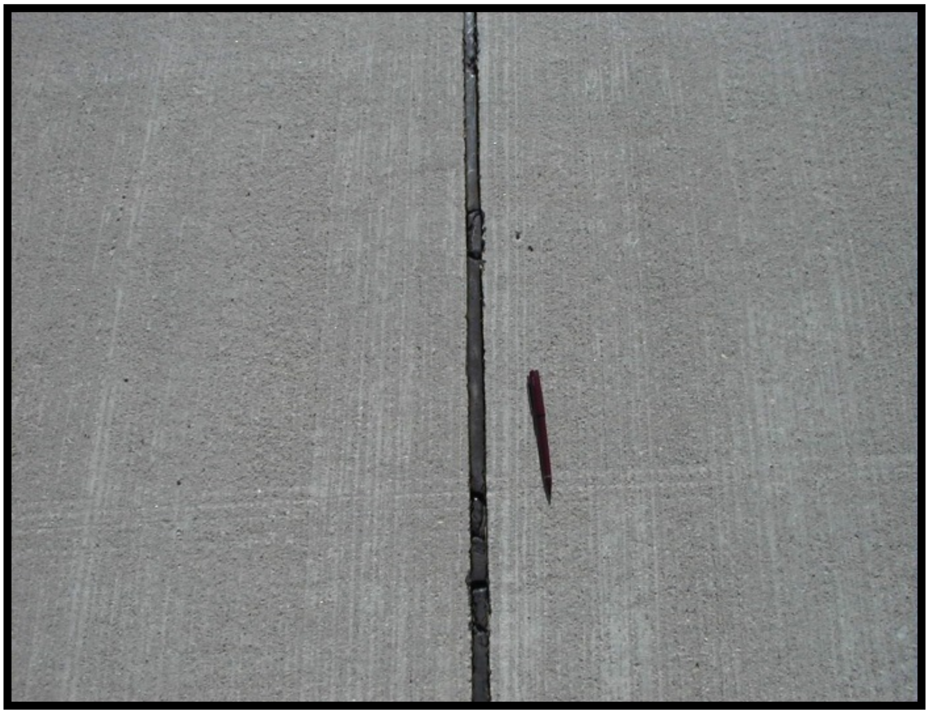

Figure B-17 High-Severity Joint Seal Damage

B-7 PATCHING, SMALL (LESS THAN 5.5 FT^2 [0.5 M^2]) (66) {6}.

B-7.1 Description.

A patch is an area where the original pavement has been removed and replaced by a filler material. For condition evaluation, patching is divided into two types: small (less than 5.5 square feet [0.5 square meter]) and large (over 5.5 square feet [0.5 square meter]). Large patches are described in the next section.

B-7.2 Severity Levels.

L Patch is functioning well, with little or no deterioration.

M Patch has deteriorated and/or moderate spalling can be seen around the edges. Patch material can be dislodged with considerable effort (minor FOD potential).

H Patch has deteriorated, either by spalling around the patch or cracking within the patch, to a state that warrants replacement.

B-7.3 How to Measure.

If one or more small patches having the same severity level are located in a slab, it is counted as one slab containing that distress. If more than one severity level occurs, it is counted as one slab, with the higher severity level being recorded. If a crack is repaired by a narrow patch (e.g., 4 to 10 inches [100 to 250 millimeters] wide), only the crack and not the patch is recorded at the appropriate severity level. If the original distress of a patch is more severe than the patch itself, the original distress type is recorded.

Figure B-18 Low-Severity Small Patch

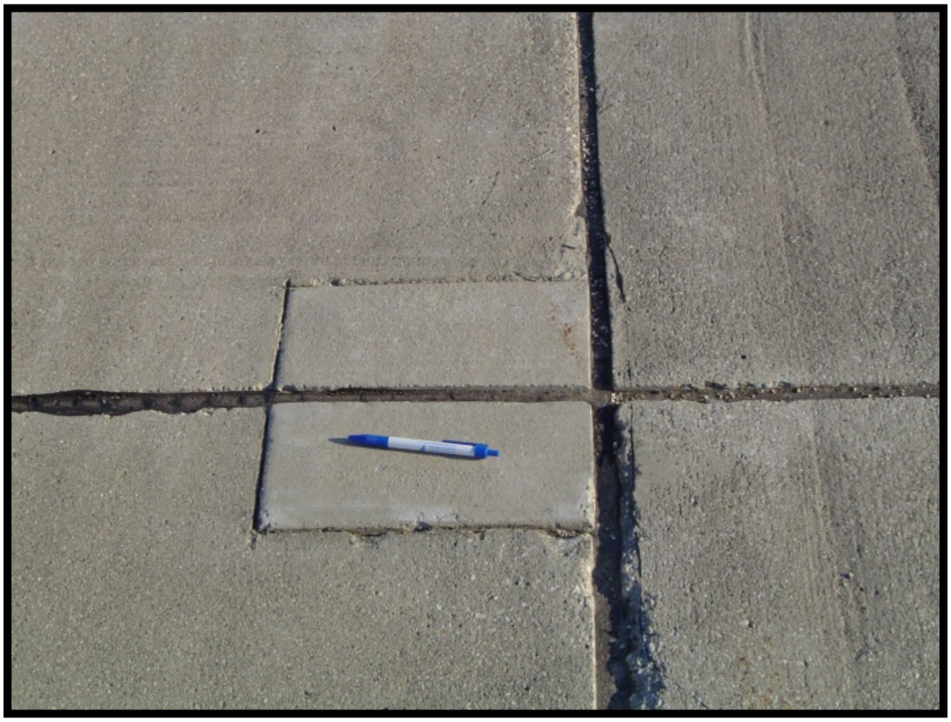

Figure B-19 Medium-Severity Small Patch

Figure B-20 High-Severity Small Patch

B-8 PATCHING, LARGE (OVER 5.5 FT^2 [0.5 M^2]) AND UTILITY CUT (67) {7}.

B-8.1 Description.

Patching is the same as defined in paragraph B-7. A utility cut is a patch that has replaced the original pavement because of placement of underground utilities. The severity levels of a utility cut are the same as those for regular patching.

B-8.2 Severity Levels.

L Patch is functioning well, with very little or no deterioration.

M Patch has deteriorated and/or moderate spalling is visible around the edges. Patch material can be dislodged with considerable effort, causing some FOD potential.

H Patch has deteriorated to a state that causes considerable roughness and/or high FOD potential. The extent of the deterioration warrants replacement of the patch.

B-8.3 How to Count.

The criteria are the same as for small patches (paragraph B-7).

Figure B-21 Low-Severity Large Patch

Figure B-22 Medium-Severity Large Patch

Figure B-23 High Severity Large Patch

B-9 POPOUTS (68) {8}.

B-9.1 Description.

A popout is a small piece of pavement that breaks loose from the surface due to freeze-thaw action in combination with expansive aggregates. Popouts usually range from approximately 1 inch (25 millimeters) to 4 inches (100 millimeters) in diameter and from 0.5 inch (13 millimeters) to 2 inches (50 millimeters) deep.

B-9.2 Severity Levels.

No degrees of severity are defined for popouts; however, when popouts are extensive, they are counted as a distress; i.e., average popout density exceeds approximately three popouts per square yard (square meter) over the entire slab area.

B-9.3 How to Count.

Always measure the density of the distress. If there is any doubt about the average being greater than three popouts per square yard (square meter), at least three random 1-square-yard (1-square-meter) areas are checked. When the average is greater than this density, the slab is counted.

Figure B-24 Popouts

B-10 PUMPING (69) {9}.

B-10.1 Description.

Pumping is the ejection of material by water through joints or cracks caused by deflection of the slab under passing loads. As the water is ejected, it carries particles of gravel, sand, clay, or silt and results in a progressive loss of pavement support. Surface staining and base or subgrade material on the pavement close to joints or cracks are evidence of pumping. Pumping near joints indicates poor joint sealer and loss of support, which will lead to cracking under repeated loads. Identify the joint seal as defective before pumping can be said to exist. Pumping can occur at cracks as well as joints.

B-10.2 Severity Levels.

No degrees of severity are defined. It is sufficient to indicate that pumping exists.

B-10.3 How to Count.

Slabs are counted as follows: one pumping joint between two slabs is counted as two slabs; however, if the remaining joints around the slab are also pumping, one slab is added per additional pumping joint.

Figure B-25 Pumping

Figure B-26 Pumping

B-11 SCALING (70) {10}.

B-11.1 Description.

B-11.1.1 Scaling is surface deterioration caused by construction defects, material defects, and environmental factors. Generally, scaling is exhibited by delamination or disintegration of the slab surface to the depth of the defect.

B-11.1.2 Construction defects include over-finishing, addition of water to the pavement surface during finishing, lack of curing, and attempted surface repairs of fresh concrete with mortar. Generally, this occurs over a portion of a slab.

B-11.1.3 Material defects include inadequate air entrainment for the climate. Generally, this occurs over several slabs that were affected by the concrete batches.

B-11.1.4 Environmental factors include freezing of concrete before adequate strength is gained and thermal cycles from certain aircraft. Generally, this occurs over a large area for freezing and in isolated areas for thermal effects.

B-11.1.5 Typically, the FOD from scaling is removed by sweeping but the concrete will continue to scale until the affected depth is removed or expended.

B-11.2 Severity Levels.

L Minimal loss of surface paste that poses no FOD hazard. No FOD potential.

M The loss of surface paste that poses some FOD potential, including isolated fragments of loose mortar, exposure of the sides of coarse aggregate (less than one-fourth of the width of the coarse aggregate), or evidence of coarse aggregate coming loose from the surface.

H The high severity is associated with low-durability concrete that will continue to pose a high FOD hazard. Typically, the layer of surface mortar is observable at the perimeter of the scaled area and is likely to continue to scale due to environmental or other factors. Indication of high-severity FOD is that routine sweeping is not sufficient to avoid FOD issues.

B-11.3 How to Count.

If two or more levels of severity exist on a slab, the slab is counted as one slab having the maximum level of severity. If "D" cracking or alkali-silica reaction (ASR) is counted, scaling is not counted.

Figure B-27 Low-Severity Scaling

Figure B-28 Medium-Severity Scaling

Figure B-29 High-Severity Scaling

B-12 SETTLEMENT OR FAULTING (71) {11}.

B-12.1 Description.

Settlement or faulting is a difference of elevation at a joint or crack caused by upheaval or consolidation.

B-12.2 Severity Levels.

Severity levels are defined by the difference in elevation across the fault and the associated decrease in ride quality and safety as severity increases.

Table B-2. Difference in Elevation

Severity	Runways/ Taxiways	Aprons
L	< 0.25 inch (< 6 mm)	0.125–0.5 inch (3–13 mm)
M	0.25–0.5 inch (6–13 mm)	0.5–1 inch (13–25 mm)
H	> 0.5 inch (> 13 mm)	> 1 inch (> 25 mm)

B-12.3 How to Count.

In counting settlement, a fault between two slabs is counted as one slab. A straightedge or level is used to aid in measuring the difference in elevation between the two slabs.

Construction-induced elevation differential is not rated in PCI procedures. Where construction differential exists, it can often be identified by the way the high side of the joint was rolled down by finishers (usually within 6 inches [150 millimeters] of the joint) to meet the low-slab elevation.

Figure B-30 Low-Severity Settlement or Faulting

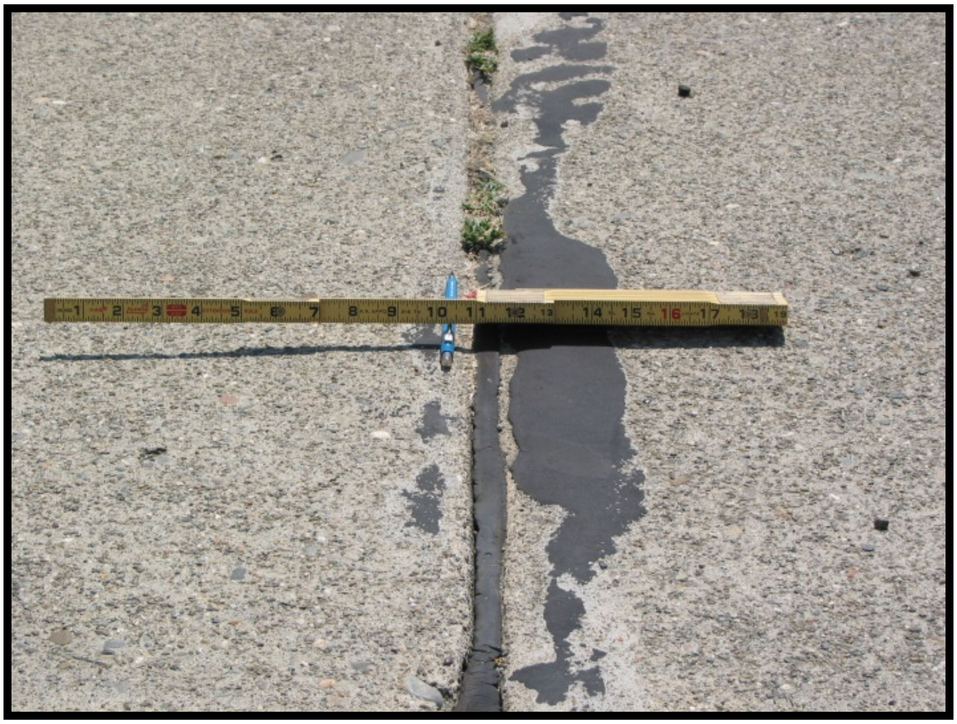

Figure B-31 Low-Severity Settlement or Faulting

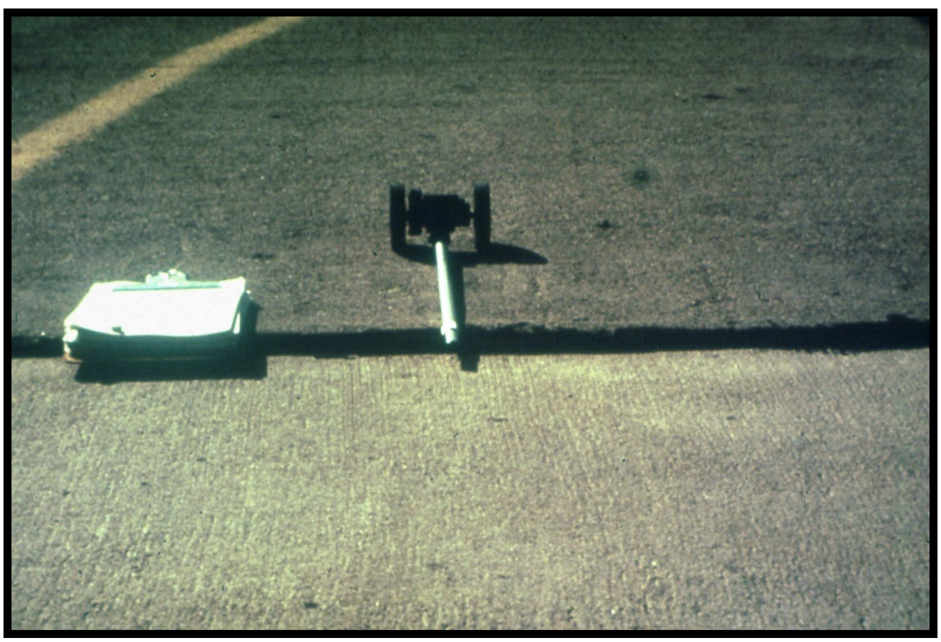
Figure B-32 High-Severity Settlement or Faulting



B-13 SHATTERED SLAB/INTERSECTING CRACKS (72) {12}.

B-13.1 Description.

Intersecting cracks are cracks that break the slab into four or more pieces because of overloading and/or inadequate support. The high-severity level of this distress type, as defined below, is referred to as a shattered slab. If all pieces or cracks are contained within a corner break, the distress is categorized as a severe corner break.

B-13.2 Severity Levels.

L Slab is broken into four or five pieces predominantly defined by low-severity cracks.

M (1) Slab is broken into four or five pieces, with over 15 percent of the cracks of medium severity (no high-severity cracks); or (2) slab is broken into six or more pieces, with over 85 percent of the cracks of low severity.

H At this level of severity, the slab is called shattered: (1) slab is broken into four or five pieces, with some or all of the cracks of high severity; (2) slab is broken into six or more pieces, with over 15 percent of the cracks of medium or high severity.

B-13.3 How to Count.

No other distress such as scaling, spalling, or durability cracking is recorded if the distress is medium- or high-severity level since the severity of this distress substantially affects the slab's rating. Shrinkage cracks are not counted in determining whether or not the slab is broken into four or more pieces.

Figure B-33 Low-Severity Shattered Slab/Intersecting Cracks

Figure B-34 Medium-Severity Shattered Slab/Intersecting Cracks

Figure B-35 High-Severity Shattered Slab/Intersecting Cracks

B-14 SHRINKAGE CRACKS (73) {13}.

B-14.1 Description.

Shrinkage cracks are hairline cracks that are usually only a few feet (meters) long and do not extend across the entire slab. They are formed during the setting and curing of the concrete and usually do not extend through the depth of the slab.

B-14.2 Severity Levels.

No degrees of severity are defined. It is sufficient to indicate that shrinkage cracks exist.

B-14.3 How to Count.

If one or more shrinkage cracks exist on one particular slab, the slab is counted as one slab with shrinkage cracks.

Figure B-36 Shrinkage Cracks

B-15 JOINT SPALLING (TRANSVERSE AND LONGITUDINAL JOINTS) (74) {14}.

B-15.1 Description.

Joint spalling is the breakdown of the slab edges within 2 feet (600 millimeters) of the side of the joint. A joint spall usually does not extend vertically through the slab but intersects the joint at an angle. Spalling results from excessive stresses at the joint or crack caused by infiltration of incompressible materials or traffic loads. Weak concrete at the joint (caused by overworking) combined with traffic loads also causes spalling.

Frayed condition as used in the test method in the following table indicates that material is no longer in place along a joint or crack. Spalling indicates material may or may not be missing along a joint or crack.

B-15.2 Severity Levels.

Table B-3 Severity Levels of Spalling

	Spall Length	Description
L	< 2 feet (600 mm)	Spall is broken into pieces or fragmented; little FOD or tire damage potential exists.
L	> 2 feet (600 mm)	(a) Spall is broken into no more than three pieces defined by low- or medium-severity cracks; little or no FOD potential exists; or (b) joint is lightly frayed; little or no FOD potential exists.
M	< 2 feet (600 mm)	Spall is broken into pieces or fragmented, with some of the pieces loose or absent, causing considerable FOD or tire damage potential.
M	> 2 feet (600 mm)	(a) Spall is broken into more than three pieces defined by light or medium cracks; (b) spall is broken into no more than three pieces, with one or more of the cracks being severe, with some FOD potential existing; or (c) joint is moderately frayed, with some FOD potential.
H	> 2 feet (600 mm)	(1) Spall is broken into more than three pieces defined by one or more high-severity cracks with high FOD potential; or (2) joint is severely frayed, with high FOD potential.

B-15.3 How to Count.

If the joint spall is located along the edge of one slab, it is counted as one slab with joint spalling. If spalling is located on more than one edge of the same slab, the edge having the highest severity is counted and recorded as one slab. Joint spalling can also occur along the edges of two adjacent slabs. If this is the case, each slab is counted as having joint spalling. If a joint spall is small enough to be filled during a joint seal repair, it is not recorded.

Figure B-37 Low-Severity Joint Spall

Figure B-38 Medium-Severity Joint Spall

Figure B-39 High-Severity Joint Spall

Figure B-40 High-Severity Joint Spall

B-16 SPALLING (CORNER) (75) {15}.

B-16.1 Description.

Corner spalling is the raveling or breakdown of the slab within approximately 2 feet (600 millimeters) of the corner. A corner spall differs from a corner break in that the spall angles downward to intersect the joint, while a break extends vertically through the slab.

B-16.2 Severity Levels.

L One of these conditions exists: (1) spall is broken into one or two pieces defined by low-severity cracks (little or no FOD potential); or (2) spall is defined by one medium-severity crack (little or no FOD potential).

M One of these conditions exists: (1) spall is broken into two or more pieces defined by one or more medium-severity cracks and a few small fragments may be absent or loose; (2) spall is defined by one severe, fragmented crack that may be accompanied by a few hairline cracks; or (3) spall has deteriorated to the extent that loose material is causing some FOD potential.

H One of these conditions exists: (1) spall is broken into two or more pieces defined by one or more high-severity fragmented cracks, with loose or absent fragments; (2) pieces of the spall have been displaced to the extent that a tire damage hazard exists; or (3) spall has deteriorated to the extent that loose material is causing high FOD potential.

B-16.3 How to Count.

If one or more corner spalls having the same severity level are located in a slab, the slab is counted as one slab with corner spalling. If more than one severity level occurs, it is counted as one slab having the higher severity level.

A corner spall smaller than 3 inches (76 millimeters) wide, measured from the edge of the slab and filled with sealant, is not recorded.

Figure B-41 Low-Severity Corner Spall

Figure B-42 Medium-Severity Corner Spall

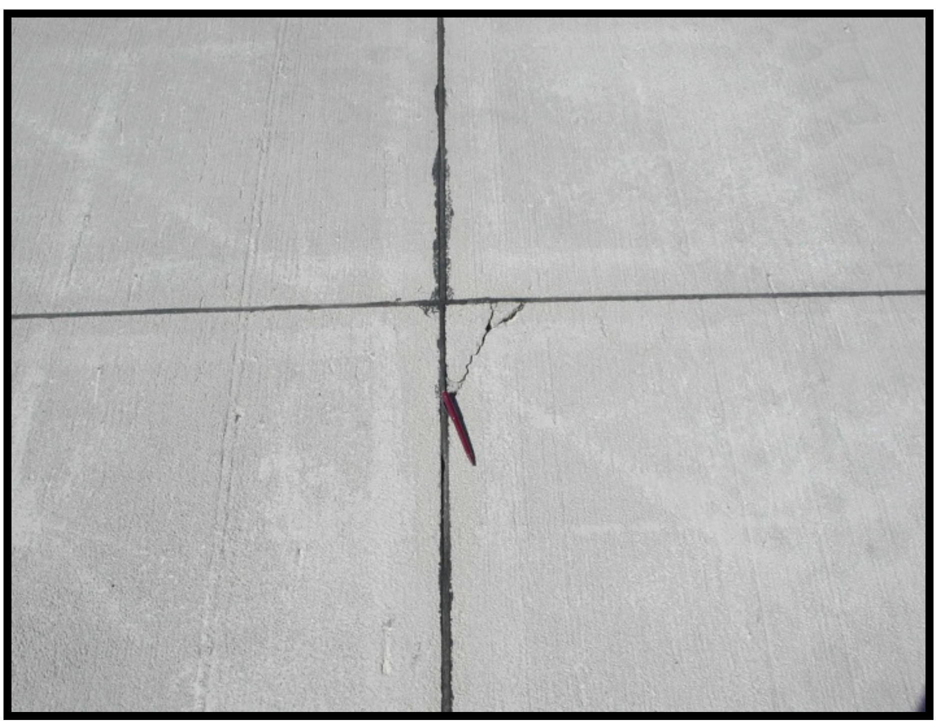


Figure B-43 High-Severity Corner Spall

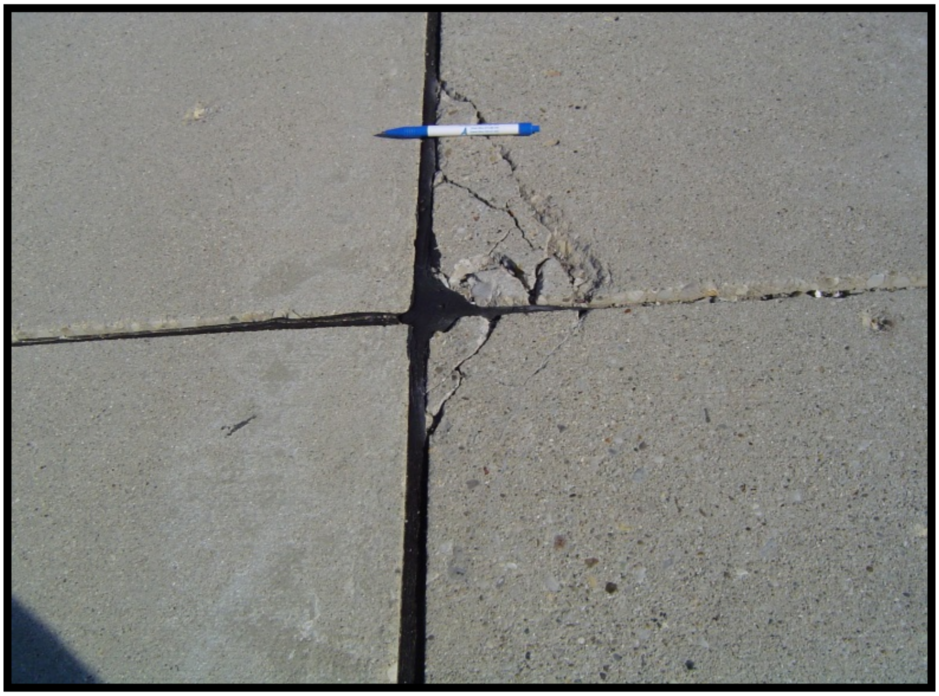

B-17 ALKALI-SILICA REACTION (ASR) (76) {16}.

B-17.1 Description.

ASR is caused by a chemical reaction between alkalis and certain reactive silica minerals, which form a gel. The gel absorbs water, causing expansion that may damage the concrete and adjacent structures. Alkalis are most often introduced by the portland cement within the pavement. ASR cracking may be accelerated by chemical pavement deicers. Visual indicators that ASR is present include:

- Cracking of the concrete pavement (often in a map pattern)
- White, brown, gray, or other colored gel or staining possibly present at the crack surface
- Aggregate popouts
- Increase in concrete volume (expansion) that may result in distortion of adjacent or integral structures or physical elements. Examples of expansion include shoving of asphalt pavements, light can tilting, slab faulting, joint misalignment, and extrusion of joint seals or expansion joint fillers.

Because ASR is material-dependent, it is generally present throughout the pavement section. Coring and concrete petrographic analysis is the only definitive method to confirm ASR. Keep these factors in mind when identifying the presence of ASR through visual inspection:

- Generally, ASR distresses are not observed in the first few years after construction. In contrast, plastic shrinkage cracking can occur the day of construction and is apparent within the first year.
- ASR is differentiated from D-cracking by the presence of cracking perpendicular to the joint face. D-cracking predominantly develops as a series of parallel cracks to joint faces and linear cracking within the slab.
- ASR is differentiated from map cracking/scaling by the presence of visual signs of expansion.

B-17.2 Severity Levels.

L Minimal to no FOD potential from cracks, joints, or ASR-related popouts; cracks at the surface are tight (predominantly 0.04 inch [1 millimeter] or less). Little to no evidence of movement in pavement or surrounding structures or elements.

M Some FOD potential; increased sweeping or other FOD removal methods may be required; there may be evidence of slab movement and/or some damage to adjacent structures or elements. Medium ASR distress is differentiated from low by having one or more of the following: increased FOD potential, increased cracking of the slab, some fragments along cracks or at crack intersections, possible surface popouts of concrete, pattern of wider cracks (predominantly 0.04 inch [1 millimeter] or wider) that may be subdivided by tighter cracks.

H One or both of these conditions exists: (1) loose or missing concrete fragments that pose high FOD potential; (2) slab surface integrity and function significantly degraded and pavement requires immediate repair; may also require repairs to adjacent structures or elements.

B-17.3 How to Count.

No other distresses are recorded if high-severity ASR is recorded.

APPENDIX F GLOSSARY

F-1 ACRONYMS.

AC	asphalt concrete
ASR	alkali-silica reaction
CDV	corrected deduct value
DOD	Department of Defense
FOD	foreign object damage
ft	foot
ft^2	square foot
HDV	highest deduct value
in.	inch
L&T	longitudinal and transverse
m^2	square meter
mm	millimeter
PCC	portland cement concrete
PCI	pavement condition index
PFC	porous friction course
UFC	Unified Facilities Criteria

F-2 DEFINITIONS OF TERMS

Additional sample — a sample unit inspected in addition to the random sample units to include non-representative sample units in the determination of the pavement condition. This includes very poor or excellent samples that are not typical of the section and sample units that contain an unusual distress such as a utility cut, oil spillage, or jet blast. If a sample unit containing an unusual distress is chosen at random, it should be counted as an additional sample unit and another random sample unit should be chosen. If every sample unit is surveyed then there are no additional sample units.

Asphalt concrete (AC) surface — aggregate mixture with an asphalt cement binder. This term also refers to surfaces constructed of coal tars and natural tars for purposes of this test method. Sometimes referred to as a flexible pavement.

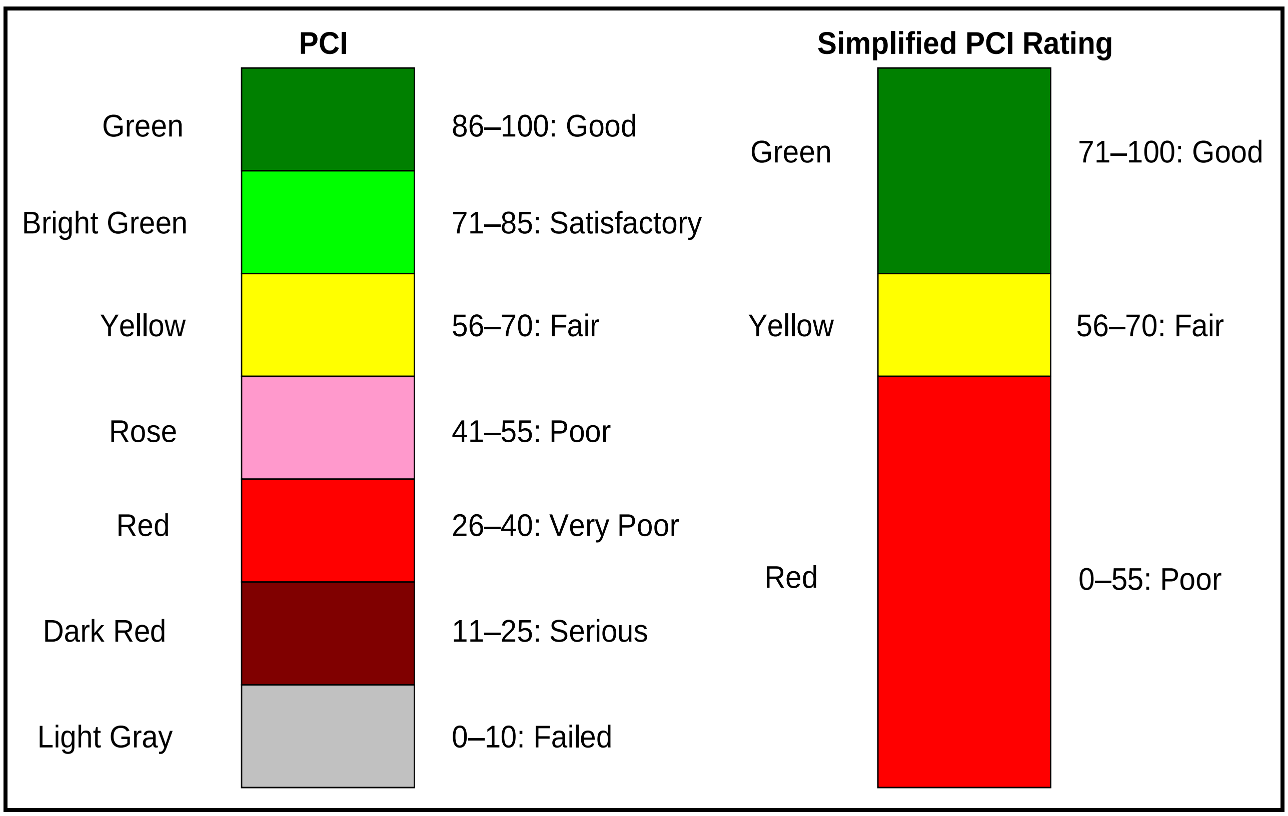
Deduct value (DV) — a number from 0 to 100, with 0 indicating the distress has no impact on pavement condition and 100 indicating an extremely serious distress that causes the pavement to fail.

Pavement branch — a branch is an identifiable part of the pavement network that is a single entity and has a distinct function. For example, each runway or taxiway is a separate branch.

Pavement condition index (PCI) — a numerical rating of the pavement condition that ranges from 0 to 100 with 0 being the worst possible condition and 100 being the best possible condition.

Pavement condition rating (PCR) — a verbal description of pavement condition as a function of the PCI value. This AEP establishes a standard color code for the seven condition codes developed by DOD and also for a corresponding simplified PCI rating system of Good (PCI = 71 to 100), Fair (PCI = 56 to 70), and Poor (PCI = 0 to 55), as depicted in Figure F-1. This system was adopted by and is also described in ASTM D5340.

Figure F-1 Pavement Condition Index (PCI) and Simplified PCI Rating Scales



Pavement distress — external indicators of pavement deterioration caused by loading, environmental factors, construction deficiencies, or a combination thereof. Typical distresses are cracks, rutting, and weathering of the pavement surface. Distress types and severity levels detailed in Appendix A for AC and Appendix B for PCC pavements must be used to obtain an accurate PCI value.

Pavement sample unit — a subdivision of a pavement section that has a standard size range: 20 slabs (±8 slabs if the total number of slabs in the section is not evenly divided by 20, or to accommodate specific field condition) for PCC pavement, and contiguous 5000 square feet ± 2000 square feet (465 square meters ± 185 square meters) if the pavement is not evenly divided by 5000 (or to accommodate specific field condition) for AC pavement.

Pavement section — a pavement area having uniform construction, maintenance, usage history, and condition. A section should have the same traffic volume and load intensity.

Portland cement concrete (PCC) pavement — aggregate mixture with portland cement binder including non-reinforced and reinforced jointed pavement. Sometimes referred to as a rigid pavement.

Random sample — a sample unit of the pavement section selected for inspection by random sampling techniques such as a random number table or systematic random procedure.

Primary Pavement — mission-essential pavements such as runways, parallel taxiways, main parking aprons, arm-disarm pads, alert aircraft pavements, turnabouts (hammer heads), and overruns (when the overrun is used as a taxiway or for takeoff roll). In general, only pavements that have aircraft use on a daily basis or frequently used transient taxiways and parking areas are considered primary.

Secondary Pavement — mission-essential but occasional-use airfield pavements, including ladder taxiways, infrequently used transient taxiway and parking areas, overflow parking areas, and overruns (when there is an aircraft arresting system present). In general, any pavements that do not have daily use by aircraft are secondary.

Tertiary Pavement — includes pavements used by towed or light aircraft, such as maintenance hangar access aprons, wash racks, overruns (when not used as a taxiway or to test aircraft arresting gear), and paved shoulders. In general, any pavement that does not support aircraft taxiing under their own power, areas where jet blast is limited, or is used only intermittently by aircraft is considered a tertiary pavement.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-260-17, *O&M Manual: Standard Practice for Dust Control on Roads, Airfields and Adjacent Areas*

Superseding: UFC 3-260-17, *Dust Control for Roads, Airfields and Adjacent Areas*, dated 16 January 2004, and Air Force ETL 09-3, *Chemical Dust Control for Contingency Roads, Base Camps, Helipads, and Airfields*, dated 3 March 2009.

Description: This UFC provides guidance for dust control materials and methods that are used successfully on roads, airfields, base camps, and areas adjacent to these structures to reduce airborne dust. This UFC applies to Army, Navy, and Air Force installations.

Reasons for Document:

The primary reason for the document update was to bring the document in compliance with UFC 1-300-01, *Criteria Format Standard*. A number of editorial changes were also needed to improve readability and correct typographical errors.

Impact:

Cost impact is negligible; improved guidance typically results in improved performance and reduced lifecycle cost.

Unification Issues:

None.

Disclaimer: Use of the name or mark of any specific manufacturer, commercial product, commodity, or service in this publication does not imply endorsement.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides guidance for dust control materials and methods used on roads, airfields, base camps, and areas adjacent to these structures to reduce airborne dust. Dust develops naturally in unpaved, denuded, or sparsely vegetated areas. Dust is created in unsurfaced areas subjected to concentrated foot or vehicular traffic and is a problem on shoulders of surfaced aircraft areas. Dust control improves health, safety, and wellness, limits increased costs associated with damage and maintenance on vehicles and other equipment, and minimizes dust signatures during military operations.

This UFC discusses dust control methods and materials that have proven effective to reduce dust; provides suggestions for rates and methods of application of materials for various soil types and environmental conditions; and discusses factors, such as availability, curing time, durability, logistics, and economics, which are significant in the ultimate choice of material. Agronomic, topical, and admixture methods are discussed; however, the primary focus is on dust palliatives. Appendix B addresses the specific problem of dune sands and how they may be partially controlled.

1-2 APPLICABILITY

This UFC applies to all military Service elements and contractors involved in the planning, design, construction, maintenance, repair, or preservation of DOD pavements worldwide. This UFC provides guidance for dust control materials and methods that are used successfully on roads, airfields, base camps, and areas adjacent to these structures to reduce airborne dust. This UFC outlines standard practices and will result in better oversight of work and help identify problem areas during application of the maintenance and repair (M&R) process.

1-3 REFERENCES.

Appendix A contains a list of references used in this UFC. The publication date of the code or standard is not included in this UFC. In general, the latest available issuance of the reference is used.

1-4 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

1-5 DEFINITION AND CAUSE.

The term “dust” is defined as particles of soil that have become airborne. Dust consists mainly of soil particles finer than 0.003 inch (0.074 millimeter) (i.e., passing the No. 200 sieve as described in ASTM E11). Dust is produced whenever the outside force(s) acting on a soil particle exceeds the force(s) holding it in place. Dust may occur naturally from the force of wind, although the production of dust is accelerated in areas of soil experiencing actual physical abrasion caused by the environment, vehicles, or activity. Dust is reduced by ground covers (such as grass, mulch, and geotextiles) that prevent wind forces from acting on the soil grains. Another mechanism is by adhesion between fine soil grains due to surface tension from liquids (such as water) or a physical bonding agent (such as portland cement). Agglomeration of fines increases the effective particle size, limiting the ability to become airborne. Other terms unique to this UFC are listed and defined in the following paragraphs.

1-5.1 Traffic Areas.

Traffic areas include roadways and vehicle parking areas; walkways; open storage areas; construction sites; runways, taxiways, shoulders, overruns, and parking areas of airfields and heliports; and tank trails.

1-5.2 Non-Traffic Areas.

Non-traffic areas include graded construction areas prior to turfing; graded construction areas that remain dormant for an extended period of time; denuded areas around the periphery of completed construction projects; areas bordering all airfield or heliport complexes; protective petroleum, oil, and lubricant (POL) dikes; magazine embankments of ammunition storage barricades; bunkers and revetments; cantonment, warehouse, storage, and housing areas, excluding walkways and roadways; unimproved grounds; and areas experiencing windborne sand (see Appendix B).

1-5.3 Occasional-Traffic Areas.

Occasional-traffic areas include shoulders and overruns of airfields used by propeller or jet aircraft; shoulders, hover lanes, and peripheral areas of heliports and helipads; and non-traffic areas where occasional traffic becomes necessary.

1-5.4 Dust Palliative.

A dust palliative is a material applied to soil to prevent soil particles from becoming airborne. Other terms used to indicate a dust control material include dustproofer, soil stabilizer, soil waterproofer, and dust control agent.

1-5.5 Pre-Wet.

Pre-wetting is the initial application of water on a soil surface prior to applying a liquid surface penetrant. This action primes the soil, improving the penetration and coverage of water-based palliatives.

CHAPTER 2 FACTORS FOR CONSIDERATION

2-1 GENERAL.

A wide selection of dust palliatives for dust control is available to the engineer; however, no one material is singled out as being the most acceptable for all situations. The successful control of dust and erosion in an area depends on several factors, the most important of which are:

- Influencing factors
- Environmental factors
- Expected traffic
- Topography
- Soil type
- Soil surface feature(s)
- Climate

2-2 FACTORS INFLUENCING DUST.

The presence of dust-size particles in a soil does not indicate a dust problem or severity of the dust problem that results in various situations. Many factors contribute to the formation, severity, and endurance of dust, including soil texture and structure, soil moisture content, soil density, presence of salts or organic matter in the soil, smoothness of the ground surface, vegetative cover, wind velocity and direction, and humidity. Depending on these factors, an external force imposed on a ground surface generates volumes of dust of varying density, size, and height above ground which are referred to as dust clouds. Figure 2-1 shows three typical dust clouds rising from military vehicles. Dust clouds are generated by drafts of moving air from windstorms, aircraft engines, or ground vehicles, which not only produce drafts of moving air but also abrade the soil surface.

2-3 ENVIRONMENTAL FACTORS.

For the selection and use of control methods and dust palliatives, consider applicable local safety, health, and environmental requirements. In the United States, material compliance with existing Environmental Protection Agency (EPA) rules and regulations is required.

Figure 2-1 Three Examples of Typical Dust Clouds

2-4 EXPECTED TRAFFIC.

The areas requiring treatment are divided according to the amount of traffic expected: those with no traffic, with occasional traffic, and with channelized traffic (i.e., roadway or taxiway). Where the extent of traffic is predicted or regulated, savings in time and material(s) is realized by adjusting the type and amount of treatment an area receives according to use.

2-4.1 Non-Traffic Areas.

These areas require treatment to withstand the effects of airblast due to wind or nearby vehicle operations and are not subjected to actual traffic of any kind. If traffic is applied, the treated area typically is damaged and repairs are required. In the majority of cases, establishing vegetative ground cover is the best solution for long-term dust and erosion control. However, for the short term, intermittent dust control is needed following construction or other activities that disturb the soil.

2-4.2 Occasional-Traffic Areas.

Besides resisting wind, helicopter rotor downwash, aircraft propwash, and airblast from jet engines, these areas also are subjected to occasional traffic by vehicles, aircraft, or personnel. Treatment for jet airblast is more involved than that required for helicopter and aircraft propellers; however, treatment for either is adequate to support occasional, non-channelized, vehicular traffic. If traffic conditions change and multiple passes or repeated crossings along the same path occur, the treated area has the potential to be damaged and repairs required. As with non-traffic areas, establishing vegetative ground cover is the best solution for long-term dust and erosion control.

2-4.3 Traffic Areas.

These areas require treatment to withstand regular channelized traffic by vehicles, aircraft, or personnel. Areas treated to withstand regular channelized traffic typically withstand airblast from aircraft and helicopters when applicable.

Perform an economic analysis of the cost to maintain an unsurfaced road versus the costs associated with a paved surface road on a case-by-case basis. Give consideration to the amount of maintenance required, level of traffic, ease of construction, and local costs. Where these areas are considered permanent, treat as specified in existing guidance publications.

2-5 TOPOGRAPHY.

2-5.1 Distinction Between Flat and Hillside Areas.

Consider the overall topography of the area as either flat or hillside. “Flat” is defined as an average ground surface slope of 5 percent or less while “hillside” refers to an average ground surface slope steeper than 5 percent. Place emphasis on the fact that the entire topography of the area to be treated is considered and not specific spot areas. Spot areas are given special attention as needed.

2-5.2 Dust Control for Flat and Hillside Areas.

Dust control depends on the type of traffic expected, etc.; however, the final dust palliative selected is affected by the slope. Liquid dust palliatives flow instead of penetrate on sloped surfaces. Tilling the dust palliatives, either liquid or powder, is recommended on hillside surfaces.

2-6 SOIL TYPE.

The soil type is one of the key features used to determine which method and material is used for dust control. Soils to be treated for dust control have been placed in five general descriptive groupings based on the Unified Soil Classification System (USCS) (see ASTM D2487).

- G = Gravel
- S = Sand
- M = Silt
- C = Clay
- O = Organic

2-6.2 Silts or Clays (High Liquid Limit).

The relatively impervious, plastic, fine-grained soils encompass USCS types CH, OH, and MH.

2-6.3 Silts or Clays (Low Liquid Limit).

The moderately permeable, low- to medium-plasticity, fine-grained soils encompass USCS types ML, CL, ML-CL, and OL.

2-6.4 Sands or Gravels (With Fines).

The moderately permeable, coarse-grained soils contain an appreciable amount of fines, encompassing USCS types SM, SC, SM-SC, GM, GC, GM-GC, and GW-GM.

2-6.5 Sands (With Little or No Fines).

The highly permeable sands or gravelly sands contain little or no fines, encompassing USCS types SW-SM, SP, and SW.

2-6.6 Gravels (With Little or No Fines).

The highly permeable gravels or sandy gravels contain little or no fines, encompassing USCS types GP and GW.

2-7 SOIL SURFACE FEATURES.

Soil surface features refer to both the state of compaction and degree of saturation of the soil in the area being considered.

2-7.1 Loose and Dry or Slightly Damp.

The surface consists of a cover, 0.25 to 2 inches (6 to 51 millimeters) thick, of unbound or uncompacted soil overlying a relatively firm subgrade and ranging in moisture content from dry to slightly damp. This surface is acceptable for treatment where no traffic or only occasional traffic is expected.

2-7.2 Loose and Wet or Slurry.

A surface condition consists of a cover, 0.25 to 2 inches (6 to 51 millimeters) thick, of unbound or uncompacted soil overlying a soft to firm subgrade and ranging in moisture content from wet to slurry consistency. Soil in this state cannot be treated until it is dried to the condition defined in either paragraph 2-7.1 or paragraph 2-7.3.

2-7.3 Firm and Dry or Slightly Damp.

The surface condition consists of a less than 0.25-inch (6-millimeter) -thick layer of loose soil, ranging in moisture content from dry to slightly damp, overlying a bound or compacted firm soil subgrade. This surface is acceptable for treatment for dust control regardless of the expected traffic.

2-7.4 Firm and Wet.

This surface condition is similar to that defined in paragraph 2-7.3 but has a wet surface. Soil in this condition cannot be treated until it is dried to the condition defined in paragraph 2-7.3.

2-8 CLIMATE.

2-8.1 Adverse Effects.

The climate in the area where dust control is desired could adversely affect the dust palliative(s) during storage (prior to placement), during placement (the construction and/or cure period), and after placement. The climate at the time of placement and after placement is considered when selecting a palliative. Agronomic methods are initiated at the onset of the growing season, which in some cases is limited to a few weeks.

2-8.2 Weather Extremes.

Weather extremes accelerate the aging and/or deterioration of most materials, and dust palliatives are no exception. Salts become ineffective during extended periods of no rainfall and when the relative humidity falls below 30 percent. Other palliatives (e.g., salts, polysaccharides) may leach from the soil during rain.

2-8.3 Freezing Effects.

Store, place, and permit liquid dust palliatives to cure at temperatures above 40 degrees Fahrenheit (4.4 degrees Celsius). Water-based palliatives (e.g., emulsions) are subject to freezing, which has detrimental effects on the physical properties, performance, and placement equipment. Some dust palliatives become brittle when exposed to extreme cold; therefore, do not traffic (if possible).

2-8.4 Storage of Liquids.

Storage of liquids may result in the settling of some components in the liquid. Mix concentrated liquid stabilizers by recirculating or mechanically stirring the material within the container. At temperatures above 90 degrees Fahrenheit (32.2 degrees Celsius), some bituminous products become tacky. Emulsions stored in containers in the sun can dry to a film in the headspace above the liquid. Once dried, the film does not re-disperse in the liquid. If the film dislodges into the liquid, it clogs spray nozzles, causing significant problems if proper filtering is not employed.

CHAPTER 3 DUST CONTROL METHODS

3-1 GENERAL.

This chapter describes three readily available types of dust control methods and the type of traffic areas where a dust palliative is applicable. Each dust control method is considered in relation to the specific job requirements. The dust control treatment methods commonly used are:

- Agronomic
- Topical application
- Admixtures

The agronomic method requires knowledge of the indigenous vegetation and access to farm-type equipment. Topical applications are the easiest to apply. Topical application requires a material placement procedure (i.e., spreading aggregate or geotextile over the area) or a material-spraying procedure. One of these two methods suffices for the majority of dust control cases. The admixture method requires standard road-building techniques using construction equipment. The agronomic and admixture methods are more complex and require more time and equipment to implement. These methods require specific handling, equipment, and procedures. When using any chemicals, adhere to the manufacturer's precautions for the use of personal protective equipment (e.g., masks, safety glasses, gloves) as required.

3-2 AGRONOMIC METHODS.

This method consists of establishing or extending and preserving vegetative cover, mulch, windbreaks, and rough tillage. It includes tasks such as seeding, sprigging, sodding, adding topsoil, fertilizing, mulching, and disking. Agronomic methods are not prescribed for traffic areas. Large areas are cleared for most construction projects, stripping the project area of the existing vegetation and all topsoil. Keep the extent of stripping to a minimum and the stripped topsoil with vegetative residue stockpiled for later use.

3-2.1 Vegetative Cover.

Vegetative cover is considered the most satisfactory form of dust palliative based on aesthetic aspects, durability, cost, and maintenance. This is the preferred method wherever it can be economically established and maintained. Areas of application are best limited to nontraffic areas. Where vegetative cover is to be ultimately established, select any dust palliative used for immediate surface protection with a view to minimize impairment to subsequent plant growth. While dense vegetation is certainly the most effective cover, more sparse native vegetation typical of semiarid and arid regions is a fully effective dust palliative under natural wind conditions so long as it is not damaged by traffic or other causes.

3-2.2 Mulch.

Use mulch only for non-aircraft applications due to the potential for damage to aircraft. A well-anchored mulch of vegetative material is used to stabilize soil against wind and water erosion in low- or non-traffic areas. Mulch refers to any substance, such as straw, hay, or other vegetative material, which is spread over the ground surface to protect it from the wind. Vegetative mulches are effective for one year and applied during any season.

Hydroseeds and hydromulches/fibrous mulches (blends of water, organic fibers, fertilizer, seed, and adhesive) are common and effective materials used for establishing vegetation. Bonded fiber matrix is a specialized method of hydroseeding that is hydraulically applied. A hydroseeder equipped with a spraying mechanism is used to place hydroseeds and hydromulches.

3-2.3 Windbreaks.

Any barrier of hedges, shrubs, or trees high and dense enough to protect facilities and unsurfaced soil areas is considered to be a windbreak. Windbreaks are placed at right angles to the direction of the prevailing wind. Several parallel windbreaks are required for high wind velocities; the higher the average wind velocity, the closer they are spaced. Their practical applicability solely for dust control is limited. Windbreaks supplement other dust control measures by reducing wind velocity. The use of windbreaks is recommended wherever they do not interfere with intended area activities.

3-2.4 Rough Tillage.

Chisels and turning plows are used to till strips across non-traffic areas that are sources of dust. Several strips are placed in parallel as an emergency measure to control dust in semiarid regions. Ensure the soil is cohesive enough to produce soil clods (lumps of earth with a minimum dimension of 1 inch [25 millimeters] measured in any direction). Strips are tilled at 25- to 100-foot (7.6- to 30.5-meter) intervals at right angles to the prevailing wind. As the strips become smooth through erosion, new strips are plowed adjacent to the earlier ones. The success of this method depends upon the formation of a cloddy, rough surface that breaks up the sweep of soil particles. Tillage of dry soil typical of desert areas is sometimes harmful rather than beneficial to dust control if a cloddy surface is not produced. Rough tillage is considered a temporary control measure to be followed by permanent vegetative cover, but it is sufficient as the only treatment if traffic is excluded from the area and the existing vegetation is capable of regeneration. Disk-type tillage tools are not used for rough tillage as they tend to pulverize the soil (i.e., soil clods are not formed). However, if long, narrow grooves are created, resulting in channelized runoff water, lay out the tillage on horizontal contours to prevent water damage.

3-3 TOPICAL APPLICATIONS.

3-3.1 Surface Penetration.

In the surface penetration method, a liquid dust palliative is applied directly on the soil surface by spraying or sprinkling and allowed to penetrate and/or seal the surface. This is the most common method of dust control due to the lower cost and ease of application compared to the admixture method. This method provides satisfactory—although temporary—dust abatement when significant penetration of the surface is achieved. However, if proper penetration is not achieved, a thin surface crust results, which is easily disturbed by traffic, allowing the underlying material to produce dust. Surface crusts are also more detrimental to aircraft than the dust itself, as larger particles and sheets of material become dislodged under airblast, presenting serious foreign object debris (FOD) potential. This is a concern in sandy and/or unprepared soils. A penetration depth of at least 1 inch (25 millimeters) is recommended for polymer emulsion products to minimize FOD potential. This recommendation is extended to all types of liquid dust palliatives applied topically.

Surface penetration applications are placed with a liquid pressure distributor, by a gravity-flow water distributor, or by hand-held devices. Position the spray apparatus 8 to 14 inches (203 to 355 millimeters) directly above the area being treated to preclude winddrift. Runoff is avoided by decreasing the application rate or applying the dust palliative at one-half the manufacturer's recommended rate and repeating the treatment before curing of the palliative begins.

3-3.1.1 Effectiveness.

The effectiveness of the surface penetration method depends on the depth of penetration, which is a function of the viscosity, surface tension of the liquid, and the permeability of the soil. This is a problem on compacted soils typical of most roads and airfields. Numerous products are designed with low viscosities, surfactants, and other surface-tension-reducing additives to improve penetration. For water-based palliatives, penetration is facilitated by lightly pre-wetting the surface with water before applying the dust palliative. This procedure reduces surface tension, which improves penetration and helps assure uniform coverage. Rapid-setting emulsions are particularly susceptible to forming surface crusts and are more suitable for the admixture method. Humectants require contact with air, having a relative humidity above 30 percent to absorb moisture into the soil; thus, they are well-suited for topical applications.

Surface penetrants require reapplication as they leach during rainfall, penetrate further into the soil over time, age, and wear from traffic. Reapplication rates vary between locations due to soil type, climate, rainfall, and traffic.

Surface penetration is well-suited for non-traffic areas and is temporarily effective for heavy or occasional traffic areas, provided the soil has adequate strength or has been conditioned for the stated use.

3-3.1.2 Types of Materials.

Types of materials used as surface penetrants:

- Humectants (calcium and magnesium salts, organic humectants)
- Petroleum products
- Polymer emulsions
- Synthetic fluids
- Plant resins (binders and natural oils)
- Biopolymers and polysaccharides

3-3.2 Surface Cover.

This method includes the use of aggregates, mats (i.e., AM-2 landing mat), or geotextiles (membranes or meshes) to create a surface cover or membrane for dust control. Geosynthetics/geotextiles and mats require extensive anchoring to be used around aircraft. Standard construction equipment is used effectively to place any of the systems applicable to the surface cover method.

In arid areas where most vegetative covers do not survive because of low rainfall, crushed or uncrushed gravel, slag, or tone aggregate (2 inches [51 millimeters] maximum size) is used as a dust palliative on nontraffic or occasional traffic areas. Aggregate is not recommended in close proximity to aircraft traffic because gravel particles can potentially be picked up and thrown by airblast, with possible damage to aircraft and ground personnel. Spread aggregate in a layer 2 inches (51 millimeters) thick and ensure it contains a minimum 80 percent by weight of particles retained on the 1.25-inch (32-millimeter) screen. Traffic over aggregate-covered areas presses the material into the soil and pulverizes the surface; therefore, this treatment is not recommended where channelized traffic is expected.

3-3.2.1 Effectiveness.

The surface cover method is applicable to nontraffic, occasional traffic, and heavy traffic areas, provided the soil has adequate strength or has been conditioned for the stated use. Aggregate and geotextiles are easy to place and withstand considerable rutting. Once a surface cover treatment is torn or otherwise compromised and the soil exposed, subsequent traffic or airblast increases the damage to the exposed soil. Begin repairs (maintenance) as soon as possible to protect the material in place and keep the dust controlled.

3-4 ADMIXTURE METHOD.

In the admixture method, the dust palliative is blended with the soil to produce a uniform mixture. This method takes more effort, time, and equipment than the penetration and surface cover methods; however, it also increases soil strength and improves performance of the additives. An admixture method is used when it is necessary to improve the soil and provide dust control. Emulsions and powdered additives are well-suited for the admixture method.

For in-place mixing, the surface soil is graded and loosened (if necessary) to a depth 1 to 2 inches (25 to 51 millimeters) greater than the design thickness of the treated layer. The dust palliative is added and blended with the loosened surface soil and the mixture is compacted. Powders may be spread by hand, by bag, or by a mechanical spreader; apply liquids with spray devices. The recommended mixing equipment includes rotary tillers and reclaimer-stabilizers. A grader, when used, is slow and inefficient at blending the additive with the soil. Ensure blending results in a uniform color of soil, both horizontally and vertically. Use compaction equipment and procedures for in-place mixing uses and soil-stabilization procedures (see UFC 3-250-11) for changing soil characteristics and soil strength used in road construction. For dust control on a nontraffic area, compaction is achieved by trafficking the entire surface with a 5-ton dual-wheel truck.

3-4.1 Depth of Treatment.

A minimum treatment of 3 inches (76 millimeters) is satisfactory for all nontraffic areas. To provide a dustproof surface in traffic areas, a minimum treatment depth of 4 inches (102 millimeters) is required. Mixing is accomplished in-place or offsite and is adaptable to a large variety of soil types. (The admixture method is not suitable for areas where a vegetative cover is to be established.)

3-4.2 Offsite Mixing.

Offsite mixing is used where in-place mixing is not desirable and/or soil from another source is needed to meet design requirements. Offsite mixing is accomplished with a stationary mixing plant or by windrow mixing with graders in a central working area. Processing the soil and dust palliative through a central plant produces a more uniform mixture than in-place mixing. The disadvantage in any offsite operation is having to transport and spread the mixed material.

3-4.3 Effectiveness.

The admixture method is effective for dust palliatives that provide increased soil strength, such as portland cement, asphalt and polymer emulsions, natural resins, and synthetic fluids (with binder).

3-4.4 Pertinent Areas.

The admixture method is applicable to nontraffic and occasional-traffic areas but is limited for traffic areas due to costs and manpower associated with construction.

This Page Intentionally Left Blank

CHAPTER 4 DUST PALLIATIVES

4-1 GENERAL.

4-1.1 Dust Palliative Categories.

This section describes the different categories of chemical dust palliatives. The objective of a dust palliative is to prevent soil particles from becoming airborne. Dust palliatives are required for controlling dust on nontraffic or traffic areas, or both. For nontraffic areas, a palliative is needed that resists the maximum intensity of air impingement caused by weather or nearby aircraft. For traffic areas, ensure dust palliatives withstand the abrasion of wheels, tracks, or airblast. Although a dust palliative provides resistance against air impingement, it is unsuitable as a wearing surface. An important factor limiting the applicability of a dust palliative in traffic areas is the extent of surface rutting that occurs under traffic. Rutting occurs if the bearing capacity of the soil is such that the soil surface depresses or compacts as a result of vehicle traffic. The effectiveness of a dust palliative treatment is destroyed by rutting and abrasion and any remaining dust palliative is quickly stripped from the ground surface. Some palliatives tolerate deformations better than others, but ruts 1 inch (25 millimeters) or greater result in the destruction of any treatment method.

4-1.2 Hard or Soft Crust.

Dust palliatives either form a hard crust or soft crust on the soil surface. There are advantages and disadvantages to both types of crusts. Hard crust palliatives cause soil particles to form brittle physical bonds, which is stable, but apply the product so there is sufficient penetration (2 to 3 inches [51 to 76 millimeters]) to prevent punctures of the crust during traffic. A soft crust palliative coats the soil particles but does not create a brittle crust, which is advantageous in that punctures caused by traffic do not create loose pieces.

4-1.3 Waterproofing Soils.

Often, a dust palliative also functions to waterproof the soil. When this occurs, the dust palliative not only prevents dust but also helps preserve soil strength during wet weather conditions. Ensure dust palliatives are not harmful to existing vegetation and/or make it difficult to establish vegetation in treated areas.

4-1.4 Materials General Overview.

The descriptions of materials in this chapter are intended to provide an overview of the various categories of products commercially available. There are numerous manufacturers of dust palliatives and some products do not fall clearly into the listed category. The guidelines given for use in this UFC are general for that category. Follow manufacturers’ suggested guidance where there are differences.

4-2 DETAILED DUST PALLIATIVE DESCRIPTION.

4-2.1 Water.

Water sprinkled on the soil surface is a temporary measure for reducing dust. As long as the ground surface remains moist or damp, soil particles resist becoming airborne. Depending on the soil and climate, frequent treatment may be required. Do not apply water to clay soil surfaces in such quantity that puddles form, since a muddy or slippery surface results where the soil remains wet.

4-2.2 Chloride Salts.

Salts (sodium, calcium, and magnesium chloride) are used extensively as dust palliatives due to their low cost. These salts are purchased as a powder, pellet, flake, or water solution. They absorb moisture from the air (deliquescence) or from dew and rainfall (hygroscopic), holding it in the soil. Calcium and magnesium chlorides are used more frequently than sodium chloride and retain soil moisture when the relative humidity is 30 percent or greater. A secondary effect of chlorides is a weak cement action when dry due to crystallization. All chlorides are soluble in water and leach from the soil surface over time, depending on the soil permeability and amount of rainfall; thus, maintenance is eventually required. Continued applications of salt solutions ultimately build up a thin, crusted surface that is hard and free of dust. **1**\ Do not use chloride salts within 25 feet (7.6 meters) of airfield pavements subject to aircraft traffic to reduce the possibility of corrosion to aircraft and airfield metals. /**1**/ Calcium chloride and magnesium chloride require relative humidity levels to be a minimum of 30 percent for adequate results. Sodium chloride requires humidity levels greater than 50 percent and is much less frequently used. Ensure the dust palliative selected and the quantity used meets manufacturer’s instructions and does not exceed local environmental protection regulations.

4-2.3 Petroleum Products.

4-2.3.1 Asphalt Emulsions.

Emulsified asphalts are a bituminous product used for dust control. Emulsified asphalts provide dust mitigation by binding surface particles and are used to treat both traffic and nontraffic areas. Bituminous materials impart waterproofing to the treated area that remains effective as long as the treatment remains intact but are sensitive to weather extremes. Do not place emulsions in the rain or when rain is expected.

Asphalt emulsions are a blend of asphalt, water, and an emulsifying agent, and are available either as anionic or cationic emulsions. Ambient temperature, relative humidity, and wind speed affect the rate at which emulsions cure. Do not place emulsions at temperatures below 50 degrees Fahrenheit (10 degrees Celsius). Heating emulsions reduces curing time. Never exceed the upper heating limit of 185 degrees Fahrenheit (85 degrees Celsius) because the asphalt and water separates (breaks), resulting in material damage. Under favorable ground temperature and weather conditions, emulsions are sufficiently cured in eight hours. The slow-setting (SS) anionic emulsions of grades SS-1 and SS-1h are diluted with one to five or more parts water to one part emulsified asphalt by volume prior to use. A three-parts-water-to-one-part-emulsion dilution meets most manufacturers' recommendations. The cationic slow-setting (CSS) emulsions of grades CSS-1 and CSS-1h are used without dilution. If dilution is required, ensure the water used is free of any impurities, minerals, or salts that might cause separation (breaking) of the emulsion within the distribution equipment.

4-2.3.2 Cutback Asphalts.

Diesel fuel, cutback asphalts, motor oil, and road tars are rarely used due to environmental concerns; however, they may still be in use in some areas of the world that have not implemented strict environmental regulations and where asphalt emulsions are not available.

A cutback asphalt is a blend of an asphalt cement and a petroleum solvent. Cutbacks are classified as rapid curing (RC), medium curing (MC), and slow curing (SC), depending on the type of solvent used and its rate of evaporation. Each cutback is further graded by its viscosity. The RC and SC grades of 70 and 250, respectively, and MC grades of 30, 70, and 250, are generally used. Regardless of classification or grade, the best results are obtained by preheating the cutback. Spraying temperatures range from 120 degrees to 300 degrees Fahrenheit (48.9 to 148.9 degrees Celsius). The actual range for a particular cutback is much narrower; therefore, request the actual range from the supplier at the time of purchase. The user is cautioned that some cutbacks are heated above their flash point for spraying purposes so no smoking or open flames is permitted during application or cure. MC-30 grade is sprayed without being heated if the temperature of the asphalt is 80 degrees Fahrenheit (26.7 degrees Celsius) or above. A moist soil surface assists penetration. Curing time for cutbacks varies with the type. Under favorable ground temperature and weather conditions, RC cures in one hour, MC in three to six hours, and SC in one to three days. In selecting the material for use, consider local environmental protection regulations.

4-2.4 Lignins.

Lignin and lignin derivatives are byproducts of the manufacture of wood pulp. They provide dust control by physically binding soil particles. They are soluble in water and therefore readily penetrate soils. Do not use gray or salt water for dilution. Its solubility also makes it susceptible to leaching from the soil; thus, application is repeated as necessary after rainfall.

4-2.5 Polymer.

Polymer emulsions are excellent products for soil stabilization and dust control. These materials have good adhesive characteristics and provide stiffness, toughness, and water resistance. Do not mix polymer emulsions with gray or salt water for dilution. Soils stabilized with polymer emulsions are similar to those that can be stabilized by bitumen.

Polymer emulsions used for dust control are generally vinyl acetate or acrylic-based copolymers suspended in water by surfactants. They consist of 40 to 60 percent solid particles by weight of emulsion. Once they are applied, the polymer particles begin to coalesce as the water evaporates from the system, leaving a soil-polymer matrix that prevents small dust particles from escaping the surface. The polymers used for dust control typically have excellent tensile and flexural strength, adhesion to soil particles, and resistance to water. Immediately rinse equipment used to apply polymers to prevent damage. Polymer products are limited by a short shelf life (less than two years). Due to some vendors diluting polymer emulsion products in the past, it is recommended that random samples of the bulk product be tested to ensure the bulk product includes at least 40 percent solids according to ASTM D2834.

Polymer products can also be purchased in the form of a water-soluble powder. The polymer undergoes a chemical reaction upon curing and forms a water-resistant film that binds soil grains.

4-2.6 Synthetic Fluids.

Synthetic fluids are hydrocarbon-based liquids that are clear, odorless, non-corrosive, and applied without water dilution. The fluids act by agglomerating soil particles. They are non-curing, re-workable, and are regraded and re-compacted if the road or airfield surface needs smoothing. They are applied with standard spray equipment at a wide range of temperatures, even well below freezing. The re-workable binder is ready for immediate use upon application and maintains effectiveness for several months, depending on traffic level and surface conditions at time of placement. Because synthetic fluids do not harden, they are recommended for expedient helipads due to their minimal curing time and low probability of FOD generation.

4-2.7 Polysaccharides.

Polysaccharides are solutions or suspensions of sugars, starches, and surfactants in water. They may be diluted with water, depending on the intended use. Polysaccharides provide dust abatement by encapsulating soil grains and providing a binding network in the ground. Many polysaccharides are humectant (absorb water from the air) and hygroscopic (hold water after wetting); therefore, they are best used in climates with average relative humidity above 30 percent and with occasional rainfall. They are considered to be biodegradable materials and may leach from the soil with exposure to precipitation.

4-2.8 Cementing Materials.

Cementing type powders (portland cement, hydrated lime, and fly ash) are primarily used to improve the strength of soils (see UFC 3-250-11); however, when they are mixed with soils in relatively small quantities (2 to 5 percent by dry soil weight), the modified soil becomes more resistant to dusting. Portland cement is generally suited for all soil types, provided uniform mixing is achieved, whereas hydrated lime is better suited for soils containing a high percentage of clay. Fly ash may be used in combination with either portland cement or lime. Keep the compacted soil surface moist for a minimum of seven days prior to traffic.

4-2.9 Polyacrylamides.

Polyacrylamides are water-soluble polymers that provide dust control through moisture retention. These materials are used as super-absorbents in baby diapers, chemical spill containment, and other applications. They are generally applied in powder or granular form because polyacrylamides cause very large increases in viscosity when dissolved in water. The solution has the consistency of mayonnaise and is difficult to apply to soil. Polyacrylamides swell when they come in contact with water and may cause volume changes in the soil. For this reason, they are not recommended for use on roads.

4-2.10 Alternative Materials.

New commercial off-the-shelf products are continually introduced to the market. Some examples of different products are blends including glycerin, vegetable oils, surfactants, or other polymers. Test sections for new products are always recommended before using the products. The glycerin blend and vegetable oil products do not harden on the surface and provide dust control when FOD is of concern.

4-2.11 Vendor Summary and Selection.

4-2.11.1 Potential Vendors.

A list of potential vendors is summarized in Appendix B-2, Table B-1.

4-2.11.2 Logical Considerations.

Make logical considerations, such as duration of effectiveness, equipment required, shipping, storage, and shelf life, when determining which chemicals to use for dust control. In cases where water is not available, either use products that do not require dilution or water should be shipped. **1**\ Salts (such as calcium and magnesium chloride) cause corrosion to vehicles and aircraft, which is a reason to select a different, possibly more expensive, product. /**1**/

4-2.11.3 Emulsified Products.

Emulsified products have limited shelf lives. They consist of finely dispersed hydrophobic particles suspended in water. This dispersion is relatively unstable and results in the settling of solid particles. Normal mixing procedures do not allow these particles to go back into solution, and the product will not perform as designed. Keep emulsions from extreme heat, ultraviolet light, and freezing temperatures. Chloride salts, powdered polymers, and synthetic fluids do not have limitations on shelf life.

4-2.11.4 Choosing a Dust Palliative.

Choosing a dust palliative is ultimately governed by the existing need for dust control. Some products work better for helipads, while others are more effective on roads or airfields. Use soft crust palliatives on helipads to prevent FOD generation. Consider each type of palliative's benefits and limitations before selecting a product.

This Page Intentionally Left Blank

CHAPTER 5 DUST PALLIATIVE APPLICATION

5-1 GENERAL APPLICATION INFORMATION.

The following section describes the primary considerations and methods for applying the recommended dust palliatives.

5-1.1 Soil Type.

The soil type affects the performance of dust palliatives. Fine-grained soils present a larger problem with dust generation and are more difficult to control. These soils require greater quantities of product to treat. Penetration is also hindered by the small pore sizes between soil grains. Multiple applications are required to treat fine-grained soils (silts and clays) to prevent ponding or surface runoff. Coarse-grained soils (sands and gravels) have higher infiltration rates to minimize ponding or runoff. Soil type is classified according to ASTM D2487.

5-1.2 Application Equipment.

Select application equipment based upon the types available and the application method. Projects occurring on or near military installations are more likely to have a broader range of choices for equipment types. Expeditionary missions in active theaters preclude the use of many types of machinery. The ultimate goal is to use equipment that allows the most efficient progress for placing dust palliatives. Larger areas need dispersion systems with large capacities. Liquid discharge is usually not the most time-consuming process. A hydroseeder can be used to spray over 100 gallons per minute. Other systems using a distribution bar spray around 50 gallons per minute. The time required to empty any tank at this rate is relatively small. The process dominating the construction time (for topical applications) is transporting and filling the equipment. For large jobs, it is important to use methods that reduce these steps. For treating small areas, time may not be as critical of a factor.

Rinse all equipment with water after transferring dust palliatives. Additionally, it is important to flush all distribution systems with water after applying dust palliatives. Film-forming products (polymers, lignosulfonates) coagulate within the distribution system and clog equipment. Cleaning the equipment after this occurs typically requires significant disassembly. Organic solvents may also be required to completely remove remaining polymer. It is important to rinse equipment after spraying chloride salts because of their tendency to corrode metal and initiate rust formation. Rinsing may be optional when using synthetic fluids for dust control. They tend to lubricate equipment and have not been found to generate problems. Cleaning is necessary if other types of liquids are to be placed in the equipment for other purposes.

5-1.3 Application Rates.

Choose application rates according to the soil type, the intended use of the treated area, and the necessary duration of use. Target a penetration depth of 1 inch (25 millimeters) for most applications where subjected to traffic. Dust palliatives applied to areas subjected to traffic are applied at a rate of 0.8 to 1.2 gallons per square yard (3.6 to 5.4 liters per square meter) and a lower rate used for nontraffic areas. **1**\ Synthetic fluids are applied at lower rates because they contain 100 percent active ingredients (often 0.4 gallon per square yard). /**1**/ Polymeric emulsions require application rates of greater than 1 gallon per square yard (4.5 liters per square meter) in areas of heavy traffic or for helipads. For example, using polymer emulsions on helipads requires an application rate of 1.2 gallons per square yard (5.4 liters per square meter) to produce thicker surface crusts to reduce FOD potential. Note that higher application rates are required if the polymer emulsions/polysaccharides are pre-diluted by the vendor as evidenced by less than 40 percent solids as measured according to ASTM D2834. Trial and error is necessary to achieve proper application rates.

Reapplication of dust palliatives is necessary as product effectiveness diminishes over time. Areas treated with chloride salts or synthetic fluids are rejuvenated by applying more palliative at half the original application rate. Troublesome areas or exposed, untreated soils require site preparatory work before spraying. Existing polymer film, if left undisturbed, typically repels the emulsion and prevents penetration of additional product.

5-1.4 Dilution Ratios.

Some products require dilution with water. These are typically any emulsified products (asphalt and polymer). Diluting the emulsion reduces the viscosity and improves penetration. In general, three parts water is added for each part product. Note that the recommended dilution ratio needs to be reduced if the palliatives have been pre-diluted by the vendor to less than 40 percent solids as measured according to ASTM D2834.

5-1.5 Topical Method.

Topical applications are the most commonly used technique for dust control. Spraying the surface of the soil with a dust palliative temporarily solves most dust problems. Alternative methods are used when the area to be treated is structurally deficient for the anticipated traffic or when greater durability is needed. Do not apply hard crust palliatives topically where heavy traffic is expected; soft crust palliatives can be applied topically on roads with sufficient bearing capacity. Topical applications are accomplished by spraying the dust palliative onto the native or prepared soil surface. It is imperative to maintain uniformity while dispersing the liquid. Application quantities are determined by estimating the area of ground surface to be treated and multiplying that area by the manufacturer's recommended application rate.

5-1.6 Admixture Method.

Admixture methods are designed to incorporate dust palliatives deeper into the soil and to provide longer-lasting dust abatement. These methods are usually necessary when heavy repetitive loading is introduced to the soil. Roads and airfields (runways, taxiways, or parking aprons) generally require admixture applications to achieve the desired results. Admixture depths for roads are typically a minimum of 3 inches (76 millimeters). The spray/till/compact/spray procedure (Figures 5-1 through 5-4) is recommended for incorporating the dust palliative into the soil.

1. Grade the soil using a motor grader (Figure 5-1).
2. Spray half of the total palliative application rate onto the soil surface.
3. Blend into top 3 inches (76 millimeters) of soil using a rotary mixer (Figure 5-2).
4. Compact using a steel-wheeled vibratory compactor until no significant change in density of the road surface is observed (Figure 5-3).
5. Spray remaining product onto compacted surface (Figure 5-4).

This method provides optimal performance of most palliatives; however, for more in-depth details and information on soil stabilization, consult UFC 3-250-11. Note that some palliatives do not provide any strength increase and may decrease the bearing capacity of the soil, which is important for airfield dust control.

Figure 5-1 Grading Road Surface Prior to Treatment

Figure 5-2 Applying Product with Hydroseeder and Mixing into Road Surface with Rotary Mixer

Figure 5-3 Compacting Road Surface After Mixing

Figure 5-4 Applying Final Spray to Seal Road Surface After Compaction

5-2 DISTRIBUTION EQUIPMENT.

A variety of distribution equipment is used to spray apply the palliatives. Appendix B, Table B-2, lists some manufacturers of spray equipment used for placing a variety of dust palliatives.

5-3 DETAILED APPLICATION GUIDANCE.

This section provides detailed guidance for treating helipads, roads, base camps, and fixed-wing airfield facilities.

5-3.1 Dust Abatement on Helipads.

This paragraph provides guidance for mitigating dust on unsurfaced helipads. A 150-foot by 150-foot (45.7-meter by 45.7-meter) helipad size is recommended for cargo helicopters, and a 100-foot by 100-foot (30.5-meter by 30.5-meter) helipad size is recommended for utility and attack helicopters. The equipment requirements may be modified, depending upon availability and mission requirements. Synthetic fluid is used as an example for the following procedures; however, the general types of equipment and process are similar for other liquid dust palliatives.

5-3.1.1 For dust abatement on helipads, provide and use the following:

- Motor grader for initial grading

- Vehicle(s) to haul the chemical totes, pumps, etc., and tow the distribution equipment
- Hydroseeder or other spray distribution system compatible with the selected chemical
- Dust palliative (synthetic fluid), typically in 275-gallon (1041-liter) totes (two to four required)
- Centrifugal pump and hoses with quick-connect ends to transfer the material from the tote to the distributor if the distributor does not include a pump
- Personnel (three)

5-3.1.2 The following steps will treat an expedient helipad:

1. Survey and visibly establish the area to be treated.
2. Place the synthetic fluid into the hydroseeder/distributor (Figure 5-5).
    - 450 gallons (1703.4 liters) for 100-foot by 100-foot (30.5-meter by 30.5-meter) helipad for smaller rotary-wing aircraft
    - 1000 gallons (3785.4 liters) for 150-foot by 150-foot (45.7-meter by 45.7-meter) helipad for larger rotary-wing aircraft
    - Quantities will be larger for treating with a polymer emulsion as an alternative solution; follow manufacturer’s dilution/application guidance
3. Position the hydroseeder/distributor on the edge of the helipad.
4. Use the tower gun and a long-distance nozzle to spray half of the product on half of the helipad. A hose attachment may also be used (Figure 5-6).
5. Move to the opposite side of the helipad and spray the remaining product.
6. If the distributor does not have standoff spray capability, it may be necessary to traverse the helipad ensuring spray overlap. **Note:** If the helipad ruts significantly under the distributor, smooth and re-treat the ruts by a hand wand to keep the ruts from acting as erosion focal points during aircraft operations.
7. Helicopters can land immediately on areas treated with synthetic fluids; however, best results occur after 24 hours (Figure 5-7). If a polymer emulsion is used as the alternative solution, allow the material to cure for a minimum of 24 hours prior to allowing traffic on the helipad.

Figure 5-5 Filling Hydroseeder from Material Tote

Figure 5-6 Topical Application from Hydroseeder Tower Gun (Top) or Hose (Bottom)

Figure 5-7 UH-1 Rotary-Wing Aircraft Operating on Treated Helipad

5-3.2 Dust Abatement on Roads.

5-3.2.1 Topical Application or Admixture Methods.

Complete dust abatement on roads using a topical application or admixture methods. Performing only a topical application provides dust abatement on aggregate roads with a high load-bearing capacity; however, when applying dust palliatives to unimproved roads, topical applications may not allow for manufacturer-recommended penetration. Thin surface crusts are prone to disintegration with increased traffic, allowing the underlying material to produce dust. Using a rotary mixer or soil stabilizer to incorporate dust palliatives into the soil is recommended. It is not necessary that the road be tilled prior to spraying the product. As long as runoff of the product does not occur, mixing can be performed after spraying onto the existing road surface to minimize construction efforts. Disturb the surface if the product does not readily soak into the road or if working on an inclined or crowned surface.

5-3.2.2 Equipment.

Modify the equipment requirements, depending upon availability and mission requirements. Polymer emulsion is used for the following example at a 3:1 water/emulsion mixing ratio. However, the types of equipment and process are similar for other types of liquid palliatives.

5-3.2.3 Supplies.

Provide and use the following:

- Motor grader for initial grading
- Vehicle(s) to haul the chemical totes, pumps, etc., and tow the distribution equipment
- Hydroseeder or other chemical distributor compatible with products
- Polymer emulsion mixed with water in appropriate amounts
- Rotary mixer
- Steel-wheeled vibratory compactor
- Personnel (three)

5-3.2.4 Application Procedures.

The application procedures using a diluted polymer emulsion are as follows:

1. Determine the length of road that can be treated per tank (hydroseeder/distributor capacity):

$$length\ (yd) = \frac{tank\ capacity\ (gal)}{[application\ rate\ (gsy) \times road\ width\ (yd)]}$$

$$length\ (m) = \frac{tank\ capacity\ (liter)}{[application\ rate\ (lsm) \times road\ width\ (m)]}$$

2. Place 675 gallons (2555 liters) of water into hydroseeder/distributor (minimum 900-gallon [3406-liter] capacity). For smaller distribution equipment, compute quantities to match the manufacturer recommended dilution ratio.
3. Add 225 gallons (852 liters) of polymer emulsion.
4. Mix for five minutes, using mechanical agitation.
5. Apply to the road surface for the determined length using a distribution bar or wide fan nozzle on the tower gun.
6. Immediately till the road surface to a 3-inch (76-millimeter) depth, using a rotary mixer (Figure 5-2).
7. Grade the road to establish grade requirements and correct distresses.
8. Compact the soil until the desired density is achieved (Figure 5-3).
9. Repeat steps 2 through 8, as needed.
10. Spray a light application (0.2 gallon per square yard [0.9 liter per square meter]) over the compacted road surface (Figure 5-4).
11. Repeat steps 1 through 10 for subsequent road lengths to be treated.

5-3.3 Dust Abatement in Base Camps and Other Non-Traffic Areas.

5-3.3.1 This paragraph provides guidance for mitigating dust in general base camp areas and other non-traffic areas. The topical application method is recommended. This method is less robust but cost-effective since the surface is subjected to lower loading requirements; thus, do not use this guidance for areas directly exposed to vehicle traffic. Synthetic fluid is used as an example for the following procedures. Modify the equipment requirements, depending upon availability and mission requirements.

5-3.3.2 Provide and use the following:

- Vehicle(s) to haul the chemical totes, pumps, etc., and tow the distribution equipment
- Hydroseeder or other chemical distributor compatible with products
- Dust palliative (synthetic fluid*)
- Personnel (three)

* Calculate quantities based upon recommended application rate of 0.4 gallon per square yard (1.8 liters per square meter) and the area to be treated.

5-3.3.3 The application procedures are as follows:

1. Determine the area of road that can be treated per tank (hydroseeder/distributor capacity):

$$area\ (yd^2) = \frac{product\ (gal)}{application\ rate\ (gsy)}$$

$$area\ (m^2) = \frac{product\ (liter)}{application\ rate\ (lsm)}$$

2. Fill the distribution equipment with synthetic fluid.
3. Apply to the road surface using a distribution bar, wide fan nozzle on tower gun, or hand wand/hose.
4. Repeat steps 1 through 3, as needed.

5-3.4 Dust Abatement Around Fixed-Wing Airfields.

5-3.4.1 Safety.

Due to safety concerns associated with surface friction requirements, dust palliatives are not recommended for use on any primary operating surface of the airfield. These areas are treated as a soil stabilization issue. Additionally, since the shoulders of unsurfaced airfields are designed to support occasional aircraft loading, it is also not recommended that the products be used on the shoulders of unsurfaced airfields; thus, the use of chemical dust palliatives is limited to the graded areas of unsurfaced airfields. For paved airfields, dust palliatives are used on any unpaved area around the perimeter of the pavement, including unpaved shoulders and graded areas. Due to potential FOD concerns, use synthetic fluids for this application. If a polymer emulsion or hard crust palliative is used, mix the material into the soil to minimize FOD potential. Polymer emulsions or other crust-forming stabilization additives cannot be topically applied around fixed-wing airfields due to the potential to form thin crusts capable of generating FOD. Modify the equipment requirements, depending upon availability and mission requirements; however, the types of equipment and process are similar to the previous section on dust abatement in base camps and other non-traffic areas.

5-3.4.2 Size Consideration.

Consider the size of the area to be treated around fixed facilities. The width of treatment along the perimeter is not an issue; however, the length of treatment for airfields can range from 1 to 3 miles (1.6 to 4.8 kilometers) per side of the runway. The resulting treatment area accumulates quickly. An analysis of the propeller/jet airblast was performed for the C-130 and C-17, respectively, to develop recommendations for the width of the treated area. The minimum treatment width is based upon the wingspan of the aircraft and the highest intensity plume, while the optimum treatment width is based upon the distance required to reduce the exhaust plume to a maximum velocity of 50 feet per second (15.2 meters per second) or 35 miles per hour (56 kilometers per hour). The treatment widths along each side of the runway and around any turnarounds or aprons are:

- C-130 minimum treatment width: 27 feet (8.2 meters)
- C-130 optimum treatment width: 50 feet (15.2 meters)
- C-17 minimum treatment width: 50 feet (15.2 meters)
- C-17 optimum treatment width: 100 feet (30.5 meters)

For unsurfaced fixed-wing facilities, begin the treatment at the edge of the shoulder and apply outward into the graded area and transition area. For paved fixed-wing facilities, begin the treatment at the edge of the paved surface and extend outward to the recommended width.

This Page Intentionally Left Blank

CHAPTER 6 ECONOMICS

6-1 GENERAL.

Dust control is based on many factors and methods. More than one dust palliative is found to meet the needs for the method selected. Consider economics to determine the dust palliative selected for use.

6-2 ECONOMIC FACTORS.

Economic factors include, but are not limited to, the following items:

- Initial cost of the dust palliative(s) at site
- Equipment and labor costs (by method if applicable)
- Maintenance costs (see paragraph 6-2.3.4)
- Material storage costs (if applicable)
- Shipping costs
- Equipment acquisition/modification costs
- Area preparation (clearing and grubbing is expected at all sites)

6-2.2 Initial Cost.

The initial cost of the dust palliative is typically not the governing factor in making the selection. Consider any suitable dust palliative already on hand, especially when placement equipment is available.

6-2.3 Equipment and Labor Costs.

6-2.3.1 Agronomic Method.

Costs associated with this method closely parallel the local turf seeding or landscape planting operational costs in the area where dust control is desired (UFGS 32 05 33). Landscape contractors or similar firms are a source to provide rough estimates for planning purposes.

6-2.3.2 Surface Penetrant and Surface Cover.

Both of these methods recommend some spray-on dust palliatives, which are placed with an asphalt distributor or hydroseeder. Aggregate and membrane costs are taken from the supplier(s) near the area where dust control is planned. Labor costs associated with these two methods vary according to method type.

6-2.3.3 Admixture Method.

This method is probably the most expensive method described but is the most effective long-term. It requires equipment and manpower similar to that associated with soil stabilization techniques. The admixture method requires a rotary tiller mixer or reclaimer/stabilizer mixer to blend the admixture into the soil and other equipment used for pavement construction (e.g., motor grader, compactor). The material cost; cement, lime, or bituminous material is determined from the local supplier(s) nearest the area where dust control is desired (see UFC 3-250-11).

6-2.3.4 Maintenance.

No dust control method or dust palliative provides a maintenance-free solution. When frequent maintenance is required, order enough material for initial application plus an equal amount for 12 months' maintenance. In the case of trafficked areas, maintenance is minimized by prohibiting quick stops and sharp turns for all using vehicles and limiting traffic to essential vehicles only. Tanks and other tracked vehicles will obliterate most dust control methods employed.

6-2.3.5 Material Storage Costs.

Consult the manufacturer prior to purchase for storage information/requirements. Provide theft-proof storage for all dust palliatives until they are applied. Protect the liquid dust palliatives from freezing temperatures. Powders such as lime and cement are typically stored in a dry place with low humidity.

6-2.3.6 Shipping Costs.

Shipping or transportation costs are incurred directly or indirectly with all dust palliatives.

6-2.3.7 Area Preparation.

Most sites require some preparation. As a minimum, remove all large rocks (> 6 inches [152 millimeters]) and all large sticks and stumps.

6-3 FINAL SELECTION.

Some of the economic factors outlined in paragraph 6-2 are difficult to determine with certainty, especially where placement crews have no prior experience with dust palliative placement or the expected traffic use is not known; however, by considering these factors the final selection of a dust palliative is reasonably made.

APPENDIX B BEST PRACTICES

B-1 CONTROL OF WINDBORNE SAND.

B-1.1 Introduction.

Many factors, including low rainfall, high evaporation, sparse vegetation, and seasonal winds, contribute to rock weathering and sand movement. Methods for controlling sand movement have met with varying degrees of success. This section summarizes the latest available information on windborne sand control and lists recommended methods for sand movement stoppage and diversion. Marine and river sand movement control are not discussed.

B-1.2 Wind, Wind Direction, Crosswind.

Wind is defined as any natural movement of air, whether of high or low velocity, or great or little force. Most regions have a predominant wind direction, some section of the compass from which the wind blows most often and with the greatest velocity. Crosswinds are winds directed at some angle to the predominant wind direction.

B-1.3 Forms of Dunes.

A dune is defined as a mound or ridge of windblown material, usually sand, formed in arid regions. Local conditions under which dunes are developed vary widely and, consequently, there is a broad range in their shape and size. The shape may assume almost any configuration and the size may vary from an insignificant lone sand pebble to mounds higher than 100 feet (30.5 meters). Some coastal dune formations have reached 1000 feet (304.8 meters) in height. The three general types of sand dunes are described below; only the third type (moving sand dunes) requires control.

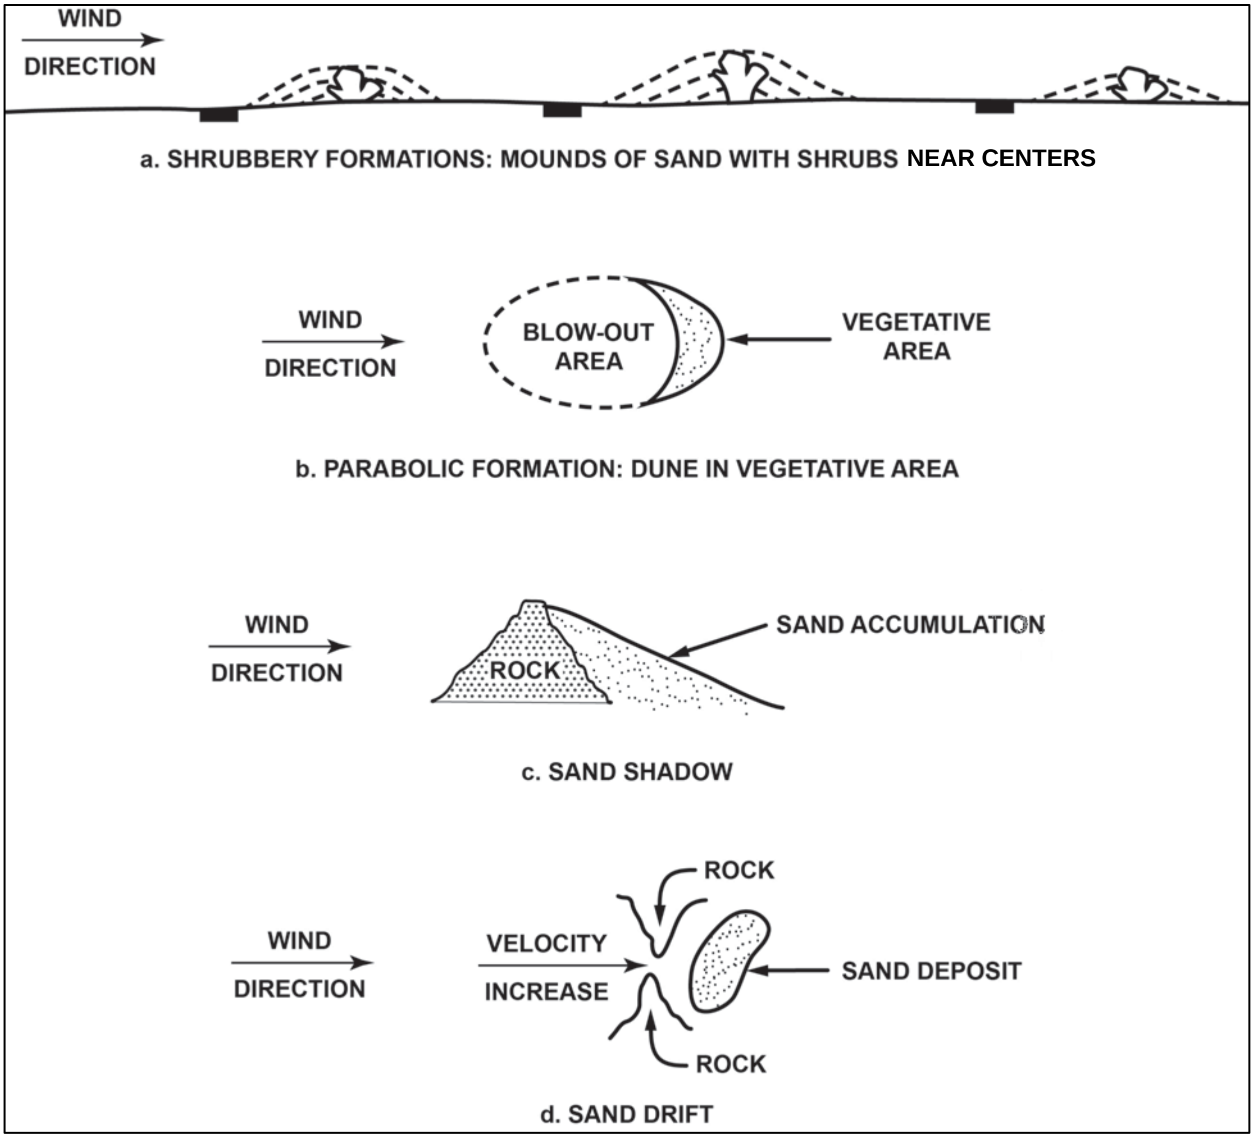
B-1.3.1 Sand Sheets.

These sheets occur in a generally flat, barren area with a predominant wind direction. They present no control problems because the sand does not accumulate.

B-1.3.2 Fixed Sand Dunes.

These dunes result from the accumulation of sand particles adjacent to fixed obstructions such as hills, cliffs, shrubs, and buildings. Fixed sand dunes may range in size from an accumulation around small shrubbery to sand shadows more than 50 feet (15.2 meters) deep. Because the fixed sand dune is immobile, it typically does not present a control problem. Figure B-1 shows types of fixed sand dune formations.

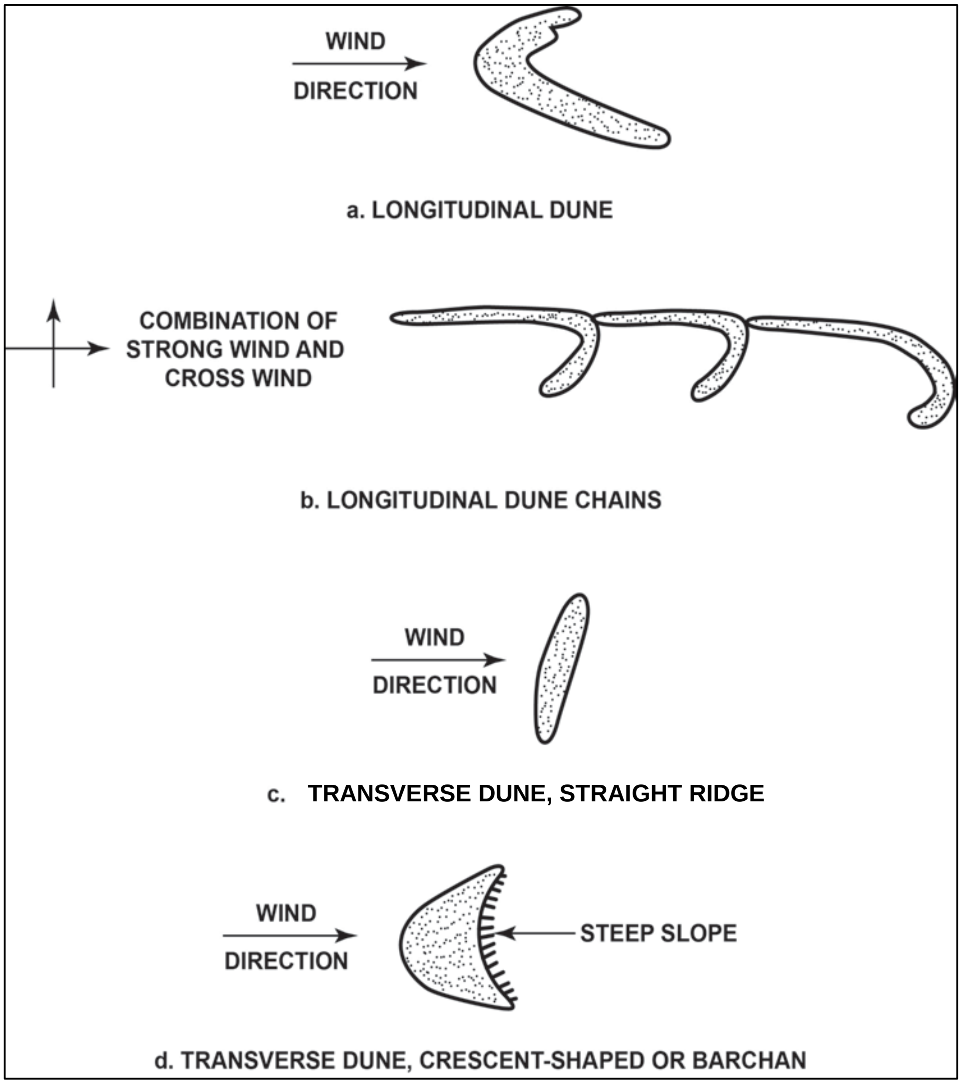
Figure B-1 Types of Fixed Sand Dunes



B-1.3.3 Moving Sand Dunes.

This type of sand mass exists independent of fixed surface features and may move from place to place, maintaining its initial form. Moving sand dunes are common in vast areas of sand with little or no vegetation. The control methods described below are applicable for this type of dune. With relation to predominant winds, moving sand dunes are classified either as longitudinal or transverse (Figure B-2). Longitudinal dunes are distinct ridges elongated in the direction of the predominant wind. A combination of predominant winds and crosswinds will produce a regular succession of dunes (longitudinal dune chains). Transverse dunes are formed by winds of steady direction blowing across an extensive source of loose sand, such as a sandy beach, and building ridges transverse to the wind direction. Low-velocity winds form straight parallel ridges and stronger winds form the more typical crescent-shaped or barchan transverse dune.

Figure B-2 Types of Moving Sand Dunes



B-1.4 Migration of Dunes.

After a dune is formed, the predominant wind may blow sand over the crest to the leeward slope. By this migration of particles, the dune then moves forward at a rate depending on wind velocity, topography, size of dune, and other factors. For example, along the Bay of Biscay on the west coast of France, dunes travel at rates up to more than 100 feet (30.5 meters) per year.

B-1.5 Sand Control.

There are many methods of sand control, with certain advantages and disadvantages in each method. The methods described below for the stabilization and/or destruction of windborne sand dunes are the most effective. These methods may be used alone or in combination.

B-1.5.1 Fencing.

This method of control employs flexible, portable, inexpensive fences to destroy the symmetry of a dune formation. The fence need not be a solid surface and may even have 50 percent openings, as in snow fencing. Any material such as wood slats, slender poles, stalks, or perforated plastic sheets bound together in any manner and attached to vertical or horizontal supports will be adequate. Rolled bundles that can be transported easily are practical. Prefabricated fencing is desirable because it can be erected quickly and economically. Because the wind tends to underscour and undermine the base of any obstacle in its flow path, the fence should be installed 1 foot (0.3 meter) above ground level. To maintain the effectiveness of the fencing system, a second fence should be installed on top of the first fence on the crest of the sand accumulation. The entire windward surface of the dune should be stabilized with dust-control materials, such as bituminous material, prior to erecting the first fence. The old fences should not be removed during or after the addition of new fences. Figure B-3 shows a cross-section of a stabilized dune with porous fencing. As long as the fences are in place, the sand will remain trapped. If the fences are removed, the sand will soon move downwind, forming an advancing dune. The proper spacing and number of fences required to protect a specific area can only be determined by trial and observation. Figure B-4 illustrates a three-fence method of control. If the supply of new sand to the dune is eliminated, migration is accelerated and dune volume decreases. As the dune migrates, it may move great distances downwind before it completely dissipates. An upwind fence may be installed to cut off new sand supply if the object to be protected is far downwind of the dune. This distance usually should be at least four times the width of the dune.

Figure B-3 Cross-Section of Dune Showing Initial and Subsequent Fences

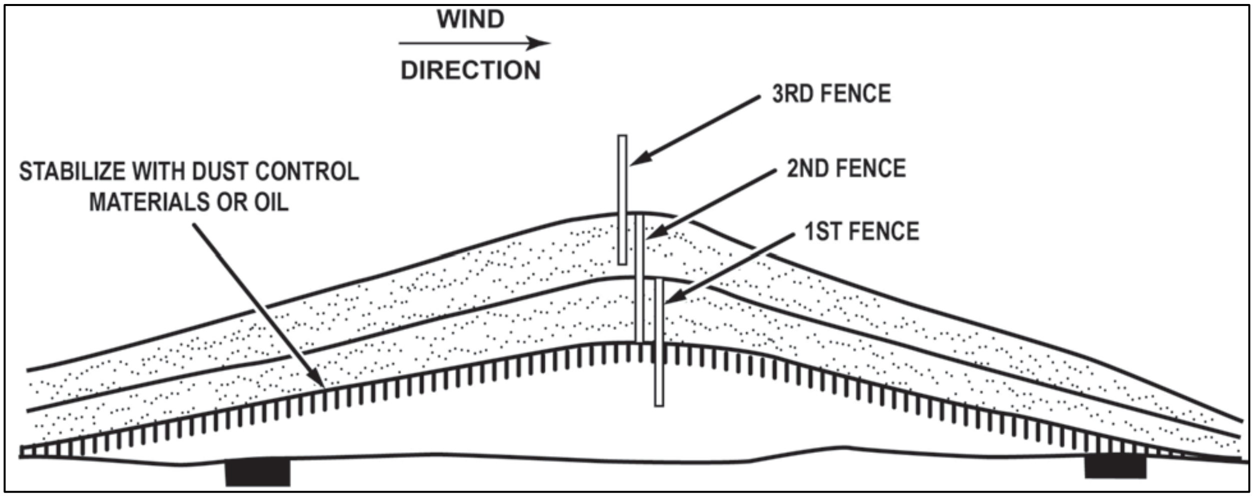


Figure B-4 Three Fences Installed to Control Dune Formation

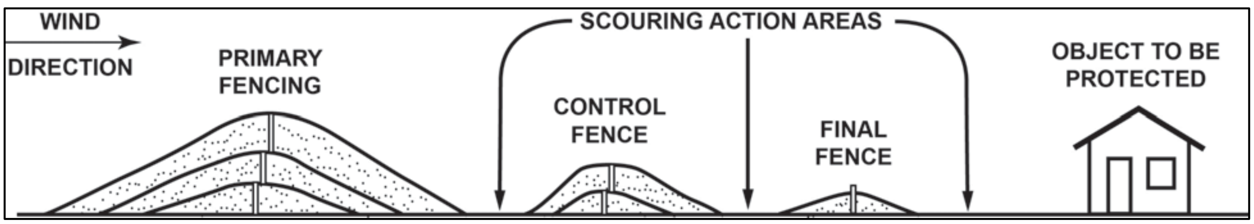
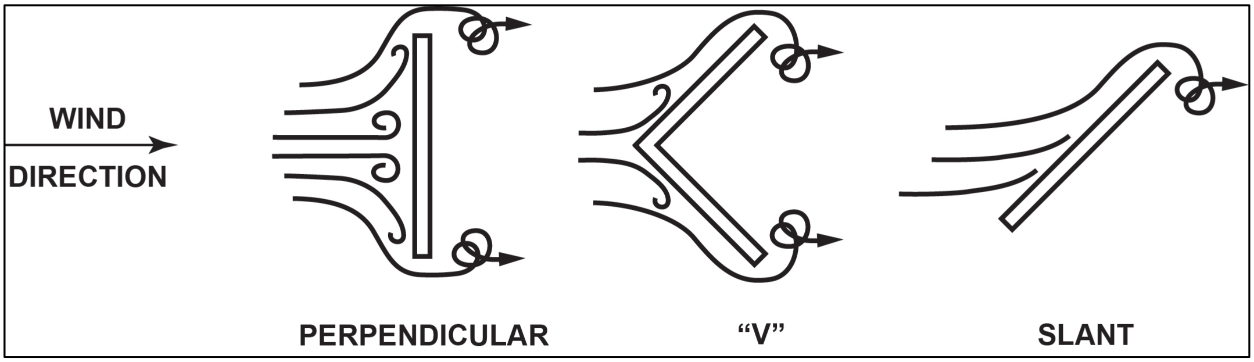


B-1.5.2 Paneling.

Solid barrier fences of metal, wood, plastic, or masonry can be used to stop or divert sand movement. To stop sand, the barriers should be constructed perpendicular to the wind direction. To divert sand, the panels should be placed obliquely or nearly parallel to the wind. They may be single slant or “V” in pattern (Figure B-5). When first erected, paneling appears to give excellent protection; however, panels are not self-cleaning. Promptly remove the initial accumulations by mechanical means. If the accumulation is not removed, sand will begin to flow over and around the barrier and soon submerge the object to be protected. Mechanical removal is costly and endless. This method of control is unsatisfactory because of inefficiency and expense and should be employed only in conjunction with a more permanent control, such as planting, fencing, or using dust palliatives. Equally good protection at less cost is achieved by the fencing method.

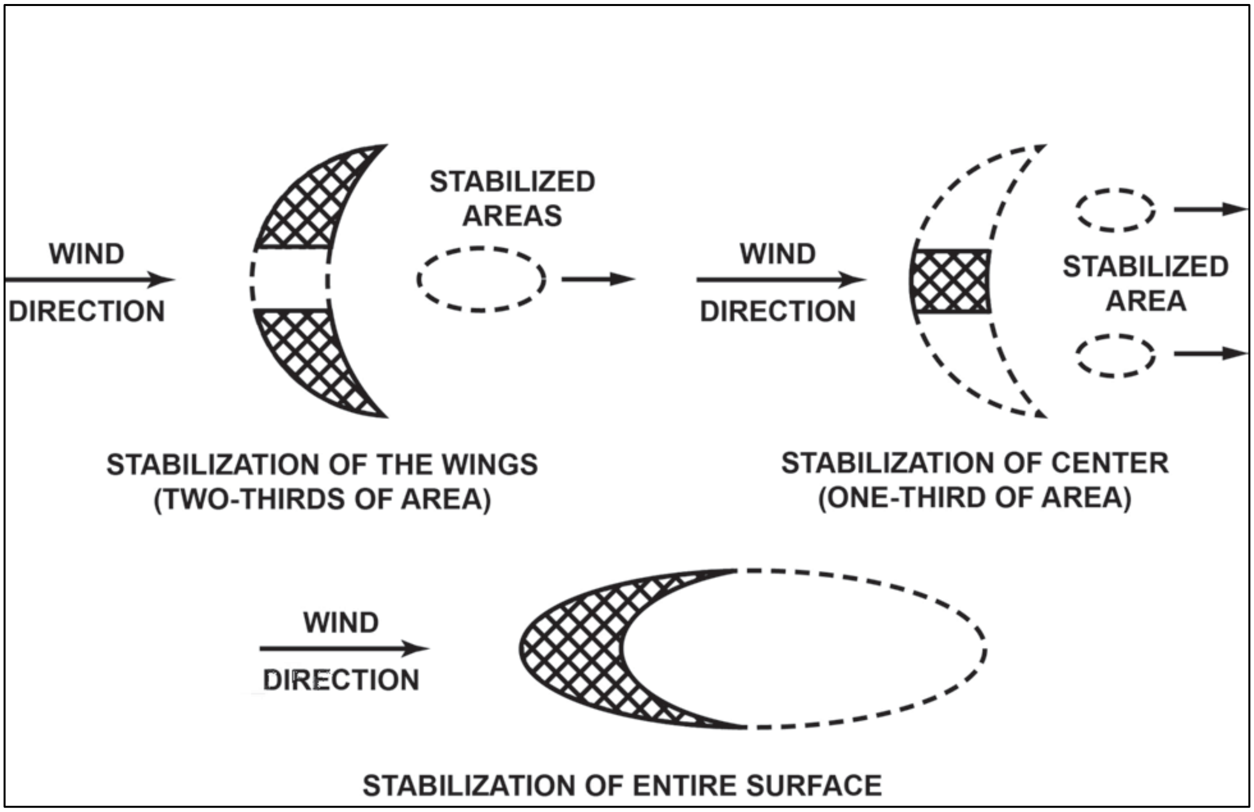
Figure B-5 Three Types of Solid Fencing or Paneling for Control of Dune Formation



B-1.5.3 Bituminous Materials.

Destruction of dune symmetry by spraying bituminous materials at either the center or the ends of the dune is an inexpensive and practical method of sand control. Petroleum resin emulsion and asphalt emulsions have been found to be effective. The desired stickiness of the sand is obtained by diluting one part petroleum resin emulsion with four parts water and spraying at the rate of 0.5 gallon per square yard (2.3 liters per square meter). Generally, the object to be protected should be downwind a distance of at least twice the tip-to-tip width of the dune. The center portion of a barchan dune can be left untreated or can be treated and the unstabilized portions allowed to reduce in size by wasting. Figure B-6 shows destruction of a typical barchan dune and stabilization, depending on the area treated.

Figure B-6 Schematic of Dune Destruction or Stabilization by Selective Treatment



B-1.5.4 Vegetative Treatment.

Vegetative cover is an excellent method of sand stabilization. Ensure vegetation to be established is drought-resistant and adapted to the climate and soil. Most vegetative treatments are effective only if the supply of new sand is cut off. On the upwind side, water, fertilizers, and mulch are liberally used. To prevent the engulfment of the vegetation, the upwind boundaries are protected by fences or dikes and the seed may be protected by mulch sprayed with a bituminous material. Seed on slopes may be anchored by mulch or matting. Oats and other cereal grasses may be planted as a fast-growing companion crop to provide protection while slower-growing perennial vegetation becomes established. Typically, the procedure is to plant clonal plantings, followed by shrubs used as an intermediate step, followed by the planting of long-lived trees. There are numerous suitable vegetative treatments for use in different environments. The actual type of vegetation selected should be chosen by qualified individuals familiar with the type of vegetation that thrives in the affected area. Stabilization by planting has the advantages of permanence and environmental enhancement wherever water can be provided for growth.

B-1.5.5 Mechanical Removal.

In small areas, sand may be removed by heavy equipment, but conveyor belts and power-driven wind machines are not recommended because of their complexity and expense. Mechanical removal may be employed only after some other method has been used to prevent the accumulation of more deposits. Except for its use in conjunction with another method of control, the mechanical removal of sand is not practical or economical.

B-1.5.6 Trenching.

A trench may be cut either transversely or longitudinally across a dune to destroy its symmetry. If the trench is maintained, the dune will be destroyed by wastage. This method has been used successfully in the (Yuma Desert) Arizona highway program, but it is expensive and requires constant inspection and maintenance.

B-1.5.7 Water.

Water may be applied to sand surfaces to prevent sand movement. It is widely used and an excellent temporary treatment. Water is required for establishing vegetative covers. The need for frequent reapplication and an adequate and convenient source constitute two major disadvantages of this method.

B-1.5.8 Surface Covers.

Any material that forms a (semi) permanent cover and is immovable by the wind will serve to control dust. Solid covers, though expensive, are excellent protection and can be used over small areas. This method of sand control accommodates pedestrian traffic as well as a minimum amount of vehicular traffic. Surface covers may be made from bituminous or concrete pavements, prefabricated landing mat, membrane, aggregate, seashells, and saltwater solutions. After placement of any of the above-listed materials, a spray application of bituminous material may be required to prevent cover decomposition and subsequent dust.

B-1.5.9 Salt Solutions.

Water saturated with sodium chloride or other salts can be applied to sand dunes to control dust. Rainfall will leach salts from the soil in time. During periods of no rainfall and low humidity (below 30 percent), artificial moisture in the form of water may have to be added to the treated area at a rate of 0.1 to 0.2 gallon per square yard (0.5 to 0.9 liter per square meter) to activate the salt solution.

B-2 POTENTIAL VENDORS AND DISTRIBUTION EQUIPMENT.

B-2.1 Potential Vendors.

A list of potential vendors is summarized in Table B-1 to assist in the procurement of products. It is not intended to be a complete listing of vendors as there are numerous large and small companies that provide a wide range of materials for dust abatement. **\1** The USDA (United States Department of Agriculture) maintains a product list for BioPreferred and Certified Biobased dust suppressants in the Construction section of the BioPreferred Catalog at:

https://www.biopreferred.gov/BioPreferred/faces/catalog/Catalog.xhtml. /**1**/ Inclusion on this list does not represent endorsement of any kind. The list is provided to assist the Soldiers, Sailors, Marines, and Airmen working in the field. **1**\\ Additional information on products and practices are available in the ERDC/GSL Technical Reports in Appendix A. /**1**/ Complete a small test section prior to using each product to evaluate the effectiveness and determine the placement details.

FOREWORD

Facilities Criteria (FC) provide functional requirements (i.e., defined by users and operational needs of a particular facility type) for specific DoD Component(s), and are intended for use with unified technical requirements published in DoD Unified Facilities Criteria (UFC). FC are applicable only to the DoD Component(s) indicated in the title, and do not represent unified DoD requirements. Differences in functional requirements between DoD Components may exist due to differences in policies and operational needs.

All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the FC), the SOFA, the HNFA, and the BIA, as applicable. Because FC are coordinated with unified DoD technical requirements, they form an element of the DoD UFC system applicable to specific facility types. The UFC system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applicable to the Military Departments, Defense Agencies, and the DoD Field Activities. The UFC System also includes technical requirements and functional requirements for specific facility types, both published as UFC documents and FC documents.

FC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQ USACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

FC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

AUTHORIZED BY:

RANDY E. BROWN, SES II, DAF
Director
Air Force Civil Engineer Center

FACILITIES CRITERIA (FC)
NEW SUMMARY SHEET

Document: FC 3-260-18F, *AIR FORCE AIRCRAFT ARRESTING SYSTEMS (AAS) INSTALLATION, OPERATION, AND MAINTENANCE (IO&M)*

Superseding: None

Description: Unless specified otherwise, requirements within this FC are mandatory and apply to all military, Department of Defense (DoD) or Department of Transportation (DoT) Federal Aviation Administration (FAA) civilians, or DoD contracted personnel who are tasked to install, operate, maintain, repair, or otherwise participate in or affect operation or use of an AAS owned or operated by the Air Force. This includes firefighters or other first-responder personnel and augmentees. Specifically, installation, maintenance and operation of all Air Force AAS must comply with the requirements provided in **\1** AFMAN 32-1040 *Civil Engineer Airfield Infrastructure Systems* **/1/** UFC 3-260-01, *Airfield and Heliport Planning and Design*, UFC 3-260-02, *Pavement Design for Airfields*, and UFC 3-535-01, *Design Standards for Visual Air Navigation Facilities.* Maintenance procedures, repair parts, and materials necessary to install, operate, and maintain each energy absorbing system, net engaging barrier, or hook cable support system, must comply with the requirements in this FC and in the appropriate and specific 35E8 Series Technical Order (T.O.) or approved Manufacturer's Manual.

Reasons for Document:

- Provide technical requirements for installation, operation, and maintenance of Aircraft Arresting Systems.
- Consolidate criteria located in multiple documents.
- Update information to reflect new and revised standards.

Impact: There are minor cost impacts associated with this FC. However, the following benefits should be realized

- Standardized guidance has been prepared to assist engineers in the development of the plans, specifications, calculations, and Design/Build Request for Proposals (RFPs).

Unification Issues

None

Note: Use of the name or mark of any specific manufacturer, commercial product, commodity, or service in this FC does not imply endorsement by the Air Force.

TABLE OF CONTENTS

FIGURES

TABLES

This Page Intentionally Left Blank

CHAPTER 1 OBTAINING AIRCRAFT ARRESTING SYSTEMS

1-1 NEW SYSTEMS

1-1.1 For new systems refer to **\1** AFMAN 32-1040 *Civil Engineer Airfield Infrastructure Systems* **/1/**.

1-2 TEMPORARY SYSTEMS (CONSTRUCTION PROJECTS, AIR SHOWS, EXERCISES)

Submit requests for temporary use of expeditionary Aircraft Arresting Systems (AAS) to HQ AFIMSC/IZB at least two months before the system must be in place and operational. (Air National Guard units request support through the Air National Guard Civil Engineer Technical Support Center [NGB/A7OC], Minot, ND).

1-2.3 Information Required

Give the following information in all requests:

- Number of systems needed.
- Reason the systems are needed, including the type of aircraft that will be using the systems.
- Geographic location of the requirement including the Stock Record Account Number (SRAN).
- Date the systems need to be operational.
- Date the systems can be removed.
- Points of contact and telephone numbers for the AAS Shop, Airfield Management, Safety, and Fire Department.

1-2.4 Operations and Maintenance Personnel

With the request for temporary AAS support for a mission, specify the intended source and the number of personnel who will operate and maintain the expeditionary system(s) at the site, including qualification levels.

1-2.5 Funding Source

The requesting activity must provide a fund citation to cover all costs associated with supporting the expeditionary installation. Including costs for:

- Shipment of the equipment.
- Transportation and per diem for temporary duty personnel.

- Expendable materials such as tapes, cables, and repair materials and parts including fuels, oils and lubricants.
- Repair or replacement of damaged items.
- Installation costs for equipment, materials, and other supplies.

1-2.6 Where to Send Requests

Send the information to the appropriate MAJCOM Civil Engineer at the appropriate address below (e-mail requests are encouraged):

AFIMSC Det 8 (ACC),

AFCENT/A7O,

NGB/A7OC,

AFIMSC Det 4 (USAFE),

AFIMSC Det 2 (PACAF)

1-2.7 Processing Time

The appropriate MAJCOM Civil Engineer evaluates each request on the basis of availability of personnel, equipment, and priority. It approves or disapproves requests within 10 working days.

CHAPTER 2 SITING SYSTEMS

2-1 INTRODUCTION

AAS and emergency overrun barriers are installed in several configurations. Typically, overrun barriers (nets such as MA-1A and BAK-15) and emergency arrestors such as E-5 chain gear (CHAG), Textile Brake, or soft ground arrestor systems (such as Engineered Material Arrestor Systems (EMAS) are installed as redundant systems for emergency recovery only. As such, they are installed in the overrun area of the runway. Operational arresting systems, such as BAK-12, are usually installed between the runway thresholds. This is necessary to allow pilots to touch down on the normal landing surface and stabilize the tail-hook before engagement. Fairlead beams or runway edge sheaves are used to direct the purchase tape path, and are installed on the runway shoulders to allow the energy absorber to be installed outside the mandatory zone of frangibility (at least 84 meters [275 feet] away from the runway centerline). Support ramps are constructed to lead up to exposed vertical surfaces of fairlead beams and tape tubes, allowing an aircraft to roll over them smoothly. Arresting gear that is installed on grade must have an "airfield friendly" structure built over it to protect the equipment from environmental degradation. The design should be in compliance with Typical Installation Drawings 67F2011A (on-grade with shelter) or 67F2012A (installed below grade within a vault), as applicable, this instruction, the applicable 35E8-series T.O., and the requirements detailed within UFC 3-260-01 (Chapter 3 and Appendix B13). Do not install any arresting system where the run-out will conflict with any other arresting system or any obstacle such as elevated airfield lights or signs. Although intervening taxiways may be within the run-out area, such cases should be avoided if possible to preclude blocking the intersection during an engagement, and increased wear to tapes caused by dragging them through the warped pavement interface between a centerline crowned taxiway and the runway. In cases where criteria cannot be met, a waiver must be established according to UFC 3-260-01 and/or the applicable 35E8-series T.O., as appropriate.

2-2 SITING OPERATIONAL SYSTEMS

The large rectangular pavement markings (fixed distance markings) located 300 meters (1000 feet) from the threshold represent the ideal aim point for pilots on approach to landing. Other visual landing aids, such as the visual glide slope indicator system, cue the pilot to touch down approximately 300 meters (1000 feet) from the threshold. This ensures a minimum threshold crossing height of at least 11 meters (35 feet). Since stabilizing the tail-hook after touchdown requires a distance of 150 to 240 meters (500 to 800 feet), the best location for an arresting system that accommodates approach end engagements is 450 to 540 meters (1500 to 1800 feet) from the threshold. Runways used extensively during instrument meteorological conditions may require that the system be sited as much as 670 meters (2200 feet) from the threshold; however, if aircraft that are not compatible with trampling the pendant must operate on the same runway, the installation commander may shift the installation site as close to the threshold as possible, but not closer than the distance that will allow an unobstructed runout with a standard BAK-12 system set-up (see paragraph 3.14 and T.O. 35E8-2-5-1, *Operation and Maintenance Instructions – Aircraft Arresting System Model BAK-12*). It is critical that the runout area for an aircraft engaging the system from either direction not conflict with other AAS components (cables or cross runway troughs) or other equipment such as threshold or runway end light fixtures. Other operating scenarios, such as northern tier locations with heavy snow or ice accumulation, may dictate that you place an additional system at the midpoint of the runway. The installation commander must approve installation of a midfield AAS after coordinating the plan with the host MAJCOM/A3, SE, and MAJCOM Civil Engineer.

2-3 SITING EMERGENCY SYSTEMS

Locate unidirectional AAS and barriers (nets) in the overrun area of the runway. The energy-absorbing device dictates the distance from the threshold because of the need to maximize system run-out. Do not locate unidirectional systems or net barriers closer than 11 meters (35 feet) from the threshold of the runway. Note: Runway threshold markings begin 6 meters (20 feet) inboard of the full-strength pavement; therefore, do not install a unidirectional system within 17 meters (55 feet) of the beginning of the longitudinal threshold markings. Do not mark AAS warning markings on the pavement in overruns, or install arresting gear marker (AGM) lighted signs adjacent to AAS in the overrun to identify the locations of these systems. Installation of these markings and signs might cause a pilot to attempt an approach end engagement with the system.

CHAPTER 3 INSTALLATION REQUIREMENTS

3-1 MANDATORY REQUIREMENTS AND WAIVERS

Comply with the following standards when locating, configuring, installing, or repairing an AAS. BCEs must obtain the installation commander's approval and coordinate with MAJCOM/A3, SE, and MAJCOM Civil Engineer before deviating from these standards. A waiver to UFC 3-260-01 or the applicable 35E8-series T.O. will be required if these standards cannot be met. See paragraph 3-10 for information with regard to systems installed under previous standards.

3-2 LOCATING ARRESTING SYSTEMS

The BCE's designated representative determines the configuration and location of arresting systems in cooperation with representatives from A3 and SE. Design must conform to the configuration criteria of the appropriate 35E8-series T.O., the Typical Installation Drawings, the requirements in this FC, and UFC 3-260-01. In cases where criteria cannot be met, a waiver must first be established and approved according to UFC 3-260-01 and/or the applicable T.O., as appropriate.

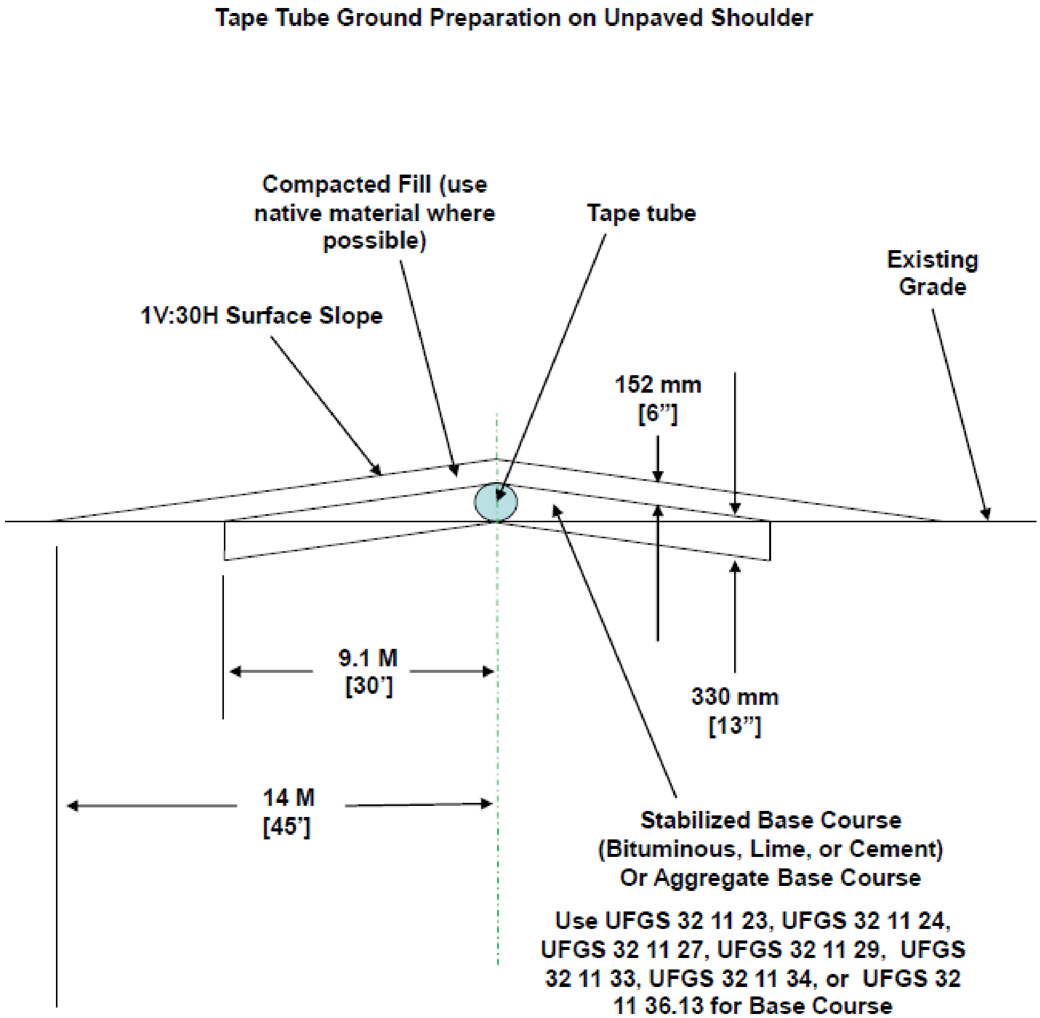
3-3 PLACEMENT OF ENERGY ABSORBERS

Locate all energy absorbers below grade or at least 84 meters (275 feet) from the runway centerline. (Exceptions: MA-1A and E-5 ship’s anchor chains and textile brake modules may be located along the runway overrun shoulders. Bi-directional textile brake modules may be located either along the overrun or runway shoulders.) Provide paved transitions and buried crushed stone ramps around the arresting system components and a paved service road to the site from the runway, as well as a location other than the runway (beyond the controlled movement area or outside the Runway Safety Area (RSA) on civil airfields). Pit-type installations may be sited closer to the runway as long as they meet the minimum split-distance required (15.2 meters (50 feet) for BAK-12); however, all above-grade appurtenances must be frangible, the transition to the pit cover must meet runway shoulder grade allowances given in Chapter 3 of UFC 3-260-01, and the pit cover and door must be designed to support wheel loads in accordance with UFC 3-260-01, Chapter 3, “Shoulders” (paved or unpaved, as applicable).

3-4 SHOULDER REQUIREMENTS

Where fairlead beams, edge sheaves, and tape tubes project above the grade of the existing runway shoulders, provide suitable fill materials and compaction next to or over these components to a finished grade of 1V:30H or flatter. Tape tubes must be steel or ductile iron. Tape tubes of other materials must be programmed for replacement and inspected monthly for signs of damage or degradation. For new installations, select tape tubes that are capable of supporting wheel loads in accordance with UFC 3-260-01, Chapter 3, “Shoulders” (paved or unpaved, as applicable). See Figure 3-1 for construction details.

Figure 3-1 Unpaved Runway Shoulder Construction Details Adjacent to Tape Tubes



3-5 OBSTRUCTION MARKING AND LIGHTING REQUIREMENTS

Provide obstruction marking and lighting and arresting system location marking and lighting according to the provisions of **\1** UFC 3-260-04, *Airfield and Heliport Marking* **/1/** and UFC 3-535-01, *Visual Air Navigation Systems*. This requirement also applies to temporary installations for construction or air shows unless waived within the temporary waiver by the Installation Commander or the designated authority. See UFC 3-260-01, Appendix B, Section 1. Do not mark AAS warning markings on the pavement in overruns, or install arresting gear marker (AGM) lighted signs adjacent to AAS in the overrun to identify the locations of these systems. Installation of these markings and signs might cause a pilot to attempt an approach end engagement with the system.

3-6 ABOVE-GRADE SYSTEM SHELTERS

Provide protective shelters constructed for on-grade installations must be constructed from lightweight framing materials and sheathing using connections that will allow the structure to break away or collapse if struck by an aircraft wing. See UFC 3-260-01, Appendix B, Section 13. Provide shelters with a removable roof or end wall, or a door opening to facilitate major maintenance or replacement of the equipment. Also provide proper ventilation and windows that will allow the operator to view the runway and tape sweep areas in both directions. See Typical Installation Drawing 67F2011A, Sheet 2, Note 3.

3-7 PAVEMENT ADJACENT TO CABLES

3-7.1 The center 23 meters (75 feet) of pavement extending out for 60 meters (200 feet) on both the approach and departure sides of the arresting system pendant are critical areas. Exception: 46 meter (150-foot) -wide runways with BAK-14 systems, the critical area is limited to the off-center engagement capability for the BAK-14 system, which is the center 18 meters (60 feet) of runway pavement. For wider runways, the critical area is the center 23 meters (75 feet) of runway pavement for BAK-14 or any other model AAS, regardless of the stated off-center engagement capability.

3-7.2 Within these critical areas, protruding objects such as centerline lights or reflectors, excessive paint build-up, and undulating surfaces are detrimental to successful tail-hook engagements and are not allowable. The maximum permissible longitudinal surface deviation in this area is ±3 millimeters (±0.125 inch) in 4 meters (12 feet). This does not apply to the channels in grooved pavement surfaces.

3-7.3 The prohibition on changes in pavement type does not apply to arresting system cables located in overruns because overruns are constructed of asphaltic pavement, and the first 305 meters (1000 feet) of runways are constructed from Portland cement concrete (PCC).

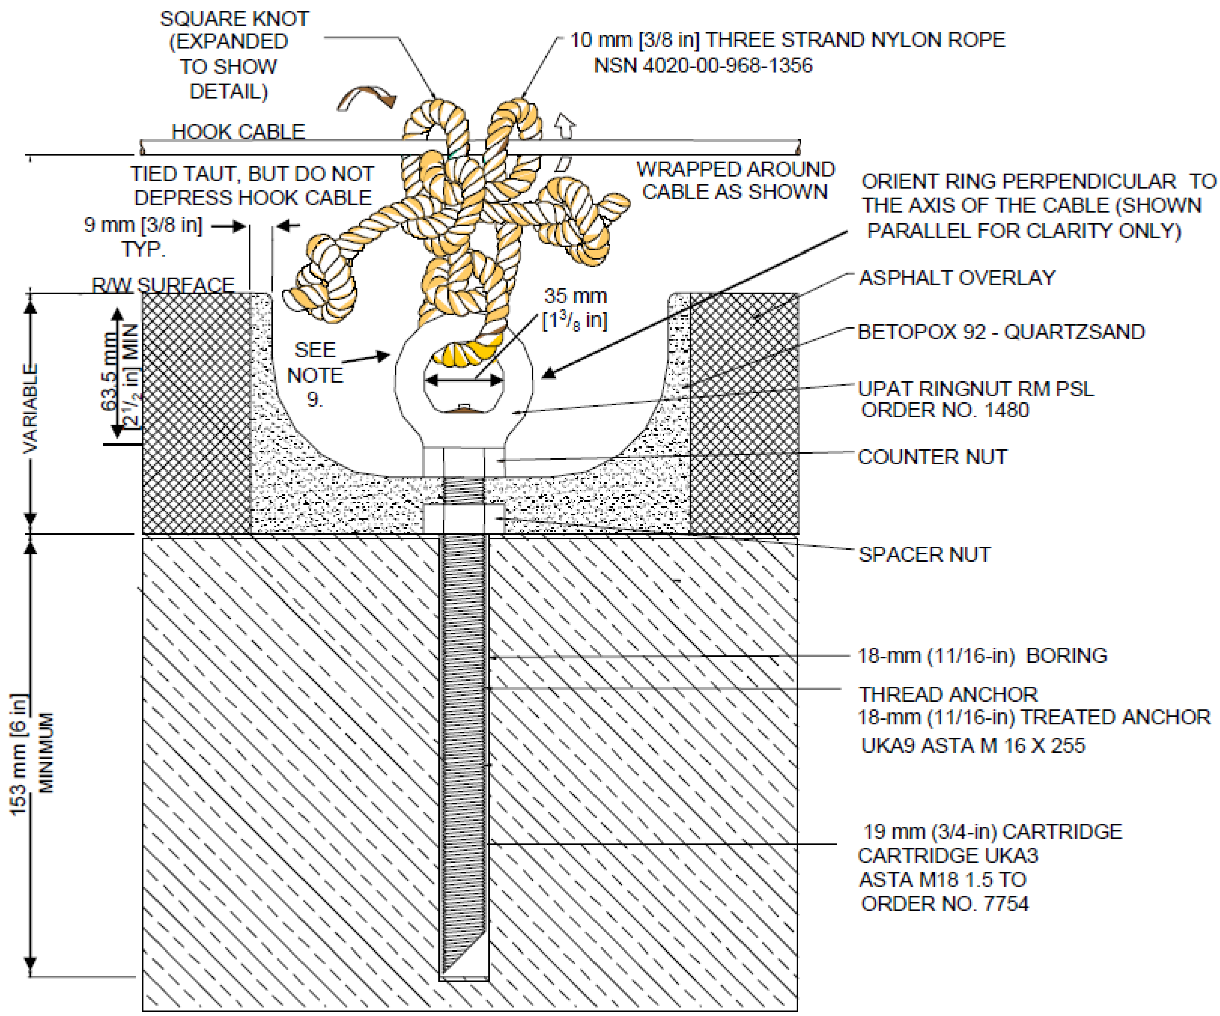
3-7.4 Grooves to improve surface drainage and surface friction characteristics are not permitted within 3 meters (10 feet) of arresting system cables due to potential for increased surface wear due to cable slap during trampling.

3-7.5 Changes in pavement type or an interface between rigid and flexible pavements are not permitted within 60 meters (200 feet) of arresting system cables in the center 23 meters (75 feet) of the runway. This does not apply to emergency systems located within overruns, sacrificial panels installed beneath cables, or to PCC anchor blocks installed for anchoring cable tiedowns in flexible pavement systems. These are not considered a change in pavement type because the individual foundations are not formed continuously from one tiedown to the next. This specifically prohibits rigid inlays from being used as a surface repair material beneath the cable in flexible runway pavement systems like hot mixed asphalt (HMA). This type repair causes high hook-skip potential when the flexible pavement consolidates, exposing the leading edge of the rigid pavement. However, rigid pavement must be used as a foundation under sacrificial panels installed beneath AAS cables in both rigid and flexible pavement systems. In these cases, no part of the rigid foundation can be used as a top-wearing surface.

3-8 CABLE ANCHOR INSTALLATION REQUIREMENTS

Install cable tiedown anchors for operational systems (systems located between the runway thresholds) to limit cable bounce and potential aircraft damage during aircraft rollover. Install eight anchors for all operational systems regardless of primary aircraft supported on the airfield. Program systems with four anchor points to be upgraded to eight anchor points. When using the Mobile Aircraft Arresting System (MAAS) or other expeditionary cable systems for other than an air show or a short-term construction project, add cable tiedowns to the runway to prevent aircraft damage during aircraft roll-over and engagements. This also applies at forward operating locations, but may have to be postponed until time and materials are available to accomplish the work. Install anchors at 3-meter (10-foot) intervals centered on the runway width for eight-point tiedowns. For rigid pavements, it is desirable that all anchor locations be offset at least 609 millimeters (24 inches) from pavement joints. The minimum offset from pavement joints for anchor locations is 300 millimeters (12 inches). If sacrificial panels will be installed, see paragraph 3-14 for anchor spacing. See Figures 3-2 through 3-6 for various cable tiedown designs and installation details. Any of the three styles of anchors may be used for flexible or rigid runway pavements but the anchor block details shown in Figure 3-6 and the Typical Installation Drawings 67F2011A and 67F2012A are specifically designed for flexible pavement systems.

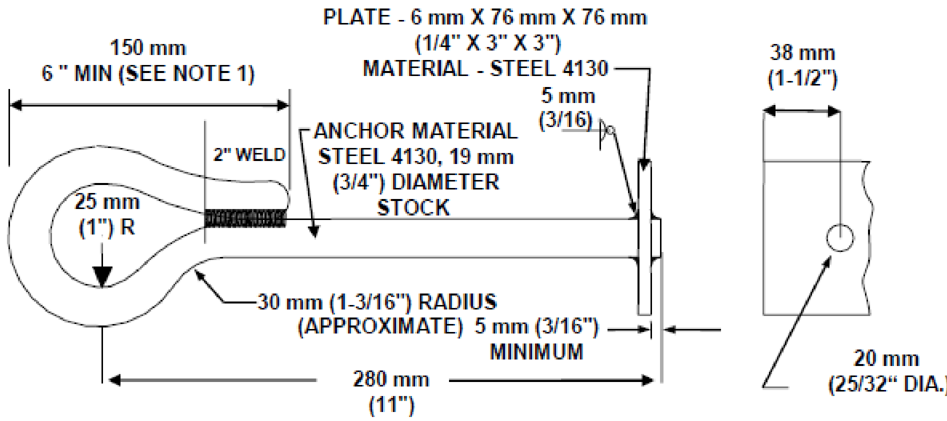
Figure 3-2 Designed Tiedown for Porous Friction Surfaces
(formerly "Alternate Cable Tiedown Anchor Installation")



NOTES:

1. See paragraph 3-8 on cable tie-downs and locations for number and placement of tie-downs.
2. Tie-down ropes will be approximately 1,200 millimeters (48 inches) long.
3. Ring nut shall be perpendicular to pendant cable.
4. Minimum anchor insertion into Portland cement concrete shall be 153 millimeters (6 inches).
5. Tie-down anchor bowl shall not exceed 127 millimeters (5 inches) in diameter.
6. Ring nut shall be tightened to full thread depth and locked to the anchor with a thread locking compound.
7. Threaded anchors shall be set with an impact type drilling machine.
8. See paragraph 3-8 for placement of anchors within 609 millimeters (24 inches)
9. Top of ring nut shall be recessed approximately 12 millimeters (0.5 inch) below the runway surface.

Figure 3-3 4130 Grade Steel Cable Tiedown Anchor



NOTE:

This area must be cadmium plated and conform to spec QQ-P-416 Class 1, Type 1.

Figure 3-4 Installation of 4130 Grade Steel Cable Tiedown Anchor

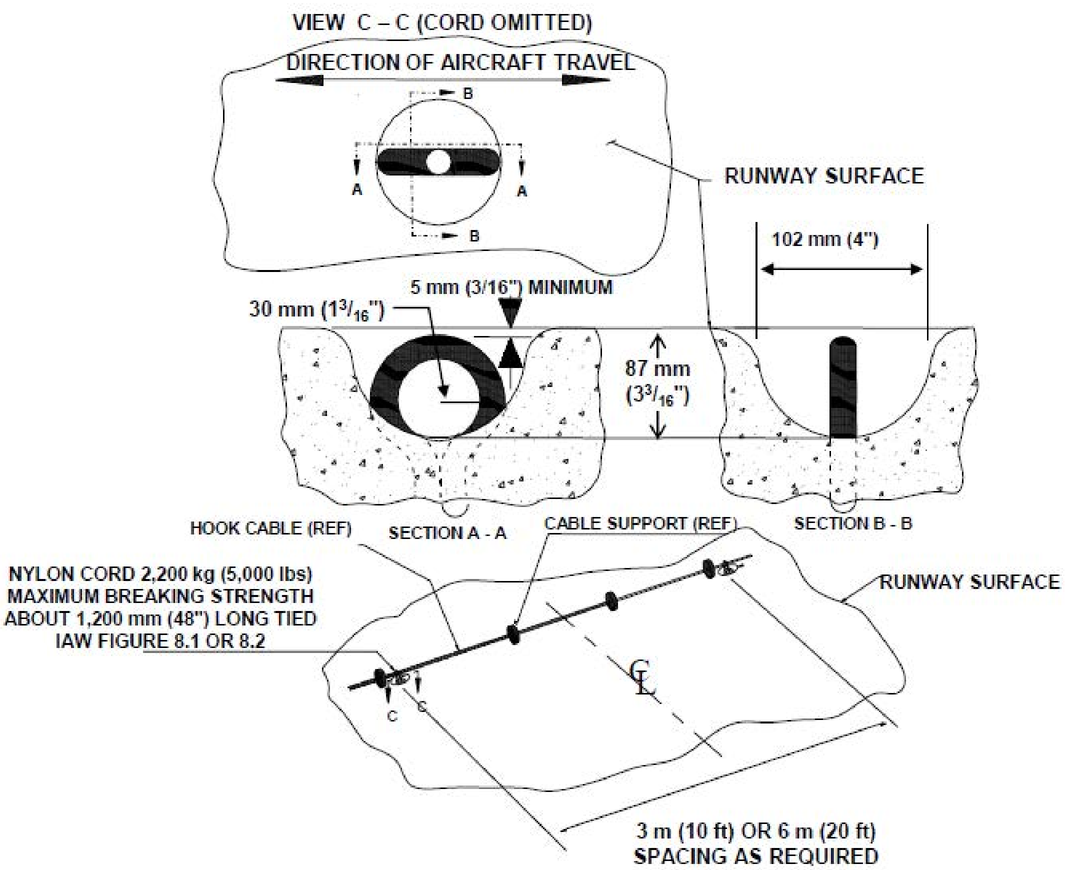


Figure 3-5 Locally Manufactured Cable Tiedown Anchor

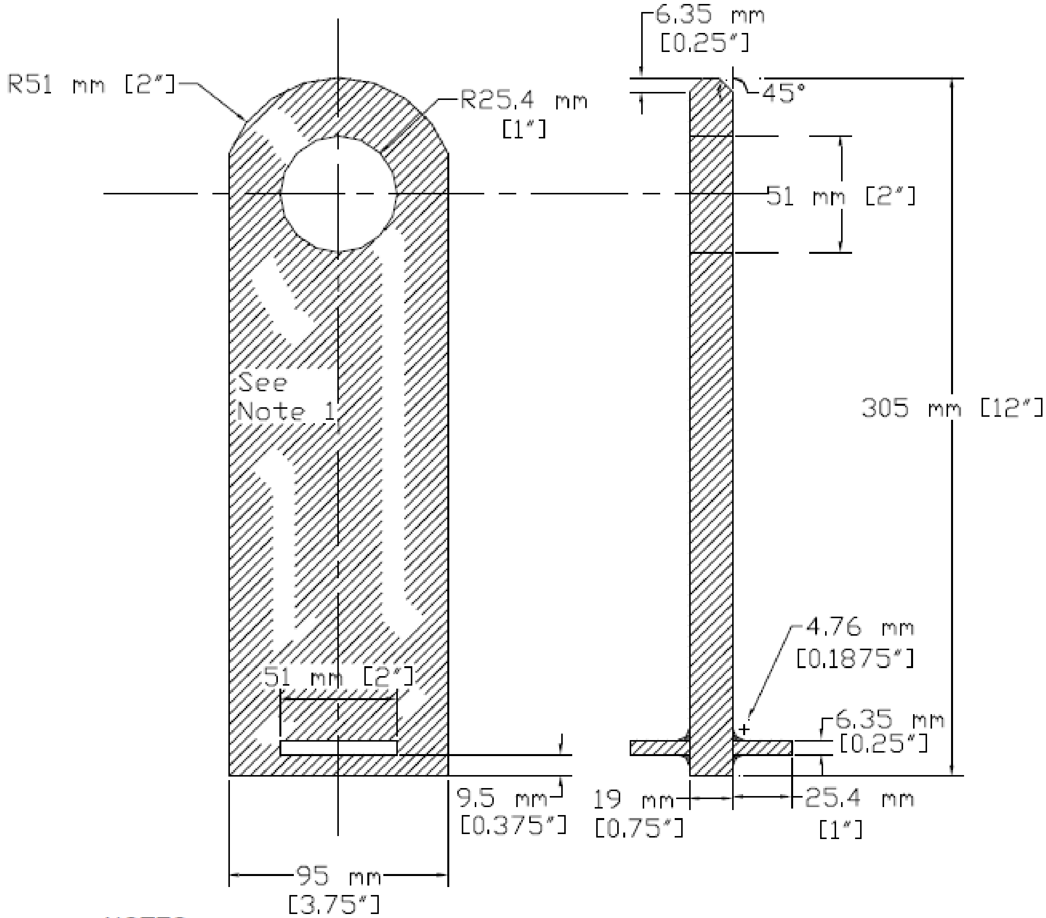
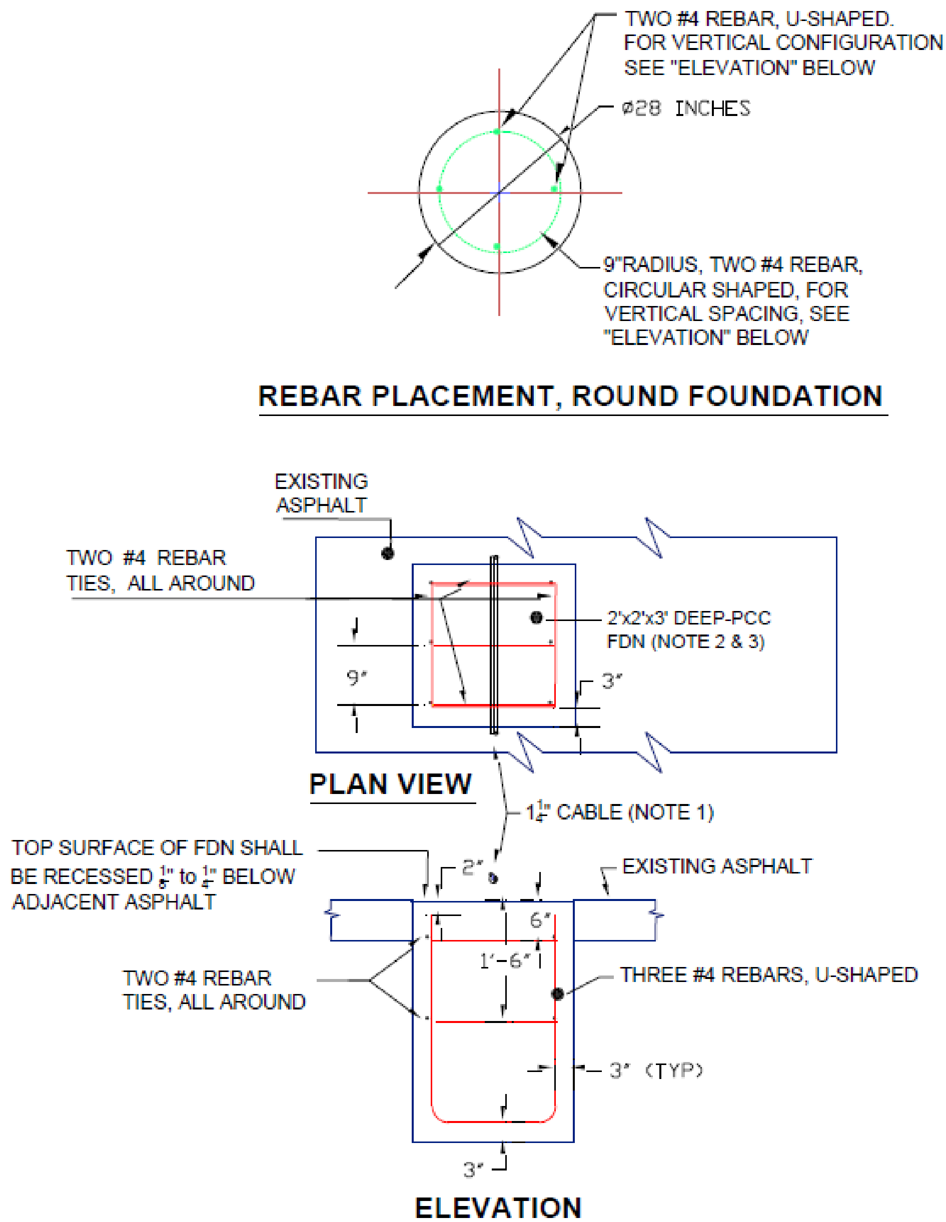


NOTES:

1. Anchor stock is ASTM A36 steel, 19 mm [$\frac{3}{4}$"] by 95 mm [3.75"].
2. Anti-pull-out wings are 6.35 mm [1/4"] by 51 mm [2"] by 25.4 mm [1"] ASTM 36 flat bar with 4.76 mm [$\frac{3}{16}$"] fillet weld all around.
3. Chamfer top edges of anchor radius 6.35 mm [$\frac{1}{4}$"] at 45°.
4. Remove sharp edges from 52 mm [2"] diameter through hole.
5. Coat with cold galvanized coating or two-part epoxy paint suitable for marine applications.
6. Orient anchor with the hole aligned parallel with the cable.

Figure 3-6 Tiedown Foundation Detail for Flexible Pavement Systems



NOTES:

1. CENTER FOUNDATION UNDER CABLE.
2. LOCATE ANCHOR IN CENTER OF FOUNDATION.
3. CUT ASPHALT AS REQUIRED TO EXCAVATE FOR, AND PLACE PORTLAND CEMENT CONCRETE FOUNDATION. FOUNDATION MAY BE ROUND (28" DIAMETER) TO ALLOW USE OF AUGER FOR EXCAVATION.

3-10 GRANDFATHERED SYSTEMS

On-grade BAK-12 systems installed before 1 July 1977 that are sited at least 76.2 meters (250 feet) from the runway centerline do not have to be relocated to meet the minimum setback requirement of 84 meters (275 feet) from the runway centerline. All systems equipped with 2-roller edge sheaves or 2-roller fairlead beams must be programmed for retrofit with 3-roller fairlead beams or edge sheaves to eliminate the longitudinal wheel abutment along the runway shoulder. Replacement foundations must be constructed as described in paragraphs 3.3, 3.4, and Typical Installation Drawings 67F2011A or 67F2012A to comply with the 1V:30H (3.3 percent) maximum slope requirement along the runway shoulder (see UFC 3-260-01, Table 3.2). The unpaved shoulder areas adjacent to the tape tubes must be constructed to comply with Figure 3-1.

3-11 INSTALLING SYSTEMS AT JOINTLY-USED AIRPORTS

3-11.1 The FAA acts for and on behalf of the DoD Service component in operating arresting systems installed at jointly used civil airports for the primary use of U.S. military aircraft.

3-11.2 Site arresting systems on civil airports jointly used by civil and military aircraft according to FAA Advisory Circular (AC) 150/5220-9, *Aircraft Arresting Systems*.

3-11.3 To install an arresting system at a jointly used civil airport, the installation commander must first notify the airport manager (or authority) of the need. If the airport manager agrees, the installation commander submits the plan with sketches or drawings to the Air Force liaison officer at the FAA regional office. Refer any disagreement between the responsible officials to the next higher level within the chain of command.

3-11.4 If construction involves a lease agreement that does not allow placing additional structures on the leased premises, contact the MAJCOM Civil Engineer.

3-11.5 Third-party claims presented for damage, injury, or death resulting from FAA operation of the system for military aircraft or from the Air Force or Air National Guard maintenance of the system may be the responsibility of the Air Force. Process such claims under the appropriate Air Force regulatory guidance (AFI 51-502, *Personnel and Government Recovery Claims*).

3-11.6 The FAA is responsible for claims presented for damage resulting from FAA operation of the system for civil aircraft; therefore, separate agreements between DoD and FAA concerning liability for such damage are not necessary.

3-11.7 The MAJCOM negotiates the operational agreement with FAA for a jointly used civil airport. The MAJCOM may delegate this authority to the installation commander. The agreement describes FAA functions and responsibilities concerning the remote-control operation of arresting systems by FAA air traffic controllers. See Appendix C for a sample letter of agreement.

3-12 MILITARY RIGHTS AGREEMENTS FOR FOREIGN LOCATIONS AND USE BY NON-U.S. GOVERNMENT AIRCRAFT

3-12.1 Install these systems under the military rights agreement with the host government. The installation commander coordinates any separate agreements required with the local U.S. diplomatic representative and negotiates the agreement with the host nation. If the parties are unable to agree, refer the issue to the MAJCOM.

3-12.2 In an emergency, the pilot of a non-U.S. Government aircraft may request and use arresting systems at Air Force bases and jointly used airports within the CONUS and overseas.

3-13 STANDARD BAK-12 SYSTEM SETUP

3-13.1 For any of the three installation methods described within T.O. 35E8-2-5-1, site selection should be made to accommodate a standard system configuration for the allowable runout area.

3-13.2 For a 1200-foot (366-meter) runout, a standard system configuration for maximum BAK-12 runout includes a 1260-foot (384-meter) paved runout area (maximum runout plus aircraft length). Establish synchronization pressure, cam advancement, relief valve setting, tape stack height and cam gearbox drive sprocket size according to T.O. 35E8-2-5-1 Chapter 5. The system must also be equipped with a 1.25-inch (32-millimeter) -diameter pendant, supported by 6-inch (152-millimeter) -diameter support disks (donuts) or a BAK-14 or Type-H Hook cable support system.

3-13.3 For a 950-foot (290-meter) runout, a standard system configuration for a standard BAK-12 overrun runout includes a 1010-feet (308-meter) paved runout area (standard runout plus aircraft length).. Establish synchronization pressure, cam advancement, relief valve setting, tape stack height and cam gearbox drive sprocket size according to T.O. 35E8-2-5-1 Chapter 5. The system must also be equipped with a 1.25-inch (32-millimeter) -diameter pendant, supported by 6-inch (152-millimeter) -diameter support disks (donuts) or a BAK-14 or Type-H hook cable support system.

3-13.4 For a 900-foot (274-meter) runout, a standard system configuration for a 900-foot (274-meter) BAK-12 overrun runout includes a 960-feet (293-meter) runout area (standard runout plus aircraft length). Establish synchronization pressure, cam advancement, relief valve setting, tape stack height and cam gearbox drive sprocket size according to T.O. 35E8-2-5-1 Chapter 5 The system must also be equipped with a 1.25-inch (32-millimeter) -diameter pendant, supported by 6-inch (152-millimeter) -diameter support disks (donuts) or a BAK-14 or Type-H Hook cable support system.

3-13.5 For runway widths greater than 200 feet (61 meters), the control cam must be changed. Refer to T.O. 35E8-2-5-1 Table 5-5.

3-13.6 Once the site has been selected and the system installed, the Aircraft Arresting Systems Report (RCS: HAF-ILE [AR] 7150) must be submitted in accordance with paragraph 7, and a copy provided to the airfield manager. Information pertaining to location (with respect to runway thresholds) and runout must be published within the DoD Flight Information Program (FLIP). Once this has been reported and published, any change to the standard configuration (system runout, pendant cable diameter, or donut size) must not be made without an approved waiver from the Air Force Life Cycle Management Center (AFLCMC) and concurrence from the installation commander, and the MAJCOM Civil Engineer.

3-14 INSTALLATION OF ULTRA-HIGH MOLECULAR WEIGHT (UHMW) POLYETHYLENE PANELS BENEATH CABLES FOR HEAVILY TRAFFICKED PAVEMENTS

3-14.1 In cases where aircraft repeatedly trample donut-supported AAS cables, the pavement directly beneath the cable will erode to form a transverse groove in the pavement across the runway. This section provides procedures, material requirements, and other pertinent information for installation of UHMW polyethylene panels under AAS cables to prevent this damage. It also includes panel specifications and installation. Inspection guidelines are listed in Chapter 4.

3-14.2 Requirements of this FC are mandatory where UHMW panel installations are necessary. Designers should also consider a thickened slab under UHMW panels for new construction to ensure adequate runway pavement strength and sufficient anchoring depth is provided for panel studs and cable tiedown anchors. Installation of UHMW panels is also the preferred method of repair for existing pavements that are distressed from cable trampling. Other repair options such as installation of a hook cable support system (like BAK-14 or Type H) may be justified based on economy or mission.

3-14.3 AAS cables impact underlying pavement by eroding a groove in the pavement directly beneath the cable. The pendant support disks (donuts) must rest in the groove when the cable is in a pre-tensioned state, lowering the effective pendant height (EPH), and reducing the potential for a successful engagement. When the EPH is below 38 millimeters (1.5 inches) there is even higher potential the aircraft hook may not engage the cable, as well as a requirement to publicize the reduced engagement potential to aviators (see paragraph 4-5.2). These areas must be repaired to maintain a uniform pavement surface and the proper EPH to ensure reliability of the arresting system.

3-14.4 Materials must be easily installed and must be minimally susceptible to warping or rapid wear. They must also be cost effective. The Air Force has used numerous pavement repair materials under arresting system cables with varying performance, from satisfactory to very poor. Most of these repairs have been costly and/or eroded quickly. Therefore, the pavements subject matter experts have established that in cases where preformed panels are the best repair option, UHMW panels should be specified. Further, it is absolutely critical to keep panels flush with, or, preferably, slightly recessed 1.6 to 3.2 millimeters (0.0625 to 0.125 inches) below the adjacent pavement surface. Thermal compatibility of the panel material and pavement, security of the anchoring system, and elevation and smoothness of the adjacent pavement and joint seals are extremely important. If possible, plan to install the panels and sealant during average annual temperatures to allow for optimum sealant placement. If the panels are placed in cold weather the joints will tend to close completely in hot weather. If placed in hot weather the joints will tend to be too wide during cold weather. For this reason, it is desirable to use light-gray colored panels to help minimize thermal expansion and contraction (see some recommended panel colors in Figure 3-7).

Figure 3-7 Preferred Panel Colors from FED STD 595, *Colors Used in Government Procurement*

36173		Low solar absorbent gray #17
36231		Gray #23 (36231 replacement of MIL-MIL-DTL-700, Formula 20L)
36270		Low solar absorbent gray #27 (also with anti-stain properties)
36307		Gray #30 (Bulkhead gray)
36373		Low solar absorbent gray #37 (Light gray, color#26373)
36492		Gray #49 (Gull or pearl gray)

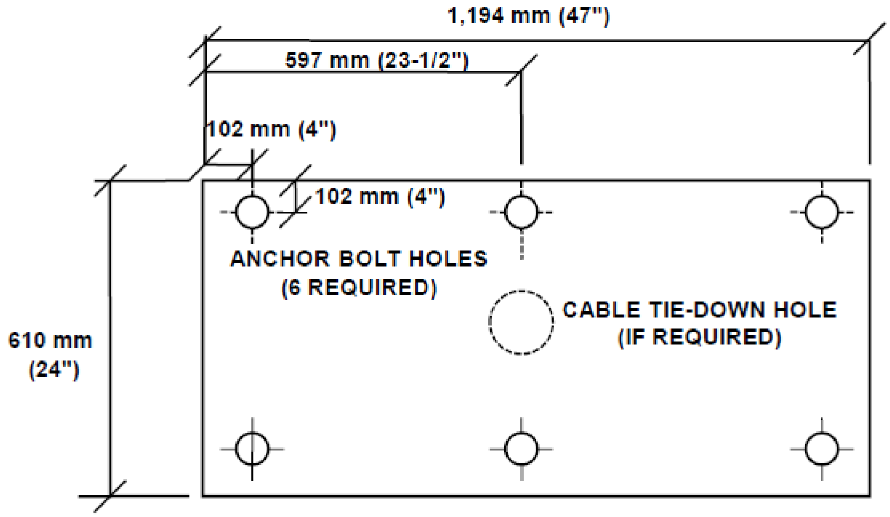
3-14.5 Generally, uncut panel stock is 1220 millimeters (48 inches) wide by 3048 millimeters (10 feet) long by 38 millimeters (1.5 inches) thick (panel stock must not be less than 36.5 millimeters (1.4375 inches) nor more than 38.1 millimeters (1.5 inches)). This allows five 1220 millimeter (48 inch) –long panels to be cut from the 3048-millimeter (10-foot) -long stock with minimal waste. To reduce panel warping and damage to joints from cable impact, panels should nominally be 610 millimeters (24 inches) wide for all installations. Cut panels in lengths so panel joints line up with runway pavement joints. Do not allow panels to overlap pavement joints. This prevents pavement, anchor, or panel failure due to thermal expansion or contraction. For runways with slabs sized in 1524-millimeter (5-foot) increments, such as those having 6-meter (20-foot) longitudinal paving lane joint spacing, panels should be 1207 millimeters (47.5 inches) long. Panels may be shorter but must never exceed 1219 millimeters (4 feet). Order prefinished panels in lengths to suit slab width(s) located beneath the AAS cable on the runway. Take care to ensure there will be no overlap of panels and pavement joints, and no panel anchors will be set closer than 4 inches from any joint. Overlap of joints will cause premature failure. Panels should be drilled and counter-bored for hold-down anchors, and a 4-inch hole cut in the center of panels for those that must accommodate a cable tiedown anchor.

3-14.5.1 Panel Dimensions. Order panels cut to 24 inches wide by 48 inches long or less. Tolerance on panel length and width will be ±3.2 millimeters (±0.125 inch). Panel thickness will be no greater than 38.1 millimeters (1.5 inches) or less than 36.5 millimeters (1.4375 inches).

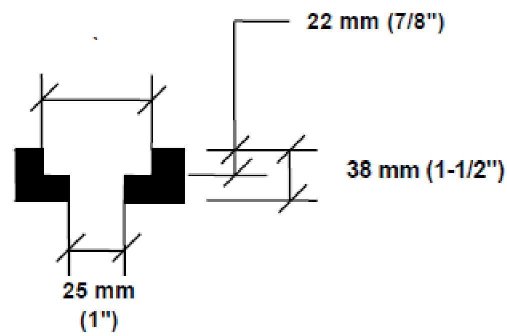
3-14.5.2 Anchor Stud Hole Locations and Dimensions. Each full-sized panel will have six anchor stud holes centered 102 millimeters (4 inches) from the edges of the panel corners and at mid-length. Each partial-sized panel will have four anchor stud holes centered 102 millimeters (4 inches) from the edges of the panel at each corner. The anchor stud hole will be 25.4 millimeters (1 inch) for the through hole and 51 millimeters (2 inches) for the countersink hole. The countersink hole will be 22 millimeters (0.875 inch) deep with square shoulders for a flat washer to lie against. Figure 3-9 shows dimensions and drilling details. Tolerances on dimensions for locations and diameters of anchor holes will be ±1.6 millimeters (±0.0625 inch).

3-14.5.3 Locating Cable Tiedown Anchor Holes. The agency ordering panels must specify the total number of panels required to be drilled to accommodate cable tiedown anchors (four or eight per inlay). The cable tiedown anchor hole must be 102 millimeters (4 inches) in diameter and drilled completely through the panel. Cable tiedown anchor holes will be located in the center of the panel. The location of the cable tiedown anchor hole is shown in Figure 3-8. Cable tiedowns must not be located closer than 305 millimeters (12 inches) from existing pavement joints. Install cable tiedown anchors for operational systems (systems located between the runway thresholds) to limit cable bounce and potential aircraft damage during aircraft rollover. Install eight anchors for all operational systems regardless of primary aircraft supported on the airfield. Program systems with four anchor points to be upgraded to eight anchor points (ref: paragraph 3-8).

Figure 3-8 Panel Dimensions and Anchor and Tiedown Locations



PANEL DIMENSIONS AND ANCHOR HOLE LOCATIONS



Detail of Anchor Hole

3-14.5.4 As indicated above, panel lengths must be sized to ensure panel joints do not overlap longitudinal pavement joints, or joints in the panel foundations. Lengths selected must also accommodate cable tiedown anchor spacing and minimize warping. To accomplish these goals, some slabs will require longer panels, mixed with some partial-length panels. These should be patterned to minimize the number of lengths needed, and spread uniformly across the runway width. Partial panels should never be used to accommodate a cable tiedown anchor. They should only be drilled at each corner. Tiedown anchors should only be placed in full length panels with six anchors. Figures 3-9 through 3-13 shows exact panel, and partial panel lengths, as well as appropriately adjusted spacing for cable tiedown anchors for various slab widths. The dimensions shown allow for 13-millimeter (0.5-inch) -wide joints between panels and pavement edges.

Figure 3-9 Cable Tiedowns for Panels Placed on 3.8-Meter (12.5-Foot) Slabs

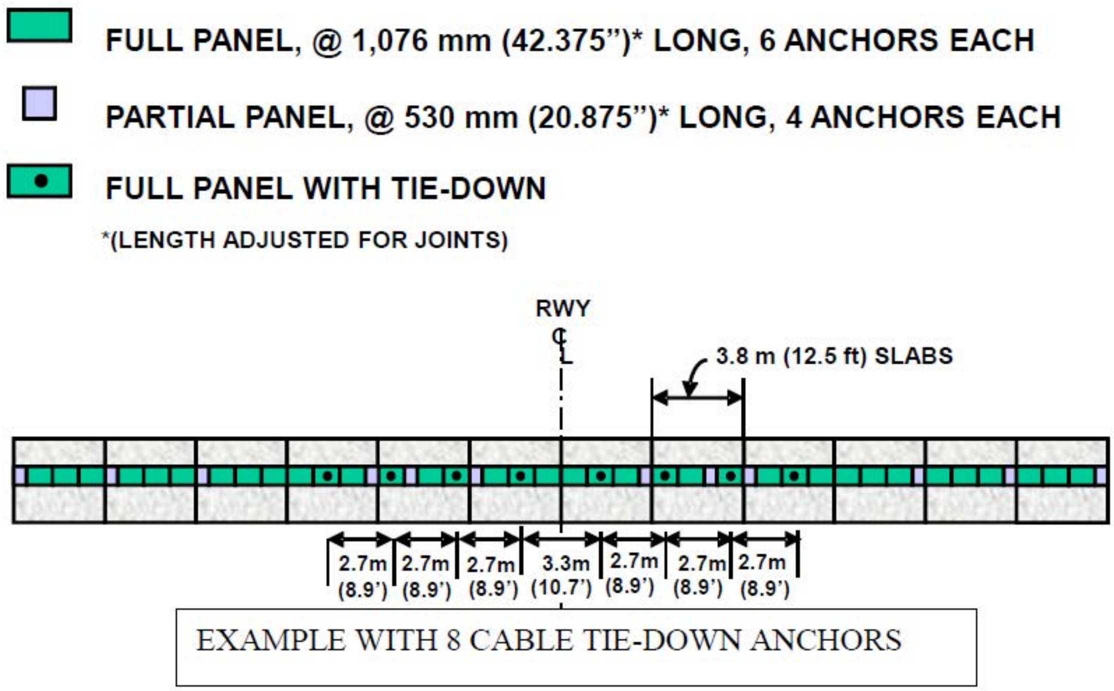


Figure 3-10 Cable Tiedowns for Panels Placed on 4.6-Meter (15-Foot) Slabs

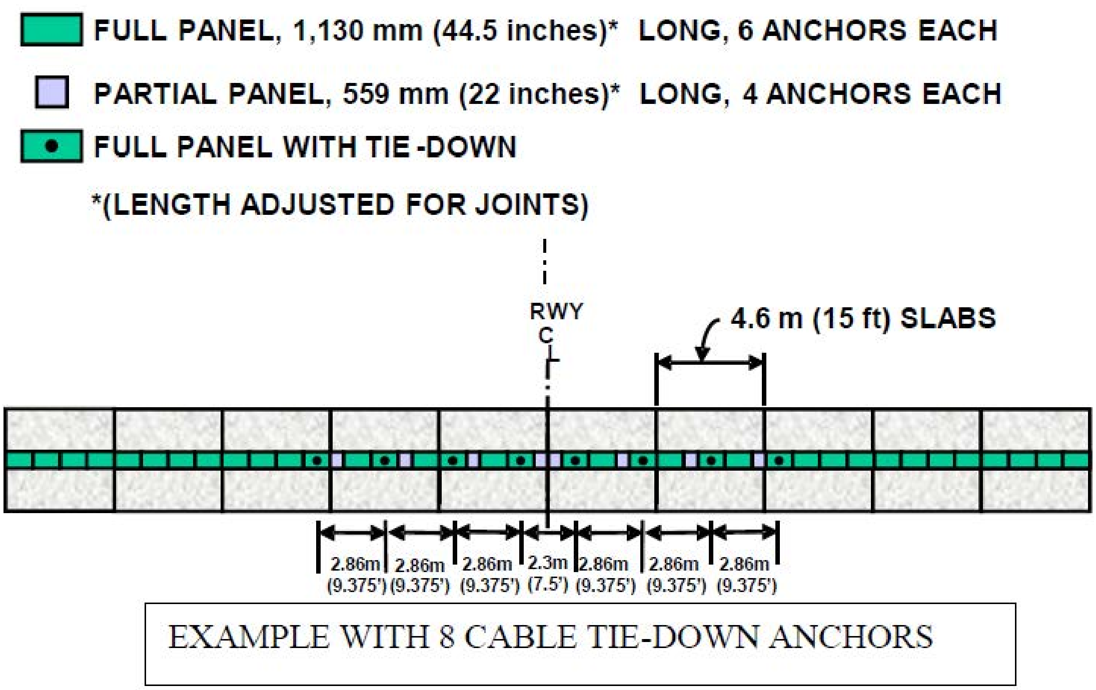

Figure 3-11 Cable Tiedowns for Panels Placed on 5.7-Meter (18.75-Foot) Slabs

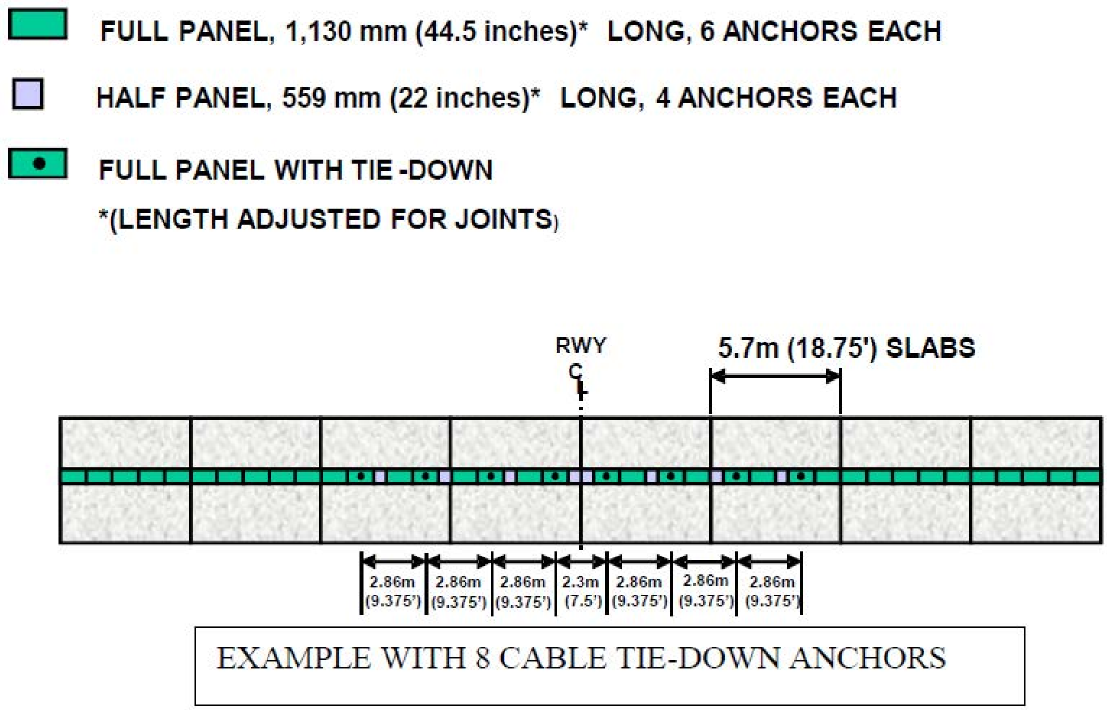

Figure 3-12 Cable Tiedowns for Panels Placed on 6-Meter (20-Foot) Slabs

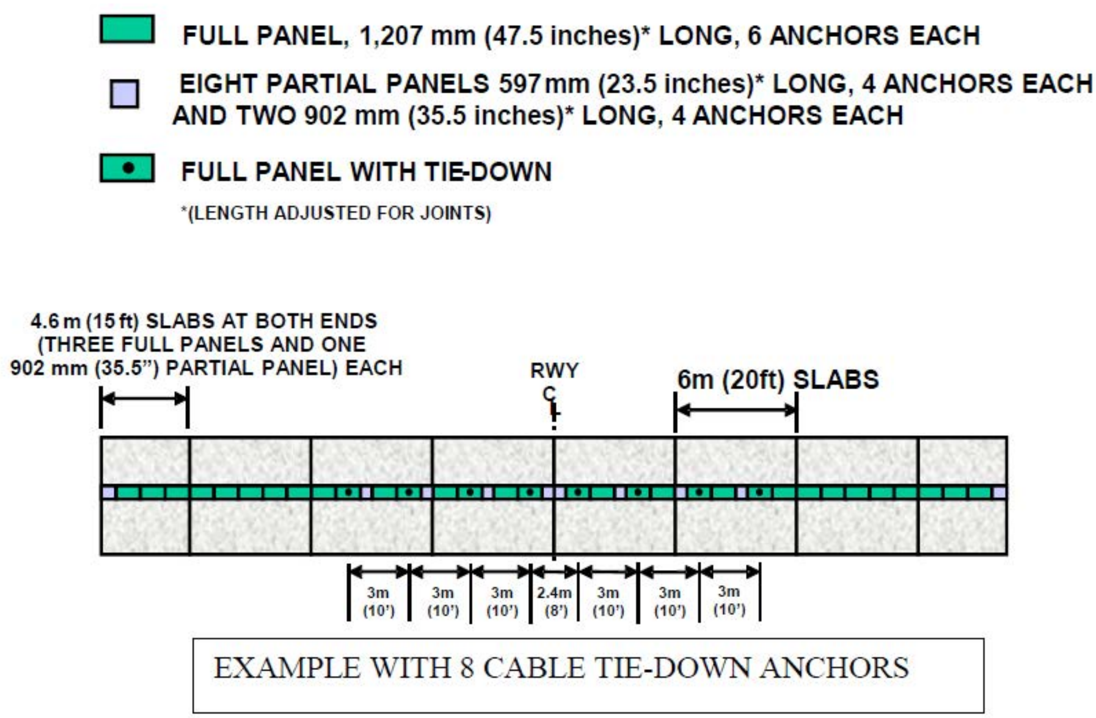

Figure 3-13 Cable Tiedowns for Panels Placed on 7.6-Meter (25-Foot) Slabs

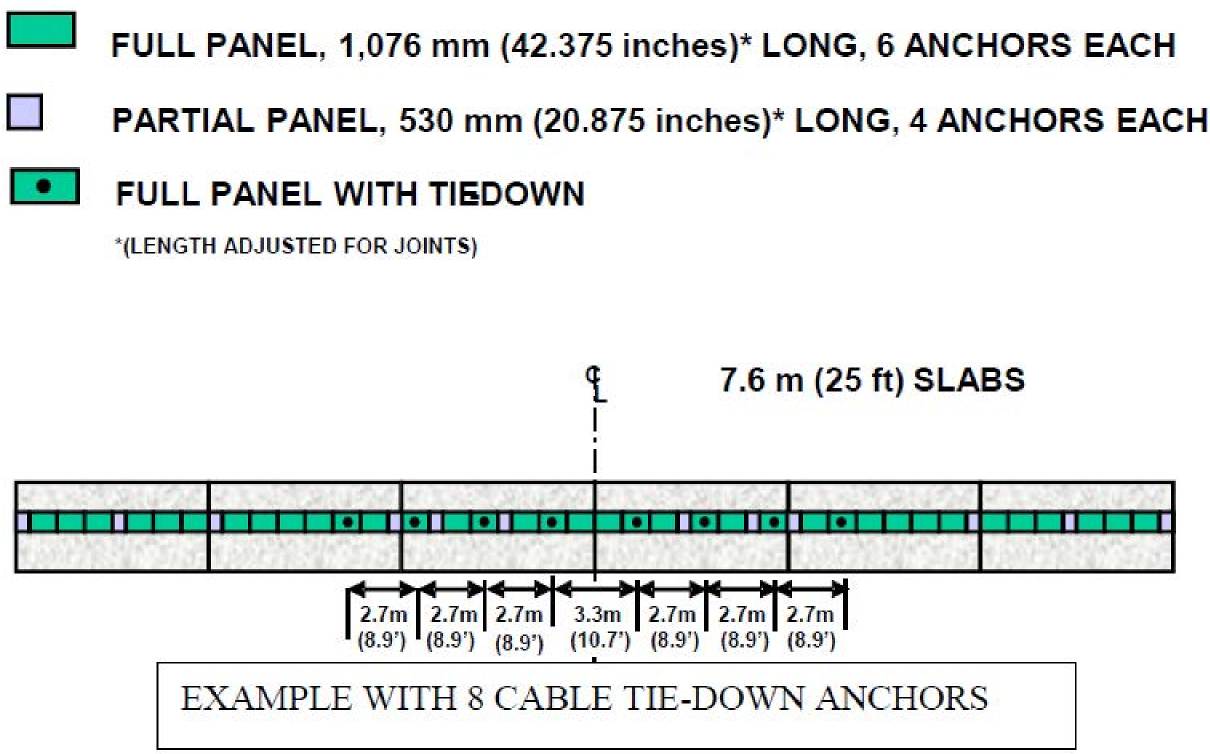


3-14.6 The panels must be fabricated from virgin and/or recycled UHMW polyethylene and will be a variable shade of gray in color, and UV-stabilized. An antistatic additive must be added to the UHMW polyethylene and it must meet the physical requirements of Table 3-1.

Table 3-1 Physical Requirements for UHMW Polyethylene

Property	**Test Method**	**Requirement**
Density	ASTM D1505	0.92–0.94 g/cm
Tensile elongation at break	ASTM D638	300–400 percent
Tensile yield strength	ASTM D638	2800–4000 psi
Shore hardness "D"	ASTM C886	60–70
Coefficient of friction	ASTM D3028	0.2
Izod impact strength	ASTM D256, Method A (see Note)	>20 ft-lb/inch
Note: The test specimens must have two opposing 15-degree notches.		

3-14.7 When considering the installation of UHMW panels it is important to verify thickness of the existing pavement. The panels must be anchored in a sound concrete foundation. A typical anchor stud is 245 millimeters (9.625 inches) long and the foundation is drilled slightly deeper to ensure the anchor does not protrude above the panel when installation is completed. For this reason, a minimum slab thickness of 280 millimeters (11 inches) is needed to properly anchor the panels. If the existing concrete is not thick enough, you must remove and replace it with adequate thickness concrete prior to UHMW panel installation, or select alternative repair methods.

3-14.7.1 Flexible Pavement Systems

3-14.7.1.1 For installation in asphalt pavement:

- Saw-cut and remove a minimum 635-millimeter (25-inch) –wide transverse section of the asphalt and underlying materials to a depth of 915 millimeters (3 feet).

- Backfill the bottom of the trench with a well-graded crushed stone material and compact to a 305-millimeter (12-inch) thickness in 150-millimeter (6-inch) lifts.

- Place the 570 millimeters (22.5 inches) -thick concrete foundation for panel installation.

- Ensure the concrete foundation is finished on the same plane as the runway surface (matches transverse runway slope), and at the proper depth for the panel surface to be slightly below the adjacent pavement.

- Once the concrete is cured, proceed with installing and anchoring the panels as outlined in this section.

These instructions describe an installation procedure for an existing asphalt pavement. However, if installing UHMW panels in conjunction with construction of new flexible pavement (or reconstruction of an existing pavement), the above procedure is still recommended to allow uniform longitudinal compaction.

3-14.7.1.2 Installation in a Rigid Pavement System

For installation in Portland cement concrete (PCC) pavement:

- Prepare the receiving slot.
- Place a cementitious setting bed.
- Install the UHMW panels.
- Install panel anchor studs.
- Install new cable tiedown anchors.
- Seal the joints.

3-15 Step-by-Step Procedures for Preparing Installation of UHMW Panels

3-15.1 Prepare Receiving Slot

Prepare the receiving slot by first removing the concrete. The dimensions of the area of concrete removed depend upon the number of panels installed. For example, for a runway with 3.8-meter (12.5-foot) slabs, each full panel is 1076 millimeters (42.375 inches) long by 610 millimeters (24 inches) wide, and partial panels are 530 millimeters (20.875 inches) long and 610 millimeters (24 inches) wide, with 13-millimeter (0.5-inch) gaps between panels. Therefore, for a 22.86-meter (75-foot) -long inlay of 18 full panels and six partial panels across the runway (11.4 meters [37.5 feet]) on each side of the runway centerline, the saw cut area must be:

- 22.87 meters (75 feet, 0.5 inch) long
- 635 millimeters (25 inches) wide
- At least 64 millimeters (2.5 inches) deep

3-15.2 Saw Cut Perimeter of Inlay

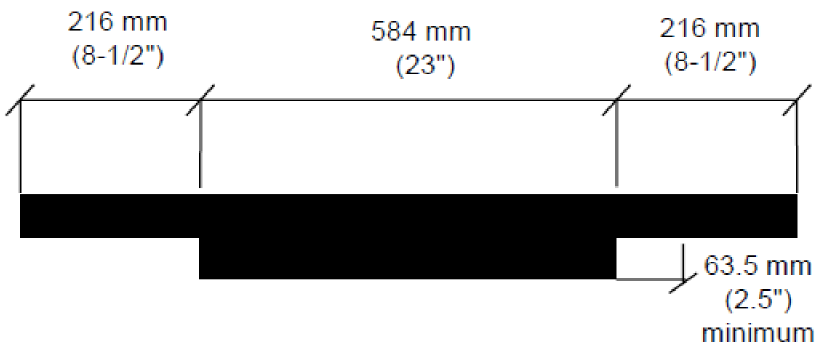
Perimeter saw cuts must be 76 millimeters (3 inches) deep and overlap at least 76 millimeters (3 inches) to ensure that corners are perfectly square when pavement is removed. Remove all loose, unsound concrete within the area. Additional saw cuts inside the perimeter will make removing the concrete easier (using chipping hammers) and result in a more uniform concrete profile

NOTE: For partial-runway-width installations, provide a means of drainage for the receiving slot to prevent damage from trapped water or dirt that may enter at leaks in the joint seals. Several saw cuts made to run from the ends of the inlay to the shoulders and cut at the same depth as the receiving slot will typically suffice.

3-15.3 Inspect Receiving Slot Following Concrete Removal

With a notched board (Figure 3-14), check the depth of the concrete within the recessed setting bed. Use a chipping hammer to remove any portions less than 64 millimeters (2.5 inches) from the surface of the adjacent pavement then visually check the concrete, sound it with a steel rod to identify any unsound portions, and remove all unsound concrete. Cut existing AAS cable tiedown anchors flush with the bottom of the concrete substrate before placing the setting bed.

Figure 3-14 Notched Board Used to Check the Receiving Slot



3-15.4 Remove Existing Tiedown Anchors

Cut existing AAS cable tiedown anchors flush with the bottom of the concrete substrate before placing the setting bed.

3-15.5 Clean Concrete Substrate

Upon removal of concrete from the slot, it is important to adequately clean the slot to ensure the new setting bed material will adhere to the substrate. Particular care should be taken to remove the laitance from the smooth faces of the saw cut walls; sandblast or use wire brushes, followed by compressed air.

3-15.6 Place a Setting Bed

Place a cementitious setting bed under the panels and allow the bed to cure before drilling and anchoring the panel anchor studs. Use ordinary PCC at airfield strength (34,474 kPa [5000 psi] compression/4482 kPa [650 psi] flexural strength in 28 days) when several hours' cure time is available. As a suggested mix, use:

- A lean seven-bag mix with 10-millimeter (0.375-inch) maximum size aggregate.
- Water-to-cement ratio not to exceed 0.3:1.
- Plasticizer admixture.
- Substitute fly ash for -50 sieve size sand as required.

This mixture will allow drilling within 18 to 24 hours. For short-cure-time applications, a prepackaged material such as Rapid Set® Concrete Mix is satisfactory. Rapid Set® Concrete Mix is packaged in 27-kilogram (60-pound) bags that yield approximately 0.014 cubic meters (0.5 cubic foot) of concrete when mixed with water (refer to Table 3-3 for ordering information). Placing a small test sample in a disposable pail the same depth as the setting bed may also serve as a helpful tool in determining adequate cure time for drilling operations

3-15.7 Positioning Mixing Equipment

Position two mechanical mortar or concrete mixers approximately 6 meters (20 feet) from the prepared inlay near the center of the runway. Transport mixed mortar in a wheelbarrow. Mortar mixers are preferred. Depending upon the type of material used, drum mixers may not agitate the material enough to produce the desired workability when the recommended amount of water is used.

3-15.8 Mixing and Placing Rapid Set® Concrete Mix

- Place 2.8 to 3.8 liters (3 to 4 quarts) of water in the mixer. In hot climates, using cold water can extend the setting time of the mix. In cold climates, using hot water and heating the substrate may shorten the setting time.
- Add one bag of Rapid Set® Concrete Mix and mix for two to three minutes. Note that this mix "wets" slowly. Do not add more water until the full mixing time has elapsed. Over-wetting will weaken the final mix. Place the material within 10 minutes after mixing. If temperature is above freezing, wet the substrate first. If below freezing, do not wet the substrate.

3-15.9 Finishing

Finish the material from the center of the bed to the edges to achieve proper bonding along the side walls of the excavation.

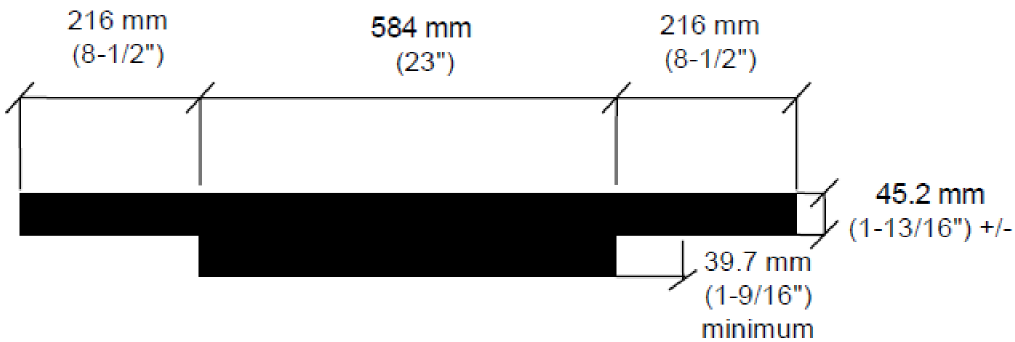
3-15.10 Curing

After initial set, when the surface becomes hard to the touch, fog- or spray-mist-cure with water for one hour. Do not add an excessive amount of water. Over-wetting will weaken the setting bed.

3-15.11 Leveling the Setting Bed

Mechanically vibrate the concrete before you screed to consolidate the mass. Even simple hand-tamping with a garden rake greatly reduces the percent of voids in the mix. Level the concrete to the proper depth in the setting bed using a notched screed board (Figure 3-15). Strike the screed periodically to ensure proper depth and uniform surface. The 39.7-millimeter (1.5625-inch) depth of the screed board is based upon a panel thickness of 38 millimeters (1.5 inches). Measure the actual thickness of each panel upon delivery to ensure they are all the same thickness and to establish the required screed dimensions. The setting bed must be level and of the proper depth to correctly support the panels. A properly-placed setting bed will help avoid a lot of aggravating manual labor. A setting bed that is not level or is placed at an improper depth requires excessive grinding of the pavement and/or shims, or may require grinding of the adjacent pavement surfaces. Shims should be used only as a last resort, not planned into the job. When required, the shim stock should be a nonferrous metal and should be sized to provide full surface support for the panel, not just point support at the anchor locations.

Figure 3-15 Notched Screed



3-15.12 Joints

Extend existing pavement joints through the setting bed by saw-cutting or using an expansion board. The saw cut should be a single blade-width and extend completely through the setting bed. Expansion boards must be set the full depth of the setting bed.

3-16 INSTALLATION OF UHMW PANELS

3-16.1 Allow the setting bed to harden (approximately 4 hours, depending on the type bed used) to the minimum strength that allows drilling without damage to the concrete.

3-16.2 Lay the panels in place and inspect to ensure that the top surface of the panel is at least 1.6 millimeters (0.0625 inch) lower than the adjacent pavement surface. Grind the bedding material or panel edges as necessary so that the panel surface is slightly recessed (1.6 to 3.2 millimeters [0.0625 to 0.125-inch]) below the adjacent pavement surface. Panel height is especially critical in the center half of the runway.

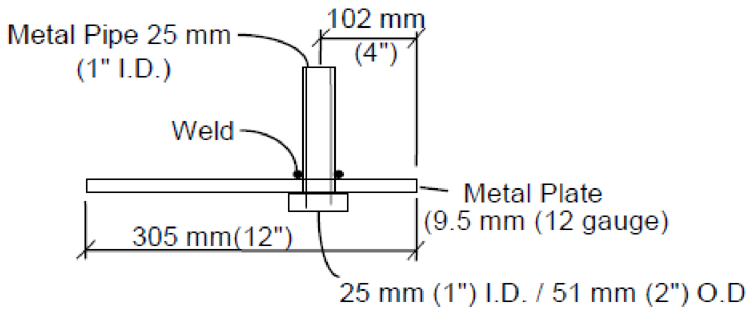
3-16.3 Set spacing between panels using 13-millimeter (0.5-inch) -thick shims and secure all panels in place with wood wedges (minimum four sets per panel) to prevent panels shifting during drilling of anchor stud holes. UHMW panels expand and contract greatly with temperature changes. The panels should be placed and anchored at the median annual temperature for the given location to allow for movement either way with temperature changes.

3-17 INSTALL PANEL ANCHOR STUDS

For a list of required tools and equipment, see Table 3-2.

3-17.1 Position the locally fabricated alignment tool (Figure 3-16) over each predrilled hole in the panel and drill 22-millimeter (0.875-inch) -diameter holes in the setting bed. Not all anchor studs are consistent in length as ordered, so check actual anchor stud lengths and drill to accommodate the longest stud. The depth of the hole is critical — if it is not deep enough, the stud will protrude above the panel surface and require excessive grinding; if it is too deep, the adhesive capsule will be positioned below the stud and not provide adequate coverage. Use a drill-mounted depth gage rod or mark a position on the drill bit shaft the length of the stud plus the depth of the alignment tool to ensure proper hole depth when drilling.

Figure 3-16 Drill Guide (Anchor Boring Alignment Tool)



3-17.2 Thoroughly clean debris from the drilled hole with a round wire brush and compressed air. A 9- to 13-millimeter (0.375- to 0.5-inch) -diameter tube attached to the compressed air line is necessary to remove all fines from the holes. Insert tubing to the bottom of the hole before purging to ensure all particles are removed. **CAUTION: Wear eye protection.**

3-17.3 Install each anchor stud as described below. To avoid work stoppage while the adhesive cures, plan to have at least 12 cap nuts available for setting anchors.

3-17.3.1 Insert an adhesive capsule into each hole with the rounded end facing the bottom of the hole. Screw a cap nut (or other manufacturer-provided adapter) onto the end of the anchor bolt and attach the unit to a heavy-duty drill (or rotary impact hammer). Insert a flat washer onto the threaded stud just below the adapter, or position the washer over the panel hole inside the counter-bore. Drive the anchor stud to the bottom of the hole to break the capsule(s) and mix the adhesive (in accordance with the manufacturer's instructions for drill speed and mixing time). Once the anchor stud is in position, do not disturb it until the adhesive has gelled. Allow the adhesive to cure as recommended by the manufacturer before the cap nut can be removed without disturbing the stud position.

3-17.3.2 Remove cap nut and flat washer; seal around stud with silicone sealant; reinsert flat washer and a thread-locking compound, then install a nut to the top of the anchor stud.

- Allow adhesive to fully cure according to the manufacturer's instructions and then torque the nuts to 81 newton meters (N•m) (60 pound feet [lb ft]).
- Grind off any portion of a stud that protrudes above the panel surface.

CAUTION—Take care to set anchors at the proper depth to avoid the need to grind the anchor rods. Excessive grinding will cause rapid build-up in the temperature of the anchor. Some epoxy manufacturers indicate heating the epoxy to 250^0 F or greater will degrade or destroy the strength of the epoxy bond.

3-18 INSTALL NEW CABLE TIEDOWN ANCHORS

Install cable tiedown anchors for operational systems (systems located between the runway thresholds) to limit cable bounce and potential aircraft damage during aircraft rollover. Install eight anchors for all operational systems regardless of primary aircraft supported on the airfield. Program systems with four anchor points to be upgraded to eight anchor points (ref: paragraph 3-8).

3-18.1 Each cable tiedown anchor hole will be located in the center of the appropriate panel. Refer to Figures 3-9 to 3-13 for location and spacing.

3-18.2 When installing cable tiedowns, ensure the top of the tiedown is at least 5 millimeters (0.1875 inch) to 13 millimeters [0.5 inch]) below the final panel surface height.

3-18.3 Depending on the location of existing runway pavement joints in relation to the runway centerline and the longitudinal joint spacing, UHMW panels may be installed with a panel joint or panel center falling on the runway centerline.

3-18.4 Figures 3-9 through 3-13 depict recommended cable anchor tiedown locations when installing standard full-sized and partial panels in various slab sizes. The partial panels are required to permit acceptable tiedown spacing and to avoid overlapping joints in the existing slabs. For installation in slabs sized other than those shown, consult the AAS engineer.

3-19 SEAL THE JOINTS

Use silicone sealant and apply joint seals in spacing between panels, around anchors and tiedowns, and between panels and pavement edges.

3-19.1 The joint surface must be recessed at least 6.35 millimeters (0.25 inch) below the panel top surface. Silicone sealants should be used in lieu of hot-pour asphalt or tar sealants.

3-19.2 The size of the backer rod must be carefully selected due to the expansion properties of the panels. The spaces between panels should be noted when the panels are in their contracted state to ensure an undersized backer rod is not used. Undersized backer rod may allow sealants to leak.

3-19.3 A non-shrinkable, non-absorbent, highly compressible foam backer rod should be used, sized to span the maximum expected gap but placed at the medium temperature and set at a depth to ensure a proper shape factor is created for the sealant reservoir.

3-20 INSTALLATION TOOLS, EQUIPMENT, AND MATERIALS

Table 3-2 provides a list of tools and equipment, with recommended quantities, needed to install a typical UHMW panel inlay for the full width of a 46-meter (150-foot) wide runway.

Table 3-2 Typical Tools and Equipment for Installation

Quantity	Unit	Description
1	each	Concrete saw, self-propelled
1	each	Hand-held portable saw
2	each	Saw blades
1	each	Water distributor
50	LF	Expansion board, asphalt impregnated, 102 mm x 13 mm (4 in x 0.5 in)
3	each	Mortar mixer, 4 cubic feet (two for use, one spare)
1	each	Sandblast unit for air compressor
3	each	Jackhammer, 40 kg (90 lb), with chisel and spade bits
1	each	Heavy-duty disc-type electric grinder
2	each	5 L (1.25 gal) containers for mixing water
3	each	Electric generators (1 per drill)
3	tons	Pea gravel (clean, washed gravel, 9 mm [0.375 in])
150	bags	Rapid Set® Concrete Mix repair material
4	buckets	5 gal size, for measuring aggregate
1	board	Notched screed, 51 mm x 102 mm x 1 m (2 in x 4 in x 40 in)
1	board	Notched depth gauge, 51 mm x 102 mm x 1 m (2 in x 4 in x 40 in)
As required (30 in this case)	panels	UHMW polyethylene, 610 mm (24 in) wide, sized, drilled and counter-bored.
As required (192 in this case)	each	Anchor studs, 19-mm (0.75-in) diameter, 245 mm (9.65 in) long, fully-threaded, with nuts, flat washers and vinyl ester resin vials (six per panel plus spares)
12 (min)	each	Cap nuts, 19-mm (0.75-in), 10 UNC
2	each	Magnesium floats
1	pair	Vice grips for cap nut removal
1	each	Screwdriver to help with cap nut removal
1	each	Concrete vibrator, small size

Table 3-2 Typical Tools and Equipment for Installation

Quantity	Unit	Description
2	each	Steel trowels
4	each	Shovels, square point
1	each	Electric drill, 13-mm (0.5-in) drive
1	each	Torque wrench to apply 81 N●m (60 lb ft) torque
1	each	TYMCO® airfield sweeper
1	each	Air compressor
1	each	Front end loader
2	each	Dump trucks
2	each	Wheelbarrow, 4 cu ft
2	each	Knives
1	each	Pickup truck
2	each	Hammer
2	each	Steel chisel, hand-held
1	each	Joint seal kettle with SS-S-1401 joint seal. **Note:** Silicone joint seal is also recommended and preferred. A recommended silicone joint seal is Dow Corning® 890-SL in 0.8-L (29-oz) tubes (96 tubes required) and a caulking gun for 0.8-lL (29-oz) caulk tubes.
3	each	Electric impact drill (Hilti HE72 or equivalent) with 22-mm (0.875-in) -diameter by 530-mm (21-in) -long masonry bits.
1	each	Gooseneck wrecking bar, 1220 mm (4 ft) long, minimum
1	each	Pick for debris breakout and removal
2	each	Wire brushes for slot cleaning
1	each	Roll of heavy cloth or plastic tape for marking drill bits for drilling depth
2	each	Alignment tools for drilling holes vertically
As req'd		Wood wedges to secure panels in position, minimum eight tapered wood wedges per panel
As req'd		Safety equipment including, but not limited to, dust masks, goggles, ear protectors, work gloves, and safety shoes *Ensure an eye wash is available.
As req'd		Wood spacers, approximately 13 mm (0.5 in) thick by 102 mm (4 in) by 76 mm (3 in), used to maintain spacing between panels during panel installation
As req'd		String line, spray paint, straightedge board, and a 30-m (100-ft) tape to measure and mark for saw cuts

3-21 MATERIALS AND SUPPLIES

Table 3-3 provides a list of materials, supplies and the recommended quantities needed to install a typical UHMW panel inlay for the full width of a 46-meter (150-foot) wide runway.

Table 3-3 Estimated Material Cost and Suggested Sources of Supply (150-Foot Wide Runway)

Quantity	Item	Suggested Source	Cost
30 each	UHMW polyethylene panels, predrilled with six counter-sunk anchor holes	Röchling Engineered Plastics http://www.roechling-plastics.us/ or Ultra Poly http://www.ultrapoly.com/	$16,900
192 each	Anchor studs, 19 mm (0.75 in) diameter, 245 mm (9.65 in) long, full-threaded (Hilti PN 068660) with vinyl ester bonding vials (Hilti PN 256702), nuts, and flat washers (Hilti HVA Adhesive Anchor System with HEA 19-mm [0.75-in] capsule and HAS 19-mm [0.75-in] rod)	Hilti Fastening Systems http://www.us.hilti.com/ or Williams Form Engineering Corporation http://www.williamsform.com/	$2,662
4 each	Drive sockets (PN 65279)	Hilti Fastening Systems	$74
4 each	Drive socket shafts (setting tool, square drive): SDS Max Connector, P/N 32221, **or** SDS Top Connector, P/N 332169		$484 $299
4 each	Masonry drill bits, 22 mm (0.875 in) diameter, 530 mm (21 in) long	Hilti Fastening Systems	$650
25 each	Cap nuts, 19 mm (0.75 in) diameter, 10 UNC (P/N 91855A036)	McMaster-Carr http://www.mcmaster.com/	$163

Table 3-3 Estimated Material Cost and Suggested Sources of Supply (150-Foot Wide Runway)

Quantity	Item	Suggested Source	Cost
150 bags	Rapid Set Concrete Mix	CTS Products www.ctscement.com or www.rapidset.com/rs Midwestern Regional Office 1211 South 6th Street St. Charles, IL 60174 Phone: (312) 773-4949 1-800-929-3030	$4,550
96 tubes	Silicone joint seal (Dow Corning 890-SL)	The Fred R. Hiller Company http://www.fredhiller.com/	$3,250
Note: Costs do not include shipping. Suggested vendors are provided to assist in locating sources. The use of the name or mark of any specific manufacturer, commercial product, commodity, or service in this FC does not imply endorsement by the Air Force.			

3-22 TYPICAL SCHEDULE OF EVENTS

Table 3-4 provides an example schedule of events for installing eight panels (partial width installation).

Table 3-4 Installation Schedule for Eight Panels

Day	Times	Event Description
1	1800–2200	Perimeter saw cutting, Runway 33. Crew size: 2 men. Saw cuts 76 mm (3 in) deep.
2	1500–1745	Excavation starts on Runway 33 inlay. Crew size: 9 men. Concrete removed using three 40-kg (90-lb) jackhammers and one cold milling cutter drum on a Bobcat 843 skid-steer loader. Debris loaded into dump truck using front-end loader. Large rubble removed by hand and shovel; small debris removed using the suction wand of the airfield sweeper.
2	1745–1915	Excavation complete. Slot cleaned with high-pressure air. Substrate sounded and delaminated (unsound, hollow) material removed. Approximate final slot size: 30 m (100 ft) long by 635 mm (25 in) wide by 76 mm (3 in) deep. Notched depth gauge board used to check depth in the center 12.2 m (40 ft) area where panels will be installed.
2	1915–2000	Final slot inspection. Loose hollow-sounding areas removed with jackhammer and pick. (Hand-held hammer and steel chisel may also be used.) Slot side walls cleaned with wire brushes. Slot cleaned and dried with high-pressure air.

Table 3-4 Installation Schedule for Eight Panels

Day	Times	Event Description
2	2000–2230	Mixing and placing of setting bed begins. Both concrete mixers used. Ten-person crew used. No bonding agent used or needed. Notched board used to keep setting bed at the correct level below the surrounding pavement surface.
2	2030–2242	Curing compound applied periodically as the setting bed is placed.
2	2242–2300	Cleanup accomplished and runway cleared. Approximately 90 bags of mortar placed.
3	0855–1030	Joints and cracks saw-cut through the mortar patches, both flush and recessed patch areas. Hand-held portable saw used for recessed setting bed cracks/joints and self-propelled pavement saw used for flush patches.
3	1015–1045	Panel placement begins. Panels positioned and tightly wedged into place using wood spacers and wood shims (wedges). (Panels as ordered for the job have predrilled anchor bolt holes.)
3	1050–1130	Drilling bolt holes begins. Three heavy-duty electric impact drills (two Hilti HE72, one Milwaukee) used and work well. Three minutes drilling time per hole required. Portable drill alignment tool used to keep drill bit positioned vertically to start hole. Drill bits marked with tape to control hole depth. Long slender tube inserted completely to bottom of bolt holes delivers compressed air to thoroughly clean holes. Recommended wire brushing of holes is not accomplished.
3	1130–1345	Panel anchor studs set in position using electric drill with adapter attachment. Anchor studs anchored into pavement with adhesive capsule inserted before inserting anchor stud in hole. Installation of anchors is delayed during first hour while new adapter is fabricated locally for anchor installation. After first adapter is tried and proven, two more adapters are fabricated. Anchor stud installation then progresses rapidly with most anchor studs installed in last hour. Applying oil on ends of studs aids adapter removal after stud installation.
3	1340–1400	Shims removed. Site cleaned with compressed air to remove all particles before sealing around panels with joint sealant.
3	1710–1730	Studs torqued to 81 N•m (60 lb ft) with torque wrenches. All studs torqued adequately but several stud ends protrude above panel surface.

Table 3-4 Installation Schedule for Eight Panels

Day	Times	Event Description
3	1810–1820	High studs ground down flush with surface using a heavy-duty disc-type electric grinder. **CAUTION—Excessive grinding will cause rapid build-up in the temperature of the anchor rod. Some epoxy manufacturers indicate heating the epoxy to 250^0 F or greater will degrade or destroy the strength of the epoxy bond. Take care to set anchors at the proper depth to avoid anchor failure.**
3	1720–1820	Sealant applied to joints around panels using kettle with hot-applied, single-component, non-jet-fuel-resistant sealant (SS-S-1401). Job complete.
3	1820–1830	Final inspection and job site cleanup completed.

CHAPTER 4 OPERATION, MAINTENANCE, CERTIFICATION, AND INSPECTION

4-1 INTRODUCTION

4-1.1 This chapter provides basic information on inspection, maintenance, certification, operation, maintenance records, and deficiency reporting for AAS. Information contained in this chapter is intended to be general in nature. Specific technical information may be found in the applicable 35E8-series T.O.s.

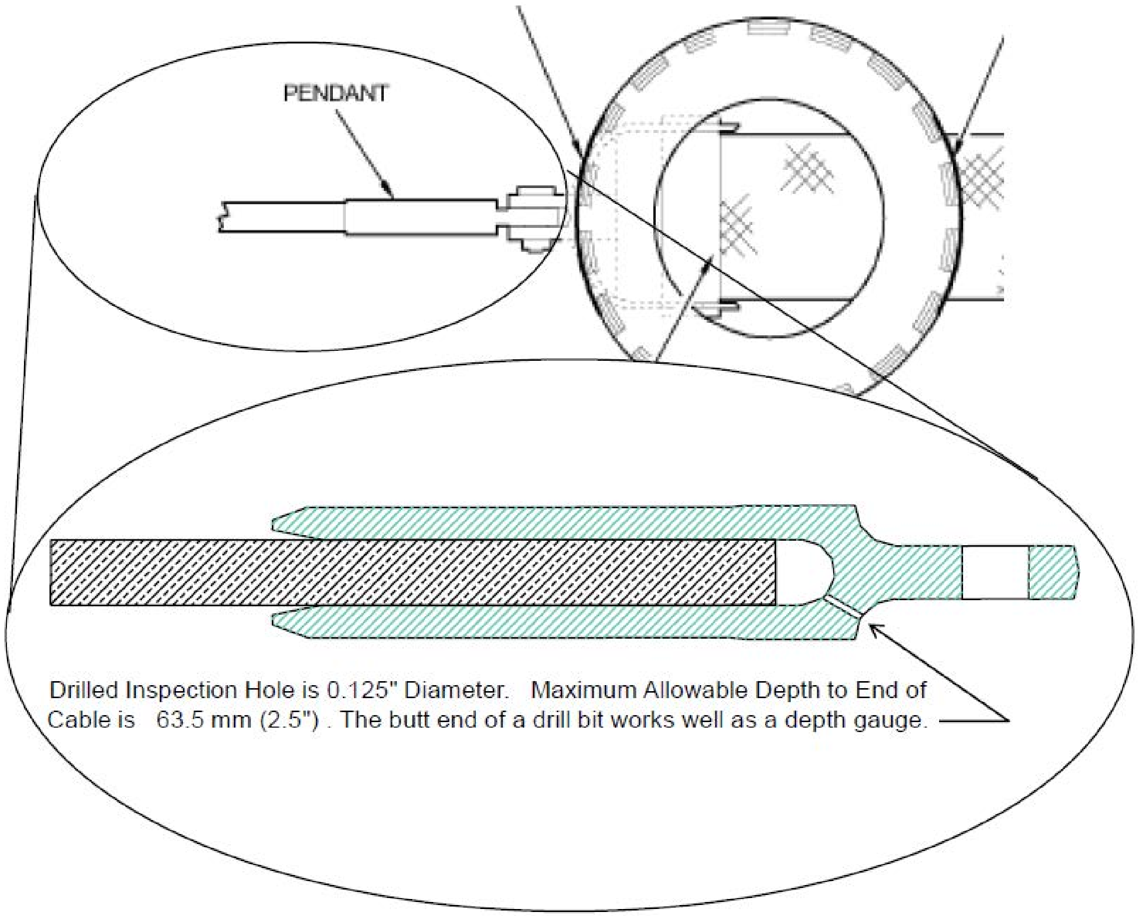
4-1.2 The BAK-12 T.O. provides alternate procedures for removing an aircraft from the cable after engagement. These alternate procedures are commonly referred to as a "slingshot" removal of the aircraft. Potential for aircraft damage is high when using these methods; therefore, use these procedures only during contingencies or in-flight emergencies that require rapid removal of an aircraft from a cable. The procedure must be approved by the installation commander before being used for routine disengagement of aircraft during local exercises or scheduled testing of the arresting system (e.g., certification).

4-2 CABLE (PENDANT) INSPECTIONS

4-2.1 Inspections must be performed in accordance with the applicable T.O., information contained within this instruction, and the 35E8-series work cards.

4-2.2 In-service pendant cables must be inspected daily and after each engagement. Use cable inspection criteria from BAK-12 or BAK-13 T.O.s for textile brake AAS. For all AAS cables (pendants), measure and record the swaged end cable insertion depth measurement in the maintenance records before placing any arresting system cross-runway pendant in service (see Figure 4-1). Do not install cables with swaged end depth measurement greater than 63 millimeters (2.5 inches). The previous requirements to mark the cable with paint or some other means of permanent marking and to perform post-arrestment measurements have been made optional at the discretion of the AAS shop supervisor. Spare pendants should be stored indoors or on their original shipping container.

Figure 4-1 Swaged End Measurement for Cable to Terminal End Fitting



4-3 EXPEDIENT TRIM PAD ANCHORING SYSTEM CABLE INSPECTIONS

4-3.1 Expedient trim pad anchoring systems can be installed using K-M anchoring components from the MAAS. Use ETL 06-4, *Expedient Trim Pad Anchoring Systems*, to install and inspect expedient trim anchors. Use the following guidance for cable inspection and disposition if AAS pendants are used to restrain the aircraft during trim operations.

4-3.2 Cables used with the expedient trim pad setup shall be kept separate from cables used for aircraft engagements, and shall only be used for trim operations (e.g., cables used for trim operations shall not be used for aircraft engagements, and cables that have been used for engagements shall not be used for trim operations).

4-3.3 Develop a use and inspection log for each new cable and record the date and pertinent details of each trim operation in the log. Maintain the log for the life of the cable. There is no limit to the number of trim operations that can be performed with a single cable within a 36-month period; however, all cables will be removed from service 36 months after their initial installation date unless they fail to meet the requirements stated below.

4.3.2.1 Before installing any cable, measure and record the swaged end cable insertion depth as prescribed above in paragraph 4-2.2. Also, inspect the cable in accordance with instructions in T.O. 35E8-2-5-1. Do not install cables with defects identified in the T.O. or if the insertion depth measurement exceeds 63 millimeters (2.5 inches).

4-3.2.2 After each trim pad operation, inspect the cable in accordance with instructions in T.O. 35E8-2-5-1. Also, measure and record the swaged end cable insertion depth for each end, or inspect for swaged end movement if the swaged end position has been marked as described in paragraph 4-2.2 above. Remove the cable from service if it fails to meet the inspection requirements of T.O. 35E8-2-5-1 or shows any change in the swaged end position on the cable.

4-4 TAPES, NETS, SUSPENSION STRAPS, AND BARRIER WEBBINGS

4-4.1 Crop exposed tape between the runway edge sheave (fairlead beam) and the tape connector on the BAK-12 according to the appropriate 35E8-series T.O. Crop the tape between the absorber base and the tape connector according to the appropriate 35E8-series T.O. on expeditionary systems if a tape tube is not used. Perform (end-for-end) on the tapes on all systems according to the appropriate 35E8-series T.O. No nylon tapes should be retained in service longer than T.O. requirements or if usage exceeds the maximum allowable for engagements, pull-outs or tape stack height in the applicable 35E8-series T.O. Due to the negative effects of UV light on nylon, every effort must be made to protect tapes from direct sunlight. For this reason, all spare nylon tapes must be stored indoors with the original protective seal in place.

4-4.2 For MA-1A and BAK-15, a new webbing assembly and suspension straps must be installed after each engagement according to the appropriate 35E8-series T.O. Inspect pendant cables and replace if required.

4-5 PAVEMENTS ADJACENT TO AND BENEATH AAS CABLES

4-5.1 Critical Pavements

The center 23 meters (75 feet) of pavement extending out for 60 meters (200 feet) on both the approach and departure sides of the arresting system pendant are critical areas. Protruding objects, excessive paint build-up, excessive joint sealant material, warped sacrificial panels, and undulating surfaces are detrimental to successful tail-hook engagements and are not allowed. This area of the runway must be visually inspected at least monthly for indications of the above noted conditions. Suspect areas, such as pavement cracks and joints, pavement, and panels beneath the cable must be inspected more closely, and when warranted, checked to ensure the effective pendant height is adequate for successful engagements. Increased attention will be necessary after each freeze-thaw cycle.

4-5.1.1 Problem areas must be immediately identified to the installation pavements engineer for a more thorough inspection and corrective action. The airfield manager must also be notified so that Notice(s) to Airmen (NOTAMs), local NOTAMs, and aircrew briefings can be issued to highlight the potential problem pending corrective action.

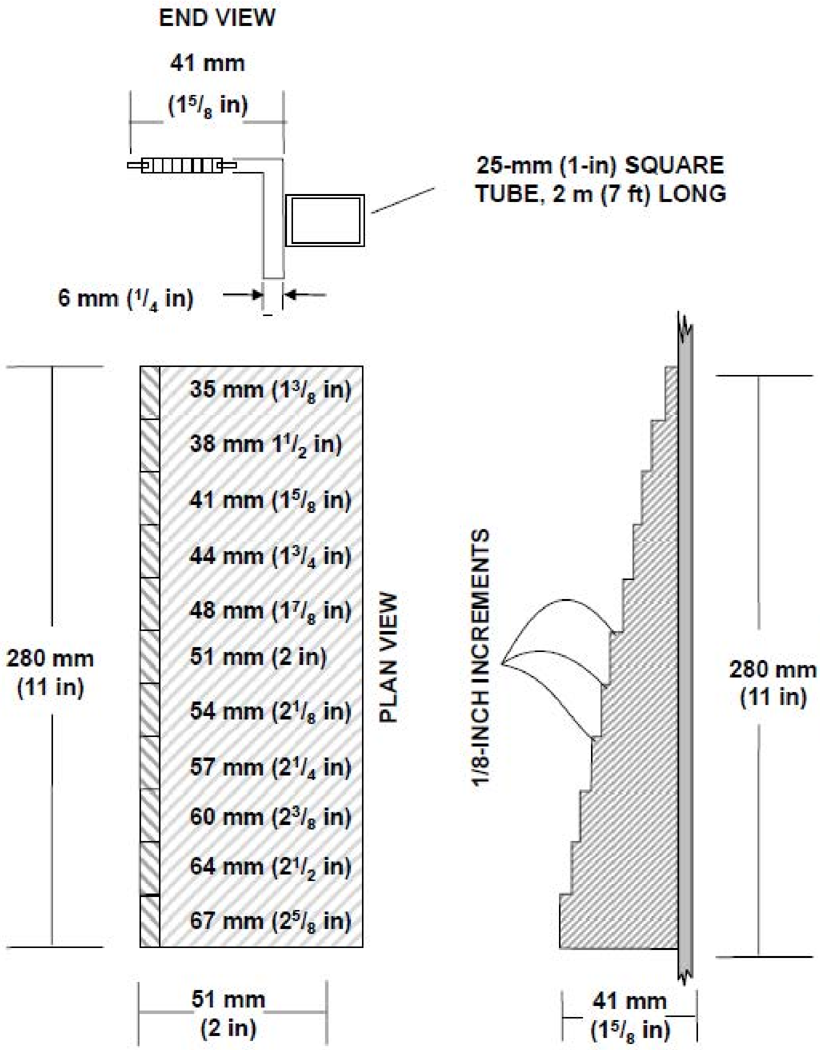
4-5.1.2 Perform more detailed inspections of suspect areas with a 4-meter (12-foot) straightedge. Begin on the runway centerline and check the pavement in the immediate area of the cable for high spots, depressions, or other undulations. Perform the inspection out to a point beyond the first transverse pavement joint on rigid pavements or for approximately 3 meters (10 feet) past the suspect area, or for a minimum longitudinal distance of 6 meters (20 feet), whichever is greater. Repeat this procedure within 1 meter (3 feet) on both sides of the runway centerline, and then at not more than 2-meter (6-foot) intervals across the runway, for a total distance of 11.5 meters (37.5 feet) on either side of the runway centerline. Grind flush any high spots exceeding 3 millimeters (0.125 inch). Report depressions exceeding 3 millimeters (0.125 inch) in depth to the installation pavements engineer for corrective action.

4-5.2 Effective Pendant Height (EPH)

The EPH is the vertical distance (in millimeters or inches) from the underside of the pendant to the pavement surface, or if worn, a projected surface representing the original plane of the runway surface beneath the cable. The EPH for an undamaged or non-grooved runway surface is approximately 60 millimeters (2.38 inches) for a 32-millimeter (1.25-inch) pendant cable. Maintaining this cable height as near to maximum as possible greatly increases the probability the aircraft tail-hook will successfully engage with the arresting system pendant cable. However, as the cable is trampled by aircraft, the rotational oscillations induced by roll-over cause the pavement to wear.

4-5.2.1 Measure the EPH along the center third of the runway width at 3-meter (10-foot) intervals or less using an EPH-measuring tool (see Figure 4-2). Manufacture the tool locally for use by the AAS shop. Perform measurements with AAS cable under tension. Ensure cable tiedowns are not pulling the cable towards the runway surface. Preferably perform measurements in the area between cable support disc.

Figure 4-2 EPH Stepped Feeler Gauge

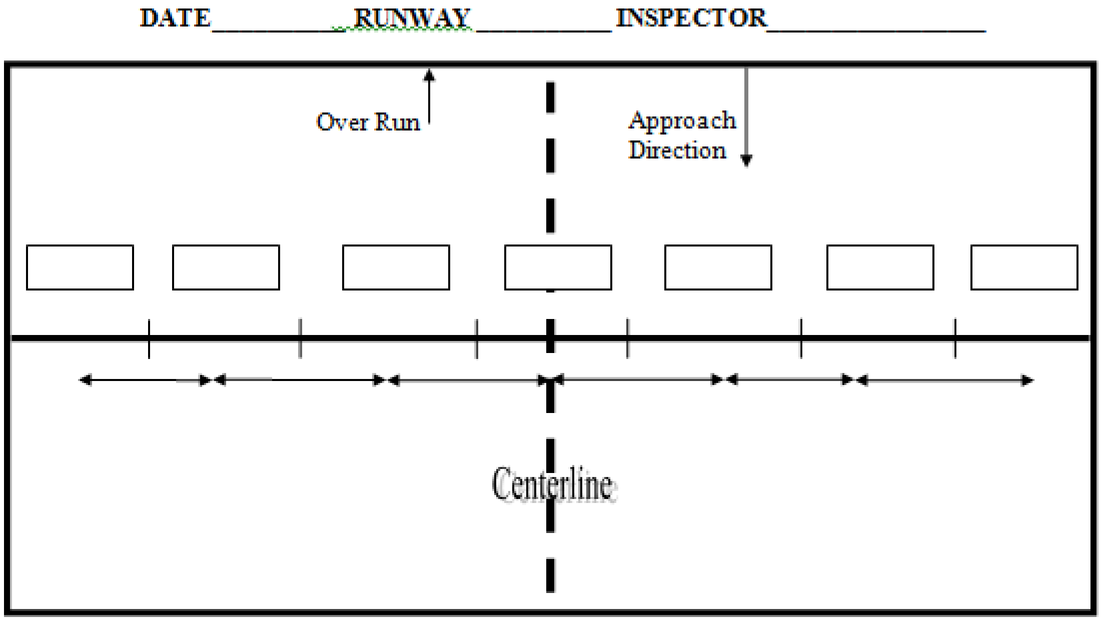


EPH MEASURING TOOL CONSTRUCTED FROM 51-mm (2-in) ANGLE STOCK
(NOT TO SCALE)

4-5.2.2 Start measuring when pavement erosion or grooving is noticed and repeat measurements at least monthly until repaired. As the EPH approaches 38 millimeters (1.5 inches), take and record measurements daily until repaired.

4-5.2.3 Record EPH measurements in the arresting system maintenance log, using a sketch to demonstrate the EPH values and the distance to the location where the measurement was taken (see Figure 4-3). Distance between measurements should not exceed 10 feet. Measurements should be taken in the center most point between cable support disk. Indicate the distance between measurements left and right of the runway centerline. Perform and record measurements while facing the runway approach for documentation consistency.

Figure 4-3 EPH Measurement Log Sample



4-5.2.4 AAS maintenance personnel must notify the local Pavements Engineer, MAJCOM representative and local Airfield Manager when EPH measurements become necessary. Provide status reports of changes to the EPH as they occur. Problem areas must be immediately identified to the installation pavements engineer for a more thorough inspection and corrective action. The Airfield Manager must also be notified so that Notice(s) to Airmen (NOTAMs), local NOTAMs, and aircrew briefings can be issued to highlight the potential problem pending corrective action.

4-5.2.5 Arrange for pavement repairs when any EPH measurement drops to 44 millimeters (1.75 inches) or less. Make the repair before the lowest EPH drops below 38 millimeters (1.5 inches). Perform emergency repairs (permanent or temporary) when any EPH measurement is less than 38 millimeters (1.5 inches).

4-6 ULTRA HIGH MOLECULAR WEIGHT (UHMW) POLYETHYLENE PANEL INSPECTION AND MAINTENANCE

Installations should establish formal procedures to ensure satisfactory performance of UHMW panels. UHMW panels should be inspected daily and monthly for effects of aircraft traffic and thermal movement (expansion/contraction/warping) in accordance with the following.

4-6.1 Daily Inspection. Panel inspection should be added to the daily arresting system inspection checklist for power production personnel. Visually check for panel buckling, warping, and surface variations. If disparity is found, initiate corrective measures.

4-6.2 Weekly Inspection. Check for panel buckling, warping, and surface variations by placing a steel straightedge on top of each panel parallel with the runway centerline at:

- Each joint between panels.
- At least two locations within each panel.
- Any other location that appears raised or irregular.

The straight edge must be long enough to overlap the pavement on each side of the panel by a minimum of 305 millimeters (12 inches). Immediately report raised edges or high spots exceeding 3.2 millimeters (0.125 inch) above the plane of the adjacent runway to the installation Pavements Engineer, local Airfield Manager and to the MAJCOM AAS engineer for further evaluation. Take color photographs to document findings.

4-6.3 Monthly Inspection. The installation pavements engineer should participate once each month in the daily inspections with the AAS personnel. Record all panel conditions, including (but not limited to):

- Erosion affecting a reduction in EPH.
- Distresses in the pavement or panels.
- Warping or edge curling.
- Soundness.
- Delamination.
- Anchor nuts and studs. (Note that anchor stud-nuts may be over-torqued if tightened repeatedly. If any are found loose, use a thread-locking compound such as Loctite® on the threads before tightening, then reseal.)
- Joint Seals.
- Spalling.

Report any deterioration or other problems to the appropriate AFIMSC Detachment for further evaluation.

4-6.4 Joint Maintenance. Joints should be resealed as needed, and just prior to onset of cold weather to prevent moisture accumulation and freezing below the panels. Ice formation beneath panels may cause panel failure, anchor failure, or excessive panel warping.

4-7 CERTIFICATION

4-7.1 All Air Force arresting gear (excluding MA-1A, E-5, BAK-15, textile brake, and soft ground arrestor systems) that have not been engaged at a speed sufficient to exercise the hydraulic system within the past 12 months must be certified by an aircraft engagement. *Refer to* **\1** *AFMAN 32-1040 Civil Engineer Airfield Infrastructure Systems* **/1/**. Report all engagements or missed engagements per **\1** AFMAN 32-1040 **/1/**.

4-7.2 Maintenance and recovery crews will also be evaluated during certification engagements. The following factors will be considered:

- Evaluate crew proficiency in disconnecting the aircraft and returning the AAS to service.
- Evaluate adequacy of maintenance, training records, established Special Levels of replacement parts and supplies, and engagement data.
- Evaluate availability of necessary tools, bench stock, and special equipment.

4-7.3 Responsibility for assuring that certification is accomplished according to this instruction, appropriate 35E8-serise T.O. and **\1** AFMAN 32-1040 *Civil Engineer Airfield Infrastructure Systems* **/1/** rests with the host command. AAS personnel must provide an information copy of each record of certification engagement or certification inspection report to airfield management for their file. Records of certifications will also be maintained in accordance with requirements for Maintenance Records in this FC.

4-8 OPERATION

4-8.1 Refer to **\1** AFMAN 32-1040 *Civil Engineer Airfield Infrastructure Systems* **/1/**, for unidirectional barrier net and pendant cables located in the overruns of the approach end of the runway.

4-8.2 Maintain operational arresting systems like BAK-12 and MAAS in the ready position on the approach and departure ends of the runway and in overruns (but not underruns) unless the installation commander directs otherwise.

4-8.3 AAS, Barriers and interconnected hook cables may be removed from the overrun and runway during snow and ice removal operations. However, coordinate removal with airfield management, then return the AAS, Barriers and interconnected hook cables to operational status as soon as possible.

4-8.4 Hook cable support and retraction systems are not designed to operate in the up position with repeated aircraft rollovers. Repeated high-speed rollovers will damage the system components, reduce system reliability, increase the chance of a missed engagement, and increase maintenance costs.

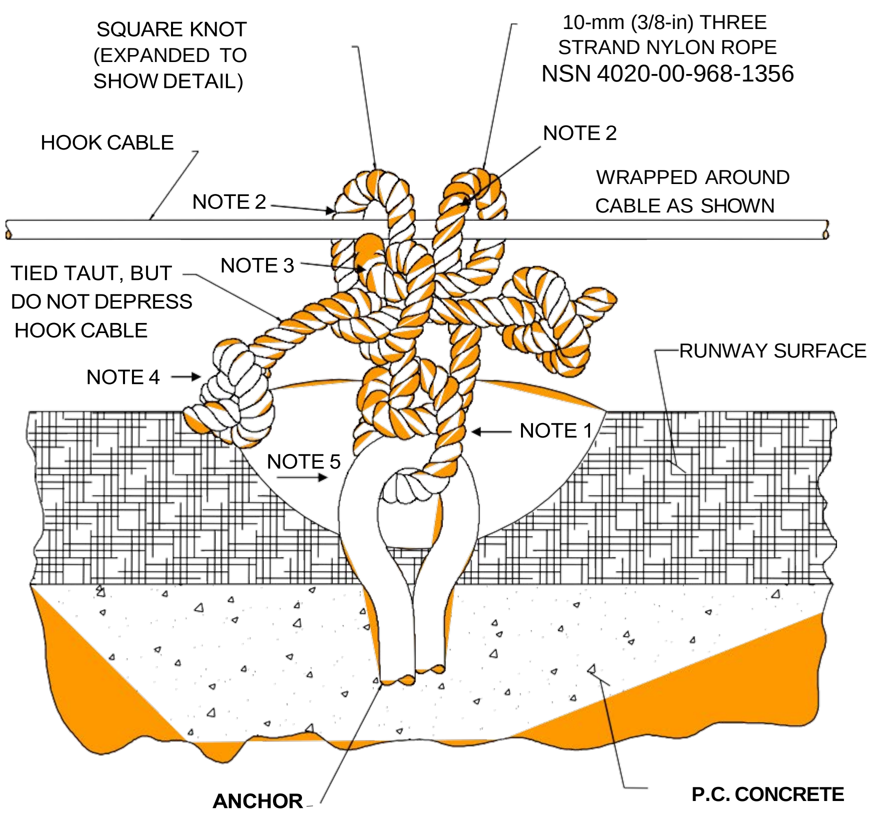
4-8.4.1 Low-speed taxi rollovers must also be kept to a minimum to prevent degradation of system performance.

4-8.4.2 If the AAS is not required to stop the aircraft, air traffic control (ATC) should lower the BAK-14 or Type H cable support system prior to aircraft rollover.

4-8.4.3 Local airfield operating instructions should include provisions for ensuring the BAK-14 or Type-H cable support system is lower prior to the arrival or departure of non-hook equipped or arrestment-capable aircraft

4-8.5 Secure the cable to the cable tiedown anchors with a length of 10-millimeter (0.375-inch) -diameter, three-strand nylon rope (nsn 4020-00-968-1356) approximately 1200 millimeters (48 inches) long (2200 kilograms [5000 pounds] maximum breaking strength). The rope must be fastened to the anchor with a simple overhand knot then tied to the cable with a square knot that is finished on the underside of the cable. Tie a simple overhand knot as close to the square knot as possible with the remaining rope. This will prevent the square knot from becoming loose. See Figure 4-4.

Figure 4-4. Securing Cable with Tiedown Rope



NOTES:
1. **Tie one half of a square knot on the anchor.**
2. **One end of the rope comes over the cable on the long side of the runway. The other end of the rope comes over the cable from the threshold side.**
3. **After the ropes are looped over the cable, tie a square knot underneath the cable.**
4. **Tie knots in ends of rope as close as possible to square knot.**
5. **Orient ring perpendicular to the axis of the cable. Shown parallel for clarity only.**

4-9 RADIO PROCEDURES AND STANDARD PHRASEOLOGY

When performing duties associated with AAS and barriers in the airfield environment, it will be necessary to communicate with ATC, ground control, fire emergency services, and airfield management by two-way radio. Follow local procedures established within the airfield operating instruction (AOI) and the base airfield driving regulations and program. General terms to be used for radio communication are provided in AFI 13-204, Volume 3, *Airfield Operations Procedures and Programs*, AFI 13-213, *Airfield Driving*, and Federal Aviation Administration (FAA) Order JO 7110.65T, *Air Traffic Control, "*Pilot/Controller Glossary." The most common terms for use and their definitions are provided below. Appendix B-2 also provides definitions for the various terms that relate specifically to the airfield and airfield operational areas, including the method used to designate the in-use runway. The phrase "clear" must not be used when communicating with tower personnel.

- "Acknowledge" — Request that you have received and understand the message.
- "Affirmative" — Yes.
- "Negative" — No.
- "Say Again" — Request to repeat the message.
- "Roger" — I have received and understand the last transmission.
- "Hold Short" — Do not proceed per the tower's instructions.
- "Wilco" — I have received and will comply with your message.

4-10 Reporting System Status

Report the status of an AAS or Barrier to the ATC using the terms "operational," "not operational," "in-service," "out of service" or "pendant cable disconnected and off the runway" consistently when reporting status to the airfield authority. These terms are easy-to-understand descriptions of AAS or Barrier status. The specific terms selected for each installation should be specified within the local AOI.

4-11 Reporting System Location

When communicating the location of an AAS on the active runway, use the active runway designation and refer to the system in question by approach, midfield, or departure end AAS, or approach or departure end barrier. In this case, it is important to differentiate between AAS and barriers. BAK-12 and BAK-14 systems are AAS systems, not barriers. Net systems such as MA-1A and BAK-15 systems are barriers. See the definition of terms in Appendix B-2 of this FC. The active runway (the runway in use) is identified by the numeric designation of the approach end of the runway. For example, for Runway 12/30, the active runway would be "Runway 12" when aircraft are taking off from or landing toward the end of Runway 12, or are on a 120-degree compass heading.

4-12 Hand Signals

Standard hand signals for use between AAS crewmembers and aircrew members are provided in AFI 11-218, *Aircraft Operations and Movement on the Ground*. Standard hand signals for use between AAS crewmembers are shown in Figures 4-5 and 4-6. During night operations or restricted visibility, the ground crew will use a pair of same color light wands and done a Type III reflective vest.

4-13 MAINTENANCE DOCUMENTATION AND RECORDS

4-13.1 Document all activities (maintenance and inspections, etc) in a log book as soon as the task has been accomplished. Identify the time and date of the activity, location of the activity, all personnel performing the work and on the work site, as much information as is available for parts and materials used (including part number, manufacturer's name and CAGE Code, serial number (if any), contract number, batch, and date of manufacture) and status of the AAS or barrier.

4-13.1.1 Maintain the log book until all systems referenced are removed or replaced.

4-13.1.2 The AAS supervisor will ensure a record of inspections, repairs, and authorized modifications are kept in a log and that arresting system historical records are maintained in the AAS work center.

4-13.1.3 The AAS supervisor will review and sign the log daily except weekends or holidays. Work accomplished on weekends and holidays will be reviewed and signed off the next duty day

4-13.1.4 The AAS supervisor will perform quality assurance inspections on the installation and maintenance of AAS, historical records and the vehicles and tools used to perform AAS activities. Quality assurance inspections will be documented in the AAS log book.

4-13.1.4 Log books shall be retained and stored for 5 years from the date of the last entry.

4-13.2 Establish a historical maintenance record for each system for the overhaul service life of the system, and document, at a minimum, the following information in the record:

- AAS or Barrier type, date installed, location on airfield, and serial numbers (number of system engagements on BAK-12, and MAAS).

- Last overhaul date (including fairlead beams or edge sheaves).
- Last non-destructive inspection (NDI) date with results.
- Daily inspections.
- Weekly inspections.
- Monthly inspections.
- Quarterly inspections
- Semi-annual inspections
- Annual inspections
- Multi-year inspections
- Purchase Tape data (date installed, contract number, manufacturer, usage data for each tape and serial number of the AAS the purchase tape installed).
- Cable replacement data (date installed, manufacturers' identification code, serial number, and contract number).
- System certification and certification inspection records/reports. (Submit all engagement reports per **\1** AFMAN 32-1040 *Civil Engineer Airfield Infrastructure Systems* **/1/**
- Aircraft engagement reports.
- Replacement parts and/or materials (including part number, manufacturer's name and CAGE Code, serial number (if any), contract number, batch, and date of manufacture)

4-13.3 Historical records must be kept with the system for the life of the equipment to ensure they are returned to the overhaul facility when the system is changed out. This includes War Reserve Materiel (WRM) systems in storage, as well as systems designated for training use only, as applicable. Provide a copy of maintenance records to the overhaul facility or WRM location when the system removed.

The AAS supervisor will review and sign each historical record entry to verify accuracy of the entry. Work accomplished on weekends and holidays will be reviewed and signed off the next duty day

4-13.4 The AAS supervisor shall establish and maintain an AAS status board in the AAS work center that indicates at a minimum for all installed and stored AAS and/or barriers:

- Current status each AAS and/or barrier
- Current pendant or net system configuration
- Due dates for maintenance activities
- Current tape count, pendant count, and system count
- Date of installation for tapes, pendants and textile systems and nets
- Last engagement date

4-14 DEFICIENCY REPORTING

Report all deficiencies discovered with AAS and components to base supply according to T.O. 00-35D-54, USAF Material Deficiency Reporting, Investigation, and Resolution.

CHAPTER 5 SYSTEMS USED ON USAF INSTALLATIONS

5-1 DESCRIPTION

Aircraft arresting systems consist of engaging devices and energy absorbers. Engaging devices are net barriers such as MA-1A and BAK-15, disc-supported pendants (hook cables), and cable support systems such as BAK-14 and the Type H that raise the pendant to the battery position or retract it below the runway surface. Energy-absorbing devices are ships' anchor chains, rotary friction brakes (such as the BAK-12), tearing strap modules such as textile brake systems, and soft ground systems such as the Engineered Material Arresting System (EMAS). Tables 5-1 and 5-2 below show the leading particulars for Air Force energy-absorbing systems**.**

Table 5-1 USAF Aircraft Arresting System Energy Absorber Leading Particulars (Except Textile Brake)*

System Type	BAK-12 66-Inch Reel	Dual BAK-12 66-Inch Reel	MAAS 990-Foot Runout	MAAS 1200-Foot Runout***
Nominal Aircraft Weight (lb)	50,000	100,000	40,000	68,400
Energy Capacity (ft-lb)	85×10^6	170×10^6	40×10^6	98×10^6
Nominal Runout (ft)	1,200	1,200	990	1200
Tape Strength (lb)	105,000	105,000	105,000	105,000
Cable Strength (lb)	130,000	130,000	130,000	130,000
Maximum Speed (kn)**	180	180	150	180

* The operating characteristics given in this table are described in inch-pound units as reported by the original equipment manufacturers.

****** 190 knots is the dynamic limit for steel cables used in AAS. Random failures will occur at 190 knots and above; therefore, 180 knots is established as the working limit for cable-engagement systems.

******* MAAS configured for 1200-foot runout in the 31-stake, PCC, or set-back anchoring schemes having the same technical characteristics as a 66-inch BAK-12.

Table 5-2 USAF Textile Brake Aircraft Arresting System Leading Particulars*

System Type	MB 60.9.9.C	MB 100.10C
Cable diameter/strength	1.25 inches/130,000 lb	1.25 inches/130,000 lb
Stage 1 runout (length of available braking force)	551 feet	N/A
Energy capacity stage 1 (ft-lb)	26×10^6	N/A
Total system energy capacity (ft-lb)	52×10^6	44×10^6
System runout (total length of available braking force)	1000 feet	889 feet

Energy capacity calculated at 160 knots.

Note: Twelve percent increase in energy capacity when using a net.

* The operating characteristics given in this table are described in inch-pound units as reported by the original equipment manufacturers.

5-2 CHAIN ABSORBER ARRESTING GEAR (CHAG) SYSTEMS

5-2.1 MA-1A

The MA-1A emergency arresting system consists of a net barrier and cable system designed to engage the main landing gear of an aircraft (Figure 5-1). Because it is a unidirectional system, it must always be installed in the overrun area. Aircraft engaging this system above the speed and weight limits provided in Figure 5-3 (or Chart 1-1 of T.O. 35E8-2-2-1) will result in a runout greater than 305 meters (1000 feet) or cable failure. Most MA-1A systems employ ships' anchor chains as the energy absorber. These systems require a runout area of at least 259 meters (850 feet) plus the length of the aircraft. The chains lie on either side of the runway overrun, beginning at the barrier location and running in the direction of aircraft travel; however, some MA-1A systems use a BAK-9 instead of a ship's anchor chain as the energy absorber. These systems require a runout area of at least 290 meters (950 feet) plus the length of the aircraft. This configuration is an MA-1A/BAK-9.

5-2.2 MA-1A Modified

The MA-1A may also be complemented with a hook-cable interconnect to accommodate hook engagement. This arrangement is shown in Figure 5-2. The MA-1A is not currently in production as a system. Do not consider it for new installations unless you can salvage the necessary equipment from another facility. Obtain further technical information on this system from T.O. 35E8-2-2-1.

Figure 5-1 MA-1A Barrier

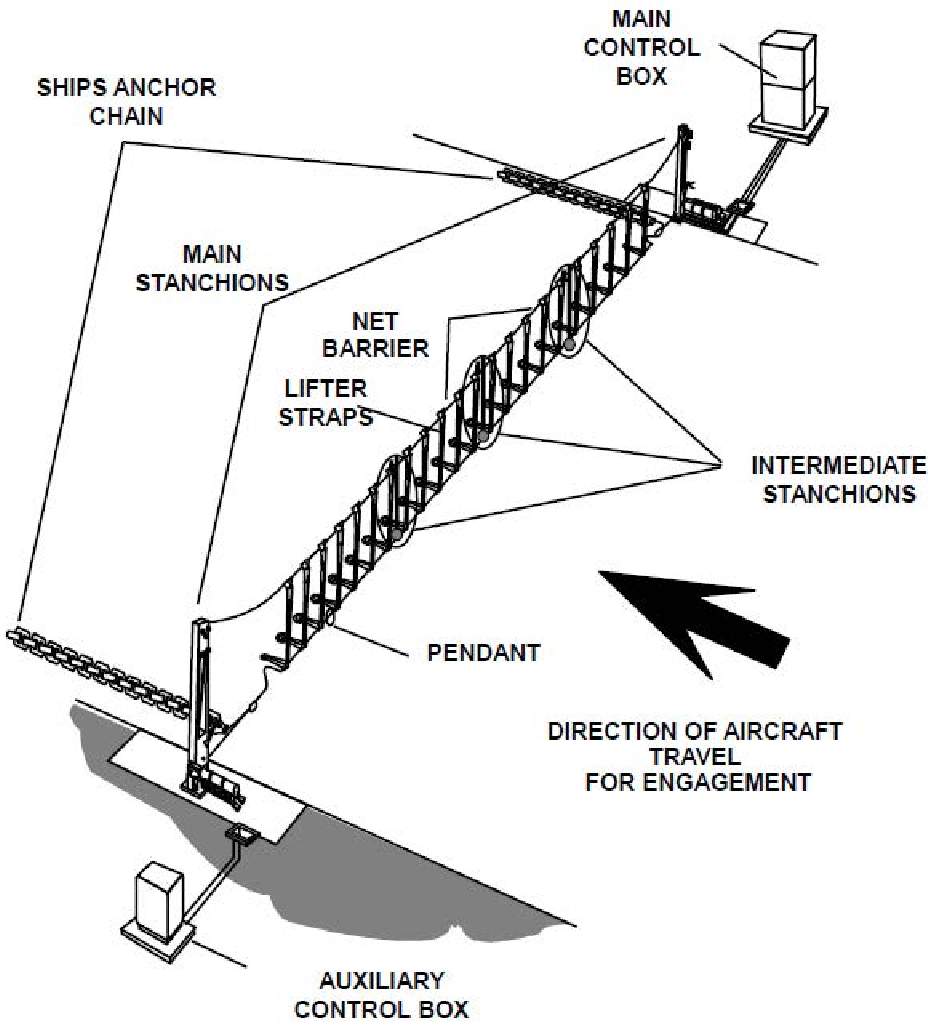

Figure 5-2 MA-1A Modified Barrier With Hook Cable Interconnect

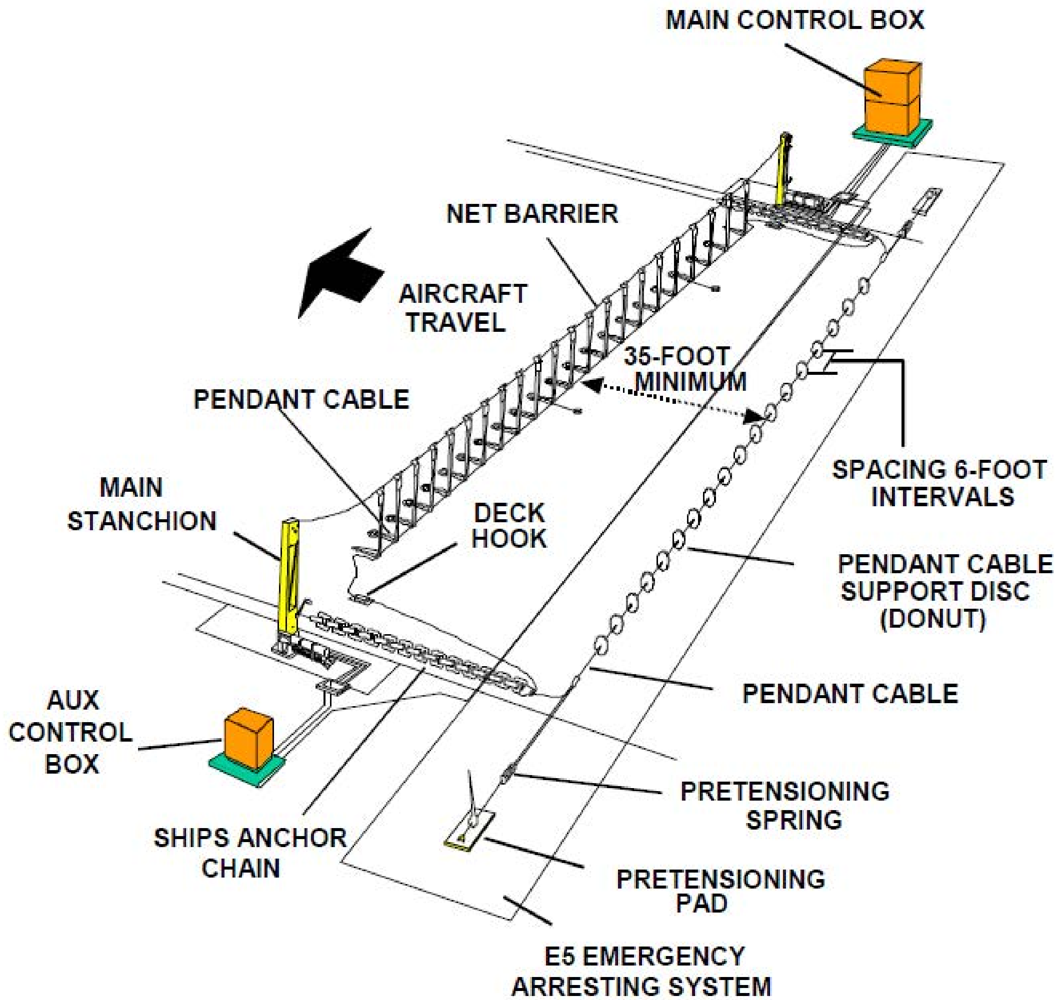

Figure 5-3 Speed and Weight Chart for Chain Gear

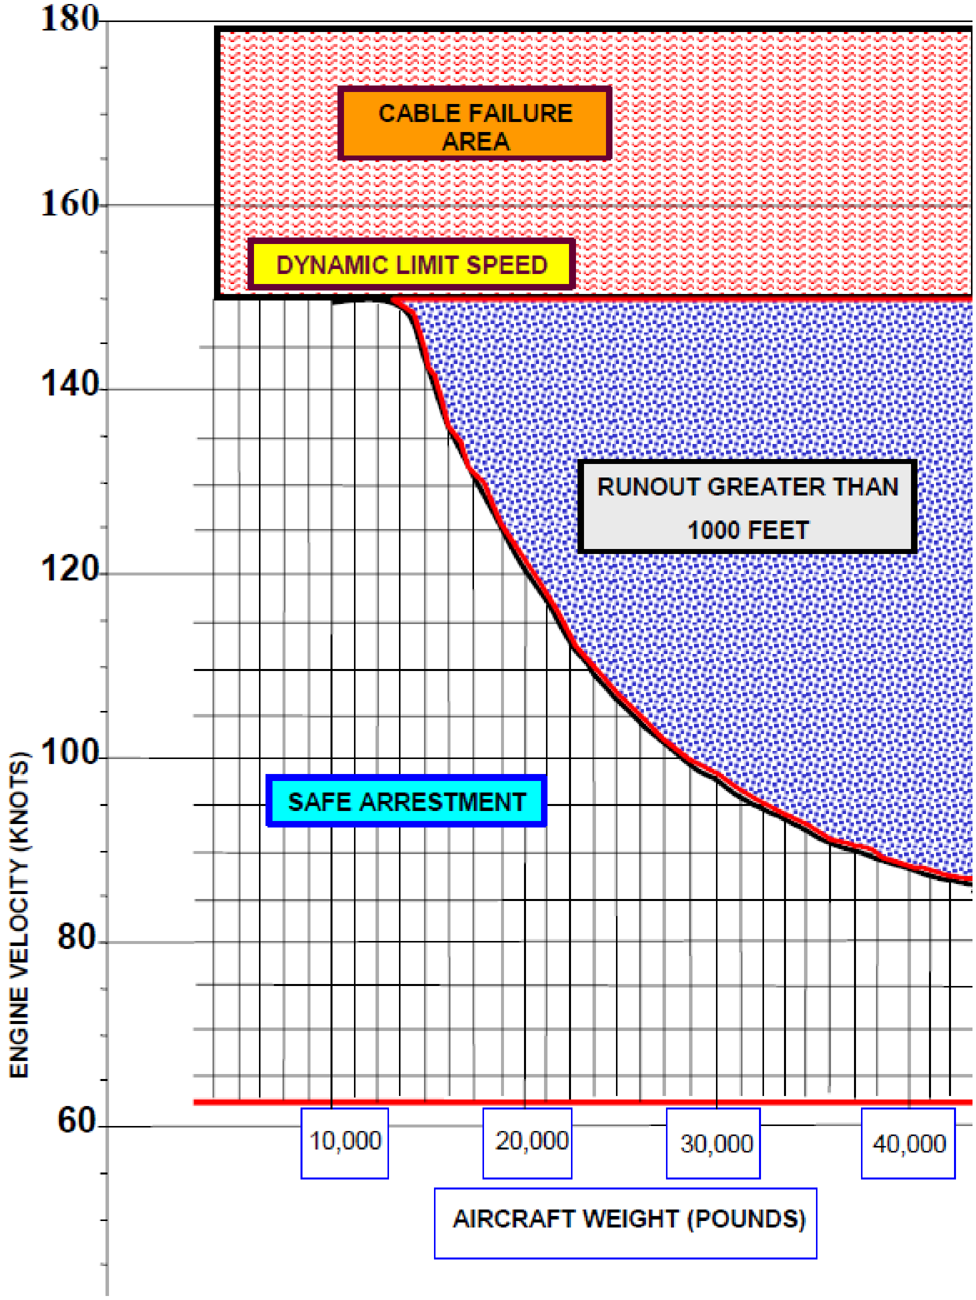
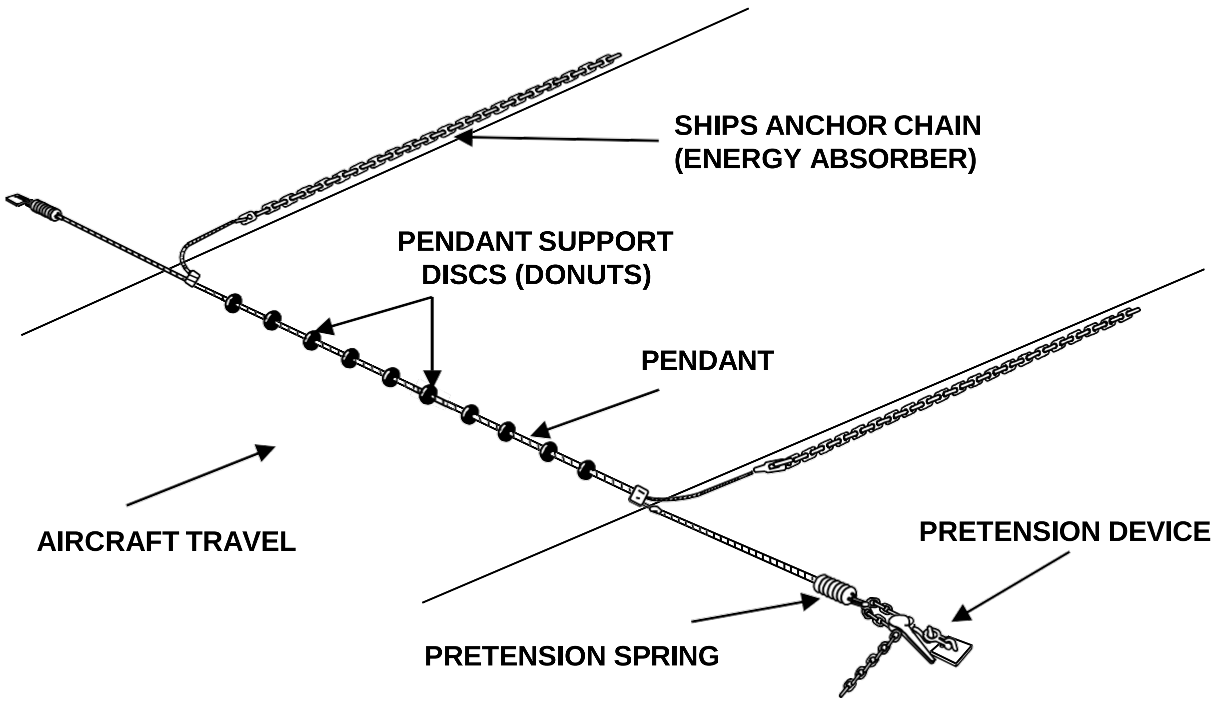


5-3 E-5

This unidirectional emergency arresting system is a U.S. Navy design and designation. Much like the MA-1A, this system uses several shots of ship's anchor chain as the energy absorber but these systems are never connected with a barrier (net). For the Navy or Marine Corps, these systems can have from one to four disc-supported hook cables, with designations of E-5 and E-5 Mod 1 through E-5 Mod 3. Obtain further technical information on the Navy configuration of this system from the Naval Air Warfare Center, Lakehurst, New Jersey. For the Air Force, these systems use only one pendant and are sited and maintained as described in the MA-1A T.O. (TO 35E8-2-2-1). They are designated as an E-5 (Figure 5-4).

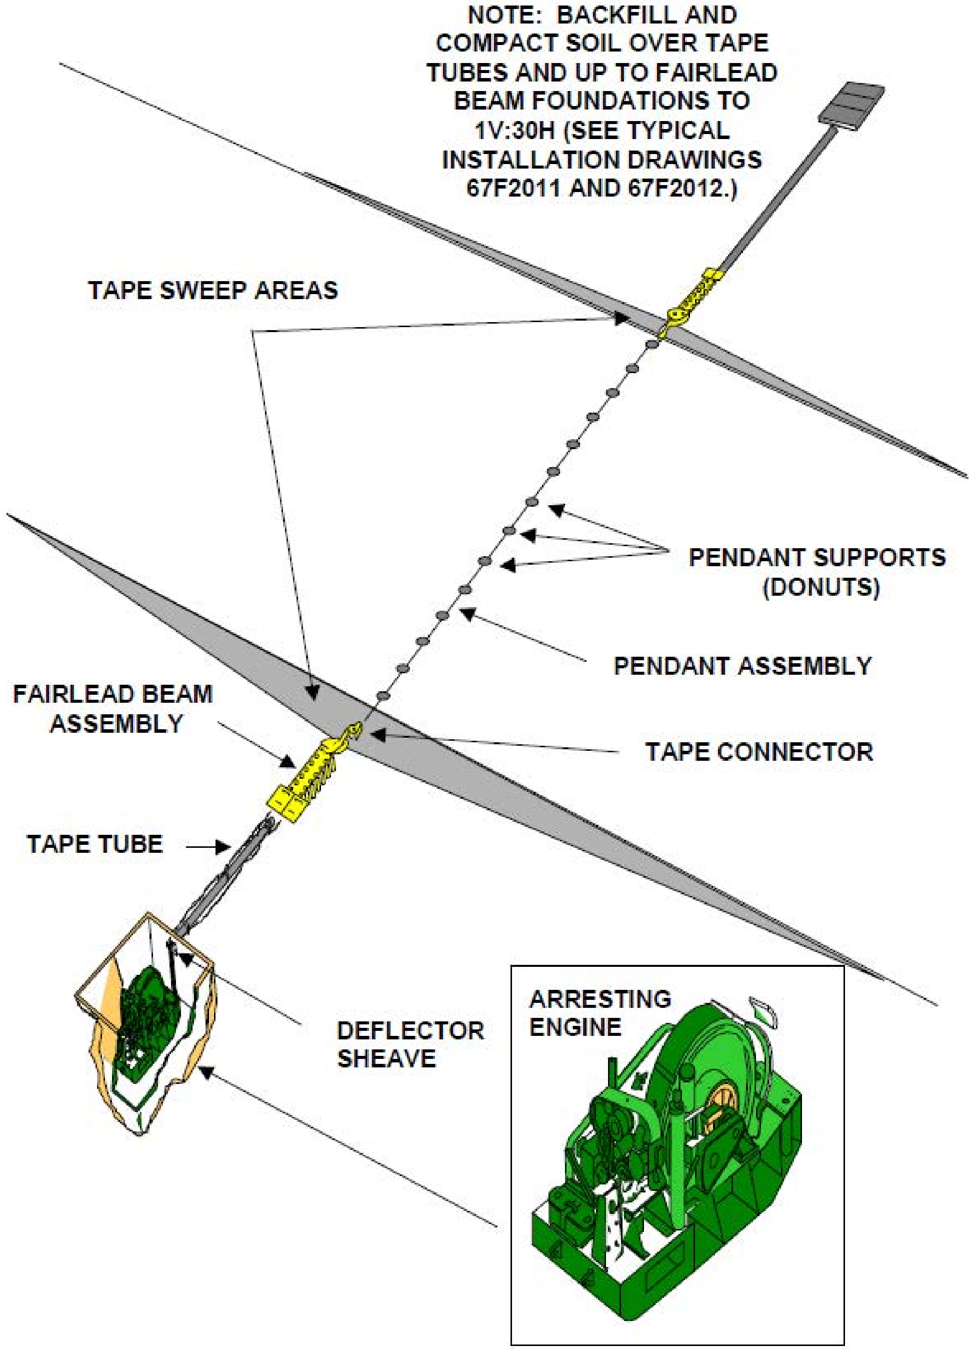
Figure 5-4 E-5 Hook Cable CHAG



5-5 BAK-12 Rotary Friction Brake Absorber

5-5.1 The BAK-12 (Figure 5-5) is the standard Air Force operational AAS. This bi-directional system employs two energy absorbers. Each absorber consists of two multi-disc rotary friction brakes mounted on either side of the purchase-tape reel on a common shaft. The energy absorbers are located on opposite sides of the runway or overrun, connected to a 32-millimeter (1.25-inch) disc-supported pendant by the purchase tapes. Ideally, the energy absorbers should be in a below-grade pit with a minimum split distance of 15.24 meters (50 feet). (Split distance is a measurement taken between the lead-on sheave of the fairlead beam or edge sheave, and the energy absorber.) Split distances of up to 91 meters (300 feet) are acceptable for all BAK-12 installations. You may also install BAK-12 systems above grade in one of two configure-tions, the selection depending upon site conditions and operational requirements. These are the expeditionary installation for periods of up to one year, and the semi-permanent installation, well-suited for long-term use and typically selected when site conditions will not allow a pit-type installation. Siting and grading requirements are in Section 3 of T.O. 35E8-2-5-1. *Typical Installation Drawings for pit-type installations (drawing number 67F2012A*) and permanent surface type installations (drawing number 67F2011A) are available from AFCEC/COS and the AFLCMC.

Figure 5-5 BAK-12 Aircraft Arresting System



5-5.2 Originally, BAK-12 energy absorbers were fitted with a 60-inch purchase-tape storage reel. This design allowed the maximum energy expected to be imparted during an aircraft engagement to dissipate within a runout of 290 meters (950 feet) plus the length of the aircraft. Designers have since improved the BAK-12 to meet increased demands of heavier and faster aircraft. The energy absorbers have been retrofitted with larger 66-inch or 72-inch tape storage reels to accommodate increased runout, thus increasing the total energy capacity of the system. These systems require 366 meters (1200 feet) plus the length of the aircraft for maximum runout. The 72-inch reel systems are special-purpose systems configured for 610 meters (2000 feet) of runout.

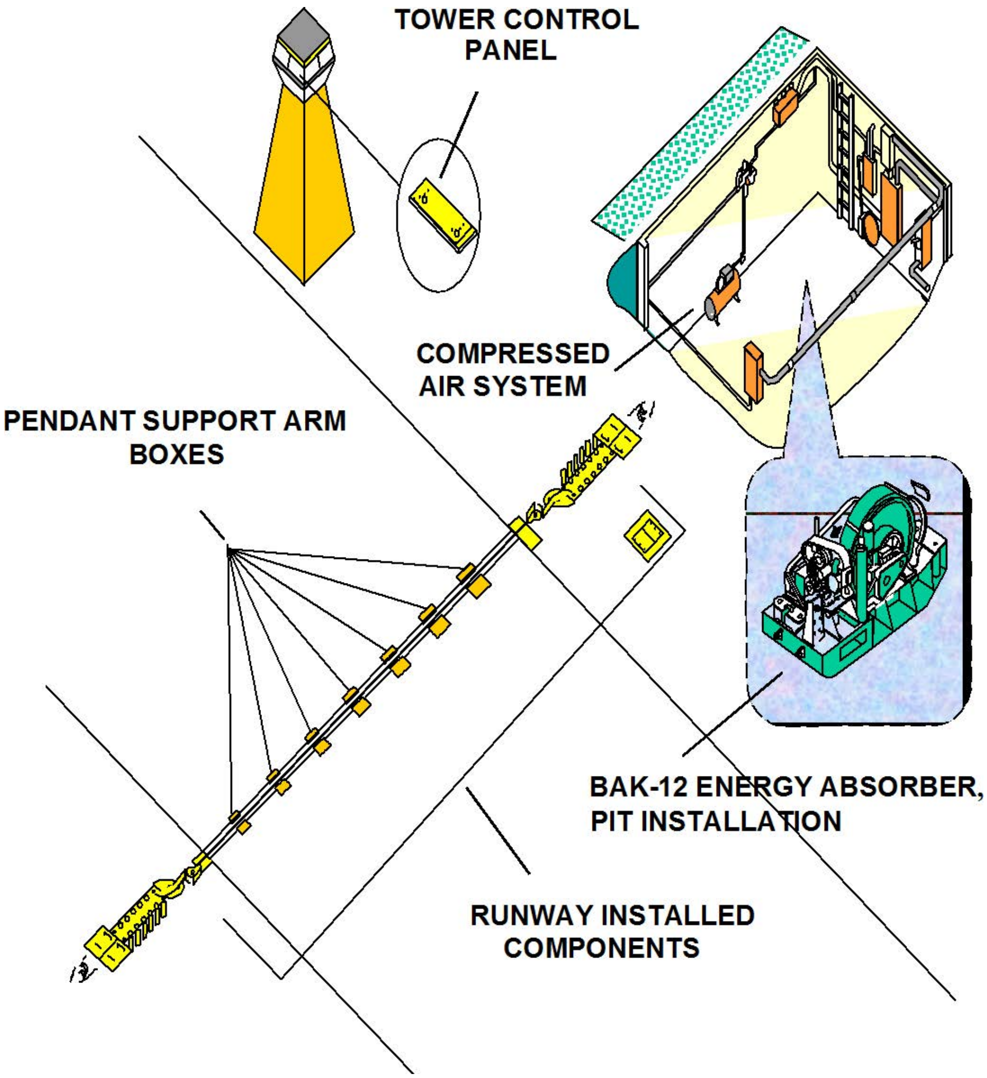
5-5.3 The standard BAK-12 is configured for cross-runway separations of up to 61 meters (200 feet) (distance between fairlead beams or edge sheaves). For installations with cross-runway spans exceeding 61 meters (200 feet), replace the BAK-12 control valve cam to accommodate full runout of the system. Refer to T.O. 35E8-2-5-1 to identify the part number for the correct replacement cam and installation procedures. Also select a pendant length of at least 80 percent of the distance between the fairlead beams to avoid adverse cable dynamics. Selected cable length should be at least 2 meters (6 feet) less than the total span between runway edge sheaves. This will allow sufficient exposed tape on each side of the runway (at least 0.6 meter [2 feet]), as well as an offset between the runway centerline and the center point of the cable, to further reduce cable dynamics by disrupting parity in the kink wave caused by the engagement.

5-5.4 Dual BAK-12 systems are special-purpose installations configured to accommodate high-energy engagements of aircraft ranging from 27,200 to 63,500 kilograms (60,000 to 140,000 pounds). These configurations consist of four BAK-12 energy absorbers arranged in pairs on either side of the runway. The energy absorbers may be standard BAK-12s, or be equipped with 72-inch-diameter tape storage reels to accommodate 610 meters (2000 feet) of runout. Special tape connectors and edge sheaves are needed for these installations. For details of these components and other special considerations, see Section VIII of T.O. 35E8-2-5-1.

5-6 BAK-14 AND TYPE H HOOK CABLE SUPPORT SYSTEMS

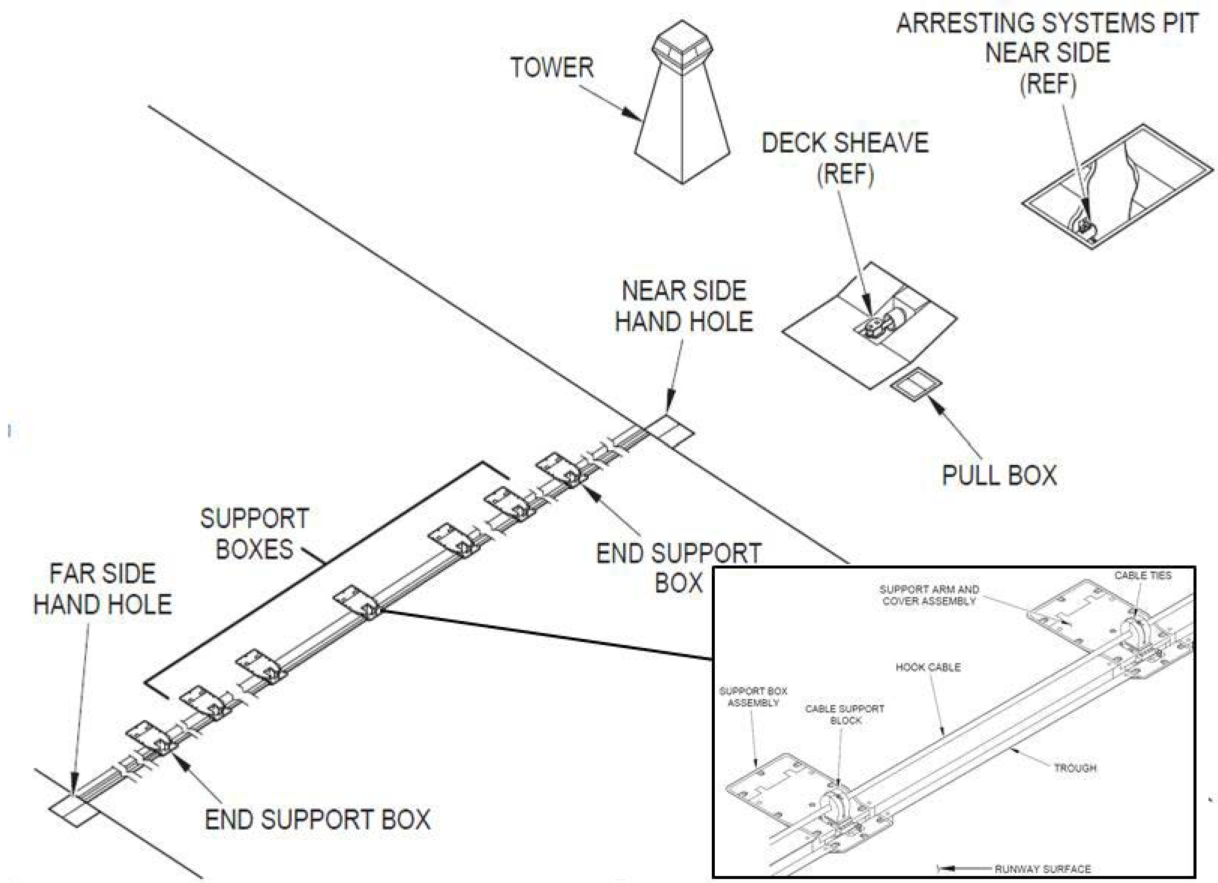
5-6.1 The BAK-14 hook cable support system (Figure 5-6) is a bidirectional hook cable (pendant) support system used in conjunction with the BAK-12, or a comparable pair of arresting system absorbers to engage and safely stop a hook-equipped aircraft. It provides the means to support the pendant at least 51 millimeters (2 inches) above the runway surface while giving Air Traffic Control the means to lower the pendant below the surface of the runway to prevent damage to low-undercarriage aircraft, the pendant, and the pavement below the pendant during trampling. These systems can accommodate 45-, 60-, and 90-meter (150-, 200-, and 300-foot) -wide runways, and can be ordered to suit the specific application. The control side BAK-12 pit or protective shelter and foundation must be enlarged to house the compressed air and control systems needed to operate these supplemental systems. The site and utility considerations for installation are in T.O. 35E8-2-8-1, *Operation, Maintenance, and Installation Instructions with Illustrated Parts Breakdown, Hook Cable Support System, Model BAK-14*.

Figure 5-6. BAK-14 Cable Support and Retraction System



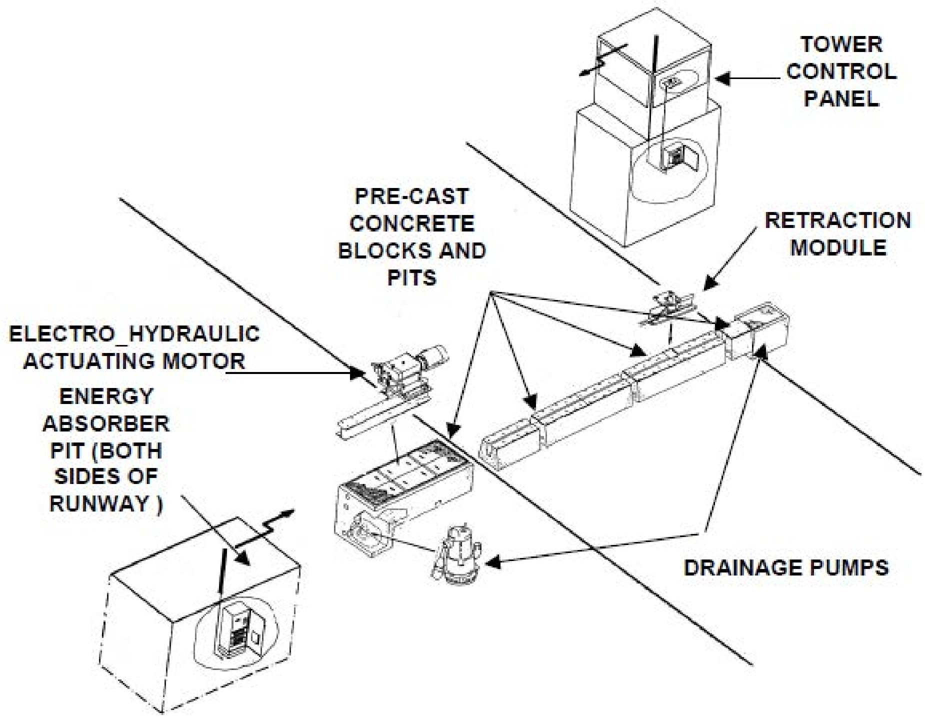
5-6.2 The BAK-14 Modified or BAK-14M (Figure 5-7) is a bidirectional hook cable (pendant) support system used in conjunction with the BAK-12, or a comparable pair of arresting system absorbers to engage and safely stop a hook-equipped aircraft. The system consists of either 14 or 20 support blocks which support the hook cable 3 inches (nominal) (two inches minimum) above the surface of the runway while giving Air Traffic Control the means to lower the pendant below the surface of the runway to prevent damage to low-undercarriage aircraft, the pendant, and the pavement below the pendant during trampling. The system can accommodate 45-, 60-, and 90-meter (150-, 200-, and 300-foot) -wide runways. The BAK-14M contains modified support box covers that provide easier maintenance access and rapid support box replacement. The site and utility considerations for installation are in T.O. 35E8-2-8-1-11, *Operations Manual for the BAK-14 Hook Cable Support Systems (Pit Mounted with Heaters)14 and 20 Box Systems.*

Figure 5-7. BAK-14M Cable Support and Retraction System



5-6.3 The Type H hook cable support system (Figure 5-8) is a bi-directional hook cable support system that can be used in conjunction with any type of energy- absorbing device. It provides a means to raise a cable at least 51 millimeters (2 inches) above a runway surface or lower it below the runway surface in less than 1.5 seconds. It can be supplied to accommodate runway widths of 46, 60, and 90 meters (150, 200, and 300 feet). A radio remote-control system provides Air Traffic Control the means to operate the system and to monitor its operational status. It typically consists of 14 to 18 (depending on runway width) retraction modules installed into pre-cast concrete blocks across the runway and connected together by metallic rods to form a rigid loop. This loop is actuated by an electro-hydraulic motor located in a concrete pit on one side of the runway. Detailed information (i.e., description, operation, maintenance, illustrated parts list), are provided in T.O. 35E8-2-8-12, *Type H45-200 Aircraft Arresting Cable Retraction System Abbreviated Component Maintenance Manual With Illustrated Parts List* and Aerazur Technical Manual 256-722, *Type H45-200* Component Maintenance Manual With Illustrated Parts List. Installation drawings are available from the manufacturer. It should be noted, three-phase power is needed at the Type H installation site to power the hydraulic pump actuator.

Figure 5-8. Type H Hook Cable Support System



5-7 BAK-15 (61QSII)

5-7.1 The BAK-15 aircraft arresting barrier consists of a pair of electro-hydraulically powered steel masts that provide support and remote-controlled movement for a unidirectional nylon net barrier (Figure 5-9). The masts are installed on opposite sides of the runway overrun on concrete foundations. The ATC tower contains a remote-control panel which can be hard-wired, but most commonly is radio-controlled.

5-7.2 The barrier must be augmented with an energy-absorbing device such as a ship's anchor chain, BAK-12, or textile brake. During an aircraft engagement, shear links in the net suspension straps separate by the force of the aircraft engaging the net. The net then envelops the aircraft and seats on the leading edge of the wings, transferring the forward momentum of the aircraft to the energy-absorbing device.

5-7.3 The system can be complemented with a standard disc-supported pendant to accommodate tail-hook engagements through interconnect configuration hardware similar to that used for the MA-1A Modified. The hook cable interconnect kit is designated as the 62 NI (net interconnect). System operation and maintenance instructions are in T.O. 35E8-2-12-1, *Operation And Maintenance Instructions BAK-15 Aircraft Arresting Systems.* Obtain installation drawings from the manufacturer through the procuring activity at the time of procurement.

5-8 MOBILE AIRCRAFT ARRESTING SYSTEM (MAAS) CONFIGURATION

5.8.1 The MAAS (Figure 5-10) is essentially a BAK-12 AAS mobilized through installation on a specially developed trailer. It is configured for a maximum aircraft runout of 302 meters (990 feet). This system was initially developed and tested to accommodate recovery of fighter aircraft returning to a battle-damaged airfield. Such cases require rapid deployment and installation and may require that only the minimum essential anchoring hardware be installed to accommodate this scenario. When installed for this purpose, the MAAS is installed along the shoulder of the runway this configuration can be either unidirectional or bi-directional (upgrade kit required) engagement capability with a maximum aircraft weight and speed of 18,144 kilograms (40,000 pounds) at 150 knots

(Table 1-1). Installing the MAAS without a set-back configuration limits the system weight capabilities and the type of aircraft capable of operating on the airfield. For detailed instructions on this system, refer to T.O. 35E8-2-10-1, *Operation and Maintenance Instructions, Arresting Systems, Aircraft, Mobile*.

5.8.2 When the MAAS is installed in the set-back configuration it presents a significantly reduced profile on the runway edge allowing the airfield to accommodate wide body aircraft. The MAAS set-back configuration is accomplished with Mobile Runway Edge Sheave (MRES) (Figure 5-11) or Lightweight Fairlead Beam (LWFB) (Figure 5-12) and postures the MAAS in a bi-directional engagement capability for a maximum aircraft runout of 366 meters (1200 feet). The engagement capability in the set-back configuration is a maximum aircraft weight and speed of 31026 kilograms (68,400 pounds) at 180 knots. For detailed instructions on this system, refer to T.O. 35E8-2-10-1, *Operation and Maintenance Instructions, Arresting Systems, Aircraft, Mobile*.

5.8.3 The MAAS can be installed over soil, concrete, asphalt, and asphalt over soil or concrete. The MRES and LWFB can only be installed over soil and concrete. Careful planning should take place to fully understand the obstacles of the proposed installation site. The California Bearing Ratio (CBR) will be a determining factor when a MAAS is planned to be installed over soil. Expeditionary soil installation should not be used if the anticipated period of service is longer than one year. Waivers to extend use longer than one year are processed through AFLCMC. The preferred method of installation for an anticipated period extending beyond one year is concrete pads for the MAAS and MRES or LWFB. Contact AFCEC/COS for drawings.

Figure 5-10 Mobile Aircraft Arresting System (MAAS)

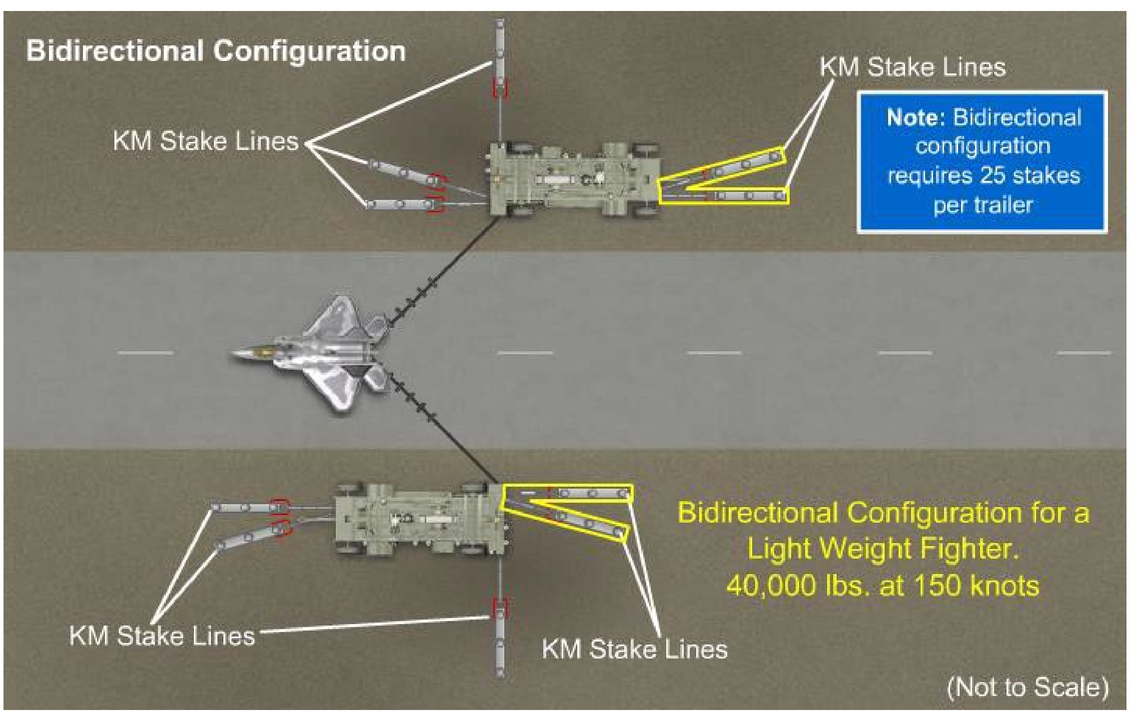

Figure 5-11 Mobile Aircraft Arresting System (MAAS) in Set-Back Configuration with Mobile Runway Edge Sheave (MRES)

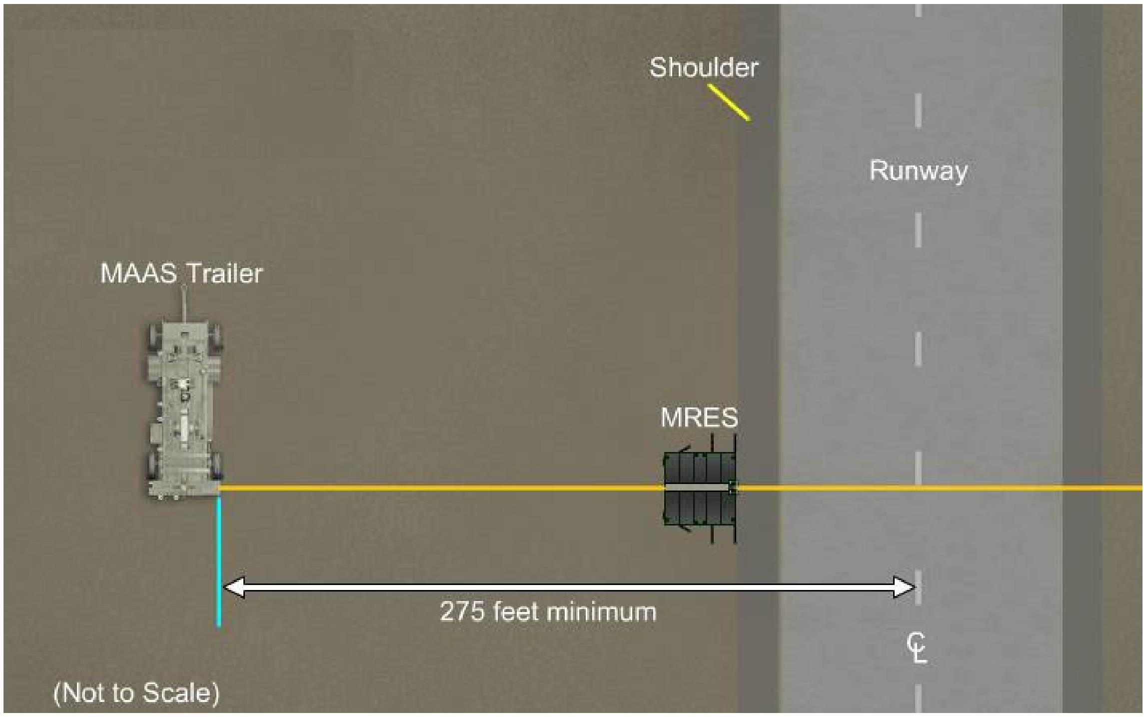

Figure 5-12 Mobile Aircraft Arresting System (MAAS) in Set-Back Configuration with Lightweight Fairlead Beam (LWFB)

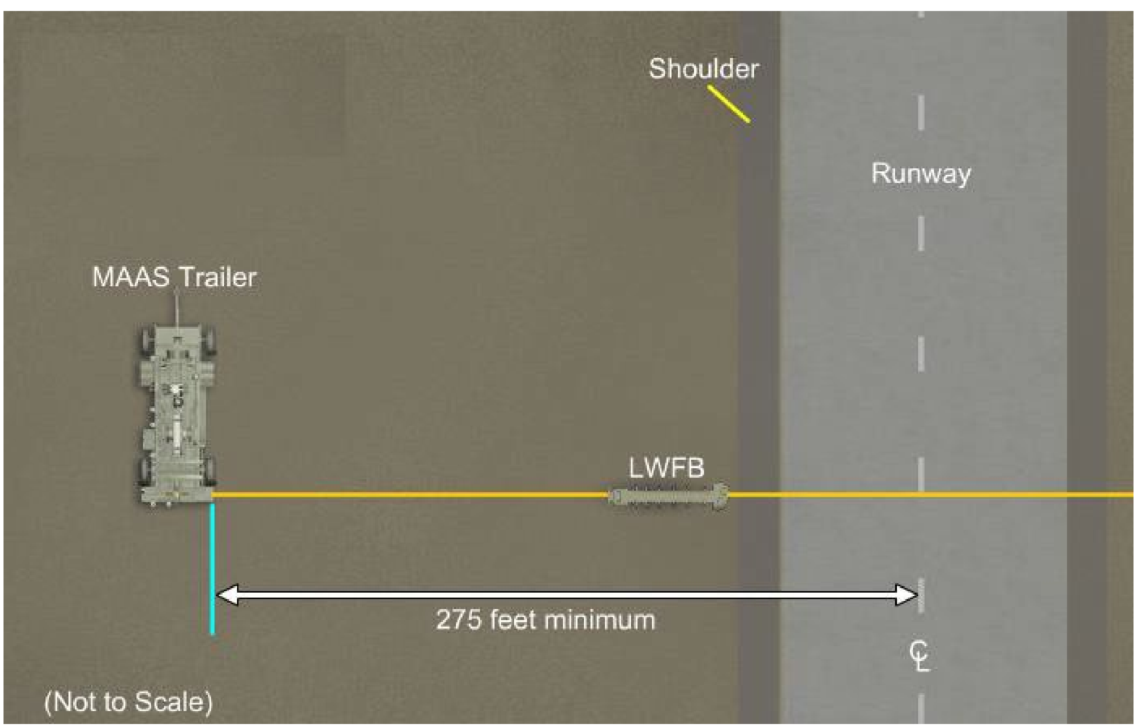

5-9 TEXTILE BRAKE

5-9.1 This modular arresting system is primarily intended as an emergency back-up system for standard operational systems. It is composed of multiple modules arranged in equal numbers on both sides of the overrun (or runway if a bidirectional model) that contain specially woven textile tearing straps to absorb the kinetic energy generated during an engagement. One end of each module is anchored to the ground, and the other end is connected to a tensioned cable or barrier positioned across the runway to engage an aircraft. The system is available in a two-stage unidirectional configuration (Figure 5-13) see Table 5-2 and T.O. 35E8-2-13-1, *Operation, Service, Overhaul with Illustrated Parts Breakdown Textile Brake and Hook Cable Aircraft Arresting System, Type MB 60.9.9.C*, . For information on the single-stage bi-directional system (Figure 5-14) MB 100.10.C, see Table 5-2 and T.O. 35E8-2-14-1, *Operation and Service, Overhaul Instructions, Illustrated Parts Breakdown for Textile Brake and Hook Cable Aircraft Arresting System, Type MB 100.10.C*.

5-9.2 The advantages of the two-stage system (MB 60.9.9.C) over the MB 100.10.C bi-directional system are higher system capacity and lower costs for reconfiguration after low-energy engagements. The modules in a stage (breaking line) are expended upon aircraft engagement and must be replaced; however, a life cycle analysis indicates system costs are approximately 50 percent of the life cycle cost for a BAK-12 installed in the overrun area of a runway due to the low number of engagements that occur there. These systems are designed for tail-hook-equipped fighter aircraft but can also be complemented with a net barrier such as the BAK-15 or a net and cable interconnect system. They may also be configured for expeditionary or temporary installations.

5-9.3 If the bi-directional version of the textile brake arresting system is installed on the operational runway surface due to a non-standard length overrun, the arresting gear marker (AGM) signs should be blanked when viewed from the approach. This is because the system is a low-energy-capacity system (compared with BAK-12) and is not intended for approach end engagements.

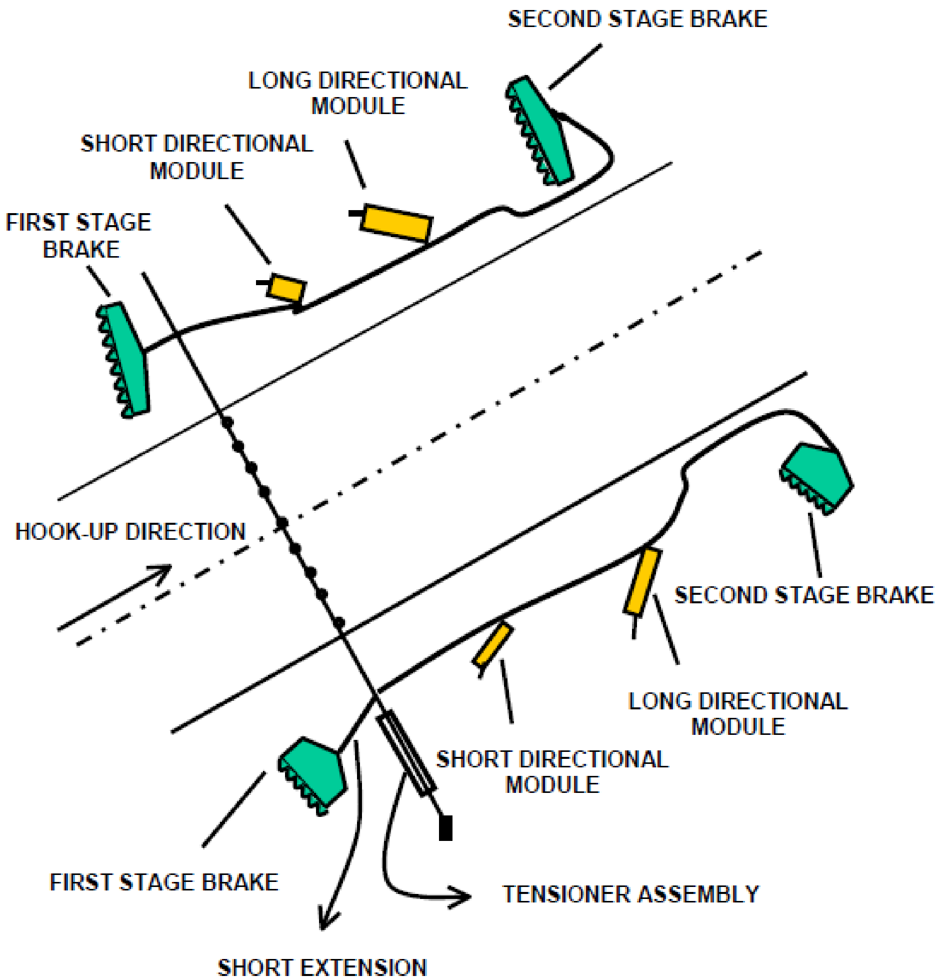

Figure 5-14 Textile Brake, Model MB.100.10.C

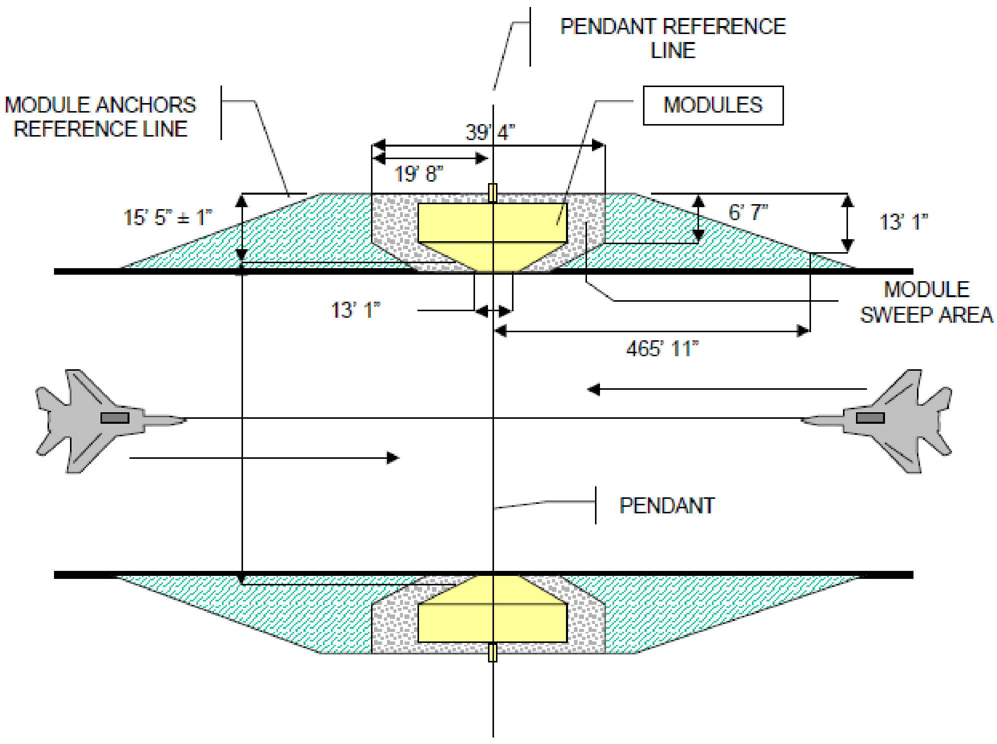
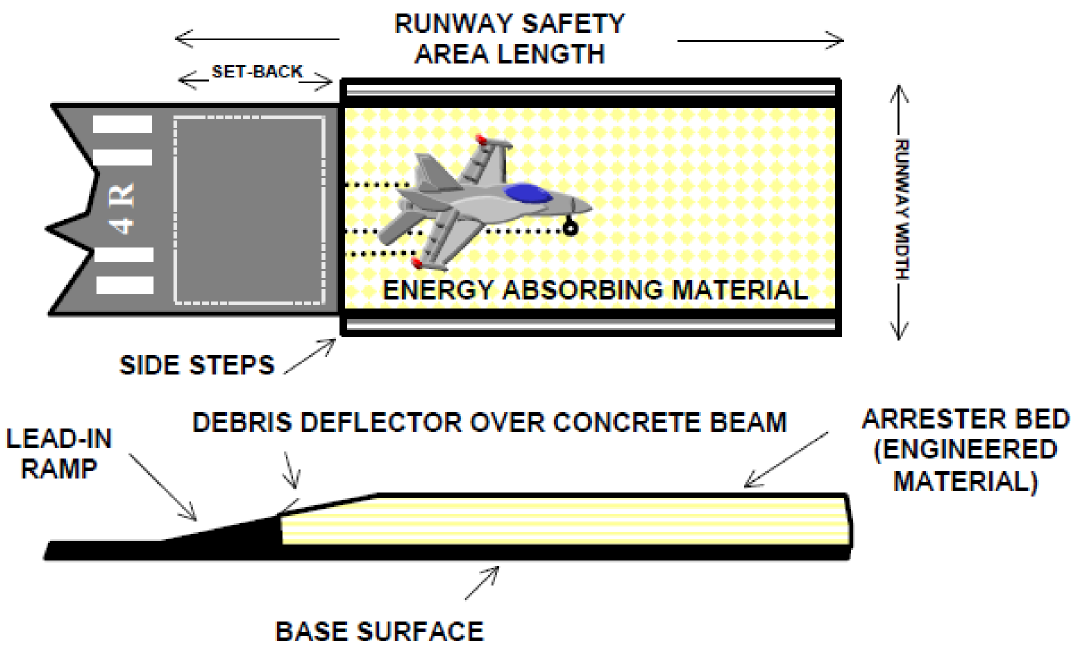


5-10 SOFT GROUND TYPE AAS

The Engineered Material Arresting System (EMAS) is an FAA-approved soft ground system normally used for civil airports to mitigate short safety areas (less than 305 meters [1,000 feet] long) at runway ends. The system is constructed of cellular foam concrete of specific strength and thickness to decelerate an aircraft that overruns the runway through rolling resistance. The design for each system is aircraft-specific, based upon the type of aircraft that will use the runway. FAA AC 150/5220-22, *Engineered Materials Arresting Systems (EMAS) for Aircraft Overruns*, provides the design basis. It is intended for use where it is impractical to obtain the standard 305-meter (1000-foot) overrun (FAA term Runway Safety Area (RSA)) and other alternatives are not feasible. See Figure 5-15 for layout of a typical soft ground type system. For purposes of design, the soft ground arrestor system can be considered fixed by function and frangible since it is designed to fail at a specific impact load; therefore, a soft ground system is not considered an obstruction under Federal Aviation Regulation (FAR) 14 Code of Federal Regulation (CFR) Part 77, Subpart C--*Standards for Determining Obstructions to Air Navigation or Navigational Aids of Facilities*. Soft ground systems are located beyond the end of the runway, centered on the extended runway centerline. They will usually begin at some distance from the end of the runway to avoid damage to the system due to jet blast or short landings. This distance will vary depending on the area available and the specific system design.

Figure 5-15 Typical Soft Ground Aircraft Arrestor System



CHAPTER 6 NUMBER AND TYPES OF SYSTEMS AUTHORIZED

6-1 Use the following examples for guidance, keeping in mind the primary mission aircraft, climatic region, and other operational factors dictate the total number, type, and location of AAS required on runways. The MAJCOM operating the tail-hook-equipped aircraft, or other aircraft compatible with net barrier or soft ground systems requiring support makes this determination through operational risk management (ORM), considering runway length and configuration, and proximity to other airfields and other factors.

6-2 The typical configurations described in paragraphs 6-2.1 through 6-2.3 for both runways and overrun systems may not necessarily be required in all cases.

6-2.1 A runway intended primarily for operating tactical or training tail-hook-equipped aircraft should typically have an emergency system in each overrun and an operational system at each end of the runway to provide a safety factor for possible missed engagements. However, some locations at forward operating bases or where snow and ice accumulation warrants, two operational systems may be necessary for each runway end, and a midfield installation may be needed as well.

6-2.2 Runways that are primary divert facilities for bases operating tactical or training tail-hook-equipped aircraft should typically have an emergency system in each overrun, and an operational system on each end of the primary runway.

6-2.3 Bases that are occasional hosts to arrestment-capable transient aircraft should have an emergency system installed in each overrun of the primary runway, or an operational system on each end of the primary runway.

CHAPTER 7 AIRCRAFT ARRESTING SYSTEM LOCATION REPORT [REPORT CONTROL SYMBOL (RCS): HAF-ILE (AR) 7150]

7-1 DoD needs an accurate accounting of all AAS to determine worldwide operational capabilities. BCE representatives are responsible to ensure that the status and locations of their arresting systems are correct in the DoD FLIP. Report changes in the arresting system array promptly so that other agencies can validate and publish the addition or correction. Report all information in inch-pound units.

7-2 Submit arresting system location report information to the local installation airfield manager for inclusion in the DoD FLIP. Provide a courtesy copy to AFCEC/COS at the following address:

AFCEC/COS
Attn: Aircraft Arresting System SME
139 Barnes Drive, Suite 1
Tyndall AFB FL 32403-5319
afcec.co@us.af.mil (e-mail submissions are encouraged)

7-3 Submit the following information, along with a diagram similar to the diagram in Figure 7-1:

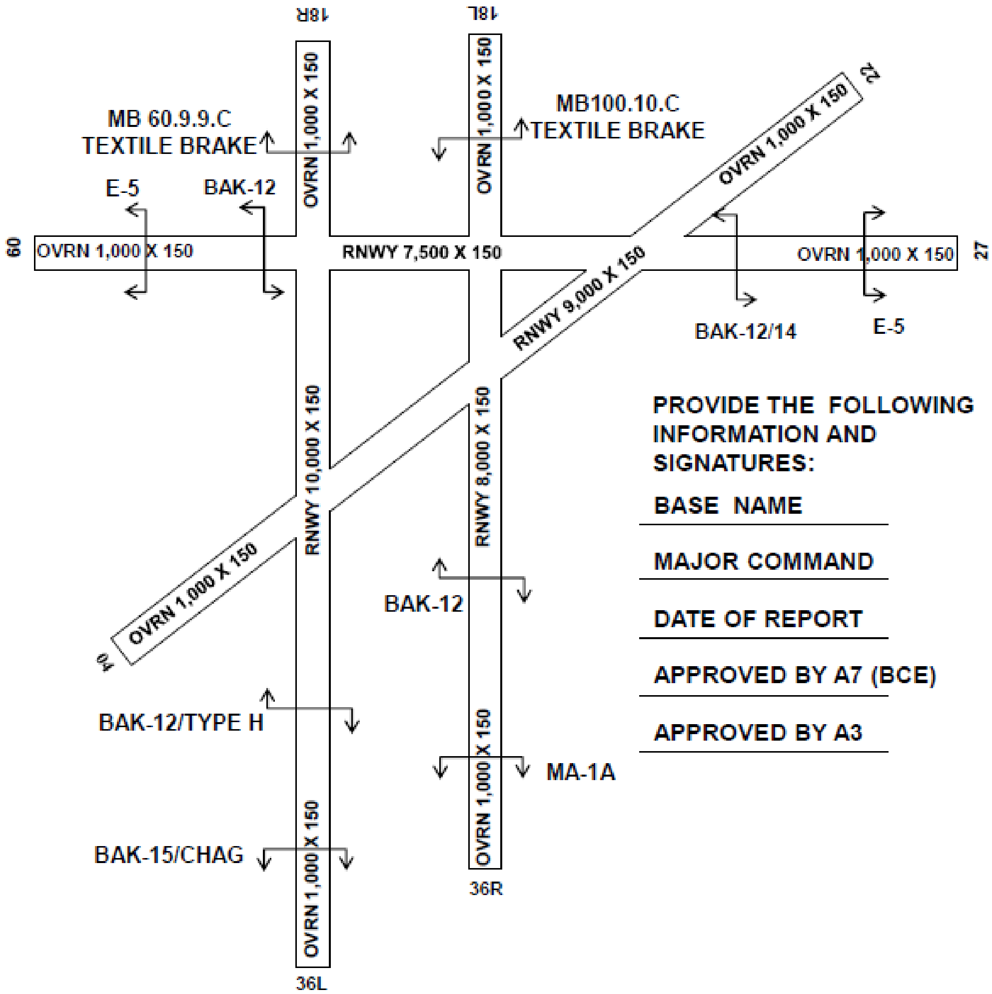
- Base name
- MAJCOM or sponsor
- Runway designations
- System type
- Length of runway to the nearest 100 feet (threshold to threshold)
- Width of runway, in feet
- Length of overrun, in feet (threshold to end of overrun)
- Longitudinal location of the arresting system with respect to the threshold, in feet (for example, “plus (+) 950" indicates that the system is 950 feet from the threshold on the runway; "minus (-) 35" indicates that the system is 35 feet from the threshold into the overrun)

7-4 Describe the arresting system installation characteristics for each system indicated on the airfield scheme using the following notations:

- AG — above ground
- BG — below ground
- EX1 — expeditionary system (BAK-12)

- EX2 — expeditionary system (MAAS)
- IC — barrier interconnected with a hook cable
- RR — remote radio control
- RH — remote hard-wired control
- MO — manually operated barrier net (raised and lowered)
- Z — owned by another service, country, or agency
- O — out of service, inoperative
- SR — 950-foot runout
- ER — 1200-foot runout
- NSR — nonstandard runout (indicate runout in feet following code entry)

Figure 7-1 Sample Airfield Diagram for Aircraft Arresting Systems Report



PROVIDE THE FOLLOWING INFORMATION AND SIGNATURES:

BASE NAME __________

MAJOR COMMAND __________

DATE OF REPORT __________

APPROVED BY A7 (BCE) __________

APPROVED BY A3 __________

NOTES:

1. Indicate runway and overrun lengths and widths for all runways as shown above.
2. Indicate runway designations as shown above.
3. Indicate arresting system locations as shown above.
4. Include remarks describing any non-standard configurations or conditions (attach additional sheets as necessary).

B-2 DEFINITION OF TERMS

Active Runway—One or more runway(s) used simultaneously for takeoff or landing operations on an airfield or airport. When multiple runways are used, they are all considered active runways.

Aircraft Arresting Barrier—A device, not dependent on an aircraft arresting hook, used to stop an aircraft by absorbing its forward momentum in an emergency landing or aborted takeoff. (Joint Publication 1-02, *Department of Defense Dictionary of Military and Associated Terms*)

Aircraft Arresting Cable—The part of an aircraft arresting system (AAS) that spans the runway surface or flight deck landing area and is engaged by the aircraft arresting hook.

Aircraft Arresting System (AAS)—A series of components used to engage and absorb the forward momentum of a routine or emergency landing or an aborted takeoff.

Arrestment-Capable Aircraft—Aircraft with flight manual procedures for an arrestment.

Cycle Time—A measure of time between engagement of an aircraft, and the point in time when the arresting system is certified fully operational and ready for another engagement.

Effective Pendant Height (EPH)—The vertical distance in inches from the underside of the pendant cable to a projected surface representing undamaged runway surface.

Energy Absorber—The component of the arresting system that dissipates the kinetic energy of the arrested aircraft.

Location Identification—A description identifying the location of arresting systems by the approach or departure end, runway designation, and position in hundreds of meters/feet from the threshold. For example, the location identification extended runout BAK-12 at +457.2 meters (+1500 feet) on approach runway 36 indicates a 365.7-meter (1200-foot) runout BAK-12 located 457.2 meters (1500 feet) beyond the threshold of runway 36.

Missed Engagement—Any unsuccessful attempt to engage an AAS hook cable with a successfully deployed aircraft tail-hook or Barrier System (net system).

Mobile Aircraft Arresting System (MAAS)—A self-contained, trailer-mounted BAK-12 AAS that accommodates rapid installation during contingencies.

Movement Area (USAF/FAA)—The runways, taxiways, and other areas of an airport/heliport used for taxiing/hover taxiing, air taxiing, take-off, and landing of aircraft, exclusive of loading ramps and parking areas. At airports/heliports with a tower, specific approval for entry onto the movement area must be obtained from Air Traffic Control (ATC). For USAF, the movement area is determined by the airfield operations flight commander and defined in the installation airfield operations and airfield driving instructions in accordance with AFI 13-204V3 and AFI 13-213.

Movement Area (ICAO)—That part of an airport used for the take-off, landing and taxiing of aircraft, consisting of the maneuvering area and the apron(s).

Overrun (USAF)—An area beyond the take-off runway designated by the airport authorities as able to support an airplane during an aborted take-off. The FAA/ICAO term for this is “stopway.” UFC 3-260-01 identifies this area as one that prevents serious damage to aircraft that overrun or undershoot the runway.

Pendant—The part of an AAS that spans the runway surface or flight deck landing area and is engaged by the aircraft tail-hook.

Reset Time—The time required to ready the arresting system for another engagement after aircraft release. (This does not include time to disengage the aircraft from the arresting system but does include the time required to inspect and certify the system as fully operational.)

Stopway (FAA/ICAO)—An area beyond the take-off runway designated by the airport authorities as able to support an airplane during an aborted take-off. The Air Force term for this is “overrun.”

This Page Intentionally Left Blank

APPENDIX C LETTER OF AGREEMENT WITH THE FEDERAL AVIATION ADMINISTRATION (FAA)

In cases where a military activity needs to install an arresting system on a civil or jointly used airfield, the following example may be used as a guide in developing the agreement.

AGREEMENT: The [FAA office and address] and [designated MAJCOM] agree to the following provisions for the operation and use of aircraft arresting equipment installed on [designated runway, airport name, and address].

General Provisions:

This agreement describes FAA functions and responsibilities concerning the remote-control operation of arresting systems by FAA air traffic controllers. It governs use of arresting barriers and hook cable arresting systems for military aircraft and, in an emergency, at pilot request for civil aircraft.

The conditions and procedures described in this agreement become effective when it is signed and dated by the parties and the tower chief receives written notice from the installation commander that one of the following conditions exists:

> The arresting system has been accepted from the contractor and is commissioned and fully operational.
>
> The arresting system is available for emergency use only. If the arresting system has not been accepted from the contractor, this notification must come with a written statement from the contractor authorizing emergency use of the system and waiving any claim against the FAA for damage to the system as the result of such use.
>
> A NOTAM has been issued specifying one of the above conditions. Before receiving the letter from the installation commander, the military crew de-energizes the tower arresting system controls and the chief controller labels them "Inoperative." Tower personnel may not energize the controls under any circumstances.

Automatic arresting systems may be installed on the runway or in the overrun. Control tower personnel raise or lower the barrier or hook cable through a remote-control panel in the control tower.

Air traffic controllers operate the tower arresting system controls at the request of:

> The pilot of any military aircraft (regardless of the Service concerned, type of aircraft, or nature of the operation).
>
> The pilot of a civil aircraft in an emergency, when in commission or emergency use status as described above.
>
> A mobile control unit, the airfield manager, or a designated representative.

The military crew originates NOTAMs covering operational or outage status of a barrier or hook cable. During a NOTAM outage for repair or maintenance, tower personnel operate the controls, provided that the outage NOTAM contains the statement "available for emergency use" and the tower possesses a copy. Otherwise, the military crew deenergizes the tower controls and the chief controller labels them "Inoperative." In this event, tower personnel may not energize the controls under any circumstances.

During NOTAM outages due to failure of controls or when tower personnel advise of malfunction of the system, the military crew at the system site has full and final responsibility for operating the arresting device. The arresting system crew maintains a listening watch on air and ground frequencies and has transmitting and receiving capability with the tower on the ground control frequency keeping personnel informed of the position of the system.

Operations:

Typically, all military aircraft take off and land toward an operational arresting system in the "ready" configuration. The pilot asks the control tower operator to raise or lower the barrier or hook cable. For example, the pilot says "Duluth Tower, Joy 32 on base, gear down and locked, raise cable."

For normal landings, the request involves the approach-end cable.

For normal takeoffs, the request involves the departure-end barrier and cable.

When tower personnel receive a request to raise or lower the barrier or cable, they must inform the pilot of the intended barrier or cable position as part of takeoff or landing information. For example, they say "Joy 32 cleared for takeoff, barrier indicates up."

The pilot may request barrier or cable operating status at any time.

The barrier and cable controls are in the down position except when pilots or other authorized personnel request that either or both be raised.

Tower personnel raise the departure-end barrier and both approach- and departure-end cables for known or suspected radio failure landing by any military arrestment-capable aircraft. Activate the arresting system even if you doubt the aircraft's ability to engage the system.

The standard phraseology for emergency requests to raise the barrier is "barrier, barrier, barrier." The standard phraseology for emergency requests to raise the cable is "cable, cable, cable."

Tower personnel start normal crash procedures when an aircraft engages the barrier or cable if these procedures are not in progress.

When there is a malfunction of the barrier, hook cable mechanism, or remote control system, the tower personnel notify airfield management immediately.

Change No.	**Date**	**Location**
1	7 March 2022	Added Chapter 22 on maintenance approach of specific areas critical to F-35B/C operations. Added Paragraph 21-3.6 Epoxy Coatings and 21-3.7 Joint Sealants. Updated third paragraph of 20-1, 21-1, 21-3, 21-3.1, 21-3.3, 21-4.4, 21-4.6, 21-5.1, and Appendix B References – Army.

This UFC supersedes UFC 3-270-01, dated 15 March 2001; UFC 3-270-02, dated 15 March 2001; UFC 3-270-03, dated 15 March 2001; UFC 3-270-04, dated 15 March 2001; UFC 3-250-06, dated 16 Jan 2004; Air Force ETL 96-4, dated 9 July 1996; Air Force ETL 97-2, dated 28 July 1997; Air Force ETL 02-7, dated 7 August 2002; Air Force ETL 02-8, dated 5 September 2002; Air Force ETL 11-26, dated 21 December 2011; and Air Force ETL 14-2, dated 21 November 2014.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 3-270-01, *O&M: Asphalt and Concrete Pavement Maintenance and Repair*

Superseding: UFC 3-270-01, *Asphalt Maintenance and Repair*; UFC 3-270-02, *Asphalt Crack Repair*; UFC 3-270-03, *Concrete Crack and Partial-Depth Spall Repair*; UFC 3-270-04, *Concrete Repair*; UFC 3-250-06, *Repair of Rigid Pavements Using Epoxy Resin Grouts, Mortars, and Concretes*; ETL 96-4, *Temporary Joint Sealing Details and Procedures for Pavements;* ETL 97-2, *Maintenance and Repair of Rigid Airfield Pavement Surfaces, Joints and Cracks;* ETL 02-7, *Preventing Concrete Deterioration Under B-1 and F/A-18 Aircraft;* ETL 02-8*, Silicone Joint Sealant Specification for Airfield Pavements;* ETL 11-26, *Using Asphalt Surface Treatments as Preventive Maintenance on Asphalt Airfield Pavements;* and ETL 14-2, *Preventing and Repairing Concrete Deterioration Under MV-22 and CV-22 Aircraft*;

Description: UFCs 3-270-01, 3-270-02, 3-270-03, 3-270-04 and UFC 3-250-06 are hereby cancelled and combined into this UFC. To reflect the combination of these four UFCs into one document, the title of UFC 3-270-01 is changed from *Asphalt Maintenance and Repair* to *O&M Manual: Asphalt and Concrete Pavement Maintenance and Repair*. Many figures are updated and the document reviewed to ensure recent developments are included. In addition, the following Air Force Engineering Technical Letters (ETLs) are cancelled and incorporated into this UFC: ETL 96-4, ETL 97-2, ETL 02-7, ETL 02-8, ETL 11-26, and ETL 14-2.

Reasons for Document: This UFC provides engineers with information on the options for maintaining and repairing, as well as preserving and extending, the service life of pavements. It also provides information on which methods are appropriate to address observed pavement distresses. It also outlines materials, equipment, techniques, and cautions required to produce a cost-effective and durable pavement. The overlap in the five superseded UFCs and six cancelled ETLs made it difficult to ensure consistency between documents as modifications to each were added. Combining these UFCs and ETLs into one document facilitates user comprehension and maintains internal consistency during future updates.

Impact: These changes enhance user access to the technical guidance in the documents (one document instead of eleven). This effort reduces the cost to maintain this guidance by reducing ambiguity and reducing the number of documents. There is a potential decrease in initial and lifecycle costs due to increased options available to sustain the pavements throughout the life of the pavement and which will extend to the life of the pavement.

Unification Issues: There are no unification issues.

Disclaimer: Use of the name or mark of any specific manufacturer, commercial product, commodity, or service in this publication does not imply endorsement.

TABLE OF CONTENTS

FIGURES

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC contains information on materials, equipment, and procedures for repairing and maintaining hot mix asphalt (HMA) and portland cement concrete (PCC) pavements. Typical maintenance and repair (M&R) methods, and problems that might be encountered in using these methods, are discussed. Guidance is provided for using each of these M&R methods. Additional information can be found in the references listed in Appendix A.

This UFC is intended for use as a field UFC for airfield and roadway pavement repair for all U.S. Navy, Army, and Air Force pavements. The described techniques are applicable for airfields, roads, parking lots, and other pavement uses. Probable causes of pavement problems are discussed and suggested M&R measures described in order to correct pavement surface problems at the source.

Not covered in this UFC are maintenance and repairs of surface water drainage systems, pavement markings, ground lighting, and unpaved margins.

1-2 APPLICABILITY.

This UFC applies to all military Service elements and contractors involved in the planning, design, and construction, maintenance, repair, or preservation of DOD pavements worldwide. This UFC is for the M&R of asphalt and concrete pavements. Follow standard practices to ensure good performance and to obtain required pavement service life. Projects where standard practices were not followed resulted in poor performance. In many cases, those providing oversight were not knowledgeable about standard practices. This UFC outlines standard practices and will result in better oversight of work and help identify problem areas during application of the M&R process.

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DOD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4 REFERENCES.

Appendix A contains a list of references used in this UFC. The publication date of the code or standard is not included in this UFC. In general, the latest available issuance of the reference is used.

1-5 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

CHAPTER 2 TYPES OF MAINTENANCE AND REPAIR FOR PAVEMENTS

2-1 INTRODUCTION.

The purpose of M&R of asphalt and concrete pavements is to extend the useful life of the pavement, maintain a smooth riding surface, reduce mission impact, and prevent water from entering the underlying soil.

2-1.1 Maintenance and Repair.

Typical maintenance on asphalt and concrete pavements consists principally of the care of joints, sealing of cracks, surface treatments, replacement of random broken slab panels, full-depth and partial-depth repairs, dowel bar restoration, diamond grinding, slab-jacking, sub-sealing, petroleum, oil, and lubricant (POL) contamination removal, and the correction of minor settlement and drainage faults. Repair consists of the work required to restore a distressed pavement so it may be used at its original designed capacity and/or accommodate the current mission as provided for by applicable Service instructions.

2-1.2 Pavement Management.

Use an effective pavement management and inspection system that provides timely M&R to keep a pavement in optimal condition. Identify the root cause of the pavement distress and address the underlying problem. To implement an effective pavement management and inspection program, use UFC 3-260-16FA, *Airfield Pavement Condition Survey Procedures*, and UFC 3-270-08, *Pavement Maintenance Management*. These UFCs describe all asphalt and concrete pavement distresses and severity levels.

2-1.3 Quality Control.

Perform quality control, whether work is performed in-house or by contract, to obtain effective durable maintenance and repairs. Use an independent certified testing laboratory, referred to herein as the QC lab. Quality control (QC) functions are performed by the QC lab, which are necessary to monitor the work. Mix designs, soil cement design, soils analysis for compaction control, and supporting construction process monitoring are performed by the QC lab. The minimum daily monitoring requirements are described in specified UFGSs. Submit QC lab qualifications for review and approval to the government contracting officer or their designated technical representative. The government contracting officer or their designated technical representative will review the qualifications of the laboratory and, if necessary, visit the QC lab. Include, as a minimum, local area industry standards, , ASTM C78, *Standard Test Method for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading),* ASTM C1260, *Standard Test Method for Potential Alkali Reactivity of Aggregates (Mortar-Bar Method),* ASTM C1077, *Standard Practice for Agencies Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Testing*

Agency Evaluation, ASTM D3666, *Standard Specification for Minimum Requirements for Agencies Testing and Inspecting Road and Paving Materials*, and respective state highway department certifications, when applicable, in evaluation criteria used to determine the suitability of the QC lab.

Before proceeding with the work, construct a test section to demonstrate the capability to perform to the intent of the specification. Demonstrate within the test section the ability to do pavement removal, subgrade preparation, base placement, and concrete mixing, placing, and finishing for both partial- and full-depth repairs. Incorporate the construction of joints, protection of the work, and QC procedures into the test section. Use all procedures and materials used to construct an acceptable test section as the standard of evaluation for performing the work. Incorporate equipment, materials, and procedures used for the approved test section into the work.

2-2 PAVEMENT MATERIALS.

2-2.1 Safety.

Safety hazards, such as fire/explosion hazards, toxicity, and reactivity, are associated with pavement repair materials and equipment. Always provide a Material Safety Data Sheet (MSDS) from the manufacturer with the material. Review the MSDS for personal protective equipment (PPE) and other safety precautions before use.

2-2.2 Importance of Weather.

2-2.2.1 Weather Effects – Asphalt.

2-2.2.1.1 Preferably, perform patching or resurfacing work only during dry weather and on dry surfaces. Place courses only when the surface temperature of the underlying course is greater than 40 degrees F (4 degrees C) for course thicknesses greater than 3 inches (75 millimeters) and 45 degrees F (7 degrees C) for course thicknesses 3 inches (75 millimeters) or less. When hot asphalt mixtures are placed on cold pavements they may quickly cool, making adequate compaction difficult. Moreover, asphalt and asphalt mixtures do not bond adequately to damp surfaces.

2-2.2.1.2 Mixtures containing emulsified or cutback asphalt require more curing time in high humidity. Low temperatures also reduce the rate of evaporation of emulsified or cutback binders during curing. Cationic emulsions generally are less affected by the weather than anionic emulsions. As a result, many agencies specify cationic emulsions for M&R work. Cutback asphalts are now seldom used due to environmental concerns; however, cutback asphalt may be encountered outside of the US.

2-2.2.1.3 Moisture affects seal coats and other surface treatments in the first few hours after placement. Rainfall prior to the time the liquid asphalt solidifies allows the leaching away or separation of asphalt from the aggregate. This results in the loss of some or all of the applied surface treatments.

2-2.2.1.4 Repairs cannot always be made in warm, dry weather. Therefore, QC, quality assurance (QA), equipment, and procedures are required when repairs are made during poor weather conditions as the repairs are less likely to perform satisfactorily. Sometimes mission requirements take precedent, which requires repairs as soon as practical even though they may only be temporary. Further, delaying repairs may allow small surface defects to become major failures.

2-2.2.2 Weather Effects – Concrete.

2-2.2.2.1 Weather conditions at a job site, hot or cold, windy or calm, dry or humid, may be vastly different from the optimum conditions assumed at the time a concrete mix is specified, designed, or selected. Concrete can be placed in hot or cold weather conditions, provided adequate precautions are taken to alleviate the negative impacts of high or low ambient temperatures.

2-2.2.2.2 The precautions required to ensure a quality end product will vary depending on the actual conditions during concrete placement and the specific application for which the concrete will be used. Do not place concrete when the air temperature is below 40 degrees F (4 degrees C) in the shade. When the air temperature is likely to exceed 90 degrees F (32 degrees C), use concrete having a temperature not exceeding 90 degrees F (32 degrees C) when placed. Keep the surface of placed concrete damp with a water fog until the approved curing medium is applied.

In general, if the temperature at the time of concrete placement will exceed 77 degrees F (25 degrees C) or below 50 degrees F (10 degrees C), develop a plan to negate the effects of temperatures.

2-2.2.3 Hot Weather Effects on Concrete.

Any operation of concreting done at atmospheric temperature above 77 degrees F (25 degrees C) is termed hot weather concreting. The effect of hot weather may be as follows:

- A higher temperature of fresh concrete results in a more rapid hydration and leads to reduced workability/accelerated setting. This reduces the handling time of concrete.
- Concrete mixed, placed, and cured at higher temperature typically develops higher early strength than concrete produced and cured at normal temperature, but at 28 days or later the strength is generally lower.
- Rapid evaporation may cause plastic shrinkage and cracking and subsequent cooling of hardened concrete will introduce tensile stresses.
- Rapid drying of the existing repair surface will lead to premature failure due to poor or failed bond.

2-2.2.4 Cold Weather Effects on Concrete.

Any concreting operation done at a temperature below 50 degrees F (10 degrees C) is termed cold weather concreting. In the absence of special precautions, the effect of cold weather concreting may be as follows:

- When the temperature is falling to about 50 degrees F (10 degrees C) or below, the development of strength of concrete is retarded compared with development at normal temperature. Thus, the time period for removal of form work has to be increased as well as the time to allow for traffic.
- Permanent damage may occur when the concrete in fresh stage is exposed to freezing temperatures before hardening. Concrete may suffer irreparable loss in its properties to an extent that compressive strength may get reduced to 50 percent of what could be expected for normal temperature concrete.
- Large temperature differentials within the concrete member may promote cracking and adversely affect its durability.

2-2.2.5 Precautions.

Precautions may include some or all of the following for hot weather placement:

- Moisten subgrade, steel reinforcement, and form work prior to concrete placement.
- Erect temporary wind breaks to limit wind velocities and sunshades to reduce concrete surface temperatures.
- Cool aggregates and mixing water added to the concrete mixture to reduce its initial temperature. The effect of hot cement on concrete temperature is only minimal.
- Use a concrete consistency that allows rapid placement and consolidation.
- Protect the concrete surface during placement with plastic sheeting or evaporation retarders to maintain the initial moisture in the concrete mixture.
- Provide sufficient labor to minimize the time required to place and finish the concrete, as weather conditions substantially affect the times to initial and final set.
- Consider fogging the area above the concrete placement to raise the relative humidity and satisfy moisture demand of the ambient air.
- Provide appropriate curing methods as soon as possible after the concrete finishing processes have been completed.

- In extreme conditions, consider adjusting the time of concrete placement to take advantage of ambient temperatures, such as early morning or night time placement.

Note: With proper planning and execution, concrete can be successfully placed and finished to produce high-quality, durable concrete at hot or cold temperatures.

2-2.3 Asphalt Pavement Materials.

Asphalt concrete**,** commonly called asphalt, blacktop, or pavement**,** is a composite material commonly used to surface roads, parking lots, and airfields. It consists of mineral aggregate bound together with asphalt, laid in layers, and compacted. The terms "asphalt (or asphaltic) concrete," "bituminous asphalt concrete," and "bituminous mixture" are typically used in engineering and construction, which define concrete as any composite material composed of mineral aggregate adhered with a binder. The abbreviation "AC" is sometimes used for "asphalt concrete" but can also denote "asphalt content" or "asphalt cement," referring to the liquid asphalt portion of the composite material. A variety of specialty asphalt concrete mixtures have been developed to meet specific needs, such as stone-matrix asphalt, which is designed to ensure a very strong wearing surface, or porous asphalt pavements, which are permeable and allow water to drain through the pavement for controlling storm water. Mixing of asphalt and aggregate is accomplished in one of several ways described below.

2-2.3.1 Hot Mix Asphalt Concrete (HMAC).

Hot mix asphalt concrete (commonly abbreviated as HMAC or HMA) is produced by heating the asphalt binder to decrease its viscosity and drying the aggregate to remove moisture prior to mixing. Mixing is generally performed with the aggregate at about 300 degrees F (roughly 150 degrees C) for virgin asphalt, 330 degrees F (166 degrees C) for polymer modified asphalt, and asphalt cement at 200 degrees F (93 degrees C). Perform paving and compaction while the asphalt is sufficiently hot. In many countries, paving is restricted to summer months because in winter the compacted base will cool the asphalt too much before it is able to be packed to the required density. HMAC is the form of asphalt concrete most commonly used on high-traffic pavements such as those on major highways and airfields.

2-2.3.2 Superpave Mix Design.

One of the principal results from the Strategic Highway Research Program (SHRP) was the Superpave mix design method. Superpave, short for "superior performing asphalt pavement," is a pavement system designed to provide longer-lasting roadways. The Superpave mix design method was designed to replace the Hveem and Marshall methods. The volumetric analysis common to the Hveem and Marshall methods provides the basis for the Superpave mix design method. The Superpave system ties asphalt binder and aggregate selection into the mix design process, considers traffic and climate as well, and evaluates the finished product. The compaction devices from the Hveem and Marshall procedures have been replaced by a gyratory compactor and the compaction effort in mix design is tied to expected traffic.

2-2.3.3 Marshall Mix Design.

The basic concepts of the Marshall mix design method were originally developed by Bruce Marshall of the Mississippi Highway Department around 1939 and then refined by the U.S. Army. Currently, the Marshall method is used in some capacity by about 38 states. The Marshall method seeks to select the asphalt binder content at a desired density that satisfies minimum stability and range of flow values. The Marshall method continued to be refined through the 1950s, with various tests on materials, traffic loading, and weather variables. Today, the Marshall method, despite its shortcomings, is probably the most widely used mix design method in the world. It has become so widely used because it was adopted and used by the U.S. military all over the world during and after WWII and it is simple, compact, and inexpensive.

2-2.3.4 Stone Mastic Asphalt (SMA).

SMA can be used as wearing course for roads, paths, and other traffic surfaces. It is a standard method of construction on motorways, federal roads, and city streets with heavy and very high demand traffic. For maintenance of traffic surfaces, SMA is especially suited for thin layers. One of SMA's special advantages is that, within limits, it can be paved in different thicknesses to even out a surface without worrying about possible differences in post compaction.

Wearing courses made with SMA are especially stable and durable. They have proven their superior performance even in areas with heavy traffic and independent of any climatic influence. A wearing course made from SMA with the correct design and mix production as well as proper paving shows the following characteristics due to the high chippings content together with the mastic-like mortar:

- Better resistance to permanent deformation
- High-wearing resistance
- Less cracking due to cold or mechanical stress
- Coarse surface texture
- Good macro roughness
- Good long-term behavior

2-2.3.5 Porous Friction Course (PFC).

Porous or permeable friction courses (PFC) are HMA mixtures placed at the surface of a pavement structure in a thin layer to produce several benefits for the traveling public in terms of safety, economy, and the environment. It is a sacrificial wearing course consisting of an aggregate with relatively uniform grading, little or no fines and mineral filler, and it is designed to have a high air void content compared to dense-graded mixtures. Special repair procedures specifically applicable to these porous friction surfaces are presented and discussed in Chapter 10.

2-2.3.6 Warm Mix Asphalt (WMA) Concrete.

Warm mix asphalt concrete (commonly abbreviated as WMA) is produced by adding either zeolites, waxes, asphalt emulsions, or sometimes even water to the asphalt binder prior to mixing. This allows significantly lower mixing and laying temperatures and results in lower consumption of fossil fuels, thus releasing less carbon dioxide, aerosols, and vapors. Not only are working conditions improved, but the lower laying-temperature also leads to more rapid availability of the surface for use, which is important for construction sites with critical time schedules. The use of these additives in HMA (2.2.3.1 above) may afford easier compaction and allow cold weather paving or longer hauls. Use of WMA is rapidly expanding.

2-2.3.7 Cold Mix Asphalt Concrete.

Cold mix asphalt concrete is produced by emulsifying the asphalt in water with (essentially) soap prior to mixing with the aggregate. While in its emulsified state, the asphalt is less viscous and the mixture is easy to work and compact. The emulsion will break after enough water evaporates and the cold mix will, ideally, take on the properties of cold HMAC. Cold mix is commonly used as a patching material and on lesser-trafficked service roads.

2-2.3.8 Cut-back Asphalt Concrete.

Cut-back asphalt concrete is produced by dissolving the binder in kerosene or another lighter fraction of petroleum before mixing with the aggregate. While in its dissolved state the asphalt is less viscous and the mix is easy to work and compact. After the mix is laid down the lighter fraction evaporates. Because of concerns with pollution from the volatile organic compounds in the lighter fraction, cut-back asphalt has been largely replaced by asphalt emulsion.

2-2.3.9 Mastic Asphalt Concrete.

Mastic asphalt concrete or sheet asphalt is produced by heating hard-grade blown bitumen (oxidation) in a green cooker (mixer) until it has become a viscous liquid, after which the aggregate mix is then added. The bitumen aggregate mixture is cooked (matured) for around six to eight hours and, once it is ready, the mastic asphalt mixer is transported to the work site where experienced layers empty the mixer and either machine or hand lay the mastic asphalt contents on to the road. Mastic asphalt concrete is generally laid to a thickness of around 0.75 to 1.1875 inch (20 to 30 millimeters) for footpath and road applications, and around 0.375 inch (10 millimeters) for flooring or roof applications. In addition to the asphalt and aggregate, additives, such as polymers, and antistripping agents may be added to improve the properties of the final product.

Natural asphalt concrete can be produced from bituminous rock, found in some parts of the world, where porous sedimentary rock has been impregnated with upwelling bitumen.

2-2.4 Grading System for Asphalt Emulsions.

Most asphalt surface treatments contain an emulsified binder. Do not use solvent-based or cutback materials unless approved by the local environmental authority. Use emulsions appropriate for local conditions to ensure proper break and set time. Coal tar emulsions, usually used only as fuel-resistant sealers, are not discussed in this UFC.

Emulsions are classified (ASTM D977, *Standard Specification for Emulsified Asphalt*), on the basis of how quickly the asphalt droplets coalesce, resulting in "breaking" of the emulsion. RS, MS, QS, and SS refer to rapid-setting, medium-setting, quick-setting, and slow-setting, respectively. The breaking time increases from RS to SS. RS emulsions cannot be combined with aggregate. MS emulsions can only be mixed with coarse aggregate. QS and SS emulsions can be mixed with any aggregate. Designations 1 and 2 in emulsion nomenclature refer to the viscosity of the emulsion, with 2 being more viscous. The h designation refers to a base asphalt that is harder (lower penetration). Some emulsions have a HF designation, referring to high float. HF emulsions can provide a thicker asphalt film on aggregates, which is thought to enhance durability. Emulsions suspended by cationic surfactants are designated with a C. No designation refers to emulsions with anionic surfactants. Table 2-1 gives common emulsion grades for different types of surface treatments.

Table 2-1 Common Asphalt Emulsion Grades

Surface Treatment	Typical Asphalt Emulsion Grade Used
Liquid fog seal	RS-1, MS-1, HFMS-1, SS-1, SS-1h, CRS-1, CSS-1h, CQS-1h
Liquid and sand spray seal	RS-1, RS-2, HFRS-2, HFRS-2h, MS-1, HFMS-1, CRS-1, CRS-2, CRS-2h
Slurry seal	SS-1h, CSS-1h, CQS-1h
Microsurfacing	CQS-1h

2-2.4.1 Emulsion Breaking and Curing.

Breaking an asphalt emulsion refers to separating water from the asphalt and the evaporation of water. Some emulsions break when sufficient water has evaporated. Others break through chemical means. Breaking time is reduced by adding chemicals.

Curing asphalt emulsions involves the development of mechanical properties as the asphalt particles coalesce and the water is removed through evaporation. Typical curing times range from 30 minutes to 24 hours. Cure times are a function of environmental conditions, application rate, substrate properties, and product dilution ratios. Follow the manufacturer’s recommendations for closing the pavement to traffic.

2-2.4.2 Shelf Life.

Some asphalt materials have a limited shelf life; therefore, give particular attention to the manufacturer’s recommended shelf life when selecting a material. Shelf life typically ranges from three months to two years and depends on storage conditions, such as temperature, humidity, and packaging.

2-2.5 Concrete Pavement Materials.

A concrete pavement consists of a surface layer of concrete placed over a base (granular or stabilized) and subbase (typically granular) over the subgrade, which may incorporate a fill material. Concrete is a mixture of paste and aggregates. The paste, composed of cementitious materials and water, coats the surface of the fine and coarse aggregates. Through a chemical reaction called hydration, the paste hardens and gains strength to form concrete. The cementitious material primarily consists of portland cement but may also incorporate fly ash, slag cement (ground granulated blast furnace slag), silica fume (not common), or proprietary materials. Concrete is made with or without additives (e.g., air entraining, water-reducing) to achieve the required workability, strength, and durability properties. Concrete generally achieves its initial set within about one hour after water is added and will become fairly hard within six to eight hours of placement. Normal concrete will achieve about 90 percent of its long-term strength within about 30 days and will continue to gain strength at an ever-decreasing rate for many years as long as moisture is retained within the consolidated concrete mass and there is no adverse chemical reaction either internally or due to external action. Normal concrete is typically designed to achieve about 4,000 pounds per square inch (psi) (27.5 megapascals) compressive strength at 28 days. Rapid-set or high-early-strength concrete can be designed to achieve strengths of about 2,500 to 3,000 psi (17.2 to 20.7 megapascals) within 12 to 24 hours to allow for early opening of repair areas to traffic. Many rapid-set materials include proprietary cementitious materials.

2-2.5.1 Portland Cement Concrete (PCC).

PCC is generally accepted as the most appropriate material for the partial-depth repair of existing concrete pavements. Typical mixes combine Type I, Type II, or Type III portland cement with aggregate not larger than one-half the minimum repair thickness. Use a material that is a low-slump mixture of air-entrained concrete having a water-to-cement ratio not exceeding 0.44. Type I or Type II PCC can be used when the patch material can be protected from traffic for at least 24 hours. For faster-setting materials such as Type III cements, patches can be opened as soon as the material can withstand loads without plastic deformation. Type I or Type II portland cement, with or without admixtures, is more widely used than most other materials because of its relatively low cost, availability, and ease of use. In cooler weather, insulating layers can be used to retain the heat of hydration and reduce curing time.

Several proprietary portland cement-based repair materials are also available to achieve high early strength and can be used for partial-depth repairs.

2-2.5.2 Gypsum-Based Concrete.

Gypsum-based concrete (calcium sulfate) repair materials gain strength rapidly and can be used in any temperature above freezing. However, gypsum concrete may not perform well when exposed to moisture and freezing weather. Additionally, the presence of free sulfates in the typical gypsum mixture may promote corrosion of reinforcing steel in pavements.

2-2.5.3 Magnesium Phosphate Concrete.

Magnesium phosphate concretes set very rapidly and produce a high-early-strength, impermeable material that will bond to clean, dry surfaces. However, this type of material is extremely sensitive to water, either on the substrate or in the mix (even very small amounts of excess water can reduce strength). Furthermore, magnesium phosphate concrete is very sensitive to aggregate type (for example, some limestone aggregates are not acceptable). In hot weather (i.e., above 90 degrees F [32 degrees C]), many commonly available mixes experience short setting times (e.g., 10 to 15 minutes).

2-2.5.4 Calcium Aluminate Cement.

Calcium aluminate cements gain strength rapidly, have good bonding properties (on a dry surface), and very low shrinkage. However, due to a chemical conversion that occurs in calcium aluminate cement, particularly at high temperatures during curing, strength loss over time is likely to occur; consequently, these materials are not recommended for use as a patching material.

2-2.5.5 Polymer-based Concrete.

Polymer-based concretes are formed by combining polymer resin, aggregate, and an initiator. Aggregate is added to the resin to make the polymer concrete more thermally compatible with the existing concrete (which would otherwise lead to debonding), to provide a wearing surface, and for economy. The main advantage of polymers is that they set much quicker than most of the cementitious materials. However, they are expensive and can be quite sensitive under certain field conditions. Polymers used for pavement repairs can be classified into four categories: epoxies, methacrylates, polyester-styrenes, and urethanes.

When using polymeric materials for partial-depth repairs, use spall repair materials in accordance with TSPWG M 3-270-01.08-4, *Testing Protocol for Polymeric Spall Repair Materials*.

2-2.5.5.1 Epoxy Concrete.

Epoxy concrete repair materials are impermeable and have excellent adhesive properties. When used, it is important that the epoxy concrete be compatible with the concrete in the pavement. Differences in the coefficients of thermal expansion (CTE) between the repair material and the concrete can cause repair failures, but the use of thermally compatible aggregate increases the volume stability and helps reduce the likelihood of debonding. Place deep epoxy repairs in multiple lifts to control heat buildup.

2-2.5.5.2 Methyl Methacrylate (MMA) Concrete.

MMA concretes and high molecular weight methacrylate (HMWM) concretes have long working times, high compressive strengths, and good adhesion. Furthermore, they can be placed over a wide range of temperatures, from 40 to 130 degrees F (4 to 54 degrees C). MMA is manufactured with either an ultra-low viscosity, which is used as a penetrating crack sealer or to fortify extremely porous concrete substrates, or a medium viscosity, which is used as a neat mortar for grouting or thin patches and can be filled with pre-packaged coarse aggregate and used for partial or full-depth patching in a single pour. However, many methacrylates are volatile and may pose a health hazard to those exposed to the fumes for prolonged periods.

2-2.5.5.3 Polyester-styrene Polymers.

Polyester-styrene polymers have many of the same properties as MMA, except that they have a much slower rate of strength gain, which limits their usefulness as a rapid repair material. Polyester-styrene polymers generally cost less and are used more widely than MMA.

2-2.5.5.4 Polyurethane Resin

Polyurethane repair materials generally consist of a two-part polyurethane resin mixed with aggregate. Polyurethanes are generally very quick-setting (90 seconds), which makes a very quick repair. Some polyurethanes claim to be moisture-tolerant; that is, they can be placed on a wet substrate with no adverse effects. These types of materials have been used for several years with variable results.

2-2.5.6 Rapid-set Cement and Polymers.

There are a number of other polymeric materials available for partial-depth repairs, most of which exhibit rapid strength gain and a high degree of impermeability. Furthermore, some of these materials exhibit certain elastic properties that allow them to be placed across a joint without the need for an insert to maintain the joint.

Use rapid-set proprietary patching materials in compliance with the manufacturer's recommendations. This includes bonding, placing, time required before opening to traffic, and temperature ranges. Evaluate epoxy mortar and epoxy concrete mix designs in the laboratory before use. Precondition the epoxy resin catalyst before blending to produce a liquid blended between 75- and 90-degrees F (24- and 32-degrees C). Mix the epoxy components in compliance with the manufacturer's recommendations prior to adding aggregate. Blend the material in a suitable mixer until homogenous. Mix only the quantity of material that can be used within one hour (dependent on materials and air temperature, may be less than one hour) in each batch.

When using rapid-set cement and polymeric materials for partial-depth repairs, use spall repair materials in accordance with TSPWG M 3-270-01.08-2, *Testing Protocol for Rapid Setting Rigid Repair Material*.

Caution: **Use repair materials that are thermally compatible with the existing concrete. When an aggregate is used to extend the repair material, use aggregate that is thermally compatible with the aggregate in the existing concrete; otherwise, the risk of debonding will be high.**

2-2.5.7 Bonding Grout.

Bonding grout may be used when using cement-based repair material. The grout consists of one-part portland cement to one-part sand by volume with sufficient water to produce a mortar with a creamy consistency. The grout is applied as a light coat to the patch area. Place the concrete before the grout dries. If the grout dries or hardens prior to placement of this concrete, remove it by sandblasting. Do not place patches using normal-set concrete when the air temperature is below 50 degrees F (10 degrees C). At temperatures below 55 degrees F (13 degrees C), a longer curing period and/or insulation mats may be required. If the grout cannot be applied correctly, it is preferable not to use the grout and instead lightly dampen the repair area with water, including the vertical sides, just before application of the grout material in the repair area.

For rapid-set proprietary materials, follow the manufacturer's instructions regarding the use or non-use of the bonding grout. Remove all sandblasting residue using oil-free air-blowing equipment just prior to placing the bonding grout, if used. Apply the bonding grout using a stiff bristle brush and scrub into the patch area. Apply evenly in a thin coat (approximately 0.0625 inch [2 millimeters] thick).

Caution: **Irrespective of the type of bonding grout used, always apply it to a clean surface and never allow it to puddle or get dry before application of the repair material. If water is used to dampen the repair surfaces, the water is not allowed to pond on the repair surface.**

2-2.5.8 Recycled Concrete Pavement Material

Recycled concrete pavement material has many potential uses, which are addressed in UFC 3-250-07, *Standard Practice for Pavement Recycling*. When using recycled concrete pavement materials, consider testing the recycled materials to mitigate potential detrimental risks associated with harmful reactivity such as alkali-silica reaction (ASR), alkali-carbonate reaction (ACR), or sulfate attack.

2-2.6 Concrete Pavements Types.

2-2.6.1 Jointed Plan Concrete Pavement (JPCP).

JPCP may be doweled or not doweled at transverse joints; however, these pavements are always doweled along longitudinal construction joints. Transverse joint spacing used on airfields in the past ranged from about 15 feet (4.5 meters) to about 25 feet (7.5 meters), depending on slab thickness. Currently, the design joint spacing ranges from about 10 feet (3 meters) to about 20 feet (6 meters).

2-2.6.2 Jointed Reinforced Concrete Pavement (JRCP).

JRCP incorporates steel reinforcement and has longer transverse joint spacing, ranging from about 40 to 60 feet (12 to 18 meters) or longer. One or more transverse cracks may develop in each panel and the reinforcement keeps these cracks tight. The transverse joints are doweled. These pavements are not widely used anymore.

2-2.6.3 Continuously Reinforced Concrete Pavement (CRCP).

CRCP has not been widely used by the military. A higher level of reinforcement is used and transverse joints are not provided, except near structures. Use of the high level of reinforcement leads to the development of closely spaced cracking at about 3 to 6 feet (1 to 2 meters) and the steel holds the crack very tight.

2-2.6.4 Jointed Concrete Pavement.

Joints are created in jointed concrete pavements to control cracking locations and provide for unrestrained expansion and contraction of the concrete panels. If the panel contraction is restrained as a result of locked joints during service or improper joint-forming during construction, mid-panel cracking can develop. If the panel expansion is restrained during hot weather, joint spalling can develop and, in extreme cases, joint blow-up may result. Therefore, it is important to make sure that any joint repair activity does not restrict the contraction and expansion of the slab panels.

2-2.7 Cement Standards.

To ensure a level of consistency between cement-producing plants, certain chemical and physical limits are placed on cements. These chemical limits are defined by a variety of standards and specifications. For instance, portland cements and blended hydraulic cements for concrete in the U.S. conform to ASTM C150, *Standard Specification for Portland Cement*, ASTM C595, *Standard Specification for Blended Hydraulic Cement*, or ASTM C1157, *Performance Specification for Hydraulic Cements*.

Table 2-2 Cement Classification Standards

In the US, three separate standards may apply, depending on the category of cement. For portland cement types, ASTM C150 describes:	
Cement Type	**Description**
Type I	Normal
Type II	Moderate sulfate resistance
Type II (MH)	Moderate heat of hydration (and moderate sulfate resistance)
Type III	High early strength
Type IV	Low heat hydration
Type V	High sulfate resistance
For blended hydraulic cements (specified by ASTM C595) the following nomenclature is used:	
Cement Type	**Description**
Type IL	Portland-limestone cement
Type IS	Portland-slag cement
Type IP	Portland-pozzolan cement
Type IT	Ternary blended cement
However, with an interest in the industry for performance-based specifications, ASTM C1157 describes cements by their performance attributes:	
Cement Type	**Description**
Type GU	General use
Type HE	High early-strength
Type MS	Moderate sulfate resistance
Type HS	High sulfate resistance
Type MH	Moderate heat of hydration
Type LH	Low heat of hydration

2-2.7.1 Concrete Pavement Performance.

A concrete pavement provides a relatively long service life when properly designed, constructed, and maintained. In general, the service life of a pavement ends when, under the effects of traffic, weather, and/or lack of proper maintenance, the pavement breaks into small unstable sections, surface and joint problems develop, and extensive maintenance is required on a regular basis.

Properly designed and constructed concrete pavements do not exhibit significant distresses (e.g., cracking, joint faulting) for at least 15 years. As distresses develop, the service life of concrete pavements can be extended by timely maintenance, especially at joints and cracks. Maintaining the joints and cracks to minimize the infiltration of water and prevent the entry of incompressible material into the joint or crack is essential for long pavement service life. Frequent aircraft loadings greater than those for which the pavements were designed will cause early structural failure of the pavement.

2-2.7.2 Concrete Pavement Rigidity.

Concrete pavements are classified as rigid pavements. Concrete pavements bridge small, soft, or settled areas of a subgrade through their slab action or resistance to bending. Overloading of pavements can result from applied loads being greater than the design load, more passes than assumed in the design, or the foundation support being reduced as a result of pumping, excessive moisture, or settlement due to poor construction. Usually, once cracks develop in a panel, continued loading will cause additional cracking and/or panel breaks until the pavement is no longer functional.

2-2.7.3 Concrete Pavement Strength.

Military airfield and roadway concrete pavement design is based on limiting the concrete tensile stresses produced by aircraft or highway truck loads. Flexural strength of concrete is used in the design of concrete pavements. Loads applied to the pavement surface cause bending, with tensile stresses developing at the slab bottom (mid-slab locations) or at the slab top (corner locations, typically) and compressive stresses at the corresponding opposite surface. Since compressive strength of concrete is typically eight to ten times greater than the tensile or flexural strength, the ratio of load-induced tensile stresses at the bottom of the slab to the flexural strength of the concrete typically controls the structural behavior and performance of jointed concrete pavements.

The strength and durability of concrete is directly affected by:

- Quality of cementitious materials
- Water quality
- Cleanliness, durability, strength, and gradation of the aggregates
- Water-cementitious materials ratio
- Density (consolidation) of concrete

- Amount and types of admixtures
- Proportioning and mixing of materials
- Placement, finishing, and curing methods

2-3 PAVEMENT DISTRESSES.

Pavement distresses include items such as cracking, rutting, raveling, or other types of surface deterioration which indicate a decline in the pavement's surface condition or structural load-carrying capacity. Pavement distresses are discussed in detail in UFC 3-260-16FA. Having a pavement distress dictionary will improve communications within the pavement community by fostering more uniform and consistent definitions of pavement distress. Highway agencies, airports, parking facilities, and others with significant investment in pavements will benefit from adopting a standard distress language.

2-3.1 Asphalt Concrete (AC) Pavement Distresses.

1. Cracking
   a. Alligator or fatigue cracking
   b. Block cracking
   c. Edge cracking
   d. Joint reflection cracking
   e. Longitudinal cracking
   f. Slippage cracking
2. Patching and potholes
   a. Patching and utility cut patching
   b. Potholes
   c. Railroad crossing
3. Surface deformation
   a. Bumps and sags
   b. Corrugation
   c. Depression
   d. Rutting
   e. Shoving
   f. Swell

4. Surface defects
    a. Bleeding
    b. Polished aggregate
    c. Raveling
    d. Weathering
5. Miscellaneous distresses
    a. Lane/shoulder drop-off

2-3.2 Portland Cement Concrete (PCC) Pavement Distresses.

1. Cracking
    a. Corner break
    b. Divided slab
    c. Linear cracking
    d. Shrinkage cracking
    e. Spalling, corner
    f. Spalling, joint
2. Joint/crack related
    a. Faulting
    b. Joint/crack spalling
    c. Blowup/buckling
    d. Pumping
    e. Railroad crossing
3. Material related
    a. Alkali-silica reactivity (ASR)
    b. Durability (“D”) cracking
4. Surface distress
    a. Polished aggregate
    b. Popouts
    c. Patching, large and utility cuts
    d. Patching, small
    e. Scaling

5. Miscellaneous distresses
    a. Lane/shoulder drop-off

2-4 TYPES OF MAINTENANCE AND REPAIR.

A considerable investment is made in the construction of asphalt and concrete pavements and the vehicles/aircraft that use these surfaces. Therefore, costs decrease dramatically for every additional year of pavement use that does not cause vehicle/aircraft damage or require repeated patching or other repair activity. Routine periodic inspections and rapid pavement repair are essential for reducing the lifecycle costs of these pavements and maintaining the facility in an operation-ready status. A properly constructed and maintained pavement can last for many years and effectively meet the needs of the military.

The primary purposes of sealing cracks, repairing spalls, applying surface treatments, and carrying out other repairs in asphalt and concrete pavements is to reduce the costs associated with vehicle/aircraft damage due to foreign object damage (FOD), to extend the service life of the pavement, and to reduce the lifecycle costs for the pavement structure. Usually, there are multiple options for repairing a distress. First, determine the root cause of a distress then select a repair method to best resolve the cause. Do not apply repair options following pre-established intervals without taking the pavement’s condition into consideration. Pavement M&R is grouped into three categories;

2-4.1 Global Preventive Maintenance (PM).

Global PM is used to retard or slow pavement deterioration on a large scale, usually covering more than one section. Generally, global PM is effective at the beginning of pavement life and/or when the climatic-caused distresses have not started or the severity is low. Global PM may be performed periodically like localized PM, but is more commonly performed on a recurring schedule (i.e., at set time intervals).

2-4.2 Localized Preventive Maintenance (PM).

Localized PM consists of M&R actions performed on individual distresses to slow down the rate of pavement deterioration.

2-4.3 Operational Maintenance.

Also referred to as safety maintenance, stop-gap maintenance, and breakdown maintenance, operational maintenance is performed to mitigate distresses on pavements that are below the critical pavement condition index (PCI) to keep them operationally safe for use.

There are numerous types of M&R methods for asphalt and concrete pavements, which include patching, crack sealing, and surface treatments. This UFC presents basic M&R procedures along with relevant distresses. Overlays and new construction are covered under the UFC 3-250-XX pavement series. M&R procedures presented in this UFC include the following:

2-4.3.1 Summary of Asphalt Pavement Repairs.

The following concrete pavement repairs are discussed in this UFC:

- Chapter 3: Full-Depth Asphalt Patches
- Chapter 4: Procedural Steps (Partial-Depth Patch)
- Chapter 5: Sprayed Asphalt Surface Treatments
- Chapter 6: Bituminous Surface Treatment
- Chapter 7: Double Bituminous Surface Treatment
- Chapter 8: Asphalt Slurry Seals and Microsurfacing
- Chapter 9: Asphalt Crack Sealing
- Chapter 10: Porous Friction Surfaces
- Chapter 11: Diamond-Grinding Asphalt Concrete Pavements

Each of the above repair methods addresses specific distresses. Some of the repairs may be performed in combination.

2-4.3.2 Summary of Concrete Pavement Repairs.

The following concrete pavement repairs are discussed in this UFC:

- Chapter 12: Concrete Pavement Crack Sealing
- Chapter 13: Partial-Depth Repair of Concrete Pavements
- Chapter 14: Full-Depth Repair of Concrete Pavements
- Chapter 15: Concrete Pavement Slab Jacking
- Chapter 16: Subsealing Jointed Concrete Pavements
- Chapter 17: Concrete Pavement Diamond Grinding
- Chapter 18: Concrete Pavement Load Transfer Restoration
- Chapter 19: Concrete Pavement Retrofitted Edge Drainage
- Chapter 20: Maintenance of Heat-Resistant Concrete
- Chapter 21: Repair of PCC Damaged by POL

Each of the above repair methods addresses specific distresses. Some of the repairs may be performed in combination. Materials-related distresses, such as ASR and D-cracking, are not addressed in this UFC.

2-5 PAVEMENT REPAIR EQUIPMENT.

Inspect all equipment employed in the pavement repair operations before and during the repair project to ensure safe operation and proper application. Follow proper safety procedures in accordance with OSHA guidelines and standard practices for the protection of all project personnel. Make hand tools available for working in areas where machinery is not practical or allowed.

2-5.1 Equipment Inspection.

Inspect all repair equipment before and during actual construction. Inspection will determine if the equipment is being properly maintained, if all of the required safety devices are present, if the equipment and technique being used is damaging the pavement, and if the equipment is being operated correctly and safely.

2-5.2 Equipment.

Pavement repair equipment includes the following:

2-5.2.1 Router.

A router is used to create a sealant reservoir by enlarging meandering cracks to the desired depth and width. A vertical spindle router with a diamond bit is recommended to minimize damage to the pavement. However, an impact router may be used if it is equipped with carbide-tipped vertical-sided bits. Do not use impact routers not equipped with carbide-tipped bits or those equipped with V-shaped bits because they tend to chip and damage the pavement. When using a vertical spindle router, use a belt-driven router bit to help prevent injury to the operator and damage to the pavement if the bit jams in the crack. If damage to the pavement is observed, discontinue work until corrective action is taken. Such corrective action may require replacing worn router bits, changing operators, or replacing the equipment.

2-5.2.2 Concrete Saw.

A concrete saw with a water-cooled diamond blade or abrasive disk can be used to widen straight cracks to the desired width and depth. Concrete saws may be used in place of a router if the blade has a diameter of 6 inches (150 millimeters) or less. The 6-inch (150-millimeter) diameter blade allows the saw to follow slightly meandering cracks. However, a saw blade does not follow the meandering crack as well as a router. If a saw is used to widen the crack, a high-pressure water stream can be used to remove the debris created by the saw. Use care to avoid damaging the adjacent pavement when the saw is used.

2-5.2.3 Cold Milling.

Pavement milling (cold planing, asphalt milling, or profiling) is the process of removing at least part of the surface of a paved area such as a road, bridge, or parking lot. Milling removes anywhere from just enough thickness to level and smooth the surface to a full-depth removal. There are a number of different reasons for milling a paved area instead of simply repaving over the existing surface. Recycling of the road surface is one of the main reasons for milling a road surface. Milling is widely used for pavement recycling, where the pavement is removed and ground up to be used as the aggregate in new pavement. For asphalt surfaces, the product of milling is reclaimed asphalt pavement (RAP), which can be recycled in hot mix asphalt (HMA) (pavement) by combining with new aggregate and asphalt cement (binder) or a recycling agent. This reduces the impact that resurfacing has on the environment.

Milling can also remove distresses from the surface, providing a better driving experience and/or longer roadway life. Milling can remove the following issues:

- Raveling: Aggregate becoming separated from the binder and loose on the road
- Bleeding: The binder (asphalt) coming up to the surface of the road
- Rutting: Formation of low spots in pavement along the direction of travel, usually in the wheel path
- Shoving: A washboard-like effect transverse to the direction of travel
- Ride quality: Uneven road surface, such as swells, bumps, sags, or depressions
- Damage: Resulting from accidents and/or fires

It can also be used to control or change the height of part or all of the road. This can be done to control heights and clearances of other road structures, such as curb reveals, manhole and catch basin heights, shoulder and guardrail heights, and overhead clearances. It can also be done to change the slope or camber of the road or for grade adjustments, which can help with drainage.

2-5.2.4 Dimond Grinding.

Diamond grinding is one of the most cost-effective concrete pavement restoration (CPR) techniques. It consists of “grinding” 0.1875 to 0.25 inch (5 to 7 millimeters) of the surface of JPCP using closely spaced diamond saw blades. The result is a level, smooth, and generally quieter riding surface. The closely spaced grooves left after grinding give the riding surface excellent texture and frictional properties. The same technique and equipment is used for diamond grooving; however, while the purpose of grinding is mainly to restore ride quality and texture, grooving is generally used to reduce hydroplaning and accidents by providing escape channels for surface water. In terms of design, the main difference between grinding and grooving is in the distance between the grooves—about six times higher in the case of grooving. Diamond grinding can also be performed on asphalt pavement.

2-5.2.5 Water Blasting.

The water blasting equipment includes a trailer-mounted water tank, pumps, high-pressure hose, and wand with safety release cutoff control, nozzle, and auxiliary water resupply equipment. Provide and use the water tank and auxiliary resupply equipment of sufficient capacity to permit continuous operations. Provide and use hoses, wands, and nozzles capable of cleaning the crack faces and the pavement surface on both sides of the crack for a width of at least 0.5 inch (13 millimeters). Provide and use a pressure gauge mounted at the pump that shows the pressure in psi (kPa) at which the equipment is operating.

2-5.2.6 Hot Compressed Air (HCA) Heat Lance.

The HCA heat lance is used to warm, dry, and clean the crack when performing the sealing operation in less-than-desirable conditions. Such conditions occur following rain or when the pavement temperature is below 50 degrees F (10 degrees C). The heat lance can also be used to remove small amounts of vegetation from cracks. Heat lances are capable of producing heated air at 3,000 degrees F (1,650 degrees C) at velocities of up to 3,000 feet per second (915 meters per second); therefore, use extreme care or the asphalt adjacent to the crack can be damaged. Do not remain stationary with the heat lance over one spot but keep moving to ensure the asphalt is not overheated. Overheating will cause the pavement to become charred and brittle, resulting in premature sealant bond failure. Do not heat the cracks using direct flame methods. It is important to remove all debris from the crack but over-blasting could cause the pavement to ravel or create voids in the crack face.

2-5.2.7 Compressed Air.

Compressed air can be employed for the final cleaning phase of the project. Provide and use an air source that produces sufficient pressure and contains no oil that may foul the surface prior to sealing. Some compressors have in-line sources for the constant lubrication of air tools. Remove these devices along with the oil-coated pressure hoses. Install in-line oil and water traps to provide clean air for the air-blasting operation.

2-5.2.8 Sandblasting Equipment.

Sandblasting equipment is used to remove residue left by a saw, loosened aggregate left by a router, vegetation, and other debris. If debris is left in the crack, the sealant will not bond adequately to the asphalt, causing premature failure. Equipment for sandblasting consists of an air compressor, hoses, and a venturi-type nozzle with an opening not to exceed 0.25 inch (6 millimeters). Equip the air compressor with traps that keep the compressed air free of oil and moisture. Use a compressor capable of supplying air at 150 cubic feet per second (4 cubic meters per second) and maintaining a line pressure of 90 psi (620 kilopascals). Exercise caution to prevent over-blasting the crack. It is important to remove all debris from the crack but over-blasting could cause the pavement to ravel or create voids in the crack face. One disadvantage of sandblasting is the requirement to clean the debris after blasting. This cleaning can be difficult and time-consuming.

2-5.2.9 Hot-applied Sealant Applicator (Melter).

Use equipment to heat and install the hot-applied sealant that consists of a double-boiler, agitator-type kettle. The heat transfer medium in the outer space is an oil with a high flash point. The double-boiler helps eliminate hot spots in the heating kettle and the agitator provides mixing for uniform heating of the sealant. Do not allow use of a direct-heating kettle. Transfer the sealant from the kettle to the crack by means of a direct-connected pressure-type extruding device (hose) with a nozzle that will insert into the crack. Heat the hose or the sealant recirculated. Design equipment to allow the sealant to be circulated back into the inner kettle when sealing is not being performed. Positive temperature devices are used to control the temperature of the oil bath and measure the temperature of the sealant. Recording-type thermometers are useful for monitoring the temperature of the sealant in the kettle as work progresses. Recording-type thermometers are not normally installed on the equipment at the manufacturer but can be installed by the contractor. Position thermometers so they are easy to read.

2-5.2.10 Cold-applied Sealant Applicator.

The necessary equipment for application of cold-applied sealants depends on whether the sealant is a single-component or a two-component mix and whether the material is hand-mixed or machine-mixed. Two-component machine mixers, recommended for larger crack-sealing projects, consist of an extrusion pump, air compressor, and the associated hoses to dispense the components through separate nozzles and mixed in a 50:50 ratio with less than ±5 percent error just prior to discharge from the nozzle. Hand-mixing equipment for two-component sealants is generally a slow-speed electric drill with a paddle mixer or an air-powered mixer. Mix single-component sealants to overcome any segregation before they are applied to the pavement. Small hand-held caulking guns can also be employed for small jobs.

2-5.2.11 Wire Brushes.

Wire brushes are helpful in removing debris and vegetation from shallow cracks, but they do not easily remove debris, such as saw residue, from the walls of the cracks. Debris on the crack faces will cause the sealant to lose adhesion with the pavement and prematurely fail. Do not use worn brushes to clean the cracks because they will not effectively remove residual debris. Take care when wire brushes are used to clean cracks that have been previously sealed; the brushes will have a tendency to smear the old sealant residue on the crack wall instead of removing it.

2-5.2.12 Power Brooms.

To remove debris from the pavement surface and reduce the potential for FOD, use a vacuum-type power broom.

2-5.2.13 Jackhammers.

For large patching operations where full-depth repairs are needed, use a 30-pound (13.6-kilogram) jackhammer model. For smaller jobs, use a 10- to 15-pound (4.6- to 6.8-kilogram) model. Equip the jackhammer with a chipping hammer and work at an angle of between 45 and 90 degrees relative to the pavement surface. Take special care not to damage the layer of concrete under the spall repair area or cause microcracking around the crack. For partial-depth repairs, do not use a jackhammer that is larger than 30 pounds (13.6 kilograms).

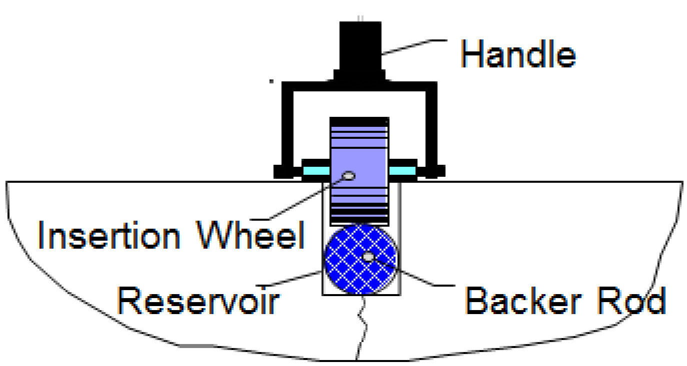
2-5.2.14 Mixers.

Drum or mortar mixers are usually employed for most patching operations. Use a bucket with a hand-held, electric drill-powered (or pneumatic), paddle-wheel mixer for smaller operations.

2-5.2.15 Backer Rod Installation Equipment.

Backer rod may be placed by hand (not recommended, except for short length placement) and many contractors have constructed their own hand-held equipment for this operation. Devices are also available that place the backer rod at a consistent depth without undue stretching or tearing of the backer materials (Figure 2-1).

Figure 2-1 Installation of Backer Rod



2-5.2.16 Sealant Applicators Not Recommended.

Pouring pots or gravity-fed sealant applicators are not recommended for sealing cracks. These applicators have a tendency to trap air in the sealant as it is applied into the crack, creating voids in the sealant. When spot repairs are made to cracks that have been sealed, it may not be feasible to use the hot-applied sealant applicator as described above and pour pots may be used. Equip the pour pot with a nozzle that will fit inside the crack in the same manner as the nozzle of the hot-applied sealant applicator.

2-5.2.17 Hand Tools.

Due to the meandering nature of cracks, hand tools are required to insert the backer rod materials in cracks deeper than 0.75 inch (19 millimeters). Do not twist, cut, or damage the backer rod material with these tools. Ensure the tool is capable of placing the material to the proper depth. When approved by the contracting officer, use hand tools used for repairing or cleaning cracks or removing old crack sealant. Examine the tools to ensure they will not damage the pavement in any manner when properly used.

This Page Intentionally Left Blank

CHAPTER 3 FULL-DEPTH ASPHALT PATCHES

3-1 INTRODUCTION.

A full-depth patch repairs distresses of medium to high severity, such as alligator cracking, corrugation, depression, oil spillage, rutting, swelling, edge cracking, bumps and sags, and existing patches. A partial-depth patch is used to maintain/repair distresses of low and medium severity, such as corrugations, depressions, rutting, shoving, slippage cracking, swelling, and existing patches.

Full-depth repairs involve removal of the complete pavement down to the subgrade or to an intermediate base or subbase layer that is intact. Partial-depth repairs usually involve removing the failed asphalt surface, excluding the base course, and replacing the surface layer with hot asphalt plant mix.

Procedural steps for partial-depth patches are in Chapter 4.

3-2 PROCEDURAL STEPS (FULL-DEPTH PATCH).

Place full-depth patches using the following steps:

3-2.1 Mark Repair Area.

Use a string line or straightedge to mark straight lines around the repair area. Clearly mark the lines so they are easily visible when sawing the pavement. Mark repair areas to form a square or rectangle with at least 12 inches (300 millimeters) beyond the distressed area.

3-2.2 Make Saw Cut Through Pavement.

Use a concrete saw equipped with a diamond-tip or abrasive blade (Figures 3-1 and 3-2, respectively) to saw the pavement. Saw the perimeter of the patch since milling tends to leave a rough edge. Overlap saw cuts so that a vertical and square corner is formed (Figure 3-3). Since diamond-tip blades usually require water, completely dry the repair area before placing the prime or tack coat. However, there are some types of diamond-tip blades designed to dry-cut asphalt pavements. The abrasive saw blade is less costly and does not require water when sawing, but they tend to wear quickly. Always confirm the saw blade is the correct diameter to allow cutting to the full pavement depth. Make sure the saw blade is rated for the revolutions per minute (rpm) of the saw; otherwise, the blade could shatter during sawing due to the mismatch.

Figure 3-1 Diamond Tip Saw Blade

Figure 3-2 Abrasive Blade

Figure 3-3 Damaged Pavement Removed by Sawing

3-2.3 Removal of Defective Material.

Remove the defective material by milling, backhoe, or with a jackhammer. Small areas are sometimes removed with a backhoe, small milling head, or jackhammer, while large areas are usually removed with a milling machine or milling head attachment (Figure 3-4). Saw-cut the perimeter of the patch as vertical as possible, regardless of the method used to remove material.

Use an asphalt bit in the jackhammer. Start the jackhammer from the middle of the repair area and work outward toward the edges. Making an additional saw cut a few inches from the border will allow the cut edges to remain square when removing the asphalt mixture. (Do not rock the hammer near the edge—this will damage the vertical face.) After completing the removal of material, remove and discard the loose material.

Figure 3-4 Small Milling Head Attachment

3-2.4 Remove, Replace, and Compact the Base.

When performing a full-depth patch, inspect the base to ensure adequate material conditions. Remove all unacceptable base, subbase, or subgrade and replace the poor-quality material with acceptable material that can be satisfactorily compacted. If subgrade material is removed, crushed stone or other suitable base material may be used to backfill to the top of the subgrade. Place new materials in 2- to 3-inch (50- to 75-millimeter) lifts, with each lift compacted to the required density. When removing the entire thickness of asphalt pavement, the base material is always disturbed; therefore, reshape and recompact the base material prior to performing the next step. After removal of material, make provision to remove any water that enters the resulting hole.

3-2.5 Apply Tack Coat (and Prime Coat, If Used).

Apply a thin tack coat to the edges and bottom of the patch. This coating provides an improved bond between the old and new materials. Ensure the patch area edges are clean, dry, and free of any dust so the tack coat will bond to the edges. Use tack coat materials that are cutback grades RC-70 or RC-250, or emulsion grades RS-1, MS-1, SS-1, SS-1h, CSS-1, or CSS-1h. The same grade of asphalt binder used in the asphalt mix can also be used as a tack coat, but this is difficult in small areas. If used, apply it hot and apply the patch material hot enough to soften the asphalt cement to obtain the required bond.

Use a prime coat can by spraying the sides and bottom of the hole to be patched with hot-asphalt plant mix if a tack coat is not used. Prime coat materials cutback grades RC-70, MC-30, MC-70, or SC-70, or emulsion grades SS-1, SS-1h, CSS-1, or CSS-1h. Applying too much material can cause bleeding. Allow prime coats time to penetrate the base material. They are usually absorbed into the underlying material within two to three hours and fully cured in less than 48 hours. Use a prime coat application rate of 0.05 to 0.2 gallon per square yard (0.23 to 0.90 liter per square meter), depending on the porosity of the material treated. Use a tack coat application rate of 0.05 to 0.10 gallon per square yard (0.23 to 0.45 liter per square meter). Use a hand-spray wand to apply the tack coat at the bottom and sides of the patch (Figure 3-5) if the area is large enough. If a wand is not available or if the area is too small, use a stiff brush. To prevent bleeding, do not apply excess tack to the patch areas.

Figure 3-5 Hand-spraying Edge of Cut

3-2.6 Place the Patch Material.

Use good-quality HMA to fill the patch. Place and compact the material in 2- to 3-inch (50- to 75-millimeter) lifts. In order for the patch to be level with the surrounding pavement, overfill the patch area to allow for compaction (Figure 3-6). When placing by hand, a good rule of thumb is to overfill by 40 percent thicker than the desired compacted thickness, depending on the mix; e.g., 3 inches (76 millimeters) compacted = 4.25 inches (108 millimeters) uncompacted. Do not overwork patch material with a lute, shovel, or rake since this tends to segregate materials and creates additional mixture cooling. When placing with an asphalt paver, a good rule of thumb is to place the asphalt mixture about 20 to 25 percent thicker to allow for compaction.

Figure 3-6 Overfill Prior to Compaction

3-2.7 Compact the Patch Area.

Compact the mix to the proper level using methods described in UFC 3-250-03, *Standard Practice Manual for Flexible Pavements*. It is important to ensure that sufficient material was provided to the patch so adequate density is obtained. The size of the patch determines which type of compactor to use. For a very small patch area or areas, a hand tamper can be used. Larger areas require a vibratory plate tamper (Figure 3-7), a steel-wheel roller (Figure 3-8), or similar compactor. To ensure the required compaction, use the proper equipment as dictated by the patch size. Always compact the edges of the patch first, followed by compaction of the remaining patch area in the direction of traffic. Overlap previous compaction lanes by approximately 6 inches (150 millimeters) across the patch area (Figure 3-8). When the patch is completely compacted, ensure its level is no higher or lower than 0.125 inch (3 millimeters) above or below the surrounding surface (Figure 3-9). Good oversight and density and smoothness testing are required to achieve a good patch.

Figure 3-7 Vibratory Plate Compactor

Figure 3-8 Steel Wheel Roller

Figure 3-9 Check Level of Patch Surface

3-2.8 Ensure Surface of Patch is Watertight.

If performed satisfactorily, the tack coat material applied to the side of the prepared hole is a good sealer between the existing edge and the patch. However, if the surface appears open at the edge of the patch or the surface of the patch is open then additional sealing may be needed on the surface. If the edge is open, seal it with a sand emulsion mix to give it the texture of a slurry seal (Figure 3-10). Refer to the International Slurry Surfacing Association guidelines (https://slurry.org/guidelines) for additional information. Ensure the edge seal is no more than 2 inches (50 millimeters) wide. If the entire surface is open then seal the entire surface with the slurry seal. Apply this material with a small brush for small sections or with a broom or small squeegee for larger sections.

Figure 3-10 Seal the Edges

3-2.9 Problem Areas.

Adequate compaction and obtaining satisfactory smoothness are major challenges when constructing patches. Use care in removing material to ensure the edges and bottom of the repair are square. Remove all unsatisfactory material when patching. It is critical that the underlying material is compacted before applying the patch. Compaction lifts less than 3 inches (75 millimeters) work best. If a spray wand is used to apply tack coat, perform a test on an adjacent area to ensure the correct application rate. Use care when applying tack coat to the edges. For best results, follow recommended best practices for spray nozzles, equipment settings, and other operations.

Note: If using cutback asphalts as a tack coat, comply with local environmental regulations.

This Page Intentionally Left Blank

CHAPTER 4 PROCEDURAL STEPS (PARTIAL-DEPTH PATCH).

4-1 INTRODUCTION.

Partial-depth patch procedural steps are identical to full-depth patch (Chapter 3). The one exception is that when saw cutting the pavement, control the patch depth to only allow cutting to the depth required for the repair. Furthermore, removal of the material in the area is usually performed with a cold milling or cold planing device. If the material has delaminated from the layer below, a light-weight jackhammer (10 to 17 pounds [4.5 to 7.7 kilograms]) and/or a shovel or equipment bucket may be used to remove the material from the repair area.

This Page Intentionally Left Blank

CHAPTER 5 SPRAYED ASPHALT SURFACE TREATMENTS

5-1 INTRODUCTION.

Use a sprayed asphalt surface treatment at an appropriate time to provide beneficial preventive maintenance. Placing a surface treatment too soon can prevent the surface of the asphalt mix from becoming sufficiently stiff to resist deformations under traffic. Delaying treatments too long will limit the treatment's ability to provide preventive maintenance. Severely weathered or cracked pavements are candidates for maintenance by replacement and will not significantly benefit from surface treatments. Do not place surface treatments on runway pavements unless approved by the Pavements Discipline Working Group (DWG) or their designated representative since they can cause FOD and reduce friction.

5-2 PRIME COAT.

A prime coat is a spray application of bituminous material applied to the surface of a base course that is to be covered with an asphalt pavement layer. The primary purpose of the prime coat is to waterproof the unbound material until it can be covered with asphalt mixture. The prime coat can also help prevent damage to the base during construction. Materials that can be used for prime coats are described in paragraph 3-2.5.

5-2.1 Procedural Steps (Prime Coat).

Conduct the following steps to apply a prime coat:

5-2.1.1 Prepare the Surface.

Ensure the surface is free of all loose material such as dirt, clay, dust, or any other undesirable material. Use a light brooming to remove these undesirable materials. If the base is excessively dry, lightly sprinkle with water prior to application of the prime coat to improve penetration of the material into the underlying layer.

5-2.1.2 Apply the Prime.

Use a distributor if the area to be primed is large. Use a hand spray wand to apply prime coat applications on smaller areas. Prime coat application rates are 0.05 to 0.2 gallon per square yard (0.23 to 0.9 liter per square meter). Coat the entire area. Since the primary purpose of a prime coat is to protect the underlying layer from rain until it is covered, the prime coat is sometimes omitted in patched areas when the surface can be covered with HMA prior to rainfall.

5-2.1.3 Allow Prime to Cure.

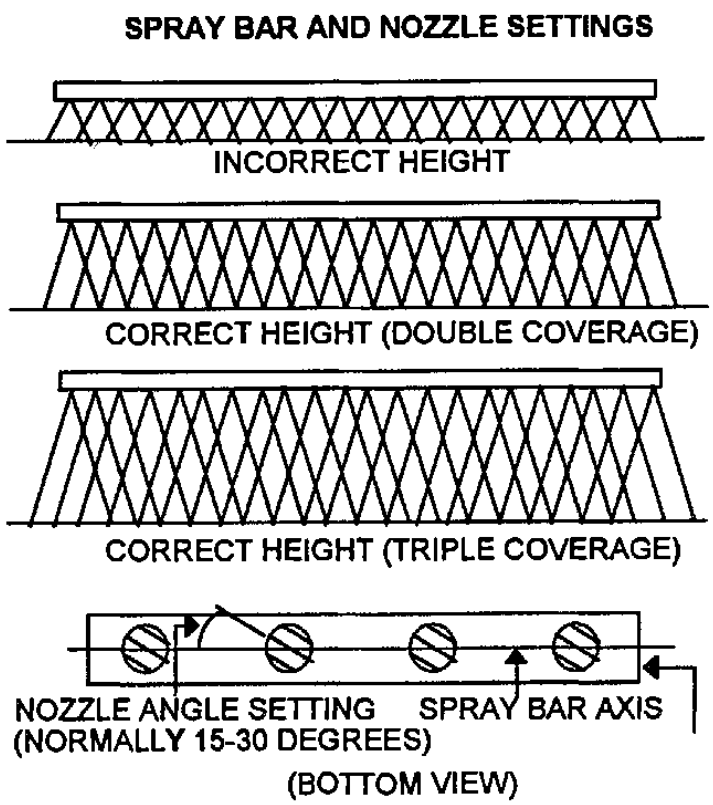
Cure prime coats for as long as necessary. Required curing time is typically 48 hours but satisfactory curing will likely occur in less time, especially in hot, windy conditions.

Blot with find sand or mineral dust if there is excess prime on the surface after penetration into the underlying materials is complete.

5-2.2 Problem Areas (Prime Coat).

A major potential problem is applying too much prime coat material so there is excess on the surface. Test application rates prior to priming. Determine application rates in accordance with ASTM D2995, *Practice for Determining Application Rate for Bituminous Distributors*. Check proper nozzles and settings on the distributor spray bar or hand-wand. Use nozzles with openings that are the same size. Check nozzles to ensure they are not plugged and are set at the proper angle and height (Figure 5-1). Comply with local environmental regulations when using RC-70 or other cutbacks as a prime coat.

Figure 5-1 Spray Bar and Nozzle Settings



5-3 TACK COAT.

The tack coat is applied to an existing pavement surface before it is overlaid with a new asphalt overlay. The tack coat provides a bond between the old and new pavement. Guidance for materials is provided in paragraph 2-2.

5-3.1 Procedural Steps (Tack Coat).

Conduct the following steps to apply a tack coat:

5-3.1.1 Prepare the Surface.

Clean and dry the surface and ensure it is free of dust, loose dirt, and other debris. Clean the surface around and inside the patch with brooms, air, and water.

5-3.1.2 Apply the Tack.

Use a distributor to apply tack coats over large areas. Use a hand-wand for small patches and hard-to-apply areas. If a wand is not available, apply the tack coat to patch edges with a stiff brush. Apply the tack coat at a proper application rate in an even and uniform coat over the entire area. Apply no more tack material than can be covered by the end of a working day. Application rates for tack coats range from 0.05 to 0.1 gallon per square yard (0.23 to 0.45 liter per square meter).

5-3.1.3 Allow Tack to Cure.

Allow the tack coat to cure before placing the overlay or patch material. Cure times will vary according to the type of tack material used and climatic conditions but typically it is a few minutes up to one or two hours. When asphalt cement is used as a tack coat, no cure time is required.

5-3.2 Problem Areas (Tack Coat).

An excessive application of tack will cause bleeding and slippage; therefore, apply at the proper application rate. Test application rates in accordance with ASTM D2995 prior to spraying the tack material. Check nozzles and settings on the distributor spray bar or hand-wand to ensure they are proper. Check nozzles to ensure they are not plugged and adjust nozzles to the proper angle and height. Clean and dry areas prior to tack coating. Comply with local environmental regulations when using RC-70 or other cutbacks as a tack coat. Overlay material that is tacked on the same day; however, as long as traffic is kept off of the surface and it remains clean, the tack may be effective for several days. It may be necessary to slightly increase the tack coat application if it has been in place for too long.

5-4 FOG SEALS AND REJUVENATORS.

Consider surface treatments for use when non-load-associated surface distresses such as non-structural cracking or raveling first begin. The recommended sealer process, once non-structural cracking and/or raveling is first observed, is a fog seal (except for runways). Continue application of the fog seal on an approximately three-year cycle, depending on pavement condition, as long as surface friction is maintained and texture depth is at least 0.03 inch (0.8 millimeter) when tested according to the grease smear test (FAA AC 150/5320-12C, *Measurement, Construction, and Maintenance of Skid-Resistant Airport Surfaces*).

A fog seal is a spray application of a diluted asphalt or tar emulsion. Emulsions used for fog seals are SS-1, SS-1h, CSS-1, or CSS-1h.

Rejuvenators are commercially available products used to restore oxidized pavement surfaces. Rejuvenators do not solve raveling issues (unless raveling is very minor) or reduce cracking problems (unless cracking is very minor hairline cracking). Often, rejuvenators can cause pavement surfaces to be slippery for up to a year; therefore, choose areas and application rates with extreme care. Since there are numerous commercially available products, a list of rejuvenators is not presented in this UFC. Fog seals and rejuvenators are normally used as preventive maintenance procedures on roads and only on airfield shoulders and overruns. Do not apply over airfield pavements without approval of the Pavements DWG or their designated representative.

5-4.1 Procedural Steps (Fog Seals and Rejuvenators).

Apply fog seals and rejuvenators using the following steps:

5-4.1.1 Prepare the Surface.

Thoroughly clean the surface prior to application of fog seals or rejuvenators. Repair distresses before application of fog seal or rejuvenator.

5-4.1.2 Determine Proper Application Rate.

The application rate will vary according to the quantity of material the pavement absorbs and the texture of the surface; therefore, spray small field test sections with different application rates to determine the best rate to apply. Adjust the rate so the treated surface has good friction, is not unstable, and does not contain excess material remaining on the surface after 12 to 24 hours of curing.

5-4.1.3 Dilute the Material.

The material can be used undiluted but is usually diluted. Dilution rates can be as high as 1 part emulsion to 10 parts water, with an average rate of 1 part emulsion to 4 parts water. Follow the manufacturer’s dilution directions. Diluting the rejuvenator with water requires a higher application rate.

5-4.1.4 Apply the Material.

Apply the material with a calibrated asphalt distributor (Figure 5-2). The calibration of the distributor is critical. Important procedures are discussed in paragraph 5-2. To avoid excessive reduction in friction, apply the asphalt material in multiple applications over the entire area so each small increase in application rate can be evaluated for its effectiveness prior to adding another application.

Figure 5-2 Asphalt Distributor

5-4.1.5 Cure Time.

Fully cure the fog seal before allowing traffic on the treated pavement. Cure time is usually 12 to 24 hours.

5-4.2 Problem Areas (Fog Seals and Rejuvenators).

Calibrate, adjust, and clean the distributor as discussed in paragraph 5-2.2 to avoid problems with coverage. Do not apply rejuvenator on airfields without prior approval from the AFCEC Pavements subject matter expert (SME), USACE Pavements SME, NAVFAC Pavements SME, or USACE/TSMCX pavement engineer. Follow proper application and dilution rates to avoid potential problems with excessive material application. Conduct preliminary tests on small test sections to determine the proper application and dilution rates.

This Page Intentionally Left Blank

CHAPTER 6 BITUMINOUS SURFACE TREATMENT

6-1 INTRODUCTION.

Single and double bituminous surface treatments (SBST and DBST, respectively) consist of sprayed asphalt applications followed immediately by one or more layers of aggregate. These treatments are used to retard deterioration of raveling, improve skid resistance, seal small cracks, and waterproof the surface. Do not use SBST or DBST on airfield pavements except for overruns and not within 200 feet (61 meters) of the threshold, but SBST or DBST can be used on light-traffic roads, parking lots, and overruns. Another type of bituminous surface treatment, sandseal, is presented in Chapter 7. A variation of SBST to repair bleeding is presented and consists of applying hot sand followed by rolling.

6-2 SINGLE BITUMINOUS SURFACE TREATMENT (SBST).

Use the following bituminous materials for SBST: cutback (RC-250, RC-800, or RC-3000) or emulsion (RS-1, RS-2, CRS-1, or CRS-2). MS and SS asphalt emulsions and medium-curing (MC) cutback asphalt can be used in some cases; however, these materials are not typically recommended because the time for cure is extended and this may result in the treatment being tender for an extended period of time. Use of any other material is prohibited without the approval of the Pavements DWG or their designated representative.

6-2.1 Procedural Steps (SBST).

Place SBST using the following steps:

6-2.1.1 Prepare the Area (SBST).

Repair all failed areas prior to applying an SBST and thoroughly clean all surfaces prior to treatment. Apply prime and/or tack coats in accordance with the procedures in Chapter 5.

6-2.1.2 Apply the Binder Material (SBST).

Apply the binder (asphalt material) with an asphalt distributor. Calibrate the distributor prior to each use. Use the same precautions as discussed for sprayed asphalt treatments in Chapter 5. An asphalt emulsion changes in color from brown to black as it breaks and cures. Apply the aggregate before the binder material has broken and turned black. Provide materials meeting one of the gradations in Table 6-1. Apply the binder and aggregates using the application rates shown in Table 6-2. Do not use Gradation 1, which is a coarse grading for SBST.

6-2.1.3 Apply the Aggregate (SBST).

Apply the aggregate immediately after binder material is applied. Apply the aggregate with tailgate spreaders on dump trucks or by self-propelled hopper-type spreaders (Figures 6-1 and 6-2, respectively). Calibrate spreaders to ensure uniformity of the aggregate at the required rate. Use only aggregate that is clean, dry, and free of dust or other undesirable material. A slightly damp aggregate can be used and works best with emulsions since this small amount of moisture will ensure better coating of the aggregate. Use aggregates that are hard, angular, and abrasion-resistant. Lightweight aggregates are sometimes used to improve friction properties. Construct a test section to ensure the resulting surface is satisfactory prior to large scale or production applications. Construct a test section when making adjustments to the treatment as necessary to provide a satisfactory surface.

Table 6-1 Aggregate Gradations for SBST

% Passing by Weight, Gradation Designation			
Sieve Size	**No. 1 SBST**	**No. 2 SBST**	**No. 3 SBST**
1 in. (25.4 mm)	100	—	—
0.75 in. (19.1 mm)	90 - 100	100	—
0.5 in. (12.7 mm)	20 - 55	90 - 100	100
0.375 in. (9.5 mm)	0 - 15	40 - 70	85 - 100
No. 4 (4.8 mm)	0 - 5	0 - 15	10 - 30
No. 8 (2.4 mm)	—	0 - 5	0 - 10
No. 16 (1.2 mm)	—	—	0 - 5

Table 6-2 SBST Binder and Aggregate Application Rates

Gradation No.	Binder Application Rates gal/yd^2 (l/m^2)	Aggregate Application Rates lb/yd^2 (kg/m^2)
1 SBST	0.40–0.50 (1.81–2.26)	40–50 (22–27)
2 SBST	0.30–0.45 (1.36–2.04)	25–30 (14–16)
3 SBST	0.20–0.35 (0.91–1.58)	20–25 (11–14)

Figure 6-1 Applying Aggregate with Tailgate Spreader on Dump Truck

Figure 6-2 Applying Aggregate with Self- Propelled Hopper-type Spreader

6-2.1.4 Roll the Aggregate (SBST).

Roll the aggregate immediately after application. Use a pneumatic-tire roller with tire pressures of 60 to 80 psi (414 to 552 kilopascals) and tire loads (weights) equal to the largest tire load that will operate on the surface. Use a pneumatic-tire roller to avoid crushing the aggregate. If approved by the contracting officer, a steel-wheel roller can be used; however, use a weight that is heavy enough to seat the aggregate but not so heavy as to crush the aggregate. The steel wheel will bridge over low spots and may not properly seat the aggregate. Continue to roll the treatment area until all aggregate particles are properly seated.

6-2.1.5 Sweep the Area (SBST).

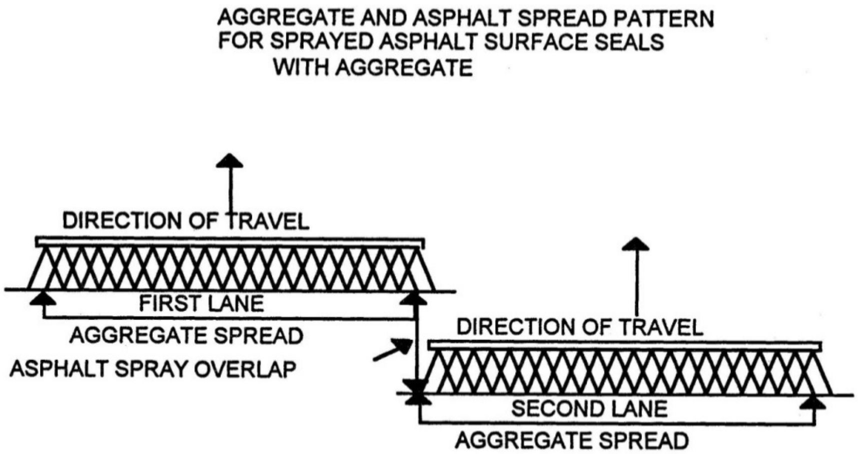
Allow the treated area to cure for at least 24 hours before brooming to remove loose particles. Broom during the coolest portion of the day to prevent dislodging aggregate. Use only enough pressure on the broom to remove the loose particles and not dislodge seated aggregate.

6-2.2 Problem Areas (SBST).

Calibrate all equipment before material placement. Use a test section to ensure all equipment is calibrated and working properly. Use building paper where the spreading of the binder and aggregate begins and ends to make clean and straight transverse joints (Figure 6-3). Remove the paper after application to form a straight edge. Do not spread the aggregate beyond the area of full binder thickness to prevent a buildup of aggregate along the longitudinal joint (Figure 6-4). This distance varies according to the spray width of the nozzle, but it is usually about 6 to 8 inches (150 to 200 millimeters) from the edge of the spray. On the adjacent pass, apply aggregate from the edge of the aggregate on the first pass to about 6 to 8 inches (150 to 200 millimeters) from the edge of the asphalt spray on the opposite side. After completing the work and opening the treated area to traffic, post for 3 days speed limits of no more than 20 miles per hour (32 kilometers per hour). This will ensure that the asphalt is fully cured, help to ensure better seating of the aggregate, and minimize dislodging of additional aggregate.

Figure 6-3 Use Paper for Straight Edge

Figure 6-4 Aggregate and Sprayed Asphalt Spread Pattern



This Page Intentionally Left Blank

CHAPTER 7 DOUBLE BITUMINOUS SURFACE TREATMENT.

7-1 INTRODUCTION.

This treatment is essentially the same as the SBST, except that more than one application of binder and aggregate is used. The most common treatment is the DBST. The same bituminous materials used for SBST can also be used for DBST. Aggregate gradations and application rates to be used are shown in Tables 7-1 and 7-2.

7-1.1 Procedural Steps (DBST).

Place DBST using the following steps:

7-1.1.1 Prepare the Area.

Follow the SBST procedures (Chapter 6).

7-1.1.2 Apply the Binder Material.

Follow the SBST procedures (Chapter 6), except two applications of binder and aggregate are placed using rates shown in Tables 7-1 and 7-2.

Table 7-1 Aggregate Gradations for DBST

Sieve Size	% Passing by Weight, Gradation Designation			
	No. 1 DBST	No. 2 DBST	No.3 DBST	No. 4 DBST
1 in. (25.4mm)	100	—-	—-	—-
0.75 in. (19.1 mm)	90 - 100	100		—-
0.5 in. (12.7 mm)	20 - 55	90 - 100	100	—-
0.375 in. (9.5 mm)	0 - 15	40 - 70	85 - 100	100
No. 4 (4.8 mm)	0 - 5	0 - 15	10 - 30	85 - 100
No. 8 2.4 mm)	—-	0 - 5	0 - 10	10 - 40
No. 16 (1.2 mm)	—-	—-	0 - 5	0 - 10
No. 50 (300 µm)	—-	—-	—-	0 - 5

Table 7-2 DBST Binder & Aggregate Application Rates

First Application		
Gradation No.	**Bituminous Material* gal/yd^2 (l/m^2)**	**Aggregate lb/yd^2 (kg/m^2)**
1 DBST	0.20–0.30 (0.91–1.36)	40–50 (22–27)
2 DBST	0.15–0.20 (0.68–0.91)	25–30 (14–16)
Second Application		
Gradation No.	**Bituminous Material** gal/yd^2 (l/m^2)**	**Aggregate lb/yd^2 (kg/m^2)**
3 DBST	0.30–0.45 (1.36–2.04)	20–25 (11–14)
4 DBST	0.20–0.30 (0.91–1.36)	15–20 (8–11)

* If an emulsion is used, increase the application rate by 10 percent.
** Ensure the second application is approximately 50 percent greater than first application.
Note: Use gradations in pairs. If gradation 1 is used for the first application then use gradation 2 for the second application and the same for gradations 3 and 4.

7-1.1.3 Apply the Aggregate.

Use the SBST procedures (paragraph 6-2.1.3).

7-1.1.4 Roll the Aggregate.

Use the SBST procedures (paragraph 6-2.1.4).

7-1.1.5 Sweep the Area.

Use the SBST procedures (paragraph 6-2.1.5).

7-1.1.6 Apply Second Application.

To apply the second application of binder and aggregate, the same steps are followed as for the first application.

7-1.2 Problem Areas (DBST).

DBST applications suffer from the same problems as SBST (paragraph 6-2.2). Remedy or mitigate these problems using the same procedures.

7-1.3 Sandseal (DBST).

Sand seal can be used to address a bleeding pavement surface or provide a thin sealer. When used to address bleeding, do not apply asphalt binder before the sand seal is placed since the primary purpose is to blot up the excess binder on the surface. Use sand with the gradations in Table 7-3. Use gradation 2 for a thinner application of sand. Potential problems include difficulty in getting an even application of sand and difficulty in treating a non-uniform surface underneath. Hence, it is possible that excessive sand will be placed in some areas and not enough in others. When binder is used, select the binder similar to that for SBST (Chapter 6).

Table 7-3 Aggregate Gradations for Sandseal (SS)

Sieve Size	% Passing by Weight, Gradation Designation	
	No. 1 SS	No. 2 SS
0.5 in. (12.7 mm)	—	—
0.375 in. (9.5 mm)	100	—
No. 4 (4.8 mm)	85 - 100	100
No. 8 (2.4 mm)	10 - 40	10 - 40
No. 16 (1.2 mm)	0 - 10	0 - 10
No. 50 (300 µm)	0 - 5	0 - 5

7-1.4 Sand Application and Rolling.

Use the following steps when treating a pavement with bleeding problems:

7-1.4.1 Apply Hot Sand.

Heat the sand to above 275 degrees F (135 degrees C) and spread the sand with a tailgate or box spreader, or by hand. Apply at a rate of 10 to 15 pounds per square yard (5 to 8 kilograms per square meter).

7-1.4.2 Roll the Sand.

Immediately roll the sand with a pneumatic roller after spreading.

7-1.5 Sweep Excess Material.

Sweep the area with a vacuum sweeper after the treated area has sufficiently cooled to remove excess sand.

7-1.5.1 Aggregates.

Use clean, angular, and durable aggregate in a slurry seal or microsurfacing. The minimum sand equivalent value for aggregate used in a slurry seal is 45 (ASTM D2419, *Standard Test Method for Sand Equivalent Value of Soils and Fine Aggregate*, AASHTO T176, *Standard Method of Test for Plastic Fines in Graded Aggregates and Soils by Use of the Sand Equivalent Test*) and a maximum Los Angeles abrasion test value of 35 in the parent rock (ASTM C131, *Standard Test Method for Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine*, AASHTO T96, *Standard Method of Test for Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine*).

Ensure the aggregate used in microsurfacing has a minimum sand equivalent value of 65 and a maximum Los Angeles abrasion test value of 30 in the parent rock. In addition, limit the maximum soundness value of aggregates for slurry seals and microsurfacing to 15 percent in the parent rock using Na_2SO_4 (sodium sulfate) or 25 percent using $MgSO_4$ (magnesium sulfate) testing (ASTM C88, *Standard Test Method for Soundness of Aggregates by Use of Sodium Sulfate or Magnesium Sulfate*, AASHTO T104, *Standard Method of Test for Soundness of Aggregate by Use of Sodium Sulfate or Magnesium Sulfate*).

7-1.6 Problem Areas.

Table 7-4 lists the impacts for each type of surface treatment. Many problems associated with surface treatments occur after its service life has passed. Actual service life depends on the product, application method, application rate, and pavement surface preparation. Some surface treatments are only intended to last a few years while others remain effective in excess of eight years.

Table 7-4 Potential Negative Impacts of Surface Treatments to Airfields

Surface Distress	Liquid Spray Seal	Liquid and Sand Spray Seal	Slurry Seal	Microsurfacing
Decreased friction	H	H	P	N
Debonding	N	P	H	P
Raveling	N	P	P	P

N - Not a significant concern

P - Potential for minor impact

H - High potential for impact

CHAPTER 8 ASPHALT SLURRY SEALS AND MICROSURFACING

8-1 INTRODUCTION.

A slurry seal is a mixture of asphalt emulsion, aggregate, water, and mineral filler. Slurry seals are used to seal and protect worn, weathered, and cracked pavement from the effects of further weather and traffic. Another use is to improve friction properties. A special form of slurry seal has been used in high-traffic areas up to and including interstate highways. Microsurfacing is a heavy-duty slurry seal and includes the use of a polymer-modified asphalt binder. This product has been used to fill ruts on high-volume roadways. In traffic areas, use microsurfacing or slurry seals a maximum of two times between overlays and consider on five- to seven-year cycles. Do not use a slurry seal or microsurfacing on airfield pavements or other high-traffic areas without approval from the contracting officer or Pavements DWG or their designated representative.

8-2 MIXTURE MATERIALS.

8-2.1 Emulsions.

Use one of the following emulsions in a slurry seal: SS-1, SS-1h, CSS-1, or CSS-1h. Use a polymer-modified asphalt binder for microsurfacing. Some microsurfacing mixtures are proprietary products.

8-2.2 Aggregate.

Use clean, angular, and durable aggregates in slurry seals or microsurfaces. Slurry seals and microsurfacing use well-graded aggregates and are classified according to the gradation of the aggregate used. Use aggregates with a minimum sand equivalent value of 45 (ASTM D2419, AASHTO T176) and a maximum Los Angeles abrasion test value of 35 in the parent rock (ASTM C131, AASHTO T96) in slurry seals. Use aggregates with a minimum sand equivalent value of 65 and a maximum Los Angeles abrasion test value of 30 in the parent rock in microsurfaces. In addition, limit the maximum soundness value of aggregates for slurry seals and microsurfacing to 15 percent in the parent rock using Na_2SO_4 (sodium sulfate) or 25 percent using $MgSO_4$ (magnesium sulfate) testing (ASTM C88, AASHTO T104).

Use the aggregate gradations in Table 6-1 and application rates in Table 6-2 when slurry sealing or microsurfacing. The gradations typically include 0.5 to 3.0 percent mineral filler. Use only Type II and Type III gradations for airfield applications. Aggregate gradations to be used are shown in Table 8-1.

8-2.3 Filler.

Use portland cement or hydrated lime if a filler is needed in the slurry. The filler tends to improve the stability of the mixture. If stability or segregation problems occur, use mineral filler at 0.4 to 0.5 percent of the total mixture. Water is the primary control for workability of the mixture; therefore, use only potable water.

Table 8-1 Aggregate Gradations for Microsurfacing and Slurry Seals

Sieve Size	% Passing by Weight, Gradation Designation		
	Type 1	Type 2	Type 3
3/8 in. (9.5 mm)	100	100	100
No. 4 (4.8 mm)	100	90 - 100	70 - 90
No. 8 (2.4 mm)	90 - 100	65 - 90	45 - 70
No. 16 (1.2 mm)	65 - 90	45 - 70	28 - 50
No. 30 (600 µm)	40 - 65	30 - 50	19 - 34
No. 50 (300 µm)	25 - 42	18 - 30	12 - 25
No. 100 (150 µm)	15 - 30	10 - 21	7 - 18
No. 200 (75 µm)	10 - 20	5 - 15	5 - 15
Application Rate (lb/yd^2 dry aggregate)	8 - 12	12 - 20	18 - 30

8-3 SLURRY SEAL PROCEDURAL STEPS.

Place a slurry seal using the following steps:

8-3.1 Prepare the Surface.

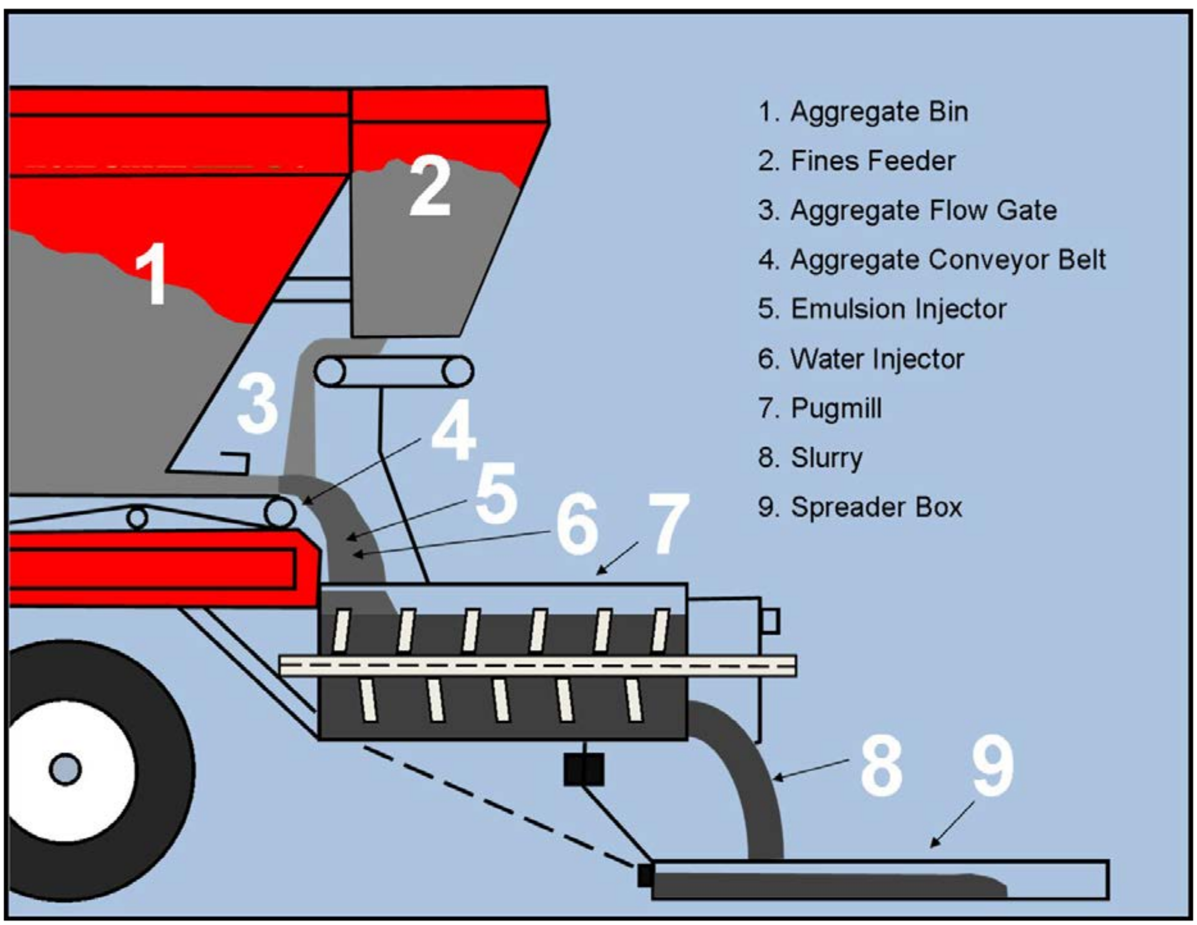
Remove all loose material (including any loose or flaking paint), dirt, and vegetation from the surface. Seal cracks greater than 0.125 inch (3 millimeters) wide. Place the sealant 0.125 to 0.25 inch (3 to 6 millimeters) below the surface during crack sealing. After sealing all cracks and cleaning the surface, spray a very light tack coat at a rate of 0.05 to 0.10 gallon per square yard (0.23 to 0.45 liter per square meter) and allow to fully cure.

8-3.2 Apply the Slurry.

Apply a fog spray of water to the surface with the spray bar on the slurry machine immediately before applying the slurry. Ensure there is no standing water after the spray. Adjust the spray to compensate for temperature, surface texture, humidity, and dryness of the surface. Apply the slurry with a slurry machine (Figure 8-1). The slurry machine is a self-propelled, continuous-flow mixing unit. Provide and use a device that is capable of delivering the proper amount of aggregate, water, mineral filler, and emulsion to the mixing unit. The mixing unit is either a single or double pugmill mixer. The mixing unit discharges the material into the spreader box that is equipped with flexible squeegees and width adjustment. Other parts of the machine include the spray bar for wetting the pavement and an aggregate prewetting device.

Use a burlap drag behind the spreader box to improve the joints and improve the texture and appearance of the mixture. Apply the slurry from 0.125 inch (3 millimeters) up to but no more than 0.25 inch (6 millimeters) thick in one pass. If more than one pass is applied, fully cure the previous layer before applying the second application.

Figure 8-1 Slurry Seal Spreader Machine



8-3.3 Rolling the Slurry.

A slurry seal is not always rolled but rolling does provide improved performance. Roll the slurry to reduce voids, limit surface imperfections, and increase the slurry's resistance to water. Roll the slurry after it has cured enough to support the roller without removing any of the slurry mixture. Use a 5-ton (4,540-kilogram) pneumatic-tire roller with tire pressures of 50 pounds per square inch (345 kilopascals) to roll the slurry.

Cure the Slurry.

The time to allow for curing will vary according to the application rate of the emulsion and aggregate and weather conditions. The slurry cures by evaporation of water from the surface, by deposition of asphalt on the aggregate which frees the water, or by a combination of these. The material at the top will typically cure faster than the material at the bottom. Fully cure the slurry seal before opening the treated area to traffic.

8-3.4 Problem Areas.

Construct a test strip to ensure proper slurry machine calibration and correct mixture. Do not overwork the slurry when hand-applying the slurry; overworking causes the emulsion to break prematurely. Apply the second lane while the edge of the previous lane is still fluid and workable, if possible. If the previous lane's edge is not workable then allow the slurry material to cure enough for the spreader box to not damage the previous lane. Keep the burlap drag clean and replace when necessary. Material buildup on the burlap drag causes streaking and gouging. Inspect the flexible lining of the spreader box for wear or accumulation of cured slurry. Replace the lining when worn. Remove any cured slurry from the lining.

8-3.4.1 General Rule.

Do not place surface treatments on asphalt concrete pavements during the first year of service without approval of the Pavements DWG or their designated representative.

8-3.4.2 Fog Seal Consideration.

Do not apply a fog seal over a slurry seal or microsurface without approval of the Pavements DWG or their designated representative.

8-3.4.3 Slurry Seal Consideration.

Do not use slurry seals on airfield pavements where frequent ice/snow removal occurs without approval of the Pavements DWG or their designated representative. Ice/snow removal equipment can potentially tear the slurry from the underlying pavement.

8-3.4.4 Surface Treatments and Fuel Spillage.

Do not use these surface treatments in areas prone to fuel spillage without approval of the Pavements DWG or their designated representative. Alternative fuel-resistant sealers are appropriate for these areas.

8-3.4.5 Surface Treatments and Crack Sealing.

The use of surface treatments does not negate the need for routine crack sealing. Crack sealing is an additional maintenance procedure required to extend the life of asphalt concrete pavements. Using a slurry seal or microsurfacing results in smaller cracks being sealed but larger cracks will continue to need sealing.

8-3.5 Negative Impacts.

Table 7-4 lists the potential negative impacts for each type of surface treatment. Many problems associated with surface treatments occur after its service life is passed. Actual service life depends on the product, application method, application rate, and pavement surface preparation. Some surface treatments are only intended to last a few years, while others remain effective in excess of eight years.

This Page Intentionally Left Blank

CHAPTER 9 ASPHALT CRACK SEALING

9-1 INTRODUCTION.

The purpose of sealing cracks in asphalt pavements is to protect the pavement structure from premature failure. The use of proper crack preparation and sealing techniques can extend the effective life of the sealant, thereby increasing the life of the pavement and reducing maintenance costs. Unsealed cracks allow water intrusion and debris retention in the crack opening. Water intrusion in the cracks penetrates into the base and subbase materials, creating the potential for a loss of strength in these materials. The weakened pavement structure can result in load-related failures such as alligator cracking (Figure 9-1). The debris retention can cause the pavement to “push up” at the edges of the crack when the pavement expands due to thermal changes. This decreases the rideability of the pavement surface. These failures and deficiencies increase the lifecycle cost of the pavements by requiring increased maintenance.

Figure 9-1 Alligator Cracking

9-2 WHEN TO SEAL.

9-2.1 Field Evaluations.

Conduct field evaluations at least twice a year, once during the summer months and once during the winter months. Seasonal evaluations will enable a determination of the number and size of cracks and allow performance evaluations of any existing sealant when the cracks are at their smallest and largest width. Consider sealing when cracks have become approximately 0.25 inch (6 millimeters) wide. Do not seal cracks less than 0.25 inch (6 millimeters) wide unless they cover a large percentage of the pavement.

Use a surface treatment such as seal coating or overlay on pavements that have many cracks less than 0.25 inch (6 millimeters) wide or smaller.

9-2.2 Schedule.

Plan and schedule crack sealing in accordance with field evaluations. Make spot repairs to sealed cracks where the sealant material has failed. Figures 9-2 and 9-3 show typical areas in need of sealing. Consider a major resealing project when a large percentage of the area has failed sealant or cracks with no sealant at all.

Figure 9-2 Reflective Cracking

Figure 9-3 Longitudinal Cracking

9-2.3 Climatic Conditions.

Schedule crack sealing projects during the normal construction season. A normally low rainfall period in the spring or fall is preferred. Do not seal crack(s) until the temperature of the pavement is 50 degrees F (10 degrees C) and rising. Do not seal crack(s) until the crack is free of moisture and debris.

9-2.4 Porous Friction Surfaces.

The guidelines for sealing cracks in a porous friction surface (PFS) are different from a normal asphalt surface. Use the procedures in Chapter 10 for sealing cracks in a PFS.

9-3 SPECIFICATIONS.

9-3.1 ASTM.

Use crack sealant conforming to ASTM D6690, *Joint and Crack Sealants, Hot Applied, for Concrete and Asphalt Pavements*. When selecting a sealant, consider climatic regional temperature performance. Also consider sealant characteristics in high-volume pedestrian traffic where some materials have a tendency to track onto the pavement and stick to the soles of shoes.

9-3.2 Other Specifications.

Rubberized asphalt sealants that are not covered by the above specifications can be used only on roads and only when an appropriate state department of transportation (DOT) or local municipality material specification is available and after the sealant has been approved by the AFCEC Pavements SME, NAVFAC Pavements SME, or USACE Transportation Systems Center (TSMCX) pavement engineer. The DOT and local specifications will often be modified to account for the temperature variations of the region. Asphalt cements that contain synthetic fibers have been used successfully on a limited basis as a crack sealant. Use state or municipality specifications for these materials but only after the sealant has been approved by the Pavements DWG or their designated representative.

9-3.3 Testing.

Test the crack sealant material by a government-approved independent laboratory for specification conformance before it is used on a project. If the quantity of sealant for the project is less than 500 pounds (227 kilograms) then the manufacturer’s certificate of compliance may be accepted in place of testing. Evaluate local field performance data from past sealing projects, if available, to determine which type of sealant to seal the cracks.

9-4 CRACK SEALING PROCEDURAL STEPS.

9-4.1 Crack Size Guidelines.

Procedures for sealing will vary depending upon the size of the crack. Use the following steps as a guide:

9-4.1.1 Hairline Cracks (Less Than 0.25 Inch [6 Millimeters]).

See Figure 9-4. It is very difficult to successfully insert sealant material into a crack that is less than 0.25 inch (6 millimeters). Typically, these cracks are not sealed unless they cover 80 percent or more of the pavement area. If the cracks do require sealing, a surface treatment could be the most effective method. The surface treatment used will depend upon the area being treated and the predicted future traffic. A SBST or DBST could be satisfactory for a roadway or parking lot but not for an airfield. Surface treatments and slurry seals are not recommended for airfields that will encounter jet and high-tire-pressure aircraft because the surface treatment or slurry seal will normally deteriorate quickly. Consider options such as an asphalt overlay or pavement recycling for airfield pavements. For additional information on various types of surface treatments, see UFGS 32 12 36.13, *Asphaltic Seal and Fog Coats,* UFGS 32 12 11, *Bituminous Surface Treatment,* and UFC 3-250-03.

9-4.1.2 Small and Medium Cracks (0.25 to 2 Inches [6 to 50 Millimeters]).

See Figures 9-5 and 9-6. Widen small cracks to a nominal width of 0.125 inch (3 millimeters) greater than the existing nominal or average width. Widening the cracks 0.125 inch (3 millimeters) will help eliminate the potential for raveling of the pavement along the edges of the crack and will provide a sealant reservoir with vertical faces. After the crack has been cleaned and inspected, it is ready for sealing. The depth of the cracks to be sealed is determined and, if the depth is greater than 0.75 inch (19 millimeters), a backer rod material is inserted. If the depth of the crack is not deep enough to accommodate the backer rod and maintain a sealant depth of 0.5 to 0.75 inch (13 to 19 millimeters) then the crack can be routed or the backer rod material omitted.

9-4.1.3 Large Cracks (Greater Than 2 Inches [50 Millimeters]).

See Figure 9-7. Fill cracks that are 2 inches (50 millimeters) and larger with a sand asphalt or fine-graded asphalt mix and compacted. The procedures and equipment used are identical to those used to repair potholes. Cut or route the edges vertical and clean the cracks to obtain a patch that meets the specified requirement. The asphalt material could prematurely fail if the proper cleaning and patching procedures are not followed. Square by sawing, fill with asphalt mix, and compact the cracks. Refer to TM 5-624/NAVFAC MO-102/AFJMAN 32-1040, *Maintenance and Repair of Surface Areas*, for additional information.

9-4.1.4 Cracks in Pavements to be Overlaid.

Small and medium cracks in pavements to be overlaid are usually not filled prior to overlay. Also, if milling occurs, it is very difficult to locate these small cracks so sealing will be very difficult. However, many designers require these cracks to be filled with an emulsion, a sand emulsion mixture (Figure 9-9), or one of the types of sealants previously mentioned. Recess the material in the crack a minimum of 0.25 inch (6 millimeters) to prevent the material from “bleeding” through the overlay. Bleeding occurs when the asphalt cement in the crack sealant material is drawn to the surface of the overlay. Bleeding causes the pavement above the crack to become soft and a crack or bump in the overlay is usually the end result.

9-4.2 Crack Widening.

Use a router to widen meandering cracks. Use a saw with a small-diameter blade to widen straight cracks. When a saw is used, clean the crack with a high-pressure water stream or a sandblaster to remove debris created by the saw. The recommended procedure is to use a router since water would not be required. When resealing, remove all of the old sealant from the crack. After the crack has been widened or the existing sealant has been removed, clean the crack to prevent any debris from contaminating the crack.

9-4.3 Initial Crack Cleaning.

Use the sandblasting equipment, water-blasting equipment, HCA heat lance, or wire brushes to clean cracks. Information about this equipment follows:

9-4.3.1 Sandblasting.

When sandblasting equipment is used, establish a technique that enables both faces of the crack to be sandblasted. Use a multiple-pass technique consisting of positioning the sandblaster nozzle approximately 1 inch (25 millimeters) above the pavement surface, sandblasting the entire length of one crack face then sandblasting the entire length of the opposite crack face. Sandblast approximately 1 inch (25 millimeters) of the pavement surface on both sides of the crack to remove debris. Do not over-blast the cracks. Over-blasting can damage the pavement, causing raveling and premature bond failure of the sealant. Demonstrate the cleaning technique on 5 feet (1.5 meters) of cracks in an area not subject to direct wheel traffic to ensure proper techniques are used.

9-4.3.2 Water Blasting.

Water-blast the crack faces and pavement surfaces extending a minimum of 0.5 inch (13 millimeters) from the crack edges. Use a multiple-pass technique until the surfaces are free of dust, dirt, old sealant residue, or foreign debris that might prevent the sealant material from bonding to the asphalt pavement. After final cleaning and immediately prior to sealing, blow out the cracks with compressed air and leave them completely free of debris and water. Excessive water pressure can cause damage to the asphalt adjacent to the crack and result in loss of material. If the pressure is too low then the joint will not be properly cleaned. Demonstrate the cleaning technique on 5 feet (1.5 meters) of cracks in an area not subject to direct wheel traffic to ensure proper techniques are used.

9-4.3.3 HCA Heat Lance.

Use the HCA heat lance when the pavement is wet and/or cold (pavement temperature below 50 degrees F [10 degrees C]). Use extreme care to ensure the crack faces do not become overheated or burned. Overheating the crack faces will greatly reduce the life expectancy of the seal and adjacent pavement. Adhesion failure of the sealant or additional cracking of the pavement between the area that was overheated and the remainder of the pavement is expected.

9-4.3.4 Wire Brushes.

Wire brushes are sometimes used during sealing projects; however, wire brushes are not always capable of removing debris from the crack faces and this debris can cause adhesion failures. Inspect the wire brushes to ensure they are not worn. Inspect the cleaned crack to ensure all debris and dust have been removed.

9-4.4 Debris Removal.

Remove debris from the crack after water-blasting or sandblasting. This method normally removes the debris more effectively with less chance of pavement damage.

9-4.5 Final Crack Cleaning.

Once the old sealant and debris have been removed from the crack, clean the crack with compressed air. The compressed air is blown into the crack to remove sand or any debris that was loosened during the initial cleaning. The compressed air also helps remove moisture.

9-4.6 Inspection.

Inspection is the final phase of crack preparation. Inspect the crack for cleanliness and dryness. It is essential for the crack to be clean and dry so the sealant will adhere to the pavement. One method to check for cleanliness is to rub one’s finger along the crack face. If a dusty residue is left on the finger, re-clean the crack. If there is no residue, the crack is ready for sealing.

9-4.7 Crack Cleaning Summary.

The cleanliness of the crack is one of the most important factors in crack preparation that affects the life of the sealant. It is not the only important factor, but it is one that can be controlled. After the crack has been inspected and approved for cleanliness, the crack is ready to be sealed (Figure 9-8).

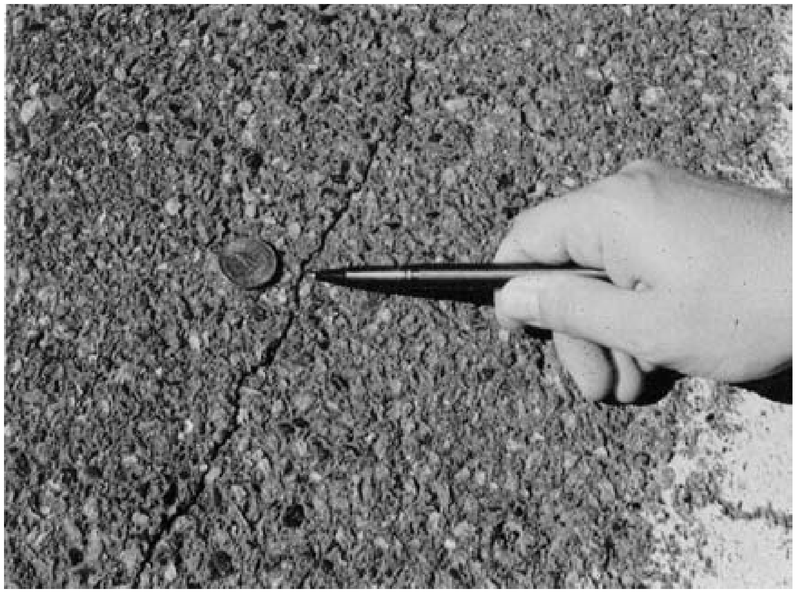

Figure 9-5 Small Crack

Figure 9-6 Medium Crack

Figure 9-7 Large Crack

Figure 9-8 Crack After Cleaning

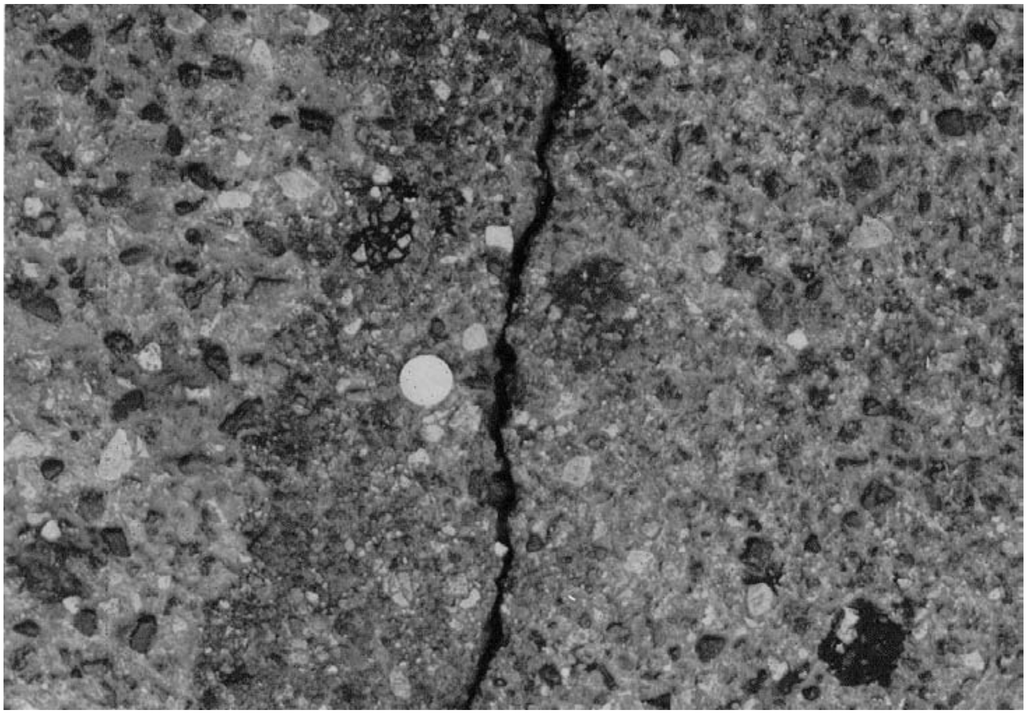

Figure 9-9 Filling Crack with Sand Emulsion Mixture

9-4.8 Backer Rod Material.

The backer rod (Figure 9-10) is a compressible, non-shrinking, non-absorptive material. Provide and use backer rods whose melting point is higher than the pouring temperature of the sealant. Provide and use backer rod that is approximately 25 percent wider in diameter than the nominal width of the crack. The larger size will enable the sealant to be inserted without dislodging the backer rod. Place the backer rod to a depth that will provide a shape factor (depth-to-width ratio) of approximately 1 for petroleum-based sealants. However, do not place the top of the backer rod deeper than 0.75 inch

(19 millimeters). This will provide a reservoir for the sealant that will minimize the internal stresses in the sealant. High internal stresses can create cohesion failure, split the material, or dislodge loose aggregate from the pavement, damaging the effectiveness of the seal. However, if the shape factor is too small, adhesion failure can occur; therefore, it is important to maintain the proper shape factor.

Figure 9-10 Examples of Backer Rod Materials

9-4.9 Inspection Prior to Sealing.

Inspect the cracks immediately prior to sealing. Ensure the backer rod is at the specified depth and that debris has not been blown into the crack. Clean cracks are essential in obtaining adhesion between the sealant and the crack face.

9-4.10 Sealant Temperature and Application.

Check the temperature of the sealant to ensure it is at the manufacturer's recommended application temperature. Insert the nozzle of the application equipment into the crack and seal the crack from the bottom to the top (Figure 9-11). Sealing in this manner minimizes bubbling of the sealant due to entrapped air. Recess the sealant approximately 0.125 to 0.25 inch (3 to 6 millimeters) below the pavement surface to prevent tracking. Remove excess sealant with a squeegee or similar equipment.

Figure 9-11 Sealing the Crack

9-4.11 Crack Sealing Delays.

Blow out with compressed air before sealing any cracks that are not sealed the same day they are prepared. Clean and dry cracks again if rain delays the sealing operation to remove any debris that may have been washed into the crack by rain. Use the sandblaster, wire brushes, or HCA heat lance, but not by using only compressed-air cleaning to remove debris washed in by the rain.

9-4.12 Inspection After Sealing.

Inspect the sealant to ensure the sealant is bonding to the pavement and that the cracks were not overfilled after the cracks have been sealed (Figure 9-12). Overfilled material can track onto the pavement surface and/or stick to pedestrians' shoes. Inspect the sealant to ensure the proper sealant recess has been obtained. Sealants that are not properly recessed will be pushed above the pavement surface as the pavement expands and become damaged by traffic. Cracks that have been under-filled can have additional crack sealant applied.

Figure 9-12 Crack After Sealing

9-5 PROBLEM AREAS.

9-5.1 Categories of Problems.

Many problems that arise during a sealing project can be divided into three categories: crack sealant materials, crack preparation, and crack sealant application. The following information is presented for these three sealing problems:

9-5.1.1 Materials.

One of the main problems associated with sealant materials is nonconformance to the required specification. Test the sealant through an independent laboratory to minimize this problem. Another problem is a combination between materials and application that involves the sealant not setting up or curing after it has been applied to the crack. This problem is often caused by overheating the sealant before it is applied to the crack. The overheating can be caused by heating the sealant at too high a temperature or heating it at the recommended pouring temperature for a longer period of time than recommended by the manufacturer.

Most sealants used to seal cracks in asphalt concrete pavements are asphalt cement-based materials and overheating causes the light volatiles to “cook off” or evaporate. This causes the sealant to become brittle, resulting in premature failure of the sealant. Monitor the temperature of the sealant in the application equipment and discard any material that is overheated or heated for longer than four hours to eliminate this problem. Discard the sealant remaining in the equipment and thoroughly clean the equipment after each day’s work has been completed.

9-5.1.2 Preparation.

The main problem associated with crack preparation is the cleanliness of the crack. The crack sealant will not adequately bond to the pavement if there is oil, dust, debris, or loose aggregate remaining in the crack. Damaging the pavement during the routing process can also be a problem. Prevent jamming in the crack by following each crack and controlling the speed of the equipment. Dry the crack prior to placing sealant to prevent the moisture from vaporizing when the sealant is placed, which will result in loss of bond to the crack wall.

9-5.1.2.1 Dust and Debris.

Checking for dust and debris in the crack is a relatively simple procedure: rub a finger along the crack; if the finger gets dusty, the crack is dirty. Checking for moisture is more of a judgment decision. There is no test for checking the moisture of a crack except by observation or feeling with one’s hand. It is important that the crack is dry at the time of sealant application so the sealant will bond to the pavement.

9-5.1.2.2 Crack Preparation Methods.

An additional problem dealing with crack preparation is deciding which method to use. This is a problem because most cracks are not uniform in size and the surrounding pavement will have varying degrees of deterioration. Make adjustments as work progresses. The main consideration for crack preparation is that the crack be cleaned without damaging the surrounding pavement.

9-5.1.3 Application.

There are two major problems associated with crack sealant application. The first problem is brittleness of the sealant material due to overheating or prolonged heating. Brittleness is a materials problem because some sealant materials are more susceptible to overheating than others, but it is also an application problem because it can be corrected by implementing a good quality control program. Monitor the temperature of the sealant and discard any material that is overheated or heated for longer than four hours to eliminate this problem. Discard the sealant remaining in the equipment and clean the equipment thoroughly after each day’s work has been completed.

The second problem is overfilling the crack. The sealant can be tracked onto the pavement and abraded if the crack is overfilled. Reduce, if not eliminate, overfilling the crack by vigilant quality control measures and inspection. Remove excess sealant with a squeegee or similar object before the sealant cools. Fill from the bottom up to prevent entrapped air.

CHAPTER 10 POROUS FRICTION SURFACES.

10-1 INTRODUCTION.

A porous friction surface (PFS) is an open-graded asphaltic concrete wearing surface containing a large amount of air voids that allow water to drain vertically and laterally through the pavement structure (Figure 10-1). These surfaces are usually 0.75 to 1 inch (19 to 25 millimeters) thick and the large void content provides a means to prevent hydroplaning at high speeds. The surface texture of the PFC provides excellent skid resistance and decreases tire spray under wet conditions. Several procedures to repair a PFS are presented in the following paragraphs.

Figure 10-1 View of a Porous Friction Surface (PFS)

10-2 SEALING CRACKS.

The guidelines for sealing cracks in a PFS are different from a normal asphalt surface. The materials used for sealing cracks on a PFS are the same as for a normal asphalt pavement. Use the following steps for sealing cracks on a PFS:

10-2.1 Prepare the Crack.

To prepare the crack, remove all loose material and ensure the crack is free of dust and dirt.

10-2.2 Seal the Crack.

Follow the same sealant placement procedures as for an asphalt surface (Chapter 9). Do not seal cracks 0.25 inch (6 millimeters) wide or less unless loose debris is causing a FOD problem. Seal cracks from 0.25 to 0.75 inch (6 to 19 millimeters) if they are raveling and causing a FOD problem. Fill cracks greater than 0.75 inch (19 millimeters) wide with a PFS asphalt mixture and rolled with a steel-wheel roller. Only seal longitudinal cracks when regular sweeping methods no longer remove all loose aggregate from the surface. The loose aggregate can block internal drainage. Seal transverse cracks except those perpendicular to the water flow. In any case, do not seal the joint if it will interfere with water drainage.

10-2.3 Patching PFS.

If correctly performed, a PFS patch is indistinguishable from the remainder of the surface. Patch PFS using the following steps:

10-2.3.1 Remove Defective PFS.

Do not saw PFS when patching. Only use a milling machine to remove any defective PFS. Mill the full depth and extent of PFS damage.

10-2.3.2 Clean and Tack Repair Area.

Remove the defective material and, if necessary, repair the underlying pavement. Thoroughly clean the repair area before placing the tack coat. Apply a light tack coat to the bottom of the repair area. Do not apply tack coat to the edges of the repair areas as this will clog or interfere with the flow of water through the PFS.

10-2.3.3 Place Patch Material.

Provide and use repair material that conforms to the existing PFS. Roll the repair material using the same method as the original construction after material is placed. A cold-mix asphalt can be used for a temporary repair.

10-2.4 Raveling Control.

Apply a very light spray of asphalt emulsion to help control raveling of the PFS until replacement of the area can be completed. If this procedure is performed, do not apply so much as to hinder drainage of the PFS.

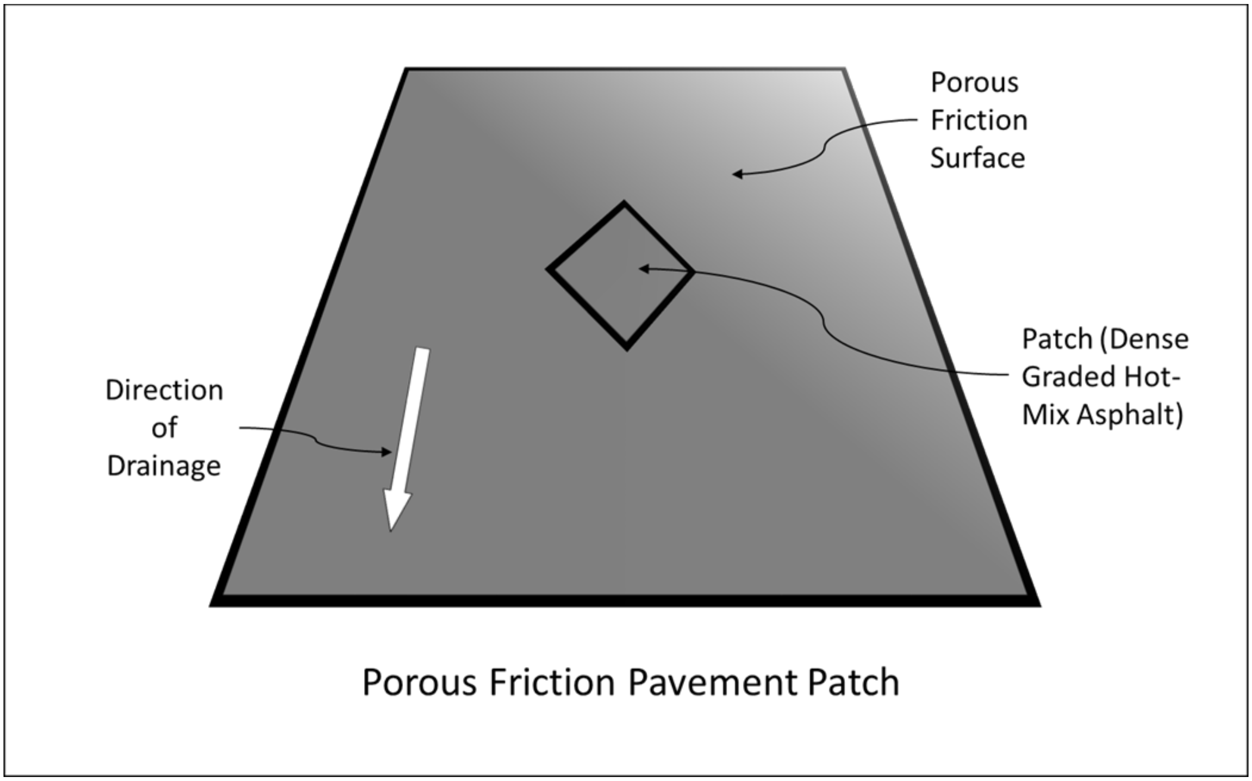
10-2.5 Patching Using Standard Hot Asphalt Plant Mix.

If a standard hot asphalt plant mix is used to repair a PFS, employ the following steps:

10-2.5.1 Mark the Repair Area.

Lay out and mark the boundaries of the repair for saw cutting. Shape the patch as a diamond with a point of the diamond at the highest elevation (Figure 10-2). This will allow water to flow around the patch area.

Figure 10.2. Porous Friction Pavement Using Hot-Asphalt Plant Mix



10-2.5.2 Remove Defective PFS.

Saw the area to the thickness of the porous friction surface. Remove defective material. Do not damage the edges of the patch.

10-2.5.3 Place Patch Material.

Apply tack coat to the sides and bottom of the patch area. Do not over-apply the tack coat. After the tack coat has cured, place and compact a well-graded hot asphalt plant mix.

CHAPTER 11 DIAMOND-GRINDING ASPHALT CONCRETE PAVEMENTS

11-1 INTRODUCTION.

Diamond grinding, using closely spaced diamond saw blades mounted on a rotating shaft, removes a thin layer of the concrete surface to correct for faults at joints and crack locations and correct for surface defects, such as wheel path rutting. As such, diamond grinding results in re-profiling the pavement and improves the pavement's ride quality.

Diamond grinding removes bumps, re-profiles pavements, removes surface defects, and restores the pavement to a smooth surface. Because the hardness of the aggregate will influence the grinding operation, identify the type of aggregate in the asphalt pavement when the work is to be contracted. Limit grinding to small, localized areas. Do not grind more than 10 percent of the surface area without prior approval of the Pavements DWG or their designated representative.

11-2 NEED FOR GRINDING.

Consider diamond grinding when a pavement has bumps in excess of 0.125 inch (3 millimeters), roughness in excess of 0.125 inch (3 millimeters) in a 10-foot (3-meter) length, or rutting up to 0.375 inch (10 millimeters). If skid resistance is to be examined, examine skid resistance on the areas not scheduled for grinding for any of the previously mentioned defects. **[caution missing as in Ch. 17]**

11-3 GRINDING PROCESS.

The diamond-grinding process results in less impact than milling. The pavement grinder is similar to a wood plane. The front wheels are designed to pass over a fault or bump, the cutting head shaves it off, and the rear wheels ride in a smooth path left by the cutting head. Diamond grinding requires heavy, specially designed equipment (Figure 11-1) that uses diamond saw blades gang-mounted on a cutting head. Spacers are placed between the saw blades to reduce the amount of cutting to be done. This combination of saw blades and spacers gives the pavement the characteristic corduroy texture that improves skid resistance.

Figure 11-1 Diamond Grinding Equipment

11-4 TEST SECTION.

Before work begins, use the equipment in a test section to ensure that proper blade spacing is being used for the specific aggregate on the project. The width of the spacers between the saw blades varies depending on the hardness of the aggregates. The harder the aggregate, the thinner the spacing between the blades. When grinding aggregate susceptible to polishing, use a wider spacing.

11-5 GRINDING PROCEDURE.

When areas have been identified as being too rough, set a level of restoration and grind sections having excess roughness. Test the roughness again following the grinding. Test using a California profilograph (Figure 11-2), Mays Ride Meter, or 12-foot (3.7-meter] straightedge. Establish the grade prior to grinding. Do not use the old pavement surface as the reference unless a long beam or skid is used. Grinding a sag will not remove roughness.

Skid resistance can be improved by grinding. Only grind those lanes needing improved friction. Feather the edges of the ground areas into the adjoining pavement to eliminate a sharp drop-off. Grind the pavement in the longitudinal direction. Produce a uniform finished surface and provide positive lateral surface drainage. Continuously remove the slurry residue resulting from the grinding operation. Do not permit the grinding slurry to flow across adjacent lanes into gutters or flow into other drainage facilities.

Figure 11-2 California Profilograph

11-6 ACCEPTANCE TESTING.

Test the pavement for smoothness after completing the grinding and texturing. Accept only those pavement surfaces that meet the surface tolerance for a new pavement as required by the specifying agency. Use the same test equipment and procedure used in the initial evaluation for the acceptance testing. Do not reduce the nominal load-carrying capacity of the pavement through grinding without prior approval of the Pavements DWG or their designated representative.

This Page Intentionally Left Blank

CHAPTER 12 CONCRETE PAVEMENT CRACK SEALING

12-1 INTRODUCTION.

Concrete pavement cracking is a result of tensile stress in the concrete slab exceeding the tensile strength of the concrete at the time of cracking. The cracking may develop soon after concrete placement or develop after some time. The cracking may be due to a number of factors such as marginal pavement design, poor construction practices, environmental conditions, and repeated traffic loading (fatigue related). The cracking may include the following types of cracks: transverse cracking, longitudinal cracking, corner cracking, or randomly oriented cracking.

Crack sealing, together with joint resealing, is the most commonly performed pavement maintenance activity. It reduces the amount of moisture that can infiltrate a pavement structure, thus reducing moisture-related distresses such as pumping, crack faulting, base and subbase erosion, and corner breaks at crack locations. It also prevents the intrusion of incompressible materials so compression-related distresses such as crack spalling, blowups, and slab shattering are minimized. The compression-related damage typically occurs at or along cracks oriented in the transverse direction; however, joint spalling can be of concern for cracks oriented in other directions.

Crack sealing is most effective when performed on concrete pavements that exhibit low-severity structural deterioration and when the cracks are full-depth but relatively narrow, with minimal spalling. Crack sealing may be used on cracks of low or medium severity where the crack width is 0.5 inch (13 millimeters) or less. If load transfer restoration (LTR) or partial-depth patching at the crack location is to be applied, seal cracks after these activities have been completed. If the cracks have deteriorated and exhibit a high degree of spalling, consider full-depth patching.

12-2 KEY STEPS.

The key steps in performing effective crack sealing include the following:

- Old sealant removal, if any
- Crack sawing/routing to specified depth and width
- Crack reservoir cleaning by sandblasting, water-blasting, and air-blasting
- Backer rod installation to control depth of sealant
- New sealant installation, typically hot-poured or cold-poured

12-3 GENERAL PRACTICE.

The general practice is to make only small sections of repair at a time to prevent the sawed or routed crack faces from being exposed to weather for more than 24 hours. If the cracks are wet, dry them with a high-pressure air compressor before placing the sealant and backer rod.

12-4 TEST SECTION.

Saw or route a test section of approximately 200 linear feet (60 meters) of cracks. Do not begin the full crack-sealing project until the contracting officer has approved a successful test section. Re-accomplish the test section until it meets requirements and is approved. Use the same procedures and materials in the full project that were used and approved in the approved test section. Demonstrate that crack sawing or routing does not cause spalling exceeding 0.25 inch (6 millimeters) in width or depth. Demonstrate cleaning of the crack faces before placement of any sealant. For two-component sealants, demonstrate and verify the mixing ratio is within a specified tolerance according to the manufacturer’s specifications for that particular sealant. If using hot-applied sealants, use calibrated thermometers to verify correct application temperatures. Demonstrate that all equipment is in good working condition.

Use sealant that conforms to UFGS 32 01 19, *Field Molded Sealants for Sealing Joints in Rigid Pavements,* or the applicable ASTM specifications and is approved for use at a particular facility by the base engineer.

12-5 CRACK SEALANTS.

Concrete crack repair sealants are essentially the same as joint sealants. Crack sealants mitigate two problem areas: moisture intrusion into the pavement base and debris retention in the crack opening. Crack sealants are either hot-applied thermoplastic materials or cold-applied thermosetting materials.

12-5.1 Hot-Applied Sealants.

Hot-applied thermoplastic sealant materials are bitumen-based materials that typically soften upon heating and harden upon cooling, usually without a change in chemical composition. These sealants vary in their elastic and thermal properties and are affected by weathering to some degree. Thermoplastic sealants are typically applied in a heated form and include the following:

- Rubberized asphalt: Self-leveling (most commonly used)
- Polymeric materials: Self-leveling
- Elastic materials: Jet fuel-resistant
- Elastomeric polyvinyl chloride (PVC) coal tar: Jet fuel-resistant

12-5.2 Cold-Applied Sealants.

Cold-applied thermosetting sealant materials are typically one- or two-component materials that either set by the release of solvents or cure through a chemical reaction. These sealants cost more than the commonly used rubberized asphalt sealants. Liquid oxygen (LOX) is a one-component cold-applied thermosetting compatible sealant. Thermosetting sealants include the following:

- Silicone (most widely used):
    - Non-sag, toolable, low modulus
    - Self-leveling, low modulus
    - Self-leveling, ultra-low modulus
- Polysulfide and polyurethane: Self-leveling, low modulus
- Two-component elastomeric polymer: Jet fuel-resistant
- W.R. Meadows Poly-Jet LOX

<u>Caution:</u> The performance of sealant material is sensitive to crack reservoir moisture and cleanliness. Do not use expensive sealant materials unless good sealant installation practices can be assured at the job site.

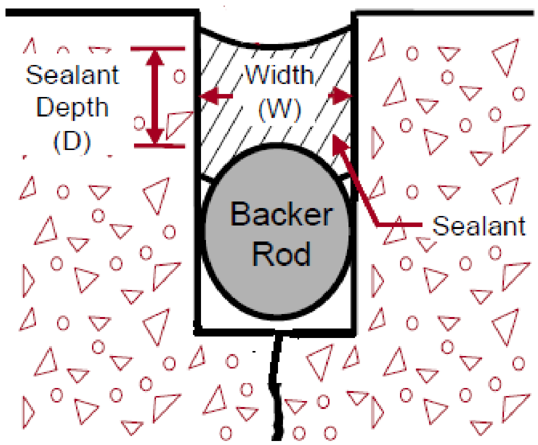
12-5.3 Fuel- and Blast-Resistant Sealants.

Additional considerations for crack repair material are jet fuel and jet blast resistance. The crack to be repaired may be located in an area where fuel or lubricating or hydraulic fluid spillage may occur or in an area subjected to high temperature from jet blast or exhaust from auxiliary power units (APU). Use repair materials that conform to UFGS 32 01 19 or ASTM specifications designated for joint and crack sealants for use in these areas.

12-6 SEALANT SHAPE FACTOR.

For crack sealing to be effective over the long term, route or saw the crack to the designated width and depth for the particular type of sealant employed in the crack repair. The dimensions of a typical crack reservoir (Figure 12-1) are defined by a shape factor, S, that is the ratio of the depth of the sealant (D) to its width (W). Shape factors generally range from 0.5 to 2.0, with 1.0 being most common; however, these dimensions may be specific to the type of sealant employed in the repair operation and a recommended value will be supplied by the sealant manufacturer. The depth of the sealant is controlled by use of a backer rod, as shown in Figure 12-1.

Figure 12-1 Crack Sealant Reservoir Shape Factor



Silicone sealants require a shape factor of approximately 0.5. For example, if the width (W) of the sawed crack is 0.5 inch (13 millimeters), saw the crack to a minimum depth of 1.25 inches (30 millimeters) to accommodate a backer rod of 0.625 inch (16 millimeters). The top of the backer rod will be 0.5 inch (13 millimeters) below the pavement surface. This allows for a depth (D) of 0.25 to 0.375 inch (6 to 9 millimeters) of silicone sealant on top of the crown of the backer rod to keep the sealant at 0.125 to 0.25 inch (3 to 6 millimeters) below the pavement surface.

12-7 BACKER ROD AND SEPARATING MATERIALS.

12-7.1 Backer Rod Materials.

The backer rod is placed in the sawed or routed crack to minimize excess stress on the sealant material from an improper shape factor and to prevent three-sided adhesion that would inhibit the ability of the sealant to expand and compress under thermal stress. Use a backer rod material that is chemically inert to prevent reaction with the sealant, flexible to conform to the shape of the crack path, non-absorptive to prevent water retention, non-shrinkable, and compressible to allow for easy installation.

Typical backer rod materials are polychloroprene, polystyrene, polyurethane, and polyethylene closed-cell forms. Do not use paper, rope, or cord. Use a backer rod material with a melting temperature that is at least 25 degrees F (14 degrees C) higher than the sealant application temperature to prevent damage during sealant placement.

Provide and use a backer rod with an uncompressed diameter at least 25 percent larger than the sealant reservoir width to ensure it remains in position during the sealing operation. Use a backer rod when repairing cracks by sealing.

12-7.2 Separating Materials.

A separating tape may be used when the sealant reservoir dimensions correspond to that for the proper shape factor for the sealant material to be used and the use of a backer rod would lead to an incorrect shape factor for that sealant material. The separating material is usually a thin adhesive tape or a flexible plastic strip employed to prevent three-sided adhesion of the sealant. Use materials that are flexible enough to deform with the sealant as the concrete expands and contracts. However, only use this repair method when the crack has been sawed to provide a reservoir of the proper depth and width.

12-8 CRACK PREPARATION.

12-8.1 Introduction.

One essential element of the crack-sealing operation is proper preparation of the crack and the crack face. If the prepared crack faces are dirty or wet, the sealant will not adhere to the concrete surface and eventually will separate from the crack wall. Schedule the crack-sealing operation such that the prepared cracks are sealed as soon as possible to prevent contamination of the crack faces before sealant application. If vegetation is growing in the cracks, remove it and use a hot lance or a water-based herbicide to kill the weeds within the cracks. Oil-based herbicides can leave a residue that may prevent adhesion of the sealant to the crack face.

Route or saw the cracks to the proper depth and width according to the shape factor previously discussed or designated by the manufacturer's recommendations for the particular sealant being used. The random orientation of most concrete pavement cracks makes it difficult to create a uniform sealant reservoir directly over the crack.

After completing the sawing or routing operation, clean the crack face to remove laitance, sawing debris, and other foreign material. Perform cleaning with a multiple-pass technique in which one side of the sawed crack face is cleaned, followed by the other face. Sand or water-blast the pavement surface directly adjacent to the sawed crack to remove any debris or material that may cause problems during crack sealing.

12-8.2 Cleaning.

The importance of proper cleaning of the crack faces cannot be over-emphasized. Surface dust, debris, and laitance remaining in the sawed crack can prevent adhesion of the crack sealant to the prepared crack face. Follow the initial cleaning operation with final cleaning using high-pressure air to remove material remaining in the sawed cracks. Do not use water blasting for final cleaning as it will require additional time to dry out the crack faces. Repeat this cleaning process immediately prior to placing the sealant in the sawed reservoir if the sealant is not placed within three hours of the cleaning. Use a vacuum sweeper, shop vacuum, power broom, or hand broom to remove sand and dust adjacent to the crack to prevent the sand and dust from reentering the crack.

12-9 CRACK SEALING PROCEDURES.

12-9.1 Introduction.

Only seal cracks when the air and the pavement temperatures are above 50 degrees F (10 degrees C) and rising. Constantly monitor application temperatures for hot-applied crack sealants to ensure they are in the correct range.

12-9.2 Process.

Ensure the crack faces are clean and free of moisture. If moisture is present, use compressed air to dry the crack face before sealing. Seal the crack using the following steps:

1. Fill the crack from the bottom up to prevent air from becoming trapped under the sealant and bubbling.
2. Fill the crack from beginning to end in one smooth operation whenever practical.
3. Fill the crack to a depth of 0.25 inch (6 millimeters) below the surface of the pavement
4. Do not open the sealed pavement to traffic until the sealant has adequately cooled or cured so as not to be picked up by vehicle tires.
5. Remove all excess sealant application or spills and any other debris from the sealant application work and properly dispose of it.
6. For hot-applied sealants, remove and discard sealant remaining in the pot at the end of a day’s work. Do not reheat and use the sealant unless the sealant supplier allows reheating and use.

12-9.3 Cautions.

Comply with the following precautions:

- For crack resealing, completely remove the old sealant.
- Do not start sealing cracks if rain is imminent or within 10 miles and moving toward the worksite.
- Do not begin, continue, or apply sealant if there is any sign of moisture on the surface adjacent to the crack or along the prepared crack faces.
- Follow the sealant manufacturer’s installation instructions.
- Avoid getting voids or bubbles in the applied sealant.
- Do not apply sealant that rises above a point that is 0.25 inch (6 millimeters) below the pavement surface or rises over the pavement surface as it will be picked up by traffic or it will be pushed above the

pavement surface during hot weather and make the sealing process ineffective.

- Provide and use equipment with all safety mechanisms and guards in place and functioning properly during the crack sawing or routing and cleaning operations. Do not permit operators to use equipment without the proper use of required personal protective gear.

12-10 TEMPORARY CRACK/JOINT SEALING PROCEDURES FOR PCC.

12-10.1 Introduction.

Short-term performance (less than two years) of pavement joint and crack repairs is acceptable in circumstances identified by the contracting officer or engineer in charge. Example: The pavement is scheduled to be abandoned in two years but is maintained due to FOD potential from spalling. This guidance provides standard procedures and details for temporarily sealing joints and cracks in rigid pavements.

12-10.2 Repair Procedures Neoprene Compression Seal (NCS) Joints.

12-10.2.1 Compression Seal Removal Procedures.

See Figures 12-2 and 12-3. Perform the following key steps when removing seals:

1. Remove compression seal.
2. Remove all loose and poorly bonded concrete from the joint and joint walls.
3. Sandblast joint walls and bottom.
4. Air blow reservoir to remove debris and dry joint.
5. Install separating tape along joint bottom.
6. Prime joint reservoir walls if recommended by sealant manufacturer's published installation procedures.
7. Fill reservoir to within 0.375 inch (9 millimeters), ± 0.125 inch (3 millimeters) of slab surface.

Figure 12-2 Existing Spalled NCS Joint

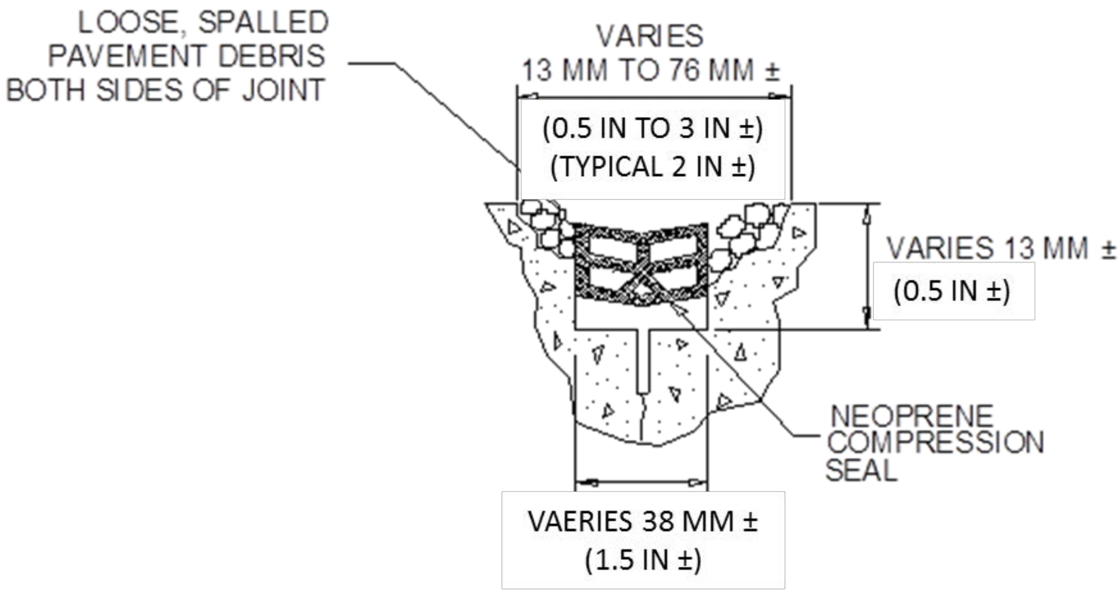


Figure 12-3 Repaired NCS Joint, Compression Seal Removed

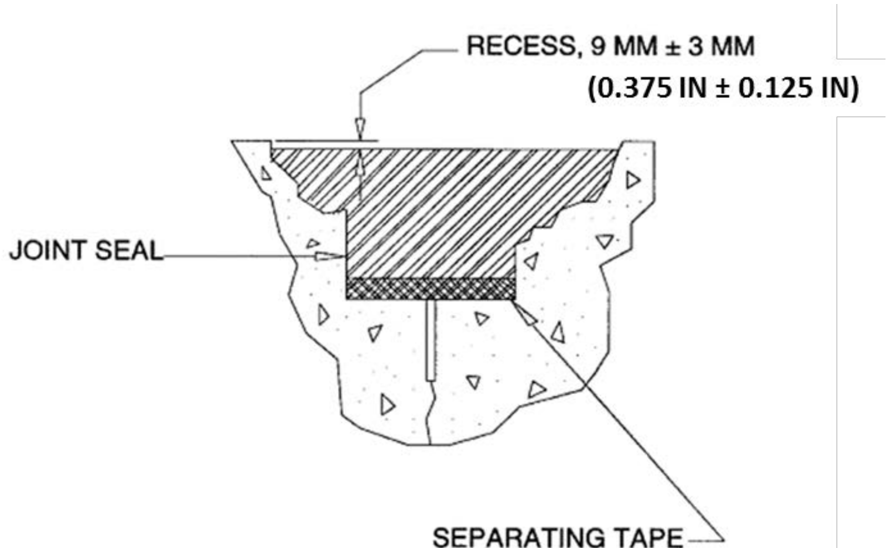

12-10.2.2 Compression Seal in Place Procedures.

See Figures 12-4 and 12-5. The key steps in performing effective seal in place include the following:

1. Remove loose or delaminated concrete by hand, chisel, or other tool as required.
2. Air-blast to a clean condition.
3. Fill with sealant to top of existing compression seal.

Figure 12-4 Existing NCS Random Spall Area

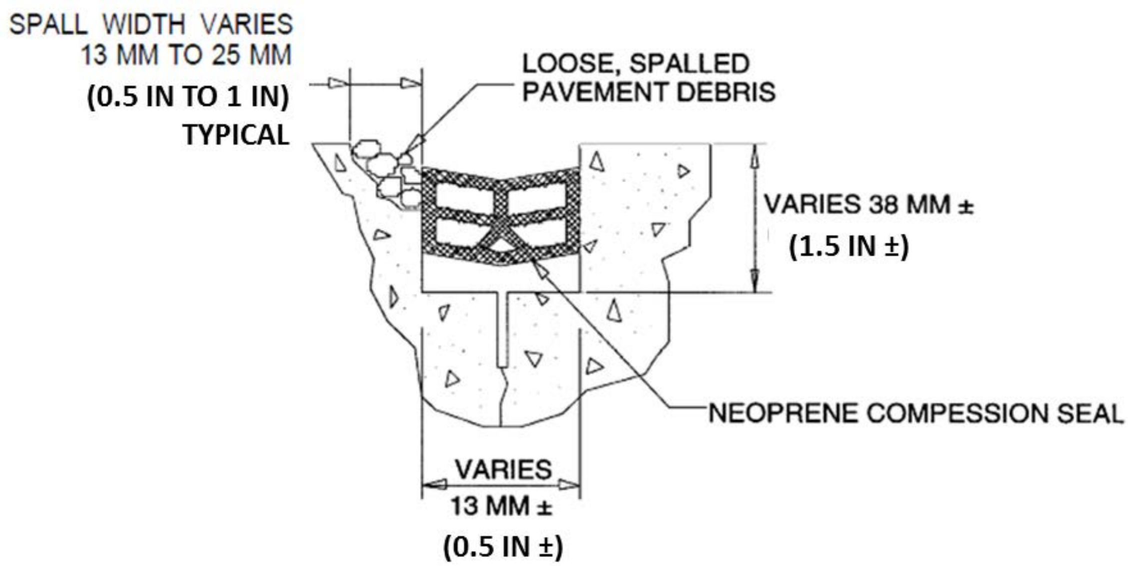

Figure 12-5 Repaired NCS Random Spall Area, Compression Seal in Place

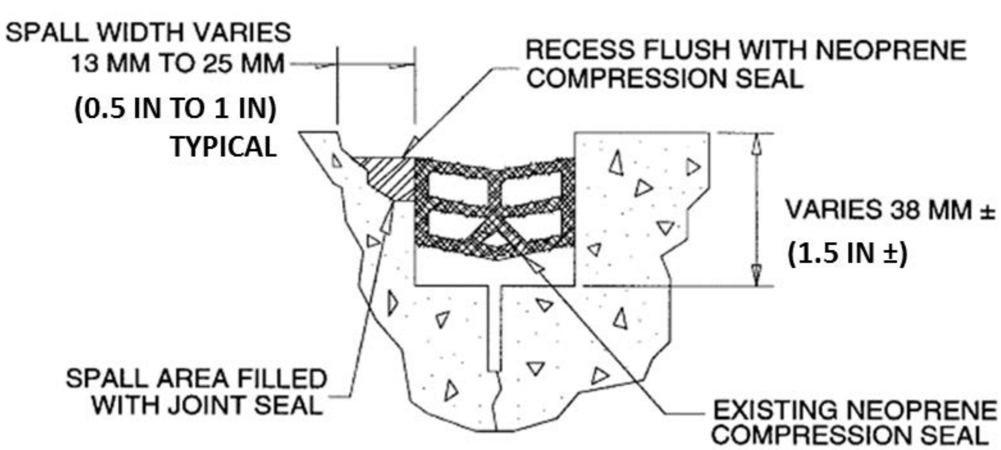
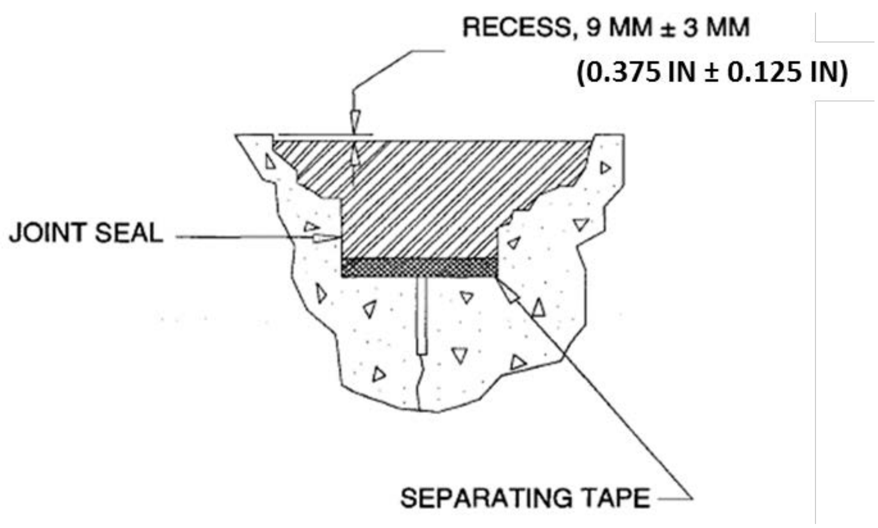


12-10.2.3 Section of Compression Seal Removed.

See Figures 12-6. The key steps in performing effective seal removal include the following:

1. Cut and remove neoprene compression seal.
2. Remove all loose, poorly bonded, and delaminated concrete from joint and joint walls.
3. Sandblast joint walls and bottom.
4. Air-blow reservoir to remove debris and dry joint.
5. Install separating tape along joint bottom.
6. Prime joint reservoir walls if recommended by sealant manufacturer's published installation procedures.
7. Fill reservoir to within 0.375 inch (9 millimeters), ± 0.125 inch (3 millimeters) of slab surface.

Figure 12-6 Repaired NCS Random Spall Area, Section of NCS Removed



12-10.3 Random Cracks.

See Figures 12-7 and 12-8. The key steps in performing effective random crack sealing include the following:

1. Rout crack with vertical spindle router or crack chasing saw. Width of cut: 0.5 inch (13 millimeters), minimum; depth of cut: 0.625 inch (17 millimeters), minimum. Use a vertical spindle router where crack chasing saw kerf (0.5-inch [13 millimeters] width) will not remain over cracks.

2. Flush crack seal reservoir with high-pressure water only if wet sawing of crack reservoir is used.
3. Remove all loose, poorly bonded, and delaminated concrete debris from crack seal reservoir (walls and bottom) by chipping with hammer or chisel.
4. Sandblast both walls and bottom of crack seal reservoir.
5. Air-blow reservoir to remove debris and dry joint.
6. Install separating tape in bottom of crack seal reservoir.
7. Prime joint reservoir walls if recommended by sealant manufacturer's published installation procedures.
8. Fill reservoir to within 0.125 to 0.25 inch (3 to 6 millimeters) of slab surface.

Figure 12-7 Existing Random Crack

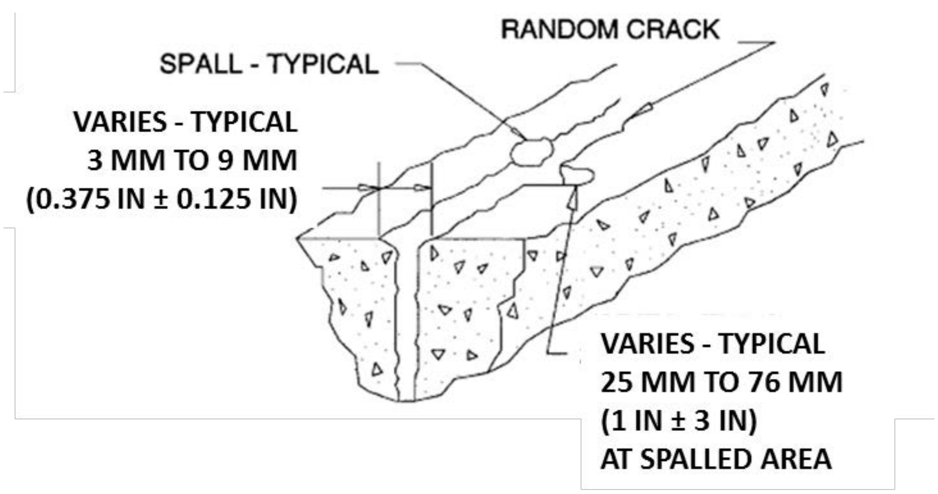


Figure 12-8 Repaired Random Crack

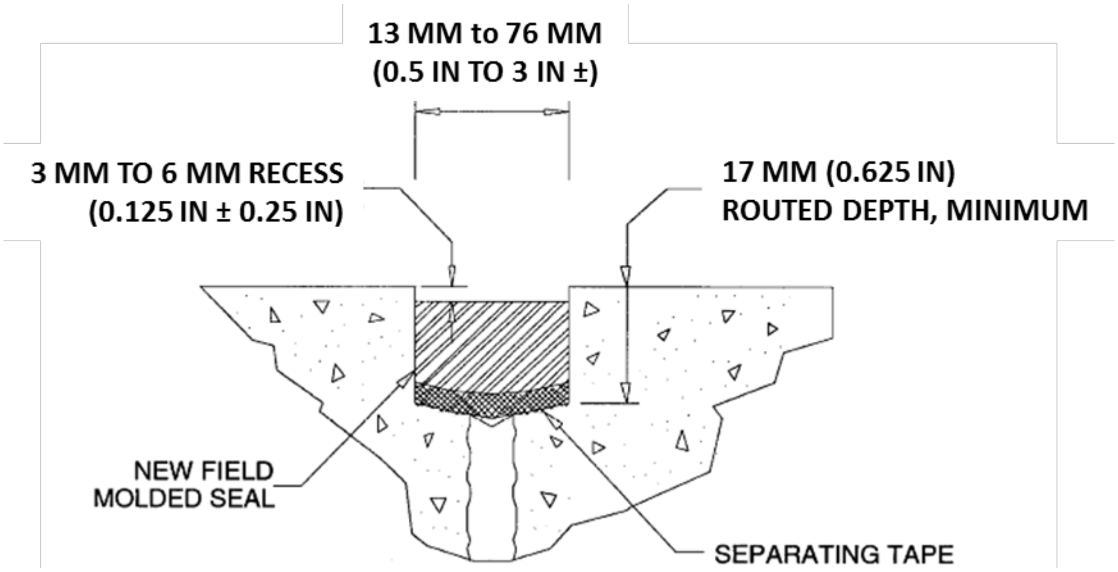

12-10.4 Field Molded Joints.

See Figures 12-9, 12-10, and 12-11. The key steps in performing effective field molded crack sealing include the following:

1. Remove existing seal by saw-cutting with gang of saw blades. Width of cut: one saw blade width greater than existing joint width (excluding spalls); depth of cut: 0.625 inch (17 millimeters), minimum. For joints with backer rod, remove to bottom of backer rod. Existing joint seal or expansion board below saw-cut may remain in bottom of joint. Where spalling has widened the joint reservoir, saw-cut width need not be expanded beyond width required for unspalled condition.

2. Flush joint seal reservoir with high-pressure water only if it was wet sawed.

3. Remove all loose, poorly bonded, and delaminated concrete debris from joint seal reservoir (walls and bottom) by chipping with a hammer or chisel.

4. Sandblast both walls and bottom of joint seal reservoir.

5. Air-blow reservoir to remove debris and dry joint.

6. Install separating tape or backer rod in bottom of joint seal reservoir. See details for proposed repair of joints.

7. Prime joint reservoir walls if recommended by sealant manufacturer's published installation procedures.

8. Fill reservoir to within 0.125 to 0.25 inch (3 to 6 millimeters) of slab surface.

Figure 12-9 Existing Spalled Field Molded Joint

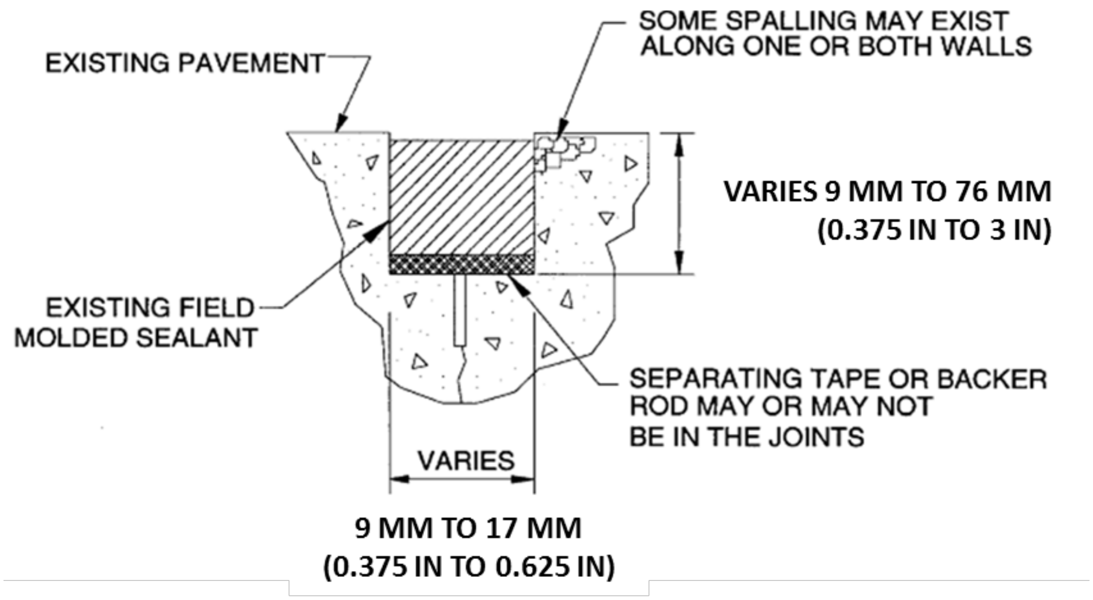

Figure 12-10 Resealed Field Molded Joint with Separating Tape

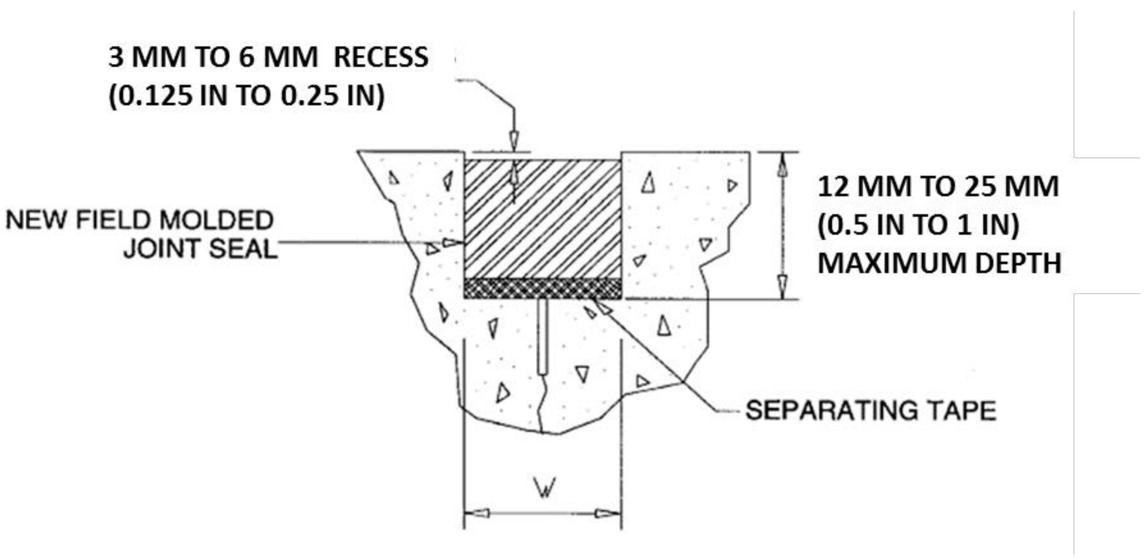

Figure 12-11 Resealed Field Molded Joint with Backer Rod

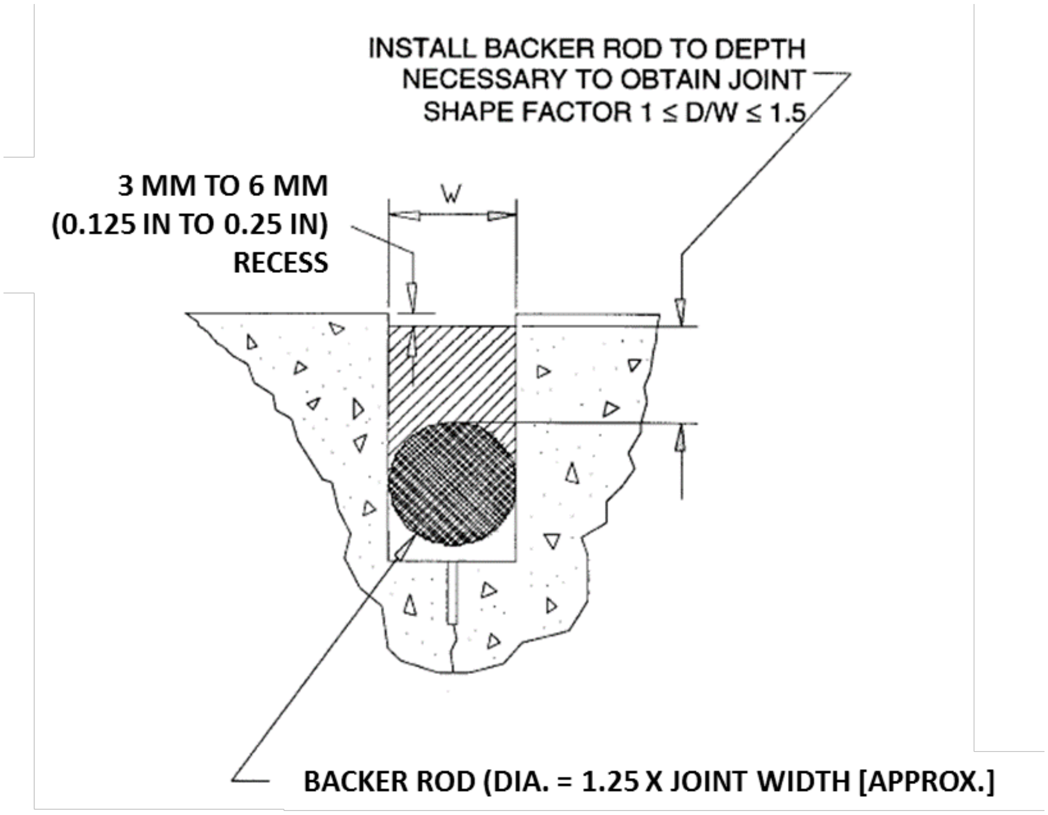

12-10.5 Partial-depth Joints.

See Figures 12-12 and 12-13. The key steps in performing effective partial-depth crack sealing include the following:

1. Make vertical saw-cut 2 inches (51 millimeters) deep, approximately 3 inches (76 millimeters) from distressed area. Overlap corner saw-cuts by 1 inch (25 millimeters), minimum.
2. Remove all concrete and loose material within the sawed area to sound concrete (3 inches [76 millimeters] minimum depth).
3. Use a separating medium to maintain and protect joints.
4. Use bonding agent to insure good contact between the pavement and patch as recommended by manufacturer's instructions.
5. Apply patch.
6. Apply curing compound to the patch surface if recommended by manufacturer's instructions.
7. After patch has cured, clean joint and apply joint sealant.

CHAPTER 13 PARTIAL-DEPTH REPAIR OF CONCRETE PAVEMENTS

13-1 INTRODUCTION.

The purpose of partial-depth repairs is to correct localized areas of concrete pavement distress. Repair of this type restores rideability, deters further deterioration, reduces FOD potential, and provides proper edges so joints can be effectively resealed. Spalling can be a significant distress for airfield pavements because spalling leads to loose material, which results in FOD. Timely spall repairs can extend the service life of the pavement. Partial-depth repairs of spalled joint areas also restore a well-defined uniform joint sealant reservoir prior to joint resealing.

Partial-depth repairs perform well when installed correctly; however, partial-depth repair can exhibit premature failures due to improper installation techniques.

13-2 NEED FOR PARTIAL-DEPTH REPAIR.

Partial-depth repair is typically used to repair spalling either at pavement joints and cracks (Figure 13-1) or at mid-slab locations. In this chapter, reference is made to joint spalling repair only; however, the discussion is also applicable to crack spalling repair. Spalling is typically a localized distress and therefore warrants a localized repair.

If several severe spalls are present along one joint, it may be more economical to place a full-depth repair along the entire joint than to repair individual spalls. Also, if the spall depth is greater than one-third of the slab thickness, use full-depth patching.

13-2.1 Joint Spalling.

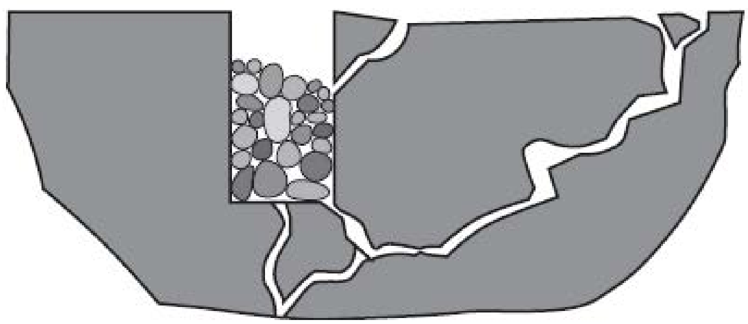
Spalling along a joint can occur when unsealed joints are filled with incompressible materials that prevent expansion of the slab in hot weather and result in breakage of the concrete (Figure 13-2). Other causes of spalling at joints include keyway failures (of oversized, poorly designed keyways), poor construction, poor repairs, dowel bar lockup, improperly located dowels, and dowels in reamed-out sockets. Minor spall at joints may also be caused by snowplows.

13-2.2 Mid-slab Spalling.

Spalling at mid-slab is generally caused by reinforcement that is too close to the surface and foreign matter or poor surface finish in the original PCC. Spalls create a rough ride and can accelerate deterioration.

Figure 13-1 Pavement Joint Spall

Figure 13-2 Incompressible Causing Spalling at a Joint or Crack



13-2.3 Partial-depth Repair Key Steps.

The key steps in performing a partial-depth spall repair include the following:

1. Selection of repair boundaries
2. Removal of existing unsound concrete
3. Cleaning the repair area
4. Joint preparation for joint spall repair
5. Selection of the patch (repair) material
6. Placement of the patch material
7. Finishing activities

8. Treatment of saw-cut runouts and patch/slab vertical interface
9. Patch curing
10. Joint resealing

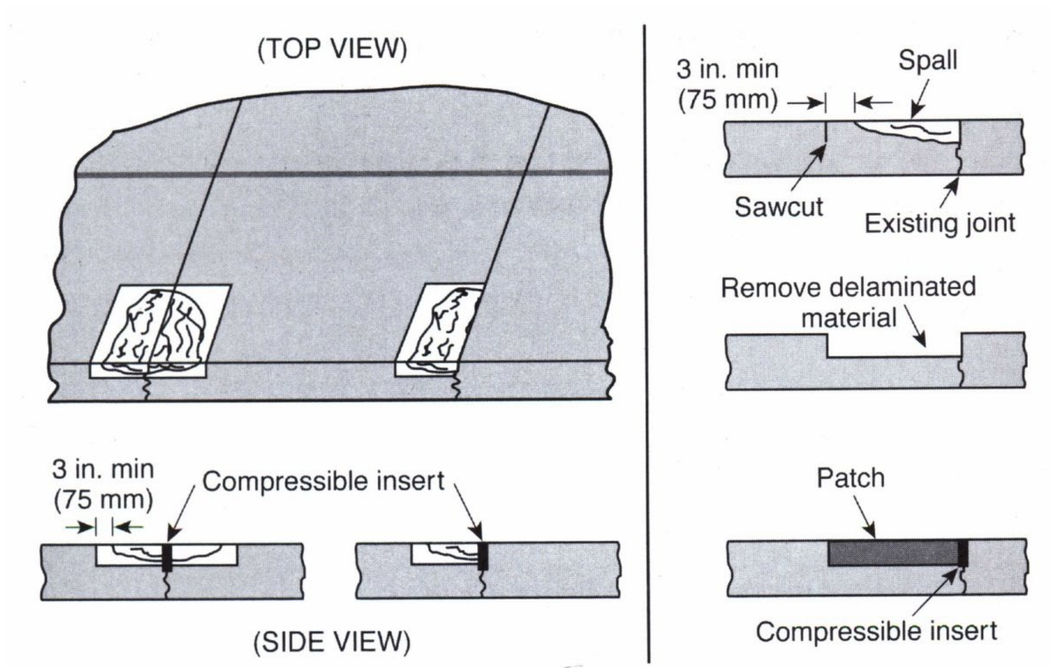
13-3 SELECTION OF REPAIR BOUNDARIES.

Prior to commencing work, survey the pavement to determine areas of unsound or delaminated concrete to establish the repair boundaries. During the survey, use a sounding technique to identify all areas of unsound concrete or delamination. Sounding the pavement to find delamination and spall removal areas is accomplished by striking the existing concrete surface with a steel rod or carpenter's hammer (Figure 13-3). Delaminated or unsound concrete will produce a dull or hollow thud, while sound concrete will produce a sharp metallic ring. Locate and remove all weak and deteriorated concrete to ensure the repair is effective.

Extend the repair boundaries beyond the detected delaminated or spalled area by 3 inches (75 millimeters) to assure removal of all unsound concrete (Figure 13-4). Keep the repair boundaries square or rectangular in line with the jointing pattern to avoid irregular shapes; irregular shapes may cause cracks to develop in the repair material. Consider combining repair areas along a joint if they are closer than 24 inches (600 millimeters) apart. This will help reduce costs and eliminate numerous small patches.

Figure 13-3 Sounding with a Hammer

Figure 13-4 Typical Spall Repair Boundaries



It is good practice to use rectangular-shaped repairs for all partial-depth spall repairs. The minimum length and width of the rectangular saw-cut boundary around a joint spall is 6 inches (150 millimeters). For corner spalls, do not make the rectangular saw-cut boundaries closer than 6 inches (150 millimeters) from the joint corner.

13-4 REMOVAL OF EXISTING CONCRETE.

13-4.1 Sawing and Chipping.

To remove concrete by sawing and chipping, make a minimum 2-inch (50-millimeter) -deep saw cut (in a rectangular pattern at least 3 inches [76 millimeters] outside all visible deterioration) around the perimeter of the repair area. This will provide a vertical face of sufficient depth to provide stability to the patch (Figure 13-4). Additional saw-cuts may be made within the repair area to speed chipping. A saw cut 2 inches (50 millimeters) away from joints might reduce the possibility of damaging the opposite joint face. A saw cut along the opposite joint face made by skimming the blade along the joint face will remove sealant residue and leave a clean vertical joint face. Remove concrete within the repair area to the bottom of the saw cuts or to 0.5 inch (13 millimeters) into visually sound and clean concrete, whichever is deeper, with light pneumatic tools (Figure 13-5). It is important that the proper tools are used. The recommended maximum size of the chipping hammer for partial-depth repairs is 30 pounds (13.6 kilograms).

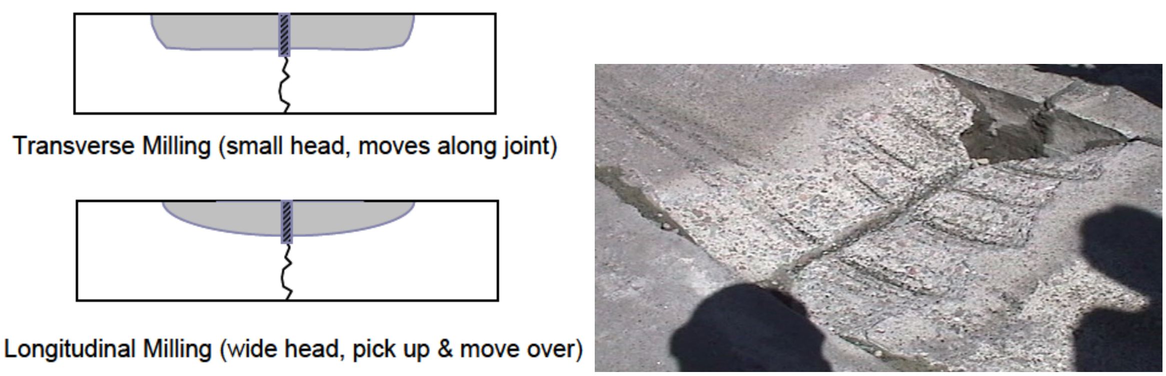
Figure 13-5 Repair Boundary Sawing and Use of Chipping Hammer

13-4.2 Milling Process.

Concrete within the repair area can also be removed by carbide-tipped cold milling equipment. Cold milling is especially effective where the repair area extends over the majority of the slab width (Figure 13-6) or along a long length of a longitudinal joint. Equip milling machines with a device for stopping at a preset depth to prevent excessive removal or damage to existing dowel bars or reinforcement.

After removal of the concrete in the repair area, survey by sounding the pavement again to ensure all unsound or delaminated concrete has been removed.

Figure 13-6 Milling Techniques



13-4.3 Partial Versus Full-depth Repair.

Occasionally, surface spalling will actually extend through the full slab depth or for more than one-third the slab depth. Do not attempt partial-depth repair at such locations. Mark the area and perform a full-depth repair. Make full-depth repairs if the concrete below one-third the slab depth is damaged during chipping or if dowel bars or reinforcing are encountered during removal.

Caution: Do not, under any circumstances, rest/place partial-depth repair material directly upon dowel bars or reinforcement. Typically, if a dowel bar is exposed within the repair area, it would indicate that the depth of repair is not acceptable. Completely expose steel reinforcement that is encountered in spall areas by removing at least 0.5 inch (13 millimeters) of concrete around the steel bars and the bars cleaned and covered with the patch material.

13-5 CLEANING.

Prior to patching, clean the exposed faces, bottom of the patch area, and any exposed steel to remove all loose particles, oil, dirt, dust, asphaltic concrete, rust, and other contaminants. As a minimum, air-blow with compressed air, wash with high-pressure water, and air-blow again (Figure 13-7). Check the prepared surface prior to placing the new patch material. Thoroughly clean the area with a power broom, vacuum sweeper, or hand broom to prevent debris from reentering the repair zone. Any contamination of the surface will reduce the bond between the patch material and the existing concrete.

Figure 13-7 Cleaning Repair Area (Sandblasting/Water Blasting, and Air Blowing)

13-6 JOINT PREPARATION.

When placing a partial-depth patch along a joint, do not allow the repair patch to bond to the joint face of the adjacent concrete and do not allow the repair material to penetrate into the joint. The most frequent cause of failure of partial-depth repairs at joints is excessive compressive stresses on the repair material abutting the adjacent concrete joint face. Partial-depth repairs placed directly against transverse joints will be crushed by the compressive forces created when the slabs expand and insufficient room is provided for the thermal expansion. Failure may also occur when the repair material is allowed to infiltrate the joint opening along the sides of the repair area and below the bottom of the repair, resisting slab movement and thereby preventing the joint from functioning.

13-6.1 Joint Bond-Breaking.

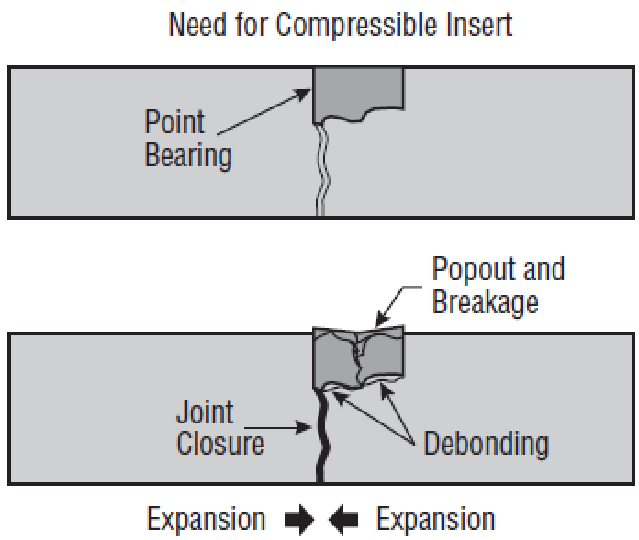
Elimination of bond between the patch and the adjacent concrete face can be accomplished by using a compressible insert. Styrofoam, asphalt-impregnated fiberboard (Figure 13-8), and plastic joint inserts are commonly used along the joint prior to placing the patch material. Patches that abut working joints or cracks that penetrate the full depth of the slab require a compressible insert or other bond-breaking medium to reform the joint or crack and prevent the repair material from flowing into the side and bottom of the joint areas undergoing repair. Use of an insert will form a uniform face against which the joint or crack can be properly sealed and will separate the patch from the adjacent slab.

Figure 13-8 Compressible Insert

13-6.2 New Joint/Crack Width.

Ensure the new joint or crack width adjacent to the repair is equal to or more than the width of the existing joint or crack. Failure to reform the joint or crack as described can result in point bearing stress at the repair area and failure by blowup, delamination, or new shear planes, sometimes in the adjacent slab (Figure 13-9).

Figure 13-9 Failure Due to Non-use of Compressible Insert



13-6.3 Shoulder Joints.

When placing a partial-depth patch along a shoulder joint, place a piece of joint material along the slab edge even with the surface to prevent the patch material from penetrating the open shoulder interface. A wooden form may also be used for this purpose. Otherwise, the material may restrict longitudinal movement of the slab in response to thermal changes and result in damage to the repair or the shoulder.

13-7 PLACEMENT OF PATCH MATERIALS.

The volume of material required for a partial-depth repair is usually less than 2 cubic feet (0.056 cubic meter); therefore, mix cement-based patching material onsite in a small mobile drum or paddle mixer. Transit mix trucks and other large equipment cannot efficiently produce such small quantities since maximum mixing times for a given temperature may be exceeded, decrease the quality, and result in waste of material. Slightly overfill the repair area to compensate for consolidation. Tamp the repair to consolidate the repair material. The patch material also may be consolidated by small spud vibrators to eliminate voids at the interface of the patch and the existing concrete. Vibrators greater than 1 inch (25 millimeters) in diameter are not recommended for this work. On very small repairs, hand tools are sufficient to work the repair and attain adequate consolidation.

When using premixed or proprietary materials, follow the vendor’s instructions related to patch material placement. If the patch material packaging is damaged, do not use the patch material.

13-8 FINISHING.

Finish the patch area flush to the cross-section of the existing pavement without leaving excess material on the adjacent pavement surface (Figure 13-10). The recommended finishing procedure is to screed from the center of the patch area to the patch boundaries. By moving the screed toward the patch boundaries, the material is pushed toward the vertical interface to increase the potential for high bond strength. After finishing, give the patch a burlap drag or broom finish to approximately match the surface finish of the existing adjacent concrete pavement unless a grinding operation is to follow.

Figure 13-10 Finished Patches

13-9 TREATMENT OF SAW-CUT RUNOUTS AND PATCH/SLAB INTERFACE.

Use the paste portion of the repair material to fill any saw-cut runouts that extend beyond the patch perimeter at patch corners. This will prevent any spalling at these locations.

If the repair material is properly placed in the patch area there will not be any need to place any sealer type material along the perimeter of the patch surface. However, if within a few days or few weeks, the patch material appears to be pulling away from the existing concrete, seal the patch/slab interface with a cement grout or an epoxy material. Use of a joint sealant for this purpose is not recommended.

13-10 CURING.

Proper curing of cement-based partial-depth repairs is very important due to the large surface of small patches compared to the volume of patch material, as well as the fact that concrete gains bond strength much slower than it gains compressive strength. Proper curing requires the application of curing compound at the time bleed water, if any, has evaporated from the surface of the patch. Because curing is critical for cement-based patches, for the first 24 hours wet-cure with burlap or a similar material and apply a curing compound after that period. In hot or dry climates, cure the patches for three days with a double mat of saturated burlap covered with polyethylene sheeting over which plywood or lumber is placed. Remove the covering and re-saturate the burlap as often as is necessary, but at a minimum of once a day, and the covering re-placed.

For premixed and proprietary repair materials, follow the manufacturer's directions regarding curing. Some rapid strength material may not require curing application and can be opened to traffic within four hours.

13-11 JOINT/CRACK RESEALING.

Resealing the repaired joint is extremely important because it will help prevent moisture and incompressible materials from entering the joint or crack and causing further damage. It is important that the new transverse and longitudinal joints constructed within the patch area be formed or sawed to provide the proper joint seal reservoir and match surrounding joints. Ensure the joint faces are clean and dry for good sealant performance.

CHAPTER 14 FULL-DEPTH REPAIR OF CONCRETE PAVEMENTS

14-1 INTRODUCTION.

When normal maintenance procedures can no longer correct the deteriorated concrete pavements, full-depth repair may become necessary to restore damaged areas to their original condition and extend the service life of the pavement. Full-depth repairs are generally necessary when slabs have been shattered (Figure 14-1) or have deteriorated to such an extent that the safe support of the required load is no longer possible. Full-depth repairs are an effective means of restoring the rideability and structural integrity of deteriorated concrete pavements and, therefore, extending their service life.

14-2 NEED FOR FULL-DEPTH REPAIR.

There are several types of distress that occur at or near transverse joints that may require full-depth repair when classified as medium- or high-severity level distress. Comprehensive distress manuals (ASTM D6433, *Standard Practice for Roads and Parking Lots Pavement Condition Index Surveys,* and ASTM D5340, *Standard Test Method for Airport Pavement Condition Index Surveys*) are available that define distress types and severity levels.

14-2.1 Rigid Pavement Distress Types.

Types of distress that occur in rigid pavements that may justify full-depth repair when classified as medium- or high-severity distresses include:

- Blowup
- Corner break
- Durability (“D”) cracking
- Patch deterioration
- Shattered slab (a slab broken into four or five pieces with some or all cracks of high severity or a slab broken into six or more pieces with over 15 percent of the cracks of medium or high severity) (Figure 14-1)
- Spalling (if spalling extends to greater than one-third the slab thickness)
- Punchout
- Railroad crossing distress

Figure 14-1 Shattered Slabs

14-2.2 Other Rigid Pavement Concerns.

Concrete pavements may also exhibit spalling and faulting at intermediate cracks. This deterioration may be caused by repeated heavy traffic loads, failure of doweled joints to function properly, and/or the intrusion of incompressible materials in the open cracks. If the spalling extends to greater than one-third the slab thickness or if the faulting is in excess of 0.5 inch (12 millimeters), full-depth repair at the crack locations may be considered.

14-2.3 Full-Depth Repair Key Steps.

The key steps in performing a full-depth repair include the following:

1. Selection of repair boundaries
2. Sawing of repair boundaries
3. Removal of existing concrete
4. Restoring the repair area support (subgrade and base preparation)
5. Dowel bar and tie-bar placement
6. Replacing reinforcement, if any
7. Restoring expansion joints, if any
8. Use of filler material at joints
9. Dowel bar placement
10. Concrete placement
11. Concrete finishing and texturing
12. Curing

13. Joint sealing
14. Opening to traffic.

<u>Caution:</u> Successful performance of full-depth repairs requires proper restoration of the base and subgrade and provision of effective load transfer across trafficked joints, other than thickened edge slip joints. Also, full-depth repairs are not effective over the long-term if the existing pavement exhibits materials-related distress, such as D-cracking or ASR.

14-2.4 Selection of Repair Boundaries.

First, conduct a detailed survey to accurately identify the required repair areas so all significant underlying distresses are identified and corrected. Quite often, and particularly in freeze-thaw climates, the deterioration near joints and cracks is greater at the bottom of the slab than is apparent from the top of the slab.

In both plain jointed and reinforced jointed concrete pavement, partial-slab replacement is acceptable where the distresses are within one-half of the slab length. Full-width slab patching is required if the original slab width is less than 20 feet (6 meters) or full-depth cracks are located within the interior area of the slab. A minimum slab length is required to avoid rocking and pumping of the repair. General experience indicates that 10 feet (3 meters) is a minimum length for airfield applications. For roadways with 11- to 14-foot (3.4- to 4.3-meter) -wide lanes, the repair area needs to be full lane width with a minimum length of 6 feet (1.8 meters). If the repair extends over half the length of the panel, consider full panel replacement.

14-2.4.1 Saw Cut.

Saw cut will be a minimum of 3 feet (900 millimeters) from a joint and the minimum patch length will be 6 feet (1.8 meters). Saw cut in lines forming rectangles parallel with or perpendicular to the jointing pattern.

14-2.4.2 Patch Boundary.

Extend the patch boundary to the joint(s) if the length of the patch is greater than half the length of the panel.

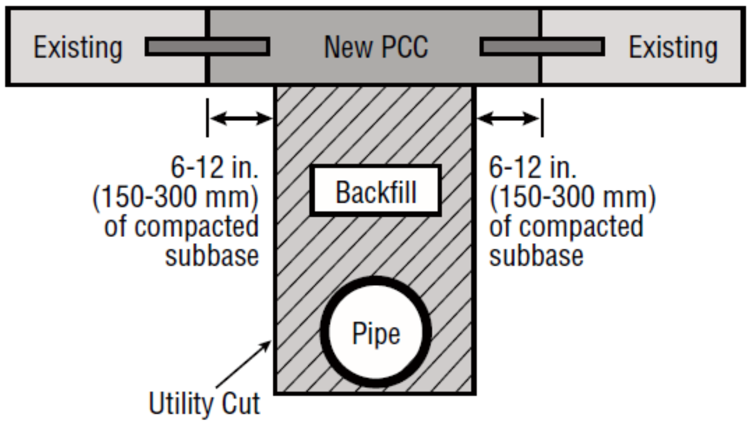
14-2.4.3 Utility Cut.

If the patch is a utility cut, make cut about 12 inches (300 millimeters) beyond limits of the excavation and any sloughing of the trench. This saw cut limit of the excavation area allows the repair concrete to extend beyond the excavation. (Figure 14-2)

14-2.4.4 Continuously Reinforced Concrete.

For continuously reinforced concrete, position the patch area so the distressed portion is in the middle of the patch area. Patch at least 6 feet (1.8 meters) in length if reinforcing steel is to be tied, and at least 4 feet (1.2 meters) long if welded or if mechanical splices are used to connect reinforcing steel.

Figure 14-2 Utility Cut



14-2.5 Sawing Cutting Repair Boundaries.

The repair boundaries of mesh-reinforced, plain doweled, and plain undoweled jointed concrete pavement are typically cut full-depth using diamond blade sawing (Figure 14-3). Sawing is the recommended method.

14-2.5.1 Hammer Use.

Do not use hammers to outline the area. The rough joint formed by hammers typically spalls in service and it is difficult to lift out the concrete within the repair boundaries or break it up with large pavement breakers.

14-2.5.2 Partial-Depth Cuts.

The use of the partial-depth saw cut is not recommended. The partial-depth saw cut does provide some aggregate interlock due to a rough face but micro-cracking will develop at the bottom of the repair area and the bottom of the slab may spall when using a large pavement breaker to shatter the concrete within the repair boundaries.

14-2.5.3 Full-Depth Cuts.

Full-depth saw cuts will completely separate the concrete that is to be removed, leaving undamaged vertical faces, and eliminate damage at the bottom of the remaining slab.

14-2.5.4 Warm Weather.

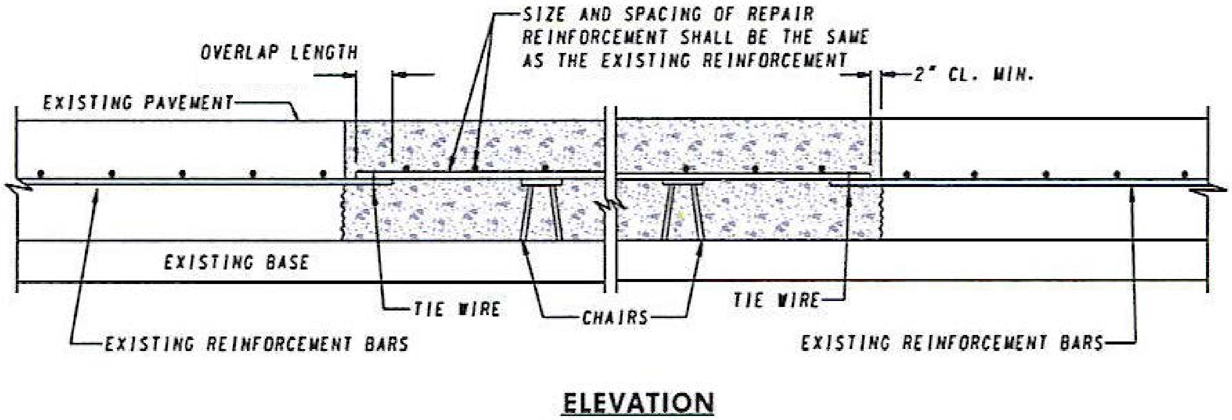
On warm days, a double saw cut method may be necessary to prevent binding of the sawing blade.

Figure 14-3 Diamond Blade Sawing

14-2.5.5 Continuously Reinforced Concrete (CRC).

The repair boundaries of CRC pavement are provided by sawing full depth at the repair boundaries. Partial-depth saw cuts above the reinforcing steel are then provided at a distance (typically about 20 inches [500 millimeters]) required by the lap length of the reinforcement) from the repair boundaries (Figure 14-4). Locate the partial-depth saw cuts at least 18 inches (450 millimeters) from the nearest tight crack and do not saw across an existing crack. If any of the reinforcing steel is cut during partial-sawing, extend the repair area by the required lap length of the reinforcement.

Figure 14-4 CRC Pavement Full-depth Repair Layout



14-2.5.6 Matching Joints.

Matching joints in adjacent lanes (typically for roadways) is not necessary as long as a debonding material (e.g., fiberboard) has been placed along the longitudinal joint to separate the lanes. However, if the distressed areas in both lanes are similar and both lanes are to be repaired at the same time, it is a good practice to align repair boundaries to avoid small offsets and maintain continuity.

14-2.6 Removal of Existing Concrete.

Do not use procedures for removal that spall or crack adjacent concrete or significantly disturb the base or subgrade. There are two basic methods to remove concrete pavement, as discussed below.

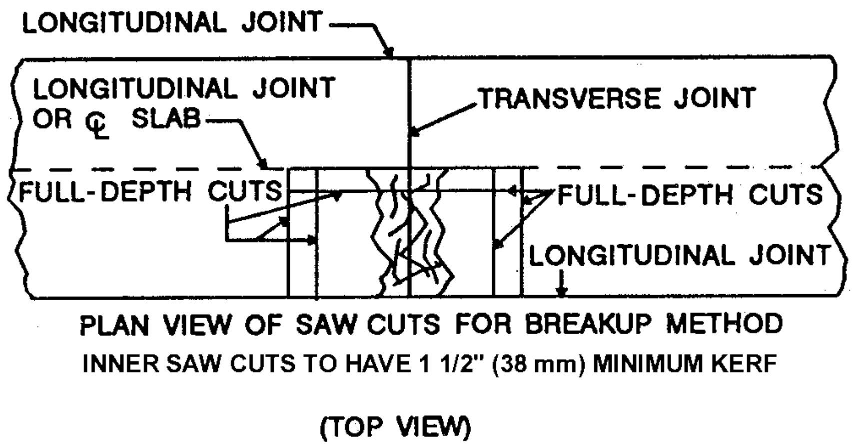
14-2.6.1 Breakup and Cleanout Method.

Concrete breakup is accomplished using a pavement breaker with removal by a backhoe (Figure 14-5). This method disturbs the base and requires base replacement or filling with concrete. It also has the potential to damage the adjacent slab if proper sawing procedures are not followed. This is not a preferred method for concrete removal.

After the repair is isolated by full-depth saw cuts, additional saw cuts using a wheel saw with at least 1.5-inch (38-millimeter) kerf, are made within the repair area, parallel and approximately 1.5 feet (450 millimeters) from each perimeter saw cut or joint (Figure 14-6). Begin breakup in the center of the removal area within the inner saw cuts. After breakup of the inner area, a backhoe can be used to gently pull the outer region free of the adjacent slab, or this strip can be broken up with light hand-held jackhammers.

Figure 14-5 Concrete Removal Using Backhoe

Figure 14-6 Additional Saw Cuts (Breakup Method)



14-2.6.2 Lift-out Method.

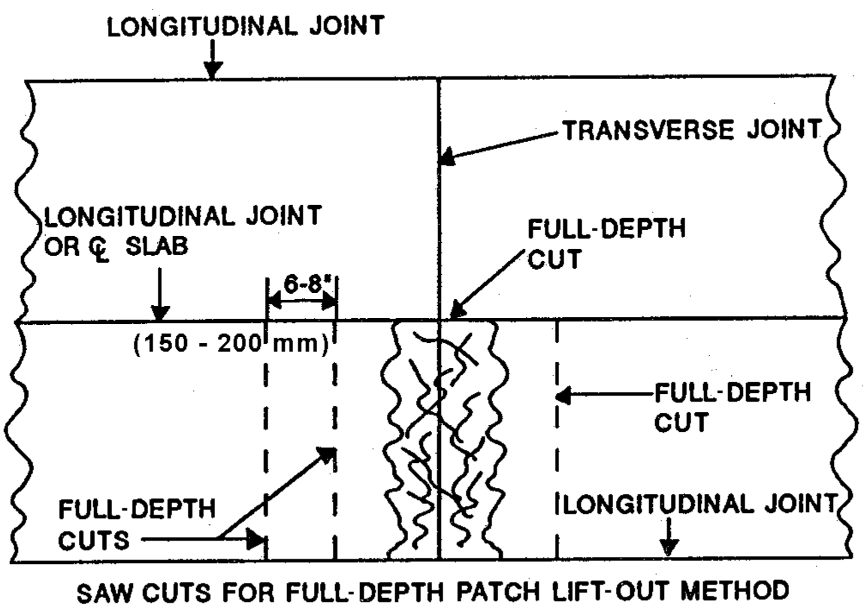
This is a recommended practice as it results in little damage to the base and the subgrade. This procedure is accomplished using a crane or front-end loader to lift the deteriorated concrete from its in-place position (Figure 14-7). Closely control lift-out operations to prevent accidents. After the repair area is isolated by full-depth saw cuts, holes are drilled through the slab and fitted with lift pins and the slab is then lifted in one or more pieces. If it is necessary to decrease the load, the slab may be saw cut into smaller pieces.

Figure 14-7 Lift-out Method

During hot weather, the sawing equipment may bind during initial transverse sawing procedures. It may be necessary to perform sawing at night when the temperatures are lower and the slabs are contracting. Another solution is to use a carbide-tipped wheel saw to provide a pressure relief cut within the patch area prior to the perimeter sawing (Figure 14-8). It is strongly recommended that the carbide-tipped wheel saw cut be made no closer than 6 to 8 inches (150 to 200 millimeters) from the proposed patch boundary due to the possibility of damage and micro-cracking in adjacent concrete. The same procedures may be used for the removal of CRC. Carefully remove concrete in the two reinforcing lap areas by jackhammering so as not to damage the reinforcing.

For CRC pavements, after the concrete between the two full-depth saw cuts is removed, remove the concrete between the full-depth saw cuts and the partial-depth saw cuts by jack-hammering to expose the steel reinforcement.

Figure 14-8 Pressure Relief Cuts for Lift-out Method



(TOP VIEW)

14-2.7 Subgrade and Base Preparation.

After the deteriorated and loose concrete has been removed, examine the base course. Remove all excess disturbed material. Compact the patch area using a plate compactor (Figure 14-9). If excessive moisture exists in the repair area, remove it or dry the repair area before re-grading and compacting the base. It is difficult to adequately compact granular material along the perimeter and the corner areas of the patch, which may result in settlement of the patch under future traffic loading. Replacing some or all disturbed base material with lean concrete or flowable fill is a very good alternative for critical operational areas.

Figure 14-9 Patch Area Compaction

14-2.8 Dowel and Tie-Bar Placement.

In full-depth repair of jointed concrete pavements, good load transfer across the transverse repair joints is a critical factor affecting the performance of the full-depth repairs. Load transfer is best achieved by properly installed dowel bars of sufficient size and number. For dowel bar size and spacing, follow the recommendations provided in Table 18-1.

Deformed tie-bars along longitudinal joints in new construction are used to restrict movement at these joints. These bars are typically #5 or #6 in size and spaced at about 30 inches (750 millimeters). For roadway full-depth repairs, tie-bars along interior joints (e.g., centerline joint) are necessary for repair lengths exceeding 40 feet (12 meters) to prevent drifting of the full-depth patch.

For full-depth repair of airfield pavements, incorporate dowel bars along longitudinal joints within the patch and dowel all edges to the existing pavement (longitudinal and transverse).

14-2.8.1 Smooth Dowel Bars.

Use of smooth dowel bars at the joints provide load transfer across these joints while allowing the joint to open and close as the surrounding pavement expands and contracts in response to temperature and moisture changes.

14-2.8.2 Deformed Dowel Bars.

In contrast to smooth dowel bars, deformed dowel bars are used along certain repair joints to provide both load transfer and prevent movement at the specific joints. Since in repair both smooth and deformed dowel bars have a load transfer role, select their dimensions and spacing based on the design loading for that facility.

14-2.9 Drilling Dowel and Tie-Bar Holes.

Installation of smooth or deformed dowel bars and deformed tie-bars requires drilling holes at specified locations into the exposed (saw cut) face of the existing slab. Gang drills are available to drill multiple holes simultaneously (Figure 14-10). The gang drill maintains the drills in a rigid frame to prevent the drill bits from wandering and holds them in a horizontal position at the correct height (typically, one-half the slab thickness). Make the depth of the holes approximately one-half the length of the dowel or tie-bar. Do not use hand-held drills to drill holes for dowel bars as the required dowel alignment cannot be easily achieved.

Figure 14-10 Drilling Multiple Holes at Mid-depth for Dowel Bars

Hole diameters exceeding the bar diameter by 0.125 inch (3 millimeters) or less are recommended when using epoxy materials. Clean the drilled holes using air blasting before injecting the epoxy grout into the hole. Take care during the drilling to ensure that spalling around the drilled hole at the joint face is kept to a minimum. Ensure spalling does not exceed the diameter of the retainer ring used to keep the epoxy from flowing out of the drilled hole. In case of such minor spalling, the epoxy is used to patch the spalls. For larger spalls around the drilled holes, the spalled area needs to be repaired before installing the dowel bars.

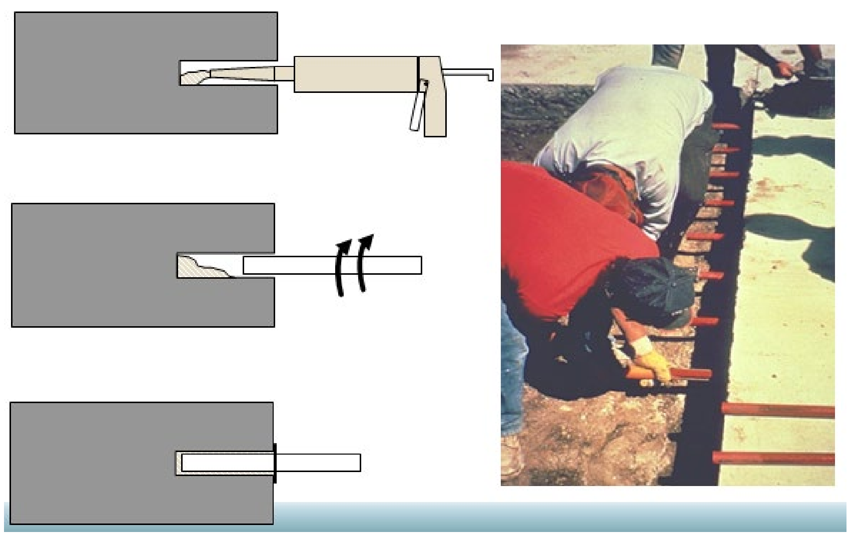
14-2.10 Dowel and Tie-Bar Installation.

Use dowels, tie-bars, or reinforcement that are clean and free of flaking rust. Specify appropriate sizes of dowels (at least matching the size of dowel bars used in the existing pavement) for different thicknesses of pavements (refer to UFC 3-260-02, *Pavement Design for Airfields,* for required sizes). Exercise care in epoxy grouting dowels or tie-bars to ensure complete coverage and support of the bars. Use grout retention devices that fit tightly over the dowel or tie-bar and seal the hole to prevent loss of epoxy. The steps for correctly installing dowel bars after air-blasting the holes are illustrated in Figure 14-11.

The proper installation of the smooth dowel bars is very important. Misaligned dowels can lead to early joint failure (spalling around the dowel bars) or cracking in the slab panel adjacent to the joint. The smooth dowels allow movement of the adjoining slabs. Oil or treat with a debonding material the portion of the bars that extend into the repair when using dowels to prevent bonding of the bars with the repair concrete. Cap one end of dowels used at expansion joints, in addition to oiling or treating with a debonding material, to permit further penetration of the dowels into the concrete when these joints close during warm weather.

Deformed tie-bars with surface ridges provide a locking anchorage with surrounding concrete. These tie-bars are placed in joints that are not intended to have movement.

Figure 14-11 Dowel Bar Installation



A. Injecting the epoxy into the back of the hole in sufficient amount to ensure full coverage around the inserted dowel bars

B. Inserting dowel bars into the hole with a slight twisting motion

C. Using a retainer ring to stop the epoxy from flowing out of the hole

14-2.11 Continuous Reinforced Concrete (CRC) Pavement Repair.

Successful performance of CRC pavements requires good load transfer across all transverse cracks and repair joints. Failure to provide adequate load transfer will cause the repair and the surrounding pavement to fail due to excessive deflection at the joints.

For conventional full-depth repair of CRC pavements, the longitudinal reinforcing is generally carried through the repairs by carefully removing the old concrete to allow the appropriate length of steel (lap length) from the existing pavement to extend into the repair area. This steel is then tied, welded, or mechanically connected to new reinforcing steel that extends through the repair area. When replacing reinforcing steel in the patch area, match the original rebar in size (diameter), grade, and number. Place the new bars on bar supports to ensure proper position and cover. Do not extend bars closer than 2 inches (51 millimeters) to the patch/slab interface.

14-2.11.1 Tied Splices.

Lap tied splices the proper length that provides full bar strength. The recommended lap length for tying longitudinal steel is a minimum of 25 times the diameter of the steel bars.

14-2.11.2 Welded Splices.

Use the proper length for the welding procedure chosen when using welded splices. Lap bars at the center of the repair area to avoid the potential buckling of bars on hot days.

14-2.11.3 Mechanical Splices.

Use mechanical splices in accordance with the supplier’s instructions.

14-2.12 Expansion Joints.

Expansion joints are placed in concrete pavements to provide relief for expansion of the concrete pavement due to temperature changes. Generally, expansion joints are installed at all intersections of pavements with structures or when a pavement ends near a structure but are rarely required within pavement features.

Expansion joints may be required if longer-length full-depth repairs are made during cool weather when adjacent concrete is in a contracted state or crushing and spalling of concrete at the joints may occur during subsequent hot weather when the concrete expands. Keep expansion joints in pavements to the minimum necessary to minimize future maintenance issues. The types of expansion joints commonly used by the military are the thickened-edge expansion joint (Figure 14-12) and the doweled type expansion joint (Figure 14-13).

Figure 14-12 Thickened-edge Expansion Joint

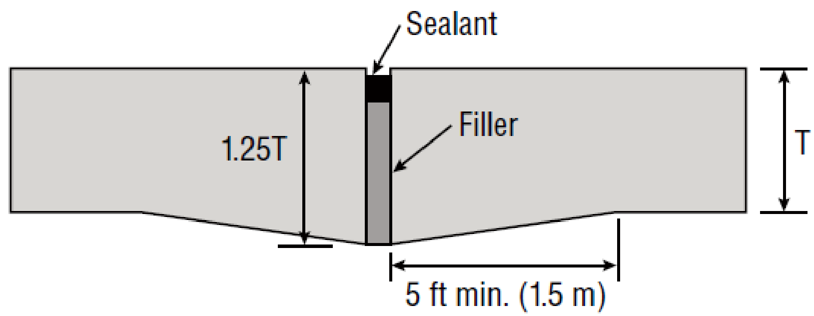


Figure 14-13 Doweled Expansion Joint

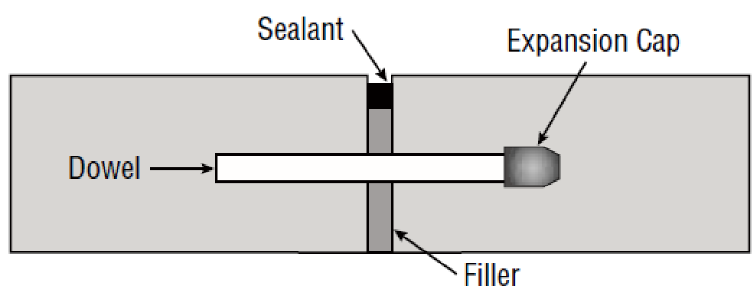


14-2.12.1 Thickened-edge Longitudinal Expansion Joint (Without Dowels).

The thickened-edge type is suggested for longitudinal expansion joints (slip joints) within airfield pavements. Dowels are not used in thickened edge longitudinal expansion joints because differential expansion and contraction parallel with the joints may develop undesirable localized stresses and possibly failure of the existing concrete or the full-depth patch, especially near the corners of existing slabs at transverse joints.

14-2.12.2 Thickened-edge Isolation Joint (Without Dowels).

The thickened-edge isolation joint (without dowels) is the expansion joint best suited to surround or separate any structure that projects through, into, or against the pavement (approaches to buildings, drainage inlets, roadway bridges, and hydrant refueling outlets).

14-2.12.3 Doweled Transverse Expansion Joints.

Use doweled transverse expansion joints within roadway pavements. However, at the angular intersection of pavements, it might be desirable to allow some slippage in the transverse joint to prevent the expansion of one pavement from distorting the other. In such instances, design the transverse expansion joint as a thickened-edge expansion joint.

14-2.13 Filler Material.

Use non-extruding type material for filler material for the thickened-edge and doweled-type expansion joint. The type and thickness of the filler material will depend upon the particular project. Usually, a preformed material of 0.75-inch (20-millimeter) thickness will be adequate, but in some instances a greater thickness may be required, depending on the geometric design of the facility and temperature at the time of full-depth repair. Use a heavy coating of bituminous material not less than 0.25 inch (6 millimeters) in thickness or a standard non-extruding type material not less than 0.25 inch (6 millimeters) in thickness for filler material for thickened-edge slip joints.

Filler material at expansion joints where dowels are used require that the dowels be securely placed and properly aligned. Drill or punch the non-extruding filler material to the exact diameter at the location of the dowels. Furnish it in lengths equal to the width of the placement. When more than one length of the filler board is used along a joint, hold the abutting ends of the filler in alignment. Hold the filler boards firmly in place and extend downward completely to the bottom of the slab and hold the top edge about 0.5 inch (13 millimeters) below the surface of the pavement. Protect the top edge of the filler material while the concrete is being placed. Use a zip strip to accomplish this, where available.

14-2.14 Concrete Placement.

Conventional concrete is typically used for full-depth repairs. The concrete mixture selection depends on the curing time available to reach required strength before the repair area is opened to traffic. If it is acceptable for the concrete to cure for several days (similar to new construction), regular concrete mixtures using Type I or Type II cement can be used. If an earlier opening time (12 hours to 3 days) is needed, a high early-strength concrete, incorporating a higher volume of Type I or Type II cement or using Type III cement, can be used. However, carefully consider the use of a higher volume of cement in areas subject to ASR in concrete. Follow standard concrete placement procedures, including concrete consolidation procedures.

Place the concrete when the ambient temperature is between 40 and 90 degrees F (4 and 32 degrees C).

14-2.14.1 Vibration Adjacent to Edge.

Give extra attention to ensure that the concrete is vibrated well around the edges and beneath the reinforcement.

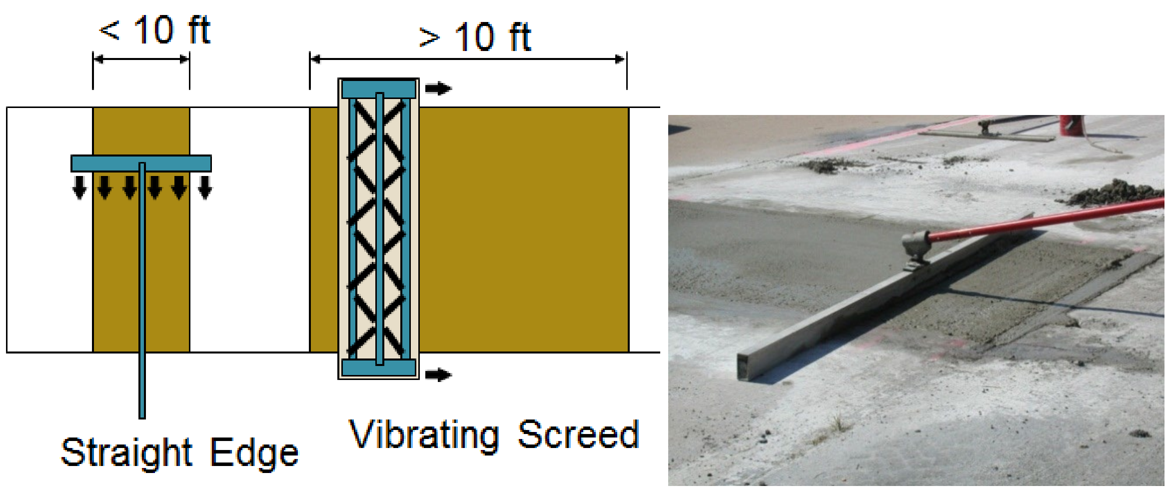
14-2.14.2 Rapid-set Proprietary Cementitious Materials.

Rapid-set proprietary cementitious materials that attain sufficient strength for opening to traffic in as little as four hours are available. Use rapid-set proprietary materials in compliance with the manufacturer’s recommendations. These recommendations typically include mixture proportioning, placing, consolidation, curing, time required before opening to traffic, and allowable placement temperature ranges.

14-2.15 Concrete Finishing and Texturing.

Follow standard procedures when finishing. For repairs less than 10 feet (3.048 meters) in length, strike off the surface of the concrete with the screed parallel to the centerline of the pavement. For repairs more than 10 feet (3 meters) in length, strike off the surface with the screed perpendicular to the centerline of the pavement. Give extra attention to ensure the concrete is not over-finished. Before the concrete becomes non-plastic, give the surface a burlap drag or broom finish to approximately match the surface finish of the existing adjacent concrete pavement unless a grinding operation is to follow the repair work. Typical finishing techniques are illustrated in Figure 14-14.

Figure 14-14 Typical Finishing Techniques for Full-depth Repairs



14-2.16 Curing.

There are many ways to cure concrete. Wet burlap (with or without sand) or white pigmented curing membranes are commonly used for full-depth repairs. Although ponding and constant spraying are the best curing methods, it is generally not practical to do so. Use of white pigmented curing membrane is better for indication of proper coverage and minimizes heating from solar radiation on warm, sunny days. Start curing as soon as the concrete has set sufficiently and the bleed water, if any, has evaporated, but typically no later than 45 minutes after concrete finishing. In hot weather conditions, curing may need to be initiated earlier to minimize the risk of plastic-shrinkage cracking. Proper concrete curing is crucial to achieving a good repair.

14-2.17 Joint Sealing.

Seal any longitudinal or transverse joints around the perimeter of the repair area and any intermediate joints within the repair area. This reduces the entry of water, which may cause pumping and faulting, and reduces the incidence and severity of spalling along the joints. Saw, do not form, the transverse and longitudinal joint sealant reservoirs at the repair area.

14-2.17.1 Inspection of Saw Cuts.

After joint sawing for sealing purposes, inspect the saw cuts for spalling. Repair spalls that extend more than 0.25 inch (6 millimeters) horizontally from the sidewall of the saw cuts. Patch void areas caused by honeycombing of the concrete to provide a solid joint sidewall for the sealant to bond.

14-2.17.2 Cleaning Joints.

Following the sawing operation, clean the joint by sandblasting to remove laitance, sawing dust, and other foreign debris from the joint sidewalls and from the pavement surface adjacent to the joint to a width of approximately 1 to 2 inches (25 to 50 millimeters). A multiple-pass technique has proven very successful in removing foreign debris. When using the multiple-pass technique, the nozzle is directed at one of the joint faces and that face is sandblasted the entire length of the slab. After one face has been completed, the nozzle is directed at the other joint face and it is sandblasted for the entire length of the slab. The pavement surface adjacent to the joint is then sandblasted to remove all surface debris. If water-blasting is used instead of sandblasting, employ a multiple-pass technique and dry the joints before starting the sealing operation. Cleaning the joint is one of the most important steps in obtaining high-quality sealed joints. If the joints are not clean and dry before the sealant is installed, the sealant will usually prematurely fail.

After the joint has been cleaned by sandblasting, clean it again with compressed air to remove any remaining sand or dust. However, complete the final air cleaning of the joint immediately before sealing to prevent sand and dust from blowing back into the joint. A vacuum sweeper can be used to clean around the joints, which will help reduce the amount of debris that blows back into the joints.

14-2.17.3 Installing Backer Rod.

After the joint is cleaned, install the backer rod or separating material. Do not leave the backer materials in the joint for an extended period of time before sealing. These materials may work loose and move up or down in the joint or may even come completely out. Do not twist, stretch, or otherwise damage these materials when they are installed in the joint. Damaging the backer material can cause sealant failure or a poor-quality finished product. Inspect the backer rod or separating material after installation to ensure it has been placed at the proper depth and has not been damaged. After installation of the backer or separating material, the joint is ready for the sealant material. However, seal the joint only if all steps have been properly performed.

14-2.17.4 Sealant Specifications.

Special considerations for the sealant material are jet fuel and jet blast resistance. The full-depth repair may be located in an area where fuel or lubricating or hydraulic fluid spillage may occur or in an area subjected to high temperature from jet blast or exhaust from APUs. Provide and use sealant material that conforms to UFGS 32 01 19 or to ASTM specifications designated for joint and crack sealants for use in these areas.

14-3 PRECAUTIONS.

Comply with the following precautions when performing full-depth repairs:

- Avoid undercutting spalled areas at bottom of remaining existing slab; saw back into adjacent slab until sound concrete is encountered.
- Avoid damaging remaining concrete when lifting out damaged concrete pieces.
- Keep repair areas dry before concrete application.
- Ensure dowel bars are properly aligned.

Although not a common practice for roadway full-depth repairs, consider reinforcement (about 0.2 percent of the cross-sectional area) along the long direction of the full-depth patch at the mid-width location for airfield applications. The reinforcement will keep any crack that may develop tight.

CHAPTER 15 CONCRETE PAVEMENT SLAB JACKING

15-1 INTRODUCTION.

The purpose of slab jacking is to raise one or several adjacent slabs in place permanently as a result of settlement of the support under the pavement. Concrete pavement settlements sometimes occur in areas of poor foundation support. Such settlements not only provide riding discomfort, they also can create large stresses in the slab that can lead to cracking and shattered slabs.

<u>Caution:</u> **Slab jacking involves injection of a grout or polyurethane foam under the settled slab and raising the slabs slowly under pressure to the desired elevation. Use only experienced contractors to perform the slab jacking work due to the complexity and specialized equipment required for the work. The risk of over-stressing the slab being raised is high if the work is not performed with care. Slab jacking is not recommended for repairing faulted joints. Correct faulted joints using a combination of subsealing and diamond grinding of the faulting. Subsealing is also called slab sealing, slabsealing, slab subsealing, slab stabilization, undersealing, and pavement grouting.**

15-2 NEED FOR SLAB JACKING.

Consider slab jacking for any condition that has resulted in slab settlement, such as embankment settlement, settlement of approach slabs, settlement over culverts or utility cuts, voids under the pavements, differences in elevation of adjacent pavements, and pavement slabs that rock under traffic.

The effectiveness of slab jacking is highly dependent on closely monitoring the amount of lift being performed at any one location. It is very important that the slab not be lifted more than 0.25 inch (6 millimeters) at a time to prevent the development of excessive stresses in the slab. Care is required to get the slab to initially move as the grout applied under pressure can cause the slab to move unexpectedly and more than intended. Where careful monitoring during the uplift has been conducted, slab jacking has been effective at leveling out isolated depressed areas

15-3 SLAB JACKING GROUT MATERIALS.

A variety of grout materials have been successfully used for slab jacking and subsealing (Chapter 16). These materials include the following:

15-3.1 Cement-Fly Ash Grout.

The grout typically consists of one-part portland cement (typically Type I or Type II cement) three parts Class F or Class C fly ash, three to seven parts fine aggregates, water in sufficient amount to produce the desired consistency, and wetting agents or other additives may also be used to increase the flowability. The use of a wetting agent lubricates the grout, permitting runs of up to 6 feet (1.8 meters). It also tends to reduce "pyramiding." (A stiff grout may form a pyramid under the slab, leaving unfilled cavities.)

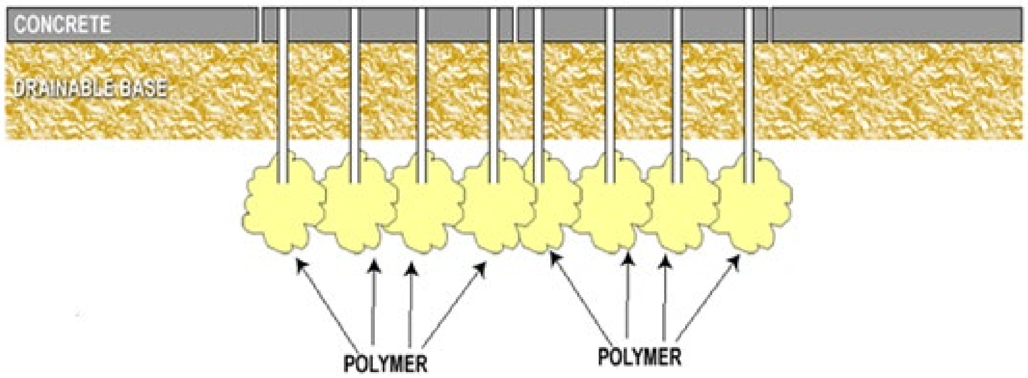
Use a repeated and consistent method of proportioning the grout mixture to ensure uniform consistency. The proper consistency to be used for any given condition is best determined by experience. Generally, a mix of stiff consistency is used to raise the pavement slabs. Check the consistency by a flow cone (CRD-C-611, *Test Method for Flow of Grout Mixtures (Flow-Cone Method)*, ASTM C939, *Standard Test Method for Flow of Grout for Preplaced-Aggregate Concrete (Flow Cone Method)*) at least twice each day. Typical flow-cone times vary between 16 to 30 seconds, depending on the type of materials used in the grout mix. Specify strength requirements of the grout mixture consistent with the location of the grout and the design loads on the pavement. A common requirement is 600 psi (4,134 kilopascals) at seven days as determined by ASTM C39, *Standard Test Method for Compressive Strength of Cylindrical Concrete Specimens*. The grout mixing equipment is shown in Figure 15-1.

Figure 15-1 Grout Mixing Equipment

15-3.2 High-density Polyurethane Polymer Deep Injection.

High-density polyurethane polymer materials are made of two specially formulated liquid chemicals that combine to form a strong, light-weight, foam-like substance. After being injected beneath the pavement into the soil mass, the low-viscosity polymer flows into the voids and weak zones in the soil mass. As the polymeric reaction occurs, the expanding polymer compacts the surrounding soils (Figure 15-2). As more polymer material is injected, the compacted soil mass lifts upwards and raises the profile of the settled slab. The polymer injection process is controlled to ensure the desired uplift of the slab. Because of the complexity of the operation, only use a qualified contractor to perform this process. When using this process, store, proportion, and blend all material within a self-contained pumping unit. Handle and use these materials in accordance with the material manufacturer's instructions and specifications.

Figure 15-2 The Polymer Deep Injection Process



In this chapter, only the generic process using the cement-fly ash grout is presented. Information on the polymer injection process is not presented here because of the proprietary nature of the process. Information can be obtained from contractors on a project-by-project basis.

15-4 INJECTION HOLE LOCATIONS.

Identify the location of injection holes in the field. The slab jacking crew superintendent normally locates the holes, taking into consideration the size or length of the pavement area to be raised, the elevation differences, subgrade and drainage conditions, location of joints or cracks, and the manner in which the slabs will be tilted or raised.

As a general rule, do not place holes less than 12 inches (300 millimeters) or more than 18 inches (450 millimeters) from a transverse joint or slab edge. Do not place the holes more than 6 feet (1.8 meters) center to center so that not more than approximately 25 to 30 square feet (2.33 to 2.79 square meters) of slab is raised by pumping any one hole. Additional holes may be required if the slab is cracked. Where the pavement has settled and the slabs are in contact with the subbase, a single hole located in the middle of the panel may be sufficient.

15-5 DRILLING INJECTION HOLES.

Holes that are 1.25 to 2 inches (32 to 50 millimeters) in diameter are drilled by pneumatic drills, core drills, or other devices capable of drilling grout injection holes through the concrete pavement and base material. Provide and use equipment that is in good condition and operated in such a manner that the holes are vertical and round. Do not exceed 200 psi (1,379 kilopascals) of down-feed pressure. Where the concrete pavement is tight against the base material, the use of an airline or blow pipe may be necessary to form a cavity under the pavement slab for the grout pressure to take effect.

Where the pavement is placed and bonded to a cement-treated or other stabilized base material, drill grout holes completely through the base material. Inject the grout below the base material rather than between the pavement and base material. Do not leave grout holes ungrouted overnight and grout holes within four hours.

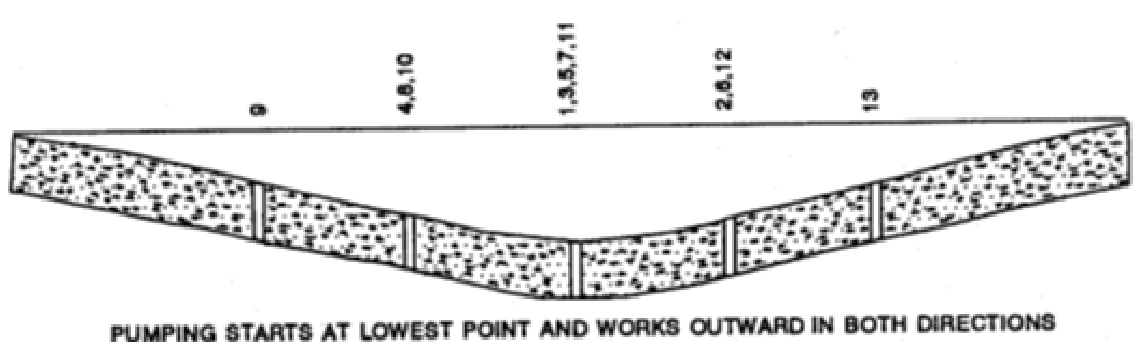
15-6 GROUT PUMPING.

Start pumping and jacking operations at the lowest point in a depressed area and work outward in both directions (Figure 15-3). Pumping progresses by lowering into successive holes an injection pipe connected to the discharge hose of the grout pump. An expanding rubber packer is used to seal the open space between the pipe and the drill hole. Do not extend the injection pipe below the bottom of the pavement. Provide and use an injection pipe equipped with a return line to circulate the grout while no grout is being placed. Lift in increments of about 0.25 inch (6 millimeters), with frequent changes in injection locations to minimize slab stresses and avoid cracking.

Use a rate of grout injection that is uniform and as slow as possible, usually a minimum of 0.5 cubic foot (0.014 cubic meter) per minute to a maximum of 2 cubic feet (0.056 cubic meter) per minute. Initial pumping is normally at the lower rate and is increased as lifting progresses. As the desired elevation is approached, reduce the lifting rate. When grout is extruded from joints, cracks, or from the pavement edge before the target elevation is reached, regrouting in new drill holes and additional slab jacking will be necessary. Applied pressures for slab jacking are normally in the range of 75 to 200 psi (517 to 1,379 kilopascals), with short pressure surges up to 600 psi (4,134 kilopascals) to initiate lifting of bonded slabs.

Constant observation and monitoring of the applied pressure is the most important single factor affecting the successful application of slab jacking. A rapid increase in the applied pressure can signal a stoppage of flow that could be followed by excessive lifting of the slab and slab cracking if pumping continues. A sudden reduction of pressure could indicate a loss of lift due to subsurface leakage of the grout.

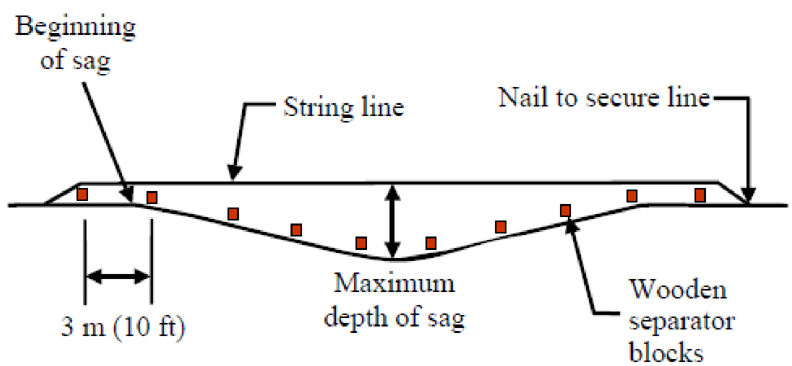
Figure 15-3 Grout Pumping



15-7 ELEVATION CONTROL DURING SLAB JACKING.

Before slab jacking operations are started, **e**stablish a method of controlling the amount the slab is to be raised and establish the finished elevation of the pavement. For short dips up to approximately 50 feet (18.3 meters) in length, a tight string line is adequate, provided the joints are true and plane with those of the adjacent pavement (Figure 15-4). For dips in excess of 50 feet (18.3 meters) in length, use an engineer's level and rod or a laser-based elevation control system to check the profile well beyond the dip; this will avoid building a localized bulge into the pavement.

Figure 15-4 Elevation Control

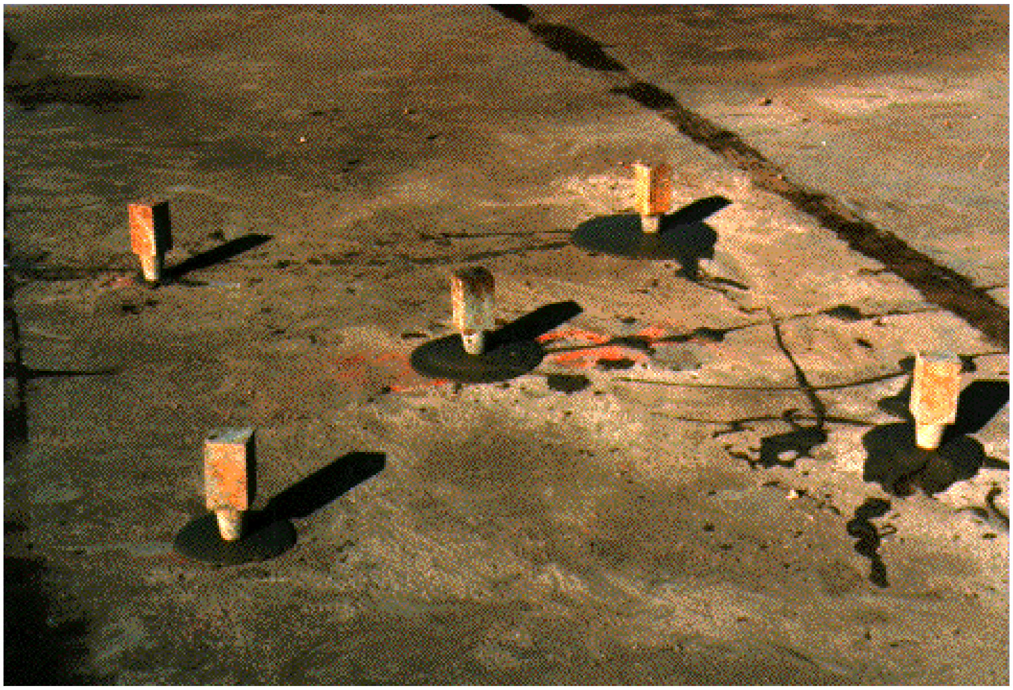


15-8 PLUGGING AND CLEANUP.

After completing slab jacking at a hole and the discharge pipe is removed, plug the hole immediately. Place temporary tapered wooden plugs into the injection hole to retain the grout pressure and stop any mixture return flow (Figure 15-5). Once the slab is jacked to the desired elevation, the temporary plugs are removed and the injection holes are filled with a stiff one-part-water, three-part-cement grout, or an approved concrete mixture, or a proprietary patching product. These areas are then finished flush with the existing pavement surface. Keep surfaces adjacent to the grouting operation clean of excess grout and other materials. Broom and wash off grout on the pavement to avoid unsightly discoloration and to remove the grout before it bonds to the concrete surface.

Caution: **The primary concern with slab jacking is excessive raising of the slab, which can induce stress concentrations in the slab and produce cracking. Therefore, it is critical to raise the slab slowly and no more than 0.25 inch (6 millimeters) at a time when pumping grout at each hole.**

Figure 15-5 Temporary Plugs



CHAPTER 16 SUBSEALING JOINTED CONCRETE PAVEMENTS

16-1 INTRODUCTION.

The purpose of subsealing is to stabilize the pavement slab by restoring support under the slab, typically at joint and crack locations. Subsealing is also called slab sealing, slabsealing, slab subsealing, slab undersealing, slab stabilization, undersealing, and pavement grouting. Pumping at joints and cracks with subsequent loss of support under the slab can occur beneath concrete pavements due to the presence of an erodible base or subbase, presence of moisture under the pavement, or significant slab deflections due to heavy traffic loadings.

Poor support conditions can lead to joint or crack faulting and corner breaks. Loss of support (voids) is indicated by signs of pumping at joints or by means of nondestructive deflection testing at joints. Subsealing involves the injection of a cementitious grout through holes drilled in the slab. The cementitious grout will, without raising the slab, fill the voids under it, displace water from the voids, and reduce the damaging pumping action caused by excessive pavement deflections. Subsealing reduces deflections at joints and cracks and retards the development of additional pavement deterioration.

16-2 NEED FOR SUBSEALING.

For jointed concrete pavement, accomplish subsealing as soon as significant loss of support is detected at slab corners. Symptoms of loss of support include increased deflections under vehicular loading, transverse joint faulting, corner breaks, and the accumulation of fines in or near joints or cracks on traffic lanes or shoulders. Consider subsealing at all existing repairs that show evidence of pumping or settlement. To be effective, perform subsealing before the voids become so large that they cause pavement failure.

<u>Caution:</u> To be most effective, it is important that slab undersealing be performed prior to the onset of pavement damage due to loss of support. Also, before considering undersealing of the slabs exhibiting loss of support, it is important that the cause(s) of the condition that led to the slab loss of support be addressed. This may require improving subsurface drainage conditions and/or restoration of load transfer at joints and cracks. Undersealing slabs where loss of support does not exist may be detrimental to pavement performance.

16-3 PAVEMENT SUBSEALING KEY STEPS.

The key steps for effective undersealing include the following:

1. Void (loss of support) detection
2. Selecting the grout material

3. Establishing the grout hole pattern
4. Drilling holes
5. Grout injection
6. Testing effectiveness of grouting
7. Grinding, if necessary, to restore profile at affected joint and crack location

16-4 SUBSEALING GROUT MATERIALS.

A variety of grout materials have been successfully used for slab jacking and subsealing. These materials are described in paragraph 15-3. The difference between slab jacking and subsealing is that when subsealing, the cementitious or polymer injection process is stopped at the point where all voids are filled to ensure there is no raising of the slab.

16-4.1 Polyurethane Polymer Subsealing.

The application of high-density polyurethane polymer material is similar to the application using cementitious grout. The polymer is injected directly into the void under the slab so as to fill the void with the high-density polymer foam (Figure 16-1).

Figure 16-1 Polymer Subsealing Process

In this chapter, only the generic processes using the cement-fly ash grout and polymer foam to directly fill the voids are presented. Information on the polymer deep injection process is not presented here because of the proprietary nature of the process. Information can be obtained from contractors on a project-by-project basis. Also note that in the past, asphaltic materials were used to underseal concrete pavements. This practice is no longer widely used and therefore not discussed.

16-5 VOID DETECTION.

Conduct a comprehensive survey to determine void locations beneath concrete pavement. Take void detection measurements during the preliminary evaluation and the repair process. Void detection can be a complicated process as natural wetting and drying cycles and thermal variations can cause slab curling. Interpretation of field conditions by experienced personnel is always desirable. Suggested methods follow.

16-5.1 Visual Inspection.

The simplest method is a visual inspection of the pavement to locate areas of distress. The presence of ejected subgrade or base material, staining of pavement surfaces adjacent to joints, excessive vertical movement at joints or cracks under traffic, and faulting of joints are evidence of possible voids under the slab.

16-5.2 Proof Rolling.

A common method of determining the presence of voids is called “proof rolling.” In this procedure a heavily loaded vehicle (minimum 18,000-pound [80-kilonewton] axle load) drives slowly over a transverse joint while observing deflection of the slabs. If deflection is visually observed, under-seal the joint. Deflections during proof rolling can be measured by devices equipped with sensitive dial gauges that contact the pavement. Gauges are attached to a firm base located off the pavement or at a sufficient distance from the test locations. The dial gauges are read visually or recorded electronically. Under-seal any slab showing deflection in excess of 0.015 inch (0.38 millimeter).

16-5.3 Nondestructive Deflection Testing.

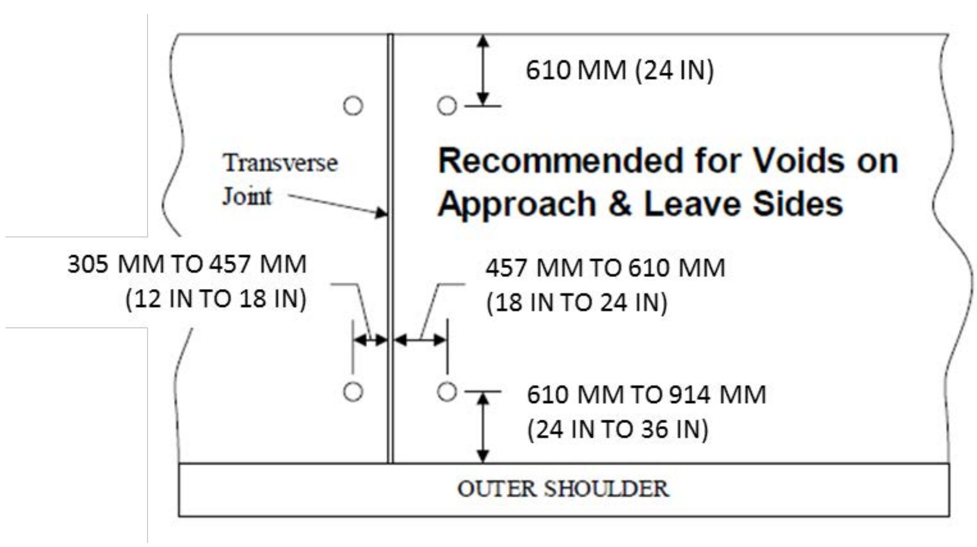
On large critical projects, the most effective method to locate voids under the pavement slab is the falling-weight deflectometer (FWD). The device measures deflections at a joint under several load levels and the deflection data is analyzed to determine the extent of void at the test location (Figure 16-2).

Figure 16-2 Falling Weight Deflectometer

16-6 INJECTION HOLE LOCATIONS.

Subsealing injection hole locations are similar to slab jacking (paragraph 15-4), the exception being to locate subsealing at pavement joints where the most common hole pattern is a four-hole pattern with two holes on each side of a transverse joint. The holes are located in the wheel tracks, with the approach slab holes nearer the joint than the leave slab holes. Typical distances from the joint are 12 to 18 inches (305 to 457 millimeters) for the approach slab and 18 to 24 inches (457 to 610 millimeters) for the leave slab (Figure 16-3). It is noted that in some cases the slab undersealing may be needed only on the leave (exhibiting void) side of the joint. Also, additional holes may be required for voids under the longitudinal joints or along the shoulder edge.

Figure 16-3 Four-hole Pattern at Joint for Grout Injection



16-7 DRILLING HOLES.

Drilling holes is identical to paragraph 15-5.

16-8 GROUT INJECTION.

Grout injection proceeds by lowering into successive holes a pipe connected to the discharge hose of the grout pump. The grout hole is sealed by a device called a packer. Two types are commonly used, as described below. The drive packer consists of a tapered pipe tapped into and out of the grout hole. Drive packers are used with 1-inch (25-millimeter) -diameter holes, and the expanding rubber packer consists of a threaded inner pipe, a thin-walled steel outer sleeve, and a short rubber sleeve at the bottom. This type of packer is used with 1.5-inch (33-millimeter) -diameter and larger holes.

Monitor movement (uplift) of the slabs during the grouting operation. To properly monitor movement of the slabs, gauges capable of reading movement of 0.001 inch (0.025 millimeter) must be used. Place the base for the gauge 3 to 4 feet (0.91 to 1.22 meters) off the slab being monitored. The gauges are set up at the joint corner locations and are not moved until grouting of the joint is completed. Typical pumping pressure are in the range of 40 to 60 psi (275 to 413 kilopascals) range. Always start grout injection with a low pumping rate and pressure. Stop pumping if the slab begins to rise or when no material is being injected at the maximum allowable pressure of 100 psi (689 kilopascals). Pumping of short surges up to 200 psi (1,378 kilopascals) are allowable for the grout to penetrate the void structure. If grout returns through an adjacent hole, stop pumping and insert the packer into another hole. If water or diluted grout is observed flowing from joints or cracks in the pavement, continue pumping until undiluted grout is observed.

Generally, when pumping the four-hole pattern at a joint, begin pumping first at the centerline and then continue with the holes closest to the shoulder. This sequence will drive any trapped water to the outside of the slab and through the transverse and shoulder joints. Where there is also void along the shoulder and extra holes are required, the sequence of grout injection becomes more complicated. Usually, the shoulder joint locations are pumped last.

<u>Caution:</u> To ensure that the slab is not raised, place straightedges with gauges attached over the slab to measure any upward movement of the slab. At the first indication of movement, stop the grout-injecting procedure. If the slab is raised, high slab stresses may develop, leading to slab cracking.

16-9 RETESTING SLAB CORNERS.

After a minimum of 24 hours has elapsed following completion of subsealing, test the grouted slabs for stability at the same points as previously tested. Conduct this testing using the same procedure used for the pre-grouting test. Include other joints that were not grouted in this test for use as a control. If loss of support still exists after grouting, re-grout the slab. In each regrouting, new holes will be needed. It is recommended that if voids are still present after three attempts to stabilize the slab, do not attempt any further regrouting and consider other repair methods such as full-depth repair in lieu of regrouting.

16-10 PLUGGING AND CLEANUP.

Plugging and cleanup is identical to paragraph 15-8.

CHAPTER 17 PCC PAVEMENT DIAMOND GRINDING

17-1 INTRODUCTION.

Diamond grinding, using closely spaced diamond saw blades mounted on a rotating shaft, removes a thin layer of the concrete surface to correct for faults at joints and crack locations and correct for surface defects, such as wheel path rutting. Diamond grinding results in re-profiling the pavement and improves the pavement's ride quality.

Note that diamond grinding is a different process than diamond grooving. Diamond grooving is a process in which parallel grooves in the transverse direction are cut into new airfield runway pavements using diamond saw blades with a typical center-to-center blade spacing of 0.75 inch (19 millimeters). The principal objective of grooving is to provide escape channels for surface water, thereby reducing the incidence of hydroplaning that can cause wet weather crashes. Diamond grooving is typically not used for roadway pavements except at sharp curves.

17-2 NEED FOR GRINDING.

Consider diamond grinding when a pavement survey reveals surface defects such as faulted joints and cracks in excess of 0.125 inch (3 millimeters), roughness in excess of 0.125 inch (3 millimeters) in a 10-foot (3-meter) length, or rutting up to 0.375 inch (10 millimeters). If skid resistance is to be examined, examine it on the areas not scheduled for grinding for any of the previously mentioned defects. If a large area requires grinding to improve skid resistance, economics may favor grinding the entire pavement surface.

<u>Caution:</u> Note that diamond grinding primarily improves the pavement's ride quality and does not directly improve the structural condition of the pavement. Diamond grinding is frequently used in combination with other concrete pavement repair techniques that improve the structural condition of the pavement. Diamond grinding may not be effective over the long term if the pavement exhibits significant deterioration or if causes of faulting are not addressed. Do not consider diamond grinding for pavements exhibiting concrete materials-related distress, such as D-cracking and ASR. Perform any partial-depth and full-depth patching before grinding.

17-3 GRINDING PROCESS.

The diamond grinding process is free of impact and does not damage joints. The pavement grinder is similar to a wood plane. The front wheels are designed to pass over a fault or bump, the cutting head shaves off the fault or bump, and the rear wheels ride in a smooth path left by the cutting head.

Diamond grinding requires heavy, specially designed equipment (Figure 17-1) that uses diamond saw blades gang-mounted on a cutting head (Figure 17-2). Spacers are placed between the saw blades to reduce the amount of cutting to be done. This combination of saw blades and spacers gives the pavement the characteristic corduroy texture that also improves skid resistance (Figure 17-3).

Because the hardness of the aggregate will influence the grinding operation, identify the type of aggregate in the PCC pavement when contracting the work. Grinding a pavement with extremely hard aggregate (such as trap rock, river gravel, or quartzite) takes more time and effort than grinding a pavement with a softer aggregate (such as limestone) and will cost more.

Figure 17-1 Grinding Equipment

Figure 17-2 Gang-mounted Diamond Saw Blades

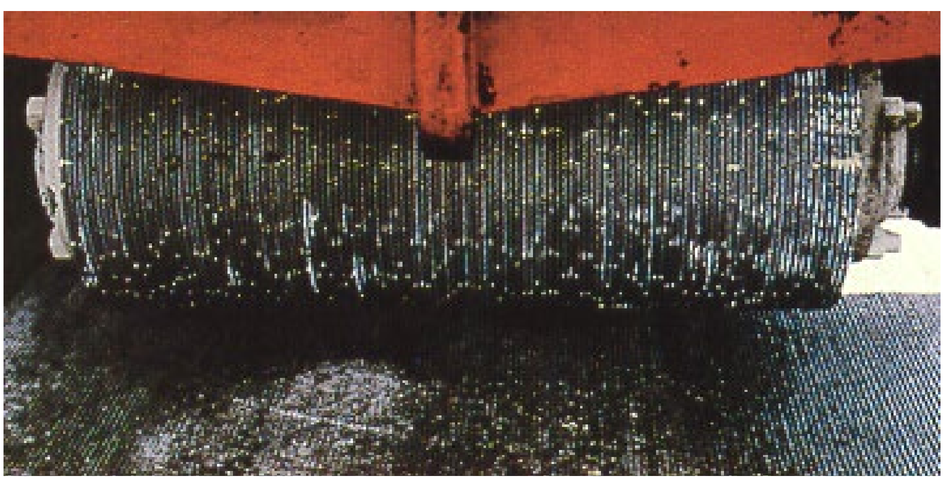


Figure 17-3 Diamond-ground Surface

17-4 TEST SECTION.

Before work begins, test the equipment on a small section of the pavement to ensure that proper blade spacing is being used for the specific aggregate on the project. The width of the spacers between the saw blades is varied depending on the hardness of the aggregates. Use a thinner (smaller) spacing between the blades with harder aggregate. As the diamond grinding head cuts the surface of the pavement, thin fins of concrete are left between the cutting blades. These fins typically break off during the grinding process. If these fins do not break off, use a grinding head with thinner spacers. When grinding aggregate susceptible to polishing, provide more area between the blades.

Use a fin depth (land area thickness) measured at the thickest point of 0.08-inch (2-millimeter) minimum and have an average thickness of 0.1 inch (2.5 millimeters). For harder aggregates not subject to polishing, use a minimum fin depth of 0.065 inch (1.7 millimeters) and an average thickness of 0.08 inch (2 millimeters).

17-5 GRINDING PROCEDURE.

Grinding equipment uses diamond blades mounted in series on a cutting head. The cutting head typically has a width ranging from 48 to 50 inches (1.22 to 1.27 meter). The desired corduroy texture is produced using a spacing of 50 to 60 blades per foot (164 to 197 blades per meter). New, improved grinding machines and grinding blades have greatly increased the capability to provide extremely smooth profiles. Always start and end grinding perpendicular to the pavement centerline and consistently maintain the grinding parallel to the centerline.

The grinding and grooving operation produces slurry consisting of ground concrete and the water used to cool the blades. This slurry is picked up by onboard wet-vacuums. Continuously remove the slurry residue. Do not permit grinding slurry to flow across adjacent lanes into gutters or other drainage facilities. Dispose of grinding slurry in accordance with local environmental regulations.

The following grinding procedures are for roughness and fault removal.

17-5.1 Roughness Removal.

For areas identified as being too rough, establish a level of restoration and grind the nominated sections. Following grinding, test the roughness again. Testing is typically accomplished using equipment such as the California profilograph (Figure 17-4). Prior to grinding, establish the grade. Do not use the old pavement surface as the reference unless using a long beam or skid. Where sags in the pavement are encountered, first remove the sags by slabjacking. Grinding at a sag point will not remove roughness. Reinvestigate the pavement following slabjacking to revise the grinding requirements, if necessary.

Figure 17-4 California Profilograph

17-5.2 Fault Removal.

Prior to grinding the faulted joints (and cracks), underseal the slabs to prevent the fault from recurring. Cut in to the faulted joint during grinding to produce smoother joints and a more efficient operating surface. Feather the fault back some distance into the slab. The distance required depends on the allowable roughness. The American Concrete Pavement Association has a general guideline of 1 foot (300 millimeters) for every 0.1 inch (2.5 millimeters) of faulting. This is slightly rougher than 0.125 inch (3 millimeters) in 10 feet (3 meters). Feathering distances necessary to meet straight-edge requirements of 0.125 inch (3 millimeters) in 10 feet (3 meters) are shown in Table 17-1. If the entire slab is to be ground, feather out the depth of the cut to the next joint to remove the fault.

Table 17-1 Feathering Distances

Fault Height Inches (Millimeters)	Feathering Distance Feet (Meters)
0.125 (3)	2.5 (0.76)
0.25 (6)	5.0 (1.52)
0.375 (10)	7.5 (2.29)
0.5 (13)	10.0 (3.04)
0.625 (16)	12.5 (3.81)
0.75 (19)	14.0 (4.27)

17-5.3 Skid Resistance.

Grinding can improve skid resistance. Grind only those lanes needing treatment. Feather the edges of the ground areas into the adjoining areas to eliminate a sharp drop-off. Grind the pavement in a longitudinal direction that begins and ends at a line marked perpendicular to the pavement centerline. A successful grinding operation produces a uniformly finished surface that is free of joint or crack faults and provides positive lateral surface drainage.

17-6 ACCEPTANCE TESTING.

After completing grinding and texturing, test the pavement for smoothness. Accept only pavement which meets the surface tolerance for a new pavement as required by the specifying agency. Specify use of the same test equipment in the acceptance testing as used in the initial evaluation along with the procedures to be followed in acceptance testing. Do not reduce the thickness of the pavement through grinding by an amount that reduces the nominal load-carrying capability of the pavement without prior approval of the Pavements DWG or their designated representative.

This Page Intentionally Left Blank

CHAPTER 18 CONCRETE PAVEMENT LOAD TRANSFER RESTORATION

18-1 INTRODUCTION.

New pavement joints typically exhibit good load transfer, particularly if the joints are doweled. However, repeated heavy loads over time can cause an elongation of the dowel sockets and result in dowel looseness and a reduction of load transfer efficiency. As the load transfer efficiency decreases, the load-related deflections along the joints, especially at corner locations, increase. This can accelerate the development of joint-related distresses, such as pumping, spalling, faulting, and slab corner cracking. For non-doweled concrete pavements, aggregate interlock at joints is relied upon to provide load transfer across a joint. However, under traffic loading and due to concrete drying shrinkage over time, aggregate interlock becomes less effective. If the non-doweled pavement continues to carry heavy traffic, the non-doweled joints may be good candidates for load transfer restoration (LTR).

For many years, the typical way to transfer shear at a construction joint was with a keyed joint. Many steel bulkhead forms are available with a keyed profile. However, most experts no longer recommend keyed joints since they seldom stay tight enough to provide positive shear transfer. In accordance with ACI 360R-10, *Guide to Design of Slabs-on-Ground*, the male and female components lose contact when the joint opens due to drying shrinkage, which can lead to breakdown of the joint edges and failure of the top side portion of the key.

Restoration of load transfer is used to retard further deterioration of the concrete pavement by reducing the potential for joint-related distresses. Restoration of load transfer can improve pavement performance by reducing pumping, faulting, and corner breaks, and also by retarding the deterioration of transverse cracks. In most instances, the pumping and faulting distresses can be corrected by installing joint load transfer devices. Diamond-grinding the pavement surface is often done in conjunction with LTR to restore rideability.

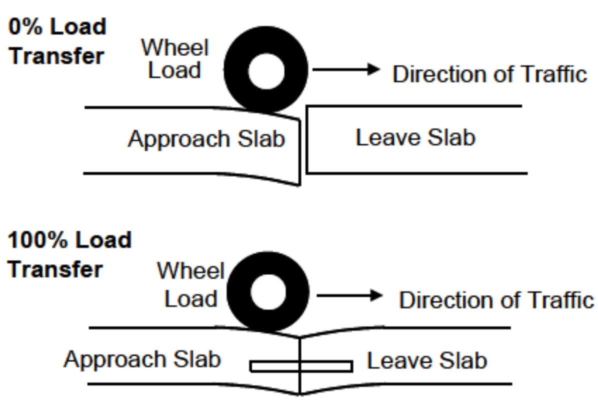
<u>Caution:</u> LTR is not used for heavily trafficked airfield concrete pavements. The shear stresses caused by the heavy loading may be greater than the bond strength between the slot patch material and the existing concrete. This can cause dowel bars in the slots to break out of the slots under repeated aircraft loadings.

18-2 NEED FOR LOAD TRANSFER RESTORATION.

Transverse joints or cracks that would benefit from improved load transfer can be identified by measuring the existing load transfer efficiency using a nondestructive deflection testing device such as the FWD. Conduct these tests during periods of cooler temperatures (less than about 80 degrees F [27 degrees C]) when the slab joints and cracks are not tightly closed. Consider LTR for joints or cracks having a measured load transfer efficiency (ratio of the deflection on the unloaded side of a joint or crack divided by the deflection of the loaded side) of less than 50 percent.

For thicker airfield pavements being considered for LTR, use the heavier version of the FWD, commonly called the heavy weight deflectometer (HWD). The HWD can apply loading up to 50,000 pounds-force (222 kilonewtons) that better simulates the loading of the heavier aircraft. For concrete pavements 12 inches (300 millimeters) or less in thickness, a standard FWD meets the testing needs and test loads of up to 20,000 pounds-force (89 kilonewtons) can be applied. The concept of load transfer at a joint is illustrated in Figure 18-1. Take deflection measurements as near as possible to the joint or crack. Take deflection measurements in the center of the load plate, positioned tangentially along the joint, and at 12 inches (300 millimeters) across the joint (from the center of the load plate).

Figure 18-1 Load Transfer at a Joint



18-3 LOAD TRANSFER RESTORATION (LTR) KEY STEPS.

The key steps in performing LTR include the following:

1. Correct causes of poor load transfer
2. Create slots at the joints being treated by saw-cutting and chipping concrete
3. Place load transfer devices, typically dowel bars, into the slots and properly align the bars
4. Use compressible inserts
5. Place repair material into the slots, ensuring good coverage under the dowel bars
6. Restore the joint at the slot locations and seal the joints
7. Grind at joint locations or over the full pavement width and length to improve ride quality

18-4 CORRECTION OF DEFICIENCIES.

Before load transfer devices are installed, it is necessary to determine the cause of the joint or crack distress. Attempt to correct the cause(s) of these deficiencies prior to LTR. Slabs exhibiting extensive distress along a joint may require portions of or the entire slab to be replaced. Also, successful installation of load transfer devices requires sound concrete adjacent to the joint or crack. If the concrete near the joint or crack is significantly deteriorated, perform full-depth repair (with provisions for load transfer) in lieu of LTR. Perform the following additional work if required prior to LTR. Subsealing (essential if loss of support exists) to fill voids in the pavement structure and to restore support to the pavement slabs, and full-depth and spall repairs to replace highly distressed joints and slabs with corner breaks, "D" cracking, etc.

18-5 DOWEL LOAD TRANSFER RESTORATION (LTR) PROCESS.

Installing round dowel bars is the primary method of restoring load transfer at existing joints or cracks. In the past, use of proprietary devices was attempted but has fallen out of favor because of cost and uneven performance in the field. Field experience indicates that round dowel bars can effectively transfer loads across joints and cracks.

18-5.1 Dowel Size Requirement.

Specify different size dowels for different thicknesses of pavements. Dowel size and spacing for construction, contraction, and expansion joints are shown in Table 18-1.

Table 18-1 Dowel Size Requirements

Pavement Thickness, inches (millimeters)	Dowel Length, inches (millimeters)	Dowel Spacing, inches (millimeters)	Dowel Bar Diameter, inches (millimeters)
8 to 11.5 (200 - 290)	16 (400)	12 (300)	1 (25)
12 to 15.5 (300 -395)	18 (450)	15 (380)	1.25 (32)
16 to 20.5 (400 - 520)	20 (500)	18 (450)	1.5 (38)
21 to 21.5 (530 - 550)	24 (600)	18 (450)	2 (50)
>26 (660)	30 (762)	18 (450)	3 (75)

For roadway pavements, four dowel bars are typically used for each wheel path. The bars are typically spaced at 12 inches (300 millimeters).

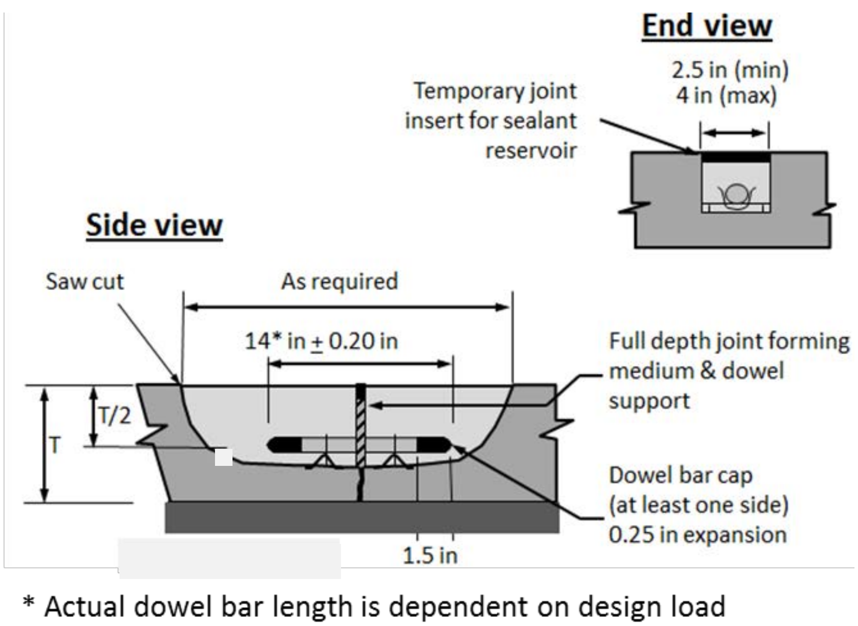
18-5.2 Cutting Slots for Dowel Installation.

Slots for installing dowels are cut using diamond-blade saws. Gang-mounted multiple blade saws are recommended to speed operations (Figure 18-2). Cut the slots so the dowels can be placed horizontally parallel to the pavement surface, perpendicular to the joint, and at mid-depth of the slab (Figure 18-3).

Figure 18-2 Gang-Mounted Multiple Saw Blades for Slot Cuts

Where slab movement at the crack/joint location is required, cut slots to allow dowel placement parallel to the pavement surface at mid-depth and perpendicular to the orientation of the crack/joint.

Figure 18-3 Dowel Placement in Slot

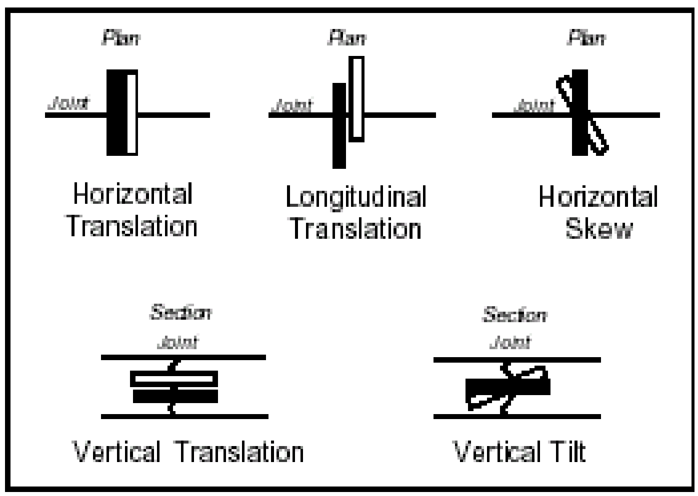


Take care to ensure the dowel bars are correctly aligned in the slots. Poor dowel alignment, as shown in Figure 18-4, can cause joint locking (or a working crack), spalling in the patch material, and poor load transfer efficiency.

Figure 18-4 Types of Dowel Bar Misalignment and Effect on Performance

Type of Misalignment	Effect on Spalling	Cracking	Load Transfer
Horizontal Translation	—	—	yes
Longitudinal Translation	—	—	yes
Vertical Translation	yes	—	yes
Horizontal Skew	yes	yes	yes
Vertical Tilt	yes	yes	yes

Categories of dowel misalignment are illustrated below.



Misalignment categories.

18-5.3 Concrete Removal & Dowel Installation.

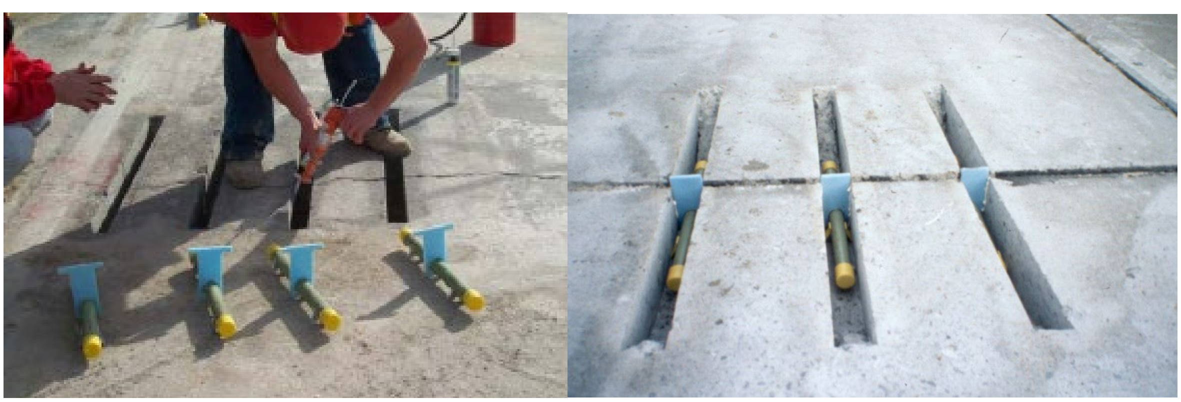
Light-weight (10 to17 pounds [4.5 to 7.7 kilograms]) chipping hammers are used to remove the concrete within the saw cuts (Figure 18-5). Take care not to punch through the slot bottom. The slot is then cleaned by sandblasting or any method that will ensure removal of all sawing residue, dirt, or oil that may prevent bonding of the patch material to the slot faces.

Figure 18-5 Use of Chipping Hammers to Remove Concrete

Each dowel is placed upon a support chair to allow the patch material to surround the dowel. One end of the dowel is oiled and painted and an expansion cap placed at the end of the dowel bars (Figure 18-6). Provide and use the dowels with a filler board or Styrofoam material at mid-length to prevent intrusion of the patch material into the joint or crack (causing point bearing and compression failure during warm weather) and to form the joint in the slot (Figure 18-6).

Before installing the dowel bar, caulk the perimeter of the joint within each slot to prevent the intrusion of the patch material into the joint (Figure 18-6).

Figure 18-6 Use of Compressible Insert



18-5.4 Patching Material.

High early-strength concrete or proprietary cementitious materials extended with small-sized aggregate have been used to fill the slot at most installations to date. The patch material used with load transfer devices is a critical factor in performing this technique. It is necessary to ensure there is thermal compatibility between the patch material and the existing concrete; therefore, use aggregates in the patch material that have a coefficient of thermal expansion (CTE) property similar to that of the aggregates used in the existing concrete.

It is important that a laboratory evaluation be made of any patch material utilized for patching the slots. Evaluate the following key factors: working time, rapid early-strength gain, thermal compatibility with existing concrete, and shrinkage property.

18-5.5 Placing Patch Material.

After properly cleaning the patch area, apply a bonding agent if required by the patching material manufacturer. The type of bonding agent depends on the bond development requirements for opening to traffic and type of patching material used. Follow the manufacturer's recommendations with all patching materials. Use bonding agents recommended by the manufacturer for the placement conditions. Bonding agents or grouts may not be needed when using high-early-strength concrete.

Place and consolidate the patch material to eliminate all voids at the interface of the patch and the existing concrete and at the load transfer device and the patch material (Figure 18-7). Each slot requires two to four short, vertical penetrations of a small-diameter spud vibrator. Place the patch material flush with the adjacent concrete and take care to prevent intrusion of the patch material into the adjacent joint areas. However, the patch material is finished slightly "humped" (no more than 0.125 inch [3.175 millimeters]) if diamond grinding is to be employed.

Figure 18-7 Placing and Consolidating Patch Material

After consolidation and finishing, place a curing compound on the patching material to minimize rapid patch material shrinkage. Depending upon the type of repair material, the pavement may be opened to traffic in as little as a few hours. The minimum compressive strength required to open a repair to traffic is about 2,000 psi (13.7 megapascals) for slabs 8 inches (200 millimeters) or thicker.

18-5.6 Finishing Activities.

LTR may result in increased roughness at joint locations if the patch materials are not properly finished. This is typically due to differences in elevation between the finished repair area and the existing pavement, or perhaps due to shrinkage or settlement of the repair material. Consequently, the joint locations or the entire pavement project being rehabilitated is often diamond-ground to provide a smooth-riding surface. Complete grinding as soon as is feasible after the patch material has attained the specified strength, typically 4,000 psi (27.4 megapascals) compressive strength.

After the patch material has cured and the surface diamond-ground, re-establish the transverse joint at the affected joints by sawing over the length of the joints and through the filler board then prepare and seal the joint.

18-6 KEYED JOINTS LOAD TRANSFER RESTORATION PROCESS.

Although not recommended for new construction, keyed construction joints (Figure 18-8) are still found in existing airfield pavements. In addition to the loss of load transfer due to shrinkage, the female keyed flanges are prone to spalling. For this reason, keyed joints are recommended to be removed and replaced with a doweled joint.

Figure 18-8 Keyed Joint

18-6.1 Keyed Joint Key Steps.

Restoration of keyed joints is identical to full-depth repair of concrete pavements (Chapter 14), with the following exceptions.

18-6.1.1 Keyed Joint Concrete Removal.

Depending on the joint stress severity, remove the complete keyed joint for the entire edge of the slab. The male end of the keyed joint needs to be removed with a concrete saw, leaving the joint flush, vertical, and ready to accept new dowels. The female end needs to be cut far enough back to allow the use of a dowel drill. This can be as much as 4 feet (1.2 meters) for the typical gang-operated concrete dowel drill (Figure 18-9).

Figure 18-9 Gang-operated Dowel Drill

18-6.1.2 Dowel Bar Placement and Installation.

Install dowels along the face where the keyed joint male end has been removed. Place and install the dowel bars in accordance with paragraph 18-5.

18-6.1.3 Tie Bar Placement and Installation.

Secure the newly cut joints other than the existing keyed joint with tie bars. Install tie bars in the same manner as the dowel bars (paragraph 14-2.10), but both ends are permanently secured.

This Page Intentionally Left Blank

CHAPTER 19 CONCRETE PAVEMENT RETROFITTED EDGE DRAINAGE

19-1 INTRODUCTION.

The presence of moisture under pavement, if not removed quickly, leads to poorly performing pavement or failure. One of the most critical considerations for pavement design is how to control water entering the pavement. The primary source of water under the pavement is rainwater that infiltrates into the pavement due to poorly sealed transverse and longitudinal joints and cracks. Many older concrete pavements have non-drainable bases and subbases with no provision to quickly remove water from the pavement system. The infiltration of water through the pavement causes saturation of the base and subbase. Without drainable layers, traffic loads cause pumping at joints and crack locations. Over time, repeated traffic loading leads to a loss of support along joints and cracks, resulting in high deflections and slab cracking.

19-2 NEED FOR PAVEMENT-EDGE DRAINAGE.

- The following conditions may warrant the addition of pavement-edge drainage:
- Inadequate surface drainage facilities (shallow ditches or absence of ditches)
- Water table may rise within the pavement system
- Surface water entering the pavement system at joints or cracks, surface edges, or percolating through the shoulders
- Water in the subgrade rising vertically via capillary action

19-3 DRAINAGE SYSTEM CLASSIFICATIONS.

Pavement drainage is grouped into two major classifications: surface and subsurface. When both types are required for efficient maintenance and protection of the pavement, it is generally a good practice for each system to function independently.

19-3.1 Surface Drainage.

Surface drainage keeps surface water (rain) out of the pavement system, typically by incorporating adequate cross-slopes and longitudinal grades and properly designed and maintained ditches.

19-3.2 Subsurface Drainage.

Subsurface drainage quickly removes water that has entered the pavement system. These systems are designed so the outflow capacity is greater than the long-term maximum inflow into the pavement system. These systems may consist of drainage layers discharging to daylight or in conjunction with built-in edge drains. One way to provide for subsurface drainage for an existing system without an effective subsurface drainage system is to retrofit edge drainage along the shoulder.

19-4 EDGE DRAINAGE REQUIREMENTS.

Edge drainage in an existing pavement is required where seasonal fluctuations of ground water are expected to rise in the subgrade water table to less than 1 foot (0.305 meter) below the bottom of the base course or seeping water in a pervious stratum will raise the ground water table to a depth of less than 1 foot (0.305 meter) below the bottom of the base course.

19-5 EDGE DRAINAGE CANDIDATES.

A good candidate project for retrofitted edge drainage is a pavement showing early signs of moisture-related damage. Additionally, projects with acceptable surface geometrics (longitudinal grades and transverse cross-slopes) and adequate depth and condition of roadside ditches are good candidates for retrofitted edge drainage.

Retrofitted edge drainage is not effective at extending the service life of concrete pavements already experiencing significant moisture-related deterioration. Concrete pavements in which the following conditions are present are poor candidates for retrofitted edge drainage:

- More than 15 percent of the slabs exhibit full-depth cracking, all of which require extensive corrective work to return the pavement to an adequate level of service
- A high number of transverse joints are spalled
- Pumping has occurred
- A cement-treated base exists that is no longer intact
- The existing base contains greater than 15 percent fines (material passing the 0.075-millimeter [No. 200] sieve). Base materials with these characteristics may be too impermeable for effective use of a retrofitted edge drainage system.

19-5.1 Edge Drainage Key Steps.

The key steps in providing retrofitted edge drainage include the following:

1. Select edge drainage system and materials
2. Locate the edge drainage
3. Dig a trench

4. Place edge drainage material (e.g., filter fabric [geotextile], perforated flexible drainage pipe [or fin drain], backfill filler material, outlet pipes)
5. Finish the surface of the edge drainage system

Note: Consider retrofitting edge drainage by itself or in combination with other repair techniques, such as full-depth repairs and dowel bar retrofit.

19-6 EDGE DRAINAGE MATERIALS.

While this chapter discusses edge drainage systems using perforated pipes, most of the steps discussed are also applicable to fin drain systems. Edge drainage systems require the following materials:

19-6.1 Drainage Pipe.

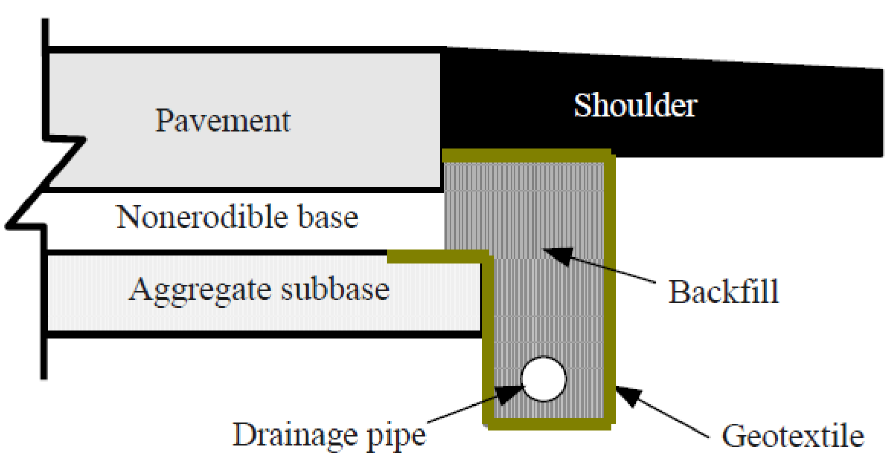
Although in the past several different types of pipe of various materials, lengths and diameters have been used in edge drainage systems, the pipe that is currently widely used is the perforated corrugated plastic pipe. These pipes are flexible. Select the type of pipe based on local requirements, such as the condition of the soil, loading and amount of cover, cost, and availability of pipe. Most highway agencies use flexible, corrugated polyethylene (CPE) adhering to AASHTO M252, *Standard Specification for Corrugated Polyethylene Drainage Pipe*.

19-6.2 Perforated Drainage Pipe.

A typical retrofitted edge drainage system is illustrated in Figure 19-1. Such an edge drainage system incorporates a perforated drainage pipe.

Aggregate trench drains (drainable aggregate material) constructed along pavement edges are not generally recommended because they have poor stability, a relatively low hydraulic capacity, and are difficult to maintain.

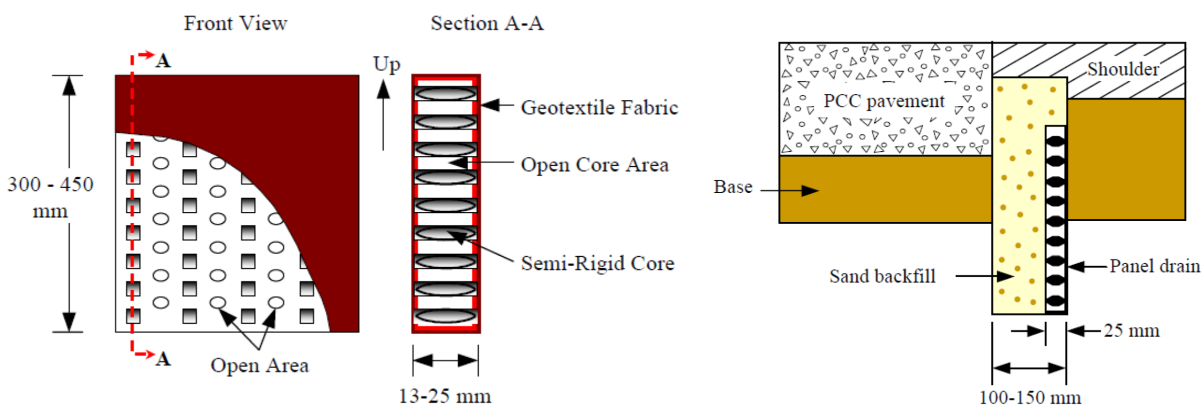
Figure 19-1 Typical Retrofitted Edge Drainage System



19-6.3 Fin Drains.

Fin (geocomposite) drains are another acceptable type of edge drainage system. This system comprises an extruded plastic drainage core wrapped with a geotextile filter. Figure 19-2 shows details of a typical geocomposite edge drain and recommended installation details. Geocomposite edge drains are typically 0.5 to 1 inch (13 to 25 millimeters) thick and manufactured in long strips coiled into rolls.

Figure 19-2 Geocomposite Edge Drain Features & Installation Details



19-6.4 Filter Material.

19-6.4.1 When possible, for economic reasons, use locally available processed sands and gravels. Use filter material that is more permeable than the material being drained. Provide and use only filter materials with a grain size curve that is smooth (no gap grading) and parallel to or flatter than that of the protected material. Standard concrete aggregates can be used as a filter, but provide and use aggregates that meet the filter criteria. Provide and use filter material fine enough to prevent infiltration of the material from which drainage is occurring. To avoid contamination of the filter by fines by the material in the layer being drained, the required ratio of d15 percent passing size of filter material / d85 percent passing size of material being drained is < 5, where d15 is the equivalent grain diameter (millimeters) at which 15 percent of the material is finer by weight and d85 is the equivalent grain diameter (millimeters) at which 85 percent of the material is finer by weight. The required ratio of d50 percent passing size of filter material / d50 percent passing size of material being drained is < 25, where d50 is the equivalent grain diameter (millimeters) at which 50 percent of the material is finer by weight. Use these criteria when protecting all soils, except for nondispersive lean clay (CL) or fat clay (CH) soils without sand or silt particles, whereupon disregard the d50 percent size relationship.

19-6.4.2 It is essential to use well-graded filter material. The required coefficient of uniformity equates to d60 percent passing size of filter material / d10 percent passing size of filter material having a value less than or equal to 20, where d60 is the equivalent grain diameter (millimeters) at which 60 percent of the material is finer by weight and d10 is the equivalent grain diameter (millimeters) at which 10 percent of the material is finer by weight.

19-6.4.3 To prevent clogging of perforated pipe or screens, the required ratio of d85 percent passing size of filter material / slot width or hole diameter slot or hole diameter is > 1.2.

19-6.4.4 To prevent clogging of the openings in porous pipe the ratio of d15 percent passing size of aggregate in porous pipe / d85 percent passing size of filter material is < 5.

19-6.5 Dispersive Clays.

If dispersive clays are encountered, obtain the services of a geotechnical expert having experience detecting and determining the best way to handle these clays. Dispersive clays normally deflocculate when exposed to water with a low salt content. This behavior is the opposite of aggregated clays that remain flocculated in the same soil-water systems. Generally, dispersive clays are highly erosive, are subject to high shrink-swell potential, and have lower permeability rates than aggregated clays.

19-6.6 Filter Fabrics.

The use of woven or nonwoven geotextile materials meeting the requirements of AASHTO M288, *Standard Specification for Geotextile Specification for Highway Applications*, are widely accepted as filters in pavement edge drainage systems. In some instances, these materials may replace one or more components of a graded filter. Filter fabrics may be used to wrap the collector pipe, thus permitting use of a relatively fine backfill material; or line the trench (most common), allowing use of a relatively coarse backfill material. Filter fabrics are rarely used without the entire granular backfill. The only instance where a geotextile can completely replace a granular system is when the subgrade soil is a clean, granular material.

19-6.6.1 Filter Fabric-wrapped Collector Pipe.

When a geotextile is used to wrap the collector pipe, the required ratio of d85 percent passing size of granular filter material (millimeters) / apparent opening size (AOS) of geotextile (millimeters) is > 1.0, where apparent opening size is a property that indicates the approximate largest particle that will effectively pass through the geotextile. This is for a gradient ratio < 3, where gradient ratio is the ratio of the hydraulic gradient through a soil-geotextile system to the hydraulic gradient through the soil alone. For woven geotextiles, do not use a cloth with an open area that is less than 4 percent or greater than 36 percent of the total area. Where these criteria are met, the criteria given for perforated pipe or screens are no longer applicable.

19-6.6.2 Filter Fabric-lined Drainage Trench.

Where geotextiles are used to line a drainage trench and the geotextile adjacent to granular materials containing 50 percent or less by weight of fines (minus No. 200 materials) the required ratio of d85 percent size of the material (millimeters) / apparent opening size (AOS) (millimeters) is > 1 and a gradient ratio < 3. For woven geotextiles, do not use cloth with an open area that is less than 4 percent or greater than 36 percent.

19-6.6.3 Filter Fabric and All Other Soil Types.

For geotextiles adjacent to all other types of soil and an AOS no larger than the opening in U.S. Standard Sieve No. 70 and gradient ratio < 3, do not use cloth with an open area that is less than 4 percent or greater than 10 percent. Where these criteria are met, the criteria for stability and permeability are no longer applicable and the backfill may be selected based on the criteria for perforated pipe or screens.

19-6.6.4 Filter Fabric Clogging.

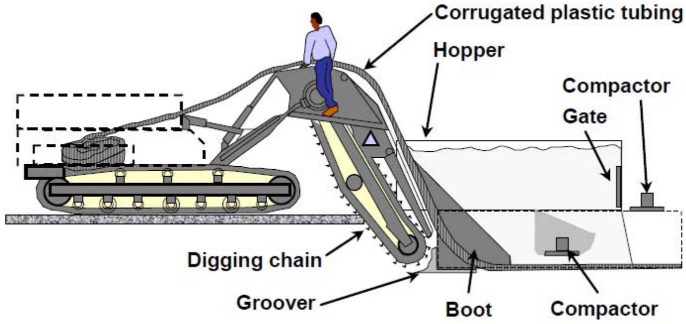
To reduce the possibility of clogging, specify no geotextile with an AOS smaller than the openings of U.S. Standard Sieve No. 100. When possible, it is preferable to specify a geotextile with openings as large as allowed by the above criteria. Do not use geotextiles for soils with 85 percent or more passing the No. 200 sieve.

Methods for determining the AOS and gradient ratio of geotextiles are given in ASTM D4751, *Test Method for Determining Apparent Opening Size of a Geotextile,* and ASTM D5101, *Standard Test Method for Measuring the Filtration Compatibility of Soil-Geotextile Systems*, respectively. Percent open area is defined as the summation of the open areas divided by the total area of the geotextile (refers to woven geotextiles only).

19-7 SUBSURFACE DRAIN INSTALLATION.

Subsurface drains are typically installed using trenchers or other suitable equipment (Figure 19-3). Grade control and elevations are normally obtained from the pavement surface. A minimal slope of 0.15 foot (0.04 meter) in 100 feet (30.4 meters) is recommended for subsurface drains. Cap or plug the upstream end of drainage pipes not terminating in a structure.

Figure 19-3 Trenching Equipment for Installing Pipe Edge Drains



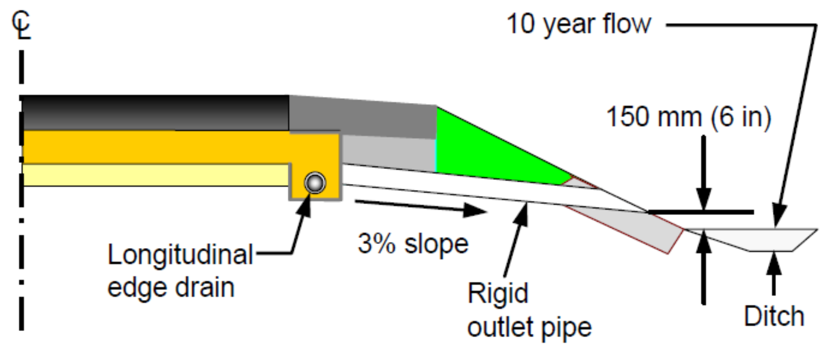
19-7.1 Filter Material Placement.

Place a minimum thickness of 6 inches (152 millimeters) of filter material around all types of subsurface drains. Place the backfill material using chutes or other means to avoid dumping the material onto the pipe from the top of the trench. To prevent displacement of drainage pipes during compaction, do not compact the filter material until the trench is backfilled above the level of the top of the pipes. Do not allow the filter material to become segregated or contaminated prior to, during, or after installation. Segregation results in zones of material too fine to meet the permeability requirements and other zones too coarse to meet the stability requirements. Contamination can clog voids in the material and render the drainage system useless. Nominally compact filter material in trenches and cover up with an appropriate material.

19-7.2 Drainage Pipe Outlets.

Where practicable, feed outlets from drainage pipes into existing storm drainage manholes. Protect outlets 12 inches (304 millimeters) in diameter and smaller, not terminating in a manhole with rodent screens, and locate them to prevent surface water from entering the system. The outlet pipe is typically a 4-inch (100-millimeter) -diameter stiff, non-perforated, smooth-walled PVC or high-density polyethylene (HDPE) pipe, installed with minimum slope of about 3 feet in 100 feet (0.03 meter/meter) (Figure 19-4). Good compaction control of the backfill below, around, and above the outlet pipe is required to avoid transverse shoulder sags. Place the outlet end at least 6 inches (150 millimeters) above the 10-year ditch flow line and protect with a headwall and splash block that is blended into the slope. Mark the outlet end (headwall) to prevent damage by mowers or other equipment.

Figure 19-4 Outlet Pipe Design



19-7.3 Drainage Pipe Access.

Provide manholes or other access points for inspection and cleaning approximately every 250 to 500 linear feet (75 to 150 linear meters), depending on grades, and at the upper ends of runs. If elbows are used instead of manholes, provide and use pipes with a radius and diameter of the pipe of sufficient size to allow cleaning and inspection equipment to pass.

19-7.4 Caution.

<u>Caution:</u> Take care to ensure that construction equipment does not track over the completed edge drainage system as it can damage the drain pipe. Also, monitor the drainage system regularly by checking the functioning of the drains at outlet ends or by using a video-based pipe inspection system. A damaged edge drainage system that retains water within the trench is more damaging to pavement performance than having no edge drainage system.

CHAPTER 20 MAINTENANCE OF HEAT-RESISTANT CONCRETE

20-1 INTRODUCTION.

Concrete pavement damage resulting from high temperatures of jet blast includes spalling, delamination, aggregate popouts, scaling, cracking, and loss of joint sealant (Figure 20-1). Such damage can result in FOD that can damage aircraft engines.

Figure 20-1 Heat-damaged Concrete

Spalling and Scaling **Delamination and Blistering**

Conventional PCC rapidly loses free moisture around 212 degrees F (100 degrees C) and starts to lose its chemically combined water at around 250 degrees F (121 degrees C). The highest rate of dehydration occurs around 350 degrees F (177 degrees C). At temperatures above 350 degrees F (177 degrees C), pavement damage increases exponentially. In accordance with this UFC and UFGS 32 13 13.43, *High Temperature Concrete for Airfields with Applied Pavement Temperatures of 482 Degrees C (900 Degrees F) or Higher Using Lightweight and Traprock Aggregates*, use of high-temperature concrete is mandatory where operations apply temperatures at the surface of the concrete from 900 degrees F to 1700 degrees F (482 degrees C to 926 degrees C), even for durations of a fraction of a second. Operations that apply temperatures at the surface of the concrete from 300 degrees F to 900 degrees F (148 degrees C to 482 degrees C) for longer durations may use this UFC and UFGS 32 13 11. If using UFGS 32 13 11, modify the specification to require only traprock for the coarse aggregate for durations greater than 1 minute.

High-temperature concrete (HTC) has been used in vertical landing zones (VLZ), aprons, forward arming and refueling pads (FARP), taxiway hold points, trim pads, and engine warm-up or run-up pads. The pads are usually associated with the operations of \1\ V-22 /1/, F-35B, and AV-8 aircraft but have also been used in parking areas affected by APUs on B-1 and F-18 aircraft.

20-2 MAINTENANCE AND REPAIR.

Material and construction requirements are intended to provide the longest performance available. Periodic maintenance is required at installations subject to high heat scenarios as described below.

20-2.1 Pavement Markings.

Commonly available pavement marking paints are not expected to maintain a bond or survive repeated heat applications from vertical landing (VL) operations from aircraft on the high-temperature range. Markings are on the perimeter of the VL pad so they will experience damage only when aircraft land near the safety zone. Paint may not adhere to pavement surfaces coated with sodium silicate. Avoid over spraying areas treated with surface sealers.

20-2.2 VL Pad Surface Grinding.

Tests indicate the HTC used for the VL pad may need 0.125 to 0.25 inch (3.2 to 6.4 millimeters) ground off the surface after about 500 landings in the same location. The time required for 500 landings in the exact same location is a function of the operational tempo of the VL pad and landing accuracy. It is reasonable to expect that grinding will be required every three to seven years to reduce spalling and potential FOD. Grinding removes damaged HTC and maintains the slope for required surface drainage. Add an additional 0.5 inch (12.7 millimeters) to the VL pad design thickness to allow future grinding.

20-2.3 Frequency and Depth.

Visually determine frequency and depth of grinding by examining the VL pad pavement surface. Do not exceed 2 inches (50 millimeters) total depth of grinding during the lifetime of the VL pad pavement. Beyond this depth, the concrete cover over the continuous reinforcement is too thin for proper performance. Distresses (e.g., additional cracking or spalling) may begin to develop. The surface area to be ground includes the VL pad plus a limited portion of the adjacent safety zone. Grinding of the remainder of the safety zone or the shoulder areas is not required. Pavement markings and the isolation joint sealant will need to be replaced in areas affected by grinding.

20-2.4 Diamond Grinding Procedures.

20-2.4.1 Pre-Planning.

Prior to grinding, consult the as-built drawings to determine the surface grades and better plan the grinding depth and area to maintain drainage. In the absence of as-built drawings, field-survey the pad using conventional survey equipment. A survey grid of 10 feet by 10 feet (3 meters by 3 meters) is adequate; however, use a grid that matches the width of the grinding machine cutting head for enhanced control of final surface elevations.

20-2.4.2 Diamond Grinding Equipment.

Use concrete grinding machines, not milling machines with hardened teeth. Provide and use grinding machine saw blades impregnated with an industrial diamond abrasive. Assemble saw blades in a cutting head mounted on a machine designed specifically for diamond grinding, which will produce the required texture and smoothness level without damage to the concrete pavement or joint faces.

Provide and use saw blades 0.125 inch (3 millimeters) wide, with a minimum of 60 blades per 12 inches (300 millimeters) of cutting head width, depending on the hardness of the aggregate. Provide and use machines capable of cutting a path 3 feet to 4 feet (0.9 meter to 1.2 meters) wide. Grinding equipment that causes ravels, aggregate fractures, spalls, or disturbance to the joints is prohibited. Ensure finished surfaces are free of raised slivers (commonly referred to as “fins”).

20-2.5 Water Cutting.

It may be possible to remove the recommended 0.125 to 0.25 inch (3 to 6 millimeters) using special high-pressure water-cutting machines fitted to pavement surface scrubbers. These are substantially more advanced machines than a conventional pressure washer, and are typically trailer-mounted with a pressure rating of approximately 10,000 psi (68.9 megapascals). This procedure requires validation by USACE (CEMP-ET), the AFCEC pavements SME, or NAVFAC EXWC for up-to-date guidance.

20-2.6 Surface Sealing.

Re-apply sodium silicate solution after grinding. Prior to application, clean the VLZ concrete areas (including the VL pad and safety zone, at a minimum) using a rotary power washer/scrubber. To remove tire rubber and, to the extent possible, fuel and oil spills, use a rotary power washer/scrubber. Apply the sealer as described for a new installation. Ensure all joint seals are in good condition prior to any application of surface sealers. Replace any damaged, cracked, debonded, or missing joint seals in accordance with UFC 3-250-08FA, *Standard Practice for Sealing Joints and Cracks in Rigid and Flexible Pavements,* before applying any surface sealer.

20-2.7 HTC Patching and Materials.

Do not design or construct partial-depth patches on areas subject to vertical take-off or landing or short take-off operations of the F-35B or located on a VLZ without prior approval of the Pavements DWG. Partial-depth patches are allowed on pavement that is continuously reinforced in both directions provided the partial-depth patching uses hydro-demolition to remove material within 2 inches (50 millimeters) of the rebar and the bottom of the repair is at least 2 inches (50 millimeters) below the bottom of the rebar. If the remaining concrete is cracked or less than 2 inches (50 millimeters), continue to remove all the concrete and treat as a full-depth repair. Patches of areas not subject to vertical take-off or landing or short take-off operations of the F-35B and not located on VLZs can be design and constructed as a partial-depth repair when full-depth cracks are not present in the repair area. Otherwise, a full-depth patch must be designed and constructed in these areas.

Design and construct partial-depth patches with a minimum 3 inches (75 millimeters) deep, ± 0.25 inch (± 6 millimeters), instead of the standard 2-inch (50-millimeter) minimum used for conventional concrete pavements. Shallower repairs separate from the rest of the pavement due to thermal expansion cycles. Partial-depth patches deeper than 3 inches (75 millimeters) in reinforced areas are not recommended, as the depth of cover of the longitudinal reinforcement is 4 inches (100 millimeters) unless hydro-demolition is used to excavate the patch area at least 2 inches (50 millimeters) below the bottom of the rebar.

Provide and use materials for patching HTC surfaces that match the materials used to originally construct the pad. If the original HTC materials are not available, specify and use only materials that will survive high-temperature applications and are approved by the contracting officer or for in-house work by the Pavements DWG. Some prepackaged rapid-repair materials that will survive high-temperature applications are available on the GSA schedule at the time of the publication of this UFC.

20-2.8 PCC Patching.

Applying high temperatures to a PCC safety area may generate spalling. The surface sealer may allow the PCC to survive a few landings per location. Landing on PCC may also result in very thin delamination, which can be corrected by brooming and resealing with sodium silicate. Repeated landings at the same PCC location or over-exposure to high temperatures generates more severe spalling. Repair the PCC with HTC patching materials or conventional PCC. Do not use rapid spall repair materials (e.g., epoxy-based or activated fly-ash products) if sited near the VL pad due to the risk of future high-temperature exposures.

20-3 SUMMARY OF MITIGATION TIPS.

20-3.1 Water/Cement Ratio.

Use concrete with a low water/cement ratio (below 0.42). Properly cure the concrete. Leaner concrete mixes (low cement to aggregate ratio) perform better than richer mixes.

20-3.2 PCC Mix.

Use of hydrated portland cement that has lower calcium hydroxide content is preferable to those with higher calcium hydroxide content for high-temperature applications. For temperatures of 1,500 degrees F (816 degrees C) or more, high alumina cement provides superior performance.

20-3.3 Construction Quality.

Proper consolidation of concrete and proper finishing is critical. Minimize the amount of paste on the surface to minimize scaling.

20-3.4 Proper Material.

Aggregate selection is the most important single material-related factor; however, there is no standard specification for heat-resistant aggregate. Aggregates with low coefficients of thermal expansion (CTE) are desirable. The optimal aggregate is formed at a temperature higher than the expected exposure temperature, such as igneous trap rock. Lightweight aggregates, such as expanded shale and expanded slate, tend to perform better than conventional natural concrete aggregates subject to high temperature. Air-cooled slag aggregates also provide good results.

This Page Intentionally Left Blank

CHAPTER 21 REPAIR OF PCC DAMAGED BY POL

21-1 INTRODUCTION.

Engine exhaust combined with petroleum, oil, and lubricant (POL) contamination can damage ordinary PCC pavements. Damage occurs in the form of scaling or spalling of the top 1 to 2 inches (25 to 50 millimeters) of the pavement. Pavement fragments from these surface scales can cause FOD to aircraft engines. High exhaust temperatures, coupled with spilled fluids (POL), damage ordinary PCC airfield pavements. Damage occurs progressively to the pavement surface under repeated thermal cycling and chemical reaction of the spilled aircraft fluids with the cement paste.

PCC surface treatments reduce or eliminate spalling, scaling, and other surface damage caused by heat and POL. These treatments are suitable for repairing PCC damaged by POL and heat from B-1, F-18, F-35, \1\ V-22 /1/ operations. Apply these treatments prior to POL contamination, where possible. When in doubt as to the length or number of operations, treat the affected area.

Do not use this UFC to deny or restrict operations of any aircraft, including \1\ V-22s /1/. Use it to identify and establish projects and protocols to effectively support air operations.

\1\ When selecting a pavement surface treatment, consider the pavement condition, duration and frequency of operations, and any scheduled maintenance/repair work.

Most concrete coatings only work on clean, uncontaminated concrete. On pavement with petroleum, oil and lubricant (POL) stains, coatings slow, but do not eliminate, degradation. Contaminated concrete slabs fail below the coating and the coating delaminates.

For newly replaced or pavement in otherwise good condition free of POL contamination, supporting daily operations that require long-term performance, use Epoxy Coatings per Paragraph 21-3.6 and High Temperature Aggregates per Paragraph 21-4.6. /1/

21-2 PRIMARY DAMAGE MECHANISMS.

Testing has revealed three primary damage mechanisms: thermal fatigue, vapor pressure, and chemical degradation. Thermal fatigue has produced failures without the presence of POL. Vapor pressure damage has been observed when the water vapor pressure cannot be relieved fast enough during the heating phase. Chemical degradation results in a significant loss of strength—up to 50 percent in some cases—which accelerates failure. Chemical degradation by itself can result in raveling of the concrete, which has been observed under APUs for the B-1 and F-18; it does not produce scaling, but accelerates scaling.

21-3 REPAIR TECHNIQUES/MATERIALS.

The following techniques can reduce damage from combined exhaust heat and POL.

\1\ Repair and treat effected area larger than the area subject to damage directly under each Nacelle. Repair and treat the surface all concrete slabs (the entire slab) which have any portion of the slab within 20 feet from the vertical nacelle of the parked aircraft or asphalt within 20 feet of the nacelle.

Repair and treat areas where aircraft are likely to release POL and expose the contaminated pavement to heat from the nacelles for more than two to five minutes in the same location.

Repair and treat any locations used as a FARP. If a FARP is asphalt instead of PCC, use a fuel resistant asphalt inlay per UFGS 32 12 17.19 Fuel Resistant Asphalt Paving For Airfields - Surface Course or protect with a fuel resistant micro surface such as Grip-flex. /1/

21-3.1 Sodium Silicate Application.

\1\ Recommend limiting sodium silicate application to use as a surface hardener. Sodium silicate solutions are ineffective as waterproofing sealers since they have a limited depth of penetration and are unable to stop or reduce hydrostatic pressure.

Sodium silicate treatments do not eliminate the degradation under the V-22 Nacelles. The sodium silicate slows, but does not stop POL penetration and may suffice for transient aircraft, but not for permanently assigned aircraft. Apply surface treatment prior to any POL contamination. Allow a minimum of 70 days prior to applying sodium silicate coating to a surface after the PCC curing compound removal. /1/

21-3.2 Multifilament Fibers.

Multifilament polypropylene fibers at a dosage of 3 pounds per cubic yard (1.8 kilograms per cubic meter) of concrete further improves concrete durability when subjected to exhaust heat.

21-3.3 Polymer Coatings.

The US Army Corps of Engineers, Engineering Research and Development Center Geotechnical and Structures Laboratory performed laboratory test and field demonstrations with two polymer coats which, when combined with a sealer, provided results equal to or greater than coal tar emulsions. If polymer coatings are used on the airfield pavements, specify or use materials and methods recommended in ERDC/GSL Technical Report TR 03-24. Do not specify or use any materials or methods other than those included in this report without prior approval of the Pavements DWG. Do not specify or use polymer coating on any areas used for landing or take-off of jet, turbo-prop, \1\ or V-22 /1/ aircraft. These products have been used on parking aprons and FARPs.

21-3.4 Surface-Applied Penetrating Chemically Reactive Silicates.

Surface-applied penetrating water-soluble, chemically reactive silicates migrate through micropores and chemically bond with calcium hydroxide and calcium chlorides in cements to form calcium silicates which inhibit hydrolysis with POL esters. They also fill micropores, reducing the permeability of concrete. If surface-applied penetrating water-soluble, chemically reactive silicates are used on the airfield pavements, specify or use materials and methods that do not leave a surface film or coating and cannot be scraped or removed from the surface using mechanical means. Specify and use only those products and methods that reduce the chloride ion penetration in PCC by at least 60 percent, as determined by ASTM C1202, AASHTO T277, or AASHTO T259, and that penetrate at least 0.75 inch (19 millimeters) into the surface of the concrete. Materials and methods proven effective on airfield pavements are documented in “Auxiliary Power Unit (APU) Resistant Concrete: State-Of-The-Art,” by Anderson, John R., et al, 1 March 2000. Do not specify or use any materials or methods other than those included in this report without prior approval of the Pavements DWG.

21-3.5 Magnesium Phosphate Cement (MPC)

MPC is a different cement formulation than conventional PCC. MPC is less sensitive to reaction with acids than PCC. It can be extended with any normal aggregate; however, for applications under B-1 aircraft, using aggregate that is not reactive with acids (limestone is reactive) is necessary. MPC is a fast-setting cement that reaches high strength (above 5000 psi [34.5 megapascals]) in less than one hour, with an ultimate strength after several hours of approximately 8000 psi (55.1 megapascals). It is more resistant to the types of aviation fluids that have caused damage to pavement under Navy F/A-18 Hornet fighter aircraft (TDS NAVFAC EXWC-CI-1403, *Mitigating Concrete Damage Caused by Engine Exhaust Surface Temperature Below 500 °F]*).

\1\

21-3.6 Epoxy Coatings

The US Army Corps of Engineers, Engineering Research and Development Center Geotechnical and Structures Laboratory performed laboratory testing on and field demonstrations with multiple coatings. Two epoxy coatings identified as suitable for protecting clean concrete surfaces from POL penetration that support aircraft traffic are Epoxy-A Addagrip 1000 System, and Mod Epoxy-1 PolySpec Thiokol FEC 2234. If using epoxy coatings on newly placed airfield concrete pavement, specify or use materials and methods recommended in Transportation Research Record TRR 20-07019, Full Scale Evaluation of Surface Treatments for Airfield Concrete Pavement Repair, 26 April 2021, https://journals.sagepub.com/doi/full/10.1177/03611981211008882. Using any materials or methods other than those included in this technical report requires prior Pavements DWG approval. Do not specify or use epoxy coating on any area used by jet, turboprop, or V-22 aircraft for landings or take-offs. Only use these products on parking aprons free from POL contamination.

THIOKOL Primer and Polysulfide Sealant are elastomeric joint sealants and are not suitable for V-22 Parking Aprons. Do not use; Transpo T-70 (HMWMMA) or TK Products epoxy (TK-2110) as they do not adequately adhere.

21-3.7 Joint Sealant

Engine exhaust from the V-22 deteriorates standard joint seal material in concrete pavements. During ground operations with inoperative exhaust deflectors, applying moderately high power settings or ground power assurance checks can cause surface spalling.

Use Silicones joint seals in accordance with ASTM D5893 for general applications where the V-22 does not take-off vertically or perform ground runs. Use Chloroprene (Neoprene) or fluorocarbon adhesive joint seals in accordance with ASTM D2628 for locations where the V-22 takes-off vertically or performs ground runs for operations or training. Neoprene shows good chemical resistance and heat resistance up to 550ºF. Fluorocarbon adhesive shows excellent chemical and heat resistance up to 750ºF.

Plan to reapply join sealant every five to 10 years. Preventing POL contamination of PCC is the key to long-term performance. This requires cleaning and resealing the joints when there is any joint seal failure. Plan to reseal the joints when re-sealing the surface even if not failed. For damaged surface coatings (i.e. chipped or cracked), or if the underlying PCC cracks along with the surface seal, decontaminate the area and reseal before re-contamination with POL. /1/

21-4 REQUIREMENTS.

21-4.1 Cleaning.

Before applying surface sealants, remove all contaminants such as POL, dust, curing compound, and moisture. If water is used to clean the pavement, dry the pavement and keep it dry for at least 24 hours prior to any surface application.

21-4.2 When to Seal.

Initiate steps to protect the pavement within six months of commencing operations; however, apply surface sealants, such as sodium silicate, no earlier than 70 days after placing pavement.

For locations subject to less than two operations per week, this time may be extended to 12 months. Surface treatments are most effective when placed prior to the application of heat loads and prior to any contamination by POL. Damage to PCC has been observed as early as six months and as late as 60 months after operations commence.

21-4.3 Distress Repairs.

When possible, repair the following distresses within the treatment area prior to the placement of surface treatments: damaged joint and crack seals, spalls, and medium- and high-severity patches as defined by ASTM D5340. Surface treatments can be applied before completing these repairs; however, retreatment of the surface within 6 inches (150 millimeters) of the repair area is recommended after completing the repairs. If the repair includes the placement of concrete or magnesium phosphate-based cements, do not reseal the surface of the repair during the first 70 days after placement.

21-4.4 Existing Distress Effects.

There are some distresses that, if present, reduce the effectiveness of the surface treatment; therefore, if you have shattered slabs, medium- or high-level durability cracking (D cracking), medium- or high-severity scaling, or medium- or high-level ASR as defined in ASTM D5340, the surface treatment can be omitted because they are not effective. In rare cases where older pavements have had their entire surfaces scaled and additional scaling or surface cracking has ceased, surface treatments can increase the life span of the pavement and can be effectively applied. Parking/operating the \1\ V-22 /1/ on pavements with these types and levels of distresses increases the rate of deterioration under the nacelles. Applying surface treatments to pavements with low-severity distresses of these types increases the service life of the pavement.

21-4.5 Where to Seal.

Seal those areas most susceptible to POL and direct exhaust, a circular area with a minimum 15-foot (4.5-meter) radius, centered where the engine exhaust is directed at parking, maintenance, and preflight check areas, including parking/maintenance ramps, forward area refueling points (FARP), and hot refuel/re-arm pads.

21-4.6 High-Temperature Aggregates.

If constructing new or replacing existing pavement to support \1\ V-22 /1/, or F-35A/B parking, maintenance, FARP, or hot refuel/re-arm operations, a high-temperature aggregate such as an igneous trap rock, expanded shale, or expanded slate may be used as the coarse aggregate in the concrete mix design. Unlike a concrete mix for a vertical landing pad, the fine aggregate can be a natural sand. If the cost of the pavement using high-temperature aggregates is more than twice the cost of standard \1\ airfield /1/ PCC then construct/repair the pavement using standard \1\ airfield /1/ PCC. Apply sodium silicate. However, do not apply the sealant any earlier than 70 days after placement of the concrete repair material. Where practical, include multifilament polypropylene fibers at a dosage of 3 pounds per cubic yard (1.8 kilograms per cubic meter) of concrete in any PCC or PCC with high-temperature aggregates.

21-5 PCC SODIUM SILICATE SURFACE SEALING.

The sodium silicate surface sealer is absorbed into the top 0.125 inch (3 millimeters) of the concrete, providing resistance to high exhaust temperatures and POL stains. Sodium silicate requires reapplication if surface wear occurs. Do not apply sodium silicate surface sealers to asphalt pavement.

21-5.1 Sodium Silicate Solution.

Provide and use a sodium silicate surface sealer that is a colorless, water-based solution containing 9 percent sodium silicate. While many manufacturers provide a product with this concentration, it often comes in 40 percent solutions. Higher-concentration products can be diluted to 9 percent sodium silicate. The 9 percent sodium silicate provides optimum concrete penetration with three applications. In order to dilute a 40 percent solution of sodium silicate to 9 percent, add 3.5 parts of water to 1 part of the 40 percent solution, i.e., for every gallon of 40 percent solution add 3.5 gallons of water. The sodium silicate sealer is applied to PCC subject to heat and POL, such as from F-35B, \1\ V-22 /1/ engines. Use of concentrations higher than 9 percent results in an excess buildup that will bubble and discolor under the heat load of the nacelles. If this occurs, remove the excess material by washing the area with warm water. Use a scrub brush and/or a high-pressure pump to speed removal. In extreme cases, use ultra-high-pressure rubber removal equipment. The portion of the sodium silicate that has combined with the concrete surface remains in place.

21-5.2 Surface Cleaning.

Before application, clean the concrete with a rotary power washer/scrubber to remove tire rubber, curing compound, and POL. If heavy POL contamination is present or if the sodium silicate will not penetrate the surface, follow the procedures in paragraph 21-6 before applying the pavement sealant.

21-5.3 When to Seal.

Do not apply the sodium silicate earlier than 70 days after the pavement has been placed. Testing has determined that sodium silicate applications prior to 70 days result in surface flaking of the PCC. Ensure all curing compound has been removed prior to sealing the PCC.

21-5.4 Joint Sealing.

Properly seal the pavement joints before applying the sodium silicate. If the joint seals are not in good condition then repair or replace them before applying the sodium silicate.

21-5.5 Paint Markings.

Ensure all paint markings (including shadow markings) are in place, in good condition, and contain no cracks or chips before applying the sodium silicate. Repair or replace damaged markings before applying the sodium silicate.

21-5.6 Environmental Conditions.

Do not apply the sodium silicate until the concrete surface has been dry for at least 24 hours and the pavement markings have been applied. Do not apply the sodium silicate until the air temperature is 40 degrees F (4.4 degrees C) or higher and relative humidity is 80 percent or less, both during application and for 48 hours after application. It is acceptable to apply the sodium silicate over pavement markings and glass beads.

21-5.7 Surface Seal Application.

Apply three coats of the sodium silicate solution with low-pressure airless spraying equipment to ensure uniform application or use a roller with a 0.25-inch to 0.5-inch (6-millimeter to 13-millimeter) nap. Start applying the solution at the highest point in the pavement and continue downgrade. Each coat will cover no more than 200 square feet per gallon (4.9 square meters per liter). Avoid excessive application, as it may cause efflorescence and reduce friction. Allow the sodium silicate to penetrate for two hours then wash off any visible excess (ponded) solution. Allow the area to dry for at least 24 hours between each coat.

21-5.8 Final Evaluation.

After allowing the last coat to dry for 24 hours, evaluate the surface for any excess silica or dusting. Wash off any excess silica or dusting as needed. Protect the application from any pedestrian or vehicular traffic until the last coat has dried.

21-6 CLEANING POL CONTAMINATION FROM PCC AND PCC JOINTS.

21-6.1 Stains.

If POL stains are present, treat the entire stain before sealing the pavement. Several methods to remove POL stains and, in the case of POL stains on joints, improve the bond to the joint surface are described below. Most stains require several applications and may require the use of more than one treatment method. By implementing all of these steps maximum removal will be achieved; however, one or more of the steps can be omitted to achieve acceptable results. Steam may be used; however, steam alone will provide some cleansing of the immediate surface but not penetrate deep enough to provide a long-term result. Properly collect and dispose of any POL-contaminated water, paste, or solids.

21-6.2 Dawn (or Simple Green) Dishwashing Detergent and Hot Water.

Apply to the stained area and scrub to develop a thick lather. Let set for five minutes then rinse with warm/hot water. Use of steam to pretreat the area and rinse may aid removal.

21-6.3 Tri-Sodium Phosphate (TSP).

TSP (also called sodium orthophosphate) is available in hardware stores.

Note: Some states have banned this product because phosphate can cause problems with waterways. Check with the environmental office before using.

Mix one measure of TSP with six measures of water. Apply over the stain with a paintbrush and allow to dry completely before scraping off the dried paste. Rinse the surface and scrub with a stiff brush and clean water.

Caution: DO NOT MIX TSP WITH ANY ACID! A violent reaction can occur and release noxious gas. You can use both products but use them separately, with a thorough rinsing with water between applications.

Alternate application method: Dissolve 1 pound, 6 ounces of TSP in a gallon of water. Add enough finely ground calcium carbonate (also called whiting or agricultural lime) to make a thick paste. Agricultural lime is available at garden supply stores. Spread the paste over the stain and allow it to dry for a day, if possible. Brush off the dry paste with a stiff brush and scrub the concrete with water. Provide and use PPE and keep the paste away from aircraft due to the high pH of the paste. If it is windy, protect the treated area until the area is cleaned and rinsed to keep the caustic material from blowing around the apron.

21-6.4 Sodium Hydroxide.

If TSP is not available or not allowed, use sodium hydroxide. Prepare and use a solution of 5 percent sodium hydroxide (caustic soda: $NaOH$). Apply it over the stain with a paintbrush and allow to dry for at least 24 hours. Rinse and scrub with clean water then repeat as required. Provide and use PPE and keep the solution away from aircraft due to the high pH of the solution. If it is windy, protect the treated area until the area is cleaned and rinsed to keep the caustic material from blowing around the apron.

21-6.5 Super Washing Soda.

Washing Soda or Super Washing Soda, sodium carbonate, can be used as a substitute for TSP or sodium hydroxide; however, it does not work as well and may take more applications to remove the POL. Apply in accordance with manufacturer directions. Rinse well with water. This is an organic salt. If it is windy, protect the treated area until the area is cleaned and rinsed to keep the salt from blowing around the apron.

21-6.6 Phosphoric Acid Cleaner.

Apply phosphoric acid cleaner in accordance with manufacturer directions. Rinse well with water and sodium carbonate (washing soda or soda ash) to neutralize the pH then rinse with clear water. This product will etch the concrete so do not leave it on too long and ensure the area is rinsed well to ensure no acid is left on the concrete. Acid deteriorates ordinary Portland cement.

21-6.7 Bacteria and Enzymes that Remove Oil Stains in Concrete.

Biological materials (bacteria and enzymes) that consume POL can also help to remove stains. Use a biologic product as a final treatment prior to sealing. The bacteria stay in the concrete and help eliminate any remaining POL over time. Follow the product directions.

21-6.8 Replacement.

If the contamination is too extensive, consider removal/repair.

CHAPTER 22 F-35B AND C CRITICAL AREAS

22-1 BACKGROUND.

This chapter provides guidance concerning maintenance and repair of rigid and flexible pavements with regard to F-35 variant critical areas. Critical areas include, but are not limited to, areas designated for short take-off, flight carrier landing practice, and vertical landing and take-off operations which are further defined in 22-6 Definition of Critical Areas. Because of the asymmetrical external pressures of the F-35 variants, it is necessary to maintain an elevated maintenance policy for pavement within the critical areas the F-35 perform their operations.

22-2 ASPHALT CONCRETE PAVEMENT.

22-2.1 Distresses in Asphalt Concrete Pavement.

Certain asphalt pavement distresses, as described in UFC 3-260-16 *O&M Manual: Standard Practice for Airfield Pavement Condition Surveys*, are especially susceptible to asymmetrical applications of the F-35 variant exhaust pressures. Asphalt pavements that exhibit the distresses of; block cracking, corrugation, swelling, and slippage of all severities, joint reflection cracking, and longitudinal and/or transverse cracking, of medium and high severities and shoving of all severities are all distresses that put asphalt pavements in critical areas at risk of partial or full depth delamination or “erosion”. Many of the distresses listed are found in concrete to asphalt transitional areas.

22-2.2 Maintenance of Asphalt Concrete Pavement.

Maintenance of asphalt pavement in critical areas must be considered as stop-gap maintenance only until reconstruction with concrete can be contracted. For the purposes of stop-gap maintenance, the distresses of block cracking, corrugation, swelling, and slippage of all severities require full depth asphalt concrete patching in the critical areas. The distresses of joint reflection cracking, and longitudinal and transverse cracking of medium and high severities require shallow depth asphalt concrete patching in the critical areas. Lastly, the distress of shoving of all severities require shallow depth asphalt concrete patching in the critical areas. The definitions of pavement distresses and severity levels and stop-gap maintenance recommendations are described in reference UFC 3-260-16 *O&M Manual: Standard Practice for Airfield Pavement Condition Surveys*. The critical areas are defined in 22-6 *Definition of Critical Areas*. Perform all repairs in accordance with UFC 3-270-01 O&M Manual: Asphalt and Concrete Pavement Maintenance and Repair, Chapter 3 *Full-Depth Asphalt Patches* and Chapter 4 *Procedural Steps (Partial-Depth Patch).* The required asphalt pavement stop-gap maintenance in the critical areas is cost prohibitive over time; therefore, consideration must be made to either limit the mission or convert these pavements to plain jointed concrete pavements.

22-3 PLAIN JOINTED CONCRETE PAVEMENT.

22-3.1 Distresses in Plain Jointed Concrete Pavement.

Concrete pavement distresses, as described in UFC 3-260-16 *O&M Manual: Standard Practice for Airfield Pavement Condition Surveys*, are also susceptible to asymmetrical impacts of the F-35 variant exhaust pressures. Concrete pavements that exhibit full depth corner breaks, full depth linear cracking, joint sealant damage, joint and corner spalls, and partial depth repairs in critical areas, as described in 22-6 *Definition of Critical Areas*, can result in failure by separation or "erosion". Distresses that diminish mechanical restraint (aggregate interlock or bond) are especially susceptible to failure and include joint and corner spalls, and debonded partial depth concrete repairs.

22-3.2 Maintenance of Plain Jointed Concrete Pavement.

The following are distress repairs required within critical areas as defined in 22-6 *Definition of Critical Areas*: Existing partial depth repairs (small and large patches) of all severities require full depth concrete repairs. Joint and Corner spalls of medium and high severity require full depth concrete repairs. Joint Sealant damage of medium and high severity requires localized joint sealant replacement. Full depth concrete repairs must include dowels to ensure repairs are mechanically fixed in place. Any linear cracking or corner breaks that exhibit lack of aggregate interlock require full depth repairs. If linear cracking and corner breaks are mechanically fixed by dowels and aggregate interlock, then only crack sealing per UFC 3-270-01 *O&M Manual: Asphalt and Concrete Pavement Maintenance and Repair*, *Chapter 12 Concrete Pavement Crack Sealing* is necessary. Due to the requirement of full depth repairs, if slabs have multiple distresses it may be more economical to replace the entire slab. The definitions of pavement distresses and severity levels can be found in UFC 3-260-16 *O&M Manual: Standard Practice of Airfield Pavement Condition Surveys*. Perform all repairs in accordance with UFC 3-270-01 O&M Manual: Asphalt and Concrete Pavement Maintenance and Repair, Chapter 14 Full-Depth Repair of Concrete Pavements.

22-4 MAINTENANCE OF CONTINUOUSLY REINFORCED CONCRETE PAVEMENT

Refer to UFC 3-270-01 *O&M Manual: Asphalt and Concrete Pavement Maintenance and Repair*, Chapter 20 *Maintenance of Heat-resistant Concrete* for maintenance of continuously reinforced concrete pavements. The partial depth repair methods described for heat resistant concrete can be applied for use in conventional concrete.

22-5 REQUIRED MATERIAL FOR MAINTENANCE AND REPAIR

Cementitious material used for full depth patches must be like parent concrete material to be repaired. Conventional concrete must be used in non-heat resistant concrete critical areas. Heat-resistant concrete is required in heat resistant concrete critical areas. Due to the temperatures of the F-35 variant exhaust only use ASTM D5893/D5893M silicone joint sealant.

22-6 DEFINITION OF CRITICAL AREAS

22-6.1 Short Take-off (STO) Areas

The critical area boundaries for STO operations is defined as the full width of the runway, and 457 meters (1,500 feet) in length (122 meters (400 feet) behind and 355 meters (1,100 feet) in-front of the F-35B engine). It is necessary that field operations designate a starting position for this operational maneuver. Refer to Figure 22-1 *STO Critical Area Scenario 1* and Figure 22-2 *STO Critical Area Scenario 2*.

22-6.2 Flight Carrier Landing Practice (FCLP) Critical Areas

The critical area boundaries for FCLP operations is defined as to the runway edge left of the centerline and 50 feet right of the centerline, and 396 meters (1,300 feet) in length (91.5 meters (300 feet) from runway threshold to 488 meters (1,600 feet) from runway threshold). Refer to Figure 22-3 *FCLP Critical Areas*.

22-6.3 Vertical Landing Pad (VLP) Critical Areas

The critical area boundaries for a VLP is defined as the Vertical Landing Pad and the 61 meter by 61 meter (200 foot by 200 foot) Safety Zone UFC 3-260-01 *Airfield and Heliport Planning and Design*, Figure 8-23 *Vertical Landing (VL) Pad Facility Outline with Safety Zones*.

22-6.4 LHD STOVL Critical Areas

The critical area boundaries for a LHD STOVL Facilities is defined as Area A and Area D per UFC 3-260-01 *Airfield and Heliport Planning and Design*, Figure 8-21 *LHD Pavement Surface Types* and Figure 8-22 *LHD Pavement Surface Types Detail*.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Pavement management involves determining the quantity of pavement assets on each installation, organizing information on these assets in a well-defined structure known as a pavement inventory, evaluating the condition of these assets, then analyzing the data to predict future condition, determine maintenance and repair (M&R) requirements, and develop a pavement management plan (PMP).

1-2 PURPOSE AND SCOPE.

This UFC provides guidance on pavement management concepts, processes, and standards.

It addresses requirements for both paved and unpaved airfield, heliport, road, and parking pavements. It defines standards for using automated tools, including the PAVER pavement management application and the Pavement Computer Assisted Structural Engineering (PCASE) application, with a focus on standards for collecting, analyzing, and reporting pavement management data as well as how to use products from these applications to prioritize maintenance and/or repair requirements and develop PMPs.

1-3 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 3-270-08, *Pavement Maintenance Management*, dated 16 January 2004.

1-4 APPLICABILITY.

This UFC applies to all Service elements and contractors responsible for managing pavements. This includes Service evaluation teams or contractors performing pavement evaluations as well as personnel at installations responsible for using pavement evaluation data to develop and execute PMPs.

1-5 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high-performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-6 GLOSSARY.

Appendix B contains acronyms, abbreviations, and terms.

1-7 REFERENCES.

Appendix C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

1-8 NATO AIRFIELD AND OPERATIONS STANDARDS.

Comply with NATO STANAG 7131, *Aircraft Classification Number (ACN)/Pavement Classification Number (PCN)*, and NATO Standard AEP-46, *ACN/PCN*, when evaluating/reporting the PCN of airfields used by NATO forces or NATO campaigns. Comply with NATO STANAG 3634, *Runway Friction and Braking Conditions*, and NATO Standard AATMP-13, *Runway Friction and Braking Conditions*, when assessing/reporting the friction characteristic of the airfields used by NATO forces or NATO campaigns. Comply with NATO STANAG 7181, *Standard Method for Airfield Pavement Condition Index (PCI) Surveys*, and NATO Standard AEP-56, *Standard Method for Airfield Pavement Condition Index (PCI) Surveys*, when surveying/reporting the condition of airfields used by NATO forces or NATO campaigns. Comply with TSPWG Manual 3-260-00.NS7210, *Standards for NATO Deployed Air Operations*.

CHAPTER 2 PAVEMENT MANAGEMENT

2-1 DESCRIPTION.

Pavement management is a systematic process used to determine M&R requirements, maintain the safety of operations, and optimize the life cycle cost of paved and unpaved airfield, road, and parking pavement. The overarching concept is to manage pavements to extend life and optimize life cycle cost rather than just repairing or reconstructing pavement when it fails, also known as "worst first."

The pavement management process uses the Pavement Condition Index (PCI) to define the surface condition of the pavement. While the PCI is a key index in pavement management, other indexes developed for other types of evaluations are also used to get a more holistic assessment of the pavement condition, capability, and performance, which is key to developing a PMP and a rational determination of feasible M&R alternatives. Pavement management is implemented at either the network level or project level. The distinctions between the two are the factors considered in the analysis as well as the sampling process/rate used when conducting a PCI survey. This chapter outlines basic concepts and the overall process.

2-1.1 Pavement Condition Index (PCI).

The PCI is a numerical rating based on the type, severity, and quantity of distresses identified during a pavement condition survey. UFC 3-260-16, *O&M Manual: Standard Practice for Airfield Pavement Condition Surveys*, provides instructions for conducting PCI surveys, distress definitions, and PCI computation details. The PCI captures data on the surface condition of the pavement and is used in conjunction with other indexes and considerations to manage pavements.

2-1.2 PAVER Pavement Management Application.

a. Executive Order (EO) 13327, *Federal Real Property Asset Management*, directs efficient and economical use of the federal government's real property assets. The 2013 Under Secretary of Defense (Acquisition, Technology, & Logistics) policy letter mandated a standardized process for facility condition assessments. It also established the Sustainment Management System (SMS) suite of software tools (including PAVER) as the facility and infrastructure condition assessment methodology for DoD to implement EO 13327.

b. PAVER was in use well before OSD mandated its use. It was created to automate the PCI computation process and provide tools used to organize, collect, and analyze pavement management data. PAVER has two versions—a distributed (PC-based) version intended for individual users and a server-based version to provide multiple users access to a central pavement database. Both provide the same engineering functionality but each Service determines whether they use the PC-based, the server-based, or a combination of both versions of PAVER.

c. DoD personnel can download PAVER with a common access card (CAC) from the Tri-Service Pavement Site, https://transportation.erdc.dren.mil/triservice. Installation and activation instructions are also available at this site. Consultants may get PAVER from the Colorado State distribution center, http://www.paver.colostate.edu/, or the American Public Works Association, https://www.apwa.net/store/.

d. Governmental and commercial entities around the world use PAVER. The user can select a language from a list under the **Preferences** drop-down. This capability is useful when dealing with overseas installations or working with NATO partners. Any PAVER database developed for any of the Services will be delivered with preferences set to the English language. Details for using the language option are outlined in the PAVER user manual.

2-1.3 Network-Level Pavement Management.

Fewer samples are inspected for Network-Level Pavement Management, but the samples inspected are representative of the entire section. UFC 3-260-16 defines the required minimum number of inspected samples. In the Network-Level approach, the confidence level in the measured condition is lower. This approach is used when a higher degree of risk is acceptable. Each Service defines when to use Network-Level Pavement Management based on mission requirements.

2-1.4 Project-Level Pavement Management.

Project-Level Pavement Management requires inspecting more samples. UFC 3-260-16 defines the procedure to determine the required number of and the location of the samples based on the systematic random sampling process. The Project-Level approach results in a 95 percent probability that the reported pavement condition index (PCI) is within ±5 points of the true mean PCI (the PCI obtained if all the sample units were inspected), given a defined standard deviation. Use this approach when a higher degree of risk is not acceptable. Each Service determines when to use Project-Level Pavement Management based on mission requirements.

2-2 PAVEMENT INVENTORY ORGANIZATION.

Whether using the Network-Level or Project-Level Pavement Management approach, organize the pavement inventory following the guidance in this UFC to facilitate data collection and analysis for both the PCI survey and other types of evaluations.

The pavement inventory is simply all pavements grouped by their function. Create a separate PAVER database for each pavement inventory at an installation. For example, include all airfield pavements in one database and all road and parking pavements in a separate database.

2-2.1 Inventory Mapping.

Whether doing a PCI survey or structural evaluation and either creating a new inventory or updating an existing inventory, the first step in organizing the inventory is creating a geospatially correct map using a Geographic Information System (GIS) application such as Esri ArcMap or AutoCAD Map 3D. This map defines the geospatial extent of the pavement inventory. It is subdivided into polygons for the networks, branches, sections, and sample units that make up the inventory. Inventory mapping is covered in detail in paragraph 3-2.

2-2.2 Pavement Inventory.

The pavement inventory map imported into PAVER can have inventory attributes included. When it does not, the inventory associated with the map is defined in PAVER. In this case, use the PAVER **Inventory** form to input network, branch, section, and sample unit data, then link the data to the inventory map polygons using the **GIS Assignment** tool. Next, populate the work history for each section and the real property asset information to complete the inventory.

When the GIS is used to create some or all of the inventory as part of the mapping process, the inventory is already linked to the polygon when the map is imported to PAVER.

2-3 PAVEMENT EVALUATION.

Pavement evaluation encompasses activities involving data collection, analysis, and report generation for various aspects of pavement condition, performance, or capability. In addition, two other publications, UFC 3-260-16, *Standard Practice for Pavement Condition Surveys* and UFC 3-260-03, *Airfield Pavement Evaluation*, provide pavement evaluation guidance.

The results of the various types of evaluations provide data on pavement structural capability, surface friction characteristics, roughness, the presence of voids, and the potential for foreign object damage (FOD). While much of this UFC focuses on the PCI and PAVER processes used to define M&R requirements, these other pavement evaluation factors play a significant role in prioritizing requirements, determining courses of action to repair pavement, and developing PMPs.

2-4 DEVELOPING PAVEMENT DETERIORATION MODELS.

PAVER's **PCI Deterioration Families** tool uses PCI and work history data to determine pavement performance. The user groups pavements with similar uses and characteristics into families to develop a deterioration model for each family. This past pavement performance defines the deterioration rate of each family and is used in the PAVER **Condition Performance Analysis** tool and in **Work Planning** to predict the future condition of the pavement in the inventory.

PAVER also uses the family model to generate a **Current Predicted PCI** that provides a real-time estimate of the PCI today. Both the PCI at last inspection and the **Current Predicted PCI** are available in multiple reports and in the **Project Planning** module.

2-5 DEFINE WORK PLANNING PARAMETERS.

PAVER's **M&R Family Model** tools define the parameters used to develop work plans. These parameters are defined for each M&R category: localized operational (aka safety or stopgap), localized preventive, global, and major M&R.

The parameters defined include work types, cost by work type, distress maintenance polices, consequence of maintenance policy, consequent surface, minimum condition, and cost by condition. M&R family models are created for each M&R category then sections are assigned to the appropriate M&R family models.

2-6 DETERMINE WORK REQUIREMENTS.

PAVER's **M&R Work Planning** tool is used to develop work plans based on the PCI deterioration models, M&R family models, and other parameters defined in the **M&R Work Planning** tool based on specific scenarios.

These M&R work plans define near-term and long-term work requirements for each M&R category for each budget scenario. The near-term requirements include specific work types and estimated quantities and costs identified in the year following the latest inspection. The long-term requirements define costs for each M&R category but do not include specific work type or quantity requirements.

2-7 DEVELOP PAVEMENT MANAGEMENT PLANS (PMP).

Work plans generated by PAVER provide a list of repair requirements to develop PMPs. This part of the process involves a person with knowledge of pavement management, design, and construction who uses the PAVER products to prioritize and group requirements into executable tasks and projects.

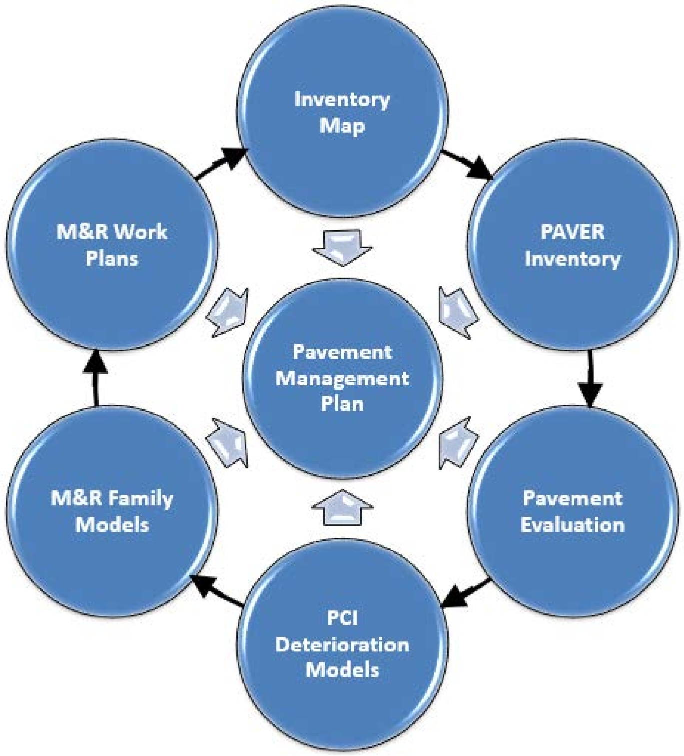
2-7.1 Other Pavement Management Plan (PMP) Considerations.

In addition to the PCI, other important factors such as pavement load-carrying capacity, FOD risk, surface friction characteristics, existing waivers, and operational considerations are used to prioritize and group requirements into executable tasks and projects.

2-7.2 Required Work and Project Planning Tool.

Once requirements are grouped into an executable task for in-house execution or a project for contract execution, they are entered into PAVER using the **Required Project** tool or the **Project Formulation Wizard**. Then rerun the M&R work plan with the required work included to develop a revised work plan. This process may go through several iterations until the entire PMP is defined. The overall process defined above is shown in Figure 2-1.

Figure 2-1 PAVER Pavement Management Process



2-8 STRATEGIC PAVEMENT MANAGEMENT.

Another important aspect of pavement management is the ability to do strategic pavement management analysis. By combining the databases for each installation into a single database, the Services can analyze and generate reports on condition, performance, and M&R requirements at the enterprise level.

This combined database is also known as a “rollup database.” A rollup database is created for airfield pavements and a separate rollup database is created for road and parking pavement. To facilitate enterprise analysis, each PAVER database that is combined in a rollup database must adhere to the standards outlined in this UFC. Services may supplement these standards based on mission-specific requirements.

2-9 SERVICE PAVEMENT EVALUATION PROGRAMS.

Each Service has a centrally managed pavement evaluation program for performing some or all the following evaluation types on a regular cycle: structural pavement evaluations, pavement condition index surveys, friction characteristics evaluations, and void detection surveys.

2-9.1 Airfields.

The types of evaluations performed and the evaluation cycle are determined by Service mission requirements.

2-9.2 Roads and Parking

Road and parking evaluations are typically constrained to PCI surveys but are also performed on a regular cycle as defined by each Service. The organizations listed in paragraph 2-9.3 are responsible for their respective evaluation programs and may be contacted for more information. These organizations are referred to as Service pavement POCs in this UFC.

2-9.3 Points of Contact (POC).

2-9.3.1 U.S. Army.

- Installation Management Command (IMCOM), Army Dams & Transportation Infrastructure in San Antonio, Texas has overall program responsibility.

- Engineer Research and Development Center (ERDC) Geotechnical and Structures Laboratory in Vicksburg, Mississippi performs airfield evaluations.

2-9.3.2 U.S. Navy.

- Naval Facilities Engineering Systems Command (NAVFAC) Atlantic in Norfolk, Virginia has overall program responsibility. NAVFAC/EXWC in Port Hueneme, California provides support to the overall program.

- NAVFAC Airfield Pavement Evaluation Teams perform airfield evaluations.

2-9.3.3 U.S. Air Force.

- The Air Force Civil Engineer Center (AFCEC) at Tyndall AFB, Florida has overall program responsibility.

- The AFCEC Airfield Pavement Evaluation Team performs airfield evaluations.

CHAPTER 3 PAVEMENT INVENTORY

3-1 INTRODUCTION.

Pavement inventory organization is the foundation for pavement management data collection and analysis. When performing a pavement evaluation for airfield or road and parking pavement, use the inventory structure from the previous evaluation as a starting point. Update the inventory to ensure it meets the standards outlined in this UFC but maintain the same inventory structure to the maximum extent possible. The intent of this guidance is to maintain continuity and facilitate analysis between successive evaluations. The following pavement inventory components are used to properly manage pavement assets.

3-2 INVENTORY MAP.

An accurate map showing the location and geospatial extents of pavement on an installation is critical when evaluating and managing pavement assets. These maps must be geospatially correct and are typically created using a geographic information system (GIS) such as Esri's ArcMap or AutoCAD Map 3D.

3-2.1 Mapping Guidelines.

PAVER uses the inventory map to navigate between segments in the inventory and to generate map-based PAVER reports.

a. Pavement mapping for DoD installations uses each installation's GIS data, called the Common Installation Picture (CIP). The CIP must comply with the Spatial Data Standards for Facilities, Infrastructure, and Environment (SDSFIE). Each Service has an approved SDSFIE adaptation and each has a Pavement Feature Class with "entities" and "attributes" that align with the required PAVER data structure standards as outlined in the PAVER user manual. Information on the SDSFIE is available at http://www.sdsfieonline.org.

b. At a minimum, the map must subdivide the inventory into polygons for the networks, branches, sections, and sample units. The map may also have attributes associated with these network, branch, section, and sample unit polygons, but if populated with the map data in the GIS, the attributes must align with the PAVER data structure standards as described above.

c. The pavement inventory map is exported from the GIS to a shapefile or table imported into PAVER. If the map is imported into PAVER with just the inventory geometry and without the inventory attributes, these attributes are populated in PAVER and are assigned to the inventory polygons using the **GIS Assignment** tool in PAVER.

3-2.2 Mapping Metadata.

When performing an evaluation, check the CIP metadata to determine if it was developed from surveyed geometry or digitized geometry. If it is the latter, determine the accuracy of the imagery; this dictates the accuracy of the map. Do not use a lower accuracy to change the network, branch, or section polygons.

3-2.3 Coordinate Systems.

Optimally, maps are created using the World Geodetic System (WGS) 84 datum, but the State Plane Coordinate System (SPCS) for bases within the United States or the Universal Transverse Mercator (UTM) Coordinate System for bases outside the United States may be used if that is the datum used to create the CIP.

3-2.4 Use of Imagery.

Imagery can be used to check maps for accuracy and update the map if the imagery is at the same or a higher accuracy than was used to create the original map (the CIP). Environmental Systems Research Institute (Esri) has world imagery on which you can overlay a shapefile to check geometry. Imagery may be imported into PAVER in a Tagged Image File Format (TIFF) as a context map. This imagery is useful when performing pavement evaluations, but when the database is combined into a rollup database, the imagery is removed to reduce file size.

3-2.5 Topology Validation.

Always validate a shapefile using the GIS application or in PAVER using the **GIS Manager** tool. The most important things to check for are that polygons have no gaps and are not overlapping.

> Once topology is validated, **delete** the validation information before exporting a new shapefile. If the topology is not deleted, PAVER will import it and the shapefile is rendered “unassignable.”

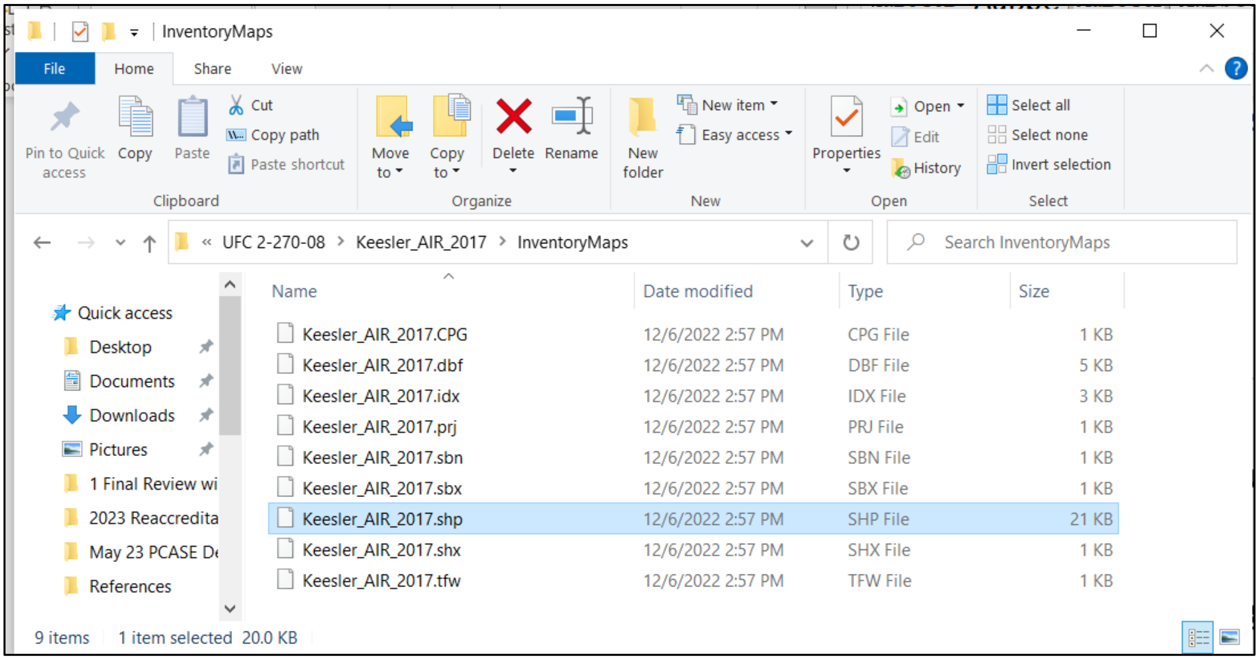
3-2.6 Importing Inventory Maps.

PAVER does have a section split wizard for altering the polygons on a map, but map changes are typically done in a GIS. PAVER uses the **GIS Tabular Import and Update** tools to bring maps into the database. PAVER stores the map data in a folder named **Inventory Maps** within the folder containing all the files associated with the database.

The main files needed in the **Inventory Maps** folder are the *.shp, *.prj, *.dbf, and *.shx files. If any of these files is missing, you will likely get an "unassignable" shapefile error message. There will be other files in this folder if you imported attributes in addition to the polygons. The file name used for each of these files must be the same, with the exception of the extension, and must clearly identify the network so it can be distinguished from other network maps in a rollup database (see Figure 3-1).

- Use **Site Name_Air_Year** for the name of airfield inventory map files.
- Use **Site Name_Road_Year** for the name of roads and parking inventory map files.

Figure 3-1 Inventory Maps



3-2.7 Exporting SDSFIE Data.

Once the attributes associated with the polygons in a database are updated, export the map to a shapefile or other compatible file format outlined in the PAVER User Manual for import into the installation's GIS. When using a shapefile, the field names have a limited length and some PAVER field names must be translated to SDSFIE-compliant field names.

3-3 INVENTORY DATA.

The pavement inventory is simply all pavements grouped by their function. An airfield database has the inventory for all airfield pavements at an installation and a separate database with inventory of all road and parking pavements at an installation. The terms "inventory" and "database" are often used interchangeably; however, the database includes the inventory, condition data, performance data, system tables with M&R policies, and work plans.

3-3.1 Database File Names.

a. Each Service maintains a repository for pavement evaluation databases. Database naming standards facilitate database management in these repositories. The site name/location, inventory type (airfield or road), type of evaluation, and date of the evaluation are required. Services may supplement the requirement with standard conventions for airfield type or type of evaluation to improve clarity.

b. Use **Installation Name_Air_Comp_Year** for the name of an airfield database when the most recent evaluation has both PCASE and PAVER data.

c. Use **Installation Name_Air_Str_Year** for the name of an airfield database when the most recent evaluation just has PCASE data.

d. Use **Installation Name_Air_PCI_Year** for the name of an airfield database when the most recent evaluation just has PAVER data.

e. Use **Installation Name_Road_PCI_Year** for the name of a road and parking database when the most recent evaluation just has PAVER data. Typically, all road and parking databases are for PCI surveys, but the same approach used for airfields is applied to roads if there are structural evaluation data in the database.

3-3.2 Database Properties.

Many government and commercial organizations around the world use the PCI and PAVER. These organization use both standard and user-defined data fields to meet their needs. The DoD limits the use of user-defined fields and uses specific standard data fields not typically used by other PAVER users. Select **File>>Database Properties** to open the form shown in Figure 3-2 to set the **DoD database properties**.

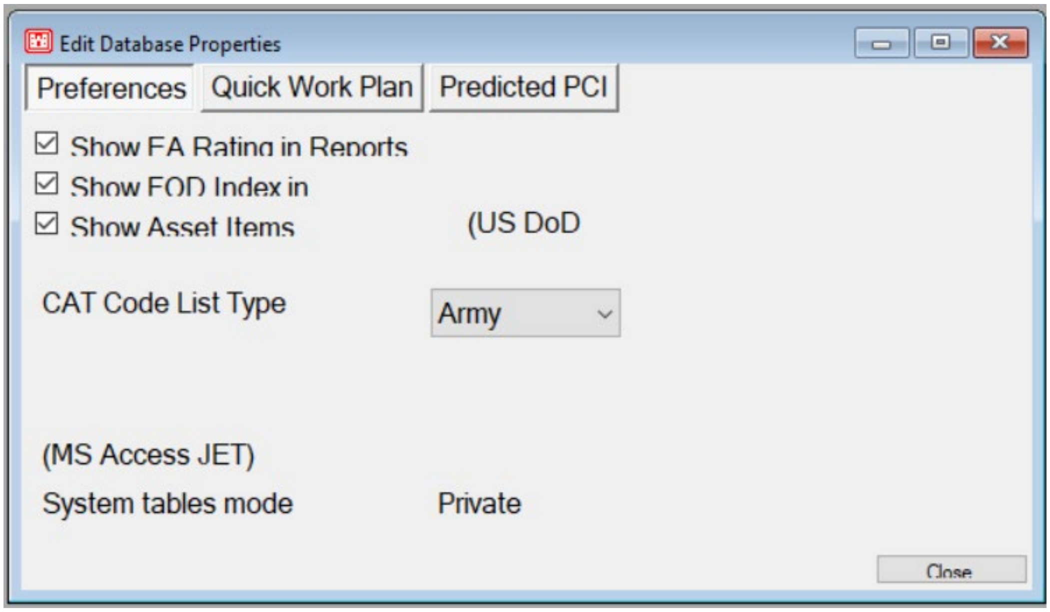
3-3.2.1 Airfield Database Properties.

Once the **Edit Database Properties** form is open, check the boxes for **Show EA Rating in Reports**, **Show FOD Index in Reports**, and **Show Asset Items** Select the appropriate Service from the **Cat Code List Type** drop-down.

3-3.2.2 Road and Parking Database Properties.

For road and parking databases, **Show Asset Items** is checked and both **Show EA Rating in Reports** and **Show FOD Index in Reports** are unchecked. Select the appropriate Service from the **Cat Code List Type** drop-down.

Figure 3-2 Edit Database Properties Form



3-3.3 Network Definition.

An airfield or road and parking pavement inventory will have one or more networks. Following are conventions for creating and naming networks. Note that the same network, branch, and section hierarchy is used for all pavement evaluation types, e.g., a structural evaluation uses the same inventory as a PCI evaluation for a given site.

3-3.3.1 Airfield versus Road and Parking Networks.

Since airfield and road and parking pavements are maintained in separate inventories, there is no need to distinguish between them in the network ID.

3-3.3.2 Multiple Sites on an Installation.

When an installation has multiple sites as indicated by the real property site unique identifier (RPSUID), include sites in the proximity of the main installation in the same inventory but make them separate networks.

If the site is separated from the main installation such that it cannot be legibly shown on the same inventory map, create a separate inventory (database) for the site. For example, create a separate database for an auxiliary airfield or a range complex geographically separated from the main installation.

3-3.3.3 Housing Pavement Networks.

Create a separate network for pavement in housing areas whether the housing is privatized or not. The Services will each establish a standard field in a rollup database to filter housing area pavement for data analysis and reporting purposes. This field may vary based on Service-specific real property regulations and the real property management applications used by each Service. See paragraph A-1 for a recommended procedure.

3-3.3.4 Other Networks Based on Ownership.

Create a separate network for pavements when a different organization has ownership / maintenance responsibility for the pavement. For example, create a separate network for pavements that are maintained by a National Guard or Reserve unit that is collocated on an active duty installation.

3-3.3.5 Paved and Unpaved Surfaces.

Include both paved and unpaved surfaces in an airfield or road and parking network.

3-3.3.6 Network ID Standard.

a. Each network must have a network ID based on the site name. The network ID is the primary field used to navigate between networks in PAVER and must clearly identify the network so it can be distinguished from other networks, particularly those in a rollup database.

b. The network ID field is limited to ten characters, so truncate the site name as required. The recommended approach is to use camel case (capitalize the first letter of each word in the name) when populating network IDs, e.g., ChinaLake or MtHome. If you have multiple networks in a database, truncate the site name and add characters at the end to make the distinction. For example, the landing zone for Little Rock AFB would be LittleRoLZ.

c. Privatized housing will use the truncated site name with a PH suffix (FtRuckerPH) and unprivatized housing will use the truncated site name with a UH suffix (FtRuckerUH).

d. If an asset management system used by a Service, e.g., iNFADS, requires a specific naming convention for network IDs in the future, that requirement will govern for that Service.

3-3.3.7 Network Name Standard.

Each network must have a network name based on the site name. The network name has a 60-character limit, which is more detailed than the network ID and is used to provide more detail about the network. For example, Fort Hood Privatized Family Housing.

3-3.3.8 Other Network-Level Inventory Fields.

A database can have one or more networks in the inventory for a specific installation. The network IDs are used to filter data for analysis and reporting purposes. When working with a rollup database with multiple installations, the network ID has limitations as a filtering tool. The recommended solution is for each Service to create a standard set of network level user-defined fields saved in a system table template. Import this template into each database. This ensures the unique ID for these user-defined fields are the same in every database. This procedure provides a means of filtering networks for analysis and reporting to meet specific mission and pavement management requirements. For example, a user-defined field for a major command provides the ability to generate reports by command and user-defined fields for housing and privatized pavements provides a means of filtering out these networks when running M&R plans.

Once the template is imported, the field remains a part of the database but the value for that field can be modified as required over time. For example, the value of the Major Command field could be updated if it changes, but the “unique ID” for the field will remain the same.

3-3.4 Branch Definition.

A network consists of one or more branches, which are defined by use. For example, a runway, named taxiway, named road, or contiguous parking area would each be a branch. Each branch must have the branch ID, branch name, and branch use fields populated.

3-3.4.1 Branch ID Standard.

The branch ID field is limited to ten characters. It must consist of a prefix indicating the branch use and the short name (truncated) for the branch. For example, RW1028 or RDPerimete. Branch prefixes are related to branch uses which are in turn related to the category codes that define the use of an asset in the real property records.

Each Service has asset types that are similar, whereas others are unique to that Service. Table 3-1 lists the standard branch prefixes for asset types that are similar. Each Service establishes a standard naming convention policy for its unique branch/asset uses consistent with the approach used in Table 3-1. Some Services allow a pavement facility to have multiple category codes. When multiple category codes are allowed, the branch naming convention will use some prefixes as suffixes. For instance, a runway facility consists of the runway, overrun, and shoulder pavement. The branch name for the runway shoulder is RW1028SH and the overrun is RW1028OR. A similar approach would be used with an apron or taxiway shoulder; for example, PAMainSH or TWASH.

Table 3-1 Branch Prefixes

Airfield Branch ID Prefixes	Road and Parking Branch ID Prefixes
RW = Runway	RD = Paved Road
TW = Taxiway	UR = Unpaved Road
PA = Parking Apron	PL = Paved Parking Area
AP = Other Apron	UP = Unpaved Parking Area
OR = Overrun	DW = Paved Driveway
HP = Helipad	UD = Unpaved Driveway
SH = Shoulder	MP = Motor Pool
	SA = Staging Area or Parade Deck

3-3.4.2 Branch Name Standard.

The branch name has a 60-character limit, so it is more detailed than the branch ID and is used to provide more detail about the branch. For example, Runway 10/28 or Perimeter Road.

3-3.4.3 Branch Use.

The branch use field is used to filter data for analysis and reports. It is also used to prioritize M&R work requirements when used in conjunction with the pavement rank. There is also an important relationship between the branch use and the real property category code, which can also be used to filter data and is discussed in more detail in paragraph 3-5.

Table 3-2 has a list of the PAVER default branch use categories used by the DoD. PAVER allows users to create user-defined branch uses, but Services will only use these default categories for DoD pavement evaluations. Services will submit new default branch uses to the PAVER Tri-Service Working Group to add it to the UFC and PAVER.

Table 3-2 Branch Use Categories

Airfield Branch Use		Road and Parking Branch Use	
Use Code	**Description**	**Use Code**	**Description**
APRON	APRON	CLOSED-RD	CLOSED ROADWAY
BLAST PAD	BLAST PAD	DRIVEWAY	DRIVEWAY
CARGO	CARGO	MTRPOOL	MTRPOOL
CLOSED-AF	CLOSED AIRFIELD	OTHER	OTHER
DEICING PAD	DEICING AREA	PARKING	PARKING
HELIPAD	HELIPAD	ROADWAY	ROADWAY
LINE VEHICLE	GROUND EQUIPMENT	ROUND	ROUNDABOUT
OVERRUN	OVERRUN	SHOULDER-RD	ROAD SHOULDER
RUNWAY	RUNWAY	STORAGE	STORAGE
SHOULDER-AF	AIRFIELD SHOULDER		
TAXIWAY	TAXIWAY		

3-3.5 Section Definition.

Each branch consists of one or many sections but the guidance for determining airfield sections varies from guidance for roads.

3-3.5.1 Airfield Sections.

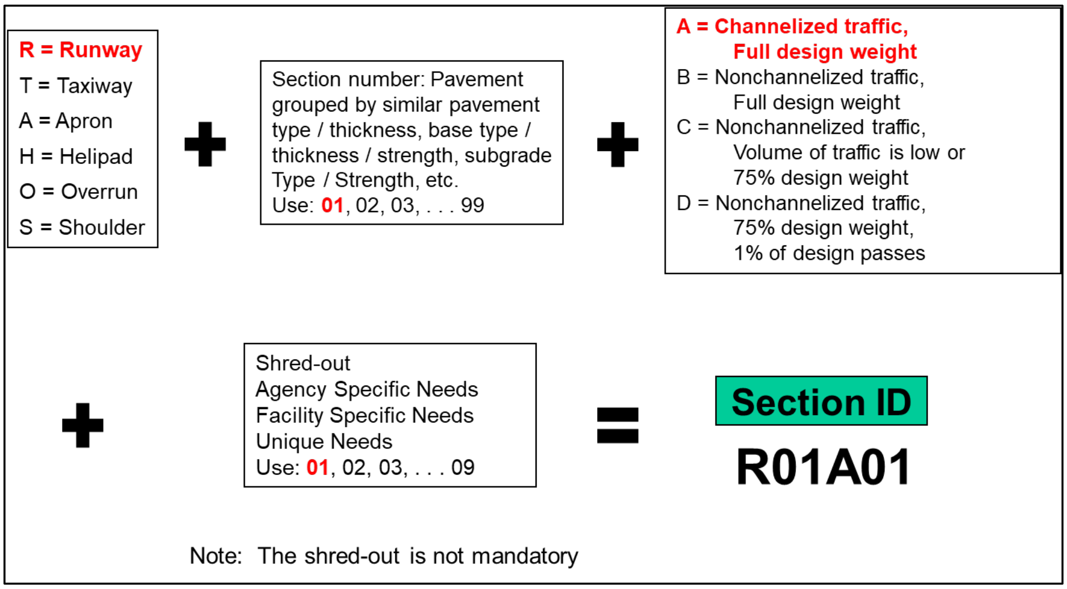
Define airfield sections by physical characteristics such as pavement type or thickness, construction history, or traffic area. Use test data, imagery, UFC standards, pavement design documents, or construction records to determine where to divide sections. Refine the location of section changes or further subdivide sections based on visual changes or structural evaluation. The overall intent is to ensure that all pavement in a section is uniform in terms of surface condition and structural capability.

3-3.5.2 Airfield Section ID Standard.

The airfield section ID consists of a prefix that indicates the use, a number, and a letter that indicates the traffic area. All pavement with a given section ID is structurally the same from an allowable load perspective. See Figure 3-3 for a section ID example.

The section ID may also include an additional number, known as a shred-out. The shred-out is used to distinguish pavements that are structurally similar but need to be segmented further for a specific reason. This may include pavement that is structurally the same but is part of a separate branch or a portion of a section whose surface condition is consistently different from other areas of the section. The prime example of this is the keel section of a runway versus the outer portions of the runway. Note that an airfield section ID for a given installation is unique for that installation.

Figure 3-3 Airfield Section Identification Example



3-3.5.3 Road and Parking Sections.

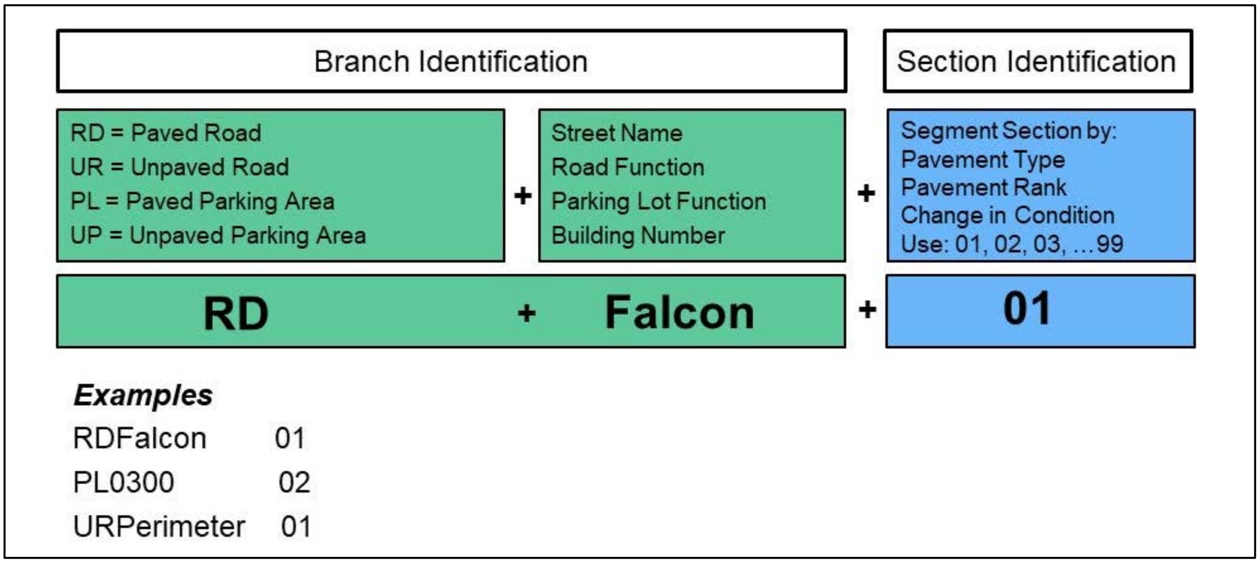
Sections for road and parking pavements must have the same pavement type and are assumed to be structurally similar. Sections for roads can be defined based on other characteristics such as the number of lanes. When the road is consistent along its length, sections are typically defined based on set intervals such as a section break at the edge of each intersection. When intersections are infrequent, sections are defined every 0.25 mile (402 meters) for roads in main installation areas and every 0.5 mile (804 meters) for lower volume roads outside the main installation.

A contiguous parking area (including the pavement to access that parking area) with the same pavement type is considered a section. If other physical characteristics such as thickness, construction history, or subsurface conditions are known, they can be used to better define the section. The overall intent is that all pavement in a section is uniform in surface condition and assumed or known structural capability.

3-3.5.4 Road and Parking Section ID Standard.

Unlike airfield section IDs, road and parking section IDs are not unique for a given installation. They are numbered sequentially for a given branch. To uniquely identify a road and parking section, use the concatenation of the branch ID and the section ID. Table 3-1 gives a complete list of branch prefixes and Figure 3-4 provides an example of how they are used to identify a section.

Figure 3-4 Road and Parking Section Identification Example



3-3.5.5 Mandatory Section Fields.

There are five mandatory section fields for asphalt concrete (AC) pavements and five mandatory section fields for portland cement concrete (PCC) pavements. These fields are mandatory for both airfield and road and parking pavement. PCC pavement has two additional fields required by DoD policy: slab length and slab width. Table 3-3 lists the mandatory fields. When updating a database, change any user-defined fields to default (standard) PAVER fields and delete the user-defined fields from the database.

Table 3-3 Mandatory Section Fields for PCC Pavement

Field	Description
Section ID	Identifies a specific area of pavement within a branch. The entire section must have the same pavement type.
Surface Type	PAVER has a list of default surface types that must be used. User-defined surface types are not allowed. The list of surface types is available in PAVER at **System Tables and Tools**>>**Edit Inventory Picklists**>>**Engineering Fields** and in the PAVER user manual.
Rank	Pavement rank is used to prioritize work requirements. PAVER has a list of default pavement ranks, but the only ones used by DoD are primary (P), secondary (S), tertiary (T) and unused (U). Rank definitions are in paragraph 3-3.5.6.
Last Construction Date	The last construction date is the last date that major M&R was performed that brought the PCI back to 100.
True Area	The section area is measured or determined from the GIS mapping application.
Slab Length	The representative measured longitudinal length of the slabs in the section. This field only applies to PCC pavement.
Slab Width	The representative measured transverse length of the slabs in the section. This field only applies to PCC pavement.

3-3.5.6 Section Rank Definitions.

Pavement ranks are listed on the section rank tab in PAVER at **System Tables and Tools**>>**Edit Inventory Picklists**>>**Engineering Fields**. When developing PMPs, use the section rank in conjunction with the branch use priority to prioritize M&R requirements at the section level.

Following are definitions for airfield and road and parking pavement section ranks. The rank definitions for roads are derived from Army SDDCTEA Pamphlet 55-17, *Better Military Traffic Engineering.*

Table 3-4 Pavement Section Rank

Airfield Section Rank		
Rank	**Code**	**Description**
Primary	P	Primary pavements are mission-essential pavements such as runways, parallel taxiways, main parking aprons, arm-disarm pads, alert aircraft pavements, and overruns (when used as a taxiway or for takeoff). In general, only pavements that have aircraft use on a daily basis or frequently used transient taxiways and parking areas are considered primary.
Secondary	S	Secondary pavements are mission-essential but occasional-use airfield pavements, including ladder taxiways, infrequently used transient taxiway and parking areas, overflow parking areas, and overruns (when there is an aircraft arresting system present). In general, any pavements that do not have daily use by aircraft are secondary.
Tertiary	T	Tertiary pavements include pavements used by towed or light aircraft, such as maintenance hangar access aprons, aero club parking, wash racks, and overruns (when not used as a taxiway or to test aircraft arresting gear). Paved shoulders are classified as tertiary. In general, any pavement that does not support aircraft taxiing under their own power or is used only intermittently is considered a tertiary pavement.
Unused	U	Unused pavements include any pavements that are abandoned (not maintained) or scheduled for demolition.
Road and Parking Section Rank		
Rank	**Code**	**Description**
Primary	P	Primary pavements include installation roads and streets that serve as the main distributing arteries (arterials) for traffic originating outside or within an installation. These pavements have high traffic volumes and speeds of 35 to 55 mph, but may include collector or local streets that service mission-critical facilities. Primary vehicle parking areas are restricted to those areas associated with access to mission-essential facilities, such as alert facilities, munitions facilities, and medical facilities.
Secondary	S	Secondary pavements include collector streets that gather and disperse traffic between arterials and local streets. They will have lower traffic volumes than primary pavements and speeds of 25 to 40 mph. Most parking areas that support daily traffic on a base are considered secondary pavements unless a specific mission dictates otherwise.
Tertiary	T	Tertiary pavements include local streets that provide access from collector roads to individual facilities. Unsurfaced roads are also typically classified as tertiary. Any parking area that is not used on a daily basis or is excess to the standard facilities requirements is considered a tertiary pavement.
Unused	U	Unused pavements include any pavements that are abandoned (not maintained) or scheduled for demolition.

3-3.6 Sample Unit Definition.

Subdivide each section into one or many sample units. A sample unit is a defined portion of a pavement section designated only for the purpose of pavement inspection. The number of samples inspected in a PCI survey is dictated by whether a network- or project-level inspection is called for.

Sample unit size requirements and the number of sample units inspected for both network- and project-level inspections are outlined in UFC 3-260-16. Use PAVER's **Inspection Report/Forms/Setup Wizard** to create a new inspection using the same samples inspected in the previous inspection. Add any new sections to the inspection. Specify the requirements in the contract statement of work if a higher sampling rate or a 100 percent inspection is required to better define the scope of a project.

3-4 WORK (CONSTRUCTION) HISTORY.

The term "work history" is often used interchangeably with the term "construction history." Both mean the same thing: a record of the type of work performed on each section and the date it was performed. Accurate work history dates play a critical role in creating PCI family models and defining the deterioration rate of a pavement. Use Paver's **Work History** tool or **Work Entry Wizard** to populate the work history. When work history is updated in a GIS application, use the PAVER **Add Work History from GIS or Tabular Data** tool. Details on these tools are outlined in the PAVER User Manual.

3-4.1 Last Construction Date.

Update the PAVER work history with the last major M&R date for each section. This is known as the Last Construction Date (LCD) and indicates the last work performed that brought the PCI of the pavement to 100. PAVER uses the LCD to determine the pavement deterioration rate, which in turn is required to predict the future condition of the pavement and generate future M&R requirements.

3-4.2 Unknown Last Construction Date.

When no construction records are available to indicate the last construction date, use the **Last Construction Date Wizard** to backcalculate a construction date based on the current PCI, using either a fixed rate of deterioration or using a deterioration family generated for similar sections at the installation with known LCDs.

3-4.3 Complete Work History Record.

In addition to the LCD, document any other M&R actions in the work history. This includes any localized preventive M&R such as crack sealing or global M&R such as applied surface treatments. An accurate construction history helps users determine the effectiveness of M&R strategies, better understand the development of pavement distresses, and develop better courses of action for future M&R.

3-5 REAL PROPERTY ASSET DATA.

When OSD mandated the use of PAVER, the primary driver was to get accountability of pavement assets from a real property perspective. This mandate created a requirement for PAVER to report pavement inventory in terms of each asset (facility) as outlined in GSA *Guidance for Real Property Inventory Reporting*.

From a pavement management perspective, DoD pavement inventories were historically segmented into networks, branches, sections, and sample units, but not facility. So, while PAVER pavement management inventories for DoD installations provide accurate information on location, area, type, and condition of pavements, the segmentation was historically not related to real property facilities in the Real Property Asset Database (RPAD). Linear segmentation resolves that issue.

3-5.1 Linear Segmentation.

Create a map showing the location and geospatial extents of each pavement asset (facility) on an installation as the first step in aligning pavement management data with the RPAD pavement assets (facilities). **Note:** This is not the same as a map from an earlier pavement evaluation that shows networks, branches, and sections because these maps give no indication of the location or geospatial extent of each real property pavement facility. Creating a pavement facility map requires the participation of real property, engineering, and GIS personnel and can be complicated, depending on the level of detail available in the real property record. Once the pavement facility map is completed, each real property pavement asset can be associated with a branch in the PAVER inventory allowing an installation to meet OSD requirements to account for pavement assets via the regularly scheduled pavement evaluations performed by the Services.

DoD Guide for Segmenting Types of Linear Structures provides guidelines for segmenting pavements. The Services implemented linear segmentation initiatives but gaps still exist in completing the effort to identify the location and geospatial extent of pavement facilities (pavement facility maps) and then linking the facilities to pavement management data; the effort is ongoing. Following are terminology and guidelines for linear segmentation that supplement *DoD Guide for Segmenting Types of Linear Structures* and the PAVER user manual.

3-5.2 Populating Real Property Asset Data in PAVER.

There are several ways to import pavement real property asset data into PAVER. These include manually entering each asset for an installation into PAVER, using the **Inventory**>>**Asset Management**>>**Import/Assign Asset Items Using GIS/Tabular Import** tool or using the **Inventory**>>**Centralized Asset Management**>>**asset file** tool.

Details for each of these procedures are outlined in the PAVER User Manual. The following sections describe required fields. Importing and assigning pavement asset data can be done as a one- or two-step process.

3-5.2.1 One-step Asset Assignment Process.

When the GIS or tabular data file has both inventory (network, branch, and section) fields populated and the required asset data fields populated when it is imported into PAVER, all asset data will appear in the appropriate tables and the assignment is complete.

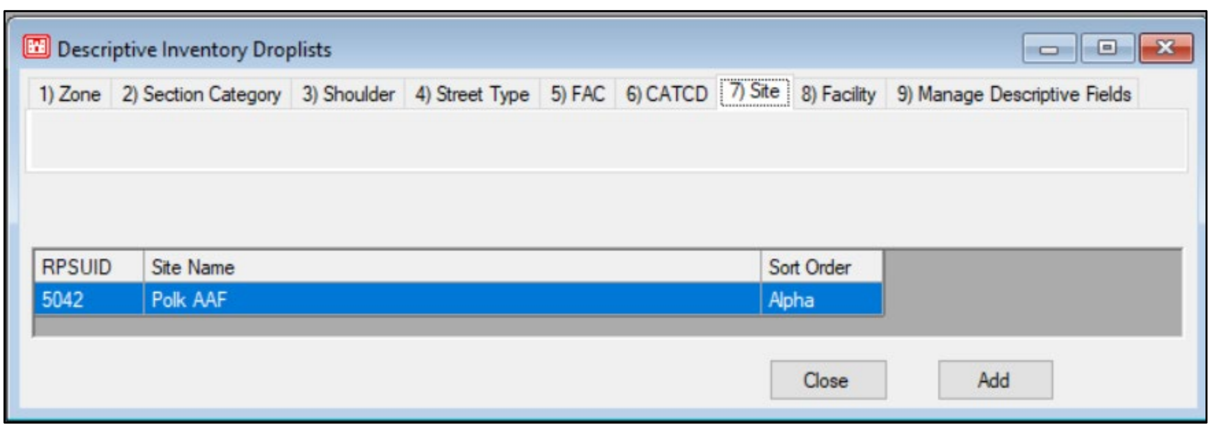
3-5.2.2 Two-step Asset Assignment Process.

When the GIS or tabular data file just has the map or the map with the inventory (network, branch, and section) fields included, but does not have the required asset data fields populated, the asset data must be entered manually or imported into PAVER and the assets must be assigned to the appropriate branch using the **Inventory**>>**Asset Management**>>**Assign/Unassign Asset Items** tool.

3-5.3 Real Property Site Unique ID (RPSUID).

The RPSUID is a code assigned by OSD to define a site permanently and uniquely. An installation can have multiple sites associated with it. Each will have its own RPSUID. If manually entering the field into PAVER, get the correct RPSUID for each site from the RPAD. Enter the RPSUID into PAVER using **System Tables and Tools**>>**Edit Inventory Picklists**>>**Descriptive Fields**>>**7) Site** (see Figure 3-5). If there is preexisting data in the database, add missing RPSUIDs and site names from the RPAD for all sites included in the installation database and delete any RPSUIDs not associated with the installation.

Figure 3-5 Adding a Real Property Site Unique ID (RPSUID)

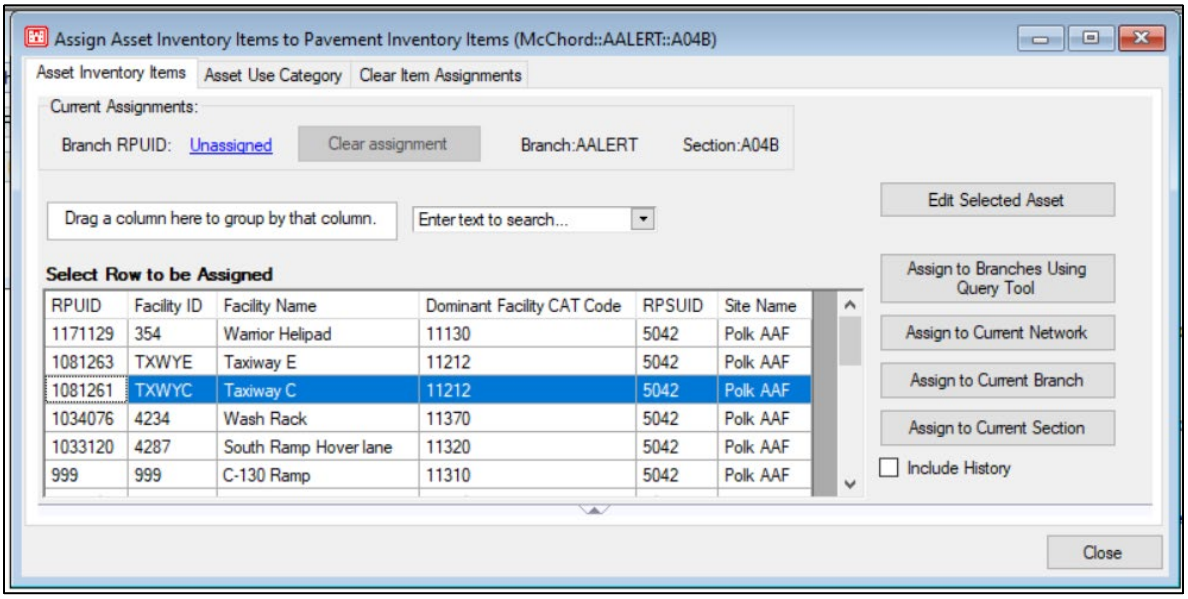


3-5.4 Real Property Unique ID (RPUID).

The RPUID is a code assigned by OSD to define a DoD real property asset (facility) permanently and uniquely. The RPUID is the key field used to link the real property pavement asset (facility) data to pavement management data. While PAVER allows the RPUID to be assigned at the network, branch, or section level in the event of future policy changes, the current policy is to assign the RPUID to the branch.

To assign the RPUID to a branch, navigate to the branch you want to update, then select **Inventory**>>**Define Inventory**. Select the **Assign Asset Items** button on the branch tab to open the assign asset items form. On the **Asset Inventory Items** tab, select the correct RPUID row for the current branch and assign it to the current branch. See Figure 3-6.

Figure 3-6 Assigning a Real Property Unique ID (RPUID)



3-5.5 Facility Number / ID.

The facility number is a code assigned by the installation or Service to define a real property asset. This code may or may not be unique to the enterprise and may change over time. However, this number will correlate to an RPUID and is often used when developing pavement facility maps. It is associated with the RPUID when asset data is imported into PAVER but can also be entered/updated manually at **System Tables and Tools**>>**Edit Inventory Picklists**>>**Descriptive Fields**>>**8) Facility**. When the RPUID is assigned to a branch, the facility number/ID is also assigned as shown in Figure 3-6.

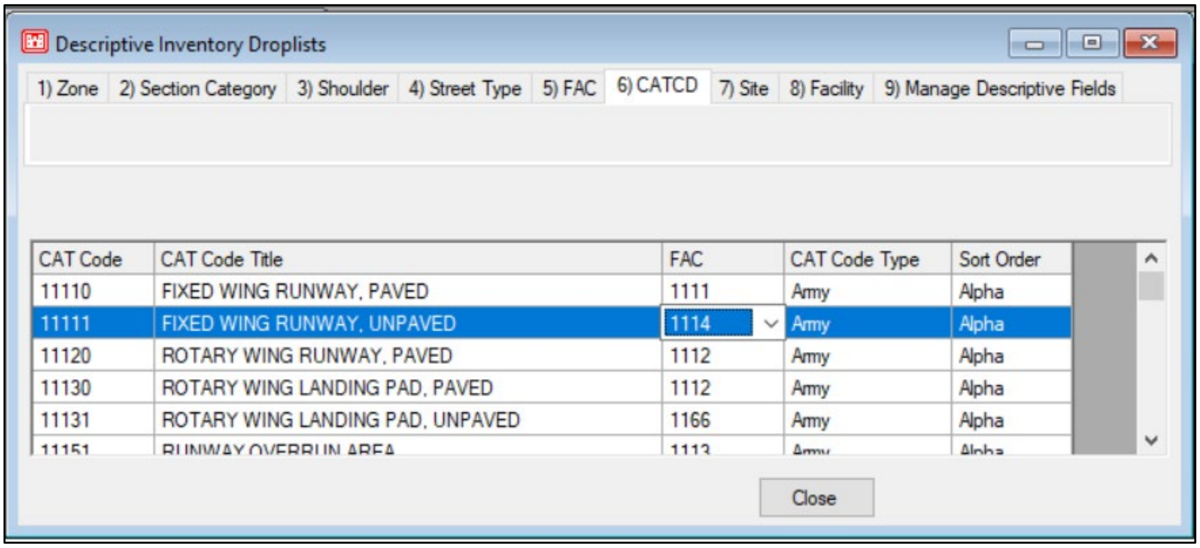
3-5.6 Facility Analysis Code (FAC).

The FAC is a classification of real property types within a "Basic Category," represented by a four-digit code. DoD FACs aggregate Military Department categories into common groupings based upon commonality of function, unit of measure, and unit costs. FACs are used in UFC 3-701-01, *DoD Facilities Pricing Guide*, to define replacement unit costs (RUC) and sustainment unit costs (SUC). RUCs form the basis for calculating plant replacement value (PRV) and SUCs serve as the basis for projecting OSD sustainment budget requirements.

The FAC is populated in PAVER in the **System Tables and Tools**>>**Edit Inventory Picklists**>>**Descriptive Fields**>>**6) CATCD** in association with the Category Code (see

Figure 3-7). It is assigned when the Category Code is assigned at the branch (or section) level.

Figure 3-7 Adding a Facility Analysis Code (FAC)

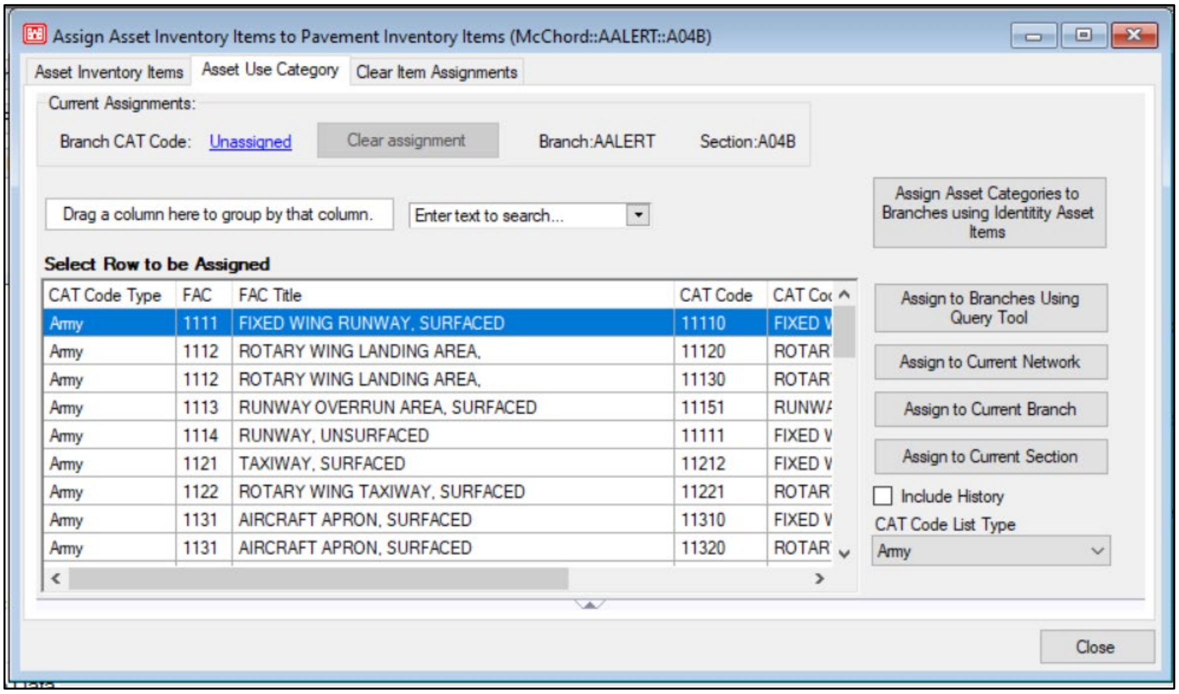


3-5.7 Category Code (CAT Code).

The FAC is further broken into Category Codes (CAT Codes) as shown in Figure 3-7. The CAT Code is the most detailed classification of real property that describes a specific real property type and function. It is represented by a numerical five- (Army and Navy) or six- (Air Force) digit code. CAT Codes are established by the Military Departments, so the CAT Code for a respective asset type may be different for each Service. Standard practice is to assign the CAT Code at the branch level.

From the **Inventory**>>**Define Inventory** form, open the **Assign Asset Items** form. On the **Asset Use Category** tab, select the correct CAT Code row for the current branch and then assign it to the current branch. When Service real property guidance allows for a facility to have more than one CAT Code, the predominant CAT Code for the branch must also be populated. See Figure 3-8.

Figure 3-8 Assigning a Category Code (CAT Code)

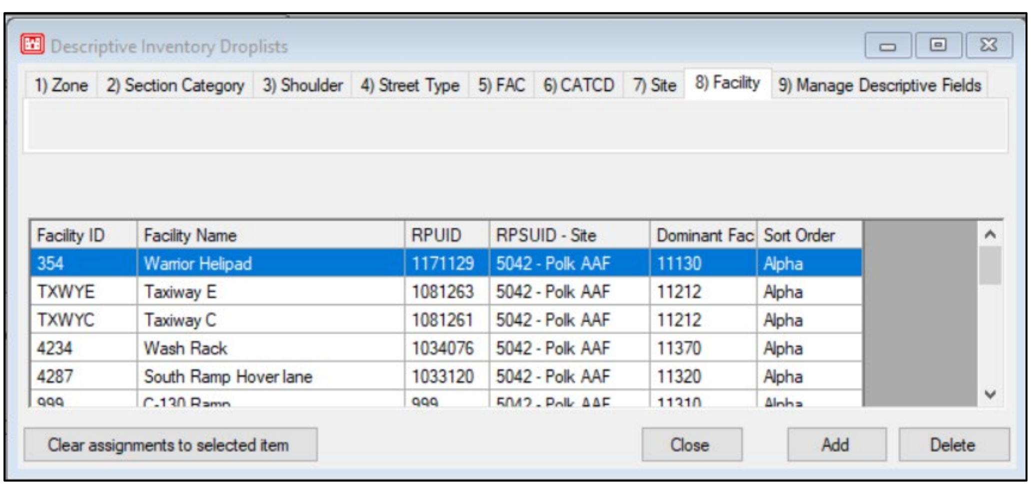


3-5.8 Predominant Facility CAT Code.

"Predominant use" is the term to describe the primary use of a real property asset based upon the largest quantity of usage for a specific activity or function. If there is only one CAT Code for a facility, leave the Dominant Facility CAT Code field in PAVER blank. If a pavement facility has more than one CAT Code, populate the Dominant Facility CAT Code field in PAVER based on the CAT Code with the greatest area.

Use the **System Tables and Tools**>>**Edit Inventory Picklists**>>**Descriptive Fields** form. Select **8) Facility**, then select the dominant facility CAT Code field for a row using the drop-down to select the predominant CAT Code as shown in Figure 3-9.

Figure 3-9 Assigning a Category Code



3-5.9 Facility Condition Index.

The DoD regularly collects data on the condition of every DoD facility to assess the health of its facility infrastructure. GSA *Guidance for Real Property Inventory Reporting* requires a Condition Index (CI) data element for all real property assets. The CI is defined as "a general measure of the constructed asset's condition at a specific point in time."

From the pavement management perspective, DoD uses the weighted area average of all the sections in a facility to define the facility PCI. This is not the same as the real property Facility Condition Index (FCI). The FCI is calculated as the ratio of the M&R requirement cost to the plant replacement value (PRV) cost, expressed in dollars. It is considered a critical metric for real property professionals who require accurate and consistent FCI data. PAVER does not compute the FCI at this time but is used to compute the M&R cost for each section in a facility. The sum of these section costs can be used to define the M&R cost for the facility for the FCI computation. To compute the FCI, these M&R costs are entered in the respective Service asset management programs, e.g., iNFADS for the Navy and Tririga for the Air Force.

CHAPTER 4 PAVEMENT EVALUATION

4-1 INTRODUCTION.

Pavement evaluation encompasses several different assessment types. Each is conducted to gather data on a different aspect of the properties or physical characteristics of the pavement. This data is used to analyze performance, define current capability, and predict future condition. The result of each is typically an index or metric that defines the condition, performance, or capability regarding the focus of the evaluation. Some or all of these evaluation types may be performed and, when results are taken together, they paint a more complete picture of condition, capability, and performance. This is key to developing a PMP and making a rational determination of feasible M&R alternatives.

In addition to the PCI survey, other evaluation types include structural, surface friction characteristics, void detection, and roughness evaluations. Details on these evaluation types are covered in UFC 3-260-03, commercial standards, and other Service-specific criteria. Following is a summary of evaluation types and a discussion of the indexes and products generated.

4-2 PAVEMENT CONDITION INDEX SURVEYS.

4-2.1 PCI Survey Process.

4-2.1.1 PCI Survey Mapping and Inventory.

PCI surveys involve collecting data on the type, quantity, and severity of distresses to determine the surface condition (PCI) for each section. Before conducting a PCI survey, create the mapping and inventory as outlined in Chapter 3. Note that the terms “PCI survey” and “inspection” are used interchangeably.

4-2.1.2 PCI Survey Planning.

After establishing the mapping and inventory, determine whether the inspection is network or project level. This defines the sampling requirements as outlined in UFC 3-260-16. A network-level survey requires the team to identify representative samples in the field. For a project-level survey, the team can plan the specific samples to be inspected before starting the survey. When a project-level PCI Survey has not been previously conducted, use the systematic random process described in UFC 3-260-16 to select the specific samples to be inspected. When a PCI Survey was previously conducted, inspect the same sample units inspected in the previous PCI Survey. Services may define more stringent sampling rates based on mission requirements.

Whether performing an initial inspection or a re-inspection, use PAVER’s **Inspection Report**>>**Forms**>>**Setup Wizard** to plan the inspection. This wizard generates inspection records and inspection forms to collect data and, if previously inspected, generates a re-inspection report for quality checks. The PAVER user manual has details on using this wizard.

4-2.1.3 PCI Survey Field Work.

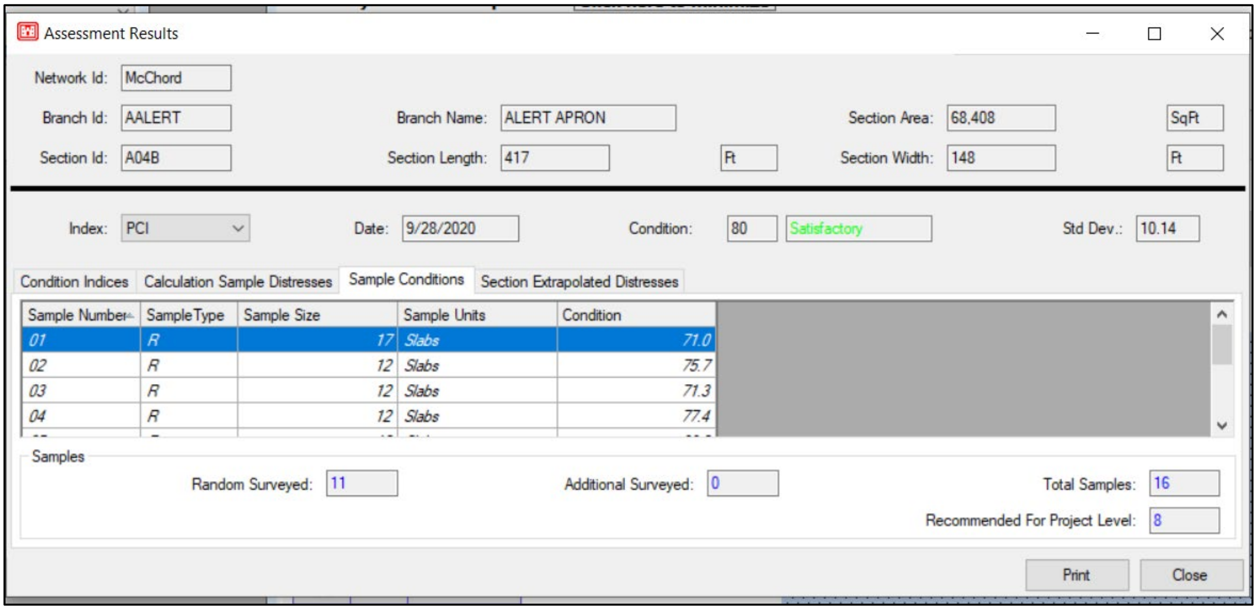
a. PCI surveys involve collecting data on the type, quantity, and severity of distresses to determine the surface condition (PCI) for each section. Before conducting a PCI survey, the mapping and inventory must be created as outlined in Chapter 3. Note that the terms “PCI survey” and “inspection” are used interchangeably.

b. A best practice is to perform the PCI survey with a GPS-enabled tablet, but it can also be performed using paper forms. If using paper forms, a tablet that is not GPS-enabled, or if you have poor GPS coverage, mark the sections and sample unit designations on the ground using paint, chalk, or a lumber crayon before performing the inspection. This allows inspectors and quality control personnel to easily locate them. A best practice is to perform the layout ahead of the inspection team(s).

c. Survey tools include a measuring wheel that measures to 0.1 foot (30 mm), a 10-foot (3 m) straightedge or string line, a scale or tape measure that reads to 1/8 inch (3 mm), a map of the pavements being inspected, and PCI distress handbooks. Handbooks for asphalt and concrete airfield or road and parking pavements are available at https://transportation.erdc.dren.mil/paver/Manuals.htm. The information in the handbooks is also available when entering data in the PAVER **Edit Inspection** tool.

d. Whether performing the survey using a tablet or paper forms, enter the distress data into PAVER using the **Edit Inspection** tool. Once the distress data is entered for each sample unit, PAVER computes the PCI for that sample unit. Once the distress data for all inspected sample units is complete, PAVER computes the section PCI. Record any sample units that are not representative of the section (for a project-level survey) as “Additional” sample units. “Additional” sample units are handled differently in the computation than random samples.

Figure 4-1 PAVER Sample Conditions Tab



e. Select the **Show Conditions** button on the **Edit Inspection** form once the selected sample units have been inspected, then select the **Sample Conditions** tab on the **Assessment Results** form to determine if enough samples were inspected to get a 95 percent confidence level for a project-level inspection as shown in Figure 4-1. If the **Recommended for Project Level** field indicates that more samples are needed, inspect more random samples to achieve the required confidence level.

f. Repeat this inspection process for each section. UFC 3-260-16 outlines PCI inspection and computation details. PAVER also calculates other condition index values based on the PCI Survey.

4-2.2 Structural Condition Index.

Pavement distresses are categorized as load related, climate/durability related, and other. The other category includes distresses caused by material or construction issues or related to repairs. The Structural Condition Index (SCI) is based on the deduct values for only the load-related distresses, as shown in Equation 4-1. So, like the PCI, 100 is a good rating and 0 is a bad rating. The PAVER user manual identifies load-related distresses.

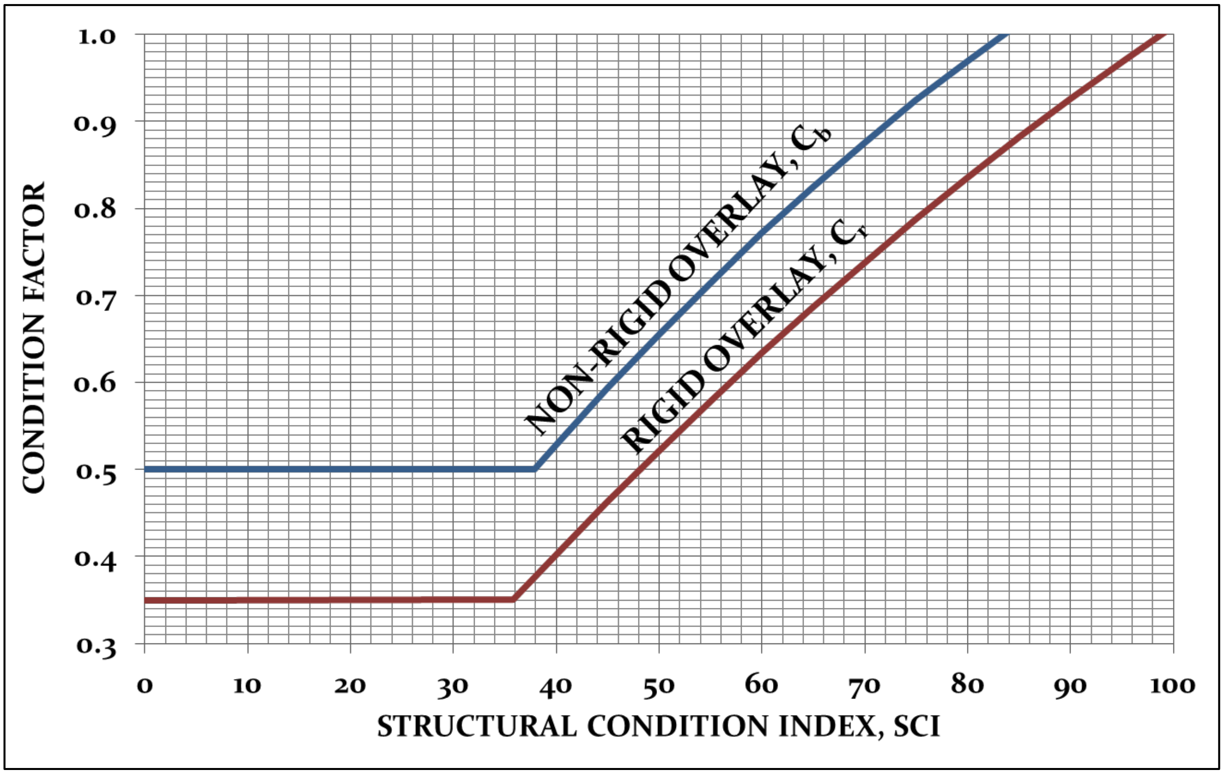
Equation 4-1. Structural Condition Index

$$SCI = 100 - CDV_{LR}$$

Where:
SCI = Structural Condition Index
CDV = Corrected Deduct Value
LR = Load Related

The SCI is used in the layered elastic analysis procedure to define failure in rigid pavements. This prediction is based on a relationship between design factor and stress repetitions as related to crack formation in the PCC slabs due to load. Details are found in UFC 3-260-02, *Pavement Design for Airfields*, and UFC 3-260-03, *Airfield Pavement Evaluation*. The SCI is also used to determine overlay requirements for rigid pavements by relating the SCI to the condition factor for bituminous overlays (C_b) and rigid overlays (C_r), as shown in Figure 4-2. UFC 3-260-02 and UFC 3-260-03 provide guidance for determining an appropriate overlay type based on the condition factor.

Figure 4-2 Using SCI to Determine Condition Factors



4-2.3 Foreign Object Damage (FOD) Index.

The FOD Index is also determined using PCI survey data but is calculated by considering only the distresses/severity levels capable of producing FOD. Table 4-1 lists the FOD-producing distresses and severities for AC pavement and Table 4-2 lists them for PCC pavement.

When calculating the PCI for determining the FOD Index (see Equation 4-2), note that a multiplier, or modification factor, of 0.6 is applied to the deduct value for alligator cracking and a multiplier, or modification factor, of 4.0 is applied to the deduct value for joint seal damage. The computation results in a value from zero to 100, but, unlike the PCI and the SCI, a low FOD Index value is good and a high value is bad. PAVER calculates the FOD index at the same time as the PCI.

Equation 4-2. Foreign Object Damage (FOD) Index

$$FOD\ Index = 100 - PCI_{FOD}$$

Where:
FOD = Foreign object damage
PCI = Pavement Condition Index

Table 4-1 FOD-Producing Distress List for AC Pavements

Distress Type	Severity Levels (L = Low, M = Medium, H = High)
Alligator cracking (modification factor: 0.6)	L, M, H
Block cracking	L, M, H
Jet blast erosion	N/A
Joint reflection cracking	L, M, H
Longitudinal and transverse cracking	L, M, H
Oil spillage	N/A
Patching	M, H
Raveling and weathering	L, M, H
Shoving	M, H
Slippage cracking	N/A

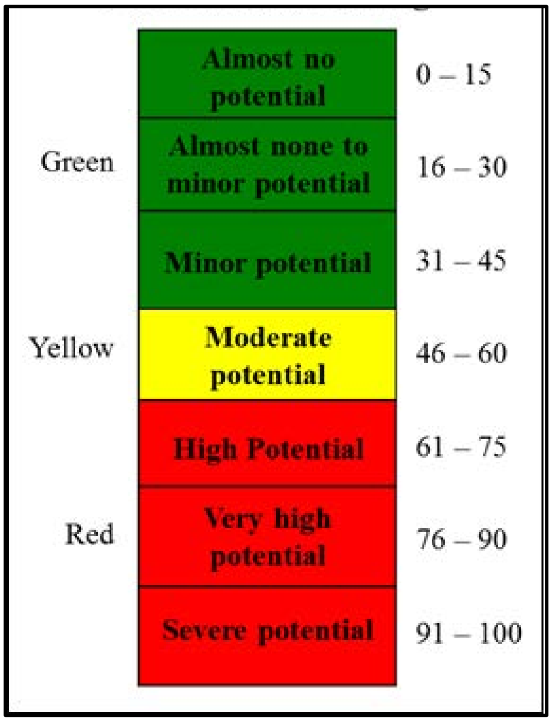
Table 4-2 FOD-Producing Distress List for PCC Pavements

Distress Type	Severity Levels (L = Low, M = Medium, H = High)
Blow-up	L, M, H
Corner break	L, M, H
Durability cracking	M, H
Linear cracking	L, M, H
Joint seal damage (modification factor: 4.0)	L, M, H
Small patching	L, M, H
Large patching	L, M, H
Popouts	N/A
Pumping	N/A
Scaling	L, M, H
Shattered slab	L, M, H
Joint spalling	L, M, H
Corner spalling	L, M, H

4-2.4 FOD Potential.

a. The FOD potential relates the FOD Index to the FOD susceptibility of three aircraft groups. A FOD potential scale ranging from 0 to 100 is used to indicate the potential for FOD problems. Figure 4-3 shows the numerical FOD potential scale and corresponding descriptive categories.

Figure 4-3 FOD Potential Scale



b. The FOD potential depends on the type of aircraft using the pavement, the type of pavement surface (asphalt or concrete), and the FOD Index. The FOD Index and the FOD potential rating are determined from the most current PCI survey.

c. Relationships between FOD indexes and FOD potential were developed for three aircraft groups: F-16, KC-135, and C-17. These three aircraft were selected as a representative cross-section due to engine height above the pavement surface and engine susceptibility to FOD (e.g., engine type, size, air flow, thrust). Table 4-3 provides recommendations on which standard aircraft group curve (F-16, KC-135, or C-17) to use when determining the FOD potential for other aircraft.

Table 4-3 FOD Potential Aircraft Groups

Standard Aircraft	For Aircraft Listed Below, Use FOD Index/FOD Potential Relationship Curve for Standard Aircraft (Left Column)
F-16	A-37, AT-38, F-15, F-22, F-35, T-37, T-38
KC-135	A-300, A-310, A-320, A-321, A-330, A-340, A-380, AN-124, B-1, B-2, B52, B-707, B-720, B-737, B-747, B-757, B-767, B-777, C-21, C-32, C38, C-40, C-135, DC-8, DC-10, E-3, E-4, E-8, EC-18, EC-135, IL-76, KC-10, L-1011, MD-10, MD-11, P-8, T-1A, T-43, VC-25, VC-137
C-17	A-10, B-717, B-727, C-5, C-9, C-12*, C-20, C-22, C-23*, C-27, C-37, C38, C-41, C-130*, C-295, CN 235, CV-22, DC-9, MC-12, MD-81, MD82, MD-87, MD-90, MV-22*, P-3*, RC-26, RQ-4, T-6*
* Denotes turboprop or turboshaft-equipped aircraft	

d. Figures 4-4 and 4-5 show the relationship between the FOD Index and FOD potential for asphalt and concrete pavements, respectively.

Figure 4-4 FOD Index and FOD Potential Relationship for AC

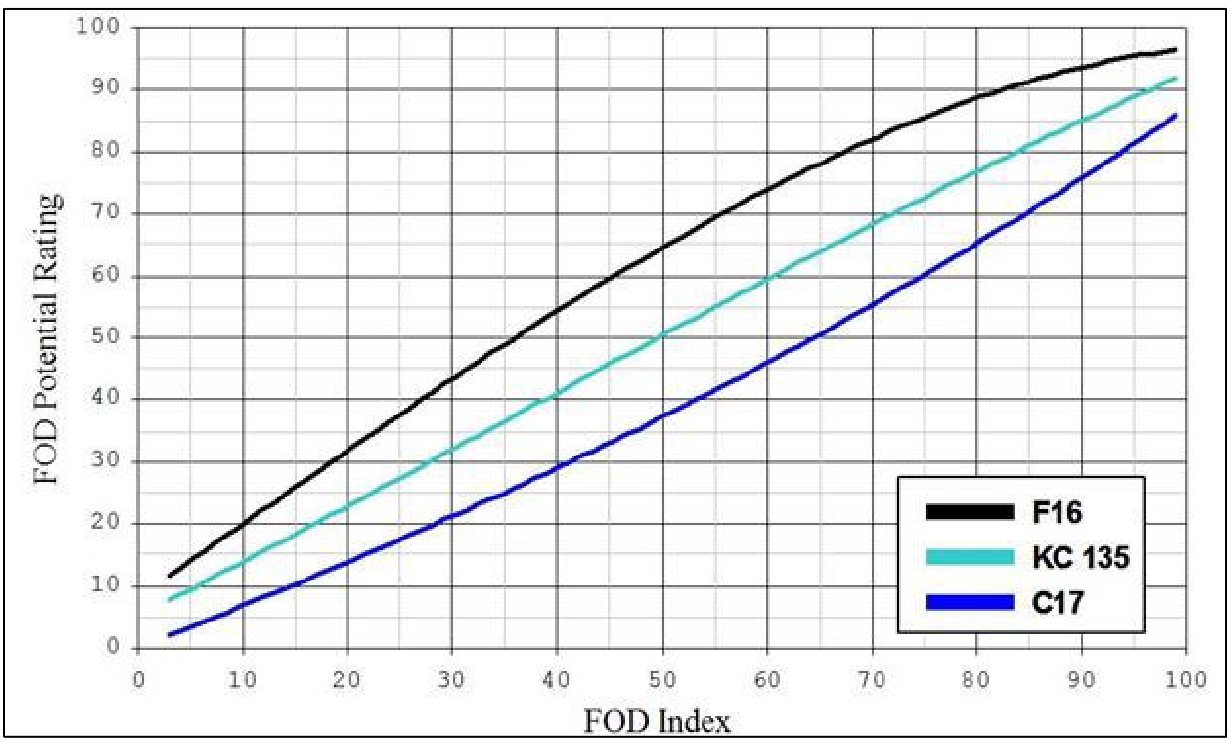


Figure 4-5 FOD Index and FOD Potential Relationship for PCC

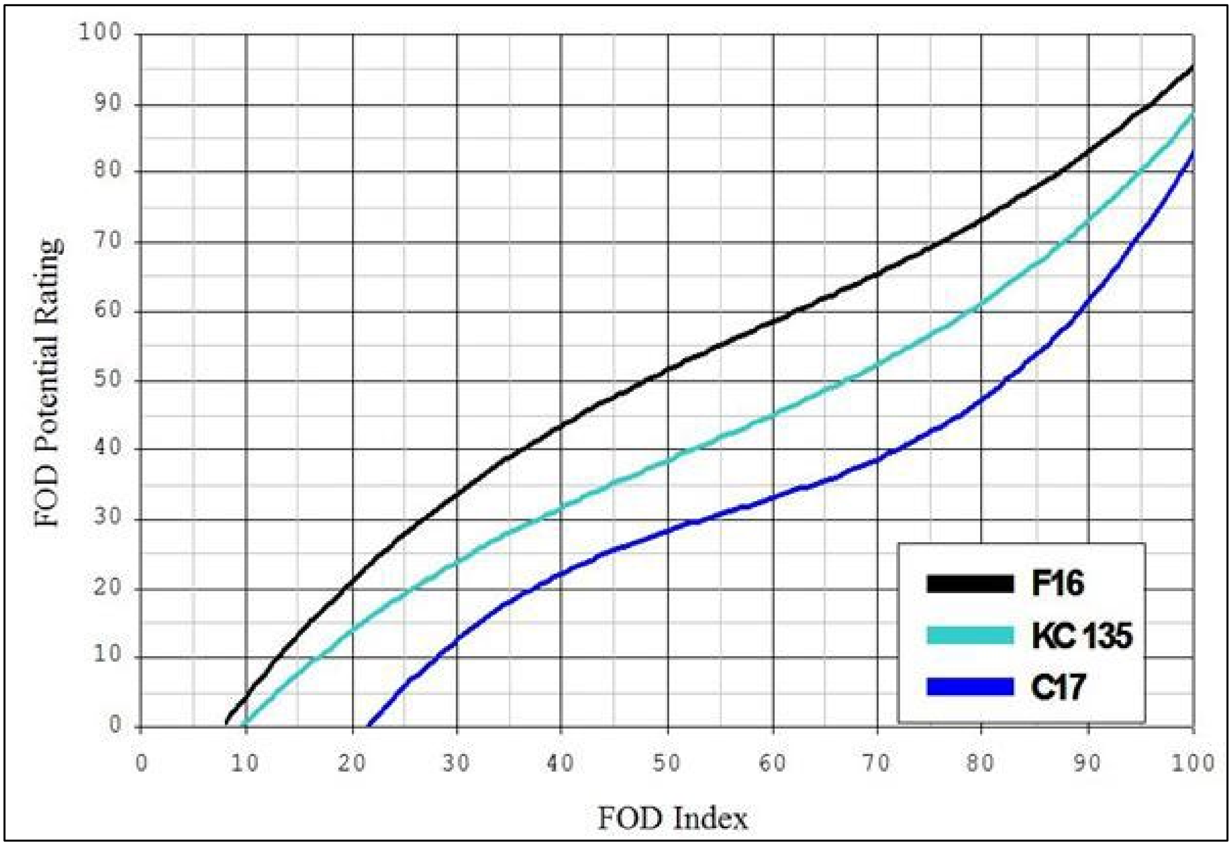


e. The aircraft group curves in Figures 4-4 and 4-5 were used to determine the FOD potential risk levels in Table 4-4. The FOD Index and the FOD potential group for a section corresponds to the low, medium, and high FOD potential risk for that section. The FOD potential can be displayed on a color-coded airfield layout map, using green for the corresponding rating of low, yellow for medium, and red for high.

Table 4-4 FOD Potential Risk Level

FOD Potential Risk Level		**FOD Index**					
		F-16		**KC-135**		**C-17**	
		AC	**PCC**	**AC**	**PCC**	**AC**	**PCC**
Low	0–45	0–32	0–41	0–44	0–60	0–59	0–77
Medium	46–60	33–45	42–62	45–60	61–78	60–75	78–89
High	61–100	46–100	63–100	61–100	79–100	76–100	90–100

4-3 STRUCTURAL PAVEMENT EVALUATIONS.

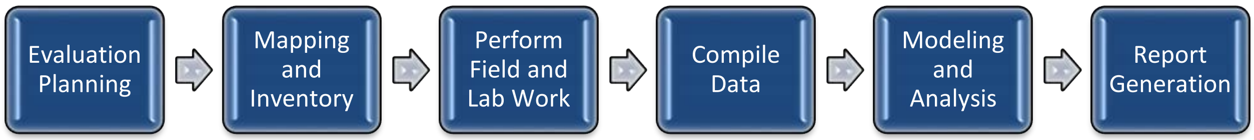
a. The objective of a structural evaluation is to determine the allowable load, allowable passes, and the Pavement Classification Number (PCN) (for airfields only) for a specific mix of traffic. UFC 3-260-03 uses the terms “nondestructive testing” and “direct sampling” to describe the two approaches to structural evaluation testing procedures. Both approaches determine the layer types and thicknesses and characterize the material properties of each layer.

b. Specifically, nondestructive testing uses tools such as the falling weight deflectometer (FWD) to determine modulus of elasticity or ground penetrating radar (GPR) to determine pavement thickness, whereas direct sampling uses test methods such as coring to determine pavement thickness, the dynamic cone penetrometer (DCP) to determine the California Bearing Ratio (CBR) for flexible pavements, or the Modulus of Subgrade Reaction (K) for rigid pavement. Each approach also uses different performance models for analysis.

c. Like PCI surveys, structural evaluations are performed on a section-by-section basis using the same inventory structure used for the PCI survey. Structural pavement evaluation data is often used to delineate pavement sections since each section represents a unit of the pavement network that is uniform in structural composition and subjected to consistent traffic loadings.

d. Service evaluation teams perform regularly scheduled airfield structural evaluations. Consultants may perform structural evaluations or geotechnical investigations in conjunction with specific project designs. Service evaluation teams or consultants may also perform structural evaluations for roads and parking pavement on an as-needed basis. Evaluations follow the general process shown in Figure 4-6. More details are provided in UFC 3-260-03.

Figure 4-6 Structural Evaluation Process



4-3.1 Structural Evaluation Planning.

Planning involves gathering data from the installation and doing a records review of the historical data from previous evaluations and other sources to develop a test plan. The test plan will vary depending on the type of testing and the availability of construction history and previous test data.

4-3.2 Structural Evaluation Mapping and Inventory.

The data gathered in planning is used to create/update maps and inventory as discussed in Chapter 3. The same maps and inventory used for PCI surveys are also used for structural evaluations. Update the maps and inventory to the maximum extent possible before conducting a structural evaluation. Maps and inventory may be adjusted in the field based on testing results. If testing includes coring or DCP testing, the test plan will include a map showing the test locations. The map helps communicate testing requirements and timing to installation personnel and is used to process work clearance requests for the evaluation.

4-3.3 Structural Evaluation Field/Laboratory Data Collection and Testing.

4-3.3.1 Structural Evaluation Field Testing.

Field work involves collecting data regarding traffic, pavement use, temperature, climate, water table, and geology as well as test data to determine layer types, thicknesses, and properties. When doing a nondestructive evaluation, use one or more of the test methods shown in paragraph 4-3.3.2 to determine layer types and thickness. Use the FWD to gather data for the backcalculation procedure to determine the modulus of each layer. The direct sampling evaluation will use one or more test methodologies shown in paragraph 4-3.3.2 to determine layer types and thicknesses as well as CBR (for flexible pavement) or K (for rigid pavement) values. UFC 3-260-03 and Service-specific guidance outline details for the test methods shown in paragraph 4-3.3.2. Any samples collected that cannot be tested in the field are returned to the laboratory for additional testing.

4-3.3.2 Structural Pavement Evaluation Test Methods.

- California Bearing Ratio (CBR)
- Concrete split tensile testing
- Dynamic cone penetrometer (DCP)
- Falling weight deflectometer (FWD)
- Ground-penetrating radar (GPR)
- Pavement coring
- Plate bearing
- Soil laboratory testing
- Ultrasonic testing (MIRA)

4-3.4 Compile Structural Evaluation Data.

Compile the field and laboratory test data in the physical property data (PPD) table. If a previous structural evaluation was done, use the PPD from the previous evaluation as a starting point. The PPD content may vary based on the type of evaluation performed and mission requirements, but, at a minimum, must have the information in Table 4-5.

Table 4-5 Physical Property Data

Physical Property Data Table Requirements	
Section ID	Thickness of each soil layer
Section name	Description of each soil layer
Thickness of each pavement layer	Modulus, CBR, or K for each layer depending on analysis procedure
Description of each pavement layer	
Flexural strength of PCC layers	

4-3.5 Data Modeling and Analysis.

Import the field test data into the PCASE application. Define the section properties for each section in the inventory, including the evaluation type (airfield or road/parking), traffic area (A, B, C, or D), PCI, traffic pattern, and analysis type (layered elastic or CBR/K). The process varies from this point depending on the analysis type: layered elastic analysis using FWD data or a conventional analysis using CBR/K evaluation procedures.

4-3.5.1 Layered Elastic Modeling and Analysis.

a. The first step in Layered Elastic Analysis is reviewing the test data (known as deflection basins). Use the PCASE Nondestructive Test **FWD Data** tool when one file has test data for multiple sections. Parse out the test points and assign them to the appropriate sections. When a file only has test data for a specific section, just assign the test data to the section without any parsing.

b. Next, use the layer structure data compiled in the PPD to create a layer model in PCASE for each section and select basins for backcalculation for each of these sections. This process involves reviewing the basin data to eliminate outliers to achieve a coefficient of variation below 20 for the data set.

c. The PCASE backcalculation procedure determines modulus values for each basin in the test data as well as the convergence error for each basin. PCASE also performs representative basin computations and selects a representative basin for the data set. A low percent error for either the convergence error or the representative basin computation does not necessarily indicate a good result. Review the results to determine whether they are reasonable. If not, re-evaluate the input parameters, adjust the model, and repeat the process until the results are reasonable. The reasonableness of results is typically determined based on published modulus ranges for different material types and the other evaluation test results.

d. After determining a reasonable set of modulus values for the layer model, run the analysis to determine the allowable load, allowable passes, and

Pavement Classification Number (PCN). Based on the results, the user may re-evaluate the model parameters and repeat the process. Details for both the layered elastic backcalculation and analysis procedures are outlined in UFC 3-260-03 and the PCASE User Guide.

4-3.5.2 Conventional Analysis Using CBR/K Analysis Procedures.

While field testing may be less complicated with the CBR/K procedure, the analysis is not as robust as the layered elastic procedure, especially when dealing with non-standard pavement structures. With that said, the CBR/K procedures have served well for many years and are especially useful for contingency evaluations.

Once section properties are defined in the PPD based on the test results, use the data compiled for each section to create a layer model in PCASE. Like the layered elastic procedure, the layer model may combine similar layers to facilitate analysis. Run the analysis to determine the allowable load, allowable passes, and PCN for each section. Based on the results, the user may re-evaluate the model parameters and repeat the process.

4-3.6 Report Generation.

PAVER and PCASE both generate a variety of reports. These reports are typically Excel spreadsheets that the user incorporates in their design analysis or pavement evaluation report.

4-3.7 Aircraft Classification Number (ACN).

The ACN number expresses the relative structural effect of an aircraft in terms of a standard single-wheel load on flexible or rigid pavement types for four specified standard subgrade strengths. UFC 3-260-03 discusses the standard procedures for determining the ACN of an aircraft. The specifics of the computation are given in the International Civil Aviation Organization (ICAO) *Aerodrome Design Manual, Part 3, Pavements*. The rigid pavement ACN algorithm used by the DoD considers all loads (tires) within eight times the radius of stiffness as opposed to three times, which is used in the ICAO *Aerodrome Design Manual*. Aircraft manufacturers publish ACN values for each aircraft using the ICAO procedure. The PCASE application also calculates ACNs using the ICAO procedure but uses a linear relationship between the minimum and maximum load that can vary slightly from the manufacturer’s ACN values.

4-3.8 Pavement Classification Number (PCN).

The PCN number expresses the relative load-carrying capacity of a pavement in terms of a standard single-wheel load on flexible or rigid pavement types for four specified standard subgrade strengths. The numerical PCN value for a pavement is determined from the allowable load for a defined aircraft at a specified number of passes on the pavement. Once the allowable load is established, determine the PCN value by converting that load to a standard single-wheel load and then to a standard relative value. PCNs are discussed in more detail in UFC 3-260-03 and the criteria for converting allowable loads to PCN values are presented in the ICAO *Aerodrome Design Manual, Part 3, Pavements*.

4-3.8.1 Publishing PCNs.

An airfield pavement structural evaluation report publishes a PCN for each section in the inventory and may publish a limiting PCN for each branch (runway, taxiway, and apron). The Air Force Air Mobility Command (AMC) publishes PCNs in their Airfield Site Suitability Reports for installations used by the Services in the U.S. and overseas. The "Giant Report" is a summarized compilation of the information in the Site Suitability Reports and includes the PCN. In addition, the National Geospatial Intelligence Agency publishes the PCNs for runways, taxiways, and aprons generated by these airfield pavement evaluations in Flight Information Publications (FLIP) used by the military and civil aviation community.

4-3.8.2 PCN Based on Standard versus Controlling Aircraft.

The PCN is based on the allowable load of an aircraft at a specified number of passes. There are two alternatives for selecting the aircraft the PCN is based on for a specific airfield. The first uses the controlling aircraft at a specified number of passes based on the traffic mix for that specific installation. The second uses a standard aircraft at a set number of passes established by the Service. The PCN computed using either alternative is used to compute the ACN/PCN ratio. Each Service can use one or both procedures when publishing PCNs in their reports.

The procedure using the specific traffic mix for the installation relies on information from the installation regarding the types of aircraft that use the airfield as well as the number of operations of each. When the information provided is accurate, this approach provides greater fidelity for managing aircraft traffic on pavements at the local level but does not work as well when comparing capability between installations. Note that the controlling aircraft and passes can vary between sections on an installation. While the controlling aircraft and passes used to compute the PCN are published in the pavement evaluation report, just the PCN is published in the Giant Report or FLIP. The standard aircraft procedure can be used to manage traffic on pavements at the local level but has the inherent benefit of knowing the controlling aircraft and number of passes when looking at capability between sections and between installations since the controlling vehicle does not vary. The controlling aircraft and passes are published in the structural evaluation report, the AMC Site Suitability Report, and the Giant Report, but this detail is not published in the FLIP.

4-3.9 ACN/PCN Ratio.

The ACN/PCN is a method for reporting weight-bearing capacity intended to provide planning information for individual flights or multi-flight missions to avoid overloading pavement facilities. While it was not originally intended as an evaluation procedure, it is used this way. The ACN/PCN procedure provides a means to compare the ACNs published by aircraft manufacturers to the PCNs published in evaluation reports and the

FLIP. The system is structured so that a pavement with a PCN value greater than or equal to the aircraft ACN value can support that aircraft without weight restrictions.

4-3.9.1 Structural Index (SI).

The DoD pavement community applies the ACN/PCN ratio as a pavement management metric and uses the term “structural index” (SI) in this context. This metric compares the ACN of the critical aircraft at a specified load for each section to the published PCN for that section. See Equation 4-3.

Equation 4-3. Structural Index (SI)

$$SI = ACN/PCN$$

Where:
ACN =Aircraft Classification Number
PCN = Pavement Classification Number

4-3.9.2 ACN Critical Aircraft.

The critical aircraft used to determine the ACN varies based on the traffic using the pavement. For example, the critical aircraft for the runway at an installation may be the P-8 but aprons or taxiways that the P-8 does not traffic will use a different critical aircraft to determine the ACN.

The critical aircraft used to determine the ACN can be the same as the controlling aircraft used to determine the PCN for a given section, but when using the standard aircraft alternative to determine the PCN, the primary assigned mission aircraft using respective sections at that installation are used as the critical aircraft to determine the ACN. Adjust the aircraft load used to compute the ACN such that the results of SI computation align with the allowable gross loads (AGL) published in the report. For example, you do not want the SI as defined in the next paragraph to indicate load restrictions when the AGL report showed that there were no load restrictions.

4-3.9.3 Structural Index (SI) Ratios.

The SI is used differently in Service-specific pavement management processes based on mission requirements, but in all cases when used for pavement management, the SI is interpreted as outlined in Table 4-6.

Table 4-6 Structural Index (SI) Ratios

Structural Index (SI)	Description
SI ≤ 1.1	The pavement structure for the section is adequate to support the mission traffic for the defined design life.
1.1 < SI ≤ 1.4	The pavement structure for the section will not support the mission traffic for the defined design life. Aircraft loads or the number of passes may be limited to extend the life of the pavement.
SI > 1.4	The pavement structure for the section will not support the mission traffic for the defined design life. Aircraft traffic must be closely monitored. Overlay or reconstruction must be performed if the pavement is required to support mission traffic for the defined design life.

4-3.9.4 Structural Index (SI) versus Critical PCI.

An SI ≥ 1.1 indicates that the section is structurally inadequate to support the mission traffic for the defined load and passes, but this fact alone will not typically drive overlay or reconstruction unless the pavement capability must be increased due to a mission change. If the pavement is above the critical PCI, continue preventive maintenance (PM), and when the pavement drops below critical, incorporate an increase in structural capability in your repair solution.

4-4 SURFACE FRICTION CHARACTRISTICS EVALUATIONS.

Surface friction characteristics evaluations are typically performed on runways but may be performed on taxiways in certain circumstances. They are used to determine the hydroplaning potential of a surface under standardized wet conditions. They are carried out on multiple sections, but the results for each section can be extrapolated.

The procedure includes friction tests using continuous friction measuring equipment (CFME), slope measurements, and texture measurements. Procedures and equipment generally correspond to those outlined in FAA Advisory Circular (AC) 150/5320-12C, *Measurement, Construction, and Maintenance of Skid Resistant Airport Pavement Surfaces*.

4-4.1 Mu (Friction) Values.

Mu (μ) numbers (friction values) measured by CFME operated at 40 and 60 mph (65 and 95 km/h) test speeds are used as guidelines for evaluating the surface friction deterioration of runway pavements, prioritizing M&R requirements when developing a PMP, and for identifying the appropriate corrective actions necessary for safe aircraft operations.

4-4.2 Friction Level Classification.

The friction value use varies in Service-specific pavement management processes based on mission requirements, but in all cases the friction level classification will correspond to the friction values defined in FAA AC 150/5320-12C, *Measurement, Construction, and Maintenance of Skid Resistant Airport Pavement Surfaces*. When used for pavement management, interpret the friction classification level as outlined in Table 4-7. According to these guidelines, poor friction conditions for short distances on the runway do not pose a safety problem to aircraft, but long stretches of “slippery” pavement are a serious concern and require prompt remedial action.

Table 4-7 Friction Level Classification

Friction Level Classification	Description
Minimum	When the averaged Mu value on the wet pavement surface is below the minimum friction level for a distance of 500 feet (152 m), and the adjacent 500-foot (152 m) segments are below the maintenance planning friction level, take corrective action immediately after determining the cause(s) of the friction deterioration.
Maintenance Planning	When the averaged Mu value on the wet pavement surface is less than the maintenance planning friction level for a distance of 1000 feet (305 m) or more, determine the cause(s) and extent of the friction deterioration and take appropriate corrective action.
New Construction	The averaged Mu value on the wet pavement surface for each 500-foot (152 m) segment is no less than the new design/construction friction level shown in the FAA AC 150/5320-12C friction level classification for runway pavement surfaces.

4-5 VOID DETECTION SURVEYS.

Void detection surveys determine the existence and extent of voids under pavements as well as their effect on the load-bearing capability of the pavement. They are typically conducted on a portion of a section or sections where there are indications of issues such as localized cracking or in areas with a greater potential for voids, such as near drainage structures or in areas where karst formations are present.

4-5.1 Void Detection Tools.

These surveys use some or all of the following tools: ground penetrating radar (GPR), falling/heavy weight deflectometer (FWD/HWD), coring, and dynamic cone penetrometer (DCP) testing. UFC 3-260-03 outlines void detection testing procedures.

While GPR can locate potential voids, the HWD is the primary tool for identifying weak areas. Coring and DCP testing are used to verify the existence of a void or weak subgrade area.

4-5.2 Impulse Stiffness Modulus (ISM).

HWD testing produces a value termed the impulse stiffness modulus (ISM) to assess the relative pavement strength at a test location. Determine ISMs by dividing the load by the deflection at the respective deflection sensor (typically D1 through D7). Manually compute or use the PCASE FWD module to determine ISMs for sensors D1 through D7.

The deflection at sensor D1 reflects the state of the pavement, whereas D7 reflects the state of the subgrade. Using D1 alone is not sufficient to successfully detect voids under the pavement. Analyze the data by plotting the ISMs for sensors one through seven. If required, normalize the data by dividing each plot by the highest value in the plot to determine relative effects of pavement weaknesses on each sensor.

4-5.3 ISM Interpretation.

Once the data are plotted, use the following rules to determine potentially weak areas:

- An ISM value below 1000 kips per inch on a concrete pavement is of concern
- An ISM value below 300 kips per inch on an asphalt pavement is of concern
- Relative ISM decay indicates an unexpected weakness
- Weakness in ISM1 indicates it is shallow (less than 3 feet [0.9 m])
- Weakness in ISM7 indicates it is deep (3 to 20 feet [0.9 to 6 m])
- Weakness in both ISM1 and ISM7 indicates a general lack of support

4-5.4 Void Verification.

The DCP is the primary tool used to verify the existence of near-surface voids and determine the void’s depth and extent. UFC 3-260-03 and TM 3-34.48-2, *Theater of Operations: Roads, Airfields, and Heliports – Airfield and Heliport Design*, describe the DCP and how to use it. The DCP is designed to reach a depth of 4 feet (1.2 m), but extensions can increase testing depth for voids.

Plot DCP results as CBR versus depth at each test location. The CBR indicates the strength of the underlying soil. Soil with CBR values below 8 are marginal and CBR values below 4 are of concern. CBR values approaching 1 indicate no strength, very loose soil, or an actual void (sinkhole). Since the main concern is the effect on load-carrying capacity, no distinction is made between very loose soil and actual voids if their effect on load-carrying capacity is equal.

4-5.5 Void Risk Categories.

Table 4-8 Risk Categories

Risk	Description
Low	No weakness or voids detected. No action required.
Moderate	Test results did not definitively determine the presence of a weak area or void. Take action to conduct additional testing, perform maintenance or repair, or monitor section for changes, depending on the situation. **Additional Testing:** When GPR scan encounters suspect areas deeper than DCP testing can reach or DCP results indicate soft pockets of soils, perform a video scan of drainage structures. If GPR test results are inconclusive and standing water was noted in structures, indicating a loss of drainage, conduct a drainage study to identify drainage paths and determine if drainage structure connections and sizes are adequate. **Perform Maintenance:** Testing did not indicate a structural weakness, but there are medium- or high-severity pavement distresses or nearby drainage structures need maintenance or repair. Perform pavement maintenance, repair broken structures, or clean inlets and outfalls as required **Monitor Area:** Testing did not indicate a structural weakness and the pavement has only low-severity distresses. Monitor the area for changes such as depressions, cracking, or ponding.
High	Void detected with GPR and verified with the HWD and/or DCP. Take immediate action for full-depth repair of pavement and drainage structure, if applicable.

4-6 ROUGHNESS SURVEYS.

The highway industry defines pavement roughness in terms of the ride quality experienced by a passenger. Automotive manufacturers design suspension systems to reduce the impact of common surface irregularities and improve overall ride quality. In contrast, the primary purpose of an aircraft suspension system is to absorb energy expended during landing. Aircraft suspension systems have less capacity to dampen the impact of surface irregularities compared to the magnitude of the energy that must be addressed during landing. Airfield pavement roughness is defined in terms of fatigue on aircraft components (increased stress and wear) and/or other factors that impair the safe operation of the aircraft (e.g., cockpit vibrations, excessive g-forces).

4-6.1 Airfield Roughness Survey.

A runway roughness evaluation examines the elevation profile of the runway surface and evaluates aircraft response to this profile. Newly constructed runway pavements are evaluated to help ensure longitudinal slopes meet established design criteria. Longitudinal and transverse slope criteria for airfields are defined in UFC 3-260-01, *Airfield and Heliport Planning and Design*. As a pavement ages, the longitudinal surface profile may vary from the original design standards due to factors such as frost heave or subgrade settlement and cause excessive roughness. When roughness evaluations are performed on multiple sections, the results for each section can be extrapolated.

The Services do not routinely conduct this type of evaluation, but, when performed, use the guidance in FAA AC 150/5380-9, *Guidelines and Procedures for Measuring Airfield Pavement Roughness*. Installations requiring a runway roughness evaluation can contact their Service POCs for assistance (see paragraph 2-9.3).

4-6.1.1 Single Event Bump.

Single event bumps are isolated events where changes in pavement elevation occur over a relatively short distance of 100 meters (328 feet) or less. Such elevation changes may occur as an abrupt vertical lip or as a more gradual deviation from a planned pavement profile. A basic “virtual straightedge” analysis as outlined in FAA AC 150/5380-9 can identify single event bumps. Riding the pavement in a passenger vehicle might reveal shorter length bumps but finding longer length bumps may require a thorough analysis of the pavement profile.

4-6.1.2 Profile Roughness.

Profile roughness is the surface profile deviations present over a portion of the runway that cause airplanes to respond in ways that can increase fatigue on airplane components, reduce braking action, or impair cockpit operations. Response depends on airplane size, weight, and operation speed. Roughness may affect the fatigue life of airplane components or decrease operational safety of the airplane. Depending upon airplane characteristics and operating speed, an airplane may be excited into harmonic resonance due to profile roughness, which can increase inertial forces or vibrations within the airplane structure.

4-6.1.3 Boeing Bump Index (BBI).

While not routinely conducted by DoD, FAA AC 150/5380-9 calls for using the “Boeing Bump” procedure and uses the results of this procedure to develop the BBI. The BBI procedure defines three evaluation zones—acceptable, excessive, and unacceptable—that are defined based on a relationship between the BBI and the bump length. BBI values below 1.0 are in the acceptable zone. Values of BBI greater than 1.0 fall in either the excessive or unacceptable zones. The BBI may be used in Service-specific pavement management guidance. When used, the guidance in Table 4-9 defines required maintenance action.

Table 4-9 Boeing Bump Index (BBI) Roughness Levels

Roughness Levels	Description
Acceptable	Newly constructed or rehabilitated pavement to result in bump height and length combinations that fall within the lower region of the acceptable range. No repair is required on existing pavement.
Excessive	Immediate pavement repairs are necessary at this level, but closure of the affected pavement is not required.
Unacceptable	Roughness levels in the unacceptable zone warrant immediate closure of the affected pavement. Repairs are necessary to restore the pavement to an acceptable level.

4-6.2 Roughness Criteria for Aircraft Arresting Systems.

The 200 feet (60 m) of pavement on both the approach and departure sides of an arresting system pendant is a critical area. Protruding objects and undulating surfaces are detrimental to successful tail hook engagements and are prohibited. The roughness criteria for aircraft arresting systems are defined in UFC 3-260-01. Determine conformance with these requirements using differential leveling that may be performed by installation personnel or contractors.

4-6.3 Road Roughness Surveys.

UFC 3-201-01, *Civil Engineering*, calls for roads to be designed in accordance with SDDCTEA Pamphlet 55-17, AASHTO *A Policy on Geometric Design of Highways and Streets* (also known as The Green Book), AASHTO *Roadside Design Guide*, and AASHTO *Guidelines for Geometric Design of Low-Volume Roads*, as applicable. Just as with airfields, as a pavement ages, the longitudinal surface profile may vary from the original design standards due to factors such as frost heave or subgrade settlement and cause excessive roughness. Roughness evaluations are typically carried out on multiple sections, but the results for each section can be extrapolated. DoD does not currently make extensive use of roughness surveys because the “automated” surveys used to determine the International Roughness Index (IRI) (see paragraph 4-6.4) may not be cost-effective for military installations and the vehicle operating speeds on military installations as well as issues with items like utility appurtenances (manholes) raise questions about the viability of the IRI results. Information on roughness and the IRI is presented in this UFC for use when the IRI data is available.

4-6.4 International Roughness Index (IRI).

The IRI is the standard for expressing pavement smoothness on roads. It can be computed using profile measurements obtained from devices such as the inertial profiler, Dipstick®, and rod and level. There are documents that provide standardized methods to compute the IRI, including AASHTO R 43M/R 43-07, *Standard Practice for Quantifying Roughness of Pavements*, and ASTM E1926, *Standard Practice for*

Computing International Roughness Index of Roads from Longitudinal Profile Measurements.

The IRI is computed from a longitudinal profile measurement using a quarter-car simulation at a speed of 50 mph (80 km/h). The IRI is reported in either inches per mile (in./mile) or meters per kilometer (m/km; **note:** 1 m/km = 63.36 in./mile). The IRI scale starts at zero for a road with no roughness and covers positive numbers that increase in proportion to roughness. Table 4-10 provides typical IRI values with verbal descriptors of required maintenance actions when the IRI is used in Service-specific pavement management guidance.

Table 4-10 IRI Ranges and Maintenance Actions

IRI Range (in./mile)	Description
$0 < IRI \leq 380$	No repairs are required based solely on IRI.
$380 < IRI \leq 500$	Pavement repairs are necessary at this level, but reduction of traffic speed or closure of the affected pavement is not required.
$IRI > 500$	Immediate pavement repairs are necessary to restore the pavement to an acceptable level. Consider reduction of traffic speed or closure of the affected pavement if pavement repairs cannot be performed.

This Page Intentionally Left Blank

CHAPTER 5 DETERIORATION MODELS AND PERFORMANCE ANALYSIS

5-1 INTRODUCTION.

Pavement deterioration models are known as PCI family models. PCI family models are generated using the **PCI Deterioration Families** tool in PAVER as part of regularly scheduled airfield or road and parking PCI surveys. These deterioration models are based on past pavement performance and are used to predict future pavement condition to determine repair requirements based on that condition. Installation personnel may review or update PCI family models to determine where a pavement section is in its life cycle, determine effectiveness of maintenance actions, or determine deterioration rates for a specific subset of the pavement network.

5-2 PCI FAMILY MODEL PARAMETERS.

The DoD typically uses the pavement type and section rank as the primary parameters to define PCI Family Models for both airfield and road and parking pavement. When the Coefficient of Correlation is low and the standard deviation of error is high for a model, refine the model by creating separate models for different pavement types, e.g., AC and AAC, creating models for each Branch Use, or using other parameters such as whether the pavement has had localized preventive or global M&R performed, to create families with reasonable accuracy.

5-2.1 Pavement Surface Type.

The most important parameter for a deterioration model is the surface type, given that the deterioration rate of asphalt will typically be higher (average 2 to 3 points per year) than concrete (average 0.5 to 1.5 points per year).

5-2.2 Pavement Rank.

The pavement rank is the recommended standard for the second parameter. Group primary asphalt pavements, primary concrete pavements, etc. Secondary and tertiary pavement may be grouped together if model statistics are acceptable. Otherwise, create separate models for secondary and tertiary asphalt and concrete pavements as required.

5-2.3 Branch Use.

If model statistics do not meet the requirements outlined below, refine the models further to include the branch use. For example, when modeling statistics indicate the deterioration rate of the runway varies significantly from other primary pavements.

5-3 PCI FAMILY MODEL NAMING STANDARD.

Naming standards ensue the user can distinguish between models for a specific installation and are critical when distinguishing between family models in a rollup database. The standard is to use the convention **Site NameYr_Pavement Type_Rank** as the PCI family model name. For example, the deterioration model for Tyndall AFB primary PCC pavements last inspected in 2018 is **Tyndall18_PCC_P**.

If the branch use is used to create a family model for a specific reason as described above, name the model **Site NameYr_Pavement Type_Rank_Branch Use**; for Example, **Tyndall18_PCC_P_Road**. If the model must be created for specific branches rather than rank to achieve the required model statistics, replace the rank with the branch use; for example, **Tyndall18_PCC_Apron**.

5-4 PCI FAMILY MODEL PROCESS STANDARDS.

The PCI family model defines the deterioration rate of a pavement by plotting the condition of sections with similar characteristics against the age of the pavement in those sections. A minimum of five data points is required to define a deterioration model. This can be five inspections over time for one section, one inspection for five sections with similar surface types, or some other variation to get five points.

The PAVER user manual provides a description of the process of creating and assigning PCI family models. Following are supplemental instructions and standards for creating PCI family models for pavements on DoD installations.

5-4.1 Family Modeling - Review Model Data.

a. The **Review Model Data** tab (Figure 5-1) in the PAVER **PCI Deterioration Families** tool allows the user to create, copy, rename, or delete family models as well as review model data and add or delete specific data points.

Figure 5-1 Review Model Data Tab

b. When creating family models, PAVER gives the option of excluding inspection data based on backcalculated construction dates. Standard practice is to select **No** for this option unless there is evidence that using these points negatively affects the model, for example, when most of the points plot on a single line. In this case, rerun the model without the points with backcalculated construction dates.

c. As shown in Figure 5-1, data outliers are indicated by red triangles in the family model graph and identified in the status column of the table at the bottom of the form. Investigate outliers to determine if the age or PCI are accurate and correct any issues. If the age and PCI are correct, investigate the outliers from the current PCI inspection that are below the outlier boundary to determine the cause of the high rate of deterioration. Evaluation teams and consultants will document these issues in the report. These data may also be useful to determine when to refine the family model and when developing the PMP.

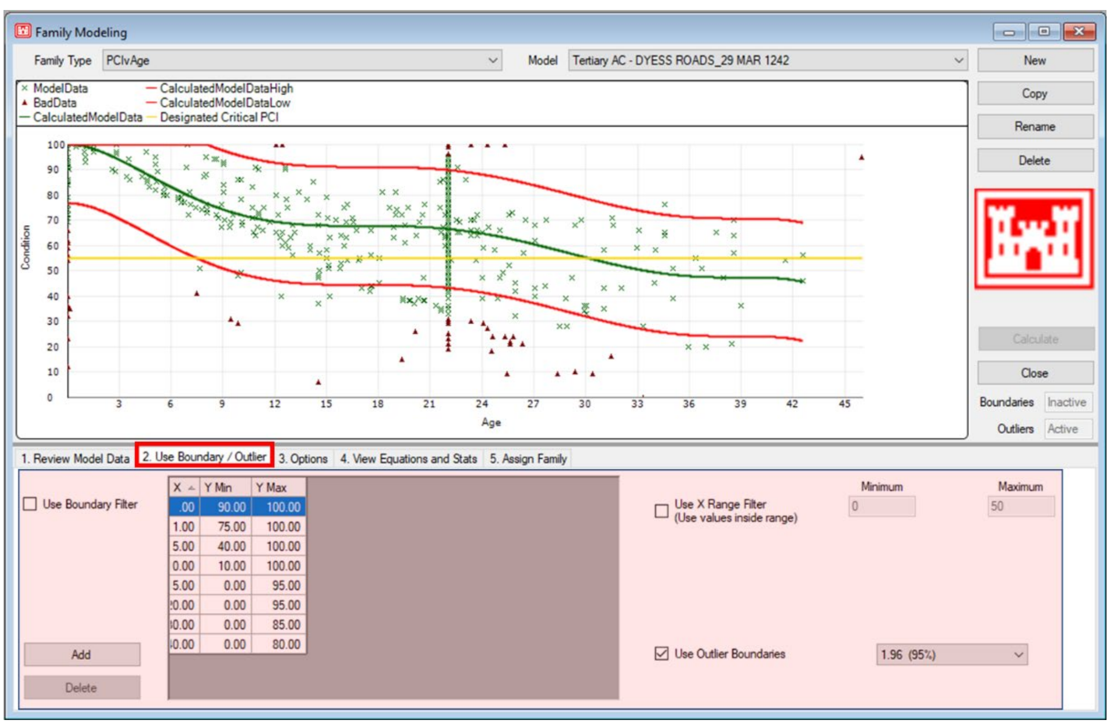
d. Review the data for the model when data points are “stacked,” as shown in Figure 5-1. A column of data points is a good indication that the age of the pavement (last construction date) is incorrect. Correct the issue by updating work using installation records or by backcalculating the last construction dates.

5-4.2 Family Modeling - Use Boundary / Outlier.

PAVER offers several options for filtering data used in deterioration models. As shown in Figure 5-2, the standard practice is to use the outlier boundary filter set at 1.96 (95 percent) confidence level. Only use the other filter options if there is a specific issue with the model that cannot be resolved by modifying the family parameters; for example, using a different model for AAC and AC surface types or separating secondary and tertiary pavement models.

The **Use Boundary Filter** option sets minimum and maximum PCI values for specified pavement ages. Any data points outside these values are filtered. Only use this option if there is a clear issue with the data model that filtering can resolve. The **Use X Range Filter** option defines the age range used for the model and filters any data points outside these values. Only use this option for DoD PCI Family Models when there is a clear issue with the data model that filtering can resolve, for example, when a deterioration model does not indicate any deterioration as it gets beyond 50 years. This can occur when the pavement in the model was designed in the 1950s or early 1960s for a much heavier load than it was subsequently used for and is therefore not seeing any deterioration, especially in a moderate climate.

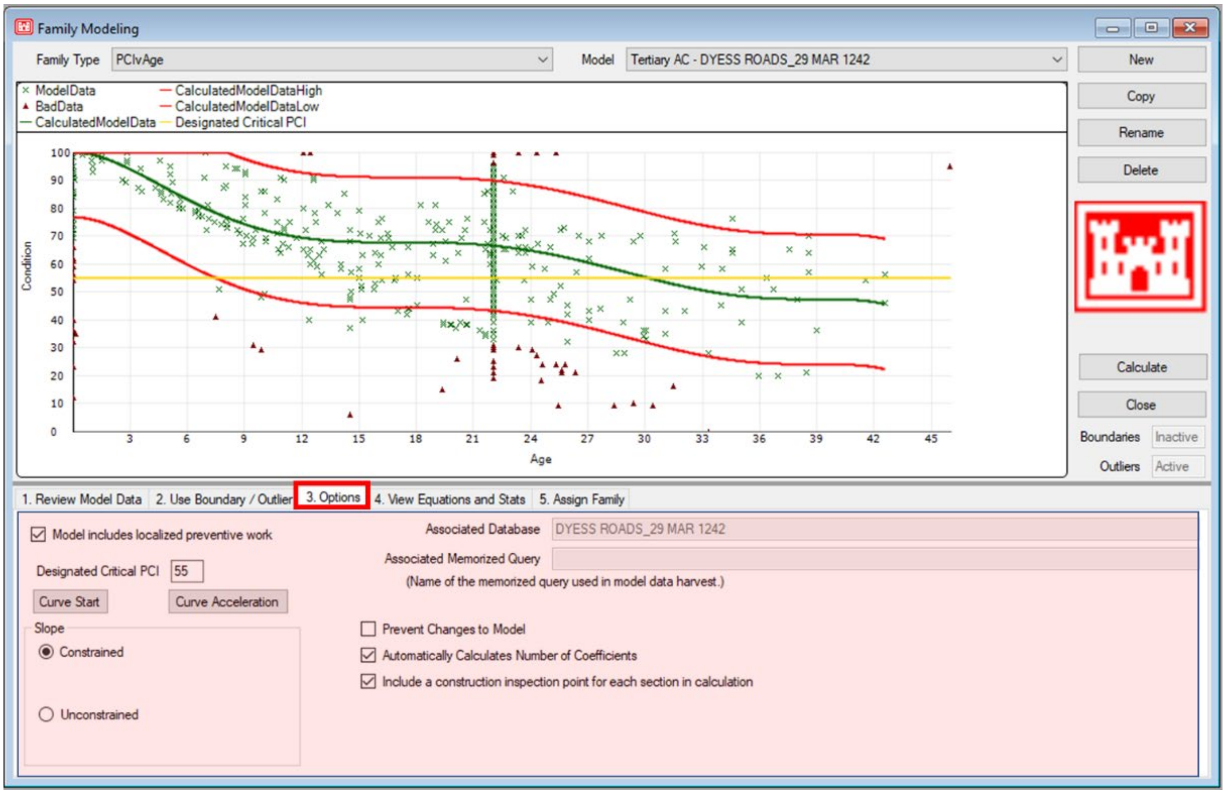
Figure 5-2 Use Boundary / Outlier Tab



5-4.3 Family Modeling - Options.

The **Options** tab is also called the Option card in the PAVER user manual. It plays a significant role in defining the deterioration model and has implications for work planning. Figure 5-3 shows the **Options** tab. Following are the key fields for this tab.

Figure 5-3 Options Tab



5-4.3.2 Model Includes Localized Preventive Work.

Unless there is specific information to the contrary, always check this box to indicate that PM is performed to indicate the deterioration model is based on this assumption. If PM is stopped, the rate of deterioration increases. Conversely, if PM was not previously performed and was subsequently started, the rate of deterioration decreases.

5-4.3.3 Critical Condition.

Theoretically, the critical condition is the point at which PM is no longer cost-effective and major M&R is triggered. The critical condition for all Services is currently set by policy at 70 for primary pavements. Service policies for critical condition on secondary and tertiary pavements range from 55 to 65, based on mission requirements.

5-4.3.4 Critical Condition Computation Tools.

The Services currently use the policy conditions outlined in paragraph 5-4.3.3 but PAVER has features to identify inflection points for consideration as a critical PCI. The

Curve Start and **Curve Acceleration** tools shown in Figure 5-3 can be used to validate the policy PCI or aid in prioritizing requirements for the PMP. They are only valid for fourth degree polynomials (4 coefficients) or higher. **Note:** A high degree model may have two inflection points.

5-4.3.5 Slope.

The constrained slope option will not allow the model to curve upward. The unconstrained option allows the model to curve upward as the pavement ages. Standard policy is to constrain the slope.

5-4.3.6 Automatically Calculates Number of Coefficients.

Once the points are plotted, the user can allow PAVER to determine a best-fit curve for the data that defines the changing rate of deterioration over time or the user can define the degree of the polynomial used to describe the deterioration. The user-defined option is typically used when the user wants to define a linear model (set the number of coefficients to two).

The linear model is useful when trying to define a simple rate of deterioration, but it does not take advantage of PAVER's ability to define the changing rate of deterioration over time. An example of both the linear and best fit models are shown in Figures 5-4 and 5-5 for the **View Equations and Stats** tab. The recommended practice is to run the linear model to calculate a rate of deterioration that can be incorporated into the report but assign the best fit model determined by PAVER to sections for M&R work planning.

5-4.3.7 Prevent Changes to Model.

Standard policy is to leave **Prevent Changes to Model** unchecked (allows changes to the model).

5-4.3.8 Include a Construction Inspection Point for Each Section in Calculation.

This option allows the user to include a data point for PCI = 100 at age 0 for each pavement section in the model that reflects the condition at construction. When not selected, you can experience issues with the standard deviation, especially when pavement construction dates are grouped within a specific range rather than having a good age spread. Including a construction inspection point resolves these issues. The standard policy is to leave this checked.

5-4.4 Family Modeling - View Equations and Stats.

The **View Equations and Stats** tab shown in Figure 5-4 is also called the View Equations and Stats card in the PAVER user manual. It displays the intercept and coefficient values for the equation that best fits the data. It also lists various "goodness-of-fit" statistics for the model.

The minimum acceptable value for the coefficient of correlation is 0.70 and the maximum acceptable value for the standard deviation of error is 15.00. If statistics for a model are outside of these thresholds, review the model, determine potential causes, and revise the model. For example, the deterioration rate of milled and overlaid (AAC) pavements is typically higher than asphalt (AC) pavement. Creating separate models can resolve goodness-of-fit issues. **Note:** Five data points are required to create a model.

Figure 5-4 View Equations and Stats – Best Fit Model

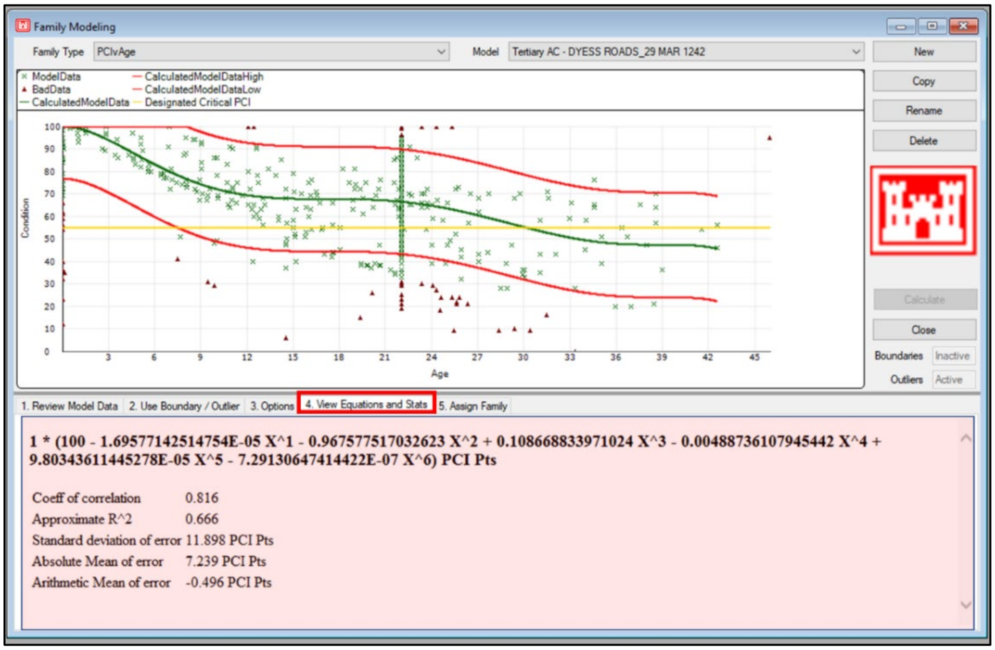


Figure 5-5 View Equations and Stats – Linear Model

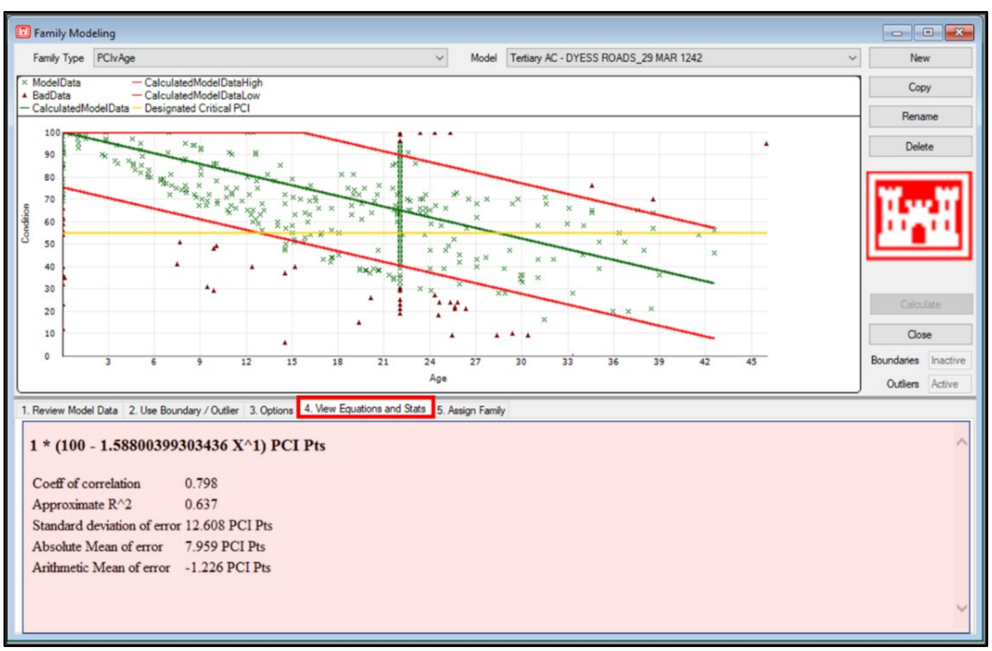
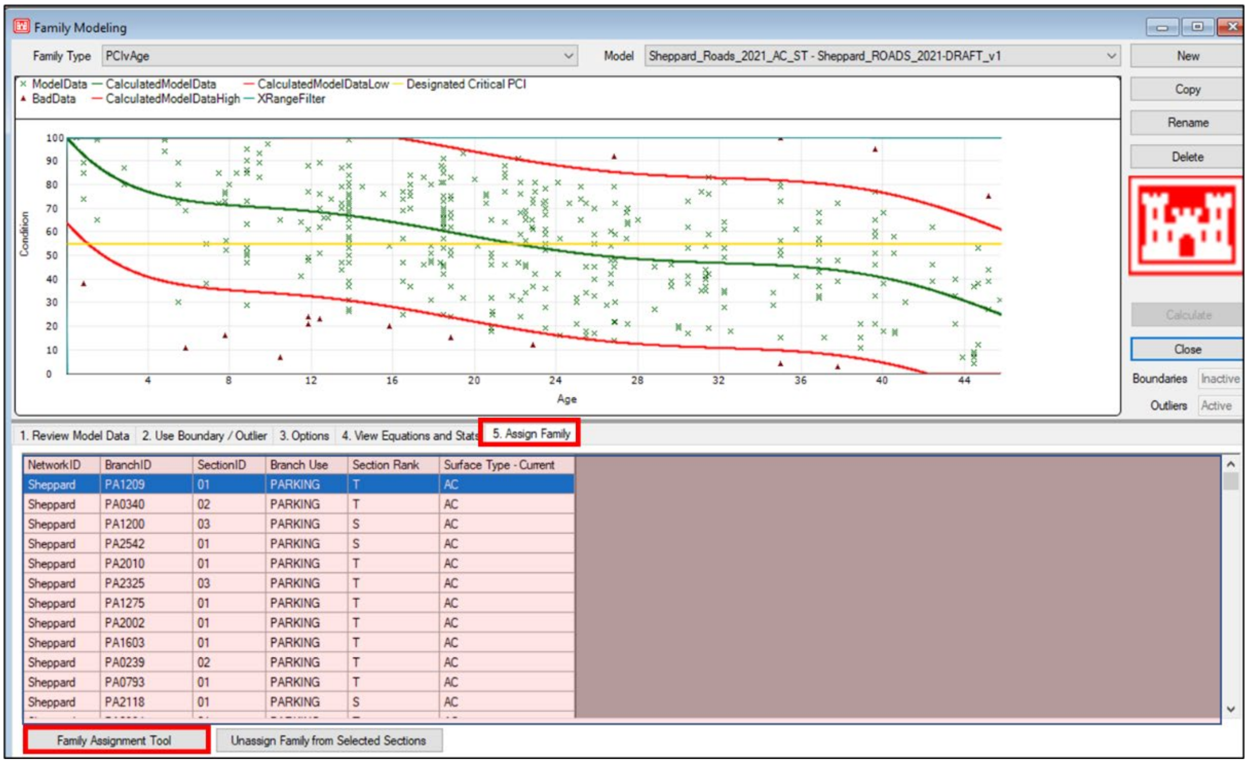


5-4.5 Family Modeling - Assign Family.

After defining the PCI deterioration family model curves, go to Tab 5 and select the **Family Assignment Tool**. Select the **Show Subset** button to open the query tool and filter the data to the appropriate sections for the model, then assign the model to the sections.

Figure 5-6 Assign Family Model



5-4.5.1 Active Paved Section Model Assignment.

It is important to ensure that all active (section rank P, S, or T) paved sections are inspected and assigned to the appropriate family model. When doing work planning, PAVER uses the assigned family to determine future condition and bases M&R requirements on that condition.

5-4.5.2 Active Unpaved Section Model Assignment.

All unpaved (gravel) pavement sections are included in the inventory for use in reporting but are not typically inspected. Since there is no inspection, there is no data to determine a deterioration model, so, whether active or unused, these sections are assigned to a family model and are excluded from M&R work planning.

5-4.5.3 Unused Paved Section Model Assignment.

All unused pavement sections are included in the inventory for use in reporting but are not typically inspected, so unused (section rank of U) pavements are not assigned to a family model and not included in M&R work plans. Note that if there is a need to develop an M&R plan for currently unused pavement, a PCI family model based on data from other, similar sections can be assigned.

5-4.5.4 Unprivatized Housing Section Model Assignment.

Pavements in housing areas are included in the inventory for reporting purposes. Approaches between the Services vary on whether these pavements are inspected or not when the housing area is not privatized. If they are inspected, assign a family model. If they are not inspected, do not assign a model.

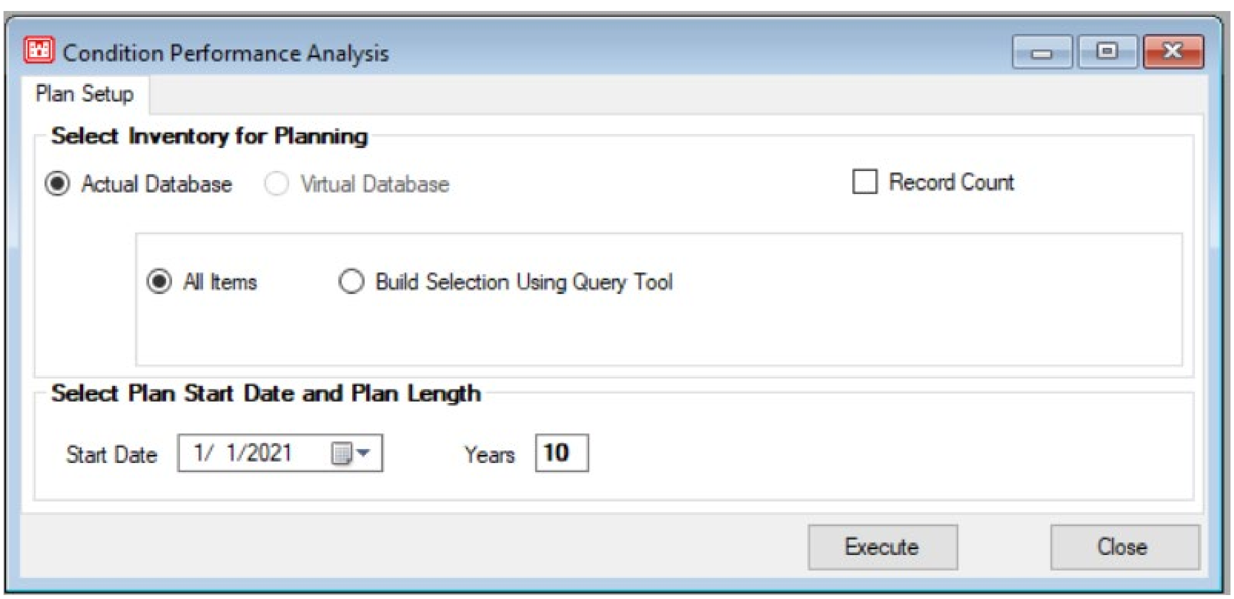
5-4.5.5 Privatized Housing Section Model Assignment.

Pavements in housing areas are included in the inventory for reporting purposes. Pavements may or may not be included in privatization agreements. If included in the privatization agreement, the pavement is typically not inspected and not included in M&R work plans, so do not assign a model for these sections. If not included in the privatization agreement and they are inspected, assign a family model and include them in the M&R work plans.

5-5 CONDITION PERFORMANCE ANALYSIS.

The **Condition Performance Analysis** feature in PAVER (Figure 5-7) uses the deterioration models assigned to each section to predict the future condition of the pavement networks in a database or any subset of the networks. The deterioration models are based on prior inspection data, so PAVER uses past performance to predict future condition. The user defines the pavements included in the analysis, the start date, and the duration of time for the analysis. PAVER produces summary, detail, and map views of the analysis results. The PAVER user guide describes each of these views.

Figure 5-7 Condition Performance Analysis



This Page Intentionally Left Blank

CHAPTER 6 MAINTENANCE AND REPAIR (M&R) FAMILY MODELS

6-1 INTRODUCTION.

M&R family models are created for each M&R category. These M&R family models define work plan parameters. Just as with PCI family models, PAVER uses a two-step process: Create the M&R family model and assign the model to the appropriate sections.

6-2 MAINTENANCE AND REPAIR (M&R) CATEGORIES.

Each M&R category has a different focus for the type, scope, and timing of work. M&R categories include localized operational (aka safety or stopgap), localized preventive, global, and major M&R.

6-2.1 Localized Operational M&R.

Localized Operational (aka Safety or Stopgap) M&R is performed when a pavement is below the critical PCI to maintain the safety of operations by repairing individual distresses such as spalls, linear cracking, or alligator cracking at specific locations. Since the focus is on safety of operations, the maintenance and repair policy for operational M&R focuses on medium- and high-severity distresses that pose a risk to operations. Examples include repairing a large pothole at the main entrance to an installation or repairing high-severity spalling at the end of a runway to mitigate FOD risk.

6-2.2 Localized Preventive M&R.

Localized Preventive M&R is performed when a pavement is above the critical PCI. It includes maintenance actions performed on individual distresses intended to slow the rate of pavement deterioration and extend the life of the pavement. Localized preventive M&R may include repairs on low-, medium-, or high-severity distresses. An example is repairing medium- or high-severity longitudinal and transverse cracking on a parking area or apron. This action extends the life of the pavement by preventing water from migrating through cracks and damaging the base or causing other issues such as pumping.

6-2.3 Global Preventive M&R.

Global preventive M&R retards or slows pavement deterioration but is generally applied across entire sections or branches rather than localized areas. There are two primary approaches to global M&R: condition-based and age-based. In the condition-based approach, global M&R is planned within a specified condition range. The age-based approach sets a minimum age before starting global M&R. In either case, the basic principle is that global M&R is most effective early in pavement life when climate-related distresses have not progressed. There are instances where global M&R is used later in the pavement life to address low- or medium-severity distresses. Global M&R is commonly performed on a recurring schedule without regard to the distresses present. Surface treatments on asphalt pavements are the primary example of global M&R.

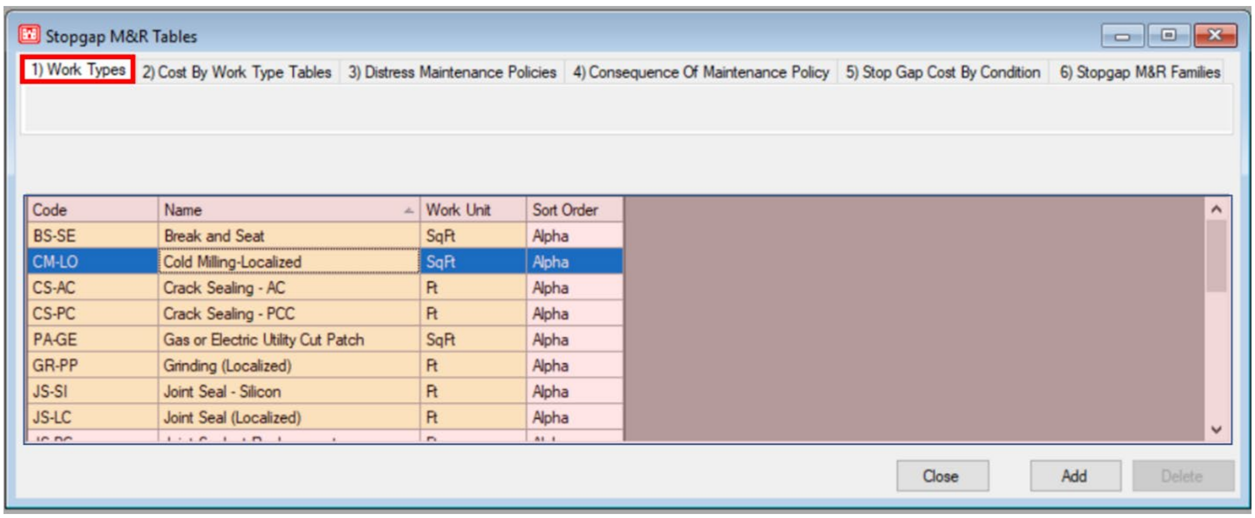
6-2.4 Major M&R.

Major M&R is defined as activities applied to an entire pavement section to correct or improve existing structural or functional issues. Functional issues include deteriorated pavement surfaces that pose a risk to aircraft or ground vehicles. Major M&R includes mill and overlay, structural overlay, or reconstruction of asphalt pavements and slab replacement or reconstruction for PCC pavement. The distinguishing feature is that any of these treatments bring the PCI value back to 100.

6-3 LOCALIZED M&R TABLES.

Localized preventive and operational (aka safety or stopgap) M&R tables define the preventive and operational work planning parameters. As shown in Figure 6-1, M&R tables include work types, cost by work type tables, distress maintenance policies, consequence of maintenance policy, and cost by condition. Standards for these tables are outlined below and in the appendices. M&R families are defined on **6) Stopgap M&R Families** using input from tabs 1 through 5. The example below is for stopgap, but preventive M&R tables are similar.

Figure 6-1 Localized M&R Tables



6-3.1 Localized M&R Work Types.

The **Work Types** table (tab 1) in Figure 6-1 lists the standard PAVER work types shown in Table 6-1. These work types are applicable to both localized preventive and operational M&R. While users can create user-defined work types in PAVER, they are not permitted in DoD PAVER databases. When doing work planning for a new inspection, user-defined work types in an existing database are changed to standard work types and the user-defined work types are deleted from the database. If a Service requires a work type that is not in the localized M&R table, submit the requirement to the Tri-Service Pavement Working Group for inclusion in PAVER.

The work types in Table 6-1 are used in the **Cost by Work Type Tables** (tab 2) and **Distress Maintenance Policies** (tab 3) tables in Figure 6-1. The same PAVER work types are used for both airfield and road and parking M&R, but the maintenance policies differ. Details for the work elements for most work types are outlined in UFC 3-270-01, *O&M Manual: Asphalt and Concrete Pavement Maintenance and Repair*, and in UFC 3-250-08FA, *Standard Practice for Sealing Joints and Cracks in Rigid and Flexible Pavements*.

Table 6-1 Localized M&R Work Types

Code	Name	Work Unit	Description
BS-SE	Break and Seat	SqFt	Crack or break and seat are fractured slab technologies used to minimize the occurrence and severity of reflection cracks. They involve breaking the concrete pavement and seating the broken slabs using a pneumatic roller to reestablish support between the base and the slabs prior to overlaying. Crack and seat is performed on plain, jointed concrete. Break and seat is used on reinforced PCC and breaks the slabs into smaller pieces. Both fractured slab technologies are typically performed on entire sections and rarely used for localized repair.
CM-LO	Cold Milling-Localized	SqFt	Pavement milling (cold planing, asphalt milling, or profiling) is the process of removing at least part of the surface of a paved area using milling machines or cold planers. When used for localized repair, milling removes just enough thickness to level and smooth the surface but may also be used to remove the full depth of the pavement. See UFC 3-270-01, Chapter 13.
CS-AC	Crack Sealing - AC	Ft	Remove old sealant (if any), saw/route cracks, clean crack reservoir, install backer rod to control depth of sealant, and seal using an approved hot-applied sealant. Note that the procedure will vary depending on the width of the crack. See UFC 3-270-01, Chapter 9.
CS-PC	Crack Sealing - PCC	Ft	Remove old sealant (if any), saw/route cracks, clean crack reservoir, install backer rod to control depth of sealant, and seal using an approved hot- or cold-applied sealant. Note that the procedure will vary depending on the width of the crack. See UFC 3-270-01, Chapter 12.
ED-RF	Retrofitted Edge Drain	Ft	Retrofitting edge drains is typically done for an entire section but may be done for localized areas. It involves removing existing edge drains, trenching, and placing the new edge drain system. A good candidate for retrofitted edge drainage is a pavement showing early signs of moisture-related damage. Additionally, pavements with acceptable surface geometrics (longitudinal grades and transverse cross-slopes) and adequate depth and condition of roadside ditches are good candidates for retrofitted edge drainage. See UFC 3-270-01, Chapter 19.
GR-AC	Grinding - AC (Localized)	Ft	Diamond grinding, using closely spaced diamond saw blades mounted on a rotating shaft, removes a thin layer of the asphalt surface to correct for heaving at PCC interface locations and correct surface defects, such as wheel path rutting. The diamond-grinding process results in less impact than milling. See UFC 3-270-01, Chapter 11.

Code	Name	Work Unit	Description
GR-PC	Grinding – PCC (Localized)	Ft	Diamond grinding, using closely spaced diamond saw blades mounted on a rotating shaft, removes a thin layer of the concrete surface to correct for faulting at joints and crack locations. The diamond-grinding process results in less impact than milling. See UFC 3-270-01, Chapter 17.
HR-PD	Partial Depth Heat Resistant PCC Repair	SqFt	A partial-depth heat-resistant PCC repair applies to pavement in vertical landing zones subject to deterioration from heat by aircraft with vectored thrust such as the V-22, F-35B, and AV-8 aircraft. There are restrictions on where a partial-depth repair is allowed. It involves sawing and removing concrete to a minimum depth of 3 inches or to sound concrete, but not more than 1/3 the thickness of the pavement, then cleaning the repair area, placing new heat-resistant concrete, and re-sealing the surface with sodium silicate. Note that maintaining the joint is critical on any repair adjacent to a joint. See UFC 3-270-01, Chapter 20.
HR-FD	Full Depth Heat Resistant PCC Repair	SqFt	A full-depth heat-resistant PCC repair applies to pavement in vertical landing zones subject to deterioration from heat by aircraft with vectored thrust such as the V-22, F-35B, and AV-8 aircraft. There are instances when a full-depth repair is required. It involves sawing and removing the full depth of the concrete, repairing and recompacting the base or subgrade below the slab, placing dowels and tie-bars, then placing new heat-resistant concrete and re-sealing the surface with sodium silicate. Note that maintaining the joint is critical on any repair adjacent to a joint. See UFC 3-270-01, Chapter 20.
HR-CR	Partial Depth Continuously Reinforced Heat Resistant PCC Repair	SqFt	A partial-depth continuously reinforced heat-resistant PCC repair applies to pavement in vertical landing zones subject to deterioration from heat by aircraft with vectored thrust such as the V-22, F-35B, and AV-8 aircraft. There are restrictions on where a partial-depth repair is allowed. It involves sawing and removing concrete and reinforcement then replacing the reinforcement and tie bars, placing new heat-resistant concrete, and re-sealing the surface with sodium silicate. Note that maintaining the joint is critical on any repair adjacent to a joint. See UFC 3-270-01, Chapter 20.
JS-LC	Joint Seal (Localized)	Ft	Joint seal replacement is typically done on entire sections but may be done for localized areas. The procedure varies depending on type of seal: hot pour, silicone, or preformed compression seals, but in general involves removing the old sealant, cleaning the reservoir, and placing new joint seal. See UFC 3-270-01, Chapter 12.
LT-PC	Load Transfer Restoration – PCC (Localized)	Ft	Load transfer restoration is typically done for an entire section but may be done for localized areas. It involves saw-cutting and chipping concrete to create slots at the joints, placing load transfer devices, typically dowel bars, into the slots and properly aligning the bars, placing repair material into the slots, restoring the joint at the slot locations, sealing the joints, and grinding at joint locations or over the full pavement width and length to improve smoothness. It is used to retard further deterioration of the concrete pavement by reducing the potential for joint-related distresses. Restoration of load transfer can improve pavement performance by reducing pumping, faulting, and corner breaks, and by retarding the deterioration of transverse cracks. See UFC 3-270-01, Chapter 18.

Code	Name	Work Unit	Description
NONE	No Localized M & R	SqFt	When the severity of the distress does not negatively impact the operational safety of the pavement or trying to repair a distress (especially a low-severity distress) will potentially create more of a risk than the existing distress, the best choice is to take no action and monitor the distress for further deterioration.
PA-AD	Patching - AC Deep	SqFt	Full-depth asphalt repairs involve removing the pavement down to the subgrade or to an intermediate base or subbase layer that is intact then replacing the base or subbase with materials that meet the specifications for these respective layers and replacing the wearing surface with HMA concrete (cold mix asphalt is not preferred but may be used if hot mix is not available). See UFC 3-270-01, Chapter 3.
PA-AL	Patching - AC Leveling	SqFt	Patching AC leveling is used to address depressions or rutting by placing microsurfacing to level the pavement when the rutting or depression is stabilized.
PA-AS	Patching - AC Shallow	SqFt	Partial-depth repairs involve removing the asphalt surface to the base, recompacting the base, and replacing the wearing surface with HMA concrete (cold mix asphalt is not preferred but may be used if hot mix is not available). See UFC 3-270-01, Chapter 4.
PA-IR	Patching-Infrared	SqFt	Infrared patching involves heating the asphalt to a working temperature of 300 °F, penetrating the asphalt to a depth of 3 to 4 inches. After removing deteriorated asphalt and raking in new asphalt, the area is compacted with a vibratory roller.
PA-PF	Patching - PCC Full Depth	SqFt	Full-depth PCC repair involves sawing and removing the full depth of the concrete, repairing and recompacting the base or subgrade below the slab, placing dowels and tie-bars, then placing new concrete. Note that maintaining the joint is critical on any repair adjacent to a joint. See UFC 3-270-01, Chapter 14.
PA-PP	Patching - PCC Partial Depth	SqFt	Partial-depth PCC repair involves sawing and removing concrete to a minimum depth of 2 inches or to sound concrete, but not more than 1/3 the thickness of the pavement, then cleaning the repair area and placing new concrete. Note that maintaining the joint is critical on any repair adjacent to a joint. See UFC 3-270-01, Chapter 13.
PA-PL	Patching – PCC Partial Depth POL Damage Repair	SqFt	PCC partial-depth POL damage repair applies to pavement areas subject to deterioration from a combination of POL and heat, which results in scaling or spalling of the top 1 to 2 inches (25 to 50 millimeters) of the pavement as can be generated by POL and heat from B-1, F-18, F-35, and V-22 operations. This work type involves sawing and removing concrete to a minimum depth of 2 inches or to sound concrete, but not more than 1/3 the thickness of the pavement, then cleaning the repair area and placing new magnesium phosphate cement. Once the repair is in place, the area may be sealed using a sodium silicate surface treatment. See UFC 3-270-01, Chapter 21.
SH-LE	Shoulder leveling	Ft	Shoulder leveling involves removing loose materials, placing, grading, and compacting aggregate to correct shoulder drop-off caused by shoulder erosion, settlement, or by building up the roadway without adjusting the shoulder level.

Code	Name	Work Unit	Description
SL-PC	Slab Replacement - PCC	SqFt	PCC slab replacement involves sawing and removing the full depth of the concrete, repairing and recompacting the base or subgrade below the slab, placing dowels, then placing new concrete and sealing the joints. Procedures generally follow those outlined in UFC 3-270-01, Chapter 14.
SS-SG	Spread Sand or Gravel	SqFt	Sand seal is used to address a bleeding asphalt pavement surface. Hot sand is placed with a spreader to blot up the excess binder on the surface. The sand is rolled with a pneumatic roller then the excess sand is removed with a vacuum sweeper. See UFC 3-270-01, Chapter 7.
ST-AL	Surface Treatment – AC (Localized)	SqFt	Surface treatments for asphalt pavement are typically applied to entire sections (global) but may be done for localized areas. Different types of surface treatment are used depending on the age, condition, and use (airfield vs. road) of the pavement. These treatments include fog seals, rejuvenators, single or double bituminous surface treatments, slurry seals, and microsurfacing. See UFC 3-270-01, Chapters 5, 6, 7, 8, and 21.
ST-PL	Surface Treatment – PCC (Localized)	SqFt	Surface treatments for concrete pavement may be applied to entire sections but may also be done for localized areas. Surface treatments for PCC pavement surfaces (e.g., sodium silicate) are used to prevent deterioration from the effects of a combination of heat and POL contamination. Optimally, the surface is cleaned and sealed as a preventative measure within 6 months of commencing operations but may be used in conjunction with other appropriate repairs such as crack sealing and patching using magnesium phosphate cement. See UFC 3-270-01, Chapters 5, 6, 7, 8, and 21.
SJ-PC	Slab Jacking - PCC	SqFt	Slab jacking involves injection of a grout or polyurethane foam under a settled slab or multiple slabs to raise the slabs slowly under pressure to the desired elevation. It is used to address settlement or improve support under the pavement. See UFC 3-270-01, Chapter 15.
UN-PC	Undersealing - PCC	SqFt	Undersealing is used to stabilize the pavement slab by restoring support under the slab, typically at joint and crack locations. Undersealing is also called slab sealing, subsealing, slab stabilization, and pavement grouting. See UFC 3-270-01, Chapter 16.

6-3.2 Localized M&R Cost by Work Type Tables.

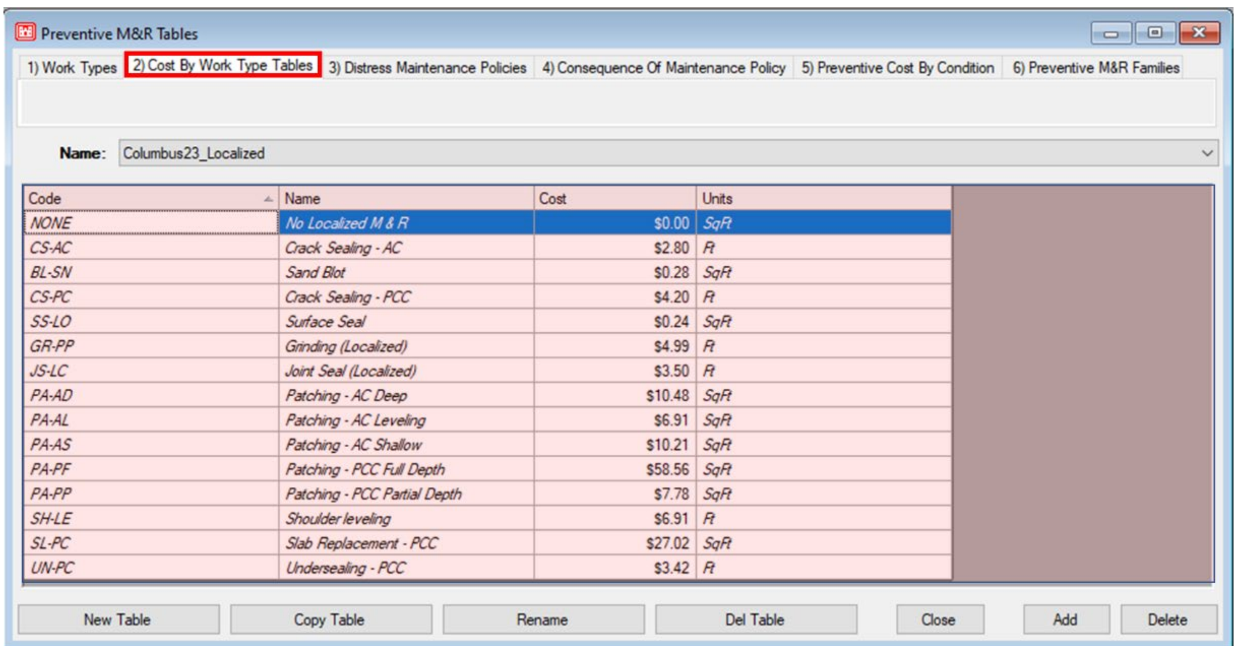
Historically the Services created standard cost by work type tables and updated them annually or used consultants to create or update them, but these tables did not follow a specific standard. This UFC defines a standard for creating and updating cost by work type tables for use by Service evaluation teams and consultants. Paragraph A-2 includes standard localized preventive and operational cost by work type tables for airfields and roads and parking pavements. This UFC defines the work elements for each of the standard work types. Based on the work element assumptions for each standard work type, generate fully burdened unit costs including O&M escalation factors using Tri-Service Automated Cost Engineering System (TRACES) applications such as the Parametric Cost Engineering System (PACES) or the Micro-Computer Aided Cost Estimating System Second Generation (MII).

Service evaluation teams and consultants performing PCI surveys use the standard cost by work type tables for each new PCI survey and apply area cost factors to adjust the standard unit costs for each work type for the specific installation. Adjust these standard cost tables when there is specific cost data available for work types at an installation. When adjusting costs, document any changes to specific work component assumptions for a given standard work type in the report. The intent is to clearly define changes to the unit cost basis. When doing work planning for a new inspection, use the updated cost table and delete any cost by work type tables used in previous inspections. Figure 6-2 is an example table.

Use the standard naming convention shown below for cost by work type tables. Costs for both AC and PCC pavement work types are included in the same table:

- **Site NameYr_Maintenance Category**
- For example, **Columbus23_AC_Localized**

Figure 6-2 Localized M&R Cost by Work Type Tables



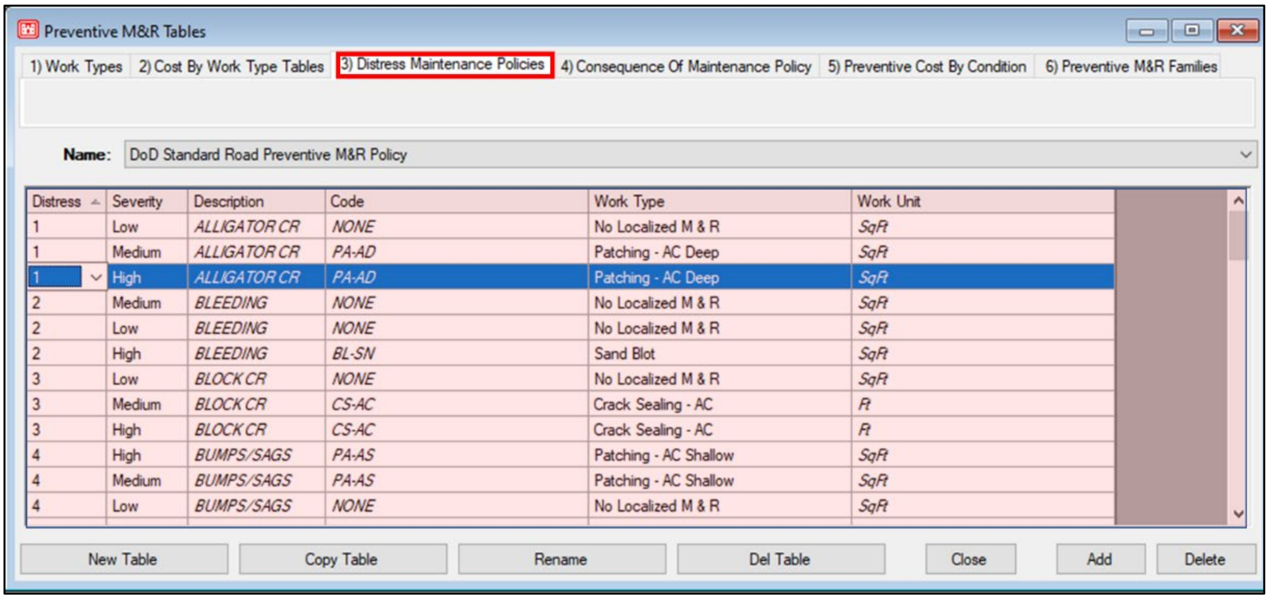
Code	Name	Cost	Units
NONE	No Localized M & R	$0.00	SqFt
CS-AC	Crack Sealing - AC	$2.80	Ft
BL-SN	Sand Blot	$0.28	SqFt
CS-PC	Crack Sealing - PCC	$4.20	Ft
SS-LO	Surface Seal	$0.24	SqFt
GR-PP	Grinding (Localized)	$4.99	Ft
JS-LC	Joint Seal (Localized)	$3.50	Ft
PA-AD	Patching - AC Deep	$10.48	SqFt
PA-AL	Patching - AC Leveling	$6.91	SqFt
PA-AS	Patching - AC Shallow	$10.21	SqFt
PA-PF	Patching - PCC Full Depth	$58.56	SqFt
PA-PP	Patching - PCC Partial Depth	$7.78	SqFt
SH-LE	Shoulder leveling	$6.91	Ft
SL-PC	Slab Replacement - PCC	$27.02	SqFt
UN-PC	Undersealing - PCC	$3.42	Ft

6-3.3 Localized M&R Distress Maintenance Policies.

Distress maintenance policies prescribe specific work types to repair specific distress types at each severity level. For example, in Figure 6-3 the first row shows high-severity alligator cracking as the distress. The **Code** and **Work Type** columns indicate to PAVER that when it encounters this distress at this severity level, it creates a requirement to perform a full-depth patch. Use separate policy tables for airfields and roads and parking pavements for both localized preventive and operational M&R. Paragraph A-3 includes standard distress maintenance policy tables.

Service evaluation teams and consultants performing PCI surveys will use the appropriate standard maintenance policy and the standard naming convention for each new PCI survey. Delete any distress maintenance policy tables from previous evaluations from the database. If a Service wants to change a standard maintenance policy, submit a change request using the UFC change request procedure on the Whole Building Design Guide (WBDG) website: https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc

Figure 6-3 Example Distress Maintenance Policies



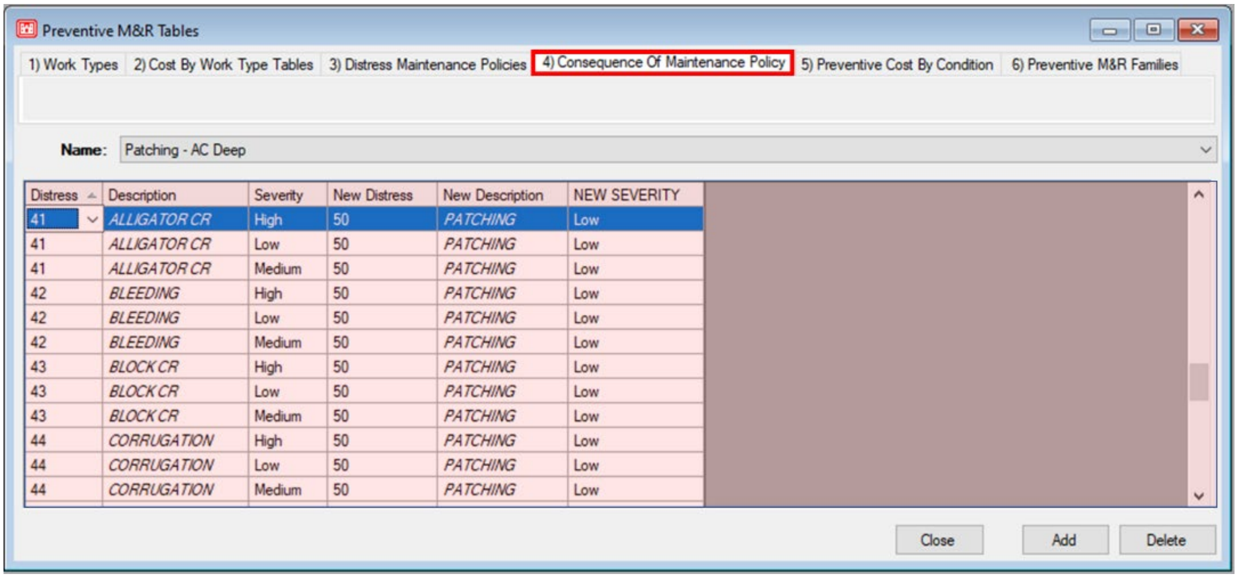
Distress	Severity	Description	Code	Work Type	Work Unit
1	Low	ALLIGATOR CR	NONE	No Localized M & R	SqFt
1	Medium	ALLIGATOR CR	PA-AD	Patching - AC Deep	SqFt
1	High	ALLIGATOR CR	PA-AD	Patching - AC Deep	SqFt
2	Medium	BLEEDING	NONE	No Localized M & R	SqFt
2	Low	BLEEDING	NONE	No Localized M & R	SqFt
2	High	BLEEDING	BL-SN	Sand Blot	SqFt
3	Low	BLOCK CR	NONE	No Localized M & R	SqFt
3	Medium	BLOCK CR	CS-AC	Crack Sealing - AC	Ft
3	High	BLOCK CR	CS-AC	Crack Sealing - AC	Ft
4	High	BUMPS/SAGS	PA-AS	Patching - AC Shallow	SqFt
4	Medium	BUMPS/SAGS	PA-AS	Patching - AC Shallow	SqFt
4	Low	BUMPS/SAGS	NONE	No Localized M & R	SqFt

6-3.4 Localized M&R Consequence of Maintenance Policy.

For every standard work type, there is an associated consequence of maintenance policy table. Each table consists of a list of all distresses related to a work type and the distress produced after performing the specified repair. This table informs PAVER about the distresses present after repair and is used to predict the condition after work is performed. For example, in Figure 6-4, when performing Patching - AC Deep to repair high-severity alligator cracking, the resulting distress is a low-severity patch. Standard consequence of maintenance policy tables are included in paragraph A-4.

Service evaluation teams and consultants performing PCI surveys will use the standard consequence of maintenance policy tables for each new PCI survey. Replace or update any consequence of maintenance policy tables from previous evaluations to match the standard consequence of maintenance policy and delete any tables for non-standard work types from the database. If a Service wants to change a standard consequence of maintenance policy, they can submit a change request using the UFC change request procedure on the WBDG website: https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc

Figure 6-4 Consequence of Maintenance Policy



Distress	Description	Severity	New Distress	New Description	NEW SEVERITY
41	ALLIGATOR CR	High	50	PATCHING	Low
41	ALLIGATOR CR	Low	50	PATCHING	Low
41	ALLIGATOR CR	Medium	50	PATCHING	Low
42	BLEEDING	High	50	PATCHING	Low
42	BLEEDING	Low	50	PATCHING	Low
42	BLEEDING	Medium	50	PATCHING	Low
43	BLOCK CR	High	50	PATCHING	Low
43	BLOCK CR	Low	50	PATCHING	Low
43	BLOCK CR	Medium	50	PATCHING	Low
44	CORRUGATION	High	50	PATCHING	Low
44	CORRUGATION	Low	50	PATCHING	Low
44	CORRUGATION	Medium	50	PATCHING	Low

6-3.5 Localized M&R Cost by Condition.

a. While PAVER can predict the future condition of a pavement section based on the PCI deterioration family model, it cannot predict specific distress types, severities, and quantities beyond the first year after a PCI survey. PAVER uses the cost by work type tables to determine the cost of required localized repairs when running a consequence of localized distress maintenance work plan. However, it uses cost by condition tables to determine M&R costs based on the future predicted condition of the pavement when running a critical PCI work plan.

b. Cost by condition tables are derived from the estimated cost of repairs developed from the cost by work type tables at the time of the most recent PCI. Cost by condition tables are created for operational, preventive, and major M&R. Each of these categories have separate tables for asphalt and PCC pavements. The results are cost by condition tables based on the current survey data and work type costs. Note that global M&R will always use cost by work type tables.

c. When running the work plan for future years, PAVER uses the cost per square foot from the table at the predicted PCI for the specified year multiplied by the true area of the section to predict the cost of M&R for each M&R category. Costs to repair a pavement increases as the pavement condition (PCI) decreases.

d. Service evaluation teams and consultants performing PCI surveys will develop standard cost by condition tables for each new PCI survey as outlined in paragraph 6-3.5.1. Create a new cost by condition table for the current inspection and delete any cost by condition tables used in previous inspections from the database when developing M&R Family Models for a new inspection.

e. Use the following standard naming convention for cost by condition type tables:

- Site **NameYr_Pavement Type_Maintenance Category**
- For example, **Columbus23_AC_PRV**

6-3.5.1 Developing Localized M&R Cost by Condition Tables.

Once the PCI survey is complete and the cost by work type and distress maintenance policy tables are updated, use the **Family Modeling** tool to create a **Cost by Condition Table**. After opening the **Family Modeling** tool, select **Local Cost v PCI Family Type**, then select **New** to open the **Options** form. Name the model using the naming convention and select the current **Distress Maintenance Policy** and **Cost by Work Type** as shown in Figure 6-5. When the **Query** tool opens, select the pavement type for the model. This generates a model like the one shown in Figure 6-6. Check the **View Equations and Stats** tab to ensure the coefficient of correlation is above 0.70. Selecting **Generate Cost Table** creates a Cost by Condition table in Excel.

Figure 6-5 Policy Unit Cost per Section

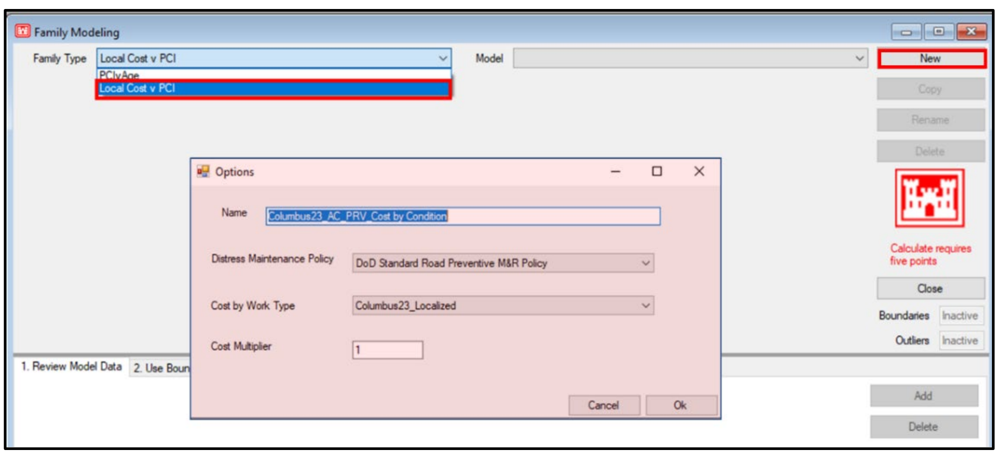


Figure 6-6 Policy Unit Cost per Section Trend Line

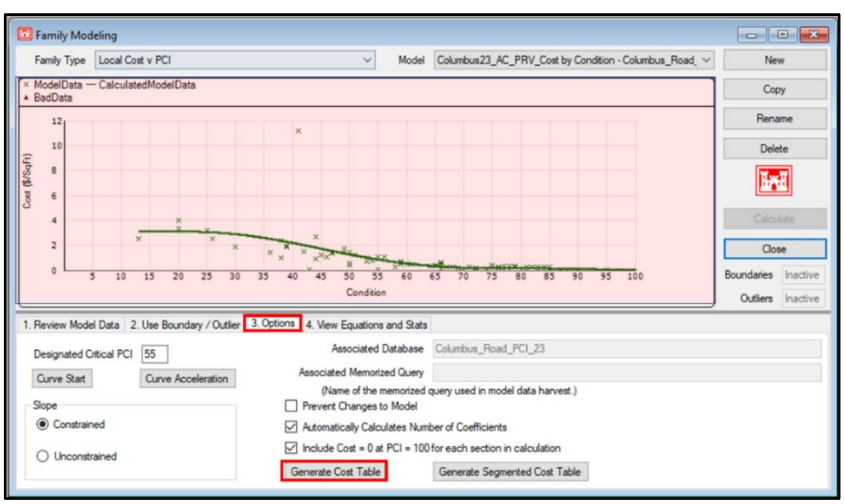
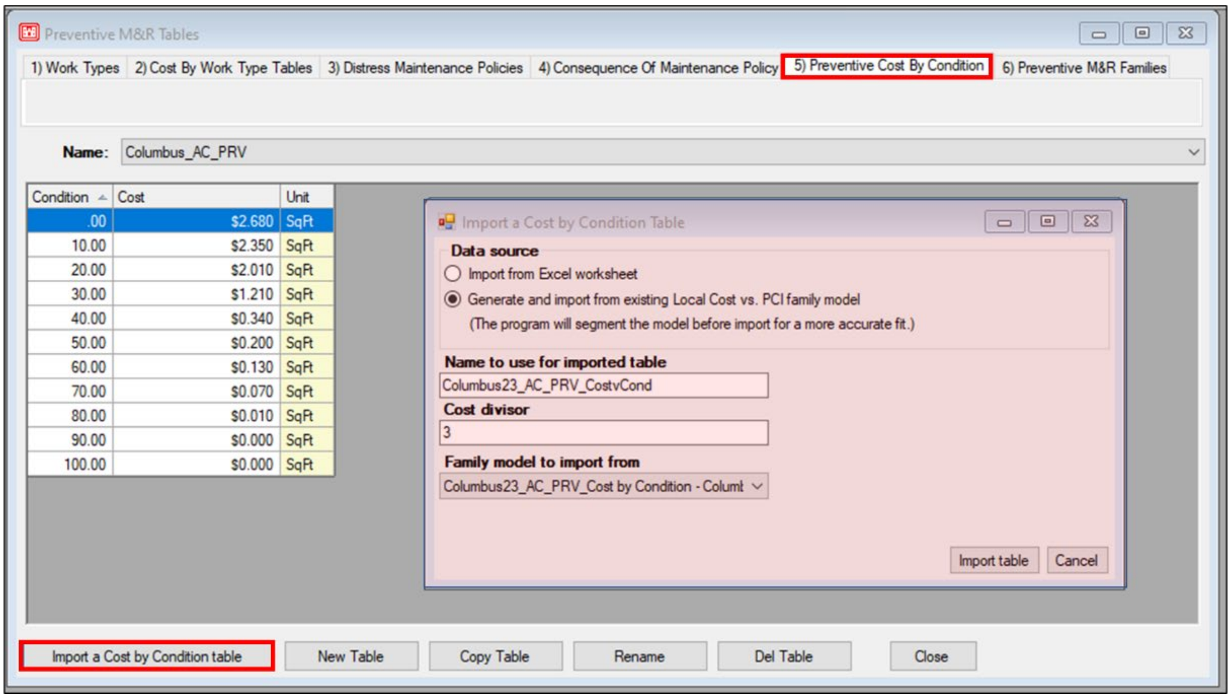


6-3.5.2 Cost by Condition Table.

After creating the Local Cost v PCI Family Model, reopen the **M&R Family Models** form, select the **Preventive Cost by Condition** tab (tab 5), then select **Import a Cost by Condition Table**. This opens the form shown in Figure 6-7 from which the user can import the Cost by Condition table from the Family Model or import it from an Excel worksheet. This results in a table that lists the cost by condition at 10-PCI intervals. When doing work planning, PAVER will interpolate the costs between these intervals. Repeat the process to create a separate table for operational AC, preventive AC, operational PCC, and preventive PCC.

Figure 6-7 Cost by Condition Table



6-3.6 Localized M&R Families.

The final step of the localized M&R family model process is creating the M&R families and assigning the distress maintenance policy, cost by work type, and cost by condition tables to the families, then assigning the model to the appropriate sections.

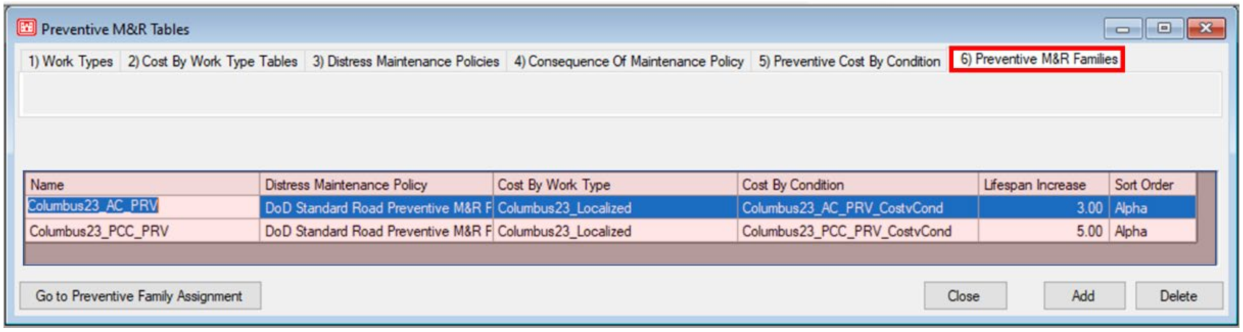
6-3.6.1 Create Localized M&R Families.

Create an asphalt and PCC family for both the preventive and operational M&R categories. Name the families using the standard convention below. Use the acronym STP for operational (aka safety or stopgap) and PRV for preventive.

- Site **NameYr_Pavement Type_M&R Category**
- For example, **Columbus23_AC_PRV**

Assign the tables to the family model using the drop-down in the **Distress Maintenance Policy**, **Cost By Work Type**, and **Cost By Condition** columns to select the appropriate table as shown in Figure 6-8. Delete all old/unused M&R family models and all unused tables.

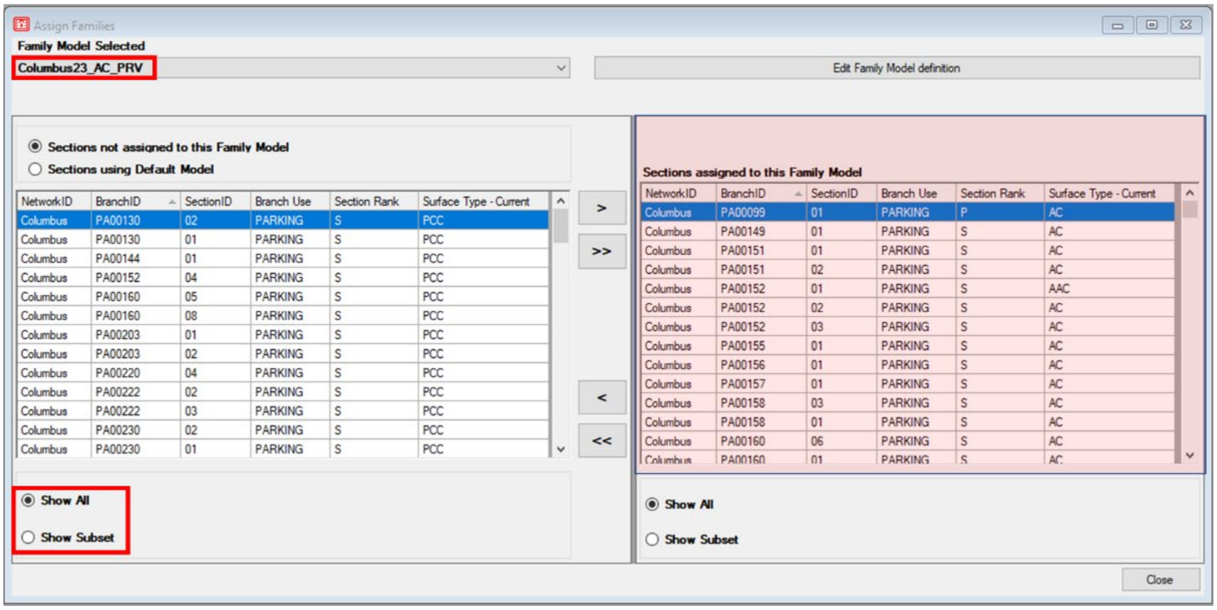
Figure 6-8 Creating a Localized M&R Family



6-3.6.2 Assign Localized M&R Families to Sections.

Use the **Go to Preventive Family Assignment** button in the lower left-hand corner of the form shown in Figure 6-8 to assign family models. Assign each of the M&R families to the appropriate sections. For example, the asphalt preventive family is assigned to all AC sections, as shown in Figure 6-9. Every paved section that was inspected must be assigned to a family. Filter sections using the **Query** tool, then use the arrows to move the selected sections from the unassigned list on the left side of the form in Figure 6-9 to the assigned list on the right. Unpaved or unused sections that did not have a PCI inspection are unassigned. In PAVER you will see these identified as **Sections using the Default Model**. These sections are excluded when running the M&R work plans.

Figure 6-9 Assigning a Localized M&R Family to Section



6-4 GLOBAL M&R TABLES.

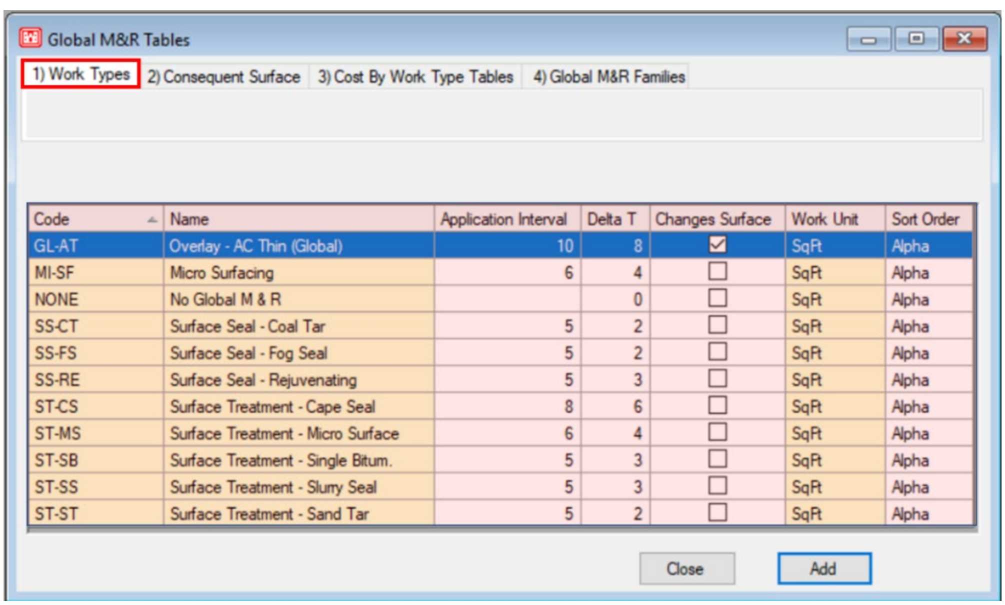
Historically, global M&R applied only to asphalt pavement. This UFC introduces global M&R for concrete pavement joint seals. The global M&R tables define global M&R work planning parameters. Tables include work types, cost by work type, and consequent surface. Standards for these tables are outlined below and in the appendices. In both the condition and time-based approach to global M&R described earlier, M&R is performed on an entire section without regard to the distresses present in that section. PAVER uses the cost by work type table to estimate costs for all future years rather than using a cost by condition table. Note that any localized maintenance identified by PAVER is done in conjunction with global to repair distresses that global maintenance will not address effectively.

6-4.1 Global M&R Work Types.

The Global M&R **Work Types** table (Tab 1) in Figure 6-10 lists standard PAVER work types. While users can create user-defined work types in PAVER, they are not permitted in DoD PAVER databases. Change any user-defined work types in a database to standard work types when doing a new inspection and delete the user-defined work types from the work type table. If a Service requires a new global work type, submit the requirement to the Tri-Service Pavement Working Group for inclusion in PAVER.

The work types shown in Figure 6-10 are used in **Cost By Work Type Tables** (tab 3) and the **Global M&R Families** table (tab 4). The same global work types are used for both airfield and road and parking M&R, although there are different policies for when and where to use these work types. Details for performing most work types are outlined in UFC 3-270-01 and UFC 3-250-03, *Standard Practice Manual for Flexible Pavements*. Table 6-2 provides a description of standard global work types.

Figure 6-10 Global M&R Work Types



Code	Name	Application Interval	Delta T	Changes Surface	Work Unit	Sort Order
GL-AT	Overlay - AC Thin (Global)	10	8	☑	SqFt	Alpha
MI-SF	Micro Surfacing	6	4	☐	SqFt	Alpha
NONE	No Global M & R		0	☐	SqFt	Alpha
SS-CT	Surface Seal - Coal Tar	5	2	☐	SqFt	Alpha
SS-FS	Surface Seal - Fog Seal	5	2	☐	SqFt	Alpha
SS-RE	Surface Seal - Rejuvenating	5	3	☐	SqFt	Alpha

Table 6-2 Global M&R Work Types

Code	Name	Application Interval (yrs.)	Delta T (yrs.)	Work Unit	Description
NONE	No Global M & R	0	0	SqFt	The no global work type allows the user to establish a policy in which there are cases or periods when global M&R is not used; for example, a policy in which Global M&R is not applied to runways.
GL-AT	Overlay - AC Thin (Global)	10	8	SqFt	Thin HMA overlays are commonly used to correct minor to moderate pavement surface defects to restore ride quality and improve friction while protecting the underlying pavement structure. Thin overlays may be applied to either concrete or asphalt pavements or over existing surface treatments and are typically not considered a structural layer. Industry convention generally defines thin overlays as no more than 1.5 to 2 inches thick, typically constructed as a single lift. See UFC 3-250-03 for more information.
GL-FR	Overlay - Fuel-Resistant AC (Global)	10	8	SqFt	Fuel-resistant HMA overlays composed of mineral aggregate, polymer-modified asphalt binder, and additives mixed in a central mixing plant are used as a surface course for locations that need a fuel-resistant surface while protecting the underlying pavement structure. Thin overlays may be applied to either concrete or asphalt pavements and are typically not considered a structural layer when less than 2 inches thick. Industry convention generally defines fuel-resistant overlays as no more than 1.5 to 3 inches thick, constructed as a single lift. See UFGS 32 12 17.19, *Fuel Resistant Asphalt Paving for Airfields - Surface Course*.
JS-CP	Joint Seal – Compression			Ft	This work type specifically addresses replacing compression seals for an entire section(s). The procedure involves removing the old sealant, routing the reservoir to achieve the correct shape factor, cleaning the reservoir, and placing new joint seal. See UFC 3-270-01, Chapter 12.
JS-HP	Joint Seal – Hot Pour			Ft	This work type specifically addresses replacing hot pour sealant for an entire section(s). The procedure involves removing the old sealant, routing the reservoir to achieve the correct shape factor, cleaning the reservoir, and placing new joint seal. See UFC 3-270-01, Chapter 12.

Code	Name	Application Interval (yrs.)	Delta T (yrs.)	Work Unit	Description
JS-SI	Joint Seal - Silicone			Ft	This work type specifically addresses replacing silicone sealant for an entire section(s). The procedure involves removing the old sealant, routing the reservoir to achieve the correct shape factor, cleaning the reservoir, and placing new joint seal. See UFC 3-270-01, Chapter 12.
SS-CT	Surface Seal - Coal Tar	5	2	SqFt	A coal-tar surface seal is a coal-tar emulsion used as a fuel-resistant sealer (FRS), which is a combination of coal-tar emulsion, fine aggregate, water, and occasionally other additives. Consider use only where the need is for a fuel-resistant surface, such as aprons where pavements are subject to fuel spills. These materials are mixed in batches and applied to HMA surfaces by hand, sprayer, or mechanical squeegee. The FRS is placed in thin layers, usually 1/16 inch (2 mm) or less. See UFC 3-250-03, paragraph 4-4. **Important:** Coal tar is a human carcinogen. Consult local and state environmental/safety regulations. Many locations prohibit the use of coal tar products. Verify the selected materials comply with federal, state, and local authority requirements.
SS-FS	Surface Seal - Fog Seal	3	2	SqFt	A fog seal is a light application of diluted asphalt emulsion (including natural asphalt such as Gilsonite), often containing polymer additives. It is used to renew old asphalt surfaces, seal small cracks and surface voids, and inhibit weathering. Consider fog seals for environmental surface distresses such as non-structural cracking or before raveling begins. Continue applying the fog seal on an approximately three-year cycle, depending on environment and pavement condition. Current guidance does not support the use of fog seals on runways without approval. See UFC 3-270-01, paragraph 5-4, and UFC 3-250-03, paragraph 3-4.
SS-RE	Surface Seal - Rejuvenating	5	3	SqFt	A “rejuvenator” is a solvent-based asphalt material (including natural asphalt such as Gilsonite), often containing polymer additives and light oils. They are used for PM to slightly soften and partially restore oxidized pavement surfaces. They do not solve raveling issues or reduce cracking problems. There are numerous commercially available products for use on roads, parking areas, airfield shoulders, and overruns. Current guidance does not support the use of rejuvenators on airfield pavement without approval. See UFC 3-270-01, paragraph 5-4, and UFC 3-250-03, paragraph 3-5.

Code	Name	Application Interval (yrs.)	Delta T (yrs.)	Work Unit	Description
ST-CS	Surface Treatment - Cape Seal	8	6	SqFt	A cape seal is surface treatment in which a bituminous surface treatment (often called a chip seal) is followed by the application of either slurry seal or micro-surfacing. The advantage of this treatment is that the chip seal seals and protects the underlying pavement, while the slurry seal helps to protect the chip seal, locking the chip seal aggregate in place to minimize chip/aggregate loss and providing a smoother final surface. Cape seals are used on roads and parking lots. Do not use cape seals on airfield pavements except for overruns and not within 200 feet (61 m) of the threshold. See guidance on bituminous surface treatment in UFC 3-270-01, Chapter 6, and UFC 3-250-03, Chapter 4.
ST-MS	Surface Treatment - Micro Surface	6	4	SqFt	Microsurfacing is a mixture of polymer-modified asphalt emulsion, crushed dense graded aggregate, mineral filler, additives, and water. It provides a thin resurfacing of 3/8 to 3/4 inch (10 to 20 mm). It is very similar to slurry seal but is typically a more durable treatment. Microsurfacing is primarily used to mitigate raveling and oxidation of asphalt pavement surfaces, but also improves friction and appearance of both asphalt and concrete surfaces. Microsurfacing can be designed with larger aggregate for use in filling shallow to moderate depth ruts in asphalt pavement and can also seal low-severity cracks. See UFC 3-250-03, Chapter 4, and UFC 3-270-01, Chapter 8.
ST-SB	Surface Treatment – Single Bituminous	5	3	SqFt	A single bituminous surface treatment (SBST) consists of a sprayed asphalt application followed immediately by a layer of aggregate. This treatment is used to retard deterioration of raveling, improve skid resistance, seal small cracks, and waterproof the surface on light-traffic roads and parking lots. Do not use SBST on airfield pavements except for overruns and not within 200 feet (61 meters) of the threshold. See UFC 3-270-01, Chapter 6, and UFC 3-250-03, Chapter 4.
ST-DB	Surface Treatment - Double Bituminous				A double bituminous surface treatment (DBST) is essentially the same as the SBST, except that more than one application of binder and aggregate is used. DBSTs are used to retard deterioration of raveling, improve skid resistance, seal small cracks, and waterproof the surface of roads and parking areas. Do not use DBST on airfield pavements except for overruns and not within 200 feet (61 meters) of the threshold. See UFC 3-270-01, Chapter 7, and UFC 3-250-03, Chapter 4.

Code	Name	Application Interval (yrs.)	Delta T (yrs.)	Work Unit	Description
ST-SS	Surface Treatment - Slurry Seal	5	3	SqFt	A slurry seal is a mixture of asphalt emulsion, aggregate, water, and mineral filler applied or screeded onto the pavement surface in a thin layer using squeegees or a spreader box. Slurry seals are used to protect the underlying surface from water infiltration, fill surface cracks and voids, and improve friction and appearance of an existing pavement. Slurry seals do not provide any structural benefit to the pavement but are a very cost-effective treatment for preserving the existing pavement surface, improving appearance, and restoring or enhancing friction. See UFC 3-250-03, Chapter 4, and UFC 3-270-01, Chapter 8.
ST-ST	Surface Treatment - Sand Tar	5	2	SqFt	Sand seal can be used to address a bleeding pavement surface or provide a thin sealer using sprayed application of asphalt emulsion followed by a covering of clean sand or fine aggregate. A pneumatic-tire roller is often used after applying the sand. Excess sand is removed from the pavement surface after rolling.

6-4.2 Global M&R Consequent Surface.

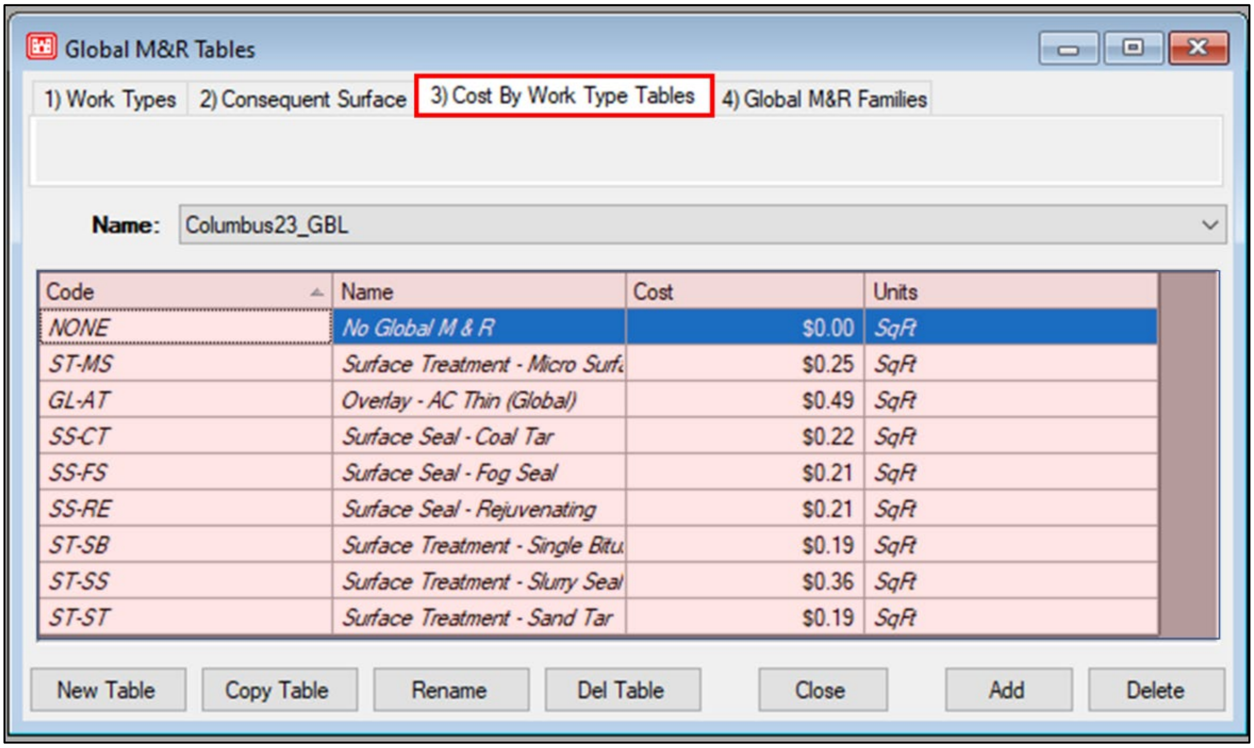
Tab 2 of the Global M&R Tables form defines the consequent (resultant) surface produced when a given work type is performed over different surface types. Only PAVER default surface types and global work types are permitted. Currently, the only work types that result in a change in surface type are Overlay – AC Thin (Global) and Overlay - Fuel-Resistant AC (Global).

6-4.3 Global M&R Cost by Work Type.

Paragraph A-2 includes global cost by work type tables for airfields and roads and parking pavements. Historically, the Services have either had consultants create cost by work type tables that did not follow a specific standard or they created their own standard cost by work type tables and updated them annually for use by their evaluation teams and consultants. This UFC defines the work elements for each of the standard work types. Fully burdened unit costs for each of these work types, including any O&M escalation factors, are generated using Tri-Service Automated Cost Engineering System (TRACES) applications such as the Parametric Cost Engineering System (PACES) or the Micro-Computer Aided Cost Estimating System Second Generation (MII), based on the work element assumptions for each standard work type.

Service evaluation teams and consultants performing PCI surveys use the standard global cost by work type tables for each new PCI survey and apply area cost factors to adjust the standard unit costs for each work type for the specific installation. Adjust these standard cost tables when there is specific cost data available for work types at an installation. When adjusting costs, clearly define and document any changes to specific work component assumptions in the report so users understand the unit cost basis for a given standard work type. Use the updated cost table when developing work plans for a new inspection and delete any cost by work type tables used in previous inspections. An example table is shown in Figure 6-11.

Figure 6-11 Global Cost by Work Type Tables



6-4.4 Global M&R Families.

The final step of the global M&R family model process involves creating the M&R families and assigning the work types and cost by work type tables to the families then assigning the model to the appropriate sections.

6-4.4.1 Create Global M&R Families.

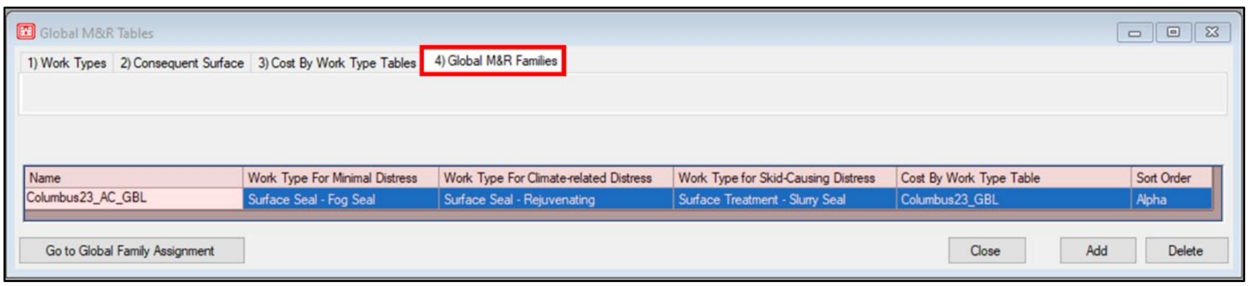
At a minimum, create a global M&R family for AC and one for PCC pavement. It is often desirable to create different global M&R families for pavements with different branch uses when required. For example, a different family can be created for roads than is used for parking pavements. The families are named using the standard convention below. Use the acronym GBL for the M&R category and include the branch use at the end of the name, if used.

- Site **NameYr_Pavement Type_M&R Category**
- For example, **Columbus23_AC_GBL**

6-4.4.2 Global Maintenance Policies.

The process for setting the maintenance policies for global M&R is integral to creating a family. After creating the family, assign the global work type using the drop-down menu for each category shown in Figure 6-12: **Work Type for Minimal Distress**, **Work Type for Climate-related Distress**, and **Work Type for Skid-Causing Distress**. Assigning the **Global Cost by Work Type Table** completes the process. Delete all old or unused global M&R family models and all unused cost by work type tables. Global maintenance policies for airfields and road and parking pavements differ; see the standard global M&R polices in paragraph A-3.3. See details on global policy in UFC 3-270-01 and UFC 3-250-03.

Figure 6-12 Global M&R Maintenance Policy Example



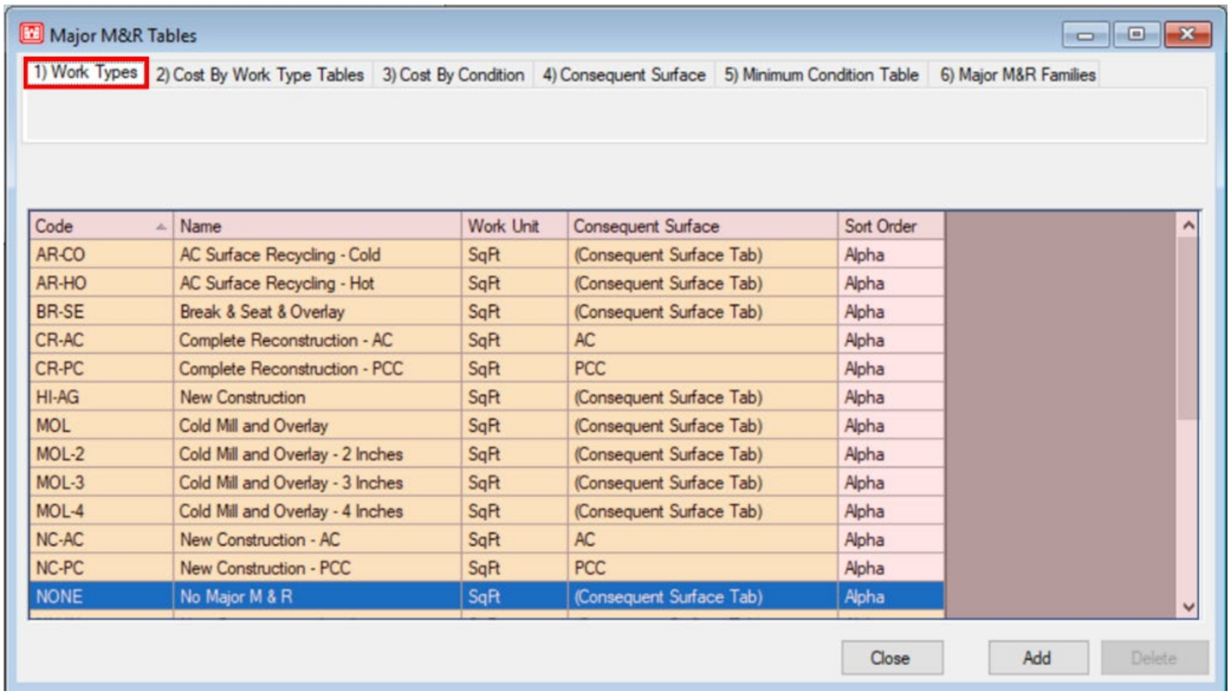
6-4.4.3 Assign Global M&R Families to Sections.

Each of the families created above are assigned to the appropriate sections. For example, assign all asphalt sections in a road and parking network to the global AC family model. Every paved section that was inspected must be assigned to a family. The default family model can be used for unpaved or unused sections as well as sections that did not have a PCI inspection, but these sections are excluded using the **Query** tool when running M&R work plans.

6-5 MAJOR M&R TABLES.

The major M&R tables define major M&R work planning parameters. Figure 6-13 shows the **Major M&R Tables** form. Tables include **Work Types** (tab 1), **Cost By Work Type Tables** (tab 2), **Cost By Condition** (tab 3), **Consequent Surface** (tab 4), and **Minimum Condition Table** (tab 5). **Major M&R Families** are defined on tab 6 using the tables on tabs 1 through 5. Standards for these tables are outlined below and in the appendices.

Figure 6-13 Major M&R Tables



Code	Name	Work Unit	Consequent Surface	Sort Order
AR-CO	AC Surface Recycling - Cold	SqFt	(Consequent Surface Tab)	Alpha
AR-HO	AC Surface Recycling - Hot	SqFt	(Consequent Surface Tab)	Alpha
BR-SE	Break & Seat & Overlay	SqFt	(Consequent Surface Tab)	Alpha
CR-AC	Complete Reconstruction - AC	SqFt	AC	Alpha
CR-PC	Complete Reconstruction - PCC	SqFt	PCC	Alpha
HI-AG	New Construction	SqFt	(Consequent Surface Tab)	Alpha
MOL	Cold Mill and Overlay	SqFt	(Consequent Surface Tab)	Alpha
MOL-2	Cold Mill and Overlay - 2 Inches	SqFt	(Consequent Surface Tab)	Alpha
MOL-3	Cold Mill and Overlay - 3 Inches	SqFt	(Consequent Surface Tab)	Alpha
MOL-4	Cold Mill and Overlay - 4 Inches	SqFt	(Consequent Surface Tab)	Alpha
NC-AC	New Construction - AC	SqFt	AC	Alpha
NC-PC	New Construction - PCC	SqFt	PCC	Alpha
NONE	No Major M & R	SqFt	(Consequent Surface Tab)	Alpha

6-5.1 Major M&R Work Types.

The **Work Types** Table (tab 1) in Figure 6-13 lists a set of standard Major M&R work types. While users can create user-defined major M&R work types in PAVER, they are not permitted in DoD PAVER databases. Change any user-defined work types in an existing database to standard work types and delete the user-defined work types from the Major M&R Work Type table when defining planning parameters for a new inspection. If a Service requires a work type that is not in the major M&R work type table, they will submit the requirement to the Tri-Service Pavement Working Group for inclusion in PAVER.

Work types in Table 6-3 are used in the **Cost By Work Type Tables** (tab 2) and **Consequent Surface** tables (tab 4). This work type table is used for airfield and road and parking M&R, but implementation varies according to this UFC, UFC 3-250-03, UFC 3-250-04, *Standard Practice for Concrete Pavements*, UFC 3-260-02, and UFC 3-250-01, *Pavement Design for Roads and Parking Areas*.

Table 6-3 Major M&R Work Types

Code	Name	Work Unit	Description
AR-CO	AC Surface Recycling - Cold	SqFt	Cold-mix recycling involves removing the existing asphalt, crushing to specified particle size, mixing with virgin material, and using it to pave secondary roads or parking areas (if a seal coat is applied) or as a base course. See UFC 3-250-07 and UFC 3-270-01.
AR-HO	AC Surface Recycling - Hot	SqFt	Hot-mix recycling involves removing the existing HMA, crushing it, and mixing it in a hot-mix plant with new aggregate, asphalt, and recycling agent, when required. This work type can be used for airfields (with restrictions noted in UFC 3-260-02), roads, or parking areas. This work type can also be accomplished with in-place recycling. See UFC 3-250-07 and UFC 3-270-01.
BR-SE	Break & Seat & Overlay	SqFt	Break and seat and crack and seat are both fractured slab technologies used on concrete pavement. Both minimize the size of the concrete slabs and then seat the broken concrete pieces. The pavement is then overlaid with HMA. See Asphalt Institute MS-4, *The Asphalt Handbook*, and MS-17, *Asphalt Overlays for Highway and Street Rehabilitation*.
BR-RB	Rubblization & Overlay	SqFt	Rubblization is a fractured slab technology used on concrete pavement. It eliminates the slab movement by converting the old concrete pavement to aggregate-size pieces. The resulting rubblized pavement layer functions as an aggregate base course. The pavement is then overlaid with HMA. This work type assumes the subgrade is strong enough for the process to work correctly, e.g., the subgrade will not quicken due to pore pressure and thus weaken it and that an underdrain design is installed prior to rubblization to relieve pore pressure and prevent settlement (unless the geotechnical analysis indicates an underdrain is not required). Ensure a geotechnical assessment is done before using rubblization. See Asphalt Institute manuals MS-4 and MS-17.
CR-AC-4	Complete Reconstruction, 4 inches AC	SqFt	Complete reconstruction AC-4 involves removing the existing pavement structure to the subgrade and replacing it. The assumption for this work type is that both the existing and new AC layer are greater than 2 inches and less than or equal to 4 inches, the existing and new base are equal to 6 inches, and there is no subbase. See 3-260-02 and UFC 3-250-03.

Code	Name	Work Unit	Description
CR-AC-6	Complete Reconstruction, 6 inches AC	SqFt	Complete reconstruction AC-6 involves removing the existing pavement structure to the subgrade and replacing it. The assumption for this work type is that both the existing and new AC layer are greater than 4 inches and less than or equal to 6 inches, the existing and new base are equal to 6 inches, and there is a 4-inch subbase. See 3-260-02 and UFC 3-250-03.
CR-AC-8	Complete Reconstruction, 8 inches AC	SqFt	Complete reconstruction AC-8 involves removing the existing pavement structure to the subgrade and replacing it. The assumption for this work type is that both the existing and new AC layer are greater than 6 inches and less than or equal to 8 inches, the existing and new base are equal to 8 inches, and there is a 6-inch subbase. See 3-260-02 and UFC 3-250-03.
CR-PC-8	Complete Reconstruction, 8 inches PCC	SqFt	Complete reconstruction PC-8 involves removing the existing pavement structure to the subgrade and replacing it. The assumption for this work type is that both the existing and new PCC layer are greater than 6 inches and less than or equal to 8 inches, the existing and new base are greater than 4 inches and less than or equal to 6 inches. See 3-260-02 and UFC 3-250-04.
CR-PC-12	Complete Reconstruction, 12 inches PCC	SqFt	Complete reconstruction PC-12 involves removing the existing pavement structure to the subgrade and replacing it. The assumption for this work type is that both the existing and new PCC layer are greater than 8 inches and less than or equal to 12 inches, the existing and new base are equal to greater than 6 inches and less than or equal to 8 inches. See 3-260-02 and UFC 3-250-04.
CR-PC-18	Complete Reconstruction, 18 inches PCC	SqFt	Complete reconstruction PC-18 involves removing the existing pavement structure to the subgrade and replacing it. The assumption for this work type is that both the existing and new PCC layer are greater than 12 inches and less than or equal to 18 inches, the existing and new base are greater than 8 inches and less than or equal to 12 inches. See 3-260-02 and UFC 3-250-04.
CR-PC-24	Complete Reconstruction, 24 inches PCC	SqFt	Complete reconstruction PC-24 involves removing the existing pavement structure to the subgrade and replacing it. The assumption for this work type is that both the existing and new PCC layer are greater than 18 inches and less than or equal to 24 inches, the existing and new base are greater than 12 inches and less than or equal to 16 inches. See 3-260-02 and UFC 3-250-04.

Code	Name	Work Unit	Description
HI-AG	New Construction	SqFt	This PAVER work type does not have a specific pavement type and is not used by DoD. If included in a DoD database, replace it with the appropriate work type for the section based on the pavement type.
MOL	Cold Mill and Overlay	SqFt	This PAVER work type does not define a specific pavement thickness and is not used by DoD. If included in a DoD database, replace it with the appropriate work type for the section based on the asphalt pavement thickness.
MOL-2	Cold Mill and Overlay - 2 Inches	SqFt	This work type involves milling 2 inches of the existing asphalt surface and replacing it with 2 inches of HMA. See UFC 3-250-07 and UFC 3-260-02.
MOL-3	Cold Mill and Overlay - 3 Inches	SqFt	This work type involves milling 3 inches of the existing asphalt surface and replacing it with 3 inches of HMA. See UFC 3-250-07 and UFC 3-260-02.
MOL-4	Cold Mill and Overlay - 4 Inches	SqFt	This work type involves milling 4 inches of the existing asphalt surface and replacing it with 4 inches of HMA. See UFC 3-250-07 and UFC 3-260-02.
NC-AC-4	New Construction, 4 inches AC	SqFt	New construction AC-4 involves constructing a new AC pavement structure. The assumption for this work type is that the AC layer is greater than 2 inches and less than or equal to 4 inches, the base is equal to 6 inches, and there is no subbase. See UFC 3-250-03 and UFC 3-260-02.
NC-AC-6	New Construction, 6 inches AC	SqFt	New construction AC-6 involves constructing a new AC pavement structure. The assumption for this work type is that the AC layer is greater than 4 inches and less than or equal to 6 inches, the base is equal to 6 inches, and there is a 4-inch subbase. See UFC 3-250-03 and UFC 3-260-02.
NC-AC-8	New Construction, 8 inches AC	SqFt	New construction AC-8 involves constructing a new AC pavement structure. The assumption for this work type is that the AC layer is greater than 6 inches and less than or equal to 8 inches, the base is equal to 8 inches, and there is a 6-inch subbase. See UFC 3-250-03 and UFC 3-260-02.
NC-PC-8	New Construction, 8 inches PCC	SqFt	New construction PC-8 involves constructing a new PCC pavement structure. The assumption for this work type is that the PCC layer is greater than 6 and less than or equal to 8 inches, the base is greater than 4 inches and less than or equal to 6 inches. See UFC 3-250-04 and UFC 3-260-02.

Code	Name	Work Unit	Description
NC-PC-12	New Construction, 12 inches PCC	SqFt	New construction PC-12 involves constructing a new PCC pavement structure. The assumption for this work type is that the PCC layer is greater than 8 and less than or equal to 12 inches, the base is greater than 6 inches and less than or equal to 8 inches. See UFC 3-250-04 and UFC 3-260-02.
NC-PC-18	New Construction, 18 inches PCC	SqFt	New construction PC-18 involves constructing a new PCC pavement structure. The assumption for this work type is that the PCC layer is greater than 12 and less than or equal to 18 inches, the base is greater than 8 inches and less than or equal to 12 inches. See UFC 3-250-04 and UFC 3-260-02.
NC-PC-24	New Construction, 24 inches PCC	SqFt	New construction PC-24 involves constructing a new PCC pavement structure. The assumption for this work type is that the PCC layer is greater than 18 and less than or equal to 24 inches, the base is greater than 12 inches and less than or equal to 16 inches. See UFC 3-250-04 and UFC 3-260-02.
NONE	No Major M & R	SqFt	When a pavement is above the critical PCI there is typically no major M&R requirement unless the pavement is being overlaid to increase the structural capacity such as when there is a mission change or when the usage pattern of a road is changed.
NU-IN	New Construction - Initial	SqFt	This is the default work type used when a new section is created. If there is no other major M&R in the work history, this item cannot be updated to reflect the specific construction, e.g., New Construction AC, but the material type field can be edited and the surface type is defined in the inventory.
NU-US	New Construction - Unsurfaced	SqFt	New construction unsurfaced involves constructing a new unpaved (gravel) structure. The assumption for this work type is that the aggregate wearing surface layer is 4 inches and the base is 6 inches.
OL-AF	Overlay - AC Fabric	SqFt	This work type involves placing an overlay to address pavement surface distresses and/or to increase the structural capability of a pavement. This overlay includes the use of a geofabric to mitigate reflective cracking issues and assumes a 2-inch overlay thickness. When thicknesses are less than or greater than these values, adjust the cost for this work type proportionately. See UFC 3-250-03 and UFC 3-260-02.

Code	Name	Work Unit	Description
OL-AS	Overlay - AC Structural	SqFt	This work type involves placing an overlay to address the surface condition of the pavement and/or to increase the structural capability of a pavement. It assumes a 4-inch overlay thickness. When the thickness is less than or greater than this, adjust the cost for this work type proportionately. See UFC 3-250-03 and UFC 3-260-02.
OL-AT	Overlay - AC Thin	SqFt	This work type involves placing an overlay to address the surface condition of the pavement but does not typically significantly increase the structural capability of a pavement. It assumes a 2-inch overlay thickness. See UFC 3-250-03 and UFC 3-260-02.
OL-PF	Overlay - PCC Fully Bonded	SqFt	This work type involves placing a fully bonded PCC overlay to increase the structural capability of a pavement. This overlay type is typically used when the existing slab is in Good condition. Action must be taken to ensure the bond. It assumes an overlay thickness greater than 2 inches and less than 5 inches. See UFC 3-250-04, Appendix B, and UFC 3-260-02.
OL-PP	Overlay - PCC Partially Bonded	SqFt	This work type involves placing a partially bonded PCC overlay to increase the structural capability of a pavement but may be used to address other issues. This overlay type is typically used when the existing slab is in Fair to Good condition. It assumes an overlay thickness of 6 inches. See UFC 3-260-02.
OL-PU	Overlay - PCC Unbonded	SqFt	This work type involves placing a bond breaker and a PCC overlay to increase the structural capability of a pavement but may be used to address other issues. This overlay type is typically used when the existing slab is in Poor to Fair condition. It assumes an overlay thickness of 6 inches. See UFC 3-260-02.
SR-AC	Surface Reconstruction - AC	SqFt	This work type involves milling the full depth of the existing asphalt surface, scarifying and recompacting the base, and placing HMA. The assumption for this work type is that the asphalt is 4 inches. When thicknesses are less than or greater than these values, adjust the cost for this work type proportionately. See UFC 3-250-07 and UFC 3-260-02.

Code	Name	Work Unit	Description
SR-PC	Surface Reconstruction - PCC	SqFt	This work type involves removing existing PCC, repairing and recompacting the base, and placing plain, jointed concrete. It assumes the pavement thickness for the existing and new concrete is greater than 6 inches and less than 8 inches. When thicknesses are greater than these values, adjust the cost for this work type proportionately. See UFC 3-250-04 and UFC 3-260-02.
SU-AC	Surface Course - AC	SqFt	This PAVER work type is intended to be used when defining work requirements for the AC surface course and leveling course separately. It is not used by DoD. If included in a DoD database, replace it with the appropriate work type for the section based on one of the approved asphalt pavement work types.
SU-DB	Surface Course - Double Bituminous.	SqFt	A double bituminous surface course is essentially the same as the single bituminous surface course, except that more than one application of binder and aggregate is used. It is not used on airfield pavements except for overruns and not within 200 feet (61 meters) of the threshold. See UFC 3-270-01, Chapter 7, and UFC 3-250-03, Chapter 4.
SU-PC	Surface Course - PCC	SqFt	This PAVER work type is intended to be used when defining work requirements for the surface course and a base course separately. It is not used by DoD. If included in a DoD database, replace it with the appropriate work type for the section based on one of the approved asphalt pavement work types.
SU-PF	Surface Course - Porous Friction	SqFt	A porous friction course is an open-graded, free-draining asphalt mixture that can be placed on an existing pavement to minimize hydroplaning and improve skid resistance. See UFC 3-260-02, Chapter 21, and UFC 3-250-03, Chapter 2.

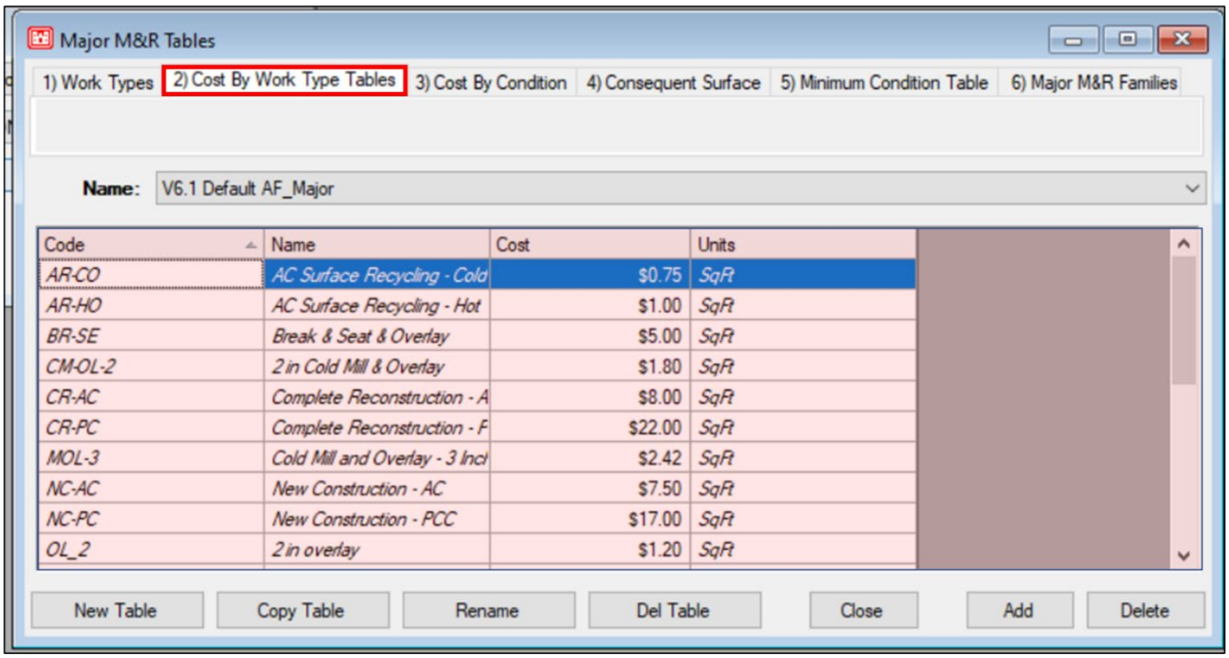
6-5.2 Major M&R Cost by Work Type.

This UFC defines the work elements for each of the standard work types. These work elements are used to define standard Major M&R cost by work type tables for airfields and roads and parking pavements. Paragraph A-2 includes cost by work type templates.

Service Evaluation Teams will update standard cost by work type tables annually using RS Means cost data or Tri-Service Automated Cost Engineering System (TRACES) applications such as the Parametric Cost Engineering System (PACES) or the Micro-Computer Aided Cost Estimating System Second Generation (MII). Use fully burdened unit costs for each of these work types, including O&M escalation factors.

Service Evaluation Teams and consultants performing a PCI survey apply the area cost factor published for that location (e.g., in RS Means) for each work type in the standard tables to adjust the standard unit costs for the specific installation. When there is specific cost data available at an installation for a specific work type, adjust the cost tables to reflect the known costs. Document changes to work component assumptions for a given standard work type in the report so clearly understand the unit cost basis. Use the most recent cost table when defining work planning parameters for a new inspection and delete any cost by work type tables used in previous inspections. An example table is shown in Figure 6-14.

Figure 6-14 Major M&R Cost by Work Type Table



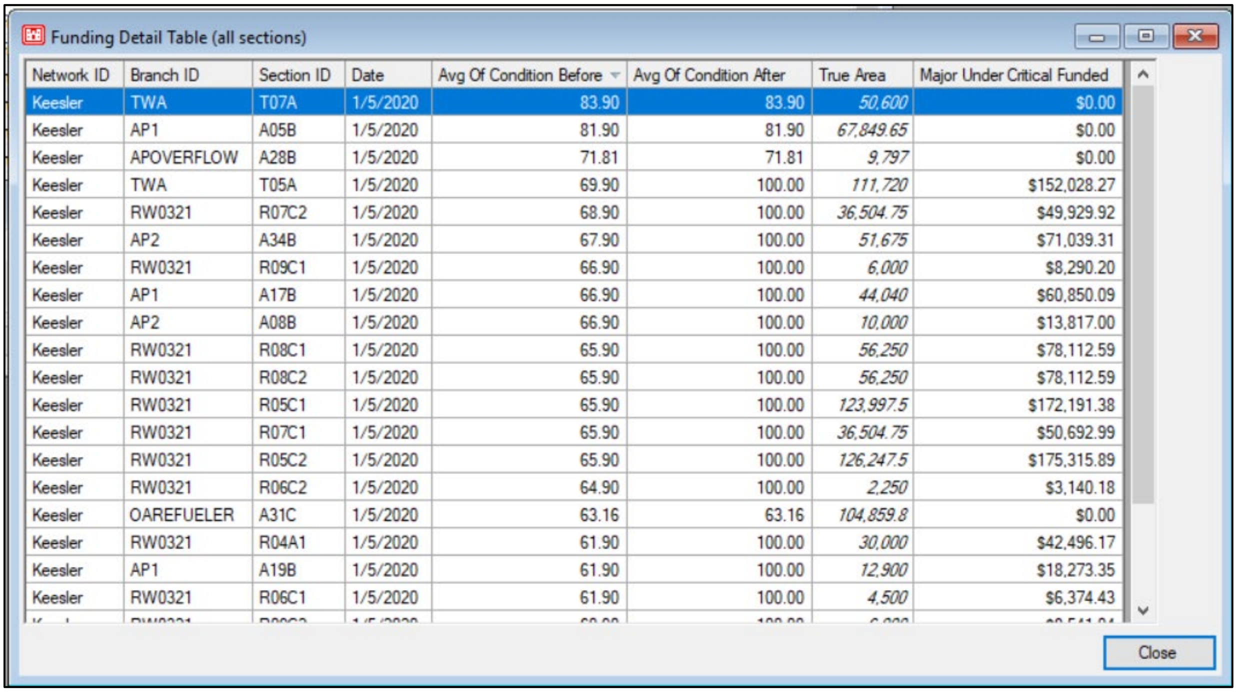
Code	Name	Cost	Units
AR-CO	AC Surface Recycling - Cold	$0.75	SqFt
AR-HO	AC Surface Recycling - Hot	$1.00	SqFt
BR-SE	Break & Seat & Overlay	$5.00	SqFt
CM-OL-2	2 in Cold Mill & Overlay	$1.80	SqFt
CR-AC	Complete Reconstruction - A	$8.00	SqFt
CR-PC	Complete Reconstruction - F	$22.00	SqFt
MOL-3	Cold Mill and Overlay - 3 Inc	$2.42	SqFt
NC-AC	New Construction - AC	$7.50	SqFt
NC-PC	New Construction - PCC	$17.00	SqFt
OL_2	2 in overlay	$1.20	SqFt

6-5.3 Major M&R Cost by Condition.

After completing the PCI survey, updating the work types and cost by work type tables, and assigning the M&R families, run a “One-year Unconstrained Budget” work plan for Major M&R on asphalt and one for concrete without “major above critical,” as described in Chapter 7.

After running the work plan, select the **Funding Detail Table (all sections)** work plan view and export it to Excel. In Excel, unhide all columns, create a column to compute the major M&R unit cost (Major Under Critical Funded / True Area) for each section, then delete the remaining unneeded columns to create a report like the one in Figure 6-15. Create a scatter plot of the unit cost versus the condition, use the Excel trend line function to create a best-fit curve for the data as shown in Figure 6-16, and display the equation. Use the equation that describes the cost by condition relationship to create the cost by condition table at a minimum of 10-PCI intervals from 0 to 100. Adjust the costs to reflect $0 at PCI 100. Use the unit cost of reconstruction for all PCI values below the Service-defined trigger point PCI for reconstruction. PAVER will interpolate the costs between the intervals when you are above this point at which reconstruction is recommended. Repeat the process to create a separate table for both AC and PCC pavement and populate the cost by condition tables in PAVER.

Figure 6-15 Major M&R Funding by Section



Network ID	Branch ID	Section ID	Date	Avg Of Condition Before	Avg Of Condition After	True Area	Major Under Critical Funded
Keesler	TWA	T07A	1/5/2020	83.90	83.90	50,600	$0.00
Keesler	AP1	A05B	1/5/2020	81.90	81.90	67,849.65	$0.00
Keesler	APOVERFLOW	A28B	1/5/2020	71.81	71.81	9,797	$0.00
Keesler	TWA	T05A	1/5/2020	69.90	100.00	111,720	$152,028.27
Keesler	RW0321	R07C2	1/5/2020	68.90	100.00	36,504.75	$49,929.92
Keesler	AP2	A34B	1/5/2020	67.90	100.00	51,675	$71,039.31
Keesler	RW0321	R09C1	1/5/2020	66.90	100.00	6,000	$8,290.20
Keesler	AP1	A17B	1/5/2020	66.90	100.00	44,040	$60,850.09
Keesler	AP2	A08B	1/5/2020	66.90	100.00	10,000	$13,817.00
Keesler	RW0321	R08C1	1/5/2020	65.90	100.00	56,250	$78,112.59
Keesler	RW0321	R08C2	1/5/2020	65.90	100.00	56,250	$78,112.59
Keesler	RW0321	R05C1	1/5/2020	65.90	100.00	123,997.5	$172,191.38

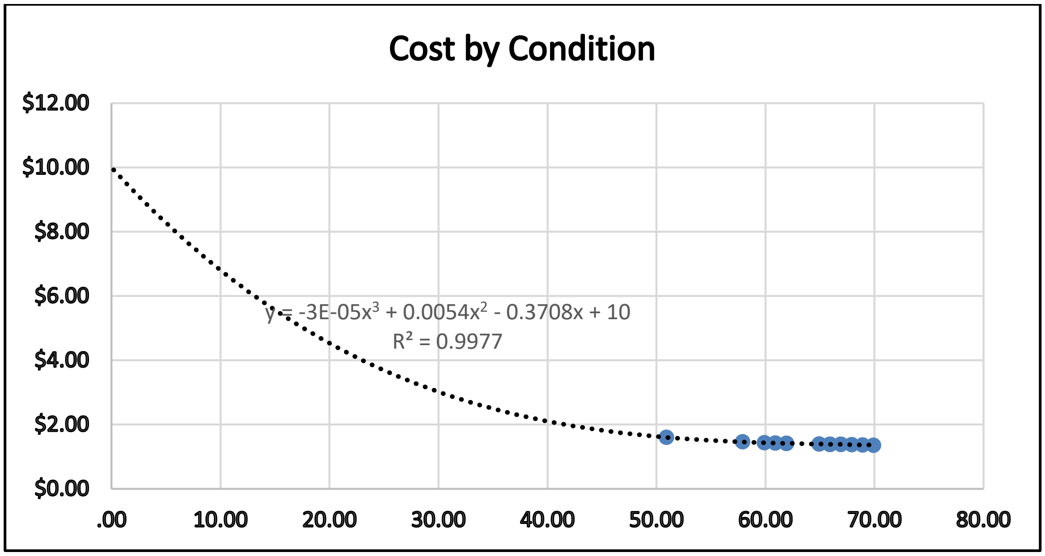
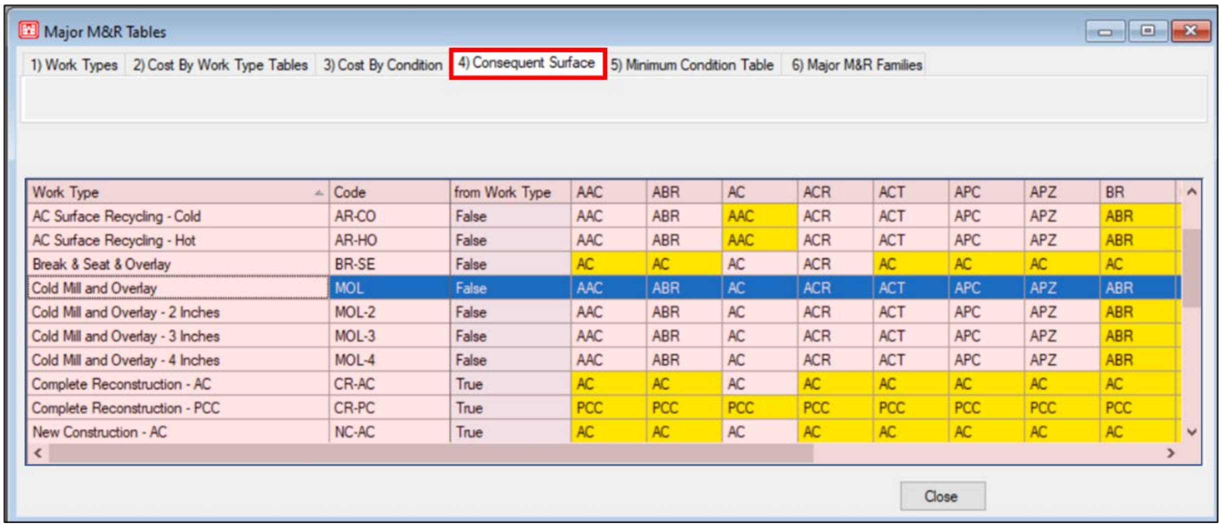
Figure 6-16 Major M&R Unit Cost by Condition Trend Line



6-5.4 Major M&R Consequent Surface.

The Major M&R Consequent Surface table defines the consequent (resultant) surface produced when a given work type is performed over different surface types. Only PAVER default surface types and Major M&R work types are permitted. Go to **System Tables and Tools**>>**Edit Inventory Picklists**>>**Engineering Fields** and delete any user-defined surface types from the database when doing a new PCI evaluation. Figure 6-17 shows an example consequent surface table.

Figure 6-17 Major M&R Consequent Surface Table



Work Type	Code	from Work Type	AAC	ABR	AC	ACR	ACT	APC	APZ	BR

6-5.5 Major M&R Minimum Condition.

The Major M&R Minimum Condition table allows the user to set the minimum acceptable condition for each year. Update this table when a Minimum Condition M&R Work Plan is required when doing M&R Work Planning. Note that the Services do not typically use Minimum Condition M&R Work Plans.

6-5.6 Major M&R Families.

The final steps of the major M&R family model process involve creating the M&R family, assigning the minimum condition and cost by condition tables to the family, and then assigning the model to the appropriate sections.

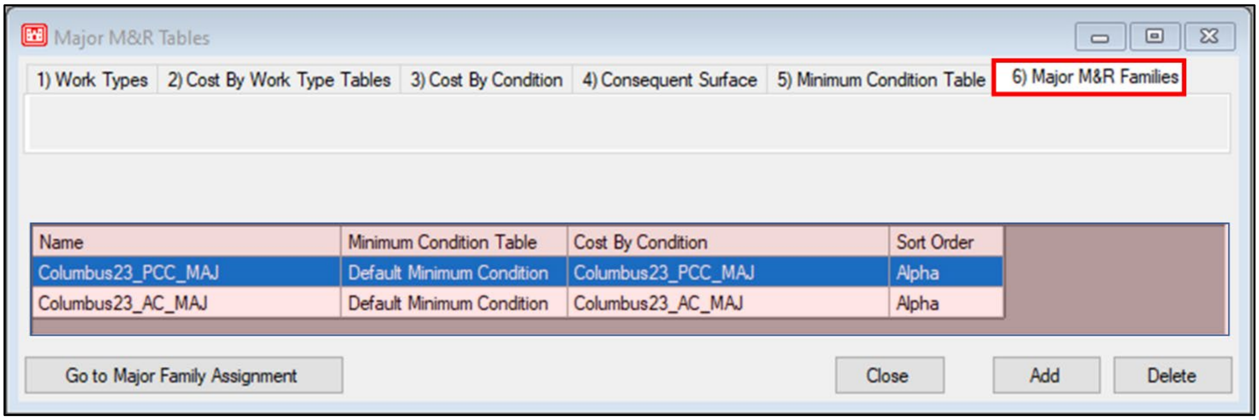
6-5.6.1 Create Major M&R Families.

Add an asphalt and PCC family using the standard convention below, with the acronym MAJ for major M&R.

- Site **NameYr_Pavement Type_M&R Category**
- For example, **Columbus23_AC_MAJ**

Assign the default minimum condition table to the major M&R family and assign the appropriate cost by condition table created in the previous section using the drop-down in the **Minimum Condition Table** and **Cost By Condition** columns as shown in Figure 6-18. Delete all old or unused major M&R family models and all unused tables.

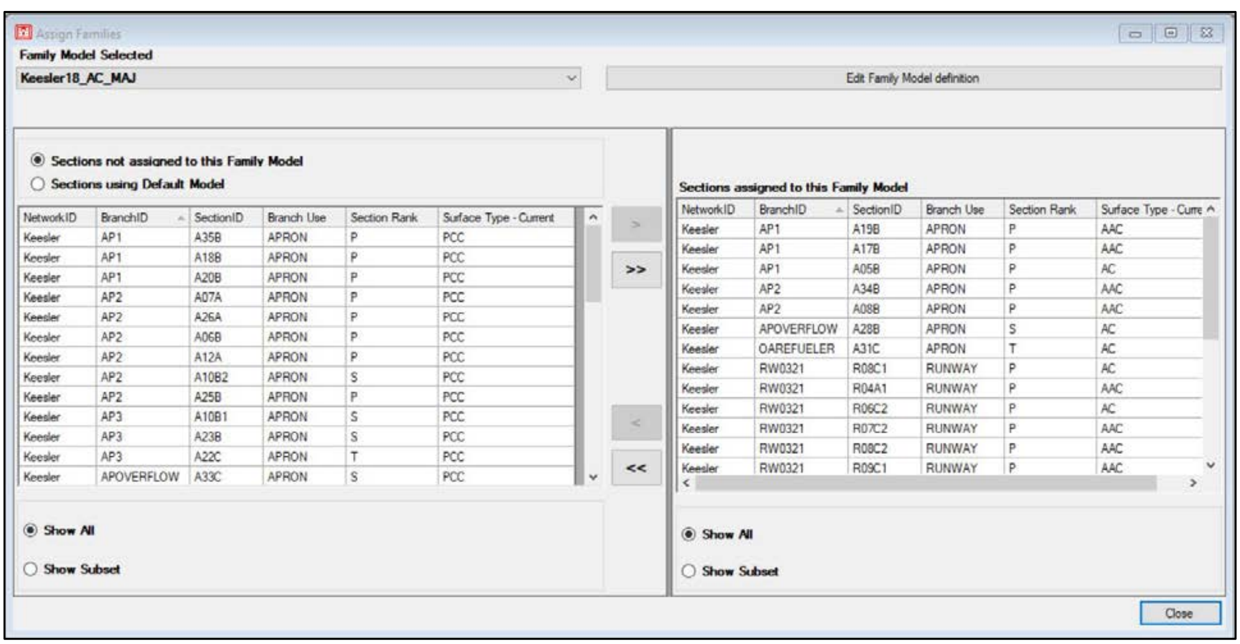
Figure 6-18 Major M&R Families



6-5.6.2 Assign Major M&R Families to Sections.

Each of the families created above are assigned to the appropriate sections by selecting the **Go to Major Family Assignment** button. For example, the asphalt major M&R family is assigned to all AC sections using the PAVER query tool. Open the query tool by selecting the **Show Subset** radio button in Figure 6-19. Assign a family to every paved section that was inspected. Unpaved or unused sections and sections that did not have a PCI inspection may be assigned to the default family model and excluded when running the M&R work plans.

Figure 6-19 Assign Sections to Major M&R Families

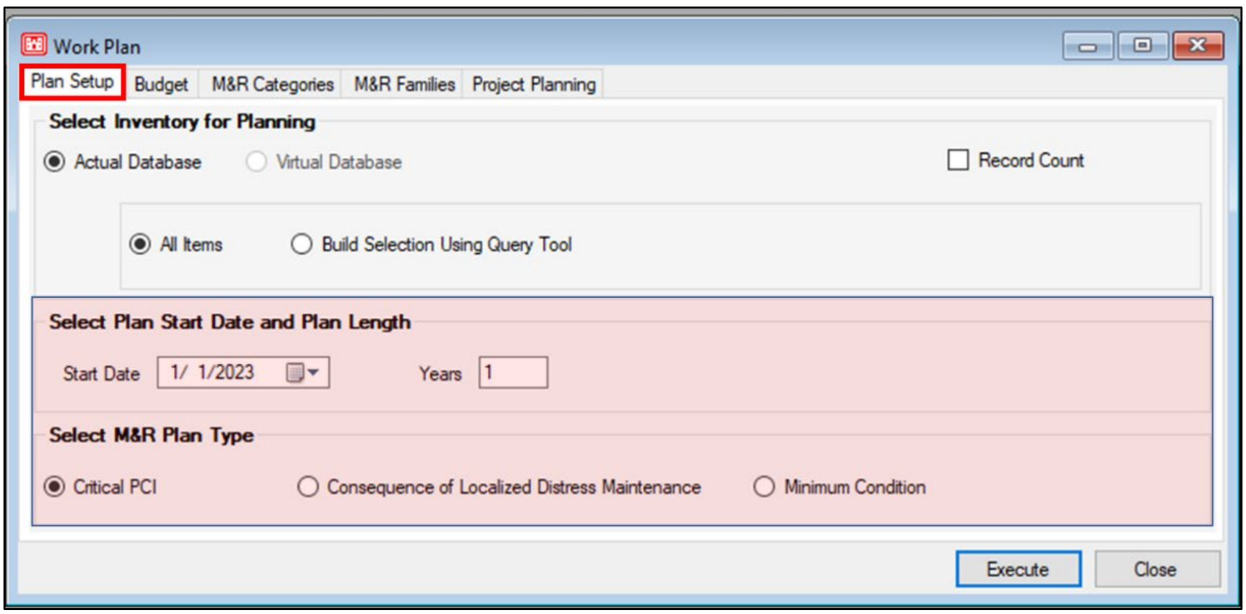


CHAPTER 7 MAINTENANCE AND REPAIR WORK PLANNING

7-1 INTRODUCTION.

M&R work plans outline the M&R requirements for each section based on the assigned PCI deterioration families, M&R family models, and parameters defined on the five work plan tabs as shown in Figure 7-1. The Services use several standard work plans described in this chapter, including consequence of localized distress maintenance, one-year unconstrained, eliminate backlog, maintain current condition, and operational (stopgap/safety) only.

Figure 7-1 M&R Work Plan Form



7-2 WORK PLAN SETUP.

Use the **Plan Setup** tab shown in Figure 7-1 to define the sections included in the work plan, set the plan start date and length, and select the M&R plan type. The other tabs and options shown on these tabs will change based on the selected M&R plan type.

7-2.1 Select Sections for Planning.

Standard practice is to use the **Actual Database** option to run work plans. When all sections in the inventory are inspected and assigned to families, use the **All Items** option, as shown in Figure 7-1. When there are sections that were not inspected or assigned to families, filter these sections using the **Build Selection Using Query Tool** option. The **Virtual Database** option runs work plans on aggregated sections in a virtual inventory. This option is not typically used for individual installations but is useful when analyzing rollup databases. This option is only active when the user creates a virtual inventory (database).

7-2.2 Select Plan Start Date and Plan Length.

As shown in Figure 7-1, standard practice is to use January first of the year following the current inspection year as the plan start date. Run both the Critical PCI Unconstrained work plan and the Consequence of Localized Distress Maintenance work plan for one year. Run Constrained Critical PCI work plans for a minimum of five years as described in paragraph 7.5.4 or for longer periods to meet Service-specific requirements.

7-2.3 Select M&R Plan Type.

There are three M&R work plan types as shown in Figure 7-1: **Critical PCI**, **Consequence of Localized Distress Maintenance**, and the **Minimum Condition** work plans. Each is described below.

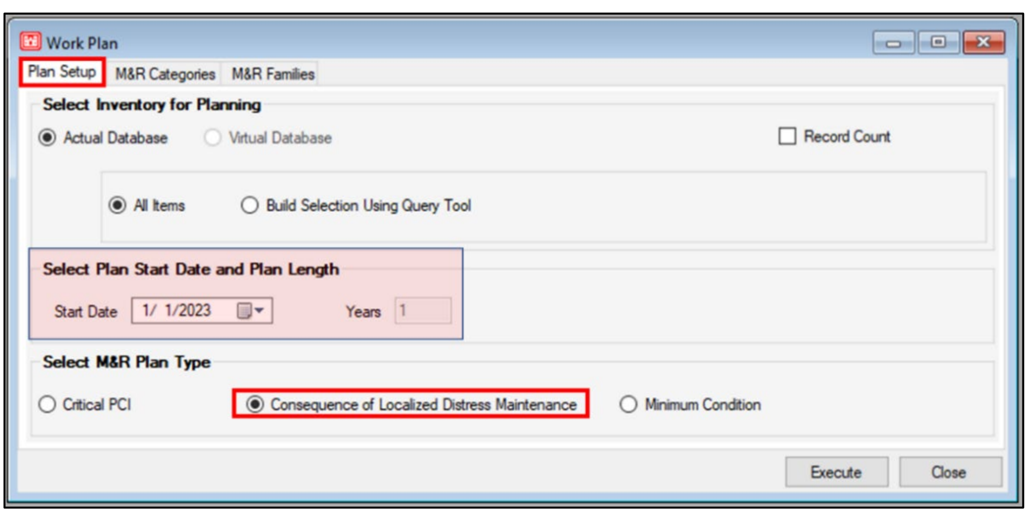
7-3 MINIMUM CONDITION WORK PLAN.

The minimum condition work plan lets the user set the lowest pavement condition (PCI) that is allowed per year using the minimum condition table (defined in the major M&R family model). The Services do not use the Minimum Condition work plan, so this UFC does not discuss the details of the Minimum Condition approach.

7-4 CONSEQUENCE OF LOCALIZED DISTRESS MAINTENANCE.

The consequence of localized distress maintenance work plan generates a list of all the localized work requirements based on the assigned distress maintenance policy, calculates the cost of each requirement based on the cost by work type tables, and computes the resulting conditions when the distresses are repaired based on the consequence of maintenance policy. The plan is set to one year by default, as shown in Figure 7-2, and is based on the PCI data from the most recent inspection. Note, the **Budget** and **Project Planning** tabs are not used when running a Consequence of Localized Distress Maintenance work plan.

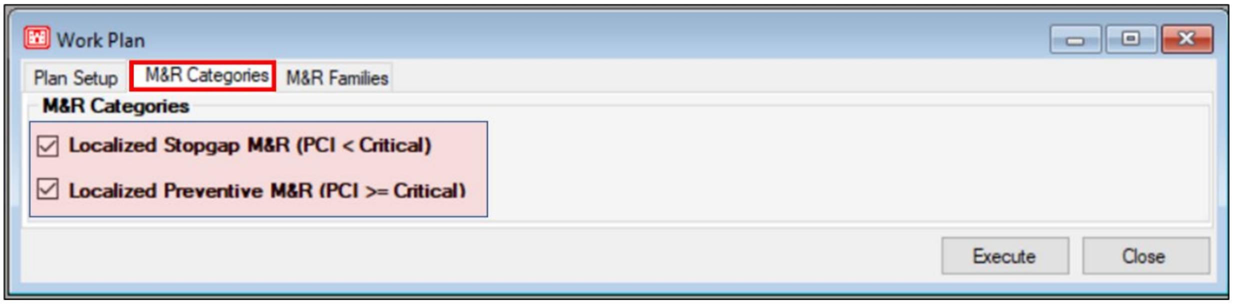
Figure 7-2 Consequence of Localized Distress Maintenance Work Plan



7-4.1 M&R Categories Tab.

Select both **Localized Stopgap M&R** and **Localized Preventive M&R** when running the consequence of localized distress maintenance work plan. Note that global and major M&R are not options on this tab since the focus is on localized M&R.

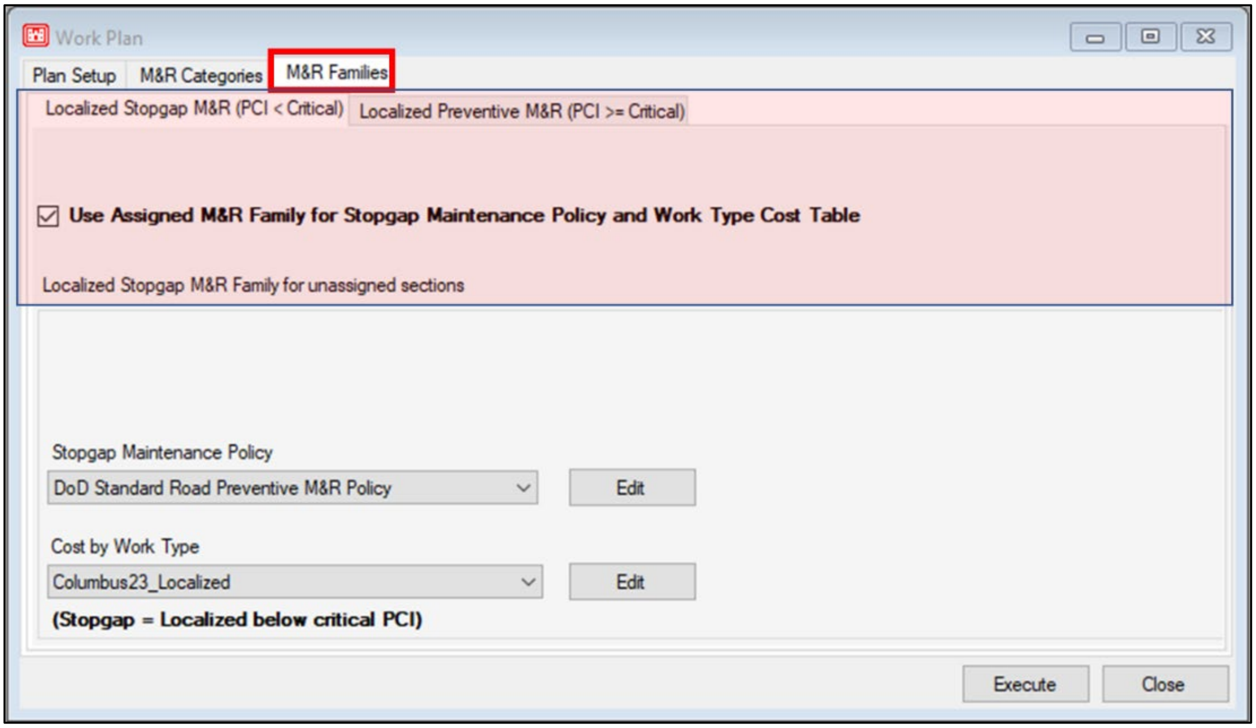
Figure 7-3 M&R Categories Tab



7-4.2 M&R Families Tab.

As shown in Figure 7-4, the **Use Assigned M&R Family for Stopgap Maintenance Policy and Work Type Cost Table** checkbox is checked by default for both **Localized Stopgap M&R** and **Localized Preventive M&R**. The option to define a default policy and cost by work type table for any unassigned sections is not typically used by the DoD since only sections with a current PCI inspection, an assigned PCI family, and an assigned M&R family are included in the work plan.

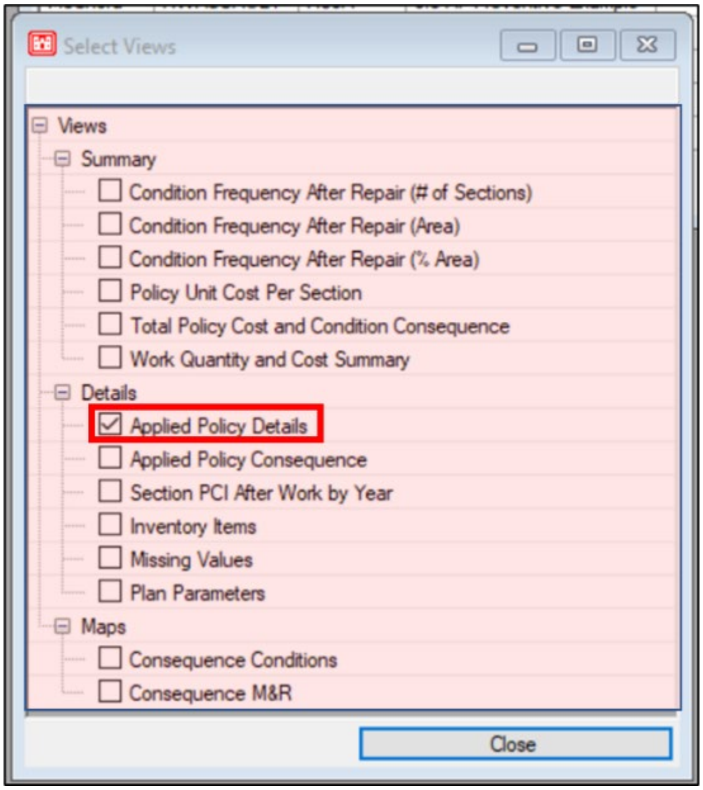
Figure 7-4 M&R Families Tab



7-4.3 Consequence of Localized Distress Maintenance Reports.

PAVER generates several reports (views) for the consequence of localized distress maintenance work plan as shown in Figure 7-5. The **Applied Policy Details** view is used to define specific work types and estimated quantities when developing a PMP, as described in paragraph 8-7. See paragraphs A-6 and A-7 for examples.

Figure 7-5 M&R Work Plan Views



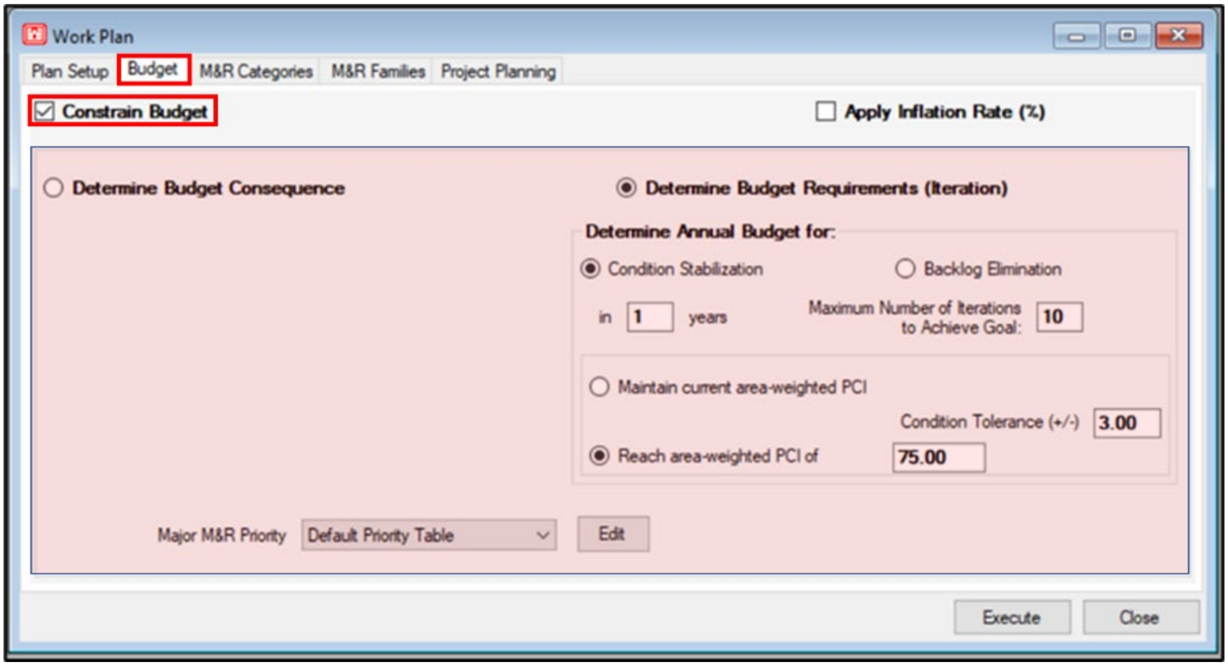
7-5 CRITICAL PCI WORK PLANS.

Select the Critical PCI M&R Plan Type on the **Plan Setup** tab to run Critical PCI work plans. These plans use the critical PCI of the section determined by the section rank, as described in paragraphs 3-4 and 5-4 as the mechanism for triggering Major M&R requirements. Select one of the critical PCI work plans as the optimal critical PCI work plan as described in Paragraph 8-5 to develop the PMP. See paragraphs A-5 and A-7 for examples.

7-5.1 Budget.

The **Budget** tab provides options to select a constrained (checked) or unconstrained (unchecked) budget. When checked, other options to define constrained budget parameters are available, as shown in Figure 7-6.

Figure 7-6 M&R Work Plan Budget Tab



7-5.2 Apply Inflation Rate.

Leave the **Apply Inflation Rate (%)** box unchecked. When selected, PAVER applies a user-defined inflation rate percentage to all work plans. Inflation rates are applied to budget requirements as part of the DoD budgeting process, so checking this box results in a double application of an inflation rate.

7-5.3 Unconstrained Budgets.

Leave the **Constrain Budget** box unchecked to create an unconstrained work plan. Set the plan length to one year on the **Plan Setup** tab to generate a work plan that addresses all current M&R requirements based on the parameters defined in the M&R family models. Grouping all M&R requirements for each section in a pavement facility provides an estimate of the total real property M&R requirements for each facility. This total facility M&R cost can be used as the numerator in the facility condition index computation for each facility when Service real property guidance permits.

The one-year unconstrained work plan is also used to develop Major M&R cost by condition tables as described in paragraph 6-5.3. Unlike running a consequence of localized distress maintenance work plan, where PAVER uses the cost by work type table to generate cost data, when running a critical PCI type plan, PAVER uses the cost by condition table to generate cost data. Therefore, you can see a cost difference for localized M&R between a one-year unconstrained work plan and the consequence of localized distress maintenance work plan. The latter is typically more accurate when running work plans at the time of a PCI inspection. An example of an unconstrained work plan is included in paragraph A-5.

7-5.4 Constrained Budget.

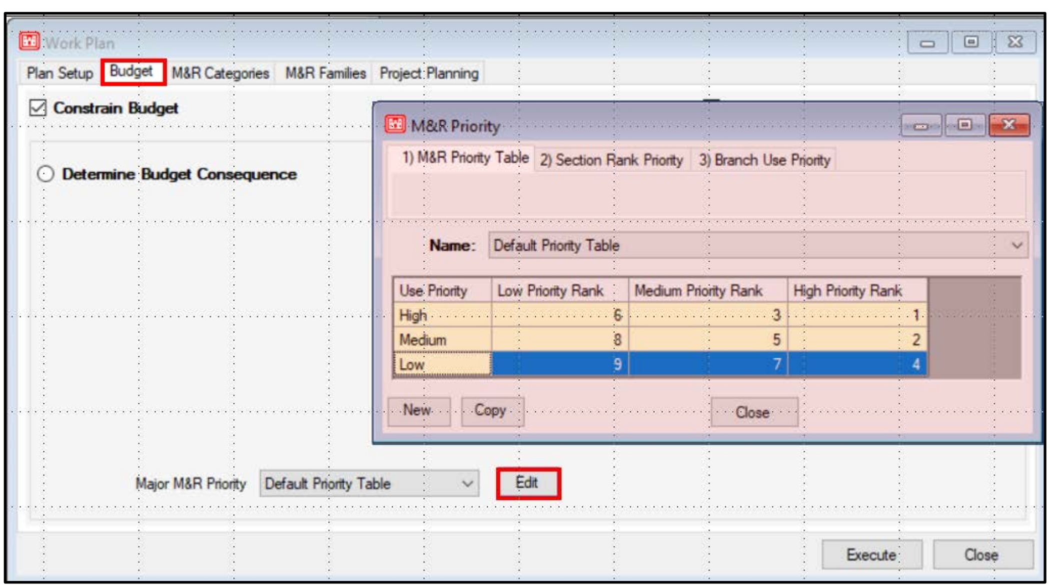
When the **Constrain Budget** box is checked on the **Budget** tab, PAVER develops a work plan to address all M&R requirements based on the parameters defined on the work plan **Budget** and **M&R Categories** tabs, as well as the M&R family models. DoD uses the eliminate backlog work plan and maintain current condition M&R work plan. The standard timeline for constrained budgets used by the DoD is five years, although circumstances or specific mission requirements may require increasing this timeline Constrained work plans are explained in more detail below and examples of constrained work plans are included in paragraph A-6.

7-5.5 Major M&R Priority Table.

When the **Constrain Budget** box is checked, the **Major M&R Priority** option is activated at the bottom of the form as shown in Figure 7-7. Select the **Edit** button to view priority tables. Only use the standard DoD priority tables defined in the UFC when doing major M&R work planning for airfield or road and parking pavements.

The **Major M&R Priority** option shown on the **Budget** tab is activated when the **Constrain Budget** box is checked, as shown in Figure 7-7. This table sets the priority PAVER uses to determine the order of requirements when running a constrained workplan. Selecting the **Edit** button brings up the form. Define the **Section Rank Priority** and **Branch Use Priority** (High, Medium, or Low) on tabs 2 and 3, then set the priority hierarchy on tab 1. Only use the standard DoD priority tables defined in this UFC.

Figure 7-7 Major M&R Priority Table



7-5.5.1 Branch Use Priority Table.

Table 3-2 defines branch use categories for both airfields and roads and parking. The priorities associated with these branch uses are defined in Table 7-1.

Table 7-1 Branch Use Priority Table

Airfield Branch Use Priority			Road and Parking Branch Use Priority		
Use Code	**Description**	**Priority**	**Use Category**	**Description**	**Priority**
RUNWAY	RUNWAY	High	ROADWAY	ROADWAY	High
TAXIWAY	TAXIWAY	Medium	MTRPOOL	MTRPOOL	Medium
HELIPAD	HELIPAD	Medium	OTHER	OTHER	Medium
APRON	APRON	Low	ROUND	ROUNDABOUT	Medium
BLAST PAD	BLAST PAD	Low	CLOSED-RD	CLOSED ROADWAY	Low
CARGO	CARGO	Low	DRIVEWAY	DRIVEWAY	Low
CLOSED-AF	CLOSED AIRFIELD	Low	PARKING	PARKING	Low
DEICING	DEICING	Low	SHOULDER-RD	ROAD SHOULDER	Low
OVERRUN	OVERRUN	Low	STORAGE	STORAGE	Low
SHOULDER-AF	AIRFIELD SHOULDER	Low			
LINE VEHICLE	GROUND EQUIPMENT	Low			

7-5.5.2 Section Rank Priority Table.

Table 3-4 defines the section ranks for both airfields and roads and parking. The priorities associated with these section ranks are defined in Table 7-2.

Table 7-2 Section Use Priority Table

Section Rank Priority Airfields, Road, and Parking		
Section Rank	**Description**	**Priority**
P	Primary	High
S	Secondary	Medium
T	Tertiary	Low
U	Unused	Low

7-5.5.3 Major M&R Priority Table.

The M&R priority hierarchy is the same for both airfields and roads and parking as shown in Table 7-3. An example implementation for an airfield is shown in Table 7-4 and a road and parking example is shown in Table 7-5.

Table 7-3 Major M&R Priority Table

M&R Priority Table			
Use Priority	High Priority Rank	Medium Priority Rank	Low Priority Rank
High	1	3	6
Medium	2	5	8
Low	4	7	9

Table 7-4 Airfield M&R Priority Table Example

Airfield M&R Priority Table Example			
Use Priority	High Priority Rank	Medium Priority Rank	Low Priority Rank
High	1 Main Runway	3 Crosswind Runway	6 Auxiliary Runway
Medium	2 Parallel Taxiway	5 Ladder Taxiway	8 Occasional Use Helipad
Low	4 Primary Apron	7 Transient Apron	9 Wash Rack

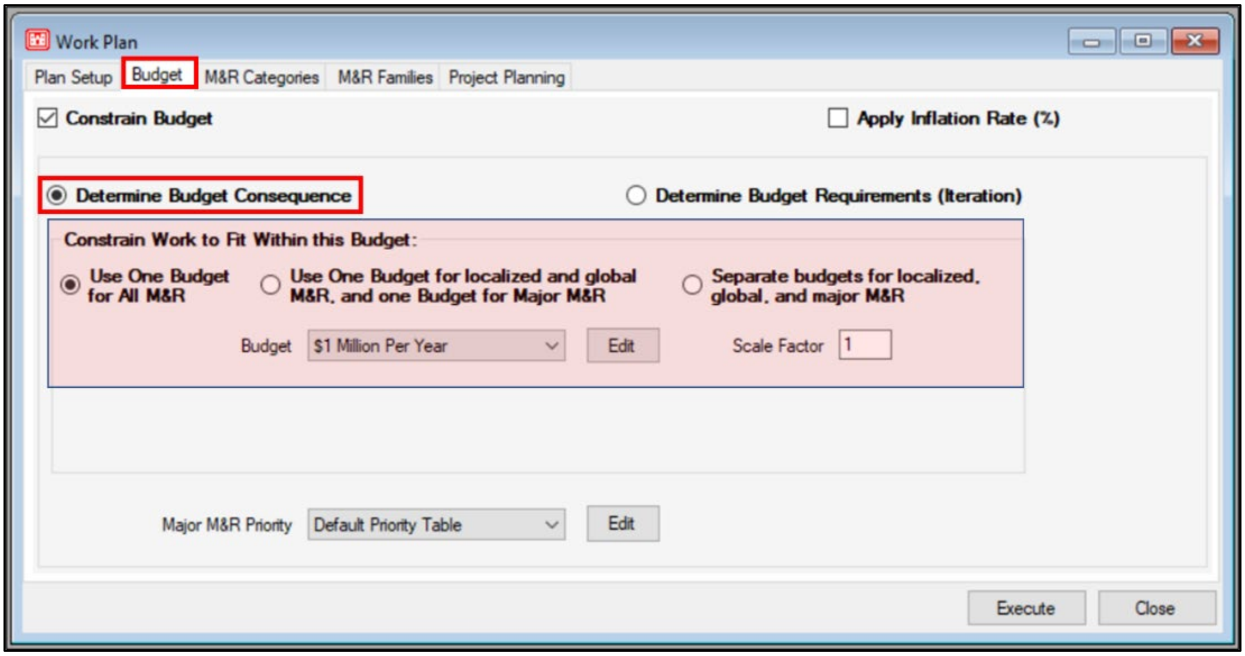
Table 7-5 Section Use Priority Table

Road and Parking M&R Priority Table Example			
Use Priority	High Priority Rank	Medium Priority Rank	Low Priority Rank
High	1 Primary Road (Arterial)	3 Collector Streets	6 Local Streets
Medium	2 Roundabout	5 Motor Pool	8 Other Pavement
Low	4 Hospital Parking Area	7 Facility Parking	9 Driveway

7-5.6 Determine Budget Consequence.

The **Determine Budget Consequence** option is activated when the **Constrain Budget** box is checked. This option allows the user to apply a known budget and have PAVER generate a work plan to fit that budget. DoD installations cannot typically predict future budgets with any level of accuracy so this option is not used by the Services.

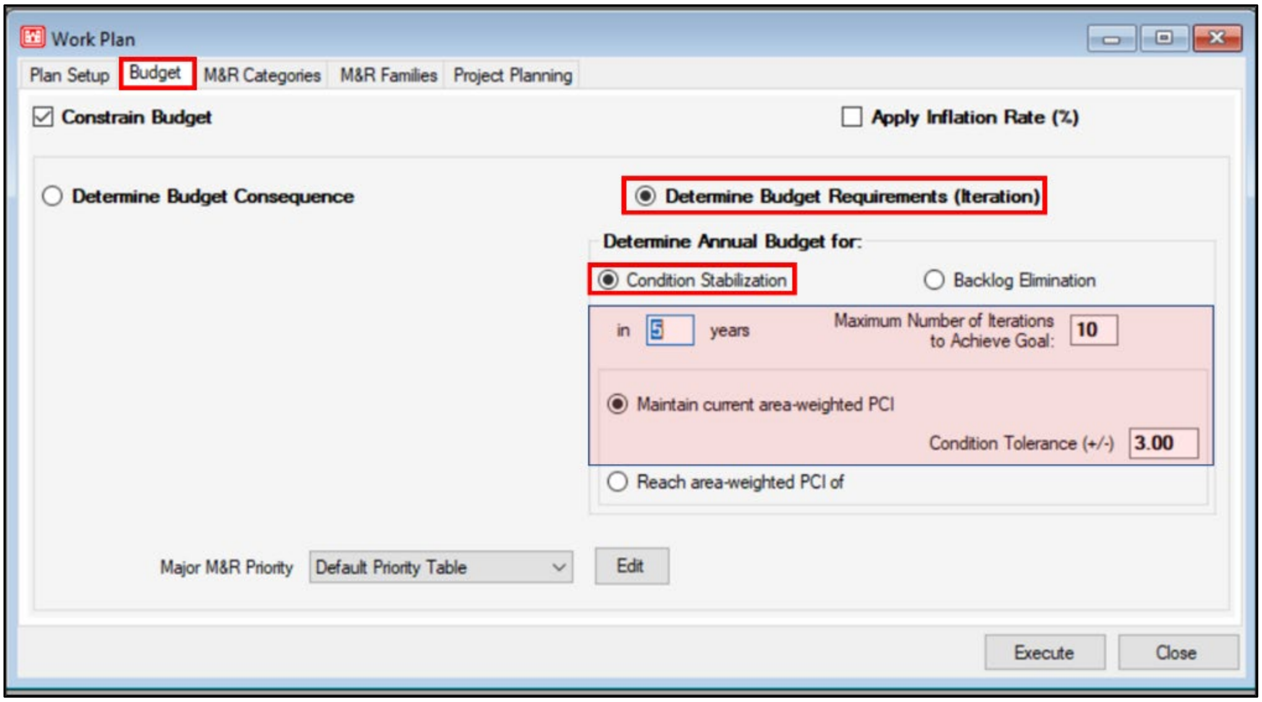
Figure 7-8 Determine Budget Consequence



7-5.7 Determine Budget Requirements.

The **Determine Budget Requirements (Iteration)** option is activated when the **Constrain Budget** box is checked. This option allows the user to determine an annual budget required to maintain the current condition (condition stabilization) or eliminate the M&R backlog, as shown in Figure 7-9. In either case, the goal is to balance the M&R work plan budget over the period of the work plan using the parameters defined on the work plan **Budget** and **M&R Categories** tabs as well as the M&R family models. PAVER generates an initial plan, but if the plan does not meet the goal, PAVER adjusts the plan and goes through another iteration until the goal is achieved.

Figure 7-9 Determine Budget Requirements – Condition Stabilization



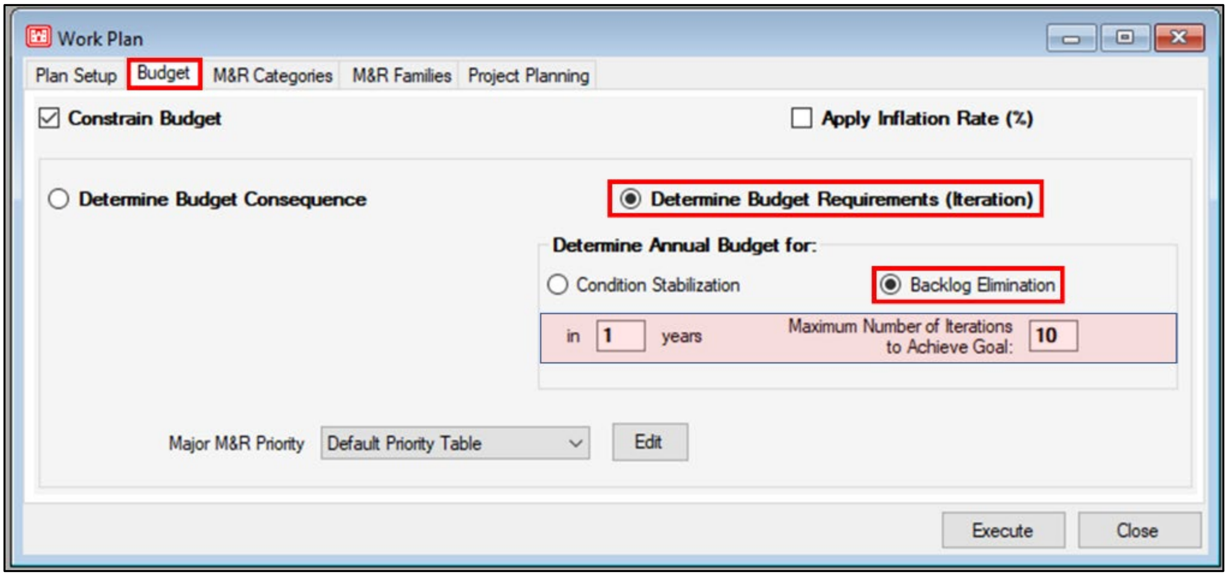
7-5.7.1 Determine Annual Budget for Condition Stabilization.

The Annual Condition Stabilization Budget is a standard work plan for DOD. This option generates a work plan that either reaches a defined area-weighted PCI within a specified period and condition tolerance or maintains the current area-weighted PCI within a specified condition and tolerance. The **Maintain current area weighted PCI** is typically used. As shown in Figure 7-9, set the plan length to five years and set the condition tolerance to ±3.00. This plan is typically the optimal critical PCI work plan when the current area-weighted PCI of the network is above 85.

7-5.7.2 Determine Annual Budget for Backlog Elimination.

The Determine Annual Backlog Elimination budget is also a standard work plan for DOD This option generates a work plan that includes Major M&R requirements for all sections below the critical PCI within the specified time frame. The plan length is set at a minimum of five years on the **Plan Setup** tab and the period is set at five years on the **Budget** tab. This plan is typically the optimal critical PCI work plan when the current area weighted PCI of the network is below 85.

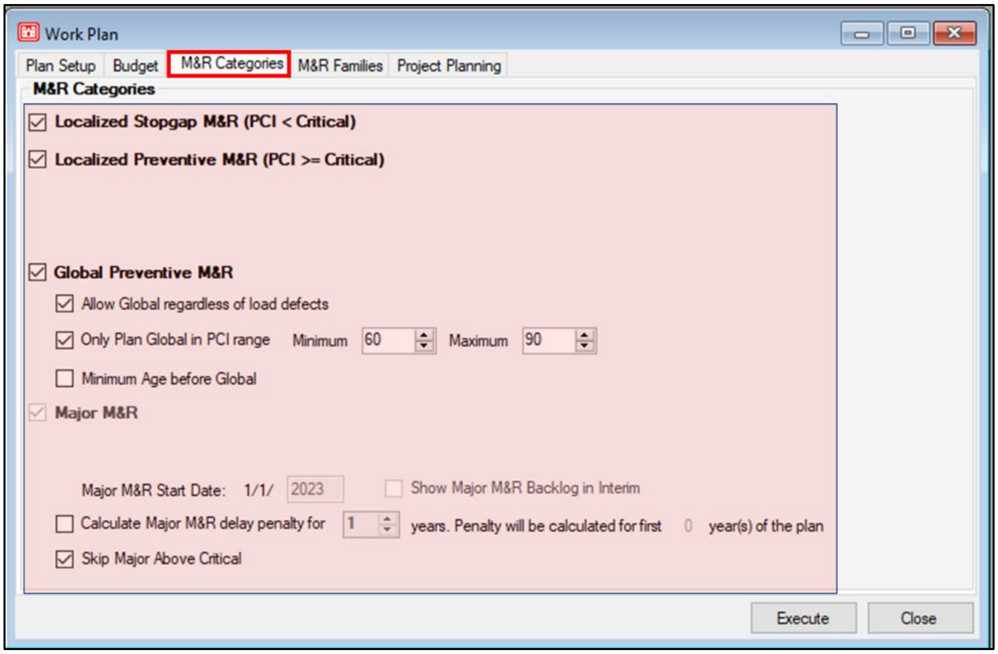
Figure 7-10 Determine Budget Requirements – Backlog Elimination



7-6 M&R CATEGORIES.

The **M&R Categories** tab allows the user to define the type of M&R included in the work plan. The standard approach is to select all M&R types when running any of the critical PCI M&R type plans, as shown in Figure 7-11.

Figure 7-11 M&R Categories Tab



7-6.1 Localized Operational (aka Safety or Stopgap) M&R.

When the **Localized Stopgap M&R (PCI < Critical)** box is checked, PAVER generates an operational M&R requirement for any section with a PCI below critical that does not have a major M&R requirement included in the work plan. This occurs when PAVER is going through the iteration process and cannot plan a major M&R requirement within the defined constraints. While the operational M&R work types are the same as those used for preventive M&R, the maintenance policy is different. The objective is to maintain safety of operations rather than pavement preservation. All cost projections are based on the cost by condition tables.

7-6.2 Localized Preventive M&R.

When the **Localized Preventive M&R (PCI > Critical)** box is checked, PAVER generates preventive M&R requirements for any section with a PCI above critical and distresses that require repair according to the preventive M&R maintenance policy. Just as with Operational M&R, PAVER uses the cost by condition table to generate cost data for localized preventive as opposed to running a Consequence of Localized Distress Maintenance work plan that uses the cost by work type table to generate cost data. When there is a difference, the Consequence of Localized Distress Maintenance work plan is typically more accurate when running work plans at the time of a PCI inspection, but may be less accurate in out-years.

7-6.3 Global Preventive M&R.

When the **Global Preventive M&R** box is checked, PAVER generates global M&R requirements for all sections included on the **Plan Setup** tab using the parameters defined in the global M&R family model and the standard global PCI range. Note that all global preventive M&R costs are generated using cost by work type tables.

7-6.3.1 Only Plan Global in PCI Range.

Set the global PCI range maximum value to 95. The minimum varies according to Service policies based on the mission aircraft. For example, a primary pavement could have a range of 70 to 95, so once the PCI of a section drops below 95, PAVER generates a global M&R requirement using the work type for the respective distress category (minimal, climate-related, and skid causing) and the application interval defined in the family model. Once the PCI drops below 70 for this example, PAVER will not generate a Global M&R requirement.

7-6.3.2 Minimum Age Before Global.

Leave the **Minimum Age before Global** box unchecked. It defines the minimum age before Global Preventive M&R is applied but is not used in DoD work plans.

7-6.4 Major M&R.

As shown in Figure 7-12, the **Major M&R** box is checked by default and is inactive because Major M&R is required to achieve the critical PCI work plan objective. PAVER generates Major M&R requirements for any section below the critical PCI.

7-6.4.1 Calculate Major M&R Delay Penalty.

PAVER reports any delay costs associated with delaying the start date of Major M&R over the length of the work plan when the **Calculate Major M&R Delay Penalty** box is checked, as shown in Figure 7-12. When the user defines the delay length, PAVER generates a report like the one in Figure 7-13. This example shows the cost for section R04A1 goes up by 7 percent if we delay Major M&R for one year, so the cost for the project after a one-year delay would be $43,104.6 * 1.07 = $46,121.92. Delay penalties are a deciding factor when scheduling PMP projects.

Figure 7-12 Critical PCI Work Plan – Major M&R Settings

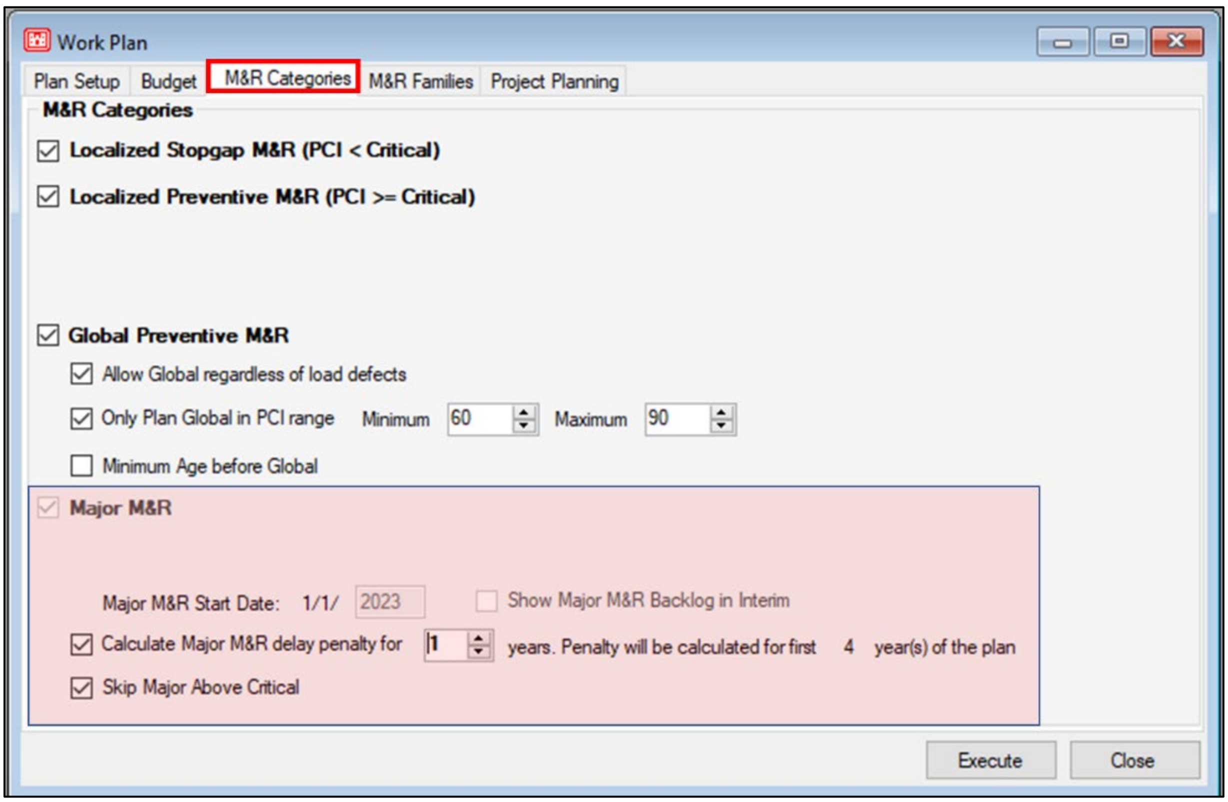


Figure 7-13 Delay Penalty

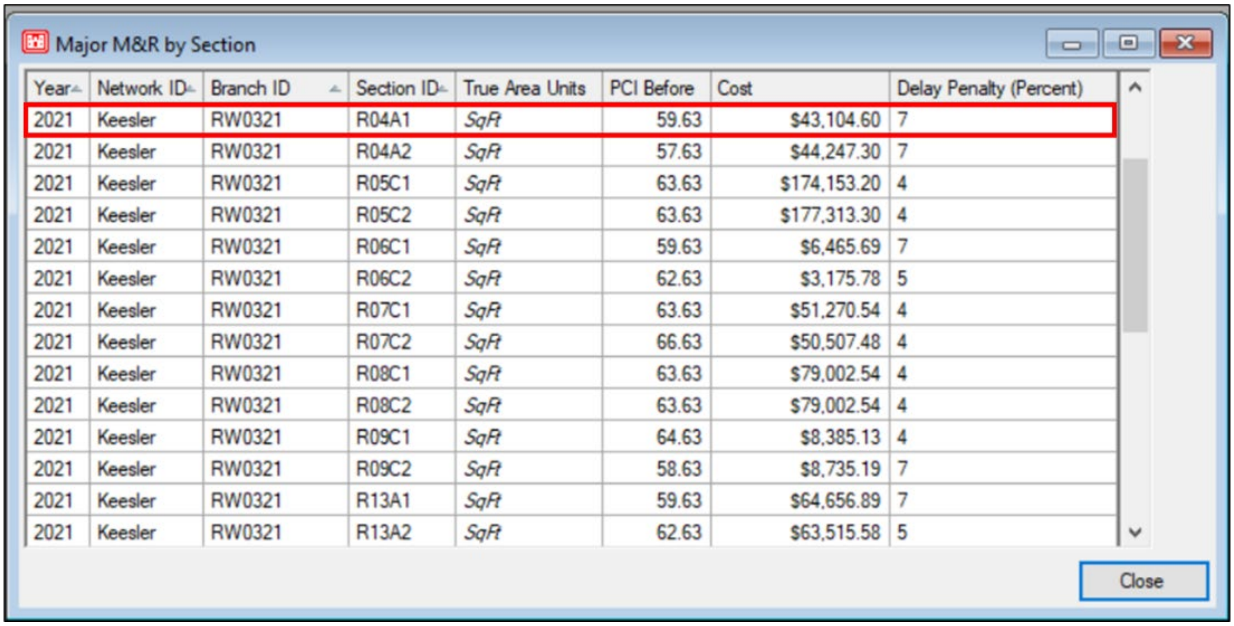


Year	Network ID	Branch ID	Section ID	True Area Units	PCI Before	Cost	Delay Penalty (Percent)
2021	Keesler	RW0321	R04A1	SqFt	59.63	$43,104.60	7
2021	Keesler	RW0321	R04A2	SqFt	57.63	$44,247.30	7
2021	Keesler	RW0321	R05C1	SqFt	63.63	$174,153.20	4
2021	Keesler	RW0321	R05C2	SqFt	63.63	$177,313.30	4
2021	Keesler	RW0321	R06C1	SqFt	59.63	$6,465.69	7
2021	Keesler	RW0321	R06C2	SqFt	62.63	$3,175.78	5
2021	Keesler	RW0321	R07C1	SqFt	63.63	$51,270.54	4
2021	Keesler	RW0321	R07C2	SqFt	66.63	$50,507.48	4
2021	Keesler	RW0321	R08C1	SqFt	63.63	$79,002.54	4
2021	Keesler	RW0321	R08C2	SqFt	63.63	$79,002.54	4
2021	Keesler	RW0321	R09C1	SqFt	64.63	$8,385.13	4
2021	Keesler	RW0321	R09C2	SqFt	58.63	$8,735.19	7
2021	Keesler	RW0321	R13A1	SqFt	59.63	$64,656.89	7
2021	Keesler	RW0321	R13A2	SqFt	62.63	$63,515.58	5

7-6.4.2 Skip Major Above Critical.

Standard policy is to check the **Skip Major Above Critical** box, let the PCI deteriorate to the critical PCI before generating a Major M&R requirement, and then address any structural issues. The exception to this is when there is a mission change at an installation that requires an increase in the structural capability of the pavement. When this box is unchecked, PAVER will generate Major M&R requirements when the PCI of a section is above critical, but the section has a structural distress density above 10 percent.

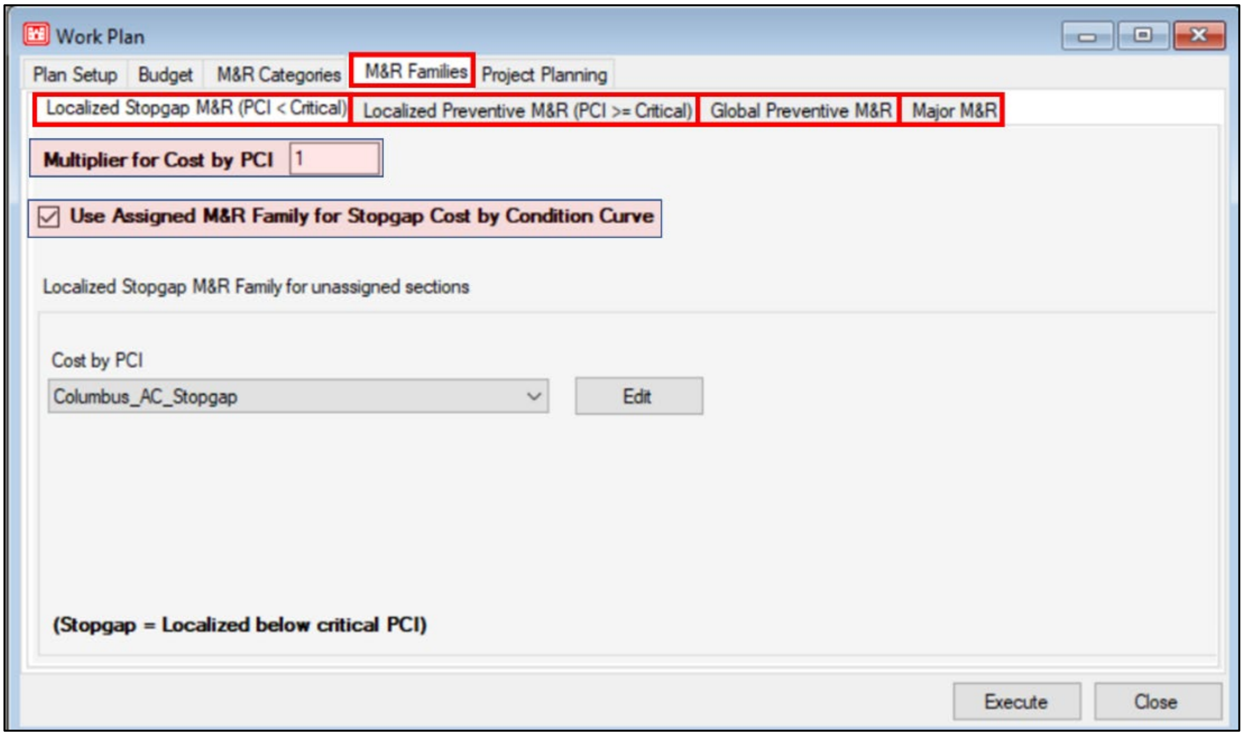
7-7 M&R FAMILIES.

The **M&R Families** tab allows the user to define the M&R family models to be used in the M&R plan. As shown in Figure 7-12, there is a tab for each M&R category. On each tab is a **Use Assigned M&R Family for Stopgap Cost Curve** checkbox. Each box is checked by default. Ensure every section that has been inspected is assigned to the appropriate family models for each M&R category. There is also an option to define a default M&R category or rule set (in the case of global). Since the standard approach is to assign all sections, the default settings are not needed. Filter out any sections that have not been inspected in the last two PCI cycles when running the work plan.

Define the M&R Family Models used in the M&R work plan on the **M&R Families** tab as shown in Figure 7-14. There is a tab for each M&R category, with the checkbox to **Use Assigned M&R Family for Stopgap Cost by Condition Curve** checked by default. So, when every inspected section is assigned to the appropriate family model for each M&R category, PAVER automatically applies the defined parameters. There is also an option to define a default M&R category or rule set (in the case of Global). Since the standard approach is to assign all sections, the default settings are not needed.

When running the work plan, use the **Query** tool to filter out any sections not inspected in the last two PCI cycles.

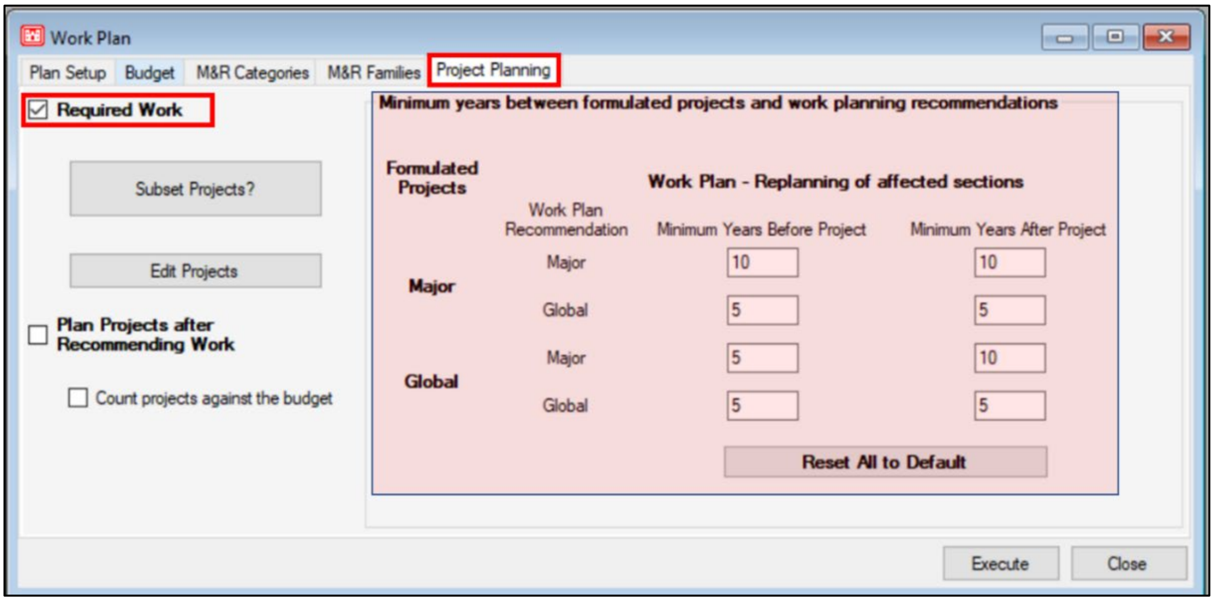
Figure 7-14 M&R Families Tab



7-8 PROJECT PLANNING

When the **Required Work** box is checked on the **Project Planning** tab, PAVER includes all or a subset of projects defined with the Required Work tool or the Project Formulation Wizard in the work plans. The **Project Planning** tab also allows the user to define other work planning parameters, such as the minimum time between projects and other work planning recommendations. Chapter 8 and paragraph A-9 discuss the process of using the M&R requirements from work plans to develop a pavement management plan (PMP). A PMP can be developed using spreadsheets or other tools but developing projects in PAVER and incorporating them into work plans to develop a PMP is considered a best practice.

Figure 7-15 Project Planning Tab



CHAPTER 8 PRIORITIZING REQUIREMENTS

8-1 OBJECTIVE

The level of detail in a pavement management plan (PMP) can range from a spreadsheet with a prioritized list of work tasks and projects in each year of the plan to a detailed document that outlines the team composition and development process, including limiting factors, assumptions, and analysis of alternatives. The objective of this UFC is to define the minimum PMP requirement, a prioritized list of work items and projects required to maintain pavements for each year in the next five calendar years.

8-2 BACKGROUND.

The goal of a PMP is to define and document M&R actions required to maintain operational safety, preserve and extend the life of pavements, and optimize life-cycle costs and pavement condition. The best approach to achieve this goal is to prioritize localized and global preventive maintenance and implement policies to perform Major M&R at the appropriate time as opposed to a "worst first" approach. In a "worst first" approach, pavements are allowed to deteriorate, localized M&R is just used to address issues that pose a safety concern, and Major M&R is prioritized based on which pavement is in the worst condition, with some consideration given to the use (e.g., runway versus taxiway or road versus parking). This UFC is intended to move the DoD away from a "worst first" approach.

8-3 RESPONSIBILITY FOR PAVEMENT MANAGEMENT PLANS.

8-3.1 Service Responsibility.

Each Service centrally manages their pavement evaluation programs and performs pavement evaluations on a regular cycle. These evaluations provide the baseline data to establish a PMP. The Services define specific PMP requirements in Service guidance to supplement the minimum standard outlined in this UFC, e.g., PMP content, development and execution responsibility, timelines, prioritization rules, and format.

8-3.2 Installation Responsibility.

Service teams or consultants gather data during regularly scheduled pavement evaluations and can provide expertise and support for developing a PMP. Installations use this data to develop the PMP in-house or assisted by a consultant, but in either case, installation-level knowledge is the key to developing an effective PMP. So, whether a Service evaluation team, a consultant, or installation personnel develop the PMP, the installation personnel are the only ones that can provide local knowledge and therefore must be fully engaged in the process of developing and maintaining their PMPs for airfield and road and parking pavement. The installation is also responsible for executing PMP projects ranging from day-to-day preventive maintenance performed in-house to larger-scale projects performed by the in-house workforce, by contract, or a combination of both.

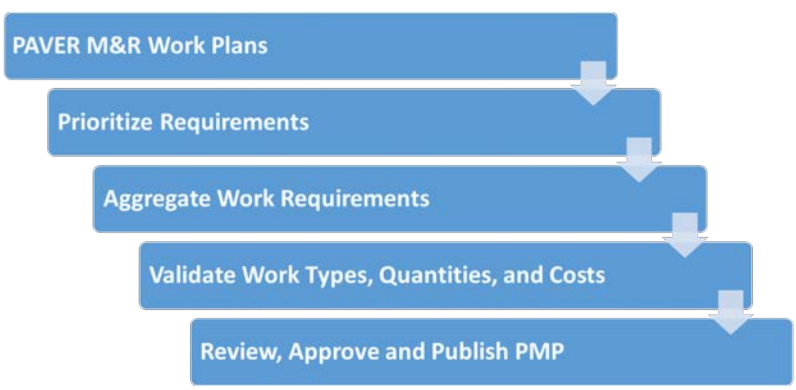
8-3.3 Team Approach.

There are many considerations that go into developing a PMP. Finding effective solutions to these considerations requires knowledge of the mission as well as knowledge of pavement management, design, and construction. The best approach to developing a PMP is to establish a team that brings the necessary skill sets and knowledge to the table. At a minimum, this team will include, if present, installation pavement engineers and technicians responsible for pavements M&R and planning, personnel responsible for managing real property and geospatial information system data, and personnel responsible for airfield management (when developing an airfield PMP).

8-4 PROCESS OVERVIEW.

Previous chapters described the tasks involved in organizing the inventory, determining pavement condition, defining deterioration rates, cost by work type and condition tables, and other work plan parameters culminating in the PAVER M&R work plans discussed in Chapter 7. These initial work plans provide the starting point for a PMP. A PMP can be developed using spreadsheets, PAVER, or other tools, but the overall process is similar for all. As shown in Figure 8-1, developing a PMP involves prioritizing the M&R requirements identified in the work plans, organizing the prioritized M&R requirements into executable work tasks and projects, and validating the work types, quantities, and costs for each year in the PMP. The final phase of the process is coordinating the PMP with the team, sending it forward for installation leadership approval (or higher approval if required by the Service), and publishing the PMP. At a minimum, review and update the PMP annually. Paragraph A-9.9 provides PMP examples.

Figure 8-1 PMP Development Process



8-5 PAVER M&R WORK PLANS.

The consequence of localized distress maintenance and optimal constrained critical PCI work plans generated by PAVER define all near-term and long-term localized, global, and Major M&R requirements. Prior to developing the PMP, decide whether the eliminate backlog, maintain condition, or other critical PCI work plan is optimal for the installation. As a general guideline, use the eliminate backlog work plan when the weighted area average PCI of all sections is below 85 and use the maintain condition workplan when this value is above 85.

8-6 PRIORITIZING REQUIREMENTS.

Using the optimal critical PCI work plan, prioritize all M&R requirements for each section by stratifying them based on risk and return on investment.

8-6.1 Defining Risk.

This UFC defines risk using the process described in paragraph 7-5.5 that assigns a use priority (based on the Branch use) and a rank priority. Combining these factors results in an indication of the level of risk, with 1 being the highest risk and 9 being the lowest risk in the priority matrix, as shown in Table 8-1. This approach is highly dependent on reasonable rank stratification. Without this stratification, there is no way to objectively prioritize requirements for different branch use categories, e.g., when most pavements are given a primary rank, the prioritization matrix does not provide sufficient differentiation. While this approach provides an objective, repeatable measure of risk, each Service can define other risk metrics to use based on the priority of the asset or impact on the mission.

Table 8-1 Maintenance and Repair Priority Table

M&R Priority Table			
Use Priority	**High Priority Rank**	**Medium Priority Rank**	**Low Priority Rank**
High	1	3	6
Medium	2	5	8
Low	4	7	9

8-6.2 Defining Return on Investment.

The fundamental concept to define the return on investment for pavements is that applying localized and global preventive maintenance when a pavement is in Good condition provides the greatest return on investment by extending the life of the pavement and the time before the pavement reaches the critical PCI. In addition, performing major M&R at the appropriate time is more cost-effective and provides a better return on investment than allowing a pavement to deteriorate to Poor condition that requires more extensive repairs. So, conceptually, the return on investment is defined by the condition of the pavement, as shown in Figure 8-2.

Figure 8-2 Return on Investment vs. Pavement Condition

≥ 0	≥ 10	≥ 20	≥ 30	≥ 40	≥ 50	≥ 60	≥ 70	≥ 80	≥ 90
Red/Unsatisfactory				Yellow/Degraded			Green/Adequate		
Low ------------------------------> Return on Investment -----------------------------------> High									

This basic approach provides an objective, repeatable measure of return on investment using the predicted condition in the planned year of execution. The Services can refine this procedure by using a composite index that incorporates other factors, such as the Structural Index (SI) and FOD Potential Rating for airfields or the International Roughness Index for roads to define this basic approach to return on investment. Alternatively, Services can define other return on investment metrics that provide greater fidelity, including the more complex “risk analysis procedure” outlined in paragraph A-10 to determine return on investment. While it is called the “risk analysis procedure,” it evaluates the M&R cost benefit. This procedure is currently implemented using spreadsheets but will be incorporated in a future version of PAVER. Regardless of the metric used, the overall objective is to define the return on investment.

8-6.3 Risk vs. Return on Investment.

Comparing the risk determined in the priority matrix in Table 8-1 to the return on investment based on the condition of the section in Figure 8-2 provides a means of determining a value in the matrix shown in Table 8-2. This value can be used to stratify the M&R requirements for each section in each year of the plan. Note that performing the sort procedure on the optimal critical PCI work plan as described in paragraphs A-6.6 and A-7.6 achieves the same result without assigning a value from the matrix to each section.

Table 8-2 Risk – Return Matrix

M&R Priority		Risk - Return Matrix									
Low ------------> Risk ------------> High	1	81	82	83	84	85	86	87	88	89	90
	2	71	72	73	74	75	76	77	78	79	80
	3	61	62	63	64	65	66	67	68	69	70
	4	51	52	53	54	55	56	57	58	59	60
	5	41	42	43	44	45	46	47	48	49	50
	6	31	32	33	34	35	36	37	38	39	40

	8	11	12	13	14	15	16	17	18	19	20
	9	1	2	3	4	5	6	7	8	9	10
ROI as Indicated by PCI		≥ 0	≥ 10	≥ 20	≥ 30	≥ 40	≥ 50	≥ 60	≥ 70	≥ 80	≥ 90
		Red/Unsatisfactory				Yellow/Degraded			Green/Adequate		
		Low ----------------------------------> Return on Investment --> High									

8-6.4 Risk – Return Categories.

The risk - return categories shown in Figure 8-3 assume that return on investment declines once the PCI at the time of execution drops below the critical PCI of 70 and that there is minimal return on investment when the PCI drops below 40. Services can adjust the scale based on mission requirements or, for secondary or tertiary pavements, have lower critical PCI. The key concept is that in the absence of a more detailed return on investment computation, this basic approach serves as an objective measure to aggregate requirements and prioritize work tasks and projects for planning purposes. Using the risk analysis procedure described in paragraph A-10 to define return on investment provides more fidelity but the process remains the same. Once projects are defined, perform a life-cycle cost analysis to further refine return on investment.

The sequence of the risk - return categories in Figure 8-3 reflects the need to balance risk and return while furthering the goal of maintaining operational safety, preserving and extending the life of pavements, while optimizing life-cycle costs and pavement condition. Table 8-3 provides the recommended execution hierarchy to achieve these goals by placing a priority on localized and global preventive maintenance while implementing policies to perform Major M&R at the appropriate time. This execution hierarchy also recognizes there are instances when a requirement with a low return is given a higher execution priority. For example, while operational repairs on high-priority sections are not cost-effective, the risk associated with not doing them is high, especially on an airfield, so these repairs should be reviewed and placed at the top of the priority list when warranted.

Figure 8-3 Risk – Return Categories

M&R Priority		Risk - Return Categories		
Low ---------------> Risk ---------------> High	1 2 3	E High Risk Low Return	C High Risk Moderate Return	A High Risk High Return
	4 5 6	H Moderate Risk Low Return	F Moderate Risk Moderate Return	B Moderate Risk High Return
	7 8 9	I Low Risk Low Return	G Low Risk Moderate Return	D Low Risk High Return
ROI as Indicated by PCI		≥ 0 ≥ 10 ≥ 20 ≥ 30	≥ 40 ≥ 50 ≥ 60	≥ 70 ≥ 80 ≥ 90
		Red/Unsatisfactory	Yellow/Degraded	Green/Adequate
		Low --------------------------------------> Return on Investment	--	------> High

Table 8-3 Risk – Return Category Description

Risk-Return Category	Requirements Description
C & E	Operational M&R - High Risk - Low Return
A & B	Localized and Global Preventive M&R - High to Moderate Risk - High Return
C	Major M&R - High - Risk - Moderate Return
D	Localized and Global Preventive M&R Low Risk - High Return
E	Major M&R High Risk - Low Return
F	Operational or Major M&R Moderate Risk - Moderate Return
G	Operational or Major M&R Low Risk - Moderate Return
H	Operational or Major M&R Moderate Risk - Low Return
I	Operational or Major M&R Low Risk - Low Return

8-7 AGGREGATE WORK REQUIREMENTS.

Once a prioritized requirements list is generated using the guidance above and in Chapters 6 and 7, the next step is to aggregate work requirements. This involves investigating opportunities to combine line items in the prioritized requirements list into executable tasks and projects (see Figure 8-4). Best practice is to combine requirements within each of the risk - return categories in Table 8-3, taking into consideration factors such as method of execution, specific work types, operational impacts, economies of scale, and phasing. Other considerations include opportunities to include pavement work in drainage, lighting, fuels, or other projects as well as addressing any outstanding waivers. PAVER provides tools to assist with setting up projects and incorporating them into critical PCI work plans. Paragraphs A-6, A-7, and A-9 provide examples of this process.

8-7.1 Method of Execution.

The method of execution is a primary consideration when combining requirements that drives how the requirements are aggregated into projects. The recommended approach adds a method of execution column to the prioritized requirements list for each work type in each section (see Figure 8-5). The detailed procedure is provided in paragraph A-9.5. Understanding the availability and capability of each of the alternatives listed below is key to developing an effective plan.

- Evaluate and maximize use of available in-house capabilities. In general, in-house capability is limited to localized Operational and Preventive Repairs but there can be instances where in-house work forces have more robust capabilities.
- Determine availability of installation and Service-level indefinite delivery / indefinite quantity (IDIQ) contracts. Generally, installation-level IDIQ contracts are used for localized repairs but can be considered for Global M&R if the contractor has the required equipment and expertise. Service-level contracts such as multiple award task order contracts (MATOC) are generally used for larger projects that include localized, global, or Major M&R.
- Competitive bid contracts are used for projects that include localized, global, or Major M&R.

8-7.2 Grouping Work Requirements.

The best practice for grouping requirements into executable tasks and projects is to combine requirements within each risk - return category as shown in Figure 8-3 and defined in Table 8-3. Start by aggregating work requirements executed by in-house work forces, then proceed to aggregating localized, global, and Major M&R

requirements that will be performed by contract. Each of these steps are discussed in more detail below and in paragraph A-9.2 provides examples of this process.

8-7.2.1 Identify In-House Work Requirements.

Determine requirements that can reasonably be performed in-house from a manpower and capability perspective in each year of the PMP. These are typically localized operational or preventive repairs, so consider maximizing use of in-house work forces for repairs in risk - return categories A and B. Ensure the in-house work force has the capability to perform all of the repairs on a given section. Avoid situations where part of the work on a section is done in-house and the rest by IDIQ task order or another contract. For example, do not include any sections that call for a combination of localized and global if the in-house work force does not have the capability to do global. Best practice is to create a prioritized in-house requirements task list for each year in the PMP by extracting the requirements from the prioritized requirements list for execution by the in-house work force as shown in Figure 8-6 and described in paragraphs A-9.5 and A-9.6.

Figure 8-6 In-House Work List

8-7.2.2 Combine Major M&R Requirements.

Major M&R requirements fall into all risk - return categories other than A, B, and D, with categories C, F, and G having the highest return on investment. Combine Major M&R requirements in these respective categories for each section in each year to determine opportunities to combine them for execution. Some examples are provided below.

- Mill and overlay requirements for various sections of a parking area are triggered when these sections drop below the critical PCI in different years, as shown in Figure 8-7. Aggregating these requirements into a single project provides economy of scale and avoids multiple road closures.
- Localized and global M&R are not performed on sections scheduled for Major M&R, but including sections in the same vicinity that require

localized or global M&R in a Major M&R project can provide both operational and cost benefits.

Figure 8-7 Combining Major M&R Requirements Example

Network ID	Branch ID	Section ID	Work Year	Branch Use	Section Rank	Risk - Return Category	Work Type	Method of Execution	Surface Type - Current	M&R Priority	Avg Condition Before	Avg Condition After	Stop Gap Funded	Preventive Funded	Global Funded	Major Under Critical Funded	Total

8-7.2.3 Combine Localized and Global M&R Requirements.

Localized and global work requirements are often executed via IDIQ or included in a competitive bid contract with Major M&R. Combine requirements within each of these respective categories for each year in the PMP. Consider the following when combining localized and global M&R requirements.

- Consider using IDIQ contract vehicles for operational repairs when in-house work forces are unavailable or do not have the capability.
- Avoid combining work requirements in widely varying risk - return categories.
- Avoid situations where part of the work on a section is done by one execution method and the remainder by another.
- Identify sections with the same M&R requirements within a given risk - return category that can be combined into a project. For example, combine requirements for several aprons that all require joint seal replacement.

8-7.2.4 Input Required Projects in PAVER.

Leverage PAVER capabilities by creating required projects in PAVER using the **Required Work** tool or the **Project Formulation Wizard** for the projects identified in the previous paragraphs. Once entered into PAVER, re-run the Critical PCI Work Plan with the required projects. PAVER will attempt to develop a balanced budget around these required projects for each year in the work plan. Use an iterative approach for a large network. Combine the highest priority requirements into required projects, then rerun the work plan and combine the lower priority requirements. Paragraph A-9 provides examples of creating required projects in PAVER and re-running the work plans.

8-7.3 Defining Work Types and Estimated Quantities.

Recall that an optimal critical PCI work plan defines a general M&R category, e.g., Major Localized Preventive, but does define specific repair requirements. Use the Applied Policy Details view of the PAVER Consequence of Localized Distress Maintenance work plan to identify specific work types for each section in each year in the PMP. The Consequence of Localized Distress Maintenance work plan outlines all localized M&R requirements and includes the extrapolated distress quantities, the policy (operational or preventive), and estimated cost based on the cost by work type tables defined in the M&R Family models.

Note: This report is based on the distress data from the most recent PCI inspection, so it provides a reasonable estimate of distress types, severities, and quantities at the time of the last inspection. The severity and quantity estimates lose fidelity as time passes, but this report still provides a good indication of the distress types and required work types for each section. An example of a using the Consequence of Localized Distress Maintenance work plan to define work types and estimated quantities in the prioritized requirements list is provided in paragraphs A-9.6 and A-9.7.

8-8 VALIDATE REQUIREMENTS, QUANTITIES, AND COSTS.

A PCI inspection uses a statistical approach to determine the pavement condition, as described in UFC 3-260-16 and paragraph 4-2 of this UFC. The types, severities, and quantities of distresses are measured for a sufficient subset of the total samples in a section to attain the desired confidence level. PAVER extrapolates the quantities for each type and severity of distress for the entire section based on the samples inspected. These extrapolated distresses are good estimates but need to be validated for projects for several reasons.

8-8.1 Validating Rigid Pavement Repair Requirements.

Rigid pavement distresses are counted at the slab level per the PCI inspection rules outlined in UFC 3-260-16. This means that a slab may have multiple distresses of the same type but only one instance of a distress is recorded at the highest severity level. This can lead to underestimating quantities in certain circumstances.

8-8.2 Validating Extrapolated Distress Quantities.

While we can predict pavement condition in future years and the extrapolated distresses provide a reasonable estimate of quantities at the time of the inspection, there is no way to accurately predict quantities for specific distress types and severities in future years.

8-8.3 Validation Procedure.

At a minimum, perform a visual inspection to validate the distress types, severities and quantities identified in the last PCI inspection. Use this data to update the in-house work tasks and projects. Verify that the distress types present during the visual inspection are the same identified in the previous inspection. Look for distress types that were not recorded in the previous inspection and determine if there has been a significant increase in the severity or quantity of distresses. The PAVER Inspection Report generated with the Inspection Report/Forms/Setup wizard described in paragraph 4-2.1 is a useful tool for project validation. Run the report for the sections of interest as a reference when performing the validation. Other considerations include the following.

- Determine if the repair recommended in the distress maintenance policy is appropriate or if there are other underlying issues that call for a different work type to address the issue. Update the PMP to reflect the appropriate work type.
- Recall that critical PCI work plan cost estimates are based on cost by condition tables and the consequence of localized distress maintenance work plan costs are based on cost by work type tables. These approaches typically provide estimates that vary and that should be validated based on current costs and quantities. Update the PMP to reflect the current costs and quantities.
- Marking distresses to be repaired while doing the validation is a good approach when work is performed by in-house work forces or pavement IDIQ.
- A good practice when validating quantities for a localized M&R project is to generate a map that shows the distress locations (commonly known as a crack map).

8-8.4 Review, Approve, and Publish PMP.

Provide an opportunity for the PMP development team to perform a final review, resolve any comments or issues, then submit the plan to leadership for approval. The approval level is dictated by the Service. Update the approved PMP as the work tasks and projects are executed. Revise work plans and update the PMP on at least an annual basis. A best practice is to update the PAVER work history to document projects as they are completed and then updating work plans.

This Page Intentionally Left Blank

APPENDIX A BEST PRACTICES

The Best Practices Appendix is considered to be guidance and not requirements. Its main purpose is to communicate proven facility solutions, systems, and lessons learned, but may not be the only solution to meet the requirement.

A-1 DESCRIPTIVE AND USER-DEFINED FIELDS.

This section discusses the use of descriptive and user-defined fields at the network, branch, and section levels.

A-1.1 Network-level Fields.

The Network-level user-defined fields listed below allow users to define the networks to include or exclude from M&R work plans or other analyses and reports. The Service POCs identified in paragraph 2-9.3 responsible for the pavement management program must create these fields. When the fields are created, PAVER gives them a unique ID. Export this database for use as a template. When this database is combined with an installation database, the fields are available with original unique ID.

This is a one-time process. Once the fields are included in each database, they are only updated if something changes, e.g., an installation's assigned command changes. These fields are useful for individual databases and are essential for filtering data in a Service combined (rollup) database.

- Major Command (List of Commands as appropriate for Service)
- Privatized (Yes or No)
- Housing (Yes or No)

A-1.2 Branch-level Fields.

The Branch Use or Category Code (a descriptive field) fields cover the requirements, so no additional user-defined fields are recommended.

A-1.3 Section-level Fields.

A user-defined Status field at the section level, with values including those listed below, provides fidelity on the reason a section was or was not inspected and is used to filter out sections that should not be included in M&R work plans or other analyses. This user-defined field is imported into the database from a template created by the Service POC as described in paragraph 2-9.3. Alternatively, a Service could use the Section Category descriptive field for the same purpose. In either case, the Service defines a standard set of fields used in all databases.

- Inspected
- Maintained by Others
- Abandoned

- No Access
- Out of Scope
- Under Construction

A-2 COST BY WORK TYPE TABLES.

The following tables define the work elements used to develop standard costs for each PAVER standard work type used by DoD to develop airfield and road and parking M&R work plans and PMPs. These are fully burdened unit costs, including mobilization, overhead, materials, disposal, and labor costs, as well as any appropriate O&M escalation factors. They are based on RS Means or the Tri-Service Automated Cost Engineering System (TRACES) applications such as the Parametric Cost Engineering System (PACES) or the Micro-Computer Aided Cost Estimating System Second Generation (MII) using the current TRACES Cost Book/Unit Price Book (UPB). Each is based on the work element assumptions for each standard work type described below. Modify the values in these cost by work type tables using the area cost factor for the specific location.

If specific, well-documented local costs data exist or existing conditions differ from the assumptions used in Tables A-1, A-2, and A-3, adjust the unit costs but fully document all work element assumptions for the change in the pavement evaluation report and the PMP.

Table A-1 Localized M&R Cost by Work Type

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
BS-SE	Break and Seat	SqFt		Crack (plain PCC) or break (reinforced PCC) slabs, seat slabs with a pneumatic roller, Overlay pavement with HMA. Overlay thickness must meet minimum thickness requirements in UFC 3-260-02, but will not be less than 4 inches, which is the assumed thickness for this line item.
CM-LO	Cold Milling-Localized	SqFt		Mill (aka cold plane) asphalt pavement just enough thickness to level and smooth the surface. This line item assumes less than or equal to 2 inches of pavement are milled and that the material is stockpiled on installation for re-use so no disposal costs are incurred.
CS-AC	Crack Sealing - AC	Ft		Remove old sealant (if any), saw/route cracks, clean crack reservoir, install backer rod to control depth of sealant, and seal using an approved hot-applied sealant.
CS-PC	Crack Sealing - PCC	Ft		Remove old sealant (if any), saw/route cracks, clean crack reservoir, install backer rod to control depth of sealant, and seal using an approved silicone sealant.
GR-AC	Grinding - AC (Localized)	Ft		This line item assumes diamond grinding for localized repair using walk-behind diamond grinding equipment.
GR-PC	Grinding – PCC (Localized)	Ft		This line item assumes diamond grinding for localized repair using walk-behind diamond grinding equipment.

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
JS-LC	Joint Seal (Localized)	Ft		Joint seal replacement is typically done on entire sections (global) but may be done for localized areas. This line item includes routing the reservoir to achieve the correct shape factor, cleaning the reservoir, placing backer rod, and placing new silicone joint seal.
NONE	No Localized M & R	SqFt	0.00	No work performed
PA-AD	Patching - AC Deep	SqFt		Remove existing pavement (5 inches assumed) and base (18 inches assumed). Compact the subgrade, replace, and compact the base in lifts, apply prime coat, replace, and compact HMA with tack coat between lifts.
PA-AL	Patching - AC Leveling	SqFt		Remove loose material from rut or depression to be repaired, seal cracks, apply micro-surfacing in 1/4-inch lifts (curing between lifts), roll, and cure the micro-surfacing.
PA-AS	Patching - AC Shallow	SqFt		Remove existing pavement (5 inches assumed), recompact the base, apply prime coat, replace and compact HMA with tack coat between lifts.
PA-IR	Patching- Infrared	SqFt		Using an infrared heater for the asphalt repair, heat the asphalt to a working temperature of 300 °F, penetrating the asphalt to a depth of 3 to 4 inches. Remove deteriorated asphalt and rake in new HMA then compact the area with a vibratory roller.
PA-PF	Patching - PCC Full Depth	SqFt		Sawcut pavement to full depth (12-inch plain PCC assumed), remove the concrete, scarify and recompact the base or subgrade below the slab, place dowels at joints to adjacent slabs to match existing dowel layout (20-foot slabs with 15" spacing of 20" 1.25" dowels assumed). Place tie-bars to remainder of existing slab then place new concrete. Maintain all joints to adjacent slabs.
PA-PP	Patching - PCC Partial Depth	SqFt		Sawcut and remove partial depth of concrete (4 inches assumed), clean the repair area, and place new concrete. This line item assumes use of a rapid-setting concrete such as those found on the Tri-Service website below. Note that maintaining the joint is critical on any repair adjacent to a joint. https://transportation.erdc.dren.mil/cacsites/TriService/pavement_repair.aspx
PA-PL	Patching – PCC Partial Depth POL Damage Repair	SqFt		Sawcut and remove partial depth of concrete (4 inches assumed), clean the repair area, and place new magnesium phosphate cement. Once the repair is in place, seal the pavement using a sodium silicate surface treatment.
SH-LE	Shoulder leveling	Ft		Remove loose materials along the length of the shoulder, place, grade, and compact aggregate to eliminate shoulder drop-off while maintaining the slope of the unpaved shoulder away from the road. This item assumes a 10-foot-wide shoulder with an average thickness of 4 inches of aggregate required for the repair.
SL-PC	Slab Replacement - PCC	SqFt		Make multiple sawcuts for the full depth of the existing slab (12 inches of plain PCC assumed) and remove the concrete. Scarify and recompact the base or subgrade below the slab, place dowels according to UFC 3-270-01 requirements, then place new concrete and seal the joints.

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
ST-AL	Surface Treatment – AC (Localized)	SqFt		This line item assumes a slurry seal is applied to a localized area (e.g., a portion of a section like a parking area). Use the global work line item when the entire section(s) (e.g., a whole parking area of multiple parking areas) receives the surface treatment. Adjust the cost when a lower cost (e.g., fog seal or rejuvenator) or higher cost (e.g., cape seal or microsurface) surface treatment is used.
ST-PL	Surface Treatment – PCC (Localized)	SqFt		This line item assumes a localized area (e.g., one or more aircraft parking spots on an apron) are cleaned and sodium silicate is applied to prevent deterioration from heat and petroleum products. Use the global work line item when the entire section(s) (e.g., a whole apron) receives the surface treatment.
SS-SG	Spread Sand or Gravel	SqFt		Place hot sand with a spreader to blot up the excess binder on the surface, roll the sand with a pneumatic roller, then remove the excess sand with a vacuum sweeper.
UN-PC	Undersealing - PCC	SqFt		This line item assumes that a high-density polyurethane polymer material is used to underseal and restore support to the pavement slab. Drill holes in the area with voids, inject grout to fill the void, plug the drill holes, and grind surface to restore the profile of the affected joint(s) or crack(s).
SJ-PC	Slab Jacking - PCC	SqFt		This line item assumes that a high-density polyurethane polymer material is used to raise a slab or multiple slabs. Drill holes in the area(s) of the slab(s), inject grout to raise the slab(s) to the desired elevation, plug the drill holes, and grind surface to restore the profile of affected joint(s) or crack(s)
LT-PC	Load Transfer Restoration – PCC (Localized)	Ft		Sawcut and chip existing concrete at joints to mid-depth (12-inch plain PCC assumed) to create slots, place the dowel bars (20-foot slabs with 15" spacing of 20" 1.25" dowels assumed) into the slots, ensuring they are properly aligned. Place repair material into the slots (assumes use of a rapid-setting concrete such as those found on the Tri-Service Website below). Restore the joint at the slot locations, seal the joints, and grind any joint discontinuity. https://transportation.erdc.dren.mil/cacsites/TriService/pavement_repair.aspx
ED-RF	Retrofitted Edge Drain	Ft		Remove existing edge drains, trench (assume a 4-foot depth), place filter fabric, place new edge drain (6-inch flexible, corrugated polyethylene [CPE] pipe assumed), and backfill using procedures in UFC 3-270-01, Chapter 19.
HR-PD	Partial Depth Heat Resistant PCC Repair	SqFt		Sawcut and remove damaged concrete (4-inch depth assumed), clean the repair area, place new heat-resistant concrete, and re-seal the surface with sodium silicate. Note that maintaining the joint is critical on any repair adjacent to a joint.
HR-FD	Full Depth Heat Resistant PCC Repair	SqFt		Sawcut pavement to full depth (12-inch plain PCC assumed), remove the concrete, scarify and recompact the base or subgrade below the slab, place dowels at joints to adjacent slabs to match existing dowel layout (20-foot slabs with 15" spacing of 20" 1.25" dowels assumed). Place tie-bars to remainder of existing slab, then place new heat-resistant concrete and re-seal the surface with sodium silicate. Note that maintaining the joint is critical on any repair adjacent to a joint.

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
HR-CR	Partial Depth Continuously Reinforced Heat Resistant PCC Repair	SqFt		Sawcut and remove damaged concrete (6-inch depth assumed) and reinforcement, clean the repair area, replace the reinforcement and tie bars, then place new heat-resistant concrete and re-seal the surface with sodium silicate. Note that maintaining the joint is critical on any repair adjacent to a joint.

Table A-2 Global M&R Cost by Work Type

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
NONE	No Global M & R	SqFt	0.00	No work elements
GL-AT	Overlay - AC Thin (Global)	SqFt		Remove all loose material, place tack coat, and place HMA overlay. This line item assumes a 2-inch overlay with asphalt provided by a local central mixing plant. Compact pavement to specified density. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.
GL-FR	Overlay - Fuel-Resistant AC (Global)	SqFt		Remove all loose material, place tack coat, place fuel-resistant HMA overlay. This line item assumes a 2-inch overlay with asphalt provided by a local central mixing plant. Compact pavement to specified density. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.
JS-CP	Joint Seal – Compression	Ft		Remove old joint seal material, route the joint reservoir to achieve the correct shape factor, clean the reservoir, and place new compression joint seal.
JS-HP	Joint Seal – Hot Pour	Ft		Remove old joint seal material, route the joint reservoir to achieve the correct shape factor, clean the reservoir, and place new hot-pour joint seal.
JS-SI	Joint Seal - Silicon	Ft		Remove old joint seal material, route the joint reservoir to achieve the correct shape factor, clean the reservoir, and place new silicone joint seal.
SS-CT	Surface Seal - Coal Tar	SqFt		Remove all loose material on surface, mix the fuel-resistant sealer in batches, and place by pouring on pavement and using squeegees to spread the material. This line item assumes two layers are applied to the HMA. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
SS-FS	Surface Seal - Fog Seal	SqFt		Remove all loose material on surface and place fog seal using a distributor calibrated to deliver the fog seal at the specified rate. This line item assumes application dilution is 1 part emulsion to 1 part water with a 0.05 gallon per square yard application rate. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.
SS-RE	Surface Seal - Rejuvenating	SqFt		Remove all loose material on surface and place rejuvenator using a distributor calibrated to deliver the material at the specified rate. This line item assumes a 0.1 gallon per square yard application rate. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.
ST-CS	Surface Treatment - Cape Seal	SqFt		Remove all loose material on surface and place binder using a distributor calibrated to deliver the material at the specified rate. Apply the aggregate immediately after the binder and roll with a rubber-tired roller immediately after applying the aggregate to seat the aggregate in the binder. This line item assumes application of a slurry seal over the bituminous surface treatment using a truck-mounted continuous-mix slurry machine. Once the slurry seal is cured, roll with a pneumatic-tired roller. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.
ST-MS	Surface Treatment - Micro Surface	SqFt		Remove all loose material on surface, apply tack coat, wet the pavement surface with water fogging, and place the micro-surface using a self-propelled mixing and placement vehicle. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.
ST-SB	Surface Treatment - Single Bituminous	SqFt		Remove all loose material on surface and place binder using a distributor calibrated to deliver the material at the specified rate. Apply the aggregate immediately after the binder and roll with a rubber-tired roller immediately after applying the aggregate to seat the aggregate in the binder. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
ST-DB	Surface Treatment - Double Bituminous			Remove all loose material on surface and place binder using a distributor calibrated to deliver the material at the specified rate. Apply the aggregate immediately after the binder and roll with a rubber-tired roller immediately after applying the aggregate to seat the aggregate in the binder. Repeat the process, applying another layer of binder and aggregate, then roll with a rubber-tired roller immediately after applying the second layer of aggregate. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.
ST-SS	Surface Treatment - Slurry Seal	SqFt		Remove all loose material on surface, apply tack coat, place the slurry seal using a truck-mounted continuous-mix slurry machine, and roll with a rubber-tired roller once the slurry seal has cured. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.
ST-ST	Surface Treatment - Sand Tar (Seal)	SqFt		Remove all loose material on surface and apply asphalt emulsion. (When used to address bleeding, do not apply asphalt binder before the sand seal is placed since the primary purpose is to blot up the excess binder on the surface.) Apply hot sand, roll the sand with a pneumatic-tire roller, and remove excess sand using a vacuum sweeper once the surface treatment is cooled. All structural distresses and crack repairs are covered by separate localized repair line items. This line item does not include pavement markings.

Table A-3 Major M&R Cost by Work Type

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
AR-CO	AC Surface Recycling - Cold	SqFt		Mill the existing asphalt, haul to crusher, and crush to specified particle size. Mix with virgin material and reuse material to pave secondary roads or parking areas (if a seal coat is applied) or as a base course. This work type assumes that both the existing and new pavement thickness is 3 inches and 4 inches when used as a base.
AR-HO	AC Surface Recycling - Hot	SqFt		Mill the existing HMA, haul millings to plant, crush millings, and mix millings in a hot-mix plant with new aggregate, asphalt, and recycling agent. Transport recycled asphalt to site, place and compact HMA, and place pavement markings. This line item assumes both the existing and new pavement thickness is 3 inches for roads or parking areas and 5 inches for an airfield. Adjust cost if in-place recycling is used but assume same thicknesses unless there is specific information regarding thickness.
BR-SE	Break & Seat & Overlay	SqFt		Minimize the size of the concrete slabs using a breaking or cracking procedure. Seat the broken concrete pieces with a heavily weighted rubber-tire roller. Overlay the pavement with HMA and place pavement markings. This work type assumes the existing plain concrete pavement is 6 inches for roads and parking and 12 inches for airfields and that the AC overlay is 3 inches for roads and parking and 5 inches for an airfield.
BR-RB	Rubblization & Overlay	SqFt		Install underdrain to relieve pressure during the rubblization process: trench (assume a 4-foot depth), place filter fabric, place new edge drain (6-inch flexible, CPE pipe assumed), and backfill using procedures in UFC 3-270-01, Chapter 19. Rubblize pavement using a multiple-head breaker or resonant pavement breaker, seat the broken pieces with a pneumatic roller, overlay the pavement with HMA, and place pavement markings. This work type assumes the geotechnical assessment cost is not included in this line item and that the existing concrete pavement is 6 inches for roads and parking and 12 inches for airfields. It also assumes the AC overlay is 3 inches for roads and parking and 5 inches for an airfield.
CR-AC-4	Complete Reconstruction, 4 inches AC	SqFt		Mill 4 inches of asphalt to base and remove existing 6-inch base to subgrade. Compact subgrade to meet UFC 3-260-02 requirements, place and compact 6 inches of base course, place and compact 4 inches of HMA in 2-inch lifts, and place pavement markings.

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
CR-AC-6	Complete Reconstruction, 6 inches AC	SqFt		Mill 6 inches of asphalt to base, remove existing 6-inch base to subbase, and remove existing 4-inch subbase to subgrade. Compact subgrade to UFC 3-260-02 requirements, place and compact 4 inches of subbase and 6 inches of base course, place and compact 6 inches of HMA in 2-inch lifts, and place pavement markings.
CR-AC-8	Complete Reconstruction, 8 inches AC	SqFt		Mill 8 inches of asphalt to base, remove existing 8-inch base to subbase, and remove existing 6-inch subbase to subgrade. Compact subgrade to UFC 3-260-02 requirements, place and compact 6 inches of subbase and 8 inches of base course, place and compact 8 inches of HMA in 2-inch lifts, and place pavement markings.
CR-PC-8	Complete Reconstruction, 8 inches PCC	SqFt		Demolish existing 8-inch plain PCC slabs, remove existing 6-inch base to subgrade, and compact top 6 inches of subgrade to UFC 3-260-02 requirements. Place and compact 6 inches of new base course and place new 8-inch plain PCC using slip form paving procedures with dowels at longitudinal joints and sawn transverse joints, apply curing compound, saw transverse joints, place compression joint seals at all joints, and place pavement markings.
CR-PC-12	Complete Reconstruction, 12 inches PCC	SqFt		Demolish existing 12-inch plain PCC slabs, remove existing 8-inch base to subgrade, and compact top 6 inches of subgrade to UFC 3-260-02 requirements. Place and compact 8 inches of new base course and place new 12-inch plain PCC using slip form paving procedures with dowels at longitudinal joints and sawn transverse joints, apply curing compound, saw transverse joints, place compression joint seals at all joints, and place pavement markings.
CR-PC-18	Complete Reconstruction, 18 inches PCC	SqFt		Demolish existing 18-inch plain PCC slabs, remove existing 12-inch base to subgrade, compact top 6 inches of subgrade to UFC 3-260-02 requirements. Place and compact 12 inches of new base course and place new 18-inch plain PCC using slip form paving procedures with dowels at longitudinal joints and sawn transverse joints, apply curing compound, saw transverse joints, place compression joint seals at all joints, and place pavement markings.
CR-PC-24	Complete Reconstruction, 24 inches PCC	SqFt		Demolish existing 24-inch plain PCC slabs, remove existing 16-inch base to subgrade, compact top 6 inches of subgrade to UFC 3-260-02 requirements. Place and compact 16 inches of new base course and place new 24-inch plain PCC using slip form paving procedures with dowels at longitudinal joints and sawn transverse joints, apply curing compound, saw transverse joints, place compression joint seals at all joints, and place pavement markings.
HI-AG	New Construction	SqFt	0.00	No work type elements
MOL	Cold Mill and Overlay	SqFt	0.00	No work type elements

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
MOL-2	Cold Mill and Overlay - 2 Inches	SqFt		Mill 2 inches of the existing asphalt surface, remove all loose material, place tack coat, place and compact 2 inches of HMA, and place pavement markings. All structural distress and crack repairs are covered by separate localized repair line items.
MOL-3	Cold Mill and Overlay - 3 Inches	SqFt		Mill 3 inches of the existing asphalt surface, remove all loose material, place tack coat, place and compact 3 inches of HMA, and place pavement markings. All structural distress and crack repairs are covered by separate localized repair line items.
MOL-4	Cold Mill and Overlay - 4 Inches	SqFt		Mill 4 inches of the existing asphalt surface, remove all loose material, place tack coat, place and compact 4 inches of HMA in 2-inch lifts, and place pavement markings. All structural distress and crack repairs are covered by separate localized repair line items.
NC-AC-4	New Construction, 4 inches AC	SqFt		Perform site preparation and grading, compact subgrade to UFC 3-260-02 requirements, place and compact 6 inches of base course, place and compact 4 inches of HMA in 2-inch lifts, and place pavement markings.
NC-AC-6	New Construction, 6 inches AC	SqFt		Perform site preparation and grading, compact subgrade to UFC 3-260-02 requirements, place and compact 4 inches of subbase, place and compact 6 inches of base course, place and compact 6 inches of HMA in 2-inch lifts, and place pavement markings.
NC-AC-8	New Construction, 8 inches AC	SqFt		Perform site preparation and grading, compact subgrade to UFC 3-260-02 requirements, place and compact 6 inches of subbase, place and compact 8 inches of base course, place and compact 8 inches of HMA in 2-inch lifts, and place pavement markings.
NC-PC-8	New Construction, 8 inches PCC	SqFt		Perform site preparation and grading, compact top 6 inches of subgrade to UFC 3-260-02 requirements. Place and compact 6 inches of new base course and place new 8-inch plain PCC using slip form paving procedures with dowels at longitudinal joints and sawn transverse joints, apply curing compound, saw transverse joints, place compression joint seals at all joints, and place pavement markings.
NC-PC-12	New Construction, 12 inches PCC	SqFt		Perform site preparation and grading, compact top 6 inches of subgrade to UFC 3-260-02 requirements Place and compact 8 inches of new base course and place new 12-inch plain PCC using slip form paving procedures with dowels at longitudinal joints and sawn transverse joints, apply curing compound, saw transverse joints, place compression joint seals at all joints, and place pavement markings.

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
NC-PC-18	New Construction, 18 inches PCC	SqFt		Perform site preparation and grading, compact top 6 inches of subgrade to UFC 3-260-02 requirements. Place and compact 12 inches of new base course and place new 18-inch plain PCC using slip form paving procedures with dowels at longitudinal joints and sawn transverse joints, apply curing compound, saw transverse joints, place compression joint seals at all joints, and place pavement markings.
NC-PC-24	New Construction, 24 inches PCC	SqFt		Perform site preparation and grading, compact top 6 inches of subgrade to UFC 3-260-02 requirements. Place and compact 16 inches of new base course and place new 24-inch plain PCC using slip form paving procedures with dowels at longitudinal joints and sawn transverse joints, apply curing compound, saw transverse joints, place compression joint seals at all joints, and place pavement markings.
NONE	No Major M & R	SqFt	0.00	No work type elements
NU-IN	New Construction - Initial	SqFt		No work type elements
NU-US	New Construction - Unsurfaced	SqFt		Perform site preparation and grading, compact subgrade to UFC 3-260-09 requirements, place and compact 6 inches of base course, place and compact 4 inches of aggregate surface layer.
OL-AF	Overlay - AC Fabric	SqFt		Remove all loose material, place tack coat, place geofabric, place and compact 2 inches of HMA, and place pavement markings. All structural distress and crack repairs are covered by separate localized repair line items.
OL-AS	Overlay - AC Structural	SqFt		Remove all loose material, place tack coat, place and compact 4 inches of HMA in 2-inch lifts, and place pavement markings. All structural distress and crack repairs are covered by separate localized repair line items.
OL-AT	Overlay - AC Thin	SqFt		Remove all loose material, place tack coat, place geofabric, place and compact 2 inches of HMA, and place pavement markings. All structural distress and crack repairs are covered by separate localized repair line items.
OL-PF	Overlay - PCC Fully Bonded	SqFt		Cold mill or shotblast the base slab to remove all deteriorated or defective concrete and all surface contamination and thoroughly clean the surface by sandblasting followed by air blasting and water blasting. Pneumatically apply a portland cement grout ahead of the concrete placement, ensuring the grout is not dry prior to placement. Place a 5-inch plain PCC overlay, apply curing compound, saw joints to match joints in base slabs, place compression joint seals at all joints, and place pavement markings.

Code	Name	Work Unit	Unit Cost ($)	Work Type Elements
OL-PP	Overlay - PCC Partially Bonded	SqFt		Remove all loose material, place a 6-inch plain PCC overlay, apply curing compound, saw joints to match joints in base slabs, place compression joint seals at all joints, and place pavement markings. All structural distress and crack repairs in the existing pavement are covered by separate localized repair line items.
OL-PU	Overlay - PCC Unbonded	SqFt		Remove all loose material, place a 2-inch asphalt bond-breaker and a 6-inch plain PCC overlay, apply curing compound, saw joints to match joints in base slabs, place compression joint seals at all joints, and place pavement markings. All structural distress and crack repairs in the existing pavement are covered by separate localized repair line items.
SR-AC	Surface Reconstruction - AC	SqFt		Mill the full depth of the existing asphalt surface to the base course, scarify and recompact the base, place a prime coat and place and compact 4 inches of HMA in 2-inch lifts, and place pavement markings.
SR-PC	Surface Reconstruction - PCC	SqFt		Remove existing plain PCC pavement, scarify and recompact the base, place new 8-inch plain PCC using slip form paving procedures with dowels at longitudinal joints and sawn transverse joints, apply curing compound, saw transverse joints, place compression joint seals at all joints, and place pavement markings.
SU-AC	Surface Course - AC	SqFt		No work type elements
SU-DB	Surface Course - Double Bitum.	SqFt		Remove all loose material on surface, place binder using a distributor calibrated to deliver the material at the specified rate. Apply the aggregate immediately after the binder and roll with a rubber-tired roller immediately after applying the aggregate to seat the aggregate in the binder. Repeat the process, applying another layer of binder and aggregate then roll with a rubber-tired roller immediately after applying the second layer of aggregate and place pavement markings. All structural distresses and crack repairs are covered by separate localized repair line items.
SU-PC	Surface Course - PCC	SqFt		No work type elements
SU-PF	Surface Course - Porous Friction	SqFt		Remove all loose material from existing AC pavement, place tack coat, place and compact 1 inch of porous friction course, and place pavement markings. All structural distresses and crack repairs are covered by separate localized repair line items.

A-3 M&R DISTRESS MAINTENANCE POLICY TABLES.

Service POCs drafted and agreed to the following Maintenance Policy tables. These policies cover most typical situations. Notes are provided to clarify alternatives.

A-3.1 Localized Operational Maintenance Policies.

Tables A-4 through A-7 provide standard localized operational maintenance policies for airfields, roads, and parking.

Table A-4 Asphalt Airfield Operational M&R Policy

Table A-9 Other Considerations - Asphalt Airfield Preventive M&R Policy

<table>
<tr><th colspan="4">Airfield Asphalt Pavement Localized Preventive M&R Policy - Other Considerations</th></tr>
<tr><th>Distress</th><th>Distress Severity</th><th>Description</th><th>Work Type Adjustments</th></tr>
<tr><td>41</td><td>Low</td><td>ALLIGATOR CRACKING</td><td>Alligator (fatigue) cracking is a structural distress. Ideally, we want to slow the progression of the distress, but sealing a low-severity asphalt crack typically requires overbanding, which presents a FOD hazard to some aircraft so the "No Localized" work type is recommended. Depending on the extent of the alligator cracking, a global surface treatment can be effective, e.g., with >1% low severity alligator cracking the PCI would drop to an 80.</td></tr>
<tr><td>43</td><td>Low</td><td>BLOCK CRACKING</td><td rowspan="3">When aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can cause delamination of the pavement when block cracking is present. When a high percentage of the area is block cracked, the PCI will go below critical, which will trigger major M&R, e.g., mill and overlay. If the block cracking is localized, Patching AC-Deep is recommended.</td></tr>
<tr><td>43</td><td>Medium</td><td>BLOCK CRACKING</td></tr>
<tr><td>43</td><td>High</td><td>BLOCK CRACKING</td></tr>
<tr><td>44</td><td>Low</td><td>CORRUGATION</td><td rowspan="3">Corrugation is an indication of delaminated asphalt layers or instability in the base or subbase. It can be caused by an unstable mix or improper compaction. Depending on the cause, grinding may be used as an initial treatment; however, it will not address the root cause, so a shallow or deep patch is recommended. When aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can cause delamination of the pavement when corrugation is present. In these cases, use Patching AC-Deep for all severity levels.</td></tr>
<tr><td>44</td><td>Medium</td><td>CORRUGATION</td></tr>
<tr><td>44</td><td>High</td><td>CORRUGATION</td></tr>
<tr><td>46</td><td></td><td>JET BLAST</td><td>When aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can be eroded up to 0.5 inch in depth. This causes smoothness and FOD concerns for any FOD-susceptible aircraft due to the greater potential of raveling. However, the treatment may range from no localized M&R to AC shallow patch and include surface treatments or shallow depth fuel-resistant asphalt for V-22 FARPs. When the standard shallow patch is applied, it must have a seal around the edge and a surface treatment to reduce the possibility of re-occurrence or at least slow the progression.</td></tr>
<tr><td>47</td><td>High</td><td>JOINT REFLECTIVE CRACKING</td><td>When joint reflective cracks are greater than 0.25 inch and less than 2 inches, routing and sealing the cracks is the standard policy. However, when cracks are greater than or equal to 2 inches or with significant raveling (FOD potential for susceptible aircraft) that cannot be mitigated by routing and sealing, the distress should be repaired using a shallow patch. UFC 3-270-01 requires the use of a well-compacted sand asphalt or a fine-grained asphalt mix when repairing cracks 2 inches wide and larger, which qualifies as a shallow patch. Note: In tertiary areas or LZs used by C-130s and C-17s, crack sealing high-severity cracks is permissible.</td></tr>
</table>

Airfield Asphalt Pavement Localized Preventive M&R Policy - Other Considerations			
Distress	**Distress Severity**	**Description**	**Work Type Adjustments**
48	High	LONGITUDINAL AND TRANSVERSE CRACKING	When longitudinal and transverse cracks are greater than 0.25 inch and less than 2 inches, routing and sealing the cracks is the standard policy. However, when cracks are greater than or equal to 2 inches or with significant raveling (FOD potential for susceptible aircraft) that cannot be mitigated by routing and sealing, the distress should be repaired using a shallow patch. UFC 3-270-01 requires the use of a well-compacted sand asphalt or a fine-grained asphalt mix when repairing cracks 2 inches wide and larger, which qualifies as a shallow patch. **Note:** In tertiary areas or LZs used by C-130s and C-17s, crack sealing high-severity cracks is permissible.
51	N/A	POLISHED AGGREGATE	While the standard policy is No Localized M&R, if the extent of distress is significant enough that it poses a safety issue to aircraft when braking, consider water blasting, grinding, microsurfacing, or shallow patch. The repair will depend on the quality of the asphalt. Oftentimes, if the aggregate is polished then the asphalt is likely too oxidized for water blasting or grinding. If so, then consider mill and overlay or microsurfacing (depending on the location on the airfield and the FOD susceptibility of the mission aircraft).
52	Low	RAVELING	While the standard policy is No Localized M&R, when the distress density exceeds 4 percent and the section PCI is above critical, global M&R is recommended
52	Medium	RAVELING	While the standard policy is Patching - AC Shallow, when the distress density exceeds 1 percent and the section PCI is above critical, global M&R is recommended. if the distress density exceeds 1 percent and the section PCI is below critical, major M&R is recommended, e.g., mill and overlay.
52	High	RAVELING	While the standard policy is Patching - AC Shallow, when the distress density exceeds 0.5 percent and the section PCI is above critical, global M&R is recommended. If the distress density exceeds 0.5 percent and the section PCI is below critical, major M&R is recommended, e.g., mill and overlay.
54	Medium	SHOVING	The standard policy is Patching - AC Shallow because it addresses the AC to PCC interface issues but, depending on the thickness of the pavement and the aircraft operating on the airfield, grinding and reestablishing and sealing the joint at the AC to PCC interface can be an acceptable solution.
55	N/A	SLIPPAGE CRACKING	The standard policy is Patching - AC Shallow, but the depth of the repair is a function of where the slip occurred. Slippage crack repair would likely not expose the base but, if the issue was a degraded underlying layer, then Patching - AC Deep is the appropriate solution.
56	Medium	SWELLING	The standard policy is Patching - AC Deep based on the assumption that the swelling is occurring due to frost action in the subgrade or by swelling soil, but a small swell can also occur on the surface of an asphalt overlay (over PCC) as a

Airfield Asphalt Pavement Localized Preventive M&R Policy - Other Considerations			
Distress	Distress Severity	Description	Work Type Adjustments
56	High	SWELLING	result of a blowup in the PCC. In this case, the appropriate repair is to replace the AC and PCC to the base. Swelling can also occur when there is delamination and water infiltration in the asphalt or AC/PCC interface combined with extreme high or freezing temperatures. In this case, Patching - AC Shallow is appropriate to replace the delaminated asphalt.
57	Low	WEATHERING	While the standard policy is No Localized M&R, global M&R is recommended to slow the rate of weathering/deterioration of the asphalt.
57	Medium	WEATHERING	While the standard policy is No Localized M&R, global M&R is recommended to slow the rate of weathering/deterioration of the asphalt.
57	High	WEATHERING	While the standard policy is Patching - AC Shallow, when the distress density exceeds 0.5 percent and the section PCI is above critical, global M&R is recommended. If the distress density exceeds 0.5 percent and the section PCI is below critical, major M&R is recommended, e.g., mill and overlay.

Table A-11 Other Considerations - Concrete Airfield Preventive M&R Policy

Airfield Concrete Pavement Localized Preventive M&R Policy - Other Considerations			
Distress	**Distress Severity**	**Description**	**Work Type Adjustments**
61	Low	BLOW-UP	The standard policy is Patching - PCC Full Depth, but depending on the location, thickness, and the aircraft using the pavement, a partial-depth PCC patch can be used on pavement greater than 12 inches when the pavement is outside the traffic area or when the aircraft using the aircraft are not susceptible to roughness or FOD issues. The primary concern is that a partial-depth patch may not address the root cause and may have shear/delamination issues.
61	High	BLOW-UP	The standard policy is slab replacement, but in some cases a full-depth patch can be used, depending on the existing damage. Whether you are doing a full-depth patch or slab replacement, it is important to install compression boards to prevent reoccurrence of the distress.
62	Low	CORNER BREAK	The standard policy is No Localized M&R because trying to do a repair on very narrow cracks can do more harm than good, but if cracks are approaching 1/8 inch (bordering on medium severity), crack sealing is appropriate to reduce the infiltration of water and slow the progression of the distress. The decision to seal the crack is also a function of the environment/pavement design. Does it have a working drainage layer or does the soil drain well? Is it subject to freeze thaw or snow plows? How will it affect the mission, e.g., is it close to arresting system or is it on a tertiary pavement?
62	Medium	CORNER BREAK	The standard policy is crack sealing, however in cases where there is faulting or the airfield is used by fighter aircraft, use a full-depth repair.
63	High	LINEAR CRACKING	The standard policy is crack sealing, but if the crack is greater than 2 inches, a full-depth patch or slab replacement is recommended, depending on the location of the crack and other factors. For instance, sympathetic cracking on a number of slabs would warrant full-depth repairs or slab replacement with a reinforced slab to stop crack propagation.
65	Medium	JOINT SEAL DAMAGE	The standard policy is Joint Seal (Localized) repair when the distress density is less than 33 percent medium and high severity. If the distress density is more than 33 percent and less than 66 percent, plan for global joint seal replacement in two to three years. When the medium- and high-severity density is greater than 66 percent, plan for global joint seal replacement in year one. For sections that do not have a drainage layer and have a history of pumping, faulting, swelling soils, or that require undersealing, plan for immediate localized repairs or global repairs in year one when the distress density is more than 33 percent and less than 66 percent.
65	High	JOINT SEAL DAMAGE	
66	Medium	SMALL PATCH	The standard policy is Patching PCC - Partial Depth, but when aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can cause delamination of partial-depth pavement repairs so a full-depth patch is required.

Airfield Concrete Pavement Localized Preventive M&R Policy - Other Considerations			
Distress	**Distress Severity**	**Description**	**Work Type Adjustments**
66	High	SMALL PATCH	The standard policy is Patching PCC - Partial Depth, but when the aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can cause delamination of partial-depth pavement repairs so a full-depth patch is required.
67	Medium	LARGE PATCH	The standard policy is Partial Depth PCC Patch, but if the patch is already full depth or if the pavement thickness is less than 8 inches, a full-depth patch is recommended. A partial-depth repair over an entire slab is, in effect, a fully bonded overlay, which is not typically allowed but may be considered for V-22 and B-1 parking positions. Note that if the base slab is damaged when doing a partial-depth repair, a full-depth repair is required. When aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can cause delamination of partial-depth pavement repairs so a full-depth patch is required.
69	N/A	PUMPING	The standard policy is Joint Seal (Localized) repair, but when pumping is significant or small voids are suspected, undersealing is required in addition to the joint seal.
70	Low	SCALING	In cases where scaling is widespread, grinding can be used to mitigate ponding issues and plow damage.
70	Medium	SCALING	The standard is a partial-depth patch, but when the scaling occurs on more than 50 percent of the slab, consider grinding or slab replacement.
71	Low	FAULTING	The standard is No Localized M&R, but when Low Severity Faulting occurs within 200 feet of an arresting system, it must be repaired. Consider grinding, slab jacking, or slab replacement to reestablish grade in these areas. Microsurfacing may be considered as an expedient solution until permanent repairs can be conducted.
71	Medium	FAULTING	The standard policy is grinding, but depending on the mission aircraft, location, and environment, consider slab jacking or slab replacement. Microsurfacing may be considered as an expedient solution until permanent repairs can be conducted.
71	High	FAULTING	The standard policy is grinding, but depending on the mission aircraft, location, and environment, consider slab jacking or slab replacement. For example, if faulting is greater than 1 inch on a runway or 2 inches on an apron, if the faulting is in a corner or if multiple slabs have faulting, replace slabs. Microsurfacing may be considered as an expedient solution until permanent repairs can be conducted.

Airfield Concrete Pavement Localized Preventive M&R Policy - Other Considerations			
Distress	**Distress Severity**	**Description**	**Work Type Adjustments**
72	Low	SHATTERED SLAB	The standard policy is No Localized because trying to do a repair on very narrow cracks can do more harm than good, but if cracks are approaching 1/8 inch (bordering on medium severity), crack sealing is appropriate to reduce the infiltration of water, which reduces potential of damage to the subgrade, freeze thaw damage, and reduces the likelihood that incompressible material will enter the crack and spall. In many cases, the cracking is not load related but a result of poor joint lay out, warping and curling, improper doweling, or other non-load-related stresses on the slab. This is especially true with 25-foot slabs that are less than 10 inches thick. As a result, the cracks may not be working cracks that generate FOD, but are functioning as joints.
72	Medium	SHATTERED SLAB	The standard policy is slab replacement, but if cracks are a result of slab geometry and are not working cracks (generating FOD), crack sealing is appropriate to reduce the infiltration of water, which reduces potential of damage to the subgrade, freeze thaw damage, and reduce the likelihood that incompressible material will enter the crack and spall. In many cases, the cracking is not load related but a result of poor joint lay out, warping and curling, improper doweling, or other non-load-related stresses on the slab. This is especially true with 25-foot slabs that are less than 10 inches thick. As a result, the cracks may not be working cracks that generate FOD, but are functioning as joints.
74	Low	JOINT SPALL	The standard policy is No Localized M&R, but some low-severity spalls may be repaired during joint resealing projects. The joint face preparation may remove some of the spall and joint seal material can be used to fill it. Note that if a joint spall is small enough to be filled during a joint seal repair, it is typically not recorded.
74	Medium	JOINT SPALL	The standard policy is Patching PCC - Partial Depth, but when aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can cause delamination of partial-depth pavement repairs so a full-depth patch is required.
74	High	JOINT SPALL	The standard policy is Patching PCC - Partial Depth, but when aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can cause delamination of partial-depth pavement repairs so a full-depth patch is required.
75	Low	CORNER SPALL	The standard policy is No Localized M&R, but if the crack associated with the corner spall is approaching 1/8 inch, crack sealing may be appropriate. When aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can cause delamination of partial-depth pavement repairs so a full-depth patch is required.

Airfield Concrete Pavement Localized Preventive M&R Policy - Other Considerations			
Distress	Distress Severity	Description	Work Type Adjustments
75	High	CORNER SPALL	The standard policy is Patching - PCC Partial Depth, but a full-depth patch is required if the partial-depth repair requires removal of more than 1/3 the slab thickness or if the repair is deep enough to expose the dowels. When aircraft operating on an airfield use thrust vectoring, e.g., the F-35, the jet blast can cause delamination of partial-depth pavement repairs so a full-depth patch is required.
76	Low	ASR	The standard policy is No Localized M&R, but recommend when work is performed, cut additional expansion joints to accommodate expansion and isolate structures such as drains, sunshades, POL, and manholes.
76	Medium	ASR	The standard policy is Partial Depth PCC Patch, but if the ASR extends across more than half of the slab, slab replacement is appropriate. In addition, if replacing areas around patches that now have ASR, consider slab replacement.

A-3.3 Global Maintenance Policies.

Tables A-14 through A-17 provide standard global maintenance and repair policies for asphalt and concrete airfield and road and parking pavement. See UFC 3-270-01 and UFC 3-250-03 for more details on global policy.

Table A-14 Asphalt Airfield Global M&R Policy

Global M&R Policy - Asphalt Airfield	
Distress Type	**Work Type**
Work type for minimal distress	Surface seal - fog seal
Work type for climate-related distress	Surface seal - rejuvenating
Work type for skid-causing distress	Surface treatment - slurry seal

Table A-15 Concrete Airfield Global M&R Policy

Global M&R Policy - Concrete Airfield	
Distress Type	**Work Type**
Work type for minimal distress	No global M&R
Work type for climate-related distress	Joint seal - silicone
Work type for skid-causing distress	No global M&R

Table A-16 Asphalt Road and Parking Global M&R Policy

Global M&R Policy - Asphalt Roads and Parking	
Distress Type	**Work Type**
Work type for minimal distress	Surface seal - fog seal
Work type for climate-related distress	Surface seal - rejuvenating
Work type for skid-causing distress	Surface treatment - slurry seal

Table A-17 Concrete Road and Parking Global M&R Policy

Global M&R Policy - Concrete Roads and Parking	
Distress Type	**Work Type**
Work type for minimal distress	No global M&R
Work type for climate-related distress	Joint seal - silicone
Work type for skid-causing distress	No global M&R

A-4 CONSEQUENCE OF MAINTENANCE POLICY TABLES.

The following consequence of maintenance policy tables (Tables A-18 through A-28) do not cover all potential alternatives for all distresses and work types but focus on the implementation of standard maintenance policy tables in this UFC.

Table A-18 Crack Sealing - AC

Crack Sealing - AC Consequence of Maintenance Policy					
Distress	**Description**	**Severity**	**New Distress**	**New Description**	**New Severity**
3	BLOCK CR	Low	3	BLOCK CR	Low
3	BLOCK CR	Medium	3	BLOCK CR	Low
3	BLOCK CR	High	3	BLOCK CR	Medium
7	EDGE CR	Low	7	EDGE CR	Low
7	EDGE CR	Medium	7	EDGE CR	Low
7	EDGE CR	High	7	EDGE CR	Medium
8	JT REF. CR	Low	8	JT REF. CR	Low
8	JT REF. CR	Medium	8	JT REF. CR	Low
8	JT REF. CR	High	8	JT REF. CR	Medium
10	L & T CR	Low	10	L & T CR	Low
10	L & T CR	Medium	10	L & T CR	Low
10	L & T CR	High	10	L & T CR	Medium
43	BLOCK CR	Low	43	BLOCK CR	Low
43	BLOCK CR	Medium	43	BLOCK CR	Low

Crack Sealing - AC Consequence of Maintenance Policy					
Distress	**Description**	**Severity**	**New Distress**	**New Description**	**New Severity**
43	BLOCK CR	High	43	BLOCK CR	Medium
47	JT REF. CR	Low	47	JT REF. CR	Low
47	JT REF. CR	Medium	47	JT REF. CR	Low
47	JT REF. CR	High	47	JT REF. CR	Medium
48	L & T CR	Low	48	L & T CR	Low
48	L & T CR	Medium	48	L & T CR	Low

A-5 ONE-YEAR UNCONSTRAINED WORK PLAN.

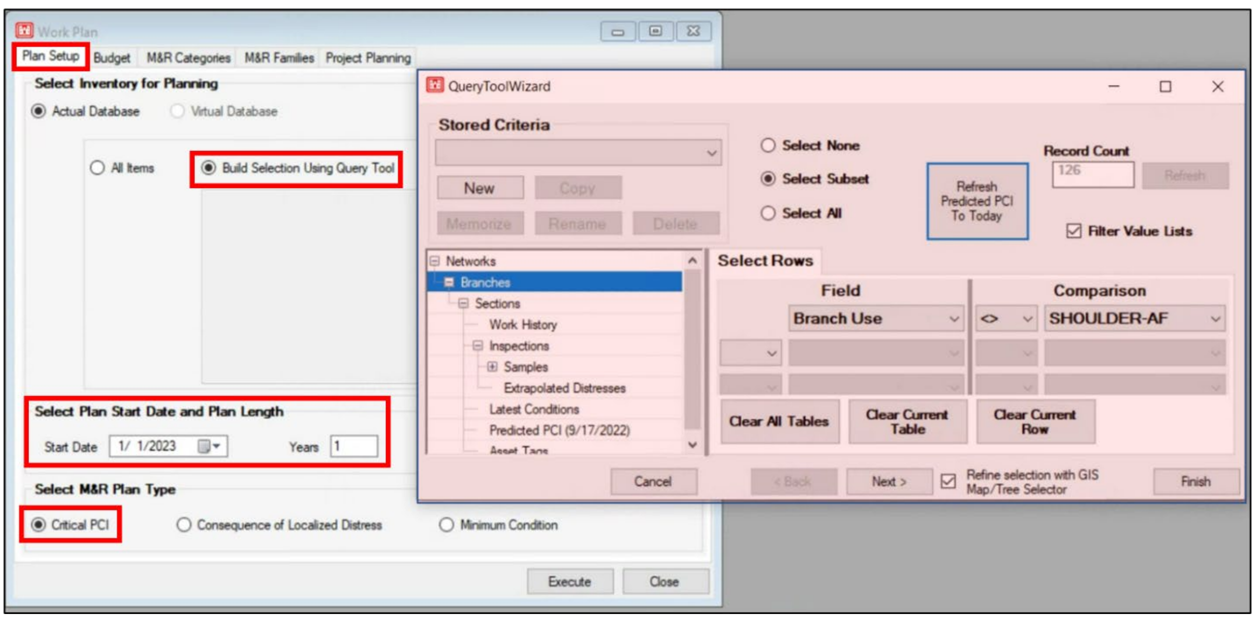
As described in paragraph 7-5.3, the one-year unconstrained work plan identifies all M&R requirements in all M&R categories to repair all sections in the current year. It is not typically used as the optimal critical PCI work plan because it is unrealistic to make all repairs in one year given funding, manpower, and contracting limitations. However, this work plan provides an indication of the magnitude of the requirements and, per paragraph 7-5.3, can be used to determine the facility condition index and develop Major M&R cost by condition tables.

A-5.1 Plan Setup Tab

This example demonstrates the steps to create a critical PCI unconstrained work plan for an airfield network. The procedure is the same for a road and parking area network. In this example, assume shoulders are not inspected, so there is no condition data available to define M&R requirements.

- Select the **Build Selection Using Query Tool** option to filter out the shoulders as shown in Figure A-1. If all sections in the network were inspected, including shoulders, select the **All Items** option on the **Plan Setup** tab.
- Set the plan start date to the first day of the next calendar year after the current PCI inspection date when the work plan is developed in conjunction with a PCI inspection. Use the first day of the calendar year after the current date when doing interim work plan updates.
- Set the plan length to one year.

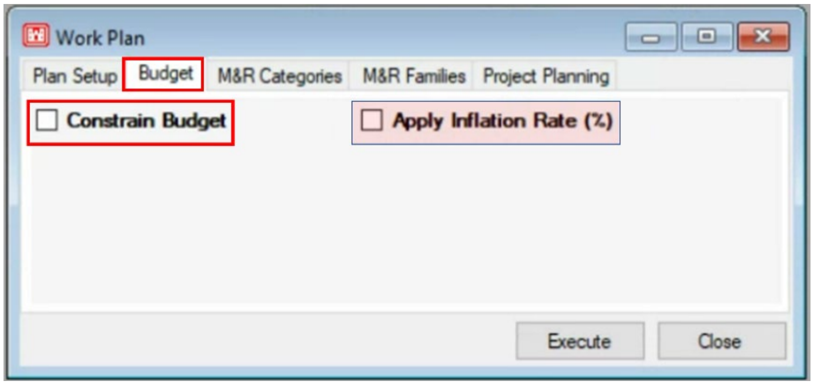
Figure A-1 Unconstrained Work Plan, Plan Setup Tab



A-5.2 Budget Tab.

Leave the **Constrain Budget** checkbox unchecked to develop an unconstrained budget. Leave the **Apply Inflation Rate (%)** checkbox unchecked as shown in Figure A-2 and discussed in paragraph 7-5.2.

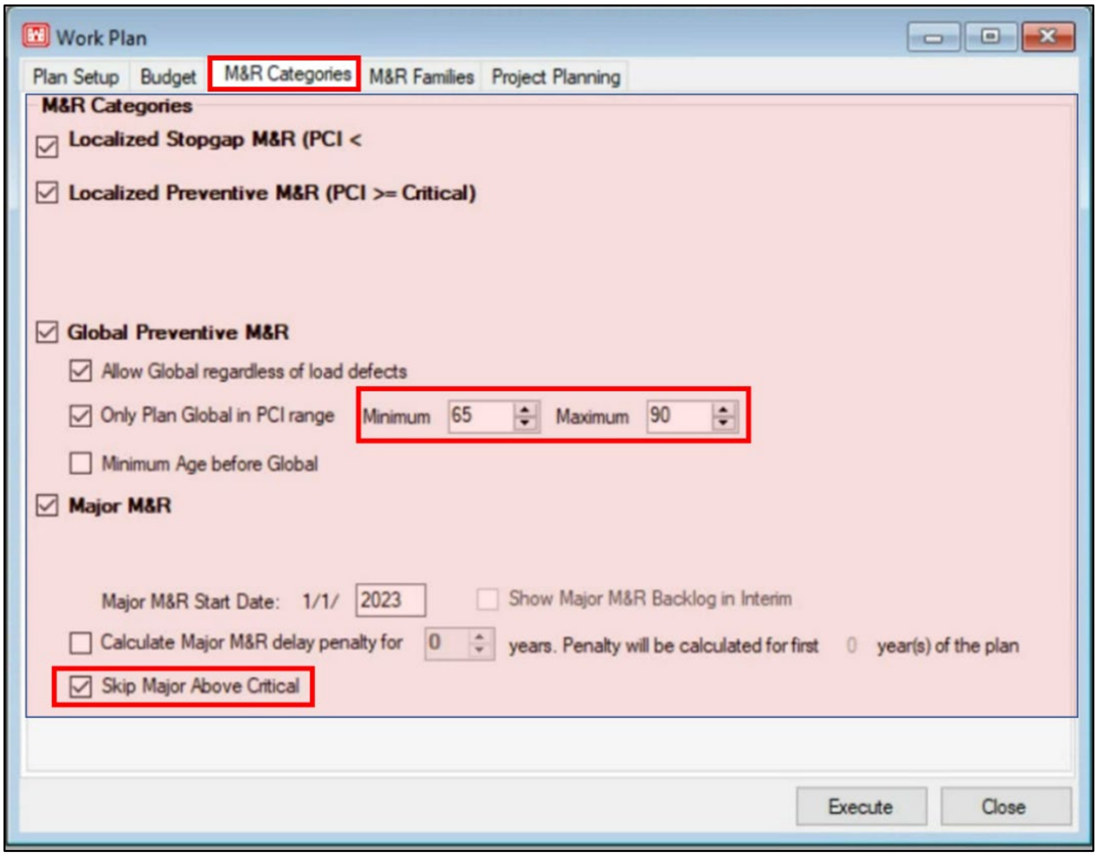
Figure A-2 Unconstrained Work Plan Setup Tab



A-5.3 M&R Categories Tab.

Since the unconstrained work plan identifies all current M&R requirements, select all M&R categories as shown in Figure A-3. This example applies global M&R regardless of load defects and generates global M&R requirements when the section PCI is between 65 and 90 (see paragraph 7-6.4). Check the **Skip Major Above Critical** box (see paragraph 7-6.4.2).

Figure A-3 Unconstrained Work Plan, M&R Categories Tab

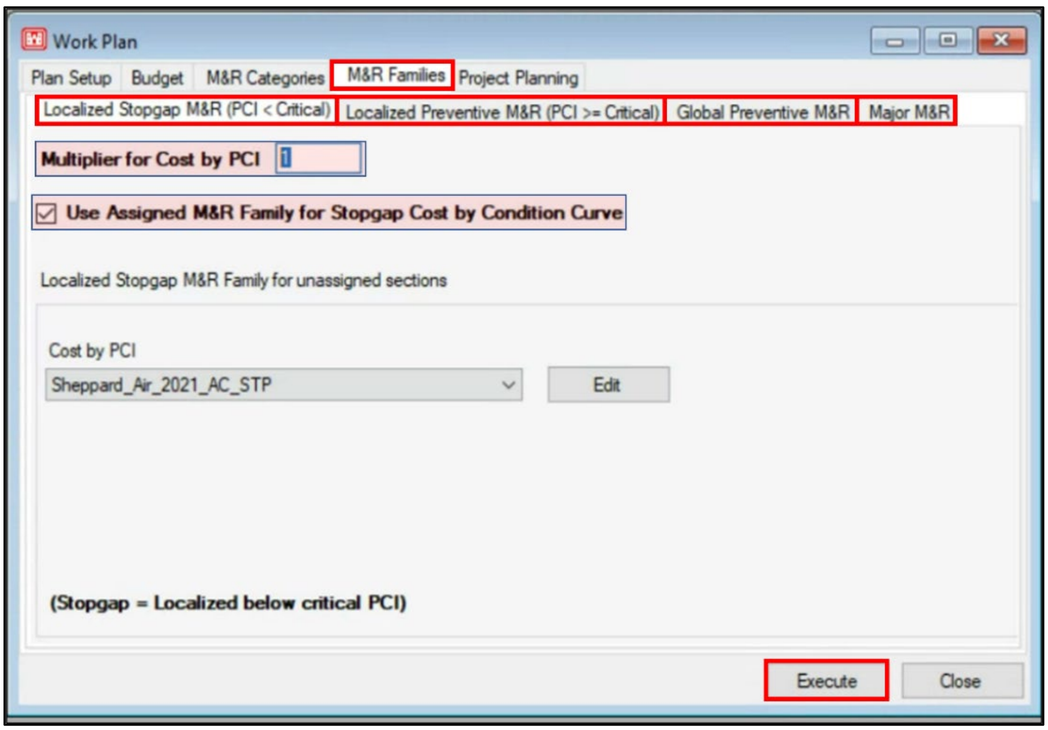


A-5.4 M&R Families Tab.

The example in Figure A-4 shows the **Localized Stopgap (M&R)** tab. Each tab for the other M&R families is similar.

- Set the value in the **Multiplier for Cost by PCI** box to 1.
- The **Use Assigned M&R Family for Stopgap Cost by Condition Curve** checkbox is checked by default for all M&R types. This example assumes all sections are assigned to the appropriate M&R families.
- The **Cost by PCI** option for unassigned sections is not used because all inspected sections are assigned to appropriate families.

Figure A-4 Unconstrained Work Plan, M&R Families Tab



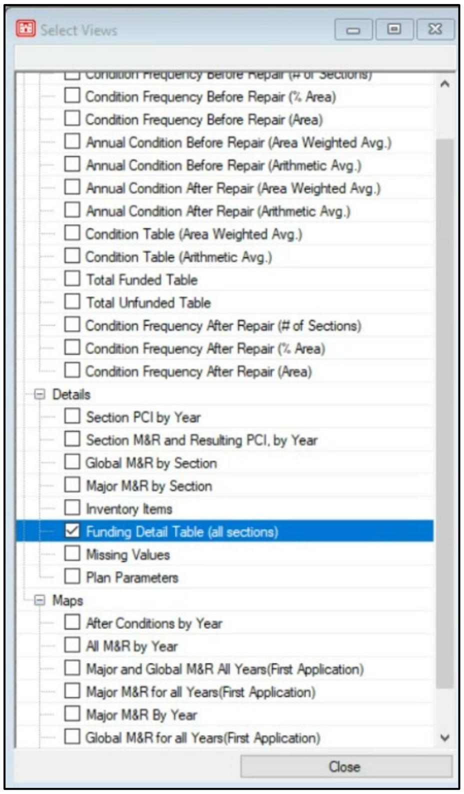
A-5.5 Project Planning Tab.

The **Project Planning** tab is not used when developing an unconstrained budget but is used when using PAVER to develop a PMP, as described in paragraph 7-8. Examples of how to use the **Project Planning** tab are provided in paragraphs A-5.5, A-6.5, A-7.5 and A-9.8.

A-5.6 Execute One-Year Unconstrained Work Plan.

Select **Execute** in the lower right-hand corner of the form as shown in Figure A-4. Once the work plan is generated, PAVER provides work plan views as shown in Figure A-5 at the Summary (Branch) level and the Detail (Section) level as well as map views of the data. These views are pre-defined reports that provide information on condition, plan parameters, missing values, M&R requirements, and costs. Any table in any of these views can be exported to Excel using a right-click and selecting the option to export to file (*.xlsx).

Figure A-5 One-Year Unconstrained Budget – Work Plan Views



- In this example, select **Funding Detail Table (all sections)**. When the table opens, right-click and select export to Excel.
- A pop-up window asks whether to include hidden columns. Respond yes.
- Open this report in Excel, unhide all of the columns.
- Find the **RPUID** column, select cut, and insert it between the **Branch ID** and **Section ID** columns.
- Sort the report by RPUID and arranging the columns as shown in Figure A-6. This allows the user to determine the M&R types and cost for each facility to determine the facility condition index or to develop Major M&R cost by condition tables, as described in paragraph 6-3.5 and paragraph 6-5.3.

Figure A-6 Funding Detail Table

Network ID	Branch ID	RPUID	Section ID	Avg Of Condition Before	Avg Of Condition After	Stop Gap Funded	Preventive Funded	Global Funded	Major Under Critical Funded	Work Type	Total

A-6 CONSTRAINED BACKLOG ELIMINATION WORK PLAN.

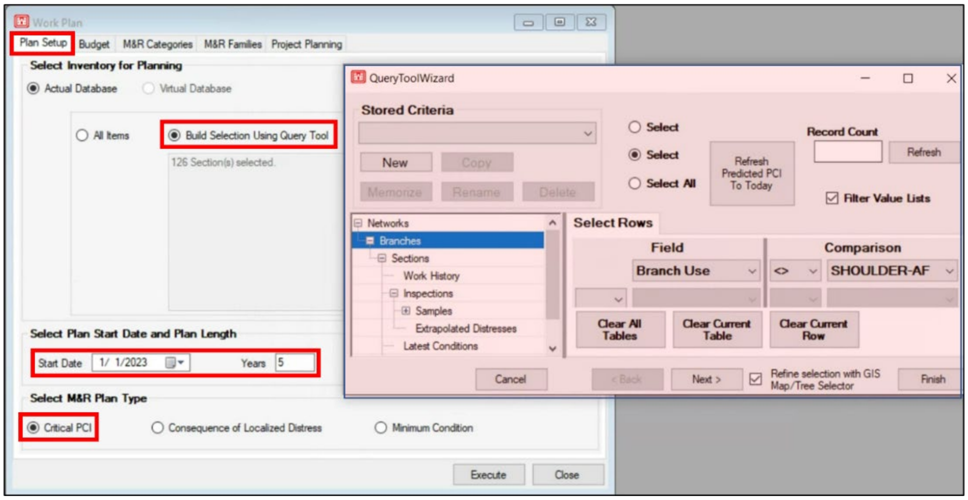
As described in paragraphs 7-5.4 and 7-5.7, the backlog elimination work plan identifies all M&R requirements in all M&R categories to repair all sections, but rather than doing it in one year, it addresses these requirements over multiple years. The standard used by the DoD is five years, although circumstances or specific mission requirements may require increasing this timeline. This work plan is typically selected as the optimal work plan used to develop the PMP when the average network PCI is below 85. The details of developing the PMP using the optimal critical PCI work plan are described in Chapter 8 and paragraph A-9.

A-6.1 Plan Setup Tab.

This example demonstrates the steps to create a critical PCI eliminate backlog work plan for an airfield network. The procedure is the same for a road and parking area network. In this example, assume shoulders are not inspected, so there is no condition data available to define M&R requirements.

- Select the **Build Selection Using Query Tool** option to filter out the shoulders, as shown in Figure A-7. If all sections in the network are inspected, select the **All Items** option on the **Plan Setup** tab.
- Set the plan start date to the first day of the next calendar year after the current PCI inspection date when the work plan is developed in conjunction with a PCI inspection. Use the first day of the calendar year after the current date when doing interim work plan updates.
- Set the plan length to five years.

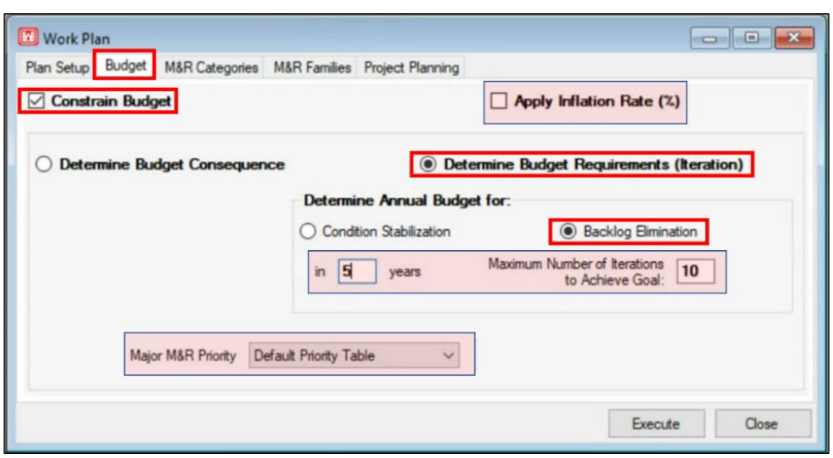
Figure A-7 Eliminate Backlog Work Plan, Plan Setup Tab



A-6.2 Budget Tab.

- Check the **Constrain Budget** checkbox to develop a constrained budget (Figure A-8).
- Leave the **Apply Inflation Rate (%)** checkbox unchecked (paragraph 7-5.2).
- Select the **Determine Budget Requirements (Iteration)** and **Backlog Elimination** options.
- Set up the plan to eliminate the backlog in five years.
- Leave **Maximum Number of Iterations to Achieve Goal** set to 10. This defines the number of times PAVER tries to develop a balanced budget in each of the five years.
- Use the **Default Priority Table** option in **Major M&R Priority** (paragraph 7-5.5).

Figure A-8 Eliminate Backlog Work Plan Setup Tab

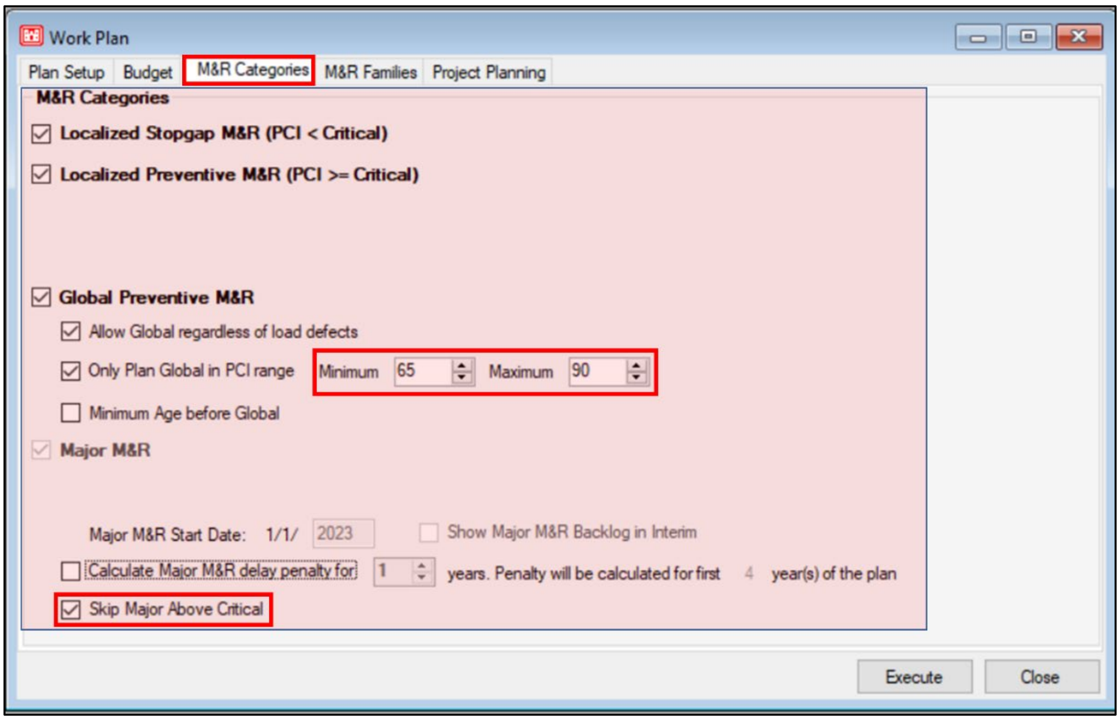


A-6.3 M&R Categories Tab.

Just as with the unconstrained work plan, the eliminate backlog work plan identifies all M&R requirements required to achieve the goal.

- Select all **M&R Categories** as shown in Figure A-9.
- This example applies global M&R regardless of load defects and generates global M&R requirements when the section PCI is between 65 and 90 (paragraph 7-6.3).
- Leave the **Calculate Major M&R delay penalty** box unchecked (paragraph 7-6.4).
- Check the **Skip Major Above Critical** box (paragraph 7-6.4.2).

Figure A-9 Eliminate Backlog Work Plan, M&R Categories Tab

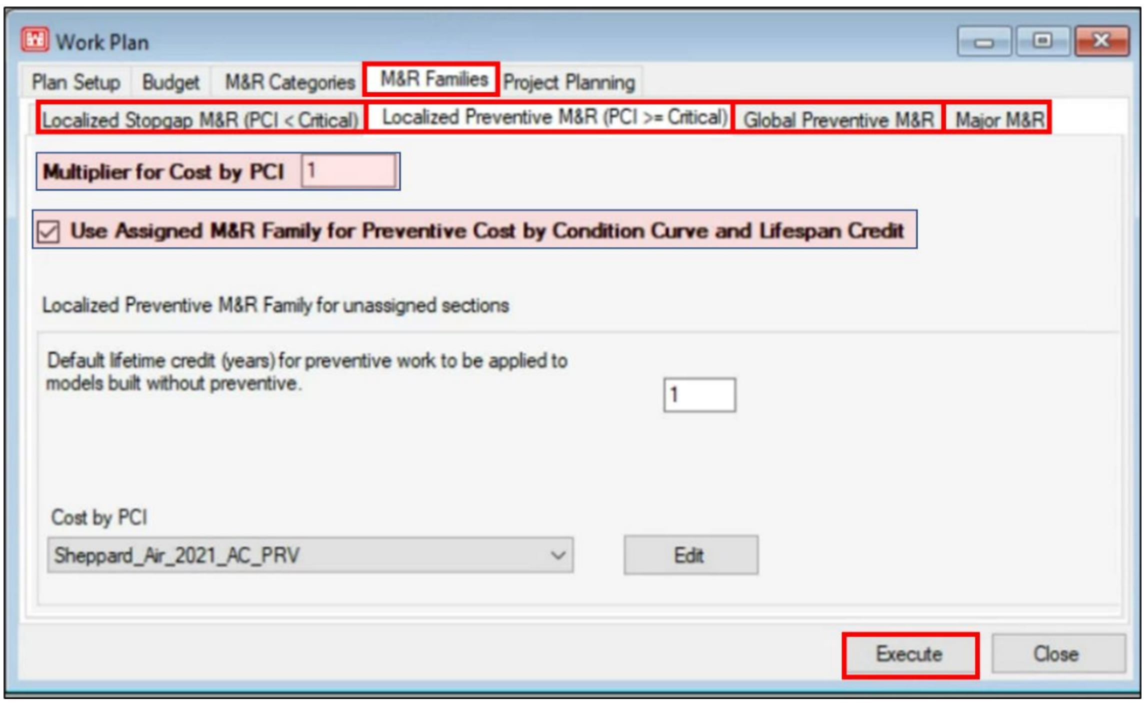


A-6.4 M&R Families Tab.

The example in Figure A-10 shows the **Localized Preventive M&R** tab. Each of the tabs for the other M&R families are similar.

- Set the value in the **Multiplier for Cost by PCI** box to 1.
- The **Use Assigned M&R Family for Preventive Cost by Condition Curve and Lifespan Credit** checkbox is checked by default for all M&R types. This example assumes all sections are assigned to the appropriate M&R families.
- The **Cost by PCI** option for unassigned sections is not used because all inspected sections are assigned to appropriate families.

Figure A-10 Eliminate Backlog Work Plan, M&R Families Tab



A-6.5 Project Planning Tab.

The **Project Planning** tab is used when using PAVER to develop a PMP, as described in paragraph 7-8. Examples of how to use the **Project Planning** tab are provided in paragraph A-9.

A-6.6 Execute Eliminate Backlog Work Plan.

Select **Execute** in the lower right-hand corner of the form, as shown in Figure A-10. Once the work plan is generated, as shown in Figure A-11, PAVER provides work plan views at the Summary (Branch) level and the Detail (Section) level as well as map views of the data. These views are pre-defined reports that provide information on condition, plan parameters, missing values, M&R requirements, and costs. Any table in any of these views can be exported to Excel using a right-click and selecting the option to export to file (*.xlsx).

- In this example, select **Funding Detail Table (all sections)**. When the table opens, right-click and select export to Excel.
- A pop-up window asks whether to include hidden columns. Respond yes.
- Open this report in Excel and unhide all of the columns.
- Use the Excel cut and insert cut functions to rearrange the columns in the table to look like the one in Figure A-12.
    - o Keep **Network ID**, **Branch ID**, and **Section ID** columns (C, D, and E) in the report.
    - o Either the **Date** column (F) or the **Work Year** column (I) can be used in the report to perform the sorting process outlined below.
    - o Hide the **Avg. of Condition Before** column and **After** column (G and H); they can be used later in the PMP development process.
    - o Move the **Branch Use** column (N), **Section Rank** column (O) and **Surface Type Current** column (P) to the right of the **Work Year** column (I).
    - o Move **Work Type** (column BB) to the right of the **Surface Type Current** column.
    - o Retain the **Stop Gap Funded**, **Preventive Funded**, **Global Funded**, **Major Under Critical Funded**, and **Total Funded** columns (J, L, AV, AY, and BE) in the report.
    - o Delete or hide the remaining columns.
- Use the Excel sort capability to sort the report by date, then **Branch Use**, then **Section Rank**. This procedure produces a prioritized list of requirements for each year in the plan.
- When the eliminate backlog work plan is selected as the optimal work plan, it is to develop the PMP as outlined in Chapter 8 and paragraph A-9.

Figure A-11 Eliminate Backlog Work Plan Views

A-7 CONSTRAINED CONDITION STABILIZATION WORK PLAN.

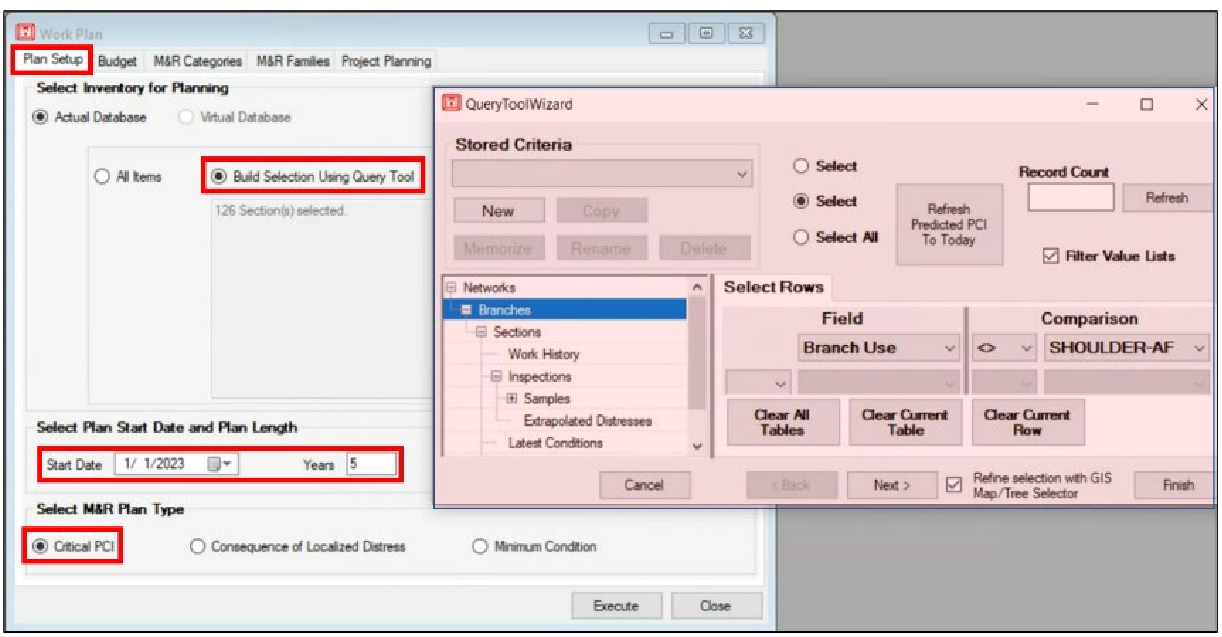
As described in paragraphs 7-5.4, 7-5.7, and 7-5.7.2, the condition stabilization work plan identifies all M&R requirements to maintain the condition of all sections within a defined tolerance for the defined number of years. The standard time frame used by the DoD is five years, although circumstances or specific mission requirements may require adjusting this timeline. This work plan is typically selected as the optimal work plan used to develop the PMP when the average network PCI is greater than or equal to 85. The details of developing the PMP using the optimal critical PCI work plan are described in Chapter 8 and paragraph A-9.

A-7.1 Plan Setup Tab.

This example demonstrates the steps to create a critical PCI condition stabilization work plan for an airfield network. The procedure is the same for a road and parking area network. In this example, assume shoulders are not inspected, so there is no condition data available to define M&R requirements.

- Select the **Build Selection Using Query Tool** option to filter out the shoulders, as shown in Figure A-13. If all sections in the network are inspected, select the **All Items** option on the **Plan Setup** tab.
- Set the plan start date to the first day of the next calendar year after the current PCI inspection date when the work plan is developed in conjunction with a PCI inspection. Use the first day of the calendar year after the current date when doing interim work plan updates.
- Set the plan length to five years.

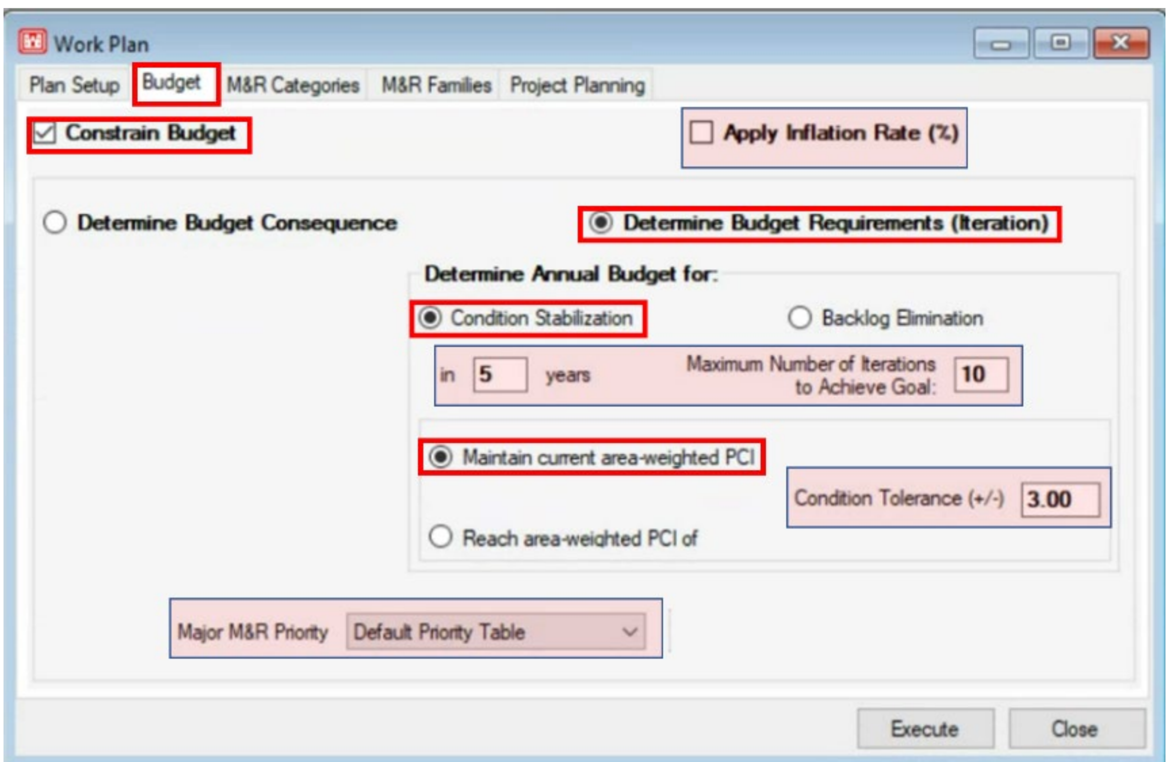
Figure A-13 Condition Stabilization Work Plan, Plan Setup Tab



A-7.2 Budget Tab.

- Check the **Constrain Budget** checkbox to develop a constrained budget, as shown in Figure A-14.
- Leave the **Apply Inflation Rate (%)** checkbox unchecked (see paragraph 7-5.2).
- Select the **Determine Budget Requirements (Iteration)** and **Condition Stabilization** options.
- Set the condition stabilization period to five years.
- Leave **Maximum Number of Iterations to Achieve Goal** set to 10. This defines the number times PAVER tries to develop a balanced budget in each of the five years.
- Select the **Maintain current area-weighted PCI** option.
- Set the **Condition Tolerance** to ±3. The tolerance can be adjusted if required.
- Use the **Default Priority Table** option in **Major M&R Priority** (see paragraph 7-5.5)

Figure A-14 Condition Stabilization Work Plan Setup Tab

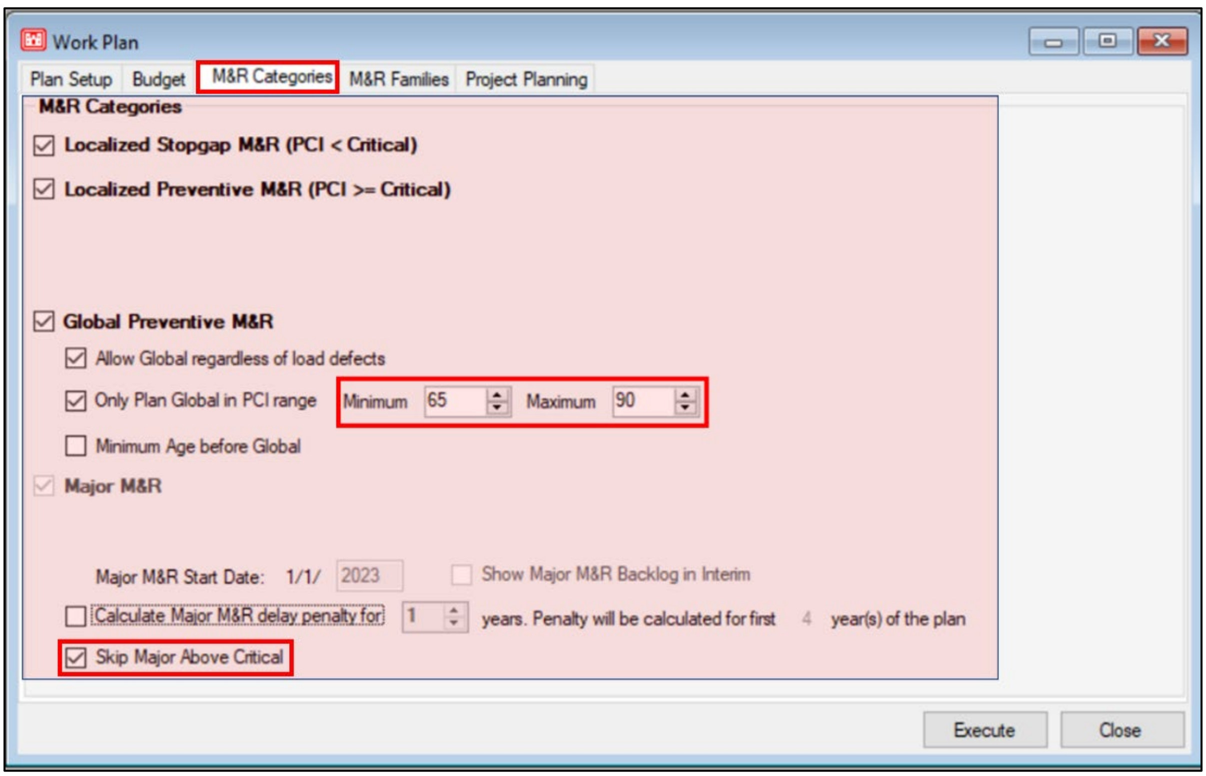


A-7.3 M&R Categories Tab.

Just as with the eliminate backlog work plan, the condition stabilization work plan identifies all M&R requirements required to achieve the goal.

- Select all M&R categories as shown in Figure A-15.
- This example applies global M&R regardless of load defects and generates global M&R requirements when the section PCI is between 65 and 90 (see paragraph 7-6.3).
- Leave the **Calculate Major M&R delay penalty** box unchecked (see paragraph 7-6.4.1).
- Check the **Skip Major M&R Above Critical** box (see paragraph 7-6.4.2).

Figure A-15 Condition Stabilization Work Plan, M&R Categories Tab

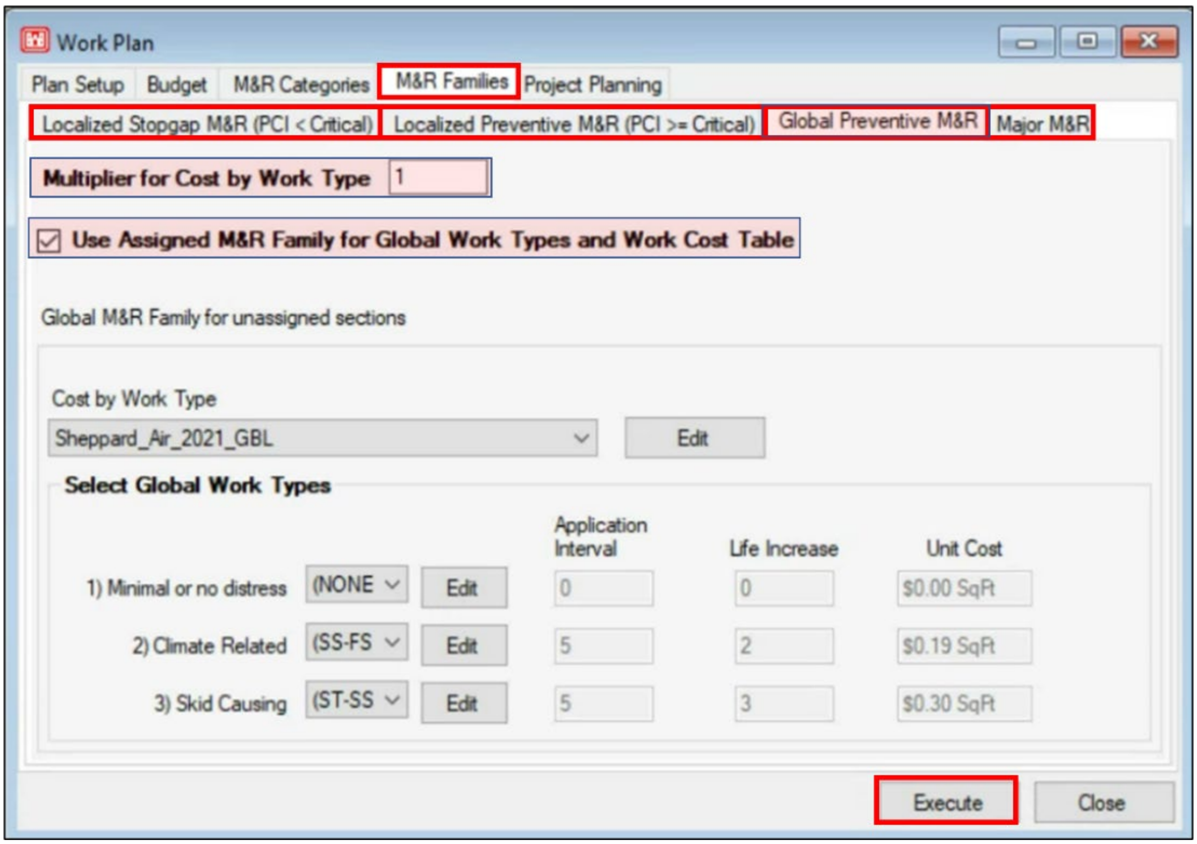


A-7.4 M&R Families Tab.

The example in Figure A-16 shows the **Global Preventive M&R** tab. Each of the tabs for the other M&R families are similar.

- Set the value in the **Multiplier for Cost by Work Type** box to 1.
- The **Use Assigned M&R Family for Global Work Types and Work Cost Table** checkbox is checked by default for all M&R types. This example assumes all sections are assigned to the appropriate M&R families.
- The **Cost by Work Type** option for unassigned sections is not used because all inspected sections are assigned to appropriate families.

Figure A-16 Condition Stabilization Work Plan, M&R Families Tab



A-7.5 Project Planning Tab.

The **Project Planning** tab is used when using PAVER to develop a PMP as described in paragraph 7-8. Examples of how to use the **Project Planning** tab are provided in paragraph A-9.

A-7.6 Execute Condition Stabilization Work Plan.

Select **Execute** in the lower right-hand corner of the form as shown in Figure A-16. Once the work plan is generated, as shown in Figure A-17, PAVER provides work plan views at the Summary (Branch) level and the Detail (Section) level as well as map views of the data. These views are pre-defined reports that provide information on condition, plan parameters, missing values, M&R requirements, and costs. Any table in any of these views can be exported to Excel using a right-click and selecting the option to export to file (*.xlsx).

- In this example, select **Funding Detail Table (all sections)**. When the table opens, right-click and select export to Excel.
- A pop-up window asks whether to include hidden columns. Respond yes.
- Open this report in Excel and unhide all of the columns.
- Use the Excel cut and insert cut functions to rearrange the columns in the table to look like the one in Figure A-18.
    - Keep **Network ID**, **Branch ID**, and **Section ID** columns (C, D, and E) in the report.
    - Either the **Date** column (F) or the **Work Year** column (I) can be used in the report to perform the sorting process outlined below.
    - Hide the **Avg. of Condition Before** column and **After** column (G and H); they can be used later in the PMP development process.
    - Move the **Branch Use** column (N), **Section Rank** column (O) and **Surface Type Current** column (P) to the right of the **Work Year** column (I).
    - Move **Work Type** (column BB) to the right of the **Surface Type Current** column.
    - Retain the **Stop Gap Funded**, **Preventive Funded**, **Global Funded**, **Major Under Critical Funded**, and **Total Funded** columns (J, L, AV, AY, and BE) in the report.
    - Delete or hide the remaining columns.
- Use the Excel sort capability to sort the report by **Work Year**, then **Branch Use**, then **Section Rank**. This procedure produces a prioritized list of requirements for each year in the plan.
- When the eliminate backlog work plan is selected as the optimal work plan, it is to develop the PMP as outlined in Chapter 8 and paragraph A-9.

Figure A-17 Condition Stabilization Work Plan Views

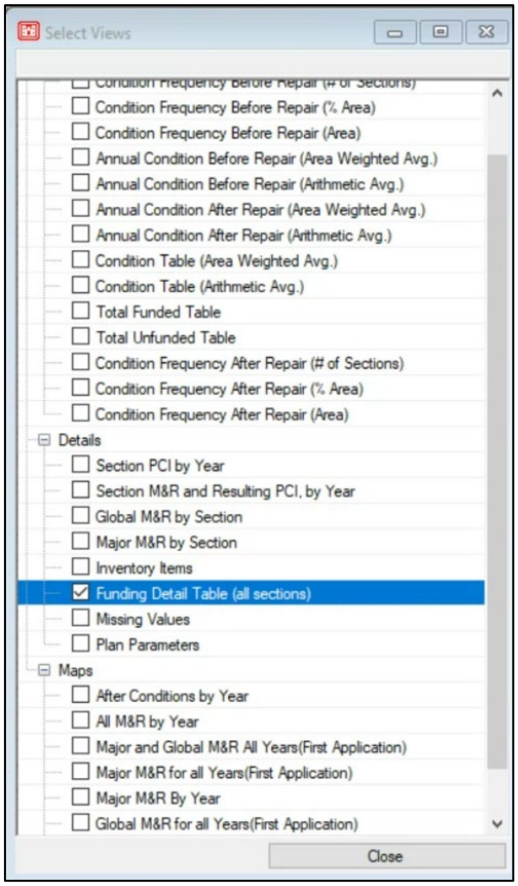


Figure A-18 Sorted Condition Stabilization Work Plan

Network ID	Branch ID	Section ID	Work Year	Branch Use	Section Rank	Surface Type Current	Work Type	Stop Gap Funded	Preventive Funded	Global Funded	Major Under Critical Funded	Total Funded

A-8 CONSEQUENCE OF LOCALIZED DISTRESS MAINTENANCE WORK PLAN.

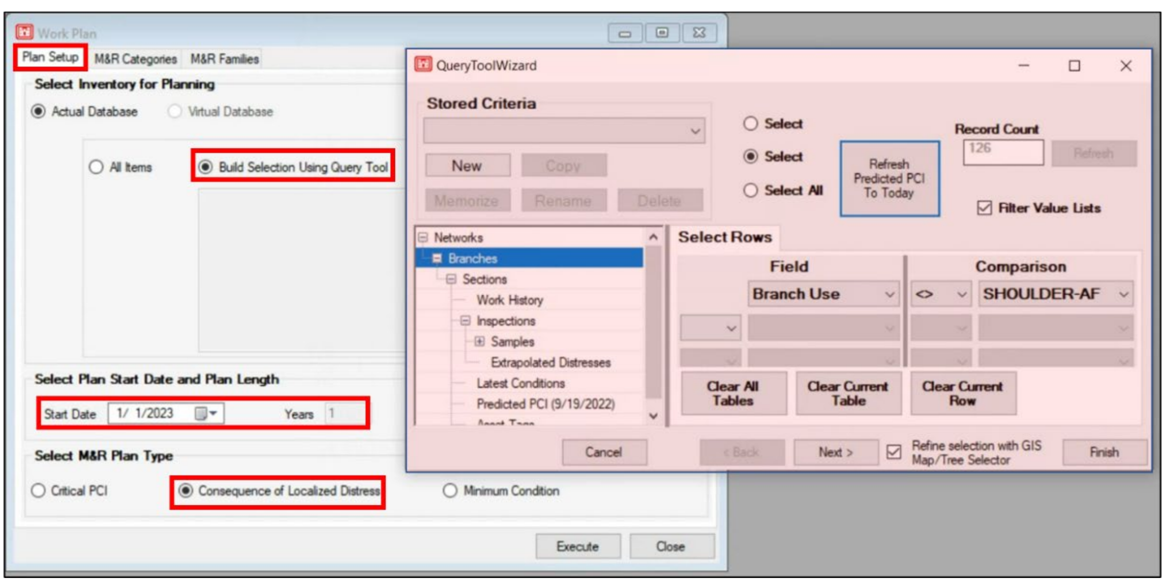
As described in paragraph 7-4, the consequence of localized distress maintenance work plan generates a list of all the localized work requirements based on the assigned distress maintenance policy, calculates the cost of each requirement based on the cost by work type tables, and computes the resulting conditions based on the consequence of maintenance policy when the distresses are repaired according to the distress maintenance policy. This work plan is used in conjunction with the optimal critical PCI work plan to develop the PMP, as described in Chapter 8 and paragraph A-9.

A-8.1 Plan Setup Tab.

This example demonstrates the steps to create a consequence of localized distress work plan for an airfield network. The procedure is the same for a road and parking area network. In this example, assume shoulders are not inspected, so there is no condition data available to define M&R requirements.

- Select the **Build Selection Using Query Tool** option to filter out the shoulders, as shown in Figure A-19. If all sections in the network were inspected, including shoulders, select the **All Items** option on the **Plan Setup** tab.
- Set the plan start date to the first day of the next calendar year after the current PCI inspection date when the work plan is developed in conjunction with a PCI inspection. Use the first day of the calendar year after the current date when doing interim work plan updates.
- The plan length is set to one year by default and cannot be changed.
- Note that the **Budget** and **Project Planning** tabs are no longer displayed.

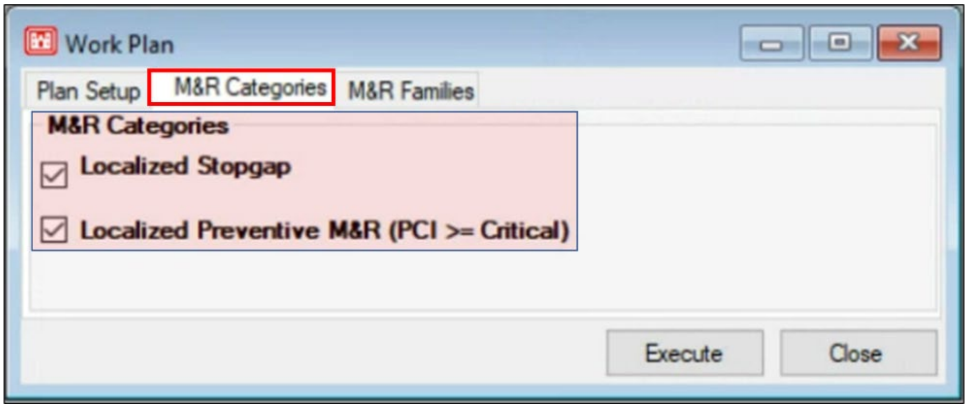
Figure A-19 Consequence of Localized M&R Work Plan, Plan Setup Tab



A-8.2 M&R Categories Tab.

The consequence of localized distress maintenance work plan just includes requirements for localized operational (stopgap) and localized preventive, as described in paragraph 7-4.

Figure A-20 Consequence of Localized M&R Work Plan, M&R Categories Tab

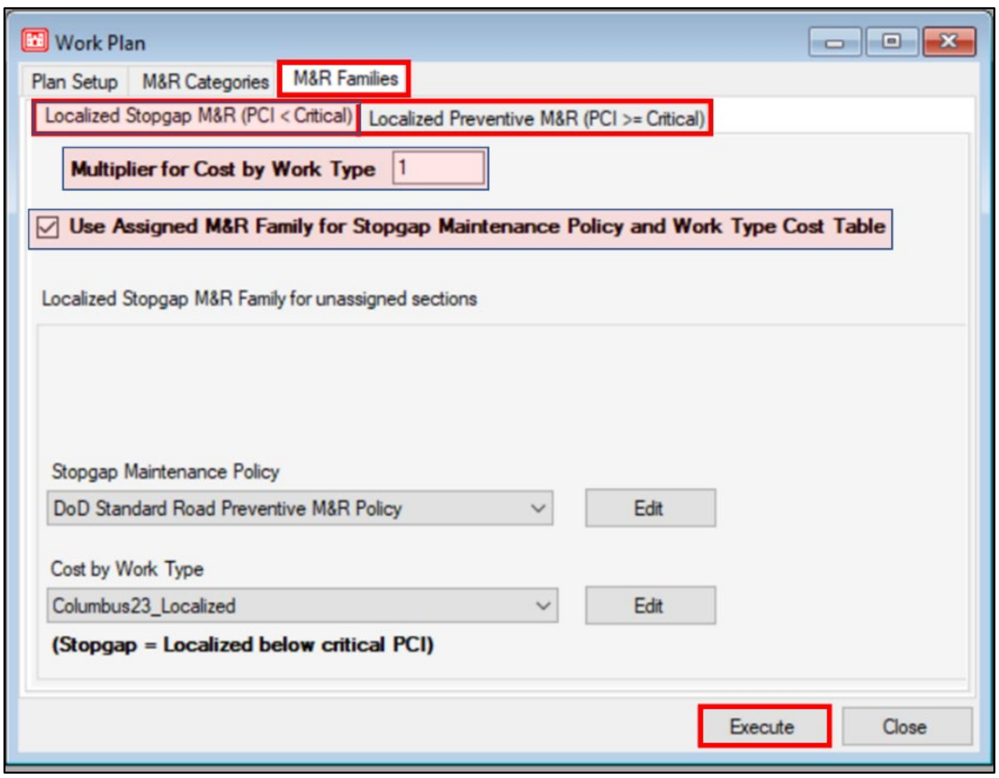


A-8.3 M&R Families Tab.

The example in Figure A-21 shows the **Localized Stopgap M&R** tab. The tab for **Localized Preventive M&R** is similar. **Note:** There are no tabs for Global or Major M&R because this work plan only considers localized.

- Set the value in the **Multiplier for Cost by Work Type** box to 1.
- The **Use Assigned M&R Family for Stopgap Maintenance Policy and Work Type Cost Table** checkbox is checked by default for all M&R types. This example assumes all sections are assigned to the appropriate M&R families.
- The **Stopgap Maintenance Policy** and **Cost by Work Type** options for unassigned sections are not used because all inspected sections are assigned to appropriate families.

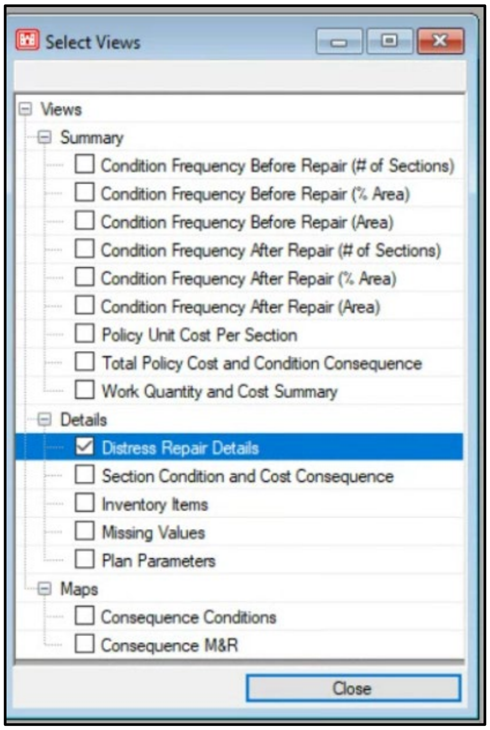
Figure A-21 Unconstrained Work Plan, M&R Families Tab



A-8.4 Execute Consequence of Localized M&R Work Plan.

Select **Execute** in the lower right-hand corner of the form as shown in Figure A-21. Once the work plan is generated, PAVER provides work plan views, as shown in Figure A-22, at the Summary (Branch) level and the Detail (Section) level as well as map views of the data. These views are pre-defined reports that provide information on condition, plan parameters, missing values, M&R requirements, and costs. Any table in any of these views can be exported to Excel using a right-click and selecting the option to export to file (*.xlsx).

Figure A-22 Condition Stabilization Work Plan Views



- In this example, select the **Distress Repair Details** view. When the table opens, right-click and select export to Excel.
- A pop-up window asks whether to include hidden columns. Respond yes.
- Open this report in Excel and unhide all of the columns.
- Use the Excel cut and insert cut functions to rearrange the columns in the table to look like the one in Figure A-23.
    - o Keep **Network ID**, **Branch ID**, and **Section ID** columns (B, D, and D) in the report.
    - o Move the **Branch Use** column (N) and **Section Rank** column (O) to the right of the **Section ID** column (D).
    - o Move the **Age at Inspection** column (AO) and the **Condition** column (AQ) to the right of the **Section Rank** column.

  - o Hide the **Distress Code** column.
  - o Move the **Work Qty**, **Work Unit**, **Unit Cost**, and **Work Cost** columns (AV, AW, AY, and AZ) to the right of the **Work Description** column.
  - o Other columns may be included in the report.
  - o Delete or hide any unused columns.
- Use the Excel sort capability to sort the report by **Branch Use**, **Section Rank**, then **Branch ID**. This procedure produces a prioritized list of requirements for each year in the plan.
- This prioritized list augments the information in the critical PCI work plan, as outlined in Chapter 7, paragraph A-6 and paragraph A-7.

A-9 DEVELOPING PAVEMENT MANAGEMENT PLANS.

A-9.1 Objective.

The level of detail in a pavement management plan (PMP) can range from a spreadsheet with a prioritized list of work tasks and projects in each year of the plan to a detailed document that outlines the team composition and development process, including limiting factors, assumptions, and analysis of alternatives. The objective of this UFC is to define the minimum PMP requirement, a prioritized list of work items and projects required to maintain pavements for each year in the next five calendar years.

A-9.2 Background.

A PMP is the end product of a team effort to prioritize and group pavement M&R requirements into executable work tasks and projects, as described in Chapter 8. There are different approaches to developing a PMP. This appendix uses the optimal critical PCI work plan and the consequence of localized work plan described in Chapter 7 and paragraphs A-6 and A-7 as the starting point for the process below.

1. Determine whether the eliminate backlog or condition stabilization work plan is optimal.
2. Export the optimal work plan and the consequence of localized M&R work plan to Excel, retaining all hidden columns.
3. Prioritize requirements in each work plan as described in paragraphs A-6 and A-7.
4. Add columns for the Priority, Risk-Return Category, and Method of Execution to the optimal work plan as described in this appendix and in Chapter 8.
5. Sort the optimal work plan and the consequence of localized work plan as described in this appendix and in Chapter 8 and group requirements into a prioritized list of executable work tasks and projects.
6. The prioritized list of executable work tasks and projects can serve as the PMP, but inputting the required work from the project list into PAVER provides a means of making the PMP development process easier over time.
    a. Enter the work tasks and projects into PAVER using the **Required Work** tool or **Project Planning Wizard**.
    b. Rerun the optimal work plan with the required work and repeat process, as required.
    c. For large installations, enter high-priority projects into PAVER, rerun the work plans, enter medium-priority projects, rerun work plans, etc.
7. Whether the PMP development team uses the PAVER project planning tools or not, the final result is a prioritized list of executable tasks and projects that is approved by leadership, maintained as work is completed, and updated at least annually.

When an installation has both an airfield network and a road and parking network, select an optimal critical PCI work plan for each; do not combine airfield and road and parking networks.

The examples in this appendix use a five-year eliminate backlog work plan for a road and parking network as the optimal critical PCI work plan. These examples do not attempt to address all the scenarios that might arise in developing a PMP, but rather provide guidance on the general process and addresses some common issues that might arise.

A-9.3 Initial Optimal Critical PCI Work Plan View.

The optimal critical PCI work plan used for this example is the eliminate backlog work plan for a road and parking network developed following the same procedure outlined in paragraphs A-6.1 to A-6.6. The result is the initial prioritized list of requirements shown in Figure A-24.

Figure A-24 Critical PCI Work Plan Funding Detail Table (All Sections)

A-9.4 Add Priority and Risk–Return Category Columns.

Using the prioritized requirements list in Figure A-24, modify the spreadsheet by adding columns as shown in Figure A-25.

- Add an M&R **Priority** column (paragraph 8-6.1).
- Add a **Risk-Return Category** column (paragraph 8-6.4).
- Assign a priority value to each requirement for each year of the work plan based on the branch use and section rank as described in paragraph 8-6.1 and Table 8-1.
- Sort the spreadsheet by **Work Year**, **Priority**, and **Average Condition Before**.
- Use the values in the **Priority** and **Average Condition Before** columns to define a risk - return category for each requirement in each year of the work plan, as described in paragraph 8-6.4 and Figure 8-3.

Figure A-25 Priority and Risk-Return Columns

A-9.5 Defining Method of Execution.

Using the requirements list in Figure A-25, modify the spreadsheet by adding a column for **Method of Execution**, as shown in Figure A-26.

- Assign a preliminary method of execution for each requirement in each year of the work plan (paragraph 8-7.2). This example assumes the following:
  - o In-house work forces have the capability to do localized AC and PCC repairs but do not have the capability to do global preventive M&R.
  - o There is an IDIQ contract in place with the capability to do global preventive M&R as well as localized AC and PCC repairs, but it does not have the capability to major M&R such as mill and overlay.
  - o Major M&R work will be done by competitive bid or existing multiple award task order contract (MATOC).
- Review the Consequence of Localized M&R Distress Repair Details Report and consider the types and severity of distresses present when determining the method of execution.
  - o The consequence of localized M&R work plan is based on the condition of the pavement at the time of the last inspection
  - o In Figure A-26, the eliminate backlog work plan called for preventive M&R whereas the consequence of localized M&R work

plan example in Figure A-27 shows no localized M&R because all distresses are low severity.

- o Differences like this arise because the eliminate backlog work plan anticipates the condition will deteriorate and preventive M&R will be required.

- o In this example, localized preventive M&R is a good option to repair any distresses that progressed to medium severity and global M&R is a good option to address the weathering. **Note:** The work plan had projected preventive and global M&R for RDLARCHER in 2025, but could be changed to 2023 given the high priority and return on investment.

A-9.6 Aggregating Requirements into Executable Tasks and Projects.

Defining the requirements for an in-house task list or a project can be accomplished using different approaches. The examples in this appendix aggregate requirements into projects by doing a series of sorts on the prioritized requirement list using the **Execution Year**, **Branch ID**, **Section ID**, **Priority**, **Risk-Return Category**, and **Method of Execution** fields to look for logical opportunities to combine requirements. The term view is used to describe the hierarchy used for each sort.

A-9.6.1 Risk Category View of M&R Requirements.

Sort the requirements for the first year of the work plan by **Risk-Return Category**, **Priority**, and **Average Condition Before**, as shown in Figure A-28. This view of the M&R requirements mirrors the hierarchy shown in Figure 8-3 and Table 8-4.

- **Note:** Set the order for **Avg Condition Before** to **Largest to Smallest**.
- Identify high-risk operational (stopgap) M&R requirements in Risk-Return Categories C and E and highlight them to indicate they are a high priority based on risk, as shown in Figure A-29.

Figure A-28 Sorting by Risk Category

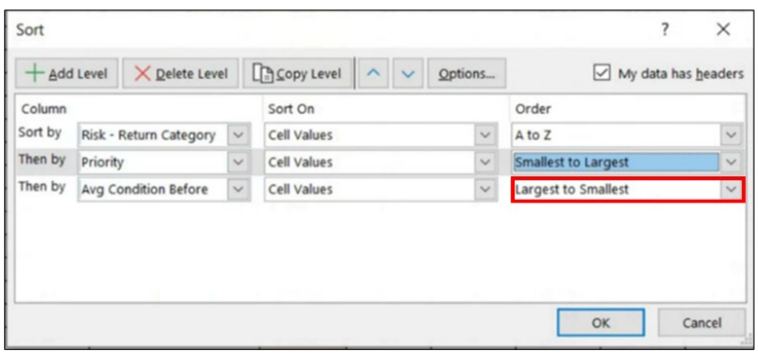

Figure A-29 Risk Category Requirements View

A-9.6.2 Adjusting Method of Execution by Branch.

Using the requirements list in Figure A-29, re-sort it to compare the method of execution for all requirements in each section for each year in the plan, as shown in Figure A-30. **Note:** The M&R priority for the branches in this example are low and work on these pavements have a low return on investment. This choice is intentional to demonstrate the same process applies to all pavements, from highest to lowest risk and return.

- Sort requirements for year one by branch and section to identify opportunities to use the same execution method (see paragraph 8-7.3) for each branch.
- Review the Consequence of Localized M&R Distress Repair Details Report and consider the types and severity of distresses present when determining changes to the method of execution
- In the example in Figure A-30, Branch PA00222 has work performed in-house and other work by IDIQ. Since the assumption is the IDIQ can handle both localized and global, update the method of execution for all to IDIQ as shown.
- Many decisions require engineering judgement. For example, Branch PA0308 in Figure A-30 has one section with execution by IDIQ and the rest in-house. Given that only one section was identified for global, postpone the global for that one section and use in-house work forces to execute all stop gap and preventive repairs for this branch.
- Repeat the process for all branches in each year of the PMP.

A-9.6.3 Adjust Year of Execution.

Using the requirements list in Figure A-31, re-sort it to compare the year of execution for all requirements in each section for each year in the plan, as shown in Figure A-32. **Note:** The M&R priority for the branches in this example are low and work on these pavements have a low return on investment. This choice is intentional to demonstrate the same process applies to all pavements, from highest to lowest risk and return.

- Sort by branch and section and investigate opportunities to adjust the year of execution (see paragraph 8-7.3).
- In the example in Figure A-32, Major M&R is scheduled for Branch PA00308 in different years in the respective sections within the branch. It would be more cost-effective to do one M&R project for all sections in the branch.
- In this example, most sections are scheduled in 2024, so change all to 2024 and adjust the other years for each section, as required.
- Consider the types and severity of distresses present in the Consequence of Localized M&R Distress Repair Details Report to define work types and determine changes to the year of execution.
- In this example, the Consequence of Localized M&R Report indicates that there is a large quantity of medium-severity climate-related distresses, so a two-inch mill and overlay is a good repair option.
- Repeat the process for all sections in each year of the PMP.

A-9.6.4 Create In-House Work Plan.

Using the requirements list in Figure A-32, re-sort it to generate an in-house work plan, as shown in Figure A-33.

- Sort the list by **Work Year**, **Execution Method**, **M&R Priority**, **Risk-Return Category**, **Branch ID**, and **Section ID**.
- Move any sections with High risk and Low ROI to the top of the list. The remainder of the list is in M&R priority order, with the highest priority on localized and global preventive M&R.
- Review each section identified for in-house execution in the critical PCI work plan. Combine these M&R requirements in an in-house work plan. Review and update the plan at least annually.
- Use the Consequence of Localized M&R Distress Repair Details Report to determine the specific work types required for each section and use the optimal critical PCI work plan to make decisions about risk, return, and timing of repairs.
- For example, Figure A-34 shows the predominant distresses are load related and that PAVER has the section scheduled for Major M&R in 2024. Given the nature of the distresses, reconstruction is the likely M&R option. Is investing in full depth repairs in 2023 essential from a safety perspective when the pavement will be reconstructed in 2024 or should the Major M&R be moved to 2023?
- Execute any requirements that exceed in-house work capacity or capability with IDIQ or competitive bid contracts.

A-9.6.5 Create a Contract Project Plan.

Use the same procedure outlined above to create a contract project plan with a list of projects with execution method.

- Review each section identified for contract execution in the critical PCI work plan. Combine these M&R requirements in a contract project plan. Review and update the plan at least annually.
- Use the Consequence of Localized M&R Distress Repair Details Report to determine the specific work types required for each section and use the optimal critical PCI work plan to make decisions about risk, return, and timing of repairs.
- Repeat the process for all sections in each year of the PMP.

Figure A-33 In-House Work Plan

Network ID	Branch ID	Section ID	Work Year	Branch Use	Section Rank	Risk - Return Category	Work Type	Method of Execution	Surface Type - Current	M&R Priority	Avg Condition Before	Avg Condition After	Stop Gap Funded	Preventive Funded	Global Funded	Major Under Critical Funded	Total

A-9.7 Using PAVER Required Work to Develop a PMP.

The previous sections demonstrated how to export work plans to Excel and use them to develop a PMP consisting of an in-house work plan and contract project plan. The PAVER Project Formulation Wizard or Required Projects tool can be used to identify required Global and Major M&R work and incorporate these projects into the prioritized critical PCI work plan.

A-9.7.1 Required Projects Tool.

This tool builds projects that include localized, global, or major M&R using a step-by-step process.

- Create a project.
- Define the sections in the project.
- Define the project-level work required.
- Define any section-level work required.
- Review work items.

A-9.7.2 Project Formulation Wizard.

This tool builds global and major M&R projects using a step-by-step process similar to the Required Projects tool but handles localized M&R differently and breaks out the steps in the process in a more sequential manner than the Required Projects tool.

- Create a project.
- Define the project-level work required.
- Define Pre-Application Localized M&R Policy.
- Define the sections in the project.
- Refine section selection set engineering field parameters.
- Define section selection set age and condition parameters.
- Define distress ranges.
- Review and refine sections using the map or query tool.
- Verify selected sections.
- Review work items.

A-9.7.3 Required Projects Tool Example.

The Required Projects tool example in the following sections uses the information in the modified critical PCI work plan and consequence of localized M&R work plan developed in previous sections as a starting place. Use the tool to filter down to the specific sections identified in the work plan, then use the consequence of localized M&R work plan to identify the specific work types to include in the project.

A-9.7.3.1 Selecting Sections in The Project.

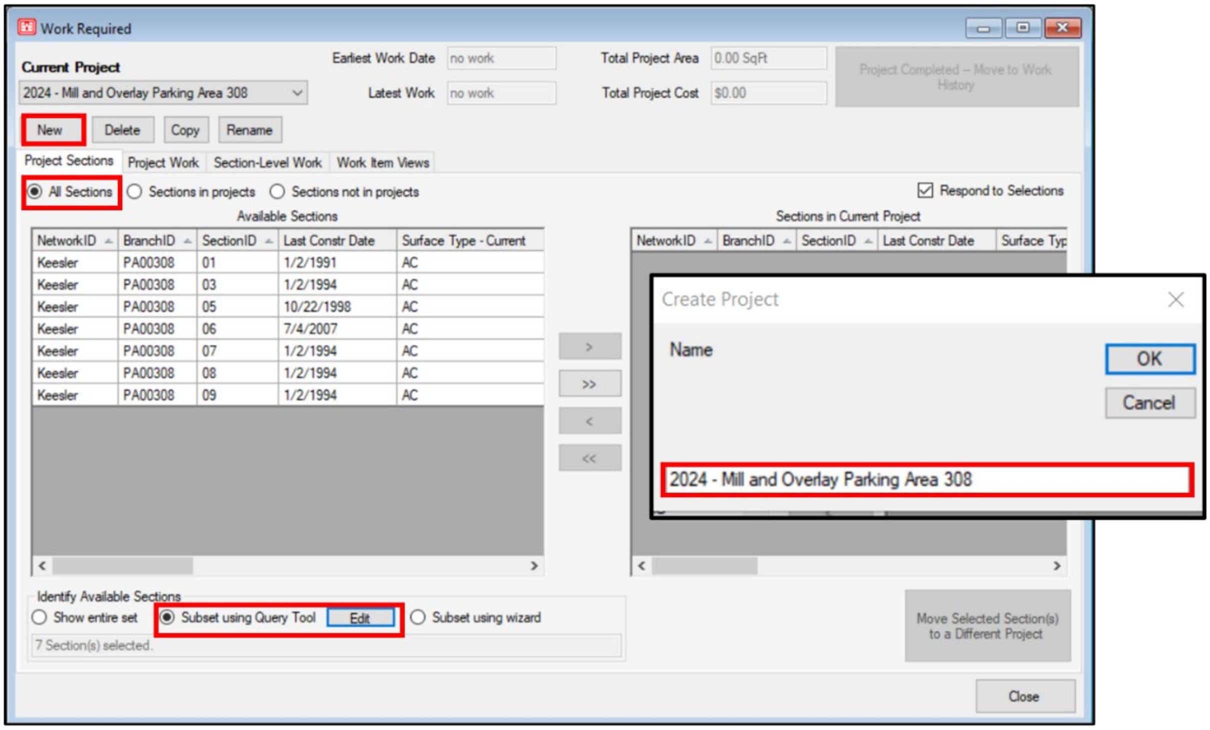
From the PAVER **Work** drop-down menu, select **Required Projects**. This opens the **Work Required** form shown in Figure A-36.

- There are several options to select sections for a project. The user can filter sections in a manner similar to the work plan sorting procedures described or select specific branches and sections based on the critical PCI work plan.
- This example demonstrates how to build a project for a specific branch. It is based on the 2024 Major M&R project in the critical PCI work plan for the Building 308 parking area from Figure A-32 and shown in Figure A-35.
- Select **New** to create a new project. Provide a descriptive name with the year of execution. For this example, use "2024 – Mill and Overlay Parking Area 308," as shown in Figure A-36.
- Select the **All Sections** option then select **Subset using Query Tool**.
- Select **Branches** on the **Query Tool** form then select **Branch ID** from the field drop-down menu, equal to "PA00308" from the **Comparison** drop-down menu.
- This filters the list down to all sections in the PA00308 branch, as shown in the left grid in Figure A-36.
- Select the double arrows **>>** to move all sections to the **Sections in Current Project** grid on the right side of the form.
- Section 06 only requires preventive M&R and is not included in the mill and overlay project. Remove it from the **Sections in Current Project** grid by highlighting it and selecting the **<** arrow to move it back to the **Available Sections** grid.

Figure A-35 PA00308 Major M&R Project

Network ID	Branch ID	Section ID	Work Year	Branch Use	Section Rank	Risk - Return Category	Work Type	Method of Execution	Surface Type - Current	M&R Priority	Avg Condition Before	Avg Condition After	Stop Gap Funded	Preventive Funded	Global Funded	Major Under Critical Funded	Total
Keesler	PA00308	01	2024	PARKING	S	I	Major Below Critical	Contract	AC	7	26.38	100.00	$0.00	$0.00	$0.00	$49,565.80	$49,565.80
Keesler	PA00308	03	2024	PARKING	S	G	Major Below Critical	Contract	AC	7	45.52	100.00	$0.00	$0.00	$0.00	$36,715.34	$36,715.34
Keesler	PA00308	05	2024	PARKING	S	G	Major Below Critical	Contract	AC	7	51.96	100.00	$0.00	$0.00	$0.00	$17,225.61	$17,225.61
Keesler	PA00308	07	2024	PARKING	S	G	Major Below Critical	Contract	AC	7	48.26	100.00	$0.00	$0.00	$0.00	$17,470.96	$17,470.96
Keesler	PA00308	08	2024	PARKING	S	G	Major Below Critical	Contract	AC	7	53.46	100.00	$0.00	$0.00	$0.00	$12,192.43	$12,192.43
Keesler	PA00308	09	2024	PARKING	S	G	Major Below Critical	Contract	AC	7	50.06	100.00	$0.00	$0.00	$0.00	$14,357.25	$14,357.25

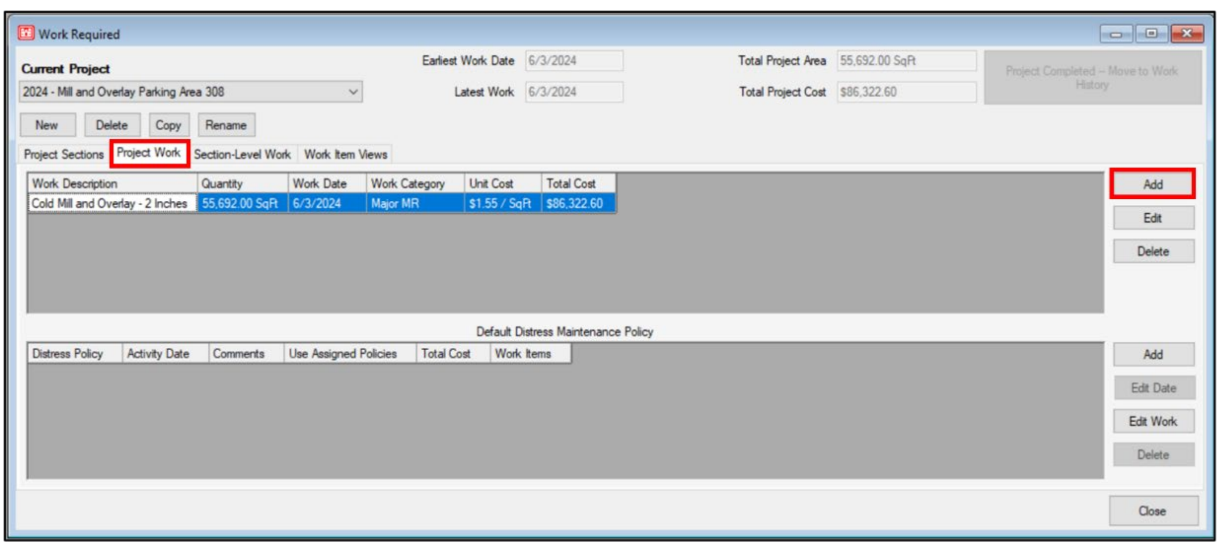
Figure A-36 Select Sections Example



A-9.7.3.2 Project Work.

After reviewing the condition and distresses in the consequence of localized work plan, a two-inch mill and overlay was selected as the best M&R option. Add this work type by selecting the **Project Work** tab, shown in Figure A-37.

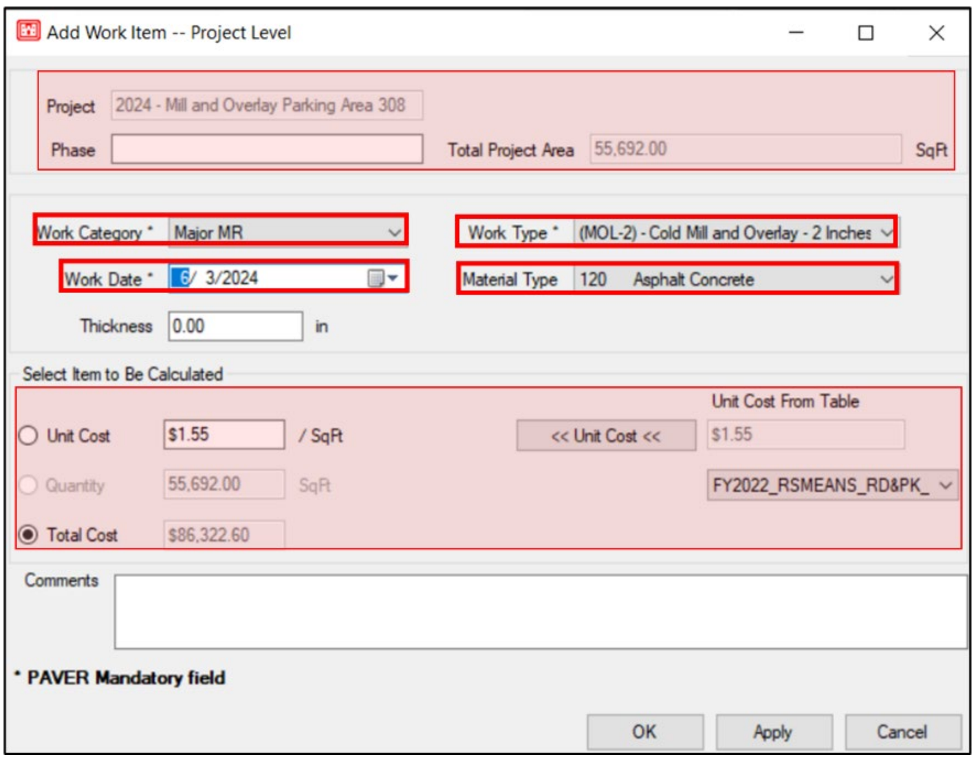
Figure A-37 Project Work Tab



- Select the **Add** button on the **Work Required** form above to open the **Add Work Item – Project Level** form shown in Figure A-38.

- The area highlighted at the top of the **Add Work Item – Project Level** form shows the **Project** name is already populated, the **Phase** field is optional, and the **Total Project Area** is populated and is the sum of the area of all sections in the project.
- Select the **Work Category** from the drop-down, then select the **Work Type**, the **Work Date** (projected date of execution), and **Material Type**.
- In this case, leave **Thickness** set to 0.00 since 2 inches of asphalt is milled and 2 inches is replaced.
- The lower portion of the form highlighted in red is for the project cost. The user can pull the unit cost from the cost by work type table for Major M&R, enter a unit cost manually, or enter the total cost of the project. In this example, the cost is coming from the FY2022_RSMEANS_RD&PK_Major cost by work type for table Major M&R.

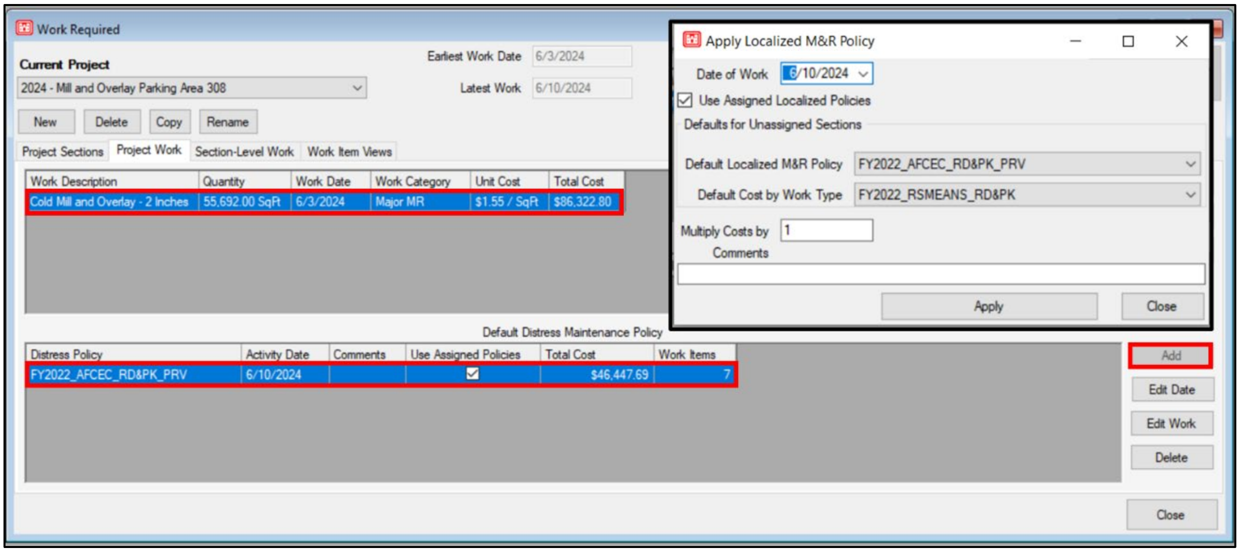
Figure A-38 Add Work Item – Project Level Form



- Select **OK** at the bottom of the **Add Work Item – Project Level** form above to close the form. The project is added to the **Project Work** tab shown in Figure A-39.
- The lower portion of the **Project Work** tab in Figure A-39 allows the user to apply localized M&R policies to the project. This is typically used when planning localized preventive or operational repair projects or when including localized work as part of a Major or global M&R project. In this case, some crack sealing and full-depth patching is appropriate after milling and prior to the overlay.

- Select **Add** to open the **Apply Localized M&R Policy** form. All sections have assigned localized M&R policies, so just select a **Date of Work** after the project start and select **Apply** to add the localized M&R work to the project, as shown in Figure A-39.

Figure A-39 Add Distress M&R Policy – Project Work Tab Cost



- **Note:** The cost of the project in Figure A-35 was higher than the estimated cost in the **Project Work** tab form in Figure A-39. The cost in Figure A-35 was based on the cost by condition tables and not associated with a specific work type. The cost in Figure A-39 was based on cost by work type. There will also be instances when the cost by condition estimates are lower than the cost by work type averages.
- Select the **Section-Level Work** tab.

A-9.7.3.3 Section-Level Work.

The **Section-Level Work** tab allows the user to review, add, edit, or delete any work item in the project on a section-by-section basis.

- The example in Figure A-40 includes Section 06. Based on the critical PCI work plan and the consequence of localized work plan, this section does not require an overlay, just crack sealing.
- Select the **Cold Mill and Overlay – 2 Inches** line item in the **Work Items for Sections** field and select **Delete**.
- Field work indicates that a patch/utility cut that was identified as low severity in the last inspection has deteriorated and will require replacement in 2024.
- Select the **Add** button to open the **Add Work Item** form and add a new work item, as shown in Figure A-41.
    - o Work Category: Localized MR

- o Work Date: 6/10/2024
- o Thickness: 0.00 in.
- o Work Type: Patching – AC Deep
- o Material Type: Asphalt Concrete
- o Use the unit cost from Localized Cost by Work Type table.
- o Enter the quantity.
- o Select **OK**.

Figure A-40 Section Work Types and Quantities

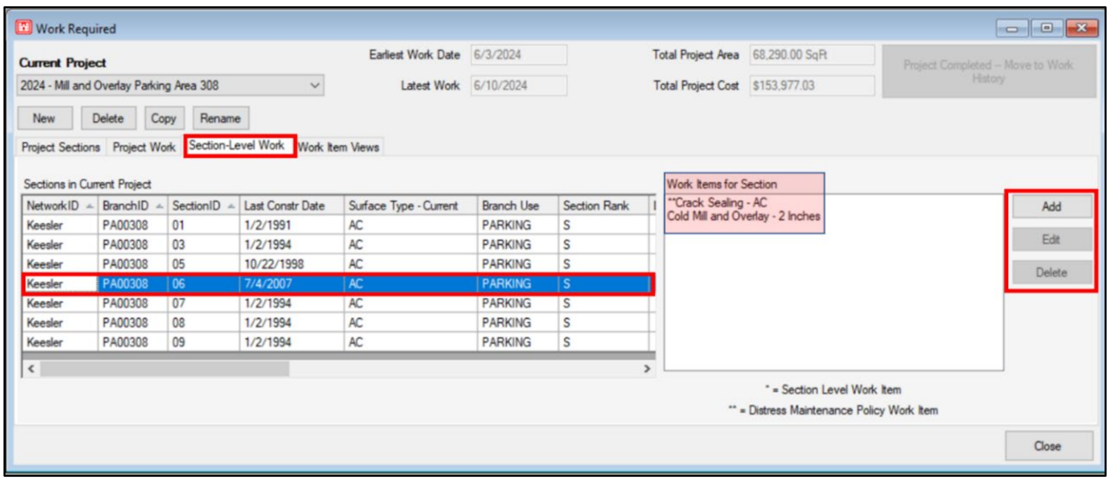


Figure A-41 Section Work Types and Quantities

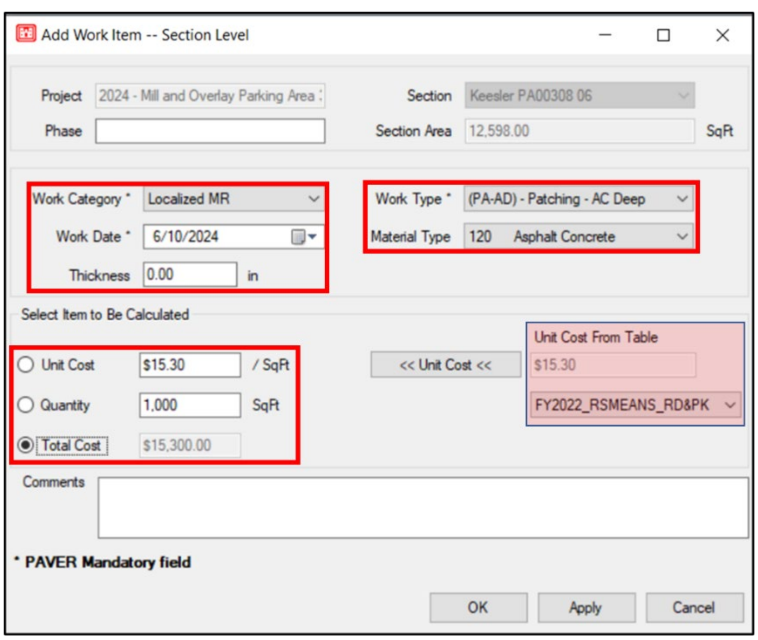
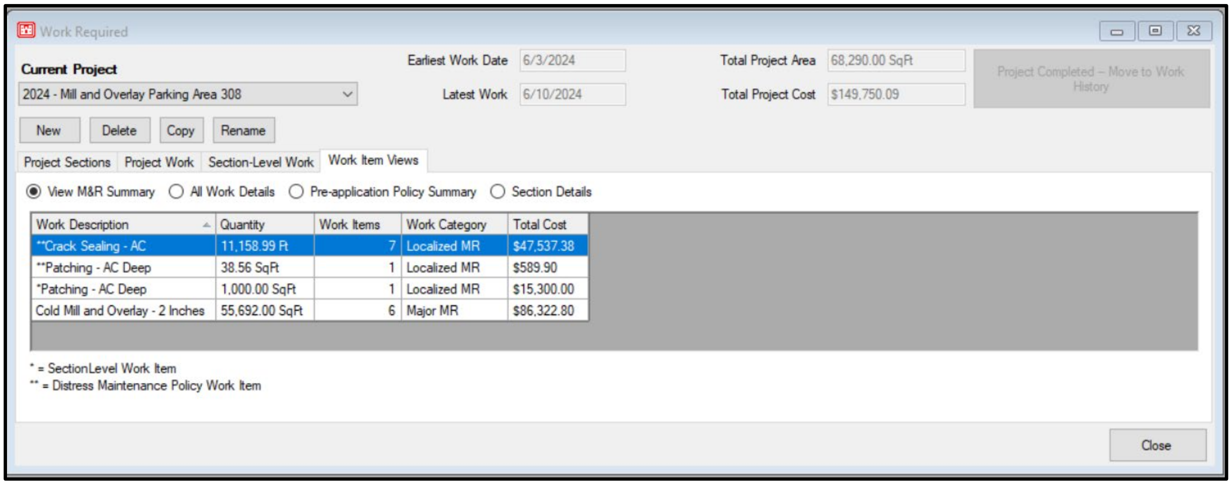


A-9.7.3.4 Work Item Views.

The **Work Item Views** tab provides summary and detail-level views of the work items in the project, describing the sections included in the project, work types, quantities, and costs.

Figure A-42 View Project and Section Item Summary



A-9.7.4 Project Formulation Wizard Example.

The Required Projects Tool example in the following sections uses the information in the modified critical PCI work plan and consequence of localized M&R work plan developed in previous sections as a starting place. Use the tool to filter down to the specific sections identified in the work plan, then use the consequence of localized M&R work plan to identify the specific work types to include in the project.

A-9.7.4.1 Define Project-Level Work.

Select the **Project Formulation Wizard** icon on the tool bar. This opens the **Project Formulation Wizard** form shown in Figure A-43.

- Enter the **Project Name**. This example is a 2023 global M&R project for roads.
- Select **Add Work** to open the **Add Work Item** form shown in Figure A-44.
  - o Work Category: Global MR
  - o Work Date: 8/1/2023
  - o Thickness: 0.50 in.
  - o Work Type: Surface Treatment – Cape Seal
  - o The Global M&R cost table did not have a cost for cape seals but based local costs are $0.31 per square foot.

- o Select **OK** to add the work item.

Figure A-43 Global M&R Example

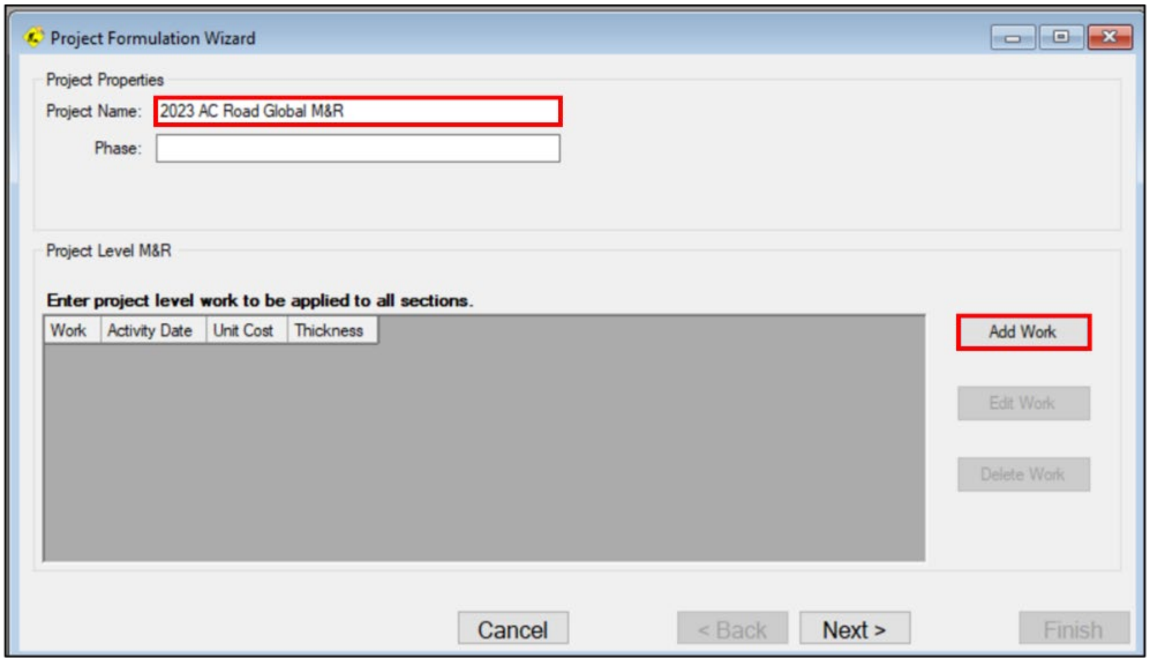


Figure A-44 Define Project-Level Work

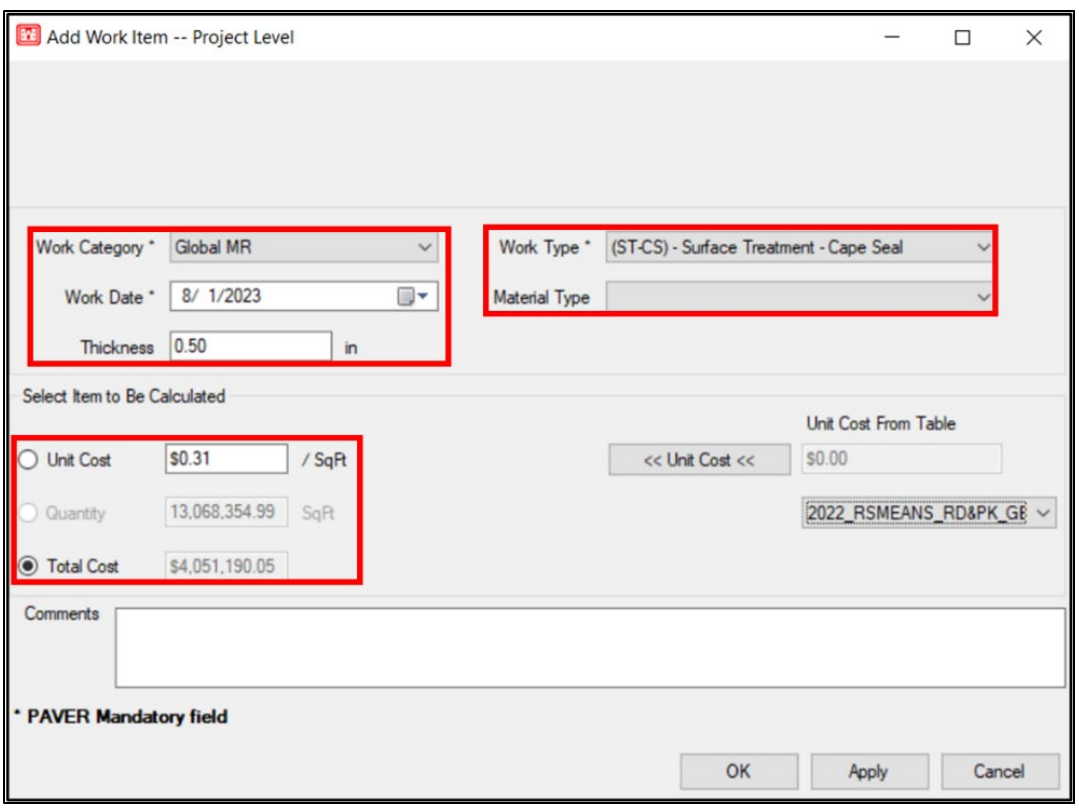
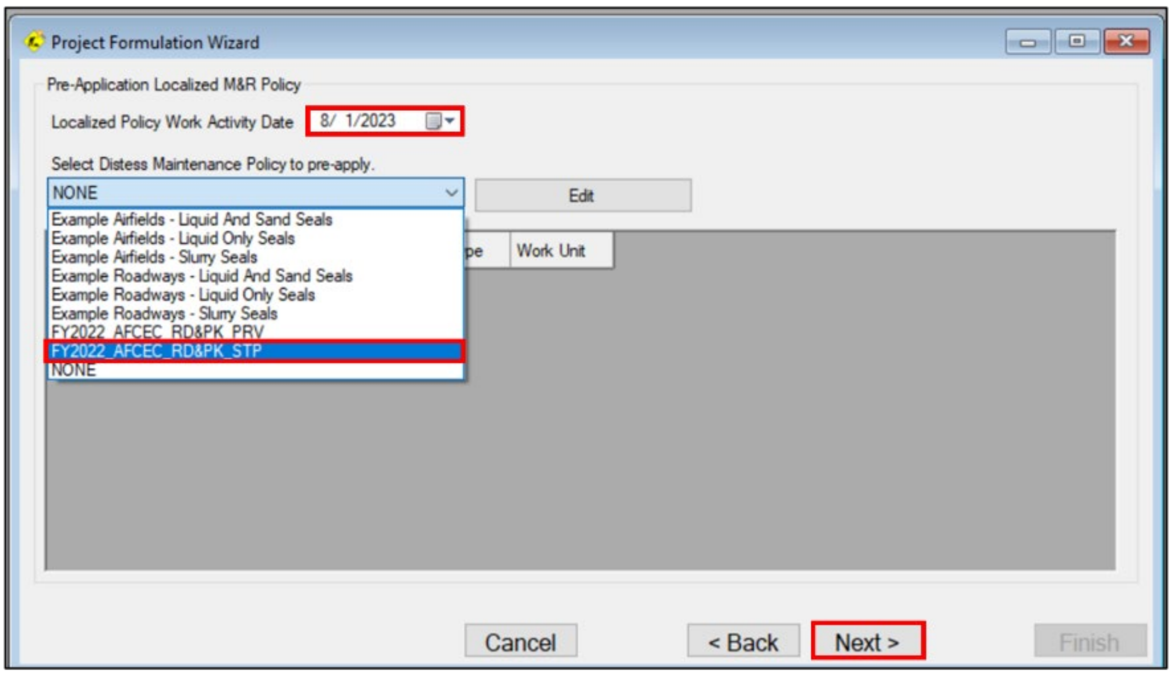


A-9.7.4.2 Pre-Application Localized M&R Policy.

Prior to applying the cape seal in this example, localized repairs are required to address some distresses.

- Select **Next >** on the **Project Formulation Wizard** form shown in Figure A-43 to open the form shown in Figure A-45.
- The **Localized Policy Work Activity Date** is the same as the project date.
- PAVER provides example policies that can be used, but for this example, select the stopgap M&R policy to repair any high-severity distresses before placing the cape seal. Review and edit the policy if required for this particular application.
- Select **Next >**.

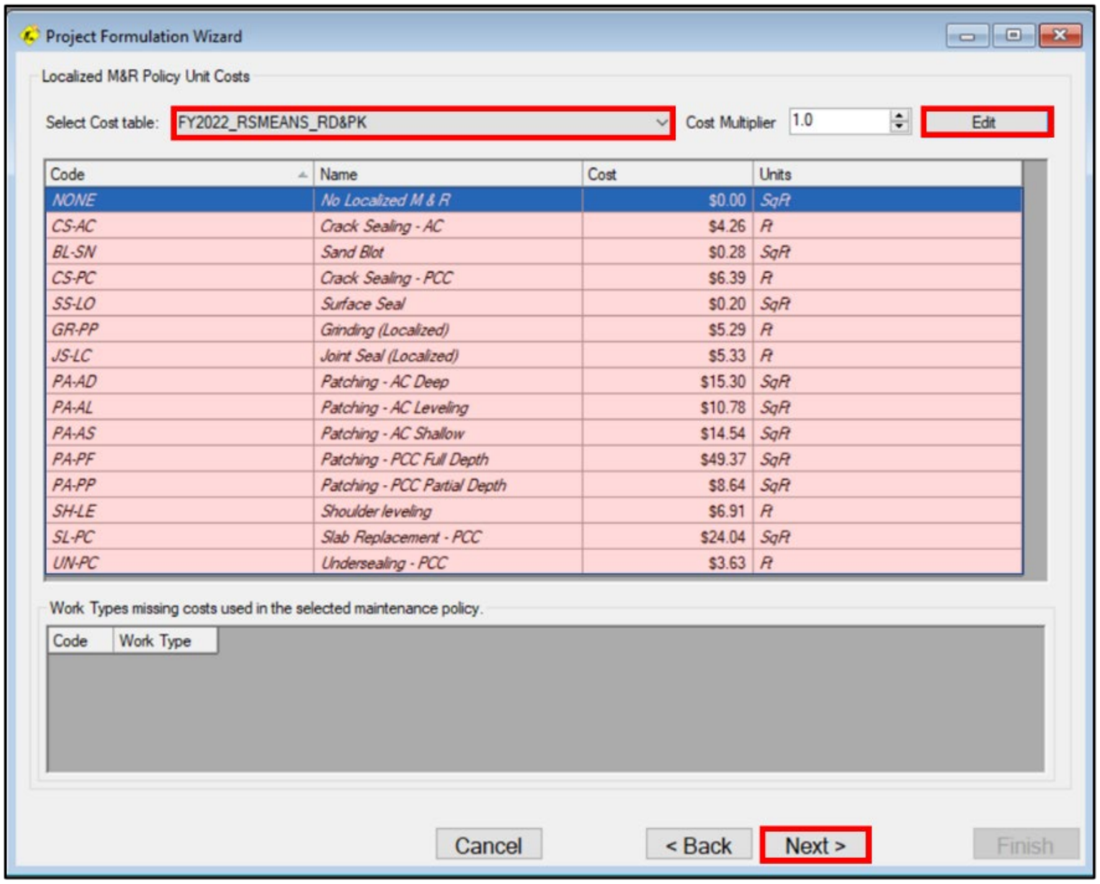
Figure A-45 Pre-Application Localized M&R Policy



A-9.7.4.3 Pre-Application Localized M&R Policy Unit Costs.

- Use the Localized M&R Policy Unit costs defined for the Localized M&R Family.
- PAVER will display any work types missing unit cost in the lower window of the form in Figure A-46. Select **Edit** to update unit costs, if required.
- Select **Next >**.

Figure A-46 Add Work Item – Project Level Form

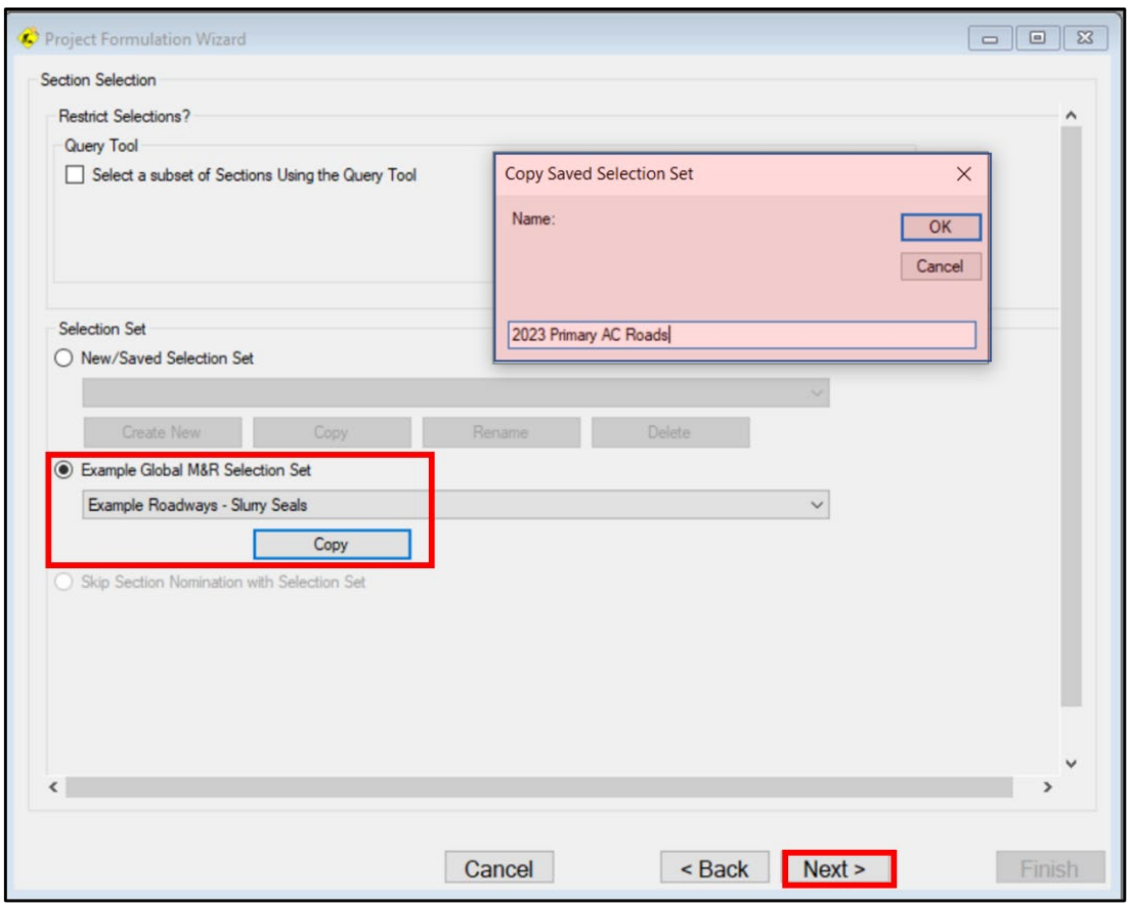


A-9.7.4.4 Define Sections in the Project.

The **Project Formulation Wizard** gives the user several options to determine the section included in a project, including the query tool used in the Required Work example, defining a new selection set, or using an example global M&R selection set to define a new selection set, which is the approach used in this example.

- Highlight the **Example Global M&R Selection Set** radio button and select **Example Roadways – Slurry Seals** from the drop-down, then select **Copy** as shown in Figure A-47.
- Give the copy of the example a new name: 2023 Primary AC Roads.
- Select **Next >**.

Figure A-47 Add Distress M&R Policy – Project Work Tab Cost

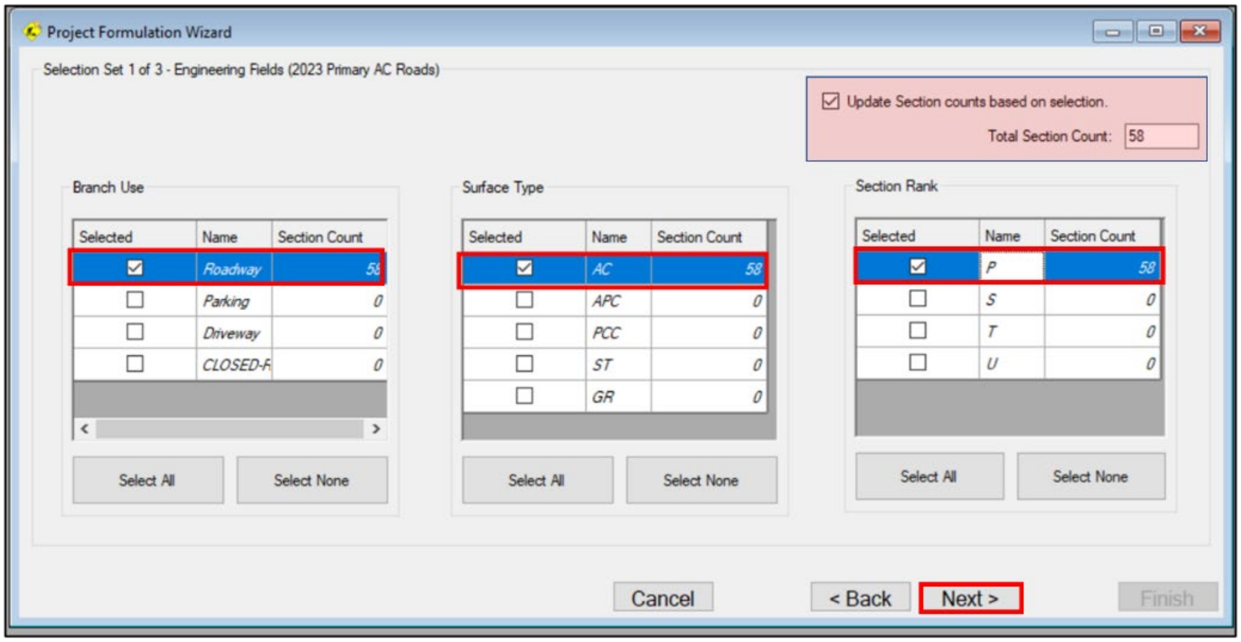


A-9.7.4.5 Selection Set - Engineering Field Parameters.

Filter the sections included in the project by checking the appropriate box for the Engineering Fields parameters, as shown in Figure A-48.

- Check the boxes for **Branch Use**: **Roadway**, **Surface Type**: **AC**, and **Section Rank**: **P**.
- The number of sections is shown in the upper-right corner of the form.
- Select **Next >**.

Figure A-48 Selection Set Engineering Field Parameters Example

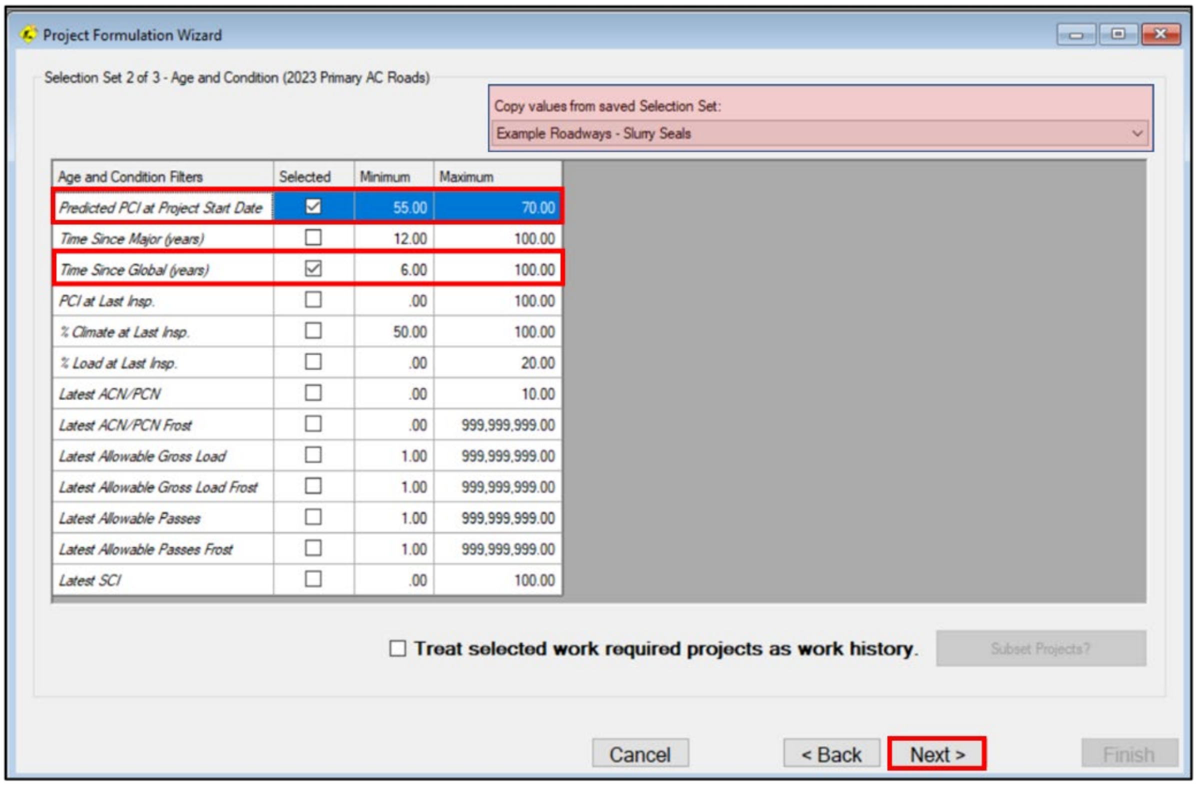


A-9.7.4.6 Selection Set – Age and Condition Parameters.

The **Selection Set - Age and Condition** parameters form opens with a standard list of parameters. The user selects the parameters for the project by checking the boxes and then setting the minimum and maximum values, as shown in Figure A-49.

- This example includes sections with a predicted PCI between 70 and 55 that have not had a global M&R application within the last six years.
- Users can save selection sets at the end of the process and reuse the parameters in future projects, as shown in the upper-right corner of the form in Figure A-49.
- Select **Next >**.

Figure A-49 Selection Set Age and Condition Parameters Example

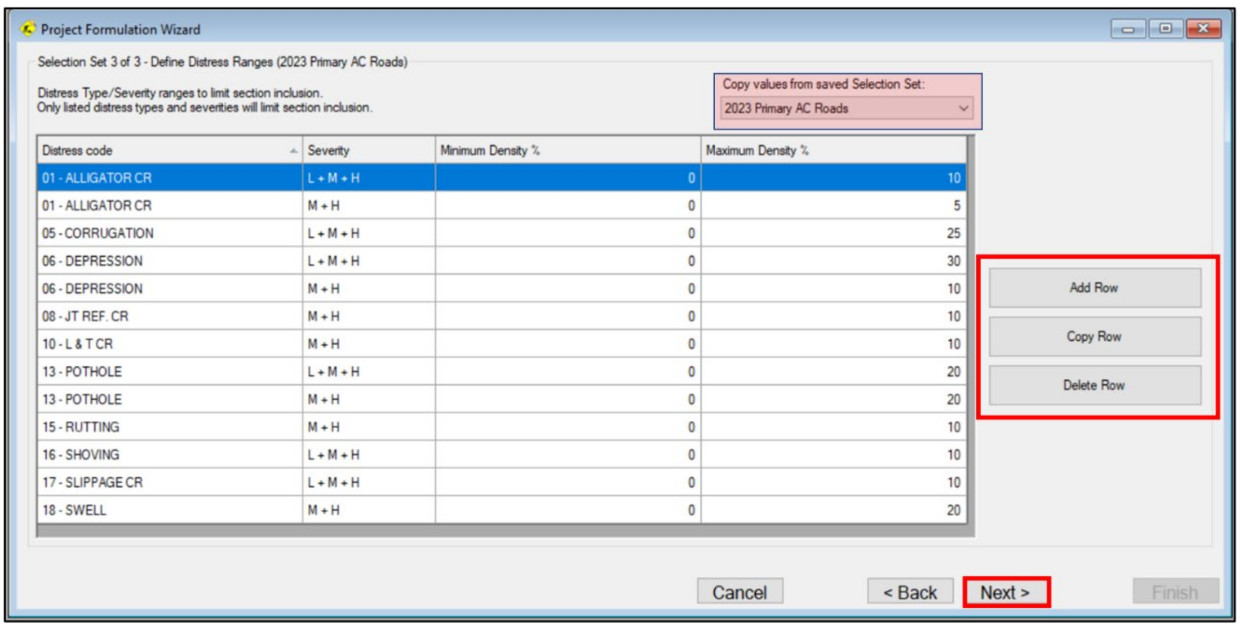


A-9.7.4.7 Selection Set – Distress Ranges.

The **Selection Set** - **Define Distress Ranges** form opens with the standard list of parameters shown in Figure A-50. The user defines the density ranges by editing the minimum and maximum density values. For example, when a section has high-severity alligator distress density above 5 percent, it would not be a good candidate for a surface treatment.

- Select **Add Row**, **Copy Row**, or **Delete Row** to tailor the parameters.
- Users can save selection sets at the end of the process and reuse the parameters in future projects, as shown in the upper-right corner of the form in Figure A-50.
- Select **Next >**.
- At the prompt to **Save Changes**, select **Yes**.

Figure A-50 View Project and Section Item Summary



A-9.7.4.8 Review and Refine Sections in Project.

The preceding steps performed the same function, selecting sections for the project as the query tool did in the Required Projects tool example.

- PAVER generates a map view of the sections based on the selection set parameters. The user can deselect a section or add a section by clicking on it in the map.
- Select **Next >**.
- PAVER generates a list view of the sections, as shown in Figure A-51, that meet the selection set parameters. Remove sections from the project by unchecking the boxes in the left-hand column.
- Select **Next >**.

Figure A-51 Project Formulation Wizard - Verify Selected Sections

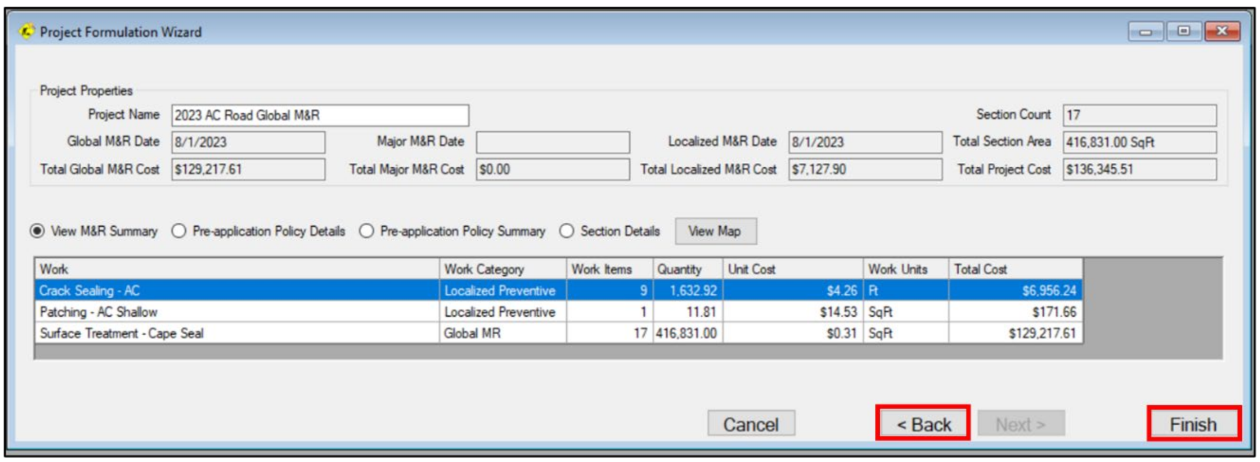
A-9.7.4.9 Review Project Information.

The final step in the **Project Formulation Wizard** process is reviewing the project information.

- This tab provides summary and detail-level views of the work items in the project describing the sections included in the project, work types, quantities, and costs.
- Select the **< Back** button to review or revise project parameters.
- Select the **Finish** button to complete the project creation.
- The user receives a message that the required project was created.
- The user can select the button to create another project or select **Close**.

Figure A-52 Project Formulation Wizard – Project Properties

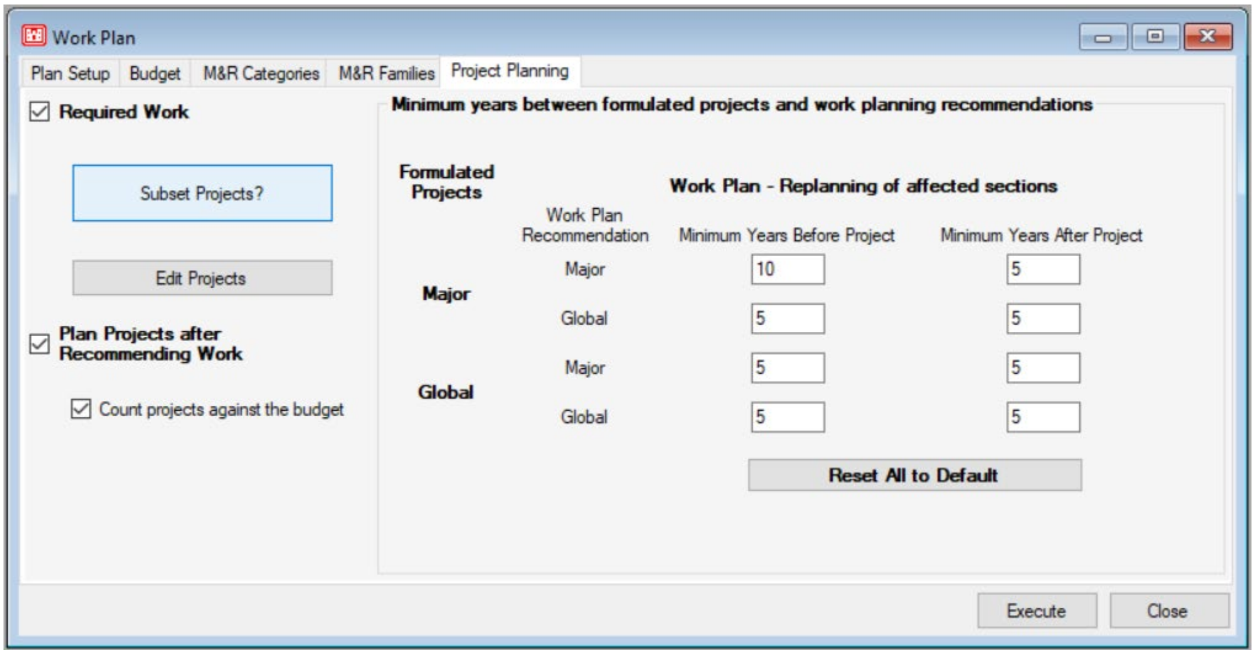


A-9.8 Project Planning.

Once the projects are generated, rerun the work plan. This can be an iterative process, run work plan, plan projects, rerun work plan, plan projects, etc.

- When rerunning the work plan, go to the **Project Planning** tab and select the checkboxes for **Required Work**, **Plan Projects after Recommending Work**, and **Count projects against the budget**, as shown in Figure A-53.
- The window for **Minimum years between formulated projects and work planning recommendations** sets the parameters PAVER uses to determine new work requirements after Major or Global M&R is performed.
- The default settings are generally acceptable but can vary based on environment. For example, the Global period is shorter for an installation that has a significant snow removal requirement.

Figure A-53 Project Planning Tab



A-9.9 Pavement Management Plan Example.

The minimum PMP is an approved list of in-house pavement M&R tasks and contract projects using the processes described in previous sections. As stated previously, the Services can augment this guidance with requirements for the specific PMP content, format, or approval process.

While the approved list of in-house pavement M&R tasks and contract projects is the core requirement, incorporating additional PMP documentation provides needed information to the approval authority and those who will implement and update the PMP.

A-9.9.3 PMP Outline.

Following is a recommended PMP outline.

- Cover sheet
- Preface
- Executive Summary
- Development team members
- Development process and deliverables
- Assumptions and limiting factors
- Prioritized Work Plan for in-house execution
- Prioritized Contract Project Plan for contract execution by year

A-9.9.4 Cover Sheet.

Include the name of the installation and whether it is an airfield or roads and parking PMP. List the initial development date and the dates of all annual updates. Service policy may also require a distribution statement, as shown in the example in Figure A-54.

A-9.9.5 Preface.

The Preface is typically a single page that provides background information on the sources of pavement evaluation data, initial PMP development, and subsequent updates, as well as information on the DoD and Service guidance the PMP implements.

Figure A-55 Preface Example

1. PREFACE

This Pavement Management Plan (PMP) documents a [Month Year] coordinated team effort between [ERDC/Contractor, Public Works, and Airfield Management when applicable] representatives to establish an Initial PMP for the airfield pavements network and the roads and parking pavements network at [Installation Name, State]. This PMP document provides information for:

- Planning and programming for pavement maintenance, repairs, and rehabilitation
- Prioritization of pavement facilities for maintenance, repair, and rehabilitation and construction projects
- Allocation of funds for annual maintenance and repair (M&R)

Army Regulation (AR) 420-1 Army Facilities Management, Department of Army Pamphlet (DA PAM) 420-1-3 Transportation Infrastructure and Dams, UFC 3-270-08 Pavement Management, and Tri-Service Pavements Working Group (TSPWG) Manual 3-270-08.14-03 outline requirements for bases to develop pavement management plans (PMP) in support of asset management.

IMCOM participated the development of an Airfield Pavement Category Intelligence Report (CIR) conducted by the Air Force. This report recommended installations develop PMPs to capitalize on efficiencies. SAF/MG approved efforts as a "go do" for the Air Force and IMCOM concurs with this recommendation for Army Installations as outlined below.

A-9.9.6 Executive Summary.

The Executive Summary outlines the purpose of the PMP and any critical issues the approval authority should be aware of. Include a summary of the annual work requirements, as shown in the example in Figure A-56. Provide a summary of the annual costs, as shown in the example in Figure A-57, and include a graphic representation of the impact of the investment in terms of condition, as shown in Figure A-58. Each of these graphics will include a brief description. The figures below are examples generated in PAVER but can also be generated using other tools.

Figure A-56 Requirements Map

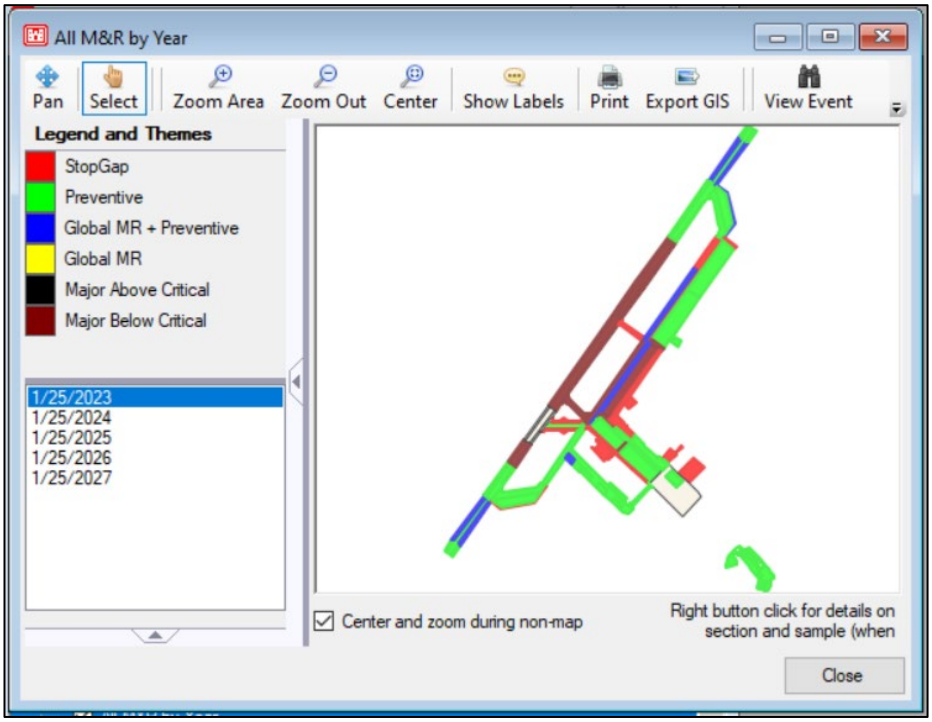

Figure A-57 Annual Funding Requirement

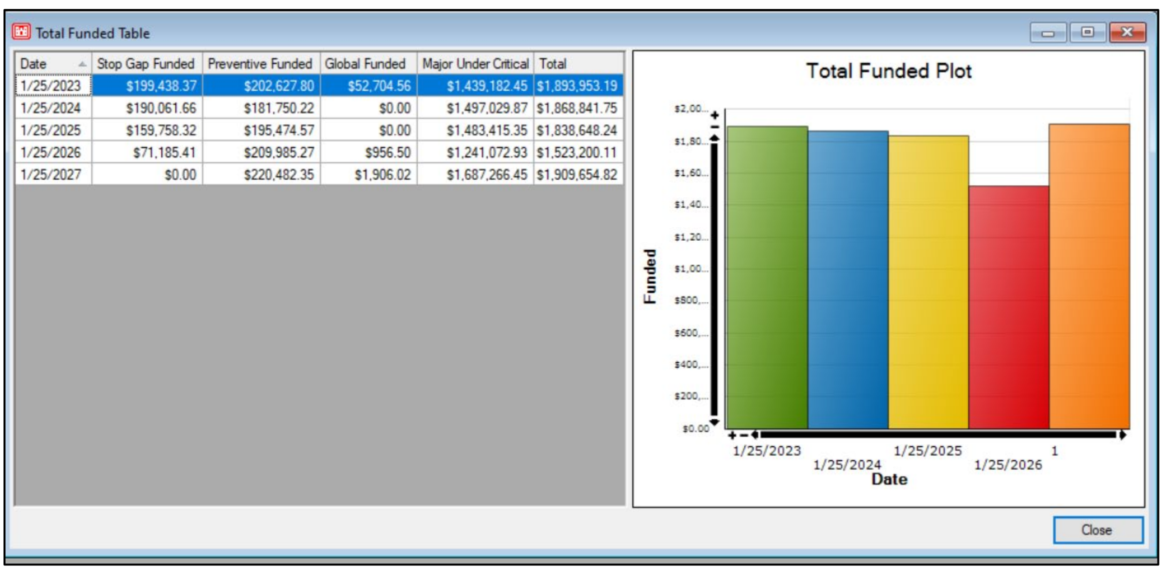

Figure A-58 Condition Table

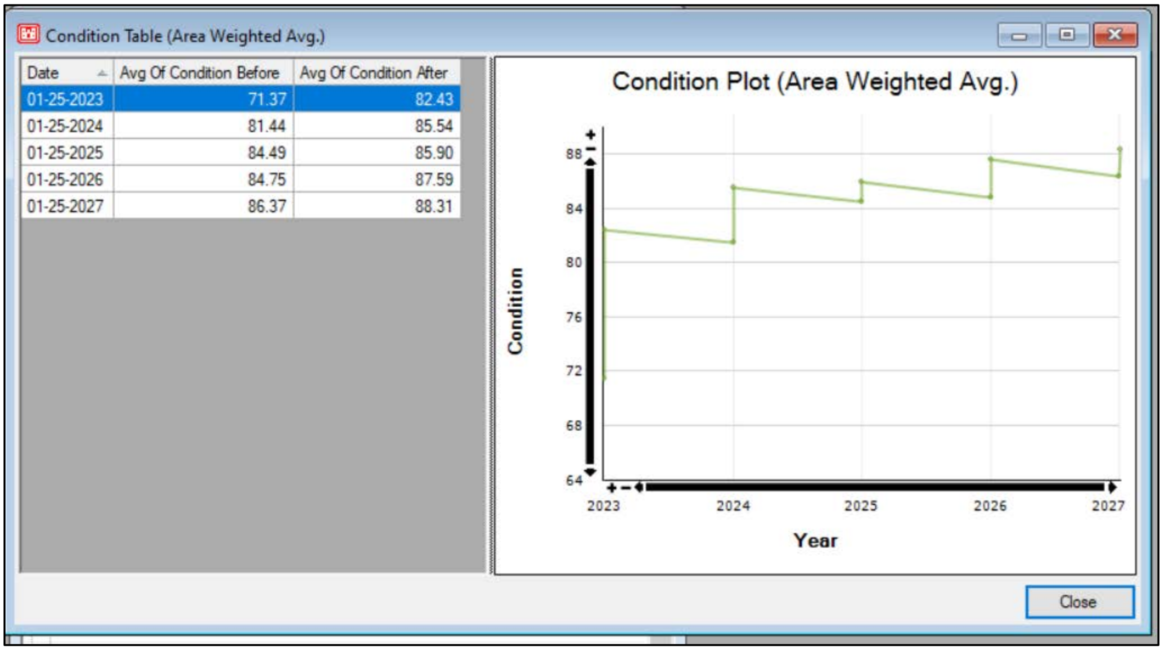

A-9.9.7 Development Team Members.

This is a list of the members of the development team members and their contact information. The list is updated annually when the team finalizes the PMP updates.

A-9.9.8 Development Process and Deliverables.

This section expands on the information provided in the Preface and Executive Summary and should include the following.

A-9.9.8.1 Pavement Management Objective.

Perform localized and global preventive maintenance to extend pavement life and perform Major M&R at the right time with the right repair method rather than letting the pavement deteriorate to poor or failed condition before taking any repair actions. This approach optimizes the lifecycle cost of maintaining the pavement.

A-9.9.8.2 Development Process.

Include a discussion of the following items to describe the development process.

- Generate work plans with M&R requirements using the most recent PCI inspection.
- Prioritize requirements, with an emphasis on localized and global M&R to maximize pavement life. Include a discussion of the prioritization process and other key performance indicators, e.g., FOD potential and structural index.

- Aggregate requirements into executable in-house work tasks and contract projects for each year of the PMP. Discuss project scoping and any other factors addressed when aggregating requirements, e.g., waivers, construction cycle, other projects, etc.
- Verify/validate method of execution, repair types, quantities, and costs for all M&R types, including a description of the field work performed to validate repair types and quantities.
- Finalize PMP and submit for approval.

A-9.9.9 Limiting Factors and Assumptions.

Limiting factors can include, but are not limited to, constraints on in-house capabilities, funding, operations tempo, and access to pavement surfaces. Describe any assumptions made with regard to limiting or other factors.

A-9.9.10 Prioritized In-House Execution Work Plan.

This section has the products generated from PAVER work plan spreadsheets as outlined in paragraph A-7.6 or generated using the PAVER Project Formulation Wizard as outlined in paragraph A-9.7. Embedding these products in the PMP Word document as an Excel spreadsheet is a best practice. This is especially useful on large installations when the in-house execution work plan can be quite extensive. Figure A-59 provides an example of an in-house execution work plan generated by one Service.

A-9.9.11 Prioritized Contract Project Plan.

This section has the products generated from PAVER work plan spreadsheets as outlined in paragraph A-7.6 or generated using the PAVER Project Formulation Wizard as outlined in paragraph A-9.7. Embedding these products in the PMP Word document as an Excel spreadsheet is a best practice.

A-10 RISK (RETURN ON INVESTMENT) ANALYSIS PROCEDURES.

This section outlines a risk analysis procedure for determining the consequence of not performing localized PM and global PM. Risk is defined as a decrease in pavement life (and thus increased M&R cost) as a result of not performing the appropriate PM at the proper time.

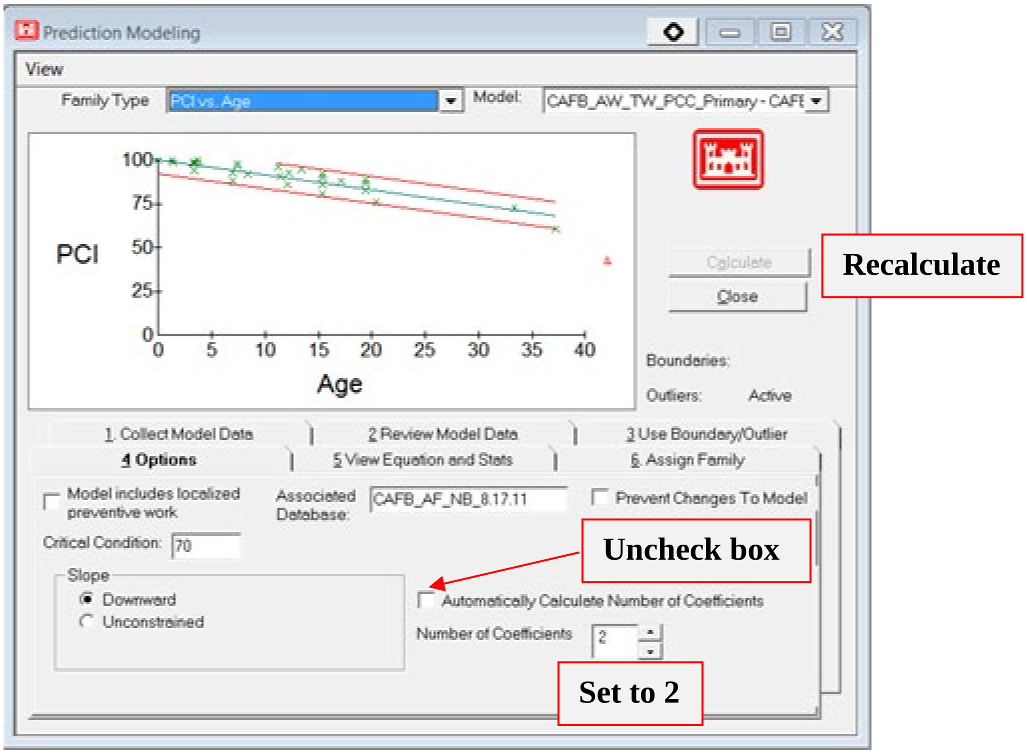
A-10.1 Risk Analysis – Localized Preventive Maintenance (PM).

A-10.1.3 Family Rate of Deterioration.

Calculate the pavement family rate of deterioration assuming localized PM has been performed in the past (R_W) and compute the rate of deterioration if localized PM is not performed (R_{WO}).

Using the steps outlined in Chapter 5 and assuming that localized PM has been performed in the past, create a family model. On tab 4, **Options**, uncheck the **Automatically Calculate Number of Coefficients** button, set the number of coefficients to 2, and press the **Calculate** button (Figure A-61). Select tab 5, **View Equation and Stats**. The second coefficient in the equation (e.g., 100 – 0.8512 X^1) is the straight-line deterioration rate (R_W = 0.85 points per year). The next step is to calculate the age (T_W) to critical PCI (PCI_C), assuming localized PM is performed.

Figure A-61 Review Model Data Tab



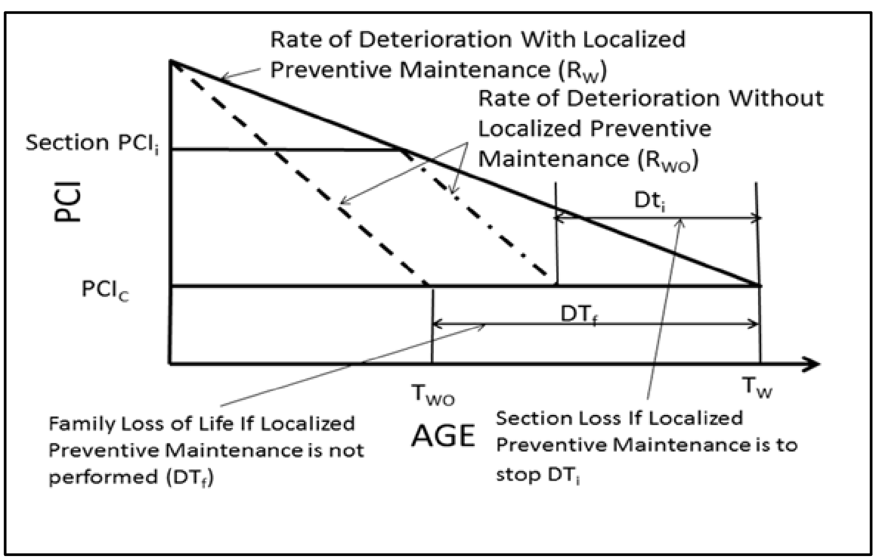
A-10.1.4 Age to Critical PCI.

The age (T_W) to critical PCI (PCI_C) is computed using the equation below.

$$T_W = (100 - PCI_C) / R_W$$

In the Figure A-62 example, assume a PCI_C = 70, T_W = (100 – 70) / 0.85 = 35.29 years.

Figure A-62 Section Deterioration



A-10.1.5 Expected Loss in Pavement Life.

Estimate the expected loss in pavement life (DT_f) caused by not performing localized PM. Loss of pavement life will depend on several factors, including pavement life with localized PM (T_W), pavement type (e.g., asphalt vs. concrete), climate, and traffic. Table A-29 provides recommended DT_f values when T_w is 20 years.

Table A-29 Recommended DTf Values

Climate	DT_{f20}, years
Dry/no freeze	5
Wet/no freeze-dry/freeze	7.5
Wet/freeze	10

The DT_f values for any other T_w can be calculated as follows:

$$DT_{fTw} = DT_{f20} * (.3691\, T_w - .0009\, {T_W}^2)/7.13$$

For example, if T_w = 35.29 years, then DT_f for dry/no freeze is calculated as:

$$5 * (.3691 * 35.29 - .0009 * (35.292))/7.13 = 8.35\, years$$

A-10.1.6 Age to Critical PCI Assuming No Localized PM.

Calculate the age to critical PCI (PCI_C), assuming localized PM is not performed (T_{WO}) using the equation below:

$$T_{WO} = T_W - DT_f$$

In the example above, assuming DT_f = 8.35 years:

$$T_{WO} = 35.29 - 8.35 = 26.94\, years$$

A-10.1.5 Rate of Deterioration Assuming No Localized PM.

Determine the pavement family rate of deterioration (R_{WO}), assuming localized PM is not performed:

$$R_{WO} = (100 - PCI_C) / T_{WO}$$

In the example above,

$$R_{WO} = (100 - 70) / 26.94 = 1.11\, PCI\ points\ per\ year$$

A-10.1.6 Expected Loss of Pavement Life with No Localized PM.

Determine the expected loss in life (DT_i) for each pavement section if localized PM is not performed:

For any pavement section (i) from the same family, DT_i can be computed if its current condition (PCI_i) is known. For this example, assume the section currently has a (PCI_i) of 85.

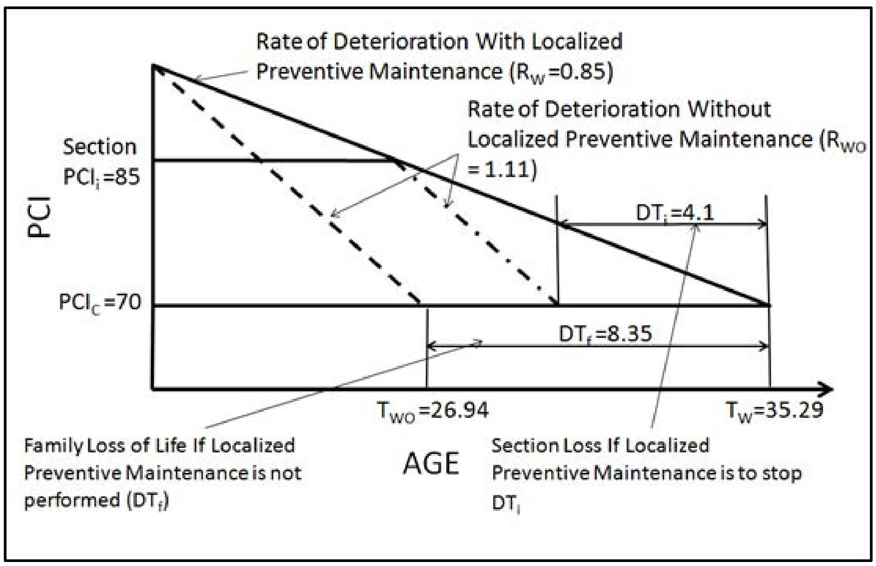
$$DT_i = (PCI_i - PCI_C) * (R_{WO} - R_W) / (R_{WO} * R_W)$$

In the above example, for a section (i) with a PCI_i = 85:

$$DT_i = (85 - 70) * (1.11 - 0.85) / (1.11 * 0.85) = 4.1\, years$$

See Figure A-63 for a depiction of the section deterioration example above.

Figure A-63 Section Deterioration Example



A-10.2 Cost of Pavement Life Loss with No Localized PM.

The procedure is based on the equivalent uniform annual cost (EUAC) economic analysis method. This method calculates the average annual cost with and without annual PM and compares the two to determine the annual cost due to loss of pavement life. The simplest form of this procedure is presented below, in which interest and inflation rates are not considered. The costs are intended to be used for comparative analysis only and not intended to represent actual project cost.

A-10.2.1 Calculate Equivalent Uniform Annual Cost (EUAC).

Determine the annual major M&R cost ($\$_{Annual\ Major\ Alt1}$) by dividing the major M&R cost at critical PCI ($\$_{Major\text{-}critical}$) by the life of the alternative T_W. $\$_{Major\ critical}$ can be estimated as one-third the cost of reconstruction for asphalt pavements and one-fourth the cost of reconstruction for concrete pavements.

In the concrete apron example above, assuming a reconstruction cost of $20.00/SF (use PACES or other estimating methods to determine estimated reconstruction costs), then $\$_{\text{Major-critical}}$ is estimated at $20/4 = $5.0/SF.

$$\$_{Annual\ Major\ Alt1} = \$5.0/35.29 = \$0.1417\ SF/Yr$$

A-10.2.2 Calculate Average Annual Cost with Localized PM.

Determine the average annual localized PM cost over the life of the alternative ($\$_{\text{Annual-Preventive}}$). This can be obtained by summing the total annual localized preventive cost over the life of the alternative (the cost will vary annually as a function of the PCI) then dividing the sum by the life (T_W). Based on unit costs in the PAVER system, this can be approximated as $0.0232/SF/YR for concrete pavements and $0.0096/SF/YR for asphalt pavements. This is a nominal average cost that can be used as constant on all analyses.

$EUAC_{Alt1}$ is determined as the sum of the $\$_{\text{Annual-Major-Alt1}}$ and $\$_{\text{Annual-Preventive}}$ costs as shown in the equation below.

$$EUAC_{Alt1} = \$_{Annual\ Major\ Alt1} + \$_{AnnualPreventive}$$

For the example above:

$$EUAC_{Alt1} = 0.1417 + 0.0232 = \$0.1649/SF/YR$$

A-10.2.3 Calculate Average Annual Cost without Localized PM.

Calculate the annual cost for the same alternative, except without a localized PM alternative ($EUAC_{Alt2}$):

Determine the annual major M&R cost ($\$_{\text{Annual Major Alt2}}$) by dividing the major M&R cost at critical PCI ($\$_{\text{Major critical}}$) by the life of the alternative (T_{WO}). $\$_{\text{Major critical}}$ can be estimated as one-third the cost of reconstruction for asphalt pavements and one-fourth the cost of reconstruction for concrete pavements.

In the example above:

$$\$_{Annual\ Major\ Alt2} = \$5.0/25.29 = \$.1977/SF/YR$$

Determine the average annual operational maintenance over the life of the alternative ($\$_{\text{Annual operational}}$). The annual operational maintenance actions are only measures taken to keep the pavement operationally safe. This can be obtained by summing the total annual operational cost over the life of the alternative (the cost will vary annually as a function of the PCI) then divide the sum by the life (T_{WO}). Based on unit costs in the PAVER system, this can be approximated as $0.0040/SF/YR for concrete pavements and $0.0004/SF/YR for asphalt pavements. This is a nominal average cost that can be used as constant on all analyses.

$EUAC_{Alt2}$ is determined as the sum of the $\$_{Annual\ Major\ Alt2}$ and $\$_{Annual\ Operational}$ costs as shown in the equation below.

$$EUAC_{\ Alt2} = \$_{Annual\ Major\ Alt2} + \$_{Annual\ Operational}$$

For the example above:

$$EUAC_{Alt2} = 0.1977 + 0.0040 = \$\,0.2017/SF/YR$$

A-10.2.4 Annual Cost Due to Loss in Pavement Life.

Calculate the annual cost due to loss in pavement life ($EUAC_{LOSS}$):

$$EUAC_{LOSS} = EUAC_{Alt2} - EUAC_{Alt1}$$

For the example above:

$$EUAC_{LOSS} = 0.2017 - 0.1649 = \$\,0.0368\ /SF/YR$$

This number is then multiplied by the losses in years from paragraph A-10.1.5, which is 4.1 years in this example, i.e., 0.0368*4.1 = $0.151/SF or approximately $1.358/SY. The section risk cost is simply the $EUAC_{LOSS}$ multiplied by the area of the section.

A-10.3 Compute Project Risk Cost.

Performing localized PM typically includes more than one pavement section. The risk for a project is simply the sum of the risk associated with every section. Set the risk cost to zero when the PCI is less than critical. The project cost is best calculated in an Excel sheet as shown in Figure A-64. The Excel sheet shown in this example was initiated in PAVER using the user-defined reports feature. The generated Excel sheet from PAVER included section area and PCI. The rest of the information in the sheet was calculated in Excel as follows.

A-10.4 Compute Risk Cost for Each Section.

Compute DT_i for each section using the equation in paragraph A-10.1.6. In the example used throughout this appendix, R_W = 0.85 and R_{WO} = 1.11

Compute the risk cost for each section as follows:

$$Section\ Risk\ Cost = DT_i * EUAC_{LOSS}$$

In this example, $EUAC_{LOSS}$ was calculated in paragraph A-10.2.4 as $0.0368/SF/YR

The project risk cost is the sum of all the section costs, which is $356,768.

Figure A-64 Project Risk Cost Table Example

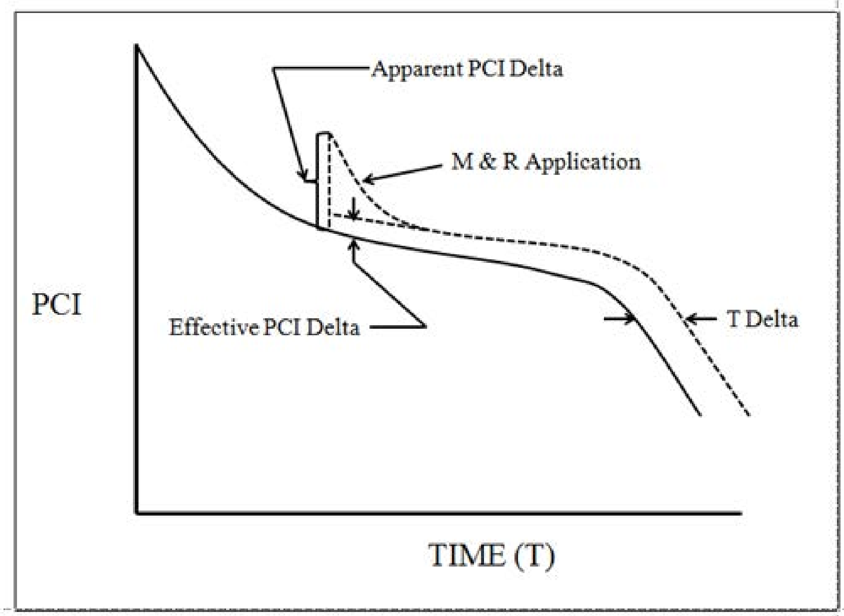
A-10.5 Risk Analysis – Global Preventive Maintenance (PM).

Typically, global PM is applied for pavements above the critical PCI at an appropriate frequency throughout the life of the pavement. Currently, global PM is limited to the application of seal coats to asphalt surfaces. In this UFC, seal coats are divided into three general applications: fog seals, rejuvenators, and slurry seals. The procedure presented below is for determining the risk for a single application. Note that in the following procedure the rate of deterioration without global PM (R_{WO_G}) is used in this analysis because the Services have not historically used global PM on airfields. If global PM has been performed in the past, use the localized preventive procedure outlined in paragraphs A-10.1 thru A-10.4.

Figure A-65 shows the general effect of applying global PM on pavement life. Pavement life is defined as the age in years from original construction or the last major M&R to the time the pavement reaches its critical PCI.

Figure A-65 Effect of Global Maintenance on PCI



A-10.5.1 Family Rate of Deterioration Without Global Preventive Maintenance (PM).

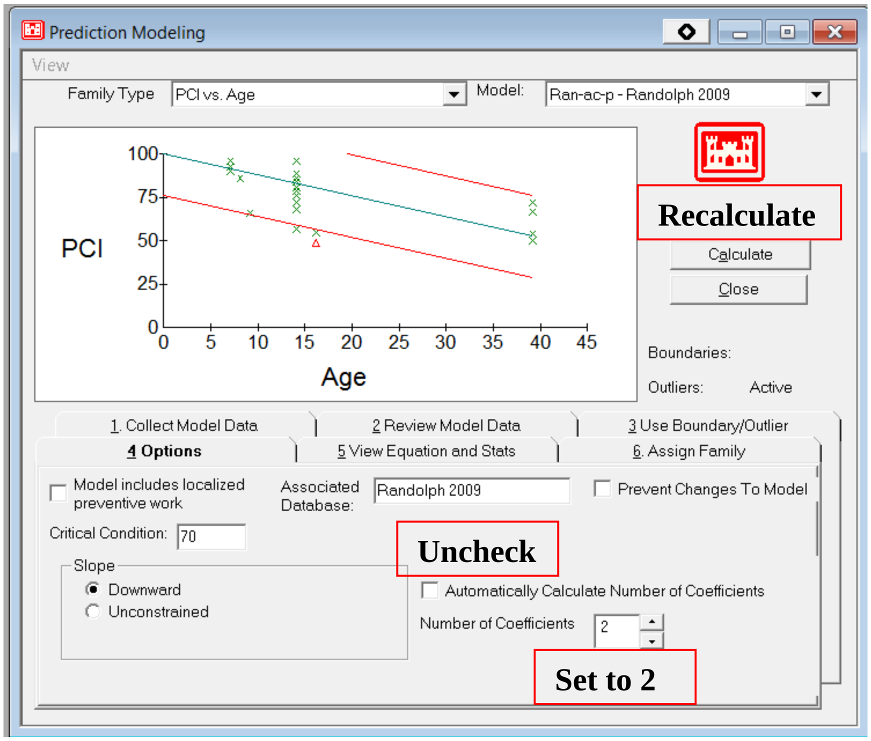
a. For each pavement section, calculate the pavement family rate of deterioration with and without performing global PM.

b. Determine the pavement family rate of deterioration (R_{WO_G}) assuming global PM has not been performed in the past.

c. Create a family curve in PAVER that includes the pavement section(s) under consideration. Figure A-66 shows an example family curve that was created for primary asphalt taxiways at an Air Force base.

d. On tab 4, **Options**, uncheck the **Automatically Calculate Number of Coefficients** button then set the number of coefficients to 2 and press the **Calculate** button as shown in Figure A-66.

Figure A-66 Effect of Global Maintenance on PCI



e. Select tab 5, **View Equation and Stats**. The second coefficient in the equation (e.g., 100 – 1.20653 X^1) is the straight-line deterioration rate (Rwo_G = 1.21 points per year). The next step is to calculate the age (T_{WO_G}) to critical PCI (PCI_C), assuming localized PM has not been performed.

A-10.5.2 Age to Critical PCI Without Global Preventive Maintenance (PM).

a. Calculate age to critical PCI (PCI_C), assuming global PM has not been performed (T_{WO_G}).

$$T_{WO\_G} = (100 - PCI_C) / R_{WO\_G}$$

b. In the example above, assuming a PCI_C = 70:

$$T_{WO\_G} = (100 - 70) / 1.21 = 24.8 \text{ years}$$

c. Delta T (DT) is the estimated effective increase in pavement life due to application of the global treatment. The value of DT is a function of a variety of factors, including pavement condition, climatic condition, and the type of treatment being applied. It normally ranges from two to six years, depending on treatment type. DT is less than the frequency at which the treatment is applied. For example, if a rubberized slurry seal is applied on a six-year cycle, the expected DT cannot be equal to or greater than six years. Table A-30 provides a range of recommended DT values for fog seals, rejuvenators, and slurry seals. Use the midpoint of the range unless local experience and conditions indicate other values within the range are more appropriate.

Table A-30 Recommended DTf Values

Type of Seal Coat	DT, years
Fog seal	2–3 years
Rejuvenator	3–5 years
Slurry seal	4–6 years

d. Calculate the age to critical PCI (PCI_C), assuming global PM is performed (T_{W_G}):

$$T_{W\_G} = T_{WO\_G} + DT$$

e. In the example above, assuming DT = 5 years:

$$T_{W\_G} = 24.8 + 5 = 29.8\ years$$

A-10.5.3 Estimate Cost Due to Loss in Pavement Section Life.

Performing global maintenance will increase pavement life, but a risk analysis must determine the consequences of not performing an action. This section determines the cost of not performing global maintenance (i.e., the loss in pavement life by not performing global maintenance). The procedure is based on the EUAC economic analysis method. This method calculates the average annual cost with and without global PM and compares the two to determine the annual cost due to loss of pavement life. The simplest form of this procedure is presented below, in which interest and inflation rates are not considered. The costs are intended to be used for comparative analysis only and not intended to represent actual project cost.

A-10.5.4 Calculate EUAC With Global Preventive Maintenance (PM).

a. Use the following procedure to calculate the EUAC for the global PM alternative ($EUAC_{Alt1}$).

b. Determine the annual major M&R cost ($\$_{Annual-Major-Alt1}$) by dividing the major M&R cost at critical PCI ($\$_{Major-critical}$) by the life of the alternative (T_{W_G}). $\$_{Major-critical}$ can be estimated as one-third the cost of reconstruction for asphalt pavements and one-fourth the cost of reconstruction for concrete pavements.

c. In the example above, assuming a reconstruction cost of $6.00/SF then $\$_{Major-critical}$ is estimated at $6/3 = $2.0/SF.

$$\$_{Annual\ Major\ Alt1} = \$2.0/29.8 = \$0.0671\ SF/Yr$$

d. Determine the annualized cost of the global treatment being applied ($\$_{Global}$).

$$\$_{Global} = Treatment\ unit\ cost/T_{W\_G}$$

e. For the example above, assuming the treatment unit cost is $0.30/SF:

$$\$_{Global} = \$0.30/29.8 = \$0.0100\ SF/YR$$

f. $EUAC_{Alt1}$ is determined as the sum of costs from $\$_{Major\text{-}critical}$ and $\$_{Global}$ above, as shown in the equation below:

$$EUAC_{Alt1} = \$_{Annual\ Major\ Alt1} + \$_{Global}$$

g. For the example above:

$$EUAC_{Alt1} = 0.0671 + 0.0100 = \$0.0771/SF/YR$$

A-10.5.5 Calculate EUAC Without Global Preventive Maintenance (PM).

Calculate annual cost for the same alternative, except without global PM alternative ($EUAC_{Alt2}$):

Determine the annual major M&R cost ($\$_{Annual\ Major\ Alt2}$) by dividing the major M&R cost at critical PCI ($\$_{Major\ critical}$) by the life of the alternative (T_{WO_G}). $\$_{Major\ critical}$ can be estimated as one-third the cost of reconstruction for asphalt pavements and one-fourth the cost of reconstruction for concrete pavements.

In the example above:

$$\$_{Annual\ Major\ Alt2} = \$2.0/24.8 = \$\,0.0806\ /SF/YR$$

A-10.5.6 Calculate Annual Cost Due to Loss of Pavement Life.

Calculate the annual cost due to loss of pavement life ($EUAC_{LOSS}$):

$$EUAC_{LOSS} = EUAC_{Alt2} - EUAC_{Alt1}$$

For the example above:

$$EUAC_{LOSS} = \$0.0806 - \$0.0771 = \$\,0.0035/SF/YR$$

This number is then multiplied by DT, which is five years in this example, i.e., 0.0035*5 = $0.0175/SF or approximately $0.1575/SY.

A-10.6 Compute Project Risk Cost.

Performing globalized PM typically includes more than one pavement section. The risk for the project is simply the sum of the risk associated with every section. Set the risk cost to zero when the PCI is less than critical. The project cost is best calculated in an Excel sheet as shown in Figure A-67. The Excel sheet in this example was initiated in PAVER using the user-defined reports feature. The generated Excel sheet from PAVER included section area and PCI. The rest of the information in the sheet was calculated in

Excel as shown above. Note that negative costs or costs shown in red/parentheses indicate these applications may not be justified based on the assumptions.

This UFC supersedes UFC 3-301-01, dated 1 October 2019.

This Page Intentionally Left Blank

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-301-01, Change 1, Dated October 2, 2023
Superseding: UFC 3-301-01, Dated April 11, 2023

\1
Description of changes:
This update to UFC 3-301-01 incorporates a change to Tsunami design provisions wherein “other utilities”, which would generally refer to elements of secondary or tertiary importance, may be designed for a reduced risk category where approved by the AHJ. Additionally, an existing prohibition against the use of fabric hangar doors in windborne debris regions has been changed to include fabric covered buildings in general in windborne debris regions.

Reason for changes:
Regarding tsunami design change: In some cases it may be infeasible to harden all elements of a utility system against tsunami effects, particularly less critical distributions systems. Accordingly, it was decided that the Authority Having Jurisdiction (AHJ) can approve the reduction of tsunami risk category for “other utilities”, which can have the effect of reducing or eliminating tsunami design requirements for secondary and/or tertiary systems.

Regarding fabric covered buildings in windborne debris regions: It became apparent that there was an omission in DoD structural criteria, wherein an existing prohibition against the use of fabric covered hangar doors existed, while there was no such prohibition against using fabric covered buildings in general, which are vulnerable to the same failure mode. Moreover, this omission would result in a prohibition against the use of a fabric door on a fabric covered building, which would prove illogical. Awareness of this omission occurred as a result of a recent emphasis on the utilization of fabric covered buildings across the Department of Defense. Fabric, unlike other construction materials is uniquely vulnerable to tearing and tear propagation do to windborne debris. Past experience with Hurricane Michael at Tyndall Air Force Base has demonstrated this vulnerability.

Impact: There are both costs and benefits to these changes

Tsunami design changes: This change will result in substantial cost savings to the Department of Defense over time, where the department is impacted by tsunami.

Fabric covered structures: A direct increase in cost will be negligible for this change, as the life cycle cost for a fabric covered building, compared to a metal clad building, will not vary significantly for windborne debris regions. Ultimately however, it is expected that this prohibition will result in considerable savings to DoD, by reducing facility loss and facility content loss due to damage caused by major hurricanes and typhoons.
/1/

Document: UFC 3-301-01, Change 2, Dated September 4, 2024
Superseding: UFC 3-301-01, Change 1, Dated October 2, 2023

\2
Description of changes (seismic coefficients):
Seismic design values for OCONUS installations have been updated (effective Sept 4, 2024). This will affect existing OCONUS RFP's and designs according to UFC 1-200-01 (Chapter 1-3.1).

Reason for changes:
Seismic acceleration coefficients (earthquake loading) for OCONUS installations have not been fully updated since the 1990's. At that time, they were prepared based on less reliable information. In 2010, the Global Earthquake Model (GEM), a non-profit foundation, began a multi-year effort to construct a global earthquake hazard model using high quality site hazard data available from governments, academia, and industry resources. This Model is continuously refined and improved. In 2021, the Department of Defense (DoD), in partnership with the Department of State (DoS), contracted with GEM to develop new seismic design values for all OCONUS DoD installations and DoS facilities using the GEM model. Results from this effort have recently become available and have been incorporated into DoD design criteria (effective Sept 4, 2024).

Impact:
There may be a significant cost increase for some locations. Because prior values were based on less reliable information, this update has resulted in numerous changes. In most cases changes are mild to moderate. However, in a few locations, values have increased markedly. For this reason, this change has the potential to result in a significant cost increase for some locations.
/2/

\2
Description of changes (fall protection):
Two separate sections referencing fall protection were consolidated and simplified.

Reason for changes:
Fall protection requirements noted within the UFC were confusing as written, redundant to the IBC and ASCE 7 and, in some cases, were not relevant to the building structure.

Impact:
There is no significant impact associated with this change.
/2/

\2
Description of changes (Roof Diaphragms Resisting Wind Loads in High-wind Regions):
An exception was added to this provision to prevent it from being applied to new buildings.

Reason for changes:
As written, the provision could be incorrectly applied to new buildings.

Impact:
There is no significant impact associated with this change.
/2/

Document: UFC 3-301-01, Change 3, Dated February 3, 2025
Superseding: UFC 3-301-01, Change 2, Dated September 4, 2024

\3
Description of changes:
-Adoption of the 2024 I-codes

-Adoption of ASCE 7-22, Minimum Design Loads and Associated Criteria for Buildings and Other Structures

-Frost depth, for the purpose of foundation design, is now to be determined by project geotechnical engineer

Reason for changes:
Maintain concurrence with model building codes and alignment with DoD building code (1-200-01).

Impact:
Typical of the code update cycle.
/3/

Document: UFC 3-301-01, Change 4, Dated June 3, 2025
Superseding: UFC 3-301-01, Change 3, Dated February 3, 2025

\4
Description of changes:
Includes sundry changes and clarifications but also a significant change to the risk category table (Table 2-2).

Reason for change:

- There is a conflict originating in the IBC, where public utilities are designated as both risk category III and IV. This has been corrected by deletion of the risk category III option for public utilities. It is not intended that this change affect current projects in any stage of design.

- The application of Risk Category V in the context of missile defense has gradually expanded beyond its original intent, which was to protect nationally critical defensive assets. The current revision realigns the category's use with its initial purpose—focusing on missile defense and other highly critical assets whose loss could result in catastrophic national consequences, rather than merely regional or local impact.

Impact: This change will result in substantial cost savings

TABLE OF CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

UFC 1-200-01 implements and supplements 2024 IBC as the building code for DoD. Chapter 2 of this UFC further modifies the IBC for structural-specific design requirements and is organized by the chapter of the IBC that each section modifies. Apply any section in the 2024 IBC, that is not specifically referenced, as it is written in the 2024 IBC. Chapter 3 of this UFC further modifies ASCE 7-22 for structural-specific design requirements and is organized by the chapter of ASCE 7 that each section modifies. Apply any section in ASCE 7-22, that is referenced by the 2024 IBC but is not modified in Chapter 3 of this UFC, as it is written in ASCE 7-22.

The 2024 IBC and ASCE 7-22 section modifications are one of four actions, according to the following legend:

[Addition] – Add new section, including new section number, not shown in 2024 IBC or ASCE 7-22.

[Deletion] – Delete referenced 2024 IBC or ASCE 7-22 section or noted portion of a section.

[Replacement] – Delete referenced 2024 IBC or ASCE 7-22 section or noted portion and replace it with the narrative shown.

[Supplement] – Add narrative shown as a supplement to the narrative shown in the referenced section of 2024 IBC or ASCE 7-22.

1-2 REISSUE AND CANCELS.

This edition of UFC 3-301-01 cancels UFC 3-301-01 dated 1 October 2019.

1-3 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) provides requirements for structures designed and constructed for the Department of Defense (DoD). These technical requirements are based on the 2024 *International Building Code* (2024 IBC), as modified by UFC 1-200-01, *DoD Building Code*, and the structural standard referenced by the 2024 IBC: ASCE/SEI 7-22 *Minimum Design Loads and Associated Criteria for Buildings and Other Structures* (hereinafter referred to simply as ASCE 7-22). The criteria further provides limited technical guidance for seismic evaluation and strengthening of existing buildings, and references ICSSC RP 10, *Standards of Seismic Safety for Existing Federally Owned and Leased Buildings* (RP 10) as well as ASCE/SEI 41-17, *Seismic Evaluation and Retrofit of Existing Buildings* (hereinafter referred to simply as ASCE 41-17). Additionally, for nonseismic retrofit of existing buildings, the criteria references the 2024 edition of the *International Existing Building Code* (2024 IEBC). This information is for use by structural engineers to develop design calculations, specifications, plans, and design-build Requests for Proposal (RFPs), and it is meant to serve as the minimum design requirement for DoD buildings.

1-4 APPLICABILITY.

This UFC follows the same applicability as UFC 1-200-01, paragraph 1-3, with no exceptions.

1-5 CONFLICTS AND MODIFICATIONS.

The 2024 IBC provisions are directed toward public health, safety, and general welfare, presenting minimum standards that must be met by the private sector construction industry. The use of industry standards for DoD projects promotes communication in the marketplace, improves competition, and results in cost savings. However, the military sometimes requires higher standards to achieve unique building performance, or to construct types of facilities that are not used in the private sector. In addition, the construction of military facilities outside the United States can introduce requirements that are not addressed in national model building codes. Modifications to the 2024 IBC and ASCE 7-22 provisions contained herein are intended to fulfill those unique military requirements. Where conflicts between the 2024 IBC or ASCE 7-22 and this UFC arise, this UFC prevails.

In addition, for construction outside the United States, conflicts between host nation building codes and the UFC may arise. In those instances, the more stringent design provisions prevail.

1-6 OVERVIEW OF THIS UFC.

Brief descriptions of the various chapters and appendices of this UFC follow.

- Chapter 2 – MODIFICATIONS TO IBC. Chapter 2 provides supplemental requirements for applying the 2024 IBC structural provisions to conventional DoD building design by listing required modifications for specific 2024 IBC sections. The 2024 IBC sections that are not referenced in Chapter 2 or otherwise modified by provisions of Chapter 6 and Appendix B apply as they are written in the 2024 IBC.

- Chapter 3 – MODIFICATIONS TO ASCE 7. Chapter 3 provides supplemental requirements for applying the ASCE 7-22 structural and nonstructural component provisions to conventional DoD building design by listing required modifications for specific ASCE 7-22 sections. The ASCE 7-22 sections that are adopted by the 2024 IBC but are not referenced in Chapter 3 or otherwise modified by provisions of Chapter 7 and Appendix B apply as they are written in ASCE 7-22.

- CHAPTER 4 - EVALUATION AND RETROFIT OF EXISTING BUILDINGS. This chapter contains provisions for the *repair*, *alteration*, change of occupancy, acquisition, *addition* to, and relocation of existing buildings. For seismic evaluation of existing buildings, this chapter adopts by reference the provisions of

ICSSC RP 10, as well as those of ASCE/SEI 41-17. This chapter also makes revisions to specific sections in RP 10. Additionally, this chapter contains modifications to the 2024 IEBC including the scope, and the prescriptive compliance method for nonseismic evaluation of existing buildings.

- CHAPTER 5 – NONBUILDING STRUCTURES. This chapter lists the names of various standards and other guidelines to be followed for the design of highway bridges, railroad bridges, tanks for liquid storage, tanks for petroleum storage, environmental engineering concrete structures, prestressed concrete tanks, water treatment facility structures, transmission towers and poles, antenna towers, and pedestrian bridges.

- CHAPTER 6 – MODIFICATIONS TO THE IBC FOR CRITICAL HEALTHCARE FACILITIES. This chapter contains a number of additional requirements for certain critical healthcare facilities identified in the chapter. The requirements are presented in the form of modifications to Chapters 16, 18, 19, 20, 21, and 22 of the IBC.

- CHAPTER 7 – MODIFICATIONS TO ASCE 7 FOR CRITICAL HEALTHCARE FACILITIES. This chapter contains a number of additional requirements for the same healthcare facilities within the scope of Chapter 6. The requirements are presented in the form of modifications to Chapters 11, 12, and 13 of ASCE 7.

- Appendix A – BEST PRACTICES. This appendix provides useful recommendations and guidance on a number of important topics such as building drift limits, impact resistant glazing, wind and seismic loads on photovoltaic arrays, etc.

- Appendix B – ALTERNATE DESIGN PROCEDURE FOR BUILDINGS AND OTHER STRUCTURES IN RISK CATEGORY IV. For buildings assigned to Risk Category IV, those that are “essential” because of their military function or post-earthquake recovery role, the 2024 IBC/ASCE 7-22 requires higher design lateral loads and more stringent structural detailing procedures than those for buildings assigned to Risk Category I, II, or III. Applying nonlinear analysis procedures may result in more economical or better-performing Risk Category IV buildings than linear elastic procedures can provide. While the 2024 IBC/ASCE 7-22 permits nonlinear static analysis procedures, it provides little guidance on how to perform them. Appendix B presents optional nonlinear static analysis procedures that may be used for Risk Category IV buildings. Apply the optional nonlinear procedures outlined in Appendix B only with the approval of the Authority Having Jurisdiction.

- Appendix C – GUIDANCE FOR SEISMIC DESIGN OF NONSTRUCTURAL COMPONENTS. Appendix C provides guidance for seismic design of nonstructural components. Requirements for design of nonstructural components in this UFC are supplemented by guidance provided in this appendix.

- Appendix D – MECHANICAL AND ELECTRICAL COMPONENT CERTIFICATION. Appendix D provides guidance in addition to what is available in ASCE 7-22 Section 13.2.2 on certification of mechanical and electrical components.

- Appendix E – MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_O, AND MINIMUM CONCENTRATED LIVE LOADS. This appendix contains Table E-1, which replaces Table 1607.1 of the 2024 IBC and includes additional occupancy or use classification for military facilities that are shown in bold italics.

- Appendix F - GUIDANCE FOR COMPOSITE TECHNOLOGIES FOR BRIDGE APPLICATIONS. The fiber reinforced polymer (FRP) technologies covered in this Appendix include carbon FRP composite prestressing systems, FRP composite external strengthening and repair systems, and FRP composite elements including bridge piles and bridge decks. This appendix also includes information on thermoplastic materials for replacement of timber bridges including thermoplastic lumber, thermoplastic piles, and thermoplastic I-beams.

- Appendix G – GLASS FIBER-REINFORCED POLYMER (GFRP) BARS FOR CONCRETE STRUCTURES. This appendix provides design resources to structural engineers interested in using glass fiber-reinforced polymer (GFRP) reinforcement in concrete structures. New standards developed by ASTM and ACI for GFRP bars are discussed along with other supporting guides and reports. This appendix identifies the limits on the use of GFRP reinforcement in concrete structures and key design considerations.

- Appendix H – GLOSSARY. This appendix lists all the abbreviated terms used in this UFC.

- Appendix I – REFERENCES. The UFC has an extensive list of referenced public documents. The primary references for this UFC are the 2024 IBC and ASCE 7-22.

1-7 COMMENTARY.

Limited commentary has been provided in the chapters. Section designations for such commentary are preceded by a “[C]”, and the commentary narrative is shaded.

1-8 OTHER CRITERIA.

Military criteria other than those listed in this document may be applicable to specific types of structures. Such structures must meet the additional requirements of the applicable military criteria.

1-8.1 General Building Requirements.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-8.2 Progressive Collapse Analysis and Design.

When required, apply UFC 4-023-03, *Design of Buildings to Resist Progressive Collapse*.

1-8.3 Design of Risk Category V Structures.

A risk category not included in the 2024 IBC/ASCE 7-22, Risk Category V, has been added to address national strategic military assets. Structures in this risk category are designed to remain elastic during the MCE_R. Refer to Table 2-2 of this UFC for the list of structures that must be assigned to RC V. Refer to UFC 3-301-02 for the design of all RC V structures.

1-8.4 Cybersecurity.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-9 REFERENCES.

APPENDIX I contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 MODIFICATIONS TO IBC

2-1 IBC CHAPTER 1 - SCOPE AND ADMINISTRATION.

2-1.1 Section 101 – GENERAL.

101.4.7 – Existing Buildings [Replacement]

For seismic evaluation and retrofit of existing buildings, the provisions of Chapter 4 of this UFC apply to all matters governing the *repair*, *alteration*, *change of occupancy*, acquisition, *addition* and relocation.

For nonseismic evaluation and retrofit of existing buildings, the provisions of the *International Existing Building Code*, as modified by Chapter 4 of this UFC, shall apply to matters governing the *repair*, *alteration*, *change of occupancy*, *addition* to and relocation of *existing buildings*.

[C] 101.4.7 – Existing Buildings [Replacement]

The purpose of this [Replacement] is to direct users to specific provisions for seismic evaluation and retrofit of existing buildings. Chapter 4 of this UFC cites a federal recommended practice document (ICSSC RP 10) and a national standard (ASCE 41-17) for seismic evaluation and retrofit of existing buildings. The chapter provides some modifications and clarifications to the requirements of RP 10 and ASCE 41-17.

Additionally, nonseismic retrofit provisions included in Chapter 4 of this UFC are also referenced here.

2-1.2 Section 116 - UNSAFE STRUCTURES AND EQUIPMENT.

116.5 – Restoration or Abatement [Replacement]

Where the structure or equipment determined to be unsafe by the AHJ is restored to a safe condition, the owner, the owner’s authorized agent, operator or occupant of the structure, premises or equipment deemed unsafe must abate or cause to be abated or corrected such unsafe conditions by repair, rehabilitation, demolition or other approved corrective action. To the extent that *repairs*, *alterations* or *additions* are made or a change of occupancy occurs during the restoration of the structure, such *repairs*, *alterations*, *additions* or *change of occupancy* must comply with the requirements of Sections 101.4.7 of this UFC.

2-2 IBC CHAPTER 2 – DEFINITIONS.

2-2.1 Section 202 – DEFINITIONS.

STRUCTURAL ENGINEER OF RECORD (SER) [Addition]

The Structural Engineer of Record (SER) is a registered design professional who performs, supervises, or approves the analysis, design, and document preparation for the building structural system. The SER is responsible for the design of the structural system, which is the completed combination of elements that serves to support the building's self-weight, superimposed dead loads, applicable live loads, and environmental loads such as wind, seismic, and thermal.

2-3 IBC CHAPTER 4 – SPECIAL DETAILED REQUIREMENTS BASED ON OCCUPANCY AND USE.

2-3.1 Section 423 – STORM SHELTERS.

423.4 – Critical Emergency Operations [Supplement]

The requirements of this section shall also apply to hurricane-prone regions (see ASCE 7 Section 26.2) and to facilities housing critical national defense functions that must be manned continuously and for which there is no redundant capability at a different location.

423.5 – Group E occupancies. [Supplement]

Delete Exception 1. Renumber Exceptions 2 and 3 as Exceptions 1 and 2 respectively.

Group E day care facilities shall include Child Development Centers (CDCs), even if classified as Group I-4, as defined by the army, the navy, the air force, the marine corps, and other branches of the military for their respective purposes.

2-4 IBC CHAPTER 16 – STRUCTURAL DESIGN.

2-4.1 Section 1603 – CONSTRUCTION DOCUMENTS.

1603.1.5 – Earthquake Design Data Item 3. [Replacement]

3. Spectral response acceleration parameters, S_s and S_1. If the data are based on site-specific response analysis, this must be noted. Site-specific source data must also include whether response spectrum or time-history analyses were performed.

1603.1.10 – Systems/Components Requiring Special Inspection for Seismic Resistance [Addition]

Construction documents and specifications must be prepared for those systems and components requiring special inspection for seismic resistance, as specified in 2024 IBC Section 1705.13 as modified by the appropriate special inspection section in UFC 1-200-01 and by the SER. Reference to seismic standards in lieu of detailed drawings is acceptable.

1603.2 – Delegated Engineered Systems [Addition]

The SER for a structure may delegate responsibility for the design of systems or components of the structure to a qualified registered professional engineer. Both the SER for the structure and the engineer receiving such delegation must comply with the requirements of this UFC.

Exception: The SER must design and detail all lateral force-resisting system connections for wind and seismic forces, including steel connections. This provision does not preclude a pre-engineered building engineer from designing primary lateral force-resisting connections where said engineer is the building SER. This would be the case with pre-engineered metal buildings and pre-engineered parking garages for example.

The following are some examples of optional delegated designs:

a. Pre-fabricated wood components (e.g. pre-engineered trusses)
b. Cast-in-place post-tensioned concrete structural systems
c. Precast, prestressed concrete components
d. Open web steel joists and joist girders
e. Specialty foundation systems
f. Simple (shear only) steel connections (lateral force-resisting system connections must be designed by SER)
g. Cold-formed steel joist/stud/truss framing and pre-fabricated components
h. Seismic design and anchorage of nonstructural components
i. Proprietary track for under-hung cranes and monorails
j. Cross-laminated timber connections (lateral force-resisting system connections must be designed by SER)

The engineer to whom design responsibility has been delegated must sign and seal all work they design. The SER must review all submittals that have been signed and sealed by the delegated engineer to verify compliance with the design intent and the specified design criteria and to ensure coordination with the contract documents and other shop drawings. All submittals from the engineer to whom design responsibility has been delegated must be approved by the SER prior to the start of fabrication of the system or component and prior to any field construction that may be affected by the system or component.

2-4.2 Section 1604 - GENERAL DESIGN REQUIREMENTS.

1604.3 - Serviceability [Supplement]

The SER must ensure that the maximum allowable frame drift is suitable for the proposed structure considering occupancy, use/function, and all details of construction. See ASCE 7-22 Appendix C “Serviceability Considerations” including commentary, and Section A-1.1 of UFC 3-301-01 for additional guidance.

1604.3.1 - Deflections [Replacement]

Deflections of structural members must not exceed the most restrictive of the limitations of: (1) Sections 1604.3.2 through 1604.3.5, (2) those permitted by Table 1604.3, or (3) those permitted by Table 2-1 of UFC 3-301-01.

Table 2-1 \4\ /4/ Wind Induced Deflection Limits for Framing Supporting Exterior Wall Finishes [a,b]

Brick veneer	*L*/600
Exterior Insulation Finish Systems	*L*/240
Cement board	*L*/360
Stone Masonry	VERIFY WITH STONE SUPPLIER
Plywood and Wood-Based Structural-Use Panels	*L*/240
Gypsum sheathing	*L*/240
Metal or vinyl siding and insulated metal panel	*L*/120

\4\ /4/

a. The wind load is permitted to be taken as 0.42 times the “component and cladding” wind loads for the purpose of determining the deflection limits herein.

b. L must be calculated as $L = kl$, where k is the theoretical effective length factor, and l is length of the member between supports.

Table 1604.5 [Replacement]

Replace Table 1604.5 of the IBC with Table 2-2 of this UFC. All references in the IBC to Table 1604.5 must be interpreted as a reference to Table 2-2 of this UFC. Items that are different from those in 2024 IBC Table 1604.5 are shown in italics.

Table 2-2 Risk Category of Buildings and Other Structures

Risk Category	Nature of Occupancy	*Seismic Factor I_e*			*Tsunami Factor I_{TSU}*	*DoD Sea Level Rise (SLR) Scenario* [f]
I	**Buildings and other structures that represent a low hazard to human life in the event of failure, including, but not limited to:** • Agricultural facilities • Certain temporary facilities • Minor storage facilities	*1.00*			*N/A* *Tsunami design not required*	*N/A*
II	**Buildings and other structures except those listed in Risk Categories I, III, IV *and V***	*1.00*			*1.00*	*Low (2065)*

Notes to Table 2-2, "Risk Category of Buildings and Other Structures"

a. For purposes of occupant load calculations, occupancies required by *IBC* Table 1004.5 to use gross floor area calculations shall be permitted to use net floor areas to determine the total occupant load. The floor area for vehicular drive aisles shall be permitted to be excluded in the determination of net floor area in parking garages.

b. Where approved by the *AHJ*, the classification of buildings and other structures as Risk Category III or IV based on their quantities of toxic, highly toxic or explosive materials is permitted to be reduced to Risk Category II, provided that it can be demonstrated by a hazard assessment in accordance with ASCE 7 Section 1.5.3 that a release of the toxic, highly toxic or explosive material is not sufficient to pose a threat to the public.

c. Risk Category V has been added to address national strategic military assets. Structures in this risk category are designed to remain elastic during the MCE_R*. Refer to UFC 3-301-02 for the design of all RC V structures.*

d. These facilities may be designed for Tsunami Risk Category I or II as approved by the AHJ.

e. These facilities may be designed for Tsunami Risk Category I, II or III as designated by the AHJ if adequate equivalent facilities are available *outside of the tsunami inundation zone or if adequate equivalent facilities within the inundation zone have been designed for the effects of tsunami.*

f. *Use the site-specific value from the DoD Regional Sea Level (DRSL) database corresponding to the designated scenario (low/medium/high/highest) for the year 2065. The DRSL database is available at https://sealevelscenarios.serdp-estcp.org*

g. *Subject to approval by the AHJ, a DoD 2065 sea level rise scenario of Medium may be used for Risk Category IV and V structures when designing for a combination of tsunami and sea level rise. Reference Section 3-3.1 within this UFC for specific limitations and requirements.*

h. **\4** *Defense Critical Assets must be explicitly listed in the OSD approved Mission Assurance tracking system. See DODI 3020.40 and 3020.45. The list of specific DCA's must follow the appropriate classification guidance.* **/4/**

1604.12 - Expansion Joints [Addition]

See guidance in *"Design of Concrete Floor Slabs-on-Ground for DoD Facilities"* posted under Related Materials for this UFC on the WBDG.

2-4.3 Section 1605 – LOAD COMBINATIONS.

1605.1.2 – Structural Members Sensitive to Vertical Ground Motion [Addition]

Where the design earthquake spectral response acceleration parameter at short periods, S_{DS}, is greater than 0.6g, the components of building and nonbuilding structures listed below must be designed for additional load combinations given in Sections 2.3.6 and 2.4.5 in Chapter 3 of this UFC for Strength Design and Allowable Stress Design, respectively.

Building Structures:

- horizontal or nearly horizontal structural members spanning 65 ft or more
- horizontal or nearly horizontal cantilever components longer than 16 ft
- horizontal or nearly horizontal prestressed components
- building components, excluding foundations, in which demands due to gravity loads exceed 80% of the nominal strength of the component
- horizontal structural elements supporting discontinuous vertical elements of the gravity load-resisting system
- base-isolated structures

Nonbuilding Structures:

- long-span roof structures (e.g., stadiums or aircraft maintenance hangar header truss)
- electric power generation facilities

Exception: Nonbuilding structures addressed by ASCE 7-22 Section 15.1.4 are not required to comply with this section.

[C] 1605.1.2 Structural Members Sensitive to Vertical Ground Motion [Addition]

The effects of vertical earthquake ground motion on buildings have traditionally been given much less attention than the effects of horizontal ground motion. This is largely due to the belief that the peak vertical ground acceleration is considerably smaller than the peak horizontal ground acceleration. A fairly large safety factor against static vertical loads also exists in engineered buildings. As a result, it is generally considered adequate to include the effects of vertical ground motions in the simplified form of $0.2S_{DS}D$, as done in the IBC and the ASCE 722 standard for many years. However, certain structural members are particularly vulnerable to vertical ground motions and require more explicit consideration of such ground motions in their design. This [Addition] addresses those specific members by incorporating additional provisions for design considering vertical ground motions.

The threshold value of S_{DS} > 0.6g was derived from a similar requirement in the 2004 edition of Eurocode 8, which specified the peak vertical ground acceleration, a_{vg}, to be greater than 0.25g for its special provisions related to vertical ground motions to apply. The derivation is as shown below:

1. From the vertical ground motion response spectrum given in ASCE 7-22 Section 11.9.2, the ratio of the peak vertical ground acceleration (spectral acceleration at $T_v = 0$) and the maximum vertical spectral acceleration (flat top portion of the response spectrum) is0.65/1.05 = 0.62.
2. The maximum vertical spectral acceleration has been traditionally assumed to be $2/3S_{DS}$.
3. So, the peak vertical ground acceleration can be expressed in terms of S_{DS} as: $a_{vg} = 0.62×(2/3S_{DS}) = 0.41S_{DS}$
4. So, a_{vg} > 0.25g => S_{DS} > 0.6g

1605.2 – Alternative Allowable Stress Design Load Combinations [Deletion]

Delete this section in its entirety.

2-4.4 Section 1607 - LIVE LOADS.

1607.1 - General [Replacement]

Live loads are those loads defined in Section 1607.1. Table E-1 of this UFC defines minimum uniformly distributed live loads and minimum concentrated live loads for the design of structures. Table E-1 is IBC Table 1607.1 with additional Occupancy or Use classifications for military facilities. The classifications that have been added to IBC Table 1607.1 are shown in bold italics within Table E-1.

Table 1607.1 [Replacement]

Replace Table 1607.1 of the IBC with Table E-1 of this UFC. (All references in the IBC to Table 1607.1 must be interpreted as references to Table E-1 of this UFC.)

1607.8.1 - Loads [Replacement]

Where a structure does not restrict access for vehicles that exceed a 10,000 pound (4536 kg) gross vehicle weight rating, those portions of said structure subject to such loading must be designed using the vehicular live loads, including consideration of impact and fatigue, in accordance with the AASHTO Bridge Design Specification.

1607.12.4 – Fall arrest and lifeline, and rope descent system anchorages [Replacement]

The applied 3100-pound load is a live load to be used with either the load combinations for allowable stress design or the load combinations for strength design.

To protect personnel during occupancy and maintenance phases, consider fall hazards at the planning and design phase of a project and eliminate them to the maximum extent possible. Also consider safe access to work location at heights.

When elimination or prevention of fall hazards is not feasible, include in design certified and labeled anchorages that are conveniently located to perform the work safely.

Where fall protection is required near weight-handling equipment, prevent conflicts between the weight-handling equipment and fall protection measures.

1607.12.5 - Hangars [Addition]

In hangars, where horizontal lifelines are used as the fall protection solution for aircraft maintenance, make sure that there will be no interference between the crane envelope inside the hangar and the horizontal lifeline system.

\4\ 1607.14 – Bridge Crane Support Structure [Addition]

Reference AISC Design Guide 7, Section 18 for design of crane supporting structure, including crane support beams (runway beams).

For seismic design categories C-F see 3-7.6 13.6.14 **/4/**

2-4.5 Section 1608 - SNOW LOADS.

1608.2 - Ground Snow Loads [Replacement]

Ground snow loads at DoD installations within the United States and its territories and possessions must be determined using the ASCE Hazard Tool hosted at

https://ascehazardtool.online

Snow loads are zero for Hawaii, except in mountainous regions as approved by the AHJ.

At locations where the ground snow load is not provided by the ASCE Hazard Tool, consult the AHJ.

1608.2.2 - Specific Locations Outside of the United States [Addition]

Ground snow loads at specific locations outside of the United States and its territories and possessions are identified using a spreadsheet that can be found on the Whole Building Design Guide Structural Engineering UFC Page as a related item for download

At locations where the ground snow load is not provided, use the best locally available information.

1608.2.3 - Snow Load Case Studies [Addition]

Snow load case studies may be done to clarify and refine snow loadings at site-specific locations with the approval of the AHJ. Where required by the AHJ, a site-specific study must be conducted. The ground snow load is to be determined based on an RC II structure for this purpose. The methodology used to conduct snow load case studies at site-specific locations is presented in the Cold Regions Research and Engineering Laboratory (CRREL) report “Database and Methodology for Conducting Site Specific Snow Load Case Studies for the United States.” by Tobiasson and Greatorex and “Site-Specific Case Studies for Determining Ground Snow Loads in the United States” by Buska, Greatorex, and Tobiasson.

2-4.6 Section 1609 - WIND LOADS.

1609.1.1 – Determination of Wind Loads [Supplement]

Add the following to the list of exceptions:

8. For winds parallel to the ridge of open buildings, the wind load delivered to the main wind force resisting system from the bare frames or partially clad end walls must be determined in accordance with the provisions of ASCE 7-22 Section 28.3.7.

1609.1.2 – Aircraft Hangar Wind Loads [Addition]

Wind load on the main wind force resisting system **\4** and components and cladding **/4/** of aircraft hangars must be determined based on the following conditions:

- Hangar doors closed for winds at the maximum design velocity. Calculate the structural forces based upon the assumption of a “partially enclosed building.” It is permissible to use the large volume reduction factor of ASCE 7 in determining the design wind pressures. Assume that a 1-inch (25-mm) strip around the perimeter of all hangar door panels is an opening and combine this with the area of all unshielded fenestration.

- Hangar doors open to the maximum extent possible with a design wind velocity of 60 mph (97 km/h). Calculate the structural forces upon the assumption of a “partially enclosed building.” Use the total open-door area in the large volume reduction factor calculation.

1609.2.3 – Vertical Lift Fabric Hangar Doors (VLFD) [Addition]

Vertical Lift Fabric Doors are prohibited within windborne debris regions.

Additionally, VLFD’s are prohibited for use in aircraft maintenance hangars where 700-year-MRI wind speeds (IBC Figure 1609.3(2), ASCE 7 Figure 26.5-1B) equal or exceed wind speeds defining a windborne debris region, namely, 130 mph (58 m/s) within one mile of the coastal mean high-water line where an Exposure D condition exists upwind of the waterline or 140 mph (63.6 m/s) anywhere else.

[C] 1609.2.3 – Vertical Lift Fabric Hangar Doors (VLFD) [Addition]

VLFD’s are currently prohibited for use in windborne debris regions defined in the IBC due to failures experienced during hurricane Michael. These failures were predominately caused by wind driven debris.

Additionally, DoD has prohibited VLFD use in locations where the 700-year-MRI wind speed exceeds the threshold wind speed for windborne debris regions. This is because the risk of damage caused by windborne debris is the same in these areas as in windborne debris regions. In essence, this has served to slightly expand windborne debris regions as defined in the IBC.

1609.2.4 – Roll Up Doors and Sectional Doors in Hurricane Prone Regions [Addition]

In hurricane prone regions, warehouse and/or garage roll up doors or sectional doors must be pressure tested for components and cladding design wind pressure and shown to pass in accordance with ANSI/DASMA 108, *Standard Method for Testing Sectional Garage Doors and Rolling Doors*. This requirement must be noted on the construction drawings in addition to the project specifications. The SER must specify the components and cladding design wind pressure for garage/sectional doors on the construction drawings.

1609.3.1 - Wind Speed Conversion [Replacement]

When required, the basic wind speed can be converted to an allowable stress design wind speed, V_{asd}, using Equation 16-18a.

$$V_{asd}=\sqrt{0.6}V \qquad \text{(Equation 16-18a)}$$

When required, the basic wind speed can be converted to a fastest-mile wind speed, V_{fm}, using Equation 16-18b.

$$V_{fm}=(\sqrt{0.6}V\text{-}10.5)/1.05 \qquad \text{(Equation 16-18b)}$$

1609.3 - Basic Wind Speed [Replacement]

Basic wind speeds at DoD installations within the United States and its territories and possessions must be determined using the ASCE Hazard Tool hosted at:

https://ascehazardtool.org

At locations where the basic wind speed is not provided by the ASCE Hazard Tool, consult the AHJ. The basic wind speeds, *V*, determined by the AHJ must be in accordance with Chapter 26 of ASCE 7.

1609.3.2 - Specific Locations Outside of the United States [Addition]

Basic wind speeds at specific locations outside of the United States and its territories and possessions can be identified using a spreadsheet that can be found on the Whole Building Design Guide Structural Engineering UFC Page as a related item for download

At locations where the basic wind speed is not provided, use the best locally available information.

1609.3.3 – Design Wind Speed for Non-permanent Structures [Addition]

For **Non-permanent** Structures, as defined in UFC 1-201-01, it is permissible to multiply the basic wind speed, *V*, as identified in UFC 3-301-01, by a reduction factor of 0.78.

This section supersedes Section 3-2.1.5 of UFC 1-201-01 and IBC Section 3103.6.1.2.

[C] 1609.3.3 – Design Wind Speed for Non-permanent Structures [Addition]

For the purpose of determining design wind speeds for non-permanent structures with design life of 5 years or less, UFC 1-201-01, 4 March 2022, Change 4, 8 August 2023, permits application of a 0.78 reduction factor to the design wind speeds determined in accordance with UFC 3-301-01 for regular structures. However, that allowance is restricted to non-hurricane prone regions only. This [Addition] revises that provision to expand the applicability of the 0.78 factor to hurricane prone regions as well.

The revision was based on a study that looked at design wind speeds at a large number of locations across the United States using a “uniform hazard” approach. For a given risk category of a non-permanent structure, wind speeds were determined for the same probability of exceedance in 5 years as that used in ASCE 7 for a 50-year design life of regular structures. For example, in ASCE 7, the design wind speed values for RC II structures are based on a return period of 700 years, which translates to about 7% probability of exceedance in 50 years. Assuming the same level of wind hazard is acceptable for a non-permanent structure over its 5-yr design life, i.e., a 7% probability of exceedance in 5 years, wind speeds for non-permanent structures assigned to Risk Category II should be determined based on 70-yr wind events. Similarly, design wind speeds for non-permanent structures assigned to Risk Category I, III, and IV need to be determined based on 30, 170 and 300-yr return period wind events, respectively. These can be determined through interpolation using the 300-yr wind speeds given in ASCE 7 Chapter 26 and 25-, 50-, and 100-yr wind speeds given in ASCE 7 Appendix CC, where the return periods are expressed on a log scale.

It was found that, wind speeds determined as described above for a total of 342 locations in the United States matched very closely with the wind speeds determined by simply reducing the ASCE 7 values by a factor of 0.78 as permitted in UFC 1-201-01. And this was seen to be as true for hurricane prone regions as it was for non-hurricane prone regions. As a result, the 0.78 factor is retained for the sake of simplicity, but its applicability is expanded to hurricane prone regions.

For a more detailed discussion on this change, please refer to the report produced by S. K. Ghosh Associates LLC titled "An Evaluation of the Wind and Seismic Provisions of UFC 1-201-01 for Temporary Structures".

The 2024 IBC has introduced a new Section 3103.6.1.2 for determining the basic wind speeds for non-permanent structures. This section in the UFC supersedes that IBC section.

2-4.7 Section 1613 - EARTHQUAKE LOADS.

1613.1 – Scope [Supplement]

For all structures, wherever ASCE 7-22 Table 12.2-1 is referenced, it must be replaced by Table 3-1 of this UFC.

[C] 1613.1 – Scope [Supplement]

Although Chapter 14 of ASCE 7-22 is not adopted by the 2024 IBC, occasional references to ASCE 7-22 Chapter 14 sections are made in this UFC.

1613.1.1 - Seismic Ground Motion Values [Replacement]

Seismic multi-period response spectra at DoD installations within the United States and its territories and possessions must be determined using the ASCE Hazard Tool hosted at

https://ascehazardtool.org

At locations where the seismic parameters are not provided by the ASCE Hazard Tool, consult the AHJ.

1613.1.1.1 - Specific Locations Outside of the United States [Addition]

Seismic ground motion parameters at specific locations outside of the United States and its territories and possessions can be identified using a load spreadsheet posted for download on the Whole Building Design Guide Structural Engineering UFC page (UFC 3-301-01)

For locations not shown, contract the Structural Criteria Working Group member for your service branch.

1613.1.1.2 – Site Specific Seismicity Study Process [Addition]

The site-specific ground motion procedures in Chapter 21 of ASCE 7 may be used to determine ground motions for any structure.

1613.1.1.3 – Ground Motion Parameters for Non-Permanent Structures [Addition]

For Non-permanent Structures, as defined in UFC 1-201-01, it is permissible to use the BSE-1E level response spectra obtained from the ASCE Hazard Tool, which correspond to a seismic hazard of 20% probability of exceedance in 50 years. The link to ASCE Hazard Tool is provided below:

https://ascehazardtool.org

The rest of the seismic design, including determination of Seismic Design Category, is to be performed as required by the IBC and ASCE 7 and as modified by this UFC, based on these reduced ground motion values.

This section supersedes Section 3-2.1.6 of UFC 1-201-01 and IBC Section 3103.6.1.4.

[C] 1613.2.1.4 – Ground Motion Parameters for Non-Permanent Structures [Addition]

For the purpose of determining design seismic loads for non-permanent structures with design life of 5 years or less, UFC 1-201-01, 4 March 2022, Change 4, 8 August 2023, permits application of a 0.6 reduction factor to the design seismic loads determined in accordance with UFC 3-301-01 for regular structures. In addition, that allowance is restricted to regions of low seismicity only. This [Addition] revises that provision based on a “uniform hazard” approach that applies to all locations, and that is more consistent with the way all seismic requirements are specified for regular structures.

Ground motion spectral response values that form the basis of seismic design of regular structures (50-yr design life) in this UFC correspond to a seismic hazard of 2% probability of exceedance in 50 years. In other words, it is deemed adequate to design a structure for a seismic hazard that has a 2% probability of exceedance in the structure’s design life. The same criterion could be applied to non-permanent structures as well where it should be adequate to design the structure for a reduced seismic hazard of 2% probability of exceedance in 5 years. In 50-yr term, a 2%-in-5-yr hazard translates to a 20%-in-50-yr hazard.

This [Addition] also allows the use of the same reduced hazard ground motion parameters for the purpose of all seismic design requirements, including determination of Seismic Design Category, for non-permanent structures. As a result, the adoption of a reduced hazard not only reduces the seismic forces, but also leads to less stringent seismic design and detailing requirements for non-permanent structures.

Note that in ASCE 7-10 a switch was made from uniform hazard MCE ground motion to risk-targeted MCE_R ground motion as the basis of design. However, the magnitudes of the two at a particular location are not sufficiently different to warrant a change in the recommendation to use of 20%-in-50-yr ground motion for non-permanent structures.

For a more detailed discussion on this change, please refer to the report produced by S. K. Ghosh Associates LLC titled “An Evaluation of the Wind and Seismic Provisions of UFC 1-201-01 for Temporary Structures”.

The 2024 IBC has introduced a new Section 3103.6.1.4 for determining the ground motion values for non-permanent structures. This section in the UFC supersedes that IBC section.

1613.4 – Ballasted Photovoltaic Panel Systems [Replacement]

Ballasted photovoltaic panel systems are not permitted.

[C] 1613.4 – Ballasted Photovoltaic Panel Systems [Replacement]

Ballasted systems are specifically disallowed by UFC 3-110-03, *Roofing*.

1613.7 - Procedure for Determining MCE_R and Design Spectral Response Accelerations [Addition]

Ground motion accelerations, represented by response spectra, must be determined in accordance with the procedure of ASCE 7-22 Sections 11.4.2-11.4.6, as modified by Chapter 3 of this UFC, or the site-specific procedure required by ASCE 7-22 Section 11.4.8 as modified by Section 3-5.3 of this UFC.

Subject to approval by the AHJ, a site-specific response analysis using the procedure of ASCE 7-22 Chapter 21 may be used in determining ground motions for any structure. Such analysis needs to include justification for its use in lieu of the ground motion data provided by ASCE 7.

A site response analysis using the procedures of ASCE 7 Section 21.1 must be used for structures on sites classified as Site Class F (see ASCE 7 Section 20.2.1), unless at least one of the following conditions is applicable:

1. The structure is exempted from site response analysis requirement in accordance with ASCE 7 Section 20.2.1.

2. The Risk-Targeted Maximum Considered Earthquake (MCE_R) spectral response acceleration at short periods, S_s, and the mapped MCE_R spectral response acceleration at 1-second period, S_1, as determined in accordance with UFC 3-301-01, are less than or equal to 0.25 and 0.10, respectively.

S_s and S_1 must be determined for installations within the United States from Section1613.1.1, added by this UFC. For installations located outside the United

States, S_s and S_1 must be determined from Section 1613.1.1.1, added by this UFC.

2-4.8 Section 1615 – TSUNAMI LOADS.

1615.1 – General [Replacement]

The design and construction of buildings and structures located in a Tsunami Design Zone, as defined by the Tsunami Design Geodatabase or by DoD tsunami mapping for at risk OCONUS installations, must be in accordance with Chapter 6 of ASCE 7, as modified by Section 3-3 of this UFC.

For at risk Pacific and Pacific Rim OCONUS installations, see the following link to access tsunami inundation and flow maps:

https://www.wbdg.org/dod/ufc/tsunami-inundation-mapping

Maps are formatted as KMZ files, which can be downloaded and opened with Google Earth, ARCGIS, or an equivalent KMZ compatible geo map application.

2-4.9 Section 1616 – STRUCTURAL INTEGRITY [Deletion].

Delete this section in its entirety.

2-5 IBC CHAPTER 17 - SPECIAL INSPECTIONS AND TESTS.

2-5.1 Section 1701 – GENERAL.

1701.1 - Scope [Supplement]

Add the following paragraph:

Contractual relationships and the composition of the architect / engineer / construction (AEC) team differ from those contemplated by the language of the IBC, when doing DoD construction. When performing design or construction using typical methods for in-house design, AE design, and contracting for construction, IBC/ASCE 7 terms of Authority Having Jurisdiction and Building Official must be as defined in MIL STD 3007

Unless noted otherwise, apply the following substitutions for implementing the IBC:

- “Building official” - defined as “Authority Having Jurisdiction” as referenced in MIL STD 3007).
- “Owner” - defined as “Authority Having Jurisdiction”
- “Permit applicant” - defined as “contractor”

[C] 1701.1 - Scope [Supplement]

The context of the IBC terms “permit”, “permit application”, “permit applicant”, and “owner” must be modified for DoD projects. DoD functions as the building department/jurisdiction and the AHJ functions as the building official. When DoD advertises a project, the building permit is effectively implied/granted. However, the overall project may still require other permits related to site storm water, air quality, demolition disposal, etc.

2-5.2 Section 1703 – APPROVALS.

1703.4 - Performance [Replacement]

New, unusual, or innovative materials, systems or methods previously untried may be incorporated into designs when evidence shows that such use is in the best interest of the Government from the standpoint of economy, lower life-cycle costs, and quality of construction. Supporting data, where necessary to assist in the approval of materials or assemblies not specifically provided for in the code, must consist of valid evaluation reports from International Code Council – Evaluation Service (ICC-ES), or other qualified testing and evaluation service with the prior approval of the AHJ.

1703.4.1 - Research and Investigation [Deletion]

Delete this section in its entirety.

1703.4.2 - Research Reports [Deletion]

Delete this section in its entirety.

2-5.3 Section 1704 – SPECIAL INSPECTIONS AND TESTS, CONTRACTOR RESPONSIBILITY, AND STRUCTURAL OBSERVATIONS.

1704.2.3 Statement of special inspections. [Replacement]

Replace the first paragraph with the following:

The SER must submit a Statement of Special Inspections in accordance with Section 107.1. This statement must be in accordance with Section 1704.3. A template ‘Statement of Special Inspections’ and a template ‘Schedule of Special Inspections’ may be downloaded from the Structural Engineering UFC (3-301-01) page on the Whole Building Design Guide.

1704.6 – Structural Observations [Replacement]

Replace the first two sentences with the following:

Where required by the provisions of Section 1704.6.1, structural observations must be performed by the SER or their designated representative who must be a Registered Design Professional. Structural observation does not include or waive the responsibility for the inspections in Section 110 or the special inspections in Section 1705 or other sections of this code.

1704.6.1 – Structural Observations for Structures [Replacement]

Replace Item 1 with the following:

1 - The structure is classified as Risk Category III or IV in accordance with Table 2-2 of this UFC.

Replace Item 4 with the following:

4 – Such observation is required by the SER.

1704.7 – Special Inspector of Record [Addition]

When the provisions of Section 1704.6.1 apply, the services of a Special Inspector of Record (SIOR) must be retained by the Contractor as a third-party quality assurance agent (see UFC 1-200-01). The SIOR must be a licensed professional engineer in a state acceptable to the AHJ. The SIOR must submit qualifications to, and be approved by, the AHJ.

1704.7.1 – Duties of the Special Inspector of Record (SIOR) [Addition]

The duties of the SIOR are defined in the following UFGS specification:

Section 01 45 35

1704.7.2 – Final Inspection Report [Addition]

When the work requiring Special Inspections is completed and all nonconforming items are resolved to the satisfaction of the SER, the Contractor needs to notify the SIOR to submit a Final Special Inspection Report to the Contracting Officer, the SER, and the Contractor. The Final Special Inspection Report must attest that Special Inspection was performed on all work requiring Special Inspection and that all nonconforming work and corrections of all discrepancies noted in the daily reports was resolved to the satisfaction of the SER and the Contracting Officer. The Final Special Inspection Report must be signed, dated, and must bear the seal of the SIOR.

2-5.4 Section 1705 – REQUIRED SPECIAL INSPECTIONS AND TESTS.

1705.3.3 – Adhesive Anchors [Addition]

The SER is required to determine the proof load (see ACI 318-19 Section 26.7.1(k)) to be used for field-testing and to indicate in the construction documents which anchors are considered critical for testing.

1705.13.6 – Plumbing, Mechanical and Electrical Components [Supplement]

Add the following before the existing text:

Special inspection and verification are required for Designated Seismic Systems and must be performed as required by the Statement of Special Inspections, and the Schedule of Special Inspections, which must be prepared for each project. Templates for these documents may be downloaded from the Structural Engineering UFC (3-301-01) page on the Whole Building Design Guide.

The SER must prepare a Statement of Special Inspections in accordance with Section 1704 for the Designated Seismic Systems. The Statement of Special Inspections must define the periodic walk-down inspections that must be performed to ensure that the nonstructural elements satisfy life safety mounting requirements. The walk-down inspections must be performed by design professionals who are familiar with the construction and installation of mechanical and electrical components, and their vulnerabilities to earthquakes. The selection of the design professional is subject to the approval of the SER.

Designated Seismic Systems require a final walk-down inspection by the SER. The final review must be documented in a report. The final report prepared by the SER must include the following:

1. Record/observations of final site visit
2. Documentation that all required inspections were performed in accordance with the Statement of Special Inspections.
3. Documentation that the Designated Seismic Systems were installed in accordance with the construction documents and inspected in accordance with the requirements of Chapter 17, as modified by this section.

2-6 IBC CHAPTER 18 - SOILS AND FOUNDATIONS.

2-6.1 Section 1808 – FOUNDATIONS.

1808.4 - Vibratory Loads. [Supplement]

Add the following to the end of the paragraph:

Design foundations in accordance with ACI 351.3R or ACI 351.4R, as applicable, and UFC 3-220-01.

1808.8.2.1 – Reinforcement. [Addition]

For footings over three feet (914 mm) thick, the minimum ratio of reinforcement area to gross concrete area in each direction must be 0.0015, with not less than one-half nor more than two-thirds of the total reinforcement required placed near any one face. Use a bar size no smaller than No. 4 (#13M) with a maximum spacing of 12 inches (305 mm). [See 13.3.4.4 of ACI CODE-318-19].

2-6.2 Section 1809 - SHALLOW FOUNDATIONS.

1809.5.2 - Frost Line Depth. [Addition]

Frost line depth for foundation construction must be specified by the project geotechnical engineer.

1809.5.3 – Footing Depth Considering Frost. [Addition]

Frost line depth for foundation construction must be specified by the project geotechnical engineer.

2-7 IBC CHAPTER 19 – CONCRETE.

2-7.1 Section 1901 – GENERAL.

1901.8 - Construction Joints [Addition]

Provide construction, contraction, and expansion joints in structures in accordance with ACI 224.3R and ACI CODE-318-19, Section 26.5.6.

1901.9 – Lightweight Concrete Water Content [Addition]

All coarse lightweight aggregate used in a concrete mixture must be saturated surface dry prior to mixing. The total allowable water in the concrete mixture must account for the water in the aggregate and admixtures. The water-to-cementitious materials ratio must not exceed 0.50.

1901.10 – Glass Fiber Reinforced Polymer (GFRP) Reinforcement [Addition]

Design and construct structural concrete which utilizes glass fiber reinforced polymer (GFRP) reinforcement in accordance with ACI CODE-440.11-22, *Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer (GFRP) Bars--Code and Commentary*. The use of GFRP reinforcement is preferred where corrosion is a durability concern. GFRP does not corrode making it an economical solution for the structures that require regular repair due to exposure to salts and seawater. GFRP is also 1/4 of the weight of steel reinforcement, making it easier to transport, handle, and place.

GFRP reinforcement has limitations to consider before useing Fire ratings for GFRP in structures are not standardized and are low. For this reason, GFRP reinforcement is:

- Not permitted in structures that have a fire rating above zero. Also not permitted in structures that may not have a fire rating but could collapse due to fire and threaten life safety (for example, GFRP reinforcing not allowed for upper deck of double-deck piers, and comparable structures similarly affected by heat zones).

- Allowed for use in architectural precast concrete; however, all connections must use steel.

Other limitations on the use of GFRP according to ACI CODE-440.11-22:

- Do not use in seismic force-resisting systems of structures assigned to Seismic Design Categories B, C, D, E, and F.

- GFRP is permitted in structural members not part of the seismic force-resisting systems of structures assigned to Seismic Design Categories A, B, and C.

- Not recommended for lightweight concrete due to insufficient research data.

- Prestressed concrete systems are not currently covered.

The limitations on seismic force-resisting systems are because GFRP reinforcement is elastic until failure. The current seismic force-resisting systems are designed to yield in certain regions to dissipate the energy generated by seismic excitation. GFRP reinforcement will be permitted if the reinforcement is designed to remain fully elastic.

Appendix G provides guidance in the design and construction of GFRP in concrete structures.

2-7.2 Section 1903 – SPECIFICATIONS FOR TESTS AND MATERIALS.

1903.4 – Additively Constructed Concrete (3D Printed Concrete) [Addition]

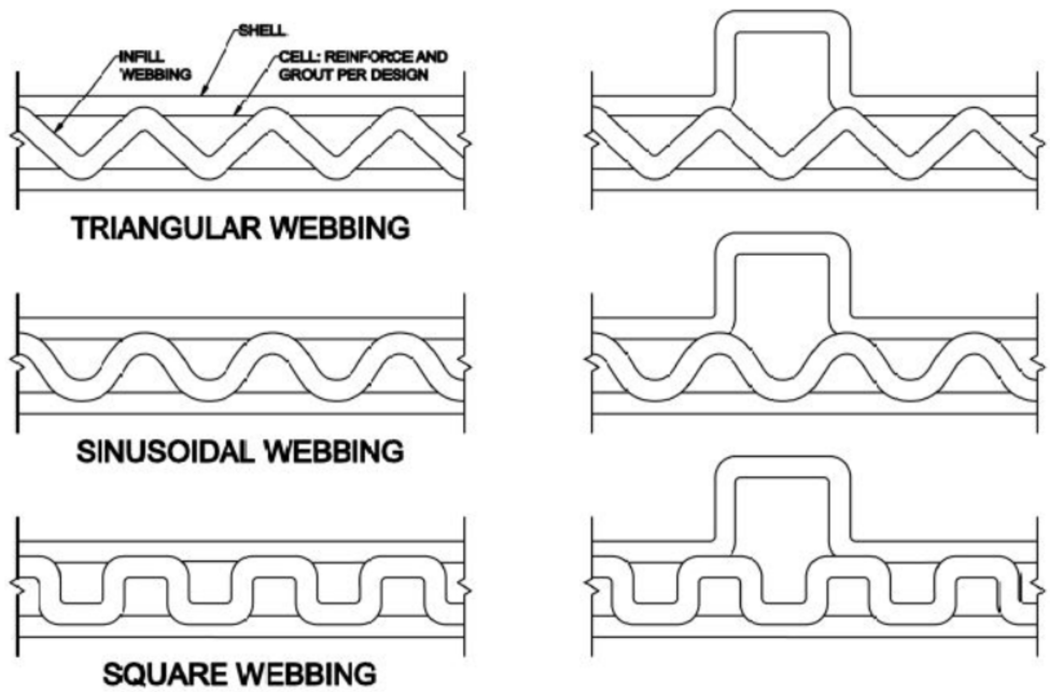
Pursuant to UFC 1-200-01 Section 104.11, concrete produced using additive construction, hereafter referred to as Additively Constructed Concrete (ACC), is allowed as alternative material, design and method of construction when complying with the following requirements and when approved in writing by the

AHJ.

ACC structures are limited to one-story, Risk Category I or II structures in Seismic Design Categories A and B only. Additionally, the following general requirements or limitations apply:

- Unreinforced concrete construction is not allowed
- ACC elements are not allowed as part of the Lateral Force-resisting System (LRFS) in Seismic Design Category B unless LFRS assemblies have been shake table tested with relevant loading or wind loads can be demonstrated to govern over seismic loads using an *R*-factor of 1.0.
- Provide a full description of concrete mixes, including how mixes will differ from region to region as applicable. Include admixtures in description, where utilized.
- Provide a narrative description of Quality Assurance and Quality Control procedures for concrete placement, including hot and cold weather placement constraints for ACC elements. if applicable
- Maintain minimum cover over reinforcement per ACI 318. Cover shall not consist of printed materials unless demonstrated through testing that ACI 318 development length requirements can be met using applicable load factors.
- Cast-in-place or post-installed anchors must not depend on printed material for shear or tensile strength unless site tested to 150% of design load.
- Diaphragm to wall connections must be shown by calculation or testing to resist in plane and out of plane forces with applicable load factors. Anchorage may not be solely dependent on printed shell material.
- Provide complete design drawings, including connection detailing sufficient to adequately depict continuous vertical and lateral load path to foundation.
- Provide mathematical demand and capacity calculations based on ACI 318 for all applicable ASCE 7 loads and affected elements. Calculations must demonstrate a complete vertical and lateral load path and may not rely on printed shell elements to resist loads except for pure compression. Alternatively, webbing may be employed with shell elements as indicated in the Figure 2-1, but only with third-party load testing validation of composite assemblies for all relevant loading. Load capacity values must be published as part of a third-party testing report and tested assemblies must be applicable to constructed assemblies.

Figure 2-1 Webbing in Shell Elements



- Design must be peer reviewed by the government a minimum of 90 days prior to construction start and will include review by subject matter experts at United States Army Corps of Engineers (USACE) Construction Engineering Research Laboratory (CERL). All comments and concerns must be resolved to the government's satisfaction.

Allowable ACC Elements and Limitations

- ACC is limited to reinforced walls no taller than ten feet, reinforced embedded wall pilasters and non-participating stay-in-place formwork for simple reinforced continuous wall footings.
- Suspended elements, including but not limited to beams, girders, or floor and roof diaphragm elements are not approved for ACC.
- ACC wall elements must consist of two printed concrete face shells acting as stay-in-place forms with a minimum interior core width of four inches and a maximum core width of twelve inches. Provide print stabilizers spanning between face shells to occur at no greater than twelve inches on center horizontally and six inches on center vertically. Provide corner stabilizers spanning from interior wall corners to exterior face shell in both directions (e.g., either side of interior corner). Larger print stabilizer spacing requires print-stability testing.
- Embedded pilasters must consist of printed shells and interior monolithic,

reinforced, cast-in-place concrete cores that are six to eight inches by six to eight inches. Larger sections require print-stability testing.

- Wall cavities adjacent to pilasters that are without webbing or monolithic cast-in-place concrete shall not be permitted unless this portion is considered to be non-structural.

Third Party Independent Testing Requirements

ACC structures must conform to the requirements noted in this section and ICC AC509 - *3D Automated Construction Technology for 3D Concrete Walls*. If AC 509 is in conflict, this UFC supersedes. Compliance to this section must be demonstrated by obtaining an ICC ES evaluation report (or equivalent) that conforms to both ICC-AC509 and the following modifications to ICC-AC509

ICC AC509 4.2.1 [Replacement] Cast specimens for compressive testing shall be tested in accordance with ASTM C31 for monolithically cast portions of wall. Cast specimens following ASTM C31 or ASTM C109 shall be permitted for printable material mixture development only. Prior to construction, conduct compressive strength testing in accordance with ASTM C109 with specimens extracted by saw cutting in accordance with ASTM C42 and prepared to meet planeness requirements according to ASTM C109. Specimens shall capture at least one interface and shall be tested for compression in the directions parallel to print direction, perpendicular to print direction, and transverse to print direction.

ICC AC509 4.2.2 [Replacement] Prior to specimen creation, the flow of the printable material shall be tested in accordance with ASTM C230. For materials that exhibit slump prior to entering the printer, the mix may be tested in accordance with ASTM C143 or C1611. Printable materials shall be tested in accordance to ASTM C230 prior to placement and within 5 minutes after leaving the printer.

ICC AC509 4.2.4 [Replacement] Unconfined compression Strength (UCS) Testing: Shall be performed in accordance with ASTM D2166, with cylindrical specimen sizes representative of the bead geometry, where the diameter or height of the specimen must be at least 5 times the maximum particle size. Prior to construction, the UCS shall be performed at 0, 15, 30, 45, 60, 90, and 120 minutes after mixing and the elastic limit at each age shall be determined. This shall be used to report the time to next layer limit based on weight of successive layers expected. Printable materials shall be tested in accordance with this test method prior to placement during printing and within 5 minutes of leaving the printer.

ICC AC509 4.3.3 [Supplement] Freeze-Thaw specimens of printed materials shall be extracted from printed components through saw cutting in accordance with ASTM C666. Specimen sizes shall be as described in ASTM C666 to include specimens with at least 1 interface on each side parallel to the length of the specimen and specimens with at least 3 layers perpendicular to the length of the specimen. For regions where freeze-thaw is not a concern this test may be forgone.

ICC AC509 4.4.1 [Replacement] Perform tests on 3D printed specimens in accordance with ASTM C341. Length change specimens of printed materials shall be extracted from printed components. Specimens shall have at least 1 interface on each side parallel to the length of the specimen. Components that will be in contact with soils with high sulfate content or exposed to salts must be tested according to ASTM C1012.

ICC AC509 4.6.2 [Addition] Tensile bond strength shall be in accordance with ASTM C496 or ASTM C1583. Shear bond strength shall be tested as described below.

4.6.2.1 Tensile bond strength tested in accordance with ASTM C496 shall use prismatic specimens consisting of at least two layers with a single interface loaded along the interface. Specimens shall be tested transverse to the print with the height being equal to a single shell width, and the height being equal to two times a single shell width, and the length being equal to at least 3 times a single shell width.

4.6.2.2 Specimens for direct shear testing shall be loaded in single or double shear using prismatic specimens consisting of at least two layers for single shear and three layers for double shear. Specimens shall have dimensions that are representative of the wall shell dimensions and a length of at least 3 times the shell width. Loading rate shall in accordance to ASTM C496.

4.6.2.3 Specimens for interface testing shall be extracted by saw cutting in accordance with ASTM C42 and prepared to meet planeness requirements in ASTM C109.

ICC AC509 4.8 [Addition] For construction geometries, a print stability test must be performed, which consists of a print mock-up representative of the wall geometry used in construction, to ensure that there are no stability issues prior to construction. Time between layers and construction shall be representative of field conditions. This is permitted to be done as part of the development of structural test samples.

ICC AC509 4.9 [Addition] Dynamic Testing

4.9.1 Testing for blast overpressure, where applicable, must be in accordance with ASTM F2247 or ASTM F2927 for door locations and ASTM F1642 or GSA TS01 for windows locations. Ballistics testing must be in accordance with MIL STD 662.

4.9.2 Wind and seismic testing shall be performed in accordance with

ASTM E2126 procedure for in-plane shear or out-of-plane bending. Where structures must meet seismic categories higher than C, shake table testing shall be performed to meet design requirements.

4.9.3 Impact testing shall be performed in accordance with ASTM E1886 for windborne debris and ASTM E695 for impact loading.

ICC AC509 5.5 [Replacement] Special Inspections shall be performed in accordance with this UFC. Quality control testing shall be performed by obtaining samples cured following ASTM C31 for compression testing and interface testing shall be performed according to Sections 4.2 and 4.6. Fresh material testing shall be performed in accordance with ASTM C31, with testing performed in accordance with Sections 4.2.2 and 4.2.4 in place of the slump test.

5.5.1 Representative components for sample extraction shall be printed at the same time as construction of the printed components to be placed in service. Each representative component shall be large enough to extract samples for compliance with Sections 4.2.1, 4.4.1, and 4.6.2.

5.5.2 Data on printing conditions and process shall be documented and reported to include: start times, print time for each layer, delay times (includes waiting between layers), reasons for delays, times at which delays occurred, and hourly temperature and humidity. If delay occurs in the middle of printing a layer, the time prior to delay and following delay should be recorded, in addition to the delay.

2-7.3 Section 1904 - DURABILITY REQUIREMENTS.

1904.3 – Environmental Severity Classification and Concrete Cover [Addition]

Conform to ACI 357.3R Table 5.5.4 for minimum concrete cover for exterior exposed concrete at project locations with an Environmental Severity Classification (ESC) C3 through C5. See UFC 1-200-01 for determination of ESC for project locations. Exposed concrete is any concrete that is not enclosed within a building envelope. In addition, concrete with a minimum of two coats of exterior grade paint is not considered exposed where properly maintained. Corrosion inhibitor coatings/additives would not qualify as a paint coating. This requirement does not apply to galvanized, stainless or epoxy coated reinforcement. Refer to ACI 318 cover requirements in these cases.

2-7.4 Section 1907 -SLABS-ON-GROUND.

1907.3 – Thickness. [Supplement]

Reference guidance in *“Design of Concrete Floor Slabs-on-Ground for DoD Facilities”* under Related Materials for this UFC (WBDG page for 3-301-01).

1907.5 – Slab-on-Ground Design. [Addition]

Slabs-on-ground supporting warehouses must have minimum reinforcement according to UFC 4-440-01.

1907.6 – Slab-on-Ground Over Permafrost. [Addition]

Design and construction of slabs-on-ground over permafrost must be in accordance with UFC 3-130-01.

1907.7 – Post-Tensioned Slab-on-Ground. [Addition]

The design of post-tensioned slabs-on-ground must be in accordance with PTI DC10.1.

2-8 IBC CHAPTER 21 – MASONRY.

2-8.1 Section 2101 – GENERAL.

Renumber Section 2101.2.1 as 2101.2.6.

2101.2.1 - Allowable Stress Design [Addition]

Masonry must be designed as reinforced unless the element is isolated from the structure so that vertical and lateral forces are not imparted to the element.

2101.2.2 - Strength Design [Addition]

Masonry must be designed as reinforced unless the element is isolated from the structure so that vertical and lateral forces are not imparted to the element.

2101.2.3 - Empirical Design [Addition]

Do not design masonry according to the empirical method.

2101.4 - Shear Wall Construction [Addition]

Shear walls must be of running bond construction only; stack bond construction is not permitted.

2101.5 - Prohibition [Addition]

The following material is not permitted:

> Celersap (common European in place clay tile forming system for concrete floors)

2-8.2 Section 2104 – CONSTRUCTION.

Renumber Sections 2104.1.1 and 2104.1.2 as 2104.1.4 and 2104.1.5, respectively.

2104.1.1 - Placing Mortar and Units [Addition]

Masonry walls below grade and elevator shaft walls must be grouted solid.

2104.1.2 - Installation of Wall Ties [Addition]

Use of corrugated metal brick ties is not permitted.

2104.1.3 - Joint Reinforcement [Addition]

Horizontal wall reinforcement must be continuous around wall corners and through wall intersections, unless the intersecting walls are separated. Reinforcement that is spliced in accordance with the applicable provisions of TMS 402-22 is permitted to be considered continuous.

2104.1.6 - Concrete Masonry Control Joints [Addition]

Spacing and placement of control joints must be in accordance with NCMA TEK 10-2C or 10-3.

2104.1.7 - Vertical Brick Expansion Joints [Addition]

Spacing, placement, and size of vertical brick expansion joints must be in accordance with BIA Technical Notes 18 and 18A.

2-8.3 Section 2106 - SEISMIC DESIGN.

2106.2 - Additional Requirements for Masonry Systems [Addition]

2106.2.1 - Minimum Reinforcement for Special or Intermediate Masonry Walls, SDC B-F [Addition]

In addition to the minimum reinforcement requirements of Sections 7.3.2.5 and 7.3.2.4 of TMS 402-22, the following applies:

> Only horizontal reinforcement that is continuous in the wall or element is permitted to be included in computing the area of horizontal reinforcement. Intermediate bond beam steel properly designed at control joints is permitted be considered continuous.

2106.2.2 - Joints in Structures assigned to SDC B or Higher [Addition]

Where concrete abuts structural masonry and the joint between the materials is not designed as a separation joint, the concrete must be roughened so that the average height of aggregate exposure is 1/8 in. (3 mm) and must be bonded to the masonry in accordance with these requirements as if it were masonry. Vertical joints not intended to act as separation joints are required to be crossed by horizontal reinforcement as required by Section 5.2.3 of TMS 402-22.

2106.2.3 - Coupling Beams in Structures Assigned to SDC D or Higher [Addition]

Structural members that provide coupling between shear walls must be designed to reach their moment or shear nominal strength before either shear wall reaches its moment or shear nominal strength. Analysis of coupled shear walls must comply with accepted principles of mechanics.

The design shear strength, ϕV_n, of the coupling beams is required to satisfy the following criterion:

$$\varphi V_n \geq \frac{1.25\left(M_{n1} + M_{n2}\right)}{L_c} + 1.4V_g$$

Where:

M_{n1} and M_{n2} = nominal moment strengths at the ends of the beam
L_c = length of the beam between the shear walls
V_g = unfactored shear force due to gravity loads

The calculation of the nominal moment strength needs to include the reinforcement in reinforced concrete roof and floor systems. The width of the reinforced concrete slab used for inclusion of reinforcement must be six times the floor or roof slab thickness.

2106.2.4 - Anchoring to Masonry [Addition]

Anchors in masonry must be designed in accordance with TMS 402-22. Additionally, at least one of the following must be satisfied for structures assigned to SDC C or higher.

a. Anchors in tension are designed to be governed by the tensile strength of a ductile steel element.
b. Anchors are designed for the maximum load that can be transmitted to the anchors from a ductile attachment, considering both material overstrength and strain hardening of the attachment.

c. Anchors are designed for the maximum load that can be transmitted to the anchors by a non-yielding attachment.

d. Anchors are designed for the maximum load obtained from design load combinations that include E, where the effect of horizontal ground motion, Q_E, is multiplied by Ω_o.

[C] 2106.2.4 - Anchoring to Masonry [Addition]

This [Addition] harmonizes design of anchors embedded in masonry with that of anchors embedded in concrete. These provisions are intended to prevent brittle failure in the connections. ACI 318-19 Chapter 17 includes similar provisions to prevent brittle failure of anchors embedded in concrete. These requirements are simplified versions of those in ACI 318-19. Note Option a is available only for anchors in tension, and not for anchors in shear. Also, Item d requires that the anchor design forces produced by the horizontal ground motions only (Q_E) be multiplied by the overstrength factor Ω_o. Anchor design forces produced by the vertical earthquake ground motions (E_V) do not need to be amplified.

2-8.4 Section 2109 - EMPIRICAL DESIGN OF ADOBE MASONRY [Deletion].

Delete this section in its entirety.

2-9 IBC CHAPTER 22 – STEEL.

2-9.1 Section 2201 – GENERAL.

2201.4 – Connections [Supplement]

Add the following to the end of the paragraph:

Compressible-washer-type direct tension indicators or twist-off-type tension-control bolts conforming to Research Council on Structural Connections (RCSC) *Specification for Structural Joints Using High-Strength Bolts* must be provided at all high-strength bolted connections.

2-9.2 Section 2202 - STRUCTURAL STEEL AND COMPOSITE STRUCTURAL STEEL AND CONCRETE.

2202.1 – General [Supplement]

Add the following to the end of the paragraph:

Design structural steel floor framing systems for vibration serviceability in accordance with AISC Design Guide 11.

2202.3 – Steel Structures in Corrosive Environments [Addition]

Protect exposed steel in corrosion prone environments with hot- dipped galvanizing or use stainless alloy. See UFC 1-200-01, section 4-1.3 for definition of corrosion prone environments. Coatings may be used alone in other environments. Select the appropriate system or material to suit the anticipated exposure. For exposed exterior steel deck and cold-formed steel members, provide ASTM A653/A653M G90 galvanizing and connect with corrosion-resistant fasteners. See Section A-5.4 of UFC 3-301-01 for additional guidance.

2-9.3 Section 2204 - COLD-FORMED STEEL.

2208.1 – Steel Roof Deck [Supplement]

Add the following to the end of the paragraph:

Steel roof deck is not permitted to be thinner than 22-gauge.

2-9.4 Section 2206 - COLD-FORMED STEEL LIGHT-FRAME CONSTRUCTION.

2206.1.1 - Seismic Requirements for Cold-Formed Steel Structural Systems [Replacement]

Design cold-formed steel light-frame construction to resist seismic forces in accordance with the provisions of Section 2206.1.1.1, and Section 2206.1.1.2 or Section 2206.1.1.3.

Renumber Sections 2206.1.1.1 and 2206.1.1.2 as 2206.1.1.2 and 2206.1.1.3, respectively.

2206.1.1.1 – Diagonal Bracing Material [Addition]

For diagonal bracing, use ASTM A653/A653M steel without rerolling.

[C] 2206.1.1.1 - Diagonal Bracing Material [Addition]

Rerolling induces strain hardening and reduces the elongation of the material and is therefore not desirable for performance under seismic loading.

2206.4 – Floor Vibrations [Addition]

Design cold-formed steel framing systems for vibration serviceability in accordance with the proposed design procedure in *Floor Vibration Design Criterion for Cold-Formed C-Shaped Supported Residential Floor Systems* by Kraus. The proposed design procedure is based on residential construction but is suitable for most applications of cold-formed steel floor construction.

2206.5 – Brick Veneer/Steel Stud Walls [Addition]

Follow the recommendations of BIA Technical Note 28B for the Design of steel stud backup for brick veneer. In particular, follow recommendations for minimum stud gage, minimum galvanization, minimum anchorage of studs to track, welding of studs, use of deflection track, allowable stud deflection, wall sheathing, and water-resistant barriers.

2206.6 – Cold-Formed Steel Connections [Addition]

Interconnect cold-formed steel members with screw fasteners or by welding. The use of pneumatic nailing is permitted only for the connection of cold-formed steel members to members made of other materials.

2206.7 – Galvanized Cold-Formed Framing [Addition]

Cold-formed steel members exposed to spray from salt, salt water, brackish water, or seawater must be galvanized with ASTM A653/A653M G90 galvanizing and all fasteners must be hot-dipped galvanized or made of stainless steel.

2-10 IBC CHAPTER 23 – WOOD.

2-10.1 Section 2308 – CONVENTIONAL LIGHT-FRAME CONSTRUCTION.

2308.2.6 – Risk category limitation [Replacement]

The use of the provisions for *conventional light-frame construction* in this section is not permitted for RC IV buildings assigned to *Seismic Design Category* C, D, E, or F, as determined per 2024 IBC Section 1613.2.

2-11 IBC CHAPTER 31 – SPECIAL CONSTRUCTION.

2-11.1 Section 3102 – MEMBRANE STRUCTURES.

3102.1 – Membrane Structures [Addition]

Structures with fabric envelopes or cladding, including but not limited to frame-supported, air-supported, cable net supported, grid shell supported, and geodesic dome supported are prohibited within windborne debris regions for Risk Categories II-V. Additionally, this prohibition applies where 1700-year-MRI wind speeds (IBC Figure 1609.3(2), ASCE 7 Figure 26.5-1C) equal or exceed wind speeds defining a windborne debris region, namely, 130 mph (58 m/s) within one mile of the coastal mean high-water line or 140 mph (63.6 m/s) anywhere else.

[C] 3102.1 – Membrane Structures [Addition]

Structures with fabric envelopes or cladding are prohibited for use in windborne debris regions due to the fabric's vulnerability to sharp flying debris. While a supporting frame may be designed to remain stable even with the loss of the fabric, risk to life and/or high value content remains. This prohibition is supported by lessons learned during recent hurricane and typhoon events.

Additionally, DoD also prohibits Structures with fabric envelopes or cladding for use in all locations where the 1700-year-MRI wind speed exceeds the threshold wind speed for windborne debris regions. This is because the risk of windborne debris damage is the same in these areas as in areas defined by the IBC as windborne debris regions. This additional requirement slightly expands IBC windborne debris regions.

This Page Intentionally Left Blank

CHAPTER 3 MODIFICATIONS TO ASCE 7

3-1 ASCE 7-22 CHAPTER 1 – GENERAL.

3-1.1 Section 1.3 - BASIC REQUIREMENTS.

1.3.1 – Strength and Stiffness [Supplement]

Add to the end of Item c.: During the design concept stage of development, documentation must be submitted to the AHJ for approval of the performance-based design approach.

1.3.1.3 – Performance-Based Procedures [Replacement]

Structural and nonstructural components and their connections must be demonstrated by a combination of analysis and testing to provide a reliability not less than that expected for similar components designed in accordance with the Strength Procedures of Section 1.3.1.1 when subject to the influence of dead, live, environmental, and other loads. Consideration must be given to uncertainties in loading and resistance.

1.3.1.3.3 – Documentation [Replacement]

Submit reports for approval to the AHJ and to an independent peer reviewer (where required), which document compliance with this section and the results of analysis and testing.

3-1.2 Section 1.5 - CLASSIFICATION OF BUILDINGS AND OTHER STRUCTURES.

Tables 1.5-1 and 1.5-2 [Replacement]

Replace Tables 1.5-1 and 1.5-2 of ASCE 7 with Table 2-2 of this UFC. All references in ASCE 7 to Tables 1.5-1 and 1.5-2 must be interpreted as a reference to Table 2-2 of this UFC. Items that are different from those in 2024 IBC Table 1604.5 are shown in italics.

3-2 ASCE 7-22 CHAPTER 2 – COMBINATIONS OF LOADS.

3-2.1 Section 2.3 - LOAD COMBINATIONS FOR STRENGTH DESIGN.

2.3.4 – Load Combinations Including Self-Straining Forces and Effects [Supplement]

Add to the end of the paragraph: The effect of load T needs to be taken into consideration on a structure. For further information see ASCE 7 Section C2.3.4.

[C] 2.3.4 - Load Combinations Including Self-Straining Forces and Effects [Supplement]

ASCE 7-22 Section 2.3.4 does not provide specific load factors to use with T. Commentary Section C.2.3.4 contains such load factors. The entire text of the commentary should be read and understood before using the load combinations in the commentary. The impact of T on serviceability and long-term performance of the facility may also need to be evaluated.

2.3.6 – Basic Combinations with Seismic Load Effects [Supplement]

Add before EXCEPTION: The following additional load combinations with seismic load effects must be considered for elements of buildings and nonbuilding structures specified in Section 1605.1.2 in Chapter 2 of this UFC. Provisions in the EXCEPTION that apply to combination 6 and 7 also apply to combinations 8 and 9, respectively.

Where the prescribed seismic load effect, E = f(E_v, E_h), defined in ASCE 7 Section 12.4.2 or 12.14.3.1, is combined with the effects of other loads, the following seismic load combinations apply:

8. $1.2D + 1.0E_{v0} + 0.3E_h + L + 0.2S$
9. $0.9D - 1.0E_{v0} + 0.3E_h$

Where the seismic load effect with overstrength, E_m = f(E_v, E_{mh}), defined in ASCE 7 Section 12.4.3, is combined with the effects of other loads, the following seismic load combinations apply:

8. $1.2D + 1.0E_{v0} + 0.3E_{mh} + L + 0.2S$
9. $0.9D - 1.0E_{v0} + 0.3E_{mh}$

The effect of vertical ground motion, E_{v0}, can be determined from one of the following:

- $E_{v0} = 0.67S_{DS}D$
- E_{v0} is determined directly from the design vertical response spectrum given in ASCE 7 Section 11.9.

[C] 2.3.6 – Basic Combinations with Seismic Load Effects [Supplement]

The additional load combinations were derived using the 100+30 rule of combining the effects from orthogonal seismic loads. The code-specified vertical ground motion effect ($0.2S_{DS}D$) can be derived by first assuming peak vertical ground motion component to be $^{2}/_{3}{}^{rd}$ of the corresponding peak horizontal component, and then combining 30% of that ($0.3 \times 0.67 S_{DS} = 0.2 S_{DS}$) with 100% of the horizontal seismic load effects. This section simply adds two more load combinations where 100% of the vertical seismic load effect is combined with 30% of the horizontal seismic load effect.

3-2.2 Section 2.4 – LOAD COMBINATIONS FOR ALLOWABLE STRESS DESIGN.

2.4.4 – Load Combinations Including Self-Straining Forces and Effects [Supplement]

Add to the end of the paragraph: The effect of load *T* needs to be taken into consideration on a structure. For further information, see ASCE 7 Section C2.4.4.

[C] 2.4.4 - Load Combinations Including Self-Straining Forces and Effects [Supplement]

ASCE 7-22 Section 2.4.4 does not provide specific load factors to use with *T*. Commentary Section C.2.4.4 contains such load factors. The entire text of the commentary should be read and understood before using the load combinations in the commentary. The impact of *T* on serviceability and long-term performance of the facility may also need to be evaluated.

2.4.5 – Basic Combinations with Seismic Load Effects [Supplement]

Add before EXCEPTIONS: The following additional load combinations with seismic load effects are to be considered for elements of buildings and nonbuilding structures specified in Section 1605.1.2 in Chapter 2 of this UFC. Provisions in the EXCEPTIONS that apply to combination 8, 9 and 10 also apply to combinations 11, 12 and 13, respectively.

Where the prescribed seismic load effect, $E = f(E_v, E_h)$, defined in ASCE 7 Section 12.4.2 or 12.14.3.1, is combined with the effects of other loads, the following seismic load combinations apply:

11. $1.0D + 0.7E_{v0} + 0.21E_h$
12. $1.0D + 0.525E_{v0} + 0.1575E_h + 0.75L + 0.75S$
13. $0.6D – 0.7E_{v0} + 0.21E_h$

Where the seismic load effect with overstrength, $E_m = f(E_v, E_{mh})$, defined in ASCE 7 Section 12.4.3, is combined with the effects of other loads, the following seismic load combinations apply:

11. $1.0D + 0.7E_{v0} + 0.21E_{mh}$

12. $1.0D + 0.525E_{v0} + 0.1575E_{mh} + 0.75L + 0.75S$

13. $0.6D – 0.7E_{v0} + 0.21E_{mh}$

The effect of vertical ground motion, E_{v0}, can be determined from one of the following:

- $E_{v0} = 0.67S_{DS}D$
- E_{v0} is determined directly from the design vertical response spectrum given in ASCE 7 Section 11.9.

[C] 2.4.5 – Basic Combinations with Seismic Load Effects [Supplement]

See the commentary to Section 2.3.6 above for some background on how the additional load combinations were derived.

3-2.3 Section 2.5 - LOAD COMBINATIONS FOR EXTRAORDINARY EVENTS.

2.5.1 – Applicability [Replacement]

When required, strength and stability must be checked to ensure that structures are capable of resisting the effects of progressive collapse according to UFC 4-023-03.

2.5.2 – Load Combinations [Deletion]

Delete this section in its entirety.

2.5.3 – Stability Requirements [Deletion]

Delete this section in its entirety.

3-3 ASCE 7-22 CHAPTER 6 – TSUNAMI LOADS.

3-3.1 Section 6.5 - ANALYSIS OF DESIGN INUNDATION DEPTH AND FLOW VELOCITY

6.5.3 – Sea Level Change [Supplement]

Subject to approval by the AHJ, a medium 2065 DoD Regional Sea Level Rise (DRSL) target may be utilized for Risk Category IV and V structures in tsunami prone regions when designing for a combination of tsunami and sea level rise. Design must incorporate future construction adaptation to either the High 2065 or Highest 2065 DRSL scenarios according to Table 2-2 for RC IV and V structures. Cost and risk must be considered when selecting adaptive design features. The adaptive design features must be included in the design analysis and in the design drawings and should be labeled, “Not in Contract (NIC)”, to permit future construction as needed with negligible additional design cost or effort. The DRSL database is available at:

https://sealevelscenarios.serdp-estcp.org

3-3.2 Section 6.14 - TSUNAMI VERTICAL EVACUATION REFUGE STRUCTURES

6.14.1 - Minimum Inundation Elevation and Depth [Supplement]

Where a 1.3 factor is required, it is not cumulative to the Tsunami factor in Table 2-2, but rather supplants the tsunami factor in Table 2-2.

3-3.3 Section 6.15 - DESIGNATED NONSTRUCTURAL COMPONENTS AND SYSTEMS

6.15.1 – Performance Requirements [Supplement]

Design mission critical systems according to the requirements of Section 6.15.1. In addition to projected sea level rise (see Table 2-2), mission critical systems must be situated above maximum inundation elevation factored up by 1.3, unless designed directly for tsunami effects and if inundation would not inhibit critical function during and after a tsunami.

3-4 ASCE 7-22 CHAPTER 7 – SNOW LOADS.

3-4.1 Section 7.4 – Sloped Roof Snow Loads, p_s [Supplement].

Add to the end of the paragraph: Where obstructions occur on the roof from equipment such as photovoltaic panels, lightning cable systems, etc., the potential for snow buildup around the obstructions needs to be considered.

3-5 ASCE 7-22 CHAPTER 11 – SEISMIC DESIGN CRITERIA.

3-5.1 Section 11.1 – GENERAL.

11.1.2 – Scope [Supplement]

The design and detailing of the components of the seismic force-resisting system must comply with the applicable provisions of ASCE 7-22 Section 11.7 and ASCE 7-22 Chapter 12, as modified by this UFC, in addition to the nonseismic requirements of the 2024 IBC.

11.1.3 – Applicability [Supplement]

Add the following at the end of the section: Buildings or structures that are not routinely occupied, but whose primary purpose is to support human activities, such as training towers, are not to be classified as non-building structures unless specifically approved by the AHJ.

3-5.2 Section 11.2 – DEFINITIONS.

DESIGNATED SEISMIC SYSTEMS [Replacement]

The designated seismic system of a structure consists of those nonstructural components that require design in accordance with Chapter 13 and for which the component importance factor, I_p, is greater than 1.0. This designation applies to systems that are required to be operational following the design earthquake. Designated seismic systems will be identified by Owner and will have an importance factor, $I_p = 1.5$.

FRAME:

Moment Frame [Replacement]

A frame in which members and joints resist lateral forces by flexure as well as along the axis of the members. Moment frames are categorized as intermediate moment frames (IMF), ordinary moment frames (OMF), and special moment frames (SMF). Every joint must be restrained against rotation.

3-5.3 Section 11.5 - IMPORTANCE FACTOR AND RISK CATEGORY.

11.5.1 - Importance Factor [Replacement]

A seismic importance factor, I_e, must be assigned to each structure in accordance with Table 2-2 of this UFC.

3-6 ASCE 7-22 CHAPTER 12 – SEISMIC DESIGN REQUIREMENTS FOR BUILDING STRUCTURES.

3-6.1 Section 12.2 – STRUCTURAL SYSTEM SELECTION.

12.2.1 - Selection and Limitations [Supplement]

Table 3-1, Replacement for ASCE 7-22 Table 12.2-1, must be used in lieu of ASCE 7-22 Table 12.2-1.

3-6.2 Section 12.6 - ANALYSIS PROCEDURE SELECTION [Supplement].

Add at the end of the section:

For RC IV structures designed using the alternate procedure of Appendix B of this UFC, only nonlinear static or nonlinear response history procedure in accordance with the provisions of Appendix B is permitted.

H. Steel Systems Not Specifically Detailed for Seismic Resistance, Excluding Cantilevered Column Systems	***AISC 360-22, AISI S100, AISI S240, ASCE 8***	3	3	3	NL	NL	NP	NP	NP

FOR SI: 1 foot (ft) = 304.8 mm, 1 pound per square foot (psf) = 0.0479 kN/m²

a. Response modification coefficient, R, for use throughout. Note R reduces forces to a strength level, not an allowable stress level.

b. Where the tabulated value of the overstrength factor, Ω_o, is greater than or equal to 2½, Ω_o is permitted to be reduced by subtracting the value of ½ for structures with flexible diaphragms.

c. Deflection amplification factor, C_d, for use in ***ASCE 7-22*** Sections 12.8.6, 12.8.7, 12.9.1.2, ***12.12.2, 12.12.3, and 12.12.4***.

d. NL= Not limited and NP = Not permitted. For metric units, use ***30*** m for 100 ft and ***50*** m for 160 ft.

e. See ***ASCE 7-22*** Section 12.2.5.4 for a description of seismic force-resisting systems limited to buildings with a structural height, h_n, of 240 feet (***75*** m) or less.

f. See ***ASCE 7-22*** Section 12.2.5.4 for seismic force-resisting systems limited to buildings with a structural height, h_n, of 160 feet (***50*** m) or less.

g. In Section 2.3 of ACI 318-19, a shear wall is defined as a structural wall.

h. In Section 2.3 of ACI 318-19, the definition of "special structural wall" includes precast and cast-in-place construction.

i. An increase in structural height, h_n, to 45 ft (***14*** m) is permitted for single story storage warehouse facilities.

j. Steel ordinary concentrically braced frames ***(OCBFs)*** are permitted in single-story buildings up to a structural height, h_n, of 60 ft (***18*** m) where the dead load of the roof does not exceed 20 psf (***1.0*** kN/m^2) and in penthouse structures.

k. See ***ASCE 7-22*** Section 12.2.5.7 for limitations in structures assigned to Seismic Design Categories D, E, or F.

l. See ***ASCE 7-22*** Section 12.2.5.6 for limitations in structures assigned to Seismic Design Categories D, E, or F.

m. In Section 2.3 of ACI 318-19, the definition of "special moment frame" includes precast and cast-in-place construction.

n. Cold-formed steel – special bolted moment frames must be limited to one-story in height in accordance with ANSI/AISI S400-20.

o. Alternately, the seismic load effect with overstrength, E_{mh}, is permitted to be based on the expected strength determined in accordance with ANSI/AISI S400-20.

p. Ordinary moment frame is permitted to be used in lieu of intermediate moment frame for Seismic Design Category B or C.

q. Structural height, h_n, shall not be less than 60 ft (18.3 m)

r. Ordinary Moment Frames are permitted to be used as part of the structural system that transfers forces between isolator units.

s. ANSI/AISC 341-22 section number.

t. ACI 318-19, Section 18.2.1.6 cites appropriate sections in ACI 318-19.

u. TMS 402-22 section number.

v. 2024 IBC section number.

w. 2021 Special Design Provisions for Wind and Seismic with Commentary (SDPWS) section number.

3-6.3 Section 12.10 - DIAPHRAGMS, CHORDS, AND COLLECTORS.

12.10.2.1 - Collector Elements Requiring Load Combinations with Overstrength Factor for Seismic Design Categories C through F

Item (c) [Replacement]. Forces calculated using the load combinations of Section 2.3.6 without overstrength factor, with seismic forces determined by Eq. (12.10-2).

EXCEPTION [Replacement]:
In structures or portions thereof braced entirely by wood light-frame shear walls, collector elements and their connections, including connections to vertical elements, need only be designed to resist forces using the load combinations of Section 2.3.6 without overstrength factor, with seismic forces determined in accordance with Section 12.10.1.1.

[C] 12.10.2.1 - Collector Elements Requiring Load Combinations with Overstrength Factor for Seismic Design Categories C through F

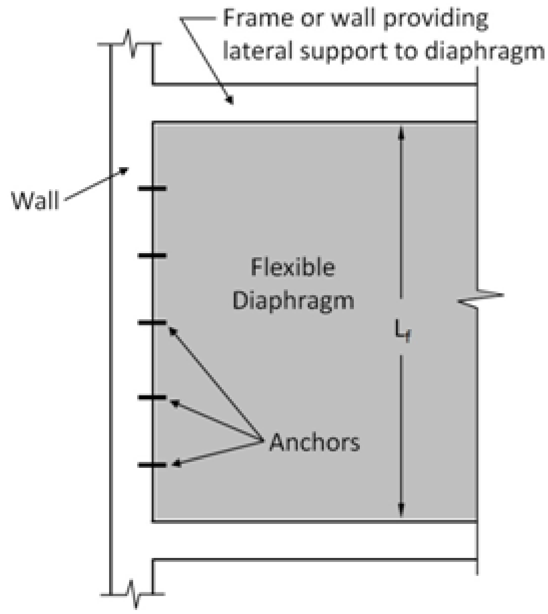
The two [Replacement] added under this section are intended to clarify that the load combinations to be used with these two provisions are the ones that do not include the overstrength factor. The text in ASCE 7-22 simply refers to the load combinations in Section 2.3.6. However, ASCE 7-22 Section 2.3.6 contains two sets of seismic load combinations – regular load combinations involving seismic load effects not amplified by the overstrength factor of the structure, and load combinations where the seismic load effects are amplified by the overstrength factor.

3-6.4 Section 12.11 - STRUCTURAL WALLS AND THEIR ANCHORAGE.

12.11.2.1 - Wall Anchorage Forces [Supplement]

Refer to Figure 3-1 for determination of the span of flexible diaphragm, L_f.

Figure 3-1 Anchorage of Walls to Flexible Diaphragm



3-7 ASCE 7-22 CHAPTER 13 – SEISMIC DESIGN REQUIREMENTS FOR NON-STRUCTURAL COMPONENTS.

3-7.1 Section 13.1 – GENERAL.

13.1.1 - Scope [Supplement]

Add as the last paragraph:

Appendix C of this UFC provides supplementary guidance on architectural, mechanical, and electrical component design requirements. Section C-2 provides guidance on architectural component design, including interior and exterior wall elements. Section C-3 provides guidance on electrical and mechanical systems design. To the extent that is practicable, subsections of Appendix C reference relevant sections of ASCE 7-22.

3-7.2 Section 13.2 - GENERAL DESIGN REQUIREMENTS.

13.2.3 - Special Certification Requirements for Designated Seismic Systems [Supplement]

Appendix D of this UFC provides verification and certification guidance.

When shake table testing is performed, the Required Response Spectra (RRS) must be either derived using ICC-ES AC156 or developed from a study based on site-specific in-structure response time history. In the case of the latter, the RRS for each axis must be generated from the time histories defined in Section 2-15.2

of UFC 3-301-02, and be peak broadened by 15%. The in-structure response spectra per Section 2-17.4.4 of UFC 3-301-02 must be used to determine demand if the Nonstructural Component is not supported at grade.

Testing must be performed in accordance with nationally recognized testing procedures such as:

1. The requirements of the International Code Council Evaluations Service (ICC-ES), *Acceptance Criteria for Seismic Qualification by Shake-Table Testing of Nonstructural Components*, ICC-ES AC156, November 2020.

2. The *CERL Equipment Fragility and Protection Procedure (CEFAPP)*, USACERL Technical Report 97/58, Wilcoski, J., Gambill, J.B., and Smith, S.J., March 1997. The test motions, test plan, and results of this method require peer review.

3. For power substation equipment only, Institute of Electrical and Electronics Engineers (IEEE), *Recommended Practices for Seismic Design of Substations*, IEEE 693-2018.

Shake table tests must include triaxial motion components that result in the largest response spectral amplitudes at the natural frequencies of the equipment for each of the three axes of motion. The Test Response Spectrum (TRS) test motions, demand RRS, test plan, and test results must be reviewed independently by a team of Registered Design Professionals. The design professionals must have documented experience in the appropriate disciplines, seismic analysis, and seismic testing. The independent review must include, but need not be limited to, the following:

1. Review of site-specific seismic criteria, including the development of site-specific spectra and ground motion histories, and all other project-specific criteria;

2. Review of seismic designs and analyses for both the equipment and all supporting systems, including the generation of in-structure motions;

3. Review of all testing requirements and results; and,

4. Review of all equipment quality control, quality assurance, maintenance, and inspection requirements.

13.2.3.1 - Component Certification and Operations & Maintenance (O&M) Manual [Addition]

For any electrical or mechanical component required by ASCE 7-22 Section 13.2.3 to be certified, evidence demonstrating compliance with the requirement must be maintained in a file identified as “Equipment Seismic Certification Documentation.” This file must be a part of the Operations & Maintenance (O&M)

Manual that is turned over to the AHJ. The project specifications must require the O&M Manual to state that replaced or modified components need to be certified per the original certification criteria.

13.2.3.2 - Component Identification Nameplate [Addition]

Any electrical or mechanical component required by ASCE 7-22 Section 13.2.3 to be certified is required to bear permanent marking or nameplates constructed of a durable heat- and water-resistant material. Nameplates must be mechanically attached to such nonstructural components and placed on each component for clear identification. The nameplate cannot be less than 5 in. x 7 in. with red letters 1 in. in height on a white background, stating “Certified Equipment.” The following statement is required to be on the nameplate: “This equipment/component is seismically certified. Modification or replacement must be approved in advance by a qualified professional engineer and documented in the “Equipment Seismic Certification Documentation” file within the O&M manuals. The nameplate needs to also contain the component identification number in accordance with the drawings/specifications and the O&M manuals.

3-7.3 Section 13.3 - SEISMIC DEMANDS ON NONSTRUCTURAL COMPONENTS.

13.3.2 - Seismic Relative Displacements [Supplement]

Egress stairways and ramps must be detailed in accordance with ASCE 7-22 Section 13.5.10.

3-7.4 Section 13.4 - NONSTRUCTURAL COMPONENT ANCHORAGE AND ATTACHMENT.

13.4.2.2 - Anchors in Masonry [Replacement]

Anchors in masonry must be designed in accordance with TMS 402-22. Additionally, at least one of the following must be satisfied in structures assigned to SDC C or higher.

a. Anchors in tension are designed to be governed by the tensile strength of a ductile steel element.

b. Anchors are designed for the maximum load that can be transmitted to the anchors from a ductile attachment, considering both material overstrength and strain hardening of the attachment.

c. Anchors are designed for the maximum load that can be transmitted to the anchors by a non-yielding attachment.

d. Anchors are designed for the maximum load obtained from design load combinations that include *E*, where the effect of horizontal ground motion, Q_E, is multiplied by Ω_{op} as given in ASCE 7-22 Tables 13.5-1 and 13.6-1.

[C] 13.4.2.2 - Anchors in Masonry [Replacement]

This [Replacement] harmonizes design of anchors embedded in concrete and masonry. ASCE 7-22 Section 13.4.2.2 includes provisions to prevent brittle failure of anchors in masonry attaching nonstructural components. This [Replacement] simply makes the requirements consistent with those of ACI 318-19. Note Option a is available only for anchors in tension, and not for those in shear. This [Replacement] also exempts anchors in SDC A and B structures from these ductility/overstrength requirements, which is consistent with what is required for anchors in concrete.

13.4.2.3 - Post-Installed Anchors in Concrete and Masonry [Replacement]

In structures assigned to SDC C or higher, post-installed mechanical anchors in concrete are required to be prequalified for seismic applications in accordance with ACI 355.2 or other approved qualification procedures. Post-installed adhesive anchors in concrete in structures assigned to SDC C, D, E, or F are required to be prequalified for seismic applications in accordance with ACI 355.4 or other approved qualification procedures. In structures assigned to SDC C or higher, post-installed anchors in masonry are required to be prequalified for seismic applications in accordance with approved qualification procedures.

[C] 13.4.2.3 - Post-Installed Anchors in Concrete and Masonry [Replacement]

This [Replacement] specifies that ACI 355.2 is for prequalification of post-installed mechanical anchors only and adds a reference to ACI 355.4 for prequalification of post-installed adhesive anchors, which is not referenced in ASCE 7-22.

3-7.5 Section 13.5 - ARCHITECTURAL COMPONENTS.

13.5.6 - Suspended Ceilings [Supplement]

For buildings assigned to RC IV, suspended ceilings must be designed to resist seismic effects using a rigid bracing system, where the braces are capable of resisting tension and compression forces, or diagonal splay wires, where the wires are installed taut. Particular attention should be paid in walk-down inspections (see Section 1705.13.6 in Chapter 2 of this UFC) to ensure splay wires are taut. Positive attachment must be provided to prevent vertical movement of ceiling elements. Vertical support elements need to be capable of resisting both compressive and tensile forces. Vertical supports and braces designed for compression must have a slenderness ratio, Kl/r, of less than 200. Additional guidance on suspended ceiling design is provided in Section C-2.2.8 of this UFC.

13.5.7 – Access Floors [Supplement]

Installed access floor components that have importance factors, I_p, greater than 1.0 must meet the requirements of Special Access Floors (ASCE 7-22 Section 13.5.7.2). Note: Equipment that requires certification (see Section 13.2.3 in this UFC) needs to account for the motion amplification that occurs because of any supporting access flooring.

3-7.6 Section 13.6 - MECHANICAL AND ELECTRICAL COMPONENTS.

13.6.1 - General [Supplement]

Stacks attached to or supported by buildings must be designed to meet the force and displacement provisions of ASCE 7-22 Sections 13.3.1 and 13.3.2. They must further be designed in accordance with the requirements of ASCE 7-22 Chapter 15 and the special requirements of ASCE 7-22 Section 15.6.2. Guidance on stack design may be found in Section C-3.2.

13.6.2 - Mechanical Components [Supplement]

Guidance on the design of piping supports and attachments is found in Section C-3.1.3 of this UFC.

13.6.3 - Electrical Components [Supplement]

Guidance on the design of electrical equipment supports, attachments, and certification is found in Appendices C and D of this UFC.

13.6.4 - Component Support [Supplement]

For buildings that are assigned to RC IV, guidance on the design of lighting fixtures is found in Section C-3.4 of this UFC.

13.6.11.3 - Seismic Controls for Elevators [Supplement]

For buildings that are assigned to RC IV or to SDC E or F, the trigger level for seismic switches must be set to 50% of the acceleration of gravity along both orthogonal horizontal axes. Elevator systems (equipment, supports, etc.) in RC IV or SDC E or F buildings will have an I_p = 1.5 and must be designed to ensure elevator operability at accelerations below 50% of the acceleration of gravity along both orthogonal horizontal axes. Additional guidance on the design of elevator systems is found in Section C-3.3 of this UFC.

[C] 13.6.11.3 - Seismic Switches [Supplement]

Note that the 0.50*g* is consistent with Article 3137, *Seismic Requirements for Elevators, Escalators and Moving Walks*, Subchapter 6, Elevator Safety Orders, California Code of Regulations, Title 8 (https://www.dir.ca.gov/title8/3137.html).

13.6.12 - Rooftop Solar Panels [Deletion]

Delete the exception to this section in its entirety.

[C] 13.6.12 - Rooftop Solar Panels [Deletion]

The exception addresses ballasted solar panels without positive direct attachment to the roof structure. Ballasted systems are specifically disallowed by UFC 3-110-03, *Roofing*.

13.6.14 - Bridges, Cranes, and Monorails [Addition]

Structural supports for those crane systems that are located in buildings and other structures assigned to SDC C with I_p greater than 1.0, or assigned to SDC D, E, or F, must be designed to meet the force and displacement provisions of ASCE 7-22 Section 13.3. Seismic forces, F_p, must be calculated using C_{AR}/R_{po} = 1, except that crane rail connections must be designed for the forces resulting from C_{AR}/R_{po} = 1.15 in all directions. When designing for forces in either horizontal direction, the weight of crane components, W_p, need not include any live loads, lifted loads, or loads from crane components below the bottom of the crane cable. If the crane is not in a locked position, the lateral force parallel to the crane rails can be limited by the friction forces that can be applied through the brake wheels to the rails. In this case, the full rated live load of the crane plus the weight of the crane must be used to determine the gravity load that is carried by each wheel. Guidance on the design of these systems is found in Section C-3.5 of this UFC.

[C] 13.6.14 - Bridges, Cranes, and Monorails [Addition]

The parameters a_p and R_p are not used in ASCE 7-22. However, there is no direct correspondence between these and the new parameters in ASCE 7-22: the Component Resonance Ductility Factor, C_{AR}, and the Component Strength Factor, R_{po}. The ratio C_{AR}/R_{po} = 1.0 preserves the previous a_p/R_p = 1.0.

Since crane rail connections are not listed in Table 13.6-1, R_{po} for those connections is taken as 1.3 which is the lowest R_{po} value in the entire Table 13.6-1. Cranes and Monorails fall under Other mechanical components and are assigned an R_{po} of 1.5. Thus, C_{AR}/R_{po} ratio is raised by a factor of 1.5/1.3 = 1.15.

13.6.14.1 - Bridges, Cranes, and Monorails for RC IV Buildings [Addition]

In addition to the requirements of Section 13.6.14 of this UFC, for bridges, cranes, and monorails for all RC IV buildings, vertical earthquake-induced motions corresponding to the MCE_R event must be considered. When a site-specific vertical spectrum is not used, the vertical response spectrum may be developed following the provisions of ASCE 7-22 Section 11.9.2.

3-8 ASCE 7 CHAPTER 15 – SEISMIC DESIGN REQUIREMENTS FOR NONBUILDING STRUCTURES.

3-8.1 Section 15.4 - STRUCTURAL DESIGN REQUIREMENTS.

15.4.5 – Drift Limit [Replacement]

Nonbuilding structures similar to buildings are required to comply with lateral drift limitations specified for buildings in ASCE 7-22 Chapter 12.

EXCEPTION: The drift limitations of ASCE 7-22 Section 12.12.1 need not apply to nonbuilding structures if a rational analysis acceptable to the AHJ indicates they can be exceeded without adversely affecting structural stability of attached or interconnected components and elements such as walkways and piping. *P*-delta effects need to be considered where critical to the function or stability of the structure.

15.4.9.2 - Anchors in Masonry [Replacement]

Anchors in masonry must be designed in accordance with TMS 402-22. Additionally, for non-building structures assigned to SDC C, D, E, or F, at least one of the following must be satisfied.

a. Anchors in tension are designed to be governed by the tensile strength of a ductile steel element.

b. Anchors are designed for the maximum load that can be transmitted to the anchors from a ductile attachment, considering both material overstrength and strain hardening of the attachment.

c. Anchors are designed for the maximum load that can be transmitted to the anchors by a non-yielding attachment.

d. Anchors are designed for the maximum load obtained from design load combinations that include E, where the effect of horizontal ground motion, Q_E, is multiplied by Ω_o as given in ASCE 7-22 Tables 13.5-1 and 13.6-1.

[C] 15.4.9.2 - Anchors in Masonry [Replacement]

This [Replacement] harmonizes design of anchors embedded in concrete and masonry. ASCE 7-22 Section 15.4.9.2 includes provisions to prevent brittle failure of anchors in masonry in nonbuilding structures. This [Replacement] simply makes the requirements consistent with those of ACI 318-19. Note Option ‘a’ is available only for anchors in tension, not shear.

15.4.9.3 - Post-Installed Anchors in Concrete and Masonry [Replacement]

Post-installed mechanical anchors in concrete in non-building structures assigned to SDC C, D, E, or F are required to be prequalified for seismic applications in accordance with ACI 355.2 or other approved qualification procedures. Post-installed adhesive anchors in concrete in non-building structures assigned to SDC C, D, E, or F are required to be prequalified for seismic applications in accordance with ACI 355.4 or other approved qualification procedures. Post-installed anchors in masonry non-building structures assigned to SDC C, D, E, or F are required to be prequalified for seismic applications in accordance with approved qualification procedures.

[C] 15.4.9.3 - Post-Installed Anchors in Concrete and Masonry [Replacement]

This [Replacement] specifies that ACI 355.2 is for prequalification of post-installed mechanical anchors only and adds a reference to ACI 355.4 for prequalification of post-installed adhesive anchors, which is not referenced in ASCE 7-22.

3-8.2 Section 15.5 - NONBUILDING STRUCTURES SIMILAR TO BUILDINGS.

15.5.6.1 - General [Supplement]

UFC 4-152-01, *Design: Piers and Wharves*, governs the seismic design of piers and wharves for the DoD.

15.5.6.2 - Design Basis [Deletion]

Delete this section in its entirety.

3-8.3 Section 15.7 - TANKS AND VESSELS.

15.7.5 – Anchorage

Item (c) [Replacement]

Post-installed anchors are permitted to be used in accordance with Section 15.4.9.3 of this UFC, provided the anchor embedment into the concrete is sufficient to develop the steel strength of the anchor rod in tension.

15.7.11.7 – Supports and Attachments for Boilers and Pressure Vessels

Item (b) [Replacement]

Anchorage must be in accordance with Chapter 17 of ACI 318. Post-installed anchors are permitted to be used in accordance with Section 15.4.9.3 of this UFC, provided the anchor embedment into the concrete is sufficient to develop the steel strength of the anchor rod in tension. For anchors in tension, where the special seismic provisions of ACI 318 Section 17.10.5.2 apply, the requirements of ACI 318 Section 17.10.5.3(a) must be satisfied.

3-9 ASCE 7 CHAPTER 26 – WIND LOADS: GENERAL REQUIREMENTS.

3-9.1 Section 26.12 - ENCLOSURE CLASSIFICATION.

26.12.1 - General. [Supplement]
Design all fire station garage bays as partially enclosed structures, with the assumption that garage bay doors have failed. The remainder of the fire station, if isolated from garage bay internal pressure, may be designed according to standard code provisions.

[C] 26.12.1 - General [Supplement]

Damage experienced during Hurricane Michael in 2018 included multiple instances of roof diaphragm loss due to exterior roll-up and sectional door failures, including a fire station where bay doors failed, followed by a total loss of roof diaphragm.

This Page Intentionally Left Blank

CHAPTER 4 EVALUATION AND RETROFIT OF EXISTING BUILDINGS

4-1 GENERAL.

For evaluation and retrofit of existing buildings, the provisions of this chapter apply to all matters governing the *repair*, *alteration*, change of occupancy, acquisition, *addition*, and relocation. For seismic evaluation and retrofit, the following document is hereby adopted:

> ICSSC RP 10, *Standards of Seismic Safety for Existing Federally Owned and Leased Buildings*, cited herein as RP 10, is applicable to all existing DoD owned and leased buildings at all locations worldwide.

For nonseismic evaluation and retrofit of existing buildings relating to all matters governing the *repair*, *alteration*, change of occupancy, acquisition, *addition*, and relocation, the following document is hereby adopted:

> International Code Council, *2024 International Existing Building Codes*, cited herein as IEBC.

Modifications are made to specific sections of RP 10 as well as IEBC. It is expected that designers may highlight or otherwise mark those paragraphs of RP 10, and IEBC that are modified by this chapter. The required RP 10, and IEBC section modifications are one of three actions, according to the following legend:

> **[Addition] –** New section added, includes new section number not shown in RP 10 or the 2024 IEBC.
>
> **[Replacement] –** Delete referenced RP 10 or 2024 IEBC section and replace it with the provisions shown.
>
> **[Supplement] –** Add provisions shown as a supplement to the provisions shown in the referenced section of RP 10 or the 2024 IEBC.

[C] 4-1 General

RP 10, *Standards of Seismic Safety for Existing Federally Owned and Leased Buildings*, gives exemptions, triggers, scope, and criteria applicable to repair, alteration, change of occupancy, acquisition, addition to and relocation of existing buildings. RP 10 uses the national standard ASCE 41-17 as the source of its criteria for seismic evaluation and retrofit.

This Chapter clarifies certain terms used in RP 10 and the application of RP 10 to various risk categories. RP 10's exemptions and benchmarking provisions are also modified by this chapter.

The IEBC, *International Existing Building Code*, establishes minimum requirements for existing buildings using prescriptive and performance-related provisions. It is founded on broad-based principles intended to encourage the use and reuse of existing buildings while requiring reasonable updates and improvements.

This Chapter contains modifications to the 2024 IEBC including the scope, and the prescriptive compliance method for nonseismic evaluation of existing buildings.

4-2 MODIFICATIONS TO RP 10.

Apply the following modifications to RP 10.

4-2.1 Circumstances Initiating Evaluation and Mitigation (Triggers).

RP10 Section 1.0 [Supplement]. Wherever RP10 cites 2021 IBC and 2021 IEBC, the corresponding section or provision of 2024 IBC and 2024 IEBC is to be used instead. Wherever RP10 cites ASCE 7-16, the corresponding section or provision of ASCE 7-22 is to be used instead.

RP 10 Section 1.2.1 Item c [Replacement]. An *addition*, *alteration*, or *repair* to a building assigned to Seismic Design Category (SDC) C, where the project construction cost is more than 50 percent of the current pre-construction replacement cost of the building (not including tenant supplied operational service equipment and fit-outs or seismic mitigation efforts).

RP 10 Section 1.2.1 Item d [Replacement]. An *addition*, *alteration*, or *repair* to a building assigned to Seismic Design Category (SDC) D, E or F, where the project construction cost is more than 30 percent of the current pre-construction replacement cost of the building (not including tenant supplied operational service equipment and fit-outs or seismic mitigation efforts).

4-2.2 Performance Objectives for Evaluation and Retrofit using ASCE 41-17.

RP 10 Section 2.0 [Supplement]. Tables 4-1(a) and 4-1(b) of this chapter must be used for structural and nonstructural components, respectively, in lieu of RP 10 Tables 2-1, 2-2, and 2-3 for determining the required performance objectives for evaluation and retrofit based on the risk category of building and the circumstance that triggered the requirement for evaluation and retrofit. At the AHJ's discretion, the nonstructural scope may be waived in areas of the building not affected by the project and not affecting DoD operations, safety, or post-earthquake occupancy.

[C] RP 10 Section 2.0 [Supplement]. Tables 4-1(a) and 4-1(b) do not revise the requirements contained in RP 10 Tables 2-1, 2-2 and 2-3, but are meant to present the same requirements with more clarity. One exception is Item i in Table 4-1(a), Unacceptable Risk Exposure (URE) trigger, where RP 10 does not provide any clear evaluation criteria but leaves it to the discretion of each agency to decide which buildings they choose to assign to the URE designation. However, NIST wanted agencies to be more proactive about retrofitting at least their URMs and similar buildings. Thus, Item i in Table 4-1(a) was developed with a focus on URMs. A fairly low threshold of Collapse Prevention in BSE-1E is used for the evaluation of these buildings in all risk categories, because these buildings are not expected to pass any higher evaluation threshold. The retrofit requirements are the same as those for other project types that require basic performance objective for existing buildings (BPOE). If attaining the retrofit performance objectives becomes a challenge for URM buildings in higher risk categories, an effective solution would be to relocate the activities housed in those buildings.

RP10 Section 2.1 [Supplement]. For definition of enhanced performance objective greater than that specified in Table 2-1 in RP10, refer to ASCE 41-17 Section 2.2.2.

Seismic multi-period response spectra for BSE-1E, BSE-2E, BSE-1N, and BSE-2N earthquakes at DoD installations within the United States and its territories and possessions can be determined using the ASCE Hazard Tool (https://ascehazardtool.org/).

For locations not included in the ASCE Hazard Tool, consult the AHJ.

[C] RP10 Section 2.1 [Supplement]. RP 10 references four seismic hazard levels – BSE-2N (2% probability of exceedance in 50 years), BSE-1N ($^2/_3$ of BSE-2N), BSE-2E (5% probability of exceedance in 50 years) and BSE-1E (20% probability of exceedance in 50 years). The ASCE Hazard Tool (https://ascehazardtool.org/) provides seismic multi-period response spectra for all four hazard levels for any location within the conterminous United States.

Table 4-1(a) Structural Performance Objectives[1,2]

Trigger	Trigger Description	Risk Category I or II		Risk Category III		Risk Category IV

[1] CP = Collapse Prevention; LmS = Limited Safety; LS = Life Safety; DC = Damage Control; IO = Immediate Occupancy

[2] See [C] RP10 Section 2.1 [Supplement] of this UFC for definitions of BSE-1E, BSE-2E, BSE-1N, and BSE-2N

[3] At the AHJ's discretion, Tier 3 evaluation at BSE-1 hazard level may also be required, for performance levels required for corresponding retrofit.

[4] For Risk Category III, Tier 1 screening or Tier 2 evaluation at the Limited Safety level are to use the Tier 1 checklists and Tier 2 procedures for Collapse Prevention performance, but M_s-factors and other quantitative limits are to be taken as the average of Life Safety and Collapse Prevention values.

[5] For Risk Category IV, Tier 1 screening or Tier 2 evaluation at the Life Safety level are to use the Tier 1 checklists and Tier 2 procedures for Collapse Prevention performance, but M_s-factors and other quantitative limits are to be taken as Life Safety values.

[1] LS = Life Safety; PR = Position Retention; OP = Operational; HR = Hazard Reduced

[2] See [C] RP10 Section 2.1 [Supplement] of his UFC for definitions of BSE-1E, BSE-2E, BSE-1N, and BSE-2N

[3] If initial evaluation indicates that damage to nonstructural components would pose an unacceptable risk exposure to the occupants or to the agency's mission, the agency may supplement the initial scope with evaluation considering the 'LS' performance level at the BSE-2E or BSE-2N seismic hazard level

[4] For buildings assigned to Risk Category I or II, a nonstructural component need only be evaluated for the 'LS' performance level if evaluation for the 'PR' performance level would, in the judgment of the federal agency, disproportionately affect project feasibility.

4-2.3 Exemptions and Benchmark Buildings.

4-2.3.1 Exemptions.

Where applied to projects involving change of occupancy, exemptions in RP 10 Section 1.3 based on occupancy or use apply to the new or intended occupancy.

RP 10 Section 1.3, Item e [Replacement]. Risk Category I or II building structures intended for incidental human occupancy not exceeding two persons per 100 ft^2 of space for a total of less than 2 hours a day.

4-2.3.2 Benchmark Buildings.

RP 10 Section 1.4 [Supplement]. Where the Benchmark Building provisions of ASCE 41-17 apply, Table 4-2 of this chapter is to replace ASCE 41-17 Table 3-2, Benchmark Building Codes and Standards for Life Safety Structural Performance at BSE-1E and Table 3-3, Benchmark Building Codes and Standards for Immediate Occupancy Structural Performance at BSE-1E.

4-3 ADDITIONAL REQUIREMENTS.

4-3.1 Combined Projects.

Alteration work performed in conjunction with an addition project must comply with the provisions for alteration projects. Repair work performed in conjunction with an addition project must comply with the provisions for repair projects.

[C] 4-3.1 Combined Projects

In general, RP 10 makes provisions based on the intended project type. This added section addresses cases where multiple project types, one of which is an addition, are undertaken. The provision is primarily a pointer to the requirements in this chapter.

4-3.2 Existing Structural Elements Carrying Lateral Load.

Where an addition is structurally independent of the existing structure, existing seismic force-resisting structural elements are permitted to remain unaltered. Where the addition is not structurally independent of the existing structure, the existing structure and its *addition* acting together as a single structure must be shown to meet the requirements of 2024 IBC Sections 1609 and 1613. For the purposes of this section, compliance with ASCE 41-17, using a Tier 3 procedure and the retrofit performance objective given in Table 4-1(a) of this chapter is to be deemed to meet the requirements of Section 1613.

Exception**:** Any existing seismic force-resisting structural element whose demand-capacity ratio with the addition considered is no more than 10 percent greater than its demand-capacity ratio with the addition ignored is permitted to remain unaltered provided the addition neither creates new structural irregularities, as defined in ASCE 7-22 Section 12.3.2, nor makes existing structural irregularities more severe. For purposes of calculating demand-capacity ratios, the demand must consider applicable load combinations that include wind or earthquake load effects. For purposes of this exception, comparisons of demand-capacity ratios and calculation of design lateral loads, forces and capacities must account for the cumulative effects of additions and alterations since original construction.

4-3.2.1 Alterations

If no alterations are made to an existing structure that receives a new structurally independent addition, then seismic evaluation of the existing structure is not required. If alterations are made to an existing structure that receives a new structurally independent addition, the requirements of RP 10 must be met for the existing structure.

4-3.2.2 Repairs

If no repairs are made to an existing structure that receives a new structurally independent addition, then seismic evaluation of the existing structure is not required. If repairs are made to an existing structure that receives a new structurally independent addition, the requirements of RP 10 must be met for the existing structure.

[LS] Only buildings designed and constructed or evaluated in accordance with these documents and being evaluated to the Life-Safety Performance Level may be considered Benchmark Buildings.

[IO] Buildings designed and constructed or evaluated in accordance with these documents and being evaluated to the Immediate Occupancy Performance Level may be considered Benchmark Buildings.

NBM - No benchmark year; buildings need to be evaluated.

NP – Not Permitted. Tri-Services guidance does not permit the use of URM.

[1] Building Type refers to one of the Common Building Types defined in ***ASCE 41-17*** Table 3-1.

[2] Buildings on hillside sites must not be considered Benchmark Buildings.

[3] For buildings in areas of Very Low Seismicity, the benchmark provisions are to be limited to the IBC, FEMA 310/ASCE 31, and FEMA 356/ASCE 41.

[4] Life Safety Structural Performance Level for the seismic hazard as defined by those provisions.

[5] Immediate Occupancy Structural Performance Level for the seismic hazard as defined by those provisions.

[6] Life Safety Structural Performance Level for BSE-1 seismic hazard as defined by those provisions.

[7] Immediate Occupancy Structural Performance Level for BSE-1 seismic hazard as defined by those provisions.

[8] The Tri-Services Criteria Benchmark Year provisions apply only to the structural aspects of the evaluation; older retrofits designed using Tri-Services Criteria need to be evaluated for compliance with the new standards. Nonstructural and foundation elements are required to have a minimum Tier 1 evaluation, in accordance with ASCE 41-17, except under the following circumstances:

a. ***The building was designed and constructed in accordance with TI 809-04 or later Tri-Services criteria; or,***

b. ***The building was evaluated in accordance with TI 809-05 or later Tri-Services criteria, and the building evaluation and rehabilitation included structural, nonstructural, geotechnical, and foundation measures.***

[9] Steel moment-resisting frames and eccentrically braced frames with links adjacent to columns must comply with the 1994 UBC Emergency Provisions, published September/October 1994, or subsequent requirements.

[10] Pre-engineered metal buildings designed in accordance with 1992 criteria using ASCE 7 loading may be considered as Benchmark Buildings for Life Safety Performance Objective, only if all other applicable restrictions are met. Pre-engineered metal buildings designed in accordance with 1998 criteria, including TI 809-30, Metal Building Systems, may be considered as Benchmark Buildings for both the Life Safety and Immediate Occupancy Performance Objectives, only if all other applicable restrictions are met.

[11] Cold-formed steel shear walls with wood structural panels only.

[12] Flat slab concrete moment frames must not be considered Benchmark Buildings.

[13] ***This benchmark year is based in the initial publication of TI 809-07, Design of Cold-Formed Load-Bearing Steel System and Masonry Veneer Steel Stud Walls, 1998.***

NBC – Building Code Officials and Code Administrators International (BOCA), *National Building Code*, 1993.

SBC – Southern Building Code Congress International (SBCC), *Standard Building Code*, 1994.

UBC – International Conference of Building Officials (ICBO), *Uniform Building Code*, ***year as shown in table***.

1982 – TM 5-809-10; NAVFAC P-355; AFM 88-3, Ch 13, Seismic Design for Buildings, 1982.

1986 – TM 5-809-10-1; NAVFAC P-355.1; AFM 88-3, Ch 13, Sec A, Seismic Design Guidelines for Essential Buildings, 1986.

1988 – TM 5-809-10-2; NAVFAC P-355.2; AFM 88-3, Ch 13, Sec B, Seismic Design Guidelines for Upgrading Existing Buildings, 1988.

1992 – TM 5-809-10; NAVFAC P-355; AFM 88-3, Ch 13, Seismic Design for Buildings, 1992.

4-4 MODIFICATIONS TO IEBC.

4-4.1 IEBC Part 1 – scope and application.

101.2 – Scope [Supplement]

ASCE 7-22 Chapter 6, Tsunami Loads and Effects, does not apply to Repairs, Alterations, and Changes of Occupancy of Existing Buildings and Other Structures as defined by the 2024 International Existing Building Code (IEBC).

[C] 101.2 - Scope [Supplement]
The IEBC does not currently incorporate Tsunami requirements. Accordingly, this [Supplement] is provided as clarification. This may change with future editions of the IEBC.

4-4.2 IEBC Chapter 5 – prescriptive compliance method.

503.12 – Roof Diaphragms Resisting Wind Loads in High-wind Regions [Replacement]

When a building alteration or repair is performed where the basic wind speed for RC II structures is greater than 130 mph (58 m/s) or where it is a special wind region in accordance with this UFC, roof diaphragms, diaphragm connections to roof framing members, and diaphragm-to-wall connections must be evaluated for wind loads specified in this UFC, provided at least one of the following conditions occurs and this provision has not been invoked in the previous 25 years:

1. The cost of the alteration or repair exceeds 50% of replacement value for the building.
2. Reroofing a Risk Category III or IV building involves removal of more than 50 percent of roofing material.

If the diaphragm and/or diaphragm connections are found incapable of resisting 75 percent of the current UFC design wind loads, they must be replaced or strengthened in accordance with current design wind loads specified in this UFC.

Exception: The following building types are exempt from this requirement:

- Reinforced concrete buildings with concrete diaphragms
- Reinforced concrete masonry unit buildings with concrete diaphragms.
- Detached one- and two-family dwellings
- Multiple single-family dwellings (townhouses) with less than eight attached dwelling units not more than three stories above grade.

- Risk Category I buildings

[C] 503.12 – Roof Diaphragms Resisting Wind Loads in High-wind Regions [Replacement]

High-Wind regions are defined in the 2024 IEBC as areas where the basic wind speed equals or exceeds 130 mph (58 m/s).

4-4.3 IEBC Chapter 7 – alterations - level one.

706.3.2 - Roof Diaphragms Resisting Wind Loads in High-wind Regions [Replacement]

Apply section 503.12 of this UFC.

CHAPTER 5 NONBUILDING STRUCTURES

5-1 HIGHWAY BRIDGE DESIGN.

Design of highway bridges is required to be in accordance with *AASHTO* LRFD Bridge Design Specifications. Design examples are available in the PCI Bridge Design Manual and the following links

- *LRFD Design Examples* (https://www.fhwa.dot.gov/bridge/lrfd/examples.cfm)
- *Reference Manual* (https://www.fhwa.dot.gov/bridge/pubs/nhi15047.pdf)

5-2 RAILROAD BRIDGE DESIGN.

Design of railroad bridges is required to be in accordance with the AREMA Manual for Railway Engineering.

5-3 TANKS FOR LIQUID STORAGE.

Design of tanks for liquid storage is required to be in accordance with NFPA 22, AWWA D100, AWWA D103, AWWA D107, AWWA D115, AWWA D110 and AWWA D120 as applicable.

5-4 TANKS FOR PETROLEUM STORAGE.

Design of tanks for petroleum storage is required to be in accordance with UFC 3-460-01.

5-5 ENVIRONMENTAL ENGINEERING CONCRETE STRUCTURES.

Design of environmental engineering concrete structures is required to be in accordance with ACI CODE-350.

5-6 PRESTRESSED CONCRETE TANKS.

Design of prestressed concrete tanks is required to be in accordance with ACI 372R.

5-7 WATER TREATMENT FACILITIES.

Design of water treatment facilities is required to be in accordance with the Water Environment Federation (WEF) Manual of Practice (MOP) 8.

5-8 TRANSMISSION TOWERS AND POLES.

Design of transmission towers is required to be in accordance with ASCE 10. Design of transmission poles is required to be in accordance with IEEE Standards Association's National Electric Safety Code.

5-9 ANTENNA TOWERS.

Design of antenna towers is required to be in accordance with ANSI/TIA-222-H.

5-10 PEDESTRIAN BRIDGES.

Design of pedestrian bridges is required to be in accordance with the AASHTO LRFD Guide Specifications for Design of Pedestrian Bridges.

CHAPTER 6 MODIFICATIONS TO THE IBC FOR CRITICAL HEALTHCARE FACILITIES

This Chapter adopts some of the modifications made by the 'A' chapters of the 2022 California Building Code for DoD's critical healthcare facilities. The 2022 CBC is based on the 2021 IBC. The 2025 CBC, based on the 2024 IBC, was not available when this Chapter was finalized. So, any reference to IBC in this Chapter is to the 2021 IBC and its referenced standards: ASCE 7-16, ACI 318-19, TMS 402-16, AISC 360-16, and AISC 341-16. This Chapter will need to be updated once the 2025 CBC is published.

6-1 IBC CHAPTER 1 – SCOPE AND ADMINISTRATION.

6-1.1 Section 101 – GENERAL.

101.2 – Scope. [Supplement]

For the seismic design of the facilities listed below assigned to SDC D, E, or F, the modifications to 2021 IBC Chapters 16, 18, 19, 21, and 22 included in this chapter apply in addition to those in Chapter 2 of this UFC. Where the provisions of this chapter and those in the 2021 IBC or in Chapter 2 of this UFC are in conflict, the provisions of this chapter govern.

- Group I-2, Condition 2 occupancies, as defined in 2021 IBC Section 308.3, having emergency surgery or emergency treatment facilities.
- Ambulatory care facilities having emergency surgery or emergency treatment facilities.

6-2 IBC CHAPTER 16 – STRUCTURAL DESIGN.

6-2.1 Section 1603 – CONSTRUCTION DOCUMENTS.

1603.1.5 – Earthquake Design Data. [Supplement]

Add the following three items to the list:

12. Applicable horizontal structural irregularities.
13. Applicable vertical structural irregularities.
14. Location of base as defined in ASCE 7-16 Section 11.2.

6-3 IBC CHAPTER 18 – SOILS AND FOUNDATIONS.

6-3.1 Section 1807 – FOUNDATION WALLS, RETAINING WALLS AND EMBEDDED POSTS AND POLES.

1807.1.1 – Design Lateral Soil Loads. [Replacement]

Foundation walls must be designed for the lateral soil loads determined by a geotechnical investigation, in accordance with Section 1803.

1807.1.3 – Rubble Stone Foundation Walls. [Replacement]

Rubble stone foundation walls are not permitted.

1807.1.4 – Permanent Wood Foundation Systems. [Replacement]

Permanent wood foundation systems are not permitted.

1807.2.2 – Design Lateral Soil Loads [Replacement]

Retaining walls shall be designed for the lateral soil loads determined by a geotechnical investigation in accordance with Section 1803 and shall not be less than eighty percent of the lateral soil loads determined in accordance with Section 1610. For use with the load combinations, lateral soil loads due to gravity loads surcharge shall be considered gravity loads and seismic earth pressure increases due to earthquake shall be considered as seismic loads. For structures assigned to Seismic Design Category D, E, or F, the design of retaining walls supporting more than 6 feet (1829 mm) of backfill height shall incorporate the additional seismic lateral earth pressure in accordance with the geotechnical investigation where required in Section 1803.2.

6-4 IBC CHAPTER 19 – CONCRETE.

6-4.1 Section 1901 – GENERAL.

1901.5 – Construction Documents [Supplement]

Add the following item to the list:

12. Detailing of openings larger than 12 inches (305 mm) in any dimension.

6-4.2 Section 1903 – SPECIFICATIONS FOR TESTS AND MATERIALS.

1903.4 – Flat Wall Insulating Concrete Form (ICF) Systems. [Replacement]

Insulating concrete form material used for forming flat concrete walls shall not be permitted for hospitals or correctional treatment centers; they shall conform to ASTM E2634 for skilled nursing and intermediate care facilities and clinics.

1903.5 – Aggregates – Modify ACI 318 Section 26.4.1.2.1(a).(1) as follows: **[Addition]**

(1) Normal weight aggregate: Aggregate shall be nonreactive as determined by one of the methods in ASTM C33 Appendix XI: Methods for Evaluating Potential

for Deleterious Expansion Due to Alkali Reactivity of an Aggregate. Aggregates deemed to be deleterious or potentially deleterious may be used with the addition of a material that has been shown to prevent harmful expansion in accordance with Appendix XI of ASTM C33, when approved by the Authority Having Jurisdiction.

1903.6 – Limits on Cementitious Materials. [Addition]

For hospitals and correctional treatment centers, modify ACI 318 Section 26.4.2.2(b) as follows:

The maximum percentage of pozzolans, including fly ash and silica fume, and slag cement in concrete assigned to all exposure categories shall be in accordance with Table 26.4.2.2(b) and Section 26.4.2.2(b) Items (1) and (2).

Where pozzolans are used as cementitious materials, duration for minimum specified compressive strength of concrete (f_c') that exceeds 28 days shall be considered an alternative system.

1903.7 – Steel Fiber Reinforcement [Addition]

Steel fiber reinforcement is not permitted.

6-4.3 Section 1905 – MODIFICATIONS TO ACI 318.

Retain Section 1905.1.8, renumbered as 1905.1.4, and replace the other modifications to ACI 318-19 made in the 2021 IBC Section 1905 with the following modifications.

1905.1.1 – ACI 318, Section 9.6.1.3. [ACI 318 Modification]

Modify ACI 318, Section 9.6.1.3 by adding the following:

This section shall not be used for members that resist seismic loads, except for the following condition:

Foundation members designed for seismic load combinations including the overstrength factor in hospitals and correctional treatment centers.

The A_s provided shall not be less than that required by 1.2 times the cracking load based upon f_r defined in Section 19.2.3.

1905.1.2 – ACI 318, Section 11.2.4.1. [ACI 318 Replacement]

Replace ACI 318, Section 11.2.4.1 as follows:

11.2.4.1 – Walls shall be anchored to intersecting elements such as floors or roofs; or to columns, pilasters, buttresses, of intersecting walls and footings with reinforcement at least equivalent to No. 4 bars at 12 inches (305 mm) on center for each layer of reinforcement.

1905.1.3 – ACI 318, Section 12.7.3 [ACI 318 Addition]

Add Section 12.7.3.4 to ACI 318 as follows:

12.7.3.4 - At least two No. 5 bars in diaphragms having two layers of reinforcement in both directions and one No. 5 bar in diaphragms having a single layer of reinforcement in both directions must be provided around openings larger than 12 inches in any dimension in addition to the minimum reinforcement required by Section 12.6. Extend bars beyond the opening sufficient to develop their capacity.

1905.1.5 – ACI 318, Section 18.12.6 [ACI 318 Addition]

Add Section 18.12.6.2 to ACI 318 as follows:

18.12.6.2 – Collector and boundary elements in topping slabs placed over precast floor and roof elements shall not be less than 3 inches (76 mm) or $6d_b$ thick, where d_b is the diameter of the largest reinforcement in the topping slab.

1905.1.6 – ACI 318, Section 26.12.2.1(a). [ACI 318 Replacement]

Replace ACI 318 Section 26.12.2.1(a) by the following:

26.12.2.1(a) Samples for strength tests of each class of concrete placed each day shall be taken not less than once a day, or not less than once for each 50 cubic yards (345 m^3) of concrete, or not less than once for each 2,000 square feet (186 m^2) of surface area for slabs or walls. Additional samples for 7-day compressive strength tests shall be taken for each class of concrete at the beginning of the concrete work or whenever the mix or aggregate is changed.

6-5 IBC CHAPTER 21 – MASONRY.

6-5.1 Section 2101 – GENERAL.

2101.1.1 – Prohibition [Addition]

The following design methods, systems, and materials in TMS 402-16 are not permitted:

1 Unreinforced masonry

2 Autoclaved aerated concrete (AAC) masonry

3 Empirical design of masonry

4 Adobe construction

5 Ordinary reinforced masonry shear walls

6 Intermediate reinforced masonry shear walls

7 Prestressed masonry shear walls

8 Simplified Direct Design procedure for masonry

6-5.2 Section 2106 – SEISMIC DESIGN.

2106.1.1 – TMS 402-16, Sections 5.3.1.4(a) and 5.3.1.4(b) [IBC Addition, TMS Replacement]

Replace TMS 402-16, Sections 5.3.1.4(a) and 5.3.1.4(b) as follows:

a. Ties must be at least 3/8 inch (10 mm) in diameter and must be embedded in grout. Top tie must be within 2 inches (51 mm) of the top of the column or of the bottom of the horizontal bar in the supported beam.

b. The spacing of column ties must be as follows: not greater than 8 bar diameters, 24 tie diameters, or one half the least dimension of the column, or 8 inches (203 mm) for the full column height.

2106.1.2 – TMS 402-16, Chapter 5 [IBC Addition, TMS Addition]

Add TMS 402-16, Section 5.6 as follows:

5.6 – Lateral Support of Members

5.6.1 – Lateral support of masonry may be provided by cross walls, columns, plasters, counterforts or buttresses where spanning horizontally, or by floors, beams, girts or roofs where spanning vertically. Where walls are supported laterally by vertical elements, the stiffness of each vertical element shall exceed that of the tributary area of the wall.

2106.1.3 – TMS 402-16, Sections 7.4.4.1 and 7.4.5.1. [IBC Addition, TMS Replacement, Deletion]

Replace TMS 402-16, Section 7.4.4.1 as follows and delete Section 7.4.5.1:

7.4.4.1 – Minimum Reinforcement Requirements for Masonry Walls.

The total area of reinforcement in reinforced masonry walls must not be less than 0.003 times the sectional area of the wall. Neither the horizontal nor the vertical reinforcement is permitted to be less than one third of the total. Horizontal and vertical reinforcement must be spaced at not more than 24 inches (610 mm) center to center. Where stack bond is used in reinforced hollow-unit masonry, the open-end type of unit shall be used with vertical reinforcement spaced a maximum of 16 inches (406 mm) on center.

7.4.4.1.1 The smallest bar diameter permitted is No. 4, except that No. 3 bars may be used for ties and stirrups. Vertical wall reinforcement needs to have dowels of equal size and equal matched spacing in all footings. Reinforcement must be continuous around wall corners and through intersections. Only reinforcement that is continuous in the wall is permitted in computing the minimum area of reinforcement. Reinforcement with splices conforming to TMS 402-16 can be considered as continuous reinforcement.

7.4.4.1.2 Horizontal reinforcing bars in bond beams must be provided at the top of footings, at the top of wall openings, at roof and floor levels, and at the top of parapet walls. For walls 12 inches (nominal) (305 mm) or more in thickness, horizontal and vertical reinforcement must be equally divided into two layers, except where designed as retaining walls. Where reinforcement is added above the minimum requirements, such additional reinforcement need not be so divided.

7.4.4.1.3 Provide trim bars around openings in reinforced masonry walls of not less than one number 5 bar (or two number 4 bars) for all openings greater than 24 inches (406mm) in any direction. Extend said trim bars 24 inches or 48 bar diameters beyond the corners of the opening, whichever is greater. Trim bars noted in this requirement are in addition to minimum reinforcement elsewhere.

7.4.4.1.4 When reinforcement in bearing walls is designed, placed, and anchored in position as for columns, the allowable stresses must be as for columns.

7.4.4.1.5 Joint reinforcement is not permitted to be used as principal reinforcement in masonry.

6-5.3 Section 2107 - ALLOWABLE STRESS DESIGN.

2107.4 – TMS 402-16, Section 8.3.4.4 Walls [IBC Addition, TMS Supplement]

Modify TMS 402-16, Section 8.3.4.4 as follows by adding:

8.3.4.4.1 The minimum thickness of walls is given in Section 8.3.4.4.2. Stresses must be determined on the basis of the net thickness of the masonry, with consideration for reduction, such as raked joints.

8.3.4.4.2 The thickness of masonry walls must be designed so that allowable maximum stresses specified in Chapter 8 of TMS 402-16 are not exceeded. Also, masonry walls are not permitted to exceed the height or length-to-thickness ratio nor be less than the minimum thickness as specified in Chapter 8 of TMS 402-16 and as set forth in Table 6-1.

8.3.4.4.3 Every pier or wall section with a width less than three times its thickness shall be designed and constructed as required for columns if such pier is a structural member. Every pier or wall section with a width between three and five times its thickness or less than one half the height of adjacent openings shall have all horizontal steel in the form of ties except that in walls 12 inches (305 mm) or less in thickness such steel may be in the form of hairpins.

2107.5 – Masonry Compressive Strength [IBC Addition]

The specified compressive strength of structural masonry must be equal to or exceed 1,500 psi (10.34 MPa). The value of specified compressive strength used to determine nominal strength value in Chapter 8 of TMS 402-16 must not exceed 3,000 psi (20.7 MPa) for concrete masonry and must not exceed 4,500 psi (31.03 MPa) for clay masonry.

6-5.4 Section 2108 – STRENGTH DESIGN OF MASONRY.

2108.4 – TMS 402, Section 9.1.9.1.1.[IBC Addition, TMS Modification]

Modify TMS 402, Section 9.1.9.1.1 as follows:

9.1.9.1.1 – Masonry Compressive Strength. The specified compressive strength of structural masonry must be equal to or exceed 1,500 psi (10.34 MPa). The value of specified compressive strength used to determine nominal strength value in chapter 9 of TMS 402-16 must not exceed 3,000 psi (20.7 MPa) for concrete masonry and must not exceed 4,500 psi (31.03 MPa) for clay masonry.

6-6 IBC CHAPTER 22 – STEEL.

6-6.1 Section 2204 – CONNECTIONS.

2204.1.1 – Restrained Welded Connections. [Addition]

In hospitals and correctional treatment centers, welded structural steel connections having a medium or high level of restraint, as defined by AWS D1.1 Annex H, shall have a minimum pre-heat temperature of not less than 150° F (66° C). Welded structural steel connections with welds to flange, web, wall or plate having a high level of restraint shall maintain a post-heat temperature of 300° F (149° C) for a minimum of 1 hour after completion of welding

2204.4 – Column Base Plate. [Addition]

When shear and/or tensile forces are intended to be transferred between column base plates and anchor bolts, provisions shall be made in the design to eliminate the effects of oversized holes permitted in base plates by AISC 360 by use of shear lugs into the reinforced concrete foundation element and/or welded shear transfer plates or other means acceptable to the Authority Having Jurisdiction, when the oversized holes are larger than the anchor bolt by more than 1/8 inch (3.2 mm). When welded shear transfer plates and shear lugs or other means acceptable to the Authority Having Jurisdiction are not used, the anchor bolts shall be checked for the induced bending stresses in combination with the shear stresses.

6-6.2 Section 2207 – STEEL JOISTS.

2207.6 – Joist Chord Bracing. [Addition]

The chords of all joists shall be laterally supported at all points where the chords change direction.

6-6.3 Section 2210 – COLD-FORMED STEEL.

2210.1.1.2 – Steel Roof Deck [Supplement]

Add the following to the end of the paragraph:

In hospitals and correctional treatment centers, steel roof deck is not permitted to be thinner than 20-gauge.

6-6.4 Section 2211 – COLD-FORMED STEEL LIGHT-FRAMED CONSTRUCTION.

2211.1.2 – Prescriptive Framing [Replacement]

Prescriptive framing systems are not permitted within the seismic force-resisting system of a building.

Table 6-1 Minimum Thickness of Masonry Walls[1,2]

Type of Masonry	Maximum Ratio of Unsupported Height or Length to Thickness[2,3]	Nominal Minimum Thickness (Inches)
Bearing or Shear Walls:		
1. Stone masonry	14	16
2. Reinforced grouted masonry	25	6
3. Reinforced hollow unit masonry	25	6
Nonbearing Walls:		
4. Exterior reinforced walls	30	6
5. Interior reinforced partitions	36	4

1. For varying thickness, use the least thickness when determining the height or length to thickness ratio.
2. In determining the height or length-to-thickness ratio of a cantilevered wall, use a dimension that is twice the dimension of the end of the wall from the lateral support.
3. Cantilevered walls not part of a building and not carrying applied vertical loads need not meet these minimum requirements but their design must comply with stress and overturning requirements.

CHAPTER 7 MODIFICATIONS TO ASCE 7-16 FOR CRITICAL HEALTHCARE FACILITIES

This Chapter adopts some of the modifications made by Section 1617A of the 2022 California Building Code to ASCE 7-16 for DoD's critical healthcare facilities. The 2022 CBC is based on the 2021 IBC. The 2025 CBC, based on the 2024 IBC, was not available when this Chapter was finalized. So, any reference to IBC in this Chapter is to the 2021 IBC and its referenced standards: ASCE 7-16, ACI 318-19, TMS 402-16, AISC 360-16, and AISC 341-16. This Chapter will need to be updated once the 2025 CBC is published.

7-1 ASCE 7-16 CHAPTER 11 – SEISMIC DESIGN CRITERIA.

7-1.1 Section 11.1 – GENERAL.

11.1.2 – Scope [Supplement]

For the facilities listed below and assigned to SDC D, E, or F, the modifications to ASCE 7-16 included in this chapter apply in addition to those in Chapter 3 of this UFC. Where the provisions of this chapter and those in ASCE 7-16 or in Chapter 3 of this UFC are in conflict, the provisions of this chapter govern.

- Group I-2, Condition 2 occupancies, as defined in 2021 IBC Section 308.3, having emergency surgery or emergency treatment facilities.
- Ambulatory care facilities having emergency surgery or emergency treatment facilities.

7-2 ASCE 7-16 CHAPTER 12 – SEISMIC DESIGN REQUIREMENTS FOR BUILDING STRUCTURES.

7-2.1 Section 12.1 – STRUCTURAL DESIGN BASIS.

12.1.7 – Structural Configuration. [Addition]

The following configuration limitations apply to structures within the scope of this chapter.

1. Bay spacing must be essentially equal and uniform throughout.
2. Transfer beams or trusses supporting upper-level columns are not to be used unless permitted on a case by case basis by the AHJ.
3. Seismic joints must be avoided, if at all possible. When required, they need to be specifically identified in the schematic design phase of the project and approved by the AHJ, subject to the following provisions:
   a. Seismic joints must be properly detailed on the working drawings;

b. Seismic joints must be sized based on the maximum expected displacements, considering the effects of story drift, diaphragm displacements and rotations, and a realistic approximation of element section properties. For materials designed considering the ultimate limit state, such as concrete, the stiffness representative of this state must be used. Seismic separations must be at least 125% of the separation required by ASCE 7-16.

4. Adjacent structures that are not integral with an existing structure must be separated by not less than 2 inches per story.

12.1.8 – Limitations on Seismic Force-Resisting Reinforced Concrete Structural Members. [Addition]

Lightweight concrete is not permitted to be used in structural members resisting seismic forces, except in concrete floors and roof slabs used as diaphragms to distribute earthquake forces to vertical seismic force-resisting members.

12.1.9 – Limitations on Seismic Force-Resisting Steel Structural Members. [Addition]

Steel eccentrically braced systems must be subject to the additional limitation that connections of nonstructural components are not to be located in the vicinity of EBF link beams. Such connections include, but are not limited to, precast panel connections, elevator guide rail supports, staircase supports, pipe supports, etc.

7-2.2 Section 12.2 – STRUCTURAL SYSTEM SELECTION.

12.2.1 – Selection and Limitations. [Supplement]

Table 7-1, Replacement for ASCE 7-16 Table 12.2-1, must be used in lieu of ASCE 7-16 Table 12.2-1. Only the structural systems included in Table 7-1 are permitted to be used in structures within the scope of this chapter.

Unless specifically prohibited in Chapter 6 of this UFC, other structural systems that are permitted by ASCE 7-16 for SDC D, E or F, including those employing seismic isolation and seismic damping systems are permitted subject to written approval by the AHJ. Proposals to obtain written approval for other structural systems must demonstrate the equivalent performance of those systems, relative to the permitted systems, considering (a) initial construction and maintenance costs, (b) requirements for bracing nonstructural components and building contents, (c) risk of economic losses and disruption to hospital functions due to earthquakes and (d) other demonstrable benefits.

12.2.3.1 – R, C_d , and Ω_o Values for Vertical Combinations. [Replacement]

Replace ASCE 7, Section 12.2.3.1, Items 1 and 2, by the following:

The value of the response modification coefficient, *R*, used for design at any story shall not exceed the lowest value of *R* that is used in the same direction at any story above that story. Likewise, the deflection amplification factor, C_d , and the system overstrength factor, Ω_o , used for the design at any story shall not be less than the largest value of these factors that are used in the same direction at any story above that story.

12.2.3.2 – Two-Stage Analysis Procedure. [Supplement]

Modify Item a, and add Items f, and g, as follows:

a. The stiffness of the lower portion shall be at least 10 times the stiffness of the upper portion. For purposes of determining this ratio, the base shear shall be computed and distributed vertically according to ASCE 7-16 Section 12.8. Using these forces, the stiffness for each portion shall be computed as the ratio of the base shear for that portion to the elastic displacement, δ_{xe} , computed at the top of that portion, considering the portion fixed at its base. For the lower portion, the applied forces shall include the reactions from the upper portion, modified as required in Item d.

f. Where Horizontal Irregularity Type 4 or Vertical Irregularity Type 4 exists at the transition from the upper to the lower portion, the reactions from the upper portion shall be amplified in accordance with ASCE 7-16 Sections 12.3.3.3, 12.10.1.1 and 12.10.3.3 as applicable, in addition to amplification required by Item d.

g. Where design of members in the upper portion is governed by the seismic load effects with overstrength, as defined in ASCE 7-16 Section 12.4.3, the amplified loads must be considered in the design of the lower portion.

FOR SI: 1 foot (ft) = 304.8 mm, 1 pound per square foot (psf) = 0.0479 kN/m²

a. Response modification coefficient, *R*, for use throughout. Note *R* reduces forces to a strength level, not an allowable stress level.

b. Where the tabulated value of the overstrength factor, Ω_o, is greater than or equal to 2½, Ω_o is permitted to be reduced by subtracting the value of ½ for structures with flexible diaphragms.

c. Deflection amplification factor, C_d, for use in ***ASCE 7*** Sections 12.8.6, 12.8.7, 12.9.1.2, ***12.12.3, and 12.12.4***.

d. NL= Not limited and NP = Not permitted. For metric units, use ***30*** m for 100 ft and ***50*** m for 160 ft.

e. See ***ASCE 7-16*** Section 12.2.5.4 for a description of seismic force-resisting systems limited to buildings with a structural height, h_n, of 240 feet (***75*** m) or less.

f. See ***ASCE 7-16*** Section 12.2.5.4 for seismic force-resisting systems limited to buildings with a structural height, h_n, of 160 feet (***50*** m) or less.

g. In Section 2.3 of ACI 318, a shear wall is defined as a structural wall.

h. In Section 2.3 of ACI 318, the definition of “special structural wall” includes precast and cast-in-place construction.

m. In Section 2.3 of ACI 318, the definition of “special moment frame” includes precast and cast-in-place construction.

r. ANSI/AISC 341-16 section number.

s. ACI 318-19, Section 18.2.1.6 cites appropriate sections in ACI 318-19.

t. TMS 402-16 section number.

u. 2021 IBC section numbers.

v. Permitted only for structures up to two-stories

w. Structural height, h_n, shall not be less than 60 ft (18.3m).

7-2.3 Section 12.3 – DIAPHRAGM FLEXIBILITY, CONFIGURATION IRREGULARITIES, AND REDUNDANCY.

12.3.3.1 – Prohibited Horizontal and Vertical Irregularities for Seismic Design Categories D through F. [Replacement]

Structures having horizontal structural irregularity Type 1b of ASCE 7-16 Table 12.3-1 or vertical structural irregularities Type 1b, 5a or 5b of ASCE 7-16 Table 12.3-2 are not permitted.

7-2.4 Section 12.7 – MODELING CRITERIA.

12.7.3 – Additional Lateral Force [Addition]

Where buildings provide lateral support for walls retaining earth, and the exterior grades on opposite sides of the building differ by more than 6 feet (1829 mm), the seismic increment of earth pressure due to earthquake acting on the higher side, as determined by a geotechnical engineer qualified in soils engineering, plus the difference in earth pressures shall be added to the design lateral forces.

Renumber existing Sections 12.7.3 and 12.7.4 as 12.7.4 and 12.7.5, respectively.

7-2.5 Section 12.12 – DRIFT AND DEFORMATION.

12.12.3 – Structural Separation. [Replacement]

Replace ASCE 7-16 Equation 12.12-1 by the following:

$$\delta_M = C_d \delta_{max} \qquad \text{(Equation 12.12-1)}$$

7-3 ASCE 7-16 CHAPTER 13 – SEISMIC DESIGN REQUIREMENTS FOR NONSTRUCTURAL COMPONENTS.

7-3.1 Section 13.2 – GENERAL DESIGN REQUIREMENTS.

13.2.2 – Special Certification Requirements for Designated Seismic Systems [Supplement]

Special Seismic Certification must be provided in accordance with the requirements of ASCE 7-16 Section 13.2.2, except for equipment and components that are on the HCAI Special Seismic Certification Preapproval (OSP) list, issued by California’s Department of Health Care Access and Information (HCAI).

Items prequalified under the Special Seismic Certification Preapproval (OSP) program of HCAI are deemed to possess Special Seismic Certification required by ASCE 7-16 Section 13.2.2.

[C] 13.2.2 – Special Certification Requirements for Designated Seismic Systems [Supplement]
HCAI has issued a Policy Intent Notice (PIN) 55 on its Special Seismic Certification Preapproval (OSP) program. This program offers a means to obtain prequalification of product lines for special seismic certification. Lists of equipment that is pre-approved by HCAI can be found at https://hcai.ca.gov/facilities/building-safety/preapproval-programs/osp/ and https://hcai.ca.gov/facilities/building-safety/preapproval-programs/osp-by-category/. The basis of HCAI preapproval is always shake table testing in compliance with ICC-ES AC156 and satisfaction of ICC-ES AC156 post-test acceptance criteria.

7-3.2 Section 13.4 – NONSTRUCTURAL COMPONENT ANCHORAGE.

13.4.2.3 – Post-Installed Anchors in Concrete and Masonry [Replacement]

Revise section title to: **Prequalified Post-Installed Anchors and Specialty Inserts in Concrete and masonry.**

Replace text with: Post-installed anchors and specialty inserts in concrete that are prequalified for seismic applications in accordance with ACI 355.2, ACI 355.4, ICC-ES AC193, ICC-ES AC232, ICC-ES AC308 or ICC-ES AC446 are permitted. Post-installed anchors in masonry must be pre-qualified for seismic applications in accordance with ICC-ES AC01, AC58 or AC106.

Use of screw anchors is limited to dry interior conditions. Screw anchors are not permitted for use in building exterior envelopes. Re-use of screw anchors or screw anchor holes is not permitted.

7-3.3 Section 13.5 – ARCHITECTURAL COMPONENTS.

13.5.7 – Access Floors [Supplement]

In hospitals and correctional treatment centers, all access floors must be special access floors in accordance with ASCE 7-16 Section 13.5.7.2, except for raised roof or exterior floor paver systems.

7-3.4 Section 13.6 – MECHANICAL AND ELECTRICAL COMPONENTS.

13.6.11.1.1 – Elevator guide rail support. [Addition]

The design of guide rail support-bracket fastenings and the supporting structural framing must use the weight of the counterweight or maximum weight of the car plus not less than 40 percent of its rated load. The seismic forces must be assumed to be distributed one third to the top guiding members and two thirds to the bottom guiding members of cars and counterweights, unless other substantiating data are provided. In addition to the requirements of ASCE 7-16, Section 13.6.11.1, the minimum ASD-level seismic forces must be 0.5g acting in any horizontal direction.

7-4 ASCE 7-16 CHAPTER 17 – SEISMIC DESIGN REQUIREMENTS FOR SEISMICALLY ISOLATED STRUCTURES.

7-4.1 Section 17.4 – ANALYSIS PROCEDURE SELECTION.

17.4.2.3 – Linear Procedures [Addition]

Linear procedures must not be used in Seismic Design Category E or F structures.

7-5 ASCE 7-16 CHAPTER 18 – SEISMIC DESIGN REQUIREMENTS FOR STRUCTURES WITH DAMPING SYSTEMS.

18.3 – Nonlinear Response History Procedure [Supplement]

Add the following to the Exception:

For this section, the MCE_R response shall be based on the largest response due to a single ground motion and not the average response of a suite of ground motions.

APPENDIX A BEST PRACTICES

A-1 STRUCTURAL DESIGN.

A-1.1 Building Drift Limits.

The topic of serviceability is addressed in IBC Section 1604.3 which requires: “Structural systems and members thereof shall be designed to have adequate stiffness to limit deflections as indicated in Table 1604.3.” Section 1604.3.1 requires: “The deflections of structural members shall not exceed the more restrictive of the limitations of Sections 1604.3.2 through 1604.3.5 or that permitted by Table 1604.3.” Sections 1604.3.2 through 1604.3.5 refer to ACI 318 requirements for concrete, AISC 360, AISI S100, ASCE 8, SJI 100 or SJI 200 requirements for steel, TMS 402 requirements for masonry, and AA ADM requirements for Aluminum. However, the section is obviously focused on structural members, not an entire building or structure.

ASCE 7-22 Section 12.12 requires interstory drift caused by code-prescribed seismic forces to be within tolerable limits as obtained from Table 12.12-1. These are the only mandatory building drift limits of the IBC.

ASCE 7-22 Appendix C, Serviceability Considerations, which is non-mandatory, states in Section C.2.2: “Lateral deflection or drift of structures and deformation of horizontal diaphragms and bracing systems caused by wind effects must not impair the serviceability of the structure.” The extensive commentary on this appendix discusses how the above objective might be accomplished, but leaves it to engineering judgment that should be exercised in consultation with the building owner.

The establishment of acceptable drift limits and load combinations that must be considered in evaluating serviceability does require significant engineering judgment. Application of a requirement that is overly stringent can significantly impact the cost of a structure. Lax requirements, on the other hand, can lead to damage of rigidly connected components.

The *Metal Building Systems Manual* provides guidance on allowable drift due to wind loads for pre-engineered metal buildings, and serviceability recommendations for metal buildings can also be found in Chapter L of AISC 360 with additional guidance in AISC *Steel Design Guide 3*.

When separate support columns are used for top-running cranes, they should be supported so that differential movement between the crane columns and building columns, due to differences in stiffness, does not overstress either set of columns and result in local column buckling.

A-1.2 Impact Resistant Glazing.

Buildings that are subjected to tornado winds can suffer some of the same missile impact damage to the exterior façade of the building as those located in windborne debris regions. The loss of glazing on a building due to missile impact can render the facility inoperable. The loss of glazing will also cause an increase in internal pressure in the building, causing further damage. ASCE 7-22 has added a whole new Chapter 32 on design for tornado loads. Tornado-Prone Region is defined in Section 32.2 as "The area of the conterminous United States most vulnerable to tornadoes, as shown in Figure 32.1-1." Section 32.12.3 is applicable in tornado-prone regions and requires: "Glazed openings shall be protected as specified in this section for Essential Facilities and for buildings and other structures required to maintain the functionality of Essential Facilities." Protection requirements for glazed openings are given in Section 32.12.3.1. Design for tornado loads given in Chapter 32 is not required for RC I or II structures. Consideration should be given to providing impact resistant glazing on facilities that are not covered by Section 32.12.3 in tornado prone areas similar to what is required in wind-borne debris regions as specified in IBC Section 1609.2.

A-1.3 Hard Wall Buildings.

In buildings constructed of load bearing tilt-up or precast structural walls, the loss of the roof diaphragm during a high wind event can lead to total collapse of the structure.

FEMA has issued an important publication, FEMA P-1026, on the seismic design of these buildings. ASCE 7-22 has added Section 12.10.4, based on the FEMA P-1026 document.

A-1.4 Wind and Seismic Loads on Photovoltaic Arrays.

Design provisions for rooftop-mounted photovoltaic panels and their attachments are included in ASCE 7-22 Section 13.6.12 for seismic loading and in ASCE 7-22 Chapters 29 through 31 for wind loading. Additional guidance on the design wind and seismic loads for rooftop-mounted photovoltaic arrays can be found in *Wind Design for Solar Arrays* (SEAOC PV2-2017) and *Structural Seismic Requirements and Commentary for Rooftop Solar Photovoltaic Arrays* (SEAOC PV1-2012), prepared by the Structural Engineers Association of California Solar Photovoltaic Systems Committee. When designing support structures for photovoltaic arrays, review requirements in UFC 3-110-03 *Roofing* concerning roof mounted systems including the requirement that supports be permanently affixed to the structure, which means that ballasted systems are not permitted. 2024 IBC Section 1607.14.4 includes gravity load requirements for roof structures that provide support for photovoltaic panel systems. This section does not disallow ballasted systems. Seismic design of ballasted photovoltaic panel systems is in fact specifically permitted by 2024 IBC Section 1613.3.

A-1.5 Wind Loads on Buildings with Large Openings.

When determining wind loads on building containing large openings such as overhead doors in warehouses, maintenance shops, etc., it is recommended that the criteria for hangars in Section 1609.1.2 of Chapter 2 of this UFC be used.

A-2 SOILS AND FOUNDATIONS.

A-2.1 Gable Bent Footings.

Moment frame reactions from metal building gable bents have horizontal thrusts at column bases which can be resisted by several methods. For large thrust forces (40 to 50 kips (118 kN to 222 kN)), tie rods are usually cost-effective. The tie rods can be embedded in a thickened slab or can be part of a tie beam between column foundations. For smaller thrust forces, hairpin reinforcing bars may be used to transfer the thrust force from the column anchor bolts into the slab-on-ground reinforcement, which acts as the tie between the columns. However, each of these methods requires close attention to detailing of joints in the slab, isolation joints around a foundation pier and other possible interruptions in the continuous slab reinforcement between columns. Also, future renovations that might require trenching across the continuous slab reinforcement could result in the loss of the tension tie. A third method must design the foundation for an overturning moment due to the thrust force at the base of the column. Each of these methods can provide the necessary resistance to the thrust force but needs to be evaluated for each project condition. For further discussion on the design of foundations for gable bent reactions, refer to *Metal Building Systems: Design and Specification* by Alexander Newman.

A-2.2 Footings on Expansive Soils.

In the presence of expansive soils, footings must be designed to withstand expansive soil movement in order to prevent significant damage to structures. Cyclical expansive soil movement from soil water content, usually caused by a combination of inadequate drainage and seasonal wetting and drying cycles, are especially troublesome. Base the design on soil testing and recommendations by qualified geotechnical engineers. Ensure soil investigations include estimates of settlement, heave, and recommendations to mitigate effects of expansive soil movement. Ensure positive drainage away from structures that will prevent ponding close to structures. Guidance on design of foundations on expansive soils can be found in UFC 3-220-01 and PTI DC 10.5-21.

A-2.3 Footing Depth Considering Frost.

Footing depth for frost must be provided by the project geotechnical engineer

A-3 CONCRETE.

A-3.1 Slab-on-Ground Concrete Strength.

Reference guidance in *"Design of Concrete Floor Slabs-on-Ground for DoD Facilities"* under Related Materials for this UFC (WBDG page for 3-301-01).

A-3.2 Slab-on-Ground Joints.

Reference guidance in *"Design of Concrete Floor Slabs-on-Ground for DoD Facilities"* under Related Materials for this UFC (WBDG page for 3-301-01).

A-3.3 Slab-on-Ground Drying Shrinkage.

Reference guidance in "Design of Concrete Floor Slabs-on-Ground for DoD Facilities" under Related Materials for this UFC (WBDG page for 3-301-01).

A-3.4 Slab-on-Ground Vapor Retarder/Barrier.

Reference guidance in "Design of Concrete Floor Slabs-on-Ground for DoD Facilities" under Related Materials for this UFC (WBDG page for 3-301-01).

A-4 MASONRY.

A-4.1 Masonry Veneer Base Detail.

The base of masonry veneer should be placed on a foundation ledge that is lower than the base of the stud wall by at least 4 inches (102 mm). The width of this foundation ledge will include the width of the masonry veneer and the cavity. This width should not be less than two-thirds of the veneer thickness plus the minimum air space.

A-5 STEEL.

A-5.1 Shelf Angles for Masonry.

Shelf angles should be hot-dip galvanized structural steel members. Angles should be provided in segments approximately 10 feet (3 m) in length, with gaps between segments. Shelf angles should be detailed to allow enough gaps for thermal expansion and contraction of the steel in angle runs and at building corners. Corners of buildings should have corner pieces with each leg no less than 4 feet (1.2 m) in length where possible.

Limit deflection of horizontal legs of shelf angles under masonry loading to 1/16 inch (1.6 mm) at the end of the horizontal leg. Rotation of the shelf angle support should be included in the horizontal leg displacement calculation.

A-5.2 Cold-Formed Continuous Beams and Joists.

Guidance on determining the effective length of the unbraced compression flange for cold-formed continuous beams and joists can be found in AISI *Effective Lengths for Laterally Unbraced Compression Flanges of Continuous Beams Near Intermediate Supports*.

A-5.3 Masonry Veneer/Steel Stud Wall Detailing.

Recommended details for masonry veneer/steel stud wall assemblies can be found in BIA Technical Note 28B.

A-5.4 Steel Structures in Corrosive Environments.

Steel structures designed for corrosive environments should include consideration of the following corrosion protection measures:

a. Box-shaped members should be designed so that all inside surfaces may be readily inspected, cleaned, and painted, or should be closed entirely, except when hot-dip galvanized, to prevent exposure to moisture.

b. The legs of two back-to-back angle members, when not in contact, should have a minimum separation of 3/8 inch (9.5 mm) to permit air circulation.

c. Pockets or depressions in horizontal members should have drain holes to prevent water from ponding in low areas. Positive drainage should be provided away from exposed steel. Column bases should be terminated on concrete curbs or piers above grade, and tops of curbs or piers should be pitched to drain.

d. Where extremely corrosive conditions exist, consideration should be given to providing cathodic protection in addition to protective coatings for steel members exposed to saltwater moisture environments.

e. Structural members embedded in concrete and exterior railing, handrails, fences, guardrails, and anchor bolts should be galvanized or constructed of stainless steel.

f. Dissimilar metals, (e.g., aluminum and steel, stainless steel and carbon steel, zinc-coated steel and uncoated steel) should be isolated by appropriate means to avoid the creation of galvanic cells which can occur when dissimilar metals come in contact.

g. Consult a corrosion specialist certified by NACE International to recommend material protection for elements exposed to heavy industrial pollution, chemicals, or corrosive soils.

h. For increased serviceability and compatibility with fireproofing, use galvanized steel deck in accordance with ASTM A653/A653M.

i. Note that some common grades of stainless alloy such as ASTM A306 or A316 are susceptible to corrosion when immersed in salt or brackish water.

Further guidance for designing steel structures in corrosive environments can be found in ASM [formerly, American Society of Metals] *Handbook Volume 13B*.

A-5.5 Steel Structures in Arctic and Antarctic Zones.

For carbon steel, the transition from ductile to brittle behavior occurs within temperatures to be expected in Arctic and Antarctic zones. Ductility is important for structures in high seismic areas. Toughness, a characteristic also affected by cold temperatures, is important for structures which could be subjected to cyclic or impact loads. Design of structures which could be subjected to cyclic or impact loads in cold climates should include consideration of the following measures to mitigate potential fatigue and fracture problems:

a. Provide ample fillets to avoid stress risers.

b. Use bolted joints whenever possible. If welded joints are used, take precautions to eliminate gas and impurities in welds. Proper preheating and post-cooling are essential.

c. Use low-carbon steels and nickel-alloy steels that have good toughness characteristics at low temperatures.

A-5.6 Steel Column Base Plate Shear Transfer.

Shear transfer between column base plates and the concrete foundation elements can be accomplished through several load paths including shear friction between the base plate and grout, anchor rods or shear keys. The design provisions in AISC *Design Guide 1: Base Plate and Anchor Rod Design* should be followed when designing base plates for shear. Research and full-scale testing of base plates in shear, conducted at the University of California, Berkeley, provide further guidance on recommended shear friction coefficient, anchor rod bending length, and concrete capacity design of shear key bearing. Results of the testing can be found in the research report *Shear Transfer in Exposed Column Base Plates*, published by AISC.

A-5.7 Steel Joist Connections.

Connections between open web steel joists and supporting girders or joist girders and building columns are in many instances covered by typical details provided by the joist supplier, which may not provide the needed capacity for lateral or uplift loading. Each joist connection should be designed specifically for the project and take into consideration the lateral and uplift loads acting on the connection.

A-6 WOOD.

A-6.1 Connections.

When using prescriptive guidelines in building codes for nailed wood connections, careful consideration needs to be given to ensuring a complete load path from the roof to the foundation. The use of metal plate connections for roof trusses, top plates and sill plates is an effective way to provide a more robust load path.

APPENDIX B ALTERNATE DESIGN PROCEDURE FOR BUILDINGS AND OTHER STRUCTURES IN RISK CATEGORY IV

B-1 GENERAL.

B-1.1 Overview.

This Appendix may be used for the alternate design of buildings and other structures assigned to RC IV.

Buildings assigned to RC IV are either unit/installation-essential or post-disaster essential (Table 2-2). This Appendix provides an optional nonlinear static and nonlinear dynamic analysis procedure for RC IV buildings and other structures that may be used as an alternative to the procedures found in the 2024 *International Building Code* (2024 IBC). This Appendix references the 2017 edition of ASCE/SEI 41, *Seismic Evaluation and Retrofit of Existing Buildings* (herein-after referred to simply as ASCE 41-17). This procedure may provide more economical or better-performing structural designs compared to linear analysis procedures. The analysis procedures outlined in this Appendix are to be used only with the approval of the Authority Having Jurisdiction.

The nonlinear procedures outlined in this Appendix require that an RC IV building meet two general structural performance objectives:

1. A Life Safety (LS) performance level for the Risk-Targeted Maximum Considered Earthquake (MCE_R) ground motions, nominally an earthquake associated with a 1% probability of structural collapse in 50 years; and,

2. An Immediate Occupancy (IO) performance level for earthquake ground motion that is two-thirds of the MCE_R ground motion. This earthquake is termed herein as the BSE-1N earthquake, adopting the terminology used in ASCE 41-17.

The procedures in this Appendix also require that the nonstructural components in an RC IV building meet the following two performance objectives:

1. A Hazard Reduced (HR) performance level for the Risk-Targeted Maximum Considered Earthquake (MCE_R) ground motion; and,

2. An Operational (OP) performance level for earthquake ground motion that is two-thirds of the MCE_R ground motion.

Performance criteria based on tolerable levels of damage are defined to ensure that these performance objectives are met. Nonlinear strength and deformation demands are determined by performing nonlinear static or nonlinear dynamic analyses and the results compared with acceptance criteria contained in authoritative documents, such as ASCE 41-17 or FEMA P-750 or developed based on laboratory data or rational analysis.

To ensure that satisfactory nonlinear behavior is achieved, restrictions are imposed on the types of seismic force-resisting systems that can be used in conjunction with this Appendix.

This Appendix replaces the provisions of Chapter 16 of the 2024 IBC, as modified by Chapter 2 of this UFC, for use in performing the alternative analysis of RC IV buildings and other structures. All other chapters of the 2024 IBC apply as modified by Chapter 2 of this UFC.

[C] B-1.1 Overview

In ASCE 7-22, MCE_R is used in conjunction with a “Collapse Prevention” performance objective. The alternate design in this chapter is required to meet a “Life Safety” performance objective. So, from a purist point of view, the procedure in this Appendix should have used MCE ground motion values, which could be determined by dividing the S_S- and S_1- values of ASCE 7-22, by risk coefficients C_{RS} (ASCE 7-22 Figure 22-18) and C_{R1} (ASCE 7-22 Figure 22-19), respectively. In view of the fact that C_{RS}- and C_{R1}-values are typically within a narrow range around 1.0, a decision was made to avoid unjustifiable complications and use MCE_R ground motion in place of MCE ground motion for the alternative designs of this Appendix. The same approach is adopted in ASCE 41-17 as well.

The Life Safety (LS) and Immediate Occupancy (IO) performance levels for structural members at MCE_R and BSE-1N ground motions, respectively, are consistent with Table 4.1(a) of this UFC, RP10 Table 2.2 and ASCE 41-17 Table 2.3.

In the past, the performance levels for the nonstructural components were Life Safety (LS) and Immediate Occupancy (IO) at MCE_R and BSE-1N ground motions, respectively. In this UFC, the performance levels are changed to Hazard Reduced (HR) and Operational (OP) at MCE_R and BSE-1N ground motions, respectively, to be consistent with Table 4.1(b) of this UFC, RP10 Table 2.2 and ASCE 41-17 Table 2.3.

B-1.2 Design Review Panel.

A design review of the seismic force-resisting system design and structural analysis must be performed by an independent team of Registered Design Professionals in the appropriate disciplines and others experienced in seismic analysis methods and the theory and application of nonlinear seismic analysis and structural behavior under extreme cyclic loads. In addition to a final review, a Design Review Panel should be convened at the beginning of a design to review proposed design methodology and strategy. Membership on the Design Review Panel is subject to the approval of the Authority Having Jurisdiction. A design review needs to include, but not necessarily be limited to, the following:

1. Any site-specific seismic criteria used in the analysis, including the development of site-specific spectra and ground motion time-histories;

2. Any acceptance criteria used to demonstrate the adequacy of structural elements and systems to withstand the calculated force and deformation demands, together with any laboratory or other data used to substantiate the criteria;

3. The preliminary design, including the selection of the structural system and the configuration of structural elements; and,

4. The final design of the entire structural system and all supporting analyses.

B-2 DEFINITIONS.

B-2.1 General.

2024 IBC Section 202 and ASCE 7-22 Section 11.2 apply. In addition, the definitions listed in Section X.1 of Resource Paper 2 of FEMA P-750, *NEHRP Recommended Provisions for Seismic Regulations for New Buildings and Other Structures*, 2009 Edition, apply.

B-3 CONSTRUCTION DOCUMENTS.

B-3.1 General.

2024 IBC Section 1603, as modified by Section 2-4.1 of this UFC, applies.

Exception:

For buildings designed using this Appendix, the Seismic Importance Factor, I_e, the design base shear, seismic response coefficient, C_s, and the Response Modification Factor, R, do not apply and need not be listed in construction documents.

B-4 GENERAL DESIGN REQUIREMENTS.

B-4.1 General.

2024 IBC Section 1604 applies, except as modified herein. Table 2-2 of this UFC must replace 2024 IBC Table 1604.5. The Importance Factor for seismic loading defined in Table 2-2 does not apply and should be taken as 1.0. Importance Factors for seismic design of nonstructural components must be determined in accordance with the criteria of ASCE7-22 Chapter 13. Importance Factors for snow and ice loads are no longer used in ASCE 7-22.

B-5 LOAD COMBINATIONS.

B-5.1 General.

RC IV buildings and other structures, and portions thereof, must be designed to resist the load combinations specified in this section. For all load combinations where earthquake-generated forces are not considered, ASCE 7-22 Section 2.3 applies. Where earthquake-generated forces are considered, ASCE 7-22 Section 2.3.6 load combinations 6 and 7, must be replaced by Equations B-1 and B-2 of this UFC. ASCE 7-22 Section 2.4 and 2024 IBC Section 1605.2 do not apply; allowable stress design is not permitted for use in this Appendix. The load combinations in ASCE 7-22 Section 2.3.6 that include seismic load effect with overstrength, E_m, does not apply; for any design situation requiring the use of load combinations with overstrength factor, Equations B-1 and B-2 apply, subject to the exceptions noted in Section B-18.1.

B-5.2 Seismic Load Combinations.

When the effects of earthquake-generated forces are considered, structures are required to resist the most critical effects from the following combinations of factored loads:

When the effects of gravity and seismic loads are additive:

$1.1(D + 0.25\,L + 0.15\,S) + E$ **(Equation B-1)**

When the effects of gravity and seismic loads are counteractive:

$0.9\,D + E$ **(Equation B-2)**

Where

D = Effect of dead load

L = Effect of unreduced design live load

S = Effect of design flat roof snow load calculated in accordance with ASCE 7-22 for a Risk Category IV building.

E = The effect of horizontal and vertical earthquake forces at the BSE-1N displacement (Δ_S) or MCE_R displacement (Δ_M), determined in the nonlinear analysis, as set forth in Section B-18.1.

Exception**:** Where the design flat-roof snow load calculated in accordance with ASCE 7-22 is less than 40 psf, the effective snow load is permitted to be taken as zero.

B-6 DEAD LOADS.

B-6.1 General.

2024 IBC Section 1606 applies.

B-7 LIVE LOADS.

B-7.1 General.

2024 IBC Section 1607, as modified by Section 2-4.4 of this UFC, applies, except that wherever Table 1607.1 is referenced, it must be replaced by Table E-1 of this UFC.

B-8 SNOW LOADS.

B-8.1 General.

2024 IBC Section 1608, as modified by Section 2-4.5 of this UFC, applies.

B-9 WIND LOADS.

B-9.1 General.

2024 IBC Section 1609, as modified by Section 2-4.6 of this UFC, applies.

B-10 SOIL LOADS AND HYDROSTATIC PRESSURE.

B-10.1 General.

2024 IBC Section 1610 applies, without the exception in Section 1610.1.

B-11 RAIN LOADS.

B-11.1 General.

2024 IBC Section 1611 applies.

B-12 FLOOD LOADS.

B-12.1 General.

2024 IBC Section 1612 applies.

B-13 ICE LOADS—ATMOSPHERIC ICING.

B-13.1 General.

2024 IBC Section 1614 applies.

B-14 TSUNAMI LOADS.

B-14.1 General.

Probabilistic Tsunami Hazard Analysis (PTHA) may be performed on either the current topography or the topography adjusted for sea level rise. Use current NAVD88 [North American Vertical Datum of 1988]/MHW still water elevation for EGL (Energy Grade Line) velocity calculations regardless of topography used for PTHA.

B-15 EARTHQUAKE LOADS – GENERAL.

B-15.1 Scope.

Every structure, and portion thereof, shall as a minimum be designed and constructed to resist the effects of earthquake motions and assigned an SDC as set forth in 2024 IBC Section 1613.2.5/ASCE 7-22 Section 11.6. The use of nonlinear analysis procedures in this Appendix minimizes the need for SDC use, but the SDC is required for establishing detailing requirements.

B-16 EARTHQUAKE LOADS – SITE GROUND MOTION.

B-16.1 Determining MCE_R and BSE-1N Response Spectra and Spectral Response Accelerations.

Where an MCE_R response spectrum is required, the Multi-Period 5% damped MCE_R response spectrum from the USGS Seismic Design GeoDatabase for the applicable site class should be used.

Exceptions:

1. Where a site-specific ground motion analysis is performed in accordance with Section 11.4.7, the response spectrum shall be determined in accordance with Section 21.2.3.

2. Where values of the Multi-Period 5% damped MCE_R response spectrum are not available USGS Seismic Design GeoDatabase, the MCE_R response spectrum shall be permitted to be determined in accordance with Section 11.4.5.2, with S_{MS} and S_{M1} substituted for S_{DS} and S_{D1} respectively.

S_{MS} and S_{M1} values can be obtained directly from the USGS Seismic Design GeoDatabase or from the MCER response spectrum by looking up the ordinates corresponding to periods of 0.2 secs and 1.0 secs respectively.

The BSE-1N spectral accelerations, adjusted for site class effects, at short periods (S_{DS}) and at 1-second period (S_{D1}) must be determined as 2/3 of S_{MS} and S_{M1}, respectively. The design response spectrum for BSE-1N ground shall be obtained by multiplying the ordinates of the Multi-Period MCE_R response spectrum by 2/3.

B-16.1.1 Site Class Definition.

ASCE 7-22 Section 20.2 applies as written.

[C] B-16.1.1 – Site Class Definition.

Note that Site Class definitions have changed in ASCE 7-22. There are now nine site classes instead of six, site class BC, CD, and DE having been added to A, B, C, D, E, and F. Also the distinction among the site classes is now solely based on shear wave velocity. Standard penetration resistance or undrained shear strength can no longer be the basis of such distinction.

If S_s and S_1 values are required, they can be obtained from the MCE_R response spectrum from Site Class BC by looking up the ordinates corresponding to periods of 0.2 sec an1.0 sec respectively. Alternatively they can be obtained directly from USGS Seismic Hazard Geodatabase.

B-16.2 Site-specific Response Analysis for Determining Ground Motion Accelerations.

B-16.2.1 Site Response Analysis

ASCE 7-22 Section 21.1 applies.

B-16.2.2 MCE_R Ground Motion Hazard Analysis.

ASCE 7-22 Section 21.2 applies.

B-17 EARTHQUAKE LOADS – CRITERIA SECTION.

B-17.1 Structural Design Criteria.

Each structure must be assigned a Seismic Design Category in accordance with 2024 IBC Section 1613.2.5/ASCE 7-22 Section 11.6, for use with required structural design and construction provisions. Each structure must be provided with complete lateral and vertical force-resisting systems capable of providing adequate strength, stiffness, and energy dissipation capacity to withstand the earthquake ground motions determined in accordance with Section B-16 within the prescribed performance objectives of Section B-18. In addition, each structure must be designed to accommodate the architectural, mechanical, and electrical component requirements of Section B-22. Ground motions must be assumed to occur along any horizontal direction of a structure. A continuous load path, or paths, with adequate strength and stiffness to transfer forces induced by the earthquake ground motions from the points of application to the final point of resistance must be provided.

B-17.2 Importance Factors.

The seismic importance factor, I_e, is not used. The component seismic importance factor, I_p, used in Section B-22, must be the value specified in Sections B-22.4.4.

B-17.3 Site Limitations.

A structure assigned to RC IV must not be sited where there is a known potential for an active fault to cause rupture of the ground surface at the structure. An *active fault* is defined in ASCE 7-22 as follows: A fault determined to be active by the Authority Having Jurisdiction from properly substantiated data (e.g., most recent mapping of active faults by the US Geological Survey).

> **[C] B-16.5 – Site Limitations.**
>
> In UFC 3-301-01, Change 1, 2 October 2023 (the previous version of this UFC), an active fault was defined as a fault for which there is an average historic slip rate of 1 mm or more per year and for which there is geographic evidence of seismic activity in Holocene times (the most recent 11,000 years). This definition dates back to the 2000 IBC.

B-17.4 Building Configuration.

The requirements of ASCE 7-22 Sections 12.3.1[Diaphragm Flexibility], 12.3.2 [Irregular and Regular Classification], and 12.3.3 [Limitations and Additional Requirements for Systems with Structural Irregularities] do not apply to facilities designed using the provisions of this Chapter.

B-17.5 Analysis Procedures.

B-17.5.1 Nonlinear Analysis.

The Alternate RC IV analysis procedure of this Appendix may be used in lieu of the Equivalent Lateral Force or Modal Response Spectrum Analysis procedures that would generally be used to comply with the 2024 IBC and Chapter 2 of this UFC. For this alternate procedure, a nonlinear structural analysis must be performed. The analysis may use either the Nonlinear Static Procedure (NSP) or the Nonlinear Dynamic Procedure (NDP).

B-17.5.1.1 Nonlinear Static Procedure.

The NSP is permitted for structures not exceeding 6 stories in height and having a fundamental period, T, not greater than $3.5T_S$, where T_S is determined in accordance with ASCE 7-22 Section 11.4.6. Application of the NSP needs to comply with the requirements of *Resource Paper 2 of FEMA P-750, NEHRP Recommended Provisions for Seismic Regulations for New Buildings and Other Structures, 2009 Edition, Part 3, Resource Papers (RP) on Special Topics in Seismic Design*, <u>subject to the modifications below</u>. In applying the NSP, the user may employ the references cited in Resource Paper 2 of FEMA P-750. Further information on NSP may be found in *FEMA P-750, NEHRP Recommended Provisions for Seismic Regulations for New Buildings and Other*

Structures, 2009 Edition, Part 2, Commentary and in NEHRP Seismic Design Technical Brief No. 4, *Nonlinear Structural Analysis for Seismic Design*, NIST GCR 10-917-5. The following should be noted:

1. To apply the FEMA P-750 NSP, the design earthquake ground motions and associated spectral accelerations must be as specified herein (MCE_R and BSE-1N), and not the design ground motions defined in FEMA P-750.
2. A target displacement must be separately determined for each of the MCE_R and BSE-1N spectra.
3. The structure as a whole and each of the elements of the lateral force-resisting system and its connections must be evaluated for their adequacy to provide Immediate Occupancy Performance at the BSE-1N target displacement and to provide Life Safety Performance at the MCE_R target displacement.
4. P-Delta effects must be included in the development of the backbone curves (see Section 2.4 of NIST GCR 10-917-5 NEHRP Seismic Design Technical Brief No 4).
5. Multidirectional and concurrent seismic effects must be included as defined in Section 7.2.5 of ASCE/SEI 41-17.
6. The following modifications must be made to Resource Paper 2 of FEMA P-750

   a. Replace references to ASCE 41-06 w/Supplement 1 with ASCE/SEI 41-17.
   b. Replace references to Section 3.3.3 of ASCE 41-06 w/Supplement 1 with Section 7.4.3 of ASCE/SEI 41-17.
   c. Replace references to Section 3.3.3.3.2 of ASCE 41-06 w/Supplement 1 with Section 7.4.3.3.2 of ASCE/SEI 41-17.
   d. Replace reference to Equation 3-16 of ASCE/SEI 41-06 w/Supplement 1 with Equation 7-32 of ASCE/SEI 41-17 and replace μ_{max} in Equation 7-32 of ASCE/SEI 41-17 with R_{max}.

B-17.5.1.2 Nonlinear Dynamic Procedure.

Application of the NDP needs to comply with the requirements of ASCE 7-22 Chapter 16.

B-17.5.2 Site Ground Motions.

Two characteristic ground motions must be required for the design of facilities using this procedure:

1. For the LS performance level, the MCE_R ground motion must be used. For the NSP, spectral response accelerations must be determined using the procedures of Section B-16.1 or Section B-16.2. For the NDP, MCE_R ground motions must be determined using procedures prescribed in ASCE 7-22 Section 16.2.

2. For the IO performance level, the BSE-1N ground motion must be used. For the NSP, spectral response accelerations must be determined using the procedures of Section B-16.1 or Section B-16.2. For the NDP, BSE-1N ground motions must be determined using procedures prescribed in ASCE 7-22 Section 16.2.

B-18 EARTHQUAKE LOADS – MINIMUM DESIGN LATERAL FORCE AND RELATED EFFECTS.

B-18.1 Seismic Load Effect, *E*.

When the NSP is used, the seismic load effect, E, for use in the load combinations of Section B-5.2 must be determined from ASCE 7-22 Section 12.4. In the application of ASCE 7-22 Section 12.4, the term S_{DS} must be interpreted as S_{MS} for the LS performance level. When the NDP is used, the seismic load effect, E, is simply the response determined from the dynamic analysis. The redundancy coefficient, ρ, must be taken as 1.0.

Exceptions:

1. Where these provisions require consideration of structural overstrength (see ASCE 7-22 Section 12.4.3), the values of member forces, Q_E, obtained from NSP analysis at the peak (maximum base shear) of the NSP pushover curve must be used in place of the quantity E_{mh}.

2. Where these provisions require consideration of structural overstrength (see ASCE 7-22 Section 12.4.3), the values of member forces, Q_E, obtained from NDP analysis at the maximum base shear found in the analysis using any of the ground motion records must be used in place of the quantity E_{mh}.

B-18.2 Redundancy.

ASCE 7-22 Section 12.3.4 does not apply to facilities designed using the provisions of this Chapter.

B-18.3 Deflection and Drift Limits.

B-18.3.1 Allowable Story Drift.

Because the Alternate Design Procedure is a nonlinear performance-based design approach, specific target drift limits are not set for designs.

B-18.3.1.1 Life Safety Performance Level.

The LS performance level must be achieved for MCE_R ground shaking. At the LS performance level, structural members may be damaged, but they retain a margin of safety of at least 1.5 against the onset of loss of gravity load carrying capacity. Some residual global structural strength and stiffness remain at the maximum lateral displacement in all stories. No out-of-plane wall failures occur. Partitions may be damaged, and the building may be beyond economical repair. Some permanent (inelastic) drift may occur. While inelastic behavior is permitted, member strength degradation needs to be limited in primary structural members (residual strength cannot be less than 80% of peak strength). Primary structural elements are those that are required to provide the building with an ability to resist collapse when ground motion-induced seismic forces are generated. For secondary structural elements (those that are not primary elements), strength degradation to levels below the nominal yield strength is permitted. Not more than 20% of the total strength or initial stiffness of a structure can be assumed to be provided by secondary elements. The LS performance objective needs to be verified by analysis - either the NSP or the NDP. The LS acceptance criteria contained in ASCE 41-17 must be used to demonstrate acceptable performance (see ASCE 41-17 Table 2-3). Alternatively, acceptance criteria can be developed by the designer and approved by the design review panel (see Section B-1.2).

B-18.3.1.2 Immediate Occupancy Performance Level.

The IO performance level must be achieved for BSE-1N ground shaking. At the IO performance level, a building remains safe to occupy, essentially retaining pre-earthquake design strength and stiffness and nonstructural elements retain position and are operational. Minor cracking of facades, ceilings, and structural elements may occur. Significant permanent (inelastic) drift does not occur. The structural system for the building remains "essentially" elastic. Any inelastic behavior does not change the basic structural response and does not present any risk of local failures. Member deformations are not permitted to exceed 125% of deformations at nominal member yield strengths. No member strength degradation is permitted, regardless of deformation. The IO performance objective needs to be verified by analysis, either the NSP or the NDP. The IO acceptance criteria contained in ASCE 41-17 must be used to demonstrate acceptable performance (see ASCE 41-17 Table 2-3). Alternatively, appropriate acceptance criteria can be developed by the designer and approved by the design review panel (see Section B-1.2).

B-18.3.2 Drift Determination and P-Delta Effects.

B-18.3.2.1 Drift and Deflection Determination for Nonlinear Static Procedure.

The design story drifts, Δ_S *and* Δ_M must be taken as the values obtained for each story at the target displacements for the BSE-1N and MCE_R, respectively.

B-18.3.2.2 Drift and Deflection Determination for Nonlinear Dynamic Procedure.

Transient as well as residual story drifts must be determined in accordance with ASCE 7-22 Sections 16.4.1.2 and 16.4.1.3, respectively.

B-18.3.2.3 P-Delta Effects for Nonlinear Static Procedure and Nonlinear Dynamic Procedure.

P-Delta (P-Δ) effects must be incorporated in all lateral load analyses.

B-18.4 Seismic Force-resisting Systems.

B-18.4.1 Permitted Seismic Force-resisting Systems.

Table B-1, Permitted Systems for RC IV Buildings Designed Using Alternate Analysis Procedure, must replace ASCE 7-22 Table 12.2-1 and Table 3-1 of this UFC. Table B-1 must be used to determine whether a seismic force-resisting system is permitted. Table B-1 also lists building height limitations for the permitted systems. Seismic force-resisting systems that are not listed in Table B-1 may be permitted if analytical and test data are submitted that establish the dynamic characteristics and demonstrate the lateral force resistance and energy dissipation capacity to be equivalent to those of the structural systems listed in the table. Such exceptions may be authorized when permission is granted by the design review panel (see Section B-1.2).

B-18.4.2 Structural Design Requirements.

B-18.4.2.1 Dual Systems.

ASCE 7-22 Section 12.2.5.1 applies.

B-18.4.2.2 Combinations of Framing Systems.

Different seismic force-resisting systems are permitted along the two orthogonal axes of a building structure, so long as both systems comply with the provisions of this Chapter.

B-18.4.2.3 Interaction Effects.

Moment-resisting frames that are enclosed or adjoined by more rigid elements that are not considered to be part of the seismic force-resisting system must be designed so that the action or failure of those rigid elements will not impair the vertical load-carrying and seismic force-resisting capability of the frame. The design needs to provide for the effect of these rigid elements on the structural system at structural deformations corresponding to the design story drift at the target displacement, as determined by analysis.

B-18.4.2.4 Deformational Compatibility.

For components that are not included in the seismic force-resisting system, ensure that ductile detailing requirements are provided such that the vertical load-carrying capacity of these components is not compromised by induced moments and shears resulting from the design story drift.

For structures assigned to Seismic Design Category D, E, or F, reinforced concrete frame members not designed as part of the seismic force-resisting system must comply with ACI 318 *Building Code Requirements for Structural Concrete,* Section 18.14.

B-18.4.3 Response Modification (*R*), System Overstrength (Ω_0), Deflection Amplification (C_d) Factors.

Because only the NDP or the NSP are permitted for the alternate design of RC IV structures the factors *R*, C_d, and Ω_o are not required.

B-18.4.4 Member Strength.

The load combination requirements of Sections B-5.1 and B-5.2 must be satisfied. Horizontal seismic load effects must be determined in accordance with Section B-18.1.

B-19 EARTHQUAKE LOADS, SOIL-STRUCTURE INTERACTION EFFECTS.

B-19.1 Analysis Procedure.

When these effects are considered, the provisions of ASCE 7-22 Chapter 19 apply.

B-20 SEISMIC DESIGN AND STRUCTURAL MEMBER LOAD EFFECTS.

B-20.1 Structural Member Load Effects.

The provisions of ASCE 7-22 Chapter 12, as modified by Chapter 3 of this UFC, apply.

B-20.2 Structural Integrity.

The provisions of 2024 IBC Section 1616 apply.

B-20.3 Soils and Foundations.

The provisions of 2024 IBC Chapter 18 apply.

B-21 SEISMIC DESIGN REQUIREMENTS FOR NONSTRUCTURAL COMPONENTS.

B-21.1 Component Design.

The provisions of ASCE 7-22 Chapter 13, as modified by Chapter 3, apply, except as noted in the following paragraphs. Appendix C provides supplementary guidance on design and analysis of some architectural, mechanical, and electrical components.

B-21.2 Performance Objectives.

The design procedure presented in this Appendix includes two overall performance objectives that influence the requirements for architectural, mechanical, and electrical components. First, the design must provide Hazards Reduced (HR) performance for the MCE_R. Second, the design must provide Operational (OP) performance for BSE-1N ground motions.

B-21.2.1 Hazards Reduced Performance Level for Nonstructural Components.

This performance level is defined as the post-earthquake damage state in which nonstructural components are damaged and could potentially create falling hazards. High-hazard nonstructural components identified in Chapter 13, Table 13-1 of ASCE 41-17 are secured to prevent falling into areas of public assembly because falling hazards from those components could pose a risk to life-safety of many people. Preservation of egress, protection of fire suppression systems, and similar life-safety issues are not addressed in this Nonstructural Performance Level.

B-21.2.2 Operational Performance Level for Nonstructural Components.

This performance level is defined as the post-earthquake damage state in which the nonstructural components are able to provide the functions they provided in the building before the earthquake. Nonstructural components in compliance with the acceptance criteria of ASCE 41-17 for Operational Nonstructural Performance and Risk Category IV nonstructural components are expected to achieve this post-earthquake state.

B-21.3 Modification of ASCE 7-22 for Hazards Reduced Design.

B-21.3.1 Ground Motion Parameters for Determination of Hazards Reduced Seismic Forces.

In the application of ASCE 7-22 Section 13.3.1, seismic forces must be determined for the MCE_R ground motion parameters.

B-21.3.2 Nonlinear Static Procedure.

In the application of ASCE 7-22 Section 13.3.1, seismic forces on components, when NSP is used, must be based on ASCE 7-22 Equations 13.3-1 through 13.3-3. The quantity S_{MS} must be substituted for the term S_{DS} found in the equations. In the application of ASCE 7-22 Section 13.3.2, the response of the building to the MCE_R ground motion must be used.

B-21.3.3 Nonlinear Dynamic Procedure.

In the application of ASCE 7-22 Section 13.3.1, seismic forces on components, when NDP is used, must be based on ASCE 7-22 Equation 13.3-7. The term a_i is the maximum acceleration at the level of the component under consideration, as determined from the dynamic analysis. In the application of ASCE 7-22 Section 13.3.2, the response of the building to the MCE_R ground motion must be used.

B-21.4 Modification of ASCE 7-22 for Operational Design.

B-21.4.1 Ground Motion Parameters for Determination of IO Seismic Forces.

In the application of ASCE 7-22 Section 13.3.1, seismic forces must be determined for the BSE-1N ground motion parameters.

B-21.4.2 Nonlinear Static Procedure.

In the application of ASCE 7-22 Section 13.3.1, seismic forces on components, where NSP is used, must be based on ASCE 7-22 Equations 13.3-1 through 13.3-3. In the application of ASCE 7-22 Section 13.3.2, the response of the building to the BSE-1N ground motion must be used.

B-21.4.3 Nonlinear Dynamic Procedure.

In the application of ASCE 7-22 Section 13.3.1, seismic forces on components, where NDP is used, must be based on ASCE 7-22 Equation 13.3-7. The term a_i is the maximum acceleration at the level of the component under consideration, as determined from the dynamic analysis. In the application of ASCE 7-22 Section 13.3.2, the response of the building to the BSE-1N ground motion must be used.

B-21.4.4 Component Importance Factors.

The component importance factor, I_p, is required for force calculations in ASCE 7-22 Section 13.3.1. I_p must be as given in ASCE 7-22 Section 13.1.3.

NP - indicates not permitted, NL – indicates not limited.

[1] Any system that is restricted by this table may be permitted if it is approved by the design review panel (see Section B-1.2).

[2] See Table 3-1 for detailing references for seismic force-resisting systems.

[3] Steel ordinary concentrically braced frames are permitted in single-story buildings, up to a structural height, h_n, of 60 ft, where the dead load of the roof does not exceed 20 psf, and in penthouse structures.

[4] Ordinary moment frames may be used in lieu of intermediate moment frames for Seismic Design Category B or C.

[5] See ASCE 7-22 Section 12.2.5.7 for limitations on structures assigned to Seismic Design Category D, E, or F.

[6] See ASCE 7-22 Section 12.2.5.6 for limitations on structures assigned to Seismic Design Category D, E, or F.

[7] Structural height, h_n, shall not be less than 60 ft (18.3m).

APPENDIX C GUIDANCE FOR SEISMIC DESIGN OF NONSTRUCTURAL COMPONENTS

C-1 INTRODUCTION.

This Appendix defines architectural, mechanical, and electrical components, discusses their participation and importance in relation to the seismic design of the structural system, and provides guidance for their design to resist damage from earthquake-induced forces and displacements. The fundamental principles and underlying requirements of this Appendix are that the design of these components for buildings in Risk Categories (RCs) I, II, and III should be such that they will not collapse and cause personal injury due to the accelerations and displacements caused by severe earthquakes, and that they should withstand more frequent but less severe earthquakes without excessive damage and economic loss. In contrast, designated components in RC IV buildings, are required to remain operational following a design earthquake (BSE-1N).

C-1.1 Design Criteria.

2024 IBC Section 1613, as modified by Chapter 2 of this UFC, governs the seismic design of architectural, mechanical, and electrical components. 2024 IBC Section 1613 references Chapter 13 of ASCE 7-22. Because ASCE 7-22 is the primary source of design requirements for these components, this Appendix cites ASCE 7-22 provisions and expands on them as appropriate.

C-1.2 Walk-down Inspections and Seismic Mitigation for Buildings in Risk Categories IV.

C-1.2.1 General Guidance.

Section 1705.13.6 of UFC 3-301-01 requires that an initial *walk-down* inspection of new RC IV buildings be performed. A walk-down inspection is a visual inspection of a building to identify possible seismic vulnerabilities of its architectural, mechanical, and electrical components. Inspections should include investigating adequacy of component load paths, anchorage and bracing, and components' abilities to accommodate differential motions with respect to supporting building structure. The walk-down inspector should become familiar with the design earthquake motions for the site, structural configuration of the building, building drawings, and documentation of all previous walk-down inspections. Inspectors should document all observations with photographs, schematic drawings, and narrative discussions of apparent vulnerabilities. Inspection reports normally do not include detailed assessments of component vulnerabilities, but they may recommend further detailed assessments. Inspectors should also define mitigation recommendations in inspection reports. Prior to building commissioning, the Authority Having Jurisdiction (AHJ) should ensure seismic mitigation recommendations are fully implemented. An example of a walk-down inspection of Madigan Army Medical Center at Fort Lewis, WA, may be found in

USACERL Technical Report 98/34, *Seismic Mitigation for Equipment at Army Medical Centers*.

C-1.2.2 Periodic Post-commissioning Walk-down Inspections.

In addition to initial walk-down inspections performed at building commissioning, periodic post- construction walk-down inspections should be conducted in RC IV buildings by installation personnel, as part of routine operations and maintenance. For RC IV buildings, such inspections should be conducted at least every second year following building commissioning, or, for affected systems, when any change to architectural, mechanical, or electrical systems occurs.

C-2 ARCHITECTURAL COMPONENTS.

C-2.1 General.

Reference should be made to ASCE 7-22 Section 13.5, Architectural Components.

Architectural components addressed in ASCE 7-22 Chapter 13 are listed in ASCE 7-22 Table 13.5-1. These components are called "architectural" because they are not part of the vertical or lateral load-resisting systems of a building, or part of the mechanical or electrical systems. Although they are usually shown on architectural drawings, they often have a structural aspect and can affect the response of a building to earthquake ground motions. Architects should consult with structural, mechanical, and electrical engineers, as appropriate, when dealing with these elements. The structural engineer must review architectural (as well as mechanical and electrical) component anchorage details, to ensure compliance with anchorage requirements. During this review, the structural engineer must also identify installed architectural (as well as mechanical and electrical) components that may adversely affect the performance of the structural system.

C-2.2 Typical Architectural Components.

Examples of architectural components that have a structural aspect requiring special attention follow.

C-2.2.1 Nonstructural Walls.

A wall is considered architectural or nonstructural when it is not designed to resist transient interior (lateral) air pressure of more than 5psf or superimposed gravity loads beyond the threshold values given in the definition for bearing walls in 2024 IBC Section 202 and ASCE 7-22 Section 11.2. To ensure that nonstructural walls do not resist lateral forces, they should either be disconnected (i.e., isolated) from the building structure at the top and the ends of the wall or be very flexible (in-plane) relative to the structural walls and frames resisting lateral forces. An isolated wall must be capable of acting as a cantilever from the floor or be braced to resist its own out-of-plane motions and loads, without interacting with the lateral force-resisting system. Such interaction may be detrimental to the wall or the lateral force-resisting system or both.

C-2.2.2 Curtain Walls and Filler Walls.

A curtain wall is an exterior wall, often constructed of masonry, that lies outside of and usually conceals the structural frame of a building. A filler wall is an infill, usually constructed of masonry, within the structural members of a frame. These walls are often considered architectural in nature if they are designed and detailed by the architect. However, they can act as shear (structural) walls. If they are connected to the frame, they will be subjected to the deflections of the frame and will participate with the frame in resisting lateral forces. Curtain walls and infill walls in buildings governed by this document should be designed so they do not restrict the deformations of the structural framing under lateral loads (i.e., they are isolated from building lateral deformations). Lateral supports and bracing for these walls should be provided as prescribed in this Appendix.

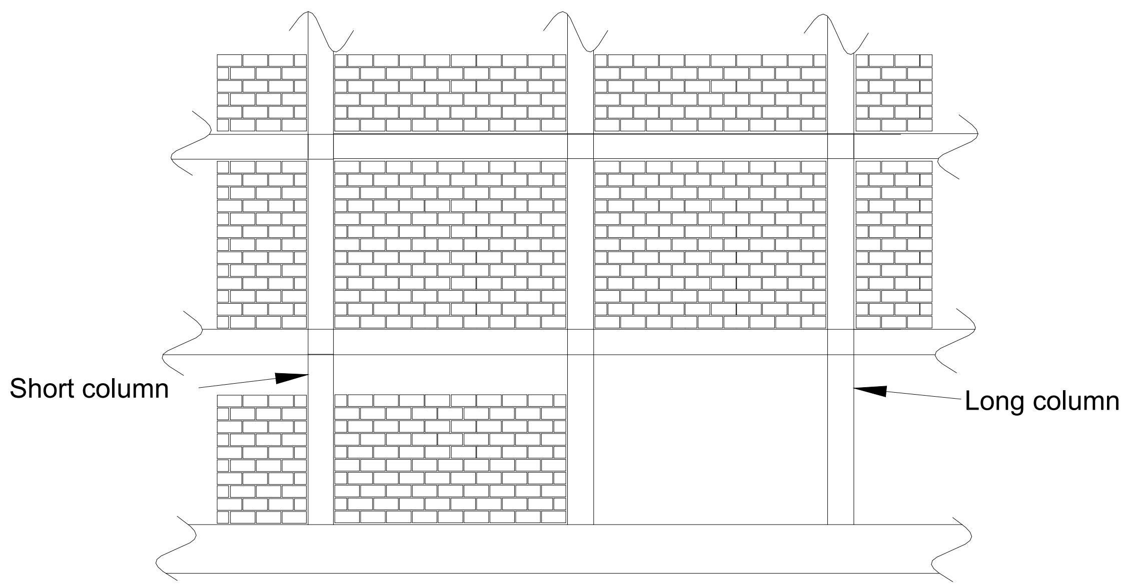
C-2.2.3 Partial Infill Walls.

A partial infill wall is one that has a strip of window between the top of the solid infill and the bottom of the floor above, or has a vertical strip of window between one or both ends of the infill and a column. Such walls require special treatment. If they are not properly isolated from the structural system, they will act as shear walls. The wall with windows along the top is of particular concern because of its potential effect on the adjacent columns. The columns are fully braced where there is an adjacent infill, but are unbraced in the zone between the windows. The upper, unbraced part of the column is a “short column,” and its greater rigidity (compared with the other, longer unbraced columns in the system) must be considered in structural design. Short columns are very susceptible to shear failure in earthquakes. Figure C-1 shows a partial infill wall, with short columns on either side of the infill, which should be avoided. All infills in buildings governed by this document should be considered to be nonstructural components, and should be designed so they do not restrict the deformation of the structural framing under lateral loads. In this instance, the partial infill should be sufficiently isolated from the adjacent frame elements to permit those elements to deform in flexure as designed.

C-2.2.4 Precast Panels.

Exterior walls that consist of precast panels attached to the building frame are addressed in a different way. The general layout and wall section for wall panels is usually shown on architectural drawings, while structural details for the support of the panels are usually shown on structural drawings. It is common for the detailed structural design of the precast panels to be delegated to a specialty engineer engaged by the General Contractor or by the precast concrete panel subcontractor. This is done because the details of design may vary depending on the manufacturing methods and facilities of the panel manufacturer. The specialty engineer is engaged to incorporate those considerations as well as means and methods of construction that the project structural engineer excludes from the scope of work. The structural engineer must review this design as needed to verify that the application of loads and the configuration of the connection details are compatible with the design of the supporting structure. In such cases, structural drawings should include design criteria and representative details in order to show what is expected. The design criteria should include the required design forces and frame deflections that must be accommodated by the panels and their connections. Particular attention should be given to the effects of deflections of the frame members supporting precast panels, to assure that appropriate reaction forces and deflections are considered. Panels with more than two attachment points between their bottom edge and the supporting frame should be avoided. Further guidance can be found in *Architectural Precast Concrete,* 3rd Edition (PCI MNL-122-07), published by the Precast/Prestressed Concrete Institute (PCI).

Figure C-1. Partial Infill Masonry Wall between Two Concrete Columns, Causing Adverse "Short Column" Effect



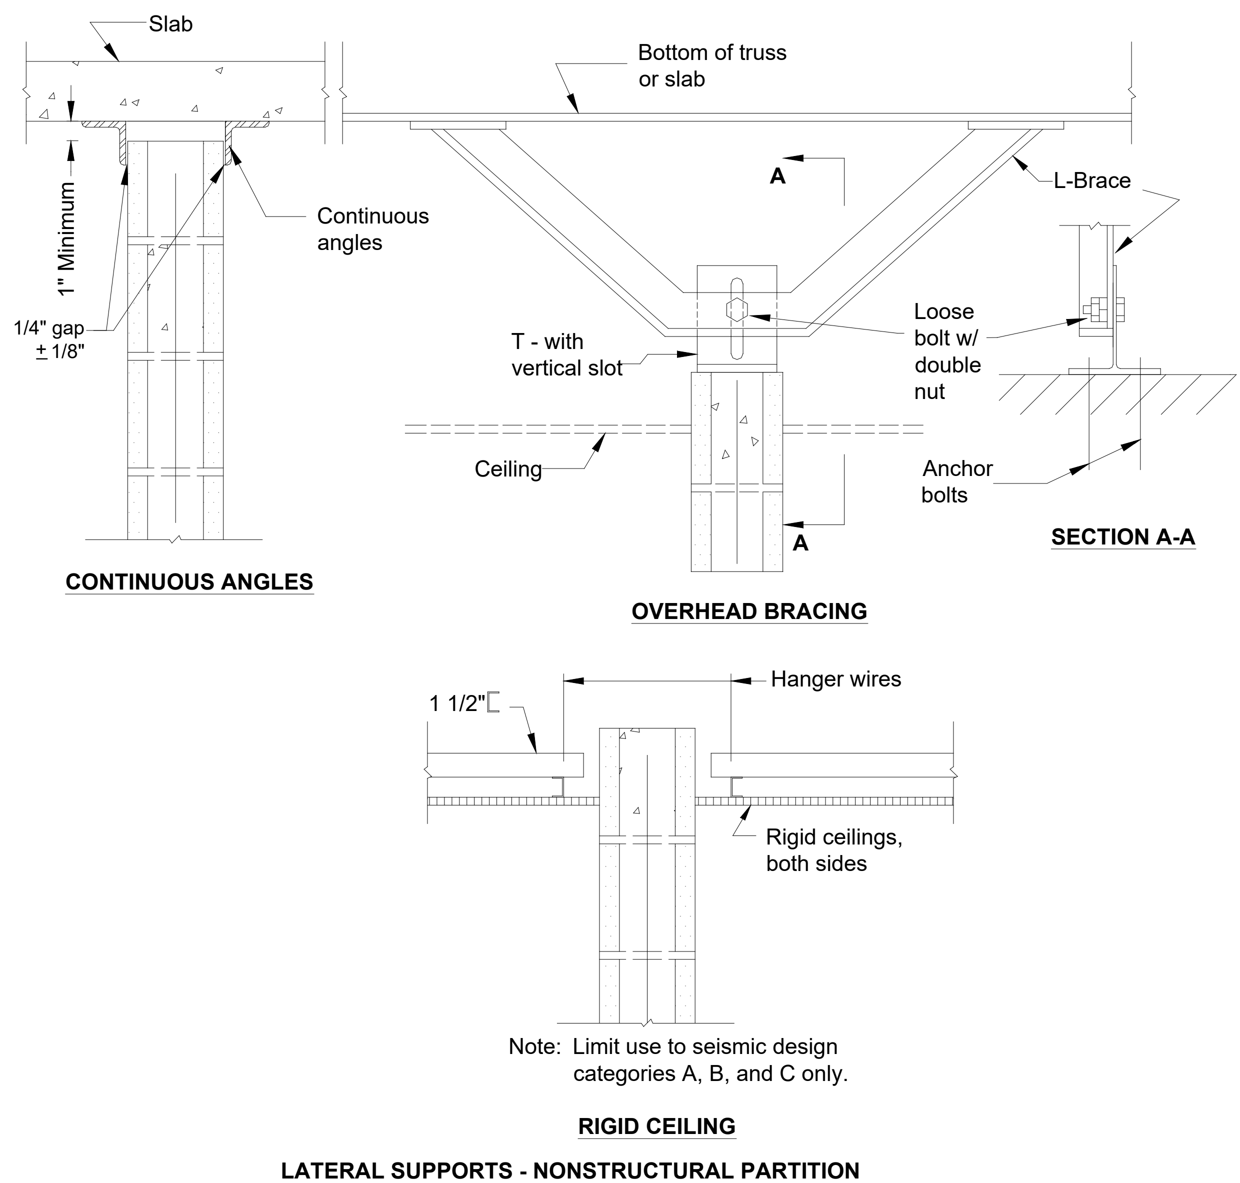
C-2.2.5 Masonry Veneer.

Reference should be made to *Building Code Requirements for Masonry Structures* (TMS 402-22). A masonry veneer is defined as a masonry wythe that provides the exterior finish of a wall system and transfers out-of-plane load directly to a backing, but is not considered to add load-resisting capacity to the wall system. A masonry veneer may be anchored or adhered. An anchored veneer is defined as a masonry veneer secured to and supported laterally by the backing through anchors and supported vertically by the foundation or other structural elements. An adhered veneer is defined as a masonry veneer secured to and supported by the backing through adhesion. Chapter 13 of TMS 402 provides requirements for design and detailing of anchored masonry veneer and adhered masonry veneer. The design of anchored veneer is addressed in Section 13.2 of TMS 402, while the design of adhered veneer is addressed in Section 13.3 of the same document.

C-2.2.6 Rigid Partition Walls.

Rigid partition walls are generally nonstructural masonry walls. Such walls should be isolated, so they are not called upon to resist in-plane lateral forces to which they are subjected, based on relative rigidities. Typical details for isolating these walls are shown in Figure C-2. These walls should be designed for the prescribed forces normal to their plane.

Figure C-2. Typical Details for Isolation of Rigid Partition Walls



C-2.2.7 Nonrigid Partition Walls.

Nonrigid partition walls are generally nonstructural partitions, such as stud and drywall, stud and plaster, and movable partitions. When these partitions are constructed according to standard recommended practice, they are assumed to be able to withstand design in-plane drift of only 0.005 times the story height (1/16 in./ft [5 mm/m] of story height) without damage. This is much less than the most restrictive allowable story drift in ASCE 7-22 Table 12.12-1. Therefore, damage to these partitions should be expected in the design earthquake if they are anchored to the structure in the in-plane direction. For RC IV, these partition walls should be isolated from in-plane building motions at the tops and sides of partitions if drifts exceeding 0.005 times the story height are anticipated in the design earthquake. Partition walls should be designed for the prescribed seismic force acting normal to flat surfaces. However, the wind or the usual 5 pounds per square foot partition load (2024 IBC Section 1607.16) will usually govern.

Economic comparison between potential damage and costs of isolation should be considered. For partitions that are not isolated, a decision has to be made for each project as to the contribution, if any, such partitions will make to damping and response of the structure, and the effect of seismic forces parallel to (in-plane with) the partition resulting from the structural system as a whole. Usually, it may be assumed that this type of a partition is subject to future changes in floor layout location. The structural role of partitions may be controlled by limiting the height of partitions and by varying the method of support.

C-2.2.8 Suspended Ceilings.

Requirements for suspended ceilings are provided in ASCE 7-22 Section 13.5.6, as modified by Chapter 3. Useful guidance is available in ICC-ES AC 368 *Acceptance Criteria for Suspended Ceiling Framing Systems*, issued by the International Code Council Evaluation Service (ICC-ES) in February 2024.

C-3 MECHANICAL AND ELECTRICAL COMPONENTS.

C-3.1 Component Support.

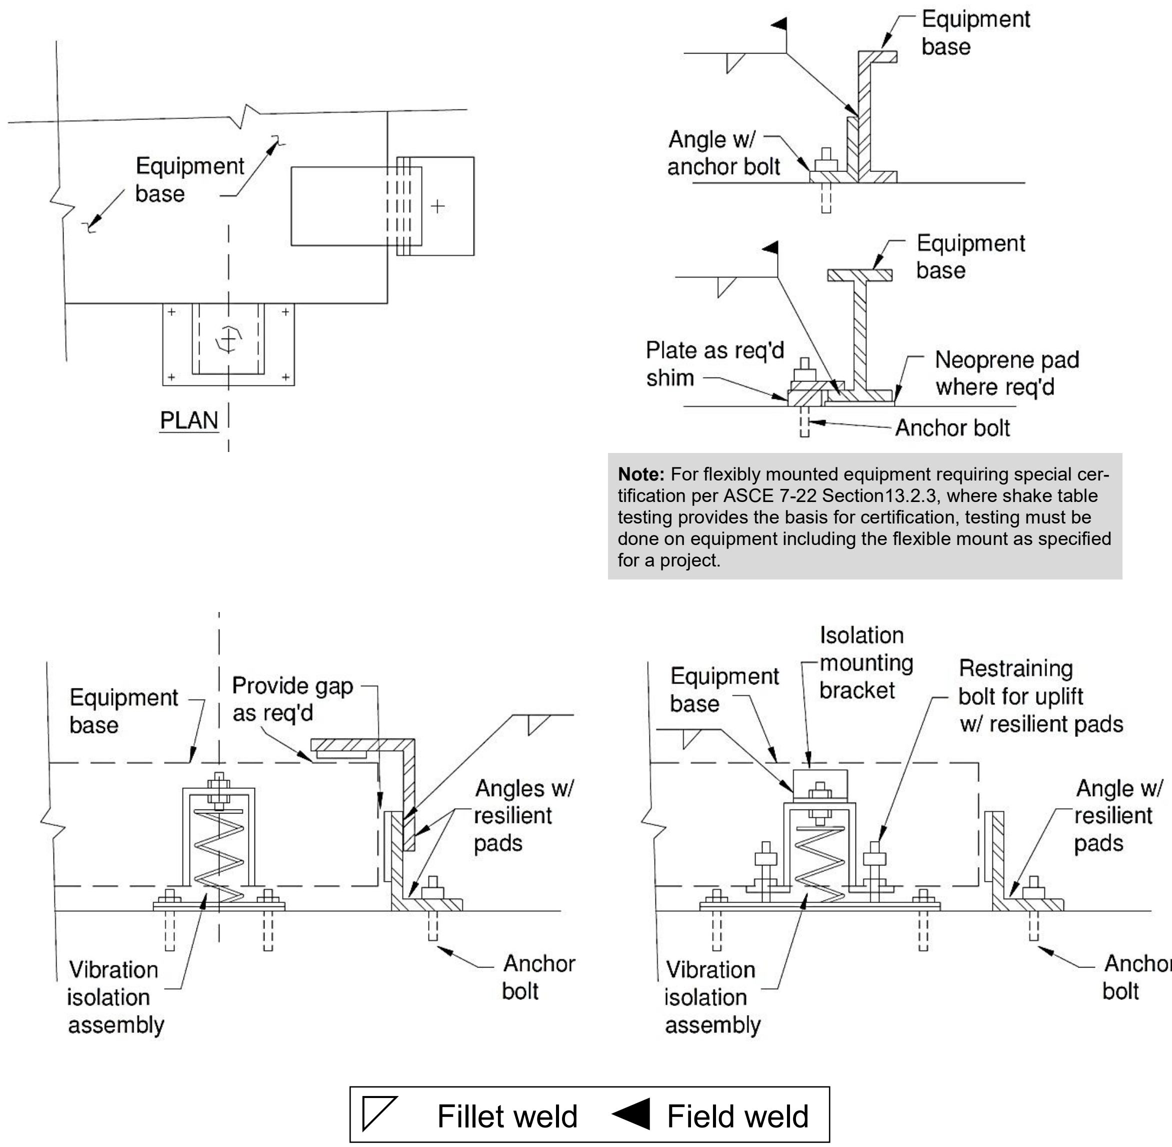
Reference should be made to ASCE 7-22 Section 13.6.4 Component Supports.

C-3.1.1 Base-mounted Equipment in RC IV.

Floor or pad-mounted mission-critical equipment installed in RC IV buildings assigned to SDC D, E, or F should use cast-in-place anchor bolts to anchor them. Alternatively, post-installed anchors are permitted to be used provided they are qualified for earthquake loading in accordance with ACI 355.2, *Qualification of Post-Installed Mechanical Anchors in Concrete*, and ACI 355.4, *Acceptance Criteria for Qualification of Post-Installed Adhesive Anchors in Concrete*, as applicable. For this equipment, two nuts should be provided on each bolt, and anchor bolts should conform to ASTM F1554-20, *Standard Specification for Anchor Bolts, Steel, 36, 55, and 105-ksi Yield*

Strength. Cast-in-place anchor bolts should have an embedded straight length equal to at least 12 times the nominal bolt diameter. Anchor bolts that exceed the depth of equipment foundation piers or pads should either extend into the concrete floor, or the foundation should be increased in depth to accommodate the bolt lengths. Figure C-3 illustrates typical base anchorage and restraint for equipment.

Figure C-3. Typical Seismic Restraints for Floor-mounted Equipment

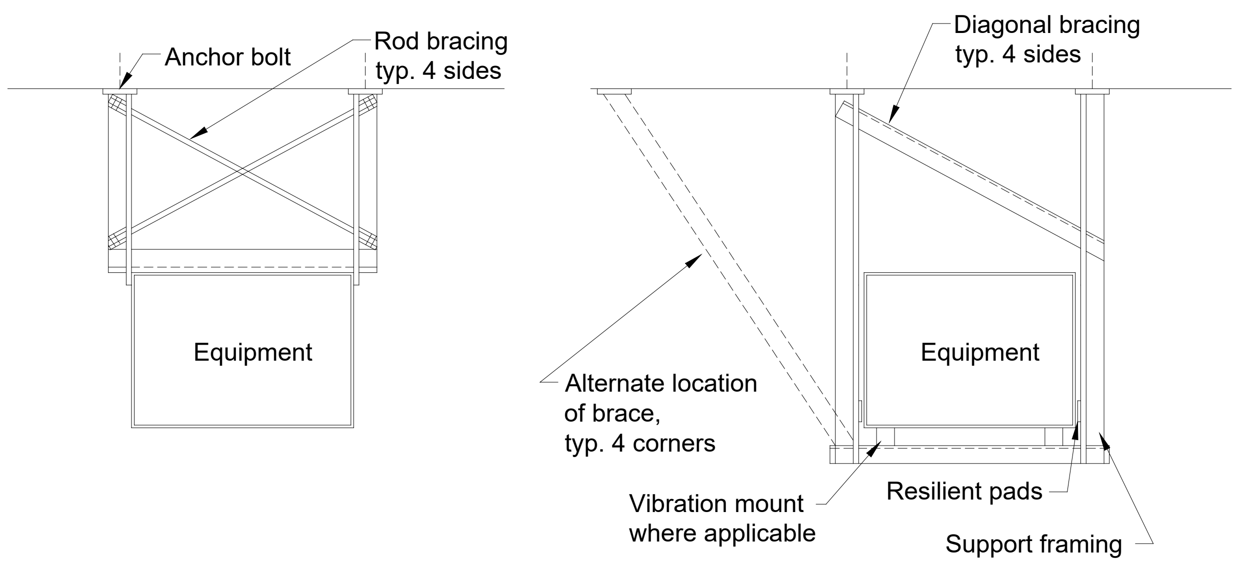


Note: For flexibly mounted equipment requiring special certification per ASCE 7-22 Section13.2.3, where shake table testing provides the basis for certification, testing must be done on equipment including the flexible mount as specified for a project.

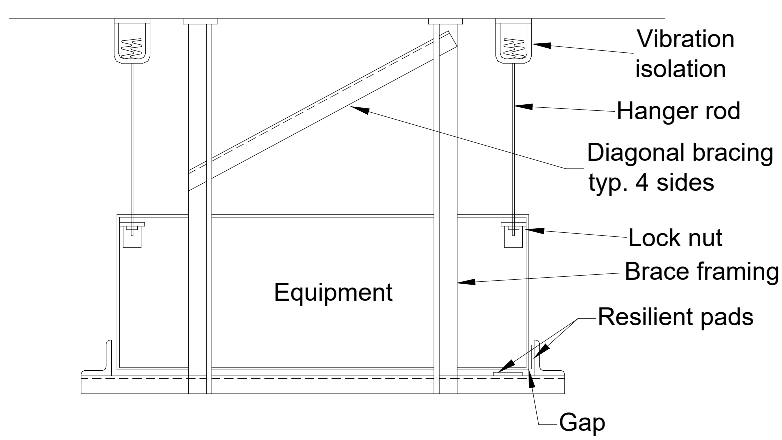
C-3.1.2 Suspended Equipment.

Seismic bracing for suspended equipment may use the bracing recommendations and details in ANSI/SMACNA 001-2008, *Seismic Restraint Manual: Guidelines for Mechanical Systems*, 3rd Edition. Trapeze-type hangers should be secured with not less than two bolts. Figure C-4 shows typical seismic restraints for suspended equipment.

Figure C-4. Typical Seismic Restraints for Suspended Equipment



SUSPENDED EQUIPMENT



SUSPENDED EQUIPMENT WITH VIBRATION MOUNT

C-3.1.3 Supports and Attachments for Piping.

Seismic supports required in accordance with ASCE 7-22-Section 13.6.7, Distribution Systems: Piping and Tubing Systems, should be designed in accordance with the following guidance. This piping is not constructed in accordance with ASME B31 or NFPA 13.

C-3.1.3.1 General.

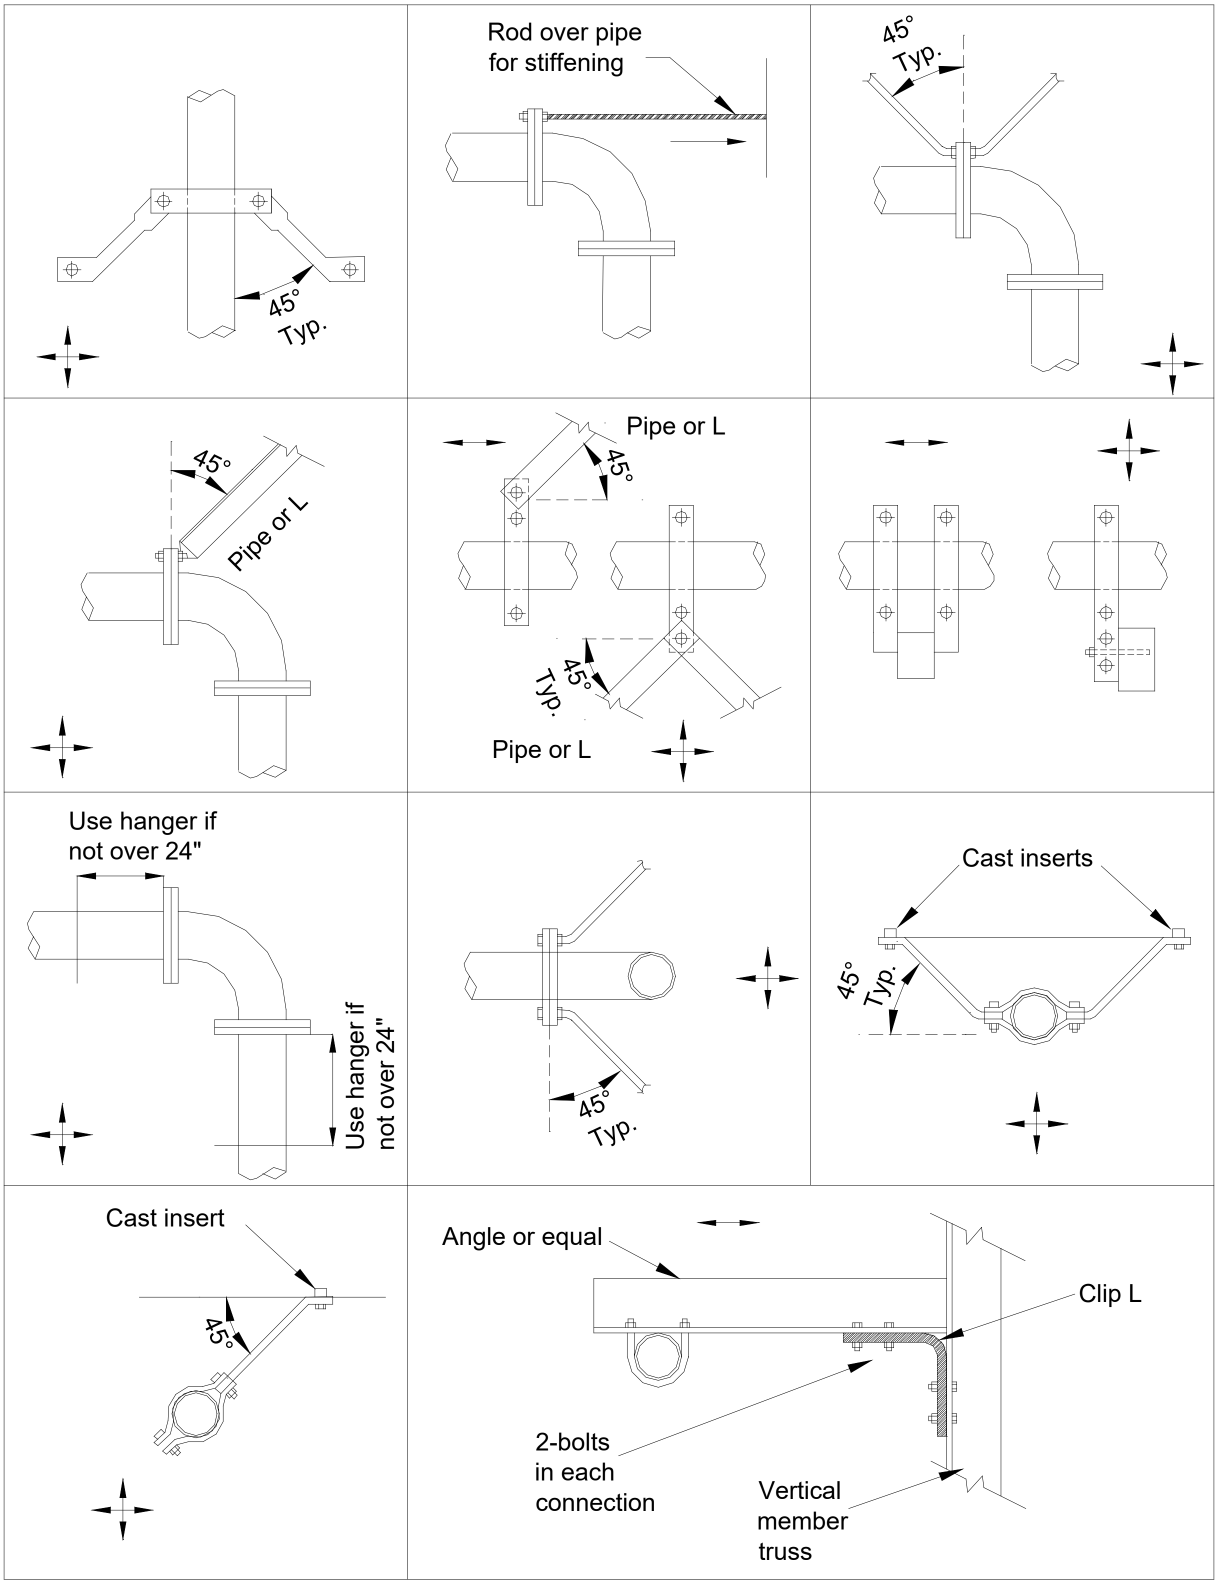
The provisions of this section apply to all risers and riser connections; all horizontal pipes and attached valves; all connections and brackets for pipes; flexible couplings and expansion joints; and spreaders. The following general guidance applies to these elements:

1. For seismic analysis of horizontal pipes, the equivalent static force should be considered to act concurrently with the full dead load of the pipe, including contents.
2. All connections and brackets for pipes should be designed to resist concurrent dead and equivalent static forces. Seismic forces should be determined from ASCE 7-22 Section 13.3.1. Supports should be provided at all pipe joints unless continuity is maintained. Figure C-5 provides acceptable sway bracing details.
3. Flexible couplings should be provided at the bottoms of risers for pipes larger than 3.5 in. (89 mm) in diameter. Flexible couplings and expansion joints should be braced laterally and longitudinally unless such bracing would interfere with the action of the couplings or joints. When pipes enter buildings, flexible couplings should be provided to allow for relative movement between the soil and the building.
4. Spreaders should be provided at appropriate intervals to separate adjacent pipelines unless pipe spans and clear distances between pipes are sufficient to prevent contact between the pipes during an earthquake.

C-3.1.3.2 Rigid versus Flexible Piping Systems.

Piping systems should be considered either rigid or flexible. The dynamic response of rigid piping systems is assumed to be decoupled from the building's amplified response, so that the component resonance ductility factor factor, C_{AR}, is set to 1.0. It is assumed that flexible pipes may couple with and further amplify building motion. Designers are encouraged to use high-deformability pipe systems that may permit longer pipe support spacing. It should be noted that when high-deformability pipe systems, which have the larger R_{po} values, are used (e.g., welded steel pipe systems), F_p, may be limited by the minimum value set forth by ASCE 7-22 Equation 13.3-3. Forces based on ASCE 7-22 Equation 13.3-3 may also govern for pipes installed in lower levels of a building.

Figure C-5. Acceptable Seismic Details for Pipe Sway Bracing



C-3.1.3.2.1 Rigid Piping System.

A piping system is assumed rigid if its maximum period of vibration is no more than 0.06 second (ASCE 7-22-Section 11.2 definition for Component, rigid). ASCE 7-16 Table 13.6-1 Footnote 1 used to indicate that a_p equals 1.0 for rigid pipes, where the support motions are not amplified. Rigid and rigidly attached pipes should be designed in accordance with ASCE 7-22 Equation 13.3-1, where W_p is the weight of the pipes, their contents, and attachments. Forces should be distributed in proportion to the total weight of pipes, contents, and attachments.

Tables C-1, C-2, and C-3 may be used to determine allowable span-diameter relationships for rigid pipes; standard (40S) pipe; extra strong (80S) pipe; types K, L, and M copper tubing; and 85 red brass or SPS copper pipe in RC IV buildings. These tables are based on water-filled pipes with periods equal to 0.06 second. Figures C-6, C-7, and C-8 display support conditions for Tables C-1, C-2, and C-3, respectively. The relationship used to determine maximum pipe lengths, L, shown in the tables, that will result in rigid pipes having a maximum period of vibration of 0.06 seconds, is given in Equation C-1 (which is excerpted from the *Shock and Vibration Handbook*, 6th Edition, 2009):

$$L = \sqrt{C \pi T_a \sqrt{\frac{EI_g}{w}}} \text{, in. or mm} \qquad \textbf{(Equation C-1)}$$

where

C = period constant, equal to 0.50 for pinned-pinned pipes; 0.78 for fixed- pinned pipes; and 1.125 for fixed-fixed pipes

T_a = natural period of pipe in its fundamental mode, set equal to 0.06 second

E = modulus of elasticity of pipe, psi or MPa

I = moment of inertia of pipe, in^4 or mm^4

w = weight of pipe and contents per unit length, lb/in. or N/mm

C-3.1.3.2.2 Flexible Piping Systems.

Piping systems that do not comply with the rigidity requirements of Section C-3.1.3.2.1 (i.e., period less than or equal to 0.06 second) should be considered flexible (i.e., period greater than 0.06 second). Flexible piping systems should be designed for seismic forces with consideration given to both the dynamic properties of the piping system and the building or structure in which it is placed. In lieu of a more detailed analysis, equivalent static lateral force may be computed using ASCE 7-22 Equation 13.3-1, with $\left[\frac{C_{AR}}{R_{po}}\right]$ = 2.5. The forces should be distributed in proportion to the total weight of pipes, contents, and attachments. If the weight of attachments is greater than 10% of pipe weight, attachments should be separately braced, or substantiating calculations should be required. If temperature stresses are appreciable, substantiating calculations should be required. The following guidance should also be followed for flexible pipe systems:

1. Separation between pipes should be a minimum of four times the calculated maximum displacement due to F_p, but not less than 4 in. (102 mm) clearance between parallel pipes, unless spreaders are provided.

2. Clearance from walls or rigid elements should be a minimum of three times the calculated displacement due to F_p, but not less than 3 in. (76 mm) clearance from rigid elements.

3. If the provisions of the above paragraphs appear to be too severe for an economical design, alternative methods based on rational and substantial analysis may be applied to flexible piping systems.

4. Acceptable seismic details for sway bracing are shown in Figure C-5.

C-3.2 Stacks (Exhaust) Associated with Buildings.

Reference should me made to ASCE 7-22 Section 13.6, as modified by Section 13.6.1 of Chapter 3 of this UFC, and ASCE 7-22 Chapter 15.

C-3.2.1 General.

Stacks are actually vertical beams with distributed mass and, as such, cannot be modeled accurately by single-mass systems. This design guidance applies to either cantilever or singly-guyed stacks attached to buildings. When a stack foundation is in contact with the ground and the adjacent building does not support the stack, it should be considered to be a nonbuilding structure (see ASCE 7-22 Chapter 15). This guidance is intended for stacks with a constant moment of inertia. Stacks having a slightly varying moment of inertia should be treated as having a uniform moment of inertia with a value equal to the average moment of inertia.

Stacks that extend more than 15 ft (4.6 m) above a rigid attachment to the supporting building should be designed according to the guidance for cantilever stacks presented in Section C-3.2.2 of this UFC. Stacks that extend less than 15 ft (4.6 m) should be designed for the equivalent static lateral force defined in ASCE 7-22 Section 13.3.1 using the C_{AR} and R_{po} values in ASCE 7-22 Table 13.6-1.

Stacks should be anchored to supporting buildings using long anchor bolts (where bolt length is at least 12 bolt diameters). Much more strain energy can be absorbed with long anchor bolts than with short ones. The use of long anchor bolts has been demonstrated to give stacks better seismic performance. A bond-breaker material should be used on the upper portion of the anchor bolt to ensure a length of unbonded bolt for strain energy absorption. Two nuts should be used on anchor bolts to provide an additional factor of safety.

C-3.2.2 Cantilever Stacks.

The fundamental period of a cantilever stack should be determined from the period coefficient (e.g., C = 0.0909) provided in Figure C-9, unless actually computed. The equation and the period coefficients, C, shown in Figure C-9 were derived from the *Shock and Vibration Handbook* (6th Edition, 2009). Dynamic response of ground-supported stacks may be calculated from the appropriate base shear equations for the Equivalent Lateral Force Procedure defined in ASCE 7-22 Section 12.8.

C-3.2.3 Guyed Stacks.

Analysis of guyed stacks depends on the relative rigidities of the cantilever component and the guy cable support system. If a cable is relatively rigid compared to the cantilever component, the stack should respond in a manner similar to the higher modes of vibration of a cantilever, with periods and mode shapes similar to those shown in Figure C-9. The fundamental period of vibration of the guyed system should be somewhere between the values for the fundamental and the appropriate higher mode of a similar cantilever stack. An illustration for a single guyed stack is shown in Figure C-10. Guyed stacks should be designed with rigid cables so that the true deflected shape is closer to that shown on the right side of Figure C-10. This requires pretensioning of guy cables to a minimum of 10 percent of stack seismic forces, F_p. Design for guyed stacks is beyond the scope of this document. However, some guidance may be found in TIA-222-I, *Structural Standard for Antenna Supporting Structures, Antennas and Small Wind Turbine Support Structures,* September 2023.

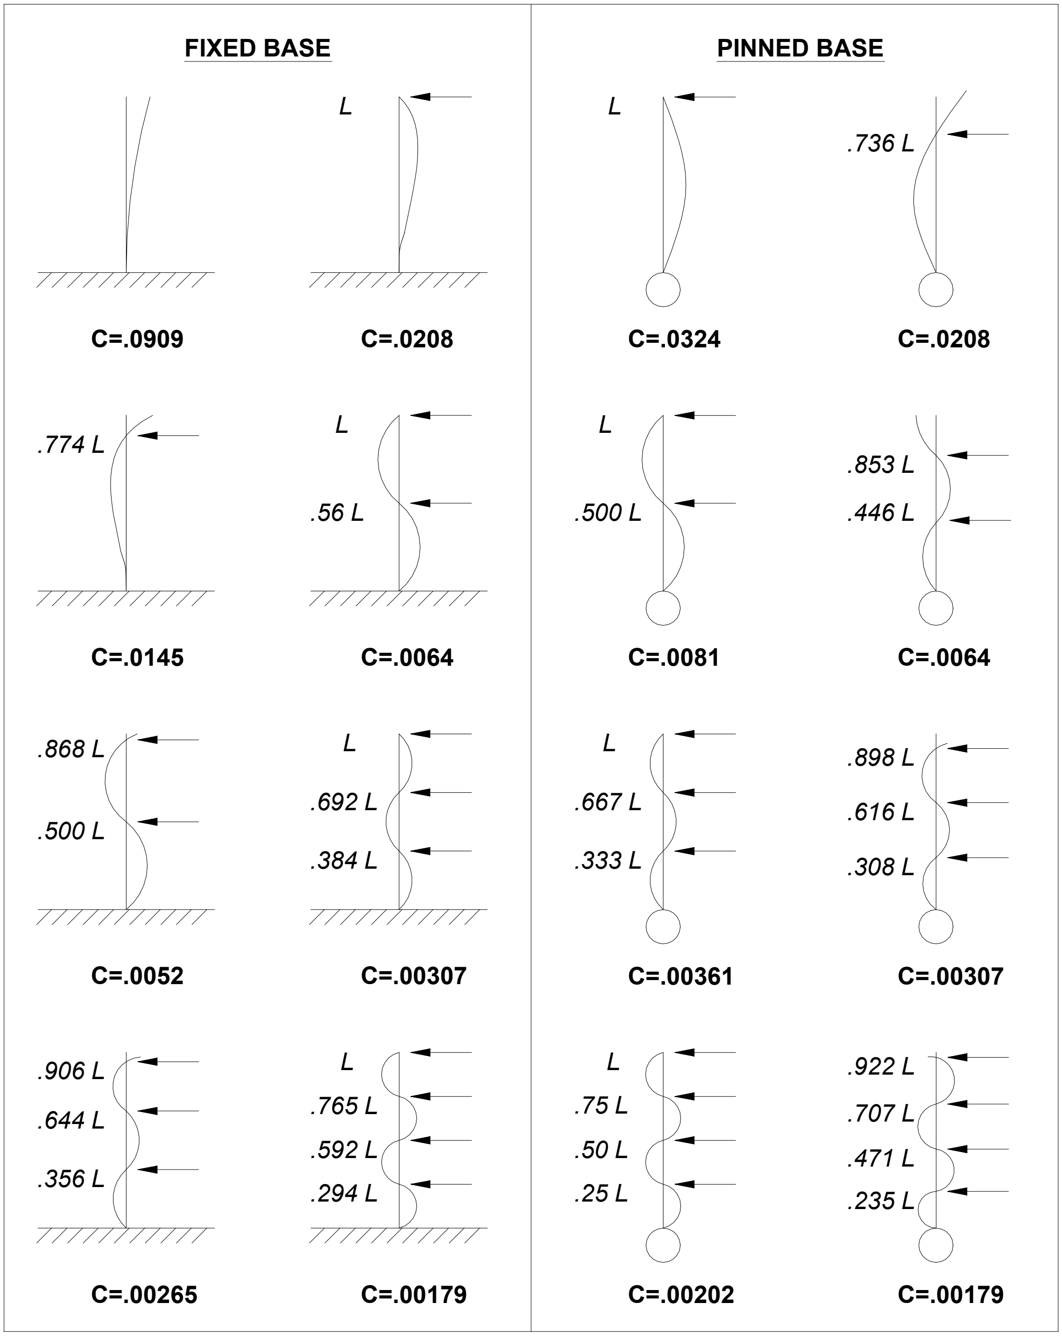
C-3.3 Elevators.

Reference should be made to ASCE 7-22 Section 13.6.11, Elevator and Escalator Design Requirements, as modified by Section 13.6.11.3 of Chapter 3 of this UFC.

C-3.3.1 General.

Elevator car and counterweight frames, roller guide assemblies, retainer plates, guide rails, and supporting brackets and framing (Figure C-11) should be designed in accordance with ASCE 7-22 Section 13.6.11. Lateral forces acting on guide rails should be assumed to be distributed one-third to top guide rollers and two- thirds to bottom guide rollers of elevator cars and counterweights. An elevator car and/or counterweight should be assumed to be located at its most adverse position in relation to its guide rails and support brackets. Horizontal deflections of guide rails should not exceed 1/2 in. (12.7 mm) between supports, and horizontal deflections of the brackets should not exceed 1/4 in. (6.4 mm).

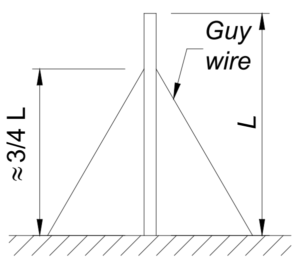
Figure C-9. Period Coefficients for Uniform Beams

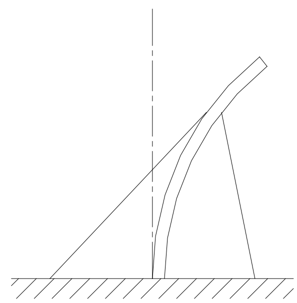


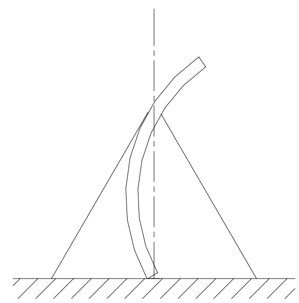
$$T_a = C\sqrt{\frac{wL^4}{EI}}$$

T_a = Fundamental period (sec)
w = Weight per unit length of beam (lb/in) (N/mm)
L= Total beam length (in) (mm)
I = Moment of inertia (in^4) (mm^4)
E = Modulus of elasticity (psi) (MPa)
C = Period constant

Figure C-10. Single Guyed Stacks

DESCRIPTION	DEFLECTED SHAPE	
	FLEXIBLE WIRE	RIGID WIRE
		






C-3.3.2 Retainer Plates.

In structures assigned to SDC D, E, and F, clearances between the machined faces of rail and retainer plates should not be more than 3/16 in. (4.8 mm), and the engagement of a rail should not be less than the dimension of its machined side face. When a car safety device attached to lower members of a car frame complies with lateral restraint requirements, a retainer plate is not required for the bottom of the car.

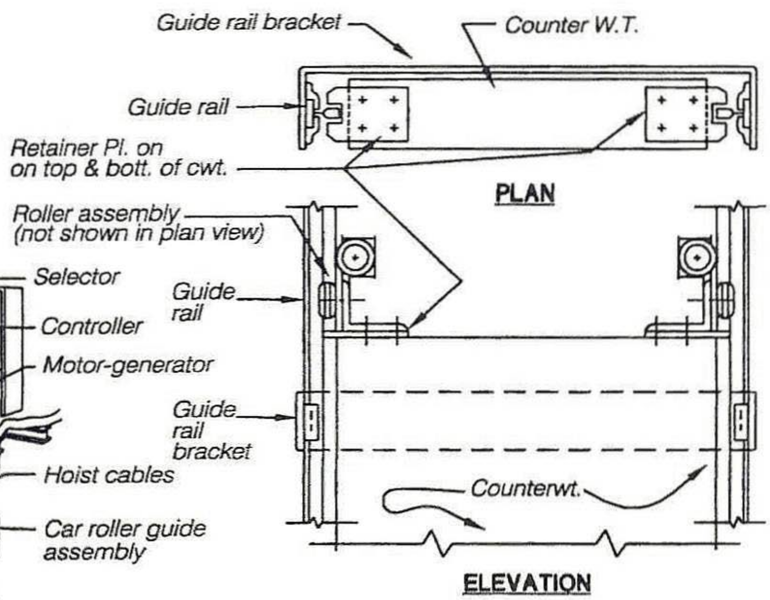
C-3.3.3 Counterweight Tie Brackets.

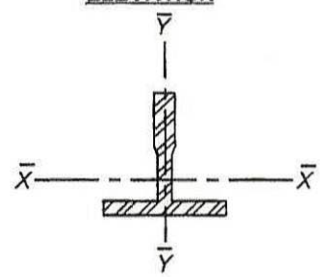
In structures assigned to SDC D, E, and F, the maximum spacing of counterweight rail tie brackets tied to a building structure should not exceed 16 ft (4.9 m). An intermediate spreader bracket, which is not required to be tied to a building structure, should be provided for tie brackets spaced greater than 10 ft (3.0 m), and two intermediate spreader brackets are required for tie brackets spaced greater than 14 ft (4.3 m).

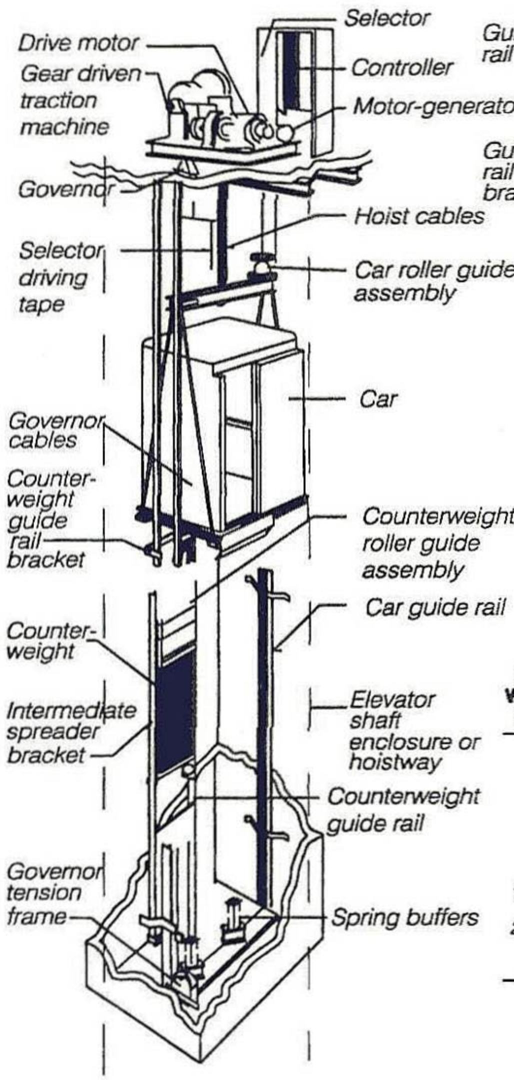
C-3.3.4 Force Calculation.

Elevator machinery and equipment should be designed for $\left[\frac{C_{AR}}{R_{po}}\right]$ = 1.0 in ASCE 7-22 Equation 13.3-1, when rigid and rigidly attached. Non-rigid or flexibly mounted equipment (which has a period greater than 0.06 second) should be designed with $\left[\frac{C_{AR}}{R_{po}}\right]$ = 2.5.

Figure C-11. Elevator Details







TRACTION TYPE ELEVATOR

Section Properties of Elevator Guide Rails

Nom. Wt. per Foot	A	$\bar{y}$	I_x	S_x	r_x	I_y	S_y	r_y

A = Area (in.^{2})
$\bar{y}$ = Distance from back of rail to axis x-x (in.)
I_x = Moment of inertia about axis x-x (in.^{4})
S_x = Section modulus about axis x-x (in.^{3})
r_x = Radius of gyration about axis x-x (in.)
I_y = Moment of inertia about axis y-y (in.^{4})
S_y = Section modulus about axis y-y (in.^{3})
r_y = Radius of gyration about axis y-y (in.)

C-3.4 Lighting Fixtures in Buildings

Reference should be made to ASCE 7-22 Sections 13.2.5 Testing Alternative for Seismic Capacity Determination, 13.5.6 Suspended Ceilings, 13.6.1 General, 13.6.2 Mechanical Components, 13.6.3 Electrical Components, and 13.6.4 Component Supports as modified by Chapter 3 of this UFC in the Sections 13.5.6, 13.6.1, 13.6.2, 13.6.3, and 13.6.4.

C-3.4.1 General.

Lighting fixtures, including their attachments and supports, in SDC C, D, E, and F buildings should conform to the following materials and construction requirements:

1. Fixture supports should use materials that are suitable for that purpose. Cast metal parts, other than those of malleable iron, and cast or rolled threads, should be subject to special investigation to ensure structural adequacy.
2. Loop and hook or swivel hanger assemblies for pendant fixtures should be fitted with restraining devices to hold their stems in the support position during earthquake motions. Pendant-supported fluorescent fixtures should also be provided with flexible hanger devices at their attachments to the fixture channel to preclude breaking of the support. Motions of swivels or hinged joints should not cause sharp bends in conductors or damage to insulation.
3. A supporting assembly that is intended to be mounted on an outlet box should be designed to accommodate mounting features on 4 in. (102 mm) boxes, 3 in. (76 mm) plaster rings, and fixture studs.
4. Each surface-mounted individual or continuous row of fluorescent fixtures should be attached to an earthquake-resisting ceiling support system. Support devices for attaching fixtures to suspended ceilings should be locking-type scissor clamps or full loop bands that will securely attach to the ceiling support. Fixtures attached to the underside of a structural slab should be properly anchored to the slab at each of their corners.
5. Each wall-mounted emergency light unit should be secured in a manner that will hold the unit in place during a seismic disturbance.

C-3.5 Bridges, Cranes, and Monorails.

Reference should be made to ASCE 7-22 Section 13.6 Mechanical and Electrical Component, as modified by Chapter 3 of this UFC in the Sections 13.6.14 Bridges, Cranes, and Monorails and 13.6.14.1 Bridges, Cranes, and Monorails for RC IV Buildings and 2024 IBC Section 1607.15.

C-3.5.1 General.

2024 IBC Section 1607.15 provides live load design guidance for cranes. Vertical restraints should be provided to resist crane uplift. Experience has shown that vertical ground motions can be amplified significantly in either crane bridges or crane rail support brackets that are cantilevered from columns. Analysis of cranes should consider their amplified response in the vertical direction, in addition to horizontal response. The criteria in Section 13.6.14 in Chapter 3 of this UFC specify C_{AR} of 1.5 and R_{po} of 1.5, resulting in $c\left[\frac{C_{AR}}{R_{po}}\right]$=1.0 in the direction parallel to crane rails, because a crane bridge would almost certainly be flexible enough along its weak axis to have a natural period greater than 0.06 seconds. The C_{AR} factor is greater than 1.0 because, at large natural periods, a crane bridge can be expected to amplify ground and building motions. This factor has a value of 1.0 perpendicular to crane rails because the bridge would be loaded axially in this direction, resulting in a natural period that is less than 0.06 second. The crane bridge is considered to be rigid when loaded axially, so that it will not amplify ground or building motions. When a crane is not in the locked position, it is reasonable to assume that upper bound forces in the direction parallel to crane rails, between the wheels and the rails, cannot exceed a conservative estimate of the force that could be transmitted by friction between the brake wheels and rails.

This Page Intentionally Left Blank

APPENDIX D MECHANICAL AND ELECTRICAL COMPONENT CERTIFICATION

D-1 COMPONENT CERTIFICATION.

D-1.1 General.

The background to mechanical and electrical component certification is explained in *Special Seismic Certification of Nonstructural Components* (Tobolski, M., Structural Engineering and Design, 2011).

ASCE 7-22 Section 13.2 states that certification must be by analysis, testing or experience data. Mechanical and electrical equipment that must remain operable following the design earthquake ground motion must be certified based on shake table testing or experience data unless it can be shown that the component is inherently rugged by comparison with similar seismically qualified components (Section 13.2.3). ASCE 7-22 Section 13.2.3 Item 2 states that "Components with hazardous substances and assigned a component Importance Factor, I_p, of 1.5 in accordance with Section 13.1.3 shall be certified by the manufacturer as maintaining containment following the design earthquake ground motion by (a) analysis, (b) approved shake table testing in accordance with Section 13.2.6, or (c) experience data in accordance with Section 13.2.7."

HCAI has issued a Policy Intent Notice (PIN) 55 on its Special Seismic Certification Preapproval (OSP) program. This program offers a means to obtain prequalification of product lines for special seismic certification. The details of this program can be found at https://hcai.ca.gov/wp-content/uploads/2022/08/PIN-55_Special-Seismic-Certification-Preapproval-OSP_080322_A-1.pdf. Lists of equipment that is pre-approved by HCAI can be found at https://hcai.ca.gov/construction-finance/preapproval-programs/hcai-special-seismic-certification-preapproval-osp-by-category/. The basis of HCAI preapproval always is shake table testing in compliance with ICC-ES AC156 and satisfaction of ICC-ES AC156 post-test acceptance criteria.

References in this appendix are made to ASCE 7-22 Section 13.2, General Design Requirements, and Chapter 3 of this UFC Section 13.2.3.

D-1.1.1 Analytical Certification.

Certification based on analysis, as noted in ASCE 7-22 Section 13.2.3 Item 3, requires a reliable and conservative understanding of the equipment configuration, including the mass distribution, strength, and stiffness of the various subcomponents. From this information, an analytical model may be developed that reliably and conservatively predicts the equipment dynamic response and potential controlling modes of failure. If such detailed information on the equipment or a basis for conservative estimates of these properties is not available, then methods other than analysis must be used. The use of analysis for active or energized components is not permitted (see ASCE 7-22 Section 13.2.3 Item 1). Examples of active designated seismic equipment include mechanical (components of HVACR systems and piping systems) or electrical (power supply distribution) equipment, medical equipment, fire pump equipment, and uninterruptible power supplies for hospitals. Any analytical qualification of equipment should be peer-reviewed independently by qualified, Registered Design Professionals.

D-1.1.2 Certification Based on Testing.

Shake table tests conducted in accordance with either ICC-ES AC156, *Acceptance Criteria for Seismic Qualification by Shake-Table Testing of Nonstructural Components,* or a site-specific study, should first use uniaxial motions along each of the three principal axes of the equipment that is being tested. The measured response recorded with vibration response monitoring instrumentation should be reviewed to determine if out-of-plane response (in terms of peak amplitude) at a given location of instrumentation exceeds 20% of the in-plane response. The in-plane direction is the direction of horizontal test motions, while the out-of-plane direction is at a horizontal angle of 90 degrees with respect to the in-plane axis. An out-of-plane response (equipment relative acceleration or equipment deformation) that exceeds 20% of the in-plane response, for either horizontal test, indicates that significant cross-coupling is occurring. In that case, the final qualification test should be triaxial, with simultaneous phase-incoherent motions along all three principal axes. If out-of-plane response is less than 20% of the in-plane response for both horizontal tests, at each critical location instrumented, then the final qualification tests can be biaxial with motions in one horizontal and the vertical directions. After post-test inspection and functional compliance verification, the Unit Under Test (UUT) may be rotated 90 degrees about the vertical axis and biaxial testing for the other horizontal direction and vertical direction can be conducted. Normally, two biaxial tests, rather than a single triaxial test, would be conducted when a triaxial shake table is not available or the displacement capacity of a triaxial shake table in one direction is small.

The development of ICC-ES AC156 is documented in *ASCE Structures Congress Proceedings: Background on the Development of the NEHRP Seismic Provisions for Non-Structural Components and their Application to Performance Based Seismic Engineering* (Gillengerten, J.D., and Bachman, R.E., ASCE Structures Congress, 2003). For RC V facilities, the site-specific seismic site response analysis will result in a set of site-specific ground motions that define the seismic hazard. The building model could be analyzed with these motions to define predicted time-history motions at each location where critical equipment must be installed. From these building response motions, response spectra could be developed, using 5% of critical damping. If the equipment will be placed at several locations in the same building or in multiple buildings, a required response spectrum (RRS) could be developed that envelopes all the spectra generated from each building response record. As an alternative to the ICC-ES AC156 procedure, the equipment could be qualified with triaxial motions fit to the RRS, but generated according to ICC-ES AC156. A second alternative approach would be to test with the predicted time history motions that have the greatest response spectra amplitude at the measured natural frequency of the equipment in each of the principal directions. Using worst-case records would require that resonance search shake table tests be conducted in each of the three principal directions as defined in ICC-ES AC156. All alternatives to ICC-ES AC156 equipment qualification testing require peer review of the development of test records and test plans by qualified, Registered Design Professionals. Post-test inspection and functional compliance verification would still be required in accordance with ICC-ES AC156.

D-1.1.3 Additional Certification Methods.

Three additional methods are permitted for defining equipment capacity: earthquake experience data, seismic qualification testing data, and the CERL Equipment Fragility and Protection Procedure. The use of these methods requires a peer review by a qualified, Registered Design Professional.

D-1.1.3.1 Earthquake Experience Data.

Earthquake experience data that were obtained by surveying and cataloging the effects of strong ground motion earthquakes on various classes of equipment mounted in conventional power plants and other industrial facilities may be used. Section 4.2.1 of the publication *Generic Implementation Procedure (GIP) for Seismic Verification of Nuclear Plant Equipment* (DOE 1992) provides these data. Based on this work, a Reference Spectrum would be developed to represent the seismic capacity of equipment in the earthquake experience equipment class. DOE/EH-0545, *Seismic Evaluation Procedure for Equipment in U.S. Department of Energy Facilities*, provides guidance on this procedure. A detailed description of the derivation and use of this Reference Spectrum is contained in DoE publication SAND92-0140, *Use of Seismic Experience Data to Show Ruggedness of Equipment in Nuclear Power Plants*. This document should be reviewed before using the Reference Spectrum. The Reference Spectrum and four spectra from which it is derived are shown in Figure 5.3-1 of DOE/EH-0545. The Reference Spectrum and its defining response levels and frequencies are shown in Figure 5.3-2 of the same document. When this approach is used, the Reference Spectrum is used to represent the seismic capacity of equipment, when the equipment is determined to have characteristics similar to the earthquake experience equipment class and meets the intent of the caveats for that class of equipment as defined in Chapter 8 of DOE/EH-0545.

D-1.1.3.2 Seismic Qualification Testing Database.

Data collected from seismic qualification testing of nuclear power plant equipment may be used in the certification of equipment. These data were used to develop generic ruggedness levels for various equipment classes in the form of Generic Equipment Ruggedness Spectra (GERS). The development of the GERS and the limitations on their use are documented in Electric Power Research Institute (EPRI) report NP-5223, *Generic Seismic Ruggedness of Power Plant Equipment in Nuclear Power Plants*. The non-relay GERS and limitations on their use are discussed in Chapter 8 of DOE/EH-0545, while the relay GERS are in Chapter 11 of the same document. The EPRI report should be reviewed by users of the GERS to understand the basis for them. The use of either the Reference Spectrum or the GERS for defining equipment capacity requires careful review of the basis for them to ensure applicability to the equipment being evaluated.

D-1.1.3.3 CERL Equipment Fragility and Protection Procedure.

The CERL Equipment Fragility and Protection Procedure (CEFAPP), defined in USACERL Technical Report 97/58, may be used for defining equipment capacity. Similar to the other methods, CEFAPP defines a response spectrum envelope of the equipment capacity. This method requires a series of shake table tests to develop an actual failure envelope across a frequency range. This experimental approach requires greater effort than the ICC-ES AC156 qualification testing. However, the resulting failure envelope provides a more accurate and complete definition of capacity, rather than simply determining that the equipment survived a defined demand environment. Unlike the AC156 procedure, site-specific testing, or the other two additional methods, CEFAPP defines actual equipment capacity and provides information on modes of failure with respect to response spectra amplitudes and frequency of motion. Definitions of equipment capacity are more accurate with respect to frequency and mode of failure than can be established using the alternative methods. When equipment capacity is compared with the seismic demands at the various locations in which the equipment must be installed, the equipment vulnerability, if any, can be clearly defined in terms of predicted mode of failure and frequency. The procedure provides information on how to protect the equipment, using isolation, strengthening, or stiffening. The use of CEFAPP requires peer review of proposed test motions, the test plan, and use of the data, by qualified Registered Design Professionals.

D-1.1.3.4 Qualification of Power Substation Equipment.

IEEE Recommended Practice for Seismic Design of Substations (IEEE 693-2018) provides detailed guidance for the qualification of equipment used in power substations. This guidance should be used for the qualification of this equipment even if installed at facilities other than substations (e.g., power plants).

APPENDIX E MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_O, AND MINIMUM CONCENTRATED LIVE LOADS

E-1 REFERENCES.

All section references are to the 2024 International Building Code (2024 IBC). Table E-1 includes 2024 IBC Table 1607.1 with additional Occupancy or Use classification for military facilities that are shown in bold italics.

Notes to Table E-1, "Minimum Uniformly Distributed Live Loads, L_o, and Minimum Concentrated Live Loads"

For SI: 1 inch = 25.4 mm, 1 square inch = 645.16 mm^2, 1 square foot = 0.0929 m^2, 1 pound per square foot = 0.0479 kN/m^2 = 0.0479 kPa, 1 pound = 0.004448 kN, 1 pound per cubic foot = 16 kg/m^3.

a. Where snow loads occur that are in excess of the design conditions, the structure must be designed to support the increased loads caused by drift buildup or greater snow loads determined by the *AHJ*. (See IBC Section 1608).

b. See IBC Section 1604.8.3 for decks attached to exterior walls.

c. Areas of occupiable roofs, other than roof gardens and assembly areas, be designed for appropriate loads as approved by the *AHJ*. Unoccupied landscaped areas of roof be designed in accordance with IBC Section 1607.13.3.

d. Live load reduction is not permitted.

e. Live load reduction is only permitted in accordance with Section 1607.13.1.2 or Item 1 of Section 1607.13.2.

f. Live load reduction is only permitted in accordance with Section 1607.13.1.3 or Item 2 of Section 1607.13.2.

g. Helipads supporting military aircraft must be designed to support the actual aircraft weight and impact loading due to landing.

h. All attics with mechanical units must be designed for mechanical equipment room loading.

i. For live loads on pedestrian bridges see AASHTO LRFD *Guide Specifications for the Design of Pedestrian Bridges.*

j. **\4** *High density data center rack space should be verified for each project as these systems are rapidly evolving and have been known to exceed 400psf in some circumstances.* **/4/**

APPENDIX F COMPOSITES FOR BRIDGING APPLICATIONS [ADDITION]

F-1 INTRODUCTION.

F-1.1 Purpose and Scope.

This Appendix provides design resources to structural engineers interested in using polymer composite technologies for bridge applications. This Appendix is not intended to provide requirements for design and construction. Fiber reinforced polymer (FRP) composite materials and systems are now available that are not necessarily covered by the current AASHTO LRFD Bridge Design Specifications, but which may have performance and cost benefits in the repair and major rehabilitation and replacement of existing highway bridges within the DoD. This Appendix provides design considerations for polymer composites, references to guide specifications published by AASHTO, ACI, ASCE, FHWA, and case studies published by FHWA and USACE. The fiber reinforced polymer (FRP) technologies covered in this Appendix include glass FRP composite reinforcing bars, carbon FRP composite prestressing systems, FRP composite external strengthening and repair systems, and FRP composite elements including bridge piles and bridge decks. This appendix also includes information on thermoplastic materials for replacement of timber bridges including thermoplastic lumber, thermoplastic piles, and thermoplastic I-beams.

F-1.2 Applicability.

This Appendix applies only to polymer composite technologies for bridge applications. The guide specifications referenced herein are not intended to supplant proper training or the exercise of judgment by the Design Professional and state only the minimum requirements necessary to provide for public safety. The Design Professional may require the sophistication of the design or the quality of materials and construction to be higher than the minimum requirements. The Design Professional should be familiar with the provisions of the *AASHTO LRFD Bridge Design Specifications* and latest interim specifications. The decision to implement polymer composite technologies not currently covered by guide specifications should be made in consultation with the Service's lead Structural Engineering POC. This consultation is to ensure less developed technologies are implemented successfully.

F-1.3 Overview of Appendix.

Brief descriptions of the various sections of this appendix follow:

- F-2 – GENERAL. Provides a brief background on thermoset FRP composites and thermoplastic composites.
- F-3 – THERMOSET FRP COMPOSITE TECHNOLOGIES. Provides general design considerations for the use of thermoset FRP composites and reference to guide specifications and case studies for thermoset FRP composite technologies for bridge applications including non-prestressed

and prestressed concrete reinforcement, external strengthening systems for concrete, and FRP bridge elements including piles and decks.

- F-4 – THERMOPLASTIC TECHNOLOGIES. Provides general considerations for the use of thermoplastic technologies and reference to specification when available and case studies for thermoplastic technologies as replacement for timber bridge elements including dimensional lumber, piles, and beams.
- F-5 – REFERENCES. Lists the references included in this Appendix.
- F-6 – ABBREVIATIONS. Lists the abbreviations used in this Appendix.

F-2 GENERAL.

Composite materials are by definition a combination of two or more materials that differ in form and composition on the macro scale. The individual components maintain their phase and are not merged or melted into a new state. The result is an engineered material with desirable characteristics derived from the mechanical properties of the components. Composite materials have been used as construction materials for decades in the form of reinforced concrete and laminated timber products. Beginning in the 1960s, advances in material processing and the need for more durable materials led to the emergence of FRP composite materials.

The fiber reinforcement in an FRP composite provides the primary strength and stiffness while the polymer matrix transfers loads between fibers, ensures proper fiber alignment, and provides protection from environmental effects. Three types of fiber commonly used include glass, aramid, and carbon. Glass is the least expensive with lower strength and stiffness compared to carbon or aramid. Carbon is typically the most expensive with the highest strength and stiffness. As a general rule of thumb, carbon fiber can be around six to ten times as expensive as glass fiber. The fiber reinforcement can take the form of either continuous strands or woven/stitched fabrics.

The two broad families of polymers used are thermosets and thermoplastics. Thermosets are more commonly used in FRP composites due to their low curing temperature, workability, flowability, and resistance to creep, compared to thermoplastics. Thermosets cure by forming long hydrocarbon chains joined by crosslinking covalent bonds through a chemical reaction. Once formed, they cannot be melted or reformed by heat. Thermoplastics are composed of long hydrocarbon chains that are not chemically bonded through crosslinking and can move with respect to each other. Thermoplastic materials typically have high ductility and lower strength than thermoset composites and can be melted and reshaped by temperature. Due to these fundamental differences in chemical structure and mechanical behavior, this Appendix is divided into thermoset FRP composites (Section F-3) and thermoplastic materials (Section F-4).

F-3 THERMOSET FRP COMPOSITE TECHNOLOGIES.

F-3.1 Thermoset FRP Composite Design Considerations.

The following design considerations for thermoset FRP composites are not intended to be comprehensive but are to alert the reader that thermosetting FRP composite materials require different considerations than traditional construction materials. More information on design considerations can be found in the publications referenced throughout F-3.2.

F-3.1.1 Anisotropic behavior.

Thermoset FRP composite materials are anisotropic with strength properties highly dependent on fiber architecture. Composites have higher strengths in the primary direction of the fibers with lower strengths in the transverse direction. Composites with fibers oriented primarily in one direction are called unidirectional composites. Unidirectional composites are used primarily in tension as they have a lower compressive strength compared to tensile strength. As a result of this lower compressive strength, design philosophies for FRP reinforcement and external strengthening systems for concrete do not rely on the contribution of unidirectional composites in compression. FRP composites can also be designed with fiber architectures that orient fibers in multiple directions. This allows composites to be optimized for loading conditions. Multidirectional composite shapes will generally have higher strengths in tension than in compression.

F-3.1.2 Stiffness and ductility.

Glass FRP composites have a stiffness of around 5,000 ksi to 7,000 ksi and a much lower ductility than steel. This lower stiffness results in the majority of glass FRP composite designs being controlled by serviceability criteria rather than strength. Carbon FRP composites can have strength and stiffness that exceed certain grades of steel but have low ductility. Both glass and carbon FRP composites display a linear elastic behavior up until failure. This linear elastic behavior coupled with low ductility has led to conservative design criteria for FRP composite reinforcement for concrete, which reinforces the tensile zone to force failure to occur in concrete compression and limits the strain in the tensile bars (limited to around .008). As a result, FRP reinforced concrete will typically be controlled by a failure mode with low ductility. Retrofits and external strengthening systems for concrete are limited to applications where failure of a bonded repair would not result in the catastrophic failure of the structure. The publications cited in F-3.2 provide further discussions on the design guidance developed in light of these behaviors.

F-3.1.3 Creep and fatigue.

Thermoset FRP composites under sustained tensile load can suddenly rupture after a time period called the endurance time. This phenomenon is known as creep rupture or static fatigue rupture. Fatigue loading can also provide similar failure modes. Creep and fatigue rupture are designed for by limiting the sustained and fatigue stresses in FRP composite elements to a percentage of their ultimate strength. The sustained and fatigue stresses in most design criteria are conservatively limited to around 20% of ultimate strength for glass composites, 30% of ultimate strength for aramid composites, and 50% of ultimate strength for carbon composites. Additional information on this topic is provided in the publications in F-3.2. Note that there are gaps in knowledge about the number of load cycles required to cause fatigue due to the effects of load reversals and about the creep response of FRP composite materials for certain applications. Research into these topics is still ongoing.

F-3.1.4 Durability.

Thermoset FRP composites are resistant to rot, insects, and corrosion. They have displayed good durability in highly corrosive environments leading to their applications in chemical storage tanks and as reinforcement in concrete. Ultra-violet (UV) radiation can degrade the polymer matrix, leading to reduced performance. UV degradation is designed for by adding UV-inhibitors to the resin during fabrication and by applying UV-resistant coatings to FRP composites exposed to direct sunlight. Durability considerations are designed for by applying material resistance factors based upon the type of FRP composite, its application, and its exposure conditions. For additional information on the general durability of FRP composites, refer to *ACI 440R Report on Fiber-Reinforced Polymer (FRP) Reinforcement for Concrete Structures*. The durability considerations found in *ACI 440R* apply directly to FRP composite reinforcement for concrete but the concepts discussed are generally applicable to other FRP composite technologies. Note that though thermoset FRP composites in many applications have demonstrated good durability, research into their long term performance is still on-going.

F-3.2 Thermoset FRP Composite Guidance and Case Studies.

The following section describes the most developed thermoset FRP composite technologies including recommended applications, current guide specifications, and case studies.

F-3.2.1 Glass Fiber Reinforced Polymer (GFRP) Reinforcing Bars.

The following applications may be suitable for deformed or sand-coated GFRP reinforcing bars, but the Design Professional should be aware of the design considerations for GFRP reinforcing bars as well as the limitations and applicability of current guidance before selecting GFRP reinforcing bars for any application:

- Reinforcement for normal weight concrete deck slabs, cast-in-place solid slab (longitudinally reinforced), and pre-cast deck bridges

- Reinforcement for normal-weight concrete beams, girders, and diaphragms.

- Reinforcement for normal-weight concrete piles, piers, and footings.

- Reinforcement for normal-weight concrete bridge railing.

F-3.2.1.1 Guidance.

The following guide specifications are available for GFRP concrete reinforcing bars:

- For guidance on the design of concrete bridge members reinforced with GFRP reinforcing bars, refer to *AASHTO LRFD Bridge Design Guide Specifications for GFRP Reinforced Concrete*. The guide specification should be reviewed carefully for its limitations and applicability as GFRP reinforcing bars may not be suitable for certain applications.

- For information on the characteristics and durability of non-prestressed FRP reinforcing bars in concrete, refer to *ACI 440.1R Guide for the Design and Construction of Structural Concrete Reinforced with Fiber-Reinforced (FRP) Bars*.

- For information on test methods to characterize FRP reinforcing bars, refer to *ACI 440.3R Guide Test Methods for Fiber-Reinforced Polymer (FRP) Composites for Reinforcing or Strengthening Concrete and Masonry Structures*.

- For information on construction specification for FRP reinforcing bars, refer to *ACI 440.5 Specification for Construction with Fiber-Reinforced Polymer Reinforcing Bars.*

F-3.2.1.2 Case Studies.

The following resources can be referred to for demonstrations and case studies related to the implementation of GFRP reinforcing bars for concrete bridge elements:

- For a case study on the use of GFRP reinforcing bars in a bridge replacement project completed by Maine DOT, refer to *Maine Demonstration Project: Hotel Road (Littlefields Bridge) Replacement Using Superstructure Slide-In Technology.* The report can be accessed via the following link: https://www.fhwa.dot.gov/bridge/composite/cpdi.cfm

- For a list of projects reports related to GFRP reinforcement, completed through the FHWA Innovative Bridge Research and Construction/Deployment (IBRC/IBRD) Program, refer to the FHWA website accessed through the following link: https://www.fhwa.dot.gov/bridge/composite/str.cfm.

- For a review of the state of the art for GFRP reinforcing bars, refer to *ACI 440R Report on Fiber-Reinforced Polymer (FRP) Reinforcement for Concrete Structures* and ACI CODE-440.11-22: *Building Code Requirements for Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer* (GFRP) *Bars – Code and Commentary*.

F-3.2.2 Carbon Fiber Reinforced Polymer (CFRP) Prestressing Systems.

The following applications may be suitable for CFRP prestressing systems, but the Design Professional should be aware of the design considerations for CFRP prestressing systems as well as the limitations and applicability of current guidance before selecting CFRP prestressing systems for any application:

- Pretensioned reinforcement for normal weight concrete beams.

- Bonded and unbonded internally post-tensioned reinforcement for normal-weight concrete beams.

F-3.2.2.1 Guidance.

The following guide specifications are available for CFRP prestressing systems for concrete beams:

- For guidance on the design of concrete bridge beams prestressed with CFRP systems, refer to *AASHTO Guide Specification for the Design of Concrete Bridge Beams Prestressed with CFRP Systems*. The guide specification should be reviewed carefully for its limitations and applicability as CFRP prestressing systems may not be suitable for certain applications.

- For requirements not specifically addressed in the previously listed publication, refer to *ACI 440.4R Prestressing Concrete Structures with FRP Tendons* for additional information. For additional information on the design philosophy and research needs for CFRP pretensioned systems, also refer to *ACI 440.4R*.

- For additional recommendations for the design of CFRP prestressing systems, refer to the Florida Department of Transportation (FDOT) *Structures Manual Volume 4: Fiber Reinforced Polymer Guidelines (FRPG)*.

F-3.2.2.2 Case Studies.

The following resources can be referred to for demonstrations and case studies related to the implementation of CFRP prestressing systems for concrete bridge beams:

- For a case study on the use of CFRP reinforcement in concrete bridge beams conducted by Virginia Transportation Research Council, refer to *Concrete Beams Prestressed Using Carbon Fiber Reinforced Polymers, Final Report VTCR 19-R29.* The report can be accessed through the following link: https://www.fhwa.dot.gov/bridge/composite/resources.cfm

- For a list of project reports related to CFRP prestressing systems completed through the FHWA Innovative Bridge Research and Construction/Deployment (IBRC/IBRD) Program, refer to the FHWA website accessed through the following link: https://www.fhwa.dot.gov/bridge/composite/str.cfm.

- For a review of the state of the art for CFRP prestressing systems, refer to *ACI 440R Report on Fiber-Reinforced Polymer (FRP) Reinforcement for Concrete Structures* and *ACI 440.4R Prestressing Concrete Structures with FRP Tendons.*

F-3.2.3 FRP External Strengthening Systems.

The following applications may be suitable for FRP repair and strengthening systems but the Design Professional should be aware of the design considerations for FRP repair and strengthening systems as well as the limitations and applicability of current guidance before selecting FRP repair and strengthening systems for any application:

- External reinforcement of concrete flexural members on the tension face to improve flexural strength.
- Wrapping of existing concrete beams and columns to improve shear strength.
- Confinement of reinforced concrete columns to enhance strength and ductility.
- Strengthening of earthquake damaged and seismically deficient structures.

F-3.2.3.1 Guidance.

The following guide specifications are available for FRP external strengthening and repair systems for concrete bridge elements:

- For guidance on the design of FRP systems for repair and strengthening of concrete bridge members, refer to *AASHTO Guide Specifications for Design of Bonded FRP Systems for Repair and Strengthening of Concrete Bridge Elements.* The guide specification should be reviewed carefully for its limitations and applicability as FRP strengthening systems may not be suitable for certain applications.
- For requirements not specifically addressed in the listed publication and for design examples, refer to *ACI 440.2R Guide for the Design and Construction of Externally Bonded FRP Systems for Strengthening Concrete Structures*.
- Note that FDOT *Structures Manual Volume 4*: *FRPG* recommends that carbon be the primary reinforcement for FRP composite systems used in repair or strengthening of concrete. It also recommends that if either a pre-cured laminate or wet layup system is used, the resin and adhesive should be a thermoset epoxy formulation specifically designed to be compatible with the fibers or pre-cured shapes. In wet layup systems, the manual recommends limiting shear and flexural reinforcement to no more than three layers except as required for anchorages.

F-3.2.3.2 Case Studies.

The following resources can be referred to for demonstrations and case studies related to the implementation of FRP external strengthening systems for concrete bridge elements:

- For a state of the art of FRP strengthening systems compiled by FHWA, refer to *Report on Techniques for Bridge Strengthening, FHWA-HIF-18-041.* This report can be accessed through the following link: https://www.fhwa.dot.gov/bridge/composite/cpdi.cfm

- For a list of project reports related to strengthening and damage repair of bridges with FRP strengthening systems completed through the FHWA Innovative Bridge Research and Construction/Deployment (IBRC/IBRD) Program, refer to the FHWA website accessed through the following link: https://www.fhwa.dot.gov/bridge/composite/str.cfm.

F-3.2.4 FRP Structural Bridge Elements.

The following applications may be suitable for FRP bridge elements but the Design Professional should be aware of the design considerations for FRP bridge elements as well as the limitations and applicability of current guidance before selecting FRP bridge elements for any application:

- FRP composite bridge fender systems.

- FRP composite stay-in place formwork for concrete bridge decks.

- Concrete-filled FRP composite tubes for bridge culverts and bearing piles.

- FRP composite bridge decking as replacement for concrete bridge decks.

F-3.2.4.1 Guidance.

The following guide specifications and pre-standards are available for FRP composite bridge elements:

- For guidance on the design of concrete-filled FRP tubes as structural members in bridges, refer to *AASHTO LRFD Guide Specifications for Design of Concrete-Filled FRP Tubes for Flexural and Axial Members*. The guide specifications apply to concrete-FRP composite members only. The limitations of this guide specification should be reviewed before use.

- For information on the design of FRP composite members for pedestrian bridges, refer to *AASHTO Guide Specification for Design of FRP Pedestrian Bridges*. Note that this guide specification is from 2008, refers to the outdated *AASHTO 17th edition*, and is only applicable to pedestrian bridges.

- For information on the design of pultruded structural members, refer to *ASCE Pre-standard for Load & Resistance Factor Design (LRFD) of Pultruded FRP Structures.* Note that this document provides design equations for pultruded structural shapes but is not specifically for bridge applications.

- For information on the design of connections for pultruded structural shapes, refer to *ASCE Manuals and Reports on Engineering Practice No. 102, Design Guide for FRP Composite Connections*. Note that this guide contains general design considerations and equations for bolted, adhesive, and mixed connections, but it is not specifically for bridge applications.

F-3.2.4.2 Case Studies.

The following resources can be referred to for demonstrations and case studies related to the implementation of FRP structural bridge elements:

- For a case study on the design and implementation of a composite bridge decking system conducted by FHWA, refer to *Composite Bridge Decking, Publication No. FHWA-HIF-13-029*. The report can be accessed through the following link: https://www.fhwa.dot.gov/bridge/composite/cpdi.cfm

- For information on a demonstration of an FRP composite bridge deck to replace a reinforced concrete bridge deck completed by USACE-ERDC, refer to *ERDC/CERL TR-16-16 Demonstration and Validation of a Lightweight Composite Bridge Deck Technology as an Alternative to Reinforced Concrete*.

- For information on a demonstration of a hybrid composite beam (HCB) system in a bridge replacement project at Fort Knox, Kentucky completed by USACE-ERDC, refer to *ERDC/CERL TR-16-22 Demonstration of Corrosion-Resistant Hybrid Composite Bridge Beams for Structural Applications*. The HCB system consisted of a glass fiber reinforced plastic (GFRP) shell, tension reinforcement using stainless steel cables, low-density foam core, and a concrete arch that provided compression reinforcement.

- For a case study on the implementation of composite piles conducted by FHWA, refer to *A Laboratory and Field Study of Composite Piles for Bridge Substructures, FHWA-HRT-04-043.* The report can be accessed through the following link: https://www.fhwa.dot.gov/bridge/composite/cpdi.cfm

- For a list of project reports related FRP pultruded structural members and composite bridge decking completed through the FHWA Innovative Bridge Research and Construction/Deployment (IBRC/IBRD) Program, refer to the FHWA website accessed through the following link: https://www.fhwa.dot.gov/bridge/composite/str.cfm.

F-4 THERMOPLASTIC TECHNOLOGIES.

Thermoplastics materials have recently emerged as a durable and cost-effective alternative to timber for short span bridges. Thermoplastic materials require no chemical preservatives, are low-maintenance and corrosion-resistant, and have reduced life cycle costs. While this technology is still under development and guidance is limited, this technology has been included to allow readers full exposure to all polymer composites.

F-4.1 Thermoplastic Material Considerations.

The following considerations for thermoplastic materials are not intended to be comprehensive but are to alert the reader that these materials require different considerations than traditional construction materials and thermoset FRP composite materials. More considerations can be found in the publications referenced throughout F-4.2.

F-4.1.1 Procurement.

Guidance on the design and use of thermoplastic materials for structural applications is limited. To implement thermoplastic materials, a performance-based procurement methodology is recommended. The following is one possible approach to this method:

To begin, the Owner would specify the performance requirements of the structure to be procured including the anticipated loads, site conditions, geometric requirements, and serviceability limits. The contractors completing the design-build process would be required to provide the ASTM testing reports of any products used in their design for review by the Owner or his consultant. Possible ASTM specifications to be used for this testing are referenced in section F-4.2.3.1. The design would then be developed based upon values from this testing, which would be reduced to provide factors of safety agreed upon by the Design Professional. Any elements or components identified as critical by the Design Professional or Owner would then be fabricated and tested to the satisfaction of all parties. As elements are fabricated, proof testing would be conducted at predefined check points to ensure that a representative batch of the material has the required mechanical properties. After the construction of the structure, the structure would be field-tested with the operating loads to check that the serviceability requirements are met.

F-4.1.2 Non-Homogenous and Anisotropic Behavior.

Thermoplastic materials are produced through an extrusion process. The thermoplastic materials are melted, pushed through a die or into a mold to form structural shapes, and cooled until hardened. The process cools the outer surface of the material faster than the interior. This results in the outer layers forming a dense, thick skin while the interior can develop voids and air bubbles. The thick outer skins provide the majority of the structural capacity to the member. Thermoplastic profiles should never be notched or split longitudinally to limit warping and to retain the capacity of the components. The extrusion process also produces a distinctive “grain” along the length of the component, parallel to the direction of extrusion. The differences in tensile and compressive strength parallel and perpendicular to this grain can be significant and should be taken into account. This directionality consideration is similar to that in timber design.

F-4.1.3 Viscoelasticity.

Since the hydrocarbon chains making up thermoplastic materials are not chemically cross-linked and can slide past each other, thermoplastic materials display viscoelastic behavior. This viscoelasticity results in a non-linear response to applied loading that is dependent upon the rate of loading, the duration of the loading, and the ambient temperature. This viscoelastic response is unique to thermoplastic materials and research into this behavior is still needed.

- Thermoplastic materials will display changes in ductility and stiffness, dependent upon the rate at which a load is applied. For example, if the same load is applied to a thermoplastic flexural member at two different load rates, the higher load rate will result in a stiffer, less ductile response in the member, compared to the same load applied to the member at the lower load rate.

- Thermoplastic materials will undergo creep if exposed to sustained loads. This tendency for creep is designed for by 1) reducing the modulus of elasticity in calculations involving long-term loads, to provide conservative design values, 2) limiting flexural members to short span lengths, and 3) incorporating chopped fiber or FRP reinforcement within the thermoplastic member to improve creep resistance.

- Thermoplastic materials are affected by ambient temperature. If exposed to extreme heat, thermoplastic materials will display an increase in ductility and a reduction in stiffness. If exposed to extreme cold, thermoplastic materials will display reduced ductility and an increase in stiffness which can lead to brittle failures. These responses to ambient temperature can be avoided by limiting the application of thermoplastics to regions with moderate temperatures.

F-4.1.4 Thermal Expansion.

Thermoplastic materials have high coefficients of thermal expansion compared to traditional construction materials, expanding and contracting noticeably in the direction of the “grain” as temperatures fluctuate. As a result, connections should be designed to accommodate this thermal movement, especially if joining materials with different coefficients of thermal expansion. Note that additional research is needed to more fully quantify this behavior and guidance for thermoplastic connection design and testing is limited.

F-4.1.5 Design Methodology.

Thermoplastic materials are designed using timber design methodologies with adjustment factors for thermoplastics. Allowable Stress Design (ASD) methods are used instead of LRFD as thermoplastic materials have not been calibrated due to their viscoelastic properties and limited empirical data. Thermoplastic materials are less stiff than timber and the majority of thermoplastic material designs are controlled by serviceability criteria and not strength.

F-4.2 Thermoplastic Material Guidance and Case Studies.

The following section describes the emerging thermoplastic technologies suitable for replacements of timber, including recommended applications, current guidance when available, and case studies.

F-4.2.1 Structural Grade Thermoplastic Lumber.

The following applications may be suitable for structural grade thermoplastic lumber, but the Design Professional should be aware of the design considerations for thermoplastic lumber as well as the limitation and applicability of current specifications:

- Decking as a replacement for timber decking.

- Pedestrian railing as a replacement for timber railing.

F-4.2.1.1 Guidance.

There is no AASHTO guidance for structural grade thermoplastic lumber. The following specifications can be reviewed for design and procurement information:

- For procedures to establish design strengths, flame spread index, and knock-down factors relative to load duration, creep rupture, temperature, and stress over time for polyethylene-based structural grade plastic lumber (SPGL), refer to *ASTM D7568 Standard Specification for Polyethylene-Based Structural-Grade Plastic Lumber for Outdoor Applications.* The limitations and applicability of this specification should be reviewed before use.

- For procedures to establish suitable span lengths, flame spread index, slip resistance, and knock-down factors relative to load duration, temperature, and creep adjustment for polyolefin-based decking boards, refer to *ASTM D6662 Standard Specification for Polyolefin-Based Plastic Lumber Decking Boards.* The limitations and applicability of this specification should be reviewed before use.

- For guidance on the procurement and construction of thermoplastic dimensional lumber, refer to *UFGS 06 10 00 Rough Carpentry*. The limitations and applicability of this specification should be reviewed before use.

F-4.2.1.2 Case Study.

For Information on construction recommendations, mechanical connection detailing, and inspection techniques for thermoplastic lumber, refer to *ERDC/CERL TR-17-45 Demonstration of Thermoplastic Composite I-Beam Design Bridge at Camp Mackall, NC*.

F-4.2.2 Thermoplastic Piles.

The following applications may be suitable for thermoplastic pile, but the Design Professional should be aware of the design considerations for thermoplastic piles as well as the limitation and applicability of current specifications:

- Piles as a direct replacement for timber piles.
- Fenders as a direct replacement for timber fenders.

F-4.2.2.1 Guidance.

There is no AASHTO guidance for thermoplastic piles. The following specifications can be reviewed for design and procurement information:

- For design criteria for round and rectangular cross-section polymer piles in axial and lateral load-bearing applications, refer to *ASTM D7258 Standard Specification Polymeric Piles.* The limitations and applicability of this specification should be reviewed carefully before use.
- For guidance on the procurement of thermoplastic piles, refer to *UFGS 35.59.13.14 20 Polymeric Piles.* The limitations and applicability of this specification should be reviewed carefully before use.

F-4.2.2.2 Case Study.

For information on the construction and inspection of thermoplastic piles for a thermoplastic bridge, refer to *ERDC/CERL TR-17-45 Demonstration of Thermoplastic Composite I-Beam Design Bridge at Camp Mackall, NC*.

F-4.2.3 Thermoplastic Structural I-beams.

The following applications may be suitable for thermoplastic structural I-beams, but the Design Professional should be aware of the design considerations for thermoplastic I-beams as well as the lack of guidance and limitations of this technology:

- Thermoplastic I-beams to replace timber beams in vehicular bridges
- Thermoplastic I-beams to replace timber beams in railroad bridges

F-4.2.3.1 Discussion.

In 2009, advances in thermoplastic material processing resulted in the development of prefabricated thermoplastic I-beams for bridge applications. The efficient shape of the I-beam reduced member weight and fabrication cost while maintaining strength and flexural rigidity. The beams were flow-molded from comingled recycled polyolefins (primarily high-density polyethylene (HDPE)) with a combination of thermoplastic coated fiber material or/and polystyrene, poly methyl methacrylate (PMMA), or a combination of the three).

This thermoplastic I-beam technology was used to replace three timber vehicular bridges and two timber railroad bridges on U.S. Army installations as part of initial demonstration of thermoplastic bridges. After these demonstrations, five full scale beams similar to the beams in the bridges were evaluated through full-scale flexural testing. The results of these tests are documented in *ERDC/CERL TR-17-18 Full Scale Testing of Thermoplastic Composite I-Beams for Bridges.* It is strongly recommended that this report be reviewed before considering the use of these beams. During the testing, two of the beams displayed brittle failures (less than 0.2% outer fiber strain as recorded during testing). The brittle failures occurred after the two beams had been cyclically loaded and the failure loads were lower than the ultimate loads applied to the beam during this cyclic loading. This behavior indicates that the flexural strength of the beams was reduced due in some part to the cyclical loading. While the beams displayed significant deflections before failure, more research and testing is needed to fully identify the possible failure modes of these thermoplastic I-beams.

No guidance is currently available for the design of thermoplastic I-beams, but it is possible to procure them with a performance-based procurement process using lessons learned from previous case studies and testing the beams using the following ASTM specifications:

- For flexural strength testing, refer to *ASTM D6109 Standard Test Methods for Flexural Properties of Unreinforced and Reinforced Plastic Lumber and Related Products*. This standard is for “as manufactured” components. As such, it is not a material property test method.

- For compression strength testing, refer to *ASTM D6108 Standard Test Method for Compressive Properties of Plastic Lumber and Shapes.* This standard is for “as manufactured” components. As such, it is not a material property test method.

- For mechanical connection strength testing, including screws, nails, and staples, refer to *ASTM D6117, Standard Test Methods for Mechanical Fasteners in Plastic Lumber and Shapes*. This standard does not cover the testing of bolted connections.

- For testing to evaluate thermal movement, refer to *ASTM D6341 Standard Test Method for Determination of the Linear Coefficient of Thermal Expansion of Plastic Lumber and Plastic Lumber Shapes Between -30 and 140°F (-34.4 and 60°C).*

F-4.2.3.2 Case Studies.

The following resources can be referenced for information on the implementation and testing of thermoplastic I-beams:

Three vehicular thermoplastic bridges using thermoplastic I-beams replaced deteriorated timber bridges at Camp Mackall, NC. The bridges were designed for HS25 loading and can support an M1 Abrams Tank. These demonstrations are documented in the following reports:

- Refer to *ERDC/CERL TR-17-45 Demonstration of Thermoplastic Composite I-Beam Design Bridge at Camp Mackall, NC* for details on the development, design, construction, and inspection for these bridges.

- Refer to *ERDC/GSL TR-10-19 Field Testing and Load Rating of the World's First Thermoplastic Bridge* for results from load rating conducted on one of these bridges.

- Refer to *ERDC/CERL TR-11-43 Remote Monitoring of a Thermoplastic Composite Bridge at Camp Mackall, NC* for information on a remote monitoring system installed on one of these bridges. This system recorded the deflection of the bridge each time a vehicle passed over the bridge.

- Refer to *ERDC/CERL TR-17-18 Full Scale Testing of Thermoplastic Composite I-Beams for Bridges* for results of material characterization and flexural tests conducted on five of these thermoplastic I-beams.

Two thermoplastic railroad bridges were built at Ft. Eustace, Virginia with thermoplastic I-beams. The railroad bridges were designed to carry the Cooper E60 load and the 260 kip alternate live load on four axles.

- Refer to *World's First Thermoplastic Railroad Bridges* for information on the development, design, construction, and load testing of these thermoplastic railroad bridges.

Summary

Composite materials in bridge design have the advantages of light weight, high strength and strong corrosion resistance, which contribute to low maintenance and long service life for structures. This contributes to life cycle cost savings and provides a long-term economic advantage over traditional materials such as steel and concrete. Because of these special properties, composite materials can have a better application in bridge engineering.

Bridge strengthening techniques using FRP composites can be used to restore capacity or add capacity for a bridge to remain open to legal and unrestricted loads. Composite materials can provide solutions to address emergency situations in a timely manner.

Some of the disadvantages involve higher short-term and uncertain long-term costs, uncertain durability and lack of ductility.

Steel, concrete, and timber bridge design involves utilization of appropriate material according to design standards, codes, and best practices predicated on the use of well-documented and standardized material types. Although there have been considerable advances made in developing design codes and procedures for composite strengthening, there is little standardization of material specifications and construction guidelines. This is due to the fact that many composite materials are producer specific. Because of this, designing with bridge composite materials may sometimes require more specialized knowledge in material behavior and manufacturing process compared to other materials.

Despite the difficulties mentioned above, ACI Committee 440 has been able to develop and publish ACI CODE-440.11-22: *Building Code Requirements for Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer (*GFRP*) Bars—Code and Commentary*. The 2024 IBC adopted a proposed change submitted by ACI as follows.

> *1901.2.1 Structural Concrete with GFRP reinforcement.*
>
> *Cast-in-place structural concrete internally reinforced with glass fiber reinforced polymer (GFRP) reinforcement conforming to ASTM D7957 and designed in accordance with ACI CODE 440.11 shall be permitted where fire resistance ratings are not required and only for structures assigned to seismic design category A.*

ACI CODE-440.11-22 is also expected to be adopted by ACI CODE-318-25.

APPENDIX G GLASS FIBER-REINFORCED POLYMER (GFRP) BARS FOR CONCRETE STRUCTURES [ADDITION]

G-1 INTRODUCTION.

G-1.1 Purpose and Scope.

This Appendix provides design resources to structural engineers interested in using glass fiber-reinforced polymer (GFRP) reinforcement in concrete structures. It is written for structural engineers proficient in the design of concrete structures using ACI 318, *Building Code Requirements for Structural Concrete*. New standards developed by ASTM and ACI for GFRP bars are discussed along with other supporting guides and reports. Other types of FRP bars, such as carbon, basalt, or aramid are not addressed, since comprehensive standards for these fibers are not yet developed. This Appendix identifies the limits on the use of GFRP reinforcement in concrete structures and key design considerations. For a more general overview on FRP material, reference Appendix F, Composites for Bridging Applications.

G-1.2 Applicability.

This Appendix applies to concrete structures that are designed in accordance with ACI CODE 440.11-22, *Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer (GFRP) Bars--Code and Commentary*. ACI CODE 440.11-22 contains the requirements for design, durability, and construction using GFRP reinforcement. ACI CODE 440.11-22 is written similarly to ACI 318, *Building Code Requirements for Structural Concrete*, and references ACI 318 for requirements that apply independently of the type of reinforcement used.

Historically, the most common application of GFRP bars is to reinforce highway bridge decks in areas where deicing salts are used on the roads and cause severe corrosion to conventional steel reinforcement. Other applications include marine structures such as seawalls or piers, flood mitigation channels, parking garages, water tanks, structures supporting MRI machines, and rail plinths for electric trains. Design reasons to use GFRP bars for other types of structures are:

- They do not corrode in the presence of chloride ions
- They do not interfere with electromagnetic fields
- They are thermally nonconductive

G-1.3 Limitations to Use.

The greatest limitation to the use of GFRP bars is related to fire. The fire ratings are very low to zero and not standardized at this time. Suggested ratings are given in the commentary to ACI CODE 440.11-22. For this reason, DoD does not allow the use of GFRP reinforcement in:

- Structures that have a fire rating above zero. Also, similar structures that may not have a fire rating but could collapse due to fire and threaten life safety (for example, GFRP reinforcing not allowed for upper deck of double-deck piers, and comparable structures similarly affected by heat zones).

- Architectural cast-in-place concrete

- In architectural precast concrete, unless all connections use steel

Other limitations on GFRP use discussed later in this Appendix are:

- Do not use in seismic force-resisting systems for Seismic Design Categories B, C, D, E, and F.

- GFRP reinforcement is permitted in structural members not part of the seismic force-resisting system for Seismic Design Categories A, B, and C.

- GFRP reinforcement is not recommended for lightweight concrete due to insufficient research data.

- GFRP use in prestressed concrete systems is not currently covered.

G-1.4 Overview of Appendix.

Brief descriptions of the various sections of this appendix follow:

- G-2 – GENERAL. Provides an explanation on the use of ASTM D7957/D7957D with ACI CODE 440.11-22.
- G-3 – GFRP REINFORCING BARS. The GFRP reinforcing bar as defined in ASTM D7957/D7957M is described. A comparison with steel reinforcement is provided.
- G-4 – DESIGN. Provides an overview of the design philosophy. Identifies design limitations that are different from those for steel reinforced structures.
- G-5 – DURABILITY. Provides an overview of the environmental and design aspects to be considered when using GFRP.
- G-6 – CONSTRUCTION. Provides a brief discussion on the use of GFRP bars in construction. Construction specification requirements are given in UFGS 03 30 00, Cast-in-Place Concrete.
- G-7 – REFERENCES. Lists the references included in this Appendix.
- G-8 – ABBREVIATIONS. Lists the abbreviations used in this Appendix.

G-2 GENERAL.

Concrete structures with GFRP bars are designed using two standards, ACI CODE 440.11-22, *Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer (GFRP) Bars--Code and Commentary*, and ASTM D7957/D7957M, *Standard Specification for Solid Round Glass Fiber Reinforced Polymer Bars*. ASTM D7957/D7957M contains the material properties need for design. ACI CODE 440.11-22 contains the requirements for design. Additional design guidance can be found in ACI 440.1 and Nanni et. al (2014). The process of design has been generally agreed on since the early 2000s. In the United States, guidance was provided in ACI 440.1, *Guide for the Design and Construction of Structural Concrete Reinforced with FRP Bars*, in 2001. Other international standard organizations developed similar design methodologies: CSA S806, *Design and construction of building structures with fiber-reinforced polymers*, in 2002; and *fib* Bulletin 40, *FRP Reinforcement in RC Structures*, in 2007. ACI 440.1 was the basis for the ACI CODE 440.11-22 code. ACI CODE 440.11-22 is dependent on ACI 318 for common structural concrete design requirements and is compatible with ASCE 7 for easy integration into practice in the United States.

One of the difficulties in bringing FRP bars to common use is the wide variety of fibers and resins along with varying manufacturing processes that can greatly change the properties of the material. Designers had to contact the manufacturer to find the properties of the material they planned to use. However, the test methods used to measure the properties were not standard. The last several years have been spent standardizing test methods and finding agreement from manufacturers on minimum performance levels, material properties, and sizes. Glass fiber is the most used fiber and is the first fiber to have a full standard for use in concrete reinforcement. ASTM D7957/D7957M has minimum guaranteed values for GFRP properties such as ultimate tensile force, transverse shear strength, modulus of elasticity, and bond strength. Manufacturers can exceed these minimum values and designers are permitted to use the higher actual values. The designer, however, would need to know the manufacturer before design and the manufacturer would need to submit certified material tests for confirmation.

G-3 GFRP REINFORCING BARS.

GFRP bars are made of continuous strands of glass fiber encapsulated in a protective resin. The bars have strength comparable to steel reinforcement in tension, but lower strength in the transverse direction. This behavior is called anisotropic, whereas steel is isotropic. The material behavior of GFRP is explained in more detail in Appendix F. The surface of the bar is modified to create a mechanical interlock with the concrete for bond. The modifications may be a sand coating or fibers wound around the bar, creating deformations.

G-3.1 Material Specification.

The material specification for GFRP reinforcing bars is ASTM D7957/D7957M. The specification establishes property limits and test methods for qualification and certification. Minimum guaranteed values for design are established. These limits must be met but the manufacturer may exceed these limits. The specification does not have grades like steel. It provides a baseline strength and durability that a designer may use without having to have a greater understanding of the fiber material and encapsulating resin.

G-3.2 Tensile Strength.

The specification establishes bar sizes similar to steel reinforcement. The bar sizes range from No. 2 to No. 10. Although there are many shapes for GFRP bars, round bars are used because of designers' and contractors' familiarity with steel reinforcement. The stress in the GFRP bar at its breaking strength decreases as bar size increases. The rate of stress reduction can vary; thus, the specification requires a minimum guaranteed ultimate tensile force rather than a stress. Consequently, the designer will have to calculate the ultimate tensile stress for each bar size. For instance, the tensile strength of a No. 2 bar is 124 ksi (855 MPa) compared to a No. 10 bar, for which it is 77 ksi (531 MPa).

GFRP bar bends are formed during the manufacturing process rather than bending a straight bar after production, which would rupture the bar. The specification establishes a minimum ultimate tensile force of a bent portion of the bar. Due to the anisotropic behavior of GFRP bars, the tensile strength at bends is lower than that of the straight portion of the bar. The specification sets this lower strength at 60 percent of ultimate tensile force of a bar. ACI CODE 440.11-22 limits the shear reinforcement stress to be compatible with this limit.

G-3.3 Material Properties.

GFRP reinforcing bars are similar in strength to steel reinforcing bars in tension. Table G-1 provides a comparison of GFRP and steel material properties. Some key observations:

- The GFRP bars are different from steel bars in that they do not yield. They demonstrate elastic behavior until they fracture.

- GFRP is about one-fourth the stiffness of steel, thus controlling deflection at service loads is essential to mitigate excessive cracking.

- Shear strength of the GFRP bar depends mostly on the resin. The bar is not as strong as steel when used as a dowel.

- GFRP bars are about one-fourth of the weight of steel. This makes the material easier to handle in the field, which can reduce construction time.

Table G-1 Comparison of GFRP and steel material properties

Property	ASTM D7957/D7957M GFRP	ASTM A615/A615M Steel
Minimum yield strength	None, elastic until failure	40, 60, 80, 100 ksi
Ultimate tensile strength	77 ksi to 124 ksi	60, 90, 105, 115 ksi
Modulus of Elasticity	6500 ksi	29,000 ksi
Transverse shear strength	19 ksi	Same as yield strength
Density	Approx. 135 lb/ft^3 at 70% fiber mass content	493 lb/ft^3

G-4 DESIGN.

The design methodology used in ACI CODE 440.11-22 is strength design, similar to the methodology in ACI 318. The main difference is that GFRP reinforcement is linear elastic until failure, unlike steel reinforcement. Steel reinforced members are designed to yield before failure. This provides some warning that an overloading of the structure is occurring before collapse. GFRP reinforced members do not have a yield plateau, so extra capacity is needed to prevent sudden failures due to overloading. This is done by reducing the Φ factors. A full explanation of the rationale is given in the Commentary to Chapter 21 of ACI CODE 440.11-22. The result is that, in flexure, either GFRP rupture or concrete crushing is an acceptable failure mode. The design requirements and discussion are provided in Chapter 22 of ACI CODE 440.11-22.

G-4.1 Shear Design.

Shear design philosophy in ACI CODE 440.11-22 is similar to that of ACI 318. The main difference is that GFRP reinforcement has lower axial stiffness than steel. This shifts the neutral axis in design, creating a smaller compression region in the cross section. The result is larger cracks. The equation for V_c has been modified to account for the lower stiffness in the longitudinal reinforcement. The GFRP shear reinforcement calculations are similar to those per ACI 318. A stress limit is placed on the shear reinforcement due to the reduced tensile strength of the reinforcement at the bend of a bar. The design requirements and discussion are provided in Chapter 22 of ACI CODE 440.11-22.

G-4.2 Serviceability.

Serviceability requirements in ACI CODE 440.11-22 often control the design of concrete slabs, joists, or beams with GFRP reinforcement. Service level effects to be considered are deflection, distribution of flexural reinforcement to reduce cracking, shrinkage and temperature reinforcement, and permissible tensile stresses. Deflections must be calculated in ACI CODE 440.11-22; one cannot choose a minimum depth for a span as permitted in ACI 318. The ACI CODE 440.11-22 calculations have been modified to use the Bischoff equations as was done in ACI 318-19. Requirements for the distribution of flexural reinforcement and shrinkage and temperature reinforcement were slightly modified to account for the less stiff material. Most importantly, a limit on service stress has been added to address creep rupture and fatigue, two important limit states that need to be addressed in GFRP reinforcement. A maximum sustained stress limit of 0.3 times the ultimate tensile stress is given. A method to calculate the sustained stress is based on the unfactored moment due to the sustained load on the member. This equation can also be used to address fatigue loading. The design requirements and discussion are provided in Chapter 24 of ACI CODE 440.11-22.

G-4.3 Development and Lap Splices.

Development of GFRP reinforcement is accomplished with a straight bar end or hook. GFRP reinforcement cannot yield so the design philosophy takes a shift. The development length of the bar need only be such that the stress of the controlling limit state rather than the ultimate strength of the bar is developed. Also, only 90-degree hooks are effective in developing the bars, due to a lack of ductility. Use lap splices for reinforcement continuity. The code provides the design requirements for a mechanical device, however, there are no commercially available devices that currently can meet these requirements for GFRP reinforcement. The commercially available mechanical splices developed for steel reinforcement damage GFRP bars and reduce strength; therefore, they are prohibited from being used with GFRP bars. The tie, stirrup, hook, and spiral provisions are modified to reflect the practice of manufacturing GFRP shapes. The design requirements and discussion are provided in Chapter 25 of ACI CODE 440.11-22.

G-4.4 Other Design Considerations.

In I-1.2, Applicability, DoD does not allow the use of GFRP reinforcement in structures that have a fire rating. Other key observations about designing with GFRP reinforcement according to ACI CODE 440.11-22:

- Do not count on moment redistribution. Since GFRP does not yield, plastic hinges cannot develop, nor can it yield in areas of greater restraint to allow for moment redistribution.
- Strength of GFRP reinforcement in compression is ignored.
- GFRP reinforcement is not recommended for lightweight concrete due to insufficient research data.
- Use of GFRP reinforcement in prestressed concrete systems is currently not covered.
- Use of GFRP reinforcement in diaphragms are not covered.
- Do not use GFRP reinforcement in seismic force-resisting systems for Seismic Design Categories B, C, D, E, and F.

- GFRP reinforcement is permitted in structural members not part of the seismic-force-resisting system for Seismic Design Categories A, B, and C.

G-5 DURABILITY

Because it is a relatively new construction material, there is some concern regarding the long-term durability of GFRP reinforcement. FRP reinforcement has been in service in North America since 1993. Since that time, there have been a couple hundred bridge decks and other structures that have been built with FRP bars.

G-5.1 Strength and Stiffness.

Depending on the materials and manufacturing process used, GFRP bars can be susceptible to reduced strength and stiffness when exposed to moisture or high-alkaline environments. Much of the testing to gage this sensitivity, however, has been done with short-term experiments using environments that are much more aggressive than the field conditions. Extrapolation of these results to field conditions and expected lifetimes is not possible in the absence of real-time data. To account for these detrimental effects, the GFRP reinforcement needs to be manufactured to a minimum quality that mitigates these effects. ASTM 7957/7957M establishes the quality assurance for long-term performance; in general, the bars have proven to be durable.

Although GFRP reinforcement has shown to be durable to date, only predictive models based on accelerated tests can estimate how long the reinforcement will remain at design level strengths. To account for the uncertainty of predictive models, ACI CODE 440.11-22 has placed an environmental reduction factor, C_E, of 0.85 to the guaranteed ultimate tensile strength. Over time, the actual performance of GFRP reinforcement will be compared to the predictive models and whether an environmental factor is necessary will be evaluated. The design requirements and discussion are provided in Chapter 20 of ACI CODE 440.11-22.

G-5.2 Creep and fatigue.

Time-dependent effects that can degrade the strength of GFRP over time are creep rupture and static fatigue. The design aspects of these effects are discussed in Section G-4.2, as part of the serviceability requirements. Creep rupture is the sudden failure of FRP material due to sustained loads over time. Static fatigue is similar in that a sudden failure will occur under sustained cyclical loading. Both can be mitigated if the stress in the reinforcement due to the sustained load or cyclical loading is restricted to a lower limit.

G-5.3 Exposure to Temperatures and Sunlight.

The potential for exposure to high temperatures needs to be considered when using GFRP reinforcement. The resin in the reinforcement will soften as the temperature approaches the glass transition temperature. ASTM D7957/D7957M requires the mean glass transition temperature to be at least 212 deg F (100 deg C). ACI CODE 440.11-22 suggests that GFRP bars should not be used in environments with a service temperature higher than 27 deg F (15 deg C) below the glass transition temperature. This calculates to an in-service limit of 185 deg F (85 deg C).

Ultra-violet radiation can be detrimental to GFRP reinforcement if exposed for long period of times to the sun before being placed in concrete. ACI 440.5 recommends if GFRP bars are stored outside for more than 4 months, they should be covered with opaque plastic. The requirement in UFGS 03 30 00, Cast-in-Place Concrete, places this limit at 2 months.

G-6 CONSTRUCTION

Construction specifications for GFRP reinforcement has been added to UFGS 03 30 00, Cast-in-Place Concrete. The information was developed from the requirements of ACI 440.5. The development of ASTM D7957/D7957M simplified the specification of GFRP reinforcement. Prior to its development, specifiers had to identify all the test methods and limits necessary for quality assurance. Manufacturers were providing different reinforcement shapes and sizes of reinforcement. ASTM D7957/D7957M established a standard bar size chart similar to steel reinforcement.

Key observations on construction with GFRP reinforcement.

- If the surface of the bar is damaged, it will need to be replaced. Visible damage is defined in the specification.
- On-site storage: cover the bars from the sun if exposed more than 2 months; and prevent exposing bars to greater than 120 °F.
- Concrete cover is different than it is for steel reinforcement.
- Support reinforcement with dielectric material or steel coated with dielectric material.
- Field cutting is permitted but bars cannot be field bent.

This UFC supersedes UFC 3-301-02, dated 3 March 2020.

This Page Intentionally Left Blank

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale should be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-301-02, Change 1, Dated February 25, 2025
Superseding: UFC 3-301-02, Dated April 11, 2023

\1
Description of changes
-Adoption of the 2024 I-codes
-Adoption of ASCE 7-22, Minimum Design Loads and Associated Criteria for Buildings and Other Structures

Reason for changes:
Maintain concurrence with model building codes and alignment with DoD building code (1 200 01).

Impact:
Typical of the code update cycle.
/1/

This Page Intentionally Left Blank

TABLE OF CONTENTS

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

UFC 1-200-01 uses and supplements 2024 IBC as the building code for DoD. UFC 3-301-01 contains all structural requirements for structures assigned to Risk Category I, II, III, or IV. Only the enhanced structural requirements for RC V structures are contained in this UFC. These enhanced requirements are revised to be consistent with the 2024 IBC and ASCE 7-22.

1-2 REISSUE AND CANCELS.

This edition of UFC 3-301-02 cancels UFC 3-301-02 dated 3 March 2020.

1-3 PURPOSE AND SCOPE.

This Unified Facility Criteria (UFC) provides enhanced design requirements for Risk Category V (RC V) structures, national strategic military assets designed and constructed for the Department of Defense (DoD). These technical requirements are based on the 2024 *International Building Code* (2024 IBC) and the structural standard referenced by the 2024 IBC: ASCE/SEI 7-22 *Minimum Design Loads and Associated Criteria for Buildings and Other Structures* (hereafter referred to simply as ASCE 7-22).

This UFC must be used for the design and analysis of buildings and other structures assigned to Risk Category V.

RC V - is assigned to facilities that are considered to be national strategic military assets (see UFC 3-301-01 Table 2-2). Special design and analysis procedures apply to RC V buildings and other structures. Design RC V structures to ensure that their foundations, superstructures and installed mission-essential nonstructural elements remain elastic, and their installed equipment remains operational when subjected to severe environmental loading.

This UFC modifies provisions of the 2024 IBC and ASCE 7-22 for use in analyzing RC V buildings and structures. In cases where a provision in the 2024 IBC or ASCE 7-22 is not modified by this UFC, first apply UFC 3-301-01 and then apply UFC 1-200-01. If neither of these UFC documents modifies the relevant provision, then apply the 2024 IBC and ASCE7-22 directly.

1-4 APPLICABILITY.

This UFC follows the same applicability as UFC 1-200-01, paragraph 1-3, with no exceptions.

1-5 CONFLICTS AND MODIFICATIONS.

The 2024 IBC provisions are directed toward public health, safety, and general welfare, presenting minimum standards that must be met by the private sector construction industry. The use of industry standards for DoD projects promotes communication in the marketplace, improves competition, and results in cost savings. However, the military sometimes requires higher standards to achieve unique building performance, or to construct types of facilities that are not used in the private sector, especially when the structures are national strategic military assets. In addition, the construction of military facilities outside the United States can introduce requirements that are not addressed in national model building codes. The provisions contained in this UFC are intended to fulfill the unique military requirements for RC V structures that are not found in the model building codes. When conflicts between the 2024 IBC or ASCE 7-22 and this UFC arise, this UFC prevails.

In addition, for construction outside the United States, conflicts between host nation building codes and the UFC may arise. In those instances, the more stringent design provisions apply. Notify the SER of where conflicts are discovered.

1-6 COMMENTARY.

Limited commentary has been added in the chapters. Section designations for such commentary are preceded by a “[C]”, and the commentary narrative is shaded.

1-7 OTHER CRITERIA.

Military criteria other than those listed in this document may be applicable to specific types of structures. Such structures must meet the additional requirements of the applicable military criteria.

1-7.1 General Building Requirements.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-7.2 Structural Requirements.

Comply with UFC 3-301-01, *Structural Engineering*. UFC 3-301-01 modifies certain structural provisions of the model building codes for the purpose of DoD structures. Use this UFC in addition to UFC 3-301-01 and the UFCs and government criteria referenced therein.

1-7.3 Progressive Collapse Analysis and Design.

Apply UFC 4-023-03, *Design of Buildings to Resist Progressive Collapse*.

1-7.4 Cybersecurity.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-8 REFERENCES.

APPENDIX A contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 DESIGN FOR ENHANCED RC V PERFORMANCE OBJECTIVES

2-1 DESIGN REVIEW.

2-1.1 Independent Structural Design Review.

A design review of the proposed seismic force-resisting system and associated structural analysis (calculations) must be conducted by an independent licensed professional engineer with at least 15 years of experience in the theory and application of nonlinear seismic analysis and structural behavior under extreme cyclic loads. The Independent Reviewer shall not be an employee of, or affiliated with, the design entity. The independent design reviewer must have previous real world design experience commensurate in complexity to the project being reviewed. Selection of the independent design reviewer is subject to the review and approval of the AHJ and the reviewer must be retained by the A/E design firm (DBB) or the General Contractor (DB). The design review must include, but is not necessarily limited to, the following:

1. Any site-specific seismic criteria used in the analysis, including the development of site-specific spectra and ground motion time-histories.

2. Any acceptance criteria used to demonstrate the adequacy of structural elements and systems to withstand the calculated force and deformation demands, together with any laboratory or other data used to substantiate the criteria.

3. The preliminary design, including the selection of the structural system; the configuration of structural elements; and supports for all architectural, mechanical, and electrical components.

4. The final design of the entire structural system and supports for all architectural, mechanical, and electrical components, and all supporting analyses.

5. All procurement documents (statements of work, specifications, and so forth.) that are developed for seismic qualification of equipment that must remain operable following the design earthquake; verification of post-earthquake operability by shake table testing, experience data, or analysis.

6. All documentation that is developed for seismic qualification of equipment that must remain operable following the design earthquake.

[C] 2-1.1 Independent Structural Design Review.

An independent Structural Design Review is to be conducted at the contractor's expense. The structural design review should be started early in the design process to ensure that the seismic design of the RC V facility is performed to the satisfaction of the Independent Structural Reviewer. The Independent Structural Reviewer should create a full report documenting the findings for each of the tasks listed in this section. A detailed list of all documents that were evaluated should be included in the report. Each evaluation should discuss how each topic was assessed, the criteria that were used for evaluation, a quantitative comparison of calculated response to allowable limits, and discussion on whether the criteria were satisfied. Additionally, the report should include discussion of critical element utilization ratios, the extent to which seismic effects govern the design of structural elements and how calculations and finite element (FE) models were evaluated, with a focus on modeling assumptions and boundary conditions.

The comprehensive report is to be signed and stamped by the independent structural reviewer and at a minimum must include:

1. Evaluation of Site Specific Seismic Hazard Analysis
    a. Evaluation of development of site specific spectra
    b. Evaluation of development of ground motion response histories
2. Evaluation of Seismic Force-Resisting System Response
    a. Evaluation of seismic force-resisting system narrative
    b. Evaluation of acceptance criteria for structural elements, including contributing and non-contributing structural elements
    c. Evaluation of seismic calculations and analyses demonstrating that structure can withstand seismic force and deformation demands
3. Evaluation of development of in-structure response spectra
4. Evaluation of nonstructural component designation as MC-1, MC-2, and NMC.
    a. Evaluation of the basis for determination of equipment designations to ensure owner/user intent has been considered and satisfied.
    b. Concurrence with the list and designations
    c. Review of draft Screening Evaluation Work Sheets (SEWS) for each MC-1 component.
    d. Evaluation of procurement documents (statements of work, specifications, qualification criteria, and so forth) for MC-1 and MC-2 architectural, mechanical, and electrical equipment and systems to ensure proper seismic qualification and labeling of equipment that must remain operable following the design earthquake.

2-1.2 Nonstructural Component Design Review.

A review of the nonstructural component design (including anchorage) must be performed by an independent licensed professional engineer with at least 15 years of experience in the theory and application of nonlinear seismic analysis and structural behavior under extreme cyclic loads. Previous design experience must be commensurate in complexity to the project being reviewed. Selection of the independent nonstructural component design reviewer is subject to the review and approval of the AHJ and the reviewer must be retained by the A/E design firm (DBB) or the General Contractor (DB). The structural and nonstructural component design review may be conducted by the same independent reviewer subject to the already noted qualifications. The nonstructural component design review should occur prior to commissioning and should include, but not necessarily be limited to, the following:

1. Review of in-structure response data and confirmation that any recommendations made by the Structural Design Reviewer have been incorporated into the in-structure response.

2. Review of component qualifications to confirm proper in-structure response was utilized.

3. Upon completion of design review of all documentation, the reviewer must perform a walk-down inspection of the project and confirm the following:

    a. Component installations are in their submitted and approved location.

    b. Identification nameplates are installed as specified in Section 2-17.8

    c. Component qualification documentation has been incorporated into the Operations & Maintenance Manual as specified in Section 2-17.7.

[C] 2-1.2 Nonstructural Component Design Review.

An independent Nonstructural Component Design Review is to be conducted at the contractor's expense. The nonstructural component design review should be started early in the construction phase of the RC V project to ensure the contractor meets the requirements of the UFC to the satisfaction of the Nonstructural Reviewer. The Nonstructural Reviewer should create a comprehensive report documenting completion of each of the tasks listed in this section. The report should contain all required data, including but not limited to, photos, field notes, equipment tags, and measurements. The report should also identify any variance to the Structural Design Review report and ultimately state whether criteria for Risk Category V have been satisfied.

The comprehensive report is to be signed and wet stamped by the Nonstructural Component Design Reviewer and at a minimum must include:

1. Review of anchorage design for all nonstructural components
2. Review of in-structure response data confirming that comments from the Structural Reviewer have been incorporated
3. Review of component qualification documents to ensure that the proper in-structure seismic demand was used
4. After completion of the design review activities listed above and before commissioning, a walk-down inspection of the facility to confirm the following:

a. Location of installed Mission Critical components

b. Installation of identification nameplates as specified in Section 2-17.8 of this UFC

c. Incorporation of component qualification documents into the O&M Manual as specified in Section 2-17.7 of this UFC

2-2 DEFINITIONS AND NOTATIONS.

2-2.1 General.

2024 IBC Section 202, as modified by UFC 3-301-01 and this section applies.

ACTIVE FAULT

An active fault is defined in ASCE 7-22 as follows: A fault determined to be active by the Authority Having Jurisdiction from properly substantiated data (e.g., most recent mapping of active faults by the US Geological Survey).

[C] ACTIVE FAULT

In UFC 3-301-02, 11 April 2023 (the previous version of this UFC), an active fault was defined as a fault for which there is an average historic slip rate of 1 mm or more per year and for which there is geographic evidence of seismic activity in Holocene times (the most recent 11,000 years). This definition dates back to the 2000 IBC.

WIND-BORNE DEBRIS REGION

For locations within the United States and its territories and possessions, areas within hurricane-prone regions located:

1. Within 1 mile (1.61 km) of the mean high water line where an Exposure D condition exists upwind of the waterline and the basic wind speed, *V*, is 130 mph (58 m/s) or greater; or

2. In areas where the basic wind speed is 140 mph (63.6 m/s) or greater.

For locations outside of the United States and its territories and possessions, any region where either of the above two conditions apply.

The wind speeds referenced above are Risk Category V wind speeds (See Section 2-9.1).

DESIGNATED SEISMIC SYSTEMS

Those nonstructural components that require design in accordance with ASCE 7-22 Chapter 13. This designation applies to systems that are required to be operational following the MCE_R for RC V structures. All systems in RC V facilities designated as MC-1 (see Section 2-17.2) must be considered part of the Designated Seismic System.

2-3 CONSTRUCTION DOCUMENTS.

2-3.1 General.

2024 IBC Section 1603, as modified by UFC 3-301-01, applies.

Exceptions**:**

1. The Seismic Importance Factor, I_e, the seismic response coefficient, C_S, the Response Modification Factor, R, and the Seismic Design Category do not apply and must not be listed in construction documents.

2. The classification of the building in RC V, that it is designed in accordance with the provisions of this UFC, and the date of this UFC, must be listed in construction documents.

3. Construction documents for architectural, mechanical, and electrical components must be prepared by a Registered Design Professional for all buildings assigned to RC V.

2-4 GENERAL DESIGN REQUIREMENTS.

2-4.1 General.

2024 IBC Section 1604, as modified by UFC 3-301-01, applies. UFC 3-301-01 Table 2-2 is to replace 2024 IBC Table 1604.5.

2-4.2 Wind and Seismic Detailing.

2024 IBC Section 1604.9 does not apply to RC V facilities.

2-5 LOAD COMBINATIONS.

2-5.1 General.

2024 IBC Section 1605 applies.

Exceptions**:**

1. For all load combinations, structural elements must be designed to remain linear (elastic).

2. Only Strength Design load combinations are permitted.

3. In load combinations involving seismic load effects, the combined effect of earthquake forces, *E*, needs to be computed using the procedures outlined in this UFC.

2-6 DEAD LOADS.

2-6.1 General.

2024 IBC Section 1606 applies.

2-7 LIVE LOADS.

2-7.1 General.

2024 IBC Section 1607, as modified by UFC 3-301-01, applies. Wherever Table 1607.1 is referenced in the IBC, it is to be replaced by Table E-1 of UFC 3-301-01.

2-8 SNOW AND ICE LOADS.

2-8.1 General.

Design snow loads are to be determined in accordance with 2024 IBC Section 1608, as modified by UFC 3-301-01. Design atmospheric ice loads on ice-sensitive structures are to be determined in accordance with ASCE 7-22 Chapter 10.

Exceptions**:**

1. Ground snow loads and winter wind parameter W2 for RC V structures must be determined using a spreadsheet found under related materials on the WBDG Risk Category V Structures UFC.

2. In the determination of atmospheric ice loads for RC V structures, the nominal values of ice thickness, and concurrent wind speed and temperature must be determined using a spreadsheet found under related materials on the WBDG Risk Category V Structures UFC.

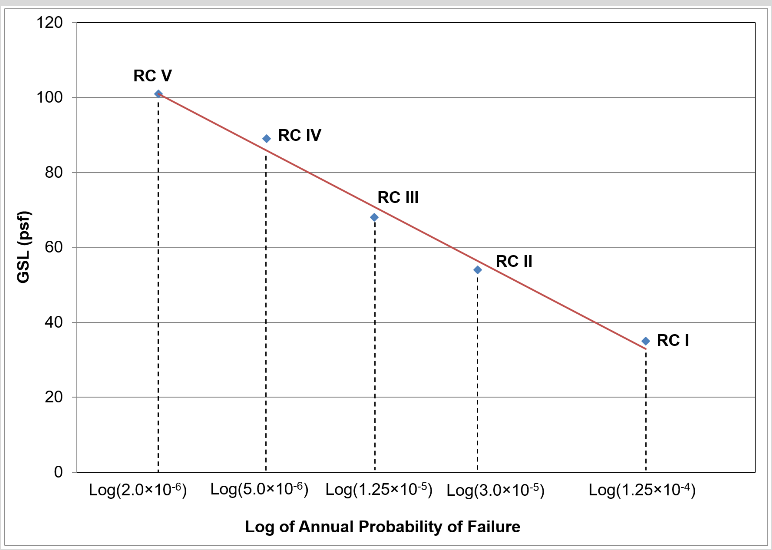
3. At locations where Risk Category V snow or ice loads are not provided, contact the AHJ for further guidance. For OCONUS locations reference the following commentary

[C] 2-8 SNOW AND ICE LOADS

Ground snow load (GSL) for an RC V structure at a given location was determined based on the GSL values at the same location corresponding to RC I, II, III and IV structures obtained from the ASCE Hazard Tool. As explained in ASCE 7-22 Commentary Section C7.2:

The ground snow load, p_g, values contained in the ASCE Design Ground Snow Load Geodatabase, mapped in Figures 7.2-1A through 7.2-1D and provided in the ASCE Hazard Tool are based on a reliability analysis consistent with the targets in Table 1.3-1 for a "failure that is not sudden and does not lead to widespread progression of damage."

In other words, the GSL values for RC I, II, III and IV structures correspond to target annual probabilities of failure (P_F) of 1.25×10^{-4}, 3.0×10^{-5}, 1.25×10^{-5}, and 5.0×10^{-6}, respectively. Plotting these GSL values against the Log of their corresponding P_F, it was observed that the points lie on an approximate straight line, as seen in the figure below. The exercise was repeated for more than 300 locations and the same linear relationship was observed. Consequently, it was decided to determine the GSL value for RC V structures based on extrapolation using the best-fitting straight line drawn through the four points described above. From ASCE 7-22 Table 1.3-1, a P_F value of 2.0×10^{-6} was deemed appropriate for RC V structures, as can be seen in the figure below.



It can be noted that, in high snow locations, the procedure described above provides lower GSL values when compared to the old method of multiplying an importance factor of 1.5 to the GSL value of RC II structures. This is expected because using a single importance factor for all locations was meant to be conservative.

The same procedure was followed to determine the nominal ice thickness for RC structures. Nominal ice thickness values for RCs I, II, III and IV structures correspond to mean recurrence interval (MRI) of 250, 500, 1000 and 1400 years, respectively. An MRI of 2500 years was assigned to RC V structures for ice loading.

2-8.2 Snow Load Case Studies.

Snow load case studies may be done to clarify and refine snow loadings at site-specific locations with the approval of the AHJ. A site-specific study must be conducted if the ground snow load is greater than 100 psf (4.78 KPa). The methodology used to conduct snow load case studies at site-specific locations is presented in the Cold Regions Research and Engineering Laboratory (CRREL) report “Database and Methodology for Conducting Site Specific Snow Load Case Studies for the United States.” by Tobiasson and Greatorex and “Site-Specific Case Studies for Determining Ground Snow Loads in the United States” by Buska, Greatorex, and Tobiasson.

[C] 2-8.2 Snow Load Case Studies.

The provisions of this section are similar to those in Section 1608.2.3 in UFC 3-301-01, except that there is a threshold GSL value of 100 psf. In UFC 3-301-01, 11 April 2023, Change 1, 2 October 2023, there was a threshold GSL value of 30 psf for having to do site-specific snow load case studies. The 30 psf service-level GSL was converted to 45 psf strength-level GSL. Since this value was for RC I through IV structures, it was brought up to 70 psf for RC V structures by multiplying with an importance factor 1.5 and then rounding up. The snow load importance factor for RC V structures was scaled up from an importance factor of 1.2 for RC IV structures. The 70 psf was increased to 100 psf based on discussions with the Designated Working Group (DWG).

2-9 WIND LOADS.

2-9.1 Design Wind Speeds Inside and Outside of the United States.

Risk Category V OCONUS wind speed can be found using a spreadsheet that is located on the Whole Building Design Guide Structural Engineering UFC Page as a related item for download

For Risk Category V CONUS wind speeds use ASCE’s hazard tool and select the wind speed for a 100,000-year return period.

At locations where the basic wind speed is not provided, use the best locally available information.

At locations where the basic wind speed is not provided, contact the AHJ for further guidance.

2-10 SOIL LATERAL LOADS.

2-10.1 General.

2024 IBC Section 1610 applies except as follows: The exception in section 1610.1 to allow the use of active soil pressure under certain conditions is disallowed for RC V structures.

2-11 RAIN LOADS.

2-11.1 General.

2024 IBC Section 1611 applies.

Exception:

1. The design rainfall intensity for RC V structures must be must be determined using a spreadsheet found under related materials on the WBDG Risk Category V Structures UFC.
2. At locations where the design rainfall intensity is not provided, contact the AHJ for further guidance and see the following commentary.

[C] 2-11 RAIN LOADS

The design rainfall intensity (in./h or mm/h) for RC V structures is based on 15-min storm of 1000-yr return period. These values can also be obtained from the following webpage on the website of National Oceanic and Atmospheric Administration (NOAA).

https://hdsc.nws.noaa.gov/pfds/pfds_map_cont.html

2-12 FLOOD LOADS.

2-12.1 General.

2024 IBC Section 1612 applies.

Exceptions**:**

1. The **DESIGN FLOOD** is to be defined as a flood with a 2 percent chance of exceedance in 50 years (2500-year mean recurrence interval).
2. The **FLOOD HAZARD AREA** is to be defined as the area within a flood plain subject to a 2 percent chance of flood exceedance in 50 years (2500-year mean recurrence interval). A probabilistic flood hazard analysis must be performed where a facility does not clearly fall outside of said area by inspection.

2-13 TSUNAMI LOADS.

2-13.1 General.

Section 2-4.8 of UFC 3-301-01 applies.

2-14 EXISTING BUILDINGS.

2-14.1 Seismic Evaluation and Retrofit.

RC V structures must be designed to ensure that during the $MCE_{R'}$ their superstructures and installed mission-essential non-structural components remain elastic and, following the $MCE_{R'}$ their installed equipment remains operational. ASCE 41 is not to be used for evaluating existing buildings that are classified as RC V facilities. For any evaluations of existing RC V buildings, the analysis procedures of this UFC apply. All strengthening of existing buildings and additions to existing buildings that must satisfy RC V performance requirements need to satisfy the requirements of this UFC.

2-15 EARTHQUAKE LOADS.

2-15.1 Structural Design Criteria.

Each RC V structure is to be designed in accordance with the provisions of this Chapter. Permissible structural systems are listed in Table 2-1. The components of a structure that must be designed for seismic resistance and the types of lateral force analysis that must be performed are prescribed in this Chapter. Each structure is to be provided with complete seismic and vertical force-resisting systems capable of providing adequate strength and stiffness to withstand the design earthquake ground motions determined in accordance with Section 2-15.2, within the prescribed deformation limits of Section 2-16.9. The design ground motions are to be assumed to occur along any horizontal direction of a structure, as well as in the vertical direction. A continuous load path, or paths, with adequate strength and stiffness to transfer forces induced by the design earthquake ground motions from the points of application to the final point of resistance must be provided.

2-15.2 Seismic Ground Motion Values.

2-15.2.1 Development of MCE_R Spectral Response Accelerations and Response History Criteria.

The Site-Specific Ground Motion Procedures outlined in ASCE 7-22 Chapter 21 are to be used to develop MCE_R ground motion acceleration time histories for RC V structures. The MCE_R can generally be characterized by a 5-percent-damped acceleration response spectrum. A lower value of damping may be more appropriate and the value should be as approved by the Structural Design Reviewer (see Section 2-1.1). In the application of seismic provisions of the 2024 IBC and ASCE 7-22, the terms S_{DS} and S_{D1} are to be replaced by S_{MS} and S_{M1}, respectively, obtained from this response spectrum.

A linear response history analysis in accordance with ASCE 7-22 Section 12.9.2 is also to be conducted to determine the in-structure demand for the design and qualification of nonstructural equipment and distributed systems. The ASCE/SEI 43-19, Section 2.4 Criteria for Developing Synthetic or Modified Recorded Acceleration Time Series must be used to develop the seismic response histories for RC V facilities.

Table 2-1 Systems Permitted for Risk Category V Buildings

Basic Seismic Force-Resisting System	Detailing Requirements
Bearing Wall Systems	
Ordinary reinforced concrete shear walls	ACI 318, excluding Ch. 18
Ordinary reinforced masonry shear walls	TMS 402
Building Frame Systems	
Steel eccentrically braced frames, moment-resisting connections at columns away from links	AISC 360
Steel eccentrically braced frames, non-moment-resisting connections at columns away from links	
Ordinary steel concentrically braced frames	
Ordinary reinforced concrete shear walls	ACI 318, excluding Ch. 18
Composite steel and concrete eccentrically braced frames	AISC 360 (LRFD) and ACI 318, excluding Ch. 18
Composite steel and concrete concentrically braced frames	
Ordinary composite steel and concrete braced frames	
Composite steel plate shear walls	
Ordinary composite reinforced concrete shear walls with steel elements	
Ordinary reinforced masonry shear walls	TMS 402
Moment-Resisting Frame Systems	
Ordinary steel moment frames	AISC 360
Ordinary reinforced concrete moment frames	ACI 318, excluding Ch. 18
Ordinary composite moment frames	AISC 360 (LRFD) and ACI 318, excluding Ch. 18
Composite partially restrained moment frames	
Cantilevered Column Systems Detailed to Conform to the Requirements for:	
Ordinary steel moment frames	AISC 360
Ordinary reinforced concrete moment frames	ACI 318, excluding Ch. 18

Note: Any system prohibited here may be permitted if approved by the Independent Structural Design Reviewer (Section 2-1.1).

At least seven 3-component ground motions must be selected and scaled from individual recorded events for in-structure response analysis. The histories must be selected from events having magnitudes, fault distances, and source mechanisms that are consistent with those that control the MCE_R for the RC V structure. Ground motion records are to be sourced from stations with similar soil profiles, defined in terms of Site Class, to that at the site of the RC V structure. The shape of the spectra of the recorded motions must be similar to that of the target spectra.

2-15.2.2 Design Response Spectrum.

[redacted] Design Horizontal Response Spectrum.

The unreduced MCE_R ground motions determined from the Site Specific Ground Motion Procedure are to be used.

[redacted] Design Vertical Response Spectrum.

The unreduced MCE_R ground motions determined from the Site Specific Ground Motion Procedure are to be used. The vertical spectrum values, S_{aMv}, cannot be lower than the minimum ordinates determined from ASCE 7-22 Section 11.9.2. Ground motions for calculating the minimum ordinates are to be the site-specific MCE_R ground motions determined in 2-15.2.2.1. The 'Gulerce Abrahamson Method' may also be used for deriving vertical acceleration if conditions for the method are met.

2-15.3 Importance Factor and Risk Category.

2-15.3.1 Importance Factor.

A seismic importance factor is not required for RC V buildings and other structures (see UFC 3-301-01 Table 2-2). However, some referenced sections of ASCE 7-22 require the use of I_e. In these cases, I_e is to be taken as 1.0.

[C] 2-15.3.1 Importance Factor

The provisions of this UFC are for designing RC V structures only. The seismic forces required in this UFC already take into account the critical nature of these structures, and as a result, are set to a very high level, which is reflected in the fact that these structures are designed to remain elastic during an MCE_R-level event. For this reason, application of an importance factor is not required.

2-15.4 Seismic Design Category.

The requirements of ASCE 7-22 Section 11.6 do not apply to RC V structures.

2-15.4.1 Design Requirements for Seismic Design Category A.

The requirements of ASCE 7-22 Section 11.7 do not apply to RC V structures.

2-15.5 Geological Hazards and Geotechnical Investigation.

2-15.5.1 Site Limitations for Risk Category V Structures.

A structure assigned to RC V must not be sited where there is a known potential for an active fault to cause rupture of the ground surface at the structure. The term *active fault* is defined in Section 2-2.1 of this UFC.

2-16 SEISMIC DESIGN REQUIREMENTS FOR BUILDING STRUCTURES.

2-16.1 Structural System Selection.

2-16.1.1 Selections and Limitations.

Table 2-1, *Systems Permitted for Risk Category V Buildings*, is to be used to determine whether a seismic force-resisting system is permitted for use in an RC V structure. Exceptions may be authorized when permission is granted by the Structural Design Reviewer (see Section 2-1.1).

Once a permitted structural system has been selected, no specific building height limitations apply. The requirement to ensure elastic behavior at the MCE_R-level earthquake mitigates the need for height limitations.

2-16.1.2 Combinations of Framing Systems.

Combinations of permitted structural systems (see Table 2-1) may be used to resist seismic forces, both along the same axis of a building and along the orthogonal axes of the building. For systems combined along the same axis of a building, total seismic force resistance is to be provided by the combination of the different systems, with each contributing resistance in proportion to its stiffness. Displacements of parallel framing systems must be shown by analysis to be compatible.

2-16.1.3 R, C_d, and Ω_0 Values for Vertical and Horizontal Combinations.

The design of RC V structures must use a linear elastic Modal Response Spectrum Analysis (MRSA) procedure. Structural response is to be restricted to elastic behavior. No yielding is to be permitted for the MCE_R ground motions. The factors R, C_d, and Ω_0 are to be set to 1.0.

[C] 2-16.1.3 R, C_d, and Ω_0 Values for Vertical and Horizontal Combinations

The factors R, C_d, and Ω_0 are meant to quantify the inelastic properties of a structure that is designed to undergo inelastic deformations in the course of resisting an MCE-level seismic event. In contrast, structures assigned to RC V are designed to remain elastic during an MCE-level event. As a result, these three seismic factors are irrelevant in the design of RC V structures.

ASCE 7-22 has removed virtually all restrictions on the use of the Equivalent Lateral Force (ELF) procedure. However, the mandatory use of the Modal Response

Spectrum Analysis (MRSA) procedure is retained here because it provides a more accurate assessment of seismic structural response.

2-16.2 Diaphragm Flexibility, Configuration Irregularities, and Redundancy.

2-16.2.1 Irregular or Regular Classification and Limitations and Additional Requirements for Systems with Structural Irregularities.

ASCE 7-22 Sections 12.3.2 and 12.3.3 do not apply.

[C] 2-17.2.1 Irregular or Regular Classification and Limitations and Additional Requirements for Systems with Structural Irregularities.

Because buildings assigned to RC V are designed to respond to MCE_R ground shaking in an elastic manner, and they are required to be analyzed by procedures that adequately account for any structural irregularity, it is not necessary to classify RC V buildings as regular or irregular. In addition, any design provisions intended to account for structural irregularities need not apply.

2-16.2.2 Redundancy.

ASCE 7-22 Section 12.3.4 applies. For the purpose of determining the redundancy factor ρ, assume the seismic design category to be D. Structural systems with a redundancy factor, ρ, equal to 1.3 are not permitted (see Section 2-16.4.1).

2-16.2.3 Upward Force for Horizontal Cantilevers.

Vertical seismic forces are to be computed from the vertical spectral accelerations specified in this Chapter. The minimum vertical force in ASCE 7-22 Section 12.4.4 applies, except that the net upward force must be 0.8D.

[C] 2-16.2.3 Upward Force for Horizontal Cantilevers.

In ASCE 7-22 Section 12.4.4, a net upward force of 0.2D for horizontal cantilever members is specified for the Design Earthquake with an implicit assumption that an upward seismic force of 1.2D is acting in conjunction with the weight (1.0D) of the cantilever member. For design using MCE_R, the vertical seismic force needs to be scaled up by a factor of 1.5, which produces an upward seismic force of 1.8D. As a result, the net upward force on the member becomes 1.8D – 1.0D = 0.8D.

2-16.3 Direction of Loading.

2-16.3.1 Direction of Loading Criteria.

When effects from the three earthquake ground motion components with respect to the principal axes of the building are calculated separately, the combined earthquake-induced response for each principal axis of the building must consist of the sum of

100% of the maximum value resulting from loading applied parallel to that axis and 40% of both maximum values that result from loading components orthogonal to that axis. Absolute values from all loading components must be used, so that all values are additive. If the three quantities are designated E_x, E_y, and E_z, they are to be combined in accordance with Equations 2-1, 2-2, and 2-3, and the maximum response, $E_{T\text{-}max}$, is to be the most severe effects of Equations 2-1, 2-2, or 2-3, for each individual structural element:

$$E_T = \pm\,[1.0\,E_x + 0.4\,E_y + 0.4\,E_z] \qquad \textbf{(Equation 2-1)}$$

$$E_T = \pm\,[0.4\,E_x + 1.0\,E_y + 0.4\,E_z] \qquad \textbf{(Equation 2-2)}$$

$$E_T = \pm\,[0.4\,E_x + 0.4\,E_y + 1.0\,E_z] \qquad \textbf{(Equation 2-3)}$$

Where:

E_x, E_y = *Maximum horizontal components of response*
E_z = *Maximum vertical component of response*
E_T = *Maximum combined response from three orthogonal components*

2-16.4 Analysis Procedure Selection.

2-16.4.1 General Requirements.

Structures assigned to RC V must be designed to ensure that their superstructures and installed mission-critical nonstructural elements remain elastic, when subjected to MCE_R ground motions, and that mission-essential equipment remains operable immediately following the MCE_R ground motions. MCE_R spectral acceleration parameters must be based on the procedures outlined in Section 2-15.2. In all analyses performed using the provisions of this Chapter, the variables R, C_d, ρ (see Section 2-16.2.2) and Ω_0 are all to be set to 1.0, as indicated in Section 2-16.1.3 of this UFC.

2-16.4.2 Horizontal and Vertical Force Determination.

Except for seismically isolated structures and structures using supplemental damping, structural analysis for horizontal and vertical force determination must be accomplished using a combined three-dimensional linear elastic Modal Response Spectrum Analysis (MRSA) in accordance with the provisions of ASCE 7-22 Sections 12.7.3 and 12.9.1. Refer to Section 2-15.3.1 for application of the Importance Factor, I_e, in ASCE 7-22 Section 12.9.1. Modal values are to be combined in accordance with the provisions of ASCE 7-22 Section 12.9.1.3. Further information on the use of the MRSA can be found in ASCE 4-16, *Seismic Analysis of Safety-Related Nuclear Structures*. For the ground motion component associated with each horizontal plan dimension of the structure, applied forces are to be determined using linear horizontal response spectra that are developed in accordance with the provisions of Sections 2-15.2.1 and 2-15.2.2.1.

For the ground motion component associated with the vertical axis of the structure, applied forces are to be determined using linear vertical response spectra that are developed in accordance with the provisions of Sections 2-15.2.1 and 2-15.2.2.2.

Exception: For structures using seismic isolation or supplemental damping, horizontal and vertical seismic forces must be determined using nonlinear dynamic analysis, in which the seismic isolators or dampers are modeled with nonlinear properties consistent with test results, and the remaining structural system is modeled as linearly elastic. The nonlinear response history analysis procedures of ASCE 7-22 Section 17.6 are to be used for the nonlinear analyses, except that vertical ground motions need to be included in the analyses.

2-16.4.3 Member Forces.

Response in structural elements and nonstructural elements that directly support critical functions must remain linear for the MCE_R ground motions, at anticipated drift demands. The requirement for linear response may be met through any combination of elastic member design, added damping or energy dissipation, or base isolation. The designer should consider the economics of these options, as well as the performance of critical installed equipment, in the structural design process.

[redacted] Low Seismicity Applications.

In areas of low seismic activity (S_{MS} < 0.25 and S_{M1} < 0.10), it is anticipated that linear response may be achieved through proper design of all structural elements in both the lateral load and gravity load systems, using one or more of the seismic force-resisting systems listed in Table 2-1. Alternatives may be used, if they are verified adequately through analysis and are approved by the Structural Design Reviewer (see Section 2-1.1).

[redacted] Moderate Seismicity Applications.

In areas of moderate seismic activity (0.25 ≤ S_{MS} ≤ 0.75, 0.10 ≤ S_{M1} ≤ 0.30), it is anticipated that linear response in the gravity load system and critical nonstructural elements may be achieved using supplemental energy dissipation (added damping) systems, in conjunction with one or more of the seismic force-resisting systems listed in Table 2-1. Where supplemental damping systems are used, they must be designed, tested, and constructed in accordance with the requirements of ASCE 7-22 Chapter 18. Analysis must conform to the requirements of ASCE 7-22 Section 18.7.1, Response Spectrum Procedure. It is recognized that damping systems generally have inherent nonlinear behavior. It is not the intent of these provisions to require linear behavior in damping or isolation systems. Alternatives may be used, if they are verified adequately through analysis and are approved by the Structural Design Reviewer (see Section 2-1.1).

[redacted] High to Very High Seismicity Applications.

In areas of high to very high seismic activity (S_{MS} > 0.75 or S_{M1} > 0.30), it is anticipated that linear response in the gravity load system and critical nonstructural elements may be achieved using seismic isolation systems, in conjunction with one or more of the seismic force-resisting systems listed in Table 2-1. In such situations, ASCE 7-22 Chapter 17 must be applied. It is recognized that isolation systems generally have inherent nonlinear behavior. It is not the intent of these provisions to require linear behavior in damping or isolation systems. Alternatives may be used, if they are verified adequately through analysis and are approved by the Structural Design Reviewer (see Section 2-1.1).

Exception: ASCE 7-22 Chapter 17 requires the use of the factor R_I for scaling the forces for structural elements above the isolation system. For RC V structures, the R_I factor is to be taken as 1.0. Table 2-1 must be used for selecting the structural system.

2-16.5 Equivalent Lateral Force Procedure.

The application of ASCE 7-22 Section 12.8 is not permitted for RC V structures.

[C] 2-16.5 Equivalent Lateral Force Procedure.

ASCE 7-22 has removed virtually all restrictions on the use of the Equivalent Lateral Force (ELF) procedure. However, the prohibition on the use of the procedure for RC V structures is retained here because Modal Response Spectrum Analysis (MRSA) provides a more accurate assessment of seismic structural response.

2-16.6 Modal Response Spectrum Analysis.

2-16.6.1 Modal Response Parameters.

Story drifts must be computed using a linear elastic MRSA procedure (see Section 2-16.4.2). Story drifts and P-Delta effects are to be determined using the procedures outlined in ASCE 7-22 Section 12.9.1. Refer to Section 2-15.3.1 for application of Importance Factor, I_e, in this section.

2-16.7 Diaphragms, Chords, and Collectors.

Diaphragm, chords, and collectors must be designed in accordance with ASCE 7-22 Section 12.10.

2-16.7.1 Design by ASCE 7-22 Sections 12.10.1 and 12.10.2.

When diaphragm forces are determined from ASCE 7-22 Section 12.10.1, apply a multiplier of 2 to the force at the uppermost level and design the diaphragm at each floor level for that force. In the application of ASCE 7-22 Section 12.10.1, the terms S_{DS} and S_{D1} are to be replaced by S_{MS} and S_{M1}, respectively (see Section 2-15.2.1 of this UFC).

The same adjustment applies to the design of collector elements by ASCE 7-22 Section 12.10.2.

ASCE 7-22 Section 12.10.1.1, is to be modified to delete the maximum force limit ($0.4S_{DS}I_e w_{px}$) that is placed on Equation 12.10-1.

[C] 2-17.7.1 Diaphragms, Chords, and Collectors

The above adjustments are intended to ensure that diaphragm behavior will remain elastic all the way up to the MCE_R. There are ample indications that the diaphragm design force levels of ASCE 7-22 Section 12.10.1 do not result in elastic diaphragm behavior even in the Design Earthquake (DE). The suggested modifications are adapted from the manual: Seismic Design of Precast/Prestressed Concrete Structures (PCI MNL-140, 2nd Edition) and the PCI Design Handbook (PCI MNL-120,8th Edition) published by the Precast/Prestressed Concrete Institute (PCI). The multiplier assumes that shear walls or braced frames form part of the seismic force-resisting system, which is typical of RC V structures.

A multiplier of 3 is appropriate when the diaphragm forces are determined based on the DE using S_{DS} and S_{D1}. However, in this UFC, all seismic forces are determined based on the MCE_R using S_{MS} and S_{M1}. As a result, the multiplier was scaled down to 2 in order to avoid an overly conservative design.

ASCE 7-22 Section 12.10.3 was introduced to address the above problem, which led to the addition of Section 2-16.7.2 of this UFC.

2-16.7.2 Design by ASCE 7-22 Sections 12.10.3.

When the alternative design provisions of ASCE 7-22 Section 12.10.3 are used, the ground motion parameters S_{DS} and S_{D1} are to be replaced by S_{MS} and S_{M1}, respectively. Diaphragm design force reduction factor, R_s, is to be taken as 1.0. The collector elements must be designed using ASCE 7-22 Section 12.10.3.4.

2-16.8 Structural Walls and Their Anchorage.

2-16.8.1 Design for Out-of-Plane Forces and Anchorage of Structural Walls and Transfer of Design Forces into Diaphragms.

Unless otherwise specified in this Chapter, transmitted seismic force, F_p, must be the maximum of F_p calculated in accordance with the provisions of ASCE 7-22 Section 12.11.2 and the actual forces computed using the procedures of this Chapter. The value of S_{MS} is to be used in lieu of S_{DS} in the equation for F_p in ASCE 7-22 Section 12.11.2. ASCE 7-22 lower-bound value for wall anchorage forces must be revised to the larger of $0.3k_aI_eW_p$ and 7.5 lb/ft^2. Refer to Section 2-15.3.1 for application of Importance Factor, I_e, in this section.

2-16.9 Drift and Deformation.

2-16.9.1 Story Drift Limit.

The design story drift (Δ) must not exceed the allowable story drift (Δ_a) for RC IV structures in ASCE 7-22 Table 12.12-1.

Exception: Where performance requirements for installed equipment or other nonstructural features require smaller allowable drifts than those permitted by this Section, the smaller drifts govern.

2-16.9.2 Deformational Compatibility.

ASCE 7-22 Section 12.12.4 does not apply.

2-17 SEISMIC DESIGN REQUIREMENTS FOR NONSTRUCTURAL COMPONENTS.

2-17.1 General.

2-17.1.1 Scope.

The provisions of ASCE 7-22 Chapter 13, as modified by UFC 3-301-01, apply, except as noted in the following paragraphs. Appendix C of UFC 3-301-01 provides supplementary guidance on design and analysis of architectural, mechanical, and electrical components. Appendix D of UFC 3-301-01 provides supplementary guidance on certification of mechanical and electrical components.

2-17.2 General Design Requirements.

2-17.2.1 General Requirements.

All architectural, mechanical, and electrical components must be designed for the in-structure horizontal and vertical response spectra developed in Section 2-17.4.4. Designs must include bracing, anchorage, isolators, and energy dissipation devices, as appropriate, for all components, in addition to the components themselves. Motion amplification through component supports must be determined and accommodated in design. Installed architectural, mechanical, and electrical components are to be classified as Mission-Critical Level 1 (MC-1), Mission-Critical Level 2 (MC-2), or Non-mission-critical (NMC). The structural engineer must classify all architectural, mechanical, and electrical components, in consultation with functional risk representatives designated by the AHJ.

Unless specifically noted otherwise in this UFC, any ASCE 7-22 Chapter 13 provision that is specific to RC IV structures must also be applied to RC V structures. Where ASCE 7-22 Chapter 13 requirements are based on the SDC of a structure, determine SDC assuming RC to be IV.

2-17.2.2 Mission-Critical Level 1 Components.

MC-1 components are those architectural, mechanical, and electrical components that are critical to the mission of the facility and must be operational immediately following the MCE_R ground shaking. MC-1 components are part of the Designated Seismic

System and as such must be certified as operable immediately following the MCE_R ground shaking in accordance with the provisions of ASCE 7-22 Section 13.2.3 as modified by UFC 3-301-01.

Exception: When shake table testing is performed, the Required Response Spectra (RRS) are not permitted to be derived using ICC-ES AC156.

2-17.2.3 Mission-Critical Level 2 Components.

MC-2 components are those architectural, mechanical, and electrical components that may incur minor damage that would be reparable with parts stocked at or near the facility within a 3-day period, by on-site personnel, following the MCE_R ground shaking. If the failure of an MC-2 component can cause the failure of an MC-1 component, then the MC-2 component must be considered as an MC-1 component. Typical MC-2 components may be suspended ceiling system components, lights, overhead cranes, and so forth. MC-2 components must be attached, anchored, and supported to resist the MCE_R-induced building motions. All supporting structures for MC-2 components must remain elastic during the MCE_R-induced building motions.

2-17.2.4 Non-Mission-Critical Components.

NMC components are those architectural, mechanical, and electrical components that may incur damage in the MCE_R ground shaking. If the failure of an NMC component can cause the failure of an MC-1 or MC-2 component, then the NMC component must be classified the same as the corresponding MC-1 or MC-2 component. NMC components must be designed so they will not cause falling hazards or impede facility egress. Typical NMC components may include bathroom vent fans, space heaters, and so forth.

2-17.2.5 Component Qualification Documentation.

The seismic qualification documentation for each piece of equipment must contain the following as a minimum:

1. The engineering submittal containing the following:

    a. Design calculations and complete description of the equipment or component with cut sheets or photographs containing all germane data including fastening requirements, welds, post-installed anchors, and so forth.

    b. Development of the in-structure response demand for vertical and horizontal shaking.

    c. For MC-1 components, development of the response capacity (fragility curve) for vertical and horizontal shaking.

    d. Design of the anchorage including anchor qualifications, calculations indicating forces predicated on the seismic loads, and capacity of the anchors.

e. A drawing indicating the equipment/component and location in the facility sufficient to be used for the installation.

All of the above elements must be checked and signed by the designer and nonstructural component design reviewer (UFC 3-301-02 Section 2-1.2). The designer must affix his/her Professional Engineer seal on the cover page. The cover page must identify the equipment/component and the performance category (MC-1 or MC-2).

2. Documentation of an independent design review of Item 1.

3. The Department of Energy (DOE) Screening Evaluation Worksheet (SEWS) of the installed MC-1 equipment/component. Documentation of the accompanying Special Inspection of any post-installed anchorages or Special Inspection of components identifying the Special Inspector. Consideration must be given to the installed condition and proximity to adjacent structures and components to avoid pounding effect.

   The appropriate DOE SEWS can be obtained from the DOE web site at: https://ehss.energy.gov/au/seismic/. Other evaluation worksheets can be used upon approval by the Authority Having Jurisdiction.

4. For MC-1 components, documentation of the independent “walk-down” inspection of the equipment in the final installed condition.

2-17.3 Seismic Demands on Nonstructural Components.

In the application of ASCE 7-22 Section 13.3.1, seismic forces are to be determined using the MCE_R ground motion parameters. The force calculations found in ASCE 7-22 Equations 13.3-1 through 13.3-3 do not apply. The following procedures must be used.

[redacted] MC-1 Components.

Forces for MC-1 components are to be determined by response spectrum analysis or equivalent static analysis, using as input the in-structure response spectra determined in accordance with Section 2-17.4.4. MC-1 components and their supports must remain elastic. MC-1 component forces are to be determined using Equation 2-4, with R_p for both components and supports set to 1.0.

$$F_p = \frac{a_{ip} W_p}{R_p} \qquad \textbf{(Equation 2-4)}$$

Where:
F_p = seismic design force centered at the component’s center of gravity and distributed according to the component’s mass distribution
a_{ip} = component spectral acceleration in a given direction, at the fundamental period of the component

W_p = component operating weight
R_p = component response modification factor

[redacted] MC-2 Components.

Forces for MC-2 components are to be determined by response spectrum analysis or equivalent static analysis, using as input the in-structure response spectra developed in accordance with Section 2-17.4.4. MC-2 component supports must remain elastic, while limited inelasticity in component response is permitted. MC-2 component forces are to be determined using Equation 2-4, with R_p for supports set to 1.0, and R_p for components as specified in Tables 2-2 and 2-3.

[C] 2-17.3.1.1 and 2-17.3.1.2 MC-1 and MC-2 Components

Major changes are made in ASCE 7-22 in the provisions for determining seismic forces in nonstructural components. One item in this revision is that the Component Response Modification Factor, R_p, is no longer there; a Component Strength Factor, R_{po} appears in its place. The primary difference between these two factors is, while R_p accounted for component ductility and overstrength, R_{po} accounts for only the component overstrength. Component ductility is now incorporated into another new parameter C_{AR} (Component Resonance Ductility Factor), which takes the place of the old a_p parameter.

In other words, in Equation 2-4, R_p cannot simply be replaced by R_{po} because then the effect of component ductility would be lost. At the same time, the new parameter C_{AR} cannot be included in Equation 2-4 either, because it also incorporates dynamic amplification of the component, which is already captured by a_{ip} in the equation.

In view of the above, it was decided to preserve the old R_p parameter in Equation 2-4 and to reproduce its values from ASCE 7-16 Tables 13.5-1 and 13.6-1 in this UFC in Tables 2-2 and 2-3, respectively. These R_p values have been a part of ASCE 7 for a long time, and should be satisfactory for the purpose of this UFC.

Note that while reproducing ASCE 7-16 Table 13.5-1 as Table 2-2, any reference to component connections or attachments have been deleted. This is because this section requires R_p for supports to be set to 1.0.

[redacted] NMC Components.

ASCE 7-22 Equation 13.3-7 must be used for NMC component force calculations. The peak in-structure floor acceleration determined in accordance with Section 2-17.4.4 is to be substituted for the term a_i, the acceleration at level i. Inelastic deformations are permitted in both component and support response. In applying ASCE 7-22 Equation 13.3-7, the values of C_{AR} and R_{po} specified in ASCE 7-22 Tables 13.5-1 and 13.6-1 are to be used. The component importance factor, I_p, is required for force calculations in ASCE 7-22 Equation 13.3-7. I_p is to be taken as 1.0, in lieu of the importance factors listed in ASCE 7-22 Sections 13.1.3.

Table 2-2 R_p Values for MC-2 Architectural Components

Architectural Component	R_p
Interior nonstructural walls and partitions	2½
Cantilever elements (unbraced or braced to structural frame below its center of mass)	
Parapets and cantilever interior nonstructural walls	2½
Chimneys where laterally braced or supported by the structural frame	2½
Cantilever elements (braced to structural frame above its center of mass)	
Parapets	2½
Chimneys	2½
Exterior nonstructural walls	2½
Exterior nonstructural wall elements	
Wall element	2½
Veneer	
Limited deformability elements	2½
Low-deformability elements	1½
Penthouses (except where framed by an extension of the building frame)	3½
Ceilings	
All	2½
Cabinets	
Permanent floor-supported storage cabinets more than 6 ft (1,829 mm) tall, including contents	2½
Permanent floor-supported library shelving, book stacks, and bookshelves more than 6 ft (1,829 mm) tall, including contents	2½
Laboratory equipment	2½
Access floors	
Special access floors (designed in accordance with Section 13.5.7.2)	2½
All other	1½
Appendages and ornamentations	2½
Signs and Billboards	3
Other rigid components	
High-deformability elements	3½
Limited-deformability elements	2½
Low-deformability materials	1½
Other flexible components	
High-deformability elements	3½
Limited-deformability elements	2½
Low-deformability materials	1½
Egress stairs and ramp fasteners	2½

Table 2-3 R_p Values for MC-2 Mechanical and Electrical Components

Components	R_p
MECHANICAL AND ELECTRICAL COMPONENTS	
Air-side HVACR, fans, air handlers, air conditioning units, cabinet heaters, air distribution boxes, and other mechanical components constructed of sheet metal framing	6
Wet-side HVACR, boilers, furnaces, atmospheric tanks and bins, chillers, water heaters, heat exchangers, evaporators, air separators, manufacturing or process equipment, and other mechanical components constructed of high-deformability materials	2½
Air coolers (fin fans), air-cooled heat exchangers, condensing units, dry coolers, remote radiators and other mechanical components elevated on integral structural steel or sheet metal supports	3
Engines, turbines, pumps, compressors, and pressure vessels not supported on skirts and not within the scope of Chapter 15	2½
Skirt-supported pressure vessels not within the scope of Chapter 15	2½
Elevator and escalator components	2½
Generators, batteries, inverters, motors, transformers, and other electrical components constructed of high-deformability materials	2½
Motor control centers, panel boards, switch gear, instrumentation cabinets, and other components constructed of sheet metal framing	6
Communication equipment, computers, instrumentation, and controls	2½
Roof-mounted stacks, cooling and electrical towers laterally braced below their center of mass	3
Roof-mounted stacks, cooling and electrical towers laterally braced above their center of mass	2½
Lighting fixtures	1½
Other mechanical or electrical components	1½
VIBRATION-ISOLATED COMPONENTS AND SYSTEMS	
Components and systems isolated using neoprene elements and neoprene isolated floors with built-in or separate elastomeric snubbing devices or resilient perimeter stops	2½
Spring-isolated components and systems and vibration-isolated floors closely restrained using built-in or separate elastomeric snubbing devices or resilient perimeter stops	2
Internally isolated components and systems	2
Suspended vibration-isolated equipment including in-line duct devices and suspended internally isolated components	2½
DISTRIBUTION SYSTEMS	
Piping in accordance with ASME B31 (2001, 2002, 2008, and 2010), including in-line components with joints made by welding or brazing	12
Piping in accordance with ASME B31, including in-line components, constructed of high- or limited-deformability materials, with joints made by threading, bonding, compression couplings, or grooved couplings	6
Piping and tubing not in accordance with ASME B31, including in-line components, constructed of high-deformability materials, with joints made by welding or brazing	9

Components	R_p
Piping and tubing not in accordance with ASME B31, including in-line components, constructed of high- or limited-deformability materials, with joints made by threading, bonding, compression couplings, or grooved couplings	4½
Piping and tubing constructed of low-deformability materials, such as cast iron, glass, and nonductile plastics	3
Ductwork, including in-line components, constructed of high-deformability materials, with joints made by welding or brazing	9
Ductwork, including in-line components, constructed of high- or limited-deformability materials with joints made by means other than welding or brazing	6
Ductwork, including in-line components, constructed of low-deformability materials, such as cast iron, glass, and nonductile plastics	3
Electrical conduit and cable trays	6
Bus ducts	2½
Plumbing	2½
Pneumatic tube transport systems	6

2-17.4 Response Analysis Procedures for Architectural, Mechanical, and Electrical Components.

2-17.4.1 General.

ASCE 4-16, *Seismic Analysis of Safety-Related Nuclear Structures*, is to serve as a reference in response analysis.

2-17.4.2 Dynamic Coupling Effects.

It is anticipated that installed mechanical and electrical systems may require significant secondary structural systems in RC V buildings. The provisions of ASCE 4-16 Section 3.7, *Dynamic Coupling Criteria*, apply.

2-17.4.3 Modeling Flooring Systems.

Structures with rigid flooring systems are to be modeled in accordance with the provisions of ASCE 4-16 Section 3.8.1.1, *Structures with Rigid Floor Diaphragms*. Structures with flexible flooring systems are to be modeled in accordance with the provisions of ASCE 4-16 Section 3.8.1.2, *Structures with Flexible Floor Diaphragms*.

2-17.4.4 In-structure Response Spectra.

Provisions of ASCE 4-16 Section 6, *Input for Subsystem Analysis*, apply for the construction of in-structure response spectra needed for the determination of accelerations and displacements for installed architectural, mechanical, and electrical components. In-structure response spectra must be developed from models of primary structures subjected to MCE_R ground motions. Frequency interval of the response spectra is to be set based on ASCE 4-16 Section 6.2.2. However, the lower-bound frequency is to be set at 0.1 Hz. Increments above 34 Hz are to be at 3 Hz and increments below 0.5 Hz are to be at 0.10 Hz.

Exception: In the application of ASCE 4-16 Section 6, those provisions that relate to spectra-to-spectra analysis in Section 6.2.1.2 do not apply.

2-17.5 Design of Architectural Components.

2-17.5.1 Suspended Ceilings.

In addition to the provisions of ASCE 7-22, as modified by UFC 3-301-01, suspended ceilings are to be designed to resist seismic effects using a rigid bracing system, where the braces are capable of resisting tension and compression forces, or diagonal splay wires, where the wires are installed taut. Particular attention should be given in walk-down inspections (see Section 2-18.4) to ensure splay wires are taut. Positive attachment is required to be provided to prevent vertical movement of ceiling elements. Vertical support elements need to be capable of resisting both compressive and tensile forces. Vertical supports and braces designed for compression must have a slenderness ratio, Kl/r, of less than 200. Additional guidance on suspended ceiling design is provided in Section C-2.2.8 of UFC 3-301-01.

2-17.6 Design of Mechanical and Electrical Components.

2-17.6.1 Seismic Controls for Elevators.

For buildings that are assigned to RC V, seismic switches are not permitted to be used. Elevator system design for RC V buildings must ensure elevator operability at accelerations computed from building response analysis. Additional guidance on the design of elevator systems is found in Section C-3.3 of UFC 3-301-01.

2-17.7 Component Qualification Documentation and Operations & Maintenance (O&M) Manual.

All MC-1 and MC-2 equipment qualification documentation as outlined in Section 2-17.2.5 must be maintained in a file identified as “Mission Critical Components and Equipment Qualifications Manual” that is to be a part of the Operations & Maintenance Manual that is turned over to the Authority Having Jurisdiction. The project specifications should require the Operations & Maintenance Manual to state that replaced or modified components need to be qualified per the original qualification criteria.

2-17.8 Component Identification Nameplate.

All MC-1 and MC-2 equipment must bear permanent marking or nameplates constructed of a durable heat and water resistant material. Nameplates must be mechanically attached to all nonstructural components and placed on the component for clear identification. The nameplate must not be less than 5" x 7" with red letters 1" in height on a white background stating MC-1 or MC-2 as appropriate. The following statement must be on the nameplate: “This equipment/component is Mission Critical. No modifications are allowed unless authorized in advance and documented in the Mission Critical Equipment Qualifications Manual.” The nameplate must also contain the component identification number in accordance with the drawings/specifications and the O&M manuals. Continuous piping, and conduits must be similarly marked as specified in the contract documents.

2-18 SPECIAL INSPECTIONS AND TESTS.

2-18.1 General.

2024 IBC Chapter 17, as modified by UFC 1-200-01 and UFC 3-301-01, applies to RC V structures.

2-18.2 Structural Observations for Structures.

Replace the text of IBC Section 1704.6.1 with the following:

Structural observations must be provided for RC V structures.

2-18.3 Special Inspections for Seismic Resistance.

Replace the existing text in 2024 IBC Section 1705.13 with the following:

Special Inspections itemized in Sections 1705.13.1 through 1705.13.9 apply to structures assigned to Risk Category V.

2-18.4 Plumbing, Mechanical and Electrical Components.

Add the following before the existing text in 2024 IBC Section 1705.13.6:

Special inspection and verification are required for Designated Seismic Systems and must be performed as required by the Statement of Special Inspections, and the Schedule of Special Inspections, which must be prepared for each project. Templates for these documents may be downloaded from the following link, under “Related Materials”:

https://www.wbdg.org/dod/ufgs/ufgs-01-45-35

The SER must prepare a Statement of Special Inspections in accordance with 2024 IBC Section 1704 for the Designated Seismic Systems.

The Statement of Special Inspections is required to define the periodic walk-down inspections that must be performed to ensure that the nonstructural elements satisfy life safety mounting requirements. The walk-down inspections must be performed by design professionals who are familiar with the construction and installation of mechanical and electrical components, and their vulnerabilities to earthquakes. The selection of the design professional is subject to the approval of the SER.

Designated Seismic Systems require a final walk-down inspection by the SER and by the Nonstructural Component Design Reviewer (see Section 2-1.2). The final review must be documented in a report. The final report prepared by the SER needs to include the following:

1. Record/observations of final site visit
2. Documentation that all required inspections were performed in accordance with the Statement of Special Inspections.
3. Documentation that the Designated Seismic Systems were installed in accordance with the construction documents and inspected in accordance with the requirements of 2024 IBC Chapter 17, as modified by this UFC.

2-18.5 Testing for Seismic Resistance.

Add the following before the first paragraph in 2024 IBC Section 1705.14:

Any requirements for structural testing for structures assigned to Seismic Design Category C or higher also apply to structures assigned to Risk Category V.

2-19 SOILS AND FOUNDATIONS.

Such provisions of 2024 IBC Chapter 18 as are consistent with the foundation remaining elastic apply to RC V structures, [except that the minimum Chapter 18 provisions applied are to be those required for SDC D structures]. In addition, the requirement in the following paragraph applies.

2-19.1 Foundation Uplift and Rocking.

The requirement for elastic response of these RC V structures may lead to the existence of significant overturning forces in the structural system, and accompanying foundation element uplift forces or rocking. The SER is to be responsible for evaluating foundation overturning and rocking in the analysis and design, and this evaluation must be reviewed by the Structural Design Reviewer (see Section 2-1.1).

This UFC supersedes UFC 3-310-08, *Non-Expeditionary Bridge Inspection, Maintenance, and Repair*, dated 16 August 2010.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and DOD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DOD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and, in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Military Departments, the Defense Agencies, and DOD Field Activities should contact the preparing Service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DOD working group. Recommended changes with supporting rationale should be sent to the respective Service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

- UFC are effective upon issuance and are distributed only in electronic media from the following source: Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-310-08, *Non-Expeditionary Bridge Inspection, Maintenance, and Repair*

Superseding: UFC 3-310-08, *Non-Expeditionary Bridge Inspection, Maintenance, and Repair,* dated 16 August 2010

Description: This document provides guidance to ensure military garrison/base bridges remain safely in operation and behave reliably for civilian and military traffic.

Reasons for Document:

- Purpose: To ensure that military installation bridges remain safely in operation and perform reliably for civilian and military traffic. The bridges inspected, operated, and maintained by military agencies should meet or exceed the same standards to which bridges under U.S. civilian jurisdiction are subject.

- Application: This UFC provides direction so all military installation bridges are appropriately inspected and the results reported in accordance with current federal standards, Federal Highway Administration (FHWA) criteria, and Federal Railway Administration (FRA) criteria. This UFC also provides direction to ensure all military installation bridges are maintained and repaired in a consistent manner and in accordance with industry standards.

Impact:

The publication of UFC 3-310-08 will not result in any increased cost to the Services. Each Service is already in compliance with the National Bridge Inspection Standards (NBIS) and the reporting requirements directed by the Code of Federal Regulations, Title 23, Part 650, Subpart C, and Title 49, Subtitle B, Chapter II, Part 237. The provisions in this UFC are already being accomplished by each Service as directed by separate Service documents (Army ER 1110-2111, Air Force ETL 07-5 [superseded by this UFC], and Navy UG-60020-OCN).

Unification Issues:

Not applicable; all agencies affected by this UFC are subject to the same requirements.

TABLE OF CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

In an effort to develop a coherent and consistent Department of Defense (DOD) policy for the inspection, evaluation, maintenance, and repair of installation bridges, this UFC was created to consolidate evolving federal bridge inspection and industry standards. As federal and state regulations, standards, guidelines, and procedures continually change, it is critical to remain current with the industry and update this UFC to ensure compliance with all bridge inspection, evaluation, load rating, maintenance, and repair requirements.

1-2 PURPOSE.

This UFC defines requirements for inspection, maintenance, and repair of bridges on military installations in accordance with current federal and industry standards. In particular, highway bridges must conform to Federal Highway Administration (FHWA) criteria (23 CFR 650 Subpart C) while railroad bridges must conform to Federal Railroad Administration (FRA) criteria (49 CFR 237). The purpose of these requirements is to ensure military installation bridges can safely and reliably carry civilian and military traffic. All bridges inspected, operated, and maintained by military agencies should meet or exceed the same standards to which bridges under U.S. civilian jurisdiction are subject.

1-3 SCOPE.

This UFC applies to all military installation bridges, whether located in the contiguous United States (CONUS) or outside the contiguous United States (OCONUS), including Alaska, Hawaii, U.S. territories and possessions, and foreign territories. Installation bridges can be classified according to the type of traffic “over” the bridge as 1) highway bridges, 2) railroad bridges, 3) pedestrian bridges, 4) golf cart bridges, or 5) taxiway bridges. This UFC does not apply to expeditionary bridges located in military theaters of operation. This UFC does not apply to Army Corps of Engineers civil works bridges located outside of an installation.

1-4 REFERENCES.

Appendix A contains a list of references used in this UFC.

CHAPTER 2 DOD BRIDGE INSPECTION AND MANAGEMENT PROGRAM

This chapter provides technical requirements for a bridge inspection and management program. Refer to the appropriate sections in this UFC for inspection, load rating, reporting, maintenance, and repair requirements for each type of bridge.

2-1 ORGANIZATIONAL STRUCTURE – RESPONSIBILITIES AND QUALIFICATIONS.

The U.S. Code of Federal Regulations (23 CFR 650.305 and 49 CFR 237) requires each Military Department to establish and maintain a bridge inspection and management program. At the head of each program is a National Bridge Program Manager who enforces the bridge program in accordance with the Military Department's policies.

Point of contact information for each Military Department's bridge program is found in Appendix B, paragraph B-3.

The credentials, qualifications, and responsibilities of the key bridge program positions are described below. The fulfillment of these duties can be accomplished using in-house personnel, contracted personnel, or personnel from another government agency.

2-1.1 National Bridge Program Manager.

The National Bridge Program Manager for each Military Department provides overall leadership and inspection guidance for every bridge in the Department's bridge inventory (CONUS and OCONUS). The National Bridge Program Manager must successfully complete an FHWA-approved comprehensive bridge inspection training course followed by an FHWA-approved refresher training course every subsequent five years. Also, the National Bridge Program Manager must either be a licensed professional engineer (P.E.) or have 10 years of bridge inspection experience. The National Bridge Program Manager should have a general understanding of all aspects of bridge engineering, including design, load rating, new construction, rehabilitation, inspection or condition evaluation, and maintenance.

Refer to Appendix B, paragraph B-10, Table B-4, for delineation of responsibilities between the National Bridge Program Manager and Installation Bridge Managers for each Military Department.

2-1.2 Installation Bridge Manager.

An Installation Bridge Manager typically carries out responsibilities delegated from the National Bridge Program Manager at a specific military installation as delineated in Appendix B, paragraph B-10, Table B-4. The Installation Bridge Manager must have completed an FHWA-approved comprehensive bridge inspection training course and must complete an FHWA-approved refresher training course every five years after completing the FHWA-approved comprehensive training course.

2-1.3 Load Rating Engineer.

As required by 23 CFR 650.309(c), each Military Department must designate a Load Rating Engineer who will be responsible for ensuring load ratings are performed as specified in this UFC. The individual responsible for load rating calculations or determining a load rating by engineering judgment must be a P.E.

For railroad bridges falling under the jurisdiction of the FRA bridge safety standards, 49 CFR 237, the Load Rating Engineer must also meet the requirements of 49 CFR 237.51 and be designated as a Railroad Bridge Engineer.

2-1.4 Railroad Bridge Engineer.

Railroad bridge inspection, maintenance, and load rating functions must be performed under the direction of a Railroad Bridge Engineer. A Railroad Bridge Engineer is a person determined by the track owner to be competent to perform the functions identified in 49 CFR 237.51(a). These functions include determining forces and stresses in railroad bridges and bridge components, prescribing safe loading conditions for railroad bridges, prescribing inspection and maintenance procedures for railroad bridges, and designing repairs and modifications to railroad bridges.

A Railroad Bridge Engineer must meet the educational qualifications as specified in 49 CFR 237.51(b), including either an engineering degree from an accredited program or current registration as a P.E.

2-1.5 Railroad Bridge Inspector.

A Railroad Bridge Inspector must meet the requirements specified in 49 CFR 237.53.

2-1.6 Inspection Team Leader (Highway Bridges).

The Inspection Team Leader must meet the requirements specified in 23 CFR 650.305. Inspection Team Leaders must complete an FHWA-approved refresher training course every five years after completing the FHWA-approved comprehensive training course.

2-1.7 Underwater Bridge Inspector.

The underwater bridge inspection diver must have a commercial diver certification. Diver training certification must conform to Section 30.A.06 of Army Engineering Manual (EM) 385-1-1, *Safety and Health Requirements*. An underwater bridge inspection diver who does not meet the qualifications of paragraph 2-1.6 must have completed an FHWA-approved comprehensive bridge inspection training course or other FHWA-approved underwater bridge inspection training course. Underwater Bridge Inspection Team Leader requirements are the same as those listed in paragraph 2-1.6. All underwater inspections will be under the direct supervision of a qualified Inspection Team Leader with underwater inspection experience.

Underwater inspector qualifications must meet host country underwater diver qualifications in addition to the requirements of the National Bridge Inspection Standards (NBIS) and with the approval of the National Bridge Program Manager.

2-1.8 Hydraulic Bridge Engineer.

Hydraulic Bridge Engineers performing scour calculations must be licensed P.E.s and have relevant work experience in bridge hydraulic modeling and scour evaluations.

2-2 BRIDGE INVENTORY DATA REQUIREMENTS.

2-2.1 Components of Bridge File.

Complete, accurate, and current bridge records must be maintained in a bridge file for each National Bridge Inventory (NBI) highway bridge in accordance with AASHTO MBE-2-M, *The Manual for Bridge Evaluation*, Section 2. It is recommended that bridge files for all other bridges follow this format. The bridge file provides a full history of the structure, including construction drawings, as-built drawings, photographs, damage, repairs, and capacity calculations. At a minimum, significant bridge file components that must be maintained include:

- Inspection reports
- Waterway information (channel cross-sections, soundings, stream profiles)
- Significant correspondence
- Special inspection procedures or requirements
- Load rating documentation, including load testing results
- Posting documentation
- Critical findings and actions taken
- Scour assessment
- Scour plan of action (POA) for scour critical bridges and those with unknown foundations and documentation of post-event inspection or follow-up
- Inventory and evaluation data and collection/verification forms.

Refer to Section 2 of AASHTO MBE-2-M, *The Manual for Bridge Evaluation*; 49 CFR 237.33; and FHWA-PD-96-001, *Recording and Coding Guide for the Structure Inventory and Appraisal of the Nation's Bridges*, for additional information regarding bridge files.

2-2.2 File Retention/Data Storage.

File retention and organization policies will be determined by the National Bridge Program Manager. Each Military Department's National Bridge Program Manager will determine the storage location in accordance with Section 2 of AASHTO MBE-2-M.

Bridge files must be readily accessible to the Installation Bridge Manager. It is highly recommended that hard copies of inspection reports and load ratings be maintained for two full inspection cycles (typically 48 months). Electronic copies of components of the bridge file, inspection reports, and load ratings will be maintained in perpetuity, along with bridge inventory database information. If components of the bridge file are found to be deficient or incomplete, a plan of corrective action will be developed to remedy future recordkeeping procedures.

2-3 QUALITY CONTROL/QUALITY ASSURANCE REQUIREMENTS.

The National Bridge Program Manager will determine the specific procedures for quality control (QC) and quality assurance (QA) reviews. At a minimum, 5 percent of bridge inspection teams and 5 percent of the inspected bridges will be audited annually in some manner (e.g., through field reviews of inspection teams or office reviews of inspection reports). FHWA *Bridge Inspector's Reference Manual* (BIRM), Topic 1.3.4, discusses the FHWA-recommended QC/QA framework.

As part of the QC/QA framework, the bridge management program will identify QC and QA responsibilities.

Once established, QC/QA procedures for each agency must be compiled in a manual that is readily available to all personnel involved with bridge inspection; this manual will be updated to reflect any procedural changes.

CHAPTER 3 HIGHWAY BRIDGES

3-1 DEFINITIONS.

3-1.1 Highway.

A “highway” is defined by 23 U.S.C. 101(a)(11) as follows:

> *(11) Highway. - The term "highway" includes –*
>
> *(A) a road, street, and parkway;*
>
> *(B) a right-of-way, bridge, railroad-highway crossing, tunnel, drainage structure including public roads on dams, sign, guardrail, and protective structure, in connection with a highway.*

Therefore, all roads on military installations are considered to be “highways.”

3-1.2 Public Road.

A “public road**”** is defined by 23 U.S.C. 101(a)(21) as follows:

> *(21) Public road. - The term "public road" means any road or street under the jurisdiction of and maintained by a public authority and open to public travel.*

Since roads on military installations are typically accessible to military personnel, government civilians, contractor personnel, and retired personnel, all road bridges on military installations are deemed to be public highway bridges regardless of the bridge’s access restrictions unless the Installation Commander designates otherwise (with the Military Department’s National Bridge Program Manager’s approval). Non-public designations will be avoided unless warranted by special circumstances.

3-1.3 Bridge.

A “bridge” is defined in 23 CFR 650.305 as follows:

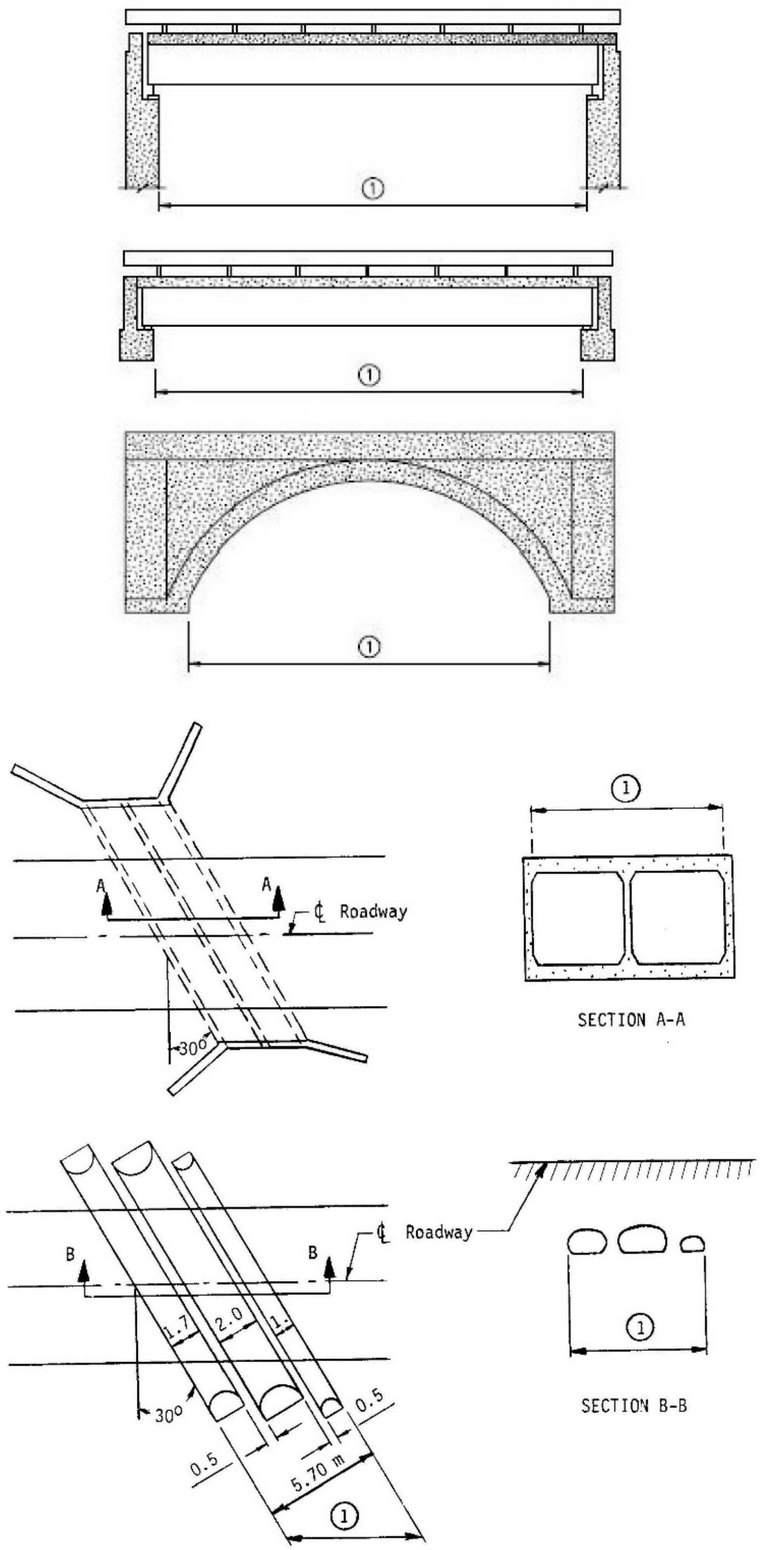
> *“A structure including supports erected over a depression or an obstruction, such as water, highway, or railway, and having a track or passageway for carrying traffic or other moving loads, and having an opening measured along the center of the roadway of more than 20 feet (6.1 meters) between undercopings of abutments or spring lines of arches, or extreme ends of openings for multiple boxes; it may also include multiple pipes, where the clear distance between openings is less than half of the smaller contiguous opening.”*

The method to measure bridge length is depicted in Figure 3-1 as taken from FHWA-PD-96-001.

The NBIS apply to installation highway bridges (in U.S. states and territories) that meet the length requirement above. Highway bridges that meet the length requirements specified in the NBIS are required to be included in the NBI. Requirements for installation bridges in foreign territories have similar requirements, as described in paragraph 3-3.2.

Culverts also qualify as bridges if the preceding definition applies. Culverts that do not meet the preceding definition may be managed similarly to other installation drainage structures.

Figure 3-1 NBIS Bridge Length



① Item 112 ~ NBIS Bridge Length

3-1.4 Strategic Highway Corridor Network (STRAHNET)

FHWA-PD-96-001 defines the Strategic Highway Corridor Network (STRAHNET) and connectors as a system of highways that are strategically important to the defense of the United States. There are no STRAHNET highways or connectors carried by bridges on military installations. For situations where an installation owns a bridge over a STRAHNET highway or connector, refer to the description of item 5A in FHWA-PD-96-001 for coding instructions.

3-2 NATIONAL BRIDGE INVENTORY (NBI) HIGHWAY BRIDGES.

All NBI highway bridges must be inspected in accordance with the NBIS. These standards establish minimum federal requirements for inspection procedures, inspection intervals, personnel qualifications, inspection reports, and bridge inventory records. Although not reproduced verbatim in this UFC, the standards are listed in Appendix A as a reference. The NBIS should be consulted whenever a question arises regarding federal inspection requirements.

The FHWA has developed 23 metrics for the oversight of the National Bridge Inspection Program. Agencies and installations must take the necessary steps to remain compliant with the NBIS as determined by FHWA and the 23 metrics. Refer to FHWA *Metrics for the Oversight of the National Bridge Inspection Program* for additional information.

3-2.1 History of the NBIS Program.

Several catastrophic bridge failures since 1967 have led to the creation of and modifications to federal laws that constitute the FHWA-managed NBIS. The NBIS provides requirements for inspecting highway bridges and reporting bridge conditions annually in the NBI database. The procedures to implement the NBIS requirements are explained in the BIRM. For a more comprehensive history of the National Bridge Inspection Program, refer to the BIRM, Chapter 1.

3-2.2 Bridge Inspection Requirements.

3-2.2.1 Inspection Types and Interval.

Bridge inspections are conducted to determine the physical condition of the structure, to develop the basis for load rating analyses, to assess the need for maintenance, and to track the functional condition and rate of deterioration over time. There are seven inspection types requiring unique levels of effort: initial/inventory, routine, damage, in-depth, fracture critical, underwater, and special.

Descriptions of and the required inspection intervals for each type of inspection are specified below. The inspection intervals may be altered but must meet all applicable NBIS criteria. See Appendix B, paragraph B-2, for inspection interval alteration procedures. Late inspections require a justification of unusual circumstances (e.g., natural disaster, ongoing bridge construction activity) and will be included in the bridge file.

3-2.2.1.1 Initial/Inventory Inspection.

The initial/inventory inspection is the first inspection after a bridge is built or added to the installation real property and becomes a part of the bridge file. Elements of the initial/inventory inspection will also apply when there has been a change in configuration of the structure (e.g., widening, lengthening, and supplemental bents). It is important for the inspectors to identify any existing problems or locations in the structure where potential problems may arise. An initial inspection must provide all Structure Inventory and Appraisal (SI&A) data. A thorough review of as-built plans will be conducted prior to the initial inspection and the inspector will note any fracture critical members (FCM) or details during this inspection. A Level 1 scour screening is required if the bridge crosses over a waterway. A revised or new load rating may be required with the initial inspection if the rating was not part of the construction submittal or if repairs affected the structural capacity. The initial/inventory inspection documents the baseline condition assessment of the bridge.

Initial/inventory inspections must be performed **within 90 days** of the bridge opening to traffic. New bridges must be added to the installation real property and become a part of the bridge file prior to opening to traffic.

3-2.2.1.2 Routine Inspection.

Routine inspections are regularly scheduled inspections serving to collect observations and measurements of any changes from the initial inspection or any previously conducted inspection. The routine inspection must be performed and reported in accordance with NBIS requirements.

All routine inspections will be conducted at regular intervals **not to exceed 24 months**. The National Bridge Program Manager may increase routine inspection intervals for bridges that meet the criteria for increased inspection intervals discussed in Appendix B, paragraph B-2.

3-2.2.1.3 Damage Inspection.

Damage inspections are one-time unscheduled inspections performed after environmental events or human actions such as collisions, floods, or earthquakes. Damage inspections are performed to 1) determine if structural damage has occurred, 2) evaluate the extent of any structural damage, and 3) determine the level of effort for required repairs.

Damage inspections must be performed within a reasonable time after a natural disaster or human-caused action. The inspectors must document all damaged members, measuring, at a minimum, any section loss, member misalignment, and any loss of foundation support. The inspection must provide all of the information necessary to determine if bridge closure is required or to perform an emergency load restriction.

Local installation personnel may make an initial assessment of the bridge if personnel meeting required inspector qualifications are not immediately available. The results of the initial damage assessment will be forwarded to the Installation Bridge Manager for review. Based on the information in the initial damage assessment, the Installation Bridge Manager will determine if additional resources (e.g., additional inspection, testing, load rating, design) are required to fully evaluate or correct the damaged condition. The Installation Bridge Manager or National Bridge Program Manager may recommend a follow-up in-depth inspection of the bridge to monitor the structure.

3-2.2.1.4 In-Depth Inspection.

In-depth inspections are hands-on, close-up inspections of one or more members above or below the waterline. In-depth inspections are more detailed and may require special access techniques to inspect areas not easily detectable in a routine inspection.

In-depth inspections are required every 24 months for fracture critical bridges. For other bridge types, in-depth inspections may be performed after damage or other special inspections are performed, at the direction of the Installation Bridge Manager or National Bridge Program Manager. For small bridges, the in-depth inspection includes inspection of all critical members of the structure. For large and complex structures, these inspections may be scheduled separately for defined segments of the bridge or bridge elements, connections, or details.

3-2.2.1.5 Fracture Critical Inspection.

Fracture critical inspections are detailed, hands-on inspections of steel bridges with FCMs that may include visual or other nondestructive evaluations. Prior to inspection, a thorough review of the design or as-built plans, fracture-critical inspection plan, previous inspection reports, load rating, and fatigue-prone details must be made. In the absence of plans or identification of fatigue-prone details, the inspector should be able to determine the fatigue-prone details based on the information provided in Table 6.6.1.2.3-1 of AASHTO LRFDUS-7, *LRFD Bridge Design Specifications*. FCMs require a “hands-on” inspection, where the inspector is capable of touching the area being inspected (arm’s length). Physical inspection methods may be necessary to more accurately assess the condition of an FCM. Advanced inspection methods may need to be employed, including nondestructive testing (NDT) methods. The hands-on inspection should identify and note the condition of problematic details prone to crack development.

For more information regarding inspection techniques for fracture critical bridges, refer to the BIRM or FHWA-NHI-11-015, *Fracture Critical Inspection Techniques for Steel Bridges Participant Workbook.* For additional information and case studies on fatigue damage in welded, bolted, and riveted structures, refer to FHWA *Manual for Inspecting Bridges for Fatigue Damage Conditions* and John W. Fisher’s *Fatigue and Fracture in Steel Bridges – Case Studies*.

Fracture critical inspections will be conducted at regular intervals not to exceed 24 months. In order to establish the criteria for fracture critical inspection intervals and level of effort, factors such as bridge age, fatigue-prone details, and known deficiencies will be considered.

3-2.2.1.6 Underwater Inspection.

3-2.2.1.6.1 Underwater inspections include diving to visually inspect and measure bridge components, probing for scour or undermining, and sounding to locate the bottom of the channel. The inspection must include such methods as necessary to adequately perform a condition assessment of the structure. If a bridge can be adequately inspected by wading, shallow probing, or with the use of cameras at low water conditions, a formal underwater inspection (divers) is not required. For bridges that do not require a formal underwater inspection, Item 93B on the SI&A form will not be coded. The Installation Bridge Manager will ensure inspections occur at low water conditions while maintaining compliance with the required bridge inspection schedule.

3-2.2.1.6.2 According to the BIRM, there are three levels of underwater inspection intensity:

- Level 1 – Visual, tactile inspection
- Level 2 – Detailed inspection with partial cleaning
- Level 3 – Highly detailed inspection with NDT or partially destructive testing (PDT)

3-2.2.1.6.3 Bridge inspectors must examine previous inspection reports or gather sufficient bridge and channel information to determine which level of underwater inspection is required when contracted or tasked to perform underwater inspections for specific bridges.

3-2.2.1.6.4 Level 1 inspections are required for all routine underwater inspections and will be performed within arm’s reach of the areas being inspected. Visual inspections are performed across the entire submerged structure, but, in areas of poor water clarity, a tactile sweeping motion of the hands and arms may be used to inspect the entire substructure.

3-2.2.1.6.5 Level 2 inspections include cleaning off marine or aquatic growth at critical inspection areas and inspecting high-stress, damaged, and deteriorated areas that may be shielded by the growth. Critical areas near the low waterline, mudline, and midway between will be inspected. Piers and abutments will have at least 1 square foot (0.09 square meter) cleaned at three or more levels on each face. For structures greater than 50 feet (15.2 meters) in length, an additional three levels will be cleaned at each exposed face. For piles, horizontal bands a minimum of 10 inches (254 millimeters) long will be cleaned along the following locations:

- Rectangular – At least three sides
- Octagonal – At least six sides
- Round – At least 75 percent of circumference
- H-pile – At least the outside faces of flanges and one side of web

3-2.2.1.6.6 Level 2 inspection is recommended for 10 percent of all underwater elements.

3-2.2.1.6.7 Level 3 inspections include the complete cleaning of a structural element and NDT or PDT. Detailed measurements will be made along with testing techniques such as ultrasonic, physical material sampling, or boring. These inspections are generally performed when a structural repair or possible replacement is being considered.

3-2.2.1.6.8 Level 3 inspections are recommended for members that require repair or rehabilitation.

3-2.2.1.6.9 For additional information, it may be helpful to review FHWA-NHI-10-027, *Underwater Bridge Inspection*. This report contains valuable information on underwater inspection techniques, underwater repair techniques, and scour issues.

3-2.2.1.6.10 Underwater inspections must be completed at regular intervals not to exceed 60 months. The Installation Bridge Manager may decrease the interval of underwater inspections based on Level 1 or Level 2 scour evaluations, evidence of substructure movement, stream migration, bank sloughing, or debris buildup. Any deviation in the underwater inspection interval must be documented in the bridge file. FHWA-NHI-10-027 provides guidance for alterations to underwater inspection intervals.

3-2.2.1.7 Special Inspection.

Special inspections monitor a known member deficiency or other conditions that warrant special attention, such as foundation settlement or scour, fatigue damage, severe section loss, critical findings, or the public's use of a load posted bridge. These inspections are not usually comprehensive enough to meet NBIS requirements for routine inspections.

Based on the recommendations in the inspection reports, the Installation Bridge Manager will determine when special inspections are required. Special inspections are scheduled based on the severity of the deficiency/condition being monitored and the anticipated rate of continued deterioration (i.e., special inspections for scour should be performed after high-water events; special inspections for section loss should be at three-, six-, or twelve-month intervals, based on the severity of deterioration and its effect on the bridge's safe load capacity).

For bridges that do not require a formal special inspection, Items 92C and 93C on the SI&A form will not be coded. For bridges where items 92C and 93C are coded, a separate report for this inspection is required. If the inspection is conducted in conjunction with other inspections, the scope, procedures, findings, and recommendations must be recorded in a separate paragraph in the bridge inspection report.

3-2.2.2 Inspection Procedures.

Each bridge must be inspected in accordance with 23 CFR 650. Guidance on various bridge inspection procedures is provided in the BIRM and AASHTO MBE-2-M. A minimum of one qualified team leader must be present at all times during initial, routine, in-depth, FCM, and underwater inspections.

3-2.3 Load Rating and Posting Requirements.

For new bridge design, load rating calculations must be a contract deliverable. Load ratings will be performed during all initial inspections or when no previous load rating exists. During routine, in-depth, fracture critical, underwater, or special inspections, any changed conditions identified that may alter the load rating will be forwarded to the Load Rating Engineer for review. If damage, deterioration, or structure alterations noted during the inspection are determined by the Load Rating Engineer to be significant, an updated load rating will be performed and load restriction may be required.

The load rating report must clearly state basic information about the bridge (e.g., configuration, material type, age), method of analysis, references, and all assumptions used to establish a valid load rating.

3-2.3.1 AASHTO Load Ratings.

Load rating must be performed for all roadway bridges that meet the NBIS definition of a bridge (over 20 feet [6.1 meters] measured along the centerline of the roadway). The load rating must be calculated in accordance with AASHTO MBE-2-M. For highway bridges on an installation in foreign territory, if the foreign country's bridge code is more stringent than AASHTO, the foreign bridge code will govern the load rating. Posting of bridges (including the specific sign) for civilian vehicles, when determined to be necessary from the load rating, will be in accordance with local requirements (typically, state legal load limits or the foreign code legal load limits); see Appendix B, paragraph B-4, for state posting loads. Highway bridges must have load ratings for special hauling vehicles (SHV) per FHWA's *Load Rating of Specialized Hauling Vehicles* Memorandum. All NBI bridges must have valid load rating calculations in the bridge file.

3-2.3.2 Military Load Classification (MLC) Load Ratings.

All installation highways that have or will have military tactical vehicles traveling on them must have military load classification (MLC) load ratings on file for the bridges. The MLC is determined using the procedures in AASHTO MBE-2-M, with the live loads shown in Appendix B, paragraph B-1. MLC methods in Army Field Manuals and Training Aids are not permitted. Appropriate MLC signs must be placed at both ends of the bridge; this must be done for all vehicular bridges requiring a load rating (i.e., all roadway bridges over 20 feet [6.1 meters] long). If an installation or roadway is deemed as "administrative" only, with no military vehicle usage, the Installation Bridge Manager may waive, at the approval of the National Bridge Program Manager, the MLC load rating requirement for the bridge. Posting of "No Tactical Vehicles on Bridge" may be required. Additionally, MLC is determined for military tactical vehicle use of the bridge only; it is not considered part of the load rating information submitted to FHWA.

3-2.3.3 Limited Information Bridges.

Bridges with limited as-built information (i.e., no design drawings or calculations) must be rated based on as-inspected field measurements and/or the procedures in Section 6.1.4 of AASHTO MBE-2-M. When material sampling from the structure is not possible, refer to the current version of AASHTO MBE-2-M for material specifications based on the approximate year of construction. The load rating report must clearly state basic information about the bridge (e.g., configuration, material type, age), method of analysis, references, and all assumptions used to establish a valid load rating. In the absence of previous design, as-built, or shop drawings, it is recommended to field-measure all member dimensions necessary to establish as-built properties for the load rating analysis.

Inventory and operating level ratings may be assigned based on design loading, given the bridge meets the requirements of the FHWA memorandum, *Action: Assigned Load Ratings*, dated September 29, 2011.

3-2.3.4 Load Posting of Bridges.

Bridges where the load rating determines that the safe load-carrying capacity is below statutory (most often the state or host nation) levels will be posted for a load restriction. The maximum safe load, as determined by the load rating, must be posted using signage in accordance with the FHWA *Manual on Uniform Traffic Control Devices for Streets and Highways* (MUTCD) R12 series signs or local requirements.

Installations will install load posting signs as soon as possible—no later than 90 days after notification that posting is required. In cases where known existing loads significantly exceed the recommended posting limit or the route is of significant importance (e.g., bus routes, emergency vehicle routes), posting more quickly is important to ensure safety.

Load posting signs must be placed at the bridge for each direction of travel, as well as a minimum of 0.25 mile (0.4 kilometer) in advance of the bridge, or at the location of the nearest intersection prior to the bridge, for each direction of travel.

3-2.4 Bridge Inventory Data Requirements.

All bridge records must be maintained by the installation, including the inspection reports, plans, and follow-up actions taken to address deficiencies identified during inspections. Findings will be recorded on standardized agency forms. Complex bridges and bridges with FCMs, underwater elements, or scour critical status must be identified and given special attention according to the appropriate procedures.

An inventory of all bridges must be maintained by the Military Department with jurisdiction over those bridges. Reporting of inspection data will be per each individual agency’s policy and FHWA-PD-96-001 (and FHWA-PD-96-001’s most current Errata Sheet). Inspection data, including inventory and appraisal data (SI&A data), will be collected and maintained for all bridges that are inspected. Refer to Appendix B, paragraph B-5, for a bridge inspection reporting flowchart.

SI&A data will be entered into the agency's inventory within 90 days of the date of updating, change, or editing.

3-2.5 Deficiencies and Critical Findings.

The Installation Bridge Manager is responsible for ensuring all deficiencies identified in bridge inspection reports are addressed as soon as possible. Maintenance issues and minor repairs can be addressed immediately using in-house resources. Other deficiencies require projects to be programmed following Military Department-specific procedures. The Installation Bridge Manager is responsible for programming and providing advocacy for projects addressing identified bridge deficiencies. The Installation Bridge Manager must ensure that critical findings are addressed in accordance with the procedures described in paragraph 7-1. The Installation Bridge Manager will maintain supporting documents showing the actions taken to address all deficiencies identified in the bridge inspection reports.

3-3 NON-NBI HIGHWAY BRIDGES.

Highway bridges in foreign territories and all other highway bridges that do not meet the span length or public road requirements of the NBIS are not included in the NBI and are referred to as "Non-NBI Highway Bridges." The requirements for these bridges are described in the following paragraphs.

3-3.1 Short Span and Non-Public Highway Bridges.

3-3.1.1 Inspection Requirements.

Highway bridges that do not meet the NBIS span length and/or public road requirements must be inspected at a frequency interval of not greater than 48 months.

The National Bridge Program Manager can approve the exemption of short span bridges from the inspection requirement if engineering judgement indicates that failure of the bridge will not significantly endanger the safety of people or property.

3-3.1.2 Load Rating Requirements.

Highway bridges less than 20 feet (6.1 meters) and bridges deemed non-public will be load rated at the discretion of the National Bridge Program Manager.

3-3.2 Highway Bridges in Foreign Territories.

3-3.2.1 Inspection Requirements.

Highway bridges in foreign territories meeting the NBIS span length and public road requirements must conform to the bridge inspection requirements of paragraph 3-2.2. The inspection interval may be extended without approval of the FHWA and at the discretion of the National Bridge Program Manager.

3-3.2.2 Load Rating Requirements.

Highway bridges in foreign territories meeting the NBIS span length and public road requirements must conform to the load rating requirements of paragraph 3-2.3.

3-3.3 Bridge Inventory Data Requirements.

An inventory of non-NBI bridges must be maintained by the Military Department with jurisdiction over those bridges. It is not necessary to transmit SI&A data to the FHWA for bridges on any installation in foreign territory or for “non-NBI” bridges owned by DOD. There is one exception to this: the FHWA needs to be advised about “non-NBI” bridges that go over a Federal-Aid highway, STRAHNET route or connector, or other important structure. Inventory data (not appraisal information) on bridges that fall into this category should be reported if no record of the bridge has been previously reported or if the bridge is modified. Refer to Appendix B, paragraph B-5, for a bridge inspection reporting flowchart.

For the purposes of internal recordkeeping, each agency’s standard SI&A form may be further modified, as desired, to better reflect bridge data in a foreign territory.

CHAPTER 4 RAILROAD BRIDGES

4-1 INTRODUCTION.

Railroad bridges differ from other types of bridges in the types of live loads they undergo, in their modes of failure and distress, and in their construction details. The FRA requires that all track owners have an implemented railroad bridge safety management program including, but not limited to, clear definitions of the roles and responsibilities of all designated qualified personnel; an inventory of all railroad bridges; bridge capacities through load ratings; and detailed bridge inspection policies. Refer to 49 CFR 237 for additional information.

4-1.1 History of FRA Railroad Bridge Inspection Regulations.

Regular inspection of railroad bridges has been an industry practice for over 100 years. Railroad operators learned early in their development through bridge failures, often resulting in fatalities, the importance of comprehensive bridge inspections to ensure that developing flaws did not lead to catastrophe. In 1968, as a result of the Silver Bridge collapse at Point Pleasant, West Virginia, the President established a White House Task Force on Bridge Safety. In support of this task force, the Association of American Railroads (AAR) organized the AAR Railroad Bridge Safety Committee. This committee solicited information from all the railroads in the United States on their bridge inspection, rating, and maintenance practices. Responses from all of the Class I railroads, which made up 94 percent of the nation’s railroad mileage, indicated that all of their bridges received a comprehensive inspection by qualified personnel at least once per year. The survey also revealed that every Class I railroad followed bridge inspection and rating practices equal to or greater than the instructions set forth in the Manual of Recommended Practice for Railway Engineering issued jointly by the AAR Engineering Division and the American Railway Engineering Association, a predecessor to the American Railway Engineering and Maintenance-of-Way Association (AREMA) *Manual for Railway Engineering*.

In 1995, the FRA issued an Interim Statement of Policy on the Safety of Railroad Bridges. This was followed in 2000 by a Final Statement of Agency Policy on the Safety of Railroad Bridges. These statements, while non-regulatory, established criteria for railroads to use to ensure the structural integrity of railroad bridges.

With the signing into law of the Railroad Safety Improvement Act of 2008, the FRA was directed to issue regulations requiring track owners to adopt and follow specific procedures to protect the safety of their bridges. As a result, the FRA issued its Bridge Safety Standards, Final Rule, on July 15, 2010. The rule became effective on September 13, 2010, with a staggered implementation schedule whereby the largest freight and passenger railroads were required to comply first, followed by the mid-size and then the smallest railroads.

4-1.2 Applicability.

FRA bridge safety standards apply to all railroad bridges located within CONUS, Alaska, or Hawaii supporting a track with a gage of 2 feet (0.6 meter) or more used to transport freight in railcars moved by railroads that are part of the general railroad system of transportation. Railroad bridges on military installations that meet these criteria fall under the jurisdiction of FRA and must comply with regulations in 49 CFR 237.

The following railroads (and bridges) on military installations do not fall under the jurisdiction of the FRA. However, non-FRA railroad bridges must also be inspected and managed in accordance with UFC paragraphs 4-2, 4-3, and 4-4.

- Bridge structures in foreign territories
- Bridge structures supporting track used exclusively for rapid transit operations
- Bridge structures located within an installation that are not part of the general railroad system and over which the movement of rail equipment is performed only by military or installation employees

4-1.3 Railroad Bridges Reportable to FHWA.

Railroad bridges that go over a Federal-Aid highway, STRAHNET route or connector, or other important structure, must be reported to the FHWA. Inventory data (not appraisal information) on bridges that fall into this category must be reported if no record of the bridge has been previously reported or if the bridge is modified.

4-2 BRIDGE INSPECTION REQUIREMENTS.

4-2.1 Inspection Types.

Bridge inspections are conducted to determine the physical condition of the structure, to develop the basis for load rating analyses, to assess the need for maintenance, and to track the functional condition and rate of deterioration over time. There are seven inspection types requiring unique levels of effort. These inspection types are initial/inventory, routine, damage, in-depth, fracture critical, underwater, and special, as described below.

Any railroad bridge that has been out of service and has not received an inspection within the scheduled time specified in the Railroad Bridge Management Program will be inspected by a Railroad Bridge Inspector and the report reviewed and approved by a Railroad Bridge Engineer prior to reopening to service. Where deemed necessary by the Railroad Bridge Engineer, an updated load rating will be performed for the bridge and filed in the bridge file prior to reopening to service. Late inspections require an explanation to be included in the bridge file.

4-2.1.1 Initial/Inventory Inspection.

The initial/inventory inspection is the first inspection after a bridge is built or added to the installation real property and becomes a part of the bridge file. Elements of the initial/inventory inspection may also apply when there has been a change in configuration of the structure (e.g., widening, lengthening, supplemental bents). It is important for the inspectors to identify any existing problems or locations in the structure where potential problems may arise. A thorough review of as-built plans should be conducted prior to the initial inspection and the inspector should note any FCMs or details during this inspection. A Level 1 scour screening is required if the bridge crosses over a waterway.

Initial inspections must be performed within 90 days of opening to rail traffic. A new railroad bridge must be added to the installation real property and becomes a part of the bridge file prior to opening.

4-2.1.2 Routine Inspection.

A routine inspection is a regularly scheduled inspection to collect observations and measurements of any changes from the initial inspection or any previously conducted inspection.

All routine inspections must be conducted at least once each calendar year, with no more than 540 days between any successive inspections. The Railroad Bridge Engineer may increase routine inspection intervals based on the physical or functional condition of the bridge. It is the responsibility of the Railroad Bridge Engineer to establish criteria for decreased inspection intervals.

4-2.1.3 Damage Inspection.

A damage inspection is a one-time unscheduled inspection to evaluate structural damage resulting from environmental or human actions such as collisions, floods, derailments, fires, or earthquakes, and is performed to establish the repair level of effort. Damage inspections must be performed within a reasonable time after a natural disaster or human-caused action. The inspectors will document all damaged members, measuring, at a minimum, any section loss, member misalignment, and any loss of foundation support. The inspection must provide all information necessary to potentially close the bridge or perform an emergency load restriction. Local installation personnel may make an initial assessment of the bridge if personnel meeting required inspector qualifications are not immediately available. The National Bridge Program Manager may recommend a follow-up in-depth inspection of the bridge to monitor the structure. The National Bridge Program Manager will maintain bridge damage inspection procedures within the railroad bridge management program specific to each event type. Examples of bridge damage inspection instructions are provided in AREMA *Manual for Railway Engineering*, Volume 2, Chapter 10.

4-2.1.4 In-Depth Inspection.

An in-depth inspection is a hands-on, close-up inspection of one or more members above or below the waterline. In-depth inspections are more detailed and may require special access techniques to inspect areas not easily detectable from a routine inspection. The Railroad Bridge Engineer is responsible, in conjunction with the Installation Bridge Manager, for establishing the need for and required interval of an in-depth inspection.

4-2.1.5 Fracture Critical Inspection.

Fracture critical inspections are detailed, hands-on inspections of steel bridges with FCMs that may include visual or other nondestructive evaluations. Prior to inspection, a thorough review of the design or as-built plans, previous inspection reports, load rating, and fatigue-prone details must be made. In the absence of plans or fatigue-prone details, the inspector should be able to determine the fatigue-prone details based on the details provided in Table 6.6.1.2.3-1 of AASHTO LRFDUS-7. FCMs require a "hands-on" inspection where the inspector is capable of touching the area being inspected (arm's length). Physical inspection methods may be necessary to more accurately assess the condition of an FCM. Advanced inspection methods may need to be employed, including NDT methods. The hands-on inspection will identify and note the condition of problematic details prone to crack development.

For more information regarding inspection techniques for fracture critical bridges, refer to the BIRM or FHWA-NHI-11-015*.* For additional information and case studies on fatigue damage in welded, bolted, and riveted structures, refer to FHWA's *Manual for Inspecting Bridges for Fatigue Damage Conditions* and John W. Fisher's *Fatigue and Fracture in Steel Bridges – Case Studies*.

Fracture critical inspections must be conducted at regular intervals not to exceed 24 months. When a routine inspection interval is decreased due to a FCM finding, it is recommended that the fracture critical inspection interval be decreased to match the routine inspection interval. In order to establish the criteria for fracture critical inspection intervals and level of effort, factors such as bridge age, fatigue-prone details, and known deficiencies must be considered.

4-2.1.6 Underwater Inspection.

4-2.1.6.1. An underwater inspection is diving to visually inspect and measure bridge components, probing for scour or undermining, and sounding to locate the bottom of the channel. The inspection will include such methods as necessary to adequately perform a condition assessment of the structure. If a bridge can be adequately inspected by wading, shallow probing, or with the use of cameras at low water conditions, a formal underwater inspection (divers) is not required. For bridges that do not require a formal underwater inspection, Item 93 on the SI&A form will not be coded. The Installation Bridge Manager will develop a mechanism to ensure inspections occur at low water conditions.

4-2.1.6.2. These inspections must be performed by experienced inspectors determined by the Railroad Program Manager to be competent in underwater inspection procedures. It is recommended that the Underwater Inspection Bridge Inspectors are divers qualified per paragraph 2-1.7 and have completed an approved equivalent to the FHWA-approved underwater bridge inspection diver training course.

4-2.1.6.3. According to the BIRM, there are three levels of underwater inspection intensity:

- Level 1 – Visual, tactile inspection
- Level 2 – Detailed inspection with partial cleaning
- Level 3 – Highly detailed inspection with NDT or PDT

4-2.1.6.4. Level 1 inspections are required for all routine underwater inspections and must be performed within arm's reach of the areas being inspected. Visual inspections are performed across the entire submerged structure, but, in areas of poor water clarity, a tactile sweeping motion of the hands and arms may be utilized to cover the entire substructure.

4-2.1.6.5. Level 2 inspections include cleaning off marine or aquatic growth at critical inspection areas and inspecting high-stress, damaged, and deteriorated areas that may be shielded by the growth. Critical areas near the low waterline, mudline, and midway between will be inspected. Piers and abutments must have at least 1 square foot (0.09 square meter) cleaned at three or more levels on each face. For structures greater than 50 feet (15 meters) in length, an additional three levels must be cleaned at each exposed face. For piles, horizontal bands a minimum of 10 inches (254 millimeters) long will be cleaned along the following locations:

- Rectangular – At least three sides
- Octagonal – At least six sides
- Round – At least 75 percent of circumference
- H-pile – At least the outside faces of flanges and one side of web

4-2.1.6.6. Level 3 inspections include complete cleaning of a structural element and NDT or PDT. Detailed measurements are typically made along with testing techniques such as ultrasonic, physical material sampling, or boring. These inspections are generally performed when a structural repair or possible replacement is being considered.

4-2.1.6.7. Underwater inspections must be completed at regular intervals not to exceed 60 months. The Railroad Bridge Engineer may decrease the interval of underwater inspections based on Level 1 or Level 2 scour evaluations, evidence of substructure movement, stream migration, bank sloughing, or debris buildup. Any deviation in the underwater inspection interval must be documented in the bridge file. Prior to requesting an alteration to underwater inspection intervals, it may be helpful to review FHWA-NHI-10-027. This report not only lists various factors that affect the needed interval of underwater inspection but also contains valuable information on underwater inspection techniques, underwater repair techniques, and scour issues.

4-2.1.7 Special Inspection.

Inspections that monitor a known member deficiency or other conditions that warrant special attention, such as foundation settlement or scour, fatigue damage, severe section loss; or to evaluate damage caused by a natural or accidental event, including, but not limited to, flood, fire, earthquake, derailment, or vehicular or vessel impact. Based on these criteria, the Railroad Bridge Engineer will determine when special inspections are required. A special inspection must be performed based on the criteria in 49 CFR 237, Subpart E, *Bridge Inspection*.

4-2.2 Inspection Procedures.

The Railroad Bridge Engineer must specify the bridge inspection procedures in conformance with the requirements of 49 CFR 237. The bridge inspection procedures will include the following:

- Methods, means of access, and level of detail to be recorded for the various components of that bridge or class of bridges
- Assurance that the level of detail and the inspection procedures are appropriate to the bridge configuration, conditions found during previous inspections, the nature of the railroad traffic, and vulnerability of the bridge to damage
- Be designed to detect, report, and address deterioration and deficiencies before they present a hazard to safe train operation

Bridge inspections must be conducted under the direct supervision of a designated Railroad Bridge Inspector. A bridge or portion of a bridge may be inspected more frequently when a Railroad Bridge Engineer deems necessary, considering the conditions noted during previous inspections, bridge type and configuration, weight and frequency of rail traffic, and the type or nature of rail traffic. In addition, bridge inspection reports will be reviewed by Railroad Bridge Engineers and railroad bridge supervisors to:

- Determine whether inspections have been performed in accordance with the prescribed schedule and specified procedures
- Evaluate whether any items on the report represent a present or potential hazard to safety
- Prescribe any modifications to the inspection procedures or inspection interval for that particular bridge
- Determine the need for further higher-level review

4-3 LOAD RATING AND LOAD RESTRICTION REQUIREMENTS.

All railroad bridges must have a load rating on file within the railroad bridge file performed by a Railroad Bridge Engineer. The load ratings will be expressed in terms of numerical values related to a standard system of train loads (i.e., Cooper E-equivalent configuration).

All railroad bridge load rating methods are recommended to abide by AREMA *Manual for Railway Engineering*, Volume 2, Chapter 7. Timber bridges are addressed in Chapter 7, concrete bridges are addressed in Chapter 8, and steel bridges are addressed in Chapter 15. As an alternative to evaluating the capacity of railroad bridge components within the aforementioned chapters, other methods prescribed by the Railroad Bridge Engineer may be utilized, such as strain gage data, deflection measurements, or non-destructive testing for identifying embedded concrete reinforcement. All methods used to determine the capacity of the bridge must be clearly stated in the bridge file.

In addition, the Railroad Bridge Engineer will issue instructions specifying the maximum equipment weight along with either the minimum equipment length or axle spacing. These instructions are for use by those persons responsible for controlling the movement of rail equipment over railroad bridges to ensure the bridges are not overloaded. For railroad bridges that present horizontal or vertical restrictions, the Railroad Bridge Engineer will issue instructions necessary to prevent damage from over-dimension loads. Refer to 49 CFR 237.73 for further information.

4-4 BRIDGE MANAGEMENT PROGRAM REQUIREMENTS.

The National Bridge Program Manager is responsible for maintaining the railroad bridge management program and ensuring its continued compliance with this UFC and FRA guidelines. At a minimum, the program must include all of the following:

- An accurate inventory of railroad bridges
- A record of the safe load capacity of each bridge
- A provision to obtain and maintain design documents, including repairs, modifications, and inspections of each bridge
- A bridge inspection program covering as a minimum:
    - Inspection personnel safety considerations;
    - Types of inspection, including required detail;
    - Definitions of defect levels and associated condition codes if condition codes are used;
    - The method of documenting inspections, including standard forms or formats;
    - Structure type and component nomenclature; and

  - Numbering or identification protocol for substructure units, spans, and individual components

The railroad bridge management program must include, at a minimum, the following requirements:

- Record of each inspection required to be performed
- Record of an inspection will be prepared from notes taken on the day(s) the inspection was made and will be dated with the date(s) the physical inspection takes place and the date the record is created
- Each bridge inspection report must include, at a minimum, the following information:
  - A precise identification of the bridge inspected;
  - Date on which the physical inspection was completed;
  - Identification and written or electronic signature of the inspector;
  - Type of inspection performed;
  - Identification of inspection findings requiring expedited or critical review by a Railroad Bridge Engineer and any restrictions placed at the time of inspection;
  - Condition of components inspected; and
  - Identification of the portions of the bridge that were inspected
- Initial report of each bridge will be placed in the bridge file within 30 calendar days of the completion of inspection
- Complete report of each bridge inspection within 120 calendar days of the completion of the inspection

Refer to 49 CFR 237.109 for additional information on what FRA requires for bridge inspection records.

CHAPTER 5 PEDESTRIAN BRIDGES AND GOLF CART BRIDGES

5-1 BRIDGE INSPECTION REQUIREMENTS.

Pedestrian bridges and golf cart bridges must be inspected at a minimum interval of 48 months if the bridge crosses a highway, crosses a railroad, or if failure of the bridge could significantly endanger the safety of people or property. The National Bridge Program Manager approves the bridges requiring inspection and the required inspection interval.

5-2 LOAD RATING REQUIREMENTS.

Pedestrian bridges and golf cart bridges must be load rated if the bridge crosses a highway, crosses a railroad, or if failure of the bridge could endanger the safety of people or property. If a pedestrian bridge load rating is less than 60 pounds per square foot (psf) (293 kilograms per square meter), the bridge must be posted for reduced pedestrian traffic. If a pedestrian bridge load rating is performed and found to be less than 40 psf (195 kilograms per square meter), the bridge must be closed to pedestrian traffic until it is repaired. AASHTO GSDPB-2-UL*, LRFD Guide Specifications for Design of Pedestrian Bridges*, is a good reference for this topic.

Pedestrian and golf cart bridges intended to support maintenance or emergency vehicles will meet the load rating and inspection requirements of highway bridges. These bridges must be posted and barricaded or equipped with bollards to prevent non-emergency vehicle use.

5-3 BRIDGE INVENTORY DATA REQUIREMENTS.

An inventory of inspected pedestrian and golf cart bridges must be maintained by the Military Department with jurisdiction over those bridges. Do not include these bridges in the NBI provided to FHWA. However, the FHWA must be advised about bridges that go over a Federal-Aid highway, STRAHNET route or connector, or other important structure. Inventory data (not appraisal information) on bridges that fall into this category will be reported if no record of the bridge has been previously reported or if the bridge is modified. Refer to Appendix B, paragraph B-5, for a bridge inspection reporting flowchart.

This Page Intentionally Left Blank

CHAPTER 6 SPECIAL BRIDGE TYPES

6-1 COMPLEX BRIDGES.

Complex bridges must be inspected and reported to the FHWA per the requirements specified in the UFC. Complex bridges include movable, suspension, and cable-stayed bridges, as well as other bridges with unusual characteristics. The National Bridge Program Manager will identify specialized bridge inspection procedures and any additional inspector training and experience necessary to safely and accurately perform the inspections.

6-2 TAXIWAY BRIDGES.

All taxiway bridges must be inspected at least every two years and load rated to ensure the bridge can safely carry airfield traffic. All requirements for NBI bridges apply for taxiway bridges. Since the NBI requires reporting of only highway bridges based on the type of traffic "over" the bridge, taxiway bridges over highways will not be included in the NBI reporting to FHWA.

6-3 MILITARY BRIDGE SET TRUSS PANEL BRIDGES.

Although originally intended for temporary, battlefield applications, prefabricated military bridge sets (i.e., Bailey and Mabey-Johnson or similar truss panel bridges) often remain in use in a permanent capacity. Army Technical Manual (TM) 3-34.23, *M2 Bailey Bridge*, contains useful information on the Bailey system and load capacities.

Because there are many variations of the Bailey and Mabey-Johnson bridge systems, it is recommended that the manufacturer's literature be consulted prior to performing a load rating of these bridge types. In lieu of using the manufacturer's loading data, it is also permissible to load-rate these bridges as a generic truss; however, this procedure will be time-consuming due to the amount of calculations involved.

Military bridge set bridges meeting the criteria for a reportable bridge must abide by the requirements of paragraph 3-2.

6-4 MODEL AND TRAINING BRIDGES.

Model and training bridges are commonly found on installations. They are often referred to as research, development, testing and evaluation (RDT&E) models, simulations, or replicas. These are not real property, are not reportable, and will not be part of the installation bridge inventory database, nor will they be part of the NBI. They must be closed off to all traffic (other than vehicles used for testing or training) and stored in a secure, locked area when not in use. If a load rating or actual regular traffic use on these bridges is desired, an initial inspection will be performed prior to adding the structure to the bridge inventory.

This Page Intentionally Left Blank

CHAPTER 7 COMMON REQUIREMENTS OF ALL BRIDGES

7-1 CRITICAL FINDINGS.

Critical findings are defined as structural or safety-related deficiencies that require immediate follow-up inspection or action. It is the responsibility of the National Bridge Program Manager to implement procedures for addressing critical deficiencies, including:

- Immediate critical deficiency reporting steps
- Emergency notification of police and the public
- Rapid evaluation of the deficiencies
- Rapid implementation of corrective or protective actions
- A tracking system to ensure adequate follow-up
- Provisions for identifying other bridges with similar structural details for follow-up inspections

The National Bridge Program Manager must establish a bridge program procedure to ensure that critical findings are addressed in a timely manner and in conformance with Appendix B, paragraph B-8, “Flow Chart for Critical Findings.” General steps must be taken to assure that critical findings are identified and resolved as quickly and efficiently as possible. Viable options include permanent repair, temporary repair, and restriction of load on a bridge. Refer to the BIRM, Topic 4.5, “Critical Findings,” for additional information and guidance on addressing critical findings.

7-1.1 Inspection Procedures and Reporting.

The bridge program procedure must require the immediate verbal notification of a potential critical finding to the National Bridge Program Manager and Load Rating Engineer. In addition to the verbal notification, the procedures should include a written notification following a standardized format in either hardcopy or electronic format. See Appendix B, paragraph B-9, for a sample Critical Inspection Finding Report form. The written notification should include notes, photographs, and sketches and/or drawings to accurately portray the potential critical finding. Temporary actions may also be taken to safeguard the public until proper repairs are completed. These actions may include:

- Load posting
- Traffic restrictions from the damaged area
- Speed restrictions
- Temporary lane closure

- Temporary shoring
- Complete bridge closure

After submittal of the written report, the finding will be assessed and severity established with the proper repair strategy or POA. The procedures will require notification of critical findings for reportable highway bridges to the FHWA.

The BIRM, Chapter 4.5.3, lists numerous examples of critical findings for timber, steel, and concrete bridges, for both reduced load capacity and public safety hazard conditions.

7-1.2 Prioritizing Maintenance Procedures.

The National Bridge Program Manager must establish prioritization criteria to help facilitate maintenance work plan strategies. A list of example priority criteria can be found in the BIRM, Topic 4.5.

7-1.3 Plan of Action (POA).

A POA will be developed and approved within seven calendar days of a critical finding. It may be necessary to begin addressing a critical finding prior to full development and acceptance of a POA. It is the responsibility of the National Bridge Program Manager, in conjunction with the Installation Bridge Manager, to implement procedures for addressing critical deficiencies, including:

- Immediate critical deficiency reporting steps
- Emergency notification of police and the public
- Rapid evaluation of the deficiencies
- Rapid implementation of corrective or protective actions
- A tracking system to ensure adequate follow-up
- Provisions for identifying other bridges with similar structural details for follow-up inspections

7-1.4 Repair.

Critical findings that significantly impact a bridge’s structural integrity and/or create a safety hazard will be addressed immediately through complete or partial bridge closure or repair. A critical finding that impacts a bridge’s structural integrity will be retrofitted through short-term repairs (i.e., temporary shoring or bracing) or permanent repairs that are designed and constructed to restore the affected member(s) to their original load capacity. This may include installation of new structural steel plates or shapes; removal and replacement of deteriorated concrete and steel reinforcing; or installation of other materials (e.g., timber, steel cable, fiber reinforced polymer composites, masonry), depending on the structure type.

Critical findings that create a safety hazard (e.g., broken railings or safety devices that may not provide proper containment or redirection; loose concrete or steel that creates a falling hazard) will be isolated by removing traffic from the area of the hazard until the hazard is removed and/or repaired.

The FHWA will be notified annually of critical finding repairs and post-repair progress which impacts data for NBI highway bridges.

7-2 SCOUR EVALUATION.

7-2.1 Scour Screening.

All existing bridges must be screened to determine their vulnerability to scour. This includes, but is not limited to, a Level 1 stream stability analysis and a review of the existing bridge plans. Critical information from the bridge plans includes, but is not limited to, the foundation types, locations, and depths. If this level of analysis indicates that the bridge is not susceptible to scour then the bridge should be appropriately coded and continue to be monitored during each routine inspection. HEC-18, *Evaluating Scour at Bridges*, Table 10.2, provides a list of items to consider when assessing the susceptibility of a bridge to scour.

7-2.2 Unknown Foundation Coding.

For bridges with an unknown foundation and determined through a Level 1 stream stability analysis to not be susceptible to scour, Code Item 113 will remain “U” and a scour critical POA will be prepared until a higher-level analysis has been performed.

7-2.3 Higher Level Scour Analysis.

If after the initial screening the bridge is susceptible to scour, additional analysis is needed. This includes the evaluation of the flooding history of the bridge and the development of a hydraulic model (typically the Army Hydrologic Engineering Center’s River Analysis System [HEC-RAS]) to determine the scour potential at the bridge site. Higher level scour evaluations must be performed by a Hydraulic Bridge Engineer who is a professional engineer with relevant work experience in bridge hydraulic modeling and scour evaluations. This scour evaluation should also consider the potential for debris collecting on the bridge substructure. Previous inspection reports, along with the current channel stability and observed debris, will provide guidance. Once the theoretical (potential) scour depth is determined from the hydraulic model, this depth should be compared to the existing foundation depths so a determination can be made as to the bridge’s overall susceptibility to scour. This process involves a multi-disciplinary team approach that should include hydraulic, geotechnical, and structural engineers to determine the reasonableness of the results. If, after this analysis, any bridge can be considered unstable should the potential scour depth be reached, it should be considered “scour critical” and a POA, including a detailed plan for potential bridge closure, should be developed. See Appendix B, paragraph B-7, for an example Scour Critical Bridge POA.

7-2.4 2D Hydraulic Model.

Some bridge crossings, such as tidally influenced bridges or a wide floodplain that contains multiple bridges, will require a higher level of hydraulic analysis. A 2D hydraulic model will be conducted to analyze the scour susceptibility.

7-2.5 Unknown Foundation Risk Analysis.

Bridges are classified as having unknown foundations when the type and depth of foundations are unknown. The initial approach is to perform extensive data mining to ensure the foundations are in fact unknown. If the foundations are in fact unknown, HEC-18, Appendix F, provides guidance for performing a risk-based analysis to prioritize bridges for further evaluation. Each Military Department is responsible for implementing a risk-based approach to reclassify bridges with unknown foundations and subsequently evaluate the susceptibility to scour. HEC-18, Appendix F, recommends to first prioritize bridges based on their functional classification. Secondly, collect historical documentation of foundation and design practices based on the date of original construction, consider the subsurface conditions and bridge standards from nearby bridges, and/or perform proven NDT to assess foundation type and length. Once the information has been gathered, perform a scour evaluation based on the data and update Code Item 113 accordingly. If the scour evaluation determines the bridge to be scour critical (items to be coded with a 3, 2, or 1), a POA will be implemented for the bridge. For bridges with unknown foundations even after a risk analysis has been performed, a POA will be implemented that includes a bridge closure plan. FHWA *Attachment "B" – Guidance for Developing and Implementing Plans of Action for Bridges with Unknown Foundations* provides recommended steps for developing POAs for bridges with unknown foundations.

7-2.6 Unknown Foundation Evaluation.

FHWA and the Florida Department of Transportation (FDOT) published a manual titled *Procedural Manual: Reclassify Unknown Foundation Bridges*, that provides detailed procedures and guidelines for evaluating bridges with unknown foundations through a risk-based approach. The manual provides multiple flow charts to assist in evaluating unknown foundations, including steps to reclassify bridges with unknown foundations, reverse engineering for estimating unknown pile embedment, and recommended NDT methods for multiple foundation types.

7-2.7 Scour Critical POA.

Bridges that are considered scour critical must have a detailed POA in the bridge file. See Appendix B, paragraph B-7, for an example Scour Critical Bridge POA.

7-3 FRACTURE CRITICAL PLAN.

A fracture critical member (FCM) is a steel member in tension or with a tension element whose failure could potentially cause a portion of or the entire bridge to collapse. A fracture critical plan identifies all FCMs on a bridge, establishes an inspection interval, and determines inspection methods. Fracture critical plans will be developed and maintained for each fracture critical bridge in the bridge file. The plan must, at a minimum, include:

- Bridge identification
- Bridge location (with map)
- Structure description
- Means of access
- Identification of all FCMs (plan and elevation sketch with FCMs identified)
- List of all relevant AASHTO fatigue-prone details with photo references

Table 6.6.1.2.3-1 in AASHTO LRFDUS-7 presents fatigue-prone details caused by in-plane stresses and categorizes them in Categories A through E. The table provides the inspector categories for classifying fatigue-prone details for fracture critical bridges. The letter designation is a rating assigned to a detail that represents its fatigue strength, with "A" being the highest and "E" being the lowest. Refer to Appendix B, paragraph B-6, for an example fatigue-prone detail form.

Refer to the BIRM, Topic 6.4, "Fatigue and Fracture in Steel," for additional information on FCMs.

7-4 SEISMIC EVALUATION.

All bridges must be evaluated to determine if further analysis is warranted for seismic activity, and, if necessary, further investigation will be recommended. Refer to Part 1 of FHWA-RD-94-052, *Seismic Retrofitting Manual for Highway Structures*. The retrofit philosophy in FHWA-RD-94-052 is performance-based and distinguishes between important new bridges and less-important bridges near the end of their service life. Based on bridge importance and desired service life, categories are assigned for screening, in-depth evaluation, and retrofitting. Numerous retrofit options exist, such as restrainers, bridge seat extensions, column jackets, footing overlays, and soil remediation.

7-5 TRAFFIC SAFETY DEVICES.

All roadsides and bridges/structures must have traffic safety devices (e.g., guardrail, end treatments, delineators) installed according to AASHTO GDHS-6, *A Policy on Geometric Design of Highways and Streets (Green Book)*, AASHTO RSDG-4, *Roadside Design Guide*, and FHWA MUTCD. For facilities that carry low-volume traffic, traffic safety devices may be installed based on the provisions of AASHTO VLVLR-1, *Guidelines for Geometric Design of Very Low-Volume Local Roads (ADT ≤ 400)*.

MUTCD Section 5A.01 defines a “low-volume road” as a facility lying outside of built-up cities, towns, and communities, and having a volume of less than 400 average annual daily traffic (AADT). Low-volume roads will not be freeways, expressways, interchange ramps, freeway service roads, roads on a designated state highway system, or a residential street in a neighborhood. For bridges not on the National Highway System, each Military Department must establish criteria for updating traffic safety devices. Factors to consider when establishing these criteria are roadway volume, posted speed limit, and approach roadway geometry (e.g., low-volume, low-speed roadways with good geometry are less prone to crashes with vehicles leaving the roadway). The AASHTO-AGC-ARTBA Task Force 13 *A Guide to Standardized Highway Barrier Hardware*, as well as local standards for traffic safety, are also recommended resources.

7-6 CLOSED BRIDGES.

Signage must be placed to identify a bridge as being closed to vehicular and/or pedestrian traffic. Physical barriers of a mass not easily moved will be positioned to prevent access to the structure.

CHAPTER 8 BRIDGE MAINTENANCE

8-1 INTRODUCTION.

A goal of this UFC is to ensure that installation bridges are maintained in a safe, usable condition. Preventive maintenance is a planned strategy of cost-effective treatments applied at the proper time to preserve and extend the useful life of a bridge.

8-2 INDUSTRY PRACTICE.

Any deficiencies requiring maintenance identified in an inspection will be expediently addressed. The Installation Bridge Manager will review all inspection reports and provide a report of deficiencies requiring maintenance to the National Bridge Program Manager in a timely manner.

Bridge maintenance must be conducted in accordance with the latest industry practice. Valuable references include American Concrete Institute (ACI) 345.1R-16, *Guide for Maintenance of Concrete Bridge Members*; ACI SP-277, *Recent Advances in Maintenance and Repair of Concrete Bridges*; AASHTO MM-4, *Maintenance Manual for Roadways and Bridges*; and FHWA-NHI-14-050, *Bridge Maintenance Training Reference Manual*.

General maintenance encompasses cleaning activities such as annually water-flushing all decks, drains, bearings, joints, pier caps, abutment seats, rails, and parapets (typically in the spring). Preventive maintenance encompasses routine activities such as painting; minor coating and sealant applications; minor deck membrane and wearing surface patching; and railing repairs. Stream channel maintenance encompasses activities such as debris removal. Consideration should be given to prioritizing any maintenance recommendations from the bridge inspection reports.

This Page Intentionally Left Blank

CHAPTER 9 BRIDGE REPAIR

9-1 INTRODUCTION.

A goal of this UFC is to ensure that bridge deficiencies are discovered and repaired in a timely manner so installation bridges remain open and in a safe, usable condition.

9-2 INDUSTRY PRACTICE.

Bridge repairs must be conducted in accordance with the latest industry practice. Valuable references include Part 2 of FHWA-RD-94-052, *Seismic Retrofitting Manual for Highway Structures*, and FHWA HEC-23, *Bridge Scour and Stream Instability Countermeasures*. Additionally, 49 CFR 237.131 and 49 CFR 237.133 include requirements for the design and supervision of railroad bridge repairs.

Repairs encompass activities such as jacking up the structure, epoxy injection of cracks, adjusting bearing systems, sealing expansion joints, major deck patching, major applications of coatings and sealants, and reinforcement of structural members like stringers, beams, piers, pier caps, pile caps, abutments, and footings. Stream channel repairs encompass activities such as stabilizing banks and correcting erosion problems. Consideration should be given to prioritizing any repair recommendations from the bridge inspection reports.

APPENDIX B BEST PRACTICES

B-1 MILITARY LOAD CLASSIFICATION (MLC) AND MILITARY VEHICLE LIVE LOAD DATA.

Excerpted from FM 3-34.343, *Military Nonstandard Fixed Bridging*, Appendix B, "Vehicle Classification", 12 February 2002, Headquarters, Department of the Army, Washington, DC:

[Note: Minor edits have been made for this appendix to eliminate non-relevant material, typos, and page number references from FM 3-34.343. Ultimately, all data herein is based on NATO STANAG 2021.]

Vehicles are assigned MLC numbers, which represent the loading effects they have on a bridge. The MLC does not represent the actual weight of a vehicle. It represents a combination of factors that include gross weight, axle spacing, weight distribution to the axles, and speed. All standard Army vehicles and special equipment that use bridges of military importance have an MLC. Trailers that are rated with a payload of 1.5 tons or less are exceptions. They have a combined classification with their towing vehicle. Classifying vehicles, trailers, or vehicle combinations with a gross weight of 3 tons or less is optional.

Table B-1 shows 16 standard classes of hypothetical vehicles ranging from 4 to 150. The weight of the tracked vehicle in short tons was chosen as the classification number. A wheeled vehicle has a weight greater than its classification number. Each classification number has a specified maximum single-axle load. Also specified are the maximum tire load, the minimum tire size, and the maximum tire pressure. The classification numbers were originally developed from studies of the hypothetical vehicles having characteristics about the same as the actual military vehicles of NATO nations.

The moment and shear forces produced by the hypothetical vehicles or single-axle loads are provided in Tables B-2 and B-3. These figures are based on the assumption that the nearest ground contact points of two different vehicles (wheeled or tracked) are 100 feet apart. Table B-1 gives critical tire loads and tire sizes.

Standard classification curves were developed for classifying vehicles, for designing nonstandard bridges, and for estimating the capacity of existing bridges. Each standard class has a moment and a shear curve (Figure B-1 and Figures B-2 through B-4). The maximum moment and shear forces were induced against the simple-span lengths by the hypothetical vehicles for each standard class. These forces were plotted to determine the curves. The actual values for the curves are found in Tables B-2 and B-3. Note that in the curves, shear is represented in units of kips; however, in Table B-3, shear is represented in units of tons. No allowance is made for impact, and the assumption is made that all vehicles will maintain the normal convoy spacing of 100 feet between ground contact points.

Table B-1 Standard Classes of Hypothetical Vehicles

Hypothetical Vehicles for Classification of Actual Vehicles and Bridges			
1	2	3	4
Class	Tracked Vehicles	Wheeled Vehicles: Axle Loads and Spacing	Wheeled Vehicles: Maximum Single-Axle Load (in Short Tons)
4			
8			
12			
16			20			
24			
30			
40			

NOTES:
1. The single-axle tire sizes shown in Columns 5, 6, and 7 refer to the maximum single-axle loads given in Column 4.
2. The bogie-axle tire sizes shown in Columns 5, 6, and 7 refer to the maximum bogie-axle loads shown on the diagrams in Column 3.
3. The maximum tire pressure for all tires shown in Column 8 should be taken as 75 psi. The first dimension of tire size refers to the overall width of the tire and the second dimension is the rim diameter of the tire.

[Note: There is a typo in Column 3, Class 12 above, as the axle loads shown do not add up to 15 tons. The middle two axles should be labeled 5, not 6.]

Table B-1 Standard Classes of Hypothetical Vehicles (cont.)

Hypothetical Vehicles for Classification of Actual Vehicles and Bridges

B-2 CRITERIA FOR NATIONAL BRIDGE PROGRAM MANAGER TO ALTER INSPECTION INTERVAL.

The National Bridge Program Manager may alter the routine inspection interval for NBI highway bridges per the following criteria and procedures. It should be noted that the routine inspection interval may be either increased or decreased from the standard 24-month interval, although FHWA approval is only required for a decreased inspection interval.

Inspection intervals must be evaluated and, if necessary, adjusted after each inspection. Regardless of the interval selected for routine inspection, individual bridge members may require differing types and intervals of inspection (e.g., FCMs, distressed members, underwater members).

B-2.1 Procedure for FHWA Approval of Increased Inspection Intervals.

The National Bridge Program Manager will submit a request to increase the routine inspection interval to more than 24 months to the FHWA Eastern Federal Lands Highway Division (EFLHD). The FHWA will send approval of acceptance to the National Bridge Program Manager. Submissions to the FHWA for increased inspection intervals must contain the following information, at a minimum:

- The criteria used in establishing the interval between inspections, outlined above
- A discussion of failure experience, maintenance history, and latest inspection findings for the group of structures identified
- The proposed inspection interval

A template for requesting an extension of the inspection interval to 48 months for Service bridges that meet specific criteria is provided in paragraph B-2.2.

B-2.2 Template for Requesting Increasing Bridge Inspection Interval to Four Years for Qualifying Bridges.

Mr. Hratch Pakhchanian, P.E. (or current EFLHD Bridge Engineer)
Bridge Engineer
Eastern Federal Lands Highway Division
21400 Ridgetop Circle, #341
Sterling, VA 20166
hratch.pakhchanian@dot.gov
(703) 404-6246

Subject: Submittal of Bureau of Reclamation's Criteria for Varying Bridge Inspection Frequency from Two-Year to a Four-Year Inspection Frequency

Dear Mr. Pakhchanian:

In accordance to the National Bridge Inspection Standards, Code of Federal Regulations, 23 Highways - Part 650, Subpart C, and Technical Advisory 5140.2 1 dated September 16, 1988, we hereby submit our application for increasing the two-year inspection interval for some of our structures to four years.

See Attachment A for our criteria for increasing the bridge inspection interval.

Should you have any questions regarding these criteria, please contact ***<insert name>*** at ***<insert phone number>***, or email at ***<insert email address>***.

Sincerely,

<insert signature block>

Attachment A

cc: Yohannes Mesfin (or current EFLHD Federal Agency Bridge Safety Engineer)
Federal Agency Bridge Safety Engineer
Eastern Federal Lands Highway Division
21400 Ridgetop Circle #341
Sterling, VA 20166
Yohannes.Mesfin@dot.gov
(703) 404-6256

ATTACHMENT A:

CRITERIA FOR INCREASING ***<insert Military Department here>*** BRIDGE INSPECTION INTERVAL FROM TWO-YEAR TO A FOUR-YEAR INSPECTION FREQUENCY

The ***<insert Military Department here>*** policy for increasing routine inspections inspection interval from the two-year requirement to four years on selected bridges is based on the general guidelines contained in *Federal Highway Administration (FHWA) Technical Advisory, Revisions to the National Bridge Inspection Standards (NBIS), TA 5140.21*. The ***<insert Military Department here>*** assessment is that the bridges selected for a decrease in routine inspection interval from the typical two-year inspection interval are in good to very good condition, will adhere to FHWA Technical Advisory 5140.21 Guidelines, and in addition meet the following criteria:

All of the following criteria must be met before a bridge will be considered for an inspection interval greater than two years. Bridges eligible for increasing inspection interval from two years to a maximum of four years are:

Bridges with condition ratings of 6 or greater. *NBI 58, 59, 60, 61, and 62 ≥ 6.*

Bridges that have inventory ratings greater than or equal to the state's legal load. *NBI 66 ≥ HS20 (36 tons) or MS18 (32.4 metric tons) or HL-93 with a rating factor ≥ 1.0.*

Structures with length of maximum span (measured from center to center of bearing points) less than or equal to 100 feet. *NBI 48 ≤ 100 feet (30.5 m).*

Structure types with load path redundancy. NBI 43B = 1, 2, 3, 4, 5, 6, 7, 11, 19. This rule applies to structures of all material types. No structure with fracture critical details will go on the extended policy, NBI 92A = N.

Bridge Roadway Width, Curb to Curb is greater than or equal to 12 feet.
NBI 51 ≥ 12.0 feet (3.66 m)

Any vertical over or under clearances are greater than or equal to 14 feet. *NBI 53 & 54 ≥ 14 feet (4.27 m)*.

Structure is not susceptible to scour. *NBI 113 > 4 and 113 ≠ 6.*

New bridge structures or newly rehabilitated structures must have received an inventory inspection and an in-depth inspection one or two years later.

Any bridge considered for inspection intervals longer than two years must have received an in-depth inspection which revealed no major deficiencies.

As a matter of policy, and in accordance with 23 Code of Federal Regulations (CFR) 650, National Bridge Inspection Standards (NBIS), the ***<insert Military Department here>*** inspects their bridges at two-year intervals and will continue to inspect most of our bridges at two-year intervals. Each ***<insert Military Department here>*** installation is responsible for inspecting bridges within their boundary; therefore, each Installation Bridge Manager in conjunction with the National Bridge Program Manager will determine which of the bridges located within their jurisdiction are eligible for an increased inspection interval of up to four years. Those structures that do not meet the criteria listed above are not eligible for increasing the inspection interval.

Note: All references to National Bridge Inventory (NBI) items are those defined by FHWA-PD-96-001, *Recording and Coding Guide for the Structure Inventory and Appraisal of the Nation's Bridges*, dated December 1995.

B-3 POINT OF CONTACT INFORMATION FOR MILITARY DEPARTMENT.

Note: This contact information is valid as of the date of publication for this UFC.

Department of the Army:

Mike Dean
Army Bridge Inspection Program Proponent

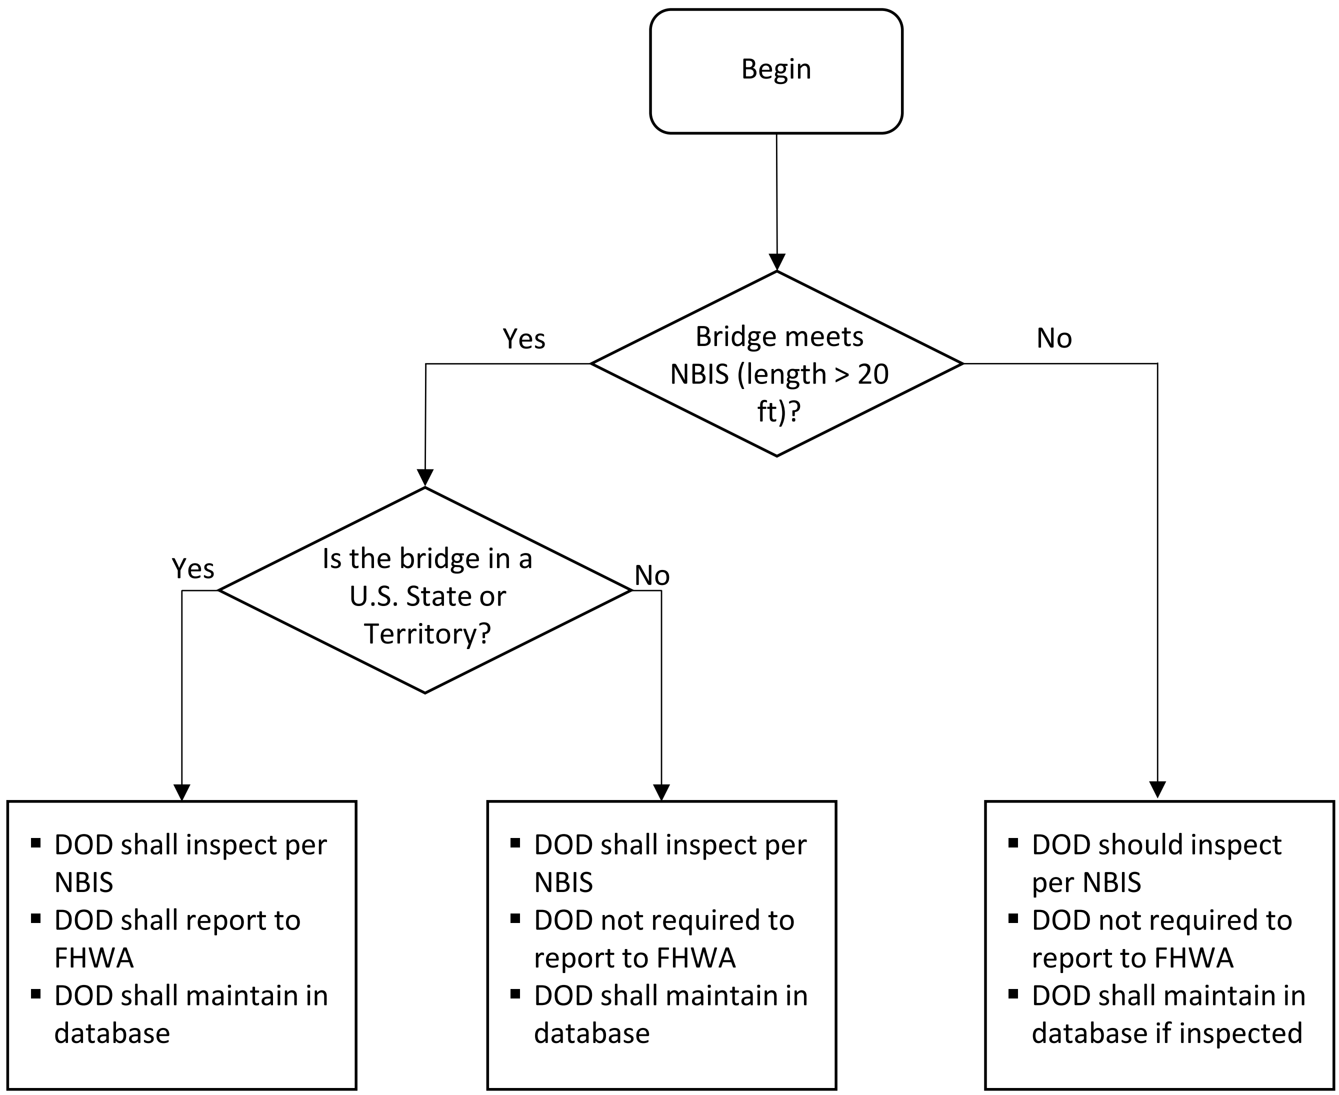
B-5 SIMPLIFIED HIGHWAY BRIDGE INSPECTION FLOWCHART.



B-6 EXAMPLE FATIGUE-PRONE DETAIL FORM FOR FCM PLAN.

Fatigue Detail Sheet

BRIDGE # : 01-139-AA05-77-001
LOCATION: CR 577 over Morrison Creek
INSPECTION DATE(S): December 10, 2014
FRACTURE CRITICAL MEMBER(S): 3 bent caps at Bents 1 through 3

CRITICAL AREA: Bottom flange and bottom half of the web plates in positive moment regions.
Top flange and top half of the web plates in negative moment regions,
and the web plates in primary shear regions.

DETAIL DESCRIPTION	FATIGUE CATEGORY	COMMENTS	PHOTO NUMBER(S)
Base metal of steel away from all welds or structural connections	A	Isolated locations with paint failure	7
Web and flange splice weld with weld reinforcement not removed	C	OK	8
Base metal at the toe of transverse connection plate welds	C'	Isolated locations of poor fusion	9, 13
Net section at open holes in member	D	OK	10
Base metal of bent cap flange at errant transverse weld	E	OK	11

(The fatigue-prone details listed above are provided as examples only. The specific fatigue-prone details for the fracture critical bridge to be inspected must be determined and listed as part of the bridge's fracture critical plan.)

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, General Building Requirements, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)

UFC 3-340-02 SUMMARY SHEET

Document: UFC 3-340-02 with Change 2
Superseding: UFC 3-340-02 with Change 1 dated 1 July 2014

Description of Changes:

- Rescinding changes to section 4-55 and figure 4-65a. The equations and figure updated in Change 1 were mistakenly based on SI units. This section now matches the 5 December 2008 version, which is based on U.S. customary units. Other Change 1 revisions are still valid.

Reason for Changes:

- To correct errors

Impact: There are no anticipated cost impacts.

UNIFIED FACILITIES CRITERIA (UFC)

UFC 3-340-02 SUMMARY SHEET

Document: UFC 3-340-02 with Change 1
Superseding: UFC 3-340-02 dated 8 December 2008

Description of Changes:

- Revised section 4-55 and figure 4-65a to incorporate updated spall and breach thresholds for reinforced concrete walls
- Implemented major revision to the masonry analysis and design guidance in sections 6-7, 6-8 and 6-9 and incorporated new example problems 6A-1a and 6A-1b, illustrating the new procedures
- Revised performance requirements for mechanical splices of reinforcing bars and added mandatory validation testing protocol to section 4-21.8
- Added guidance to the Scope sections (fourth section in each chapter) clarifying the intended applications and limitations of this document in satisfying DoD 6055.09-M requirements
- Corrected constants in equations 2-60, 2-62 and 2-63
- Expanded figure 2-152 to show peak quasistatic pressure for lower charge weight to volume ratios
- Modified figures 3-29 through 3-32 and figure 3-38 to correct errors that occurred during conversion of tri-service document Army TM 5-1300, Navy NAVFAC P-397, and Air Force AFR 88-22, Revision 1 (TM 5-1300) to UFC 3-340-02. These figures are now consistent with previous tri-service manual.
- Added supplementary minimum lap splice requirements, previously provided in TM 5-1300, and introduced guidance on acceptable applications of non-contract lap splices to section 4-21.7
- Revised variables in equation 2-47 to align equation with other DoD fragment velocity models; calculated values for the velocity change coefficient, k_v, will not be affected by this change.
- Revised Chapter 4 to exclude use of steel wire reinforcement and steel welded wire reinforcement for reinforced concrete
- Reduced support rotation limit for continuously supported reinforced concrete slabs and reinforced concrete beams designed for Protection Category 2 to 6-degrees. Per section 1-9, Protection Category 2 is used to protect equipment, supplies and stored explosives from fragment impact, blast pressures and structural response. This change should prevent any significant concrete scabbing of these elements, enhancing protection to these items.

Reasons for Changes:

- To correct errors and inconsistencies and to add clarifications
- To clarify applications and limitations of this document in satisfying DoD 6055.09-M requirements
- To update sections based on current state-of-the-knowledge and recent testing
- To improve document usability and change the document format to simplify implementation of future changes

Impact: There are no anticipated cost impacts. However, the following benefits should be realized.

- The document has a more user-friendly format including the ability to simultaneously view figures and tables with the discussion in the text
- The new masonry design procedures are based on current construction practice and allow the more cost effective use of blast resistant masonry walls
- The new mechanical splice requirements will, for the first time, allow mechanical couplers to be used in blast resistant construction, significantly reducing reinforcing bar congestion and simplifying concrete placement
- The changes to the document's format will simplify implementation of future changes

UNIFIED FACILITIES CRITERIA (UFC)
UFC 3-340-02 SUMMARY SHEET
(Provided for Archiving Purposes)

Document: UFC 3-340-02 (dated 8 December 2008)
Superseding: ARMY TM 5-1300, Navy NAVFAC P-397, and Air Force AFR 88-22 (dated November 1990)

Description of Changes:

- All substantive changes were made to Chapter 4, Reinforced Concrete Design as detailed in table below.

Description	References
Increases maximum design support rotation for nonlaced reinforced concrete elements under flexural action to 6-degrees	Section 4-9.2, Section 4-9.3, Section 4-16, Section 4-23.3, Section 4-24, Section 4-25.1, Section 4-25.3, Section 4-26.1 and Section 4-34
Increases maximum design support rotation for nonlaced reinforced concrete elements under tension membrane action to 12-degrees.	Section 4-9.3 and Section 4-25.4
Allows use of ASTM A 706 reinforcing bars in lieu of ASTM A 615 reinforcing bars.	Section 4-12.2
Updates and expands dynamic increase factor data for concrete and reinforcing bars.	Section 4-13.2, Figure 4-9a, Figure 4-9b and Figure 4-10
Revises dynamic design stresses for elements with a maximum design support rotation, θm, 5o < θm ≤ 6o.	Section 4-13.3 (Table 4-2)
Provides new equations for calculating minimum reinforcement ratios for slabs. Equations now explicitly consider the concrete's compressive strength and the reinforcing bar's yield strength.	Section 4-17.3, Table 4-3, Section 4-33.4.2 and Appendix 4A (Example 4A-1, step 6 and Example 4A-4, step 6)
Adds alternate ACI equation for calculating the allowable shear stress on the unreinforced web of an element subjected to flexure only.	Section 4-18.2

Description	**References**
Revises diagonal tension design requirements for slabs that are based upon the scaled charge distance.	Section 4-18.3
Updates minimum design shear stresses. In addition, instead of basing requirements upon close-in and far design ranges, requirements are now based upon the scaled charge distance from an element.	Section 4-18.4 and Table 4-4
Revises the equation for allowable ultimate direct shear force, Vd, that may be resisted by the concrete in a slab.	Section 4-19.2 and Section 4-19.3
Adds new sections on tension design requirements in non-laced slabs, laced slabs and beams (previously provided in section 4-68).	Section 4-20A, Section 4-26.3 and Section 4-35A
Significantly revises reinforcing bar development and lap splice requirements. In general, reinforcing bar development and lap splice lengths now calculated in accordance with the provisions of the latest ACI 318 Building Code. Supplementary requirements are noted.	Section 4-21 and subsections, Section 4-64, Section 4-65.3 and Section 4-66 subsections
Significantly expands allowable uses of single leg stirrups for diagonal tension reinforcement in slabs. Provides limits on the use of 3 different single leg stirrup types (designated as Type A, Type B and Type C).	Section 4-22 and Section 4-32
Updates figures summarizing design parameters for unlaced and laced elements to incorporate new criteria.	Figure 4-17 and Figure 4-29
Replaces minimum reinforcement ratio guidance with new equations that explicitly consider the concrete's compressive strength and the reinforcing bar's yield strength.	Section 4-38.3 and Appendix 4A (Example 4A-6, step 4d)
Provides new equations for calculating the minimum area of closed ties in columns.	Section 4-48.4
Provides new equations for calculating the minimum area of spiral reinforcement in columns.	Section 4-49.4
Section completely revised to incorporate UFC 3- 340-01's procedures for predicting concrete spall and breach. Since UFC 3-340-01 is a limited distribution document, these open distribution procedures were not previously available to the public.	Section 4-55 (including Figure 4-65, Figure 4-65a and Table 4-15a)
Defines Type A, Type B and Type C single leg stirrups and their allowable uses.	Section 4-66.3.1

Description	**References**
Section revised to eliminate now duplicate guidance for non-laced slabs, laced slabs and beams (now provided in Section 4-20A, Section 4-26.3 and Section 4-35A, respectively).	Section 4-68
Figures updated to incorporate changes to design criteria.	Figure 4-1, Figure 4-2, Figure 4-18, Figure 4-21, Figure 4-59, Figure 4-83, Figure 4-85, Figure 4-101, Figure 4-102 and Figure 4-103
Updates and expands bibliography.	Appendix 4C

UFC 3-340-02, “Structures to Resist the Effects of Accidental Explosions.”

This document is Change 2 for UFC 3-340-02. This UFC was an update of Army TM5-1300, Navy NAVFAC P-397, and Air Force AFR 88-22, dated November 1990.

Change 2 of UFC 3-340-02 has been converted into an Acrobat PDF Portfolio file. This file is essentially a folder that contains separate pdf files for each chapter, chapter appendix, and the cover pages. All of the pdf files can be accessed by using Acrobat to open the portfolio file and clicking on the appropriate file.

Two downloadable files are provided.

1. “ufc_3_340_02_dplot_v1.zip”: This zip file has an Acrobat PDF Portfolio with pdf files that will allow the plots contained within the document to be opened with Dplot pre-version 2.1, to enhance their functionality. You must have Dplot installed on your computer to use this capability. If you have a Dplot version 2.1 or later installed, you should download the file “ufc_3_340_02_dplot_v2.zip” instead of this one.
2. “ufc_3_340_02_dplot_v2.zip”: This zip file has an Acrobat PDF Portfolio with pdf files that will allow the plots contained within the document to be opened with Dplot version 2.1 or later, to enhance their functionality. You must have Dplot installed on your computer to use this capability. If you have a Dplot pre-version 2.1 installed, you should download the file “ufc_3_340_02_dplot_v1.zip” instead of this one.

Downloadable files: (Please read notes below before proceeding)
1. “ufc_3_340_02_dplot_v1.zip”: For use with Dplot (pre version 2.1) (63mb)
2. “ufc_3_340_02_dplot_v2.zip”: For use with Dplot (version 2.1 or later) (65mb)

Notes regarding the zipped files:

The UFC has been developed so that the plot files contained in the document can be opened in DPlot to enhance their functionality. Figures and tables can also be opened in a separate window by either by clicking directly on the figures and tables or by clicking on a (+) sign that is shown in the text of the pdf files next to each callout of a figure or table.

DPlot is a plotting program developed by HydeSoft Computing LLC (www.dplot.com) that allows viewing and editing of a variety of data plots.

After installing the appropriate zipped file, the source DPlot files can be opened when the plot images or the (+) sign in the text after a callout for a figure in the PDF version of UFC are clicked.

The two zipped files, representing two versions of the document differ only with regard to DPlot file compatibility.

If the user has an older version of DPlot (pre-2.1), version 1 of this document, “ufc_3_340_02_dplot_v1.zip”, should be used for compatibility. If the user has a current version of DPlot (v2.1 or later), version 2 of this document, “ufc_3_340_02_dplot_v2.zip”, should be used.

Notes regarding installation:

1. The compressed ZIP file for the document can be uncompressed to any location that the user desires.
2. The "Plots," “Figures,” and “Tables” folders must remain located adjacent to the PDF portfolio document for the hyperlinked images to run correctly. That is, the document and the folders should be co-located; the document should never be placed within any of those three folders. Extracting the zip file to a specified location on your computer should set up the appropriate file structure.

Notes regarding the Dplot File function:

Errors may occur in attempting to open the hyperlinked plot files if the user has both an older and newer version of DPlot installed. This often based on the "file associations" of the user's computer. In such case, version 2 of the document can be employed if the user re-associates the file extensions.

To re-associate the DPlot file type (*.grf) with the new version of DPlot, follow these steps:

1. Navigate in windows explorer to a DPlot file
2. Right click on the file, and select "open with" from the drop-down menu
3. Use the "Browse" button to navigate to the Program directory, selecting the "DPLOT.exe" program from the DPlot folder. Select "open" or "OK".
4. After selecting the program, the computer will return to the prior "Open With" dialogue. MAKE sure to check the box for the option to always open files of this type with the DPlot program that you selected.

This procedure will re-associate the chosen version of DPlot to open *.grf files by default.

Notes regarding document:

The PDF document features two major navigational systems, either of which may be used to move through the document.

First, the navigation pane on the left side allows the user to jump to various locations in the document. Each chapter can be expanded using the "plus" marker to its left, revealing sub-sections.

Second, the tables of contents, figures, and tables located in the text pages of the document are hyperlinked. Clicking on the text will allow the user to jump immediately to particular sections, images, or tables. After jumping to a figure or table, the user can go back to their prior location by clicking Alt+BackArrow.
