EO 14057 sets high standards for many items, including the use of renewable energy in federal buildings; 30 percent of the electrical energy consumed by federal agencies must be renewable by fiscal year 2025 and each year thereafter (note the goal is an aggregate and does not apply to each building individually). Microgrids are an effective means of using renewable energy during grid power outage situations. By effectively using microgrid resources (hardware, control systems, and software), the penetration of renewable energy may be increased during normal operation.

A-2 LOAD CHARACTERIZATION USING AMI DATA.

Load information is used to determine microgrid resources needed and for designing the microgrid system. During the initial study, the feasibility load analysis can be challenging. An AMI system, which is increasingly used, can provide detailed data. However, for specific loads, AMI data may not be available. During the feasibility study, designers must estimate load with sufficient confidence process using available information. If confidence is acceptable, designers may proceed with feasibility knowing that higher-fidelity data may inform preliminary design. Alternatively, designers may choose to pause, selectively install AMI equipment, and gather additional data before readdressing the load analysis problem.

Areas to consider for thermal and non-electrical load analysis include:

- Magnitude of Real (Watts) and Reactive (Vars) power for each phase and total
- Apparent Power in VAs for each phase and Total
- Prevalence of volatile, high-ramp rate loads, or other load following requirements
- Prevalence of Specialty or Industrial loads with motor start requirements or potential for Phase imbalance impact
- Power Factor for each phase and average
- Averages of Energy in kWh and Reactive
- Rated capacities of infrastructure
- Seasonal effects of temperature and usage

- Derating factors for equipment
- Theoretical additional load information

APPENDIX B ANALYSIS AND DESIGN MODELING TOOLS

B-1 ANALYSIS TOOLS.

Power System and Utility Modeling may include the following:

- Short Circuit Analysis: Calculates the maximum available fault current at each bus in the system
- Arc-Flash Analysis: Determines the duration, amount of energy released, and minimum distance required to protect an individual from an arc-flash
- Load Flow Analysis: Provides magnitude and phase angle of the voltage at each bus and the real and reactive power in each feeder; analysis includes generators, transformers, and renewable resources
- Voltage Profile Analysis: Load-flow analysis is used to develop voltage profiles for each scenario; this is particularly important when renewable resources are included in the system as rapid output swings may introduce instability in the system; instabilities that may not be a problem for a large utility grid may be an issue for a microgrid
- Coordination Studies: Determines the proper time versus current settings for medium-voltage relays based on feeder cables, transformer inrush current, generator size, and time-current setting of other equipment; objectives include devising relay settings to be tolerant to normal events such as inrush currents and still provide maximum protection from failure (fault) events, and having downstream circuit breakers clear first, thus compartmentalizing the outage to the smallest subsystem

Additional considerations are as listed:

- Analyzing Allowable Contribution of inverter-based power generation assets
- Grid tolerance and Grid Characterization and Modeling (if installation determines highly stressed grid or high RE penetration)

B-2 MICROGRID DESIGN MODELING TOOLS.

In accordance with Section 2911 of Title 10, DoD is required to use tools that are accurate and effective in projecting the costs and performance of potential microgrids. This appendix serves to define those requirements and provide a list of tools currently meeting these requirements, which may be used in developing microgrid projects and assessing alternatives. As microgrid design tools continue to evolve, this Appendix will be updated every three years.

Microgrid design tools are used to create conceptual designs at approximately the 10% to 20% design level and provide estimates for system performance and life cycle costs. They are used by the government to consider design alternatives, project cost estimates, establish RFP requirements, and assess alternative designs. Private sector engineering firms use them in combination with utility design tools to develop 100% designs.

B-2.1 Modeling Tool Requirements.

Section 2911 requires DoD to use tools to design and assess microgrid options. Tools must:

- Provide an accurate projection of the costs and performance of the energy resilience measure being analyzed,
- Produce resulting data that is understandable and usable,
- Consistent with standards and analytical tools commonly applied by the Department of Energy and by commercial industry,
- Adaptable to accommodate a rapidly changing technological environment,
- Peer reviewed for quality and precision,
- Measured against the highest level of development for such tools.

The following provides an assessment of available microgrid design tools relative to these requirements. Only microgrid design tools that meet Section 2911 of Title 10 requirements should be used to develop conceptual designs for DoD installation microgrids, assess cost and performance tradeoffs, and establish the requirements for future proposals for detailed designs. From the tools that meet Section 2911 requirements, installations should select one based on the design issues relevant for their installation.

B-2.1.1 Costs Requirements.

Accurate projection of costs requires the following information on finances, DER costs, and utility tariffs:

- Finances: Transparent analysis period, inflation, and discount rates are required to ensure lifecycle financial calculations are accurate and meet projects’ requirements and current financial conditions.
- DER Costs: Transparent assumptions on the capitol and O&M costs of all DERs being modeled that are consistent with industry practices and that can be modified to account for changing technologies.
- Utility Tariffs: Ability to accurate model utility tariff structure used by installations. Factors to consider include energy costs, demand charges, and time of use rates as needed.

B-2.1.2 Performance Requirements.

Accurate projection of performance requires the following information on installation energy loads and DER performance:

- Energy Load: The installations total and critical load at a resolution of one hour or less for an entire year is used to calculate the system's performance.
- DER Performance: Renewable and conventional DER performance is modeled using transparent techniques that are consistent with industry practices and can be updated to account for changing technologies.

B-2.1.3 Peer Review Requirement.

The model has been peer reviewed through publication in scientific or engineering journals.

B-2.2 Tools Reviewed.

Recent reviews[1,2,3] of existing software solutions and tools developed through DoD funding led to the consideration of the following conceptual design tools:

1. **DER-CAM** (Distributed Energy Resources Customer Adoption Model) is a decision support tool that can find optimal distributed energy resource (DER) investments for multi-energy microgrids developed and supported by Lawrence Berkeley National Laboratory (https://gridintegration.lbl.gov/der-cam). DER-CAM is publicly available and free to use.
2. **DER-VET** (https://www.der-vet.com/) developed and supported by the Electric Power Research Institute, is a free, publicly accessible, open-source platform that can optimize the value of distributed energy resources (DER) based on their technical merits and constraints for microgrids. It determines optimal size, duration, and other characteristics for maximizing benefits based on site conditions and the value that can be extracted from targeted use cases.
3. **ERA** (Energy Resilience Assessment) is a tool designed and supported by MIT Lincoln Laboratory that assists installations and missions to explore alternative microgrid technology solutions for meeting critical power requirements. It performs a system analysis of alternatives based on life

[1] Microgrid Analysis Tools Summary, https://www.nrel.gov/docs/fy18osti/70578.pdf
[2] A review of microgrid development in the United States – A decade of progress on policies, demonstrations, controls, and software tools, Applied Energy, Volume 228
[3] Assessment of Existing Capabilities and Future Needs for Designing Networked Microgrids, SAND2019-2436

cycle cost and ability to meet the critical load. It is a web-based tool that requires a DoD Common Access Card to access.

4. **HOMER** is a microgrid design software tool originally developed at the National Renewable Energy Laboratory and enhanced and distributed by HOMER Energy (https://www.homerenergy.com/products/pro/index.html). It provides simulations of grid-connected microgrid systems that combine traditionally generated and renewable power, storage, and load management. Access to the tool requires a licensing fee.

5. **MDT** (Microgrid Design Toolkit) is a free decision support software tool (https://energy.sandia.gov/download-sandias-microgrid-design-toolkit-mdt/) designed and supported by Sandia National Laboratory for microgrid designers in the early stages of the design process. The software employs powerful search algorithms to identify and characterize the trade space of alternative microgrid design decisions in terms of user-defined objectives.

6. **MicrogridUP** is a recently developed tool by National Rural Electric Cooperative Association (NRECA) (https://microgridup.org). It leverages DOE-developed solutions to lower microgrid planning costs to DoD by developing a repeatable microgrid planning framework that simplifies the process of planning for the integration of assets with legacy infrastructure. The tool is publicly available at no cost.

7. **NPS Tool** was developed by the Naval Post Graduate School (NPS) and the University of Wisconsin - Milwaukee (https://microgrid.nsetti.nps.edu/). A simple API is currently available and a microgrid simulation tool is under development. The tool is sponsored by Navy Shore Energy Technology Transition and Integration and Energy System Technology Evaluation and Program Office of Naval Research.

8. **REopt** was developed and supported by the National Renewable Energy Laboratory (https://reopt.nrel.gov/) and is a free decision support platform that evaluates how renewable energy and storage can be incorporated alongside conventional generation in grid-connected microgrids to meet critical loads at the lowest life cycle cost. REopt optimizes a microgrid system’s DERs to provide ongoing economic savings and extend site survivability during outages.

9. **XENDEE** provides a microgrid design support system (https://xendee.com/) that implements a physically based economic tool that couples financial optimization with detailed electrical power system analysis to verify resilience and financial viability. XENDEE provides support through a subscription-based service for initial feasibility studies through balance of system engineering analysis.

10. **HelioScope** is an industry leading software platform for designing high-performance solar arrays. Folsom Labs developed HelioScope, an advanced solar PV design tool.

11. **Resilience and Cost Assessment Tool** was developed by NAVFAC EXWC, creating resilience and cost models implemented with a corresponding methodology, “Resilience Assessment of Islanded Renewable Energy Microgrids.” The methodology generates the resilience and cost trade space for a site specific location. This tool enables more informed decisions on microgrids by being able to choose the microgrid architecture that provides the most cost effective resilience. The Naval Post Graduate School adapted the models to a web-based object-oriented design API incorporating the initial methodology. The tool’s development was sponsored by Navy Shore Energy Technology Transition and Integration, and Energy System Technology Evaluation and Program Office of Naval Research.

Table B-1 provides an assessment of these microgrid design tools with respect to costs of use, evaluating system performance, and peer review.

Table B-1 Microgrid Design Tools & Section 2911 Requirement Status

	Costs	Performance	Peer Review
DER-CAM	Yes	Yes	Yes
DER-VET	Yes	Yes	Yes
ERA	No	No	No
HOMER	Yes	Yes	Yes
MDT	Yes	Yes	Yes
MicrogridUp[1]	Yes	Yes	No
NPS Tool[2]	No	No	Yes
REopt	Yes	Yes	Yes
XENDEE	Yes	Yes	Yes

[1] A peer review article on MicrogridUP tool will be published in 2023.

[2] NPS plans to expand their tools capabilities to meet Section 2911 performance and cost requirements over the next few years.

The DER-CAM, DER-VET, HOMER, MDT, MicrogridUP, Reopt, and Xendee all meet Section 2911 requirements and may be used by DoD for the component of conceptual design shown under Table 4-1 to establish performance and costs options, and compare alternative opportunities. Neither ERA nor the NPS Tool meet the statutory requirements and should not be used for microgrid design work. Other tools that can demonstrate they meet these performance requirements may also be used.

This Page Intentionally Left Blank

APPENDIX C CYBERSECURITY FOR MICROGRIDS

Appendix C discusses cybersecurity as it pertains to microgrids.

The design must include strategies to assure that a cyber-attack on the grid does not also compromise the microgrid. Microgrid control design must follow the published UFC 4-010-06 for Cybersecurity of Facility-Related Control Systems. The current approach relies on a more holistic strategy of building security in, not bolting it on.

Based on the organizational mission and details of the control system, the System Owner and Authorizing Official (AO) determines impact levels (LOW, MODERATE, or HIGH) for the control system per UFC 4-010-06.

C-1 APPLYING RISK MANAGEMENT FRAMEWORK TO MICROGRID CONTROLS SYSTEMS

All microgrid control system designs must follow the Risk Management Framework (RMF) which details how risk management is applied to DoD information systems. As defined by the National Institute of Standard and Technology (NIST), the RMF is "the process of managing risks to organizational operations (including mission, functions, image, reputation), organizational assets, individuals, other organizations, and the Nation, resulting from the operation of an information system, and includes: (i) the conduct of a risk assessment; (ii) the implementation of a risk mitigation strategy; and (iii) employment techniques and procedures for the continuous monitoring of the security state of the information system."

Within DoD, each agency has an AO who determines the "Authority To Operate (ATO)" based on risk, and approves the final implementation (representing minimized, well-managed risk). When applying RMF to microgrid controls systems, the network boundary should include all control points and IP-addressable assets constructed as part of, or controlled by, the microgrid system.

Facility control systems are not information technology (IT) systems; they should not use standard IT system approaches and should not be connected to public systems, especially internet systems, and should not have remote access. The public internet system is one path for cyber-attack.

This Page Intentionally Left Blank

APPENDIX D LESSONS LEARNED AND EXAMPLES

D-1 LESSONS LEARNED.

D-1.1 Acquisition Lessons Learned.

Since microgrids cannot be procured as a single system, efficacy and competence of the final product is a function of systems integration. To the extent possible, acquisition should be "full and open" and based on "best value" with appropriate weight on performance metrics, technical approach, and past experience.

D-1.2 Design Lessons Learned.

At the preliminary design phase, performance metrics should be used to inform best-value design acquisition for both Design-Build and Design-Bid-Build. The government should seek detail regarding expected performance metrics and the level of detail of controls design needed prior to issuance of construction contract. Typically, government contracts don’t include specific language requiring exact sequence of operation and expected outcome of each action and reaction of all equipment. As such, ensure that it is done in the request for proposal stage.

D-1.3 Operations Lessons Learned.

D-1.3.1 Power Critical Communications Nodes and Servers.

A number of critical communications nodes and servers lacked sufficient or functional UPS and generation backup power systems resulting in widespread NIPR (Non-Classified Internet Protocol Router) and SIPR (Secure Internet Protocol Router) outages. Power and SIPR outages at Command Centers would have significantly degraded operations in the event of an urgent task. Connect these nodes to the microgrid, add local backup power systems with enough capacity to bridge transition times as needed, and re-test.

D-1.3.2 Identify UPS Maintenance Contract.

No standardized maintenance contract exists to support UPS units on the installation, and the party responsible for funding and overseeing maintenance is often unclear. Identify a plan to obtain a site-wide UPS maintenance contract outlining clear roles and responsibilities.

D-1.3.3 Preserve Copper Landlines.

Copper landlines are still the primary voice backbone for some bases and is a reliable system. Ensure personnel are aware that these services will function during a power outage.

D-1.3.4 Update Critical Facility Lists.

A prioritized critical facility list was unavailable during the exercise, delaying responses to important facilities. Create a list and review it with all mission owners, support services, and installation leadership.

D-1.3.5 Resolve Nuisance Fire Alarms.

Address nuisance fire alarm issues to prevent significant disruptions to missions and to ensure that critical resources are available to respond to real emergencies.

D-1.3.6 Conduct a Long-duration Test for the Entire Installation.

Conduct a long-duration (ideally multi-day) installation-wide outage to demonstrate refueling, and to fully evaluate communications interdependencies and backup power systems for facilities not connected to the microgrid. A commercial cellular communications outage inject would also be useful to ensure bases are prepared for an unplanned, long-duration, regional power outage.

D-1.3.7 Integrate Findings into the Installation Energy Plan.

Integrate lessons learned from the microgrid test into drafting the base Installation Energy Plan.

D-1.3.8 Create Preemptive Warning Prior to Non-critical Generation Shutdown.

Ensure microgrid operators have preemptive flags alerting them of an impending problem with generation units that is not critical (e.g., Tier 4 emissions) and develop a procedure to override during outage conditions.

D-1.3.9 Train Sufficient Microgrid Operators.

Ensure there are enough trained microgrid operators for continuity of operations in the event of a long-duration outage scenario.

D-1.3.10 Improve Microgrid Power Control System.

Consider the development of an automated procedure to bring the entire installation online in the event that sufficient generation capacity exists. Continue to mature the PCS software and document lessons-learned.

D-1.3.11 Evaluate the Advanced Metering Infrastructure (AMI) and SCADA system.

This will determine if additional benefit can be gained by connecting legacy infrastructure into the new microgrid system. Leveraging all utility equipment into the microgrid system could greatly strengthen capability.

D-1.3.12 Improve Microgrid Power Quality.

Address power quality concerns with the microgrid, both through distribution system devices (e.g., battery energy storage systems and capacitors) and at the local level, and continue to engage with mission owners that have expressed concerns to increase their confidence to operate this equipment in a future exercise.

D-1.3.13 Document Microgrid Lessons Learned.

Consider the development of a living microgrid lessons-learned document that can be shared broadly across DoD.

D-2 PROJECT EXAMPLES.

</table>

<u>10. DESCRIPTION OF PROPOSED CONSTRUCTION:</u>

<u>Executive Summary of Project Benefits</u>:

- ✓ Financial – The project has a payback of 25 years depending on the use and application of the microgrid. Energy cost savings were identified through demand response programs with the local utility and the value of energy security was analyzed and savings were determined by NREL
- ✓ Energy Savings – The benefits to the project go beyond energy savings as the project will demonstrate a never before achieved capability for installation wide renewable integration in a microgrid.
- ✓ Goals – This project will achieve Campaign Plan goal for energy independence by as well as meet many challenges from the DoD to achieve energy security.
- ✓ Energy Security – This project will provide energy security to all critical facilities with the use of renewable energy, energy storage, and convention fuel. This microgrid will power hundreds of buildings on the mission critical side.
- ✓ Synergistic Effect – This project will integrate many technologies such as renewable energy, direct digital controls, industrial control systems, energy storage, advanced metering, and SCADA. This microgrid project is designed to be scalable to accommodate future mission critical facilities added to the installation.

Table D-1 below shows San Diego Gas and Electric (SDG&E) Reliability Numbers. This calculation assumes a higher probability of large duration outages for the bases then has been historically observed. The future probability of outages is expected to increase but the magnitude of any reliability change is unknown. Between 2001 and 2010 for SDG&E, the average annual outage interruption per customer was approximately 1h and 45 minutes, and the average annual number of interruptions per customer was 0.7.

Table D-1 Example SAIDI/SAIFI Reliability Numbers

CRITERIA	SAIDI	SAIFI
Including CPUC Major Events (2010)	89.77	0.863
Excluding CPUC Major Events (2010)	67.74	0.543
10-Year Average (2001-2010) Including CPUC Major Events	105.59	0.691
10-Year Average (2001-2010) Excluding CPUC Major Events	64.09	0.596

This Page Intentionally Left Blank

APPENDIX E DEMAND RESPONSE

Once changes are incorporated in the commercial utility agreements, the installation can autonomously take the following actions described in E-1 through E-3.

E-1 CONTROL OF DEMAND CHARGES.

There are multiple technologies that may be used for demand response, demand reduction, including load management, energy storage, and the use of renewable and non-renewable energy sources. Microgrid designers need to consider how the design of a microgrid could be used to reduce demand or load shifting.

E-2 POWER FACTOR CORRECTION.

Electrical systems include loads that are not purely resistive. More complex energy uses, such as motors, may cause phase misalignment of voltage and current. Apparent power does not equal true power. The misalignment, called Reactive Power, is measured in units of Volt- amp reactive. Utilities may charge the installation for a power factor that is less than their established rate structure (typically 0.90 leading or lagging). Microgrid designs may typically include control systems to correct power factor. The interconnecting utility will require the project to meet certain reactive power.

The interconnecting utility will require the project to meet certain reactive power requirements at the point of interconnection. Per FERC Order No. 827, a DG project must achieve a gross dynamic reactive power requirement of at least 0.95 leading through 0.95 lagging utilizing only the dynamic reactive power capability of the planned inverters and dynamic reactive power compensation equipment installed at the substation (e.g., STATCOM). This requirement should be assumed to be applicable over a voltage range of 0.95 pu through 1.05 pu at the high side of the substation. Check with utility for rate considerations for a 0.95 +/- 0.05 power factor.

E-3 CONTRACT REVISION.

In cooperation with the local utility and by negotiating a new contract, the installation can take additional actions. Within the United States, utilities are highly regulated and do not have unlimited freedom to negotiate rates. However, they frequently have published alternative rate schedules that provide discounts to customers willing to modify consumption, or can work with installations to develop site-specific tariffs. Other options for active demand management include on-call demand reduction, fixed reduction on preset schedule.

E-3.1 On-Call Demand Reduction.

On-call demand reduction is an agreement in which the utility customer agrees to reduce its load upon request and receives a reduced rate structure in return. The number of times per month for a reduction request is usually limited and the duration and amount of the reduction is limited. The microgrid generator resources (if permitted for non-emergency use) may be used to offset the load, and control systems can be used to shed or manage the load.

E-3.2 Fixed Reduction on Preset Schedule.

This is an agreement in which the utility customer agrees to reduce its load by a fixed amount for a set time every day. The microgrid generator resources (if permitted for non-emergency use) may be used to offset the load, and control systems can be used to shed or manage the load.

Early in the microgrid design process, designers should coordinate with the local commercial power utility. Discussions and contract negotiations may extend for more than a year. The following issues and significant opportunities could arise, depending on discussions with the commercial utility provider(s).

APPENDIX F SUPPLEMENTARY ELECTRICAL FAULT PROTECTION AND GROUNDING

Early consideration should be given to the condition index of the existing electrical system. The Facility Condition Index and Condition Index/Condition Rating should be reviewed as part of the initial assessment. Validate compliance with UFC 3-550-01, NFPA 70, and IEEE C2 for requirements related to general system grounding. Specific engineering analysis is often necessary for short to ensure adequate provision of circuit protection and grounding of islanded networks predominantly energized by facility-scale distributed generation systems.

F-1 ELECTRICAL SYSTEM PROTECTION.

A challenge related to the microgrid design is electrical system protection. A pre-microgrid design includes protective devices that can identify faults and nearly instantaneously isolate the faulty circuit feeder to prevent damage to the remainder of the circuit and to the system as a whole. These devices often function by detecting high current levels associated with a fault. When connected to the grid, the utility system is capable of delivering the energy necessary to produce the high current. In microgrid mode, the distributed generators may not have capacity to provide enough energy to produce a sufficiently large current spike that could be detected by the protective equipment; the fault could go undetected and cause system damage. The onsite grid designs and protection equipment that were adequate before a microgrid was implemented may not offer adequate fault protection and may need to be revised. Analysis of the system protection design will include system simulation modeling prior to final design and construction. Protective device coordination studies will be performed as part of design and updated during construction.

F-2 SYNCHRONIZATION.

An additional challenge is synchronization. As soon as the primary grid fails, DERs begin to come online. Many of an installation’s DERs will be standard emergency generators that are associated with specific loads. The DERs will operate autonomously, as they normally do, and will tend to be out of phase with each other. When the PCC is opened and the installation’s connection to the grid is open, the DERs must synchronize before forming a microgrid. DERs must be “in phase” as they are connected (this is also true of the renewable resources that are added to the microgrid). A reference frequency is selected from among the DERs and all other DERs synchronize to the reference. The synchronization process repeats when the grid comes back online and the microgrid prepares to reconnect at the PCC. In this case, however, the microgrid DERs (in unison) use the utility frequency as their reference and synchronize to the utility.

Change No.	Date	Location

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
SUMMARY SHEET

Document: UFC 3-550-07, *Operation and Maintenance (O&M) Exterior Power Distribution Systems*

Superseding:

- AFJMAN 32-1082 (TM 5-684 and MO-200), *Facilities Engineering Electrical Exterior Facilities*.
- Air Force Handbook 32-1282 Volume 1, *Field Guide for Inspection, Evaluation, and Maintenance Criteria for Electrical Substations and Switchgear*.
- Air Force Handbook 32-1282 Volume 2, *Field Guide for Inspection, Evaluation, and Maintenance Criteria for Electrical Transformers*.

Description: UFC 3-550-07 provides guidance for the operation and maintenance of exterior power distribution systems.

Reasons for Document:

- Consolidate guidance;
- Provide technical requirements; and
- Incorporate new and revised industry standards.

Impact: There are negligible cost impacts associated with this UFC. However, standardized guidance will assist operators and maintainers in obtaining higher availability and design life from their installed systems.

Unification Issues: No unification issues noted.

TABLE OF CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

This UFC updates the requirements of and replaces AFJMAN 32-1082 /TM 5-684 /MO-200, and AFH 32-1282 V1 & V2.

1-2 PURPOSE AND SCOPE.

This UFC provides guidance for operations and maintenance of electrical power and distribution systems. Electrical systems need regular maintenance to ensure continued compliance with the codes and publications referred to in this document. Such maintenance will prevent system and equipment failures and ensure maximum safety and efficiency in the utilization of the facilities. At each installation, establish a program for proper maintenance and effectively follow it. Include in this program the scope of work, intervals of performance, and methods of application including safety requirements, practices and procedures, and operations and maintenance (O&M) of electrical power and distribution systems.

The information provided applies to the plans and procedures to operate and maintain installation electrical distribution systems. Specific installation conditions may dictate the need for procedures that exceed these minimum requirements.

These systems include substations, overhead and underground electrical distribution systems, exterior lighting systems, and electrical apparatus and components. Guidance for generators is covered in the following publications:

- UFC 3-540-01;
- UFC 3-540-07 (future UFC); and
- UFC 3-520-01.

1-3 APPLICABILITY.

The guidance and standards contained within are the minimum requirements acceptable for military installations for efficiency, economy, durability, maintainability, and reliability of electrical power supply and distribution systems. The provided guidance does not automatically supersede equipment manufacturers’ instructions and requirements. When conflicts exist, follow the most rigorous requirement. The guidance and standards herein are not intended to be retroactively mandatory. Provide, as a minimum, the level of maintenance required to meet the critical mission reliability goals.

- Comply with the requirements of Occupational Safety and Health (OSHA), General Industry Standards, and 29 CFR 1910;

- Comply with UFC 3-550-01 for minimum system and component design standards;
- Comply with UFC 3-560-01 for electrical safety requirements applicable to the installation and operation of electrical systems;
- Comply with UFC 4-010-01 and UFC 4-020-01 for security requirements related to exterior electrical distribution systems; and
- Comply with UFC 3-540-07 for operations and maintenance (O&M) of generators (future UFC).

Note: for privatized utilities, this UFC is for guidance only and compliance is not mandatory.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01. UFC 1-200-01 provides applicability of model building codes and government unique guidance for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety.

1-5 SAFETY.

Safety must always be top priority when working on or near any piece of electrical equipment. The electrical safety requirements for all electrical work activities on DoD utilities are provided in UFC 3-560-01, which provides implementation criteria for the various regulations, codes, and standards that apply to electrical safety activities.

Note: For Army installations, also comply with Army Pamphlet DA PAM 385-26.

1-5.1 Minimizing Hazards.

Material specifications, construction guidance, installation standards, material procedures, and safe working procedures have been developed to minimize hazards. Ensure all work and materials conform to the latest accepted procedures and standards, as defined in publications listed or referred to in this manual.

1-5.2 Qualifications of Electrical Workers.

Due to the inherent hazards encountered in the maintenance of electrical distribution systems and equipment, it is essential that all electrical workers be thoroughly trained and be familiar with the equipment and procedures to be followed.

1-5.3 Certification of Electrical Workers.

Properly trained electric workers will be certified in accordance with applicable publications.

1-5.4 Public Safety.

All necessary precautions will be taken to warn the public of electrical hazards or other conditions which may constitute a danger. This is especially true of temporary hazards due to work in progress.

1-5.5 Personnel Safety.

Any work on or close to electrical equipment of any kind is considered dangerous and proper safety precautions will be taken. All personnel who perform work of any kind on or near electrical equipment must be familiar with and observe all safety precautions. If an agency has a detailed labeling program or reliability program, comply with its requirements.

1-5.5.1 Safety First.

Two safety rules are mandatory as follows:

- Consider all electrical equipment is energized until it is known positively under LOCKOUT/TAGOUT (as by the presence of grounding clamps) that it is not energized. Comply with UFC 3-560-01, the applicable departmental publications, and special publications issued by the local command; and

- Work may be done only by personnel qualified by their job descriptions for that voltage level. Job descriptions to require actual hands-on work service periods to meet local utility approval. All tools and equipment must be maintained in proper operating order, be suitable for the maximum voltage level involved, and be periodically tested for compliance with all safety requirements. Consult departmental publications for specific requirements in each voltage level.

1-5.5.2 Service Safety Requirements.

This UFC addresses some safety requirements, but users must also be familiar with the service specific safety requirements.

1-5.5.3 Personal Protective Equipment.

Personal protective equipment (PPE) is equipment worn to minimize exposure to serious workplace injuries. These injuries may result from contact with electrical, chemical, physical, mechanical, or other workplace hazards. PPE may include items such as gloves, safety glasses and shoes, earplugs or muffs, hard hats, respirators, or coveralls, vests and full body suits. If PPE use is required, implement a PPE program. Address in the PPE program the hazards present; the selection, maintenance, and use of PPE; the training of employees; and monitoring of the program to ensure its ongoing effectiveness. Refer to OSHA standards and UFC 3-560-01 to become familiar with PPE requirements.

1-5.5.4 Personal Protective Temporary Grounding.

This is temporary grounding installed to protect workers engaged in de-energized line maintenance. The grounds are provided to limit the voltage difference between any two accessible points at the work site to a safe value. An expanded discussion of protective grounding principles and practices is contained in IEEE 1048; NFPA 70B; "The Lineman's and Cableman's Handbook;" and UFC 3-560-01.

1-6 CYBER SECURITY.

All control systems (including systems separate from an energy management control system or a utility control system) must be planned, designed, acquired, executed and maintained in accordance with UFC 4-010-06, DoD Instruction 8500.01 and DoD Instruction 8510.01, and as required by individual Service Implementation Policy.

1-7 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-8 GLOSSARY.

Appendix J contains acronyms, abbreviations, and terms.

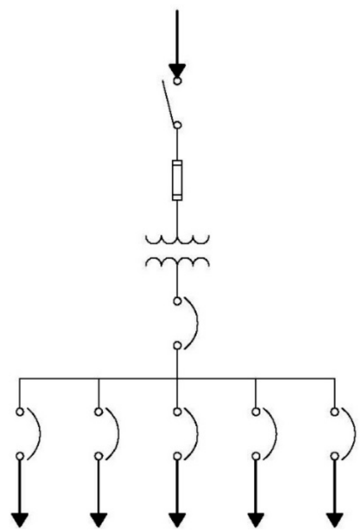
CHAPTER 2 SYSTEM CONFIGURATIONS

2-1 DISTRIBUTION SYSTEM CONFIGURATIONS.

2-1.1 Radial Feed.

Radial feed systems (Figure 2-1) are defined as having a single source and single load with no interconnections to other sources.

Figure 2-1 Radial Feed



2-1.1.1 Benefits and Limitations.

Benefits: Radial feed systems are the least expensive to build and limit losses when there is a problem as only the loads on that feed are affected.

Limitations: Radial feed systems have the highest outage impact due to being unable to feed load from other sources of power. Overhead systems typically employ fuse saving methods using reclosers and sectionalizers to minimize the impacts of the majority of faults that are self-clearing see Section 4-2.

2-1.1.2 Reliability.

System redundancy requires having identical components available and in a usable configuration so that the replacement of a failed component will not result in a long-term outage. Outages / repairs may be able to extend longer based upon the loads being served. In general, redundancy is required to meet a requirement for long-term outage sustainment. The reliability is established by the backup generator.

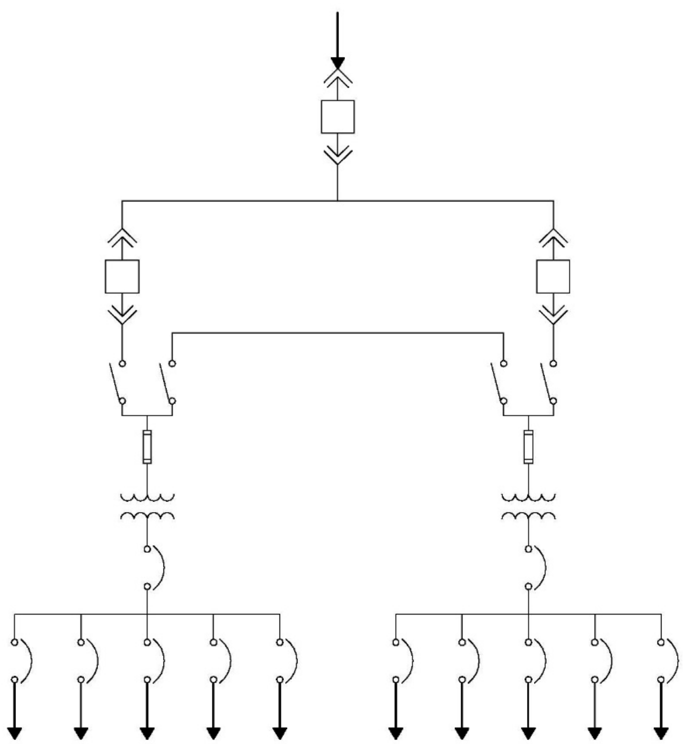
2-1.1.3 Maintenance Implications.

Maintenance tasks require components de-energizing prior to testing. Therefore, any testing must have an outage unless there are redundant feeds or redundant circuit breakers, then one component may be taken out of service and another will feed the load. Outages will be short and quick, as components can be switched out as required.

2-1.2 Loop Feed.

Loop systems (Figure 2-2) loop through the service area and then return to the source. Alternate sources or paths for the service feeder may be installed.

Figure 2-2 Primary Loop System



2-1.2.1 Benefits and Limitations.

Benefits: This is the next lowest cost system. The loop system gives another backup for the primary power feed. If a failure of the system is noted, power can be redirected through a re-configuration of the loop automatically, or manually as the system is set up. Typically, DoD installations are operated in an open loop configuration that only provides a “hot stand-by” for the system. If you operate a loop-feed closed, it can reduce the events that the entire system sees when the downstream protective devices are properly coordinated. However, more fault current is available due to the paralleling effect, which is not desirable. Limitations: By operating it open-looped, you are removing some of the benefits of building the loop. However, in the event of a typical outage caused by a blown splice on a feeder cable, the outage will take down the entire loop. Furthermore, troubleshooting may be more difficult, depending upon how the loop is installed.

2-1.2.2 Reliability.

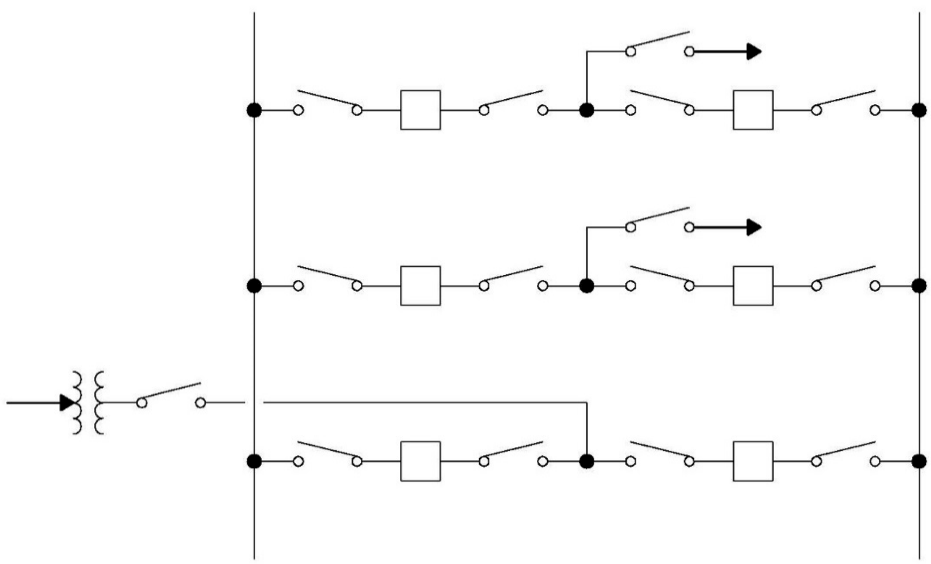
Depending on how it is operated this system is more reliable than the radial system as current has two paths to reach the loads.

2-2 SUBSTATION CONFIGURATIONS.

2-2.1 Double Feed, Double Bus.

In a double bus system (Figure 2-3), two identical busses are used in such a way that any outgoing or incoming feeder can be taken from any of the bus. Every feeder is connected to both of the buses in parallel through individual feeds. With double feeds, only the loads are individual. The system is able to have a failure of any individual feed and have a spare component substituted into its place.

Figure 2-3 Double Feed, Double Bus System



2-2.1.1 Benefit and Limitations.

Benefit: Double bus configuration increases flexibility for maintaining service through outages and performing maintenance in substations.

Limitations: Any large fault on the system will affect both buses. This is also the most expensive system, and has a lower reliability than a ring bus due to the fact that the radial feeds are not able to be maintained or replaced without taking the end load down.

2-2.1.2 Fault Tolerance.

Fault tolerance is the philosophy that states a system should survive faults with minimal downtime and if possible, automatically reconfigure itself to isolate the fault and mark it for repair. A double feed, double bus will have high fault tolerance due to the ability of the system to have alternate paths from the power source to the loads served, except to local loads. Relative fault tolerance – 3.

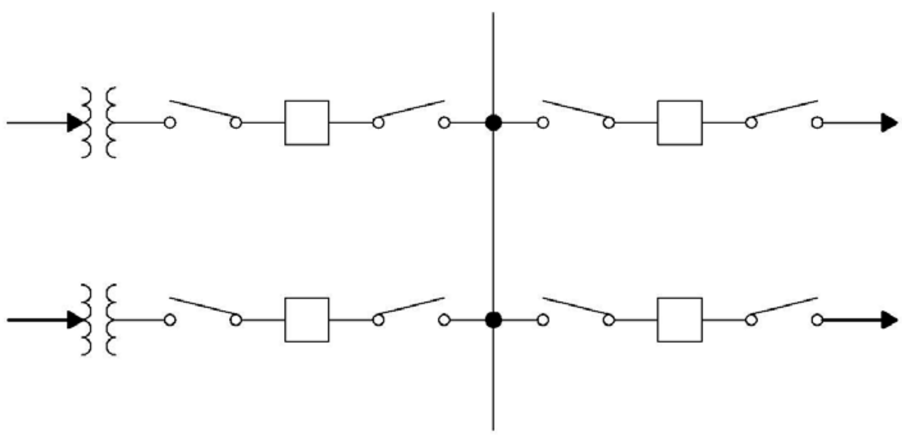
2-2.1.3 Maintenance Implications.

System maintenance is contained within the overcurrent device portion, relays, and in the cable testing.

2-2.2 Straight Bus.

A straight bus (Figure 2-4) is one where there is one source, and individual feeds to the loads. This is the same as the radial feed described above for connectivity purposes.

Figure 2-4 Straight Bus System



2-2.2.1 Benefit and Limitation.

Benefit: Straight bus/radial feed systems are the least expensive to build and radial feeds limit losses when there is a problem as only the loads on that system are affected.

Limitation: Straight bus/radial feed systems have the highest outages and highest mean time to repair due to the entire load being unable to be fed from other sources of power.

2-2.2.2 Fault Tolerance.

Straight bus systems have a very low tolerance of faults, as any one fault on the bus will take down the entire system. Relative fault tolerance – 1.

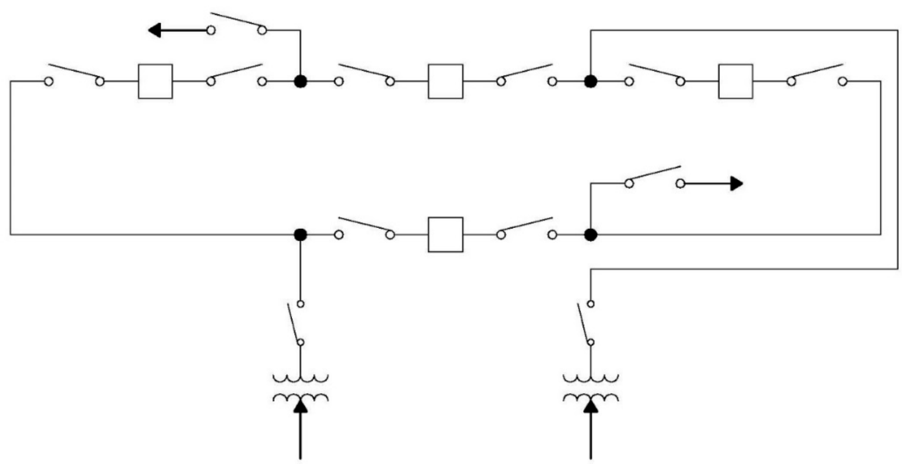
2-2.2.3 Maintenance Implications.

Maintenance tasks require the entire bus de-energized to work on without safety concerns. Outages will occur for all maintenance functions, such as insulation testing, breaker testing, etc.

2-2.3 Ring Bus.

A ring bus (Figure 2-5) is identical to a loop feed on the distribution side. This allows switching components to feed any load based upon faults anywhere on the bus structure. Loop systems must be carefully applied, as tying the two systems together, or completing the loop, will result in a future fault taking down both sides of the loop, rather than just one side. A loop system is fault tolerant to the extent that the faulted portion of the loop can usually be isolated and the entire ring placed back into service while the damaged portion is repaired.

Figure 2-5 Ring Bus System



2-2.3.1 Benefits.

A loop system loops through the service area and then returns to the source. Sometimes there are alternate sources for the power, sometimes just alternate paths.

2-2.3.2 Fault Tolerance.

This system is more expensive that a single bus, however reliability is increased based upon the ability to move feeds to loads from any direction on the bus. Relative fault tolerance – 2.

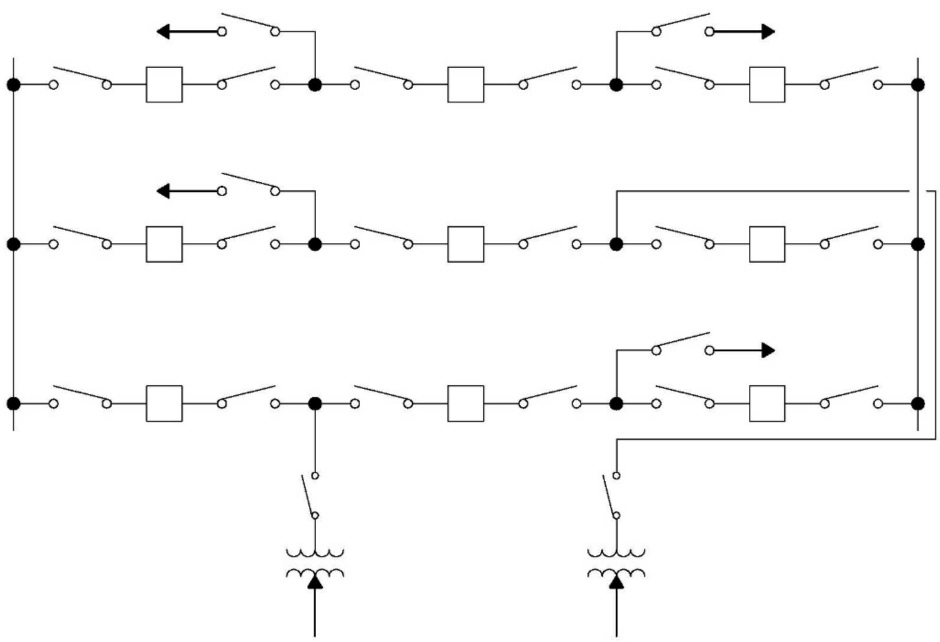
2-2.3.3 Maintenance Implications.

Maintenance tasks are easier as portions of the bus can be taken down systematically and outages required to perform them don't affect the entire system.

2-2.4 Breaker-and-a-Half.

The breaker and a half system (Figure 2-6) is an improvement on the double breaker scheme as costs are lowered by reducing the number of required circuit breakers. For every two circuits, only one spare breaker is provided. The protection is however complicated since it must associate the central breaker with the feeder whose own breaker is taken out for maintenance. Because of the high costs of equipment, even this scheme is not very popular. As shown in the figure that it is a simple design, two feeders are fed from two different buses through their associated breakers and these two feeders are coupled by a third breaker which is called tie breaker. Normally all the three breakers are closed and power is fed to both the circuits from two buses which are operated in parallel. The tie breaker acts as coupler for the two feeder circuits.

Figure 2-6 Breaker and a Half System



2-2.4.1 Benefits and Limitation.

Benefits: During any fault on any one of the buses, that faulty bus will be cleared instantly without interrupting any feeders in the system since all feeders will continue to feed from other healthy bus; however, it is cheaper than the double breaker configuration.

Limitation: This scheme is very expensive due to investment for third breaker.

2-2.4.2 Fault Tolerance.

This scheme is fairly highly tolerant for faults, as the third breaker allows a short time for switching. Relative fault tolerance – 5. Highest tolerance.

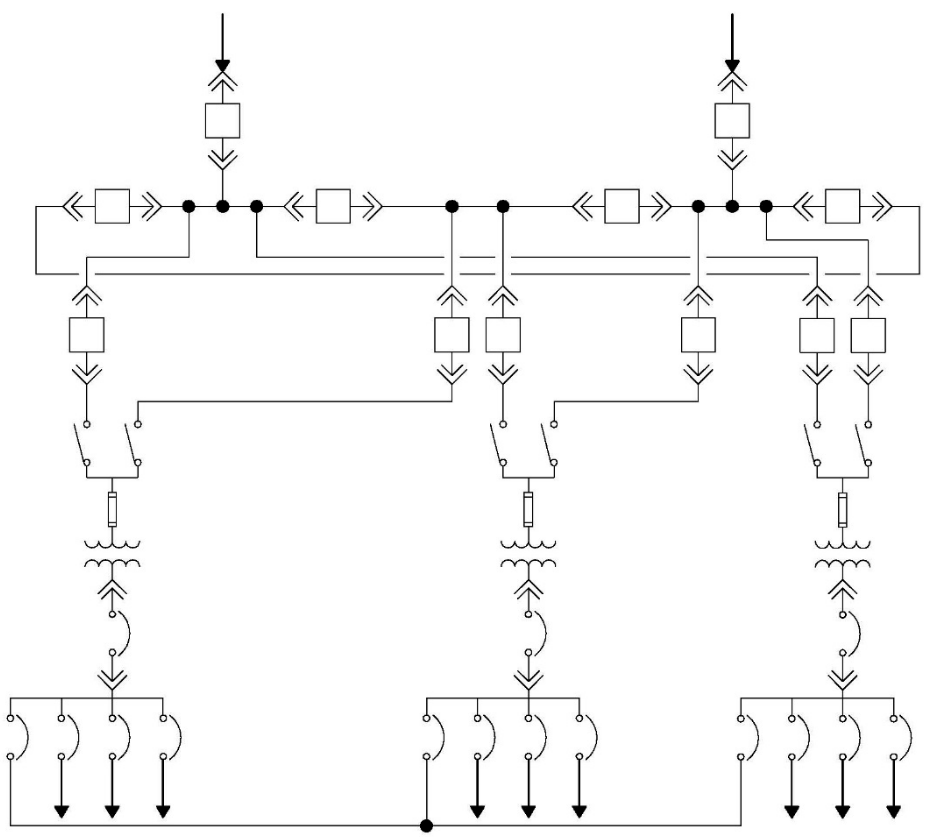
2-2.4.3 Maintenance Implications.

System maintenance is of a comparable level to the double breaker scheme.

2-2.5 Network Model.

A Network model (example provided in Figure 2-7) is a configuration using several of the above mentioned configurations. This allows many options and many configurations. However, this flexibility, because of complexity, requires a cybersecurity certified SCADA (Supervisory Control And Data Acquisition) system and highly trained operators to control feeders, monitor status, control breakers, and report maintenance issues.

Figure 2-7 Network Model



This Page Intentionally Left Blank

CHAPTER 3 DEVELOPING AN O&M PROGRAM

3-1 TRAINING.

3-1.1 Qualifications of Test Operators.

Test operators must be thoroughly familiar with the test equipment used in the type of test being performed, and sufficiently experienced to detect any equipment abnormalities or questionable data during the performance of the tests.

All qualified inspecting and repairing personnel must be thoroughly trained to perform such activities required. The following requirements are minimum:

- Familiarity with operating procedures, protective and interlocking schemes, and the equipment capabilities at the specific substation;
- Knowledge of the proper use of power distribution and utility systems control systems to ensure efficient O&M;
- Knowledge of general cybersecurity concerns and protection protocols for net-centric operations;
- Knowledge of the proper use of safety equipment, first aid procedures and equipment, and equipment grounding techniques;
- Access to safeguards such as danger signs, temporary barriers, protective clothing, tools and protective equipment, and all safety manuals and rules. Procedures to clearly indicate insulating requirements and working clearances for any category of energized-line maintenance employed; and
- Keeping proper inspection records and checklists so that observed defects or improper conditions will be promptly corrected.

3-1.2 Electric Workers, Instruments, and Reports.

Perform electrical equipment tests under the supervision of qualified electric workers. If in-house personnel are not available for these tests, the services of a qualified electrical testing agency may be used.

3-1.3 Testing Agency Qualifications.

Require the testing agency to submit proof that it is a corporately independent testing organization which can function independent of the manufacturers, suppliers, and installers of equipment or systems evaluated by the testing firm. The testing agency must meet OSHA criteria for accreditation of testing laboratories, Title 29, Part 1910-7; or be a full member company of the International Electrical Testing Association (NETA) and be regularly engaged in the testing of electrical equipment devices, installations, and systems. The lead technical agency member on-site to have a current certification by NETA or the National Institute for Certification in Engineering Technologies (NICET) in electrical power distribution system testing.

3-2 TOOLS AND EQUIPMENT.

3-2.1 Electrical Tools and Equipment Standards.

Industry standards describe the requirements for electrical protective equipment and for tools. These standards were developed so that the tools, equipment, materials, and test methods used by electrical workers will provide protection from electrical hazards. Electrical protective equipment is included in the ASTM F18 series specifications. Tool and equipment terminology and in-service maintenance and electrical testing are included in ANSI/IEEE 935 and 516 and IEEE 978 respectively. UFC 3-560-01 also contain tool and equipment requirements. In case of conflict, always use the most stringent safety requirement.

3-2.2 Standard Tools and Equipment.

For simplicity and convenience, the tools and equipment required for electrical inspection and maintenance are classified as follows:

- Tools: Tools include hand tools, digging tools, hot line tools, miscellaneous and special tools, and tackle;
- Protective equipment: Protective equipment includes rubber gloves, helmets, lie hose, matting, blankets, insulator hoods, sleeves, barricades and warning devices;
- Climbing equipment: Climbing equipment includes body belts, safety and climber straps, climbers, and ladders;
- Electrical inspecting and testing equipment: Electrical inspecting and testing equipment includes electrical and mechanical devices used to test the operation of electrical equipment, such as voltmeters, ammeters, ohmmeters, tachometers, and similar devices;
- Large portable and mobile equipment: Large portable and mobile equipment includes relatively large and easily transportable equipment for use in maintenance work, such as line trucks, aerial lift trucks, motor-generator sets, posthole diggers, and similar apparatus;
- All hand and mechanically operated tools must be used in a manner to comply with all applicable safety rules. Each worker is responsible for observing safety rules and preventing accidents;

- Energized lines: The methods used when working on energized lines, such as gloving, use of hot line tools, and provision of electrically insulated buckets, will be in accordance with the applicable services' safety manuals. Safety rules governing the use of such tools and equipment are given in these manuals and in applicable OSHA regulations, 29 CFR 1910 and 29 CFR 1926; and

- Material use: An insulating type hydraulic fluid is required in all hydraulic hand tools used on or near energized lines and in insulated sections of aerial lift trucks. Hazardous material procedures must be followed when dealing with such substances.

Apply ANSI/IEEE Std 935 for the identification of tools and equipment used in live line work. Use tools in accordance with Chapter 6 in ANSI/IEEE Std 935. Maintain live line tools and rubber goods in accordance with UFC 3-560-01. Manufactured tools must meet ASTM F18 series specifications, as appropriate to the device and material. Refer to Chapter 6 for tools and equipment associated with overhead distribution.

3-2.3 Specialty Tools and Equipment.

Consider acquiring and using the following specialty tools and equipment:

- Remote racking mechanisms for switchgear circuit breakers – several manufacturers provide remote racking mechanisms that allow the electrical worker to stay well outside the arc flash boundary during circuit breaker racking operation;

- Remote switching actuators for circuit breakers – enables remote circuit breaker operation (open or close);

- Thermal imaging cameras;

- Power quality data loggers – for evaluation of normal system parameters, such as voltage, current, power factor and harmonic distortion, as well as for evaluation of abnormal events, such as voltage swells, sags, or outages;

- Wet/dry hot stick tester;

- Pad-mounted switchgear portable motor operator – for use on pad-mounted switchgear that is not operated with a hot stick; and

- Fault locating equipment.

3-2.4 Care and Storage of Tools and Equipment.

Tools and equipment will be kept in proper operating condition and used only for the purpose for which they were designed. If proper and safe tools are unavailable, report tool needs to a Supervisor.

Inspect all tools at regular intervals and any tool that develops defects when in use will be taken from service, tagged, and not used again until restored to proper working condition.

3-2.5 Electrical Inspecting and Testing Equipment.

The number and types of testing/inspection devices needed will depend on local needs. When available, follow the manufacturer's instructions for the care and maintenance of test equipment. The schedules for the calibration and tests of instruments and meters are dependent upon the particular installation. When precision is not essential, the period between tests is not critical and may be assigned as convenient. For units provided with built-in diagnostic capabilities, check diagnostics when their associated power apparatus is checked.

3-2.5.1 Maintenance of Instruments, Meters, and Test Equipment.

Only personnel trained and qualified to maintain instruments, meters, and test equipment, or personnel under the immediate supervision of such qualified personnel, are allowed to perform accuracy tests, repairs, calibrations, and adjustments of instruments and meters. When selecting meters, match meter accuracy to the requirements of which the reading and records are being used. Procuring equipment with higher accuracy than requirements dictate must be economically justified.

3-2.5.2 Frequency of Inspections.

Use the manufacturer's maintenance recommendations intervals as the initial inspection frequencies for normal conditions. Shorten intervals where adverse conditions exist and may be lengthened only where experience under better-than-normal conditions show this can be done safely. The inspection frequency may vary for similar equipment operating under different conditions.

If calibration standards and equipment are not available, instruments and meters of nearly the same rating can be checked against each one another. When wide discrepancies are noted or the instrument or meter that is obviously incorrect, recalibrate and make any needed repairs.

3-2.5.3 Test instrument Calibrations.

Calibrate instruments every 12 months. Calibrate analog instruments every 6 months. Calibration to provide the full-scale accuracy based on the manufacturer's data, usually

1% for switchboard instruments and 0.25 % for portable instruments. Ensure dated calibration labels are visible, and maintain up-to-date calibration records, instructions, and procedures for each instrument which have had a calibration standard of higher accuracy than that of the test instrument.

3-3 HAZARDOUS MATERIAL PROCEDURES.

Implement a hazard communication program in accordance with 29 CFR 1910.1200 or 29 CFR 1926.59, and DoDI 6050.05, DoD Hazard Communication (HAZCOM) Program, as amended by Agency guidance. The major hazardous items to which electrical workers may be exposed are asbestos, polychlorinated biphenyls (PCB's), sulfur hexafluoride (SF6) and some of the chemicals used to control undesirable brush or pests or to preserve wood. For PCBs, comply with 40 CFR 761 and Overseas Environmental Baseline Guidance Document (OEBGD) DOD 4715.05-G.

3-4 SYSTEM DATA, EQUIPMENT DATA, AND DOCUMENTATION.

Prior to performing any fieldwork, review historical Electrical Preventative Maintenance (EPM) data and applicable safety requirements.

- Assemble all documentation applying to the apparatus being checked:
  - Documentation Maintenance. Installation engineering function must ensure all documentation is maintained for each specific item of electrical apparatus which makes up the facility electrical power systems.
  - Available From Design/Construction Files. The available data may include all of the inspection and testing procedures for the facility, copies of previous reports, single-line diagrams, schematic diagrams, electrical equipment plans, records of complete nameplate data, submittals, and manufacturer's service manuals and instructions.
  - Locally Prepared. Prepare local EPM forms as necessary for installed equipment. Show each item of apparatus on an equipment location plan. Provide unique apparatus designations along with a locally prepared safety electrical one-line diagram and equipment location plan.
- Specific Assembling of Data. Assemble the following data, if available, for each specific item of apparatus:
  - Locally prepared forms and as-built drawings for electric equipment layouts and elevations.

- Trend analysis data to include:
  - Installation acceptance data test results; and
  - Previous EPM reports including any previous systematic evaluations.
- Manufacturer's service manuals including practices and procedures for:
  - Installation;
  - Disassembly/assembly (interconnection);
  - Wiring diagrams, schematics, bills of materials;
  - Operation (set-up and adjustment);
  - Maintenance (including parts list and recommended spares);
  - Software programs; and
  - Troubleshooting guidance.

Systematic Evaluation of Apparatus Condition. Perform a systematic evaluation the electric apparatus condition after an EPM which indicates repairs were necessary beyond normal expected maintenance. The systematic evaluation to include:

- Reasons for the required repairs;
- Work required to complete the repairs;
- Assessment of the remaining service life; and
- Determination of the need for a more frequent EPM.

3-5 TESTING INTERVALS.

Appendix I provides recommended testing intervals.

Comply with DISA Circular 350-195-2 for testing intervals for DoD Information Network facilities' electric power systems.

3-6 RISK MANAGEMENT ANALYSIS.

Risk management is covered under IEEE 399 Chapter 12 and IEEE 493 (Gold Book) which address system reliability. IEEE 493 covers the IEEE recommended practice for the design of reliable industrial and commercial power systems. Risk management is based upon the probability of certain types of devices failing at a given period of time, and addressing maintenance according to schedules to avoid unknown or indeterminate outages. By following the recommendations in these guides, many risks can be mitigated without substantial extraneous failures.

3-7 RELIABILITY AND AVAILABILITY.

Power operational availability is the probability a system is not failed or is undergoing a repair action when it needs to be used. Availability is typically expressed as "nines." A 'three nine' availably equates to 0.999 availability or a 0.001 unavailability. A 0.001 unavailability means the system has the probability of being down 8.76 hours a year (Table 3-1). Power reliability refers to the failure probability and is typically expressed as a percentage. A very reliable system is one that can be repaired or the power brought back rapidly. Resiliency is the capacity of the system to bounce back from a failure or a fault. TM 5-698-3 provides additional reliability background information.

System redundancies, either through loop feeds and/or generators/distributed generation, combined with ability to replace quickly failed components, contribute to high overall system availability. Evaluate mission availability needs when establishing O&M program requirements, specifically address personnel training, critical tools and supplies, and contracted functions response requirements.

Table 3-1 Availability and Downtime

Availability		Unavailability (1-availability)	Hours Per Year Downtime (8760 hours/year x unavailability)	Minutes Per Year Downtime
0.99	(2-9s)	0.01	87.6	-
0.999	(3-9s)	0.001	8.76	-
0.9999	(4-9s)	0.0001	-	52.56
0.99999	(5-9s)	0.00001	-	5.256

3-8 LIFE CYCLE COST ANALYSIS.

Life cycle cost analysis (LCCA) is a good tool for establishing an O&M program or contract scope. LCCA uses the effect of equipment age on the likelihood of failure and maintenance costs to determine when replacement with new equipment becomes the most cost effective O&M solution. Use LCCA to help direct available resources to requirements with highest life cycle and mission payback.

- IEEE 493 provides guidance on recommended design practices for reliable power systems; and

- See Appendices F, G, and H for sample maintenance program checklists, LCCA maintenance work sheet, and a Man-hour Ceiling/Priority Analysis Method (MAPCO) recurring maintenance document.

3-9 RECORD DOCUMENTS - MANUALS, DIAGRAMS AND DRAWINGS.

A comprehensive file of equipment and service records provide the necessary information for aiding inspections, maintenance, or tests. In addition to indicating basic information required for proper inspection of the equipment, these records would indicate where trouble has been experienced and where special procedures may be warranted.

3-9.1 Operation and Maintenance (O&M) Manuals.

Ensure that O&M manuals are provided for any new equipment or system. O&M manual submittal requirements are included with the Unified Facilities Guide Specifications that are developed for a project. For medium voltage or high voltage circuit breakers used at substations or switching stations, refer to IEEE Std C37.12.1 for additional information.

Retain any design analysis for new projects that includes power systems analyses, including power flow, short circuit, electrical coordination, or arc flash. Refer to Section 8 for analysis requirements.

3-9.2 Electrical Drawings.

Develop and maintain the following types of drawings:

- Primary distribution system – layout drawings showing primary distribution overlaid onto the base map;
- Primary distribution system – one-line drawings; and,
- Substations and switching stations – one-line, three-line, and equipment schematic and wiring drawings.

Provide the drawings in a computer-aided drafting (CAD) format. Develop the drawings in a form that is usable for operations and maintenance. These system drawings are not construction drawings. Refer to IEEE Std 3007.1 for additional guidance regarding system drawings.

3-9.2.1 Posting.

Post the primary distribution drawings at the exterior electrical shop and at each substation or switching station.

3-9.2.2 Periodic Update.

Update the primary distribution system drawings at least annually. Coordinate with engineering and drafting personnel to ensure that all known system changes are properly shown on the drawings.

3-9.3 Operating Instructions, Records, and Logs.

Service records constitute a history of all work performed on each item of equipment and are helpful in determining the overall condition and reliability of the electrical facilities. Service records to show type of work (visual inspection, routine maintenance, tests, repair), test results (load, voltage, amperes, temperature), and any other remarks deemed suitable. It is highly recommended that service records include a log of incidents and emergency operating procedures. Logs of incidents, such as power failures, surges, low voltage, or other system disturbances are very useful in planning and justifying corrective action.

Emergency work on electrical facilities is safer and quicker when instructions are prepared and posted in advance. Prepare instructions for each general type of anticipated emergency. Each instruction to state what actions each employee will do, provide alternatives for key personnel, and establish follow-up procedures. Post instructions in the electrical shop, security guard office, substations, operating areas, and such other locations, as the responsible supervisor deems advisable. List employees by name, title, and official telephone number. These instructions must also emphasize safety under conditions of stress, power interruptions, and similar emergencies.

3-9.4 Geospatial Information Systems.

Use of a geospatial information system (GIS) for utility infrastructure is recommended. If the Activity uses GIS, provide nameplate and configuration data for replacement equipment to the organization that updates the GIS information. Coordinate equipment naming conventions and data requirements with the utility GIS analyst so naming and collected data is consistent with the information provided on the installation's CAD and GIS system drawings.

3-10 ENERGIZED WORK PROCEDURES.

3-10.1 Work on Energized Circuits.

Refer to UFC 3-560-01 for energized work requirements. OSHA 29 CFR 1910.333 limits work on live energized electrical equipment as follows: "*Live parts to which an employee may be exposed shall be de-energized before the employee works on or near them, unless the employer can demonstrate that de-energizing introduces additional or increased hazards or is not feasible due to equipment design or operational limitations*."

Some energized work activities are unavoidable. In these instances, UFC 3-560-01 requires an energized work permit prepared in advance of work execution.

3-10.2 Unique Procedures for an Energized Work Permit.

Unique operating procedures are recommended for each unavoidable routine tasks that involve working on energized electrical equipment. Provide energized work permit requests in NFPA 70E energized electrical work permit format. Use unique operating procedures to obtain energized work permit approvals as described in UFC 3-560-01. Examples of typical operating procedures for energized work on the primary distribution system include:

- Replacing fuses in medium voltage pad-mounted equipment;
- Replacing fuses on overhead circuits;
- Voltage and phase rotation checks;
- Applying and removing temporary grounds;
- Connecting or disconnecting loadbreak elbows;
- Electrical manhole inspections; and
- Pad-mounted electrical equipment inspections.

Refer to Appendix E for examples of an operating procedure.

3-11 LOCKOUT/TAGOUT PROCEDURES.

Comply with UFC 3-560-01 for lockout/tagout requirements.

3-12 CONFIRMATION OF ADEQUATE MAINTENANCE AND TESTING.

Document all maintenance and testing that is completed on electrical equipment. One form of confirmation of documented maintenance and testing is the use of calibration or maintenance stickers applied to the equipment and a documented report of the maintenance and testing that was completed.

3-12.1 Calibration Sticker Classification Codes.

Not all electrical equipment will perform properly when checked. NFPA 70B expands on the concept of a calibration sticker by also specifying a color code system that indicates the functionality of the equipment that was checked:

- White: Serviceable. If a device passes all tests satisfactorily and has met the requirements of the testing specifications, then apply a white decal to the device. This indicates that the device is electrically and mechanically sound and acceptable for return to service. There could be some minor deficiencies with the equipment but none that affect the equipment electrically or mechanically to any large degree. Examples of deficiencies include evidence of slight corrosion, incorrect circuit ID, and nameplate missing.

- Yellow: Limited Service. If the device under test has a minor problem that is not detrimental to the protective operation or major design characteristics of that particular device, then apply a yellow "Limited Service" decal to the device. Examples of limited service classifications include indicating trip targets that don't function properly, slightly lower than acceptable insulation resistance readings, and chipped arc chute.

- Red: Non-serviceable. If the device under test has a problem that is detrimental to the proper electrical or mechanical operation of that device, then apply a red "Non-serviceable" decal to the device. The non-serviceable decal would be attached to the device after attempts at field repair were made. Examples of non-serviceable classifications include no trip on one or more phases, low insulation resistance readings, mechanical trip problems, and high contact resistance readings. In addition, advise management or the owner of this condition.

If Activity uses equipment labeling as part of their testing/calibration program, use of color-coded labels is required.

3-12.2 Test Reports.

A dated test report must include, as a minimum, the following data:

- Description of equipment tested;
- Description of test;
- Test results with ALL fields completed;
- Summary of project findings and recommendations, if required for additional work;
- Documentation of the conditions at which the tests were performed; and
- Name and address of the testing firm along with contact information of the individual doing the testing.

This Page Intentionally Left Blank

CHAPTER 4 OPERATION

4-1 DEMAND LOAD.

4-1.1 Characteristics – Residential, Commercial, Industrial.

Most military Activities have power demand characteristics similar to commercial facilities. Most motor load tends to support infrastructure (sewer and water) or heating, ventilation, and air conditioning (HVAC) systems, with motors commonly less than 150 Hp. Industrial-type installations, such as systems with many large motors, including synchronous motors, are much less common.

4-1.2 Seasonal Behavior – Power Demand.

Although there are exceptions, most primary distribution systems exhibit a seasonal variation in the power demand. Figure 4-1 shows an example of a northern military base that shows a peak power demand in the summer. Figure 4-2 shows another example of a southern base with a summer peak demand that extends for several months.

Note: The scales are different for the examples shown below and reflect the actual power demand for different military bases. For example, the military base represented by Figure 4-2 has almost 4 times the peak power demand of the military base represented by Figure 4-1.

Figure 4-1 Power Demand Variation – Northern Base

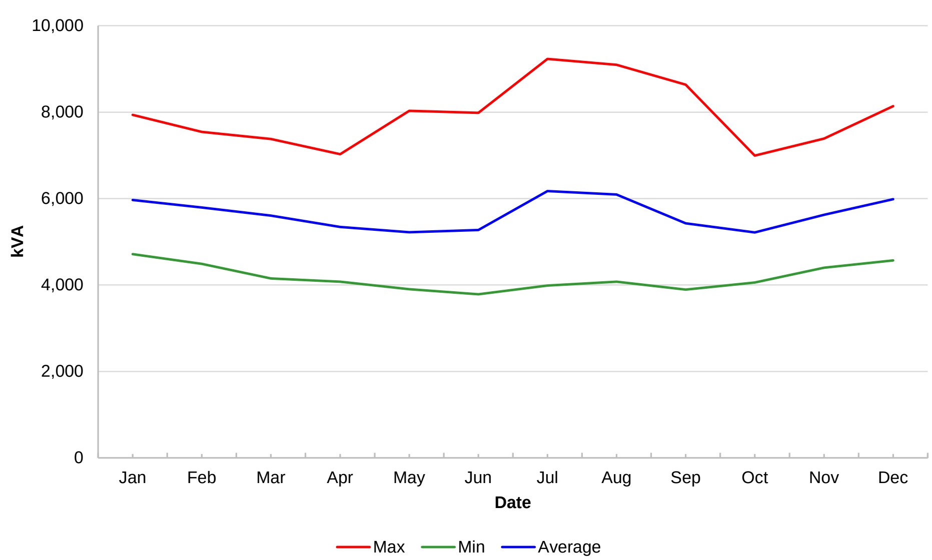


Figure 4-2 Power Demand Variation – Southern Base Demand

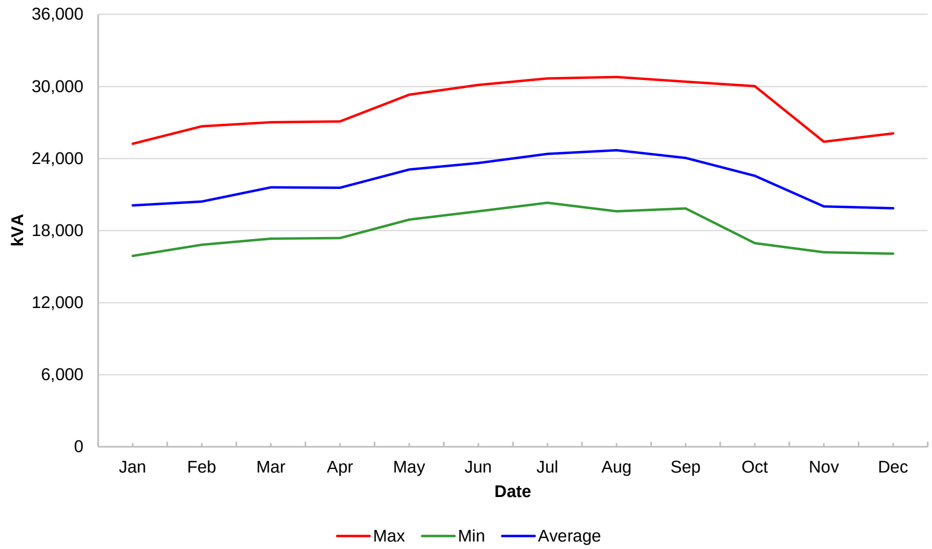
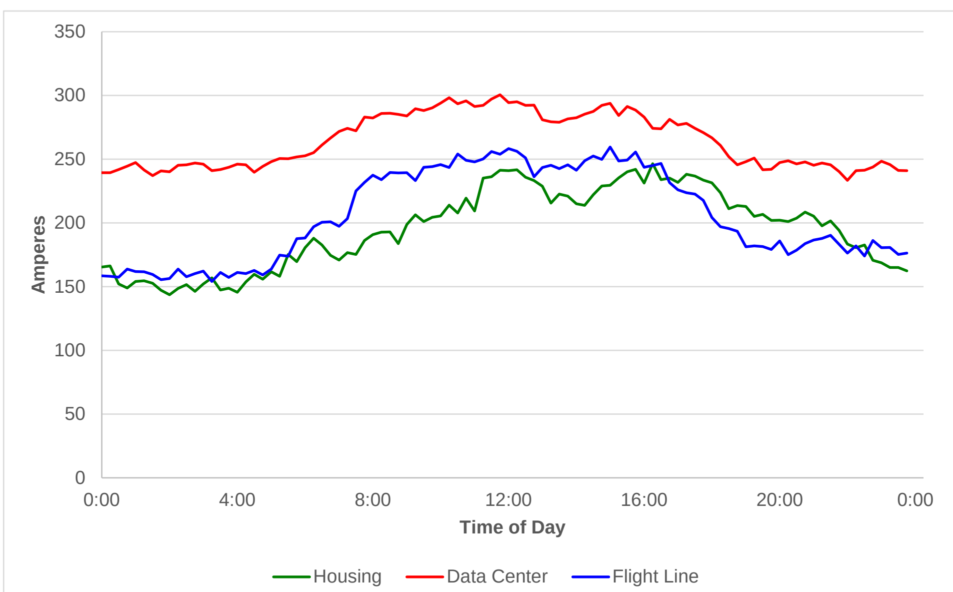


Even during the period of summer peak demand, there can be a substantial variation in the daily power demand as shown in Figure 4-3. The actual peak demand for each day might only occur for one hour in the early-to-mid afternoon time frame for a base in the northern part of the USA and it might last for several hours for a base in the southern part of the USA. Figure 4-3 shows the typical southern variation for a mainly housing circuit, a flight line industrial circuit, and a circuit with data center type loads.

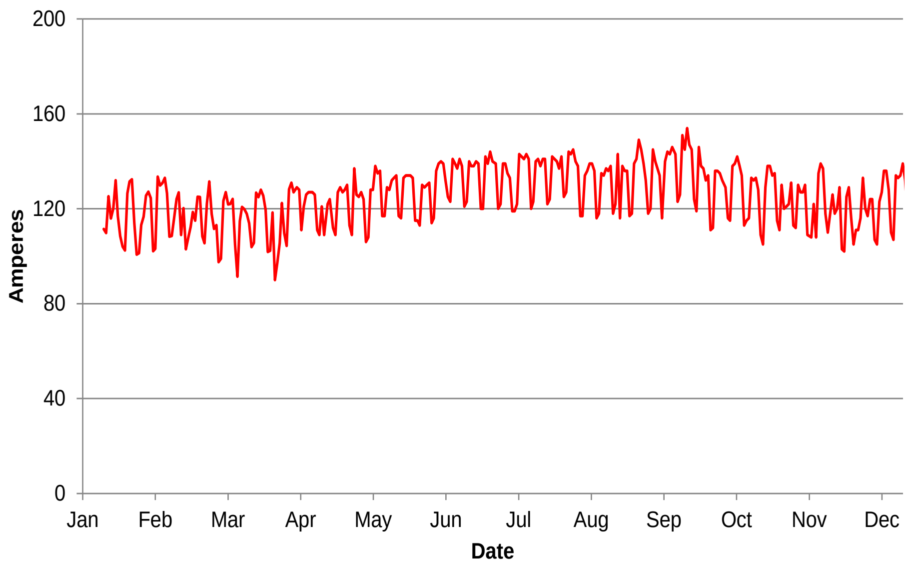
Figure 4-3 Daily Power Demand Variation



4-1.3 Circuits with Minimal Seasonal Behavior.

Not all primary distribution circuits exhibit seasonal variations. Distribution circuits that are dedicated to large facilities, such as data centers, might require year-round air conditioning, with little variation in power demand as shown in Figure 4-4.

Figure 4-4 Data Center Power Demand Variation



4-1.4 Metering Data as an Input to System Operation.

Evaluate the available metering data for the entire primary distribution system as well as for individual circuits to determine optimal operation. Use metering data for the following:

- Determine the optimal open point at cross-connect locations between distribution circuits;
- Identify peak demand loading that approaches ampacity limits on distribution circuits;
- Evaluate the extent of load growth on a distribution circuit and the potential need for upgraded circuits or additional circuits; and
- Confirm the need for additional power factor correction.

Update the metering data at least quarterly to identify any trends in power demand.

4-1.5 Load Shifting.

Load shifting, also known as Load Leveling, is the process of moving or "shifting" load from on-peak to off-peak periods. Popular methods used, but are not limited to: storage water heating, storage space heating, cool storage, and customer load shifts to take advantage of time-of-use or other special rates. Typically, there is an economic incentive built into the utility rate structure in an effort to reduce the demand placed on the system. By incentivizing the shift of load from on-peak to off-peak, the system performance can be enhanced and capital expenditure can be delayed that ordinarily would be required if the peak demand, or "peak shaving," couldn't be achieved. The result of this load shift can have a significant impact on system studies that utilize power flow analysis. If load can be shifted to other sources, any required system capitalization and expansion may be deferred. An economic example is providing an incentive for Activity to reduce their consumption at peak times to later in the day when the cost of energy is generally lower. This could include using the delayed setting on dishwashers which will postpone the operation of the dishwasher for a number of hours when the cost of energy is lower, thus distributing their consumption away from the system peak.

Load shifting can also imply the transfer of load from one source to another, either temporarily or permanently; for example, a temporary shift of load from one substation to another. In these circumstances, and if properly designed, a utility's distribution circuit can be back fed by transferring the load through the use of system 3-phase switches that will allow for maintenance or system inspection be safely performed on the original circuit while allowing most, if not all the consumers, to remain energized. This also is a consideration when a permanent system configuration is necessary and the transfer of load from a heavily loaded or overloaded substation, or circuit, to a new circuit with sufficient equipment capacity to handle the additional transferred load is required. In either case, a good understanding of the system characteristics and dynamics is needed to assure the transfer of load does not negatively affect the delivery of energy to end users. Coordinate load shifting with the utility company when shifting load between substations that are billed separately to prevent the possibility of double demand billing.

Note: Load shifting involving storage cooling or heating can increase the total KWH usage compared to no-storage cooling or heating systems.

4-1.6 Peak Shaving/Load Shedding.

Peak Shaving, or Load Shedding, is the concerted effort to remove unnecessary load from the system peak load. At its simplest, this is the turning off of load at peak load times. However, there are other philosophies, similar to Load Shifting, which provide the utility the ability to transfer large system loads onto a local standby generator(s) by remotely starting the generator(s) and completing the transfer automatically or with coordinated switching procedures with the generator's owner.

Mission operators may also have loads that can be postponed to later in the day or evening. In the case of a more complex system where it is possible to transfer some loads from one revenue meter to another, the operator may reduce the potential impact of contractual Demand Charges (kW) by moving some of the electrical loads. Because of this movement, their electrical reductions reduce the peak demands of their system. Typically, a demand rate is a contractual obligation between the utility and a larger electrical user. These charges are employed for various reasons by the utility, but are principally used to reduce demands on the system at critical times, to recover stranded equipment costs and encourage end users to distribute their electrical requirements throughout the day in order to defer future capital expansion costs. Another method of load shedding is to use distributed generation to address load shedding / peak shaving. Load peak shaving / load shedding or paralleling with the utility grid requires final approval from Agency utility leads, with an approved utility agreement, before utilizing this approach.

4-1.7 Coincidence.

Coincidence or Coincidence Factor is the ratio of the maximum demand of a system, or part under consideration, to the sum of the individual maximum demands of the base areas. In other words, it's the fraction of the peak demand of an area (or individual building), or revenue class of end user, that is in operation at the time of a system peak. Thus, it is the ratio of the installation's demand at the time of the system peak to its non-coincident peak demand. For example, a distribution system may have different classes of end users such as residential and military / commercial. The system peak may occur during the day at a time when the military / commercial Activity is high, but residential load increases late afternoon due to residents arriving home. At this time, both classes of users are placing a demand on the system and, as a whole, create a system peak, but when neither is at their individual class peak.

4-1.8 Trend Analysis.

4-1.8.1 Data.

Trend analysis data to include:

- Installation acceptance data test results;
- Previous EPM reports including any previous systematic evaluations; and
- Industrial Control System (ICS) Archive Server Feeder Trending.

In general, Trend Analysis is the review of historical information and data to determine future expectations and/or requirements. It is also used in predicting failure/risk exposure of installed electrical apparatus in guiding maintenance and replacement philosophies.

4-1.8.2 Analysis.

When applying a trend analysis to electrical distribution systems it is necessary to quantify the scope and duration of the trend. Typically, for short-range plans, a 5-year history suffices. However, as one looks further into the future as a longer-range plan develops, a more extensive historical data set is required and is typically a minimum of 10 years or more of history. These data sets would include a review of peak energy (kWh) and peak demands (kW & kVA) and where those loads are located within the system. This data provides the basis on which system load flow analysis can be used and analyzed. Load flow analysis shows how much load and where our system burdens exist. As these trends of consumption increase, various strategies can be developed based on future expectations that are shown in the analysis. Strategies such as load shedding, system capitalization / expansion, and system voltages can be explored depending upon economic justification. In addition to KW and KWH, trend analysis of cable or equipment failures (outages) is also a useful tool. Upstream outage trend analysis is a valuable part of periodic utility contract reviews. Include all this information in an annual hazard, vulnerability, and capabilities assessment in accordance with DoDI 4170.11, DoDI 4180.11, and service instructions, such as AFI 10-2501 and AFMAN 10-2504 for the Air Force.

Relative to maintenance, trend analysis can identify potential critical weak points within the system that may fail or whose ratings will be exceeded by either load flow analysis or any existing negative electrical characteristics, such as harmonics or system outages that resulted in numerous splices installed. Numerous overhead splices in a given area may indicate a more aggressive tree-trimming program is necessary. Decisions like this result from trend analysis.

4-1.9 Forecasting and Planning.

Load forecasting involves six (6) separate considerations. These are:

- Impact of nominal load growth over time. Typically, some slight growth in demand will be experienced over time. This may be upwards of ½ to 1% per year;
- Impact of equipment changes due to new equipment installations or modifications that are not part of the product (mission) plan, including environmental equipment, new technology applications, or new requirements, such as facility air conditioning or air tempering;
- New and modified production plans to meet requirements of the future product (mission) plan;
- Additional site development due to new on-site buildings(s) and added floor space. Typically, a site may be initially developed to a 15-20%

building to land ratio, with an allowance for future development of up to 30%. Some sites may be constrained for additional development;

- Impact of gas/oil conversion to electric use for some types of product (mission) heating where electric heating may actually be more economical (or reliable) due to inherent process efficiencies; and

- Other types of changes that cannot easily be categorized, such as higher density plant loading, etc.

Planning, or System Planning generally has four (4) aspects. These typically are 1-Objectives, 2-Planning, 3-Execution and 4-Control. The use of forecasting, trend analysis and standards are necessary to identify the Objectives. The long-range goals of the system are required for Planning. The necessary capital expenditures, land use, right-of-way and utility easements, overhead and underground construction costs are necessary for the Execution. Control is a periodic plan review to verify whether any of the first three (3) aspects have changed or still apply.

4-1.10 Demand Management.

4-1.10.1 Definition.

Demand Management is the collection of system load data and characteristics, and facilitates the basis of decision making when implementing any system plan. This data collection, and resulting decision making, can occur on either side of the utility electric meter, be it the producer or consumer.

4-1.10.2 Producer/Provider Demand Management.

With respect to the producer or provider, Demand Management is a means to collect relevant system data, which is then used in system studies to assist in the operation and administrative decision making of their system with the ultimate goal of providing quality, reliable energy at the lowest cost or greatest revenue depending upon mission philosophy, to end users. It allows the provider to coordinate system planning and construction in order that appropriate decisions and expenditures are used in the most efficient means with consideration to future growth, forecasting, and user’s needs.

4-1.10.3 Consumer Demand Management.

Demand management relative to the consumer is more commonly known as Demand Side Management (DSM) and is generally a contractual or economic incentive program that is brought forth by the producer that allows the end user to reduce system losses attributable to their use and consumption. It is an effort to reduce demand. Furthermore, it includes a utility action that reduces or curtails end-use equipment or processes. DSM is often used in order to reduce customer load during peak demand and/or in times of supply constraint. DSM includes programs that are focused, deep, and immediate, such as the brief curtailment of energy-intensive processes used by a utility's most demanding industrial customers, and programs that are broad, shallow, and less immediate, such as the promotion of energy-efficient equipment in residential and commercial sectors. An example of this load shedding is mentioned earlier.

4-2 RECLOSING PRACTICES AND FUSE SAVING.

Apply reclosing only on circuits where there is a reasonable expectation that faults will be temporary in nature. Do not apply reclosing unless there is a reasonable expectation that temporary faults can occur. Temporary faults are likely to occur on overhead distribution, but not on underground distribution. If reclosing capability is installed, disable reclosing if it supplies an underground distribution.

Note: The purpose of reclosing is to automatically restore power whenever a short circuit is only temporary. Industry experience with overhead lines is that 80% to 90% of faults are temporary, typically caused by lightning, wind-blown tree branches, wind-blown wires, birds, and animals. If the fault is temporary, the reclose feature allows power restoration without requiring power system line crews to respond.

Note: IEEE Std C37.104 states that reclosing should be applied only when there is a reasonable likelihood of a temporary fault. IEEE Std C37-230 states that reclosing is generally not applied on feeders with no overhead exposure, because faults on underground feeders are generally permanent.

Reclosing is authorized on distribution circuits as follows:

- Reclosing is allowed on overhead distribution circuits if there is a reasonable expectation that faults will be temporary in nature.
- Do not allow reclosing on underground distribution circuits. UFC 3-550-01 prohibits automatic circuit reclosing on underground distribution circuits.

  Note: Underground distribution faults tend to be permanent, caused by cable faults, termination failures, or improper excavation (another type of cable fault). If the reclosing feature is active when these types of faults occur, the faulted location is repeatedly reenergized until the reclosing device eventually locks out, thereby causing further damage to the fault location and unnecessarily stressing system equipment, including the substation transformer. In instances of cable damage caused by excavation, the reclose feature is an electrical safety hazard in that exposed damaged cable is reenergized with workers nearby.

  Note: Fault indicators are recommended for underground distribution circuits to assist with locating the faulted section of the line.

- For distribution circuits that contain a mix of overhead and underground distribution, treat the circuit as an underground circuit once the percentage of underground distribution exceeds 50%.

  Note: For overhead distribution circuits with main or lateral sections that convert to underground distribution, reclosing is allowed on the overhead line if a 3-gang fused cutout is included at the pole which has the aerial to underground transition point and the fuse rating is coordinated with the upstream recloser.

- For underground distribution circuits with main or lateral sections that convert to overhead distribution, reclosing is allowed at the point where the system changes to overhead distribution.

4-2.1 Reclosing Initiated at Substation or Switching Station Circuit Breakers.

When reclosing is initiated by circuit breakers at a substation or switching station, include the following:

- Provide phase and neutral instantaneous trips on the associated relays. Set the instantaneous trip low enough to be active throughout the distribution circuit; and

  Note: Downstream in-line reclosers might be required for longer distribution circuits that have a relatively low short circuit current in the remote sections of the circuit.

  Note: A sensitive instantaneous trip is desirable to allow temporary faults to clear before downstream fusing can respond.

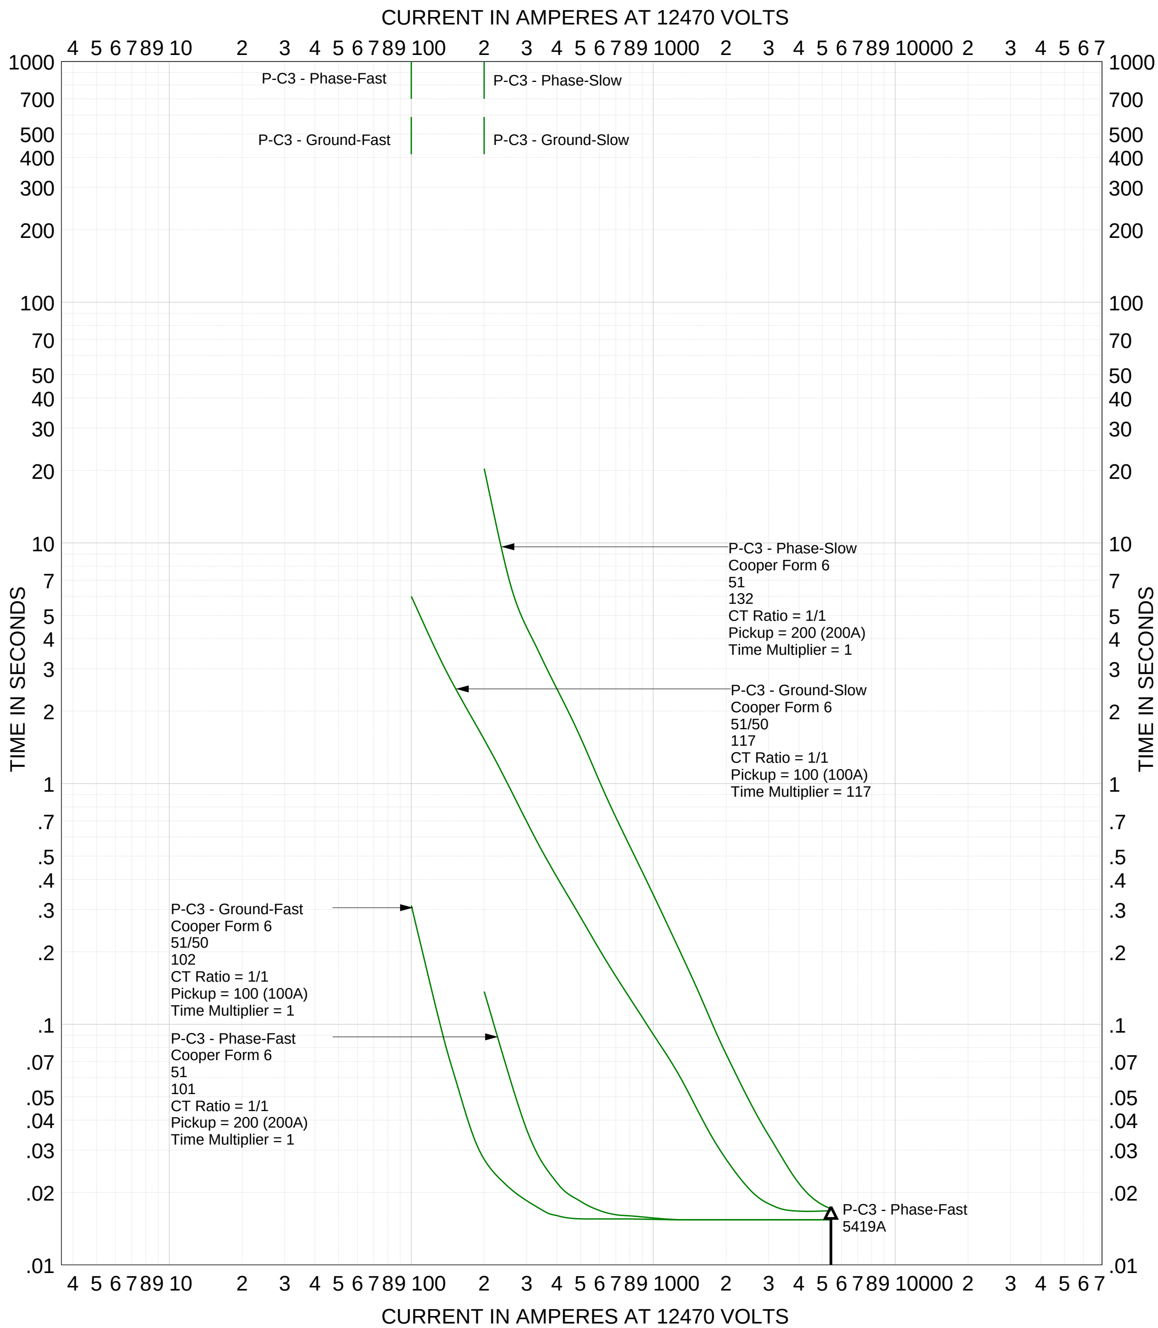
- Set up reclosing to actuate only on the instantaneous trips.

4-2.2 Reclosing Initiated at Downstream Pole- or Pad-Mounted Reclosers.

Reclosers and the associated control units are typically installed at substations, switching stations, and power poles. Reclosers might be installed in a pad-mounted configuration if they are supplying a riser to a downstream overhead distribution. Provide phase and neutral fast trip and slow trip curve settings.

> *Note: Fast trip settings are selected for sensitive rapid trips to avoid clearing of downstream fusing. Slow trip settings are selected with a longer time delay to allow downstream fusing affected by the system fault an opportunity to clear. Figure 4-5 provides an example of these settings.*

Figure 4-5 Typical Recloser Control Unit Settings



4-2.3 Maintenance Practices to Minimize Reclosing Events.

Circuit reclosing on overhead distribution systems is an efficient method for recovering from temporary faults when they occur. However, it is important to maintain the electrical distribution system in a manner that minimizes the occurrence of temporary faults. As part of the periodic review of power poles, address the need for any of the following methods to reduce the frequency of temporary faults:

- Tree trimming – ensure that nearby trees are trimmed as needed to avoid overhead lines;

- If outages are caused by bird strikes, apply IEEE Std 1651 as a guide for maintaining the overhead distribution system;

- Power pole rerouting – in some locations, it might be easier to move the power poles rather than attempt to keep a forested area trimmed;

- In outage-prone areas, consider the use of covered overhead primary (often referred to as *tree wire*) as an alternative to the standard use of bare conductors;

  Note: Tree wire is a type of polyethylene insulated wire that can prevent some direct shorts and flashovers when contact is made with tree branches. Tree wire is similar to aerial cable in that the wires are insulated and provide some level of protection from animals or limbs faulting a line. Although the polyethylene does not apply a code-rated level of insulation, it is usually adequate for preventing phase-to-phase or phase-to-ground faults.

  Note: A downed tree wire line might not allow sufficient line-to-ground current flow to ensure an upstream protective device trip, thereby leaving the line energized while lying on the ground.

- Selective insulation – in some outage-prone locations, the addition of insulating material around the bare conductors might be helpful; and

- Underground installation – in extreme cases, the frequency of temporary faults might warrant converting the overhead distribution to an underground distribution.

4-3 POWER FACTOR CORRECTION.

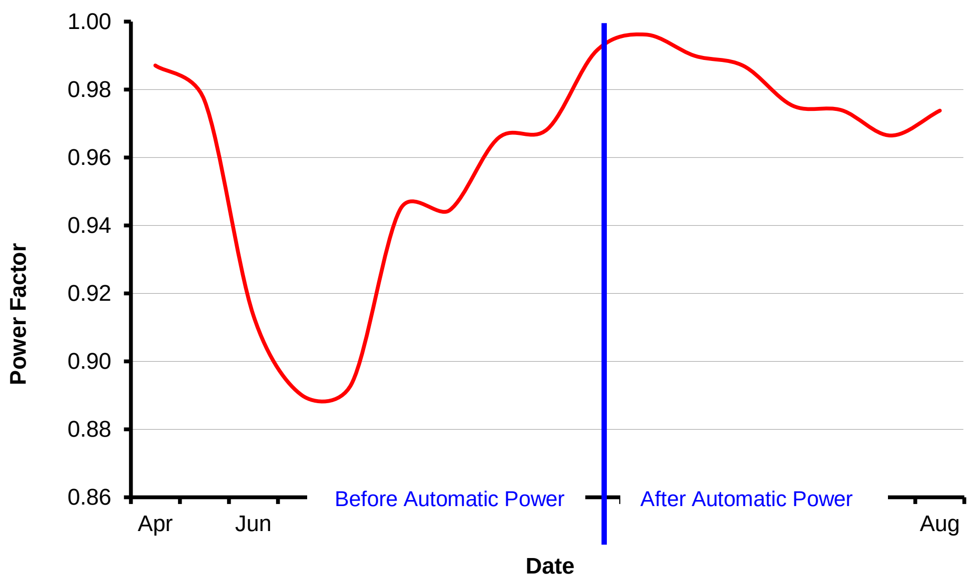
4-3.1 Power Factor Variation.

Figure 4-6 shows a typical power factor variation at a military base. In this instance, Figure 4-6 shows the effect of adding automatic power factor correction capacitors at the utility supply connection point. Before the addition of capacitors, the power factor during the summer tended to fall below 0.90. After the addition of capacitors, the power factor during the summer remains above 0.97. Evaluate available metering data to determine:

- If capacitors are needed for power factor correction; and
- If existing capacitors can be removed from service without degrading the system power factor.

Primary distribution systems that are predominantly overhead often install capacitors on each circuit. Primary distribution systems that are predominantly underground often do not require additional power factor correction.

Figure 4-6 Typical Power Factor Variation



4-3.2 Power Factor Evaluation.

Complete an evaluation of the need for power factor correction before installing or removing capacitors in the system. Figure 4-6 shows an example of the typical variation that might be seen on a primary distribution system, with and without power factor correction. The following locations are typical candidates for power factor correction.

- Substations and switching stations. Larger (typically rated for more than 1,000 kVAR) shunt capacitor installations might be installed to improve system power factor. This is also a consideration if the local utility imposes a power factor penalty;
- Overhead distribution. Smaller (typically rated for less than 600 kVAR) shunt capacitor installations intended to improve line loading and system power factor; and

- Underground distribution. Pad-mounted capacitor installations might be installed, but underground distribution circuits typically have higher natural capacitance, which reduces the need for power factor correction.

Refer to IEEE Std 18 for rating and application criteria for capacitor installations. Apply IEEE Std C37.99 for overcurrent protection. Refer to TSEWG TP-2 at http://www.wbdg.org/ccb/browse_cat.php?o=29&c=248, for examples of capacitor sizing calculations.

Note: The addition of capacitors that are routinely switched, such as with automatic power factor correction, can result in voltage transients (momentary voltage spikes) that can be damaging to sensitive electronic and electrical equipment.

4-3.3 Operation.

Capacitor installations are often left in service for extended periods and would typically only be de-energized if necessary for seasonal variations of power factor or for repairs.

Follow electrical safety requirements in UFC 3-560-01 when energizing and de-energizing capacitor installations.

4-3.4 Automatic Operation.

Automatic capacitor operation might be installed in select locations and often have two or more capacitor banks that are switched in steps as necessary to maintain power factor within a specified range. Size the capacitors for each step operation based on the system kVAR demand and ensure a lagging power factor is maintained for each step.

4-4 DISTRIBUTED GENERATION.

Distributed generation can consist of three (3) broad categories: fossil fuel facility level generators (diesel, natural gas and propane generators, natural gas micro-turbines, combined heat and power, fuel cells), fossil fueled utility scaled generation (natural gas turbines) and renewable energy (photovoltaic, wind, geothermal, landfill gas, and solid waste). Distributed generation may also include energy from existing battery systems (electric vehicles). Each of these systems has special considerations. Studies are required prior to connecting Distributed Generation (DG) to the grid. There are studies ranging from dynamic simulations to power flow and effects. Problems like transient overvoltage (TOV), power quality, etc. can occur. Time is required to determine the Minimum Daytime Load (MDL) of a circuit. DG can impact the system operation when islanding is considered. The coordination with the utility is required for safety, billing considerations, and synchronization. Refer to UFC 3-540-08 and UFC 3-440-01.

This Page Intentionally Left Blank

CHAPTER 5 MAINTENANCE, INSPECTION, TESTING AND REPAIR

5-1 SYSTEM COMPONENTS AND MINIMUM REQUIREMENTS.

5-1.1 Substations.

Recommended intervals of maintenance of various pieces of equipment are also available in Annex L of NFPA 70B and NETA MTS Appendix B Frequency of Maintenance Tests. There are four different types of maintenance: Preventative, Predictive, Breakdown or Failure, and Corrective.

5-1.1.1 Preventative Maintenance.

Preventative maintenance involves collecting data, maintaining equipment in suggested intervals and maintaining up-to-date equipment files.

5-1.1.2 Predictive Maintenance.

Predictive substation maintenance is the concept of using reliability-centered maintenance. Reliability is defined as the probability that a system will perform a given function satisfactorily for a specified time under specified operating conditions. The four (4) fundamental principles of pure reliability centered maintenance theory are:

- The primary objective of reliability-centered maintenance is to preserve the system function;
- A good reliability-centered maintenance program identifies specific failure modes to define loss of function or functional failure;
- A reliability-centered maintenance program prioritizes the importance of the failure modes; and
- A reliability-centered maintenance program identifies effective and applicable preventive maintenance tasks.

The fundamental goals of reliability-centered maintenance are to preserve the function or operations of a system and to schedule all preventive maintenance tasks to preserve the defined function. The substations system function to preserve is the delivery of safe, reliable electric power to customers (missions).

5-1.1.3 Breakdown or Failure.

Breakdown or failure is simply repairing those item(s) that break. This is not optimal because it does not tend to analyze the origin of the failure.

5-1.1.4 Corrective.

Corrective maintenance is repair and analysis of a failure and determining the root cause of the failure and attempting to mitigate the cause of failure.

5-1.1.5 Maintenance Checklists and Reports.

Generally, for (mission-owned) substations, a third party is contracted to perform substation maintenance work since most (missions) lack the resources and experience to properly maintain high-voltage equipment. An inspection checklist, tailored to a specific substation and containing all items to check, is recommended. See Substation Inspection Checklist (IEEE 141) and Technology Matrix (USDA RUS Bulletin 1724E-300). Include visual and infrared inspections of substations as part of the regular items to complete on the checklist. Tabulate, analyze, and compare in detail the periodic system data and reports, such as substation maintenance reports and min-max voltmeter readings, for trending conditions.

5-1.2 Power Transformers Recommended Intervals and Requirements.

Perform visual and mechanical inspections on an annual basis. However, general inspections can be performed anytime the power transformer is visited. Track results and trend analysis performed. Typical NETA MTS items inspected are:

- Inspect physical and mechanical condition;
- Inspect anchorage, alignment and grounding;
- Verify presence of PCB labeling, if present;
- Prior to cleaning the unit perform as-found tests, if required;
- Clean bushings and control cabinet;
- Verify operation of alarms, control and trip circuits;
- Verify that cooling fans and pumps operate correctly;
- Inspect bolted electrical connections for high resistance;
- Verify correct liquid level;
- Verify that positive pressure is maintained on gas blanketed transformers;
- Perform inspections and mechanical test on recommended by manufacturer;

- Test load tap-changer, if applicable;
- Verify the presence of transformer surge arresters;
- Perform as-left tests;
- Verify de-energized tap changer position is left as specified; and
- Check integrity of oil containment dike and drain any storm water collected.

Perform electrical inspections, such as insulation testing and gas analysis annually or every five (5) years depending upon the apparatus of the transformer, unless a fault event has occurred. These tests depend upon the critical nature of the transformer regarding dissolved gas. This could apply to 500 kVA units or higher. Smaller, oil filled units such as those that serve residential units probably require no testing. Electrical testing should be performed after any event. Track results and trend analysis performed. Typical NETA MTS items inspected are:

- Resistance measurements through bolted connections with a low resistance ohm meter, if applicable;
- Perform insulation-resistance tests;
- Perform turns ratio tests at designated tap position;
- Perform insulation power-factor or dissipation-factor test on all windings;
- Perform power-factor or dissipation-factor tests on each bushing;
- Perform excitation-current test;
- Measure the resistance of each winding at the designated tap position;
- If the core ground strap is accessible, remove and measure the core insulation resistance at 500 volt (V) direct current (DC);
- Measure the percentage of oxygen in the gas blanket, if applicable;
- Remove a sample of the insulating liquid and test for;
    - Dielectric breakdown voltage
    - Acid neutralization number
    - Specific Gravity

  - Interfacial tension
  - Color
  - Visual condition
  - Water in insulating liquids
  - Measure power factor or dissipation factor

- Remove a sample of the insulating liquid and perform a dissolved gas analysis (DGA);
  - Include Furan DGA for cellulose paper insulation degradation determination.
  - The baseline Furan Gas percentage can be used for predictive testing of remaining life of substation transformers by performing periodic Furan Dissolved Gas tests.
- Test the instrument transformers;
- Test the surge arresters;
- Test the transformer neutral ground impedance devices, if applicable; and
- When replacing transformers, 'right-size' the transformers to reduce or eliminate unnecessary arc flash incident energy levels.

5-1.3 Switching Equipment.

Switching equipment can contain numerous types of apparatus utilizing air, oil or SF_6 as an insulating medium. For this document, switching can be broken into two categories; Low Voltage (<1000V) and Medium Voltage Switching (>= 1000V). Generally, substations may contain both voltage classes. No work is allowed on switches until both sides of each phase are de-energized and properly grounded. In addition, follow the specific maintenance directions of the switch manufacturer.

5-1.3.1 Inspection Frequency.

Inspect switches visually at a frequency determined by local conditions, such as atmospheric contamination, use of contamination control coatings, operations, or fault current exposure.

5-1.3.2 Need.

If a switch cannot be maintained on a periodic basis, its service life may be affected. When operated, it is recommended that the switch be opened and closed several times in order to clean the contacts and free the moving parts.

5-1.3.3 Visual Aids.

Binoculars can facilitate spotting switches that are obviously in need of repair or maintenance because of broken insulators or other parts. Visual inspection of a wet switch, or the use of a temperature-scanning detector, may indicate hot spots which are possible sources of trouble. Directional microphones or ultrasonic detectors can be used to locate local corona sources needing removal.

5-1.3.4 Scheduling.

A relatively small amount of maintenance is required on modern switches. It is recommended that the schedule for such maintenance be coordinated with that of associated equipment. Schedule special inspection and maintenance whenever the switch has carried heavy short-circuit current.

5-1.3.5 Checking.

Examination of de-energized and grounded switches to include the following items:

- Operating Mechanism. Check the adjustment of the operating mechanism, operating rod, and interphase tie rods (if used) to ensure simultaneous and smooth operation of the switch blades. Clean and lubricate mechanisms only when so recommended, and then only in accordance with the manufacturer’s instructions as many modern switches are built with self-lubricating bearings. Examine all metallic parts of an operating mechanism including operating handle connection for signs of rust, corrosion, and loose or broken connectors. Switches located outside of a fenced and locked area, and having operating handles at ground level, require locking provisions on handles for both the open and closed positions. Switches located within a fenced and locked area, are subject to local regulations for locking.

  – Inspect all live parts for scarring, gouging, or sharp points, which could contribute to excessive radio noise and corona. Check corona balls and rings for damage which could impair their effectiveness.

  – Power-operating mechanisms for switches are usually of the motor-driven, spring, hydraulic, or pneumatic type. Follow the manufacturer’s instructions with regard to the limit switch adjustment. Check associated relay equipment for poor contacts, burned out coils, and adequacy of supply voltage. Check the complete electrical circuit of a motor-operated mechanism to ensure proper operation and wiring which is secure and free of insulation defects.

- Inspect, check, and test all safety interlocks for proper operation.

- Insulators. Examine insulators for cracks, chips, breaks, and evidence of flashover. Replace bad insulators. Clean insulators to remove any contaminating materials that may be present. Report the presence of an excessive amount of contamination to the supervisor, as it may require corrective measures;

- Mounting. Check mountings for evidence of rust and corrosion and to ensure proper alignment and securement. Ground connections must be tight;

- Blades. Inspect the blade or movable contact of the switch for evidence of overheating, which may be indicated by discolorations. If overheating is caused by poor contact, adjust and clean contacts to improve contact. Report to the supervisor any switches that appear to have overheated due to load currents in excess of rating;

- Blade Latch. A blade latch is used on a hook stick operated switch to hold the blade in closed position. Check the switch in the closed position to determine whether the catch is functioning properly;

- Contacts. Clean contacts and adjust in accordance with manufacturer's instructions. Modern switches are normally designed so that the contacts are self-cleaning by the opening and closing action of the switch. After a switch remains in either position for a long time, operate several times during a maintenance inspection. This operation will clean the contact surfaces. Operate only after getting clearance and after the circuit has been de-energized;

  - Do not use a coarse abrasive to clean contacts. If contact pitting is minor, smooth the surface with clean crocus cloth or as the manufacturer recommends.

  - Where arcing horns are used, ensure they make contact as intended during opening and closing operations.

  - Use a non-oxidizing lubricant to protect the contacts against oxidation and to lubricate the blade hinge. Silicone greases are excellent for this purpose, as they are relatively unaffected by changes in temperature and are highly water resistant.

- Terminals and connections. Check terminals to ensure that they are secure. Correct connections showing evidence of heat as a high-resistance contact is indicated; and

- Interrupting elements. Load interrupter switches are equipped with an interrupter element, designed to quench the arc that results when the switch is opened under loaded conditions. These elements are shunt devices, installed as part of the switch, through which current passes only as the switch is opened. In some higher voltage designs, the arc quenching medium is air.

5-1.3.6 Medium Voltage Switches.

For medium voltage switches and switching equipment, include all the inspection and mechanical testing identified in the low voltage section along with the following:

- Verify that expulsion-limiting devices are in place on all fuses that have expulsion-type elements;

- Verify that phase-barrier mounting is intact;

- Verify correct operation of all indicating and control devices;

- Use appropriate lubrication on moving current-carrying parts and on moving and sliding surfaces; and

- Perform as-left tests.

Electrical tests for medium voltage switches and switching equipment within a substation are comparable to those for low voltage switches with the inclusion of the following:

- Perform a dielectric withstand voltage test on each pole with switch closed. Test each pole to ground with all other poles grounded.

5-1.4 Tap Changers/Voltage Regulators.

These apparatus may be devices that are active or change internal mechanical positions several times a day depending upon the device. For example, a power transformer may have mechanically held Tap Changers which require powering off the transformer to enable the repositioning of the taps within the transformer. Other tap changers, such as Automatic Load Tap Changers can step up or down voltages through the day, similar to Voltage Regulators, as the loading of the substation changes through the day. Inspect the mechanical apparatus along with the contacts internal to the tested changer/regulator.

5-1.4.1 Visual Inspections:

Perform visual inspection and cleaning on an annual basis. Perform voltage regulator model validation along with performance testing every five (5) years. For tap changers and voltage regulators:

- Inspect physical and mechanical condition;
- Inspect anchorage, alignment and grounding;
- Record position indicator as found, maximum and minimum values, and record reading on tap changer operations counter;
- Prior to cleaning the unit, perform as-found tests;
- Clean the unit;
- Inspect bolted electrical connections for high resistance;
- Verify correct auxiliary device operation;
- Verify motor and drive train for correct operation and automatic motor cutoff at maximum lower and maximum raise;
- Verify correct liquid level in all tanks;
- Perform specific inspections and mechanical tests as recommended by the manufacturer;
- Visually inspect wear/erosion indicators on vacuum bottles, if applicable;
- Perform an internal inspection;
    1. Remove oil.
    2. Clean carbon residue and debris from compartment.
    3. Inspect contacts for wear and alignment.
    4. Inspect all electrical and mechanical connections for tightness using calibrated torque wrench.

5. Inspect tap changer compartment terminal board, contact support boards and insulated operation components for evidence of moisture, cracks, excessive wear, breakage, and/or signs of electrical tracking.

6. Electrically operate tap-changer through full range of taps.

7. Replace gaskets and seal compartment.

8. Fill with filtered oil.

- Use appropriate lubrication on moving current carrying parts and on moving and sliding surfaces;
- Perform as-left tests; and
- Record as-found and as-left operation counter readings.

5-1.4.2 Electrical Tests.

Electrical tests to:

- Perform resistance measurements through bolted connections with low-resistance ohmmeter;
- Perform insulation-resistance test in any off neutral position;
- Perform insulation power-factor or dissipation-factor tests in the off neutral position;
- Perform winding resistance test;
- Perform special tests and adjustments as recommended by the manufacturer;
- Perform turns-ratio test at all tap positions;
- Remove sample of insulating liquid and test for;
  - Dielectric breakdown voltage.
  - Color.
  - Visual condition.
- Remove sample of insulation liquid and perform DGA;

- Perform vacuum bottle integrity tests across each vacuum bottle with contacts in the open position; and

- Verify operation of heaters.

5-1.5 Relays, Instruments and Controls.

5-1.5.1 Discussion and Requirements on Controls.

Protective devices must operate during abnormal plant operating conditions and, in most instances, are the last line of defense to protect equipment from a catastrophic failure. It is critical these protective devices function properly to adequately protect the associated piece of equipment and that adjustments and calibrations are routinely conducted to eliminate the possibility of the protective device mis-operation. Therefore, it is imperative to conduct periodic maintenance testing to validate that the operational parameters of the functional protective device are properly set and coordinated, and to analyze findings to reveal trends which might lead to future failures.

5-1.5.2 Test Considerations.

Tests should simulate normal operating conditions. Avoid over testing because such tests can often cause more problems than they correct. The variables that may cause problems are relay complexity, environment, history, and facility relay-type experience. Other considerations are relay age and relay stress (relays operated at greater currents and/or control voltages because of station expansions).

5-1.5.3 Frequency.

Inspections made every 2 to 3 years are usually sufficient. Testing may be necessary after a relay operation. Additional visual inspections can be made at any time other area visual inspections are required. Check relay settings at least once a year and after any incorrect operation or redesign of the system. These inspections, supplemented by suitable tests, should be thorough enough to detect any faulty relays, settings, or wiring errors before trouble is encountered. During annual testing, provide a dated copy of the native microprocessor relay settings electronic file to the installation electrical engineer for archival purposes. For example, provide the ".rdb" file for SEL relays to the installation electrical engineer.

Completely disconnect relays from any live circuit when they are inspected or tested. Only permit specially trained electricians to repair and adjust relays, and check manufacturer's instructions for the proper procedures. Major repairs and testing should be conducted in a facility's testing laboratory or by contract personnel with access to any special testing equipment needed. NETA MTS suggestions include:

- Inspect relays and case for physical damage;

- Prior to cleaning the unit, perform as-found tests, if required;
- Clean the unit;
- Relay case;
  - Tighten case connections.
  - Inspect cover for correct gasket seal.
  - Clean cover glass.
  - Inspect shorting hardware connection paddles, and/or knife switches.
  - Remove any foreign material from the case.
  - Verify target rest.
- Relay;
  - Inspect relay for foreign material, particularly in disk slots of the damping and electromagnets.
  - Verify disk and contact clearance and spring bias.
  - Inspect spiral spring convolutions.
  - Inspect disk and contact for freedom of movement and correct travel.
  - Verify tightness of mounting hardware and connections.
  - Burnish contacts.
  - Inspect bearings and/or pivots.
- Verify that all settings are in accordance with coordination study or setting sheet supplied by owner;
- Perform as-left tests. Primary injection testing is required for end-to-end testing. Secondary injection testing of only the relay is not adequate to determine proper system operation;
- Intervals for electromechanical relays;

Table 5-1 Electromechanical Relay Test Intervals

Required Tests	Recommended Interval
Calibration maintenance	2 years
Relay functional test	2 years
Check for relay power supply indicating light	Weekly
Calibration maintenance	2 years
Relay functional test	2 years

- Contacts;
- Moving parts;
- Connections;
- Case and cover;
- Intervals for electronic relays;

Table 5-2 Electronic Relay Test Intervals

Maintenance or Test	Recommended Interval
Check for relay trouble light	Weekly
Relay functional test Monitored	6 years
Relay function test Unmonitored	4 years

- Relay functional testing of microprocessor relays will include the testing of the digital and analog inputs and outputs; and
- Monitored – A microprocessor relay is considered unmonitored unless facility monitoring meets all the following requirements:
  - Real time monitoring and alarm of the relay internal self-monitoring alarm.
  - Real time monitoring and alarm for DC supply or power supply failure.

- – Monitoring of trip coil continuity (either real time or via red light check interval).
- – If applicable, monitoring of protection telecommunication system (real time or periodically per test interval).
- – Monitoring DC battery voltage (real time or per test interval).
- – Verification of relay inputs and outputs (real time or per test interval).
- – End-to-end testing – confirmation the overcurrent test signal energized the trip coil and tripped the breaker.

5-1.6 Stationary Batteries and Battery Chargers.

Maintain substation and switching station stationary batteries in accordance with the following industry standards as modified by the requirements specified in the applicable section below.

- Vented lead acid batteries – IEEE Std 450
- Valve regulated lead acid batteries – IEEE Std 1188
- Nickel cadmium batteries – IEEE Std 1106

Use the protective equipment and follow the safety precautions specified by the applicable IEEE standard. For further battery requirements, refer to UFC 3-550-01.

5-1.6.1 Stationary Battery Approach Boundaries.

Substation and switching station stationary batteries typically operate at either 48 or 125 VDC. Observe the minimum approach distances specified in Table 5-3 and apply the arc flash PPE Category specified in Table 5-4 for the available short circuit current. Refer to UFC 3-560-01 for further information.

Table 5-3 Qualified Worker Minimum Approach Distances – DC Systems

Nominal System Voltage Range Phase to Phase	Limited Approach Boundary		Restricted Approach Boundary
	Exposed Movable Conductor	Exposed Fixed Circuit Part	Includes Reduced Inadvertent Movement Adder
<100 V	Not specified	Not specified	Not specified
100 V to 300 V	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>300 V to 1 kV	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)

Table 5-4 Arc Flash PPE Categories for DC Systems

Equipment	PPE Category	Arc Flash Boundary
Storage batteries, DC switchboards, and other DC supply sources 100 V> Voltage < 250 V Maximum arc duration and working distance: 2 sec @ 18 in.		
Short-circuit current <4 kA	1	3 ft
4 kA ≤ short-circuit current < 7 kA	2	4 ft
7 kA ≤ short-circuit current < 15 kA	3	6 ft
Storage batteries, DC switchboards, and other DC supply sources 250 V ≤ Voltage ≤ 600 V Maximum arc duration and working distance: 2 sec @ 18 in.		
Short-circuit current 1.5 kA	1	3 ft
1.5 kA ≤ short-circuit current < 3 kA	2	4 ft
3 kA ≤ short-circuit current < 7 kA	3	6 ft
7 kA ≤ short-circuit current < 10 kA	4	8 ft

5-1.6.2 Vented Lead Acid Batteries.

Perform battery inspections, tests, and maintenance in accordance with IEEE Std 450 as modified below. Correct deficient items as they are discovered.

5-1.6.2.1 Weekly. Verify the battery charger(s) is operating at the battery float voltage within battery manufacturer's specified range.

5-1.6.2.2 Monthly. Check and record the following:

- Float voltage measured at the battery terminals;
- Charger output current as expected and voltage within battery manufacturer's specified range;
- General appearance and cleanliness of the battery, battery rack or battery cabinet, and the battery area;
- Electrolyte levels adequate;
- No cracks in cells or evidence of electrolyte leakage;
- Any evidence of corrosion at terminals, connectors, racks, or cabinets; and
- Ambient temperature adequate and ventilation system operable.

5-1.6.2.3 Quarterly. Augment the monthly inspection with the following:

- Voltage measured of each cell; and
- Battery cell temperature at representative cells.

5-1.6.2.4 Annually. Augment the quarterly inspection with the following:

- Visual inspection of each cell;
- Evaluation of structural integrity of the battery rack or cabinet; and
- Measurement of cell-to-cell and terminal connection resistance or torque check in accordance with manufacturer's instructions.

5-1.6.2.5 As Required. Complete the following as specified:

- Record a complete set of specific-gravity readings upon initial installation and after two years of service;
- If the battery has experienced an abnormal condition, perform an annual inspection to verify that the battery has not been damaged. Refer to IEEE 450 for additional guidance for abnormal conditions; and

- Schedule for a battery replacement every 12 years. In lieu of a battery replacement, it is acceptable to perform the IEEE 450 battery capacity test every two years after the battery has been in service for 10 years. If capacity tests are performed, replace the battery when capacity falls below 80% of rated capacity.

5-1.6.3 Valve Regulated Lead Acid (VRLA) Batteries.

Perform battery inspections, tests, and maintenance in accordance with IEEE Std 1188 as modified below. Correct deficient items as they are discovered.

5-1.6.3.1 **Weekly.** Verify the battery charger(s) is operating at the battery float voltage within battery manufacturer's specified range.

5-1.6.3.2 **Monthly.** Check and record the following:

- Float voltage measured at the battery terminals;
- Charger output current as expected and voltage within battery manufacturer's specified range;
- General appearance and cleanliness of the battery, battery rack or battery cabinet, and the battery area;
- No cracks in cells or evidence of electrolyte leakage;
- Any evidence of corrosion at terminals, connectors, racks, or cabinets;
- Any evidence of cell/unit jar or cover distortion; and
- Ambient temperature adequate and ventilation system operable. *Note: a high ambient temperature can lead to battery thermal runaway. Correct the high temperature condition immediately.*

5-1.6.3.3 **Quarterly.** Augment the monthly inspection quarterly with the following:

- Measurement of cell/unit internal ohmic measurement. Typically, a change of 30% to 50% from a baseline is considered significant. Evaluate any measurements indicating a high internal resistance and replace the cell/unit, if needed;
- Temperature of the negative terminal of each cell/unit of battery; and
- Voltage of each cell/unit.

5-1.6.3.4 **Annually.** Augment the quarterly inspection annually with the following:

- Measurement of cell-to-cell and terminal connection resistance or torque check in accordance with manufacturer's instructions.

5-1.6.3.5 **As Required.** Complete the following as required:

- If the battery has experienced an abnormal condition, perform an annual inspection to verify that the battery has not been damaged. Refer to IEEE 1188 for additional guidance for abnormal conditions; and

- Perform a performance test of the battery capacity in accordance with IEEE 1188 after the battery has been in service for three years and every two years thereafter. Alternately, replace the battery after three years of service. If capacity tests are performed, replace the battery when capacity falls below 80% of rated capacity.

5-1.6.4 Nickel Cadmium Batteries.

Perform battery inspections, tests, and maintenance in accordance with IEEE Std 1106 as modified below. Correct deficient items as they are discovered.

5-1.6.4.1 **Weekly.** Verify the battery charger(s) is operating at the battery float voltage within battery manufacturer's specified range.

5-1.6.4.2 **Quarterly.** Check and record the following:

- Float voltage measured at the battery terminals;

- Charger output current as expected and voltage within battery manufacturer's specified range;

- General appearance and cleanliness of the battery, battery rack or battery cabinet, and the battery area;

- Electrolyte levels adequate;

- No cracks in cells or evidence of electrolyte leakage;

- Any evidence of corrosion at terminals, connectors, racks, or cabinets; and

- Ambient temperature adequate and ventilation system operable.

5-1.6.4.3 **Semi-Annually.** Augment the quarterly inspection semi-annually with the following:

- Voltage measured of each cell.

5-1.6.4.4 **Annually.** Augment the semi-annual inspection annually with the following:

- Evaluation of structural integrity of the battery rack or cabinet; and
- Measurement of cell-to-cell and terminal connection resistance or torque check in accordance with manufacturer's instructions.

5-1.6.4.5 **As Required.** Complete the following as required:

- If the battery has experienced an abnormal condition, perform an annual inspection to verify that the battery has not been damaged. Refer to IEEE 1106 for additional guidance for abnormal conditions; and
- Schedule for a battery replacement every 15 years. In lieu of a battery replacement, it is acceptable to perform the IEEE 1106 battery capacity test every two years after the battery has been in service for 12 years. If capacity tests are performed, replace the battery when capacity falls below 80% of rated capacity.

5-1.7 Instrument Transformers.

The basic difference between current and potential transformers must be observed. A voltage transformer should never be short circuited. A current transformer requires the secondary circuit always be closed. Under no circumstances open the secondary of a current transformer while the primary circuit of the transformer is energized unless the terminals of the current transformer are of the short circuiting type. Schedule instrument transformers for a maintenance inspection every 2 years. In addition, inspect visually any time the apparatus with which they are associated is inspected, but not less than every 6 months.

Maintain the bushings and terminals of an instrument transformer as described in the NETA maintenance guide. Inspect the case or tank for evidence of corrosion and leaks. Tighten all loose joints in conduit around fittings, terminal boxes and supporting clamps. Clean and paint corroded areas. Verify tightness of all bolted connections. Verify that wiring, grounding and shorting connections provide good contact. Test the proper operation of the voltage transformer withdrawal mechanisms (tip out) and grounding operation. Accomplish instrument transformers electrical testing per NETA standards.

5-1.8 Capacitors and Inductors.

Capacitors:

- Observe the condition of fuses;
- Inspect for damaged tanks and bushings and for leakage of the dielectric; and
- Recommended intervals and requirements.

Inductors:

- Very few inductors exist in military primary distribution systems.

5-1.9 Insulators.

Examine insulators for cracks, chips, breaks, and evidence of tracking or flashover. Replace bad insulators. Clean insulators to remove any contaminating materials that may be present. Report the presence of an excessive amount of contamination to the supervisor as it may require corrective measures.

Check mountings for evidence of rust and corrosion and to ensure proper alignment and securement. Ground connections must be tight.

5-1.10 Bushings.

Information in this section pertains to bushings on such substation apparatus as power transformer, sulfur hexafluoride (SF6) and oil circuit breakers, and high-voltage instrument transformers. Bushings are always an integral part of a specific apparatus and should be inspected along with that apparatus.

- Examine bushings for cracks, chips, breaks, and evidence of tracking or flashover. Replace bad bushings. Clean bushings to remove any contaminating materials that may be present. Report the presence of an excessive amount of contamination to the supervisor as it may require corrective measures, and
- Check mountings for evidence of rust and corrosion and to ensure proper alignment and securement. Ground connections must be tight.

Power factor testing of a bushing is an indication of the effectiveness of the insulation to function properly. Power-factor test bushings at the time of installation and at regular intervals. Follow IEEE Std 62.

5-1.11 Bus Structures.

A bus structure is an assembly of bus conductors with associated connection joints and insulating supports. It can have bare or insulated conductors. A busway is a grounded metal enclosure, containing factory-mounted, bare or insulated conductors, which are usually copper or aluminum bars, rods, or tubes. Each serves as a common connection between two or more circuits.

- Schedule bus structures visual inspections at regular intervals. Joints on bus structures need regular visual and infrared inspections;

- Bus cleaning is limited primarily to that of eliminating excessive contamination from the supporting insulators. It is not necessary to remove corrosion from the conductors except where it either affects contact resistance of connections or can lead to deterioration of conductors; and

Generally, no testing is required in connection with a bus structure other than infrared.

5-1.12 Terminations.

Inspect and test terminations and connections on a regular basis. Infrared thermography can provide a non-contact means of online evaluation of “hot spots” in an energized system. When a loose or corrosive connection is present under loaded conditions, the infrared viewer can detect the temperature difference between the connection and the surrounding conductors:

- When doing infrared scanning, take into account the following considerations. Infrared scanning surveys should be done during periods of maximum possible loadings, but not less than 40% of rated load of the electrical equipment being inspected. However, since many systems are not loaded to this level, the most important understanding is to measure when there is an adequate temperature difference for the scanner to detect. Try to measure at maximum possible loading, referring back to the seasonal loading chart regarding when to schedule; and

- Inspect distribution systems with imaging equipment capable of detecting a minimum temperature difference of 1 ^{0}C at 30 ^{0}C.

Ultrasound is another method of testing and evaluating terminations on a system that is energized. Ultrasound detectors are used to detect inaudible noises on equipment that could indicate potential problems:

- Test on an annual basis.

5-1.13 Grounding.

Grounding is an essential part of protecting staff and equipment from high potential caused by electrical faults. Grounding conductors of switchyard equipment and gate structures are subject to failure due to corrosion, loose connections, and mechanical damage. Grounding also may be compromised during equipment addition and removal or other construction type activities. Verifying grounding system integrity through periodic testing is an important maintenance activity:

- Check all accessible ground connections for secureness, and measure the overall ground grid resistance if it has not been done for a number of years. Since it is desirable to disconnect shield wire grounds and system neutral connections to make this measurement, de-energize the total substation for these tests. Perform visual and mechanical inspections annually. Test grounding electrode and substation/switchyard grid every 6 years (Table 5-5); and

Table 5-5 Battery Monitor System Maintenance

Maintenance or Test	Recommended Interval
Visual/physical inspection	Annually
Grounding electrode and substation/switchyard grid tests	6 years
Ground loop impedance test	6 years

- Comply with IEEE 80, IEEE 1246, and IEEE 837.

5-1.14 Fences.

Metal fences must be properly grounded and bonded. Fences, physical protection, enclosures or other protective means, where required to guard against unauthorized access or accidental contact with exposed energized conductors and circuit parts, will be maintained. Bond across all gate opening and gaps of fences from fence post to post.

5-1.14.1 Grounding.

The grounding connections will be made either to the enclosed equipment grounding system or to a separate ground:

- Fences will be grounded at each side of a gate or other opening;

- Gates will be bonded to the grounding conductor, jumper or fence;

- A buried bonding jumper will be used to bond across a gate or the opening in the fence, unless a non-conducting fence section is used;
- If barbed wire strands are used above the fence fabric, the barbed wire strands will be bonded to the grounding conductor, jumper or fence;
- When fence posts are of conducting material, the grounding conductor will be connected to the fence post or posts, as required, with suitable connecting means; and
- When fence posts are of non-conducting material, suitable bonding connection will be made to the fence mesh strands and the barbed wire strands at each grounding conductor point.

5-1.14.2 Fence Structure.

The following are minimum inspection requirements:

- Check for minimal gap under the fence or under the gate. A reasonable rule of thumb would be less than 2 inches under the fence and 4 inches under the gate;
- Ensure the fence fabric is intact and there is no rust;
- Check that the barbed wire is taut;
- Ensure the gate latches are operable;
- Ensure flexible braid-type connections are intact;
- Verify that no wire fences are tied directly to the substation fence; and
- Recommend revised corrosion control intervals and requirements based upon observed local conditions.

5-1.14.3 Structural Grounding Maintenance.

Fence maintenance consists of material preservation, maintenance of structural integrity, and maintenance of a good ground. The following procedures are recommended:

- Material preservation. In noncorrosive locations, double-dipped (ASTM A 90, Class II) hot dipped galvanizing on chain-link fences will normally furnish adequate protection for many years. In corrosive locations, use of an aluminized fabric is the preferred installation. Wood fences are not usually considered to provide adequate security for substations. Consider replacement with chain-link fencing. Screening, if required, can be provided with privacy slats of polyester-fiberglass or aluminum;

- Structural integrity. Security requires that structure integrity be maintained by replacing damaged posts or other materials as required. Keep chain-link fencing taut. Replace spalling or broken components of masonry fencing;

- Grounding. Grounding must be maintained as a safety feature. Make visual inspections as a part of the monthly inspections, especially at the gate bonding straps. Periodically test and correct defects immediately; and

- Comply with UFC 3-550-01 for policy and guidance for design criteria and standards for electrical power and distribution systems.

5-1.15 Lightning Protection.

5-1.15.1 Surge Arrestors.

Modern surge arresters require little operational maintenance and the degree to which such maintenance can be done is normally limited by lack of adequate test equipment. This limits surge arrester maintenance to visual inspection and simple electrical tests. It is recommended that defective units be replaced rather than repaired. Where an arrester is composed of two or more individually complete units, test each unit separately to allow bad unit replacement and retaining good units. Surge arresters are almost always applied with one terminal connected to an electrically energized source and one terminal to ground. No work is allowed on, or contact made with, surge arresters connected to the energized source.

5-1.15.1.1 Visual Inspections.

Periodically visual inspect to ensure that:

- The line lead is securely fastened to the line conductor and the arrester;

- The ground lead is securely fastened to the arrester terminal and ground;

- The arrester housing is clean and free from cracks, chips, or evidence of external flashover;

- The arrester is located in such a manner as not to be subject to:

  - Damaging fumes or vapors

  - Excessive dirt or other current-conducting deposits

   - Excessive humidity, moisture, dripping water, steam, or salt spray

   - Abnormal vibrations or shocks

   - Ambient temperatures in excess of 40° C

- Any external gaps are free from foreign objects and set at proper spacing.

5-1.15.1.2 Electrical Tests.

Visual inspection will not always detect a damaged arrester. Interior damage may result from a broken element, presence of moisture, a severe direct lightning stroke, or the use of an arrester with an incorrect rating. Sometimes these conditions will cause radio interference. Electrical tests, to detect inferior arrester units, may be made either in the field or shop. Tests must be made strictly in accordance with manufacturer's recommendations and the results interpreted in line with manufacturer's criteria:

- Power factor tests. Each type and class of lightning arrester has a specific power factor when new. Periodic testing of a unit will show little deviation from the original (when new) power factor so long as it remains in good operating condition. A major deviation from the original value indicates that the arrester has been mechanically damaged or contains moisture;

- Insulation resistance testing tests. An insulation resistance test can be made to provide additional information on the condition of an arrester. Such a test may indicate shorted valve elements in valve-type arresters; and

- Operation tests. Electrical tests to determine 60 Hz breakdown and leakage current may be made in the field or shop, but must be made cautiously to avoid damage to the arrester. It is questionable whether these tests can be justified for military installations, where the number of arresters potentially subject to such tests is relatively small.

5-1.15.2 Grounding Electrodes.

All grounding electrodes used for grounding of the power system, grounding of communication systems, and grounding of lightning protection systems will be effectively and permanently bonded to each other as required by the National Electric Code (NEC) and NFPA 780.

5-1.15.3 Lightning Protection – Downcomers and Air Terminals.

Lightning protection is intended primarily to dissipate the energy from a lightning strike in a manner that is safe for personnel and that causes the least amount of equipment damage. The lightning protection system may have multiple interconnections with building steel and the power system ground. Since lightning is a cloud to earth phenomenon, the resistance between the lightning protection/power system ground point the outside earth is an important factor. NFPA 780 recommended guidelines for the maintenance of the lightning protection system be provided to the owner (mission) at the completion of installation.

5-1.15.3.1 Inspection.

It is understood that all new lightning protection systems must be inspected following completion of their installation. Recommended guidelines for the maintenance of the lightning protection system are provided to the owner at the completion of installation. In addition to regular periodic inspections, inspect the lightning protection system whenever any alterations or repairs are made to a protected structure, as well as following any known lightning discharge to the system.

It is recommended that lightning protection systems be visually inspected at least annually. In some areas where severe climatic changes occur, it is advisable to visually inspect systems semiannually or following extreme changes in ambient temperatures:

- Complete, in-depth inspections of all systems every 3 to 5 years. It is recommended that critical systems be inspected every 1 to 3 years, depending on occupancy or the environment where the protected structure is located; and

- Complete testing and inspection includes the visual inspections.

5-1.15.3.2 Maintenance.

Maintenance of a lightning protection system is extremely important even though the lightning protection design engineer has taken special precautions to provide corrosion protection and has sized the components according to their particular exposure to lightning damage. Many system components tend to lose their effectiveness over the years because of corrosion factors, weather-related damage, and stroke damage. The physical as well as the electrical characteristics of the lightning protection system must be maintained in order to remain in compliance with design requirements:

- Establish lightning protection system maintenance procedures for each system and include as part of the overall maintenance program for the structure that it protects; and

- Keep complete records all maintenance procedures and routines and of corrective actions that have been or will be taken. Such records provide a means of evaluating system components and their installation. They also serve as a basis for reviewing maintenance procedures as well as updating preventive maintenance programs.

5-1.16 Structure Maintenance / Corrosion Control.

Inspect all structures in close proximity to buses, energized portions of equipment, etc., and make necessary repairs to galvanizing and painted surfaces. Test paint for hazardous material, i.e. lead, before disturbing. If lead based paint is confirmed, follow applicable handling/abatement procedures.

5-1.16.1 Material Preservation – Galvanizing.

In noncorrosive locations, the protective coating produced by the galvanizing process is normally a long-lived coating; however, the coating will eventually fail and rust will appear. It has been observed that ASTM A 90, Class II hot-dipped galvanizing in rural locations will normally furnish adequate protection for many years. The life of the coating on structural steel used in substations should generally be longer than 12 years, except possibly for upper flat surfaces of horizontal members. Any failure of the coating will usually occur in spots rather than over an entire surface. The following procedure is recommended:

- Clean the surface with a wire brush or by other mechanical means to remove rust and dirt. If the surface is contaminated with grease or oil, use a solvent to remove those contaminants. Mineral spirits or a weak solution of trisodium phosphate can be used as the solvent. A solution of 1 ounce of trisodium phosphate to 1 gallon of warm water is suggested for cleaning the metal. In the event that it is uneconomical or impractical to remove all rust, a reasonably satisfactory job can be obtained by deactivating the rust through chemical treatment. A weak solution of phosphoric acid is suggested for deactivating rust. Use proper skin and eye protection;

- Apply a priming coat to the clear dry surface using a zinc dust–zinc oxide paint. Allow ample time for the paint to dry before applying the finish coats; and

- Apply two finish coats using the same type of paint as was used for priming. Allow ample drying time between finish coats. One finish coat is needed for areas on which the galvanized coating remains intact. The color of the paint is gray, but colors in oil may be added to the finish coats to obtain other shades. Other paints normally used as final coats for metal (such as aluminum paint) may be used as the final coat in place of the zinc dust–zinc oxide paint.

In corrosive locations, use of an aluminized fabric is a preferred installation.

5-1.16.2 Material Preservation – Painting.

Most steel for indoor substations, and some steel for outdoor substations, is not galvanized and paint is used for preservation. If required spot painted covers more than 5 percent of the visible surfaces, paint the entire structure. It is recommended that painting of outdoor metalwork be done only when the temperature is above 7.2 ^{0}C (45 ^{0}F) and when the relative humidity is below 80 percent. The durability of paint coating depends on thickness, cohesion, and continuity. Generally, 5 mils (0.005 inch) is an adequate thickness. The thickness should be uniform, and paint should not be easily scraped off the metal. Pay particular attention to welds, edges, and other hard-to-coat areas. Structures of aluminum alloy normally need no surface protection. Painting of aluminum alloy members is not recommended except where esthetics is of prime importance.

- Test paint for hazardous material, i.e. lead, before disturbing. If lead based paint is confirmed, follow applicable handling/abatement procedures.

- Thoroughly remove all loose paint, blisters, and scale. Where the condition of the finish is poor remove the paint entirely. Wire brushing, sand papering, or scraping is desirable where only partial surface cleaning is necessary. Paint removers will soften and aid in removal. However, neutralize the paint remover before attempting to paint. For removal of oil and dirt, use weak solvents such as mineral spirits, other petroleum thinners, or turpentine substitutes.

- Paint as soon as possible after cleaning. Cover all bare metal with a primer. Where only chalking has occurred, one finish coat is sufficient. Primer and finish paints may be obtained from most equipment manufacturers and sometimes from local sources. A zinc chromate alkyd resin primer followed by an alkyd base paint is a suitable air-dry combination for exterior surfaces. Allow the primer coat to air-dry thoroughly and follow it with two finish coats with sufficient time allowed between coats for drying.

5-1.16.3 Material Preservation – Wood Structures.

Inspect and treat permanent wood structures.

5-1.16.4 Material Preservation – Concrete for Structure Foundation.

Visually check concrete during the course of other maintenance and repair. Repair cracks wider than about 1/16th of an inch (0.16 mm) with a sand-cement grout. Replace badly deteriorated concrete.

5-1.16.5 Structure Connections and Joints.

Regardless of material, check all connections and joints periodically for tightness of fastening hardware. Tighten or replace loose, broken, or missing parts as required to maintain a rigid structure.

5-1.17 Substation Yards.

In some cases, there may be no outdoor yard in connection with a substation. These are exceptional situations, and most substations will have an adjoining yard. Removal of vegetation, elimination of low spots in the yard, and control of grassed areas is necessary. If grass is permitted, careful maintenance is necessary both for esthetics and safety reasons. Where chemical application for removal of vegetation is required, comply with environmental requirements.

Do not permit miscellaneous storage except for those specific areas reserved for this purpose. Ensure allowed storage does not to interfere with operations and items are stored in a protected, tidy, and accessible manner.

5-1.17.1 Fences.

Fence maintenance consists of material preservation, maintenance of structural integrity, and maintenance of a good ground.

5-1.17.2 Warning Signs.

Place warning signs conforming to OSHA standards and state the voltage on each fence gate, on each substation building door accessible from outside the yard, and at intervals along the fence. At least one sign must be visible from any position along the fence. Check location and legibility of all signs as part of the monthly inspections.

5-1.18 Wildlife Deterrents.

Apply IEEE Std 1264 for the control of wildlife and birds around substations.

5-1.19 Frequency Converters (Motor-Generator (MG) Sets) and Synchronous Condenser.

For MG sets and synchronous condensers, ensure the lubrication oil or grease is installed and maintained according to manufacturer’s instructions for type. Many oils and greases are not compatible with each other and if mixed may form sludge or acids, wrecking the lubricant and pitting the bearings.

Electrical tests for these devices are comparable to those for motors of the same voltage. Perform a dielectric withstand voltage test on each pole. High potential testing is not recommended for MG sets or for synchronous condensers. Determine test frequency by operating conditions. Dusty, high-humidity conditions require more frequent testing than clean, dry conditions. A machine in a dry atmosphere may be down for several months without absorbing moisture, while a device on an island might absorb sufficient moisture while being down for one week to fail during start-up. Items to check include: bearings, noise (clues to bearing life), lubrication, and every three years – insulation tests.

5-2 MEDIUM VOLTAGE (MV) DISTRIBUTION.

5-2.1 Overhead Distribution.

Refer to Chapter 6 for requirements associated with working on overhead distribution. Chapter 6 addresses the following topics related to operation of the overhead distribution system:

- Qualified worker qualification requirements;
- Pole handling, installation, replacement, and removal;
- Pole climbing;
- Line installation;
- Aerial rope and tools; and
- Tree trimming near energized aerial lines and overgrown vegetation surrounding equipment.

Refer to IEEE Std C135.90 as a guide for all types of hardware used for overhead distribution systems.

5-2.1.1 Power Poles.

Identification.

Develop a naming convention for power poles and label each pole with its identification number. Use this number for identification on electrical distribution system drawings and for the GeoBase data system.

5-2.1.1.1 Record Keeping. Maintain records that contain the following information:

- Identification number;
- Location (can be a GPS location included in the GeoBase documentation);
- Date of installation; and

- Manufacturer and brand.

Wood Pole Inspection Frequency.

The average life span of a full-length pressure-treated wood pole can be maintained and even extended another 10 to 20 years with a proper inspection, treatment, and reinforcement program.

Perform pole inspections at the following frequency:

- Visual inspection of pole line – annually. Drive along each pole line to observe problems such as pole degradation, leaning poles, sagging lines, damaged cross-arms, blown surge arresters, open fused cutouts, or leaking pole-mounted equipment;

- Spot check of 10% of power poles – approximately every 5 years. Perform a detailed inspection of selected power poles. Apply the inspection data to determine if a 100% inspection is required and to identify any poles requiring replacement; and

- Full inspection – Perform a detailed inspection of all power poles every 12 years or as required by results of a spot inspection.

Wood Pole Visual Inspection.

Perform the following visual inspection as part of a general inspection, spot check, or full inspection. Examine each pole for the following defects:

- Excessive checking, cracking, or splitting;

- Evidence of woodpecker holes or insect colonies;

- Excessive above-ground decay;

- Lightning damage;

- Corroded or damaged guying;

- Damaged bracing;

- Leaning pole requiring resetting; and

- Any other obvious defects.

Evaluate each pole for the following additional problems:

- Sagging lines that require re-tensioning;

- Damaged cross-arms;
- Blown surge arresters;
- Open fused cutouts; and
- Leaking pole-mounted equipment.

5-2.1.1.2 Wood Pole Detailed Inspection.

Perform the following as part of a spot check or full inspection. Examine each pole for the following defects:

- External decay. Where surface decay is found at the ground line, excavate around the deteriorated section of the pole. Measure and record the pole circumference at the ground line, remove the surface decay down to sound wood, and record the new circumference of the pole;
- Internal decay. Inspection methods include sounding and boring when necessary. The sounding test is fast and completely nondestructive, but it will not reveal the extent and type of defect. It will not indicate whether the pole has a harmless void or a large and dangerous decay pocket. Boring will reveal details on the type and severity of decay but it is rather slow, somewhat destructive, and may conceivably introduce decay-causing organisms into a sound pole; and
- Pole top and cross-arm defects. Either use bucket truck or climb pole if a visual inspection from grade is indeterminate.

5-2.1.1.3 Wood Pole Maintenance Crew Instructions.

Provide crews used for pole inspections with instruction and training regarding inspection precautions, duties, safety requirements, and use of equipment. Review available pole history before starting. The duties of the crew include observing the pole tops, cross arms, and attachments; inspecting the pole to a height that can be conveniently reached from the ground; excavating and inspecting the pole below the ground line; applying ground line treatment; keeping accurate records; and associated work.

Replace or reinforce any pole that has lost strength from decay or other cause to the point of being hazardous.

5-2.1.1.4 Wood Pole Cross Arms and Structures.

Properly installed cross arms require little maintenance. Cross arms can decay; aging can cause separations such as checks or shakes; lightning can splinter cross arms; or they may twist or bend by overload. These conditions may require replacement.

Evaluate cross arms as part of each pole inspection. Check cross arms for any damage caused by lightning, woodpeckers, or other causes. Inspect for checks, splits, or decay pockets, particularly at holes bored through the arm. Replace cross arms when defects are discovered.

5-2.1.1.5 Concrete Poles.

Reinforced or pre-stressed concrete poles have a projected life of 60 to 80 years and require no attention except for replacement when damaged. Concrete poles are preferred under conditions where the life of wood poles would be unduly shortened by decay or pests.

5-2.1.2 Insulators.

If insulators require cleaning to remove contaminants, apply IEEE Std 957 for cleaning of insulators for energized and de-energized circuits.

5-2.1.3 Reclosers.

Reclosers require maintenance when they have operated the equivalent of a rated duty cycle, where a rated duty cycle is defined as the maximum number of fault interruptions a recloser is capable of performing before servicing is required. Manufacturers provide the rated duty cycle in their product literature and the duty cycle vary for each recloser type or model. In general, vacuum interrupters have a higher duty cycle compared to oil interrupters. At the completion of a duty cycle, the following can be expected:

- Oil-interrupting recloser: The interrupter assemblies, stationary contacts, and movable contacts will be badly eroded and burned. The condition of the insulating oil will be of poor quality; it will be black and dirty, with a significant amount of sludge (carbon buildup) covering the recloser's internal components. Unwanted by-products, including water, will be present in the oil; and

- Vacuum-interrupting recloser: The contacts will be eroded and worn and the vacuum interrupters will require replacement. Insulating oil will not be degraded because the arc is contained with the vacuum interrupters. But, the oil will require replacement or filtering as it might have reduced dielectric strength. Also, there might be water present in the oil.

Maintain a record of the recloser operations. If the information is available at the substation or switching station, maintain a record of fault current date, time, and magnitude for comparison to the rated duty cycle capability. Newer recloser control units also offer event recording capability. If available, review recloser control event data for comparison to the duty cycle rating.

5-2.1.3.1 Oil-Interrupting Reclosers.

Maintain oil-interrupting reclosers in accordance with the manufacturer's instructions at the following intervals:

- Before the end of a rated duty cycle;
- At least every three years;
- More frequently than every three years if operating experience indicates poor internal contact and oil condition when checked; and
- More frequently than every three years if the recloser operates frequently and no records have been maintained that indicate the fault current associated with each recloser operation.

Reclosers require periodic maintenance. Manufacturers provide detailed inspection and test requirements for their reclosers. For older reclosers, consider replacement rather than maintenance. Also, manufacturers provide modernization instructions for some older reclosers.

5-2.1.3.2 Oil- or Air-Insulated Vacuum Interrupting Reclosers.

Maintain vacuum-interrupting reclosers in accordance with the manufacturer's instructions at the following intervals:

- Before the end of a rated duty cycle;
- At least every six years;
- More frequently than every six years if operating experience indicates poor internal contact and oil condition when checked; and
- More frequently than every six years if the recloser operates frequently and no records have been maintained that indicate the fault current associated with each recloser operation.

Reclosers require periodic maintenance. Manufacturers provide detailed inspection and test requirements for their reclosers. For older reclosers, consider replacement rather than maintenance. Also, manufacturers provide modernization instructions for some older reclosers.

5-2.1.3.3 Recloser Control Units.

If the recloser has a separate recloser control unit, which is typical for larger three-phase reclosers, perform a maintenance check on the recloser control unit at the same time that recloser maintenance is performed. Include the following:

- Perform maintenance and testing in accordance with the manufacturer's instructions. If the recloser control unit is obsolete, consider replacement with a new recloser control unit;
- Test the battery in accordance with the manufacturer's instructions. Replace the battery if it is older than 6 years or if battery testing indicates that the battery capacity is inadequate; and
- Confirm that the recloser control settings are as required by the most recent electrical coordination study. Change settings as required.

5-2.1.4 Fused Cutouts and Switches.

Select and replace fuses for overhead distribution systems in accordance with IEEE Std C37.48. Perform periodic maintenance on pole-mounted air switches in accordance with IEEE Std C37.35.

5-2.1.5 Transformers.

Pole-mounted distribution transformers require no periodic maintenance or testing. As part of the annual visual inspection of poles, visually inspect pole-mounted distribution transformers for the following:

- Evidence of oil leakage;
- Damaged surge arresters; and
- Excessive corrosion.

Correct problems as they are discovered.

5-2.1.6 Conductors and Splicing.

Apply IEEE Std 1283 for the evaluation of overhead conductors and accessories in high-temperature locations.

5-2.1.7 Lightning and Surge Arresters.

Select and install surge arresters for overhead distribution systems in accordance with Section 6 of IEEE Std C62.22. Apply IEEE Std 1410 as a guide for maintaining the lightning resistance of the overhead distribution system.

5-2.1.8 Tree Trimming.

Evaluate all overhead distribution system lines annually for the need for tree trimming. Refer to Section 6-14 for tree trimming procedures.

5-2.1.9 Wildlife.

Apply IEEE Std 1651 as a guide for maintaining the overhead distribution system.

5-2.2 Underground.

5-2.2.1 Cables and Splicing.

MV power cables are exposed to a variety of environmental and operational stressors, including elevated temperatures, high UV radiation, high humidity, water submersion, and exposure to dust, dirt and corrosive contaminants. Electromechanical forces resulting from the passage of high levels of short circuit current through a power cable can cause mechanical damage to cable jacket and insulation material and cable conductors. High-voltage stress from lightning strikes or power system transients can degrade the dielectric strength of cable insulation. For an acceptable range for different types of tests and specific trend analysis flags such as rate of change in resistance levels, refer to IEEE 400, IEEE 510 and ANSI/NEMA WC 74/ICEA S-93-639.

For cables that do fail early, the failure modes are typically attributed to:

- Partial discharge – localized electrical discharge that partially bridges the insulation and causes excessive heating and degradation of the cable insulating materials and ionization of the air in the vicinity of the leakage current;

- Treeing – tree-like erosion propagated by electrical discharges in a cable insulation or covering;

- Power workmanship – direct mechanical damage, such as bending, abrasion, cutting, contact, deformation and perforation resulting from installation or maintenance activities; and

- Vermin - rodents eating insulation.

The following maintenance tests and frequencies for MV power cables are recommended:

- Time-based preventive - equipment is off-line, de-energized and disconnected from service (planned major shutdown) (Table 5-6);

Table 5-6 Time-Based Preventive Tests

Test	Comments
DC hi-potential withstand test.	Relies on a source of high DC voltage.
	Simple, portable, inexpensive, low skills required to perform the test.
	Can be destructive when performed on service-aged MV cable insulation, misses certain types of insulation defects.
Alternating Current (AC) hi-potential withstand test.	Uses AC high voltage greater than the rated voltage of tested equipment.
	Good test for conductive and high-impedance defects in cables.
	Requires much larger power source and multiple personnel which makes it expensive.
Very Low-Frequency (VLF) withstand test.	Similar to AC hi-potential but at lower frequency.
	Simple, portable, inexpensive test equipment.
	Can aggravate existing insulation defects in aged extruded cables; considered a destructive test.
Power factor/dissipation factor condition assessment test – insulation power factor.	Most common test performed to determine condition of solid insulation.
	Moderately expensive, may require additional equipment.
VLF dissipation factor condition assessment test – “tan delta” test.	Simple, extremely portable, inexpensive to purchase and operate – true diagnostic test.
	At 60 Hz, can present inaccurate cable insulation assessments results.
Off-line partial discharge condition assessment test.	“Off-line PD testing” assesses power cables insulation, identifies electrical trees, contamination, delamination.
	Newer test; capable of testing up to 3 miles of power cable.
	Limited to power cables with continuous metallic shields, requires extensive outages, most costly to perform.
Thermography of underground terminations, elbows and splices.	Non-contact.

- Time-based predictive tests – equipment is online; electrical outage is cost prohibitive (Table 5.7);

Table 5-7 Time-Based Predictive Tests

Test	Comments
Online partial discharge condition assessment test	“Online PD test” performed while the equipment is energized at normal operating voltages; provides snapshot-in-time samples.
	Not calibrated, test results are not objective and have no comparable data to factory tests or IEEE standards.

- Recommended frequency of testing after installation acceptance test for “normal” class of service; and
  - First maintenance test – 3 years
  - Second maintenance test – 8-9 years
  - Period between succeeding maintenance test – 5-6 years
- Recommended frequency of testing after installation acceptance test for “critical” class of service:
  - First maintenance test – 12-18 months
  - Second maintenance test – 2-3 years
  - Period between succeeding maintenance test – 4-5 years

5-2.2.2 Lightning and Surge Arresters.

Surge arresters may be constructed as a gapped silicon-carbide or either a gapped or a gapless metal oxide. Metal-oxide surge arresters (MOSAs) should be considered for replacement when silicon-carbide types fail. Surge arresters are usually applied with one terminal connected to an electrically energized source and one terminal to ground. Review availability and use positive failure indication arrestors to replace failed arrestors. No work is allowed on, or contact made with, surge arresters connected to the energized source.

The following time-based preventive maintenance is recommended:

- Visual inspection – semi-annually;
- Clean insulator using cleaning agents and waxes in accordance with manufacturer’s directions and check integrity of connections – 6 years; and

- Insulation resistance tests – 6 years:
  - Power frequency dielectric loss
  - DC insulation resistance
  - Power factor

5-2.2.3 Switches.

No work will be done on switches until both sides of each phase have been de-energized and properly grounded. Switches must be tested in the test position. If there is no test position (stationary interrupter switches) test after the interrupter switches have been de-energized and grounded.

The following time-based preventive maintenance is recommended:

- Visual inspection – semi-annually; and
  - Component inspection
  - Fuses and holders
  - Interrupter
  - Anchorage and grounding
- Major maintenance / overhaul function – 6 years:
  - Contact-resistance tests across each switch blade and fuse holder.
  - Insulation resistance tests on each pole phase-to-phase and phase-to-ground for one minute.

5-2.2.4 Transformers.

Oil-immersed, MV, pad-mounted transformers will be switched, de-energized and energized by trained personnel only. Completely isolate from sources of power transformers before being tested and inspected.

5-2.2.4.1 Time-Base Preventative Maintenance.

The following maintenance of transformer and accessories is recommended:

- Visually inspect transformer enclosure for rust and oil leaks every 2 years. Check and record gauges.

5-2.2.4.2 Time-Based Predictive Maintenance.

The following time-based predictive maintenance of transformer and accessories is highly recommended for mission critical transformers or primary installation substations (utility point of service). For non-mission critical transformer and accessories systems, perform visual inspections:

- Perform DGA oil test every 2 years; and
  - Take samples from the bottom for mineral oil-insulated units and from the top for less flammable liquid-insulated units.
  - Samples must be laboratory tested.
  - Acceptable test limit values for new and service-aged oil are given in IEEE 57.106.
- Check for hot spots using thermography every 2 years. Use IR equipment capable of detecting at least 1 ^{0}C temperature difference between the object and the 30 ^{0}C reference area by detecting emitted radiation and converting it to a visual signal. Scan all current-carrying equipment and conductor connections during periods of maximum possible loading. Always measure the IR temperature from several different positions to minimize errors from reflected IR energy or from solar gain for outdoor installations.

5-2.2.4.3 Corrective Maintenance.

The following corrective maintenance of transformer and accessories is recommended:

- Oil treatment:
  - Particle filtration
  - Drying
  - Outgassing
  - Cleanup and depollution
  - Oil replacement, recycling and PCB decontamination
- On-site repairs:
  - Leakages
  - Gasket replacements

– Improvement of contact resistances

5-2.2.5 Manholes and Handholes.

Underground junction boxes and vaults inspections every 5 years is suggested to determine deterioration and degradation of the junction boxes and associated wiring and supports. Check for termite infestations and include treatment for termites within manholes if found. Some base safety requirements allow entry into energized manholes for purposes of inspection only and some locations will not allow this. This must be handled safely on a case by case basis in accordance with procedures already in place.

5-2.3 Ground Systems.

Grounding is an essential part of protecting staff and equipment from high potential caused by electrical faults. Grounding conductors of switchyard equipment and gate structures are subject to failure due to corrosion, loose connections, and mechanical damage. Grounding also may be compromised during equipment addition and removal or other construction type activities. Verifying grounding system integrity through periodic testing is an important maintenance activity.

Check all accessible ground connections for secureness, and measure the overall ground grid resistance if it has not been done for a number of years. Since it is desirable to disconnect shield wire grounds and system neutral connections to make this measurement, de-energized the total substation for these tests.

- Perform visual and mechanical inspections annually. Perform grounding electrode and substation/switchyard grid tests every 6 years.

5-2.4 Metering.

Electrical meters are devices used to measure and register the cumulative value of electrical quantities with respect to time.

Routine maintenance tests are required annually and to cover the following:

- Cleanliness, connections, calibration;
- Multipliers;
- Alignment, damage, freedom of movement; and,
- Contacts.

5-2.5 Animal Control.

Apply IEEE 1264 for wildlife deterrents.

5-3 ROADWAY/STREET/PARKING AREA LIGHTING.

5-3.1 Voltage Level.

Street lighting circuits might be either low-voltage multiple circuits or high-voltage series circuits. It is important that the type of circuit be identified and placed in an electrically safe work condition before starting work because of the different voltage levels involved. Workers must wear PPE in accordance with UFC 3-560-01 when working on street lighting circuits.

5-3.2 Clearance Requirements.

Street lighting lines, fixtures, and wires must be considered energized, which requires wearing personnel protective equipment, unless a Safe Clearance permit is obtained and the line grounded. The voltage of street lighting circuit must be treated as that of the highest voltage occupying any of the poles on which the street lighting circuit is run.

5-3.3 Multiple Street Lighting Circuits.

Multiple street lighting circuits must be treated with the same precautions as the circuits to which they are connected, unless the circuit is located on a structure with a higher voltage wire, in which case it must be considered as the higher voltage level.

5-3.4 Series Street Lighting Circuits.

Before a series street lighting circuit is opened and work is performed, the following procedures must be followed:

- Disconnect the circuit from the source of supply by opening disconnecting switches or other cutouts in accordance with a Safe Clearance permit and lockout-tag out equipment. Do not depend on time switches or other automatic devices;

- Jumper the circuit to avoid an open-circuit condition; and

- In replacing street light bulbs and lamp globes in street lighting brackets, there is danger of an arc developing and causing serious damage and injury if the spring clips in the receptacle do not make contact. These springs might have been heated to the extent that they have lost their temper, or for some other reason, do not close the circuit when the lamp socket is pulled out. Use approved changers with at least 6 ft (1.8 m) handles for replacing lamps on series street lighting circuits. Workers must wear appropriate PPE when removing or installing lamps where lamp changers cannot be used.

5-3.5 Climbing Space.

Maintain safe access by hanging street lighting fixtures clear of the climbing space. All bolts, lag screws, and other hardware used in securing the fixtures must be cut, filed, or coated to eliminate sharp or protruding edges or points.

5-3.6 Time Switches.

When winding time switches and working on automatic time switches, workers must not trip the switch "on" without first pulling the transformer disconnects or first making sure that street lighting circuits cannot be energized. On time clocks with high-voltage connections, workers must always wear rubber gloves and appropriate personal protective equipment when winding, resetting, or otherwise maintaining the clock.

5-4 DISTRIBUTED GENERATION.

The same O&M concepts and requirements that apply to utility generated electrical distribution systems are directly applicable to Distributed Generation Systems (DGS), with a few notable exceptions. DGS synchronization relaying and permitting must be approved by the local utility. Therefore, operations must notify the local utility whenever modifications are made to the system, or parts are taken out for maintenance, as this will affect the stability of their network if the distributed generation is not islanded, or operated as a stand-alone system. The primary interconnect requirements are stated in NEC article 705; however, each utility will have requirements far above or beyond these minimum requirements for DGS. For safety, when a distributed generation system is modified, or a planned disconnection or re-connection, notify the local utility in advance of action.

CHAPTER 6 WORKING ON OVERHEAD DISTRIBUTION

6-1 OVERHEAD DISTRIBUTION WORK.

This chapter includes specific requirements for poles and structures, pole-mounted equipment, and aerial lines. Requirements addressed include pole handling and erection, climbing and working on poles, stringing of lines, working around pole-mounted lighting and other equipment, tool handling, and tree and brush trimming adjacent to an aerial line right-of-way.

Note: Installations in California are governed by the California Public Utilities Commission General Order 95, Rules for Overhead Electric Line Construction.

6-1.1 Working in Elevated Positions.

Additional safety requirements are needed for overhead distribution work since climbing poles is often necessary. Not all work can be accomplished from aerial lifts. Electrical workers must both recognize electrical hazards, and be trained how to prevent falls. This includes training in safe climbing procedures when the structure design cannot accommodate optimum fall protection load requirements.

Comply with OSHA Standards (29 CFR 1910 and 1926) for fall protection when working in elevated conditions. Refer to IEEE Std 1307 and UFC 3-560-01 for additional guidance.

Note: For the Navy, follow the requirements outlined in the Department of the Navy Fall Protection Guide for Ashore Facilities, which can be obtained at http://www.dcfpnavymil.org/Personnel%20Protection/Subs/Fall%20Protection/Fall%20Protection%20Guide%2015%20February%202012%20(2).pdf.

Note: For the Army, Department of the Army Pamphlet DA PAM 385-10 provides additional requirements regarding fall protection.

Note: For the Air Force, Air Force Instruction 91-203 provides additional requirements regarding fall protection.

6-1.2 Qualified Climber.

Only workers who meet “Qualified Climber” requirements are permitted to do work requiring climbing poles or trees. Each Activity must establish these requirements for both Activity personnel and contract personnel. The requirements apply to all persons whose work involves climbing.

6-1.3 Criteria for Qualified Climbers.

Comply with the requirements of OSHA 29 CFR 1910.269 (q) “Overhead Lines.” The majority of the work will be done in an elevated position above ground level. Climbing aerial line structures such as poles may be required. Situations with limited structure access can prevent use of an aerial lift bucket truck. The structure design may not accommodate positive fall protection load requirements. Only workers who meet "Qualified Climber" requirements are permitted to do work which requires climbing poles or trees. Establish “Qualified Climber” requirements both for Activity personnel and for contract personnel, including the following:

- Physical fitness required for climbing – documented not only by an annual physical, but also be validated by supervisory observation;
- Climbing duties – included as a part of routine job activities, not an occasional occurrence;
- A minimum of 2 years of documented climbing training. Include hazard recognition and hands-on-training incorporating appropriate safe climbing practices and rescue training;
- Demonstrated proficiency is required on structure types similar to those that are to be climbed, showing that these structures have been climbed on a routine basis within the last 5 years; and
- A worker in training may function as qualified only when working under the direct supervision and observation of a “Qualified Climber.”

6-2 POLE HANDLING OPERATIONS.

Precautions are necessary in handling poles safely. Poles are long, heavy, and treated with potentially hazardous pesticides and preservatives. They pose hazards to the workers involved in installation and dismantling operations. Additionally, mistreatment of poles during installation may degrade their ability to meet service requirements, and could endanger those workers who climb them.

6-2.1 General.

The authorized individual-in-charge must either do it themselves or assign a crew member to direct the handling of poles and give all signals when poles are being lifted or handled. Poles must, whenever possible, be handled starting from the top and the end of the stack. Workers must roll poles away from them using cant hooks or bars. Poles must not be caught with cant hooks while in motion. Whenever possible, carrying hooks must be used when carrying poles.

6-2.2 Pole Contact Precautions.

Creosote is applied to poles as a preservative and can cause skin burns on contact. Take the following precautions to avoid burns:

- Keep arms covered with long sleeved shirts when handling poles;
- Always wear gloves;
- Keep neck well covered with a collar or a handkerchief;
- Keep trousers as long as practical to protect ankles;
- Never rub eyes or wipe perspiration from face using hands or shirtsleeves after they have been exposed to creosote; and
- Protect hands, arms, and face with a preparation made up of one part gum acacia or gum tragacanth, and three parts lanolin where direct contact with creosote is likely to occur. If this preparation cannot be obtained, acceptable protection can be provided by petroleum jelly (such as Vaseline™). First aid treatment must be obtained immediately when bare skin or eyes come in contact with creosote.

6-2.3 Receiving Pole Shipment.

Poles are usually shipped to an Activity's pole storage yard using flatbed railway cars on which they are secured with skids, stakes, slings, and binding. Removal is safe if done properly. The principal objectives are to unload poles so that none are broken, and so that the poles do not roll onto any worker. Perform the following:

- Skids, rope lines, and slings must preferably be 1/2 in or 5/8 in (12.5 to 16 mm) wire rope. Inspect before use to ensure they are in satisfactory condition for the operation;
- Inspect all binding wire, stakes, and other fastenings for weak or broken areas before unloading;
- Always preposition lines as necessary to restrain loads when stakes and binding wires are cut;
- The authorized individual-in-charge must determine that all workers are safely in the clear before permitting binders or stakes are cut;
- Cut binding wires with long-handled wire cutters. Never cut binders from the top of the load; and
- Only one person is permitted on top of a loaded car at a time. No one is allowed on top of a carload of poles to cut wires, or if any wires or braces have been cut or removed.

6-2.4 Ground Handling.

Once on the ground the poles can be positioned by the use of cant hooks. Special precautions must be taken while using these hooks:

- Keep hooks sharp and protected when not in use;
- Inspect the hook bolt periodically for wear. If a worn hook bolt breaks in use, sudden and possibly severe injuries could result;
- Injuries most often occur when a pole handle breaks or the hook comes out. Be sure the hook is firmly set in the pole;
- The cant hook is a one-worker tool. It is likely to break if two workers double up. If a job requires two workers, two cant hooks must be used;
- Before moving the pole, make sure that there are no tripping hazards near the workers;
- Stand so the pole is rolled away. Pulling the pole allows the pole to roll on a foot or crush a leg;
- Be particularly careful if the pole is rolled over a hump, since the pole could roll back when the grip and position of the hook is changed; and
- When moving a pole by hand, with a pole cart, or with the truck derrick, warn anyone nearby who could possibly be struck. If necessary, station a worker with a red flag to warn or stop traffic.

6-2.5 Long Term Pole Storage.

- Poles that are stored for considerable periods must be stacked above the ground on racks. The racks must provide ventilation, and properly block the poles to keep them from shifting or rolling;
- Never store poles with cross-arms, braces, steps, or hardware attached;
- Store poles according to size and make them accessible; and
- Maintain an area around stored poles of at least 10 ft (3.0 m) free of grass and weeds. Provide sufficient space under poles to permit removal of leaves and debris.

6-2.6 Temporary Pole Storage.

- Poles stored temporarily on or near roadways, before erection or removal, must be placed as close as possible to the curb or edge of roadway as is safe; however, never store poles at points along the road where there are sharp turns. Do not place the poles where they interfere with traffic, driveways, or walkways;
- Place each pole so that its top points in the direction of traffic. Poles temporarily stored alongside highways must not have cross arms attached;
- When laid on an incline, poles must not be placed where they can interfere with drainage; and
- The authorized individual-in-charge must decide whether danger signs (by day) or red lights (at night) are required.

6-2.7 Hauling Poles.

- Pole hauling must be done in a manner to not endanger workers or the public;
- After being loaded on a vehicle, secure poles in at least two places and in such a manner to ensure poles will not be released when traveling over rough terrain. Never use a chain smaller than 3/8 in (9.5 mm) diameter;
- Assign a minimum of two workers (a driver and a helper) to haul a load of poles. The helper must assist the driver by watching traffic both from the sides and the rear. The helper must also check that there is ample clearance when turning corners, entering highways, or crossing intersections. When necessary, the helper acts as a flagman to warn and direct traffic; and
- Attach a warning device on poles extending more than 4 ft (1.2 m) beyond the back of a truck or trailer. Attach a red flag by day and a red light by night to the rear end of the poles being hauled. The red flag or light must be visible from the sides and rear. Observe all local and state highway regulations when poles are transported over off-base highways.

6-3 POLE INSTALLATION, REPLACEMENT, AND REMOVAL.

Poles for new aerial lines are often installed by contract workers; however, Activity workers might need to install poles to replace storm-damaged, insect-damaged, or decayed poles. Remember that poles and guys must be properly located relative to the local Activity property line or utility right-of-way.

This section provides guidance that applies mainly to wooden poles. Refer to IEEE Std 1025 for installation of concrete power poles.

6-3.1 Pole Holes.

Dig new holes if new poles are being set adjacent to existing poles being dismantled. Power tools are available for digging, such as power borers or augers, and only qualified personnel must use these tools. Rock cutting drills are generally a safer alternative than the use of explosives, where rock is encountered. Many pole holes can be dug by hand if power diggers are unavailable or cannot be used. The area where poles are being set must be scoped and all utilities identified and marked. Take special care when digging close to underground energized cables/circuits.

6-3.2 Digging Holes.

Digging a pole hole involves significant hazards that can cause major injuries. These hazards range from electrocution, shock, vehicular hazards, crushing injuries, eye injuries from flying dirt and rocks, blisters on the hands from the use of hand tools, and foot and leg injuries resulting from falling over tools, particularly shovels that have been left turned up.

6-3.3 Covering a Hole.

Cover all open pole holes as soon as they are dug when other related work must continue near the hole, except when the pole is being immediately set into the hole after digging. Install covers that are at least 30 in (760 mm) in diameter and strong enough to support two men. Place four or five shovels of soil on the cover after it is placed over the hole. If necessary, also set up cones to secure the area.

6-3.4 Hole Casings.

Casings may be required in sandy or swampy soil to prevent the sides of a hole from caving in. Casing covers are required if the pole setting is not done immediately.

6-3.5 Setting Poles.

Pole setting is a hazardous job even with experienced personnel using the best equipment. The methods authorized for manually setting poles are:

- The pike pole method;
- The winch line method; and
- The gin pole method.

The use of a line truck is the preferred method whenever possible.

6-3.5.2 Pike Pole Method.

Figure 6-1 illustrates the pike pole method. This is the earliest method of raising poles and might be used when a truck cannot be brought in. A jenny initially supports the pole, and a cant hook keeps the pole from rolling. The bump board protects the wall of the hole from being caved in by the pole butt. Pikers lift the line pole by punching into the pole, the steel spikes of the pike poles. The number of pikers required increases with the pole length as shown in Table 6-1.

Table 6-1 Average Crew Size Required to Raise Poles by Piking

Pole Length		Size of Crew	Number of Pikers	Number of Jennymen	Number of Personnel at Butt
Feet	Meters				
25	7.5	5	3	1	1
30	9.0	6	4	1	1
35	10.5	7	5	1	1
40	12.0	8	6	1	1
45	13.5	9	7	1	1
50	15.0	10	8	1	1

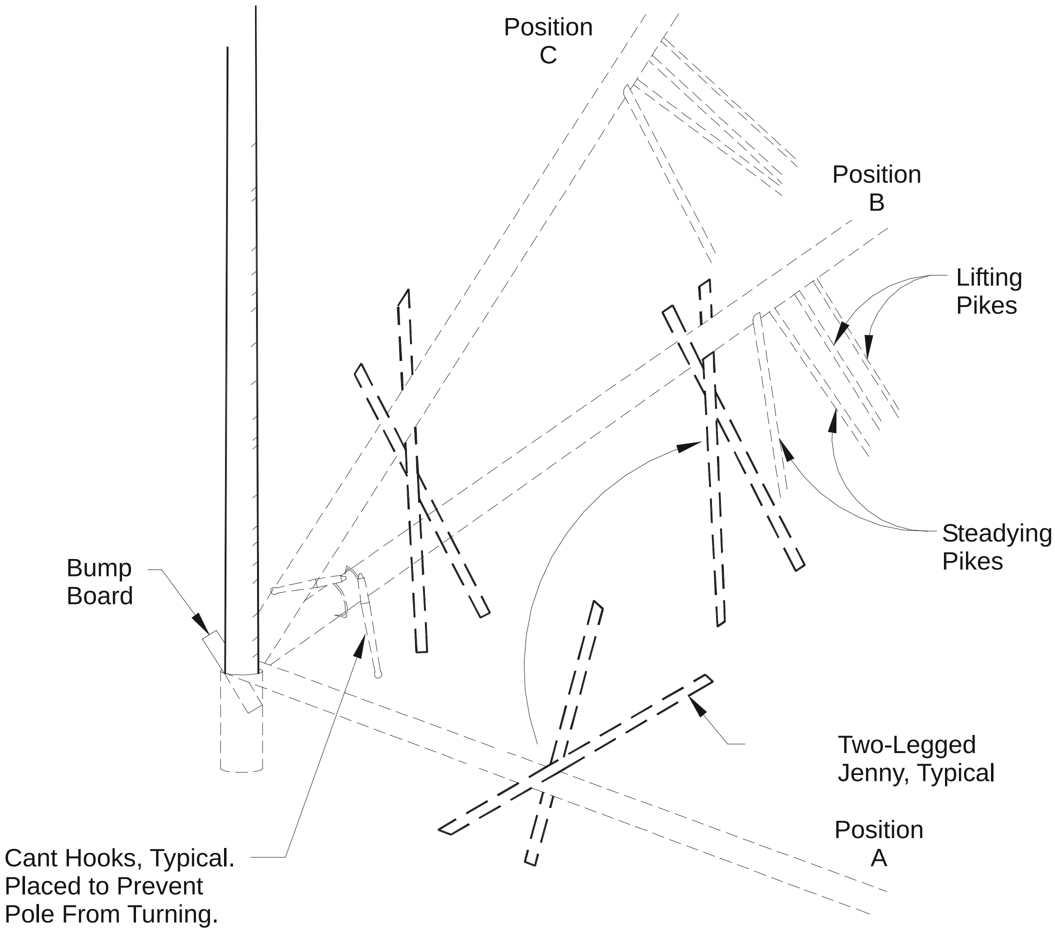
6-3.5.2.1 Preparation.

Before setting a pole, the authorized individual-in-charge must ensure there is a clear working space and that all movable obstacles are removed from the area. Personnel must not wear safety harnesses, climbing belts, or climbers when setting poles. Tools or other items must not be substituted for bump boards. Always use a jenny to support the pole until it is high enough to use pikes. Only experienced workers must use the jenny. The angle of contact between the pole and jenny must be maintained as close to 90° as possible.

6-3.5.2.2 Number of Personnel.

At least three experienced workers must be used in addition to the authorized individual-in-charge. One person must handle the butt of the pole, and a minimum of two side pikers are needed. Inexperienced workers used in this work must be thoroughly instructed on the hazards involved. A two-legged jenny must be used. It is the responsibility of the authorized individual-in-charge to verify that all pole-lifting tools are in acceptable condition prior to the lift.

Figure 6-1 Pike Pole Method



Position A:

Place jenny near top of pole at approximately right angles to pole. Footing of jenny should be at a point where it will not slip when the pole is lifted and supported by the jenny. Lift pole and jenny to Position B.

Position B:

Place two cant hooks, one to pull against, the other to prevent pole from turning. Place hooks about two feet above the probable ground line. Station a crew member to hold the hooks as the pole is being raised.

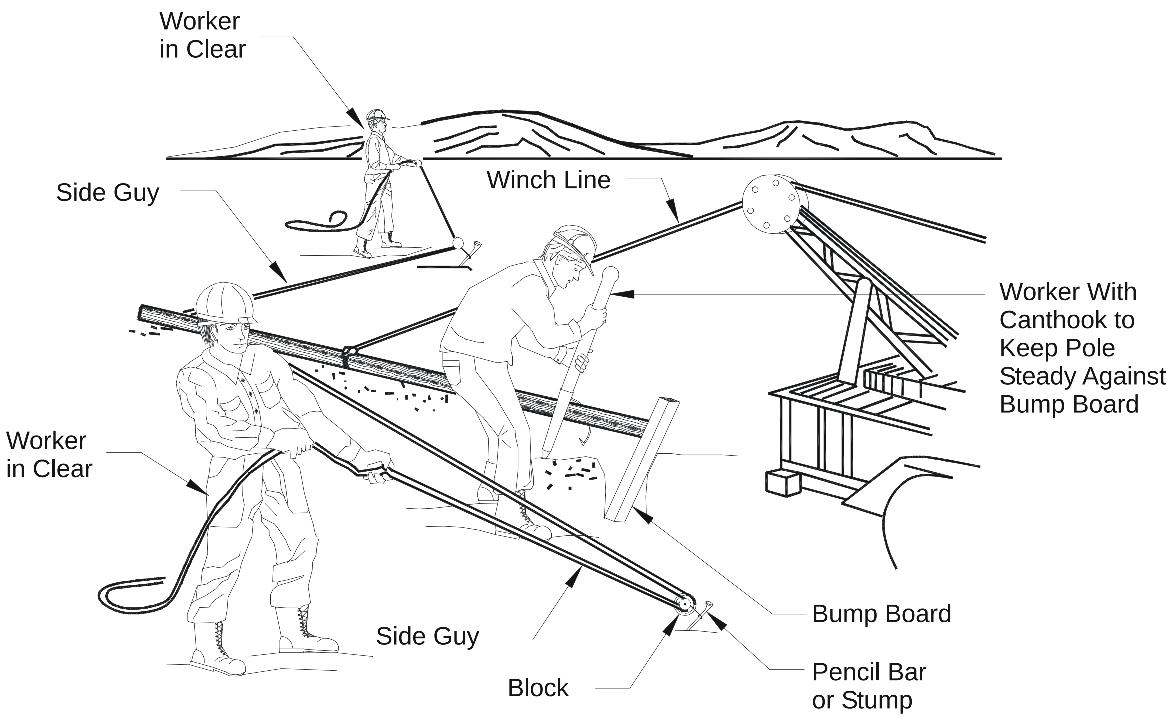
Position C:

As pole is being raised by pikers, jenny is moved down the pole until pole weight is supported by jenny (always keep fork of jenny in contact with pole). Repeat operation until pole slides into hole.

6-3.5.3 Winch Line Method.

Figure 6-2 illustrates the winch line method. When erecting poles by truck winch and winch line, ensure all workers are in the clear. Depending on the pole size and class, up to three experienced workers may be needed in addition to the authorized individual-in-charge. For a safe lift, the gins (or maneuverable rigging assembly) must have enough teeth to handle the pole. Do not use pikes in combination with a winch.

Figure 6-2 Winch Line Method



Attach side guys used in setting poles or structures to pencil bars driven into the ground. Never wrap tie lines or other guy lines around any worker's body.

6-3.5.4 Gin Pole Method.

In setting extra-heavy poles or those of 45 ft (13.5 m) or longer, it is best to use a tackle block attached to another pole rather than the pike pole method. The other pole is called the gin pole (or maneuverable rigging point), and is either existing or is especially installed for raising the new pole. The gin pole must be guyed sufficiently with not less than 5/8 in (16 mm) diameter rope to hold it erect under the strain of the load. When the new pole is raised using power from a vehicle, the temporary guy must be run from a snatch block at the bottom of the gin pole to a substantial anchor. This prevents the gin pole from slipping at the ground line. Otherwise, the gin pole must be set in a hole of depth 1 to 2 ft (305 to 610 mm).

6-3.6 Pole Setting Trucks.

Park pole setting trucks, where feasible, so that the boom will never be closer than 10 ft (3.0 m) to energized overhead conductors. When the work is being done near energized conductors and it is impossible to lower the boom sufficiently to be in the clear, place the conductors in an electrically safe work condition before starting work. When it is not possible to de-energize the conductors, and work must be done with the boom close to energized conductors, all personnel must keep away from the frame of the truck and must not touch the pole. Use pole guards or insulated blankets. Never touch with bare hands a pole that is being set in an energized line. Instead, an insulated cant hook or dry rope around the butt of the pole may be used to guide it into the hole.

6-3.7 Setting Poles in Energized Lines.

Only an electrical worker qualified as a Journeyman or Craftsman is permitted to guide poles through energized conductors. This operation is classified as “energized work” and appropriate permits and/or authorizations must be obtained. Employees must wear appropriately rated arc flash personal protective equipment as specified in UFC 3-560-01. UFC 3-560-01 does not allow Navy personnel to set poles in energized lines.

When a pole of any type is being set or removed between or near conductors energized at more than 600 V, the pole, winch cable, and truck frame must be effectively grounded with protective grounds. Lines must be covered with rubber protective equipment to prevent poles from touching energized parts, and workers must use rubber gloves. Attach a protective ground to the frame of all winches. If the pole is being erected by hand (pikes), the protective ground must be attached to the pole (using an approved grounding band) approximately 15 ft (4.5 m) from the butt end. Installing and use pole guards. In all cases, exercise extreme care to keep the pole from contacting conductors.

Note: Wood poles do not provide adequate insulation from energized lines.

6-3.8 Backfilling the Hole.

Backfill the hole after the pole placed. Use pikes to align the pole while backfilling. Do not remove pikes until sufficient tamping has been done to prevent the pole from falling.

6-3.9 Dismantling Poles.

Pole dismantling from a live line is a particularly hazardous operation. Exercise extraordinary care. Restrain each pole in at least three different directions by ropes before any work proceeds on the pole. This may be done by the following procedure:

- Make two turns around the pole with a sling and tie securely;

- Tie three lines around the sling at the proper angles;
- Insert pike poles under two sides of the sling well up the pole; and
- Snub off securely by pencil bars driven into solid ground or by any other substantial snub.

Always check the pole to see if additional support may be necessary because of pole conditions or strains. Include the following:

- Determine the condition of the pole butt before removing guys or wires, and support the pole with additional pike poles or temporary guys if necessary;
- When an old or reinforced pole is being dismantled, guy it sufficiently to withstand any altered strain on it. Include the weight of personnel who are to work on the pole while dismantling;
- When changing the strain on a pole, the authorized individual-in-charge must ensure it is sufficiently guyed to stand the altered strain and prevent the pole from falling. Do not climb a pole that is under an abnormal strain;
- A truck equipped with an “A” frame and backed up to the pole can be used to restrain the pole. The top of the “A” frame can be tied by the winch line to the pole. The pole at the ground line level can be securely tied off to the truck;
- In locations where poles cannot be lowered with a rope or derrick, attach a guideline so that the pole moves in the desired direction;
- All members of a crew who are not actively engaged in pole removal must stand well clear in case the pole must fall. Where appropriate, stop all pedestrians and traffic during pole removal; and
- When a pole is being removed, dismantle the pole before beginning the excavation around the butt.

6-4 CLIMBING AND WORKING ON POLES.

Workers must be familiar with the general rules for climbing poles and approaching the overhead work area, the differences of climbing wood poles as opposed to steel towers, and the dangers inherent in crossing overhead structures from one side to another.

6-4.1 General Rules.

- Do not work at the base of a structure or a pole while others are working above;
- Before climbing a pole the worker must first determine;
  - What circuits are energized and their voltage, and any unusual conditions which might pose a hazard.
  - The types and locations of circuits, and the direction of feeds.
  - The best climbing space to avoid all live wires, grounded wires, and signal circuits.
- Ensure there is an ample supply of rubber protective equipment on hand to completely protect the worker on the pole from all live wires, grounded wires, and signal circuits;
- Only one worker is permitted to ascend or descend a pole at any one time. Other workers must be in place on the pole or on the ground before the worker ascends or descends the pole;
- Extraordinary care is required of the workers when it becomes necessary for one worker to work above the other; and
- Before climbing poles, ladders, scaffolds, or other elevated structures; riding span wires, messengers or cables; or entering cable cars, boatswain chairs or similar equipment; each worker must first ensure the structure or device is strong enough to sustain the worker's weight.

6-4.2 Pole Inspection Before Climbing.

The type of pole being climbed affects the precautions that the worker must take in regards to climbing equipment and procedures. All types of poles must be safe to climb in terms of being strong enough to bear the weight of the climbers and their tools, and having adequate climbing space. Before allowing anyone to climb on a pole, the authorized individual-in-charge must ensure the pole is inspected, i.e. hammer tested and pike pole rocking test, and that it can be safely climbed based on the following:

6-4.2.1 Pole Condition.

Determine age, physical condition, and treatment of the pole. Do not climb a pole unless you are sure it can safely hold your weight. Before climbing, inspect the pole for the following:

- General condition – buckling at the ground line or an unusual angle may indicate pole has rotted or is broken;

- Cracks – horizontal cracks perpendicular to the grain of the pole may weaken pole. Vertical cracks can pose a hazard to the climber; keep gaffs away from them while climbing;

- Holes – hollow spots or woodpecker holes can reduce the strength of a wood pole;

- Rotting and decay – are cutout hazards and are possible indication of the age and internal condition of the pole;

- Knots – one large knot or several smaller ones at the same height may be evidence of a weak point on the pole;

- Depth of setting – evidence of the existence of a former ground line substantially above the existing ground line may be an indication the pole is no longer buried to a sufficient extent;

- Soil conditions – soft, wet or loose soil may not support any changes of stress on the pole; and

- Burn marks – burning from transformer failures or conductor faults could damage the pole.

6-4.2.2 Test Methods.

Inspect and test wood poles by the qualified employee prior to any climbing activities using one of the following methods:

- Hammer Test – rap the pole sharply with a hammer weighing about 3 lb (1.4 kg) hammer, starting near the ground line and continuing upwards circumferentially around the pole to a height of approximately 6 ft (2 m). The hammer will produce a clear sound and rebound sharply when striking sound wood. Decay pockets will be indicated by a dull sound or a less pronounced hammer rebound. Also, prod the pole as near the ground line as possible using a pole prod or a screwdriver with a blade at least 5 in (127 mm) long. If substantial decay is encountered, the pole is considered unsafe; and

- Rocking Test – apply a horizontal force to the pole and attempt to rock it back and forth in a direction perpendicular to the line. Caution must be exercised to avoid causing power lines to swing together. The force may be applied either by pushing with a pike pole or pulling with a rope. If the pole cracks during the test, it is considered unsafe.

6-4.2.3 Additional Checks.

Determine the following:

- If the configuration of conductors and equipment on the pole will provide adequate climbing space;
- If the removal of supporting conductors or guys may affect the safety of workers; and
- If the poles being climbed can be supported in such a way as to safely support workers on the poles. Pikes are not acceptable as a support method while personnel are working on poles.

6-5 POLE CLIMBING EQUIPMENT.

6-5.1 General Rules.

Observe the following:

- Make sure each worker who is authorized to climb has a full set of climbing equipment. Never loan or borrow a set of climbing equipment;
- Carefully inspect climbing equipment before each day's climbing activities. Examine leather for cuts, cracks, and enlarged buckle tongue holes. Examine metal parts for cracks, wear, or loose attachments. Examine climbers (gaffs) for proper cutting edges, length, and shape;
- The authorized individual-in-charge, or a designated worker, must inspect all tools, safety devices, and other equipment in use on a weekly basis. Any item that is not considered safe must be condemned, regardless of ownership, and must not be used;
- Ensure that employees understand that fabricated or purchased fall protection must meet or exceed the requirements outlined in ANSI Z359 and with ASTM F887. Body harnesses, meeting the requirements of ANSI Z359, with straps or lanyards, must be worn to protect personnel working at elevated locations on bucket trucks, power poles, towers, platforms, and other structures. Inspect body harnesses and straps before use each day to determine they are in safe working condition; and
- Use body harnesses instead of body belts for fall protection.

6-5.2 Wooden Pole Climbing Equipment.

6-5.2.1 Climbing Equipment.

Equipment sets each consist of a body belt (or body harness), a pole strap, and climbers (an assembly of gaffs, leg straps, and pads). Climbing equipment must meet the following requirements:

- Leg iron (shank) to be made of spring steel;
- Gaff (spur) to be forged from tool steel;
- Leg iron length must be in the range from 15 to 18 in (381 to 457 mm) from the instep to end of the shank;
- Leather straps must be at least 1-1/4 in (32 mm) wide and 22 in (559 mm) long; and
- Pads must adequately protect the calves.

Repair before use any climbers, pole straps, and other leather items that have any of the following defects:

- Cracked, dry, or rotten leather;
- Leather that is worn thin;
- Cuts or worn places which are of sufficient depth to weaken the leather;
- Broken stitches or loose rivets at buckles, D-rings, or snaps;
- Snaps which have weak springs behind the tongue or loose rivets which hold the tongue;
- Loose tongues in buckles; and
- Buckles, D-rings, or snaps that show considerable wear or which have been cracked or bent.

6-5.2.2 Leather Care.

Provide care for leather equipment as follows:

- Leather equipment in regular use must be cleaned and dressed at least every three months, and more frequently when the equipment is wet from rain or perspiration, or is soiled with dirt or mud. Leather equipment not in regular use must be cleaned and dressed at least every six months;

- Wipe off all surface dirt and mud with a sponge dampened (not wet) with water. Never use gasoline or other cleaning fluids, as they tend to dry out and harden the leather;

- Wash leather with a clean sponge in clear lukewarm water and a neutral soap (free from alkali), preferably Saddle soap. Thoroughly wash the entire length of the leather and work the lather well into all parts. Place in a cool area to dry;

- Dress leather with oil after each cleaning. Use a small quantity (about 20 milliliters (4 teaspoons)) of pure neatsfoot oil per set of equipment and apply it gradually with the hands, using long light strokes while the leather is still damp from washing. Leave in a cool place to dry for about 24 hours, and then rub the leather vigorously with a soft cloth to remove all excess oil; and

- When safety harnesses/belts and straps are not in use, store them in designated compartments on the service truck or other suitable location to protect them from damage. When stored, wrap climbers in pairs and fasten with their straps.

6-5.2.3 Climbing Equipment Inspections.

Keep climbers, straps, and pads in good conditions at all times. Inspect climbers before each use to detect nicked or dulled cutting edges on the gaff. Check them as soon as possible after striking them against hard objects such as pole hardware or nails. The worker must inspect climbers in regular use at least weekly. If any of the following conditions are found, repair or replace the climbers before using:

- Loose gaff;

- Nicks and depressions in the gaff;

- Ridge of gaff not in alignment;

- Dull gaffs;

- Broken or distorted gaff points;

- Broken, loose leg or foot strap loop;

- Excessively worn, cracked, or torn straps and pads;

- Enlarged buckle holes in the straps;
- Broken or damaged strap buckles;
- Fractured or cracked leg irons and stirrups;
- Excessively worn stirrups;
- Fractured leg iron sleeves;
- Broken or loose rivets or screws on sleeves and straps;
- Defective strap rings;
- Broken or damaged loop clip-on straps;
- Gaff guards not in good condition; or
- Improper length of gaffs.

6-5.2.4 Gaff Requirements.

Gaffs must be at least 1-1/4 in (32 mm) long, measured from the point of the gaff to the point of contact with the stirrup on the underside. Sharpen climbers using a gaff-shaping bit as follows:

- Place the climber between wood in a vise with the leg iron horizontal and the gaff on the topside;
- Use a smooth cut file and finish with a sharpening stone. Never grind with an emery wheel as this takes the temper out of the metal;
- The outer ridge of the gaff must never be filed. To obtain the proper width, a file may be used on the rounded portion. Apply strokes that follow the contour of the gaff;
- To sharpen the gaff to proper thickness, file the metal from the flat inner side of the gaff. Care must be taken to prevent notching the leg irons or stirrup. Use forward motions toward the point and down to edges of the underside of the gaff. Do not allow rocking motions of the file because this can round the edges of the gaff. After the proper thickness has been reached, the underside of the gaff must be straight to within 1/16 in (1.6 mm) of the point, then rounded slightly toward the ridge of the gaff on a radius of 1/4 in (6.4 mm). Additional sharpness may be obtained following filing by dressing the underside and rounded portion of the tip with the

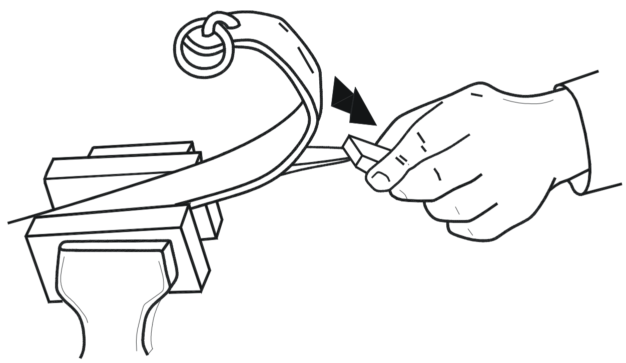
honing stone. Burrs along the edges must also be removed with the stone; and,

- Never use a climber with a gaff shorter than 1-1/4 in (32 mm), as measured on the flat side.

Restore damaged or dull gaffs to original shape by filing and honing (see Figure 6-3). If gaffs cannot be restored, replace them.

Figure 6-3 Honing a Gaff

Hone Lengthwise - Not Crosswise



6-5.2.5 Properly Sharpened Gaffs.

Three methods are normally used to determine if gaffs are properly sharpened.

6-5.2.5.1 Gaging Method.

The gaging method is used to determine the length, width, and thickness of the gaff and profile of the point. Reference lines are scored on the gage with slots provided to determine if the gaff length is satisfactory. Most gages also provide a contour test to determine if the point is properly curved. Openings are provided for determining if the point is too keen. Each manufacturer makes a gaff gage to use with its own climbers. Thus, gaff gages are not usually interchangeable. Use manufacturer's instructions if available. The "thickness" slot in the gage is used to measure the thickness of the gaff at 1/2 in (12.7 mm) from the point. These measurements are made with the outer ridge of the gaff resting flat against the part of the gage containing the scored lines. If the point of the gaff extends beyond the farthest line, the gaff is too thin. If it does not reach the nearest line, then it is too thick. The "width" slot on the gage is used to measure the width 1/2 to 1 in (12.7 to 25.4 mm) from the point. The same methods and reference line are used in measuring for thickness. A minimum length reference line is provided, intersecting the thickness measurements, to determine if the gaff meets minimum lengths.

6-5.2.5.2 Plane Test Method.

The plane test method may be used with the gage, or independently if the gaffs are sharpened by machine process. The test is made by using a soft board to determine if proper sharpness has been reached. Place the climber with the gaff side down and parallel to the board without applying downward pressure above the gaff. Push the climber along the board. If the gaff is properly contoured and sharpened, it can dig into the wood and hold within approximately 1 in (25.4 mm). If the climber continues to glide along the board for more than 1 in (25.4 mm), additional honing is required. After the "plane test" has been made, it can be supplemented by applying a cutout test. Jab the gaff into the board at about a 30-degree angle for approximately 1/4 in (6 mm). Bring the leg iron down against the wood while applying forward pressure--one hand holds the leg iron and the other holds the stirrup. If the gaff cuts out within 3 in (76 mm), it is improperly sharpened.

6-5.2.5.3 Pole Cutout Method.

The pole cutout method is used after climbers have been machine sharpened or gauged (and as often as required thereafter). Perform a pole cutout test in accordance with Table 6-2 before climbing. Check failed gaffs with a gaff gauge to determine the reason for failure and correct the deficiency.

Table 6-2 In-Use Check of Pole Climber Gaffs

Check
Initial placement. Place the climber on the leg, holding the sleeve with the hand, palm facing the pole. With the leg at about a 30 degree angle to the pole and the foot about 12 in (305 mm) off the ground, lightly jab the gaff into the pole to a distance of approximately 1/4 in (6 mm).
Intermediate action. Keeping enough pressure on the stirrup to keep the gaff in the pole but not so much as to cause the gaff to penetrate any deeper, push the climber and the hand toward the pole by moving the knee until the strap loop of the sleeve is against the pole.
Full pressure. Making certain that the strap loop is held against the pole with pressure from the leg, gradually exert full pressure of the foot straight down on the stirrup without raising the other foot off the ground (to maintain balance if the gaff does not hold).

6-5.2.6 Gaff Protection.

To protect the gaffs, use gaff guards when climbers are not being used. Gaff guards must also be used when other tools and materials are stored or transported along with the climbers.

Note: Never store or transport climbers without appropriate gaff guards.

Do not wear climbers when:

- Working on the ground;
- Traveling to and from a job;
- Piking poles;
- Walking through underbrush or rough terrain; or
- Riding in motor vehicles.

6-5.3 Concrete and Steel Pole Climbing.

OSHA standards (29 CFR 1910 and 1926) require fall protection for certain working heights. Acceptable fall protection includes the use of standard railings and toe boards, floor opening covers, or a personal fall arrest system. A body belt is no longer acceptable as part of a personal fall arrest system.

Fall protection is required for operations and maintenance activities when personnel are required to work at a height of 4 ft (1.2 m) or more above ground or to the next lower level. For construction activities, workers must be protected from falls when working at a height of 6 ft (1.8 m) or more. An approved positioning device that limits a fall to less than 2 ft (0.6 m) must be used when a worker needs to be supported on an elevated vertical surface such as a wall or utility pole, and working with both hands free while leaning. Observe the following requirements:

- A proper anchor point must be identified and evaluated by qualified personnel before an appropriate system can be selected. OSHA regulations accept pad eyes, bolt holes, and other sturdy structures capable of supporting 5,000 lb (2,200 kg) per attached worker;
- Positive systems have an anchor point independent of the support method, a harness to hold the worker, and a connecting device between the anchor point and the harness;
- Harnesses must only be used for the personal protective purpose for which they are designed. In addition to fall-arrest harnesses, there are fall-arrest/positioning, fall-arrest/suspension, fall-arrest/retrieval, and retrieval/positioning harnesses;
- Manufacturer’s instructions in regard to height and weight must be followed for sizing of the harnesses and their connecting devices, and for inspection and maintenance of the complete systems. All equipment must be taken out of service and inspected for damage after being subjected to a fall impact; and

- Workers authorized to climb must have a complete set of approved tools. The number of tools carried in tool belts must be kept to a minimum. Tools must not be carried in safety harnesses.

6-6 POLE CLIMBING AND WORK PRECAUTIONS.

Only after a determination of the pole's safety, the collection of necessary climbing equipment and work tools, and obtaining assurance that the line is placed in an electrically safe work condition, and the planned energized work is authorized, can the worker start climbing. Protect hands and arms by wearing gloves and long sleeve shirts. Refer to Section 6-4 for pole inspection requirements before climbing.

6-6.1 General Pole Climbing Precautions.

Observe the following precautions:

- Arrange tools and equipment to allow both hands to be free for climbing;

- Do not stand on mailboxes, signs, fire alarm boxes, or similar equipment that may be attached to the pole or located near it;

- Do not race up and coast down poles;

- Do not use safety straps while climbing, except when climbing over slippery or ice-coated cross arms or timbers. Whenever the hands are apt to slip off, a safety strap must be used. The use of rope safeties is prohibited;

- Remove all signs from a pole before any worker climbs or does any work above them on a pole. It is not desirable to have signs on poles, but some signs, such as street signs, may be necessary. If street signs are removed, they must be replaced as soon as possible after work is completed;

- Climb on the high side of a raked or leaning pole, if possible, but do not climb on the side where the ground wire is attached. Avoid grasping pins, brackets, cross arms, braces, or other attachments that might pull lose and cause a fall;

- Never slide down any type of pole or any guy wire. If it is impossible to use climbers for ascending and descending such places, ladders or other means must be used;

- Do not ride overhead guys or cables. (This is not intended to apply to cables installed for river crossings or otherwise designed to support workers in suitable conveyances);

- If more than one worker needs to work on the pole at the same time, the first worker must reach working position before the next worker leaves the ground. Ordinarily, no worker must work directly under another worker on the same pole. When this is necessary, take extreme care to prevent tools or other objects from being dropped on the worker below;

- Minimize the number of tools carried in tool belts. Keep all other tools on the ground until they are required. Needed tools must be raised and lowered by means of a canvas bucket attached to a hand line;

- When carrying a hand line up a pole, leave the hand line uncoiled with one end attached to the rear of the body belt or harness. When climbing with a hand line, take care to prevent the hand line from fouling on any pole attachments;

- Wear appropriately rated arc flash personal protective equipment as specified in UFC 3-560-01; and

- Discontinue work during adverse weather conditions such as thunderstorms, rain, high winds, and icy conditions. In bad weather, do not climb poles except for emergency restoration work.

6-6.2 Wooden Pole Climbing Precautions.

Observe the following precautions:

- Seat gaffs securely. Be especially vigilant when the pole is ice or sleet covered;

- Use pole steps whenever they are available, but only after checking that they can be used safely;

- Use climbers carefully on the pole to avoid injury to another worker on the pole; and

- Be careful to avoid weather cracks, checks, knots, shakes, rots, and hard places, which might cause gaffs to cut out. Remove any tack or nails which may impede safe climbing.

6-6.3 Concrete and Steel Pole and Tower Climbing Precautions.

Observe the following precautions:

- Always make sure that gloves and shoe soles are in good condition and free from grease or other lubricants. Many falls are caused by slick work gloves or slick shoes. Rough cord sole shoe or boots are recommended. Be particularly careful in wet or icy weather conditions; and

- Carefully wear and regularly inspect the safety harness since steel and concrete surfaces can easily damage or cut the harness.

6-6.4 Working on Poles.

Never change the amount of strain on a pole by adding or removing wires until you are sure that the pole can stand the altered strain. If in doubt, consult the authorized individual in charge.

6-6.5 Safety Straps.

Wear safety straps at all times when handling wires or apparatus while on a pole or structure. Take the following precautions:

- Be careful in attaching snaps to D-rings. Visually ensure that the snap keeper is fully closed in the correct ring before any weight is applied to the safety strap;

- Always be sure that safety straps are connected and not twisted while in use;

- Never depend on a cross arm or cross arm pins and braces for support;

- Never attach safety straps above the cross arm in the top gain or around insulator pins, cross arm braces, transformer hangers, pole steps, or guy wires. If there is no cross arm in the top gain, the strap must not be placed closer than 2 ft (0.6 m) to the top of the pole. In this case take precautions to assure that the strap does not slip off. Ideally the strap must be below the top pole attachment, except where that attachment is above eye level;

- Never fasten both safety harness snaps in the same D-ring in order to reach out farther on the pole. An extension safety strap must be used or the safety harness let out so that work can be performed with the safety harness snaps fastened one in each D-ring; and

- Do not attach metal hooks or other metal devices to body harnesses. Metal chains and keepers must not be used. Instead, use leather straps or rawhide thongs with hard wood or fiber keepers. Care must be taken to prevent the snaps on the safety harnesses/belts from coming in contact with anything that may open a snap. The tongue of the snap on the safety harness/belt must face away from the body.

6-6.6 Hoisting or Lowering Materials.

Take the following precautions when hoisting or lowering materials:

- Drop material that cannot be lowered safely only if there is no danger to workers or the public;
- Position workers engaged in hoisting tools and materials so that they cannot be injured by a falling item; and
- Do not leave materials and tools overhead in an insecure position. Large objects must be securely lashed.

6-7 CROSSING STRUCTURES.

To get from one side of a double-pole supported structure to the other, the worker must descend to the ground and go up the other pole unless there are adequate handholds and adequate clearances from live parts to allow safe crossing along the structure. Observe the following precautions:

- When it is necessary to climb half-way across a cross arm to inspect middle phase insulators, the worker may climb the rest of the way across, provided that a safety harness/belt can be kept strapped around a timber as a safeguard;
- Never cross through an open-air switch unless both sides are placed in an electrically safe work condition;
- Do not use air switch arcing horns for support in walking timbers since these horns break easily and a fall could result; and
- Never walk along an H-frame cross-arm with the line energized.

6-8 STRINGING OR REMOVING DE-ENERGIZED CONDUCTORS AND OVERHEAD GROUND WIRES.

6-8.1 Pre-Work Meeting.

Discuss the plan of operation, type of equipment being used, adjacent energized lines, necessary grounding devices and procedures, crossover methods, and Safe Clearance requirements before stringing or removing de-energized conductors or overhead ground wires.

6-8.2 Work Adjacent to Energized Lines.

Note: For the Navy and Air Force, work adjacent to energized lines is not authorized.

Observe the following precautions during all work activities:

- The worker attending the payout reel must wear rubber gloves when pulling wire over or near energized conductors, and be positioned on an insulated stand of a size equivalent to or larger than a standard rubber blanket;

- Ground the payout reel. The authorized individual-in-charge must approve any deviation in grounding the payout reels;

- A bull line, which must be of dry polypropylene rope ≥1/2 in (12.7 mm) diameter, must be placed in position to pull the wire before attempting to string it. The bull line must be of sufficient length to reach the distance the wire is being pulled. Fasten the wire to the end of the bull line and pull it into position;

- A vehicle used to pull the wire must be positioned so that the driver can see the signals of the reel operator. Both in pulling in and in sagging the wire, the pulling must be slow and steady to prevent swinging the wires into the energized conductors. The wire must be watched carefully to prevent its hanging up on tree limbs, weeds, and other obstructions;

- Do not touch any conductors or wires on the ground without rubber gloves;

- Wear rubber gloves and use other protective devices, as appropriate, when wires are strung and sagged over, under, or across conductors carrying a voltage of 5,000 V or less. Positively and constantly ground conductors carrying more than 5,000 V during the stringing operation. Ground the wire with standard grounding devices as soon as it is ready to dead-end;

- Discontinue operations and seek appropriate shelter when notified that a lightning warning is in effect. Electrical charges can appear on the line from a lightning strike or from induced static charges from a very dry atmosphere. Be in contact with the Base Weather Service and cease outside activities when notified of a lightning warning. Waiting for an indication of lightning can expose a work crew to adverse weather conditions; and

- Keep wires being strung along or across streets or highways higher than any expected car or truck traffic. Block traffic when this line elevation is not possible.

6-8.3 Grounding.

Refer to UFC 3-560-01 and IEEE Std 1048 for requirements for grounding of de-energized lines. Other grounding requirements are as follows:

- Permanent ground wires are installed to protect workers. All permanent grounds must be installed in accordance with the requirements of NFPA 70 or IEEE C2, as applicable. If the permanent grounds are not installed, the metallic case, covering, or mounting support of any energized piece of electrical equipment must be treated as if it is energized at full voltage;

- Install ground wires clear of all metallic line equipment (except that which is normally grounded), hardware, and street lighting fixtures; and

- Install ground wires on distribution wood poles with protective molding for the entire working length of the pole to protect them from damage. The entire working length of the pole is the distance from the point where ground wire terminates near the top of the pole to 5 ft (1.5 m) below the lowest cross arm or bracket, and from the ground line to 8 ft (2.5 m) above the ground line.

Never cut an overhead ground wire or neutral wires without the specific approval of the authorized individual-in-charge. Always avoid opening a joint in such a wire without first bridging the joint with wire of equal or larger size.

6-8.4 Handling and Stringing.

IEEE Std 524 provides general recommendations on the methods, equipment, and tools used for the stringing of overhead line conductors and ground wires. Safety precautions include:

- Use adequate braking to stop all payout reels. Do not touch or attempt to hand stop a revolving reel;

- Securely fasten the inside end of the coil wire to the reel to prevent the wire from getting loose when the wire has been extended out. If the inside end of the coil cannot be secured, a tail rope must be fastened securely to the wire before the end is reached to prevent its getting loose;

- Bond and ground all stringing equipment, such as reel stands, trailers, pullers, or tensioners;

- String the lines to clear the ground by an amount not less than that specified in IEEE C2. These minimums depend upon whether the line is above a street (consider its traffic classification), above a pedestrian way, or over or near other structures. Wire and guys that are being strung must be kept clear of any possible interference with public traffic of any type. Where it is necessary to block traffic temporarily while wires and guys are being installed, one or more members of the crew must be assigned to direct traffic; and

- Stringing by Activity personnel must normally be done by the tension method, since this keeps the conductor clear of energized conductors and clear of obstacles that might cause surface damage to the wire. Slack stringing may be appropriate for new short line extensions. Sag the lines to meet the requirements of IEEE C2:

  - Take care not to put kinks into any part of the line when stringing wires. Kinks reduce the strength of the wire and may result in fallen wires later.

  - Before changing the strains on a pole by adding wires, an engineering evaluation must be completed to ensure that the pole can safely stand the new strain.

6-8.5 Clipping-In or Tying Wires.

This involves the transferring of sagged conductors from their stringing travelers to their permanent insulator positions where they may either be clamped or tied to insulators. Safety precautions include:

- Securely tie wires at each tie-in-type insulator to prevent the wires becoming loose and falling to the ground. Where double arms are provided, line wires must be well tied-in to insulators on each arm. This applies to both pin- and post-type tie-top insulator work. Clamp-type insulators must have the clamps tightened as specified by the manufacturer;

- Test the phase wires with a potential transformer or other means, to make sure that the phase wires of one circuit are being connected to the corresponding phase wires of the other circuit when it is necessary to connect circuits at any point on the line; and

- Be sure that the phase wires are not crossed when turning the vertical angle on three-phase lines; that is, phase wires must take the same position leaving an angle as coming into it.

6-8.6 Secondary Line Installation.

Install secondary lines to meet line clearance requirements of IEEE C2. Lines can be single or triplex wires. Workers must be particularly careful in stringing secondary services to avoid the hazards of working in close proximity to primary lines. Deenergize and ground nearby or adjacent energized lines before stringing secondary wires. Take care not to injure the weatherproof covering when handling and stringing of weatherproof-covered wires.

6-8.7 Removing Lines.

Use the same general precautions as stringing wires when removing or salvaging wires. Where practical, the removed wire must be completely pulled out and laid flat on the ground before any attempt is made to coil the wire by hand or on a non-power-driven reel. Never change the strains on a pole by removing wires until certain that the pole can safely stand the altered strain. Where a pole will be weakened by the removal of the wires, it must be guyed before these wires are removed. All wires must be lowered with a hand line. Use care before cutting a wire aloft to avoid contact with other wires.

Do not allow lines which are being cut or rearranged to sag on, or be blown against other electric power lines, signal lines, signal equipment, metal sheaths of cables, metal pipes, ground wires, metal fixtures on poles, guy wires, or span wires. Do not allow wires which have been cut, or which are being arranged, to fall near or on a roadway where they might endanger traffic. Notify all persons working on lower levels of poles and all personnel on the ground well in advance of the cutting so that they may stand clear.

6-8.8 Guying.

Do not install or remove guys without engineering guidance.

6-8.8.1 Installation.

Install guys to meet the following requirements:

- When insulators are used they must be connected into the guy wire line before the guy wire is set in place. In new work, guys must generally be installed before line wires are strung. In reconstruction work, guys must be installed before any changes are made in the line wires and care must be taken not to place excessive pull on the pole and wires already in position;

- Install guys so that there is minimal interference with the climbing space, and to clear all energized wires;

- Provide guy strain insulators to obtain necessary insulation when required by building or safety codes;

- Install guys to the correct tension. Where necessary, a guy hook may be used to prevent the guy from slipping down the pole. Locate these hooks so they do not interfere with climbing, and place them so they are not convenient for use as a step. Where guys are liable to cut into the surface of a pole, the pole must be protected by a guy plate at the point where the guy is attached. The plate must be well secured to the pole to prevent the possibility of injury to a worker climbing up or down the pole;

- Install guys so that they do not interfere with street or highway traffic. Equip guys located near streets, or highways, with traffic guards. Traffic guards are sometimes called "anchor shields". Guy guards (traffic shields or anchor shields) must be yellow;
- Install guy wires so that they do not rub against messenger or signal cables; and
- Do not use guy wire containing snarls or kinks for line work. Use guy wires of the correct length to avoid splices.

6-8.8.2 Removal of Guys.

Determine the condition of the pole before removing guys. Brace the pole securely if it is weak before any changes in pole strains are made. Brace the pole temporarily if the removal of guys from a pole can change the strain and present a dangerous condition.

Where it is not possible to install side guys, poles may need bracing to be self-supporting. Install pole bracing so that it does not interfere with climbing or with street or highway traffic. Pole braced guys must not be used on poles which must be climbed.

6-8.9 Insulators.

Pick up insulators by their tops to avoid cutting gloves or hands on the insulator petticoats. Do not screw down insulators too tightly because their tops might break off, cutting gloves or hands.

6-9 ENERGIZED WORK.

Energized work requirements are provided in UFC 3-560-01.

6-10 WORKING ON OR NEAR POLE-MOUNTED EQUIPMENT.

This paragraph provides precautions applicable to equipment that is mounted above grade. Be aware that some local and state safety regulations do not permit grounding of enclosure cases on wood poles when there is a possibility that an accidental contact with bare aerial lines could occur. The equipment on the Activity might have been installed in accordance with these regulations. Transformers connected to an energized circuit must be considered as being energized at the full primary voltage unless positive verification is made that they are adequately grounded.

6-10.1 Surge Arresters.

Check that the permanent ground connection is intact before any work is done. Do not climb on or strap off to surge arresters.

6-10.2 Switches and Fuses.

The maintenance of switches and fuses might require temporary line modifications to permit repairs while maintaining service continuity. Engineering guidance must likely be required in preparing a step-by-step modification procedure. Both sides of fuses must be placed in an electrically safe work condition in order for repair work to proceed.

6-10.3 Capacitors.

Individual capacitor banks must be grounded if insulated capacitor mounting racks are not used. Provide grounding in accordance with the manufacturer's instructions.

6-10.4 Power Transformers and Voltage Regulators.

Work on energized pole-mounted transformers is prohibited except for testing, replacement of fuses, and switching. Observe the following precautions during installation:

- Carefully inspect all frames and tackles used in erecting pole-type transformers before each use. Repair defects before the frames and tackles are used;

- Wherever possible, junction poles, subsidiary poles, and street lighting poles must not be used as transformer poles. When it is necessary to install transformers on junction, subsidiary, or street lighting poles, be careful to maintain proper climbing space and to avoid crowding of wires and equipment;

- Install transformers only on poles strong enough to carry their weight. Transformer poles must be straight and, where necessary, guyed to prevent leaning or raking of the pole after the transformer is hung;

- All crew members must stand clear and detour traffic when transformers are raised or lowered. In congested traffic locations, the pole space must be roped off. Personnel on the pole must place themselves on the opposite side from that on which the transformer is being raised or lowered. Pole steps and other obstructions in the path of ascent/descent of large transformers must be removed;

- When transformers are installed, the pole climbing space must be protected so that climbing workers do not come too close to transformer cases;

- Do not install pole-type transformers until they are filled with a sufficient amount of the appropriate oil or fluid;

- Determine phase rotation before the old bank is removed, and before the new three-phase bank of pole-type transformers is installed, check voltage and phase rotation as well as the nomenclature plate;

- Only qualified climbers must be allowed to climb poles to inspect and test pole-type transformers. Never stand on or otherwise contact transformer cases;

- Disconnect all energized connections to transformers and provide a Safe Clearance from all live circuits before changing or replenishing transformer oil; and

- Do not use lighted matches or open flames of any kind when opening transformers.

6-10.5 Fuses.

When installing fuses, workers must be careful to avoid contact with any live lines and with other metal surfaces even if they are supposed to be grounded (i.e., grounded lines, the casings of grounded transformers, street lighting fixtures, signal lines, signal equipment, the metal sheathing of cables, metal conduits, span wires, or guy wires).

Before installing fuses in new cutouts, replacing fuses, or opening disconnects, workers must wear and use the appropriate personal protective equipment in accordance with UFC 3-560-01.

6-10.6 Service Wires.

Use at least two qualified workers when installing services from a transformer pole when primary conductors energized at 4,000 V or more are within contact distance of the secondary wires.

Service wires must not be installed on transformer poles, unless minimum separation requirements can be maintained between the service wires and the energized primary conductors or apparatus. The neutral wire must be connected first when making connections to secondary buses followed by the phase conductors. Reverse the procedure when disconnecting services.

6-10.7 Testing.

Qualified personnel must perform testing of transformers, autotransformers, and similar equipment. All temporary leads used in testing, such as secondary leads of potential transformers, thermometer leads, and recording voltmeter leads, must be securely supported on the pole and must clear all vehicular traffic. The positions of these leads must not interfere with the climbing space or with other maintenance work which may be required while the testing is in progress.

6-11 AERIAL ROPE.

6-11.1 Conductivity.

Properly maintained polypropylene synthetic rope (not natural-fiber rope) which meets IEEE Std 516 requirements must be used for aerial lines, hand lines, and tag lines for energized work. Keep rope stored in a clean, dry location and protected from damage and contamination. Rope lines used must be constructed without wire reinforcement, and be at least 1/2 in (12.7 mm) in diameter.

6-11.2 Terminology of Rope Use.

The following terms are used:

- Hand lines are used to raise and lower light materials and tools. They may be used for holding small transformers away from the pole during raising or lowering;
- Throw lines are used to pull a larger rope into place for performing a task beyond the capacity of a hand line. They are small diameter ropes designed to be thrown over support objects such as cross arms or tree limbs;
- Bull ropes are used when a hand line is not strong enough to raise heavier equipment. They are used also for fastening temporary poles, for holding out heavier transformers, and for lowering trunks or heavy limbs in tree trimming operations;
- Running lines are used for pulling several span lengths of wire at one time;
- A sling is a looped rope assembly useful for many purposes, such as, hoisting heavy equipment, lashing tools or materials in place; attaching a block or a snatch block to a pole; making temporary installations such as lashing an old pole to a new pole; or for tying up line wires;
- A safety line is used only for lowering a worker to the ground; and

- A snatch block is a rope sheave and hook with one side of the sheave open to avoid threading the rope through a hole.

6-11.3 Knots and Splices.

Where it is necessary to connect two aerial rope lines permanently, a splice must be made. No metal, wire, or clamps can be used in making the splices. The strength of a splice can be close to the original strength of the rope, and is always much greater than the strength of a knot.

Knots, friction tape, cord, or marlin must not be used in joining the two parts of an aerial rope line. Properly assembled splices are not normally bulky. Each end of the rope line must be finished (served) to prevent unraveling of the strands. A hand line must be dry and strong enough for use as a safety line for lowering a person safely from a pole.

6-11.4 Hand Line and Rope Line Precautions.

Although the term hand line is used in the following paragraphs, these precautions apply to all rope lines:

- Hand lines must be at least twice as long as the height of the highest cross arm, and equipped with single sheaves. No metal must be used on any hand line, except for the use of a standard hook;

- Hand lines with worn or frayed parts must be scrapped immediately;

- Hand lines must be carried up a pole uncoiled and attached to the back of body harness/belt before any work is done. A worker climbing with a hand line must take care to prevent the hand line from catching on pole attachments;

- Hand lines must not be pulled over sharp bends, sharp edges, or surfaces with splinters;

- Hand lines must be kept free from solder, oil, grease, snarls, and knots;

- Hand lines must not be stored while they are wet;

- When not in use, hand lines must be rolled up and stored in a dry and protected place. Always thoroughly dry hand lines before storing. Hand lines must never be permitted to lie on the street or highway;

- Where hand lines are being let out on the poles, at least one member of the crew must be stationed at a safe distance from the base of the pole to take care of the loading and unloading of the hand line, and to see that the ends are kept free from all street traffic; and

- One hand line must be kept in reserve and maintained in a dry condition to use as a safety line in case there is a need to rescue a worker from a pole. This hand line must be stored in a protected part of the truck where it cannot become wet.

6-11.5 Tackle Blocks.

Tackle blocks used on maintenance work must be equipped with safety snaps to prevent wire grips and live tools from coming loose and falling.

6-12 TOOLS.

Aerial line work involves the use of portable power tools and other miscellaneous tools.

6-12.1 Portable Power Tool Precautions.

Use only approved portable power tools on poles, towers, or structures:

- Keep electric tools and connected power cords a safe distance from any circuit or apparatus energized in excess of 600 V, phase to phase. Power cords must be adequately insulated and properly secured to prevent accidental contact with any conductor;

- Do not use air-driven and hydraulic-driven tools when their conducting parts can come closer than the restricted approach boundary to any energized conductor or apparatus. Cover the energized conductors or apparatus with protective equipment appropriate for the voltage involved when the minimum clearances cannot be obtained. Supply hoses must be made of non-current carrying material throughout, be properly maintained, and secured in use to prevent accidental contact with any energized conductor or apparatus;

- Use power saws in an elevated position on a pole, tower, or structure only when approved by the authorized individual-in-charge; and

- Non-current carrying metal parts of hand-held portable electric power tools must be grounded unless supplied from a ground-fault interrupting (GFI) circuit. Approved double-insulated tools and tools fed from ungrounded isolated power supplies need not be grounded.

6-12.2 Miscellaneous Tool Precautions.

- Pike pole handles must be sound and free from splinters. Spear points (gaffs) must be sharp and securely fastened to a pole. When carried on trucks, pike poles must be placed to prevent injuries;

- Maintain cant hooks and carrying hooks in a safe condition;
- Never use Jennies with cracked or broken legs, dull teeth, or loose bolts. Use only approved Jennies;
- Never use pole jacks with defective releases, or jacks that might slip when loaded;
- Only use approved bumper boards. A bumper board must be either 2 by 6 in (50 by 150 mm) board of length 6 to 8 ft (1.8 to 2.4 m), or 1-1/2 by 6 in (38 by 150 mm) channel iron of length at least 6 ft (1.8 m);
- Never use wire reels with defects evident. All wire reels must have suitable brakes;
- Close folding-type knives before placing them in toolboxes or other storage containers. Open knives must be kept in scabbards when not in use;
- Maintain personal tools in good condition; and
- Keep live-line tools clean, dry and in good condition.

6-13 AERIAL LIFTS AND INSULATED BUCKETS.

Aerial lifts must be constructed, maintained, and tested to meet the following standards:

- ANSI/SIA A92.2
- ANSI/SIA A92.3
- ANSI/SIA A92.5
- ANSI/SIA A92.6

The following provides requirements regarding their use.

6-13.1 Types of Aerial Lifts.

Aerial lifts include the following types of vehicle-mounted aerial devices used to elevate personnel to job-sites aboveground:

- Extendable boom aerial device.

6-13.2 Aerial Ladder.

- Articulating boom aerial device;

- Vertical tower; or
- A combination of any of the above.

The vehicle may be a truck, trailer, or all-terrain vehicle.

6-13.3 Insulating Versus Non-Insulating.

The aerial device manufacturer must state in the manual and on the instruction plate whether the aerial device is insulating or non-insulating. Insulating device categories are provided in Table 6-3.

Note: Insulating aerial devices do not protect personnel from phase to phase or phase to ground contacts at the platform end. When working from an insulated aerial device the primary source of insulation will be the insulating protective equipment (personal protective equipment, rubber sleeves, live-line tools, and rubber gloves).

Note: Only insulating aerial devices tested and rated for the application and use provided in Table 6-4 are allowed to be used when working on overhead lines.

Table 6-3 Insulating Device Categories

Category	Description
A	Aerial devices designed and manufactured for work in which the boom is considered primary insulation (bare-hand work) must have all conducted components at the platform end bonded together to accomplish equipotential of all such components. Mark devices at the platform indicating such bonding. Equip aerial devices with a lower test electrode system. When these devices are qualified for work above 138 kV, equip them with a gradient control device and conductive shield(s) over the lower test electrode system. For those devices with ratings 138 kV and below, conducting shield(s) over the lower test electrode system are required. The necessity of gradient control device is to be determined by the qualification test.
B	Aerial devices designed and manufactured for work in which the boom is not considered primary insulation, but secondary, such as that using insulating (rubber) gloves. Isolation or bonding of the conductive components at the platform end is not a requirement. Equip aerial devices with a lower test electrode system.
C	Aerial devices designed and manufactured for work in which the boom is not considered primary insulation, but secondary, such as that using insulating (rubber) gloves. Isolation or bonding of the conductive components at the platform end is not a requirement. These aerial devices are not equipped with a lower test electrode system and are designed for 46kV and below.

Note: Bare-hand work is prohibited.

Table 6-4 Application and Uses of Aerial Devices

Category	Bare-Hand	Gloving	Hot Stick*	Construction De-energized
A	X	**	X	X
B	**	X	X	X
C		X	X	X
Non-Insulated			X	X

** Aerial device is used as a work platform*

*** An aerial device manufactured as a Category A may be modified and used as a Category B and a Category B may be modified and used as a Category A. In the event this is done, give particular attention to the appropriate qualification test, gradient control devices, conductive shields, conductive liners, and bonding.*

6-13.3.1 Insulated Buckets.

An insulated bucket of an aerial lift is provided with a non-conductive bucket liner. Support the liner by the inside bottom surface of the basket. Do not provide drain holes or access openings in the insulating buckets.

Tools and other equipment carried in the bucket must be stowed carefully to avoid damaging the non-conductive liner.

6-13.3.2 Testing and Certification.

Establish testing intervals by the owner in accordance with the manufacturer's recommendations and ANSI/SIA 92.2. Intervals are dependent upon component function and exposure to wear, deterioration and other agents which adversely affect component life. Testing and inspection frequencies are shown below. In addition, conduct a dielectric test of the bucket liners annually in accordance with the requirements of ANSI/SIA 92.2, below:

- Frequent Inspection and Test performed at daily to monthly intervals; and
- Periodic Inspection and Test performed at one to twelve month intervals.

ANSI/SIA 92.3, ANSI/SIA 92.5, and ANSI/SIA A92.6, whichever is applicable for the construction, type and manufacture of the lifts, require more frequent inspection, testing and certification as shown below:

- Frequent Inspection performed at 3 month intervals or 150 hours of use, whichever comes first; and

- Annual Inspection performed no later than 13 months from the date of the prior annual inspection.

Note: For the Navy, maintenance and testing requirements follow the requirements of NAVFAC P-300 for aerial lifts and boom trucks.

6-13.3.3 Maintenance.

Perform periodic maintenance in accordance with the manufacturer's operations and maintenance manual. Perform electrical tests on insulation no less than annually in accordance with ANSI/SIA A92.2, to the values referenced in the following tables:

Table 6-5 Periodic Electrical Test Values for Insulating Aerial Devices with a Lower Test Electrode System (Category A and Category B)

Unit Rating	60 Hz (rms) Test			Direct Current Test		
	Voltage	Maximum Allowable Current	Time	Voltage	Maximum Allowable Current	Time
46 kV & below	40 kV	40 microamperes	1 minute	56 kV	28 microamperes	3 minutes
69 kV	60 kV	60 microamperes	1 minute	84 kV	42 microamperes	3 minutes
138 kV	120 kV	120 microamperes	1 minute	168 kV	84 microamperes	3 minutes
230 kV	200 kV	200 microamperes	1 minute	280 kV	140 microamperes	3 minutes
345 kV	300 kV	300 microamperes	1 minute	420 kV	210 microamperes	3 minutes
500 kV	430 kV	430 microamperes	1 minute	602 kV	301 microamperes	3 minutes
765 kV	660 kV	660 microamperes	1 minute	924 kV	462 microamperes	3 minutes

Unit Rating	**Voltage**	**Maximum Allowable Current**		**Voltage**	**Maximum Allowable Current**	**Time**
46 kV & below	40 kV (rms)	400 microamperes	1 minute	56 kV	56 microamperes	3 minutes
20kV and below	20 kV (rms)	200 microamperes	1 minute	28 kV	28 microamperes	3 minutes

Table 6-8 In Field Tests for Insulating Aerial Devices – ANSI/SIA A92.2 Section 5.4.3.2 Item 10(c)

Aerial Device Category	AC Voltage	Maximum Allowable Current	Time of Test
A or B	Line to Ground	1 milliampere / kVAC	3 minutes
A or B	Line to Ground	0.5 microamperes / kVAC	3 minutes
Note: This test may be used as a Periodic Test when the voltage is at least double that of any circuit on which the aerial device is to be used, but not exceeded the Qualifications Voltage of the aerial device.			

Retain all records for the annual and frequent inspections documentation for a period of at least three years for Manually Propelled Elevating Aerial Platforms (ANSI/SIA A92.3), Boom Supported Elevating Work Platforms (ANSI/SIA A92.5), and Self-Propelled Elevating Work Platforms (ANSI/SIA A92.6). Retain written, dated and signed inspection and periodic test reports and records for five years for Vehicle-Mounted Elevating and Rotating Aerial Devices as required by ANSI/SIA A92.2.

6-13.4 General Requirements.

Comply with the following requirements:

- Test lift controls each day prior to use if the lift is being used that day, to determine if the controls are in safe working condition. Test lift controls on a monthly basis when not in use;

- Do not alter the insulated portion of an aerial lift in any manner that might reduce its insulating value;

- Ensure the manufacturer's operation manual is available with any aerial lift;

- Do not allow anyone to touch the truck or equipment when aerial equipment is operating near energized conductors. The vehicle must be grounded, or if not grounded, must be considered as energized and properly barricaded. Ensure that everyone in the vicinity of the truck or equipment is aware of and protected from the hazards of step and touch potential;

- The requirements for use of rubber or other protective equipment while working on poles and structures also apply to work from aerial buckets. Consult UFC 3-560-01 for additional information on rubber protective equipment;

- Use a body harness with a secured safety lanyard for any work from an aerial bucket, basket or platform unless the manufacture of the equipment precludes use of a harness based on the manufacture of the equipment and applicable OSHA standards. Provide arc-rated harnesses in accordance with ASTM F887. Do not belt off to an adjacent pole, structure, or equipment while working from an aerial lift. Use the manufacturer's provided attachment point on the equipment;

- Do not wear climbers while performing work from an aerial lift;

- Wear personnel protective equipment in accordance with UFC 3-560-01;

- Only qualified electrical workers may operate aerial lift equipment within the restricted approach boundary distances specified in UFC 3-560-01;

- Operate any vehicle or mechanical equipment capable of having parts of its structure elevated near energized overhead lines so that a clearance is maintained in accordance with the limited approach boundary limits for exposed movable conductors in Table 3-1 of UFC 3-560-01. However, under any of the following conditions, the clearance may be reduced;

- If the vehicle is in transit with its structure lowered, the clearance may be reduced to 4 ft (122 cm). If the voltage is higher than 50 kV, increase the clearance requirement by 4 in (10 cm) for every 10 kV over that voltage.

- If insulating barriers are installed to prevent contact with the lines, and if the barriers are rated for the voltage of the line being guarded and are not a part of or an attachment to the vehicle or its raised structure, the clearance may be reduced to a distance within the designed working dimensions of the insulating barrier.

- If the equipment is an aerial lift insulated for the voltage involved, and if the work is performed by a qualified electrical worker, the clearance (between the uninsulated portion of the aerial lift and the power line) may be reduced to the restricted approach boundary distances specified in UFC 3-560-01.

- Insulated aerial lifting devices used for working on energized electrical systems must be specifically designed for that sole function. Use the aerial lift only for electrical-related work;

- Stay clear of pressurized oil or air escaping from a ruptured line or fitting. The pump, compressor, or engine must be stopped as soon as a leak is detected;

- All hydraulic and pneumatic tools that are used on or near energized equipment must have non-conducting hoses rated for no less than normal operating pressure;

- Do not exceed the manufacturers' boom and bucket load limits; and,

- Provide both platform (upper) and lower controls for articulating boom and extensible boom platforms, primarily designed as personnel carriers. Upper controls must be in or beside the platform within easy reach of the operator. Lower controls must provide for overriding the upper controls. Controls must be plainly marked as to their function. Lower level controls must not be operated unless permission has been obtained from the worker in the lift, except in case of emergency. All controls must be clearly identified as to their function and protected from damage and unintentional actuation. Design the boom position and carrying attachment controls to return to their neutral position when released by the operator.

Note: The aerial lift may become energized when the boom or the aerial basket comes in direct contact with energized conductors or equipment.

6-13.5 Training.

Train operators in accordance with the manufacturer's operation manual and the applicable ANSI standard. Any ground safety personnel acting as the ground person during the operation of the lift must be qualified and have received training in accordance with the manufacturer's operation manual and the applicable ANSI standard. Operators must also be trained for working from aerial lifts according to OSHA 29 CFR 1910.269, 1910.333(c), and NFPA 70E, Article 130.

Note: Follow the licensing requirements of NAVFAC P-300 for Navy personnel.

6-13.6 Driving Precautions.

Comply with the following requirements:

- Drivers of aerial bucket trucks must be constantly alert to the fact that the vehicle has exposed equipment above the elevation of the truck cab and will be sure that roadways provide the necessary overhead clearance. They must avoid the need to move the truck into the opposing traffic stream by prior planning of the order of work;

- Any backing of the truck must be done slowly and under the direction of one person on the ground. This person must have an unobstructed view of the intended path of the vehicle;

- Do not move a truck with the boom elevated in working position. Secure booms in the cradled position prior to any movement; and

- When traveling to and from job sites, pin-on type buckets must be removed and stored on the truck, or secured in a horizontal position to the boom, to avoid obstructing the driver's vision.

6-13.7 Setting Up and Knocking Down at the Job Site.

Upon arriving at the work area, legally park the truck while the vehicle and pedestrian warning signs, lights, and barricades are being placed. Give careful consideration to the location of overhead conductors and the surrounding conditions before the truck is moved into the work position. Make every effort to place the truck so that all work areas at that location may be reached by the boom without movement of the truck. Perform a job site "tail-gate" safety briefing including application of operational risk management principles.

Note: Air Force Only – Job site "tail-gate" safety briefings including application of operational risk management principles and actions must be documented in writing.

Comply with the following requirements:

- Examine available footing for the truck wheels and outriggers carefully and exercise extra caution if there is snow, ice, mud, soft ground, or other unusual conditions. Blind ditches, manholes, culverts, cesspools, wells, and similar construction features are additional possible hazards;

- Before lowering the stabilizers, outriggers, or hydraulic jacks, the operator must be certain that no persons are close enough to be injured. Wheels must be chocked and cribbing may be needed to ensure stability of the truck body;

- When working on an inclined road or street, check each outrigger or jack to make sure a stable setup has been achieved. The truck must be approximately level as viewed from the rear;

- A warm-up period for the truck is usually needed at the beginning of each day's work. This time must vary with different truck makes and models, and with different temperatures. Follow the manufacturer's recommendations;

- When lowering the boom to a cradled position, workers must stand clear of the path of the bucket and boom; and

- When work is completed, secure aerial ladders in the lower traveling positions by the locking device on top of the truck cab and the manually operated device at the base of the ladder before the truck is moved for highway travel.

6-13.8 Operating at the Job Site.

Comply with the following requirements:

- One worker must be responsible for all operations required in placing the bucket in operating position, use of the bucket, and restoring it to the traveling position. This worker must check to ensure the truck handbrake is set, the wheels of the truck chocked, and if the truck is equipped with outriggers or stabilizers, they are in the down position. If this worker has any doubt as to the stability of the truck, particularly because of the terrain, the outriggers or stabilizers must be specially checked for proper positioning before a load is lifted;

- When the boom must be maneuvered over a street or highway, necessary precautions must be taken to avoid mishaps with traffic or pedestrians. Consider use of a flagman;

- Workers must enter the bucket only with the bucket resting in the position for which entry was designed;

- The operator must face in the direction in which the bucket is moving so that all obstructions are noted and avoided when the bucket or boom is raised, lowered, or rotated;

- The operator must follow the proper sequence prescribed by the manufacturer in raising the boom section;

- Before reaching any area containing obstructions, the operator must test all controls of the boom and bucket to ensure that they are in proper working order;

- The operator must suspend operations upon indication the controls are not working properly;

- Raising the bucket directly above energized conductors or equipment must be kept to a minimum;

- When possible, locate buckets to the side of lines, to help workers aloft avoid contacting energized conductors and equipment;

- If the work is within reach of energized conductors or equipment, a worker must be properly protected with rubber sleeves and rubber gloves of an insulation rating appropriate for the voltage level;

- Energized conductors and equipment must be covered with protective devices when necessary to perform the work safely;

- Adequate clearance must be maintained so that protruding tools must not come in contact with conductors, tree limbs, or other obstructions;

- A worker must always stand on the floor of the bucket. Never on top of the bucket or on planks placed across the top of the bucket, or tools/materials within bucket while performing work. Do not alter buckets to facilitate additional reach;

- A worker must not belt onto an adjacent pole, structure, or equipment while performing work from the bucket;

- The operator must ensure that hand lines and tools do not become entangled with the levers that operate the boom; and

- Secure all tools not in use when working aloft.

When the bucket is being used in any manner that might result in contact between an energized conductor and the bucket, boom, or any attachment thereto, the vehicle must be considered energized at line potential, and the following safe practices observed for ground operations:

- Materials or tools must not be passed between a worker on the vehicle and a worker on the ground, unless both workers wear rubber gloves and use other required protective devices;
- Workers operating ground controls must be on the vehicle or insulated from the ground using rubber gloves and other protective equipment;
- Before entering or leaving the vehicle, a worker must make sure that the boom or bucket is not in contact with or near energized equipment;
- Workers on the ground must not work directly below the work area of the bucket; and
- Tools or materials must not be thrown to or from the elevated bucket.

6-13.9 Aerial Lift Equipment Operation near Energized Electrical Equipment.

Only qualified electrical workers may operate aerial lift equipment between the approach distances given provided in UFC 3-560-01. Comply with the following requirements:

- An approved Job Hazard Analysis (JHA) and Standard Operating Procedures (SOP) must be completed;
- The activity is being performed under the direct supervision of a designated person who is trained and competent in this type of work;
- The distances between energized parts and the aerial lift equipment is monitored while the aerial lift equipment is being moved and or repositioned;
- The aerial lift equipment is grounded; and
- No one, other than necessary workers, is allowed within 10 ft (3.0 m) of the equipment during its operation. Workers are to perform their work while on the equipment, not from a position on the ground.

6-14 TREE TRIMMING AND BRUSH REMOVAL.

Tree trimming and brush removal is necessary to maintain the integrity of electric lines and apparatus and provide right-of-way clearance.

6-14.1 Training Qualifications.

Permit only workers certified as “Qualified Climbers” to climb trees. Work accomplished from an aerial lift must only be performed by workers qualified in use of the aerial lift. If using ladders, review the requirements for their safe use. In all cases, only qualified workers must perform work near energized lines.

Trimming must be done in a manner that does not damage the tree, and meets ANSI Z133.1 requirements. The worker must be qualified to do tree trimming.

6-14.2 Public Safety.

Erect suitable signs and barriers to prevent the public from passing under trees being trimmed, and to prevent stumbling over brush on the ground. Brush must not be piled on sidewalks, or left on streets and highways overnight.

6-14.3 Tool Safety.

Raise and lower tools with a hand line. Use only saws and pruning knives or shears for cutting limbs. Do not carry unnecessary tools up the tree. Do not hang or store tools on tree limbs.

6-14.4 Work Near Energized Lines.

Be aware that lines may not always be de-energized for tree trimming operations. Review the rules for live line safety, and for climbing and working on a pole. Especially be aware of the energized lines in the area and the relevant dangers.

When working near energized lines, arrange the safety line so that a slip or fall will carry you away from the energized lines.

6-14.5 Climbing and Working on Trees.

Comply with the following requirements:

- Workers in trees must use harnesses/belts and safety straps;
- Climbing trees must be avoided unless ladders or aerial lifts cannot provide the necessary access;
- Workers in trees must be careful to prevent contact with aerial electric and telephone wires passing through the trees;
- If climbers are used, make sure they are tree climbers approved for the bark thickness of the tree being climbed. Never use pole climbers;

- Use a harness and safety strap or lifeline. Place the strap around a tree limb of sufficient size to hold the worker's weight, but never around the tree limb being cut;

- Do not stand on tree limbs too small to support your weight. Extreme care must be exercised when working in trees that have brittle wood; and

- Check each tree for dead or broken tree limbs when climbing. Remove unsound tree limbs during the climb. Lower cut-off tree limbs with a rope because falling tree limbs can cause injury or property damage.

6-14.6 Felling Trees.

Before felling trees, inspect tools to be used (such as ropes, tackle, ladders, and chain saws) to ensure they are in proper condition. Place signs warning pedestrian and vehicular traffic of the danger from work being performed. Station flagmen if necessary.

Inspect each tree for obstructions (conductors and fences) in the line of fall. If possible, de-energize nearby conductors. Trees taller than 25 ft (7.6 m) in height and larger than an 8 in (203 mm) trunk diameter must have ropes attached before felling. The ropes can be used to guide the tree as it falls. Always have a clear a path of retreat when felling a tree.

6-14.7 Power Trimming Equipment.

Chain-saw operators must be familiar with and follow the manufacturer's operating instructions. Comply with the following requirements:

- Carefully inspect chain saws prior to each use. Chain saws must be clean and sharp, and in sound mechanical condition with all guards, spark arresters, mufflers, handles, and other items properly installed and adjusted;

- Permit only workers trained in chain saw operation to perform the work;

- Clear away brush or other material that might interfere with cutting operations before starting to cut;

- Wear appropriate personal protective equipment when operating the chain saw. Eye, ear, hand, foot, and leg protection are minimum requirements;

- Never operate a chain saw when physically tired or under the influence of alcohol, medication, or other drugs;

- Do not store fuel near flammable materials. Fuel for chain saws must be stored in approved, vented containers clearly marked to show the contents;

- Do not start the chain saw within 10 ft (3.0 m) of a fuel container; and

- Do not fuel the chain saw with it running or hot, or with open flame nearby.

6-14.8 Right-Of-Way Brush Removal.

Brush clearance is part of electrical maintenance work to clear right-of-ways. Comply with the following requirements:

- Wear personal protective equipment; i.e., eye protection, hearing protection, and proper clothing;

- Cutters felling heavy brush or small trees must give sufficient clearance to other personnel. Never work so close that one worker could injure another with a swinging ax or hook;

- Brush chippers must be operated only when authorized. The worker must stand to the side of the chipper chute while feeding the butt end of brush into the chipper first. Use the automatic shut-off/stop control at the operator's station in an emergency;

- Do not hang tools such as saws, axes, bush hooks, pruning shears, scythe blades, and pitch forks in bushes or small trees, or out of the obvious view of other workers; and

- Restrict personnel assigned to remove or pile brush to maintain a safe distance behind workers using the cutting tools.

6-15 WORKING NEAR COMMUNICATIONS ANTENNAS.

If personnel work near communications antennas that are attached to electric power line structures, apply IEEE Std 1654 as a guide for the safety requirements.

CHAPTER 7 OUTAGES

7-1 TROUBLESHOOTING AND FAULT DETECTION METHODS.

Troubleshooting procedure:

- Install fault detectors
- Determine fault type
  - Open Conductor Fault – cable completely broken or interrupted at the location of the cable fault.
  - Shorted Fault – low resistance continuity path to ground.
  - High Impedance Fault – resistive path to ground (shunted fault) that is large in comparison to the cable's surge impedance.
- Test the cable
  - Fault Resistance and Loop Test – Insulation Resistance Insulation tester
  - TDR (Test Domain Reflectometer) Test
  - DC High Potential Test – surge generator connected to cable under test
  - Bridge Method
- Analyze the data
- Localize – Pre-locate the fault
- Locate – Pinpoint the fault

For cable failures, test to determine which cables to replace first:

- Insulation breakdown (water / trees). RF Test-point Injection Probing:

  Step 1: Couple an RF signal through elbow test-points;

  Step 2: Experimentally confirmed coupling greater than 1MHz signal; and

  Step 3: Measure attenuation, velocity of propagation as a function of instantaneous cable voltage. The mechanisms: at cable voltage V=0 the voids filled with water in the water tree are not connected and at higher voltage, micro-channels open due to Maxwell Mechanical Stresses and water will penetrate the channels making electrical contact.

- Loss of protective grounding shield - concentric neutrals (CN). Detected imbalances or lack of CN current as a sign of degradation:
  - Magnetic CN probing - measure current in concentric neutrals by sensing emanating magnetic field.
  - Anisotropic Magnetic Resistance (AMR) - measure return or phase imbalance currents (10%-20%).

7-2 FAULT ANALYSIS.

Fault in a circuit is any failure that interferes with the normal system operation:

- Lightning strikes cause most faults on high-voltage transmission lines producing a very high transient that greatly exceeds the rated voltage of the line:
  - This voltage usually causes flashover between the phases and/or the ground creating an arc.
  - Since the impedance of this new path is usually low, an excessive current may flow.
- Transient faults are faults involving ionized current paths. They usually clear if power is removed from the line for a short time and then restored:
  - Approximately 75% of all faults in power systems are transient in nature.
- Permanent faults where one, two or all three phases break or insulators break due to fatigue or inclement weather are faults that remain after a short removal and restoration of power.

Knowing the magnitude of the fault current in a power system is important when selecting protection equipment (type, size, etc.). Type of faults:

- Symmetrical three phase (3P) – symmetrical fault when, before the fault only AC voltages and currents are present, but immediately after the fault a transient DC component is added on top of the symmetrical AC component;

- When the fault occurs, the AC component of current jumps to a very large value, but the total current cannot change instantly because of the series inductance of the machine.
- The transient DC component is just large enough such that the sum of AC and DC components just after the fault equals the AC current just before the fault.
- The DC components decay quickly, but they initially average about 50-60% of the AC current flow the instant after fault occurs.
- There are three periods of time:
  - Sub-transient period – first cycle or so after fault – AC current is very large and falls rapidly; current can be as much as 10 times the steady-state fault current.
  - Transient period: current falls at a slower rate; current is often 5 times the steady-state fault current.
  - Steady state period – current reaches its steady value.

- Single line-to-ground (SLG) unsymmetrical fault;
- Line-to-line (LL) unsymmetrical fault; and
- Double line-to ground (DLG) unsymmetrical fault.

7-3 DOCUMENTING/REPORTING.

Documentation and reporting must be performed according to National Testing Standards (NTS). This means recording problems or failures, reasons for these problems, time to repair, costs both in materiel and labor, and suggestions to avoid future problems of the same type. Check with Activity lead office for specific outage reporting requirements. Suggested report data items include:

- Installation name;
- Incident date and time;
- Area(s) affected by outage;
- Reset date and time;
- Outage duration;
- Name of operator in charge;

- Name of person who re-set the switchgear, relay, or PLC;
- Name of person making report;
- List of contractors or personnel doing permitted work on electrical system at time of outage. Attach copies of permit(s) to the report;
- Switchgear relay readings;
- Amperage and voltages at time of outage, if possible;
- Primary alarms and outage as determined by PLC, SCADA, or switchgear;
- List outage cause(s), failed equipment, and specific failure locations;
- Implemented remedy to return to power;
  - Was damage found prior to reset, or determination of cause? (y/n);
  - Was damage fixed or isolated prior to re-energizing? (y/n);
- Estimated outage cost (labor and equipment); and,
- Suggested system or procedural modifications to make future outages less likely.

7-4 SCHEDULING AND PLANNING.

Outages consist of unplanned and planned (scheduled) events. An unplanned outage is where equipment is unexpectedly taken out of service for a variety of reasons, from weather events to grid overload. Return to service depends upon severity of outage and the resources available to evaluate and correct the failure.

A planned outage is where the equipment is taken out of service on a pre-established schedule, such as for maintenance actions or construction. Control outage costs by properly planning, sequencing, and executing the system switching and cutovers. Consider the following when planning an outage:

- Create a checklist of everything to consider before shutdown and when to consider it. Include in checklist the field verification of as-built system(s), including CT and PT ratios, conductor size and length, conductor insulation types, 100% or 133% insulation levels, and insulation temperature level MV-90 or MV-105, relay make/model/settings, breaker make/model/short circuit rating, and switchgear make/model/bus rating/short circuit rating.

- Ensure the proper tools, supplies, and technologies are available and on hand to execute the outage and accomplish the scheduled work.
- Establish good contractor relations and communication avenues for normal and emergency discussions.
- Clearly define expected contractor and in-house actions, and timing of actions, to establish an effective workflow. Review high-risk areas and update actions if planned conditions change.
- After outage is completed, evaluate shutdown effectiveness, and update procedures and checklists for future outages.

This Page Intentionally Left Blank

CHAPTER 8 POWER SYSTEM STUDIES AND COMPUTER MODELS

8-1 TOOLS, DATA AND DEVELOPMENT.

8-1.1 General Process.

Maintain a power system study for the primary distribution system. The power system study includes the following:

- Field verification of as-built system configuration including CT ratios, PT ratios, conductor size, conductor insulation type, 100% or 133% insulation level, and insulation temperature level MV-90 or MV-105, conductor length, relay make/model/settings, breaker make/model/short circuit rating, and switchgear make/model/bus rating/short circuit rating;
- Development of electrical layout and one-line drawings for the primary distribution system;
- Electrical analysis of the system; and
- Identification of recommended system changes and upgrades.

The various electrical analyses, referred to as a power system study, provide design confirmation of the inherent ability of the electrical power distribution system to perform reliably under normal and abnormal conditions. A power system study includes:

- Power flow;
- Short circuit;
- Arc flash;
- Electrical protection and coordination; and
- Specialty analyses, such as power quality or Aurora evaluation.

8-1.2 UFC 3-501-01 Requirements.

UFC 3-501-01 provides detailed requirements for electrical analyses and compliance is mandatory for the design of electrical systems at all facilities and installations. Upgrades or modifications to electrical systems to consider the design criteria in UFC 3-501-01, but it is not intended that an entire facility or system require modernization solely because of a minor modification.

Although UFC 3-501-01 does not specifically apply to an existing primary distribution system, apply its power system analysis criteria for exterior power distribution systems as supplemented by this UFC.

8-1.3 Software Requirements.

Specify the analysis software required for the power system study. If the power system study is provided by a contractor, require the contractor to provide the electronic software files with each submittal.

For the Air Force, only EasyPower is certified in accordance with AFI 33-210 for use on standard desktop systems connected to the Air Force Global Information Grid and placed on the Air Force Evaluated/Approved Products List. Other software products can be used on standard desktop systems connected to the Air Force Global Information Grid after they have been certified in accordance with AFI 33-210 and placed on the Air Force Evaluated/Approved Products List.

If the Activity has electrical analysis software, maintain the software at the latest available version. The latest software version is required for the following reasons:

- Electrical analysis software is not backwards compatible. Any models or revisions to models developed by contractors cannot be opened by an older version of the software; and
- The arc flash analysis requirements continue to evolve. The latest version of the software is required to ensure that any arc flash calculations comply with the current state of the art with respect to analysis methodology.

8-1.4 Periodic Updates.

Upon completion of an initial power system study, update the study as follows:

- Complete a new power system study every six years;
- Update the power system study when significant changes occur to the system. Examples of changes that require an update include;
  - Substation or switching station replacement.
  - Modification of utility transmission system supply.
  - Primary distribution system upgrade, such as conversion of one or more feeders from overhead distribution to underground distribution.
  - Major change to facilities within a base, such as construction of multiple facilities in support of a new mission;
- Update the power system study when significant changes occur to the industry standards that form the analytical basis for analysis. For example, an arc flash calculation will require an update if the equations

used for the analysis are changed by the applicable industry standards; and

- Complete an annual review of the electrical model when the annual electrical drawing review described in Section 3-9 is performed and update the model as necessary to reflect the existing electrical distribution system.

Note: Changes to the electrical distribution system require evaluation in accordance with UFC 3-501-01.

8-2 MODELING.

8-2.1 Equipment Naming Conventions.

Equipment naming is considered an important part of the base-wide electrical safety program. Civilian personnel, military personnel, and contractors should have no doubt regarding their work location and which equipment to work on. Coordinate with base personnel to develop a standardized naming convention for the following equipment:

- Substation equipment, including feeder designations;
- Transformers – pole mount and pad mount;
- Pad-mounted switchgear;
- Sectionalizing cubicles;
- Power poles; and
- Manholes.

8-2.2 Equipment Modeling.

Develop an electrical model of the primary distribution system that includes the following system elements as applicable for the system design:

- All utility connection points for the supply to the primary distribution system. Obtain the following from the utility for each connection access;
  - Three-phase short circuit current and associated X/R ratio.
  - Single line to ground short circuit current and associated X/R ratio.
  - Request minimum and maximum values for each short circuit type. If the variation between minimum and maximum short circuit values

has a significant effect at the primary distribution level, then provide calculations at both extremes.

- Substation equipment, including transformers, switches, circuit breakers, capacitors, and associated protective devices;
- Electrical system conductor type, size, and length – overhead and underground;
- Overhead distribution – all power poles that contain electrical equipment, lateral taps, or conductor size changes;
- Pad-mounted switchgear, including VFI settings or fuse sizes;
- Sectionalizing cubicles;
- Distribution transformers, including primary conductors from the upstream source and secondary side conductors to the service entrance equipment; and
- If the Activity is supplied by a prime power plant, include the prime power plant generators in the model and address the minimum and maximum numbers of generators that are expected to be in operation.

Identify missing data as part of the power system study and document assumptions made to complete the analysis. Examples of missing data include:

- Distribution system transformers with missing nameplates;
- Pole-mounted transformer nameplates – inaccessible without the use of lift equipment and likely corroded by outdoor exposure;
- Fuse size for internal fuses in distribution system transformers or some pad-mounted switchgear that cannot be confirmed without requiring extensive system outages;
- Size and type of aerial lines – might depend on available drawings and knowledge of exterior shop personnel; and
- Size and type of some underground lines – might depend on available drawings and knowledge of exterior shop personnel.

8-3 POWER FLOW.

8-3.1 Overview.

A power flow analysis is commonly called a load flow analysis; the terms are used synonymously. A power flow analysis determines voltages and power flow throughout the electrical system and provides insight into many aspects of system performance, including:

- Adequacy of voltage levels throughout the system;
- Current flow through all branches of the system;
- The ability of generators to supply required load without exceeding their rating;
- The ability of system equipment (such as switchgear, panels, transformers, or cables) to carry the required load without exceeding any ratings;
- Inappropriate or low reliability system lineups, including an evaluation of cross-connect and alternate feed capability;
- System expandability and choke points for load addition; and
- Equipment sizing and rating specifications for new/replacement equipment.

A power flow analysis includes an evaluation of system performance under various conditions and operating modes. Different conditions of interest might include:

- Cross connect capability between the feeders (partial or full);
- Proposed load additions;
- System changes involving re-powering loads from a different feeder (load re-balancing); and
- Variations in transformer tap settings.

8-3.2 Metering Data.

8-3.2.1 Utility Metering Data.

Obtain metering data from the utility, if applicable, for each metered location. The preferred format includes real and reactive power obtained at 15-minute intervals for a period of several years. The purpose of this data is to establish peak power demand and when peak power occurs for each metered location.

8-3.2.2 Primary Distribution System Metering Data.

If the electrical system design includes metering or recording of the current on each distribution circuit, obtain this data to help establish the power demand on each circuit.

Note: If metering data is available from an installed Advanced Meter Infrastructure (AMI) system, obtain the trended load data as an input to the power system study.

Note: If primary distribution system power demand data is available from an Industrial Control System (ICS) with feeder metering, obtain the historical trended load data as an input to the power system study.

8-3.3 System Electrical Measurements.

Obtain electrical measurements, including voltage, current, power factor, voltage harmonic distortion, and current harmonic distortion, at accessible locations in the primary distribution system. Use collected data to accurately match replacement equipment to actual facility loads.

Note: The intent of this requirement is to establish, wherever possible, the typical system load. Power system studies performed at over 50 Air Force Bases have validated that the average transformer loading is about 20% to 25% of rated value during periods of peak demand. For example, if an Air Force Base has a summer peak demand of 20,000 kVA, the total connected transformer kVA might be as much as 100,000 kVA. When replacing transformers, size for actual system loading to reduce potential arc flash incident energy levels.

Note: Low-voltage measurements can often be taken on the secondary side of distribution transformers. Medium-voltage measurements can often be taken at some pad-mounted switchgear or sectionalizing cubicles.

8-3.4 Power Flow Analysis.

Perform a power flow analysis that accomplishes the following:

- Provides an assessment of peak demand on each distribution feeder;
- Identifies any ampacity limitations throughout the electrical system;
- Calculates voltage drop throughout the electrical system;
- Identifies any unusual system voltage associated with off-nominal transformer tap ratios;

- Include emergency power load flow analysis scenarios in the power flow model;

- Include alternate feeder load flow analysis where switching paths allow alternate load flow scenarios; and

- Include any prime power generation capability, including renewable energy sources.

8-3.5 Cross-Connect Analysis.

A cross-connect analysis is an extension of a power flow analysis and evaluates the capability of each system cross-tie location. Identify any ampacity or voltage drop limitations associated with each cross-tie location.

8-4 SHORT CIRCUIT ANALYSIS.

8-4.1 Overview.

A short circuit analysis provides a means to evaluate the following aspects of a power system:

- The ability of system distribution equipment (such as switchgear, cables, disconnect switches, panels, motor control centers, or bus ducts) to withstand the available fault current without damage;

- The ability of system protective devices (e.g.;, circuit breakers, fuses) to successfully interrupt a fault without failing;

- The adequacy of electrical protective device settings and sizes;

- System lineups that result in unacceptable levels of fault current; and

- Baseline fault current levels (maximum and minimum) for calculating arc flash energy levels.

Short circuit current levels for several types of faults are generally evaluated during a short circuit analysis, including:

- Three phase bolted fault – all three phases of a three-phase system short together with no appreciable fault impedance (generally produces the highest available fault currents and always produces the most fault energy);

- Phase-to-ground fault – one phase of a three-phase system shorts to ground (also called a line-to-ground fault or ground fault);

- Phase-to-phase fault – two phases of a three-phase system short together (also called a line-to-line fault); and

- Phase-to-phase-to-ground fault – two phases of a three-phase system short together and to ground simultaneously (also called a double line-to-ground fault).

8-4.2 Short Circuit Results.

Provide short circuit results for each bus in the system, including X/R ratio at each location. Provide short circuit results throughout the primary distribution system and extending to the service entrance bus of each facility. As a minimum, include three-phase and single line to ground faults in the power system study.

8-4.3 Equipment Duty Evaluation.

All equipment exposed to the short circuit current must be capable of withstanding the mechanical and thermal stresses caused by the current until the short circuit is isolated. Identify any equipment that is potentially exposed to a short circuit current that exceeds its interrupting rating.

8-5 ARC FLASH ANALYSIS.

8-5.1 Analysis Criteria.

Perform an arc flash analysis in accordance with UFC 3-501-01. Use the following criteria:

- Apply IEEE Std 1584 and IEEE Std 1584.1 for voltages below 15 kV;

- Apply IEEE C2 for overhead distribution above 15 kV; and

- Apply the equations referred to in NFPA 70E, Informative Annex D for pad-mounted equipment for voltages above 15 kV.

  Note: Electrical analysis software automatically defaults to these equations above 15 kV.

Test all the protective devices involved in the analysis to ensure that they are functioning properly and have not deviated from the design settings. If deviations are found, the protective devices must be retested and serviced as described in the manufacturer’s instructions.

8-5.2 Arc Flash Labels.

Provide arc flash labels in accordance with UFC 3-560-01.

8-5.3 Maintenance and Testing Requirements.

An arc flash calculation result is based on the correct time-current response of an upstream protective device. If the following types of equipment are credited for clearing an arcing fault as part of an arc flash study, the equipment must have commissioning performed in accordance with NETA ATS, if new; and, periodic maintenance and testing performed in accordance with NETA MTS or NFPA 70B, if existing:

- Medium voltage power circuit breakers;
- Medium voltage pad-mounted switchgear;
- Low voltage power circuit breakers;
- Overcurrent protective relays;
- Switchboards and panel boards – main circuit breaker at each location and all circuit breakers rated for 225 amperes, or higher (molded case circuit breakers and insulated case circuit breakers); and
- Electronic trip units associated with the above equipment.

Refer to NETA MTS and NFPA 70B for the maintenance and test frequency.

8-6 ELECTRICAL COORDINATION.

8-6.1 Overview.

A properly protected and coordinated system will:

- Rapidly isolate a faulted circuit at the closest possible point upstream of the fault, while minimizing disruptions to unaffected portions of the system;
- Minimize damage to the faulted circuit or equipment by rapidly removing it from service;
- Minimize the possibility of damage to equipment upstream of the fault that “sees” the fault current, but is otherwise unaffected; and
- Minimize the possibility of catastrophic equipment failure, fire, and personnel hazards.

8-6.2 Coordination System Study Documentation and Criteria.

Ensuring proper electrical protective device settings is important to maintaining a reliable and safe electrical power distribution system. Document coordination studies in accordance with UFC 3-501-01. Include protective device settings and fuse sizes in the documentation.

Apply the coordination criteria listed in Table 8-1. The criteria apply to the following:

- Overcurrent relays;
- Recloser control units;
- Pad-mounted switchgear containing vacuum fault interrupter (VFI) trip units;
- Pad-mounted switchgear containing fuses;
- Overhead distribution fused cutouts;
- Low voltage circuit breaker electronic trip units;
- Low voltage circuit breaker thermal-magnetic trip units; and
- Low voltage fuses.

Table 8-1 Electrical Protection and Coordination Criteria

Upstream Device	Downstream Device	Criteria
Relay or Recloser	Relay	A minimum margin of 0.4 seconds between time-current (TC) curves in the time delay region. No overlap between the TC curves for instantaneous elements with 10% margin.
Relay or Recloser	Switchgear Breaker and Fuse	A minimum margin of 0.3 seconds between the TC curve and the switchgear breaker/fuse curve in the time delay region. No overlap between the TC curves for instantaneous elements with 10% margin.
Switchgear Breaker	Switchgear Breaker	No overlap between TC curves. All tolerances are accounted for in the curves.
Fuse	Fuse	Total clearing time of downstream fuse must be below the minimum melt time of upstream fuse. Alternatively, the average clearing times of the fuses must not overlap with a 10% margin applied to each fuse. Alternatively, the I^2t of the downstream fuse must be lower than the I^2t of the upstream fuse. The I^2t requirement is considered satisfied if fuse manufacturer's selectivity ratio is maintained.
Fuse	MCCB	No overlap between MCCB TC curve and minimum melt time curve for fuse. Alternatively, no overlap between MCCB TC curve and average clearing time curve for fuse with 10% margin. No coordination above intersection of fuse TC curve and MCCB instantaneous curve.
MCCB	Fuse (Non-Current Limiting)	Total clearing time of fuse must be below the minimum trip time of breaker in the time delay region. Alternatively, the fuse average clearing time must be below the minimum trip time of breaker with 10% margin. Maximum fault current sensed by MCCB must be limited to below the MCCB instantaneous pickup.
MCCB	Fuse (Current Limiting)	Total clearing time of fuse must be below the minimum trip time of breaker in the time delay region. Alternatively, the fuse average clearing time must be below the minimum trip time of the breaker with 10% margin. Peak let-through current of fuse must be below the MCCB instantaneous pickup.
Transformers		Protective device must clear the fault before the transformer damage curve is exceeded. Conservatively use frequent fault damage curves. Upstream protective device setting must allow for transformer inrush without nuisance trip.
Cables		Protective device must clear the fault before cable I^2t damage curve is exceed.

Refer to the following appendices for additional guidance:

- Appendix C – recommended fuse sizes for overhead distribution and pad-mounted switchgear fusing; and
- Appendix D – recommended pad-mounted switchgear vacuum fault interrupter (VFI) trip settings.

8-6.3 Coordination System Study – Substations and Switching Stations.

Model all protective devices. Determine the required protection settings and confirm acceptable coordination and protection for the primary distribution extending from the utility supply to the substation, and from there to downstream distribution system equipment. This includes:

- Utility supply coordination with substation primary side relaying;
- Differential protection for transformers and buses;
- Reverse power protection, if installed;
- Main circuit breaker secondary side transformer overload protection;
- Main and feeder circuit breaker coordination;
- Main and cross-tie circuit breaker coordination; and
- Feeder circuit breaker coordination with downstream primary distribution system equipment.

8-6.4 Circuit Breaker Instantaneous Trips.

8-6.4.1 Main Circuit Breaker.

Do not specify instantaneous trips on main circuit breakers unless justified in the coordination study analysis. Main circuit breakers function as backup protective devices for the feeder circuit breakers and should not trip for a feeder fault unless the feeder breaker fails to trip.

8-6.4.2 Feeder Circuit Breaker.

The decision of whether or not to include an instantaneous trip on a particular feeder circuit breaker relay depends on 1) the downstream devices with which it has to coordinate, 2) the line length, 3) the presence of automatic circuit breaker reclosing and 4) the need for coordination with downstream overcurrent protective devices. Depending on the circuit design, it might be very difficult to coordinate with downstream fusing or vacuum fault interrupter trip units unless an instantaneous trip is set very high or is disabled. Apply the following criteria:

- Provide instantaneous trips for circuit breakers supplying predominantly overhead distribution when automatic circuit reclosing is applied;

- Disable instantaneous trips for underground distribution circuits that include downstream pad-mounted switchgear fusing or vacuum fault interrupter trip units. Select circuit breaker trip time delays to coordinate with downstream protective devices; and

- Instantaneous trips can be provided for distribution circuits that supply a single facility.

8-6.5 Feeder Circuit Breaker Relay Settings for Underground Distribution.

Apply IEEE C37-230 to distribution lines as a guide for system protection. Evaluate the specified settings with downstream pad-mounted switchgear fuse sizes or vacuum fault interrupter (VFI) trip settings. Adjust settings for all protective devices as needed to optimize coordination for each distribution feeder.

8-7 AURORA ANALYSIS.

Aurora is a term applied to a particular type of power system vulnerability in which rotating electrical equipment (motors and generators) is deliberately subjected to opening breakers and closing them out of synchronism with utility frequency. The induced mechanical and electrical stresses results in equipment exceeding maximum torque limits and equipment damage/failure.

Assess each Activity regarding its Aurora vulnerability. Figure 8-1 summarizes the Aurora evaluation process. Ensure mission critical motors and prime power-capable generators are specifically evaluated during the assessment. Update assessment and protective measures whenever new critical equipment is installed.

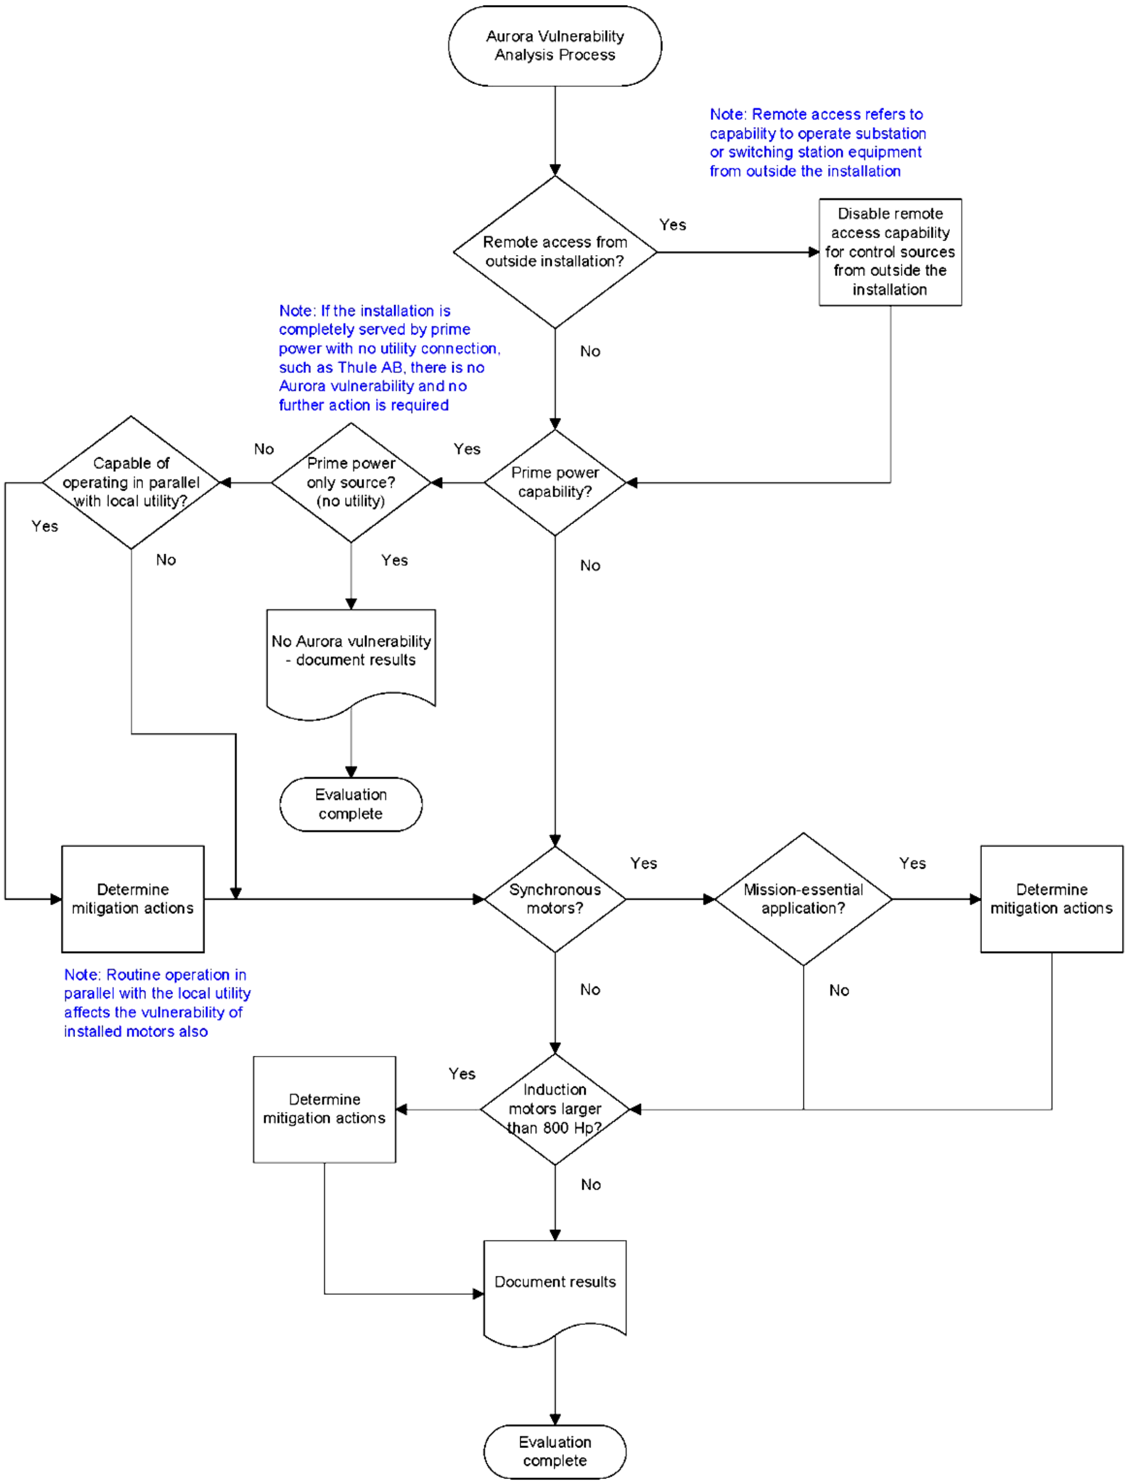
If an evaluation determines that a vulnerability exists, provide recommendations regarding protection methods. Protection options include a combination of:

- Adding protective devices designed to detect an Aurora event and isolate vulnerable systems and equipment before damage can occur. Known protective devices include the Schweitzer SEL-700G Generator Protection Relay, SEL-751A Feeder Protection Relay, and the Cooper Rotating Equipment Isolation Device (REID);

- Ensuring Activity utility control system is isolated from exterior communication networks; and

- Maintaining a strong password/access control protocol to Activity utility control network/software.

Figure 8-1 Aurora Vulnerability Assessment Flowchart



CHAPTER 9 POWER AVAILABILITY/RELIABILITY/RESILIENCY

9-1 METRICS.

The metrics for a power system include outages, time of outages, lengths of outages, time between outages and power quality (which in itself requires voltage, frequency, harmonics, and power factor).

9-2 POWER QUALITY.

Power Quality is the concept of powering and grounding electronics equipment in a manner that is suitable to the operation of the equipment and compatible with the premise wiring system and other connected equipment. A high level of power quality is generally understood as a low level of power disturbances; however, a high level of equipment tolerance may also be an effective solution. Power quality can be a broad concern depending upon the end user or mission perspective, ranging from voltage interruption, sags, transients and harmonics and/or current transients and harmonics that negatively affect utilization equipment. Understanding the implied definition by the end user will assist in determining what the root cause of the disturbance is and what/where monitoring should take place.

Evaluate power quality in accordance with IEEE 1159. Apply IEEE 519 for the evaluation of harmonic distortion limits.

9-2.1 Monitoring.

Power Quality Monitoring (PQM) generally involves line voltage sags, interruptions, voltage swells, and transients (generally short duration, high frequency voltage fluctuations). PQM can also include analysis of harmonic waveforms and grounding systems. During PQM, special attention is paid to time, duration, location, and magnitude of both voltage and current waveforms with respect to each and other system disturbances or characteristics such as capacitor switching.

9-2.2 Harmonics.

Harmonics are rarely an issue. Harmonics, by definition, is a sinusoidal component of a periodic wave or quantity having a frequency that is an integral multiple of the fundamental frequency.

Harmonics are generally a negative consequence to having non-linear loads. Typical harmonic “generators” are:

- Converters;
- Arc Furnaces;
- Static VAR Compensator;

- Inverters for Dispersed Generation;
- Electronic Phase Control;
- Switched Mode Power Supply (i.e. Computer Power Supplies);
- Pulse Width Modulation; and
- Electronic Ballasted Lighting.

These harmonic effects can cause:

- Current harmonics cause an increase in copper (conductor) losses and stray flux losses. As a result, neutral conductors and transformers can experience excessive heating, beyond what they are rated for. De-rating of electrical equipment or the use of K rated transformers, designed to handle the harmonic contribution, are differing approaches;
- Current harmonics can also cause issues with circuit breakers tripping because of reaching thermal limits. In addition, Total Harmonic Distortion (THD) levels greater than 10% may affect relay / breaker operation;
- Voltage harmonics cause an increase in iron losses within the transformer; and
- Voltage harmonics may cause the premature failure of switchgear insulation.

9-2.3 Voltage Unbalance.

Voltage unbalance is rarely an issue. Low or high voltage might be an issue, but usually not voltage unbalance unless a single-phase voltage regulator has failed.

- Voltage unbalance in a three-phase system takes place when the magnitudes of phase or line voltages are different and the phase angles differ from the balanced conditions, or both.
    - Voltage unbalance is defined as the ratio of the negative sequence voltage component to the positive sequence voltage component.
- Variations in single-phase loading cause the currents in the 3-phase conductors to be different, producing different voltage drops and causing the phase voltage to become unbalanced.
- When unbalanced phase voltages are applied to 3-phase motors, the phase voltage unbalance causes additional negative-sequence currents to circulate in the motor, increasing the heat losses primarily in the rotor.

9-2.4 Phase Current Imbalance.

Phase current imbalance describes a common condition that can cause a distribution line fuse to blow if a phase is unbalanced in relation to current on the other two phases. Connect distribution system single phase loads such that a balanced condition exists between the three individual phase currents.

9-3 PERFORMANCE AND EVALUATION.

Performance and evaluation of an electrical distribution system generally focuses on the service quality. The two aspects of service quality are power quality and system reliability. Power quality is discussed in Chapter 9. System reliability is evaluated at a number of levels:

- Utility Supply: Reliability of incoming power is of paramount importance to the end user or mission. There are numerous acceptable Reliability Indices. The three major time indices are:
  - System Average Interruption Frequency Index (SAIFI),

    $\boldsymbol{SAIFI} = \sum(N_i) \; / \; N_T$

    Where,

    Σ = Summation function.

    N_i = Total number of customers interrupted.

    N_T = Total number of customers served.

  - Customer Average Interruption Duration Index (CAIDI), in minutes;

    $\boldsymbol{CAIDI} = \sum(r_i * N_i) \; / \sum(N_i)$

    Where,

    Σ = Summation function.

    r_i = Restoration time, in minutes.

    N_i = Total number of customers interrupted.

  - System Average Interruption Duration Index (SAIDI), in minutes,

    $\boldsymbol{SAIDI} = \sum(r_i * N_i) \; / \; N_T$

    Where,

Σ = Summation function.

r_i = Restoration time, in minutes.

N_i = Total number of customers interrupted.

N_T = Total number of customers served.

- Configuration: Typically represented by one-line diagram or system map.

- Control and Protection: The one-line diagram to contain all the protective devices of the system. Utilize this to perform a protective device coordination analysis as directed by IEEE 242.

- Physical Installation: A thorough inspection of the physical condition of a (mission's) distribution system can be utilized, hopefully on a continual basis, to improve reliability. All systems serving critical loads or process should be part of a comprehensive preventive and predictive maintenance (PPM) program, which combines periodic visual inspections of equipment with mechanical and electrical testing to identify and correct deteriorating conditions before they result in unscheduled outages. Guidelines for inspection and testing of electrical equipment can be found in the relevant IEEE and ANSI standards documents, in published data, in NFPA 70B, and in the standards of the International Electrical Testing Association.

- Operations and Maintenance: Mentioned earlier that an effective PPM program is important in achieving the designed-in reliability of critical power systems, this is only one of many aspects of Operations and Maintenance that can impact reliability. Other considerations include commissioning, training, documentation, and spare parts stocking.

9-4 PREDICTIVE ANALYSIS.

Predictive analysis is based upon metrics and past documentation as a worst-case, and extrapolated using reliability factors in IEEE Std 493 (Gold Book) for a prediction of future problems. By following recommended maintenance procedures, a substantial amount of failures can be avoided.

CHAPTER 10 PHYSICAL SECURITY

10-1 PHYSICAL SECURITY.

UFC 4-010-01 and UFC 4-010-02 provide facility physical security requirements. Typically, power systems are located in locked or sealed vaults, underground junction boxes, and/or secured locations and are minimally impacted by these UFCs.

10-2 LESSONS LEARNED.

A record must be made on all switching and component failures which must list with specificity the problem, the attempted solution, and the permanent solution. This must be free of naming faults attributable to individuals in order to become a training source for the elimination of future repetitions of the same problems.

APPENDIX B IEEE COLOR BOOKS

The IEEE Color Books have been a key electrical engineering reference source for decades. But, the IEEE Color Books will eventually be phased out and replaced by the IEEE 3000 Standards Collection. As of July 2015, all IEEE Color Books are still listed as active standards and the IEEE 3000 Standards Collection is still under development, with 9 standards issued, 20 standards under active development, and additional standards planned, but not started.

For UFCs and UFGSs, the IEEE Color Books are still suitable as a reference. In some instances, the IEEE 3000 Standards Collection standards should also be referenced. Some care should be taken to confirm if either or both types of standards should be referenced. For example, IEEE 902-1998, *IEEE Guide for Maintenance, Operation, and Safety of Industrial and Commercial Power Systems* (Yellow Book), is still listed as an active standard, even though it has been replaced by IEEE 3007.1, IEEE 3007.2, and IEEE 3007.3.

The following tables list the status of the IEEE Color Books and the IEEE 3000 Standards Collection. This information was obtained from the IEEE website.

Table B-1 IEEE Color Books

IEEE Standard	Color	Title	Status
141-1993	Red	IEEE Recommended Practice for Electric Power Distribution for Industrial Plants	Active Standard
142-2007	Green	Recommended Practice for Grounding of Industrial and Commercial Power Systems	Active Standard
241-1990	Gray	IEEE Recommended Practice for Electric Power Systems in Commercial Buildings	Active Standard
242-2001	Buff	IEEE Recommended Practice for Protection and Coordination of Industrial and Commercial Power Systems	Active Standard
399-1997	Brown	IEEE Recommended Practice for Industrial and Commercial Power Systems Analysis	Active Standard
446-1995	Orange	IEEE Recommended Practice for Emergency and Standby Power Systems for Industrial and Commercial Applications	Active Standard

IEEE Standard	Color	Title	Status
493-2007	Gold	IEEE Recommended Practice for the Design of Reliable Industrial and Commercial Power Systems	Active Standard
551-2006	Violet	Recommended Practice for Calculating AC Short-Circuit Currents in Industrial and Commercial Power Systems	Active Standard
602-2007	White	IEEE Recommended Practice for Electric Systems in Health Care Facilities	Active Standard
739-1995	Bronze	IEEE Recommended Practice for Energy Management in Industrial and Commercial Facilities	Active Standard
902-1998	Yellow	IEEE Guide for Maintenance, Operation, and Safety of Industrial and Commercial Power Systems	Active Standard
1015-2006	Blue	Recommended Practice for Applying Low-Voltage Circuit Breakers Used in Industrial and Commercial Power Systems	Active Standard
1100-2005	Emerald	IEEE Recommended Practice for Powering and Grounding Electronic Equipment	Active Standard

Table B-2 IEEE 3000 Standards Collection

Standard	Title	Status
IEEE 3000 Standard: Fundamentals		
P3000	Recommended Practice for the Engineering of Industrial and Commercial Power Systems	Active Project

APPENDIX C PRIMARY DISTRIBUTION SYSTEM FUSING

C-1 OVERHEAD DISTRIBUTION FUSING.

Apply the following criteria for sizing expulsion fuses for distribution cutouts:

- Determine the optimal fuse size for each location. Future system outages can include a fuse link check, with replacements as necessary;
- Select a fuse link size based on standard industry guidance. Refer to the following tables for examples of fuse sizing for various system voltages. Scale the results as needed for other system voltages. Type K and T fuses are rated for 50% overload capability. Type H and Type QA fusing is not rated for overload capability as shown in Figure C-1. Table C-10 provides one example of fuse sizing for Type H or QA fuses;
- If the fused cutouts supply more than one pad-mounted transformer in a looped configuration, base the selected fuse link size on the combined kVA rating of the transformers, and possibly downsized by one fuse size to account for typical less than full load conditions. Note that fused cutouts might not provide adequate protection for any transformer in this configuration. Each transformer must have its own internal set of fuses for adequate protection; and
- In-line fuses must be capable of carrying the entire expected load of the downstream circuit. If the circuit must be capable of carrying another circuit via a downstream cross-connect switch, the in-line fuse size must take this additional loading into account or else this cross-connect path might not be suitable for use.

Note: UFC 3-550-01 requires IEEE C37.41 rated backup current limiting fuses in series with Type K expulsion fuses on systems that are rated 1) above 15 kV or 2) 15 kV and lower that have available fault currents equal to or greater than 7,000 asymmetrical amperes. When backup current limiting fuses are installed in series with an expulsion fuse, review and follow the manufacturer's installation requirements regarding maximum expulsion fuse size that can be installed in series with a backup current limiting fuse.

Note: All fusing for single-phase transformers is based on a phase-to-neutral connection.

—	2000	33.47	50

Note: Ensure selected fuse is rated for the applied voltage. Some fuse types can only be used on solidly grounded 34.5 kV distribution systems. Fuse sizes vary among manufacturers; select the closest available larger fuse size if the specified fuse size is not available. Refer to UFC 3-550-01 for additional requirements for fusing.

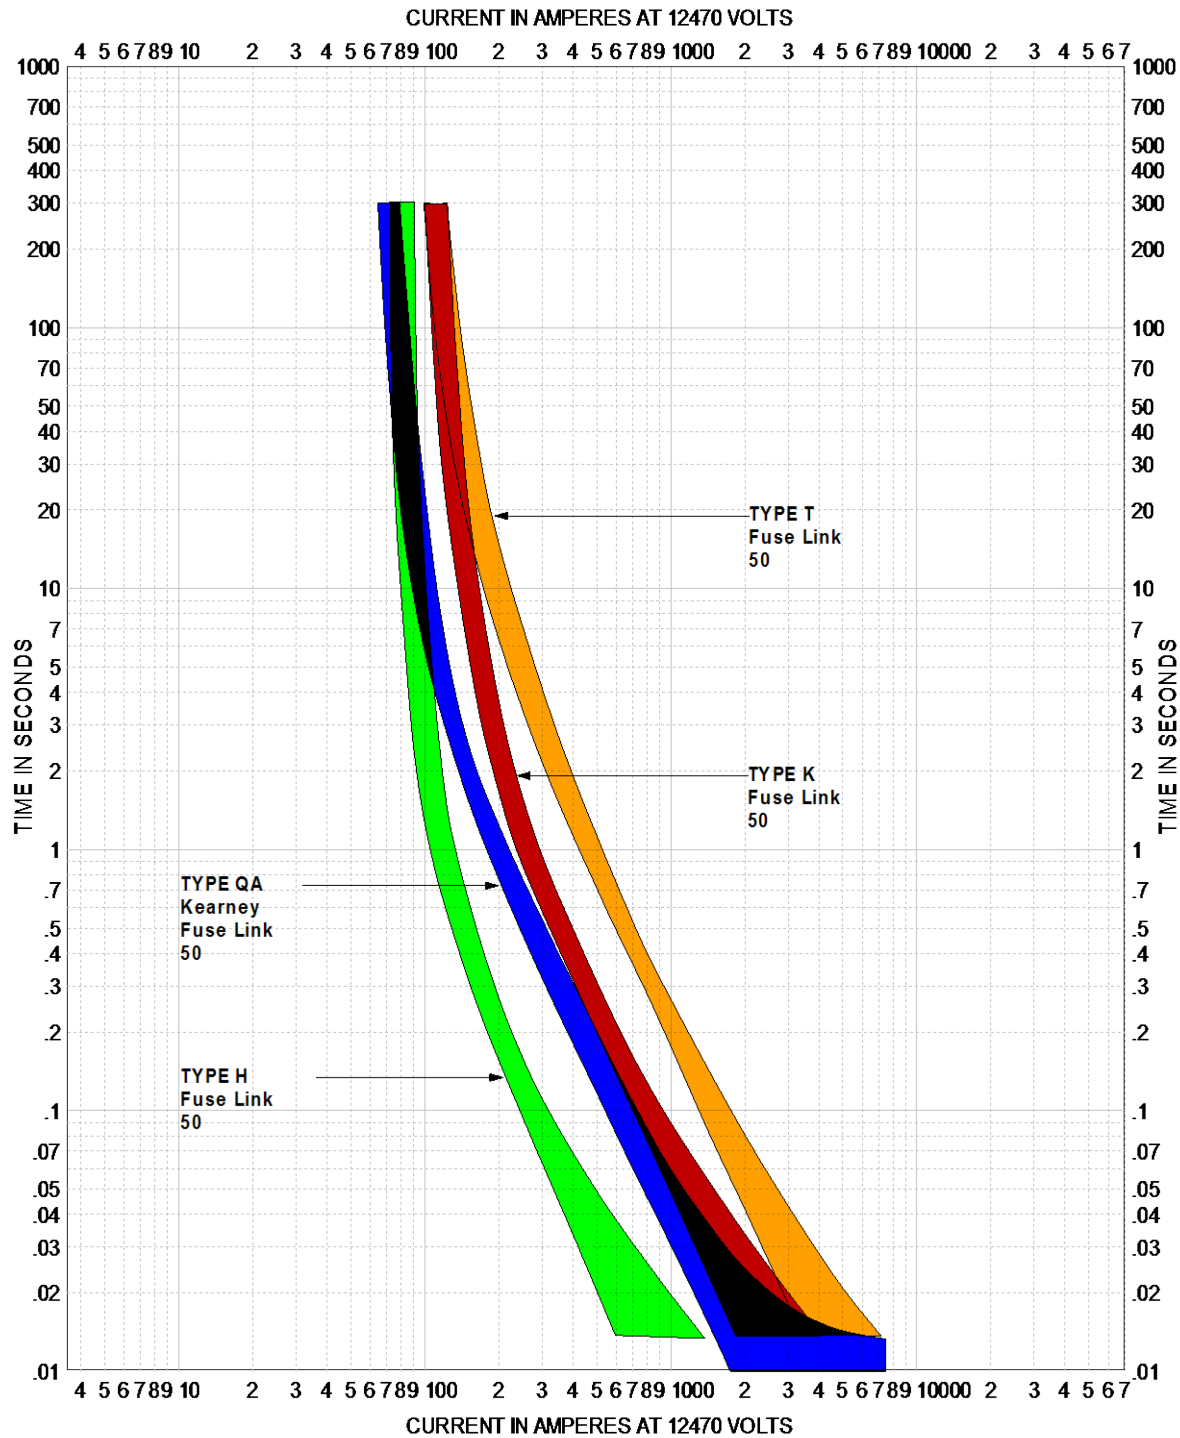
Figure C-1 Various Fuse Link Type Time-Current Response



C-2 PAD-MOUNTED SWITCHGEAR FUSING.

Apply the following general criteria for fuse sizing for air-insulated pad-mounted switchgear:

- Provide adequate protection throughout the system, taking into account the unique system design features downstream of each switchgear compartment; and
- Select fuses that are as small as possible, while considering the constraints of downstream circuit full-load and inrush capability. The goal is to encourage the fuses to clear for a downstream fault, if possible, rather than just have the main feeder relaying respond to the fault.

Based on the above, apply the following specific criteria to fusing evaluations:

- If only one transformer is supplied and it does not have internal fuses:
    - Select a fuse size that provides primary transformer protection. The following tables provide examples of fuse sizing for this application and scale as needed for different system voltages. These tables are based on S&C Type SMU-20 or Type SM standard “E” speed fusing, which is the most common fusing used in pad-mounted switchgear. The Eaton Type DBU or Cooper CMU fusing is equivalent to the SMU-20 in terms of time-current response.
- If only one transformer is supplied and it does have internal fuses:
    - Select a fuse size that is at least one size larger than the internal fuses that provide transformer protection.
- If multiple transformers are supplied from a single fused compartment:
    - Ensure selected fuse size can carry the full-load current of downstream transformers;
    - Ensure selected fuse size can withstand the inrush current of simultaneously energizing the downstream transformers;
    - Provide conductor protection; and
    - Coordinate as well as possible with upstream phase and neutral relay settings.

Note: All fusing for single-phase transformers is based on a phase-to-neutral connection.

APPENDIX D VACUUM FAULT INTERRUPTER (VFI) TRIP SETTINGS

D-1 GENERAL CRITERIA.

Apply the following general criteria for VFI trip settings in pad-mounted switchgear:

- Provide adequate protection throughout the system, taking into account the unique system design features downstream of each switchgear compartment.
- Do not leave VFI settings at the factory default values. Select VFI settings that are as small as possible, while considering the constraints of downstream circuit full-load and inrush capability. The goal is to encourage the VFIs to clear for a downstream fault, if possible, rather than have the main feeder relaying respond to the fault.

Based on the above, apply the following specific criteria for determining VFI settings:

- If only one transformer is supplied and it does not have internal fuses:
  - Select a trip setting that provides transformer protection. Refer to tables in the following sections for VFI settings and scale as needed for different system voltages. Note that each manufacturer's overcurrent trip unit is equipped with minimum settings that have to be considered. For higher operating voltages, smaller rated transformers cannot be properly protected by the minimum available VFI trip settings.
  - Note that very few transformers fall into this category. Most distribution transformers will have internal fusing.
- If only one transformer is supplied and it does have internal fuses:
  - Select a trip setting that is approximately one size larger than the internal fuses that typically provide transformer protection.
  - The purpose of this selection is to possibly allow the transformer fusing to respond to an internal fault. But, more importantly, this lateral will be removed from service as soon as possible to minimize any effect on the main feeder.
- If multiple transformers are supplied from a single compartment:
  - Ensure selected trip settings can carry the full-load current of the downstream transformers.

- Ensure selected trip settings can withstand the inrush current of simultaneously energizing the downstream transformers.

- Provide conductor protection.

- Coordinate as well as possible with upstream phase and neutral relaying.

- Allow for cross-ties if the downstream loads allow cross-connect to another feeder.

- A table is not provided for this case. Each configuration requires a specific review. For relatively small laterals with limited load, the settings will tend to be set low so that the lateral will be removed from service as soon as possible to minimize any effect on the main feeder.

- If the VFI serves as a higher ampacity cross-tie point between feeders:

  - Do not use the tables in the following sections. Perform a specific evaluation.

  - If the manufacturer's overcurrent trip unit has the capability, select a 51 relay curve, including ground trip, and coordinate the cross-tie location with the upstream feeder.

D-2 S&C VISTA PAD-MOUNTED SWITCHGEAR.

The following tables provide recommended settings for S&C Vista switchgear based on providing primary protection to an individual transformer. Refer to Section D-1 for guidance when a VFI supplies more than one downstream transformer.

Figure D-1 S&C Vista Switchgear

Notes for S&C Vista Tables:

1. *The S&C Vista switchgear typically have CT ratios of 660:1, which should be confirmed. Minimum trip setting is 25 amperes.*

2. *Available E-speed settings are 25E, 30E, 40E, 50E, 65E, 80E, 100E, 125E, 150E, 175E, 200E, 250E, 300E, and 400E.*

3. *The factory-shipped default settings are 200E.*

D-3 G&W VFI PAD-MOUNTED SWITCHGEAR.

The following tables provide recommended settings for G&W switchgear based on providing primary protection to an individual transformer. Refer to Section D-1 for guidance when a VFI supplies more than one downstream transformer.

Figure D-2 G&W VFI Switchgear

The available settings vary with the trip unit and typically have the following available settings:

- Pickup Range 15-300E: 15, 20, 25, 35, 45, 60, 75, 100, 125, 175, 225, and 300.
- Pickup Range 30-600E: 30, 40, 50, 70, 90, 120, 150, 200, 250, 350, 450, and 600.

Note: Minimum setting is either 15 or 30 amperes, and varies with the style. Select nearest available setting is trip unit configuration does not include the above settings.

Newer G&W switchgear might be equipped with electronic trip units with a variety of setting options.

D-4 COOPER VFI PAD-MOUNTED SWITCHGEAR.

D-4.1 Overview.

Figure D-3 shows a typical Cooper VFI switchgear.

Figure D-3 Cooper VFI Switchgear

The VFI trip units are referred to as Tri-Phase trip units. Different types of Tri-Phase trip units can be used, including:

- Tri-Phase – provides time overcurrent and instantaneous trip capability. Tripping can be selected for either a three-phase trip or a single-phase trip.
- Tri-Phase with Ground Trip (TPG) – provides Tri-Phase capability as well as ground fault tripping. This includes ground fault time overcurrent and instantaneous trip capability.
- Tri-Phase with minimum response accessory – improves coordination capability by allowing a minimum time delay before a time overcurrent response is activated. An instantaneous trip, if specified, can still occur without any deliberate time delay.
- SCADA Accessory Board for Tri-Phase Units – allows for inrush restraint and emergency overcurrent trip settings.

D-4.2 Trip Unit Characteristics.

The following provides additional information regarding the overcurrent trip response of these trip units:

- The EF time-current curve is an extremely inverse response curve. From the time of initial overcurrent detection (response), the total clearing time is typically less than 3 cycles. Both the initial response and the final clearing time is important.

- The minimum trip (pickup) settings are set by a series of dip switches. The default minimum phase trip is 20 amperes and the default minimum ground trip is 10 amperes. The actual pickup point will be the sum of the dip switches set to ON plus this default minimum value. The settings recommended in this document often use the minimum available values of 20 amperes for phase trips and 10 amperes for the ground trip. These minimum values are achieved by setting all phase or ground dip switches to the OFF direction. Refer to the Cooper instruction manual for additional information.

- The instantaneous trip settings are adjustable from 1X to 15X, where ‘X’ refers to the specified pickup point described above. Setting the OFF-ON switch to ON accomplishes an instantaneous trip setting of 1X and additional dip switches are set to achieve the desired setting. The instantaneous trip includes a fixed time delay of 25 milliseconds. For high fault current levels, this 25 millisecond time delay will be ignored because the EF time-current curve response shown on Figure 8 will still process an instantaneous trip.

- The EFR style of trip unit includes a minimum response time, which effectively forces a pre-set time delay beyond which time the VFI can trip. This minimum response time is adjustable from 0.050 to 0.580 seconds. If the minimum response time dip switch is set to STD, there is no minimum response time and the time-current response will follow the EF curve. This style of trip unit was installed on the first five switches of the Suwannee Feeder.

- If the ground trip block switch is turned to ON, ground tripping will be disabled if it has been provided. The phase trip settings will still be active.

- A selector switch enables either single-phase or three-phase tripping. If set on single-phase tripping, only the affected phase will trip. This selection might be used in areas using predominantly single-phase loads, such as housing areas.

- The factory-shipped default settings are:

  - Phase pickup – 80 amperes.

  - Ground pickup – 40 amperes.

  - Ground trip block – off.

  - Trip type – 3-phase.

– Emergency minimum trip multiplier – off.

– Inrush restraint minimum trip multiples – off.

– Minimum trip multiplier switch – off.

D-4.3 Example Trip Settings.

Notes:

1. *Minimum phase trip setting is 20 amperes. Minimum neutral trip setting is 10 amperes. These minimum settings provide minimal protection for the smallest distribution transformers.*

2. *Pickup settings can only be increased in increments of 10.*

3. *Instantaneous trip settings are only available in odd numbers, ranging from 1X to 15X, where X is the specified pickup setting. For example, if the pickup is specified at 20 amperes, an instantaneous trip value of 5X is 100 amperes (5 x 20 = 100).*

4. *For solely single phase installations, increase ground trip pickup as needed to ensure adequate margin for normal neutral current flow.*

Figure D-4 shows the factory default phase and ground trips:

- The phase trips have dip switches on for 20A and 40A. The phase trip factory default setting is 20 (min) + 20 + 40 = 80 amperes.

- The ground trip has its dip switches on for 10A and 20A. The ground trip factory default setting is 10 (min) + 10 + 20 = 40 amperes.

- All dip switches are off for the instantaneous trips. The instantaneous trips are OFF.

Figure D-4 Factory Default Settings

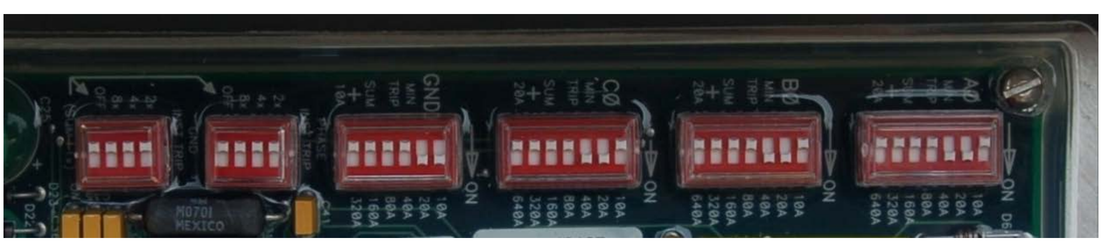

Figure D-4 shows another example trip unit:

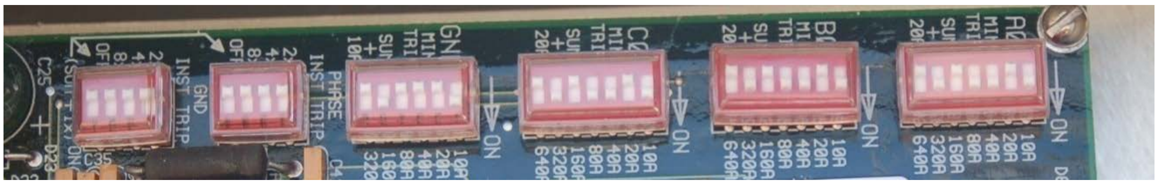
- The phase trips have dip switches on for 320A, 80A, 40A, and 10A. The phase trip setting is 20 (min) + 320 + 80 +40 + 10 = 470 amperes.

- The ground trip has its dip switches on for 160A and 10A. The ground trip setting is 10 (min) + 10 + 160 = 180 amperes.
- All dip switches are off for the instantaneous trips. The instantaneous trips are OFF.

Figure D-5 Example Tri-Phase Trip Settings – Higher Trip Values



D-4.4 Recommended Settings.

The following tables provide recommended settings for Cooper VFI switchgear based on providing primary protection to an individual transformer. Refer to Section D-1 for guidance when a VFI supplies more than one downstream transformer.

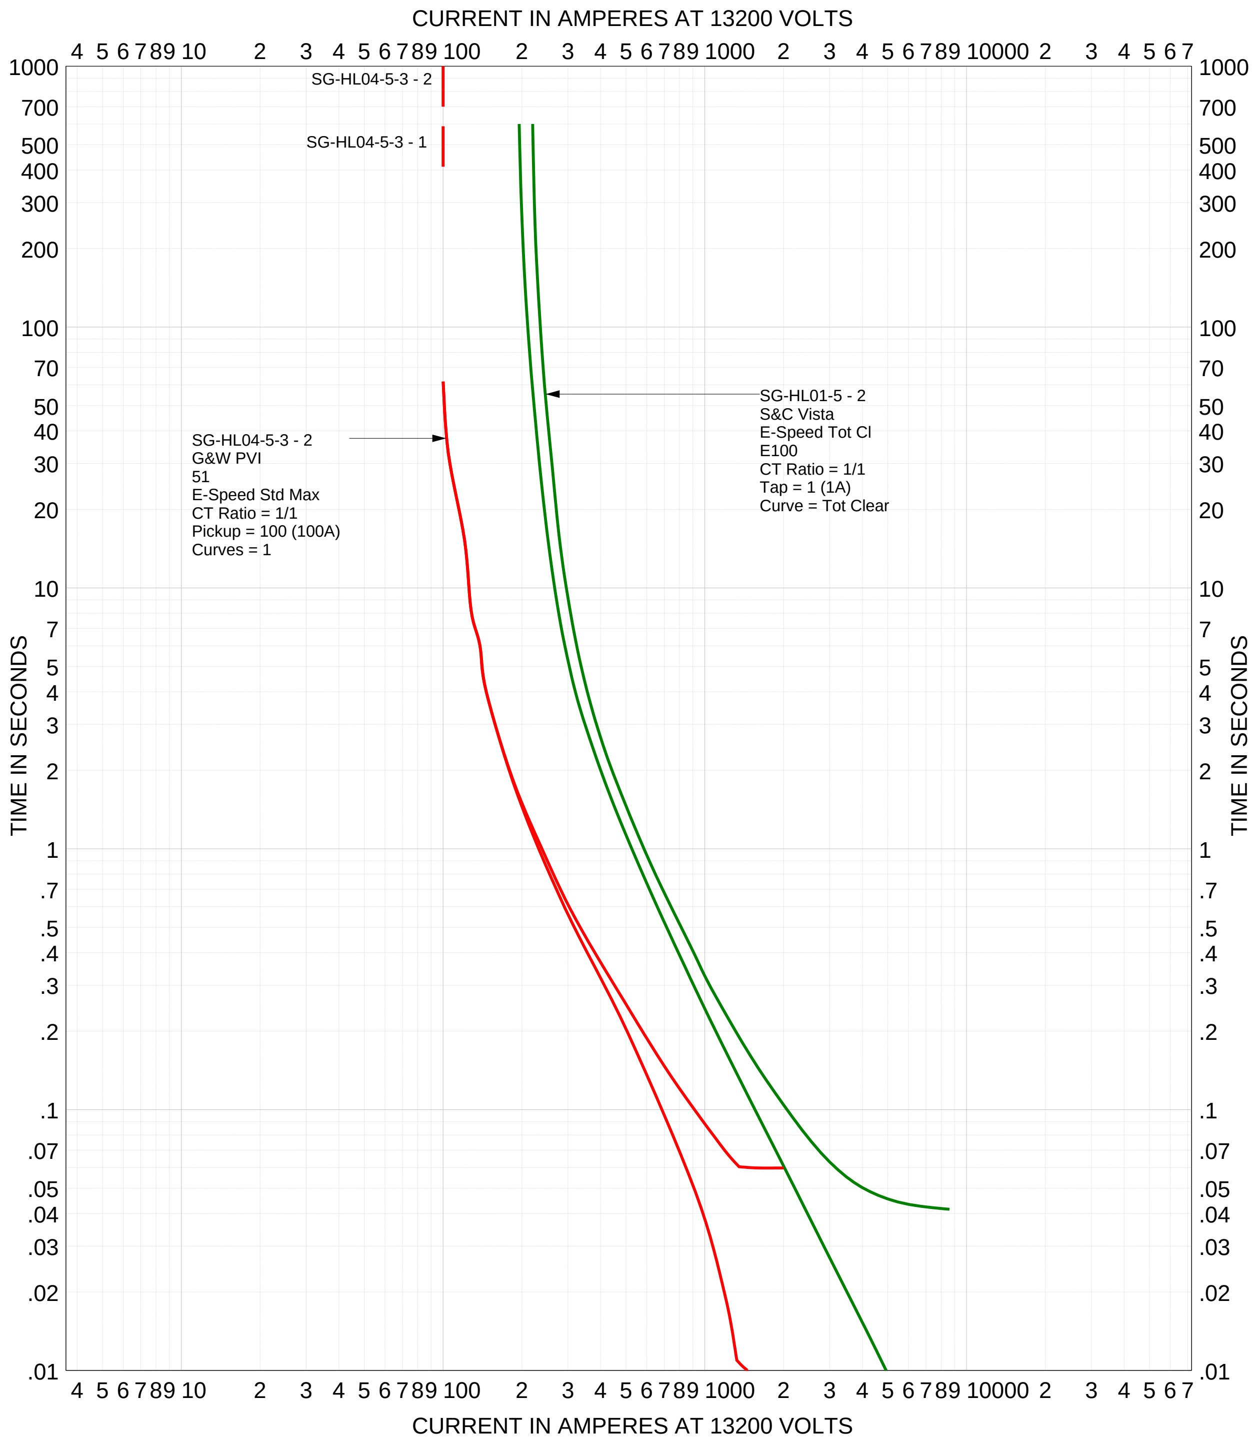
---	2000	33.47	70	40	9X	9X

Note: All settings for single-phase transformers are based on a phase-to-neutral connection.

D-5 COMPARISON OF S&C, COOPER, AND G&W TRIP SETTINGS.

The VFI trip settings for S&C, Cooper, and G&W switchgear are not equivalent. Although all types of VFIs can follow an E-speed curve, the S&C settings emulate S&C fuses, whereas the Cooper and G&W settings do not. Figure D-6 provides an example for a trip setting of 100 amperes. Notice that the G&W VFI will trip at 100 amperes, but the S&C Vista VFI will not trip until about 200 amperes. This difference in trip characteristic should be considered when establishing trip settings.

Figure D-6 Comparison of S&C Vista and G&W Switchgear VFI Settings



APPENDIX E STANDARD OPERATING PROCEDURES FOR ENERGIZED WORK PERMITS

E-1 OVERVIEW.

This appendix addresses the use of Standard Operating Procedures (SOPs) as a means of satisfying the energized work permit requirements of UFC 3-560-01. The preferred work approach is to establish an electrically safe work condition by deenergizing the equipment before allowing work. However, there are routine activities on the primary distribution system that involve energized work.

Done properly, an energized work permit is a time-consuming, detailed evaluation of the planned work and the safety precautions required to ensure the work is performed safely. For specified tasks, an SOP is a pre-approved energized work permit that can simplify the preparation for an energized work activity while still complying with mandated regulations and industry standards.

E-1.1 OSHA Criteria.

OSHA 29 CFR 1910.333 limits work on live energized electrical equipment as follows: "*Live parts to which an employee may be exposed shall be deenergized before the employee works on or near them, unless the employer can demonstrate that deenergizing introduces additional or increased hazards or is not feasible due to equipment design or operational limitations*."

E-1.2 SOP Limitations.

SOPs are recommended for electrical-related work activities that might be performed routinely. Unusual or non-routine work activities that involve working on or near energized electrical equipment require an energized work permit in accordance with UFC 3-560-01.

An SOP is a pre-approved energized work permit rather than a detailed technical procedure. The SOP assumes that the qualified electrical worker is proficient in the technical aspects of the designated work activity and the SOP focuses on the safety aspects that would be typically included in an energized work permit.

E-1.3 Items to Address in an SOP.

Develop SOPs by a risk assessment based upon job hazard analyses (JHA) using Operational Risk Management (ORM) principles. Include the following in an SOP:

- The purpose of the SOP;
- References and definitions appropriate for the work activity;
- The hazards that will be avoided by using the SOP;

- Specific procedures that will be used to reduce/minimize/eliminate the hazards;
- Potential energy sources, including limits of approach;
- Specific required training/certifications;
- Number of required employees;
- Rescue procedures and equipment;
- Potential incident energy level exposure;
- Appropriate personal protective equipment (PPE) such as arc rated clothing, face shields, and electrical gloves for exposure level; and
- Management approvals.

The following sections provide examples of SOPs that might be appropriate for working on the primary distribution system:

- Appendix E-2 provides a sample SOP for operating fused cutouts from a bucket truck; and
- Appendix E-3 provides a sample SOP for operating loadbreak elbows from grade.

E-2 SAMPLE SOP – FUSED CUTOUTS: OPENING, CLOSING, OR REPLACING FUSES.

The following is a sample SOP for operating overhead distribution fused cutouts or replacing fuse links inside cutouts.

1.0 Purpose.

This procedure defines the requirements for opening fused cutouts, closing fused cutouts, or replacing fuse links in fused cutouts on the overhead distribution system.

2.0 Applicability.

This procedure applies to exterior electrical shop personnel that are designated as a qualified person with respect to working on or near primary overhead distribution systems.

3.0 References.

- 29 CFR 1910
- UFC 3-560-01
- NFPA 70E

4.0 Definitions.

Arc Flash Hazard. A dangerous condition associated with the possible release of energy caused by an electric arc.

Arc Rating. The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm2 and is derived from the determined value of the arc thermal performance value (ATPV) or energy of breakopen threshold (EBT) (should a material system exhibit a breakopen response below the ATPV value). Arc rating is reported as either ATPV or EBT, whichever is the lower value.

Balaclava (Sock Hood). An arc-rated hood that protects the neck and head except for the facial area of the eyes and nose.

Boundary, Arc Flash. When an arc flash hazard exists, an approach limit at a distance from a prospective arc source within which a person could receive a second degree burn if an electrical arc flash were to occur.

Boundary, Limited Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

De-energized. Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Electrical Hazard. A dangerous condition such that contact or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Electrically Safe Work Condition. A state in which an electrical conductor or circuit part has been disconnected from energized parts, locked/tagged in accordance with established standards, tested to ensure the absence of voltage, and grounded if determined necessary.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Fused Cutout. A pole mounted interrupting device, equipped with fuses, that provides a method for de-energizing and protecting downstream electrical equipment.

Incident Energy. The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Live Line Tool. An insulated tool that electrically insulates the worker from the energized conductor and provides physical separation from the device being operated.

Low-Voltage. Any voltage below 600 V.

Medium Voltage. Voltages above 600 and ranging to 34,500 V.

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Shock Hazard. A dangerous condition associated with the possible release of energy caused by contact or approach to energized electrical conductors or circuit parts.

Unqualified Person. A person who is not a qualified person.

Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of "working on": 1) diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; and, 2) repair is any physical alteration of electrical equipment (such as making or tightening connections, removing or replacing components, etc.).

5.0 Training and Qualification Requirements.

Personnel using this procedure must be trained and qualified in the following:

Emergency response training. Contact release. First aid, emergency response, and resuscitation.

Qualified Person Employee training. A qualified person must be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method. For this SOP, this includes working inside an elevated bucket, handling of live-line tools, and pole-top rescue.

Document all training.

6.0 Required Approach Distances.

Table E-2-1 lists the minimum approach distances from exposed alternating current energized parts within which a qualified worker may not approach without the use of PPE appropriate for the potential electrical hazards, or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding).

Table E-2-1 Qualified Worker Minimum Approach Distances – AC Systems

Nominal System Voltage Range Phase to Phase (1)	Arc Flash Boundary	Limited Approach Boundary		Restricted Approach Boundary (3) (4)
	From Phase to Phase Voltage (5), (6)	Exposed Movable Conductor	Exposed Fixed Circuit Part	Includes Standard Inadvertent Movement Adder
50 V to 150 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>151 V to 750 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)
>750 V to 15 kV	(2)	10 ft 0 in (3.0 m)	5 ft 0 in (1.5 m)	2 ft 2 in (0.7 m)
>15 kV to 36 kV	(2)	10 ft 0 in (3.0 m)	6 ft 0 in (1.8 m)	2 ft 7 in (0.8 m)
>36 kV to 46 kV	(2	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	2 ft 9 in (0.8 m)
>46 kV to 72.5 kV	(2)	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	3 ft 3 in (1.0 m)
>72.5 kV to 121 kV	(2)	10 ft 8 in (3.3 m)	8 ft 0 in (2.5 m)	3 ft 4 in (1.0 m)
>121 kV to 145 kV	(2)	11 ft 0 in (3.4 m)	10 ft 0 in (3.0 m)	3 ft 10 in (1.2 m)

Notes for Table E-2-1:

1. *For single phase systems select the range that is equal to the system's maximum phase to ground voltage times 1.732.*
2. *The arc flash boundary is determined by an arc flash analysis.*
3. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
4. *The restricted approach distance applied to hot sticks is the distance between a worker's hand and the working end of the stick.*
5. *Only qualified workers wearing appropriate PPE are permitted within the arc flash boundary.*

7.0 Personal Protective Equipment.

Comply with NFPA 70E.

De-energizing equipment before opening equipment is the preferred work procedure. If mission prohibits de-energizing equipment:

1. Review arc flash label or arc flash calculation for potential incident energy level;

2. If no label or current arc flash calculation, perform arc flash calculation to determine potential incident energy level;

3. Select PPE equipment to exceed calculated potential incident energy level; and,

4. If calculated incident energy level exceeds available PPE rating (in-house or contracted workforce), equipment de-energizing is mandatory.

8.0 Opening a Fused Cutout.

Perform the following steps:

Note: If the overhead distribution circuit overcurrent protection includes reclosing ability, disable upstream reclosing before starting work. Enable reclosing when work is complete.

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members.

2. If possible, remove load from the fused cutouts by opening the secondary main breakers in all facilities supplied through the fused cutouts.

3. Select voltage-rated gloves with leather protectors. Inspect voltage-rated gloves and leather protectors before use. Wear voltage-rated gloves with leather protectors while performing all work inside the bucket.

4. Select and inspect the live-line insulated tool (hot stick) being used for the work. Confirm that hot sticks have been dry tested within the last 6 months and wet tested with the last 2 years. Ensure that all tools are rated for the voltage being worked on.

5. Position the insulated bucket truck in a position as far as possible from active traffic lanes. Place cones, barricades, and traffic markers as appropriate. Turn on all warning flashers and yellow beacons (day and night).

6. Enter and maneuver the bucket close enough to reach the fused cutouts with the insulated tool without having to reach or lean outside of the bucket.

7. Grasp the hot stick with both hands and insert the working end into the pull handle on the individual fused cutout. Pull it open in one smooth motion.

8. Open the remaining fused cutouts by the same process described above.

9. If changing the fuse(s), use the hot stick to lift and remove the fuse cartridge from the fused cutouts. To install the replacement fuse cartridge, pick up the fuse

cartridge with the working end of the hot stick, position the fuse, and drop into place in the fused cutout.

10. When work is complete, return all equipment (PPE, live-line tools, and voltage-rated gloves) to their protective containers. Confirm that all tools that were used are accounted for.

9.0 Closing a Fused Cutout.

Perform the following steps:

Note: If the overhead distribution circuit overcurrent protection includes reclosing ability, disable upstream reclosing before starting work. Enable reclosing when work is complete.

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members.

2. If possible, remove load from the fused cutouts by opening the secondary main breakers in all facilities supplied through the fused cutouts.

3. Select voltage-rated gloves with leather protectors. Inspect voltage-rated gloves and leather protectors before use. Wear voltage-rated gloves with leather protectors while performing all work inside the bucket.

4. Select and inspect the live-line insulated tool (hot stick) being used for the work. Confirm that hot sticks have been dry tested within the last 6 months and wet tested with the last 2 years. Ensure that all tools are rated for the voltage being worked on.

5. Position the insulated bucket truck in a position as far as possible from active traffic lanes. Place cones, barricades, and traffic markers as appropriate. Turn on all warning flashers and yellow beacons (day and night).

6. Enter and maneuver the bucket close enough to reach the fused cutouts with the insulated tool without having to reach or lean outside of the bucket.

7. Grasp the hot stick with both hands and insert the working end into the pull handle on the individual fused cutout. Lift and push closed in one smooth motion.

8. Close the remaining fused cutouts by the same process described above.

9. If changing the fuse(s), use the hot stick to lift and remove the fuse cartridge from the fused cutouts. To install the replacement fuse cartridge, pick up the fuse cartridge with the working end of the hot stick, position the fuse, and drop into place in the fused cutout.

10. When work is complete, return all equipment (PPE, live-line tools, and voltage-rated gloves) to their protective containers. Confirm that all tools that were used are accounted for.

11. If load was removed from the fused cutouts by opening the secondary main breakers in facilities supplied through the fused cutouts, restore power to the facilities by closing the secondary main breakers.

E-3 SAMPLE SOP – CONNECTING/DISCONNECTING LOADBREAK ELBOWS.

The following is a sample SOP for connecting or disconnecting load break elbows.

1.0 Purpose.

This procedure defines the requirements for or connecting or disconnecting load break elbows on an energized circuit.

2.0 Applicability.

This procedure applies to exterior electrical shop personnel that are designated as a qualified person with respect to working on or near primary underground distribution systems.

4.0 Definitions.

Arc Flash Hazard. A dangerous condition associated with the possible release of energy caused by an electric arc.

Arc Rating. The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm2 and is derived from the determined value of the arc thermal performance value (ATPV) or energy of breakopen threshold (EBT) (should a material system exhibit a breakopen response below the ATPV value). Arc rating is reported as either ATPV or EBT, whichever is the lower value.

Balaclava (Sock Hood). An arc-rated hood that protects the neck and head except for the facial area of the eyes and nose.

Boundary, Arc Flash. When an arc flash hazard exists, an approach limit at a distance from a prospective arc source within which a person could receive a second degree burn if an electrical arc flash were to occur.

Boundary, Limited Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

De-energized. Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Elbow. A connector component for connecting a power conductor to a bushing, designed so that when assembled with the bushing, the axes of the conductor and bushing are perpendicular.

Electrical Hazard. A dangerous condition such that contact or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Electrically Safe Work Condition. A state in which an electrical conductor or circuit part has been disconnected from energized parts, locked/tagged in accordance with established standards, tested to ensure the absence of voltage, and grounded if determined necessary.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Incident Energy. The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Insulated Cap. An accessory device designed to electrically insulate, electrically shield, and mechanically seal a bushing insert or integral bushing.

Insulated Parking Bushing. An accessory device designed to electrically insulate, electrically shield, and mechanically seal a power cable terminated with an elbow and installed into a parking stand.

Live Line Tool. An insulated tool that electrically insulates the worker from the energized conductor and provides physical separation from the device being operated.

Loadbreak Connector. A connector designed to close and interrupt rated load current or less on energized circuits under rated conditions.

Low-Voltage. Any voltage below 600 V.

Medium Voltage. Voltages above 600 and ranging to 34,500 V.

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Separable Insulated Connector. A fully insulated and shielded system for terminating an insulated power conductor to electrical apparatus, other power conductors, or both, and designed such that the electrical connection can be readily made or broken by engaging the connector at the operating interface.

Shock Hazard. A dangerous condition associated with the possible release of energy caused by contact or approach to energized electrical conductors or circuit parts.

Unqualified Person. A person who is not a qualified person.

Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of “working on”: 1) diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; and, 2) repair is any physical alteration of electrical equipment (such as making or tightening connections, removing or replacing components, etc.).

5.0 Training and Qualification Requirements.

Personnel using this procedure must be trained and qualified in the following:

Emergency response training. Contact release. First aid, emergency response, and resuscitation.

Qualified Person Employee training. A qualified person must be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method.

Document all training.

6.0 Required Approach Distances.

Table E-3-1 lists the minimum approach distances from exposed alternating current energized parts within which a qualified worker may not approach without the use of PPE appropriate for the potential electrical hazards, or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding).

Table E-3-1 Qualified Worker Minimum Approach Distances – AC Systems

Nominal System Voltage Range Phase to Phase (1)	Arc Flash Boundary	Limited Approach Boundary		Restricted Approach Boundary (3) (4)
	From Phase to Phase Voltage (5), (6)	Exposed Movable Conductor	Exposed Fixed Circuit Part	Includes Standard Inadvertent Movement Adder
50 V to 150 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>151 V to 750 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)
>750 V to 15 kV	(2)	10 ft 0 in (3.0 m)	5 ft 0 in (1.5 m)	2 ft 2 in (0.7 m)
>15 kV to 36 kV	(2)	10 ft 0 in (3.0 m)	6 ft 0 in (1.8 m)	2 ft 7 in (0.8 m)
>36 kV to 46 kV	(2	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	2 ft 9 in (0.8 m)
>46 kV to 72.5 kV	(2)	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	3 ft 3 in (1.0 m)
>72.5 kV to 121 kV	(2)	10 ft 8 in (3.3 m)	8 ft 0 in (2.5 m)	3 ft 4 in (1.0 m)
>121 kV to 145 kV	(2)	11 ft 0 in (3.4 m)	10 ft 0 in (3.0 m)	3 ft 10 in (1.2 m)

Notes for Table E-3-1:

1. *For single phase systems select the range that is equal to the system's maximum phase to ground voltage times 1.732.*
2. *The arc flash boundary is determined by an arc flash analysis.*
3. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
4. *The restricted approach distance applied to hot sticks is the distance between a worker's hand and the working end of the stick.*
5. *Only qualified workers wearing appropriate PPE are permitted within the arc flash boundary.*

7.0 <u>Personal Protective Equipment.</u>

Confirm equipment is de-energized/locked out/tagged out. If equipment is to remain energized,

1. View arc flash label for incident energy level.
2. If label not present, calculate equipment incident energy level.
3. Select the minimum PPE level as required by NFPA 70E for the calculated incident energy level.

Voltage-rated gloves with leather protectors (Table E-3-2) for work inside the restricted approach boundary. Select as follows:

Table E-3-2 Rubber Insulating Equipment Voltage Requirements

Class of Equipment	Color Label	Maximum Use (AC Volts)	Minimum Distance[1] in Inches (Millimeters)
00	Beige	500	1 (25)
0	Red	1,000	1 (25)
1	White	7,500	1 (25)
2	Yellow	17,000	2 (50)
3	Green	26,500	3 (75)
4	Orange	36,000	4 (100)

Notes for Table: Wear leather protectors over rubber gloves. Minimum distance is the minimum length that the exposed rubber glove must extend beyond the leather protector.

8.0 <u>Precautions.</u>

Maneuver loadbreak connectors with an eight foot fully insulated "shot gun" line-line type tool. Ensure the working area is clear of obstructions or contaminants that might interfere with the operation of the connector or cause it to fall into the exposed bushing well. The operating position should allow establishing a firm footing and enable grasping the live-line tool securely, while maintaining positive control over the movement of the loadbreak connector before, during, and directly after the operating sequence. Because of the control, speed, and force required to engage or disengage an elbow, certain operating positions are more advantageous than others. If there are any concerns regarding an adequate position for handling a loadbreak connector, the operation must be performed on a de-energized circuit.

The following lists additional precautions and limitations for handling loadbreak connectors on an <u>energized</u> circuit:

- Limit work to dry weather conditions. Do not operate loadbreak connectors during wet conditions;

- Loadbreak connectors can be operated inside manholes only if the work can be accomplished with the qualified electrical worker standing outside the manhole at grade;
- Operation (connecting or disconnecting) loadbreak connectors inside a manhole with the qualified electrical worker standing inside the manhole is prohibited;
- Making a connection into a suspected fault is prohibited. De-energize the circuit prior to connection;
- If a fault occurs during connection or disconnection, replace the elbow connector and the bushing;
- Never connect an energized load break elbow into a transformer that has not been tested for proper operation;
- Never connect loadbreak elbow type surge arresters into an energized transformer or circuit;
- Never use a loadbreak connector to switch energized capacitors; and
- Check the appropriate manufacturer's operating instructions to confirm the device(s) is rated for energized operation, either connecting or disconnecting.

9.0 Loadbreak Operation (Connecting) at Grade.

Perform the following steps:

Note: This operation might be performed as part of a switching order. If so, then coordinate the Activity with the rest of the switching order.

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members.
2. Select voltage-rated gloves with leather protectors using Table E-3-2. Inspect voltage-rated gloves and leather protectors before use. Wear voltage-rated gloves with leather protectors while performing all work.
3. Select and inspect the live-line insulated tool (hot stick) being used for the work. Confirm that hot sticks have been dry tested within the last 6 months and wet tested with the last 2 years. Ensure that all tools are rated for the voltage being worked on.
4. Ensure the area is clear of obstructions or contaminants that might interfere with the operation of the connector.

5. Open the equipment where the loadbreak connector operation will be performed.

6. Prepare the bushing for the elbow connector by removing the insulated cap. Attach the live-line tool to the insulated cap pulling eye and remove from the bushing.

7. Securely fasten a shot gun live-line tool to the load break connector pulling eye.

Note: This procedure assumes that the loadbreak connector is on an insulated parking bushing on the apparatus parking stand before work starts.

8. Without exerting any pulling force, slightly rotate the connector to break any surface friction prior to disconnection from the insulated parking bushing on the apparatus parking stand.

9. After establishing a firm footing and positive control of the elbow connector, withdraw the elbow from the insulated parking bushing on the apparatus parking stand with a fast, firm, and straight motion, while being careful to avoid the ground plane.

10. Place the elbow connector receptacle area over the bushing plug and insert the elbow male contact (arc flower portion) into the bushing until a slight resistance is felt. Immediately push the elbow into the locked position with a fast, firm, and straight motion. Apply sufficient force to engage the internal lock on the elbow connector and bushing interface.

11. When work is complete, return all equipment (PPE, live-line tools, and voltage-rated gloves) to their protective containers. Confirm that all tools that were used are accounted for.

10.0 **Loadbreak Operation (Disconnecting) at Grade.**

Perform the following steps:

Note: This operation might be performed as part of a switching order. If so, then coordinate the Activity with the rest of the switching order.

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crewmembers.

2. Select voltage-rated gloves with leather protectors using Table E-3-2. Inspect voltage-rated gloves and leather protectors before use. Wear voltage-rated gloves with leather protectors while performing all work.

3. Select and inspect the live-line insulated tool (hot stick) being used for the work. Confirm that hot sticks have been dry tested within the last 6 months and wet

tested with the last 2 years. Ensure that all tools are rated for the voltage being worked on.

4. Ensure the area is clear of obstructions or contaminants that might interfere with the operation of the connector.

5. Open the equipment where the loadbreak connector operation will be performed.

6. Place the insulated parking bushing on the apparatus parking stand.

7. Firmly tighten a shot gun live-line tool to the loadbreak connector pulling eye.

8. Without exerting any pulling force, slightly rotate the connector to break any surface friction prior to disconnection.

9. After establishing a firm footing and positive control of the elbow connector, withdraw the elbow from the bushing with a fast, firm, and straight motion, while being careful to avoid the ground plane.

10. Place the connector on the insulated parking bushing and secure.

11. When work is complete, return all equipment (PPE, live-line tools, and voltage-rated gloves) to their protective containers. Confirm that all tools that were used are accounted for.

FOLLOW UP

APPENDIX G SAMPLE LIFE CYCLE COST MAINTENANCE WORKSHEET

RECURRING WORK PROGRAM WORKSHEET

RWP Item:

Review Date	Initials	Comments	Review Date	Initials	Comments

Review Method: ☐ Requirement Elimination ☐ MAPCO ☐Life-Cycle Cost

Approximate Cost of Item Being Maintained:

Requirement Elimination:

Can the RWP item be removed due to the very low replacement cost of the item and non-mission criticality? YES NO

Can the item be replaced with any zero-maintenance components? YES NO

Can the RWP item be contracted out to a service contractor? YES NO

Comments:

Man-Hour Ceiling/Priority Analysis (MAPCO)

Note: The MAPCO method is designed to help show whether a shop has enough manning to accomplish particular RWP items and help determine alternate ways of accomplishing required RWP tasks.

Is this a mandatory RWP item? YES NO

Note: If this is not a mandatory RWP item even though it is costs effective, this particular item should be prioritized for accomplishment after all other mandatory items are completed and additional manhours are available.

Is shop manning sufficient to accomplish this RWP item as required? YES NO

Can this item be included in the 1219 program? YES NO

Can this item be done through a service contract? YES NO

Comments:

Life-Cycle Cost Analysis

Note: The Life-Cycle Cost Analysis method is used to determine the economic value of doing a particular RWP item as compared to the cost of doing no maintenance and simply replacing the piece of equipment when it breaks. This method is typically used for larg items of critical value to a facility.

1. Item replacement price (installed): $ 25,000.00
2. Item re-build cost: $8,000.00
3. Cost of RWP item per Month: __$50__(Material) + __$50__(Labor) = $ 100.00

   Cost of RWP item per Quarter:__$100__(Material) + _$100_ (Labor) = $ 200.00

   Cost of RWP item per Year:___$150___(Material) + _$150__(Labor) = $ 300.00

(A) Freq of Mx	(B) Freq of Failure	(C) Annual RWP Cost	(D) PC of Repair/Replace	(E) PC of RWP	(F) Total PC of Option
Monthly	15	$2,300.00	$8,000.00	$34,500.00	$42,500.00
Quarterly	10	$1,500.00	$12,000.00	$22,500.00	$34,500.00
Annually	5	$600.00	$24,000.00	$9,000.00	$33,000.00
Never	2	$0.00	$60,000.00	$0.00	$60,000.00

(B): Determine Frequency of Failure from manufacturer data (years until failure)

(C): Number of RWP occurences within the year x cost per occurrence from 3 above

(D): Replacement cost (item 1 above) x # of replacements needed to reach highest number in (B)

(E): Column (C) x highest number of years from Column (B)

(F): Column (D) + Column (E)

This Page Intentionally Left Blank

APPENDIX H SAMPLE MAPCO MAINTENANCE DOCUMENT

RWP: Recurring Work Program

Method 3: Man-hour Ceiling/Priority Analysis Method (MAPCO)

It can be very difficult for many work centers to provide the manpower needed to properly implement the recurring work program. Every center has a limited number of man-hours that can be committed to a project. The Operations Flight understands this, and realizes that an alternative to the life-cycle cost analysis method and RWP requirement elimination method is sometimes needed. The third and final RWP method is called, "man-hour ceiling/priority analysis method," or MAPCO. MAPCO enlists the help of program engineers, innovative problem solving in a team setting, and effective scheduling by the work center manager. There are many benefits that can be realized by this method of RWP.

To use MAPCO, the following conditions should be present:

- limitations on manpower in the work center
- the scope of RWP is known
- the locations of RWP is known
- the materials for RWP are known

There are several options for making RWP successful under the above conditions. A manager should consider using a combination of options in order to have an effective program in the work center.

The following are options for successfully implementing RWP in a work-center with limited manpower available:

- Manager can budget man-hours to RWP on a prioritized schedule so that most important issues are budgeted first. The inspection schedule should be completed every year.
- Execute RWP in conjunction with a facility visit (such as 1219-type work). When the work is scheduled, WIMS can generate a listing of RWP for that facility throughout the period between the visit and the next programmed visit. This listing will include the mandatory requirements followed by the nonmandatory requirements. As the crafts pursue the 1219 Direct Scheduled Work and Maintenance Action Sheet requirements, they complete all mandatory RWP items. At the end of the visit, if additional man-hours are available in the schedule, they can begin to complete the nonmandatory items in priority order.
- Contract redundant, manpower intensive, or critical RWP requirements. This decision is typically a team decision, made by the program engineers, work center chiefs, and senior craftsmen.
- MAPCO benefits RWP because it optimizes the program in a thorough stepped process. It also improves engineer and work center coordination, and increases engineer exposure to the infrastructure environment.

VAR	Volt Amperes Reactance
VFI	Vacuum Fault Interrupter
VLF	Very Low Frequency
VRLA	Valve-Regulated Lead Acid
X/R	Ratio of Reactance to Resistance

J-2 DEFINITION OF TERMS

Arc Flash Hazard. A dangerous condition associated with the possible release of energy caused by an electric arc.

Arc Rating. The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm2 and is derived from the determined value of the arc thermal performance value (ATPV) or energy of breakopen threshold (EBT) (should a material system exhibit a breakopen response below the ATPV value). Arc rating is reported as either ATPV or EBT, whichever is the lower value.

Balaclava (Sock Hood). An arc-rated hood that protects the neck and head except for the facial area of the eyes and nose.

Boundary, Arc Flash. When an arc flash hazard exists, an approach limit at a distance from a prospective arc source within which a person could receive a second degree burn if an electrical arc flash were to occur.

Boundary, Limited Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

Chicken Switch: Remote actuating device to operate an interrupting device from a safe distance. Typically electrically operated, magnetic device that can remotely activate a switch.

De-energized. Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Elbow. A connector component for connecting a power conductor to a bushing, designed so that when assembled with the bushing, the axes of the conductor and bushing are perpendicular.

Electrical Hazard. A dangerous condition such that contact or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Electrically Safe Work Condition. A state in which an electrical conductor or circuit part has been disconnected from energized parts, locked/tagged in accordance with established standards, tested to ensure the absence of voltage, and grounded if determined necessary.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Fused Cutout. A pole mounted interrupting device, equipped with fuses, that provides a method for de-energizing and protecting downstream electrical equipment.

Incident Energy. The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Insulated Cap. An accessory device designed to electrically insulate, electrically shield, and mechanically seal a bushing insert or integral bushing.

Insulated Parking Bushing. An accessory device designed to electrically insulate, electrically shield, and mechanically seal a power cable terminated with an elbow and to be installed into a parking stand.

Live Line Tool. An insulated tool that electrically insulates the worker from the energized conductor and provides physical separation from the device being operated.

Loadbreak Connector. A connector designed to close and interrupt rated load current or less on energized circuits under rated conditions.

Low-Voltage. Any voltage below 600 V.

Low Voltage System: An electrical system having a maximum root-mean-square (rms) voltage of less than 1,000 volts.

Medium Voltage. Voltages above 600 and ranging to 34,500 V.

Medium Voltage System: An electrical system having a maximum RMS AC voltage of 1,000 volts to 34.5 kV. Some documents such as ANSI C84.1 define the medium voltage upper limit as 100 kV, but this definition is inappropriate for facility applications.

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Separable Insulated Connector. A fully insulated and shielded system for terminating an insulated power conductor to electrical apparatus, other power conductors, or both, and designed such that the electrical connection can be readily made or broken by engaging the connector at the operating interface.

Shock Hazard. A dangerous condition associated with the possible release of energy caused by contact or approach to energized electrical conductors or circuit parts.

Unqualified Person. A person who is not a qualified person.

Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of “working on”: Diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; repair is any physical alteration of electrical equipment (such as making or tightening connections, removing or replacing components, etc.).

This UFC supersedes UFC 3-555-01N dated 16 January 2004, the electrical sections of UFC 4-121-10N, dated 16 January 2004, and the special power system requirements in UFC 4-211-01 dated 13 April 2017, Change 3 dated April 20 2021.

This Page Intentionally Left Blank

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD-3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

The purpose of this UFC is to provide technical requirements for the electrical design of specialized Point-of-Use (POU) power distribution systems for aircraft, and electrical power systems associated with aircraft hangars and aviation support facilities. This includes 400 Hertz, 270 VDC, and 28 VDC systems. Apply the criteria provided in this UFC for the development of the plans, specifications, calculations, and Design/Build Request for Proposals (RFP). It serves as the minimum electrical design requirements for design-build and design-bid-build projects. Project conditions may dictate the need for a design that exceeds these minimum requirements.

The aircraft power feeder distribution systems for new designs are required to be low voltage (less than 600 VAC) POU utility systems. Each of the 400 Hz, 270 VDC, and 28 VDC converters are prohibited from serving more than one aircraft receptacle, unless specifically noted otherwise within this document.

1-1.1 Upgrades and Modifications to Existing Systems

Modernization of electrical systems within existing facilities solely for the purpose of meeting design criteria in this UFC is not required. Minor upgrades or modifications of existing facilities should consider the design criteria in this UFC, but it is not intended that an entire facility require modernization solely because of a minor modification to a part of the facility.

- Medium voltage 400 Hz distribution systems and low voltage (less than 600 volts) 400 Hz distributed systems are also not permitted for new designs. These systems require extensive specialized technical knowledge and experience to design and maintain, and should only be utilized on limited repair type projects for existing systems.

1-2 REISSUES AND CANCELS.

This UFC replaces and cancels UFC 3-555-01N dated 16 January 2004 and incorporates canceled electrical sections of UFC 4-121-10N dated 16 January 2004.

1-3 APPLICABILITY.

The information in this UFC applies to the design of all new construction projects, including additions, alterations, and renovation projects within the United States and outside of the United States and its territories and possessions.

Note: This UFC takes precedence over the aircraft hangar UFC 4-211-01 for the specialty electrical system power. The hangar UFC will be modified to reference this UFC during its next review cycle.

1-4 CONFLICTS.

If a conflict exists between this UFC and any other referenced code, standard, or publication, this UFC takes precedence. When there is a known deviation to a normally complied with standard (such as an “exception to” or “more stringent requirement” than one in MIL-STD-704), the specific deviation is identified in either the UFC or the associated UFGS.

1-5 REGULATORY AUTHORITIES.

The military authorities having jurisdiction for Specialty Power Systems are included below.

1-5.1 Navy and Marine Corps.

Due to the new, more stringent technical requirements in the UFGS, including the 400 Hz requirement to be fully rated in kW at unity power factor vs being rated in kVA, and the 270 VDC requirements that have been developed without referring to proprietary documents, all manufacturers will have to develop and prove their new designs. These designs, including the factory routine, factory special, and field test plans, reports and backup data, must be reviewed and approved by NAVAIR and NAVFAC LANT. This is an extensive process requiring specific technical expertise in working with and verifying compliance with MIL-STD-704, and witnessing the tests at the manufacturer’s facilities.

NOTE: The manufacturer’s previous versions of military converters, and their commercial equipment, will not comply with this new criteria.

Coordination is therefore mandatory during the DD Form 1391, concept development and the design-build request for proposal (RFP) or design phases with NAVAIR (Naval Air Systems Command) and NAVFAC to determine the extent of the equipment review and approval process that is to be implemented and to identify funding requirements. The UFGSs for the converter systems identify numerous optional requirements which must also be edited appropriately based on the command requirements. It is anticipated, that until multiple manufacturers have achieved “approved designs, test plans and reports” from NAVAIR, both NAVAIR and NAVFAC LANT will need to be in the shop drawing review and approval loop.

- Contact NAVAIR POC: Henry Dent at (240) 434-6861.
  Email: henry.c.dent.civ@us.navy.mil.
  Command: Naval Air Warfare Center Aircraft Division (NAWCAD Test Methods and Facilities AB44).
- Contact NAVFAC POC: Rob Boller at (757) 322-4327.
  Email: robert.r.boller.civ@us.navy.mil.
  Command: NAVFAC Atlantic (LANT), Code PDC 44, Electrical Criteria Manager.

1-5.2 NAVAIR and NAVSEA Additional POC Information.

This criteria is not to be used for procurement of power converters installed on board aircraft or ships without specific authorization from both the Naval Air Warfare Center Aircraft Division (NAWCAD Power and Energy Division (AB43) at (301) 342-4161), and from the Naval Sea Warfare Command (contact the Technical Warrant Officer for the appropriate ship classification).

1-6 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-6.1 Facility Requirements Document (FRD).

The airframe manufacturer's FRD, or equivalent document, is an integral requirement of aircraft specialty power systems design that contains additional airframe specific facilities requirements. FRDs are typically authored by the airframe manufacturer, contain many specific details, and are voluminous. Coordinate with the project manager to obtain the pertinent sections of the FRDs that are applicable to the project.

This UFC is not a substitute for the FRD of the design airframe(s) associated with the project. However:

- The UFC and associated UFGSs may have additional technical requirements that override the FRD requirements. An example is the new requirement for 400 Hz converters to be sized in kW vs the industry standard of kVA. The Navy and Marine Corps, and the Army FRDs are being addressed to incorporate this NAVAIR and Army mandated change. See paragraph Aircraft 400 Hertz (Hz) Service for additional information.
- The FRD may have new airframes, or existing platforms may have new requirements that this UFC has not addressed. These additional technical facility requirements, data or other items may impact the aircraft power system design. When that occurs, the facility Basis of Design must identify the exceptions to criteria and how the requirement is being addressed and satisfied in addition to the requirements of this UFC.

1-7 SAFETY.

Comply with UFC 3-560-01*, Operation and Maintenance, Electrical Safety*, and NFPA 70E, *Standard for Electrical Safety in the Workplace*, for equipment-related electrical safety requirements.

Coordinate with requirements identified in paragraph Aircraft Interlock Circuit.

1-8 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, *Cybersecurity of Facility Related Control Systems* and as required by individual Service Implementation Policy.

The Electrical Designer of record must determine if the equipment being provided will include a control system (i.e. remote access panels or any other form of remote controls). If it does, edit the UFGS 25 05 11, "*Cybersecurity for Facility-Related Control Systems*" in the project documents to identify the extent of cybersecurity required.

1-9 SUPPLEMENTAL TECHNICAL INFORMATION.

APPENDIX A contains additional technical information.

1-10 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-11 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 EXTERIOR DISTRIBUTION REQUIREMENTS

2-1 POINT OF USE (POU) UTILITY SYSTEMS.

Provide a fixed Point of Use (POU) utility system based upon the number and type of aircraft to be served, ground support requirements of the particular aircraft, expected diversity and demand of the aircraft loads, and site configuration of facilities. This will include identifying the central facilities utility demands, equipment capacities, line size and routing of the distribution system, and aircraft service point requirements.

2-1.1 Planning.

The POU concept is based upon the economy of supply of aircraft utilities from a centralized plant / location using 60 Hertz (Hz) energy-efficient components. Include the following considerations in planning for each aircraft facility:

a. Orderly expansion of the system components to accommodate probable future hangar bays and parking apron service points.

b. Economic feasibility of supplying adjacent or nearby facilities (existing or future) from the centralized supply.

c. Relocatability of ground support equipment versus installed equipment.

d. Probability of function relocation or base closure.

2-1.2 Aircraft Services.

Provide electrical POU systems for ground-power operations using solid state conversion equipment to change 60-Hz input to 400-Hz, 270 VDC, and 28 VDC outputs as required for the applicable aircraft.

2-1.3 Central Equipment Facilities.

In multiple facility development, provide a central facilities area for the equipment building, and a yard area for pad mounted / substation type transformers and switchgear for the main electrical service. Include the electrical service and distribution apparatus in the building.

2-1.4 Utilities Distribution.

Provide an underground 60 Hz distribution system including equipment, manholes and ductbanks to the maintenance hangar service points and parking apron service points in accordance with UFC 3-550-01. Coordinate with the mechanical designer and the mechanical sections of UFC 4-211-01, *Aircraft Maintenance Hangars*, and route the mechanical systems (such as compressed air and pre-conditioned air) in the same trench with the electrical conduits. Locate the access manholes outside the paved areas.

2-1.5 Site Configuration.

Coordinate the layout of the POU systems with the siting of the maintenance hangars, parking apron space and taxiways in accordance with UFC 3-260-02, *Pavement Design for Airfields,* and the following requirements:

- Include load calculations and voltage drop calculations in the Basis of Design for all service and distribution feeders in accordance with UFC 3-501-01. See Table 2-1 Notes for additional discussion on the possible increased load on the input of the converter due to the full kW at Unity design requirement.
- Utilize 60 Hz service and distribution equipment rated for exterior use in accordance with NEMA 250, IEC 60529, and UFC 3-550-01. Utilize 400 Hz, 270 VDC, and 28 VDC equipment rated for exterior use in accordance with NEMA 250 and the options designated in the UFGSs.
    a. **For Navy and Marine Corps**: provide enclosures rated NEMA Type 3SX (or IEC IP55) or better, with corrosion resistant paint, provide sealed non-ventilated electronics enclosures, and conformal coating on electronic components such as PC boards.
    b. **For Army and Air Force**: provide enclosures rated NEMA Type 3S (or IEC IP55) or better. In corrosive locations, provide enclosures rated NEMA Type 3SX (or IEC IP55) or better, with corrosion resistant paint, and provide sealed non-ventilated electronics enclosures and conformal coating on electronic components such as PC boards.
- Consider the following for multiple facility and equipment location development:
    a. Locate the central equipment facility as near the hangar as practical at a location offering the most direct access to the parking apron. Minimize the length of the underground mains to the parking apron.
    b. Locate the section of underground mains between the central facilities and the first transition point outside the apron and taxiway pavements.
    c. Locate the feeder distribution center, consisting of pad-mounted equipment, off the apron as close as practical to the service points to minimize aircraft service voltage drop.
    d. When voltage drop calculations permit, the feeder distribution centers for apron service points may be located in the hangar or located outside nearer to the hangar. This may limit the amount of primary distribution that is required to be run throughout the site. It may also increase the number of distribution components that are located in dry environments instead of harsh environments which may be less expensive and require less maintenance.

e. When structures are installed on the apron for the aircraft parking spots, coordinate the location of the service points to be adjacent to, but not under the structures. Note – A new UFC is under development by the Airfield Criteria Team to clarify that these structures are designated to be "sun shades" and not "shelters". That UFC will establish requirements, including that utilities are not permitted to be under "sun shades".

f. See Figure 2-1 for one example of a typical POU system layout for serving a hangar and parking apron complex.

g. See Figure 2-2 and Figure 2-3 for examples of different layouts and types of structures installed at some bases.

For the Navy and Marine Corps, see UFC 2-000-05N; *Facility Panning for Navy/Marine Corps Shore Installations* for additional information on the parking apron layout for Navy and Marine Corps Shore Installations.

Figure 2-1 POU System "Aircraft Parking Apron" – Site Plan Layout Typical

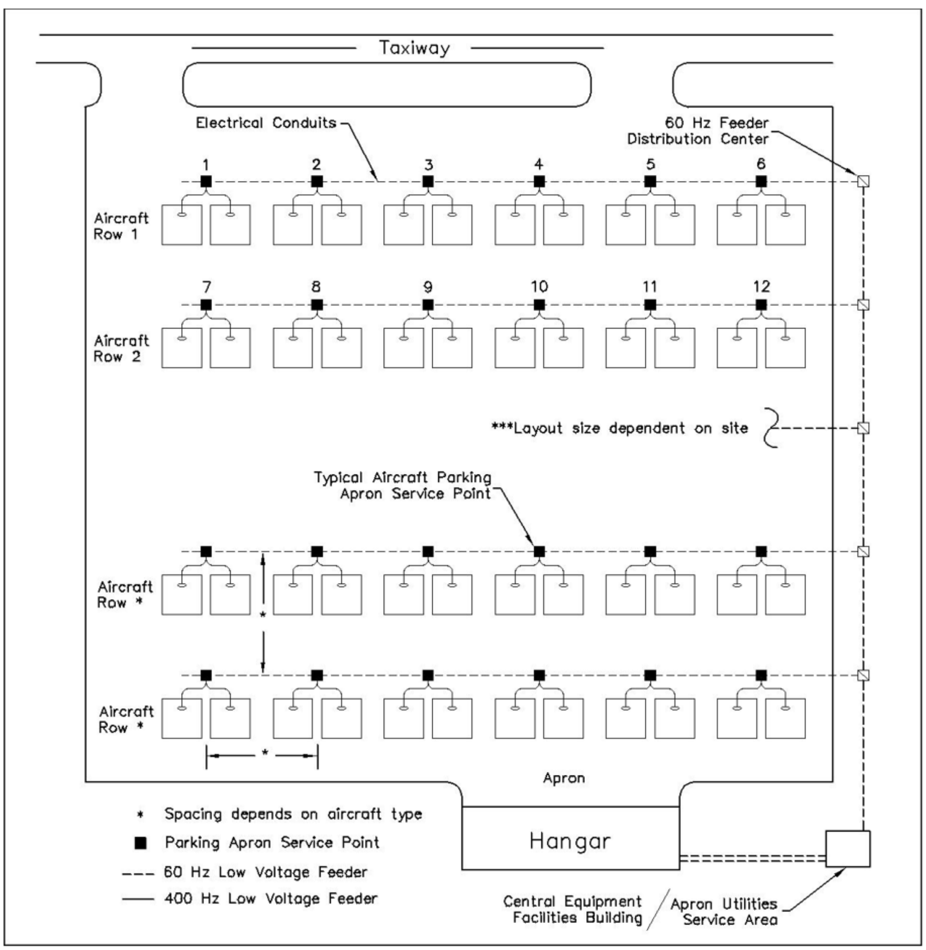

Figure 2-2 Example of Apron Layout with “Sun Shades”

Figure 2-3 Example of Apron Layout with POU Equipment

2-2 UTILITY SYSTEM LOAD DETERMINATIONS.

Use the total number and type of aircraft, plus the demands of other ground support activities to be supplied by the fixed point facilities, and determine load requirements for the utility system.

2-2.1 Aircraft Unit Demands.

For the Navy and Marine Corps: Utilize Table 2-1 Navy and Marine Corps Aircraft Electrical Requirements when completing load calculations.

Table 2-1 Navy and Marine Corps Aircraft Electrical Requirements

Aircraft Load Type	Aircraft Voltage: 400 Hz or 270 VDC	Designated Converter Size (See Notes 1 & 2)	Designated Cable Ampacity	Designated Cable Length
Fixed Wing	**400 Hz**	90 kW – see Note 3	260 Amp	105 ft (32 m)
Rotary Wing	**400 Hz**	45 kW - see Note 3	180 Amp	105 ft (32 m) (see Note 4)
Fixed Wing	**270 VDC**	72 kW - see Note 5	333 Amp	83 ft (25 m)
UAVs and limited other aircraft that are dedicated to 28 VDC	**28 VDC**	TBD – see Note 6		

Note 1: Provide designated Converter size unless there are specific project design requirements that have been approved by NAVFAC and NAVAIR. See paragraph *Regulatory Authorities* herein for POC information. Provide one cable per converter.

Note 2: Design to provide full capacity for each converter, measured at the aircraft end of the servicing cable, and utilize demand loading for utility distribution and transformer sizing. Coordinate with UFC 3-550-01 and UFC 3-501-01. Use Table 2-1, applicable to the number of aircraft being serviced in the facility under design, and apply the resulting number for the design demand factor for the Aircraft Load.

Note 3: The required load ranges for the 400 Hz converters are defined in the UFGS. The UFGS requires full load current (90 kW = 261 Amperes per phase and 45 kW = 130 Amperes per phase) compliance from the worst case lowest lagging power factor (currently 0.5 lagging), through full load at unity, up to the highest leading power factor (currently .7 leading).

a. These are very stringent requirements that are not met by a commercial off the shelf unit, or by previous converter designs. The two sizes, 90 kW and 45 kW have been standardized on, in order to facilitate approval of the equipment.

b. Because of the new requirements for the load range, converter input load will increase, possibly causing an increase in the feeder breaker conduit and wire sizes serving each unit. For new projects, and for apron unit replacement and building renovation projects where existing kVA sized units are being replaced by kW sized units, the Designer of Record (DOR) must obtain nameplate data from at least two manufacturers and document this information in their Basis of Design calculations.

c. Based on recent experiences with two manufacturers, it is imperative that NAVAIR and NAVFAC LANT POCs be involved on all projects in order to establish a database of manufacturers who have developed new designs.

d. As identified in the UFGS, these designs must be proven by the manufacturers by also developing Special and Routine Test Plans and Reports that are geared specifically to all the new requirements in the UFGS.

e. After NAVAIR approval of these test plans and the report format, the government intent is to witness the actual tests being performed at the factory.

f. Those documented reports from the witness testing would then be submitted in for NAVAIR and NAVFAC LANT final approval.

Note 4: Provide the designated Cable Length unless the project design requirements that have been approved by NAVFAC and NAVAIR identify a 90 ft (27 m) length as being required.

Note 5: The 270 VDC converters are used to supply 270 VDC (267 Amps) and limited amounts of 28 VDC electrical Interlock voltage (15 Amps), measured at the aircraft end of the servicing cable. See UFGS 26 35 44 for details.

a. The new UFGS requirements will require an identical approval process by NAVAIR and NAVFAC LANT POCs as described for the 400 Hz converters in Note 3 above.

b. For 270 VDC output systems, there is no difference in KW and KVA ratings. A 72 kW / 72 kVA DC converter must deliver 267 Amps under specified conditions.

Note 6: Per NAVAIR, when there is a requirement for a 28 VDC platform, request the specific FRD for the UAV or other limited aircraft, and coordinate with the NAVAIR POC designated in this UFC for any known special requirements that should be incorporated into the design and into a project specification. The NAVFAC LANT and NAVAIR POCs may have some sample specification paragraphs or testing requirements that could be used with a draft project specification, until an official UFGS has been developed.

2-2.2 System Load Demand.

In addition to establishing the system demand for individual apron and hangar loads, apply a system demand factor to the overall base system.

- Use Table 2-2 to establish the number of aircraft expected to exert a simultaneous demand for the portion of the system under consideration. The demand factors apply to aircraft using 270 VDC or 400 Hz.
- Base the electrical demand for the 60 Hz, 400 Hz, and 270 VDC systems, per the table; i.e. in a 36 aircraft squadron, the power demand should account for powering 12 aircraft (31 percent x 36 aircraft = 11.7, rounded up to 12). Proportion the resulting demand between parking apron service points and hangar service points with a ratio of 2 to 1 respectively.

Implement these results when establishing the service transformer and distribution equipment requirements in accordance with UFC 3-550-01 and basis of design calculations in accordance with UFC 3-501-01.

Table 2-2 System Demand Factors

Number of Aircraft	Demand Factor Percent
1	100
2	90
3	83
4	77
5	71
6	66
7 to 9	61
10 to 12	50
13 to 15	45
16 to 21	40
22 to 40	31
41 to 60	28
Over 60	25

2-2.3 Additional Load Considerations.

In addition to aircraft, there are other loads that may require 400 Hz, 270 VDC and 28 VDC power. Prior to supplying these facilities, verify that equipment installed will not be damaged by the hangar POU power tolerances. Separate local converters should normally be used for these systems. These loads include the following:

- Avionics. Repair shops for electronic equipment require specialty power for maintenance and testing. Coordinate with the using agency to obtain the actual load requirements in such cases.
- Other Facilities. Research, development, training, and other types of facilities may require 400-Hz, 270 VDC, and 28 VDC distribution systems. If the using agency cannot provide the actual load requirements, compute such loads on a watts per square foot (square meter) basis when firm loads are not available in accordance with UFC 3-501-01.

2-3 ELECTRICAL REQUIREMENTS ON APRONS.

Provide electrical service on aircraft parking aprons to accommodate the aircraft types and operational function of the squadron or group. The electrical distribution system may consist of pad mounted switches, transformers, switchboards, panelboards, service point equipment enclosures, and underground distribution feeders located near each row of planned aircraft parking. Provide a one line diagram, with legend and details clearly indicating the planned arrangement. Provide this equipment in accordance with UFC 3-550-01. An example of a one line for a typical system is shown in Figure 2-4.

2-3.1 Parking Apron Service Points.

Provide service from the Switchboards to each service point.

a. In the example distribution system indicated in Figure 2-1, each service point would serve two converters and each of these converters would serve an aircraft.

b. On some sites, a dedicated service point may be used for each aircraft parking spot if it is validated with the Activity. However, this may add more enclosures and equipment on the airfield.

c. The electrical requirements at each location, (often called an island) normally include 60 Hz receptacles and miscellaneous loads in addition to whichever special power system converters (400 Hz, 270 VDC or 28 VDC) are required. An example one line for a typical 400 Hz system is shown in Figure 2-5, and the associated legend is in Figure 2-6.

d. The UFGS now requires “individual converters”; i.e. one converter serving each parking spot. However, if space is a consideration on the apron, a single, low-profile, factory built and tested, dual converter unit is permitted. It must consist of two, independent, fully rated, simultaneous converters in a single enclosure, housing all the necessary components. The unit’s construction part of the UFGS may have to be modified to explain this exception. Coordinate with the Activity to verify that having a dual unit is acceptable, since it may entail outages for two aircraft instead of one during maintenance issue.

e. Coordinate the island locations and layout with the mechanical utilities designer to determine if a compressed air dispensing system needs to be incorporated into the main service point enclosure. If it does, incorporate the mechanical components in the rear half of the enclosure and the electrical components in the front half of the enclosure. (See UFC 4-211-01 for the mechanical requirements).

Figure 2-4 POU Aircraft Parking Apron – One Line Diagram

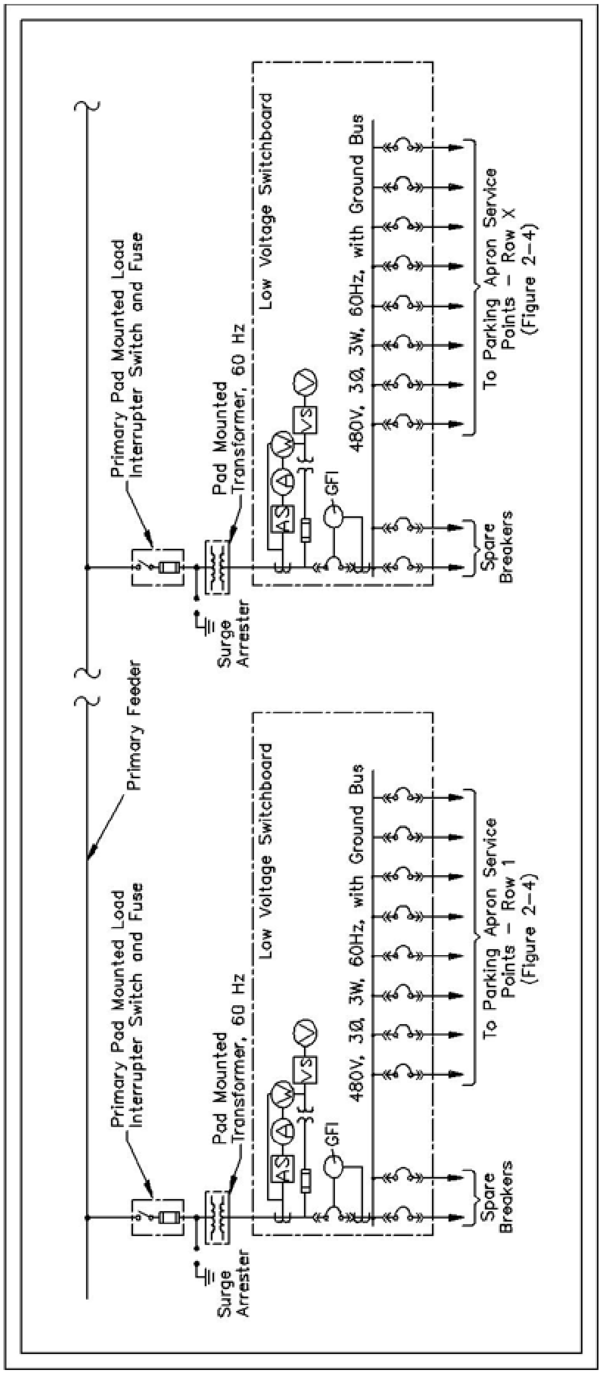

Figure 2-5 Parking Apron Service Point Arrangement / One Line

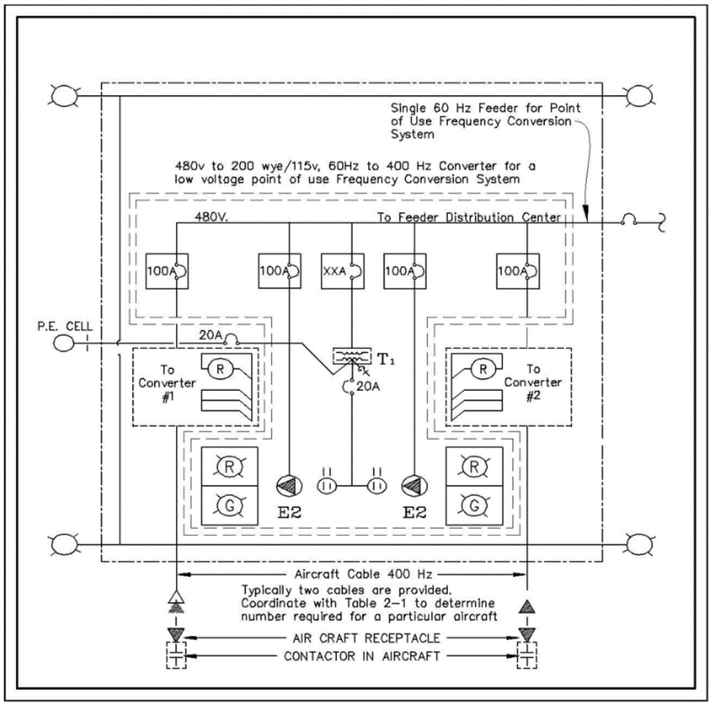

Figure 2-6 Legend

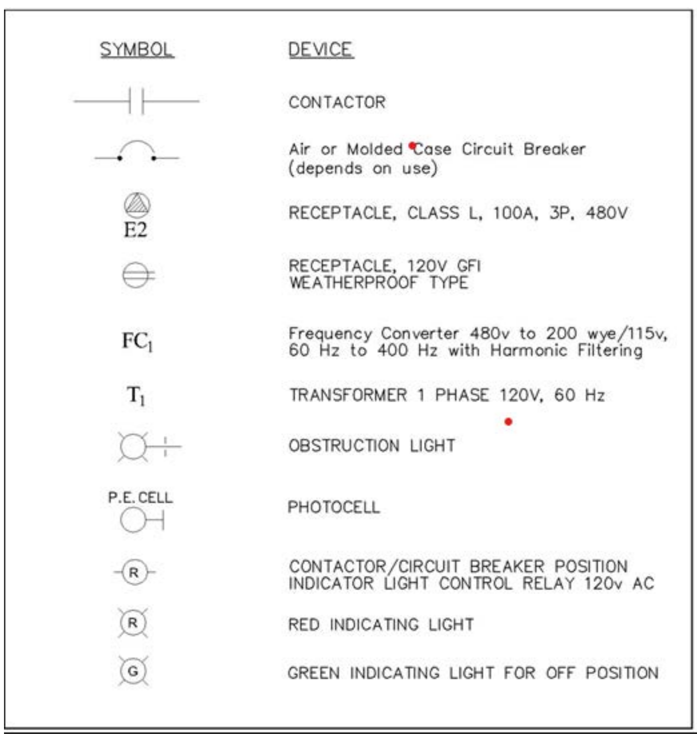

2-3.1.2 Construction.

The service point enclosures must be manufactured enclosures based on the location, and in accordance with paragraph Site Configuration. Field fabricated enclosures are not permitted. Mount the main service point enclosure assembly, and the associated converters, on a concrete base pad approximately 6 in. (152 mm) above the apron grade. Protect this entire assembly from vehicular traffic with concrete-embedded steel posts.

2-3.1.3 Electrical Equipment Components.

Provide each main service point with 60 Hz components (and the 60 Hz circuit breakers for the specialty 400 Hz or 270 VDC systems converters) as follows:

a. 60 Hz input circuit breaker(s) three-pole, 600 V. Size the input circuit breaker to include the specialty system converter loads. Operate the circuit breaker from the front of the service point enclosure. Note: all the 60 Hz breakers may be included in a panelboard / switchboard arrangement within the service point assembly.

b. Two 100 ampere and two additional, three-pole, 600 V, 60 Hz, molded case circuit breakers. Mount two breakers on the interior of each side panel. (One on each side will be used for Item c, and the second on each side will be used for the converter. Based on the new requirement for kW ratings, coordinate required ampacity of the converter breakers with at least two manufacturers.)

c. Two 100 ampere, 480 V, three-phase, four-wire, 60 Hz receptacles for Government furnished Ground Support Equipment (GSE). These receptacles are built by very few manufacturers and are identified by part numbers. Coordinate required outlet amperage (if other than 100 A) and type requirements with the users. Mount one receptacle on the exterior of each side panel.

d. One 3 kVA, one-phase, 480-120 V, 60 Hz, dry-type transformer with two-pole primary circuit breaker and a one-pole, 20-ampere secondary breaker. The transformer provides power for control, 120 V receptacles, and obstruction lights. When the mechanical system is included in the assembly, mount the transformer and the protecting breakers on the interior sheet steel barrier between the mechanical and electrical sections.

e. Two 20 ampere, 125 V, one-phase, two-pole, three-wire, 60 Hz, weatherproof receptacles with ground-fault interrupting. Mount one receptacle on each of the exterior side panels.

f. Provide obstruction warning light fixtures for each service point enclosure. Fixtures must be steady-burning red obstruction lights, FAA Type L-810. Provide in accordance with UFC 3-535-01, *Visual Air Navigation Facilities*, and FAA AC 70/7460-1. Provide fail-safe photoelectric control for the fixtures at each service island. Coordinate with the Activity to verify number required at each location. Typically, four fixtures are used, mounted near corners of the enclosure. If Activity concurs with limiting the number to two fixtures, install at opposite corners. If only one fixture is required by Activity, it must be a dual L-810 fixture.

g. Verify with Activity and Airfield Manager to determine whether or not LED fixtures are permitted.

h. Provide apron site lighting around the main service points in accordance with UFC 3-530-01, *Interior and Exterior Lighting Systems.*

i. When mechanical systems are included in the enclosure, mount one low-air-pressure warning light on the exterior panel adjacent to the mechanical system pressure gauge.

2-3.2 Converter and Cable Requirements.

Provide the converters in enclosures suitable for the exterior location of the project and in accordance with the requirements in Chapter 3.

Provide the cables in non-metallic ductbanks when underground, for the specialty systems as needed, and in accordance with the requirements in Chapter 3

CHAPTER 3 ELECTRICAL REQUIREMENTS IN HANGARS

3-1 NORMAL POWER DISTRIBUTION.

Provide normal power within Aircraft Hangars in accordance with the facility UFC 4-211-01. It is usually a 3-phase wye-connected, underground secondary service rated at 480 Volts Alternating Current (VAC). For projects outside of the United States and its territories and possessions, electric power is in accordance with UFC 3-510-01, *Foreign Voltages and Frequencies Guide.*

3-1.1 Hazardous (Classified) Locations.

Design hazardous (classified) locations including the hangar bay and adjacent spaces in accordance with NFPA 70, *National Electrical Code* requirements for hazardous locations. At a minimum, classify adjacent spaces that are not suitably cutoff as Class I Division 2 up to 18 inches (460 mm) above the floor of the hangar bay adjacent to the space.

Note: The area within 5 feet of any aircraft fuel vents and any fuel containing portion of the aircraft is Class I Division 2. For practical use and mission-flexibility, this is generally simplified to within 5 feet (1.5 m) horizontally of any aircraft surface and vertically from 5 feet (1.5 m) above the surface down to the floor.

- If a space is adjacent and communicates with a hazardous location, comply with the requirements and figures in UFC 4- 211-01.

For Navy and Marine Corps: Design all hangar bays electrically as hazardous areas for maintaining fueled aircraft regardless if the aircraft contain fuel or not. Assume all aircraft in hangar bay will enter fueled.

3-1.2 Electrical Equipment.

Comply with the facility UFC 4-211-01 for the minimum requirements for the electrical equipment enclosures in the hangars. Comply with the technical notes in the UFGSs for the equipment enclosures for converters located in the hangars.

For Army: All electrical equipment in the hangar bay is required to be in a NEMA 250 Type 3R or weather proof enclosure.

3-2 AIRCRAFT POWER DISTRIBUTION.

Aircraft have specific power requirements, including unique voltages, frequencies, and capacities. Review the aircraft requirements of the aircraft being maintained in the hangar bay to determine the appropriate services. Provide appropriate services in voltage, frequency, and capacity to service the aircraft.

Coordinate with the latest requirements in UFGS 26 35 43*, 400 Hertz (Hz) Solid State Frequency Converter* and UFGS 26 35 44*, 270 VDC Solid State Converter.* Provide permanently-mounted equipment located within the hangar bay or an adjacent space as follows:

- Permanently-mounted equipment may be installed within the hangar bay or within an adjacent space to the hangar bay. If equipment is installed in the hangar bay it may be either floor-mounted or mounted on the wall at a higher elevation. If the equipment is mounted at a higher elevation, coordinate the support of the equipment with the structural engineer. If the equipment is mounted on the floor, provide a stand for the equipment to elevate the equipment a minimum of 18 inches (0.46 m) AFF to avoid having the equipment in the Class I Division 2 hazardous space. Coordinate location of equipment to maintain the clear zone. Refer to UFC 4-211-01, paragraph 2-3: Minimum Aircraft Maintenance Bay Clearances for clear zone requirements.
- Provide a detail on the drawings that identifies the location, mounting and permitted maintenance access areas (the maintenance envelope) for each converter.
- Provide solid-state equipment for special power units.
- Permanently-mounted equipment typically has controls mounted on the face of the equipment. If the equipment is mounted at a higher elevation, or in an adjacent space, provide remote control and displays at an elevation within the hangar bay that is accessible by the user.

For Air Force:

a. Aircraft power distribution equipment is government furnished. Power distribution equipment may be provided as Service Equipment (SE) carts or permanently mounted equipment.

b. Government-furnished SE carts may be diesel powered or electrically powered. If an SE cart is diesel powered, park the SE equipment outside of the hangar bay and extend cables to the aircraft from the SE equipment. If an SE cart is electrically powered, provide a 480V, 3-phase receptacle on the wall or pedestal and extend the power from the connection to the equipment. SE carts are government furnished equipment. Coordinate the sizes and type of connection with the users and equipment available at the installation.

For Army, Navy and Marine Corps: All Converters are now required to be individual output, Point of Use (POU) converters, with each converter serving only one receptacle on an aircraft.

For Army: A combination converter (having both 400 Hz and 28 VDC outputs) is only permitted when it is specifically identified as being required on a particular project.

For Navy and Marine Corps:

a. Combination Converters, (having both 400 Hz and 270 VDC outputs, or having both 400 Hz and 28 VDC outputs) are not allowed**.**

b. Converters in hangars must be flush mounted against the wall, must not require back access for maintenance, and must comply with the “Maintenance Envelopes” identified on the project drawings.

c. Coordinate with the Navy Functional Data Sheets (FDS) and Space Types information in UFC 4-211-01 for additional information on Specialty Power Systems requirements, such as locations (like Avionics shops) where additional 400 Hz, 28 VDC, or 270 VDC services are needed.

3-2.1 Power Distribution Service Points.

Distribute aircraft power from permanently-mounted equipment located on the wall.

3-2.1.1 Wall-mounted connection points.

Different aircraft have different power requirements and connections. Match receptacle and cable type to aircraft being maintained. Provide wall-mounted connection points close to the distribution equipment. Coordinate the location of the connection points with the location of the aircraft connection point to minimize the length of the cable from the wall to the aircraft. Provide one of the following connections:

- Provide wall-mounted cable storage racks for storage of the cable. When receptacles are installed, mount receptacles above electrical hazardous location. Provide floor-mounted cable protectors from the wall across the service lane to the aircraft side of the service lane. Lay cables in the cable protector to protect cable from cross traffic while the cables are extended and in use.
- When approved by the Activity and Facilities Manager, provide wall-mounted electrically or air driven reels. Approval authority must agree to the potential additional maintenance and power quality issues related to how the power is transferred from the converter to the reel and to the cable on the reel. These additional connections and contact surfaces must be maintained. Install electric motors above the electrical hazardous location. Provide reel controls as part of the cable assembly. Coordinate motor size and type with length and weight of cable provided. If used, DOR must include reliability information from multiple manufacturers in the Basis of Design and add appropriate information to the specifications.

For Army: Cables connecting to the service point may or may not be provided as part of the service.

For Air Force:

a. Distribute aircraft power from government furnished SE carts. Government-furnished SE equipment is mobile and provides a flexible solution. The aircraft cables are typically connected to the SE cart. The equipment is owned and maintained by the maintenance mission and typically the equipment will be shared for hangar and on-ramp maintenance. A storage area may also be required for the equipment.

b. The cables connecting to the aircraft power distribution service point may or may not be provided as part of the service. Coordinate the provision of the cables with the mission owner.

For Navy and Marine Corps: Provide cables connecting to the service point as part of the service.

3-2.1.2 Permanently-Mounted Pedestal.

For Air Force, Navy and Marine Corps: Permanently-mounted pedestals are not permitted.

For Army: Provide permanently-mounted pedestals. Coordinate the connection point in the hangar floor space with the location of the aircraft. Permanently mount the pedestal to the hangar floor. Locate pedestals to avoid aircraft movements. Coordinate the location of pedestals with the clearance requirements listed in UFC 4-211-01, paragraph 2-3: Minimum Aircraft Maintenance Bay Clearances. Pedestal may have multiple mechanical, electrical, and communication services including power, compressed air, network connections, and water. Coordinate types of all service utilities to be provided on pedestal with activity. Route utility connections under the hangar floor from the wall to the pedestal. Mount all electrical utilities a minimum of 18 inches (0.46 m) AFF. Seal all electrical penetrations from the floor, per NFPA 70.

3-2.1.3 Retractable (Pop-up) Pedestal.

Retractable (Pop-up) pedestals are not permitted.

3-2.1.4 Aircraft Power Distribution Point Utility Coordination.

Other services including compressed gasses, water, and preconditioned air are required to maintain aircraft. Coordinate the location of electrical services with all other utilities.

3-3 AIRCRAFT POWER SYSTEMS.

Provide the appropriate aircraft power systems in voltage, frequency, and capacity to service the aircraft being maintained.

For Army: Special Power.

a. Use Table 3-1: Army Aviation Platform Ground Service Baseline Requirements for Service Baseline Requirements.

b. Integrate the system with the building power system and provide a complete system with all cables and connectors required to interface with the aircraft. No ground power units (carts) are allowed. Design system to provide access to each aircraft parking space without any cables or equipment passing thru the five foot clear zone around the hangar bay floor.

For Navy and Marine Corps: Refer to Table 2-1 for additional information.

Table 3-1 Aviation Platform Ground Service Baseline Requirements

GROUND SERVICE	AVIATION PLATFORM GROUND SERVICE BASELINE REQUIREMENTS							
	AHH-64A	AH-64D	UH-60A/L	UH/MH-60M, X	CH-47D	DH/MH-47E, F, G	OH-58D	ARH-70A
400 Hz 200/115 V	35 kW	35 kW	45 KW	45 kW	20 kW	40 kW	10 kW	N / A
28 VDC START	NONE	NONE	NONE	NONE	NONE	NONE	500-750A START	500-800A START
28 VDC SERVICING	NONE	NONE	NONE	NONE	300A SERVICING	300A SERVICING	200A SERVICING	200A SERVICING

3-3.1 Aircraft 400 Hertz (Hz) Service.

Design a complete, functioning 200Y/115VAC, three phase, 400 Hz power system, including converter, cables, and connectors, to support the aircraft maintenance activities. Provide Point of Use (POU) 400 Hz service in the hangar bays and in shops where 400 Hz is required by the users.

- Combination converters (having multiple 400 Hz outputs, having both “400 Hz and 28 VDC” power outputs, or having 400 Hz and 270 VDC outputs) are not permitted on Navy and Marine Corps projects. A combination converter (having both 400 Hz and 28 VDC outputs) is permitted on an Army project when it is specifically identified as being required.

- Previous versions of criteria referred to 400 Hz equipment sized only in kVA at 0.8 lagging power factor. This has changed, and designs are now required to use kW instead of kVA as the unit of power measurement for converters here and on the project drawings. This significant change in equipment designation, has been made to:

  a. Ensure that our equipment meets the full required load range, including full power at unity power factor.

  b. Eliminate the problems that have been occurring with existing equipment in the field.

  c. And to accommodate the increasing nonlinear load characteristics of Military equipment.

     - For Navy and Marine Corps documents, including their Facilities Requirements Documents (FRD)s, are being revised to coordinate with this change to kW. Army documents are in the review process. UFGS 26 35 43, *400 Hz Solid State Frequency Converter* has been rewritten to incorporate this requirement.

3-3.1.1 400 Hz Converter Sizes.

Coordinate the exact number and sizes of converters with the users supported.

For Army: Converters are sized per Table 3-1.

For Navy and Marine Corps: Provide 90 kW converters for all fixed wing aircraft and provide 45 kW converters for all rotary wing aircraft unless there are specific project design requirements approved by NAVFAC and NAVAIR. See Table 2-1. (One example, may be the direct replacement of an existing, larger kW converter),

Design the system to provide power to each aircraft parking spot. Design system to compensate for voltage drop and provide sufficient voltage at the point of service. Provide voltage drop calculations, in accordance with requirements in UFC 3-501-01, to meet the voltage requirement at the aircraft point-of-service, and to meet the requirements of the aircraft power monitor. See Appendix A for sample equations.

For Air Force: Aircraft 400 Hz systems are provided using government-furnished SE or government-furnished fixed equipment. A fixed 400 Hz system may be provided for a building, if approved by Civil Engineering (CE).

For Army, Navy and Marine Corps: 400 Hz converters, cables, and connectors are Real Property Installed Equipment (RPIE) equipment.

3-3.1.2 Aircraft 400 Hertz (Hz) Special Power Distribution Cables.

Provide 400 Hz cable in accordance with SAE AS7974 and SAE AS5756/6, consisting of six power conductors, two per phase, helically laid around one central neutral conductor and six control conductors, minimum of #18 American Wire Gage (AWG), specifically designed for 400 Hz applications.

For Army:

a. Coordinate the cable amperage and cable length between 30 and 100 ft. (9.1 to 30.5 m) with the aircraft on the project.

b. Base the size of the power conductors on the kilowatt (kW) rating of the aircraft.

c. Base the length of the cable on the distance from the distribution equipment to the aircraft location.

For Navy and Marine Corps:

a. Use the 260 Amp and 105 feet (32 meters) length options in the specification for all cable assemblies with the 90 kW converters.

b. Use the 180 Amp and 105 feet (32 meters) length for all 45 kW converters, unless the project requirements given to the designer of record specifically identify that the 90 feet (27 meters) length is sufficient.

3-3.1.3 Aircraft Cable Provision.

Coordinate how the cables are being provided for the project with the users. The cables may be part of the Military Construction (MILCON) or the cables may be equipment provided by the user. If the cables are permanently affixed to the facility distribution system, the cable is considered to be part of the MILCON. If the cables can be disconnected from the facility distribution system, the cable is provided by the user.

3-3.1.4 Aircraft Cable Interlock Circuits.

Incorporate safety requirements into the converter / cable interlock circuits. Comply with NFPA 70 E and UFC 3-560-01, which mandates the use of Standard Operating Procedures (SOPs) for electrical equipment. Confirm that any exemptions or exceptions to the safety criteria has been identified within these SOPs.

For Army, Navy and Marine Corps:

a. Provide the “split F interlock” for all new installations. This interlock is built into the cable end to ensure that the cable is not energized until it is connected to the aircraft, and that it is automatically deenergized as soon as disconnecting from the aircraft has begun. See MIL-DTL-32180 for technical information, and typical details and schematics on the operation of the interlock.

b. When the aircraft cable specification is used for existing converters, coordinate with the Activity to ensure they understand the new safety requirements being built into the new “split F interlock” cable ends, and that the Activity has the appropriate Standard Operating Procedures (SOPs) in place, per UFC 3-560-01, for the remainder of their existing equipment.

For Air Force: When involved with certain “Legacy” Air Force Aircraft, the 28 VDC may need to be changed to utilize one of the 115 V, 400 Hz phases instead. Coordinate with Activity to confirm requirements.

3-3.2 Aircraft 28 Volts Direct Current (VDC) Service.

Design a complete and functioning 28 VDC power system, including converter, cables, and connectors, to support the aircraft maintenance activities. Provide Point of Use (POU) 28 VDC service in the hangar bays and in shops where 28 VDC is required by the users.

For Army: A combination converter (having both 400 Hz and 28 VDC outputs) is permitted on an Army project when it is specifically identified as being required. This information has been incorporated as options in the UFGS 26 35 43, *400 Hertz (Hz) Solid State Frequency Converter*.

For Navy and Marine Corps: Combination converters (having multiple 28 VDC outputs, or having both “400 Hz and 28 VDC” power outputs) are no longer permitted on Navy and Marine Corps projects. Individual 28 VDC Converters are required. Contact NAVFAC Atlantic, Code DC 44 – Criteria Manager at (757) 322-4327, for a draft 28 VDC specification that can be modified for the specific project.

Coordinate the exact number and sizes of converters with the users supported. Design the system to provide power to each aircraft parking spot, when required.

For Airforce: Aircraft 28 VDC Service Distribution systems are provided using government-furnished SE cart or government furnished fixed equipment. A fixed 28 VDC system may be provided for a building, if approved by CE.

For Army, Navy and Marine Corps: 28 VDC converters, cables and connector are RPIE equipment. The use of centralized systems serving multiple aircraft are prohibited.

3-3.2.1 Aircraft 28 VDC Distribution Cables.

Provide 30 to 100 ft. (9.1 to 30.5 m) 28 VDC cable assembly, consisting of two individual power conductors banded together with non-metallic bands in accordance with SAE AS5756. Provide strain relief, and appropriate integrally molded connector in accordance with SAE AS7974. Base the size of the conductor on the kW rating of the aircraft. Base the length of the cable on the distance from the distribution equipment to the aircraft location.

Coordinate how the cables are being provided for the project with the users. The cables may be part of the Military Construction (MILCON) or the cables may be equipment provided by the user. If the cables are permanently affixed to the equipment, the cable is considered to be part of the MILCON. If the cables can be disconnected from the facility distribution system, the cable is provided by the user.

3-3.3 Aircraft 270 VDC Service.

For Air Force, Navy and Marine Corps: Design a complete and functioning 270 VDC power system, including converter, cables, and connectors, to support the aircraft maintenance activities. Provide Point of Use (POU) 270 VDC service in the hangar bays and in shops where 270 VDC is required by the users. Combination converters (having "multiple 270 VDC outputs", or having both "400 Hz and 270 VDC" power outputs) are no longer permitted.

For Air Force:

a. Coordinate the exact number and sizes of ground power units with the users supported. Design the system to provide power to each aircraft parking spot.

b. Aircraft 270 VDC systems are provided using government-furnished SE carts or government-furnished fixed equipment. A fixed 270 VDC system may be provided for a building, if approved by Civil Engineering (CE).

For Navy and Marine Corps:

a. Coordinate the exact number of ground power units with the users supported. Design the system to provide power to each aircraft parking spot.

b. The Navy and Marine Corps have standardized on one size, 72 kW for all 270 VDC converters. Coordinate with the requirements in UFGS 26 35 44, *270 VDC Solid State Converter*.

c. Aircraft 270 VDC converters, cables, and connectors are RPIE equipment.

3-3.3.1 Aircraft 270 VDC Distribution Cables.

Provide 30 to 100 ft. (9.1 to 30.5 m) 270VDC cable consisting of a single jacketed multi-conductor cable with power and controls incorporated into the cable with the appropriate connector. Base the size of the conductor on the kW rating of the aircraft. Base the length of the cable on the distance from the distribution equipment to the aircraft location.

Coordinate how the cables are being provided for the project with the users. The cables may be part of the Military Construction (MILCON) or the cables may be equipment provided by the user. If the cables are permanently affixed to the equipment, the cable is considered to be part of the MILCON. If the cables can be disconnected from the facility distribution system, the cable is provided by the user.

For Navy and Marine Corps: Refer to Table 2-1 for additional information.

3-3.4 Special Additional 60 Hz Power Service Points.

For Navy and Marine Corps: Provide special additional 60 Hz power service points in hangars as identified in the Navy Functional Data Sheets. Coordinate all requirements with users and aircraft manufacturer and dedicate adequate wall space for all equipment. The power service points may include:

a. Three-phase, 480V, 4-wire, 60 Hz, receptacles for government furnished support equipment (SE). These receptacles are built by very few manufacturers and are identified by part number. Coordinate required outlet amperage and type requirements with the users.

b. Single-phase, 120V, 60 Hz, ground fault interrupt duplex utility outlets.

c. For Triton Type IV hangars: As a minimum, provide one special receptacle for Ground Support Equipment (GSE) at each aircraft parking space (minimum four per hangar bay). The receptacle required is a 480 VAC, 100 ampere, three-phase, four-wire, 60 Hz, MIL-C-22992, Class L, Connector Size 44, with an Insert Arrangement per MS14055 Figure 5.

3-4 GROUNDING AND BONDING.

Provide grounding and bonding in accordance with UFC 3-575-01, *Lightning and Static Electricity Protection Systems*.

APPENDIX A SUPPLEMENTAL TECHNICAL INFORMATION

A-1 CALCULATIONS.

Design analysis and documentation, including electrical calculations for Specialty Electrical Systems, are required in accordance with UFC 3-501-01 utilizing power modelling software. The standard 60 Hz calculations, complete to the incoming side of the converter, should all be covered in the Basis of Design requirements for other electrical UFCs. With Point of Use systems being required for all new designs, 400 Hz, 270 VDC and 28 VDC specialty system calculations should be limited to:

a. Converter connecter via specified cables direct to aircraft connector.

b. Converter to a cable reel, then to the aircraft.

c. Feeding from a platform mounted converter, down to the wall mounted connection points, then to the aircraft.

d. Feeding from the wall mounted converter (for Army) under the clear zone (walkway), to the pedestal mounted connection points, then to the aircraft.

Note: Future updates to this UFC will look at incorporating sample calculations with power modeling software printouts.

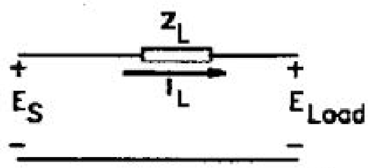
A-2 400 HZ CALCULATIONS.

The inductive contribution to the reactance voltage drop of 400-Hz systems is roughly seven times greater than that of 60-Hz systems, which necessitates certain modifications to conventional distribution and utilization system design to compensate for the increased voltage drop. The circuit diagram and formulas presented in Figure A-1 have been reproduced from the archived UFC 3-555-01N, and can be used with Table A-1 for determining 400 Hz system voltage drops.

- The minimum voltage required at the aircraft is 113 Volts.
- Therefore, maximum voltage drop allowed = 120 - 113 = 7 volts.

Table A-1 is a limited part of Table B-3 in archived UFC 3-555-01N, which was reprinted from “Actual Specifying Engineer,” February 1972. This table gives the effective A.C. resistance and inductance values for copper conductors for THHN/THWN insulations and in air, non-metallic conduits, and rigid aluminum conduits.

Figure A-1 **Simplified 400 Hz Circuit Diagram and Formulas**



E_S – Source Voltage=208Y/120

E_{Load} – Load Voltage

I_L – Line Current

Z_L – Line Impedence=R_{ac}+jwL

R_{ac} – Alternating Current Resistance

L – Inductance

w – Angular Frequency=2 x 3.14 x frequency

SIMPLIFIED CIRCUIT DIAGRAM

FORMULAS

$E_S = I_L Z_L + E_{Load}$

$E_{Load} = E_S - I_L Z_L$

Line–to–Neutral Voltage Drop= $|E_S| - |E_{Load}| = I_L\ |Z_L|$

Line–to–Line Voltage Drop= $\sqrt{3}\,(|E_S| - |E_{Load}|) = \sqrt{3}\ I_L\ |Z_L|$

NOTE: FORMULAS USING PER UNIT QUANTITIES ARE ALSO ACCEPTABLE PROVIDED ALL INFORMATION IS INCLUDED IN THE CALCULATIONS.

A-3 OTHER SYSTEM CALCULATIONS

Since FLEDS (400 Hz low voltage Flight Line Electrical Distribution Systems) and Medium Voltage 400 Hertz distribution systems are not permitted for new designs, see UFC 3-555-01N and UFC 4-211-01 for calculations that may have been used on existing systems.

Those archived UFCs also contain old sample methods for establishing a multi-facility utility demand calculation using aircraft demand loading, and for establishing a facility (Hangar) load calculation and facility transformer / service equipment sizes using converter kw loads and aircraft demand loading. However, they should be considered for informational purposes only, since they also intermix medium voltage 400 Hz and the low voltage distributed 400 Hz systems for converters that are larger than our current POU converters.

A-4 400 HZ NON-LINEAR LOAD BANK INFORMATION

In order to comply with the stringent 400 Hz non-linear load range requirements in UFGS 26 35 43, manufacturers will have to develop a means to test their converters. They must prove that they continue to meet the performance requirements when operating into a non-linear load with not less than 15 percent current Total Harmonic Distortion (THD), composed of not less than 6 percent of the third harmonic and not less than 7 percent of the 5th harmonic.

Per NAVAIR, the intent of the load description with the 15 percent current THD is to portray a 50 percent linear and 50 percent non-linear load, with a nonlinear load designed to emulate a six pulse rectifier supplying a resistive load. Figure A-2 is a sample schematic diagram that is referred to in the technical notes in UFGS 26 35 43 and has been provided by NAVAIR for manufacturer's information. If the manufacturers would like to discuss this diagram, please contact the NAVAIR POC designated in paragraph titled Regulatory Authorities in this UFC.

This UFC supersedes UFC 3-560-01, Electrical Safety, O&M, dated 14 April 2015, with Change 5 and all preceding changes.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
SUMMARY SHEET

Document: UFC 3-560-01, Operation and Maintenance: Electrical Safety

Superseding:

- UFC 3-560-01, *Electrical Safety, O&M*, Change 5.

  The following documents were superseded by the original issuance of UFC 3-560-01 in 2006.

- Air Force Manual 32-1185, *Electrical Worker Safety.* This manual was prepared in draft form, but was not issued.
- TM 5-682, *Facilities Engineering, Electrical Facilities Safety.*
- UFC 3-560-10N (previously MIL-HDBK-1025/10), *Safety Of Electrical Transmission And Distribution Systems*.
- Draft UFC 3-560-02, *Electrical Safety*. This document was made mandatory guidance by Air Force Engineering Technical Letter (ETL) 04-15, *Electrical Safety Guidance*

Description: This UFC 3-560-01 incorporates tri-service requirements into one unified document and provides electrical safety requirements for all electrical work activities.

Reasons for Document:

- Provide guidance for all aspects of electrical safety.
- Conform UFC criteria to recently issued industry standards.
- Clarify work requirements for unique activities.

Impact: There are cost impacts associated with the required use of personal protective equipment (PPE). The new requirements associated with working on exposed, energized circuits involve additional safety precautions. However, the following benefits will be realized.

- Electrical safety criteria are more consistent with industry standards and OSHA requirements.
- Personnel working on electrical systems have improved guidance to ensure a safer working environment.

Unification Issues:

- Paragraph 1-4.3 Service-Specific Criteria, lists service specific documents that add additional safety requirements to this UFC. In several places in this UFC these documents are referenced for the technical subject being discussed. As an example, in Chapter 8 Energized Work, in sub-paragraphs 8-5, 8-6, and 8-7 additional requirements are listed for the Navy, Air Force and Army, respectively. These requirements, in general, incorporate the documents from Paragraph 1-4.3.

- Chapter 12 Shore-to-Ship Electrical Power Connections has Navy specific criteria requirements.

TABLE OF CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION

1-1 PURPOSE.

This Unified Facilities Criteria (UFC) provides safety requirements for electrical workers. The requirements address various aspects associated with work safety for electrical workers. Wherever specific instructions are provided, the emphasis is on the job safety requirements; additional work instructions will likely be necessary related to the actual work being performed.

1-2 SCOPE.

This UFC provides safety requirements and guidance for anyone working on or near electrical components rated at 50 volts or above in facilities and related infrastructure. The scope includes electrical substations and switching stations, the associated distribution systems, and extending to electrical distribution systems inside facilities, including electrical equipment covered by UFC 3-501-01.

For the purposes of this UFC, low voltage is defined as 1,000 volts or less. Voltages higher than 1,000 volts are referred to as high voltage. Refer to the Glossary for definitions.

Note: The prior edition of this UFC designated 600 volts as the upper limit for low voltage because this voltage was considered the highest low voltage that would be typically encountered. The designation of 1,000 volts as low voltage has been chosen to be consistent with NFPA 70E and NFPA 70. However, NFPA 70E provides the same approach distances for voltages between 751 volts to 15 kV, and refers to voltage above 600 volts as medium voltage in its Annex D. NFPA 70 provides different requirements for voltages below 600 volts, between 600 and 1,000 volts, and above 1,000 volts.

1-2.1 Need.

Electrical personnel involved in operating and maintaining electrical facilities can be injured and equipment can be damaged whenever electrical systems and components are not handled safely. The adoption and enforcement of safe electrical practices will reduce the hazards to personnel.

1-2.2 Familiarity and Requirements.

Each worker must understand and apply those safety requirements of this UFC that apply to the work performed. This safety manual must be readily available to each worker for reference and study.

1-2.3 Mishap Prevention.

Mishap prevention is a basic responsibility of every worker. Personal safety, fellow workers' safety, and the general public's safety depend upon compliance with this manual's requirements. Safety takes precedence over work production.

1-2.4 Unclear Conditions.

If this UFC does not cover a specific working condition or job requirements are unclear, workers must obtain clear instructions from an authorized individual-in-charge before proceeding with the work.

1-2.5 Applicability.

1-2.5.1 Facilities and Related Infrastructure.

This UFC applies primarily to maintenance workers involved in electrical work at DoD facilities and related infrastructure. This UFC covers the authorized individual-in-charge, crew members, and qualified and unqualified electrical workers. The authorized individual-in-charge might be a supervisor, a foreman, or a lead electrical worker depending upon local policy. This UFC applies to operations, maintenance, and construction functions. It also applies to design functions when on project sites. Construction activities performed by contractors are subject to the requirements of this UFC only when required by appropriate contract documents. It is more common for contracted construction to have EM 385-1-1, *Safety and Heath Requirements*, specified.

Note: For Navy electronics personnel/operations, follow the guidance outlined in SPAWARINST 5100.9D, Navy Shore Electronics Safety Precautions.

1-2.5.2 OCONUS Locations.

Facilities located outside of the United States must also comply with the applicable host nation standards; refer to UFC 3-510-01 for additional information. Different voltages, frequencies, and grounding conventions often apply in other host nations; however, follow the design principles provided in this UFC to the extent practical.

1-2.5.3 Contingency Tactical Locations.

Although the principles of electrical safety apply to work on any electrical system, this UFC does not apply to the following:

- Forward operating base.
- Contingency operating base.
- Other temporarily manned contingency tactical locations.

Refer to service-specific documents for requirements.

1-2.5.4 Privatized Systems.

This UFC does not apply to electrical equipment and electrical systems owned **\2** and maintained **/2/** by other organizations outside DoD. Non-DoD organizations may typically be the local utility.

1-2.6 Work Type.

The type of work covered includes electrical construction, installation, maintenance, operation, repair, and testing of base and facility electrical systems.

1-2.7 Occupational Safety and Health Administration (OSHA).

Comply with OSHA requirements, as applicable.

1-3 REFERENCES.

Appendix A contains a list of references used in this UFC.

1-4 CODES, STANDARDS, AND PUBLICATIONS.

1-4.1 Applicable Documents.

Several codes, standards, and regulations apply to basic electrical practices; these documents cover electrical work rules, safety procedures, and requirements for electrical installations. Comply with all applicable provisions of the current issues of these consensus standards as follows and as noted elsewhere in this document. The applicable documents include:

- 29 CFR 1910, *Occupational Safety and Health, General Industry Standards*.
- 29 CFR 1915, *Occupational Safety and Health Standards for Shipyard Employment*.
- 29 CFR 1926, *Occupational Safety and Health, Safety and Health Regulations for Construction*.

- ANSI/NETA MTS, *Maintenance Testing Specifications for Electrical Power Distribution Equipment and Systems*.
- IEEE C2, *National Electrical Safety Code* (NESC).
- **\2** IEEE 1584, IEEE Guide for Performing Arc-Flash Hazard Calculations.**/2/**

- NFPA 70, National Fire Protection Association (NFPA), *National Electrical Code* (NEC).
- NFPA 70B, *Electrical Equipment Maintenance*.
- NFPA 70E, *Electrical Safety in the Workplace*.

\3 *Note: Wherever NFPA 70E is referenced in this UFC, the reference refers to the* **\2** *2021* **/2/** *edition of NFPA 70E.* **/3/**

1-4.2 NFPA 70E and IEEE C2 Applicability.

For this document, specifically for arc flash related criteria issues mainly identified in Chapter 3 (Pre-Site Safety Management), and Chapter 4 (Protective Clothing and Personal Protective Equipment), the equipment operating voltage of 1,000 volts is the delineation point (demarcation point) between the two main applicable consensus standards, NFPA 70E and IEEE C2 (NESC) as follows.

1-4.2.1 NFPA 70E.

Readily accessible equipment, for all voltage levels, mounted within an enclosure (arc in a box) on grade, below grade, or in close proximity and maintained from grade, falls under the general arc flash requirements of NFPA 70E (listed in Table 4-2) and Additional Work Tasks (provided in Table 4-3).

1-4.2.2 IEEE C2.

Address aerial (overhead) systems and equipment in accordance with the general arc flash requirements of IEEE C2 (NESC) as identified by Additional Work Tasks (Table 4-6) and Table 4-7. Table 4-7 is a modified version of IEEE C2 (NESC) Table 410-2.

1-4.3 Service-Specific Criteria.

Each service has its own documents and criteria relating to occupational safety and health. Refer to the following documents as applicable for the issuing and endorsing services:

<u>Navy</u>

OPNAVINST 5100.23G CH-1, *Navy Safety and Occupational Health Program Manual*.

NAVFACINST 5100.12, *NAVFACENGCOM Safety & Health Program*.

<u>Army</u>

EM 385-1-1, *Safety and Heath Requirements*.

Department of the Army Pamphlet (DA PAM) 385-10, *Army Safety Program*.

DA PAM 385-26, *The Army Electrical Safety Program*.

Air Force

\3 DAFMAN 91-203, *Air Force Occupational Safety, Fire, and Health Standards*

AFMAN 32-1065, *Grounding & Electrical Systems* **/3/**

1-5 ELECTRICAL SYSTEM MAINTENANCE AND TESTING.

NFPA 70E addresses the role of electrical system maintenance and testing as part of an electrical safety program. **\3** NFPA 70E-2021, Article 110.5 I, states, "*The electrical safety program shall include elements that consider condition of maintenance of electrical equipment and systems*." NFPA 70E-2021, Article 205.3, states, "*Electrical equipment shall be maintained in accordance with manufacturers' instructions or industry consensus standards to reduce the risk associated with failure. The equipment owner or the owner's designated representative shall be responsible for maintenance of the electrical equipment and documentation*." **/3/**

An electrical safety program does not comply with NFPA 70E if it fails to perform maintenance and testing of electrical equipment in accordance with established industry standards or manufacturer's recommendations. **\3** Apply ANSI/NETA MTS, NFPA 70B or maintenance programs that are based on these standards to the greatest extent possible or NFPA 70B for the maintenance and testing of electrical system equipment, **\1** and for additional guidance, reference **\2** TM 5-683/NAVFAC MO 116/AFJMAN 32-1083*, Facility Engineering Electrical Interior Facilities*. **/2/ /1/ /3/**

1-6 WAIVER AND EXEMPTION PROCESS.

MIL-STD 3007 provides the waiver and exemption process for deviations from this UFC.

1-7 VARIANCES FROM NORMAL SAFETY PRACTICES.

The safety requirements of this UFC apply to most commonly encountered working conditions. Occasionally, there might be a need to vary work practices from these requirements due to unusual or abnormal conditions. An example might be to permit work on energized equipment. In these cases, the authorized individual-in-charge must analyze and discuss alternatives with the crew prior to commencing work. Obtain required approvals according to local directives.

1-8 WARNINGS AND NOTES.

The following definitions apply to "Warnings," and "Notes" found throughout this UFC.

1-8.1 Warning.

An operating procedure, practice, or condition that might result in injury or death or equipment damage if not carefully observed or followed.

WARNING

1-8.2 Note.

An operating procedure, practice, or condition that is essential to emphasize.

Note: This is an example of a note.

1-9 ELECTRICAL HAZARDS.

Electrical hazards include electrical shock, electrical arc flash, and electrical arc blast. These electrical hazards are particularly dangerous because the human body usually does not sense electrical energy until contact is made and significant injury has already occurred. Workers must always be aware of the location of energized equipment and its voltage level at each job site. Additionally, workers must be aware of the possible sources of electrical feedback from other energized power sources into the work site. These hazards must be determined before starting work. Pre-job planning must include engineering guidance in understanding the system's operation and review of up-to-date single line and schematic as-built drawings. All apparel, tools, and other equipment required for worker safety must be identified and available before beginning the job.

1-9.1 Electrical Shock Dangers and Effects.

Electric shock results from setting up an electric current path within the human body. The current flows because there is a potential gradient (voltage difference) between an energized object and the grounded worker. Figure 1-1 shows potential gradients and the safe area or equipotential zone which has no potential gradient. Figure 1-2 indicates current flow paths. Table 1-1 indicates the effects of 60-hertz current on humans.

Figure 1-1. Ground Potential Gradient

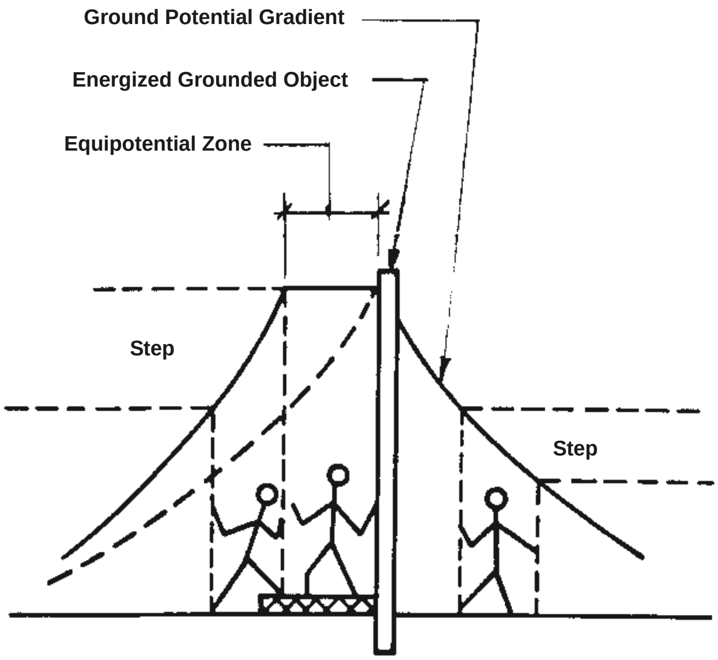

Figure 1-2. Current Path Flow

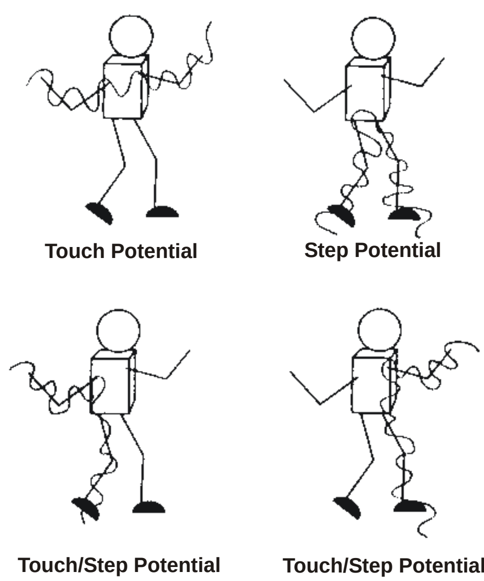


The current path will determine which tissues and organs will be damaged or destroyed. The pathway is differentiated into three groups: touch potential, step potential, and touch/step potential.

Table 1-1. Effect of 60-Hertz Current on Humans

Effect	Milliamperes	
	Men	Women[1]
Slight sensation on hand	0.4	0.3
Perception threshold	1.1	0.7
Shock, not painful and muscular control not lost	1.8	1.2
Painful shock, painful but muscular control not lost	9	6
Painful shock let-go threshold	16	10.5
Painful and severe shock, muscular contractions, breathing difficult	23	15
Ventricular fibrillation, threshold	75	75
Ventricular fibrillation, fatal (usually fatal for shock duration of 5 seconds or longer)	235	235
Heart paralysis (no ventricular fibrillation), threshold (usually not fatal; heart often restarts after short shocks)	4,000	4,000
Tissue burning (usually not fatal unless vital organs damaged)	5,000	5,000

[1]*The current values for women are lower because women typically have less body mass than men.*

1-9.2 Danger from Electrical Arc Flash and Arc Blast Hazards.

This UFC addresses arc flash criteria for electrical safety. Arcs result from the passage of electric current through air; the air failing as an insulator but serving as a conducting medium. Blasts result when the metal at the arc site expands and vaporizes. High energy arcs can be fatal even at distances of 10 ft (3.0 m) or more.

1-9.3 Workplace Dangers.

Table 1-2 indicates typical hazards that can be found in enclosures, enclosed areas, or confined workspaces. Check the applicable safety data sheets (SDS).

Table 1-2. Typical Hazards

Hazard	Source
Asbestos	Insulation, underground manholes, under houses; crawl spaces, old electric equipment, fire protecting tape, duct banks, arc chutes/shields, cables, and wiring
Polychlorinated biphenyl (PCB)	Old liquid-filled transformers, capacitors, ballasts, lead-sheathed cables
Sulfur hexafluoride (SF6)	Toxic decomposition products from electric arcs or faults acting on SF6 insulation
Combustible gases	Sewer or natural gas accumulations or from outgassing of lead-acid batteries
Carbon monoxide	Cable faults, combustion engine exhausts
Inadequate oxygen	Displaced by heavier-than-air gases
Lead	Outer sheath of lead covered conductors.

1-9.4 Health Hazards of Asbestos.

Asbestos is a known human carcinogen. Its primary route of entry to the body is by inhalation; however, exposure can occur by ingestion. Asbestos is not absorbed through the skin. The diseases caused by long term exposure to asbestos are cancer of the lungs, pleura sack surrounding the lungs, bronchus, oropharynx, stomach, and colon. Symptoms are shortness of breath, dry cough, and clubbing of the fingers. These symptoms generally do not show up for 20 years or more after initial exposure. The potential for a material containing asbestos to release breathable fibers depends on the material's degree of friability. Friable means that the material can be crumbled with hand pressure. When working around materials suspected of containing asbestos, it is important not to bump, brush or disturb the materials in any way. Wetting the materials can help to reduce the emission of fibers. Refer to Table 1-3.

Note: Employees who are not qualified to work with asbestos are not to handle or remove materials containing asbestos fibers. Refer to 29 CFR 1910.1001 (Asbestos) or 29 CFR 1926.1101 (Asbestos) for worker qualifications and requirements for handling asbestos containing materials.

Table 1-3. Precautionary Steps to Minimize Asbestos Exposure

1. Prior to disturbance, have unknown material tested for asbestos.
2. Keep unknown fibers off clothing. Wear disposable coveralls.
3. Wear proper respiratory protection: either full face or half face respirators with P-100 Filter if working with fibrous materials.
4. After working with materials, wash hands prior to eating, drinking or taking a break.

1-10 MISHAP RESPONSE.

Each worker must know what to do when a mishap occurs. Additionally, each worker must know how to report injuries and other mishaps.

1-10.1 Knowing What to Do.

Table 1-4 summarizes the first aid knowledge required of each worker. As a preplanning aid, prepare an emergency telephone number list to include the location and telephone numbers of the nearest ambulance or emergency medical treatment responders, the nearest hospital with an emergency room, the nearest helicopter evacuation service, and the nearest burn trauma center. A medical professional must evaluate all shock victims for treatment and medical follow-up.

Table 1-4. Knowing What to Do

Item	Instructions/Training
First aid/CPR	How to control bleeding and apply artificial respiration and cardiopulmonary resuscitation (CPR). How to provide pole top and manhole rescues of mishap victims. Familiarity with electric shock symptoms.
Medical provisions	Location, contents, and use of first aid kits and where located in electric line and aerial lift vehicles. How to get medical assistance.

1-10.2 Work Injuries and Mishap Reports.

Report injuries, including minor injuries, to your immediate supervisor. Every mishap involving personnel injury, property damage, or near misses must be investigated to determine the cause and the corrective action needed to prevent recurrence. Cognizant safety personnel conduct investigations. The safety staff must be notified of all mishaps that involve personnel injuries or property damage.

1-10.3 First Aid Supplies.

1-10.3.1 Storage and Inspection.

Place first aid supplies in weatherproof containers if the supplies could be exposed to the weather. Maintain each first aid kit readily available for use and inspect frequently (at least annually) to ensure expended items are replaced.

1-10.3.2 Contents.

An example of the minimal contents of a generic first aid kit is described in American National Standard (ANSI) Z308.1, *Minimum Requirements for Workplace First-Aid Kits and Supplies*. The contents of the kit listed in the ANSI standard is adequate for small worksites. When larger operations or multiple operations are being conducted at the same location, determine the need for additional first aid kits at the worksite, additional types of first aid equipment and supplies and additional quantities and types of supplies and equipment in the first aid kits.

1-10.4 Automatic External Defibrillators (AEDs).

Where emergency medical assistance is not available within four minutes, the use of AEDs may be warranted. Prior to agencies/activities purchasing AEDs, effective written programs must be established. At a minimum, address the following:

- Coordination with private sector and/or DoD medical facilities, fire departments, emergency responders.
- Training.
- Placement and availability of properly trained employees.
- Equipment maintenance.
- Legal issues.

\3 *Note: For the Air Force, refer to DAFMAN 32-1065 for requirements on AED training, including certification requirements.* **/3/**

1-11 COMMUNICATIONS.

All employees participating in a work procedure must be in constant voice contact with all other members involved in that procedure. The ability of work crew, work leader, and/or supervisor to communicate during circuit isolation, maintenance, troubleshooting, and restoration is essential. Accordingly, provide each employee with a personal communication device (radio or cellular phone) and with each assigned a unique caller identification.

1-12 ARC FLASH WARNING LABELS.

Provide arc flash warning labels on electrical equipment likely to require examination, servicing, or maintenance while energized. Some typical types of equipment include pad-mounted transformers, switchgear, switchboards, panelboards, disconnect switches, industrial control panels, meter socket enclosures, and motor control centers that are in other than dwelling occupancies.

Note: Determine if the Activity has an arc flash risk assessment program, and if so, coordinate on which label format will be used.

Note: For Army projects, comply with DA PAM 385-26, The Army Electrical Safety Program, and provide arc flash labels in accordance with NFPA 70E.

Note: AutoCAD format and Adobe PDF format files are available at http://www.wbdg.org/ccb/NAVGRAPH/arc_flash_warning_labels.zip.

\2 *Note: In the 2018 update to IEEE 1584, the requirement was added to account for factors such as enclosure dimensions and electrode configurations when performing incident energy calculations. As a result, equipment such as motor control centers, which house branch circuit overcurrent protective devices within separate enclosed cubicles, may produce unique arc flash risk analysis results for each cubicle. Once the incident energy calculations have been performed for all cubicles on a piece of equipment such as this, as an alternative to applying labels to each cubicle, it is acceptable to generate a 'Worst Case' label which can be used to represent all branch circuit cubicles. 'Worst Case' branch circuit cubicle labels should only be used with the written approval of the equipment owner and/or the entity responsible for maintaining the equipment. When 'Worst Case' branch circuit cubicle labels are used, separate unique labels must still be applied to any cubicles housing the equipment's main overcurrent device(s) or tie breakers. Any 'Worst Case' branch circuit cubicle labels should be conspicuously located on the equipment and should contain wording which clearly indicates which cubicles the label applies to.* **/2/**

The following sections list the types of arc flash label formats that have been approved. These include:

- General label.
- General label referring to OSHA.
- Detailed label, compliant with NFPA 70E.
- General label that refers to a separate arc flash calculation for requirements.
- Label for equipment that has not received adequate maintenance or testing.

- Label for equipment where an arc flash calculation identifies an available incident energy greater than 40 cal/cm^2.

1-12.1 General Arc Flash Label.

Provide labels in accordance with the format shown in Figure 1-3.

Note: Do not use this label for Army projects.

Figure 1-3 Typical Arc Flash Warning Label

Note: As part of the original development of UFC 3-501-01, Electrical Engineering, and UFC 3-560-01, Operation and Maintenance: Electrical Safety, the Tri-Service Electrical Working Group (TSEWG) deliberately specified general arc flash warning labels rather than the detailed arc flash warning labels specified by NFPA 70E. The detailed label information specified by NFPA 70E was considered inappropriate for the following reasons:

- **\2** *The equipment is in poor condition.* **/2/**
- **\2** *Routine testing and maintenance does not occur or cannot be verified to have occurred.* **/2/**
- **\2** *Detailed incident energy calculations cannot reasonably be assumed to be updated on a routine basis as requirement by NFPA 70E.* **/2/**

1-12.2 General Arc Flash Label That Refers to OSHA.

OSHA requires protection from the incident energy of an arcing fault. But, neither 29 CFR 1910 nor 29 CFR 1926 require an arc flash label. As published, the OSHA requirements do not discuss labels at all. The Federal Register publication (April 11,

2014) of the revised 29 CFR Parts 1910 and 1926 discusses why OSHA does not require arc flash labels.

A general arc flash label that refers to OSHA requirements is allowed. Figure 1-4 provides an example.

Note: Do not use this label for Army projects.

Figure 1-4 General Arc Flash Label That Refers to OSHA

1-12.3 Detailed Arc Flash Label.

For new and existing installations, a detailed label is only authorized if the Activity has an arc flash risk assessment program that includes documented periodic maintenance and testing. New installations must also have been commissioned in accordance with NETA Acceptance Test Specifications.

Note: An Activity may have two distinct arc flash risk assessment programs in place: one for the medium voltage distribution (utility) part of the electrical distribution system and one for low voltage systems inside facilities.

If the following types of equipment are credited for clearing an arcing fault as part of an arc flash study, the equipment must have commissioning performed in accordance with NETA ATS if new, and periodic maintenance and testing performed in accordance with NETA MTS or NFPA 70B if existing:

- Medium voltage power circuit breakers.
- Medium voltage pad-mounted switchgear.
- Low voltage power circuit breakers.

- Overcurrent protective relays.
- Switchboards and panelboards – main circuit breaker at each location and all circuit breakers rated for 225 amperes, or higher (molded case circuit breakers and insulated case circuit breakers).
- Electronic trip units associated with the above equipment.

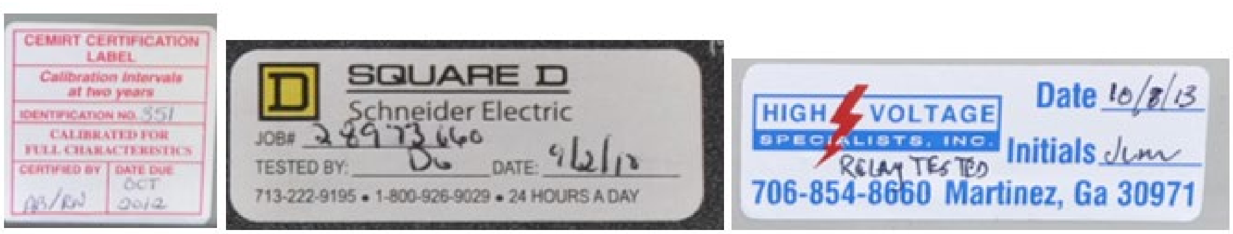
Note: Coordinate with activity to ensure funding is available for the above maintenance and testing.

1-12.3.1 Documentation of Commissioning and Maintenance/Testing.

Confirmation of commissioning and maintenance/testing consists of calibration or maintenance stickers applied to the equipment and a documented report of the maintenance and testing that was completed. Coordinate with the Activity maintenance personnel to identify the required format and content to be provided on a calibration or maintenance sticker. Figure 1-5 shows typical calibration or maintenance stickers. As a minimum, provide the following information:

- Company or organization that performed the testing.
- Date of test.
- Initials of person who performed the test.
- Date due.

Figure 1-5 Typical Calibration or Maintenance Stickers



1-12.3.2 Arc Flash Label Content.

NFPA 70E specifies the following information to be included on a detailed arc flash label:

- Nominal system voltage.
- Arc flash boundary.
- At least one of the following:

a) Available incident energy and the corresponding working distance, or the arc flash PPE category in NFPA 70E Table 130.7(C)(15)(a) or 130.7(C)(15)(b) for the equipment, but not both.

b) Minimum arc rating of clothing.

c) Site-specific level of PPE.

Note: Site-specific level of PPE is an identified requirement in NFPA 70E if it is more restrictive than item a) above. Annotate the label appropriately. This could occur based on an Activity specific issue, where the Activity is adding the additional requirement. An example of this is shown in Figure 1-8 below. **\3** [Deleted] **/3/**

In addition to the above information specified by NFPA 70E, include the following information on a detailed label:

- Equipment identification number.
- Date of arc flash calculation.

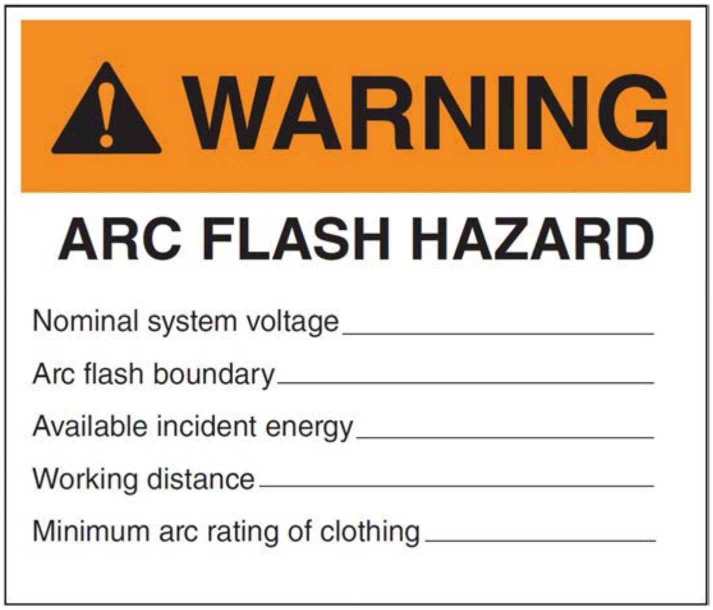
If the arc flash results can vary as a result of different operating or switching modes, include this information in the detailed label.

1-12.3.3 Arc Flash Label Examples.

\2 Figure 1-6 shows the detailed label provided by the NFPA 70E Handbook which displays the calculated available incident energy. Figure 1-7 shows a typical detailed label based on the required minimum arc rating of clothing PPE. **/2/** The arc flash label format can be modified provided that the required information is included.

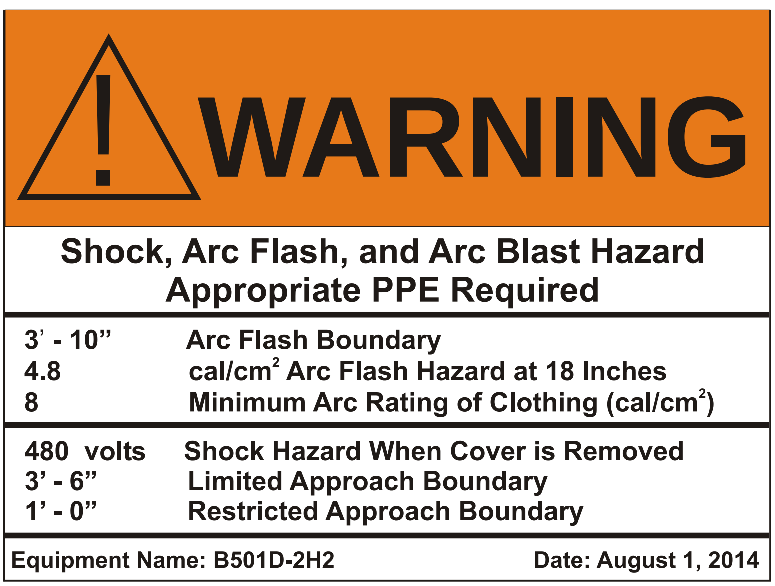
\2

Figure 1-6 NFPA 70E Handbook Arc Flash Incident Energy Warning Label



/2/

Figure 1-7 Typical Detailed Arc Flash Warning Label



1-12.3.4 Arc Flash Labels Based on NFPA 70E Tables.

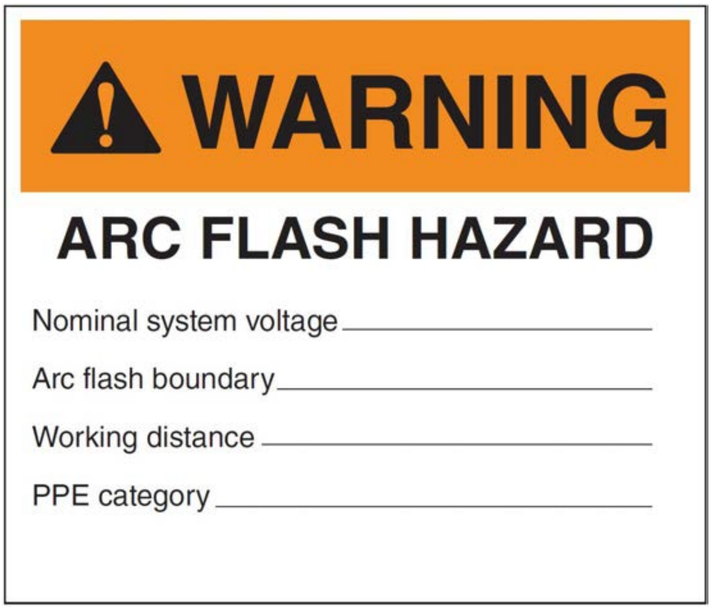
\3 Detailed labels based on NFPA 70E Table 130.7(C)(15)(a) or 130.7(C)(15)(b) can be installed if the following conditions have been verified and documented: **/3/**

- The available short circuit is less than stated in the table.
- The upstream protective device is identified and confirmed to trip within the clearing time stated in the table.

- Maintenance and testing of the upstream protective device in accordance with NETA MTS or NFPA 70B has been confirmed to be adequate and current. Typically, this equipment would have calibration or maintenance stickers applied with a documented report of the maintenance and testing that was completed.

\2 Figure 1-8 shows the detailed label provided by the NFPA 70E Handbook which displays the PPE category.

Figure 1-8 NFPA 70E Handbook Arc Flash PPE Category Warning Label



/2/

1-12.3.5 Arc Flash Label Updates.

Document the method of calculating and the data to support the information for the label. Once installed, a detailed label must be removed or replaced with a new label containing updated information under any of the following conditions:

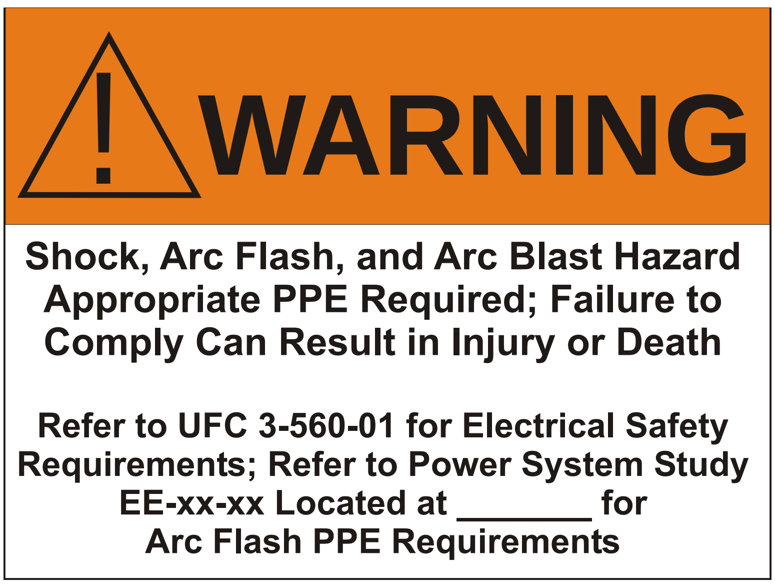
- Whenever a review of the arc flash risk assessment identifies a change that renders the label inaccurate. This includes:
    - System design changes that affect short circuit values or electrical coordination.
    - Circuit breaker trip setting changes.
- More than five years passes without maintenance and testing in accordance with NETA MTS or NFPA 70B.
- **\2** More than five years passes without a review of the arc flash risk assessment for accuracy. **/2/**

1-12.4 Arc Flash Label That Refers to a Separate Calculation.

\2 In supervised industrial installations where conditions of maintenance and engineering supervision ensure that only qualified persons monitor and service the system, instead ***/2/*** of a detailed label as specified by NFPA 70E and addressed above in Section 1-12.3, the arc flash label is allowed to refer to an arc flash calculation where the required arc flash parameters can be obtained. Figure 1-9 shows an example. The advantage of this approach is that the calculation can be periodically revised without requiring physical relabeling of the equipment. **\3** For the Air Force, the addition of a QR code for requirements is also acceptable. ***/3/***

Note: Do not use this label for Army projects.

Figure 1-9 Arc Flash Warning Label Referring to a Separate Calculation



1-12.5 Arc Flash Label for Existing Equipment Without Maintenance or Testing.

Arc flash calculation results are based on proper operation of upstream protective devices in accordance with their published time-current curves. Periodic maintenance and testing of electrical equipment is essential to confirming this proper operation. Use the standard label provided in Figure 1-10 for the following equipment locations:

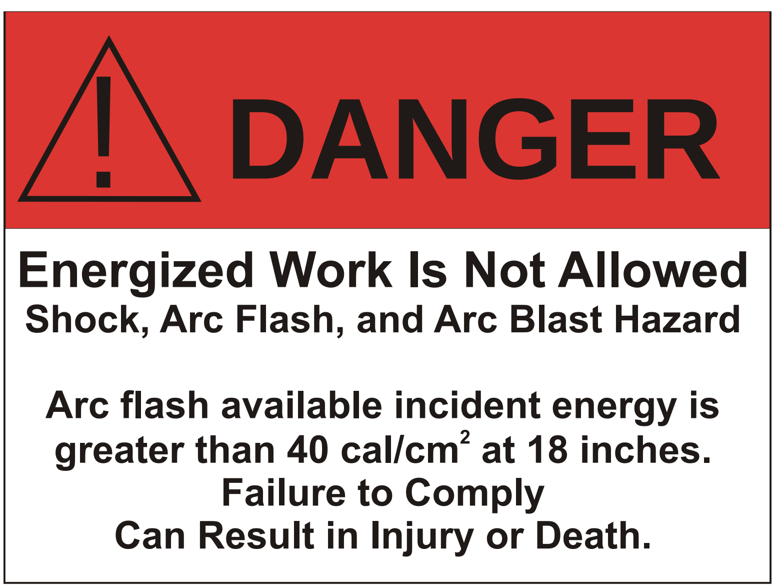
- New installations that did not include commissioning in accordance with NETA ATS.
- Existing installations without maintenance and testing in accordance with NETA MTS or NFPA 70B in the last five years.

Figure 1-10 Arc Flash Danger Label for Equipment Without Documented Maintenance and Testing

1-12.6 Arc Flash Label for Locations Identified to Be Greater Than 40 cal/cm^2.

Use a label similar to the following if the arc flash calculation identifies a location with an available incident energy greater than 40 cal/cm^2.

Figure 1-11 Arc Flash Danger Label for Locations Identified to Be Greater Than 40 cal/cm^2



CHAPTER 2 WORKER/CREW RESPONSIBILITIES

2-1 LEVELS OF RESPONSIBILITY.

Operation and maintenance of electrical distribution systems are a single work group responsibility. The same personnel will frequently perform both functions. All personnel are responsible for safety at all times. Table 2-1 lists the level of accountability for each job function.

Note: The titles and responsibilities listed in Table 2-1 are typical assignments for electrical workers at most facilities or organizations. However, titles and responsibilities might be assigned differently in accordance with local directives.

Table 2-1. Levels of Safety Accountability

Title	Accountability
Installation commander	Ultimate safety accountability
Base civil engineer	Base systems safety accountability
Electric supervisor (if assigned)	Systems safety accountability
Supervisor/lead electrical worker	Systems safety and specific work task safety
Crew members	Crew members' safety accountability is limited to doing only work for which they are qualified

2-2 ELECTRICAL WORKER QUALIFICATIONS.

Qualifications for electrical workers are normally established locally. Workers are classified as *Qualified* or *Unqualified*.

2-2.1 Qualified Persons.

\3 A qualified person shall be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method (see NFPA 70E 110.6(A)(1)). This also includes: ***/3/***

- The skills and techniques necessary to distinguish exposed live parts from other parts of electric equipment.
- The skills and techniques necessary to determine the nominal voltage of exposed live parts.
- Skills and techniques regarding how to select and use a voltage detector and phase meter.

- The clearance distances and the corresponding voltages to which the qualified person will be exposed.

2-2.2 Unqualified Person.

An unqualified person is any person who is not a qualified person.

2-2.3 Type of Training.

\3 Training can be in the classroom, interactive electronic, web-based, or on-the-job, or a combination of the two. ***/3/*** Determine the degree of training based on the risk to the employee. As a minimum, the employee must demonstrate to their supervisor or designated representatives, the capability, knowledge, and skills to understand and apply the controls required by their exposures, and that they can safely complete their assigned tasks. Each employee's possession of the necessary skills, knowledge and abilities must be determined by written or verbal tests, in conjunction with functional tests. Develop and use lesson plans or Standard Operating Procedures. Training may be contracted from outside sources, which include certified training facilities and utility companies.

Note1: Whether an employee is considered to be a "qualified person" depends upon various circumstances in the workplace. For example, it is possible and, in fact, likely for an individual to be considered "qualified" with regard to certain equipment in the workplace, but "unqualified" as to other equipment.

Note 2: An employee who is undergoing on-the-job training and who, during such training, has demonstrated an ability to perform duties safely at his or her level of training and who is under the direct supervision of a qualified person is considered to be a qualified person for the performance of those duties.

2-2.4 Cardiopulmonary Resuscitation (CPR) and First Aid Training.

Provide first aid and CPR training to employees exposed at or above 50 volts and those trades listed in Section 4-1.1. Consider including automated external defibrillator (AED) training as part of this training. First aid training is primarily received through the American Red Cross, the American Heart Association, the National Safety Council, or other private institutions. Obtain refresher training annually to maintain CPR certifications. Train employees responsible for responding to medical emergencies in the use of an AED if the emergency response plan includes the use of this device.

When employees are performing work on or associated with exposed lines or equipment energized at 50 volts or more, persons trained in first aid and CPR must be available as follows:

- For field work involving two or more employees at a work location, ensure at least two trained persons are available. Refer to Section 3-3 for those jobs requiring at least two employees.

- For fixed work locations such as generating stations, provide a sufficient number of trained persons to ensure that each employee exposed to electric shock can be reached within 4 minutes by a trained person. However, where the existing number of employees is insufficient to meet this requirement (at a remote substation, for example), train all employees at the work location.

2-2.5 Rescue Training.

All workers engaged in electrical work must receive training in methods of release from the energized conductor and in methods of rescue from poles, structures, manholes, aerial baskets, confined spaces, and other field work areas as applicable to the facility or installation.

2-2.6 Training Documentation.

Document that each employee has received the required training. Complete this documentation when the employee demonstrates proficiency in the work practices involved and maintain the documentation for the duration of the employee's employment. Include each employee's name and dates of training in the documentation file. Verify at least annually that training is current for each employee.

2-3 SAFETY MEETINGS.

Safety meetings must consist of scheduled meetings for all personnel and job briefing/tailgate meetings as needed for specific jobs.

2-3.1 Scheduled Meetings.

Schedule safety meetings in accordance with local policy. Twice a month is recommended, but once a month is the minimum; less frequent meetings tend to de-emphasize the importance of safety. Supervisory personnel must conduct these meetings but encourage other knowledgeable individuals to conduct training on specialized topics.

2-3.2 Job Briefing/Tailgate Meetings.

Meetings at the job site prior to the commencement of work are commonly called tailgate meetings. This meeting covers all aspects of the planned work, site hazards, safety precautions to be followed, special precautions, energy source controls, and personal protective equipment. The individual in charge must conduct the job brief and must ensure that each crew member understands the precautions to be observed and the procedures to be followed. Tailgate meetings are also recommended at the beginning of each work shift for longer duration jobs so that all crew members understand what is to be done, how to accomplish the job, safety hazards present, and methods used to provide worker protection.

Refer to NFPA 70E Annex I for a typical job briefing and planning checklist. Individual services also have Standard Operating Procedures or other information that provides job briefing checklists.

2-4 WORK SITE SAFETY.

Maintaining acceptable work site safety involves proper behavior, good housekeeping, maintenance of protective measures, and avoiding unsafe actions. The following tables provide examples and are not all inclusive. Table 2-2 lists prohibited actions. Report indications of unsafe worker actions listed in Table 2-3. Verify that pre-site job requirements listed in Table 2-4 are met. Significant unsafe actions and conditions are listed in Table 2-5.

Table 2-2. Prohibited Actions

Taking chances
Playing jokes
Carelessness
Smoking
Use of intoxicants or drugs
Throwing material
Quarreling
Disobedience
Unnecessary talking or noise
Working while ill or under emotional stress

Table 2-3. Unsafe Worker Indications

Lacks information
Lacks skills
Lacks experience
Unaware of safe practices
Does not realize danger

Table 2-4. Pre-Site Job Requirements

Regular safety meetings
Job hazard analysis if safe clearance (*Chapter 6*) requires it or if energized line work (*Chapter 8*) will be done
Written work procedures covering existing conditions
Job briefing/tailgate briefings

Table 2-5. Significant Unsafe Actions and Conditions

Unsafe Actions
Operating without authority; failure to secure or warn others
Operating or working at unsafe speeds
Making safety devices inoperative without proper authorization
Using unsafe equipment (hands instead of equipment) or equipment unsafely
Taking unsafe positions or postures
Working on moving or dangerous equipment
Distracting, teasing, abusing, startling
Failing to use safe attire or personal protective devices
Failing to lock-out and tag deenergized circuits
Failure to follow established safety policies
Carelessness
Defacing identifying markings on equipment
Unsafe Conditions
Improperly guarded facilities
Defects of facilities
Hazardous arrangement or procedure
Improper ventilation
Improper illumination
Unsafe dress or apparel

2-5 JOB HAZARD ANALYSIS/JOB SAFETY ANALYSIS.

Written work procedures must be prepared for unusual or complicated work activities. Table 2-6 lists the minimum requirements for a job hazard analysis or job safety analysis.

Table 2-6. Job Hazard Analysis (JHA)/Job Safety Analysis (JSA)

Identification of the work site
Description of the work to be done
Specific hazards and how to minimize or eliminate them by use of safety equipment
Use of proper arc flash and shock hazard personal protective equipment (PPE)
Instructions covering special practices for grounding, unusual equipment and tools, and first aid requirements for hazardous materials
Sequence of major steps or a detailed step-by-step work listing
A JHA or JSA, and written standard operating procedure

2-6 SAFETY COMPLIANCE.

A requirement of employment is compliance with safety requirements. Workers must not perform work they consider unduly hazardous based on their own capabilities; they are not trained or qualified to perform; or when they are not properly protected from injury. In a case where the safety requirements are not clear, the worker must obtain direction from the authorized individual-in-charge.

2-6.1 Carelessness.

A worker must challenge a fellow worker who violates any of these rules or works in an unsafe manner and must promptly report any violations of safety requirements to the authorized individual-in-charge.

2-6.2 Interpretation.

In any case where rules are not clear ask the foreman or supervisor for an interpretation.

2-6.3 Violations.

Each safety rule must be strictly enforced. Workers failing to observe the rules can be subject to penalties. Supervisors must follow appropriate guidelines and ensure the severity of the penalty is related to the seriousness of the offense.

CHAPTER 3 PRE-SITE SAFETY MANAGEMENT

3-1 WORK LOCATION SAFETY REQUIREMENTS.

The location and the public access to the work site impose additional protective or regulatory requirements.

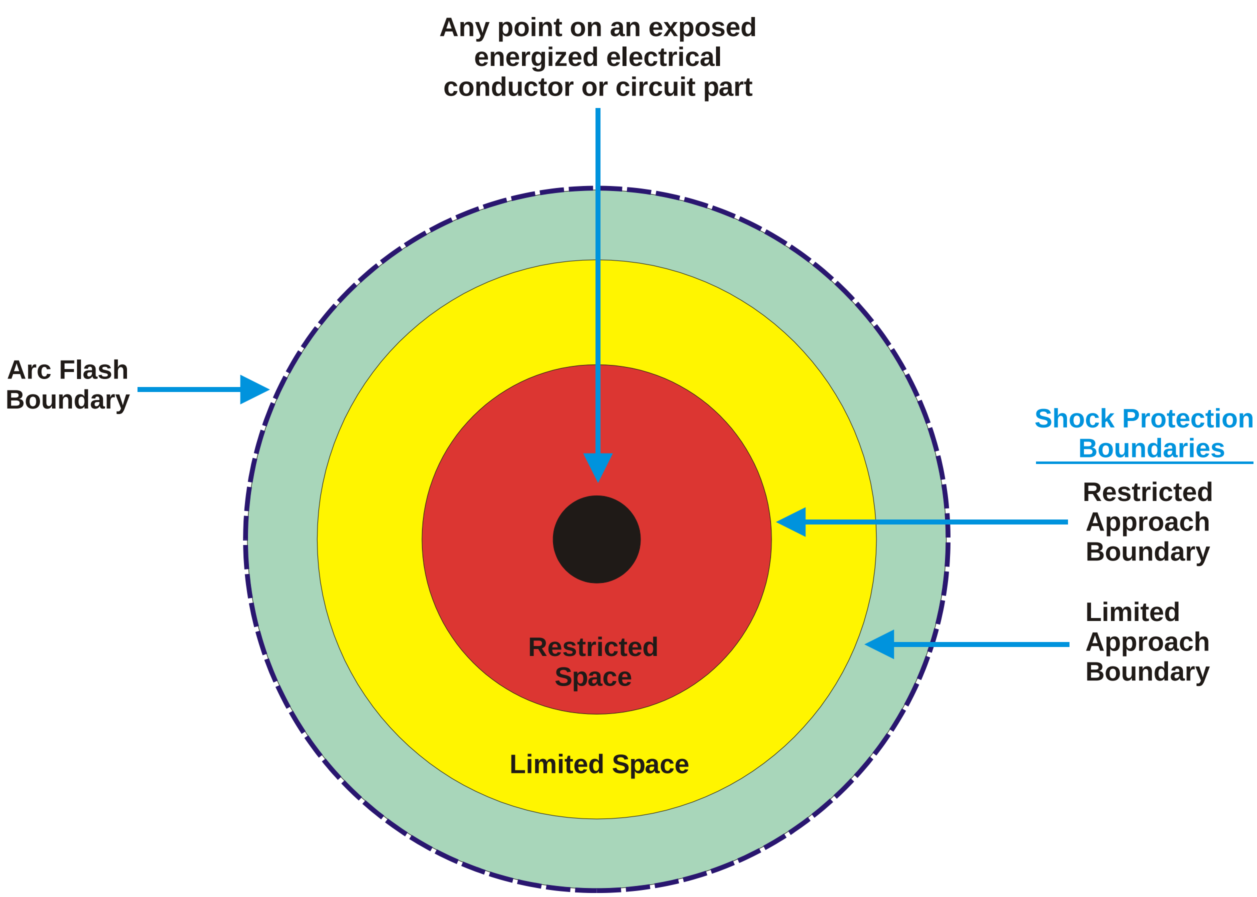
3-1.1 Working Near Energized Circuits.

Perform electrical maintenance near energized circuits with rubber blankets or other suitable guards as a safety measure. Minor work (such as cutting weeds, taking oil samples, or securing nameplate data) when done near energized apparatus or conductors located on or near the ground may be performed when workers maintain the unqualified worker minimum approach distances, as appropriate.

3-1.1.1 Minimum Approach Distances.

Figure 3-1 shows a general layout of the various approach limits. Each boundary is defined following Figure 3-1.

Figure 3-1. Approach Limits



3-1.1.1.1 Arc Flash Boundary.

The distance from an arc source (energized exposed equipment) at which the potential incident heat energy from an arcing fault on the surface of the skin is 1.2 cal/cm^2 (5 J/cm^2). Within this boundary, workers are required to wear appropriate personal protective equipment (PPE) clothing. Only qualified workers wearing appropriate PPE are permitted to be within this boundary.

3-1.1.1.2 Limited Approach Boundary.

A shock protection boundary to be crossed by only qualified persons (at a distance from a live part) that is not to be crossed by unqualified persons.

If there is a need for an unqualified person(s) to cross the limited approach boundary, a qualified person must advise him or her of the possible hazards and continuously escort the unqualified person(s) while inside the limited approach boundary. Under no circumstance is the escorted unqualified person(s) allowed to cross the restricted approach boundary.

3-1.1.1.3 Restricted Approach Boundary.

\3 An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock due to electrical arc-over, combined with inadvertent movement, for personnel working near the energized electrical conductor or circuit part. ***/3/***

3-1.1.2 Minimum Approach Distance for Unqualified Workers.

Only workers qualified by electrical training can work in areas on or with unguarded, uninsulated energized lines or parts of equipment operating at 50 volts or more. All electric lines and equipment will be treated as energized unless they are placed in an electrically safe working condition, including grounding in accordance with Chapter 7. The minimum approach distance refers to the shortest possible distance between energized electrical lines or apparatus and any part of a worker’s body and tools or material being handled.

Note: an unqualified person can enter a limited approach boundary only under the conditions stated in Section 3-1.1.1.2.

3-1.1.3 Minimum Approach Distances.

Table 3-1 lists the minimum approach distances from exposed alternating current energized parts within which a qualified worker may not approach without the use of personal protective equipment appropriate for the potential electrical hazards or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding). Table 3-2 provides similar information for direct current systems.

Table 3-1. Qualified Worker Minimum Approach Distances – AC Systems

Nominal System Voltage Range Phase to Phase (1)	Limited Approach Boundary		Restricted Approach Boundary (2) (3)
	Exposed Movable Conductor	Exposed Fixed Circuit Part	Includes Standard Inadvertent Movement Adder
<50 V	Not specified.	Not specified.	Not specified.
50 V to 150 V	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>151 V to 750 V	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)
>750 V to 15 kV	10 ft 0 in (3.0 m)	5 ft 0 in (1.5 m)	2 ft 2 in (0.7 m)
>15 kV to 36 kV	10 ft 0 in (3.0 m)	6 ft 0 in (1.8 m)	2 ft 9 in (0.8 m)
>36 kV to 46 kV	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	2 ft 9 in (0.8 m)
>46 kV to 72.5 kV	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>72.5 kV to 121 kV	10 ft 8 in (3.3 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>121 kV to 145 kV	11 ft 0 in (3.4 m)	10 ft 0 in (3.0 m)	3 ft 10 in (1.2 m)

Notes for Table 3-1:

1. *For single phase systems* ***\2*** *above 250 volts,* ***/2/*** *select the range that is equal to the system's maximum phase to ground voltage times 1.732.*
2. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
3. *The restricted approach distance applied to hot sticks is the distance between a worker's hand and the working end of the stick.*
4. *Only qualified workers wearing appropriate PPE are permitted to be within the arc flash boundary. The arc flash boundary is determined by an arc flash analysis. Refer to Chapter 4 for PPE requirements for the intended work location.*
5. ***\2*** *Refer to NFPA 70E for AC voltages above 145 kV.* ***/2/***

Table 3-2. Qualified Worker Minimum Approach Distances – DC Systems

Nominal System Voltage Range Phase to Phase (1)	Limited Approach Boundary		Restricted Approach Boundary
	Exposed Movable Conductor	Exposed Fixed Circuit Part	Includes Reduced Inadvertent Movement Adder
<50 V	Not specified	Not specified	Not specified
50 V to 300 V	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>300 V to 1 kV	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)

Notes for Table 3-2:

1. *Refer to NFPA 70E for DC voltages above 1,000 V.*

3-1.1.4 Altitude Correction for Minimum Approach Distances.

Refer to Table 3-3 for altitude correction factors for work performed at elevations greater than 3,000 ft (914 m); the minimum approach distance is determined by multiplying the distances in Table 3-1 by the appropriate correction factor from Table 3-3.

Table 3-3. Altitude Correction Factors

Altitude		Correction Factor	Altitude		Correction Factor
Feet	Meters		Feet	Meters	
3,000	900	1.00	10,000	3,000	1.20
4,000	1,200	1.02	12,000	3,600	1.25
5,000	1,500	1.05	14,000	4,200	1.30
6,000	1,800	1.08	16,000	4,800	1.35
7,000	2,100	1.11	18,000	5,400	1.39
8,000	2,400	1.14	20,000	6,000	1.44
9,000	2,700	1.17			

3-1.2 Work Location.

The location of the work will determine whether climbing or confined space training along with fall and/or respiratory protection are mandatory (refer to Chapter 4). Safety standards require protection from excessive noise and provision of minimum illumination at any applicable work site.

3-1.2.1 Noise.

Follow local procedures regarding hearing protection. Wherever hazardous noise area signs are posted, hearing protection must be used as prescribed.

3-1.2.2 Minimum Illumination.

Do not reach blindly into areas that might contain exposed energized electrical conductors or circuit parts where an electrical hazard exists. Ensure the working area has adequate illumination. Provide temporary lighting where natural or installed artificial illumination is not sufficient. Survey facility electrical equipment rooms to determine if lighting has been connected to a timer/motion control device. Ensure timers/motion control devices are disengaged prior to beginning any electrical work operations.

Where lack of illumination or an obstruction precludes observation of the work to be performed, do not perform any task within the limited approach boundary of energized electrical conductors or circuit parts operating at 50 volts or more or where an electrical hazard exists.

3-2 PUBLIC SAFETY.

Protect the public around the work area by safely guiding unqualified personnel and traffic away from workers, equipment, and excavations.

3-2.1 Warning Devices.

Locate appropriate barriers, warning signs, traffic cones, and lights at approaches to and at work areas, excavations, open manholes, parked equipment, and other hazards. Take special precautions for any areas where reduced visibility occurs, such as night operations or in fog. Immediately remove warning devices after removal of hazards and equipment. Provide flagmen if there is any doubt as to whether the warning devices will be adequate as controls, such as in areas with obstructed vehicular traffic.

3-2.2 Flagmen.

Flagmen must be used whenever there is any doubt of the effectiveness of warning devices. This often occurs on busy roadways or during commuting hours on less traveled streets. Flagmen must wear brightly colored and highly reflective warning vests.

3-2.3 Excavations.

Provide barricades around every excavation area. Keep warning barricade (cones, tape, and other items providing no physical protection) 5 ft (1.5 m) from the excavation. A protective barricade may be placed closer since it provides both a warning and physical protection. Protective barricades must have a withstand rating of at least 200 lb (90 kg) in any direction with minimal deflection. Never enter an excavation deeper than 4 ft (1.6 m) which does not have a safe access-way, which has not been inspected by a competent person before allowing an entrance, or which has equipment working next to the edge. Comply with requirements stated in *29 CFR 1926, Subpart P, (Excavations)*. Identify underground lines and services prior to starting excavations. The following tables provide additional guidance.

Table 3-4. Excavation Pre-Survey Checklist

Location	Checklist Items
Prior to leaving the shop.	1. Ensure location of underground cables has been established. 2. Verify that field sketch is available. 3. Obtain as-built/maps from facility owner(s). 4. Have subsurface facility engineering performed. 5. Conduct pre-construction meetings with facility owner(s). 6. Site and Safety Plan or Job Hazardous Analysis/Job Safety Analysis.
On the job site.	1. Check for field sketch. 2. Verify all facility marks on ground. 3. Verify all service feeds from houses or buildings. Verify all are marked or noted above ground. Draw sketch. Check for: pedestals, risers, and new trench lines. 4. Verify position of dig area to sketch. 5. Check for private facilities not marked. 6. Advise facilities owner of excavation.

Table 3-5. Performing Excavations

1. Maintain 24 in (610 mm) from marks. If digging within 24 in (610 mm), hand dig to expose and verify lines. 2. Expose all major facilities within 5 ft (1.5 m) of work area. 3. If paralleling: expose to verify location and depth of facilities every 100 ft (30.5 m). 4. Hand dig within 5 ft (1.5 m) of pedestals, risers, meters, flags, whiskers, etc. 5. Bore away from facilities. 6. Verify depth of any facilities boring across, change route or depth as required. 7. Do not place excavation dirt on locate marks, flags, whiskers, etc. 8. Support all lines exposed during excavation to avoid kinks or other damage.

Table 3-6. Backfilling

1. Prior to backfilling, contact facility owner to inspect exposed facility. 2. “Shade” all lines placed or exposed with good fill dirt. 3. Verify all fill dirt is free from rocks, cable trash, and large dirt clods. 4. No cable or personal trash may be backfilled into the trench.

Table 3-7. Damage During Backfilling of Trenching

1. If damage involves a potential risk of life, health or significant property damage, call 911 or local emergency response number.
2. All damage, including kinking or sheath damage, must be reported immediately to a supervisor and facility owner or operator.
3. Photograph the damage.
4. If a water line, other than a main, attempt to stop the damage.
5. If a gas or power line, evacuate the area, if necessary, and notify others working in the area.
6. Complete damage investigation report.

3-3 NUMBER OF WORKERS REQUIRED

All work must be performed with a sufficient number of workers to provide a safe working environment. 29 CFR 1910.269 (*Electrical power generation, transmission, and distribution*) requires more than one worker where the hazard exposure of the work is considered to be significantly reduced by the presence of additional workers. The following tables provide specific requirements:

Table 3-8. Jobs Acceptable for One Electrical Worker

1. Work on systems in an electrically safe work condition with nominal system voltages of 600 volts ac or 250 volts dc, or less.
2. Routine electrical measurements on energized systems with nominal system voltages of 600 volts ac or 250 volts dc, or less.
3. Routine operation of metal-enclosed switchgear with nominal system voltages of 600 volts ac or 250 volts dc, or less.
4. Routine operation of metal-enclosed switchgear and pad mounted switches with nominal systems voltages greater than 600 volts ac if the activity responsible can demonstrate that conditions at the site allow this work to be performed safely.
5. Routine electrical measurements or switching using gloves and live-line tools if the worker is positioned out of reach or possible contact with energized parts.
6. Emergency repair work to safeguard the general public, if previously authorized.

Table 3-9. Jobs Requiring Two Electrical Workers

Hazard Exposure	Working On
Installation, removal, or repair when working on or near lines or parts energized at:	
1. Voltages of 600 volts ac or 250 volts dc, or less.	• Installing portable monitoring equipment if it requires 1) removing covers on panels rated for greater than 240 volts or 2) disturbing circuit conductors.
2. Greater than 600 volts ac or 250 volts dc.	• Energized lines. • Deenergized lines with possible energized parts contact. • Equipment with possible energized line contact. • Mechanical equipment operation (except insulated aerial lifts) near energized parts. • Operation of insulated aerial lifts (bucket trucks). • Other work with equal or greater hazard exposure.

Table 3-10. Jobs Working In Confined Spaces That May Require More Than Two Workers

Hazard Exposure	Additional Worker Requirement
Installation, removal, or repair when working in a confined space. Manhole or vault requirements are generally classified as confined spaces.	1. An attendant with first aid and CPR training will be available on the surface in the immediate vicinity. 2. If a hazard exists within the space, or a hazard exists or is created because of traffic patterns outside the space, the attendant may not enter the confined space. 3. If the restrictions of Item 2 above do not apply, the attendant may enter the confined space to provide assistance, but only for a brief period (other than in an emergency). For extended periods of assistance, a second worker in addition to the attendant is required. For the Air Force, a minimum of three personnel must be present for manhole or vault entry.

3-4 VERIFYING SYSTEM AND EQUIPMENT PROVISIONS.

Be familiar with the electrical system to be worked on by reviewing the system's single line diagram. Check out the equipment needed such as insulating tools, hot sticks, and grounding cables.

CHAPTER 4 ARC FLASH PERSONAL PROTECTIVE EQUIPMENT (PPE)

This chapter addresses the requirements for arc flash risk assessments and the associated personal protective equipment (PPE) criteria.

4-1 PPE FOR ARC FLASH PROTECTION.

4-1.1 Applicability.

PPE that provides appropriate arc flash protection is required for all personnel working on or near exposed energized electrical equipment operating at 50 volts or more. Depending on the work location and activity, these requirements might include but are not limited to the following types of workers:

- Boiler plant operator or mechanic.
- Construction inspector.
- Electrical engineer.
- Electrical engineering technician.
- Electronic industrial controls mechanic.
- Electrical Power Controller (EPC).
- Elevator technician.
- Emergency/standby generator technician.
- Heating, ventilation, and air conditioning technician.
- High-voltage electrician.
- Industrial equipment mechanic.
- Liquid oxygen maintenance personnel.
- Low-voltage electrician.
- Maintenance mechanics.
- Mechanical engineer.
- Project manager.
- Ship-to-shore electrician.

- Utility system workers.

4-1.2 NFPA 70E PPE Summary.

\2 The PPE to be used for a piece of equipment must be determined by an arc flash risk analysis using either the incident energy analysis method or the PPE category method, but not both. Table 4-1 provides the NFPA 70E criteria for PPE as it relates to arc flash risk assessments performed using the PPE category method. Table 4-2 provides the NFPA 70E criteria for PPE as it relates to arc flash risk assessments performed using the incident energy analysis method. The results of an incident energy analysis to specify a PPE category in Table 4-1 shall not be permitted. **/2/**

Table 4-1. NFPA 70E PPE Criteria – Category Method

PPE Category	PPE
\3	Deleted **/3/**
1 (≤4 cal/cm^2)	**<u>Arc-Rated Clothing, Minimum Arc Rating of 4 cal/cm^2 (see Note 1)</u>** Arc-rated long-sleeve shirt and pants or arc-rated coverall Arc-rated face shield (see Note 2) or arc flash suit hood Arc-rated jacket, parka, rainwear, or hard hat liner (AN) **<u>Protective Equipment</u>** Hard hat (AR) Safety glasses or safety goggles (SR) Hearing protection (ear canal inserts) **\2** (see Note 3) **/2/** Heavy duty leather gloves (see Note 4) Leather footwear (AN)
2 (≤8 cal/cm^2)	**<u>Arc-Rated Clothing, Minimum Arc Rating of 8 cal/cm^2</u>** Arc-rated long-sleeve shirt and pants or arc-rated coverall Arc-rated flash suit hood or arc-rated face shield (see Note 2) and arc-rated balaclava Arc-rated jacket, parka, rainwear, or hard hat liner (AN) **<u>Protective Equipment</u>** Hard hat (AR) Safety glasses or safety goggles (SR) Hearing protection (ear canal inserts) **\2** (see Note 3) **/2/** Heavy duty leather gloves (see Note 4) Leather footwear

PPE Category	PPE
3 (≤25 cal/cm^2)	**Arc-Rated Clothing Selected so That the System Arc Rating Meets the Required Minimum Arc Rating of 25 cal/cm^2** Arc-rated long-sleeve shirt (AR) Arc-rated pants (AR) Arc-rated coverall (AR) Arc-rated arc flash suit jacket (AR) Arc-rated arc flash suit pants (AR) Arc-rated arc flash suit hood Arc-rated gloves **\2** (see Note 4) ***/2/*** Arc-rated jacket, parka, rainwear, or hard hat liner (AN) **Protective Equipment** Hard hat Safety glasses or safety goggles (SR) Hearing protection (ear canal inserts) **\2** (see Note 3) ***/2/*** Leather footwear
4 (≤40 cal/cm^2)	**Arc-Rated Clothing Selected so That the System Arc Rating Meets the Required Minimum Arc Rating of 40 cal/cm^2** Arc-rated long-sleeve shirt (AR) Arc-rated pants (AR) Arc-rated coverall (AR) Arc-rated arc flash suit jacket (AR) Arc-rated arc flash suit pants (AR) Arc-rated arc flash suit hood Arc-rated gloves **\2** (see Note 4) ***/2/*** Arc-rated jacket, parka, rainwear, or hard hat liner (AN) **Protective Equipment** Hard hat Safety glasses or safety goggles (SR) Hearing protection (ear canal inserts) **\2** (see Note 3) ***/2/*** Leather footwear

AN: as needed (optional). AR: as required. SR: selection required.

Notes:

1. *Refer to Table 4-3 for minimum PPE clothing requirements.*

2. *Face shields are to have wrap-around guarding to protect not only the face but also the forehead, ears, and neck. Use an arc-rated balaclava with an arc-rated face shield when the back of the head is within the arc flash boundary. As an alternative, an arc-rated arc flash suit hood can be worn instead of an arc-rated face shield and balaclava.*

3. ***\2*** *Other types of hearing protection are permitted to be used in lieu of or in addition to ear canal inserts provided they are worn under an arc-rated arc flash suit hood.* ***/2/***

4. *If rubber insulating gloves with leather protectors are used, additional leather or arc-rated gloves are not required. The combination of rubber insulating gloves with leather protectors satisfies the arc flash protection requirement.*

Table 4-2. NFPA 70E PPE Criteria – Incident Energy Analysis Method

Incident Energy	PPE
0-1.2 cal/cm^2	Outside the arc flash boundary and not defined by NFPA 70E. See Note 1.
1.2-12 cal/cm^2	Arc-rated clothing with an arc rating equal to or greater than the estimated incident energy (see Note 2) Long-sleeve shirt and pants or coverall or arc flash suit (SR) Arc-rated face shield and arc-rated balaclava or arc flash suit hood (SR) (see Note 3) Arc-rated outerwear (e.g., jacket, parka, rainwear, hard hat liner) (AN) Heavy-duty leather gloves, arc-rated gloves, or rubber insulating gloves with leather protectors (SR) (see Note 4) Hard hat Safety glasses or safety goggles (SR) Hearing protection Leather footwear
>12 cal/cm^2	Arc-rated clothing with an arc rating equal to or greater than the estimated incident energy (see Note 2) Long-sleeve shirt and pants or coverall or arc flash suit (SR) Arc-rated arc flash suit hood Arc-rated outerwear (e.g., jacket, parka, rainwear, hard hat liner) (AN) Arc-rated gloves or rubber insulating gloves with leather protectors (SR) (see Note 4) Hard hat Safety glasses or safety goggles (SR) Hearing protection Leather footwear

AN: as needed (optional). AR: as required. SR: selection required.

Notes:

1. *Refer to Table 4-4 for minimum PPE clothing requirements.*

2. *Arc ratings can be for a single layer, such as an arc-rated shirt and pants or a coverall, or for an arc flash suit or a multi-layer system if tested as a combination consisting of an arc-rated shirt and pants, coverall, and arc flash suit.*

3. *Face shields with a wrap-around guarding to protect the face, chin, forehead, ears, and neck area are required by NFPA 70E Article 130.7(C)(10)(c). Where the back of the head is inside the arc flash boundary, a balaclava or an arc flash hood shall be required for full head and neck protection.*

4. *Rubber insulating gloves with leather protectors provide arc flash protection in addition to shock protection. Higher class rubber insulating gloves with leather protectors, due to their increased material thickness, provide increased arc flash protection.*

4-1.3 Minimum PPE Clothing Requirements.

Any worker whose normal job includes working on or near exposed electrical equipment must wear to work as a minimum:

- Arc-rated shirt (long-sleeve) and pants (or arc-rated coveralls) with minimum arc rating of 8 cal/cm^2 (33.47 J/cm^2).

- Cotton or natural fiber underwear (conventional short sleeve t-shirt and briefs/shorts). Do not include any organizational or other insignias or decals on t-shirts.

- Leather electrical hazard-rated (EH) footwear. *Note: High voltage linemen are not required to wear EH work footwear while climbing.* **\3** Per 70E, Table 130.5(G), footnote d, footwear other than leather or dielectric shall be permitted to be used, provided it has been tested to demonstrate no ignition, melting, or dripping at the estimated incident energy exposure. ***/3/***

4-1.4 Job-Site PPE Clothing Requirements.

Any employee who goes to a job site that involves working on or near exposed electrical equipment must wear all of the following (with the exception of gloves which will be dictated by the work task in Table 4-2) as a minimum:

- Arc-rated shirt (long-sleeve) and pants (or arc-rated coveralls) with minimum arc rating of 8 cal/cm^2 (33.47 J/cm^2).

- Cotton or natural fiber underwear (conventional short sleeve t-shirt and briefs/shorts). Do not include any organizational or other insignias or decals on t-shirts.

- Leather electrical hazard-rated (EH) footwear. *Note: High voltage linemen are not required to wear EH footwear while climbing*.**\3** Per 70E, Table 130.5(G), footnote d, footwear other than leather or dielectric shall be permitted to be used, provided it has been tested to demonstrate no ignition, melting, or dripping at the estimated incident energy exposure. **/3/**

- Safety glasses (ANSI Z87.1) with side shields. Wear safety goggles (ANSI Z87.1) over metal frame and non-safety glasses.

- Hardhat (ISEA Z89.1 Type 1 Class E approved). Long hair must be secured under the hardhat. For cold weather operations, insulated hard hat liner must be arc rated. For work tasks classified as Category 2 or higher, an insulated hard hat liner does not satisfy the requirement for a sock/balaclava worn under the face shield.

- Wear leather work gloves for work tasks classified as Category 1 or 2. Wear arc-rated gloves for work tasks classified as Category 3 or 4. Voltage rated gloves with leather protectors are equivalent to arc-rated gloves. Rubber glove protectors must not be used as work gloves.

- Hearing protection using ear-canal inserts is required whenever working within the arc flash boundary. Hearing protection is also required in accordance with local procedures and whenever the sound level exceeds 84 decibels or 140 decibels peak sound level pressure for impulse or impact noise, regardless of the exposure duration. Wear a combination of insert type and circumaural types of hearing protectors (double protection) when sound levels exceed 104 db(A).

4-1.5 Required PPE Level Per Arc Flash Risk Analysis.

Table 4-3 provides the required minimum PPE level to be worn as a function of the arc flash PPE category. **\2** Table 4-4 provides the required minimum PPE level to be worn as determined by an incident energy analysis. The results of an incident energy analysis to specify a PPE category in Table 4-3 shall not be permitted**. /2/**

Table 4-3. Required PPE Per Arc Flash Category

Arc Flash PPE Category	General PPE Description (See notes)	Required Minimum PPE Arc Rating [cal/cm^2 (J/cm^2)]
\3	[Deleted]	**/3/**
1	Comply with Section 4-1.4 for clothing requirements and Table 4-1 for face shield requirements.	8 (33.47)
2	Comply with Table 4-1.	8 (33.47)
3	Comply with Table 4-1.	25 (104.60)
4	Comply with Table 4-1.	40 (167.36)

Note 1. NFPA 70E discontinued the use of Category 0, which is defined as an incident energy of less than 1.2 cal/cm^2 (5 J/cm^2). This level of incident energy is also referred to as the arc flash boundary.

Note 2. Voltage rated gloves with leather protectors must be used in accordance with NFPA 70E and as specified elsewhere in this UFC.

Note 3. For cold weather operations, an insulated hard hat liner must be arc rated. For work tasks classified as Category 2 or higher, an insulated hard hat liner does not satisfy the requirement for a sock/balaclava worn under the face shield.

Note 4. Comply with Section 4-2.2 when operating branch circuit breakers rated for 30 amperes or less used for lighting and general-purpose receptacles.

Note 5. For Air Force military qualified electrical personnel performing Category 0 tasks, comply with Section 4-1.6.

\2\ Table 4-4. Required PPE Per Available Incident Energy

Available Incident Energy	General PPE Description (See notes)	Required Minimum PPE Arc Rating [cal/cm^2 (J/cm^2)]
0-1.2 cal/cm^2	Comply with Section 4-1.4.	8 (33.47)
1.2-8 cal/cm^2	Comply with Section 4-1.4 for clothing requirements and Table 4-2 for face shield requirements.	8 (33.47)
8-12 cal/cm^2	Comply with Table 4-2.	As determined by incident energy analysis
>12 cal/cm^2	Comply with Table 4-2.	As determined by incident energy analysis

Note 1. NFPA 70E does not provide PPE requirements for under 1.2 cal/cm2 (5 J/cm^2). This level of incident energy is also referred to as the arc flash boundary.

Note 2. Voltage rated gloves with leather protectors must be used in accordance with NFPA 70E and as specified elsewhere in this UFC.

Note 3. An insulated hard hat liner does not satisfy the requirement for a sock/balaclava worn under the face shield.

Note 4. Comply with Section 4-2.2 when operating branch circuit breakers rated for 30 amperes or less used for lighting and general-purpose receptacles.

Note 5. For Air Force military qualified electrical personnel performing 0-1.2 cal/cm^2 tasks, comply with Section 4-1.6. ***/2/***

4-1.6 Air Force Military Uniforms.

For the Air Force, refer to AFI 32-1064, *Electrical Safe Practices*, Attachment 2 for proper wear of military uniforms while working on or near exposed electrical equipment.

At forward deployed locations, Mission Oriented Protective Postures equipment may directly conflict with PPE/clothing requirements for performing electrical work on or near energized circuits. For this and other contingency or wartime operations when special chemical, biological, or radiological clothing is required, the Base Civil Engineer may waive or modify requirements in this chapter, but only after evaluating all safety alternatives with mission requirements.

4-1.7 Additional PPE Clothing Requirements.

Wear arc flash rated clothing properly inside the arc flash boundary. This includes:

- Long sleeves must be rolled down and buttoned.
- The top button of shirts, coveralls, and jackets must be fastened.
- Tuck shirts into the trousers.
- Shorts are prohibited and trousers must extend the full length of the leg.
- Garments with exposed metallic fasteners must not be worn, unless the garments are properly arc rated.
- Garments, including safety harnesses, worn over arc flash rated protective clothing must be arc flash rated.

4-1.8 Clothing Prohibitions.

The following is prohibited:

- Do not wear conductive articles of jewelry (including but not limited to cloth with conductive thread, metal frame glasses, metal headgear, wristbands, watch chains, rings, bracelets, necklaces, body jewelry and piercings) within the restricted approach boundary or where they present an electrical contact hazard with exposed energized electrical conductors or circuit parts.
- Do not wear clothing that could increase the extent of injuries when exposed to electric arcs or open flames. Clothing made from acetate, nylon, polyester, and rayon, either alone or in blends, cannot be worn as undergarments when working on or near energized equipment of greater

than 50 V. Military clothing such as DCUs, field jackets, field jacket liners, Gore-Tex jackets and pants, Gore-Tex fleece liners, nylon cold weather gloves, nylon upper combat boots, chemical warfare suits, winter parkas, winter parka pants, all are polyester blend materials and not allowed to be worn when working on or near energized equipment of greater than 50 V. Shorts are prohibited and trousers must extend the full length of the leg.

- Do not wear anything made of celluloid or other flammable plastic when working near electric arcs or open flames. This may include cap visors, collars, and cuff protectors.
- Do not wear loose clothing, dangling sleeves, or neckties when working on or near moving machinery.
- Do not wear garments equipped with metal slides or zipper fasteners unless the slide or fastener is effectively covered.
- Do not wear coveralls half-dressed where the top-half is wrapped around the waist area.
- Do not wear clothing in a way in which it was unintended to be worn, such as an arc-rated shirt tied around waist with the sleeves.

4-2 ARC FLASH RISK ASSESSMENT.

Perform and document an arc flash risk assessment in accordance with NFPA 70E, Article 130.5 or IEEE C2 Paragraph 410.A.3.a, to determine the available incident energy at the intended work location.

\2 When conducting arc flash risk assessments in accordance with NFPA 70E, incident energy calculations must be performed in accordance with the latest edition of IEEE 1584. ***/2/***

Note: Refer to Section 1-4.2 for the delineation between NFPA 70E and IEEE C2.

Include the following in an arc flash risk assessment:

a. Determine if an arc flash hazard exists. If an arc flash hazard exists, include the following in the arc flash risk assessment:

   - o Appropriate safety-related work practices.
   - o The PPE to be used within the arc flash boundary.

b. Update the arc flash risk assessment when a major modification or renovation takes place. Review the arc flash risk assessment periodically, at intervals not to exceed 5 years, to account for changes in the electrical distribution system that could affect the results of the arc flash risk assessment. Typical changes that could affect the arc flash risk assessment include:

- o System design changes that affect short circuit values or electrical coordination.
- o Protective relay and circuit breaker trip setting changes.
- o Revisions to NFPA 70E, IEEE 1584, or IEEE C2 that affect the arc flash calculation methodology or allowed assumptions in the methodology.
- o Lack of maintenance and testing for the protective equipment credited by the arc flash calculations.

c. Take into consideration the design of the overcurrent protective device and its opening time, including its condition of maintenance.

Note: Improper or inadequate maintenance can result in increased opening time of the overcurrent protective device, thus increasing the incident energy. Where equipment is not properly installed or maintained, PPE selection based on incident energy analysis, or the PPE category method may not provide adequate protection from arc flash hazards.

4-2.1 Arc Flash Risk Assessments Based on Tables.

If incident energy calculations cannot be performed in support of an arc flash risk assessment, utilize the following tables. A documented arc flash risk assessment must be performed for any condition not covered by these tables. **\2** Arc flash risk assessments shall be performed using Tables 4-5, 4-6, and 4-7 only as a short-term solution until an arc flash risk assessment can be performed using an incident energy analysis. Arc flash risk assessments performed using Tables 4-5, 4-6, and 4-7 are only permitted for tasks which are included in Table 4-5 and for equipment and parameters included in Table 4-6 or Table 4-7. Interpolation or extrapolation of parameters not included in these tables is prohibited. **/2/**

a. **\3** Table 4-5 has been developed utilizing NFPA 70E-2021, Table 130.5(C). **/3/** This table determines if arc flash PPE is required for the intended energized work activity.

b. **\3** Table 4-6 has been developed utilizing NFPA 70E-2021, Table 130.7(C)(15)(a). **/3/** Once it has been determined that arc flash PPE is required, Table 4-6 provides guidance regarding the PPE arc flash category.

c. **\3** Table 4-7 has been developed utilizing NFPA 70E-2021, Table 130.7(C)(15)(b). **/3/** The arc flash PPE category depends on the battery voltage and the available short circuit current.

d. Table 4-8 addresses specific service SOPs. Table 4-8 takes precedence over Tables 4-5, 4-6, and 4-7 for any conflicts (interpretation or comparisons) between the tables.

e. Table 4-9 provides the arc flash PPE requirements for overhead distribution work and is based on IEEE C2. Refer to the notes below Table 4-9 for additional information.

f. Tools used as part of the task must be rated for the line-to-line voltage of the energized equipment.

Table 4-5. Arc Flash Hazard Identification

Task	Equipment Condition	Likelihood (see Note)
• Reading a panel meter while operating a meter switch. • Performing infrared thermography and other non-contact inspections outside the restricted approach boundary. This activity does not include opening of doors or covers. • Working on control circuits with exposed energized electrical conductors and circuit parts, nominal 125 volts ac or dc, or below without any other exposed energized equipment over nominal 125 volts ac or dc, including opening of hinged covers to gain access. • Examination of insulated cable with no manipulation of cable. • **\3** [Deleted] ***/3/*** • For dc systems, maintenance on a single cell of a battery system or multi-cell units in an open rack. •	Any	No

• For ac systems, work on energized electrical conductors and circuit parts, including voltage testing. • **\3** Operation of a CB or switch the first time after installation or completion of maintenance in the equipment. **/3/** • For dc systems, working on energized electrical conductors and circuit parts of series-connected battery cells, including voltage testing. • Removal or installation of CBs or switches. • Opening hinged door(s) or cover(s) or removal of bolted covers (to expose bare, energized electrical conductors and circuit parts). For dc systems, this includes bolted covers, such as battery terminal covers. • Application of temporary protective grounding equipment, after voltage test. • Working on control circuits with exposed energized electrical conductors and circuit parts, greater than 120 volts. • Insertion or removal of individual starter buckets from motor control center (MCC). • Insertion or removal (racking) of circuit breakers (CBs) or starters from cubicles, doors open or closed. • Insertion or removal of plug-in devices into or from busways. • Examination of insulated cable with manipulation of cable. • Working on exposed energized electrical conductors and circuit parts of equipment directly supplied by a panelboard or motor control center. • Insertion or removal of revenue meters (kW-hour, at primary voltage and current). • **\3** Insertion or removal of covers for battery intercell connector(s). **/3/** • For dc systems, working on exposed energized electrical conductors and circuit parts of utilization equipment directly supplied by a dc source. • Opening voltage transformer or control power transformer compartments. • Operation of outdoor disconnect switch (hookstick operated) at 1 kV through 15 kV. • Operation of outdoor disconnect switch (gang-operated, from grade) at 1 kV through 15 kV.	Any	Yes
• Operation of a CB, switch, contactor, or starter.	Normal	No

Task	**Equipment Condition**	**Likelihood (see Note)**
• Voltage testing on individual battery cells or individual multi-cell units. • Removal or installation of covers for equipment such as wireways, junction boxes, and cable trays that does not expose bare, energized electrical conductors and circuit parts. • Opening a panelboard hinged door or cover to access dead front overcurrent devices. • Removal of battery nonconductive intercell connector covers.		
• Maintenance and testing on individual battery cells or individual multi-cell units in an open rack • Insertion or removal of individual cells or multi-cell units of a battery system in an open rack. • **\3** Arc-resistant equipment with the DOORS CLOSED and SECURED. And where the available fault current and fault clearing time docs do not exceed that of the arc-resistant rating of the equipment in one of the following conditions: • (1) Insertion or removal of individual starter buckets • (2) Insertion or removal (racking) of CBs from cubicles • (3) Insertion or removal (racking) of ground and test device • (4) Insertion or removal (racking) of voltage transformers on or off the bus **/3/**	Abnormal	Yes

Note: The two components of risk are the likelihood of occurrence of injury or damage to health and the severity of injury or damage to health that results from a hazard. Risk assessment is an overall process that involves estimating both the likelihood of occurrence and severity to determine if additional protective measures are required. The estimate of the likelihood of occurrence contained in this table does not cover every possible condition or situation, nor does it address severity of injury or damage to health. Where this table identifies "No" as an estimate of likelihood of occurrence, it means that an arc flash incident is not likely to occur. ***\3*** *Where this table identifies "Yes" as an estimate of likelihood of occurrence, it means that additional protective measures are required to be selected and implemented according to the hierarchy of risk control identified in NFPA 70E 2021, Article 110.5(H).* ***/3/***

/3/

Note 1. Refer to NFPA 70E for additional limitations regarding the use of the above table.

\3

Table 4-7. Arc Flash PPE Category Classifications for Direct Current (DC) Systems

Equipment	Arc Flash PPE Category	Arc Flash Boundary
Storage batteries, dc switchboards, and other dc supply sources Parameters: 100 V ≤ Voltage ≤ 250 V Maximum arc duration and working distance: 2 sec @ 455 mm (18 in.)		
Available fault current < 4 kA	2	900 mm (3 ft)
4 kA ≤ Available fault current < 7 kA	2	1.2 m (4 ft)
7 kA ≤ Available fault current < 15 kA	3	1.8 m (6 ft)
Storage batteries, dc switchboards, and other dc supply sources Parameters: 250 V < Voltage ≤ 600 V Maximum arc duration and minimum working distance: 2 sec @ 455 mm (18 in.)		
Available fault/ current < 1.5 kA	2	900 mm (3 ft)
1.5 kA ≤ Available fault current < 3 kA	2	1.2 m (4 ft)
3 kA ≤ Available fault current < 7 kA	3	1.8 m (6 ft)
7 kA ≤ Available fault current < 10 kA	4	2.5 m (8 ft)

/3/

Note 1. Refer to NFPA 70E for additional limitations regarding the use of the above table.

Note 2. Obtain the available short circuit current for a particular battery from the manufacturer or the manufacturer's manual for the battery. If this information is not available, estimate the available short circuit current for a lead acid battery from the battery performance data sheet as 10 times the 1-minute ampere capability of the cell (at 77°F (25°C) to 1.75 V per cell).

Table 4-8. Additional Work Tasks and Associated PPE Requirements

Voltage	Task	Modifications and Clarifications to NFPA 70E Tables	V-Rated Gloves	V-Rated Tools
< 600 V	Overhead line work, including lighting.	Comply with Section 4-1.4 and arc-rated safety harness (see Note 1)	Y	Y
> 600 V	Overhead line work (specific tasks of gang-operated switch operation, phasing/voltage/current testing, installing or removing safety grounds, and installing/removing mechanical type live-line clamps/stirrups) at hot stick distance (> 6 ft (2 m)).	Comply with Section 4-1.4 and arc-rated safety harness with lanyard	Y	Y (Note 2)
> 600 V	Overhead line work (specific tasks of disconnect switch operation, fused cutout operation, and replacing fuses) at hot stick distance (> 6 ft (2 m)).	Category 2 and arc-rated safety harness with lanyard	Y	Y (Note 2)
< 600 V	Underground line work (excluding underground structures), including lighting.	Comply with Section 4-1.4	Y	Y
> 600 V	Underground structures (manhole or vault) with no known problems: Routine cable inspection without touching or otherwise disturbing cables.	Comply with Section 4-1.4 and arc-rated safety harness with lanyard	Y	Y
> 600 V	Underground structures (manhole or vault) with no known problems: Splicing deenergized cables in structure with energized cables.	Comply with Section 4-1.4 and arc-rated safety harness with lanyard. Any work task associated with adjusting, moving, or disturbing energized cables requires that power be secured (circuit opened) prior to beginning the task. See Chapter 10 for additional guidance.	N	N
> 600 V	Operating (open/close) SF6, vacuum and air pad-mounted switches (dead front).	Category 2	Y	N

Voltage	Task	Modifications and Clarifications to NFPA 70E Tables	V-Rated Gloves	V-Rated Tools
> 600 V	Operating (open/close) SF6, vacuum and air pad-mounted switches (live front) at hot stick distance (> 4 ft (1.25 m)).	Category 2	Y	Y (Note 2)
> 600 V	Operating (open/close) oil switches.	Must remotely operate from >20 ft (6.1 m) and comply with Section 4-1.4.	Y	N
> 600 V	Oil fused cutouts.	Category 2 Must deenergize upstream before operating cutout.	Y	N
> 600 V	Operating (open/close) oil immersed loadbreak 3-phase gang operated or single-phase pad mount transformer switches at hot stick distance and removal of load-break elbows from various equipment (> 4 ft (1.25 m)).	Category 2	Y	Y (Note 2)
> 600 V	Phasing circuits from grade (ground) at hot stick distance (> 6 ft (2 m)).	Category 2	Y	Y (Note 2)
> 600 V	Overhead series lighting at hot stick distance (> 6 ft (2 m)).	Category 2	Y	Y (Note 2)
> 600 V	Fusing: Operation of fused cutouts (or replacing fuses in fused cutouts) mounted inside a vault or building at hot stick distance (> 4 ft (1.25 m)).	Category 4	Y	Y (Note 2)
> 600 V	Fusing: Replacing fuses in pad mounted transformers or pad mounted switches at hot stick distance (> 4 ft (1.25 m)).	Category 2 Must deenergize transformer before replacing fuses.	Y	Y (Note 2)
> 600 V	Disconnecting /shorting/and grounding capacitor banks at hot stick distance (> 4 ft (1.25 m)).	Category 4	Y	Y (Note 2)
< 600 V	Ship to shore – voltage testing, testing shore power receptacle cover interlock switches and shore power receptacle interlock switches.	Category 4	Y	N

Voltage	Task	Modifications and Clarifications to NFPA 70E Tables	V-Rated Gloves	V-Rated Tools
> 600 V	Ship to shore – voltage testing, application of safety grounds at hot stick distance (> 4 ft (1.25 m)).	Category 4	Y	Y (Note 2)
> 600 V	Hi-potential testing.	Comply with Section 4-1.4.	Y	N
> 600 V	Application of safety grounds from grade (ground) at hot stick distance (>6ft (2m)) in outdoor substations.	Category 4	Y	Y (Note 2)
> 600 V	Spiking a deenergized cable to ground with a remote hydraulic spiking tool. See Note 3.	Comply with Section 4-1.4.	N	N
> 600 V	Cutting a deenergized cable with a remote hydraulic guillotine cutter. See Note 3.	Comply with Section 4-1.4.	N	N

Note 1. Treat voltage of circuits (less than 600 V) as that of the highest voltage occupying one or more poles on which the circuit is run.

Note 2. Live-line tools (minimum length as indicated) must be used.

Note 3. For manhole work, keep workers outside manhole for this task. For direct buried cables, keep workers more than 20 ft (6.1 m) away from task.

Table 4-9. Requirements for Aerial (Overhead) Systems and Equipment

Phase-to-Phase Voltage (kV)	Fault Current (kA)	Category 0	Category 2
		Maximum Clearing Time (cycles)	Maximum Clearing Time (cycles)
1.1 to 15	5	320.0	2,134.0
	10	125.0	830.0
	15	69.0	460.2
	20	44.7	297.7
15.1 to 25	5	189.6	1264.0
	10	78.0	519.8
	15	45.2	301.0
	20	30.2	201.0
25.1 to 36	5	141.3	942.0
	10	59.7	398.0
	15	35.4	235.7
	20	24.0	160.0
36.1 to 46	5	107.4	716.0
	10	46.1	307.0
	15	28.3	188.5
	20	20.2	134.7

Note 1. These calculations are based on open air phase-to-ground. This table is not intended for phase-to-phase arcs or enclosed arcs (arc in a box).

Note 2. These calculations are based on a 72-inch distance from the arc to the employee and arc gaps as follows: 1 kV to 15 kV = 5.08 cm (2 in), 15.1 kV to 25 kV = 10.16 cm (4 in), 25.1 kV to 36 kV = 15.24 cm (6 in), 36.1 kV to 46 kV = 22.86 cm (9 in). See IEEE 4.

Note 3. These calculations were derived using a commercially available computer software program. Other methods are available to estimate arc exposure values and may yield slightly different but equally acceptable results.

Note 4. The use of the table in the selection of clothing is intended to reduce the amount of injury but may not prevent all burns.

Note 5. The table identifies Category 0 and Category 2 levels. Refer to Section 4-1.5 for associated PPE requirements.

Note 6. The maximum clearing time applies to the upstream protective device(s) that provides circuit protection for the intended work location.

4-2.2 Facility Manager Authorized Tasks.

Facility Managers and Building Monitors are permitted to perform the following tasks on switchboards and panelboards rated for less than 600 volts while wearing a minimum of 8 cal/cm^2 (33.47 J/cm^2) coveralls, leather gloves, and safety glasses:

- Opening and closing circuit breakers rated for 30 amperes or less for the purpose of circuit identification and panelboard labeling, including ground fault circuit interrupter and arc fault circuit interrupter testing.

- Operating SWD or HID rated circuit breakers used for lighting control.

Resetting a branch circuit breaker rated for 30 amperes or less used for lighting and general-purpose receptacles after a known equipment or circuit overload and the overload has been removed. If circuit breaker fails to close or immediately trips after resetting, call a qualified electrical worker to investigate.

Note: If the reason for a tripped circuit breaker cannot be determined to be because of an overload, do not reclose the circuit breaker. Call a qualified electrical worker to investigate.

4-2.3 Arc Flash PPE Requirements for Low Voltage Control Circuits.

Arc flash PPE clothing is optional for work on control circuits rated for 120 volts, or less, if the control circuit is provided with upstream fusing rated for 30 amperes or less. The restricted approach boundary is “Avoid Contact” at 150 volts or less and voltage rated gloves are optional for work near 120-volt control circuits. Personnel working on these energized control circuits are required to be trained and designated as a qualified electrical worker in accordance with Section 2-2 for the activities that might be performed on an energized control circuit.

The following are examples of systems that might include these low-voltage control circuits:

- Elevator systems.

- HVAC systems.

- Fire alarm systems.

- Diesel generator control circuits.

- SCADA control circuits.

CHAPTER 5 WORK AREA PROTECTIVE EQUIPMENT AND TOOLS

This chapter addresses the work area protective equipment that supports electrical construction and maintenance, and the associated requirements for their inspection and use. Refer to manufacturer's specific instructions when available.

5-1 INSPECTION OF APPAREL, TOOLS, AND MATERIALS HANDLING EQUIPMENT.

All apparel, tools, and equipment used on the job must comply with this UFC, as well as the applicable service and OSHA requirements. Regular inspections are also necessary to prevent the use of defective items on the job. The authorized individual-in-charge may, regardless of ownership, prohibit the use of any equipment on the job which could be considered unsafe. Complete inspections as follows:

- An initial inspection of tools brought on the job by a new worker must be made by the authorized individual-in-charge. Use is permitted only if the tools are in good condition and conform to requirements of this UFC.
- Inspections of tools and equipment used by an individual worker may be made by the authorized individual-in-charge at any time.
- Before a job is started, each worker must inspect protective apparel, tools, ladders, scaffolds, ropes, and other materials handling equipment to be used. All items must be suitable for their intended uses and in good material condition.
- Use of employee-owned test equipment is prohibited.

Consider the following when selecting and using apparel:

- Maintenance of the garment – some garments may be marked for professional cleaning/dry cleaning only with home/shop laundry prohibited.
- Durability – ability and process to remove stain/oils.
- Wear ability – sizing.
- Repair – procedures utilizing proper materials.
- Intended use – based upon arc flash analysis and manufacturer's recommendations.
- Projected life of the product.
- Limitations of the garment – limited washings, as specified by the manufacturer.

- Training.

- Take care to ensure all garments meet and are labeled in accordance with ASTM F1506, *Standard Performance Specification for Flame Resistant Textile Materials for Wearing Apparel for use by Electrical Workers Exposed to Momentary Electric Arc and Related Thermal Hazards*.

5-2 RUBBER PROTECTIVE EQUIPMENT.

Rubber protective equipment consists of gloves, sleeves, blankets, and insulator hoods. Ensure all items meet or exceed the requirements of the applicable ASTM F18 series standards.

5-2.1 Job Requirements.

The authorized individual-in-charge must determine the necessary type and amount of protective equipment required on the job. Inspect rubber goods before use. Destroy any item found to be defective. Each line truck and service/trouble truck that is required to carry protective equipment, must carry enough protective equipment rated at or above the voltages that could be encountered.

Keep rubber goods inside of a bag, box, or container designed for and used exclusively for them. Transport rubber goods in a manner protected from light, temperature extremes, excessive humidity, ozone, and other injurious substances and conditions. Transport rubber goods in their natural shape, not folded, creased, inside out, compressed, or in any manner that will cause stretching or compression.

5-2.2 Use of Rubber Protective Equipment.

Rubber or other approved protective equipment must be used on all conductors or energized parts, which could be contacted by a worker climbing to or reaching from a work position. Rubber or other approved protective equipment must be rated for the voltage encountered. Table 5-1 provides the OSHA 29 CFR 1910.137 voltage and proof test requirements for rubber insulating equipment. Table 5-2 provides the rubber insulating equipment test intervals.

Table 5-1. Rubber Insulating Equipment Voltage Requirements

Class of Equipment	Color Label	Maximum Use (AC Volts)	Proof Test (AC Volts)	Retest Voltage (DC or AC – Average)	Minimum Distance[1] in Inches (Millimeters)
00	Beige	500	2,500	10,000	1 (25)
0	Red	1,000	5,000	20,000	1 (25)
1	White	7,500	10,000	40,000	1 (25)
2	Yellow	17,000	20,000	50,000	2 (50)
3	Green	26,500	30,000	60,000	3 (75)
4	Orange	36,000	40,000	70,000	4 (100)
1 – Wear leather protectors over rubber gloves. Minimum distance is the minimum length that the exposed rubber glove must extend beyond the leather protector.					

Observe the following precautions:

- Position protective equipment to protect workers against unforeseen hazards such as slipping, cutting out, leaning back, or falling.

- Protective equipment must be placed by working from a level below the wires or insulators on the pole or structure, beginning with those nearest the climbing space, and covering the live parts in the order of their distance away from the climbing space.

- Cover other points of contact, such as grounded guys, equipment, and secondary wires to provide complete protection.

- The removal of protective equipment must be done with equal care, working below the level of wires and insulators. The order of removal must be the reverse of the order of placement.

5-2.3 Use of Rubber Gloves.

Wear rubber gloves with leather protectors suitable for the purpose when climbing or working on installations or structures in the vicinity of live circuits, or in the vicinity of any wire or equipment that may become energized by remote or accidental means. Observe the following:

- Do not use rubber gloves without leather protector gloves over them.

- Before putting on rubber gloves, give each glove an air test to detect cuts and weak spots. This is accomplished by rolling up the glove tightly beginning at the gauntlet end. Listen and feel for air escaping through the palm, thumb, or fingers. Gloves that show weak spots or air leakage must be destroyed. It is recommended that one or more fingers of a defective glove be immediately cut off to ensure no other worker inadvertently uses the glove.

- Liners are available for use inside the rubber gloves to absorb perspiration.
- Use only the gloves assigned, except in case of emergency.
- Keep sleeves of wearing apparel tucked inside the cuffs of the rubber gloves.
- Put on rubber gloves (and sleeves if needed) before being within reach of the restricted approach boundary of the energized conductors.
- Do not remove gloves or sleeves until out of reach of the restricted approach boundary of energized conductors.

Note: Work involving overhead work in a bucket truck is treated differently regarding when to put on and remove rubber gloves. Put on rubber gloves before bucket departure from the cradle and do not remove rubber gloves until the bucket has been returned to the cradle.

5-2.4 Use of Rubber Sleeves.

Wear rubber sleeves whenever there is a possibility of arms coming within the restricted approach boundary specified in Table 3-1. Rubber sleeves are normally worn in conjunction with rubber glove work. Wear rubber sleeves when performing energized-line pole or bucket work within contact distance of an energized line.

5-2.5 Care and Inspection of Rubber Protective Equipment.

Inspect rubber protective equipment before each day's use and immediately following any incident that can reasonably be suspected of having caused damage. Protective equipment must not be stored in a sharply bent position or exposed to the sun's rays, light, or heat.

5-2.5.1 General Care.

Wipe dry all protective equipment before storing. Protect it from contact with oil, paint, creosote, kerosene, gasoline, acids, and other harmful materials. Rubber protective equipment must be turned in to an experienced testing laboratory for cleaning, inspection, and electrical tests. Shorter inspection periods must be considered where equipment is used frequently. Refer to Table 5-2 for required test intervals.

5-2.5.2 Care of Rubber Gloves.

When not in use, rubber gloves must be carried in glove bags. When in use, take the following precautions:

- Rubber gloves must be washed when tested at an approved laboratory and kept free from embedded foreign matter.
- Powder specifically designed for protective rubber gloves can be used after washing rubber gloves to avoid skin irritation and to prevent the rubber from sticking together.
- Store rubber gloves with the fingers up to allow perspiration to drain/dry from the gloves.

5-2.5.3 Care of Rubber Blankets and Sleeves.

Roll, never fold, rubber blankets and sleeves. When being rolled, their surfaces must be brushed clean to prevent dirt from becoming embedded in the surface of the rubber. Do not wear climbers when standing on rubber blankets.

5-2.5.4 Inspection of Rubber Blankets and Sleeves.

Inspect rubber blankets and sleeves immediately before each use. Items with cracks, holes, snags, blisters, or other defects must be discarded.

5-2.5.5 Inspection of Insulator Hoods.

Inspect hoods immediately before use. Examine hoods before each use to ensure that there are no defects and determine if they are suitable for further use.

5-2.5.6 Care of Insulator Hoods.

Line hoods must be air dried. Store hoods in compartments so that no part is strained or distorted.

5-2.6 Test Intervals for Rubber Protective Equipment.

Rubber protective equipment must be subjected to periodic electrical tests. Table 5-2 provides the OSHA 29 CFR 1910.137 required test intervals for rubber insulating equipment. Consider shorter inspection periods where equipment is used frequently.

Table 5-2. Rubber Insulating Equipment Test Intervals

Type of Equipment	Test Frequency
Rubber insulating covers	Upon indication that insulating value is suspect
Rubber insulating blankets	Before first issue and every 12 months thereafter
Rubber insulating gloves	Before first issue and every 6 months thereafter
Rubber insulating sleeves	Before first issue and every 12 months thereafter

Note: If the insulating equipment has been electrically tested, but not issued for service, it may not be placed into service unless it has been electrically tested within the previous 12 months. For rubber insulating gloves, the following examples describe when gloves must be removed from service or retested:

- *Gloves tested on January 1, 2016, and issued after six months in storage on July 1, 2016. The gloves must be removed from service by January 1, 2017. This is both 6 months from the issue date and 12 months from the test date.*

- *Gloves tested on January 1, 2016, and issued shortly after on February 1, 2016. The gloves must be removed from service by August 1, 2016. This is 6 months from the issue date but less than 12 months from the test date.*

- *Gloves tested on January 1, 2016, and issued later in the year on October 1, 2016. The gloves must be removed from service by January 1, 2017. This is only 2 months from the issue date but 12 months from the test date.*

5-3 INSULATED HAND TOOLS AND HANDLING EQUIPMENT.

When working near exposed energized conductors or circuit parts, use insulated tools or handling equipment if the tools or handling equipment might contact such conductors or parts. If the insulating capability of insulated tools or handling equipment is subject to damage, protect the insulating material during storage.

5-4 LIVE-LINE (HOT-LINE) TOOLS.

Live-line tools are only as safe as their continued care and inspection make them. ANSI/IEEE 516 and ASTM F3121/F3121M-16 provide additional information on maintenance and testing. ANSI/IEEE 935 is the guide to be used for tool terminology.

5-4.1 Manufacture.

Tools must be manufactured to meet ASTM F18 series specifications as appropriate to the device and material. The insulating tool portion must be made of fiberglass-reinforced plastic (FRP). FRP must be used as it does not absorb moisture, is impervious to oil-borne materials and solvents, is stronger, and is a better insulator than wood. Like any insulator, FRP must be kept clean and dry to maintain its insulating ability. Use only live-line tools that have a manufacturer's certification as having been tested to meet the following minimum acceptance requirements:

5-4.1.1 FRP.

A FRP tool must have withstood 100,000 V ac per ft (305 mm) of length for 5 minutes.

5-4.1.2 Wood.

Wooden tools are not authorized for use.

5-4.2 Authorized Types of Tools.

All tools must be FRP tools. Replace existing wooden tools with new FRP tools.

5-4.3 Records.

Records must be maintained for all live-line tools to demonstrate satisfactory accomplishment of laboratory and shop testing.

5-4.4 Tool Cleaning Before Use.

A live-line tool must be wiped clean before each day's use and visually inspected for cleanliness and a glossy surface. Clean live-line tools with a clean absorbent paper towel or cloth and then wipe with a clean, dry cloth (a silicone-treated cloth is also permitted). Never use cloths that have been washed in harsh solvents, soap, or detergents. Residues could be left on the tool that may be conductive. Abrasives could damage the surface gloss of the tool (thus permitting water to "wet-out" or "sheet" on the surface of the tool if later exposed to rain or heavy fog). If the surface of the tool is not glossy, or any contamination is present after wiping that could adversely affect the insulating qualities of the tool, the tool must be removed from service and tested before being returned to service.

5-4.5 Tool Inspection After Cleaning and Before Use.

After each cleaning and before use, a live-line tool must be visually inspected for defects. If any defect is present that could adversely affect the insulating qualities of the tool, the tool must be removed from service and tested before being returned to service. The following field observations warrant removing a tool from service:

- Evidence of an electrically overstressed tool, such as: electrical tracking; burn marks; or blisters caused from heat.

- Evidence of a mechanically overstressed tool, such as: damaged, bent, warped, worn, or cracked components; deep cuts, scratches, nicks, gouges, dents or delamination in the tool surface; or deterioration of the tool's glossy surface.

5-4.6 Other Conditions for Removal from Service.

A live-line tool must be removed from service if one or more of the following conditions are detected:

- It fails to pass an electrical wet test during laboratory, shop, or field-testing.

- If a tingling or fuzzy sensation is felt when the tool is in contact with energized conductors or hardware.

- If a tool has been dropped from a significant height (such as from an overhead line or a structure) or subjected to impact such that internal structural damage is suspected.

5-4.7 Returning a Tool to Service.

A tool may not be returned to service until the tool has been examined, cleaned, and repaired (if necessary), and electrically tested.

5-4.8 Waxing.

Waxing is not necessary after every use but only as needed. Use cleaning and waxing kits manufactured for live-line tools and follow directions for their use. All live-line tools must be electrically tested under wet conditions before being returned to service after any waxing.

5-4.9 Repairs and Refinishing.

Only competent personnel must make repairs, including any necessary refinishing. Generally, if there is no roughness on the surface and the live-line tool meets electrical tests, there is no need for repair. Small surface ruptures and small voids beneath the surface may need repair and refinishing. Refinishing of FRP tools typically includes abrasive smoothing of the surface and application of a clear epoxy coat. FRP tools must be electrically wet tested before returning to service after repair or refinishing.

5-4.10 Wet Electrical Testing.

FRP tools must be submitted to a wet electrical test at not more than 2-year intervals, and after any repair or refinishing. This test must be performed over the entire working length of the tool. Use of either of two procedures is acceptable to complete these tests:

- Laboratory testing in accordance with ASTM F3121/F3121M-16. FRP tools require an application of 75,000 V (ac) per ft (305 mm) for one minute.
- Shop or field testing using calibrated test equipment, such as the Hubbell Chance Wet/Dry Hot Stick Tester.

5-4.11 Precautions for Shop or Field Testing.

Follow the manufacturer's instructions and comply with the following precautions:

- Use demineralized water (such as sold in local grocery stores), if available. Otherwise use clean water of conductivity of 3.0 micromho-centimeters or less at room temperature.
- Support the tool in a horizontal position during the test.
- Avoid over-wetting. Use a mist applicator (such as a laundry-type spray bottle) and spray the test section until drops just start to run down the surface. If too much water is sprayed on the tool, water can collect in a line of drops at the undersurface, producing a false rejection because of flashover or high leakage current.
- Take overlapping readings from one end of the tool to the other but do not slide the tester on the tool. Lift up the tester before moving it. This can prevent streaks that can cause a false rejection.
- Rotate the tool 90 degrees and again test the tool from end to end. Continue in this manner until four different positions around the tool circumference have been tested.

5-4.12 Transportation.

Live-line tools must be transported with care and protected from mechanical damage. Exposure to inclement weather must be avoided. Containers must prevent damage to insulating surfaces from abrasive surfaces and bumping motions, and to minimize contamination buildup. In house fabricated containers made from PVC pipe and fittings provide excellent protection for live line tools. Special PVC fittings are also available from vendor for this purpose.

5-4.13 Storage.

Live-line tools transported on vehicles can be stored in bins or racks. If possible, avoid locations subject to temperature changes because this can permit the formation of condensation. Place tools in protective covers that are furnished with the tools. Store tools in bins and racks, constructed to prevent damage to insulating surfaces, away from dirt, moisture, and sunlight (and other sources of ultraviolet light). In house fabricated containers made from PVC pipe and fittings provide excellent protection for live line tools. Special PVC fittings are also available from vendors for this purpose.

5-4.14 Use of Live-Line Tools.

When using live-line tools, workers must use voltage rated gloves and not place their hands closer than is necessary to energized conductors or equipment or to the metal parts of the tool, and in no case closer than the restricted approach boundary specified in Table 3-1. Additional requirements on the use of live-line tools include:

- If tools used have quick-change heads, they must not be used without a “quick change safety clip”.
- Approved blocks, ropes, slings, and other tackle used in live-line tool work must not be used for any other purpose and must be kept clean, dry and free from contamination.
- Live-line tools being used to spread or raise conductors must be securely fastened and must not be held by workers except as necessary to secure or release them.
- Live-line tools must be hung on a hand line or approved tool hanger, if possible. Do not hang a tool on a conductor or bond wire.
- Never lay live-line tools on the ground. When brought to the worksite, place tools on portable racks or lay them on clean, dry tarpaulins or plastic sheeting.
- Do not use live-line tools in rain or heavy fog except in an emergency as directed by the authorized individual-in-charge. In no case must they be used when conditions permit formation of rivulets of water along the tool. After completing the job, make sure the tools are wiped dry before returning them to storage.

5-5 SKIN PROTECTION.

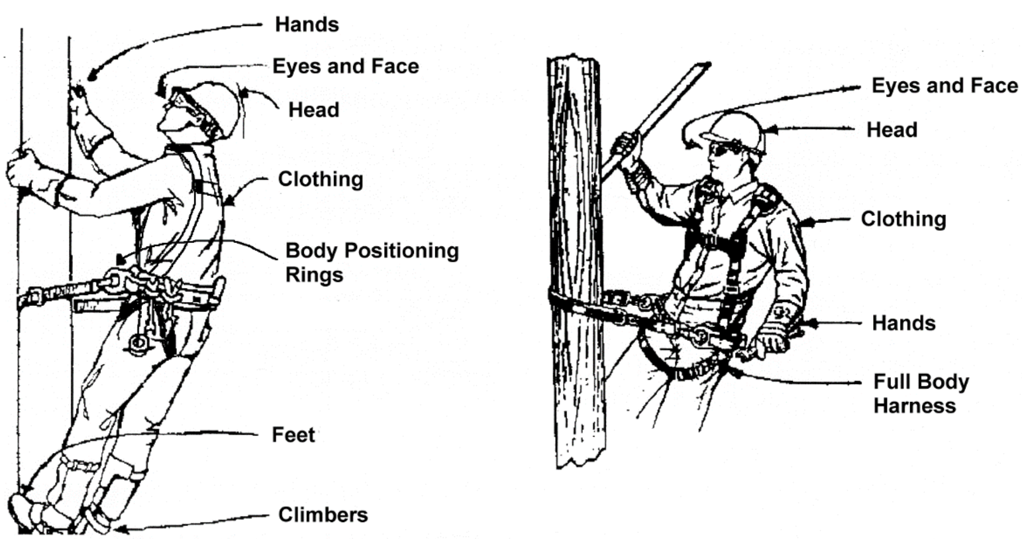
Provide protection for the worker’s skin from toxic and irritant substances where there is a possibility, they can occur at the job site. Ensure workers prevent injury by wearing suitable protective clothing. Keep protective ointments, proper cleaners for the skin, and appropriate first aid remedies on hand. Ensure protective ointments are not of a type that can damage rubber protective apparel. Keep emergency water sources on hand for flushing of irritant substances which could spill on the body, such as battery acid when working in a battery room. Keep sun-blocking ointments on hand when working outdoors.

5-6 POLE/TREE CLIMBING AND FALL PROTECTION.

5-6.1 Personal Protective Equipment.

Pole and tree climbing requires additional personal protective equipment to prevent falls. Items appropriate for work on a wood pole are shown in Figure 4-2.

Figure 4-2. Personal Protective Equipment for Working on a Pole



5-6.2 Climbing Personal Protective Equipment.

Use climbers meeting ASTM F887, *Specifications for Personal Climbing Equipment*.

5-6.3 Fall Protection Personal Protective Equipment.

Use of fall protection equipment is required in all instances while climbing or changing positions on poles or towers. Four types of fall protection are used to handle various fall situations as shown in Figure 4-3. Fall arrest equipment is effective only if adequate anchoring has been identified by a qualified person.

Figure 4-3. Types of Fall Protection

			Positioning Rings on Full Body Harness	Retrieval	Suspension	Fall arrest
Leaves hands free while positioning a worker.	Allows emergency retrieval from a confined space.	Leaves hands free and supports a worker.	For arresting a fall from an elevated position.
Use on wood pole.	Use in a manhole.	Use on structures.	With anchor points.

Positioning, retrieval, and suspension fall protection must support worker's weight plus any additional load. This type of protection does not provide fall arrest. Fall arrest must be added if it is determined that there is a fall arrest anchor point capable of meeting fall arrest requirements. Fall arrest protection requires an anchor point capable of supporting 5,000 lb (2,250 kg) plus a connection device. Protection must provide an adequate free fall distance of 6 ft (1.8 m) or with a deceleration unit a fall distance of 9.5 ft (2.8 m).

5-7 ELECTRICAL TESTING DEVICES.

Electrical testing devices are necessary to ensure maintenance of electric lines can be accomplished safely. This section covers testers that are considered necessary for normal safety considerations. Always use testing devices in accordance with the manufacturer's recommendations, and with the appropriate personal protection. Live-line tools may also be needed.

Note: For the Air Force, proximity voltage detectors are not to be used solely to verify deenergized conditions. Direct contact voltage meters must be used. Capacitive voltage test point meters are considered direct contact voltage meters when used in accordance with the manufacturer's criteria. **\3** The exceptions in NFPA 70E 120.5(7) can be considered. **/3/**

5-7.1 Electrical Testing Device Calibration.

Maintain a calibration program which assures that all applicable testing devices are maintained within rated accuracy. Ensure the accuracy is traceable to the National Institute of Standards and Technology. Maintain a testing device calibration frequency schedule not to exceed 12 months. Provide visible dated calibration labels on all test equipment. Keep up-to-date records that indicate dates and test results of the electrical devices calibrated.

When a device is not being used for NETA type testing, then as an exception to annual certification, the following apply:

- Analog low-voltage multimeters are not allowed.
- Digital multimeters, such as a Fluke, used to verify the absence or existence of voltage do not require annual certification. However, if the device shows any signs of defective operation including failure of any segment of a display element, immediately remove it from service. If the device is sent out for repair, obtain a calibration certification before placing it back in service.
- Meters used for a specific purpose, such as voltage detectors, ampere meters, or phase check meters, do not require annual certification. However, if the device shows any signs of defective operation including failure of any segment of a display element, immediately remove it from service. If the device is sent out for repair, obtain a calibration certification before placing it back in service.

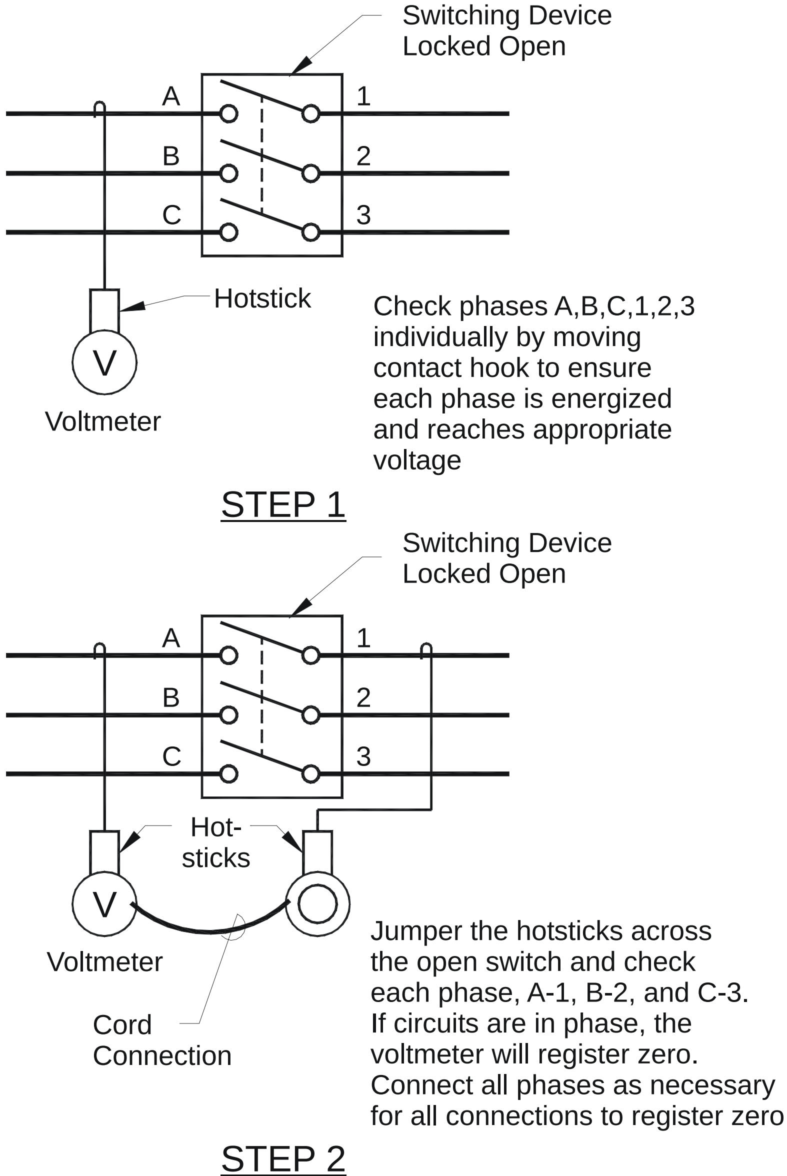
5-7.2 Voltage Detectors.

Voltage detectors (meters) are used to determine whether the line or device is energized or deenergized. The user must understand how to select the proper voltage detector (meter) for the application and where and how the detectors can be used. Some detectors cannot be used to detect or measure voltages on cables with metallic sheaths or semiconductor coatings. Some detectors cannot be used on ungrounded circuits or to detect lower voltages.

5-7.3 Phasing Testers.

Use phasing testers to determine the phase relationships and approximate voltages on energized lines and cables. Prior to paralleling two circuits, determine the correct connection for each conductor by checking the voltage level between that conductor and all other conductors. The voltage across corresponding lines or phases must be zero. A typical phasing tester consists of two high-resistance units on hot sticks connected through a voltmeter. Refer to Figure 5-2 for connections. If potential transformers are available, a voltmeter can be used to measure voltages by connecting a voltmeter between the two sides. If the lines are in phase, the voltmeter will register zero.

Figure 5-2. Phasing Check Using Hot-Stick Phasing Testers



5-7.4 Line Fault Locators.

Use line fault locators on underground lines up to 34.5 kilovolts to determine the location of line faults.

5-7.5 Insulator Testers.

Use insulator testers to measure the potential across each insulator in a suspect string of cap and pin insulators. They can be used without interrupting service.

5-7.6 Leakage-Current Monitors.

The leakage current that can occur from overcurrent conditions on insulated ladder and truck booms must be monitored for worker safety. Leakage current flows along the surface of tools or equipment due to the properties of the device's surface and surface deposits. The permissible leakage current on aerial lifts is one microampere per kilovolt ac or 0.5 microamperes per kilovolt dc. Adverse weather conditions derate the normal dielectric quality of air which results in a greater leakage current. Periodic testing is required. The use of a monitor on an aerial lift providing a continuous display of leakage current is recommended. Set the monitor to sound an alarm at a pre-set leakage current level to alert workers of danger.

5-7.7 Combustible Gas/Oxygen Detectors.

Portable monitors provide visual and audible warnings of explosive atmospheres and/or low oxygen levels which often occur in confined spaces. A continuous reading is given of any gas concentration ranging from 0 to 100 percent of the lower explosive level (LEL) and 0 to 25 percent of the oxygen level. A detector can be used to check battery rooms where ventilation is suspect. Determine if a hazardous atmosphere exists before entering a confined space. Hazardous atmospheres include: a contaminant concentration 10 percent or more of its lower flammability limit; oxygen concentration less than 19.5 percent by volume; and oxygen concentration more than 23 percent by volume, particularly if oil mist or other combustible materials are present.

CHAPTER 6 ENERGY CONTROL (LOCKOUT/TAGOUT)

6-1 SERVICE-SPECIFIC CRITERIA

Comply with the energy control (lockout and tagout) requirements specified in the following documents:

Navy

OPNAVINST 5100.23G CH-1, *Navy Safety and Occupational Health Program Manual*.

Army

EM 385-1-1, *Safety and Health Requirements*.

Department of the Army Pamphlet (DA PAM) 385-10, *Army Safety Program*.

DA PAM 385-26, *The Army Electrical Safety Program*.

Air Force

\3 DAFMAN 91-203, *Air Force Occupational Safety Fire and Health Standards*

AFMAN 32-1065, *Grounding & Electrical Systems* **/3/**

6-2 ADDITIONAL CRITERIA FOR ELECTRICAL EQUIPMENT

Refer to Appendix J for additional information regarding lockout/tagout for electrical equipment.

This Page Intentionally Left Blank

CHAPTER 7 TEMPORARY PROTECTIVE GROUNDING

7-1 TEMPORARY GROUNDING.

Temporary grounding is provided to protect workers engaged in deenergized electric line maintenance. In addition, lines and equipment are protected. Unsafe potentials can occur on the line from static charge buildup, induced voltages through magnetic and capacitive coupling from nearby energized lines, and accidental energizing of the line. The temporary grounding will cause an inadvertently energized line to become deenergized through the action of ground fault relays and will drain off induced voltages. Provide protective grounds with an impedance low enough to cause immediate operation of protective devices in case of accidental energizing of the lines or equipment. Further information on temporary grounding may be found in IEEE Standard 1048, *Guide for Protective Grounding of Power Lines*, and IEEE 1246, *Guide for Temporary Protective Grounding Systems Used in Substations*.

For 600 volts and below, temporary grounding must be installed on lines and equipment to be worked on, unless the authorized individual-in-charge determines that temporary grounding is not practical. The authorized individual-in-charge must explain to the work crew the reasons for not installing temporary grounding. If it is not practical or possible to install temporary grounding then other methods of protection must be provided, such as circuit breakers racked out to the disconnected position, removal of fuses from disconnect switches, disconnect conductors from terminals to isolate the circuit or equipment being worked on, or other methods.

7-1.1 Testing.

Test the line to be sure it is deenergized before installing protective grounds.

WARNING

Place protective grounds on the disconnected lines or equipment to be worked on in accordance with 29 CFR 1910.269(n), Grounding for Protection of Employees. However, if it can be demonstrated that installation of a ground is impracticable or that the conditions resulting from the installation of a ground would present greater hazards than working without grounds, the lines and equipment may be treated as deenergized provided all of the following conditions are met.

1. The lines and equipment have been deenergized.
2. There is no possibility of contact with another energized source.
3. The hazard of induced voltage is not present.

7-1.2 Installation Criteria.

A good temporary ground provides adequate current-carrying capacity and a low-resistance path to the reference ground and is connected at the proper points with clean tight joints. If the temporary ground is not installed correctly, a worker might feel secure but not actually be protected. When connecting grounds to conductors, maintain the minimum approach distances specified in Table 3-1 from energized lines, using live-line tools as required. Place grounds as close to the equipment/work as practical to minimize the inductive voltage loop formed by the ground cable and the worker. To avoid hazardous touch and step potentials, persons on the ground within the work area must stay at least 10 ft (3.0 m) from any protective grounds or devices, and from vehicles bonded to them. If this is not feasible, workers must wear insulated footwear or use other protective measures to minimize the hazard.

7-1.3 Temporary Grounding System Components.

Use system application (overhead, underground, substation) sets with ASTM F 855, *Temporary Grounding Systems to be Used on De-Energized Electric Power Lines and Equipment*, grounding jumpers (clamps, ferrules, and 600 volt jacketed elastomer flexible cable). Store in accordance with the requirements for electrical tools and rubber protective equipment. Assemble grounding sets and jumpers in a workbench environment and test annually using an instrument specifically designed to test grounding equipment.

7-1.3.1 Clamps.

Use the alloy (copper or aluminum) matching the conductor or device to which it is attached and meeting or exceeding the current-carrying capacity of the associated cable. Use smooth jaw clamps on buses to avoid surface marring. Use serrated clamp jaws to bite through corrosion products for attachment to conductors or metal products. Self-cleaning jaws are recommended for use on aluminum. Never use live-line clamps for grounding.

7-1.3.2 Cable.

Cables will be preferably ASTM F855, Type I, of a minimum 2/0 AWG copper and be able to withstand the available fault currents for 15 cycles for substation use and for 30 cycles for line use. Sharp bends and continuous flexing of cable can break conductor strands. Excessive cable lengths must be avoided as this increases resistance, and twists and coils also reduce their current-carrying capacity. As a general rule, limit the length of grounding cables to 30 ft (9 m) for line use and 40 ft (12 m) for substation use. Derate the Table 7-1 fault current capability by 10 percent when using multiple ground cables (which must all be of the same size and length). Verify cables prepared by facility personnel for grounding applications are highly flexible and rugged.

Table 7-1. Maximum Fault Current Capability for Grounding Cables[1]

Cable Size (AWG)	Fault Time (Cycles)	RMS Amperes (Copper)
2/0	15 30	27,000 20,000
3/0	15 30	36,000 25,000
4/0	15 30	43,000 30,000

[1]These current values are the "withstand rating" currents for grounding cables and cables as per *ASTM F 855*. These values are about 70 percent of the fusing (melting) currents for new copper conductors. They represent a current that a cable is capable of conducting without being damaged sufficiently to prevent reuse.

7-1.3.3 Ferrules.

Use ASTM F855, Type IV (stud copper base compression type) when installed on grounding cables by facility personnel. Use ferrules with a filler compound vent hole at the bottom of the cable so that employees can visually check that the cable is fully inserted into the ferrule. Install clear heat shrink over a portion of the ferrule to minimize strand breakage caused by bending. In all cases, follow the manufacturer's recommendations. Do not use aluminum alloy ferrules as they will not provide a lasting snug fit. Check for tightness periodically.

7-1.3.4 Grounding Cluster Bar.

Use to connect phase and neutral conductor jumper cables to the selected method of providing a ground electrode. Cluster bars must have an attached bonding lead. Provide temporary ground rods as stated in Table 7-2.

Table 7-2. Temporary Ground Rod Minimum Requirements

1. Single rod installed to a depth of 5 ft (1.5 m) below grade. • A minimum 5/8 in (16 mm) diameter bronze, copper, or copper-weld rod at least 6 ft (1.8 m) long. • A 6 ft (1.8 m), screw-type ground rod, consisting of a minimum 5/8 in (16 mm) diameter copper-weld shaft with a bronze auger bit and bronze T-handle, tightly connected to the rod.
2. Additional rods to provide a total of 5 ft (1.5 m) below grade where required. • Install 6 to 8 ft (1.8 to 2.4 m) apart while maintaining the 10 ft (3.0 m) step and touch potential clearance. • Bond all rods together prior to installing other electrode connections.

7-1.4 Equipotential Zone.

All metal within reach must be at the same (zero or minimum) potential with reference to ground in order to safely protect the workers. Install and connect grounding and bonding conductors in a proper manner to provide an equipotential zone of protection for workers.

7-1.5 Ground Connection and Electrodes.

Temporary grounds must be connected to the permanent ground of the structure or pole, to another grounding electrode or grounded conductor. This may be the neutral conductor, or an overhead ground wire, or the station ground, or one or more temporarily driven ground rods, driven so at least 6 ft (1.8 m) of the ground rod is in contact with moist soil. Additionally, any metallic object that is a good conductor, such as an anchor rod or permanent ground rod, which extends several feet into the ground, may be used for the connection if sufficiently low ground resistance is determined. When connecting to a metal pole or structure, always verify it has an unbroken connection to its permanent ground rod. In areas accessible to unqualified persons, provide a barricade for the ground rod as a physical and visual barrier to prevent anyone from approaching within the minimum approach distances specified in Table 3-1.

7-2 TEMPORARY GROUNDING OF SUBSTATION CURRENT-CARRYING EQUIPMENT COMPONENTS.

Ground deenergized current-carrying components of substation equipment before approaching them within the minimum distances specified in Table 3-1. Place grounds as close to the equipment/work as practical to minimize the inductive voltage loop formed by the ground cable and the worker. Special precautions are needed during oil handling. Refer to Figure 7-1, and Tables 7-3 and 7-4. Refer to Table 7-5 if oil handling is involved.

Figure 7-1. Substation Temporary Grounding

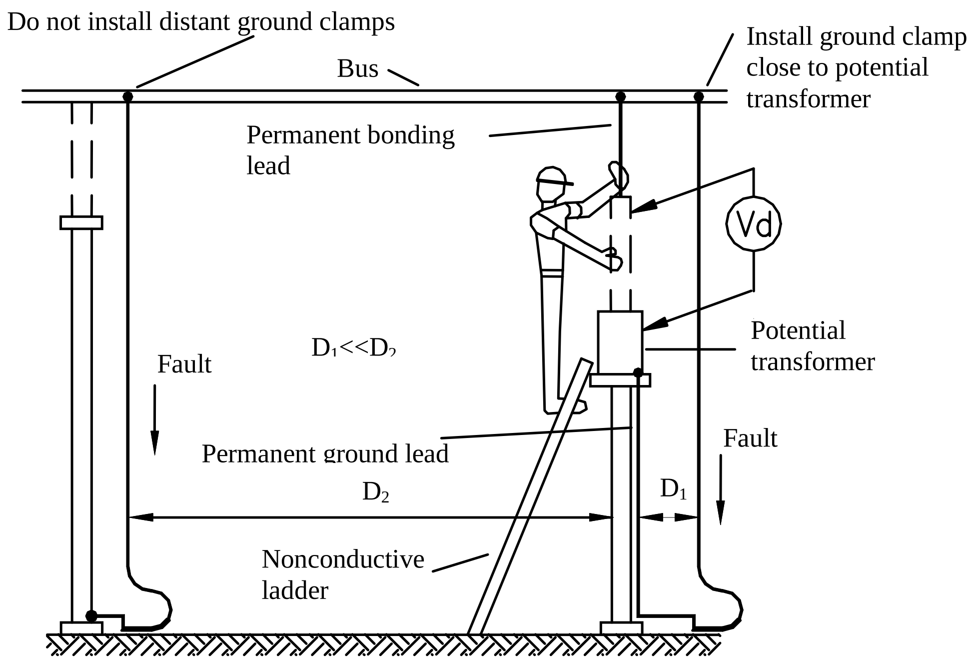

Table 7-3. Substation Protective Grounding Procedures

1	Check validity of permanent equipment grounds.
2	Install a protective ground cable and bond to a grounded structure member or to a common copper equipment bushing lead for equipment being worked on.
3	Apply personal protective grounds before working within Table 3-1 minimum approach distances on substation equipment including: • Bushings • Buses • Capacitors • Circuit breakers • Instrument transformers • Power transformers • Switches • Surge arrestors

Table 7-4. Grounding of Substation Equipment

1	Grounds must be in place before a tank is opened and the insulating medium (oil/gas) is changed. This does not apply to sampling when using a sampling valve.
2	Switches may not be used to maintain personal ground continuity except when the switch is specifically designed for that purpose.
3	Allow at least 5 minutes between opening of the capacitor switching devices and the closing of the ground switch on a fully charged capacitor bank. wait at least 5 minutes after the ground switch is closed before installing protective grounds. Maintain a capacitor bank deenergized for at least 5 minutes before re-energizing it. Include the time limits required for these maneuvers in switching orders involving capacitor banks.
4	Disconnect and discharge surge arrestors using grounding cables.
5	Do not work on grounding transformers unless they are in an electrically safe work condition. Isolate phase reactors from all energized sources and ground them before starting work on them.
6	Disconnect bushing leads from bushing terminals as necessary to permit equipment testing that requires the equipment to be ungrounded. Use a hot stick to connect test equipment and re-establish the ground as soon as the test is completed. Following an applied potential test (“Hi-Pot”), ensure the ground remains in place for a period at least two times the duration of the test period. Follow the manufacturer’s recommendations for work clearances and grounding instructions for the test equipment
7	Install separate grounds for each isolated section of the deenergized circuit if a hazard exists when working in a deenergized area of a substation where there are one or more physical breaks in the electrical circuit.

Table 7-5. Grounding of Equipment During Oil Handling

1	Bond apparatus tanks, conductive hoses, pumping or filtering equipment, drums, tank cars, trucks, and portable storage tanks to the station ground mat. Connect the vehicle end first and disconnect it last to prevent possible arcs near the vehicle.
2	Bond exposed conductors, such as transformer or circuit breaker bushings, or coil ends or transformers where bushings have been physically removed, to the same grounding point.

7-3 AERIAL LIFT TRUCK VEHICLE GROUNDING.

Ground and bond each vehicle being used at the job site when any parts of it will come within the minimum approach distances of Table 3-1. When in transit or when parked with no load and all booms lowered, the vehicle may be ungrounded if it is located outside the restricted approach boundary. Ensure the workers and the vehicle operator are aware of step and touch potential hazards near vehicles as well as near permanent and temporary ground rods and electrodes. Diggers, cranes, and other work vehicles must be bonded, if practical, to the common temporary or permanent ground electrode provided when performing work on deenergized circuits. Ground vehicles in accordance with Table 7-6 and Figure 7-2.

Table 7-6. Procedures for Grounding Insulated and Uninsulated Aerial Lift Trucks

Grounding	Procedure
Insulated boom vehicles	Bond the vehicle to a separate driven ground rod located about midway on one side and as close to the vehicle as practical. If possible, keep insulated vehicles and their ground rods at least 10 ft (3.0 m) away from the structure grounding system to minimize step and touch potentials. If workers can simultaneously contact two or more separately grounded systems, the systems will be bonded together.
Uninsulated boom and other electrical work vehicles	Bond the uninsulated boom and all other vehicles directly involved in electrical work to the grounded system using a grounding cable rated for the maximum available fault current.
Tensioning vehicles	Vehicles used to pull and hold tension on the conductor or overhead ground wire must be properly bonded to a structure ground or a temporary ground rod. Stay on the vehicle or at least 10 ft (3.0 m) away from the vehicle ground when possible.

Figure 7-2. Insulated and Uninsulated Aerial Lift Vehicle Grounding Connections

	Insulated aerial lift	Uninsulated aerial lift

7-4 TEMPORARY GROUNDING OF UNDERGROUND LINES.

Ground all possible sources of power (including transformer backfeed). If the application of grounds is considered to increase the work hazard, then the grounding method will require additional evaluation and approval in accordance with Chapter 8. Install protective grounds at equipment terminations or ground by spiking cable (using an approved tool) prior to work on the cable. Use approved ground sets of the type shown on Figure 7-3.

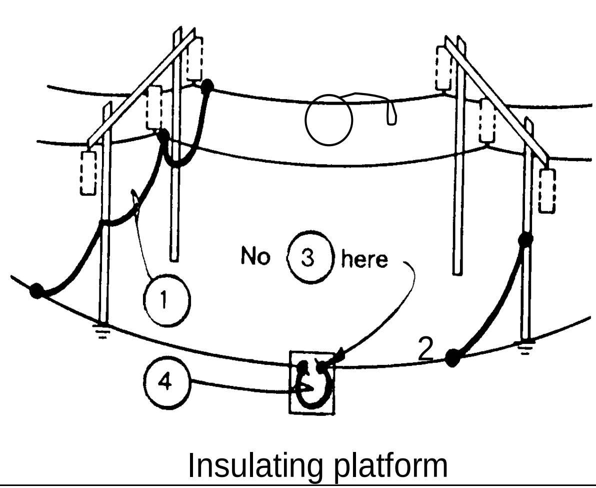
Figure 7-3. Underground System Grounding Sets

			1-1.2 Live-front pad-mount equipment grounding set	Elbow grounding set	Cable spiking grounding jumper	Cable clamps with a penetrating grounding spike

7-5 OPENING OR SPLICING DEENERGIZED CONDUCTORS.

Conductors may be spliced at ground level, from aerial lift equipment utilizing ground mats (uninsulated aerial lifts), or from insulating platforms (insulated aerial lifts). Grounding for conductive or insulating platforms is shown on Figure 7-4. Install all grounding jumpers with hot sticks. Ground any mobile equipment. Stay 10 ft (3.0 m) away from grounded items and step onto equipment or platforms as quickly as possible to minimize any adverse step and touch potentials.

Figure 7-4. Using a Conductive or Insulating Platform for Opening/Closing Deenergized Overhead Conductors



1. Three-phase ground all conductors and structure on one side of the work.
2. Single-phase ground work on conductor and structure on the other side of the work.
3. Ground conductive platform but not insulating platform.
4. Maintain integrity of conductor connection.

7-6 GROUNDING FOR STRINGING AND REMOVING LINES.

Locate grounds to meet requirements of Table 7-7 and Figure 7-5. After conductor pulling, locate grounds in accordance with Table 7-8. Stay 10 ft (3.0 m) away from grounded items and step onto equipment or platforms as quickly as possible to minimize any adverse step and touch potentials.

Figure 7-5. Composite Stringing/Removing Temporary Protective Grounds on Overhead Conductor Lines

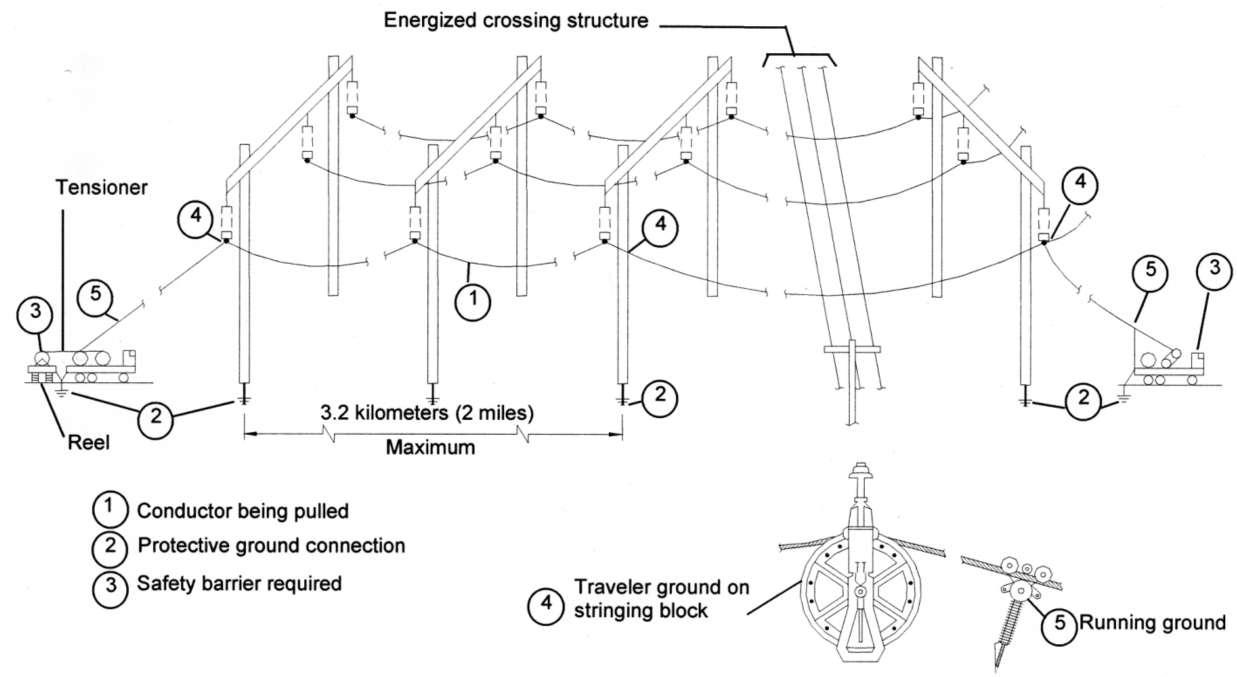


Table 7-7. Stringing/Removing Conductor Ground Locations

1	Ground all stringing equipment such as reel stands, pullers, tensioners, and other devices.
2	Provide a safety barrier around the equipment.
3	Install a running ground between pulling and tensioning equipment and their adjacent structures. *Note: "Running grounds" only work on bare conductors. If using insulated conductors (aerial cable or tree wire for example), the pulling cart and the tensioning cart will need to be grounded and all personnel working are required to wear voltage rated gloves.*
4	Ground stringing blocks at first and last structures, and at least every 2 miles (3.2 km) in between.
5	Ground stringing blocks at each structure on both sides of an energized circuit being crossed. If the design of the circuit interrupting devices protecting the lines so permits, the automated reclosing feature of those devices must be made inoperative and tagged out.

Table 7-8. Conductor Ground Location After Pulling

1	Ground at each structure next to intermediate dead ends of the stringing operation.
2	Ground at each structure where and while work (including clipping-in) is being performed on or near the conductor.
3	Remove grounds as the last phase of finished aerial installation.

7-7 TEMPORARY GROUNDING OF AERIAL LINES.

Ground by installing an overhead distribution grounding set. The grounding set provides a parallel low-level (milliohm) resistance path which limits the current flow through the worker to a very low (safe) value (milliamperes) thus limiting the potential across the worker to a safe value. If the ground resistance were in series with the worker life-endangering currents could flow through the worker under fault conditions. Avoid any ground connection which could provide violent whipping from wind action. Double-point grounds are sometimes utilized but single-point (equipotential) grounding is the preferred method. If double-point grounding is necessary, install the temporary grounds at least one span away from the work site because the grounding cables may violently move during a fault condition.

7-8 PLACEMENT OF GROUNDS.

Install grounds as close as possible to the work. Temporary grounding connection/removal procedures will be in accordance with Table 7-9. Never approach closer than distances specified in Table 3-1 until after the line/equipment has been isolated, deenergized, tested, and properly grounded. Afterwards, avoid coming closer than 10 ft (3.0 m) to minimize the hazard from step and touch potentials. Such potential differences occur from items such as down guys, ground rods, maintenance vehicles, and structure legs or ground wires during the period in which they are bonded to temporary grounds. When it is absolutely necessary to work on or near these features, use bonded conductive or insulated platforms, or approved insulated footwear to minimize the hazard from step and touch potentials. Bond separately grounded systems together if they can be simultaneously contacted.

Table 7-9. Temporary Grounding Connection/Removal Procedures

1	Select a ground electrode using either an established ground at the structure or a temporarily driven ground rod. Minimize the impedance and do not introduce a hazardous potential difference.
2	Test the deenergized line/equipment for voltage by an approved tester. Test each phase conductor or circuit part both phase-to-phase and phase-to-ground. Before and after each test, determine that the voltage detector is operating satisfactorily. The test also determines if any energized condition exists as a result of inadvertently induced voltage or unrelated voltage backfeed.
3	Visually inspect ground equipment. Check mechanical connections for tightness. Clean clamp jaws and conductor surfaces. Clean not earlier than 5 minutes before connection using a wire brush attached to a live-line tool. Use of self-cleaning equipment is also acceptable.
4	Make the ground end clamp of each grounding cable the first connection made and the last to be removed. Hot sticks will be used if the grounded system and worker are at different potentials.
5	The conductor-end clamps of each grounding cable will always be connected last and removed first by hot sticks. Apply to the nearest conductor first and proceed outward or upward until all phases have been connected. Remove in reverse order. The practice of physically holding the temporary grounding cable with gloved hand while attaching the temporary ground connector, in order to lighten the weight on the head of the stick, is strictly prohibited. The practice of holding the hot stick near the head of the hot stick to lighten the weight on the head of the stick is also prohibited. Instead, have a co-worker assist in installing heavy cables by holding the cable with another hot stick, or by using a “shepherd hook” with a pulley and a nonconductive rope to hoist the grounding cable into position.

CHAPTER 8 ENERGIZED WORK

8-1 WORK ON ENERGIZED CIRCUITS.

Do not work on energized electrical circuits operating at 50 V or more except when required to support a critical mission, prevent human injury, or protect property.

In all instances of work on energized electrical circuits, workers must be qualified for energized line work, and all required protective equipment and special tools must be available at the work site. OSHA 29 CFR 1910.333 limits work on live energized electrical equipment as follows: "*Live parts to which an employee may be exposed shall be deenergized before the employee works on or near them, unless the employer can demonstrate that deenergizing introduces additional or increased hazards or is not feasible due to equipment design or operational limitations*."

WARNING

Only workers qualified by electrical training can work in areas on or with unguarded, uninsulated energized lines or parts of equipment operating at 50 V or more. All electric lines and equipment will be treated as energized unless deenergized, locked, tagged, and tested for no voltage. In addition, provide grounding in accordance with Chapter 7. Maintain the specified minimum approach distances specified in Table 3-1 based on the voltage range. The arc flash boundary distance requires the wearing of arc rated clothing. No energized work can be performed during adverse weather conditions (ice storms, high winds, and electric storms) unless there is an emergency and the work has been approved by the designated authority. Any relaxation of these electrical safety requirements in the interest of mission continuation places both the electrical workers and the mission at risk.

8-2 EXAMPLES OF ENERGIZED WORK.

Tables 8-1 and 8-2 provide examples of energized work activities that might be performed. Comments are provided in the tables regarding each energized work activity.

Table 8-1. Typical Energized Work Activities on Interior Electrical Systems

Activity on Energized Electrical Equipment	Comments
Circuit switching (on or off) – low voltage.	This is considered by NFPA 70E as normal operation of electrical equipment.
Circuit switching (on or off) – medium voltage.	This is considered by NFPA 70E as normal operation of electrical equipment.
Troubleshooting – low voltage.	This is considered by NFPA 70E as an activity that does not require an energized electrical work permit.
Troubleshooting – medium voltage.	This is considered by NFPA 70E as an activity that does not require an energized electrical work permit.
Voltage testing – low voltage.	This is considered by NFPA 70E as an activity that does not require an energized electrical work permit.
Voltage testing – medium voltage.	This is considered by NFPA 70E as an activity that does not require an energized electrical work permit.
Remove bolted covers of energized equipment – low voltage.	This is the type of activity that might require an energized electrical work permit.
Remove bolted covers of energized equipment – medium voltage.	This is the type of activity that might require an energized electrical work permit.
Install or remove data logger from a low voltage panel.	This is the type of activity that might require an energized electrical work permit and is a good candidate for a Standard Operating Procedure.
Racking power circuit breakers manually (in or out) – low voltage.	This is the type of activity that might require an energized electrical work permit and is a good candidate for a Standard Operating Procedure.
Racking power circuit breakers manually (in or out) – medium voltage.	This is the type of activity that might require an energized electrical work permit and is a good candidate for a Standard Operating Procedure.
Racking power circuit breakers with remote mechanism (in or out) – low voltage.	A case could be made that this is not energized work in that the employee is a safe distance away from the work activity.
Racking power circuit breakers with remote mechanism (in or out) – medium voltage.	A case could be made that this is not energized work in that the employee is a safe distance away from the work activity.

Activity on Energized Electrical Equipment	Comments
Conductor termination into energized panel or switchboard.	This activity does not satisfy the OSHA requirement of "…*unless the employer can demonstrate that deenergizing introduces additional or increased hazards or is not feasible due to equipment design or operational limitations*".
Replace lighting ballasts while energized.	This activity does not satisfy the OSHA requirement of "…*unless the employer can demonstrate that deenergizing introduces additional or increased hazards or is not feasible due to equipment design or operational limitations*".
Replace lighting fixtures while energized.	This activity does not satisfy the OSHA requirement of "…*unless the employer can demonstrate that deenergizing introduces additional or increased hazards or is not feasible due to equipment design or operational limitations*".
Installing receptacles while energized.	This activity does not satisfy the OSHA requirement of "…*unless the employer can demonstrate that deenergizing introduces additional or increased hazards or is not feasible due to equipment design or operational limitations*".
Circuit breaker installation into energized panel – low voltage.	This activity does not satisfy the OSHA requirement of "…*unless the employer can demonstrate that deenergizing introduces additional or increased hazards or is not feasible due to equipment design or operational limitations*".
Batteries and Backup Power Systems	
Stationary battery maintenance.	This is the type of activity that might require an energized electrical work permit or a Standard Operating Procedure.
Stationary battery replacement, including individual cells or modules.	This is the type of activity that might require an energized electrical work permit or a Standard Operating Procedure.
Automatic transfer switches – inspection and exercising while energized.	This is the type of activity that might require an energized electrical work permit or a Standard Operating Procedure.
UPS inspection and maintenance	This is the type of activity that might require an energized electrical work permit or a Standard Operating Procedure.

Table 8-2. Typical Energized Work Activities on Exterior Electrical Systems

Activity on Energized Electrical Equipment	Comments
Overhead Distribution	
Opening or closing gang-operated air break switches	Routine activity that can be controlled by a Standard Operating Procedure.
Opening or closing single pole switches	Routine activity that can be controlled by a Standard Operating Procedure.
Opening or closing fused cutouts, including refusing.	Routine activity that can be controlled by a Standard Operating Procedure.
Voltage testing, phase rotation testing, and current measurements.	Routine activity that can be controlled by a Standard Operating Procedure. Voltage testing is also part of applying temporary grounding equipment.
Replace pole-mounted equipment, including cross-arms, conductors, transformers, switches, surge arresters, etc.	Routine activity for an electric utility. Not a routine activity at most military installations.
Underground Distribution	
Opening or closing switches, VFIs, or fused compartments on pad-mounted switchgear.	Routine activity that can be controlled by a Standard Operating Procedure.
Removing or inserting load break elbows.	Routine activity that can be controlled by a Standard Operating Procedure.
Voltage testing, phase rotation testing, and current measurements.	Routine activity that can be controlled by a Standard Operating Procedure. Voltage testing is also part of applying temporary grounding equipment.

Activity on Energized Electrical Equipment	Comments
Electrical Manholes and Vaults	
Entry into manhole containing energized circuits for insulated cable examination.	Arc flash calculation methodology does not address the unique configuration of an electrical manhole in which an arcing fault occurs inside a small, enclosed space that also contains the worker. Additional precautions are necessary. An IEEE interpretation dated 14 January 2009, regarding IEEE C2 (National Electrical Safety Code) Rule 410A3, confirms that the phrase "on or near energized parts or equipment" applies to energized insulated conductors inside manholes. IEEE C2 Rule 443 does allow a qualified employee, working alone, to enter a manhole where energized cables or equipment are in service for the purpose of inspection, housekeeping, taking readings, or similar work if such work can be performed safely.
Entry into manhole containing energized circuits for circuit installation/relocation.	See above.
Spicing electrical conductors.	See above.

8-3 ENERGIZED ELECTRICAL WORK PERMIT.

8-3.1 Normal Operation of Electrical Equipment.

Normal operation of electrical equipment, such as circuit breaker operation, does not require an energized electrical work permit if all the following conditions are met:

- The equipment is properly installed. The phrase *properly installed* means that the equipment is installed in accordance with applicable industry codes and standards (such as NFPA 70) and the manufacturer's recommendations,

- The equipment is properly maintained. The phrase *properly maintained* means that the equipment has been maintained in accordance with the manufacturer's recommendations and applicable industry codes and standards, such as NFPA 70B or NETA MTS.

- All equipment doors are closed and secured.

- All equipment covers are in place and secured.

- There is no evidence of impending failure. The phrase *evidence of impending failure* means that there is evidence such as arcing, overheating, loose or bound equipment parts, visible damage, or deterioration.

8-3.2 Prohibitions to Energized Work.

Energized work is prohibited for the following conditions:

- Energized work on equipment or systems with a nominal voltage above 34.5 kV.

- Energized work on medium voltage systems that have not received adequate maintenance and testing.

- Energized work on low voltage systems that have not received adequate maintenance and testing.

An energized electrical work permit is not authorized if there is no assurance that the electrical distribution system is capable of responding as required to overcurrent or arc flash events.

8-3.3 Energized Electrical Work Permit.

An energized electrical work permit is required under the following conditions:

- When work is performed within the restricted approach boundary.

- When an employee interacts with the equipment when conductors or circuit parts are not exposed but an increased likelihood of injury from an exposure to an arc flash hazard exists. An example of this condition is racking (inserting or removing) a circuit breaker into or out of an energized switchgear bus.

Determine appropriate safety-related work practices before any person is exposed to the electrical hazards involved by using both shock risk assessment and arc flash risk assessment. Only qualified persons are permitted to work on electrical conductors or circuit parts that have not been put into an electrically safe work condition. Energized electrical work permits must be prepared in advance in accordance with NFPA 70E and, as a minimum, include:

- Description of the circuit and equipment to be worked on and their location.

- Justification for why the work must be performed in an energized condition.

- Description of safe work practices to be employed.

- Results of the electrical task risk assessment, which includes:
    - o Results of the shock risk assessment, including voltage level, limited approach boundary, restricted approach boundary, and necessary personal protective equipment.
    - o Results of the arc flash risk assessment, including 1) available incident energy at the intended working distance or arc flash PPE category, 2) necessary PPE to protect against the hazard, and 3) arc flash boundary.
- Means employed to restrict the access of unqualified persons from the work area.
- Evidence of completion of a job briefing, including a discussion of any job-specific hazards
- Energized work approval.

Appendix B provides an example of an electrical task risk assessment checklist that can be used in support of preparing the energized electrical work permit.

8-3.4 Exemptions to Energized Electrical Work Permit.

An energized electrical work permit is not required if a qualified person is provided with and uses appropriate safe work practices and PPE under the following conditions:

- **\3** Testing, troubleshooting, or voltage measuring.
- Thermography, ultrasound, or visual inspections if the restricted approach boundary is not crossed. **/3/**
- Access to and egress from an area with energized electrical equipment if no electrical work is performed and the restricted approach boundary is not crossed.
- General housekeeping and miscellaneous non-electrical tasks if the restricted approach boundary is not crossed.

8-4 STANDARD OPERATING PROCEDURES FOR ENERGIZED ELECTRICAL WORK PERMITS.

8-4.1 OVERVIEW.

Standard Operating Procedures (SOPs) are recommended as a means of satisfying the energized electrical work permit requirements of this UFC. The preferred work approach is to establish an electrically safe work condition by deenergizing the equipment before allowing work. However, there are routine activities on the primary distribution system that involve energized work.

Done properly, an energized electrical work permit is a time-consuming detailed evaluation of the work to be done and the safety precautions that are required to ensure the work is performed safely. For specified tasks, an SOP is a pre-approved energized electrical work permit that can simplify the preparation for an energized work activity while still complying with mandated regulations and industry standards.

8-4.1.1 SOP Limitations.

SOPs are recommended for electrical-related work activities that might be performed routinely. Unusual or non-routine work activities that involve working on or near energized electrical equipment require an energized electrical work permit.

An SOP is a pre-approved energized electrical work permit rather than a detailed technical procedure. The SOP assumes that the qualified electrical worker is proficient in the technical aspects of the designated work activity and the SOP focuses on the safety aspects that would be typically included in an energized electrical work permit.

8-4.1.2 Items to Address in an SOP.

Develop SOPs by a risk assessment based upon job hazard analyses (JHA) using Operational Risk Management (ORM) principles. Include the following in an SOP:

- The purpose of the SOP.
- References and definitions appropriate for the work activity.
- The hazards that will be avoided by using the SOP.
- Specific procedures that will be used to reduce/minimize/eliminate the hazards.
- Potential energy sources, including limits of approach.
- Specific required training/certifications.
- Number of required employees.
- Rescue procedures and equipment.
- Potential incident energy level exposure.
- Appropriate personal protective equipment (PPE) such as arc rated clothing, face shields, and electrical gloves for exposure level.
- Management approvals.

Include an electrical task risk assessment as part of the SOP development in support of its specified work scope and associated electrical safety requirements. Refer to the appendices for examples of SOPs that might be appropriate for working on the primary distribution system. These sample SOPs are provided for reference; modify them as necessary for the installation, the allowed work practices, and the qualifications of the personnel.

8-5 APPLICABILITY FOR THE NAVY.

8-5.1 Navy Energized Electrical Work Permit.

For the Navy, all energized work requires written, job specific procedures approved, in writing, by the Commanding Officer/Executive Officer and considered necessary to support a critical mission, prevent human injury, or protect property. “Gloving” above 600 volts is not authorized for Navy personnel. In addition, Navy personnel are not authorized to perform energized overhead distribution (pole line) work above 600 volts with the following exceptions (these exceptions must be performed as required in the task specific SOP, which includes using the appropriate PPE and live line tools):

a. Comply with Section 4-1.4 and arc rated safety harness with lanyard:

- Gang operated switch operation.
- Phasing tests.
- Voltage tests.
- Current tests (with hook sensing head ammeter).
- Installing and removing temporary protective grounds.
- Installing and removing mechanical stirrups and live-line clamps.

b. Comply with Category 2 and arc rated safety harness with lanyard (*Note: Where limited visibility, due to environmental conditions (night time, rain, wind) will possibly create a greater hazard, a face shield is not mandatory. Remainder of PPE (including safety goggles and balaclava with hardhat), is required*):

- Disconnect switch operation.
- Opening or closing fused cutouts.
- Replacing fuses.

8-5.2 NAVFAC Standard Operating Procedures (SOPs).

Develop SOPs based upon job hazard analyses (JHA) using Operational Risk Management (ORM) principles. SOPs must ensure compliance with the codes, standards and regulations identified in Section 1-4. Address the purpose of the SOP, the hazards that will be avoided by using the SOP, specific procedures that will be used to reduce/minimize/eliminate the hazards, potential energy sources, specific required training/certifications, rescue procedures and equipment, and appropriate personal protective equipment (PPE) such as arc rated clothing, face shields, and electrical gloves.

8-5.3 SOP Priority.

Priorities for the development of SOPs are:

- The hazard may cause death, serious injury, or loss of a facility.
- May cause major injury, severe illness, or major property damage.
- May cause minor injury, minor illness, or minor property damage.

8-5.4 SOP Approval and Training.

Following completion of the JHA and development of the SOP, route SOPs through the appropriate chain-of-command and the Activity Safety Office for review and approval. Upon completion of this process, train employees on the SOP and maintain a training record by the supervisor.

SOPs that have been issued by NAVFAC Activities are available for review at the Enterprise Safety Applications Management System (ESAMS) at the following:

https://esams.cnic.navy.mil/ESAMS_GEN_2/LoginESAMS.aspx.

8-6 APPLICABILITY FOR THE AIR FORCE.

\3 For the Air Force, all energized work must be authorized by the authority referenced in AFMAN 32-1065, *Grounding & Electrical Systems*, and considered necessary to support a critical mission, prevent human injury, or protect property. Energized electrical work permits are required in advance of work and require as a minimum those items contained in AFMAN 32-1065. ***/3/*** "Gloving" above 600 volts is not authorized for Air Force personnel.

8-7 APPLICABILITY FOR THE ARMY.

For the Army, all energized work must be authorized in accordance with DA PAM 385-26, *The Army Electrical Safety Program*.

8-8 CATEGORIES OF WORK.

The approved work procedures to be used for work on energized circuits depend on the potentials at which the worker operates. These include:

8-8.1 Workers at Ground Potential.

Workers located on a structure supporting the conductor, on other work platforms, or standing on the ground (earth) remain essentially at ground potential when using tools and equipment. Apply the lockout/tagout program with temporary grounding to ensure that an appropriate ground potential and equipotential work zone is maintained.

8-8.2 Workers at Intermediate Potential.

Workers are isolated from grounded objects by insulating means, such as an aerial lift, an insulating ladder or platform, or insulating mat and they work with insulated tools and equipment. Specific approval is required for this work.

8-8.3 Workers at Line Potential.

Workers are bonded to the energized device on which work is to be performed and are insulated from grounded objects and other energized devices that are at a different potential. This is commonly known as the barehand technique and is prohibited.

8-9 ENERGIZED WORK RULES.

With the use of various types of aerial equipment and live-line tools, it is possible to perform many operations in the maintenance of overhead distribution lines while these lines are energized. Exact compliance with safety precautions is particularly important for energized work, and personnel engaged in this type of work must be trained and qualified in the procedures and the use of tools and equipment. Trained personnel must be familiar with ANSI/IEEE 516, *Guide for Maintenance Methods on Energized Powerlines*, and ANSI/IEEE 935, *Guide on Terminology for Tools and Equipment to Be Used in Live Line Working*. The “Lineman’s and Cableman’s Handbook” also provides pictorial data on many of the tools, equipment, and techniques used for energized work operations.

8-9.1 Permitted Work.

Energized work must not be performed at any facility without written authorization.

8-9.2 Personal Protective Equipment and Clothing.

Refer to Chapter 4 to determine the protective equipment and clothing that will be required.

8-9.3 Statement of Qualifications.

Each worker authorized to perform work on energized lines or equipment must be qualified and covered by a written statement that indicates the highest voltage on which the individual is authorized to work. Local policy must establish who can issue the statement of qualification. Electricians in upgrade training must work under the direct supervision of a qualified person.

8-9.4 Work Methods for Voltage Levels.

Energized work methods and the minimum approach distances must be in accordance with this UFC. For overhead line work, use the approved energized work methods given in Table 8-1 while maintaining the minimum approach distances given in Table 3-1. Use insulated (rubber) goods meeting the requirements of ASTM F 18 standards with color coding meeting the requirements of Table 5-1. Use leather protectors over rubber gloves. Use insulating tools meeting the requirements of Table 8-2 and insulating plastic guard equipment meeting the requirements of Table 8-3. The use of live-line tools without gloves to detect tool deterioration is prohibited. Use voltage-rated gloves with live-line tools. Review instructions and regulations detailing correct use and maintenance of such tools/equipment as a part of the work procedures. At least two workers, fully qualified for the voltage range (including other conductors within reach), must be available. See exceptions in Table 3-9.

Table 8-1. Approved Energized Overhead Line Work Methods by Voltage Class

Nominal AC Voltage Level	Work Method
Up to 600 volts	Use of live-line tools from electrically insulated aerial lift bucket or platform (intermediate protection) or use of live-line tools from structure mounting or an aerial lift bucket (ground potential).
>600 to 7.5 kilovolts	Use of live-line tools from electrically insulated aerial lift bucket or platform (intermediate protection) or use of live-line tools from structure mounting or an aerial lift bucket (ground potential).
>7.5 to 15 kilovolts	Use of live-line tools from electrically insulated aerial lift bucket or platform (intermediate protection) or use of live-line tools from structure mounting or an aerial lift bucket (ground potential).
>15 to 36 kilovolts	Use of live-line tools from an electrically insulated aerial lift bucket (intermediate potential).
>36 to 70 kilovolts	This work can only be performed by personnel specifically trained in the hazards associated with voltages in this range.
>70 to 230 kilovolts	This work can only be performed by personnel specifically trained in the hazards associated with voltages in this range.

Table 8-2. Insulating Tools for Electrical Workers

Standards			
ASTM F711, Specification for Fiberglass Reinforced Plastic (FRP) Rod and Tube Used in Live-Line Tools. *ASTM F3121/F3121M-16, Standard Guide for In-Service Maintenance and Electrical Testing of Hand-Held Live-Line Insulating Tools (Fiberglass-Reinforced Plastic (FRP)).*			
Minimum Test Values			
Tool Material	**OSHA Acceptance[1]**	**IEEE In-Service[2]**	**Use**
Fiberglass reinforced plastic (FRP)	100 kV/ft (0.3 m)	75 kV/ft (0.3 m)	Preferred[3]

Notes for Table 8-2:

1. *Test values manufacturers must certify for acceptance by buyer.*
2. *Test values required after acceptance and tested after use in the field.*
3. *All new tools will be FRP. Replace wood live-line tools with FRP tools immediately; permanently remove the wood tools from service and destroy.*

Notes for Table 8-3:

1. *Cover-up materials are tested at values greater than the maximum use phase-to-ground values. The maximum use phase-to-phase values relate to guarded-phase-to-guarded-phase. The units are not rated for bare-phase-to-guarded-phase potentials.*

8-9.5 Pre-Work Procedures.

Do not start work until the requirements of Table 8-4 have been completed.

Table 8-4. Pre-Work Procedures – Overhead Line

1. Determine existing conditions and complete a job hazard analysis (see Chapter 2).
2. Determine the voltage rating of circuits to be worked on, distances to other energized lines, and location of work. Evaluate the following: a. If aerial lift equipment can be used. b. What personnel qualifications are needed for the work. c. If special equipment, tools, or hazard protection are needed.
3. Prepare a written standard operating procedure.
4. Obtain energized work approval/permit (permissible work for all services is discussed in Chapter 8).
5. Review work and safety precautions with the crew before work begins (including tailgate briefing).
6. Inspect tools/equipment before starting work.

8-9.6 General Job-in-Progress Procedures.

Observe the precautions given in Table 8-5 before proceeding with the procedures provided in Table 8-6.

Table 8-5. Energized Work Precautions – Overhead Line

1. Check that circuit automatic reclosing devices have been made inoperative and tagged out while work is being performed. For the Navy, use a Special Instruction tag or a Hold tag.
2. Do not allow items of a voltage class lower than required for the work to be available to the workers at the work site.
3. Exercise special care when working in the proximity of equipment such as fuses, surge arresters, and similar equipment, or where conductor checks indicate burns or other defects in conductors, tie wires, and insulators. Procedures may require that some equipment be bypassed for the duration of the work.
4. Comply with adverse weather and number of qualified worker requirements.

Table 8-6. Voltage Level Work Procedures – Overhead Line

600 Volts and Below
1. Ground vehicles and aerial lifts in the vicinity of the work site.
2. Cover with approved protective equipment, or isolate with suitable barriers, energized phase and neutral wires, ground wires, messengers, and guy wires in the vicinity of the work. Apply covering to the nearest and lowest conductor first and remove in reverse order. Refer to Chapter 7.
3. Refer to Table 8-3 for work methods.
4. Rubber gloves with leather protectors will be worn when entering the restricted approach boundary of Table 3-1and removed only after leaving that area.
5. Protective equipment and vehicle grounds will be removed at the end of each workday.
6. Perform work on only one conductor at a time.
7. Tape or otherwise protect splices. Secure loose ends of conductors.
601 to 15,000 Volts
1. Ground vehicles and aerial lifts in the vicinity of the work site.
2. Cover with approved protective equipment, or isolate with suitable barriers, energized phase and neutral wires, ground wires, messengers, and guy wires in the vicinity of the work. Apply covering to the nearest and lowest conductor first and remove in reverse order. Refer to Chapter 7.
3. Use approved live-line tools where required by Table 8-3.
4. Rubber gloves with leather protectors will be worn when entering the restricted approach boundary of Table 3-1and removed only after leaving that area.
5. Protective equipment and vehicle grounds will be removed at the end of each workday.
6. Work performed must be under the direct supervision of a qualified work leader devoting full time and attention to the workers and the safety of their work.
7. Perform work on only one conductor at a time, although it is recognized that three-phase lifting tools may be used.
Above 15,000 to 230,000 Volts
1. Except for the replacement of fuses and switching, work on energized lines or apparatus at this voltage range must be performed by personnel specifically trained in the hazards associated with voltages in this range. Follow the requirements of Table 8-3.
2. Energized work above 36,000 volts will be done by personnel specifically trained in the hazards associated with voltages in this range.

CHAPTER 9 SUBSTATIONS AND SWITCHGEAR

9-1 SUBSTATION WORK.

9-1.1 Purpose of Substation.

A substation provides a protected area for switching power circuits and may include transforming power from one voltage to another. For the purposes of this UFC, substation refers to substations and switching stations. A substation presents an inherent safety hazard because usually only some portions of the substation apparatus can be deenergized for maintenance. For safe operation and maintenance, a thorough knowledge of the substation, including aerial and underground line connections, is necessary. Systems are designed to be safe to operate if maintained properly. Operating safely requires maintenance to be done in a manner that eliminates risks and requires knowledge of the work area, its hazards, and its design basis.

9-1.2 Diagrams and Schematics.

Electrical diagrams and schematics of the substations must be available and up to date. Diagrams and schematics must be studied to understand the operation of the systems and the location and connections of all circuits. Protective devices, alarms, and interlocking circuits all are intended to protect the system. The electrical worker must understand where, why, how, and when blocking protective devices can maintain safe working conditions.

9-1.3 Engineering Guidance.

Diagrams and schematics must be kept up to date under the supervision of the facility's engineering staff. Engineering staff guidance must be sought when performing maintenance on complex systems. Engineering input is mandatory if the maintenance work involves additions or changes to the power and control systems involved.

9-1.4 System Operation.

System single line diagrams must be permanently mounted at each substation. When Safe Clearance switching operations are performed, mimic buses on switchgear can be helpful as a visual indication of the lines or equipment being operated.

9-1.4.1 Protective Devices.

Protective devices within the system, such as relays, circuit breakers, and fuses, must retain, respectively, their correct coordination settings or be of the proper size and type. Always record previous data so that unintended changes in system coordination are not made.

9-1.4.2 Alarms.

System alarms, if blocked during maintenance, must be returned to their correct operating condition at the completion of the maintenance.

9-1.4.3 Interlocking.

Interlocking is used to maintain proper electrical operation in the case of a circuit loss or switching change. Interlocking provisions must be fully understood so to eliminate the danger of electrical feedback from another source, possible paralleling of two unsynchronized sources, or other unsafe operations. Interlocks, if bypassed during maintenance, must only be done by qualified persons, and must be returned to their correct operating condition at the completion of the maintenance.

9-1.5 Abnormal Conditions.

Maintenance accomplished after the occurrence of fault conditions that interrupted normal service imposes higher than usual maintenance risks. Faulty energized equipment and lines must always be placed in an electrically safe work condition before any work is done. All abnormal operating equipment and electrical components must be deenergized, locked and tagged tested, and grounded or isolated (whichever is applicable).

9-1.6 Defective Equipment.

Electrical apparatus found to be in a dangerous condition or not working properly must be removed from service immediately and tagged. Subsequently, a complete report on the defective equipment must be provided by the worker to the authorized individual-in-charge, the same day if feasible. Perform the following:

- Defective equipment removed from service, such as: distribution, potential, and current transformers; capacitors; and surge (lightning) arresters must positively be identified by an authorized and qualified individual before they are put in storage. Existing defective equipment in storage or at any other location must also be clearly identifiable.

- Identify defective equipment by painting a large red “X” on the body (not on the top) of the equipment. The red X must remain on such equipment until it has been repaired or until it has been properly disposed of. Local policy may dictate use of their preferred defective equipment identification marking.

- It must be considered a serious neglect of duty, and willful disobedience of instructions for a worker to deface in any way the identification marking on defective equipment or to place such equipment in service while so identified. The worker in charge of repairing any piece of defective equipment must be the only person authorized to remove the defective markings, and then only after all repairs have been made and the equipment has passed all required testing.

9-2 SWITCHING.

Opening or closing a power switch can expose the electrical worker to some degree of hazard. A mishap might occur if a switch is closed when a fault is still present on the line. To prevent a mishap, the authorized individual must prepare a switching sequence and identify all load isolation requirements. All switches operated in the switching sequence must be correctly identified. The electrical worker will review the manufacturer's operation manual for any switch that is unfamiliar, and all safety steps listed in the operation manual will be accomplished before opening or closing the switch.

WARNING

Switches can fail during switching operations, creating arc flash hazards. Wear arc rated clothing and/or switching suits during these operations in accordance with Chapter 4 requirements.

For the Navy, switching operations above 600 volts require a Switching Order. Switching operations include changing the position of circuit breakers, fused equipment, switches, and other devices.

9-2.1 Air Switches.

Many air switches cannot be opened if there is a load on the line, a large magnetizing current from a transformer, or a heavy charging current from an unloaded transmission line. Understand the interrupting capability of each switch being operated.

9-2.1.1 Disconnect Switches.

Disconnect switches of the non-load break-type must not be used to interrupt loads and magnetizing currents, unless an engineering review has determined the disconnect switch can safely interrupt the actual current. Switch sticks will be used when necessary to provide the minimum working and clear hot stick distances. Assume disconnect switches are of the non-load break-type unless you have positive proof otherwise. Operate non-load break-type switches on the following basis:

- Disconnect switches can be used to open an energized line when not under load.
- Disconnect switches can be used to open sections of deenergized lines where these lines parallel other high-voltage lines. Use caution because induced voltages can build up in the deenergized line and create dangerous switching conditions.

- Evaluate the hazard before using disconnect switches to open a tie line or to break two parallel high-voltage lines.

9-2.1.2 Airbreak Switches.

Gang-operated airbreak switches equipped with arcing horns may be rated for load-break operation, or they may only be rated for interrupting the magnetizing current of transformers or the charging current of lines, or to make and break line parallels. Operates these switches as follows:

- Provide ground mats for the operator to stand on for all substation airbreak switches when operating. Either fixed or portable small iron-mesh mats must be used. The mats must be electrically connected to the operating rod and the substation ground grid to equalize the ground gradient and prevent any potential differences in case of insulation failure or flashover.

- Appropriate arc flash rated personal protective equipment, rubber gloves, and hot sticks must be used when operating airbreak switches.

- The hinges of airbreak switches must be sufficiently stiff (and kept in this condition) so that after the blades have been turned into the open position they will not accidentally fall back on their line-side energized clips.

- The switch must be inspected after it has been opened to see that all blades have opened the proper distance. Single-throw airbreak switches must be opened to the maximum amount. Double-throw airbreak switches must be opened so that the blades clear both sides of the switch by the same amount.

- Install locks on all airbreak switch-operating mechanisms. Airbreak switches will be kept locked except when opening or shutting the switch.

9-2.1.3 Interrupter Switches.

Interrupter switches are designed to be opened under load. Metal-enclosed interrupter switches have sometimes been used in place of circuit breakers as a more economical switching method.

9-2.1.4 Inching.

The method of opening manually operated non-load break-type disconnects in a gradual manner is called inching, when the operator believes there is no load current. If a small arc occurs from the charging current, it has been assumed that a cautious opening would allow the arc to be broken; however, inching is dangerous and is prohibited.

9-2.2 Oil Switches.

The consequences of operating a faulty oil switch or closing into a faulted circuit with an oil switch are likely to be catastrophic and, often fatal. Switching procedures will be used to make sure that no energized oil switch is operated while workers are in the vicinity. Unless the switch has been equipped for remote operation (at least 20 ft (6.1 m)) away, the switch must be completely deenergized by an upstream device before switching. The switch must be locked out and tagged out before allowing maintenance. In addition, do not operate any energized high-voltage oil switch unless routine maintenance has been performed within the past year.

The switch must be deenergized at the nearest upstream device following the lockout/tagout procedures of Chapter 6. Once maintenance has been performed on the switch, the switch can be considered operational following the guidelines of this section. Oil switches must incorporate a mechanical stop to prevent inadvertent operation to ground. Any abnormalities or defects discovered in any oil switch must be reported to an authorized individual.

9-2.3 SF_6 Switches.

Follow all precautions specified by the manufacturer. Inspect the switch before operating it for any signs of degradation, such as low SF_6 pressure or signs of SF_6 leakage (accumulation of powder around seals). Verify that the SF_6 pressure gauge is in the green zone before operating the switch; operating a switch with low SF_6 pressure can result in internal flashovers that will damage the equipment and cause personal injury. Before energizing the switchgear for first use, verify that the shipping caps on all bushings and bushing wells have been replaced with elbows or insulated protective covers or plugs. The switchgear must be deenergized and grounded prior to conducting any maintenance, SF_6 sampling, or SF_6 filling procedures.

9-2.4 Oil-Filled Vacuum Switches.

Follow all precautions specified by the manufacturer. Inspect the switch before operating it for any signs of degradation, such as oil leakage; operating a switch without oil can result in internal flashovers that will damage the equipment and cause personal injury. Before energizing the switchgear for first use, verify that the shipping caps on all bushings and bushing wells have been replaced with elbows or insulated protective covers or plugs. The switchgear must be in an electrically safe work condition prior to conducting any maintenance, oil sampling, or oil filling procedures.

9-3 FUSES.

WARNING
Fuses might fail during handling if energized, creating arc flash hazards. Wear arc rated clothing or switching suits when changing energized fuses in accordance with Chapter 4 requirements.

9-3.1 Characteristics.

A fuse is a single-phase device. Fuses can be subject to partial melting or damage by currents that might not have been of sufficient magnitude to blow the fuse.

9-3.2 Fuse Handling.

Fuses must normally not be handled, except when they need to be replaced. Pull them briskly and remove completely. Use safety glasses and face shields when replacing fuses in primary fuse cutouts, do not use your free arm in an attempt to shield your eyes from possible flashes. The worker changing the fuses must stand firmly on a level surface. Where operating in an elevated position, the worker will be secured with a safety lanyard/harness to prevent a slip and fall if there is a flash. Use live-line tools to remove energized fuses. Whenever possible, deenergize the circuit before removing a fuse.

9-3.3 Operation of Energized Fuses.

Open all lines protected with energized fuses in the same manner as for air switches. Deenergize non-load-break type installations. For load-break installations, wait for a short time after fuse replacement in order to allow the fuse to interrupt any fault condition that might remain prior to the fuse replacement.

9-3.4 Open Fuse Holder.

Do not leave outdoor fuse holders open for an extended period of time. Water damage/moisture or warping could make closing them dangerous or degrade their protective ability.

9-3.5 Closed-Position Fuse Locking.

Follow the fuse or switch manufacturer's instructions, as appropriate, to be sure that the fuse is securely locked, latched, and held fast in a closed position.

9-3.6 Bypassing.

Do not bridge fuses or fuse cutouts internally.

9-4 ENERGY STORING PROTECTIVE DEVICES.

9-4.1 Electrical Charge.

WARNING

Protective devices such as surge arresters, choke coils, and capacitors store electrical charges as a byproduct of their protective mechanism. **\3** This stored charge must be discharged to ground and tested per NFPA 2021 70E 120.4(B)(6) before such devices can be considered deenergized. ***/3/*** Always wear appropriately rated personal protective equipment, including eye/face protection when deenergizing or energizing these devices., and use appropriate PPE in accordance with Chapter 4 requirements.

9-4.2 Surge Arresters.

A surge arrester limits overvoltages and bypasses the related current surge to a ground system that absorbs most of the energy. An overvoltage condition can be caused by a fault in the electrical system, a lightning strike, or a surge voltage related to load switching. All surge arrester equipment must be considered as loaded to full circuit potential, unless it is positively disconnected from the circuit. Be sure the permanent ground conductor is intact before any work is performed.

- High-voltage substation and at-grade surge arresters must always be provided with screens or fences to prevent possible contact while parts of the surge arresters may be live. The screen or fence must have a gate large enough to permit the removal of individual units. The gate must be provided with a lock and an authorized person must keep the key.

- Surge arresters must never be touched or approached, unless they are completely disconnected from all live lines and live equipment, and all parts have been discharged to ground and effectively grounded.

- Horn gap switches must be fully opened and completely separated from all live lines and equipment whenever it is necessary to work near a surge arrester.

- If the first attempt to disconnect a surge arrester is unsuccessful, wait 2 or 3 minutes before making another attempt so not to cause an internal fault.

9-4.3 Choke Coils.

Choke coils are inductors that operate in a manner similar to surge arresters, except that they operate on over-frequency rather than over-voltage.

9-4.4 Capacitors.

Capacitors consist of an electrical condenser housed in a suitable container. Power capacitors are used to provide power factor correction. Coupling capacitors are used for coupling communication circuits to metering circuits. Because capacitors can hold their charge, they are not electrically deenergized immediately after being disconnected from an energized line. Capacitors on electric lines must be provided with discharge devices to discharge the voltage to 50 V or less, within 5 minutes after the capacitors have been completely disconnected from the circuit. Wear appropriate levels of PPE identified in Chapter 4.

- Discharge circuits are intended to discharge capacitors after the circuit is deenergized. Since there could be no indication that the circuit is burned out or otherwise not functioning, always assume capacitors are fully charged until tested.

- Line capacitors removed from service for any purpose must be considered at full or higher voltage, until the terminals have been shorted together and discharged by an approved method. Do not short terminals until capacitors have been deenergized for at least 5 minutes to allow time for the voltage level to reduce.

- It is not safe to use fuses or disconnect switches to disconnect large capacitor banks (above 60 kilovolt-reactive single-phase, or 180 kilovolt-reactive three-phase). Circuit breakers or switches designed specifically for this purpose must be used.

- After disconnecting all capacitor banks, wait 5 minutes. Short together and ground all terminals; ensure the neutral is grounded. All operations must be performed using rubber gloves and a hot stick.

- Grounds and terminal shorts on capacitors must be left on until the work is completed.

- Barricade the work area as a safety measure for other workers, when working on or testing capacitors in the shop.

- Capacitors made before 1979 usually contained PCBs. Follow precautions for hazardous materials if the case is ruptured or any liquid is visible on the outside of the case.

9-4.5 Coupling Capacitors.

These capacitors have a high impedance, which results in a long discharge period. This characteristic of coupling capacitors is typically overlooked, which makes them particularly hazardous to personnel if not properly grounded. To minimize shock hazard, follow the precautions below:

- A coupling capacitor must always have a shorting wire installed.
- During maintenance, a grounding wire must be connected to each exposed metal terminal that a worker could contact. Grounding wires must be left in place for the entire duration of maintenance.

9-5 INSTRUMENT TRANSFORMERS.

9-5.1 Potential (Voltage) Transformers (PT).

PTs provide a means of obtaining a low voltage from a higher voltage circuit. They are designed and selected to operate within certain accuracy limits and burdens. Replacement transformers must have characteristics identical with the original units. The case and one of the windings of the low-voltage side of voltage transformers must always be grounded before energizing the transformer.

Be aware of the following hazards inherent in the maintenance and removal of these units:

- If the secondary windings are inadvertently shorted together when the primary windings are energized, a very high current will flow causing the windings to quickly overheat. This may also create an arc flash hazard to anyone in the vicinity of the transformer.
- On most modern switchgear, a drawout arrangement automatically disconnects and grounds the transformers when access to the fuses is necessary.
- On older obsolete switchgear, fuse replacement is potentially dangerous when the primary circuit to the transformer remains energized. Follow these additional safety precautions.
    - The authorized individual-in-charge will give specific instructions for replacing a blown primary winding fuse on a potential transformer located within switchgear and whenever it is not possible to use a standard 6 ft (1.8 m) fuse puller.
    - If a circuit breaker or sectionalizing switch is not installed to isolate a potential transformer, the worker must report the situation to the authorized individual-in-charge before replacing the fuse. The authorized individual-in-charge will arrange for deenergizing the primary circuit. Replacing a primary fuse when the potential transformer is not isolated is particularly hazardous and requires specific approval.
    - When disconnecting the primary service to the transformer, verify the absence of voltage using a suitably rated voltmeter (a handheld test meter with a high-voltage probe is not acceptable). Lamps can be

used in addition; however, note that a non-illuminated lamp, connected on the low-voltage side of a voltage transformer, is not an adequate indication that the primary side of the transformer is deenergized.

    - The secondary fuses must also be removed before replacing the primary fuse, and then reinstalled before the transformer is reenergized.

- While the transformer is deenergized, the worker must visually inspect for obvious symptoms of trouble such as a smoked or burned case, a damaged bushing, or a damaged fuse holder.

9-5.2 Current Transformers (CT).

WARNING

The most serious hazard associated with the maintenance of CTs occurs when the secondary side is opened while the primary side is energized. This causes a very high voltage to develop in the secondary winding, which both stresses the insulation and presents an extreme personnel hazard. The secondary circuit of a current transformer must never be opened while the primary side is energized; however, the secondary leads can be shorted together without damage to the transformer.

Before opening the secondary circuits of any energized current transformer, the secondary leads must be shorted together and grounded. The location of the short and ground is preferably located at the transformer secondary terminals but can be at any point between the current transformer and the location at which the secondary circuit is to be opened.

Current transformer cases and secondary circuits must be grounded before energizing any current transformer.

9-6 POWER TRANSFORMERS AND REGULATORS.

9-6.1 Transformers (Power and Distribution).

Consider all transformers energized and at full voltage unless they are disconnected from primary and secondary wires or disconnected from the primary wires and all phases shorted together and grounded. The secondary neutral normally is sufficient as a ground, provided that there is a grounding conductor interconnected with the common neutral, the transformer case, and a ground electrode. Always check continuity of the ground connection.

WARNING

Do not remove transformer covers or handhole plates or allow any work to be done on the inside of transformers until the following instructions have been completed.

Observe the following precautions:

- When transformers are installed or replaced, check the secondary terminals for correct voltage and for phase rotation (if applicable).
- When transformers are installed, and before they are energized, the ground connection must first be made to the case and to the neutral, when applicable.
- When removing transformers, case and neutral grounds must be disconnected last.
- When working on or near an energized three-phase, wye-connected transformer, or transformer bank, verify the transformer neutral is properly grounded.
- Never operate no-load (or manual) tap changers when the transformer is energized. Only load-tap-changing (LTC) type tap changers can be operated when the transformer is energized. When reenergizing a transformer after changing the position of manual tap changers, maintain the minimum approach distances specified in Table 3-1 with all required personal protective equipment until it is determined the internal switching was successful.
- If necessary to relieve pressure on a transformer, the pipe plug, pressure relief device, or inspection cover plate must be loosened slowly so the internal pressure of the transformer can dissipate gradually.
- Pressure relief valves must never be opened when there is precipitation or high humidity, except on failed transformers and when re-fusing.
- Never draw an oil sample, open a pressure relief valve, or otherwise open a transformer when there is an internal vacuum on an energized transformer. Doing so can cause an explosion.
- Transformers or tanks must not be entered unless forced ventilation or an air supply is used to maintain a minimum oxygen level of 19.5 percent by volume in the work area.
- Energized pad-mounted transformers and associated equipment must be locked or otherwise secured when unattended.

9-6.2 Voltage Regulators.

Voltage regulators are normally installed with bypass and disconnect switches. Never open or close a regulator bypass switch, unless the regulator is set on its neutral position and the control switch is open, or the automatic control feature is inactivated in accordance with the manufacturer's recommendations.

When regulators are maintained as spares in substations, their bushings must be short-circuited and grounded.

9-7 METALCLAD SWITCHGEAR.

Operate and maintain metalclad switchgear according to manufacturer's instructions and the guidance provided in this section. Perform the following prior to drawout (rack out) of a circuit breaker operating mechanism. Always rack out the switchgear breaker whenever there is work on the circuit originating from that switchgear breaker.

- In a confined space, such as pier vaults, the switchgear must be deenergized. Ground where possible. In other than confined spaces and vaults, consider deenergizing the switchgear from an upstream location. Utilize remote racking mechanisms when available, to rack breakers in and out. Wear appropriate PPE in accordance with Chapter 4.

- Open the circuit breaker.

- Discharge the stored-energy mechanism, if provided.

- Check that protective interlocks are functioning to protect against closed-position circuit breaker rack out.

- Ensure that all workers in the vicinity know the circuit breaker is being racked out.

- Access to switchgear terminals through portholes for maintenance in circuit breaker cells is limited to the following.

    - When both sets of terminals in a cell are deenergized (i.e., line and load, or bus to bus).

    - After both sets of terminals are deenergized, access to switchgear terminals through the portholes is permitted for cleaning, inspecting, and routine maintenance of terminals and bushings.

- A manufacturer-approved ground and test device can be used for access to terminals for procedures such as the application of protective grounds, phase identification on deenergized circuits, or phasing tests on live circuits. Use of this device avoids the hazardous operation of opening and shutting the shutters of a high-voltage switchgear cell. It can be an extremely hazardous device if not used according to manufacturer's instructions. Such devices are not permitted for Navy installations.

- o Do not install the device with ground cables already connected. Connect ground cables after installing the device.
- o Shut all access doors on the device while installing and removing the device. Use padlocks on any door where studs are intended to remain energized, and access is not needed for testing.
- o After installing the device, verify by using a voltage detector that exposed studs are deenergized.

- For the Navy, a manufacturer-approved grounding breaker can be used for access to the terminals for procedures of connecting temporary protective grounds to ground the main bus, ground the incoming lines or ground both the main bus and the incoming lines.
- For the Navy, phasing tests on circuits must be accomplished by using ground ball studs on outgoing cable termination pads or synchronizing check controls in conjunction with ground ball studs on outgoing cable termination pads. It is no longer permissible to conduct phasing tests using the shutters of a high-voltage switchgear cell. Retrofit existing equipment during preventive maintenance cycles.

9-8 STATIONARY BATTERIES.

9-8.1 Basis for Safety Requirements.

Batteries and DC system components are different from AC electrical system equipment. Batteries contain acid, which is harmful to skin and eyes, and the electrical shock hazards associated with DC power can be more severe than those associated with AC power for equivalent voltages and currents. Only authorized personnel who have been familiarized, trained, and qualified on battery fundamentals and maintenance procedures are allowed to perform maintenance-related activities on a battery.

In addition to substation applications, the requirements of this section apply to all stationary battery applications, including engine starting, UPS, and other backup power applications.

9-8.2 Applicable Industry Standards.

The following industry standards provide the most complete safety standards for stationary batteries and DC systems. Refer to the appropriate document for the type of battery used in a particular application.

- IEEE 450, *Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications*.

- IEEE 484, *Installation Design, and Installation of Vented Lead-Acid Batteries for Stationary Applications*.

- IEEE 1106, *Installation Maintenance, Testing, and Replacement of Vented Nickel-Cadmium Batteries for Stationary Applications*.

- IEEE 1187, *Installation Design, and Installation of Valve Regulated Lead-Acid Batteries for Stationary Applications*.

- IEEE 1188, *Maintenance, Testing and Replacement of Valve Regulated Lead-Acid Batteries for Stationary Applications*.

- IEEE 1578, *Stationary Battery Spill Containment and Management*.

- **\3** NFPA 2021 70E, *Electrical Safety in the Workplace,* Chapter 2, Article 240*, Batteries and Battery Rooms*. ***/3/***

9-8.3 Protective Equipment.

The following equipment must be available for the safe handling of the battery and protection of personnel:

- Safety glasses with side shields, goggles, and/or face shields.

- Acid-resistant gloves.

- Protective aprons and safety footwear.

- Portable or stationary water facilities for rinsing eyes and skin in case of contact with acid electrolyte.

- Class C fire extinguisher.

- For lead acid batteries, bicarbonate of soda to neutralize any acid spillage (1 lb/gal or 0.1 kg/L of water).

- Adequately insulated tools.

- Lifting devices of adequate capacity, when required.

9-8.4 Safety Precautions.

> **WARNING**
>
> Stationary batteries generate a direct current (DC) voltage, which is particularly dangerous with respect to electrical safety. Exercise extreme caution whenever working on battery systems.

Observe the following safety precautions:

- Wear proper safety clothing to prevent contact with acid or live electrical connections. Whenever working on or near batteries, wear a rubber apron and rubber gloves. Ensure goggles and face shields are available for personnel.
- Use only insulated tools in the battery area to prevent accidental shorting across battery connections. Never lay tools or other metal objects on cells; shorting, explosion, or personal injury could result. As a general rule, ensure the length of the exposed metal for any tool is less than the distance between the positive and negative posts of each cell.
- Wear only nonconductive hard hats near batteries. Metal hard hats can fall across the battery terminals or connections and create short circuits.
- Remove all jewelry, wristwatches, or clothing with metal parts that could come into contact with the battery terminals.
- Do not make or break series connections within an operating group of cells. Before proceeding, open the battery system circuit breaker to minimize the possibility of arcing.
- Vented lead acid, vented nickel cadmium batteries and valve-regulated lead acid (VRLA) batteries can generate hydrogen gas that, in sufficient concentrations, can be explosive if ignited. Never bring burning materials such as lighted matches, cigarettes, or sparks of any kind near the battery. Avoid the use of spark-producing equipment near batteries. Residual gases can remain within cells during storage and shipment. Smoking is not permitted in battery rooms or near stationary batteries. Always take these precautions while handling batteries.
- Ensure that the exit from the battery area is unobstructed.
- Minimize access to the battery by personnel unaware of battery safety precautions.
- Ensure that the battery area is suitably illuminated.

- Keep the battery and adjacent area clear of all tools and other foreign objects.

- Avoid static buildup by having personnel contact ground periodically while working on batteries.

9-9 INSULATING OIL HANDLING OPERATIONS.

Place oil insulated equipment in an electrically safe work condition before starting any oil handling procedure. Observe the following additional precautions during oil filtering, oil reclaiming, and other oil-handling operations:

- Always place potential and current transformers in an electrically safe work condition before taking oil samples.

- Have appropriate types and sizes of fire extinguishers readily available.

- Once all equipment has been placed in an electrically safe work condition and insulating oil handling operations is to begin, don an approved disposable coverall. Use extreme caution to ensure that oil does not contaminate arc-rated PPE. Immediately remove from service arc-rated PPE that has become contaminated.

CHAPTER 10 UNDERGROUND LINES

This chapter applies to work in manholes, vaults, and handholes; work on duct lines, trenches, and underground cables; and work on ground-mounted and underground equipment associated with underground electrical lines.

Note: An IEEE interpretation, dated 14 January 2009, regarding IEEE C2 (National Electrical Safety Code) Rule 410A3, confirms that the phrase "on or near energized parts or equipment" applies to energized insulated conductors inside manholes. IEEE C2 Rule 443 does allow a qualified employee, working alone, to enter a manhole where energized cables or equipment are in service for the purpose of inspection, housekeeping, taking readings, or similar work if such work can be performed safely.

10-1 AUTHORIZED WORK ACTIVITIES INSIDE CONFINED SPACES CONTAINING ENERGIZED ELECTRICAL CIRCUITS.

Deenergize all equipment inside an underground structure (including manholes and vaults) operating at high voltage levels before allowing entry into the underground structure. This includes insulated conductors. If the equipment inside the manhole cannot be deenergized, apply the guidance provided in the following sections. If a cable in an underground structure has one or more abnormalities that could lead to or be an indication of an impending fault, the defective cable must be deenergized before any employee can enter the manhole.

Note: Abnormalities such as oil or compound leaking from cable or joints, broken cable sheaths or joint sleeves, hot localized surface temperatures of cables or joints, or joints that are swollen beyond normal tolerance are presumed to lead to or be an indication of an impending fault.

An arc flash event inside an electrical manhole or vault is considered potentially more severe than arcing faults in equipment above grade. IEEE 1584 provides arc flash analysis methods for two configurations: a three-phase arc in open air and a three-phase arc in a box in which the worker is located just outside the box. For work inside an electrical manhole, the IEEE 1584 methodology, as well as an NFPA 70E alternate method, does not apply, in that the worker is located within the box, which is not a configuration covered by IEEE 1584. An arc flash risk assessment must consider that, if an arcing fault occurs, the electrical worker will be located within the plasma cloud inside a constrained environment.

10-1.1 Inspection-Only Access in Manholes Containing Energized Circuits.

Note: Entry into a manhole or vault containing energized circuits is not permitted for inspection activities if problems are suspected inside the manhole, such as conductor damage associated with a short circuit.

Note: Standing water is permitted for inspection activities provided that the standing water level is below energized and installed conductors and associated cable rack arm.

Inspection-only access to a manhole or vault containing energized circuits can be authorized by an energized electrical work permit or a standard operating procedure (SOP) for the purpose of examining insulated cable, equipment, or accomplishing other inspections not requiring touching or disturbing the energized conductors or equipment. The following are examples of the types of activities that are considered inspection-only access:

- Manhole and sump inspection.
- Sump cleaning.
- Inspection of conductors and splices, without touching or disturbing the conductors.
- Inspection of any equipment installed in the manhole.
- Installation of conduit plugs on spare conduits, provided that conductors inside the manhole will not be touched or disturbed.

Comply with Table 4-6 Additional Work Tasks and Associated PPE Requirements for the minimum PPE for this activity. Before entering, visually confirm that the manhole can be entered, and the intended activity can be accomplished without disturbing energized conductors.

10-1.2 Work Inside Manholes Containing Energized Circuits.

Note: Entry into a manhole or vault containing energized circuits is not permitted for work activities if problems are suspected inside the manhole, such as conductor damage associated with a short circuit.

Note: Standing water is permitted for the specified work activities provided that the standing water level is below energized and installed conductors and associated cable rack arm.

Note: Reracking energized conductors is not permitted. The circuits must be deenergized before the conductors can be disturbed.

Access to a manhole or vault containing energized circuits to perform specific work activities can be authorized by an energized electrical work permit or a standard operating procedure (SOP). The following are examples of the types of work that can be performed:

- Removing conduit plugs.
- Spare conduit inspection using fish tape, boroscope, or other devices.

- Splicing deenergized conductors. When splicing deenergized conductors, confirm that an 18-inch (0.5-meter) safe working distance from other energized conductors or equipment can be maintained during the work.

- Pulling new conductors in spare conduits.

- Removing abandoned (deenergized) circuits, including associated equipment, if nearby energized circuits are not disturbed.

Comply with Table 4-6 Additional Work Tasks and Associated PPE Requirements for the minimum PPE for this activity. Before entering, visually confirm that the manhole can be entered, and the intended activity can be accomplished without disturbing energized conductors.

10-1.3 All Other Work Inside Manholes Containing Energized Circuits.

Note: Standing water is permitted for the specified work activities provided that the standing water level is below energized and installed conductors and associated cable rack arm.

All other work not covered by Section 10-1.1 or 10-1.2 require a job-specific energized electrical work permit in accordance with Chapter 8. In addition to the requirements provided in Chapter 8, include the following in the energized electrical work permit:

- Description of manhole and its configuration.

- Description of planned work activities.

- Electrical shock and arc flash risk assessment.

  Note: Electrical analysis software packages that perform arc flash calculations do not account for an electrical manhole configuration in which the electrical worker is inside an enclosed area rather than standing adjacent to an enclosure. Increase the arc flash PPE requirements by a minimum of one (1) arc flash hazard category above the arc flash calculation result.

- Required PPE.

- Minimum number of qualified electrical workers.

- Means to restrict unqualified persons from the work area.

- Rescue plan.

10-1.4 Switching Activities Inside Manholes Containing Energized Circuits.

Do not switch or rack energized equipment in or out of switchgear in an underground structure. Observe the following:

- Secure, whenever feasible, all electrical power prior to start of work in electrical vaults, manholes and other confined or enclosed spaces.
- When absolutely not feasible to secure the power in these locations, refer to Chapter 8 for requirements.

10-2 CABLE PULLING.

Observe the following:

- Do not handle pull-wires or pulling-lines within reaching distance of blocks, sheaves, winch drums, and take-up reels.
- Do not remain in a manhole during pulling operations.
- Do not use wire rope to pull cable in a duct already occupied by conductors.
- Use a nonmetallic duct fishing wire or device when fishing ducts containing energized conductors.
- Always fish ducts in the direction that presents the least hazard. Consider stationing a worker at each end when fishing ducts.

10-3 BURIED ELECTRICAL CABLES.

Observe the following:

- Use area utility maps to locate existing buried cables and nearby utilities as accurately as possible. Locate/scope for buried cables along any intended digging areas. Obtain digging permits, as required.
- Use extreme care when excavating near or exposing direct-burial electric underground cables. If the depth of all direct-burial cables is definitely known, power digging equipment can be used for excavating all but the last 12 in (305 mm) of cover over the cables. The remaining cover must be removed by use of hand-digging tools with FRP handles. Where the depth of direct-burial cables is not established, power-digging equipment must not be used, except to break and remove the surface pavement.
- Do not use probe rods or bars to locate any underground direct-burial cables.

- Take extreme care to avoid damaging the cable insulation when uncovering direct-burial cables.

- Protect all exposed cables against damage in a work area with boards or other nonconductive materials. Utilize suitable nonflammable protective material when it is necessary to weld adjacent to cables.

- Do not stand, sit, kneel, or lean on unprotected direct-burial cables.

CHAPTER 11 LOW-VOLTAGE INTERIOR SYSTEMS

11-1 WORKING ON INDOOR EQUIPMENT.

11-1.1 Restricted Space.

Be alert that older installations might not meet current NEC clearance and entrance requirements for electrical rooms. Where installations do not conform to current NEC/OSHA requirements, additional safety precautions and instruction must be provided to maintenance workers. Give special attention to the guarding of live parts where current NEC clearances are not met. Ensure that unobstructed emergency exit routes are provided.

11-1.2 Grounding Systems.

Verify that existing permanent electrical system grounds are adequate for personnel protective grounding and provide additional temporary grounding as necessary.

11-1.3 Disconnection of Power Sources.

Be sure to check single line diagrams and verify that all inputs and interconnections to any electric power source are locked and tagged open. Verify single line diagram connections with the actual line connections of the applicable equipment.

11-1.4 Related Building Systems.

Do not disable or work on any fire protection and fire alarm systems without prior notification and approval of the local fire department. If the room’s ventilation system is affected by the work, ensure that adequate temporary ventilation is provided.

11-2 LOW-VOLTAGE SYSTEMS.

Complete any work with only qualified electrical workers with training and experience on low-voltage circuits. Electrical workers must be familiar with NFPA 70 requirements and must have work experience with low-voltage systems. Inform the foreman when installations do not meet the requirements of applicable codes and standards. Electrical workers must understand electrical safety requirements for low-voltage systems. In many cases, contract personnel or specially trained workers will repair complex controls and special equipment.

11-2.1 Overview.

Consult the manufacturer's instruction manual if available for the apparatus before starting work.

Unless specifically approved in accordance with Chapter 8, work is not permitted on energized circuits. Use temporary ground wires to drain off induced voltages and currents from live circuits, stored energy devices, and equipment metal guards before starting work.

11-2.2 Battery Room Hazards.

The battery safety rules provided in Section 9-8 apply to low-voltage systems.

11-2.3 Fire Alarm Systems.

Maintaining fire alarm systems with their appropriate safety requirements requires special training and must be in accordance with UFC 3-601-02, *Operations and Maintenance: Inspection, Testing and Maintenance of Fire Protection Systems*. Workers must have completed one or more of the following certifications or specialized training.

- Factory trained and certified, or
- Certified by the National Institute for Certification in Engineering Technologies (Fire Alarm Systems), or
- Certified by the International Municipal Signaling Association (Fire Alarm Systems), or
- Certified by state or local authority, or
- Trained and qualified by an organization listed by a nationally recognized testing laboratory for the servicing of fire alarm systems.

11-2.4 Solid-State Equipment.

Adjustable-speed motor controllers, frequency converters, and uninterruptible power supply (UPS) equipment are complex solid-state devices that must generally be maintained by manufacturers or specially trained contract personnel. Facility personnel are not normally trained for such work. Even after initial training, maintenance work is usually done on such an infrequent basis that workers must not be considered qualified. Facilities with these installations must contain cautionary labeling to warn workers of the electric shock dangers involved in operating and maintaining these types of equipment.

11-2.5 Low-Voltage Work Precautions.

Observe the following:

- Assume all parts of an electric circuit are energized until an electrically safe working condition has been established.

- Use only insulated hand tools when working on equipment where the tool could contact an energized source of 50 V or higher.

CAUTION

Older plastic or rubber coated tools are often not certified by the manufacturer for insulating ability, and the coating is only provided as a comfort feature for the user. If the tool has not been tested, it must be assumed to not meet OSHA requirements for use of insulated hand tools.

- Unless specific permission is provided, no work will be performed on energized electrical circuits or equipment operating at more than 50 V phase-to-phase. Follow the safe clearance requirements of Chapter 6. If work is performed on live energized circuits, select the appropriate personal protective equipment in accordance with the criteria provided in Chapter 4.

- When working on or near energized circuits, workers must stand on a dry surface.

- If using fish tape near energized parts, cover live parts with rubber equipment.

- If working near running machinery, use extreme care and provide barricades, if necessary.

- Place all tools clear of machinery before starting machinery. Never use a wrench on running machinery.

- Provide adequate illumination.

- Wear safety goggles when soldering joints or tinning lugs on connectors.

- Remove tripping hazards before starting work and do not work on slippery surfaces.

- Tape or cover bare or exposed places on one energized conductor before exposing another energized conductor. Never leave joints or loose ends of wire untapped or otherwise unprotected.

- An open knife switch can be hazardous because of the exposure to live parts and because of the arc formed when the switch is opened. Only use knife switches that are enclosed in grounded metal cabinets having the control lever operable from outside the cabinet. Install a knife switch so that the blades are deenergized when the switch is open and oriented so that gravity will not tend to close the switch.

- Provide fuses and circuit breakers in accordance with NFPA 70, properly sized to protect the downstream conductors and equipment. Substitution of conductors for fuses is not permitted. Remove fuses only after opening the upstream disconnect device. Use an insulated fuse puller. Use an insulated fuse puller and PPE in accordance with Chapter 4.

- Use properly grounded portable electric tools, particularly in damp locations or near grounded equipment or piping. Do not open a ground connection to a water pipe or ground rod until the ground wire has been disconnected at the equipment.

11-3 ROTATING MACHINERY.

11-3.1 Hazards of Rotating Machinery.

Ensure guards are provided to protect workers from accidental contact with live electrical parts, rotating parts, and hot machine surfaces. Be aware that rotation can loosen grounding connections, hold-down bolts, and fray flexible or cord connections. Be alert to sparking of brushes and insulation failures that may cause flame or molten metal to be ejected from open type motors or generators. Interior electrical work often must be done in close proximity of rotating electrical equipment such as motors and generators. Do not operate rotating machinery without protective guards.

11-3.2 Motors and Generators.

After work has been performed on circuits to rotating machines, check direction of rotation. Always take positive steps to ensure that rotating equipment under repair cannot be set into motion.

Follow appropriate mechanical safety precautions if operating a generator, including:

- Ensure engine coolant is at the proper level and has the proper amount of antifreeze. Make sure engine lubricant and fuel are at the proper levels. Check hoses for good condition.

- Ensure engine air requirements for combustion are met. Check air filters and cleaners for cleanliness and good condition.

- Verify the engine, generator, and related equipment are clean. Keep oil-soaked rags out of the generating facility to avoid a fire hazard.

CHAPTER 12 SHORE-TO-SHIP ELECTRICAL POWER CONNECTIONS

12-1 CONNECT/DISCONNECT SERVICES.

Shore Electric Utility Systems are utilized to provide dockside electrical service (Shore Power) to Ships operating in a cold iron mode. Shore Power Electric Utilities which connect and disconnect services, with the associated cable assemblies and cable maintenance, are provided as a reimbursable activity. Cable assemblies include all necessary components to allow connection from Facility Shore Power receptacles to Ship's or Submarine's Shore Power receptacles but may also require use of ship owned lug and bolt cable adapter assemblies, often called pigtails. The specific requirements and performance responsibilities for shore-to-ship connects are provided in Section 12-2. The step-by-step procedures for ship connects, infra-red testing of connections, and ship disconnects are developed at the local level following this UFC. Refer to Naval Engineering Training and Operating Procedure and Standard (NETOPS) #29, *Shore-to-Ship Power Connect and Disconnect Procedures*, for additional information.

SOPs that have been issued by NAVFAC Activities are available for review at the Enterprise Safety Applications Management System (ESAMS) at the following:

https://esams.cnic.navy.mil/ESAMS_GEN_2/LoginESAMS.aspx

12-2 SPECIFIC SHORE-TO-SHIP ELECTRICAL SYSTEM SAFETY.

This section covers connection of portable power cables to shore electrical outlet assemblies and ship electrical buses. Connection is a divided responsibility between the Shore Electrical Supervisor (ES) and the Ships Electrical Officer (EO)). Follow the Standard Operating Procedure (SOP) established by the Shore ES as identified in Section 12-1.

12-2.1 Unusual Shore-to-Ship System Hazards.

The additional risks posed by shore-to-ship power cable connections include:

- Split personnel shore/ship responsibilities for electrical safety.
- Portable power cable and outlet safety assurance.
- Electrical equipment accessibility and working space.
- An ungrounded, adequate, and correctly phased electrical power input.
- Minimizing any parallel operations.

12-2.2 Split Personnel Responsibilities.

It cannot be overemphasized how important standard operating procedures are in eliminating the hazards of split responsibilities between shore and ship. Training of both shore and ship personnel is necessary to assure safety while connecting and disconnecting cables between a pier and a ship.

12-2.3 Portable Power Cable and Outlet Safety Assurance.

> **WARNING**
> Harsh waterfront environments provide salt spray, high humidity, and cold temperature conditions. All of these result in more rapid deterioration of permanent installations. Portable power cables, if not adequately barricaded are subject to damage from the wheels of vehicles used in industrial operations and improper handling. Families welcoming returning service members, DoD personnel, and contractors working on piers may not understand or recognize the dangers these energized shore power cables installed in accessible positions poses to the public.

12-2.4 Electrical Equipment Accessibility and Working Space.

> **WARNING**
> Electrical equipment in under-pier vaults that is not readily accessible might not meet current NEC working space requirements.

12-2.5 Readily Accessible.

> **WARNING**
> The NEC defines ready accessible as capable of being reached quickly for operation, renewal, or inspections, without requiring those to whom ready access is requisite to climb over or remove obstacles or to resort to portable ladders, chairs, or other such devices. Therefore all workers in vaults must satisfy all confined space requirements.

12-2.6 Working Space.

The NEC defines working space as sufficient access provided and maintained about all electric equipment to permit ready and safe operation and maintenance of such equipment. Working space in vaults has been provided in accordance with the NEC requirements applying at the time the vault was built. As with all safety aspects affecting both the general public and maintenance workers, safety requirements have become more rigorous over the years. Although current NEC requirements do not apply to vaults built to previous NEC editions, compare the NEC current requirements with actual working space provisions.

Each activity must evaluate the comparisons as to their effect on workers safety and provide SOP's as necessary to assure safe working conditions.

12-3 SPECIALIZED SHORE-TO-SHIP SYSTEM TRAINING.

Train all employees whose job requires providing shore power services to understand the purpose and function of the hazardous energy control program, and the hazards they face. Verify that they demonstrate a working level knowledge of all process steps and applicable references, and complete site-specific training as required.

Qualification training for the operation, maintenance, and testing of the shore power systems includes:

- Power cable/connector assemblies and extensions.
- Cable phasing and paralleling methods.
- Lock-out/tag-out procedures.
- Switching operations.
- Maintaining electrical safe working conditions.

12-4 SHIP'S MAIN ELECTRICAL SERVICE COMPONENTS.

The specific safety requirements given apply to the cable assemblies from the pier's electrical outlet assemblies (commonly called "turtlebacks" on Mil-C receptacle systems, and "Connection Stations" on single pole panel mount connector systems) to the ship's electrical bus. There are other components of the shore's high-voltage electrical distribution system used to supply substations that in turn supply the pier electrical outlet assemblies. The safety requirements for the pier electrical outlet assemblies that supply line side components are covered by earlier sections. Because they are provided for ships power in addition to permanent pier electrical loads, these components are also described here to enable a clearer understanding of the dockside electrical distribution system.

12-4.1 Shore High-Voltage Distribution System.

The facility's primary electrical distribution system normally operates in the high-voltage range between 5 kV and 35 kV. For permanent pier service, dual primary feeders from the shore's primary system is preferred. Pier systems can also be furnished with single feeders. These feeders serve substations, which step down the distribution system's primary voltage to the required secondary voltage for ships electrical service of 13.2 kV, 4.16 kV or 480 volts.

12-4.2 Pier Substations.

Substations might consist of above ground installed on the top of a pier or units installed in vaults located under the pier. Vault substations are fed by shielded power cables installed in electrical duct. Above deck substations are skid-mounted and are supplied by either shielded power cables installed in duct or mine power cable installed on the pier connected to the electrical distribution system via cable coupler plugs to coupler receptacles in electrical connection outlet assemblies. Both types of substations may include one or more primary fused switches or be fed from a pad mount switchgear vacuum fault interrupter switch way, the step-down transformer, and secondary circuit breakers supplying the pier electrical outlet assemblies for ship-to-shore power cables. The following figures show these component elements.

Figure 12-1. Electrical Connection Outlet Assembly with a 15 kV Receptacle

Figure 12-2. Close-Up of Electrical Connection Outlet Assembly

Figure 12-3. Inside a Pier Vault Housing a Substation

Figure 12-4. Skid-Mounted Substation

Figure 12-5. Skid-Mounted Substation with Single-Pole Connections

Figure 12-6. Double-Deck Pier Switchgear

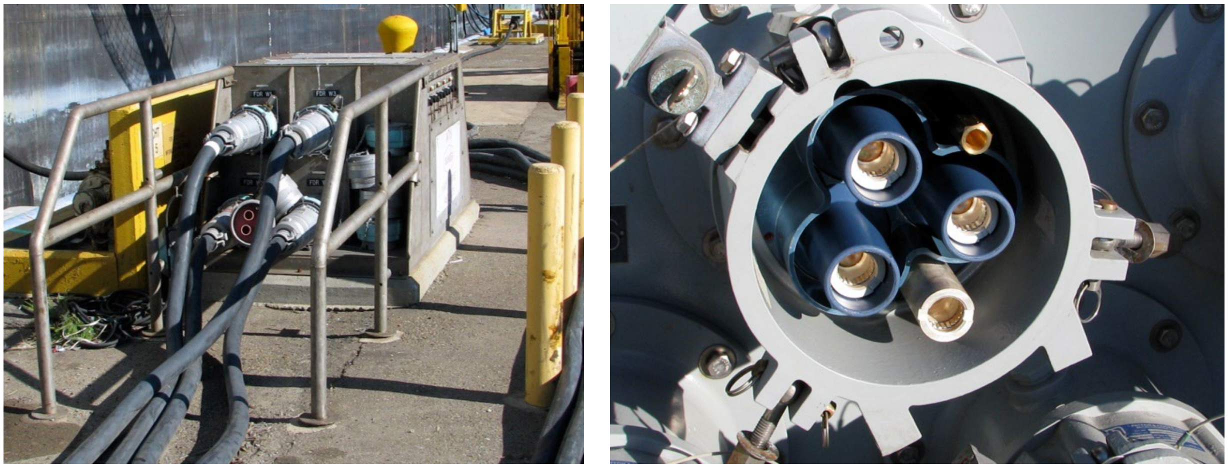
12-4.3 Ship-to-Shore Pier Electrical Outlet Assemblies.

Ships service is from pier electrical outlet assemblies that contain either multiples of single pole or three-pole, 500-ampere receptacles rated either for 450 volts ships service, 4.16 kV ships service, or 15-kV ships service as appropriate to the pier's ship electrical service requirement. Receptacles may be interlocked with their associated substation secondary circuit breaker for safety reasons. Figures 12-7 and 12-8 show three-pole outlet assemblies for 480 volt and 4.16 kV services respectively. Figure 12-9 shows the newer design for medium voltage electrical outlet assemblies.

Figure 12-7. 480 Volt Pier Electrical Outlet Assembly Without Cable Connections

Figure 12-8. 4.16 kV Pier Electrical Outlet Assembly and Outlets – Existing Installations

Figure 12-9. 4.16 kV Pier Electrical Outlet Assembly and Outlets – Newer Designs



12-4.4 Shore-to-Ship Power Cables and Connectors.

Portable shore-to-ship power cables are rated 8000 volts for operating at 4160 volts, three-phase, three-wire, ac or 600 volts for operating at 450 volts, three phase, three-wire ac. Both 4160 V and 480 V shore power systems are ungrounded (the transformer neutrals are isolated from ground).

Note: Splices are not allowed in 4.16 kV power cables. Figures 12-10 through 12-13 show examples of cables in place and various connections.

Figure 12-10. 480 Volt Pier Electrical Outlet Assembly and Cable Connections

Figure 12-11. 480 Volt Shore-Cable to Ship-Cable with Single-Pole Connection

Figure 12-12. 480 Volt Shore-Cable to Ship-Cable Plug and Receptacle Connection In Place

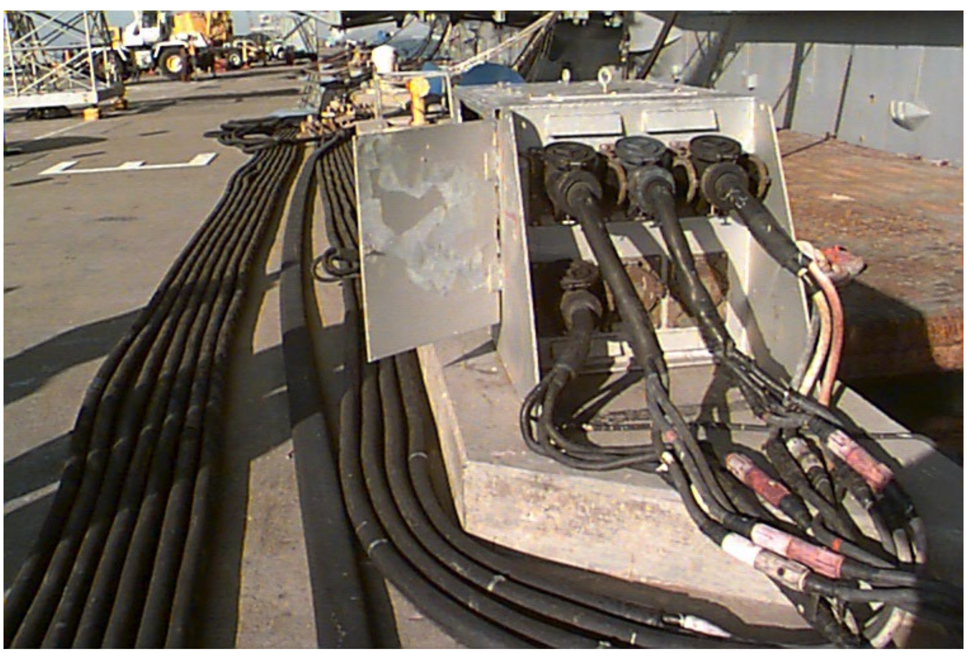


Figure 12-13. 480 Volt Shore-Cable to Ship-Cable Splice Connection in Place

12-4.5 Pier High-Voltage (4,160 Volt) Electrical Outlet Assemblies.

This assembly utilizes a three pole, 500-ampere, 4,160 volt receptacle with a matching plug. Units have the Mine Health Safety Administration approval, are provided with a safety interlock, and have been modified to remove a ground cable connector. Refer to Figure 12-14.

Figure 12-14. High-Voltage Shore Receptacle

12-4.6 Low-Voltage Terminations.

The system provides a 480 volt, three-phase, three-wire, ungrounded 60 hertz source to the ship. Refer to Figure 12-15.

Figure 12-15. Low-Voltage (480 Volt) Shore Receptacle

APPENDIX B ELECTRICAL TASK RISK ASSESSMENT CHECKLIST

Appendix B provides an example checklist in support of the risk assessments specified by NFPA 70E. An energized electrical work permit requires a shock risk assessment and an arc flash risk assessment. Table B-1 provides an example checklist. The format and method of documentation is optional; however, any electrical task risk assessment must address the topics listed in Table B-1. References to numbered sections and tables (such as Section 4-2 or Table 4-7) apply to sections and tables in this UFC. References to lettered sections (such as Section C) apply to sections within the Electrical Task Risk Assessment Checklist.

Table B-1 Electrical Task Risk Assessment Checklist

Section A, Task Identification					
Facility Location:					
Equipment:					
Scope of Work/Task:					
Work Order No.					
Submitter:		**Submitter Signature:**		**Date:**	
Section B, General					
	*Mark **"Y"** or **"N"** as appropriate*				
No.	**Item**	**Yes**	**No**	**Instructions**	
1.	Is the equipment operating at 50 volts or more or is a shock hazard present?			*If **No**, hazard analysis is not required.* *If **Yes,** proceed to Line 2.*	
2.	Is the required working distance available?			*If **Yes**, proceed to Line 3.* *If **No**, do not proceed. Additional risk assessment is required before any work is performed.*	
3.	Is the working space clear?			*If **Yes**, proceed to Line 4.* *If **No**, do not proceed. Additional risk assessment is required before any work is performed.*	
4.	Was an incident energy analysis performed?			*If **Yes**, proceed to Section C* *If **No**, proceed to Line 5*	
5.	Is the equipment properly installed and maintained and there is no evidence of impending failure?			If ***Yes***, arc flash PPE may not be required if doors are, and will remain, closed and secured and if covers are, and will remain, secured in place. If work will be performed on exposed energized electrical equipment as stated in Section 8-3.3, proceed to Section C. If ***No***, arc flash PPE is required, proceed to Section C.	
Section C, Shock Information – All Methods *Refer to Table 3-1 or Table 3-2, as applicable, as well as Table 3-3.*					

6.	Phase voltage:		*Establish the shock boundaries*
	Limited Approach Boundary:		*Proceed to Lines 7 and 8.*
	Restricted Approach Boundary:		
7.	Are rubber insulating gloves required for the task?		*Proceed to Section D if an incident energy analysis has been or needs to be performed. Proceed to Section E if using the Arc Flash PPE Category (Table) method.*
8.	Are insulated or insulating hand tools required for the task?		
Completed By:		**Signature:**		**Date:**	

Section D, Arc Flash Information – Incident Energy Analysis Method (Default Method)
(*To Be Completed by Engineering Personnel if Unknown or Not Previously Analyzed)*

9.	Incident energy: ___ Working Distance: ___		*Include at least one and establish the arc flash boundary. Working distance must be provided with incident energy determination. Note method used:* • **\3** *Section 4-2 (Based on NFPA 70E 2021, Article 130.5) for interior electrical equipment or for exterior pad-mounted equipment.* **/3/** • *Section 4-2 and Table 4-7 (Based on the National Electrical Safety Code) for overhead distribution.*

APPENDIX C SAMPLE SOP – VOLTAGE AND CURRENT DIAGNOSTIC MEASUREMENTS

This appendix is optional and provides a typical SOP. Refer to Section 8-4 for requirements associated with SOPs.

1.0 **Purpose.**

This procedure defines the requirements for measuring voltage and current, monitoring the performance of electrical systems with data loggers, and confirming correct phase rotation. Modify this SOP as appropriate for the installation, the allowed work practices, and personnel qualifications.

This procedure can also be used as part of circuit lockout/tagout to confirm that a circuit has been deenergized.

2.0 **Applicability.**

This procedure applies to personnel that are designated as a qualified person with respect to working on or near electrical equipment rated at 50 volts or above.

3.0 **References.**

- 29 CFR 1910, *Occupational Safety and Health, General Industry Standards*
- Unified Facilities Criteria (UFC) 3-560-01, *Operation and Maintenance: Electrical Safety*
- NFPA 70E, *Electrical Safety in the Workplace*

4.0 **Definitions.**

Arc Flash Hazard. A dangerous condition associated with the possible release of energy caused by an electric arc.

Arc Rating. The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm2 and is derived from the determined value of the arc thermal performance value (ATPV) or energy of breakopen threshold (EBT) (should a material system exhibit a breakopen response below the ATPV value). Arc rating is reported as either ATPV or EBT, whichever is the lower value.

\3\ Balaclava (Sock Hood). An arc-rated head-protective fabric that protects the neck and head except for a small portion of the facial area.

Boundary, Arc Flash. The distance from an arc source (energized exposed equipment) at which the potential incident heat energy from an arcing fault on the surface of the skin is 1.2 cal/cm^2 (5 J/cm^2). ***/3/***

Boundary, Limited Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

De-energized. Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Electrical Hazard. A dangerous condition such that contact, or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Electrically Safe Work Condition. A state in which an electrical conductor or circuit part has been disconnected from energized parts, locked/tagged in accordance with established standards, tested to ensure the absence of voltage, and grounded if determined necessary.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Incident Energy. The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Live Line Tool. An insulated tool that electrically insulates the worker from the energized conductor and provides physical separation from the device being operated.

Low-Voltage. Any voltage below 1,000 V.

Medium Voltage. Voltages above 1,000 and ranging to 72,500 V.

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

\3\ Shock Hazard. A source of possible injury or damage to health associated with current through the body caused by contact or approach to exposed energized electrical conductors or circuit parts. **/3/**

Unqualified Person. A person who is not a qualified person.

\3\ Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of "working on":

> **Diagnostic (testing)** is taking readings or measurements of electrical equipment, conductors, or circuit parts with approved test equipment that does not require making any physical change to the electrical equipment, conductors, or circuit parts.
>
> **Repair** is any physical alteration of electrical equipment, conductors, or circuit parts (such as making or tightening connections, removing or replacing components, etc.). **/3/**

5.0 Training and Qualification Requirements.

Personnel using this procedure must be trained and qualified in the following:

Emergency response training. Contact release. First aid, emergency response, and resuscitation.

Qualified Person Employee training. A qualified person must be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method.

Document all training.

6.0 Required Approach Distances.

Table 1 lists the minimum approach distances from exposed alternating current energized parts within which a qualified worker may not approach without the use of personal protective equipment appropriate for the potential electrical hazards or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding). Table 2 provides similar information for direct current systems.

Table 1 Qualified Worker Minimum Approach Distances – AC Systems

Nominal System Voltage Range Phase to Phase (1)	**Arc Flash Boundary**	**Limited Approach Boundary**		**Restricted Approach Boundary (3) (4)**
	From Phase to Phase Voltage (5), (6)	**Exposed Movable Conductor**	**Exposed Fixed Circuit Part**	**Includes Standard Inadvertent Movement Adder**
50 V to 150 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>151 V to 750 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)
>750 V to 15 kV	(2)	10 ft 0 in (3.0 m)	5 ft 0 in (1.5 m)	2 ft 2 in (0.7 m)
>15 kV to 36 kV	(2)	10 ft 0 in (3.0 m)	6 ft 0 in (1.8 m)	2 ft 9 in (0.8 m)
>36 kV to 46 kV	(2	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	2 ft 9 in (0.8 m)
>46 kV to 72.5 kV	(2)	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>72.5 kV to 121 kV	(2)	10 ft 8 in (3.3 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>121 kV to 145 kV	(2)	11 ft 0 in (3.4 m)	10 ft 0 in (3.0 m)	3 ft 10 in (1.2 m)

Notes for Table 1:

1. *For single phase systems* **\2** *above 250 volts,* **/2/** *select the range that is equal to the system's maximum phase to ground voltage times 1.732.*
2. *The arc flash boundary is determined by an arc flash analysis.*
3. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
4. *The restricted approach distance applied to hot sticks is the distance between a worker's hand and the working end of the stick.*
5. *Only qualified workers wearing appropriate PPE are permitted to be within the arc flash boundary.*
6. **\2** *Refer to NFPA 70E for AC voltages above 145 kV.* **/2/**

Table 2. Qualified Worker Minimum Approach Distances – DC Systems

Nominal System Voltage Range	Limited Approach Boundary	Restricted Approach Boundary
	Exposed Fixed Circuit Part	**Includes Reduced Inadvertent Movement Adder**
<50 V	Not specified	Not specified
50 V to 300 V	3 ft 6 in (1.0 m)	Avoid contact
>300 V to 1 kV	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)

Notes for Table 2:

1. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
2. *Only qualified workers wearing appropriate PPE are permitted to be within the limited approach boundary and the arc flash boundary. The arc flash boundary is determined by calculation.*
3. ***\2** Refer to NFPA 70E for DC voltages above 1 kV. **/2/***

7.0 **Personal Protective Equipment.**

Comply with UFC 3-560-01 for PPE requirements. Perform the following:

1. Review electrical task risk assessment for this SOP for the potential incident energy level.
2. Select PPE equipment to exceed calculated potential incident energy level.

Voltage-rated gloves with leather protectors (Table 3) are required for work inside the restricted approach boundary or when handling live-line tools. Select as follows:

Table 3 Rubber Insulating Equipment Voltage Requirements

Class of Equipment	Color Label	Maximum Use (AC Volts)	Minimum Distance[1] in Inches (Millimeters)
00	Beige	500	1 (25)
0	Red	1,000	1 (25)
1	White	7,500	1 (25)
2	Yellow	17,000	2 (50)
3	Green	26,500	3 (75)
4	Orange	36,000	4 (100)

Notes for Table 3: Wear leather protectors over rubber gloves. Minimum distance is the minimum length that the exposed rubber glove must extend beyond the leather protector.

8.0 **Low-Voltage Electrical Measurements – Voltage and Current.**

Take electrical measurements in accordance with the following procedure:

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members, if applicable.

2. Select voltage-rated gloves with leather protectors using Table 3. Inspect voltage-rated gloves and leather protectors before use.

3. Select and inspect the tools and devices to be used for the electrical measurements. Ensure that all are rated for the voltage to be tested.

4. Check the arc flash label installed at the location where electrical measurements will be taken. **\2** Before starting work, obtain and wear the correct arc-rated PPE rated at or above the incident energy or arc flash hazard category listed on the arc flash label, with a minimum rating of 8 cal/cm^2 or Category 2 respectively. ***/2/***

5. Open the cabinet or enclosure where electrical measurements will be taken. Ensure PPE is worn properly before exposing energized electrical circuits. Wear voltage-rated gloves with leather protectors before entering the restricted approach distance. Only voltage-rated gloves with leather protectors are allowed inside the restricted approach distance.

6. Test the meter with a known energized source. Confirm the meter is operational and displaying correctly.

7. Apply the voltage leads of the meter to the test point on the system or device being tested to check for voltage. Check voltage on all phases.

8. If testing for current, position the meter's ammeter sensor so that the wire(s) or conductor(s) to be tested pass through the sensor. Document the current reading and repeat for all phases.

9. If voltage testing was performed to verify a deenergized circuit as part of a lockout/tagout procedure, test the meter again with a known energized source.

10. When testing is complete, restore the equipment to normal and return all devices (test equipment, PPE, and voltage-rated gloves) to their protective containers. Confirm that all tools and test equipment that were used are accounted for. If covers were removed as part of gaining access to the equipment, confirm that the covers are fully secured with no missing screws.

9.0 **Medium-Voltage Electrical Measurements – Voltage and Current.**

This procedure applies to all systems with a voltage above 600 volts. Take electrical measurements in accordance with the following procedure:

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members, if applicable.

2. Select voltage-rated gloves with leather protectors using Table 3. Inspect voltage-rated gloves and leather protectors before use.

3. Select and inspect the tools and devices to be used for the electrical measurements. Ensure that all are rated for the voltage to be tested. Confirm that live-line tools (hot sticks) have been wet tested within the last 2 years. Inspect tools before use.

4. Check the arc flash label installed at the location where electrical measurements will be taken. **\2** Before starting work, obtain and wear the correct arc-rated PPE rated at or above the incident energy or arc flash hazard category listed on the arc flash label, with a minimum rating of 8 cal/cm^2 or Category 2 respectively. ***/2/***

5. Open the cabinet or enclosure where electrical measurements will be taken. Ensure PPE is worn properly before exposing energized electrical circuits. Wear voltage-rated gloves with leather protectors before entering the restricted approach distance. Only the voltage-rated gloves with leather protectors are allowed inside the restricted approach distance.

6. Test the meter with a known energized source or test medium. Confirm the meter is operational and displaying correctly.

7. Apply the tip of the touch meter to the test point on the system or device being tested to check for voltage. Check voltage on all phases.

8. If testing for current, attach the clamp-on/inductive type ammeter to the insulated hot stick. Position or move the meter's ammeter sensor so that the wire(s) or conductor(s) to be tested pass through the sensor. Document the current reading and repeat for all phases.

9. If voltage testing was performed to verify a deenergized circuit as part of a lockout/tagout procedure, test the meter again with a known energized source.

10. When testing is complete, restore the equipment to normal and return all devices (test equipment, PPE, and voltage-rated gloves) to their protective containers. Confirm that all tools and test equipment that were used are accounted for. If covers were removed as part of gaining access to the equipment, confirm that the covers are fully secured with no missing screws.

10.0 **Low-Voltage Data Logging Electrical Measurements.**

Take electrical measurements using a data logger in accordance with the following procedure:

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members, if applicable.

2. Select voltage-rated gloves with leather protectors using Table 3. Inspect voltage-rated gloves and leather protectors before use.

3. Select and inspect the tools and devices to be used for the electrical measurements. Ensure that all are rated for the voltage to be tested. Inspect the current transformers (CTs)/clamp-on leads that will be used for testing; confirm the leads are in good condition and are fully insulated.

4. Check the arc flash label installed at the location where electrical measurements will be taken. **\2** Before starting work, obtain and wear the correct arc-rated PPE rated at or above the incident energy or arc flash hazard category listed on the arc flash label, with a minimum rating of 8 cal/cm^2 or Category 2 respectively. ***/2/***

5. Open the cabinet or enclosure where electrical measurements will be taken. Ensure PPE is worn properly before exposing energized electrical circuits. Wear voltage-rated gloves with leather protectors before entering the restricted approach distance. Only the voltage-rated gloves with leather protectors are allowed inside the restricted approach distance.

6. Determine where all leads will be attached.

7. Apply the voltage leads to the selected exposed energized phases.

8. Attach the CT clamp-on leads around the selected conductors.

9. After all leads are connected and confirmed to be in place, start the data logger to start monitoring.

10. While data logging is in progress, close and secure the cabinet or enclosure where the data logger leads are connected. If the cabinet or enclosure cannot be sealed because of its configuration, place warning signs around the equipment and secure the area to prevent unauthorized access.

11. When testing is complete, perform Steps 1 through 5 and reopen the cabinet or enclosure to allow access to the data logger and its leads. Stop the data logger and remove the voltage and CT clamp-on leads.

12. Close the cabinet or enclosure where measurements were taken.

13. When testing is complete, restore the equipment to normal and return all devices (test equipment, PPE, and voltage-rated gloves) to their protective containers. Confirm that all tools and test equipment that were used are accounted for. If covers were removed as part of gaining access to the equipment, confirm that the covers are fully secured with no missing screws.

11.0 **Low-Voltage Phase Rotation Checks.**

Take phase rotation measurements in accordance with the following procedure:

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members, if applicable.

2. Select voltage-rated gloves with leather protectors using Table 3. Inspect voltage-rated gloves and leather protectors before use.

3. Select and inspect the tools and devices to be used for the electrical measurements. Ensure that all are rated for the voltage to be tested.

4. Check the arc flash label installed at the location where electrical measurements will be taken. **\2** Before starting work, obtain and wear the correct arc-rated PPE rated at or above the incident energy or arc flash hazard category listed on the arc flash label, with a minimum rating of 8 cal/cm^2 or Category 2 respectively. ***/2/***

5. Open the cabinet or enclosure where electrical measurements will be taken. Ensure PPE is worn properly before exposing energized electrical circuits. Wear voltage-rated gloves with leather protectors before entering the restricted approach distance. Only the voltage-rated gloves with leather protectors are allowed inside the restricted approach distance.

6. Confirm presence of voltage in accordance with Paragraph 8 above.

7. If possible, deenergize the circuit or equipment before connecting the phase rotation meter leads. Attach the leads of the phase rotation meter to the exposed energized conductors.

8. Press the meter's actuating button, check for proper phase rotation, and release.

9. If possible, deenergize the circuit or equipment before disconnecting the phase rotation meter leads. Remove the leads.

10. When testing is complete, restore the equipment to normal and return all devices (test equipment, PPE, and voltage-rated gloves) to their protective containers. Confirm that all tools and test equipment that were used are accounted for. If covers were removed as part of gaining access to the equipment, confirm that the covers are fully secured with no missing screws.

12.0 **Medium-Voltage Phase Rotation Checks.**

This procedure applies to all systems with a voltage above 600 volts. Take phase rotation measurements in accordance with the following procedure:

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members, if applicable.

2. Select voltage-rated gloves with leather protectors using Table 3. Inspect voltage-rated gloves and leather protectors before use.

3. Select and inspect the tools and devices to be used for the electrical measurements. Ensure that all are rated for the voltage to be tested. Confirm that live-line tools (hot sticks) have been tested within the last 6 months. Inspect tools before use.

4. Check the arc flash label installed at the location where electrical measurements will be taken. **\2** Before starting work, obtain and wear the correct arc-rated PPE rated at or above the incident energy or arc flash hazard category listed on the arc flash label, with a minimum rating of 8 cal/cm^2 or Category 2 respectively. ***/2/***

5. Open the cabinet or enclosure where electrical measurements will be taken. Ensure PPE is worn properly before exposing energized electrical circuits. Wear voltage-rated gloves with leather protectors before entering the restricted approach distance. Only the voltage-rated gloves with leather protectors are allowed inside the restricted approach distance.

6. Confirm presence of voltage in accordance with Paragraph 9 above.

7. Use two personnel to hold the hot sticks for phase rotation checks. Perform dry run, with PPE, without touching the energized source. This step is performed to confirm that there is sufficient access for the task and that the two crewmembers can coordinate their movements.

8. Apply the touchmeters to the test points on the system being tested to check for proper phasing. Check all phases.

9. When testing is complete, restore the equipment to normal and return all devices (test equipment, PPE, and voltage-rated gloves) to their protective containers. Confirm that all tools and test equipment that were used are accounted for. If covers were removed as part of gaining access to the equipment, confirm that the covers are fully secured with no missing screws.

This Page Intentionally Left Blank

APPENDIX D SAMPLE SOP – WORKING ON STATIONARY BATTERY SYSTEMS

This appendix is optional and provides a typical SOP. Refer to Section 8-4 for requirements associated with SOPs.

1.0 **Purpose.**

This procedure defines the requirements for working on or near stationary battery systems and applies to the following activities:

- Battery or cell inspections.
- Battery or cell maintenance or testing.
- Battery or cell replacement.

Modify this SOP as appropriate for the installation, the allowed work practices, and personnel qualifications.

This procedure applies to stationary battery systems consisting of either nickel cadmium batteries, vented lead acid batteries, or valve-regulated lead acid (VRLA) batteries. It applies to batteries installed on battery racks or installed inside cabinets, including UPS systems.

Batteries and dc system components are different from ac electrical system equipment. Lead acid batteries contain a sulfuric acid electrolyte, which is harmful to skin and eyes, and the electrical shock hazards associated with dc power can be more severe than those associated with ac power for equivalent voltages and currents.

Batteries and cells are always energized and a fully charged stationary battery contains a tremendous amount of energy. A short circuit between the battery or cell terminals can produce explosive fault currents.

Only authorized personnel who have been familiarized and trained on battery fundamentals and maintenance procedures should be allowed to perform maintenance activities on a battery.

2.0 **Applicability.**

This procedure applies to personnel that are designated as a qualified person with respect to working on or near electrical equipment rated at 50 volts or above, including working on stationary battery systems.

3.0 **References.**

- 29 CFR 1910, *Occupational Safety and Health, General Industry Standards*

- Unified Facilities Criteria (UFC) 3-560-01, *Operation and Maintenance: Electrical Safety*

- NFPA 70E, *Electrical Safety in the Workplace*

4.0 Definitions.

Arc Flash Hazard. A dangerous condition associated with the possible release of energy caused by an electric arc.

Arc Rating. The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm2 and is derived from the determined value of the arc thermal performance value (ATPV) or energy of breakopen threshold (EBT) (should a material system exhibit a breakopen response below the ATPV value). Arc rating is reported as either ATPV or EBT, whichever is the lower value.

Battery. Two or more cells connected to form one unit for producing electric energy at the required voltage and current levels.

Battery Rack. A structure used to support a group of cells.

Boundary, Arc Flash. The distance from an arc source (energized exposed equipment) at which the potential incident heat energy from an arcing fault on the surface of the skin is 1.2 cal/cm^2 (5 J/cm^2).

Boundary, Limited Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

Cell. An electrochemical device, composed of positive and negative plates, separator, and electrolyte, that is capable of storing electrical energy; when encased in a container and fitted with terminals, it is the basic component of a battery.

Electrical Hazard. A dangerous condition such that contact, or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrolyte. The conducting medium in which the flow of electric current takes place by the migration of ions. For example, the electrolyte for a lead-acid cell is an aqueous solution of sulfuric acid.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Incident Energy. The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Shock Hazard. A dangerous condition associated with the possible release of energy caused by contact or approach to energized electrical conductors or circuit parts.

Unqualified Person. A person who is not a qualified person.

Valve-Regulated Lead-Acid (VRLA) Cell. A lead-acid cell that is sealed with the exception of a valve that opens to the atmosphere when the internal gas pressure in the cell exceeds the atmospheric pressure by a pre-selected amount. VRLA cells provide a means of recombination of internally generated oxygen and the suppression of hydrogen gas evolution to limit water consumption.

Vent. A normally sealed mechanism which allows the controlled escape of gases from within a cell.

Vented Cell. A lead-acid cell in which the gaseous products of electrolysis and evaporation are allowed to escape to the atmosphere as they are generated. A vented cell is also referred to as a flooded cell.

Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of "working on": Diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; repair is any physical alteration of electrical equipment (such as making or tightening connections, removing or replacing components, etc.).

5.0 Training and Qualification Requirements.

Personnel using this procedure must be trained and qualified in the following:

Emergency response training. Contact release. First aid, emergency response, and resuscitation.

Qualified Person Employee training. A qualified person must be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method.

Only authorized personnel who have been familiarized and trained on battery fundamentals and maintenance procedures should be allowed to perform maintenance or work activities on a battery.

Document all training.

6.0 Required Approach Distances.

Table 1 lists the minimum approach distances from exposed direct current energized parts within which a qualified worker may not approach without the use of personal protective equipment appropriate for the potential electrical hazards or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding).

Table 1. Qualified Worker Minimum Approach Distances – DC Systems

Nominal System Voltage Range	Limited Approach Boundary	Restricted Approach Boundary
	Exposed Fixed Circuit Part	Includes Reduced Inadvertent Movement Adder
<50 V	Not specified	Not specified
50 V to 300 V	3 ft 6 in (1.0 m)	Avoid contact
>300 V to 1 kV	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)

Notes for Table 1:

1. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
2. *Only qualified workers wearing appropriate PPE are permitted to be within the limited approach boundary and the arc flash boundary. The arc flash boundary is determined by calculation.*
3. ***\2** Refer to NFPA 70E for DC voltages above 1 kV. **/2/***

7.0 Personal Protective Equipment.

Comply with UFC 3-560-01 for PPE requirements. Wear Class 0 voltage rated gloves with leather protectors for DC voltages 600 volts and below. Select arc-rated PPE in accordance with the PPE category specified in Table 2.

T able 2. Arc Flash PPE Categories for Direct Current Systems

Equipment	PPE Category	Arc Flash Boundary
Storage batteries, dc switchboards, and other dc supply sources Parameters: 100 V ≤ Voltage < 250 V Maximum arc duration and working distance: 2 sec @ 18 in.		
Short-circuit current < 4 kA	2	3 ft
4 kA ≤ short-circuit current < 7 kA	2	4 ft
7 kA ≤ short-circuit current < 15 kA	3	6 ft
Storage batteries, dc switchboards, and other dc supply sources Parameters: 250 V < Voltage ≤ 600 V Maximum arc duration and working distance: 2 sec @ 18 in.		
Short-circuit current < 1.5 kA	2	3 ft
1.5 kA ≤ short-circuit current < 3 kA	2	4 ft
3 kA ≤ short-circuit current < 7 kA	3	6 ft
7 kA ≤ short-circuit current < 10 kA	4	8 ft

Note: Apparel that can be expected to be exposed to battery electrolyte must meet both of the following conditions:

1. *Be evaluated for electrolyte protection in accordance with ASTM F1296, Standard Guide for Evaluating Chemical Protective Clothing.*

2. *Be arc-rated in accordance with ASTM F1891, Standard Specification for Arc Rated and Flame Resistant Rainwear, or equivalent.*

Note: Obtain the available short circuit current for a particular battery from the manufacturer. If this information is not available, estimate the available short circuit current from the battery performance data sheet as 10 times the 1-minute ampere capability of the cell (at 77°F (25°C) to 1.75 V per cell) for lead-acid batteries.

8.0 Safety Precautions.

The following sections provide basic safety precautions for working around lead acid batteries and dc equipment.

8.1 Personal Safety General Precautions.

Batteries are inherently dangerous; they can generate lethal currents and contain acidic or caustic electrolyte. Take the following personnel safety measures should be take whenever working around batteries or other dc system equipment.

1. Lead acid batteries contain a sulfuric acid electrolyte that can cause burns and other serious injury. Avoid any skin contact with the electrolyte. In the event of skin contact with the electrolyte, flush immediately and thoroughly with water. If the electrolyte comes into contact with eyes, flush immediately with water and seek medical assistance. Be familiar with how to use emergency eyewash equipment, which should always be close at hand.

2. Neutralize sulfuric acid electrolyte spills on clothing or other material with a bicarbonate of soda (baking soda) solution (1 pound of bicarbonate of soda per gallon of water). Apply the solution to any spills until bubbling stops and rinse with clean water.

3. Whenever working with battery electrolyte, wear a rubber apron and rubber gloves. Ensure goggles and face shields are available.

4. Batteries can generate hydrogen gas. Never bring burning materials such as matches, cigarettes, or sparks of any kind near the battery. Avoid the use of spark-producing equipment near batteries. Residual gases can remain within cells during storage and shipment. Take these precautions at all times while handling batteries.

5. Use only insulated tools in the battery area to prevent accidental shorting across battery connections. Never lay tools or other metal objects on cells; shorting, explosion, or personal injury could result. As a general rule, the length of the exposed metal for any tool should be less than the distance between the positive and negative posts of each cell.

6. Remove all jewelry, wristwatches, or clothing with metal parts that could come into contact with the battery terminals.

7. Do not make or break series connections within an operating group of cells. Before proceeding, open the battery system circuit breaker to minimize the possibility of arcing.

8. Ensure that the exit from the battery area is unobstructed.

9. Do not overheat anticorrosion grease when preparing it for battery terminations. Some compounds have a flash point as low as 90°F. Follow the manufacturer's instructions carefully.

10. Minimize access to the battery by personnel unaware of battery safety precautions.

8.2 Equipment Safety General Precautions.

The previous section summarized safety precautions applicable to personnel. Improper handling or maintenance can also damage the battery. The following summarizes common considerations for the battery.

1. Install stationary batteries only on racks designed for the types of cells to be installed. Follow the manufacturer's guidance with regard to the design and material of the battery rack.

2. Do not lift any cell by its terminal posts. Use a lifting belt, spreader board, or other device approved by the manufacturer to move cells; internal cell damage can result if the cells are mishandled.

3. Do not adjust or tamper with seal nuts around cell posts, if installed.

4. Never use solvents or unapproved greases on cells or connections. Solvents can attack and even crack the plastic cell case. Unapproved greases can also attack plastic materials on the cell. Use only clean water and the proper neutralizing compound, as necessary, to clean the battery racks and containers.

5. Do not use a steel brush, brass brush, emery cloth, sandpaper, steel wool or metal file to clean cell posts and connectors; these tools can damage the lead plating.

6. Keep battery tops clean and neutralize any spilled electrolyte to minimize the possibility of electrical shock and short circuit, and to reduce rack corrosion.

7. Use two insulated wrenches when checking the connection torque to minimize stress on the connection hardware.

8. Unless required by the manufacturer for the particular battery design, do not remove flame arrestors. Use the filling funnel to add water or check the electrolyte.

9. Provide proper support for cables connected to cell terminals. Excessive strain from improper cable arrangements can damage cell terminal posts and seals.

10. Do not use cables as handles. This practice can stress the termination points and cause terminal post seal leakage.

9.0 Working on Stationary Battery Systems.

Perform work on or around a stationary battery in accordance with the following procedure:

1. Conduct pre-job brief; include unique precautions for working on battery and DC systems. Confirm communication is established with all crew members, if applicable.

2. Select required PPE in accordance with Table 2. Ensure all personnel are wearing required PPE.

3. Wear Class 0 voltage-rated gloves with leather protectors if working within the restricted approach boundary for battery systems rated for 300 volts or higher. Inspect voltage-rated gloves and leather protectors before use.

4. Select and inspect the tools and devices to be used for work. Ensure that all tools are insulated.

5. Perform work in accordance with the pre-job brief.

   Note: Depending on the work to be performed, a separate procedure might be required. This SOP addresses only the safety considerations for working on or near battery systems.

6. When work is complete, restore the equipment to normal and return all devices (tools, test equipment, PPE, and voltage-rated gloves) to their protective containers. Confirm that all tools and test equipment that were used are accounted for. If covers were removed as part of gaining access to the equipment, confirm that the covers are fully secured with no missing screws.

APPENDIX E SAMPLE SOP – INSERTING OR REMOVING (RACKING) CIRCUIT BREAKERS TO/FROM AN ENERGIZED BUS

This appendix is optional and provides a typical SOP. Refer to Section 8-4 for requirements associated with SOPs.

1.0 **Purpose.**

The following is a sample SOP for racking circuit breakers in and out of switchgear. The following activities are covered by this SOP.

- Manually racking circuit breakers out of switchgear.
- Manually racking circuit breakers into switchgear.
- Racking circuit breakers out of and into switchgear using a remote racking mechanism.

The process of racking a drawout circuit breaker into and out of the connected position is one of the most frequent exercises that exposes an operator to risk. A malfunction during this operation has the potential for catastrophic consequences to equipment and personnel. Supervised, closed door circuit breaker racking is a fundamental recognized safety practice. Furthermore, older breakers are more complex and vulnerable to mechanical failures that create safety problems.

Manual racking refers to switchgear circuit breaker removal or insertion using a hand-operated racking device while standing in front of the circuit breaker. Given the potential risk, Category 4 (40 cal/cm^2) PPE and voltage-rated gloves with leather protectors are specified for this activity.

Remote racking refers to switchgear circuit breaker removal or insertion using a remote racking mechanism that allows the operator to stand up to 25 feet away from the circuit breaker; Figure 1 shows an example of one type of unit. Remote racking reduces the risk of circuit breaker racking and standard Category 2 (8 cal/cm^2) clothing is specified for this activity.

Figure 1. Remote Racking Mechanism

Modify this SOP as appropriate for the installation, the allowed work practices, and personnel qualifications.

2.0 Applicability.

This procedure applies to personnel that are designated as a qualified person with respect to working on or near electrical equipment rated at 50 volts or above.

3.0 References.

- 29 CFR 1910, *Occupational Safety and Health, General Industry Standards*
- Unified Facilities Criteria (UFC) 3-560-01, *Operation and Maintenance: Electrical Safety*
- NFPA 70E, *Electrical Safety in the Workplace*

4.0 Definitions.

Arc Flash Hazard. A dangerous condition associated with the possible release of energy caused by an electric arc.

Arc Rating. The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm2 and is derived from the determined value of the arc thermal performance value (ATPV) or energy of breakopen threshold (EBT) (should a material system exhibit a breakopen response below the ATPV value). Arc rating is reported as either ATPV or EBT, whichever is the lower value.

\3\ Boundary, Arc Flash. The distance from an arc source (energized exposed equipment) at which the potential incident heat energy from an arcing fault on the surface of the skin is 1.2 cal/cm^2 (5 J/cm^2). ***/3/***

Boundary, Limited Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

De-energized. Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Electrical Hazard. A dangerous condition such that contact, or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Electrically Safe Work Condition. A state in which an electrical conductor or circuit part has been disconnected from energized parts, locked/tagged in accordance with established standards, tested to ensure the absence of voltage, and grounded if determined necessary.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Incident Energy. The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Inserting (Racking In) Circuit Breaker. The act of inserting a breaker into its cell, effectively placing it into a position to control or connect the electrical supply to the load connections mounted in the rear of the cell.

Live Line Tool. An insulated tool that electrically insulates the worker from the energized conductor and provides physical separation from the device being operated.

Low-Voltage. Any voltage below 1,000 V.

Medium Voltage. Voltages above 1,000 and ranging to 72,500 V.

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Shock Hazard. A dangerous condition associated with the possible release of energy caused by contact or approach to energized electrical conductors or circuit parts.

Test Position. Breaker position for testing the breaker operation during maintenance. When in the test position, the breaker is not connected to the line or load side stabs (bus).

Unqualified Person. A person who is not a qualified person.

Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of "working on": Diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; repair is any physical alteration of electrical equipment (such as making or tightening connections, removing, or replacing components, etc.).

5.0 Training and Qualification Requirements.

Personnel using this procedure must be trained and qualified in the following:

Emergency response training. Contact release. First aid, emergency response, and resuscitation.

Qualified Person Employee training. A qualified person must be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method.

Personnel using this procedure must also be trained in circuit breaker racking, either manually or with a remote racking mechanism if available.

Document all training.

6.0 Required Approach Distances.

Table 1 lists the minimum approach distances from exposed alternating current energized parts within which a qualified worker may not approach without the use of personal protective equipment appropriate for the potential electrical hazards or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding).

Note: Racking operations are not performed with the qualified electrical worker next to exposed energized parts. The equipment to be racked out is dead-front design. However, because of the higher risk associated with racking operations, observe these approach distances and wear the PPE specified in Section 7.

Table 1 Qualified Worker Minimum Approach Distances – AC Systems

Nominal System Voltage Range Phase to Phase (1)	**Arc Flash Boundary**	**Limited Approach Boundary**		**Restricted Approach Boundary (3) (4)**
	From Phase to Phase Voltage (5), (6)	**Exposed Movable Conductor**	**Exposed Fixed Circuit Part**	**Includes Standard Inadvertent Movement Adder**
50 V to 150 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>151 V to 750 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)
>750 V to 15 kV	(2)	10 ft 0 in (3.0 m)	5 ft 0 in (1.5 m)	2 ft 2 in (0.7 m)
>15 kV to 36 kV	(2)	10 ft 0 in (3.0 m)	6 ft 0 in (1.8 m)	2 ft 9 in (0.8 m)
>36 kV to 46 kV	(2	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	2 ft 9 in (0.8 m)
>46 kV to 72.5 kV	(2)	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>72.5 kV to 121 kV	(2)	10 ft 8 in (3.3 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>121 kV to 145 kV	(2)	11 ft 0 in (3.4 m)	10 ft 0 in (3.0 m)	3 ft 10 in (1.2 m)

Notes for Table 1:

1. *For single phase systems* ***\2*** *above 250 volts,* ***/2/*** *select the range that is equal to the system's maximum phase to ground voltage times 1.732.*
2. *The arc flash boundary is determined by an arc flash analysis.*
3. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
4. *Only qualified workers wearing appropriate PPE are permitted to be within the arc flash boundary.*
5. ***\2*** *Refer to NFPA 70E for AC voltages above 145 kV.* ***/2/***

7.0 **Personal Protective Equipment (PPE).**

Comply with UFC 3-560-01 for PPE requirements, as well as the additional requirements specified in the sections below.

7.1 **PPE for Manual Racking.**

Review electrical task risk assessment for this SOP for the potential incident energy level to confirm there are no locations with an incident energy rating above 40 cal/cm^2. Wear the following arc-rated clothing, minimum of 40 cal/cm^2, while performing manual racking operations:

Note: Some locations where racking will be performed will be rated for an incident energy of less than Category 4 (40 cal/cm^2) or lower. Category 4 clothing is specified for this activity because of the unique risk posed by this activity,

Note: The following PPE is required regardless of whether the circuit breaker compartment door is open or closed during racking.

- Arc-rated flash suit pants and jacket.
- Arc-rated flash suit hood.
- Leather electrical hazard rated (EH) work shoes/boots.
- Hearing protection.
- Voltage-rated gloves with leather protectors.

Select voltage-rated gloves with leather protectors (Table 2) based on the line-to-line voltage rating of the switchgear. Select as follows:

Table 2 Rubber Insulating Equipment Voltage Requirements

Class of Equipment	Color Label	Maximum Use (AC Volts)	Minimum Distance[1] in Inches (Millimeters)
00	Beige	500	1 (25)
0	Red	1,000	1 (25)
1	White	7,500	1 (25)
2	Yellow	17,000	2 (50)
3	Green	26,500	3 (75)
4	Orange	36,000	4 (100)

Notes for Table: Wear leather protectors over rubber gloves. Minimum distance is the minimum length that the exposed rubber glove must extend beyond the leather protector.

7.2 PPE for Remote Racking.

Remote racking operations will be performed with the qualified electrical worker located well outside the limited approach boundary and the arc flash boundary, which reduces the risk associated with this activity. Comply with UFC 3-560-01 for minimum arc flash clothing requirements.

8.0 Manual Racking.

8.1 Manual Racking – Breaker Removal (Rack Out) from an Energized Bus.

Perform the following steps:

1. Conduct pre-job brief and identify/confirm the circuit breaker(s) that will be operated and racked. Confirm communication is established with all crew members, if applicable.

2. Check the electrical task risk assessment for this SOP for the location where racking will occur. If the arc flash incident energy exceeds Category 4 (40 cal/cm^2) at the stated working distance, stop work. The switchgear must be deenergized and placed in an electrically safe work condition before racking is allowed.

3. Ensure personnel that will perform manual racking operations are wearing PPE required by Section 7.

4. Open the circuit breaker to be racked out, using a remote-control device if available.

5. Rack out the circuit breaker using the racking tool.

   Note: Count the number of revolutions required to fully rack out the circuit breaker. Use this number as a guide in the future when racking the circuit breaker back in.

6. If circuit breaker removal is part of a lockout/tagout procedure, complete the lockout/tagout. If desired for additional confirmation of lockout/tagout, pull the control power fuses for the circuit breaker.

8.2 Manual Racking – Breaker Insertion (Rack In) to an Energized Bus.

Perform the following steps:

1. Conduct pre-job brief and identify/confirm the circuit breaker(s) that will be operated and racked. Confirm communication is established with all crew members, if applicable.

2. Check the electrical task risk assessment for this SOP for the location where racking will occur. If the arc flash incident energy exceeds Category 4 (40 cal/cm^2) at the stated working distance, stop work. The switchgear must be deenergized and placed in an electrically safe work condition before racking is allowed.

3. Ensure personnel that will perform manual racking operations are wearing PPE required by Section 7.

4. Remove any lockout/tagout tags and locks, if applicable. If removed, replace the control power fuses for the circuit breaker.

5. Open the compartment and confirm that the circuit breaker is squarely aligned in the cell and is seated into the starting position. Visually confirm that the circuit breaker is open.

6. Rack the circuit breaker into the cell using the racking tool.

   Note: Count the number of revolutions required to fully rack in the circuit breaker. This should be the same number as was required to rack out the circuit breaker.

7. Visually confirm the circuit breaker is racked in.

8. If needed for system operations, close the circuit breaker, using a remote-control device if available.

9. Open the circuit breaker compartment door and visually confirm that the circuit breaker is closed.

9.0 **Remote Racking.**

9.1 **Remote Racking – Breaker Removal (Rack Out) from an Energized Bus.**

Perform the following steps:

1. Conduct pre-job brief and identify/confirm the circuit breaker(s) that will be operated and racked. Confirm communication is established with all crew members, if applicable.

2. Check the electrical task risk assessment for this SOP for the location where racking will occur. If the arc flash incident energy exceeds Category 4 (40 cal/cm^2) at the stated working distance, stop work. The switchgear must be deenergized and placed in an electrically safe work condition before racking is allowed.

3. Ensure personnel that will perform remote racking operations are wearing PPE required by Section 7.

4. Open the circuit breaker to be racked out, using the remote-control device.

5. Align the remote racking mechanism in front of the circuit breaker and connect to the circuit breaker racking rod.

6. Set up to operate the remote racking mechanism in accordance with the manufacturer's instructions.

7. Ensure all personnel in the area are a minimum of 20 feet away from the circuit breaker to be racked.

8. Rack out the circuit breaker using the remote racking mechanism.

9. If circuit breaker removal is part of a lockout/tagout procedure, complete the lockout/tagout.

9.2 **Remote Racking – Breaker Removal (Rack Out) from an Energized Bus.**

Perform the following steps:

1. Conduct pre-job brief and identify/confirm the circuit breaker(s) that will be operated and racked. Confirm communication is established with all crew members, if applicable.

2. Check the electrical task risk assessment for this SOP for the location where racking will occur. If the arc flash incident energy exceeds Category 4 (40 cal/cm2) at the stated working distance, stop work. The switchgear must be deenergized and placed in an electrically safe work condition before racking is allowed.

3. Ensure personnel that will perform racking operations are wearing PPE required by Section 7.

4. Remove any lockout/tagout tags and locks, if applicable. If removed, replace the control power fuses for the circuit breaker.

5. Open the compartment and confirm that the circuit breaker is squarely aligned in the cell and is seated into the starting position. Visually confirm that the circuit breaker is open.

6. Align the remote racking mechanism in front of the circuit breaker and connect to the circuit breaker racking rod.

7. Set up to operate the remote racking mechanism in accordance with the manufacturer's instructions.

8. Ensure all personnel in the area are a minimum of 20 feet away from the circuit breaker to be racked.

9. Rack the circuit breaker into the cell using the remote racking mechanism.

10. Visually confirm the circuit breaker is racked in.

11. If needed for system operations, close the circuit breaker, using a remote-control device if available.

12. Open the circuit breaker compartment door and visually confirm that the circuit breaker is closed.

APPENDIX F SAMPLE SOP – FUSED CUTOUTS: OPENING, CLOSING, OR REPLACING FUSES

This appendix is optional and provides a typical SOP. Refer to Section 8-4 for requirements associated with SOPs.

The following is a sample SOP for operating overhead distribution fused cutouts or replacing fuse links inside cutouts. Modify this SOP as appropriate for the installation, the allowed work practices, and personnel qualifications.

1.0 **Purpose.**

This procedure defines the requirements for opening fused cutouts, closing fused cutouts, or replacing fuse links in fused cutouts on the overhead distribution system.

2.0 **Applicability.**

This procedure applies to personnel that are designated as a qualified person with respect to working on or near primary overhead distribution systems.

3.0 **References.**

- 29 CFR 1910, *Occupational Safety and Health, General Industry Standards*
- Unified Facilities Criteria (UFC) 3-560-01, *Operation and Maintenance: Electrical Safety*
- NFPA 70E, *Electrical Safety in the Workplace*

4.0 **Definitions.**

Arc Flash Hazard. A dangerous condition associated with the possible release of energy caused by an electric arc.

Arc Rating. The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm^2 and is derived from the determined value of the arc thermal performance value (ATPV) or energy of breakopen threshold (EBT) (should a material system exhibit a breakopen response below the ATPV value). Arc rating is reported as either ATPV or EBT, whichever is the lower value.

\3\ Balaclava (Sock Hood). An arc-rated head-protective fabric that protects the neck and head except for a small portion of the facial area.

Boundary, Arc Flash. The distance from an arc source (energized exposed equipment) at which the potential incident heat energy from an arcing fault on the surface of the skin is 1.2 cal/cm^2 (5 J/cm^2). ***/3/***

Boundary, Limited Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

De-energized. Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Electrical Hazard. A dangerous condition such that contact, or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Electrically Safe Work Condition. A state in which an electrical conductor or circuit part has been disconnected from energized parts, locked/tagged in accordance with established standards, tested to ensure the absence of voltage, and grounded if determined necessary.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Fused Cutout. A pole mounted interrupting device, equipped with fuses, that provides a method for de-energizing and protecting downstream electrical equipment.

Incident Energy. The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Live Line Tool. An insulated tool that electrically insulates the worker from the energized conductor and provides physical separation from the device being operated.

Low-Voltage. Any voltage below 1,000 V.

Medium Voltage. Voltages above 1,000 and ranging to 72,500 V.

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Shock Hazard. A dangerous condition associated with the possible release of energy caused by contact or approach to energized electrical conductors or circuit parts.

Unqualified Person. A person who is not a qualified person.

Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of "working on": Diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; repair is any physical alteration of electrical equipment (such as making or tightening connections, removing or replacing components, etc.).

5.0 Training and Qualification Requirements.

Personnel using this procedure must be trained and qualified in the following:

Emergency response training. Contact release. First aid, emergency response, and resuscitation.

Qualified Person Employee training. A qualified person must be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method. For this SOP, this includes working inside an elevated bucket, handling of live-line tools, and pole-top rescue.

Document all training.

6.0 Required Approach Distances.

Table 1 lists the minimum approach distances from exposed alternating current energized parts within which a qualified worker may not approach without the use of personal protective equipment appropriate for the potential electrical hazards or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding).

Table 1 Qualified Worker Minimum Approach Distances – AC Systems

Nominal System Voltage Range Phase to Phase (1)	**Arc Flash Boundary**	**Limited Approach Boundary**		**Restricted Approach Boundary (3) (4)**
	From Phase to Phase Voltage (5), (6)	**Exposed Movable Conductor**	**Exposed Fixed Circuit Part**	**Includes Standard Inadvertent Movement Adder**
50 V to 150 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>151 V to 750 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)
>750 V to 15 kV	(2)	10 ft 0 in (3.0 m)	5 ft 0 in (1.5 m)	2 ft 2 in (0.7 m)
>15 kV to 36 kV	(2)	10 ft 0 in (3.0 m)	6 ft 0 in (1.8 m)	2 ft 9 in (0.8 m)
>36 kV to 46 kV	(2	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	2 ft 9 in (0.8 m)
>46 kV to 72.5 kV	(2)	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>72.5 kV to 121 kV	(2)	10 ft 8 in (3.3 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>121 kV to 145 kV	(2)	11 ft 0 in (3.4 m)	10 ft 0 in (3.0 m)	3 ft 10 in (1.2 m)

Notes for Table 1:

1. *For single phase systems* ***\2*** *above 250 volts,* ***/2 /****select the range that is equal to the system's maximum phase to ground voltage times 1.732.*
2. *The arc flash boundary is determined by an arc flash analysis.*
3. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
4. *The restricted approach distance applied to hot sticks is the distance between a worker's hand and the working end of the stick.*
5. *Only qualified workers wearing appropriate PPE are permitted to be within the arc flash boundary.*
6. ***\2*** *Refer to NFPA 70E for AC voltages above 145 kV.* ***/2/***

7.0 **Personal Protective Equipment.**

Comply with UFC 3-560-01 for PPE requirements.

De-energizing equipment before opening equipment is the preferred work procedure. If mission prohibits de-energizing equipment:

1. Review electrical task risk assessment for this SOP for the potential incident energy level.

2. Select PPE equipment to exceed calculated potential incident energy level.

Voltage-rated gloves with leather protectors (Table 2) are required for work inside the restricted approach boundary or when handling live-line tools. Select as follows:

Table 2 Rubber Insulating Equipment Voltage Requirements

Class of Equipment	Color Label	Maximum Use (AC Volts)	Minimum Distance[1] in Inches (Millimeters)
00	Beige	500	1 (25)
0	Red	1,000	1 (25)
1	White	7,500	1 (25)
2	Yellow	17,000	2 (50)
3	Green	26,500	3 (75)
4	Orange	36,000	4 (100)

Notes for Table: Wear leather protectors over rubber gloves. Minimum distance is the minimum length that the exposed rubber glove must extend beyond the leather protector.

8.0 <u>Opening a Fused Cutout.</u>

Perform the following steps:

Note: If the overhead distribution circuit overcurrent protection includes reclosing ability, disable upstream reclosing before starting work. Enable reclosing after work is complete.

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members.

2. If possible, remove load from the fused cutouts by opening the secondary main breakers in all facilities supplied through the fused cutouts.

3. Select voltage-rated gloves with leather protectors using Table 2. Inspect voltage-rated gloves and leather protectors before use. Wear voltage-rated gloves with leather protectors while performing all work inside the bucket.

4. Select and inspect the live-line insulated tool (hot stick) to be used for the work. Confirm that hot sticks have been wet tested within the last 2 years. Ensure that all tools are rated for the voltage to be worked on.

5. Position the insulated bucket truck in a position as far as possible from active traffic lanes. Place cones, barricades, and traffic markers as appropriate. Turn on all warning flashers and yellow beacons (day and night).

6. Enter and maneuver the bucket close enough to reach the fused cutouts with the insulated tool without having to reach or lean outside of the bucket.

7. Grasp the hot stick with both hands and insert the working end into the pull handle on the individual fused cutout. Pull it open in one smooth motion.

8. Open the remaining fused cutouts by the same process described above.

9. If changing the fuse(s), use the hot stick to lift and remove the fuse cartridge from the fused cutouts. To install the replacement fuse cartridge, pick up the fuse cartridge with the working end of the hot stick, position the fuse, and drop into place in the fused cutout.

10. When work is complete, return all equipment (PPE, live-line tools, and voltage-rated gloves) to their protective containers. Confirm that all tools that were used are accounted for.

9.0 **Closing a Fused Cutout.**

Perform the following steps:

Note: If the overhead distribution circuit overcurrent protection includes reclosing ability, disable upstream reclosing before starting work. Enable reclosing when work is complete.

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members.

2. If possible, remove load from the fused cutouts by opening the secondary main breakers in all facilities supplied through the fused cutouts.

3. Select voltage-rated gloves with leather protectors using Table 2. Inspect voltage-rated gloves and leather protectors before use. Wear voltage-rated gloves with leather protectors while performing all work inside the bucket.

4. Select and inspect the live-line insulated tool (hot stick) to be used for the work. Confirm that hot sticks have been wet tested within the last 2 years. Ensure that all tools are rated for the voltage to be worked on.

5. Position the insulated bucket truck in a position as far as possible from active traffic lanes. Place cones, barricades, and traffic markers as appropriate. Turn on all warning flashers and yellow beacons (day and night).

6. Enter and maneuver the bucket close enough to reach the fused cutouts with the insulated tool without having to reach or lean outside of the bucket.

7. Grasp the hot stick with both hands and insert the working end into the pull handle on the individual fused cutout. Lift and push closed in one smooth motion.

8. Close the remaining fused cutouts by the same process described above.

9. If changing the fuse(s), use the hot stick to lift and remove the fuse cartridge from the fused cutouts. To install the replacement fuse cartridge, pick up the fuse cartridge with the working end of the hot stick, position the fuse, and drop into place in the fused cutout.

10. When work is complete, return all equipment (PPE, live-line tools, and voltage-rated gloves) to their protective containers. Confirm that all tools that were used are accounted for.

11. If load was removed from the fused cutouts by opening the secondary main breakers in facilities supplied through the fused cutouts, restore power to the facilities by closing the secondary main breakers.

This Page Intentionally Left Blank

APPENDIX G SAMPLE SOP – CONNECTING/DISCONNECTING LOADBREAK ELBOWS

This appendix is optional and provides a typical SOP. Refer to Section 8-4 for requirements associated with SOPs.

The following is a sample SOP for connecting or disconnecting load break elbows on an energized bus. Modify this SOP as appropriate for the installation, the allowed work practices, and personnel qualifications.

1.0 **<u>Purpose.</u>**

This procedure defines the requirements for or connecting or disconnecting load break elbows on an energized circuit.

2.0 **<u>Applicability.</u>**

This procedure applies to personnel that are designated as a qualified person with respect to working on or near primary underground distribution systems.

3.0 **<u>References.</u>**

- 29 CFR 1910, *Occupational Safety and Health, General Industry Standards*
- Unified Facilities Criteria (UFC) 3-560-01, *Operation and Maintenance: Electrical Safety*
- NFPA 70E, *Electrical Safety in the Workplace*

4.0 **<u>Definitions.</u>**

Arc Flash Hazard. A dangerous condition associated with the possible release of energy caused by an electric arc.

Arc Rating. The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm2 and is derived from the determined value of the arc thermal performance value (ATPV) or energy of breakopen threshold (EBT) (should a material system exhibit a breakopen response below the ATPV value). Arc rating is reported as either ATPV or EBT, whichever is the lower value.

\3\ Balaclava (Sock Hood). An arc-rated head-protective fabric that protects the neck and head except for a small portion of the facial area. **/3/**

Boundary, Arc Flash. The distance from an arc source (energized exposed equipment) at which the potential incident heat energy from an arcing fault on the surface of the skin is 1.2 cal/cm^2 (5 J/cm^2).

Boundary, Limited Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

De-energized. Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Elbow. A connector component for connecting a power conductor to a bushing, designed so that when assembled with the bushing, the axes of the conductor and bushing are perpendicular.

Electrical Hazard. A dangerous condition such that contact, or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Electrically Safe Work Condition. A state in which an electrical conductor or circuit part has been disconnected from energized parts, locked/tagged in accordance with established standards, tested to ensure the absence of voltage, and grounded if determined necessary.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Incident Energy. The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Insulated Cap. An accessory device designed to electrically insulate, electrically shield, and mechanically seal a bushing insert or integral bushing.

Insulated Parking Bushing. An accessory device designed to electrically insulate, electrically shield, and mechanically seal a power cable terminated with an elbow and to be installed into a parking stand.

Live Line Tool. An insulated tool that electrically insulates the worker from the energized conductor and provides physical separation from the device being operated.

Loadbreak Connector. A connector designed to close, and interrupt rated load current or less on energized circuits under rated conditions.

Low-Voltage. Any voltage below 1,000 V.

Medium Voltage. Voltages above 600 and ranging to 72,500 V.

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Separable Insulated Connector. A fully insulated and shielded system for terminating an insulated power conductor to electrical apparatus, other power conductors, or both, and designed such that the electrical connection can be readily made or broken by engaging the connector at the operating interface.

Shock Hazard. A dangerous condition associated with the possible release of energy caused by contact or approach to energized electrical conductors or circuit parts.

Unqualified Person. A person who is not a qualified person.

Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of “working on”: Diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; repair is any physical alteration of electrical equipment (such as making or tightening connections, removing, or replacing components, etc.).

5.0 Training and Qualification Requirements.

Personnel using this procedure must be trained and qualified in the following:

Emergency response training. Contact release. First aid, emergency response, and resuscitation.

Qualified Person Employee training. A qualified person must be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method.

Document all training.

6.0 Required Approach Distances.

Table 1 lists the minimum approach distances from exposed alternating current energized parts within which a qualified worker may not approach without the use of personal protective equipment appropriate for the potential electrical hazards or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding).

Table 1 Qualified Worker Minimum Approach Distances – AC Systems

Nominal System Voltage Range Phase to Phase (1)	**Arc Flash Boundary**	**Limited Approach Boundary**		**Restricted Approach Boundary (3) (4)**
	From Phase to Phase Voltage (5), (6)	**Exposed Movable Conductor**	**Exposed Fixed Circuit Part**	**Includes Standard Inadvertent Movement Adder**
50 V to 150 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>151 V to 750 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)
>750 V to 15 kV	(2)	10 ft 0 in (3.0 m)	5 ft 0 in (1.5 m)	2 ft 2 in (0.7 m)
>15 kV to 36 kV	(2)	10 ft 0 in (3.0 m)	6 ft 0 in (1.8 m)	2 ft 9 in (0.8 m)
>36 kV to 46 kV	(2	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	2 ft 9 in (0.8 m)
>46 kV to 72.5 kV	(2)	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>72.5 kV to 121 kV	(2)	10 ft 8 in (3.3 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>121 kV to 145 kV	(2)	11 ft 0 in (3.4 m)	10 ft 0 in (3.0 m)	3 ft 10 in (1.2 m)

Notes for Table 1:

1. *For single phase systems* ***\2*** *above 250 volts,* ***/2/*** *select the range that is equal to the system's maximum phase to ground voltage times 1.732.*
2. *The arc flash boundary is determined by an arc flash analysis.*
3. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
4. *The restricted approach distance applied to hot sticks is the distance between a worker's hand and the working end of the stick.*
5. *Only qualified workers wearing appropriate PPE are permitted to be within the arc flash boundary.*

7.0 **Personal Protective Equipment.**

Comply with UFC 3-560-01 for PPE requirements.

De-energizing equipment before opening equipment is the preferred work procedure. If mission prohibits de-energizing equipment:

1. Review electrical task risk assessment for this SOP for the potential incident energy level.

2. Select PPE equipment to exceed calculated potential incident energy level.

Voltage-rated gloves with leather protectors (Table 2) are required for work inside the restricted approach boundary or when handling live-line tools. Select as follows:

Table 2 Rubber Insulating Equipment Voltage Requirements

Class of Equipment	Color Label	Maximum Use (AC Volts)	Minimum Distance[1] in Inches (Millimeters)
00	Beige	500	1 (25)
0	Red	1,000	1 (25)
1	White	7,500	1 (25)
2	Yellow	17,000	2 (50)
3	Green	26,500	3 (75)
4	Orange	36,000	4 (100)

Notes for Table: Wear leather protectors over rubber gloves. Minimum distance is the minimum length that the exposed rubber glove must extend beyond the leather protector.

8.0 **Precautions.**

Maneuver loadbreak connectors with a fully insulated “shot gun” live-line type tool; the live-line tool length is optional provided that the resulting working distance is less than or equal to that assumed in the electrical task risk assessment developed for this SOP. Ensure the working area is clear of obstructions or contaminants that might interfere with the operation of the connector or cause it to fall into the exposed bushing well. The operating position should allow establishing a firm footing and enable grasping the live-line tool securely, while maintaining positive control over the movement of the loadbreak connector before, during, and directly after the operating sequence. Because of the control, speed, and force required to engage or disengage an elbow, certain operating positions are more advantageous than others. If there are any concerns regarding an adequate position for handling a loadbreak connector, the operation must be practiced first on a de-energized circuit.

The following lists additional precautions and limitations for handling loadbreak connectors on an energized circuit:

- Limit work to dry weather conditions. Do not operate loadbreak connectors during wet conditions.
- Loadbreak connectors can be operated inside manholes only if the work can be accomplished with the qualified electrical worker standing outside the manhole at grade.
- Operation (connecting or disconnecting) loadbreak connectors inside a manhole with the qualified electrical worker standing inside the manhole is prohibited.
- Making a connection into a suspected fault is prohibited. De-energize the circuit prior to connection.
- If a fault occurs during connection or disconnection, replace the elbow connector and the bushing.
- Never connect an energized load break elbow into a transformer that has not been tested for proper operation.
- Never connect loadbreak elbow type surge arresters into an energized transformer or circuit.
- Never use a loadbreak connector to switch energized capacitors.
- Check the appropriate manufacturer's operating instructions to confirm the device(s) is rated for energized operation, either connecting or disconnecting.

9.0 Loadbreak Operation (Connecting) at Grade.

Perform the following steps:

Note: This operation might be performed as part of a switching order. If so, then coordinate the Activity with the rest of the switching order.

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members.
2. Select voltage-rated gloves with leather protectors using Table 2. Inspect voltage-rated gloves and leather protectors before use. Wear voltage-rated gloves with leather protectors while performing all work.
3. Select and inspect the live-line insulated tool (hot stick) to be used for the work. Confirm that hot sticks have been wet tested within the last 2 years. Ensure that all tools are rated for the voltage to be worked on.
4. Ensure the area is clear of obstructions or contaminants that might interfere with the operation of the connector.

5. Open the equipment where the loadbreak connector operation will be performed.

6. Prepare the bushing for the elbow connector by removing the insulated cap. Attach the live-line tool to the insulated cap pulling eye and remove from the bushing.

7. Securely fasten a shot gun live-line tool to the load break connector pulling eye.

Note: This procedure assumes that the loadbreak connector is on an insulated parking bushing on the apparatus parking stand before work starts.

8. Without exerting any pulling force, slightly rotate the connector to break any surface friction prior to disconnection from the insulated parking bushing on the apparatus parking stand.

9. After establishing a firm footing and positive control of the elbow connector, withdraw the elbow from the insulated parking bushing on the apparatus parking stand with a fast, firm, and straight motion, while being careful to avoid the ground plane.

10. Place the elbow connector receptacle area over the bushing plug and insert the elbow male contact (arc flower portion) into the bushing until a slight resistance is felt. Immediately push the elbow into the locked position with a fast, firm, and straight motion. Apply sufficient force to engage the internal lock on the elbow connector and bushing interface.

11. When work is complete, return all equipment (PPE, live-line tools, and voltage-rated gloves) to their protective containers. Confirm that all tools that were used are accounted for.

10.0 **Loadbreak Operation (Disconnecting) at Grade.**

Perform the following steps:

Note: This operation might be performed as part of a switching order. If so, then coordinate the Activity with the rest of the switching order.

1. Conduct pre-job brief. Ensure all personnel are wearing required PPE. Confirm communication is established with all crew members.

2. Select voltage-rated gloves with leather protectors using Table 2. Inspect voltage-rated gloves and leather protectors before use. Wear voltage-rated gloves with leather protectors while performing all work.

3. Select and inspect the live-line insulated tool (hot stick) to be used for the work. Confirm that hot sticks have been wet tested within the last 2 years. Ensure that all tools are rated for the voltage to be worked on.

4. Ensure the area is clear of obstructions or contaminants that might interfere with the operation of the connector.

5. Open the equipment where the loadbreak connector operation will be performed.

6. Place the insulated parking bushing on the apparatus parking stand.

7. Firmly tighten a shot gun live-line tool to the loadbreak connector pulling eye.

8. Without exerting any pulling force, slightly rotate the connector to break any surface friction prior to disconnection.

9. After establishing a firm footing and positive control of the elbow connector, withdraw the elbow from the bushing with a fast, firm, and straight motion, while being careful to avoid the ground plane.

10. Place the connector on the insulated parking bushing and secure.

11. When work is complete, return all equipment (PPE, live-line tools, and voltage-rated gloves) to their protective containers. Confirm that all tools that were used are accounted for.

APPENDIX H SAMPLE SOP – ELECTRICAL MANHOLE/VAULT ENTRY

This appendix is optional and provides a typical SOP. Refer to Section 8-4 for requirements associated with SOPs.

1.0 **Purpose.**

This procedure defines the requirements for work performed inside electrical manholes and vaults. Modify this SOP as appropriate for the installation, the allowed work practices, and personnel qualifications.

Arc flash calculation methodology does not address the unique configuration of an electrical manhole in which an arcing fault occurs inside a small, enclosed space that also contains the worker. Additional precautions are necessary.

An IEEE interpretation dated 14 January 2009, regarding IEEE C2 (National Electrical Safety Code) Rule 410A3, confirms that the phrase “on or near energized parts or equipment” applies to energized insulated conductors inside manholes. IEEE C2 Rule 443 does allow a qualified employee, working alone, to enter a manhole where energized cables or equipment are in service for the purpose of inspection, housekeeping, taking readings, or similar work if such work can be performed safely.

In some instances, it can be difficult to deenergize all circuits inside a manhole when accomplishing repair or installation activities because of the number of circuits inside the manhole. Accordingly, this SOP provides guidance regarding the type of work activities permitted inside manholes containing energized circuits.

2.0 **Applicability.**

This procedure applies to personnel that are designated as a qualified person with respect to working on or near electrical equipment rated at 50 volts or above.

3.0 **References.**

- 29 CFR 1910, *Occupational Safety and Health, General Industry Standards*
- Unified Facilities Criteria (UFC) 3-560-01, *Operation and Maintenance: Electrical Safety*
- NFPA 70E, *Electrical Safety in the Workplace*

4.0 **Definitions.**

Arc Flash Hazard. A dangerous condition associated with the possible release of energy caused by an electric arc.

Arc Rating. The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm2 and is derived from the determined value of the arc thermal performance value (ATPV) or energy of breakopen threshold (EBT) (should a material system exhibit a breakopen response below the ATPV value). Arc rating is reported as either ATPV or EBT, whichever is the lower value.

\3\ Boundary, Arc Flash. The distance from an arc source (energized exposed equipment) at which the potential incident heat energy from an arcing fault on the surface of the skin is 1.2 cal/cm^2 (5 J/cm^2). **/3/**

Boundary, Limited Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach. An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

De-energized. Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Electrical Hazard. A dangerous condition such that contact, or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Electrically Safe Work Condition. A state in which an electrical conductor or circuit part has been disconnected from energized parts, locked/tagged in accordance with established standards, tested to ensure the absence of voltage, and grounded if determined necessary.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Incident Energy. The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Low-Voltage. Any voltage below 1,000 V.

Medium Voltage. Voltages above 1,000 and ranging to 72,500 V.

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Shock Hazard. A dangerous condition associated with the possible release of energy caused by contact or approach to energized electrical conductors or circuit parts.

Unqualified Person. A person who is not a qualified person.

Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of "working on": Diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; repair is any physical alteration of electrical equipment (such as making or tightening connections, removing, or replacing components, etc.).

5.0 **<u>Training and Qualification Requirements.</u>**

Personnel using this procedure must be trained and qualified in the following:

Emergency response training. Contact release. First aid, emergency response, and resuscitation.

Qualified Person Employee training. A qualified person must be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method.

Document all training.

6.0 **<u>Required Approach Distances.</u>**

Table 1 lists the minimum approach distances from exposed alternating current energized parts within which a qualified worker may not approach without the use of personal protective equipment appropriate for the potential electrical hazards or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding).

Table 1 Qualified Worker Minimum Approach Distances – AC Systems

Nominal System Voltage Range Phase to Phase (1)	Arc Flash Boundary	Limited Approach Boundary		Restricted Approach Boundary (3) (4)
	From Phase to Phase Voltage (5), (6)	Exposed Movable Conductor	Exposed Fixed Circuit Part	Includes Standard Inadvertent Movement Adder
50 V to 150 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>151 V to 750 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)
>750 V to 15 kV	(2)	10 ft 0 in (3.0 m)	5 ft 0 in (1.5 m)	2 ft 2 in (0.7 m)
>15 kV to 36 kV	(2)	10 ft 0 in (3.0 m)	6 ft 0 in (1.8 m)	2 ft 9 in (0.8 m)
>36 kV to 46 kV	(2	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	2 ft 9 in (0.8 m)
>46 kV to 72.5 kV	(2)	10 ft 0 in (3.0 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>72.5 kV to 121 kV	(2)	10 ft 8 in (3.3 m)	8 ft 0 in (2.5 m)	3 ft 6 in (1.0 m)
>121 kV to 145 kV	(2)	11 ft 0 in (3.4 m)	10 ft 0 in (3.0 m)	3 ft 10 in (1.2 m)

Notes for Table 1:

1. *For single phase systems* ***\2*** *above 250 volts,* ***/2/*** *select the range that is equal to the system's maximum phase to ground voltage times 1.732.*
2. *The arc flash boundary is determined by an arc flash analysis.*
3. *The restricted approach boundary is defined as the distance between energized parts and grounded objects without insulation, isolation, or guards.*
4. *The restricted approach distance applied to hot sticks is the distance between a worker's hand and the working end of the stick.*
5. *Only qualified workers wearing appropriate PPE are permitted to be within the arc flash boundary.*
6. ***\2*** *Refer to NFPA 70E for AC voltages above 145 kV.* ***/2/***

7.0 **Personal Protective Equipment.**

Comply with UFC 3-560-01 for PPE requirements. Review the electrical task risk assessment for this SOP for the potential incident energy level.

Voltage-rated gloves with leather protectors if energized circuits can be or will be touched. Select as follows:

Table 2 Rubber Insulating Equipment Voltage Requirements

Class of Equipment	Color Label	Maximum Use (AC Volts)	Minimum Distance[1] in Inches (Millimeters)
00	Beige	500	1 (25)
0	Red	1,000	1 (25)
1	White	7,500	1 (25)
2	Yellow	17,000	2 (50)
3	Green	26,500	3 (75)
4	Orange	36,000	4 (100)

Notes for Table: Wear leather protectors over rubber gloves. Minimum distance is the minimum length that the exposed rubber glove must extend beyond the leather protector.

7.0 <u>Electrical Manhole Entry.</u>

7.1 <u>Access for Inspection Only – No Known Problems.</u>

Note: Entry into a manhole containing energized circuits is not permitted for inspection activities if problems are suspected inside the manhole, such as conductor damage associated with a short circuit.

Note: A small amount of standing water is permitted for inspection activities.

The following activities are allowed:

1. Manhole and sump inspection.
2. Sump cleaning.
3. Inspection of conductors and splices, without touching or disturbing the conductors.
4. Inspection of any equipment installed in the manhole.
5. Installation of conduit plugs on spare conduits.

Perform the following steps:

1. Conduct pre-job brief. A minimum of two qualified persons are required for this activity. Confirm communication is established with all crew members, if applicable.

2. Follow all requirements for confined space entry.

3. Ensure qualified persons are wearing PPE required by Section 6.

4. Open the electrical manhole or vault. Before entering, visually confirm that the manhole can be entered, and the activity can be accomplished without disturbing energized conductors.

5. One qualified person is required to remain outside the electrical manhole or vault.

6. One or more qualified persons are allowed to enter and perform the allowed activities.

7.2 **Authorized Work Inside Manholes Containing Energized Circuits.**

Note: Entry into a manhole containing energized circuits is not permitted for inspection activities if problems are suspected inside the manhole, such as conductor damage associated with a short circuit.

Note: No standing water is permitted for work.

Note: Reracking energized conductors is not permitted. The circuits must be deenergized before the conductors can be disturbed.

The following activities are allowed:

1. Removing conduit plugs.

2. Spare conduit inspection using fish tape, boroscope, or other devices.

3. Splicing deenergized conductors. When splicing deenergized conductors, confirm that an 18-inch (0.5-meter) safe working distance from other energized conductors or equipment can be maintained during the work.

4. Pulling new conductors in spare conduits.

5. Removing abandoned (deenergized) circuits, including associated equipment, if nearby energized circuits are not disturbed.

Perform the following steps:

1. Conduct pre-job brief. A minimum of two qualified persons are required for this activity. Confirm communication is established with all crew members, if applicable.

2. Follow all requirements for confined space entry.

3. Ensure qualified persons are wearing PPE required by Section 6.

4. Open the electrical manhole or vault. Before entering, visually confirm that the manhole can be entered, and the planned work activity can be accomplished without disturbing energized conductors.

5. One qualified person is required to remain outside the electrical manhole or vault.

6. One or more qualified persons are allowed to enter and perform the allowed planned work activities.

7.3 **Other Work Inside Manholes Containing Energized Circuits.**

Other work not covered by Section 7.1 or Section 7.2 require a job-specific energized electrical work permit. Include the following in the energized electrical work permit:

1. Description of manhole and its configuration.

2. Description of planned work activities.

3. Electrical shock and arc flash risk assessment.

   Note: Electrical analysis software packages that perform arc flash calculations do not account for an electrical manhole configuration in which the electrical worker is inside an enclosed area rather than standing adjacent to an enclosure. Increase the arc flash PPE requirements by a minimum of one (1) arc flash hazard category above the arc flash calculation result.

4. Required PPE.

5. Minimum number of qualified electrical workers.

6. Means to restrict unqualified persons from the work area.

7. Rescue plan.

This Page Intentionally Left Blank

APPENDIX I SAMPLE SOP – PROHIBITED ENERGIZED WORK ACTIVITIES

This appendix is optional and provides a typical SOP. Refer to Section 8-4 for requirements associated with SOPs.

This SOP is an example of how to prohibit certain electrical work activities if the system cannot be deenergized. Modify this SOP as appropriate for the installation, the allowed work practices, and personnel qualifications.

1.0 **Purpose.**

This procedure defines the requirements for the following activities:

- Replacing ballasts on lighting circuits.
- Replacing or installing low-voltage receptacles.
- Installing a molded case circuit breaker into a panelboard or switchboard.

The associated electrical systems must be deenergized before performing any of the above activities. The basis for this limitation includes:

Replacing lighting system ballasts, installing receptacles, or inserting molded case circuit breakers while energized do not meet the minimum safety criteria established by OSHA for working on energized electrical circuits. OSHA 29 CFR 1910.333 limits work on live energized electrical equipment as follows:

"Live parts to which an employee may be exposed shall be deenergized before the employee works on or near them, unless the employer can demonstrate that deenergizing introduces additional or increased hazards or is not feasible due to equipment design or operational limitations."

Performing the above listed tasks on energized electrical systems do not meet the OSHA criteria.

The procedures provided in this SOP for replacing lighting system ballasts, installing receptacles, or inserting molded case circuit breakers into a panelboard or switchboard are based on first deenergizing the circuit. If the area occupants do not allow the circuit(s) to be deenergized, then the procedures specify to stop work and notify your supervisor that the work will need to be rescheduled.

2.0 **Applicability.**

This procedure applies to personnel that are designated as a qualified person with respect to working on or near electrical equipment rated at 50 volts or above.

3.0 References.

4.0 Definitions.

De-energized. Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Electrical Hazard. A dangerous condition such that contact, or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrical Safety. Recognizing hazards associated with the use of electrical energy and taking precautions so that hazards do not cause injury or death.

Exposed (as applied to energized electrical conductors or circuit parts). Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to electrical conductors or circuit parts that are not suitably guarded, isolated, or insulated.

Low-Voltage. Any voltage below 1,000 V.

Medium Voltage. Voltages above 1,000 and ranging to 72,500 V.

Qualified Person. One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Unqualified Person. A person who is not a qualified person.

Working On (energized electrical conductors or circuit parts). Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of “working on”: Diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; repair is any physical alteration of electrical equipment (such as making or tightening connections, removing or replacing components, etc.).

5.0 Training and Qualification Requirements.

Personnel using this procedure must be trained and qualified in the following:

Emergency response training. Contact release. First aid, emergency response, and resuscitation.

Qualified Person Employee training. A qualified person must be trained and knowledgeable in the construction and operation of equipment or a specific work method and be trained to identify and avoid the electrical hazards that might be present with respect to that equipment or work method.

Document all training.

6.0 Required Approach Distances.

Table 1 lists the minimum approach distances from exposed alternating current energized parts within which a qualified worker may not approach without the use of personal protective equipment appropriate for the potential electrical hazards or place any conductive object without an approved insulating handle, unless certain other work techniques are used (such as isolation, insulation, shielding, or guarding).

Table 1 Qualified Worker Minimum Approach Distances – AC Systems

Nominal System Voltage Range Phase to Phase (1)	Arc Flash Boundary	Limited Approach Boundary		Restricted Approach Boundary (3) (4)
	From Phase to Phase Voltage (5), (6)	Exposed Movable Conductor	Exposed Fixed Circuit Part	Includes Standard Inadvertent Movement Adder
50 V to 150 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	Avoid contact
>151 V to 750 V	(2)	10 ft 0 in (3.0 m)	3 ft 6 in (1.0 m)	1 ft 0 in (0.3 m)

6. ***\2*** *Refer to NFPA 70E for AC voltages above 145 kV.* ***/2/***

7.0 **Personal Protective Equipment.**

Comply with UFC 3-560-01 for PPE requirements.

8.0 **Lighting Ballast Replacement**

Replace a ballast on a lighting circuit as follows:

1. Deenergize the associated lighting circuit before starting work.
2. If the area occupants do not allow lighting to be deenergized while replacing one or more lighting ballasts, stop work. Inform the area occupants that work will be rescheduled by your supervisor. Inform your supervisor that lighting ballasts were not replaced. The supervisor will work with the area occupants to establish a future date when the lighting system can be deenergized for a short period for ballast replacement.
3. After the lighting system has been deenergized, replace the lighting ballasts.
4. Comply with fall protection requirements while working.
5. After the ballasts have been replaced, restore power to the lighting circuit. Confirm lighting fixtures appear to be operating normally.

9.0 **Receptacle Installation.**

Install a low-voltage receptacle as follows:

1. Deenergize the associated electrical circuit before starting work.
2. If the area occupants do not allow the electrical circuit to be deenergized, stop work. Inform the area occupants that work will be rescheduled by your supervisor. Inform your supervisor that the scheduled work was not completed. The supervisor will

work with the area occupants to establish a future date when the electrical system can be deenergized for a short period for receptacle installation.

3. After the electrical system has been deenergized, install the receptacle(s) as specified.

4. After the receptacles have been installed, restore power. Confirm the circuit(s) appears to be operating normally.

10.0 **<u>Circuit Breaker Installation.</u>**

Install a molded-case circuit breaker into a panelboard or switchboard as follows:

1. Deenergize the associated panelboard or switchboard before starting work.

2. If the area occupants do not allow the electrical circuit to be deenergized, stop work. Inform the area occupants that work will be rescheduled by your supervisor. Inform your supervisor that the scheduled work was not completed. The supervisor will work with the area occupants to establish a future date when the electrical system can be deenergized for a short period for circuit breaker installation.

3. After the electrical system has been deenergized, install the circuit breakers as specified.

4. After the circuit breakers have been installed, restore power. Confirm the circuit appears to be operating normally.

This Page Intentionally Left Blank

APPENDIX J LOCKOUT/TAGOUT GUIDANCE

This appendix is optional and provides typical lockout/tagout guidance that is applicable to electrical systems. Refer to Chapter 6 for requirements.

Occupational Safety and Health Organization programs address energy control (lockout and tagout) for a variety of potential hazards, including non-electrical hazards. NFPA 70E addresses energy control specifically targeted towards electrical systems and is recommended as a reference for lockout/tagout programs for electrical equipment. The following sections provide additional information associated with lockout/tagout for electrical systems.

J-1 SAFE CLEARANCE (SWITCHING ORDER) AND LOCKOUT/TAGOUT PROCEDURES

The basic safety rule governing safe clearance and lockout/tagout procedures is that all conductors and equipment are considered energized until:

- All sources of electrical energy (verified by checking applicable up-to-date drawings, diagrams, and identification tags) have been disconnected or otherwise prevented from energizing the equipment or circuits being worked on.
- A qualified person has operated the equipment operating controls or otherwise verified that the equipment cannot be restarted.
- And a qualified person used test equipment to test the circuit elements and electrical parts of equipment to which employees will be exposed and verified that the circuit elements and equipment parts are deenergized. The test also determines if any energized condition exists as a result of inadvertently induced voltage or unrelated voltage backfeed even though specific parts of the circuit have been deenergized and presumed to be safe.

Even with safe clearance and lockout/tagout procedures applied, all lines (circuits) and apparatus must be tested for no voltage and grounded with approved grounding methods. This will reduce the voltage across the worker to the lowest practical value possible in case the line or equipment being worked on is accidentally energized. Table J-1 summarizes the sequence of events associated with lockout and tagout. If the lines (circuits) or equipment cannot be grounded, due to its design or other restrictions, it must be isolated. As part of safe working practices, the lockout/tagout process requires a circuit be deenergized, tested dead, isolated, tested dead, locked out, tagged, and grounded.

Table J-1 Lockout/Tagout Sequence

Steps to Place a Circuit in an Electrically Safe Work Condition	
1	Notify all affected workers of hazards, their control, and any possible stored energy.
2	Prior to shut down, check voltage to ensure test meters are working properly.
3	Shut down the system by isolation of energy sources. System is made inoperative.
4	Secure all energy source shutdown methods by lockout/tagout/tryout of controls. Tryout refers to verification of successful lockout/tagout.
5	Release any stored energy and verify such release.
6	Verify by testing that the system is deenergized (no voltage). Test each phase conductor or circuit part both phase-to-phase and phase-to-ground. Before and after each test, determine that the voltage detector is operating satisfactorily. The test also determines if any energized condition exists as a result of inadvertently induced voltage or unrelated voltage backfeed.
7	Test meter on known source to ensure testing meters are working properly. Do not use a meter's "self-check" feature to verify the test meter is working properly in lieu of using a known source.
8	Provide temporary grounding.
Steps to Reenergize a Circuit	
1	Inspect the work area for an operationally intact system and remove nonessential items.
2	Notify all affected workers that system will be reenergized and warn them to stand clear.
3	Remove temporary grounding.
4	Remove lockout/tagout devices.
5	Visually determine that all affected workers are clear of the circuit.
6	Check voltage and phasing before re-energizing system.
7	Proceed with restoring service.

J-1.1 Development of Procedures.

Establish safe clearance and lockout/tagout procedures at each base or facility. Each service has documents controlling this process; refer to Section 6 for a list of documents.

J-1.2 Lockout.

If a device is listed on the Safe Clearance and is capable of being locked out, then apply a lock. Release any stored energy and verify such release. Use of only tagout and not lockout must be justified on the Safe Clearance. This might occur when the device is not physically configured to accept and cannot be adapted for a lockout device. In these cases, the Safe Clearance must include provisions for other means to provide a level of safety equivalent to that obtained by a lockout.

J-1.3 Tagouts.

Apply Danger (red) tags to prohibit changing the position of devices by unauthorized persons. All energy-isolating devices must be provided with a Danger tag, even those locked out. Use a Danger tagout for each Safe Clearance. Use Caution (yellow) tags in connection with a Safe Clearance to provide precautions necessary before operation of a switch or other device. Out-of-Order tags are not used as part of a Safe Clearance. If used, green tags indicate placement of a ground on a circuit or equipment. Tags and tag ties must be nonreleasable, with a minimum strength of no less than 50 lb (23 kg).

J-1.4 Preparation of the Safe Clearance Form (Switching Order).

The details and the person preparing the Safe Clearance must include:

- Details of blocking, switching, tags, and locks. A second worker who is at least classified as an electrical journeyman must check this information. This check must be done before beginning any switching. Enter details in their proper sequence, reading down the form. Include any switch operations (such as opening or shutting) necessary to transfer load or put other equipment into operation.

- Supplemental direction, if necessary, to be provided to the crew involved in the work to ensure their understanding of boundaries of coverage of the Safe Clearance.

J-1.5 Issue (Approval) of the Safe Clearance Form (Switching Order).

Only designated persons must be authorized to issue (approve) Safe Clearances for work by qualified personnel. These persons must be designated in writing in accordance with local procedures. The designated person in issuing (approving) a Safe Clearance must ensure that the following objectives have been met:

- Inclusion of the correct switching and equipment operations sequence.

- Provisions are included to discharge and ground capacitors and other sources of stored electrical energy that might endanger personnel.

- Provisions are included to discharge or block the release of stored non-electric energy (such as springs) in any device that could cause electric circuits to re-energize.

- Selection of a qualified worker who is authorized to receive the approved Safe Clearance and then perform the required switching and operations.

The qualified worker must have previously been approved in writing as one authorized to receive a Safe Clearance.

- Arrangements have been made for any necessary interruption of service, such as notifying users and notifying the utility company supplying power to the facility. Notifications to the utility company must be given to the person designated by the utility company to receive such information. In the event this individual cannot be reached, the nearest system operating or load dispatching office of the company must be informed.

J-1.6 Safe Clearance Form Description.

Detailed information follows section by section, for completing the Safe Clearance form.

J-1.6.1 Record Number.

A consecutive number must be assigned from records maintained in the appropriate (locally designated) office.

J-1.6.2 Other Clearance Numbers.

When feasible, only one safe clearance should be issued. If more than one safe clearance will be issued, or more than one crew assigned to the work, one authorized individual-in-charge must be responsible for all the crews and supervise the receipt of all safe clearances and the removal of lockouts and tagouts. Additionally, if more than one safe clearance is to be issued on the same line or equipment, show the serial numbers of the other clearances in the upper right-hand box.

J-1.6.3 Issued By, Time, and Date.

Provide the name and signature of the person issuing the Safe Clearance and time and date of issuance. This person is often the electrical supervisor.

J-1.6.4 Issued To.

Fill in the name of the person receiving the Safe Clearance. Safe Clearances must be issued only to workers authorized to receive them. A list of all such workers must be kept in the office that contains Safe Clearance records. The worker receiving a Safe Clearance is responsible for checking all lockouts and tagouts, especially being assured that all points of possible feed, including stored-energy devices, are open, locked out, and provided with correct tagouts.

J-1.6.5 Line/Equipment Involved.

Give a brief description of the lines or equipment on which work is to be performed. This information is prepared prior to issuance of the Safe Clearance.

J-1.6.6 Details of Blocking and Tagging.

Step-by-step instructions and supplemental information are provided relative to hanging tags and installing lockouts. This information is prepared prior to issuance of the Safe Clearance.

J-1.6.7 Time Applied.

Progressing downward in proper sequence of the form, fill in the actual time each step of the details is performed.

J-1.6.8 Released By, Time Released, and Date Released.

Provide the name and signature of the person releasing the Safe Clearance. This is usually the authorized individual-in-charge for the job. The person releasing a Safe Clearance is responsible for making sure that all workers and temporary grounds are clear and that the line or equipment is ready to return to service.

Note: Switching operations, and removal of lockouts and tagouts are not yet approved or accomplished at this point.

J-1.6.9 Accepted By.

Provide the name and signature of the person accepting the release of the Safe Clearance. This is often the same person that issued the Safe Clearance. If more than one Safe Clearance is issued for the same equipment or location, this person is also responsible for ensuring all Safe Clearances are released before any change is made in lockouts or tagouts. Once accepted, removal of lockouts and tagouts may be authorized, and switching operations may be performed to restore the line or equipment to service.

J-1.6.10 Time Removed.

Beginning with the last detail of switching, lockout, and tagout on the Safe Clearance, perform the reverse operation, progressing upward on the form, and enter the time each operation is performed. For instance, if a detail of switching, lockout, and tagout reads “Switch ‘A’ open and hang danger tag” the opposite operation is “remove danger tag and Switch ‘A’ shut.” Do not operate the equipment or perform any switching operation after removing your danger tag if it is still tagged with another danger tag.

Note: If lockouts and tagouts have been installed for more than one Safe Clearance on the same equipment or line, perform no switching operations until releases have been accepted for all Safe Clearances.

J-1.6.11 Notification.

Return the completed Safe Clearance form to the office that retains Safe Clearance records.

J-1.7 Lockout and Tagout Precautions.

J-1.7.1 Single Blade Stick-Operated Disconnect Switches.

A single blade, stick-operated disconnect switch cannot be mechanically blocked open and ordinarily is not capable of being locked out. In this case, a danger tag hung on each phase would normally be considered an acceptable provision for electrical safety. Suitable tag holders, made of insulating material and designed for installation with a hot stick, must be used on single blade stick-operated disconnect switches, fused cutouts, open jumpers, and similar visible line breaks.

J-1.7.2 Gang-Operated Switches.

Gang-operated switches are normally designed to be locked open and a single danger tag must be tied on the locked switch. Tag must be secured with minimum 50-pound pull-rated tie.

J-1.7.3 Overhead Lines.

On overhead lines, a visible line break must be provided at all points of possible feed. An opened circuit breaker is not normally acceptable in lieu of a visible line break on overhead systems and must be used only when it is not feasible to remove the line side leads from the circuit breaker bushings and it is not possible to provide a visible line break near the circuit breaker. If a circuit breaker is used for electrical isolation, the circuit breaker must be mechanically blocked or locked open, and a danger tag tied on the circuit breaker. Additionally, the authorized individual-in-charge must ensure workers are particularly careful in determining that the line is actually deenergized. Also, temporary grounds must be installed on overhead systems as close as possible to the worker. Tag must be secured with minimum 50-pound pull-rated tie.

J-1.7.4 Underground Lines.

On underground systems, it is often not feasible to provide a visible line break. For these systems, use of a circuit breaker or subway disconnect switch locked or blocked mechanically in the open position and provided with a danger tag is acceptable. The authorized individual-in-charge must ensure workers are particularly careful in determining that the line is actually deenergized. Also, temporary grounds must be installed on underground system as close as possible to the worker.

J-1.7.5 Fused Cutouts.

Fuse cutouts must be blocked or locked in the open position, the fuse block removed, and the clamp provided with a Danger tag.

J-1.7.6 Normally Open Switches.

A Caution tag must be hung on a normally open switch if it has been closed to tie two lines together prior to taking a line out of service. For example, a normally open switch might be closed to provide an alternate source for a line that is downstream of the intended work location. The position of the switch with the Caution tag must not be changed without prior approval of the authorized individual-in-charge. When all work is completed, this Caution tag will be removed as part of returning the system to its normal operating lineup. If the position of the switch with the Caution tag is to remain in the changed position (the normally open point in the system has moved to another location), the Safe Clearance must be updated with the new position and the date and time the change was made. Update system documentation to reflect the modified system configuration. Tag must be secured with minimum 50-pound pull-rated tie.

J-2 ENERGY CONTROL (LOCKOUT/TAGOUT).

J-2.1 Low-Voltage Levels.

Maintain the minimum approach distances given in Table 3-1 and wear appropriate personal protective equipment until the lines and equipment are positively proven to be in an electrically safe working condition. Safe Clearance procedures apply to low-voltage levels. Lines and equipment must be positively proven to be in an electrically safe work condition before work is begun. A locally approved voltage detector may be used for this test in conjunction with a direct contact voltmeter. Test each phase conductor or circuit part both phase-to-phase and phase-to-ground. Before and after each test, determine that the voltage detector is operating satisfactorily. Determine by test if any energized condition exists as a result of inadvertently induced voltage or unrelated voltage backfeed. A meter's "self-check" feature cannot be used to verify the test meter is working properly in lieu of using a known source. All energized conductors or equipment within reach of workers must be covered with insulating material or approved rubber protective equipment. Temporary grounding must be installed on lines and equipment to be worked on, unless the authorized individual-in-charge determines that temporary grounding is not practical. The authorized individual-in-charge must explain to the work crew the reasons for not installing temporary grounding. If it is not practical or possible to install temporary grounding then other methods of protection must be provided, such as, circuit breakers racked out to the disconnected position, removal of fuses from disconnect switches, disconnect conductors from terminals to isolate the circuit or equipment being worked on, or other methods. When pulling in new conductors near energized conductors, the new conductors must be provided with temporary grounds, and treated as if energized until the work is complete. Always treat bare wire communication conductors and neutrals on power poles as energized lines and use appropriate personal protective equipment.

J-2.2 High-Voltage Levels.

Maintain the minimum approach distances given in Table 3-1 and wear appropriate personal protective equipment until the lines and equipment are proven to be in an electrically safe work condition. Use a locally approved voltage detector for this purpose. Test each phase conductor or circuit part both phase-to-phase and phase-to-ground. Before and after each test, determine that the voltage detector is operating satisfactorily. Determine by test if any energized condition exists as a result of inadvertently induced voltage or unrelated voltage backfeed. A meter's "self-check" feature cannot be used to verify the test meter is working properly in lieu of using a known source. If an energized conductor is not available for the check, the detector may be checked on a spark plug of a running gasoline-powered engine. Commercially available spark testing devices can also be used. Include the following:

- Confirm that reactors and connected equipment are in an electrically safe work condition.

- Discharge surge arresters and stored energy devices in accordance with manufacturer's recommendations or local instructions.

After the lines or equipment have been proven to be in an electrically safe work condition, install a cluster mount ground on the pole the worker is working. When installing temporary grounds, make the earth connection first and then connect to the conductor or equipment. Use a hot stick when making the connection to the conductor due to the hazard of static discharge. When removing temporary grounds disconnect the earth connection last. Refer to Section 7 for additional grounding information.

APPENDIX K GLOSSARY

Abbreviations and Acronyms:

ac—Alternating Current

AED—Automatic External Defibrillator

AFCEC—Air Force Civil Engineer Center

AFI—Air Force Instruction

AHJ—Authority Having Jurisdiction

ANSI—American National Standards Institute

AR—Arc Rated

ASTM—American Society for Testing and Materials

AWG—American Wire Gauge

BIL—Basic Impulse Insulation Level

cal/cm^2—Calories per centimeter squared

CFR—Code of Federal Regulations

cm—Centimeter

CPR—Cardiopulmonary Resuscitation

CT—Current Transformer

dB—Decibel

dc—Direct Current

DoD—Department of Defense

EM—Electromagnetic

EMS—Emergency Medical Service

ER—Engineering Regulation

FRP—Fiberglass-Reinforced Plastic

ft—Feet or foot

HID—High Intensity Discharge

HQ—Headquarters

HVAC—Heating, Ventilating, and Cooling

Hz—Hertz

I—Amperes

IEEE—Institute of Electrical and Electronics Engineers

in—inch

ISEA – International Safety Equipment Association

J—Joules

J/cm^2—Joules per centimeter squared

JHA—Job Hazard Analysis

JSA—Job Safety Analysis

kg—Kilogram

kW—Kilowatts

kWh—Kilowatt Hours

kV—Kilovolts

kVA—Kilovolt-Amperes

L—Liter

lb—Pound

LEL—Lower Explosive Level

m—Meter

MDF—Main Distribution Frame

MI—Mineral Insulated

MIL HDBK—Military Handbook

mm—Millimeter

MOV—Metal Oxide Varistor

MTS—Maintenance Testing Specifications

NAVFAC—Naval Facilities

NEC—National Electrical Code

NEMA—National Electrical Manufacturers Association

NESC—National Electrical Safety Code

NETA—International Electrical Testing Association

NFPA—National Fire Protection Association

O&M—Operations and Maintenance

ORM— Operational Risk Analysis

OSHA—Occupational Safety and Health Administration

PCB—Polychlorinated Biphenyl

PPE—Personal Protective Equipment

PT—Potential Transformer

R—Resistance

RE—Remote

RMS—Root-Mean-Square

SDS—Safety Data Sheet

SF_6—Sulfur Hexafluoride

SOP—Standard Operating Procedure

SWD—Switching Duty

W—Watts

X—Reactance

X/R—Ratio of Reactance to Resistance

Terms:

Note: The terms listed here are provided for clarification of the design criteria provided in this UFC. Refer to IEEE 100, *The Authoritative Dictionary of IEEE Standards Terms*, for additional electrical-related definitions.

Accessible, Readily (as applied to equipment)— Capable of being reached quickly for operation, renewal, or inspections without requiring those to whom ready access is requisite to actions such as to use tools, to climb over or remove obstacles, or to resort to portable ladders, and so forth.

Ampacity—The current, in amperes, that a conductor can carry continuously under the conditions of use without exceeding its temperature rating.

Approved—Acceptable to the authority having jurisdiction.

Arc Duration—The time span of an arc from initiation to extinction, usually specified as a number of cycles of current, typically 60 Hz or 50 Hz.

Arc Energy—The total energy discharged to a surrounding area by an electric arc.

Arc Rating—The value attributed to materials that describes their performance to exposure to an electrical arc discharge. The arc rating is expressed in cal/cm^2 and is derived from the determined value of the arc thermal performance value or energy of breakopen threshold. Arc rated clothing or equipment indicates that it has been tested for exposure to an electric arc. Flame resistant clothing without an arc rating has not been tested for exposure to an electric arc. All arc rated clothing is also flame resistant.
Arc Thermal Protective Value—For protective clothing is the minimum incident thermal energy that causes the onset of a second-degree burn based on the energy transmitted through the clothing.

Authority Having Jurisdiction (AHJ)— An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

Authorized Person—A person approved or assigned by a supervisor to perform a specific duty or duties or to be at a specific location or locations at the job site.

Available Short-Circuit Current—The maximum current that the power system can deliver through a given circuit point to any negligible impedance short circuit applied at the given point, or at any other point that will cause the highest current to flow through the given point.

Barehand Work—A technique of performing work on live parts, after the employee has been raised to the potential of the live part.

Barricade—A physical obstruction such as tape, cones, or structures intended to provide a warning about and to limit access to a hazardous area.

Barrier—A physical obstruction that is intended to prevent contact with equipment or energized electrical conductors, or to prevent unauthorized access to a work area.

Blocking—Placing a switch in the open or closed position and mechanically ensuring the position of the switch cannot be accidentally changed.

Bolted Fault—The highest magnitude short circuit current for a particular fault location. The impedance at the fault location is usually very low or zero for a bolted fault.

Bonding—A reliable connection to assure electrical conductivity. In terms of grounding, the permanent joining of metallic parts to form an electrically conductive path to assure electrical continuity with the capacity to conduct safely any current likely to be imposed.

Bonding Conductor—A conductor used specifically for the purpose of bonding.

Boundary, Arc Flash—The distance from an arc source (energized exposed equipment) at which the potential incident heat energy from an arcing fault on the surface of the skin is 1.2 cal/cm^2 (5 J/cm^2). Within this boundary, workers are required to wear protective clothing, such as arc rated shirts and pants and other PPE. This boundary was previously referred to as the Flash Protection Boundary by NFPA 70E.

Boundary, Limited Approach—An approach limit at a distance from an exposed energized electrical conductor or circuit part within which a shock hazard exists.

Boundary, Restricted Approach—An approach limit at a distance from an exposed energized electrical conductor or circuit part within which there is an increased likelihood of electric shock, due to electrical arc-over combined with inadvertent movement, for personnel working in close proximity to the energized electrical conductor or circuit part.

Cardiopulmonary Resuscitation (CPR)—An emergency medical procedure which includes opening and maintaining an airway, providing ventilation through rescue breathing, and providing artificial circulation through the use of external cardiac compression.

Circuit Breakers Incorporating Ground Fault Protection—Circuit breakers that perform all normal circuit breaker functions and also trip when a current to ground exceeds some predetermined value.

Circumaural—ear protection type that covers the outer/external part of the ear.

Clearing Time—The total elapsed time between the beginning of an overcurrent and the final interruption of the circuit at rated voltage. For a fuse, the clearing time is considered the sum of the melting time and the arcing time. For a breaker, the clearing time is the elapsed time between the actuation of a release device and the instant of arc extinction on all poles of the primary arcing contacts.

Conductor—A material (usually a wire, cable, or bus bar) for carrying an electric current. *Note: This term is used only with reference to current carrying parts which are sometimes alive (energized)*.

Cycle—One cycle equals 1/60th of a second for 60 Hz current, or 1/50th of a second for 50 Hz current.

Dead Front—Without live parts exposed to a person on the operating side of the equipment.

Deenergized—Free from any electrical connection to a source of potential difference and from electrical charge; not having a potential different from that of the earth.

Earth Ground—An electrical connection to earth obtained by a grounding electrode system.

Electrical Hazard—A dangerous condition such that contact, or equipment failure can result in electric shock, arc flash burn, thermal burn, or blast.

Electrically Safe Work Condition—A state in which a conductor or circuit part has been disconnected from energized parts, locked/tagged in accordance with established standards, tested to ensure the absence of voltage, and grounded if determined necessary.

Emergency Lighting System—A system capable of providing minimum required illumination specified in NFPA 101, *Life Safety Code*, Section 5.9. It includes the lighting units, related backup power source(s), and required connections.

Energized—Electrically connected to, or is, a source of voltage.

Energized Work—Work on or near (e.g., part of tools being used or worker's body less than restricted approach boundary) energized or potentially energized lines (i.e., grounding, live-tool work, hotstick work, gloving, and bare hand work).

Equipment—A general term, including fittings, devices, appliances, luminaires, apparatus, machinery, and the like, used as a part of, or in connection with, an electrical installation.

Equipment – Climbing—Includes body belts, safety and climber straps, climbers, and ladders.

Equipment – Electrical Inspecting and Testing—Electrical and mechanical devices such as voltmeters, ammeters, ohmmeters, phase meters, and similar devices.

Equipment – Mobile and Portable Large Equipment—Relatively large equipment items easily transported for maintenance, which must include line trucks, aerial lift trucks, motor-generator sets, pole hole diggers, and similar apparatus.

Equipment – Protective— Includes rubber gloves, matting, blankets, insulator hoods, and sleeves, in addition to barricades and warning devices.

Equipment Grounding Conductor—The conductor used to connect the non-current carrying parts of conduits, raceways, and equipment enclosures to the grounded conductor (neutral) and the grounding electrode at the service equipment (main panel) or secondary of a separately derived system, such as an isolation transformer.

Exposed (as applied to energized electrical conductors or circuit parts)—Circuit is in such as position that, in case of failure of supports or insulation, contact with another circuit may result. Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to parts that are not suitably guard, isolated, or insulated.

Gloving—A method of performing maintenance on energized electrical conductors rated above 600 volts and equipment whereby a worker or workers, wearing specially-made and tested insulating gloves, with or without sleeves, and using cover-up equipment while supported by the structure or insulated aerial lift equipment, work(s) directly on the energized electrical conductor or equipment.

Ground—A conducting connection, either intentional or accidental, by which an electric circuit or equipment is connected to the earth, or to some conducting body of relatively large extent that serves in place of the earth.

Grounded (Grounding)—Connected (connecting) to ground or to a conductive body that extends the ground connection.

Grounded Neutral—A point of an electrical system that is intentionally connected to ground.

Grounded, Solidly— Connected to ground without inserting any resistor or impedance device.

Ground-Fault Circuit Interrupter—A device intended for the protection of personnel that functions to deenergize a circuit or portion thereof within an established period of time when a current to ground exceeds some predetermined value that is less than that required to operate the overcurrent protective device of the supply input.

Heat Flux—The thermal intensity of an arc that is incident by the amount of energy transmitted per unit area and per unit of time, measured in calories per square centimeters per second ($cal/cm^2/sec$).

High Voltage—For the purposes of this UFC, high voltage is defined as above 1,000 volts. IEEE 100 defines a high voltage system with a rms voltage above 72,500 volts.

I^2t—Heating caused by current as a function of time.

Incident Energy— The amount of thermal energy impressed on a surface, a certain distance from the source, generated during an electrical arc event. Incident energy is typically expressed in calories per square centimeter (cal/cm^2).

Job Hazard Analysis (JHA)—see Job Safety Analysis.

Job Safety Analysis (JSA)—A method for studying a job in order to identify hazards or potential hazards associated with each step or task involved. Additionally, it is used to develop controls or solutions to eliminate or mitigate those hazards identified. Also, referred to as a Job Hazard Analysis (JHA).

Listed—Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

Live (Energized or exposed)— “Hot” electrically connected to a source of potential difference or electrically charged to have a potential significantly different from the earth in the vicinity. The terms “live” or “hot” are sometimes used in place of the term “current carrying” where the intent is clear to avoid repetition of the longer term.

Live Front—With live parts exposed to a person on the operating side of the equipment.

Live-Line Tool—A type of insulating tool used in various operations of energized work. This includes hot sticks.

Live Parts—Energized conductive components.

Low Voltage System—An electrical system having a maximum root-mean-square (rms) voltage of less than 1,000 V.

Mishap—An unplanned or unsought event or series of events that results in death, injury, or occupational illness or damage to or loss of equipment or property.

Medium Voltage System—An electrical system having a maximum rms ac voltage of 1,000 to 72,500 volts. For the purposes of this UFC, any voltage above 1,000 volts is referred to as “high voltage.”

Qualified Person—One who has demonstrated skills and knowledge related to the construction and operation of electrical equipment and installations and has received safety training to identify and avoid the hazards involved.

Risk Assessment—An overall process that identifies hazards, estimates the potential severity of injury or damage to health, estimates the likelihood of occurrence of injury or damage to health, and determines if protective measures are required.

Supervisor—Refers to the supervisor of “employees or workers” as used in this instruction. Generally, includes the supervisor responsible for exterior electrical systems, the zone supervisor or foreman, and the infrastructure support element supervisor. Titles are necessary to assign specific responsibilities to a specific individual.

Shock Hazard—A dangerous condition associated with the possible release of energy caused by contact or approach to energized electrical conductors or circuit parts.

Switch, Isolating—A switch intended for isolating an electric circuit from the source of power. It has no interrupting rating, and it is intended to be operated only after the circuit has been opened by some other means.

Tagging—Placing a safety tag directly on a circuit opening device or equipment for additional safety to ensure it is not used or its position altered.

Tags—Temporary signs (usually attached to a piece of equipment or part of a structure) to warn of existing or immediate danger.

Unqualified Person— Any person who is not a qualified person.

Voltage—The greatest root-mean-square (rms) (effective) difference of potential between any two conductors of the circuit concerned.

Working On (Energized Electrical Conductors or Circuit Parts)—Intentionally coming in contact with energized electrical conductors or circuit parts with the hands, feet, or other body parts, with tools, probes, or with test equipment, regardless of the personal protective equipment (PPE) a person is wearing. There are two categories of “working on”: Diagnostic (testing) is taking readings or measurements of electrical equipment with approved test equipment that does not require making any physical change to the equipment; repair is any physical alteration of electrical equipment (such as making or tightening connections, removing or replacing components, etc.).

This UFC supersedes UFC 3-570-02A, dated March 2005 and 3-570-02N dated January 2004.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

(Installations and Environment)

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 3-570-01, *Cathodic Protection*

Superseding: UFC 3-570-02A, *Cathodic Protection*, March 2005
UFC 3-570-02N, *Electrical Engineering Cathodic Protection*, Jan 2004

Description: This UFC provides general design guidance for cathodic protection (CP) systems. This UFC applies to all Army, Navy, and Air Force service elements and contractors.

Reasons for Document:

- Update the format of the manual (more of a policy and guidance manual instead of a technical cookbook on design) and unify UFC 3-570-02A and UFC 3-570-02N.

- Incorporate policy, guidelines, and procedures previously identified in Engineering Technical Letters and Interim Technical Guidance Documents.

- Provide additional guidance to the Project Design Engineer (PDE) in managing CP design contracts and guidance on commissioning of CP systems.

- Incorporate information regarding new technologies and update obsolete technical information.

Impact:

- Clarifies policy where CP must be provided. Provides more guidance to the PDE managing a CP Architect-Engineer (A-E) design contract to help improve designs. Previously, the manual only described technical requirements for the actual designers. Helps ensure CP provided where necessary and properly designed to ensure economical long-term facility/structure life cycle cost.

Unification Issues

- \1\Para 2-2 Structures for which CP is Mandatory. Navy has relaxed this for some structures and requires these structures to be evaluated for CP requirements.

- Para 2-3 Navy has relaxed the mandatory requirement that DoD CP systems reviewers be certified. /1/

TABLE OF CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides policy and design requirements for cathodic protection (CP) systems. This document provides the minimum design requirements, and must be utilized in the development of plans, specifications, calculations, and Design/Build Request for Proposals (RFP).

UFC 3-501-01, *Electrical Engineering*, provides the governing criteria for electrical systems, explains the delineation between the different electrical-related UFCs, and refers to UFC 3-570-01 for Cathodic Protection requirements. Refer to UFC 3-501-01 for design analysis, calculation, and drawing requirements.

1-2 APPLICABILITY.

Compliance with this UFC is mandatory for Department of Defense (DoD) facilities located on or outside of DoD installations, whether acquired by appropriated or non-appropriated funds, or third party finance and constructed.

\1\For Navy projects, third party financed and constructed projects are not required to meet this UFC's requirements except for provision and extension of Navy-owned or Government-owned systems and infrastructure that are extended to the third party's site. /1/

1-3 GENERAL BUILDING REQUIREMENTS.

UFC 1-200-01, *General Building Requirements*, provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, sustainability, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

\1\For Navy projects, the reference date is set by the contract or RFP date. /1/

1-5 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

1-6 CYBERSECURITY.

All control systems (including systems separate from an energy management control system), remote monitoring units, and automated data collection units must be planned, designed, acquired, executed and maintained in accordance with UFC 4-010-06; and as required by individual Service Implementation Policy.

1-7 RECONCILIATION WITH OTHER UNIFIED FACILITIES CRITERIA.

The CP requirements and criteria in this document will be reconciled with CP requirements and criteria in other UFCs so that the required criteria are located in a single location; the other UFCs and criteria documents will refer to UFC 3-570-01. In the event there is a conflict between these criteria and other criteria in another document, these criteria govern. The documents listed in Table 1-1 are known to be affected by the requirements and criteria in this document.

Table 1-1. UFC Documents Requiring Reconciliation of CP System Requirements and Criteria

DOCUMENT	TITLE

CHAPTER 2 CATHODIC PROTECTION SYSTEM PLANNING

2-1 INTRODUCTON.

In accordance with DoD Instruction 5000.67, *Prevention and Mitigation of Corrosion on DoD Military Equipment and Infrastructure*, consider corrosion prevention and control (CPC) as an integral part of the design, construction, sustainment, restoration and maintenance of all DoD infrastructure. Utilize CP systems to reduce corrosion of buried or submerged metallic structures, thus reducing the probability of failure and concomitant environmental, operational, safety, and economic repercussions. Petroleum, oil and lubricant (POL) systems, waterfront structures, and utility systems have been found to be the most critical facilities in terms of a combination of risk from corrosion, the need for continuous direct support of base operations, and the life cycle cost effectiveness of utilizing appropriate corrosion control systems.

CPC requirements development, pre-design surveys, system designs, and acceptance surveys must be accomplished under the supervision of one of the following individuals:

- NACE International certified Corrosion Specialist or Cathodic Protection Specialist with a minimum of five years of experience in the applicable CP system being designed.
- Where the qualification requirements are more restrictive or more stringent than any one of the above requirements, an appropriately certified person as required by applicable state/local laws, regulations, or requirements (primarily for underground storage tanks).

2-2 STRUCTURES FOR WHICH CP IS MANDATORY.

Regardless of soil or water corrosiveness, provide both CP systems and protective coatings for the following buried or submerged metallic structures:

- Petroleum, Oil, and Lubricants (POL) pipelines
- Underground POL/gas storage tanks, piping, and ancillary items
- Underground hazardous substance storage tanks
- Natural Gas and Propane Pipelines, including metallic components of non-metallic lines
- Fire protection water storage tanks
- Interior of all steel water distribution storage tanks, including the interior of elevated tank risers
- Oxygen Pipelines
- Other facilities with hazardous products as identified by the major commands, major claimants, or other competent authorities

\1\For Army and Air Force projects, CP for the following structures and systems is mandatory. For Navy projects, the following structures and systems are not considered mandatory by this UFC, but may be mandatory by specific system UFC or other documents. Evaluate these structures for CP by the paragraph titled Other Structures for Which Cathodic Protection must be Evaluated:

- Oil/water separators and all associated metallic fittings in contact with soil
- New Waterfront Structures
- Piping or water lines used with fire protection water storage tanks, including metallic components of non-metallic lines (i.e., PIV's, fire hydrants, change of direction devices, valves, metallic sections under building slabs and elsewhere, etc.)
- Metallic water distribution pipelines (including steel, ductile and cast iron pressurized piping) buried under concrete slabs (building foundations, runways, taxiways, parking aprons, wharf decks, and similar)
- Metallic components of force mains
- Sewage lift stations (all metallic components in contact with soil or liquids)
- Underground heat distribution and chilled water piping in metallic conduit/1/

2-2.1 POL Facilities and Structures.

Provide CP systems along with other corrosion control measures such as protective coatings and materials selection for all POL liquid fuel pipelines and storage facilities following the provisions of Code of Federal Regulations (CFR) Title 49 Chapter 1, Part 195, Transportation of Liquids by Pipeline, and CFR Title 40 Chapter 1, Part 112, Oil Pollution Prevention. Overseas installations must comply with the requirements of the Host Nation standards, DoD Overseas Environmental Baseline Guidance Document (OEBGD), and related specific Area Governing Standards. Coordinate CP system design with other POL related requirements in UFC 3-460-01.

2-2.2 Underground Storage Tank System.

Provide CP systems along with other corrosion control measures such as protective coatings and materials selection for all steel underground storage tank (UST) systems in accordance with CFR Title 40 Part 280, Technical Standards and Corrective Action for Owners and Operators of Underground Storage Tanks. By definition, the underground storage tank system includes the storage tank and associated piping. In addition, comply with State and Local government laws that may dictate additional or more stringent requirements. Overseas installations must comply with the requirements of the Host Nation standards, DoD OEBGD, and related specific Area Governing Standards. Ensure that UST CP systems are designed by a certified CP Specialist.

2-2.3 Natural Gas Pipe Lines.

Provide CP systems along with other corrosion control measures such as protective coatings and materials selection for all metallic natural gas pipelines in accordance with the provisions of CFR Title 49 Chapter 1, Part 192, Transportation of Natural and Other Gas by Pipeline.

2-2.4 Waterfront Structures.

Provide CP systems in conjunction with other protective measures such as proper material selection, protective coatings, and encasement, for the following submerged metallic waterfront structural systems:

- Steel sheet pile bulkheads along the waterfront or waterway
- Steel bearing piles for piers and wharves
- Steel fender piles for piers and wharves
- Submerged mooring components

Specify the proper type and size of galvanic or impressed current anodes to meet the desired CP system life. Do not specify magnesium anodes as the primary CP system for structures immersed in salt water.

2-2.5 Buried or Submerged Steel Utility Piping.

For all other steel utility piping, provide CP systems and bonded protective coatings on buried or submerged steel utility piping in which the electrolyte (soil or water) resistivity is less than 30,000 ohm-cm at the installation depth at any point along the piping installation.

2-2.6 Ductile or Cast Iron Utility Piping.

For all other ductile or cast iron utility piping and fittings, provide CP systems and protective coatings on buried or submerged new ductile or cast iron pipe in which the electrolyte resistivity is less than 30,000 ohm-cm at the installation depth at any point along the piping installation. Do not use unbonded protective coatings such as loose polyethylene wraps. Additionally, provide joint bonding for all ductile and cast iron installations. For non-metallic pipe with ductile or cast iron fittings, provide CP systems and protective coatings on buried or submerged new ductile or cast iron fittings in which the electrolyte resistivity is less than 30,000 ohm-cm.

\1\For Navy projects, the use of unbonded protective coatings, such as loose polyethylene wraps, is not prohibited. /1/

2-2.7 Potable Water Storage Tanks.

Provide CP and protective coatings for the interior submerged surfaces of potable water storage tanks, including bolted panel tanks in accordance with National Sanitation Foundation (NSF) Standard 61. Include requirements in the contract specifying that the contractor is responsible for providing an interior coating system and ensuring that the coating system is compatible with an impressed current CP (ICCP) system, if specified, and NSF Standard 61. For bolted panel storage tanks, require the contractor to ensure all panels of a bolted panel storage tank are electrically continuous.

2-2.8 Fire Protection Water Storage Tanks.

Fire protection water storage tanks are mission critical facilities and must be properly protected against corrosion. Provide an ICCP system for the interior submerged surfaces of all fire protection water storage tanks, including bolted panel tanks. When the backfill beneath an on-grade tank is corrosive, provide an ICCP system for the exterior bottom of the on-grade tank. Include requirements in the contract specifying that the contractor is responsible for providing an interior coating system and ensuring that the coating system is compatible with the ICCP system. For bolted panel storage tanks, require the contractor to ensure all panels of a bolted panel storage tank are electrically continuous.

\1\For Navy projects, allow ICCP or sacrificial anode (GCP) systems for fire protection water storage tanks. /1/

2-3 OTHER STRUCTURES FOR WHICH CATHODIC PROTECTION MUST BE EVALUATED.

Evaluate the economic feasibility of providing CP systems for the following buried or submerged systems:

- Gravity sewer lines
- Existing steel waterfront structures
- Reinforcing steel in concrete
- New or existing cast or ductile iron potable water lines (unless installed under a concrete slab) in soils with resistivity greater than 30,000 ohm-cm along its entire length
- Exterior bottom of on-grade steel water storage tanks
- Buried hydraulic elevator cylinders
- Other buried/submerged metallic structures not covered above

Installation of CP systems on these types of structures must be based on life-cycle economics. The overall corrosion protection system must include a combination of CP systems, protective coatings, proper material selection, encasement, or other methods. CP system requirements determined by non-DoD personnel (e.g., A/E's, private contractors, private consultants, etc.) must first be reviewed by a DoD qualified Corrosion Engineer or DoD NACE International certified cathodic protection specialist who subsequently recommends government approval prior to implementation.

\1\For Navy projects, delete the requirement that all CP system requirements be reviewed by a DoD Qualified Corrosion Engineer or DoD NACE International certified cathodic protection specialist. When available, DoD qualified CP personnel must be used for review. /1/

2-4 PROTECTIVE COATINGS SPECIFICIED IN CONJUNCTION WITH CATHODIC PROTECTION.

Protective coatings to be applied to a new metallic structure in conjunction with CP must have the minimum characteristics as described in NACE International SP0169 and the appropriate UFGS. Coordinate the coating type and requirements with the CP system being specified. Utilize the appropriate protective coating UFGS and supplement the UFGS requirements, as necessary, with the minimum coating characteristics indicated in NACE International SP0169, *Control of External Corrosion on Underground or Submerged Metallic Piping Systems*. Do not delete the CP requirements simply because it is not compatible with a particular coating.

2-5 ISOLATION OF COPPER WATER PIPES FROM FERROUS PIPES.

Dielectrically isolate copper water service lines from ferrous pipe in accordance with the requirements in NACE International SP0286, *Electrical Isolation of Cathodically Protected Pipelines*, unless not economically practicable. Where not practicable, design the CP system to include protection of both the copper and ferrous piping.

2-6 CP PROJECT PLANNING.

2-6.1 General CP Requirements.

Include CP system requirements as a separate line item in project documentation for the construction of new or the repair/upgrade of existing metallic structures as required by paragraphs 2-1 and 2-2. Cathodic protection systems are often not included in a project design because they are not appropriately identified in the project planning documents. Addition of these requirements later in the process often results in funding problems and other delays. Coordinate CP system requirements with the appropriate service CP subject matter expert or Major Command Corrosion Engineer. Refer also to the best practices in Appendix B.

2-6.2 Environmental/Site Concerns.

Identify environmental and site concerns. Prepare proper environmental Categorical Exclusions (CATEX), or if necessary, Environmental Impact Assessments (EIA) documentation prior to project execution. Refer also to paragraph 3-3.5.

This Page Intentionally Left Blank

CHAPTER 3 DESIGN REQUIREMENTS

3-1 INTRODUCTION.

This chapter identifies CP system technical design requirements and defines the data that must be developed to establish engineering design bases and to evaluate the proper type of CP system(s) to be provided.

3-2 APPLICABLE CODES AND REGULATIONS.

In addition to the policy in Chapter 2, ensure that the CP system design complies with the legal requirements in any of the applicable codes, regulations, and other documents:

- CFR Title 40 Chapter 1, Part 112, *Oil Pollution Prevention*
- CFR Title 40 Part 280, *Technical Standards and Corrective Action for Owners and Operators of Underground Storage Tanks*
- CFR Title 49, Chapter 1, Part 192, *Transportation of Natural and Other Gas by Pipeline*
- CFR Title 49, Chapter 1, Part 195, *Transportation of Liquids by Pipeline*
- Department of Defense, *Overseas Environmental Baseline Guidance Document* and the appropriate regional/country Final Governing Standards.
- State or locality laws and regulations with more stringent CP requirements than the Federal laws and regulations.

Design agents doing Air Force designs will also comply with the requirements in Air Force Instruction 32-1054, *Corrosion Control*.

3-3 SYSTEM DESIGN.

Design CP systems in accordance with the policy in Chapter 2, applicable codes and regulations in paragraph 3-2, and the requirements of this section. Refer also to the best practices and lessons learned in Appendix B.

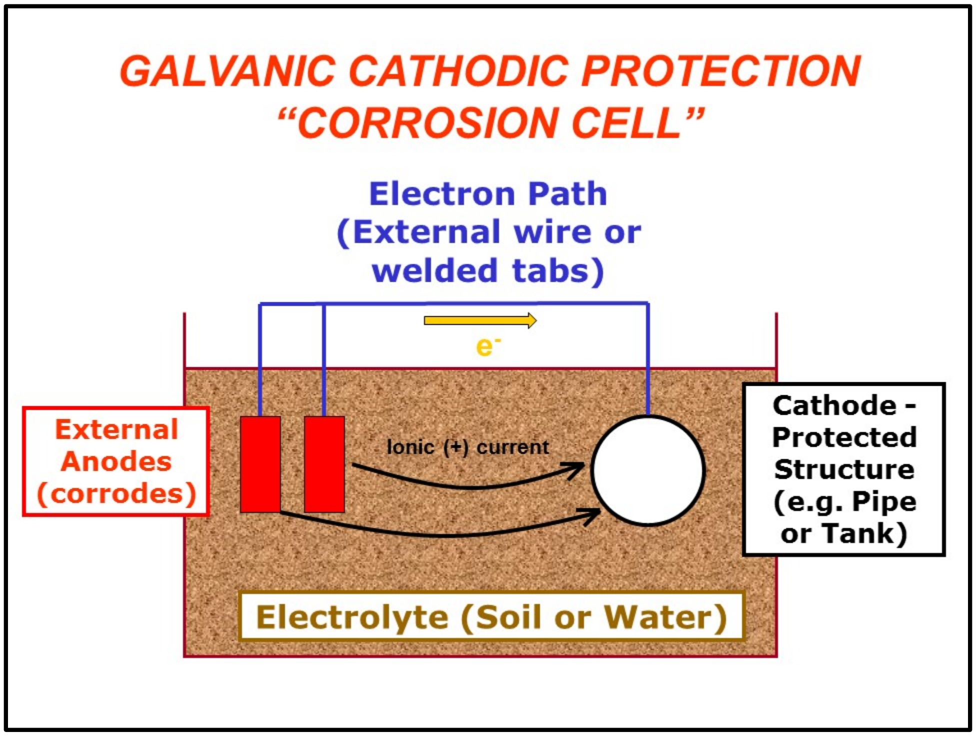
3-3.1 Two types of CP systems.

Select the CP system type, sacrificial anode (GCP) or ICCP, based on feasibility and cost. An economic analysis may be necessary to determine the system with the best life-cycle cost. In general, systems with small stable current requirements (0.5 Amp or less per 100 linear feet of structure) are more likely to be protected using sacrificial anode type systems. Those structures with larger current requirements (1 amp or more per 100 lineal feet of structure), or where the current requirements vary considerably with time, are more likely to require ICCP systems.

3-3.1.1 Galvanic (Sacrificial) Anode Systems.

A galvanic (sacrificial) anode CP system is essentially a controlled electrochemical cell. Figure 3-1 illustrates such a system. The structure becomes the cathode in the electrochemical cell, and corrosion that would have occurred on the structure being protected is mitigated due to the corrosion of the anode. The anode is consumed in the process but can usually be replaced when consumed. Anode life of 10 to 15 years is common, although lifetime can be limited by other factors such as mission requirements or mechanical damage.

Figure 3-1 Schematic Illustration of a GCP System

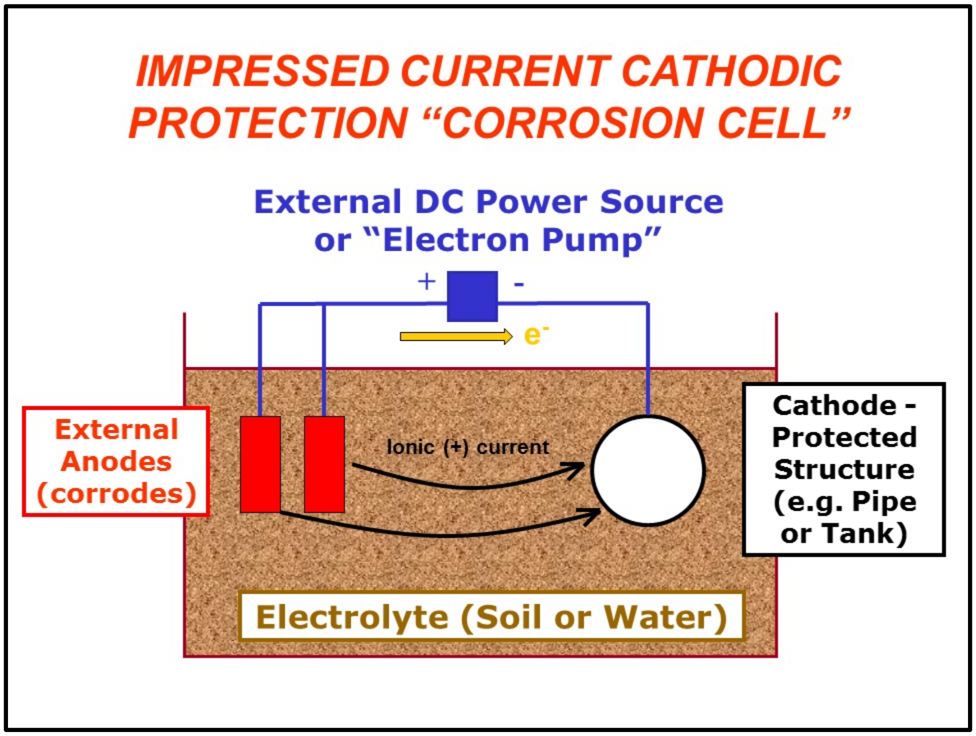


The structure and ancillary components intended for protection by sacrificial anodes must be electrically continuous. Conversely, other buried metals electrically continuous with the structure to be protected, but are not intended to be protected by the CP system, must be electrically isolated from the protected structure.

3-3.1.2 Impressed Current Systems.

Impressed current CP systems are also essentially controlled electrochemical cells. However, in the ICCP system, a supply of direct electrical current is used to develop the potential difference between the anode and the structure being protected as Figure 3-2 illustrates. The direct current source supplies current from the anode through the electrolyte to the surface of the structure being protected. Like sacrificial anodes, ICCP anodes are also consumed, although typically at a much lower consumption rate. Anode life of 20 to 25 years is common; although similar to GCP systems, lifetime can be limited by other factors such as mission requirements or mechanical damage.

Figure 3-2 Schematic Illustration of an ICCP System



As with GCP systems, the structure and ancillary components intended for protection by ICCP systems must be electrically continuous. Conversely, other buried metals electrically continuous with the structure to be protected, but are not intended to be protected by the CP system, must be electrically isolated from the protected structure.

3-3.2 Field Surveys and Tests.

Conduct a field survey to determine site conditions required to adequately design a CP system. Perform specific investigations and field tests at the proposed installation site(s) to evaluate as a minimum:

- Electrolyte corrosivity (resistivity, pH, etc.)
- CP system current requirements
- Suitable anode bed locations, including geological concerns
- Available electrical power
- Location of rectifiers
- Overall terrain around the structure (location of test stations)
- Easement issues for structures located off station
- Possible environmental concerns
- Constructability issues (physical and operational)

- Location of existing nearby CP systems and potential stray current concerns. Review of a published Base Corrosion Control Plan.
- Security restrictions that may impact cost
- Communication with local Corrosion Coordinating Committees for structures located off station

3-3.3 Availability of AC Power (ICCP Systems).

During the site survey, determine the availability of alternating current (AC) power at the site as the cost of installing new AC power service may be an important factor in determining whether a sacrificial or ICCP system is the more practical solution for the specific application. Where practicable, locate the ICCP rectifier nearby a building with available AC power and comply with applicable fire safety codes.

Design required electrical service in accordance with UFC 3-501-01. The electrical service design must be accomplished under the supervision of a registered professional electrical engineer.

3-3.4 Environmental/Site Concerns.

Consider the numerous environmental and safety concerns that may significantly impact the selection of CP system type, materials specified, system component installation procedures and controls, design document preparation, and the overall cost of the project. Consult with environmental and safety personnel during the early stages of design to identify the concerns and allow ample time for the designer to address these concerns. The following are some examples:

3-3.4.1 Hazardous Material.

Identify existing hazardous material at the proposed project site. These should be identified in the required environmental documents.

3-3.4.2 Archaeological/Historic Preservation Requirements.

Identify archaeological/historic preservation requirements and limitations at the proposed project site. This should also be identified in the required environmental documents.

3-3.4.3 Federal, State and Local Regulations.

Review and comply with Federal, state and local regulations that may affect the CP system installation. Some states have specific regulations regarding the design and installation of CP systems for underground storage tanks.

3-3.4.4 Mercury-Containing Anodes.

Avoid specifying mercury-containing aluminum alloy anodes. Consult with local/state regulators regarding concerns about the use of zinc anodes in certain situations.

3-3.4.5 Water Storage Tanks.

Specify anodes and other related components in water storage tanks that comply with National Sanitation Foundation/American National Standards Institute (NSF/ANSI) Standard 61.

3-3.4.6 Issues That May Impact Construction/Installation.

Address issues that may impact the construction/installation process, particularly, the drilling or excavation for installation of the anodes:

- Address requirements and specify procedures and controls when hazardous material is encountered.
- Address requirements and specify procedures and controls when drilling into the ground water table. Specify controls for preventing cross contamination of ground water aquifers.
- Specify construction site controls to prevent pollution of the environment.
- Specify safety requirements applicable to the site and specific installation.

Review the appropriate UFGS sections for environmental and safety requirements to ensure the applicable concerns are addressed. Provide design documents to the base/DoD installation environmental and safety personnel for review to ensure the requirements are properly addressed.

3-3.5 Electrical Continuity.

Determine locations and provide bonding to ensure electrical continuity of all buried metallic structures that are intended to be protected by the CP system. All electrically discontinuous section(s) of the structure(s) to be protected must be properly bonded into the system to ensure adequate protection. Common causes of electrical discontinuities include:

- Dresser couplings.
- Mechanical pipe section connections such as found in ductile iron pipe.
- Plastic valves and fittings.
- Non-metallic sections of pipeline (new, existing or future installation).
- Improper bonding (or lack of bonding) on joints, flanges or previously installed dielectric isolation unions or flanges.

If electrical discontinuities cause the pipeline system to be too fragmented, and continuity bonding is not feasible, consider providing multiple smaller separate CP systems for the electrically discontinuous sections of structure. Some isolated sections of pipelines may be small enough to use a GCP system, but the designer must consider possible interference problems on these sections.

3-3.5.1 Tracer Wires on Plastic Pipe.

When plastic pipe is used to replace or extend existing pipe, exothermically weld an insulated No. 8 American Wire Gage (AWG) copper wire to the existing steel pipe and run the wire along the full length of the plastic pipe for continuity and locator tracing purposes. As this may not always be technically feasible; alternatively, install tracer wires/tapes/devices directly above the plastic pipe at a depth that will be detectible by current detection equipment and technologies.

3-3.6 Identification of Other Structures in the Area.

Locate existing or planned Tburied or submerged structures. Determine if the other structures will impact or be impacted by the planned CP system. Identify the location of such structures in the design documents for interference testing during commissioning. Locate new CP anode beds to minimize the possibility of interference, while providing the best current distribution possible. Although resistivity is an important factor in anode bed location, the location of other structures in the area is just as important.

3-3.6.1 Pipeline Crossings.

For a new pipeline installation, require/specify a minimum clearance of twelve inches between all pipelines lines at crossings. If practicable, specify 24 inches of clearance. Indicate that direct contact between crossing or adjacent pipelines must be avoided. Also where practicable, specify installation of insulating mats between pipelines at crossings if substantial earth currents are detected in the area or if a newly coated line is crossing a poorly coated or uncoated line.

3-3.6.2 Cathodic Protection Interference.

Stray currents, also called interference, result from external electromotive forces and can greatly accelerate corrosion. Stray current corrosion can be caused by voltage gradients (current flow) resulting from DC transit systems, HVDC Transmission systems, DC welding, telluric earth currents, and CP systems. The amount of corrosion caused is directly proportional to the amount of DC current flowing in the electrolyte. Steel corrodes at a dissolution rate of about 20 pounds per ampere-year. CP systems can impress large amounts of current from their anodes, through the electrolyte, to the cathode. When a metallic structure not connected to or not intended to be protected by the CP system (referred to as the “foreign” structure) is immersed in the same electrolyte in the vicinity of the protected structure, it is subjected to stray current corrosion because of the electromotive force being applied through that electrolyte, and can undergo extremely severe corrosion without proper mitigation.

Provide test stations with provisions for bonding at all crossings for stray current interference testing and mitigation. Specify any additional appropriate methods and procedures to mitigate stray currents. Contact the users (owners, if not government owned) of the existing pipelines and inform them of the planned project. As any solutions to problems at pipeline crossings require cooperative efforts, effective coordination is essential. Identify coordination points of contact on the design drawings, particularly if non-government owned structures are impacted. For off base locations, Corrosion Coordinating Committees have been established in many areas to facilitate coordination of such efforts.

3-3.7 Electrical Isolation.

Determine locations and provide electrical isolation from buried metallic structures that are not intended to be protected by the CP system. Electrical isolation is essential to minimizing current requirements for both GCP and ICCP systems and ensuring the intended structure can be adequately protected. Also provide insulating joints to isolate sections of structures so that each section can be protected separately when necessary (e.g. a pipeline with multiple road crossings). For POL pipelines, provide surge arrestors across the electrical isolation device per UFC 3-460-01.

3-3.8 Connecting Electrical Wires and Cables.

Specify proper selection of cable size and type of insulation for ampacity, mechanical strength and electrically safe, reliable system operation. Use only copper cables in any CP installation. The DC output connecting cables used between the various components of CP systems are vital to the proper performance of the system. Any break in the primary circuit will result in failure of the system. Breaks in the auxiliary connections such as those used to test the system will also result in difficulties in proper adjustment and inspection of the system. See also paragraphs 4-2.4 and 4-3.3.

3-3.9 Connections and Splices.

Wire splices and connections are a source of undesirable circuit resistance and are a weak point in the reliability of the system as they often fail due to either corrosion or mechanical damage. Wire splices are not permitted in the following situations:

- Submerged GCP and ICCP anode lead wires or anode header cables
- Buried individual GCP and ICCP anode lead wires. Provide anodes with lead wires of sufficient length to reach an anode junction box/test station
- Buried sections of anode header cables unless specific site conditions or mission requirements prohibit the installation of an anode junction box/test station
- Buried sections of structure lead wires/header cables in highly corrosive environments

Keep connections to an absolute minimum and specify types of connections that have low resistance, high reliability, and good resistance to corrosion. See also paragraph 4-4.2.

3-3.10 Hazards Associated with Cathodic Protection.

3-3.10.1 Explosive Hazard Concerns.

Design both ICCP and sacrificial anode CP systems to comply with the regulations governing the hazardous area where flammable liquids or explosive gasses may be present. Such areas include, but are not limited to:

- Fuel storage farms
- Fuel terminals and fueling areas
- Refineries
- Ammunition depots
- Manholes (sewer gas)

Cathodic protection rectifiers used in such applications must be special oil-immersed explosion-proof types, or must be located outside of the hazardous area. In addition, all connections must be made in explosion-proof housings, and electrical conduits entering the housings properly sealed.

3-3.10.2 Bonding for Electrical Safety.

Provide electrical bonding points to prevent static discharge as required for safety where ships, vehicles, or aircraft are fueled or loaded. Any voltage gradient in the soil can result in a potential difference between structures located at different points, resulting in dangerous arcing. Cathodic protection systems are one source of such voltage gradients. Normal electrical bonding methods used in such circumstances is sufficient to mitigate this hazard. Voltage gradients caused by CP systems can also cause arcing during pipeline repairs when the pipeline is severed. Specify that a temporary bond be provided across the area to be cut to prevent this hazard before cutting a pipeline.

3-3.10.3 Installation Work near High Voltage Power Lines.

Installation work around high voltage power lines constitute a safety hazard from either direct contact with the power lines or induced voltage from these power lines. If the potential for such occurrences exists at the project site, then include provisions in the design documents addressing these concerns during construction.

3-3.10.4 Induced Alternating Current Concerns.

Alternating current (AC) can be induced on underground or aboveground components of CP systems, as well as large structures being protected in the vicinity of AC electrical transmission lines. This is particularly true if the structure is well coated or isolated from the ground, and the probability and intensity of induced current increases the more the pipeline is oriented parallel to the AC transmission lines. Pipelines using the same right-of-way as the AC transmission lines are particularly susceptible to induced AC voltages. In addition to causing corrosion damage, these voltages can be dangerous to personnel who may come in contact with the structure or CP system.

Identify the location of the AC transmission lines during the design of CP systems and assess the effects of induced currents. Where practicable, avoid placement of CP system components and test stations in areas where induced currents may exist. Provide the appropriate combination of safety features to mitigate the effects of induced current for equipment that must be located within induced current areas and prevent electric shock to maintenance personnel such as.

- Electrical test stations and cabinets with a lockable dead front
- Gradient control mats around pipeline appurtenances engineered to provide safe (15 volts or less) touch-and-step voltages during both load and fault conditions
- Grounding systems for pipeline appurtenances and nearby independent isolated metallic structures
- Distributed galvanic anodes connected to the pipeline as part of the grounding system
- High resistivity crushed stone around pipeline appurtenances (use in conjunction with grounding/gradient control system)

Include induced current safety precautions and test procedures in the specifications for CP system commissioning field surveys or other electrical tests in the vicinity of AC transmission lines

3-3.10.5 CP Systems Near Communication Equipment.

Electrical filters are used to both increase the efficiency of the rectifier by reducing alternating current ripple and to reduce interference with communications equipment. Efficiency filters can increase the efficiency of single-phase bridge type rectifiers by 10 to 14 percent and their use must be based upon a first cost versus operating (power) cost basis. Efficiency filters are not commonly used with three-phase rectifiers as the alternating current ripple in these units is inherently lower.

Specify noise interference filters where operational requirements mandate their use. Verify requirements with the user during the design survey. Where necessary, retrofit noise interference filters into an existing rectifier when noise problems are encountered and are significantly affected by turning the unit on and off.

3-3.11 Special Requirements.

Identify any special requirements in the proposed CP system description such as the need for remote monitoring units, automated data collection units, unique structure or procedural features that may impact the CP system design, operation, or maintenance. Refer to paragraph 4-5 and the best practices in Appendix B. These special requirements will impact the construction cost.

All control systems, remote monitoring units, and automated data collection units must be planned, designed, acquired, executed and maintained in accordance with DoD Instruction 8500.01 and DoD Instruction 8510.01, and as required by individual Service Implementation Policy.

3-3.12 Easement Issues.

Easements are usually not an issue since most projects are located on-installation where easements are not necessary. In the case of CP systems for distribution pipelines and other structures located off-installation, identify easement issues as early as possible during the design process if not already addressed during the planning stages. Obtaining easements can be a long legal process; therefore, should be identified as early as possible before the start of construction. Involve installation real estate personnel for assistance. Ensure easement issues are well documented and the documents kept on file in the event property owners contest the location of the CP equipment years after installation.

3-3.13 CP System Protection Criteria.

Design all CP systems to provide protective levels according to the requirements and criteria for adequate protection identified in the NACE International standards appropriate for the structure(s) being protected.

3-3.14 System Maintainability.

Identify operation and maintenance (O&M) requirements for the end users early on in the design process as end user O&M capabilities may impact the CP system design. Refer to UFC 3-570-06. The following paragraphs briefly summarize the general O&M requirements and design features that facilitate O&M:

3-3.14.1 GCP Systems.

Conduct structure-to electrolyte (S/E) potential tests semiannually (or at least annually as a minimum) to determine adequacy of the CP system. Read and record potential reading at all established test points. Inspect junction boxes and test boxes. Tighten wire connections and perform minor repairs as necessary. Test insulating joints annually.

3-3.14.2 ICCP Systems.

Inspect each rectifier monthly (bimonthly as a minimum), to ensure the system is operating. Read and record rectifier input and output voltage and current readings. Inspect, clean, and tighten output wire connections. Conduct structure-to electrolyte (S/E) potential tests quarterly (or at least annually as a minimum) to determine adequacy of the CP system. Read and record potential reading at all established test points. Adjust or repair rectifiers if test potentials indicate inadequate protection. Test insulating joints annually.

3-3.14.3 Design Requirements to Facilitate O&M.

Specify CP system features and configuration that will save time by making it easier for base facilities management personnel to operate, maintain, adequately test, and troubleshoot the CP system, and ensure adequate CP is being provided to the intended structure throughout the life cycle of the system. The capability for maintaining the CP system at the installation may affect the decision on the type of CP system to be installed. Examples of features, configuration, and design considerations include but are not limited to:

- Location of CP equipment where they will be readily maintainable
- Provision of equipment cabinets suitable for the environment
- Provision of an adequate number of test stations in readily accessible areas. Where possible avoid test station installation in the middle of roads. Without sufficient test stations and test access, a system may be impossible to accurately evaluate for adequacy of protection
- Provision of test stations that preclude maintenance personnel from having to enter confined spaces
- Specification of time saving features such as remote monitoring and automated data collection units where feasible
- Identification of the location of all CP equipment and test points on the design drawings
- Specifications that include training of base maintenance personnel by the contractor and/or manufacturer
- Specifications that include provision of maintenance manuals to the base maintenance personnel by the contractor and/or manufacturer

Refer also to the best practices in Appendix B-8.

3-3.15 Design Submittals.

Project managers or Architects/Engineers-in-charge should contact the service CP system Technical Expert or Major Command Corrosion Engineer regarding the CP system design during the various project phases, and upon request, provide the design documents for review. Design submittals must include the following as a minimum:

3-3.15.1 Design Basis.

The Design Basis must include a narrative description of the proposed CP system and rationale for selecting the type of system, electrolyte (soil, water, etc.) corrosivity data, CP system current requirement test data (if applicable), and all design calculations. The design basis shall also address the anticipated CP system maintenance requirements for the installation.

3-3.15.2 Drawings.

Drawings must include CP system one line diagrams, locations of all CP equipment (anodes, rectifiers, test stations, etc.), stray current test points, installation details, dielectric insulating fittings, and electrical continuity bond connections.

3-3.15.3 Specifications.

Specifications must describe all CP system equipment and installation procedures; acceptance testing procedures including static (native) potentials, initial and final system potentials, and interference tests; special contractor qualifications; and applicable reference standards.

3-3.16 Design Build.

Design build contracts are generally based upon performance specifications. Successful application of CP for the system life will be significantly dependent upon the requirements detailed in the request for proposal (RFP). The contractor selected is responsible to design a CP system that will meet the RFP requirements. Requirements that are too general and are not explicit in performance will result in the installation of a minimum system that will not perform over the anticipated system life. Typically, the contractor’s warranty is one-year, while the system design life is typically 15 - 25 years. Include the following CP system requirements in the RFP:

3-3.16.1 CP Requirements.

Include CP system requirements in the performance technical specifications. If necessary, mark-up guide specifications (UFGS) with prescriptive requirements where a particular system type or specific features are required based on experience

3-3.16.2 CP System Life.

Require a minimum CP system life of 15 - 20 years for GCP systems and 20 -25 years for ICCP systems, unless specific mission requirements or overarching project requirements dictate otherwise.

3-3.16.3 CP System Maintainability.

Require the contractor to address CP system maintainability. Many bases may have a limited ability to readily maintain the CP system.

3-3.16.4 CP System Commissioning.

Require the contractor to provide explicit CP system commissioning requirements. Require commissioning reports be sent to qualified base/installation government personnel for review.

3-3.16.5 CP System Warranty Testing.

Require the contractor to test and maintain the CP system(s) for first year. Include requirements for test data submission to the government.

3-4 DESIGN FOR CONSTRUCTABILITY.

Cathodic protection systems must be properly installed in order for effective protection to be achieved. Problems during construction and installation do occur, and many are due to unforeseen conditions. In some cases, these issues may already be known by installation personnel and it would be beneficial to identify these during the early stages of the design process.

3-4.1 Identification of Issues During Design Field Survey.

During the design field survey, identify and resolve issues that may impact the ability to construct the CP system. Evaluate the following as a minimum:

- Site conditions differing from those shown on installation development maps and as-built drawings. Specify CP system component locations to avoid interference from existing structures
- Site conditions may also be a significant factor in the determination of the type of system selected and the materials used for the components of the system
- Site conditions that may impact construction safety. Coordinate with the installation construction management office/safety officer for any site specific requirements
- Environmental/ archaeological concerns
    - Pollution prevention considerations
    - Preservation of historical structures or site conditions
    - Excavation, drilling and other permits
- Communication with installation personnel regarding
    - Operational requirements that may impact site access, materials of construction, installation or schedule.
    - Future construction at or nearby the project site that may affect the location of the CP system components
    - Security or operational requirements that may impact personnel/construction equipment access and construction schedule (e.g. inside of a shipyard controlled access area)
    - Easement issues if located off-base

The appropriate UFGS sections contain sections that generally address many of the above issues, and site conditions may require the designer to modify these sections for a particular site. Provide copies of the design submissions to installation personnel, including the local construction management office, to ensure that the requirements have been adequately addressed.

3-4.2 Prevention of Damage to Existing Structures/CP System Components.

Include requirements for the contractor to pay particular attention to maintaining the condition of the coating on the structure and maintaining the structural continuity and isolation required for proper CP system operation when working around existing structures. If the coating on a structure is damaged and not repaired, CP requirements will increase dramatically, and the new or existing CP system for the structure may not function properly. Damage to/removal of existing continuity bonds or dielectric isolating devices are common causes of inadequate protection or interference on nearby pipelines that can cause accelerated corrosion damage.

3-4.3 Commissioning.

Specify adequate commissioning procedures so that the system is energized and fully tested to ensure its proper operation before being accepted from the contractor. The cathodic protection UFGS listed below provide detailed commissioning and testing procedures that must be considered and tailored for the specific system being designed.

- UFGS 26 42 13.00 20, Cathodic Protection by Galvanic Anodes
- UFGS 26 42 14.00 10, Cathodic Protection System (Sacrificial Anode)
- UFGS 26 42 15.00 10, Cathodic Protection System (Steel Water Tanks)
- UFGS 26 42 17.00 10, Cathodic Protection System (Impressed Current)
- UFGS 26 42 19.00 20, Cathodic Protection by Impressed Current
- UFGS 26 42 22.00 20, Cathodic Protection System for Steel Water Tanks

Proper commissioning by qualified personnel ensures the system is properly operating from the onset and helps identify system deficiencies, both design and construction, that should be corrected before the system is accepted. A properly commissioned system will help simplify maintenance and operation, and commissioning test data can be used as a baseline for future operation and troubleshooting. See also Appendix B-11.

3-4.3.1 General Commissioning Requirements.

Require the CP systems to be tested and inspected by the Contractor's corrosion engineer/CP Specialist in the presence of the Contracting Officer's corrosion protection/ CP engineer or approved representative. Also require the contractor to record test data, including date, time, and locations of testing and submit a report to the Contracting Officer. Specify that the contractor shall correct, at his expense, all deficiencies in the materials and installation observed by these tests and inspections, and must pay for retests made necessary by the corrections.

3-4.3.2 Required Tests.

Commissioning testing must include the following measurements as a minimum:

- Baseline Potential Tests

- Insulation Joint Testing
- Electrical Continuity Testing
- Rectifier System Testing (ICCP systems)
- Permanent Reference Electrode Calibration (if included in the design)
- Pipe Casing Testing (if applicable)
- Energized Potential Tests
- Interference Testing (If ICCP system is specified or exists nearby)

Refer to the detailed requirements and procedures in the UFGS identified in Paragraph 3-4.3.

3-4.3.3 Warranty Period Testing.

For most CP systems, specify the contractor also conduct periodic testing during warranty. Refer to the detailed requirements and procedures in the UFGS identified in Paragraph 3-4.3.

CHAPTER 4 CATHODIC PROTECTION SYSTEM COMPONENTS

4-1 INTRODUCTION.

There are two main types of CP systems, GCP or ICCP, and they can be applied many different ways to cathodically protect different types of structures. There are many different types and sizes of anodes for either type of CP system that can be installed either horizontally or vertically. Since CP is applied to prevent corrosion of a wide variety of structures in a variety of environments, each situation will require special consideration. There are fundamental requirements that should be followed in each case, and the method of application of CP to a particular structure depends upon unique design factors.

4-2 GALVANIC ANODE SYSTEMS.

Specify GCP systems where economically practical unless specific site conditions or mission requirements require the use of an ICCP system. GCP systems generally require less maintenance efforts than ICCP systems; however, this may not be true for extensive piping systems with numerous distributed anode connection points. The design must consider the DoD installation’s ability to maintain and operate the system specified.

Do not specify GCP systems where the electrolyte resistivity is more than 30,000 ohm-cm, on large/extensive bare or poorly coated storage tank and distribution pipeline structures, or on structures that cannot be practically electrically isolated from all other structures, unless specific site conditions or mission requirements prohibit the use of a GCP system. Do not specify GCP systems for the exterior bottoms of aboveground (on-grade) fuel storage tanks with a clean sand backfill and a secondary containment liner unless specific site conditions or mission requirements prohibit the use of an ICCP system.

4-2.1 Anodes.

Specify the type and size of GCP anode that will provide the optimum performance based upon site conditions, electrolyte characteristics, system life, and economic feasibility. The minimum GCP design life is 15 years unless mission or operational requirements dictate otherwise (e.g. a particular structure will be in service for less than 15 years). The design basis and calculations must provide clear rationale for the anode selection and must address:

- Anode life
- Anode current output
- Specific environmental conditions that may impact performance
- Material costs
- Installation costs

Specify the proper type and size of GCP anodes to meet the desired CP system life for structures immersed in seawater or brackish water. Do not specify magnesium anodes as the primary CP system for structures immersed in salt water.

4-2.1.1 Zinc Anodes.

Zinc anodes are most commonly used in immersion service either in fresh or salt water. They are also occasionally used in the protection of buried structures when soil or water resistivity is low and special circumstances are encountered. Do not use zinc anodes where the soil or water resistivity is greater than 2,000 ohm-cm. Ensure that the proper type of zinc anode is specified. Two zinc anode compositions are commonly available; a standard alloy formulated for use in fresh water and soil, and an alloy specially formulated for use in seawater.

In some fresh waters, the potential between steel and zinc can reverse at temperatures above 140 degrees F, in which case, the steel will act as anode and corrode to protect the zinc. Do not specify zinc anodes to protect steel in such cases (e.g. do not use zinc anodes to protect a steel hot water storage tank).

4-2.1.2 Magnesium Anodes.

Magnesium anodes are most commonly used in soils with higher resistivity and fresh or brackish water immersion service. Do not use magnesium anodes for waterfront structures immersed in sea water, as they do not have a favorable economic life in such environments. Also, do not use magnesium anodes in soil where the soil resistivity is less than 2,000 ohm-cm unless determined to be more feasible for the specific soil conditions. In such cases, ensure that sufficient anode quantities are provided to meet the desired design life.

Ensure that the proper type of magnesium anode is specified. Two compositions are commonly available; a standard alloy and a high-purity (high potential) alloy. Specifications should include provisions that prohibit contractors from inter-mixing the anode types, particularly if the high potential anode is specified.

4-2.1.3 Aluminum Anodes.

Specify aluminum anodes for structures immersed in salt water, brackish water or other low resistivity or high chloride aqueous environments such as sewage effluent unless specific conditions are more favorable to zinc anodes. Specify only the indium activated (Type III) aluminum anodes. Do not specify anodes containing mercury unless specific site conditions or mission requirements dictate their use.

Do not use aluminum anodes for GCP systems for the interiors of potable water tanks. They have been used in past installations in cold climates, but are no longer preferred.

4-2.2 Backfill.

Specify anodes pre-packaged by the manufacturer in backfill consisting of a mixture of hydrated gypsum, bentonite, and sodium sulfate for GCP anodes that will be installed in soil. Besides providing a uniform resistivity environment which reduces the self-corrosion rate, the backfill is hygroscopic and will absorb moisture from the surrounding soil to lower the resistivity and improve the anode current output.

4-2.3 Connecting Wires.

For sacrificial anode CP systems, the electrical currents are usually quite low, and the size of the conductors is normally more a function of mechanical strength than of ampacity or resistance. In systems where sacrificial anodes are used in groups as remote anode beds, the currents can be larger and the voltage drop in the cable must be considered. Calculate the most economic wire size with No. 12 AWG or foreign equivalent being the minimum size wire that must be used.

4-2.3.1 Wire and Cable Insulation.

Specify high molecular weight polyethylene (HMWPE) insulated stranded copper cable for anode leads and structure leads, with the wire appropriately sized for current carrying capacity, mechanical strength, and total CP circuit resistance. Wire size must conform to the requirements in the National Electrical Code (NEC). For submerged applications or chemical environments, specify the appropriate insulation that bests resists deterioration in that environment.

Test station wires carry only very small currents and insulation requirements are not critical, but should be selected to match the environment. Specify stranded copper wires, No. 12 gauge AWG with thermoplastic (THW), cross-linked polyethylene (RHW or USE), or HMWPE insulation for this application unless otherwise dictated by economics or site conditions.

4-3 IMPRESSED CURRENT SYSTEMS.

4-3.1 Anodes.

Specify the type and size of ICCP anode that will provide the optimum performance based upon site conditions, electrolyte characteristics, system life, and economic feasibility. The design basis and calculations must provide clear rationale for the anode selection. The minimum design life is 25 years unless mission or operational requirements dictate a shorter economic life.

4-3.2 Backfill.

Provide special carbon backfill, referred to in the industry as coke breeze, in the anode hole for soil applications. Some specific backfill requirements are as follows:

4-3.2.1 Backfill Specific Gravity.

Specify backfill with the appropriate specific gravity for the type of anode hole so that the particles will settle and compact themselves. Where applicable, include procedures for installing and tamping the backfill in lifts to avoid voids and bridging in the anode hole. Where tamping is not practicable, specify calcined petroleum coke backfill for its spherical shaped particles that can better settle into the hole and compact itself.

4-3.2.2 Backfill Particle Size.

Specify backfill with the appropriately sized particles for optimum contact between the anode and backfill for the type of installation being designed. At the same time, consider the permeability of the backfill to gases that will be generated to prevent gas blockage.

4-3.3 Anode/Structure Lead Wires and Header Cables.

For ICCP systems, select connecting cables and wires based upon consideration of the following factors:

- Current carrying capacity
- Voltage attenuation (IR drop)
- Mechanical strength
- Economics (first cost versus power costs)
- Dielectric strength of insulation
- Durability (abrasion & cut resistance) of insulation

4-3.3.1 ICCP Power Supply to Structure Cables.

Specify HMWPE insulated stranded copper cable, with the wire appropriately sized for current carrying capacity, mechanical strength, and total CP circuit resistance. Wire size must conform to the requirements in the NEC. For submerged applications or chemical environments, specify the appropriate insulation that bests resists deterioration in that environment.

4-3.3.2 ICCP Power Supply to Anode Cables.

Wire size must conform to the requirements in the NEC. The insulation in these cables is critical. The connection between the CP power source and the anodes for ICCP systems, are typically buried or submerged, and are extremely susceptible to failure as they are operated at highly positive potentials. Any contact between the metallic conductors and the environment will result in rapid deterioration of the conductor and loss of continuity of the protective circuit. Specify HMWPE insulation, 0.110 inches thick, as a minimum, for these cables in most buried applications. Where exposure to chlorine will be encountered, such as in seawater or in deep well applications, specify chlorine resistant composite insulation consisting of an HMWPE outer jacket for abrasion resistance combined with an ethylene-chlorotrifluroethylene copolymer inner jacket.

4-3.4 Deep Anode Bed Design.

A deep anode bed consists of one or more anodes installed vertically at a nominal depth of 15m (50 feet) or more below the earth’s surface in a drilled hole for the purpose of supplying CP for an underground or submerged metallic structure. Refer to Figure 4-1. The deep anode bed design must consider several important factors essential to ensuring the proper installation and operation of the well. Refer to the best practices and lessons learned in Appendix B-10.1.

4-3.4.1 Location of Anode Well.

Consider the following when selecting a location for a deep well anode bed:

4-3.4.1.1 Geological Considerations.

Consider subsurface stratigraphy, hydrology, and lithology. Avoid rock, as it is a generally high resistivity environment that could hamper installation and proper operation. In sand environments specify methods to keep hole open during drilling and anode installation. Select a location with consistent subsurface resistivity as much as practicable to help ensure a uniform current discharge from the anodes.

4-3.4.1.2 Ground Water Aquifers.

Consider the location of ground water aquifers. From a geological standpoint, indicate in the design documents if artesian well conditions will be encountered. Such conditions will hamper drilling and anode installation operations, and installation procedures must be specified to account for these conditions. From an environmental standpoint, consider installation methods that will prevent contamination of a water aquifer during installation and operation of the anode well. Refer also to paragraph 4-3.4.5.

4-3.4.1.3 Communication with the Community.

Communicate with both on base and off base community where applicable. Where the CP system is located off base, communicate with the local community in order to identify easement issues, coordinate with local planning for future developments that could result in future easement issues, and coordinate with owners of buried utility pipelines and other buried structures in the area.

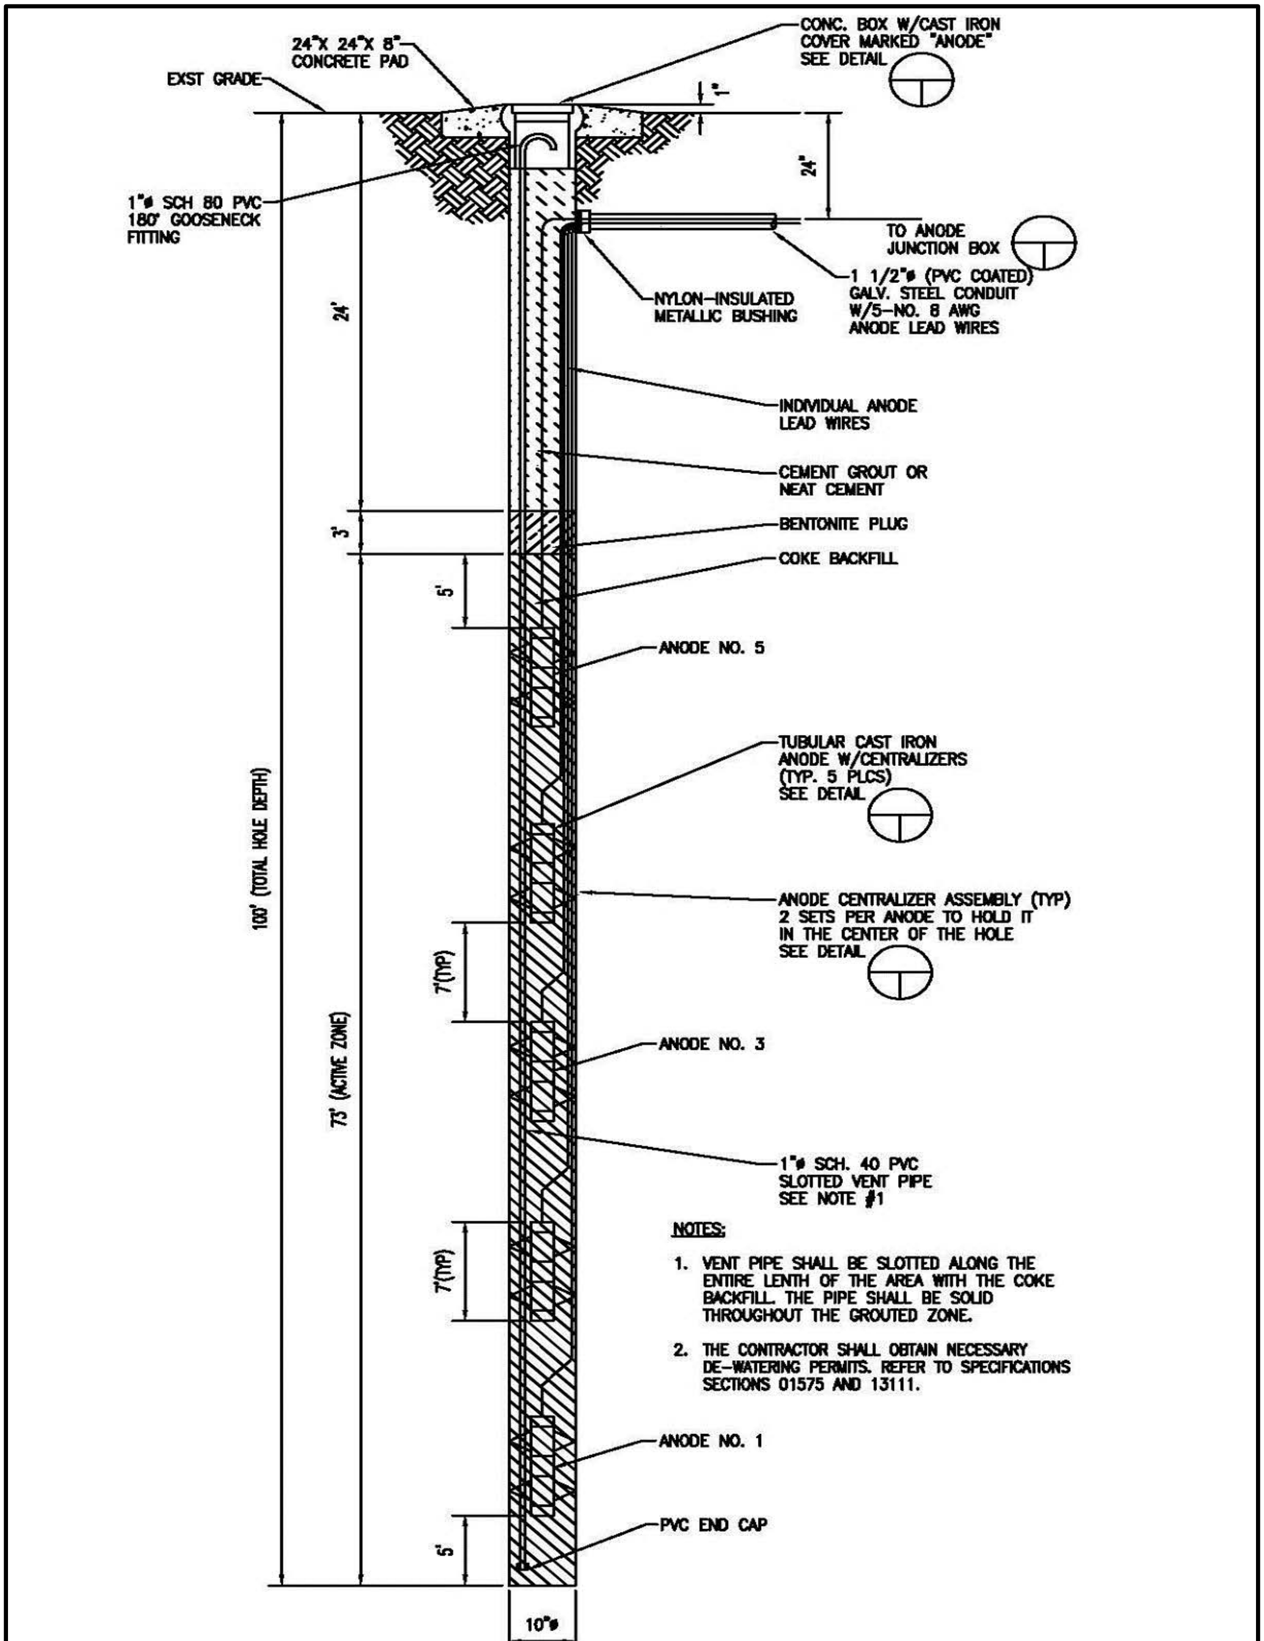
4-3.4.2 Anode Column.

Some anode column design requirements and considerations are as follows:

4-3.4.2.1 Anode Selection.

Select anode type for optimum performance and reduced difficulty of installation. Local subsurface conditions influence the selection of anode type, and anode selection affects the design for the column, i.e. quantity of anodes, depth and diameter of the column, and installation procedures.

Figure 4-1 Schematic of a typical deep well anode bed



4-3.4.2.2 Anode Centralizers.

Provide anode centralizers to help ensure the anodes are completely surrounded by backfill to lessen the chance of premature failure. Design/specify centralizers that do not significantly reduce total anode discharge area. Avoid the attachment of centralizers directly to anode surfaces that are subject to crevice corrosion such as mixed metal oxide or platinum coated titanium or niobium.

4-3.4.2.3 Anode Column Venting.

Provide vent pipes in the anode well to vent gases generated around the anode out of well to avoid gas blockage. Gas blockage can result in increased anode resistance and uneven current discharge from the anode surface resulting in premature failure. Specify vent pipes with holes or slots small enough to prevent the backfill from entering and clogging the vent pipe. Do not terminate the vent pipe inside of the anode junction box. The chlorine gas will cause corrosion of junction box hardware and detrimentally affect operation of the CP system. Also, do not terminate the vent in the anode well head box. The concentration of chlorine gas can result in corrosion of the well head box cover if it is made of steel or cast iron, and can degrade the insulation around the anode lead wires, and result in loss of the anode.

4-3.4.2.4 Anode Installation Procedure.

Follow the anode installation procedures as indicated in UFGS 26 42 17.00 10 and UFGS 26 42 19.00 20. In most cases specify that the contractor must not use the anode lead wire to lift, transport or install the anode. Handling the anode by using the lead wire can compromise integrity of wire and anode connection. Where the situation requires the use of the anode lead wire for anode installation, specify the appropriate pull out strength of the wire-to-anode connection and provide destructive test procedures to verify conformance with the specifications. Refer to UFGS 26 42 17.00 10 and UFGS 26 42 19.00 20.

4-3.4.3 Anode Column Backfill.

Provide a special carbon coke breeze backfill in the anode hole or column for all underground deep anode bed installations, except for open hole, replaceable anode deep wells. Consider open hole deep anode beds only where there is sufficient low resistivity groundwater to keep the anode well filled with water and provide the uniform environment for uniform distribution of current. Environmental concerns must be addressed. Anodes in open holes are more easily replaced in the event of failure. Specific backfill requirements are as follows:

4-3.4.3.1 Backfill Specific Gravity.

Since deep anodes are typically installed in the ground water table, specify backfill with high specific gravity so that the particles will settle and compact themselves since they cannot be tamped. Specify calcined petroleum coke backfill for its spherical shaped particles that can better settle into the deep column and compact itself without tamping.

4-3.4.3.2 Backfill Particle Size.

Specify backfill with small particles for optimum contact between the anode and backfill. Also consider the permeability of the backfill to prevent blockage of gases generated in the well.

4-3.4.3.3 Backfill Installation.

Backfill must be installed by pumping a slurry of the backfill into the hole from the bottom up to preclude voids or “bridging”. Do not use the vent pipe to install the backfill, as it will clog the vent pipe. Large particles specified to prevent gas blockage will be difficult to pump.

4-3.4.4 Anode Lead Wires.

Anode lead wires are a very important component of the anode installations, and many deep anode installations have failed because of improperly specified lead wires. Some considerations for anode lead wires for deep anode beds include:

4-3.4.4.1 Wire Insulation.

Specify HMWPE insulation. For chlorine ion environments, specify a dual insulation consisting of an inner ethylene-chlorotrifluoroethylene layer with an HMWPE outer layer for abrasion resistance.

4-3.4.4.2 Splices Not Allowed.

Provide individual anode lead wires to the anode junction box instead of splicing them to a single header cable from the rectifier. Specify that splices <u>are not allowed</u> in the anode lead wires. Splices are a point of premature failure of anode lead wires.

4-3.4.4.3 Damage Insulation Not Acceptable.

Specify that nicks or other damaged to the wire insulation <u>are not acceptable</u>. As with splices, and even more so with damaged wire insulation, nicks and damaged insulation are points of premature failure of anode lead wires.

4-3.4.5 Environmental Concerns.

Installation of a deep anode bed can impact the environment. Environmental concerns must be considered during the early design stages. Consult with base environmental personnel and ensure that they are afforded the opportunity to review the design. Failure to consider environmental concerns can result in:

- Delays in completing the final design if an environmental issue is identified too late in the design
- Delays in obtaining construction permits

- Work stoppage and costly construction delays if environmental issues must be settled after construction is awarded, with the potential for disapproval of work and cancellation of the installation
- Pollution of the environment and the resulting costly cleanups
- Fines for violating environmental regulations
- Other legal ramifications

4-3.5 Rectifiers and Other DC Power Supplies.

Any source of direct current of appropriate voltage and current can be used as a source of power for ICCP systems. Select the power supply based upon local conditions at the site and evaluation of economics, availability of AC power or fuel, and the availability of maintenance capability. Design drawings must identify the specific source of power and any necessary additional electrical equipment components required to provide power to the rectifiers.

4-3.5.1 Transformer-Rectifier.

Unless AC power is unavailable, specify a transformer-rectifier, or more simply, a rectifier. They are by far the most commonly used power supply type for ICCP systems, as they are readily available in a wide variety of types and capacities that are specifically designed and constructed for use in ICCP systems. The most commonly used type of rectifier has an adjustable step down transformer, rectifying units (stacks), meters, circuit breakers, lightning arresters, current measuring shunts, and transformer adjusting points (taps), all in one enclosure. Ensure rectifiers and associated wiring and conduit are installed according to applicable electrical and safety codes and guidance.

4-3.5.2 Solar Power-Rectifier.

Consider the use of storage batteries and solar panels (Figure 4-2) for ICCP power supplies at remote sites where electrical power is not available. Security must be considered with solar power systems to avoid theft and vandalism especially in off-base locations. Environmental and safety considerations must address procurement, maintenance and disposal of battery electrolytes.

Specify high efficiency (96-98%) controls that have flexibility to match the anode ground bed and its fluctuating conditions. In order to maintain constant CP levels, specify a control unit that has either constant potential (with reference to a permanent reference electrode) control or constant current output capability. Select the controller unit that minimizes the mismatch loss between the PV array and the storage batteries. Finally, consider providing a controller that has built–in current interruption capability so that IR free (more accurate) structure potentials of the pipelines can be measured. NAVFAC Engineering Service Center (ESC) Technical Report TR-2312-SHR *CPC Program Final Report Solar Powered Cathodic Protection System,* documents some of the key considerations and lessons learned when considering the use of solar power.

Figure 4-2 Small Solar Powered CP System. Solar Panels Shown in Picture on Left. Battery Bank and Control Center Shown on Right.

4-3.5.3 Other Power Supplies.

Consider usage of other types of power supplies such as engine or wind driven generators or thermoelectric generators in remote locations where electrical power is not available and solar power is not practicable. They must be justified by life-cycle economic analysis.

4-4 OTHER COMPONENTS.

4-4.1 Electrical Continuity and Isolation.

Electrical continuity or isolation requirements must be determined to design an effective CP system for the structure and ensure it will receive adequate CP as intended. For electrically discontinuous structures, provide continuity bonds (Figure 4-3) or provide independent CP systems for each electrically isolated section of the structure.

Conversely, provide electrical isolation if only a portion of a larger structure will be protected, or other buried metallic structures not intended to be protected are electrically continuous with the structure to be protected.

4-4.1.1 Electrical Bond Wires.

These wires carry more current than test wires, and may require mechanical strength. Specify No. 4 or 8 AWG stranded copper cable with HMWPE insulation for all bond wires unless a larger wire size is required for current carrying capacity.

Figure 4-3 Bond Wire Installed Between Two Electrically Isolated Pipe Sections

4-4.1.2 Electrical Isolation Joints (Insulating Fitting).

Provide dielectric insulation joints (flanges or unions) between sections of a structure to electrically isolate the structure into sections that can be protected by independent CP systems, or to separate sections that require CP from those that do not. Electrical isolation is provided to minimize current requirement for both GCP and ICCP systems by isolating structures that are not intended to be protected by the CP system. Insulating joints are sometimes used to isolate sections of structures so that each section can be protected separately when necessary.

Unless it is not feasible, install electrical isolation devices where the pipe emerges from the ground or in valve pits. Where the isolation joints absolutely must be buried, provide two-wire test stations to allow testing of the electrical isolation joint. Coordinate with the design team/users to ensure mechanical or structural features will not unintentionally bypass the electrical isolation. For example:

- Electrical grounding system connection points that result in the area grounding system (bare copper wire and ground rods) being connected to the CP system
- Tank gauging system or other electrical conduits that unintentionally bypass electrical isolation
- Pipe racks supporting the pipe to be protected as well as pipe not intended to be protected and/or electrical conduits connected to grounding systems

- Small diameter bypass pipelines that bypass the dielectric isolation gasket in the main larger diameter pipeline

Consider the need for surge and fault current protection at isolation devices. If an insulation flange is installed in a hazardous classified area per the NEC, provide a sealed, weatherproof surge arrester across each isolation device. The arrester must be the gapless, self-healing, solid state type (e.g., metal oxide varistor). Cable connections from arresters to isolating devices must be short, direct, and of a size suitable for short-term, high current loading.

4-4.1.2.1 Insulation Joints and Surge Arresters on POL Pipelines.

For POL pipelines, provide surge arrestors across all aboveground insulated flanges connected to below ground cathodically protected piping per UFC 3-460-01. Require surge arrestors to be designed for use with insulated flanges and for use in NEC Class I, Division 1 areas. Provide covers over flanges to preclude dirt from degrading surge arrestors.

4-4.1.2.2 Insulation Flanges and Surge Arresters on Fire Protection Pipelines.

Provide insulation flanges in fire protection risers or in other piping extending from below grade into the building. Install insulation flanges in fire riser piping or other piping, above the floor slab. Additionally, consider installation of AC/DC decoupling devices across the insulation flanges per the NEC. The NEC allows the underground piping extending into the building to be bonded into and used as part of the building grounding system, which can result in premature corrosion failure of the buried piping due to DC component currents discharging to ground via the buried piping.

4-4.2 Connections and Splices.

While connection of wires to the structure can be either by exothermic weld or mechanical connections, utilize exothermic welding (Figure 4-4) as much as practicable. Avoid mechanical connections as much as practicable (Figure 4-5), as corrosion of the mechanical connection tends to result in a high resistance connection over time that could prevent the CP system from properly operating. Insulate underground connections with either epoxy encapsulation or other type of mastic compatible with the pipeline coating. Above grade connections such as wires in test stations are usually mechanical connections. Specify that they be carefully taped in order to prevent corrosion due to the entry of moisture.

Include details on the design drawings showing a typical exothermic welding process and include notes describing the step by step procedure. The UFGS include sections detailing the requirements for exothermic welding. Ensure the project specifications include the applicable requirements including the requirements regarding safety.

Figure 4-4 Exothermic Weld of CP System Wiring to the Structure

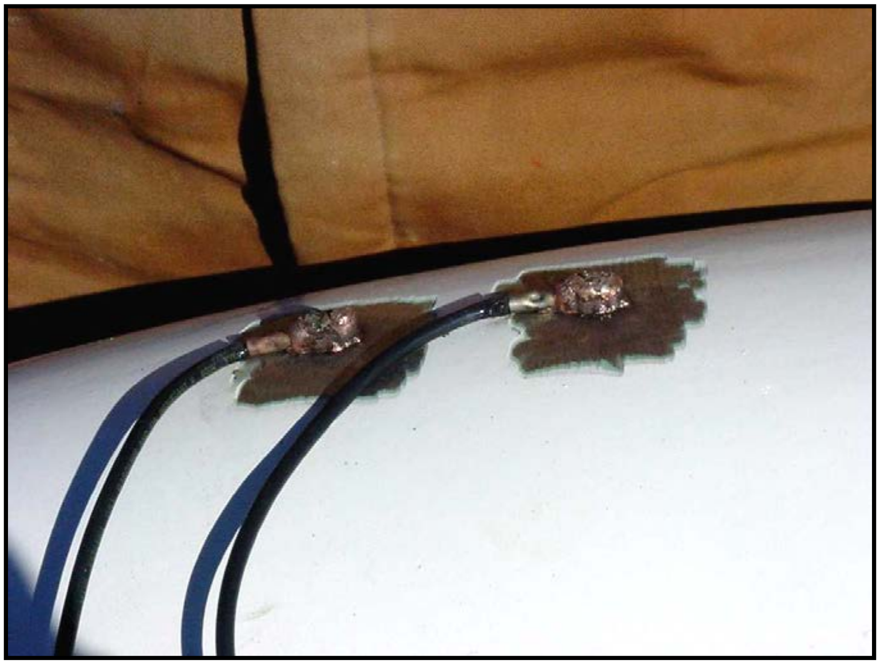


Figure 4-5 Mechanical Connection of Wiring to the Structure

4-4.2.1 GCP Systems.

The following connections are required for GCP anode systems and must be shown on the design drawings:

- Connection between anode(s) and structure through a test station
- Connection between cable and anode (must be factory made with wire connection attached to cast-in core)
- Necessary bonds and test wires

4-4.2.2 ICCP Systems.

The following connections are required for ICCP systems and must be shown on the design drawings:

- Connection between power source and structure
- Connection between anode bed(s) and power source (anode header cable)
- Connection between anode header cable and each anode
- Connection between cable and anode (must be factory made)
- Necessary bonds and test wires

Carefully insulate all connections, particularly in the anode to power supply portion of the circuit where any loss of insulation integrity will result in rapid system failure. All connections in the power source to anode bed portion of the circuit and all cable-to-cable connections must be insulated by encapsulation in epoxy using commercially available kits made expressly for this purpose.

The cable to structure connection is less critical and either epoxy encapsulation or insulation with mastic must be used on this connection.

4-4.3 Test Stations.

Provide a sufficient number of test stations to allow access to the structure for potential surveys to determine if adequate CP has been achieved. They are also necessary to perform recurring maintenance, troubleshooting and repair of the system during its life cycle.

4-4.3.1 Test Station Location and Function.

Accurately identify test station locations on the design and as built drawings. Include details of the schematic wiring of all test stations in the system design. Specify test stations manufactured specifically for the intended purpose. Provide flush mounted test stations in paved areas or other areas where damage by vehicles, etc. is anticipated. Provide above grade test stations where they are not subject to vehicle damage or are located in areas where flush mounted test stations can easily be covered over and lost.

Provide test stations on all foreign structures that cross the protected structure or are in the vicinity of the anode bed. Also provide test stations for all pipeline casings, underground dielectric insulation unions and flanges, and other components such as bonds. Provide test station markers for flush mount test stations on cross country pipelines to facilitate location of these test points.

4-4.3.2 Test Station Wiring.

All test stations must include at least two wires to each structure protected or impacted by the CP system. Provide non-corroding metal or plastic identification tags on all test wires to identify them and indicate the system component to which they are connected.

Since test stations are manufactured in many different types and configurations, ensure that they are adequately sized and configured for the number of test wires and intended purpose of the test station. Some small flush mount test stations are manufactured with five or more terminals on the terminal board, but when installed with thick polyethylene insulated wire, are difficult to open and close, often resulting in damage to the wiring terminals and measuring shunts. Provide test stations large enough to appropriately accommodate the wire quantity, size and insulation type and facilitate maintenance and testing.

4-4.4 Permanent Monitoring Electrodes and Probes.

For structures that will have limited access to the electrolyte after construction, provide permanent electrodes, probes or other means to allow structure-to-electrolyte testing and other means to demonstrate CP system effectiveness. Following are some examples:

- Exterior bottoms of on-grade fuel storage tanks with a secondary containment liner
- Water storage tank interior
- Rebar in a concrete structure
- Submerged waterfront structure

4-4.4.1 Permanent Reference Electrodes.

Provide the type of permanent reference electrode suitable for the electrolyte and specific environment conditions.

4-4.4.1.1 Seawater and Brackish Water.

Specify silver-silver chloride reference electrodes (SCE) for most sea water and brackish water environments. Do not specify copper-copper sulfate reference electrodes (CSE) in these environments.

4-4.4.1.2 Soil and Fresh Water.

Specify CSE or zinc reference electrodes (ZRE) for most soil and fresh water environments. Ensure that reference electrodes for use inside of potable water storage tanks are approved in accordance with NSF/ANSI Standard 61. For soil applications, specify reference electrodes that are prepackaged in backfill SCE by the manufacturer.

4-4.4.1.3 Concrete.

For reinforced concrete, specify SCE manufactured for use embedded in concrete.

4-4.4.1.4 Aboveground Storage Tanks.

Specify dual element CSE/ZRE for the exterior bottom of aboveground (on-grade) storage tanks.

4-4.4.1.5 Industrial Hot Water Tanks.

For industrial hot water tanks, refer to paragraph 4-5.6.2

4-4.4.2 Reference Electrodes with Coupons.

Provide reference electrodes with coupons where voltage drop (IR) free structure-to-electrolyte measurements are necessary and interruption of the CP current is not practicable. NAVFAC ESC Technical Report TR-3559-SHR *Corrosion Protection Utilizing IR Drop Free Sensors and Data Acquisition for Cross Country Pipelines,* includes lessons learned regarding the application of reference electrodes with coupons to monitor CP effectiveness on a buried pipeline.

4-4.4.3 Electrical Resistance Probes.

Provide electrical resistance (ER) probes where it is necessary to demonstrate a reduction of corrosion rate in addition to structure-to-electrolyte measurement to demonstrate CP system effectiveness. Ensure the design includes provisions for protecting the connection point of the lead wires to the probe body. Any corrosion in the connection will render the probes useless. Technical Report TR-NAVFAC EXWC CI-1301 *CPC Program Final Report Electrical Resistance Probe Corrosion Sensors for In Situ Assessment for Waterfront Structures,* documents some of the technical considerations and lessons learned when considering the use of ER probes in submerged waterfront structure applications.

4-5 SPECIAL TECHNOLOGICAL CONSIDERATIONS.

Refer to Appendix B-10 for best practices and lessons learned regarding the special considerations in this section.

4-5.1 Remote Monitoring.

For critical or remote locations, consider the use of remote monitoring equipment to monitor the CP system and the protected structure. Required periodic monitoring of ICCP rectifiers requires a crew to travel to the location to perform testing and can result in up to 60 days between inspections. Remote monitoring systems help reduce testing costs and aid in collection and management of data for historical records.

Remote monitoring units commonly communicate by cell phone technology or satellite transmission technology. Technical Report TR-NAVFAC EXWC CI-1405 *CPC Program Final Report Satellite Based Remote Monitoring Systems for Cathodic Protection Systems in Remote Locations,* documents some of the key considerations and lessons learned when considering the use of satellite remote monitoring. Technical Report ERDC/CERL TR-07-25 *Remote Monitoring of Cathodic Protection and Cathodic Protection System Upgrades for Tanks and Pipelines at Fort Carson,* documents the use of and lessons learned regarding "drive-by" remote monitoring systems. Refer to paragraph 1.6 for cybersecurity requirements.

4-5.2 Pre-engineered CP for Underground Storage Tanks.

USTs and oil water separators that conform to the Steel Tank Institute STI-P3-90 include a pre-engineered sacrificial anode CP system that is one part of the overall pre-engineered external corrosion control system for the underground steel storage tank (Figure 4-6). The STI-P3® system combines three basic methods of underground corrosion control, all installed on the tanks during manufacture:

- Cathodic Protection
- Protective Coating
- Electrical Isolation of the tank from other underground metallic structures

Figure 4-6 STI-P3® Tank

***** CAUTION - RISK OF INADEQUATE CP *****

The CP system for an STI-P3® tank is intended only to protect the tank. Pipelines associated with the tank will not be protected. A separate CP system must be provided for the associated pipelines to comply with UST regulations. Also note that the integrity of the isolating bushings for an STI-P3® tank must be maintained. Loss of this electrical isolation can result in inadequate protection of the tank because of electrical shorts to other buried metallic structures in the vicinity.

Do not specify these types of pre-engineered CP systems where field survey conditions indicate they are not feasible. For new STI-P3® tanks specify provision of manufacturer provided PP4 CP testing equipment or provide separate appropriate test stations and wiring, to allow proper testing of the CP system.

4-5.3 Aboveground (on-grade) Storage Tanks.

Provide ICCP systems for the exterior bottoms of aboveground (on-grade) storage tanks with a secondary containment liner. Anodes must be installed in the backfill between the tank bottom and the containment liner. Do not specify GCP systems unless mission requirements preclude the use of ICCP systems. Provide a combination of permanent reference electrodes, corrosion probes, and reference electrode tubes to allow sufficient long-term testing and monitoring of the CP system effectiveness. Provide a separate CP system for buried distribution pipelines associated with the tank.

Provide a properly designed ICCP system for aboveground storage tank bottoms without secondary containment liners. With the many other systems incorporated into these storage facilities (e.g. tank gauging systems, fire protection systems, etc.), complete electrical isolation can be difficult to achieve. The tank may also be connected to a grounding system for safety, precluding the possibility of complete tank isolation. Provide CP for buried distribution pipelines associated with the tank. Consider electrical isolation issues, stray current interference issues, and life cycle costs to determine the need for a single integrated CP system for the tank and pipelines or separate CP systems for the tank and pipelines.

4-5.4 CP Systems for Reinforcing Steel in Concrete.

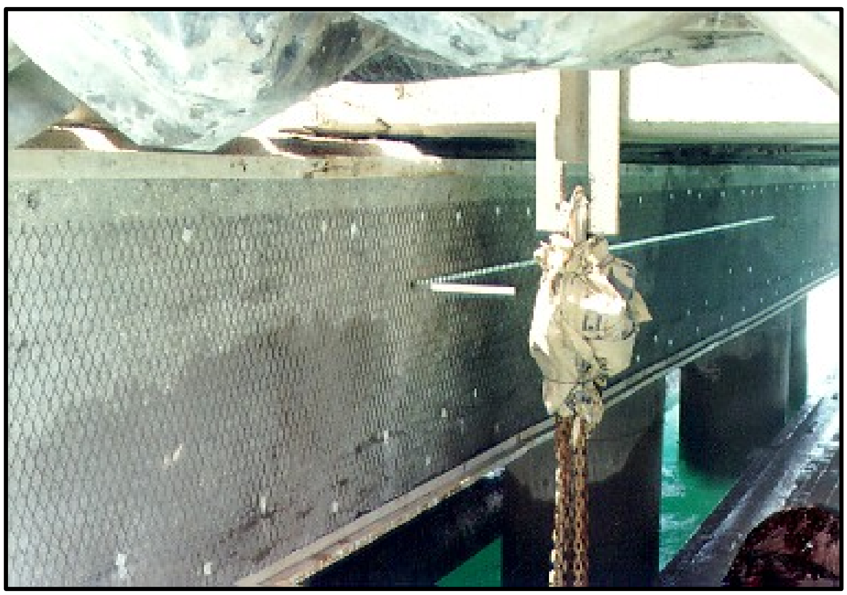
CP systems are not required for reinforcing steel (rebar) for new reinforced concrete structures. Instead, comply with the requirements of the appropriate UFC and UFGS documents that include concrete design considerations that enhance corrosion prevention and control of the rebar. However, for major concrete structure repair projects, provide CP for the rebar in concrete where economical over the life cycle of the structure. CP systems for rebar in concrete must be designed by a qualified person experienced in the design of CP systems for rebar in concrete. Provide permanent reference electrodes or corrosion probes to allow testing and monitoring of the CP system effectiveness.

4-5.4.1 ICCP Systems.

For corrosion protection of reinforced concrete structures requiring significant structural concrete repairs, consider one or a combination of the three different types of ICCP anode systems that is most appropriate for the type of concrete structure and repairs being accomplished.

- Titanium mesh system consisting of mixed metal oxide coatings on an expanded titanium mesh fastened to the concrete surface (Figure 4-7) and overlaid with a cementitious material, usually a Portland cement concrete mix. This type of system is commonly used on deck surfaces, piles or columns
- Titanium ribbon (mesh) slotted system consisting of mixed metal oxide coatings on either solid titanium ribbon strips or on expanded titanium mesh strips (ribbons). The ribbons are installed between the rebar and concrete substrate or in slots cut in the concrete surface and backfilled with a cementitious mix. This type of system is commonly used on deck surfaces

Figure 4-7 Titanium Mesh Anodes Fastened to a Concrete Beam



- Discrete anode system that typically consist of short strips of mixed metal oxide coated expanded titanium mesh, ceramic anodes, or platinized titanium wire typically installed in drilled holes and backfilled with cementitious grout. The length and spacing of the discrete anodes depends on the density of rebar and protection current requirements. These systems are most economical for beams, piles and columns

4-5.4.2 GCP Discrete Anode System.

When cracked and spalled concrete structures containing high chloride contamination are repaired by patching, consider installation of GCP discrete anode systems (DAS) in the vicinity of the patched area. The GCP discrete anodes are sacrificial zinc anodes in a special backfill (Figures 4-8 and 4-9). Unless a large area of concrete is removed during spall repairs, provide discrete anodes areas near the outer edges of the patch before applying the concrete patch. The type, length and spacing of the discrete anodes depend on the density of rebar and patch dimensions.

The intent of the DAS anodes installed along with patches is not to provide adequate CP to the entire structure, but to minimize the galvanic corrosion effects between the rebar surrounding the patched area and the rebar within the patched area. Technical Report TR-NAVFAC EXWC CI-1412 *CPC Program Final Report Alkali Activated Zinc Grouted Anode System for Concrete Reinforcing Steel,* includes details on design considerations for the application of DAS anodes in a waterfront structure.

Figure 4-8 Discrete Zinc Anode (Wrapped in Green Mesh) in Concrete Deck Repair. Device with Yellow Lead Wire is a Permanent Reference Electrode.

4-5.4.3 Pre-engineered CP for Pier Pilings.

Integrated concrete pile repair and corrosion protection systems (Figure 4-9 and 4-10) contain pre-engineered CP systems for the pile reinforcing steel. Consider these type of systems as a viable alternative for long-term repairs of waterfront structures with reinforced concrete piles containing high chloride contamination, and significant spalling/delamination of concrete due to corrosion of reinforcing steel. These systems can increase the service life of a pier patch repair up to 20 years in contrast to only six to seven years if pier pilings containing high chloride levels are only patched. For piles with only minimal damage, prepare a life cycle cost analysis to help determine the economic viability of this technology. NAVFAC ESC Technical Report TR-2292-SHR

CPC Program Final Report Integrated Concrete Pier Piling Repair and Corrosion Protection System, documents an innovative repair technique known as “Lifejacket” which integrates both concrete pile repair and a zinc mesh GCP system.

Figure 4-9 Discrete Zinc Anodes in Fiberglass Jacket for Pile Installation.

Figure 4-10 Photos Showing “Before” and “After” Installation of Integrated Pile Repair Systems

4-5.5 Water Storage Tanks.

Water storage tank CP systems must be designed by a qualified person experienced in the design of CP systems for water storage tanks to ensure its proper operation. Refer also to the best practices and lessons learned in Appendix B-10.4.

4-5.5.1 Interior of Potable Water Tanks.

Ensure that CP system materials are approved for use inside of potable water storage tanks in accordance with NSF/ANSI Standard 61. Coordinate CP system requirements with the interior protective coatings designer to eliminate conflicting requirements. Include requirements in the contract specifying that the contractor is responsible for providing an interior coating system and ensuring that the coating system is compatible with the ICCP system. For bolted panel storage tanks, require the contractor to ensure all panels of a bolted panel storage tank are electrically continuous.

4-5.5.2 CP for Interior of Water Tanks Subject to Icing Conditions.

There is a persistent problem at DoD installations with CP systems for water storage tanks located in areas with cold winters. Water tank interior CP system anodes are typically suspended from the roof of the tank with wires and cables such that they are submerged in the water. Such systems are often prematurely damaged or destroyed when surface ice forms in the tank in very cold environments. ICCP systems to protect the interior surfaces of water storage tanks in cold climates must be designed to prevent damage from ice. Specify a CP system consisting of mixed metal oxide wire anodes along with a flotation and support system that keeps the anodes submerged in water underneath surface ice, regardless of the water level, where they will no longer be subject to ice damage. Technical Report ERDC/CERL TR-07-22 *Demonstration of Ice-Free Cathodic Protection Systems for Water Storage Tanks at Fort Drum*, documents considerations for designing ICCP systems for water tanks subject to icing conditions. Refer to the material and installation requirements in UFGS 26 42 15.00 10.

4-5.5.3 Bolted or Riveted Water Storage Tanks with Interior Glass Lining.

Where a CP system is planned for a bolted or riveted steel water storage tank with an interior glass lining, include provisions to ensure electrical continuity between the riveted steel plates. The interior glass lining may electrically isolate adjacent plates. For other types of protective coatings, include requirements in the contract specifying that the contractor is responsible for providing an interior coating system and ensuring that the coating system is compatible with the CP system.

4-5.5.4 Monitoring Water Tank CP Effectiveness.

Provide a CP monitoring system that will allow monitoring of system effectiveness without having to physically climb the tank. Design the monitoring system such that test lead terminals are conveniently located in, or nearby the rectifier at ground level. Consider the use of remote monitoring systems.

4-5.6 Hot Water Storage Tanks.

Steel hot water storage tanks need protection against internal corrosion to prevent chronic leaking and premature failure. Corrosion caused leaks could cause extensive water damage to structures and mission critical electrical and mechanical equipment that may be co-located in rooms where the water storage tanks are located. Furthermore, the resulting leaks will eventually cause an accumulation of moisture that will promote mold and bacteria growth. Technical Report ERDC/CERL TR-07-26 *Cathodic Protection of Hot Water Tanks at Fort Sill*, documents the economics of the application of CP systems for hot water storage tanks. Refer also to Appendix B-10.5.

4-5.6.1 Domestic Hot Water Heaters/Tanks.

Provide factory-equipped glass linings and sacrificial anodes for domestic and smaller hot water heaters/tanks (75 – 1000 GA capacity). The glass linings and sacrificial magnesium anodes are economical for corrosion protection due to the reduced maintenance and monitoring for these systems.

4-5.6.2 Industrial Hot Water Heaters/Tanks.

Provide ICCP systems that use mixed metal oxide titanium rod anodes for larger industrial hot water heaters/tanks where corrosion of the interior has historically been a problem. Provide a capillary pore tube measurement port or bridge that facilitates CP system testing with a reference electrode located outside the hot water tank with the tip held against the ionically conductive capillary tube (see Appendix B-10.5.2.1).

4-5.6.3 ICCP for Water Boxes in Power Plants.

Water boxes can contain a mixture of many different metallic materials. Some of the materials such as titanium, austenitic stainless steels, and super alloy stainless steels are more noble than the rest of the water box components. As a result, without CP, water box components can experience substantial galvanic corrosion. However, improperly designed ICCP systems for water boxes can result in metallurgical problems such as:

- Hydride formation in titanium tubes under excessive CP results in reduced ductility as the hydride forms.
- Generation of chlorine gas at the anodes under excessive CP resulting in pitting corrosion in the upper tubes of austenitic stainless steel tube bundles.
- Hydrogen embrittlement of stainless steel under excessive CP.

Cathodic protection systems must be carefully designed to operate within selected operating potentials, and be properly maintained within these potentials to prevent any metallurgical problems from occurring. Designs must be accomplished by personnel qualified and experienced in these types of systems.

APPENDIX B BEST PRACTICES

B-1 CATHODIC PROTECTION PLANNING.

Cathodic protection systems are often not included in a project design because they are not appropriately identified in the project planning documents. CP systems reduce corrosion of buried or submerged metallic structures, thus reducing the probability of failure and concomitant environmental, operational, safety, and economic repercussions. However, in many cases, CP requirements are not considered during the early planning or design of such systems. Also, repairs to existing structures without CP can easily result in accelerated corrosion of the repaired section. Finally, while CP does add additional costs initially, they will generally be the best economic alternative over the life cycle of the structure.

Identifying the CP requirements early on in the process enhances the chances of a successful design. CP requirements added to the scope during the later stages of the process are less likely to be adequately designed or implemented because of limited budgets (often resulting in mediocre design efforts and greater likelihood that the CP requirement will be eliminated), limited time schedules, and resistance from project design teams to further complicate and delay their design process at later stages.

B-1.1 Project Documentation.

The project documents indicate general intent and the final product may change based upon the designers analysis. Even if the designer later determines that a CP system is not required, or a type of CP system different from that identified in the project documents is required, as a minimum, the requirement has been considered. It is usually easier to modify or delete a requirement than it is to add the “new” requirement, particularly in the later design stages.

B-1.1.1 Cost Estimates.

Provide CP system cost estimate information as part of the project documentation. Detailed cost information sheets are most helpful, but if such information is not available, estimate CP system costs based on a percentage of the cost of the structure being repaired, replaced or constructed. Table B-1 provides general guidelines:

Table B-1. General CP System Cost Guidelines

PROJECT COST OR STRUCTURE REPAIR, REPLACEMENT, OR CONSTRUCTION COST	CP SYSTEM COST PERCENTAGE (%)
< $500,000	15 – 20
$500,000 - $5,000,000	10 – 15
> $5,000,000	5 - 10

B-1.1.2 Sketches and Drawings.

Provide proposed CP system sketches and drawings as part of the project documentation when such information is available. Such information may be available from base corrosion/CP surveys, early stage design drawings, previous CP system installation drawings, or facility condition assessment reports.

B-1.2 Corrosion Control/CP System Assistance.

Bases/Installations/Activities should seek assistance from the service CP subject matter experts, MAJCOM Corrosion Engineers, or service execution agents.

B-2 CP SYSTEM DESIGN CONTRACT PROCESS.

B-2.1 Project Documentation.

When properly planned, infrastructure project documentation should already identify general corrosion prevention/CP system requirements. If not, discuss these requirements with the user to ensure that they are included in the process from the onset of design. This will allow the user ample time to arrange for funding for the CP system design and construction if not already included. Addition of these requirements later in the process often results in funding problems and other delays.

B-2.2 Developing A-E Scope of Work.

Spend a conscientious effort in preparing the A-E scope of work. The scope of work describes the nature of the project and the results expected from the designer. In the design contracting world DoD will not get what is desired unless specified in the design.

B-2.2.1 References.

Reference the policy and requirements in Chapter 2. Reference any applicable codes, regulations, and other applicable UFC documents.

B-2.2.2 Designer Field Survey.

Include costs and effort for the A-E to conduct a field survey to determine site conditions required to adequately design a CP system. The A-E designer must conduct specific field tests at the proposed installation site(s) to evaluate as a minimum, the electrolyte corrosiveness (resistivity, pH, etc.) and CP system current requirements.

B-2.2.3 Typical Field Survey Time.

Typically, allot about two days on site for the designer to inspect the project site conditions, conduct field measurements, research as built drawings of existing structures and associated or nearby CP systems, meet with the installation user and engineering personnel, and determine CP system equipment locations. Additional field time may be necessary, for extensive or complex structures.

B-2.2.4 Electrolyte Environment Data Provided by the Government.

It is generally not recommended that the A-E be asked to design a CP system based on electrolyte information provided by the government. The designer must obtain such information during his own field survey. In isolated cases where a field survey cannot be conducted and an adequate amount of reliable historical information is available, it may be beneficial to ask the designer to base his design on the information provided by the government, however, this may release the A-E from liability if the system is inadequate.

B-2.3 What Information to Provide A-E.

A-E firms must be qualified to design the technical aspects of a project, and an integral part of a good design is the incorporation of user requirements. To aid with the preparation of good CP system designs, provide the designer with user preferences and operational requirements that will affect the design. These requirements can either be written into the design scope of work or discussed during a pre-design meeting.

B-2.3.1 Documents with Pertinent Structure Information.

Documents commonly provided by the government include:

- A copy of a published Base Corrosion Control Plan
- General layout of project site showing location of nearby CP systems
- Drawings of existing CP systems on the existing structure or nearby CP systems if the structure is or will be newly constructed. Also provide the latest Base CP System Assessment Survey and available CP system data if appropriate and requested
- Drawings of the facility for which CP is being designed
- Past historical work effort and manpower maintenance requirements for existing systems (if available)

B-2.3.2 Project Limitations and Constraints.

Information regarding user/Base operational requirements and restrictions should be made known to the designer that may impact the design and/or construction of the CP system.

- Access/Security policies and requirements
- Any special limitations on working hours
- Budget limitations for the project
- Anticipated timeframe for construction

- User Operations limitations that may affect construction schedule (e.g. operational schedules that may prohibit shutdown of the facility, access limitations on airfields or waterfront areas, restricted areas, etc.).
- Safety requirements (e.g. hot work permits)
- Environmental and historical preservation limitations

B-2.4 Deliverables – What to Expect from the A-E.

Assuming proper scope of work has been prepared, design submittals must include, as a minimum:

- Design Basis
- Drawings
- Specifications
- Cost Estimate

B-2.5 Common Problems/Lessons Learned with A-E Designs.

B-2.5.1 Ensure That the CP Design Engineer is Qualified.

CP systems must only be designed by a National Association of Corrosion Engineers (NACE) International Certified Cathodic Protection or Corrosion Specialist. In addition to the certification requirements, the CP design engineer should also have a minimum of five years of experience in the design and successful installation of the type of CP being proposed. Include these requirements in the contract statement of work. Refer to paragraph 3-3.2.

B-2.5.2 Vague Statement of Work (SOW).

Disagreement on design results sometimes occur because of a vague statement of work. Ensure that the scope of work explains the expected results. Ensure that all of the structures intended to be protected are identified. Identify specific system features that are desired. For example, if an ICCP system is desired, then clearly state this in the SOW. Consult with service CP subject matter experts for assistance.

B-2.5.3 Appropriate Level of Effort.

Ensure all levels of effort are identified when negotiating with the contractor. Appropriate design survey field time is a common level of effort causing disagreement. In most cases, CP systems cannot be accurately designed without allowing the designer field survey efforts.

B-2.5.4 Maintain Lines of Communication.

Maintain lines of communication between all interested parties. Operational requirements often change during the design and installation process, and the CP engineer, often a sub-contractor, is sometimes not notified of the change that can result in inadequate CP design (e.g. structure size increased, or additional buried structures added). Miscommunication between disciplines as to which drawings will show certain details sometimes results in neither one doing it, or conflicts between different drawings or between drawings and specs which can lead to installation problems.

B-3 CP SYSTEM DESIGN DOCUMENTATION.

B-3.1 DESIGN BASIS.

The design basis must include a narrative description of the proposed CP system, field test data, design calculations, catalog cuts of proposed CP equipment, responses to review comments. The basis must address any environmental and historic preservation requirements and considerations that may impact project execution. Significant amounts of time are often required to comply with environmental and historical preservation requirements. Although the base or installation is typically responsible for processing the environmental requirements, the basis of design must identify these requirements to help ensure that they are addressed early on in the process and prevent delays in construction. Where the protected structure is located outside of the base, the contractor should identify potential easement issues and appropriate contacts for resolving these issues, as well as local Cathodic Protection Coordinating Committee contacts.

B-3.1.1 Narrative Description.

The narrative will help determine that the A-E designer understands the scope of work, the nature of the project, and the expected results. The narrative description must discuss the rationale for selecting the type of system, including the impact of seasonal variations on the CP system design, and include discussion of special requirements and limitations that may impact construction, operation and maintenance.

B-3.1.2 Field Test Data.

The basis of design must include all field test data taken preferably in tabular form including, but not limited to:

- All electrolyte (soil, water, etc.) corrosivity data as necessary (resistivity, pH, chloride content, sulfide/sulfate content, soil classification, and reviews of available soil borings)
- CP system current requirement test data (existing structures as applicable)
- Operational test data for existing or nearby CP systems
- Results of interference tests
- Historical information deemed important to the new CP system design

B-3.1.3 Design Calculations.

The basis for design must include all design calculations including, but not limited to:

- Calculation of surface area of the structure to be protected
- Determination of the CP current requirement. For existing structures, this should almost always be determined by on-site field current requirement tests
- Determination of type of system to be used based on existing variables and cost
- Determination of anode size and quantity
- Determination of CP system circuit resistance
- Determination of rectifier size
- A/C power calculations including short circuit analysis (ICCP systems only)
- Calculation of appropriate wire and conduit size
- Other related electrical calculations as necessary
- Attenuation calculations where appropriate

Section B-6 provides additional details regarding these calculations. Technical Papers 16, *Impressed Current Anode Material Selection and Design Considerations*, and 17, *Galvanic (Sacrificial) Anode Material Selection, Design Considerations*, provide examples of typical design considerations, process and calculations for the project engineer as a guide to follow when reviewing A-E designs. Do not direct A-E designers to follow these examples, and do not cite these examples as standard DoD design procedures. Qualified designers should be able to design a CP system without having to reference these examples.

B-3.2 DESIGN DRAWINGS.

The CP system design drawings must include sufficient detail and clarity to ensure the system is properly constructed. The design drawings should include, but not be limited to:

- Plan view(s) indicating locations of all CP equipment (anodes, rectifiers, test stations, foreign pipeline crossings, stray current test points, dielectric insulating fittings, electrical continuity bond connections, etc.)
- Details of anodes indicating size and weight
- Installation details of the anodes. Where applicable provide notes indicating allowances, if any, for relocating anodes
- Details of the rectifier showing type (air, oil, explosion proof, automatic, multiple circuit, etc.), size and capacity
- Installation details of the rectifiers (pad, wall, pole, grounding, etc.)

- Details of test stations (type, size, terminal boards, quantity and type of shunts and other wire terminals, quantity and size of wires and conduits terminating in the test station)
- Details of anode junction boxes
- Locations and details of dielectric insulating fittings
- Locations and details of electrical continuity bond connections
- Exothermic weld details
- CP system electrical one line diagram(s)
- Electrical installation details such as cable/wire identification schemes and appropriate legends

Refer to Appendix D for examples of typical details.

B-3.2.1 Quantity and Size of Details.

The number of details shown on one sheet and the size of the details must be appropriately sized so that the details are clearly legible when reproduced at half size. Half size drawings with clearly legible details will also facilitate testing and maintenance by base personnel.

B-3.2.2 Notes.

Provide notes on the drawings to further describe and clarify important/critical items in the details, particularly for critical items. Even if critical items are already described in the specifications, it is still useful to have these also included as notes on the drawings. Contractor personnel usually have the drawings at the work site, while the specifications are usually in the office. It is easy to miss some critical installation items if the notes are not included on the drawings. The notes on the drawings will help preclude unnecessary rework and consternation from both the contractor and construction management personnel. Installation notes also help facilitate testing and maintenance by base personnel.

B-3.3 Specifications.

Boiler plate sections include general specifications. Technical sections include descriptions of all CP system equipment and installation procedures; acceptance testing procedures including static (native) potentials, initial and final system potentials, and interference tests; special contractor qualifications; and applicable reference standards. The UFGS include common, standard recommended clauses for:

- Appropriate references to standards and other governing documents
- Contactor qualifications – do not delete this section without approval
- Required submittals
- Specifications of all CP system equipment and materials

- Specifications describing installation procedures
- Specifications describing commissioning and testing procedures
- Maintenance instructions

Open brackets indicate choices where appropriate. The standard and non-optional clauses should generally not be edited without government review and approval. However, since many CP systems are somewhat unique and the UFGS cannot include accurate clauses for every situation encountered, the designer should add missing or delete non-applicable requirements as necessary. Pay attention to user notes in the guide specifications that provide background information on some of the options for standard phrases. When using SPECSINTACT, turn on the “display notes” before deciding to use or delete certain paragraphs.

B-3.3.1 Protective Coatings Specified in Conjunction with Cathodic Protection.

Protective coatings to be applied to a new metallic structure in conjunction with CP must have the minimum characteristics as described in NACE International SP0169 and the appropriate UFGS. Coordinate the coating type and requirements with the CP system being specified. Many of the coatings specified in recently revised UFGS are compatible with CP systems. Utilize the appropriate protective coating UFGS and supplement the UFGS requirements, as necessary, with the minimum coating characteristics indicated in NACE International SP0169. Do not delete the CP requirements simply because it is not compatible with a particular coating.

B-3.4 Common Problems/Lessons Learned with Design Documents.

B-3.4.1 Computer Aided Design.

The use of computers has greatly aided in the design of CP systems (e.g. drawing programs, word processors, and spreadsheets). Many designers use previously completed designs as templates for new designs, and in their haste, forget to change some of the parameters from the previous design. Review all design documents to ensure that the information is accurate.

B-3.4.2 Notes on Drawings for Important/Critical Items.

For important/critical installation process, provide notes on the drawings even if the process is already included the specifications. Contractor personnel in the field often work off of the drawings and important processes can be missed. The notes on the drawings will help preclude unnecessary rework and consternation from both the contractor and construction management personnel.

B-3.4.3 Size of Details on the Drawings.

Avoid details on the drawings that are too small in size. Ensure details are sufficiently legible at half size drawing reduction. In order to minimize the number of sheets, smaller sized details are sometimes crammed in on a sheet. While they may appear sufficiently legible on full size prints or enlarged on a computer screen, the half size drawings may not be as legible. Contractor personnel in the field often have the half size drawings. Good contractor personnel will ask if something is illegible, while others will not and will interpret the drawings to their advantage.

B-3.4.4 Insufficient Environmental Considerations.

Ensure environmental personnel review the design during its early stages. They may identify unknown requirements that may increase the cost estimate significantly (archaeological, environmental controls, water management during drilling, hazardous waste disposal, and work in/adjacent to wetlands). It is better to delay the design completion date and identify additional funding early on, than to delay construction (change orders) and attempt to obtain additional funding which may not be available forcing reduction in scope or cancellation.

B-3.4.5 Electrical Review of CP Designs.

Review CP designs for conformance to the National Electrical Code (NEC). Many CP design engineers are unfamiliar with the NEC particularly with wire size and conduit. Also, the commonly specified electrical wire and cable for CP systems is the HMWPE type insulation. This insulation is thicker than normal and harder to pull through long conduit runs and bends even though the design conforms to code. It is sometimes necessary to specify a larger size conduit to improve constructability.

B-3.4.6 Design Build CP Designs.

Design build contracts are generally based upon performance specifications. Successful application of CP for the system life will be significantly dependent upon the requirements detailed in the request for proposal (RFP). The contractor selected is responsible to design a CP system that will meet the RFP requirements. The government will have to provide or assume certain conditions to make the project awardable such as soil resistivity, detailed description of structure to be protected and if possible the preferred type of CP system. Requirements that are too general and are not explicit in performance will result in the installation of a minimum system that will not perform over the anticipated system life. Typically, the contractor’s warranty is usually one-year, while the system design life is typically 15 - 25 years. There are instances where a contractor has proposed/installed minimal systems “to save the government money”, but those systems have not performed over the anticipated life. Evaluate Contractors technical proposal with the CP system requirements in mind. Discuss CP system requirements at the design/construction kick-off meeting and ensure the contractor implements them on the plans at each submittal stage.

B-3.4.7 As Built Drawings.

Require the contractor to maintain as-built drawings of the CP system and provide them to the Contracting Officer upon completion of the construction contract. Indicate on the drawings the location of all CP components, especially if installed differently from that indicated on the original design.

B-4 TYPES OF CP SYSTEMS.

There are two main types of CP systems, GCP or ICCP, and they can be applied many different ways to cathodically protect many types of structures. The anodes in either type of system can be either distributed or remote, and in an ICCP system the remote anodes can be shallow or deep. There are many different types and sizes of anodes for either type of CP system that can be installed either horizontally or vertically. Since CP is applied to the prevention of corrosion of a wide variety of structures in a variety of environments, each situation will require special consideration. There are fundamental procedures that should be followed in each case, and the method of application of CP to a particular structure depends upon unique design considerations. These considerations help determine alternatives and methods of protection to use in each specific case.

Two main design factors, which considered together can generally indicate the type of protection recommended; the resistivity of the earth and structure coating quality. For buried structures, poor or lack of protective coating and/or high earth resistivity can virtually eliminate the practical application of GCP systems in many specific applications.

B-4.1 GALVANIC CP SYSTEMS.

A GCP system, sometimes called sacrificial anode or “passive” system, is essentially a corrosion cell being utilized in a beneficial way. The structure to be protected is coupled with a more active metal when both are immersed in an electrolyte and connected with an external path as shown in Figure 3-1. In this case the entire surface of the metal being protected becomes the cathode, and the more active anode metal corrodes during the process and is sacrificed. The anode must be periodically replaced, but it is often much more economical to replace the anode than the protected structure.

B-4.1.1 Advantages and Limitations of Galvanic Systems.

Galvanic systems have several advantages over ICCP systems, but unfortunately also have several limitations. Table B-2 summarizes these advantages and limitations.

B-4.1.1.1 Main Advantages.

The main advantages include generally lower installation cost, less maintenance requirements, and unlikelihood of interference to other structures.

B-4.1.1.1 Limitations.

The main limitations stem from their set voltage. The low driving potential between the GCP anode and the structure (less than a volt) often cannot overcome high soil resistivity (ohms law) and/or provide sufficient current to protect a bare or poorly coated structure. Also, GCP systems require isolation, which sometimes is impractical or impossible to accomplish.

Table B-2. Advantages/Limitations of GCP Systems

ADVANTAGES	LIMITATIONS AND DISADVANTAGES
• No external power required • No regulation required • Easy to install • No or minimum of cathodic interference • Anodes can be readily added • Minimum of maintenance • Uniform current distribution • Installation can be inexpensive for new construction • Minimum right of way/easement costs • Efficient use of protective current	• Limited driving potential • Lower/limited current output • Retrofit installation can be expensive • Poorly coated/bare structures require many anodes • Can be ineffective in high resistivity soils. • Inability to meet desired system life for certain anode types for structures immersed in seawater or brackish water.

The use of certain GCP anodes is also limited for use on some structures immersed in seawater or brackish water. Operational requirements may limit the size of anodes, and hence, the CP system life. Ensure that the proper type and size of GCP anodes are specified to meet the desired CP system life for structures immersed in seawater or brackish water.

B-4.1.2 Where Galvanic Systems Not Recommended.

Generally, GCP systems are not economical for structures in electrolytes with resistivity over 30,000 ohm-cm or on bare or poorly coated structures. They are also impractical on systems that cannot be isolated from all other structures.

Specify the proper type and size of GCP anodes (or ICCP system if appropriate) to meet the desired CP system life for structures immersed in seawater or brackish water. Do not specify magnesium anodes as the primary CP system for structures immersed in salt water.

B-4.1.3 Distributed Galvanic System Applications.

Most GCP systems are distributed anode systems. This means the anodes are distributed geometrically along or around the structure to be protected. Individual anodes are spaced with each anode protecting only a portion of the structure. Continuous “ribbon” anodes are also available and installed along the structure or installed with the structure in the same trench. The quantity, size, and spacing of the anodes as well as the distance of the anodes from the structure are determined by the anode output current and the structure current requirement.

B-4.1.3.1 When Distributed Anode System Cost Effective.

A distributed anode system is most cost effective when it is installed during construction of the structure. Generally, a distributed anode system requires a very good coating and isolation of the structure being protected.

B-4.1.3.2 Common Uses.

Common uses of distributed GCP anode systems include well coated, isolated pipelines or underground storage tanks in low soil resistivity when installed for new construction, for application on existing underground storage tanks under the same conditions, and on submerged waterfront structures.

B-4.1.3.3 Common Misapplications.

Common misapplications of distributed GCP anode systems include bare or poorly coated pipelines, tank bottoms or tanks; non-isolated structures; structures in high soil resistivity; or for application on existing distribution systems.

B-4.1.4 Galvanic (Sacrificial) Remote System Applications.

In limited circumstances, GCP systems can be installed in one or more remote locations to provide protection to an entire structure. Individual anodes would be located in the remote locations with the number, size, and spacing determined by the current requirement, individual current output and total current requirement.

B-4.1.4.1 When Remote Anode System Cost Effective.

Remote GCP systems can be very cost effective for new or existing structures that are small in size (surface area), are coated with an extremely good coating (99.7% efficiency), are electrical isolated from other buried metallic structures, and installed in very low resistivity soils, (typically under 3,000 ohm-cm).

B-4.1.4.2 Common Uses.

Common uses include extremely well coated, short isolated sections of pipelines or underground storage tanks in very low soil resistivity.

B-4.1.4.3 Common Misapplications.

Common misapplications include bare or poorly coated pipelines, tank bottoms or underground storage tanks; non-isolated structures; and structures in medium or high soil resistivity.

B-4.2 IMPRESSED CURRENT SYSTEMS.

An ICCP system, sometimes called a “rectifier” or “active” system, like a GCP system, is also essentially a corrosion cell with one main difference. Instead of relying on the natural “driving” potential between two metals, an external power source, usually a transformer-rectifier, provides the driving force. Figure 3-2 illustrates a simple ICCP system.

B-4.2.1 Advantages and Limitations of ICCP systems.

B-4.2.1.1 Main Advantages.

The driving potential of an ICCP system is only limited by the size of the rectifier and the circuit resistance. Most systems are designed to a maximum of 50 amps and can range to over 200 volts, although typical systems are usually under 100 volts and 30 amps. Nearly all ICCP systems have adjustable outputs, an advantage over GCP systems whose outputs are normally not adjustable. ICCP systems can overcome all the limitations of a GCP system; however they do have some limitations and disadvantages as well. Table B-3 summarizes these advantages and limitations.

Table B-3. Advantages/Limitations of ICCP Systems

ADVANTAGES	LIMITATIONS AND DISADVANTAGES
• Can be designed for wide range of voltage and current and structures with high current requirements • Variable voltage and current output • Applicable in high-resistivity environments and applications in water having low resistivity. • High ampere year output available from a single ground bed • Large areas can be protected by a single installation • Effective in protecting uncoated and poorly coated structures, although good coatings would significantly reduce costs. • Effective in protecting structures that cannot be economically electrically isolated from other buried metal structures • Can be easier to retrofit on existing large structures	• Requires external power - monthly power costs • Subject to power failure and vandalism • Higher maintenance and operating cost than GCP systems. Requires more frequent periodic inspection and maintenance • Can cause cathodic interference problems • Overprotection can cause coating damage

B-4.2.1.1 Main Disadvantages.

With this increased voltage and current there is more concern over current distribution and interference to other structures. More care and testing are required for the design and installation. There is a recurring power cost and a much higher maintenance cost. This higher maintenance cost includes more rigorous testing and higher repair and troubleshooting requirements.

B-4.2.2 ICCP Anode Installation Methods for Buried Structures.

There are several common methods of installing ICCP anodes for buried structures.

B-4.2.2.1 Shallow Vertical Anode Placement.

This is the most common method of installing shallow anodes for both remote and distributed anodes. This generally results in lower anode to earth resistance than horizontally installed anodes, and results in more CP current for a given voltage. The top of the anode is normally buried as deep as or deeper than the structure.

B-4.2.2.2 Horizontal Anode Placement.

This method of installing shallow anodes for both remote and distributed anodes is sometimes required due to rock strata, other special ground conditions or space limitations which preclude the use of vertical anode placement. It is important for these anodes to be deeper than the structure. This method results in a higher anode to earth resistance than vertical anodes, and generally requires more anodes (shorter spacing).

B-4.2.2.2 Deep Anode Placement.

Deep anode beds are generally installed in single vertical columns much deeper than shallow vertical anodes. The top anode is normally installed more than 50 feet deep from the ground surface. In effect the anode bed is installed remotely from the structure by being installed deep in the ground.

B-4.2.3 ICCP Anode Installation Methods for Submerged Structures.

There are also several common methods of installing anodes for submerged structures.

B-4.2.3.1 Distributed Anodes.

The most common method of installing anodes for submerged structures is a distributed anode ICCP system in which the anodes are distributed geometrically over the entire structure submerged in the same electrolyte as the structure.

B-4.2.3.2 Land Based Anodes for Waterfront Structures.

Generally, CP system anodes must be installed in the same electrolyte as the protected structure in order for the CP system to properly operate and adequately protect the structure. For waterfront structures such as steel sheet pile bulkheads and steel pilings for piers running parallel to the shoreline, land based deep well anode systems may be installed to protect the submerged portions of the structure.

B-4.2.4 Distributed Anode ICCP System Applications.

Distributed anode ICCP systems are systems for which the anodes are distributed geometrically over the entire structure. They are most cost effective when they are installed along with the installation of the structure. They do not require a good coating or isolation of the structure being protected, although either would reduce costs.

B-4.2.4.1 Advantages.

In addition to those listed in Table B-3, the advantages of distributed anode ICCP systems include:

- Low installation cost when installed with the structure
- Lesser probability of causing interference than remote anode bed ICCP systems.

B-4.2.4.2 Disadvantages.

In addition to those listed in Table B-3, the disadvantages of distributed anode ICCP systems include:

- Greater chance of premature failure
- Is not cost effective to install (exorbitant trenching, boring and excavation costs) on an extensive existing structure, such as a distribution system; and
- damage to anode cables by future excavations is a big problem with this type of system. Protection and maintainability of the extensive anode leads should be addressed by the design and the installation.

B-4.2.4.3 Common Uses.

Common uses of distributed anode ICCP systems include:

- Pipelines with limited easement or land space to install anodes,
- On-grade storage tank bottoms,
- Newly constructed underground storage tanks, and application of CP to existing underground storage tanks or aboveground storage tank bottoms.

This is the only type of ICCP system used for water tank interiors.

B-4.2.4.4 Common Misapplications.

Common misapplications of distributed anode systems include the failure to distribute the anodes over the entire structure, or distribution of the anodes at excessive intervals.

Either case will result in poor current distribution and lack of protection between or at a distance from the nearest anodes while overprotecting the structure near the anodes.

B-4.2.5 Remote Anode Bed ICCP System Applications.

Remote anode bed ICCP systems can be used regardless of structure coating quality, soil resistivity or current requirements. They do not require any coating on the structure, and may not require isolation of the structure being protected (although either would reduce costs). Therefore, this method can be used on many types of existing structures. Multiple remote systems are commonly used to protect very large or extensive structures, such as cross country pipelines and large distribution systems. Multiple remote systems are several remote systems, distributed and geometrically placed, to provide current to different areas of extensive structures.

B-4.2.5.1 Advantages.

In addition to those listed in Table B-3, the advantages of remote anode ICCP systems include:

- Longer runs of pipelines can be protected with a single system
- Improved chances in finding a good anode bed location

B-4.2.5.2 Disadvantages.

In addition to those listed in Table B-3, the disadvantages of remote anode ICCP systems include:

- Interference to other structures is of high concern and the mitigation of interference should be part of the design and installation
- Easement issues when located off base
- Damage to anode cables by future excavations

B-4.2.5.3 Common Uses.

Common uses of remote ICCP anode systems include:

- Long pipeline runs or extensive pipeline distribution systems (e.g. fuel and natural gas distribution systems)
- On-grade storage tank bottoms
- Fuel storage tank farms with multiple on-grade storage tanks
- Situations where distributed anodes or shallow anodes in closer proximity to the structure(s) is not possible (e.g. pipelines running under an airfield or waterway)

A deep anode bed installation, described in paragraph B-4.2.6, is considered a remote system.

B-4.2.5.4 Common Misapplication.

A common misapplication of remote anode systems is installation of the anodes too close to parts of the structures where they are not truly remote from the entire structure. Poor or uneven current distribution results from not being truly remote from the structure and can result in inadequate protection of remote areas of the structure, while overprotecting parts of the structure nearby the anodes.

B-4.2.6 Deep Anode Bed ICCP System Applications.

A deep anode bed system is considered a remote anode bed system; its remoteness from the structure attained by installing the anodes deep in the ground below the structure. The top-most anode of a deep anode bed is normally installed at least 50 feet deep. Multiple deep anode systems, geometrically located, are commonly designed to protect very large or extensive structures, such as cross country pipelines, large storage tank farms, large distribution systems, and sheet pile bulkheads. Each individual system is commonly limited to approximately 60 amps. By installing the anode deep in the ground, remote from a structure, high current levels can be evenly distributed over very large or extensive areas of a structure or distribution system.

B-4.2.6.1 Advantages of Deep Anode Bed Systems.

In addition to those listed in Table B-3, the advantages of deep anode bed systems include:

- Longer runs of pipelines or multiple structures electrically bonded together can be protected with a single system. Improved current distribution, since the deep well is generally remote from the structure(s)
- High current output, but with less chance of causing stray current interference on nearby foreign structures
- Improved chances in finding a good anode bed location
- Installation of the deep well anode system may be easier
- Minimized excavations, particularly in congested areas
- Less likelihood of damage to anode leads, especially when the rectifier is located adjacent to the top of the anode bed installation
- Fewer problems with easement issues for systems located off base. The system can often be installed within the structure easement
- Land and waterside of waterfront structures can be protected with landside installations
- Less affected by seasonal moisture variations

B-4.2.6.2 Disadvantages of Deep Anode Bed Systems.

In addition to those listed in Table B-3, the disadvantages of deep anode bed systems include

- Generally higher cost and greater difficulty for well drilling and environmental considerations (e.g. implementing measures during design and construction to satisfy local water authority concerns about water aquifer contamination)
- Designer must be familiar with the geological factors that will impact the installation
- Prediction of deep anode performance is more difficult and less exact than for shallow beds
- Higher chance of premature failure if not properly designed, installed, and maintained
- Compaction of anode backfill may be difficult to achieve
- Must vent chlorine and other gas generated in the anode well to ensure proper operation (usually accomplished by installation of a vent pipe in the anode well)
- Environmental considerations for preventing contamination of groundwater may complicate installation

B-4.2.6.3 Common Uses.

Common uses of ICCP deep anode systems include:

- Multiple underground structures with high current requirements
- Installation of a single landside ICCP system to protect both land and seaside of steel sheet pile bulkheads
- Long or extensive pipeline distribution systems, particularly where space availability and easement issues limit the installation of anode beds (e.g. fuel and utility distribution systems)
- Long or extensive pipeline distribution systems or other structures in congested areas where stray current interference on foreign structures must be minimized (e.g. fuel and utility distribution systems)
- Existing large on-grade storage tank bottoms
- Existing fuel storage tank farms with multiple on-grade storage tanks
- Structures buried deep in the earth such as missile silos and well casings
- Situations where distributed anodes or shallow anodes in closer proximity to the structure(s) are not possible (e.g. pipelines running under an airfield or waterway)

B-4.2.6.4 Common Misapplications.

Common misapplications of deep anode systems include:

- Installation of deep anodes without considering all of the geological and environmental factors that affect the installation and operation
- Installation of anodes too shallow in the ground where they are not truly remote from the entire structure. The top anode is normally installed at a minimum of 50 feet deep. Installing the anodes too shallow will result in poor current distribution and the lack of adequate protection to remote areas of the structure, while overprotecting nearby parts of the structure

B-5 GENERAL DESIGN PRINCIPLES.

B-5.1 DESIGN APPROACH.

There are several different approaches to designing a CP system. Each approach must consider the set of design parameters affecting the structure to be protected to help determine the type of system best suited for the specific case. These design parameters include (but are not limited to):

- Type and geometry of structure to be protected
- Electrolyte conditions (mainly resistivity, but also pH, chloride content, moisture content, and sulfide content)
- Cathodic protection current requirement
- Type and quality of the structure coating
- Presence of other structures in the area
- Presence of other CP systems in the area

The first consideration in the decision process is to establish if the structure to be protected is existing, new, or a new structure that will be connected to existing structures with existing CP systems. The next decision is to determine if a GCP or ICCP system should be specified based on the design parameters and economics. If a GCP system cannot be ruled out, a design for both GCP and ICCP must be accomplished, and a determination made by evaluating the installation and maintenance life cycle cost.

B-5.1.1 CP System Operation Dependent Upon Local Environment.

The actual functioning of any CP system is dependent upon the local environment at each point on the surface of the structure to be protected, condition of the structure, and the actual level of protective current supplied to each point of the structure. It is impractical to determine the exact environmental conditions at each point on the structure, and as the environmental conditions change due to changes in soil moisture and aeration. It is also difficult to predict the actual distribution of protective current on the structure in many cases due to differing environment; the presence of other metallic structures in the vicinity of the structure to be protected, both known and unknown; and limitations on the ability to place anodes at ideal locations due to property boundaries or other limitations. Thus, while a good approximation of the system requirements can be obtained through field surveys, and a good approximation of current distribution can be made when allowances are made for differing environments and interfering structures, the installed system will, at a minimum, require initial adjustments to balance the system and periodic adjustments to maintain that balance. In some cases, particularly in the case of previously unknown interfering metallic structures in the vicinity of the structure being protected, modifications to the initially designed system may be required in order to achieve adequate protection. The design and operation of CP systems may be an iterative procedure.

B-5.2 DESIGN PARAMETERS AND CONSIDERATIONS.

B-5.2.1 Electrolyte Resistivity.

Electrolyte (soil, water, etc.) resistivity is one of the major parameters that affect CP system designs. The electrolyte resistivity must be measured during a field survey, and this parameter is used to determine anode to electrolyte resistance. The anode to electrolyte resistance is a major factor in selecting the type of CP system, the type of anodes, and the size and quantity of anodes, since the anode resistance often accounts for most of the CP system circuit resistance. High resistivity environments preclude the use of GCP systems, and the higher the resistivity, the greater the likelihood that an ICCP system will be required. Also, the higher the resistivity, the longer the anode must be, and the greater the quantity of anodes that will be required to reduce circuit resistance.

Seasonal variations at a particular location can result in significant fluctuations in soil resistivity due to changing moisture content and temperature. The designer must discuss the impact of the seasonal variations with local knowledgeable personnel as such resistivity variations will affect the CP systems design calculations, and in extreme situations, may dictate the type of CP system specified.

B-5.2.2 Cathodic Protection Current Requirement.

The current requirement is the amount of current that is required for adequate protection of the structure, and is used to help determine the type of system and the size and quantity of anodes. High current requirements increase the likelihood that ICCP systems will be required. For existing structures, the current requirement should be determined by field measurement, while for new structures, the current can be estimated using current densities appropriate for the environment.

B-5.2.3 New Construction or Existing Structure.

For existing structures, ICCP is usually more cost effective, unless the structure surface area is small and well coated. The electrolyte resistivity around existing structures and the current requirement for the structure must be measured during the design field survey. Without this resistivity and current requirement information, a CP system for the existing structure cannot be accurately designed.

-5.2.3.1 New Construction.

For new construction, the type of coating on the structure can be specified and the electrolyte resistivity measured, but accurately designing CP can be challenging due to unknown conditions that can occur during installation. Current requirements cannot be accurately calculated for new construction which is not electrically isolated.

Also for new construction other factors such as other existing CP systems and locations of other structures become very important. If the design is for new construction which connects to existing utilities, the type of system should be the same. In some cases the existing utilities CP system can protect the new construction with no further CP design or installation.

B-5.2.3.2 Structures with Existing CP Systems.

This parameter can often help easily determine the type and design of the CP system. Replacing the existing system in kind is all that is needed if the existing system functioned properly. However, GCP systems at the end of their design life are sometimes more economically replaced by ICCP systems. Also, if the previous system did not function properly, the new system should be designed to overcome the problems encountered with the existing CP system.

B-5.3 GENERAL CATHODIC PROTECTION DESIGN PROCESS.

B-5.3.1 Field/Site Surveys.

The first and foremost step of a CP system design is the field/site survey. In most cases, conduct a field/site survey in order to establish the actual environmental conditions that will be encountered, determine user requirements, and identify constructability parameters. There are only a very few instances in which a CP system can be properly designed without a field survey; therefore, always allow the designer field survey efforts when planning a CP design effort. The level of effort will be dependent upon the size and complexity of the structure(s) to be protected and whether the structure is new or existing. For submerged systems, all that is generally required is a water analysis, current requirement test (if the structure is existing), identification of interfering structures, determination of AC power sources, or other special circumstances. For buried systems, more extensive information may be required.

B-5.3.2 Electrolyte Characteristics.

Electrolyte resistivity is the single most important characteristic used in the design of CP systems for buried structures. Protective current requirements, sacrificial anode outputs, and ICCP anode bed resistance are all dependent upon electrolyte resistivity.

Other electrolyte characteristics may have a significant impact on electrolyte corrosivity and CP current requirements. Sulfide, sulfate, chloride, pH, and other chemical constituents may affect the current requirements necessary for CP as well as the protection criteria for some materials. Unless experience in the area has shown otherwise, analysis for sulfate, sulfide, and chloride content should be performed on electrolyte samples from the site.

B-5.3.2.1 Determining Electrolyte Resistivity of Soils In-Situ.

Most designers will measure soil resistivity in situ using the Wenner 4-electrode method as shown in Figures B-3 and B-4. In this method, a current is passed through two electrodes and a drop in potential through the soil due to the passage of the current is measured with a second pair of intermediary electrodes. All four electrodes are setup equidistant, and in a straight line. A specialized instrument is used to supply the current and measure the potential drop. In order to reduce the influence of any stray currents in the area and polarization at the electrodes, alternating current is used in the instrument. The soil resistivity is calculated from the indicated reading by using the following formula:

$$\rho = 191.5 \times a \times R$$

where

ρ	=	Soil resistivity (ohm-cm)
a	=	electrode spacing (feet)
R	=	meter resistance reading (ohms)

In the Wenner 4-electrode method, the average resistivity of the soil between the two center electrodes to a depth equal to the electrode spacing is measured. If the electrode spacing is increased then the average soil resistivity to a greater depth is measured. If the average resistivity increases as the electrode spacing increases, there is a region of higher soil resistivity in the deeper soil layers. If the average soil resistivity decreases with depth, there is a region of lower soil resistivity in the deeper soil layers.

B-5.3.2.2 Determining Electrolyte Resistivity Using a Soil Box.

When it is impractical to make field measurements of soil resistivity, soil samples can be taken from an appropriate depth and the resistivity of the sample can be determined by the use of a soil box. The measurement made using the soil box is essentially an application of the 4-electrode method (Figure B-5). Metal contacts in each end of the box represent the two outer electrodes in the 4-pin method, and are used to pass current through the sample. Potential drop is measured across probes on the soil box inserted into the soil. The resistivity is calculated using constants furnished with the particular size of soil box being used. Due to the disturbance of the soil during sampling and possible drying out of the soil during shipment, this method of soil resistivity measurement is less accurate than actual field tests by the preferred Wenner 4-electrode method. To minimize drying out of samples they should be placed in soil sample jars and sealed prior to shipment.

Figure B-3 Wenner Four Electrode Method Schematic

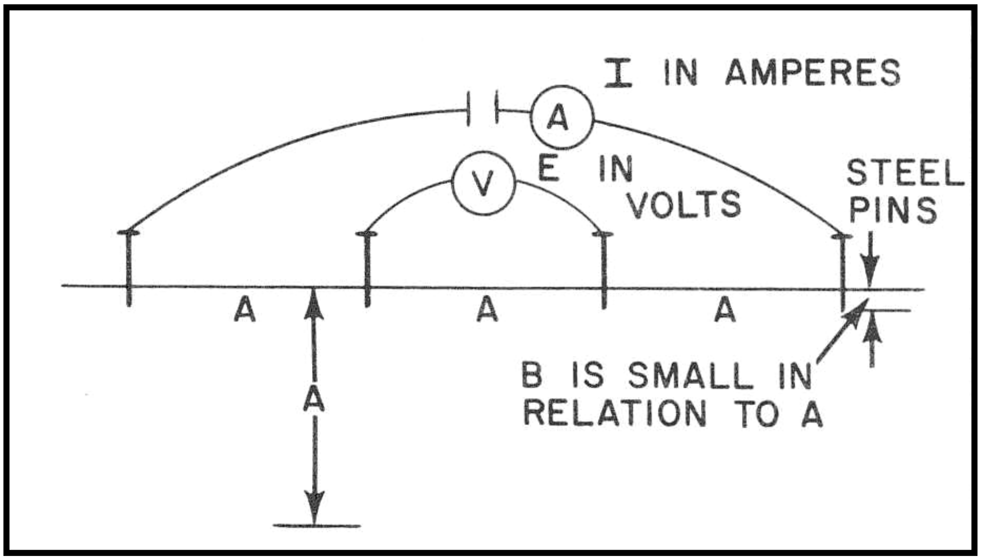

Figure B-4 Wenner Four Electrode Method for Measuring Soil Resistivity

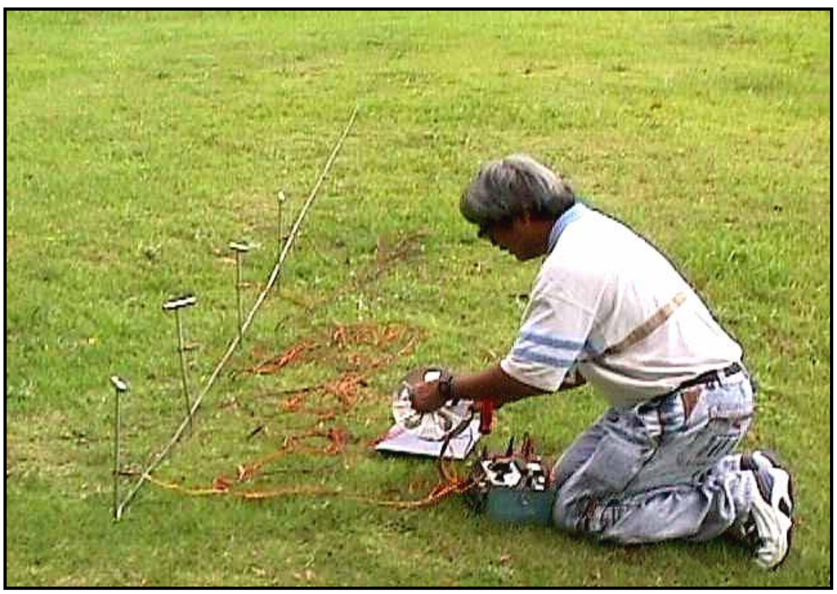

Figure B-5 Measuring Soil Resistivity in a Soil Box

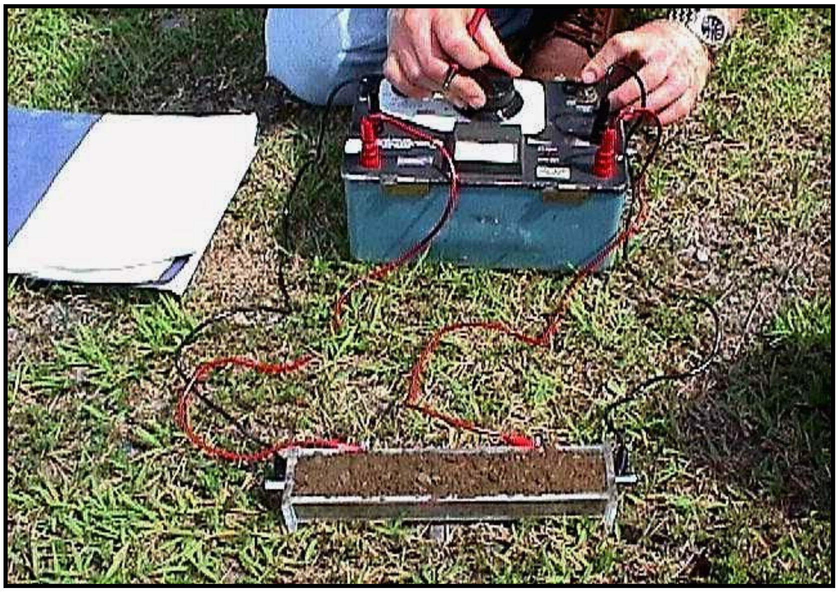

B-5.3.2.3 Water Analysis.

If the CP system is being installed inside of a water tank or other submerged structure, samples of water should be analyzed for pH, chloride, sulfate, and resistivity at a minimum. Other factors such as hardness may be pertinent to the specific circumstance. The resistivity of liquids can be measured using the Wenner 4-electrode method and a soil box or by using a conductivity meter which is specifically designed for the measurement of the conductivity of solutions. Conductivity is the inverse of resistivity.

$$\rho_w = \frac{1}{C}$$

where

ρ_w = water resistivity (ohm-cm)

C = water conductivity (mhos or siemens)

B-5.3.3 Determine CP System Current Requirement.

B-5.3.3.1 Current Requirement Testing on Existing Structures.

The most desirable means of determining the amount of current required for protection of an existing structure is to measure the actual amount of current required to achieve protection through installation and operation of a temporary CP system. Perform measurements of the temporary CP currents supplied and the structure-to-electrolyte potentials achieved on the structure to establish the current required to protect the structure.

If the temporary system cannot provide sufficient current to protect the entire structure, one method to determine the total amount of current required would be to protect a section of the structure, then multiply the result to estimate the amount of current to protect the entire structure. For example if 5 amps will protect one mile of pipeline, then 10 amps should protect 2 miles. A second method is extrapolation of the current and protection levels. For example, if 5 amps provide half the required current (half the required potential shift for protection) then linear extrapolation of the current versus potential line on a graph to the desired potential shift will yield the estimated required current to protect the structure.

Verify that the current requirement test results are reasonable by comparing them to a theoretical current requirement calculation as described in paragraph B-6.2. A large variation between the results of the field tests and theoretical calculations could be a result of:

- Incorrect assumptions about the existing protective coating condition.
- Electrical continuity with other structures in the vicinity (electrical isolation may be required).
- Unknown electrical isolation of portions of segments of the structure (electrical continuity bonding may be required).
- Specific electrolyte characteristics affecting the current requirement.

B-5.3.3.2 Current Requirement Calculations for New Structures.

For the design of CP systems to be installed in conjunction with the installation of a new structure, the estimated current requirements can be calculated as described in paragraph B-6.2.

B-5.3.4 Determine Coating Conductance.

In the design of CP systems the condition of protective coatings is an important factor. Protective coatings can both reduce corrosion of structures and reduce CP current requirements. For this reason, both coatings and CP should be applied synergistically on buried or submerged structures. For existing buried structures the condition of the coating can be determined by electrical field tests of the effective electrical resistance of the coating. The resistance measurements are then usually converted to conductivity per unit area, or conductance. Procedures for determining coating conductance are beyond the scope of this UFC.

B-5.3.5 Determine Electrical Continuity and Isolation.

B-5.3.5.1 Electrical Continuity Testing.

Continuity testing is important to determine if the structure being protected is electrically continuous. It is also used to determine which foreign structures are continuous to the structure being protected. For purposes of a current requirement test, it is very important to know what structures are connected to the structure being tested for proper evaluation of the current requirement.

B-5.3.5.2 Electrical Isolation Joints (Insulating Fitting).

Determine locations where electrical isolation is necessary. Electrical isolation is necessary to minimize current requirement for both GCP and ICCP systems by isolating structures that are not intended to be protected by the CP system. Insulating joints are sometimes used to isolate sections of structures so that each section can be protected separately when necessary.

B-5.3.6 Locate Other Structures in the Area.

Buried or submerged structures other than the intended structure to be protected may impact or be impacted by the planned CP system, and the site survey should include the location of any such structures. Buried structures such as pipelines which have risers, valves, etc., in the area can be traced using electronic tracers. The presence of buried structures in the area that do not have any surface indications are difficult to locate, and the maintenance of accurate records showing all buried structures and utilities is extremely important.

B-5.3.7 Selection of GCP or ICCP Systems.

The decision between using sacrificial anode or ICCP systems is based upon two major factors, feasibility and cost. Often, a CP system using both methods is designed for a given structure and the systems are directly compared in order to select the most appropriate type of system. Economic analysis may be necessary to determine the least cost system. In general, systems with small stable current requirements (0.5 Amp or less per 100 lineal feet of structure) are more likely to be protected using sacrificial anode type systems and those structures with larger (1 Amp or more per 100 lineal feet of structure) or where the current requirements vary considerably with time are more likely to be protected using ICCP systems. ICCP systems are generally used where larger amounts of current than can be supplied by a sacrificial anode system are required.

B-5.3.8 Determine Availability of AC Power.

During the site survey, determine the availability of AC power at the site as the cost of installing new AC power service may be an important factor in determining whether a GCP or ICCP system is the more practical solution for the specific application.

B-6 TYPICAL DESIGN CALCULATIONS.

This section provides general information and practices about the CP system design calculation process. Technical Papers 16 and 17 provide additional considerations during the design process as well as simplified examples of CP system designs that the project engineer can use as guides for reviewing actual CP system designs.

B-6.1 Calculate Structure Surface Area to be Protected.

For new structures which will be protected by CP systems, field current requirement tests in most cases cannot be conducted and the current requirements will need to be calculated. The total bare surface area of the buried or submerged structure to be protected (e.g. the uncoated submerged areas of a water tank interior or the uncoated areas of a buried pipeline) must be calculated in order to calculate the current requirements. If the structure has/will have a protective coating, then the bare surface area of the structure to be cathodically protected can be significantly reduced dependent upon the protective coating efficiency. The current required to protect a well coated structure can be several orders of magnitude less than the current required to protect the same structure if it is uncoated. The reduced amount of current required for the protection of well coated structures reduces the cost of protection as well as reducing other problems such as interference with other structures.

B-6.2 Calculate Cathodic Protection Current Requirements.

For existing structures, current requirement tests should already have been conducted during the field survey. The designer should verify that the current requirement test results are reasonable by comparing them to theoretical current requirement calculations. For the design of CP systems to be installed in conjunction with the installation of a new structure, the estimated current requirements can be calculated by multiplying the required current density by the area of the structure to be protected using the equation.

$$I = A \times CD$$

where

A	=	Area of structure to be cathodically protected (ft^2)
I	=	Current required for cathodic protection (amperes)
CD	=	Current density (milliamperes/ft^2)

Table B-4 provides current density ranges for typical environments.

B-6.3 Determine CP System Circuit Resistance.

After the current requirement is determined, next determine the circuit resistance of the system. This requires calculation of the anode-to-electrolyte resistance, resistance of lead wires and the structure-to-electrolyte resistance.

Table B-4. Current Density Requirements for Cathodic Protection of Bare Steel

ENVIRONMENT	MILLIAMPERES (mA) PER SQUARE FOOT (mA/ft²)
Soil with resistivity <1,000 ohm-cm	6.0 - 25.0
Soil with resistivity 1,000 - 10,000 ohm-cm	3.0 - 6.0
Soil with resistivity 10,000 - 30,000 ohm-cm	2.0 - 3.0
Soil with resistivity >30,000 ohm-cm	1.0 - 2.0
Highly aggressive soil with anaerobic bacteria	15.0 - 40.0
Still fresh water	2.0 - 4.0
Moving fresh water	4.0 - 6.0
Turbulent fresh water	5.0 - 15.0
Hot fresh water	5.0 - 15.0
Still seawater	1.0 - 3.0
Moving seawater	3.0 - 25.0
Concrete	0.5 - 1.5

B-6.3.1 Structure to Electrolyte Resistance.

For some GCP systems, the structure-to-electrolyte resistance may be a factor, if the structure is very small or small with a good dielectric coating. In most ICCP systems, the major factor in the determination of the total circuit resistance is the anode-to-electrolyte resistance. If ICCP systems are used to protect very small or small well coated structures, the structure-to-electrolyte resistance could be a factor. Anode and structure leads are normally sized so that lead wire resistance is often negligible. Lead wire resistance may be significant if long runs of wire are required, or anode-to-electrolyte resistance is very low.

B-6.3.2 Calculate Anode to Electrolyte Resistance.

Also known as "ground bed resistance" or “anode bed resistance,” this is often the parameter that most impacts the CP system circuit resistance. Anode-to-electrolyte resistance is dependent upon the electrolyte resistivity, but can be varied within limits by the use of different sizes or quantities of anodes.

Calculate anode-to-electrolyte resistance calculations from data on soil resistivity, anode type, size, shape, and configuration of multiple anode arrays. First, arbitrarily choose the type, size, and shape of the anode to be used. Next, calculate the resistance of a single anode. Then determine the effect of the use of multiple anodes. The process is iterative and several attempts may be necessary to determine the optimum anode system and corresponding anode-to-electrolyte resistance.

During actual operation, the environmental resistivity may not be uniform, or may undergo seasonal variations, and the calculation of anode-to-electrolyte resistivity is only an approximation of the actual resistance to be encountered. Therefore, the actual CP system operation results may be somewhat different than that calculated. Thus, after installation, the system may need to be adjusted periodically to provide the required protective current output.

B-6.3.2.1 Effect on System Design and Performance.

For ICCP systems the anode-to-electrolyte resistance is an important factor in the determination of the driving potential required to provide the current required for effective CP in ICCP systems. The lowest anode-to-electrolyte resistance commensurate with total system cost is desirable since it will reduce the power costs by lowering the output potential of the power supply. This lower power supply output potential also results in higher reliability for other system components, particularly the insulation on cables, splices, and connections. In general, anode bed resistances below 2 ohms are desirable and are rarely designed over 4 ohms.

B-6.3.2.2 Basic Equations.

The formulas developed by H. B. Dwight for a single cylindrical anode are commonly used as part of an iterative calculation process to determine the anode-to-electrolyte resistance. The formulae shown below are only some of several formulae used for CP design calculations and are provided for information only. Do not reference these formulae as DOD policy. Misapplication of these formulae by unqualified personnel can result in improperly operating CP systems. The formula for a vertically oriented anode is:

$$R_v = 0.0052\ \rho/L \times [\ln(8L/d) - 1]$$

The formula for a horizontally oriented anode is:

$$R = 0.0052\ \rho/L \times \ln\{[4L^2 + 4L(s^2 + L^2)^{1/2}]/ds\} + s/L - (s^2 + L^2)^{1/2} - 1$$

where

R_v	=	electrolyte-to-anode resistance for a single vertical anode to a remote reference (ohms)
R_h	=	electrolyte-to-anode resistance for a single horizontal anode to a remote reference (ohms)
ρ	=	electrolyte resistivity (ohm-cm) at the location and depth of the anode
L	=	anode length or backfill column length if backfill is used (feet)
d	=	effective diameter of anode or backfill column (feet)
s	=	twice depth of anode (feet)

B-6.3.2.3 Special Formulae for Water Tanks.

For water tanks where circular arrays of anodes are commonly used and where the structure surrounds the anodes and electrolyte, special formulae have been developed to calculate the anode-to-electrolyte resistance. For a single cylindrical anode, the formula developed by E. R. Shepard is commonly used:

$$R = 0.012\ \rho_w \log (D/d)/L$$

where

R	=	anode-to-electrolyte resistance (ohms)
ρ_w	=	water resistivity (ohm-cm)
L	=	length of a single anode (feet) (backfill is not used)
D/d	=	ratio of anode diameter (d) to tank diameter (D) (same units for each)

The anodes are usually arranged in a circular array in the tank bowl. Determine the optimum diameter of this array by the following formula:

$$r = DN/[2(\pi + N)]$$

where

r	=	radius of anode array (feet)
D	=	tank diameter (feet)
N	=	number of anodes

B-6.3.3 Effect of Backfill.

Backfill is very important and is usually used to surround the anodes with a material of uniform resistivity to allow the anode to emit current evenly from its entire surface and reduce localized or uneven dissolution of the anode. In the case of ICCP anodes, backfill also reduces anode-to-electrolyte resistance; increases porosity around the anodes to insure that any gasses formed during operation will be properly vented; and reduces polarization effects. Under favorable circumstances, the anode-to-electrolyte resistance can be reduced to one-half through the use of backfill. In extremely low resistance environments most anodes can be used without backfill; however, except for anodes submerged in water, the use of backfill is highly recommended.

B-6.3.3.1 Backfill for GCP anodes.

For use in soil, the backfill must be used with GCP anodes in most cases and is highly desirable in most instances. The backfill typically consists of mixture of hydrated gypsum, bentonite, and sodium sulfate. Besides providing a uniform resistivity environment which reduces the self-corrosion rate, the backfill is hygroscopic and will absorb moisture from the surrounding soil to lower the resistivity and improve the anode current output.

B-6.3.3.2 Backfill for ICCP anodes.

For nearly all underground ICCP installations, provide a special carbon backfill, referred to in the industry as coke breeze, in the anode hole or column. Some of the reasons for using this special backfill include the following:

- Lower anode ground bed resistance, hence, resulting in lower rectifier design voltages and reduced probability of stray current interference.
- Improved current distribution along the anode since the backfill will provide a generally uniform environment. Helps avoid premature anode failure.Prolonged anode life since the carbon backfill is also consumed instead of anode.Stability of the anode hole or well.Permeable medium for migration of gases, thereby avoiding premature increase in anode bed resistance.When backfill is used with ICCP anodes, the effective diameter of the anode installation is the diameter of the backfill column rather than the diameter of the anode itself. This often results in a significant reduction in anode-to-electrolyte resistance which can be useful in reducing the number of anodes required, the required rectifier driving voltage, or both. Ensure that the appropriate type of backfill is specified and provided.

Backfill for ICCP anodes is carbonaceous material from several sources. It can be coke breeze (crushed coke), flake graphite, or round particle calcined petroleum coke. Specify calcined petroleum coke, or coke that has been heated to remove high resistivity petroleum by-products. The calcined petroleum coke has a lower total bulk resistivity and its more spherical particles aid in the compaction of the backfill. Experience has shown that round particle calcined petroleum coke has many advantages over coke breeze made from coal. Also, specify backfill that has a carbon content greater than 92%, preferably greater than 99%, for greater anode system life. Specify small diameter calcined petroleum coke for deep well anode installations. Because the material can be pumped and has good porosity and particle-to-particle contact, round particle petroleum coke backfill is the most desirable material and its higher cost will be justified for deep anode installations.

B-6.3.3.3 Anodes Prepackaged with Backfill.

In areas where the soil is extremely wet or loose, such as in a swampy area, it may not be possible to properly install or tamp the backfill material. Packaged anodes with the backfill contained in metal cylinders (cans) or cloth sacks surrounding the anodes may be useful in these circumstances. The package anodes will have a higher cost, but are generally easier to install than separate installation of anode and backfill. Besides the higher costs, packaged anodes also have the following additional disadvantages:

- High unit weight reduces ease of handling
- Possibility of voids developing in backfill during transportation and handling
- The critical anode cable and connection between the anode and cable are hidden and difficult to inspect

B-6.3.4 Calculate Operating Considerations.

For GCP systems, determine the circuit resistance which is the sum of the anode to electrolyte resistance, the structure to electrolyte resistance and the lead wires. The driving potential is set by the natural potential difference between the GCP anode and the polarized structure. The current can only be adjusted by adding additional anodes to increase current, or installing fewer anodes or a resistor with each anode to decrease current.

For ICCP systems, the driving potential is not set by the natural potential difference. System current is dependent upon the circuit resistance and the voltage of the power source. System current can be adjusted by changing the voltage applied to the system or by changing the circuit resistance. Circuit resistance is determined by selection of the anode size, number of anodes and anode spacing.

B-6.3.5 Determine the Number of Anodes Required.

The quantity of anodes required for the CP system is dependent upon the system current requirement and the maximum individual anode current output. The system current requirement is a function of the structure size, coating, and environment in which it is installed. The maximum individual anode current output is dependent upon anode type, anode size, and environment resistivity. For GCP anodes, anode life is determined by anode current, anode type, and anode efficiency. For ICCP anodes, anode life is a direct result of current and time. Each anode has a specific weight loss per ampere-year calculated from Faraday’s Law or from manufacturer charts in anode life versus current discharge.

For GCP anodes such as zinc, magnesium and high purity magnesium, calculate the anode life based on anode type, anode efficiency, effective useful life factor and anode current. The anode efficiency is a percent of the anode discharge for CP compared to the anodes self-corrosion rate. Zinc is normally 90 percent, while magnesium and high potential magnesium is 50 percent. The effective useful life factor is the percentage of weight loss before anode failure. For most anodes, failure will occur after 80 percent of the weight is lost.

$$\text{Anode Life} = \frac{W * u * e}{I * S}$$

where

W	=	Total Anode Weight
u	=	Anode Effective Useful Life Factor

e = Anode Efficiency

I = Anode Current Output in Amperes

S = Anode Consumption Rate

In the case of ICCP bulk anodes such as High Silicon Chromium Bearing Cast Iron (HSCBCI), the manufacturer or distributor for the anode will provide the anode consumption rate. HSCBCI is usually 1 pound per amp year. The effective useful life factor is usually 80 percent. In systems with multiple anodes, use the maximum anode output to calculate life of the anode system (not the average anode output).

$$\text{Anode Life} = \frac{W * u}{I * S}$$

where

W = Total Anode Weight

u = Anode Effective Useful Life Factor

I = Anode Current Output in Amperes

S = Anode Consumption Rate

In the case of dimensionally stable ICCP anodes such as mixed metal oxide and platinized niobium, charts are available from the manufacturer or distributor for the specific anode, usually in years at specific current outputs.

B-6.3.6 Power Supply Requirements (ICCP Systems).

B-6.3.6.1 Determine Power Supply Requirements.

Calculate the power supply requirements, namely current and voltage, using Ohm’s law and the required current for protection of the structure and the calculated or measured total circuit resistance. Include factors for anode back voltage and current losses due to unknown electrical shorts to other structures as necessary.

B-6.3.6.2 Select Power Supply Type.

Any source of direct current of appropriate voltage and current can be used as a source of power for ICCP systems. The selection of power supply depends upon local conditions at the site and should be evaluated based upon economics, availability of AC power or fuel, and the availability of maintenance.

B-6.3.6.3 Transformer-Rectifiers.

Transformer-rectifiers, or more simply, rectifiers, are by far the most commonly used power supply type for ICCP systems. They are available in a wide variety of types and capacities specifically designed and constructed for use in ICCP systems. The most commonly used type of rectifier has an adjustable step down transformer, rectifying units (stacks), meters, circuit breakers, lightning arresters, current measuring shunts, and transformer adjusting points (taps), all in one case.

The rectifier selected for a specific ICCP application must be matched to both the electrical requirements and the environmental conditions at the site. Rectifiers are available in many electrical types and specifically designed for use in ICCP systems in many environments. Technical Paper 16 provides additional details about rectifier selection as well as simplified examples of CP system designs that the project engineer can use as guides for reviewing actual CP system designs.

B-6.3.6.4 Solar Power.

For solar powered systems, solar cells convert sunlight directly into direct current electricity. Consider using solar panels for CP power supplies at remote sites where neither electrical power nor fuel is available. In order to supply current continuously, solar cells are used in a system that both supplies power to the CP system and also recharges a set of batteries when sunlight is received (Figure 4-2). When sunlight is not being received, the batteries supply the required current.

Solar powered CP systems should use high efficiency (96-98%) controls that have flexibility to match the anode ground bed and its fluctuating conditions. The controller unit should also be selected to minimize the mismatch loss between the PV array and the storage batteries. Finally, consider providing a controller that has built–in current interruption capability so that IR free (more accurate) structure potentials of the pipelines can be measured.

B-6.3.6.5 Batteries.

When current requirements are low, storage batteries can be used to supply power for ICCP systems at remote sites. They must be periodically recharged and maintained. Again, environmental and safety considerations must include procurement, maintenance and disposal of battery electrolytes, usually acids.

B-6.3.6.6 Generators.

Engine or wind driven generators can also be used to supply direct current power for ICCP systems at sites where AC power is not available.

B-7 OTHER CP SYSTEM COMPONENT DESIGN CONSIDERATIONS.

In addition to calculation and selection of the anodes used and the source of power for cathodic protection, CP systems contain other important components. The entire system must be reliable in order to provide effective protection.

B-7.1 Connecting Wires.

The connecting cables used between the various components of CP systems are vital to the proper performance of the system. Any break in the primary circuit will result in failure of the system and will require repair to restore the flow of protective current. Breaks in the auxiliary connections such as those used to test the system will also result in difficulties in proper adjustment and inspection of the system. Proper selection of cable size, type of insulation and routing is necessary for proper and reliable system operation.

Use only copper cables in any CP installation. High connection resistances and difficulty in making welded connections associated with the use of aluminum wires precludes their use in cathodic protection.

B-7.1.1 Determination of Connecting Wire Size and Type.

For sacrificial anode CP systems, the electrical currents are usually low, and the size of the conductors is normally more a function of mechanical strength than of ampacity or resistance. In systems where sacrificial anodes are used in groups such as remote anode beds, the currents can be larger and the resistive drop in the cable must be considered. Calculate the most economic wire size, but do not use wire sizes smaller than No. 12 AWG or foreign equivalent.

For ICCP systems, connecting cables should be selected based upon consideration of the following factors:

- Current carrying capacity
- Voltage attenuation (IR drop)
- Mechanical strength
- Economics (first cost versus power costs)
- Dielectric strength of insulation
- Durability (abrasion & cut resistance) of insulation

B-7.1.2 Wire Insulation.

B-7.1.2.1 GCP Systems.

For GCP systems, the connecting wires are, themselves, cathodically protected, and insulation is not as critical as in portions of ICCP systems. Specify Type TW, Type RHW-USE or HMWPE insulation. Specify HMWPE, a heavier insulation, where mechanical strength is desired. For submerged applications or chemical environments, specify the appropriate insulation that bests resists deterioration in that environment.

B-7.1.2.2 ICCP Systems.

For ICCP systems, the connection between the CP power source and the anodes are usually submerged or buried at least over part of their length. These cables are extremely susceptible to failure as they are operated at highly positive potentials. Refer to paragraph B-7.1.3.4

B-7.1.3 Recommended Cables for Specific Applications.

Because of similarities in required characteristics of the various connecting cables in many CP systems, the following paragraphs detail the established general specifications for cable sizes and types for many CP system requirements.

B-7.1.3.1 Test Wires.

Test station wires carry only very small currents and, as they are themselves cathodically protected, insulation requirements are not critical, but should be selected to match the environment. Specify solid copper wires, No. 12 gauge AWG, minimum, with type TW, RHW-USE or polyethylene insulation for this application unless otherwise dictated by economics or site conditions.

B-7.1.3.2 Bond Wires.

These wires carry more current than test wires, and may have a positive potential with respect to surrounding structures. Specify No. 4 or 8 AWG stranded copper cable with HMWPE insulation for all bond wires unless a larger wire size is required for current carrying capacity.

B-7.1.3.3 Power Supply to Structure Cables.

Specify HMWPE insulated stranded copper cable, with the wire appropriately sized for current carrying capacity, mechanical strength, and total CP circuit resistance. Wire size must conform to the requirements in the National Electrical Code. For submerged applications or chemical environments, specify the appropriate insulation that bests resists deterioration in that environment.

B-7.1.3.4 Power Supply to Anode Cable.

The insulation in these cables is critical. The connections between the CP power source and the anodes for ICCP systems, are typically buried or submerged, and are extremely susceptible to failure as they are operated at highly positive potentials. Any contact between the metallic conductors and the environment will result in rapid deterioration of the conductor and loss of continuity of the protective circuit. Specify HMWPE insulation, 0.110 inches thick, as a minimum, on these cables for most buried applications. Where exposure to chlorine will be encountered, such as in seawater or in deep well applications, specify chlorine resistant composite insulation consisting of an HMWPE outer jacket for abrasion resistance combined with an ethylene-chlorotrifluroethylene copolymer (ECTFE) inner jacket. For less critical applications such as test wires, and above ground wiring, specify thermoplastic insulation (Type TW), synthetic rubber (RHW USE), or HMWPE.

The minimum anode connection wire size is No. 8 AWG. The wire used to interconnect the anodes to the junction box or header cable, and to connect the anode bed with the power supply is commonly in the range of No. 2 AWG or larger. The actual wire size must conform to the requirements in the National Electrical Code (NEC).

B-7.1.4 Economic Wire Size.

For GCP systems, determine the most economic wire size when currents larger than one ampere flow in any portion of a sacrificial anode circuit. Compare the cost of additional anodes to overcome the resistive losses to the annual fixed costs for the cable size being analyzed.

For ICCP systems, select the size of the connection between the structure, anode bed and the power supply in ICCP systems to minimize overall cost. This can be determined by calculating the annual fixed cost of the selected wire and comparing them with the cost of power losses for the system. When the annual fixed cost and the cost associated with power losses are equal, their sum is minimal and the most economical selection of wire size is confirmed. If the power losses exceed the annual costs, a larger wire size is required. If the annual fixed costs exceed the power loss, then a selection of a smaller wire size would be appropriate. The formula for determining power loss costs is:

$$V = MK_m$$

where:

$$M = 0.0876\ I^2R$$

$$K_m = \frac{LP}{E}$$

and:

V	=	Annual cost of power losses ($)
I	=	Current Flow (Amperes)
R	=	Resistance of 100 feet of cable
P	=	Power Cost (cents/KWH)
E	=	Power Source (Rectifier) Efficiency (%)
L	=	Length of Cable (feet)

The formula for determining the annual cost of fixed charges is:

$$F = E \times S \times L$$

where:

F	=	Annual Fixed Charges ($/yr)
E	=	Estimated annual charges *
S	=	Initial Cable Cost ($/ft)
L	=	Cable Length (ft)

* The estimated annual charges used will vary. They are the sum of depreciation, interest, taxes, insurance, operation and maintenance.

B-7.2 Connections and Splices.

Wire splices and connections are a source of undesirable circuit resistance and are a weak point in the reliability of the system as they often fail due to either corrosion or mechanical damage. Buried wire splices are not permitted in many situations. Refer to the appropriate UFGS. Keep wire splices and connections to an absolute minimum, and the type of connection used must have low resistance, high reliability, and good resistance to corrosion. While connection of wires to the structure can be either by exothermic weld or mechanical connections, specify exothermic welding (Figure 4-4) as much as practicable. Avoid mechanical connections as much as practicable (Figure 4-5), as corrosion of the mechanical connection tends to result in a high resistance connection over time that could prevent the CP system from properly operating. Insulate underground connections with either epoxy encapsulation or other type of mastic compatible with the pipeline coating. Above grade connections such as wiring in test stations are typically mechanical connections and must be carefully taped in order to prevent corrosion due to the entry of moisture.

Carefully evaluate the need for additional connections and splices. Specifically show the location of all necessary splices and connections on the design drawings. The designer of the system must determine the need for additional splices and connections. Do not leave this determination to the discretion of the installer.

B-7.2.1 GCP Systems.

The following connections are required for GCP anode systems and must be shown on the design drawings:

- Connection between anode(s) and structure through a test station.
- Connection between cable and anode (Must be factory made or connection is attached to cast-in core)
- Necessary bonds and test wires

B-7.2.2 ICCP Systems.

The following connections are required for ICCP systems:

- Connection between power source and structure
- Connection between anode bed(s) and power source (anode header cable)
- Connection between anode header cable and each anode
- Connection between cable and anode (must be factory made)
- Necessary bonds and test wires

Carefully insulate all connections, particularly in the anode to power supply portion of the circuit where any loss of insulation integrity will result in rapid system failure. All connections in the power source-to-anode bed portion of the circuit and all cable-to-cable connections must be insulated by encapsulation in epoxy using commercially available kits made expressly for this purpose.

The cable to structure connection is less critical and either epoxy encapsulation or insulation with mastic must be used on this connection.

B-7.3 Bonds and Insulating Joints.

CP designs must include provision of electrical continuity bonds where necessary to ensure electrical continuity of all of the structures to be protected. Portions of metallic utility distribution pipeline systems are often replaced with non-metallic pipe sections, introducing electrical discontinuities into the pipeline system. Base utility distribution system plans are not always updated to reflect these replacements, and the designer should be allowed to conduct field current requirement and continuity tests to verify continuity if any doubt. If electrical discontinuities cause the pipeline system to be too fragmented, consider providing multiple smaller CP systems. Some isolated sections of pipelines may be small enough to use GCP anodes.

Use HMWPE insulated seven-strand copper cable, No. 8 AWG or larger cable for bonds between sections of the protected structure or between the protected structure and a foreign structure (Figure 4-3). Run all resistive bonds into a test station to allow for adjustment. Also run direct bonds into test stations if future adjustments or connections may be required. Make all bond-to-structure connections using exothermic weld connections, insulated by epoxy or mastic encapsulation.

B-7.4 Test Stations - Location and Function.

Include the location and wiring of all test stations in the system design. Color code all test wires, or identify them with non-corroding metal or plastic identification tags indicating the system component to which they are connected. Locate test stations either flush with the pavement or soil surface as shown in Figure B-6, or above grade as shown in Figure B-7. In either case, use test stations manufactured specifically for the intended purpose. Flush mounted test stations are preferred in paved areas or other areas where damage by vehicles, operational equipment, etc. is anticipated. Above grade test stations are preferable in unpaved areas and areas where flush mounted test stations can easily be covered over and lost. Provide test stations for all foreign structures that cross the protected structure or are in the vicinity of the anode bed. Provide test stations for all pipeline casings, underground dielectric insulation unions and flanges, at all foreign line crossings, and other components such as bonds to facilitate testing.

Balancing resistors are sometimes required when multiple anode beds are used with a single rectifier. Install these resistors in an above grade terminal box as shown in Figure B-8.

Figure B-6 Typical Ground Flush Mount Test Station

Figure B-7 Above Grade Test Stations. PVC Pipe Mount on the Left, Pole Mount in the Center, and Wall Mount on the Right.

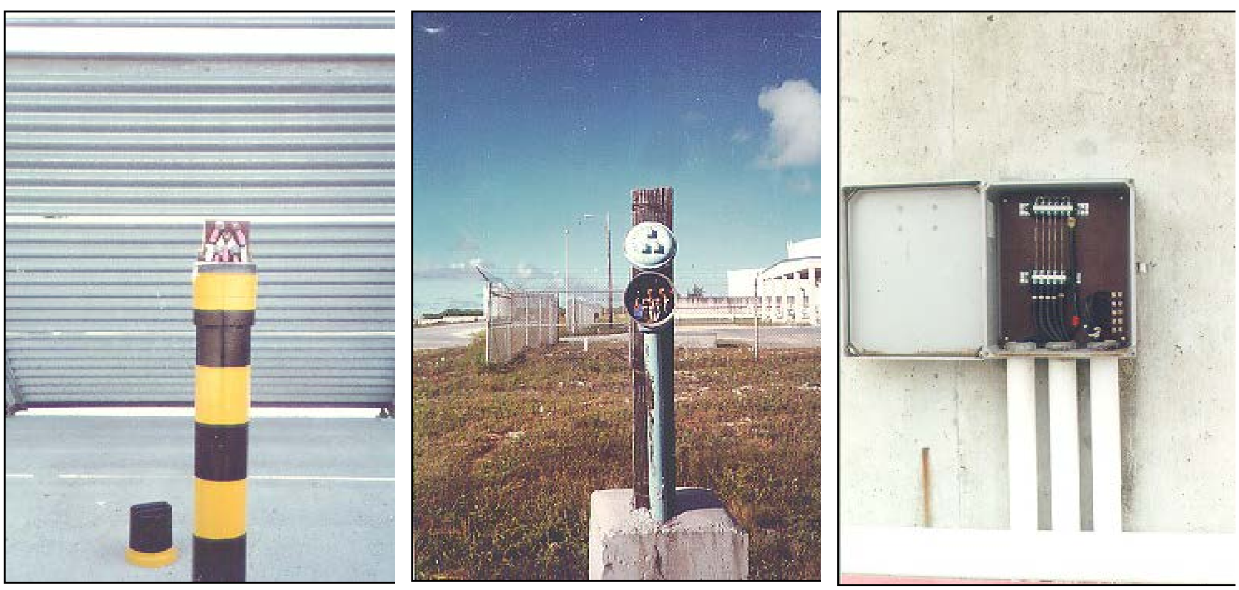

Figure B-8 Resistors in an Above Grade Terminal Box

B-7.4.1 GCP systems.

The most common type of test station used in GCP systems is the current-potential test station shown in Figures B-13 through B-11. In this test station, the anode lead wire is connected to the structure lead using a 0.01 ohm resistor (shunt) which is used to measure the current output by measuring the voltage drop across the shunt. The second structure lead is used to measure the structure potential using a non-current carrying connection thus eliminating any potential drop along the conductor. The second structure connection can also be used as a spare if the primary structure connection is damaged. Test stations for GCP systems can either be of the flush mounted or above grade type.

If flush mounted test stations are used, the soil exposed in the bottom of the test station can be used to measure the structure to electrolyte potential. Location of such test stations directly over the structure is advantageous as IR drops due to current flowing through the soil are minimized. Other test stations which are used in GCP systems are the potential test station, the soil contact test station, the line current (IR Drop) test station, the insulating joint test station, the casing insulation test station, and the bond test station.

Figure B-9 Flush Mounted Current-Potential Test Station

Figure B-10 Pipe Mounted Test Station. Figure on Right is a Close-Up of the Test Station "Head" or Terminal Board.

Figure B-11 Wall/Pole Mount Type Test Station.

B-7.4.2 ICCP systems.

There are five basic types of test stations used in ICCP systems:

- The potential test station (see Appendix D)
- The soil access test station (see Appendix D)
- The line current (IR Drop) test station
- The casing insulation test station
- The bond test station (see Appendix D)

Specify solid copper wires, No. 12 AWG, either TW or RHW-USE insulated. If future bonding across flanges or between structures may be required, connect HMWPE insulated stranded copper cables, No. 8 AWG or larger if required, to the structure(s) and run them into a test station for future use.

B-8 DESIGN PRACTICES THAT FACILITATE OPERATION AND MAINTENANCE.

Design of the system must include required items needed to conduct operations and maintenance on the system. Over the life cycle of the system, these items will save time by making it easier for personnel to perform the required testing, troubleshooting and repair of the system. Without sufficient test stations and test access, it may be impossible to accurately evaluate a CP system for adequacy of protection.

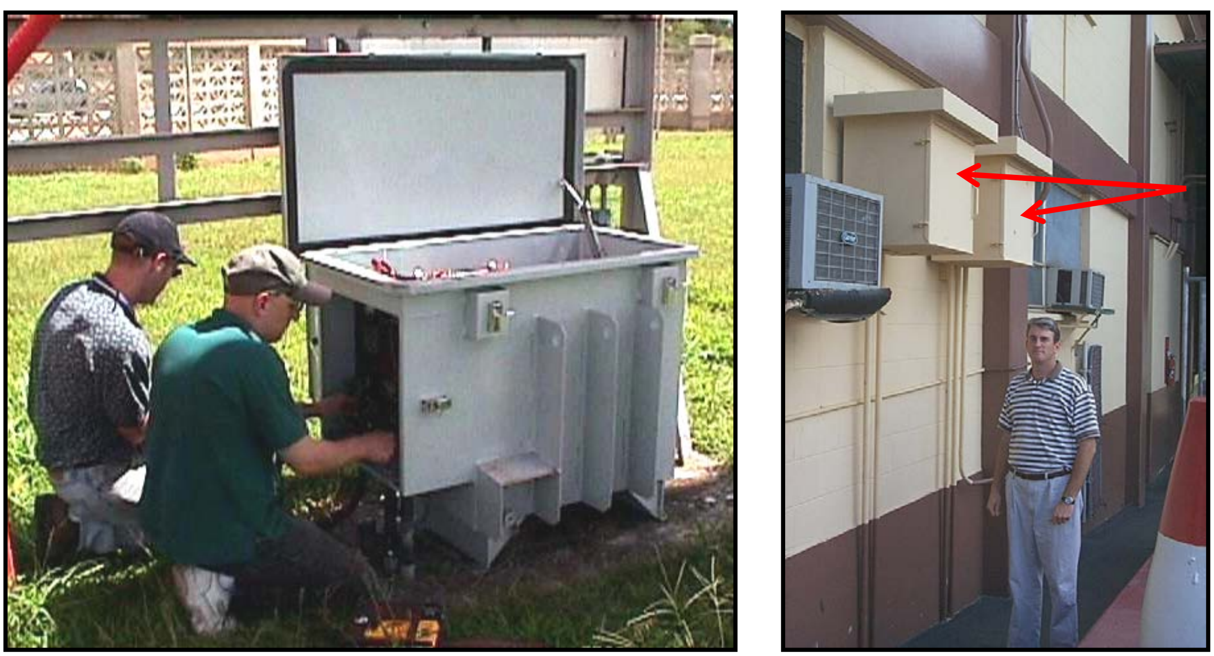
B-8.1 As Built Drawings.

Require accurate and detailed drawings of the installed system and the structure be provided upon project completion to allow base personnel to perform comprehensive evaluation, testing, troubleshooting or repair. The accurate location of all CP components, especially anodes and anode cables, can save days of effort by repair crews attempting to repair breaks in these cables. Structure leads, although less likely to fail, can be extremely difficult to locate and repair. Proper evaluation of CP systems requires accessing all test points on the structure and all CP components. As built drawings save a great deal of time when locating the test stations, finding the permanent reference cell locations, and other testing requirements, such as foreign line crossings, bonds, isolations and casings.

B-8.2 Locate Equipment Where Readily Maintainable.

Locate CP equipment where they would be readily maintainable. Locate rectifiers where they may be easily inspected and repaired. Rectifiers that are inaccessible are not likely to be properly maintained (Figure B-12). The rectifier in the picture on the left of Figure B-12 is easily accessed. The two rectifiers in the picture on the right are mounted over six feet high and will likely not be properly maintained Provide test stations that are appropriate for the environment in which they are located. For example, do not specify flush mount test stations where there is a high probability that they will be covered by soil or vegetation. If flush mount test stations must be used in such areas, provide test station markers (Figure B-13). Provide insulating joints where they can be readily tested.

Figure B-12 Rectifiers Located for Ease of Maintenance. .



B-8.3 Test Stations.

Provide test stations to allow access to the structure for potential surveys to determine if adequate CP has been achieved. They are also necessary to perform recurring maintenance, troubleshooting and repair of the system during its life cycle. Installing a sufficient number of test stations to allow access to and testing of the structure at all locations is essential to maintaining the system. All test stations must include two wires to each structure protected or impacted by the CP system. This allows the maintenance crew to test the connection to the structure and allows for possible bonding or interference bonding. It is also important to have access to foreign lines to provide for interference testing and possible mitigation.

Provide test stations on all foreign lines that cross the protected structure or are in the vicinity of the anode bed. These test stations must be accurately shown on the as built drawings, especially if they are not located over the protected structure. Provide test stations for all pipeline casings, at all foreign line crossings, and for other components such as bonds. Provide test station markers (Figure B-13) for flush mount test stations on cross country pipelines to facilitate location of these test points.

Figure B-13 Test Station Marker for Flush Mount Test Station.

Since test stations are manufactured in many different types and configurations, ensure that they are adequately sized and configured for the number of test wires and intended purpose of the test station. Some small flush mount test stations are manufactured with five or more terminals on the terminal board, but when installed with thick HMWPE insulated wire, are difficult to open and close often resulting in damage to the wiring terminals and measuring shunts (Figure B-14). Provide test stations large enough to appropriately accommodate the wire quantity, size and insulation type and facilitate maintenance and testing.

Figure B-14 Small Flush Mounted Test Station with Too Many Large Sized Wires.

B-8.4 Markers and Labeling.

Clearly mark and label wires in all test stations and rectifiers. Wire colors, markings and test station labeling must be uniform and systematic. Rectifiers and test stations must be numbered and accurately included in the as built drawings. Rectifier anode and structure leads must be permanently marked; and very importantly, anode leads and structure leads must never be mixed up, as catastrophic results would ensue. Refer to paragraph B-9.1.4.

B-8.5 Test Access.

Provide soil access test stations to allow the reference electrode to contact the same electrolyte that is in contact with the protected structure (e.g. where a pipeline runs under an extensive paved area such as an airfield parking apron). Reference electrodes cannot “read” through non-electrolytes such as plastic, rubber, oil or asphalt. Reference electrodes also cannot accurately “read” through concrete, especially if it is reinforced concrete. Possible shorts of the reinforcing steel to the protected structure would cause the reference cell to “see” the rebar, instead of the protected structure. Therefore, provide sufficient soil access test stations to allow for accurate monitoring, evaluation, and troubleshooting of the CP system.

B-8.6 Permanent Reference Electrodes (PRCs).

Provide PRCs in locations to facilitate testing of the CP potentials on a structure where portable reference electrodes cannot access the electrolyte, or access would be difficult or dangerous. Provide PRCs at locations such as under storage tanks, between pipeline crossings, under pavement or concrete, inside of water tanks and elevated water towers, and along waterfront structures. PRCs also allow for reliable and repeatable data and are often installed at specific points along the structure. Also install PRCs at critical points to allow them to be monitored remotely. When practical, install multiple PRCs in hard to reach areas, such as under the bottoms of on-grade storage tanks and inside elevated water tanks, to allow remote testing of the structure using the PRC. One PRC can be used to test the accuracy of another PRC. PRCs used to control automatic rectifiers are especially prone to failure and should have multiple back up PRCs installed to allow for testing of the PRCs and swapping of the control PRC if required.

B-8.7 Electrical Resistance Probes.

Where it is beneficial to also know actual cumulative corrosion rates in addition to CP system effectiveness, provide electrical resistance (ER) probe(s) in addition to PRCs. An ER probe monitoring system consists of an electrical resistance meter, usually with data logging functions, connected to a probe. This technique operates by measuring the change in electrical resistance of a metallic element immersed in a product media relative to a reference element sealed within the probe body. If the corrosion occurring in the vessel or structure under study is roughly uniform, a change in resistance is proportional to an increment of corrosion. Although universally applicable, the ER method is uniquely suited to corrosive environments having either poor or non-continuous electrolytes such as vapors, gases, soils, hydrocarbons, and non-aqueous liquids. ER probes are manufactured in various configurations, and Figure B-15 illustrates is an example of one type of ER probe.

Figure B-15 Example of an ER Probe

Metal loss from and ER probe is cumulative over time. The electrical resistance meter measures the resistance and an algorithm calculates the cumulative corrosion rate over the period of time since the initial measurement. After a probe is connected to a CP system, declining corrosion rates suggest that the CP system has mitigated corrosion of the probes. The cumulative corrosion rates on a structure with an effective CP system would be expected to continue to decrease to negligible rates with time.

When used to monitor a structure under CP, the ER probe should be allowed to freely corrode for a short period of time before electrically connecting it to the cathodically protected structure. Over time, it will be necessary to temporarily disconnect the ER probe to make a measurement after which, the probe must be reconnected back to the cathodically protected structure. Since the system is measuring very small resistances, take the following measures to prevent premature failure of the ER probe system:

B-8.7.1 Probe Location.

Select and install probes in locations to preclude physical damage. On waterfront applications, avoid locations where floating debris and day to day operations can result in damage to the probes or connecting wires.

B-8.7.2 Prevent Water Intrusion.

For submerged applications, it is imperative to take every effort to prevent water intrusion into, and the subsequent corrosion of the connector between the probe and its lead wire. Encapsulate the probe connection to the lead wire (Figure B-16). For submerged applications, pre-assemble sections of conduits to be submerged before installation. This is also necessary to prevent water infiltration into probe-lead wire connection (Figure B-17).

B-8.7.3 Connection to CP System.

After allowing the probe to freely corrode for a short period of time, connect the probe to the cathodically protected structure as soon as practical after the CP system is energized. For probes to be installed in the vicinity of CP systems, particularly those operating at high CP system current levels, the potential for stray current effects and resulting pre-mature failure of the probe is high. Design a good connection means between the probe and the cathodically protected structure that will easily enable temporary disconnection to take measurements with the ER meter.

B-8.7.4 Backup PRC.

If a monitoring location is critical, provide a backup PRC adjacent to the probe in the event the probe fails and cannot be immediately replaced.

Figure B-16 Probe with Encapsulated Connector.

Figure B-17 Pre-Assembled Conduit System, Probe, and PRC for Submerged Use.

B-8.8 Coupon Test Station System.

Coupon test stations include a small sample of metal (coupon) made of similar material as the protected structure usually packaged with a PRC. The packaged coupon/PRC is typically installed adjacent to a buried or submerged structure with test wires running to a convenient measuring point (test station). Such devices allow for error free reading when the CP current to the structure cannot be easily interrupted.

Potential measurements of underground structures made with a PRC placed on the electrolyte surface or buried PRCs often contain an error known as voltage (IR) Drop error. IR Drop error results from the interaction of the CP current with the soil resistance. One way of accounting for this error is to momentarily interrupt the CP current and measure the potential immediately after interruption. This so-called "instant-off" potential can be substantially free of IR Drop error. Even in cases where current interruption is possible, there may be other sources of current at that location such as those from nearby CP systems, stray currents or telluric currents. Cathodic protection coupons, sometimes called instant off sensors, provide a means to make instant off potential measurements under those conditions.

Coupons are sometimes installed for structures protected by a GCP system with numerous distributed sacrificial anodes. It is nearly impossible to feasibly interrupt CP current on such systems and coupons provide a means to measure IR free potentials.

B-8.9 Anode Current Output.

Design systems with capability to monitor anode output currents. Provide readily accessible test stations with individual current measuring shunts to simplify measuring of individual anode current outputs to ensure that anodes are properly operating and are not being overdriven. Ensure terminals are prominently identified and wires are tagged. Figure B-18 illustrates an example anode junction box.

B-8.10 Electrical Isolation Testing.

Locate dielectric isolating flanges or unions where they may be readily inspected and tested. Preferably, locate these joints in valve pits, or located above grade.

Figure B-18 Anode Junction Box

B-8.11 Remote Monitoring.

For critical or remote locations, consider the use of remote monitoring equipment to monitor the CP system and the protected structure. A remote monitoring unit (RMU) can include components to monitor rectifier output, potential reference cells, interference test bonds, critical bonds, or foreign structure potentials. Remote monitoring can give an instant alarm if the system goes above or below set points. Monthly monitoring can result in up to 60 days between checks, and requires a crew to travel to the location and perform testing. Most RMUs are paid for by savings in these testing costs over a short period of time, when there are sufficient quantities of systems or distance between CP equipment locations. Remote monitoring systems also aid in collection and management of data for historical records.

B-8.11.1 Remote Monitoring Communication Methods.

Remote monitoring units commonly communicate by cell phone technology; telephone land lines; Supervisory, Control and Data Acquisition (SCADA) systems; or satellite transmission technology. Remote monitoring units, and automated data collection units must be planned, designed, acquired, executed and maintained in accordance with DoD Instruction 8500.01 and DoD Instruction 8510.01, and as required by individual Service Implementation Policy.

B-8.11.2 Remote Monitoring Selection Considerations

The following are some important considerations for selecting and installing a remote monitoring unit.

B-8.11.2.1 Rectifier Information.

Prior to selecting the RMU unit, collect adequate information about the rectifier and the location of the installation in order to obtain properly sized/configured RMU components.

- Rectifier maximum DC output voltage and current
- Availability of A/C power, including the operating A/C voltage, and means of running AC power cables to the unit
- RMU mounting location and method of mounting
- Need for one way or two-way communication
- Characteristics of the local operating environment

B-8.11.2.2 RMU Unit Type and Suitability.

Research the various units to determine which units would be most suitable for their intended application. Prior to selecting a satellite communication unit, ensure satellite coverage/location of satellites will allow sufficient communication signal strength where the RMUs will be installed. Install the antennas in a location that allows good communication.

B-8.11.2.3 RMU Power Source.

Ensure that the units selected have a reliable power source. Select units utilizing A/C power or solar power as the primary source and batteries serving as a back-up/secondary power source in the event the primary power source fails.

B-8.11.2.4 Surge Protection.

Provide units with proper surge protection and isolation if the locations of these units are subject to frequent AC power surges or lightning strikes during inclement weather.

B-8.12 GPS Synchronizable Interruption.

For long pipelines that may require close interval, instant off surveys, the installation of GPS synchronizable interrupters in all rectifiers can reduce costs of all future surveys. These are normally used for gas and fuel lines that are monitored in house. The interruption cycle start and stop times are set by computer, then the survey is completed during that time. All rectifiers are turned on and off at specific intervals for a specific time, synchronized together using GPS signals.

B-9 LESSONS LEARNED AND OTHER PRECAUTIONS FOR CP SYSTEM DESIGN.

B-9.1 Common Problems and Design Deficiencies.

B-9.1.1 Qualified Personnel.

Ensure new projects are designed, reviewed, monitored and inspected by qualified personnel. New systems that are not designed, installed, or tested properly result in inadequate corrosion control or even corrosion damage and significant loss in life cycle costs of government infrastructure and assets. Work accomplished by qualified personnel provides greater reliability of critical assets such as fuel systems, fire protection, gas and other infrastructure required for mission accomplishment, safety and environmental protection.

B-9.1.2 Improper Application of GCP Systems.

Table B-5 provides some commonly found problems with CP designs of GCP systems, particularly when unqualified personnel accomplish the design, that result in inadequate CP of the structure or other problems associated with cathodic protection.

B-9.1.3 Improper Structure Bonding/Electrical Discontinuities.

Application of ICCP to a pipeline distribution system with electrical discontinuities will result in unprotected areas and possible interference to the electrically discontinuous section(s) of the structure intended to be protected. All electrically discontinuous section(s) of the structure(s) to be protected must be properly bonded into the system to ensure adequate protection. Common causes of electrical discontinuities include

- Dresser couplings
- Mechanical pipe section connections such as found in ductile iron pipe
- Plastic valves and fittings
- Non-metallic sections of pipeline (new, existing or future installation)
- Improper bonding (or lack of bonding) on joints, flanges or previously installed dielectric isolation unions or flanges

Provide electrical continuity bonds where necessary to ensure electrical continuity of all of the structures to be protected.

Table B-5. Common Problems with GCP System Designs

PROBLEM	SOLUTION
Use of GCP system for bare or poorly coated structures, for example aboveground storage tank bottoms or pipeline distribution systems. In most cases, GCP system cannot economically protect bare or poorly coated structures.	• Use ICCP system. • Where applicable, isolate the structure into smaller sections for which GCP systems are feasible.
Use of GCP system in high soil resistivity, for example underground pipelines, underground storage tanks.	• Use ICCP system. • Where feasible, consider non-metallic materials for the structure.
Use of GCP system for isolated laterals to a main with ICCP system results in interference problems on the lateral.	• Consider using deep well anodes for the ICCP system. • Include provisions for proper bonding. • Consider ICCP system for entire structure.
Use of GCP system for improperly electrically isolated structures. Failure of existing dielectric unions or flanges and other shorts result in loss of protection to the entire structure. One electrical short can result in loss of protection to the entire structure.	• Properly electrically isolate the protected structure. • Install electrical isolation in readily maintainable location. • Consider if ICCP system feasible.
Excessive spacing of sacrificial anodes resulting in inadequate protection of the structure between successive anodes. This is often caused by improper design, over estimating the coating efficiency, or under estimating the soil resistivity or anode output (resistance to earth).	• Ensure qualified designer. • Do not guess the coating efficiency. Conduct field test. • Do not guess the soil resistivity. Conduct field test. • Do not guess on current requirement. Conduct field test. • Use correct parameters in calculations.

Portions of metallic utility distribution pipeline systems are often replaced with non-metallic pipe sections, introducing electrical discontinuities into the pipeline system. Base utility distribution system plans are not always updated to reflect these replacements; therefore, allow the designer to conduct field current requirement and continuity tests to verify continuity if any doubt. Where feasible, during installation of new non-metallic pipe, provide adequately sized tracer wire for the non-metallic pipe sections that can double as a bond wire. As this may not always be technically feasible; alternatively, install tracer wires/tapes/devices directly above the plastic pipe at a depth that will be detectible by current detection equipment and technologies. If electrical discontinuities cause the pipeline system to be too fragmented, consider providing multiple smaller CP systems. Some isolated sections of pipelines may be small enough to use GCP anodes, but the designer must consider possible interference problems on these sections.

B-9.1.4 Improper structure connection.

Improper connection of the structure to an ICCP system is another common problem. Examples of improper connection include:

B-9.1.4.1 Improper Connection to Conduit Pipe.

An ICCP system is improperly applied to a high temperature hot water distribution system with structure connections to the inner carrier pipelines instead of the outer conduit that results in interference and corrosion of the conduit. In this case, the CP was intended for the outer conduit, not the interior carrier pipe.

B-9.1.4.2 Improper Connection of Rectifier Lead Wires.

ICCP rectifier positive and negative lead wires (rectifier positive lead is improperly connected to the structure to be protected and the negative lead to the anode bed) that results in serious corrosion of the structure. This results in the structure protecting the anodes, and the structure suffering severe corrosion damage in a relatively short time. For proper CP system operation, ensure connection of the rectifier negative lead to the structure and the positive lead to the anode bed.

B-9.1.5 Improper Consideration of Permanent Reference Electrodes (PRCs).

PRCs do not last forever. PRCs used in water tanks and water towers, especially when used in conjunction with an automatic rectifier, often fail with time, resulting in excessive current (automatic rectifier increases its output in attempt to attain proper potential readings with the PRCs) that can cause cathodic disbondment of the coating.

PRCs used under on-grade storage tank bottoms fail because of one or more of the following causes:

- High resistivity of, plus a lack of moisture in the tank bedding material that causes excessive contact resistance and inability to obtain accurate potential readings
- Fuel contamination of the PRC again affecting the accuracy of the PRC or causing deterioration of the insulation of the connecting wires and eventual failure

The difficulty in replacing these PRCs often result in the PRCs not being replaced, leaving base personnel with little or no means to determine if the structure is adequately protected. In extreme cases, the anodes may also fail for the same reasons and with the loss of the PRCs it becomes impossible to determine if adequate protection is present. Alternative solutions for consideration include:

- Providing dual element (copper-copper sulfate/zinc) PRCs
- Providing a secondary means of measurement consisting of several perforated/slotted plastic pipes in the tank bedding installed radially to allow insertion of a portable reference electrode in the tube at any distance between the tank outer edge and the center

B-9.1.6 High Temperature Hot Water (HTHW) Systems.

HTHW distribution systems have many problems associated with electrical isolation reliability and failure of GCP systems; therefore, provide an ICCP system instead, capable of protecting the structure without requiring electrical isolation at numerous locations. Inadvertent failure to install a single insulator, thermal failure of a single installed insulator, or inadvertent removal of a single insulator during routine maintenance can render a GCP system to be ineffective. An ICCP system will generally have some spare capacity to adjust the output current in case of such an event. However, an ICCP system design may result in large current requirements, and to preclude interference, may require bonding or interference mitigation on other buried metal structures in the vicinity. Such an ICCP system should only be designed by a certified CP Specialist. Base the design on data taken during a design field survey that is representative of the entire system. Do not base the design of a CP system for a HTHW piping system upon a single soil resistivity measurement.

B-9.1.7 Aboveground (On-grade) Fuel Storage Tanks.

Provide ICCP systems for the exterior bottoms of aboveground storage tanks with a secondary containment liner. Anodes must be installed in the backfill between the tank bottom and the containment liner. Do not specify GCP systems unless mission requirements preclude the use of ICCP systems. Provide a combination of permanent reference electrodes, corrosion probes, and reference electrode tubes to allow sufficient long-term testing and monitoring of the CP system effectiveness. Provide a separate CP system for buried distribution pipelines associated with the tank.

Provide a properly designed ICCP system for aboveground storage tank bottoms without secondary containment liners. With the many other systems incorporated into these storage facilities, complete electrical isolation can be difficult to achieve. Automated tank gauging systems, product recovery systems, leak detection systems, electrical grounding systems, fire protection systems, bonding systems and other miscellaneous conduits and controls include components that will inadvertently bypass installed electrical isolation devices. The tank may also be connected to a grounding system for safety, precluding the possibility of complete tank isolation. Provide CP for buried distribution pipelines associated with the tank. Consider electrical isolation issues, stray current interference issues, and life cycle costs to determine the need for a single integrated CP system for the tank and pipelines or separate systems for the tank and pipelines.

B-9.1.8 Excessive Cathodic Protection (Overprotection) Concerns.

Excessive CP (overprotection) is caused by application of excessive amounts of CP current and voltage. In addition to being wasteful of anode material or electrical power, excess potentials can cause disbondment of protective coatings; hydrogen embrittlement of certain types of steels, especially high strength steels; and corrosion damage of amphoteric metal structures made of aluminum and lead. Excessive CP current can also cause stray current (or interference) corrosion damage other metal structures in the vicinity.

B-9.1.8.1 Coating Disbondment.

Excess CP current results in protective potentials above established limits, and can result in the generation of hydrogen gas. Cathodic protection levels at potentials exceeding a polarized potential of -1.1 V with respect to a copper/copper sulfate reference electrode, result in the generation of excessive amounts of hydrogen gas on the surface of a protected metallic structure. When more gas is generated than can permeate the coating, bubbling or blistering of the protective coating occurs, causing disbonding of the coating from the structure surface. Electrolyte (water) can subsequently fill the space left between the coating and the metal, and as the coating is an electrical insulator, sufficient current for effective CP cannot flow to the affected area between the coating and the structure surface. Without CP, corrosion of the structure under the disbonded coating will occur.

Coating disbondment is a particular problem in water tanks in which the type of coating provided is especially prone to hydrogen disbondment and protective potentials exceed polarized potentials of -1.1 Volts DC. In soil environments where high quality coatings were provided, disbondment seldom occurs at potentials less negative than -1.1 Volts DC polarized potential (instant off).

B-9.1.8.1 Hydrogen Embrittlement.

The hydrogen produced when CP currents are excessive can also result in the reduction of the ductility of steel. This is particularly true for high strength steels (in excess of 130,000 pounds per square inch yield strength). This could lead to cracking from stress and loss of yield strength.

B-9.1.9 Stray Currents or Interference Concerns.

Stray currents, also called interference, result from external electromotive forces and can greatly accelerate corrosion. Stray current corrosion can be caused by voltage gradients (current flow) resulting from DC transit systems, HVDC Transmission systems, DC welding, telluric earth currents, and CP systems. The amount of corrosion caused is directly proportional to the amount of DC current flowing in the electrolyte. Steel corrodes at a dissolution rate of about 20 pounds per ampere-year. CP systems can impress large amounts of current from their anodes, through the electrolyte, to the cathode.

When a metallic structure not connected to or intended to be protected by the CP system (referred to as the “foreign” structure) is immersed in the same electrolyte in the vicinity of the protected structure, it is subjected to stray current corrosion because of the electromotive force being applied through that electrolyte and can undergo extremely severe corrosion without proper mitigation.

B-9.1.9.1 Mechanism of Stray Current by CP Systems.

A CP system is a large corrosion cell, a result of an electro-chemical reaction that involves electrical current flow and chemical ion migration. The current flowing from the anodes of a CP system flows through an infinite number of paths in the electrolyte toward all parts of the intended protected structure. Since the CP system is an electrical circuit, all of the electrical current provided by the rectifier through the anodes and the electrolyte must eventually return to the rectifier. In doing so, the basic laws of electrical current flow prevail, and most of the current will flow through the path of least resistance. A “foreign” metallic structure in the vicinity of the protected structure may provide such a low resistance path back to the rectifier. Figure B-19 illustrates an example of interference on a pipeline in the vicinity of DC rail systems. Figure B-20 illustrates an example of interference on “foreign” pipelines in the vicinity of a CP system.

Where the current flows from the electrolyte onto the “foreign” structure, the current will collect and flow along the foreign structure until a low resistance path, commonly where the “foreign” and protected structures physically cross or are in close proximity, will allow the current to flow off of the foreign structure into the electrolyte towards and onto the protected structure to eventually return to the rectifier. At these points where the current flows off of the “foreign” structure (discharges) into the electrolyte, oxidation reactions (corrosion) occur. At metal dissolution rates of 20 pounds per ampere-year, significant interference concentrated at discharge points such as a coating holiday on the foreign structure could cause significant amounts of corrosion in a very short amount of time, in some cases, as quickly as several days.

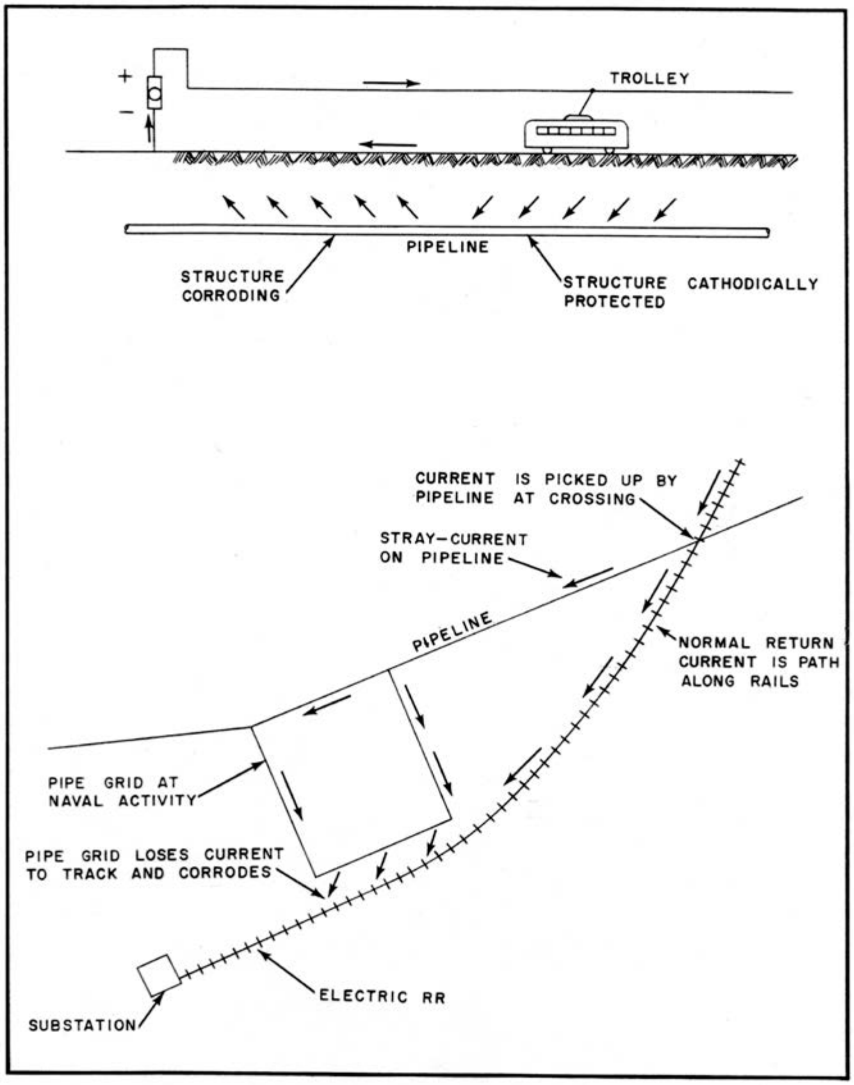
B-9.1.9.2 Impact of Stray Currents on the Protected Structure.

Although corrosion is not usually accelerated on the protected structure, cathodic interference can disturb the desired current distribution on the protected structure, and can reduce the amount of CP in some areas of the protected structure to inadequate levels.

B-9.1.9.3 Detecting Interference.

Cathodic protection interference problems are most commonly detected through the measurement of structure-to-electrolyte potentials. Where necessary, conduct stray current interference testing as part of the design field survey.

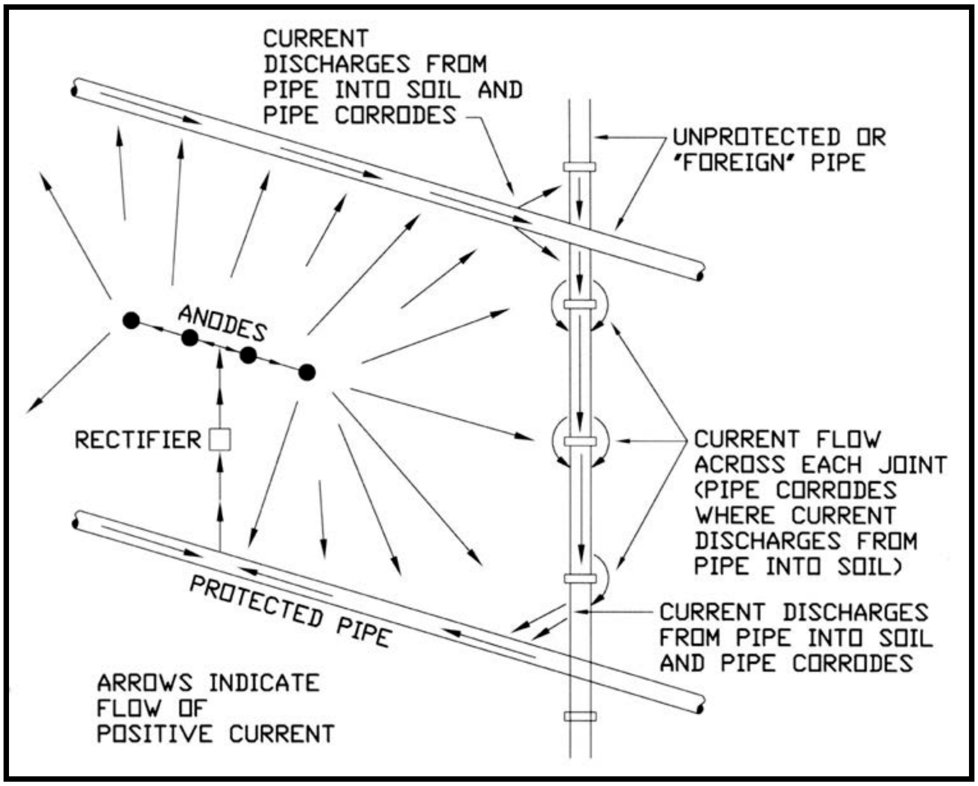
Figure B-19 Interference on Pipeline in Vicinity of a DC Powered Rail System.



B-9.1.9.4 Mitigating Interference.

Include mitigation methods for interference detected during the design field survey tests or anticipated based on structure layout in the drawings and specifications. In other cases interference may not be detected until after the CP installation, during system commissioning, and the interference mitigation methods will need to be determined immediately after the commissioning. Interference can be mitigated by several methods, depending on the ownership of the foreign structure, the protective coatings on each structure, and the surrounding soil conditions. If the foreign structure is owned by the same party, consider interference mitigation on the foreign structure as part of the CP system design.

Figure B-20 Interference on Foreign Pipelines in the Vicinity of a CP System.

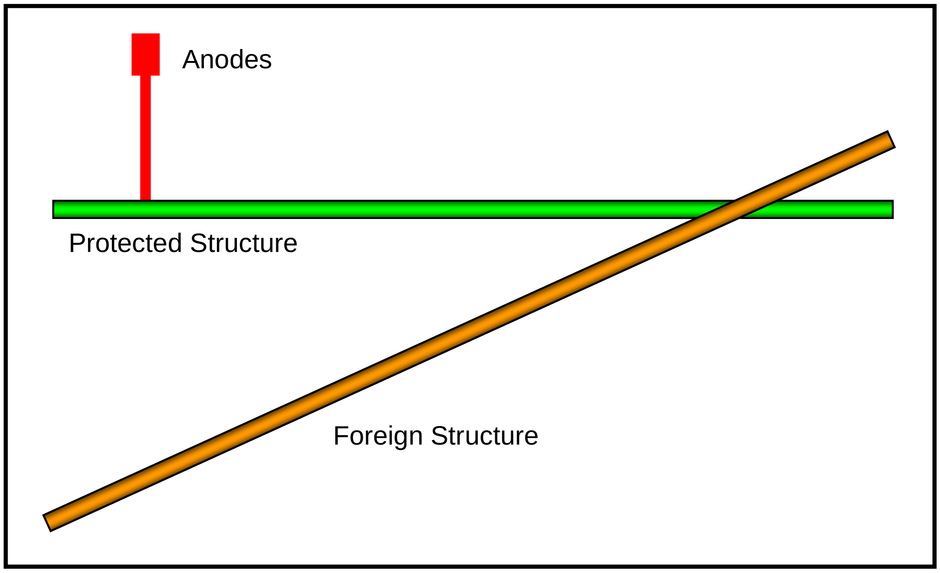


B-9.1.9.4.1 Anode Bed Location.

A significant factor in controlling interference is proper location of the anode bed. In general, the remote anode beds commonly used in ICCP systems cause more problems with interference than do sacrificial anode systems where the anode-to-structure distances are usually in the order of 10 feet or less and the driving potential is small (less than one volt). The influence on foreign structures is a primary consideration in the location of remote anode beds. Figure B-21 shows an example of an anode bed located to minimize interference on a foreign structure. Placing the anodes in between the two pipelines, nearby the crossing point or on the opposite side of the foreign pipeline would likely result in significant interference.

Deep anode beds generally have a significantly lower possibility of causing interference to foreign structures, as the foreign structures, in this case, usually do not provide lower resistant paths for the current from the anodes.

Figure B-21 Placing Anodes to Minimize Interference.



B-9.1.9.4.2 Direct Bonding.

Another technique for mitigating interference is to bond the foreign structure to the protected structure. The bonding can either be a direct low-resistance connection or a resistive bond. Bonding both structures together essentially provides CP to both structures. This can be accomplished to mitigate interference even if complete protection cannot be provided to the foreign structure. Direct bonding of a foreign structure to a protected structure will often require designing a larger capacity CP system than would be required just for the protected structure since the foreign structure can drain away substantial amounts of CP current intended for the protected structure.

Typically, provide the bond in a location where the structures physically cross or are in close proximity. Provide a test station at the direct bond location in order to verify the continuity of the bond, and to measure the current flowing through the bond. Specify insulated copper wire of appropriate size to properly carry the anticipated electrical bond current, and with a minimum wire size of No. 8 AWG for mechanical strength. Do not specify bare copper wire (e.g. grounding wires). Bare copper wire can drain away substantial amounts of CP current intended for the protected structure, and the insulated wire is necessary to minimize the amount of bare metal introduced to the CP system. Where interference testing cannot be conducted during the design survey, provide a bond station wherever pipelines cross and at other locations where interference is possible to allow for future bonding and testing. A bond test station must have two wires to each structure and room for possible installation of a resistor required in the future.

B-9.1.9.4.3 Resistance Bonding.

Direct bonding may not be desirable when the existing CP system cannot supply enough current to protect both the protected structure and bonded foreign structure (usually because of current distribution problems), or the foreign structure is not owned by the same installation as the protected structure. In the latter case, the structure owner supplying the CP current may desire to reduce the current provided to the foreign structure to just the minimum levels required to mitigate the interference. In either case, provide a resistive bond between the structures that can be adjusted to supply only the minimum amount of current to the foreign structure to bring its potential to its normal level prior to provision of the CP system for the protected structure.

Provide bond test stations where resistive bonds are used in order to facilitate testing of the corrective action and adjustment of the resistor, if required in the future. The resistor may either be a commercially supplied wire wound adjustable resistor of the proper resistance and current rating or may be fabricated from nickel-chromium alloy (nichrome) resistance wire cut to appropriate length in the field and wound into a coil. Adjustment of the resistor to correct the interference is determined by installing a temporary resistive bond and measuring the current through the resistor and the changes in potential achieved by the temporary bonding.

B-9.1.9.4.4 Use of Galvanic (Sacrificial) Anodes to Mitigate Interference.

Where the interference is localized, and the magnitude of the interference current is small, typically less than one ampere, sacrificial anode(s) on the foreign structure at the point of discharge may be an acceptable method to mitigate the interference. In order to determine the feasibility of using the sacrificial anode mitigation method, first measure the amount of bond current required to negate the interference. Next, calculate the ability of the GCP anodes to provide sufficient current based on the soil resistivity in the interference area. Size the GCP anode(s) to provide current in excess of the required bond current to control the interference. Provide test stations to monitor the potentials of both structures and GCP anode current outputs.

B-10 SPECIALIZED CP TECHNOLOGY AND CONSIDERATIONS.

B-10.1 Deep Anode Beds.

A deep anode bed according to the NACE International, is one or more anodes installed vertically at a nominal depth of 15m (50 ft) or more below the earth’s surface in a drilled hole for the purpose of supplying CP for an underground or submerged metallic structure. Refer to Figure 4-1.

B-10.1.1 Advantages/Disadvantages of Deep Anode Bed Systems.

Paragraphs B.4.2.6.1 and B.4.2.6.2 describe the advantages and disadvantages of deep anode bed systems.

B-10.1.2 Deep Anode Bed Design.

Deep anode bed calculations are fairly simple and follow the process for calculating a shallow vertical anode bed, except that the anode well resistance would be calculated using the Dwight equation for a single anode, whose length is that of the entire active zone. However, equally important and more difficult to determine factors must be considered when designing a deep well anode system.

B-10.1.2.1 Location.

Determining a good location for the deep anode column is essential to help ensure the proper design, installation, and operation of the column. Paragraph 4.3.4.1 describes requirements to consider in locating a deep anode bed.

B-10.1.2.2 Anode Column.

Some anode column design requirements and considerations are as follows:

B-10.1.2.2.1 Anode Type.

Select anode type for optimum performance and reduced difficulty of installation. Local subsurface conditions influence the selection of anode type, and anode selection affects the design for the column, i.e. quantity of anodes, depth and diameter of the column, and installation procedures. Technical Paper 16 provides information on the operational characteristics of different anodes in different environments.

B-10.1.2.2.2 Anode Centralizers.

Provide anode centralizers (Figure B-22) to help ensure the anodes are completely surrounded by backfill to lessen the chance of premature failure. Design/specify centralizers that do not significantly reduce total anode discharge area. Avoid the attachment of centralizers directly to anode surfaces that are subject to crevice corrosion such as mixed metal oxide or platinum coated titanium or niobium.

B-10.1.2.2.3 Anode Column Venting.

Provide vent pipes in the anode column to vent gases generated around the anode out of well to avoid gas blockage. Gas blockage can result in increased anode resistance and uneven current discharge from the anode surface resulting in premature failure. Specify vent pipes with holes or slots small enough to prevent the backfill from entering and clogging the vent pipe. Do not terminate the vent pipe inside of the anode junction box. Any chlorine gas generated will cause corrosion of the junction box hardware and detrimentally affect operation of the CP system. Terminate the vent pipes outside of the junction box as shown in Figure B-23 and seal the conduit to prevent gas from entering the junction box. Also, where practicable, do not terminate the vent in the anode well head box. The concentration of chlorine gas can result in corrosion of the well head box cover if it is made of steel or cast iron as shown in Figure B-24, and can degrade the insulation around the anode lead wires, and result in loss of the anode.

Figure B-22 Centralizers Installed on High Silicon Cast Iron Anodes

B-10.1.2.2.4 Anode Installation Procedure.

Follow the anode installation procedures as indicated in UFGS 26 42 17.00 10 and UFGS 26 42 19.00 20. In most cases specify that the contractor must not use the anode lead wire to lift, transport or install the anode. Handling the anode by using the lead wire can compromise integrity of wire and anode connection. Where the situation requires the use of the anode lead wire for anode installation, specify the appropriate pull out strength of the wire-to-anode connection to prevent damage to the connection, and provide destructive test procedures to verify conformance with the specifications. Refer to UFGS UFGS 26 42 17.00 10 and UFGS 26 42 19.00 20.

B-10.1.2.3 Anode Column Backfill.

Provide a special carbon backfill, referred to in the industry as coke breeze, in the anode hole or column for nearly all underground deep anode bed installations. Paragraph 4.3.4.3 describes requirements to consider for anode column backfill. Technical Report TR-NAVFAC EXWC CI-1425 *Environmentally Friendly Cathodic Protection Anode Beds*, describes a conductive concrete anode system that includes an impermeable backfill that can be considered as an option in deep anode bed CP systems where cross contamination of ground water aquifers is a concern or where artesian well conditions may complicate installation of the deep anode bed. Backfill is not required for open-hole, replaceable deep anode columns. Open-hole deep anode columns are considered where there is sufficient low resistivity groundwater to keep the anode well filled with water. In this case, the water provides the uniform environment for uniform distribution of current, with the advantage of more easily replaced anodes in the event of failure.

Figure B-23 Anode Column Vent Pipes Run Outside of Anode Junction Box.

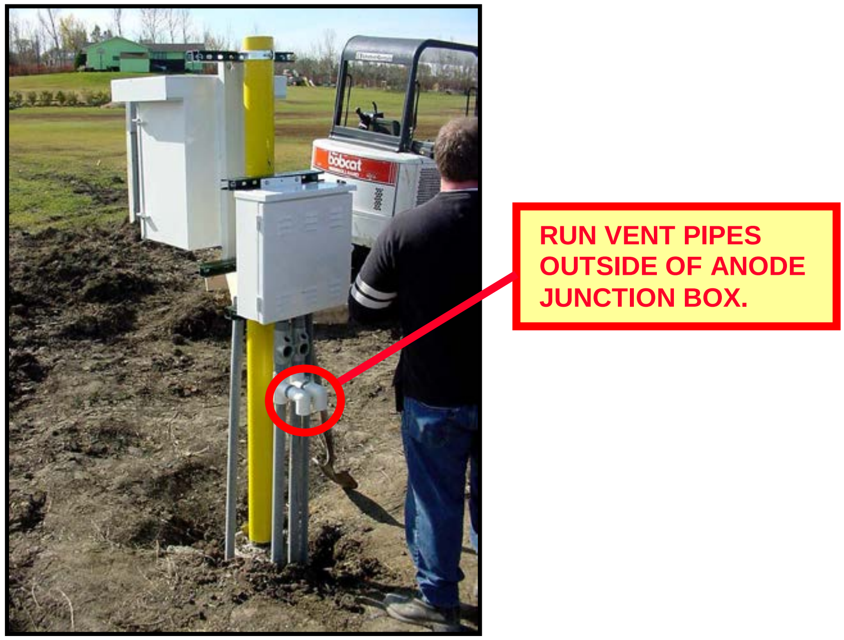


Figure B-24 Severe Corrosion of Cast Iron Cover on the Anode Well Head Box Caused By Chlorine Gas Vented into the Box.

B-10.1.2.4 Anode Lead Wires.

Anode lead wires are very important components of the anode installations, and many deep anode installations have failed because of improperly specified lead wires. Some considerations for anode lead wires for deep anode beds include:

B-10.1.2.4.1 Wire Insulation.

Specify HMWPE insulation. For chlorine ion environments, specify a dual insulation consisting of an inner ethylene-chlorotrifluoroethylene layer with an HMWPE outer layer for abrasion resistance.

B-10.1.2.4.2 Splices Not Allowed.

Provide individual anode lead wires to the anode junction box instead of splicing them to a single header cable from the rectifier. Anode columns that traverse differing soil strata can result in uneven current distribution from the anodes (i.e. higher current output of individual anodes located in low resistivity strata) that can lead to premature failure of that anode. Loss of anodes can then result in overload of the remaining anodes that may then prematurely fail. This domino effect will eventually result in premature failure of the anode column. Specify that splices are not allowed in the anode lead wires. Splices are a point of premature failure of anode lead wires.

B-10.1.2.4.1 Damaged Wire Insulation Not Acceptable.

Specify that nicks or other damaged to the wire insulation are not acceptable. As with splices, and even more so with damaged wire insulation, nicks and damaged insulation are points of premature failure of anode lead wires.

B-10.1.2.5 Environmental Concerns.

Installation of a deep anode bed can impact the environment. Environmental concerns must be considered during the early design stages. Consult with base environmental personnel and ensure that they are afforded the opportunity to review the design. Failure to consider environmental concerns can result in:

- Delays in completing the final design if an environmental issue is identified too late in the design
- Delays in obtaining construction permits
- Work stoppage and costly construction delays if environmental issues must be settled after construction is awarded with the potential for disapproval of work and cancellation of the installation
- Pollution of the environment and the resulting costly cleanups
- Fines for violating environmental regulations
- Other legal ramifications

B-10.2 Pre-engineered Cathodic Protection for Underground Storage Tanks.

USTs and oil water separators that conform to the Steel Tank Institute STI-P3-90 standard include a pre-engineered sacrificial anode CP system that is one part of the overall pre-engineered external corrosion control system for the underground steel storage tank (Figure B-25). The STI-P3® system combines three basic methods of underground corrosion control, all installed on the tanks during manufacture:

- Cathodic protection
- Protective coating
- Electrical Isolation of the tank from other underground metallic structures

Do not specify these types of pre-engineered CP systems where field survey conditions indicate they are not feasible. For new STI-P3® tanks specify provision of manufacturer provided PP4 CP testing equipment or provide separate appropriate test stations and wiring, to allow proper testing of the CP system.

***** CAUTION - RISK OF INADEQUATE CP *****

The CP system for an STI-P3® tank is intended only to protect the tank. Pipelines associated with the tank will not be protected. A separate CP system must be provided for the associated pipelines to comply with UST regulations. Also note that the integrity of the isolating bushings for an STI-P3® tank must be maintained. Loss of this electrical isolation can result in inadequate protection of the tank because of electrical shorts to other buried metallic structures in the vicinity.

Figure B-25 STI-P3® Tank

B-10.2.1 Dielectric Coating.

Every STI-P3® underground storage tank is protected with one of the three generic types of coating that have been tested to STI requirements and then approved for adoption into the STI-P3® specification: coal tar epoxy, urethane, or isophthalic polyester resin. This first line of defense against corrosion completely covers the external surface of the tank. A coating is applied to a blast-cleaned, prepared surface. If this coating is flawless, external corrosion cannot occur. Also, even if not perfect, the protective coating serves to reduce the amount of protective current needed for CP.

B-10.2.2 Cathodic Protection.

The only practical approach to a pre-engineered CP system for this application is using GCP anodes attached to the tank. GCP anodes develop their own protective current because of the natural potential difference between the anode metal and the metal being protected. This means that the anode system is self-activated after the tank is buried and will continue to provide corrosion control until the anode is consumed by corrosion.

Sacrificial GCP anodes made of either high-purity zinc or magnesium prevent corrosion of any exposed metallic surfaces, such as nicks or scratches in the coating that may occur during transportation or installation of the tank. Welded to the tank, these anodes control the direction of electrical current flow and will deteriorate in place of the steel. Based on the estimate of the average current produced by the anodes in a given soil, the estimated useful life of the anode system can be calculated. If the coating remains undamaged, the anodes will serve merely as back-up protection. Zinc anodes are provided where the soil resistivity is less than 2,000 ohm-cm. Otherwise magnesium anodes are provided.

B-10.2.3 Electrical Isolation.

All STI-P3® tanks must be electrically isolated from all other metallic underground structures that will be exposed to the backfill. This includes hold down straps installed to prevent the tank from floating out of the excavation during a high water table. Tank openings are electrically isolated by use of dielectric nylon bushings or flange isolators that will be compatible with stored product. By preventing contact between the tank and other nearby metal structures through the piping system, the chance of stray current corrosion is minimized, and the current demand that such contact would add is eliminated. This isolation, which defines the area to be protected by anodes, is intact when shipped from the factory.

B-10.2.4 Test Stations.

The STI-P3® design uniquely enables the testing of the tank's corrosion protection system. Varying federal and state regulations require that periodic CP tests be performed on single-wall STI-P3® tanks. For new STI-P3® tanks, specify provision of PP4 CP testing equipment or provide appropriate test stations and wiring, to allow proper testing of the CP system.

B-10.3 CP Systems for Reinforcing Steel in Concrete.

The chemical and alkaline nature of reinforced concrete normally results in the rebar developing a passive surface film that mitigates the effects of corrosion. Corrosion normally occurs around the tidal and splash zones due to the intrusion of oxygen, moisture, and chloride ions that will destroy the passive film. Most of the spalling and crack damage is a result of corrosion of the steel reinforcing bar (rebar) due to the presence of chlorides in the concrete. The reinforcing steel corrosion products (rust) occupy a larger volume of space than the original bar, and will exert enough force on the concrete to cause structural cracks, delaminations, and spalling of the concrete structure. Structural engineers contracted to design the structural repairs frequently specify the industry state-of-the-practice repairs for damaged piles, typically, patching of spalled concrete and epoxy injection to repair cracks. Such repairs are expected to last for 20 – 25 years; however, repairs by patching do not stop the existing rebar corrosion process due to the continued presence of chlorides, and will often cause increased corrosion of the rebar just adjacent to the patched areas, resulting in larger spalled and cracked areas after only six to seven years.

CP systems are generally not required for rebar for new reinforced concrete structures. Instead, comply with the requirements of the appropriate UFC and UFGS documents that include concrete design considerations that enhance corrosion prevention and control of the rebar. However, for major concrete structure repair projects, provide CP for the rebar in concrete where economical over the life cycle of the structure. CP systems for rebar in concrete must be designed by a qualified person experienced in the design of CP systems for rebar in concrete. Provide permanent reference electrodes or corrosion probes to allow testing and monitoring of the CP system effectiveness.

B-10.3.1 ICCP Systems.

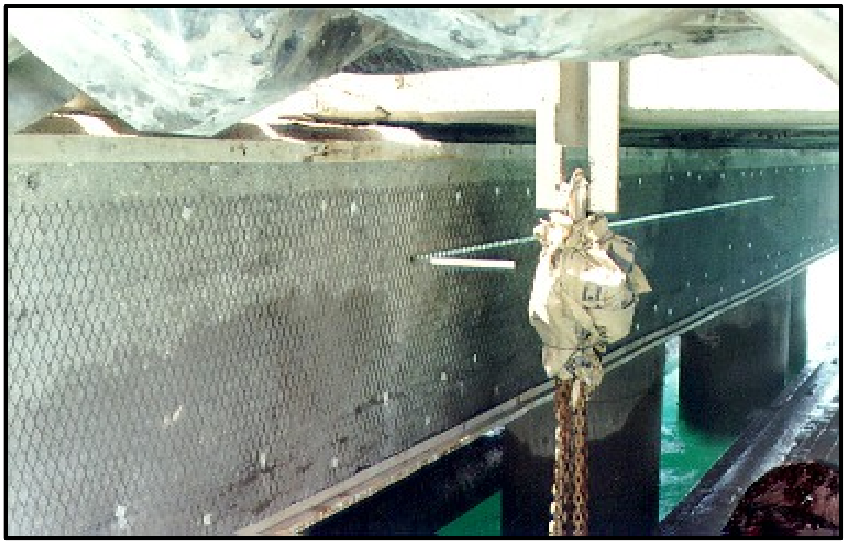
For corrosion protection of reinforced concrete structures requiring significant structural concrete repairs, CP can be applied to protect the reinforcing steel from corrosion where economical. While several different types of ICCP anode systems are manufactured, consider one or a combination of the three different types of ICCP anode systems that is most appropriate for the type of concrete structure and repairs being accomplished.

- Titanium mesh system consisting of mixed metal oxide coatings on an expanded titanium mesh fastened to the concrete surface (Figure B-26), and overlaid with a cementitious material, usually a Portland cement concrete mix. This type of system is commonly used on deck surfaces, piles or columns

- Titanium ribbon (mesh) slotted system consisting of mixed metal oxide coatings on either solid titanium ribbon strips or on expanded titanium mesh ribbon strips. The ribbons are installed between the rebar and concrete substrate or in slots cut in the concrete surface, and backfilled with a cementitious mix. This type of system is commonly used on deck surfaces

- Discrete anode system that typically consist of short strips of mixed metal oxide coated expanded titanium mesh, ceramic anodes, or platinized titanium wire typically installed in drilled holes and backfilled with cementitious grout. The length and spacing of the discrete anodes depends on the density of rebar and protection current requirements. These systems are most economical for beams, piles and columns

Figure B-26 Titanium Mesh Anodes Fastened to a Concrete Beam



B-10.3.1 GCP Discrete Anode System (DAS).

When cracked and spalled concrete structures containing high chloride contamination are repaired by patching because of funding limitations, consider installation of GCP discrete anodes in the vicinity of the patched area. The GCP discrete anodes are sacrificial zinc anodes in a special backfill (Figure B-27 and B-28). Unless a large area of concrete is removed during spall repairs, provide discrete anodes areas near the outer edges of the patch before applying the concrete patch. The type, length and spacing of the discrete anodes depends on the density of rebar and patch dimensions. The intent of the DAS anodes installed along with patches is not to provide adequate CP to the entire structure, but to minimize the galvanic corrosion effects between the rebar surrounding the patched area and the rebar within the patched area.

B-10.3.2 Pre-engineered CP for Pier Pilings.

While GCP DAS can be provided for corrosion protection during the repair of reinforced concrete piles (Figure B-29), another alternative is an integrated concrete pile repair and corrosion protection system (Figure B-30) containing pre-engineered CP systems for the pile reinforcing steel. Refer to paragraph 4-5.4.3. Consider this type of system as a viable alternative for long-term repairs of waterfront structures with reinforced concrete piles containing high chloride contamination, and significant spalling/delamination of concrete due to corrosion of reinforcing steel. This system can increase the service life of a pier patch repair up to 20 years in contrast to only six to seven years if pier pilings containing high chloride levels are only patched. For piles with only minimal damage, prepare a life cycle cost analysis to help determine the economic viability of this technology.

Figure B-27 Discrete Zinc Anode (Wrapped in Green Mesh) in Concrete Deck Repair. Device with the Yellow Lead Wire is a Permanent Reference Electrode.

Figure B-28 Discrete Zinc Anodes in Fiberglass Jacket for Pile Installation.

Figure B-29 Photos Showing "Before" and "After" Installation of Integrated Pile Repair and CP Systems

B-10.3.2.1 System Description.

The integrated pile repair corrosion protection system is comprised of high purity expanded zinc mesh CP anode mounted into a durable, stay in place fiberglass form that positions the anode material the appropriate distance relative to the steel rebar in the piling. In addition, the form creates an essential annular space for filling with concrete material to complete/improve the structural repairs to the piling. A supplemental bulk anode is added to protect the submerged portion of the pile and minimize current demand on the lower portion of the anode mesh (see figure B-30).

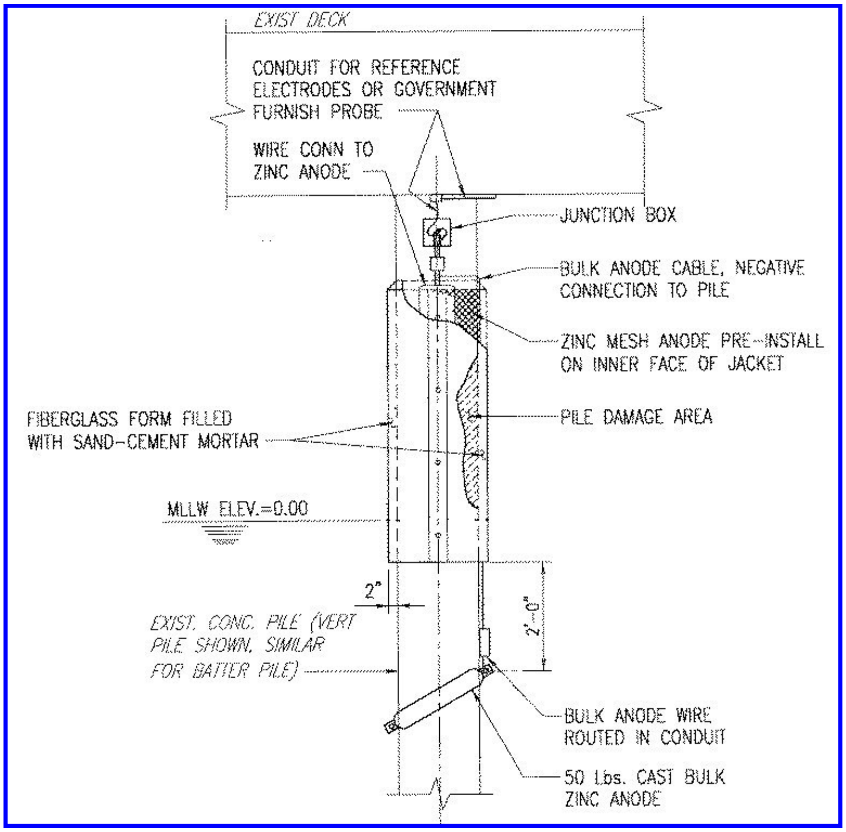
The system comes complete and ready to install with all components pre-positioned and fixed in place. The external jacket material is a durable fiberglass shell that is equipped with unique interlocking seams that literally snap together. Manufacturer's literature indicates that non-specialty contractors and supervised general laborers can do the job. Once installed, the system requires very little maintenance or monitoring, an expense that is often neglected with other ICCP systems that becomes a burden during the ICCP system life cycle. Based on results from a DOD demonstration project of this technology, the estimated average service life of the zinc CP system mesh is in excess of 25 years.

The system can be designed for a wide variety of pier piling structure configurations and can easily be integrated with the other pier piling repairs already being designed (removal of spalled concrete, replacement of badly corroded rebar sections, patching of spalled concrete areas, and repairs to small cracks in the concrete).

B-10.3.2.2 System Design.

Most Architect-Engineering (A-E) firms and even CP firms do not have experience with this technology. Close coordination between the design agent, the A-E designer, the product manufacturer, and service CP technical experts is necessary to ensure the system is properly designed, and adequate testing facilities are incorporated to permit monitoring of these systems.

Figure B-30 Typical Lifejacket Installation



B-10.3.2.2.1 Anticipated Concrete Repair Scope Creep.

From past experience in concrete waterfront repair projects, the scope of concrete repairs tends to increase over the design requirements as demolition of spalled concrete uncovers unseen damaged areas. Ideally, demolition of all spalled and cracked concrete should be completed prior to ordering jacket system materials to ensure proper jacket lengths and no negative impacts to the system installations. However, as the pile jacket systems may be a long lead time item, this plan would delay their installation and would also complicate installation as specific jackets would need to be matched to specific piles. It may be more reasonable and prudent to specify a jacket of length from two feet below the low water level to three or four feet above the high water level. Unforeseen additional damage found during demolition beyond the jacket length would be repaired in accordance with the appropriate typically prescribed repairs designed for concrete damage on piles without this system.

B-10.3.2.2.2 Pile Rebar Electrical Continuity.

Electrical continuity among all of the reinforcing steel in the pile is necessary for proper operation and effectiveness of the CP system. The normal manufacturer's recommended procedure is for the contractor to drill several small holes in the concrete piles to locate rebars and permit testing to determine electrical continuity between the rebars. Where not found electrically continuous, the contractor is required to install bond wires between such rebars to ensure electrical continuity. Since this process is essentially a trial and error process, it would require the contractor's corrosion technician to be on site for long amounts of time during this process, and the process may slow down the installation. If during a repair project, a large quantity of piles require repair, it may be more cost and time efficient for the contractor to demolish a band of concrete around the entire perimeter of the piles to expose all of the rebars in the piles (Figure B-31), and weld a continuous metal bar to each of the rebars in the pile to ensure their continuity. This will reduce the time needed for the contractor's corrosion engineer to conduct continuity testing, reduce the time for installation, and also ensure that the piles would not have to be reworked because of electrical discontinuities found during system commissioning.

B-10.3.2.2.3 System Installation.

Most contractors also do not have experience with this technology; therefore, specify requirements for project execution procedures for close coordination between the user, designer, contractor, and the product supplier/ manufacturer. Prior to commencement of construction, meet with the contractor to resolve issues that he may not understand or are not technically feasible in the design. Closely coordinate with the contractor to develop a system installation procedure as part of their quality control plan.

Figure B-31 Concrete Demolished Around Entire Pile to Permit Installation of a Bar Welded to Each Rebar to Establish Electrical Continuity.

B-10.3.2.2.5 Monitoring Test Stations.

A typical integrated concrete pile repair and corrosion protection system installation will come with a small test box mounted just above or on one of the jacket faces. Also consider the installation of several special monitoring test boxes along the pier or wharf deck in various random areas throughout the structure to facilitate testing of these systems. The additional cost for these special test boxes will be offset by

- Eliminating the cost and time need to obtain and launch a boat to navigate to the piles during each round of testing. By having test boxes mounted on the deck of the pier, a significant amount of time is saved while conducting the tests. For example, a full round of tests for an averaged sized pier can be conducted on the pier deck in one to two hours versus the several hours to almost a day that would have been required using a boat
- Providing a stable surface on which to conduct the tests. Due to the constantly moving boat in the water, two people would be required during testing; one to hold the boat as steady as possible against the piles while the other conducts the test measurements. Only one person is required to conduct the tests at the deck mounted test boxes. Tide levels also impact testing procedures

B-10.4 Interior of Potable Water Tanks.

Water storage tank CP systems must be designed by a qualified person experienced in the design of CP systems for water storage tanks to ensure its proper operation. Ensure that CP system materials are approved for use inside of potable water storage tanks in accordance with NSF/ANSI Standard 61. Coordinate CP systems requirements with the interior protective coatings designer to eliminate conflicting requirements.

B-10.4.1 CP for Interior of Water Tanks Subject to Icing Conditions.

There is a persistent problem at DoD installations with CP systems for water storage tanks located in areas with cold winters. Water tank interior CP system anodes are typically suspended from the roof of the tank with wires and cables such that they are submerged in the water. Such systems are often prematurely damaged or destroyed when surface ice forms in the tank in very cold environments.

Older water tank CP systems used heavy silicon-iron or graphite anodes. Such systems were vulnerable to failure not only due to ice, but also due to the weight of the suspended anodes pulling on the wire and electrical connections. Ceramic-coated anodes have been used as a lightweight alternative to the silicon-iron and graphite anodes in recent years. These anodes are typically made by depositing mixed metal oxides (MMO) onto titanium substrates including rods, wire, and discs. The MMO-coated anode eliminates the problems caused by anode weight, but when they are suspended from the roof of the tank, the anodes, cables, and wiring are still susceptible to ice damage. ICCP systems to protect the interior surfaces of water storage tanks in cold climates must be designed to prevent damage from ice. Specify a CP system consisting of MMO wire anodes along with a flotation and support system that keeps the anodes submerged in water underneath surface ice, regardless of the water level, where they will no longer be subject to ice damage. Refer to material and installation details in UFGS 26 42 15.00 10.

B-10.4.1.2 System Design.

The design to prevent ice damage uses MMO-coated wire anodes along with a flotation and support system that keeps the anodes submerged in water underneath surface ice, regardless of the water level. Because the anodes and their supports are kept away from the ice, they will not be subject to ice damage. There are several design considerations for anode support systems developed by industry. One design example utilizes an octagonal-shaped buoy constructed on-site inside the tank from 4-inch diameter Schedule 40 PVC pressure pipe sections (Figure B-32). The sections cannot be pre-assembled because the finished buoy would be too large to insert through a tank hatch. The buoy is tethered with polyester ropes to the bottom of the riser in the center of the tank. This installation may not be practical during cold weather, as the PVC cement for joining pipes would not set properly in the cold weather conditions.

An alternative design for installation in cold weather, successfully demonstrated by the U.S. Army, consists of 4-inch diameter Schedule 40 PVC pressure pipes installed in a pattern of the “spokes” of an octagonal umbrella-like support structure (Figure B-33). These anode support arms are attached to the riser via hinged connectors. Polyester marine rope forms the outer hoop of the support structure, and the anode wire is wrapped around the rope. PVC legs at each corner of the octagon oriented downward from the plane of the hoop prevent contact between the anode and the tank walls. Four commercial fishing net floats are attached at the far end of each anode support arm to prevent the hoop from sinking. The positive lead wires (attached to the anode wire on two diametrically opposite sides and connections water-proofed) are also spirally wound around the buoy and terminated outside the tank through a tank-entrance pressure fitting. A lead wire from a copper/copper-sulfate reference electrode permanently mounted on the hoop leg is also terminated outside via this fitting. The negative lead wire is exothermically welded to the steel tank access tube ladder strut, coated with epoxy, and also terminated outside the tank through the pressure fitting. This system design does not require on-site assembly of PVC pipe sections, thus it is possible to install it during cold weather.

B-10.4.2 Bolted or Riveted Water Storage Tanks with Interior Glass Lining.

Where a CP system is planned for a bolted or riveted steel water storage tank with an interior glass lining, include provisions to ensure electrical continuity between the riveted steel plates. The interior glass lining may electrically isolate adjacent plates. For other types of protective coatings, include requirements in the contract specifying that the contractor is responsible for providing an interior coating system and ensuring that the coating system is compatible with the CP system.

Figure B-32 Octagonal Shaped Buoy Design.

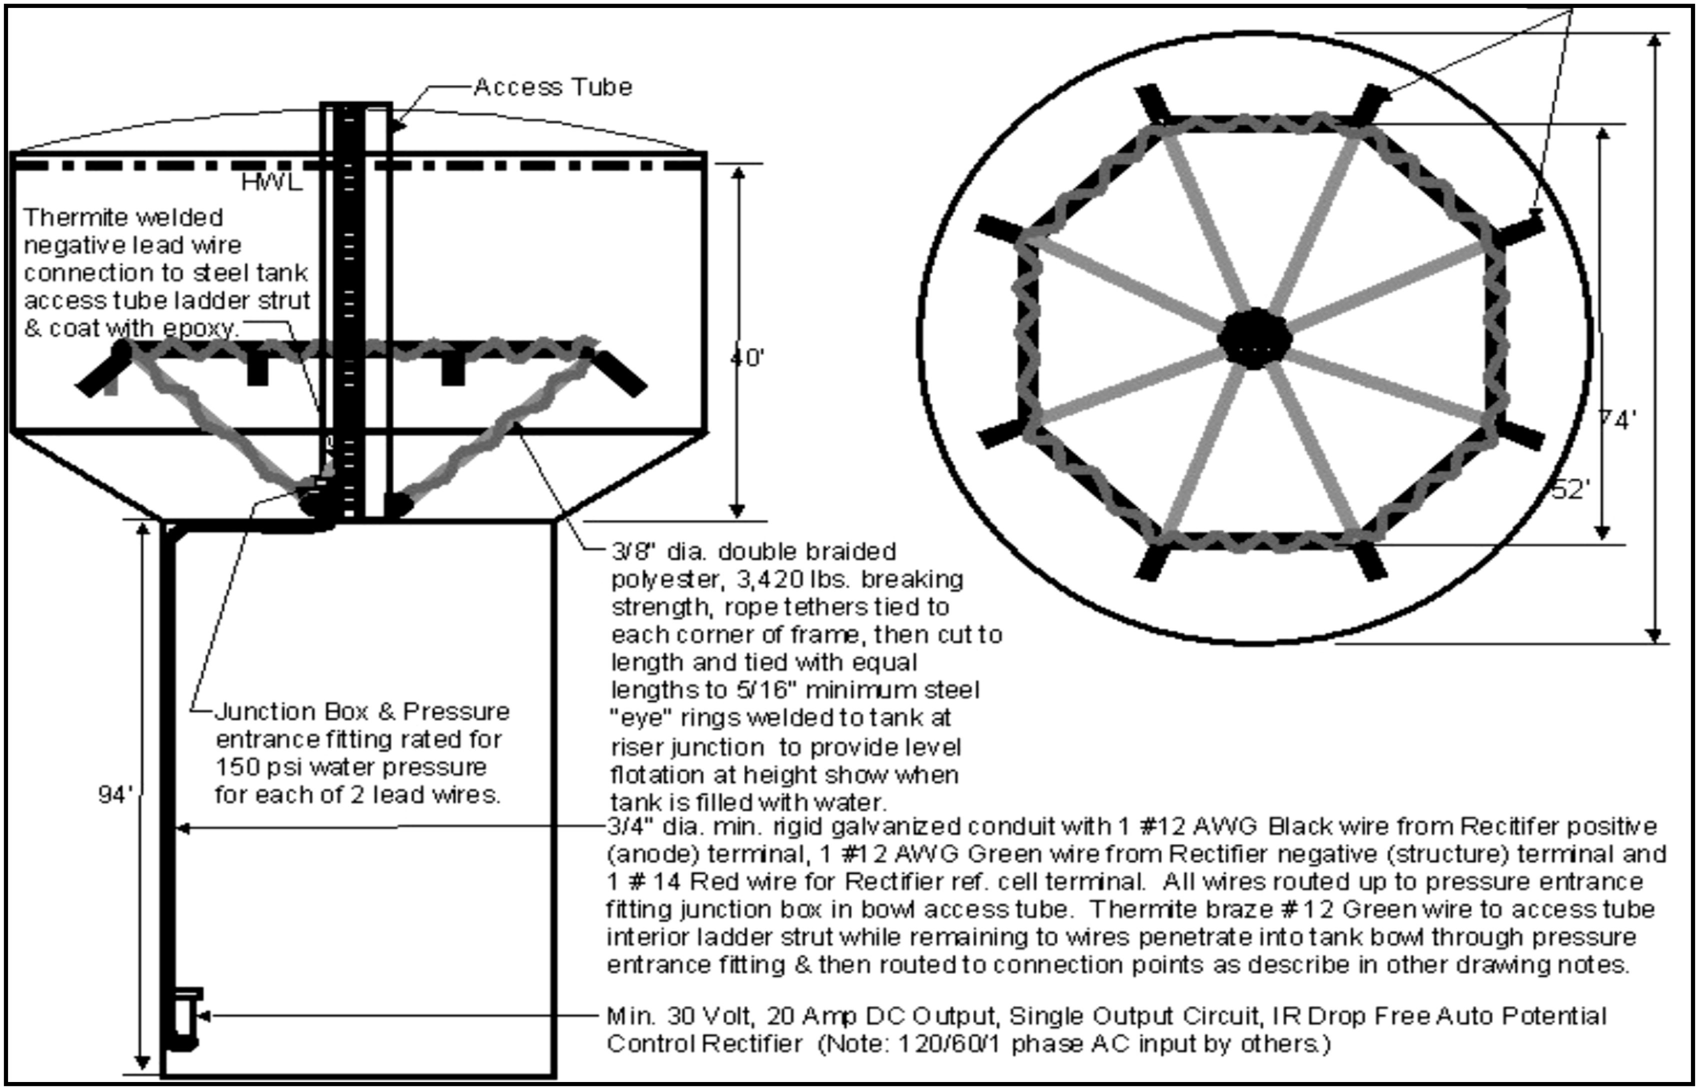


Figure B-33 Umbrella-like Anode Support Structure Design.

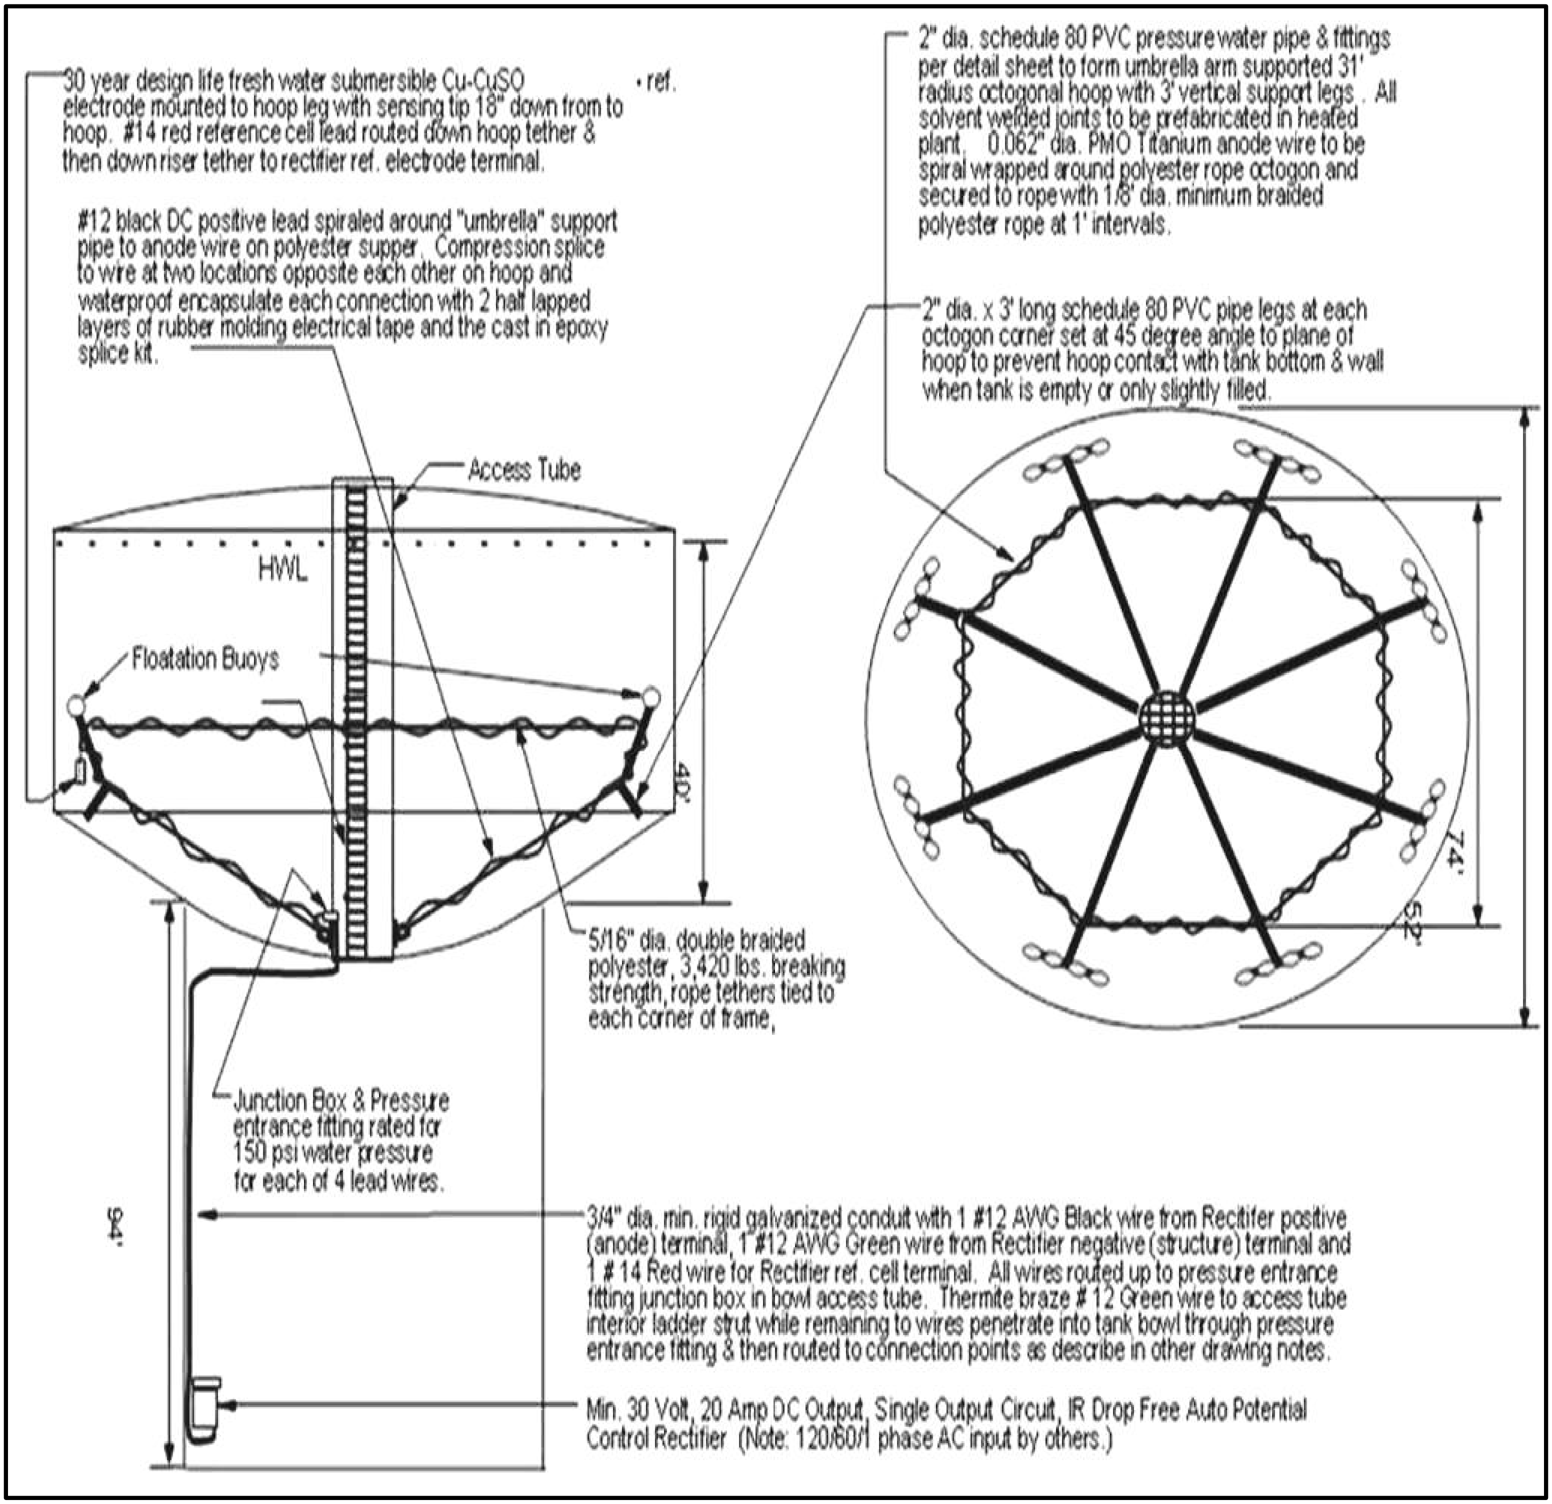

B-10.4.3 Monitoring Water Tank CP Effectiveness.

Provide a CP monitoring system that will allow monitoring of system effectiveness without having to physically climb the tank. Design the monitoring system such that test lead terminals are conveniently located in, or nearby the rectifier at ground level. Consider the use of remote monitoring systems.

B-10.5 Hot Water Storage Tanks.

Steel hot water storage tanks need protection against internal corrosion to prevent chronic leaking and premature failure. Corrosion caused leaks could cause extensive water damage to structures and mission critical electrical and mechanical equipment that may be co-located in the same rooms with the water storage tanks. Furthermore, the resulting leaks will eventually cause an accumulation of moisture that will promote mold and bacteria growth.

B-10.5.1 Domestic Hot Water Heaters/Tanks.

Provide factory-equipped glass linings and sacrificial anodes for domestic and smaller hot water heaters/tanks (75 – 1000 GA capacity). The glass linings and sacrificial magnesium anodes are economical for corrosion protection due to the reduced maintenance and monitoring for these systems.

B-10.5.2 Industrial Hot Water Heaters/Tanks.

Provide ICCP systems that use mixed metal oxide titanium rod anodes for larger industrial hot water heaters/tanks. Such systems have been successfully installed in Navy and Army installations. Figure B-34 illustrates a system installed in a vertical tank with a man-way access opening. In this example, a separate sacrificial anode is also installed to protect the man-way access cover since the sealing gasket prevented electrical continuity to the rest of the tank.

If an existing tank does not have a man-way access opening to permit work from the inside of each tank, utilize flexible and joinable mixed metal oxide coated anode rods, which can be bent and inserted into the tanks in 4-ft-long segments. This avoids having to break out any walls to provide clearance for their installation. Subsequent segments could be screw coupled to the first and subsequent segments as the assembly is pushed into the tank until the far end of the tank is reached (may require four or five segments). Insertion and penetration of the anode rod at each end of the tank can be made through a 1-in.-diameter “weld-o-let” fitting that is welded in place from the exterior on opposite ends of the tank (Figures B-35 and B-36). These provide threaded holes for high pressure stainless steel compression sealing elements minimizing the impact on the pressure vessel tank wall. The wire with black insulation in Figure B-36 is the positive lead wire from ICCP rectifier unit attached to the anode. The white insulation wire is rectifier system negative wire.

Figure B-34 CP System for a Vertical Hot Water Tank with a Man-Way Access Opening.

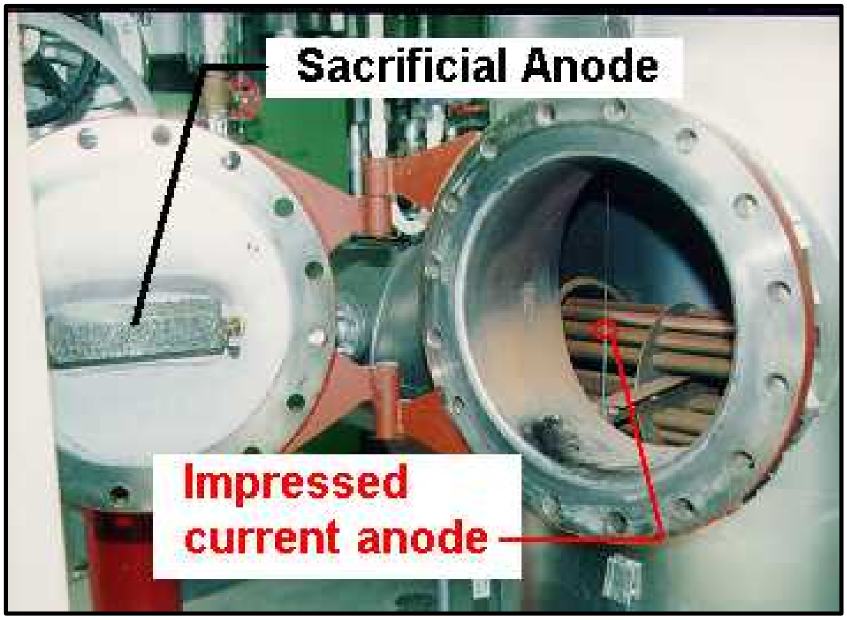

Figure B-35 CP System Rectifier and Anode Condulet Fitting on Side of Water Tank.

Figure B-36 Close up of Condulet Fitting Showing Anode Rod Extending Out of the Storage Tank.

B-10.5.2.1 Monitoring Water Tank CP Effectiveness.

Manufacturers of commonly used reference electrodes for CP system testing may not guarantee the accuracy of a permanently installed reference electrode in the high temperatures of a hot water storage tank. Instead, provide a capillary pore tube measurement port or bridge that facilitates taking these measurements with a reference electrode located outside the hot water tank with the tip held against the ionically conductive capillary tube (Figure B-37).

Figure B-37 Reference Electrode Placed in Contact with Moist Wadding Temporarily Placed Inside of the Capillary Tube Monitoring Port.

B-10.5.3 ICCP for Water Boxes in Power Plants.

Water boxes can contain a mixture of many different metallic materials. Some of the materials such as titanium, austenitic stainless steels, and super alloy stainless steels are more noble than the rest of the water box components. As a result, without CP, water box components can experience substantial galvanic corrosion. However, improperly designed ICCP systems for water boxes can result in metallurgical problems such as:

- Hydride formation in titanium tubes under excessive CP results in reduced ductility as the hydride forms
- Generation of chlorine gas at the anodes under excessive CP resulting in pitting corrosion in the upper tubes of austenitic stainless steel tube bundles
- Hydrogen embrittlement of stainless steel under excessive cathodic protection

Cathodic protection systems must be carefully designed to operate within selected operating potentials, and be properly maintained within these potentials to prevent any metallurgical problems from occurring. Designs must be accomplished by personnel qualified and experienced in these types of systems.

B-11 CP SYSTEM COMMISISONING.

B-11.1 System Commissioning Procedures.

Proper commissioning of the new CP system plays an important role in the operation and maintenance of the CP system. Proper commissioning by qualified personnel helps ensure the system is properly operating from the onset and helps identify system deficiencies, both design and construction, that should be corrected before the system is accepted. A properly commissioned system will help simplify maintenance and operation, and commissioning test data can be used as a baseline for future operation and troubleshooting. Specify adequate commissioning procedures so that the system is energized and fully tested to ensure its proper operation before being accepted from the contractor. General commissioning procedures are detailed in the UFGS listed in paragraph 3-4.3, and the following are examples of requirements from these specifications that should be tailored towards the specific CP system being designed.

B-11.1.1 General.

Specify that the systems shall be tested and inspected by the Contractor's corrosion engineer in the presence of the Contracting Officer's corrosion protection engineer or an approved representative. Include requirements to record test data, including date, time, and locations of testing and submit required reports to the Contracting Officer. Require that the contractor shall correct, at his expense, all deficiencies in the materials and installation observed by these tests and inspections, and must pay for retests made necessary by the corrections.

B-11.1.2 Base Potential Tests.

Prior to energizing the CP system, require the contractor to measure the base (native) structure-to-electrolyte potentials of the structure. Require that the measurements be made at anode junction boxes, test stations and other locations suitable for test purposes (such as service risers or valves) at intervals along the structure with measurements at each end point and the midpoint as a minimum. Indicate that the locations of these measurements shall be identical to the locations specified for measuring energized structure-to-electrolyte potentials. For USTs, take a minimum of three measurements with the reference electrode located as follows:

- Directly over the longitudinal and transverse centerlines of the tank at intervals not exceeding the diameter of the tank and to a distance from the tank of two times the tank diameter.
- At points directly around the circumference of the tank.]

B-11.1.3 Permanent Reference Electrode (PRC) Calibration.

Specify that the contractor must verify calibration of the PRC by measuring the potential difference between the PRC and an independent (portable) calibrated reference electrode placed in the soil or water adjacent to or as close as practicable to the PRC. Potential differences between the two electrodes of the same generic type should not exceed 15 millivolts. Zinc PRCs should be within the range of -1000 to -1150 millivolts when calibrated with a CSE. Require that permanent reference electrodes not within these potential differences shall be removed from the construction site by the end of the day and replaced at the contractor's expense. The testing provision shall also apply to replacement reference electrodes as well.

B-11.1.4 Insulation Joint Testing.

Require the contractor to perform insulation integrity testing at each dielectric insulating joint or fitting before and after the CP system is energized. Before energizing, test using an insulation checker. After energizing, test the insulation by measuring the potential shift on both sides of the insulating joint. Indicate that this testing shall demonstrate that no metallic contact or short circuit exists between the two insulated sections of the pipe or structure. Require the contractor to report and repair defective insulating fittings at their expense.

B-11.1.5 Electrical Continuity Testing.

Require the contractor to conduct electrical continuity testing of the structures intended to be cathodically protected prior to backfilling of the structure.

B-11.1.6 Rectifier System Testing.

Upon completion of the installation, "Baseline Potential Tests", "Insulation Joint Tests", and "Electrical Continuity Tests", indicate that the contractor can energize and adjust each rectifier and conduct the following inspections and tests:

- Verify the correct AC power supply to the rectifier
- Inspect and record the rectifier DC output panel meters
- Verify the panel meter readings using portable, calibrated meters and shunts
- Adjust the rectifier output as required to attain effective cathodic protection levels
- Correct noted deficiencies

This testing shall demonstrate that the rectifier system is capable of functioning properly as required to provide effective cathodic protection.

B-11.1.7 Pipe Casing Testing.

Before final acceptance of the CP installation, require the contractor to test the electrical insulation of the carrier pipe from casings and correct any short circuits.

B-11.1.8 Energized Potential Tests.

With the entire CP system put into operation require the contractor to measure structure-to-electrolyte potentials along the structure using a portable reference electrode(s) appropriate for the electrolyte and a voltmeter having an input impedance of not less than 10 megohms. The locations of these measurements must be identical to the locations used for the base potential measurements.

B-11.1.9 Interference Testing.

Perform interference testing with respect to any crossing and nearby foreign pipelines in cooperation with the owner of the foreign pipelines. The testing shall verify that the subject CP system does not have a deleterious effect on the foreign pipelines, and vice versa. Prepare a full report of the tests, giving all details including remedial actions taken or recommendations to correct noted interference problems.

B-11.2 System Commissioning FAQs.

Refer to Technical Paper 18, *Frequently Asked Questions About Cathodic Protection System Equipment Commissioning and Testing*, for additional information and FAQs regarding CP system commissioning.

APPENDIX C GLOSSARY

ACRONYMS

AC	Alternating Current
A-E or A/E	Architect-Engineer
AFCEC	Air Force Civil Engineer Center

UST	Underground Storage Tank
ZRE	Zinc reference electrode

DEFINITION OF TERMS

Amphoteric material: Material subject to attack by both acid and alkaline environments; include aluminum, zinc, and lead.

Anode: The electrode of an electrochemical cell at which oxidation occurs. (The anode is usually the electrode where corrosion occurs and metal ions enter the solution).

Bimetallic corrosion: (See galvanic corrosion).

Bond: See continuity bond.

Cathode: The electrode of an electrochemical cell at which reduction occurs.

Cathodic protection: A technique to prevent the corrosion of a metal surface by making that surface the cathode of an electrochemical cell.

Coating: A dielectric material applied to a structure to separate it from its environment.[1]

Conductivity: The measurement of a material's ability to conduct electrical current.

Continuity bond: Metallic connection that provides electrical continuity.

Corrosion: The deterioration of a material or its properties due to a reaction of that material with its chemical environment.

Corrosion potential: The potential of a corroding metal surface relative to a reference electrode under specific conditions in an electrolyte.

Corrosion rate: The rate at which corrosion proceeds.[1]

Crevice Corrosion: Localized corrosion resulting from a concentration cell formed between two metal surfaces or between a metal and non-metallic surface.

Current density: The current per unit area.

Electrical isolation: Condition of being electrically separated from other metallic structures or the environment. [1]

Electrode: A conductor used to establish electrical contact with an electrolyte and through which current is transferred to or from an electrolyte.[1]

Electrolyte: A chemical substance or mixture containing ions that migrate in an electric field. Examples are soil and seawater.

Fiber Reinforced Plastics (FRP): A broad group of composite materials composed of fibers embedded in a plastic resin matrix.

Foreign structure: Any structure that is not intended as a part of the system of interest.

Galvanic anode. A metal that, because of its relative position in the galvanic series, provides sacrificial protection to metal or metals that are more noble in the series, when coupled in an electrolyte. These anodes are the current source in one type of cathodic protection.[1]

Galvanic cell: A corrosion cell in which anode and cathode are dissimilar conductors, producing corrosion because of their innate difference in potential.

Galvanic corrosion: Corrosion resulting from the coupling of dissimilar metals in an electrolyte.

Holiday: A discontinuity in a coating that exposes the metal surface to the environment.

Hydrogen embrittlement: The severe loss of ductility of a metal when hydrogen has been introduced into the metal structure.

Hydrogen overvoltage: Voltage characteristic for each metal-environmental combination above which hydrogen gas is liberated.

Impressed current: Direct current supplied by a power source external to the electrode system. For the purposes of this manual, direct current for cathodic protection.

Interference: Any electrical disturbance on a metallic structure as a result of stray current.

Interference bond: A metallic connection designed to control electrical current interchange between metallic systems.

IR drop: Voltage across a resistance according to Ohm's Law. [1]

pH: A measure of hydrogen ion activity defined by: $pH = \log_{10} (1/aH^+)$ where aH^+ = hydrogen ion activity = molal concentration of hydrogen ions multiplied by the mean ion activity coefficient (= 1 for simplified calculations).

Pipe-to-soil potential: The potential difference between the pipe metallic surface and electrolyte that is measured with reference to an electrode in contact with the electrolyte. See also structure-to-electrolyte potential.[1]

Polarization: The deviation from the open circuit potential of an electrode resulting from the flow of current.

Reference electrode: A reversible electrode with a potential that may be considered constant under similar conditions of measurement.

Resistivity: The measurement of a material's ability to oppose the flow of electric current.

Rust: A reddish-brown corrosion product of iron that is primarily hydrated iron oxide.

Sacrificial anode: See galvanic anode.

Stray current: Current flowing through paths other than the intended circuit.

Stray current corrosion: Corrosion resulting from stray current flow through paths other than the intended circuit.

Structure-to-electrolyte potential (also structure-to-soil potential): The potential difference between a buried metallic structure surface and electrolyte that is measured with reference to an electrode in contact with the electrolyte. See also pipe-to-soil potential.

Structure-to-structure voltage (also structure-to-structure potential): Difference in voltage between metallic structures in a common electrolyte.

Surge arrestors: A protective device for limiting surge voltages by discharging or bypassing surge current, and it also prevents continued flow of follow current while remaining capable of repeating these functions. Designed primarily for connection between a conductor of an electrical system and ground to limit the magnitude of transient (surge) overvoltages on equipment. Also known as arrestor or arrester, surge arrester, lightning arrestor or arrester.

Uniform corrosion: Corrosion attack of a metal that is essentially the same at all exposed areas of its surface.

Voltage: An electromotive force, or a difference in electrode potentials expressed in volts.

This UFC supersedes UFC 3-570-06, dated January 2003.

FOREWORD

The UFC system is prescribed by MIL-STD 3007; provides planning, design, construction, sustainment, restoration, and modernization criteria; and applies to the Military Departments, the Defense Agencies, and the Department of Defense (DoD) Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFAs), Host Nation Funded Construction Agreements (HNFAs), and, in some instances, Bilateral Infrastructure Agreements (BIAs). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-570-06, *Operation and Maintenance: Cathodic Protection Systems*

Superseding:

- UFC 3-570-06, Operation and Maintenance: Cathodic Protection Systems, 31 January 2003
- Public Works Bulletin 420-49-29, *Operation and Maintenance of Cathodic Protection Systems,* 2 December 1999

Description: This document provides technical personnel guidance for inspection and maintenance of cathodic protection (CP) systems.

Reasons for Document:

- Updated to reflect industry standards.
- Recommended changes from Air Force, Army, and Navy personnel to ensure this document applies to all branches.
- New industry technology and guidance.
- Chapter 2, “Principles of Operation,” and Chapter 7, “Test Procedures“ converted into technical papers with appropriate updates.
- Troubleshooting techniques placed in an appendix.
- Appendixes labeled properly to include service-specific guidance, training and certification, and additional references.
- Contents adjusted to account for new formatting per UFC 1-300-01.

Impact:

- Cost impact is negligible.

Unification Issues:

- None.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides guidance for operation and maintenance of CP systems. It should be used by field personnel to perform scheduled inspections and preventive maintenance and to troubleshoot and repair CP systems. Information on non-routine field measurements is also included to enable technical assistance personnel to troubleshoot problems beyond the normal capability of field personnel to isolate or correct.

1-2 APPLICABILITY.

CP is an electrochemical (half electrical and half chemical) method used to control corrosion of buried or submerged metallic structures. It prevents corrosion by making the protected structure a cathode by installing a more anodic metal (sacrificial or galvanic) anode or a metallic (impressed current) anode connected to a direct current (DC) power source. When the proper amount of current is applied, all of the anodic areas on the structure are changed to the same potential, thereby removing all of the anodic locations and allowing the entire structure to become a cathode. Since all corrosion occurs at the anode, the structure no longer corrodes. The electrons move in the metallic path, reduction (chemical) reactions occur at the surface of the cathode, and oxidation (chemical) reactions occur at the surface of the anode. Reduction reactions at the cathode result in a hydrogen coating and a more alkaline environment, and the oxidation reaction at the anode results in corrosion and a more acidic environment. After a CP system is installed and adjusted to provide adequate protection, currents and potentials should remain relatively stable; typically, a plus or minus ten percent change in currents or potentials indicates a problem.

Employ CP within the following equipment/systems:

- Underground fuel storage tanks and ground-level tank bottoms.
- Fuel distribution and storage systems.
- Elevated and ground-level water storage tank interiors and ground-level tank bottoms.
- Potable water distribution systems.
- Natural gas or propane distribution systems.
- Compressed gas distribution systems, such as air, oxygen, and nitrogen.
- Fire protection water storage tanks, piping, or water lines.
- Sewage tanks, lift stations, and effluent pipelines.
- Steel sheet pile seawalls, pier support/fender piles, and other submerged steel structures.
- Concrete reinforcing steel.
- Industrial waste pipelines.

- Dams and lock systems.
- Cooling towers.
- Recirculating water systems (hot or cold).

1-3 OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA).

Comply with all OSHA requirements, as applicable.

1-4 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies. Comply with all applicable provisions of the current issues of these consensus standards as follows and as noted elsewhere in this document. Appendix G contains additional useful references.

1-5 GLOSSARY.

Appendix E contains acronyms, abbreviations, and terms.

1-6 BENEFITS.

For utilities, there are two choices: (1) install and maintain CP; or (2) periodically replace the utility when the leak failure rate becomes an operational (or financial) burden. Properly installed and maintained CP systems dramatically reduce life cycle costs by indefinitely extending a utility's lifetime. CP systems also reduce the government's potential liability from premature failure of utilities, such as gas line explosions and jet fuel leaks. Environmental cleanup, transportation, and disposing of contaminated soil, monitoring requirements, and other costs connected to a “reportable” leak can cost the government over $1 million. Notices of Violations (NOVs) can carry stiff fines and penalties. CP is essential to maintaining any metallic structure in a corrosive environment at the lowest life cycle cost.

1-7 CP SYSTEM MAINTENANCE.

System performance can be monitored by measuring the supplied current, by measuring the potential of the structure to the electrolyte with proper reference cell, or (preferably) by a combination of the two methods. Scheduled maintenance and preventive maintenance may include inspection and adjustment of equipment items, such as current rectifiers or anodes; unscheduled maintenance may include troubleshooting and repair of items identified as defective during scheduled inspections, such as anode beds or electrical conductors and connections.

1-8 CP PROGRAM ELEMENTS.

A CP program includes:

- Corrosion control by CP design.
- Corrosion control during in-house and contracted job orders, work orders, and projects.
- Use of CP to eliminate electrochemical reactions (corrosion).
- Use of protective coatings to reduce CP current requirements.
- Location of CP components for excavation permits.
- Scheduled inspections and preventive maintenance.
- Troubleshooting and repair.
- Failure analysis and initiation of corrective actions on corrosion failures caused by materials, design, construction, or the environment.
- Historical records and documentation required for demonstration of compliance and efficient operations and maintenance of CP systems.

Note: Guidance in this UFC applies to both galvanic anode cathodic protection (GACP) and impressed current cathodic protection (ICCP) systems.

This Page Intentionally Left Blank

CHAPTER 2 CRITERIA

2-1 POTENTIAL MEASUREMENT.

To comply with environmental regulations, public law, and industry standards, adequate CP is required to stop corrosion on all protected structures. Adequate CP is a level of CP that meets one, or all, of the criteria detailed in this chapter. This chapter includes criteria and inspection actions that, when used either separately or in combination, indicate whether adequate CP of protected structures (infrastructure) has been achieved. The effectiveness of CP or other corrosion control measures can be affirmed by visual observation, measurements of pipe wall thickness, or by use of internal inspection devices. Because such methods sometimes are not practical, meeting any criterion or combination of criteria in this chapter is evidence that adequate CP has been achieved. When access to or excavations of the structure are made for any purpose, the protected structure should be inspected for evidence of corrosion and/or coating condition. See Chapter 4, or apply sound engineering practices as defined in Appendix B, to determine the methods and frequency of testing required to satisfy these criteria.

Potential measurement, based on the theory of measuring an unknown potential by relating it to a known reference electrode, is the principal test procedure used to determine the efficiency and adequacy of CP systems. In evaluating the potential measurement results against existing criteria, sources of error and the limitations of criteria must be considered.

The most commonly protected structures are buried or submerged metallic pipeline systems. The criteria herein are taken from National Association of Corrosion Engineers (NACE®) International SP0169, with minor revisions. The current revision of this standard should be consulted. Other types of infrastructure may use other NACE International Standards. References to other standards are contained in Appendix G-2.1.

2-1.1 Sources of Potential Error.

Before taking a potential measurement of a structure to determine if adequate CP has been achieved, there are five sources of error that must be addressed to ensure accurate measurements.

2-1.1.1 Accuracy of Equipment.

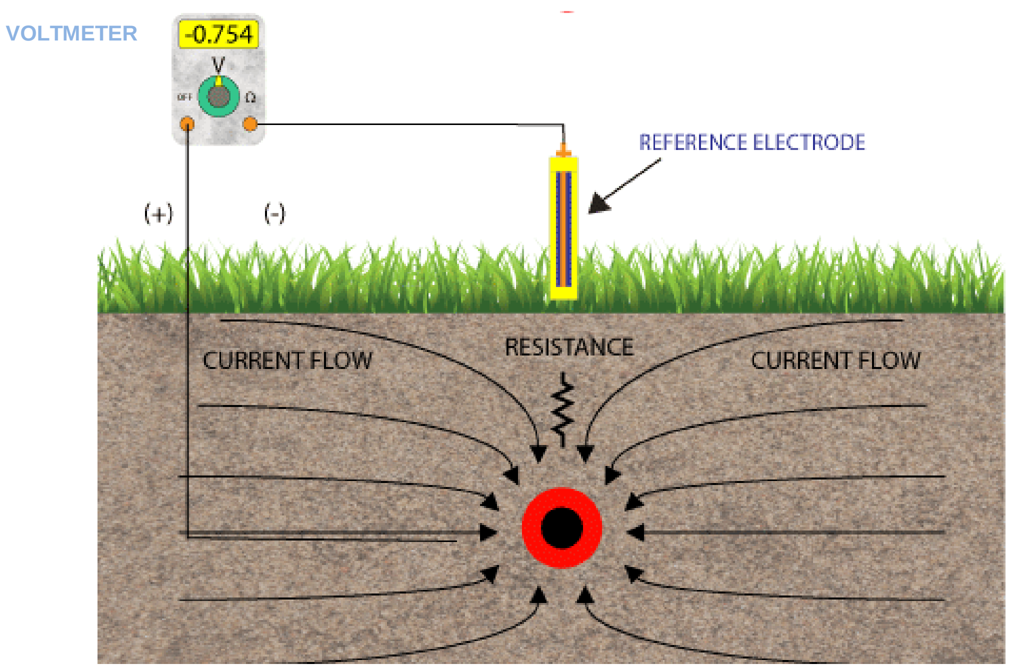
The accuracy of the reference electrode and meter being used must be verified or certified. Voltmeters must be calibrated annually. The reference electrode must be maintained according to manufacturer's specifications annually and must be verified before use.

WARNING
Metered leads should be fully insulated and undamaged to ensure electrical safety and accuracy of measurement. Employ applicable electrical safety practices to avoid damage to equipment or electrical shock to personnel.

2-1.1.2 Voltage Drop.

A voltage drop is caused by current flowing through resistance. See Figure 2-1. When CP is enabled, the current flowing through the electrolyte causes a voltage drop between the reference electrode and the protected structure, adding a more negative component to the displayed voltage on the meter (i.e., −0.85 volts DC versus −0.75 volts DC). This error increases with higher currents or resistivities and with greater distances from the reference electrode to the structure or nearest holiday.

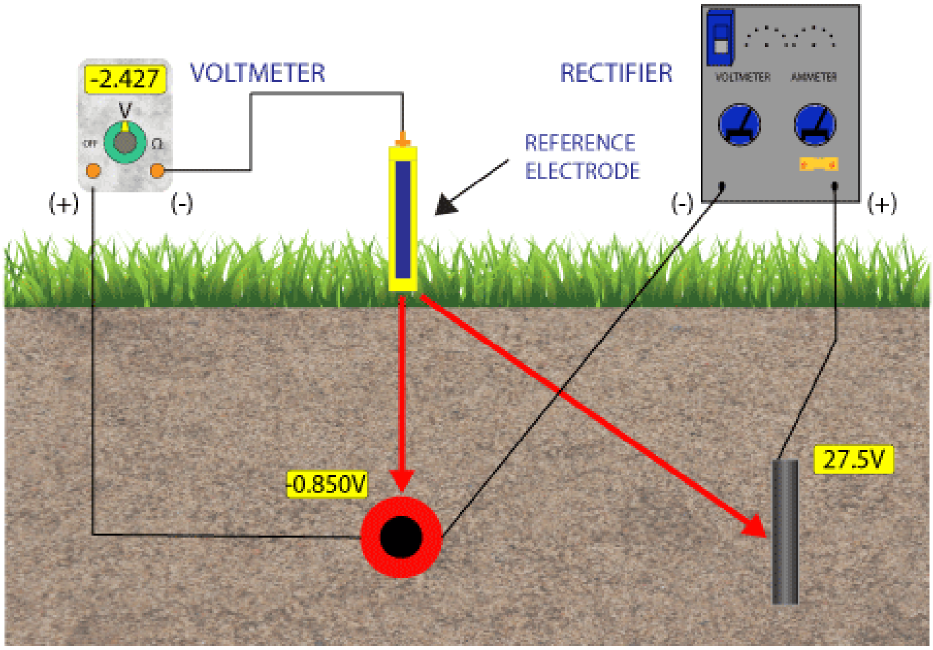
Figure 2-1 Voltage Drop



2-1.1.3 Anode Gradient Field.

The voltage gradient of the anode causes an error when the anode is connected in the circuit during testing (current is on). See Figure 2-2. For galvanic anodes, the potential must be taken as remote as possible from the anodes and as close as possible and directly over the structure being tested. For ICCP systems, when current is applied, the rectifier voltage at the anode is a component of the potential measurement throughout the system. All rectifiers must be synchronized and interrupted to remove this error. Well coated structures and CP systems with high rectifier voltages or distributed anode systems must be interrupted to provide accurate potential measurements.

Figure 2-2 Anode Gradient Field



2-1.1.4 Contact Resistance.

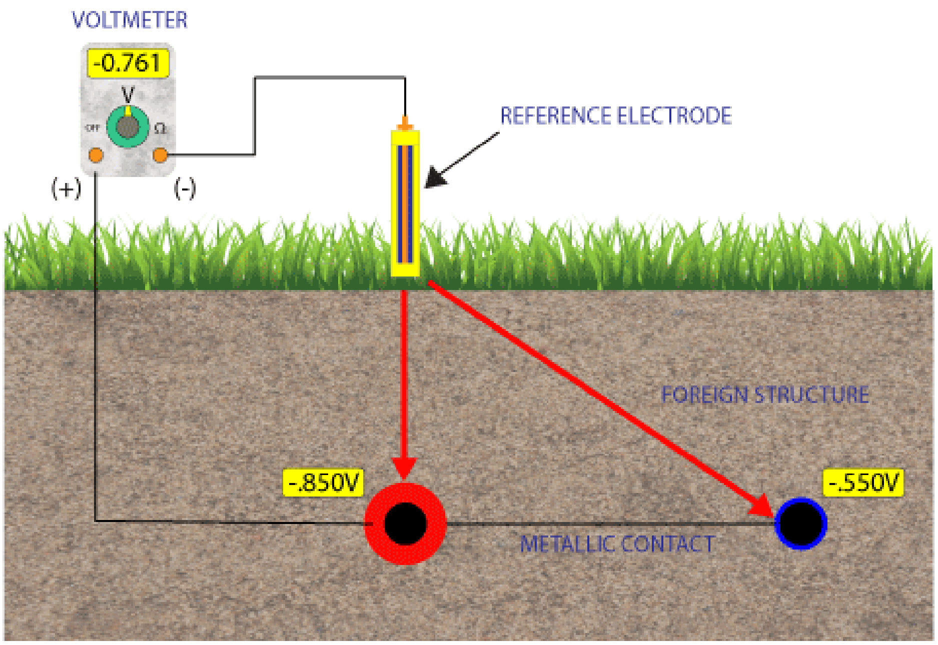
Contact resistance error is present when the reference electrode is not in good contact with the electrolyte. This resistance provides a positive error in the measurement. A high input impedance voltmeter also reduces this error. A selectable input resistance voltmeter can be used to determine if this error is present. By increasing the input resistance, the measurement becomes more negative when this error is present.

The application of water to the electrolyte at the reference electrode contact point reduces this error. In dry or high resistivity areas, water or an extremely high input impedance meter or both must be used to obtain accurate measurements.

2-1.1.5 Mixed Metal Potential.

This error results when a potential measurement being taken on the structure is mixed with the potential of other structures also connected to the circuit being tested. See Figure 2-3. If the structure being tested is not isolated from other structures or has bimetallic components (composed of different metals), the potential measurement is a weighted average of the different metals and must be considered to determine adequate protection. For all bimetallic or non-isolated structures, the 100 mV drop criteria must meet the criteria for the most negative metal and, in the case of steel, must meet the 850 instant off criteria as described in 2-1.2. In the case of connection to a more active metal, such as zinc ribbon or magnesium anodes in ICCP systems, there are negative errors that must be considered.

Figure 2-3 Mixed Metal Potential



2-1.2 Criteria for CP.

The criteria in this section have been developed through laboratory experiments and/or have been verified by evaluating data obtained from successfully operated CP systems. Situations may exist where a single criterion for evaluating the effectiveness of CP may not be satisfactory for all conditions. Often, a combination of criteria is needed for a single structure.

2-1.2.1 Corrosion Leak History.

Corrosion leak history is valuable in assessing the effectiveness of CP. However, corrosion leak history by itself must not be used to determine whether adequate levels of CP have been achieved unless it is impractical to make electrical surveys.

2-1.2.2 Applicability.

Special conditions in which CP is ineffective or only partially effective sometimes exist. Such conditions may include elevated temperatures, disbonded coatings, thermal insulating coatings, shielding, bacterial attack, and unusual contaminants in the electrolyte. Deviation from the recommended practice may be warranted in specific situations, provided corrosion control personnel in responsible charge are able to demonstrate that the objectives expressed in the recommended practice have been achieved.

Criteria are intended to serve as a guide for establishing minimum requirements for control of corrosion on the following systems.

2-1.2.2.1 New Piping Systems.

Corrosion control by coating supplemented with CP, or by some other proven method, should be provided in the initial design and maintained during the service life of the piping system, unless investigations indicate that corrosion control is not required. Consideration should be given to the construction of pipelines in a manner that facilitates the use of in-line inspection tools.

2-1.2.2.2 Existing Coated Piping Systems.

CP should be provided and maintained unless investigations indicate that CP is not required.

2-1.2.2.3 Existing Uncoated Piping Systems.

Studies should be conducted to determine the extent and rate of corrosion on existing uncoated piping systems. When these studies indicate that corrosion will affect the safe or economic operation of the system, adequate corrosion control measures should be taken.

2-1.2.3 References.

Personnel responsible for corrosion control are not limited to criteria in this chapter. Criteria that have been successfully applied on existing piping systems can continue to be used on those piping systems. Any other criteria used must achieve corrosion control comparable to that attained with the criteria within this chapter.

All criteria described in this chapter are in accordance with NACE standards. See Appendix A.

2-1.2.4 Steel and Cast Iron Piping.

Corrosion control can be achieved at various levels of cathodic polarization depending on the environmental conditions. However, in the absence of specific data that demonstrate that adequate CP has been achieved, one or more of the following conditions shall apply:

2-1.2.4.1 Cathodic Potential of at Least −850 mV.

A cathodic potential of at least −850 mV with the CP applied must exist. This potential is measured with respect to a saturated copper/copper sulfate reference electrode contacting the electrolyte. Voltage drops other than those across the structure-to-electrolyte (S/E) boundary must be considered for valid interpretation of this voltage measurement.

Note: Consideration is understood to mean the application of sound engineering practices in determining the significance of voltage drops by methods such as:

- Measuring or calculating the voltage drop(s).
- Reviewing the historical performance of the CP system.
- Evaluating the physical and electrical characteristics of the pipe and its environment.
- Determining whether or not there is physical evidence of corrosion.

2-1.2.4.2 Polarized Potential of at Least −850 mV.

A polarized potential (the potential across the structure/electrolyte interface that is the sum of the corrosion potential and the cathodic polarization) of at least −850 mV relative to a saturated copper/copper sulfate reference electrode must exist.

2-1.2.4.3 Minimum of 100 mV of Cathodic Polarization.

A minimum of 100 mV of cathodic polarization must exist between the structure surface and a stable reference electrode contacting the electrolyte. The formation or decay of polarization can be measured to satisfy this criterion. This criterion may not be valid when bimetallic corrosion; such as when connected to copper grounding, is present.

2-1.2.4.4 Special Conditions.

- On bare or ineffectively coated pipelines where long line corrosion activity is a primary concern, the measurement of a net protective current at predetermined current discharge points from the electrolyte to the pipe surface, as measured by an earth current technique, may be sufficient.
- In some situations, such as the presence of sulfides, bacteria, elevated temperatures, acid environments, and dissimilar metals, the criteria in paragraph 2-1.2.4 may not be sufficient.
- When a pipeline is encased in concrete or buried in dry or aerated high resistivity soil, values less negative than the criteria listed in paragraph 2-1.2.4 may be sufficient.

Note: Using polarized potentials less negative than −850 mV is not recommended for CP of pipelines when operating pressures and conditions are conducive to stress corrosion cracking.

Note: Use of excessive polarized potentials (greater than −1200 V) on coated pipelines should be avoided to minimize cathodic disbondment of the coating. Further investigation is required to determine if other current sources, such as interference pickup or previously installed galvanic anodes, are affecting the structure.

Note: Polarized potentials that result in excessive generation of hydrogen should be avoided on all metals, particularly higher strength steel, certain grades of stainless steel, titanium, aluminum alloys, and pre-stressed concrete pipe.

Note: The earth current technique is often meaningless in multiple pipe rights-of-way, in high resistivity surface soil, for deeply buried pipe, in stray current areas, or where local corrosion cell action predominates.

2-1.2.5 Aluminum Piping.

A minimum of 100 mV of cathodic polarization between the structure surface and a stable reference electrode contacting the electrolyte must exist. The formation or decay of this polarization can be used in this criterion.

2-1.2.5.1 Excessive Voltages

If aluminum is cathodically protected at voltages more negative than −1200 mV (measured between the pipe surface and a saturated copper/copper sulfate reference electrode contacting the electrolyte) and compensation is made for the voltage drops other than those across the pipe–electrolyte boundary, it may suffer corrosion as the result of the buildup of alkali on the metal surface. A polarized potential more negative than −1200 mV must not be used unless previous test results indicate that no appreciable corrosion will occur in the particular environment.

Note: Aluminum may suffer from corrosion under high pH conditions, and application of CP tends to increase the pH at the metal surface. Therefore, careful investigation or testing must be conducted before applying CP to stop pitting attack on aluminum in environments with a natural pH in excess of 8.0.

2-1.2.6 Copper Piping.

A minimum of 100 mV of cathodic polarization between the structure surface and a stable reference electrode contacting the electrolyte must exist. The formation or decay of this polarization can be used in this criterion.

2-1.2.7 Dissimilar Metal Piping.

A negative voltage between all pipe surfaces and a stable reference electrode contacting the electrolyte equal to that required for the protection of the most anodic metal should be maintained.

Note: Amphoteric materials that could be damaged by high alkalinity created by CP should be electrically isolated and separately protected.

2-1.2.8 Other Considerations.

2-1.2.8.1 Determining Voltage Drops.

Methods for determining voltage drop(s) must be selected and applied using sound engineering practices. Once determined, the voltage drop(s) may be used for correcting future measurements at the same location, provided that conditions (such as pipe and CP system operating conditions, soil characteristics, and coating quality) remain similar.

Note: Placing the reference electrode next to the pipe surface may not be at the pipe–electrolyte interface. A reference electrode placed at a coated pipe surface may not significantly reduce soil voltage drop in the measurement if the nearest coating holiday is remote from the reference electrode location.

2-1.2.8.2 Sound Engineering Practices.

When it is impractical or considered unnecessary to disconnect all current sources to correct for voltage drop(s) in the pipe–electrolyte potential measurements, sound engineering practices should be used to ensure that adequate CP has been achieved.

2-1.2.8.3 In-Line Inspection of Pipes.

In-line inspection of pipelines may be helpful to determine the presence or absence of pitting corrosion damage. Absence of corrosion damage or the halting of its growth may indicate adequate corrosion control. The in-line inspection technique, however, may not be capable of detecting all types of corrosion damage. The technique also has limitations in its accuracy and may report items that are not corrosion as anomalies. For example, longitudinal seam corrosion and general corrosion may not be readily detected by in-line inspection. Also, possible thickness variations, dents, gouges, and external ferrous objects may be detected as corrosion. The appropriate use of in-line inspection must be carefully considered.

2-1.2.8.4 Stray Currents and Stray Electrical Gradients.

Situations involving stray currents and stray electrical gradients that require special analysis may exist. If needed, interference testing may need to be performed (see Appendix B for more information).

2-1.2.9 Alternative Reference Electrodes.

2-1.2.9.1 Alternative to Saturated Copper/Copper Sulfate.

Other standard reference electrodes may be substituted for the saturated copper/copper sulfate reference electrode. Table 2-1 lists commonly used reference electrodes as listed in SP0169, *Control of External Corrosion on Underground or Submerged Metallic Piping Systems*.

Table 2-1 Common Reference Electrodes

Reference Electrodes	Electrolyte Solution	Potential at 25ºC (V/SHE)*	Potential at 25ºC (V/CSE)**	Temperature Coefficient (mV/ºC)	Typical Usage
$Cu/CuSO_4$	Sat. $Cu/CuSO_4$	+0.316	0	0.9 (0.5)	Soils, fresh water
Ag/AgCl	0.6 M NaCl (3.5%)	+0.256	−0.06	−0.33 (0.18)	Seawater, brackish
Ag/AgCl	Sat KCl	+0.222	−0.094	−0.70 (0.39)	
Ag/AgCl	0.1 N KCl	+0.288	−0.028	−0.43	
Zn	Saline solution	−0.79 ± 0.1	−1.1 ± 0.1		Seawater
Zn	Soil	−0.80 ± 0.1	−1.1 ± 0.1		Underground

**SHE – standard hydrogen electrode, **CSE – copper sulfate electrode*

2-1.2.9.2 Alternative Metallic Material or Structure.

An alternative metallic material or structure may be used in place of the saturated copper/copper sulfate reference electrode if the stability of its electrode potential is ensured and if its voltage equivalent referred to a saturated copper/copper sulfate reference electrode is established.

2-1.3 Criteria Limitations.

2-1.3.1 Mixed Metal Potentials.

The 100 mV criteria should not be used on bimetallic systems due to errors from mixed potentials. Adequate CP must be 100 mV from instant off to the most active potential of the most active metal. In the case of steel, instant off must be −850 mV.

2-1.3.2 Structure-to-Earth Resistance.

For small, well coated structures in high resistivity electrolytes and using galvanic anodes, it may be physically impossible to meet either −850 mV instant off or 100 mV shift. The structure may have a resistance to earth of over 200 ohms, and one galvanic anode may have a resistance to earth of over 50 ohms. After two anodes, additional anodes do not noticeably lower the resistance or provide additional current. It is generally accepted that if the on potential (mixed potential) is over 850 mV, what little corrosion exists is occurring at the anode. This is common in nonmetallic water systems with metallic elbows, tees, risers, or valves.

This Page Intentionally Left Blank

CHAPTER 3 SCHEDULED INSPECTIONS AND SURVEYS

3-1 GALVANIC.

To comply with environmental regulations, public law, and industry standards, preventive maintenance is required for all installed CP systems. Minimum maintenance actions for both GACP and ICCP systems are detailed in this chapter to ensure all protected structures comply with the criteria outlined in Chapter 2.

3-1.1 Galvanic Corrosion Survey.

The galvanic corrosion survey is conducted to determine if adequate CP exists on the protected structure. A close-interval potential survey (CIS) should be conducted after installation and polarization using the procedures in paragraph 3-2.5 for impressed current systems.

3-1.1.1 Survey Interval.

Conduct a galvanic corrosion survey at the following intervals:

- Within 30 days after major modification to the CP system or the protected structure.
- After any corrosion failure or leak of the protected structure.
- After any inspection or survey that indicates potential measurements are out of compliance.
- 1 year from last corrosion survey.

3-1.1.2 Minimum Requirements.

- Using data from the most recent CIS, or using sound engineering practices, choose a sufficient number of locations for potential testing to ensure the entire structure has adequate CP.
- Test CP system components in accordance with Table 3-1. Table 3-2 presents requirements for potential testing of the protected structure.

Table 3-1 Corrosion Survey Component Testing

CP System	Test Measurement(s)
GACP (at each test station)	• One S/E potential measurement with the reference electrode placed directly over/adjacent to the protected structure at the location(s) nearest the anode(s) • One S/E potential measurement with the reference electrode placed directly over/adjacent to the protected structure midway between anode(s) • One anode-to-electrolyte potential measurement with the reference electrode placed directly over/adjacent to the anode with the anode lead disconnected • Anode-to-structure current using (in order of preference): 1) a clamp-on milliammeter, 2) a multimeter measuring millivolts across a calibrated shunt, or 3) a multimeter connected in series measuring milliamperes
ICCP	Rectifier operational inspection (paragraph 3-2.1)

Table 3-2 Corrosion Survey Potential Measurements

Structure Type	Potential Measurement Locations
Pipelines	Locate the reference electrode: • Over the pipeline at all test stations and at all points where the structure can be contacted (where it enters/exits the ground, passes through a pit, or is exposed). • Over the pipeline at least every 1,000 feet (305 meters) for pipelines off the installation. • Over the pipeline at least every 500 feet (152 meters) for pipelines on the installation.
On grade storage tanks	Locate the reference electrode: • Next to the tank at four equally spaced locations around the tank circumference at compass points or as specified on a drawing. • At a distance one tank radius away from the tank at eight equally spaced locations around the tank circumference.
Underground storage tanks	Locate the reference electrode: • Over the center and over each end of the tank. • Over each end of the feed/return piping. • Over the manhole, fill pipe, and vent pipe. • Over all metallic structures in the area if readings indicate an isolated system is shorted to a foreign structure.

Structure Type	Potential Measurement Locations
Isolated structures	Take one S/E potential measurement on each side of all dielectric fittings/couplings without moving the reference electrode. **Note:** If the potential difference between measurements on each side of a dielectric coupling is less than 10 mV, verify its integrity using an isolation flange tester.
All structures with foreign line crossings	Locate the reference electrode: • Over the foreign line at all points where it crosses the protected structure. • Over the foreign line where it passes nearby the anode bed.
All structures with cased crossings	Locate the reference electrode: • Over the protected structure on each side of all casings. • Over each end of the casing on all casings. **Note:** If the casing is shorted or partially shorted to the pipeline and the potentials over the pipeline are depressed below the criteria described in Chapter 2, take immediate action to clear the short.
Waterfront structures	Take measurements at all permanent reference electrodes. Locate portable reference electrodes: • Adjacent to the structure at all test stations. • Every 150 feet (46 meters) along a continuous length of sheet pile wall at both the surface and at the bottom. • At other test points identified in maintenance manuals or past surveys.
Other structures	Locate the reference electrode at test points identified in the maintenance manual or other past surveys.
All structures	Annotate the soil condition (or tide level for waterfront structures) for comparison to past and future measurements.

3-1.2 Galvanic Anode System Check.

Conduct the galvanic anode system check to monitor the system between corrosion surveys.

3-1.2.1 Inspection Interval.

The check must include 10 percent of the test stations, including the three lowest and the three highest potential measurements from previous surveys. Conduct a galvanic corrosion survey as defined in the NACE standards and Department of Transportation (DOT) regulations.

3-1.2.2 Minimum Requirements.

a. Review all potential readings.

b. For all structures, compare the potential measurements to those previously taken at the same locations to identify changes. Low potentials can indicate a short or other problem. High potentials can indicate interference.

c. If the potential measurements reveal current output that does not satisfy criteria in Chapter 2, adjust or supplement the system as necessary. After 30 days, perform the survey again.

3-1.3 Galvanic Anode Check.

Conduct the galvanic anode system check to determine its operational condition.

3-1.3.1 Maintenance Interval.

Perform the galvanic anode system check as required to locate problems indicated by other surveys.

3-1.3.2 Minimum Requirements.

a. Measure the potential of the structure with the reference electrode located directly over the structure, adjacent to an anode (structure-to-earth, volts DC).

b. Measure the potential of the structure with the reference electrode located directly over the structure, midway between anodes (remote structure-to-earth, volts DC). In this case, remote is as far as possible from the anodes, directly over the protected structure.

c. Disconnect the anode lead from the structure and measure potential of the anode with the reference electrode located directly over the anode (anode-to-earth, volts DC).

d. Measure structure-to-anode current (anode output current, mA) using (in order of preference): 1) a clamp-on milliammeter, 2) a multimeter measuring millivolts across a calibrated shunt, or 3) a multimeter connected in series measuring milliamperes.

e. Compare measurements to those previously taken at the same location.

f. Inspect junction and test boxes, tighten any loose wire connections, and test insulating joints.

Note: Loss of anode-to-earth potential indicates a failed (consumed) anode or failed anode lead.

Note: Loss of anode output current with stable anode-to-earth potential indicates consumption of the anode and pending failure.

Note: Loss of structure-to-earth potential with stable anode-to-earth potential and anode output current indicates loss of isolation or other problems that require further troubleshooting.

3-2 IMPRESSED CURRENT.

3-2.1 Rectifier Operational Inspection.

The purpose of the rectifier operational inspection is to determine the serviceability of all components required to apply current to the anodes of the impressed current system. A thorough inspection ensures dependable current until the next inspection.

3-2.1.1 Inspection Interval.

Perform this inspection together with the CIS, the corrosion survey, and the water tank calibration, or when any inspection or survey indicates that problems with the rectifier may exist.

3-2.1.2 Minimum Requirements.

a. Visually check all rectifier components, shunt box components, safety switches, circuit breakers, and other system power components.

b. Tighten all accessible connections and check temperature of all components and connections.

c. Use vacuum or blower to clean inside of rectifier cabinet or more detailed cleaning as required.

d. Using a calibrated meter, measure the output voltage and current, and calibrate the rectifier meters, if present.

e. For rectifiers with more than one circuit, measure the output voltage and current for each circuit using a calibrated meter, and calibrate the rectifier meters, if present.

f. For rectifiers with potential voltmeters, using a calibrated meter, measure the potentials for each voltmeter, and calibrate that rectifier meter.

g. Using a maintained reference electrode, measure the potential difference to the installed permanent reference electrode by placing both electrodes together in the electrolyte with CP current off. If the difference is more than 10 mV, replace the permanent reference electrode.

h. Calculate the CP system circuit resistance of each circuit by dividing the rectifier DC voltage output of each circuit by the rectifier DC ampere output for that circuit.

i. Calculate the rectifier efficiency by dividing the calculated output DC power by the factored input alternating current (AC) power. (This also includes timing the revolutions of the kilowatt hours (kWh) meter and annotating the meter factor from the face of the kWh meter.)

3-2.2 ICCP System Check.

The ICCP system check ensures that the system is operating at the same level as the last CIS or corrosion survey. This is a non-interrupted check, and the potential measurements must be compared to previous ON cycle potential measurements.

The locations for the potential measurements must be taken from the last CIS or corrosion survey, whichever is most recent, to reasonably ensure that the current output of the system is still being applied and is still adequate.

3-2.2.1 Maintenance Interval.

Conduct the ICCP system check within 60 days of the last CIS, corrosion survey, or ICCP system check. More frequent checks may be required by public law or local regulations.

Note: Underground storage tank CP rectifiers must be inspected at a frequency not exceeding 60 days to ensure compliance with regulations. Check with state Environmental Protection Agency (EPA) authorities, as state regulations may be more stringent or may impose additional requirements.

3-2.2.2 Minimum Requirements.

a. Measure rectifier DC voltage and DC ampere outputs.

b. Verify the DC ampere output of the rectifier meets the current (ampere) requirement found on the last CIS or corrosion survey. If necessary, adjust the rectifier output, and measure outputs again. Repeat procedure as necessary.

c. Calculate the rectifier system circuit resistance by dividing the rectifier DC output voltage by the rectifier DC output current. If the rectifier has more than one circuit, calculate the resistance of each circuit.

d. Take S/E potential measurements at the locations of the three lowest and three highest potential measurements identified in the most recent CIS or corrosion survey.

e. Compare the potential measurements to previous measurements at the same locations and determine if changes have occurred. If potential measurements do not satisfy criteria in Chapter 2 and the rectifier current output meets the current requirement from the last survey, adjust or supplement the CP system as necessary. See Appendix B.

f. Conduct a corrosion survey 30 days after adjustment or modification to the CP system.

3-2.3 Corrosion Survey.

The corrosion survey is conducted to ensure adequate CP still exists as proven on the last CIS. The procedures are the same as the CIS, with different minimum requirements for the potential measurements. The CIS data should be used to determine where potential measurements must be taken to reasonably ensure that the criteria of CP are being met for the entire structure being protected and no interference problems exist on any foreign structures.

3-2.3.1 Survey Interval.

Conduct a corrosion survey at the following intervals:

- 30 days after major modification to the CP system or the protected structure.
- After any corrosion leak on the protected structure.
- After any inspection or survey that indicates that the current requirement of the last corrosion survey is not valid (low or high potential measurements at the proper current output level).
- 1 year from last CIS or corrosion survey.

3-2.3.2 Minimum Requirements.

a. Perform the rectifier operational inspection (paragraph 3-2.1).

b. Using data from the most recent CIS, or using sound engineering practices, choose a sufficient number of locations for potential testing to ensure the entire structure has adequate CP.

c. Test CP system components in accordance with Table 3-1. Table 3-2 presents requirements for potential testing of the protected structure.

3-2.4 Anode Bed Survey.

The impressed current anode bed survey is a non-interrupted survey of the anode bed to determine the condition of the anodes. It identifies any possible problem with the impressed current anodes. It may also be used to predict failure and to program replacement.

3-2.4.1 Survey Interval.

This survey would normally be done together with the CIS. It can also be done during troubleshooting.

3-2.4.2 Minimum Requirements.

At a minimum, an impressed current anode bed survey should include ON potential over the anodes at intervals described in Table 3-3, unless the system has incorporated other means for monitoring the anodes (e.g., individual anode leads in an anode junction box).

Table 3-3 Recommended Over-the-Anode Intervals for the Impressed Current Anode Bed Survey

CP System Type	Test Measurement
All ICCP	Perform rectifier operational inspection.
Remote shallow anode beds	• Measure anode-to-soil potentials at 2-foot (0.6-meter) intervals along the length of the anode bed, beginning 10 feet (3 meters) before the first anode and ending 10 feet (3 meters) past the last anode in the anode bed. • Plot test results on graph paper to give a visual indication of the anode bed condition.
Distributed shallow anode beds	Measure one anode-to-soil potential with the reference electrode located directly over each anode.
Deep anode beds	• In lieu of anode potential measurements, measure anode circuit current using (in order of preference): 1) a clamp-on milliammeter, 2) a multimeter measuring millivolts across a calibrated shunt, or 3) a multimeter connected in series measuring milliamperes. • Measure the anode current for each anode if separate leads are available.

3-2.5 Close-Interval Potential Survey.

The CIS is an interrupted potential survey on impressed current systems and a non-interrupted potential survey on GACP systems; it can be labor intensive. The purpose of this survey is to ensure that adequate CP is maintained over the entire protected structure. It identifies problems within the protected structure or any interference problem on all foreign structures.

The interruption cycle must have an ON cycle of minimum duration four times longer than the OFF cycle, and the OFF cycle should not exceed 1 second. For surveys on GACP systems, measurement errors must be considered, typically through application of sound engineering practices that address the location of the reference electrode, the protected structure, the anodes, the condition of the coating, the soil resistivity, and the depth of the protected structure (refer to Chapter 2). If test stations are installed at each anode, this also can be an interrupted potential survey.

3-2.5.1 Survey Interval.

Conduct CIS at the following intervals:

- 30 days after CP system is installed, energized, and properly adjusted.
- 5 years from the last CIS.

Note: Typically, DoD fuel pipelines are maintained by the Defense Logistics Agency (DLA)-Energy command via two Centrally Managed Programs (CMPs): Integrity Management Program (IMP) and CP. An IMP survey is typically executed every 5 years on a rotating schedule and is normally inclusive of a coating assessment, a CIS, a direct current voltage gradient (DCVG) or alternating current voltage gradient (ACVG) study, and an internal pipe/smart pig survey. Therefore, CP surveys typically do not include a CIS of fuel pipelines.

3-2.5.2 Minimum Requirements.

a. Test CP system components in accordance with Table 3-4 and perform potential measurements of the protected structure in accordance with Table 3-5.

b. Review all potential readings.

c. Annotate the low potential measurements, the high potential measurements, and other significant potential measurements to re-evaluate those locations when performing the corrosion survey.

d. If the data taken show that the current output is not sufficient to satisfy the criteria in Chapter 2, adjust or supplement the system as necessary. See Appendix B.

e. After 30 days, perform a corrosion survey for those locations identified in the paragraph above.

Table 3-4 Test Measurements for Close-Interval Potential Survey

CP System Type	Test Measurement
GACP (at each test station)	• One anode-to-soil potential measurement with the reference electrode placed over the anode and the anode lead disconnected. • Anode-to-structure current using (in order of preference): 1) a clamp-on milliammeter, 2) a multimeter measuring millivolts across a calibrated shunt, or 3) a multimeter connected in series measuring milliamperes. • S/E potential measurement with the reference electrode placed over the structure adjacent to the anode. • S/E potential measurement with the reference electrode placed over the structure remote from the anode.
ICCP	• Rectifier operational inspection (paragraph 3-2.1). • Impressed current anode bed survey (paragraph 3-2.4).

Table 3-5 Close-Interval Potential Survey Potential Measurement Locations

Structure Type	Potential Measurement Locations
Pipelines	Locate the reference electrode over the pipeline at intervals not to exceed the depth of the pipeline, normally every 3 to 5 feet (1 to 1.5 meters).
On grade storage tanks	Measure at permanent reference electrodes, if installed. Locate the reference electrode: • Next to the tank every 6 feet (1.8 meters) around the tank circumference. • At a distance one tank radius away from the tank at eight equally spaced locations around the tank circumference. • In pull tubes at intervals of 3 to 5 feet (1 to 1.5 meters), if installed.
Underground storage tanks	Locate the reference electrode: • Every 3 feet (1 meter) over the tank. • At least every 3 feet (1 meter) over feed and return piping. • Over the manhole, fill pipe, and vent pipe. • Over all metallic structures in the area if readings indicate that an isolated system is shorted to a foreign structure.

Structure Type	Potential Measurement Locations
Isolated structures	Take one S/E potential measurement on each side of all dielectric fittings/couplings without moving the reference electrode. **Note:** If the potential difference between measurements on each side of a dielectric fitting/coupling is <10 mV, verify its integrity using an isolation flange tester.
All structures with foreign line crossings	Locate the reference electrode: • Over the foreign line at all points where it crosses the protected structure. • Over the foreign line where it passes near the anode bed.
All structures with cased crossings	Locate the reference electrode: • Over each end of the casing on all casings. **Note:** If the casing is shorted or partially shorted to the pipeline and the potentials over the pipeline are depressed below criteria described in Chapter 2, high priority must be given to clear the short.
All structures in soil	Record the soil condition for comparison of past/future potential and current measurements.

3-2.6 Water Tank Calibration.

The water tank calibration is to ensure that CP is maintained over the entire surface of the tank interior, as well as to ensure there are no excessive voltages on any part of the tank interior that could damage the coating.

Water tank calibration comprises an interrupted potential survey on ICCP systems or a non-interrupted potential survey on GACP systems. The interruption cycle must have an ON cycle that is a minimum of four times longer than the OFF cycle where the OFF cycle is normally 1 second.

On a GACP system, measurement errors must be accounted for using sound engineering practices, including reference electrode placement, anode positions, and coating condition. If the system design permits, this may also include an interrupted potential survey.

3-2.6.1 Survey Interval.

Conduct water tank calibrations according to the following intervals:

- 30 days after the CP system is installed, modified, or adjusted.
- 1 year from the last water tank calibration.

3-2.6.2 Minimum Requirements.

Inspect water tanks in accordance with Tables 3-6 and 3-7. For all tanks, compare potential measurements to measurements previously taken at the same locations to determine if changes have occurred.

If potential measurements do not satisfy Chapter 2 criteria and the current output meets the current requirement from the last survey, adjust or supplement the system as necessary. See Appendix B. After 30 days, perform a water tank calibration.

WARNING
AC voltage (over 100 V) is still present inside the rectifier with the rectifier panel circuit breaker or power switch OFF. Employ applicable electrical safety practices to avoid damage to equipment or electrical shock to personnel.

Table 3-6 Water Tank Calibration CP System Component Test

CP System Type	Test Measurement
GACP	Measure anode-to-structure current using (in order of preference): 1) a clamp-on milliammeter, 2) a multimeter measuring millivolts across a calibrated shunt, or 3) a multimeter connected in series measuring milliamperes.
ICCP	• Perform the rectifier operational inspection (paragraph 3-2.5). • Calculate the rectifier efficiency by dividing the calculated output DC power by the factored input AC power.

Table 3-7 Water Tank Calibration Potential Measurements

Structure Type	Potential Measurement Locations
Tank walls	Position the reference electrode near the water surface, at mid-depth, and at the bottom in the following locations: • Next to the tank wall directly adjacent to each anode string. • Next to the tank wall midway between two adjacent anode strings.
Tank bottom	Locate the reference electrode: • 2 inches (5 centimeters) above the tank bottom directly beneath each anode string. • 2 inches (5 centimeters) above the tank bottom and as far away from the anode strings as possible.
Metallic riser (elevated water tanks)	Locate the reference electrode adjacent to the riser wall at intervals of 5 feet (1.5 meters) from the top to the bottom of the riser.

Structure Type	Potential Measurement Locations
Permanent reference electrodes	Measure and compare the potential of each permanent reference electrode to a portable reference electrode to determine its accuracy.
All tanks	Annotate the water level for comparison to past and future measurements.

3-2.7 Leak Survey.

The leak survey identifies the cause of all leaks and the action required to prevent future leaks from occurring or to reduce the leak rate.

3-2.7.1 Survey Interval.

Conduct leak surveys after excavation and before backfilling of any leak on any pipeline or tank.

3-2.7.2 Minimum Requirements.

a. Measure the pH of the soil where it contacts the pipeline or tank.

b. Measure the “as found” S/E potential of the pipe or tank where it contacts the soil. “As found” means before any adjustments of existing CP systems, addition of any form of CP, or installation of isolation or bonding components.

c. Determine the cause of the leak.

d. Evaluate the condition and determine appropriate repairs to the pipe or tank coating system.

e. Measure the “as left” S/E potential of the pipe or tank where it contacts the soil. “As left” means after all actions are taken to prevent future leaks.

Note: If these actions are taken after backfill operations, surface potentials are acceptable as described in Chapter 2.

Note: If the leak survey determines the cause to be corrosion, determine the type of corrosion. Table 3-8 lists recommended corrective actions to prevent future leaks.

Table 3-8 Recommended Corrective Actions for Preventing Leaks

CP System Type	Recommended Action
Structure not cathodically protected	Take appropriate action to reduce the possibility of future leaks according to the type of corrosion found.
Structure cathodically protected	• Determine the presence of interference, and, if found, take action to mitigate interference corrosion. • Install isolation couplings, electrical continuity bonds, or CP as appropriate.

3-2.8 Resistance Bond Check.

The resistance bond check is an operational inspection of two metallic structures connected with some type of semiconductor or resistor. This survey ensures that the structures affected by the bond are maintained at adequate levels and interference is mitigated. The bond may include reverse current switches, diodes, resistors, or other protective devices whose failures would jeopardize structure protection. These bonds may be between different sections of a protected structure or may be between a protected structure and any other metallic structure (unprotected or protected with a different CP system).

This is a non-interrupted check and the potential measurements must be compared to previous ON cycle potential measurements taken at the same locations. The locations for the potential measurements and meter connections must be the same and the operational status of any CP systems must be known.

3-2.8.1 Survey Intervals.

- Every 60 days for critical bonds. (Critical bonds are bonds that, when failed, result in loss of adequate protection to the facility.)
- After each corrosion survey and CIS for non-critical bonds.
- Immediately after CP system failure on either or both sides of the bond (unless immediate repair is possible).

More frequent checks may be required by public law or local regulations.

3-2.8.2 Minimum Requirements.

- Potential measurement of protected structure at bond location.
- Potential measurement of structure bonded to protected structure.
- Measurement of structure-to-structure current direction and current magnitude (amps or milliamps, depending on current magnitude), using (in order of preference) 1) a clamp-on milliammeter, 2) a multimeter

measuring millivolts across a calibrated shunt, or 3) a multimeter connected in series measuring milliamperes.

- Measurement of rectifier DC voltage and ampere output of the CP system on either (or both) side(s) of the resistance bond. For troubleshooting bonds with rectifiers on either (or both) structure(s), interrupting rectifier(s) may be required to troubleshoot or adjust bond.
- Evidence of proper functioning, which may include current output, normal power consumption, a signal indicating normal operation, or satisfactory CP levels on the structures, according to the function or design of the bond.
- Comparison of all measurements to previous surveys.
- If the potential measurements, current flow, current direction, or other measurement has changed from the last check, investigation to determine if bond is operating as intended or if troubleshooting or adjustments are required.
- Adjustment or repair of the component as necessary, and repeat of bond test.

3-2.9 Direct Current Voltage Gradient (DCVG) Survey.

A DCVG survey is an accurate method used to size and locate pipe coating defects (holidays). The technique is based on measuring the voltage gradients in the soil above a cathodically protected pipeline. In a DCVG, a DC signal is applied to the pipeline and the voltage (potential) gradient in the soil above the pipeline is measured. Voltage gradients, as measured between two calibrated reference electrodes spaced apart, arise as a result of the current pickup or discharge at pipeline coating holiday locations. This potential gradient can be detected between two electrodes placed on the soil surface with a sensitive analog mV meter; therefore, the location of the coating defect can be determined with precision of 4 to 8 inches (10 to 20 centimeters).

The size or severity of the coating defect is characterized by a relative number, the Indication Severity %IR calculation.

Once the survey technician has recorded the DCVG measurements and GPS locations, the %IR values are calculated. The calculations involve using the signal magnitude at a contact point and remote earth, creating a pipe-to-remote earth voltage gradient value. Over-the-line-remote earth value is then measured and the %IR value is calculated. See Equation 3-1.

Equation 3-1. %IR Calculation

$$\%\boldsymbol{IR} = \frac{\boldsymbol{Over - the - Line - Remote - Earth - Value}}{\boldsymbol{Calculated\ Pipe - to - Remote\ Earth\ Value}} \boldsymbol{X100}$$

Depending on the magnitude of the %IR, a determination can be made where physical examination of the pipe and coating repair are necessary. The DCVG survey uses the pipeline's ICCP system. If no ICCP system is installed, a temporary ICCP system can be used.

3-2.9.1 Survey Intervals.

Conduct a DCVG survey at the following intervals:

- 30 days after new pipeline installation.
- After a CIS has been performed.
- On demand when a coating evaluation is needed, such as when a pipeline excavation and recoat has been performed, when a third-party excavation has been performed and coating damage is suspected, when a new pipeline segment has been installed, when determined due to coating age and condition that a DCVG survey is required, and at the discretion of operations.
- Every 7 years when evaluating high consequence area (HCA).

3-2.9.2 Minimum Requirements.

- Perform DCVG survey at locations where potentials do not achieve criteria of CIS.
- Review all survey data.
- Annotate the locations indicating coating holidays and prioritize using the %IR.

CHAPTER 4 PRIORITIES FOR TESTING, TROUBLESHOOTING, AND REPAIR

4-1 INTRODUCTION.

To properly operate and maintain a CP system, it is essential to apply continuous protection to the protected structure. Interruptions in protection result in irreversible corrosion damage to the structure. Along with the importance or cost of the structure, the factors that affect the rate of corrosion also relate directly to priority considerations. The long-term strategy to prevent corrosion of infrastructure is outlined in USC Title 10-2228*, Office of Corrosion Policy and Oversight* and in DoD Instruction 5000.36, *Prevention and Mitigation of Corrosion on DoD Military Equipment and Infrastructure*.

While scheduled inspections and surveys are performed to ensure continued satisfactory performance of CP systems, problems that require troubleshooting and maintenance outside scheduled times can occur. These problems may require unscheduled maintenance actions. For instance, if potentials that do not meet the criteria for CP are found (see Chapter 2), troubleshooting and repair must be performed (see Appendix B). Addressing these issues ensures the consistent operation of the system and greatly reduces the life cycle cost of the infrastructure being protected. In addressing unscheduled maintenance issues, the priority of restoration of the system affected, as well as the budget and equipment available to correct the problem, must also be considered. A priority, either emergency or routine, must be assigned to restore adequate CP to affected structures. The following priority considerations are detailed to allow a knowledge-based priority determination.

4-2 EMERGENCY PRIORITY CONSIDERATIONS.

GACP systems are inherently maintenance-free. ICCP systems require a higher level of maintenance. Maintaining adequate CP on all protected, buried, or submerged metallic structures is critical to prevent or mitigate corrosion. An assignment of emergency priority means an issue needs to be addressed immediately.

Failure of CP systems that affect public safety and/or those that are federally regulated must be given emergency priority to repair or replace. This would include pipelines, underground storage tanks, aboveground storage tanks, and other structures with CP that contain hazardous chemicals, fuels, or natural gas. High-pressure transmission lines in HCAs should be given emergency priority.

Any metallic structure or utility that would adversely affect the mission capability if a failure occurs must be given high priority. This includes fire protection pipelines, sea walls, locks, flood gates, and other critical metallic structures or utilities required for mission accomplishment. Other examples include underground oxygen pipelines to hospitals and underground air, steam, or other pipelines whose failure would compromise mission requirements.

4-3 ROUTINE PRIORITY CONSIDERATIONS.

The factors affecting the scheduling of routine priority work orders for restoration of adequate CP depend on the type of utility, mission impact of failure, and seriousness of the corrosion probability. All inadequate levels of CP adversely affect the life cycle cost of the infrastructure. Corrosion problems listed below affect the rate of corrosion and should be considered for scheduling purposes to troubleshoot, repair, and restore adequate CP.

4-3.1 Interference.

The presence of interference can be extremely corrosive to structures where current picked up from a foreign source is discharging from a metallic structure or utility, especially if that utility is coated. Corrosion failures can occur in an extremely short amount of time, possibly in days if the interference is extremely serious. This usually occurs where underground pipelines cross other pipelines or electrical grounds where the interference is being applied by another CP system that is not isolated. The seriousness is determined by the potential measured and can easily be a positive potential to a saturated copper/copper sulfate reference electrode.

For every amp-year of current (1 amp for 1 year), 20.7 pounds of steel are lost. When this metal loss is discharging from coating defects, extremely short time to failure occurs. This mode of failure is usually only discovered after failure has occurred, and the highest possible priority must be given to mitigate further failures. If it is found before failure, the same applies—corrosion failure is imminent.

4-3.2 Corrosiveness of the Soil.

For underground or submerged metallic structures, the electrolyte resistivity is the basic measurement for the corrosiveness of the electrolyte—the lower the resistivity, the higher the corrosion rate. See Table 4-1.

Table 4-1 Soil Corrosiveness

Soil Corrosiveness	Soil Resistivity (Ω-cm)
Severely corrosive	0 to 500
Very corrosive	500 to 999
Corrosive	1,000 to 2,999
Moderately corrosive	3,000 to 9999
Slightly corrosive	10,000 to 25,000
Relatively less corrosive	>25,000

4-3.3 Determining Scheduling Priority.

The potential difference between the measured potential and the potential required for adequate protection should be considered and compared with the corrosiveness to determine priority. Other corrosiveness factors, such as high temperature and acidic electrolytes, increase the corrosion rate and elevate the priority.

Table 4-2 can be used as a tool to determine scheduling priority. For each factor, the appropriate measurement is taken. Based on the measurement, a factor value is assigned and a sum is then calculated.

- If sum is over 5, assign emergency priority.
- If sum is 5, schedule before any other action; expedite parts.
- If sum is 4, schedule immediately if possible; rush parts, maximum of 30 days.
- If sum is 3, schedule maximum of 60 days.
- If sum is 2 or below, schedule before next inspection cycle.

Table 4-2 Scheduling Considerations Based on Factor Value Sum

Factor	Factor Value								
	5	**4**	**3**	**2**	**1**	**0**	**-1**	**-2**	**-3**
Electrolyte resistivity (ohm-cm)	<1000	1001 to 2000	2001 to 4000	4001 to 8000	8001 to 16000	16001 to 100000	100001 to 200000	200001 to 400000	>400000
Temperature (ºF)	>210	201 to 210	191 to 200	181 to 190	170 to 180	33 to 169	0 to 32	<0	—
pH	<3.5	3.5 to 4	4.1 to 5	—	—	—	9 to 10	10.1 to 11	>11
Potential (mV)	>+200	0 to +200	0 to −200	−201 to −300	−301 to −400	−401 to −600	−601 to −700	−701 to −800	−801 to −850
Hazardous storage (Yes/No)	—	Yes	—	—	—	—	No	—	—
Mission essential (Yes/No)	—	—	Yes	—	—	—	No	—	—
HCA* (Yes/No)	—	—	—	—	Yes	—	No	—	—
High value or leak repair cost (Yes/No)	—	—	—	Yes	—	—	No	—	—

*For hazardous storage tanks and pipelines only.

4-3.3.1 Scheduling Examples.

4-3.3.1.1 Example 1.

Example 1 concerns an underground water distribution pipeline in 2,500 ohm-cm soil at ambient temperature with pH 9.5. Instant off potential is –710 mV. It is not hazardous, mission essential, or of high value. See Table 4-3.

Table 4-3 Example 1 Values

Factor	Measurement	Factor Value Based on Table 4-2
Electrolyte resistivity (ohm-cm)	2,500	3
Temperature (ºF)	60	0
pH	9.5	–1
Potential (mV)	−710	–2
Hazardous storage (Yes/No)	No	–1
Mission essential (Yes/No)	No	–1
HCA* (Yes/No)	N/A	0
High value or leak repair cost (Yes/No)	No	–1
Sum	—	–3

The factor value sum is −3, so work should be scheduled before the next inspection cycle.

4-3.3.1.2 Example 2.

Example 2 concerns an underground fuel pipeline in 15,000 ohm/cm soil at ambient temperature with pH 7.5. Instant off potential is −612 mV. It is hazardous, not in an HCA, and not mission essential, and it is a high value for leak repair cost. See Table 4-4.

Table 4-4 Example 2 Values

Factor	Measurement	Factor Value Based on Table 4-2
Electrolyte resistivity (ohm-cm)	15,000	1
Temperature (ºF)	60	0
pH	7.5	0
Potential (mV)	–612	–1
Hazardous storage (Yes/No)	Yes	4
Mission essential (Yes/No)	No	–1
HCA* (Yes/No)	No	–1
High value or leak repair cost (Yes/No)	Yes	2
Sum	—	4

The sum of all factor values is 4, so work should be scheduled immediately if possible; rush parts, maximum of 30 days.

4-3.3.1.3 Example 3.

Example 3 concerns an underground fuel pipeline in 1500 ohm-cm soil at ambient temperature with pH 4.5 and instant off potential of –615 mV. It is hazardous, is not in an HCA and is not mission essential, and it is a high value for a leak repair cost. See Table 4-5.

Table 4-5 Example 3 Values

Factor	Measurement	Factor Value Based on Table 4-2
Electrolyte resistivity (ohm-cm)	1500	4
Temperature (ºF)	60	0
pH	4.5	3
Potential (mV)	–615	–1
Hazardous storage (Yes/No)	Yes	4
Mission essential (Yes/No)	No	–1
HCA* (Yes/No)	No	–1
High value or leak repair cost (Yes/No)	Yes	2
Sum		10

The factor value sum is 10, so work should be assigned emergency priority.

4-3.4 Estimated Time to Failure.

For any infrastructure not categorized above, the priority is dependent on the estimated time to failure compared to the resulting loss in life cycle costs or costs of the release, cleanup, and repair of the failure.

4-3.5 Past Leak History.

Past leak history can show a trend and should also elevate the priority to troubleshoot the cause of the previous leaks and apply a mitigation plan to prevent further failures. The leaks may not be caused by corrosion, and other steps may be necessary. If the leaks are caused by corrosion and have had adequate CP, additional actions may still be required. Increasing current density or additional actions, such as locating and repairing damaged or unbonded coatings, may be required.

4-4 INFRASTRUCTURE WITHOUT CATHODIC PROTECTION.

There may be metallic infrastructure without CP. A plan to evaluate all other metallic infrastructure should be in place. Periodic review of buried metallic or submerged metallic structures should be conducted to determine if CP would be economically feasible to lower the life cycle cost of these infrastructure investments.

4-5 CORROSION ISSUES BEYOND CAPABILITY OF EXISTING RESOURCES.

If problems cannot be completed due to economic, personnel, or other limitations, identify the requirement and submit a budgetary plan for required upgrades. Identify additional requirements that add reliability to existing systems. Identify and submit cost-effective initiatives to increase the CP to protected or unprotected structures. If the capability to maintain, troubleshoot, or repair CP systems is not available by government employees, submit requirements for contracted assistance to accomplish all of the goals of the Corrosion Control Program to mitigate corrosion and lower the life cycle cost of the infrastructure.

4-6 UPGRADE EQUIPMENT.

Consider cost-effective measures to make data collection more timely or effective or to make recordkeeping easier or more complete, or consider upgrading equipment to minimize time required for surveys, troubleshooting, or data collection.

4-6.1 Remote Monitoring.

Remote monitoring can be installed to instantly identify readings that are below or above set points. These remote monitoring systems can monitor rectifier AC input voltage, DC output voltage and current, structure potentials, and many other things such as structure bonds, resistance bonds, test station potentials, and galvanic anode currents. Immediate notification of these problems can greatly accelerate the time required to repair the cause of the alarm. These systems can accelerate the data collection and recordkeeping functions, as well as provide much needed data for effective troubleshooting.

4-6.2 Equipment.

New and upgraded equipment that greatly reduces survey time, troubleshooting time, and personnel is available. See TSEWG TP-24, *Cathodic Protection Test Procedures* for available equipment and capabilities.

4-7 COMMON PROBLEMS.

Common problems that can occur in GACP or ICCP systems outside of scheduled maintenance times can be found in Appendix B-1.1 and B-2.1, respectively. Specific references for Army, Air Force, and Navy can be found in Appendix G-3.

APPENDIX B BEST PRACTICES

B-1 TROUBLESHOOTING GALVANIC SYSTEMS.

Galvanic CP is inherently maintenance free. The current is a result of the potential difference of the two metals. Recurring maintenance checks are performed to ensure continued satisfactory performance. Galvanic anodes sacrifice themselves to protect the structure. They normally consume themselves at a constant rate, and failure can be predicted by current measurement versus time. The starting point for all troubleshooting for galvanic systems is at the anode (or anode connection). For galvanic systems, there must be an anode test lead for conclusive testing of the anodes.

B-1.1 Common Problems.

The most common problems in sacrificial anode systems are shorts or failure of dielectrics on isolated protected structures. Due to the very limited voltage, sacrificial anodes usually cannot supply sufficient current to protect the structures if isolation is lost. On well-coated structures, the contact resistance to earth is high. Other metals in the earth that are not coated have a very low contact resistance, providing a low-resistance path for anode current. Maintaining the dielectrics in an isolated system is essential to continued satisfactory performance of sacrificial anode systems. One failed dielectric can result in loss of protection for the entire system. See paragraph B-1.5 for detailed procedures to locate failed dielectrics.

B-1.2 Lead Wires.

Failure of the anode lead wires is uncommon, since copper exposed by nicks or insulation defects are cathodically protected by the anodes. However, these wires can be cut by extraneous excavations. Exercising control over digging permits in the areas of the anode ground beds may ensure that if the wires are cut, they can be repaired on site, before backfilling occurs. Troubleshooting to locate the break at a later date is usually not successful, and replacement of a prematurely failed anode is more economical in almost all cases. A sudden zero anode current output reading may indicate failed lead wires.

B-1.3 Anode Consumption.

When sacrificial anode systems reach the end of their useful life, potential, current, and voltage measurements begin to change. When performing recurring maintenance, a significant drop in anode current indicates imminent failure of the anode. Potential measurements over the protected structure begin to show dips or drops in the areas of failed anodes. A significant drop in anode potential indicates a failed anode. Anode current may actually reverse after failure, due to the copper center tap of the anode being cathodic to the protected structure. When drops in the potential of the protected structure begin to occur, a closer inspection should be made to determine the extent of the damage to the anodes.

B-1.4 Improper Use.

Except on small or extremely well coated structures, such as underground storage tanks or short pipelines with butyl rubber/extruded polyethylene coatings, it is normally not economical to replace a distributed galvanic anode system. When galvanic anodes begin to fail on a distributed system, ICCP should be considered.

B-1.5 Dielectric Testing Procedures.

B-1.5.1 Background.

If a CP system is designed to protect an isolated structure, shorted dielectrics normally result in loss of adequate protection to that structure. Shorts may also result in poor current distribution or shielding, resulting in the loss of adequate protection to areas of the structure. Testing an installed dielectric presents several problems. Since typical installations normally include many dielectrics, all of which are in a parallel circuit, failure of one dielectric can effectively short the entire system. There are indications of the shorted condition of one dielectric at many, or all, other dielectrics installed. Usually, the farther the distance between the dielectric being tested and the dielectric that is shorted, the easier it is to test that dielectric.

Most methods of testing a dielectric give a reliable indication of only one condition of the dielectric (either shorted or not shorted condition) and further testing may be required for the other condition. The radio frequency tester (insulated flange tester), because of its wavelength and the strength of the signal, is the only method that gives a totally reliable indication of the condition of that specific dielectric. This method does not read through other parallel paths, even when these paths are in the immediate vicinity. In fact, this method can pinpoint the fault to a particular flange bolt or the flange gasket. Therefore, this method should be used for testing when any other method is not conclusive.

B-1.5.2 Testing Methods.

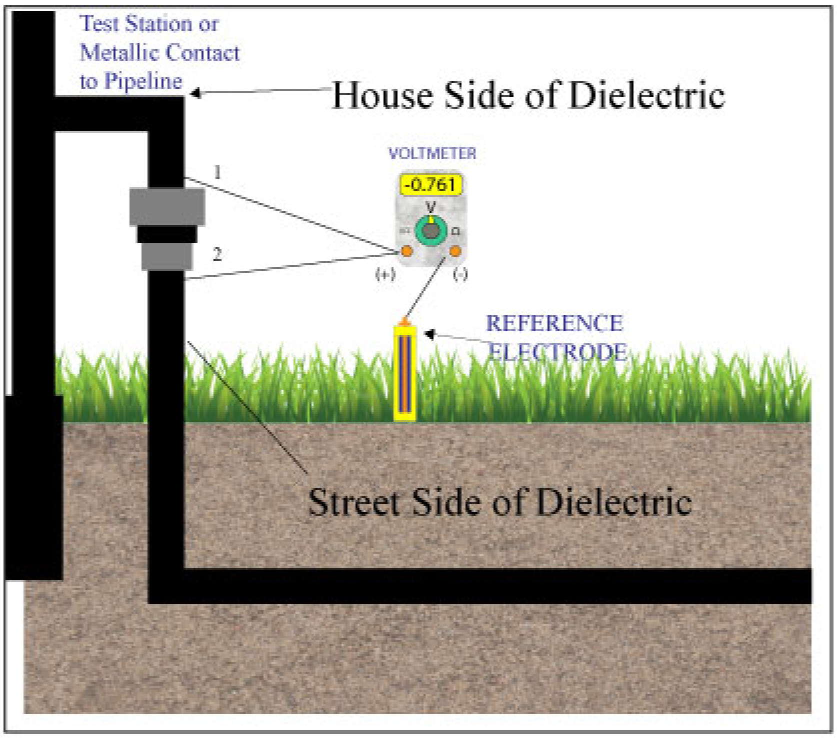
The preferred method to determine if a dielectric may be shorted is by potential testing. This method provides an immediate indication if the dielectric is not shorted and, at the same time, provides valuable potential data. If this method indicates that the dielectric may be shorted, other methods of verification are required. The radio frequency tester (insulated flange tester) should be used when a shorted condition is indicated by potential measurements. The pipe locator and the power supply methods of verification may be used to test installed dielectrics. The pipe locator method (paragraph B-1.5.3) can determine that an installed dielectric is bad but does not give conclusive evidence if the test indicates that the dielectric is good. The power supply method, which can determine that an installed dielectric is good, does not give conclusive evidence if the test indicates that an installed dielectric is bad.

CAUTION
Do not use an ohmmeter to measure resistance of an installed dielectric. If the dielectric is good, current flows through the meter and damage could result. If the current damages the meter, the measurement does not give a valid resistance value.

B-1.5.3 Testing for a Shorted Dielectric.

Take a potential measurement of both sides of the installed dielectric by changing only the structure connection, without moving the saturated copper/copper sulfate reference electrode. See Figure B-1.

Figure B-1 Testing for a Shorted Dielectric



B-1.5.3.1 Significantly Different Potential Measurements.

If the two potential measurements are significantly different (over 10 mV), the dielectric is good. The street side of the dielectric, under normal conditions (with CP), should be at a potential more negative than –0.85 volts DC, and the house side of the dielectric should be between approximately –0.15 and –0.45 volts DC (a difference of between 400 and 700 mV). If the dielectric is good and the house side of the dielectric has a potential more negative than expected, another shorted dielectric in the area should be suspected, and further investigation is required (for example, if the house side potential reading is over –0.65 volts DC, with a street side potential the same or more negative).

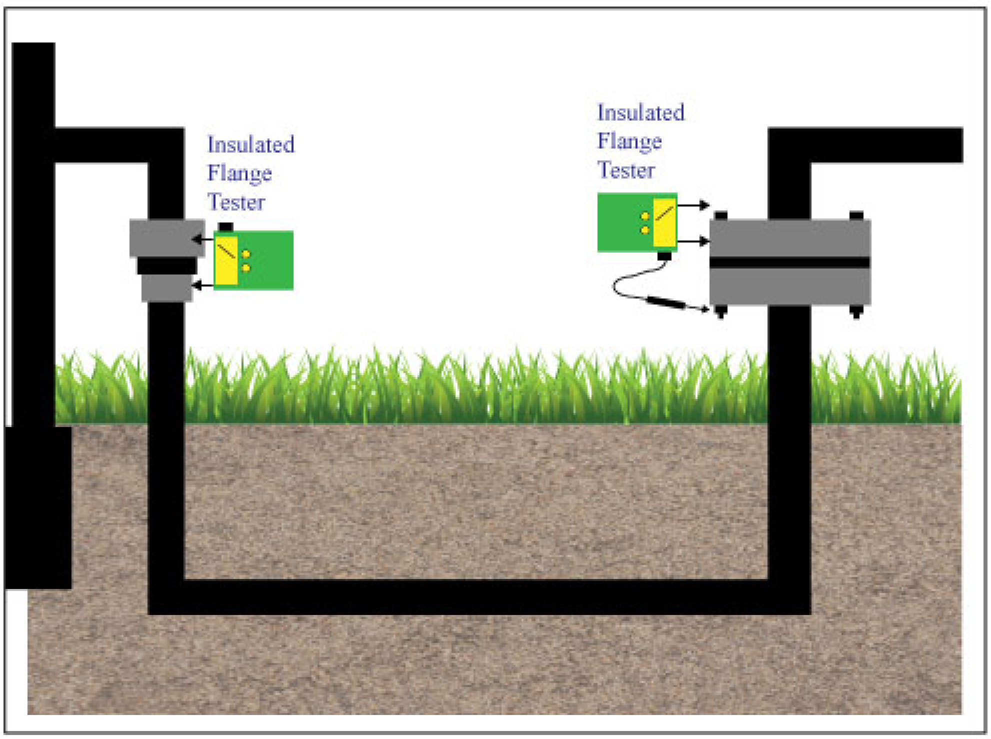
B-1.5.3.2 Not Significantly Different Potential Measurements.

The dielectric may be shorted and additional testing is required if the two potential measurements are not significantly different (under 10 mV). The preferred method is to use a radio frequency tester (insulated flange tester) to test that specific dielectric (paragraph B-1.5.2). Other possible methods that may or may not be conclusive include using the pipe locator method (paragraph B-1.5.3) or the impressed test current method (paragraph B-1.5.4).

B-1.5.4 Using a Radio Frequency Tester.

This method is the most accurate and conclusive method of testing a dielectric. Turn the insulated flange tester test switch to “zero,” turn the control knob on, and zero the needle indicator. Turn the test switch to “test” and, without turning the control knob, test the dielectric. See Figure B-2.

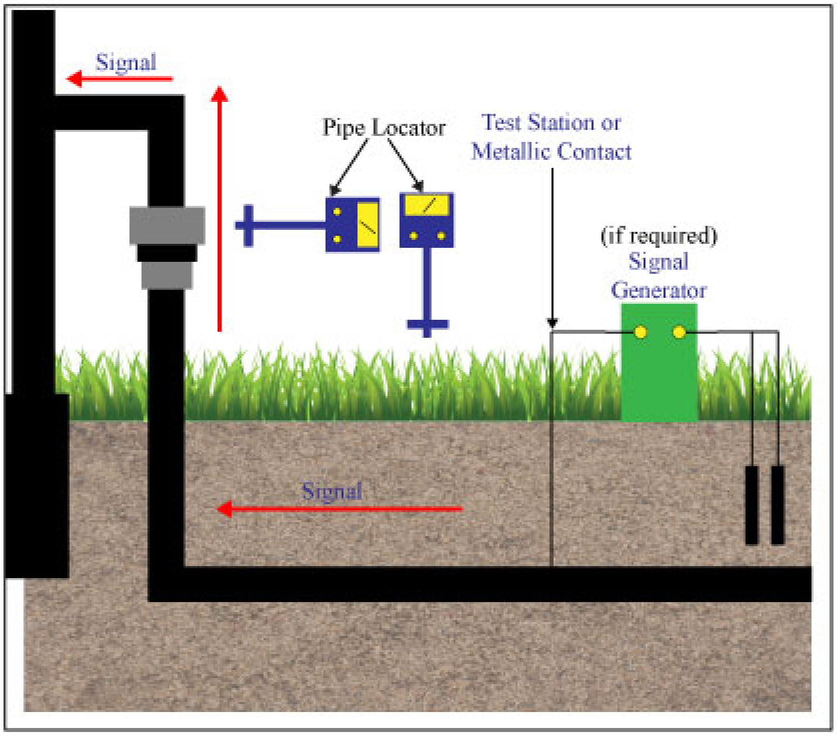
Figure B-2 Testing an Installed Dielectric with Insulated Flange Tester



B-1.5.5 Using a Pipe Locator.

Using two different types of pipe locators may indicate that a dielectric is bad. One uses a short wavelength signal (paragraph B-1.5.3.2), and one uses the signal from an impressed current system (60-cycle “noise”—this method can only be used on impressed current systems with a single-phase rectifier) (paragraph B-1.5.3.1). These methods give a rapid indication if the dielectric is shorted but may not be conclusive. See Figure B-3.

Figure B-3 Testing for Shorted Dielectric with Impressed Test Current



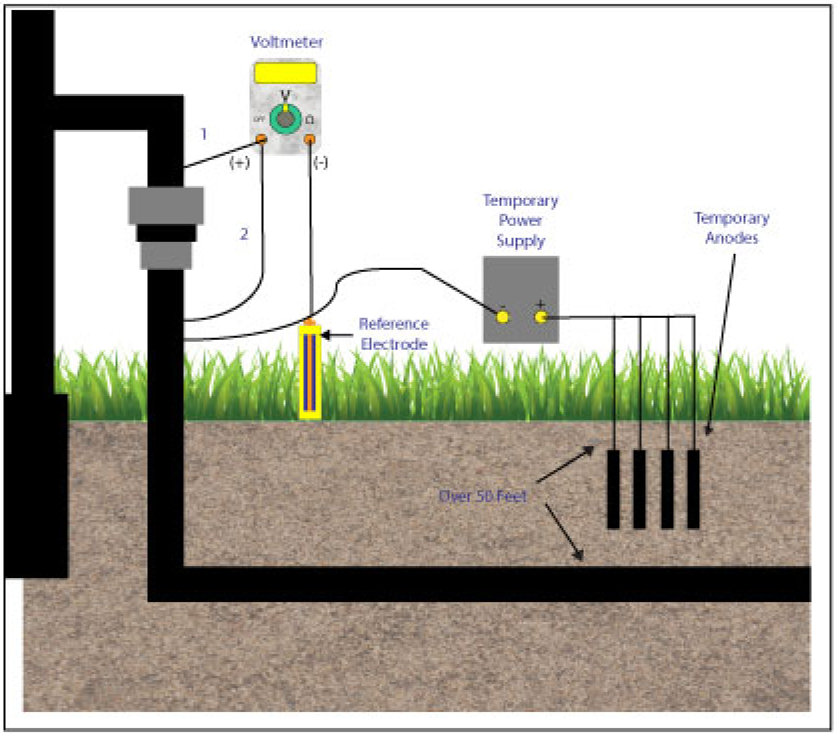
B-1.5.5.1 Pipe Horn, Model FDAC200.

The Pipe Horn, Model FDAC200, detects the signal from a single-phase rectifier. With the impressed current system on, this locator can be used to follow the underground pipeline. If a dielectric is shorted and the current is sufficient, the locator follows the signal across the dielectric. Consequently, if the signal is followed through the dielectric, that dielectric is bad. If no signal can be followed, verify with the insulated flange tester (paragraph B-1.5.2).

B-1.5.5.2 Short Wavelength Pipe Locator.

A short wavelength pipe locator, using a direct connection, detects the signal from a signal generator. To obtain a strong signal, ensure that a good metallic connection is made, a good battery is installed in the signal generator, and, most importantly, that the signal generator has a good, low-resistant ground. This locator can then be used to follow the underground pipeline. If a dielectric is shorted, and the signal is sufficient, the locator follows the signal across the dielectric. Consequently, if the signal is followed through the dielectric, that dielectric is bad. If no signal can be followed, verify with the insulated flange tester (paragraph B-1.5.2). See Figure B-4.

Figure B-4 Testing for Shorted Dielectric with Power Supply



B-1.5.6 Using a Temporary Ground to Impress Test Current.

Use a temporary ground to impress test current to the street side of the dielectric, or, if possible, merely increase the current level of the existing system. Note that the temporary ground should be installed where the current distributes to the location being tested. Repeat the potential measurement of both structures. If the potential of the house side of the dielectric remains approximately the same or changes in a positive direction (less negative) when the potential of the street side of the dielectric changes in a negative direction, they are not shorted. If both potential measurements change in a more negative direction as current is increased, the two structures are shorted together.

B-2 TROUBLESHOOTING IMPRESSED CURRENT SYSTEMS.

B-2.1 Common Problems.

The following section lists how to troubleshoot common problems associated with ICCP systems.

B-2.2 Zero Output Current.

The following lists the possible causes and troubleshooting steps for the condition when there is zero output current and slight increase in output voltage. Historical data indicate that output has remained relatively constant for a long period of time.

B-2.2.1 Troubleshooting Broken Anode Lead (Header Cable).

- With power OFF, disconnect anode lead(s) at P4.
- Connect P4 (positive terminal) to an alternative isolated metallic structure (isolated from structure being tested; if doubt exists, measure continuity to structure lead), such as a metal culvert or fence, or install temporary ground rods.
- For a short period of time, turn power ON and note AC (paragraph B-2.7). One of two conditions exists: either current is now present (changed) or it is not present (not changed).

Note: If the structure being tested is the inside of a water tank or tower, and the lack of water does not allow current flow (no electrolyte), fill the tank and then retest.

- If current exists, the anode lead is broken or the anodes have failed (proceed to paragraph B-2.13).
- If no current exists, the structure lead may be broken (see next section).

B-2.2.2 Troubleshooting Broken Structure Lead.

- The temporary or alternative anode should be connected to terminal P4 as described in previous section.
- With power OFF, disconnect structure lead at N4.
- Connect N4 (negative terminal) to alternative isolated metallic structure (isolated from structure being tested; if doubt exists, measure continuity to structure lead), such as a metal culvert or fence, or install temporary ground rods.
- For a short period of time, turn power ON and note AC. One of two conditions exists: either current is now present (changed) or it is not present (not changed).
- If current still does not exist (not changed), the temporary anode bed is not sufficient. Supplement the temporary anode bed, and then perform steps in paragraph B-2.8.
- If current is present (changed), the structure connection is broken. Use the fault detector and cable locator connected directly to the structure lead at N4 to trace the structure lead from the rectifier toward the structure. This can be extremely difficult in some cases.

- An alternative method is to locate the first structure connection (from drawings, markers, or induction methods). Excavate to the structure and measure continuity back to the rectifier using a CP multi-combination meter continuity check circuit.
- Use the fault detector and cable locator connected directly to the structure lead to trace the lead from the structure toward the rectifier. If this is still unsuccessful, replace the structure lead from the rectifier to the structure.

Note: When using the direct connection method, it is essential to have a low-resistance, isolated ground for the fault detector or cable locator to put strong locator signals on the cable under test.

B-2.3 Zero Output Current and Maximum Output Voltage.

The following lists the possible causes and troubleshooting steps for the condition when there is zero output current and maximum output voltage. Historical data show that system voltage increased several times and output current decreased slowly at first, then faster as time progressed.

B-2.3.1 Troubleshooting Failed Anode Bed.

- Determine from records if there is sufficient anode material to attempt locating and repairing the fault.
- Calculate current and time to amp-years.
- Compare that calculation to the weight of the installed anodes and the weight loss of the anode material. This indicates if the anodes are expended or have significant life remaining. Another indicator is that if there is a gradual failure over a period of time, the anodes have failed. See paragraph B-2.13 for further direction.

B-2.4 Zero Output Current and/or Zero or Minimal Output Voltage.

The following lists the possible causes and troubleshooting steps for the condition when there is zero output current and/or zero or minimal output voltage. No historical data are immediately available.

B-2.4.1 Troubleshooting Loss of AC Power.

- Check all fuses and measure AC voltage input to the rectifier.
- With power OFF, remove all fuses at the rectifier and any fusible disconnect.
- Measure the continuity of fuses with a handheld multimeter. Set scale to ohms; measure resistance of each fuse. Corrosion on fuse end caps or fuse holders also causes loss of voltage.
- Replace any fuse with measurable resistance, or clean and reinstall fuses if corrosion is found.

- If a disconnect exists, measure the AC voltage with a handheld multimeter on the AC volts scale.
- Measure the voltage on the rectifier side of the disconnect. If a disconnect does not exist, measure the AC voltage from the circuit breaker of the rectifier with a handheld multimeter on AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A3 (output of circuit breaker) and ground (cabinet). Turn power to the rectifier ON and the rectifier circuit breaker ON; measure voltage from the rectifier circuit breaker.
- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and (instead of cabinet ground) the output side of the circuit breaker on the second power lead.
- If voltage is present, either the transformer or the connections inside the rectifier are faulty (proceed to paragraph B-2.14).
- If voltage is not present, there is a loss of AC power to the rectifier.
- Measure the AC voltage to the circuit breaker of the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A1 and A4. Turn power to the rectifier ON; measure voltage to rectifier.
- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and input side of the circuit breaker (A1) on the second power lead.
- If voltage is not present, proceed to paragraph B-2.15.
- If voltage is present, replace circuit breaker or fuse.
- Verify the circuit breaker has not tripped or fuse has not blown.
- If properly operating, measure the AC voltage from the circuit breaker or fuse where power is supplied to the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase systems, open the circuit breaker panel or fuse panel and connect meter to the output of circuit breaker or the output side of the fuse and ground or neutral bar.
- For 220/240 V, single-phase systems, use the same procedures, but connect the meter to the output lugs of the circuit breakers or the output side of the fuses.
- If voltage is present, locate the break in the power feed from that point to the rectifier circuit breaker (or rectifier fusible disconnect, whichever was last tested).

- If voltage is not present, measure the AC voltage to the circuit breaker or fuse supplying power to the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase systems, open the circuit breaker panel or fuse panel and connect the meter to the main lugs of the circuit breaker panel or the input side of the fuses and ground.
- For 220/240 V, single-phase systems, use the same procedures, but check individual lugs separately.
- If voltage is not present, locate the circuit breaker panel or transformer supplying power to the panel and apply the applicable procedures in paragraph B-2.15.
- If voltage is present, replace the circuit breaker or fuses.

B-2.4.2 Troubleshoot Defective Meters.

- This symptom indicates defective diodes/selenium plates or improper AC input.
- To troubleshoot AC input to the stacks, measure the AC voltage input to the stacks of the rectifier with a handheld multimeter on the AC volts scale.
- Measure voltage from F6 to C6 (tap bars). One of two conditions may exist: voltage may be near zero or near normal.
- If voltage is near zero, there is a loss of AC power to the rectifier, bad fuses or circuit breakers, or a bad transformer (or connections) in the rectifier.
- Check all fuses and measure AC voltage input to the rectifier. With power OFF, remove all fuses at the rectifier and any fusible disconnect.
- Measure the continuity of fuses with a handheld multimeter. Set scale to ohms; measure resistance of each fuse.
- Corrosion on fuse end caps or fuse holders also causes loss of voltage.
- Replace any fuse with measurable resistance, or clean and reinstall fuses if corrosion is found.
- If disconnect exists, measure the AC voltage with a handheld multimeter on the AC volts scale.
- Measure the voltage on the rectifier side of the disconnect.
- If disconnect does not exist, measure the AC voltage from the circuit breaker of the rectifier with a handheld multimeter on AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A3 (output of circuit breaker) and

ground (cabinet). Turn power to the rectifier ON and the rectifier circuit breaker ON; measure voltage from the rectifier circuit breaker.

- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and (instead of cabinet ground) the output side of the circuit breaker on the second power lead.
- If voltage is present, either the transformer or the connections inside the rectifier are faulty (proceed to paragraph B-2.14).
- If voltage is not present, there is a loss of AC power to the rectifier. Measure the AC voltage to the circuit breaker of the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A1 and A4. Turn power to the rectifier ON; measure voltage to rectifier.
- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and input side of the circuit breaker (A1) on the second power lead.
- If voltage is not present, proceed to paragraph B-2.15; if voltage is present, replace circuit breaker or fuse.
- If voltage is near normal, there are faulty diodes/selenium plates or bad connections inside the rectifier. Check the diodes/selenium plates of the rectifier with a handheld multimeter on the diode check scale.
- With power OFF, remove the tap bars or shorting wires and the anode lead (P4) and/or the structure lead (N4).
- Check the diode/selenium plate sets by connecting one test lead to N4 and the other to F6 (diode 3), then to C6 (diode 4). Both should beep or not beep.
- Reverse test leads and repeat connections. The beep should be opposite (both should not beep or beep). Repeat the test using P4 instead of N4 to test diodes/selenium plate sets (diodes 1 and 2).

Note: An ohms scale may be used. A good diode has very high resistance in one direction and low resistance in the other direction.

- With power OFF, check for loose connections from F6 to F7, C6 to C7, P1 to P2, P2 to P4, and N1 through N4, and continuity of all wires between those points.
- Repair or replace loose connections and replace damaged or broken wires, if possible. If no problems are found, replace the stacks.
- If the rectifier does not have taps, proceed to paragraph B-2.6; if that test is normal, the rectifier must be removed from the cabinet for checkout.

- Refer to specific rectifier manual to troubleshoot the diodes/selenium plates and the transformer.
- For general reference, see paragraph B-2.12 for the stacks and paragraph B-2.14 for the transformer.
- If the current is normal and a rectifier ammeter reading is significantly different, either the shunt, the connections, or the ammeter is/are faulty. Measure DC with a handheld multimeter connected in series and with the meter on the DC amps scale.
- Disconnect anode header cable at P4 and measure current from P4 to anode lead.
- Compare the measured current value to the current value taken in paragraph B-2.7. If values are significantly different, replace the shunt. If values are the same, the current is normal, the rectifier ammeter reads normal, and structure potentials are still significantly changed from normal, there may be a change in the protected structure.
- If the protected structure is isolated, check all dielectrics and repair or replace faulty ones.
- If the protected structure is not isolated, check for additions to the protected structure or new structures in the area that are continuous with the protected structure, increase current to protect larger structure(s), isolate other structure(s), or install additional impressed current system(s) as required.

WARNING

AC voltage is still present inside the rectifier with the rectifier circuit breaker or power switch OFF. To prevent possible injury or death, employ electrical safety practices for working with live circuits when needlepoint leads are used with power ON.

- With power OFF, check for loose connections from N2 through N9, including any press-to-test switches or buttons, and continuity of all wires between those points. This requires disconnection of AC power from the rectifier cabinet and possibly removal of the rectifier from the cabinet. Note that loose connections are characterized by heat, discoloration of the connection, and melted insulation.
- Repair or replace loose connections and replace damaged or broken wires or proceed to the next step.
- With power OFF, remove ammeter from rectifier. This requires disconnection of AC power from the rectifier cabinet and possibly removal of the rectifier from the cabinet.
- Disconnect one end of the resistors on reverse side of meter.

- Measure the resistance of the resistors with a handheld multimeter on the ohms scale and compare to the value of the resistor (if no resistors are present, replace meter).
- Replace resistor or meter as required.

B-2.4.3 Troubleshoot Broken Anode or Structure Leads.

- With power OFF, disconnect anode lead(s) at P4.
- Connect P4 (positive terminal) to an alternative isolated metallic structure (isolated from structure being tested; if doubt exists, measure continuity to structure lead), such as a metal culvert or fence, or install temporary ground rods.
- For a short period of time, turn power ON and note AC (paragraph B-2.7). One of two conditions exists: either current is now present (changed) or it is not present (not changed).

Note: If the structure being tested is the inside of a water tank or tower and the lack of water does not allow current flow (no electrolyte), fill the tank and then retest.

- If current is present, the anode lead is broken or the anodes have failed. Before a great deal of time is expended troubleshooting an anode bed, it should be determined from records if there is sufficient anode material to attempt locating and repairing the fault. Generally, if the current and time is calculated to amp-years, comparing that number to the weight of the installed anodes and the weight loss of the anode material indicates if the anodes are expended or have significant life remaining.
- Another indicator is that if a gradual failure occurred over a period of time, the anodes have failed. If the failure was sudden, a cable break can be expected. If failed anodes are found, replace the anode bed.
- If a broken anode lead is found, repair the cable. The first step to locating the break is to find the location of any excavations that have occurred in the area of the anode cable. There are two methods of troubleshooting anode beds, depending upon whether all anodes have failed (no current) or some (or most) of the anodes have failed.
- If one or more anodes are functioning, the best method is first to locate the functioning anodes, then an anode bed gradient graph to isolate and locate the problem.

Note: If separate anode lead wires in a junction box were installed, use these to measure the anode current and determine the functioning anodes.

- Perform a CIS over the anode bed. For the purpose of troubleshooting, you may adjust the rectifier to the highest voltage setting that would not result in coating damage to the structure to allow easier location of the anodes.

- Measure the potentials over the anodes with a handheld multimeter on the volts DC scale. With power ON, connect the positive lead of the multimeter to the structure lead (N4) of the rectifier.
- Using a saturated copper/copper sulfate reference cell connected to the negative lead of the multimeter, locate the point of highest voltage on the surface of the ground (directly over an anode).
- Repeat by locating all operational anodes.
- Mark each anode found and compare to system drawings.
- Starting in a straight line 10 feet (3 meters) from the first anode, perform a potential test every 2 feet (0.6 meters) over the entire length of the anode bed to a point 10 feet (3 meters) past where the last anode is (or is supposed to be) located.
- Using graph paper and using vertical lines to represent the measured potentials and horizontal lines to represent the 2-foot (0.6-meter) intervals, graph all readings. This shows the condition of all anodes and indicates if a broken header cable (anode lead) or failed anodes exist. It shows a broken cable between functional and non-functional anodes. If anodes are failing, the gradients peak differently or the gradients fall, then rise intermittently.
- If no anodes are operational, use the fault detector and cable locator connected directly to the anode cable P4 to trace the anode lead from the rectifier toward the anode bed. This can be extremely difficult in some cases.
- An alternative method is to locate the first anode (from drawings, markers, or induction methods).
- Excavate to the first anode and measure continuity back to the rectifier using a CP multi-combination meter continuity check circuit.
- Use the fault detector and cable locator connected directly to the anode to trace the anode lead from the anode toward the rectifier.
- If this is still unsuccessful, replace the anode lead from the rectifier to the anode.

Note: When using the direct connection method, it is essential to have a low-resistance, isolated ground for the fault detector or cable locator to allow a strong locator signal on the cable under test.

- If no current exists, the structure lead may be broken.
- The temporary or alternative anode should remain connected to terminal P4 as described in paragraph B-2.8.
- With power OFF, disconnect structure lead at N4.

- Connect N4 (negative terminal) to an alternative isolated metallic structure (isolated from structure being tested; if doubt exists, measure continuity to structure lead), such as a metal culvert or fence, or install temporary ground rods.
- For a short period of time, turn power ON and note AC. One of two conditions exists: either current is now present (changed) or it is not present (not changed).
- If current still does not exist (not changed), the temporary anode bed is not sufficient. Supplement the temporary anode bed, then perform the steps in paragraph B-2.8.
- If current is present, the structure connection is broken. Use the fault detector and cable locator connected directly to the structure lead at N4 to trace the structure lead from the rectifier toward the structure. This can be extremely difficult in some cases.
- An alternative method is to locate the first structure connection (from drawings, markers, or induction methods).
- Excavate to the structure and measure continuity back to the rectifier using a CP multi-combination meter continuity check circuit.
- Use the fault detector and cable locator connected directly to the structure lead to trace the lead from the structure toward the rectifier.
- If this is still unsuccessful, replace the structure lead from the rectifier to the structure.

Note: When using the direct connection method, it is essential to have a low-resistance, isolated ground for the fault detector or cable locator to put strong locator signals on the cable under test.

- The temporary or alternative anode should remain connected to terminal P4 as described in paragraph B-2.8.
- With power OFF, disconnect structure lead at N4.
- Connect N4 (negative terminal) to an alternative isolated metallic structure (isolated from structure being tested; if doubt exists, measure continuity to structure lead), such as a metal culvert or fence, or install temporary ground rods.
- For a short period of time, turn power ON and note AC. One of two conditions exists: either current is now present (changed) or it is not present (not changed).
- If the current is present, the structure connection is broken. Use the fault detector and cable locator connected directly to the structure lead at N4 to trace the structure lead from the rectifier toward the structure. This can be extremely difficult in some cases.

- An alternative method is to locate the first structure connection (from drawings, markers, or induction methods).
- Excavate to the structure and measure continuity back to the rectifier using a CP multi-combination meter continuity check circuit.
- Use the fault detector and cable locator connected directly to the structure lead to trace the lead from the structure toward the rectifier.
- If this is still unsuccessful, replace the structure lead from the rectifier to the structure.

Note: When using the direct connection method, it is essential to have a low-resistance, isolated ground for the fault detector or cable locator to put strong locator signals on the cable under test.

- If current still does not exist (not changed), the temporary anode bed is not sufficient. Supplement the temporary anode bed, then repeat paragraph B-2.8.

B-2.4.4 Troubleshoot Blown Fuses or Tripped Circuit Breakers.

- Check all fuses and measure AC voltage input to the rectifier.
- With power OFF, remove all fuses at the rectifier and any fusible disconnect.
- Measure the continuity of fuses with a handheld multimeter. Set scale to ohms; measure resistance of each fuse.
- Corrosion on fuse end caps or fuse holders also causes loss of voltage.
- Replace any fuse with measurable resistance, or clean and reinstall fuses if corrosion is found.
- If a disconnect exists, measure the AC voltage with a handheld multimeter on the AC volts scale. Measure the voltage on the rectifier side of the disconnect.
- If a disconnect does not exist, measure the AC voltage from the circuit breaker of the rectifier with a handheld multimeter on AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A3 (output of circuit breaker) and ground (cabinet). Turn power to the rectifier ON and the rectifier circuit breaker ON; measure voltage from the rectifier circuit breaker.
- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and (instead of cabinet ground) the output side of the circuit breaker on the second power lead.
- If voltage is present, either the transformer or the connections inside the rectifier are faulty (proceed to paragraph B-2.14).

- If voltage is not present, there is a loss of AC power to the rectifier. Measure the AC voltage to the circuit breaker of the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A1 and A4. Turn power to the rectifier ON; measure voltage to rectifier.
- If voltage is present, locate the break in the power feed from that point to the rectifier circuit breaker (or rectifier fusible disconnect, whichever was last tested).
- If voltage is not present, measure the AC voltage to the circuit breaker or fuse supplying power to the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase systems, open the circuit breaker panel or fuse panel and connect the meter to the main lugs of the circuit breaker panel or the input side of the fuses and ground.
- For 220/240 V, single-phase systems, use the same procedures, but check individual lugs separately. If voltage is not present, locate the circuit breaker panel or transformer supplying power to the panel and apply the applicable procedures in paragraph B-2.15; if voltage is present, replace the circuit breaker or fuses.

B-2.4.5 Troubleshoot Loose or Bad Wire Connections.

- Check the diodes/selenium plates of the rectifier with a handheld multimeter on the diode check scale. With power OFF, remove the tap bars or shorting wires and the anode lead (P4) and/or the structure lead (N4).
- Check the diode/selenium plate sets by connecting one test lead to N4 and the other to F6 (diode 3), then to C6 (diode 4). Both should beep or not beep.
- Reverse test leads and repeat connections. The beep should be opposite (both should not beep or beep).
- Repeat the test using P4 instead of N4 to test diodes/selenium plate sets (diodes 1 and 2).

Note: An ohms scale may be used. A good diode has very high resistance in one direction and low resistance in the other direction.

- With power OFF, check for loose connections from F6 to F7, C6 to C7, P1 to P2, P2 to P4, and N1 through N4, and check continuity of all wires between those points. Repair or replace loose connections and replace damaged or broken wires, if possible. If no problems are found, replace the stacks.

- Before a great deal of time is expended troubleshooting an anode bed, it should be determined from records if there is sufficient anode material to attempt locating and repairing the fault. Generally, if the current and time are calculated to amp-years, comparing that number to the weight of the installed anodes and the weight loss of the anode material indicates if the anodes are expended or have significant life remaining. Another indicator is that if a gradual failure occurred over a period of time, the anodes have failed. If the failure was sudden, a cable break can be expected.
- If failed anodes are found, replace the anode bed.
- If a broken anode lead is found, repair the cable. The first step to locating the break is to find the location of any excavations that have occurred in the area of the anode cable.
- There are two methods of troubleshooting anode beds, depending upon whether all anodes have failed (no current), or some (or most) of the anodes have failed. If one or more anodes are functioning, the best method is first to locate the functioning anodes, then an anode bed gradient graph to isolate and locate the problem.

Note: If separate anode lead wires in a junction box were installed, use these to measure the anode current and determine the functioning anodes.

- Perform a CIS over the anode bed. For the purpose of troubleshooting, you may adjust the rectifier to the highest voltage setting that would not result in coating damage to the structure to allow easier location of the anodes.
- Measure the potentials over the anodes with a handheld multimeter on the volts DC scale.
- With power ON, connect the positive lead of the multimeter to the structure lead (N4) of the rectifier.
- Using a saturated copper/copper sulfate reference cell connected to the negative lead of the multimeter, locate the point of highest voltage on the surface of the ground (directly over an anode).
- Repeat by locating all operational anodes.
- Mark each anode found and compare to system drawings. Starting in a straight line 10 feet (3 meters) from the first anode, perform a potential test every 2 feet (0.6 meters) over the entire length of the anode bed to a point 10 feet (3 meters) past where the last anode is (or is supposed to be) located.
- Using graph paper and using vertical lines to represent the measured potentials and horizontal lines to represent the 2-foot (0.6-meter) intervals, graph all readings. This shows the condition of all anodes and indicates if a broken header cable (anode lead) or failed anodes exist. It shows a broken cable between functional and non-functional anodes. If anodes are

failing, the gradients peak differently or the gradients fall, and then rise intermittently.

- If no anodes are operational, use the fault detector and cable locator connected directly to the anode cable P4 to trace the anode lead from the rectifier toward the anode bed. This can be extremely difficult in some cases.
- An alternative method is to locate the first anode (from drawings, markers, or induction methods).
- Excavate to the first anode and measure continuity back to the rectifier using a CP multi-combination meter continuity check circuit.
- Use the fault detector and cable locator connected directly to the anode to trace the anode lead from the anode toward the rectifier.
- If this is still unsuccessful, replace the anode lead from the rectifier to the anode.

Note: When using the direct connection method, it is essential to have a low-resistance, isolated ground for the fault detector or cable locator that allows a strong locator signal on the cable under test.

B-2.5 Rectifier Voltage Is Half of Normal.

The following lists possible causes and troubleshooting steps for the condition when the rectifier voltage is about half of normal. Rectifier output is required to be turned up to regain proper amount of current.

B-2.5.1 Troubleshoot Lightning or Other Power Surges.

- Check all fuses and measure AC voltage input to the rectifier. With power OFF, remove all fuses at the rectifier and any fusible disconnect.
- Measure the continuity of fuses with a handheld multimeter. Set scale to ohms; measure resistance of each fuse.
- Corrosion on fuse end caps or fuse holders also causes loss of voltage.
- Replace any fuse with measurable resistance, or clean and reinstall fuses if corrosion is found.
- If a disconnect exists, measure the AC voltage with a handheld multimeter on the AC volts scale. Measure the voltage on the rectifier side of the disconnect.
- If a disconnect does not exist, measure the AC voltage from the circuit breaker of the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A3 (output of circuit breaker) and ground (cabinet). Turn power to the rectifier ON and the rectifier circuit breaker ON; measure voltage from the rectifier circuit breaker.

- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and (instead of cabinet ground) the output side of the circuit breaker on the second power lead.
- If voltage is present, then either the transformer or the connections inside the rectifier are faulty (proceed to paragraph B-2.15).
- If voltage is not present, then there may be loss of AC power to the rectifier. Measure the AC voltage to the circuit breaker of the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A1 and A4. Turn power to the rectifier ON; measure voltage to rectifier.
- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and input side of the circuit breaker (A1) on the second power lead.
- If voltage is present, replace circuit breaker or fuse.
- If voltage to the rectifier is not present, measure the AC voltage from the circuit breaker or fuse where power is supplied to the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase systems, open the circuit breaker panel or fuse panel and connect meter to the output of circuit breaker or the output side of the fuse and ground or neutral bar.
- For 220/240 V, single-phase systems, use the same procedures, but connect the meter to the output lugs of the circuit breakers or the output side of the fuses.
- If voltage is present, locate the break in the power feed from that point to the rectifier circuit breaker (or rectifier fusible disconnect, whichever was last tested).
- If voltage is not present, measure the AC voltage to the circuit breaker or fuse supplying power to the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase systems, open the circuit breaker panel or fuse panel and connect the meter to the main lugs of the circuit breaker panel or the input side of the fuses and ground.
- For 220/240 V, single-phase systems, use the same procedures, but check individual lugs separately. If voltage is not present, locate the circuit breaker panel or transformer supplying power to the panel and repeat paragraph B-2.15; if voltage is present, replace the circuit breaker or fuses.

B-2.5.2 Troubleshoot Sudden Decrease in Soil Resistivity Due to Long Period of Heavy Rain.

- Check all fuses and measure AC voltage input to the rectifier. With power OFF, remove all fuses at the rectifier and any fusible disconnect.
- Measure the continuity of fuses with a handheld multimeter. Set scale to ohms; measure resistance of each fuse. Corrosion on fuse end caps or fuse holders also causes loss of voltage.
- Replace any fuse with measurable resistance, or clean and reinstall fuses if corrosion is found.
- If disconnect exists, measure the AC voltage with a handheld multimeter on the AC volts scale.
- Measure the voltage on the rectifier side of the disconnect.
- If disconnect does not exist, measure the AC voltage from the circuit breaker of the rectifier with a handheld multimeter on AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A3 (output of circuit breaker) and ground (cabinet). Turn power to the rectifier ON and the rectifier circuit breaker ON; measure voltage from the rectifier circuit breaker.
- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and (instead of cabinet ground) the output side of the circuit breaker on the second power lead.
- If voltage is present, either the transformer or the connections inside the rectifier are faulty (proceed to paragraph B-2.15).
- If voltage is not present, there is a loss of AC power to the rectifier. Measure the AC voltage to the circuit breaker of the rectifier with a handheld multimeter on the AC volts scale.
- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A1 and A4. Turn power to the rectifier ON; measure voltage to rectifier.
- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and input side of the circuit breaker (A1) on the second power lead. If voltage is not present, proceed to paragraph B-2.15; if voltage is present, replace circuit breaker or fuse.

B-2.6 Rectifier Output Is Decreased.

The following lists the causes and troubleshooting steps for the condition when the rectifier output is decreased but the voltage is near normal.

B-2.6.1 Troubleshoot Rectifier Is Half Waving and One of the Diodes or Selenium Plates Burned Out.

- Measure the DC voltage output of the rectifier with a handheld multimeter. With power ON and scale on volts DC, measure voltage from N4 to P4 (see Figure B-6). One of three conditions may exist: voltage may be near zero (proceed to paragraph B-2.7.1), near half of normal (proceed to paragraph B-2.7.2), or near normal (proceed to paragraph B-2.7.3).
- With power OFF, check for loose connections from P2 to P3, N2 and N5 through N7, including any press-to-test switches or buttons, and continuity of all wires between those points. This requires disconnecting AC power from the rectifier cabinet and possibly removal of the rectifier from the cabinet. Note that loose connections are characterized by heat, discoloration of the connection, and melted insulation.
- Repair or replace loose connections and replace damaged or broken wires. If problems are not found, proceed with paragraph B-2.7.3.
- With power OFF, remove voltmeter from rectifier. This requires disconnecting AC power from the rectifier cabinet and possibly removal of the rectifier from the cabinet.
- Disconnect one end of the resistors on reverse side of meter.
- Measure the resistance of the resistors with a handheld multimeter on the ohms scale and compare to the value of the resistor (if no resistors are present, replace meter).
- Replace resistor or meter as required.

B-2.6.2 Troubleshoot Failure of Some Anodes or Anode Leads When Soil Is Dried Out (Increased Resistivity).

- Measure the DC output of the rectifier with a handheld multimeter on the mV scale. Measure mV from N2 to N3. Multiply the indicated reading by the appropriate multiplication factor (see Figure B-7).
- One of three conditions may exist:

a. The current may be near zero, indicating a break in the anode lead, failed anodes, or a break in the structure lead (proceed to paragraph B-2.8.1).

b. The current may be near half of normal, indicating a defective diode/selenium plate; a break in the header cable between anodes; or, if there are multiple anode leads, loss of one anode lead or anode bed. Measure the DC voltage output of the rectifier with a handheld multimeter on the volts DC scale. Measure the voltage from N4 to P4. If voltage is also half of normal, proceed to paragraph B-2.13 to troubleshoot the diodes/selenium plates. If voltage is normal, proceed to paragraph B-2.14 to troubleshoot the anode bed.

c. The current may be near normal. Proceed to paragraph B-2.8.3 for detailed instructions.

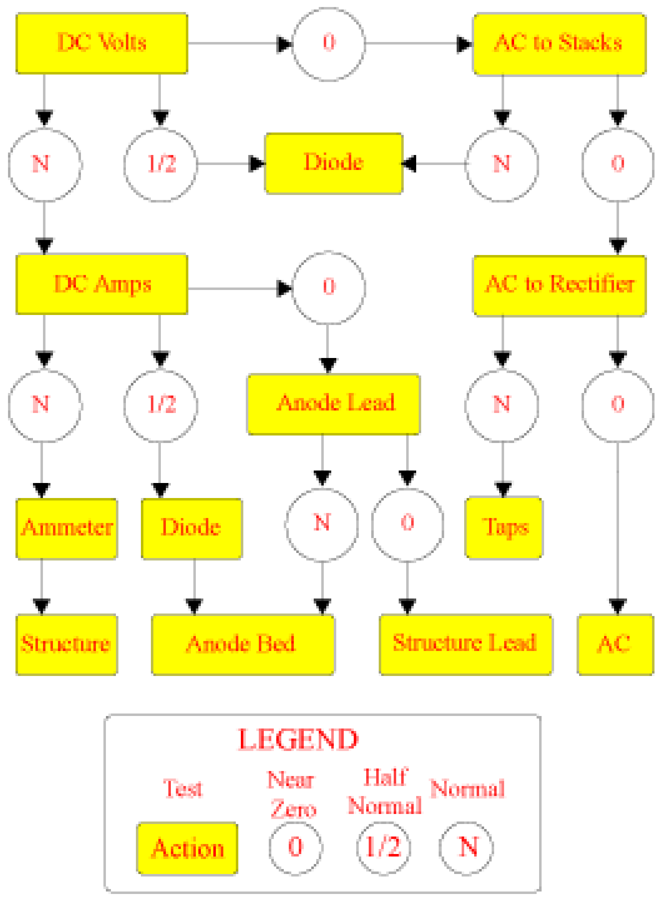
WARNING
All connections should be made with alligator clip leads with the rectifier circuit breaker or power switch OFF. To prevent possible injury or death, employ electrical safety practices for working with live circuits when needlepoint leads are used with power ON.

The starting point for all impressed current systems troubleshooting is at the rectifier. Indications of all problems are present at this location. The greatest aids to troubleshooting are historical data and drawings of the system. Usually, the fault may be isolated and then verified by testing. There are sufficient test points on the face plate of the rectifier to isolate the faulty component. Figure B-5 depicts the troubleshooting block diagram.

WARNING
AC voltage is still present inside the rectifier with the rectifier circuit breaker or power switch OFF. All connections inside the rectifier cabinet should be made with alligator clip leads connected with the power to the rectifier OFF. To prevent possible injury or death, employ electrical safety practices for working with live circuits when needlepoint leads are used with power ON.

WARNING
For Navy projects, when conducting work on or near circuits, energized lines, or parts of equipment operating at or above 50 V, utilize work practices identified in OPNAV P-45-117-6-98.

Figure B-5 Troubleshooting Block Diagram



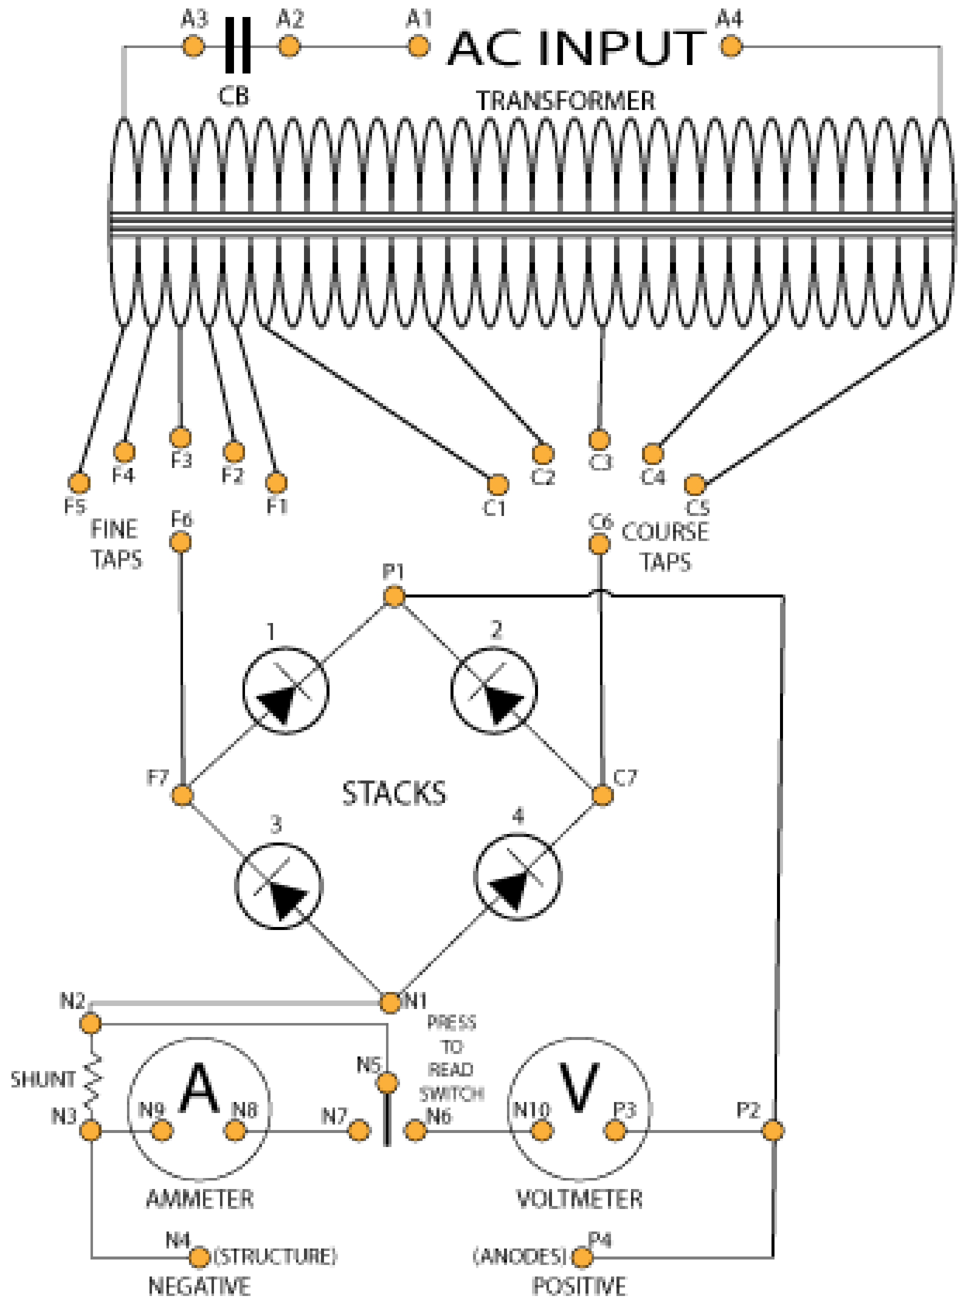
B-2.7 DC Voltage.

Measure the DC voltage output of the rectifier with a handheld multimeter. With the power ON and the scale on volts DC, measure voltage from N4 to P4 (see Figure B-6). One of three conditions may exist: voltage may be near zero (proceed to paragraph B-2.7.1), near half of normal (proceed to paragraph B-2.7.2), or near normal (proceed to paragraph B-2.7.3).

- With power OFF, check for loose connections from P2 to P3, N2 and N5 through N7, including any press-to-test switches or buttons, and continuity of all wires between those points. This requires disconnection of AC power from the rectifier cabinet and possibly removal of the rectifier from the cabinet. Note that loose connections are characterized by heat, discoloration of the connection, and melted insulation. Repair or replace loose connections and replace damaged or broken wires. If problems are not found, proceed to paragraph B-2.7.3.
- With power OFF, remove voltmeter from rectifier. This requires disconnection of AC power from the rectifier cabinet and possibly removal of the rectifier from the cabinet. Disconnect one end of the resistors on

reverse side of meter. Measure the resistance of the resistors with a handheld multimeter on the ohms scale and compare to the value of the resistor (if no resistors are present, replace meter). Replace resistor or meter as required.

Figure B-6 Typical Rectifier Wiring Diagram



B-2.7.1 No DC Voltage.

No DC voltage indicates that one of the components in the rectifier is faulty or there has been a loss of AC power (proceed to paragraph B-2.11).

B-2.7.2 Half the Normal Voltage Output.

This case indicates defective diodes/selenium plates or improper AC input. Proceed to paragraph B-2.11 to check the AC input to the stacks and paragraph B-2.13 to troubleshoot the diodes/selenium plates.

B-2.7.3 Normal DC Voltage.

This case indicates a break in the anode lead, failed anodes, or a break in the structure lead (proceed to paragraph B-2.10). If the voltage is normal and the rectifier voltmeter reads significantly different, the connections or the voltmeter are faulty (proceed to paragraph B-2.10).

B-2.8 DC Current.

Measure the DC current output of the rectifier with a handheld multimeter on the mV scale. Measure the mV from N2 to N3 across the shunt resistor. Multiply the indicated reading by the appropriate multiplication factor. See Figure B-7. One of three conditions may exist: the current may be near zero (proceed to paragraph B-2.8.1), near half of normal (proceed to paragraph B-2.8.2), or near normal (proceed to paragraph B-2.8.3).

Figure B-7 Shunt Multiplication Factors

SHUNT SIZE		MEASURE	X	FACTOR	=	AMPS
50 mV	100A	___mV	X	2	=	___A
50 mV	75A	___mV	X	1.5	=	___A
50 mV	50A	___mV	X	1	=	___A
50 mV	45A	___mV	X	.9	=	___A
50 mV	40A	___mV	X	.8	=	___A
50 mV	35A	___mV	X	.7	=	___A
50 mV	30A	___mV	X	.6	=	___A
50 mV	25A	___mV	X	.5	=	___A
50 mV	20A	___mV	X	.4	=	___A
50 mV	15A	___mV	X	.3	=	___A
50 mV	10A	___mV	X	.2	=	___A
50 mV	5A	___mV	X	.1	=	___A
a mV	b A	___mV	X	$\frac{bA}{amV}$	=	___A

B-2.8.1 Normal DC Voltage with Near Zero Current.

This condition indicates a break in the anode lead, failed anodes, or a break in the structure lead (proceed to paragraphs B-2.9 and B-2.10).

B-2.8.2 Half the Normal Current Output.

This condition indicates either a defective diode/selenium plate; a break in the header cable between anodes; or, if there are multiple anode leads, loss of one anode lead or anode bed. Measure the DC voltage output of the rectifier with a handheld multimeter on the volts DC scale. Measure the voltage from N4 to P4. If voltage is also half of normal, proceed to paragraph B-2.13 to troubleshoot the diodes/selenium plates. If voltage is normal, proceed to paragraph B-2.12 to troubleshoot the anode bed.

B-2.8.3 Current Is Normal and Rectifier Ammeter Reads Differently.

If the current is normal and a rectifier ammeter reading is significantly different, then the shunt, the connections, or the ammeter is faulty (proceed to paragraph B-2.8.3.a)). If the current is normal, the rectifier ammeter reads normal, and structure potentials are still significantly changed from normal, proceed to paragraph B-2.8.3.d).

a. Measure DC with a handheld multimeter connected in series and with the meter on the DC amps scale. Disconnect anode header cable at P4 and measure current from P4 to anode lead. Compare the measured current value to the current value taken in paragraph B-2.7. If values are significantly different, replace the shunt. If values are the same, proceed to paragraph B-2.8.3.d).

WARNING

AC voltage is still present inside the rectifier with the rectifier circuit breaker or power switch OFF. All connections should be made with alligator clip leads with the rectifier circuit breaker or power switch OFF. To prevent possible injury or death, employ electrical safety practices for working with live circuits when needlepoint leads are used with power ON.

WARNING

For Navy projects, when conducting work on or near circuits, energized lines, or parts of equipment operating at or above 50 V, utilize work practices identified in OPNAV P-45-117-6-98.

b. With power OFF, check for loose connections from N2 through N9, including any press-to-test switches or buttons, and continuity of all wires between those points. This requires disconnection of AC power from the rectifier cabinet and possibly removal of the rectifier from the cabinet. Note that loose connections are characterized by heat, discoloration of the connection, and melted insulation. Repair or replace loose connections and replace damaged or broken wires. If problems are not found, proceed to paragraph B-2.8.3.c).

c. With power OFF, remove ammeter from rectifier. This requires disconnection of AC power from the rectifier cabinet and possibly removal of the rectifier from the cabinet. Disconnect one end of the resistors on reverse side of meter. Measure the resistance of the resistors with a handheld multimeter on the ohms scale and compare to the value of the resistor (if no resistors are present, replace meter). Replace resistor or meter as required.

d. Normal current values accompanied by loss of potential shifts indicate a change in the protected structure. If the protected structure is isolated, all dielectrics and repair or replace faulty ones. If the protected structure is not isolated, check for additions to the protected structure or n check ew structures in the area that are continuous with the protected structure, increase current to protect larger structure(s), isolate other structure(s), or install additional impressed current system(s) as required.

B-2.9 Anode Lead Wires.

With power OFF, disconnect anode lead(s) at P4. Connect P4 (positive terminal) to an alternative isolated metallic structure (isolated from structure being tested; if doubt exists, measure continuity to structure lead), such as a metal culvert or fence, or install temporary ground rods. For a short period of time, turn power ON and note AC. One of two conditions exists: either current is now present (changed) or it is not present (not changed).

Note: If the structure being tested is the inside of a water tank or tower, and the lack of water does not allow current flow (no electrolyte), fill the tank and then retest.

B-2.9.1 Current Is Present.

If current exists, the anode lead is broken or the anodes have failed (proceed to paragraph B-2.14).

B-2.9.2 Current Is Not Present.

If no current exists, the structure lead may be broken (proceed to paragraph B-2.10).

B-2.10 Structure Lead.

For this test, the temporary or alternative anode should remain connected to terminal P4. With power OFF, disconnect structure lead at N4. Connect N4 (negative terminal) to an alternative isolated metallic structure (isolated from structure being tested; if doubt exists, measure continuity to structure lead), such as a metal culvert or fence, or install temporary ground rods. For a short period of time, turn power ON and note AC. One of two conditions exists: either current is now present (changed) (proceed to paragraph

B-2.9.1) or it is not present (not changed). If current still does not exist (not changed), the temporary anode bed is not sufficient. Supplement the temporary anode bed, then repeat paragraph B-2.8.

B-2.10.1 Structure Connection Broken.

Since current is now present, the structure connection is broken. Use the fault detector and cable locator, connected directly to the structure lead at N4, to trace the structure lead from the rectifier toward the structure. This can be extremely difficult in some cases. An alternative method is to locate the first structure connection (from drawings, markers, or induction methods). Excavate to the structure and measure continuity back to the rectifier using a CP multi-combination meter continuity check circuit. Use the fault detector and cable locator, connected directly to the structure lead, to trace the lead from the structure toward the rectifier. If this is still unsuccessful, replace the structure lead from the rectifier to the structure.

Note: When using the direct connection method, it is essential to have a low-resistance isolated ground for the fault detector or cable locator to put strong locator signals on the cable under test.

If current still does not exist (not changed), the temporary anode bed is not sufficient. Supplement the temporary anode bed, then repeat paragraph B-2.8.

B-2.11 AC Voltage to Stacks.

Measure the AC voltage input to the stacks of the rectifier with a handheld multimeter on the AC volts scale. Measure voltage from F6 to C6 (tap bars). One of two conditions may exist: voltage may be near zero (proceed to paragraph B-2.11.1) or near normal (proceed to paragraph B-2.11.2).

B-2.11.1 Voltage Near Zero.

This indicates loss of AC power to the rectifier, bad fuses or circuit breakers, or a bad transformer (or connections) in the rectifier (proceed to paragraph B-2.12).

B-2.11.2 Voltage Near Normal.

This indicates faulty diodes/selenium plates or bad connections inside the rectifier (proceed to paragraph B-2.13). If the rectifier does not have taps, proceed to paragraph B-2.12; if that test is normal, the rectifier must be removed from the cabinet for checkout. Refer to specific rectifier manual to troubleshoot the diodes/selenium plates and the transformer. For general reference, see paragraph B-2.13 for the stacks and paragraph B-2.14 for the transformer.

B-2.12 Fuses.

Check all fuses and measure AC voltage input to the rectifier. With power OFF, remove all fuses at the rectifier and any fusible disconnect. Measure the continuity of fuses with a handheld multimeter. Set scale to ohms; measure resistance of each fuse. Corrosion on fuse end caps or fuse holders also causes loss of voltage. Replace any fuse with measurable resistance, or clean and reinstall fuses if corrosion is found. If a disconnect exists, measure the AC voltage with a handheld multimeter on the AC volts scale. Measure the voltage on the rectifier side of the disconnect. If a disconnect does not exist, measure the AC voltage from the circuit breaker of the rectifier with a handheld multimeter on AC volts scale. For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A3 (output of circuit breaker) and ground (cabinet). Turn power to the rectifier ON and the rectifier circuit breaker ON; measure voltage from the rectifier circuit breaker. For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and (instead of cabinet ground) the output side of the circuit breaker on the second power lead (not shown on drawing). If voltage is present, proceed to paragraph B-2.12.1. If voltage is not present, proceed to paragraph B-2.12.2.

B-2.12.1 Voltage Is Present.

This indicates that either the transformer or the connections inside the rectifier are faulty (proceed to paragraph B-2.15).

B-2.12.2 Voltage Is Not Present.

This indicates loss of AC power to the rectifier. Measure the AC voltage to the circuit breaker of the rectifier with a handheld multimeter on the AC volts scale.

- For 110/120 V, single-phase rectifiers, turn power to the rectifier OFF, open cabinet, and connect meter to A1 and A4. Turn power to the rectifier ON; measure voltage to rectifier.
- For 220/240 V, single-phase rectifiers, use the same procedures, but connect meter to A4 and input side of the circuit breaker (A1) on the second power lead.

If voltage is not present, proceed to paragraph B-2.16; if voltage is present, replace circuit breaker or fuse.

B-2.13 Diodes.

Check the diodes/selenium plates of the rectifier with a handheld multimeter on the diode check scale. With power OFF, remove the tap bars or shorting wires and the anode lead (P4) and/or the structure lead (N4). Check the diode/selenium plate sets by connecting one test lead to N4 and the other to F6 (diode 3), then to C6 (diode 4). Both should beep or not beep. Reverse test leads and repeat connections. The beep should be opposite (both should either not beep or beep). Repeat the test using P4 instead of N4 to test diodes/selenium plate sets (diodes 1 and 2).

Note: An ohms scale may be used. A good diode has very high resistance in one direction and low resistance in the other direction.

With power OFF, check for loose connections from F6 to F7, C6 to C7, P1 to P2, P2 to P4, and N1 through N4, and continuity of all wires between those points. Repair or replace loose connections and replace damaged or broken wires, if possible. If no problems are found, replace the stacks.

B-2.14 Anode Bed.

Before a great deal of time is expended troubleshooting an anode bed, it should be determined from records if there is sufficient anode material to attempt locating and repairing the fault. Generally, if the current and time are calculated to amp-years, comparing that number to the weight of the installed anodes and the weight loss of the anode material indicates if the anodes are expended or have significant life remaining. Another indicator is that if a gradual failure occurred over a period of time, the anodes have failed. If the failure was sudden, a cable break can be expected. If failed anodes are found, replace the anode bed. If a broken anode lead is found, repair the cable. The first step to locating the break is to find the location of any excavations that have occurred in the area of the anode cable. There are two methods of troubleshooting anode beds, depending upon whether all anodes have failed (no current) or some (or most) of the anodes have failed. If one or more anodes are functioning, see paragraph B-2.14.2. If no anodes are functioning, see paragraph B-2.14.3.

If one or more anodes are functioning, the best method is first to locate the functioning anodes, then an anode bed gradient graph to isolate and locate the problem.

Note: If separate anode lead wires in a junction box were installed, use these to measure the anode current and determine the functioning anodes.

B-2.14.1 Linear Anode ICCP Systems.

These systems are commonly used to protect long line structures, such as pipelines. This is usually the most economical choice when the pipeline due to poor or aged coating requires a continuous and close coupled current. This type of anode bed is used to protect pipelines with poor coating and can be installed up to several miles along a pipeline. The distance from the structure is normally 5 to 10 feet (1.5 to 3 meters). In most cases, the anode is installed with a separate header cable to minimize voltage drop. Mixed metal oxide (MMO) anodes or polymer anodes are typically used for this type of installation.

B-2.14.1.1 Mixed Metal Oxide Anodes.

MMO anodes exhibit favorable design life characteristics while providing current at very high density levels. The oxide film is not susceptible to rapid deterioration due to anode acid generation, rippled DC, or half wave rectification, as is common with other precious metal anodes. The composition of the anode consists of a titanium rod, wire, tube, or expanded mesh with the oxide film baked on the base metal. In oxygen evolution environments, such as soils, the oxide consists of ruthenium crystals and titanium halide salts in an aqueous solution that is applied like paint on the base metal and baked at 400ºC to 800ºC, forming a rutile oxide. Normally, titanium experiences physical breakdown around 10 V, but the oxide film is so highly conductive (10^{-5} ohm-cm resistivity) that the current, which takes the path of least resistance, is discharged from the oxide rather than the base metal, even with a rectifier voltage of 90 V in soils. This contrasts with the insulating titanium dioxide film that naturally forms on the surface of bare titanium. When the MMO film has been consumed, the insulating titanium dioxide film covers the anode and does not allow current to discharge unless the applied voltage is greater than 10 V in seawater or 50 to 70 V in fresh water.

The anode life is based on the thickness of the oxide film. Typical thicknesses result in a 30- to 50-year anode life.

Anodes in soil or mud should be backfilled with fine, low-resistance, calcined petroleum coke breeze for maximum life and performance. Consumption rates range from 0.5 milligrams per amp-year in seawater to 5 milligrams per amp-year in coke breeze, fresh water, and sea mud. As with any anode, the connection must be constructed to be moisture proof, watertight, and have no more than 0.001 ohms of resistance.

B-2.14.2 Close Interval Survey.

Perform a CIS over the anode bed. For the purpose of troubleshooting, adjust the rectifier to the highest voltage setting that would not result in coating damage to the structure to allow easier location of the anodes. Measure the potentials over the anodes with a handheld multimeter on the volts DC scale. With power ON, connect the positive lead of the multimeter to the structure lead (N4) of the rectifier. Using a saturated copper/copper sulfate reference cell connected to the negative lead of the multimeter, locate the point of highest voltage on the surface of the ground (directly over an anode). Repeat by locating all operational anodes. Mark each anode found and compare to system drawings. Starting in a straight line 10 feet (3 meters) from the first anode, perform a potential test every 2 feet (0.6 meters) over the entire length of the anode bed to a point 10 feet (3 meters) past where the last anode is (or is supposed to be) located. Using graph paper and using vertical lines to represent the measured potentials and horizontal lines to represent the 2-foot (0.6-meter) intervals, graph all readings. This shows the condition of all anodes and indicates if a broken header cable (anode lead) or failed anodes exist. It shows a broken cable between functional and non-functional anodes. If anodes are failing, the gradients peak differently, or the gradients fall and then rise intermittently.

B-2.14.3 Anodes Are Non-operational.

If no anodes are operational, use the fault detector and cable locator connected directly to the anode cable P4 to trace the anode lead from the rectifier toward the anode bed. This can be extremely difficult in some cases. An alternative method is to locate the first anode (from drawings, markers, or induction methods). Excavate to the first anode and measure continuity back to the rectifier using a CP multi-combination meter continuity check circuit. Use the fault detector and cable locator, connected directly to the anode, to trace the anode lead from the anode toward the rectifier. If this is still unsuccessful, replace the anode lead from the rectifier to the anode.

Note: When using the direct connection method, it is essential to have a low-resistance, isolated ground for the fault detector or cable locator in order to allow a strong locator signal on the cable under test.

B-2.15 Rectifier Taps.

Measure the AC voltage on the taps of the rectifier with a handheld multimeter on the AC volts scale. Remove the tap bars or shorting wires. Measure the voltage from F5 to F4, F4 to F3, F3 to F2, F2 to F1, and F1 to C1. All readings should be approximately the same. Measure the voltage from C5 to C4, C4 to C3, C3 to C2, and C2 to C1. All readings should be approximately the same. Any lead that tests differently must be checked for connection (proceed to paragraph B-2.15.1).

Note: On some rectifiers, F1 to C1 may be a unique voltage.

B-2.15.1 With Power Off.

Note: Loose connections are characterized by heat, discoloration of the connection, and melted insulation.

- Check for loose connections from F1 through F5 and C1 through C5, including any tap bar or shorting wire, and continuity of all wires between those points. Repair or replace loose connections and replace damaged or broken wires, if possible. If only one tap is inoperative, a different tap setting may be operational, and testing reveals functioning taps. If replacement of wire is not possible, replace the transformer. If no problems are found, proceed with the next step.
- Check for loose connections from A2 through A4 and continuity of all wires between those points. Repair or replace loose connections and replace damaged or broken wires, if possible. If replacement of wire is not possible, replace the transformer.

Note: Checkout of transformers or pole fuses requires personnel certified for work on high-voltage lines and proper equipment beyond the scope of these procedures.

B-2.16 Rectifier Input Voltage.

First, verify that the circuit breaker has not tripped or the fuse has not blown. If properly operating, measure the AC voltage from the circuit breaker or fuse where power is supplied to the rectifier with a handheld multimeter on the AC volts scale. For 110/120 V, single-phase systems, open the circuit breaker panel or fuse panel and connect meter to the output of circuit breaker or the output side of the fuse and ground or neutral bar. For 220/240 V, single-phase systems, use the same procedures, but connect the meter to the output lugs of the circuit breakers or the output side of the fuses.

If voltage is present, locate the break in the power feed from that point to the rectifier circuit breaker (or rectifier fusible disconnect, whichever was last tested).

If voltage is not present, measure the AC voltage to the circuit breaker or fuse supplying power to the rectifier with a handheld multimeter on the AC volts scale.

- For 110/120 V, single-phase systems, open the circuit breaker panel or fuse panel and connect the meter to the main lugs of the circuit breaker panel or the input side of the fuses and ground.
- For 220/240 V, single-phase systems, use the same procedures, but check individual lugs separately. If voltage is not present, locate the circuit breaker panel or transformer supplying power to the panel and repeat paragraph B-2.15; if voltage is present, replace the circuit breaker or fuses.

WARNING

AC voltage is still present inside the rectifier with the rectifier circuit breaker or power switch OFF. All connections should be made with alligator clip leads with the rectifier circuit breaker or power switch OFF. To prevent possible injury or death, employ electrical safety practices for working with live circuits when needlepoint leads are used with power ON.

WARNING

For Navy projects, when conducting work on or near circuits, energized lines, or parts of equipment operating at or above 50 V, utilize work practices identified in OPNAV P-45-117-6-98.

APPENDIX C SERVICE-SPECIFIC GUIDANCE

C-1 ARMY.

C-1.1 If Required.

C-2 AIR FORCE.

C-2.1 Sample Base Corrosion Control Operating Instructions.

C-2.1.1 Purpose.

The following sections outline responsibilities and procedures required to establish and conduct a continuing and recurring Corrosion Control Program for Sample Air Force Base (AFB), XX.

C-2.1.2 Criteria.

This UFC is applicable to all Civil Engineering Squadron personnel involved, directly or indirectly, in the development and maintenance of an effective Corrosion Control Program.

C-2.1.3 Responsibility.

C-2.1.3.1 AFCEC.

AFCEC has overall responsibility for the Air Force Facility and Infrastructure Corrosion Control Program. AFCEC is responsible for the functional adequacy of Air Force new construction.

C-2.1.3.2 Base Engineering.

Base Engineering with AFCEC consultation is responsible for its Corrosion Control Program and ensures it develops, establishes, and maintains Infrastructure Systems that ensure an effective comprehensive Corrosion Control Program with personnel adequately trained to carry out their responsibilities.

Base Engineering must establish and maintain a Corrosion Control Program for each activity within the squadron at Sample AFB. The Chief of the Engineering Flight and the Chief of Operations Flight work together to assign the Base Corrosion Control Engineer (BCCE). They also appoint a Base Industrial Water Treatment Engineer and a Base Protective Coatings Engineer as required. The Chief of Operations appoints the CP and industrial water treatment craftsmen in consultation with the Chief of Infrastructure Systems.

C-2.1.3.3 BCCE.

The BCCE is responsible for the overall management of the base Corrosion Control Program and coordinates this program with the Chief of Operations Flight, Chief of

Operations Engineering Element, Chief of Infrastructure Support Element, CP craftsmen, industrial water treatment craftsmen, protective coatings personnel, and other appropriate functions within the operations flight. The BCCE establishes and chairs a Base Corrosion Control committee that meets at least quarterly. Minimum participants are: (1) Chief of Operations, (2) Chief of Operations Engineering, (3) Chief of Infrastructure Systems, (4) Lead craftsmen in Mechanical, Electrical, Structural, and Sanitation, (5) Lead planner, and (6) Others as appropriate.

C-2.1.3.4 Engineering Construction Management.

Engineering Construction Management and/or Service Contract personnel monitor every phase of coatings operations to include Simplified Acquisition of Base Engineering Resources (SABER) contract and general contract operations. For all other corrosion work, whether contract or in-house, this office provides the coatings test equipment and expertise to evaluate work and investigate coating failures.

C-2.1.4 Reference.

See AFI 32-1054, Attachment 1, for directives and guidance that have an impact on corrosion control engineering.

C-2.1.5 Work Procedures.

C-2.1.5.1 Operations/Engineering.

- The Civil Engineer (CE) appoints, by letter, a Corrosion Control Engineer with the advice of the Chief of Engineering, Chief of Operations, and Chief of Operations Engineering.
- Chief of Operations and/or Engineering assigns corrosion control duties to the engineer appointed by the CE and ensures the appointee receives adequate training to carry out these responsibilities (see AFI 32-1054).
- Chief of Operations appoints at least 2 CP craftsmen and other corrosion control craftsmen from the appropriate shops as he or she deems necessary to facilitate corrosion control duties. Personnel involved in corrosion control duties should receive adequate training on an annual basis and be appointed in writing. A file containing a current roster of corrosion control personnel is in the Operations Branch and contains training status and training program information. Send updated copies of appointment letters for corrosion control duties to the BCCE.

C-2.1.5.2 BCCE.

The BCCE manages the overall Engineering Squadron Corrosion Control Program. This includes the following tasks:

- Develop program and management procedures.

- Review engineering drawings and specifications developed under base direction for adequacy of corrosion control.
- Review engineering drawings for Military Construction (MILCON) projects for adequacy of corrosion control.
- Maintain base corrosion control records.
- Retain logs compiled by appropriate shops to be collected at the end of the calendar year. CP craftsmen shall retain and log readings on the appropriate forms during the year and forward to the BCCE at the end of the calendar year.
- Review corrosion records monthly.
- Complete a CIS every 5 years.
- Include requirements and criteria of AFI 32-1054 in the Corrosion Control Program.
- Establish a CP system master plan and show all installed rectifiers, ground beds, test stations, and anodes. Update the maps to show any modifications made on the systems. Indicate the location of neighboring structures.
- Conduct an annual CP performance survey with qualified CP craftsmen; accomplish by contract if capability is not available with shop. This includes:
    - Taking S/E potential measurements on all pipelines (building gas service risers), both sides of isolating insulation, hydrant outlets in petroleum, oil, and lubricant (POL) systems, and surface and underground tanks.
    - Internally inspecting water storage tanks.
    - Updating the Cathodic Protection Annual Performance Booklet.
    - Updating the CP program record.
    - Determining actions required to provide complete protection and preparing maintenance action sheets.
- Ensure the necessary corrosion tests and system examinations are performed on boiler water.
- Ensure the treatment equipment is adequate and working for cooling water.
- Investigate all reported leaks and corrosion failures, determine cause of failure and corrective action required to prevent recurrence. Do not restrict viewpoint to fluid-carrying systems or high-value steel structures, expand

to include other items, such as metal roofing and flashing, that leak and cause water damage to structures and contents.

- Maintain data on corrosion failures and record each location where an underground failure occurs on a base layout map.
- Analyze data for patterns that indicate major problem areas.
- Assist Operations in procuring proper CP test equipment.
- Assist Engineering in procuring necessary paint inspection equipment.
- Assist other corrosion control craftsmen in procuring leak detection equipment, test instruments, chemical treatment equipment, and consumables as necessary to conduct an effective Corrosion Control Program.
- Perform life cycle cost analysis of corrosion control measures.
- Arrange for technical assistance as required through AFCEC.
- Call corrosion control committee meetings, establish agenda items, and ensure coordination of all corrosion control activities through this committee.

C-2.1.5.3 CP Craftsmen.

CP craftsmen perform tests consisting primarily of electrical measurements to indicate the condition of system components. Maintenance duties include:

- Performing rectifier checks for current and voltage output, meter function, proper operation, and adjustment to maintain the current required (as recorded at the last annual survey) for adequate protection.
- Conducting S/E potential measurements at the four test points established by annual surveys of impressed current systems.
- Conducting S/E potential measurements and current output of anode systems, and the addition of anodes as required for complete protection.
- Performing minor system repairs.
- Submitting maintenance requirements for major work.
- Entering operational data in appropriate logs and forwarding to the BCCE for filing and maintenance.
- Conducting an annual CP survey under the BCCE. Accomplish by contract if capability is not available with shop.
- Procuring and retaining custody of instruments authorized and required in routine maintenance of installed CP systems.

C-2.1.5.4 Engineering Construction Management.

Engineering Construction Management and/or Service Contract personnel keep every phase of coating operations under surveillance. This includes:

- Recording coating type, thickness, and bonding.
- Checking the above items against specifications.
- Checking surface preparation prior to coating application.
- Documenting subsequent coating performance.
- Reporting any damage found during inspections.
- Assuring repair of reported damage by recommended methods.
- Procuring and retaining custody of test equipment necessary for inspection (film thickness gauges, blasting standards, holiday detector, and paint test kit).
- Coordinating requirements for coating operations with the BCCE, SABER contractor, service contractor and general contractors as required, ensuring adequate corrosion control operations.
- Forwarding all test data to the BCCE for filing and retention.

C-2.1.5.5 Corrosion Control Craftsmen.

Corrosion control craftsmen perform tasks necessary to accomplish corrosion control to the maximum extent possible in their areas of responsibility. The following areas may require a corrosion control craftsman.

C-2.1.5.6 Potable Water Systems.

Potable water systems and treatment corrosion control craftsman will (OPR: Infrastructure Systems Element):

- Perform raw analysis every 3 years; accomplish by contract if capability is not available with shop.
- Record treatment performed daily on AF Form 1461, Water Utility Operating Log.
- Determine and record consumption monthly.
- Maintain water treatment logs in Facility 62515, Water and Waste Building, for review by the BCCE.
- Use AF Form 1687, Leak/Failure Data Record, as appropriate, and forward to the BCCE.
- Monitor water distribution systems' pressure meters hourly to determine possible water leaks.

C-2.1.5.7 Boiler Water Systems and Treatment.

Boiler water systems and treatment corrosion control craftsmen will (OPR: Facility System Elements):

- Maintain complete records of boiler water treatment daily on AF Form 1459, Water Treatment Operating Log for Steam and Hot Water Boilers. This includes internal treatment with chemicals and external treatment with deaerators, softeners, and decarbonators.
- Test make-up water, quantity, and quality monthly.
- Check for leaks in steam valves, flanges, and unions in boiler plants daily.
- Test heat exchangers for leaks monthly.
- Check pressure and temperature of deaerating heater daily.
- Determine conductivity of return condensate daily at a minimum; hourly for large plants.
- Have condensate corrosion tests performed monthly.
- Test ion exchanger output quality daily at a minimum; more often if required.
- Check mechanical rooms with hot water heat exchangers for signs of corrosion problems semiannually.
- Check all tanks annually.
- Check boiler plant piping systems daily.
- Use AF 1687, Leak/Failure Data Record, as appropriate, and forward to the BCCE.
- Procure and retain custody of test equipment necessary for corrosion control testing of boiler water systems.

C-2.1.5.8 Cooling Water Systems and Treatment.

Cooling water systems and treatment corrosion control craftsmen will (OPR: Facility System Elements):

- Maintain complete records of cooling water treatment as required. Use AF Form 1457, Water Treatment Operating Log for Cooling Tower Systems at a minimum. Maintain these records in the shop for review by the BCCE.
- Check cooling towers for algae and scale buildup monthly.
- Together with the BCCE, ensure monthly that treatment equipment is adequate and is working.
- Calculate cycles of concentration and maintain according to survey recommendations monthly.

- Procure and retain custody of test equipment necessary for corrosion control testing of cooling water systems.
- Use AF Form 1687, Leak/Failure Data Record, as appropriate, and forward to the BCCE.

C-2.1.5.9 Water Distribution Systems.

Water distribution systems corrosion control craftsmen will (OPR: Infrastructure Systems Element):

- Perform leak/failure inspections as required. Notify the BCCE of leaks and failures in the water distribution systems.
- Use AF Form 1687, Leak/Failure Data Record, for all leaks detected in the water distribution systems and forward to the BCCE.
- Coordinate with the water systems and treatment corrosion control craftsmen (Water & Waste) on possible water distribution leaks.
- Procure and retain custody of test equipment necessary for leak detection in the water distribution system.

C-2.1.5.10 Protective Coating Corrosion Control.

Protective coating corrosion control is normally accomplished by Service Contract (OPR: Operations Engineering):

- Update painting records as required.
- Report any damage found to the BCCE for subsequent repair or recommendations.
- Ensure Service Contractor applies suitable coatings to the structure and environment and ensure compatibility with previously applied coatings and other protective methods, such as CP.
- Together with the BCCE, inspect coatings on all high-cost steel structures semiannually.
- Coordinate closely with Operations Engineering to ensure compliance.
- Use AF Form 1687, Leak/Failure Data Record, an appropriate, and forward to the BCCE.

C-2.1.5.11 POL/JP4 Distribution Systems.

POL/JP4 distribution systems corrosion control craftsmen will (OPR: Infrastructure Systems Element):

- Perform leak/failure inspections as required. Notify the BCCE of leaks and failures in the POL/JP4 distribution systems.

- Use AF Form 1687, Leaks/Failure Data Record, for all leaks detected in the POL/JP4 distribution systems and forward to the BCCE.
- Procure and retain custody of test equipment necessary for leak detection in the POL/JP4 distribution systems.

C-2.1.6 Record Procedures.

Maintain the following records to support the Corrosion Control Program at Sample AFB as indicated.

C-2.1.6.1 Personnel Files.

Operations Flight and the BCCE maintain a current roster of corrosion control craftsmen. File contains training status and training program information.

C-2.1.6.2 Equipment Information.

BCCE maintains a list of corrosion control equipment with operational status. File contains the following information:

- Manufacturers' data on installed equipment.
- Lists of repair parts.
- Names and addresses on sources and parts.
- Current price lists.
- Repair, operating, and maintenance instructions.

C-2.1.6.3 System Information.

BCCE maintains files on water treatment systems, CP installations, protective coatings, and all other systems of corrosion control. File includes the following information:

- Standard design and construction specifications.
- Cross-reference listing of projects containing corrosion control.
- Shop and as-built drawings updated to show modifications.
- Cathodic Protection Program Records Booklet.
- Cathodic Protection Annual Performance.

C-2.1.6.4 Failure Records.

BCCE maintains records of corrosion control damage and facility failures. Forward to the BCCE the AF Form 1687, Leak/Failure Data Record, after completion by the appropriate corrosion control craftsmen. The BCCE further investigates the failure as appropriate. The BCCE indicates the location of the leak or failure on the base layout map. The BCCE records the corrective maintenance, repair, or applied corrosion control measures, including costs. Distribution of this form is one copy to each of the following:

- BCCE's record.
- Facility jacket.
- Cathodic Protection Annual Performance Booklet.
- AFCEC corrosion control Subject Matter Expert (SME).

C-2.1.6.5 Survey Records.

The BCCE maintains a continuous and current file of corrosion survey results and recommendations. These records contain the following information:

- Corrosion analysis team surveys, recommendations, and implementation plans.
- Architecture - Engineering (A-E) surveys and recommendations.
- Water and gas leak surveys.
- AF Form 1688, Annual Cathodic Protection Performance Survey.

C-2.1.6.6 Test Results.

The BCCE maintains records of test data and results. This file contains the following information:

- Boiler water analysis.
- Corrosion tester/coupon reports.
- Interference testing record sheets.
- Area of Influence Test Worksheet, using a modified AF Form 1688, Annual Cathodic Protection Performance Survey.
- AF Form 1689, Water Tank Calibration (for tank interiors).

C-2.1.6.7 Operational Logs.

The BCCE periodically reviews all operational logs. Distribute the following logs as indicated:

- The Non-Commissioned Officer in Charger (NCOIC), Water and Fuels Systems Maintenance, completes AF Form 1461, Water Utility Operating Log, and maintains it in Building 417. Upon request from BCCE, the NCOIC forwards a copy for review.
- The CP craftsman completes AF Form 491, Cathodic Protection Operating Log for Impressed Current System, and AF Form 1686, Cathodic Protection Operating Log for Sacrificial Anode System, and forwards copies to the BCCE for inclusion in the CP facility jacket folder and the Cathodic Protection Annual Performance Booklet.

- Heating, ventilation, and air conditioning (HVAC) boiler water systems and treatment corrosion control craftsman completes AF Form 1459, Water Treatment Operation Log for Steam and Hot Water, and forwards a copy to the BCCE.
- The cooling water systems and treatment corrosion control craftsman forwards one copy of all records maintained by their function to the BCCE.

C-2.1.6.8 Equipment Maintenance.

Maintain equipment maintenance records and maintenance action sheets (MASs) according to AFI 32-1001, *Operations Management*. Keep a copy of the AF Form 1841, *Maintenance Action Sheet*, in the facility jacket folder for corrosion control activities.

C-2.1.6.9 Cost Records.

The BCCE maintains continuous records. This file includes the following information:

- Failure costs from AF Form 1687, *Leak/Failure Data Record*.
- All other corrosion control costs, to include projects containing corrosion control measures. These costs include initial installations, recurring maintenance, and surveys. It is especially important to include all repairs by replacement projects and work orders to historically record the life cycle costs of the base infrastructure.

C-2.1.6.10 Requirements and Management Plans.

The BCCE includes corrosion control items for each system and component to minimize system life cycle costs.

C-2.2 Air Force Forms.

C-2.2.1 Form 491.

Entries on AF Form 491 must be made on a monthly basis. No readings of the S/E potentials are to be taken where the electrode is in contact with frozen ground. Readings are to be made with the authorized meters only (see note under item 10 of instructions). See Tables C-1 and C-2 for form items and specific instructions for completing each item. See Figures C-1 and C-2 for completed example forms.

Table C-1 Form 491 Item Descriptions

Item	Name	Description
1	Installations	Enter the official name and location of the installation (i.e., ROBINS AFB, GA). Do not abbreviate or use unit designations.
2	Year	Enter calendar year.
3	Protected Structure	Enter the name of the protected structure and its number as shown on United States Air Force (USAF) Real Property Report (RCS: HAF-PRES(SA)7115) as “Water Tank 603” or “Gas piping system family housing.”
4	Rectifier Number	Enter the number of the rectifier as assigned by the corrosion engineer. Numbers are consecutive starting with number 1 and are conspicuously shown on the rectifier.
5	Rectifier Data (from nameplate)	• **Manufacturer:** Enter full name and address of manufacturer. • **Model Number:** Enter model number as shown on nameplate. • **Serial Number:** Enter serial number as shown on nameplate. • **AC Rated Capacity:** Enter AC voltage and phase. • **DC Rated Capacity:** Enter DC voltage and amperage. • **Date Installed:** Enter date installed. This information is to be obtained from the BCCE. Where no detailed information is available, estimate and enter approximate date.
6	Ground Bed Data	• **Anode Material:** Enter the name of the material and alloy designation, if known, as “graphite,” “aluminum 3003,” or “high-silicon cast iron.” • **Size of Anode:** Enter the dimensions or the standard size designation as 1½" x 60" or 3" x 60." • **Number of Anodes:** Enter number of anodes. • **Type of Backfill:** Enter the type of backfill used around the anodes as “coke breeze” or “natural soil.” • **Date Installed:** Enter the date when the anode bed was installed.

Item	Name	Description
7	Location Reference Drawing Number	Enter the location of rectifier and test stations as recorded on the drawings. Enter the number of the drawing and the sheet number for easy reference.
8	Current Required	Enter the amount of current needed to give complete protection and the date such determination was made.
9	Location and Description	Enter a brief description of the location of the rectifier and test points in order to easily find them, as “west leg of tower,” “pole 468-1,” or “300 feet east of the side entrance of building 1450.” The test points indicated here and in items 10H through 10K for recording values are the same test points.
10	Operating Record	See Table C-2.
***Signature:** Each monthly log must be signed by the cathodic protection technician (CPT) and the BCCE before submission to higher headquarters.		

Table C-2 Form 491 Item 10 Operating Record

Name	Description
A	Enter the month tests are performed.
B	Enter the date of the month.
C* & E*	Enter the as found (before any adjustments are made) DC voltage in Column C and the DC current in column E.
D* & F*	If required, adjust the DC voltage level until the DC current is equal to or greater than the current requirement (item 8) and enter the as adjusted DC voltage in column D and DC current in column F.
G	The corrosion engineer must compute the circuit resistance using Ohm’s Law and enter the value in column G. $$Resistance = \frac{Adjusted\ Voltage}{Adjusted\ Amperage}$$
H	Test point 1 (referred to as “maximum potential area”) must be determined using data obtained from the annual performance survey. This point is located closest to the ground bed and is to be taken over the structure in that area. Enter this value in column H. Care must be taken to read the correct polarity.
I-K	Test points 2, 3, and 4 are the lowest potential points of the protected structure being protected by the rectifier. These test points must be determined using data obtained from the annual performance survey. They are subject to change as directed by the corrosion engineer. Enter the values found for the appropriate points.
L	State whether soil is wet, moist, dry, or powdery. **Note:** For the testing of S/E potentials, only authorized multimeters and potentiometers are used. For S/E potential readings, the potentiometer circuit must be used. If the ground is frozen, do not take readings and state so in column L by entering “GF.”
*Columns C through F are readings of DC voltage and DC current only. Readings must be taken with handheld calibrated meters, not rectifier meters.

REMARKS (Date and Initials)	CORRECTIVE ACTION (Date and Initials)
20 April 2018 NCP	Current dropped, troubleshooting determined bad Diode, replaced stacks.
15 June 2018 NCP	Cleaned rectifier cabinet and tightened connections.
18 August 2018 GF	Performed anode bed CIS, one failed anode, adjusted rectifier to meet current requirement.
14 Nov 2018 NCP	Current dropped below the current requirement, adjusted rectifier up one fine.

C-2.2.2 Form 1686.

Entries on AF Form 1686 are made biannually or more often if required by the parent command. No readings of the S/E potentials are to be taken where the ground is frozen. Readings are to be made with the authorized meters only. See Tables C-3 and C-4 for items and descriptions. Figures C-3 and C-4 depict examples of a completed form.

Table C-3 Form 1686 Items and Descriptions

Item	Name	Description
1	Installations	Enter the name of the protected structure and its number as shown on USAF Real Property Report (RCS: HAF-PRE(SA)7115), such as "Underground Gas Pipeline Capehart Hsg Nr 220."
2	Year	Enter calendar year.
3	Protected Structure	Enter the name of the protected structure and its number as shown on USAF Real Property Report (RCS: HAF-PRE(SA)7115), such as "Underground Gas Pipeline Capehart Hsg Nr 220."
4	Test Station Number	Enter the number of the test station where the reading of the potential is to be taken. Test stations should be numbered consecutively starting with number 1 for the entire base.
5	System Data	• **Number of Anodes:** From record, find the number of existing anodes on this system and enter it on the form. Also, note under remarks on back of form if any new anodes were installed during the last year and how many. • **Number of Test Stations:** Enter here the total number of test stations for this piping system. List the test stations by number.
6	Anode Data	• **Type:** Enter the name of the anode, trade name, its manufacturer, and the name of the material, as "magnesium H-1" or "zinc." • **Size:** Enter the dimensions or the standard size designations as "2" by 5' long" or "17 lbs.," or "32 lbs." • **Type of Backfill:** Enter the type of backfill used around the anodes as "prepackaged," "bentonite," "coke breeze," or "none." • **Location:** Enter a brief description of the location of the anode so that it can be located easily, as "gas line 50' W to 10' N of building 2263." • **Date Installed:** Enter date of installation. This date is supplied by the corrosion engineer. Where no detailed information is available, estimate and enter the approximate date.
7	Operating Record	See Table C-4.
***Signature:** Each log must be signed by the CPT and the BCCE before submission to higher headquarters.		

Table C-4 Form 1686 Item 7 Operating Record

Column	Description
A	Enter the month tests are performed.
B	Enter the date of the month of the survey.
C	S/E Potentials At Test Station (Volts). This reading is usually taken at the test station(s) of the system. Where no test stations are installed, readings must be taken at point as directed by the corrosion engineer. Enter the value found in column C.
D	S/E Potential Between Anodes (Volts). This is the potential-to-ground of the structure halfway between two anodes (or the most remote point of a structure from the anode protecting it). It is important to know how far the protection of an anode extends. Enter the value in column D.
E	Anode-to-Soil (Volts). This reading represents the open-circuit voltage of the anode with the structure (load) disconnected. Enter the reading in Column E.
F	Anode-to-Structure (Milliamps). Connect the milliamp meter between the structure and anode at the test station and enter the value in column F.
G	Soil Conditions. State whether soil is wet, moist, dry, or powdery. The condition of soil is approximately 1 foot below surface. If the ground is frozen, do not take readings and so state by entering “GF.”
H	Initials of Technician. The initials of the CPT must be shown in this column.

C-2.2.3 Form 1687.

Table C-5 lists the items and descriptions for Form 1687. See Figures C-5 and C-6 for completed example forms.

Table C-5 Form 1687 Items and Descriptions

Item	Description
Report Control Symbol	N/A
Installation	Enter the official name and location of the installation, such as “Fairchild AFB, WA.” DO NOT ABBREVIATE OR USE UNIT DESIGNATIONS, SUCH AS “FAFB.”
Facility Number	Enter the number of the facility, such as “Building 1376”or “Water Tank 904.”
Area/Specific Location	Enter the area, such as “North side of building 1376, 50' west of the fire hydrant.”
Drawing Number	Show drawing number of the map upon which this leak is located for the purpose of recording installation leak history.
Fluid Transported or Stored	Mark (x) in the block for the type of fluid or fill in the other (specify) block with the appropriate name of the fluid.
Average Temperature of Fluid	Enter average temperature in degrees Fahrenheit (°F).
Date	Enter the date of the structure (i.e., pipe, valve, or tank) installation.
Design Life	Enter the number of years (life expectancy) of the structure.
Type and Location of Storage Facility or Transport	Mark (x) in the appropriate block or fill in the other (specify) block for those not listed.
Date Leak/Failure Discovered	Enter the appropriate date, in day, month, and year format, such as “1 Feb 98.”
Size/Diameter	Enter the size of the storage facility or transport, such as “6"” or “500-gallon capacity.”
Line or Tank Depth	Enter the depth of the corroded structure.
Cause of Failure	Mark (x) in the appropriate block or enter the information in the block for other (specify).
Metal(s) and/or Substrate Affected	Write in the appropriate type of metal or substrate.
Specific Action Taken to Repair Leak	Write in the specific action taken to make repairs and identify the specific area(s) affected on the drawing.
*Cathodic Protection	Mark (x) if applicable.

Item	Description
Type System	Mark (x) in the appropriate block.
Protective Coatings	Mark (x) if applicable.
Coatings System Used	Specify the type of coating and/or wrap used if applicable.
Industrial Water Treatment	Mark (x) if applicable.
Type System	Mark (x) in the appropriate block.
As Found Condition	Describe the condition of the structure when the problem was discovered.
As Left Condition	Describe the work accomplished to repair the structure.
Specific Action Taken to Repair Cause of Leak or Failure	Describe the measures taken to prevent a reoccurrence of this problem.
Signatures	The form must be signed by the CPT and the BCCE before submitting to a higher authority.
*Second page – corrosion engineer directs.

C-2.3 Annual Performance Booklet.

The annual survey should be a hard cover, three-ring binder, and only one copy of the Cathodic Protection Annual Performance Booklet should be prepared. The booklet must be completed by 1 February following the year of survey for review and kept for review by any higher headquarters personnel.

The binder contains basic information and the annual survey data. Table C-6 lists the order of this information.

Table C-6 Annual Performance Booklet Binder Information

Tab	Tab Title	Description
A	Title Page	List the base, type of survey, date survey was completed, and the names of the corrosion engineer and the CPT.
B	Index	
C	General Description	Describe in detail and in numerical order what the CP systems on the base consist of: impressed current or galvanic, sacrificial anode system; how many systems installed and for which utilities or structures, such as: water distribution systems, gas distribution systems, POL, heating, and storage tanks. Add information on type of metal used in mains and service lines, types of coatings, when installed, and by whom.
D	Summary of Survey Analysis and Actions Required	Describe in detail reasons or probable reasons for either high- or low-potential measurements. Describe actions needed to provide protective potentials, estimated costs, and completion dates.
E	Base Cathodic Protection Operation and Maintenance Procedures	Provide a copy of the CP operations and maintenance procedures.
F	Cathodic Protection Program Record	Provide a copy of the CP program record. This record must be updated yearly, as necessary. It must have its individual data sheets, showing location of test points by building number or other landmarks. Maximum and minimum test points as required by AF Form 491 must be identified, such as 7h, 7i, 7j, 7k, for rectifier number 7.
G	Maintenance Action Sheet	

Tab	Tab Title	Description
H	Leak/Failure Data Records	Complete and provide one copy of AF Form 1687 for each failure that was caused by corrosion during the preceding year. This record must be kept on all systems without regard to the application of CP.
I	Master Plan Tab G-8	A copy of Tab G-8 of the master plan must be included.
J	Cathodic Protection Operating Logs	The operating logs from the preceding year must be included for each system.
K	Equipment	This tab should be used to list all CP equipment on hand and the condition of equipment.
L	Annual Performance Survey Data	All survey data must be provided, including areas that are resurveyed after rectifier adjustments are made. Each system as listed in the program record (Tab F) must have its individual data sheets, showing location of test points by building number or other landmarks. Maximum and minimum test points as required by AF Form 491 must be identified, such as 7h, 7i, 7j, 7k, for rectifier number 7.
M	Sketches and Drawings	A sketch must be provided for each underground tank system indicating location of tank and where readings were taken. Include any additional drawings that will assist in the evaluation of the survey data.
N	Personnel Roster	Provide a list of names and grades of the corrosion engineer and CPT, along with a description of their training in CP and along with the date received.

C-3 NAVY.

C-3.1 Naval Shore Facilities Corrosion Control Report.

C-3.1.1 Introduction.

The annual cost of corrosion within the Navy shore establishment is estimated to exceed $10 million, and facilities and equipment with a plant value of over $60 million are at risk of failure due to corrosion. Corrosion of Navy facilities is a common and serious problem and must be addressed to ensure their safe and economical operation. Corrosion impacts shore facilities in many more ways and to a far greater degree than regularly considered:

- Costly system repairs and replacements.
- Downtime and disruption of service.
- Expensive loss of product.

- Environmental and safety hazards.
- Decreased system capacities.
- Adverse impacts on operational readiness.

Action to control corrosion and to repair corrosion damage is among the most frequent reasons for performing maintenance on our facilities. By formulating and executing a facility corrosion protection plan, system life is extended and operational costs are reduced. It is important that we obtain maximum benefit from our facilities by applying corrosion control measures as lessening amounts of funds are available for maintaining and repairing facilities to meet critical mission requirements.

It is important to consider corrosion control during the design and construction of new facilities or the repair/replacement of existing facilities. In most cases, it is less costly to eliminate causes of corrosion and include corrosion control measures during the design and construction phase than to correct the problem after construction is complete.

C-3.1.2 Corrosion Control Program.

Corrosion control **is** considered as an integral part of the design, construction, operation, and maintenance of all facilities under the cognizance of Naval Facilities Engineering and Expeditionary Warfare Center (NAVFAC EXWC). POL systems, waterfront structures, utility systems, and antenna systems have been found to be the most critical facilities in terms of a combination of risk from corrosion, the need to provide a continuity of direct fleet support, and the cost effectiveness of utilizing appropriate corrosion control systems.

Corrosion control systems are planned, designed, installed, monitored, and maintained for:

- All POL liquid fuel pipelines and storage facilities in accordance with the provisions of Code of Federal Regulations (CFR) Title 49 Chapter 1, Part 195, Transportation of Liquids by Pipeline and CFR Title 40 Chapter 1, Part 112, Oil Pollution Prevention.
- All natural gas pipelines in accordance with the provisions of CFR Title 49 Chapter 1, Part 192, Transportation of Natural and Other Gas by Pipeline.
- All steel underground storage tank systems in accordance with CFR 40 Part 280, Technical Standards and Corrective Action for Owners and Operators of Underground Storage Tanks, or more stringent state/local regulations as applicable.
- All buried or submerged metallic shore facilities in which the electrolyte (soil or water) resistivities are below 10,000 ohm-cm at the installation depth at any point along the installation.
- Other facilities as indicated in NAVFACENGCOM letter 11012 04C/cmm of 31 May 1994, Cathodic Protection Systems, Interim Technical Guidance.

- Overseas activities should comply with the requirements of the DoD Overseas Environmental Baseline Guidance Document and applicable area governing standards.

NAVFACENGCOM letter 11012 04C/cmm of 31 May 1994, Cathodic Protection Systems, Interim Technical Guidance describes the policy in more detail. For any questions on the policy, please contact your Engineering Field Division (EFD) CP program manager or the NAVFACENGCOM Cathodic Protection Technical Expert at the Naval Facilities Engineering Service Center (NFESC).

C-3.1.3 Corrosion Control.

The corrosion control systems described below are those most commonly used on shore facilities.

C-3.1.3.1 Protective Coatings.

Coatings provide protection to a variety of substrates (e.g., metals, wood, concrete) by forming a barrier to the surrounding environment. The continuing integrity of this barrier film is necessary for continuing protection.

C-3.1.3.2 Cathodic Protection.

Metal structures (including rebar), buried or immersed in electrolyte (e.g., soil, water, concrete), can be cathodically protected from external corrosion. This method of protection, normally used in conjunction with coatings, is achieved by transferring the corrosion to other cheaper “anode” materials that are sacrificed to protect the structure. The two basic types of CP systems are “sacrificial (galvanic) anode” and “impressed current.” All CP systems require periodic maintenance and adjustment to ensure system integrity and continuous control of corrosion.

C-3.1.3.3 Other Methods.

Other corrosion control methods include:

- Proper design techniques to eliminate conditions conducive to corrosion (e.g., contact of dissimilar metals).
- Selection of materials resistant to the particular environment.
- Use of chemical inhibitors or treatments in a closed system.

C-3.1.4 NAVFACENGCOM Headquarters.

NAVFACENGCOM Headquarters establishes policy, provides oversight, and provides budget guidance.

C-3.1.5 CP System Reporting.

Figures C-10, C-11 and C-12 are sample report forms. Similar report forms having the test data described below may be substituted. Contact the cognizant EFD for more information on CP system reporting, special report form requirements, and approval of substitute report forms.

- Structure-to-electrode potential readings generally shall be recorded quarterly, but no less than annually.
- Rectifier settings and outputs generally shall be recorded no less than bimonthly.

APPENDIX D TRAINING AND CERTIFICATION

D-1 INTRODUCTION.

All personnel assigned to CP duties must receive initial, annual, and/or refresher training and/or required certifications. This training should equip personnel with the ability to apply NACE criteria to determine the effectiveness of applied CP and the ability to troubleshoot the CP system if inoperative. Applicable personnel may require specialized training for protective coatings, industrial waste treatment, and/or for design and construction projects.

D-2 SOURCES.

CorrDefense is a DoD web site for the Office of Corrosion Policy and Oversight and is operated and maintained by the Logistics Management Institute. CorrDefense offers technical papers, key corrosion documentation, briefs by academia, Government, and Industry, and links to training opportunities. These resources can be accessed at www.corrdefense.org.

NACE International® - NACE is a professional organization for corrosion control offering CP training opportunities. For more information on available courses and upcoming seminars providing training opportunities, see NACE International (www.nace.org).

APPENDIX E TYPES OF CORROSION

It is convenient to classify corrosion by the forms in which it manifests itself, the basis for this classification being the appearance of the corroded metal. Each form can be identified by visual observation, although, in some cases, magnification is required. Valuable information for the solution of a corrosion problem can often be obtained through careful observation of the corroded test specimens or failed equipment. Examination before cleaning is particularly desirable.

Some of the eight forms of corrosion are unique, but all of them are more or less interrelated. The eight forms are: (1) uniform, or general attack, (2) galvanic, or two-metal corrosion, (3) crevice corrosion, (4) pitting, (5) intergranular corrosion, (6) selective leaching, or parting, (7) erosion corrosion, and (8) stress corrosion. This listing is arbitrary but covers practically all corrosion failures and problems. The forms are not listed in any particular order of importance. Below, the eight forms of corrosion are discussed in terms of their characteristics, mechanisms, and preventive measures. Hydrogen damage, although not a form of corrosion, often occurs indirectly as a result of corrosive attack and is, therefore, included in this discussion.

E-1.1 Uniform Attack.

Uniform attack is the most common form of corrosion. It is normally characterized by a chemical or electrochemical reaction that proceeds uniformly over the entire exposed surface or over a large area. The metal becomes thinner and eventually fails. For example, a piece of steel or zinc immersed in dilute sulfuric acid normally dissolves at a uniform rate over its entire surface. A sheet iron roof shows essentially the same degree of rusting over its entire outside surface.

Uniform attack, or general overall corrosion, represents the greatest destruction of metal on a tonnage basis. This form of corrosion, however, is not of too great concern from the technical standpoint, because the life of equipment can be accurately estimated on the basis of comparatively simple tests. Merely immersing specimens in the fluid involved is often sufficient. Uniform attack can be prevented or reduced by (1) proper materials, including coatings, (2) inhibitors, or (3) cathodic protection.

E-1.2 Galvanic or Two-Metal Corrosion.

A potential difference usually exists between two dissimilar metals when they are immersed in a corrosive or conductive solution. If these metals are placed in contact (or otherwise electrically connected), this potential difference produces electron flow between them. Corrosion of the less corrosion-resistant metal is usually increased, and attack of the more resistant material is decreased, as compared with the behavior of these metals when they are not in contact. The less resistant metal becomes anodic and the more resistant metal becomes cathodic. Usually the cathode or cathodic metal corrodes very little or not at all in this type of couple. Because of the electric currents and dissimilar metals involved, this form of corrosion is called galvanic, or two-metal, corrosion. It is electrochemical corrosion, but we shall restrict the term galvanic to dissimilar-metal effects for purposes of clarity.

E-1.3 Crevice Corrosion.

Intense localized corrosion frequently occurs within crevices and other shielded areas on metal surfaces exposed to corrosives. This type of attack is usually associated with small volumes of stagnant solution caused by holes, gasket surfaces, lap joints, surface deposits, and crevices under bolt and rivet heads. As a result, this form of corrosion is called crevice corrosion or, sometimes, deposit or gasket corrosion.

E-1.4 Pitting.

Pitting is a form of extremely localized attack that results in holes in the metal. These holes may be small or large in diameter, but in most cases they are relatively small. Pits are sometimes isolated or so close together that they look like a rough surface. Generally a pit may be described as a cavity or hole with the surface diameter about the same as or less than the depth.

Pitting is one of the most destructive and insidious forms of corrosion. It causes equipment to fail because of perforation with only a small percent weight loss of the entire structure. It is often difficult to detect pits because of their small size and because the pits are often covered with corrosion products. In addition, it is difficult to measure quantitatively and compare the extent of pitting because of the varying depths and numbers of pits that may occur under identical conditions. Pitting is also difficult to predict by laboratory tests. Sometimes the pits require a long time—several months or a year—to show up in actual service. Pitting is particularly vicious because it is a localized and intense form of corrosion, and failures often occur with extreme suddenness.

E-1.5 Intergranular Corrosion.

Grain boundary effects are of little or no consequence in most applications or uses of metals. If a metal corrodes, uniform attack results since grain boundaries are usually only slightly more reactive than the matrix. However, under certain conditions, grain interfaces are very reactive and intergranular corrosion results. Localized attack at and adjacent to grain boundaries, with relatively little corrosion of the grains, is intergranular corrosion. The alloy disintegrates (grains fall out) and/or loses its strength.

Intergranular corrosion can be caused by impurities at the grain boundaries, enrichment of one of the alloying elements, or depletion of one of these elements in the grain-boundary areas. Small amounts of iron in aluminum, wherein the solubility of iron is low, have been shown to segregate in the grain boundaries and cause intergranular corrosion. It has been shown that, based on surface tension considerations, the zinc content of a brass is higher at the grain boundaries. Depletion of chromium in the grain-boundary regions results in intergranular corrosion of stainless steels.

E-1.6 Selective Leaching.

Selective leaching is the removal of one element from a solid alloy by corrosion processes. The most common example is the selective removal of zinc in brass alloys (dezincification). Similar processes occur in other alloy systems in which aluminum;

iron, cobalt, chromium, and other elements are removed. Selective leaching is the general term to describe these processes, and its use precludes the creation of terms such as dealuminumification, decobaltification, etc. Parting is a metallurgical term that is sometimes applied, but selective leaching is preferred.

E-1.7 Erosion Corrosion.

Erosion corrosion is the acceleration or increase in rate of deterioration or attack on a metal because of relative movement between a corrosive fluid and the metal surface. Generally, this movement is quite rapid, and mechanical wear effects or abrasion are involved. Metal is removed from the surface as dissolved ions, or it forms solid corrosion products, which are mechanically swept from the metal surface. Sometimes, movement of the environment decreases corrosion, particularly when localized attack occurs under stagnant conditions; this is not erosion corrosion because deterioration is not increased.

Erosion corrosion is characterized in appearance by grooves, gullies, waves, rounded holes, and valleys and usually exhibits a directional pattern. In many cases, failures because of erosion corrosion occur in a relatively short time, and they are unexpected largely because evaluation corrosion tests were run under static conditions or because the erosion effects were not considered.

E-1.8 Stress-Corrosion Cracking.

Stress-corrosion cracking refers to cracking caused by the simultaneous presence of tensile stress and a specific corrosive medium. Many investigators have classified all cracking failures occurring in corrosive media as stress-corrosion cracking, including failures due to hydrogen embrittlement. However, these two types of cracking failures respond differently to environmental variables. To illustrate, cathodic protection is an effective method for preventing stress-corrosion cracking; whereas, it rapidly accelerates hydrogen-embrittlement effects. Hence, the importance of considering stress-corrosion cracking and hydrogen embrittlement as separate phenomena is obvious. For this reason, the two cracking phenomena are discussed separately in this chapter.

During stress-corrosion cracking, the metal or alloy is virtually unattacked over most of its surface, while fine cracks progress through it. This cracking phenomenon has serious consequences, since it can occur at stresses within the range of typical design stress. Exposure to boiling $MgCl_2$ at 310°F (154°C) is shown to reduce the strength capability to approximately that available at 1200°F.

F-2 DEFINITIONS

amphoteric metal: A metal that is susceptible to corrosion in both acid and alkaline environments.

anode: The electrode of an electrochemical cell at which oxidation occurs. (Electrons flow away from the anode in the external circuit. It is usually the electrode where corrosion occurs and metal ions enter solution.)

anode bed: One or more anodes installed—underground or submerged—for the purpose of supplying cathodic protection. It is often called a "ground bed."

backfill: Material placed in a hole to fill the space around the anodes, vent pipe, and buried components of a cathodic protection system. For the purposes of this standard, "backfill" is also defined as the material (native or imported) used to fill a pipeline trench.

beta curve: A plot of dynamic (fluctuating) stray current or related proportional voltage (ordinate) versus the corresponding structure-to-electrolyte potentials at a selected location on the affected structure (abscissa). For the purposes of this standard, "beta curve" is defined as a correlation between the pipe-to-soil potential of the affected pipeline and the open-circuit potential between the affected pipeline and the stray current source.

cable: One conductor or multiple conductors insulated from one another.

casing: A metallic pipe (normally steel) installed to contain a pipe or piping.

cathode: The electrode of an electrochemical cell at which reduction is the principal reaction. (Electrons flow toward the cathode in the external circuit.)

cathodic disbondment: The destruction of adhesion between a coating and the coated surface caused by products of a cathodic reaction.

cathodic polarization: (1) The change of electrode potential caused by a cathodic current across the electrode/electrolyte interface; (2) a forced active (negative) shift in electrode potential. See *polarization*.

cathodic protection: A technique to reduce the corrosion of a metal surface by making that surface the cathode of an electrochemical cell.

cathodic protection criterion: Standard for assessment of the effectiveness of a cathodic protection system.

coating: (1) A liquid, liquefiable, or mastic composition that, after application to a surface, is converted into a solid protective, decorative, or functional adherent film; (2) (in a more general sense) a thin layer of solid material on a surface that provides improved protective, decorative, or functional properties. Coatings used in conjunction with cathodic protection are electrically isolating materials applied to the surface of the metallic structure that provide an adherent film that isolates the metallic structure from the surrounding electrolyte. The thickness and structure of the coating type vary according to the environment and application parameters.

coating disbondment: Loss of adhesion between a coating and the pipe surface.

coating system: The complete number of coats and type applied to a substrate in a predetermined order. (When used in a broader sense, surface preparation, pretreatments, dry film thickness, and manner of application are included.)

conductor: A material suitable for carrying an electric current. It can be bare or insulated.

continuity bond: A connection, usually metallic, that provides electrical continuity between structures that can conduct electricity.

correlation: (1) A causal, complementary, parallel, or reciprocal relationship, as by having corresponding characteristics. (2) (As used in Section 9) Simultaneous measurement of two dynamic (time-varying) parameters, e.g., voltage and current, presented in an X-Y plot to determine the relative relationship between the two parameters and whether the fluctuations over time are caused by one or more sources of stray current.

corrosion: The deterioration of a material, usually a metal, that results from a chemical or electrochemical reaction with its environment.

corrosion potential (Ecorr): The potential of a corroding surface in an electrolyte measured under open-circuit conditions relative to a reference electrode (also known as “electrochemical corrosion potential,” “free corrosion potential,” and “open-circuit potential”).

corrosion rate: The time rate of progress of corrosion. (It is typically expressed as mass loss per unit area per unit time, penetration per unit time.)

current applied potential: The half-cell potential of an electrode measured while protective current flows through the electrolyte environment, typically measured with respect to a reference electrode placed at the soil surface.

current density: The electric current to or from a unit area of an electrode surface.

diode: A bipolar semiconducting device having a low resistance in one direction and a high resistance in the other.

disbondment: The loss of adhesion between a coating and the substrate.

distributed-anode impressed current system: An impressed current anode configuration in which the anodes are “distributed” along the structure at relatively close intervals such that the structure is within each anode’s voltage gradient. This anode configuration causes the electrolyte around the structure to become positive with respect to remote earth.

electrical isolation: The condition of being electrically separated from other metallic structures or the environment.

electrical shielding: Preventing or diverting the cathodic protection current from its intended path.

electrical survey: Any technique that involves coordinated electrical measurements taken to provide a basis for deduction concerning a particular electrochemical condition relating to corrosion or corrosion control.

electrode: A material that conducts electrons and is used to establish contact with an electrolyte and through which current is transferred to or from an electrolyte.

electrolyte: A chemical substance containing ions that migrate in an electric field. For the purposes of this standard, “electrolyte” refers to the soil or liquid adjacent to and in contact with an underground or submerged metallic piping system, including the moisture and other chemicals contained therein.

electrolytically contacted pipeline casing: A casing that contains soil or water electrolyte in contact with both the casing and the carrier pipe.

electro-osmotic effect: Passage of a charged particle through a membrane under the influence of a voltage. Soil or coatings can act as the membrane.

empirical: Originating in or based on observation or experience.

foreign structure: Any metallic structure that is not intended as a part of a system under cathodic protection.

free corrosion potential: See *corrosion potential*.

galvanic anode: A metal that provides sacrificial protection to another metal that is more noble when electrically coupled in an electrolyte. This type of anode is the electron source in one type of cathodic protection.

galvanic series: A list of metals and alloys arranged according to their corrosion potentials in a given environment.

holiday: A discontinuity in a protective coating that exposes unprotected surface to the environment.

impressed current: An electric current supplied by a device employing a power source that is external to the electrode system. (An example is direct current for cathodic protection.)

in-line inspection: The inspection of a pipeline using an electronic instrument or tool that travels along the interior of the pipeline.

instant off potential: The polarized half-cell potential of an electrode taken immediately after the cathodic protection current is stopped, which closely approximates the potential without IR drop (i.e., the polarized potential) when the current was on.

interference: Any electrical disturbance on a metallic structure as a result of stray current.

interference bond: An intentional metallic connection between metallic systems in contact with a common electrolyte designed to control electrical current interchange between the systems.

IR drop: See *voltage drop*.

isolation: See *electrical isolation*.

line current: The direct current flowing in a pipeline.

linear anode impressed current system: An impressed current anode configuration in which a continuous anode is installed parallel to the structure such that the structure is within the anode voltage gradient.

long line current: Current through the earth between an anodic and a cathodic area that returns along an underground metallic structure (usually used only where the areas are separated by considerable distance and where the current results from concentration-cell action).

mechanical damage protection: Any material or equipment used to eliminate or minimize damage to the piping system (as might be caused from soil stresses and damage caused from rocks, debris, or other outside forces) without inhibiting or interfering with CP.

mechanical damage protection system: Consists of multiple processes and products to achieve protection for the piping and coating system.

mechanical shielding: Protective cover against mechanical damage. See *mechanical damage protection* and *mechanical damage protection system*.

microbiologically influenced corrosion (MIC): Corrosion affected by the presence or activity, or both, of micro-organisms.

mixed potential: A potential resulting from two or more electrochemical reactions occurring simultaneously on one metal surface.

nonadhered: Not bonded to the surface by chemical reaction or mechanical means.

nonshielding coating system: A coating system with a failure mode (e.g., loss of adhesion) that does not prevent distribution of cathodic protection current to the metal substrate.

oxidation: (1) Loss of electrons by a constituent of a chemical reaction; (2) Corrosion of a material that is exposed to an oxidizing gas at elevated temperatures.

pipe-to-electrolyte potential: See *structure-to-electrolyte potential*.

pipeline casing: See *casing*.

polarization: The change from the open-circuit potential as a result of current across the electrode/electrolyte interface.

polarized potential: (1) (general use) The potential across the electrode/electrolyte interface that is the sum of the corrosion potential and the applied polarization; (2) (cathodic protection use) The potential across the structure/electrolyte interface that is the sum of the corrosion potential and the cathodic polarization.

reduction: Gain of electrons by a constituent of a chemical reaction.

reference electrode: An electrode having a stable and reproducible potential, which is used in the measurement of other electrode potentials.

reverse current switch: A device that prevents the reversal of direct current through a metallic conductor.

shielding: (1) Protecting; protective cover against mechanical damage; (2) Preventing or diverting cathodic protection current from its natural path. For the purposes of this standard, see *electrical shielding* and *mechanical shielding*.

shorted pipeline casing: A casing that is in direct metallic contact with the carrier pipe.

sound engineering practices: Reasoning that exhibits or is based on thorough knowledge and experience, is logically valid, and has technically correct premises that demonstrate good judgment or sense in the application of science.

stray current: Current through paths other than the intended circuit.

stray-current corrosion: Corrosion resulting from stray current.

structure-to-electrolyte potential: The potential difference between the surface of a buried or submerged metallic structure and electrolyte that is measured with reference to an electrode in contact with the electrolyte.

telluric current: Current in the earth as a result of geomagnetic fluctuations.

unbonded: To have lost the ability to adhere to a surface to which it has been applied and has become disbonded or to have never been adhered (nonadhered) to a surface to which it has been applied.

voltage: An electromotive force or a difference in electrode potentials expressed in volts.

voltage drop: The voltage across a resistance when the current is applied in accordance with Ohm’s Law. This term is also referred to as “IR drop.”

weak acids: Acids that only partially dissociate to form hydrogen (H+) ions at moderate concentrations.

wire: A slender rod or filament of drawn metal. In practice, the term is also used for smaller-gauge conductors.

Record of Changes (changes are indicated by \1\…/1/)

Change No.	Date:	Location
1	1 October 2021	Critical and substantive CCRs and service-specific requirements throughout Chapters 1-3; new Chapter 4.

This UFC supersedes MIL-HDBK 1004/6, *Lightning Protection*, and Army TM 5-811-3/ Air Force AFM 88-9 Chapter 3, *Electrical Design, Lightning and Static Electricity Protection*.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFCs will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFCs are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Center for Engineering and the Environment (AFCEE) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFCs are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFCs printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
CHANGE SUMMARY SHEET

Document: UFC 3-575-01, *Lightning and Static Electricity Protection Systems*

Superseding: MIL-HDBK 1004/6, *Lightning Protection*, and Army TM 5-811-3/ Air Force AFM 88-9 Chapter 3, *Electrical Design, Lightning and Static Electricity Protection*.

Description: **\1** UFC 3-575-01 provides guidance for design criteria, establishes standards for static electricity protection and lightning protection from both direct and indirect strikes and surges, and describes bonding and grounding methods related to those static and lightning protection systems. This UFC applies to facilities and other structures. **/1/**

Reasons for Document:

- **\1** Incorporate new and revised industry standards applicable to DoD.
- Provide technical requirements for systems that protect assets and personnel.
- Describe and allow the use of equivalent protection when supported by calculations or justification.
- Clarify who is qualified to decide “equivalency” of substitutions in material and equipment submittals.
- Provide standard methods of inspection to ensure LPS systems remain compliant with codes and regulations (NFPA and OSHA). **/1/**
- Standardize the Tri-service criteria using NFPA 780. Applicable portions of UL 96A are incorporated, but UL 96A is no longer relied upon as a basis for compliance.

\1\ Impact: The following benefits should be realized:

- Improved guidance for surge protective device requirements. **/1/**
- Standardized guidance to assist engineers in the development of the plans, specifications, calculations, and Design/Build Request for Proposals (RFP).
- **\1** Standardized guidance to assist maintenance and inspection personnel in repairs which involve minimal design.
- Coordination with all electrical-related UFCs and UFGSs and consistency in guidance with the other electrical-related UFCs and UFGSs. **/1/**

Unification Issues:

- The Air Force uses a Shepherd's Crook design for static ground protection, which is shown in Figure 2-2. Although not considered a unification issue, it is listed as an Air Force-only criterion since the Army no longer uses this style and the Navy never did use this style.
- A 100% test point inspection is required by all services. This inspection must be performed by a third party (not the designer and not the installer). This must also be accomplished on smaller projects, such as roofing and HVAC, where lightning protection systems are installed on the facility **\1** to ensure the LPS is not damaged or reconfigured during construction.
- **For Navy:** Explosives Safety must be involved in a 100 percent test point inspection prior to acceptance, with 100 percent testing repeated at six months and one year.
- **For Army:** 100 percent review of test points plus requirements in Army Pamphlet 385-64 will be the basis of approval. **/1/**

TABLE OF CONTENTS

FIGURES

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE.

This UFC provides policy and design requirements for static electricity protection, and for lightning protection systems and related grounding for facilities and other structures. The information provided herein must be utilized by electrical engineers, including A/Es, in the development of the plans, specifications, calculations, and Design/Build requests for Proposal (RFP) and must serve as minimum electrical design requirements. It is applicable to the traditional electrical services customary for Design-Bid-Build construction contracts. Project conditions may dictate the need for a design that exceeds these minimum requirements. A design analysis is required.

UFC 3-501-01, *Electrical Engineering*, provides the governing criteria for electrical systems, explains the delineation between the different electrical-related UFCs, and refers to UFC 3-575-01 for static electricity protection and lightning protection system requirements. Refer to UFC 3-501-01 for design analysis, calculation, and drawing requirements.

\1\ For Air Force: One set of half-size drawings is required for AFCEC/COSM at each design milestone. **/1/**

1-2 APPLICABILITY.

Compliance with this UFC is mandatory for DoD facilities located on or outside DoD installations, whether acquisition is by appropriated or non-appropriated funds or by third party finance and construction. Facilities cover all temporary or permanent structures, including waterfront facilities, outside storage, and shore protection for ships and aircraft.

Criteria in this UFC apply to DoD-leased facilities outside DoD installations, whether by appropriated or non-appropriated funds, or by third party finance and construction, when DoD or DoD contractor maintains the facility.

1-3 GENERAL BUILDING REQUIREMENTS.

UFC 1-200-01, *General Building Requirements*, provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, sustainability, and safety.

Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein. **\1** If conflicts between UFCs are noted, this UFC takes precedence for LPS and static systems. **/1/**

\1

1-4 EQUIVALENCY.

Equivalency is an alternative to codes and specifications that has the same protective results as the method or equipment specified. Equivalency must be determined only by a certified person trained to perform installation, maintenance, testing, and repair of the systems addressed in this UFC, or by an electrical engineer. **/1/**

1-5 REFERENCES.

Appendix B contains a list of references used in this UFC. References applicable to a specific topic are also listed and described in the appropriate sections of this UFC.

1-6 KEY CODES AND STANDARDS.

Comply with the following codes and standards:

- IEEE 142, *IEEE Recommended Practice for Grounding of Industrial and Commercial Power Systems*
- **\1** IEEE 1100, Powering and Grounding Electronic *Equipment*, “Emerald” Book **/1/**
- NFPA 70, *National Electrical Code*
- NFPA 70B, *Recommended Practice for Electrical Equipment Maintenance*
- NFPA 77, *Recommended Practice on Static Electricity*
- NFPA 780, *Standard for the Installation of Lightning Protection Systems*
- UL 96, *Lightning Protection Components*
- UL 467, *Grounding and Bonding Equipment*
- **\1** (ANSI/)UL 1449, *Standard for Surge Protective Devices*, Fourth Edition or later **/1/**

Ordnance facilities or locations where ordnance and explosives are handled and stored require special protective measures. Comply with the following documents for these systems:

- UFC 4-420-01, *Design: Ammunition and Explosives Storage Magazines* (DRAFT)
- NAVSEA OP-5, Volume 1, *Ammunition and Explosives Ashore*
- **\1** AFMAN 32-1065, *Grounding Systems*
- Air Force Manual (AFMAN) 91-201, *Explosive Safety Standards*
- Air Force Manual (AFMAN) 91-118, *Safety Design and Evaluation Criteria for Nuclear Weapon Systems* **/1/**
- Department of the Army Pamphlet 385-64, *Ammunition and Explosives Safety Standards*
- **\1** MIL-STD 188-124B, *Grounding Bonding and Shielding for Common Long Haul Tactical Communication Systems Including Ground Based Communications Electronics Facilities and Equipment* (U. S. Navy) **/1/**

Additional requirements associated with grounding, bonding, and shielding of communications facilities are provided in MIL-HDBK 419A, *Grounding, Bonding and Shielding for Electronic Equipment and Facilities*.

\1 Note: Ground testing of equipment is the responsibility of the equipment owner/user. **/1/**

This Page Intentionally Left Blank

CHAPTER 2 STATIC ELECTRICITY PROTECTION

2-1 STATIC GROUNDING AND BONDING REQUIREMENTS.

Identify hazardous classified locations in accordance with NFPA 70. Provide grounding and bonding for these areas in accordance with NFPA 77 to support the intended operations.

Include a listing of hazardous materials, containers, and operating units in the design, and indicate fixed operating equipment locations on the drawings. Identify portable and movable equipment requiring static electricity grounding distinctively by location and with type of grounding method each location requires.

\1

2-1.1 Bonding and Grounding Conductors.

Bonding and grounding conductors must be sturdy enough to withstand mechanical damage and must not be smaller than 6 AWG copper. For added flexibility, use braided cable or flexible bonding straps for static grounds on portable or movable equipment. Install at least two separate braided cables or flexible bonding straps on portable or movable equipment such as doors, hinged shelves, or tables, for redundancy. Flexible cables or straps have a shorter life than solid copper, especially since they must be replaced once 50% of the strands are broken. Conductors are typically uninsulated. Apply bonding for other facilities in accordance with NFPA 70 and NFPA 780. Before securing any bond, prepare for electrical continuity by removing any paint, oil, dirt, or rust on contact surfaces. If factory coatings are removed by chemicals used in the preparation process, that coating must be reapplied to protect against corrosion. A resistance reading of one ohm or less is required across bonds, to indicate continuity. **/1/**

2-1.2 Connections.

Do not connect static grounds above grade to:

- Electrical equipment grounding systems.
- Telecommunications systems grounds.
- Gas, steam, oil, hydraulic, hot water or airlines.
- Sprinkler systems.
- Any component of the lightning protection system (LPS).
- **\1** Down conductors. **/1/**

These systems must be interconnected below grade. As an exception to performing the calculations required by NFPA 780, the 6 foot (1.83 m) bonding requirement allowed by UL 96A may be used. The preferred method for reducing the potential for side-flash is to increase the separation distance between the static ground and the six items above, so that a bond is not required. The minimum size of the bonding conductor is 6 AWG copper.

\1 A static ground should never be bonded to a down conductor. It should be bonded to the building power system ground either at the service ground rod or at the main distribution panel or motor control center where the neutral bus bar and ground bus bar are bonded together.

Static bonds must be bonded only to component paths designed for static dissipation. **/1/**

2-1.3 Static Bus Bars.

A static bus typically consists of 2 inch x ¼ inch (51 mm x 6 mm) copper bars installed on the interior wall of the facility, as shown in Figure 2-1. Static bus bars must be used only for static grounding. Bus bars, especially those used in the telecommunications industry, may come with insulators, if specified when ordering. Static bus bars must be isolated from other grounding subsystems as much as possible and must be isolated when used for ordnance grounding and from lightning protection down conductors including steel columns used as the down conductor. The grounding system for the static bus bars is typically connected to the building grounding system by running at floor level on the interior until it can be routed to the exterior to the single point facility ground rod or be bonded to a ground rod and the ground rod bonded to the ground ring electrode. This configuration will allow the static bus bar to be grounded even if the ground ring electrode is broken or compromised, or requires replacement.

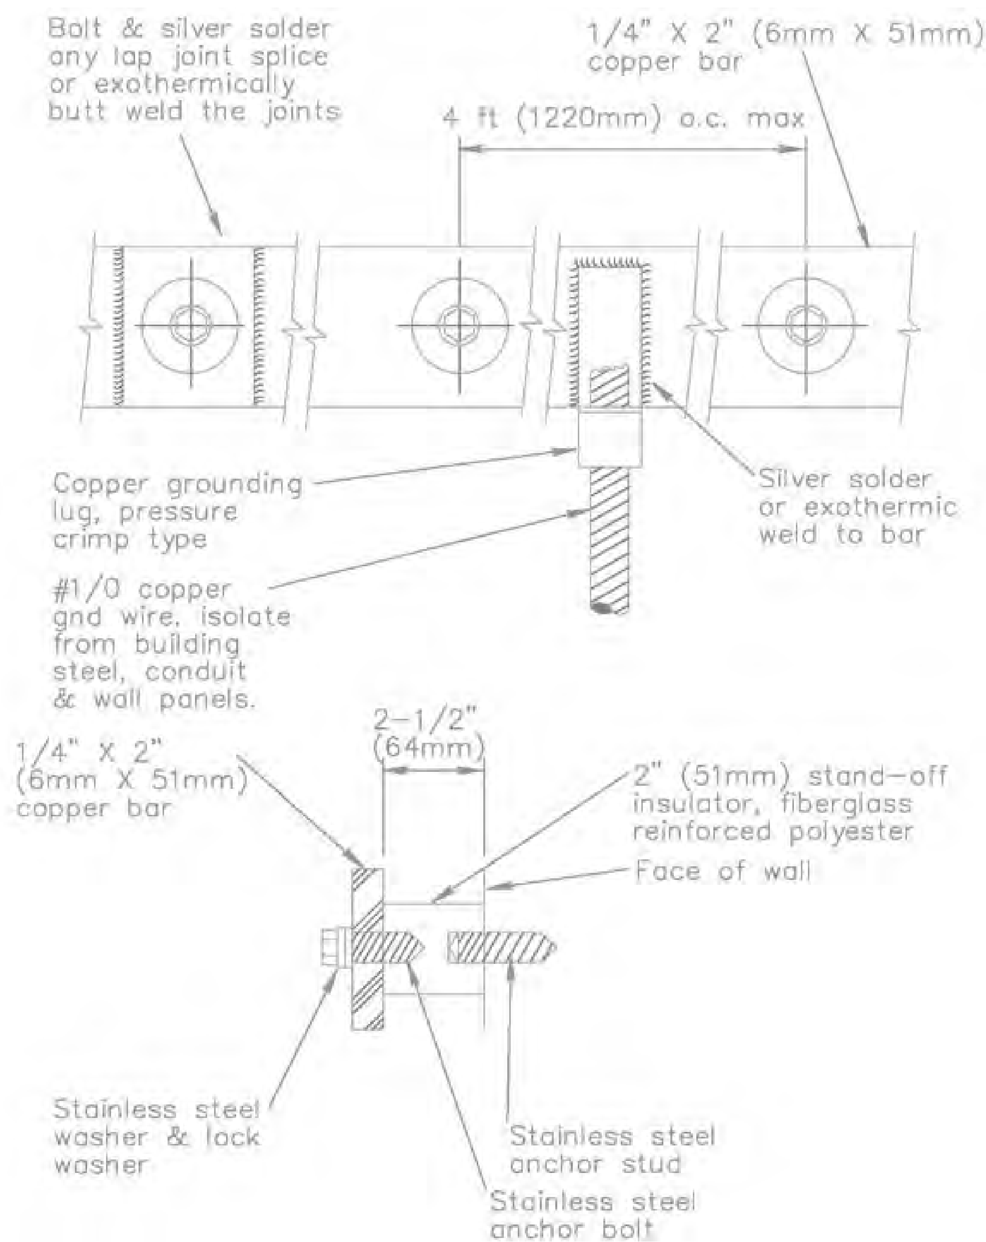
2-1.4 Resistance to Ground.

Current caused by static electricity is typically on the order of milliamperes. A resistance to ground of 10,000 ohms is more than adequate to bleed off normal static charges. All grounds used for static protection in DoD facilities, including those for aircraft and fuel tanks, must have a maximum resistance of 10,000 ohms. Any danger of electrical shock hazard caused by the 10,000 ohm value can be eliminated by proper bonding to other grounding media.

2-1.5 Ground Grab Bars.

Ground grab bars **\1** should **/1/** be installed immediately outside entrance doors to operating buildings, rooms or structures where special hazards exist. A ground grab bar consists of a length of non-corroding conductive pipe or bar which is connected to the earth electrode system (EES).

Figure 2-1 Static Bus Bar



2-2 GENERAL APPLICATIONS.

2-2.1 Conditions.

\1 This UFC does not identify all applications where static electricity protection should be provided. The electrical designer must analyze suspected potential static electrical charges and address the conductive paths that could reasonably exist between them. The following conditions are critical examples. For other concerns such as wrist stats, gloves, or boots, contact the Electrostatic Dissipation Association (ESDA). **/1/**

- Hazardous area classifications and locations, as listed in the NFPA 70. The electrical design must incorporate the requirements of the using service relative to hazardous materials, equipment, and containers to enable the construction contractor to proceed with a full understanding of static electricity protection requirements.
- **\1** Locations where hazardous materials are handled need to be assessed on an individual basis to determine if static electricity is a problem. **/1/**
- Relocatable and portable equipment having static-electricity-generating capabilities potentially dangerous to personnel.
- Locations containing explosives or related types of materials must comply with applicable Service requirements for ordnance facilities; refer to the paragraph entitled “Key Codes and Standards.”

2-2.2 Applications.

Comply with NFPA 77, including the following types of applications:

- Spray painting operations; also apply NFPA 33.
- Conductive flooring.
- Conductive conveyor belts and V-belts.
- Humidification. If humidification is used to control static electricity discharges, daily checks are required to ensure humidity levels are maintained within specified levels.

Static electricity protection for other facilities must satisfy the requirements within this UFC. Protection for other facilities must be assessed on a project-by-project basis only. Where criteria of other Federal agencies conflict with criteria contained in this UFC, the more stringent criteria apply.

Ionization techniques are covered in NFPA 77. Ionization techniques are not to be used in hazardous areas. Radioactive ionization sources are not allowed.

2-3 SPECIFIC APPLICATIONS.

\1

2-3.1 Petroleum Oil Lubricants (POL) Facilities.

This paragraph pertains to static electricity protection for pumping, distribution, and fueling and defueling storage and handling facilities. Fueling and defueling of fixed wing aircraft on the ground is discussed in the paragraph entitled “Aircraft Parking Aprons”. Comply with UFC 3-460-01.

Impressed current type cathodic protection systems can cause voltage gradients on the surface. The aircraft requires protection from those gradients, so an isolation flange is installed. Since we are protecting aircraft and personnel from those gradients, the grounding points are required on the aircraft side of the flange.

The following items must be grounded directly to an earth electrode system (EES). Resistance to ground must not exceed 10,000 ohms.

- Installations that use a static grounding/bonding reel must ensure the resistance through the reel is 10 ohms or less. This means the resistance to ground plus the resistance of the reel must be 10 ohms or less.
- For aircraft direct fueling stations and hydrant fuel pits, locate grounds on the aircraft side of any insulating flange used for cathodic protection isolation systems. Cathodic protection systems (impressed current) can cause voltage gradients on the surface. The aircraft needs to be protected from those gradients, so an isolation flange is installed. Since we are protecting aircraft and personnel from those gradients, the grounding points need to be on the aircraft side of that flange. **/1/**

2-3.2 Hospitals.

Comply with NFPA 99 for static protection required for hospitals.

2-3.3 Aircraft Parking Aprons and Hangar Floors.

Do not use static grounds or grounding receptacles for **\1** aircraft lightning protection. **/1/**

2-3.3.1 Aircraft Parking Aprons.

2-3.3.1.1 Static Grounds.

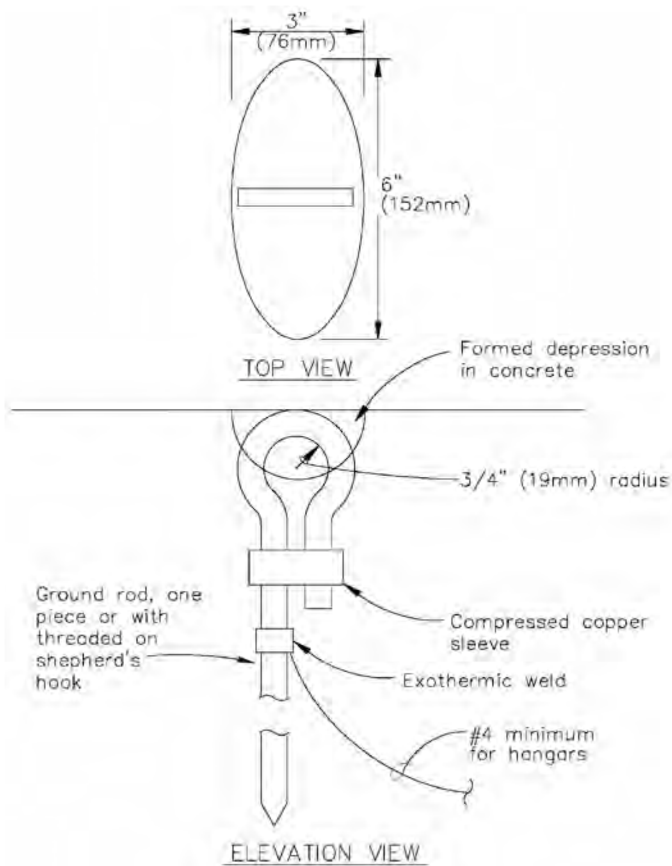
Provide static grounds with less than 10,000 ohms on aprons, in airplane parking-hydrant fueling and defueling areas, and near each hydrant pit.

- **\1** Mooring eyes/tiedowns are permitted to be used as static grounding points if criteria are met. When the dimensions of the mooring eye rebar are larger than the normal static ground clamp used by the Activity for the aircraft, determine if the Activity will utilize adapters on their clamps, or if they require a separate ground system. If a ground system is required to obtain a power ground (25 ohms), use the grounding receptacle, per Figure 2-3 with a grid arrangement as described in Section 2-3.3.2. Coordinate with Activity on whether or not the receptacle cover and ball chain are required to be removed for Foreign Objects and Debris (FOD) prevention. **/1/**

\1\ For the Air Force: Provide static grounds in concrete as illustrated in Figure 2-2, commonly called a Shepherd's Crook. **/1/**

- **\1** Static grounds may not be used as tie-downs. Tie-downs may be used as static grounds if testing indicates less than 25 ohms to ground. If tiedowns are intended to also be used as static grounds, soil conditions may require that a ground rod be installed. When a ground rod is included, it <u>must</u> be bonded to the tie-down bar. **/1/**

Figure 2-2 Air Force Static Grounding Point



2-3.3.1.2 Power Grounds.

If a power ground system with less than 25 ohms is required on an apron, use the grounding receptacle with grid per Figure 2-3.

2-3.3.1.3 Aircraft Fueling.

In addition to the criteria given herein, apply NFPA 407 when aircraft fueling is involved.

2-3.3.2 Aircraft Hangar Floors.

Grounding devices installed in floors are intended to serve as aircraft static and equipment grounding. A static grounding system conforming to NFPA 77 is suitable for dissipation of any aircraft static electricity to ground. However, because NFPA 70 requires a maximum of 25 ohms resistance to ground for equipment grounding, the 25-ohm requirement governs for this dual-purpose grounding system. Interconnect floor grounding systems electrodes below concrete in a grid arrangement, and interconnect to the hangar electrical service grounding system. Use a minimum of 4 AWG bare copper for interconnections. Where hangar floors are modified, extensions to grounding receptacles must remain load bearing to match original installation and the cover must be kept level with the finished floor.

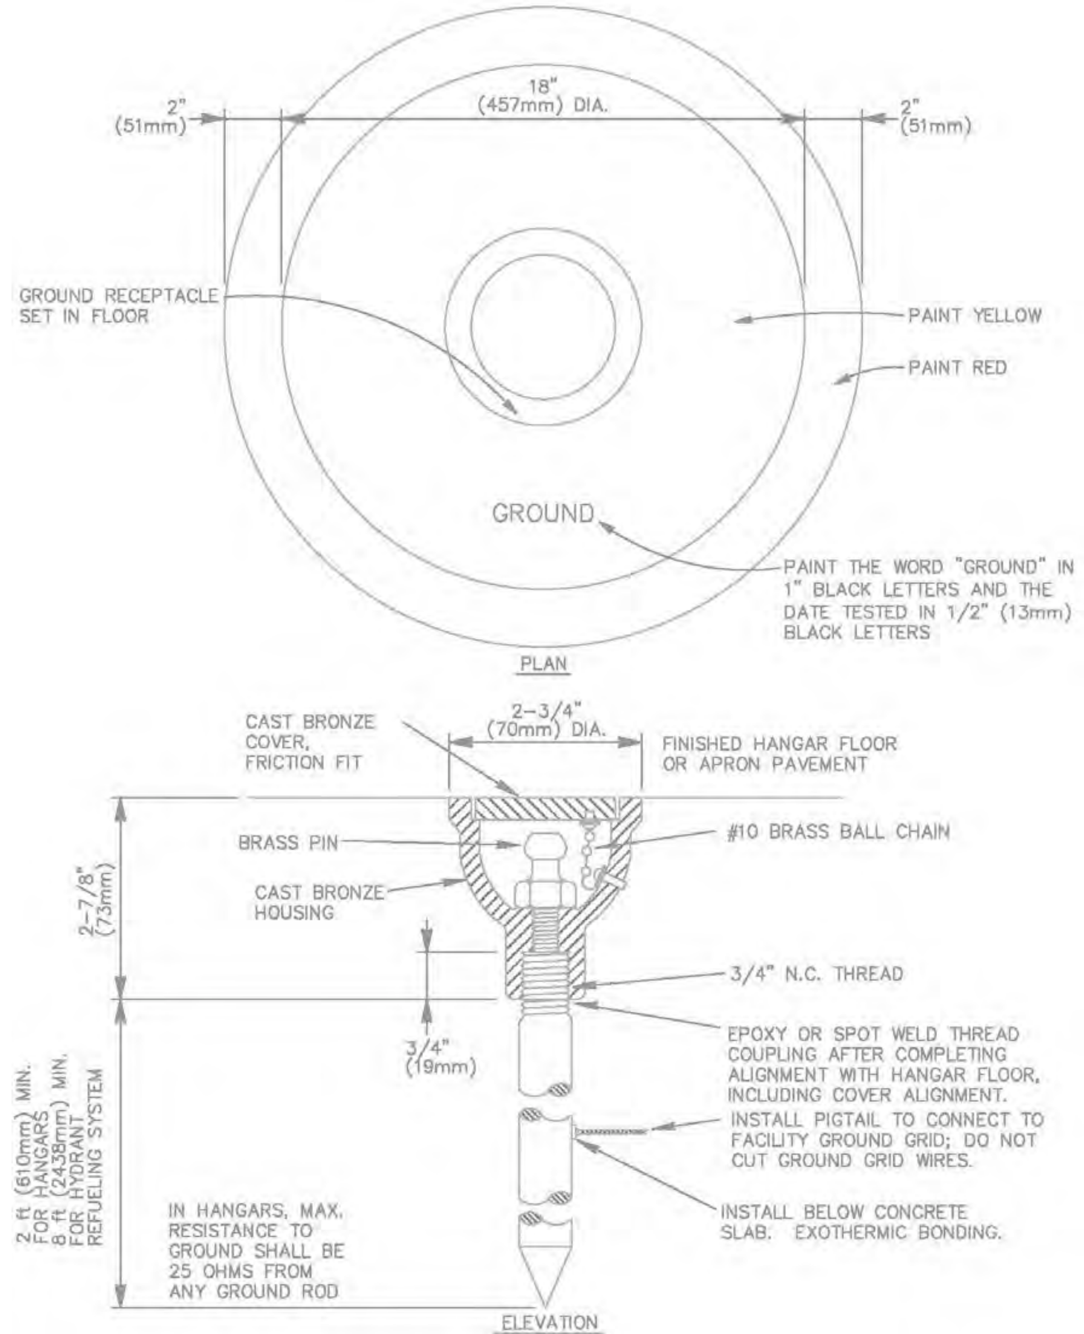
The tie-downs or grounding receptacles must be interconnected with bare copper cable. UFC 3-260-01, Appendix B, Section 11, provides guidance on layout and configuration of the grounding receptacles, relative to some aircraft. Floor layouts for receptacles must conform to the following:

- In the absence of other guidance, hangars that will be used for a specific number and type of aircraft must provide one grounding electrode for each aircraft space, approximately 10 ft (3 m) from the centerline of the aircraft space in the vicinity of one of the main landing gears.
- For general purpose hangars, provide electrodes for each aircraft space approximately 10 ft (3 m) from the centerline of the aircraft space, installed at 50 ft (15 m) intervals. Spacing of electrodes from wall lines or columns must not exceed 50 ft (15 m).
- Additional aircraft grounding guidance (operations and maintenance) is provided in MIL-HDBK-274 (AS).

2-3.3.3 Grounding Receptacle.

- Aircraft hangar floors must use a grounding receptacle as illustrated in Figure 2-3.
- If a separate ground system is required for aircraft parking aprons, use the grounding receptacle with grid as illustrated in Figure 2-3.
- **\1** Do not paint grounding receptacles.
- Receptacles with brass ball chain for cover attachment are required inside hangars.
- Receptacles within hangars may have double pin for multiple grounding. **/1/**

Figure 2-3 Grounding Receptacle



Note 1: Paint colors associated with static grounding services vary with application and service. The paint is applied directly to the hangar floor or apron pavement, and is not applied to the receptacle.

Note 2: When directed by the using activity, receptacle covers with brass ball chain shown on Figure 2-3 are not required for apron pavement areas.
\1 Note 3: Inside hangars, a grounding grid is recommended.

In general, any aircraft parked in hangar should be electrically grounded. The grounding should be done from basic aircraft structure to a low resistance ground. Grounding of the aircraft is usually done to:

- protect aircraft and personnel against hazards from lightning discharge.
- provide current return paths.
- protect personnel from shock hazard.
- prevent accumulation of static charge.

During de-fueling or refueling, the aircraft is grounded to the fuel truck. In general, the aircraft are grounded to a point where the impedance is less than 10,000 ohms referenced to earth for static grounding. For power grounding, it should be less than 10 ohms to power systems neutral. Aircraft are not grounded to the hangar structure as the external power supply, when connected, is grounded to that. **/1/**

Note 4: The above criteria will be reconciled with criteria in other UFCs so that the required criteria is located in a single location; the other UFCs and criteria documents will refer to UFC 3-575-01. In the event there is a conflict between this criteria and other criteria in another document, this criteria governs. The following documents are known to be affected by the above criteria:

Document	Title
MIL-HDBK-274A(AS)	Electrical Grounding for Aircraft Safety
UFC 3-260-01	Airfield and Heliport Planning and Design
UFC 4-211-01N	Aircraft Maintenance Hangars: Type I, Type II and Type III
UFC 4-211-02NF	Corrosion Control and Paint Finishing Hangars
UFC 4-211-02	Aircraft Corrosion Control and Paint Facilities (99% Draft – September 2011; included here to ensure the UFC is reconciled with this criteria)

This Page Intentionally Left Blank

CHAPTER 3 LIGHTNING PROTECTION SYSTEMS

3-1 DETERMINING THE REQUIREMENTS FOR LIGHTNING PROTECTION.

\1

3-1.1 Risk Assessment.

3-1.1.1 Facilities that house explosives and critical communications facilities require lightning protection systems. For general facilities, provide a risk assessment in accordance with NFPA 780 Annex L, Section L-5, *Simplified Risk Assessment.* Summarize recommended requirements, on engineering decisions, based on experience and good engineering practice. Document reduced or enhanced requirements resulting from engineering decisions and good engineering practice, with justification for changes. Note: These assessment tools are very conservative and may not contain variables that the designer and/or the AHJ would consider in making the final decision. AHJ should be consulted during design and before written recommendation. AHJ may provide some applicable local information which could affect the installation of LPS. Depending on location, if direct strikes are not probable, and if assets are less than the cost of the LPS and its maintenance, use surge protective devices to provide protection for indirect strikes and voltage surges from other sources. SPDs will also protect against switching surges from power outages and restorations of power.

3-1.1.2 Per NFPA 780, Annex L, paragraph L.1.1 “There are some cases where the need for protection should be given serious consideration regardless of the outcome of the risk assessment. Examples are those applications where the following are factors: (1) Large crowds (2) Continuity of critical services (3) High lightning flash frequency (4) Tall isolated structure (5) Building containing explosive or flammable materials (6) Building containing irreplaceable cultural heritage.”

3-1.1.3 If, after calculations, the indication is that a LPS is “recommended,” this allows the authority having jurisdiction (AHJ) to make a decision based on local conditions, strike density, and other variables which might make an LPS necessary for one military installation where it would not be necessary for a military installation at another location, even if using the same design. Since lightning protection systems are not a one-size-fits-all, and must be truly designed anew for each facility, the NFPA 780 committee, combines Annex L with AHJ responsibilities and authorities throughout NFPA 780 to tailor the LPS to conditions that may not be the same in all situations. Consider Florida compared to North Dakota.

3-1.1.4 Even if a “required” is a result of calculation, the AHJ is still allowed to check the local conditions and variables, consider the contents, and make the final decision. We are protecting the contents of the facility/structure, not the roofs or walls. This method of decision combining Annex L with an AHJ familiar with the region of the military installation -- provides the best opportunity to “fit” the requirements to the installation without overdesign.

3-1.1.5 Decisions by the AHJ are required to be documented in the test records of the facility/structure, as future documentation. **/1/**

3-1.2 Certification of Lightning Protection Systems.

If lightning protection is required, provide an LPS in accordance with NFPA 780 criteria, using components manufactured in accordance with UL 96.

Provide certification from a commercial third-party inspection entity whose sole work is lightning protection, stating that the lightning protection system complies with NFPA 780. Third party inspection entity cannot be the system installer or the system designer.

For Army: Provide a UL Lightning Protection Inspection Master Label Certificate for each facility indicating compliance with NFPA 780.

For Navy: LPS is required for A&E facilities for DSER and Service policy and must meet NAVSEA OP-5 requirements in addition to NFPA 780. A UL Certificate is not required.

U. S. Army Corps of Engineers- and NAVFAC-managed projects for the Air Force must comply with the requirements of the Air Force; e.g., AFMAN 32-1065 and NFPA 780.

3-1.3 Additions to Existing LPS.

Projects calling for an LPS addition to an existing LPS project must consider the configuration of the final LPS in the initial design. Projects of this type must ensure the final LPS as a whole is compliant with AFMAN 32-1065 (for Air Force only) and NFPA 780 (for all services). The same third-party inspector requirements apply.

Evaluate planned facility modifications and additions, and determine if an LPS will be required or if an existing LPS will be affected by the modification/addition. The resulting LPS for the whole facility must be addressed in the planning and design stages. This may require some adjustment to the existing LPS. If the mission of a facility changes, determine if an LPS is required.

Note: Ensure that systems currently compliant with respect to lightning protection are not made noncompliant by facility modifications and additions. LPS must be considered in the design of any project for a facility that has an LPS. This includes paint projects, roofing projects, projects requiring roof penetrations, installation of new HVAC or other metallic equipment, antenna installation, or other work. Additions and modifications to the facility envelope require re-evaluation of the LPS for the completed facility as a whole. The LPS required by the addition or modification must not be a simple addition to the LPS. The LPS must be considered a single entity and must comply with requirements of a single LPS upon completion.

3-1.4 Explosives Facilities.

Facilities or locations which are used for the development, manufacturing, testing, handling, storage, inspection, holding or maintenance of ammunition or explosives are required to have lightning protection unless specific conditions are met. Provide a UL Lightning Protection Inspection Certificate for the facility. This certificate must be certified to NFPA 780, Chapter 8 and the 100 ft (30.5 m) radius rolling sphere, unless otherwise indicated by that Service; refer to the paragraph entitled "Key Codes and Standards."

\1

3-1.4.1 Air Force Recordkeeping and Review.

3-1.4.1.1 Inspectors and testers must compile and maintain records of their inspections and tests. Records should include a sketch of the grounding and lightning protection system, showing test points and where services enter the facility. The sketch should also show the location of the probes during the ground resistance test. (Separate sketches are suggested for static, earth ground, and lightning protection systems on large complex facilities.) Sketches should capture the following:

- Date action was performed.
- Inspector's or tester's name.
- General condition of air terminals, conductors, and other components.
- General condition of corrosion protection measures.
- Security of attachment for conductors and components.
- Resistance measurements of the various parts of the ground terminal system.
- Variations from the requirements of this UFC, citing equivalency or better.
- Discrepancies noted and corrective actions taken.
- Dates of repairs.

3-1.4.1.2 The BCE will review records for deficiencies and analyze the data for undesirable trends. If test values differ substantially from previous or original tests obtained under the same test procedure and conditions, determine the reason and make necessary repairs and document repairs.

3-1.4.1.3 Inspectors and testers will keep test and inspection records in accordance with DODD 6055.09-M-V2, *Ammunition and Explosives Safety Standards.* **/1/**

3-2 CONVENTIONAL LIGHTNING PROTECTION SYSTEMS.

Nonconventional systems, such as dissipation arrays and those using early streamer emission-type air terminals and attachments of multiple terminal points to the air terminal, are prohibited.

3-2.1 Air Terminals.

Air terminals mounted on or adjacent to equipment which is exhausting hazardous vapors must be a minimum of 60 inches (1524 mm) above the equipment to allow for the vapor to be dispersed. These air terminals require special mechanical supports per NFPA 780. **\1** Air terminals installed on "rubber" (EPDM) type roofs must use adhesive shoes with adhesive approved by the roof manufacturer. In areas of snow and/or constant wind, ensure that a section of roofing material is first glued to the roof and then the air terminal is glued to it unless the roof manufacturer recommends another solution. This section of roofing material must be a minimum 1 ft^2 (92,900 mm^2).

A nonconductive pole may be used only when heights and structural strength permit and must be provided with metal air terminals and two bare copper down conductors not less than 1/0 AWG connected to an earth electrode. The down conductors must be placed as near as possible to 180 degrees apart and must not be run inside the pole.

For Air Force: Adhesive fasteners can be a source of high maintenance and damage to the building/structure when not installed in accordance with manufacturer's instructions and the surface properly cleaned. In lieu of adhesive fasteners, consider installing a mast or catenary system. This will minimize testing and visual inspections to buildings/structures by reducing the number of test points. It will also minimize damage to the building and LPS during storms and hurricanes. If adhesive fasteners must be used, an inspector who is familiar with installation of these adhesive fasteners must watch during the installation, and verify in writing (print name after signature) in the test records for that facility/structure that the installation was in accordance with manufacturer's instructions. Note that adhesive fasteners in desert areas may be dependable for up to 10 years. The Air Force goal would be to minimize use of air terminals, taking advantage of mast/catenary systems, to minimize maintenance, testing, repair and storm damage by up to 90%. **/1/**

3-2.2 Masts.

\1

3-2.2.1 Steel Masts

/1/

Masts of heights up to 40 ft (12.2 m) must be of single section design. When down conductors are required because metal mast thickness is less than 3/16 inches (0.1875 inches or 4.8 mm), the down conductors must be placed as near as possible to 180 degrees apart. All conductors and connections to the ground loop must be run on, and bonded to, the outside of the mast.

Wind and ice loading on the mast and on associated overhead wires must be considered during design. Provide damping in accordance with manufacturer's recommendations.

Metal mast foundation designs must take into account wind loading and ice loading. Foundations for setting metal masts must be in accordance with the following:

- Steel or aluminum, mounted by anchor bolts set in a concrete foundation poured in place. Follow manufacturer's recommendations for foundation design and type and for setting of anchor bolts.
- Steel, mounted by means of a stub set directly into a concrete foundation.
- Corrosion-resistant steel masts may be set directly into earth where soil conditions permit.

\1

- Steel masts for a catenary system must be rated for transmission/distribution line use by the manufacturer because of the directional forces at the top of the mast.
- Steel masts for a single mast do not require transmission/distribution line rating because the force is all vertical.

3-2.2.2 Wooden Masts.

Wooden masts require air terminals and two paths to ground, as with all active (excluding fasteners) components of an LPS. A wooden mast as part of a system of masts in a catenary may use horizontal components (cross conductors (catenary)) as one or both path(s) to ground. If a cross conductor is used as one of the paths, the connection point between the air terminal and cross conductor attachment must be less than 25 ohms to ground.

Wooden masts of a catenary system must be transmission/distribution line rated (based on larger diameters at the tops and bases – this is a "CLASS" adjustment.) Example: A Class 4 pole may become a Class 3 or Class 2 pole, depending upon the pole height required to accomplish the rolling sphere area under which protection is provided by the LPS. The rolling sphere must be shown valid in a drawing based on a combination of pole heights and cross conductor heights.

Wooden masts of a mast system (one or more masts without cross conductors) do not require the larger class pole. The rolling sphere must be shown valid in a drawing based on pole heights. **/1/**

3-2.3 Joint Design.

Slip-joint design must meet the following requirements:

- Ensure overall structural integrity of the mast.
- Include a field assembly requirement to ensure a snug fit, so that joints of the mast will not loosen when subjected to vibration modes caused by wind or other means after erection.
- Be compatible with field erection requirements to facilitate ease of installation at the site.
- Have good metal-to-metal contact, so that electrical conductivity is equal to or better than the parent metal.

3-2.4 Down Conductors.

Do not install down conductors inside down spouts.

3-3 GROUNDING AND BONDING FOR LPS.

Bond equipment or subsystems into a single grounding system for the facility. Apply UFC 3-550-01 for general grounding system requirements. Include the following additional requirements for the LPS:

- When a power ground ring is required, install the ground ring in accordance with UFC 3-550-01. This will require the ring to be installed at a minimum depth of 30 inches (762 mm) rather than the minimum 18-inch (457 mm) depth required by NFPA 780.
- **\1** Terminate each down conductor to a grounding electrode located inside a test well for easy access, or to a ground ring electrode (counterpoise) dedicated to the LPS. Consider a ground rod/test well between the down conductor and counterpoise, so that if the counterpoise is cut, the down conductor remains adequately grounded. This could be more of a consideration for explosives facilities and communications facilities. If a ground ring is used, the ground ring is deemed to be associated with the LPS and thereby meets the requirements for a dedicated grounding electrode.
- In accordance with NFPA 780, facilities exceeding 75 feet (23 m) in height must be protected with Class II materials. Explosives facilities require a ground ring electrode of 1/0 copper (NFPA 780 change pending). **/1/**
- When a facility requires an additional dedicated ground ring for a catenary lightning protection system, this ring must be designated the primary ground ring. It must be installed not less than 3 ft (914 mm) beyond the first (inner or secondary) ground ring and the two ground rings must be bonded together in at least two locations.
- As an exception to performing the side flash calculations required by NFPA 780, the 6 foot (1.83 m) bonding requirement allowed by UL 96A can be used.
- Bond metal ladders to the system at both the upper and lower ends of each ladder.

\1

- Ensure that LPS ground rods (grounding electrodes) meet the size and dimensions for LPS in NFPA 780, which is 5/8” by 8’, with bottom of rod buried 10 feet below grade (top of ground rod approximately 2’ below grade). **/1/**

3-4 SURGE PROTECTION.

\1 Surge protection is required to provide protection against the high magnitudes of voltage present with indirect lightning strikes and other surges like power outages and power faults, particularly in this environment of increasing electronics. **/1/**

Provide appropriate class surge arresters at the distribution transformer supplying the facility. Provide surge protective devices for all systems identified in NFPA 780. Refer to UFC 3-520-01 for the requirements.

\1\ For Air Force: Surge protective devices must comply with the following requirements for WSAS, MSAS, and communications facilities. **/1/**

- Standard, published, minimum 10-year unlimited replacement warranty on product. Entire unit must be replaced upon detection of the failure of any mode.
- All mode (10 modes), directly connected protection elements (l-n, l-g, l-l, n-g). Direct clamping l-n and l-l is required.
- F1 polycarbonate enclosure or National Electrical Manufacturers Association (NEMA) 4 or NEMA 4X steel enclosure: Inaccessible to unqualified persons.
- Internal over-current fusing on each phase for self-protection from failed component(s) and an internal disconnect for each phase.
- Individual component level thermal fusing.
- Bi-polar protection.
- The SPD must contain continuous self-monitoring devices with indicator lamps for each mode. These may be located inside the enclosed areas such as mechanical rooms if an indicator lamp is provided in a visible area. For WSAs and MSAs, the indicator lamp should be installed in a location that can be seen from a vehicle, allowing maintenance personnel to drive through the large areas and quickly identify devices that have operated. Indicator lamps that can be seen in this way will allow maintenance personnel to determine whether a group of SPDs have operated, providing information about the circuit.
- Cable connections between a bus and SPD must be minimum No. 10 AWG for installation at main distribution panels and branch panels.
- **\1** SPDs may not be manufacturer-installed inside the service panel. The wrong panel has been known to be ordered, resulting in a long lead from the SPD to the bus, rendering the SPD useless. In addition, the SPD may not be installed inside a panel, in accordance with UFC 3-520-01, para 3-4.1.
- Visible indicators of SPD operation on the exterior of facilities. Drive-by visual inspections may be an effective means of inspecting SPDs.
- Non-modular. The entire unit must be replaced upon detection of the failure of one mode of operation. Ease of installation must not be traded for possible minimized protection levels. **/1/**

3-5 REQUIREMENTS FOR ORDINARY FACILITIES AND STRUCTURES.

3-5.1 Non-Reinforced Concrete or Wood Frame Building.

The fastener selected must be appropriate for the application and suitable for attachment to concrete or wood. Aluminum fasteners must not be mounted to concrete.

3-5.2 Reinforced Concrete Buildings.

Do not use reinforcing steel for down conductors.

\1\

3-5.3 Steel Frame Buildings.

Down conductors may not be required when air terminals are mounted on steel which is at least 3/16 inch (4.763 mm) thick and in direct contact with the ground. Steel used as structural components is typically in the form of an I-beam or other steel members. I-beams under 7/32 inch thickness do not exist according to Standard I-Beam Sizes Chart at https://amesweb.info/Profiles/Standard-Steel-I-Beam-Sizes-Chart.aspx and exceed the requirement for thickness. At the thicknesses and weights indicated in this chart, unless some kind of insulation is between joined sections, the steel is inherently continuous due to the weight of the steel. Use of steel framework in lieu of down conductors is permitted only if documentation is provided at the base of each column that the resistance to ground (ground rod or ground loop conductor, if present) at the base of the column is less than or equal to 25 ohms. Provide initial test readings between connected steel (beams and columns) components to validate the electrical continuity of the steel framework tests at less than 1 ohm at the time of construction.

3-5.3.1 Air Terminal Construction.

For areas subject to hurricanes and other areas of high winds, follow these recommendations:

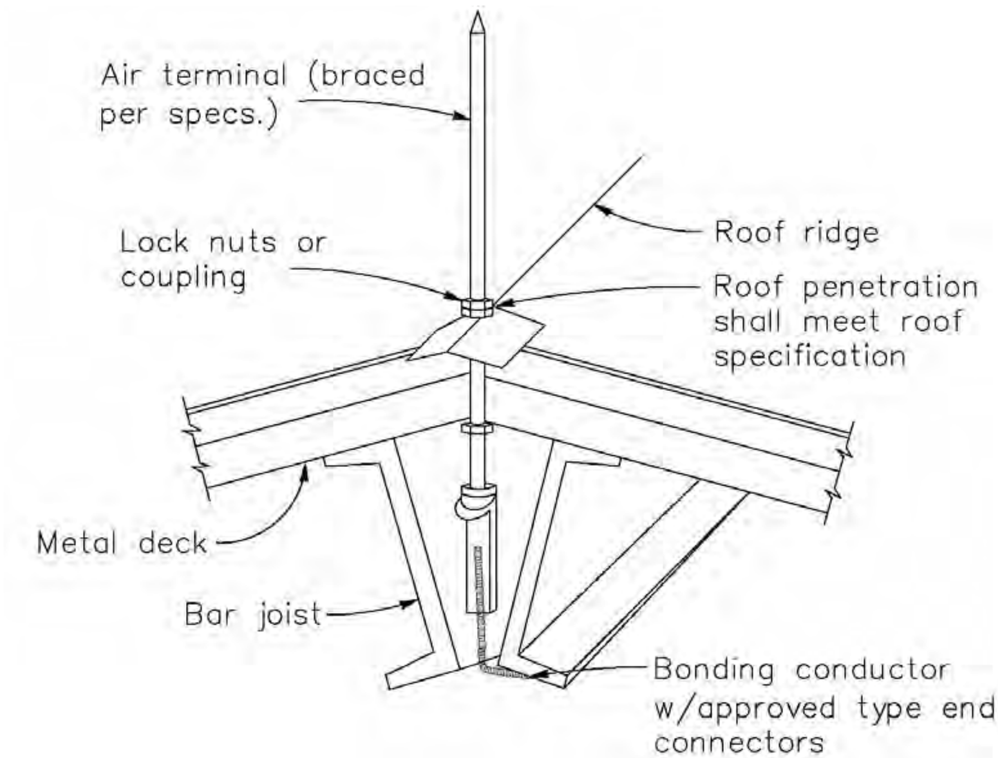
a. In lieu of attaching conductors with conductor connectors, attach with strips of membrane installed by the roofing contractor. For built-up and modified bitumen membranes, use strips of modified bitumen cap sheet, approximately 9 inches wide minimum. If strips are torch-applied, avoid overheating the conductors. For single-ply membranes, use self-adhering flashing strips, approximately 9 inches wide, minimum. Start the strips approximately 3 inches from either side of the air terminal base plates. Place strips that are approximately 3 ft long, followed by a gap of approximately 3 inches.

b. In lieu of pronged splice connectors, use bolted splice connectors.

For Air Force: Do not use adhesive fasteners for air terminals or down conductors. Lack of proper preparation of the surfaces and uses on surfaces unapproved by the fastener manufacturer has led to adhesive not performing to the standards of the manufacturer. Result has been costly damage to facilities.

For Air Force: If steel I-beams or round steel beams are used as structural elements with sufficient cross sectional area, no air terminals are required if structural elements are verified as continuous by conducting continuity checks on questionable joints. If those are verified to be continuous, then the remaining joints may be considered inherently bonded. Figure 3-1 would not apply to the Air Force. If steel is continuous, the entire building acts as a single air terminal. Nothing is gained by installing an air terminal on an air terminal. Protection of a sheet metal roof or a canvas cover is not considered; the purpose of an LPS is to protect contents. A direct strike will routinely involve repair of the roof at the point of the strike. **/1/**

Figure 3-1 Typical Air Terminal Assembly Using Steel Framing As Conductor



3-5.3.2 Nonmetallic Exterior Walls with Metallic Roof.

When roof sections are insulated from each other, bond the metal roof sections together so that they are electrically continuous.

3-5.4 Metal Roof with Metal Walls.

Bond metal roof and metal walls so that they are electrically continuous.

3-5.5 Ramps and Covered Passageways.

Verify that ramps and covered passageways do not extend beyond the zone of protection of a facility. If ramps and covered passageways do extend beyond the zone of protection or if an existing structure is affected, refer to the paragraph "Determining the Requirements for Lightning Protection" to ensure that the facility certification is maintained.

3-5.5.1 Post Tension Systems.

On construction utilizing post tension systems to secure precast concrete sections, the post tension rods must not be used as a path for lightning to ground. Provide down conductors on structures using post tension systems; down conductors must have sufficient separation from post tension rods to prevent side-flashing. Bond post tension rods to the lightning protection and grounding systems only at the base of the structure; perform this bonding in accordance with the recommendations of the post tension rod manufacturer.

\1

3-5.6 Buildings Containing Hazardous Areas.

Bond metallic objects located within hazardous areas (as defined in NFPA 70) and within 10 ft (3 m) of an LPS, to the nearest down conductor. Per NFPA 780, do not use structural members in hazardous areas as a replacement for down conductors. Bond metal frames of doors and windows located within hazardous areas to the structural column, or provide a bond from the frames to the building counterpoise system or a ground rod. Bond doors to metal frames using flexible braid-type copper conductors. Where tested resistance is less than 1 ohm between doors and their respective doorframes (this may be measured across hinges), and a test plan is maintained identifying that location, a flexible braid-type copper conductor connection is not required if the door is inherently bonded to the door frame (measure across the hinge from the door to the frame). Remove paint sufficiently so that meter probes are in contact with the steel door and steel frame. Identify the test points on LPS bonding records. **/1/**

3-5.7 Aircraft Control Navigation Aids.

Protect one-floor frame buildings which house equipment for Instrument Landing System (ILS) and Tactical Air Navigation (TACAN) facilities and other similar type structures with no fewer than two air terminals on each facility. **\1** Ideally, air terminals should be on opposite corners. **/1/**

3-5.8 Weapons Systems Electronic Facilities, Above Grade.

This section pertains to designs for the protection of radars, antennae, electronic equipment vans, launchers, missile controls, and guided missile batteries when permanently installed. Perform the following in the absence of any specific guidance from the agency in charge of the installation:

- **\1** The protection patterns must comply with NFPA 780 and consist of a mast or mast with catenary style LPS, unless specific guidance is provided for that weapons system platform. Ensure patterns are not interrupted by penetration of the pattern by any part of the LPS. **/1/**
- Locate and arrange protection equipment so as not to obstruct or interfere with the operation of any radar electronic acquisition or tracking beam.
- Where vans are clustered, ground rods for the vans must be interconnected in compliance with MIL-HDBK 419A.

Protect separate buildings containing support equipment for weapons systems electronic facilities in accordance with the building construction type.

3-5.9 Weapons Systems Electronic Facilities, Below Grade.

3-5.9.1 Protection Included with Other Protection Systems.

When an external grounding system design is included for electromagnetic pulse (EMP) protection, electromagnetic interference (EMI) shielding or other protection system, additional lightning protection is not required. Lightning protection is provided by the EMP/EMI system.

3-5.9.2 Requirements Not Included in Other Protection Systems.

When external grounding system design does not include EMP, EMI shielding, or other protection, provide a ground ring including connections to underground metallic objects, such as the following:

- Electrical conduit.
- Mechanical piping.
- Metal tanks.
- Manhole grounds.
- Missile cells or equivalent.
- Internal grounding system of control buildings and power plants.
- Metal ducts for fans.
- Tunnels.

The ground ring is not required if validated by mission operations and documented in the design analysis.

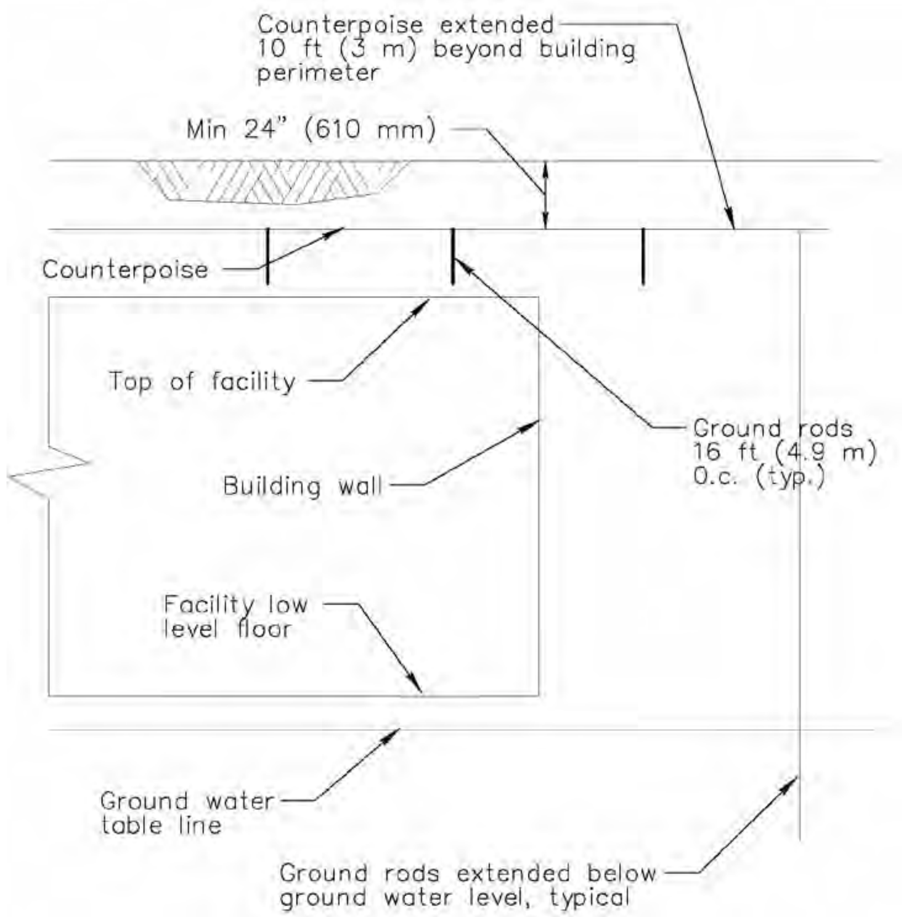
\1

3-5.9.3 Installation of Ground Ring.

Install the ground ring above each buried weapons system building, at least 18 inches (460 mm) below finished grade, and extend beyond the building perimeter not less than 3 ft (914 mm) nor more than 10 ft (3 m). Connect the ground ring to ground rods located as in Figure 3-2, and driven to a point at least 6 inches (152 mm) below normal ground water table level, where earth is available for driving. Metal equipment and metallic enclosures of equipment extending above ground must be bonded to a ground rod and the ground rod bonded to the ground ring.

For Air Force: Installation of a ground rod between the equipment/metallic enclosures and the ground ring will ensure that the ground ring is not compromised if equipment is relocated. The ground rod can remain. **/1/**

Figure 3-2 Below-Grade Weapons Systems Electronics Facilities – Ground Ring, Cross Section Elevation



\1\

3-5.10 Electrically-Controlled Target Training System.

In the absence of any specific guidance or standards for targeting systems, apply the following. Run shielded control cables (from targets to controls) or enclose the cables in metal conduit. Provide surge protection on all incoming and exiting signal and power lines in accordance with NFPA 780 and UL 1449*, Standard for Surge Protective Devices*, Fourth Edition. ***/1/***

3-5.10.1 Control Tower.

Provide a complete protection system with at least two air terminals installed on the roof.

3-5.10.2 Target Control System.

Where each target mechanism box assembly station has a separate control relay, a lightning protection ground ring or grid is not required for protection of the down-range target area. Where such control relays are not provided, a ground ring or grid must be provided below grade above wiring in trenches to all targets.

3-5.10.3 Remote Targeting Engagement System (RTES).

Ensure the LPS and grounding comply with NFPA 780. Bonding is the more important for this unmanned system. Weapon enclosure, hatch, and stairway must be bonded to the LPS.

3-5.11 Petroleum Oil Lubricants (POL) Storage Tanks.

Where above-ground steel storage tanks are constructed on foundations of concrete or masonry, provide grounding in accordance with the grounding schedule shown in Table 3.1, regardless of tank height. Where underground steel tanks are constructed in direct contact around the entire perimeter with not less than 18 inches (458 mm) of earth cover, grounding is not required.

Table 3-1 Fuel Storage Tank Grounding Schedule

Tank Circumference (Feet)	Tank Circumference (Meters)	Ground Connections Minimum Number
200 and less	61 and less	2
201 through 300	61.2 through 91.5	3
301 through 400	91.7 through 122	4
401 through 500	122.2 through 152	5
501 through 600	152.7 through 183	6
601 through 800	183.2 through 244	7
801 and more	244.2 and more	8

\1

3-5.12 Satellite Dishes.

Locate a satellite dish within a zone of protection. One or more of the following methods must be used to determine the overall zones of protection: air terminal placements, as described in Section 4.7; the angle (geometric) method, as described in Section 4.8.2; and the rolling sphere method, as described in Section 4.8.3, all of NFPA 780.

3-5.13 Aircraft Sunshades and Shelters.

Apply NFPA 70 grounding and bonding requirements to aircraft sunshades and shelters. Obtain current guidance from each service. Additional requirements are being developed and will be included in the next change to this UFC. Obtain interim requirements from the AHJ at the associated service. Validate (document in writing and date) confirmation of additional requirements or no additional requirements as of that date.

For Air Force: If lightning protection is required and the structure is steel I-beam or round heavy beam construction and continuous to ground, air terminals are not necessary as the structural steel forms a large air terminal. Grounding will be addressed specific to each facility. Tubular steel assemblies do not meet the intent of protection against lightning. **/1/**

This Page Intentionally Left Blank

CHAPTER 4 \1\ AIR FORCE LPS INSPECTION REQUIREMENTS

4-1 EXISTING FACILITIES.

The contract for a lightning protection system project, or for any project on/to a facility which possesses a lighting protection system, requires an in-house LPS inspection and documentation of condition prior to contract start and completion. BCE repairs to existing facilities do not require a commercial third-party inspection. A BCE representative must certify the work.

4-2 NEW FACILITIES.

A third-party inspection is required for the LPS of the project, prior to acceptance of the project. The inspection must be a 100% inspection using the test point locations identified by the contractor. Test readings must either be observed by the inspector as the contractor is performing the initial tests, or test readings must be independent matching those documented by the contractor, within tenths of ohms. Note the intent is to validate integrity, not to obtain the exact reading.

4-3 ADDITIONS TO EXISTING FACILITIES.

The design and construction of LPS additions to existing facilities must ensure that the LPS, if required, joins to the existing LPS to form a single LPS, not an LPS attached to an LPS. Deviations to the existing LPS may be caused by an uncoordinated design between the existing LPS and the LPS addition. Changes may be required to the existing LPS at or near points of inter-connection for the two systems.

4-4 INSPECTIONS FOR NEW FACILITIES AND ADDITIONS TO EXISTING FACILITIES.

This final LPS project inspection must be performed by a third-party inspector ("third-party" excludes the designer or any part or subsidiary of his/her company, and the installer). whose sole work is lightning protection, or by an LPS maintenance person from the base, delegated the authority to accept LPS by the BCE in writing, by virtue of experience and training which requires an examination prior to certification of qualification.

4-5 CERTIFICATION STATEMENT.

LPS must be certified in writing by this third-party inspector as compliant with AFMAN 32-1065 and NFPA 780, prior to project acceptance. A UL certification on its own is not adequate for acceptance of any Air Force LPS project. A comprehensive inspection and compliance with this UFC and AFMAN 32-1065 is also required and UL does not inspect to these documents. Inspections may not be posted to any web site available to the public. Note that, for in-house repairs and construction, and for in-house replacement design (i.e., replacement of poles, repairs of catenary), certification by the BCE representative in lieu of a commercial third party inspection is sufficient. **/1/**

A-2 DEFINITION OF TERMS.

Activity: The end use of a facility.

Approved: Acceptable to the Authority Having Jurisdiction.

Bonding: An electrical connection between an electrically conductive object and a component of a lightning protection system intended to significantly reduce potential differences created by lightning currents.

Catenary System: A lightning protection system consisting of one or more overhead wires. Each overhead wire forms a catenary between masts, and serves the function of both a strike termination device and a main conductor.

Conductor, Bonding: A conductor used for equalizing potential between metal bodies and the lightning protection subsystem.

Contractor: Person(s) doing actual construction portion of a project.

Copper Clad Steel: Steel with a coating of copper bonded on it.

Designer of Record: The engineer responsible for the actual preparation of the construction documents.

Down Conductor, Lightning: The conductor connecting the roof conductors or overhead ground wire to the earth ground subsystem.

Labeled: Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed: Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

Power Ground: Driven electrode at service entrance.

Qualified: Compliant with NEC/NFPA definitions and, for Air Force, experience and training meeting AFI 32-1065.

User: Facility occupants or Facility Manager.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

TABLE OF CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides design criteria for telecommunications spaces, pathways, cabling, and interconnecting components necessary to support the infrastructure for voice, data, video, smart buildings, and Internet of Things (IoT) systems. It does not address the design and specifics of the technologies that employ information communications technology infrastructure. "Video systems" includes the necessary infrastructure for closed circuit television (CCTV); community antenna television (CATV), commonly referred to as cable TV; video teleconferencing (VTC); and video walls.

1-2 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 3-580-01, 1 June 2016; MIL-HDBK-1012/3, dated 31 May 1996; and Army publications *Installation Information Infrastructure Architecture (I3A)*," dated February 2010, "*Installation Information Infrastructure Architecture (I3A) for Outside Plant Only*," dated November 2017, "*Outside Plant Design and Performance Requirements (OSPDPR)*," dated February 2009, "*OSPDPR Addendum 1 – Core and Distribution Fiber Sizing Criteria for Installation Campus Area Network Design and Implementation*," dated September 2014.

1-3 APPLICABILITY.

This UFC applies to planning, design, construction, sustainment, restoration, and modernization of DoD-owned facilities. It applies to all methods of project delivery and levels of construction as defined by UFC 1-200-01, Section 1-3.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01. UFC 1-200-01 provides applicable model building codes and government-unique criteria for typical design disciplines and building systems, as well as accessibility, antiterrorism, security, high performance and sustainability, and safety requirements. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced within.

1-5 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service implementation policy.

1-6 Governing Criteria for Electrical Systems.

UFC 3-501-01 provides the criteria for electrical systems, delineates among electrical-related UFCs, and refers to UFC 3-520-01 for interior electrical system requirements.

1-7 Modernization Within Existing Facilities.

Modernization of information communications technology systems within existing facilities solely for the purpose of meeting design criteria in this UFC is not required.

1-8 Activity Specific Telecommunications Managers.

Throughout this UFC, the term “Telecommunications Manager” refers to:

- Army – the Network Enterprise Center (NEC) or the Information Officer (G6, S6, J6)
- Navy – a group of individuals with responsibilities as shown in Figure 6-1.
- Marine Corps – G6.
- Air Force – A6.

1-9 GLOSSARY.

Appendix B contains acronyms, abbreviations, and terms.

1-10 References.

Appendix C contains a list of references used in this UFC. Publication dates are not included; the most recent issuances apply unless otherwise specified.

CHAPTER 2 DESIGN REQUIREMENTS

2-1 General Guidance.

Design information communications technology infrastructure to meet the needs of the activity and supporting facilities in accordance with this UFC. Final drawings and specifications for design-bid-build and design-build projects must be stamped by a Building Industry Consulting Service, International (BICSI), Inc., Registered Communications Distribution Designer (RCDD).

Because construction phases may be concurrent with design in design-build projects, and because multiple phases of construction may be approved, the final documents for each construction phase must be stamped when approved.

2-1.1 U.S. Government- (USG-) Designed Projects.

On USG-designed projects (in-house design), the USG designer must:

- Obtain the approval of the Service-appointed information communications technology agent at the beginning of design in accordance with regulations, policies, memorandums, and guidance.
- Ensure that the bid documents require an RCDD stamp on the contractor's telecommunications shop drawings submitted for approval.
- Ensure final drawings and specifications for design-bid-build and design-build projects have been reviewed and approved by a BICSI RCDD.

2-1.2 Small Scale Projects.

Small scale projects limited to adding work area outlets from existing telecommunications rooms do not require an RCDD stamp, provided the work is being accomplished under the technical authority of an RCDD or the USG Information Communications Technology Manager.

2-1.3 Design Elements.

The complexity of Information and Communications Technology (ICT) design requires that the Designer of Record (DOR) engage early to achieve successful outcomes. Tables 2-1 and 2-2 list expected submissions and when they are due in the process. These timeframes may be adjusted for fast-tracked or other delivery mechanisms to align with design processes.

Table 2-1 ICT Design Submittal Schedule

DESIGN LEVEL	0%	30%	60%	90%	100%
	Charrette	Design Development	Interim Design	Final Design Submittal	Corrected Final Design

Design Analysis					
DA	DA^{SD}	DA^{DD}	DA^{ID}	DA^{FD}	DA^{CFD}

Table 2-2 Required Drawings

DRAWINGS	DESCRIPTION*
T0	Site information
$T0^{DD}$	Site drawing should show existing ICT utilities at DD
$T0^{ID}$	Routing and quantities of new ICT utilities
$T0^{FD}$	Final site ICT drawings
T1	Buildings
$T1^{ID}$	Show all workstation outlets, service oulets, and ICT elements on floor plans
$T1^{FD}$	Complete ICT design
$T1^{CFD}$	Incorporate approved comments generated during the final review into final design
T2	Serving zone information
$T2^{ID}$	Show all serving zones and ICT spaces with primary and secondary pathways, as applicable
$T2^{FD}$	All pathways and drop locations and other elements are complete
$T2^{CFD}$	Incorporate the approved comments generated during the final review into the final design
T3	Telecommunications rooms

DRAWINGS	DESCRIPTION*
$T3^{DD}$	The floor plan needs to be locked in early. The ICT designer must perform work early and up-front preparing T3 telecommunication rooms plan views to ensure that adequate space is allocated for the equipment, including working clearances for the life cycle of the facility.
$T3^{ID}$	Show all equipment including Facility Related Control System (FRCS) and other OT along with IT.
$T3^{FD}$	Complete ICT design.
$T3^{CFD}$	Incorporate approved comments generated during the final review into the final design.
T4	Details
$T4^{FD}$	All details complete, including labeling schemes, rack elevations, work station outlet details, wireless access points (WAP) mounting.
$T4^{CFD}$	Incorporate approved comments generated during final review into final design.
T5	Schedules
$T5^{FD}$	All schedules complete and cable plant management including cut-overs complete
$T5^{CFD}$	Incorporate approved comments generated during final review into final design
T6	Network diagrams, riser diagrams, and boundary diagrams
$T6^{DD}$	The floor plan needs to be locked in early. The ICT designer must perform work early and up-front preparing T3 telecommunication rooms plan views to ensure that adequate space is allocated for the equipment, including working clearances for the life cycle of the facility.
$T6^{ID}$	Show all equipment including Facility Related Control System (FRCS) and other OT along with IT.
$T6^{FD}$	Complete ICT design.
$T6^{CFD}$	Incorporate approved comments generated during the final review into the final design.
S^{ID}	List all applicable specifications and include even if unedited.
S^{FD}	All ICT specifications complete
S^{CFD}	Incorporate approved comments generated during final review into final design.
DA^{SD}	All ICT systems identified in the design scope should be listed with points of contact (POC) for systems.
DA^{DD}	A subsection for each ICT system and all design criteria should be listed.

DRAWINGS	DESCRIPTION*
DA^{ID}	The design analysis must be an entirely updated analysis (not amendments to 30% submittal) to permit verification that the design complies with the criteria furnished, the approved 30% design phase, and approved review comments. Information required at the 30% design phase must be included with more detail.
DA^{FD}	ICT sections of design analysis complete
DA^{CFD}	Incorporate approved comments generated during final review into final design.

* Refer to TIA 606 for additional details.

2-2 SECURE SPACE INFRASTRUCTURE.

Secure spaces include classified networks such as Secret Internet Protocol Router Network (SIPRNet), Joint Worldwide Intelligence Communications System (JWICS), or National Security Agency Intranet (NSANet). These networks process National Security Information (NSI) and have unique requirements.

2-2.1 RED/BLACK Telecommunications Systems.

All equipment, wirelines, components, and systems that process NSI are considered RED. Equipment, wirelines, components, and systems that process encrypted NSI and non-NSI are considered BLACK. BLACK lines and other electrically conductive materials that egress the inspectable space are potential carriers of compromising emanations (CE) that can inadvertently couple to the RED lines. Various signal line isolation techniques such as separation and filtering are used to protect the signal line, the distribution system, or other fortuitous conductors from conducting compromising signals beyond secure areas.

Apply fundamental RED/BLACK separation in accordance with Committee on National Security Systems Advisory Memorandum (CNSSAM) 1-13 to prevent inadvertent transmission of classified data over telephone lines, power lines, signal lines, and electrical components, circuits, and communication media. Application of RED/BLACK separation establishes areas where equipment that processes classified information (RED) is isolated from areas where equipment processing unclassified (BLACK) is located.

2-2.2 Telecommunications Space.

Account for the space required for equipment rooms and telecommunications rooms and ensure it is adequate to meet separation requirements before floor plans are locked in. The minimum sizing in this UFC is presented with a single black network and does not account for RED networks and the separations between the racks or cabinets in the space. A telecommunications space that contains equipment for multiple networks such as SIPRNet, JWICS, and NIPRNet all requiring RED/BLACK separation is considered as substantial information technology (IT) electronics which would require use of an equipment room.

2-2.3 Telecommunication Cabling System.

Cabling, patch panels, connector blocks, work area outlets, and cable connectors must be color-coded to distinguish their classification level. If color-coding is not possible, cabling must be clearly marked to indicate classification level. Provide detail sufficient for the security officer to submit and obtain approval from the certified TEMPEST technical authority. Design submittals must document RED/BLACK and checklist items from Intelligence Community Directive (ICD) Tech Spec, including the TEMPEST checklist items specific to telecommunications systems.

2-2.4 Protected Distribution Systems.

Use a protected signal distribution system (PDS) to protect unencrypted NSI that enters an area of lower classification, unclassified area, or uncontrolled (public) area. The PDS must comply with Committee on National Security Systems Instruction (CNSSI) No. 7003. Mount standard PDSs 1 inch (25 millimeters) from walls and other objects. To prevent obfuscating repairs made to the raceway, paint must not be field-applied. With prior approval from the Telecommunications Manager, galvanized rigid steel conduit (GRC) or electrical metallic tubing (EMT) may be used in addition to other approved surface mount raceways. Compression-type fittings are required with black epoxy glue applied to prevent tampering and as an aid to visual inspection. GRC compression or threaded fittings may be used with epoxy.

Due to inspection requirements, avoid using PDS whenever possible. To avoid PDS, keep cabling that transmits unencrypted NSI within the protected perimeter.

2-2.5 Alarmed Carrier.

An alarmed carrier may be used as an alternative to a physical PDS. Refer to CNSSI 7003.

2-2.6 Sensitive Compartmented Information Facility (SCIF) and Special Access Program Facility (SAPF).

Refer to UFC 4-010-05 and CNSSAM 1-13 RED/BLACK installation guidance.

2-2.7 Stand Alone SIPRNet Terminal Space.

Paragraphs 2-2.7.1 through 2-2.7.3 describe where a SIPRNet workstation outlet is required in a facility that lacks secure telecommunications spaces.

2-2.7.1 Pathways.

Provide PDS between the telecommunications enclosure and the lockable workstation outlet. Maintain a 6-inch (150-millimeter) separation between the workstation outlet and any other workstation outlet.

2-2.7.2 Telecommunication Equipment Enclosure.

When secure telecommunications spaces in a facility build-out are not equipped, specify a GSA-approved information processing system (IPS) container to house electronics that will permit a black-to-red transition. The container door must be specified and equipped with a Federal Specification FF-L-2740 lock.

2-2.7.3 Workstation Outlet Enclosure.

Enclosures must not have knockouts and must be metallic 16 gauge or greater. Hinges must be continuous and non-removable. Enclosures must not be field-painted, but may have factory-baked enamel or be galvanized. Enclosures must be continuously sealed with epoxy or welding of all joints except the hinged opening. Non-removable hasps must be equipped that will accept a lock meeting FF-P-110-J. Enclosures for workstation outlets must be GSA-approved.

2-3 SYSTEM DESIGN REQUIREMENTS.

Provide a complete, standards-based, flexible information communications technology design, including telecommunications spaces, pathways, outlets, connectors, cabling, grounding, bonding, and static protection in accordance with paragraphs 2-3.1 through 2-4.

2-3.1 Telecommunications Spaces.

Provide telecommunications spaces in accordance with Telecommunications Industry Association (TIA)-569. Refer to Figure 2-1.

Note: This UFC uses commercial terminology for spaces in accordance with the TIA-569-E errata sheet (e.g., telecommunications room, equipment room versus distributor room A and B, and telecommunications enclosure versus distributor enclosure).

2-3.1.1 Types of Telecommunications Spaces.

a. Telecommunications Entrance Facility. An entrance facility (EF) is the space housing the point of entrance of the information communications technology service. The EF is also the space where the inter-building backbone and intra-building backbone facilities join. Telecommunication-related antenna entrances and electronic equipment may be located in the EF. The demarcation point between the outside plant (OSP) cabling and the inside plant distribution cabling is the protected entrance terminal (PET). See Chapters 2 and 3 for PET requirements.

The DOR should coordinate with the Telecommunications Manager for additional physical security requirements inside the EF including, but not limited to, colocation cabinet(s) if required for commercial or other carriers.

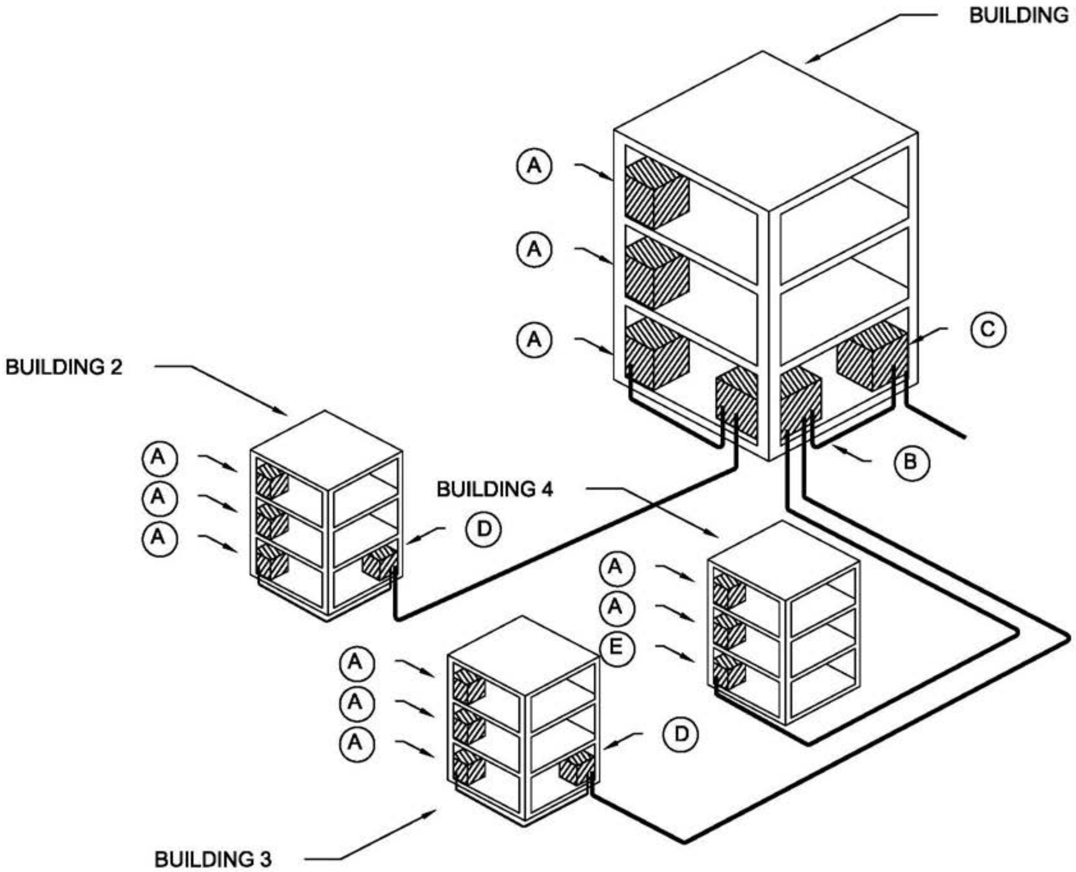
b. Telecommunications Room. A telecommunications room (TR) is an architectural space designed to contain information communications technology equipment, cable terminations, and cross-connect cabling. It contains the information communications technology equipment for connecting the horizontal cabling with the backbone cabling system. The TR may also function as the telecommunications EF.

c. Equipment Room. An equipment room (ER) is an environmentally-controlled, centralized space for information communications technology equipment that typically houses a main or intermediate cross-connect. Any or all the functions of a TR or EF may be provided by an equipment room.

d. Telecommunications Enclosure. A telecommunications enclosure (TE) is a case or housing for telecommunications equipment, cable terminations, and cross-connect cabling.

Although TEs serve much like TRs, a TE must not replace a TR. TEs may be considered for buildings with fewer than 10 occupants when approved by the COR for contract designs or the Government design lead for in-house designs. The TE is referred to as a distributor enclosure in TIA-569. TEs must meet TIA-569's requirements for distributor enclosures.

Figure 2-1 Telecommunications Spaces and Cabling



LEGEND	
TR	TELECOMMUNICATIONS ROOM
ER	EQUIPMENT ROOM
EF	ENTRANCE FACILITY
HC	HORIZONTAL CROSSCONNECT
IC	INTERMEDIATE CROSSCONNECT
MC	MAIN CROSSCONNECT

BD	BUILDING DISTRIBUTOR
CD	CAMPUS DISTRIBUTOR

A	SPACE	CONTAINS	
Ⓐ	TR	HC (FD)	DA
Ⓑ	ER	MC (CD)	DC
Ⓒ	EF		
Ⓓ	ER	IC (BD)	DB
Ⓔ	EF	IC/HC(BD/FD)	DA/DB

2-3.1.2 Architectural Considerations.

2-3.1.2.1 Location and Access.

Locate telecommunications spaces so that the maximum cable length from the patch panel through the structured cabling system to the furthest outlet does not exceed 295 feet (90 meters). Telecommunications spaces must be dedicated spaces not shared with other non-information communications technology functions (electrical rooms, mechanical rooms, plumbing). Avoid locations that are restricted by building components that may limit expansion, such as elevators, outside walls, or other fixed building walls. Spaces must be capable of expanding on no less than two sides. Evaluate locations for risk to critical infrastructure (water, dust, electromagnetic impulse (EMI) influence). Locate the telecommunications space away from sources of electromagnetic interference or design the space to mitigate the effects of this interference. Give special attention to electrical power supply transformers, motors and generators, x-ray equipment, and radio or radar transmitters. Locate spaces in an accessible area of the building (e.g., common hallway), but limit access to personnel having an information communications technology requirement or mission. The space must be accessible for delivery of equipment such as network switches, equipment racks, and cabinets.

In renovation projects, avoid rooms containing transformers, air handling units, and similar equipment. If shared facilities cannot be avoided, comply with TIA-569.

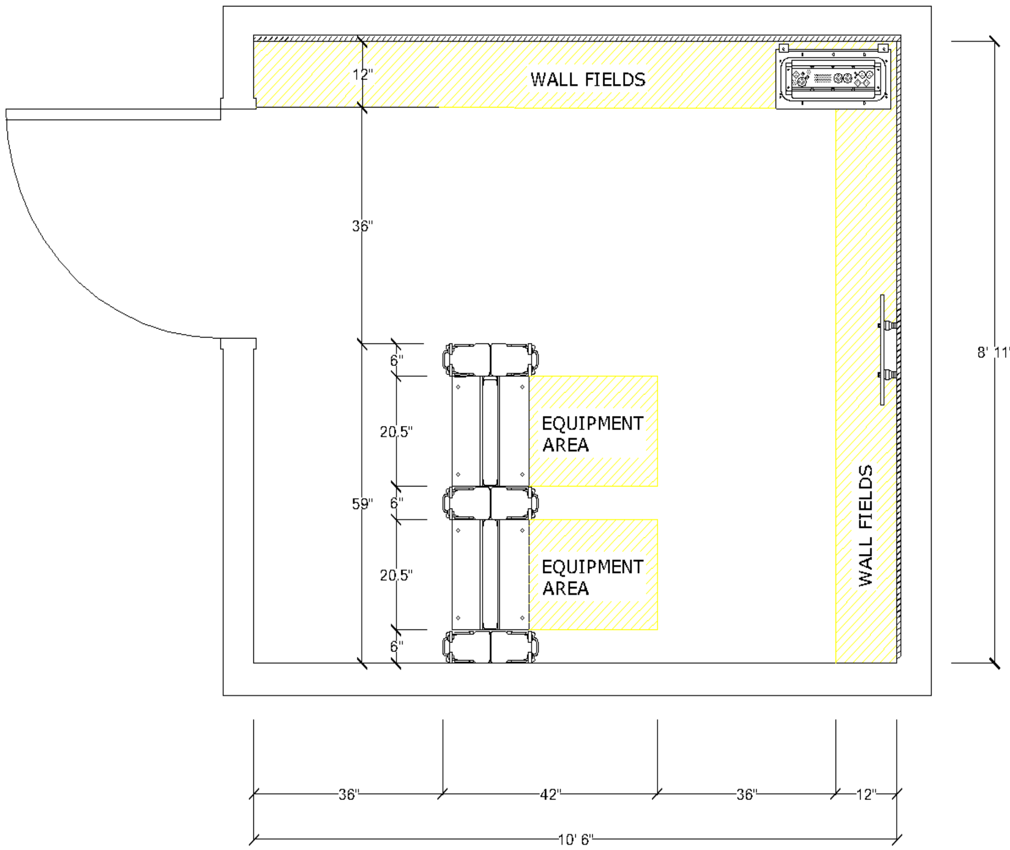
2-3.1.2.2 Telecommunication Spaces Sizing and Quantity.

a. Space for working clearances is critical to allow maintenance activities including moves and changes.

b. Size each TR in accordance with ANSI/TIA-568, with the exception that the minimum TR size for DoD buildings is 10 feet, 6 inches by 9 feet (3.2 meters by 2.7 meters) in buildings larger than 5,000 square feet (464.5 square meters) (Figure 2-2). This will allow a minimum of one spare rack for telecommunication spaces that can be served by one rack to comply with paragraph 2-3.1.5.3 and allows space for equipment mounted on walls.

Adjust the dimensions if vertical cable management for cable longer than shown in Figure 2-2 is required.

Figure 2-2 Minimum Telecommunications Spaces Sizing



c. As best practice, size TRs to approximately 1.1 percent of the area it serves. For example, a 10,000 square foot (929 square meter) area should be served by a minimum of one 10 foot-by-11 foot (3 meter-by-3.4 meter) TR. Divide large floor areas into "serving areas" with TRs for each serving area. Serving area must be no larger than 10,000 square feet (929 square meters) and must not serve more than 20,000 square feet (1,858 square meters). When a TR is designed to serve spaces larger than 10,000 square feet, verify the size of the TR is adequate. Allow for code-required clearances in space allocations.

d. Heating, ventilation, and air conditioning (HVAC) requirements may be substantially affected if additional systems are required in the TR. Consult with the architectural designer or facilities engineer when additional systems requirements (audio visual systems, servers, disk storage arrays) are integrated into the TR.

e. Consider using an ER for areas that exceed 10,000 square feet or for buildings that house substantial IT electronics.

Note: One TR may be adequate for multi-story buildings or in unique facilities. Refer to paragraph 2-3.1.2.5.

f. Ensure adequate space in TRs to accommodate tenant-owned data and information communications technology systems, including FRCS. Support equipment requirements in tenant-installed freestanding cabinets or racks. Total TR space as a percentage of the building's area must be scaled upward to reflect any increase in horizontal drops to each workspace in buildings with more than the standard number. Examples may include command and control facilities or health care facilities.

2-3.1.2.3 Floors, Walls, and Ceilings.

For floors, walls, and ceilings in telecommunications spaces, meet the requirements in TIA-569. Do not install suspended ceilings in telecommunications spaces.

2-3.1.2.4 Doors and Windows.

Exterior and interior doors must satisfy fire rating requirements for TRs in TIA-569 and National Fire Protection Association (NFPA) 101®. For security reasons, exterior windows or architectural window equivalents are not permitted

2-3.1.2.5 Multi-Story Buildings and Unique Facilities.

Provide a minimum of one TR per floor. Provide additional rooms when the floor area is greater than 20,000 square feet and/or the total cable distance to the outlet is over 295 feet (90 meters). Serve all information communications technology outlets from the TR located on that floor. Vertically align TRs on successive floors to allow the risers to align on the same walls. In the case of small and unique facilities, a single TR may be adequate for the entire facility. These facilities include, but are not limited to, air traffic control towers, warehouses, firing ranges, and range and weapons towers.

2-3.1.3 Utility Considerations.

2-3.1.3.1 Lighting.

Design lighting for telecommunications spaces in accordance with UFC 3-530-01. Illumination over aisles should coordinate with overhead runway systems.

2-3.1.3.2 Power.

Provide a dedicated electrical branch circuit panel board for each TR meeting the following minimum requirements: 120/208 volt (V), 3-phase or 120/240V, 1-phase, 24- (or 20- for 1-phase) space panel with a minimum 100 ampere (A) bus rated capacity. Feed loads within the TR from this dedicated TR panel. Loads must include, but are not limited to, convenience receptacles, dedicated rack or cabinet receptacles, and HVAC systems (including exterior units for split systems). Provide 125V, 20A duplex convenience receptacles at 6-foot (1.8-meter) intervals on-center around perimeter walls.

Unless otherwise specified by the Telecommunications Manager, provide a minimum of one receptacle at each rack. To minimize accidental shutoff, equip power strips with indicator lights, but no integral on/off switch. Provide matching (National Electrical

Manufacturers Association (NEMA) configured) twist-lock type receptacles fed from dedicated circuits in the TR panel or from a busway to power each power strip. Install twist-lock receptacles above the rack or cabinet mounted to an information communications technology cable tray. As some rack- or cabinet-mounted equipment may require more power, consult with the local information communications technology group having jurisdiction to determine exact electrical power requirements for each TR.

2-3.1.3.3 Heating, Ventilation, and Air Conditioning.

Design telecommunications spaces to meet HVAC requirements of TIA-569, including the Class B requirements for temperature and humidity as outlined in American Society of Heating, Refrigeration, and Air Conditioning Engineers (ASHRAE) *Thermal Guidelines for Data Processing Environments*. Class B space includes only temperature control. When the IT equipment (ITE) load includes enterprise servers, volume servers, storage products, and other computing environment, the space may be categorized as A4 or A3. TRs will be Class B. ERs may be Class B or Class A4, depending upon the user's equipment load. Work with the system owner to understand the environmental needs and coordinate them with the full design team.

2-3.1.3.4 Room Climate Control.

a. Provide each TR with its own independent thermostat for climate control, capable of supporting year-round ambient temperature control (24 hours per day, 365 days per year) to protect all installed electronic equipment as defined in TIA-569. The mechanical system designer of record must determine the type of system required to meet the environmental condition requirements for all telecommunications spaces. Data centers may require a narrower environmental envelope to safeguard equipment function. Do not include heating and cooling systems within TRs on building time clocks or other temperature setback mechanisms. Provide rooms with positive atmospheric pressure to minimize dust when required by system owners or equipment manufacturers.

b. Design cabinets and rows to avoid recirculation of exhaust air into equipment intakes. Specify blanking panels and baffles as needed to mitigate intra-cabinet circulation. Equipment should be arranged into hot and cold aisles when more advanced schemes of cooling are not used.

c. Do not use electrical name plate data for cooling requirement calculations. Manufacturer heat load data by equipment is best for use in calculating cooling requirements but is not always available. The mechanical designer must determine the amount of cooling required, but will need to collaborate with the telecom designer to understand requirements.

d. Design cooling load capacity to include growth capabilities for IT refresh planning in accordance with ASHRAE 90454. For calculated loads less than one ton (12,000 British thermal units per hour (BTU/hr)), provide a single air conditioning (A/C) unit with space and power capacity to install another identical unit for future load growth. For loads greater than one ton, install two identical units sized for 50% to 60% of the load each, and provide space and power capacity for an additional identically-sized unit for future load growth. For loads greater than 10 tons (120,000 BTU/hr), and where redundant uninterruptable power systems (UPS) have been installed in the telecommunications space, provide more than two A/C units to meet the N+1 redundancy criteria, where N is the number of A/C units required to meet the load (not less than 2), and 1 is the identically-sized redundant spare. In addition to the one redundant spare A/C unit, provide space and power capacity for one additional identically-sized A/C unit for future load growth. Other redundancy requirements may be required by the mission. Ensure IT, power, and mechanical cooling requirements are aligned with the mission.

e. Utility piping serving telecommunications spaces must not be routed over communications racks or cabinets or electrical panels. Where routing over sensitive areas cannot be avoided, provide all wet and drainage piping with special protection, such as double-wall containment piping or drip pans with leak detection to protect the space below from leakage and/or condensation.

2-3.1.4 Room Contaminants.

Do not install information systems equipment in spaces where moisture, liquid or gaseous spillage, or other contaminants may be present, as defined in TIA-569. Do not design spaces that will have a wet wall that can provide ingress of liquids or potentially require maintenance from inside of the telecommunications space for unrelated utilities.

2-3.1.5 Space Components.

For all ICT components, use manufacturer’s standard catalog products that conform to the latest published industry and technical society standards at the date of contract award. Do not use shop- or field-fabricated components that are not manufacturer's standard catalog products or that do not conform to the industry and technical society standards.

2-3.1.5.1 Plywood Backboards.

Provide backboards in accordance with TIA-569. Fire retardant treated wood must comply with International Building Code, Section 2303.2. Backboards must be fire-retardant-treated wood, bearing the manufacturer’s stamp. Backboards are not required to be painted unless requested by the Information Communications Technology Manager for illumination reflectance. They must display at least one fire-rated stamp after wall-mounted equipment is installed and they are painted. Cover a minimum of two adjacent walls with backboards. Allow 1 foot (305 millimeters) of depth space for wall-mounted equipment when calculating room sizes. If equipment with a known depth greater than 1 foot will be used, also allow for that space and required clearance. When renovating an existing TR that does not have adequate space, size the backboard as large as possible to accommodate wall-mounted equipment.

2-3.1.5.2 Protected Entrance Terminals.

TIA-758 identifies two types of building entrance terminals (BET) -- protected and non-protected. Provide protected entrance terminals (PET) in accordance with TIA-758. Equip PETs with modules to protect the inside plant cabling and equipment from power surges. Furnish solid state or gas tube modules adequate for all used pairs plus 25%, but not to exceed the total pair count. Provide 110-type insulation displacement connector (IDC) terminal blocks or cable stubs. See paragraph 2-4 for grounding requirements. Refer to Chapter 3 for OSP requirements.

2-3.1.5.3 Equipment Racks.

Provide 19-inch (475-millimeter) floor-mounted equipment racks. A minimum of 36 inches' (900 millimeters') space, both in front and behind the rack measured from the equipment, and a minimum side clearance of 36 inches on at least one end of the rack or row of adjacent racks is required. Allow a front-to rear-space of 42 inches (1067 millimeters) to accommodate equipment. Coordinate with the Information Communications Technology Manager to determine the space and weight requirements for the USG-provided active equipment. A four-post rack may be required to support equipment due to weight or mounting requirements. Provide 25% spare rack unit capacity within each rack used. Provide one spare rack for every four used racks, with a minimum of one spare rack per telecommunication space.

In existing facilities with narrow or crowded telecommunication spaces, equipment racks may be wall-mounted with the approval of the Information Communications Technology Manager. Workspace around the cabinet/rack is still required even if the cabinet is mounted 6.5 feet (2 meters) off the floor. Refer to Figure 2-3.

2-3.1.5.4 Equipment Cabinets.

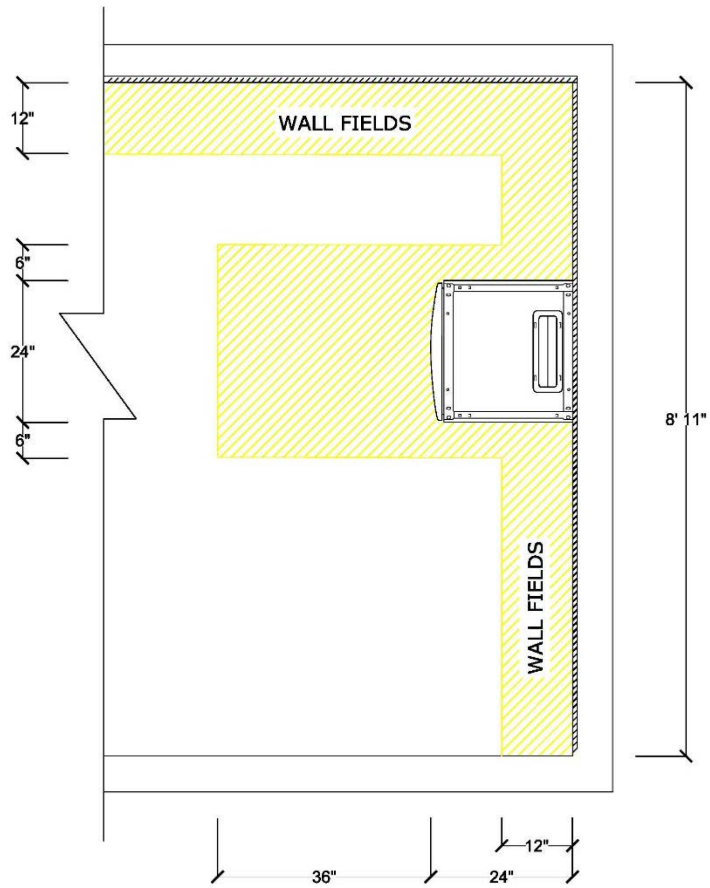
Provide equipment cabinets in lieu of racks where:

- identified by Service-specific chapters in this UFC.
- required by the Information Communications Technology Manager.
- physical security is required, such as to mount secure or mission critical equipment.
- separately controlled access is desired (when multiple systems are collocated within the room).

a. Provide a minimum 24 inch- (600 millimeter-) wide cabinets with cooling fans (when required) and internal rails to support 19-inch (475-millimeter) equipment. Locate cabinets in rows with front and rear clearance. A minimum space of 36 inches (900 millimeters), both in front and behind the cabinet, and a minimum side clearance of 24 inches (600 millimeters) on at least one end of the cabinet or row of adjacent cabinets is required. When an aisle is against a wall, cabinets should not exceed eight in a row.

b. Design cabinets with 63% mesh doors with blanks and baffling to ensure front-to-rear air flow and avoid intra-cabinet air circulation, unless another cooling method is designed. In instances where other air flow is needed, use manufacturer-approved penetrations and sealing to maintain airflow. For hot and cold aisles, use an airflow scheme engineered for the solution.

Figure 2-3 Wall Mounted or Floor Mounted Cabinet Clearance



c. Coordinate with the Information Communications Technology Manager to determine space requirements for the USG-provided active equipment. Provide 25% spare capacity within each cabinet used. Provide one spare cabinet for every four cabinets used, with a minimum of one spare cabinet per telecommunication space.

d. In existing facilities with narrow or crowded telecommunication spaces, equipment cabinets may be wall-mounted with the approval of the Information Communications Technology Manager. FRCS may require wall-mounted cabinets. Where space is limited and clearances are affected, use swing-out cabinets. See Figure 2-3.

2-3.1.6 Horizontal and Vertical Cable Management.

Provide horizontal cable management panels above and below each patch panel. The required ratio of horizontal cable management to patch panels is 1:1. Provide vertical cable management between racks and at the end of racks when required to protect, manage, and organize cables. Vertical cable management panels must be a minimum of 6 inches (150 millimeters) wide, and sized based on total anticipated cable plus 50%. Allow space against the wall for operation of vertical management covers.

2-3.1.7 Ladder and Wire Cable Tray.

Use ladder-type cable trays in telecommunication spaces to provide distribution between the plywood backboard, equipment racks, backbone conduits, and the distribution cable tray. Bond all metallic cable tray sections and bond the cable tray system to the primary bonding busbar (PBB) or secondary bonding busbar (SBB).

2-3.1.8 Copper Pair Patch Panels.

For patch panels, use 8-position, 8-contact (8P8C) modular jacks with rear-mounted 110-type IDC terminations, category rated for the copper cabling being installed, and arrange in rows or columns on 19-inch (475-millimeter) rack-mounted panels. For small projects (fewer than ten users), 19-inch TIA category-qualified wall mounted block or backboard patch panels may be used. Provide T568A jack pin/pair configuration per ANSI/TIA-568. T568B jack pin/pair configuration may be used only if required to maintain uniformity in an existing facility. Provide modular jacks that conform to the requirements of ANSI/TIA-568, rated for use with the installed cable plant. Install unshielded twisted pair (UTP) patch panels in the same rack or in the rack immediately adjacent to the local area network (LAN) equipment to minimize patch cord lengths. Provide a minimum spare capacity of 25 percent.

2-3.1.9 Fiber Optic Patch Panels.

Use patch panel connectors and couplers of the same type and configuration as used elsewhere in the system. Unless otherwise directed, use duplex lucent connectors (LC) or keyed LC connectors on 19-inch rack-mounted panels to support legacy installations. Provide a 3-foot (0.9-meter) slack loop of fiber within each panel and include strain relief for cables within the panel. Provide proper termination, splice storage, routing, radius limiting, cable fastening, strand storage, and cross-connection in all patch panels. Install fiber optic patch panels in the same rack or in the rack immediately adjacent to the LAN equipment to minimize patch cord lengths. Provide a minimum spare capacity of 25 percent.

Consider multi-fiber termination push-on (MTP®) factory-terminated fiber optic systems using cassettes to break out fibers. This has many advantages, including factory testing, shorter installation times, future-proofing connection types, and tap port options.

In existing facilities, other connector types may be used to match the current infrastructure with the approval of the Information Communications Technology Manager.

2-3.2 Telecommunications Pathways.

A pathway is a facility for placement of information communications technology cable.

2-3.2.1 Backbone Pathways.

Backbone pathways are structures that conceal, protect, support, and provide access to cables between telecommunications spaces. Examples of backbone pathways include conduit, sleeves, slots, cable trays, telecommunication spaces, and miscellaneous support facilities.

For intra-building backbone distribution, use a minimum of two 4-inch (100-millimeter) conduits between TRs located on the same floor, or a pathway that provides equivalent capacity (e.g., cable tray installed to support backbone and horizontal distribution).

In multistory buildings, use a minimum of three 4-inch conduits, sleeves, or an equivalently-sized slot between stacked TRs on successive floors in accordance with TIA-569. Design at least N+1 raceways to support moves, adds, and changes (MAC). Nationally Recognized Testing Laboratory (NRTL)-rated fire assembly is required for penetrations through telecommunication space walls.

2-3.2.2 Horizontal Pathways.

Horizontal pathways are structures that conceal, protect, support, and provide access to cables between the telecommunications spaces and the work area outlet. Examples of horizontal pathways include conduit, cable trays, ceiling distribution, access floors, and non-continuous cable supports (J-hooks).

There are many methods to distribute cable from the telecommunication space to the work area, and many buildings may require a combination of two or more types of pathway systems to meet all distribution needs. The DoD-required horizontal pathway is a ceiling distribution system employing a centralized cable tray system originating in the telecommunication space and continuing out into the serving areas. Use cable trays for horizontal distribution to the maximum extent possible (maximum horizontal distance: 50 feet (15,240 millimeters) in open face hangers). The remaining pathway to the work area outlet may be implemented in a variety of ways combining conduit, non-continuous cable supports, and stub-ups/outs.

2-3.2.2.1 Open Office Wiring.

Open office wiring refers to work space divided by modular furniture and partitions rather than fixed walls. The electrical designer, the architect, and the interior designer must coordinate layout of all furniture with electrical and information communications technology outlets during the design process. Typically, furniture is selected and ordered when construction is nearing completion; without proper coordination early in the design process, field interface problems will occur.

a. Systems Furniture. Use architectural columns and perimeter walls to the maximum extent possible for information communications technology distribution to systems furniture workstations. Where permitted, use utility columns in the absence of architectural columns or when systems furniture is located away from perimeter walls. Only if no other alternative exists, use under-floor conduits designed and installed in accordance with TIA-569. Include a spare conduit to under-floor outlet boxes for future expansion. Design systems furniture wiring connections in accordance with ANSI/TIA-568 and TIA-569.

Due to the uncertainty of final furniture type and layout, design wiring length for furniture outlets to the farthest point of each furniture group, plus 10 feet of extra wiring. If systems furniture has been selected and has pathways sufficient for pre-terminated cabling, consider consolidation points with factory patch cords.

b. Protection and Separation in Systems Furniture and Utility Columns. When systems furniture does not provide a metallic separation or have power in a metallic raceway, ensure separation between telecommunication and power wiring in the utility columns and systems furniture track in accordance with TIA-569 and NFPA 70®.

c. Horizontal Distribution in Small Facilities and Renovations. In new construction involving small, mixed-use (non-administrative) facilities or construction projects involving renovation of existing buildings, use of J-hooks, flexible cable trays, and alternative support systems specifically certified for Category 6A cable is permitted, but not desirable. In renovation projects where access to the walls for installation of conduit and outlet boxes is not possible, or where historical requirements prohibit alteration of the building structure, surface-mounted non-metallic raceway may be used.

2-3.2.3 Pathway Components.

2-3.2.3.1 Cable Trays.

Use solid bottom, slotted bottom, or welded wire cable trays to provide a centralized cable management/distribution system.

a. Use the cable tray for horizontal distribution to the maximum extent possible (80 percent to 90 percent of the horizontal cable length).

b. Design cable trays to accommodate an initial calculated fill ratio of 25 percent.

Note: This allows for future growth within the cable tray. Due to random placement of cables and space between the cables, a 25 percent fill ratio means that the tray is half filled.

c. Follow manufacturers' recommendations for weight, considering both tray capacity and cable loading capacities.

d. Maximum fill ratio of any cable tray is 50%.

e. Maximum fill depth of any cable tray is 6 inches (150 millimeters).

f. Do not use ladder cable trays for horizontal distribution outside of the TR or ER due to possible cable deformation when using large quantities of cable.

g. Maintain a minimum of 12 inches (300 millimeters) access headroom above a cable tray system or cable runway and 12 inches (300 millimeters) side access clearance on one side of the cable tray system or cable runway. Where this cannot be achieved, maintain an 8-inch (203-millimeter) clearance including seismic restraints.

h. Side and top encroachment distance may be less than 3 feet (914 millimeters) in a 20-foot (6096-millimeter) section of cable tray provided it does not prohibit access to raceways that feed into the tray. These encroachments must be approved by the AHJ with written consent by the Information Communications Technology Manager.

2-3.2.3.2 Conduit.

Design conduit systems in accordance with TIA-569. Install EMT conduit from the cable backbone distribution system, whether cable tray or enclosed duct, to each outlet, unless a conduit-less system is approved by the Information Communications Technology Manager. For standard outlets, use a minimum 1-inch (27-millimeter) EMT conduit. When cable tray or enclosed duct is not used, use individual conduits from the TR to each outlet. Coordinate conduit bend radius with cable bend radius. Arrange conduit entries at outlet and junction boxes so that cables passing through the box enter and exit at opposite sides of the box. Do not use flexible metal conduit for information communications technology wiring except when installing floor access boxes in a raised floor where the floor access box may be relocated within a specified service area. In this case, the length of the flexible metal conduit must not exceed 20 feet (6096 millimeters) for each run, per TIA-569.

Avoid using in-slab and below grade conduit systems for interior designs as these systems provide the least flexible horizontal distribution system. If an in-slab or below grade conduit system is used in the design, comply with NFPA 70® and use listed cables rated for wet locations. Do not use plenum or riser rated cable, gel-filled OSP, and unlisted cables in such an environment. Cables rated for a wet location typically have a larger outside diameter which may affect conduit fill rates and conduit sizing. Larger conduit sizing in the slab may affect the integrity of the structure. For in-floor conduit systems, provide home runs back to the TR serving that area. Serve all outlets from the TR located on that floor.

Use an optimal conduit fill ratio of 40 percent for conduit sizing. Do not exceed a fill ratio of 50 percent. Do not install more than four, four-pair cables in a 1-inch

(27-millimeter) conduit. Do not use conduit in a Family Housing project unless the project is a high-rise apartment building.

2-3.2.3.3 Non-continuous Cable Supports.

Non-continuous cable supports are not permitted in:

- place of the cable tray system or as the sole distribution system in place of home-run conduit. Design non-continuous cable supports to support the category rating of the cable.
- spaces that exceed 50 feet (15,240 millimeters) total length through a non-continuous cable support system.
- ceilings in which infection control protocol affects ceiling tile removal.
- spaces where cable must be protected.

When using non-continuous cable supports, comply with TIA-569. Supports must not exceed 20 cables or 50 percent of the fill capacity, whichever is less.

2-3.2.3.4 Pull and Splice Boxes.

A pull box is a housing located in a pathway run to facilitate placement of wire or cables. A splice box is a box located in a pathway run to house a cable splice. Place pull and splice boxes in conduit runs in accordance with TIA-569.

2-3.3 Telecommunications Cabling.

In accordance with ANSI/TIA-568, backbone and horizontal cabling is typically installed in a hierarchical star configuration. Provide alternative topology when required by the mission and approved by the technical authority. Paragraph 2-3.1.1 pertains to copper and fiber optic backbone and horizontal cabling. Cable to support CCTV and CATV is addressed in paragraphs 2-3.5.1 and 2-3.5.2.

2-3.3.1 Backbone Cabling.

Paragraphs 2-3.3.1.1 and 2-3.3.1.2 pertain to copper and fiber optic intra-building backbone cable. Use no more than two hierarchical levels of cross-connects (main and intermediate) for the intra-building backbone. Use copper backbone cable only for voice circuits. Use fiber optic cable for data backbone circuits.

2-3.3.1.1 Copper.

Comply with the following:

- Use multi-pair voice backbone cable that and satisfies requirements of ANSI/TIA-568 for riser or plenum-rated UTP cable.
- Use solid untinned copper, 24 American Wire Gauge (AWG) conductors.

- Coordinate the copper backbone design with the Information Communications Technology Manager to minimize the amount of copper used.
- Use minimal copper backbone to support traditional two-wire phones and legacy systems as the transition to an all-fiber backbone occurs.
- For facilities that will use unified communications (voice, video, and data over Internet Protocol (IP)), use a minimum 25-pair copper backbone to each TR. Provide additional cable counts to support actual legacy system requirements.
- For facilities using legacy systems, use copper backbone cables sized to support no more than 1.5 pairs for every outlet connected to the serving TR.

Terminate OSP cable on a PET. Terminate the copper backbone cable originating in the main TR or main cross-connect in each TR on 110-type, insulation-displacement wiring blocks mounted on the backboard or rack-mounted. If rack-mounted, isolated from the rack bonding busbar (RBB) and route appropriate ground to PBB for PET. Provide 110-type terminal blocks on the same backboard as the PET and in each TR for copper backbone distribution. Use intermediate cross-connects when required by the Information Communications Technology Manager.

2-3.3.1.2 Fiber Optic.

a. Use single mode fiber optic cable with a minimum of 12 strands between the main telecommunications room or main cross connect and each TR. Where required by NFPA 70® or by local regulations, fiber optic cable must be plenum-rated. Place non-armored fiber in innerduct. Furnish bullet bonding for armored fiber cabling.

b. Indicate the proper color coding of optical fiber cabling on design drawings. Use the TIA-598 jacket color coding scheme for fiber-optic (FO) cable (Table 2-3).

Table 2-3 Jacket Colors

MODE	COLOR
Single-mode (ranges between 8 and10um) (OS1)	Yellow
Single-mode (ranges between 8 and10um) (OS2)	Yellow
Multimode 62.5/125um (OM1)	Slate LEGACY
Multimode 50/125um (OM2)	Orange LEGACY
Multimode 50/125um laser optimized (OM3)	Aqua
Multimode 50/125u (OM4)	Violet or aqua
Multimode 50/125um laser optimized (OM5)	Lime green

c. Table 2-4 provides typical distances for the fiber optic cable types listed in Table 2-3. Work with the system owner to select the appropriate media type to match the requirements of the installation. Consideration technology refreshes that can be expected to occur over the life of the installed plant.

Table 2-4 Fiber Speeds

Speed Fiber Type	100 MB	1 Gb	10 Gb	40 Gb	100 Gb
OM1	1800 ft (549 m)	722 ft 220 m)	108 ft (33 m)	N/A	N/A
OM2	1800 ft (549 m)	1800 ft (549 m)	269 ft (82 m)	N/A	N/A
OM3	1800 ft (549 m)	1800 ft (549 m)	984 ft (300 m)	328 ft (100 m)	328 ft (100 m)
OM4	1800 ft (549 m)	3281 ft (1000 m)	1800 ft (549 m)	500 ft (152 m)	500 ft (152 m)
OM5	N/A	N/A	1800 ft (549 m)	500 ft (152 m)	500 ft (152 m)
SM	N/A	32800 ft (9997 m)	32800 ft (9997 m)	32800 ft (9997 m)	32800 ft (9997 m)

d. Terminate backbone fiber-optic (FO) cabling, at each end, on cabinet/rack-mounted patch panels with integrated circuit (IC) or MPT-type connectors unless otherwise required by the activity or recommended by the system manufacturer. Do not use straight tip or mechanical transfer registered jack (MT-RJ) fiber optic adapters and connectors for new construction unless specifically required for interface with existing equipment reused on installations. Provide fiber optic adapters and connectors in accordance with the appropriate TIA-604, Fiber Optic Connector Intermateability Standard (FOCIS). Fusion-splice backbone fibers to factory produced pigtails or use factory MTP® cables with breakout cassettes.

e. Coordinate with the Information Communications Technology Manager for the connector and fiber type. Table 2-5 lists some of the fiber and connector quantities and types for commercially available transceivers for 100G connections:

Table 2-5 100G Transceiver and Connector Types

Transceiver	Fiber	Qty Fiber	Connector	Distance (meters)
100G-SR10	OM3/OM4	20	24F MTP®	100/150
100G-SR10 MXP	OM3/OM4	24	24F MTP®	100/150
100G-SR4	OM3/OM4	8	12F MTP®	70/100
100G-XSR4	OM3/OM4	8	12F MTP®	300
100G-LRL4	OS2	2	LC	2,000
100G-CWDM4	OS2	2	LC	2,000
100G-LR4	OS2	2	LC/SC	10,000
10X10-LR	OS2	20	24F MTP®	1,000
100G-PSM4	OS2	8	12F MTP®	500
100G-SWDM4	OM3/OM4	2	LC	70/100
100G-SR-BD	OM3/OM4	2	LC	70/100
100G-FR	OS2	2	LC	2,000
100G-DR	OS2	2	LC	500

2-3.3.2 Horizontal Cabling.

2-3.3.2.1 Copper UTP.

a. Category 6A (CAT6A). Provide one CAT6A UTP cable to each standard 8-pin modular jack. Use only cable that has passed the Underwriter's Laboratory (UL) LAN certification program and is labeled with UL acceptable markings. Provide plenum rated cables in accordance with NFPA 70®, or when directed by the facility safety officer or UFC 3-600-01. Do not use Category 3, 5, 5e, or 6 rated cabling in new construction or rehabilitation projects for ICT. See Table 2-3 for cable types for non-IT, OT, and Power over Ethernet (PoE). See paragraph 2-3.3.3 for passive optical network (PON) fiber requirements in the horizontal.

Note: When specifically required by other criteria or needed for the application, such as high bandwidth uncompressed video, designers may use screened or shielded twisted pair (ScTP or STP) cabling (as in Europe or secure areas).

b. CAT6A Termination. Terminate UTP cabling at the work area outlet and patch panel using an 8-pin, RJ45 type modular jack rated for the category of the installed cable. Terminate horizontal cables in the telecommunications spaces on Category 6A rack-mounted patch panels. Facilities with minimal outlet requirements (normally less than 12) may use a small cabinet or backboard-mounted CAT6A patch panel. Terminate cables from the same outlet on the same patch panel and individually identify the cables. Wire all terminations to the TIA 568, T568A configuration. Do not use the T568B wiring configurations unless specifically requested by the user and approved by the AHJ and approved by the COR for contract designs or the Government design lead for in-house designs. Do not split copper cables between multiple modular connectors.

Note: Coordinate with the Information Communications Technology Manager to determine if it is necessary to separately identify and differentiate “voice” and “data” systems.

c. CAT6A UTP Patch Cords. Use 4-pair, minimum size 24 AWG stranded UTP copper patch cords rated for Category 6A (match the horizontal infrastructure), with 8-pin modular plugs at each end. Due to performance and testing requirements, only factory-manufactured patch cords of the same category as the cabling plant are permitted. Use plenum patch cords in plenum spaces. For applications requiring a male termination, a male plug terminated link (MPTL), may be used conforming to TIA standards. Use patch cords of various lengths to terminate all required connections. Use 25% spare patch cords when requested by the technical authority. Length, color, and quantity of each must be approved by the COR for contract designs or the Government design lead for in-house efforts.

d. Cable Length. In accordance with TIA 568, limit copper data cable length to 295 feet (90 meters) from patch panel termination in the TR to the data outlet termination. PONs may exceed the 295-foot (90-meter) length. See paragraph 2-3.3.3 for PON cabling.

2-3.3.2.2 Fiber Optic.

a. Cabling. Use fiber optic cable to each outlet and endpoint only when required by the mission and approved by the Information Communications Technology Manager. Use 50/125-um diameter laser optimized (OM3) multi-mode when the user requires multimode fiber optic cable. When the Information Communications Technology Manager requires it, use single-mode fiber optic cable (OS1) or (OS2). Use plenum cables in accordance with NFPA 70®, or when directed by the facility safety officer or UFC 3-600-01.

Specify legacy fiber optic cable only when mating to existing installed base including 50/125-um diameter (OM2) or 62.5/125-um diameter (OM1) multimode fiber.

b. Termination. Terminate FO cable in cabinet/rack-mounted patch panels, and at the outlet using LC or MTP® type connectors in accordance with the appropriate TIA-604 series document. Do not use ST or MT-RJ fiber optic adapters and connectors for new construction unless specifically required for interface with existing equipment reused on installations. Use fiber optic adapters and connectors in accordance with the appropriate TIA-604 FOCIS. Use individual patch panels and distribution panels with 12 duplex LC connectors on each bulkhead. Consider using MTP® connectors on cassettes with breakouts to duplex LC to allow for future upgrades to the system. When designing bulkheads, specify that vertical or horizontal be applied universally on the project to ease labeling and administration.

c. Patch Cords. Use fiber optic patch cable types and connectors of the same type as those on the patch panels with which they are interconnecting. Use duplex patch cords. Due to performance and testing requirements, use factory manufactured pre-connectorized patch cords. Provide sufficient fiber optic patch cords, of various appropriate lengths, to terminate all fiber optic patch panel appearances, plus 25% spare. Use 25% spare patch cords when requested by the technical authority. Length, color, and quantity of each must be approved by the COR for contract designs or the Government design lead for in-house designs. Consider specifying a drawer in racks and cabinets to house spare patch cords.

2-3.3.3 Passive Optical Network and Fiber to the Network Edge Active Ethernet.

2-3.3.3.1 Passive Optical Network.

PON architecture employs optical switch ports centralized with a passive optical splitter to deliver connectivity to multiple endpoints via simplex single mode optical fibers. Obtain approval from the technical authority before designing PON infrastructure, and work with the network architect to understand the type of PON being deployed, as different splitter ratios are allowed. Loss budgets must be understood and incorporated into the design.

The horizontal portion of the PON infrastructure must be installed using a simplex optical fiber cable. Consider using a duplex optical fiber cable to the work area to future-proof the installation. Terminate it in the TR to allow the network engineer to patch into and change the passive optical splitter as the network evolves. When the network will include radio frequency (RF) over fiber, use of angled physical connectors (APC) will be required to reduce back reflections. Angle polished connectors (APC) are recommended for PON network connections. Connections between backbone cabling and cassettes and splitter cassettes may be made with MTP® or other high-density fiber optic termination methods allowing use of pre-manufactured cabling systems.

Optical network terminals (ONT) can be mounted at the desktop to provide copper connectivity to workstations and IP telephones. Small form pluggable (SFP)-based ONTs can be inserted into servers to allow direct connection into servers with the PON fiber. Standards such as ANSI/TIA-568 provide both minimum and maximum channel attenuation. Use these values for passive optical LANs within a building. PONs can permit 128 ONTs per optical line terminal (OLT) or greater. Backbone designs that aggregate 32 OLT per single mode (SM) fiber in the riser serve to future-proof the installation and simplify design. Based upon backbone fiber counts typically being available in 12 counts, this allows the designer to plan for layout.

a. TR Requirements. HVAC requirements can be reduced in TRs as PONs are, by definition, passive connectivity and will not generate heat. If only PON equipment exists in a TR, no additional HVAC loads need to be accounted for.

PON has the potential to reduce telecommunication spaces in a facility, but other systems may rely upon traditional horizontal cabling. FRCS such as Building Automation Systems (BAS), wireless access points (WAP), or enterprise survivable servers (ESS) may not aggregate into the PON infrastructure. If the decision is to have only PON infrastructure in a facility, the number of TRs per floor can be reduced to one because of the distances supported by a PON. The decision to reduce the size of the TR should be weighed against the risk of future systems not fitting into the space. A shallow TR room layout in accordance with TIA 569-E for PON accommodates the passive optical system per floor, but consideration needs to be given for:

- reduced corridor access during TR work.
- security needs of equipment and the need to have doors open for moves, adds, and changes.
- FRCS needs and real estate requirements.

For these reasons, it is recommended that an appropriately-sized TR for every 20,000 square feet of floor space, as a minimum, be maintained to support building telecommunication systems. Verify this space is adequate to house all systems.

b. Fiber Types. Consult the International Telecommunication Union – Telecommunication Standardization Sector (ITU-T) Series G recommendations for guidance on fiber specification for PON networks. For premises applications deploying 10 Gigabit-Passive Optical Network (10G-PON), ITU-T G.657 fiber can be used. For longer reaches, use bend-insensitive fiber meeting ITU-T G.652.

Loss of the optical path cannot be too high or too low. Discrete attenuation may need to be accounted for and designed into the system or the commissioning process.

Table 2-6 Maximum Attenuation

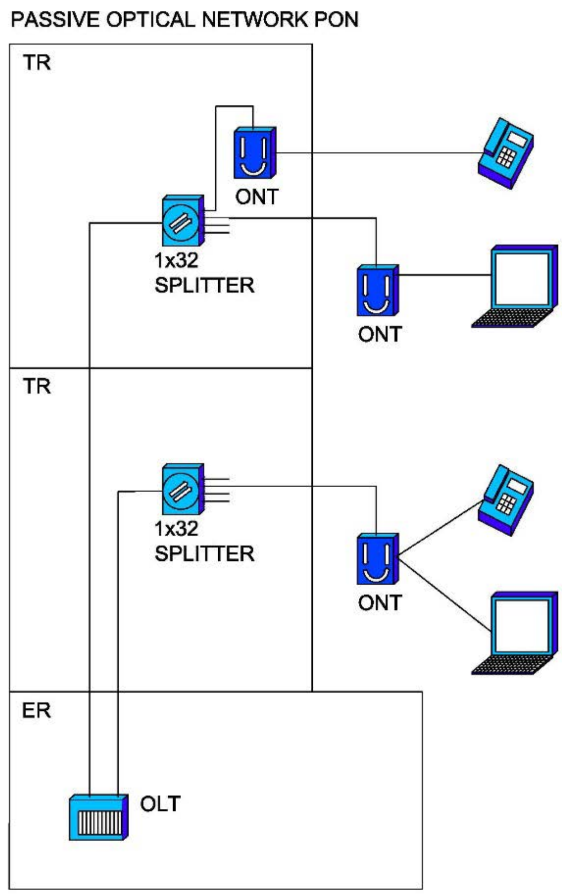
PON Type	Standard	Maximum Distance	Maximum Attenuation
EPON	IEEE 802.3ah	6.2 miles	20 dB
10G-EPON	IEEE 802.3av	12.5 miles	29 dB
GPON	ITU-T G.984	37 miles	32 dB
10G-PON	ITU-T G.987	25 miles	31 dB

Table 9 of ANSI/TIA-568 gives design parameters between 13 dB and 28 dB for premise optical network parameters. Calculate the loss budget for the network and design it to fall within this range, as follows:

Loss of cable	0.5dB/km for outside plant	1.0dB/km for inside plant
Loss of connectors	0.75 dB per connector pair	
Loss of splices	0.3 dB per splice	
Loss of splitter(s)	Varies based upon ratio and type	
Patch cord and mating loss		
Sum above losses		

Note: Plan for headroom of about 3 dB to allow for changes during the life of the cable plant.

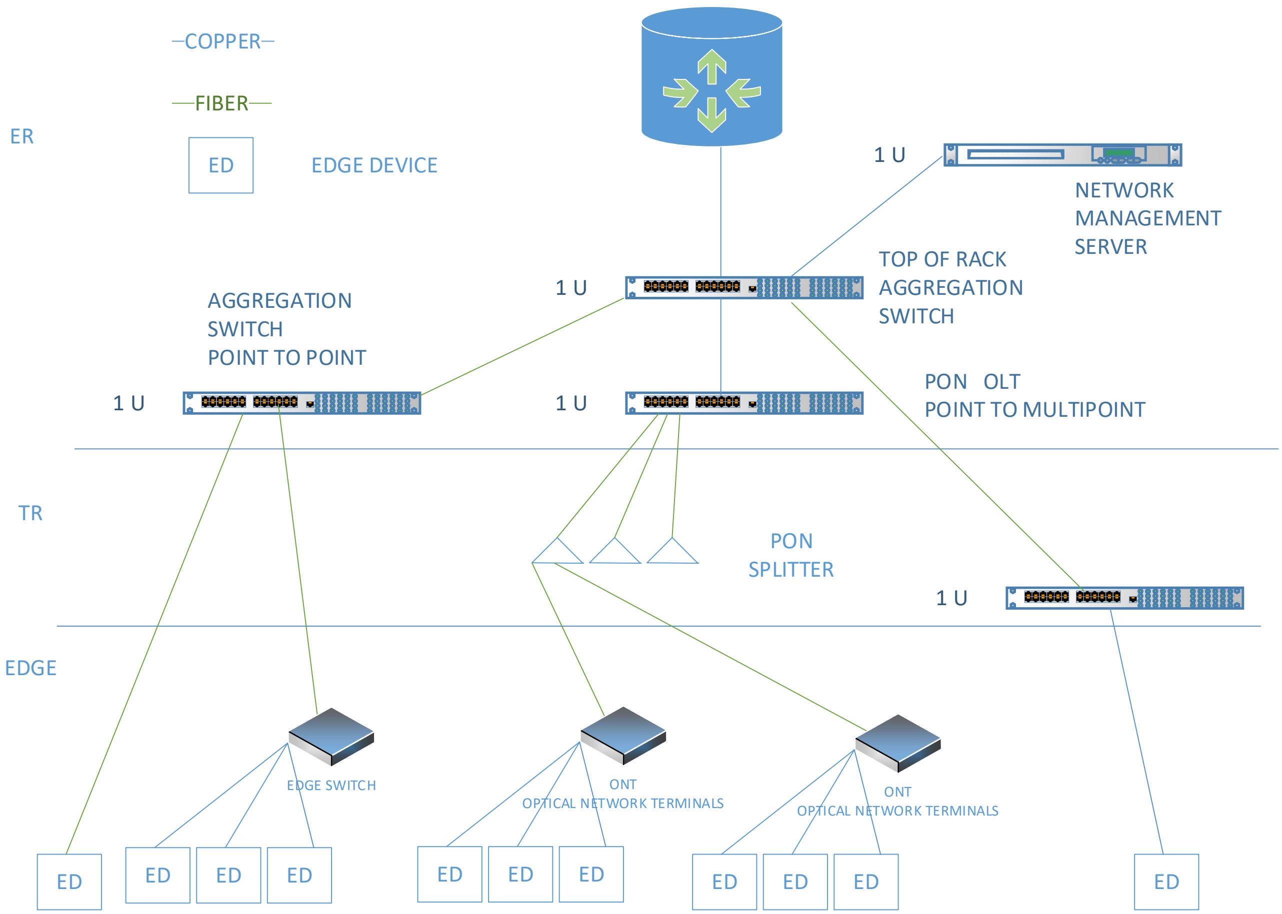
Figure 2-4 Passive Optical Network



2-3.3.3.2 Fiber to the Edge.

While most ONT/software defined access networks (SDAN) use only one fiber (standard connector (SC) angle polished connector (APC) simplex connection), consider using two fibers to each ONT/SDAN for redundancy and/or future capacity. When the network will include analog RF over glass, APC connectors will be required to reduce back reflections. Connections between backbone cabling and cassettes and splitter cassettes may be made with MTP® or other high-density fiber optic termination methods allowing use of pre-manufactured cabling systems.

Figure 2-5 Fiber to the Edge



2-3.3.3.3 Centralized Low Voltage DC Power.

a. Composite Copper/Fiber Cables. Class 2 power can be delivered via composite copper/fiber cables to ONT/SDANs and other utilization equipment that can be powered by PoE. Consider specifying cables that provide both fiber connectivity for data and copper conductors for National Electrical Code® (NEC®) Article 725 light (LPS) DC Class 2 power (low voltage at <60 volts direct current (VDC)/<100 volt-amps (VA) of power).

b. Cable Construction. Composite cables incorporate single mode fibers for network connectivity and pairs of stranded copper for low voltage direct current (LVDC) power distribution. These cables typically will have from 1 to 24 single mode fibers and 2 to 12 copper conductors ranging from 20 American Wire Gauge (AWG) to 12 AWG. Larger gauge copper will allow power to be delivered over longer distances (less voltage drop). Use a gauge of wire that will support the longest lengths needed for the application. Some composite cables also can be provided in armored configurations, indoor/outdoor jackets, or plenum rated jackets. Table 2-7 can be referred to as a guide for equipment operating between 44 and 56V input with PoE passthrough or DC power.

Table 2-7 Composite Cable Distances

Example Composite Cable Distances (1 Pair)			
	30 Watts	60 Watts	75 Watts
20 AWG	590 ft (180 m)	295 ft (90 m)	235 ft (72 m)
18 AWG	940 ft (286.5 m)	470 ft (143 m)	375 ft (114 m)
16 AWG	1,500 ft (457 m)	750 ft (228 m)	600 ft (183 m)
14 AWG	>2,000 ft (>610 m)	1,190 ft (363 m)	950 ft (290 m)
12 AWG	>2,000 ft (>610 m)	1,895 ft (578 m)	1,500 ft (457 m)

By delivering the network power over the composite cable, the power system can be centralized and provide uninterruptible power supply (UPS) backup to prevent network interruptions during building power loss.

c. Fault Managed Power (FMP). NEC® Article 726 (FMP) provides designers with the ability to deliver power for ICT appliances in excess of the 100 watts afforded to Class 2 power and PoE applications from a centralized location. Centralizing power provides centralized UPS power and administration of the system. Cabling can be routed with Class 2 power without separation in the same raceway or cable support system to the utilization equipment and is not required to be installed in conduit. Wattage available at the utilization equipment is system and cable dependent. Equipment and the cable specified must be listed by an NRTL.

2-3.3.3.4 Cabling Requirements.

Even though a PON requires only a single strand of single mode optical fiber cabling to the ONT, the ICT distribution designer should consider two or more strands at the work area to allow for future topology change. This further allows the facility owner the capability to use a mixture of peer-to-peer (P2P) and PON, as there will be instances when non-aggregated traffic will be advantageous.

2-3.3.4 Power Over Ethernet.

PoE is a method of delivering both power and data to a workstation outlet via a category cable. The proliferation of IOT devices is adding to the traditional appliances that were good candidates for PoE. In addition to WAPs, IP telephones, and IP cameras, anticipate appliances that require data and can operate on 100W will be added to the mix. Examples of these items can include displays, BAS, lighting, wayfinding, public address, clocks, and many others.

The Institute of Electrical and Electronics Engineers (IEEE) defines types of PoE according to Table 2-8.

Table 2-8 IEEE 802.3 PoE

Standard	Type	Power
802.3af	1	15.4W
802.3at	2	30W
802.3bt	3	60W
802.3bt	4	100W

2-3.3.5 Bundling

a. The table furnished in NFPA 70® and covered by Figure 2-6 is designed to keep bundles to a size that will not cause an increase in temperature that would damage the insulation. The information is presented for life safety and not performance. Elevated temperatures affect data transmission performance. This is true regardless of the source, so designers are cautioned to consider ambient temperature in the design.

b. American National Standards Institute/Telecommunications Industry Association (ANSI/TIA) TSB-184 provides information about bundle sizes. The recommendations are based upon a cable with a jacket rating of 140 °F being placed in an ambient temperature as high as 113 °F and designed to keep bundle sizes that will not allow an increase to exceed the cable rating. To comply with the NEC®, cables are not allowed to exceed their temperature ratings.

Note: The NEC® must be effective for new design projects awarded after January 1 of the year following the issuance of a revised edition unless specifically identified otherwise in contract documents.

c. Patch cords for PoE applications must be 24 AWG or larger. Bundling cable should be avoided. Reference the *Telecommunications Distribution Methods Manual (TDMM)*, 14th edition. This is a safe design parameter that will prevent problems. It allows a 48-port patch panel to have a bundle of 24 from each side.

d. Cables laid into wire basket or other non-solid tray system and not bundled do not require evaluation for heat gain, as air flow is considered sufficient. Cable trays considered 100% full generally have only 50% of the space occupied by cable, with the balance due to inefficiencies of cables not being square in shape or neatly organized.

e. It is important to understand that use of PoE is expected to increase during the life of the cabling plant. For this reason, mixing powered with non-powered devices in bundles will not remain constant throughout the life cycle of the horizontal cabling.

Figure 2-6 NFPA 70® 2020 Edition Table 725.144 Flow Chart

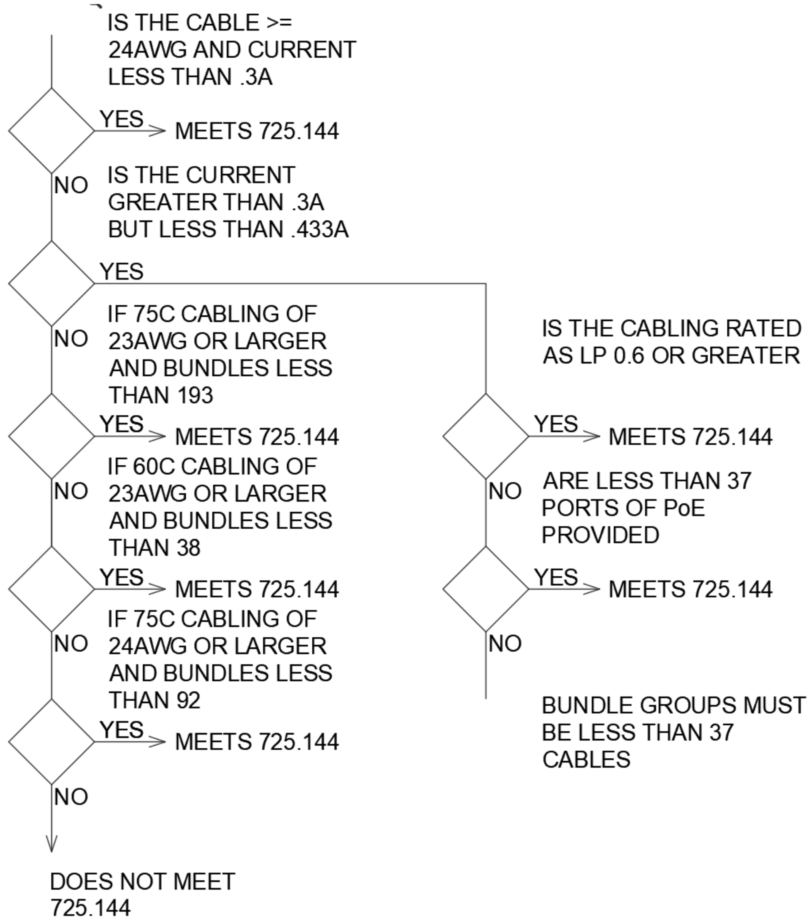


Table 2-9 Recommended Minimum Cable Types PoE

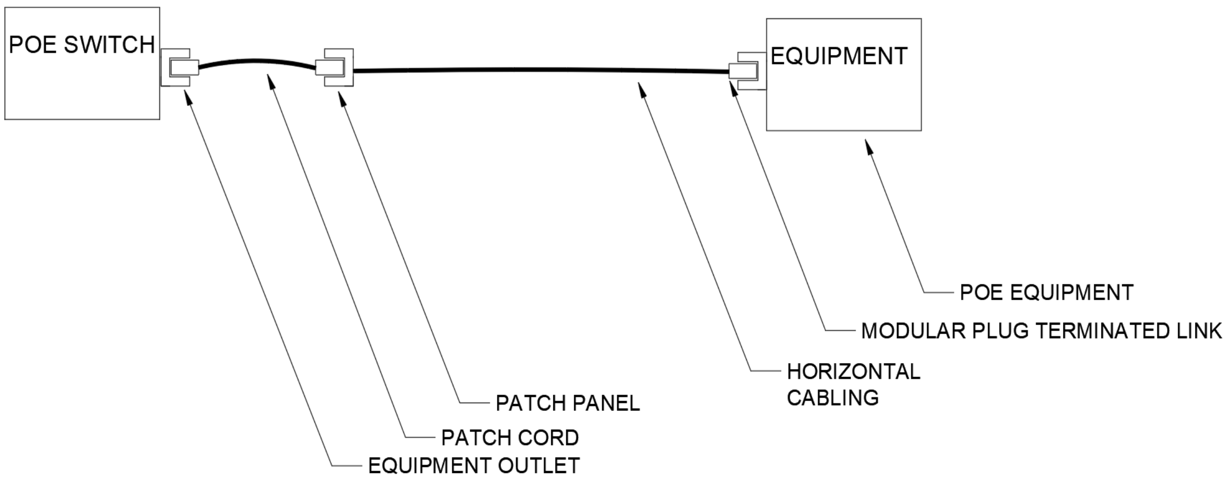
Application	Data Needs	Power Needs	Minimum Cable
BAS	Low	Low	Cat 6
AV	High	High	Shielded Cat 6A
Lighting	Low	High	Cat 6 23 AWG
WAPs	High	High	2 ea Cat 6A
Workstation outlets	High	Medium	Cat 6A

2-3.3.6 Male Plug Terminated Link Modular Plug Terminated Link.

Standards organizations including TIA and BICSI have traditionally required that horizontal cable be terminated on a workstation outlet or a patch panel. This has always precluded the field application of male RJ45 plugs because of the associated high failure rate. The proliferation of non-traditional appliances that require power and data from the horizontal equipment combined with the development of the MPTL led to inclusion and testing in the ANSI/TIA-568 standard. This is required when a female to factory patch cord is not possible.

Figure 2-7 MPTL Link Detail



MPTL connectors are designed to be field-applied to horizontal cable to allow the required quality needed for insertions over the life of the plant. The bodies have metal to assist with the dissipation of heat associated with PoE cabling. This application is useful for nontraditional IP including cameras, WAPs**,** and IOT appliances.

2-3.3.7 Single Pair Ethernet.

FRCS operational technology (OT) that relies on IEEE 802.3 Ethernet is evolving as standards are being published supporting single pair power over data line (PoDL) connections. IEEE 802.3cg standard for 10 megabits per second (Mb/s) lists the following types:

10BASE-T1S	Link segment (point-to-point), 4 connections, 15 meter reach, PoDL power
10BASE-T1L	Link segment (point-to-point), 10 connections, 1000 meter reach, PoDL power
10Base-T1S	Mixing segment (multidrop), 8 nodes, 25 meter reach

TIA single pair Ethernet topologies include:

SP1-400	23 AWG 400M maximum
SP1-1000	18 AWG 1000M maximum
10Base-T1S	Mixing segment (multidrop), 8 nodes, 25m reach

IoT devices will not require batteries or battery changes and can be powered from a switch with a UPS.

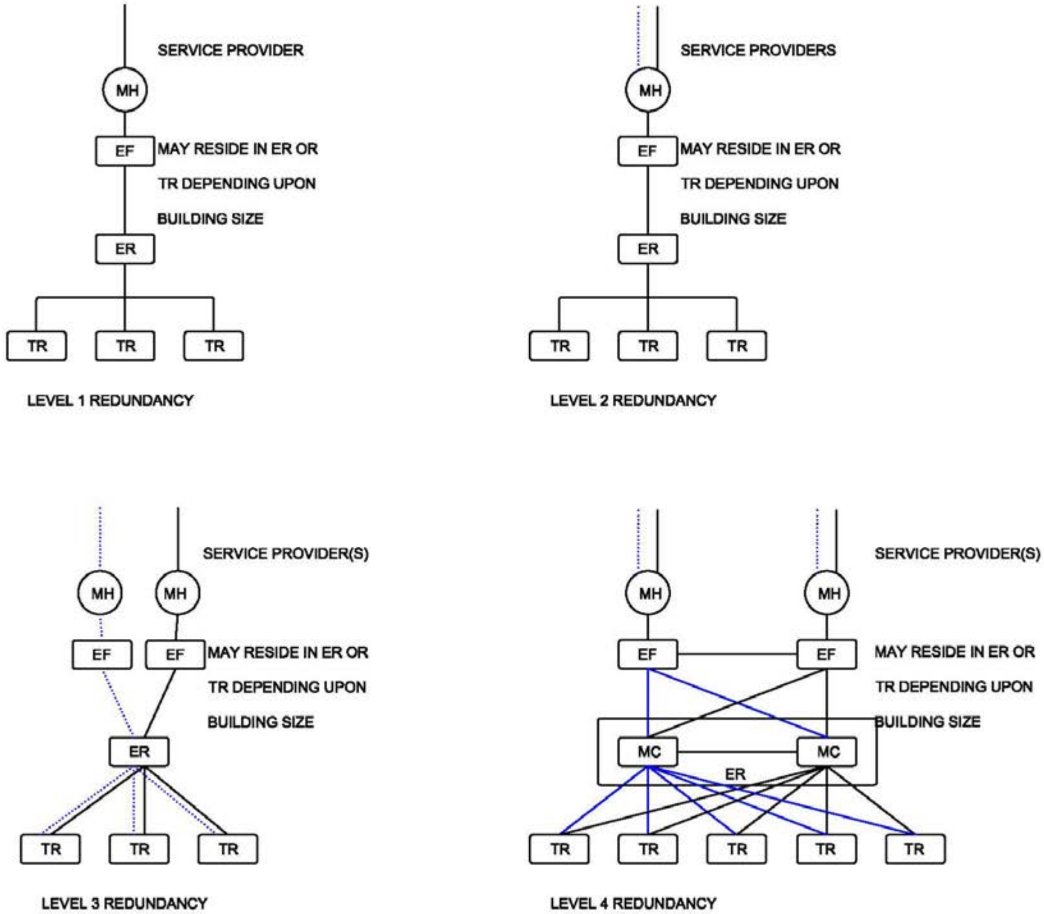
Two 10Base-T1L connectors are recognized by this UFC. They include LC style rated to IP20 and an LC style rated to IP65/67 that are included in International Electrotechnical Commission (IEC) 63171-1 and are not proprietary.

2-3.3.8 Redundancy.

Layer 1 redundancy is a function of mission requirements. Those mission requirements are covered by UFCs and other criteria and outside of the scope of this UFC. Redundancy requirements must be vetted through the proper channels. When the mission requires redundancy, the following information is included to assist in specifying a level of redundancy in the backbone to permit common understanding of the design elements. Additional information on rated levels of redundancy can be found in TIA 942 and on classes of systems in ANSI/BICSI 002 latest edition.

Four levels of redundancy are defined in this UFC. The features of each are illustrated in Figure 2-8 and further described in Table 2-10. It is important to recognize that not all areas of the building may require the same levels of redundancy. There will often be administrative areas in a facility that are collocated for efficiency of operations and will not need the same level of service. To serve all areas with the same level of redundancy would needlessly strain capital. The entire design team must be engaged early to coordinate utilities to ensure the desired outcome is reached. There will be power and cooling requirements that will need to align with the ICT to achieve a desired uptime.

Figure 2-8 Redundancy Levels



LEGEND	
TR	TELECOMMUNICATIONS ROOM
ER	EQUIPMENT ROOM
EF	ENTRANCE FACILITY
HC	HORIZONTAL CROSSCONNECT
IC	INTERMEDIATE CROSSCONNECT
MC	MAIN CROSSCONNECT
FD	FLOOR DISTRIBUTOR
BD	BUILDING DISTRIBUTOR
CD	CAMPUS DISTRIBUTOR
MH	MAINTENANCE HOLE

A	SPACE	CONTAINS	
(A)	TR	HC (FD)	DA
(B)	ER	MC (CD)	DC
(C)	EF		
(D)	ER	IC (BD)	DB
(E)	EF	IC/HC(BD/FD)	DA/DB

Table 2-10 System Levels

System Level	Description	Pathway Notes
Level 1	Non-redundant	
Level 2	Multiple service providers in the ER	
Level 3	Multiple service providers served from diverse pathways in the OSP. Backbone diversity with multiple connections but not pathway diversity in the building.	Maintenance holes (MH) should be 66 feet (20 meters) apart and ideally on opposite sides of the building.
Level 4	Multiple service providers served from diverse pathways. Backbone diversity with pathway diversity in the building.	MHs should be 66 feet (20 meters) apart and ideally on opposite sides of the building. Internal pathways should be separated by 4 feet (1.2 meters) whenever practicable or otherwise designed for pathway survivability.

2-3.4 Work Area.

A work area is the building space where occupants interact with information communications technology terminal equipment. In this UFC, consolidation points (CP), multi-user telecommunications outlet assemblies (MUTOA), and service outlets (SO) are included.

2-3.4.1 Outlets.

2-3.4.1.1 Wall-mounted Workstation Outlet Boxes.

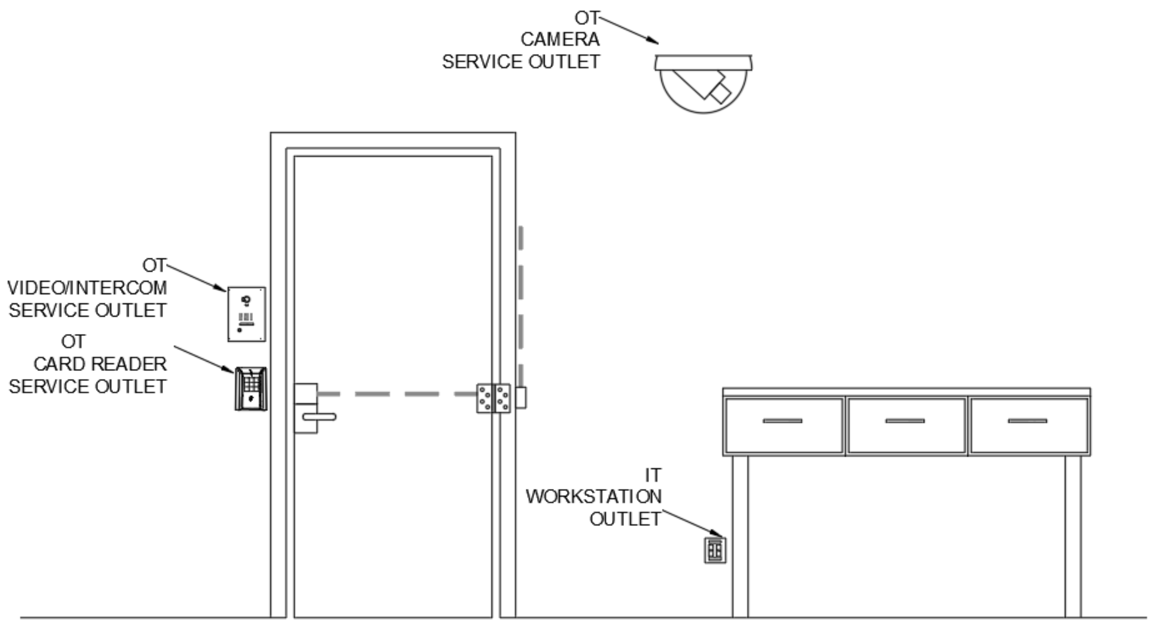
Use double gang electrical boxes, minimum standard size 4-11/16 inches (120 millimeters) square and 2-1/8 inches (54 millimeters) deep with plaster ring for connection of single gang faceplate. Design outlet boxes for recessed mounting with the faceplate flush with the wall surface, at the same height as the electrical outlets. Locate a quadruplex electrical outlet within 6 inches (152 millimeters) of all work area outlets to serve information communications technology loads associated with that outlet.

For the power outlet circuits, assume that each location of two duplex receptacles will power one personal computer with a monitor along with typical office appurtenances such as task lights, and assume that there will be no diversification of this load.

2-3.4.1.2 Service Outlet Boxes.

ANSI/BICSI 007-2020 defines a service outlet (SO) as an outlet that connects equipment to ICT infrastructure. Service outlets are typically used by FRCSs and are not subject to frequent disconnections or relocations. Service outlets need to be aligned with the operational technology (OT) equipment that they serve for mounting heights and box sizes.

Figure 2-9 Service Outlet



2-3.4.1.3 In-floor Outlet Boxes.

Use in-floor outlet boxes only if no other alternative exists for feeding systems furniture, classroom desks, lecterns in lecture halls, and other free-standing furniture. In some instances, an in-floor grid type system may be required to provide necessary flexibility. Account for environmental conditions and the maintenance of floor outlet boxes in the design.

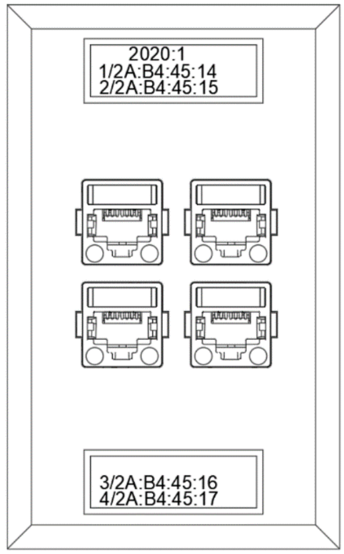
2-3.4.2 Faceplates.

2-3.4.2.1 Outlet Faceplate.

Use a single gang, four position, modular faceplate for each work area outlet. Standard configuration is two RJ-45 modular jacks and two blanks for future applications as shown in Figure 2-10. Provide other copper and fiber optic configurations to support special or legacy telecommunications systems when required.

Figure 2-10 represents a single gang faceplate with four CAT6A modules and sample labeling.

Figure 2-10 Typical Faceplate Configuration



2-3.4.2.2 Wall-Mounted Faceplate.

Use a single gang, single position modular faceplate with one wired modular jack and mounting lugs for each wall-mounted phone.

2-3.4.2.3 Coaxial Faceplate.

Use a single gang**,** single position modular faceplate with one F-type coaxial adapter or a faceplate with four modules with an F-type connector and three blanks.

2-3.4.3 Modular Jacks, Connectors, and Adapters.

Requirements in paragraphs 2-3.4.3.1 through 2-3.4.3.3 pertain to copper, fiber optic and coaxial cable jacks, connectors, and adapters. For copper systems, use the same category rating for cable, jacks, and patch panels throughout the entire system.

2-3.4.3.1 Copper Modular Jack.

Provide unkeyed Category 6A modular jacks in accordance with ANSI/TIA-568, terminated per T568A configuration. Information Communications Technology Manager approval is required for:

- use of T568B configuration to maintain existing system uniformity.
- use of keyed modular jacks where required to maintain system uniformity, security, or other user-specified reasons.

2-3.4.3.2 Fiber Optic Connectors and Adapters.

Provide unkeyed duplex LC connectors and adapters in accordance with ANSI/TIA-568. Terminate fiber optic cabling at both ends using duplex LC connectors, and use adapters at faceplates and patch panels to align and connect fiber optic cables. Consider using 12 or 24 fiber MPT assemblies with breakout cassettes to improve installation times and standardize quality with factory terminated and tested assemblies.

Information Communications Technology Manager approval is required for:

- use of other types of connectors and adapters such as SC, ST, and MT-RJ that are required to support existing systems.
- use of keyed fiber connectors with color coding where required to maintain system uniformity, security, or other user specified reasons.
- high fiber count with high density patch panels.

2-3.4.3.3 Coaxial Connectors and Adapters.

Provide F-type adapters and crimp on connectors in accordance with ANSI/TIA-568.

Terminate coaxial cabling at both ends using threaded, crimp-on connectors for CATV or other systems. Use of any other connectors, such as Bayonet Neill Concelman (BNC), requires Information Communications Technology Manager approval. Coordinate with the cable service provider where franchise agreements are in place.

2-3.4.4 Outlet Types and Density.

The number of work area outlets per square area (outlet density) required in a building varies greatly depending on the type of facility. Table 2-11 lists facility space categories, work area outlet types, and densities commonly used in military construction projects. The outlet configuration options in Table 2-11 must be selected by the proponent and the Information Communications Technology Manager. These outlet types do not address all possible user-required configurations. Provide user-defined outlets that have a corresponding valid requirement, such as multiple levels of classification or dedicated systems. Provide outlet configurations that comply with this UFC and the current versions of ANSI/TIA-568 and TIA-569. Outlet densities are provided for planning purposes when actual outlet locations are not known and cannot be determined with available information. Actual designs must include outlets in work areas, office automation outlets, private office outlets, conference rooms, and wall or access phones as necessary.

Outlet densities are based on gross area (overall building footprint without deducting for areas such as hallways, equipment rooms, and restrooms). Outlet configurations, densities, and locations for all special-purpose spaces not identified in Table 2-11 must be determined by the user and the Information Communications Technology Manager. These can be modified if it is validated (documented in writing, signed, and dated by the Information Communications Technology Manager) that mission operations require a quantity, configuration, or design other than specified in this UFC.

Table 2-11 Outlet Types

Facility Space Category	Outlet Configuration	Planning Area (ft^2(m^2)) per Outlet
Administrative space, to include private offices, conference rooms, classrooms, medical/ clinics, headquarters and special users	Two 8-pin modular (RJ45 type) outlet/connector OR One 8-pin modular and one duplex fiber optic connector OR Two duplex fiber optic connectors in a single gang outlet faceplate.	80(7.5) with a minimum of two (2) dual outlets on different walls for private offices
Open office	Two 8-pin modular (RJ45 type) outlet/connector OR One 8-pin modular and one duplex fiber optic connector OR Two duplex fiber optic connectors in a modular furniture outlet faceplate with outlet box extender	See paragraph 2-3.4.4.1.
Non-admin spaces (CDCs, chapels, recreation centers)	Two 8-pin modular (RJ45 type) outlet/connector OR One 8-pin modular and one duplex fiber optic connector OR Two duplex fiber optic connectors in a single gang outlet faceplate	500(46.5)
Barracks or dormitory space/Bachelors Quarters	Refer to paragraph 2-3.4.4.2.	
Warehouse space	Two 8-pin modular (RJ45 type) outlet/connector OR One 8-pin modular and one duplex fiber optic connector OR Two duplex fiber optic connectors in a single gang outlet faceplate	5000(465)
Wall outlet	One 8-pin modular (RJ45 type) connector in a single gang stainless outlet faceplate with mounting lugs.	As needed
Family Housing units	Refer to paragraph 2-3.3.4.3.	

2-3.4.4.1 Systems Furniture.

Provide a minimum of one systems furniture work area outlet per single occupancy cubicle and a minimum of two systems furniture outlets per cubicle designated for additional scanners, printers, copiers, or fax machines.

Coordinate with the furniture manufacturer to determine the workstation area outlets required for the furniture selected. Calculate cabling to the farthest point of each office furniture set, plus 10 feet (3 meters)

2-3.4.4.2 Barracks, Dormitory, Bachelor Quarters.

Provide one CAT6 modular jack (RJ-45 type) in each bedroom and common area (living room) of the suite configured per TIA-570.

2-3.4.4.3 Family Housing Units.

Provide a complete structured information communications technology system throughout housing unit in accordance with TIA-570. Provide Grade 1 wiring outlets (one telephone outlet and one CATV outlet) as required by TIA-570 and any other appropriate location, including attached garages. UTP cabling and modular jacks must be a minimum CAT6.

2-3.4.4.4 Utility Rooms.

Provide at least one wall-mounted information communications technology outlet in each utility room (e.g., electrical, mechanical, and telecommunications spaces) to accommodate energy management systems.

2-3.4.4.5 Elevators.

Provide a minimum of one work area outlet to the elevator machine room for each elevator. Coordinate the location with the elevator manufacturer.

2-3.4.4.6 Safety, Courtesy, and Convenience.

Provide wall-mounted telephone outlets at all logical locations to support safety, courtesy, and convenience. Examples include:

- Safety: barracks hall, laundry room
- Courtesy: building lobby/entrance
- Convenience: break rooms, rear (unmanned) entrances

2-3.4.4.7 Multi-user Telecommunications Outlet Assembly (MUTOA).

A MUTOA is a grouping in one location of several telecommunications' outlet/connectors. ANSI/TIA-568 allows MUTOAs in an open office environment. This option provides greater flexibility in an office that is frequently reconfigured. A MUTOA facilitates termination of single or multiple horizontal cables in a common location within a furniture cluster or similar open area. Cables from MUTOAs to workstations in system furniture or open offices are supported by the systems furniture raceway and the length must be calculated in accordance with ANSI/TIA-568 when establishing the total channel length. MUTOAs do not include an additional connection and are limited to terminating a maximum of 12 users. Locate MUTOAs and route cables within systems furniture in accordance with ANSI/TIA-568.

2-3.4.4.8 Consolidation Point.

A consolidation point (CP) is an interconnection point within the horizontal cabling using ANSI/TIA-568- or ANSI/TIA-568-compliant connecting hardware. It differs from the MUTOA in that it requires an additional connection for each horizontal cable run. A CP may be useful when reconfiguration is frequent, but not so frequent as to require the flexibility of the MUTOA. CPs are limited to terminating a maximum of 12 users. Locate CPs in accordance with; ANSI/TIA-568.

2-3.5 Other System Requirements.

2-3.5.1 CCTV System.

Where closed-circuit television is required, provide either a 75-ohm broadband quad-shield coaxial cable, single-mode fiber optic cable, or a category rated cable system. Coordinate with the system owner to design an RF or digital solution (such as internet protocol television [IPTV]) based upon system requirements. Ensure the correct cable is used in CCTV systems. Provide plenum cables in accordance with NFPA 70®, UFC 3-600-01, or when directed by the facility technical reviewing authority. CCTV cable distances are affected by multiple variables such as signal strength at the source, signal loss of cable, and CCTV components.

For CCTV security systems or video security systems (VSS), consult UFC 4-021-02.

2-3.5.2 CATV System.

Community antenna television systems are typically referred to as cable TV. Provide a complete system consisting of backboards or cabinets, cable, conduit, and outlets with jacks in all offices and other user required locations. Coordinate with the local CATV service provider.

Include amplifiers, splitters, combiners, line taps, cables, outlets, tilt compensators and all other parts, components, and equipment necessary to provide a complete and usable system. Include the head end amplifier as part of the system when required by the local provider. Passive CATV devices must support 1 GHz bandwidth.

Provide an ANSI/TIA-568- and NFPA 70®-compliant system. Use a star topology distribution system with each CATV outlet connected to a TR with a feeder cable or a drop cable, and each TR connected to the head end equipment with a trunk cable. Provide a high-quality signal to all outlets with a return path for interactive television and cable modem access. The system must operate within the 5- to 1000-MHz bandwidth using 1000 MHz passive devices and a minimum of 750 MHz active devices. Provide a minimum signal level of 0 decibel millivolts (dBmV) (1000 microvolts) and a maximum of 15 dBmV at 55 and 750 MHz at each outlet.

a. Cabling. Use a combination of 75-ohm broadband quad-shield coaxial cable, hard line, or single-mode fiber optic cable system. For fiber optic cables, follow horizontal and backbone cabling requirements. For coaxial systems less than 295 feet (90 meters) from head end equipment to the TR, or from TR to TR, provide RG-11 coaxial trunk cable as a minimum, and calculate the loss budget. For systems exceeding 295 feet from the head end equipment to the TR, or from TR to TR, consider using 625 series cable to reduce system losses and calculate the loss budget. Use RG-6 coaxial cables for drops from the TR (or head end) to the wall outlet. Do not use RG-59 for CATV projects.

The Telecommunications Manager and service provider may require a category cable system in lieu of an RF distribution system. Coordinate with each and provide a complete operable system.

b. HDBaseT™. HDBaseT™ is a trademark of the HDBaseT Alliance. This standard allows the transport of uncompressed ultra-high definition video, digital audio, power, Ethernet, USB 2.0 and other AV control over a single category cable up to 328 feet (100 meters) in length. Support for High Definition Copy Protocol (HDCP) high-bandwidth digital content protection is embedded in the standard to support the ability to use protected content without the 7ms violation breaking the link.

100 watts of power is supported by sending 25 watts over each of the four pairs in a horizontal cable. Power over HDBaseT™ is abbreviated as POH. HDBaseT™ 3.0 includes aggregate data rates of 16 Gb/s. Cat6A screened must be specified in the design. Consider specifying cabling with 22 AWG and screened conductors.

Supporting uncompressed video at 18 Gb/s over High Definition Multimedia Interface (HDMI) can be challenging to design due to cable distance limitations and cable size. Use of horizontal cabling as supported by HDBaseT™ offers flexibility to deliver AV solutions using standard 8P8C connectors and cabling.

2-3.5.3 WAP.

When a wireless local area network (WLAN) system or a wireless intrusion detection system (WIDS) is required, design in accordance with TIA Telecommunications Systems Bulletin 162-A (TSB-162-A) and ANSI/BICSI 008-2018. Give careful consideration to:

- building type
- availability requirements
- uses of the system RTLS
- bandwidth requirements

- coordination of systems, FRCS, IOT, and guest Wi-Fi
- system manufacturer recommendations
- facility type and use

2-3.5.3.1 Existing Facilities,

Once the needs assessment has been completed and the type of service determined, the next step is to create a layout of expected locations for access points. This will be followed up by a site survey. Based upon the output of the site survey, placement of access points in the design follows.

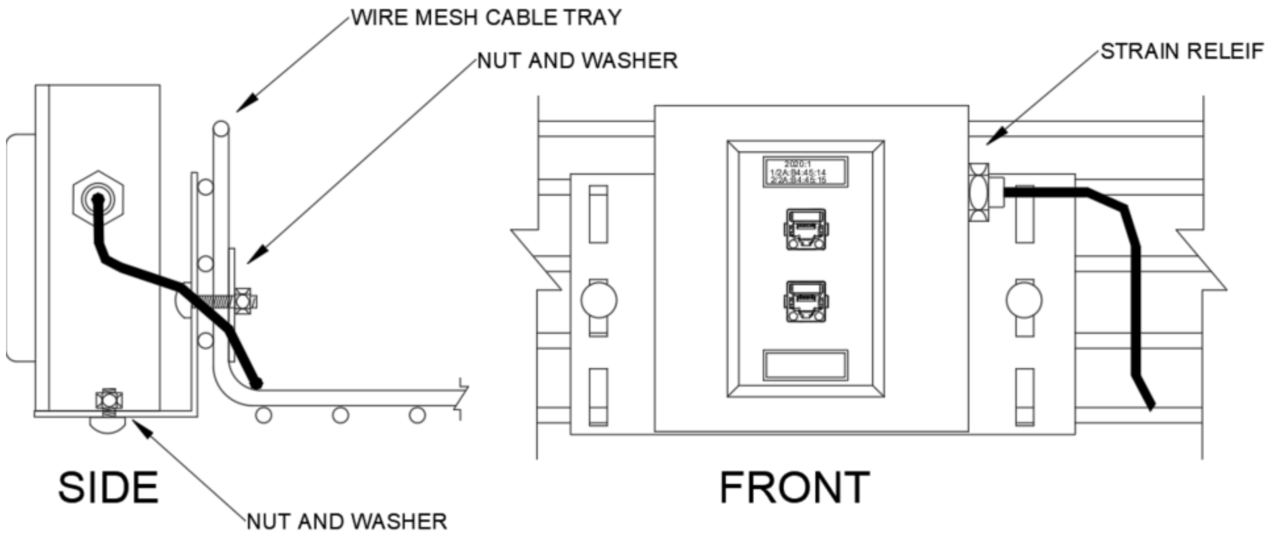
The IEEE 802.11ax, WiFi 6 by the Wi-Fi Alliance, is a 10 Gps application necessitating a Category 6A cable for 328 foot reach. The current best practice and compliance with TIA TSB-162-A recommends use of two category 6A (or higher) horizontal cables or OM3 (or higher) optical fiber cabling. This offers flexibility to use one of the horizontal cables to connect to additional WAPs when commissioning structures when data rates per WAP are less than 10 Gps. IEEE 802.11be uses connectivity greater than 10 Gps, requiring two category 6A cables per WAP.

a. Interior Layout. Work with the network architect to understand density requirements for number of users and use cases potentially including RTLS or other applications. Signal propagation best practice will require use of predictive RF design software to produce heat maps to determine the best layout. The commissioning signal survey may require adjustment in positions and quantities of WAPs that the designer must consider. If predictive RF design software is not available, the radius of the coverage area should not exceed 43 feet (13 meters) (based upon a standard radio in an office environment). Use hexagonal shapes to determine needed overages. Coordinate with the facility to provide TIA-606 compliant administration including location of above ceiling infrastructure.

b. PoE Wireless. NFPA 70®, the NEC®, requires that cables not be allowed to exceed their temperature ratings. The *Telecommunications Distribution Methods Manual*, 14th edition, gives guidance that bundles should not exceed 24 cables. Cables laid loosely in wire mesh cable trays and similar installations improve air flow around cables and reduce heat dissipation. Refer to additional PoE information in this chapter.

c. Horizontal Connection Points. It is advantageous to allow for maximum flexibility of final placement of WAPs. When designing an HCP, allow for a minimum of two permanent link connections for each WAP that is anticipated to be 802.11ax or higher.

Figure 2-11 WAP Outlet Detail



Provide two twisted-pair cables, Category 6A terminated on standard 8-pin modular connectors or two fiber multimode optical fiber strands, OM3 or higher for each wireless access point. Install the WAP cabling infrastructure in the same manner as other information communications technology outlets required in this UFC. Include the cable tray and conduit or J-hooks to support the cable connected to the WAP. Use of “J” hooks, flexible cable tray(s), and alternative support systems specifically certified for the cable used is permissible to support the WAPs from the cable tray. Do not exceed a 50 percent fill ratio for the “J” hooks. Support horizontal cabling to distribution areas in cable trays. Patch cables must match the cable rating.

Confirm power with the Telecommunications Manager if the WAP appliances will not be PoE-powered.

2-3.5.4 Emergency Radio and Cellular Distributed Antenna System (DAS).

2-3.5.4.1 Emergency Radio Codes and Standards.

- NFPA 1221
- NFPA 72® 24.9

2-3.5.4.2 Approval.

These radio systems are operating on frequencies assigned by a licensing authority to a jurisdiction, and coordination with the license holder and approval by the frequency manager or the FCC are required prior to installation. Coordination with the license holder should include a written approval.

The AHJ may require a permit be issued that is renewable after successful testing. This permit may be a condition precedent to an occupancy permit.

2-3.5.4.3 Cabling.

Cabling must be plenum-rated. Backbone cables are required to route through a 2-hour rated pathway from the donor antenna to the equipment enclosure matching the building's fire rating. Coordinate with the Fire Protection engineer for satisfaction of this requirement. Mount to the bottom of the communication tray where room is available or in a divided cable tray.

Connection between the backbone cables and the antenna cables must be made within an enclosure that matches the building's fire rating. Provide a 2-hour rated room to house the equipment.

In facilities where emergency responder radio coverage is required and such systems, components, or required equipment could have a negative impact on the normal operations of that facility, the fire code official has the authority to accept an automatically activated emergency responder radio coverage system. Reference NFPA 1221.

2-3.5.4.4 Coverage Area.

a. Design coverage and testing in accordance with NFPA 1221, Chapter 9. Predictive modeling software is recommended for design.

b. NFPA 1221 divides coverage into two categories. Critical areas are areas considered critical by the Fire Protection engineer. Examples include fire command centers, fire pump rooms, exit stairs, exit passageways, elevator lobbies, standpipe cabinets, and sprinkler sectional valve locations. These areas are required to have 99 percent floor area radio coverage. General building areas must be provided with 90 percent floor area radio coverage.

c. NFPA 1221 defines the requirement to have minimum inbound signal strength sufficient to provide usable voice communications. As this is difficult to quantify for design, the 2021 International Fire Code® (IFC®), Section 510 (a) 510.4.1.1 minimum signal strength of -95 dBm is recommended for use. The building is considered to have acceptable emergency responder radio coverage when signal strength measurements in 95 percent of all areas on each floor of the building meet the signal strength requirements of -95 dBm receivable and the agency's radio system can receive a signal strength of -95 dBm from transmissions inside the building.

d. Buildings may be well-served from existing terrestrial sources and not require radio communications enhancement systems. A survey of the signal strength outside the building combined with RF predictive software can go a long way in determining any need for enhancement. Equip buildings and structures that cannot support the required level of radio coverage with a system that includes RF-emitting devices certified by the radio licensing authority to achieve the required adequate radio coverage.

e. Design radio enhancement systems to support two portable radios simultaneously transmitting on different talk paths or channels, where the facility owner has required the radio enhancement system to support more than one channel or talk path.

f. In addition to quantitative signal strength requirements, qualitative requirements mandate that the signal have a delivered audio quality (DAQ) of 3.0 for either analog or digital systems, meaning that speech is understandable with slight effort, only requiring occasional repetition due to noise or distortion.

g. Consider spaces for pathway to a donor antenna and spaces for enhancement equipment during the design phase unless sure that enhancements will not be required. Drywall and glass must be installed in a building before preliminary functionality testing can be effective. This sometimes occurs late enough in the project that adding an enhanced system affects building occupancy dates.

2-3.5.4.5 Design Personnel Licenses and Certifications.

- general radio operator's license issued by the Federal Communications Commission (FCC)
- manufacturer certificate or nationally recognized organization certification

2-3.5.4.6 Isolation.

When a two-way radio communications enhancement system is installed, isolation between the donor antenna and all interior antennas must be a minimum of 20 dB under all operating conditions. Predictive RF design software should assist with proper placement of antennas near windows to maintain proper isolation.

2-3.5.4.7 Enclosures.

Equipment enclosures must be NEMA 4 or NEMA 4X, except for battery enclosures that require ventilation, and those must be NEMA 3R.

2-3.5.4.8 Interfaces with Facility Fire Alarm Control Panel.

When a two-way radio communications enhancement system is installed, numerous supervisory and trouble notifications must be reported to the Facility Fire Alarm Control Panel (FACP).

2-3.5.4.9 Testing.

Test in accordance with NFPA 1221, Chapter 11. The building floor is divided into 20 equal size test areas and a calibrated portable radio of the model used by the agency is used to talk through the agency's radio communications system. A test is conducted in the center of each test area as a pass/fail. Quantitative and qualitative readings are gathered, and a report produced. A spectrum analyzer must be used to ensure oscillations are not being generated by the amplified signal. The report must include the amplifier gain values and the results and is kept on file with the building owner.

2-3.5.4.10 Power Supply.

a. Provide at least two independent and reliable power supplies for all components, one primary and one secondary. The primary must be from a dedicated branch circuit and comply with NFPA 72®. The secondary power source must supply 12 hours of 100 percent system operation and be arranged in accordance with NFPA 10.6.10, or a battery system with 2 hours of 100 percent system operation and an automatic-starting generator service with a dedicated branch circuit arranged in accordance with NFPA 72®.

b. NFPA 1221 requires power supplies to be monitored by the system the same as for a fire alarm system.

c. Provide a dedicated annunciator within the fire command center to annunciate the status of all RF emitting devices and active system component locations. This device must provide visual and labeled indications of the following for each system component and RF-emitting device:

- normal AC power
- loss of normal AC power
- battery charger failure
- low-battery capacity (to 70% depletion)
- donor antenna malfunction
- active RF-emitting device malfunction
- active system component malfunction

d. The communications link between the annunciator and the two-way radio communications enhancement system must be monitored for integrity.

e. An emergency power off (EPO) switch may be required by the Fire Protection engineer to kill both the normal and redundant power supplies simultaneously.

2-3.5.4.11 Types of Systems.

Work with the building owner to determine the appropriate type of distribution system for the facility. Options are summarized in Table 2-12.

Table 2-12 Facility Distribution System Design Options

	System		
	Passive	**Active**	**Hybrid**
Distance	Limited	Extended	Extended in backbone
Horizontal Cable	Coax	Fiber or copper	Coax
Backbone Cable	Coax	Fiber	Fiber
Cost	Low	High	Medium
Advantages	• Lower cost, electronics for digital conversion not required • Power not required at the antennas	• Longest reach • Shares common building system infrastructure	• Extended backbone distances • Less expensive than active
Disadvantages	• Link budget calculations add to design complexity • Limited distance	• Dedicated power required at access points and antennas • Most expensive	• Installation complexity with multiple media types

2-3.5.4.12 Passive DAS Topology.

Passive DAS are typically used in spaces smaller than 80,000 square feet. They use coaxial cable, splitters, repeaters or bi-directional amplifiers and antennas to distribute the signal.

Passive systems can be single or multi-carrier and are cost-effective solutions. More extensive design adds to the complexity of the system.

2-3.5.4.13 Hybrid DAS Topology.

Hybrid systems combine use of active fiber backbone cable to intermediate nodes and distribute signals to passive antennas via coaxial cable.

2-3.5.4.14 Active DAS Topology.

Active DAS systems are often deployed in high-rise buildings and stadiums where distances between the source and antennas are long. They use a fiber optic head-end distribution to the intermediate nodes, and fiber or copper structured cabling for distribution to the antennas. The fiber is an APC solution, and the designer will need to work the selected solution vendors to design the system. Power is required for the access points and other equipment.

2-3.5.4.15 Cellular Coverage.

Work with the system owner to determine how the signal will enter the facility. The most common methods include:

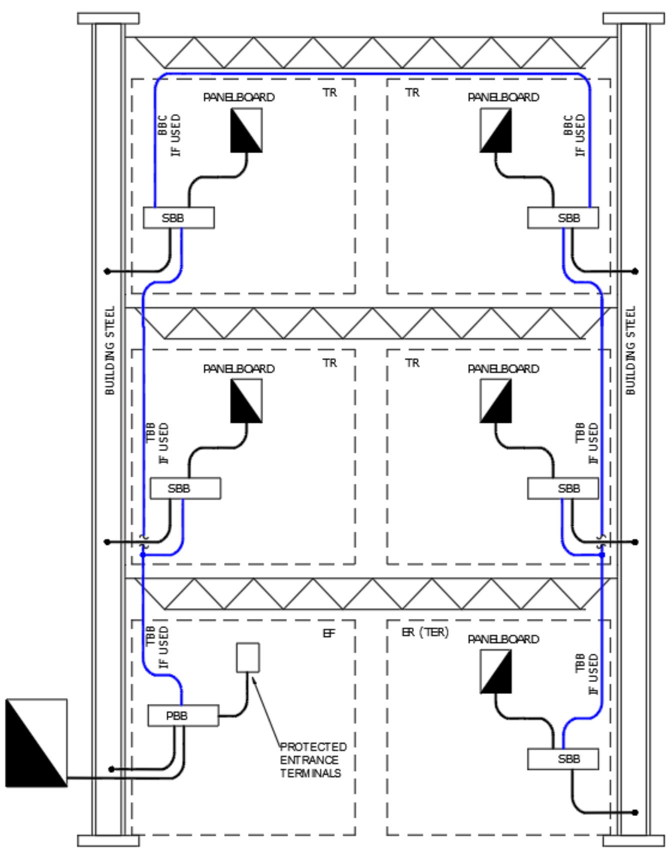
- Off air: The DAS uses an external donor antenna to capture cellular signals from local cell towers.
- Base Transceiver System (BTS): The DAS draws signals directly from the provider via optical fiber cables.
- Small cell: The DAS uses an internet connection to create a secure link to the carrier's network.

Coordinate and get approval for any devices that will amplify or distribute a licensed carrier's signals. If a multicarrier system is possible, all vendors are required to provide written approval of the design.

2-4 GROUNDING, BONDING, AND STATIC PROTECTION.

Comply with NFPA 70® for grounding and bonding requirements. Provide a telecommunications bonding and grounding system in accordance with TIA-607. Refer to Figure 2-12. Building grounding systems are covered in UFC 3-520-01.

Figure 2-12 Telecommunications Grounding and Bonding Infrastructure



BBC	Backbone Bonding Conductor
EF	Entrance Facility
ER	Equipment Room
GEC	Grounding Electrode Conductor
PBB	Primary Bonding Busbar
SBB	Secondary Bonding Busbar
TBB	Telecommunications Bonding Backbone
TBC	Telecommunications Bonding Conductor
TR	Telecommunications Room
TEBC	Telecommunications Equipment Bonding Conductor
RBB	Rack Bonding Busbar

Note: TIA-607 identifies a bonding conductor known as the telecommunications bonding backbone (TBB) which is intended to equalize potentials between TRs. The impedance of the TBB increases with length, thereby reducing its ability to equalize potentials between TRs. The ICT designer must consider that the TBB for a large site may be very costly to achieve. As an alternative, the SBB in each TR and PBB can be bonded to the electrical panel board in the space and to structural steel where applicable. Install bonding conductors in the shortest and most direct paths feasible.

Table 2-13 Grounding Terminology

TIA-607-B Term	TIA-607-C Term
Grounding equalizer (GE)	Backbone bonding conductor (BBC)
Telecommunications main grounding busbar (TMGB)	Primary bonding busbar (PBB)
Rack grounding busbar (RGB)	Rack bonding busbar (RBB)
Telecommunications grounding busbar (TGB)	Secondary bonding busbar (SBB)
Bonding conductor for telecommunications (BCT)	Telecommunications bonding conductor (TBC)

2-4.1 Cable Entrance Grounding.

Connect all metallic shields and strength members for outside plant cable entering a building to the electrical service grounding electrode system in accordance with NFPA 70®, Article 800. Bond the OSP cable shield, armor, and metallic strength member to the main building ground as close as possible to the building point of entrance with a No. 6 AWG or larger ground wire. When possible, preference is OSP cabling straight to the PET and not splice case. Use a non-bonded splice case for the transition from OSP-rated cable to interior-rated cable where a splice case is required by the AHJ. If the OSP cable extends past 50 feet (15 meters), bond the metallic strength member to the TBB with a No. 6 AWG or larger copper ground wire, as close to the conduit egress point as possible.

2-4.1.1 Protected Entrance Terminals.

Terminate all incoming OSP copper cables on UL-listed primary protector blocks located within the building entrance terminal cabinet. Provide protector blocks equipped with 5-pin solid state, gas, or hybrid protector modules for the number of pairs terminated plus 25 percent. Bond the protector blocks to the main electrical service ground via the PBB or SBB with a No. 6 AWG or larger copper ground wire.

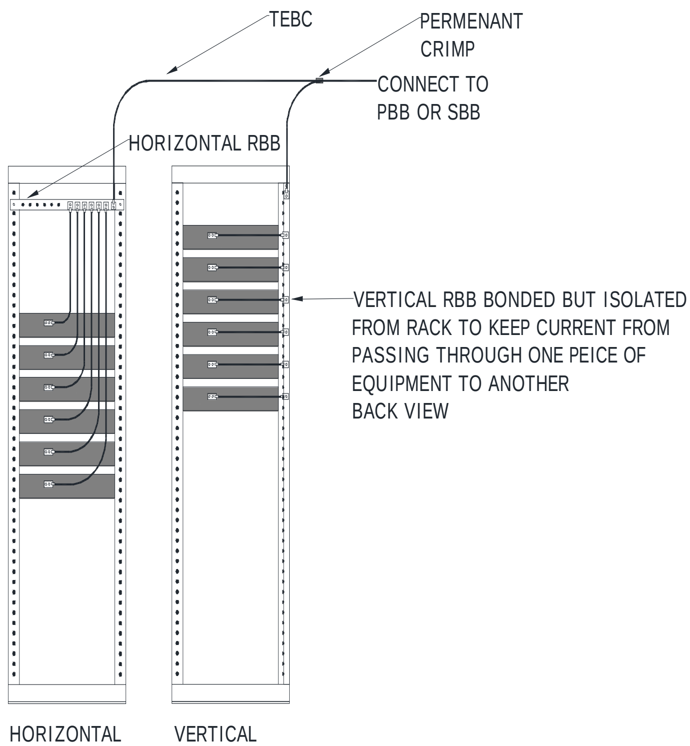
2-4.2 Telecommunications Spaces Bonding and Grounding.

Bond all telecommunications spaces and infrastructure in accordance with TIA 607 where applicable. When building steel is used as a grounding (earthing) electrode, the ICT distribution designer must specify that the telecommunications busbars be installed as close as practicable to a structural steel member within the ER, TR, or EF.

2-4.3 Telecommunications Rack and Supporting Structure.

Bond all telecommunications racks and supporting metallic structures (cable trays, ladders, conduits and baskets) in accordance with TIA-607and NFPA 70®. Non-continuous distribution systems (stub-ups, J-hooks) do not require bonding. Unless otherwise requested by the Telecommunications Manager, do not design rack bonding per Example C in TIA-607. See Figure 2-13 for allowable rack bonding methods. Only bond appliances that have manufacturer bonding connections available.

Figure 2-13 Rack Grounding and Bonding



2-5 TELECOMMUNICATIONS SYSTEM ADMINISTRATION.

Provide administration for the complete telecommunications system in accordance with TIA-606. Determine the minimum class of administration by evaluating the size and complexity of the premise infrastructure. Ensure the format for identifiers is backwards-compatible with TIA-606 for installations in existing facilities or per ISO/IEC TR4763-1 for new facilities unless otherwise directed by the Telecommunications Manager. Consult Appendix A and coordinate with the Telecommunications Manager for any additional service-specific labeling or administration requirements. Color-coding of telecommunications infrastructure and components is recommended, but not required. The DOR must identify the class of system in design documents.

CLASS 1 – Single equipment room (ER)

- the only telecommunications space (TS) administered
- no telecommunication rooms (TRs) and no cabling subsystem 2 and 3 cabling or outside plant cabling systems to administer

CLASS 2 – Single building served by multiple TRs

Identifiers included in Class 1 administration plus:

- one or more TRs within a single building
- cabling subsystem 2 and 3 cabling, multi-element bonding and grounding systems and fire stopping

CLASS 3 – Campus environment

Identifiers included in Class 2 administration plus:

- multiple buildings and building pathways, spaces, and outside plant elements

CLASS 4 – Multi-site (multi-campus)

Identifiers included in Class 3 administration plus:

- campus or site identifier

Labeling must be mechanically printed, except those requiring signatures, and must be legible.

2-6 TELECOMMUNICATIONS SYSTEM TESTING.

Installed backbone and horizontal telecommunications cabling and connecting hardware must meet minimum performance requirements and be tested in accordance with ANSI/TIA-568. Provide reports of all test results and certifications to the proponent and Telecommunications Manager upon completion.

2-6.1 Unshielded Twisted Pair Cabling and Connecting Hardware.

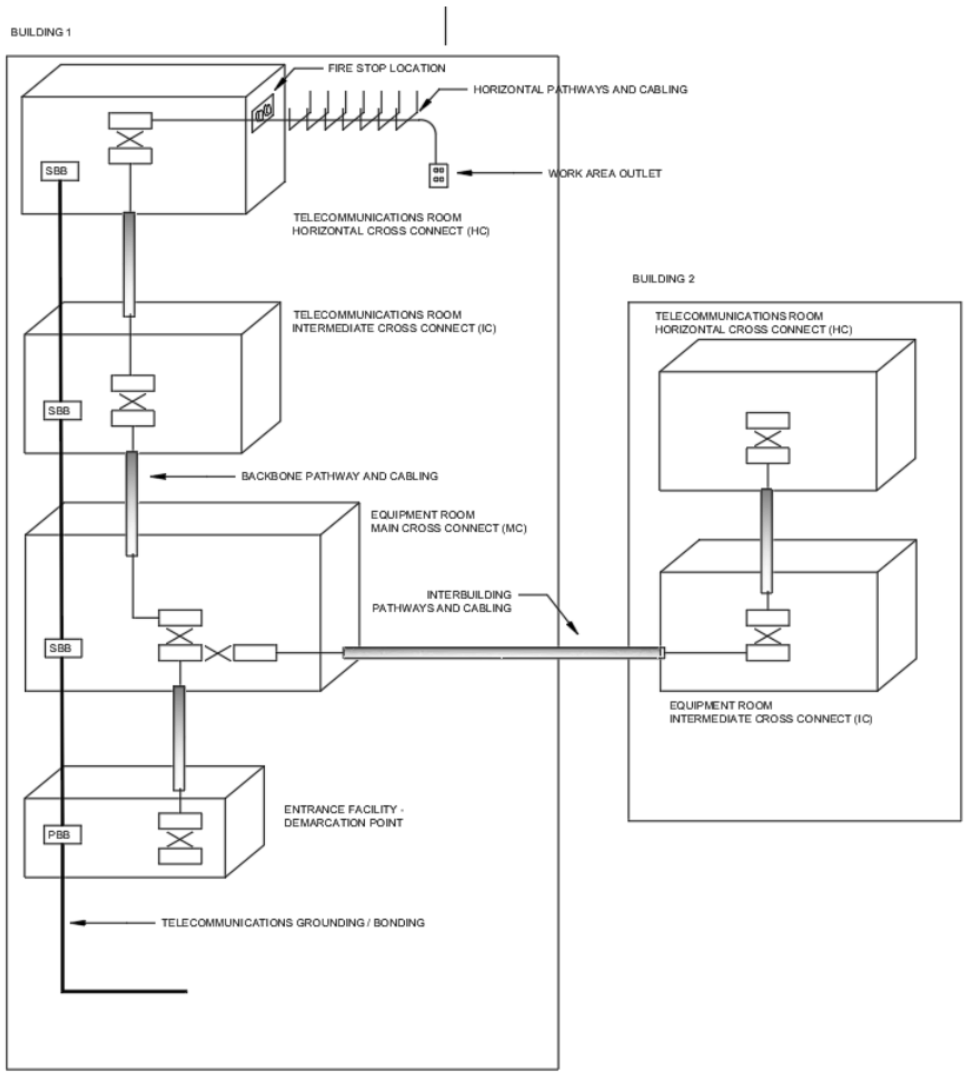
Perform all required testing to ensure minimum performance requirements are met in accordance with ANSI/TIA-568. There are different levels of certification test equipment for field testing and the correct level must be used to certify cabling plant.

Table 2-14 Certification Test Equipment Levels

Level	Frequency	Cable Category
IIe	100 MHz	5e and class D
III	250 MHz	6 and class E
IIIe	500 MHz	6A and class EA
IV	1000 MHz	8 and class F/FA*

*Currently, field tester accuracy to cover Class F cabling to 1000 MHz is not defined.

Figure 2-14 Telecommunications Labeling



TELECOMMUNICATIONS INFRASTRUCTURE REQUIRED LABELING

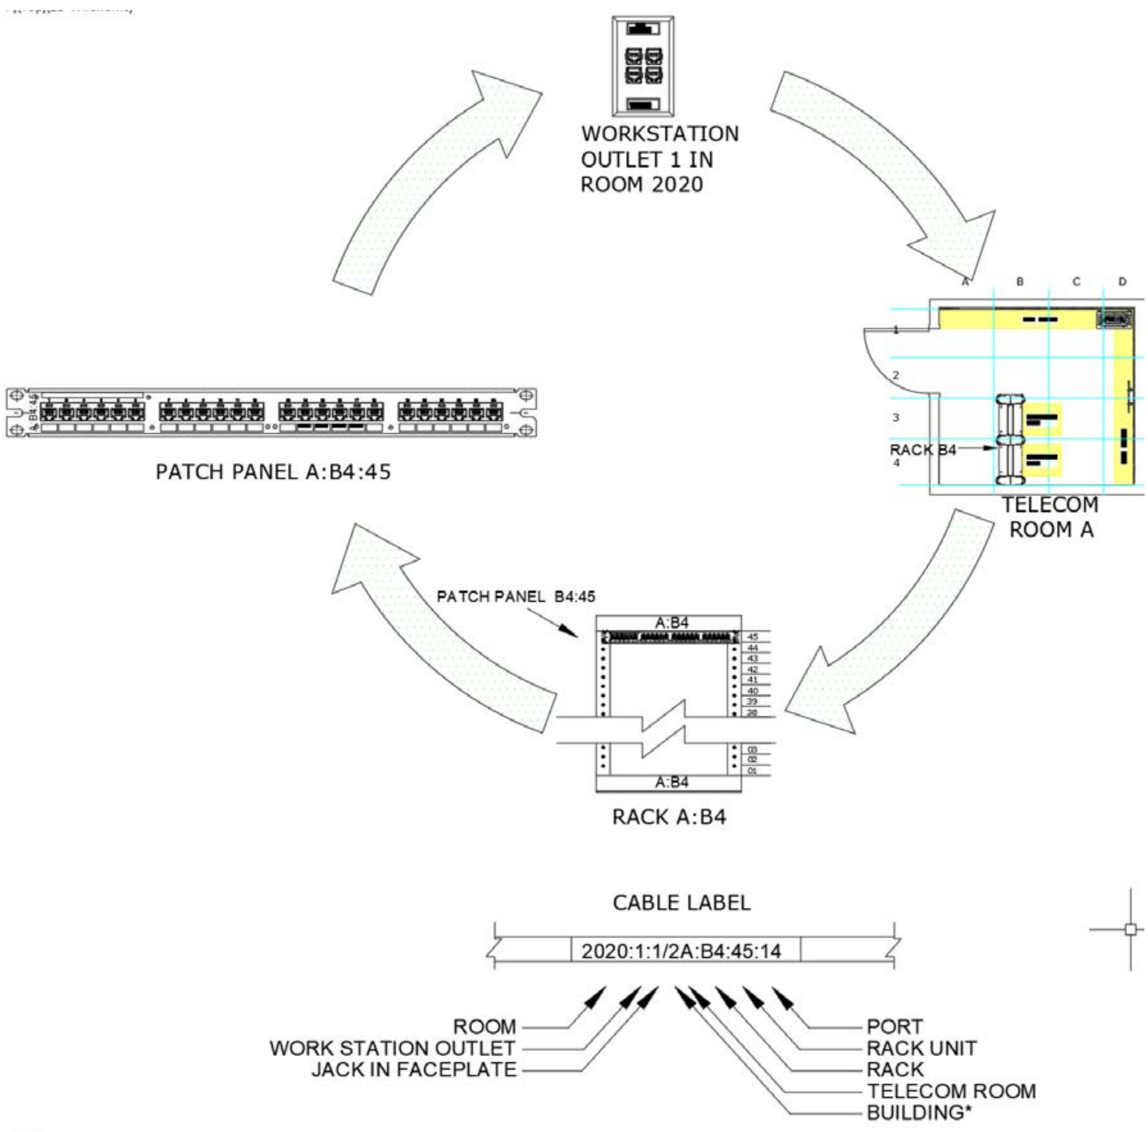
• Telecommunications room
• Equipment room with switches, servers and routers

Pathways & Cabling
• Horizontal pathways
• Backbone pathways
• Interbuilding pathways

Fire Stopping Locations
Bonding Locations
Grounding Locations

Figure 2-15 Sample Labeling System



2-6.2 Fiber Optic Cabling and Connecting Hardware.

Perform all required testing in accordance with ANSI/TIA-568 on the link. Test the link at both standard frequencies bidirectionally for multimode and single mode. The testing method must comply with TIA 526-7A using the single jumper method.

An optical time domain reflectometer (OTDR) is required for all OSP and inside plant lengths in excess of 500 feet (152 meters) and when requested by the Telecommunications Manager using the launch cables and exit cables of the required length for the fiber type.

2-6.3 PON Testing and Certification.

Bidirectional loss at both 1310 nanometers and 155 nanometers must be conducted between the OLT and every cable in every ONT connected through the splitter.

2-6.4 Coaxial Cabling and Connecting Hardware.

Perform all required testing to ensure minimum performance requirements are met in accordance with ANSI/TIA-568.

2-6.5 Test Plan.

The contractor must submit for USG review a test plan of all proposed cabling and equipment being installed under the project. After the contractor has completed the installation and testing of the information technology system, the contractor must submit a test report for all fiber and copper cabling. The contractor's Registered Communications Distribution Designer (RCDD) must approve both the test plan and the test report before submitting to the USG.

Note: Test plans for small scale projects (less than 5,000 square feet (464.5 square meters)) described in paragraph 2-1.2 do not require RCDD approval.

The test plan must include, along with all testing system reports, a complete project test summary spreadsheet with indexed room numbers, outlet labels, jack labels, and the pass/fail status, and causes for failures along with a total number of outlets installed, jacks/cable runs installed and the total number of jacks/cable runs that passed and failed the tests. Failed tests require the contractor to correct the failures prior to turnover of the system. Testing, data, and analysis is required by the USG at the contractor's expense if original testing does not prove adequate for identifying causes of failures, and if the USG is responsible for paying for any repairs not within the original scope of contract.

The test plan will include subsequent testing of 5% of the cabling plant with the USGs quality assurance (QA) representative to verify that the contractor's quality control (QC) program is functioning correctly. Unsatisfactory results of the QA verification will require additional remediation of the QC plan.

2-7 COMMISSIONING.

Commissioning (Cx) of the telecommunications system must be accomplished for projects where more than passive equipment is provided. Cx must begin in the design phases and may extend beyond the building occupancy date. The designer must edit applicable Unified Facilities Guide Specifications (UFGS). They must include requirements for pre-functional checklists and submission of prefunctional testing, submittals reviewed and approved by the Cx Agent (CxA), development of functional checklists by the Commissioning Manager (CxM), establishment of roles and responsibilities, and test reports similar to those provided for mechanical and electrical systems. Commissioning activities must include required cybersecurity activities for FRCS systems in accordance with UFC 4-010-06.

Performance testing and operation of systems is required to ensure systems work in a coordinated manner and according to manufacturers' specifications, codes, rules, and standards. Commissioning also provides testing of failure modes and operational procedures in all modes, under all electrical conditions, both isolated and integrated with other systems. Commissioning a building system must clearly identify real and potential issues with the building system and the affiliated subsystems during all phases of the project.

2-8 NETWORK EQUIPMENT.

Active network equipment has unique requirements and considerations beyond the scope of this UFC. Any active equipment (controllers, IP switches, radios, IP-based components) must be designed in accordance with UFC 4-010-06, and may require a corresponding 25 05 11 specification.

CHAPTER 3 OUTSIDE PLANT CRITERIA

3-1 INTRODUCTION.

3-1.1 Scope.

This UFC provides a consolidated source of USG-approved standards and practices to facilitate the planning, design, construction, and installation of exterior unclassified OSP information communications technology infrastructure. This includes the minimum requirements for OSP spaces, pathways, cabling, and distribution systems. Special considerations may be given to unique circumstances that dictate a need to exceed the minimum criteria defined herein.

Standards and practices for planning, design, construction, and installation of classified information infrastructure must be coordinated with a Certified TEMPEST Technical Authority (CTTA) and Designated Accreditation Authority (DAA) responsible within that area. Hardened Carrier Distribution Systems (HCDS) are not within in the scope of this UFC and are expected to be fully compliant with CNSSI 7003.

3-1.2 Applicability.

Criteria and standards within this UFC are the minimum to provide DoD base/post/camps/stations (B/P/C/S) with efficient, economic, sustainable, scalable, maintainable, and reliable OSP information communications technology infrastructure. They apply to new work and upgrades and are not intended to be retroactively mandatory to existing, in-place infrastructure.

All construction performed outside the contiguous United States (OCONUS) is also governed by additional mandates that include SOFA, HNFA, and in some instances, BIA. Therefore, the team performing any planning, design, construction, and installation must ensure compliance with the most stringent requirements of any of these agreements that are in place.

3-1.3 Special Considerations.

Special considerations may apply in some locations involving aesthetics, historical preservation, archeological sites, environmental conditions, restricted areas, and wildlife preservation areas. These may include considerations such as use of underground pathways versus aerial; the type of building entrance; mounting of terminals; placement of pedestals; or routing of cables. Consultation is required prior to and throughout planning, design, construction, and installation of all OSP information communications technology infrastructure to ensure all special considerations are captured.

3-2 SPACE REQUIREMENTS.

3-2.1 Types of Outside Plant Supporting Structures.

3-2.2 Cable Vault.

A cable vault (CV) is an enclosed, unmanned information communications technology structure constructed of precast or cast-in-place reinforced concrete, is structurally solid, and installed underground to accommodate cables, splice enclosures, racking systems, low-voltage electronic equipment, lighting, and ventilation. Cable vaults are typically provided at core node and area distribution node (ADN) locations that require copper cable plant distribution to end user buildings (EUB) for voice services and/or support large concentrations of fiber optic cable (FOC). Cable vaults must not be shared with high or low voltage electrical equipment installations other than whatever low voltage equipment is required to support low-voltage electronic equipment and infrastructure within the space.

3-2.2.1 Size.

The cable vault must to future growth of 25 percent. At a minimum, the cable vault must extend the entire length of the main distribution frame (MDF) and have a minimum ceiling height of 7 feet (2.1 meters) above the finished floor (AFF). The cable vault must be designed to provide ample space for installation and splicing of all new and future cabling requirements.

3-2.2.2 Layout.

New cable vaults must be constructed to extend beyond the building’s external wall and provide one interior and one exterior personnel entrance with either a ladder or stairs to access the space. Each entrance hatch must be a minimum of 36 inches (914 millimeters) wide by 36 inches (914 millimeters) long to allow rescue personnel to safely enter the confined space in the event of an emergency while using a self-contained breathing apparatus. The interior and exterior walls of the cable vault must be properly sealed and waterproofed to protect the interior space from pests and environmental damage. Protected cage-style industrial lighting must be installed inside the cable vault to provide a minimum horizontal illumination of 50 foot-candles (fc) (500 lux) at 36 inches (914 millimeters) AFF within the space to support routine work operations and the passage of employees in a safe and healthful manner. The cable vault must be provided with adequate ventilation using an exhaust fan with a high-level exhaust stack and a low-level air intake to maintain safe oxygen levels and avoid harmful buildup of combustible gases as defined by the Occupational Safety and Health Administration (OSHA). The cable vault floor must be designed with a constant 1.0% slope elevation to a sump pit equipped with an electric sump pump for the removal of water that may enter the cable vault. The sump pit must be a minimum of 18 inches (457 millimeters) long by 18 inches (457 millimeters) wide by 18 inches (457 millimeters) deep with a grating cover of sufficient strength to support expected loads. The sump pump must be connected to a drainage line and stubbed out through the cable vault wall to the nearest storm drainage structure for sump pump discharge. An SBB must be installed in the cable vault to bond all metallic structures in accordance with the requirements of TIA-758. All vault electrical receptacles must be installed on a ground fault circuit interrupter (GFCI) circuit for the protection of personnel in accordance with NFPA 70®. Cable racking must be installed in the cable vault to support the splice enclosures required to splice the tip cables to the OSP cables. The center of the cable vault is preferred for the installation of cable racking; however, if required, cable racking may also be installed on the cable vault wall. Angled pulling tubes must be placed in the opposite wall in-line with the conduit entrance to facilitate installation of new and future cabling within the cable vault.

3-2.2.3 Maintenance Holes.

MHs are used to facilitate placement and splicing of OSP cables. The MH accommodates cables, splice enclosures, racking systems, and low-voltage electronic equipment. Telecommunications MHs must not be shared with high or low voltage electrical equipment installations other than whatever low voltage equipment is required to support low-voltage electronic equipment and infrastructure within the space. Measurements between MHs are from MH cover to MH cover, center-to-center (C-C), unless otherwise indicated. Measurements from MHs to buildings, pedestals, riser poles, and other structures are from the center of the MH cover to the outside wall, pedestal base, bottom of riser pole (center-to-point).

MHs are either precast or cast-in-place reinforced concrete structures provided with a removable lid that permits internal access to the housed components. All MHs must have an American Association of State Highway and Transportation Officials (AASHTO) working stress design minimum load rating is HS-20 for heavy vehicular traffic. Splayed MHs should be provided at main feed and distribution points where copper cables and high cable counts are planned.

A typical large MH interior size is 12 feet by 6 feet by 7 feet (3.7 meters [length] by 1.8 meters [width] by 2 meters [height]). A typical medium-sized MH is approximately 8 feet by 6 feet by 7 feet (2.4 meters by 1.8 meters by 2 meters). Other sizes and configurations may be used with approval from the COR for contract designs or the Government design lead for in-house designs.

3-2.2.3.1 Maintenance Hole Precast.

The preferred MH structure is precast reinforced concrete. Precast MH types are splayed, non-splayed, or multi-directional with cast-in single or multiple plastic duct terminators to accept the conduits. Splayed MHs are the preferred type when a precast MH structure is used. Suppliers of precast MH structures must have a National Precast Concrete Association (NPCA) certified manufacturing facility that implements and maintains a NPCA certified quality control program. MHs must be H-20 rated for continuous heavy vehicle traffic.

3-2.2.3.2 Maintenance Hole Cast-in-Place.

Cast-in-place MHs may be used where precast structures are not suitable (e.g., overbuild, unique shapes, and limited areas for hole placement). Cast-in-place MH structures must be constructed in accordance with Rural Utilities Service (RUS) Bulletins 1751F-643 and 1751F-644, using Class 1D concrete with high early strength Portland cement consolidated by mechanical vibration. RUS Bulletin 1751F-643,

Table 5, defines the reinforcement bar spacing for each category of structure. If the category of a cast-in-place MH structure is not explicitly stated in the design criteria, the minimum category for the precast MH structure must be 10.0. Conduit window locations and attachment points must be designed so core drilling is eliminated and drilling for anchors is minimized to the greatest extent possible. Drawings for all proposed cast-in-place MH structures must be submitted for approval prior to construction. Drawings must depict the conduit locations, size, and placement of structural reinforcement bars.

3-2.2.4 Hand Holes.

Hand Holes (HH) are reinforced concrete units provided with a removable cover that permits internal access to the housed components. The acceptable pull-point HH size is 4 feet by 4 feet by 4 feet (1.2 meters by 1.2 meters by 1.2 meters) and should be placed only as the last structure before a EUB and where there is no possibility that the conduit system will be extended. The acceptable splice-point HH size is 6 feet by 4 feet by 4 feet (1.8 meters by 1.2 meters by 1.2 meters). HHs with larger dimensions are considered to be MHs. An HH should not be used in place of an MH in a main conduit system. HHs should not contain more than four, 4-inch conduits per wall. Telecommunications HHs must not be shared with high or low voltage electrical equipment installations other than whatever low voltage equipment is required to support low-voltage electronic equipment and infrastructure within the space. All HHs must have an AASHTO working stress design minimum load rating of HS-20 for heavy vehicular traffic, or the Tier 22 rating.

3-3 SUPPORTING STRUCTURE REQUIREMENTS.

3-3.1 Common Installation Practices.

New OSP supporting structures must be installed and placed to support the locations of junction points, offsets, load points, and curvatures within the conduit run. Spacing of OSP supporting structures is determined by the environment (e.g., cantonment or range area); cable type (e.g., copper cables only; fiber optic cables only, or copper and fiber optic cables); number of changes in direction (e.g., bends); cable reel length; proximity to cable origination and termination points; and allowable pulling tension of the cable. Subparagraphs (a) through (k) list a few required common installation practices:

a. Additional MHs or HHs are required once the total number of changes within the planned route exceed 180°.

b. MHs and HHs that contain copper cables of 600 pairs or greater must not be spaced more than 600 feet (180 meters) apart, provided the restriction noted in subparagraph (a) is not exceeded.

c. MHs and HHs that contain both fiber optic and copper cables of less than 600 pairs can be spaced in excess of 600 feet (180 meters), provided the restriction noted in subparagraph (a) is not exceeded.

d. MHs and HHs used as splice points in direct buried applications can be placed as required within the planned route.

e. OSP supporting structures must be installed on a leveled, crushed, washed gravel base of sufficient depth, not less than 6 inches (150 millimeters) in thickness under the entire OSP supporting structure, to allow for proper drainage and stability. The gravel base must extend 1 foot (300 millimeters) beyond the entire perimeter of the OSP supporting structure. Refer to Figure A-19 to show placement of gravel base.

f. Installation of OSP supporting structures must comply with the American Society for Testing and Materials (ASTM) C891-19.

g. Precast concrete supporting structures must be manufactured in accordance with ASTM C858-19.

h. Flowable fill (slurry) must be used to fill in the voids up to the base of the paved areas around all OSP supporting structures. Refer to Figure A-16.

i. In geographical areas with a high-water table, OSP supporting structures must be designed to mitigate the risk of buoyancy (floating) in accordance with the American Concrete Pipe Association (ACPA), *Design Data (DD) 41 - Maintenance Hole Flotation*. Any deviations from these guidelines require approval of the USG. A spreadsheet calculator can be found at https://www.concretepipe.org/wp-content/uploads/2014/09/DD_41-Manhole-Flotation-Analysis.xls to determine if the MH installation is stable with respect to buoyancy. Additional buoyancy design criteria can be found on the NPCA web site at: https://precast.org/wp-content/uploads/2018/11/BuoyancyWhite-Paper2018.pdf.

j. The annular area, which is the space between the walls of the OSP supporting structure and the conduits, must be sealed to prevent infiltration of water, debris, rodents, insects, and other foreign matter.

k. Some OSP supporting structures may require alarm systems to be installed and must be validated with the authorizing official or the PDS owner.

3-3.2 Common Maintenance Hole/Hand Hole Structural Components.

Each new MH/HH must be equipped with an egress frame and cover, grade ring, physical security, exterior attachment hardware (secure and non-secure applications), sump, and interior hardware (e.g., pulling irons, cable racks/hooks). All components must be designed for use within the MH/HH structural space.

3-3.2.1 Egress Frame and Cover.

The MH/HH structure must include a frame and cover to provide a point of egress for maintenance personnel. Egress frame and cover design criteria are defined based upon the area of installation; traffic areas or non-traffic areas. MH/HH structures placed in or near traffic areas must meet the following criteria:

- The frame and cover must be circular and not less than 30 inches (765 millimeters) in diameter and must meet or exceed the AASHTO working stress design minimum load rating of HS-20 for heavy vehicular traffic of the MH/HH structure.
- The cover must fit into a steel frame and, at a minimum, be at grade level, unless otherwise dictated by project installation design.

Oversized frames and covers and/or additional covers may be used for MH/HH structures with special requirements (e.g., supporting structures containing carrier or loading equipment, or supporting structures in congested areas). Steel double hatched cover sidewalk doors are preferred for shallow MH/HH structures with an interior working height of less than six feet (1.8 meters) AFF and placed in non-traffic areas.

3-3.2.2 Grade Rings.

The MH/HH structure must include a grade ring that meets the following minimum design criteria:

- Grade rings must be precast concrete and meet all requirements of ASTM C478/C478M-20. Grade rings must be a minimum of 6 inches (150 millimeters) in height.
- Grade rings must incorporate slots or holes to accommodate 0.75-inch (20-millimeter) diameter frame anchor bolts, unless otherwise specified by the structural engineer.
- When grade ring sections are stacked, grade ring sections must be precisely matched with each other and contain no overhangs to prevent injury to personnel and/or equipment entering or exiting the MH/HH.
- Grade rings installed with cracks or fractures passing through the height of the grade ring, or any continuous crack extending for a length of 3 inches (75 millimeters) or more is unacceptable and will be rejected.
- Grade rings installed with damaged edges which prevent completing a satisfactory joint are unacceptable and will be rejected.
- Installation without a grade ring must be approved by the civil engineer. **Note:** Installation without a grade ring would provide only 10 inches (250 millimeters) of cover (height of egress frame and cover) over the MH.

3-3.2.3 Physical Security.

Lockable cover(s) must be provided for the MH/HH structure when required by the project documentation and/or the site owner. When required, the lockable cover uses a lever and clamp mechanism placed into a receiver installed within the cover. The mechanism should allow the cover to be replaced without indexing the cover to the frame. When in a locked position, the mechanism must be flush with the frame surface, minimizing the potential for the cover to be dislodged. The bolt used to secure the cover must be accessible only by using a special adapter that can be turned only with a socket provided by the manufacturer. The securing bolt design for the cover is available in several different manufacturer's configurations. The desired manufacturer and bolt configuration will be determined by the site owner. A disposable tamper-evident plastic cap that snaps into the locking body mechanism's covering housing the recessed bolt must be installed to help keep dirt and other debris out of the bolt area.

3-3.2.4 Exterior Attachment Hardware.

3-3.2.4.1 Attaching Hardware for Non-Secure Applications.

Two anchoring methods may be used when attaching frames and frames with grade ring(s) to non-secure MH/HH structures:

- Drop-in Anchors: If drop-in anchors are used, each anchor must be a minimum of 0.7 inches (20 millimeters) in diameter. Drop-in anchors must be installed in accordance with the manufacturer's recommendations using the manufacturer's recommended concrete adhesive best suited for the environmental conditions at the installation site. Prior to setting the drop-in anchor, the anchor hole must be brushed and blown out thoroughly to remove all foreign contaminants that could affect proper adhesion.
- Wedge Anchors: Wedge Anchors are acceptable for non-secure applications. When using wedge anchors, the drill bit and anchor diameters are equal. Concrete adhesive cannot be used for wedge anchors, as there is insufficient space between the anchor and concrete for the adhesive to bond.

Anchoring components used for attaching frames and frames with grade ring(s) to non-secure MH/HH structures must satisfy the testing conditions defined in ASTM E488/E488M-18 or equivalent standard. The USG reserves the right to randomly select and test anchoring components for compliance.

3-3.2.4.2 Attaching Hardware for Secure Applications.

Attachment of frames and frames with grade ring(s) to secure MH/HH structures can be accomplished by mechanical methods, non-mechanical methods, or by a combination of both. To attain maximum physical security of the MH/HH structure, a combination of the methods must be used. Levels of security for each method or combination of methods are shown in Table 3-1.

The mechanical method of attachment uses drop-in anchors installed in accordance with the manufacturer's recommendations using the manufacturer's recommended concrete adhesive as described in paragraph 3-3.2.4.1. Additional physical security is attained by replacing the anchors' standard fasteners with tamper-proof fasteners.

The alternative non-mechanical method of attaching frames and frames with grade ring(s) to the MH/HH structure is to use a Type 1, epoxy-resin-base bonding system that satisfies the requirements of ASTM C881/C881M-20a. The epoxy-resin-base bonding system must be applied in accordance with the manufacturer's recommendations and procedures.

Table 3-1 MH/HH Physical Security Levels

Method	Description	Security
1	Mechanical: Tamper proof fasteners	Low
2	Non-mechanical: Type 1 epoxy	Medium
1 & 2	Combination of mechanical and non-mechanical	High

3-3.2.5 Sump.

A sump must be cast into the floor of the MH/HH structure. Design the floor of the MH/HH structure with a constant 1.0% slope to a sump located in the center for the removal and proper drainage of water that may enter the MH/HH. The sump must be a minimum 13-inch by 13-inch (330-millimeter by 330-millimeter) square or a 13-inch (330 millimeter) diameter circle. Either choice must be a minimum of 4 inches (100 millimeters) in depth and covered with a removable grated or perforated cover of sufficient strength to support expected loads.

3-3.2.6 Interior Hardware.

Interior hardware typical for most common MH/HH structure sizes is listed in the Table on Figure A-5. Interior hardware, to include cable pulling irons, cable racks, cable rack supports, and any other interior hardware accessories required, must be corrosion resistant. Size and location of MH/HH structure interior hardware must conform to RUS Bulletin 1751F-643 and RUS Bulletin 1753F-151 to support the weight of the cable(s) and splice case(s). Provide corner racks at the in-line end of the MH/HH structure. A device or method to lock the hooks to the cable rack (step locks) must be provided for all hooks that will be installed to support splice cases.

3-3.3 Water Resistance.

Reasonable efforts must be made to prevent water from infiltrating all OSP supporting structures. At a minimum, apply the following guidelines as long as they do not violate the manufacturer’s recommendations or product warranty.

- Place water-resistant gaskets or seals between the sections of pre-cast OSP supporting structures.
- Place water-resistant gaskets or seals between the cover(s), frame(s), grade ring(s), and OSP supporting structure top(s).

3-3.4 Stenciling.

Stencil new OSP supporting structures inside the structure with an identifier designated by the site owner. Place the stencil near the top of the OSP supporting structure so that it is visible when the cover is open. In addition, conduit windows in both new and reutilized OSP supporting structures must be stenciled (if not already) to denote where conduits are connected.

3-3.5 Grounding.

New supporting structures, regardless of size, must have an integrated ground system, and be clearly identified by the manufacturer, either on drawings or inside the supporting structure. A bonding ribbon must be installed around the interior of each supporting structure so that splice cases and rack anchors can be bonded. Install a bonding ribbon in each half of two-part MHs. Permanently bond the top and bottom ribbons to the integrated ground system.

New splice cases and cases that are reopened and contain conductive elements (e.g., conductors, metallic sheaths, armor, and strength members) must be bonded to the grounding straps system or the existing grounding system. Never open an underground cable sheath for the sole purpose of bonding it to ground.

3-3.5.1 Ground Rod.

For existing underground supporting structures not equipped with an integrated ground system, or older structures requiring supplemental ground rods, ground rods must be steel that is copper-clad and a minimum of 0.75 inches (20 millimeters) in diameter and a minimum of 10 feet (2.75 meters) long. Ground rods must meet requirements and be installed in accordance with NEMA GR 1. Four inches (100 millimeters) of the rod, plus or minus 0.5 inches (13 millimeters), must extend above the finished floor level, if installed in the existing MH. The rod must not enter the supporting structure more than 3 inches (80 millimeters) or less than 2 inches (50 millimeters) from the vertical surface of the adjacent wall. Ground rod electrodes must be permanently and legibly marked with the manufacturer’s identification, and the catalog or equivalent designation within 12 inches (300 millimeters) of the driving end of the ground rod electrode.

3-3.5.2 Ground System Inspection.

Grounding system connections must be verified for mechanical tightness. Tighten loose connections to the manufacturer’s specifications. Inspect grounding electrode system terminations for evidence of corrosion. Clean areas of corrosion and treat with corrosion inhibitor. For in-building grounds, accomplish two-point bonding resistance measurements to verify resistance less than 100 milliohms (0.1Ω) between any two points. For alternating current (AC) and direct current (DC) measurements, amperage measurements should be taken on all accessible grounding electrode conductors to verify less than one AC ampere (1A) and less than five hundred milliamperes (500 mA).

3-3.5.3 Bonding Ribbon.

Bonding ribbon placed around the inside perimeter of the CVs, MHs, and HHs (halos) is not required if they are equipped with an integrated ground system.

3-4 EXTERIOR PATHWAYS.

OSP telecommunications infrastructure projects include several general requirements that must be accomplished prior to the start of any work. These include, but are not limited to, determination of rights-of-way, utility locates, digging permits, traffic closure procedures, crossing obstructions, rock excavation, and unstable soil excavation. These requirements and conditions must be captured, documented, and reviewed with the local government zoning authority to determine proper local procedures.

3-4.1 Utility Easement/Rights-of-Way.

A utility easement/rights-of-way is written permission established to allow aboveground or underground physical infrastructure to be placed along a specific route through a property that belongs to another landowner or federal, state, or local municipality. Some projects may require OSP telecommunications infrastructure to pass through these utility easements/rights-of-way requiring a documented utility easement/rights-of-way to be established. Approval must be established and obtained within a timely manner with the AHJ prior to the start of any work to ensure compliance and to ensure use of new and existing utility easements/rights-of-way is maximized.

3-4.2 Existing Utility Location.

Utility location is the process of identifying and marking existing underground utilities such as telecommunications, electrical distribution, natural gas, storm drainage, water mains, wastewater pipes, and is required to be done prior to the start of any excavation work. The site owner is responsible for the processes and procedures for performing utility locates. Coordination with the Directorate of Public Works (DPW) to ensure strict adherence with these processes and procedures are followed, and to ensure the required lead times to completion are captured. - The utility marking paint must adhere to the American Public Works Association (APWA) Uniform Color Code, be clearly visible, and chalk based not permanent. The utility location marks at the work location must be maintained until the work is completed and they are no longer required.

3-4.3 Existing Utility Verification.

Utility verification is required to positively determine the exact location and depth of the marked utilities and obstructions within the excavation area to avoid damage and safety risks to personnel. The exact location of existing utilities can be determined only by physically seeing the utility. The preferred method for utility verification at each work location must be coordinated with the site owner. Acceptable methods for utility verification are described in paragraphs 3-4.3.1 and 3-4.3.2.

3-4.3.1 Pot holing.

Pot holing is the practice of digging a test hole to provide visual confirmation of underground utilities or obstructions within 24 inches (600 millimeters) of a proposed excavation site to avoid potential damage. When pot holing in road surfaces, the initial hole must be no larger than 12 inches by 12 inches (300 millimeters by 300 millimeters). There are several pot holing methods:

- Hand digging. Hand digging is the safest method of pot holing where digging is accomplished manually with handheld equipment such as a spade shovel.

- Machine digging. Machine digging is the method of digging by mechanical means with heavy equipment such as a backhoe. Powered excavation equipment is not allowed within 24 inches (60 millimeters) of either side of a utility location marking. Clearance restrictions may vary depending on the site owner.

- Vacuum excavation (e.g., slot trenching). Vacuum excavation uses either air or water pressure to break up the soil and a vacuum device to collect the spoils. This technique may be used within congested areas having poorly marked underground utilities and obstructions that cannot be avoided.

3-4.3.2 Ground Penetrating Radar.

Ground penetrating radar (GPR) is a technology that uses radar pulses to image the subsurface area of the earth. This technology can be used to non-destructively locate subsurface objects and structures in various materials such as soil, rock, concrete, asphalt, wood, and water. In historical locations or areas where the existing utility infrastructure is over 35 years old, GPR must be employed to the greatest extent possible to ensure that planned routes are clear of undocumented obstacles.

3-4.4 Digging and Excavation Permits.

Digging and excavation permits complying with all local codes, ordinances, and regulations must be obtained from the site owner prior to starting any excavation and/or construction work. It is highly recommended that all involved parties carefully plan and execute this portion of the project in unison to avoid unexpected problems.

3-4.5 Traffic Closures.

Roadways and parking lots must be closed only for as long as is necessary to complete the project work. Traffic closures must be coordinated with the site safety office. Construction signs, flag personnel, rerouting of traffic, cutting restrictions, and steel plates may be required.

3-4.6 Crossing Obstructions.

3-4.6.1 Paved Surface Crossing.

Pavement crossings must be constructed using one of the following methods: cutting or sawing perpendicularly across the pavement (commonly known as a “T” cut); trenching perpendicularly across the pavement; horizontal directional drilling (HDD) under the pavement; or jack and bore under the pavement.

The preferred method for crossing a paved surface is cutting or sawing perpendicularly across the pavement. When this method is used, concrete encasement is required. The concrete encasement must extend a minimum of 6 feet (1.8 meters) beyond the road bed on each side. If concrete encasement is not practical, then an alternative method that meets the required loading conditions is permitted (e.g., galvanized steel rigid metallic conduit (RMC)). Depending on the location, single step or double step “T” cuts may be required by the site owner. Cutting and restoration of paved crossings must be coordinated with the site owner.

Note: Jack and bore and/or directional drilling must be used only for special circumstances. If additional sections of pipe are required to be welded during the process, local Fire and Safety personnel must be notified.

3-4.6.2 Paved Areas.

OSP supporting structures placed within paved areas must be backfilled with flowable fill (slurry).

3-4.6.3 Range Road Crossing.

For road crossings on installation ranges, concrete encasement must be extended a minimum of 6 feet (1.8 meters) beyond the edges of the road bed on each side. If concrete encasement is not practical, then an alternative method that meets the required loading conditions is permitted (e.g., galvanized steel RMC).

3-4.6.4 Railroad Crossing (Underground).

Push and bore with steel casings is the preferred method for railroad crossings unless otherwise dictated by the commercial railroad owner. Where multiple conduit formations are placed, a minimum of a 12-inch (300-millimeter) diameter steel casing, with a minimum wall thickness of 3/16 inch (5 millimeters) must be used. The casing must extend no less 12 feet (3.7 meters) beyond the centerline of the track or the outermost track if multiple tracks are crossed. The casing must be located no less than 50 inches (1.27 meters) below the top of the rails in accordance with the National Electrical Safety Code® (NESC®). In addition, the casing must be no less than 36 inches (900 millimeters) below the bottom of any crossed drainage ditch adjacent to the railroad bed.

HDD must not be used to place conduits below commercial railroad beds. HDD is not the preferred method of placing conduits below USG railroad beds; however, if HDD is used, the conduit must be placed a minimum of 15 feet (4.6 meters) below the railroad bed in typical soil. The conduit must be placed at such a depth so that standard E-80 live and impact loads of 80,000 lb/ft (119,500 kg/m) must not produce more than five percent deflection in the proposed conduit formation.

3-4.6.5 Pier and Bridge Crossings.

Coordinate design and installation for crossing military, commercial, and privately owned piers and bridges and accomplish in accordance with the requirements and procedures dictated by the state and local bridge authorities, and USG bridge authorities.

Conduit systems installed on all piers or bridges must employ either polyvinyl chloride (PVC) coated steel RMC or red-threaded fiberglass conduit (RTFC), which is the preferred choice. Either conduit type used must be installed using only manufacturer-approved hardware (e.g., hangers).

Place pull boxes at all critical points within the conduit run. Critical points include where the structure has a change in direction, where access for a ship berth is required, and at 90-degree bends. Conduit expansion joints are required at each pier or bridge expansion joint and within approximately 5 feet (1.5 meters) of where the conduit enters a distribution point.

Place expansion joints in the raceway system to coincide with the expansion joints in the structures that are supporting the raceways.

3-4.7 Rock.

Excavate rock from all areas where OSP supporting infrastructure will be placed. Rock excavation is excavation of all hard, compacted, or cemented materials that require use of ripping and excavating equipment larger than defined for common excavation.

Unclassified excavation is excavation of all materials encountered, including rock materials, regardless of their nature or the manner in which they are removed.

3-4.7.1 Classifications.

Refer to the United States Department of Agriculture (USDA) Natural Resources Conservation Service “National Engineering Handbook” Part 631, dated January 2012, for classifications of rock and excavation.

Rock is defined as limestone, sandstone, granite, or similar aggregate found in solid beds or masses in the original or stratified position which can be removed only by continuous drilling, blasting, or use of pneumatic tools. Pavement is not to be considered rock.

Rock which cannot be moved without systematic drilling, blasting, or use of a rock saw includes:

- boulders measuring 0.5 cubic yard (yd^3) (0.382 cubic meter [m^3]) or larger
- other material such as rock in ledges, bedded deposits, un-stratified masses, and conglomerate deposits
- below-grade concrete masonry structures

Table 3-2 Excavation Characteristics of Rock[1]

Classification Elements	Class I	Class II	Class iii
	Very hard ripping to blasting	Hard ripping	Easy ripping
	Rock material requires drilling and explosives or impact procedures for excavation may classify as rock excavation	Rock material requires ripping techniques for excavation may classify as rock excavation	Rock material can be excavated as common material by earth-moving or ripping equipment may classify as common excavation
Head cut erodibility index, k_h [1]	$k_h \geq 100$	$10 < k_h < 100$	$k_h < 10$
Seismic velocity, approximate	> 8,000 ft/s (> 2,450 m/s)	7,000–8,000 ft/s (2,150–2,450 m/s)	(< 7,000 ft/s (< 2,150 m/s)
Minimum equipment size (flywheel power) required to excavate rock. Machines assumed to be heavy-duty, track-type back-hoes or tractors equipped with a single tine, rear-mounted ripper.	260 kW (350 hp), for $k_h < 1,000$ 375 kW (500 hp), for $k_h < 10,000$ Blasting, for $k_h > 10,000$	185 kW (250 hp)	110 kW (150 hp)

3-4.7.2 Excavation.

Excavate rock to a minimum of 6 inches (15 millimeters) below the excavation depth required for placement of conduit formation or cable. Prior to placing the conduit or cable, the contractor must backfill the rock excavation and all excess trench excavation with a cushion of sand at least 6 inches deep. Refer to Figure A-23 for additional excavation details.

[1] **National Engineering Handbook Part 628 Dams**, Chapter 52 Field "Procedure Guide for the Headcut Erodibility Index", Section 52-1, "The head cut erodibility index, k_h, represents a measure of the resistance of the earth material to erosion. The index is the scalar product of the indices for its constituent parameters. The index takes the general form:

$$k_h = M_s \times K_b \times K_d \times J_s$$

Where:

M_s = material strength number of the earth material
K_b = block or particle size number
K_d = discontinuity or interparticle bond shear strength number
J_s = relative ground structure number"

3-4.8 Soil Types.

Soil classification is defined in OSHA Standard 29 CFR 1926 Subpart P, Appendix A. The soil classification system identified in this subpart provides a method of categorizing soil and rock deposits based upon a hierarchy of their stability in decreasing order -- Type A, Type B, and Type C. The categories are determined based on an analysis of the properties and performance characteristics of the soil and rock deposits and the environmental conditions. Type C consists of mostly unstable soil and rock deposits and is considered the most dangerous of the soil types. Unstable soil and rock deposits are defined as soil and rock that by physical characteristics will not stay in place on its own and therefore will require the use of shoring and/or sloping to hold in place. In locations where unstable soil and rock deposits are identified, the unstable soil and rock deposits must be removed to establish a sound base capable of properly supporting the OSP supporting infrastructure.

3-5 SPECIAL CONDITIONS.

Most DoD locations contain areas that may be affected by special conditions. These special conditions must be discussed and documented with the site owner. All procedures from the AHJ must be followed.

3-5.1 Building and Landscape Aesthetics.

Building and landscape aesthetic standards establish an appropriate theme within an area of development without jeopardizing the historical, cultural, and environmental fabric of an installation and its surrounding community. The goal is to maximize the visual and environmental assets and to minimize liabilities, while enhancing the ability of the installation to continue to perform its mission requirements. Assets are visual or natural elements that enhance the image, environmental quality, or sustainability of the installation and must be preserved, enhanced, replicated, and incorporated into the overall OSP supporting infrastructure design. Visual and natural elements include architecture, roads and paths, parking areas, landscape, signage, site furnishings, lighting, utilities, and security. Liabilities are elements or features that detract from the visual image, environmental quality, or sustainability of the installation. Liabilities must be identified so they can be eliminated and avoided. Strict coordination must be accomplished with any local building and installation design requirements and procedures to ensure that visual and environmental assets are incorporated into the OSP, supporting infrastructure design, mitigating liabilities, and preserving the historical, cultural, and environmental character of the installation.

3-5.2 Historical and Cultural Preservation.

Military installations contain an abundance of historical and cultural locations that must be considered when planning for the installation of OSP supporting infrastructure. Historical and cultural locations include historical buildings, structures, objects, districts, landscapes (e.g., battlefields), and archaeological sites that are eligible for or listed in the National Register of Historic Places, as well as sites sacred to federally recognized Native American tribes. During planning, detailed coordination must be conducted with the local historical and cultural resource managers to ensure strict adherence to any local building and installation design requirements and procedures for these locations. Early identification and planning in these locations will help to avoid project delays and additional required funding resulting from inadvertent discovery of historical and cultural resources within the proposed project areas. In addition, any federal, state, and local environmental laws, requirements, and policies must be considered and prioritized throughout this process.

3-5.3 Natural Resource Preservation.

Military installations contain an abundance of natural resources that must also be considered when planning for the installation of OSP supporting infrastructure. Natural resources include threatened and endangered species, wetlands, wildlife preservation areas, forests, undisturbed land, and viewsheds. During planning, detailed coordination must be accomplished with the local natural resource manager to ensure strict adherence to any local installation design requirements and procedures for these locations. Early identification and planning in these locations will help to avoid project delays and additional required funding resulting from inadvertent discovery of impacted natural resources within the proposed project areas. In addition, any federal, state, and local environmental laws, requirements, and policies must be considered and prioritized throughout this process.

3-5.4 Restricted Areas.

Restricted areas on an installation must be avoided during planning and execution of OSP supporting infrastructure installations. Restricted areas include, but are not limited to, areas that contain unexploded ordinance (UXO), hazardous soils, human remains, biological hazards, and landfills. During planning, if it is determined that work within a restricted area cannot be avoided, detailed coordination must accomplished with the site owner to ensure strict adherence to any local installation design requirements and procedures for these locations. In addition, restricted areas of work that contain contaminated soils must comply with the local requirements and procedures for proper removal and disposal of these contaminated soils and/or waste materials. Early identification and planning in locations that contain potential restricted areas will help to avoid project delays and additional funding.

3-6 UNDERGROUND PATHWAYS.

Underground pathways consist of conduit structures used for installation of OSP cable plant between different points of access. Employ practices described this section for design and installation of underground pathways.

3-6.1 Trenching.

Trench width and depth must be determined by the minimum requirements to support the size of the conduit formations, spacing between the conduits, required embedment, and required soil cover. At a minimum, at least 24 inches (600 millimeters) of cover is required above the top of the conduit formation. At least 18 inches (450 millimeters) of cover is required under roads or sidewalks. For conduits installed in solid rock, the cover must consist of at least 6 inches (150 millimeters) of concrete. If rock is encountered below grade, the minimum cover above the concrete-encased conduit must be 12 inches (300 millimeters).

3-6.2 Frost Line.

Movement of underground pathways due to frost heaving can cause damage to OSP cabling. The 50-year frost line data must be used to determine the underground pathway depth requirements. The top of the underground pathway must be buried below the frost line. In areas where frost lines exist at excessive depths, determine the minimum depth requirements to support local frost line requirements.

3-6.3 Shoring and Benching.

The contractor must rigorously adhere to the OSHA, host nation, and local requirements for shoring or sloping. For CONUS projects, the contractor must follow the safety and trenching requirements in 29 CFR 1926, Subpart P. The contractor must follow the specification of Appendix B, 29 CFR 1926, Subpart P. The trench width for conduit must be wide enough to permit tamping of dirt on the sides of the conduit formation.

Excavations over 5 feet (1.5 meters) deep that a person must enter or work within must have walls shored or benched as approved by a competent person meeting the requirements of 29 CFR 1926, Subpart P.

3-6.4 Hand Digging.

Hand digging must be accomplished in all locations around all MHs, HHs, building entrance points, utility crossings, under curbs, and any other obstacles identified by the site owner.

3-6.5 Plowing.

Plowing must be used only in range environments or other areas where there are no significant obstacles and where cable runs typically exceed 1,000 feet (305 meters) between supporting structures. Plowing paths must be within designated zones that are based on specified distances from the centerline of the road. The zone width is based on minimum and maximum setback distances from the centerline of the road. Designated zones and setback distance criteria must be coordinated with the site owner.

3-6.6 Horizontal Directional Drilling.

HDD is a trenchless utility installation method for installing underground conduit that involves using a directional drilling machine to accurately drill along the chosen bore path and back ream the required conduit. The vertical profile of the bore alignment is typically in the shape of an inverted arc.

3-6.6.1 Methodology.

HDD is a multi-stage process that consists of drilling a pilot hole along a predetermined path and then pulling the desired conduit product back through the drilled space. Back reaming must be used when it is necessary to enlarge the pilot bore hole.

To minimize friction and provide a soil-stabilizing agent, a drilling fluid is introduced into the annular space created during the boring operation. The rotation of the bit in the soil wetted by the drilling fluid creates a slurry that acts as a stabilizer of the surrounding soil, preventing bore hole collapses and loss of lubrication.

3-6.6.2 Drilling Fluids.

Use a mixture of bentonite clay and fresh clean potable water of the proper phosphate (pH) level as the cutting and soil stabilization fluid. Viscosity must vary to best fit soil conditions. No other chemicals are to be used in the drilling fluid without written consent of the USG and after a determination is made that the chemical additives are environmentally safe. When drilling in suspected contaminated ground, the drilling fluid must be tested for contamination and disposed of appropriately in accordance with applicable federal, state, and local environmental regulations.

3-6.6.3 Pits.

Sump areas must be created at the drill entrance and exit locations to contain any escaping free-flowing slurry (drilling fluids) at the ground surface that might damage or be hazardous to the surrounding work area. Excavation for entry, recovery pits, slurry sump pits, or any other purpose must be accomplished in accordance with UFGS 31 23 00.00 20.

3-6.6.4 Tracking.

A method of locating and tracking the drill head during the pilot bore must be employed during the drilling process. Conduit must be installed so that conduit location can be readily determined by electronic designation after installation is complete. For non-conductive installations, this must be accomplished by attaching a continuous conductive material, such as a copper wire line or coated conductive tape, externally, internally, or integrally with the product.

3-6.6.5 Conduit Requirements.

Conduit materials for HDD must meet or exceed the standards defined in Table 3-2.

Table 3-3 Conduit Standards for Directional Boring

Material Type	Standard	Title
High-density polyethylene (HDPE)	ASTM D2239	Standard Specification for Polyethylene (PE) Plastic Pipe (SIDR-PR) Based on Controlled Inside Diameter
High-density polyethylene (HDPE) (SDR)	ASTM D3485	Standard Specification for Coilable High Density Polyethylene (HDPE) Cable in Conduit (CIC)
High-density polyethylene (HDPE)	ASTM F1962	Standard Guide for Use of Maxi-Horizontal Directional Drilling for Placement of Polyethylene Pipe or Conduit Under Obstacles, Including River Crossings
High-density polyethylene (HDPE)	ASTM F2160	F2160 Standard Specification for Solid Wall High Density Polyethylene (HDPE) Conduit Based on Controlled Outside Diameter (OD)

HDPE conduit must be manufactured for inside diameter control (manufactured based on the specified inside diameter). Four-inch (100-millimeter) HDPE conduit must have a minimum wall thickness standard internal dimension ratio (SIDR) of 11.5. When connecting HDPE conduits, the internal diameter of the adjoining HDPE conduits must be within 0.030 inches (0.75 millimeters). PVC conduit that uses mechanical-type connectors made for the purpose of horizontal directional drilling may be used in lieu of HDPE, with USG approval. All conduit used for HDD must be placed within soil-tight joints. Joint requirements are defined in paragraph 3.6.8.3.

3-6.6.6 Restrictions.

The HDD trenchless utility installation method may be used only in locations approved by the site owner. Conduits installed under roads by means of HDD must be of sufficient depth to clear existing utilities and meet the H-20 load ratings. The conduits placed by HDD must not directly enter an MH, but must be attached to conduit stub-outs that extend a minimum of 10 feet (3 meters) from the MH. The maximum radius curvature of a bore is limited to the maximum conduit diameter multiplied by 100 feet per inch (30.5 meters per 25 millimeters).

3-6.6.7 Environmental Restoration.

The work location must be restored to the pre-construction condition after installation is complete. The work location must be cleaned of all excess slurry or spoils and properly disposed of in accordance with applicable federal, state, and local environmental regulations as the conduit is introduced. Excavated areas must be restored in accordance with UFGS 31 23 00.00 20. Damage caused by heaving, settling, escaping drilling fluid (fracout), or the HDD operation to roads, parking lots, pavement, curbs, sidewalks, driveways, lawns, storm drains, landscapes, and other facilities must be restored by the installer performing the work.

3-6.7 Jack and Bore.

Jack and bore (auger boring) is a trenchless utility installation method where a horizontal auger is driven through a jacked steel casing into the soil. The steel casing is advanced simultaneously with the boring operation using a hydraulic jacking system. Jack and bore must be accomplished in accordance with UFGS 33 05 23 and conform to the following criteria:

- Materials. Galvanized RSC must be fabricated from weldable quality steel. Steel pipe casings must comply with Grade B requirements of ASTM A139/A139M-16 or ASTM A252/A252M-19.
- Grout. Conduits placed through casing pipe must be grouted with non-shrinking cement grout. Grout must conform to ASTM C1107/C1107M-20.
- Conduit Spacers. Plastic spacers must provide at least 1 inch (25 millimeters) of spacing between conduits as necessary to allow encasement material to fully surround each conduit. Use of bricks or wood as spacers is not permitted. Placement between spacers must be no greater than five feet (1.5 meters). Use bands to secure bore spacers and conduits together. Banding must follow the best practices of the latest issuance of NEMA TCB 2-2017.
- Steel Casing Size. Sizing of casing is determined by the total diameter of the conduit formation. See Table 3-3 for casing sizing guidelines per 4-inch (100-millimeter) conduit formation.

Table 3-4 Casing Size per Four-inch (100-milimeter) Conduit Formation

Casing Size	Wall Thickness inches (millimeters)		Inside Diameter inches (millimeters)		Measured	Number of conduits
	Protected	Non-protected	Protected	Non-protected		
14	0.219 (5.6)	0.311 (7.9)	13.562 (344.5)	13.376 (339.75)	O.D.	4
16	0.219 (5.6)	0.312 (7.9)	15.562 (395.3)	15.376 (390.55)	O.D.	5
18	0.281 (7.1)	0.344 (8.7)	17.500 (444.5)	17.312 (439.73)	O.D.	7
22	0.344 (8.7)	0.375 (9.5)	21.376 (542.9)	21.250 (539.75)	O.D.	9
30	0.438 (11.1)	0.469 (11.9)	29.188 (741.38)	29.062 (738.17)	O.D.	16

3-6.8 Conduit.

3-6.8.1 Types.

Underground pathways consist of conduit structures built using the following acceptable conduit types:

- rigid nonmetallic conduit Schedule 40 – for direct burial or encasement in concrete. Must meet the requirements of NEMA TC-2-2020
- rigid nonmetallic conduit Schedule 80 – for direct burial or encasement in concrete. Must meet the requirements of NEMA TC-2-2020
- metallic pedestal disconnect (MPD) – for direct burial or installation in conduit
- RMC – for direct burial or encasement in concrete
- intermediate metallic conduit (IMC) – for direct burial or encasement in concrete
- RTRC and fittings – for direct burial or encasement in concrete
- innerduct PE – for direct burial or installation in conduit
- innerduct PVC – for direct burial or installation in conduit
- microduct for air blown fiber (ABF) applications
- HDPE – for plowing and HDD

3-6.8.2 Innerduct/Textile Innerduct.

For underground installation, new fiber optic cable plant must be installed in either an innerduct, subduct, or textile fabric mesh solution. More than one fiber optic cable may occupy a multi-cell textile fabric mesh solution. When existing underground pathway conduits systems are reutilized, determine the preferred solution for the location in which the installation is being completed. Fiber optic cables must never be installed directly into a 4-inch (100-millimeter) duct.

3-6.8.3 Joints.

Conduits must be joined to be soil tight. Joints must form a sufficiently smooth interior surface between joining sections so that cables are not damaged during pulling. Joints between dissimilar types of conduits (e.g., PVC, HDPE) must use appropriate connectors designed to provide a seal between the conduit types and prevent damage to cables pulled through these joints. These joint connections must be rated at a minimum of 125 pounds per square inch (psi) (0.862 megapascal (MPa)). Prepare joint surfaces in accordance with the manufacturer's recommended practices. HDPE to HDPE connections can be made by heating using one of the following techniques: socket, butt, electrofusion, or mechanical coupling.

Accomplish heat fusion in accordance with procedures detailed in ASTM F2620 and the procedures established by the manufacturer of the equipment being used. Prior to installing and joining HDPE conduits with an internal diameter of greater than 3 inches (75 millimeters), the conduit must be re-rounded and all inner edges beveled.

3-6.8.3.1 Socket Fusion.

This technique requires use of specially-designed hot irons to simultaneously heat both the external surface of the pipe and the internal surface of the socket coupling. Socket fusion is designed for outside diameter controlled standard dimensional ratio (SDR) material. Although this fusion joining method does not create a bead on the inside of the conduit created by the fusion process, telecommunications application requires internal diameter controlled or SIDR material. If socket fusion fittings are available for SIDR conduit, this method will be acceptable for joining HDPE together. Fabricate socket fusion joints in accordance with the latest issuance of ASTM F2620.

3-6.8.3.2 Butt Fusion.

This technique uses specially developed machines that secure, face, and precisely align the PE conduit for the flat face hot iron fusion process.

The butt fusion process produces an internal bead of equal or larger size than the visible outer bead. This method is acceptable only if verification can be provided that either the internal bead will have a negligible impact on the cable installation, or it can be demonstrated that the internal bead can be removed and the conduit will successfully pass a mandrel test. Fabricate butt fusion joints in accordance with the latest issuance of ASTM F2620.

Electrofusion differs from the hot iron (socket) fusion method described in (a). The main difference is the method used to apply heat. Electrofusion employs a special electrofusion fitting with an embedded wire coil. Electrofusion coupling must be accomplished in accordance with the procedures established by the manufacturer of the equipment being used.

3-6.8.3.3 Mechanical Coupling.

There are various coupling devices available to connect conduits of like material and for conduits of differing materials. Mechanical joints may be entirely mechanical, or a combination of mechanical and heat fusion or solvent weld. Mechanical couplers must meet or exceed the minimum pressure rating of 125 psi (862 kPa) and provide a smooth transition to prevent damage to cables pulled through this type of joint. The coupling must be encased within concrete in all mechanically joined conduits.

Accomplish heat fusion in accordance with procedures detailed in ASTM F2620 and the procedures established by the manufacturer of the equipment being used. Prior to installing and joining HDPE conduits with an internal diameter of greater than 3 inches (75 millimeters), the conduit must be re-rounded and all inner edges beveled.

3-6.8.4 Bends and Sweeps.

No more than the equivalent of two 90 degree bends (180 degrees total) may be used between pull points, including offsets and kicks with a curvature radius of less than 100 feet (30 meters). Avoid back-to-back 90 degree bends. The following definitions apply:

- 90 degree bend: Any radius bend in a piece of conduit that changes the direction of the conduit by 90 degrees.
- Kick: A bend in a piece of conduit, usually less than 45 degrees, made to change the direction of the conduit.
- Offset: Two bends usually having the same degree of bend, made to avoid an obstruction blocking the run of the conduit.
- 90 degree sweep: A bend that exceeds the manufacturer’s standard size 90 degree bend (e.g., 24 inches (600 millimeters) is standard for a 4-inch (100-millimeter) conduit).
- Back-to-back 90 degree bend: Any two 90 degree bends placed closer together than 10 feet (3 meters) in a conduit run.

Use radius-manufactured bends to the maximum extent possible. Manufactured bends may be used on lateral conduits at the riser pole or building entrance. RTSC bends and sweeps may be used where there is a potential to burn through the conduit during cable pulling. Where a conduit enters a building and sweeps up through the floor’s slab, galvanized RSC must be used. Bends and sweeps must be concrete-encased to protect the conduit from the pressures developed while pulling cables.

3-6.8.5 Minimum Formation Sizing.

The orientation of the conduit arrangements must maintain integrity throughout the entire run. Determine the number and size of conduits within the pathway based on the number of cables, cable diameter, known future growth, and sparing. Follow cable manufacturer conduit sizing charts or recommendations, if available. Conduit formations include:

- Node conduits: Conduits between a core node and the first MH should be based upon the types of services, the size of cables, the number of outside cables (not just limited to FOC), and 100% future growth.
- Main conduits: A main conduit run includes the MHs and conduits from the first MH away from the node and in locations where the cable routes diverge into multiple directions providing the pathways for large feeder cables and/or core FOCs.
- Lateral conduits: Lateral conduits run from the sidewall of an MH to the supporting structure (HHs, cross-net cabinets, pedestals, poles).
- Subsidiary conduits: Subsidiary conduits extend from the end wall of an MH, run along the main conduit run for some distance, and then turn to feed a structure.

- Entrance conduits: Entrance conduits run from an MH, HH, or pole to the EUB.

Sizing requirements include:

- one four-inch (100 millimeter) conduit for every four-way two-inch (50 millimeter) conduit system
- a minimal conduit size of 2 inches (50 millimeters) for pathways between supporting structures and end-user facilities
- for large copper cables, conduit with a diameter at least 1.15 times greater than the diameter of the cable, or one-half trade size larger in diameter than the diameter of the cable to be installed

3-6.8.6 Spacing.

Spacers are required for all conduit formations (both encased and non-encased) to properly support the conduits and maintain their integrity of orientation and must be installed in accordance with the manufacturer's specifications. Plastic spacers must provide a minimum of 2 inches (50 millimeters) of spacing between conduits, with the only exception being where conduits are placed in rock, a minimum of 1 inch (25 millimeters) of spacing will be acceptable. Use of bricks or wood as spacers is not permitted. However, use of concrete cinder blocks as spacers (and tie-downs) is an acceptable alternative with the approval of the COR. Conduits and spacers must be securely banded together. Spacers must be installed at a minimum of one spacer every 5 feet (1.5 meters). Direct buried conduit formations must be installed with embedment material around and between the conduits.

3-6.8.7 Placement.

Sweep down new conduits and install in the lowest available conduit positions within the MH or CV. In node and main conduit runs, install new conduit formations at a depth where a duct formation of equal size could be placed above the existing formation while maintaining 24 inches of cover or below the frost line, whichever is greater. New lateral, subsidiary, and entrance conduit runs must allow for 24 inches of cover or be below the frost line, whichever is greater. New conduits must not prevent placement of future conduits in the upper conduit positions. Conduits must terminate in bell ends or conduit terminators at the point of entrance into the MHs and HHs to assist in pulling cable. Main conduits entering cast-in-place or precast MHs must be located in the lower portion of the end wall. Conduits leaving side walls must be located a minimum of 4 inches (100 millimeters) from the end walls located farthest from the central office or serving node. Clearances of 12 inches (300 millimeters) must be maintained between main conduit formations and the roofs or floors of MHs. Unless the construction drawings indicate otherwise, wall recesses must be provided at conduit entrances. Locate lateral conduits leaving the MH to provide clearances of 4 inches (100 millimeters) from roofs and adjacent walls.

Conduits entering the walls of the supporting structure must be perpendicular to the face of the exterior wall. Conduits must remain perpendicular for a minimum 5 feet (1.5 meters) away from the exterior wall.

3-6.8.7.1 Stub-outs.

Stub-outs are short pieces of conduit that extend beyond the wall of a building or supporting structure offering an interface for future expansion. Stub-outs must be capped at the soil end and plugged and tagged within the building or supporting structure. Stub-outs for buildings with under-slab entrances must be RMC (refer to Figure A-11). Stub-outs must extend past the wall at least 5 feet (1.5 meters).

3-6.8.7.2 Transition.

For conduits transitioning from the lower conduit window of an MH to the nominal trench depth, the transition must be accomplished in no less than 30 linear feet (9.1 meters) from the MH to reduce the radius of the bends.

3-6.8.7.3 Clearances.

Clearances of 12 inches (300 millimeters) must be maintained between conduit formations and the roofs or floors of the supporting structure. Subsidiary conduits entering MHs must be located to provide clearances of 4 inches (100 millimeters) from roofs and adjacent walls.

3-6.8.7.4 Maintenance Holes.

Conduits entering the end wall of an MH must be located in the lowest portion available and remain together. Alternatively, the contractor may divide the conduit window of a multidirectional MH in half, leaving the other half of the window for future conduit systems. Highest conduits in the formations are reserved for fiber. The contractor must present the conduit pattern and identify conduit locations to the COR for approval prior to construction.

3-6.8.7.5 Existing Conduits.

New conduits installed with an existing conduit system must be placed above the existing conduit formation if the minimum depth requirements can be maintained. If sufficient cover is not available to maintain the depth requirement, the new conduit must be placed beside the existing conduit formation.

3-6.8.7.6 Rerouting of Existing Conduits.

Existing conduits must be joined to new MHs (pre-cast or cast-in-place) by rerouting the designated conduits from the demolished or abandoned MH to the new MH. Rerouting must begin , at least 30 feet (9 meters) from the old MH to allow for standard bending radii and pulling tension. Continuity of operations on the affected cables must be maintained during the conduit rerouting actions.

3-6.8.7.7 Conduit Termination.

Conduits must terminate in bell ends or conduit terminators at the point of entrance into supporting structures (MHs, HHs, cable vaults and buildings).

3-6.8.8 Concrete Encasement.

3-6.8.8.1 Vehicle Traffic.

Nonmetallic conduits placed under paved roads by open cut must be protected by concrete-encasement. In addition, conduits placed under paved road surfaces and certain heavy traffic non-surfaced roads must be protected by one of the following methods: concrete-encased conduit; galvanized RSC; steel pipe casings; or HDD of HDPE conduits.

3-6.8.8.2 Concrete Type.

The concrete type must be a wet type mix and be placed to ensure the concrete completely surrounds all conduits. Concrete used to encase conduits must have a minimum compressive strength of 3,000 psi (20,700 kPa). Additional concrete mix requirements may be required by the local jurisdiction and will be furnished by COR. Portland type cement must conform to American Society for Testing and Materials ASTM C94/C94M. Flowable fill must not be used as a substitute for concrete encasement.

3-6.8.8.3 Encasement Requirements.

Concrete must flow around and encase all conduits. The top of the concrete encasement must be a uniform finish and must be consolidated by mechanical vibration to ensure no air or voids are trapped in the mix. Provide a minimum 3 inches (75 millimeters) on each side and top, and 1.5 inches (38 millimeters) between the bottom row of conduit and the trench bottom.

a. New conduit systems must be connected to all supporting structures with dowels (those with or without conduit windows). Refer to Figure A-17.

b. For existing supporting structures, both precast and cast in place, that require core drilling, reinforcement bars must be placed 3 inches (75 millimeters) away from the outside wall and tied to dowels. Secure dowels to supporting structure using ASTM C881-rated epoxy. Refer to FigureA-17.

c. For conduits that will be encased in concrete, the contractor must tie down the conduits to minimize movement during the placement of concrete. The conduits in a concrete-encased pathway must be tied down at least every 10 feet (3 meters) using an industry-recognized method such as metal rods/stakes and strapping. The metal rods must be a minimum of 1/4 inch (6 millimeters) thick. As an alternative, the contractor may use concrete cinder blocks as both spacers and tie downs, with approval from the COR.

d. Concrete forms must be used when encasing conduits to OSP supporting structures to limit blockage of empty conduit knock-outs or windows in the OSP supporting structure.

e. The contractor must contact the on-site USG representative of the time and location prior to pouring any concrete over the conduit formations. The onsite USG representative will inspect the spacers and tie-downs prior to encasing the conduit formation.

f. Concrete encasement of the conduits for a “core path” is required where no alternate paths are present. All conduits between core buildings and serving MHs must be concrete encased.

g. Concrete encasement must be used in stream/drainage areas subject to washing out; in major construction zones; and for all sweeps or bends.

h. New encasement must be doweled to the existing encasement.

3-6.9 Detection and Marking of Underground Pathways.

3-6.9.1 Warning Signs.

3-6.9.1.1 Cantonment Areas.

Warning signs or route markers must be placed along the cable route to denote the location of below ground building entrances, changes in cable route, and in congested utility crossing locations. The signage or route marker must be permanent.

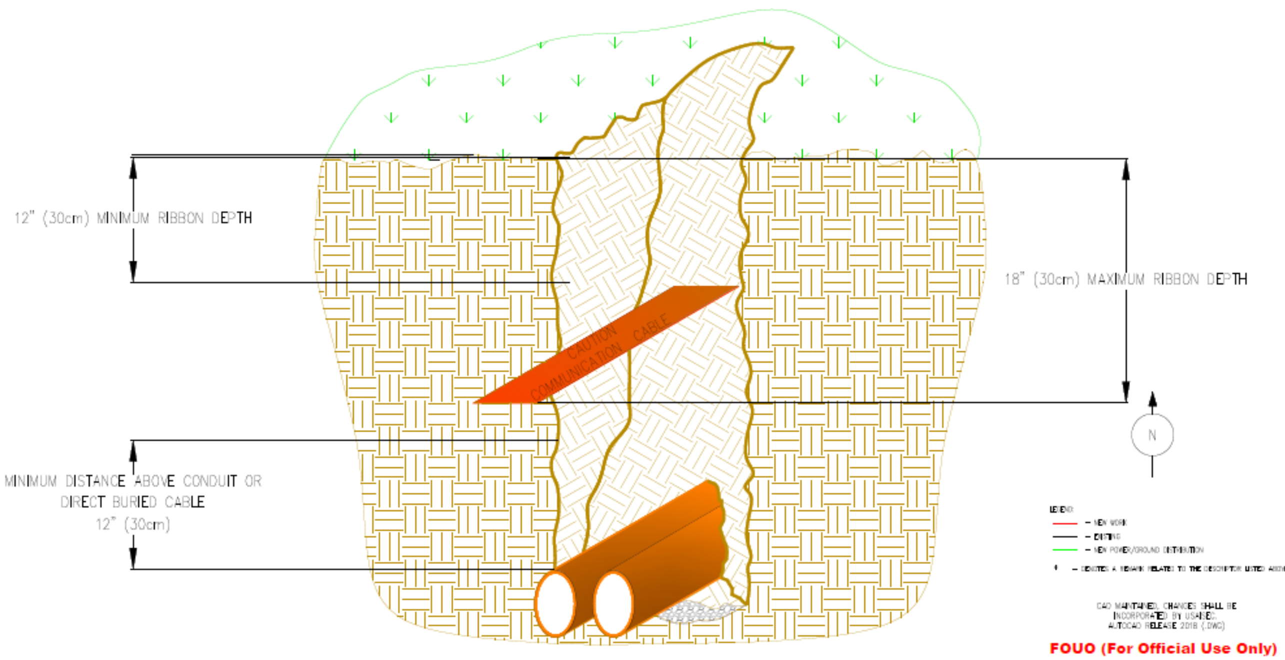
3-6.9.1.2 Non-Cantonment Areas.

Warning signs or route markers must be placed along the cable route at intervals of no greater than every 250 feet (75 meters), at each change in route, on both sides of each street crossing, over pipelines, and over buried power lines. The warning signs or route markers must be color-coded and orange in color.

3-6.9.2 Warning Tape.

Warning tape must meet the requirements of the latest version of UFGS 31 00 00. Warning tape must be installed at least 12 inches (300 millimeters) below the surface level and maintain a minimum separation of 6 inches (150 millimeters) between the warning tape and non-metallic conduit formations and DB cable installations (Figure 3.1). Warning tape must not exceed the manufacturer’s recommended depth below grade. For DB cable and non-metallic conduit formations placed by plowing, the warning tape should not be wider than the plow.

Figure 3-1 Warning Tape Placement



3-6.9.3 Detection Wire for Direct Buried Cable.

Detection wire for DB cable must be a minimum of #12 AWG insulated, single strand, solid copper wire, coated with a minimum 30-mil PE jacket designed specifically for buried use. Splices within the detection wire must be connected using a compression-type connector to ensure continuity. Wire nuts must not be used. After installation, the detection wire must be tested to verify end-to-end continuity and submitted in a report to the USG.

3-6.9.4 Detection Wire for Conduit Formations.

Detection wire must be installed within all new conduit formations. One detection wire must be installed per conduit formation. The detection wire must be placed as centrically as possible within the top of the conduit formation. When dielectric cable is installed in existing conduit formations that do not contain toneable cables, a detection wire must be installed along with the dielectric cable. Detection wire must be terminated on a terminal block and placed either within the MH near the opening, or in a “test well” so that the detection wire can be accessed without physically entering the MH confined space. Each detection wire and termination must be labeled to indicate the path of the detection wire (e.g., “TO MH-3”). Splices in the detection wire must be connected using a compression-type connector to ensure continuity. Wire nuts must not be used. After installation, the detection wire must be tested to verify end-to-end continuity and submitted in a report to the USG. No detection wires are required when the conduit formation contains an integrated detection wire (e.g., toneable conduit/textile innerduct).

3-6.9.5 Conduit Embedment.

Embedment is not required when the conduit formation is concrete-encased. Non-concrete encased conduit formations must be backfilled in accordance with NEMA TC2 and UFGS 31-00-00, using whichever is more stringent. Backing terminology includes:

- Bedding and initial backfill zone. The embedment zone of a conduit trench is that portion of the trench from approximately four inches (100 millimeters) below the bottom of the first row of conduits to approximately six inches (150 millimeters) above the top of the final row of conduits.

The external loading capacity of flexible conduits largely depends upon the type of embedment material chosen and the quality of the installation of the material in the embedment zone.

- Embedment material. The best materials for use in the embedment zone are coarse-grained materials such as crushed stone, sand, and pea gravel. Coarse-grained soils mixed with silts or clays can also be satisfactory, provided the mix is compactible and stable. Soils not recommended in the embedment zone are the highly organic materials and the highly plastic clays. The maximum particle size in the embedment zone should be limited to one inch (25 millimeters) in diameter.

- Final backfill zone. The final backfill zone of the conduit trench is that portion of the trench extending from the top of the embedment zone to the top of the trench.

- Final backfill materials. The final backfill is not critical for conduit performance, but can be important for providing a proper foundation for a road or other structure which may be constructed over the conduit trench. Selection of the final backfill materials is not critical for the conduit; all types of soils are acceptable, provided they do not contain particles that can damage the conduit. For conduit systems that will be under roads or parking lots, flowable fill is the preferred material.

3-6.9.6 Backfilling.

All excavated areas around new OSP supporting structures, conduits, and/or cables must be backfilled in accordance with the latest issuance of UFC 3-220-04FA.

Prior to placing any embedment or backfill, the pathway must be inspected by the onsite USG representative to verify the acceptability of the new supporting structures, pathway, and cables. In accordance with UFGS-31 00 00, all excavated areas around the new supporting structures, conduits, bore pits, and cables must be backfilled with approved materials.

3-6.9.6.1 Materials.

Material larger than 1 cubic foot (0.028 cubic meters) is not allowed in the backfill and must be removed. Materials must be free from hydrocarbons and other chemical contaminates. Approved materials can be a mixture of earth to include loam, sandy clay, sand, gravel, and soft shale. Backfill materials must be placed into the excavation and then tamped in 1-foot (300-millimeter) layers.

If native soil is of a suitable type, it may be used as embedment and backfill material. Blasted rock, large boulders, broken concrete, or pavement must not be used a backfill materials. Final backfill is a topsoil used that is conducive to growth of plants and grass. Material larger than 1 inch (25 millimeters) in diameter is not allowed in the final backfill.

3-6.9.7 Flowable Fill (Slurry).

Flowable fill, also known as slurry, must used for backfilling the portion of the trench above concrete-encased conduit systems under roads and parking lots. The flowable fill must meet the compressive strength requirements defined in Military Detail (MIL-DTL)-32537, and placed using the traditional (wet) method. Flowable fill must not be used as a substitute for concrete encasement. Backfilling the portion of the trench above concrete-encased conduit systems under roads and parking lots with clean backfill is acceptable only when approved by the COR. Reference paragraphs 3-6.9.6 and 3-6.10 for backfill and restoration requirements.

3-6.10 Restoration.

Restore disturbed areas to the same density, grade, and vegetation as adjacent undisturbed material. Grade the earth to a reasonable uniformity. Resurface paved areas with the same type of material and to the same thickness as the original surface. Paved surfaces must be restored in accordance with UFC 3-270-01. Restore road surface markings, including but not limited, to yellow lines, white lines, cross walks, and parking lot stripes, to the original location and condition. Clean the work site of debris and restore it to original condition.

3-6.11 Proof, Rod, and Clean Conduits.

Proof new conduits and existing vacant pathways prior to use. Proofing must be witnessed by the USG representative. Conduit with existing cable or that will not allow the passage of a mandrel must be rodded and cleaned.

3-6.11.1 Rodding.

Rodding entails inserting or pushing a rod through the conduit to determine the length, locate the other end, determine if the conduit is usable, and insert a pull string.

3-6.11.2 Cleaning.

When necessary, clean conduits using high pressure jetting, wire brushes, rubber conduit swabs, and leather washer conduit cleaners.

3-6.11.3 Proofing.

Proofing a conduit consists of pulling a test mandrel or slug through the duct to ensure the integrity and alignment of the ducts. New ducts in main and subsidiary duct runs must be mandrelled with a test mandrel (non-flexible) or slug that is approximately 12 inches (300 millimeters) in length and 0.25 inches (6 millimeters) less than the duct inside diameter. Use the test mandrel to verify the integrity of duct joints, to test for out-of-round duct, and to verify that sweeps are not so severe as to preclude placement of multiple cables or large diameter cables. A 6-inch (150-millimeter) length test mandrel may be used to test duct runs to buildings or riser poles. Pull the mandrel through all conduits to ensure proper alignment. Pulling the test mandrels through the conduits should be accomplished after backfilling, but prior to replacing any grass, sod, or repaving.

3-6.12 Pull String/Rope/Tape.

Place a pull string, pull rope, or pull tape, rated at not less than 200-pound (890-newton) tensile strength within each new conduit and innerduct. Provide a minimum of 5 feet (1.5 meters) of slack at each end of the conduit, tied and secured to the back of the conduit plug to prevent being accidently pulled back into the conduit. When installing new cable in existing conduit, place and secure a pull string, pull rope, or pull tape alongside the new cable so it cannot be accidently pulled back into the conduit.

3-6.13 Subdividing Conduit.

Subdividing conduit is the practice of using either innerduct or fabric-mesh to facilitate the initial and subsequent placement of multiple cables within a single conduit space.

The preferred count for fabric mesh in a 4-inch (100-millimeter) conduit is two, where each has three cells. Cut off fabric mesh at the end of each conduit run, leaving a minimum of 2 feet (600 millimeters) of spare slack. Roll up the spare slack and place it back inside the end of the conduit. Subdivision requirements of conduit can differ at each B/P/C/S and must be coordinated prior to installation with the AHJ.

3-6.14 Conduit Sealing.

3-6.14.1 Vacant New Conduit.

Seal new vacant conduits, multi-ducts, and innerducts using a mechanical reusable conduit plugs at each end. Conduit plugs must have a means of attaching pull strings. Cap stub-outs at the soil end, and plug and tag them within the building or OSP supporting structure.

3-6.14.2 Existing Occupied Conduit.

After placing new cables in existing conduit, seal the pathway at both ends. Sealant must be designed for use within telecommunication applications to block entry of water and debris and be removable without damage to the conduits or cables. Install sealant in accordance with the manufacturer recommendations and procedures. When using expandable foam, encapsulate only the first 6 inches (100 millimeters) of conduit by placing removable materials within the conduit to block any unnecessary expansion of the foam.

3-6.15 Conduit Rehabilitation.

The preferred method of installing new cables uses existing pathways. Rehabilitation of existing conduits is an alternative to installation of new conduit when the cost, location, or magnitude of new construction is prohibitive. Conduits intended as candidates must be surveyed to ensure that rehabilitation is feasible. The survey must include an inspection from the MH/HH or building entrance endpoints, either visually or by a conduit video system, from both ends of the conduit. If a pathway is found blocked or damaged, coordinate with the COR to discuss an acceptable solution. Collapsed or crushed conduit must not be used for rehabilitation. Several acceptable methods of rehabilitating conduit have been found, which include, but are not limited to, split conduit repair, resin-impregnated tube, conduit clamps, or conduit replacement. Accomplish conduit rehabilitation in accordance with the latest issuance of ASTM F1216, using ASTM-compliant products and processes. Completed rehabilitated conduit must be inspected by a conduit video system to verify it was restored to a usable system that meets the minimum requirements defined within this UFC.

3-7 DIRECT BURIED INSTALLATION.

DB is a type of installation where the infrastructure is in direct contact with the soil, without extra protection from the elements. DB solutions are implemented via trenching or plowing. Install DB cable in accordance with the latest issuance of RUS Bulletins 1751F-640, 641, and 642. Refer to Figure A-10 for typical pedestal measurements for DB.

3-7.1 Cable Type.

Rodent-protected (armored) cable must be used for DB applications.

3-7.2 Direct Buried Fiber Optic Cable.

DB FOC must be placed at a depth providing a minimum top cover of 48 inches (1200 millimeters) or below the frost line, whichever is greater. In solid rock, the minimum top cover must be 6 inches (150 millimeters).

3-7.3 Direct Buried Copper.

DB copper cable must be placed at a depth providing a minimum top cover of 24 inches (600 millimeters) in soil, 36 inches (900 millimeters) at ditch crossings, and 6 inches (150 millimeters) in solid rock (RUS Bulletin 1753-150/RUS Form 515A).

3-8 AERIAL INSTALLATION.

Aerial cable plant systems are not preferred. However, exceptions may include range cables or other long runs through undeveloped areas, locations where underground systems cannot be installed (e.g., wetlands), or locations where compliance with local mandates are required and require site owner approval. The desired or required reliability (99.999 percent) of some communications systems may preclude use of aerial pathways. Supporting documentation for aerial placement is available in RUS Bulletin 1751F-630 and 1751F-635.

3-8.1 Aerial Fiber.

Do not use aerial fiber splices without USG approval. Place fiber optic splices in a pedestal at the bottom of the pole. The cable alone must not support the aerial splice case. Fiber splice locations must include enough cable slack to allow the splice case to be moved into a splice trailer or tent for maintenance or service. Secure the cable slack to the existing messenger. Organize slack on aerial FOCs neatly, using aerial fiber optic storage loops ("snowshoes"). Base the snowshoe's size on the cable bend radius.

3-8.2 Aerial Copper.

Support all terminals and splice cases by direct attachment to the messenger strand, pole, building, or pedestal. The cable alone must not be used for support. Use pole-mounted and fixed-count terminals and place them so that no single drop exceeds 500 feet (150 meters) in length.

3-8.3 Messenger Strand.

The smallest messenger strand used for all new installations must be 6.6M. A 2.2M strand should be used only as an extension of existing 2.2M strands. FOC must be installed on its own messenger. Do not lash copper and fiber cables on the same messenger without site owner approval. A figure-eight type cable may be used; however, no additional cable must be lashed to it.

3-8.4 Guys and Anchors.

Place new guys and/or anchors for each new messenger strand at each applicable location (cable turns, wind loading, cable ends). The down guy must be sized to the next larger strand. Permission may be required to use an existing anchor.

3-8.5 Water Protection.

Weatherproof all outdoor connections by using weather boots or other approved methods. Form a rain-drip loop at all cable entrances into buildings at the point of ingress. Slant conduit sleeves placed through the entrance wall downward towards the outside a minimum of 0.5 inch (13 millimeters). Waterproof all building entrance points.

3-8.6 Horizontal Clearances for Poles/Aerial Cable.

Adhere to horizontal clearance standards in accordance with the latest issuance of the NESC®.

3-8.7 Vertical Clearances for Aerial Cable.

Communications cables must be no closer to power cables than 40 inches (1,000 millimeters) at the pole. At midspan, communication cables must be no closer than 75 percent of the separation distance at the pole. Adhere to vertical clearance standards in accordance with the latest issuance of the NESC®.

3-8.8 Aerial Cable Slack.

Slack on aerial cables must be neatly organized, using aerial fiber optic storage loops (“snowshoes”). Base the snowshoe’s size on the cable bend radius. Calculate the minimum amount of slack as follows:

- road crossings (aerial): 100 feet (30.5 meters)
- aerial per linear mile: three locations, each with 100 feet (30.5 meters)

3-9 EXTERIOR OUTSIDE PLANT CABLING.

Install cable plant to avoid kinks and other sheath deformities. Cables must be rated in accordance with the latest requirements of the National Electrical Code (NFPA 70®) for the environment in which they will be installed.

3-9.1 Cable Pulling Tension.

When pulling cable into ducts, inner ducts, or sub-ducts, do not exceed the manufacturer’s recommended pulling tension. Use of properly rated breakaway swivels is recommended. Various commercial cable lubricants compatible with different types of cable sheathing materials are available for pulling cables. During installation, a cable lubricant should be used in the proper amount specified by the lubricant manufacturer. Environmental conditions such as temperature can affect the overall performance of the pulling lubricant and must be conveyed to the manufacturer when making the proper selection. Pulling must comply with all manufacturer’s recommendations.

3-9.2 Evaluating Existing Cable Plant.

When installation includes work on existing cable plant (e.g., copper cable and fiber optic cable) that is to be re-used, test all affected pairs and/or strands before performing any splice work or cable throws. Test results must be compiled, to include any defective pairs and/or strands identified, and submitted to the COR to be addressed by the USG prior to proceeding with installation.

3-9.3 Cable Transfers, Cuts, and Throws.

Cable transfers, cuts, and throws must maximize use of existing resources. Cables and terminals affected by cable count transfers must be retagged in the field to reflect all new changes. Coordinate cable transfers, cuts, and throws with the site owner.

3-9.4 Service Loops.

For supporting structures with fiber optic splice cases, install a 75-foot (25-meter) splice loop on each side of the fiber optic splice case. In addition, 75-foot (25-meter) service loops are required at the last MH prior to building entrances. The service loop should be properly labeled and securely supported by two cable hooks. Position cable hooks so the highest one supports the underside of the top of the coil and the bottom hook supports the underside of the bottom of the coil.

3-9.5 Copper Cable.

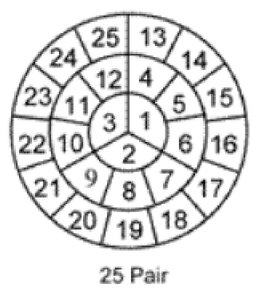
Copper cabling in outside plant implementation is diminishing rapidly with fiber centric backbones, but smaller copper counts may still be needed for legacy systems. Size all copper cables to provide a minimum of six copper pairs to each building.

3-9.5.1 North American Telephone Copper Cable Specifications.

North American telephone copper cable must be UL-listed and meet the specifications of Telcordia, GR-421-CORE. The conductors within the copper cable must be color coded using a basic color coding scheme to provide different color combinations on the insulation of each cable pair. The North American standard is based on a 25-pair binder group (see Figure 3-2) defined by Telcordia, GR-421-CORE, with the following colors:

- Tip: white (pairs 1-5), red (pairs 6-10), black (pairs 11-15), yellow (pairs 16-20), violet (pairs 21-25)
- Ring: blue (pairs 1, 6, 11, 16, 21), orange (pairs 2, 7, 12, 17, 22), green (pairs 3, 8, 13, 18, 23), brown (pairs 4, 9, 14, 19, 24), grey (pairs 5, 10, 15, 20, 25)

Figure 3-2 GR-421-CORE, 25 Pair Binder Group Structure



3-9.5.2 European Telephone Copper Cable Specifications.

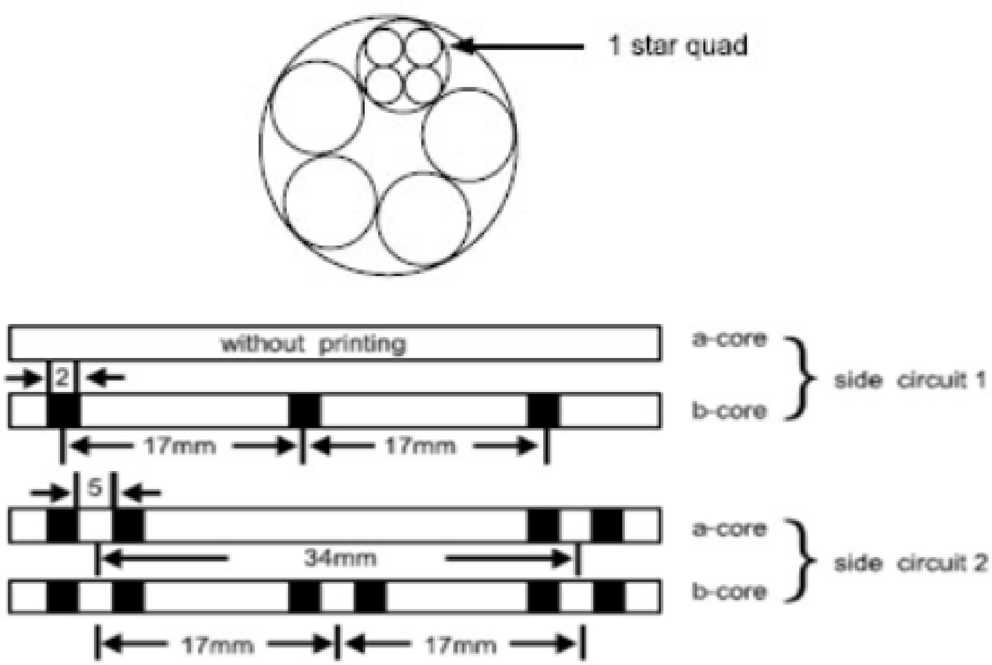
European telephone copper cable must meet the specifications of DIN VDE 0815/A1:1988-05 and DIN VDE 0816-1:1988-02. Commercially available, industry standard cables must be type A-02YSOF (L) 2Y …x2x0.6 ST III BD. The ellipsis (…) represents the required pair count. The conductors within the copper cable must be color-coded using a basic color-coding scheme to provide different color combinations on the insulation of each cable pair. The European standard is based on a 10-pair (five star-quads) sub-unit (Figure 3-3) defined by DIN VDE 0816-1:1988-02 with the following characteristics:

- Each star-quad of the sub-unit is defined by a unique insulation color. The first star-quad is red, the second star-quad is green, the third star-quad is grey, the fourth star-quad is yellow, and the fifth star-quad is white.
- The first or pilot sub-unit is marked by an open helix of red plastic tape.
- Remaining sub-units are marked with open helix of white or transparent plastic tape.
- Insulation of single conductors within a star-quad is marked with black rings.

3-9.5.3 Gauge and Resistance.

The cable gauge (copper conductor size) must be #24 American Wire Gauge (AWG) in North America and 0.6 millimeters in Europe.

Figure 3-3 DIN VDE 0816-1:1988-02, 10 Pair Sub-Unit Structure



3-9.5.4 Loading.

Analog telephone sets or circuits must not exceed 18,000 feet (5,490 meters) unless approved by the USG. If approved, these telephone sets or circuits must be loaded. When loading copper cables, use H88, loading 3,000 feet (914 meters) from the telephone switch or digital loop carrier for the first load (includes calculations for tip cables, jumper wires,) and every 6,000 feet (1,830 meters) thereafter. End sections, to include all drops and station wire, must be greater than 3,000 feet (914 meters) and less than 12,000 feet (3,660 meters). Proprietary digital or Integrated Services Digital Network (ISDN) telephone sets used with the telephone switch must not be loaded. Design build-out capacitors on trunk circuits for placement between telephone switches and load points shorter than 6,000 feet (1,830 meters) or between loads and end sections. Cable pairs used for data circuits must not be loaded.

3-9.5.5 Splicing.

Splice copper cable in accordance with the latest issuance of RUS Bulletin 1753F-401. Splice cable as one continuous length using one of two common modular splicing techniques: the inline or the fold-back technique. The inline technique places the conductor in a straight-across arrangement, providing for little slack within the conductor. The fold-back technique allows the conductors to be folded into the splice, facilitating future work within the splice. The fold-back technique is preferred. Completed splices must meet performance and mechanical specifications similar to those for a single copper cable of the same overall length.

3-9.5.5.1 Connectors and Caps.

Use self-piercing, electrical, filled connectors when plastic-insulated conductors are spliced. Connectors must be placed and installed using a tool specifically designed to place them. In North America, a 25-pair splicing module 3M-type MS2, or equivalent, must be used. In Europe, a 10-pair splicing module must be used. The same modules must be used throughout each project and must be consistent with previously installed connectors to preclude the requirement for a variety of installation tools. The integrity of all binder groups within the splice must be maintained. All dead pairs in a copper cable must be spliced through if the size of the continuing cable allows a clear and cap at the end. Use only UL-listed material for capping cable pairs.

3-9.5.5.2 Splice Cases.

Use encapsulant-fillable closures on underground and buried splice cases and fill with encapsulant upon the completion of the splice(s) in accordance with RUS Bulletin 345-72. Use of non-encapsulated, re-enterable splice cases in aerial or underground non-pressurized networks is permitted for non-direct buried applications. Do not install splice cases allowing their weight to be supported by the cables on the cable hooks in the MH. Installed splice cases must not interfere with ingress and egress into the OSP supporting structure space for technicians entering to perform maintenance. The preferred method for installing splice cases is to hang them from an overhead support structure (e.g., pipe supported by a set of cable hooks above the splice case). Do not place splice cases near or on the floor of the OSP supporting structure. To ensure continuity, bond new splice cases, existing splice cases that are reopened, and their associated components that contain conductive elements (e.g., conductors, metallic sheaths, armor) to the grounding electrode system of the OSP supporting structure in accordance with the requirements of this UFC.

3-9.5.6 Bend Radius.

The minimum bend radius for non-gopher-resistant OSP twisted-pair cable during installation must not be less than ten times the cable diameter, and after installation must not be less than eight times the cable diameter, as specified in ANSI/TIA-758.

The minimum bend radius for gopher-resistant OSP twisted-pair cable during installation must not be less than fifteen times the cable diameter, and after installation must not be less than ten times the cable diameter, as specified in ANSI/TIA-758. If the manufacturer's recommended installation and post installation bend radius requirements are more stringent, then follow the manufacturer's specifications.

3-9.5.7 Count Assignment.

When assigning new copper cable counts, the center of the cable must be the last pairs assigned on a cable route. The higher pair counts within the cable must be used first. The highest pair count in the cable must be located nearest to the telephone switch, and the lowest pair count must be farthest away. Per the requirements of 6-pair and/or 12-pair terminals, Pair 13 (of a binder group) rather than Pair 1 must be spared. If existing cable plant is reused and the cable pair count assignment differs from this layout, coordinate updated cable count assignments with the site owner.

3-9.5.8 Building Terminations.

3-9.5.8.1 Protected Entrance Terminal.

A PET is a device that provides electrical protection and a demarcation termination point where the OSP cabling transitions to the inside plant (ISP) cabling within an EUB.

PETs must be UL-listed and must be of flame-retardant construction and equipped with a build-in splice chamber; either 5-pin solid state or gas protector modules; locking cover; and output onto either 110 blocks or RJ21 connectors. PETs used for European projects must be equipped with protected, line-sharing adapter plus (LSA+) terminal blocks. Connect PETs to the building's lightning protection grounding system as required in NFPA 780. Terminate OSP copper cable pairs on the primary protector blocks of the PET, equipped with either 5-pin solid state or gas protector modules.

3-9.5.8.2 Main Distribution Frame.

The MDF serves as the intermediate interface between the OSP cable and the telephone switch cables at core node and ADN locations. The iron framework of the MDF supports the horizontal blocks and vertical connectors. Equip the MDF with guard rails and end rails. When re-using an existing MDF, install additional horizontal blocks and/or new vertical connector sections to support new cable plant if none are available. A minimum of 36 inches (900 millimeters) of clearance around the guard and end rails of the MDF is required for safety.

a. Horizontal Blocks. The horizontal blocks are mounted on the horizontal side of the MDF and terminate the telephone switch cables between the telephone switch and the MDF. The type and number of horizontal blocks on the frame are based upon the telephone switch solution and must be determined prior to installation. Stencil horizontal blocks to show the termination identification information.

b. Vertical Connectors. Vertical connector blocks are mounted on the vertical side of the MDF. Each vertical protector block must protect either 100 or 200 OSP cable pairs. Equip each vertical connector block with tip cables that are pre-terminated. The tip cables are routed either from the MDF through the floor to the cable vault, or over the MDF to the wall, where they are spliced to the OSP cable plant. Provide connectors for the tip cables as either stub-up or stub-down, as required by the type of installation. Vertical connectors protect the electronics within the telephone switch room by providing lightning and surge protection. Each termination corresponds to a pair of the OSP cables. All OSP cable pairs must be terminated on connectors. Stencil each vertical connector block to show the cable number and the pair counts for all connectors on that particular vertical connector block. Connectors must show the count terminated. A schematic of the vertical side of the MDF is shown in Figure A-11. Use space-saver type MDF connectors unless directed otherwise by the USG.

c. Cross-Connects. Install cross-connects between the OSP terminations on the vertical connectors and the switch terminations on the horizontal blocks. This process connects an OSP pair to a telephone number or other analog circuit. Leave approximately 8 inches (200 millimeters) of slack in the cross-connect wire to allow re-termination for future moves, additions, or changes.

d. Special Circuits. Special circuits, such as data circuits, T-1s, or alarms, are non-switched and must be treated differently than voice circuits. Various colors of protector modules are available to help with differentiation. Coordinate the specific color and marking for each special circuit type with the site owner. Cross-connect special circuits to designated blocks on the horizontal side and not to telephone switch horizontal blocks that provide telephone numbers.

3-9.5.9 Acceptance Testing.

Conduct end-to-end testing to ensure every cable pair installed, spliced, and terminated is installed in accordance with applicable USG and industry standards. Complete end-to-end tests in accordance with RUS Bulletin 1753F-201, IEEE Standard 743-1995, and other applicable documents referenced within. End-to-end tests that must be completed, include, but are not limited to, the following:

- direct current (DC) insulation resistance
- short/crosses
- grounds
- opens
- reversals
- splits
- transpositions
- shield continuity
- loop resistance

- insertion loss
- capacitance

Document and compile test results into an official test report format, to include raw data files, for submission to the USG. One hundred percent (100%) of all pairs within a cable must past initial acceptance testing prior to installation. After installation, 99 percent (99%) of all cable pairs must pass final acceptance testing unless the failed percentage of defective cable pairs are deemed by the USG not economical to recover. All defective cable pairs must be identified by their location and the type of fault(s). Any faults caused by defective cable pair splices must be corrected.

Existing copper cable being rehomed and re-terminated must be tested end-to-end following the testing protocols in this section for new cable to recertify the newly completed permanent link. If existing cable pairs are damaged during rehoming and re-termination, they must be properly repaired.

3-9.6 Fiber Optic Cable.

3-9.6.1 Cable Types.

There are two types of fiber optic cable used in OSP; single-mode (SM), and multi-mode (MM). New OSP fiber optic cable must be SM; however, designers may use MM to mate with existing plant in coordination with all stakeholders. Loose tube cable construction is better suited for the OSP environment. Tight-buffered cables are not recommended for use above the frost line except to edge devices that may not readily accept loose tube connections because they may be subject to damage from freezing water or moisture.

3-9.6.1.1 Multi-mode Fiber Optic Cable.

Fiber strands must have a nominal core/cladding diameter of 50/125 microns. All cabled MM fibers must have the characteristics in Table 3-6 over the entire specified temperature range.

Table 3-5 Multi-mode Dual-Windowed Fiber Optic Cable Characteristics

Function	Parameters for 50 Microns	Parameters for 62.5 Microns LEGACY ONLY
Core/cladding diameter (microns)	50/125	62.5/125
Coating diameter (microns)	250	250
Core eccentricity maximum	6%	6%
Core ovality	6%	6%
Refractive index delta	1%	2%
Core diameter (microns)	50 (+/- 3)	62.5 (+/- 3)

Function	Parameters for 50 Microns	Parameters for 62.5 Microns LEGACY ONLY
Cladding diameter (microns)	125 (+/- 3)	125 (+/- 3)
Numerical aperture	0.20 (+/- 0.015)	0.275 (+/- 0.015)
850 nm		
Maximum attenuation dB/km	3.5	3.75
Minimum bandwidth MHz-km	500*	160
1,300 nm		
Maximum attenuation dB/km	1.5	1.0
Minimum bandwidth MHz-km	600*	500
Cable tensile load rating	2,670 N (600 lb)**	
Cable minimum bending radius	15 x cable diameter under no load 0-800 N (0-180 lb)** 20 x cable diameter under load 800-2,700 N (181-600 lb)**	
*Building/breakout cables (tight buffer). Minimum bandwidths do not apply to tight buffered or breakout type cables. Minimum bandwidths for tight-buffered cable are 400 MHz-km at both 850 nm and 1,300 nm. The index of refraction profile of MM fiber must be near-parabolic graded index. **Building/breakout cables (tight buffer). Tensile load rating and minimum bending radius do not apply to tight-buffered breakout-type cables.		

dB=decibel; km=kilometer; MHz=megahertz; nm=nanometer

3-9.6.1.2 Single-mode Fiber Optic Cable.

Use SM FOC as defined in ANSI/TIA-568, TIA-758, and International Telecommunication Union-Telecommunication Standardization Sector (ITU-T) G.652 through ITU-T G.657 documents. All cabled SM fibers must have a maximum attenuation value of 0.5 dB/km for high grade at 1,310 nanommeters over the entire specified temperature range.

Table 3-6 Single-mode Dual-Windowed Fiber Optic Cable Characteristics

Function	Parameters
Maximum attenuation dB/km @ 1,310 nm	0.5*
Maximum attenuation dB/km @ 1,550 nm	0.4*
Zero dispersion range	1,310 nm (+/- 10)
Maximum dispersion range	3.2 ps/nm-km (range 1,285 to 1,330 nm) 19 ps/nm-km (range 1,550 nm)

Function	Parameters
Cable minimum bending radius	15 x cable diameter under no load. 0-800 N (0-180 lb)** 20 x cable diameter under load 800-2,700 N (181-600 lb)
*Building/breakout cables (tight buffer). Minimum attenuations do not apply to tight-buffered or breakout type cables. The maximum attenuation for tight-buffered cable is 1.00 dB/km @ 1,310 nm and 1.0 dB/km @ 1,550 nm. **Building/breakout cables (tight buffer). Tensile load rating and minimum bending radius do not apply to tight-buffered breakout-type cables.	

ps=picosecond

3-9.6.1.3 Non-zero Dispersion-shifted Fiber.

Fiber optic cables installed to high bandwidth optical transport equipment (e.g., Dense Wave Division Multiplexing (DWDM), Optical Transport Node (OTN), PON) must employ non-zero dispersion-shifted fiber (NZDSF) FOC when cable distances exceed 25 miles (40 kilometers). NZDSF FOC must meet or exceed the recommendations of ITU-T Recommendation G.655, Table 1/G.655.C and Table 2/G.655.D. Table 3-6 presents an extract from the ITU-T G.655 recommendation. If use of standard fiber versus NZDSF for the distance is in question, determine which fiber optic cable type will support the channel capacity for the distance at which the cable will be installed.

Table 3-7 Non-zero Dispersion-shifted Fiber Single-mode Fiber Optic Cable Characteristics

Fiber Attributes		
Attribute	**Detail**	**Value**
Mode field diameter	Wavelength	1,550 nm
	Range of nominal values	8-11 µm
	Tolerance	+/- 0.7 µm
	Number of turns	100
	Maximum at 1,625 nm	0.50 dB
Chromatic dispersion coefficient wavelength range: 1,530-1,565 nm	λ_{min} and λ_{max}	1,510 nm and 1,565 nm
	Minimum value of D_{min}	1.0 ps/nm-km
	Minimum value of D_{max}	10.0 ps/nm-km
	Sign	positive or negative
	D_{max} - D_{min}*	≤ 5.0 ps/nm-km*
	Maximum PMD_Q	0.20 ps/ √ km

λ=wavelength; µm=micrometer; D=chromatic dispersion coefficient; M=cable sections

3-9.6.2 Bend Radius.

The minimum bend radius for FOC during and after installation must conform to the latest issuance of ANSI/TIA-568. If the manufacturer's requirements are more stringent, follow the manufacturer's installation practices.

3-9.6.3 Cable Count.

Assign new fiber optic cable strand counts in a similar manner to copper counts. Drop the highest number strands within the cable count first; Strand 1 will be the farthest from the serving core node or ADN. Fiber counts must be split, handled, and/or terminated in groups or bundles of 12 strands. Drop groups or bundles designated as spares (dark fibers) in the nearest OSP supporting structure (e.g., MH, HH, or cable vault) stipulated by the site owner to position them for future growth. If the existing cable plant is reused and the strand count assignment differs from this layout, coordinate the updated strand count assignments with the site owner.

3-9.6.4 Splicing.

Fiber optic cable splicing permanently joins two fiber strands together and must be accomplished in accordance with TIA 609A000. There are two fiber splicing methods: mechanical splicing and fusion splicing. Mechanical splicing doesn't physically fuse two optical fibers together; rather, two fibers are held end-to-end mechanically. In fusion splicing, two fiber strands are fused together with an electric arc. Use the fusion method when splicing FOC into one continuous length. Fusion splices must have an insertion loss of <0.05 dB and return loss of >55 dB for loose tube fiber, or must have an insertion loss of <0.10 dB and return loss of >55 dB for ribbon fiber. FOC splice cases must meet requirements of TIA/EIA 515B000 and be tested using the manufacturer's recommended testing procedures to validate the integrity of the splice case seal. FOC splice cases must be installed within OSP supporting structures (e.g., MH, HH, or cable vault) in accordance with RUS Bulletin 1751F-642. Direct-buried splices may be used only in emergency situations (restoration of communications) and must be locatable through the installation of a permanent in-ground marker. Loop-through splicing must be used in lieu of dedicated cables (home runs) to the serving location. In loop-through splicing, only the fiber strands branching off from the main cable run to enter an EUB are cut and spliced, and the remaining fiber strands are not. The remaining fiber strands are folded back within the splice case and routed on to the next branch point. Binder group integrity must be maintained during this process. Splice unused spare fibers (dark fibers) through if the size of the FOC allows for the installation of a clear and cap at the end. Prepare unused spare fibers (dark fibers) for future splicing requirements. All splicing must be fusion spliced except for instances of emergency restoration when fusion splicing is not available.

3-9.6.5 Building Terminations.

3-9.6.5.1 Devices.

Strands of OSP FOC plant entering an EUB, ADN, or core node from an exterior pathway must be properly terminated within each facility on fiber optic patch panels (FOPP). Extend the OSP fiber optic cabling from the building's entrance facility to the main telecommunications room in accordance with NFPA 70® requirements. The main telecommunications room will house the FOPPs and serve as the facilities demarcation point where the OSP cabling transitions to ISP cabling. All FOPPs must be stenciled with the panel number, cable identification, and cable count.

3-9.6.5.2 Methods.

Accomplish new FOC terminations using the physical contact (PC) family of small form fit connectors and adapters. PC connectors and adapters, also referred to as polished connectors, are designed to support network devices with connection rates of 10 Gbps or higher. PC connectors and adapters that can be used include ultra PC (UPC), super PC (SPC), and angle PC (APC). APC connectors are typically used in video and RF signal transport where UPC are more suited for data networks. Use duplex LC connectors for new installation. If existing FOC plant and FOPPs are being reworked, subscriber connector (SC) or straight tip (ST) (ST™ compatible) connectors and adapters may be used to mate to existing plant with the approval of the site owner. All connectors and adapters must meet the requirements defined in TIA 604. OSP FOC strands must be fusion spliced to factory produced and compatible pigtails for FOPP termination.

3-9.7 Design Criteria.

The DoD currently employs a number of architectural topologies for OSP at each B/P/C/S. The intent is to provide voice and data services at the lowest possible cost, to include the total cost of ownership. Each B/P/C/S and project-specific criterion must be individually analyzed to determine the best technical solution based on available funding. One of the most important guiding principles for design and implementation of OSP infrastructure is to ensure single points of failure that would impact the user populace are eliminated in accordance with the Uniform Capabilities Requirements (UCR).

Paragraph 3-9.7.1 provides minimum criteria when specific guidance is not provided in project documentation.

3-9.7.1 New Cable Installation Minimum Requirements.

If the design requires installation of new cable, the requirements in Table 3-8 apply to all buildings unless the facility is designated as a special case. Special case buildings must meet the minimum requirements defined in Table 3.9.

Table 3-8 Standard Fiber Cable Sizing Between Buildings

From	To	Minimum Existing Fiber Strands	Minimum Fiber Strands if Installing New Cable	Notes
Core node	Core node	144	288	1, 2, 4
Server farm IPN/ISN	Core node	72	144	1, 2, 4
ADN	ADN/ core node	72	144	1, 2, 4
ADN	EUB	12	12	3, 5

IPN=Installation Processing Node; ISN=Installation Servicing Node; ADN=Area Distribution Node; EUB=End User Building

Notes:
1. The physical path of the cable from a physical ADN location to each adjacent core node/ADN should be direct to the connected core node/ADN without routing through or patching through any other building, with the exception of stand-alone cable huts or vaults.
2. The physical pathway between building locations must be dual-homed where two connections are run over two physically diverse paths or over a single concrete encased path.
3. Single physical pathway between building locations where a single connection is established.
4. Designs for new FOC must include at least 25-percent spare, unused strands, with cables designed in multiples of 12-strand groups.
5. Designs for new FOC must include at least 50-percent spare, unused strands, with cables designed in multiples of 12-strand groups.

Table 3-9 Special Case Fiber Cable Sizing between Buildings

COMMAND AND CONTROL USERS	
User Classification	**Description**
Special C2 users	• President of the United States of America • Secretary of Defense • Chairman of the Joint Chiefs of Staff • Commanders of the united commands • RED Switch subscribers

COMMAND AND CONTROL USERS	
User Classification	**Description**
C2 users	• Users that have the requirement for C2 communication, but do not meet the criteria of special C2 users. • Includes any person (regardless of position in the chain of command) who issues guidance or orders that direct, control, or coordinate any military forces, regardless of the nature of the military mission, whether said guidance or order is issued or effected during peace or war time.
Other Users	• Do not meet the criteria for special C2 users and C2 users. • May also be denied access during national emergencies.

Note: User classifications pertain to Defense Switched Network (DSN) access. Originally defined and applied to voice services, their use has been extended to data services by implication.

Table 3-10 Infrastructure Requirements for Buildings Requiring Connections to Multiple Nodes

User Classification	Building Entrance Requirements	Standards Document
Special C2 users	Diverse dual entrance facilities with a minimum separation of 20 feet (6 meters)[1] Entrance conduits at a minimum will be concrete encased.	NFPA 1221, 8.4.3.2[2] Specific requirements defined as the mission dictates Requirements listed here are the absolute minimum for design purposes.
C2 users	Diverse dual entrance facilities with a minimum separation of 20 feet (6 meters)[1]	NFPA 1221, 8.4.3.2[2] Requirements listed here are the absolute minimum for design purposes.
Main data facilities	Diverse entrance facilities with a minimum separation of 66 feet (20meters) The building entrance or the serving conduits will be below ground.	NFPA 1221, 8.4.3.2[2] Latest issuance of ANSI/TIA 942 ANSI TIA/942 does not state if the entrance facility is above or below ground.

User Classification	Building Entrance Requirements	Standards Document
Hospitals	Diverse dual entrance facilities with a minimum separation of 20 feet (6 meters)[1] The building entrance or the serving conduits will be below ground.	NFPA 1221, 8.4.3.2[2] NFPA 99
Emergency Operation Centers	Diverse dual entrance facilities with a minimum separation of 20 feet (6 meters)[1] The building entrance or the serving conduits will be below ground.	NFPA 1221, 8.4.3.2[2]
Fire stations (as mission dictates)	Diverse dual entrance facilities with a minimum separation of 20 feet (6 meters)[1] The building entrance or the serving conduits will be below ground.	NFPA 1221, 8.4.3.2[2]
Garrison headquarters	Diverse dual entrance facilities with a minimum separation of 20 feet (6 meters)[1] The building entrance or the serving conduits will be below ground.	NFPA 1221, 8.4.3.2[2]
Military Police (if not co-located with EOC)	Diverse dual entrance facilities with a minimum separation of 20 feet (6 meters)[1] The building entrance or the serving conduits will be below ground.	NFPA 1221, 8.4.3.2[2]

[1]Minimum separation is the same minimum separation for medical facilities.
[2]NFPA 1221, 8.4.3.2: Where multiple communications centers that serve a jurisdiction are not located in a common facility, at least two circuits with diverse routes, arranged so that no singular incident interrupts both routes, must be provided between communications centers.

Note 1: Non-concrete encased underground conduits and direct buried cables are considered diverse if the minimum separation between them is greater than 20 feet (66 meters).

Note 2: Except for Special C2 uses, node connections can share the same conduit system if the shared pathway is concrete-encased.

3-9.7.2 Passive Optical Networks in the Outside Plant Architecture.

The designer must obtain approval from the technical authority before designing a PON architecture. The way in which a PON influences the OSP design depends on whether the PON solution serves an individual building, multiple buildings, or an entire campus. PON is a point to multi-point architecture where signals from the headend or central office are divided by a passive optical splitter and fed downstream to many end users. In a single building PON solution the feeder fiber from the central node would traverse through the MH and duct system and the splitter would typically be located in the building. A PON serving multiple buildings or an entire campus would involve placing a splitter or series of splitters in the OSP section of the architecture (e.g., MH, HH, enclosure).

3-9.7.3 Air Blown Fiber in the Outside Plant Architecture.

ABF systems are an alternative to traditional optical fiber and innerduct solutions. ABF systems push FOC through preinstalled micro-ducts or tubes utilizing compressed air. ABF systems can be useful in scenarios where frequent moves, adds, and changes to the infrastructure are necessary or where it is not realistic to break ground to install new OSP infrastructure (e.g., airports, runways, training campuses). It is important to note that ABF systems often require proprietary equipment such as blowers, micro-ducts/tubes, fiber cable, and manufacturer’s accessories. The maximum distance most vendors will support without advanced blowing techniques is just over a half mile (3280 feet or 1 kilometer). The designer must obtain approval from the technical authority before implementing an ABF system. All blown fibers must be installed in new or existing micro-duct and manufacturers couplers must be used as required.

3-9.7.3.1 Fiber Optic Cable Testing.

Testing must be completed on all FOCs (OSP cable, premise distribution, patch cords), cable connections, splices, and terminations. Test using Tier 1 and Tier 2 test equipment, or a combination of both. Both a light source and power meter (LSPM) and optical loss test set (OLTS) are used for Tier 1 testing. An OTDR is used for Tier 2 testing. Tier 1 and Tier 2 testing must be accomplished in accordance with ANSI/TIA-568 and TIA-526 Series, SM fiber optic cable must be tested at wavelengths 1310 nanometers and 1550 nanometers for both Tier 1 and 2 testing. MM fiber optic cable must be tested at wavelengths 850 nanometers and 1300 nanometers for both Tier 1 and 2 testing. All connectors and bulkheads must be thoroughly cleaned prior to performing any testing. The following tests must be done at minimum for each tier:

- Tier 1 Testing:
  - Optical power
  - Optical loss (insertion loss) single reference jumper
- Tier 2 Testing:
  - Unidirectional (pre-installation)
  - Bidirectional (post-installation) with minimum 0.63 mile (1 kilometer) long launch and receive cables.

– Fiber characterization (chromatic dispersion (CD), polarization mode dispersion (PMD))

a. For new fiber optic cable installations, end-to-end testing using Tier 1 and Tier 2 test equipment must be performed on every fiber strand installed, spliced and/or terminated as follows. Prior to installation, Tier 2 testing (unidirectional) must be performed on all strands per bundle of new fiber optic cable while the cable is still on the manufactures cable reel. This test will verify the cable functionality is free from defects or damage from the manufacturer before installation. Factory test results are not acceptable, as damage may have occurred during shipment to the project location. Any fiber optic cable strands that fail pre-installation testing must be documented and reported to the USG prior to moving forward with installation.

b. Following completion of fiber optic cable installation, to include permanent placement, splicing and connector termination, both Tier 1 and Tier 2 (bidirectional) testing must be performed on all new strands per bundle of fiber optic cable.

c. For existing fiber optic cable that is being rehomed and reterminated, Tier 2 testing (unidirectional) must be performed from the originating or unaffected end prior to the start of work to identify existing defects or anomalies that need to be corrected. Once work has been completed on the existing fiber optic cable as part of the rehoming/retermination effort, Tier 1 testing must be completed from the end of the new work completed. Upon completion of Tier 1 testing, Tier 2 testing (bidirectional) must be completed to recertify the completed permanent link. Any existing fiber optic cable strands damaged during the rehoming/retermination effort must be repaired and restored to working order.

d. A test report must be developed that contains a strip chart for each fiber strand tested, to include the cable ID, strand ID, source location, test set location, dB loss at each wavelength and fiber length, and whether a strand has passed or failed. The test report must also include all raw data files collected from the test equipment used. All strands that passed testing prior to installation must pass testing after installation is complete.

3-9.8 OSP Cable Labeling.

3-9.8.1 Cable Identification/Cable Tags.

Cable Identification/cable tags must be installed at all termination points (terminals) and splices, including house cables. In all OSP supporting structures, all new and existing cables that are part of the project must be tagged and/or retagged between the splice and the wall and on both sides of a splice loop or maintenance loop. When a cable is rehomed to a new location all existing cable tags and terminal labels on the rehomed cable must be re-tagged and re-labeled to reflect the new information. One tag is required for a copper cable pull-through, and two tags are required for an FOC pull-through if there is no service loop. Labels in MHs and HHs must be machine-produced on a durable material suitable for the environment. Handwritten labels are not acceptable.

3-9.8.2 Cable Label Schemes.

The unique identifier for each cable will include an indicator of the originating location of the cable unless directed otherwise by unique project requirements. For a copper cable, it can be as simple as a local policy; e.g., cables 1 through 15 originate from Building xxx; cables 16 through 25 originate from Building yyy. For fiber optic cable, the originating number could be included as part of the identifier. Use the following cable label schemas:

- To identify a copper cable, size + type and cable identification + count are needed. Cable sizes must be identified with an abbreviation. For example, a 1,200 pair cable must be identified as “P12-24PF.” The “24” represents the AWG. PF (plastic insulated cable (PIC) fill) refers to the cable type (fluorinated ethylene propylene). All cables with fewer than 25 pairs must include an “X.” (Refer to the examples.)

Note: Only an existing cable is identified with a “CA” prefix.

  - 6-pair = P6X-24PF
  - 12-pair = P12X-24PF
  - 18-pair = P18X-24PF

- To identify a 900-pair, 24 AWG copper cable:
  - P9-24PF = cable size and type
  - 03, 1-900 = cable number and pair count

- To identify two different copper cables under the same sheath:
  - P18-24PF
  - 07, 1-1,500 + T1, 1-300

- To identify a 10-pair, 0.6 mm European copper cable:
  - 10x2x0.6 = size and type
  - 01, 1-10 = cable number and count

- To identify an 800 pair, 0.6 mm European copper cable:
  - 800x2x0.6 = size and type
  - 05, 1-800 = cable number and count

- To identify a fiber optic cable, use the cable identification + strand count and then the cable size + type.
  - FOC 01, 1-72 = cable identification and strand count
  - 172 SM = type of cable

- To identify a ribbon type fiber optic cable, use the cable identification + strand count and then the cable size + R (for ribbon) + type.
  - FOC 01R, SM, 1-72 = cable identification and strand count
  - 172 SM = type of cable

3-9.8.3 Identification of Core Network, Distribution Backbone, and Other Unique Cables.

The following requirement does not apply to cables to end user buildings. New cables placed to support core networks, the distribution backbone, and other unique cables must have at a minimum the cable name applied to the cable sheath during the manufacture of the cable. Refer to the site unique requirements for other characters that may need to be applied during the manufacturing process. The number of additional characters that can be applied to the cable sheath varies from 28 to 120 characters by cable manufacturer. Cable tagging is still required for these cables.

Note: Cable naming schemas should not include building numbers, as cable may be rehomed.

3-9.8.4 Existing Cable Labeling.

When an existing cable is rehomed to a location, the new location identifier should apply to all of the rehomed cable, to include laterals. Therefore, all the existing cable tags, the labels on the building terminals, and associated cable records must be changed to reflect the new information. This requirement is not to be construed as a requirement to place labels on cables that do not have existing tags unless the identification of the cable is easy to determine with minimal or no impact on the project's cost or schedule. An example of this is when there is only one cable in the MH, and the identifier and count were verified in the previous MH.

3-9.8.5 Tamper Evident Labeling.

Tamper evident labels must be affixed to all splice cases opened or installed as part of a project and any other major warranted components of the OSP infrastructure. Label components include the following and must be documented:

- type of component
- location of component
- date label was applied to the component
- photograph(s) that show the component and the location where the label was applied

Documentation of components must be provided to the COR at the conclusion of all work.

3-9.9 Demarcation Point Requirements.

The demarcation point is the point where OSP cabling transitions to ISP cabling and where termination and testing can take place.

- A PET is a device that provides electrical protection and a termination point for outside plant cable and indoor house wiring.
- Fiber optic patch panels are devices that provide a termination point for OSP FOC and ISP FOC.

3-9.9.1 Building Entries.

The standard method for entering buildings is through RMC. Refer to Figure A-10 for building entrance details. Use of above-ground entries in lieu of underground entries is permissible with USG approval. The preferred method for creating above ground cable entrance is to use el-shaped rigid conduit bodies (LL, LB, and LR). The riser conduits to must be RMC. Refer to Figure A-21 for above ground building entrances.

Typical foundation types include slab-on-grade, crawl space, full basement, and deep drilling on piles. Refer to Figure A-10 for duct assignment details. Footers encountered may be continuous or non-continuous. The footer portion of the foundation must not be cut. Entrance conduits must pass below footers or through the building foundation wall. RMC must be placed where the entrance conduits pass through foundation walls. Annular spaces between the conduits and floors and walls must be sealed to prevent water intrusion and must be fire stopped in accordance with UFGS 07 84 00, the NEC®, and local codes. The most stringent code applies. Conduits must extend between four to six inches (100 to 150 millimeters) above the finished floor or below the ceiling with bell ends to aid in pulling cables. Entrance conduits must be plugged or sealed to prevent water intrusion. Where conduits entering through the floor cannot be placed within 3 inches (75 millimeters) of a wall, as shown in Figure A-10, the conduits must enter a pull box within the building.

3-9.9.2 Above Ground Entrances.

Entrance conduits must not be mounted on the exteriors of buildings unless previously approved by the USG. Annular spaces between the conduits and floors and walls must be sealed to prevent water intrusion and must be fire stopped in accordance with UFGS 07 84 00, the NEC®, and local codes. The location of existing main telephone terminal rooms on floors above the ground level is insufficient cause to justify mounting entrance conduits on the exteriors of buildings. Where approved by the USG, the number of conduits mounted on the external walls of buildings must be minimized.

3-9.9.3 Pull Boxes and Conduit Bodies.

Pull boxes and conduit bodies must be sized in accordance with the cable manufacturer's recommended cable bending radius to accommodate the fiber optic and copper cables sized for the building. Conduit bodies are preferred for use where conduits enter the exterior walls. The contractor must obtain approval from the COR to install external pull boxes in lieu of installing conduit bodies. Conduit bodies are more robust and have a smaller footprint than pull boxes. The contractor must coordinate the location and finish of the above ground building entrances with the COR.

3-9.9.4 Transition.

The transition from plastic to RMC for entrance conduits must take place at the bottom of the trench prior to sweeps or bends to the building.

3-9.9.5 Building Telecommunications Grounding.

The contractor must ensure that the various grounding electrode systems, electrical grounding system, lightning protection grounding systems, telecommunications grounding system, and cable grounding system are bonded together. Unclassified TRs must be connected to the building's earth electrode subsystem in accordance with the latest issuance of ANSI/TIA 607. An acceptable grounding system encompasses fault protection grounds, lightning protection grounds, signal grounds, and DC power grounds (when applicable). Refer to UFC 3-575-01 for proper lightning protection and to NFPA 70® for proper fault protection grounding. The contractor must review applicable project drawing(s) to ensure that the lightning and fault protection grounds are addressed by the appropriate disciplines.

3-9.9.6 Building Ground.

The contractor must bond all edge and core network devices to the building earth electrode system (EES) in accordance with the latest issuance of ANSI/TIA 607. The contractor must be conscious of the proposed use of the facility; international, national, or local codes; DoD and Service standards; and/or manufacturers' equipment specifications, and should plan accordingly.

3-9.9.7 Cable Entrance Grounding.

The contractor must ensure that lightning protection complies with UFC 3-575-01 and ensure all grounding electrode systems are bonded together. All metallic shields and strength members for OSP cable entering a building must be bonded to the lightning protection ground system.

3-9.9.8 Copper Cable Entrance.

The designer must use a non-bonded splice case for the transition from OSP-rated cable to interior-rated cable or must indicate that the implementer must not install the splice case carry-through bonding conductor. The OSP copper cable shield, armor, and metallic strength member must be bonded to the lightning protection ground as close to the building point of entrance as possible with a No. 6 AWG bonding conductor in accordance with the latest issuance of ANSI/TIA 607. If the contractor extends the OSP copper cable past 50 feet (15 meters), in accordance with NFPA 70®, the metallic strength member must be bonded to the lightning protection ground as close to the conduit egress point as possible with a No. 6 AWG copper bonding conductor.

3-9.9.9 Surge Protector.

The contractor must terminate all OSP copper cables using surge protectors. Surge protectors are primary protector blocks equipped with 5-pin solid state or gas protector modules. The guidance on surge protection and proper bonding to the grounding system is found in IEEE C62.43. The protector blocks must be bonded to the building ground system with a No. 6 AWG bonding conductor. Terminals, surge protection modules, and hardware must be UL-listed. The PET for European projects must be equipped with protected, LSA+ terminal blocks.

3-9.9.10 FOC Entrance.

The designer must use a non-bonded splice case for the transition from OSP-rated cable to interior-rated cable or must indicate that the implementer must not install the splice case carry-through bonding conductor. The OSP FOC armor and metallic strength member must be bonded to the lightning protection ground as close to the building point of entrance as possible with a No. 6 AWG bonding conductor. If the contractor extends the OSP FOC armor past 50 feet (15 meters), in accordance with NFPA 70®, the metallic strength member must be bonded to the lightning protection ground as close to the conduit egress point as possible with a No. 6 AWG copper bonding conductor.

CHAPTER 4 AIR FORCE SPECIFIC REQUIREMENTS

4-1 REDUCE COSTS, ENHANCE SAFETY.

Follow industry trends of roll pipe and air-assisted cable pathway utilization to reduce the real property cost and complexity of traditionally designed MH and ducting systems from the Bell System era.

Retirement of high pair count, large diameter copper-cabling-based plain old telephone and time domain multiplexing (TDM) equipment has greatly reduced the need for expensive large capacity MHs and ducting. New conduit and cabling system installation technologies have the potential for significant cost avoidance because installations can be designed with longer uninterrupted spans, and do not adhere to the same requirements for maximum number of degrees of direction change before MH installation is needed for traditional “pulled installation” cable. This results in far fewer, if any, MHs within the design, reducing cost and number of additional dangerous confined spaces to an installation’s infrastructure baseline.

4-1.1 Copper Cable.

Install new copper cable only when the end equipment cannot be updated to fiber optic transmission.

4-1.2 High-Density Polyethylene Microduct Bundles.

a. Where there is no existing and available MH and ducting, directly bury HDPE-jacketed microduct bundles using methods described in this UFC.

b. HDPE microduct bundles between main communication nodes (MCN) must include no fewer than seven individual micro-ducts.

c. HDPE microduct bundles between EUBs must include no fewer than four individual microducts.

d. HDPE microduct bundles must not exceed 2000 feet (610 meters) in length without MH/HH or above-ground enclosure access to the span.

4-1.3 Conduit Access Points.

To reduce the number of confined spaces on Air Force installations and in areas of rocky terrain, use above-ground enclosures for conduit access points whenever possible.

4-1.4 Cable Sizing.

Adhere to Table 3.8, “Standard Fiber Cable Sizing Between Buildings,” with the following modifications:

- Column 3 heading: Originally Installed Fiber Strands Shall Not Exceed
- Column 4 heading: Do Not Exceed Strand Count if Installing New Cable

This Page Intentionally Left Blank

CHAPTER 5 ARMY SPECIFIC REQUIREMENTS

5-1 INTRODUCTION.

5-1.1 Purpose.

This chapter provides additional requirements and guidance for Department of Army projects.

5-1.2 Army Technical Authority.

The Army's technical authority for this UFC is an Army employee regularly engaged in the design of information and communication technology. The Army Technical Authority should also have a BICSI RCDD certification. The delegated role of the Authority Having Jurisdiction (AHJ) does not change.

5-2 SPECIFIC REQUIREMENTS.

5-2.1 USG-Designed Projects.

Refer to Chapters 2 and 3.

5-2.2 Classified Infrastructure.

Use the following documents for projects that include SIPRNET requirements:

- *SIPRNET Technical Implementation Criteria*, U.S. Army Information Systems Engineering Command (AKO login required). https://www.us.army.mil/suite/files/5744948

- UFGS 27 05 29.00 10
  https://www.wbdg.org/ffc/dod

5-2.3 Telecommunications Spaces.

5-2.3.1 Collocation of Other Telecommunication Systems.

CATV, CCTV, fire alarm and electronic security systems (ESS) may be collocated inside the TR.

5-2.3.2 Multi-Story Buildings.

Refer to Chapter 2.

5-2.3.3 Barracks, Dormitory, and Bachelor Quarter Telecommunications Room Sizing Considerations.

Standard TIA-569 TRs are typically too large for these types of facilities. Provide an 8-foot by 10-foot (2.4-meter by 3.0-meter) main TR on the first floor and provide a minimum of one 6-foot by 8-foot (1.8-meter by 2.4-meter) TR on subsequent floors.

Provision the TRs in these facilities in accordance with TIA-569. Telecommunication enclosures are acceptable in barracks with non-linear designs..

5-2.4 Telecommunications Pathways.

Refer to Chapter 2.

5-2.5 Fiber Optic Backbone Cable.

The Defense Information System Network (DISN) Enterprise Network Installation and Campus Area Network (ICAN) design and implementation standards and specifications dictate use of single mode fiber cables for building backbones on Army projects.

5-2.6 Work Area.

5-2.6.1 Outlet Types and Density for Barracks, Dormitories, and Bachelor Quarters.

Use outlets with a minimum of a “F” type jack and a category CAT6A jack. Locate outlets in the kitchen, living room, family room, and all bedrooms adjacent to a duplex electrical receptacle.

5-2.6.2 General Range Information Infrastructure Design.

With the advent of digital ranges, the preferred infrastructure to ranges is an underground infrastructure, consisting of a two-way conduit system. Direct-buried cable may be used when directed by the USG.

The minimum conduit size for ranges must be no less 1.5-inch (40-millimeter) trade size conduits. The minimum depth for conduit or cable placement is 48 inches (1200 milimeters). Coordinate with the mission owner to determine the required depth.

a. Splices must be placed in underground concrete supporting structures with an HS-20 load rating. Use of buried composite concrete fiberglass is not permitted. Support structures must be large enough to accommodate cable service loops and splice cases.

b. Concrete encasement or galvanized RMC must be used in range projects under road crossings, heavy equipment (tank) crossings, and high-traffic areas. The contractor must plan for a minimum of two, 1.5-inch (40-millimeter) conduits under road crossings. For heavy equipment traffic loads (e.g., tank crossings), the contractor must design and install a pathway based on the maximum expected wheel load. The encasement and/or galvanized RMC must be extended a minimum of 6 feet (1800 millimeters) beyond the road bed for all road crossings.

c. The contractor must also specify a minimum of 12 strands of SM FOC to the individual ranges or range buildings.

5-2.6.4 Inter-Building and Outside Plant Requirements.

Follow Chapter 3 of this UFC.

This Page Intentionally Left Blank

CHAPTER 6 NAVY SPECIFIC REQUIREMENTS

6-1 INTRODUCTION.

6-1.1 Purpose.

This chapter provides additional guidance and planning information for Department of the Navy (DoN) projects that will require Navy and Marine Corps Internet (NMCI) network connections. Navy medical facilities must comply with the Defense Medical Facilities Office (DMFO) criteria, including UFC 4-510-01, and are not normally part of NMCI.

Note: For this UFC, the term “NMCI” references the network provided for use by the Navy and Marine Corps; Next Generation Enterprise Network (NGEN) references the contract between the USG and the contractor providing the NMCI network service.

All Naval Facilities Engineering Systems Command (NAVFAC), Facilities Engineering Commands (FEC), Public Works Departments (PWD), Resident Officer in Charge of Construction (ROICC) offices, BCO, and other concerned parties must refer to this UFC when designing, planning, or preparing documentation for new projects that will require operational NMCI support.

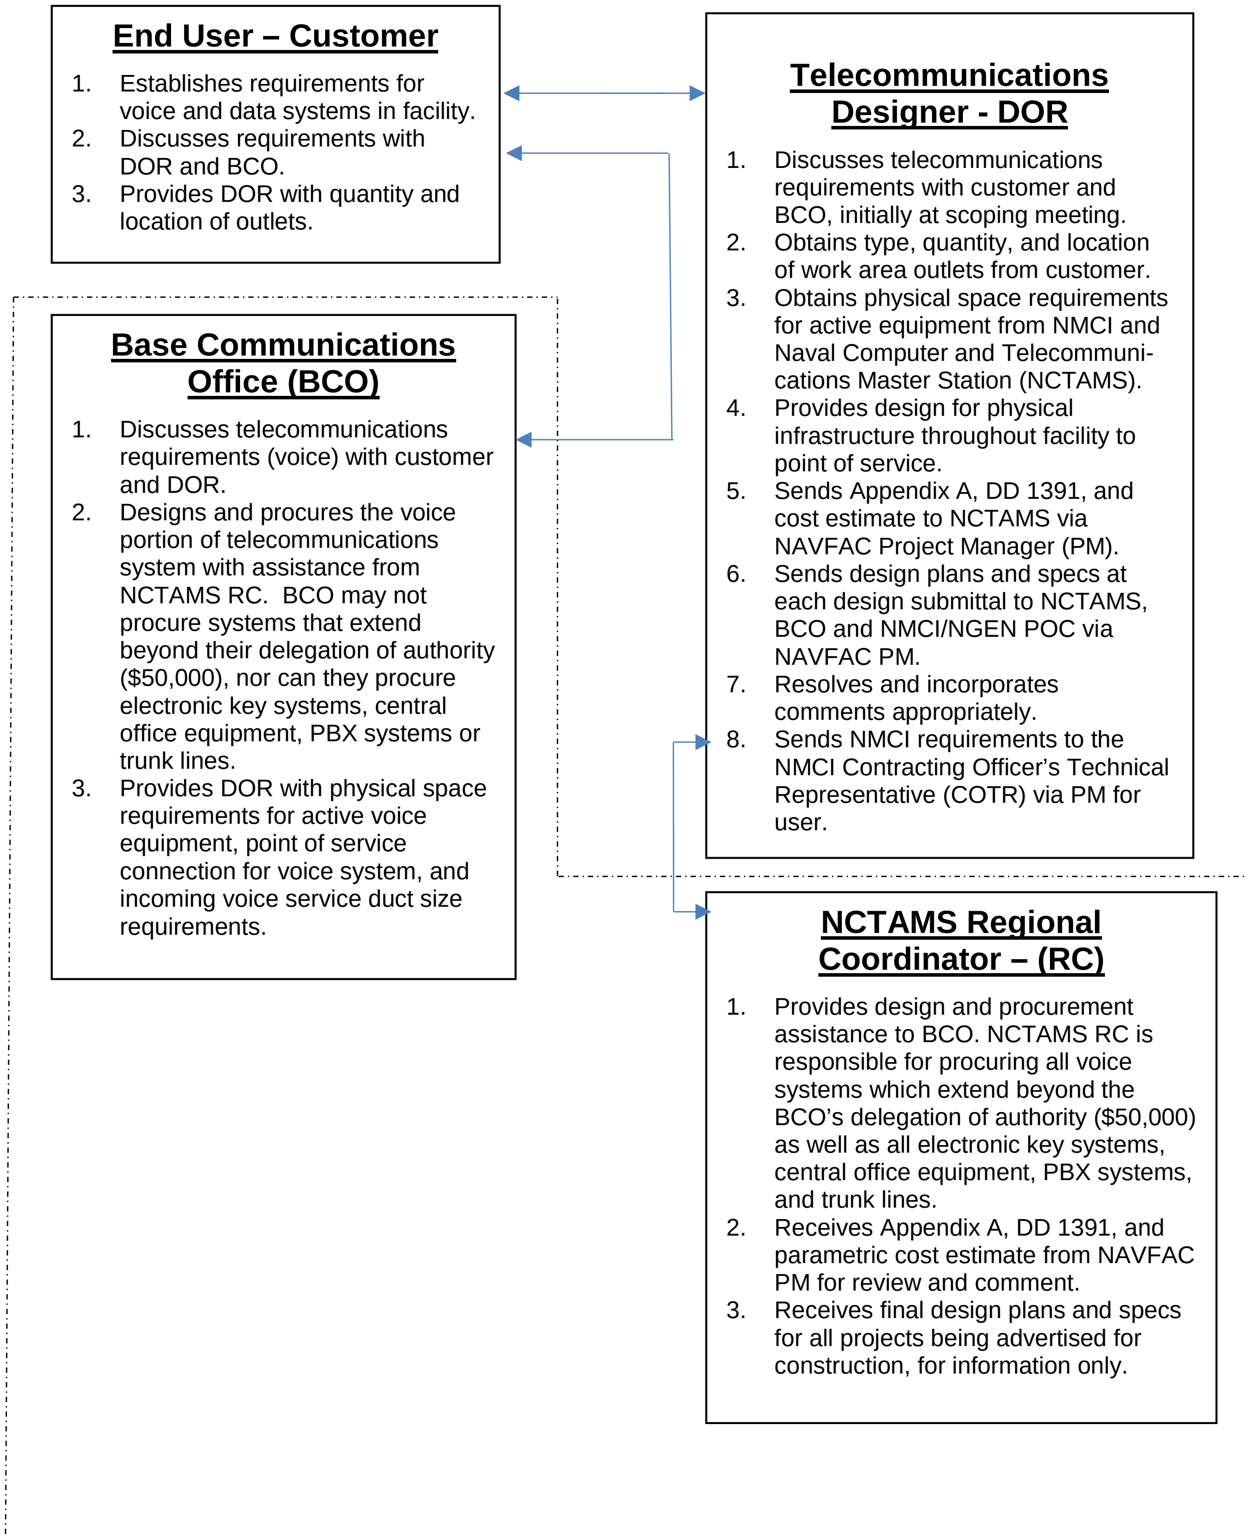
6-1.2 Order of Precedence.

If conflicts arise between this UFC and the NGEN contract, the NGEN contract governs.

6-1.3 Coordination.

Although this UFC was written to be as inclusive as possible, IT installations may vary greatly from building to building. It is therefore imperative that the USG facilities team (Naval Enterprise Networks (NEN) Program Office, Commander Navy Installations Command (CNIC), and NAVFAC components), facility design team, and construction contractor coordinate closely at each stage of planning, design, and construction. The telecommunications system DOR must coordinate their efforts for each design with the applicable entities identified in Figure 6-1.

Figure 6-1 Navy Telecommunications Coordination Chart for Typical Design/Bid/Build for Non-National Capital Region Projects



6-2 SPECIFIC REQUIREMENTS FOR NAVY INTRANET CONSTRUCTION.

6-2.1 Collocating Various Systems.

Provide adequate space in TRs to facilitate tenant-owned telecommunications systems and other low-voltage systems such as fire alarm, CATV, CCTV, and ESS.

6-2.2 Bachelor Quarters Considerations.

Standard TIA-569 TRs are normally too large for these types of facilities. For multi-story quarters, provide a minimum of one 8 feet (2.4 meters) by 10 feet (3 meters) main TR on the first floor and a minimum of one 6 feet (1.8 meters) by 8 feet (2.4 meters) TR on subsequent floors. Provide additional TRs on the main and subsequent floors as required to meet system limitations.

6-2.3 Fiber Optic Backbone Cabling.

Provide single mode fiber optic cabling (OS1) on all projects for building backbones to future proof the network and standardize the backbone. Additionally, this permits the option of flattening the network via direct connection to switches in TRs other than the main TR. In existing Navy facilities with multimode cables and switches, coordinate with the activity and the NMCI/NGEN contractor to determine whether the switch optics will be changed to use the single mode backbone, or if multimode cable must also be provided in addition to the single mode. If using multimode, OM3 (which permits data rates up to 10 Gigabits) is first choice. OM2 and OM1 should be used only to supplement existing systems.

6-2.4 Navy-Specific Technical Authorities.

For the purposes of implementing fiber to the desktop, the DOR must have justification in writing from the end user certifying that the 1391 supports this requirement, and from the NMCI/NGEN POC certifying that this requirement is included in their planned system.

6-2.5 Barracks, Dormitory, Bachelor Quarters.

Provide a minimum of one standard telecommunications outlet in each bedroom and common area (living room) of the suite. Comply with FC 4-721-10N.

6-2.6 Utility Rooms.

Coordinate with other disciplines and the Activity to determine if a voice or data outlet is needed in mechanical or electrical utility spaces (for smart metering or automated building control systems).

6-3 OUTSIDE CABLE PLANT.

See Chapter 3.

6-3.1 Pathways.

Coordinate with the NMCI contractor to determine if the NMCI pathways can be routed in the same duct bank with other telecommunication conduits. If so, conduits beyond the 5-foot (1.5-meter) line and manholes are MILCON funded to the closest manhole where service exists. The location of underground structures and the necessary interconnecting ducts must be explicitly described and identified in the contract documents.

For new buildings, provide a minimum of one, 4-inch (103 millimeter) conduit for NMCI service. Provide a minimum of two conduits for multi-story buildings. Use three innerducts (two, 1.5-inch (41-millimeter) and one, 1-inch (27-millimeter)) or three fabric mesh innerducts in each conduit. Install a pull wire inside each of the innerducts. This is in addition to the conduits required for other telecommunications services (telephone, cable television, fire alarm and intrusion detection).

6-3.2 Detection.

Provide electronic detection for each pathway in accordance with the following:

- Use detectable warning tape or tracer wire above the duct back for new installations.
- Use tracer wire when pulling new cable in existing duct systems.
- Terminate all tracer wire in test stations for utility locating personnel with a cover/lid marked “Test Station.”

6-3.3 Cabling.

Standard NMCI practice employs SM FOC with a minimum core size of 8 microns as the transport medium between building EFs.

- Install fiber underground in conduit.
- A minimum of 12 strands of SM fiber is required. Coordinate with the NMCI contractor for additional requirements. Provide fiber with facility contract.
- If classified seats are supported and unencrypted classified communication occurs over the outside plant cabling, conduits are required and normally must be encased in concrete. Comply with applicable PDS requirements, including IA PUB 5239-22.

CHAPTER 7 MARINE CORPS SPECIFIC REQUIREMENTS

7-1 INTRODUCTION.

7-1.1 Purpose.

This chapter will be used by the Marine Corps to provide additional guidance and planning information for USMC projects that will require telecommunications or IT network connections.

Marine Corps projects must use an optical solution as the first course of action when planning and designing new projects. Exceptions to this can be granted only by the Marine Corps installation's advocate or where life safety is concerned due to local building codes. Refer to Chapter 2 of this UFC for non-optical solutions.

Naval Facilities Engineering Systems Command (NAVFAC), Facilities Engineering Commands (FEC), Public Works Departments (PWD), Resident Officer in Charge of Construction (ROICC) offices, installations' G/S-6, and other concerned parties in the process must refer to this UFC when designing, planning, or preparing documentation for new projects.

7-1.2 Marine Corps-Technical Authority.

Telecommunications infrastructure must meet the needs of the activity and supporting facilities in accordance with this UFC. Architect/Engineer (A/E) contractor-generated final drawings and specifications for Design-Bid-Build and Design-Build projects must be stamped by a BICSI RCDD. Design and construction may be concurrent efforts in Design-Build projects, and multiple phases may be approved. Therefore, each phase and/or project must be stamped.

Modernization of telecommunications systems within existing facilities solely for the purpose of meeting design criteria in this UFC is not required.

7-1.3 Coordination.

Although this UFC was written to be as inclusive as possible, cable plant electronics installations may vary greatly from building to building. It is therefore imperative that the USG facilities team as stated above, facility designer, and construction contractor coordinate closely at each stage of planning, design and construction. The DOR must coordinate their efforts for each design with the applicable entities identified in Figure 7-1.

Figure 7-1 Marine Corps Telecommunications Coordination Chart for Typical Design-Build and Design-Bid-Build Projects

Note: Solid lines represent customer coordination requirements within installation staff and their tenants. Dashed lines represent contractor-to-installation communication.

7-2 SPECIFIC REQUIREMENTS FOR MARINE CORPS PROJECTS.

7-2.1 USG-Designed Projects.

USG-designed (in-house) projects require the approval of the Service-appointed telecommunications agent, prior to bid, in accordance with regulations, policies, memorandums, and guidance.

7-2.2 Classified Infrastructure.

Classified work areas, rooms and facilities must comply with MCO 5530.14A.

7-2.3 Collocation of Other Telecommunication Systems.

CATV, CCTV, control systems, fire alarm and electronic security systems (ESS) may be collocated inside the TR. Tenant owned systems that are not considered part of the facility are not accorded space within a TR. Planning for an equipment room will be considered as required if there are no other hosting capabilities available. Final decision authority is the site owner.

7-2.4 Telecommunications Rooms.

Follow the general requirements of Chapter 2 with the following additional requirements. Minimum dimensions are 10 feet, 8 inches (3.25 meters) by 12 feet (3.6 meters), meeting all TIA-569 standards with the following exceptions.

- Base sizing of room on the additional systems requirements of the service space such as Building Management System (BMS), Automated Control Management System (ACMS), Intrusion Detection System (IDS), fire-alarm panels, and A/V equipment.
- Provide a minimum of two standard 19-inch (0.5-meter) cabinets per TR. Equipment racks will be used by exception due to physical security requirements and other specific facility requirements.
- In facilities or structures that require only the minimum infrastructure to the EF, one cabinet may be used, and the room resized appropriately. FRCS substations and remote locations may be served by a splitter or other passive connection in a pedestal.
- Mount all cabinets to the permanent floor, centered in the TR to meet Americans with Disabilities Act (ADA) access requirements.
- Colocation support agreements will be established at local level being first Flag Officer (FO)/General Officer (GO).

Treat floors, walls, and ceilings to eliminate dust by providing eggshell or semi-gloss paint finish, light in color, to enhance room lighting. Provide one wall outlet installed at or near the entry door for emergency or primary voice communications.

7-2.5 Cabinet Layout.

Existing TR cabinet layout will include ONTs and optical splitters. Future layouts will have splitter/patch panel in cabinets and ONT at work stations. Locate OLTs at the area distribution node.

7-2.6 Facility Optical Network Terminal Placement.

Do not place rack-mounted ONTs with more than 120 Gigabit Ethernet (GbE) interfaces per PON port off of the OLT. Current ONTs configured with 24-ports are grouped in multiples of five onto a 1:8 or 2:8 (for pathway redundancy) passive optical splitter.

7-2.7 Optical Splitters.

Locate splitters at a central aggregation point or EF when feeding a single ONT at a remote location, EUB, or hybrid A/V rack area. This is the demarcation point of an EUB. Place the optical splitter at the ADN if the facility will house four to five ONTs and will require only a single (or two for redundancy) strand(s) of OSP fiber to the OLT. The minimum strand count for OSP run to remote location is 24 strands. However, if this EUB requires dual homing or special redundancy, locate a secondary 2:1 splitter to connect the ONT and allow for two OLTs to be interfaced into the EUB 2:1 splitter.

It is important to ensure that the optical loss budget is taken into account. As the common point of load (PoL) budget is from -8 to -28dB, there may be a requirement to attenuate the optical signal via a splitter or attenuator to allow for proper ONT operation.

7-2.8 Patch Panels and Patch Cords.

Provide patch panels to support locking or keyed patch cords for improved physical security and the ability to meet fixed emergency communication location requirements. Code or key patch cords in accordance with the type of service they are providing – primary voice, data, video, or Supervisory Control and Data Acquisition (SCADA). Provide a reference color code and naming convention for baseline consistency.

Provide bend-insensitive, pre-terminated patch cords capable of being locked into place to avoid accidental disruption of services or tampering. For OLT to fiber optic patch panel (FOPP) connections, provide SC-UPC to SC-APC patch cords. Provide all other patch cords to match the patch panel they are connecting. LC-APC connectors and patch panel adapter bulkheads are acceptable for increased density; however, they are not permissible at the information outlet faceplate.

7-2.9 Telecommunications Pathways Interior Conduit.

Provide wall-mounted work area outlets with rigid metal conduit stubbed up from the outlet to the horizontal cable distribution system. Use cable trays or non-continuous supports (J-hooks) to support the cable from the TR to the top of the wall containing the work area outlet, then route the cable in the wall cavity to a low-voltage mounting bracket.

7-2.10 Work Area Outlets.

Connect work area outlet face plates to a double-gang, 4-inch by 4 inch (100 millimeter by 100 millimeter) outlet box, at least 3.5 inches (90 millimeters) deep to accommodate fiber inserts, slack management, and potential in-wall signal converters.

7-2.10.1 Type 1 Outlet.

Terminate Type I horizontal fibers in a traditional face plate. Because ONTs typically allow multiple Ethernet interfaces, a single fiber interface per workstation/classification is typically all that is required. This consists of a traditional wall plate equipped with two single-port SC-APC connectors. This scenario provides flexibility in that any ONT type can be used in the design, along with other traditional duplex send and receive fiber pair technologies that may be required under special circumstances.

When using fiber outlets for desktop or surface mounted ONTs, the outlet connectors for the horizontal fiber drop must be an individual snap-in style and fit securely into the face plate housing. The connector must be compatible with single-mode SC-APC fiber. SC-APC is recommended throughout the installation to ensure compatibility with RF video service and future 10G-PON applications employing the 1577 nanometer wavelengths. Angled connectors or inserts with hinged dust covers are recommended to minimize fiber end face contamination.

7-2.10.1.1 Optical Network Terminal Copper Ethernet Interfaces.

For ONTs equipped with Ethernet interfaces, provide a minimum of one (1) 10/100/1000 RJ-45 interface conforming to IEEE 802.3 standards. A quantity of two or four 1000 Base-T interfaces are recommended to comply with current industry best practices. 10/100 Base-T interfaces and those not supporting PoE or PoE+ are not permissible except in scenarios where RF video or plain ordinary telephone services (POTS) are being provided.

7-2.10.1.2 Optical Network Terminal Copper Analog Interfaces.

ONTs equipped with analog POTS provide various quantities (2, 4, or 24 depending on the model) of RJ-11 or RJ-21 telephone jacks for connection of analog devices (telephones, faxes, modems). These interfaces may provide 600 or 900 ohm terminations and adhere to typical analog voice wire length specifications.

7-2.10.1.3 Optical Network Terminal Coaxial Outlet/Connector.

ONTs equipped with RF video interfaces can provide broadcast television service or any RF frequency up to 1 GHz. The coaxial outlet/connector integrated within the ONT is a standard, male 75-ohm “F” type connector. The designer must coordinate with the cable service provider where franchise agreements are in place and additional head-end components such as an RF combiner, laser modulator, and erbium-doped fiber amplifier (EDFA) will be required for PoL distribution of RF services.

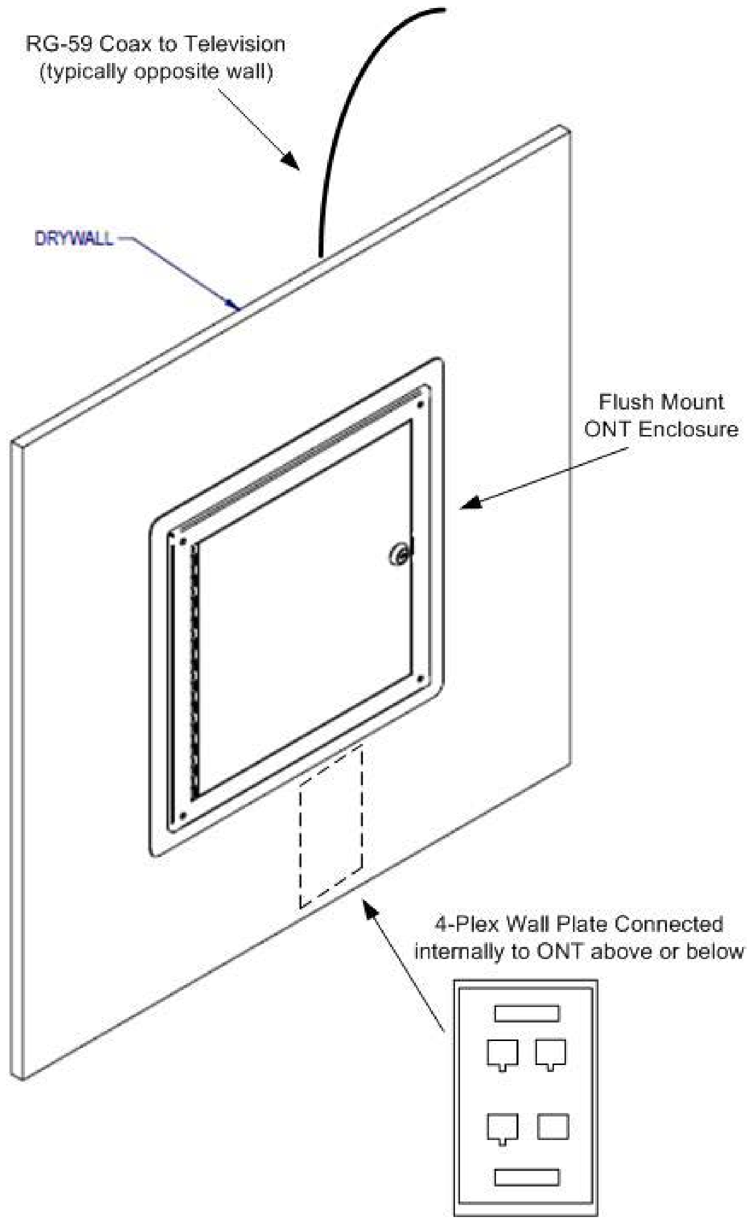
7-2.10.1.4 Optical Network Terminal Density (Port Sharing).

Consider end user requirements for the number of information outlets at a workstation when designing a POL system layout. While some IP endpoints (including printer locations, IP surveillance, access control entry points, and building automation systems) may require multiple ports for connectivity to various Ethernet devices or multiple networks, there are many instances where a workstation or IP endpoint need only connect to perhaps one or two network interfaces. In this scenario, it is acceptable to allow for port sharing between ONTs to increase the operational and financial savings associated with the POL deployment. In the port sharing deployment, adjacent cubicles or modular workstations can share the ports of a single ONT by distributing copper Ethernet patch cords between the cubicles. The quantity depends upon the number of required interfaces for each workstation and/or the forecasted growth of the end user's network requirements. In many cases, an IP telephone can be installed in tandem with a user's PC or workstation eliminating the need for a duplex Ethernet jack per user. This allows for as many as four users to share a single, four-port ONT, for example. Another scenario provides two jacks per workstation so that the ONTs are shared at a 2:1 ratio. Regardless of port sharing, the designer must provide a single work area outlet (WAO) at each workstation for future growth and flexibility.

7-2.10.2 Type 2 Outlet.

The Type 2 outlet mirrors the approach of a Type 1 deployment with the exception of the termination of the ONT at the end user workstation or IP endpoint. The Type II deployment will provide protection of the ONT from tampering, disruption of service, and environmental anomalies such as liquid spills, dust, or even vandalism. Enclosures are also recommended in medical facilities, conference rooms, or common areas to conceal cabling and ensure continuity of operation. All connectivity to the ONT (power, fiber port, Ethernet, analog voice, and RF video) may be contained within the enclosure and end user information outlets can either extend externally from the enclosure to a face plate apparatus, or exit the enclosure via pass-through devices. The location of the information outlets is dependent upon end user requirements and whether the enclosure is surface-mounted or flush-mounted. See Figure 7-2.

Figure 7-2 Flush-mounted ONT Enclosure



7-2.10.3 Type 3 Outlet.

Type 3 deployments allow for a hybrid approach to passive optical LATB infrastructures. Type 3 deployments are appropriate where TRs exist and are not planned to be re-purposed after installation of the PON. Type 3 deployments are also appropriate where a viable copper cabling infrastructure exists and is not in need of a technology refresh. Type 3 systems use high-density ONTs (typically 24 Ethernet ports) which are then patched to the horizontal copper cabling drops as does a legacy system using workgroup switches. Type 3 deployments allow for a migration strategy to fiber-to-the-desktop architectures and can readily accommodate technology refreshes where the legacy work group switches must be replaced.

The workstation outlet used in a Type 3 architecture consists of standard category rated copper cabling per Chapter 2 of this UFC. The WAOs in this architecture are commonly in place prior to the upgrade or replacement of the active electronics to POL. A new copper plant is recommended, but not required, to provide flexibility in the types of networks patched into the POL or for special sources.

Note: Refer to Chapter 2 of this UFC for additional outlet types and design standards for copper or optical-based interior telecommunication wiring.

7-2.11 Installations Communications Grid (ICG) or Backbone Cabling.

Provide a minimum telecommunications service to all new facilities consisting of one 25pr copper cable and one 24 strand, single mode (OS1) fiber optic cable through a minimum of two, 4-inch (100-millimeter) ducts. Provide additional cable count in accordance with maximum population and workspace requirements per facility type.

B-2 DEFINITION OF TERMS.

core node: On an installation (B/P/C/S), a core node (also referred to as a main communications node or area distribution node) is a physical location that typically hosts the commercial point of presence and serves as the aggregation point for the area distribution nodes.

intra-building backbone: Connectivity for the voice, video, and data networks between the entrance facility or equipment room, to a telecommunications room.

inter-building backbone: Connectivity between buildings, also referred to as part of outside plant (OSP).

ps: chromatic dispersion coefficient (Table 3-5)

UNIFIED FACILITIES CRITERIA (UFC)

FIRE PROTECTION ENGINEERING FOR FACILITIES

UNIFIED FACILITIES CRITERIA (UFC)

FIRE PROTECTION ENGINEERING FOR FACILITIES

U.S. ARMY CORPS OF ENGINEERS

NAVAL FACILITIES ENGINEERING SYSTEMS COMMAND (Preparing Activity)

AIR FORCE CIVIL ENGINEER CENTER

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	28 Nov 2016	Change to definition of '*AHJ*' (paragraph 2-1.3) required modifications to paragraphs 1-7.2.2, 1-9, 9-16.1, and 9-18.5.1. Change to paragraph 9-13.1.3 was a technical change.
2	25 Mar 2018	Clarification to definitions *Fire Water Demand* (2-1.11) and *Multi-Family Housing* (2-1.26), in addition to many clarifications of requirements. Paragraphs added for Hydroelectric Generating Plants(4-20) and Navigation Locks" (4-31). Change in requirements for Liquid Oxygen (4.3-33). Army eliminated the requirement for two water storage tanks. DLA requires redundant fire pump for large risk facilities. Dry pipe systems require nitrogen.
3	10 May 2019	Added Paragraph 1-2.1.3.1 referring to new Appendix G Change Paragraph 4-14.1 to apply to all family housing. Added Paragraph 4-46 for wildland-urban interface. Moved Paragraph 9-2.2.2 to where it should have been located.

		Clarified Paragraph 9-5.3.2 to follow NFPA 20 for run time. Changed Paragraph 9-6.3.5 friction loss requirements. Added Paragraph 9-19.2.3, CO detection for large spaces. Added Appendix G, requirements for Host Nation projects in Japan. Some changes made to clarify requirements.
4	3 Feb 2020	Added/changed requirements (9-9.3 and 9-17) to comply with 2020 NDAA. Added 4-38.2 to allow FEMA approved Tank and Pump Systems. Other changes added clarity.
5	24 Sep 2020	Added section 4-2, Additive Manufacturing to address 3-D printing. Added section 4-39, Privacy Pods or Privacy Enclosures Included Lake Projects to section 4-32, Navigation Locks. Added a requirement in section 4-32 to protect hydraulic reservoir and pumping equipment. Added section 10-5, Communicating Space to provide clarity to the code allowances. Made changes to Chapter 34 to simplify requirements. Other changes were made to provide coordination, clarification, or correct formatting.
6	6 May 2021	Added the following sections: 4-7, Animal Housing Facilities; 4-8, Battery Energy Storage Systems – Lithium; and, Section 10-7 Accessible Means of Egress Updated section 4-6, Anechoic Chambers, Updated and renamed the Ordnance section (4-33) to Ammunition and Explosives (4-5) Update section 9-3.6, Pressure Regulating Valves Changed “Authority Having Jurisdiction” to “Component Fire Protection Engineer”

This UFC supersedes UFC 3-600-01, dated 26 September 2006, Change 3 and all preceding changes.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force \2\ Civil Engineer Center (AFCEC) /2/ are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)

REVISION SUMMARY SHEET

Document: UFC 3-600-01, *Fire Protection Engineering for Facilities*

Superseding: This UFC supersedes UFC 3-600-01, dated 26 September 2006, Change 3 and all preceding changes.

Description of Changes: This update to UFC 3-600-01 clarifies many of the requirements in the 26 September 2006, Change 3, 1 March 2013 version, as well as updates references, and further coordinates the Services' requirements. This update also coordinated requirements with consensus standards and reorganized the document to match the organization of the IBC to make it easier to use for the Architectural-Engineering Firms. New criteria for the following were added:

- Planning Section
- Definitions
- Facilities Housing Unmanned Aerial Vehicles (UAV) or Remotely Piloted Aircraft (RPA)
- Military Operations on Urban Terrain (MOUT) Trainers
- Sensitive Compartmented Information Facility (SCIF)

Reasons for Changes:

- Planning Section is to help scope projects properly and assist in ensuring the proper funding is requested
- Definitions are to help clarify requirements
- Requirements were added for UAVs to ensure the UAVs and the facility are properly protected
- Information was added for MOUTs to ensure they have the proper protection and are not provided with unnecessary requirements.
- Requirements were added for SCIFs to ensure coordination with the security requirements.

Unification Issues:

Some criteria are Service specific as it will reference a Service UFC, FC, Instruction, or Manual.

Navy Unification Issues:

- Paragraph 7-2 – The spacing allowed by the IBC for the identification of the rated wall is too large and will not be easily seen by trade personnel performing work.

Air Force Unification Issues:

- Paragraph 9-5.4.3 – This paragraph is an option allowed by code. This choice only adds a single engine driven generator and associated maintenance burden, rather than add multiple engine driven drivers and the associated maintenance burden.
- Paragraph 34-10.1.1 – There are many existing Air Force Lodging and Billeting Facilities without sprinkler protection. Requirements are different and exceed those found in minimum criteria, including NFPA 101. The requirements are unique to the Air Force and this section is needed to prevent change to Air Force facilities simply because it is different.

Army Unification Issues:

- Paragraph 4-3.4.8 – Provides additional requirements for facilities that support UAV or UAS.\4\
- /4/Paragraphs 9-6.3.2 and 9-18.2 – Requires fire protection shop drawings prepared under the immediate supervision of and sealed by a professional engineer, who must certify in writing that the system was installed as designed.

TABLES

CHAPTER 1 INTRODUCTION

1-1 SCOPE AND ADMINISTRATION.

This UFC establishes fire protection engineering policy and criteria for Department of Defense Components (*DoD Components)*. These criteria are based on commercial requirements set forth by national insurance underwriters and may exceed minimum national code requirements. The requirements in this UFC reflect the need for the protection of life, mission continuity, and property (building or contents) while taking into account the costs of implementing the criterion and risks associated with the *Facility*. These criteria have been established in the best interest of DoD.

1-2 APPLICABILITY.

1-2.1 General.

1-2.1.1 The provisions of this UFC are applicable to all new and existing DoD *Facilities* located on or outside of DoD *Installation*s, within the United States and its territories and possessions or outside the United States and its territories and possessions, whether owned or leased, by appropriated or non-appropriated funds, or third party financed and constructed.

1-2.1.2 The provisions of this UFC are applicable to all types of *Facilities* and their contents, structures, whether considered permanent, semi-permanent or temporary construction, mobile and stationary equipment, civil works or military facilities, hydroelectric plants, waterfront facilities, outside storage, and shore protection for ships and aircraft. \5\As required by DoDI 4165.56, these provisions are applicable to any structure that is used to provide the same capabilities as real property acquired facilities and structures./5/

1-2.1.3 Projects outside the United States and its territories and possessions must comply with provisions of this UFC and the host nation fire protection requirements. For conflicts between this UFC and the host nation fire protection requirements, the \6\ *DFPE* /6/ must be consulted.

1-2.1.3.1 \3\For projects in Japan, see specific mandatory requirements in Appendix G: "Criteria for Projects in Japan"./3/

1-2.2 Acronyms, Abbreviations, Defined Terms, and Referenced Criteria.

Acronyms and abbreviations used within this UFC are defined in Appendix F. The full name of referenced criteria, codes or standards can be found in Appendix A. Terms defined in Chapter 2 are italicized in this UFC.

1-2.3 Fire Department Operations.

Matters relating to fire department operations, staffing and firefighting equipment are outside the scope of this UFC.

1-3 PURPOSE.

This UFC must be used as the minimum standard for the planning and development of projects and, design, construction and commissioning documentation used for the procurement of Facilities. Examples include, but are not limited to, the development of scopes of work, DD1391 documentation, drawings, specification and request for proposals. It is the primary fire protection criteria reference document for services provided by architectural and engineering (A&E) firms and consultants in the development of both design-bid-build and design-build contracts. It is not intended to be used in lieu of detailed design documents in the procurement of *Facility* construction.

1-4 CRITERIA.

1-4.1 Federal Laws.

This UFC complies with all applicable Federal laws, including but not limited to:

UNITED STATES CODE http://uscode.house.gov/.

a. USC Title 10, Chapter 8, Subchapter II, Military Child Care.

b. USC Title 15, Section 272 Utilization of Consensus Technical Standards by Federal Agencies.

c. USC Title 15, Section 2225 Hotel-Motel Fire Safety.

d. USC Title 15, Section 2227 Fire Administration Authorization Act (also referred to as the Fire Safety Act).

e. USC Title 42, Section 4151 Architectural Barriers Act of 1968.

1-4.2 DoD Criteria.

1-4.2.1 UFC 3-600-01 supplements the requirements listed in UFC 1-200-01. UFC 3-600-01 supersedes NFPA and other industry standards, except where not specifically addressed by this UFC.

1-4.2.2 Features in excess of the requirements in this UFC must be approved by the \6\ *Component Fire Protection Engineer (CFPE)* /6/.

1-4.2.3 Where the IBC references the International Fire Code (IFC), the IFC must be replaced with NFPA 1, except where superseded by this UFC.

1-4.2.4 For leased *Facilities*, the criteria in this UFC must apply, unless it is determined by the *DFPE* it is not in the best interest of DoD. For conflicts between this UFC and the local municipal jurisdiction, the *DFPE* must be consulted.

1-4.2.5 \6\ /6/ *DoD Component*s issue specific technical guidance that expands the requirements of this UFC. For example, \6\ the Army issues engineering construction bulletins (ECB); the Navy issues interim technical guidance (ITG); and the Air Force issues guidance memorandums (AFGM) /6/.

a. For Army, Air Force, and Navy, see http://dod.wbdg.org/.

b. For Washington Headquarters Service (WHS), see WHS Building Code, http://www.wbdg.org/ccb

1-4.2.6 Where criteria are not included in this UFC, fire protection criteria must conform to the requirements of the latest editions of the National Fire Codes. Where criteria are not available from the National Fire Codes, a fire protection design analysis must be submitted to the *DFPE* for approval.

1-4.3 Standards, Codes and Guides.

Fire protection criteria must conform to the requirements of standards, codes and guides as modified or referenced in this UFC. The primary references include, but are not limited to, the most recent editions of the following:

a. National Fire Codes, published by the National Fire Protection Association (NFPA).

b. FM Global (http://www.fmglobal.com/) Property Loss Prevention Data Sheets, as referenced by this UFC.

Note: NFPA 5000, state or local building or fire codes must not be used.

1-4.4 Antiterrorism and Security Standards.

Antiterrorism and security requirements noted in UFC 4-010-01, UFC 4-020-01 and other 4 series UFCs must not preclude any fire protection requirements. This UFC will be in coordination with the ATFP sections as noted in the other 4 series UFCs.

1-5 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, general building requirements. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-6 REFERENCES AND DATES OF PUBLICATION.

1-6.1 General.

Appendix A contains a list of references used in this document. The publication date of codes or standards are not included in this document. Unless modified by UFC 1-200-01, this document or the applicable contract, the latest available issuance of a reference must be used.

1-6.2 Project Delays.

For projects that have a delay, as defined in UFC 1-200-01, the *DFPE* has the responsibility to determine if design revisions are required based on an analysis performed by the *Qualified Fire Protection Engineer (QFPE)*.

1-7 FIRE PROTECTION ENGINEERING SERVICES.

1-7.1 General.

1-7.1.1 *Major Projects* require the design, review and oversight services of a *QFPE*. A *QFPE* must be involved in every aspect of the design, construction and testing/commissioning as it relates to fire protection and life safety. This includes, but is not limited to, building code analysis, life safety code analysis, design of automatic fire alarm, detection and suppression systems, water supply analysis, a multi-discipline review of the entire project, construction inspections and witnessing of fire protection acceptance testing/commissioning.

Note: Utilization of multiple *QFPEs* on the same project is permitted, but not preferred.

1-7.1.2 This requirement is applicable to engineering services for design-bid-build projects as well as all phases of design-build projects including RFP development, design development, and construction.

1-7.1.3 For the purpose of this UFC, the *QFPE* must submit, upon request, a written copy of their resume indicating education, professional registration and work experience, along with a letter attesting to their compliance with the requirements of this Section. The letter must include an imprint of their professional engineering stamp with signature.

1-7.2 Fire Protection Design Analysis and Life Safety Plans.

1-7.2.1 A fire protection design analysis and life safety plans must be provided for all *Major Projects* and must address the fire protection requirements of the project as required by this UFC. The fire protection design analysis and life safety plans must be submitted with the initial design submission, separate from other disciplines. The final design analysis and life safety plans must be signed and sealed by the *QFPE.*

Note: When directed by the *DFPE*, projects with little or no fire protection considerations may not require a fire protection design analysis or life safety plans.

1-7.2.2 Fire Protection Design Analysis.

Where applicable, discuss the following minimum fire protection provisions (include required vs. provided):

a. Identification of all fire protection and life safety related codes and standards applicable to the project, including the edition. This includes Host Nation requirements.

b. Building code analysis (e.g., type of construction, height and area limitations, building separation, exposure protection, etc.).

c. Classification of occupancy (both IBC and NFPA 101).

d. Requirements for fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions, compartmentation and special hazard protection (both horizontal and vertical). Include the associated fire resistance rating.

e. Requirements for protection of horizontal and vertical penetrations and openings as well as the associated fire resistance rating.

f. Separation from hazards per NFPA 101.

g. Interior finish ratings.

h. Means of egress provisions and components (occupant load, exit capacity, exit width, travel distance, common path of travel, dead-end corridors, use of suites, etc.).

i. Water supplies, water distribution, location of fire hydrants, Fire Flow calculations.

j. Location of fire department connections (FDCs).

k. Location of post indicator valves (PIVs) and other control or isolation valves.

l. Analysis of automatic sprinkler and suppression systems and protected areas. Include supporting calculations used to establish system performance requirements such as hydraulic analysis of water demand or agent concentration and quantity.

m. Standpipe systems.

n. Portable fire extinguishers.

o. Fire detection (the type of detection and type/location of detectors).

p. Fire alarm system (the type of alarm system, location of the fire alarm equipment and mass notification).

q. Smoke management or control methods.

r. Connection to and description of base Fire Alarm Reporting System.

s. Coordination with security and antiterrorism requirements, including connection to Installation-wide Mass Notification System.

t. Fire department access.

u. \6\ *CFPE* /6/ approved equivalencies \1\/1/ (see the paragraph entitled "Equivalencies" below).

v. For projects not within the United States or its territories, identify code/criteria conflicts and \6\ *CFPE* /6/ approved design solutions\1\ or/1/ equivalencies \1\/1/to DoD or Host Nation criteria necessary to resolve. The analysis must also identify the associated impact on project cost.

w. Initial, or draft, integrated performance verification and testing plan(s) where multiple systems across multiple trades rely on an integrated operation to perform the desired result.

1-7.2.3 Life Safety.

Where applicable, the following minimum fire protection provisions must be included on the life safety plans:

a. All minimum fire protection provisions listed above, on a separate code summary sheet.

b. Capacity and number of occupants using each major means of egress component (e.g., stairs, stair doors, exterior doors, assembly exit doors).

c. Maximum travel distance, dead-end corridor, common path of travel, accessible means of egress and exit components for each floor and occupancy classification. When suites are used, indicate type, location, area and arrangement.

d. IBC and NFPA occupancy classification of each room, area or compartment (on the drawings or in tabular form). Include occupant load of each room, area or compartment. Similar occupancies can be grouped together for occupant load calculations.

e. Location and rating of all fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions (both horizontal and vertical). Barriers requiring fire resistance rated supporting construction must be specifically identified for coordination with the structural design.

f. Location of hazardous materials storage, handling and use that exceed the maximum allowable quantities.

g. Structural fireproofing locations and associated ratings.

1-7.2.4 Code Compliance Plans.

1-7.2.4.1 Code Compliance Summary Sheet.

Provide the building code and life safety code analyses included in the \4\ fire protection design analysis/4/. Specifically call out any approved criteria exemptions. For projects outside the United States and its territories and possessions, identify code/criteria conflicts and proposed design solutions to resolve.

1-7.2.4.2 Code Compliance Site Plan.

Where applicable, the following minimum fire protection provisions must be included on the Code Compliance Site Plan:

a. Line of encroachment identifying assumed property lines and minimum separation distances from adjacent buildings.

b. Building perimeter used for frontage increases.

c. Fire department access.

d. Fire lane width, marking and locations, approach roads and turn radius and location.

e. Type and quantity of antiterrorism secure access.

f. Intended fire department main entrance to facility.

g. Location of fire department connections.

h. Fire hydrants, post indicator valve or valves and their connected water distribution mains serving facility.

i. Fire pump room.

j. Water storage tanks.

k. Hazardous material spill containment\6\ /6/.

l. Backflow prevention assembly or assemblies serving water-based fire protection systems (if located outside of building).

1-7.2.5 Preliminary Hydraulic Analysis.

1-7.2.5.1 Prepare a preliminary hydraulic analysis to demonstrate that the anticipated water demand(s), including those for fire, domestic, and industrial needs, will be satisfied by the available water supply. This analysis must include an estimate for the minimum required capacity of water, along with minimum volumetric waterflow rate and water pressure, with all assumptions clearly defined and referenced and must demonstrate that the available water supply is capable of meeting the required water demands in any project. Include a graphical analysis of the relationship between the *Fire Water Demand* and the available water supply.

1-7.2.5.2 For design-build projects, prepare the preliminary hydraulic analysis prior to advertisement of the request for proposal.

1-7.3 Final Design Submission.

The *QFPE* must review the complete 100 percent design drawings and specification submission (all disciplines) and document in writing that the design is in compliance with this UFC and all applicable fire protection and life safety design criteria. The review must provide verification that all items listed in the design analysis are correctly shown on the drawings and in the specification and list any approved equivalencies or deviations from this UFC. This design compliance document must be submitted with the final design submission as part of the design analysis and must bear the signature and professional seal of the *QFPE*.

1-7.4 Host Nation.

For projects outside the United States and its territories and possessions, a Host Nation Code Compliance certification must be performed by a Host Nation fire protection consultant. For each item of conflict or nonconformance with the Host Nation codes, the certification must include the following:

a. Item of conflict.

b. Translation of Host Nation requirement to the English language.

c. Recommended resolution.

d. Additional costs, both engineering effort to prepare the design modification and estimated construction costs.

1-8 EQUIVALENCIES.

Alternative design approaches proposed as equivalencies to established criteria must be approved by the \6\ *CFPE* /6/. Requests for approval must include written justification for the deviation from established criteria and demonstrate how the proposed alternative solution provides an equivalent level of fire protection and life safety. Requests must also include hazard analysis, compensatory features, comparative cost analyses (first cost and life cycle cost), criteria used, and other pertinent data. Lack of funds is not considered sufficient justification for an equivalency to established criteria. Approved equivalencies and alternatives apply only to the specific *Facility* or project involved, and do not constitute blanket approval for similar cases.

1-9 EXEMPTIONS.

Exemptions to established criteria must be submitted to the \1\Service Signature Authority/1/ for determination. The *exemption* must demonstrate that the criteria cannot be technically executed, or execution of the criteria will increase a hazard or create a new hazard and no technical alternatives exist. Written request for exemptions must include justification, hazard analysis, cost comparison, alternatives considered, and other pertinent data. Lack of funds or cost savings are not considered sufficient justification for deviation from established criteria. *Exemptions* will only apply to the specific *Facility* or project involved and do not constitute blanket approval for similar cases. *Exemptions* must follow the process outlined in MIL-STD-3007.

1-10 PERFORMANCE-BASED FIRE SAFETY DESIGN.

1-10.1 General.

1-10.1.1 The use of performance-based fire safety design methods may only be permitted upon authorization by the \6\ *CFPE* /6/.

1-10.1.2 Performance-based fire safety design must comply with the procedures, provisions and applicable requirements of Appendix C.

Note: Appendix C is in accordance with the performance-based option of NFPA 101 and the performance-based fire safety design approach of the Society of Fire Protection Engineers (SFPE), Introduction to Performance-Base Fire Safety.

1-10.1.3 A *QFPE* must perform the performance-based fire safety design.

1-10.2 Application.

1-10.2.1 Performance-based fire safety design methods may not be used to eliminate required exiting requirements of NFPA 101, nor may it be used to eliminate automatic sprinkler systems required by DoD criteria.

1-10.2.2 The use of performance-based fire safety design will only be considered for the following:

1-10.2.2.1 Existing facilities where it is not feasible to meet prescriptive requirements of this UFC.

1-10.2.2.2 New facilities for which established prescriptive criteria does not exist.

1-11 FIRE PROTECTION DURING CONSTRUCTION.

Contract specifications must reference the USACE Engineering Manual (EM), EM-385-1-1 and NFPA 241 and must contain the requirement that the *Installation's* fire regulations be followed.

1-12 PLANNING\2\ (CONTRACT DOCUMENT DEVELOPMENT)/2/.

1-12.1 General.

1-12.1.1 The criteria in this UFC must be used in project planning or the development of projects \2\and contract documents/2/. The information in this section must be reviewed during the planning phase to verify that adequate *Installation* infrastructure exists.

1-12.1.1.1 It is DoD's responsibility to determine whether or not the *Installation* infrastructure is adequate to support the project.

Note: Examples of infrastructure include water supply and fire department access.

1-12.1.2 The requirement for a *QFPE* must be included in the statement of work for design services as well as design/build services.

1-12.2 *Installation* Water Supply.

1-12.2.1 The quantity of water required is equal to the greater of the largest *Fire Water Demand* or *Fire Flow* for the required duration. This quantity represents fire water supply requirements only, that must be available at all times. Water supply for domestic, industrial, and other demands must be added to these requirements to determine the total amount of water required at an *Installation*.

1-12.2.2 The water supply analysis must include an analysis of the domestic water quantity using diurnal curves if time of day water curves are not available The analysis must include historical data to address seasonal water supply fluctuations, peak water demand and average daily demand and its effect on fire suppression water availability.

1-12.3 *Installation* Water Distribution.

Note: The requirements of this section apply to the *Installation*, as defined in Chapter 2, not the individual *Facility*.

1-12.3.1 Except as modified below, water distribution mains, service mains and service laterals must be designed in accordance with AWWA M31, NFPA 24 and UFC 3-230-01.

1-12.3.2 \2\For *service laterals* \6\ /6/, the velocity must not exceed 10 feet per second (3 m/s).

1-12.3.3 /2/One or more of the following reliable means must provide fire protection water to an *Installation*:

1-12.3.3.1 Multiple connections to looped or gridded public *Service Main*(s) arranged so that during any single-point failure, at least 50 percent of the maximum required *Fire Flow* plus 100 percent of domestic demand can still be supplied to the *Installation*.

1-12.3.3.2 A single connection to a public *Service Main(s)*, plus on-site storage sized in accordance with UFC 3-230-01, in the event the connection to the public system is lost.

1-12.3.3.3 One or more on-site sources, such as wells or open bodies of water, with treated water storage capacity sized in accordance with UFC 3-230-01.

1-12.3.4 For a small *Installation*, such as a Reserve Training Center, a single connection to a looped or gridded public water *Service Main*, capable of providing concurrent domestic demand and *Fire Flow* to the *Installation*, is acceptable.

1-12.3.5 For service mains served by fire pumps or service laterals serving fire pumps, velocities must be calculated using 150 percent of the rated capacity of the fire pump.

1-12.4 *Installation* On-Site \2\Water/2/ Storage.

\2\/2/

1-12.4.1 Water level must be remotely monitored in accordance with NFPA 22 and NFPA 72 at a constantly attended location, preferably at the *Installation*'s remote supervising station.

1-12.4.2 In geographic locations having a 99.6% dry bulb temperature less than 32°F (0°C) per UFC 3-400-02 Engineering Weather Data, water temperature of aboveground storage tanks must likewise be monitored at a constantly attended location.

1-12.4.3 Provide an external visual water-level gauge on each non-elevated or below ground tank.

1-12.5 Waterflow Testing.

1-12.5.1 Conduct waterflow tests, in accordance with the procedures contained in NFPA 291, to determine available water supply for the water-based fire extinguishing systems. The flow test must be performed under the direction of the *DFPE*. Advertisement of the project must not occur without obtaining water supply information.

1-12.6 *Fire Flow.*

1-12.6.1 *Fire Flow* for any proposed *Facility* must be calculated to determine if upgrades to the *Installation* water supply is required. *Fire Flow* must be calculated in accordance with Chapter 9.

1-12.6.1.1 Where the *Fire Flow* cannot be met, the *DFPE* is permitted to approve a reduction in *Fire Flow*.

1-12.6.2 When the required *Fire Flow* cannot be provided by the existing infrastructure, a cost and benefit analysis must be conducted by the *DFPE*, or their representative, to determine if additional fire protection systems, features, or design changes that provide more favorable factors, such as type of construction or sprinkler protection, are more cost effective than providing the required *Fire Flow*.

1-12.7 Fire Pumps.

1-12.7.1 The *DFPE* must determine the need for a fire pump in the planning stages of a project in order to ensure adequate space is available at the *Facility*.

1-12.7.2 The *DFPE* must determine if a *Reliable Power Source* is available to the *Installation* or *Facility* in the planning stages of the project in order to ensure that the cost and space associated with secondary power is considered and included in the project.

1-12.7.3 \2\Where a fire pump is needed, a single pump is satisfactory for ordinary value and ordinary use structures. For structures with critical missions or very high values, the \6\ *CFPE* /6/ may require redundancy in fire pump capacity such, as two pumps at 100% capacity or three pumps at 50% capacity. /2/

1-12.8 Automatic Sprinkler Systems.

1-12.8.1 \2\For facilities that do not require sprinkler protection as required in the "Special Detailed Requirements Based On Use" or "Fire Protection Systems" chapters of this UFC,/2/ the *DFPE* must determine if an automatic sprinkler or other fire suppression system is required for the *Facility* based on mission, hazard of contents, value of contents or other criteria. This determination must be included in the contract documents for design services or design-build services.

1-12.8.2 Prior to the installation of backflow preventers in an existing fire suppression system, a thorough hydraulic analysis, including hydraulic calculations and flow test, must be performed to ensure that the water supply is still adequate for the system with the backflow preventer. If the backflow preventer causes the demand to exceed the water supply, the backflow preventer must not be installed until the water supply is corrected to support the new demand.

1-12.9 Clean Agent Fire Extinguishing Systems.

The DFPE must determine if a connected reserve supply should be provided.

Note: A reserve supply should only be considered if replacement cannot be delivered to the site within 24 hours. This would typically apply to locations outside the United States and its territories and possessions.

1-12.10 Rural, Remote, \3\and Range/3/ Locations.

Fire protection water supplies supporting rural, remote, \3\or range/3/ *Facility* locations without water distribution systems must be in accordance with NFPA 1141 and NFPA 1142.

1-12.11 Military Operations on Urban Terrain (MOUT) Trainers.

1-12.11.1 See the paragraph entitled "MOUT" in the “Special Detailed Requirements Based on Use” Chapter in this UFC.

1-12.12 Warehouses and Storage *Facilities.*

1-12.12.1 The DFPE must determine if sprinkler protection must be provided for *facilities* less than 5,000 ft^2 containing materials, equipment and supplies that are critical to operations, pose a severe fire hazard, are of high monetary value, pose a safety or environmental health risk, or expose an important structure.

1-12.12.2 The DFPE must determine the commodity classification and maximum storage height and include this information in the contract documents when this information differs from the minimum noted in the section on "Warehouse and Storage *Facilities*" in this UFC.

1-12.12.3 \2\Information such as the storage configuration (racks, shelves, palletized, bin box, and solid-piled), aisle width, clearance to ceiling, and ceiling sprinkler temperature rating must be evaluated prior to developing contract documents in order to provide the proper sprinkler protection./2/

1-12.12.4 See the section on "Warehouse and Storage *Facilities*" in this UFC for additional requirements.

1-12.13 Existing *Facilities*.

1-12.13.1 When planning any \5\ work /5/ to existing facilities, determine if the facility has any existing or outstanding fire protection or life safety deficiencies and include them into the work being planned.

1-12.13.2 If work is being phased, the total floor area of all the phased work must be used to determine if the facility needs to be brought into compliance with new criteria in lieu of just the work being performed. See the section for "Phased Projects" in this UFC.

1-12.13.3 See the "Existing Facilities" Chapter in this UFC for additional requirements.

1-13 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with DoD Instruction 8500.01, DoD Instruction 8510.01, and as required by individual Service Implementation Policy.

CHAPTER 2 DEFINITIONS

2-1 GENERAL.

The definitions contained in this chapter apply to the terms used in this UFC. Where terms are not defined in this chapter or within another chapter, they are defined in the referenced UFC, code or standard applicable to the context in which they are used. Plural terms must have the same definition as singular terms.

2-1.1 Addition.

An increase in the building area, aggregate floor area, building height, or number of stories of a structure. [NFPA 101]

2-1.2 \6\ Ammunition and Explosives.

Includes, but is not limited to, all items of U.S.-titled (i.e., owned by the U.S. Government through the DoD Components) ammunition; primers, propellants, liquid and solid; pyrotechnics; high explosives; guided missiles; warheads; devices; and chemical agent substances, devices, and components presenting real or potential hazards to life, property, and the environment. Excluded are wholly inert items and nuclear warheads and devices, except for considerations of storage and stowage compatibility, blast, fire, and nonnuclear fragment hazards associated with the explosives. [DESR 6055.09] /6/

2-1.3 /1/Bin Storage.

Bin storage consists of five-sided, open from top or side storage containers, stacked in rack structures. They are commonly used in automatic storage and retrieval systems.

Note: Bin storage requires unique considerations for fire protection. Bin storage configurations do not limit oxygen supply. Horizontal flame spread can be rapid. The narrower the aisles and the higher the storage, the less ceiling sprinkler water penetration is delivered to control the fire.

2-1.4 \5\/5/ \6\ Component Fire Protection Engineer (CFPE).

The term "*CFPE*" as used in this UFC means the Fire Protection Engineer assigned to the Military Department or Defense Agency office of responsibility listed below. Where the codes and standards referenced in this UFC refer to an individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure will be interpreted to mean the *CFPE*. The exercise of *CFPE* is contingent upon maintaining the qualifications required of the Fire Protection Engineer. For the Defense Departments or Defense Agencies not listed, and where a listed Defense Component is unable to maintain the qualifications of the Fire Protection Engineer, *CFPE* falls to the Military Service with jurisdiction of the *Installation* on which the facility is located. /6/

\6\ *CFPE* /6/ offices are as follows/1/:

a. U.S. Army - HQ USACE/CECW-CE.

b. U.S. Navy - NAVFACENGSYSCOM HQ, \6\ Chief Fire Protection Engineer /6/.

c. U.S. Marine Corps - HQMC Code LF.

d. U.S. Air Force - AFCEC/CO.

e. \1\Defense Logistics Agency (DLA), DS-IE./1/

f. National Geospatial-Intelligence Agency (NGA) - Security and Installations.

g. National Reconnaissance Office (NRO) - MS&O/ESO.

h. Washington Headquarters Services (WHS) - Office of the Pentagon Fire Marshal.

i. National Security Agency/Central Security Service - Office of Occupational Health, Environmental and Safety Services (NSA/CSS OHESS).\1\

2-1.5 Distribution Main.

Any pipe in a water distribution system other than a *Service Main* or *Service Lateral*. A distribution main carries water from the original source (i.e. tank or underground water source) to the *Service Main*. A distribution main can be connected to the source, *Service Main* or another distribution main. A distribution main cannot connect to a *Service Lateral*.

2-1.6 DoD Component.

The specific DoD branch or subunit of a branch or service. For the purpose of this UFC, this includes, but is not limited to, Army, Navy, Marines, Air Force, NRO, WHS, NGA and NSA.

2-1.7 Dwelling Unit.

One or more rooms arranged for complete, independent housekeeping purposes, with space for eating, living, and sleeping; facilities for cooking; and provisions for sanitation. [NFPA 101]

2-1.8 Electronic Equipment Area.

Areas of a *Facility* that include, but are not limited to data centers, communication centers, and command and control systems. Electronic equipment areas are also areas containing telecommunication equipment that serves more than one *Facility*, a portion of an *Installation* or the entire *Installation*. This section does not apply to the room in a *Facility* that contains the incoming telecommunications service for that specific *Facility* or *Incidental Electronic Equipment* rooms.

2-1.9 Exemption.

The authority to deviate from a UFC requirement indefinitely. See MIL-STD-3007.

2-1.10 \6\ Exposed Explosives.

Explosives that are open to the atmosphere (such as unpackaged bulk explosives, or disassembled or open components) and that are susceptible to initiation directly by static or mechanical spark, or create (or accidentally create) explosive dust, or give off vapors, fumes, or gases in explosives concentrations. This also includes exudation and explosives exposed from damaged munitions such as gun powder or rocket motors. [DESR 6055.09_and AFMAN91-201] /6/

2-1.11 Facility.

This includes all types of buildings and their contents, structures, mobile and stationary equipment, civil works or military buildings, hydroelectric plants, waterfront structures, outside storage, and shore protection for ships and aircraft. A facility can be either of temporary or permanent construction.

2-1.12 Fire Alarm Reporting System.

Fire alarm reporting systems are the *Installation*-wide reporting systems that connect the *Facility* fire alarm control panel(s) to a constantly attended location staffed with qualified operators for the receipt and processing of emergency communications. Consider compatibility of extensions of fire reporting systems with existing equipment.

2-1.13 Fire Area.

The aggregate floor area enclosed and bounded by fire walls, fire barriers, exterior walls or horizontal assemblies of a *Facility*. Areas of the *Facility* not provided with surrounding walls must be included in the *Fire Area* if such areas are included within the horizontal projection of the roof or floor above. [IBC]

2-1.14 Fire Flow.

The flow rate of a water supply, measured at 20 psi (138 kPa) residual pressure that is available for firefighting. [NFPA 1]

2-1.15 Fire Water Demand.

The fire water demand is the water flow required for the fire suppression system plus \2\interior/exterior hose stream demands./2/

2-1.16 Fire Protection Engineer.

2-1.16.1 Designated (or Service) Fire Protection Engineer (DFPE).

The DoD fire protection engineer that oversees that Area of Responsibility for that project. This is sometimes referred to as the "cognizant" fire protection engineer.

Note 1: For USACE, this is usually the District or Center FPE.

Note 2: For NAVFAC, this is usually the Facilities Engineering Command (FEC) FPE.

2-1.16.2 Qualified Fire Protection Engineer (QFPE).

\2\An individual who is a registered professional engineer (P.E.) who has passed the fire protection engineering \6\ /6/ examination administered by the National Council of Examiners for Engineering and Surveying (NCEES) and has relevant fire protection engineering experience./2/

[C] 2-1.16.2

The QFPE can act as the designer of record and/or quality control representative for fire protection matters.

2-1.17 Incidental Electronic Equipment.

Word processing stations, printers, and systems; desk top computers; office automation systems; individual data output stations (i.e. printers, etc.); individual computer work stations; telephones; communication equipment; video conference centers; administrative telephone rooms; reproduction equipment; and similar equipment. Incidental Electronic Equipment includes building only or building-wide communication/telephone/LAN equipment typically found in communication, data or telephone rooms that do not serve an essential mission or purpose for National Defense. This includes the room in a *Facility* that contains the incoming telecommunications service for that specific *Facility*.

2-1.18 \5\/5/Installation.

As used in this document, the Installation is the DoD base, post, camp, fort, station, airfield or other similar complex that shelters military equipment or personnel or facilitates training and operation. An Installation includes one or more DoD *Facilities*.

2-1.19 Life Safety System.

Those systems that enhance or facilitate evacuation, smoke control, compartmentalization or isolation. [NFPA Glossary of Terms]

2-1.20 Major Project.

A project that includes any one of the following:

a. \5\ Adding /5/ to an existing *Facility*.

b. \5\Work to a facility that consists /5/ of 50 percent or more of the total floor area of an existing *Facility*.

c. Design or construction of a new *Facility*.

d. New installation or \5\ work to /5/ an area of construction greater than 5,000 ft^2 of floor area that involves existing or new fire barriers or fire-rated construction; *Life Safety Systems*; \6\ modifying, moving, adding 20 or more sprinklers; /6/ fire alarm or detection systems; fire suppression systems.

e. New installation or \5\ work to an /5/ existing HVAC systems that removes or installs the duct work passing through fire-rated or smoke partitions/barriers or interconnected plenum areas serving an area greater than 5,000 ft^2 of floor area.

2-1.21 Mass Notification System.

Refer to UFC 4-021-01.

2-1.22 \2\/2/Medical Facilities.

Also referenced as Medical Treatment Facilities (MTFs), includes medical and dental treatment facilities, medical training facilities, medical research facilities, and veterinary facilities in the Military Health System (MHS)

2-1.23 Missile Alert Facilities (MAF).

The aboveground *Facilities* that support underground ballistic missile launch control centers.

2-1.24 Missile Assemblies.

Missile assemblies are considered to be large rocket type, cruise missiles without their ordnance, intercontinental ballistic missiles, or Poseidon missiles.

2-1.25 \5\/5/Multi-Family Housing.

More than two *Dwelling Unit*s under one roof intended for occupancy by spouses or dependents of DoD personnel. \2*Multi-Family Housing* does not include multiple single-family dwellings, i.e., townhouses./2/

2-1.26 Noncombustible Material.

A material that, in the form in which it is used and under the conditions anticipated will not ignite, burn, support combustion, or release flammable vapors, when subjected to fire or heat. Materials that are reported as passing ASTM E136 must be considered noncombustible materials. [NFPA 102]

2-1.27 Ordnance Facility.

A *Facility* or area used for the manufacturing, storage, maintenance or demilitarization of ordnance including, but not limited to, munitions, weapons, missile assemblies.

2-1.28 \5\/5/Reliable Power Source.

2-1.28.1 For a *Facility* located on an *Installation*, reliability is determined at the power source serving the *Installation*. For a *Facility* not located on an *Installation*, reliability is determined at the power source to the *Facility*.

Note: For example, if the building in question is located on a Navy Base, Army Post or similar, reliability is determined by when power is lost to the entire Base, Post or similar, not the actual building. If the building is located away from a Base, Post or similar, reliability is determined by when power is lost to the building itself.

2-1.28.2 Unless otherwise noted, a reliable power source is a power source having forced down time, excluding scheduled repairs, that does not exceed 8 consecutive hours for any one incident within the last 3 years, or more than 24 hours cumulatively over the last 3 years.

2-1.29 \5\ /5/Review Stamp.

A stamp certifying that the *QFPE* has reviewed the document and finds that it meets all contractual requirements. A Review Stamp is not a professional engineer stamp or seal.

2-1.30 Sensitive Compartmented Information Facility (SCIF).

Accredited areas, room(s), or building(s) where Sensitive Compartmented Information (SCI), is stored, used, processed or discussed. SCIF are only required for SCI and not necessarily required for Secret or Top Secret information. [UFC 4-010-05]

2-1.31 Service Lateral.

A pipe that connects to the *Service Main* and terminates at a fire hydrant or a *Facility*. A service lateral to a *Facility* is permitted to have no more than two fire hydrants. A service lateral does not connect from one *Service Main* to a second *Service Main*. \4\/4/.

2-1.32 Service Main.

A pipe that transports water from the *Distribution Main* to the *Service Lateral*. A service main can be connected to a *Distribution Main*, *Service Lateral* or another service main. A main with three or more fire hydrants connected to it is a service main. A main from a fire pump to more than one building is a service main.

2-1.33 Stakeholders.

A group of identified individuals or representatives, typically having authoritative control or input, having a share or interest in the successful completion of a project. A project's identified stakeholders must include the building's design and construction team members, security, the \6\ *CFPE* /6/, accreditation agencies, tenants, supported commands and emergency responders.

2-1.34 Telecommunications Equipment Areas.

See “Electronic Equipment Areas”.

2-1.35 Tension Membrane Structure.

A membrane structure incorporating a membrane and a structural support system such as arches, columns, and cables, or beams wherein the stresses developed in the tension membrane interact with those in the structural support so that the entire assembly acts together to resist the applied loads. [NFPA 102]

2-1.36 Very Early Warning Smoke Detection.

Detection that is listed as being capable of providing the level of protection as defined in NFPA 76 for Very Early Warning Fire Detection. Aspirating smoke detection installed in Europe must comply with Class A requirements as specified in EN54 (Fire Detection and Fire Alarm Systems), Part 20 (Aspirating Smoke Detection) (EN54-20).

The maximum area of coverage per detector, or sampling point, is 200 ft^2 (18.5 m^2) for one level of detectors. A minimum of one alert and one alarm level are provided.

This Page Intentionally Left Blank

CHAPTER 3 USE AND OCCUPANCY CLASSIFICATION

3-1 GENERAL

This UFC utilizes criteria from both IBC and NFPA 101. Care must be exercised when using this UFC to ensure proper use of IBC and NFPA 101.

3-2 INTERNATIONAL BUILDING CODE (IBC).

3-2.1 General.

3-2.1.1 The IBC must be used where dictated by UFC 1-200-01 except where noted in this UFC.

3-2.1.2 The IBC must be utilized to determine the occupancy classification as it relates to allowable construction type, building height, building area, building separation distance, occupancy separation and associated requirements.

3-2.1.3 Medical funded projects, including but not limited to, healthcare, ambulatory healthcare and all facilities required to comply with The Joint Commission standards must comply with NFPA 101 in its entirety.

3-3 NFPA 101.

3-3.1 General.

3-3.1.1 NFPA 101 must be utilized to determine the occupancy classification as it relates to fire/smoke resistance rating of interior non-load bearing partitions (other than occupancy separation), means of egress, interior finish, features of fire protection (including vertical openings) and associated requirements.

3-3.1.2 Where specific criteria is provided in NFPA 101 related to occupancy location within a building (i.e. story), conform to the requirements of NFPA 101 based on the equivalent construction type.

Note: Where IBC permits a particular occupancy classification on the third floor of a building of Type IIB construction and NFPA 101 only permits that occupancy classification on the second floor for Type II (000), the occupancy is only permitted on the second floor.

3-3.1.3 Appendix D provides a cross reference between the construction types referenced in NFPA 220 and the IBC.

3-4 HAZARDOUS MATERIALS.

For the purpose of occupancy classification, the maximum allowable quantities (exempt amounts) noted in NFPA 400 must be used \6\ with the exception of *ammunition and explosives*, for which the maximum allowable quantity noted in IBC Chapter titled

"Occupancy Classification and Use" must be used /6/. Where the maximum allowable quantities are exceeded in NFPA 400, the H occupancy classification (H-1, H-2, etc.) must be defined in accordance with IBC for High-Hazard Group H occupancies, except as modified by this UFC. IBC Chapter titled "Occupancy Classification and Use" must be utilized to determine the IBC occupancy type. IBC Chapter titled "Special Detailed Requirements Based on Use and Occupancy" is not to be utilized for hazardous materials requirements \6\ except as specifically noted herein. See Table 3-1. /6/

Table 3-1 Hazardous Materials Classification

HAZARDS	NFPA 400 & NFPA 1 CLASSIFICATION	NFPA 400 & NFPA1 PROTECTION LEVEL	IBC GROUP H CLASSIFICATION
Detonation Hazard	High Hazard Level 1	Protection Level 1	H-1
Deflagration Hazard	High Hazard Level 2	Protection Level 2	H-2
Physical Hazard	High Hazard Level 3	Protection Level 3	H-2 or H-3
Health Hazard	High Hazard Level 4	Protection Level 4	H-4
HPM Facility	Not Applicable	Not Applicable	H-5

CHAPTER 4 SPECIAL DETAILED REQUIREMENTS BASED ON USE

4-1 GENERAL.

This Chapter provides specific criteria for special or unique occupancies and hazards and supersedes IBC Chapter 4 in its entirety. For special or unique occupancies and hazards not addressed in this Chapter, comply with the requirements of NFPA 101. This Chapter either supersedes or is in addition to requirements in other Chapters of this UFC.

4-2 \5\ADDITIVE MANUFACTURING (3D PRINTING TECHNOLOGY AND COLD SPRAY MATERIAL-DEPOSITION PROCESS TECHNOLOGY).

4-2.1 General.

Additive manufacturing includes manufacturing process using polymer, glass, or ceramic powders including any material with minimum ignition energy greater than 10mJ (ASTM E2019 or EN 13821).

4-2.2 Additive manufacturing processing equipment.

Additive manufacturing process equipment using combustible powders with a maximum ignition energy of 10mJ or less, including metal powders such as stainless steel (any alloy mix), aluminum (any alloy mix), and titanium (any alloy mix) must comply with the following:

a. Must be located in a separate building, or:

b. Be located in a separate room with an exterior wall and separated by construction of not less than 2-hour fire rating, and,

c. Have explosion venting through the exterior wall. Explosion venting may comply with either FM Global or NFPA 68; or for European countries, VDI 3673 (Verein Deutscher Ingenieure).

Note: See NFPA 652, NFPA 68, and FM Global Loss Prevention Data Sheet 7-76 for additional information./5/

4-3 AIRCRAFT ACOUSTICAL ENCLOSURES.

4-3.1 Complete Enclosures (Hush House).

For Air Force, Aircraft Acoustical Enclosures are not classified facilities (real property); they are classified equipment and as such are managed by the Air Force Sustainment Center, Air Force Logistic Complex, Propulsion Support Equipment, Hush Houses/ Noise Suppressors (AFLCMC/WNZEC) Robins AFB, GA. The criterion of the UFCs does not apply to this equipment. These systems are centrally managed and are not constructed nor maintained as facilities under this UFC. The fire protection system controls in such enclosures are provided with connection to the installation fire alarm communication network by the installation.

4-3.1.1 Conform to the requirements listed in the paragraph entitled "Aircraft Facilities". Provide separate manual controls for actuation of each foam system.

4-3.2 Out of Airframe Acoustical Enclosures (Test Cells).

Fire protection system for Test Cells must consist of the following:

a. Overhead water deluge system having a density of 0.35 gpm/ft^2 (14.3 L/min/m^2) over the entire floor area.

b. Water spray system for the engine having a density of 0.50 gpm/ft^2 (20.4 L/min/m^2) of engine surface area.

c. Water spray system for the floor area beneath the engine having a density of 0.50 gpm/ft^2 (20.4 L/min/m^2) over the entire shadow area.

Note: The overhead deluge system need not extend into the area where the water spray systems for the engine and floor are present.

4-4 AIRCRAFT FACILITIES.

4-4.1 Aircraft Hangars.

For fixed wing and rotary wing aircraft fuel cell maintenance facilities, alert, storage, depot-level and general-purpose maintenance hangars comply with UFC 4-211-01. For corrosion control hangars, comply with UFC 4-211-02.

4-4.2 Tensioned-Membrane Hangars.

4-4.2.1 Construction type must conform to NFPA 409. Tension fabric hangars must utilize rigid-steel-frame structures.

4-4.2.2 The minimum separation between tensioned-membrane hangars and all other structures must be 100 feet (30.5 m), with a clear zone of 50 feet (15.3 m) immediately adjacent to the tension fabric structure. The clear zone cannot be used for storage and must be clear of vegetation (maintained lawn is permitted). The clear zone may be used as a street or driveway, but not for vehicle parking. The clear zone must be clearly striped to indicate no storage or parking.

Note: For Navy, see OPNAVINST 11010.33 for regulations and restrictions on the use of relocatable facilities.

4-4.3 Aircraft Weather Covering.

4-4.3.1 \6\ Weather coverings are structures that control the amount of direct sunlight on aircraft parked on the flight line, see Figure 4-1 and Figure 4-2. Weather coverings used for aircraft on the flight line must comply with all of the following:

a. Constructed of noncombustible materials,

b. If using fabric material, the fabric must meet the requirements of Test Method 2 contained in NFPA 701,

c. Open on all sides,

[C] 4-4.3.1

The weather covering being open on all sides allows for the dissipation of heat, dispersion of vapors from flammable or combustible liquids, and will not restrict firefighting operations from any side of the structure. The open sides maintain the current conditions on the flight line.

d. Any permanent electrical devices or equipment (receptacles, lighting, or other similar devices) installed on the aircraft weather covering (sunshade) must comply with the requirements of NFPA 70, Article entitled “Aircraft Hangars”, as well as the criteria for fuel servicing safety zone found in the individual DoD Service’s criteria (i.e. AF T.O. 00-25-172, NAVAIR 00-80R-14, NAVAIR 00-80T-109 or AR 420-90).

4-4.3.2 A fire detection or suppression system is not required. /6/

Figure 4-1 Examples of Weather Covering

Figure 4-2 Example of Weather Covering

4-4.4 *Facilities* Housing Unmanned Aerial Vehicles (UAV) or Remotely Piloted Aircraft (RPA).

4-4.4.1 \2\For this UFC, an Unmanned Aerial Vehicle (UAV) or Remotely Piloted Aircraft (RPA) consists of just the vehicle; and, an Unmanned Aerial System (UAS) consists of the vehicle, launcher, and any other associated equipment for that system./2/

4-4.4.2 *Facilities* designed to support \2\UAS,/2/ UAV, or RPA that have both of the following must be protected in accordance with the section for Aircraft Hangars in this UFC:

a. Combined fuel capacity of all \2\UAS,/2/ UAV, or RPA equal to or greater than 240 gallons (908.4 L) and

b. Access to a runway that supports manned aircraft.

4-4.4.3 *Facilities* designed to support \2\UAS,/2/ UAV, or RPA that have both of the following must be protected in accordance with the section for Aircraft Hangars in this UFC:

a. Has a door opening greater than \2\or equal to/2/ 20 feet (6.1m) in height and

b. Access to a runway that supports manned aircraft.

4-4.4.4 *Facilities* designed to support \2\UAS,/2/ UAV, or RPA that have both of the following must be \2\provided with sprinklers designed/2/ in accordance with NFPA 30, \2*Storage of Liquids in Containers – Storage Occupancies*/2/:

a. Combined fuel capacity of all \2\UAS,/2/ UAV, or RPA is equal to or greater than 240 gallons (908.4 L) and

b. No access to a runway that supports manned aircraft.

4-4.4.5 *Facilities* designed to support \2\UAS,/2/ UAV, or RPA that have both of the following must be \2\provided with sprinklers designed/2/ in accordance with NFPA 30, \2*Storage of Liquids in Containers – Storage Occupancies*/2/:

a. Has a door opening less than 20 feet (6.1m) in height and

b. Access to a runway that supports manned aircraft.

4-4.4.6 *Facilities* designed to support \2\UAS,/2/ UAV, or RPA that have both of the following must be protected with automatic sprinklers:

a. Combined fuel capacity of all \2\UAS,/2/ UAV, or RPA is \2\more/2/ than \2\120 gallons (454.2 L) and less than/2/ or equal to 240 gallons (908.4 L) and

b. No access to a runway that supports manned aircraft.

4-4.4.7 *Facilities* designed to support \2\UAS,/2/ UAV, or RPA that have all of the following do not require automatic sprinklers:

a. Combined fuel capacity of all \2\UAS,/2/ UAV, or RPA is less than 120 gallons (454.2 L) per control area (as defined by NFPA 30),

b. No access to a runway that supports manned aircraft,

c. Sprinkler protection is not required by the "Application Requirements" paragraph in the section for Automatic Sprinkler Systems in this UFC,

d. Supports small, human packable, portable UAV or RPA, and

e. The facility is separated from other structures by a minimum of 100 feet (30.5 m).

4-4.4.8 \2\For Army, in addition to the aforementioned paragraphs, *Facilities* designed to support UAS or UAV must be protected as follows. If there is a conflict between the aforementioned paragraph and this paragraph, follow the more stringent paragraph.

a. *Facilities* housing Group 4 UAS or UAV must be protected in accordance with the section for Aircraft Hangars in this UFC. Group 4 UAV weigh more than 1,320 LBS.

b. *Facilities* housing Group 3 UAS or UAV, where the fire area of the aircraft servicing or storage area exceeds 7,500 ft^2, must be protected in accordance with the section for Aircraft Hangars in this UFC. Group 3 UAV weigh more than 56 LBS but less than 1,320 LBS.

c. *Facilities* housing Group 3 UAS and UAV, where the fire area of the aircraft servicing or storage area does not exceed 7,500 ft^2, but is required by another section of the UFC to have sprinklers, must have the aircraft servicing or storage area protected in accordance with NFPA 30, Storage of Liquids in Containers – Storage Occupancies. All operations outside the UAV or UAS housing area must be isolated from the UAV or

UAS housing area by 1-hour fire barrier walls. Floor elevations must be arranged to prevent a spill within the UAV or UAS housing area from flowing into adjacent areas. Adjacent areas are not permitted to have their required egress through the UAV or UAS housing area, except for normally unoccupied rooms less than 100 ft^2.

d. *Facilities* housing Group 3 UAS and UAV, where the fire area of the aircraft servicing or storage area does not exceed 7,500 ft^2, and is not required by another section of the UFC to have sprinklers, is not required to have a suppression system. All operations outside the UAV or UAS housing area must be isolated from the UAV or UAS housing area by 1-hour fire barrier walls. Floor elevations must be arranged to prevent a spill within the UAV or UAS housing area from flowing into adjacent areas. Adjacent areas are not permitted to have their required egress through the UAV or UAS housing area, except for normally unoccupied rooms less than 100 ft^2./2/

Note: The reference to NFPA 30 in this section pertains to sprinkler requirements only and is not intended to follow all of the requirements in NFPA 30.

4-5 \6\ AMMUNITION AND EXPLOSIVES FACILITIES.

[C] 4-5

The section was titled Ordnance. The terminology was changed to better coordinate with the DoD explosive safety standards.

4-5.1 General.

This section includes Facilities that are used for the manufacturing, processing, dispensing, use, storage, maintenance, inspection or demilitarization of ammunition and explosives, primers, propellants, and oxidizers related to ammunition and explosives. This section addresses general fire protection and life safety criteria associated with Ammunition and Explosives (A/E) Facilities with the objective to minimize risk to life and protect property. Separate explosives safety criteria also apply to these types of facilities. Any equivalencies approved by the appropriate CFPE as defined in this document only apply to the fire protection and life safety requirements specified herein. This does not exempt the facilities from conformance with any applicable explosives safety requirement.

4-5.2 Criteria.

4-5.2.1 Compliance.

Comply with the requirements specified herein, and with the fire protection requirements in Defense Explosives Safety Regulation DESR 6055.09 and in the applicable service explosives safety regulation. In cases of conflict the most specific and stringent criteria will apply. Where it is not possible to meet all criteria, coordinate with the DFPE for guidance. The service explosives safety regulations include:

- For Navy projects, NAVSEA OP-5, Volume 1.
- For Army projects, AR 385-10 and DA PAM 385-64
- For Air Force projects, DESR 6055.09_AFMAN 91-201.

4-5.2.2 In the absence of specific guidance in this UFC, DESR 6055.09, or the service regulations follow the applicable requirements of the IBC for Group H occupancies, including applicable portions of IBC Chapter titled “Special Detailed Requirements Based on Occupancy and Use”, section titled “Hazardous Materials”, and section titled “Groups H-1, H-2, H-3, H-4 and H-5”.

4-5.3 Design Analysis.

The design analysis for ammunition and explosives facilities must include identifying the material being stored or processed, the hazard division, and the maximum expected quantities of ammunition and explosives to be stored or used and must address toxic and/or hazardous material types, classification categories and quantities. Where toxic or hazardous materials are also present in ammunition and explosives facilities, the more stringent of these and other applicable special detailed requirements based on use and occupancy defined elsewhere in the UFC must apply. Areas requiring electrical classification will also be identified. The methods of protection from hazards must be indicated in the design analysis. Separate floor plans must be submitted identifying the location of anticipated content and process. Information must be provided with the first design submittal and updated as the design is developed.

4-5.4 Building Code and Life Safety Criteria.

4-5.4.1 Egress requirements must meet the applicable NFPA 101 requirements for high hazard industrial or storage occupancies except as modified herein.

4-5.4.2 Control areas not exceeding the allowable quantities of explosives identified in IBC chapter 3 are permitted to prevent classification of the building as an H-1 or H-2 occupancy. Control areas must meet the requirements of IBC chapter 4. The number of control areas, the quantity in the control area and fire resistance of control areas must comply with the requirements of IBC Table 414.2.2, titled Design and Number of Control Areas. Supporting construction of control areas must be not less than the fire resistive rating of the control area.

4-5.4.3 *Ammunition and Explosives Facilities* classified as an H-1 or H-2 must be constructed as detached buildings from other occupancies. Supporting spaces necessary to provide direct support for the *ammunition and explosives* operation and the personnel that directly work with the explosives operations are permitted to be attached to the H-1 or H-2 structure. The supporting spaces must be separated with fire rated barriers or fire walls in accordance with IBC. The fire rated separation of H-1 occupancies from supporting spaces must not be less than the required separation of H-2 occupancies from other occupancies and must also comply with any fire rated requirements of DESR 6055.09 and service explosive safety regulations.

[C] 4-5.4.3

Supporting spaces permitted include control spaces; desk space for the workers whose duties require direct access to the ammunition and explosives as a part of their daily duties; small break rooms; required laboratory space; small conference rooms needed for safety briefings and similar activities; toilet rooms, showers, and locker rooms, as well as mechanical, electrical, and similar spaces. First line supervisors and quality control staff may be considered as requiring direct access as part of their daily duties. Desk space must not be provided for any personnel who do not require direct access to the ammunition and explosives in the facility as a part of their regular duties. Conference rooms and break rooms must be sized to only support explosives personnel regularly working in the building and must not be large enough to be considered an assembly occupancy. Individual toilet rooms do not require rated separation.

4-5.4.4 *Ammunition and Explosives Facilities* must be located on the property in accordance with DESR 6055.09, the service regulations, and this section. *Ammunition and Explosives Facilities* classified as an H-1 occupancy must be set back not less than 75 feet to lot lines, and facilities classified as H-2 must be set back not less than 50 feet to the lot line. Multiple H-1 facilities may be attached to each other with fire walls in accordance with IBC requirements. A minimum of 25% of the perimeter of each H-1 building must be an exterior wall.

4-5.4.5 The *CFPE* may approve increases in the allowable building area, height, and number of stories of Type IIB and better construction where buildings cannot be constructed within the allowable area limits of the IBC due to the size of the *ammunition and explosives* or due to special mission needs or production process requirements.

4-5.4.6 Reduced separation distance or attached buildings may be allowed by the *CFPE* when there is a decreased risk over separated *facilities* or where site constraints dictate reduced separation combined with protective construction. Where a reduction in the separation distance between *facilities* specified by IBC or an attached building is proposed an equivalency must be submitted to the *CFPE* defined in this document. The equivalency must document why the equivalency is needed, along with additional protective features being provided

[C] 4-5.4.6

Example: In chemical de-militarization processes a detached building might increase the risk that nerve agent is released to the environment when moving the munition from one part of the operation to another. A mitigation would be 4-hour fire rated concrete blast containment walls.

4-5.4.7 Exterior walls must be rated in accordance with IBC Chapter titled "Types of Construction".

4-5.5 Fire Suppression Systems.

4-5.5.1 Complete automatic sprinkler protection and/or water spray systems must be provided for all *Ammunition and Explosives Facilities*, except as modified herein or as modified by a service regulation. Water based automatic suppression systems are permitted to be omitted where application of water may intensify or spread the fire or increase the hazard of explosion. Where critical electronic process control equipment is required for continued safe operation and/or safe shutdown of hazardous operations, automatic clean-agent fire suppression systems may be provided in addition to water based automatic suppression systems in the control, electrical, and telecommunications rooms only.

[C] 4-5.5.1

Note that the cooling effects of water application during a fire of water sensitive materials may reduce propagation of the fire and of overall property damage.

4-5.5.2 Where testing involves the intentional ignition of energetic materials, the suppression system must be designed to prevent sprinkler discharge during testing, or sprinkler system may be omitted from the area with the approval of the *DFPE*.

4-5.5.3 Automatic sprinkler and water spray systems in *Ammunition and Explosives Facilities* must be protected from movement in accordance with NFPA 13 for protection of piping where subject to earthquakes, regardless of seismic design category. Where the applicable standard does not address seismic protection, NFPA 13 or ASCE 7 methodology must be followed. Contractor must use a minimum seismic coefficient (Cp) of 0.5.

4-5.5.4 Sprinkler systems protecting *Ammunition and Explosives Facilities* must be wet pipe or deluge systems. Automatic sprinkler systems must be designed and installed in accordance with NFPA 13, this UFC and as specified in the service regulations. Sprinkler water demand for areas containing *ammunition and explosives* must meet or exceed the design requirements for ordinary hazard as defined in this UFC. Service regulations, areas with special or *exposed explosives*, and special processes may require higher hazard classification or higher densities and larger areas to provide proper protection or provide cooling to prevent propagation of fires to other ammunition and explosives.

4-5.5.5 Water Spray Systems: Water spray systems, including high speed and ultra-high-speed deluge systems must be designed and installed in accordance with NFPA 15 unless otherwise noted herein or in the applicable DoD or Service explosives safety regulation.

4-5.5.5.1 High-Speed Deluge Systems: High-speed deluge systems will be provided where specified herein or in the applicable DoD or Service explosives safety regulation. High-speed deluge systems are required to have a response time of 500 ms or less.

4-5.5.5.2 Ultra-High-Speed Deluge Systems: Comply with the requirements of NFPA 15, except as noted herein or in the applicable DoD or service explosives safety regulation. NFPA 15 limits on use of ultra-high-speed deluges systems must not be used to eliminate DoD requirements for the system. Ultra-high-speed deluge systems must be designed to have a response time of not more than 100 ms, unless a risk assessment or other data indicates a need for a faster response time.

a. Timers.

   1. Timers or similar devices to stop water flow after a predetermined time are permitted if they are fail-safe (i.e., water continues to flow in the event of a timer failure).

   2. b. Timers or similar devices that shut off the water flow after a predetermined time (typically 1 to 2 minutes) when the optical fire detectors no longer detect a fire are permitted. In case of a failure, timers must be fail-safe (i.e., water continues to flow in the event of a timer failure).

b. Qualifications. Due to the sensitivity and complexity of ultra-high-speed deluge systems only designers, engineers, and installers who have at least two years' recent experience with ultra-high-speed deluge systems must design and install ultra-high-speed deluge systems.

c. Water Demand. Water supplies for ultra-high-speed deluge systems must be adequate to supply the largest total demand of the ultra-high-speed deluge system and the corresponding largest sprinkler demand in the fire area at the specific residual pressure required by the systems. The combined system must be deemed to operate for at least 90 minutes. Where the water supply to an ultra-high-speed is on a timer or there is a reliable means to shut the system down, the ultra-high-speed system must be designed to operate for a period of at least 15 minutes unless a hazard analysis indicates a longer flow time is needed.

4-5.5.6 Small Self-Contained Deluge Systems. Small self-contained deluge systems may be used in conjunction with the ultra-high-speed deluge systems discussed in this section, or alone if an adequate water supply is not available for the *Facility*, or as otherwise permitted by the DESR or applicable Service regulation. Self-Contained ultra-high-speed deluge systems may also be used for short term operations. These small self-contained deluge systems are primarily intended for personnel protection, although they provide limited building/equipment protection.

4-5.5.6.1 When used, self-contained deluge systems must be connected to the existing water supply.

4-5.5.6.2 Portable, self-contained ultra-high-speed deluge systems must meet the following:

- Multiple nozzles,
- Multiple optical fire detectors,
- Pressurized water tank (typically 100 gal (380 L) of water),
- Response time must not exceed 100 ms (detection to water at the nozzle).

4-5.5.6.3 Pressurized sphere ultra-high-speed deluge systems must meet the following:

- One or more optical fire detectors,
- At least one pressurized (typically 500 psi (3,447 kPa)) water sphere (typically 2.6 to 7.9 gal (10 to 30 L)) with a rupture disc and internal squib, and an electronic controller,
- Response time must be less than 10 ms (detection to water at the nozzle).

4-5.6 Fire Detection and Alarm Systems.

4-5.6.1 Fire detection and alarm systems must be provided in Ammunition and Explosives Facilities except as modified herein.

4-5.6.2 All fire protection systems protecting *Ammunition and Explosives Facilities* must have complete supervision so that any deficiency that develops that would affect the speed or reliability of sprinkler system operation will give a distinct signal in the facility.

4-5.6.3 Heat detection equipment of any type is acceptable if equipment meets the operating time limitations and is suitable in other respects, such as complying with explosion-proof requirements. When pneumatic-type detection equipment is used, not more than three detectors, and preferably only one, must be on a single circuit in the same heat influence area.

4-5.6.4 Detection systems for high-speed and ultra-high speed deluge systems must comply with the requirements of NFPA 15.

4-5.7 Requirements for Specific Types of Ammunition and Explosives Facilities.

4-5.7.1 Accessory Magazines and Armories. 4-5.7.1.1 Accessory magazines and armories containing limited quantities of *ammunition and explosives* for reasons of operational necessity at police stations, security *facilities* and similar type *facilities* are not required to comply with the *ammunition and explosives* section of this UFC. These facilities must comply with other requirements of this UFC and with UFC 4-215-01.

4-5.7.2 *Ammunition and Explosives* Storage *Facilities*.

4-5.7.2.1 *Ammunition and explosives* storage *facilities* are permitted to be either Earth Covered Magazines (ECM) or above ground storage facilities as defined by DESR 6055.09. An *ammunition and explosives* storage *facility* is used for *ammunition and explosives* storage only with the exception of minor activities incidental to storage. These activities and the equipment involved must be explicitly approved and consistent with the DoD principles of storage. Refer to explosives safety regulations for relevant policy.

4-5.7.2.2 Compliance with IBC or NFPA 101 is not required for eCMS.

4-5.7.2.3 Automatic sprinklers and hydrant protection are not required for ECMs or aboveground magazines. Provide sprinkler protection for all aboveground storage of missile assemblies. Consideration must be given to including appropriate fire protection systems in ammunition and explosives storage facilities used for the storage of critical assets. Hydrant protection should also be considered where needed to protect ammunition storage facilities from fires originating at other facilities.

[C] 4-5.7.2.3

Missile assemblies are considered to be large rocket type, Cruise missiles without warheads, Intercontinental Ballistic Missiles or Poseidon missiles.

4-5.7.2.4 Fire alarm and detection systems are not required for ECMs or above ground magazines except as noted herein. Fire alarm and detection systems must be provided in any ammunition and explosives storage facility with an automatic fire suppression system and must be considered in other aboveground storage facilities.

4-5.7.3 Explosives Operating *Facilities*.

4-5.7.3.1 Explosives operating *facilities* are those facilities where *explosives and ammunition* are present for operations to include production, manufacturing, maintenance, assembly, processing, inspection, demilitarization, testing, quality assurance, servicing, and other handling. This also includes facilities in which propellants and oxidizers or related devices containing these materials are present for operations.

4-5.7.3.2 Risk Assessment. A risk assessment will be performed in accordance with DESR 6055.09 and the applicable Service regulation to identify potential fire and thermal threats and to assess the level of risk. When a final risk assessment cannot be accomplished during the design, a preliminary risk assessment must be performed. The hazard(s) must be accurately defined. A potential fire or thermal hazard with an unacceptable risk requires personnel protection in accordance with explosives safety requirements. The risk assessment will consider factors such as:

- Initiation sensitivity,
- Quantity of material,
- Heat output,
- Rate of burn,
- Potential ignition and initiation sources,
- Protection capabilities of shields, types of clothing, and fire protection systems,
- Personnel exposure,
- Munitions configuration.
- Process equipment and layout,
- The building layout.

4-5.7.3.3 Fire Suppression. Provide complete automatic fire suppression throughout. Provide additional localized automatic fire suppression system(s) based on the Risk Assessment and as follows:

- Provide high-speed, pre-primed deluge systems wherever *exposed explosives*, pyrotechnics, or propellants are processed in *Ammunition and Explosives Facilities*. Complete protection of such locations is essential.
- Where the risk assessment shows that exposed thermally energetic materials are handled that have a high probability of ignition, a large thermal output and a high probability of causing personnel injury, operations must be protected using ultra-high-speed deluge systems.
- Ultra-high-speed deluge systems must be provided where mixing of explosives occurs.
- Consult special detailed requirements for hazardous materials herein where other than energetic materials (acids, corrosives, oxidizers, etc.) are present in or near explosives operating *facilities*. The more restrictive of the applicable requirements shall apply. Provide sprinkler protection for outdoor storage vessels.

4-5.7.4 Combat Related *Ammunition and Explosives Facilities*.

4-5.7.4.1 Combat related *Ammunition and Explosives Facilities* are those permanent *facilities* used for support of combat missions, such as alert aircraft *facilities*. This section does not apply to temporary combat related *facilities* in support of contingency operations.

4-5.7.4.2 Due to combat mission needs it may be necessary to construct combat related *Ammunition and Explosives Facilities* that do not comply with the detached building requirement of IBC for H-1 and H-2 occupancies. Where an H-1 building area is attached to a living or sleeping area, a minimum of a 4-hour fire wall must be provided between the areas.

4-5.7.5 *Facilities* Containing Chemical and Nuclear Warheads.

4-5.7.5.1 *Facilities* containing *ammunition and explosives* with chemical or nuclear warheads will comply with the requirements of this section for *Ammunition and Explosives* and all other DoD criteria applicable to chemical and nuclear weapons to include FC 4-420-07F and DA PAM 385-61. /6/

4-6 ANECHOIC CHAMBERS.

\6\ **[C] 4-6**

See FM Global Data Sheet 1-53, Anechoic Chambers, for additional information and guidance for installation of systems and other possible protection as each chamber may necessitate additional protection or features.

4-6.1 Protecting Contents and Anechoic Chamber.

4-6.1.1 Provide a FM Approved clean agent system in the anechoic chamber including the space created under raised floors and inside utility trenches.

[C] 4-6.1.1

Three clean agents have been tested by FM Global and are FM Approved for the use in anechoic chambers. As stated in FM Global Data Sheet 1-53, Anechoic Chambers, they are: Novec 1230 (6.1% concentration), Inergen (49% concentration), and FM200 (9% concentration).

4-6.1.2 Provide an equally sized reserve supply of gaseous suppression agent. The reserve supply must be physically connected to the system and controlled by a manually activated switch that is supervised by the releasing panel.

4-6.1.3 Sprinkler protection that complies with the following “Sprinkler Protection” paragraph in this section may be used in lieu of a clean agent system.

4-6.1.4 Use Air-Aspirated High Sensitivity Smoke Detection to activate the clean agent fire suppression system.

4-6.2 Safeguard of the Surrounding Occupancy and Building.

4-6.2.1 Separate the room or space containing the anechoic chamber from the remainder of the facility with 2-hour fire rated construction.

4-6.2.2 Provide sprinkler protection inside the anechoic chamber that complies with the following “Sprinkler Protection” paragraph in this section.

4-6.2.3 Provide sprinkler protection above and around the anechoic chamber, within the 2-hour fire rated construction, that meets the requirements for the occupancy hazard of that space.

4-6.2.4 Provide sprinkler protection above the anechoic chamber if there is at least three feet of clearance between the top of the anechoic chamber and the ceiling/floor above.

4-6.3 Sprinkler Protection.

4-6.3.1 Use either quick-response sprinklers with a minimum K-factor of 11.2 or control mode k-factor of 11.2 sprinklers.

4-6.3.2 Extended coverage sprinklers are prohibited.

4-6.3.3 Design the sprinklers to provide a minimum density of 0.6 gpm/ft2 (24.4 L/m/m2) over the most remote 2,000 ft2 (186 m2) of floor area or over the entire chamber floor area, whichever is less.

4-6.3.4 Limit the sprinkler coverage to a maximum of 80 ft2 (7.4 m2), with the maximum spacing between sprinklers or between branch lines not to exceed 9 ft (2.7 m).

4-6.3.5 Use upright sprinklers in the pendent position.

4-6.3.6 Where the anechoic chamber exceeds 15 ft (4.6 m) in height, install at least one level of sprinklers along the walls approximately one-half to two-thirds of the height above the floor

4-6.3.7 Where the anechoic chamber exceeds 25 ft (7.6 m) high, install one level of sprinklers at the 15 ft (4.6 m) height and an additional level every 10 ft (3 m) vertically.

4-6.3.8 Use upright sprinklers in the sidewall position for the sidewall protection.

4-6.3.9 Arrange sprinkler drops into chamber so that the sprinkler deflector extends at least 6 in. (150 mm) beyond the tip of the absorber liner material for pyramids up to 1 ft (0.3 m) long, and 12 in. (0.3 m) for pyramids exceeding 2 ft (0.6 m). The extension may be interpolated for intermediate pyramid lengths. /6/

4-7 \6\ ANIMAL HOUSING FACILITIES.

This section applies to all DoD facilities housing government-owned or -managed animals. These facilities must comply with NFPA 150 and the requirements of this UFC.

This section does not apply to retail kennels, riding stables, private or club stables, or similar facilities that are not included in DoD real property inventory, nor to shelters provided for either domesticated or feral animals that do not confine the animals.

4-7.1 Sprinkler Protection.

Provide automatic sprinkler protection throughout the facility.

4-7.2 Fire Alarm.

4-7.2.1 Provide smoke detection in the animal housing area.

4-7.2.2 Audible notification in the animal housing area must not disturb the animals. The use of chimes or other “soft” notification is acceptable. The use of private operating mode for the animal housing area is acceptable as determined by the *DFPE*.

4-7.2.3 Visual notification in the animal housing area may be omitted in order to avoid disturbing the animals.

4-7.3 Animal Housing Separation.

Provide a minimum one-hour fire rated construction to separate the animal housing area from the remainder of the facility.

4-7.4 Air Handling.

Provide a separate air handling system for the animal housing area that does not support any other part of the facility.

[C] 4-7.4

Providing a separate air handling system will prevent the spread of smoke and heat from the other areas of the facility into the animal housing area that could affect the working animals or research animals. This maybe more critical with research animals.

4-7.5 Smoke Control.

The DFPE will determine if a smoke control system will be required.

[C] 4-7.5

Animal housing or animal research facilities may require smoke control in order to ensure a clean atmosphere in the animal housing or research area is maintained in the event of a fire. If products of combustion enter the animal housing or research area, it could compromise the animals and impact the animals working ability or research to be terminated due contamination of the animals resulting in the loss of years of training or research.

4-7.6 Veterinary Care and Animal Research Facilities.

Comply with UFC 4-510-01. /6/

4-8 \6\ BATTERY ENERGY STORAGE SYSTEMS – LITHIUM

This section applies to battery energy storage systems that use any lithium chemistry (BESS-Li). Unoccupied structures housing BESS-Li must comply with NFPA 855, except where modified by this section.

[C] 4-8

There are no current commercially available lithium battery chemistries that provide a significantly different margin of fire safety over any other lithium battery chemistry. This includes lithium iron phosphate chemistry.

See NFPA 855 including Appendix A and NFPA 1 chapter entitled “Energy Storage Systems” for additional guidance related to energy storage systems.

4-8.1 BESS-Li in Unoccupied Structures.

The structure must be dedicated to the BESS-Li operation. BESS-Li structure may not be used for any other purpose other than the lithium batteries and required/approved switching.

[C] 4-8.1

In many cases these structures and the battery systems are not DoD real property or equipment, rather are owned by public and private utilities and other energy providers. The owner’s technical guidance may be used, provided it meets or exceeds the requirements of this UFC; however, it must not be used to reduce the minimum requirements of this UFC.

4-8.1.1 Location. Unoccupied Structures housing lithium battery must be located no closer than 100 feet (30 m) to an occupied structure or an identified outdoor use area.

A perimeter fence or wall in accordance with the installation's facility standards must be provided not less than 100 feet from the structure. An adjacent facility exterior wall maybe part of the perimeter separation.

[C] 4-8.1.1

For information pertaining to fire potential, see articles and fire report on the energy storage fire at the McMicken Energy Storage facility located in utility Arizona Public Service territory just outside of Phoenix on 19 April 2019.

4-8.1.1.1 Other electrical utility switching, transformers, and distribution equipment may be within the perimeter in accordance with the appropriate electrical safety requirements or specific utility technical requirements.

4-8.1.2 Doors. Each doorway leading into the structure housing lithium batteries must be equipped with locks and kept locked. Provision for emergency access for fire and security purposes in accordance with installation guidance is required.

4-8.1.2.1 A minimum of two separate doors must be provided. The doors must be spaced a minimum distance apart equal to the long dimension of the structure, or a minimum of 75% of the diagonal distance apart, whichever is greater. Door swing must be in the direction of egress travel.

4-8.1.3 Ventilation. General ventilation must comply with NFPA 855.

4-8.1.4 Explosion/Deflagration Venting. Explosion/deflagration venting must be provided for the BESS-Li room. See NFPA 855 for guidance on design of explosion/deflagration venting.

4-8.1.5 Signage. All sides of the structure and the doors to the structure must be provided with ANSI compliant signs indicating; “DANGER – In Emergency Call XXX-XXX-XXXX Before Any Entry”, where XXX-XXX-XXXX is the lithium energy storage system operator 24-hour emergency response center; “WARNING – LITHIUM Battery Energy Storage System”; and “DANGER – High Voltage”.

[C] 4-8.1.5

It is assumed any energy supplier has a 24-hour emergency response capability. In the absence of such a capability, sign should indicate in event of an emergency entry to the structure should not be attempted by anyone including DoD emergency responders or installation craftsmen.

4-8.2 BESS-Li in Occupied Structures.

The BESS-Li room must be dedicated to DoD owned and operated BESS-Li operation. BESS-Li rooms must not be used for any other purpose other than the lithium batteries and required/approved switching. Third party owned and operated BESS-Li that are supporting power generation equipment (photovoltaic panels, wind turbines, and other similar equipment) are not permitted in DoD facilities.

[C] 4-8.2

UFC 3-520-01 prohibits the use of any type of lithium energy storage system in an occupied facility. This UFC technical section does not exempt the use prohibition in UFC 3-520-01.

This section provides requirements for standalone BESS-Li structures and requirements for an occupied facility in the event an exemption is approved through the UFC exemption approval process in MIL-STD-3007G.

4-8.2.1 Location. BESS-Li rooms must have one exterior wall, i.e., located where the room can be ventilated to the outside air without using flues or ducts.

4-8.2.2 Size. BESS-Li rooms must not contain more than 600 kWh energy system.

4-8.2.3 Walls, Roofs, and Floors. The walls and roof of the BESS-Li room must be constructed of materials that have approved structural strength for the conditions with a minimum fire resistance of 3 hours.

4-8.2.3.1 A floor in contact with the earth must be of concrete that is not less than 4 in. (100 mm) thick. A floor that is constructed with a vacant space or other stories below it must have approved structural strength for the load imposed thereon and a minimum fire resistance of 3 hours.

4-8.2.3.2 For the purposes of this section, studs and wallboard construction is prohibited. Sturdy construction with impact resistance equivalent to reinforced concrete or concrete masonry units (CMU) is required.

4-8.2.4 BESS-Li Separation. The BESS-Li cabinets or open battery racks must be separated from other BESS-Li cabinets or open battery racks by a minimum of 3 feet (1 m) or by partitions extending from floor to ceiling/roof/floor above. The partitions must be constructed of masonry units. The partitions need to extend 6 inches (150 mm) beyond the cabinet or open battery rack. For cabinets that meet UL 9540A, the partitions can be constructed of one layer of 5/8-inch Type X gypsum board on both sides of noncombustible studs. Penetrations through the partition must be firestopped as a 1-hour assembly.

[C] 4-8.2.4

The partitions separating the battery cabinets or open battery racks will help limit the spread of a fire from one battery or battery system to another. The partitions need to be floor to ceiling/roof/floor above. Any penetrations need to be firestopped for an hour rating. The partitions are not going to be a true fire rated partition or fire wall. The partitions will help limit or prevent the spread of a fire from the high-energy battery system going through thermal runaway.

4-8.2.5 Doorways. Each doorway leading into an BESS-Li room from the building interior must be provided with a door that has a minimum fire rating of 3 hours. The DFPE may require such a door for an exterior wall opening where conditions warrant.

4-8.2.6 Doors. Doors must be equipped with locks and kept locked. Access is restricted to qualified persons. Doors must swing in the direction of egress travel and be equipped with listed panic hardware.

4-8.2.6.1 When two separate doors are required, the doors must be spaced a minimum distance apart equal to the long dimension of the room, or a minimum of 75% of the diagonal distance apart, whichever is greater.

4-8.2.6.2 Doors to the BESS-Li room must be provided with ANSI compliant signs indicating; “DANGER – In Emergency Call XXX-XXX-XXXX Before Any Entry”, where XXX-XXX-XXXX is the lithium energy storage system operator 24-hour emergency response center; “WARNING – LITHIUM Battery Energy Storage System”; and “DANGER – High Voltage”.

4-8.2.7 Exhaust Ventilation. Exhaust ventilation must comply with NFPA 855, section entitled “Exhaust Ventilation”. The exhaust system must be activated by the sprinkler system protecting the BESS-Li room or the room smoke detection.

4-8.2.8 Explosion/Deflagration Control. Provide explosion/deflagration venting for the BESS-Li room as required by NFPA 855, section entitled “Explosion Control”.

4-8.2.9 Sprinkler Protection. Design the sprinkler protection to provide a minimum density of 0.6 gpm/ft2 (24.4 L/m/m2) over the entire room. Water supply must be able to support 120 minutes of sprinkler flow plus not less than 500 gpm (1,900 l/min) hose stream allowance.

4-8.2.10 Smoke Detection. Design a smoke detection system for the entire BESS-Li room such that each fire area is identified separately.

4-8.2.11 Water Pipes, Conduits, and Accessories. Any pipe, conduit, or duct system foreign to the BESS-Li installation must not enter or pass through the BESS-Li room. Piping or other utilities provided for BESS-Li room fire protection or for cooling must not be considered foreign to the BESS-Li installation.

4-8.2.12 Storage in BESS-Li Rooms. Flammable and combustible materials must not be stored in BESS-Li rooms.

4-8.2.13 Use Group. For Building Code and Life Safety code purposes, BESS-Li rooms in occupied structures must be classified as occupancy Use Group H-3.

4-8.2.14 Battery Management System. Provide an approved battery management system for monitoring and balancing cell voltages, currents, and temperatures within the manufacturer's specifications. Transmit signals to an approved location if potentially hazardous temperatures or other conditions including short circuits, overvoltage (i.e., overcharge) or under voltage (i.e., over discharge) are detected. /6/

[C] 4-8.2.14

The battery management system should be monitored and send any abnormal conditions to a location that can dispatch qualified personnel to evaluate the situation and make any necessary corrections or request additional support.

4-9 CHILD DEVELOPMENT PROGRAMS.

4-9.1 Child Development Centers (CDC).

Comply with UFC 4-740-14. For Navy, comply with FC 4-740-14N.

4-9.2 Continuous Child Care Facilities (24/7).

Comply with UFC 4-740-15.

4-9.3 Other Child Development Programs.

Other child development programs include part-day, preschool, kindergarten, before and after school programs, school-age *Facilities*, etc. Comply with the provisions of educational occupancies in NFPA 101.

4-9.4 Youth Centers.

Youth centers must comply with UFC 4-740-06.

4-10 COAL.

4-10.1 General.

Coal storage and handling must comply with NFPA 850 and FM Loss Prevention Data Sheet 8-10.

4-10.2 Pulverizing Equipment.

Use components designed and constructed in accordance with requirements of NFPA 850.

4-11 COMMISSARIES AND EXCHANGES.

4-11.1 Mixed Occupancy.

Commissaries and Exchanges that are part of another facility (i.e., mixed occupancy) and the Commissary or Exchange area is greater than 8,000 ft2 (743.2 m2) gross floor area, the entire facility must meet the requirements of the sprinkler "Application Requirements" section of this UFC.

4-11.2 Standalone.

Commissaries and Exchanges that are a separate facility (i.e. standalone) and greater than 8,000 ft2 (743.2 m2) gross floor area must be provided with automatic sprinkler protection regardless of construction type.

4-12 COMPACT MOBILE SHELVING.

4-12.1 Reserved.

4-13 DEPARTMENT OF DEFENSE EDUCATION ACTIVITY (DODEA).

DoDEA *Facilities* must comply with the requirements in this UFC.

4-14 DETENTION AND CORRECTIONAL *FACILITIES*.

4-14.1 Requirements.

Comply with NFPA 101 and the following:

4-14.1.1 Individual *Fire Area*s must not exceed 50,000 ft^2 (4,647 m^2).

4-14.1.2 \6\ /6/Provide a minimum separation from other structures and public ways of 20 feet (6.1 m).

4-14.1.3 Provide complete automatic sprinkler protection. Design must utilize institutional (breakaway) type sprinklers in areas accessible to detainees or inmates. Sprinkler piping in detainee or inmate areas must be concealed.

4-14.1.4 Provide an automatic smoke control system in cell areas. In addition, provide manual system activation controls at a continuously manned position outside of the cell area. Design the smoke control system in accordance with NFPA 92.

4-14.1.5 Provide for constant visual supervision of cell areas. Central supervisory control area must be separated from cell areas by not less than one-hour fire-rated construction.

4-14.1.6 Fire alarm notification in cell areas must be at a constantly attended location, with detainees or inmates notified by the staff of fire events. Positive alarm sequence is permitted to be provided in accordance with NFPA 72.

4-14.1.7 Locking Devices.

Provide mechanical or electrical gang release, and individual release devices whenever 10 or more locks must be operated to release prisoners confined in cells. Require gang release devices to open doors necessary to evacuate prisoners to an area of refuge. Require heavy, identically keyed, prison-type locks for exit and corridor doors not requiring gang release devices that must be opened for evacuation in the event of fire.

Dormitory-style confinement facilities are not required to meet the above criteria.

4-14.1.8 Interior Finish.

Interior finish including padded cells must be Class A flame spread (i.e., 25 or less) and must have a smoke development rating not exceeding 50 when tested in accordance with ASTM E84.

4-14.1.9 Navy *Facilities* must also comply with the ACA's Planning and Design Guide for Secure Adult and Juvenile Facilities.

4-15 ELECTRONIC EQUIPMENT AREAS.

This section applies to *Electronic Equipment Areas* and telecommunications areas as defined in this UFC.

4-15.1 General.

4-15.1.1 Construct and protect *Electronic Equipment Areas* in accordance with NFPA 75, except as modified by this UFC.

4-15.1.2 For Air Force *Facilities*, \6\ it is recommended to follow TSFPEWG G 3-600-01.01-18 /6/ for fire protection criteria, in lieu of this section.

4-15.2 Telecommunication Equipment Areas.

This section applies to areas containing telecommunication equipment that serves more than one *Facility*, a portion of an *Installation* or the entire *Installation*. This section does not apply to the room in a *Facility* that contains the incoming telecommunications service for that specific *Facility*.

4-15.2.1 Telecommunication areas must comply with NFPA 76, in lieu of NFPA 75.

Buildings housing telecommunication areas must be of noncombustible construction.

4-15.2.2 Co-located *Facility*.

For *Facilities* that house telecommunication areas that have occupancies and uses other than telecommunication, the entire *Facility* must be provided with sprinkler protection, including the telecommunication area.

4-15.2.3 Stand-alone *Facilities*.

4-15.2.3.1 For stand-alone *Facilities* greater than 2,500 ft^2 (232 m^2), provide a fire extinguishing system in accordance with \2\either/2/ the paragraph entitled "Clean Agent Fire Extinguishing Systems" \2\or “Sprinkler Systems”/2/ below.

4-15.2.3.2 For stand-alone *Facilities* greater than 7,500 ft^2 (696 m^2), provide a sprinkler system in accordance with the paragraph entitled "Sprinkler Systems" below. A clean agent fire extinguishing system can be provided in addition to, but not in lieu of, the sprinkler system.

4-15.2.3.3 Single-story *Facilities* may be of Type II-B construction.

4-15.3 Smoke Detection.

4-15.3.1 *Electronic Equipment Areas* must be protected by Very Early Warning Smoke Detection systems.

4-15.3.2 Smoke detection must provide not less than two distinct alarm conditions (levels) indicating increasing smoke/combustion levels.

4-15.3.3 Smoke detection must notify equipment operators of all distinct threshold conditions/levels. Where operators are not in constant attendance, alarm signals must notify the constantly attended alarm receiving location.

4-15.4 Sprinkler Systems.

4-15.4.1 *Electronic Equipment Areas* must be located in *Facilities* protected by wet pipe automatic sprinklers, except those telecommunication areas identified above.

4-15.4.2 Provide complete wet pipe sprinkler protection throughout the *Electronic Equipment Area*.

4-15.4.3 The *Electronic Equipment Area* must be able to be isolated from other areas by a zone control valve assembly. The control valve assembly must include a control valve, \6\ check valve, /6/ waterflow switch, and inspector’s test connection.

Note: Consult with the DFPE to determine the extent, or boundary, of the *Electronic Equipment Area*.

4-15.4.4 For areas with finished ceilings, use concealed pendent or concealed sidewall sprinklers. For areas without finished ceilings, use upright sprinklers with listed sprinkler guards or concealed sidewall sprinklers.

4-15.4.5 Fire sprinklers must not be provided below raised floors.

4-15.5 Clean Agent Fire Extinguishing System.

Note: Consideration may be given to the use of a supplementary, \2\/2/clean agent fire extinguishing system inside the electronic equipment units or a total flooding system for the room and raised floor.

4-15.5.1 Clean agent fire extinguishing systems must not be utilized as a substitute for automatic sprinklers.

4-15.5.2 Where the requirements of the paragraph entitled “Power and Communication Cabling” are not met, the room and the effected space above the ceiling and below the floor in the room must be protected by a \2\/2/clean agent fire extinguishing system. Where only the below floor area is affected, it is acceptable to provide a \2\/2/clean agent fire extinguishing system below the floor only.

4-15.5.3 *Very Early Warning Smoke Detection* must be used to activate a clean agent fire extinguishing system.

4-15.6 Electronic Equipment Power Disconnect.

4-15.6.1 A means to disconnect power to critical electronic equipment must be provided as required by NFPA 70.

4-15.6.2 The power disconnect method may be by manual means for *Electronic Equipment Areas* with one of the following:

a. Areas that are constantly occupied (24 hours per day, 7 days a week) by personnel familiar with the electronic equipment, or

b. Areas located within a *Facility* that are constantly staffed by a trained response force having ready access to the *Installation* and trained in emergency shutdown procedures.

4-15.6.3 Where multiple rooms that utilize power disconnect simultaneous to water discharge are located in one area, coordinate with the customer on the shutdown requirements. If all adjacent areas may be considered as one, with power to all discontinued simultaneously, the entire area may be protected by one sprinkler system. However, if the customer requires each physically separated area to operate independently of the other, provide separate shutdown capabilities for the separated areas.

4-15.6.4 Electrical equipment must be protected by disconnecting the power upon activation of the fire sprinkler system in the electronic spaces, unless power disconnect is permitted by manual means indicated above.

4-15.6.4.1 The disconnect must be installed downstream of any UPS or similar equipment such that when the disconnect switch is activated, the UPS cannot supply power to the equipment.

4-15.6.4.2 Electrical power disconnect is not required when approved by the *DFPE*.

4-15.7 Power and Communication Cabling.

Power and communication (data) cabling installed in spaces above ceilings or below raised floors must be plenum rated or installed in non-combustible conduit in accordance with NFPA 70.

4-16 ELEVATORS.

4-16.1 General.

This section provides criteria for electric traction, machine room-less equipment and hydraulic elevators. Elevators must comply with the requirements of ASME A17.1 except as modified by this section.

4-16.2 \2\/2/Fire-Resistant Construction.

4-16.2.1 The machine room must have the same fire resistance rating of the elevator shaft it serves.

4-16.2.1.1 This requirement applies to the room containing the elevator controller for machine room-less elevator systems.

4-16.3 Detection.

4-16.3.1 Provide smoke detectors at all elevator lobbies not open or exposed to the exterior (i.e. open parking structures and similar elevator lobbies) and all elevator machine rooms, including where machine room-less controllers are located.

4-16.3.2 Provide smoke detectors at the top of elevator hoistway only when automatic sprinklers are provided in the hoistway.

4-16.3.3 Provide listed control relays within 3 feet (915 mm) of the elevator controller to provide a supervised interface between the fire alarm system and the elevator controller as required by NFPA 72. The wiring between the control relays and the fire alarm control unit must be monitored for integrity as required by NFPA 72.

4-16.3.4 Activation of any elevator machine room, hoistway, or lobby smoke detector must activate the *Facility* fire alarm system and send the affected elevators to the designated floor.

4-16.4 Sprinkler Protection.

4-16.4.1 Where sprinklers are provided in the *Facility*, provide sprinklers for the elevator as noted below.

4-16.4.2 Elevator Machine Room.

4-16.4.2.1 Provide sprinkler(s) with listed sprinkler guard(s) in the machine room(s).

4-16.4.2.2 Provide a supervised shut-off valve, check valve, waterflow switch, and test valve in the sprinkler line supplying the machine room(s). These items must be located outside of and adjacent to the machine room(s).

4-16.4.2.3 Actuation of the waterflow switch must remove power to the elevator(s) served by that machine room, by direct connection from the waterflow switch (i.e. DPDT switch) to the shunt trip breaker.

4-16.4.2.4 The waterflow switch must have no time delay capability.

4-16.4.2.5 Provide an inspector's test connection for each waterflow switch associated with the elevator machine room. Locate the test connection outside the machine room. Route test connection piping to a floor drain location that can accept full flow or where water may be discharged without property damage. Discharge to a floor drain may be permitted only if the drain is sized to accommodate full flow (minimum of 40 gpm). Discharge to service sinks or similar plumbing fixtures is not permitted.

4-16.4.3 Top of Hoistway.

4-16.4.3.1 Provide sprinklers at the top of the hoistway when elevator machinery is located within the shaft.

4-16.4.3.2 When sprinklers are provided at the top of the hoistway, a supervised shut-off valve, check valve, waterflow switch, and test valve must be provided in the sprinkler line supplying the top of hoistway.

4-16.4.3.3 Actuation of the waterflow switch must remove power to the elevator(s) served by that hoistway, by direct connection from the waterflow switch (i.e. DPDT switch) to the shunt trip breaker.

4-16.4.3.4 The waterflow switch must have no time delay capability.

4-16.4.3.5 Provide an inspector's test connection for each waterflow switch. Locate the test connection outside the hoistway. Route test connection piping to a floor drain location that can accept full flow or where water may be discharged without property damage. Discharge to a floor drain may be permitted only if the drain is sized to accommodate full flow (minimum of 40 gpm). Discharge to service sinks or similar plumbing fixtures is not permitted.

4-16.4.3.6 The top of the hoistway and machine room sprinklers may be served by the same control valve assembly and flow switch.

4-16.4.4 Hoistway Pit.

4-16.4.4.1 Provide sprinklers in elevator pits as required by NFPA 13.

4-16.4.4.2 Provide a supervised shut-off valve in the sprinkler line supplying the pit. Locate the valve outside of and adjacent to the pit. Actuation of the pit sprinkler must not disconnect power to the elevator.

4-16.5 Host Nation.

Comply with the requirements of \3\this section and Host Nation requirements. If requirements in this section violates host Nation laws, follow the Host Nation laws. For Host Nation projects in Japan, see Appendix "Criteria for Facility Projects in Japan" in this UFC./3/

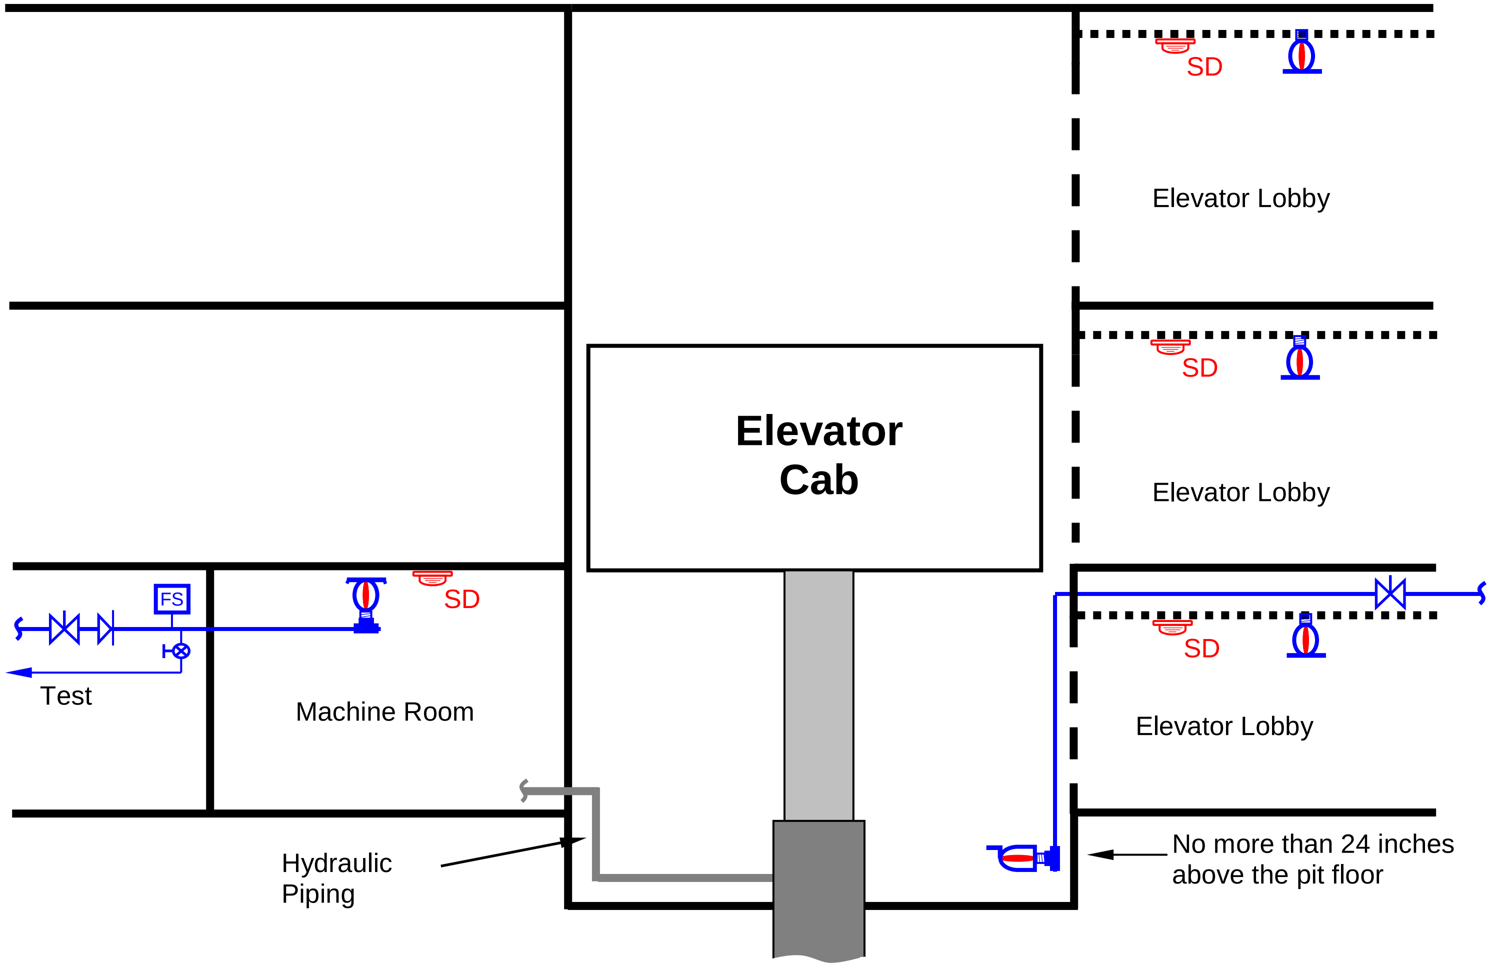

Figure 4-4 Holeless and Roped Hydraulic Elevator

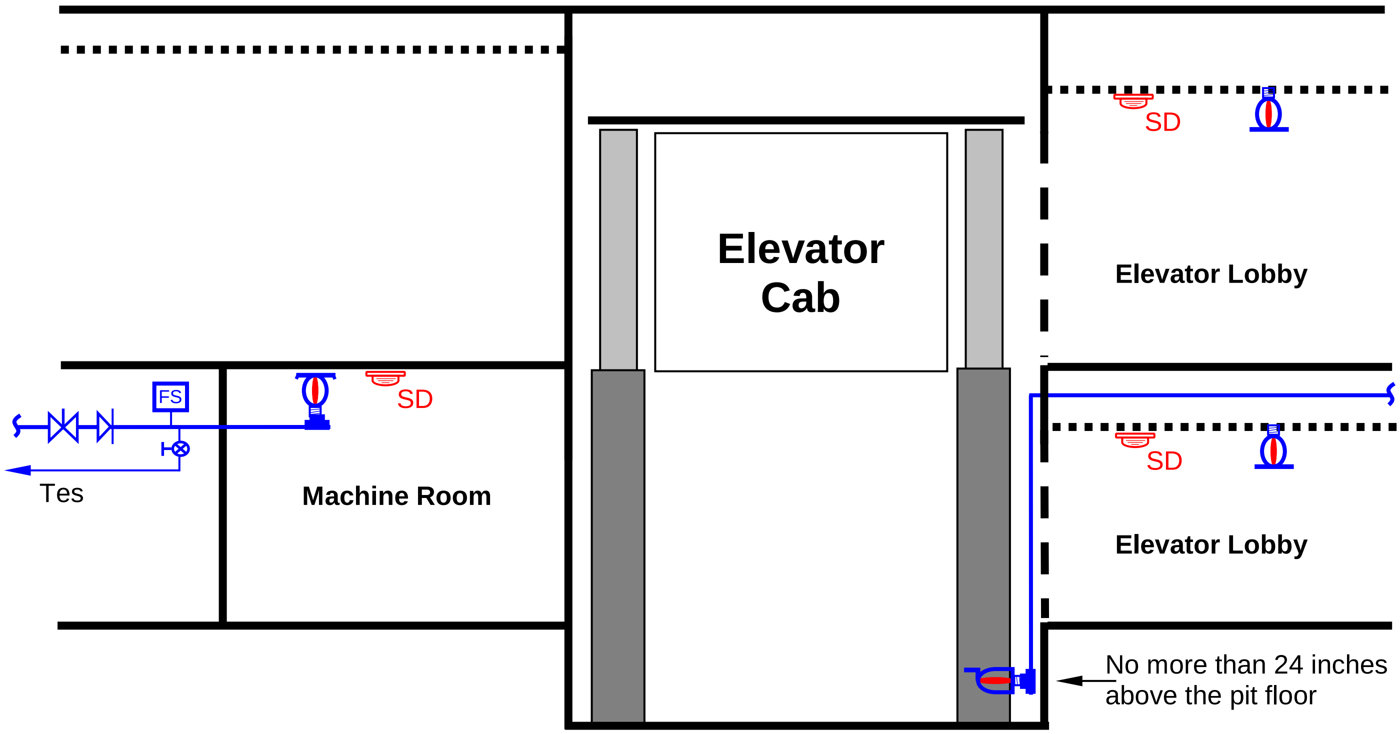

4-17 EMERGENCY SERVICES COMMUNICATIONS CENTERS.

Facilities and equipment that are used for the receipt of alarm signals and telephone calls for assistance, and dispatching of fire, police, or emergency medical services personnel and equipment must comply with this UFC and NFPA 1221.

4-18 FAMILY HOUSING.

4-18.1 General.

This section includes \3\all family housing/3/.

4-18.2 Off-*Installation* Family Housing within the United States and its Territories.

Family housing located outside military *Installations* or bases must comply with provisions of this section and must comply with applicable local fire and building codes when the local fire department has the primary responding responsibility or a local building permit is required.

4-18.3 Family Housing Outside the United States and its Territories and Possessions.

Family housing outside the United States and its territories and possessions, constructed or leased-constructed, must comply with provisions of this section and the Host Nation fire protection requirements.

4-18.4 DoD-Leased Family Housing.

4-18.4.1 DoD personnel occupying DoD-leased housing deserve the same level of protection as those in DoD-owned housing. Implementation of these standards is therefore mandatory for all DoD-leased housing. \5\ /5/This requirement does not apply to housing leased by individuals.

4-18.4.2 New Buildings.

Buildings that are built to lease to DoD must comply with the standards for new construction.

4-18.4.3 Existing Buildings.

For new leases or renewals of leases of existing *Facilities*, the *Facilities* must comply with the requirements for new construction.

4-18.5 *Multi-Family Housing*.

Multi-Family Housing must comply with the IBC and NFPA 101 as required by other sections of this UFC.

4-18.6 One- and Two-Family Housing.

One- and two-family housing must comply with the IRC.\2\

4-18.7 /2/Cooking Areas.

A range top extinguishing system is not required within family housing for cooking areas provided with residential appliances.

4-19 FOOD PREPARATION IN *FACILITIES*.

4-19.1 Commercial Cooking Equipment.

4-19.1.1 Hood and duct systems for commercial cooking equipment that produces smoke or grease-laden vapors must comply with NFPA 96.

4-19.1.2 Range hood fire extinguishing systems must be wet chemical or water assisted wet chemical designed and installed in accordance with NFPA 96.

4-19.2 Residential Cooking Equipment.

4-19.2.1 Non-sprinklered Areas, Other than Housing.

4-19.2.1.1 Residential type range top cooking surfaces must be equipped with a UL 300A listed residential range top extinguishing system or the cooking surface must be equipped with burners and controls that have their temperature limited to a maximum temperature of 662 degrees F (350 degrees C).

4-19.2.1.2 The extinguishing system must be connected to the *Facility* fire alarm system, if provided, to sound a general *Facility* fire alarm and must automatically shut off all sources of fuel and electric power that produce heat to the equipment being protected by that unit.

4-19.2.2 Sprinklered Areas, Other than Housing.

4-19.2.2.1 Residential range top extinguishing systems are not required in sprinklered areas.

4-19.2.2.2 If a residential range top extinguishing system is provided, it must be connected to the *Facility* fire alarm system to sound a general *Facility* fire alarm and must automatically shut off all sources of fuel and electric power that produce heat to the equipment being protected by that unit.

4-19.2.3 Housing.

See "Personnel and Family Housing" section of this UFC for requirements related to cooking facilities in housing.

4-20 HAZARDOUS MATERIALS AND HAZARDOUS WASTE.

4-20.1 General.

Hazardous materials and hazardous waste (hazardous materials) include flammable and combustible liquids, flammable and combustible gases, flammable solids as well as other materials that are classified as hazardous materials. The requirements of this section apply to the storage or use of hazardous materials in excess of the maximum allowable quantities permitted by NFPA 400.

4-20.1.1 Comply with the requirements of NFPA 400, except as noted in this section.

Note: As defined in NFPA 30, hazardous materials storage lockers and premanufactured storage buildings may be used to increase the maximum allowable quantities in accordance with NFPA 400.

4-20.1.1.1 Provide protection for facilities storing flammable and combustible liquids and other petroleum oil lubricant (POL) products in accordance with NFPA 30.

4-20.1.1.2 Class IIIB combustible liquids must be protected as required by NFPA 30 for Class IIIA combustible liquids in accordance with UFC 3-460-01 and NFPA 30.

4-20.1.2 A single building is often used for storage of both flammable and combustible liquids and hazardous materials. Requirements for the storage of hazardous waste are separate and distinct from the storage of hazardous materials.

4-20.1.3 Comply with the requirements of UFC 4-440-01.

4-20.1.4 All other hazardous materials storage and use must comply with NFPA 400.

4-20.2 Hazardous Materials Storage Areas.

4-20.2.1 Maximum Storage Height and Arrangement.

The maximum allowable height and arrangement for storage of hazardous materials must be in accordance with NFPA 400.

4-20.2.2 Fire Protection.

4-20.2.2.1 Complete automatic sprinkler protection must be provided throughout all hazardous material areas regardless of area or construction type.

4-20.2.2.2 \4\/4/Where the rack storage arrangement for hand picking operations provides multiple levels of storage less than 6 feet (1.8 m) above the walking surface and in-rack sprinklers are required for the storage arrangement, provide one extra row of in-rack sprinklers in the longitudinal flue space at the 3 feet (915 mm) level.

4-20.2.3 Hazardous material storage areas or rooms must be identified in accordance with NFPA 704.

4-20.2.4 In rooms storing water reactive materials, provide automatic sprinklers that can be isolated with an indicating valve. Locate the indicating valve outside the water reactive storage area.

4-20.3 Hazardous Waste Storage *Facilities*.

For hazardous waste storage *Facility* requirements, comply with NFPA 400 \6\ and UFC 4-440-01, /6/ except as noted below.

4-20.3.1 Fire Protection.

The following minimum criteria must be provided:

a. Exterior walls must consist of 4-hour fire-resistive construction when the *Facility* is attached to a structure or it is located within 10 feet (3 m) of another building or property line.

b. Exterior walls must consist of 2-hour fire-resistive construction when the *Facility* is located more than 10 feet (3 m) but less than or equal to 50 feet (15.3 m) from a building or property line.

c. Exterior walls must be of noncombustible construction when the *Facility* is more than 50 feet (15.3 m) from another building or property line.

d. Interior walls/ceilings must be 4-hour fire barriers if the *Facility* shares at least one wall with a *Facility* that houses other occupancies.

e. Interior walls/ceilings must be a minimum 2-hour fire barrier when the area of the room is greater than 300 ft^2 (28 m^2) and the *Facility* is not located within a structure that houses other occupancies.

f. Interior walls/ceilings must be a minimum 1-hour fire barrier when the area of the room is 300 ft^2 (28 m^2) or less and the *Facility* is not located within a structure that houses other occupancies.

4-20.3.2 Sprinkler Protection.

Install sprinkler systems suitable for a corrosive environment.

4-20.4 Spill Control and Containment.

Provide spill control and containment complying with NFPA 400 for hazardous materials and hazardous waste storage areas.

4-20.5 Electric Wiring and Equipment.

\2\Where flammable liquids are dispensed or transferred between containers, electric wiring and equipment must be suitable for classified locations in accordance with NFPA 70. Where flammable liquids are not dispensed or transferred between containers, unclassified locations for electrical equipment may be provided./2/

4-20.6 Ventilation.

4-20.6.1 Ventilation must be provided for all hazardous materials storage areas. Ventilation must meet the requirements of NFPA 400.

4-20.6.2 Fan motors located outside of the hazardous materials storage area are permitted to be classified for ordinary locations in accordance with NFPA 70.

4-20.7 Prefabricated Structures.

Prefabricated structures (portable or permanent) are permitted to store hazardous materials and hazardous waste provided they meet the requirements of NFPA 400.

4-20.8 Outdoor Storage Limitations and Separation.

4-20.8.1 \2\Outdoor storage must comply with all of the following:

4-20.8.1.1 The building or structure must be constructed of noncombustible materials, and,

4-20.8.1.2 Walls must not obstruct more than two sides of the structure, or, walls may obstruct portions of multiple sides of the structure, provided that the sum of the walls does not exceed 50 percent of the structure's perimeter./2/

4-20.8.2 The outdoor storage area must not be more than 400 feet (122 m) long or wide and each area must be separated by 100 feet (30.5 m).

4-20.8.3 No containers or portable tanks in a pile are permitted to be more than 200 feet (61 m) from a 40 feet (12.2 m) wide minimum fire lane.

4-20.8.4 Fire hydrants must be installed in accordance with NFPA 24, but spaced not more than 300 feet (91 m) apart. Provide a minimum of two hydrants located so that protected exposures can be reached through hose runs not exceeding 300 feet (91 m).

4-21 HIGH-RISE BUILDINGS.

4-21.1 General.

High-rise buildings must be provided with smokeproof enclosures. Design and install in accordance with NFPA 101. Design and install stair pressurization in accordance with NFPA 92.

4-21.2 Emergency Command Center.

4-21.2.1 Emergency command centers must comply with the following:

a. Provided with exterior and interior access.

b. Enclosed by a 1-hour fire-rated barrier.

c. Provide a minimum area of 200 ft^2 (18.5 m^2) with a minimum dimension of 10 feet (3 m).

4-21.2.2 In addition to the requirements of NFPA 101, the emergency command center must also include the following:

a. Air-handling system status indicators and controls.

b. Fire department control panel for smoke control systems (includes visible status indicators and controls).

c. Schematic building plans indicating the typical floor plan and detailing the building core, means of egress, fire protection systems, fire-fighting equipment and fire department access.

4-21.3 Fire Service Access Elevators.

When the occupied floor level exceeds 120 feet (36.5 m) above lowest fire department vehicle access, provide at least two fire service access elevators that comply with Fire Service Access Elevator requirements in the IBC.

Mechanical penthouses and mechanical stories are not considered occupied floor levels.

4-21.4 Buildings Greater than 420 feet (128 m).

The provisions of this UFC are not intended to apply to buildings greater than 420 feet (128 m) in height. For buildings exceeding 420 feet (128 m) in height, the *DFPE* must be consulted for any additional requirements.

4-22 HISTORIC FACILITIES.

4-22.1 General.

Projects in \2\historic facilities are expected to meet the requirements of the chapter entitled “Existing Facilities” in this UFC./2/

4-23 HYDRAULIC SYSTEMS.

4-23.1 General.

Any combustible liquids under pressure must be treated as a flammable liquid.

4-23.2 Petroleum-Based Hydraulic Fluids.

4-23.2.1 Provide automatic sprinklers directly over and at least 20 feet (6.1 m) beyond the hydraulic equipment. Complete sprinkler protection is required if the structure is of combustible construction, regardless of floor area. Sprinklers may be omitted near a single small system or multiple adjacent small systems not exceeding 100 gal (380 L) aggregate capacity, and if the construction is noncombustible and ignition sources are not normally present, and provisions exist for automatic or manual shutdown of the system(s).

4-23.2.2 An automatic switch, activated by sprinkler waterflow alarm, fusible link, or other fire detector, must be provided to shut down the hydraulic system if there is 100 gal (380 L) or more aggregate capacity of hydraulic fluid.

4-23.3 Hydraulic Test Systems.

4-23.3.1 For hydraulic systems that use pressures exceeding 200 psi (1380 kPa), SAE 1010 dead-soft, cold-drawn, seamless-steel tubing (or equivalent) must be used. A safety factor of eight over normal working pressure must be used. For systems with working pressures in excess of 2,500 psi (17,240 kPa), a factor of safety of four times the burst pressure is acceptable. Tubing is preferable to pipe. Tubing can be bent to fit in restricted spaces with a minimum number of fittings, reducing the number of possible leakage points. Solderless, steel fittings of the flareless "locking-sleeve" type or flare type must be used.

4-23.3.2 Use of threaded pipe must be avoided. Where threaded connections are used, requirements of ANSI B1.20.1 must be met. A safety factor of eight over normal pressure must be used.

4-23.3.3 Tubing runs must have as few bends as possible, but must have at least one bend to provide for thermal expansion and contraction. The minimum radius of tube bend must be three tube diameters.

4-23.3.4 Where hose must be used for flexible connections, it must be steel reinforced, designed for the hydraulic fluid being used, and capable of withstanding five times the actual operating pressure. Hose couplings and fittings and minimum bending radius must be in accordance with the hose manufacturer's instructions. Hose must be installed so as not to rub against objects as a result of machine movement, vibration, or pressure surges.

4-23.3.5 Piping and tubing must be anchored or secured to minimize failure due to vibration. Pipe supports must not prevent normal thermal expansion.

4-23.3.6 There must be an accessible, well-marked, emergency shutoff switch for each pump.

4-23.3.7 Provide an automatic shutoff switch to deactivate hydraulic pump upon loss of pressure.

4-24 \2\HYDROELECTRIC GENERATING PLANTS.

4-24.1 Hydroelectric Generating Plants.

Hydroelectric plants must comply with the section in this UFC for "Power Generating And Utilization Equipment" except as modified in this section. Also, hydroelectric plants must comply NFPA 850, especially the chapter for Identification and Protection of Hazards for Hydroelectric Generating Plants, except as modified by this section.

4-24.2 Indoor Transformers

Indoor transformer equipment spaces such as transformer vaults must contain the appropriate fire barrier rating for all partitions and those items installed in the partitions.

4-24.2.1 Automatic fire suppression systems are not required for the following indoor transformers.

a. Dry type indoor transformers.

b. FMDS 5-4 "less flammable" fluid filled transformers contained within 3-hour fire rating barriers.

c. Transformers rated less than 35 kV containing less than 100 gallon capacity and contained within 3-hour fire rating barriers.

4-24.2.2 Automatic fire suppression systems must be provided for all other indoor transformers rated 35 kV or greater and all must be enclosed by 1-hour fire-rated barriers. Fire suppression system type must be one of the following.

a. Water mist system with operating pressure greater than 175 psi in accordance with NFPA 750.

b. Clean agent in accordance with NFPA 2001.

4-24.3 Outdoor Transformers.

Structures and equipment in the vicinity of outdoor oil-filled transformers must be protected by separation, fire barriers, or water spray systems.

4-24.3.1 Where outdoor transformers are located on the hydroelectric plant structure and not protected by water spray systems, provide a structural analysis of the exposed supporting and adjacent structure(s) proving that these structure(s) can withstand the design fire without collapse or severe damage. The design fire must be based upon the "Heat Flux Calculations" of ANSI/IEEE 979. Severe damage is defined as that preventing occupancy or facility use following a fire or based upon an estimated repair cost as compared to estimated project cost.

4-24.3.2 Fire barriers may be constructed of materials other than concrete block or reinforced concrete construction where the materials provide 2-hour fire resistance rating. Fire barriers must be designed to resist wind loads.

4-24.3.3 Where outdoor transformers are located on the hydroelectric plant structure containment must be provided for the transformer oil volume plus the 24 hour, 25 year stormwater volume.

4-24.3.4 Automatic fire suppression water spray systems must comply with the following:

a. The water supply must be adequate for 2 hours of operation of the water spray system at maximum demand. A hose stream demand of 500 gpm (1900 L/min) must only be included for existing facilities with existing hydrants for reuse or replacement.

b. Containment must be provided for the water volume produced by the water supply for 2 hours of operation.

4-24.4 Hydroelectric Generators.

All hydroelectric generators and ancillary equipment contained in generators must be protected by one of the following automatic fire suppression systems regardless of winding insulation material construction.

a. High or Low Pressure CO2 system in accordance with NFPA 12.

b. Clean Agent in accordance with NFPA 2001.

4-24.5 Oil Storage and Oil Purification Rooms.

Oil storage and oil purification rooms must be protected by one of the following automatic fire suppression systems.

a. Water mist system with operating pressure greater than 175 psi in accordance with NFPA 750.

b. Clean Agent in accordance with NFPA 2001.

4-24.6 Paint and Flammable Liquid Storage Rooms.

Paint and flammable liquid storage rooms must be protected with automatic fire suppression as specified for oil storage and oil purification rooms./2/

4-24.7 \5\ Fire Alarm.

For fire alarm, detection, and notification systems, provide secondary power under supervisory conditions for 24 hours and all alarm devices for an additional 15 minutes. /5/

4-25 HYDROGEN FACILITIES.

4-25.1 Liquid Hydrogen (LH_2).

Install LH_2 storage and fueling in accordance with NFPA 52 and FM Global Data Sheet 7-91.

4-25.2 Gaseous Hydrogen (GH_2).

Install GH_2 compression, gas processing, and storage in accordance with NFPA 52 and FM Global Data Sheet 7-91.

4-25.3 Indoor Fueling or Dispensing.

Indoor fueling or dispensing of LH_2 or GH_2 is prohibited.

4-26 HYPERBARIC AND HYPOBARIC CHAMBERS.

4-26.1 Hyperbaric Chambers.

Hyperbaric chambers must comply with NFPA 99 Chapter entitled "Hyperbaric Facilities". Incorporate criteria contained in UFC 4-159-01N and SS 521-AA-MAN-010 into the design of hyperbaric chambers.

4-26.2 Hypobaric Chambers.

Hypobaric chambers must comply with NFPA 99B.

4-27 LABORATORIES.

4-27.1 General.

Laboratories using chemicals must comply with NFPA 45.

[C] 4-27.1

The occupancy specific maximum allowable quantities in NFPA 45 take precedence over the general maximum allowable quantities in NFPA 1.

4-28 HISTORIC RESOURCE LIBRARIES, ARCHIVES, AND FACILITIES.

4-28.1 General.

4-28.1.1 Comply with NFPA 909 or NFPA 232.

For Navy projects, comply with FC 4-760-10N.

4-28.1.2 Libraries storing materials that are not culturally significant (e.g., primary or secondary school library) are not required to comply with this section.

4-28.1.3 Facilities for the restoration of culturally significant materials must comply with this section.

4-28.1.4 Use noncombustible wall and ceiling finish materials.

4-28.1.5 Provide complete automatic wet pipe sprinkler protection throughout *Facilities* containing libraries.

4-28.1.6 Water mist fire protection systems complying with paragraph entitled "Water Mist Fire Protection Systems" in this UFC may be used in those areas of the *Facility* containing rare or unique materials that are particularly susceptible to water damage.

4-29 LIMITED ACCESS AND UNDERGROUND STRUCTURES.

4-29.1 General.

Comply with the requirements of NFPA 101, except as noted below.

4-29.2 Limited Access Structures.

4-29.2.1 A manually activated smoke exhaust system must be provided for structures three stories or more in height. The smoke exhaust system must be designed for a minimum of six air changes/hour throughout the entire building.

4-29.2.2 Provide complete automatic sprinkler protection for all limited access structures regardless of floor area or construction type.

4-29.3 Underground Structures.

4-29.3.1 A manually activated smoke exhaust system must be provided when there are two or more occupied levels or when an occupied level is greater than 30 feet (9.1 m) below grade plane. The smoke exhaust system must be designed for a minimum of six air changes/hour throughout underground occupied levels.

4-29.3.2 Provide complete automatic sprinkler protection for all occupiable underground structures regardless of floor area or construction type.

4-30 MEDICAL FACILITIES.

These facilities must conform to UFC 4-510-01 and NFPA 101.

4-31 MILITARY OPERATIONS ON URBAN TERRAIN (MOUT) TRAINERS.

The DFPE must be consulted during the planning phase to determine what specific fire protection and life safety requirements are necessary.

Note: These structures are unique as they can be designed and constructed to mimic conditions in other locations. Guidance can be found in NFPA 101 for Special Amusement buildings.

4-32 MISSILE ALERT FACILITIES (MAF).

4-32.1 Sprinkler Protection.

Protect all missile alert facilities with a sprinkler system designed and installed in accordance with NFPA 13R. Systems must be supplied from the existing domestic water storage tank; a separate water storage tank is not required. Use dry pendent or dry sidewall heads for rooms/spaces exposed to freezing temperatures.

4-32.2 Heat Detectors.

Thermal detection devices must be provided in rooms, areas and spaces that are not protected by automatic sprinkler protection in accordance with NFPA 13R.

4-32.3 Fire Hydrants.

Provide a dry fire hydrant installed on the domestic water tank to allow local fire departments the ability to draft firefighting water during emergencies.

4-33 MORALE WELFARE AND RECREATION FACILITIES (MWR).

Clubs, bowling centers, craft shops (including hobby shops, woodworking, auto centers), and similar recreational facilities with an occupant load of 50 or more must be protected with automatic sprinkler systems regardless of floor area or construction type.

4-34 NATURAL GAS SERVICE.

4-34.1 General.

4-34.1.1 Gas service mains must be installed in accordance with NFPA 54 and NFPA 58.

4-34.1.2 Gas service mains are not permitted within the perimeter of foundation lines.

4-34.1.3 Provide natural draft cross ventilation for *Facility* crawl spaces containing gas service piping.

4-34.1.4 Raise supply connections from the gas service mains above grade outside the foundation wall\2\./2/

4-34.1.5 Locate pressure regulators outside of the *Facility* or vent to the outside away from air intakes.

4-35 \2\NAVIGATION LOCKS \5\AND LAKE PROJECTS/5/.

\5\This section applies to navigation locks and dams on rivers and other waterways, as well as operating control towers at lake projects.

4-35.1 General.

4-35.1.1 Protection of Petroleum Based Hydraulic Fluid Power Equipment and Hydraulic Fluid Reservoir. Protect hydraulic reservoir and pumping equipment with fire suppression system or separate from remainder of facility by fire barrier walls. A fire suppression system must be an automatic sprinkler, water mist, clean agent, or other suppression system approved by DFPE. Fire barrier walls must be 2-hour rated concrete construction with opening protection.

4-35.2 Navigation Locks./5/

4-35.2.1 Pump Requirements.

Two fire water pumps of the equal size are required, one of which must be redundant. Pump sizing must be based on either the gate spray sprinkler systems or hose stations, whichever is greater. Minimum pump design flow must be 250 gpm, to serve the five hose stations with each flowing 50 gpm. The minimum pump pressure must be 100 psi, and increased as required to provide at least 60 psi at each hose station.

4-35.2.2 Hose Station Requirements.

Hose stations in accordance with NFPA 14 must be located 25 feet upstream and downstream of each gate. These hose stations must be equally spaced at no more than 300 feet intervals along the walls on both sides of the lock chamber. Hose stations will consist of 150 feet of hose in a permanent cabinet. Hose must be 1-1/2 inch synthetic lined and conform to NFPA 1961.

4-35.2.3 Miter Gate Spray System Requirements.

Miter gates (upstream and downstream in lock chamber) must be fitted with a fixed gate spray sprinkler system for coverage of 0.25 gpm/sf of gate. Spray nozzles in accordance with NFPA 15 must be open type with a flat spray pattern operating at 45 psi and a minimum angle of 50 degrees. Nozzle must be brass or stainless steel and sized and spaced to provide complete coverage. Sprinkler piping and bracing must be stainless steel in accordance with NFPA 13 and protected against damage. Connect gate piping with a stainless steel swivel joint with stainless steel ball bearings and grease fittings for lubrication and installed to completely drain. Gate spray system must be separated from hose stations, using a motorized valve.

4-35.2.4 Aboveground Piping Requirements.

Aboveground piping and embedded pipe must be corrosion resistant and in accordance with ASTM A312, Schedule 40. All fittings must have a minimum rated working pressure of 175 psi.

4-35.2.5 Underground Piping Requirements.

Underground piping must be cement-mortar lined ductile-iron with a 150 psi working pressure and in accordance with AWWA C151 and C104. Pipe will be polyethylene encasement in accordance with AWWA C105.

4-35.2.6 Fire Alarm System Requirements.

Provide a fire alarm system in accordance with NFPA 72. The system must consist of an outside electric horn with alarm switches located strategically throughout the project. Electric power for the alarm must be taken from the house-current supply line on the line side of the main switch through an independent switch and circuit breaker. Provide automatic dialers, to facilitate a quick emergency response.

4-35.2.7 Supply Water Intake Requirements.

Water supply to fire pumps may be from the river. If the area is contaminated by zebra mussels, then the fire pump intake must have suitable control strategies implemented. Provide intakes with double type strainers and exterior stainless steel screens./2/

4-36 OXYGEN.

4-36.1 General.

4-36.1.1 Comply with NFPA 55 and NFPA 400, except as modified by this UFC.

4-36.2 Gaseous oxygen (GOX).

4-36.2.1 Bulk GOX Systems.

4-36.2.1.1 Comply with provisions of NFPA 55 for the installation and location of bulk GOX.

4-36.2.1.2 Bulk GOX must be located either above ground and outdoors, or installed in a building of fire-resistant construction that is adequately vented and is used exclusively for storing GOX.

4-36.2.1.3 Containers and associated equipment for Bulk GOX should not be located beneath or be exposed to the failure of electric power lines or piping containing any flammable liquid or gas.

4-36.2.2 GOX System Design.

4-36.2.2.1 GOX systems must be designed to control potential ignition energy mechanisms.

4-36.2.2.2 Automatic safety devices such as system safety valves, flow regulators, and equipment safety features must be installed to automatically control hazards.

4-36.2.2.3 Alarms and warning systems must monitor the parameters of the storage, handling and use of GOX that may endanger personnel and cause property damage.

4-36.2.2.4 System flow velocity in GOX must not exceed 100 feet/second.

4-36.2.2.5 Quick-acting valves must not be used to start or stop GOX systems.

4-36.2.2.6 Remotely operated shutoff valves must be operated only using inert gas or air, and oxygen gas must never be used to operate valves.

4-36.3 Liquid Oxygen (LOX).

4-36.3.1 Liquid Oxygen Tanks.

4-36.3.1.1 Comply with the applicable provisions of NFPA 51 and NFPA 99, regardless of occupancy.

4-36.3.1.2 Fixed tanks having combined capacity of 100 gal (380 L) or less or portable tanks, \2\/2/must comply with applicable provisions NFPA 51 and NFPA 99, regardless of occupancy.

4-36.3.1.3 Where tanks have a single or combined capacity of more than 100 gal (380 L), tanks must be fixed except as modified in the paragraph entitled "Oxygen Bulk Tanks".

4-36.3.2 Oxygen Bulk Tanks.

Use fixed bulk tanks \2\or portable high-pressure bulk units/2/ having a single or combined capacity of more than 100 gal (380 L) that conform to NFPA 55 and NFPA 99 except as modified \2\below:

4-36.3.2.1 Locate bulk oxygen storage out of doors or in a detached noncombustible structure used solely for this purpose and separated as follows:

a. 75 ft (23 m) from:
   1) Aboveground ignitable-liquid tanks of 1,000 gal (3.8 m^3) or greater capacity.
   2) Aboveground tanks of liquefied flammable gases of over 1,000 gal (3.8 m^3) aggregate water capacity.
   3) Low-pressure flammable-gas storage holders of 5,000 ft^3 (140 m^3) or greater capacity.
   4) Unsprinklered combustible buildings.
   5) Combustible yard storage.
   6) Wood exterior walls.

b. 25 ft (7.6 m) from:
   1) Aboveground ignitable-liquid tanks of less than 1,000 gal (3.8 m^3) capacity.
   2) Aboveground tanks of liquefied flammable gases of 1,000 gal (3.8 m^3) or less aggregate water capacity.
   3) Filling or vent connections to underground ignitable liquid tanks.
   4) Low-pressure flammable-gas storage holders of less than 5,000 ft^3 (140 m^3) capacity.
   5) Sprinklered buildings or buildings with both noncombustible construction and light or ordinary hazard occupancy.
   6) High-pressure bulk flammable-gas storage.
   7) Ignitable-liquid unloading stations.

c. 5 ft (1.5 m) from:

1) 1) Noncombustible construction having blank walls 10 ft (3 m) above and 10 ft (3 m) on each side of the equipment.

4-36.3.2.2 Regulators and other control equipment are permitted to be located indoors in a noncombustible building detached or cut off from main buildings or combustible storage. Cutoffs should have at least a 1 hour fire resistance rating.

4-36.3.2.3 Locate outdoor oxygen-storage equipment on a base of crushed stone or concrete./2/

4-36.3.3 \2\Storage/Parking of LOX Carts/2/.

Separation distances for LOX \2\/2/carts are as follows:

4-36.3.3.1 A minimum of 100 feet (30.5 m) from aircraft parking, fueling, or servicing areas.

4-36.3.3.2 A minimum of 100 feet (30.5 m) from any flammable or combustible liquids handling, servicing, processing, or storage area.

4-36.3.3.3 A minimum of 50 feet (15.3 m) from any building.

4-36.3.4 \2\Parking of LOX Vehicles/2/.

Parking for \2\LOX/2/ vehicles that service fixed tanks must be designed in accordance with the separation requirements of NFPA 55 for fixed bulk tanks except as modified in the paragraph entitled "\2\ Storage/Parking of LOX Carts"/2/.

4-36.3.5 LOX Storage for Propellant Applications.

Use liquid oxygen storage for propellant applications that comply with 29 CFR 1910.109 except as modified in the paragraph entitled "LOX Tank and Cart Storage/Parking".

4-36.4 Combined LOX and GOX *Facilities*.

LOX and GOX can use the same *Facility* provided they meet the requirements for each.

4-37 PERSONNEL HOUSING AND SIMILAR LODGING FACILITIES.

4-37.1 General.

This section is applicable to all personnel housing and similar lodging facilities where sleeping occurs, regardless of the number of occupants sleeping.

\6\ /6/ These facilities are commonly referred to as *Billeting* and include barracks, dormitories including apartment style, lodges, temporary or transient living facilities, and sleeping quarters. For duty, and similar rooms, \6\ provide smoke detection in duty room sleeping space and outside the space similar to the follow Section titled “Smoke Detection” below. /6/

4-37.2 Automatic Sprinkler Protection.

Complete automatic sprinkler protection must be provided, regardless of floor area or construction type.

4-37.3 Smoke Detection.

4-37.3.1 Provide smoke detectors in accordance with NFPA 101.

4-37.3.2 A smoke detector must be provided for each sleeping room and the shared/common space of a suite regardless of occupancy or the presence of other detection or protection systems in the *Facility*.

4-37.3.2.1 Upon detection of smoke, an audible signal must be activated in all sleeping rooms and the shared/common space(s) within the *Dwelling Unit*, send a distinct sleeping room smoke detector signal to the *Facility* fire alarm control panel and to the *Installation* fire reporting system, but not activate the *Facility* notification appliances.

Note: The signal to the FACP and fire reporting system may be an alarm or supervisory signal, as determined by the *DFPE*.

4-37.3.2.2 The audible signal in the dwelling unit must be low frequency as required by NFPA 72.

4-37.3.3 Primary and secondary power for the smoke detectors must be provided from the fire alarm control panel. Detectors that are not powered from the fire alarm control panel are not permitted.

4-37.3.4 Activation of a smoke detector in a room dedicated as an ABA/ABAAG accessible room must also activate all visible notification appliances in the room.

4-37.3.5 Sounder bases must not be provided in open sleeping bays with voice evacuation notification. Activation of smoke detector in open sleeping bays must activate building-wide notification appliances.

4-37.4 Cooking Areas.

4-37.4.1 A range top extinguishing system is not required for cooking equipment provided with residential appliances in fully sprinklered *Facilities*. This applies to both the *Dwelling Units* and in common areas.

4-37.4.2 In non-sprinklered areas, a range top extinguishing system must be provided for cooking equipment, regardless of the location in the building.

4-38 PESTICIDE STORAGE AND HANDLING FACILITIES.

4-38.1 General.

4-38.1.1 Locate facilities or operations involving the storage, mixing, or handling of non-flammable pesticides a minimum of 100 feet (30.5 m) from the nearest *Facility* or occupied structure.

4-38.1.1.1 Facilities of Type I construction as defined by the IBC, may be located less than 100 feet (30.5 m) from the nearest *Facility* or occupied structure, but not less than 30 feet (9.1 m) in any case.

4-38.1.1.2 Facilities protected by an automatic sprinkler system may be located less than 100 feet (30.5 m) from the nearest *Facility* or occupied structure, but not less than 30 feet (9.1 m) in any case.

4-38.1.2 Existing facilities involving the storage, mixing, or handling of non-flammable pesticides are permitted in a *Facility* when all the following are provided:

a. The *Facility* is completely protected, including the pesticide area, by an automatic sprinkler system.

b. The pesticide area is separated by not less than one-hour fire-rated construction from the remainder of the *Facility*.

4-38.1.3 Comply with local environmental regulations related to containment of fire sprinkler water discharge.

4-39 PETROLEUM, OILS & LUBRICANTS (POL) FACILITIES.

4-39.1 General.

4-39.1.1 Petroleum fuel facilities consist of but not limited to facilities that receive, store, distribute, or dispense liquid fuels. This includes all storage tanks from bulk storage tanks to individual storage tanks and includes fuel tanks supporting diesel generators, day tanks, and protected aboveground tanks.

4-39.1.2 POL *Facilities* must comply with UFC 3-460-01.

4-39.1.3 Warehouses that store flammable or combustible liquids, regardless of container size or configuration, must comply with the requirements in this UFC.

4-39.2 Fuel Testing Laboratories.

Laboratories must comply with the requirements of \6\ UFC 4-310-03. /6/

4-39.3 Fuel Piers.

Protection for piers with fixed piping systems used for the transfer of flammable or combustible liquids must be in accordance with the following:

a. UFC 4-152.01.

b. UFC 4-150-02.

c. NFPA 30.

d. NFPA 30A.

e. NFPA 307 (if liquids are handled in bulk quantities across general purpose piers and wharves).

f. "Guide on Marine Terminal Fire Protection and Emergency Evacuation", Oil Companies International Marine Forum.

4-40 POWER GENERATING AND UTILIZATION EQUIPMENT.

4-40.1 Power Generating Plants.

Power generating plants must comply with NFPA 850.

4-40.2 Substations.

4-40.2.1 Comply with NFPA 70, NFPA 850 and FMDS 5-4.

4-40.3 Stationary Combustion Engines, Gas Turbines, and Generators.

Internal combustion engines, gas turbines, and generators must comply with NFPA 37 and NFPA 110.

4-40.4 Indoor Transformers.

Indoor transformers must be installed and located in accordance with NFPA 70.

4-40.5 Outdoor Transformers.

4-40.5.1 Outdoor Transformers must be installed and located in accordance with NFPA 70 and ANSI/IEEE 979, except as modified by this UFC.

4-40.5.2 Where transformers are located on or above noncombustible roofs, suitable curbed and drained concrete mats or welded steel plates must be underneath units and located so as not to expose roof structures.

4-40.5.3 Oil-filled transformers must not be installed on combustible roofs.

4-40.5.4 Buildings or equipment exposed by outdoor liquid-insulated transformers must be protected either by separation, a fire barrier, or automatic fire suppression.

4-40.5.4.1 When separation is utilized, the separation distance between *Facilities* and transformers must be as indicated in Table 4-4. The horizontal distance is measured from the edge of the transformer to the *Facility*.

4-40.5.4.2 The separation distance between other equipment (including adjacent transformers) must be as indicated in Table 4-5.

4-40.5.4.3 When fire barriers are utilized, comply with the following:

a. Barriers must be of concrete block or reinforced concrete construction adequate for 2-hour fire resistance.

b. The exposed wall must extend the horizontal and vertical distances from the transformer specified in Table 4-4.

c. Roofs exposed to oil-insulated transformers must be Class A rated for the horizontal distance noted in Table 4-4 for non-combustible construction.

d. For equipment, barriers must extend 1-foot (305 mm) vertically and 2 feet (610 mm) horizontally beyond transformer components that could be pressurized as the result of an electrical fault. This will typically include bushings, pressure relief vents, radiators, tap changer enclosures, and other similar devices.

4-40.5.4.4 When automatic fire suppression is utilized, it must comply with the following:

a. A discharge density of 0.30 gpm/ft^2 (12.2 L/min/m^2) must be provided over transformer surfaces, except areas under the transformer.

b. The water supply must be adequate for 2 hours and must include a hose stream demand of 500 gpm (1900 L/min).

c. Components of the water spray system, such as piping, spray nozzles, and other components must be a minimum of 18 in. (0.45 m) from the transformer.

d. Piping must not pass over the top of the transformer or be exposed by tank relief vents.

e. Do not direct water spray nozzles at bushings.

f. For multiple transformer installations, the water spray system must be designed based on simultaneous operation of the water spray systems for the transformers not meeting the separation distances of Table 4-4.

g. When the ground around the transformer is non-absorbing, water spray must be provided at a density of 0.30 gpm/ft^2 (12.2 L/min/m^2) for the diked area or for a distance of 10 feet (3 m) from the transformer in all directions.

4-40.5.4.5 When utilizing fire barriers or automatic fire suppression, the following additional requirements must be applied:

a. There must be no window openings in first-story walls within a horizontal distance of 10 feet (3 m) from the transformers. Existing window openings must be closed using brick or concrete block.

b. Overhanging eaves, where they exist, must be noncombustible.

Table 4-4 Separation Distance Between Outdoor Insulated Transformer \6\ Containment /6/ and Buildings

Liquid	Liquid Volume gal (m³)	Horizontal Distance[a] 2-hr Fire-Resistant \6\ Wall /6/ ft. (m)	Horizontal Distance[a] Non-Combustible \6\ Wall /6/ ft. (m)	Horizontal Distance[a] Combustible \6\ Wall /6/ ft. (m)	Vertical Distance ft. (m)
Less Flammable	≤10,000 (37.9)	5 (1.5)	5 (1.5)	25 (7.6)	25 (7.6)
	>10,000 (37.9)	15 (4.6)	15 (4.6)	50 (15.2)	50 (15.2)
Mineral Oil	<500 (1.9)	5 (1.5)	15 (4.6)	25 (7.6)	25 (7.6)
	500 - 5,000 (1.9 - 19)	15 (4.6)	25 (7.6)	50 (15.2)	50 (15.2)
	>5,000 (19)	25 (7.6)	50 (15.2)	100 (30.5)	100 (30.5)

[a] If FM-approved transformers are used; the separation distances must follow the requirements of FM Global Data Sheet 5-4, which allows for reduced separation distances.
Less Flammable: See NFPA 70.

Table 4-5 Separation Distance Between Outdoor Fluid Insulated Transformers and Equipment (Including Other Transformers)

Liquid	Fluid Volume gal (m^3)	Distance ft. (m)
Less Flammable	≤10,000 (37.9) >10,000 (37.9)	5 (1.5) 25 (7.6)
Mineral Oil	<500 (1.9) 500 - 5,000 (1.9 - 19) >5,000 (19)	5 (1.5) 25 (7.6) 50 (15.2)
Less Flammable: See NFPA 70.		

4-41 \5\PRIVACY PODS OR PRIVACY ENCLOSURES.

Privacy pods or privacy enclosures (pods) are freestanding enclosures and typically used as a lactation space, temporary private office, sound enclosure, counseling space, or similar use.

4-41.1 Sprinkler Protection.

Pods can be an obstruction to the water distribution rules for automatic sprinklers in the space or room they occupy. Pods must follow Table 4-5a.

TABLE 4-5a Pods Sprinkler Logic Table

INPUTS			RESULTS		
Pod Size*	**Pod Ceiling**	**Room Sprinklers (external to Pod)**	**Sprinkler Required In Pod**	**Modify Room Sprinklers**	**No Room Sprinkler Modification**
Small	Open	Obstructed		X	
Small	Open	Unobstructed			X
Small	Enclosed	Obstructed		X	
Small	Enclosed	Unobstructed			X
Large	Open	Obstructed		X	
Large	Open	Unobstructed			X
Large	Enclosed	Obstructed	X	X	
Large	Enclosed	Unobstructed	X		

* Small pod has a silhouette projected on the floor less than 25 ft^2 (2.3 m^2).
Large pod has a silhouette projected on the floor equal to or greater than 25 ft^2 (2.3 m^2).

4-41.1.1 Open-Grid Ceiling.

Open-grid ceiling is defined in NFPA 13. The open-grid ceiling must cover a minimum of 75% of the pod’s silhouette area to be considered as an open ceiling in Table 4-5a.

4-41.1.2 Grouping: Pods separated by less than 4 feet (1.2 m) are considered a group. The size of the group will be determined by the area of the pods, plus the area between the pods. A group of pods having a total area less than 75 ft^2 (7.0 m^2) will follow the requirements of Table 4-5a; otherwise, a sprinkler must be installed inside of each pod in that group.

4-41.2 Fire alarm.

Pods must meet the notification requirements, either audibility or visual, for a fire alarm system; otherwise, a visual notification appliance must be installed inside the pod.

4-41.3 Life Safety.

The location of pods, including door swing, must not impede or protrude into the required means of egress. /5/

[C] 4-41.3

Example: If a 72-inch (1.8 m) wide corridor has a required egress width of 44-inches (1.1 m) and a 24-inch (0.61 m) wide pod with a door that swings full 180 degrees is located in the corridor, there is no compromise of the means of egress; however, a 36-inch (0.91 m) wide pod, or a pod with a 90degree door swing would not be acceptable.

4-42 RANGES AND REMOTE LOCATIONS.

4-42.1 \2\Water Supply.

When the \6\ *CFPE* /6/ determines a water supply is necessary for the range or remote location, follow the method of calculating minimum water supply as defined in NFPA 1142.

4-42.2 \4\Facilities.

FEMA approved freestanding "FEMA Tank and Pump System (TPS)" or internal "Next Generation FEMA Tank and Pump System (TPS)" are acceptable for use for fixed and relocatable facilities. Installation of the sprinkler system must comply with NFPA 13D./4/

4-42.3 Fire Department Vehicle Access.

Ranges and other remote locations are not required to meet the requirements of the “Fire Department (Emergency) Vehicle Access” section of this UFC or NFPA 1141./2/

4-43 RELOCATABLES.

4-43.1 General.

4-43.1.1 Relocatable facilities must have the same fire protection \2\and/2/ construction \2\/2/requirements as non-relocatable facilities.

4-43.1.2 Provide a minimum separation of 50 feet (15.3 m) between groups of high hazard occupancies, as defined by NFPA 101 and 15 feet (4.6 m) for all other groups.

Note: For Navy, refer OPNAVINST 11010.33 for regulations and restrictions on the use of relocatable facilities.

4-43.2 Location.

4-43.2.1 Do not group critical relocatable facilities, such as electronic equipment vans, to form areas greater than 6,000 ft^2 (557 m^2) for non-sprinklered facilities and 12,000 ft^2 (1,115 m^2) for sprinklered facilities.

4-43.2.2 Do not group relocatable facilities having high hazard occupancies, as defined by NFPA 101, to form areas greater than 4,000 ft^2 (372 m^2) for non-sprinklered facilities and 8,000 ft^2 (743 m^2) for sprinklered facilities.

4-44 SENSITIVE COMPARTMENTED INFORMATION FACILITY (SCIF).

4-44.1 General.

Note: SCIF's should not be confused with radio-frequency shielded enclosures and/or anechoic chambers.

4-44.1.1 See UFC 4-010-05 for additional information.

4-44.1.2 As part of the initial design process for a SCIF, the Certified TEMPEST Technical Authority (CTTA) and the security Accrediting Official (AO) must establish both TEMPEST and physical security building element controls prior to designing means and methods of implementing fire protection systems into the SCIF.

4-44.2 Physical Security Door Hardware.

4-44.2.1 All security door hardware installed on a means of egress door, must comply with the provisions of NFPA 101.

4-44.2.1.1 Sliding deadbolts are strictly prohibited.

4-44.2.1.2 A spin-dial combination lock, similar to the Lockmaster CDX-10, equipped with a life safety push-button feature, is acceptable provided the button feature is enabled at all times the SCIF is occupied.

4-44.2.1.3 Door personnel "access control systems" must not restrict free egress at all times. Badge ID readers may be installed on the interior side of a door for personnel "audit" purposes only, but must not be connected to any physical security door hardware (i.e. electric door strikes, magnetic locks, etc.) that would restrict single-motion door operation.

4-44.3 Fire Alarm and Mass Notification System (MNS).

4-44.3.1 See UFC 4-010-05 for requirements pertaining to the installation of fire alarm and MNS devices within a SCIF.

4-44.3.2 Self-amplified fire alarm audio speakers, and associated wiring circuits, can be installed within a SCIF with concurrence of the CTTA.

Note: Self-amplified speakers are limited to 0.5 - 24VRMS audio input signal levels. Typically, most fire alarm voice systems are designed for 70.7VRMS audio circuits, and therefore careful economic consideration must be made on how to introduce the fire alarm audio signals into a SCIF.

4-44.4 Fire Sprinkler Systems.

4-44.4.1 See UFC 4-010-05 for requirements pertaining to the installation of fire sprinkler piping penetrations into a SCIF.

4-44.4.2 Any security mitigation method imposed directly on a sprinkler pipe must comply with NFPA 13.

4-44.4.3 Metallic dielectric unions or grounding clamp(s) and wire(s) are permitted.

4-45 TENSIONED-MEMBRANE STRUCTURES.

4-45.1 General.

4-45.1.1 Tensioned-membrane (fabric) structures must meet the requirements of NFPA 101 and NFPA 102 as well as all life safety, fire protection, and allowable area requirements for the specific occupancy, in accordance with the other provisions of this UFC.

4-45.1.2 Tensioned-membrane (fabric) structures must also meet the requirements of the applicable use paragraph in this UFC.

4-45.1.3 \5\When this section or other applicable use paragraphs in this UFC require the installation of sprinkler or other fire protection features, the requirements must be identified in the tension-membrane structure procurement documents to ensure the structural elements are adequately designed to support the dead and live loads of the fire protection features.

4-45.2 /5/Allowable Area and Separation Distance.

4-45.2.1 Table 4-6 provides the maximum allowable area and separation requirements for all tension fabric structures intended to exceed 12 months of use.

4-45.2.2 The separation area must be a clear zone adjacent to the tension fabric structure.

4-45.2.2.1 The clear zone cannot be used for storage and must be clear of vegetation (maintained lawn is permitted).

4-45.2.2.2 The clear zone may be used as a street or driveway, but not for vehicle parking.

Note: For Navy, see OPNAVINST 11010.33 for regulations and restrictions on the use of relocatable facilities.

Table 4-6 Basic Allowable Area for Tensioned-Membrane/Fabric Structures

SEPARATION DISTANCE	TYPE of CONSTRUCTION - In Square Feet (Square Meters)			
	Noncombustible Material		Combustible Material	
	Sprinkler Protection	No Sprinkler Protection	Sprinkler Protection	No Sprinkler Protection
20 feet (6 m)	36,000 (3,344)	12,000 (1,114)	24,000 (2,229)	8,000 (743)
40 feet (12 m)	72,000 (6,689)	24,000 (2,229)	48,000 (4,459)	16,000 (1,486)
60 feet (18 m)	UNLIMITED	UNLIMITED	UNLIMITED	UNLIMITED

4-45.3 Tensioned-Membrane (Fabric) Hangars.

Tensioned-membrane (fabric) hangars must comply with the paragraph entitled "Aircraft Facilities".

4-46 TRASH/RECYCLING COLLECTION AND DISPOSAL AREAS.

4-46.1 Central Trash/Recycling Collection and Dumpsters.

Place central trash/recycling collection units and dumpsters 15 feet (4.6 m) or more away from wood frame or metal *Facilities* or from openings in masonry-walled *Facilities*.

4-46.2 Collection, Baling, Processing and Storage Rooms.

Rooms for collection, baling and storage must be separated from the remainder of the building by a 1-hour fire barrier and protected with automatic sprinklers.

Where the *Facility* is not protected with automatic sprinklers, the sprinkler system is permitted to be connected to the domestic water system when permitted by NFPA 13.

4-46.3 Trash/Recycling Chutes.

Provide automatic sprinklers in all trash/recycling chutes installed within a *Facility*

4-47 VEHICLE PARKING, STORAGE, MAINTENANCE, AND REPAIR *FACILITIES*.

4-47.1 General.

4-47.1.1 Facilities used for parking or storage of motor vehicles must comply with NFPA 88A.

4-47.1.2 Facilities used for maintenance and repair of motor vehicles must comply with NFPA 30A.

4-47.1.3 Facilities used for the fueling and dispensing of compressed natural gas (CNG) or liquefied natural gas (LNG) for vehicles or vessels must comply with NFPA 52.

4-47.2 Refueler Vehicle Facilities.

Facilities that are covered and enclosed on at least three sides and that are used for the parking, storage, maintenance, and repair of aircraft refueler vehicles must comply NFPA 30A and be provided with the following features:

4-47.2.1 Automatic sprinkler system \4\ throughout.

4-47.2.2 /4/Class I Division 1 electrical equipment and wiring throughout the entire pit area (below floor level) in accordance with NFPA 70.

4-47.2.3 Class I Division 2 electrical equipment and wiring throughout the entire servicing area and areas not suitably cut-off in accordance with NFPA 70.

Note: This includes the area up to the underside of the roof.

4-48 WAREHOUSE AND STORAGE *FACILITIES*.

4-48.1 General.

4-48.1.1 Comply with UFC 4-440-01, except as modified by this UFC.

4-48.1.2 This section applies to *Facilities* (except ordnance) with a ceiling height greater than 12 feet (3.7 m) used for storage, shipping, receiving, packing, and processing of materials.

4-48.1.3 Storage of hazardous materials, including flammable or combustible liquids, must comply with this section and the requirements of the section "Hazardous Materials and Hazardous Waste" in this UFC.

4-48.2 Sprinkler Protection.

4-48.2.1 Complete automatic sprinkler protection must be provided for warehouses and storage *Facilities*, regardless of floor area or construction type.

4-48.2.1.1 Automatic sprinkler systems may be omitted for *Facilities* with an area less than 5,000 ft^2 (465 m^2) with approval of the *DFPE.*

Note: See the "Planning" section of this UFC for guidance on determining if sprinkler protection may be omitted for smaller *Facilities*.

4-48.2.1.2 \2\The use of extended coverage control mode specific application sprinklers is permitted./2/

4-48.2.2 Sprinkler protection must include covered loading docks.

4-48.2.3 Sprinkler protection must follow the design requirements found in NFPA 13. The design density, area of application and hose stream requirements of \3\paragraph "Automatic Sprinkler Systems" in "Fire Protection Systems"/3/ chapter of this UFC do not apply to high-pile storage as defined by NFPA 13.

4-48.2.3.1 Sprinkler protection, at a minimum, must be based on Class IV, non-encapsulated commodities, as defined by NFPA 13, unless a more severe class of storage is anticipated, and must be based on the maximum potential height of storage. The maximum potential height of storage is based on the roof or ceiling height.

4-48.2.4 If provided, in-rack sprinklers must be supplied from risers that are separate from the ceiling sprinklers, except in existing facilities.

4-48.2.5 Racks with solid shelves over 12 feet (3.7 m) in height must be protected with in-rack sprinklers at every tier or shelf level.

4-48.2.6 Sprinkler riser control valves must be readily accessible to the fire department from the exterior.

4-48.2.7 Duration.

The water supply must be capable of providing the minimum duration requirements of NFPA 13 for the protection method selected.

4-48.2.8 Hose Stream Allowance.

Provide a hose stream allowance as required by NFPA 13 for the protection method selected.

4-48.2.9 Roof Slope.

Maximum roof slope must be in accordance with NFPA 13.

4-48.3 Bin Storage.

4-48.3.1 Requirements.

4-48.3.1.1 Protect in accordance with NFPA 13, except as noted below.

4-48.3.1.2 The ceiling density must be increased by 10 percent or one additional level of in-rack sprinklers where combustible bins are stored in racks.

4-48.3.1.3 Mini-storage and retrieval systems and carousel storage must be protected in accordance with FM Global Data Sheet 8-33 or FM Global Data Sheet 8-34.

4-48.4 Column Protection.

Steel columns must be protected as required by NFPA 13.

4-48.5 *Fire Areas*.

4-48.5.1 Warehouse *Fire Area*s must not exceed 60,000 ft^2 (5,574 m^2). Warehouse *Fire Area*s may be increased to 120,000 ft^2 (11,148 m^2) when all of the following provisions are met:

4-48.5.1.1 Ceiling sprinkler design area must be increased by 10 percent. This requirement does not apply when ESFR sprinklers are utilized.

4-48.5.1.2 Dedicated looped *service mains* must be provided with enough sectional valves to isolate each *Service Lateral* around the warehouse.

4-48.5.2 Separation of *Fire Areas*.

4-48.5.2.1 *Fire Areas* must be separated from other *Fire Area*s by 4-hour fire walls in accordance with the IBC Chapter entitled "Fire and Smoke Protection Features".

4-48.5.2.2 Other occupancies, such as offices or shops, must be separated from the warehouse and storage area by a minimum of 1-hour fire-rated construction, unless a higher rating is required by the IBC.

4-48.6 Conveyor and Mechanical Handling System Penetrations.

4-48.6.1 When mechanical handling systems, such as conveyors, penetrate fire barriers, the opening must be protected by a fire door or fire shutter.

4-48.6.2 When a fire door or shutter is not feasible due to the operation of the conveyor, the *DFPE* must be consulted to determine the appropriate protection criteria.

4-49 WATERFRONT FACILITIES.

Waterfront and harbor facilities must comply with all of the following, as applicable:

a. NFPA 303.

b. NFPA 307.

c. NFPA 312.

d. UFC 4-152-01.

e. UFC 4-150-02.

f. UFC 4-151-10.

g. UFC 4-213-10.

h. UFC 4-213-12

i. NAVSEA OP-5 (for Navy only).

4-50 \3\WILDLAND-URBAN INTERFACE LOCATIONS.

4-50.1 General.

As required by Executive Order 13728, facilities within the wildland-urban interface must follow the requirements of the International Wildland-Urban Interface Code./3/

CHAPTER 5 GENERAL BUILDING HEIGHTS AND AREAS

5-1 GENERAL.

Allowances or exceptions that require the *Facility* to be protected throughout by an approved automatic sprinkler system may only be applied where the system is an approved, electrically supervised automatic sprinkler system as described in NFPA 101. References to IBC Section 903.3.1.1 are replaced with NFPA 13. References to IBC Section 903.3.1.2 are replaced with NFPA 13R.

5-2 BUILDING HEIGHT LIMITATIONS.

Conform to the requirements of IBC Chapter 5.

5-3 BUILDING AREA LIMITATIONS.

Conform to the requirements of IBC Chapter titled "General Building Heights and Areas \6\ except as modified by this UFC /6/.

[C] 5-3

IBC Chapter 5 does not permit area increases for sprinkler systems if the sprinkler system is designed per NFPA 13R.

5-4 OCCUPANCY SEPARATION.

5-4.1 General.

5-4.1.1 Occupancy separation must comply with the IBC Chapter 5. Do not use NFPA 101 for occupancy separation requirements, except as noted below.

5-4.1.2 NFPA 101 must be utilized for occupancy separations of medical funded projects, healthcare, ambulatory healthcare, and all facilities required to comply with The Joint Commission standards.

5-4.1.3 \3\For the location of an occupancy within a facility, see paragraph "NFPA 101" in Chapter "Use and Occupancy Classification" of this UFC./3/

5-5 INCIDENTAL USE.

NFPA 101 must be utilized for protection from hazards. IBC requirements for separation of incidental uses are not permitted.

This Page Intentionally Left Blank

CHAPTER 6 TYPES OF CONSTRUCTION

6-1 GENERAL.

Conform to the requirements of IBC Chapter 6, except as modified by this UFC.

6-2 SEPARATION BETWEEN BUILDINGS.

Conform to the requirements of the IBC, except as modified by this UFC.

This Page Intentionally Left Blank

CHAPTER 7 FIRE AND SMOKE PROTECTION FEATURES

7-1 GENERAL.

Conform to the requirements of NFPA 101 except as noted below.

Where IBC Chapter 5 or 6 specifically references IBC Chapter 7, utilize the specific IBC Chapter 7 reference.

Note: For example, IBC Section 508.4.4.1 specifically references IBC Sections 707 and 711. When utilizing IBC Section 508.4.4.1, utilize IBC Sections 707 and 711, otherwise IBC Sections 707 and 711 are not to be used unless specifically referenced.

7-2 MARKING AND IDENTIFICATION.

Conform to the requirements of the IBC for marking and identification of fire walls, fire barriers, fire partitions, smoke barriers, smoke partitions or any other wall required to have protected openings.

For Navy and NRO, stenciling must be provided and spaced no more than 10 foot, measured edge to edge horizontally along the wall or partition.

7-3 NON-LOAD BEARING PARTITIONS AND BARRIERS.

Comply with NFPA 101 for fire resistance ratings of non-load bearing partitions and barriers, except occupancy separation as indicated in Chapter 5.

7-4 PROTECTION OF STRUCTURAL MEMBERS.

7-4.1 General.

Comply with IBC Chapter 7 for protection of structural members, except as noted below.

7-4.2 Sprayed Fire-Resistant Materials.

7-4.2.1 Sprayed fire-resistant materials must be medium or high density cementitious or an intumescent thin-film coating.

Note: Intumescent thin-film coating is not the same material as intumescent paint.

7-4.2.2 Mineral fiber or low-density cementitious materials are not permitted.

7-4.2.3 Provide UL-listed floor/ceiling and UL-listed roof/ceiling assemblies that do not require the underside of the roof or floor deck to have spray-applied fireproofing. The assembly must be designed so only columns, beams, and trusses receive spray-applied fireproofing to achieve the rating for the assembly.

7-4.3 Ceilings.

Listed floor/ceiling or roof/ceiling assemblies that utilize suspended gypsum wallboard or acoustical tile ceilings must not be used to achieve required fire resistance rating of building structural elements.

7-5 SMOKE AND HEAT VENTS.

7-5.1 General.

7-5.1.1 Smoke and heat vents must not be provided unless specifically required by this UFC.

Note: Smoke and heat vents should be considered in *Facilities* where a high rate of heat release is anticipated during a fire such as indoor firing ranges with rubber impact zones.

7-5.1.2 Where provided in *Facilities* without automatic sprinklers, smoke and heat vents must be arranged to operate automatically in accordance with NFPA 204.

7-5.1.3 Where provided in *Facilities* with automatic sprinkler protection, smoke and heat vents must be arranged to operate in the manual mode only.

Note: Skylights can be used as a method of providing manual smoke and heat vents.

7-6 HIGH VOLUME LOW SPEED (HVLS) FANS.

Comply with NFPA 13, except all HVLS fans must be interlocked to shut down immediately upon any fire alarm activation.

7-7 PLASTIC PIPE AND CONDUIT.

7-7.1 Penetrations.

Penetrations by plastic pipe or conduit through fire-rated walls, partitions, shafts, and floors must be fire stopped by an approved or listed method in accordance with ASTM E814 or UL 1479.

7-7.2 Prohibited Locations.

Plastic pipe and conduit must not be installed in exit stair enclosures, or in air plenum spaces, unless specifically listed for that application.

CHAPTER 8 INTERIOR FINISHES

8-1 GENERAL.

Conform to the requirements of NFPA 101.

8-2 DROP-OUT PANELS.

Drop-out panels, as defined in NFPA 13, must not be used.

8-3 INSULATION.

8-3.1 Requirements.

8-3.1.1 Use thermal and acoustical insulation with a flame spread (FS) rating not higher than 75, and a smoke developed (SD) rating not higher than 150 when tested in accordance with ASTM E84 (NFPA 255).

8-3.1.2 Exposed insulation in concealed spaces of sprinklered buildings must be specified to have a flame spread of 25 or less and a smoke developed rating of 50 or less (including \2\/2/covering).

Note 1: This is to prevent the space from being defined as a combustible concealed space, which would require sprinkler protection in accordance with NFPA 13.

Note 2: Acceptable types of insulation blankets per Federal Spec HH-521F are Type I, Type II (Class A only), and Type III (Class A only).

8-3.2 Exceptions to Insulation Criteria.

For certain types of insulation installation, the exceptions described in paragraphs entitled "Flame Spread – No Smoke Developed Rating Limitation" and "No Flame Spread or Smoke Limitation" below will apply.

8-3.2.1 Flame Spread - No Smoke Developed Rating Limitation.

Compliance with the SD rating limitation is not required, and a FS rating up to 100 is permitted for insulation, including insulating sheathing installed within wall assemblies. In such installations, conform to the requirements for interior finish with a minimum fire resistance rating of 15 minutes when tested in accordance with ASTM E119.

8-3.2.2 No Flame Spread or Smoke Limitation.

Compliance with FS and SD limitations are not required for the following applications:

a. Insulation installed above poured concrete or poured gypsum roof decks, nominal 2-in. (50.8 mm) thick tongue-and-groove wood plank roof decks, or precast roof deck panels or planks that are approved by a Nationally

Recognized Testing Laboratory (NRTL), as noncombustible roof deck construction.

b. Insulation installed above roof decks where the entire roof construction assembly, including the insulation, is UL-listed as Fire Classified, or FM-approved for Class I roof deck construction or equal listing or classification by a NRTL.

c. Insulation contained entirely within panels where the entire panel assembly used in the construction application meets the cited FS and SD limitations.

d. Insulation isolated from the interior of the building by masonry walls, masonry cavity walls, insulation encased in masonry cores, or concrete floors.

e. Insulation installed over concrete floor slabs and completely covered by wood tongue-and-groove flooring without creating air spaces within the flooring system.

f. Insulation completely enclosed in hollow metal doors.

g. Insulation installed between new exterior siding materials and existing exterior siding or wood board, plywood, fiberboard, or gypsum exterior wall sheathing.

Note: The exception to SD limitations described in this paragraph is not applicable to correctional facilities.

CHAPTER 9 FIRE PROTECTION SYSTEMS

9-1 FIRE DEPARTMENT (EMERGENCY) VEHICLE ACCESS.

9-1.1 All-Weather Ground Access.

All *Facilities* greater than 5,000 ft^2 (465 m^2), or more than two stories in height, must have at least one means of all-weather ground access to allow emergency vehicles unimpeded access to the *Facility*. All-weather ground access must be paved, start from the road, and terminate no farther than 33 feet (10 m) from an exterior door accessible for fire department ingress (i.e. a stair door or some other exterior door that provides access to the *Facility* interior). The route between the access surface and exterior door must be able to be traversed without the use of a ladder.

An engineered all-weather surface that is not paved may be provided if approved by the *DFPE*.

9-1.2 Aerial Apparatus Access.

New facilities four stories or more in height and all new warehouses must be provided with suitable all-weather ground access for aerial apparatus on a minimum of two sides of the perimeter of the structure. The access \6\ for buildings four stories or more in height /6/ must be parallel to at least one entire side of the *Facility* with windows \6\ or other openings /6/ to allow aerial access \6\ for fire department ingress /6/ to the entire side. The distance between the aerial apparatus access and the *Facility* must be based on the responding aerial apparatus and *Facility* height and be approved by the *DFPE*.

[C] 9-1.2

The intent of this paragraph is to provide aerial apparatus access to two sides of the building for all buildings four stories or more in height and for all warehouses. It is also the intent to provide aerial access on one side along the entire side of the building with window or other opening access for buildings four stories or more in height so that the aerial apparatus has multiple locations to set up operations and accommodate aerial rescue operations. Consideration should be given to providing roof access locations for warehouse facilities to accommodate aerial suppression operations.

9-1.3 Vehicle Access.

All force protection equipment, such as bollards or gates, must not require more than one person to remove or open. Access may require fire apparatus to drive over a curb. Any locking device controlling vehicle access must be under control of the fire department or 24-hour security personnel located at the specific *Facility*. Dimensions of fire lanes and turnarounds must comply with NFPA 1. Vehicle access must be coordinated with the *Installation* or responding fire department.

9-1.4 Fire Department Connection.

Facilities with fire department connections for fire suppression systems must be provided with suitable all-weather ground access surface for any apparatus within 150 feet (45 m) of such fire department connections.

9-2 *FIRE FLOW* FOR *FACILITIES*.

9-2.1 Sprinklered *Facilities*.

\4\Provide *Fire Flow* for sprinklered *Facilities* in accordance with NFPA 1 or 1,000 gpm at 20 psi (3,785 L/min at 138 kPa), whichever is greater/4/. Where the *Fire Flow* cannot be met, the *DFPE* is permitted to approve a reduction in *Fire Flow*. *Fire Flow* is calculated independently of the *Fire Water Demand.*

9-2.2 Non-sprinklered *Facilities*.

Fire Flow must be in accordance with NFPA 1, except the following special *Facilities*.

9-2.2.1 Ship Berthing and Drydock *Facilities*.

Refer to the paragraph entitled "Waterfront *Facilities*" for *Fire Flow* requirements for ship berthing and drydock facilities.

9-2.2.2 \3\Aircraft Parking and Refueling *Facilities*.

A minimum *Fire Flow* of 1,000 gpm (3,785 L/min) for a 2-hour duration is to be provided for all such *Facilities*.

9-2.2.3 Yard and Outdoor Storage.

9-2.2.3.1 Yard and outdoor storage must comply with the requirements of NFPA 80A, and FM Global Data Sheet 1-20.

9-2.2.3.2 Aisle widths and separation distances must be maintained to limit the exposure to nearby *Facilities* and to facilitate manual firefighting operations.

9-2.2.4 Vehicle Parking Areas.

A minimum *Fire Flow* of 500 gpm (1900 L/m) for a 2-hour duration must be provided for all such areas.

9-2.3 \3\Family Housing.

The *Fire Flow* for family housing must be as follows:

a. One-story - 500 gpm (1,900 L/min) for 90 minutes.

b. Two-story - 750 gpm (2,840 L/min) for 90 minutes.

c. Three-story and above - 1,000 gpm (3,785 L/min) for 90 minutes./3/

9-3 *SERVICE MAINS AND LATERALS*.

9-3.1 General.

9-3.1.1 *Service Mains and Service Laterals* must comply with AWWA M31, NFPA 24 and UFC 3-230-01, except where specifically modified by this UFC.

9-3.1.2 \2\For service laterals \6\ /6/, the velocity must not exceed 10 feet per second (3 m/s)./2/

9-3.1.3 This section applies to both dedicated (fire only) and combined (domestic and fire) water distribution systems.

9-3.1.4 For *Service Mains* served by fire pumps or *Service Laterals* serving fire pumps, velocities must be calculated using 150 percent of the rated capacity of the fire pump.

9-3.1.5 Provide appropriate corrosion protection based on pipe material and corrosive properties of the water supply and earth.

9-3.1.6 Where cathodic protection is indicated based upon present conditions, comply with the following \6\ UFC 3-570-01, Cathodic Protection. /6/

9-3.2 *Service Mains*.

9-3.2.1 *Service Mains* must be sized to accommodate *Fire Flow* plus domestic and industrial demands that cannot be restricted during fires.

9-3.2.2 *Service Mains* must be looped to provide at least 50 percent of the required *Fire Flow* in case of a single break.

9-3.2.3 *Service Mains* must not be dead-end.

9-3.2.4 *Service Mains* must be sized so that the minimum residual pressure available, at 150 percent of a *Facility* fire pump rating, if provided, is not less than 20 psi.

9-3.3 *Service Lateral*s.

9-3.3.1 Not more than two fire hydrants can be located on a *Service Lateral*.

9-3.3.2 Minimum size *Service Lateral* for fire sprinkler systems must be not less than 6-in. (150 mm) in diameter.

9-3.3.2.1 For NFPA 13R systems, the *Service Lateral* is permitted to be 4-in. (100 mm) if supported by hydraulic calculations.

9-3.3.2.2 For NFPA 13D systems, the minimum *Service Lateral* size must be based on hydraulic calculations.

9-3.3.3 The minimum residual pressure in a *Service Lateral* must not be less than 20 psi at the greater of *Fire Flow* or *Fire Water Demand*. This residual pressure must be maintained at the inlet of the backflow preventer or suction side of the fire pump, whichever is closer to the *Service Main*.

9-3.3.4 A *Service Lateral* supplying a fire pump must be able to support 150 percent of the fire pump rated capacity without falling below the required net positive suction head (NPSH) at the suction side of the pump. Where NPSH cannot be met at 150 percent of the fire pump rated capacity, the *DFPE* is permitted to reduce the required flow at NPSH, but in no case is it permitted to be less than the required fire suppression system demand.

Note: Piping downstream of the fire pump is not a *Service Lateral*. Piping downstream of the fire pump must be sized based on the *Fire Water Demand* of the *Facility* or the minimum required by NFPA 20, whichever is greater, not 150 percent of the fire pump rated capacity.

9-3.4 Valves.

9-3.4.1 Control valves must be provided in each source of water supply, such as tanks and pumps.

9-3.4.2 A control valve must be provided on the *Service Lateral* downstream of the connection to the *Service Main*.

9-3.4.3 A sufficient number of sectional valves must be provided on the *Service Main*, so that not more than a combined total of five hydrants or the *Service Laterals* to not more than three separate buildings are out of service due to a single break.

9-3.4.4 Sectional valves on *Service Mains* may be key-operated type. New valves must open by counter-clockwise rotation of the stem.

9-3.4.5 Supervision.

When provided, PIV's must be supervised using a lock or tamper seal, at a minimum.

9-3.5 Fire Hydrants.

9-3.5.1 Fire hydrants must be UL-listed, FM-approved, or listed or classified by an NRTL and must have two 2 1/2-in. (65 mm) hose outlets and one 4 1/2-in. (115m) outlet with national standard fire hose threads in accordance with NFPA 1963.

Comply with the *Installation* fire department or local responding fire department when they require a different arrangement or hose threads.

9-3.5.2 Wet barrel or California-type hydrants are preferable in areas where there is no danger of freezing. Dry barrel or traffic-type hydrants must be used in areas where there is a danger of freezing. Hydrants must be aboveground type and match the type used on the *Installation*.

9-3.5.3 In DoD *Installations* serviced by only local fire departments, hydrant hose threads must meet local requirements.

9-3.5.4 See AWWA Manual M 17 and AWWA Manual M 31 for additional information.

Note: Overseas *Installations* with current below grade hydrants in accordance with local national policy are acceptable.

9-3.5.5 \1\/1/Hydrant caps/barrels must be color coded to prevent cross-connection. In the absence of an *Installation* established color code standard, the following colors must be used; red for non-potable water, yellow for potable water, and purple for reclaimed/reuse water. All hydrants must also be marked based on the *Fire Flow* capacity, in accordance with NFPA 291 or by the *Installation* established marking standard

9-3.5.6 Clearly mark each new hydrant with an identification number assigned by the *Installation*.

9-3.5.7 Construction Requirements.

a. Installation must be in accordance with NFPA 24 except as modified by this UFC.

b. Hydrants must be installed adjacent to paved areas, accessible to fire department apparatus.

c. *Service Lateral* supplying hydrants must be minimum 6-in. (150 mm) and valved at the connection to the *Service Main*.

d. Barrels must be long enough to permit at least 18-in. (450 mm) clearance between the center of the 4 1/2-in. (115 mm) outlet and grade.

e. The ground must be graded so that any surface drainage is away from the hydrant.

f. The 4 1/2-in. (115 mm) outlet must be perpendicular to the street to allow straight connection to the pumper.

g. Landscaping, fencing, bollards and similar must be located a minimum of 24-in. (610 mm) from the \4\vertical/4/ centerline of the hydrant and not directly in front of any outlet.

h. \6\ Install fire hydrants adjacent to airfield pavement not more than 24 inches (610 mm) above the level of the adjacent airfield pavement. Local airfield obstruction authority may approve individual hydrants up to 30 inches (760 mm) above the adjacent airfield pavement. /6/

[C] 9-3.5.7.h

For additional information see the Service specific airfield clearance criteria. The measurement is taken from the airfield pavement (aircraft travel surface) edge closest to the hydrant, not the paved or unpaved shoulder. Standard airfield construction includes slopes to the airfield pavement, paved shoulder, and unpaved shoulder that provide adequate clearance to install commercially available hydrants with a listed grade to top height of 24 to 30 inches (610 to 760 mm). Where the recommended negative shoulder slope is not present or the slope is positive, the hydrant may have to be installed in a designed excavation with retaining walls sized to accommodate all hose connections. The use of subsurface / below grade hydrants should be avoided.

9-3.5.8 Spacing Requirements.

9-3.5.8.1 A sufficient number of hydrants must be provided so that *Fire Flow* can be met without taking more than 1,250 gpm (4,740 L/min) from any single hydrant.

9-3.5.8.2 All parts of the *Facility* exterior must be within 350 feet (106 m) of a hydrant with consideration given to accessibility and obstructions.

9-3.5.8.3 Hydrants must be located with consideration given to emergency vehicle access.

9-3.5.8.4 Hydrants must be spaced in accordance with the following requirements:

a. At least one hydrant must be located within 150 feet (45 m) of the fire department connection.

b. Hydrants protecting warehouses must be spaced \2\along the sides of the *Facility* with fire department access/2/ at 300 feet (91 m) maximum intervals.

c. Exterior storage and military/tactical equipment/vehicle parking must be provided with hydrants spaced at 300 feet (91 m) maximum intervals around the perimeter.

Note: Military/tactical equipment/vehicle parking applies to large parking areas typically found at reserve facilities or similar locations. \6\ /6/

d. Hydrant spacing must be spaced at 600 feet (182 m) maximum intervals for non-sprinklered family housing.

e. Hydrant spacing must not exceed 1,000 feet (305 m) in areas where all family housing is provided with sprinkler protection.

f. \2\ Fire hydrants protecting aircraft parking and servicing aprons must be spaced at 300 feet (91 m) maximum intervals along one side./2/

9-3.5.9 Protection.

Hydrants located adjacent to parking areas, vehicle traffic areas or other areas subject to mechanical damage, must be protected by bollards. The bollards must be located so they are not directly in front of an outlet. The bollards must allow clearance to attach hoses, allow for the removal of the hydrant caps, and for the hydrant to be opened and closed without obstructions. Refer to UFC 3-260-01 where bollards are required for hydrants located adjacent to aircraft parking and servicing aprons.

9-3.6 Pressure-Regulating Valves (PRVs).

9-3.6.1 \6\ General.

9-3.6.1.1 All dedicated fire protection piping, including *Distribution Mains*, *Service Mains*, *Service Laterals*, risers, interior sprinkler piping, must be designed to withstand the maximum available pressure, without the use of PRVs.

9-3.6.1.2 Combination fire and domestic distribution system is permitted to use PRVs if normal pressures exceed 175 psi (690 kPa), subject to the approval of the *CFPE*. The design must be such that routine domestic flow causes the PRV to function daily, or at least once per week. Designs are not permitted that have PRVs (normally closed) supplying pipes that only flow during a fire event or periodic testing.

9-3.6.1.3 In large *Installations* with terrain that has grade elevation changes exceeding 100 feet (30.5 m), the use of PRVs in the form of altitude valves is acceptable. Specific approval of the *CFPE* is required. The design must be such that the valve(s) routinely activate. Designs are not permitted that have PRVs (normally closed) supplying pipes that only flow during a fire event or periodic testing. /6/

9-4 *FACILITY* ON-SITE WATER STORAGE.

9-4.1 General.

9-4.1.1 On-site fire protection water storage must comply with NFPA 22, except where specifically modified by this UFC.\2\

9-4.1.2 /2/The discharge or suction line(s) from each individual tank or reservoir section must be sized to deliver the maximum required flow.

9-4.2 Quantity.

9-4.2.1 The total \2\usable/2/ supply stored \2\/2/must be \2\equal to 120% of/2/ the *Facility's* maximum required *Fire Water Demand* for the applicable duration specified in this UFC\2\ plus any applicable domestic or industrial/2/ demand.

9-4.2.2 In calculating the fire protection water storage requirement, a reduction in storage capacity is acceptable if an adequate replenishment source is available. Factors that must be evaluated include the reliability of the makeup supply, its sustained flow capacity, its method of operation (automatic or manual), and flow limitations imposed by the capacity of treatment operations.

9-4.3 Replenishment of Storage.

The water storage must be capable of being self-replenished to its required volume within 48 hours, during normal domestic and industrial consumption of the supplying utility.

9-4.4 Monitoring.

9-4.4.1 The water level must be remotely monitored in accordance with NFPA 22 and NFPA 72 by the *Installation Fire Alarm Reporting System*.

9-4.4.2 In locales subject to freezing, water temperature of aboveground storage tanks must likewise be monitored by the *Installation Fire Alarm Reporting System.*

9-5 FIRE PUMPS.

9-5.1 General.

9-5.1.1 Fire pumps must comply with NFPA 20, except where specifically modified by this UFC.

9-5.1.2 Fire pumps must be located in a detached, noncombustible pump house or located in a fire-rated room in accordance with NFPA 20 with direct access from the exterior.

9-5.1.3 Maintenance access must be provided to the pump and driver so that either can be removed from the fire pump room. Access is permitted to be via double doors or overhead door directly to the exterior. This is in addition to the normal means of egress required by NFPA 101.

9-5.1.4 Provide a minimum of 3 feet (915 mm) of clearance on one side of the fire pump assembly for maintenance and in front of the pump controller or the minimum required by NFPA 70. A clear width of 3 feet must be provided from the room entry to the fire pump assembly and controller.

9-5.1.5 Provide a minimum of 3 feet (915 mm) access to and in front of all equipment and 6-in. (150 mm) behind the equipment, (e.g., control valves, check valves, etc.).

9-5.1.6 Provide labeling on the surfaces of the piping in the pump room to show the water flow direction and pipe function (e.g., "Suction", "Discharge", "To Fire Dept. Connection", "To Bypass", "To Test Header", "To Standpipe", "To Sprinkler System").

Provide white painted stenciled letters and arrows, a minimum of 2-in. (50 mm) in height and visible from at least three sides when viewed from the floor.

9-5.1.7 The maximum \2\fire suppression system demand must/2/ not exceed 140 percent of rated pump capacity. The pressure at the inlet of the pump at 150 percent of the rated pump capacity must not be less than the required net positive suction head in accordance with NFPA 20. Where NPSH cannot be met at 150 percent of the fire pump rated capacity, the *DFPE* is permitted to reduce the required flow at NPSH, but in no case is it permitted to be less than the required fire suppression system demand.

9-5.1.8 Terminate all drainage piping and test piping from the fire pump or associated appurtenances (e.g., circulation relief valve, bowl drains, etc.), including backflow preventers, to a floor drain or to the exterior of the *Facility* so it will not cause damage.

9-5.1.8.1 Provide concrete pads or splash blocks where discharge location is to other than a concrete slab. Splash blocks must be large enough to mitigate erosion and must not become dislodged during a full flow of the drain. Ensure all discharged water drains away from the *Facility* and does not cause property damage

9-5.1.8.2 Discharge to the exterior must not interfere with exiting from the *Facility*. Water discharge must not cross an exit or exit discharge.

9-5.1.8.3 Drainage piping of less than 3/4-in. (20 mm) may discharge to a floor drain.

9-5.1.9 Full flow relief valve piping must discharge safely in accordance with NFPA 20. If an on-site water storage tank or reservoir is provided, the piping must discharge back to the tank or reservoir.

9-5.1.10 \2\For DLA, a reserve fire pump of the same size must be provided when the total value at risk is greater than $100 million./2/

9-5.2 Pump Type.

A fire pump may be either a horizontal or vertical centrifugal pump, or a vertical turbine pump; whichever is most economical and appropriate for the intended use.

9-5.3 Pump Start and Shutdown.

9-5.3.1 Fire pumps must be arranged to start automatically.

9-5.3.2 Fire pumps must be arranged to automatically shut down after reaching the stop pressure and the expiration of \3\the minimum run time determined by NFPA 20/3/. Stop pressure must be at least 5 psi below maximum churn pressure at the lowest available static pressure.

Note: The lowest available static pressure should be utilized in determining churn pressure so that the stop pressure can be achieved with low pressure. The 5 psi differential is used to allow for gauge error.\2\

9-5.3.3 /2/Fire pump activation (run) must transmit an alarm condition to the *Installation* receiving station, or remote receiving station, but not activate the *Facility* notification appliance circuits (i.e. no audible/visual notification in the protected *Facility*(s)).

9-5.4 Pump Drive.

9-5.4.1 Electric power must comply with NFPA 20. Where electric power is available from a *Reliable Power Source* of adequate capacity, electric motor driven fire pumps must be used.

9-5.4.2 When a *Reliable Power Source* is not available, electric motor driven fire pumps must be provided with a secondary power source (i.e. emergency generator with automatic transfer switch). See Chapter 2 for the definition of *Reliable Power Source*.

9-5.4.3 A diesel engine driven fire pump is permitted in lieu of an electric motor driven fire pump when a *Reliable Power Source* is not available.

Note: Air Force preference is to utilize electric motor driven fire pump(s) with a secondary power source when a *Reliable Power Source* is not available.

9-5.4.4 Diesel engine driven fire pumps must not be arranged to start automatically upon loss of normal power.

9-5.5 Controllers.

9-5.5.1 Soft start, reduced voltage controllers are required for electric motor driven fire pumps equal to or greater than 100 hp or when the fire pump is connected to an emergency generator.

9-5.5.2 Any starting method permitted by NFPA 20 is acceptable for electric motor driven fire pumps less than 100 hp\2\/2/ and \2\not connected to an emergency generator/2/\6\ /6/.

9-5.5.3 Limited service controllers are permitted when approved by a NRTL and NFPA 20.

9-5.5.4 Variable speed controllers are permitted when approved by a NRTL.

9-5.6 Pump Bypass.

Provide a bypass in accordance with NFPA 20 around all fire pumps that take suction from a *Service Lateral*.

9-5.7 Electric Circuits for Diesel Engine Driven Pumps.

Provide separate hard-wired electric circuits for the pump controller, engine starting system battery charger and hard-wired electric circuit for the engine block heater.

9-5.8 Test Connections.

9-5.8.1 Provide a test header manifold on the *Facility* exterior that permits flow testing directly from the header. Coordinate the location of test header with other disciplines to ensure flow from test header does not discharge onto other equipment or cause property damage.

9-5.8.2 Provide a flow meter installed in accordance with NFPA 20.

9-5.8.2.1 The flow meter must be installed in series with the test header unless it is piped to discharge into a water storage tank or reservoir.

9-5.8.2.2 Where a water storage tank or reservoir provides suction to the fire pump, the flow meter discharge must be piped back to a water storage tank or reservoir.

9-6 FIRE SUPPRESSION SYSTEMS.

9-6.1 General.

9-6.1.1 This section applies to all fire suppression/extinguishing systems including, but not limited to: automatic sprinkler systems; water spray systems; foam systems; standpipe systems; dry chemical extinguishing systems; wet chemical extinguishing systems; clean agent fire extinguishing systems; water mist fire protection systems; carbon dioxide systems; and, halon 1301 systems.

9-6.1.2 Fire suppression systems must be designed and installed in accordance with the applicable NFPA standard, except where specifically modified by this UFC.

9-6.2 Connections to *Fire Alarm Reporting Systems*.

9-6.2.1 Where fire suppression systems are installed in or at *Facilities* on *Installation*s with *Fire Alarm Reporting Systems*, the fire suppression systems must be connected to the *Fire Alarm Reporting System* for transmission of alarms, supervisory and trouble signals. \3\NFPA 13D systems are not required to be connected to the *Fire Alarm Reporting System*./3/

9-6.2.2 Where installed in areas without an *Installation Fire Alarm Reporting System*, the fire suppression system must be connected to a remote supervising station for alarm, supervisory and trouble signals.

9-6.3 Plans and Calculations.

9-6.3.1 All working (shop) drawings, regardless of the type of fire suppression system, must meet the drawing requirements in NFPA 13 for Working Drawings, unless the system specific standard has requirements for working drawings.

9-6.3.2 For new or modified systems, working (shop) drawings and calculations must be prepared by an individual that has obtained National Institute for Certification in Engineering Technologies, Automatic Sprinkler Systems, Level III certification or Special Hazards Suppression Systems, Level IV certification, as applicable to the project. The *QFPE* must review the shop drawings, hydraulic calculations and material submittals. The shop drawings must bear the *Review Stamp* of the *QFPE* prior to submitting the fire extinguishing system shop drawings to the *DFPE*.

For Army projects, construction (shop) drawings and calculations must be prepared by, or prepared under the immediate supervision of, the *QFPE*. The *QFPE* must affix their professional engineering stamp with signature to the shop drawings, calculations and material data sheets, indicating approval prior to submitting the fire extinguishing system shop drawings to the *DFPE*. The *QFPE* must monitor the installation of the fire protection systems and certify in writing that the fire protection systems have been constructed and operate as intended in the design plans and specifications.

9-6.3.3 When 20 or less sprinklers are modified or relocated, shop drawings, hydraulic calculations and material submittals are not required to be submitted.

9-6.3.4 The preparer of the shop drawings must perform calculations (i.e. hydraulic calculations, agent flow calculations) in accordance with the applicable NFPA standard, demonstrating that the design will provide an adequate supply for the fire suppression systems. Calculations must be submitted no later than the first shop drawing submission.

9-6.3.5 Hydraulic calculations must include a minimum pressure drop across backflow preventers. \3\For a reduced pressure backflow preventer, use a minimum of 12 psi (82.7 kPa). For a double check backflow preventer, use a minimum of 8 psi (55.2 kPa)./3/

9-6.3.6 When nitrogen is utilized in dry or preaction sprinkler systems, a C-factor of 120 is permitted to be used in hydraulic calculations.

9-6.3.7 The dimension from the edge of standpipes and fire suppression system risers to the nearest adjacent wall(s) must be indicated on the drawings when located in stairs or other portions of the means of egress.

9-6.3.8 The *QFPE* must consult with the DFPE or *Installation* fire safety agency to clarify location of fire department connection(s) or type of hose threads.

Note: The *Installation* fire safety agency will typically be the fire department.

9-6.4 Waterflow Testing.

Conduct waterflow tests, in accordance with the procedures contained in NFPA 291 to determine available water supply for the water-based fire extinguishing systems. The flow test must be performed under the direction of the *QFPE*.

Note: Hydraulic calculations should be based on a waterflow test that was performed no more than 6 months prior to submission of the calculations.

9-6.5 *Fire Water Demand.*

Domestic demand and hose stream are not required to be included in the *Fire Water Demand* when supplied from a utility or source separate from that supplied to the fire suppression system (i.e. tank for fire, water main for hydrant or domestic). Domestic or industrial demands are not included in the *Fire Water Demand* where means are provided to restrict these demands during a fire incident.

9-6.6 Backflow Prevention and Cross Connection Control.

The installation of backflow prevention and cross connection control must comply with AWWA Manual M 14.

9-6.6.1 Potable Water Supply.

For new fire suppression systems using water only, follow the *Installation* requirements for proper type of backflow prevention.

9-6.6.2 Installation \6\ of Backflow Preventers /6/.

9-6.6.2.1 Install a reduced pressure type backflow prevention device where antifreeze, foam or other chemicals are added into the system.

9-6.6.2.2 For locations subject to freezing, backflow preventers must be located in the *Facility* or within a heated enclosure. Provide a low temperature supervisory alarm connected to the *Facility* FACP for heated enclosures. Heat trace must not be used unless a heated enclosure cannot be provided.

9-6.6.2.3 Install horizontal backflow preventers so that the bottom of the assembly is no greater than 24-in. (610 mm) above the finished floor/grade. Install vertical backflow preventers so that the upper operating handwheel is no more than 6 feet (1.8 m) above the finished floor/grade.

9-6.6.3 Prior to the installation of backflow preventers in an existing fire suppression system, a thorough hydraulic analysis, including hydraulic calculations and flow test, must be performed to ensure that the water supply is still adequate for the system with the backflow preventer. If the backflow preventer causes the demand to exceed the water supply, the backflow preventer must not be installed until the water supply is corrected to support the new demand.

9-6.6.4 When installed as part of a fire pump system, piping and fittings suitable for potable water must be used upstream of the backflow preventer in accordance with local environmental requirements. The backflow preventer must be located where required by NFPA 20 unless the local environmental requirements differ.

9-6.6.5 Test Header.

9-6.6.5.1 All new water-based fire suppression systems must have test valves installed downstream of the backflow preventer. These valves must be angle or globe valves with 2.5-inch male National Standard Hose Threads with cap and chain. Provide one valve for each 250 gpm, and fraction thereof, of system design flow (e.g., a volumetric waterflow rate of 450 gpm would require two valves).

9-6.7 Meters.

Where meters are installed on a *Service Lateral* serving fire suppression systems, hydrants, or standpipe systems, they must be listed by a NRTL as fire service meters.

9-6.8 Painting and Labeling.

9-6.8.1 Labeling must be in accordance with MIL-STD-101, except as modified by this section.

9-6.8.2 Provide labeling on the surfaces of all feed and cross mains to show the pipe function (e.g., "Sprinkler System", "Fire Department Connection", "Standpipe"). \2\For pipe sizes 4-inch and larger (100 mm),/2/ provide white painted stenciled letters and arrows, a minimum of 2-in. (50 mm) in height and visible from at least two sides when viewed from the floor. \2\For pipe sizes less than 4-inch (100 mm), provide white painted stenciled letters and arrows, a minimum of 0.75-in. (18 mm) in height and visible from the floor./2/

9-6.8.3 All fire suppression system valves must be marked with permanent tags indicating normally open or normally closed.

9-7 AUTOMATIC SPRINKLER SYSTEMS.

9-7.1 General.

9-7.1.1 Automatic sprinkler systems must comply with NFPA 13, except where specifically modified by this UFC.

9-7.1.2 When automatic sprinkler protection is required by this UFC, it is meant that a wet pipe sprinkler system is to be provided, unless environmental concerns indicate otherwise (e.g., freezing conditions).

9-7.1.3 Sprinkler systems must use equipment and devices listed by a NRTL.

9-7.2 Application Requirements.

9-7.2.1 Complete automatic sprinkler protection must be provided \5\ where required by other codes or standards and for the following/5/:

9-7.2.1.1 Single-story, Type I or II construction *Facilities* greater than 15,000 ft^2 (1,394 m^2) gross floor area

9-7.2.1.2 Multi-story *Facilities*, regardless of floor area or construction type.

9-7.2.1.3 Single-story, Type III, IV and V construction greater than 5,000 ft^2 (465 m^2)

9-7.2.1.4 As specified by other sections of this UFC.

9-7.2.1.5 As required by the IBC for area, height or construction type modifications.

9-7.2.1.6 \2\ See the paragraph entitled "Automatic Sprinkler Systems" in the "Planning (Contract Document Development)" section of the "Introduction" Chapter in this UFC./2/

9-7.2.2 The requirement for automatic sprinkler protection for tension fabric structures must be determined by the DFPE

9-7.2.3 New or modified automatic sprinkler protection for existing *Facilities* must comply with the requirements of the "Existing Facilities" chapter of this UFC.

9-7.2.4 Sprinkler protection must be provided for additions \6\ or Modifications, as defined by NFPA 101, /6/ of existing *Facilities* if the entire gross floor area of the *Facility* (including the addition, if provided) exceeds the area limitations noted above \2\ or is multistory/2/.

9-7.2.4.1 \3\\2\The addition or portion of the building being modified must include sprinkler protection and be designed to support /3/sprinklers for the remainder of the *Facility*/2/.

9-7.2.4.2 \6\ Sprinkler protection is not required for minor Modifications when approved by the *CFPE*. /6/

9-7.3 Design Requirements.

9-7.3.1 *Facilities* requiring sprinkler protection must be provided with sprinkler systems that are designed using the Area/Density Method of NFPA 13, except the discharge requirements for non-storage occupancies must be in accordance with Table 9-3, unless otherwise specified in this UFC.

Note: Common DoD hazard classifications that are not noted in NFPA 13 can be found in Appendix B.

9-7.3.1.1 Residential occupancies must comply with the residential design criteria in NFPA 13, NFPA 13R or NFPA 13D, as applicable.\2\

9-7.3.1.2 /2/Storage occupancies, in mixed use *Facilities*, must follow the miscellaneous storage and storage provisions of NFPA 13.

9-7.3.2 Wet pipe, single-interlock preaction, and non-interlock preaction sprinkler systems must use the requirements for “wet” listed in Tables 9-3 and 9-4. Dry pipe, double-interlock preaction and deluge systems must use the requirements for “dry” listed in Tables 9-3 and 9-4.

9-7.3.3 Where NFPA 13 uses the term ordinary hazard group 1 or ordinary hazard group 2, the density, k-factor, hose stream and duration must be in accordance with the ordinary hazard classification listed in Tables 9-3 and 9-4.

9-7.3.4 Where NFPA 13 uses the term extra hazard group 1 or extra hazard group 2, the density, k-factor, hose stream and duration must be in accordance with the extra hazard classification listed in Tables 9-3 and 9-4.

Table 9-3 Sprinkler Design Demand and Minimum K-Factor

		(gpm/ft²)/ft² (mm/min)/m²[minimum K factor]							
		Ceiling Height up to 30 ft (9.1 m)		Ceiling Height >30-45 ft (9.1 m - 13.7 m)		Ceiling Height >45-60 ft (13.7 m - 18.3 m)		Ceiling Height >60 - 100 ft (18.3 m - 30.5 m)	
Hazard Classification		Wet	Dry	Wet	Dry	Wet	Dry	Wet	Dry
Light	Design	0.1/1500 (4/140)	0.1/1500 (4/140)	0.2/2500 (8/230)	0.2/3500 (8/330)	0.2/2500 (8/230)	0.2/3500 (8/330)	12 @ 7 psi	NA
	K-factor	5.6 (80)	5.6 (80)	11.2 (160)	11.2 (160)	11.2 (160)	11.2 (160)	25.2 (360)	NA
Ordinary	Design	0.2/2500 (8/230)	0.2/3500 (8/330)	0.2/2500 (8/230)	0.2/3500 (8/330)	0.2/2500 (8/230)	0.2/3500 (8/330)	12 @ 7 psi	NA
	K-factor	8.0 (115)	8.0 (115)	11.2 (160)	11.2 (160)	11.2 (160)	11.2 (160)	25.2 (360)	NA
Extra	Design	0.3/2500 (12/230)	0.3/3500 (12/330)	0.3/3600 (12/340)	0.3/4600 (12/430)	0.5/3000 (20/280)	0.5/4000 (20/370)	12 @ 7 psi	NA
	K-factor	11.2 (160)	11.2 (160)	11.2 (160)	11.2 (160)	11.2 (160)	11.2 (160)	25.2 (360)	NA
Note: For ceiling heights > 60 feet, the design demand is based on the number of sprinklers at an end sprinkler pressure (i.e. 12 sprinklers at 7 psi end pressure).									

9-7.3.5 Hose stream requirements must be in accordance with Table 9-4 unless otherwise modified by this UFC.

Table 9-4 Hose Stream Demand and Duration

Hazard Category	Hose Demand, gpm (lpm) Ceilings 60 ft (18.3 m) or less	Hose Demand, gpm (lpm) Ceilings greater than 60 ft (18.3 m)	Duration, min
Light	250 (950)	500 (1900)	60
Ordinary	250 (950)	500 (1900)	60
Extra	500 (1900)	500 (1900)	90

9-7.3.6 The design areas noted above or in NFPA 13, as applicable, must be increased by 30 percent for sloped ceilings that exceed a slope of 2 in 12.

9-7.3.7 The design area reductions in NFPA 13 for quick-response sprinklers are not permitted.

9-7.4 Sprinkler Coverage.

9-7.4.1 In *Facilities* protected by automatic sprinklers, sprinklers must provide coverage throughout the *Facility*.

9-7.4.1.1 Sprinklers may be omitted where permitted by NFPA 13, NFPA 13R or NFPA 13D, as applicable.

9-7.4.1.2 Sprinklers may be omitted from small rooms in specific occupancies in accordance with NFPA 101.

9-7.4.2 Sprinklers must be provided in electrical rooms, regardless of the fire resistance rated separation.

9-7.4.3 The use of extended coverage sprinklers is not permitted \2\except as noted below.

9-7.4.3.1 Extended coverage sprinklers may be used for the protection of loading docks.

9-7.4.3.2 Extended coverage sprinklers maybe used for the protection of historic structures and unique spaces subject to the written approval of the DFPE./2/

9-7.4.4 Listed or approved residential sprinklers are permitted to be used at their listed/approved spacing and coverage.

9-7.5 Hydraulic Calculations.

9-7.5.1 Sprinkler systems must be designed using hydraulic calculations.

9-7.5.1.1 Sprinkler systems permitted by this UFC to be supplied from the domestic plumbing may be designed using the pipe schedule method in NFPA 13.

9-7.5.1.2 The addition of no more than 20 sprinklers to an existing system is permitted to be designed using the pipe schedule based on the layout of the existing system.

9-7.5.2 Where the sprinkler system is supplied by interconnected risers, the sprinkler system must be hydraulically calculated using the hydraulically most demanding single riser. The calculations must not assume the simultaneous use of more than one riser.

9-7.6 Piping.

9-7.6.1.1 Galvanized piping is only permitted for deluge sprinkler systems, valve trim piping and drain piping exposed to the *Facility* exterior.

9-7.6.1.2 Black steel pipe must be used for the addition, repair or relocation of existing galvanized pipe in wet pipe, dry pipe or preaction systems.\2\

9-7.6.2 /2/Piping 2-in. (50 mm) and less must be minimum Schedule 40. Piping larger than 2-in. (50 mm) must be minimum Schedule 10. \2\For DLA, use Schedule 40 steel piping for all sprinkler systems and all pipe sizes.

9-7.6.3 CPVC is only permitted for residential occupancies. \6\ Air Force permits the use of CPVC and other listed plastic sprinkler pipe in any occupancy for which an approved listing exists when installed in strict accordance with the approved listing. /6/

9-7.6.4 /2/Plain end fittings with mechanical couplings and fittings that use steel gripping devices to bite into the pipe are prohibited.

9-7.6.5 Steel piping with wall thickness less than Schedule 40 must not be threaded.

9-7.6.6 Saddle tees using rubber gasket fittings are only permitted when connecting to existing piping for additions or modifications. Saddle tees must use a connection method that completely wraps around the pipe.

9-7.6.7 Fittings, mechanical couplings, and rubber gaskets must be from the same manufacturer.

9-7.6.8 The use of flexible sprinkler hose with fittings intended for direct connection to sprinklers \2\must be approved by the \6\ *DFPE* /2/ /6/.

9-7.6.9 Changes in pipe sizes must be made through tapered reducing pipe fittings.

9-7.6.10 Threaded fittings must use Teflon tape or manufacturer's approved joint compound.

9-7.7 Nitrogen Generation Systems.

9-7.7.1 Design the nitrogen generation system so all equipment is installed within the confines of the riser room with the exception of a connection for a manual gas analyzer.

9-7.7.2 Provide a nitrogen generation system that is capable of delivering a minimum of 98 percent nitrogen composition throughout all of the system piping within 14 days from the commencement of the inerting process.

9-7.7.3 The nitrogen generation system must be self-contained with "drop-in" operability with a simple one step direct connection of the nitrogen gas supply line to each zone.

9-7.7.4 The use of stand-alone compressed nitrogen bottle system is not permitted.

9-7.7.5 A process that involves continuous venting of the piping network is not permitted.

9-7.7.6 Any air maintenance device used in conjunction with the nitrogen generation system must be listed or approved for use on sprinkler systems.

9-7.8 Preaction Systems.

9-7.8.1 Preaction systems must utilize nitrogen complying with the "Nitrogen Generation Systems" section of this UFC\2\/2/.

9-7.9 Dry Pipe Systems.

9-7.9.1 Dry pipe systems must utilize \2\/2/nitrogen \2\complying with the "Nitrogen Generation Systems" section of this UFC./2/

9-7.9.2 The delivery of water from the dry pipe valve to the system test connection \2\must not exceed 60 seconds/2/. Water delivery times must be measured starting at the normal nitrogen\2\/2/ pressure on the system.

9-7.9.3 All rubber gasket grooved-end pipe fittings for dry pipe systems must be listed or approved for dry pipe systems.

9-7.10 System Requirements.

9-7.10.1 Provide a minimum clearance of 3 feet (915 mm) access to and in front of all equipment and 6-in. (150 mm) behind the equipment (e.g., control valves, backflow preventer, check valves, floor control valve assemblies, waterflow switches, etc.).

9-7.10.2 Thrust rod all pipe penetrations through the grade floor slab, unless flanged or welded joints are used throughout the below slab piping. All pipe penetrations through the grade floor slab must be sleeved and sealed.

9-7.10.3 The *QFPE* must coordinate with the Structural Engineer to determine the proper seismic design category for the project, in accordance with the IBC or ASCE guidelines. Seismic restraint is not required for Seismic design category A or B, except as otherwise required in this UFC.

Note: See UFC 3-301-01 for more information.

9-7.10.4 Drain and Test Connections.

9-7.10.4.1 Provide a permanently piped drain/test connection for each waterflow switch, including the waterflow switch for elevator power shunt.

9-7.10.4.2 Terminate all main drains and inspector's test connections piping to the exterior of the *Facility* so it will not cause damage. Discharge to the exterior must not interfere with exiting from the *Facility*. Water discharge or runoff must not cross an exit or exit discharge path. Do not discharge to the roof.

9-7.10.4.3 Termination points interior to the building are permitted to be approved by the *DFPE* when exterior termination is not practical.

9-7.10.4.4 Provide concrete splash blocks at all drain and inspector's test connection discharge locations if not discharging to a concrete surface. Splash blocks must be large enough to mitigate erosion and must not become dislodged during a full flow of the main drain. Ensure all discharged water drains away from the *Facility* and does not cause property damage.

9-7.10.4.5 Any drains, test connection pipe, etc., that penetrate the exterior wall must do so no greater than 2 feet (610 mm) above finished grade, and at no time below grade.

9-7.10.4.6 The drain/test connection must be piped to a location that will accept full flow and will not cause property damage when water is discharging.

Note: Comply with any applicable state or local environmental requirements pertaining to the handling of sprinkler discharge water.

9-7.10.5 Individual floor control assemblies are to be provided for each respective floor when there are three or more floor levels. Floor area meeting the IBC definition of a mezzanine is not considered a floor level when applying this requirement.

9-7.10.6 Provide a dedicated control valve assembly for piping serving rooms that require shunt-tripping of equipment power prior to or simultaneously to the application of water. Locate the control valve assembly outside of the area it serves in an easily accessible identified location.

9-7.10.7 Normally open valves required by NFPA 13 or NFPA 13R \4\/4/to be supervised must be electrically supervised (i.e. tamper switch).

9-7.10.8 Normally closed valves required by NFPA 13, NFPA 13R or NFPA 13D to be supervised must be locked or sealed, unless otherwise required by this UFC.

9-7.10.9 Provide listed or approved sprinkler guards for sprinklers that are less than 7 feet (2.1 m) above finished floor (in unfinished areas) or subject to mechanical damage or can be grabbed from the floor level.

9-7.10.10 Sprinklers installed in any detention areas, regardless of the *Facility* occupancy classification, must be listed/approved institutional sprinklers.

9-7.10.11 Piping up to the backflow preventer, when the fire protection system is connected to a domestic water source, must be disinfected. Disinfection of all other aboveground fire protection system piping is not required.

9-7.11 Family Housing.

When sprinkler systems are provided in family housing in geographic locations having a 99.6% dry bulb temperature less than 32°F (0°C) per UFC 3-400-02 Engineering Weather Data, sprinkler piping is prohibited from being located in attic spaces or exterior walls (except for the incoming service). Locate upper story piping only in interior walls and utilize sidewall sprinklers.

9-8 WATER SPRAY SYSTEMS.

Water spray systems must comply with NFPA 15 and the "Fire Suppression Systems" requirements of this UFC.

9-9 FOAM SYSTEMS.

9-9.1 General.

9-9.1.1 Foam systems must comply with NFPA 11 and NFPA 16, and the "Fire Suppression Systems" requirements of this UFC, except as modified below.\4\

9-9.1.2 /4/New systems must use potable water or a water source that is supplied from a potable water system (i.e. a water storage tank that is filled from a potable water system). The use of saltwater, brackish or other untreated water source must be approved by the \6\ *CFPE* /6/.

9-9.1.3 Foam storage tanks must be labeled indicating vendor, model, type, and quantity of foam held within the tank via permanent sign.

9-9.1.4 \2\Consider all local environmental regulations to determine the control, treatment and/or remediation measures for the discharge of fire suppression effluent./2/

9-9.2 Piping.

9-9.2.1 Foam solution piping must be Schedule 40 steel pipe.

9-9.2.2 Foam concentrate piping must be stainless steel pipe with roll grooved fittings, welded joints and fittings, or flanged joints and fittings. If using welded joints and fittings, consideration must be given to the maintenance of the system and provide flanged joints at certain locations to allow for the ease of maintenance and equipment removal. Gasket material must be approved by the foam concentrate manufacturer.

9-9.2.3 Any concealed concentrate piping must use welded or flanged fittings.

9-9.2.4 Trim piping on all deluge valves, flow control valves, and alarm check valves must be brass.

9-9.2.5 Foam concentrate lines must be located above grade.

9-9.3 Aqueous Film-Forming Foam (AFFF) \4\Systems/4/.

9-9.3.1 \4\Installation of a new AFFF system is prohibited.

9-9.3.2 Discharged AFFF solution must be contained and collected. The containment and collection system must use double-walled \6\ /6/ storage tank(s) for collection of the AFFF solution. \6\/4//6/

9-9.3.3 Foam Systems that utilize AFFF must only use AFFF concentrate meeting Military Specification MIL-F-24385F.

9-9.4 Foam Concentrate Pumps.

Foam concentrate pumps must be used where the distance from the tank to the proportioner exceeds 50 feet (15.3 m), or the manufacturer recommended distance based on water supply, whichever is less.

9-9.5 Foam Concentrate Storage Tanks.

9-9.5.1 Foam concentrate storage tanks can be atmospheric or horizontal bladder.

9-9.5.2 Do not use vertical bladder tanks.

9-9.5.3 Atmospheric tanks must be translucent or opaque, double-walled, polyethylene.

9-9.6 Foam Concentrate Control Valves.

9-9.6.1 For automatic control of foam concentrate, provide valves listed or approved for use with foam concentrate.

9-9.6.2 Isolation control valves must be full port ball type with an operating handle that indicates the on/off position of the valve. Unit must be socket weld or flanged type. Valve body and ball must be 316 stainless steel complying with ASTM A351.

9-9.6.3 All foam system valves affecting foam delivery must be electrically supervised for correct position.

9-9.7 Foam Concentrate Spill Control.

9-9.7.1 Spill control must be provided around foam storage tank(s) to help prevent spilled/leaked foam concentrate from reaching any drains.

9-9.7.2 Spill control must consist of a minimum 4-in. (100 mm) high concrete berm or similar and sized for the full volume of the tank. Double-walled polyethylene tanks can qualify as acceptable spill control provided there are no taps or outlets in the sides or bottom of the tank.

9-9.8 Test Liquid.

Surrogate test liquid (alternate test liquid) is permitted to be used for initial acceptance testing and routine testing if the liquid and test method is approved by a *DoD Component*.

9-9.9 Foam Discharge.

Foam solution discharge for maintenance and testing purposes must be in accordance with local *Installation* environmental requirements.

9-10 STANDPIPE SYSTEMS.

9-10.1 General.

When required, standpipe systems must comply with NFPA 14 and the "Fire Suppression Systems" requirements of this UFC, except as modified below.

Residual pressure requirements for *Facilities* under 150 feet (45 m) in height may be met by fire department apparatus when hydraulic calculations demonstrate that fire department apparatus can provide the required pressure via the building fire department connection(s)\6\ /6/.

9-10.2 Class I Standpipe Systems.

9-10.2.1 A Class I standpipe system must be provided in all required exit stairs of *Facilities* four stories or more in height.

9-10.2.2 For *Facilities* less than four stories in height, \2\provide a/2/ Class I standpipe system\2\ where all portions/2/ of the building (on any floor) \2\cannot be reached from an exterior door in less than/2/ 450 feet (140 m).

9-10.2.2.1 When required by this section, standpipes must be installed in all required exit stairs and on both side of horizontal exits.

9-10.2.3 Standpipes and hose valves must not encroach into the means of egress especially on stair landings.

9-10.3 Class II and III Standpipes.

Class II and III standpipes, as defined in NFPA 14 are not permitted.

9-11 DRY CHEMICAL EXTINGUISHING SYSTEMS.

Note: Fixed dry chemical extinguishing systems are appropriate for the protection of certain types of special occupancies, hazards, and facilities such as dip tanks, and other operations involving flammable liquids.

9-11.1 General.

Dry chemical extinguishing system must comply with NFPA 17 and the "Fire Suppression Systems" requirements of this UFC, except as modified below.

9-11.2 Limitations.

Dry chemical agents must not be used to protect sensitive electronics. Dry chemical extinguishing systems must not be used for the protection of cooking equipment.

9-12 WET CHEMICAL EXTINGUISHING SYSTEMS.

Note: Fixed wet chemical extinguishing systems are suitable for protection of certain types of special occupancies, hazards, and facilities, such as cooking surfaces, cooking exhaust systems, and dip tanks.

9-12.1 General.

Wet chemical extinguishing systems must comply with NFPA 17A and the "Fire Suppression Systems" requirements of this UFC, except as modified below.

9-12.2 Testing.

Testing must be performed by liquid discharge, utilizing the manufacturer’s recommended flushing concentrate, to demonstrate equal distribution of chemical and no leakage at pipe joints.

9-13 CLEAN AGENT FIRE EXTINGUISHING SYSTEMS.

Note: Clean agent fire extinguishing systems are suitable for protection of certain types of special occupancies, hazards, and facilities.

9-13.1 General.

9-13.1.1 Clean agent fire extinguishing systems must comply with NFPA 2001 and the "Fire Suppression Systems" requirements of this UFC, except as modified below.

9-13.1.2 Clean agent fire extinguishing systems are not permitted to substitute for required automatic sprinkler systems.

9-13.1.3 Fire extinguishing agents that have been identified for future manufacturing or use limitations must not be used, regardless if current installation is permitted by regulatory authorities in the country of application.\1\/1/

9-13.2 Requirements.

9-13.2.1 Provide stand-alone (not dependent upon the *Facility* fire alarm system for operation) control panels that are listed for releasing device service and monitored by the *Facility* fire alarm system.

9-13.2.2 Careful consideration must be given to compartment under/over-pressurization during the discharge of total flooding clean agent systems. Pressure relieving vents, located near the finished ceiling, may be necessary to regulate rapid pressure changes during discharge. Comply with the manufacturer's recommended procedures relative to enclosure venting.

9-13.2.3 Provide a manually activated \2\permanent/2/ exhaust system to facilitate the extraction of any remaining clean agent after the required hold time of the total flooding clean agent system.

9-13.2.3.1 The exhaust system can be integrated into the HVAC system for the enclosure, but in no case \2\/2/ designed for less than six air changes per hour.

9-13.2.3.2 The manual activation switch must be located outside of the protected area.

9-13.2.3.3 Permanent signage must be provided indicating "Fire Suppression Exhaust System – Fire Department Use Only".

9-14 WATER MIST FIRE PROTECTION SYSTEMS.

Note: Water mist fire protection systems are suitable for protection of certain types of special occupancies, hazards, and facilities. Water mist fire protection systems are not a substitute for required automatic sprinkler systems.

9-14.1 General.

9-14.1.1 Water mist fire protection systems must comply with NFPA 750 and the "Fire Suppression Systems" requirements of this UFC, except as modified below.

9-14.1.2 Provide stand-alone (not dependent upon the *Facility* fire alarm system for operation) control panels that are listed for releasing device service and monitored by the *Facility* fire alarm system.

9-15 CARBON DIOXIDE SYSTEMS.

Note: Carbon dioxide (CO_2) systems are normally effective against flammable liquid (Class B) and energized electrical (Class C) fires.

9-15.1 General.

9-15.1.1 Carbon dioxide system must comply with NFPA 12 and the "Fire Suppression Systems" requirements of this UFC, except as modified below.

9-15.1.2 New total flooding systems are not permitted in normally occupied areas.

9-15.1.3 Do not locate CO_2 piping in any area where a pipe break or leak could make a normally occupied area untenable.

9-15.1.4 Careful consideration must be given to compartment under/over-pressurization during the discharge of total flooding CO_2 systems. Comply with NFPA 12 and the manufacturer's recommended procedures relative to enclosure venting.

9-15.1.5 Provide a manually activated exhaust system to facilitate the extraction of any remaining CO_2 after the required holding time of the total flooding CO_2 system. The exhaust system can be integrated into the HVAC system for the enclosure but in no case \2\/2/ designed for less than six air changes per hour. The manual activation switch must be located outside of the protected area.

9-16 HALON 1301 SYSTEMS.

9-16.1 General.

Installation of a new Halon 1301 system is prohibited except by special approval of \1\Service Signature Authority/1/.

9-16.2 Halon Turn-In Procedures.

For projects involving the demolition of existing Halon 1301 systems, refer to the following for turn-in requirements: http://www.dla.mil/aviation

9-17 PORTABLE FIRE EXTINGUISHERS.

9-17.1 General.

General purpose portable fire extinguishers \4\must be provided where required by NFPA 101./4/

9-17.2 Location.

9-17.2.1 When provided, portable fire extinguishers must be located in accordance with NFPA 10.

9-17.2.2 If provided in *Electronic Equipment Areas*, clean agent type portable fire extinguishers must be used.

9-17.2.3 Portable fire extinguishers utilizing carbon dioxide (CO_2) are only permitted to be used in enclosed rooms if they exceed 1,000 ft^2 (92.9 m^2).\2\

9-18 /2/FIRE ALARM SYSTEMS.

9-18.1 General.

\4\Provide fire alarm systems when required by NFPA 101 or when automatic detection or suppression systems are required./4/

9-18.1.1 Fire alarm systems (detection and notification) must comply with the applicable provisions of NFPA 72 and the ABA, except as modified by this UFC.

9-18.1.1.1 Buildings or portions of the building that are not required to comply with ABA/ABAAG, must still comply with NFPA 72.

9-18.1.2 Fire alarm systems must be independent, stand-alone systems that are not an integral part of a security, energy monitoring and control system (EMCS), or other system.

9-18.1.2.1 The fire alarm system must be combined with a *Facility* mass notification system or with a combination *Facility* mass notification and public address system when mass notification is required by UFC 4-010-01. The fire alarm system, or combined *Facility* mass notification and fire alarm system, may be separate from a public address system.

9-18.1.2.2 The fire alarm system is permitted to be connected to the EMCS or similar system to affect shutdown of HVAC units that require shutdown according to UFC 4-010-01 and UFC 4-021-01, but are otherwise not required to be controlled by the fire alarm system.

9-18.1.2.3 Fire alarm systems may be connected to security systems or an EMCS for monitoring purposes only, but must in no way rely on those other systems for operation or reporting.

9-18.1.3 Wireless interior fire alarm systems and devices are not permitted.

9-18.2 Plans and Calculations.

For new or modified systems, construction (shop) drawings and calculations must be prepared by an individual that has obtained National Institute for Certification in Engineering Technologies, Fire Alarm Systems, Level III certification, at a minimum. The *QFPE* must review the shop drawings, calculations and material submittals. The shop drawings must bear the *Review Stamp* of the *QFPE* prior to submitting the fire alarm system shop drawings to the *DFPE*.

For Army, construction (shop) drawings and calculations must be prepared by, or prepared under the immediate supervision of, the *QFPE*. The *QFPE* must affix their professional engineering stamp with signature to the shop drawings, calculations and material data sheets, indicating approval prior to submitting the fire alarm system shop drawings to the *DFPE*. The *QFPE* must monitor the installation of the fire alarm system and certify in writing that the fire alarm system has been constructed and operates as intended in the design plans and specifications.

9-18.3 *Fire Alarm Reporting System.*

9-18.3.1 *Fire Alarm Reporting Systems* must conform to NFPA 72 and NFPA 70.

9-18.3.2 The *Facility* fire alarm system must be connected to the *Fire Alarm Reporting System*.

9-18.3.3 The following signals, at a minimum, must be transmitted via the *Fire Alarm Reporting System*:

a. Alarm signal by device type (e.g., waterflow, manual pull station, sleeping room smoke detector).

b. General supervisory signal.

c. General trouble signal.

9-18.3.4 New exterior fire alarm boxes are not required at DoD *Installations*, nor is it required to replace existing boxes that are not needed for the transmission of automatic alarms.

9-18.3.5 *Fire Alarm Reporting Systems* must provide the following where applicable:

a. Transmission of coded signals to fire department headquarters or other central locations;

b. Permanent record of alarm signal, time, and date;

c. Automatic supervision of alarm initiating circuits;

d. Automatic testing of radio signaling devices;

e. A dedicated transmitter that will transmit alarm, supervisory and trouble signals for each *Facility*; and

f. Transmitters must be listed or approved for use with the existing *Fire Alarm Reporting System*.

9-18.4 Control Panels.

9-18.4.1 The fire alarm control panel must be analog/addressable, site programmable panel, and must have, or be capable of, the following:

a. The ability to store at least 400 events in the history log. These events must be stored in a non-volatile memory and remain in the memory until the memory is downloaded or cleared manually.

b. Resetting of the control panel must not clear the memory from being retrieved on the integral LCD display.

c. An integral LCD 80 character (minimum) alphanumeric display.

d. Provide all smoke detectors connected to the FACP with an adjustable alarm verification feature. Initially set the alarm verification at 20 seconds.

Existing fire detection systems that are controlled by *Facility* management, energy or utility management systems are permitted to remain.

9-18.4.1.1 A conventional control panel is permitted to be used for systems monitoring sprinkler system alarm, supervisory and trouble conditions only as permitted by NFPA 101 (e.g. a warehouse).

9-18.4.2 \3\/3/Locate the control panel and supplemental control panels in a year-round environmentally conditioned space within the *Facility* that complies with the environmental conditions required in the panel approval or listing.

Note: Environmental condition values (temperature and humidity) are taken from UFC 3-400-02.

9-18.4.3 If the fire alarm control panel is not located at the designated primary entrance, provide a remote annunciator at the designated primary entrance unless directed otherwise by the contract documents. Provide remote annunciator with control functions the same as the main control panel. Control functions must be accessible only by user code or secured behind a locked panel.

9-18.5 Detection.

Note: Detection systems, especially smoke detection systems, require significant maintenance. It is critical that the required detectors are properly installed and maintained. Providing detectors in locations that are not required increases the already high maintenance costs of alarm systems and strains the maintenance program for critical detection systems. If a *Facility* warrants protection and criteria does not require detection, protection must be accomplished by a wet pipe sprinkler system. Wet pipe sprinklers provide superior protection with little maintenance.

9-18.5.1 General.

9-18.5.1.1 Fire detection systems must be provided in areas required by this UFC or where required by NFPA standards and must be limited to these applications unless an *Exemption* is approved\1\/1/.

9-18.5.1.2 The area of protection for smoke detection devices permitted by NFPA 72 must be reduced by 50 percent where destratification (ceiling) fans are used (e.g., this may require additional smoke detectors for that area being protected).

9-18.5.1.3 The above reduction is in addition to any other reductions in spacing required by NFPA 72 (e.g., high ceiling, high air-flow).

9-18.5.2 Requirements.

Detection systems must be arranged to alert *Facility* occupants and to transmit an alarm signal via a *Fire Alarm Reporting System*.

9-18.6 Notification.

9-18.6.1 Notification must be provided throughout the entire *Facility* \6\ when a fire alarm system is provided. /6/

9-18.6.2 Where a mass notification system is required, fire alarm notification must be via a voice evacuation system and must serve as the method of notification for the mass notification system.

9-18.6.3 Audible and Visible Notification Appliances.

a. Provide a minimum of one notification appliance circuit per floor. Each notification appliance circuit must include 25 percent spare capacity.

b. Sleeping room speakers must produce a 520 Hz signal temporal three (T3) signal for fire in accordance with NFPA 72.

c. Provide a 520 Hz signal temporal four (T4) signal for carbon monoxide in accordance with NFPA 72 when required by the "Carbon Monoxide (CO) Detection" section of this UFC.

d. The provision of a sounder base does not negate the requirement of the *Facility*'s audible notification appliances for each sleeping room.

e. The performance requirements for audible notification must be met with all doors, fire shutters, movable partitions, and other similar devices closed.

f. Visible notification must be provided in all normally occupied, public and common use areas (e.g., break rooms, corridors, auditoriums or conference rooms).

g. Visible notification must be provided in all normally unoccupied areas (such as mechanical rooms, electrical rooms, janitor rooms, storage areas, communication closets and other similar spaces) greater than 900 ft^2 (84 m^2).

h. Visible notification is required in any normally unoccupied area where the ambient noise is loud enough to require hearing protection (e.g., compressor room).

i. Visible notification must be provided in all offices that are designed for, or may contain, more than four persons at any one time. For Air Force, visual notification must be provided in all offices that are designated for, or may contain, two or more persons at any one time.

Note: This must be determined by the furniture plan. If \3more than four/3/ chairs with work surfaces are assigned to the room, visible notification is required. For Air Force if two or more chairs (with or without work surfaces) are assigned to the room, visual notification is required.

j. Visible notification is not required in single person offices, unless the office is assigned to a person with a hearing impairment that would require a visible notification appliance.

k. Visible notification is not required in bathrooms serving single person offices, unless the office is assigned to a person with a hearing impairment that would require a visible notification appliance.

l. Visible notification appliances must be provided with a clear lens marked "Alert". The use of "Fire" is not permitted.

9-18.6.4 Mass Notification System (MNS).

Refer to UFC 4-021-01.

9-18.6.5 Voice Message.

For systems using voice evacuation or combined with the mass notification system, the default fire alarm voice evacuation message\2\ should/2/ be a female voice and state the following:

> (Temporal 3 Alert Tone) "May I have your attention please. May I have your attention please. A fire emergency has been reported in the building. Please leave the building by the nearest exit or exit stairway. Do not use the elevators". <provide a 2 second pause> "May I have your attention please..." (repeat the message).

Installations with formally established and approved/published in accordance with the Service/Agency policy standard signals and messages are permitted to utilize those standard signals and messages. \2\/2/The general format must be a specific alert signal tone(s) followed by a voice announcement(s) and then repeats the cycle for a specific number of cycles or continuously as appropriate for the message.

Note 1: For single-story *Facilities*, delete "or exit stairway. Do not use the elevators" from the voice message.

\2\Note 2: See "Appendix E" for guidance on other messages./2/

9-18.7 Initiating Devices.

9-18.7.1 Sprinkler Waterflow.

Provide a separate address for each sprinkler waterflow switch.

9-18.7.2 Sprinkler System Supervisory Air or Gas.

Monitor high and low air or gas pressure on dry pipe and preaction systems on a per riser room basis as a supervisory function with the *Facility* fire alarm system.

9-18.7.3 Valve Tamper.

No more than five adjacent valve tamper switches within the same room are permitted to be monitored by the same addressable device or supervisory circuit.

9-18.7.4 Manual Pull Station.

9-18.7.4.1 \2\Manual pull stations must be provided at all exits, regardless of occupancy. Manual pull stations must be located within five feet of the exit door. The 200 foot travel distance to a manual pull station noted in NFPA 101 is not applicable./2/

9-18.7.4.2 Provide addressable double-action type manual pull stations with mechanical reset features. If the manual pull station requires a key for reset, it must be the same key as required for the fire alarm control panel.

9-18.7.4.3 Conventional single-action manual pull stations are permitted in hazardous areas, wet and damp locations, and other areas where specialty listings are required. Where a conventional manual pull station is used, it must be provided with a separate address.

9-18.7.5 Smoke Detection.

9-18.7.5.1 Provide 24 Vdc photoelectric smoke detectors in all sleeping rooms and duty rooms located in business or other occupancies. Not applicable to inpatient sleeping rooms of healthcare occupancies.

9-18.7.5.2 Upon detection of smoke, an audible signal must be activated in the respective sleeping room, dwelling unit/suite or duty room, send a distinct signal to the *Facility* fire alarm control panel, if required by other sections of this UFC, and to the *Installation* fire reporting system, but not activate the *Facility* notification appliances.

9-18.7.5.3 See Chapter 4 for Open Bay Personnel Housing.

9-18.7.5.4 The audible signal must be low frequency as required by NFPA 72.

9-18.7.6 Under-floor Smoke Detector Identification.

When under-floor smoke detectors are provided, provide a framed CAD drawn floor plan showing the location of the devices in the room and their corresponding address. Locate a single framed drawing of the location of the smoke detectors outside of the space and adjacent to the main entrance.

9-18.8 Power Disconnect.

For disconnecting power supplies, provide listed control relays located within 3 feet (915 mm) of the shunt trip breaker. Operation of relay must be controlled by a listed fire alarm control unit. Relay must function within the voltage and current limitations of the fire alarm control unit. Relay contacts must be listed for the connected load.

9-18.9 Wiring, Circuits and Conduit.

9-18.9.1 \6\/6/ Pathways for addressable detection, notification, and signaling line circuits \6\ must be Class B, unless otherwise approved by the Service *DFPE*. /6/

9-18.9.2 All conductors must be installed in conduit (EMT minimum).

9-18.9.3 Conductors.

9-18.9.3.1 Pull all conductors splice free; conductors must be continuous from device to device. The use of wire nuts, crimped connectors, or twisting of conductors is prohibited.

9-18.9.3.2 Run all wiring to and within control panels in the vertical or horizontal plane, make all turns at 90 degree angles, and tightly bundle, wrap, and identify all conductors individually with permanent markings. Conductor markings must be printed labels, permanently affixed to the conductor via shrink wrap.

9-18.9.4 Conductor Type.

9-18.9.4.1 Wiring may be solid copper or stranded as permitted by NFPA 70.

9-18.9.4.2 All signaling line circuits must be minimum 18 AWG. Initiating device and notification appliance circuits must be minimum 16 AWG.

9-18.9.4.3 Initiating device circuits used for optical flame detection devices must use shielded cable.

9-18.9.5 Device Termination.

All devices must have screw terminals. Where devices are only provided with pigtails from the manufacturer, pigtails must be landed on terminal strips mounted within the junction box.

9-18.9.6 Conductor Terminations.

All terminations must be at a terminal strip or the device screw terminals. Terminal strips are only permitted where direct connection to a device is not possible. (e.g., pigtails off a rate-compensating heat detector).

9-18.9.7 Identification.

9-18.9.7.1 \5\In unfinished areas, all /5/ conduit, junction/back boxes, covers, and couplings, when provided, must be factory painted red \5\/5/(e.g., above ceilings, mechanical rooms, \4\concealed spaces,/4/ etc.).

9-18.9.7.2 \5\In finished areas, all /5/\4\exposed/4/ conduit, junction/back boxes, covers and couplings, when provided, \4\\5\/5/ must be factory painted red\5\ or /5/conduit, junction/back boxes, covers, and couplings are permitted to be painted to match the room finish and/4/ the inside cover of the junction box must be identified as "Fire Alarm"\4\/4/.

9-18.10 Surge Suppression.

9-18.10.1 Provide surge suppression (SPD) for all signaling line circuits, indicating device circuits, or notification appliance circuits that leave or enter a *Facility's* exterior enclosure.

9-18.10.2 SPD must be provided at the first location where connections are made that is close to where the circuit enters or leaves the *Facility*, prior to connection to any other devices when feasible.

9-18.10.3 SPD is not required for devices connected directly to the *Facility* exterior when the *Facility* itself is provided with lightning protection (i.e. an electric bell or speakers mounted on the exterior wall of the *Facility*.)

9-18.11 Power.

9-18.11.1 Provide primary power in accordance with UFC 3-520-01. This includes the provision of a lock-on circuit breaker.

9-18.11.2 Provide SPD on all 120 Vac circuits to control panels, subpanels, transmitters, amplifier panels, and booster panels. SPD must have both a UL 1449 and UL 1283 listing and must be located in an adjacent hinged terminal box.

9-18.11.3 Secondary Power.

Provide rechargeable batteries per NFPA 72 to operate the fire alarm system under supervisory conditions for 48 hours and all alarm devices for an additional 15 minutes. Where the fire alarm system also serves as a mass notification system, refer to UFC 4-021-01 for additional requirements.

9-18.12 Releasing Control Panels.

9-18.12.1 In addition to the requirements specified above for fire alarm control panels, panels used for control or release of fire suppression systems must be listed by a NRTL for releasing service.

9-18.12.1.1 Provide a separate releasing panel independent of the *Facility* fire alarm system panel to activate the system.

9-18.12.1.2 A combined fire alarm/releasing panel is permitted for small *Facilities* with the approval of the *DFPE*.

9-18.12.2 Electronic solenoids used for release of the suppression system must be listed by a NRTL for use with both the releasing panel and the suppression equipment.

9-18.12.3 Provide rechargeable batteries per NFPA 72 to operate the releasing panel under supervisory conditions for 48 hours and alarm conditions for an additional 15 minutes. Include the full current draw of the solenoid in the battery calculations.

9-18.12.4 When more than one panel is used, each panel must be monitored independently by the *Facility* fire alarm control panel.

9-18.12.5 Locate the panel adjacent to, but not in, the hazard/area served. The releasing panel and supplemental control panels must be located in a year-round environmentally conditioned space that complies with the environmental conditions required in the listing.

9-18.12.6 When required, pre-discharge and discharge alarms must consist of audible and visible notification appliances that are different than the *Facility* fire alarm system notification appliances.

9-19 CARBON MONOXIDE (CO) DETECTION.

9-19.1 General.

9-19.1.1 Provide carbon monoxide detection in facilities with combustible fuel burning equipment (e.g., air handling units, heaters, stoves, fireplaces).

9-19.1.2 Carbon monoxide detection must conform to the requirements of NFPA 72 and the manufacturer’s requirements, except as modified by this UFC.

9-19.1.3 Carbon monoxide detectors must be powered by the fire alarm control panel (i.e. 24 Vdc). Where a fire alarm system is not provided, 120 Vac \2\ carbon monoxide alarms/2/ are permitted.

9-19.2 Installation.

9-19.2.1 Detectors must be located in each room/space where the fuel burning appliances(s) are located.

9-19.2.2 \2\Where HVAC equipment utilizes fuel burning equipment, one detector must be located downstream of the fuel burning equipment./2/

9-19.2.3 \3\For large open spaces with ceiling heights greater than 12 feet, i.e, storage facilities, aircraft hangar bay, large industrial spaces, and similar spaces, carbon monoxide detection is not required./3/

9-19.3 Notification.

9-19.3.1 Where a fire alarm voice evacuation system is provided, activation of a carbon monoxide detection device must initiate a unique voice notification message.

9-19.3.1.1 The alert signal portion of the voice alarm message for carbon monoxide detection must be a 520 Hz temporal 4 (T-4) signal. The alert signal must repeat twice before the voice announcement.

9-19.3.1.2 A sample message is as follows: (Temporal 4 Alert Tone) "Attention….Attention….Carbon monoxide has been detected in the building. Please leave the building by the nearest exit." (Temporal 4 Alert Tone)

9-19.3.2 Where a voice evacuation system is not provided, activation of a carbon monoxide detector must initiate an audible alarm distinctly different from other audible alarm signals in the *Facility*. Distinct visible notification is not required.

9-19.3.3 When part of the fire alarm system, activation of a carbon monoxide detector must send a separate "carbon monoxide detector" alarm signal to the *Fire Alarm Reporting System*.

9-19.3.4 Sleeping room audible appliances must provide a 520 Hz temporal 4 (T4) signal for carbon monoxide in accordance with NFPA 72. The provision of a sounder base does not negate the requirement of the *Facility's* audible notification appliances for each sleeping room."

9-20 SMOKE CONTROL SYSTEM

9-20.1 General.

9-20.1.1 Design must be in accordance with NFPA 92.

9-20.1.2 Design parameters must be documented and be based on industry standards of practice, such as the SFPE Handbook of Smoke Control Engineering. Other source documents, such as peer-reviewed research articles, may be used with approval of the *DFPE*.

9-20.1.3 Controls must be designed and listed as required by NFPA 92.

9-20.1.4 Fire alarm control unit must be ANSI/UL 864, category UUKL listed.

9-20.1.5 HVAC controls must be ANSI/UL 864, category UUKL listed where required by NFPA 92.

9-20.1.6 Fire alarm system sequence of operations matrix must include all automatic and firefighter's smoke control station functions.

9-20.1.7 Design must include a preliminary test plan.

9-20.2 Installation.

9-20.2.1 Prior to installation and programming, provide a single submittal that includes all smoke control system components.

9-20.2.2 Submittal must document all aspects of integration between the involved systems and trades, such as the interface between the fire alarm and HVAC systems.

9-20.2.3 Documentation must include the physical interface and logic interface. Physical interface description must include location of control devices and wiring diagrams for all components. Logic interface description must include the complete sequence of operations, from input to final output.

9-20.2.4 Submittal must include an updated test plan, tailored to the specific devices and arrangements to be installed. Test plan must include all proposed test procedures.

9-20.3 Testing.

9-20.3.1 Testing must be in accordance with NFPA 92.

9-20.3.2 Individual components must be tested in accordance with the relevant UFC. For example, fire alarm system components must be tested in accordance with UFC 3-600-01 and NFPA 72. Fans must be tested in accordance with Air Movement and Control Association (AMCA) Publication 203.

9-20.3.3 Submit a revised test plan that incorporates any as-built conditions that differ from the smoke control submittal, prior to the start of any acceptance testing.

This Page Intentionally Left Blank

CHAPTER 10 MEANS OF EGRESS

10-1 GENERAL.

10-1.1 Requirements.

Comply with NFPA 101 for all components and features related to means of egress. IBC must not be used for any means of egress features, except as specifically noted below.

10-1.2 Accessible Means of Egress.

Comply with NFPA 101 \6\ and the Section below titled "Accessible Means of Egress". /6/

10-2 MEANS OF EGRESS MARKING.

10-2.1 Requirements.

10-2.1.1 Incandescent or fluorescent fixtures are not permitted for new installation or replacement of fixtures.

10-2.1.2 Use of the graphic emergency exit symbols with and without directional arrows (NFPA 170 or Host Nation equivalents) in lieu of the text "EXIT" is permitted.

10-2.1.3 In locations outside the United States and its territories and possessions, additional markings may be required to remain consistent with local national standards; colors must be consistent with local national standards, and bilingual signs are recommended.

10-2.2 Radioluminous Exit Signs.

Radioluminous exit signs are not permitted in DoD *Facilities*.

10-2.3 Photoluminescent Exit Signs and Markings.

10-2.3.1 Photoluminescent exit signs and egress path markings are permitted and must be designed and installed per the requirements of NFPA 101. The charging light source must be continually illuminated at all times with normal power. The charging light source must not be on a switched circuit.

10-2.3.2 The illumination source must be energized at all times during building occupancy. Such lighting must not be controlled by automatic timers, automatic sensors including area occupancy sensors, or accessible manual switches. Controls for such lighting must be accessible only to authorized personnel.

10-3 OCCUPANT LOAD.

10-3.1 Occupant load factors.

Occupant load must be calculated in accordance with NFPA 101, except as noted in Table 10-1 below:

Table 10-1 Supplemental Occupant Load Factors

Use	Occupant Load Factor (sf/person)
Waiting spaces other than those in theaters and assembly occupancies where persons are admitted to the building at times when seats are not available	15 net
Exhibit galleries, museums	30 net
Courtrooms, hearing rooms – other than fixed seating areas	40 net
Conference rooms with tables and chairs	15 net
Community shelters (e.g., spaces designated for 'shelter in place' for \2/2/hurricane, disaster recovery, or similar)	20 net
\2\Community shelters for tornado	7 net/2/
Recreation – indoor tennis courts	50 gross
Recreation – squash, racquetball	4 per court
Locker rooms	50 gross or maximum anticipated number, whichever is higher
Bowling centers	5 persons per lane plus 7 net for additional areas
Dormitories (bunks)	50 gross
Mechanical, electrical, other building equipment spaces	500 gross
IT equipment rooms including those with small work areas in accordance with NFPA 75 or telecommunications rooms in accordance with NFPA 76	300 gross
Manufacturing areas	200 gross
Parking garages	200 gross
Telecommunications buildings (standalone)	500 gross
Aircraft hangars – aircraft storage and servicing areas	500 gross
Magazines and bunkers	Maximum anticipated number of personnel

10-3.2 Maximum occupant load.

The maximum occupant load for any space or *Facility* must not exceed one person per 7 ft^2 (0.65 m^2) of net floor space or the maximum capacity of the required egress components, whichever is less.

10-4 STAIR TO ROOF ACCESS.

Stair to roof access must be in accordance with the IBC.

10-5 \5\COMMUNICATING SPACE.

Communicating spaces must meet the open and unobstructed provision of NFPA 101. Smoke detection is not an alternative method of meeting this provision./5/

10-6 \6\ RESERVED. /6/

10-7 \6\ ACCESSIBLE MEANS OF EGRESS.

10-7.1 Where Required.

An accessible means of egress must be provided for newly designed and constructed facilities, and altered or leased portions of existing facilities unless exempted directly by ABA Standards Chapter 2, Scoping Requirements, or this Section

10-7.1.1 When more than one means of egress is required from the space, each accessible area must be provided with at least two accessible means of egress unless otherwise exempted in NFPA 101 paragraph 7.5.4.1.1.2 through paragraph 7.5.4.1.1.4.

10-7.1.2 Where two exits are required from any portion of the accessible exit access, the exit doors must be separated by a distance of at least one-half of the length of the maximum overall diagonal dimension of the building or area served. Where the building is sprinkler protected, the separation distance is permitted to be one-third of the length of the maximum overall diagonal. [NFPA 101, section 7.5.4.2]

10-7.1.3 A single accessible means of egress is permitted for a mezzanine.

10-7.1.4 A single accessible means of egress is permitted where the common path of travel of the accessible route for access to the wheelchair spaces meets the following requirements:

- The clear width of aisles with seating on both sides is at least 30 inches where serving 14 seats or less, 36 inches where serving 50 seats or less, or 42 inches where serving more than 50 seats.
- The clear width of aisles with seating on one side is at least 30 inches where serving 14 seats or less or 36 inches where serving more than 14 seats.

- The clear width between an aisle stair handrail and seating where an aisle does not serve more than five rows on one side is at least 23 inches.

10-7.2 Continuity and Components.

Accessible means of egress are required to be continuous to a public way or area of refuge and must consist of at least one of the following components: accessible routes, enclosed exit stairway, accessible elevator, platform lift, horizontal exit, or smoke barrier.

10-7.2.1 Accessible stories that are four or more stories above or below a story of exit discharge must have at least one elevator. Where elevators are required, a smokeproof enclosure is not required in sprinkler protected buildings. [NFPA 101 paragraph 7.5.4.7 and paragraph 7.5.4.8]

10-7.3 Enclosed Exit Stairways.

10-7.3.1 Where the exit providing egress from an area of refuge to a public way includes stairs, the clear width must be 48 inches.

10-7.3.2 The 48-inch clear width is not required where the area of refuge is separated by a horizontal exit.

10-7.3.3 The 48-inch clear width is not required in existing stairs with a clear width of 37 inches.

10-7.3.4 Areas of refuge are not required in fully sprinklered buildings. [NFPA 101 paragraph 7.2.12.2.3]

10-7.4 Elevators.

Where an elevator provides access from an area of refuge to a public way, the following criteria must be met [NFPA 101, paragraph 7.2.12.2.4]:

a. Elevator must be approved for fire fighter’s emergency operations as provided in ASME A17.1/CSA B44.

b. Power supply must be protected against interruption from fire occurring within the building but outside the area of refuge.

c. Elevator must be located in a shaft system meeting the requirements for smokeproof enclosures.

10-7.5 Platform Lifts.

Platform lifts are not permitted to be part of an accessible means of egress, except where they are part of one of the following accessible routes:

10-7.5.1 An accessible route to a performing area and speakers' platforms in assembly occupancies.

10-7.5.2 An accessible route to spaces that are not open to the general public with an occupant load of five or less.

10-7.5.3 An accessible route within a dwelling or sleeping unit.

10-7.5.4 An accessible route to wheelchair seating spaces located in outdoor dining terraces intended for participation in or viewing of outdoor activities where the means of egress from the dining terraces to a public way are open to the outdoors.

10-7.5.5 An accessible route to raised judges' benches, clerks' stations, jury boxes, witness stands, and other raised or depressed areas in a court.

10-7.5.6 An accessible route where existing exterior site constraints make use of a ramp or elevator infeasible.

10-7.6 Areas of Refuge.

Required areas of refuge must have accessible means of egress meeting all requirements in NFPA 101, paragraphs 7.2.12.2 and 7.2.12.3 and meet requirements for maximum travel distance requirements for the occupancy in NFPA 101, section entitled "General".

10-7.6.1 Areas of refuge must be sized to accommodate one wheelchair space of 30 inches by 48 inches for each 200 occupants, based on the occupant load of the area of refuge and areas served by the area of refuge. Wheelchair spaces are not permitted to reduce the required means of egress width for the occupant load served and to not less than 36 inches. [NFPA 101 paragraph 7.2.12.3.1]

10-7.6.2 Areas of refuge are required to be separated by a barrier having a minimum 1-hour fire resistance rating, unless a greater rating is required by other provisions in the Life Safety Code or if the existing barrier has a minimum 30-minute fire resistance rating (NFPA 101 §7.2.12.3.4).

10-7.6.3 Areas of refuge are required to be provided with two-way communication between area of refuge and central control point. If the central control point is not constantly attended, the area of refuge must also have controlled access to a public telephone system. Location of central point to be approved by the fire department. Two-way communication must include both audible and visible signals (NFPA 101 §7.2.12.1.1 and §7.2.12.2.5).

10-7.6.4 Areas of refuge with two-way communication systems are required to have instructions on the use of the area under emergency conditions. Instructions must include the following:

a. Directions to find other accessible means of egress.

b. Persons able to use the exit stairway do so as soon as possible unless assisting others.

c. Information on planned availability of assistance in the use of stairs or supervised operation of elevators and how to summon such assistance.

d. Directions for use of the emergency communications system.

10-7.6.5 Areas of refuge must be identified by a sign reading: AREA OF REFUGE that conforms to the requirements of the ABA Standards and display the international symbol of accessibility. Signs must also be located at each door opening providing access to the area of refuge, at all exits not providing an accessible means of egress, and where necessary to indicate clearly the direction to an area of refuge. Signs are required to be illuminated as required. Tactile signage complying with the ABA Standards must be located at each door opening to an area of refuge (Replaces NFPA 101 §7.2.12.3.5).

10-7.7 Signage.

Signage indicating the location of an accessible means of egress is required at exits and elevators serving a required accessible space but not providing an approved accessible means of egress.

10-7.8 Exterior Area for Assisted Rescue.

An exterior area for assisted rescue must be provided and be open to the outside air and meet the requirements specified in the following paragraphs:

10-7.8.1 An exterior area for assisted rescue must be at least 50% open, and the open area above the guards must be distributed so as to minimize accumulation of smoke or toxic gases.

10-7.8.2 Exterior exit stairways that are part of the means of egress for the exterior area for assisted rescue must provide a clear width of 48 inches.

10-7.8.3 Exterior areas for assisted rescue must have identification as required for area of refuge complying with paragraph 10-7.6.5. /6/

This Page Intentionally Left Blank

CHAPTER 11 ACCESSIBILITY

11-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 11 provisions.

CHAPTER 12 INTERIOR ENVIRONMENT

12-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 12 provisions.

CHAPTER 13 ENERGY EFFICIENCY

13-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 13 provisions.

CHAPTER 14 EXTERIOR WALLS

14-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 14 provisions.

CHAPTER 15 ROOF ASSEMBLIES AND ROOFTOP STRUCTURES

15-1 ROOF COVERINGS.

Use roof coverings approved and listed by a NRTL. Class C roof coverings, as defined in the UL Roofing Materials and Systems Directory, are only permitted for single and duplex style housing and *Facilities* less than or equal to 5,000 ft^2 (465 m^2).

15-2 ROOF DECK ASSEMBLIES.

15-2.1 General.

15-2.1.1 For non-sprinklered *Facilities* or *Facilities* \2\greater than or equal to/2/ 8,000 ft^2 (743 m^2), roof deck assemblies must be FM Class I approved, or UL-listed as fire classified or equal listing or classification by an NRTL.

15-2.1.2 Where a non-combustible roof is installed over an existing combustible roof, the existing combustible roof materials must be removed or the space between the existing and new roof must be protected as a combustible concealed space per NFPA 13.

Note: FM Class I or II ratings and UL "Fire Classified" ratings are measures of the resistance, of the entire roof assembly, to ignition from exposure to a fire within the building, heating the underside of the roof deck. These two ratings cannot be equated and are not interchangeable.

15-2.1.3 Where the HVAC or similar equipment is located on the existing roof and not removed, the space between the existing and new roof must be protected as and considered a combustible concealed space per NFPA 13.

15-2.1.4 Rooftop solar photovoltaic (PV) panels must be mounted to facilitate application of water from fire department vehicles to fires on the roof deck surface. Arrangement of PV panels must meet the requirements of UFC 3-440-01.

CHAPTER 16 STRUCTURAL DESIGN

16-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 16 provisions.

CHAPTER 17 SPECIAL INSPECTIONS AND TESTS

17-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 17 provisions.

CHAPTER 18 SOILS AND FOUNDATIONS

18-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 18 provisions.

CHAPTER 19 CONCRETE

19-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 19 provisions.

CHAPTER 20 ALUMINUM

20-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 20 provisions.

CHAPTER 21 MASONRY

21-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 21 provisions.

CHAPTER 22 STEEL

22-1 GENERAL.

For fire protection requirements, no changes to the IBC chapter 22 provisions.

CHAPTER 23 WOOD

23-1 FIRE RETARDANT TREATED (FRT) WOOD.

Conform to the requirements of IBC for permitted use of FRT wood. FRT plywood must not be used in any part of the roof or roofing system.

\2\/2/

CHAPTER 24 GLASS AND GLAZING

24-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 24 provisions.

CHAPTER 25 GYPSUM BOARD, GYPSUM PANEL PRODUCTS AND PLASTER

25-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 25 provisions.

CHAPTER 26 PLASTIC

26-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 26 provisions.

CHAPTER 27 ELECTRICAL

27-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 27 provisions.

CHAPTER 28 MECHANICAL SYSTEMS

28-1 AIR HANDLING.

28-1.1 General.

Fire protection features for air handling, heating, ventilation, and exhaust systems, such as duct smoke detectors, fire dampers and smoke dampers, must comply with the requirements of NFPA 90A, except as modified by this UFC.

Duct smoke detectors are not required where air distribution systems are incapable of spreading smoke beyond the enclosing walls, floors and ceilings of the room or space in which the smoke is generated.

\2\Duct smoke detectors are not required when the air distribution system supplies a space or room that has area smoke detection./2/

28-1.2 Plenums.

Plenums may be used as an integral part of an air handling system only if they conform to the requirements of NFPA 90A. Under no circumstances may combustible materials be located within the plenum space. Electrical wiring passing through the space, including telephone and communication wiring must be plenum rated or must be in metal conduit.

Rooms or areas that form a plenum space or that are used as a plenum must not be occupied for any purpose except during repairs or maintenance operations to the air handling equipment.

28-1.3 Computer Room Air Conditioning (CRAC).

28-1.3.1 CRAC units must not automatically shut down if electronic equipment remains energized and heat generated in the room will be sufficient to activate sprinkler heads.

CHAPTER 29 PLUMBING SYSTEMS

29-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 29 provisions.

CHAPTER 30 ELEVATORS AND CONVEYING SYSTEMS

30-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 30 provisions.

Comply with requirements of the "Elevators" section of this UFC.

CHAPTER 31 SPECIAL CONSTRUCTION

31-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 31 provisions.

CHAPTER 32 ENCROACHMENTS INTO THE PUBLIC RIGHT-OF-WAY

32-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 32 provisions.

CHAPTER 33 SAFEGUARDS DURING CONSTRUCTION

33-1 GENERAL.

For fire protection requirements, no changes to the IBC Chapter 33 provisions.

CHAPTER 34 EXISTING FACILITIES

34-1 GENERAL.

34-1.1 Minimum Requirements.

Facilities, as they exist, must meet the requirements of NFPA 101, for existing occupancies. *Facilities* that do not meet the requirements of NFPA 101 for existing occupancies must conform to one of the following:

a. Upgrade the deficiency to meet the existing occupancy requirements, or

b. Establish management protocols to provide a level of life safety equivalent to that required by NFPA 101 for existing occupancies, until an upgrade project can be completed. Management protocols must be in writing and approved by the \6\ *CFPE* /6/.

34-1.2 \2\/2/Work in Existing Facilities.

34-1.2.1 Conform to the requirements of the Building Rehabilitation chapter of NFPA 101 for design and construction projects in existing buildings \5\except as specified in this UFC.

The entire facility, at a minimum, must comply with the applicable existing occupancy chapter of NFPA 101 before beginning the project for work in existing facilities. The project may include bringing the facility into compliance with the applicable occupancy chapter of NFPA 101. /5/

[C] 34-1.2.1

The areas of the facility where no work is being performed must meet the applicable existing occupancy chapter of NFPA 101. Thus if the work involves 5,000 ft^2 of an existing 15,000 ft^2. office building, then the remaining 10,000 ft^2 not involved in the project must be brought up to meet the applicable existing occupancy chapter of NFPA 101 before beginning the project or be included as part of the project.

34-1.2.2 Where multiple categories of rehabilitation work are planned as part of a single project, identify each category of rehabilitation work to be performed, including what is required and what will be provided, within each one.

34-1.2.3 Phasing of construction and demolition operations must be planned so that the integrity of fire-rated separations, smoke-tight boundaries, means of egress, exit enclosures, and vertical openings are maintained to the highest level possible.

34-1.2.3.1 The phasing plan must ensure that obstruction of the means of egress is avoided or minimized.

34-1.2.3.2 If exits are obstructed during construction, provide alternate means of egress and exit routes during each phase of construction and identify the alternate routes on the construction drawings as part of the phasing plan(s).

34-1.2.4 Minimize, to the extent possible, any impairments or disruptions to active fire protection features. Delineate phasing of construction to ensure that installations of new features (or systems) or modifications to existing ones are expedited.

34-1.2.4.1 Where possible, maintain existing systems in service until the replacement work has been deemed operational.

34-1.2.5 Prior to taking any actions to impair a fire protection feature or disrupt its performance, ensure alternative procedures have been prepared and incorporated and confirm that official notification of system impairments and schedules have been given to the staff of the *Facility*.

34-1.2.6 \2\See paragraph "Automatic Sprinkler Systems" in the "Fire Protection Systems" Chapter of this UFC for additional requirements./2/

34-1.2.7 \5\Where the Building Rehabilitation chapter of NFPA 101 requires newly constructed elements, components, and systems to comply with new construction requirements in the Code, then it must also comply with new construction requirements in this UFC.

34-1.2.8 Floor plan reconfigurations that exceed 50 percent of the area of a floor require that the entire floor be brought up to the requirements for new construction in this UFC and NFPA 101. The means of egress serving this floor, including portions not located on this floor, must conform to the requirements for new construction in this UFC and NFPA 101. The notification appliances for the fire alarm and mass notification system must be upgraded throughout the remainder of the building as required to provide a uniform notification strategy. Floor plan reconfigurations that bring the building more into compliance with NFPA 101 must not count towards the 50 percent floor area threshold.

[C] 34-1.2.8

The intent of upgrading fire alarm and mass notification devices throughout the remainder of the building is to provide a uniform notification strategy. For example, a facility may have existing clear and amber strobes throughout with no textural signs. The new requirement may be only clear strobes with textural signs. The floor being brought up to new UFC and new NFPA 101, and means of egress serving this floor, will require clear strobes and textural signs installed per the new criteria. The remainder of the floors will be modified so there are only clear strobes and textural signs, and the work must not make these other floors less conforming to the UFC and NFPA 101.

34-1.2.9 If the project cost exceeds 50 percent of the building replacement value, then the entire building must be brought up to the requirements for new construction. Project costs to bring the building more into compliance with NFPA 101 must not count towards the 50 percent threshold.

[C] 34-1.2.9

The intent of meeting requirements for new construction in this UFC is that this also applies to any requirements in applicable UFC 4-series, unless the UFC 4-series states otherwise.

34-1.2.10 Dimensional criteria for existing stairs in NFPA 101 for height of risers, tread depth, headroom, and height between landings is acceptable in lieu of meeting the requirements for new construction. The minimum headroom for existing buildings per NFPA 101 is acceptable in lieu of meeting the requirements for new construction.

[C] 34-1.2.10

If feasible, the new dimensions in NFPA 101 for height of risers, tread depth, headroom, and height between landings should be followed. Any reconstruction should involve the entire stair so there is no change in these dimensions when descending from the highest level. However, the intent of allowing use of the existing stair criteria in NFPA 101 for riser height, tread depth, headroom, and height between landings is to avoid very expensive or even unfeasible structural modifications to the facility. Utilities such as HVAC and lighting are not a reason to follow headroom requirements for existing buildings in NFPA 101 in lieu of the requirements for new.

34-1.3 /5/Change in Use.

34-1.3.1 When a change in use occurs, the area of the change, and its associated means of egress, must comply with the requirements for new construction.

34-1.3.1.1 When any \5\building with an occupant load of less than 11, or portion thereof, is changed from its current use of a building with an occupant load greater than 10, personnel housing and similar lodging facilities, or assembly occupancy /5/ for one year or more, the building must meet the requirements for new construction.

[C] 34-1.3.1.1

Examples would include: a warehouse (occupant load less than 11) being changed to administrative use with an occupant load greater than 10; an administrative use with an occupant load of less than 11 being changed to an assembly occupancy or personnel housing and similar lodging facilities; an assembly occupancy being changed to personnel housing and similar lodging facilities, or vice versa.

34-1.3.1.2 When any building, or portion thereof, is \5\changed /5/ from its current use to support a mission that will exist for one year or more, the building must meet the requirements for new construction.

[C] 34-1.3.1.2

An example would include a *Facility* used as a hangar that is going to be changed to a warehouse.

34-1.3.1.3 Changing groups of occupants within the occupancy classification does not constitute a change of use; however, any deficiencies must be corrected prior to the new occupants occupying the space.

[C] 34-1.3.1.3

An example of changing groups of occupants would include an *Installation* Personnel function occupying the office space formerly used by an *Installation* Contracting function.

34-1.3.2 When a change in use results in a higher occupant load that exceeds the existing egress capacity, the *Facility* must meet the requirements for new construction as specified in this UFC.

34-1.4 Vacant Buildings.

34-1.4.1 When a vacant building is considered for reuse, the building must be evaluated for the occupancy that is planned to be in the building and all deficiencies must be corrected prior to occupancy. This includes a building to be reused for the same occupancy, i.e., last use was a warehouse and the new use will be a warehouse.

34-1.4.2 The vacant building must be evaluated to the requirements for new construction in this UFC and NFPA 101.

34-2 PHASED PROJECTS.

34-2.1 General.

\5\Projects or programs involving floor plan reconfiguration that will encompass more than 50 percent of the area of a floor, or project or program costs exceeding 50 percent of the building replacement value,/5/ that are planned in a phased approach or have separate projects to improve various parts of the facility must conform to the requirements of \5\new construction as stated above

34-2.1.1.1 /5/These requirements are not applicable if the time from the start of design of the first phase to the start of design of the phase \5\involving floor plan reconfiguration that exceeds 50 percent of the area, or project cost exceeds 50 percent of the building replacement value,/5/ is greater than five years.

34-3 COOKING AREAS.

Cooking equipment in common areas in existing, non-sprinklered *Facilities* that are provided with residential type range top cooking surfaces must be equipped with an approved residential range top extinguishing system or the stoves must be equipped with burners and controls that have their temperature limited to a maximum temperature of 662 degrees F (350 degrees C). The range top extinguishing system must be connected to the *Facility* fire alarm system to sound a general *Facility* fire alarm and must automatically shut off all sources of fuel and electric power that produce heat to the equipment being protected by that unit.

34-4 DETENTION AND CORRECTIONAL *FACILITIES*.

\5\/5/ Navy facilities must also comply with MIL HDBK 1037/4.

34-5 ELECTRONIC EQUIPMENT AREAS.

For existing facilities that contain non-plenum rated cables under the raised floor and do not have an automatic fire extinguishing system under the raised floor must provide a \2\/2/clean agent fire extinguishing system for the area below the raised floor.

34-6 FAMILY HOUSING.

34-6.1 Projects that exceed 50 percent of the Replacement Cost.

34-6.1.1 1-hour fire-resistive construction must be provided between *Dwelling Unit*s, and between the *Dwelling Unit* and attached parking.

34-6.1.2 Sprinkler protection must be provided throughout the *Facility*, designed and installed in accordance with \3\NFPA 13, NFPA 13R, or NFPA 13D as applicable/3/.

34-6.1.3 Multiple-station, interconnected, hard-wired, 120 Vac smoke detectors must be provided inside each sleeping room and at least one on each floor, including basements.

34-6.1.4 Air Force allows interconnected wireless smoke alarms for use in single-family and duplex housing.

34-6.2 Projects that are less than 50 percent of the Replacement Cost.

34-6.2.1 Multiple-station, interconnected, hard-wired, 120 Vac smoke detectors must be provided inside each sleeping room and at least one on each floor, including basements. Air Force allows interconnected wireless smoke alarms for use in single-family and duplex housing.

34-6.2.2 Sprinkler protection must be considered for installation in the *Facility*.

34-7 FIRE PROTECTION SYSTEMS.

34-7.1 General.

See the paragraphs entitled "Fire Suppression Systems" \2\and “Automatic Sprinkler Systems”/2/ in the "Fire Protection Systems" Chapter in this UFC for requirements related to backflow prevention devices.

34-8 FIRE ALARM SYSTEMS.

34-8.1 General.

34-8.1.1 When the existing control panel is replaced, it must be replaced with a new addressable control panel.

34-8.1.1.1 Existing devices are permitted to remain when listed for use with the new control panel or they are interfaced via listed monitor modules or control modules.

34-8.1.1.2 Battery calculations must be submitted to verify the power supply provided is capable of supporting the electrical load of the new and existing devices.

34-8.1.2 Where a new control panel is provided as part of a partial *Facility* \5\rehabilitation/5/, the renovated areas must comply with the requirements of this section. The existing circuits in the non-renovated areas of the *Facility* are permitted to be connected to the new fire alarm control panel via monitor modules or control modules.

34-9 HAZARDOUS MATERIALS.

Existing storage and use of flammable and combustible liquids must comply with NFPA 30.

Existing storage and use of other hazardous materials must comply with NFPA 400.

34-10 PERSONNEL HOUSING.

34-10.1 \5\Common Areas.

Cooking areas in existing, non-sprinklered *Facilities* that are provided with residential type range top cooking surfaces must be equipped with an approved residential range top extinguishing system or the stoves must be equipped with burners and controls that have their temperature limited to a maximum temperature of 662 degrees F (350 degrees C). The range top extinguishing system must be connected to the *Facility* fire alarm system, if provided, to sound a general *Facility* fire alarm and must automatically shut off all sources of fuel and electric power that produce heat to the equipment being protected by that unit.

34-10.2 Air Force.

Existing Air Force non-sprinklered *Facilities* with the following features are considered acceptable until protection is compliant with the "Personnel Housing and Similar Lodging Facilities" section of this UFC is provided: Heat and smoke detection installed in each sleeping room and the shared/common space of a suite. Activation of the heat detector must sound a general building alarm and transmit a signal to the fire department or to a constantly monitored central location. Activation of the smoke detector must sound a local alarm within the room/suite. The smoke detector is permitted to be powered from an unsupervised 120 Vac source. The use of battery backup for secondary power is not required./5/

34-11 ROOF COVERINGS.

For re-roofing existing nonconforming metal roof decks, roofing components (insulation, underlayment, etc.) must be specified as having a maximum flame spread rating of 75 and a maximum smoke-development rating of 150 in accordance with ASTM E84.

APPENDIX B OCCUPANCY HAZARD CLASSIFICATION FOR DETERMINING AUTOMATIC SPRINKLER DENSITIES AND HOSE STREAM DEMANDS

B-1 CLASSIFICATION OF OCCUPANCIES.

The principal occupancy classifications are light hazard, ordinary hazard, and extra hazard. Listed below are the classifications with examples of common DoD occupancies listed under each. Where an occupancy is not listed, the applicable NFPA standard must be used, along with engineering judgment, to determine the appropriate occupancy hazard classification.

B-1.1 Light Hazard Occupancies.

Occupancies or portions of occupancies where the quantity and combustibility of the contents are low and fires with relatively low rates of heat release are expected. Small, scattered amounts of flammable liquids in closed containers are allowable in quantities not exceeding 5 gal (20 L) per *Fire Area*. This classification includes but is not limited to the following occupancies:

a. Clinics (dental, outpatient, patient areas only)

b. Mess areas

c. Dispensaries (patient areas only)

d. Drill halls (not used for storage or exhibition)

e. Disciplinary barracks

f. Child Development Centers

B-1.2 Ordinary Hazard Occupancies.

Occupancies or portion of occupancies where quantity and combustibility of contents is moderate, storage does not exceed 12 feet (3.7 m), and fires with moderate rate of heat release are expected. Moderate, scattered amounts of flammable liquids in closed containers are allowable in quantities not to exceed 50 gal (189 L) per *Fire Area*. Small amounts of flammable liquids may be exposed as required by normal operations. This classification includes but is not limited to the following occupancies:

g. Armories

h. Sheet metal shops

i. Bowling alleys

j. Ship fitting shops

k. Clubs (officer, enlisted personnel, etc.)

l. Kitchens and bakery

m. Small stores

n. Fitness Centers

o. Gymnasiums

p. Theaters and auditoriums

q. Welding shops

r. Forge shops

s. Laundries

t. Mechanical rooms, with or without boilers or fuel-fired equipment

u. Electrical rooms, other than transformer vaults

v. Small storage rooms

w. Commissaires

x. Exchanges

y. Aviation depots

z. Electrical maintenance shops

aa. \6\ /6/Laboratories

bb. Refrigeration and air compressor rooms

cc. Machine rooms

dd. Printing shops (using inks having flash points above 110°F (44°C)

ee. Libraries

ff. Piers and wharves

gg. Vehicle repair garages

hh. Woodworking shops

B-1.3 Extra Hazard Occupancies.

DoD occupancies, that might be classified as extra hazard, are often addressed by unique occupancy specific criteria/guidance rather than being addressed generically as extra hazard.

B-1.4 Special Occupancies.

Special occupancies are *Facilities* or areas that DoD does not assigned a specific occupancy hazard classification because of special protection requirements. Refer to Chapter 4 for fire protection requirements for the following occupancies:

ii. Flammable and combustible liquids

jj. Aircraft hangars

kk. Engine test cells

ll. \6\ Engine and generator rooms /6/

mm. Missile assembly

nn. Ordnance plants

oo. Rubber tire storage

pp. Warehouses (piled or rack storage)

qq. Foam rubber or plastic storage

This Page Intentionally Left Blank

APPENDIX C PROCEDURE FOR PERFORMANCE-BASED FIRE SAFETY DESIGN

C-1 EQUIVALENT LEVEL OF SAFETY AND PROTECTION.

Any proposed performance-based fire safety design must demonstrate, to the satisfaction of the \6\ *CFPE* /6/, a level of safety equivalent to the minimum applicable prescriptive requirements of this UFC.

C-2 FIRE SAFETY DESIGN DOCUMENTATION.

Any *Facility* designed using performance-based fire safety design methods must have supporting documentation, including a Fire Protection Engineering Design Brief, Performance-Based Design Report, Specification, Drawings, Building Operation & Maintenance Manuals, and Warrant of Fitness.

C-2.1 Fire Protection Engineering Design Brief.

This is a separate document from the project \4\ Fire Protection Design Analysis/4/, prepared by the *QFPE* and containing general qualitative project information that has been agreed upon by the *Stakeholders*. As a minimum, the design brief includes the project scope, *Facility* and occupant characteristics, project goals and objectives, performance criteria, design fire scenarios, technical references and resources, at least two trial designs, documentation of project design engineers and their qualifications, and a record of agreement on the aforementioned components.

C-2.1.1 Project Scope.

This section describes the boundaries of the performance-based design as agreed upon by all *Stakeholders*, and includes realistic and sustainable design information regarding *Facility* use, design purpose and approach, project constraints, and applicable regulations. The project budget must be clearly defined, so that the limitations and available budget for the proposed solutions can be known.

C-2.1.2 Facility and Occupant Characteristics.

Facility characteristics include an accurate and complete description of the *Facility* construction, operations, systems, physical contents and occupants. Occupant characteristic description includes the number, age, *Facility* familiarity, gender, occupant loading, and potential for self-preservation of a *Facility's* occupants. Accurately identify any necessary occupant response and interaction needed to provide hazard mitigation or securing of specific process or operational equipment. The occupant load is the maximum number of people realistically expected to occupy an area, as agreed upon by the *Stakeholders*, but not less than the prescriptive occupant load densities of NFPA 101.

C-2.1.3 Goals.

Detail and document the goals of life safety, property protection, continuity of operations, and the limitation of the environmental impact of the fire, as defined by NFPA 101, and as additionally defined by the *Stakeholders*. Adequately address the allied fire safety goals of historic preservation and environmental protection from fire protection measures. Identify each goal - realistically, quantifiably, and remaining constant throughout the design process. Address each goal by each proposed trial design, regardless of the goal's individual importance.

C-2.1.4 Objectives and Acceptable Levels of Risk.

Clearly identify *Stakeholder* and design objectives associated with each of the required and user-defined goals.

C-2.1.4.1 *Stakeholder* objectives are the specific project objectives based upon agreed fire safety goals and must be stated in terms of objectives, functional statements, or performance objectives. *Stakeholders*' objectives may be defined in terms of acceptable or sustainable loss or in terms of an acceptable level of risk. Where a design requires the determination of an acceptable level of risk, the \6\ *CFPE* /6/ must ensure that the appropriate *Stakeholders* make the determination. The level of risk may affect an entire base/community/command; therefore it is essential to ensure the persons determining the level of risk are authorized to do so.

C-2.1.4.2 Design objectives are developed by the design engineer based on the *Stakeholder* objectives, and are stated in engineering terms. Use design objectives as the basis for the development of performance criteria, against which the predicted performance of a trial design will be evaluated.

C-2.1.5 Performance Criteria.

Develop quantitative performance criteria to represent the intent of each design objective and retained prescriptive requirement. Completely describe and document these criteria. The performance criteria reflect the event consequences that need to be avoided to fulfill the design objectives, and include realistic values that are capable of being evaluated or measured using existing engineering tools and methods.

C-2.1.5.1 The performance criteria must be a combination of the life safety and property protection criterion, along with criteria developed from *Stakeholder* objectives.

Note: NFPA 101 and the SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings provide guidance regarding the development and evaluation of appropriate performance criteria.

C-2.1.6 Design Fire Scenarios.

Document complete descriptions of the reasoning, intent, and details of all required and *Stakeholder* defined fire scenarios. Use realistic and accurate fire scenarios, with respect to all fire elements, including initial fire location, early rate of growth in fire severity, and smoke generation. Indicate in the description of the fire scenarios all applicable data, characteristics and assumptions, which must remain consistent between all fire scenarios. Ensure the omission of certain details will not reduce the reality of the proposed design fire scenario. The *QFPE* must justify any design fire scenario data that is omitted or cannot be considered by available evaluation methods, and this justification must be noted and approved by the \6\ *DFPE* /6/.

C-2.1.7 Technical References and Resources.

Thoroughly document all technical references, including methodologies, data and sources. Identify the scientific basis of each engineering calculation method or model. Develop, review and validate these methods using a consensus, peer-review process, or obtain from resource publications. Where the chosen methods do not permit the incorporation of all data or do not accurately address the incorporation of the data, perform a sensitivity analysis for any design, performance criteria, or fire scenario data that cannot be included or used in the chosen methods. Address all degrees of conservatism and factors of safety, and clearly identify the limitations of the calculation methods. Any method whose outcome is significantly altered by the omission of trial design or fire scenario details must not be approved, and the omission of critical data is prohibited. The use of proprietary and non-peer reviewed data or source is not permitted. The \6\ *DFPE* /6/ must approve the assessment methods, data, and sources, and confirm the validity of all technical references and resources prior to the design evaluation. Provide the technical reviewer, upon request, any technical references or resources.

C-2.1.7.1 The performance criteria must be capable of being proved or measured using existing engineering tools and methods.

C-2.1.8 Trial Designs.

Identify and document the general details, including the proposed construction, systems, and protection methods. Include in the documentation the safety factors associated with each trial design, as agreed upon by the *Stakeholders*. Clearly identify the impact of the safety factors so that a reasonable decision can be made as to whether their level is appropriate and sufficient. State any retained prescriptive requirements. Where the interaction of emergency response personnel is a designed protection method, accurately identify and confirm the impact and responsibility of the emergency personnel.

The performance criteria must be equally considered and addressed by each trial design against each fire scenario.

Evaluate each trial design in each fire scenario using the agreed upon performance criteria.

C-2.1.9 Project Team and Qualifications.

Provide the qualifications and contact information for the entire design team, including the *QFPE* as part of the required documentation. A performance-based, fire safety design must be prepared by a *QFPE* with experience in performance-based fire safety design and specific experience with the engineering tools and methodologies that are anticipated for a particular project.

C-2.2 Performance-Based Fire Safety Design Report.

This documentation must be prepared by the *QFPE*, and used for general guidance. The report must indicate that the *Facility* was designed using a performance-based fire safety design approach, and must convey the expected hazards, risks, and system performance over the entire *Facility* life-cycle. Include the project scope, design goals and objectives, performance criteria, design fire scenarios, critical design assumptions, critical design features, final design, cost benefit analysis, design engineer's qualifications and capabilities, and data and evaluation method references.

C-2.2.1 Cost Benefit.

The performance-based fire safety design report must indicate how the performance-based design maximizes the benefits/cost ratio while maintaining a level of safety equivalent to the established prescriptive requirements. A performance-based design must not be undertaken where the prescriptive requirements provide the same level of safety for a lesser cost. Where multiple acceptable proposed design scenarios exist, the cost benefit analysis must aid in the identification and determination of the best solution.

C-2.3 Building O&M Documentation.

The *QFPE* must produce Building Operation and Maintenance documentation for the facility based on the objectives, performance criteria, limitations, and final design. Include all associated specifications and design drawings, and a description of the required maintenance procedures that need to be performed to ensure continued compliance with performance-based fire safety design.

C-2.4 Warrant of Fitness.

The host-tenant agreement must require that an annual Warrant of Fitness be prepared for any subsystem, system, or *Facility* that has been designed using performance-based fire safety design methods. Submit this warrant to the \6\ *DFPE* /6/ for review and assurance that the current facility characteristics comply with the requirements of the approved performance design. This warrant must reflect any existing or proposed changes in *Facility* occupancy, operation, features, systems, or emergency personnel response. Where emergency response is a critical element in the accepted fire safety design, reevaluate the design when changes are made to the operational procedures, location, or structure of the emergency response personnel.

C-3 REVIEW OF TRIAL DESIGNS.

Provide every performance-based fire safety design with a technical review, and develop a Review Brief. Analyze each trial design to determine the compliance with the required performance criteria. The reviewer must be an individual capable of providing a thorough evaluation of the proposed design, and must have the same minimum qualifications as the *QFPE*. If the authority responsible for the review of the performance-based fire safety design does not have the required qualifications, they must direct the designer to submit the design to a qualified third party for review.

C-3.1 Review Brief.

The Review Brief details how each proposed design compares with the required fire safety goals, objectives and performance criteria. The Brief provides a brief description of the details of each trial design, the technical resources and references, any concerns about steps in the design process and general concerns about the designer's performance-based fire safety design approach. The Brief indicates the acceptability of each design, the reasoning for each acceptance or rejection, and which design is recommended for final acceptance. It must also discuss levels of confidence over validation. The Brief must indicate how personnel and property protection are considered, which objectives the design stresses, a statement of what has been checked, the design solution, and the entire design approach and process.

C-3.2 Third Party Review.

When required, an assigned third party must provide an objective review of the project, and must not provide the actual fire safety design. When a third party is reviewing the design, the \6\ *DFPE* /6/ remains a *Stakeholder* and ultimately is responsible for the approval of the final design. When a review is assigned to a third party, provide the \6\ *DFPE* /6/ with a Review Brief.

C-3.3 Compliant Fire Safety Design.

A compliant fire safety design must meet the stated performance criteria when subjected to each design fire scenario. A subsystem, system or *Facility* design that complies with all requirements of the applicable prescriptive criteria is deemed as satisfying the minimum fire safety goals and objectives, and does not need to be evaluated against the design fire scenarios. Completely evaluate a performance-based fire safety design that incorporates only portions of applicable prescriptive criteria, as it is not considered to provide the minimum levels of protection.

Where a design does not meet the performance criteria, it may be revised and reevaluated. The revision must not reduce any agreed upon goals, objectives, performance criteria, or level of performance to ensure a proposed design complies with the stated requirements. Criteria may be changed based on additional analysis and the consideration of additional data.

APPENDIX D INTERNATIONAL BUILDING CODE AND NFPA 220 EQUIVALENTS

This table provides the corresponding types of construction from the various codes. This table is for information only.

IBC	NFPA 220
	Type I (442)
Type I-A	Type I (332)
Type I-B	Type II (222)
Type II-A	Type II (111)
Type II-B	Type II (000)
Type III-A	Type III (211)
Type III-B	Type III (200)
Type IV (HT)	Type IV (2HH)
Type V-A	Type V (111)
Type V-B	Type V (000)

This Page Intentionally Left Blank

APPENDIX E RECOMMENDED FIRE ALARM AND EMERGENCY NOTIFICATION MESSAGES

GENERAL ANNOUNCEMENTS AND PAGING

AUDIBLE in the following sequence:

Pre-announcement Sound – Ding-Dong – Percussive pairs of 700 and 570 Hz tones each damped to zero (one cycle)

Announcement – spoken message.

VISIBLE none

FIRE EMERGENCY / FIRE ALARM {GENERIC} MESSAGES:

AUDIBLE [Audible must sound for not less than 180 seconds (NFPA 72)] in the following sequence:

Alert Sound – NFPA Temporal 3 (T-3) - 422-775Hz upward sweep over 850 ms for three-pulses each separated by 1 second followed by a 1.5 second delay (repeat 2 cycles)

Announcement: Voice – Tom (repeat 2 cycles):

Option 1: *A FIRE EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT.*

Option 2: *A FIRE EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO YOUR ASSEMBLY LOCATION*

Option 1E: *A FIRE EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT DO NOT USE THE ELEVATORS.*

Option 2E: *A FIRE EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT; DO NOT USE THE ELEVATORS AND REPORT TO YOUR ASSEMBLY LOCATION*

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *Strobe or other listed* \5*clear* /5/ *appliance.*

Textual message signs (if provided).

CARBON MONOXIDE DETECTION {GENERIC} MESSAGES:

AUDIBLE [Audible must sound for not less than 180 seconds (NFPA 72)] in the following sequence:

Alert Sound – Temporal 4 (T-4) pattern tone - 520Hz over 850 ms for four-pulses each separated by 1 second followed by a 1.5 second delay (repeat 2 cycles)

Announcement: Voice – Tom (repeat 2 cycles):

Option 1: *CARBON MONOXIDE HAS BEEN DETECTED IN THE BUILDING; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT.*

Option 2: *CARBON MONOXIDE HAS BEEN DETECTED IN THE BUILDING; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO YOUR ASSEMBLY LOCATION*

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *Strobe or other listed* \5*clear* /5/ *appliance.*

Textual message signs (if provided).

Note: The Security / Force Protection messages are only shown as examples if prerecorded messages are desired. Security / Force Protection situations are a variety of circumstances and having a prerecorded message or a variety of messages that will satisfy all conditions will be very difficult and may provide inaccurate information for the situation at hand. Give careful consideration in determining if Security / Force Protection prerecorded messages are going to be used.

SECURITY / FORCE PROTECTION THREATS {GENERIC} MESSAGES

SHELTER IN PLACE:

AUDIBLE [Audible must sound for not less than 180 seconds] in the following sequence:

Alert Sound – Siren - 600-1250 hz up and down sweep in 4 seconds; 1.5 second delay (repeat 2 cycles)

Announcement: Voice – Tom (repeat 2 cycles):

Option 1: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE TAKE SHELTER IN A DESIGNATED SAFE AREA IMMEDIATELY.*

Option 2: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE SEEK A DESIGNATED SAFE LOCATION IMMEDIATELY.*

Option 1E: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE TAKE SHELTER IN A DESIGNATED SAFE AREA IMMEDIATELY; DO NOT USE THE ELEVATORS.*

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *Strobe or other listed* \5*clear* /5/ *appliance.*

Textual message signs (if provided).

EVACUATE:

AUDIBLE [Audible must sound for not less than 180 seconds] in the following sequence:

Alert Sound – Hi-Lo - 780 to 600 hz alternately, 0.52 each (repeat 2 cycles)

Announcement: Voice – Tom (repeat 2 cycles):

Option 1: *A [force protection emergency] [ ] HAS BEEN DECLARED;; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT.*

Option 2: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO YOUR ASSEMBLY LOCATION*

Option 1E: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT DO NOT USE THE ELEVATORS.*

Option 2E: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT; DO NOT USE THE ELEVATORS AND REPORT TO YOUR ASSEMBLY LOCATION*

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *Strobe or other listed* \5*clear* /5/ *appliance.*

Textual message signs (if provided).

Note: The Weather / Natural Disaster Warnings (Tornado, Tsunami, Hurricane, Earthquake, Volcano, Etc.) messages are only shown as examples if prerecorded messages are desired. Weather / Natural Disaster situations will come in a variety of circumstances and having a prerecorded message or a variety of messages that will satisfy all conditions will be very difficult and may provide inaccurate information for the situation at hand. Give careful consideration in determining if Weather / Natural Disaster Warning prerecorded messages are going to be used.

WEATHER / NATURAL DISASTER WARNING(S) (TORNADO, TSUNAMI, HURRICANE, EARTHQUAKE, VOLCANO, ETC.) {GENERIC} MESSAGES

AUDIBLE - [Audible must continue to sound for not less than 180 seconds] in the following sequence:

Alert Sound – NOAA Standard alert tone - 1050 hz (8 seconds)

Announcement: Voice – Donna (repeat 2 cycles) (Systems may have multiple weather/natural disaster warning messages depending on the individual installation requirements and potential weather threats):

<u>SHELTER IN PLACE:</u>

Option 1: *A [weather] [ ] EMERGENCY HAS BEEN DECLARED; PLEASE TAKE SHELTER IN A DESIGNATED SAFE AREA IMMEDIATELY.*

Option 2: *A [weather] [ ] EMERGENCY HAS BEEN DECLARED; PLEASE SEEK A DESIGNATED SAFE LOCATION IMMEDIATELY.*

Option 1E: *A [weather] [ ] EMERGENCY HAS BEEN DECLARED; PLEASE TAKE SHELTER IN A DESIGNATED SAFE AREA IMMEDIATELY; DO NOT USE THE ELEVATORS.*

Option 2E: *A [weather] [ ] EMERGENCY HAS BEEN DECLARED; PLEASE SEEK A DESIGNATED SAFE LOCATION IMMEDIATELY; DO NOT USE THE ELEVATORS.*

<u>EVACUATE:</u>

Option 1: *A [earthquake] [ ] EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT.*

Option 2: *A [earthquake] [ ] EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO YOUR ASSEMBLY LOCATION.*

Option 1E: *A [earthquake] [ ] EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT; DO NOT USE THE ELEVATORS.*

Option 2E: *A [earthquake] [ ] EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO YOUR ASSEMBLY LOCATION; DO NOT USE THE ELEVATORS.*

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *strobe or other listed appliance.*

Textual message signs (if provided).

ALL CLEAR RETURN TO NORMAL OPERATIONS MESSAGES

AUDIBLE in the following sequence:

Pre-announcement Sound – Ding-Dong – Percussive pairs of 700 and 570 Hz tones each damped to zero (one cycle)

Announcement: Voice – Donna *(repeat two cycles)* – THE *EMERGENCY HAS BEEN RESOLVED; RETURN TO NORMAL OPERATIONS*

VISIBLE none

AUTOMATED MONTHLY TEST MESSAGES

SCHEDULE the first Wednesday of each month at 1200 hours local.

AUDIBLE in the following sequence:

Pre-TEST Sound – NOAA Standard alert tone - 1050 hz (8 seconds)

Announcement: Voice – Tom – TEST, TEST, TEST, THIS IS AN EMERGENCY NOTIFICATION AUDIO SYSTEM TEST; *YOU MAY CONTINUE NORMAL OPERATIONS, TEST, TEST, TEST.*

VISIBLE [Visible must flash/operate during the pre-test sound and the announcement and then stop]:

\5*Clear* /5/ *strobe or other listed appliance.*

Textual message signs (if provided).

<u>SPECIAL OCCUPANCIES</u>

FIRE EMERGENCY / FIRE ALARM {Child Development Centers and Medical Facilities including Ambulatory} MESSAGES:

AUDIBLE [Audible must sound for not less than 180 seconds] in the following sequence:

Alert Sound – Three Pulse Chime - 575Hz, three-0.5 second pulses separated by 0.5 seconds followed by a 1.5 second delay (repeat 3 cycles)

Announcement: Voice – Donna (repeat 2 cycles):

For outside assembly: *A FIRE EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO THE ASSEMBLY LOCATION*

For those Centers with horizontal exiting: A FIRE EMERGENCY HAS OCCURRED IN THIS PART OF THE BUILDING; PLEASE MOVE TO THE [define area} SAFE AREA.

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *Strobe or other listed* \5*clear* /5/ *appliance.*

Textual message signs (if provided).

CARBON MONOXIDE DETECTION: {Child Development Centers and Medical Facilities including Ambulatory} MESSAGES:

AUDIBLE [Audible must sound for not less than 180 seconds] in the following sequence:

Alert Sound – Four Pulse Chime - 575Hz, four-0.5 second pulses separated by 0.5 seconds followed by a 1.5 second delay (repeat cycles)

Announcement: Voice – Donna (repeat 2 cycles):

For outside assembly: *CARBON MONOXIDE HAS BEEN DETECTED IN THE BUILDING; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO THE ASSEMBLY LOCATION*

For those Centers with horizontal exiting: CARBON MONOXIDE HAS BEEN DETECTED IN THIS PART OF THE BUILDING; PLEASE MOVE TO THE [define area} SAFE AREA.

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *Strobe or other listed* \5*clear* /5/ *appliance.*

Textual message signs (if provided).

SECURITY / FORCE PROTECTION THREATS MESSAGES (Child Development Center and Medical Facilities including Ambulatory)

SHELTER IN PLACE:

AUDIBLE [Audible must sound for not less than 180 seconds] in the following sequence:

Alert Sound – Chime – Percussive 700 Hz chime tone for 10 seconds (one cycle)

Announcement: Voice – Donna (repeat 2 cycles):

Option 1: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE TAKE SHELTER IN A DESIGNATED SAFE AREA IMMEDIATELY.*

Option 2: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE SEEK A DESIGNATED SAFE LOCATION IMMEDIATELY.*

Option 1E: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE TAKE SHELTER IN A DESIGNATED SAFE AREA IMMEDIATELY; DO NOT USE THE ELEVATORS.*

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *Strobe or other listed* \5*clear* /5/ *appliance.*

Textual message signs (if provided).

<u>EVACUATE:</u>

AUDIBLE [Audible must sound for not less than 180 seconds] in the following sequence:

Alert Sound – Chime – Percussive 700 Hz chime tone for 10 seconds (one cycle)

Announcement: Voice – Donna (repeat 2 cycles):

Option 1: *A [force protection emergency] [ ] EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT.*

Option 2: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO YOUR ASSEMBLY LOCATION*

Option 1E: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT DO NOT USE THE ELEVATORS.*

Option 2E: *A [force protection emergency] [ ] HAS BEEN DECLARED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT; DO NOT USE THE ELEVATORS AND REPORT TO YOUR ASSEMBLY LOCATION*

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *Strobe or other listed* \5*clear* /5/ *appliance.*

Textual message signs (if provided).

FIRE EMERGENCY / FIRE ALARM {Aircraft Hangar} MESSAGES:

AUDIBLE [Audible must sound for not less than 180 seconds] in the following sequence:

Alert Sound – NFPA Temporal Whoop - 422-775Hz upward sweep over 850 ms for three-pulses separated by 1 second followed by a 1.5 second delay (repeat 2 cycles)

Announcement: Voice – Tom (repeat 2 cycles):

<u>ACTIVATION FROM SUPPRESSION SYSTEM, MANUAL FIRE ALARM STATION, OR DETECTION (if provided) IN THE AIRCRAFT SERVICING AREA</u>

Option 1: *A FIRE EMERGENCY HAS OCCURRED IN THE AIRCRAFT SERVICING AREA; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT. DO NOT EXIT THROUGH THE AIRCRAFT SERVICING AREA.*

Option 2: *A FIRE EMERGENCY HAS OCCURRED IN THE AIRCRAFT SERVICING AREA; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO YOUR ASSEMBLY LOCATION. DO NOT EXIT THROUGH THE AIRCRAFT SERVICING AREA.*

Option 1E: *A FIRE EMERGENCY HAS OCCURRED IN THE AIRCRAFT SERVICING AREA; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT DO NOT USE THE ELEVATORS. DO NOT EXIT THROUGH THE AIRCRAFT SERVICING AREA.*

Option 2E: *A FIRE EMERGENCY HAS OCCURRED IN THE AIRCRAFT SERVICING AREA; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT; DO NOT USE THE ELEVATORS AND REPORT TO YOUR ASSEMBLY LOCATION. DO NOT EXIT THROUGH THE AIRCRAFT SERVICING AREA.*

<u>ACTIVATION FROM SUPPRESSION SYSTEM, MANUAL FIRE ALARM STATION OR DETECTION (if provided) IN THE ADJACENT SUPPORT AREA</u>

Option 1: *A FIRE EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT.*

Option 2: *A FIRE EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT AND REPORT TO YOUR ASSEMBLY LOCATION*

Option 1E: *A FIRE EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT DO NOT USE THE ELEVATORS.*

Option 2E: *A FIRE EMERGENCY HAS OCCURRED; PLEASE LEAVE THE BUILDING BY THE NEAREST EXIT; DO NOT USE THE ELEVATORS AND REPORT TO YOUR ASSEMBLY LOCATION*

VISIBLE [Visible must flash/operate until system is reset]:

\5*Clear* /5/ *Strobe or other listed* \5*clear* /5/ *appliance.*

Textual message signs (if provided).

Messages will be generated by the text- to-speech system Speechify*,* Nuance, 2005 as used by NOAA for weather information and Emergency Alert System (EAS) messaging. The voices used will be "Tom" and "Donna" as identified for each message type. The current Nuance text-to-speech product is *Vocalizer 5.0,* Nuance, 2013.

NFPA 72 sound pressure levels applies to "public mode" notification devices "Alert Sound – NFPA Temporal Whoop - 422-775Hz upward sweep over 850 ms for three-pulses separated by 1 second followed by a 1.5 second delay". Sound levels are measured:

a. Maximum level at 10 feet horizontally perpendicular to the notification appliance at 5.5 feet above the finish floor.

b. Minimum levels at no closer than ten feet from walls and other vertical obstructions at 5.5 feet above the finish floor.

NFPA 72 sound pressure levels apply to "private mode" fire alarm notification device as required in NFPA 72.

NFPA 72 sound pressure levels do not apply to other notification devices.

NFPA 72 voice intelligibility applies to all voice messages. Intelligibility measurements are not required in large open areas such as industrial work areas, warehouses, and aircraft servicing areas, garages, and similar facilities.

APPENDIX G \3\ CRITERIA FOR PROJECTS IN JAPAN

Purpose: The intent of this Appendix is to provide clarification on the use of Japanese products and standards. Japanese products and standards should be used to the maximum extent possible providing it does not change the intended level of life safety and fire protection specified in this UFC. Example: It is acceptable to use Japanese emergency public address system in lieu of a NRTL listed mass notification system; however, for sprinkler protection of various facilities, the paragraph “Design Requirements” in the “Fire Protection Systems” chapter of this UFC will be followed (see below for more specific requirements pertaining to these systems). The DFPE can make project level decisions based on the intent of this Appendix.

G-1 **GENERAL**. This appendix provides guidance on the specifically negotiated equivalencies/alternatives for all construction and facility maintenance in Japan in achieving the intended fire and life safety performance for DoD missions and personnel in accordance with this UFC.

G-1.1 DFPE. A DFPE is an individual who is a registered professional engineer (P.E.) who has passed the fire protection engineering written examination administered by the National Council of Examiners for Engineering and Surveying (NCEES) and has a minimum of five (5) years of relevant fire protection engineering experience. Where this section states DFPE, it means the DFPE as defined in this section, and it also includes an authorized representative deemed qualified by the DFPE.

G-1.2 Applicability. The requirements of this Appendix apply to all Host Nation Funded and Constructed DoD projects in Japan.

G-1.2.1 Japanese standards, materials, and installation practices will be used to achieve the criteria policy requirements of this UFC to the maximum extent practical and as modified below.

G-1.2.2 When the Japanese market place cannot accommodate a UFC required feature, means will be provided to achieve that requirement. Example, Japanese fire alarm standards do not provide for visual notifications and products do not exist in the market place, however, Japanese fire alarm equipment can power NRTL listed visual notification devices. Solution is to install NRTL listed visual devices powered by the Japanese equipment.

G-1.2.3 When Japanese standards do not mandate a feature normally required by this UFC such as circuit supervision, means will be identified to ensure Japanese optional features are included as mandatory requirements in Host-Nation projects. Example, UFC requires circuit supervision, certain types of Japanese control panels offer optional circuit supervision. Solution is to limit control panel choices to those panels offering optional circuit supervision.

G-1.3 Criteria Evaluations.

G-1.3.1 DFPE will coordinate with the Host Nation to evaluate and determine acceptable fire protection engineering policy, criteria, codes, manufactured equipment and materials to meet the intent of this UFC. If the DFPE is unable to successfully negotiate suitable alternatives, the DFPE will coordinate and obtain approval from the DoD Fire Protection Engineering Working Group (FPEWG).

G-1.3.2 The DFPE will submit coordinated alternatives to the FPEWG for inclusion in this Appendix.

G-1.4 Products, Standards, and Installation Methods Evaluations.

G-1.4.1 The DFPE will coordinate with the Host Nation to determine acceptable Japanese materials, equipment and installations standards meeting the intent of this UFC.

G-1.4.2 DoD service DFPE for Japan will share any approvals/disapprovals with the other services and the DOD FPEWG.

G-1.5 Host Nation Design Process.

G-1.5.1 Criteria and concept packages including the development of the Life Safety and Building Code plans and analysis, architectural floor plans and the fire protection design analysis, in English, will be under the review and oversight of a QFPE and reviewed and approved by the DFPE. The packages will comply with NFPA 101, Life Safety Code, and the International Building Code (IBC), as referenced and modified by this UFC. A fire protection design analysis meeting the section “Fire Protection Design Analysis and Life Safety Plans” will be included in the packages.

G-1.5.2 Design drawings, plans, and specifications are developed by Host Nation qualified engineers and architects. DFPE reviews the drawings, plans, and specifications to ensure compliance with this UFC.

G-1.5.3 During the construction and acceptance process, the DFPE will review shop drawings with identified changes from the design drawings to ensure compliance with criteria. The DFPE will provide construction inspection support when needed or requested. The DFPE will witness final acceptance testing of all fire protection systems.

G-1.6 Host-Nation Requirements.

G-1.6.1 Host Nation requirements in excess of this UFC do not require approval by the \6\ *CFPE* /6/.

G-1.6.2 The QFPE services is limited to the criteria and concept package submittal stages only. The process identified in paragraph “Applicability” in this Appendix will meet the QFPE requirements during the construction and acceptance stages.

G-1.6.3 The code compliance certification is not required to address compliance with host-Nation Codes and standards. The QFPE will review the criteria and concept package drawings and document in writing that the package is in compliance with the this UFC and all applicable fire protection and life safety design criteria. A Host Nation fire protection consultant is not required

G-1.6.4 For conflicts between this UFC and the Host-Nation fire protection criteria, the DFPE will be consulted.

G-1.6.5 Fire protection features installed to exclusively comply with Japanese fire protection requirements are not required to be documented in the fire protection design analysis.

G-1.6.6 Identifying code/criteria conflicts and DFPE approved design solutions to meet the requirements of the UFC will be documented in the fire protection design analysis.

G-1.6.7 Shop drawing prepared in accordance with the Japanese Building Standards and Fire Service Law and reviewed in accordance with this Appendix meet the intent of this UFC. NICET preparation of the shop drawings and QFPE reviews are not required.

G-1.7 Acceptance Testing. Inspections, evaluations, and approvals required under the Japanese Fire Service Act should be conducted jointly by the local Japanese Fire Authority and the cognizant DoD activity. Failure of the DoD authority to participate will not limit the Japanese Fire Authority from executing the requirements of the Japanese Fire Service Act.

G-1.7.1 Japanese authorities, generally, only evaluate the features required by Japanese law (The Building Standard Act and the Fire Service Act). DoD will normally accept the Japanese determination the Japanese required features are acceptable/unacceptable.

G-1.7.2 It is DoD's responsibility to evaluate all additional DoD requirements and their appropriate interface with the Japanese required features ensuring a complete and usable facility system.

G-2 **AIRCRAFT HANGARS**.

G-2.1 General. Use the requirements of UFC 4-211-01, Aircraft Maintenance Hangars.

G-2.2 Optical Detectors and Releasing Controls. Comply with paragraphs “Releasing Service Fire Alarm Control Unit (RSFACU)” and “Optical Flame Detection” in Chapter “Air Force Specific Criteria” in UFC 4-211-01, and paragraph “Releasing Service Fire Alarm Control Unit (RSFACU)” in Chapter “Navy Specific Criteria” in UFC 4-211-01.

G-2.3 Floor Grate Nozzles and Flow Control Valves. Comply with paragraph "\6\ /6/ Trench Nozzle System" in Chapter "General Hangar Requirements" in UFC 4-211-01.

G-2.4 Other Components. Japanese materials and installation practices are acceptable.

G-3 **ELEVATORS**

G-3.1 Doors. The use of a 60 minute elevator door is acceptable regardless of the required fire rating of the shaft.

G-3.2 Fire Service Operations. Fire service emergency operations Phase I and Phase II in accordance with ASME A17.1 are required on all elevators.

G-3.3 Shaft and Machine Room. Elevator shaft and machine room will be fire rated in accordance with NFPA 101 with the exception of the elevator doors and machine room doors. These doors are allowed to be 60 minute fire doors regardless of the required fire rating of the shaft or machine room.

G-4 **FIRE ALARMS AND MASS NOTIFICATION.**

G-4.1 General. Install fire alarm systems where required by this UFC, including referenced codes and standards as modified by this UFC.

G-4.2 Control Panels.

G-4.2.1 Fire Alarm and Notification. Japanese traditional Type P1 control panels and Japanese addressable Type R are permitted to be used when traditional or addressable type panels are required by this UFC. Type R will be used when an emergency communication system is provided.

G-4.2.1.1 All the Japanese optional features for supervision of devices and circuits are required regardless of which panel is used.

G-4.2.1.2 Detection devices, manual pull stations, supervisory devices will be provided where required by this UFC.

G-4.2.1.3 Visual notification appliances are required. Listed devices by a NRTL will be used and located in accordance with the distribution requirements of NFPA 72.

G-4.2.1.4 Audible notification devices are required. Japanese devices will be used and located in accordance with installation standards referenced is this UFC.

G-4.3 Mass Notification.

G-4.3.1 Japanese emergency public address systems will be used to provide mass notification. This meets the intent of UFC 4-021-01.

G-4.3.2 All available Japanese optional features for supervision of speakers and circuits are required when used on DoD installation in Japan.

G-4.3.3 Provide audible notification devices in all areas and rooms when the audible requirements of NFPA 72 cannot be met.

G-4.3.4 Mass notification system are recommended to be used for general paging.

G-4.3.5 Voice intelligibility may be assessed by the manual method and approved by the DFPE.

G-5 **FIRE DOORS.**

G-5.1 General. Fire doors of an equal or greater fire resistance will be provided where fire doors are required by this UFC.

G-5.1.1 Latching. All fire doors must be able to latch in the closed position.

G-5.1.2 Use of a Japanese design specification 20- and 60-minute fire door is permitted. Doors must be labeled as required by Japanese standards. See Figures G-5.1.3.1 and G-5.1.3.2 for door label examples and locations.

G-5.1.3 Use of a Japanese tested and labeled 60-minute door is permitted.

Fig G-5.1.3.1 60 Minute Label

FIG G-5.1.3.2 Label Location

G-6 FIRE PUMPS.

G-6.1 Vertical Lift Fire Pumps. Fire pumps for vertical lift such as taking suction from a cistern as is found in many Japanese sprinkler and other fire protection systems will be Japanese vertical turbine type.

G-6.2 Supervision of Power for Electric Fire Pumps. The loss of power, reverse polarity, and pump running conditions must be monitored and a signal must be sent to a constantly attended location, normally the fire alarm receiving center.

G-7 WATER SUPPLY.

G-7.1 Water Supply for Sprinklers and Fire Protection Systems. When Japanese 20 minute cisterns are used, an automatic resupply connection will be provided meeting the design demand for not less than 40 minutes.

G-7.2.1 The Japanese 20-minute cistern is not considered a water storage tank. (Reference: 9-4)

G-8 SMOKE AND CARBON MONOXIDE ALARMS.

G-8.1 General. Install smoke and carbon monoxide alarms as required in this UFC.

G-9 SPRINKLERS.

G-9.1 General. Provide sprinkler protection when required by this UFC, including referenced codes and standards as modified by this UFC. Sprinklers protection will be designed in accordance with the Japanese technical requirements based on using Japanese equipment.

G-9.1.1 Japanese residential type sprinklers are permitted anywhere a NRTL type residential sprinkler is allowed to be used.

G-9.1.2 Japanese condominium style sprinklers are permitted in multi-story apartment applications.

G-9.2 Special Conditions. Situations where requirements do not exist in Japanese technical requirements, use technical requirements referenced in this UFC. The use of Japanese equipment is acceptable if such products exist in the Japanese market.

G-9.2.1 Ceiling Height Above 30 Feet (10m). Provide ceiling sprinklers. Design will be based on area and density requirements in the “Fire Protection Systems” chapter of this UFC.

G-9.2.2 Storage Above 12 Feet. Provide ceiling sprinklers. Design will be based on area and density methods in NFPA 13.

This UFC supersedes UFC 3-601-02, dated 8 September 2010.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense agencies, and the DoD field activities in accordance with USD (AT&L) Memorandum, dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing Service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD Working Group. Recommended changes with supporting rationale may be sent to the respective DoD Working Group by submitting a Criteria Change Request (CCR) via the internet site listed below.

UFCs are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-601-02, *Fire Protection Systems Inspection, Testing, and Maintenance*

Superseding: UFC 3-601-02, dated 8 September 2010, and all subsequent changes.

Description of Changes: This Unified Facilities Criteria (UFC) provides best practice maintenance methods from the DoD, other government agencies, and the private sector for inspection, testing, and maintenance of fire protection systems. Criteria for the following technical areas was added/updated/revised:

- Update Naval Facilities Engineering Command to Naval Facilities Engineering System Command.
- Update Naval Facilities Engineering System Command signature block.
- Adds U.S. Space Force.
- Revises the term “authority having jurisdiction (AHJ)” to conform to UFC 1-200-01 and UFC 3-600-01.
- Life-cycle guidance, Section 2-2.2, “Fire Detection and Alarm System.”
- Fire watch procedures.
- Extreme weather events and natural disasters – guidance for pre-event preparation, trans-event actions, post-event recovery actions.
- Nitrogen generation systems.
- Low-pressure water mist systems.
- Hybrid water mist systems.
- Deletes product information in Halon system ITM
- Fire and smoke barrier opening protectives.
- Heat and combustion products removal and venting systems.
- Ignitable liquid floor drainage assemblies.
- Guidance on AFFF control during ITM (2020 National Defense Authorization Act).
- General guidance on life cycle and obsolescence.
- Air Force guidance on excess features (2008 A4C Policy Letter).
- Navy requirements for contract technicians qualifications.

Reasons for Document:

- This UFC provides updated requirements for inspection, testing, and maintenance (ITM) of fire protection and life safety features in DoD facilities.

Impact:

- Personnel safety and continuity of mission are primary considerations.

Unification Issues:

- None.

TABLE OF CONTENTS

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

This Unified Facilities Criteria (UFC) has been developed from an evaluation of Department of Defense (DoD) facilities, from surveys of maintenance methods, and from selection of the best practices of the DoD, other government agencies, and the private sector. This UFC is based on recognized reliability-centered maintenance (RCM) concepts and reliability-centered risk management. It was prepared using model building maintenance codes, National Fire Protection Association (NFPA®) National Fire Codes®, industry standards, and other recognized standards to the maximum extent feasible. It does not directly adopt the tasks requirements from the model codes. Personnel safety and continuity of mission were primary considerations.

1-2 PURPOSE AND SCOPE.

This UFC provides requirements for inspection, testing, and maintenance (ITM) of active and passive fire protection and life safety features in DoD facilities. Do not deviate from these criteria without prior approval of the Component office of responsibility.

Compliance with criteria issued in accordance with this UFC does not constitute an exception to the public laws. Fire protection criteria must conform to the requirements of this UFC and the NFPA National Fire Codes®, except as modified by this UFC and specifically referenced by this UFC. Additional criteria include portions of the FM Global Property Loss Prevention Data Sheets, as specifically referenced by this UFC.

This UFC for DoD compliance with all U.S.C. Title 10, 15 and 29 occupational health and safety requirements related to fire protection feature maintenance fully meets the intent of the U.S.C. requirements. Any questions related to compliance should be directed to the Component office of responsibility.

1-3 APPLICABILITY.

\1 In addition to the applicability of UFC 1-200-01, paragraph 1-3, this UFC applies to USACE Civil Works. It also applies **/1/** to DoD-leased facilities where DoD, as the lessee, is responsible for maintaining the fire protection and life safety features.

In **\1** Navy-leased **/1/** facilities where the lessor is responsible for maintaining the fire protection and life safety **\1** features **/1/**, the **\1** Navy **/1/** lessee should use this UFC as a guide along with the requirements of the lease contract to the extent possible.

1-3.1 Commercial Facilities on Government Property.

\1 This UFC does not apply to commercially owned and occupied facilities on DoD installations. **/1/** In commercially owned facilities occupied via a ground lease, inspection, testing, and maintenance of fire protection systems will be the sole responsibility of the commercial lessee. The lease agreement may use as guides:

- this UFC;
- the requirements of the local (off-installation) authority having jurisdiction;
- the lessee's internal ITM standards; or
- national consensus codes and standards.

1-4 AUTHORITY.

10 U.S.C. § 1794 requires **\1 ** life threatening **/1/** ITM deficiencies identified in youth program facilities be corrected immediately **\1** or the facility closed by the installation commander **/1/**; non-life-threatening ITM deficiencies **\1** identified in youth program facilities **/1/** may be waived **\1** by the installation commander **/1/** for up to 90 days **\1** while corrections are undertaken **/1/**, after which the **\1** installation commander **/1/** is required to close the facility **\1** when corrections are incomplete **/1/** until corrections are completed.

15 U.S.C. § 272 identifies the necessary consensus technical standards required to implement policy objectives and activities within the area of fire protection engineering including the ITM of installed fire protection features.

1-5 GLOSSARY.

Appendix B contains acronyms, abbreviations, and terms.

1-6 REFERENCES.

Appendix **\1** C **/1/** contains a list of references used in this document. The publication date of the code or standard is not included. Unless otherwise specified, the most recent edition of the referenced publication applies.

1-7 OBJECTIVE.

ITM tasks in this UFC represent the minimum required to achieve a 99 percent overall system reliability in response to an actual fire event.

A byproduct of the reliability centered maintenance analysis is a list of ITM tasks and how often they must be accomplished (frequencies) to achieve the minimum desired 99 per cent (0.99) reliability. The methodology used to develop the ITM tasks in this UFC is summarized in AFCESA/CES Technical Report 01-10, "Risk Based Reliability Centered Maintenance of DoD Fire Protection Systems, 1999 (Defense Technical Information Center AD-A392898)." The model used in the report assumed a system demand of one event in fifty (1/50) years and a task effectiveness (ITM is "done right") of 99 percent. This RCM analysis emphasized task thing to do and is it done right?") and timeliness ("Is it done before a demand?"). The resulting list of tasks and frequencies, therefore, considers frequency and probability effectiveness ("Is it the right of demands and failures.

1-8 CRITERIA.

Use the task frequencies in this UFC in lieu of the tasks and frequencies in the National Fire Codes.

1-8.1 Systems and Applications Not Covered.

When a specific system or application is not addressed by this UFC, follow national building codes, recognized industry standards, and standard engineering practices. In the absence of technical information, contact the DoD Component office of responsibility.

This UFC does not cover acceptance testing, system commissioning, or integrated systems testing. Do not use this UFC for construction contract acceptance or commissioning of fire protection systems or features.

Fire Emergency Services (FES) operations, staffing, and equipment are not addressed in this UFC.

1-8.2 Medical Facilities.

Medical facilities require Joint Commission **\1** accreditation. **/1/** Follow the task frequencies indicated in the related NFPA codes and standards, except when otherwise approved by the Joint Commission.

1-8.3 Conflicts.

If a conflict exists between this UFC and any other DoD document, referenced code, standard, or publication, this UFC takes precedence.

1-9 COMPONENT OFFICE OF RESPONSIBILITY.

The term “authority having jurisdiction (AHJ)” as used in the codes and standards referenced in this UFC means the Component technical representative for fire protection engineering (CFPE) assigned to the Military Service or Defense Component office of responsibility or the Service delegated designated fire protection engineer (DFPE). For additional information on the CFPE and DFPE, see UFC 3-600-01 and Service-specific delegation direction.

The Component offices of responsibility are:

- U.S. Army: HQ USACE/CECW-CE.
- U.S. Navy: NAVFACENGSYSCOM HQ, Chief Fire Protection Engineer
- U.S. Marine Corps: NAVFACENGSYSCOM HQ, Chief Fire Protection Engineer
- U.S. Air Force: AFCEC/CO
- U.S. Space Force: AFCEC/CO

- Defense Logistics Agency (DLA): DS-IE
- National Geospatial-Intelligence Agency (NGA): Security and Installations
- National Reconnaissance Office (NRO): MS&O/ESO
- Washington Headquarters Service (WHS): Office of the Pentagon Fire Marshal
- National Security Agency/Central Security Service: Office of Occupational Health, Environmental and Safety Services (NSA/CSS OHESS).]

1-10 PERSONNEL QUALIFICATIONS.

1-10.1 ITM Tasks.

ITM tasks must be performed by technicians qualified in the maintenance and repair of the specific fire protection system or subsystem.

"Qualified" personnel must only perform ITM and repair tasks on systems for which these personnel have been specifically qualified. Qualified personnel **\1** are permitted to **/1/** supervise other less qualified personnel in the execution of the tasks covered in this UFC. At no time will apprentice-level technicians be allowed to execute the ITM tasks in this UFC without a qualified co-worker on the job site.

1-10.2 Qualified Personnel.

1-10.2.1 Technicians.

\1 Technicians **/1/** meeting any of the following are qualified personnel:

- Recognized journeyman or craftsman-level qualifications for fire protection systems:
  - National Institute for Certification in Engineering Technologies (NICET) Level II **\1** or higher **/1/** certification in Fire Alarm Systems;
  - NICET **\1** Level II certification in Inspection and Testing of Fire Alarm Systems **/1/**;
  - NICET Level II **\1** or higher **/1/** certification in Inspection and Testing of Water-Based Systems; or
  - NICET **\1** certification in **/1/** Special Hazard Suppression Systems.

NICET Level I personnel must work under the direct supervision of a NICET level **\1** III or IV certified **/1/** technician. **\1** Level IV technicians are authorized to supervise personnel across all technical areas covered in this UFC.) **/1/**

- Other recognized journeyman or craftsman-level qualifications for the specific fire protection feature, formalized labor organization-based journeyman training, or similar programs.

- Technicians completing the Fire Suppression Systems Maintenance course (J3AZR3E451 01FB) at the Technical Training Center, Sheppard Air Force Base, Texas. The 82nd Training Wing, 782nd Training Group, 366th Training Squadron, provides engineer craftsman skills training for all DoD branches. **\1** Air Force personnel have priority for enrollment; a total of 10 percent of annual enrollments will be allocated across all other branches on a first-come, first-serve basis. (366TRS.WFSM.Supplemental@us.af.mil) /1/
- Individually qualified or endorsed by an equipment manufacturer for the specific equipment item maintained.
- A valid, current qualification or license from any state (or local jurisdiction if delegated authority by the state). Local jurisdictions and other organizations may require varying levels of continuing education to maintain recognized journeyman or technician-level qualifications.
- Military personnel holding specific Service qualifications equivalent to journeyman or craftsman technicians and approved by their unit commander.

In OCONUS locations, local nation technicians must hold either one of the previously listed qualifications or a national/local license issued by the government where the installation is located. Individual Status of Forces Agreements (SOFA) will take precedence where technical qualifications are addressed. Overseas locations **\1** will **/1/** contact their command Fire Protection Engineering office (or Component office of responsibility) for **\1** additional **/1/** guidance on local qualification requirements.

1-10.2.2 BOS Contractors.

Installation or base operating support (BOS) contractors must have at least one qualified **\1** supervisor **/1/** technician (1-10.2.1) present on the installation when contractor personnel are executing ITM and repair tasks. All ITM and repair tasks will be accomplished under the supervision of a qualified technician.

Navy BOS contractors must have the specific qualifications identified in Appendix A for Fire Protection ITM technicians.

1-10.2.3 Other Contractors.

Other Service contractors performing ITM and repair tasks must have at least one qualified technician (1-10.2.1) present on the job site when contractor personnel are executing ITM and repair tasks.

Other Navy contractors must have the specific qualifications identified in Appendix A for Fire Protection ITM technicians.

1-10.3 Other Inspections.

This UFC also lists inspection tasks **\1** to **/1/** be performed during other regularly scheduled facility inspections or evaluations that are not part of the ITM requirements covered herein. Qualified fire prevention personnel, safety personnel, maintenance technicians, or other individuals **\1** are qualified to **/1/** perform these inspection tasks.

1-11 RECORDS.

Each installation must maintain a permanent record of completed ITM tasks in accordance with each agency's program for reoccurring facility maintenance record keeping. Records **\1\ /1/ \1** must be readily available to craft persons and supervisors **/1/**. Where no agency-wide programs exist, records must be developed locally. Records must be maintained for every facility and include, as a minimum, each ITM task, date scheduled, date completed, and the technician completing the task.

When ITM actions modify or change systems or features from the original as-built configuration, the ITM activity is responsible for identifying the required changes to the maintainer of the as-built records.

1-12 SYSTEM IMPAIRMENT OR OUT-OF-SERVICE TAGGING.

System ITM technicians must physically mark any impaired or out-of-service fire protection feature using a red tag.

Impaired and out-of-service tags must provide the following minimum information:

- identification of the system inspected
- employer of the technician performing the inspection
- name of technician
- licenses or certification information required by the component office of responsibility
- interval of inspection

Inspection tags are to be made of durable, weatherproof, colorfast material and must be securely attached to the system pressure gauge, control panel, or other readily visible part of the system.

1-13 SYSTEM IMPAIRMENT OR OUT-OF-SERVICE NOTIFICATION/ WARNING.

Building managers must notify building occupants, users, and the public whenever any of the systems specified in Chapter 2 are either out of service or impaired **\1** and increasing **/1/** risk to any occupants. (Occupational Safety and Health Administration [OSHA] general industry standards are contained in Title 29, Code of Federal Regulations [CFR], Parts 1910.160(b)(2) Occupational Safety and Health Standards, Fire Protection, Fixed extinguishing systems, general and 1960.26(b)(5) Basic Program Elements For Federal Employees Occupational Safety and Health, Programs and Related Matters, Subpart D – Inspection and abatement, Conduct of inspections).

The sign shown in Figure 1-1 must be posted by the facility manager, custodian, official in charge of the workplace, or a person empowered to act, **\1\ /1/** at all principal public and employee entrances to the building. The sign must appear as follows:

- 7 inches high by 10 inches wide in an American National Standards Institute (ANSI) Z535.2-2011-compliant format
- safety orange background color
- black type and graphic
- Arial font (ANSI Z535.1 2017)

\1\ Note: This sign can be downloaded as an editable PDF from https://www.wbdg.org/dod/ufc/ufc-3-601-02 for local printing. **/1/** Signs complying with this format **\1** can **/1/** be ordered from many commercial safety sign manufacturers on a wide variety of materials. **\1** Commercial **/1/** computer software **\1** and hardware **/1/** is available to print this and other safety signs on color printers.

Figure 1-1 System Out-of-Service or Impaired Sign

1-14 REPAIR OR CORRECTION OF IMPAIRMENTS TO SYSTEM OR FEATURE PERFORMANCE.

\1

1-14.1 Response to Abnormal Conditions.

NFPA 72 Chapter 26 provides guidance for the response to abnormal conditions received at the proprietary supervising/alarm receiving centers.

- Alarm signals – Notify the appropriate responders for immediate response.
- Supervisory signals – Dispatch personnel to arrive within 2 hours to investigate and correct the abnormal conditions.
- Trouble signals – Dispatch personnel to arrive within 4 hours to initiate maintenance and repair actions as necessary.

/1/

1-14.2 Impairment Correction.

Correct impairments affecting the performance of installed fire protection features immediately when identified using the highest priority in the appropriate work identification and management system. These processes must meet the OSHA general industry standards requirements for repair or correction of impairments (29 CFR Part 1910.160(b)(2) and 160(b)(6)).

1-14.3 Maintenance Activity Notifications.

The maintenance activity must notify the local fire emergency service authority and the facility or area user when impairments cannot be corrected immediately when identified. The maintenance activity must also advise the facility or area user of the need to post the Warning sign, Figure 1-1, Out-of-Service or Impaired Sign. The fire authority must advise and consult with the facility or area user to determine the immediate measures that must be taken to ensure personnel safety and mission continuity.

1-14.4 Extended Impairment Measures.

When the impairment will exist for more than 72 hours, the local maintenance activity, the local fire authority, the local safety authority, and the facility or area user must jointly develop written compensatory measures to ensure personnel safety and, to the maximum degree possible, mission continuity. **\1\ /1/** The facility user is the lead to coordinate the compensatory measures package. The jointly developed package must also identify the remaining mission risk exposure. In the absence of compensatory measures, evacuate the facility or stop operations. Implementation of compensatory measures must not reduce the priority of the correction of the impairment.

1-14.4.1 Mitigating Measures.

The need for mitigating measures is typically determined on a case-by-case basis. This considers the building, occupancy type, nature and duration of impairment, building occupancy level during the impairment period, active work being conducted on the fire protection features during the impairment, condition of other fire protection systems and features (for example, sprinklers, structural compartmentation), and hazards and assets at risk.

Appropriate mitigating measures **\1\ /1/** range from simple occupant notification to increased fire safety checks or inspections by user or installation fire and safety personnel to full-time fire watch; for example, measures **\1\ /1/** range from minor operational changes to completely ceasing operations. Determining factors vary from testing-related impairments and maintenance activities during **\1** routine **/1/** business through extensive impairments to high-value, high-hazard situations.

1-14.4.2 New Extended Impairments.

The maintenance activity must inform installation and operational commanders of new impairments not corrected within 72 hours, of the jointly developed compensatory measures being recommended, and of the remaining mission risk exposure.

1-14.4.3 Commander Actions.

Commanders **\1** can **/1/** require evacuation of the workplace until impairments are corrected (OSHA general industry standard: 29 CFR Part 1910 Subpart L App A, *Fire Protection*).

Commanders **\1** can **/1/** also limit operations and have an emergency action plan **\1** specifying **/1/** evacuation actions (OSHA general industry standard: 29 CFR Part 1910 Subpart L App A).

1-14.4.4 Fire Watch.

1-14.4.4.1 Fire Watch Personnel Qualifications.

A fire watch is a dedicated function: the individual(s) assigned fire watch responsibilities as mitigating or compensatory measures would not be expected to have other duties beyond fire safety, occupational safety, or security. **\1\ /1/** Dedicated fire safety, occupational safety, or security personnel **\1\ /1/** can be assigned to conduct mitigating or compensatory fire watch activities as part of their functions.

Fire Watch personnel must also be trained in the use of portable fire extinguishers.

1-14.4.4.2 Fire Watch Procedures.

When fire watches are specified as a mitigating or compensatory measure in response to fire protection system impairments, comply with the following requirements:

- Fire watch personnel must make rounds visually observing the area under watch at scheduled times. **\1\ /1/** The area under watch is observed at least once an hour; however, more frequent observation may be necessary.
- Fire watch personnel must keep a record of all time periods of duty, including a signed log entry or other auditable reporting method for each time the facility was patrolled.
- Fire watch personnel must use the telephone or radio equipment to summon aid in case of an emergency.
- Fire watch personnel must notify building occupants in case of an emergency and evacuation is necessary.
- Impairment of fire sprinkler or fire alarm systems protecting the entire facility will require the rounds include all spaces throughout all levels, including the inspection of basements, attics, and concealed spaces.
- Impairment of fire sprinkler or fire alarm systems protecting a portion of the building will require the rounds include all spaces impacted by the impairment.

1-15 SYSTEM IMPAIRMENTS AND REPAIRS AND CORRECTIONS REPORTING.

The maintenance activity must regularly inform installation and operational commanders, not less than twice a year, of the system impairments, compensatory measures in place, projected correction completions, and corrections completed since the last report.

1-16 EXTREME WEATHER EVENTS AND NATURAL DISASTERS.

Extreme weather events, hurricanes, tornados, and severe cold temperature events, as well as other natural disasters **\1** including **/1/** earthquakes and wildland fires, can impact the availability and performance of fire protection systems **\1** and life safety features **/1/**. Fire protection system impacts include broken piping, broken sprinklers, water damage to electrical and electronic system components, and damage to the utility infrastructure serving these systems. These events also increase the risk of accidental fires.

When sufficient warnings are provided, ITM activities and building inspection activities **\1\ /1/** reduce the impact of these events on the fire protection systems. Additional ITM activities during and after these events can **\1\ /1/** help to reduce property damage and bring the facilities back online sooner.

1-16.1 Hurricanes, Typhoons, and Tropical Storms.

Hurricanes, typhoons, and tropical storms **\1\ /1/** cause building damage due to high wind velocities, impacts from wind-borne objects, and water damage due to heavy rains and local flooding. Advance notice of these storm events does allow time to initiate some ITM tasks **\1\ /1/ \1** to **/1/** reduce the impact of these events on fire protection systems.

1-16.1.1 Pre-Event Actions.

Pre-event ITM actions include:

- Work with installations facilities maintenance personnel to make sure the building envelope is adequately secured. If doors, windows, skylights, and other building openings are broken or not adequately secured, bring it to the attention of installation facilities maintenance personnel so these conditions can be corrected, or temporary measures can be put in place to secure the buildings.
- Verify electrical and fire alarm junction boxes are closed up, conduit is closed up, and the fire alarm panels are closed up and secured.
- Verify firewater storage tanks are filled.
- Verify sufficient fuel supplies are provided for engine driven fire pumps and emergency generator installations.
- Verify fire pump houses are provided with protection from flooding. Ensure drains in the pump rooms are flowing adequately and provide sand bags at pump room entrances if necessary, to prevent flooding of the pump room in low lying areas.

1-16.1.2 Actions During the Event.

Safety of all persons sheltering on the installation regardless of affiliation takes priority during these storm events. Inspection, damage control activities, and system repairs will need to wait until hazardous conditions subside and these activities can be undertaken without risk to personnel.

1-16.1.3 Post Event Actions.

Post event ITM actions include:

- Initial ITM tasks **\1\ /1/** focus on damage control: shutting down damaged systems to reduce water damage **\1** and control of fire extinguishing agents **/1/**.
- Perform visual inspections of all systems, including all system piping and equipment, to identify system damage and to prioritize system repairs.
- Verify radio fire alarm reporting antennas are still in place and connected.
- Verify water supply availability to each facility. Work with installation facility and utilities maintenance personnel to identify damage and repair requirements for the installation water supply.

- Verify if fire alarm systems have been subjected to water damage. Identifying specific alarm system trouble conditions at the fire alarm control panel (FACP) can help to investigate and prioritize system repairs.
- Initiate system impairment procedures for any buildings re-occupied prior to system repairs being completed.
- When the water supply feeding the facility has been damaged, the underground piping needs to be adequately flushed.
- Any water-based fire suppression systems damaged, or are located in buildings structurally damaged, **\1** must **/1/** be subjected to hydrostatic testing prior to putting the systems back in service.

1-16.2 Tornados.

Tornados **\1\\ /1/** cause damage to buildings and building systems due to high wind velocities, impacts from wind-borne objects, and water damage.

1-16.2.1 Pre-Event Actions.

Tornado warnings can provide some advanced warning to seek shelter, but there is not usually sufficient time to initiate any pre-event ITM tasks after these warnings. Prior to tornado season, however, ITM actions include:

- Work with installation facilities personnel to **\1** ensure **/1/** the building envelope is adequately secured. If doors, windows, skylights, and other building openings are broken or not adequately secured, bring it to the attention of installation facilities personnel so these conditions can be corrected, or temporary measures can be put in place to secure the buildings.
- Verify electrical and fire alarm junction boxes are closed up, conduit is closed up, and the fire alarm panels are closed up and secured.
- Verify firewater storage tanks are filled.
- Verify sufficient fuel supplies are provided for engine driven fire pumps and emergency generator installations.

1-16.2.2 Actions During the Event.

Safety of all persons sheltering on the installation regardless of affiliation takes priority during these tornado events. Inspection, damage control activities, and system repairs will need to wait until hazardous conditions subside and these activities can be undertaken without risk to personnel.

1-16.2.3 Post Event Actions.

Post event ITM actions include:

- Initial ITM tasks **\1\ /1/** focus on damage control, shutting down damaged systems to reduce water damage **\1** and control of fire extinguishing agents **/1/**.
- Perform visual inspections of all systems, including all system piping and equipment, to identify system damage and to prioritize system repairs.
- Verify water supply availability to each facility. Work with installation facility and utilities maintenance personnel to identify damage and repair requirements for the installation water supply system.
- Initiate system impairment procedures for any buildings re-occupied prior to system repairs being completed.
- When the water supply feeding the facility has been damaged, the underground piping needs to be adequately flushed.
- Any water-based fire suppression systems damaged or located in buildings structurally damaged **\1** must **/1/** be subjected to hydrostatic testing prior to putting the systems back in service.

1-16.3 Flooding and Extreme Rain Events.

Flooding and extreme rain events cause damage to buildings and building systems due to water infiltration and water immersion.

1-16.3.1 Pre-Event Actions.

Pre-event ITM actions include:

- Work with installation facilities personnel to make sure the building envelope is adequately secured. If doors, windows, skylights, and other building openings are broken or not adequately secured, bring it to the attention of base facilities personnel so these conditions can be corrected, or temporary measures can be put in place to secure the buildings.
- Verify electrical and fire alarm junction boxes are closed up, conduit is closed up, and the fire alarm panels are closed up and secured.
- Verify fire water storage tanks are filled.
- Verify sufficient fuel supplies are provided for engine driven fire pumps and emergency generator installations.
- Verify fire pump houses are provided with protection from flooding. Ensure drains in the pump rooms are flowing adequately and provide sand bags at pump room entrances if necessary to prevent flooding of the pump room in low lying areas.

1-16.3.2 Actions During the Event.

Safety of base personnel and contractor personnel takes priority during these heavy rain and flood events. Inspection, damage control activities, and system repairs will need to wait until hazardous conditions subside and these activities can be undertaken without risk to personnel.

ITM actions during the event include:

- Periodic inspection of accessible fire pump installations to ensure pump facilities remain protected from flooding.
- Periodic inspection of fire water storage tanks to identify tank damage and required repairs.
- Respond to system activations or trouble conditions to provide damage control during the event, when safe to do so.

1-16.3.3 Post Event Actions.

Post event ITM actions include:

- Initial damage control: shutting down damaged systems to reduce water damage **\1** and controlling fire extinguishing agents **/1/**.
- Perform visual inspections of all systems, including all system piping and equipment, to identify system damage and to prioritize system repairs.
- Verify water supply availability to each facility. Work with installation facility and utilities maintenance personnel to identify damage and repair requirements for the Installation water supply system.
- Initiate system impairment procedures for any buildings re-occupied prior to system repairs being completed.
- When the water supply feeding the facility has been damaged, the underground piping needs to be adequately flushed.
- Any water-based fire suppression systems damaged or located in buildings structurally damaged **\1** must **/1/** be subjected to hydrostatic testing prior to putting the systems back in service.

1-16.4 Arctic Vortices and Other Low Temperature Extremes.

Sustained freezing temperatures can lead to frozen fire protection piping, resulting in pipe failures, water leakage, and property damage, in addition to rendering the fire protection systems out of service. System design and installation takes this freezing potential into account; therefore, ITM activities associated with systems in areas subject to severe cold temperatures must focus on the equipment provided to protect these systems from freezing.

Low temperature events can occur via two different modalities; the first is a known weather event where the installation weather office can issue advance weather warning allowing for pre-event actions to prevent damage; the second is an unplanned/ unanticipated utility system failure requiring emergency response action in a compressed time frame to prevent adverse facility/mission impacts.

1-16.4.1 Pre-Event Actions.

Several ITM tasks identified in the ITM tables in Chapter 2 for water-based fire protection systems involve equipment provided to prevent these systems from freezing. These tasks need to be scheduled prior to the onset of cold weather so the equipment functions as required.

Pre-event actions include:

- Work with Installation facilities personnel to make sure the building heating systems are operating properly. If building heating systems do not appear to be operating properly, bring it to the attention of Installation facilities personnel so these conditions can be corrected.
- Verify dry-pipe sprinkler systems are in good operating condition.
- Verify drum drips are in good condition and are drained.
- Verify ball drips are in operating condition.
- Where low temperature alarms are provided, these sensors and their alarm outputs **\1** must **/1/** be checked for proper operation and alarm notification.
- Verify eaters provided in non-occupied fire pump rooms, fire riser rooms, and other similar locations are working properly, and thermostats are set appropriately.
- Verify proper operation of firewater storage tank heaters where provided.

1-16.4.2 Actions During the Event.

Action plans addressing utility system failures are based on the anticipated duration of the utility outage. The most critical utilities are electrical, steam, hot water and/or an area wide facility control system maintaining the facility environmental systems.

ITM actions during the event include:

- Monitor building temperatures and low temperature alarms, particularly in unoccupied or low-occupancy buildings. This includes fire riser rooms, fire pump installations, and firewater storage tank installations.
- If sprinkler systems need to be shut down due to low temperature conditions, implement system impairment procedures.

1-16.5 Earthquakes.

Severe earthquakes can result in building structural damage or failure, failure of sprinkler system piping, and sprinkler system piping damage from impacting building walls and ceilings, or other structural members or equipment. The local utility infrastructure supporting the fire protection systems **\1** can **/1/** be damaged in the earthquake.

Post-earthquake building fires are a significant risk due to structural damage and damage to building utilities resulting from an earthquake.

1-16.5.1 Pre-Event Actions.

Although there is typically no warning of a strong earthquake event, ITM tasks identified in the ITM Tables in Chapter 2 are important to ensuring the survivability of these fire protection systems during an earthquake. Performing the required visual inspections of piping, hangars, and bracing improves the robustness and survivability of these systems.

Also, keep firewater storage tanks filled, and ensure adequate fuel supplies for engine driven fire pumps and generators are maintained at all times.

1-16.5.2 Post-Earthquake Actions.

- Initially, ITM tasks focus on damage control: shutting down damaged systems to reduce water damage **\1** and controlling fire extinguishing agents **/1/**.
- Perform visual inspections of all systems, including all system piping and equipment, to identify system damage and to prioritize system repairs.
- Verify water supply availability to each facility. Work with installation facility and utilities maintenance personnel to identify damage and repair requirements for the installation water supply system.
- Initiate system impairment procedures for any buildings re-occupied prior to system repairs being completed.
- When the water supply feeding the facility has been damaged, the underground piping needs to be adequately flushed.
- Any water-based fire suppression systems damaged or located in buildings structurally damaged **\1** must **/1/** be subjected to hydrostatic testing prior to putting the systems back in service.
- Fire alarm systems **\1** will **/1/** have been subjected to mechanical damage as well. Identifying specific alarm system trouble conditions at the FACP can help to investigate and prioritize system repairs.
- After initial fire sprinkler system visual inspections have been completed, conduct an investigation of the underground fire protection supply piping.

This **\1** includes **/1/** hydrant flow testing and fire sprinkler system main drain testing. Results of the post event tests **\1** must **/1**/ be compared to previous test results to identify any compromised underground piping.

1-16.6 Wildland Fires.

Wildland fires can result in large-scale destruction to installation facilities and utilities. Although building fire protection systems **\1** can **/1/** be overwhelmed by the severe fire exposure from wildland fires, operational sprinkler systems within exposed buildings reduce building damage and reduce the fire exposure to adjacent buildings.

1-16.6.1 Pre-Event Actions.

Pre-event ITM actions include:

- Verify firewater storage tanks are filled.
- Verify sufficient fuel supplies are provided for engine driven fire pumps and emergency generator installations.
- Verify fire hydrants are accessible and vegetation is not blocking or hindering access to hydrants.
- Work with installation facilities personnel to make sure buildings are adequately secured. If doors, windows, skylights, and other building openings are broken or not adequately secured, bring it to the attention of installation facilities personnel so these conditions can be corrected, or temporary measures can be put in place to secure the buildings.

1-16.6.2 Actions During Wildfire Events.

Safety of base personnel and contractor personnel takes priority during wildland fire events. Inspection, damage control activities, and system repairs will need to wait until hazardous conditions subside and these activities can be undertaken without risk to personnel.

ITM actions during the event include:

- Periodic inspection of accessible fire pump installations to ensure pump facilities remain operational and adequate fuel supplies are being maintained for fire pumps and emergency generators.
- Periodic inspection of firewater storage tanks to identify any tank damage, and to verify water supplies remain available for firefighting use.
- Respond to system activations or trouble conditions to provide damage control during the event, if safe to do so.

1-16.6.3 Post Wildland Fire Actions.

- Initially ITM tasks focus on damage control: shutting down damaged systems to reduce water damage **\1** and controlling fire extinguishing agents **/1/**.
- Perform visual inspections of all systems, including all system piping and equipment, to identify system damage and to prioritize system repairs.
- Verify water supply availability to each facility. Work with installation facility and utilities maintenance personnel to identify damage and repair requirements for the installation water supply system.
- Initiate system impairment procedures for any buildings re-occupied prior to system repairs being completed.
- When the water supply feeding the facility has been damaged, the underground piping needs to be adequately flushed.
- Any water-based fire suppression systems damaged or located in buildings structurally damaged, must be subjected to hydrostatic testing prior to putting the systems back in service.

1-17 LIFE CYCLE/OBSOLESCENCE.

Fire protection features have widely-varying operational life cycles and degrees of obsolescence. Some of these are code- or standard-driven and are addressed in the Chapter 2 text and tables requiring specific replacement schedules. Other fire protection feature life cycles are driven by more esoteric requirements **\1** determining **/1/** when components and systems must be replaced. Simply being old does not make features obsolesce.

- Manufacturers' expiration dates: Manufacturer establishes a specific expiration date based on manufacture date or installation date; target plan and program for replacement within one year of the date.
- Manufacturer's modification or updates: Failure to install manufacturer recommended modifications or updates within one year of recommended installation date. Target plan and program installation with the manufacturer's recommended time frame.
- Manufacturer's obsolescence: Manufacturer announces phase-out or ceases to support a product line or model. Target plan and program replacement for not later than one year after manufacturer's end of support.
- Software upgrades or updates: Failure to install vendor required or recommended upgrades or updates within 30 days of vendor recommended installation date.

- Software obsolescence: Vendor announces they will cease to provide maintenance and update support for software. Target plan and program replacement for not later than one year after manufacturers' end of support.

1-18 EXCESS FEATURES \1\ (AIR FORCE ONLY) /1/.

For Air Force, removal of existing installed fire protection features in excess of the minimum requirements for new construction established in UFC 3-600-01 is authorized in accordance with Air Force policy established by HQ USAF/A7C Memorandum, "Excess Fire Protection Features," 17 June 2008, and codified in this UFC. Removal of **\1** unrequired **/1/** features reduces unnecessary ITM requirements and unnecessary sustainment, repair, and maintenance costs. Features will not be removed reducing fire protection below the new construction level mandated in UFC 3-600-01. Consult with AFCEC/COS (afcec.rbc@us.af.mil) for additional information and guidance.

\1

1-19 REPLACEMENT PARTS.

Replacement parts must conform to the original equipment manufacturer's recommendations. When required parts are not available, see paragraph 1-16. Replace listed parts with listed parts conforming to the original listing standard or current edition of the standard when indicated by the manufacturer's recommendations. Listing by the original listing nationally recognized testing laboratory is not required.
/1/

This Page Intentionally Left Blank

CHAPTER 2 FACILITY SYSTEMS

2-1 ITM METHODOLOGY.

The objective of ITM for fixed fire protection systems is to assure systems will function on demand. RCM analysis identifies any defects responsible for system malfunction and how they can be detected and corrected before a fire.

2-1.1 Features Requiring Maintenance.

All fire protection and life safety features installed in DoD facilities must be maintained in accordance with this UFC. Features disabled in place pending removal are not considered installed **\1** and do not require maintenance when appropriately locked and tagged as out-of-service pending removal **/1/**.

2-1.2 Non-required Features.

A critical component of any RCM program is ensuring the components being maintained are required to be present. Remove fire protection features not specifically required by UFC 3-600-01 to minimize the maintenance workload burden. Non-required features can be abandoned in place pending final removal if all public interface devices (for example, manual fire alarm pull stations) are removed.

2-2 ITM TASK DESCRIPTIONS AND FREQUENCIES.

2-2.1 Task Descriptions.

The ITM tasks in Tables 2-1 through 2-31 and 3-1 through 3-3 were selected to ensure the fire protection system will function on demand. Technical tasks must be performed according to the manufacturer's instructions.

2-2.1.1 Electrically Supervised Components.

Electrical supervision of components increases the likelihood that conditions or faults will be detected without an inspection activity. In these cases, the ITM task is to respond to the alarm and to test the supervisory device (for example, valve tamper switch) periodically. Accordingly, the tables reflect the improved fault or condition detection by specifying less frequent inspections. Different frequencies are recommended for monitored and for unmonitored fire alarm control equipment. A monitored system transmits supervisory and trouble conditions to a remote supervising station (for example, installation fire reporting system).

2-2.1.2 Event-Driven Tests.

Some tests **\1** will **/1/** be event driven. For example, a main drain test is specified to verify the open condition of a control valve on the water supply to a sprinkler or water spray system and needs to be performed when the control valve has been operated for maintenance or testing.

2-2.1.3 Excluded National Fire Code Tasks.

Some tasks recommended in the National Fire Codes are not included in these frequency tables. The detailed analysis documented in AFCESA/CES Technical Report 01-10, *Risk Based Reliability Centered Maintenance of DoD Fire Protection Systems,* excluded tasks that did not contribute to the overall system operational reliability and did not need to be performed. These deleted tasks do not improve the operability of the systems because: (1) the faults they detect are not significant; (2) the faults are detected by other tasks or means; or (3) the faults will be self-evident ("fix it when it breaks") and do not significantly impair the system. The deleted tasks are not required to be accomplished and must not be included in reoccurring maintenance programs.

2-2.1.4 Non-ITM Activities.

Inspection activities listed at the end of each ITM table are not part of the ITM program, but are part of building overall inspection and are listed for information only. They were not included in the model used to develop the 99 percent reliability requirements; however, they must be incorporated into each DoD Component activity's fire prevention, safety, facility condition, and related inspection or evaluation program.

2-2.1.5 Fire Extinguishers.

Maintenance of portable fire extinguishers and fire extinguisher cabinet maintenance is not addressed in this UFC.

2-2.2 Fire Detection and Alarm Systems.

The type and frequency of ITM tasks for fire detection and alarm systems depend on whether the system is monitored or not. Guidance on the tasks is contained in the "Inspection, Testing, and Maintenance" section of NFPA Standard 72 (NFPA 72), *National Fire Alarm and Signaling Code®*. Residential smoke alarms are addressed in Chapter 3 of this UFC.

WARNING

Fire alarm systems with abnormal conditions (multiple trouble conditions) are outside their minimum tested or listed operating parameters and may not meet their performance requirement for receipt or transmission of subsequent alarm or additional trouble conditions.
(Table 2-1, Task Monthly, 1.2 and Task Annual 2.5)

WARNING

Any fire alarm system with more than three unexplained activations (fire indication conditions) within a 6-month period is experiencing a system instability requiring evaluation by a qualified technician or engineer; **\1** implement **/1/** appropriate corrective measures immediately

CAUTION

Alarm systems in a single TROUBLE condition **\1** must **/1/** be able to transmit an ALARM condition while in trouble; however, because a TROUBLE condition is not a normal or acceptable alarm system status, immediate maintenance action is indicated. (Table 2-1, Task Monthly, 1.2; Task Annual 2.5; and Table 2-2, Task Annual 1.5)

CAUTION

The ITM tasks specified also apply to fire suppression releasing panels and fire detection devices for fire suppression releasing service. Personnel testing systems must be knowledgeable of and experienced with the operation of these fire suppression systems and the hazards involved with inadvertent activations of these systems. Prior to performing any of the testing described in the tables, secure the fire suppression system from inadvertent activation by disconnecting release solenoids or actuators; closing control valves; or performing other actions required to secure the systems during the testing period. **\1** Do not use bypass switches employing a system program as the sole means of safeguarding a releasing system. **/1/** (Table 2-1, Task Annual 3.b.1 and 3.b.6; and 2-year Tasks 2.1 and 2.4)

Table 2-1 Fire Detection and Alarm System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Panels and Annunciator Equipment (unmonitored only)	1. Inspect panel condition (connections, fuses, light-emitting diodes [LEDs]). 2. Resolve any trouble indications.
Annually	1. Control Panel and Annunciator Equipment (monitored)	1. Test to verify proper receipt of alarm, supervisory, and trouble signals (inputs, one of each type) and operation of notification appliances and auxiliary functions (outputs, one of each type). 2. Verify all lamps and LEDs are illuminated. 3. Load test backup batteries using a meter (when provided). 4. Verify condition of power supplies and batteries. 5. Resolve any trouble indications.
	2. Remote Power Supplies and Notification Appliance Circuit Power Extenders	1. Verify all lamps and LEDs are illuminated. 2. Load test backup batteries using a meter (when provided). 3. Verify condition of power supplies and batteries.
	3. Initiating Devices: a. Manual Fire Alarm Stations	1. Verify station is accessible (visual).
	b. Radiant Energy-Sensing Detectors (optical detectors)	1. If used for releasing service, inhibit releasing function. 2. Test to verify alarm initiation and receipt. 3. Verify no facility change affects performance. 4. Verify alignment of the positioning markings at all adjustment locations. 5. If used for releasing service, configure system for automatic operation. 6. If used for releasing service, restore to releasing service.
	c. Gas Detectors	1. Test to verify alarm initiation and receipt. 2. Verify no facility change affects performance.

Frequency	Component	Tasks
	d. Carbon Monoxide Detectors	1. Test to verify alarm initiation and receipt. 2. Verify no facility change affects performance.
	4. Notification Appliances and Voice Communication (telephone, speakers, horns, and strobe lights)	1. Test to verify operability.
	5. Digital Alarm Transmitters and Receivers	1. Test to verify operability.
	6. Radio Alarm Transmitters and Receivers	1. Test to verify operability.
2 Years	1. Initiating Devices: a. Manual Fire Alarm Stations	1. Operate to verify alarm receipt.
	b. Heat Detectors (restorable) (Remove devices not required by UFC 3-600-01.)	1. Test with a heat source to verify alarm initiating and receipt. 2. Verify no facility change affects performance.
	c. Smoke Detectors (single-station detectors, system detectors, and air sampling detectors) (Remove devices not required by UFC 3-600-01 or other directives.)	1. Test with manufacturer-approved smoke simulant to verify smoke entry and alarm initiation and receipt. 2. Verify no facility change affects performance.
	d. Supervisory Devices (low air pressure, temperature, water level)	1. Test to verify initiation and receipt of supervisory alarm.
	2. Fire Suppression Devices (low air pressure, temperature, water level)	1. Inhibit releasing function. 2. Test to verify proper operation and system response. 3. Configure system for automatic operation. 4. Restore releasing function.

Frequency	Component	Tasks
5 Years	1. Smoke Detectors (Remove devices not required by UFC 3-600-01.)	1. Test detector sensitivity to ensure the detector has remained within its listed and marked sensitivity range (or 4 percent obscuration light gray smoke, if not marked).
10 Years	1. Carbon Monoxide Detectors	1. Replace detectors.
	2. Radiant Energy-Sensing Detectors (optical detectors)	1. Verify manufacturer's service life for detection elements. UV detection element's **\1\ /1/** service life is 10 years; others vary by manufacturer. 2. Replace detectors exceeding manufacturer's recommended service life for detection elements.
	3. **\1** Rate Compensated Detectors **/1/**	1. **\1** Replace detectors exceeding manufacturer's recommended service life. **/1/**
	4. **\1** Smoke Alarms (single station or interconnected **/1/**	1. **\1** Replace smoke alarms. **/1/**
20 Years **\1** and As Part of Other Building Inspection (not part of ITM requirements) **/1/**	1. Smoke Detectors **\1** not monitored internally or by the control panel for sensitivity or obscuration as appropriate, **/1/** (single-station detectors, and system detectors)	1. Replace detectors.

Frequency	Component	Tasks
	2. Air Sampling Smoke Detectors	1. Replace detection element.
	3. Control Panel and Annunciator Equipment	1. Verify manufacturer's service life for control elements. 2. Verify manufacturer has continued technical and parts support for the specific model. 3. Replace control equipment exceeding manufacturer's recommended service life limits or if the manufacturer has ceased to provide technical and parts support.
	4. Entire System	1. Visually check: a. Detectors unblocked and uncovered. b. Panels secured and indicator lamps functional. c. Notification appliances in place. d. Manual stations in place and unobstructed. 2. Exercise evacuation notification appliances for audibility, clarity, and visibility.

2-2.3 Mass Notification Systems.

Guidance on these tasks is contained in the *Inspection, Testing, and Maintenance* section of NFPA 72.

The inspection, testing, and maintenance of combined fire alarm and mass notification systems must comply with Section 2-2.2 in addition to this section.

Table 2-2 Mass Notification System ITM Tasks

Frequency	Component	Tasks
Annually	1. Fire Alarm Control Panel with Integrated Mass Notification (FMCP)	1. Test to verify proper receipt of signals (inputs) from Local Operating Consoles (LOCs) and the installation's site-wide system and operation of notification appliances and auxiliary functions (outputs). 2. Verify all lamps and LEDs are illuminated. 3. Load test backup batteries using a meter (when provided). 4. Verify condition of power supplies and batteries. 5. Resolve any trouble indications.
	2. LOCs	1. Verify station is accessible (visual).
	3. Notification Appliances and Voice Communication (speakers and strobe lights)	1. Test to verify operability.
	4. Text Message Signs	1. Test to verify operability.
2 Years	1. FMCP and LOCs	1. Operate microphone to verify proper operation. 2. Operate all pre-recorded message activation switches to verify proper operation. 3. Operate all notification zone selection switches, if provided, to verify proper operation.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. FMCP and LOCs are not blocked or obstructed. b. Panels secured and indicator lamps functional. c. Notification appliances in place. 2. Exercise notification appliances for audibility, clarity, and visibility.

2-2.4 Installation Fire Alarm Reporting Systems.

Reserved

2-2.5 Carbon Monoxide (CO) Detection.

Carbon monoxide detectors installed as initiating devices on fire alarm and detection systems are covered in Section 2-2.2. ITM requirements for single station carbon monoxide alarms installed in buildings without fire alarm systems are provided below. Guidance on the tasks is contained in the “Inspection, Testing, and Maintenance” section of NFPA 72.

Table 2-3 Carbon Monoxide (CO) Detection ITM Tasks

Frequency	Component	Tasks
Annually	1. Single Station Carbon Monoxide Alarms	1. Test to verify alarm activation. 2. Verify no facility change affects performance.
7-10 Years	1. Single Station Carbon Monoxide Alarms	1. Replace Detector

2-2.6 Hydrants and Monitors.

Technical guidance on the tasks is contained in UFC 3-230-02; American Water Works Association (AWWA) Manual 17 (M17), *Fire Hydrants: Installation, Field Testing, and Maintenance,* for hydrants and monitors supplied from potable distribution systems; and NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems,* for hydrants and monitors supplied by non-potable distribution systems. **\1** Accomplish **/1/** flow testing in accordance with AWWA M17, Chapter 6.

WARNING

Flow tests results that have decreased more than 20 percent from the previous test readings or the original acceptance readings indicate an emergency situation. In this case, immediate distribution system flow testing is indicated. Immediately conduct main drain tests on all adjacent sprinkler systems to determine the extent to which the sprinkler systems are compromised. (Table 2-4, Task 5-Year 1.2 and Table 2-5, Task 5-Year 1.2)

CAUTION

Flow tests results that have decreased more than 10 percent from previous test readings or the original acceptance readings require immediate evaluation to determine the cause. (Table 2-4, Task 5-Year 1.2 and Table 2-5, Task 5-Year 1.2)

Table 2-4 Hydrant ITM Tasks

Frequency	Component	Task
2 Years	1. Hydrants (public and private potable water distribution systems) 2. Hydrants - dedicated fire protection water distribution systems 3. Hydrants - reuse (gray) water systems if specifically installed to meet a fire protection requirement.	1. Inspect for accessibility, leaks, and worn threads. 2. Lubricate hydrant to ensure ease of operation. 3. Flush the hydrant not less than 1 minute or until water runs clear, whichever is longer. 4. Verify drainage of barrel (after all operations and before cold weather).
5 Years	1. Underground and Exposed Piping	1. Conduct flow tests as recommended by AWWA M17, Chapter 6. Coordinate with the 2-year ITM tasks whenever possible. **\1** Not less than **/1/** 20 percent of the installation's hydrants must be tested each year. At the end of **\1** each **/1/** 5-year cycle, every hydrant must have had a flow test conducted and recorded. Select test hydrants **\1** to ensure **/1/** piping condition/flow capability in each area of the installation is verified **\1** each year **/1/**.) 2. Document flow test results and provide a copy to the fire and emergency service organization delivering fire suppression services for the installation. 3. Verify results are within acceptable limits or identify corrective measures.
After Flow	1. Strainers	1. Inspect and clean after each flow.
As Required	1. Hydrants	1. Apply protective coatings (paint) to prevent corrosion. 2. Identify by hydrant barrel color code the water distribution system to which the hydrant is connected, per AWWA Standards: a. potable water b. non-potable fire protection water c. non-potable reuse (gray) water 3. Identify by hydrant bonnet (top) color code the water flow available from the hydrant. (Color codes follow AWWA or NFPA 291 recommendations **\1** unless local alternatives are officially adopted **/1/**.)
Following System or	1. Underground Distribution and Valves.	1. Conduct flow tests as recommended by AWWA M17, Chapter 6. **\1\ /1/**

Frequency	Component	Task
Hydrant Modification or Repair		

Table 2-5 Yard Hydrant Monitors and Hose Houses ITM Tasks

Frequency	Component	Task
2 Years	1. Yard Monitor Nozzles (**\1** dedicated fire protection water distribution systems and **/1/** non-potable systems)	1. Inspect for condition. 2. Conduct flow test to verify proper function and range of motion. 3. Lubricate to ensure proper operating conditions.
	2. Hose Houses	1. Inspect for accessibility and physical condition. 2. Verify inventory and equipment condition. 3. Replace hose that has exceeded the expected service life.
5 Years	1. Underground and Exposed Piping	1. Conduct flow tests as recommended by AWWA M17 Chapter 6. (**\1** Not less than **/1/** 20 percent of the installation's hydrants **\1** must **/1/** be tested each year. At the end of **\1** each **/1/** 5-year cycle, every hydrant has had a flow test conducted and recorded. **\1\ /1/** 2. Document flow test results. 3. Verify results are within acceptable limits or identify corrective measures.
After Flow	1. Strainers	1. Inspect and clean after each flow.

2-2.7 Water Supply Tanks.

Technical guidance on these tasks is contained in NFPA 22, *Standard for Water Tanks for Private Fire Protection,* and NFPA 25.

Table 2-6 Water Supply Tank ITM Tasks

Frequency	Component	Tasks
Weekly (during freezing weather)	1. Tank Heating System (without electric supervision)	1. Verify water temperature. 2. Verify operability of tank heaters.
Monthly	1. Control Valves (without seals, locks, or electric supervision)	1. Verify proper valve position.
Quarterly	1. Water Level (without remote supervision of water level)	1. Verify proper water level in tank.
Before the Onset of Freezing Weather	1. Tank Fill Valve Enclosure Heating	1. Verify operability at the beginning of the heating season (annually for constant cold areas).
	2. Low Temperature Alarm	1. Verify initiation and receipt of alarm at the beginning of the heating season.
Annually	1. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.
	2. Water Level (with remote electric supervision of water level)	1. Verify proper water level in tank.
	3. Tank Heating System (with remote electric supervision of water temperature)	1. Verify operability of tank heater (prior to cold weather). 2. Test temperature alarms to verify proper operation. (Maintain thermometer in accordance with manufacturer’s recommendations.)
	4. Tank	1. Inspect exterior for condition, damage, corrosion, and accessibility. 2. Verify air pressure (for pressure tanks).
	5. Cathodic Protection	1. Inspect to ensure proper operation.
2 Years	1. Control Valves (including drain valves)	1. Operate valve through entire travel to verify function. 2. Lubricate valves to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
	2. Water Level Alarms and Level Indicators	1. Test water level alarms to verify operability and set points.

Frequency	Component	Tasks
	3. Automatic Fill Valve	1. Actuate valve automatically by lowering the water level in the tank. 2. Measure refill rate and record data.
	4. Tank Vent	1. Inspect and clean tank vents.
3 Years	1. Tank (without cathodic protection)	1. Conduct internal tank inspection to determine condition and amount of corrosion.
5 Years	1. Tanks (with cathodic protection)	1. Conduct internal tank inspection to determine condition and amount of corrosion.
	2. Pressure Gauges	1. Calibrate or replace gauges.
	3. Check Valves	1. Inspect interior of valves.
	4. Level Indicator Test	1. Calibrate level indicator.
	5. Automatic Fill Valve	1. Perform internal inspection of automatic fill valve.

2-2.8 Fire Pumps.

Technical guidance on these tasks is contained in NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection,* and NFPA 25. When generators are installed specifically to meet fire protection requirements, or generators are used to provide standby power for fire pumps, conduct all the requirements related to the engine drives on the generator engines. These requirements must not supersede requirements for generators serving demands other than fire protection. Generators serving both fire protection and other demands must conform to the most stringent guidance.

WARNING

Fire pump systems with redundant pumps must have all pumps and pump drivers in-service to meet redundancy requirements. Redundant pumps are not spare or stand-by pumps. Redundant pumps ensure the minimum number pumps will start if any minimum required pump fails to start. A redundant pump out-of-service means the pumping capacity is degraded/impaired and any supported fire protection features downstream are degraded/impaired. Two or more pumps out-of-service where there is redundancy means the pumping system is out-of-service as are all the supported fire protection features downstream. (Table 2-7, Tasks Monthly 6.1)

WARNING

Fire pump stations without redundant pumps must have all pumps and pump drivers in-service. A pump or pump driver out-of-service means the pumping capacity is out-of-service and any supported fire protection features downstream are out-of-service. (Table 2-7, Tasks Monthly 6.1)

Table 2-7 Fire Pump ITM Tasks

Frequency	Component	Tasks
Monthly	1. Pump House	1. Inspect for proper condition, ventilation, and heating. 2. Check packing leakage for proper water lubrication. 3. Verify proper drainage.
	2. Control Valves and Isolation Valves (without seals, locks, or electric supervision)	1. Verify proper valve position.
	3. Pressure Gauges	1. Check reading and verify gauge operability.
	4. Controllers	1. Verify automatic controllers are in the automatic (AUTO) setting. 2. Inspect electric connections. 3. Operate manual and automatic starting methods. 4. Resolve all trouble indications.
	5. Batteries	1. Verify proper charge. (Replace batteries in accordance with the driver manufacturer's recommendations or when the full recharged battery voltage or current falls below either the driver or battery manufacturer's recommendations.)
	6. Pumps	1. Start and churn to verify operability. (Where equipment permits, allow water to flow back to the source.) [Operate electric pumps for 10 minutes and operate engine-driven pumps for 30 minutes.] 2. Verify operation of relief valves. 3. Verify fuel level (for engine-driven pumps). 4. Inspect exhaust system for leaks (for engine-driven pumps). 5. For engine driven pumps, start again using second battery set and churn to verify operability. (Where equipment permits, allow water to flow back to the source.)

Frequency	Component	Tasks
Semi-Annually	1. Fuel (**\1** combustion engine-drivers **/1/**)	1. **\1** Verify fuel level if not supervised. **/1/**
Annually	1. Control Valves (sealed, locked, and electrically supervised)	1. Verify proper valve position.
	2. **\1** Combustion Engine Drivers **/1/**	1. **\1** Change all fluids per manufacturer's guidance. 2. Change all filters per manufacturer's guidance. **/1/**
2 Years	1. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
	2. Controllers	1. Calibrate pressure switches. 2. Exercise circuit breakers and switches to verify operability. 3. Inspect fuses.
	3. Pumps	1. Check coupling alignment to ensure the shaft is aligned. 2. Check pump shaft endplay. 3. Lubricate bearings. 4. Lubricate couplings. 5. Lubricate right-angle drives.
	4. Relief Valves	1. Calibrate valves.
	5. Emergency Power Supply	1. Test to verify availability and capacity for pump motor.
	6. **\1** Fuel (combustion engine-drivers) **/1/**	1. **\1** Sample fuel and test to verify quality. **/1/**
5 Years	1. Pump	1. Conduct flow test to verify pump output. Test **\1** will **/1/** be through a flow meter returning the water to a storage reservoir or through the test header. Recirculation of water to the suction piping is not permitted. In a multi-pump installation, each pump may be tested separately at not less than 100 percent design capacity for 30 minutes. 2. Verify the results are within acceptable limits or identify corrective measures.
	2. Gauges and Flow Meters	1. Calibrate or replace flow meter prior to fire pump flow test.
\1 As Required **/1/**	1. **\1** Generators Providing Emergency	1. **\1** Follow Service-specific generator maintenance guidance for

Frequency	Component	Tasks
	Power to Electric Fire Pumps When Required. **/1/**	emergency/standby generators. **/1/**

2-2.9 Backflow Prevention Devices.

Technical guidance on the tasks is contained in UFC 3-230-02 and AWWA Manual 14 (M14). Backflow prevention and cross-connection devices are considered part of the water distribution system; however, their maintenance and full operation is critical to the function of fire suppression systems supplied by the potable distribution system. UFC 3-230-02 requires each installation to have a backflow prevention and cross-connection maintenance program. All backflow prevention devices are required to have a test connection downstream of the backflow device capable of flowing the fire protection system's maximum fire flow demand. Reduced pressure backflow prevention devices have a specific approved friction loss operating range; full flow testing is required to demonstrate the device is operating within the manufacturer's listed friction loss curves.

Table 2-8 Backflow Prevention Device ITM Tasks

Frequency	Component	Tasks
Annually	1. All Backflow Prevention Devices	1. Conduct full flow test to ensure flow and pressure meet or exceed system demand.
5 years	1. All Backflow Prevention Devices	1. Conduct internal inspection of backflow prevention assembly to verify all components operate correctly, move freely, and are in good condition.

2-2.10 Standpipe Systems.

Detection devices for actuation, where provided, are addressed in Section 2-2.2, "Fire Detection and Alarm Systems." Technical guidance on the tasks is contained in NFPA 14, *Standard for the Installation of Standpipes and Hose Systems,* and NFPA 25.

Table 2-9 Standpipe Systems ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seals, locks, or electric supervision)	1. Verify proper valve position.
Semi-Annually	1. Hose Connection and Pressure Reducing Valves	1. Inspect for damage, leaking, missing caps, and obstructions.

Frequency	Component	Tasks
Annually	1. Fire Department Connections	1. Verify accessibility and condition. 2. If caps are removed or missing, check for obstructions. 3. Verify system check valve is not leaking. 4. Verify gaskets are present. 5. Lubricate if swivels do not rotate smoothly. 6. Verify proper operation of ball drip drain prior to the cold season.
2 Years	1. Piping	1. Inspect for damage to piping and pipe supports.
	2. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate stem. 3. Verify valve supervisory switches detect a change in valve position. 4. Verify proper valve position
5 Years	1. Standpipe	1. Conduct flow test to verify flow capacity and minimum discharge pressure. (Test must confirm only flow/pressure -- not duration of supply). 2. Hydrostatic test to ensure integrity (dry standpipe systems only).
	2. Pressure Reducing Hose Valves	1. Conduct flow test to verify operation of pressure reducing hose valves (test to confirm pressure and flow). 2. Confirm setting of pressure reducing hose valves.
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring the water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers b. connections for obstruction c. piping for leaks d. riser condition

2-2.11 Wet Pipe Automatic Sprinkler Systems.

Technical guidance on the tasks is contained in NFPA 25. Residential sprinkler systems are addressed in Chapter 3.

WARNING

Main drain static or residual test pressures that have decreased more than 20 percent from the original acceptance readings or the previous test readings indicate an **\1\ /1/** emergency situation. In this case, immediate distribution system flow testing is indicated. Immediately conduct main drain tests on all adjacent sprinkler systems to determine the extent to which the sprinkler systems are compromised. (Table 2-10, Task Annual 4.3)

CAUTION

Main drain static or residual test pressures that have decreased more than 10 percent from the previous test readings require immediate evaluation to determine the cause. (Table 2-10, Task Annual 4.3)

Table 2-10 Wet Pipe Sprinkler System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seal, lock, or electric supervision)	1. Verify proper valve position.
Annually	1. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.
	2. Water Flow Alarm Devices	1. Verify initiation and receipt of alarm (alternate use of alarm test line and inspector's test connection annually). 2. Verify operation of exterior water flow alarm (if present). 3. Verify alarm test valve alignment and tamper switch (if sealed or electrically supervised).
	3. Alarm Valve and Trim	1. Visually check the exterior of valves, gauges, trim alignment. 2. Verify valve pressure and legibility of the hydraulic nameplate.

Frequency	Component	Tasks
	4. Main Drain	1. Conduct a main drain test to verify supply (valve position). 2. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge. 3. Compare results with results from previous main drain tests and original acceptance test. 4. Verify results are within acceptable limits or identify corrective measures.
	5. Fire Department Connection	1. Verify accessibility and condition. 2. If caps are removed or missing, check for obstructions **\1** and replace missing caps/covers **/1/**. 3. Verify system check valve is not leaking. 4. Verify gaskets are present. 5. Lubricate if swivels do not rotate smoothly. 6. Verify proper operation of ball drip drain prior to the cold season.
2 Years	1. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
5 Years	1. Alarm Valve	1. Clean and inspect internally to verify condition.
	2. Anti-freeze Loops	1. Determine solution type. If solution type is no longer permitted or cannot be positively identified, drain system completely and replace with an acceptable solution. 2. Confirm correct solution mixture.
	3. Strainers	1. Inspect internally and clean to good condition.
	4. Automatic Air Release Valve	1. Confirm proper operation.
10 Years	1. Gauges	1. Calibrate or replace gauges.
	2. Dry Barrel Sprinklers	1. Replace all sprinklers. **\1**[1]**/1/**
20 Years **\1** and Every 10 Years Thereafter **/1/**	1. **\1** Fast-Response Sprinklers and Extra High Temperature Sprinklers **/1/**	1. Replace all **\1** sprinklers or test a sample of sprinklers to verify response characteristics.[1] **/1/**
50 Years and Every 20 Years Thereafter	1. Standard Sprinklers	1. Replace all sprinklers or test a sample of sprinklers to verify response characteristics. **\1**[1]**/1/**

Frequency	Component	Tasks
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring the water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers and seismic bracing b. sprinklers for obstruction c. piping for leaks d. riser condition e. verify sprinkler spares

\1[1]**/1/** A representative sample of sprinklers for testing must consist of one (1) percent of the sprinklers installed of the same type, with a minimum of four (4) sprinklers sampled. Submit sprinklers to a **\1** nationally **/1/** recognized testing laboratory for these tests.

2-2.12 Dry Pipe Automatic Sprinkler Systems.

Technical guidance for these tasks is contained in NFPA 25.

WARNING

Main drain static or residual test pressures that have decreased more than 20 percent from the original acceptance readings or the previous test readings indicate an **\1\ /1/** emergency situation. In this case, immediate distribution system flow testing is indicated. Immediately conduct main drain tests on all adjacent sprinkler systems to determine the extent to which the sprinkler systems are compromised. (Table 2-11, Task Annual 4.3)

CAUTION

Main drain static or residual test pressures that have decreased more than 10 percent from the previous test readings require immediate evaluation to determine the cause. (Table 2-11, Task Annual 4.3)

Table 2-11 Dry Pipe Automatic Sprinkler System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seal, lock, or electric supervision)	1. Verify proper valve position.
Before the Onset of Freezing Weather	1. Low Point Drains	1. Drain all low points to remove condensation prior to the cold season.
	2. Dry Pipe Alarm Valve Enclosure Heating	1. Verify operability at the beginning of the heating season (annually for constant cold areas).
	3. Low Temperature Alarm	1. Verify initiation and receipt of alarm at the beginning of the heating season.
Annually	1. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.
	2. Water Flow Alarm Devices	1. Operate alarm test valve to verify initiation and receipt of alarm. 2. Verify alarm test valve alignment and tamper switch (if sealed or electrically supervised).
	3. Dry Pipe Alarm Valve and Trim	1. Visually inspect the exterior of valves, gauges, trim alignment. 2. Verify valve pressure and legibility of the hydraulic nameplate. 3. Verify valve position of provided quick opening devices are in the normal position.
	4. Main Drain	1. Conduct main drain test to verify supply (valve position). 2. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge. 3. Compare results with results from previous main drain tests and original acceptance test. 4. Verify results are within acceptable limits or identify corrective measures.

Frequency	Component	Tasks
	5. Fire Department Connection	1. Verify accessibility and condition. 2. If caps are removed or missing, check for obstructions. 3. Verify system check valve is not leaking. 4. Verify gaskets are present. 5. Lubricate if swivels do not rotate smoothly. 6. Verify proper operation of ball drip drain prior to the cold season.
	6. Low Point Drains	1. Drain all low points to remove condensation prior to the cold season.
2 Years	1. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
	2. Dry Pipe Alarm Valves	1. Trip valve to verify operability. 2. Inspect internal condition before resetting and clean valve seat. 3. Check priming water level (before and after trip test).
	3. Quick-Opening Devices	1. Test to verify operability.
	4. Low/High Air Pressure Alarms	1. Test to verify initiation and receipt of supervisory alarms.
	5. Automatic Air Pressure Maintenance Devices	1. Inspect to verify proper operation.
5 Years	1. Strainers	1. Inspect internally and clean to verify condition.
10 Years	1. Gauges	1. Calibrate or replace gauges.
10 Years	1. Dry Barrel Sprinklers	1. Replace all.[1]
20 Years **\1** and Every 10 Years Thereafter **/1/**	1. **\1** Fast-Response Sprinklers and Extra High Temperature Sprinklers **/1/**	1. Replace all **\1** sprinklers or test a sample of sprinklers to verify response characteristics.[1] **/1/**

Following System Modification or	1. Main Drain (following maintenance or repair	1. Conduct main drain test to verify supply (valve position).

Frequency	Component	Tasks
Repair	action requiring the water supply to be shut off)	2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify the results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch x 5-inch tag and secure it to the system pressure gauge.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers and seismic bracing b. sprinklers for obstruction c. piping for leaks d. riser condition e. sprinkler spares

\1[1]**/1/** A representative sample of sprinklers for testing must consist of one (1) percent of the sprinklers installed of the same type, with a minimum of four (4) sprinklers sampled. The sprinklers must be submitted to a **\1** nationally **/1/** recognized testing laboratory for these tests.

2-2.13 Deluge Sprinkler Systems.

Detection devices for actuation are addressed in Section 2-2.2, “Fire Detection and Alarm Systems.” Technical guidance on these tasks is contained in NFPA 25 and NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*.

WARNING

Main drain static or residual test pressures that have decreased more than 20 percent from the original acceptance readings or the previous test readings indicate a **\1\ /1/** emergency situation. In this case, immediate distribution system flow testing is indicated. Immediately conduct main drain tests on all adjacent sprinkler systems to determine the extent to which the sprinkler systems are compromised. (Table 2-12, Task Annual 4.3)

CAUTION

Main drain static or residual test pressures that have decreased more than 10 percent from the previous test readings require immediate evaluation to determine the cause. (Table 2-12, Task Annual 4.3)

Table 2-12 Deluge Sprinkler System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seal, lock, or electric supervision)	1. Verify proper valve position.
Before the Onset of Freezing Weather	1. Valve and Riser Heated Enclosure (if provided)	1. Verify operability at the beginning of the heating season.
	2. Low Temperature Alarm	1. Verify initiation and receipt of alarm at the beginning of the heating season.
	3. Low Point Drains	1. Drain all low points after deluge valve test and before cold weather.
Annually	1. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.
	2. Water Flow Alarm Devices	1. Operate alarm test valve to verify initiation and receipt of alarm. 2. Verify alarm test valve alignment and tamper switch (if sealed or electrically supervised).
	3. Deluge Alarm Valve and Trim	1. Inspect exterior of valves, gauges, trim alignment. 2. Verify valve pressure and legibility of hydraulic nameplate.
	4. Main Drain	1. Conduct a main drain test to verify supply (valve position). 2. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge. 3. Compare results with results from previous main drain tests and original acceptance test. 4. Verify results are within acceptable limits or identify corrective measures.
	5. Fire Department Connection	1. Verify accessibility and condition. 2. If caps are removed or missing, check for obstructions. 3. Verify system check valve is not leaking. 4. Verify gaskets are present. 5. Lubricate if swivels do not rotate smoothly. 6. Verify proper operation of ball drip drain prior to the cold season.

Frequency	Component	Tasks
2 Years	1. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
	2. Deluge Valve	1. Trip to verify operability. 2. Verify manual actuators are operable. 3. Inspect internal condition and clean valve seat before resetting.
	3. Low Point Drains	1. Drain all low points after each valve trip.
5 Years	1. Strainers	1. Inspect internally and clean to verify condition.
10 Years	1. Gauges	1. Calibrate or replace.
	2. Deluge Valve	1. Conduct full flow test.
	1. Distribution System	1. Verify nozzle (sprinkler) coverage during flow test. 2. Inspect piping and nozzles for condition and location.
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers and seismic bracing b. sprinklers/nozzles for obstruction c. piping for leaks d. riser condition e. sprinkler spares 2. Ensure: a. manual stations are in place and unobstructed. b. detectors are unblocked/uncovered. c. panels are secured and indicator lamps functional. d. notification appliances are in place.

2-2.14 Pre-Action Automatic Sprinkler Systems.

Detection devices for actuation are addressed in Section 2-2.2, "Fire Detection and Alarm Systems." Technical guidance on these tasks is contained in NFPA 25.

WARNING

Main drain static or residual test pressures that have decreased more than 20 percent from the original acceptance readings or the previous test readings indicate an **\1\ /1/** emergency situation. In this case, immediate distribution system flow is indicated. Immediately conduct main drain tests on all adjacent sprinkler testing systems to determine the extent to which the sprinkler systems are compromised. (Table 2-13, Task Annual 4.3)

CAUTION

Main drain static or residual test pressures that have decreased more than 10 percent from the previous test readings require immediate evaluation to determine the cause. (Table 2-13, Task Annual 4.3)

Table 2-13 Pre-Action Automatic Sprinkler System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seal, lock, or electric supervision)	1. Verify proper valve position.
Before the Onset of Freezing Weather	1. Valve and Riser Heated Enclosure (if provided)	1. Verify operability at beginning of heating season.
	2. Low Temperature Alarm	1. Verify initiation and receipt of alarm at the beginning of the heating season.
	3. Low Point Drains	1. Drain all low points before cold weather (if unheated area).
Annually	1. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.
	2. Water Flow Alarm Devices	1. Operate alarm test valve to verify initiation and receipt of alarm. 2. Verify alarm test valve alignment and tamper switch (if sealed or electrically supervised).
	3. Pre-Action Valve and Trim	1. Inspect exterior of valves, gauges, trim alignment. 2. Verify valve pressure and legibility of hydraulic nameplate.

Frequency	Component	Tasks
	4. Main Drain	1. Conduct a main drain test to verify supply (valve position). 2. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge. 3. Compare results with results from previous main drain tests and original acceptance test. 4. Verify results are within acceptable limits or identify corrective measures.
	5. Fire Department Connection	1. Verify accessibility and condition. 2. If caps are removed or missing, check for obstructions. 3. Verify system check valve is not leaking. 4. Verify gaskets are present. 5. Lubricate if swivels do not rotate smoothly. 6. Verify proper operation of ball drip drain prior to the cold season.
2 Years	1. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
	2. Pre-Action Valve	1. Trip to verify proper operation. 2. Verify function of manual actuators (if provided). 3. Inspect internal condition and clean valve seat before resetting.
	3. Low Point Drains	1. Drain all low points after pre-action valve trip test.
	4. Air Supply (if present)	1. Test automatic air pressure maintenance device. 2. Test low/high air supply alarms.
5 Years	1. Strainers	1. Clean and inspect interior to verify condition.
10 Years	1. Gauges	1. Calibrate or replace gauges.

Frequency	Component	Tasks
10 Years, and Every 10 Years Thereafter	1. Dry Sprinklers	1. Replace all sprinklers or test a sample of sprinklers to verify response characteristics.[1]
20 Years, and Every 10 Years Thereafter	1. Fast-Response Sprinklers and Extra High Temperature Sprinklers	1. Replace all sprinklers or test a sample of sprinklers to verify response characteristics. **\1**[1]**/1/**
50 Years, and Every 10 Years Thereafter	1. Standard Sprinklers	1. Replace all sprinklers or test sample closed-head sprinklers to verify response characteristics. **\1**[1]**/1/**
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring the water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers and seismic bracing b. sprinklers for obstruction c. piping for leaks d. riser condition e. sprinkler spares 2. Ensure: a. manual stations are in place and unobstructed. b. detectors are unblocked/uncovered. c. panels are secured and indicator lamps functional. d. notification appliances are in place.

\1[1]**/1/** A representative sample of sprinklers for testing must consist of one (1) percent of the sprinklers installed of the same type, with a minimum of four (4) sprinklers sampled. The sprinklers must be submitted to a **\1** nationally **/1/** recognized testing laboratory for these tests.

2-2.15 Nitrogen Generation Systems.

Technical guidance for these tasks is contained in NFPA 25 and the manufacturer's recommendations.

Table 2-14 Nitrogen Generation System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Generation System	1. Verify generation system is free of physical damage. 2. Verify proper valve positions. 3. Verify generation system is in **\1** automatic **/1/** operating condition. 4. Verify the power wiring to the generation system is free of physical damage. 5. Verify piping from generation system to system served is intact and free of physical damage.
Annually	1. Filter Elements	1. Replace the activated carbon and coalescing filter elements.
	2. Intake Filters	1. Clean the air compressor intake filter elements, replace intake filters if necessary.
	3. Strainer Screens	1. Clean air tank blow-down strainer screens.
	4. System Concentration	1. Verify the generation system is maintaining a nitrogen composition of 98% in the system served. Verify nitrogen composition at remote test locations.
2 Years	1. System Operation	1. Verify generation system operates on the proper pressure drop and ceases operation at the proper set point. 2. Verify generation system does not overheat or present any unusual noise or vibration during operation. 3. Verify the means of anchoring the generation system to the structure is secure, tight, and free of physical damage.
	2. Safety Relief Valves	1. Manually test safety relief valves.
5 Years	1. Leakage Test	1. Inspect system served by generation system for leaks by conducting a pressure loss test.
	2. System Performance	1. Verify generation system restores **\1\\ /1/**gas pressure and concentration in the system served within the required timeframe.

2-2.16 Water Spray Systems.

Detection devices for actuation are addressed in Section 2-2.2, "Fire Detection and Alarm Systems." Technical guidance on these tasks is contained in NFPA 25.

WARNING

Main drain static or residual test pressures that have decreased more than 20 percent from the original acceptance readings or the previous test readings indicate an **\1\ /1/** emergency situation. In this case, immediate distribution system flow testing is indicated. Immediately conduct main drain tests on all adjacent sprinkler systems to determine the extent the sprinkler systems are compromised. (Table 2-15, Task Annual 4.3)

CAUTION

Main drain static or residual test pressures that have decreased more than 10 percent from the previous test readings require immediate evaluation to determine the cause. (Table 2-15, Task Annual 4.3)

Table 2-15 Water Spray System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seal, lock, or electric supervision)	1. Verify proper valve position.
Before the Onset of Freezing Weather	1. Valve and Riser Enclosure Heater	1. Verify operability at the beginning of the heating season.
	2. Low Temperature Alarm	1. Verify initiation and receipt of alarm at the beginning of the heating season.
	3. Low Point Drains	1. Drain all low points before cold weather.
Annually	1. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.
	2. Water Flow Alarm Devices	1. Operate to verify initiation and receipt of alarm. 2. Verify alarm test valve alignment and tamper switch (if sealed or electrically supervised).
	3. Deluge Valve and Trim	1. Inspect exterior of valves, gauges, trim alignment. 2. Verify valve pressure and legibility of hydraulic nameplate.

Frequency	Component	Tasks
	4. Main Drain	1. Conduct a main drain test to verify supply (valve position). 2. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge. 3. Compare results with results from previous main drain tests and original acceptance test. 4. Verify results are within acceptable limits or identify corrective measures.
	5. Fire Department Connection	1. Verify accessibility and condition. 2. If caps are removed or missing, check for obstructions. 3. Verify system check valve is not leaking. 4. Verify gaskets are present. 5. Lubricate if swivels do not rotate smoothly. 6. Verify proper operation of ball drip drain prior to the cold season.
2 Years	1. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
	2. Water Spray Valve	1. Trip to verify operability. 2. Verify manual actuators (if provided). 3. Inspect interior of valve and clean valve seat before resetting.
	3. Low Point Drains	1. Drain all low points after pre-action valve trip test.
	4. Distribution System	1. Verify nozzle (sprinkler) coverage during flow test. 2. Verify spray pattern. (If experience shows nozzles are not moved, this can be extended to 10 years or after modifications.) 3. Inspect piping hangers, sprinklers, and nozzles for condition and location.

Frequency	Component	Tasks
5 Years	1. Strainers	1. Clean and inspect interior to verify condition.
10 Years	1. Gauges	1. Calibrate or replace.
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring the water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers and seismic bracing b. sprinklers for obstruction c. piping for leaks d. riser condition e. sprinkler spares 2. Ensure: a. manual stations are in place and unobstructed. b. detectors are unblocked/uncovered. c. panels are secured and indicator lamps functional. d. notification appliances are in place.

2-2.17 Water Mist Systems.

Table 2-16 lists required ITM tasks for high-pressure water mist systems. Detection devices for actuation are addressed in Section 2-2.2, “Fire Detection and Alarm Systems.” Technical guidance on these tasks is contained in NFPA 25 and NFPA 750, *Standard on Water Mist Fire Protection Systems*.

Table 2-1 contains required ITM tasks for low-pressure water mist systems.

For hybrid water mist systems, use the specific manufacturer’s ITM frequencies and procedures.

Table 2-16 High Pressure Water Mist System ITM Tasks

Frequency	Component	Task
Weekly	1. Water Tanks (without electric remote supervision of water level)	1. Check water level.
	2. Air Compressor/Receiver/ Cylinders (without electric remote supervision of air pressure)	1. Check air pressure.
Semi-annually	1. Pumps	1. Complete churn test to ensure operability.
	2. Air Compressors	1. Start to ensure operability.
	3. System Operating Components	1. Inspect to verify valve is aligned and free of damage.
Annually	1. Water Tanks (remote electrically supervised and monitored)	1. Check water level detection device and supervisory controls.
	2. Air Compressors/Receivers/ Cylinders (electric remote supervision of air pressure)	1. Check air pressure and supervisory pressure switch.
	3. Water Flow Alarm	1. Operate to verify initiation and receipt of alarm.
	4. Pumps	1. Conduct full flow functional test.
	5. Pressure Relief Devices	1. Manually operate to ensure operability.
	6. Manual Actuators	1. Verify operability.
	7. Control Valve (sectional water supply valve)	1. Verify operability and position.
5 Years	1. Pressure Cylinders (normally at atmospheric pressure)	1. Pressurize to verify operability.
	2. System	1. Conduct flow test.
	3. Water	1. Verify water quality when refilling.
	4. Water Tanks	1. Drain and refill tank. 2. Inspect tanks for structural integrity (interior and exterior) prior to refilling.
	5. Water Mist Nozzles Subject to Harsh Environments	1. Replace all nozzles or test a sample of nozzles to verify response characteristics.[1]

Frequency	Component	Task
5-12 Years	1. Storage Vessels	1. Conduct hydrostatic test for pressure cylinders in accordance with OSHA and U.S. Department of Transportation (DOT) standards.
20 Years	1. Water Mist Nozzles in Areas Other Than Harsh Environments	1. Replace all nozzles or test a sample of nozzles to verify response characteristics.[1]
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers b. nozzles for obstruction c. piping for leaks d. riser condition e. nozzle spares 2. Ensure: a. manual stations are in place and unobstructed. b. detectors are unblocked/ uncovered. c. panels are secured and indicator lamps functional. d. notification appliances are in place.

\1[1]**/1/** A representative sample of nozzles for testing must consist of one (1) percent of the nozzles installed of the same type, with a minimum of four (4) nozzles sampled. The nozzles must be submitted to a **\1** nationally **/1/** recognized testing laboratory for these tests.

2-2.18 Foam and Foam-Water Systems.

WARNING

Use of any fire suppression foam concentrate or solution containing per- or poly-fluorinated alkylated substances (PFAS) for inspection, test, and maintenance is not permitted

WARNING

Release of any fire suppression foam concentrate, **\1** solution, or testing surrogates, **/1/** regardless of chemical composition, during inspection, test, and maintenance to the environment, is not permitted.

CAUTION

Release of any non-PFAS foam concentrate, solution, or testing surrogates to a regulated waste stream including industrial or sanitary treatment facilities must be fully permitted and authorized by the system operator and by appropriate regulatory authorities.

Table 2-17 addresses low-expansion foam systems for **\1** ignitable **/1/** liquid tanks as covered in NFPA 11, *Standard for Low-, Medium-, and High-Expansion Foam.* Table 2-18 addresses low-expansion foam spray and sprinkler systems, including AFFF, as covered in NFPA **\1** 11 **/1/**. Table 2-19 addresses low-expansion foam monitor nozzle systems for multiple applications as covered in NFPA 11. Table 2-20 addresses low-expansion grate nozzle foam systems for aircraft hangar applications as covered in NFPA 11. Table 2-21 addresses high-expansion foam systems as covered in NFPA 11.

Detection devices for actuation are addressed in Section 2-2.2, “Fire Detection and Alarm Systems.”

\1

2-2.18.1 Disposal of Foam Concentrates.

All foam concentrates, foam-water solutions, or testing surrogates discharged during ITM processes must be contained, collected, and disposed of in accordance with current environmental guidance (Title 15 United States Code (U.S.C.) Chapter 115, *Perfluoroalkyl and Polyfluoroalkyl Substances and Emerging Contaminants*).

Fluorine surfactant-based foam (commercial or military specification AFFF concentrate or solution waste) must be disposed of using approved methods. Removed parts including bladders and tanks contaminated with fluorine-based foams must be disposed of using approved methods.

2-2.18.2 PFAS-Containing Concentrates.

Replace all PFAS-containing foam concentrates with DoD- or Component-approved fluorine free foam concentrates not later than by 2024 unless extended by the Secretary of Defense to 2026.

The 2020 National Defense Authorization Act requires DoD to stop any non-emergency release of per- and polyfluoroalky (PFAS) substances, a broad group of chemicals including PFOA, PFOS, GenX, and others. The 2020 NDAA requires DoD to phase out the use PFAS substances by 2024 (SecDef extendable until 2026). AFFF (military specification and commercial products) and FFFP are PFAS-containing substances and will be phased out. Non-PFAS containing foam concentrates include high expansion foams (Hi-Ex), fluorine free foams (FFF), and testing surrogates, and are not affected by the 2020 NDAA phase-out. At the date Change 1 of this UFC, some Components have issued specific phase-out guidance; others are still developing guidance. Consult with the appropriate CFPE for additional/evolving information and guidance.

2-2.18.3 Maintenance of Locked Out/Tagged Out Systems.

Foam concentrate systems locked out/tagged out by Service/Agency specific direction do not require maintenance actions. Other system components remaining in service require maintenance appropriate the in-service components.

2-2.18.4 Systems Converting from AFFF to FFF.

Systems converted from Military Specification aqueous film forming foam (AFFF) to Military Specification fluorine free foam (FFF) MIL-PRF 72325 will continue to provide the maintenance actions for FFF as required for AFFF. FFF foam concentrate, and solution will require the same containment and mitigation action as AFFF. Release to ground, storm, or surface water is not permitted. Reporting of FFF releases/discharges will conform to Service specific environmental guidance.
/1/

Table 2-17 Low-Expansion Foam System for Ignitable Liquid Tank ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seals, locks, or electric supervision)	1. Verify proper valve position.
Annually	1. Foam Concentrate	1. Inspect for quality and evidence of sludge or deterioration. 2. Take sample and test in accordance with manufacturer’s instructions.
	2. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.
	3. System Actuators	1. Confirm function of all manual and automatic actuation functions.
	4. Foam Concentrate Strainers	1. Inspect and clean if necessary.
	5. Distribution Piping/Discharge Devices	1. Ensure discharge devices are free of damage. 2. Inspect pipe and hangers to verify support and pitch.

Frequency	Component	Tasks
	6. Main Drain	1. Conduct main drain test to verify supply (valve position). 2 Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge. 3. Compare results with results from previous main drain tests and original acceptance test. 4. Verify results are within acceptable limits or identify corrective measures.
	7. Fire Department Connection	1. Verify accessibility and condition. 2. If caps are removed or missing, check for obstructions. 3. Verify system check valve is not leaking. 4. Verify gaskets are present. 5. Lubricate if swivels do not rotate smoothly. 6. Verify proper operation of ball drip drain prior to the cold season.
2 Years	1. Foam Proportioning System/ Foam Pumps	1. Test to verify operability and proper proportioning (concentration must be within 10 percent of original acceptance test results, but no more than 10 percent below minimum design standard). 2. Flush pumps after operation.
	2. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
5 Years	1. Distribution Piping (including underground)	1. Spot-check piping interior for evidence of deterioration.
	2. Strainers (water supply)	1. Inspect and clean if necessary.
	3. Fire Department Connection	1. Hydrostatically test piping from the fire department connection to the fire department check valve at 150 psi (10 bar) for 2 hours.
10 Years	1. Foam Concentrate Tank	1. Drain, flush, and perform internal inspection for corrosion. If pressure vessel, perform hydrostatic test.

Frequency	Component	Tasks
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring the water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers and seismic bracing b. generators for obstruction (air intake or foam discharge) c. generator nozzles for obstruction and generator screens for damage d. piping for leaks e. riser condition 2. Ensure: a. panels are secured and indicator lamps functional. b. notification appliances are in place. c. manual stations are in place and unobstructed.

Table 2-18 Low Expansion Foam Spray and Sprinkler System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seal, lock, or electric supervision)	1. Verify proper valve position.
Semi-Annually	1. Foam Concentrate	1. Inspect for quality and evidence of sludge or deterioration. 2. Verify adequate supply.
	2. Foam Proportioning System/ Foam Pumps (if provided)	1. Test pump to ensure operability. 2. Inspect proportioning system for proper valve alignment and system condition. 3. Flush pumps after operation.
Annually	1. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.

Frequency	Component	Tasks
	2. Foam Concentrate	1. Take sample and test in accordance with manufacturer's instructions.
	3. Foam Concentrate Strainers	1. Inspect exterior to ensure blow down valve is closed.
	4. Main Drain	1. Conduct main drain test to verify supply (valve position). 2. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge. 3. Compare results with results from previous main drain tests and original acceptance test. 4. Verify **\1\ /1/** the results are within acceptable limits or identify corrective measures.
	5. Fire Department Connection	1. Verify accessibility and condition. 2. If caps are removed or missing, check for obstructions. 3. Verify system check valve is not leaking. 4. Verify gaskets are present. 5. Lubricate if swivels do not rotate smoothly. 6. Verify proper operation of ball drip drain prior to the cold season.
2 Years	1. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
	2. Foam Proportioning System	1. Conduct full flow test to ensure proper system function. 2. Verify proper concentration (concentration must be within 10 percent of original acceptance test results, but no more than 10 percent below minimum design standard).
	3. Actuators	1. Verify operability of manual and automatic actuators.

Frequency	Component	Tasks
	4. Distribution System	1. Verify nozzle (sprinkler) coverage during flow test. 2. Inspect piping hangers, sprinklers, and nozzles for condition and location.
	5. Foam Concentrate Strainers	1. Inspect and clean after flow test.
5 Years	1. Balancing Valve	1. Flush to prevent concentrate buildup on diaphragm.
	2. Strainers (water supply)	1. Inspect and clean if necessary.
10 Years	1. Foam Concentrate Tank	1. Drain, flush, and perform internal inspection for corrosion. If pressure vessel, perform hydrostatic test.
20 Years, and Every 10 Years Thereafter	1. Fast-Response Sprinklers and Extra High Temperature Sprinklers	1. Replace all sprinklers or test a sample of sprinklers to verify response characteristics.[1]
50 Years, and Every 10 Years Thereafter	1. Standard Sprinklers	1. Replace all sprinklers or test sample closed head sprinklers to verify response characteristics.[1]
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring the water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify the results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.

Frequency	Component	Tasks
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers b. sprinklers/nozzles for obstruction c. piping for leaks d. riser condition e. sprinkler spares 2. Ensure: a. detectors are unblocked/uncovered. b. panels are secured and indicator lamps functional. c. notification appliances are in place. d. manual stations are in place and unobstructed.

\1[1]**/1/** A representative sample of sprinklers for testing must consist of one (1) percent of the sprinklers installed of the same type, with a minimum of four (4) sprinklers sampled. The sprinklers must be submitted to a **\1** nationally **/1/** recognized testing laboratory for these tests.

Table 2-19 Low Expansion Foam Monitor Nozzle System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seals, locks, or electric supervision)	1. Verify proper valve position.
Annually	1. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.
	2. Foam Concentrate	1. Inspect for quality and evidence of sludge or deterioration. 2. Inspect to verify adequate supply. 3. Take sample and test in accordance with manufacturer's instructions.
	3. Foam Concentrate Strainers	1. Inspect exterior to ensure blow down valve is closed.
	4. Nozzle and Nozzle Driver	1. Lubricate in accordance with manufacturer's directions. 2. Ensure nozzle elevation is set to not apply foam on aircraft surfaces. 3. Manually operate oscillation with garden hose to ensure proper movement and pattern.

Frequency	Component	Tasks
	5. Main Drain	1. Conduct main drain test to verify supply (valve position). 2. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge. 3. Compare results with results from previous main drain tests and original acceptance test. 4. Verify the results are within acceptable limits or identify corrective measures.
2 Years	1. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify the valve supervisory switches detect a change in valve position.
	2. Foam Proportioning System/Foam Pumps (if provided)	1. Conduct full flow test to ensure proper system function. (**\1** Perform test **/1/** using a test connection or through the foam nozzles. Discharge only until full foam flow appears from each nozzle; then end foam injection.) 2. Verify proper concentration. (Concentration must be within 10 percent of original acceptance test results, but no more than 10 percent below minimum design standard). 3. Flush pumps after operation.
	3. Actuators	1. Verify operability of manual and automatic actuators.
	4. Distribution System	1. Verify nozzle coverage during flow test (water only). 2. Inspect piping hangers and nozzles for condition and location.
	5. Foam Concentrate Strainers	1. Inspect and clean after flow test.
5 Years	1. Balancing Valve	1. Flush to prevent concentrate buildup on diaphragm.
	2. Strainers (water supply)	1. Inspect and clean if necessary.
10 Years	1. Foam Concentrate Tank	1. Drain, flush, and perform internal inspection for corrosion. If pressure vessel, perform hydrostatic test.

Frequency	Component	Tasks
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring the water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers and seismic bracing b. nozzle for obstruction c. piping for leaks d. riser condition 2. Ensure: a. detectors are unblocked/ uncovered. b. panels are secured and indicator lamps functional. c. notification appliances are in place. d. manual stations are in place and unobstructed.

Table 2-20 Low Expansion Grate Nozzle Foam System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seals, locks, or electric supervision)	1. Verify proper valve position.
Annually	1. Foam Concentrate	1. Inspect for quality and evidence of sludge or deterioration. 2. Inspect to verify adequate supply. 3. Take sample and test in accordance with manufacturer's instructions.
	2. Foam Nozzles	1. Inspect to verify condition.
	3. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.

Frequency	Component	Tasks
2 Years	1. Foam Nozzles	1. Conduct test to verify operability. (Test **\1\ /1/** with water only.)
	2. Actuators	1. Verify all manual and automatic actuator function.
	3. Foam Proportioning System/Foam Pumps (if provided)	1. Conduct full flow test to ensure proper system function. (**\1** Perform test using **/1/** a test connection or through the foam nozzles. Discharge only until full foam flow appears from each nozzle, then end foam injection.) 2. Verify proper concentration. (Concentration **\1** must **/1/** be within 10 percent of original acceptance test results, but no more than 10 percent below minimum design standard). 3. Flush pumps after operation.
	4. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
10 Years	1. Foam Concentrate Tanks	1. Drain, flush, and perform internal inspection for corrosion. If pressure vessel, perform hydrostatic test.
After Activation	1. Strainers	1. Inspect and clean after system actuation or flow test.
	2. Manual Pull Stations	1. Visually Inspect NEMA 4 pull stations to confirm seals prevented foam **\1** -water **/1/** from entering device. 2. Internally inspect all non-NEMA 4 pull stations for damage.
	3. Flushing	1. Flush system upon completion of any testing where foam concentrate has been introduced to the system.
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring the water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify results are within acceptable limits or identify corrective measures. 4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.

Frequency	Component	Tasks
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually Check: a. Pipe hangers, seismic bracing, and mounts. b. Nozzles for obstruction. c. Piping for leaks. d. Riser condition. 2. Ensure: a. Detectors unblocked/uncovered. b. Panels secured and indicator lamps functional. c. Notification appliances in place. d. Manual stations in place and unobstructed.

Table 2-21 High-Expansion Foam System ITM Tasks

Frequency	Component	Tasks
Monthly	1. Control Valves (without seals, locks, or electric supervision)	1. Verify proper valve position.
Annually	1. Foam Concentrate	1. Inspect for quality and evidence of sludge or deterioration. 2. Inspect to verify adequate supply. 3. Take sample and test in accordance with manufacturer's instructions.
	2. Foam Generator	1. Inspect to verify condition from ground level and proper valve alignment.
	3. Main Drain	1. Conduct main drain test to verify supply (valve position). 2. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge. 3. Compare results with results from previous main drain tests and original acceptance test. 4. Verify results are within acceptable limits or identify corrective measures.
	4. Control Valves (sealed, locked, or electrically supervised)	1. Verify proper valve position.
2 Years	1. Foam Generator	1. Conduct test to verify operability. (Water-powered **\1** must be accomplished **/1/** with water only.)

Frequency	Component	Tasks
	2. Actuators	1. Verify all manual and automatic actuators function.
	3. Foam Proportioning Systems/Foam Pumps (if provided)	1. Conduct full flow test to ensure proper system function. (**\1** Perform test **/1/** using a test connection. **\1\ /1/** 2. Verify proper concentration. (Concentration **\1** must **/1/** be within 10 percent of original acceptance test results, but no more than 10 percent below minimum design standard.) 3. Flush pumps after operation.
	4. Control Valves	1. Operate valve through entire travel to verify function. 2. Lubricate valves and stems to ensure operability. 3. Verify valve supervisory switches detect a change in valve position.
After Water-only Test and Foam Flow Test	1. Strainers	1. Inspect and clean after flow test.
After System Activation	1. Strainers	1. Inspect and clean after system activation.
	2. Manual Pull Stations	1. Visually inspect NEMA 4 pull stations to confirm seals prevented foam from entering device. 2. Internally inspect all non-NEMA 4 pull stations for damage **\1** or foam or moisture incursion. 3. Replace all pull stations indicating foam or moisture incursion. **/1/**
	3. Control Panels	1. Internally inspect all system control units exposed to foam.
	4. Flushing	1. Flush system upon the completion of any testing where foam concentrate has been introduced to the system.
10 Years	1. Foam Concentrate Tank	1. Drain, flush, and perform internal inspection. If pressure vessel, perform hydrostatic test.
Following System Modification or Repair	1. Main Drain (following maintenance or repair action requiring the water supply to be shut off)	1. Conduct main drain test to verify supply (valve position). 2. Compare results with results from previous main drain tests and original acceptance test. 3. Verify the results are within acceptable limits or identify corrective measures.

Frequency	Component	Tasks
		4. Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers and seismic bracing b. generators for obstruction (air intake or foam discharge) c. generator nozzles for obstruction and generator screens for damage d. piping for leaks e. riser condition 2. Ensure: a. detectors are unblocked/uncovered. b. panels are secured and indicator lamps functional. c. notification appliances are in place. d. manual stations are in place and unobstructed.

2-2.19 Dry Chemical Systems.

Automatic initiating devices (for example, heat detectors, smoke detectors) used for system actuation are addressed in Section 2-2.2, “Fire Detection and Alarm Systems.” Technical guidance for these tasks is contained in NFPA 17, *Standard for Dry Chemical Extinguishing Systems*.

There is no requirement to replace existing dry chemical systems protecting cooking surfaces, hoods, and ducts. These existing systems passing the required ITM may continue in service, and these systems may be serviced and repaired as necessary. Existing systems protecting cooking surfaces, hoods, and ducts may not be removed and reinstalled at another location even if the systems met all ITM requirements. All new or replacement systems to protect cooking surfaces, hoods, and ducts must **\1** meet the requirements of UFC 3-600-01 **/1/**.

Table 2-22 Dry Chemical System ITM Tasks

Frequency	Component	Tasks
Semi-Annually	1. Hazard	1. Verify the hazard has not changed.
	2. Piping	1. Inspect piping for obstructions and proper support. 2. Verify presence of required blow-off caps. 3. Verify nozzles are appropriately aimed at the hazard.
	3. Storage Vessels	1. Inspect agent container for condition. 2. Verify storage pressure of propellant.
	4. Agent	1. Verify quantity of agent through ultrasonic measuring.
	5. Actuators	1. Inspect manual actuators for accessibility. 2. Inspect detection devices (fusible links or heat detectors) for contamination, and clean. 3. Test actuation system without agent release. (Coordinate with annual replacement of fixed temperature sensing elements.) 4. Verify interfaces (gas shutoff, power shutoff) operate properly. 5. Replace fixed temperature sensing elements (fusible links/metal alloy type).
5-12 Years	1. Storage Vessels	1. Conduct hydrostatic test for pressure cylinders in accordance with OSHA and DOT standards.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers b. nozzles for obstruction c. pipe condition 2. Ensure: a. detectors are unblocked/uncovered. b. panels are secured and indicator lamps are functional. c. notification appliances are in place. d. manual stations are in place and unobstructed. e. nozzle covers (blow-off caps) are in place. f. pressure gauge is within operating range.

2-2.20 Wet Chemical Systems.

Automatic initiating devices (for example, heat detectors, smoke detectors) used for system actuation are addressed in Section 2-2.2, “Fire Detection and Alarm Systems.” Technical guidance on these tasks is contained in NFPA 17A, *Standard for Wet Chemical Extinguishing Systems*.

Table 2-23 Wet Chemical System ITM Tasks

Frequency	Component	Tasks
Semi-Annually	1. Hazard	1. Verify hazard has not changed.
	2. Piping	1. Inspect piping for obstructions and proper support. 2. Verify presence of required blow-off caps. 3. Verify nozzles are appropriately aimed at the hazard.
	3. Storage Vessels	1. Inspect agent container for condition. 2. Verify storage pressure of the propellant.
	4. Agent	1. Verify quantity of agent using ultrasonic measuring.
	5. Actuators	1. Inspect manual actuators for accessibility. 2. Inspect detection devices (fusible links or heat detectors) for contamination and clean or replace as necessary. 3. Test actuation system without agent release. 4. Verify interfaces (gas shutoff, power shutoff) operate properly.
		5. Replace fixed temperature-sensing elements (fusible link metal alloy type and automatic sprinkler metal alloy type).
5-12 Years	1. Storage Vessels	1. Conduct hydrostatic test for pressure cylinders in accordance with OSHA and DOT standards.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers b. nozzles for obstruction and proper alignment c. riser condition 2. Ensure: a. detectors are unblocked/uncovered. b. panels are secured and indicator lamps functional. c. notification appliances are in place.

Frequency	Component	Tasks
		d. manual stations are in place and unobstructed. e. nozzle covers (blow-off caps) are in place. f. pressure gauge is within operating range.

2-2.21 Halon Systems.

Detection devices for actuation are addressed in Section 2-2.2, "Fire Detection and Alarm Systems." Technical guidance on these tasks is contained in NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*.

WARNING

To prevent accidental release of Halon gas to the environment, do not disconnect and weigh cylinders to accomplish the annual agent quantity verification. Disconnecting cylinders to verify agent quantity damages seals and O-rings. Use only liquid level methods to determine agent quantity. (Table 2-24, Task Annual 5.1)

Table 2-24 Halon System ITM Tasks

Frequency	Component	Tasks
Annually	1. Hazard	1. Verify hazard has not changed.
	2. Piping	1. Inspect piping and nozzles for condition and orientation.
	3. Flexible Hoses	1. Inspect for damage.
	4. Storage Vessels	1. Inspect exterior of storage containers (tanks, spheres, cylinders).
	5. Agent and Propellant	1. Verify quantity of the agent is sufficient. Use ultra-sound or level sensing technology. Do not disconnect and weigh tanks. 2. Verify pressure of the agent/propellant is sufficient and pressure gauge is within operating range.
	6. Actuators	1. Inspect manual actuators for accessibility. 2. Test actuation without agent release.
	7. Auxiliary Equipment	1. Test to verify interfaces (equipment shutdown, dampers, and door closures)

Frequency	Component	Tasks
		operate properly and are activated by the system actuation.
	8. Valves	1. Verify valves are in proper alignment.
2 Years	1. Protected Enclosure/Room	1. Inspect enclosure to verify integrity and ability to maintain agent concentration.
5 Years	1. Cylinders	1. Complete external inspection of non-discharged cylinders to ensure suitability for use.
	2. Flexible Hoses	1. Pressure test hoses to ensure suitability for use.
As Required	1. Agent Cylinders	1. Hydrostatic testing of cylinders is required only when cylinders are to be re-filled/re-charged. Periodic hydrostatic testing is not required.
After Modification to Compartment/ Protected Enclosure	1. Protected Enclosure/Room	1. Inspect enclosure to verify integrity and ability to maintain agent concentration. 2. If uncertainty exists, follow enclosure procedures in NFPA 12A.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers b. nozzles for obstruction c. piping for leaks d. riser condition 2. Ensure: a. detectors are unblocked/uncovered. b. panels are secured and indicator lamps functional. c. notification appliances are in place. d. manual stations are in place and unobstructed. e. nozzle covers are in place. f. pressure gauge is within operating range.

2-2.22 Clean Agent Systems.

Detection devices for actuation are addressed in Section 2-2.2, "Fire Detection and Alarm Systems." Technical guidance on these tasks is contained in NFPA 2001, *Standard on Clean Agent Fire Extinguishing Systems*.

WARNING

To prevent accidental release of extinguishing agents to the environment, do not disconnect and weigh cylinders to accomplish the annual agent quantity verification. Disconnecting cylinders to verify agent quantity damages seals and O-rings. Use only liquid level methods to determine agent quantity. (Table 2-25, Task Annual 5.1)

Table 2-25 Clean Agent System ITM Tasks

Frequency	Component	Tasks
Annually	1. Hazard	1. Verify hazard has not changed.
	2. Piping	1. Inspect piping and nozzles for condition and orientation.
	3. Flexible Hoses	1. Inspect for damage.
	4. Storage Vessels	1. Inspect the exterior of storage containers (tanks, spheres, cylinders).
	5. Agent and Propellant	1. Verify adequate quantity of agent. Use ultra-sound or liquid level sensing. Do not disconnect and weigh tanks. 2. Verify adequate pressure of agent/propellant and pressure gauge within operating range.
	6. Actuators	1. Inspect manual actuators for accessibility. 2. Test actuation without agent release.
	7. Auxiliary Equipment	1. Test to verify interfaces (equipment shutdown, dampers, and door closures) operate properly and are activated by the system actuation.
	8. Valves	1. Verify valves are in proper alignment.
2 Years	1. Protected Enclosure or Room	1. Inspect enclosure to verify integrity and ability to maintain agent concentration.
5 Years	1. Cylinders	1. Perform complete external inspection of non-discharged cylinders to ensure suitability for use.
	2. Flexible Hoses	1. Pressure test hoses to ensure suitability for use.

Frequency	Component	Tasks
After Modification to Compartment/ Protected Enclosure	1. Protected Enclosure/Room	1. Inspect the enclosure to verify integrity and ability to maintain agent concentration. 2. If uncertainty exists, follow the enclosure procedures in NFPA 2001.
As Part of Other Building Inspection (not part of ITM requirements)	1. Entire System	1. Visually check: a. pipe hangers b. nozzle for obstruction c. piping for leaks d. riser condition 2. Ensure: a. detectors are unblocked/uncovered. b. panels are secured and indicator lamps functional. c. notification appliances are in place. d. manual stations are in place and unobstructed. e. nozzle covers are in place. f. pressure gauge is within operating range.

2-2.23 Carbon Dioxide Systems.

Detection devices for actuation are addressed in Section 2-2.2, "Fire Detection and Alarm Systems." Technical guidance on these tasks is contained in NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems.*

Table 2-26 Carbon Dioxide System ITM Tasks

Frequency	Component	Tasks
Semi-Annually	1. Liquid Level (low pressure carbon dioxide [CO_2])	1. Verify adequate liquid level with tank level gauge.
Annually	1. Hazard	1. Verify hazard has not changed.
	2. Piping and Nozzles	1. Inspect piping for condition and proper support. 2. Check nozzles for obstruction and alignment.
	3. Flexible Hoses	1. Inspect for damage.
	4. Low Pressure Tanks	1. Check level and pressure gauges. 2. Verify valve alignment.
	5. High Pressure Cylinders	1. Inspect for condition and securing.

Frequency	Component	Tasks
	6. Actuation System	1. Exercise control panel function, including zone valve operation. 2. Inspect manual actuators for accessibility. 3. Check times and time delay (pre-discharge).
	7. Auxiliary Equipment	1. Test to verify interfaces (shutdown, door closers, and dampers) operate properly and are activated by the control panel.
2 Years	1. High Pressure Cylinders	1. Verify CO_2 quantity by weighing cylinders.
After Modification to Compartment/ Protected Enclosure	1. Protected Enclosure/Room	1. Inspect the enclosure to verify integrity and ability to maintain agent concentration. 2. If uncertainty exists, follow the enclosure procedures in NFPA 2001.
As Part of Other Building Inspection (not part of the ITM requirements)	1. Entire System	1. Visually check: a. Pipe hangers. b. Nozzles for obstruction. c. Piping for leaks. d. Riser condition. 2. Ensure: a. Detectors unblocked/uncovered. b. Panels secured and indicator lamps functional. c. Notification appliances in place. d. Manual stations in place and unobstructed. e. Nozzle covers in place.

2-2.24 Emergency Lighting Systems.

Emergency lighting systems include individual battery-powered lighting units, central battery-powered units, and standby generator-powered lighting systems. Technical guidance on the task is located in NFPA 101, *Life Safety Code;* NFPA 110, *Standard for Emergency and Standby Power Systems;* and NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems*. Figure 2-2 shows typical systems.

CAUTION

Battery-powered emergency lights generally require from 1 to 7 days to initially charge or to re-charge following a 90-minute discharge or activation. (Table 2-27, Task Annual 2.1)

Table 2-27 Emergency Lighting System ITM Tasks

Frequency	Component	Tasks
Annually	1. Individual Battery-Powered Lighting Units	1. Activate for not less than 90 minutes to verify battery voltage and capacity.
	2. Central Battery-Powered Lighting Systems	1. Activate for not less than 90 minutes to verify battery voltage and capacity.
	3. Emergency Generator-Powered Lighting Systems	1. During regularly scheduled generator and transfer switch maintenance, visually check operation of each emergency generator-powered fixture.
5 to 10 Years	1. Individual Fixtures' Replaceable Batteries or Unitized Fixtures	1. Replace battery or complete unitized fixture in accordance with manufacturer's **\1\ /1/** service life **\1** guidance **/1/**.

Figure 2-1 Typical Emergency Lighting Systems

Typical Emergency Light Units with a 5-year Manufacturer's Estimated Service Life Battery

Typical Emergency Light Units and Florescent Fixture Ballasts with a 10-year Manufacturer's Estimated Service Life Battery

Typical Central Emergency Power Sources with a 10-year Manufacturer's Estimated Service Life Battery

2-2.25 Egress Marking Systems.

Egress lighting systems include individual battery-powered lighting units, central battery-powered units, and standby generator-powered lighting systems. Figures 2-2 and 2-3 show typical units.

\1 New and replacement internally illuminated egress marking fixtures must be Energy Star® compliant. **/1/**

CAUTION

Battery-powered emergency egress marking generally requires from 1 to 7 days to initially charge or to re-charge following a 90-minute discharge or activation. (Table 2-28, Task Annual 4.3)

Table 2-28 Egress Marking System ITM Tasks

Frequency	Component	Tasks
Annually	1. Externally Illuminated and Non-illuminated Marking Fixtures	1. Inspect fixture condition and mounting. 2. Ensure emergency light source, if required, is functional.
	2. Photo-luminescent Marking Fixtures	1. Inspect fixture condition and mounting. 2. Inspect charging light source and mounting. 3. Ensure charging light source is functional (unswitched 5 foot-candles fluorescent or greater). Charging light must be on at all times the building is occupied.
	3. Internally Illuminated Marking Fixtures	1. Inspect fixture condition and mounting. 2. Ensure the bulb or light source is functional. 3. For electroluminescent marking, ensure the power source is operational.
	4. Internally Illuminated Marking Fixtures with Standby Battery Backup	1. Inspect fixture condition and mounting. 2. Ensure the bulb or light source is functional. 3. Activate on battery power for not less than 90 minutes to verify battery voltage and capacity. 4. **\1** Replace any fixtures or battery, if replaceable, that fails to remain illuminated for 90 minutes. **/1/**
	5. Internally Illuminated Marking with Emergency Generator	1. Inspect fixture condition and mounting. 2. Ensure the bulb or light source is functional.

	Backup	3. During regularly scheduled generator and transfer switch maintenance, visually check the operation of each emergency generator-powered fixture.
5 to 10 years	1. Internally Illuminated Marking with Standby Battery Backup	1. Replace battery or fixture if battery is not replaceable (unitized fixture) in accordance with manufacturer's service life **\1** guidance **/1/**.

Figure 2-2 Typical Egress Marking Units with a 10-year Manufacturer's Estimated Service Life Battery

Figure 2-3 Typical Combination Egress Marking and Emergency Light Units with a 5-year Manufacturer's Estimated Service Life Battery (Not Energy Star® Compliant)1

[1]LED egress marking devices without battery backup are **\1\ /1/** considered to have a 25-year **\1\ /1/** service life. (Consult the manufacturer's technical materials for specific guidance.)

2-2.26 Fire and Smoke Barrier Opening-.

Detection devices for actuation are addressed in Section 2-2.2, "Fire Detection and Alarm Systems." Electric hold-open devices are tested as part of the fire alarm system in "Fire Detection and Alarm Systems." Technical guidance on these tasks is contained in NFPA 80, *Standard for Fire Doors and Other Opening Protectives,* and NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.

Table 2-29 Fire and Smoke Barrier Opening Protection ITM Tasks

Frequency	Component	Tasks
Annually	1. Hinged Fire Doors	1. Test magnetic hold-open devices for release on activation of fire alarm. 2. Inspect closers for proper operation. 3. Verify door closes and latches.
	2. Sliding Doors	1. Test magnetic hold-open devices for release on activation of fire alarm. 2. Ensure weights have a free and unobstructed path of travel. 3. Verify door closes and latches
	3. Rolling or Sliding Fire Shutters	1. Test magnetic hold-open and other mechanical latches or actuators for release on activation of fire alarm. 2. Operate the shutter through its entire travel.
1 Year after Construction and Every 6 Years Thereafter	1. Fire and Smoke Dampers	1. Test electric (magnetic) hold-open and other mechanical latches or actuators for release on activation of fire alarm. 2. Inspect travel path for anything obstructing or interfering with free operation.
As Part of Other Building Inspection (not part of ITM requirements)	1. Hinged Fire Doors	1. Inspect door condition, gaskets, and mounting hardware. Ensure proper lubrication. 2. Inspect fusible links, if present, for paint or other accumulations that slow thermal response.
	2. Sliding Doors	1. Inspect door condition and mounting hardware. Ensure proper lubrication. 2. Inspect fusible links, if present, for paint or other accumulations slowing thermal response. 3. Inspect travel path for anything obstructing or interfering with free operation.
	3. Rolling or Sliding Fire Shutters	1. Inspect door condition and mounting hardware. Ensure proper lubrication. 2. Inspect fusible links, if present, for paint or other accumulations slowing thermal response. 3. Inspect travel path for anything obstructing or interfering with free operation.
	4. Fire and Smoke Dampers	1. Inspect fixture condition and mounting. 2. Inspect fusible links, if present, for paint or other accumulations that slow thermal response.

Frequency	Component	Tasks
	5. Installed Fire Stopping, Listed Sleeves, Penetrations, Seal Bags, and Other Fire Stopping Material	1. Inspect fire-resistive barriers for new or other unprotected penetrations of rated walls, floors, or ceilings.

2-2.27 Smoke Control Systems.

Detection devices for actuation are addressed in Section 2-2.2, "Fire Detection and Alarm Systems." Technical guidance on these tasks is contained in NFPA 92, *Standard for Smoke Control Systems*.

Table 2-30 Smoke Control ITM Tasks

Frequency	Component	Tasks
Semi-Annually	1. Dedicated Systems	1. Operate the smoke control system through each operational sequence provided for in the original system design. 2. Verify the operation of the correct output for each given input. 3. If applicable, conduct tests under standby power.
Annually	1. Fans, Fire and Smoke Dampers, and System Controls	1. Operate the smoke control system through each operational sequence provided for in the original system design. 2. Verify the operation of the correct output for each given input. 3. If applicable, conduct tests under standby power. Testing must determine and document airflow quantities and pressure differences across smoke barrier openings, at the air make-up locations, and at smoke exhaust fans for comparison to original acceptance testing results.

Frequency	Component	Tasks
Upon System Modification or Building Renovations or Additions	1. All Systems	1. Operate the smoke control system through each operational sequence provided for in the original system design. 2. Verify the operation of the correct output for each given input. 3. If applicable, conduct tests under standby power. Testing must determine and document airflow quantities and pressure differences across smoke barrier openings, at the air make-up locations, and at smoke exhaust fans for comparison to original acceptance testing results.

2-2.28 Heat and Combustion Product Removal/Venting Systems.

Technical guidance on these tasks is contained in NFPA 204, *Standard for Smoke and Heat Venting*.

Table 2-31 Heat and Combustion Product Removal/Venting System ITM Tasks

Frequency	Component	Tasks
Annually	1. Mechanically Opened Vents	1. Inspect for changes in appearance, damage to any components, fastener security, weather tightness, presence of foreign objects, and changes in roof flashing condition.
	2. Thermoplastic Drop-out Vents	1. Inspect for changes in appearance, damage to any components, fastener security, weather tightness, and changes in roof flashing condition.
	3. Mechanical Smoke Exhaust Systems	1. Inspect for damage to any components. 2. Verify exhaust outlets and air inlets are unobstructed. 3. Verify power sources. 4. Test system to verify equipment is operational and functions as intended.
5 Years	1. Mechanically Opened Vents	1. Test vents by releasing the restraining cable at the heat-responsive device, releasing the restraint, and allowing the trigger or latching mechanism to operate. 2. Test manual releases to verify vents operate as designed. 3. Verify correct temperature of fusible link.

\1

2-2.29 Ignitable Liquid Floor Drainage Assembly.

Required ITM tasks for are contained in Table 2-32.

a. Internal drainage channel inspection is accomplished using a sewer/drain inspection endoscope (pipe inspection camera).

b. Internal drainage channel cleaning is accomplished using a sewer/drain high pressure (1500 – 3000 psi) jetting hose and nozzle. Rotating nozzles are recommended. Nozzles are inserted from the drainage trench end and travel up to the flushing header and pulled back to clean each channel.

c. Section 2-2.8, "Fire Pumps," provides guidance for maintenance of fire pumps. Maintenance for industrial trash pumps must comply with Section 2-2.8 since these pumps perform a similar critical function to a fire pump for a suppression system.

Table 2-32 Ignitable Liquid Floor Drainage Assembly ITM Tasks

Frequency	Component	Task
Weekly	1. Water Supply Tanks (without electric remote supervision of water level)	1. Check level.
	2. Effluent Collection/Retention Tanks (without electric remote supervision of water level)	1. Check level.
	3. Air Compressor/Receiver/ Cylinders (without electric remote supervision of air pressure) [if present]	1. Check air pressure.
Semi-Annually	1. System	1. Operate full system in maintenance flushing for not less than 5 minutes. Ensure visually equal flow in every channel. 2. Visually inspect the hangar floor for any indication of obstruction or blockage in the deck channels while flushing.
	2. Air Compressors (if present)	1. Start to ensure operability.
	3. System Operating Components	1. Inspect to verify valve alignment and valves are free of damage.
Annually	1. Water/Effluent Tanks (remote electrically supervised and monitored)	1. Check water level detection device and supervisory controls.

Frequency	Component	Task
	2. Air Compressors/Receivers/ Cylinders (electric remote supervision of air pressure) [if present]	1. Check air pressure and supervisory pressure switch.
	3. Liquid Sensors	1. Operate to verify initiation and receipt of alarm. 2. Verify effluent pump start. 3. Verify flushing water valve opens.
	4. Pressure Relief Devices	1. Manually operate to ensure operability.
	5. Manual Actuators	2. Verify operability.
	6. Deck Channels	1. Verify operability, flow, in all channels, and ensure no blockage/ restriction forcing water to backflow through drainage holes. 2. Pressure-wash any channels in the deck indicating blockage or restriction.
	7. Decking and Ramps	1. Visually inspect deck and ramps for missing screws and replace any missing screws with manufacturer's recommended replacements.
	8. Exercise Manual and Automatic Valves.	1. Operate each valve through its full operating range for not less than 2 full cycles. 2. Ensure each valve is reset to the operating position.
5 Years	1. Deck Channels	1. Visually inspect 20% of floor channels using sewer endoscope. 2. If debris is in half or more of channels inspected, conduct 5-10 year deck channel cleaning.
	2. Water Tanks When Used to Supply the Flushing System	1. Drain and refill tank. 2. Inspect tanks for structural integrity (interior and exterior) prior to refilling.
5-20 Years	1. Floor Channels	1. Pressure-wash each channel in the floor deck.
As Part of Other Building Inspection (not part of the ITM requirements)	1. Entire System	1. Ensure: a. manual stations are in place and unobstructed. c. panels are secured and indicator lamps functional.

/1/

CHAPTER 3 MILITARY FAMILY HOUSING SYSTEMS

3-1 SCOPE.

\1

3-1.1 DoD Military Family Housing.

/1/

The maintenance concepts for MFH fire protection systems are based on the management and controls unique to the MFH program. In the civilian sector, an owner or tenant makes a personal choice to occupy a dwelling unit and is responsible for its maintenance and repair and any associated fire protection devices. In MFH, occupants are assigned housing units, and the housing management activity is responsible for the maintenance and repair of units and associated fire protection devices. All MFH occupants are required to attend a briefing on their responsibilities as MFH occupants prior to occupying an MFH dwelling. These briefings include the occupant's responsibilities for conducting tests and cleaning installed fire protection features. On average, MFH maintenance teams conduct change of occupancy maintenance every one to two years; therefore, scheduled maintenance performed by the housing management activity is centered on this change of occupancy.

\1

3-1.2 Privatized Military Family Housing.

Privatized military family housing contractors are responsible for developing their own maintenance programs in accordance with their lease agreement and national consensus codes and standards. Contractors are permitted to adopt requirements of this UFC chapter in meeting their maintenance and safety goals. (Chapter 1, Section 1-3).

/1/

3-2 RESIDENTIAL SMOKE ALARMS.

MFH units are required to have hard-wired, interconnected smoke alarms. Each installation develops programs to train occupants in testing and maintenance actions for installed smoke alarms. Actions required as part of change of occupancy maintenance by the housing management activity are listed **\1** (Table 3-1) **/1/**.

3-3 RESIDENTIAL SPRINKLER SYSTEMS.

New MFH units are required to have sprinkler systems **\1**(UFC 3-600-01, Chapter 4).**/1/**

3-3.1 Multi-Family Residential Buildings.

Residential sprinkler systems in multi-family buildings up to four stories are **\1\\ /1/** constructed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems,* or NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Residential Occupancies* **\1** (UFC 3-600-01, Chapter 4). **/1/** Maintain these systems in accordance with the tables in Chapter 2 of this UFC. Building occupants are not expected to conduct **\1** sprinkler **/1/** system tests or maintenance actions.

3-3.2 One- and Two-family Residences and Townhouse-style Units.

Residential sprinkler systems in one- and two-family dwellings and townhouse-style units are **\1** installed **/1/** in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, or NFPA 13R. **\1** (UFC 3-600-01 Chapter 4) **/1/** Installations develop their own programs to train occupants in the testing and maintenance actions required. Actions required as part of change of occupancy maintenance by the housing management activity are listed **\1** (Table 3-1) **/1/**.

3-4 CARBON MONOXIDE ALARMS.

MFH units **\1** must **/1/** have carbon monoxide detectors connected to the building fire alarm system, or they **\1** must **/1/** have single station carbon monoxide alarms. Carbon monoxide detectors connected to the fire alarm system are addressed in Section 2-2.2 in Chapter 2 of this UFC. For single station carbon monoxide alarms, actions required as part of change of occupancy maintenance by the housing management activity are listed in Table 3-3.

3-5 ITM TASK DESCRIPTIONS.

ITM tasks **\1** must **/1/** be part of the housing maintenance conducted between occupancies.

CAUTION

Battery-powered smoke alarms are not permitted, and when found, must be replaced with interconnected hardwired smoke alarms on change of occupancy. Air Force allows hardwired **\1** and **/1/** wireless interconnected smoke alarms for use within single-family and duplex housing. (Table 3-1, Change of Occupancy, Task 3.1)

Table 3-1 MFH Residential Smoke Alarm ITM Tasks

Frequency	Component	Tasks
Change of Occupancy	1. Smoke Alarms (hardwired single-station and multi-station smoke alarms)	1. Activate each smoke alarm with an approved smoke simulant. 2. Remove cover and inspect for grease buildup; replace and relocate smoke alarms with evidence of grease buildup in the smoke alarm. 3. Vacuum smoke alarm and replace cover. 4. Activate each smoke alarm with the installed test button. 5. Replace any smoke alarm failing to activate on either the smoke simulant or the test button.
	2. Backup Battery (if present)	1. Replace battery.
	3. Battery-only powered smoke alarms **\1** if present. **/1/**	1. Replace with hardwired smoke alarms complying with requirements in UFC 3-600-01 for new construction.
10 Years	1. Smoke Alarms (hardwired single-station and multi-station smoke alarms)	1. Replace smoke alarm. If replacing existing smoke alarms without an interconnection feature, replacement smoke alarms must include interconnection, **\1** hardwired or wireless, **/1/** between all smoke alarms in the dwelling unit.

Table 3-2 MFH Residential Sprinkler System ITM Tasks

Frequency	Component	Tasks
Change of Occupancy	1. Sprinklers	1. Inspect all sprinklers. 2. Clean or replace sprinklers as necessary. Sprinklers that have been painted must be replaced; cleaning is not permitted. 3. Inspect ceilings or wall at sprinkler for signs of leakage or water stains.

Frequency	Component	Tasks
	2. Valves	1. Inspect valves to ensure they are open and sealed.
	3. Water Flow and Alarm Devices	1. Test to verify operability.
20 Years and Every 10 Years Thereafter	1. Fast-Response Sprinklers	1. Replace all sprinklers or test a sample of sprinklers to verify response characteristics.[1]

\1[1]**/1/** A representative sample of sprinklers for testing must consist of one (1) percent of the sprinklers installed of the same type, with a minimum of four (4) sprinklers sampled. The sprinklers must be submitted to a **\1** nationally **/1/** recognized testing laboratory for these tests.

Table 3-3 Carbon Monoxide Alarm ITM Tasks

Frequency	Component	Tasks
Change of Occupancy	1. Carbon Monoxide Alarm (hardwired single-station and multi-station alarms)	1. Activate each alarm device with an approved CO simulant. 2. Activate each alarm device with the installed test button. 3. Replace any alarm device failing to activate on either the CO simulant or the test button.
	2. Backup Battery (if present)	1. Replace battery.
10 Years, or Upon End-of-Life Signal from Detector, Whichever Is Less.	1. Combination Smoke/Carbon Monoxide Alarms (hardwired single-station and multi-station alarms)	1. Replace alarm devices. If replacing existing alarm devices without an interconnection feature, replacement alarm devices must include interconnection between all smoke alarms in the dwelling unit.
\1 10 years or **/1/** Upon End-of-Life Signal from Detector **\1** Whichever Is Less. **/1/**	1. Carbon Monoxide Alarms (hardwired single-station and multi-station alarms)	1. Replace alarm device.

APPENDIX A NAVY CONTRACT TECHNICIAN QUALIFICATIONS

A-1 INTRODUCTION.

Contract fire protection inspection, test, and maintenance (ITM) services must be managed by a qualified individual who is NICET Level III certified in fire alarm or NICET Level III certified in special hazards systems. The fire protection services manager provides daily supervision over all fire protection services.

Personnel executing ITM tasks on fire protection systems must be certified in accordance with requirements **\1** in paragraphs A-2 through A-4. **/1/**

A-2 FIRE ALARM SYSTEMS.

- Fire Alarm detection, supervision, and notification controls and devices: NICET Level II certification in Fire Alarm Systems.
- Detection and releasing systems for Special Hazard Systems **\1** including **/1/** those found in aircraft hangars and computer server rooms: NICET Level II certification in Special Hazard Systems.

A-3 WATER BASED SUPPRESSION SYSTEMS.

- Wet Pipe and Dry Pipe Sprinklers: - NICET Level II certification in Inspection and Testing of Water Based Systems.
- Pre-Action, Deluge, Foam and Antifreeze Systems: NICET Level III certification in Inspection and Testing of Water Based Systems.

A-4 SPECIAL HAZARD SYSTEMS.

- Clean Agent, CO_2 and Combination Detection/Releasing Systems: NICET Level II certification in Special Hazard Systems.
- Pre-Engineered Kitchen Fire Extinguishing Systems: NICET Level II certification in Special Hazards Suppression Systems or certified by ICC/NAFED in Pre-Engineered Kitchen Fire Extinguishing Systems.

Personnel without NICET certification **\1** are permitted to **/1/** assist NICET Levels II and III certified personnel in the execution of inspection, testing, maintenance and repair tasks. At no time are uncertified personnel allowed to execute inspection, testing, maintenance and repair tasks without a qualified NICET Level II or III certified person physically present within the same facility where the inspection, testing, maintenance and repair tasks are being executed.

B-2 DEFINITION OF TERMS

Nationally Recognized Test Laboratory (NRTL): CONUS including all states, territories, and possessions; an independent third-party organization that certifies products for the North American market. These organizations are recognized as meeting the legal requirement in 29 CFR 1910.7 to perform testing and certification of products using consensus based test standards. (https://www.osha.gov/nationally-recoganized-test-laboratory-program/current-list-of nrtls)

Nationally Recognized Test Laboratory (NRTL): OCONUS; any organization on the OSHA approved list or an independent third-party organization or governmental organization in a country that certifies products for the country or location market. Some countries allow manufacturer self-certification to government standards under government oversight. See specific country guidance or consult with the CFPE.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

TABLE OF CONTENTS

CHAPTER 1 INTRODUCTION

1-1 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 3-701-01, 23 May 2018.

1-2 PURPOSE AND SCOPE.

The DoD Facilities Pricing Guide supports a spectrum of facility planning, investment, and analysis needs. **6**\ This version of the Guide reflects updated cost and pricing data for FY 2025 intended to support the preparation of **3**\ programming cost /**3**/ estimates for the DoD budget in FY 2028 and beyond. /**6**/ It includes reference information organized into five chapters, as follows:

1-2.1 Chapter 2: Unit Costs for Military Construction Projects.

Chapter 2 describes the usage of facility unit cost data for selected DoD facility types in support of preparing Military Construction (MILCON) project documentation (DD Forms 1391) and other **3**\ programming cost estimates in accordance with UFC 3-730-01 /**3**/.

1-2.2 Chapter 3: Unit Costs for DoD Facilities Cost Models.

Chapter 3 describes the usage of unit costs in support of DoD facilities cost models. These unit costs are based upon the reported average DoD facility size or an established benchmark size, as annotated for each Facility Analysis Category (FAC) in the DoD Real Property Classification System (published separately). These unit costs are intended for macro-level analysis and planning rather than individual facilities or projects.

1-2.3 Chapter 4: Cost Adjustment Factors.

Chapter 4 describes the usage of cost adjustment factors for location and price escalation that are applicable to the base unit costs in both Chapters 2 and 3.

1-2.4 Chapter 5: Replacement Cost.

Chapter 5 describes the usage of the replacement cost. The replacement cost is used as required by other UFCs or design criteria.

1-2.5 \2\ Chapter 6: Unit Cost for Supporting Facilities. /2/

Chapter 6 describes the usage of supporting facilities unit cost in support of preparing Military Construction (MILCON) project documentation (DD Forms 1391) and other **3**\ programming cost estimates in accordance with UFC 3-730-01 /**3**/.

1-3 APPLICABILITY.

6\ This UFC follows the same applicability as UFC 1-200-01, paragraph 1-3, with no exceptions. /**6**/

1-4 DATA TABLES.

All data tables in this UFC are found in a combined file under "Related Materials" accompanying this UFC on the WBDG web site: https://www.wbdg.org/dod/ufc/ufc-3-701-01.

6\ Source date for the data tables is current as of October 1, 2024. /**6**/

1-5 GLOSSARY.

APPENDIX A contains acronyms, abbreviations, and terms.

1-6 REFERENCES.

APPENDIX B contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 UNIT COSTS FOR MILITARY CONSTRUCTION PROJECTS

2-1 OVERVIEW.

The facility unit costs in this chapter apply to the preparation of programming cost estimates for constructing military facilities in accordance with the methodology described in UFC 3-730-01.

All data tables in this UFC are found under "Related Materials" in a combined file accompanying this UFC on the WBDG web site: https://www.wbdg.org/dod/ufc/ufc-3-701-01.

2-2 FACILITY UNIT COST TABLE.

Table 2 provides facility unit costs for various DoD facility types in dollars per square meter ($/SM) and equivalent English unit cost data in dollars per square foot ($/SF) as of **6**\ October 2024 /**6**/. The listed facility types represent only those facilities most frequently constructed by the Military Services, and the application of a facility unit cost may not be directly applicable for those facilities with unique requirements. See UFC 3-730-01 for additional guidance on facility unit costs and their application.

The unit costs in Table 2 are average unit costs for new construction based on no less than three project awards per building type occurring since **6**\ September 2021 /**6**/ for Army, Navy, Air Force, Defense Education Activities (for **4**\ dependent /**4**/ school projects) and Defense Health Agency (for medical projects) facilities as entered into the Historical Analysis Generator **6**\ Second Generation /**6**/ (HII) unit cost database prior to **6**\ 05 December 2024 /**6**/. Facility additions which are less than 25% of the Reference Size of the listed facility type, and projects outside of the continental United States (OCONUS), are included only for Family Housing and DoD Schools. For additional information regarding how the facility unit costs are determined, refer to paragraph 2-3, Guidance Unit Cost Development.

2-3 GUIDANCE UNIT COST (GUC) DEVELOPMENT METHODOLOGY.

2-3.1 Data Source.

The data source for the facility unit costs is all reliable **6**\ HII /**6**/ project records, after excluding records for reasons stated in paragraph 2-2. In general, all project records for the CONUS and projects from Alaska and Hawaii are included.

Facility level information from all three Services projects is entered into HII database for comparable service category codes (CATCODEs). Normalized **4**\ facility /**4**/ unit costs are statistically analyzed to eliminate outliers before calculating the guidance unit cost (GUC). Refer to section 2-3.3 for Data Normalization.

2-3.2 Business Rules.

The business rules are reviewed annually prior to updating Table 2 Facility Unit Costs for Military Construction. The business rules include the following components.

- The Tri-Service CATCODEs Cross-walk table groups like service CATCODEs to a common Office of the Secretary of Defense (OSD) Code. OSD Codes are not published and are only utilized for this task of segregating data. A minimum of three projects are required within **4**\ the three-year period /**4**/ to create a dataset. If there is insufficient data available within the three-year period, the dataset search is extended four years.
- Projects are new construction only.
- Projects are located within the CONUS, plus Hawaii and Alaska, except where noted otherwise in Table 2.

2-3.3 Data Normalization.

Each facility-specific data set is normalized to the National Average Area Cost Factor (ACF=1) and number of bidders, and escalated to October of the year of interest, before unit costs are averaged.

- Escalation: The DoD Selling Price Index (DoD-SPI), which is an average of three commonly accepted national construction price escalation indices, is utilized to escalate actual project award cost data to **6**\ 01 October 2024 /**6**/ for this UFC,
- Number of Bidders: Based on actual bid data for the data set,
- Location: Normalize each project award by the appropriate ACF to the national average of 1.0, and
- Facility Size: Normalize each facility award amount in the dataset for facility size, using a normalization process that looks at the facility size as compared to the average facility size of the selected dataset by OSD code.

2-3.4 Primary Facility Included Costs.

The facility unit costs include the following:

- Minimum antiterrorism design features (reference UFC 4-010-01, “DoD Minimum Antiterrorism Standards for Buildings”) inside the building meeting **2**\ /**2**/ standoff distance requirements,
- Sales tax on building materials,

- Building information system costs (e.g., conduits, racks, trays, telecommunication rooms) without any specialized communications requirements,
- Installed (built-in) building equipment and furnishings normally funded with MILCON funds,
- Energy Management Control System (EMCS) connections,
- Intrusion Detection System (IDS) infrastructure, including conduits, racks, and trays,
- Sustainable design and construction features - energy consumption reduction requirements mandated before **2**\\ four years prior to the source date of the data tables /**2**/; and all other sustainable design features for criteria in effect **2**\\ three years prior to the source date of the data tables /**2**/ with the exception of renewable energy generation elements,
- Progressive Collapse premiums for the following specific facility types: Inpatient Hospital/Medical Center and Primary Care Clinic (Attached), **4**\\ and facilities with 3 or more floors, /**4**/
- Standard foundation systems (e.g., strip/spread footings, thickened edge slab for slab on grade).

2-3.5 Primary Facility Excluded Costs.

3\\ The unit costs do not include the following:

- Gross receipt taxes or gross taxes, gross excise taxes, or state commerce taxes,
- “Acts of God” or unusual market conditions,
- Supporting facility costs,
- Equipment acquired with other fund sources, including pre-wired workstations or furnishing systems, intrusion detection systems,
- Sustainable design and construction features - renewable energy generation elements; energy consumption reduction requirements mandated on or after **2**\\ four years prior to the source date of the data tables /**2**/; and all other features mandated since **2**\\ three years prior to the source date of the data tables /**2**/; these will be estimated separately in accordance with component guidelines and documented on DD Form 1391 per DoD Instruction 4170.11, Installation Energy Management,
- Special foundations (e.g., pre-stressed concrete piles, caissons),
- Intrusion detection system installation,
- Electronic security system (ESS) (rough-in),
- Hazardous and toxic material removal/abatement,

- Base exterior architectural preservation guidelines,
- Enhanced Anti-Terrorism (AT) standards (exceeding the minimum in UFC 4-010-01, or when minimum standoff distances **2**\ /**2**/ are not achieved) construction contingency allowances,
- System commissioning,
- Cybersecurity costs,
- Supervision, inspection, and overhead (SIOH),
- Design costs (design-build contracts), and post-award construction cost growth, for example, resulting from user changes, unforeseen site conditions, or contract document errors and omissions. /**3**/

2-3.6 Primary Facility Cost Considerations.

The following are cost considerations for primary facilities:

- Medical facilities: Unit costs include category A and category B equipment and building infrastructure for category C equipment,
- Housing for Unaccompanied Military Personnel: Unit costs for barracks, dormitories, and Unaccompanied Officers Quarters do not include free-standing kitchen equipment.
- Child Development Centers: Unit costs do not include free-standing food service equipment or playground area and equipment,
- Family housing: Unit costs are based upon gross area and include sprinkler systems or fire-rated construction. Unit costs include post-award design costs,
- Reserve facilities other than reserve centers: Use the unit cost of the appropriate facility type,
- **2**\ /**2**/
- Costs are independent of the acquisition strategy and are not specific to any single construction type.

CHAPTER 3 UNIT COSTS FOR DOD FACILITIES COST MODELS

3-1 OVERVIEW.

This chapter describes the unit costs and related factors used in support of DoD facilities cost models. These unit costs are intended for macro-level analysis and planning and are not reliable for individual facilities or project cost estimates.

Unit costs and related factors are associated with FACs represented by a 4-digit code in the DoD Real Property Classification System (RPCS), which is a hierarchical scheme of real property types and functions that serves as the framework for identifying, categorizing, and modeling the DoD's inventory of land and facilities. FACs are common across the department and suitable for department-wide applications. For each FAC, Table 3 identifies the associated unit cost to be used in DoD facilities cost models and metrics.

Whenever possible, unit costs and factors have been based upon approved government or commercial benchmarks. Detailed supporting data for unit costs is available, and accompanies this UFC on the WBDG web site. All data tables in this UFC are found in a combined file under "Related Materials" accompanying this UFC on the WBDG web site: https://www.wbdg.org/dod/ufc/ufc-3-701-01.

3-2 PRV UNIT COSTS (PUC).

3-2.1 Definition and Use of PRV Unit Costs.

PRV unit costs (PUC) form the basis of calculating Plant Replacement Value (PRV) in a consistent manner across DoD, representing a complete and useable facility built to current DoD design standards. PUC can also support large-scale program-level cost estimates for re-stationing plans with the addition of allowance for site preparation, earthwork, landscaping, and related factors. PUC should not be used for individual project estimates.

PUC include construction of standard foundations, all interior and exterior walls and doors, the roof, utilities out to the 5-foot line, all built-in plumbing and lighting fixtures, security and fire protection systems, electrical distribution, wall and floor coverings, heating and air conditioning systems, and elevators. PUC does not include project costs such as design, supporting facility costs, special foundations, equipment acquired with other funding sources (e.g., mission-funded components), contingency costs, or supervision, inspection, and overhead (SIOH). PUC also do not include items that are generally considered personal property such as computer systems, and furniture. See paragraph 3-5, Revising Unit Costs, for guidance on requesting changes to PUC in Table 3.

3-2.2 Plant Replacement Value (PRV).

PRV is the cost to design and construct a notional facility to current standards to replace an existing facility on the same site. The factor values are provided in the "Report of the

Plant Replacement Value (PRV) Panel, August 2001-May 2003" published by the Office of the Deputy Under Secretary of Defense (Installations and Environment). The standard DoD formula for calculating PRV is:

Equation 3-1. Calculating PRV

$$PRV = Q \times PUC \times ACF \times HF \times PD \times SIOH \times CF$$

Where:

PRV is plant replacement value

Q is facility quantity, in the same unit of measure as the PUC

PUC is PRV unit cost found in Table 3 of this UFC

ACF is area cost factor found in Table 4-1 of this UFC, to account for geographical differences in the costs of labor, materials, and equipment

HF is an adjustment of 1.05 to account for increased costs for replacement of historical facilities or for construction in a historic district. If the facility does not qualify as "historical", this factor is 1

PD is a factor to account for the planning and design of a facility; the current value of this factor is 1.09 for all but medical facilities, and 1.13 for medical facilities

SIOH is the factor to account for the supervision, inspection, and overhead activities associated with the management of a construction project. Application of SIOH rates will be in accordance with PTDO PDASD(EIE) (14 Apr 2022) for Military Construction Supervision, Inspection and Overhead Fixed Rates for Fiscal Year 2024 and Future projects. For a list of applicable remote locations, refer to NAVFACINST 7820.0 (8 Aug 2022) for Navy and the cognizant design agency for Army and Air Force. The aforementioned documents are included as "Related Materials" accompanying this UFC on the WBDG web site: https://www.wbdg.org/dod/ufc/ufc-3-701-01.

CF is a factor of 1.05 to account for construction contingencies

3-3 SUSTAINMENT UNIT COSTS (SUC).

3-3.1 Definition.

Sustainment provides for maintenance and repair activities necessary to keep a typical inventory of facilities in good working order over its expected service life. It includes the following:

- Regularly scheduled adjustments and inspections, including maintenance inspections (e.g., fire sprinkler heads, HVAC systems) and regulatory inspections (e.g., elevators, bridges),
- Preventive maintenance tasks,
- Emergency response and service calls for minor repairs, and
- Major repair or replacement of facility components (usually accomplished by contract) that are expected to occur periodically throughout the facility service life.

Sustainment includes regular roof replacement, refinishing wall surfaces, repairing and replacing electrical, heating, and cooling systems, replacing tile and carpeting and similar types of work as well as overhead costs which include architectural and engineering services. It does not include repairing or replacing non-attached equipment or furniture, or building components that typically last more than 50 years (such as foundations and structural members). Sustainment does not include restoration, modernization, environmental compliance, facility leases, specialized historical preservation, general facility condition inspections and assessments, planning and design (other than shop drawings), or costs related to Acts of God, which are funded elsewhere. Other tasks associated with facilities operations (such as custodial services, grass cutting, landscaping, waste disposal, and the provision of central utilities) are also not included.

3-3.2 Use of Sustainment Unit Costs.

Sustainment unit costs represent the annual average sustainment cost for each FAC, and serve as the basis for calculating annual facilities sustainment requirements for DoD using the following formula:

Equation 3-2. Calculating Sustainment Requirement

$$SR = Q \times SUC \times SACF \times I$$

Where:

SR is sustainment requirement

Q is facility quantity, in the same unit of measure as the SUC

SUC is sustainment unit cost found in Table 3

SACF is sustainment area cost factor found in Table 4-1

I is the value(s) representing future-year escalation for operation and maintenance accounts, published in Table 4-4.

The Sustainment Requirement for each qualifying asset in the DoD inventory is aggregated by sustaining organization and sustainment fund type in the Facilities Sustainment Model (FSM), published annually.

3-4 UNIT COST SOURCES.

Unit costs for DoD cost models are developed using a variety of sources. These sources fall into the three categories described below, listed in order of preference of use. The source description and source group for each unit cost are identified in Table 3. Supporting documentation for each unit cost calculation is available in the "Supporting documentation" file download accompanying this UFC document on the WBDG web site: https://www.wbdg.org/dod/ufc/ufc-3-701-01.

3-4.1 Source 1 Published Data.

Standard, easily accessible published data that is highly applicable to the FAC. Source 1 is the most desirable due to ease of access, general applicability, and lack of bias. Examples include the DoD Tri-Service Committee on Cost Engineering, Service-specific cost guidance (USACE), commercial cost-estimating guidelines or models, or other Government-published cost guidance from federal, state, or local government agencies (e.g., Fairfax County (Virginia) Park Authority). Non-DoD source 1 data may require refinement for application in DoD, but is still considered source 1 if it closely matches the design attributes of the FAC.

3-4.2 Source 2 Similar Data.

Data that is applied to facilities with similar but not identical characteristics (e.g., sewage waste treatment facilities and industrial waste treatment facilities). Source 2 also includes unpublished government or trade association cost data, and Component-validated costs for non-standard facilities that have no commercial counterparts (e.g., missile launch facilities or military ranges).

3-4.3 Source 3 Derived Data.

Unpublished project-specific data derived from Component project documents (e.g., DD Forms 1391) or from calculating costs from reported Plant Replacement Value and inventory, or derived from using a ratio of sustainment to construction from a similar source 1 Facilities Analysis Category (e.g., FAC 2115, Aircraft Maintenance Hangar, Depot derived from FAC 2111, Aircraft Maintenance Hangar).

3-5 REVISING UNIT COSTS.

Users of this UFC are encouraged to suggest revisions to the published cost factors, particularly for facilities unique to their mission. Submit proposed changes as Criteria Change Request (CCR) on the WBDG web site (www.wbdg.org) in accordance with the following guidelines:

- Revised costs should come from an equivalent or superior source,

- Revised costs should be easily audited,
- Revised costs should be consistent with the functional definitions,
- Revised costs should be consistent with the FAC scope, and
- Revised costs should be suitable for application throughout DoD.

This Page Intentionally Left Blank

CHAPTER 4 COST ADJUSTMENT FACTORS

4-1 LOCATION ADJUSTMENTS.

Table 4-1 provides area cost factors (ACFs) to be used for adjusting “bare” unit costs to location-specific costs for the most common locations.

All data tables in this UFC are found in a combined file under “Related Materials” accompanying this UFC on the WBDG web site: https://www.wbdg.org/dod/ufc/ufc-3-701-01.

4-1.1 Application.

4\\ For military construction projects, use the MILCON ACFs with the facility unit costs from Chapter 2 or approved Air Force, Army, or Navy MILCON Pricing Guide and supporting facilities unit cost from Chapter 6. /**4**/ For calculating Plant Replacement Value, use the MILCON ACFs with the appropriate PUCs from Chapter 3. For calculating sustainment costs, use the sustainment ACFs with the appropriate SUCs from Chapter 3. **5**\\ /**5**/

5\\ Do not use the MILCON ACFs to modify detailed quantity take-offs, unit price book (UPB) line items, commercial cost data, or user-generated unit costs. These cost estimating methods and databases have their own processes and factors for adjusting costs to different locations. MILCON ACFs or any component(s) that make up MILCON ACFs are only applicable to construction cost and should not be applied or utilized for any other purpose. /**5**/

4-1.2 Data Source.

In general, the Tri-Service Cost Engineering ACF software program evaluates the local costs for a United States market basket of eight labor crafts, 18 construction materials, and four equipment items. These materials, labor and equipment (MLE) items are representative of the types of products, services, and methods used to construct most military facilities in the United States. Each of the MLE costs is normalized and weighted to represent its contribution to the total cost of a typical facility. The normalized MLE is then modified by seven matrix factors that cover local conditions affecting construction costs. These matrix factors include weather, seismic, climatic (frost zone, wind loads, and HVAC systems), labor availability, contractor overhead and profit, logistics, and labor productivity and are relative to the U.S. standard. The resultant ACF for each location is normalized again by dividing by the 96-Base-City average to provide a final ACF that reflects the relative relationship of construction costs between that location and the 96-Base-City average as 1.00.

MILCON ACFs are calculated using a MLE ratio of 63/35/2. Sustainment ACFs are calculated using a MLE ratio of 46/53/1.

4-1.3 Survey.

Both CONUS and OCONUS construction market surveys were conducted in **6**\ 2024 /**6**/. The CONUS survey covered 213 locations that included 96 Base Cities (two per state in the continental U.S.). The OCONUS survey included 55 locations, and was based on a market basket of goods for typical U.S. labor, material, equipment, and construction methods.

CONUS and OCONUS surveys are performed annually. When local materials and construction methods differ from those represented by the published ACF, specific adjustments may need to be added to the cost estimate to account for any differences. There is no easy correlation between the current MILCON ACFs and previous MILCON ACFs for specific locations. No common benchmarks exist because both the Base City average and the relationships between cities change with each survey. It is possible, however, to compare differences between several locations in this database with differences between the same locations in previous databases.

4-1.4 Force Majeure.

The ACF is not intended to, or capable of, responding to rapid changes in the market place. Examples include Acts of God, accelerated construction schedules, changes in the demand and supply for construction materials, labor, and equipment. An increased demand for labor beyond what the local market can supply may require the enticement of premium pay, overtime hours, temporary living expenses, and travel expenses.

4-1.5 User Requested Revisions.

Users may request revisions to published ACFs when market conditions unexpectedly change. Each request must be initiated as a Criteria Change Request (CCR) on the Whole Building Design Guide (www.wbdg.org). The local cost engineer shall provide updated market basket ACF software input factors with adequate backup documentation to HQUSACE or NAVFAC for them to update the Tri-Service Cost Engineering ACF software.

4-2 ESCALATION.

Tables 4-2, 4-3, and 4-4 provide escalation (inflation) factors used to adjust unit costs in Tables 2 and 3 (expressed in base-year dollars) to the desired year, as follows:

4-2.1 Military Construction.

Military construction **3**\ programming cost /**3**/ estimates that use unit costs from Table 2 should use the military construction escalation factor from table 4-2 for the expected midpoint of construction as described in UFC 3-730-01.

4-2.2 Plant Replacement Value Escalation Rates.

PRV calculations that use PUC from Table 3 should use the escalation factor from Table 4-3 for the desired program year.

4-2.3 Facilities Sustainment.

Modeled facilities sustainment cost estimates that use unit costs from Table 3 should use the O&M escalation factor from Table 4-4 for the desired program year.

This Page Intentionally Left Blank

CHAPTER 5 REPLACEMENT COST

5-1 REPLACEMENT COST.

5-1.1 Definition of Replacement Cost.

Replacement cost is a stand-alone cost that represents the total cost to design and construct a new facility based on current codes, UFC and other design criteria that replaces an existing facility. This may be computed using the methodologies in UFC 3-730-01. Replacement cost is distinctly different from the PRV calculation defined in Chapter 3.

The replacement cost includes the demolition and disposal of the existing facility, hazmat removal, and special construction features such as special foundations and historic considerations. The replacement cost generally excludes site work and utilities outside the 5-foot line except when current codes, UFC and other design criteria require utilities and site work outside the 5-foot line to be modified, replaced/modernized and/or upgraded.

5-1.2 Use of Replacement Cost.

Use replacement cost as a benchmark to compare to the renovation cost of an existing facility. For renovation projects, the ratio of renovation cost to replacement cost is used to identify additional facility upgrades (such as **4**\ anti-terrorism/force protection (ATFP) /**4**/, seismic evaluation and retrofit, and sustainability) as determined by the requirements in UFC's or other design criteria.

5-1.3 Considerations.

If the UFC and other design criteria require utilities and sitework outside the 5-foot line to be modified, replaced/modernized, and/or upgraded, the cost for this is included in the replacement cost.

Replacement of an existing facility of the same size and location may not be ideal for every project. If the replacement facility is to be located at a different site from the existing facility, the cost of sitework and supporting facilities should be included.

This Page Intentionally Left Blank

CHAPTER 6 \2\ UNIT COST FOR SUPPORTING FACILITIES

6-1 OVERVIEW.

The supporting facilities unit costs in this Chapter apply to the preparation of programming cost estimates **5**\ in accordance with the methodology described in UFC 3-730-01. /**5**/

All data tables in this UFC are found in a combined file under "Related Materials" accompanying this UFC on the WBDG web site: https://www.wbdg.org/dod/ufc/ufc-3-701-01.

6-2 SUPPORTING FACILTIES UNIT COST TABLE.

Table 6 provides supporting facilities unit costs in dollars per unit of measure ($/UOM). The list reflects common cost items that are typically included in construction projects.

6-3 SUPPORTING FACILITY UNIT COST DEVELOPMENT METHODOLOGY.

6-3.1 Methodology and Data Source.

The unit costs for supporting facilities are developed using the **6**\ 2024 /**6**/ Costbook database. The Costbook database provides material, labor, and equipment cost for the CONUS area. The costs were escalated to **6**\ 01 October 2024 /**6**/ using the DoD SPI. Cost items are for new construction only.

The supporting facilities unit costs are built as assemblies in Micro Computer-Aided Cost Engineering System 2nd Generation (MCACES/MII) using cost items from the Costbook database. Mark-ups are applied in the cost estimate to adjust cost items to the average market conditions.

6-3.2 Supporting Facility Included Costs.

The unit costs include the following:

- Installed pricing with full contractor mark-ups
- A summary of mark-ups and other included cost are included in a file under "Related Materials" on the WBDG web site

6-3.3 Supporting Facility Excluded Costs.

The unit costs do not include the following:

- Location Adjustment
- Escalation
- Design Build Cost

- Construction Contingency
- SIOH

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Programming cost estimates are to be prepared as accurately as possible to reflect the cost of providing facilities. To do this, basic data is to be accurate and applied consistently. A basic cost model that reflects all applicable factors derived from accurate data forms the basis for determining facility programming cost at a specific location and under specific conditions.

1-2 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 3-730-01, dated 6 June 2011.

1-3 PURPOSE AND SCOPE.

This UFC establishes criteria and standards for development of programming cost estimates for constructing military facilities using published guidance unit cost (GUC) or using a parametric estimating program. The most current GUCs are provided in UFC 3-701-01 or the U.S. Army Corps of Engineers *Army Facilities Pricing Guide, PAX Newsletter 3.2.2*. The Tri-Services approved Parametric Cost Engineering System (PACES) may also be used for development of programming cost estimates for constructing military facilities.

This UFC addresses programming cost estimates for new construction and alteration projects, and includes cost data (based on historic data and experience) and factors for adjusting facility costs to reflect project conditions. This UFC also addresses supporting facilities cost and project cost.

The equations and examples in this UFC are represented in English units. This does not alleviate the requirement to comply with MIL-STD-3007 to use metric units in criteria documents.

1-4 APPLICABILITY.

This UFC applies to military construction (MILCON) and military operations and maintenance (O&M) projects.

1-5 GLOSSARY.

Appendix D contains acronyms, abbreviations, and terms.

1-6 REFERENCES.

Appendix E contains a list of references used in this UFC. The publication date of the code or standard is not included. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 ESTIMATING NEW PRIMARY FACILITIES (LESS FAMILY HOUSING)

2-1 COST ESTIMATE PREPARATION.

Cost estimates may be prepared using the latest approved software for each cognizant design agency and other authorized cost and pricing sources.

2-2 COST ESTIMATES USING PUBLISHED GUIDANCE UNIT COST.

2-2.1 Guidance Unit Cost (GUC).

Cost estimates may use GUCs published in either UFC 3-701-01 or the Army *PAX Newsletter 3.2.2*. These publications contain a listing of expected facility unit costs, updated annually. The prices for facilities in both documents are based on criteria existing at the time of preparation, as authorized by existing regulations.

2-2.2 Adjusted Guidance Unit Cost Equation.

A unit cost for a facility, which should reflect the adjusted GUC conditions for the facility, can be obtained by using the following equation:

Equation 2-1. Formula to Estimate Facility Adjusted Guidance Unit Cost

$$\$A = \$GUC \times S \times ACF \times CE \times TU \times DC \times HR \times SS$$

Where:
$A = adjusted guidance unit cost
$GUC = guidance unit cost
S = size factor
ACF = area cost factor
CE = cost escalation
TU = technological updating factor
DC = design contingency
HR = historical requirement factor
SS = site sensitivity factor

2-2.3 Basic Adjustment Factors.

Programming cost estimates are to include proper allowances for all factors that may be reasonably expected to influence cost through the expected construction period. However, deviations which are significantly above or below the factored unit cost must be explained in detail. If the adjusted cost estimate is over the statutory limit (e.g., family housing), a waiver including complete substantiating data is to be requested in accordance with cognizant agency policy.

2-2.3.1 Size Factor (S).

Use size factors in Table 2-1 when facility gross area differs from a similar type facility's reference size (see Table 2 of UFC 3-701-01). Calculate the size ratio by dividing the programmed facility size by the facility reference size. Use the project size factors in Table 2-2 for barracks/dormitories and Table 2-3 for military family housing facilities. The size factors in Tables 2-1 through 2-3 do not include progressive collapse or seismic requirements; calculations for facilities of three or more stories should include these costs.

Note: Table 2 of 3-701-01 is posted with "Related Materials" on the Whole Building Design Guide at: https://www.wbdg.org/FFC/DOD/UFC/ufc_3_701_01_2022_c3_Data_Tables.xlsx.

2-2.3.2 Area Cost Factor (ACF).

The ACF, updated annually, reflects average statistical differences in normal labor, material, and equipment costs for similar facilities built in different geographical locations. See Table 4-1 of UFC 3-701-01 for factors to adjust estimated costs to specific geographical areas.

2-2.3.3 Cost Escalation (CE).

The unit costs shown in Table 2 of UFC 3-701-01 reflect historical costs only, normalized to the "as of" reference date in the table. These costs are to be escalated to the expected midpoint of construction using the appropriate cost escalation. Table 4-2 of UFC 3-701-01 is updated annually and provides data to use to project cost escalation due to inflationary factors affecting construction costs. Determine the midpoint of construction for each facility based on a realistic assessment of the construction schedule. Refer to the cognizant agency for more details. It may be necessary to interpolate between the escalation rates for the months between the stated years. When using the Army PAX Newsletter for projects scheduled differently than the assumed midpoint of construction, follow the guidance in the newsletter.

2-2.3.4 Technological Updating (TU) Factor.

Technological advances in equipment and operational techniques used in some specialized facilities are being developed rapidly, often resulting in obsolescence before design and construction are completed. Also, revisions in criteria to provide life cycle cost benefits may increase initial funding requirements before feedback data can reflect the added cost. A TU factor may be appropriate in these situations. Fully document and explain use of these factors in the cost estimate notes. Table 2-4 lists technological updating factors by DoD Basic Category group codes of facilities.

Table 2-1 Size Factors

Size Ratio	Size Factor	Size Ratio	Size Factor
≤0.0500	1.2750	1.6000	0.9570
0.1000	1.2690	1.6500	0.9550
0.1500	1.2320	1.7000	0.9530
0.2000	1.2020	1.7500	0.9510
0.2500	1.1750	1.8000	0.9490
0.3000	1.1520	1.8500	0.9470
0.3500	1.1320	1.9000	0.9450
0.4000	1.1140	1.9500	0.9430
0.4500	1.0980	2.0000	0.9420
0.5000	1.0840	2.0500	0.9400
0.5500	1.0720	2.1000	0.9390
0.6000	1.0600	2.1500	0.9370
0.6500	1.0500	2.2000	0.9360
0.7000	1.0410	2.2500	0.9350
0.7500	1.0330	2.3000	0.9330
0.8000	1.0250	2.3500	0.9320
0.8500	1.0180	2.4000	0.9310
0.9000	1.0110	2.4500	0.9300
0.9500	1.0050	2.5000	0.9290
1.0000	1.0000	2.5500	0.9280
1.0500	0.9950	2.6000	0.9270
1.1000	0.9900	2.6500	0.9260
1.1500	0.9860	2.7000	0.9250
1.2000	0.9820	2.7500	0.9240
1.2500	0.9780	2.8000	0.9240
1.3000	0.9740	2.8500	0.9230
1.3500	0.9710	2.9000	0.9220
1.4000	0.9680	2.9500	0.9210
1.4500	0.9650	3.0000	0.9210
1.5000	0.9620	3.0500	0.9200
1.5500	0.9600	>3.05	0.9200

Table 2-2 Barracks/Dormitories Project Size Factors

Numbers of Service Members in the Project	Project Size Factor
1-99	1.07
100-149	1.03
150-199	1.00
200-299	0.97
300+	0.95

1-9	1.25
10-19	1.15
20-49	1.10
50-99	1.04
100-199	1.00
200-299	0.93
300+	0.90

Table 2-4 Technological Updating Factors

DoD Basic Category	Category Series Description	TU Factor
300	Research, Development, Test, & Evaluation facilities	1.10
500	Hospital and medical facilities	1.05

2-2.3.5 Design Contingency (DC).

The cost estimate may include a DC based on the lack of maturity of design data. The DC covers component items that cannot be analyzed or evaluated at the time the cost estimate is prepared; however, these items are susceptible to cost evaluation as engineering and design progresses. The DC depends on the reliability and refinement of the data on which the cost estimate is based, so reliability and refinement diminishes as design progresses from programming through the design completion stage. Though it decreases at each successive design stage, the initial magnitude of the DC at programming depends on the technical complexity of the project for which the cost estimate is being prepared. The level of technical complexity must be a prerequisite for determining the magnitude of the DC. DC is listed in Table 2-5. If a cost and schedule risk analysis (CSRA) is required during programming, develop the design contingency using CSRA. Refer to UFC 3-740-05 for further guidance.

Table 2-5 Design Contingency

Technical Complexity Level	Description	Design Contingency
Low	Site adapted, repetitive standard design project involving routine technology	1.050
Medium	Unique design involving complex technology	1.100
High	Unique design involving highly complex technology	1.200
Ultra-high	Unique design involving extremely complex or innovative technology	1.300

2-2.3.6 Historical Requirements (HR) Factor.

A factor for unique architectural features to comply with HR is permitted for facilities to be built at locations listed in the National Register of Historical Places. The factor for HR is typically 1.05. Deviation above the allowed factor must be explained in detail.

2-2.3.7 Site Sensitivity (SS) Factor.

An SS factor may be necessary for special cases where the unique nature of both the site and the project, in relation to one another, will cause a significant impact on the cost. As recommended practice, analysis for SS factor should consider only those unique site conditions which will influence cost by virtue of the uniqueness of the conditions involved. The method outlined in Section 2-5 may be used to determine the cost impact caused by the influence of a project upon itself, resulting from an extremely large concentration of construction effort, or from extreme site limitations, or from both. Appendix B lists examples of SS considerations and computations with a range of values, where applicable, from above normal to substantially below normal. This listing only provides examples and is not comprehensive.

2-3 COST ESTIMATES USING PARAMETRIC MODELS.

2-3.1 Parametric Cost Estimating.

Parametric cost estimating is a computer-based methodology that uses factors based on engineering parameters developed from historical cost databases, construction practices, and engineering and construction technology. These factors include physical properties that describe project definition characteristics, such as size, building type, foundation type, exterior materials, roof type and materials, number of floors, functional space requirements, and utility requirements. The major advantage of parametric cost estimating is that it can provide detailed construction cost relatively quickly with only limited analysis of the facility. Parametric cost estimating is only as good as the effort expended in identifying the key project inputs. It must be based upon an accurately developed construction scope. All parametric assumptions and key project inputs must be documented to provide rationale for development of the cost estimate. All major entities involved with the project must be energized and actively participate in project scope validation, including installation personnel, the Project Manager, and the Project Delivery Team (PDT). At this time, the only Tri-Services approved computer-based parametric estimating program is PACES, and training is required prior to use.

2-4 OTHER ALLOWABLE COSTS FOR PRIMARY FACILITIES.

There may be situations where additional costs will be required for the project, which are not part of the GUC or parametric model and may be itemized separately. Use of these itemized costs must comply with cognizant design agency guidance and be fully documented and explained in the cost estimate notes.

2-5 ADJUSTED GUIDANCE UNIT COST ESTIMATE EXAMPLE.

The equation for the guidance unit cost adjustment determination is:

$$\$A = \$GUC \times S \times ACF \times CE \times TU \times DC \times HR \times SS$$

Where:
$GUC = guidance unit cost
S = size factor
ACF = area cost factor
CE = cost escalation
TU = technological updating factor
DC = design contingency
HR = historical requirement factor
SS = site sensitivity factor

Paragraphs 2-5.1 through 2-5.10 provide an example for calculating the facility cost estimate for a 48,750 square foot general purpose administration building, Navy category code 61010, to be built at Naval Station Norfolk, Virginia, in the FY25 program. This example assumes a contract award in FY25, a construction start date of Oct 2026, and a construction completion date of Oct 2027.

2-5.1 Step 1 - Unadjusted Cost.

In Table 2 of UFC 3-701-01, find the unit cost for the applicable building type closest to the building type being programmed. The Administrative Facilities: Multi-Purpose Administration facility is the comparable facility with a unit cost of $503/sf and a reference size of 45,000 square feet. **Note:** UFC 3-701-01 Table 2 is updated annually; numbers used within this example may not correspond or be current.

2-5.2 Step 2 - Size Factor.

Calculate a size ratio by dividing the programmed building size by the reference size. Using the closest comparable size ratio, determine the size adjustment factor from Table 2-1 of this UFC. The 48,750 square foot programmed building size divided by the 45,000 square foot reference building size yields a size ratio factor of ~1.08. Using Table 2-1, find the size ratio of 1.05 and obtain an adjustment factor of 0.9950.

2-5.3 Step 3 - Area Cost Factor.

Determine the location adjustment factor from Table 4-1 of UFC 3-701-01. For Naval Station Norfolk, Virginia, the 0.92 applies.

2-5.4 Step 4 - Cost Escalation.

Make allowance for cost growth due to economic factors anticipated between the dates on which the cost and pricing data in Table 2 of UFC 3-701-01 are based and the expected midpoint of construction date for the project being programmed. For this FY25 example project, construction start is Oct 2026 and construction completion is Oct 2027. The midpoint of construction will be six months after the start date. Using UFC 3-701-01, dated March 2022, Change 1, which reflects historical cost and pricing data normalized to Oct 2021 for preparation of the DoD budget for FY25, projected escalation factors from Table 4-2 of UFC 3-701-01 are 1.0000 for October 2021, 1.1062 for October 2026, and 1.1284 for October 2027. The escalation factor to October 2025 would be 1.1062/1.000 or 1.1062. Interpolating for six additional months of projected escalation factor and adding this to the 1.1062 projected escalation factor will provide the total projected escalation factor to be used.

$$(1.1284 - 1.1062) \div 12 = 0.00185$$

$$6 \text{ months} \times 0.00185 = 0.0111$$

$$1.1062 + 0.0111 = 1.1173$$

2-5.5 Step 5 - Technological Updating Factor.

Make allowance for cost adjustment due to updated technology by using the technological updating factor from Table 2-4. For this example, administrative facilities are not represented in the table; therefore, the factor is 1.00.

2-5.6 Step 6- Design Contingency.

Determine the DC in accordance with Table 2-5. The building is considered a low complexity. Using Table 2-5, the DC is 1.05.

2-5.7 Step 7 - Historical Requirements Factor.

Make allowance for cost adjustment due to historical requirements by using the HR factor of 5%, or 1.05.

2-5.8 Step 8 – Site Sensitivity Factor.

Make allowance for cost adjustment due to site sensitivity by using the SS factor of 4.55% or 1.0455.

2-5.9 Step 9 - Adjusted Cost.

Calculate adjusted cost using the equation for the adjusted GUC as follows:

$$\$A = \$GUC \times S \times ACF \times CE \times TU \times DC \times HR \times SS$$

$$\$A = \$503/sf \times 0.995 \times 0.92 \times 1.1173 \times 1.00 \times 1.05 \times 1.05 \times 1.0455$$

$$= \$593.00/sf$$

2-5.10 Step 10 – Facility Cost.

Determine the estimated facility cost by multiplying the size of the facility being programmed by the adjusted unit cost ($A) derived in Step 9, and then round off the product. The size 48,750 square feet multiplied by $593.00 per square foot yields a facility cost estimate of $28,908,750, which when rounded to the nearest million dollars yields $29,000,000.

CHAPTER 3 SUPPORTING FACILTIES COSTS AND PROJECT COSTS.

3-1 SUPPORTING FACILITIES UNIT COSTS.

Cost estimates may use supporting facility unit costs published in UFC 3-701-01. Supporting facilities are items of construction directly related to the project such as utilities, roads and parking, and site improvements. Supporting facilities' unit costs need to be adjusted by applying a location adjustment factor, cost escalation, and design contingency. Specific details for unit costs are defined in paragraphs 3-1.1 through 3-1.1.2.

3-1.1 Munitions and Explosives of Concern (MEC) Unit Cost.

Unit costs for MEC are available in UFC 3-701-01. The unit cost is based on surface area. The user will need to determine the depth necessary for MEC investigation to determine which MEC unit costs to include.

3-1.1.1 MEC Investigation and Removal Process (8 Step).

The following steps are part of a typical MEC investigation and removal process. Other items may need consideration depending upon site conditions.

- Step 1: GPS Survey – Survey of subject site boundaries.
- Step 2: Area Assessment – Walkthrough visual assessment of site for potential items on surface.
- Step 3: Area Preparation – Basic site clearing (does not include vegetation clearing (e.g., trees and shrubs).
- Step 4: Surface Clearance – Scan of surface with metal detectors.
- Step 5: Subsurface Detection – Scan of site with high density metal detectors typically reaching to a depth of 2 feet below surface without excavation.
- Step 6: Excavation – Excavation of site removing the top 2-foot layer to allow subsurface scanning 2 feet below the previous scan.
- Step 7: Access and Identification – Object located by scan and identified as possible MEC or other.
- Step 8: Disposal – Removal and disposal of MEC object.

3-1.1.2 Types of MEC Unit Costs.

Two unit costs are available for MEC based on the required depth of investigation. They are listed below and indicate which steps from paragraph 3-1.1.1 apply.

- Surface Investigation (includes Steps 1-5, 7 and 8) – Investigation and clearing.

- Deep Investigation (includes Steps 1-8) – Clearing to 4 feet below surface.

3-2 PROJECT COST.

Project cost is defined as the sum of construction costs, including primary facility costs, supporting facilities' costs, any other allowable costs, cost allowances for contingencies, other allowances for supervision, inspection, and overhead (SIOH), and design-build design cost.

3-2.1 Construction Contingencies.

As recommended practice, include in each programming cost estimate a separate item as a reserve for construction contingencies to cover construction requirements which cannot be foreseen before the contract is awarded. The contingency reserve is used for some adverse or unexpected condition that cannot be predetermined from the data at hand during engineering and design and at the time of contract award -- usually latent difficulties such as unforeseeable relocations; unforeseeable foundation conditions; utility lines in unforeseeable locations; or other unforeseen problems. The contingency reserve is not an allowance for omissions of work items known to be required, but for which quality or quantity has not yet been determined by specific design.

In addition, as recommended practice, make reasonable allowances for all foreseeable requirements in the cost estimate, or include an allowance for cost adjustment. Application for construction contingency reserves must conform to cognizant design agency guidance. The construction contingency reserve for military construction programs and family housing new or replacement construction will typically be five percent of the total contract cost, but may be higher based on the results of the CSRA. Refer to UFC 3-740-05 for CSRA guidance.

3-2.2 Supervision, Inspection, and Overhead (SIOH).

Including a separate item for SIOH in each programming cost estimate is recommended. Application of SIOH rates must comply with Office of the Assistant Secretary of Defense, Energy, Installations, and Environment Memorandum, "Military Construction Supervision, Inspection, and Overhead Fixed Rates for Fiscal Year 2024 and Future Projects," April 14, 2022 (https://www.wbdg.org/FFC/DOD/UFC/ufc_3-701-01_MilCon_SIOH_Rates_Change_14Apr22.pdf).

For a list of applicable remote locations for Navy, refer to NAVFACINST 7820.0 (8 Aug 22) (https://www.wbdg.org/FFC/DOD/UFC/ufc_3-701-01_NAVFACINST_7820.2_SIOH.pdf), and the cognizant design agency for Army and Air Force.

3-2.3 Design-Build Design Cost.

Design-build projects may include a design-build design cost. The percentage used will comply with cognizant design agency guidance.

3-2.4 Other Allowable Cost.

Other allowable costs may include post-construction contract award services (PCAS), commissioning, other taxes (excise tax, gross receipts tax (GRT)), cybersecurity commissioning, low impact development (LID), sustainability, operations and maintenance support information (OMSI), progressive collapse, and design during construction.

Some states and nations do not have sales tax, but impose either GRTs (named variously among the states) or gross excise taxes. (Delaware, Nevada, Ohio, Oregon, Tennessee, Texas, and Washington have varying amounts of GRTs in lieu of a sales tax. Hawaii has a general excise tax.)

3-3 PROJECT COST ESTIMATE EXAMPLE.

Continuing the example from Chapter 2, determine the project cost by adding contingency and SIOH factors to facility cost with adjusted guidance unit cost and supporting facilities cost. (Assume a supporting facilities cost of $500,000.) Since this project is new construction and location is CONUS, a contingency factor of 1.05 and a SIOH factor of 1.065 should be applied as follows:

$$\text{Project Cost} = (\$28{,}908{,}750 + \$500{,}000) \times 1.05 \times 1.065 = \$32{,}886{,}335$$

In accordance with Appendix A, the project cost is $33,000,000.

This Page Intentionally Left Blank

CHAPTER 4 ESTIMATING ALTERATION PROJECTS

4-1 ESTIMATING FACILITY ALTERATON.

Alteration is defined as a change to interior or exterior facility arrangements to improve or change its current purpose. This includes installed equipment made a part of the existing facility, but does not include additions, expansions, or extensions. The procedures described in this paragraph provide a step-by-step method for preparing programming cost estimates for facility alteration when current design data is not available. The procedures are based on the ASTM E1557-09 UNIFORMAT II work breakdown structure (WBS) and relate the alteration work to new facility requirements as a percentage of new work.

Figure 4-1 is an example of a completed DA Form 7307-R. Appendix C tabulates the ratio of WBS cost to facility cost based on DoD military construction historical cost data. Table 4-1 shows the percentage of installation cost required for removal and the percentage cost required for installation.

% of Installation Cost Required for Removal: This is judgmental, assuming a percentage to remove (as compared to 100% for install).

% of Cost Required for Installation: The 35% is based on direct cost breakdown of UFC 3-701-01, paragraph 4-1. MILCON ACFs are calculated using a material/labor/equipment (MLE) ratio of 63/35/2.

Note: DA Form 7307-R, Cost Estimating Worksheet – Facility Alteration, is available at: https://armypubs.army.mil/pub/eforms/DR_a/pdf/A7307_R.pdf.

Table 4-1 Cost of Removal Versus Cost of Installation

WBS#	Description	% of Installation Cost Required for Removal	% of Cost Required for Installation
A10	Foundations	50	35
B10	Superstructure	50	35
B20	Exterior Closure	50	35
B30	Roofing	50	35
C10	Interior Construction	50	35
C30	Interior Finishes	50	35
D10	Conveying	50	35
D20	Plumbing	50	35
D30	HVAC	50	35
D40	Fire Protection	50	35
D50	Electrical	80	35
E10	Equipment	80	35
E20	Furnishings	50	35
F10	Special Construction	50	35

4-2 FACILITY ALTERATION COST ESTIMATE EXAMPLE.

Consider an FY25 alteration project for an existing 40,600 square foot multi-purpose administration building, category code 61010, at Naval Station Norfolk, Virginia, with midpoint of construction of April 2027. Step-by-step procedures using DA Form 7307-R in Figure 4-1 include:

Step 1: Identify the percentage of the building systems to be removed and enter in blocks 16a and 21a. Data for this block should be based on the scope of work (in many cases based on best judgment). A walk-through of the facility to be altered is the best way to obtain accurate data. Assume for this example that the substructure, superstructure, and exterior closure are not affected; that 80% of the interior and special construction is to be replaced; and that 75% of the electrical, mechanical, fire protection and plumbing are to be replaced.

Step 2: Using data obtained from Table 4-1, enter in block 16b the percentage of installation cost required for removal and in block 16c the percentage of cost required for installation.

Step 3: Obtain the ratio of WBS systems cost to facility cost for multi-purpose admin building from Appendix C and enter in blocks 16d and 21b.

Step 4**:** Calculate block 16e by multiplying entries in blocks 16a, 16b, 16c, and 16d. Calculate block 17, removal/demolition factor (RDF), by adding all entries in block 16e, which is 9.6% of the cost to build the building new. To calculate the total removal/demolition cost (RDC) for the project, use the following:

Equation 4-1. Formula to Calculate Removal/Demolition Cost

$$RDC = \$GUC \times S \times ACF \times CE \times TU \times DC \times HR \times SS \times RDF$$

Where:
$GUC = guidance unit cost
S = size factor
ACF = area cost factor
CE = cost escalation
TU = technological updating factor
DC = design contingency
HR = historical requirement factor
SS = site sensitivity factor
RDF = removal/demolition factor

$$RDC = \$503 \times 1.0110 \times 0.92 \times 1.1173 \times 1.00 \times 1.05 \times 1.05 \times 1.0455 \times 0.096 = \$57.84$$

Step 5: Determine replacement/new portion factor. The same method is used in the calculation for removal, except the cost includes 100% labor material and equipment. Calculate block 21c by multiplying entries in blocks 21a and 21b. Calculate block 22, replacement new factor (RNF), by adding all entries in block 21c. Total RNF is 47.5% (block 22) of the cost to build the facility new. Calculate the total new work cost (NWC) as follows:

Equation 4-2. Formula to Calculate New Work Cost

$$NWC = \$GUC \times S \times ACF \times CE \times TU \times DC \times HR \times SS \times RNF$$

$NWC = \$503 \times 1.0110 \times 0.92 \times 1.1173 \times 1.00 \times 1.05 \times 1.05 \times 1.0455 \times 0.475 =$ $\$286.20$

Step 6: Consider adding a special adjustment factor (SAF) due to construction limitations. Allowed demolition/removal and replacement construction limitations include:

- dust protection for adjacent work areas: 2-7%
- limited use of equipment (noise/power) limitations: 1-6%
- limited storage of construction materials: 1-6%
- protection of completed work: 2-6%
- shift work: 2-10%

Any other adjustment factor must be defined and justified. SAF due to construction limitations may be applied either to the total unit cost or to the total cost of the project. Using the SAF from block 25 of the completed DA Form 7307-R, the demolition and replacement costs are adjusted:

Adjusted RDC:

= RDC x (1+SAF%)
= \$57.84 x 1.15 = \$66.52/sf

Adjusted NWC:

= NWC x (1+SAF%)
= \$286.20 x 1.15 = \$329.13/sf

Total alteration cost:

= adjusted RDC + adjusted NWC
= \$66.52/sf + \$329.13/sf
= \$395.65/sf

Step 7: Determine the facility estimated alteration cost by multiplying the area of the facility being programmed for alteration by the total alteration cost as follows:

= \$395.65/sf x 40,600 sf
= \$16,063,390

Step 8: Determine the project cost in accordance with the example in paragraph 3-3.

DA FORM 7307-R, APR 1994

CHAPTER 5 ESTIMATING FAMILY HOUSING

5-1 FAMILY HOUSING COST MODEL.

Paragraphs 5-1.1 through 5-1.18 may be used to calculate cost estimates for construction of new and replacement family housing.

5-1.1 FY.

FY is the fiscal year in which the project is proposed.

5-1.2 Location.

Location is the installation and state in which the proposed construction will take place.

5-1.3 # Units.

This is the number of family housing dwelling units which will be constructed in this project. Note that for replacement projects, the number of units may be equal to or less than the number of units to be demolished.

5-1.4 AGSF.

AGSF is the average gross square feet (AGSF) of the units proposed for construction. Size of dwelling units must comply with UFC 4-711-01.

5-1.5 $/GSF.

$/GSF is the cost to construct family housing per gross square foot (GSF). The cost will correspond to the fiscal year of the project. Cost includes only the primary facility with sprinklers, including attached two car garage (though GSF of garage is excluded, cost of attached garage GSF is included) and attached exterior bulk storage, but not the supporting infrastructure, demolition, supporting amenities or special construction requirements.

5-1.6 5' Line Cost.

The 5-foot line cost is the cost for the dwelling unit only, and is equal to the number of units multiplied by the AGSF multiplied by the cost per GSF.

5-1.7 ACF.

The ACF adjusts the prescribed costs to the location of the proposed project. These factors are listed in UFC 3-701-01, Table 4-1, and are updated annually based on a construction market survey.

5-1.8 Project Size.

The project size factor allows for economies of scale and depends upon the project size. The prescribed unit cost ($GSF) is based on an average project size. Projects involving a large number of units will realize economies of scale, resulting in a smaller project size factor. Table 2-3 lists project size factors for family housing projects

5-1.9 Project Factor.

The project factor equals the ACF multiplied by the project size factor. One project factor applies to all units being constructed in a project. Do not calculate a separate factor for each type of unit (for example, two-, three-, and four-bedroom junior noncommissioned officers).

5-1.10 Adjusted Housing Cost.

The adjusted housing cost equals the 5-foot line cost multiplied by the project factor.

5-1.11 Solar Cost and Information System Cost.

These are additional costs not captured in the 5-foot line cost. If a project will include solar energy features, multiply the estimated solar cost by the ACF by the number of dwelling units to arrive at the total project solar cost. Note that such features must be justified based on a life cycle cost analysis. The information system cost must be added to every family housing construction project. This cost represents telephone and cable television connections and wiring inside the buildings' 5-foot line. Include cost per dwelling unit for communication and cable television. To arrive at the information system cost, multiply the cost per dwelling unit for communication and cable television by the ACF by the number of dwelling units.

5-1.12 Other.

In some instances, site conditions may involve additional costs for the primary facility (inside the 5-foot building line). Examples include rock excavation, special foundation requirements, soil stabilization, basements, or special architectural features.

5-1.13 Average Unit Cost.

Add the housing unit cost, the solar and information system cost (if any), and any "other" cost, and divide by the number of units.

5-1.14 Supporting Cost.

This includes all work outside the 5-foot building line, such as site preparation, roads, utilities, recreation, landscaping, site amenities, and demolition. Where support cost estimates can be documented, show the unit cost and how derived. Often, support costs for family housing projects are difficult to identity for various reasons. Proposed units may be sited where existing units are planned for demolition or the site is undeveloped. If documenting support cost is difficult, use a percentage of the housing unit cost until a detailed analysis is completed. A separate cost breakout for demolition of existing units is recommended. Environmental conditions and individual state regulations must be considered when determining demolition cost. When using a "generic" for support cost and demolition, consider the ACF to arrive at the total support cost.

5-1.15 Estimated Construction Cost.

The summary subtotal consists of the -housing unit cost; solar cost, if any; other cost, if any; and the support cost.

5-1.16 Project Cost.

The project cost equals the estimated construction cost multiplied by the contingency cost by the SIOH. Include the appropriate design fee for Design-Build projects in project cost. Refer to paragraph 3-2.3.

5-1.17 Rounded Project Cost.

The rounded project cost is the project cost rounded in accordance with the Congressional rounding rule (see Appendix A).

5-1.18 Project Cost/SF.

The project cost per square foot equals the project rounded cost divided by the product of the number of units multiplied by the AGSF.

This Page Intentionally Left Blank

APPENDIX A CONGRESSIONAL ROUNDING RULE

Amount	Nearest
Less than or equal to 1,000,000	10,000
1,000,001 to 5,000,000	50,000
5,000,001 to 10,000,000	100,000
10,000,001 to 15,000,000	200,000
15,000,001 to 20,000,000	500,000
20,000,001 or greater	1,000,000

This Page Intentionally Left Blank

APPENDIX B SAMPLE SITE SENSITIVITY COST CONSIDERATIONS

Table B-1 Impact Identifier: Housing Availability

Condition	SS factor	Narrative Description of Condition with Resulting Assumptions and Computations
Normal	0	Adequate housing available in local area, no cost impact
Slightly below	+0.0525	Adequate housing not available in local area; however, housing is available within commuting distance. Assumptions: Provide travel allowance to location of adequate housing for key personnel and critical crafts. Computation example: Assume a travel allowance of $60/day ($0.60/mile for a 100-mile round trip commute), using 20 work days per month for a $1200/month travel allowance. Travel Allow Per Month/Avg Monthly Wages x Key Personnel + Critical Crafts Labor Costs as % of Total/Project Costs as 100%. (use $50/hour for a 40-hour work week and 4 weeks per month or $8,000) = Adjustment Factor ($1,200/8,000) x (35%/100%) = 0.0525
Substantially below normal	+0.0700	Inadequate housing in local area. Housing is not available within commuting distance. Assumptions: Provide trailer housing for majority of contractor personnel and skilled crafts. Computation example: Assume rental of trailers and sale of used trailers will not offset all original cost. Land lease and site development cost to be included in project cost. Loss on Trailers Lease and Development Cost/Total Project Cost = Adjustment Factor $2,000,000/$10,000,000 x (35%/100%) = 0.0700

Table B-2 Impact Identifier: Material Availability

Condition	SS Factor	Narrative Description of Condition with Resulting Assumptions and Computations
Normal	0	Project requirements do not exceed the capabilities of the local area. Site is within the normal delivery distance. No cost impact.
Slightly below	+0.0126	Project requirements do not exceed the capabilities of the local area, but site is outside normal delivery range. Assumptions: Additional hauling allowance required. Computation example: Add'l Cost for Hauling Beyond Normal Delivery Zone/Total Normal Mat'l Cost x Mat'l Cost as % of Total/Project Cost as 100% = Adjustment Factor $1,000,000/$50,000,000 x 63% = 0.0126
Substantially below normal	+0.0252	Project requirements exceed the capabilities of the area. Assumptions: Additional hauling allowance and onsite facilities required. Computation Example: Add'l Cost for Hauling & Storage Allowance/Total Normal Mat'l Cost x Mat'l Cost as a % of Total/Project Cost as 100% = Adjustment Factor $2,000,000/$50,000,000 x 63% = 0.0252

Table B-3 Impact Identifier: Local Site Peculiarities*

Condition	SS Factor	Narrative Description of Condition with Resulting Assumptions and Computations
Congested work area	+0.0280	Lost productivity caused by congested work area Assumptions: 3 hrs of non-productivity per week Computations: Unproductive Hrs Per Week/Productive x Labor Cost as a % of Total/Project Cost = Adjustment Factor (3/37) x (35%/100%) = 0.0280
Inadequate parking	+0.0175	Inadequate onsite parking for labor force. Assumptions: $400 per month parking allowance will be required. Computations: Parking Allowance Per Month/Avg Wage Per Month x Labor Cost as a % of Total/Project Cost as 100% = Adjustment Factor ($400/$8,000) x (35%/100%) = 0.0175

***Individual cost model analysis as required to justify each cost consideration**

Table B-4 Sample Site Adjustment Factor Summary

Impact identifier	Condition	SS Factor	Narrative Description of Condition with Resulting Assumptions and Computations
Housing availability	Normal	0	Adequate housing available in the local area
Material availability	Normal	0	Local area can meet all project requirements
Local site peculiarities	Individual analysis to justify each consideration	0.0280	Small congested work site
		0.0175	No parking onsite. No free parking near site.

Site Sensitivity Factor = 0 + 0 + 0.0280 + 0.0175 = 1.0455

Notes:
1. The first number in the SSF equation will always be 1 because the SSF must always be equal to or greater than 1.
2. The method outlined in this appendix may be used to determine the cost impact resulting from an extremely large concentration of construction effort, or from extensive site limitations, or both.
3. Determine the site sensitivity adjustment based on an analysis of site conditions, which will influence cost.
4. Factors applied take into account a material/labor/equipment (MLE) ratio of 63/35/2.

APPENDIX D GLOSSARY

D-1 ACRONYMS.

A	adjusted unit cost
ACF	area cost factor
AGSF	average gross square feet
CE	cost escalation
CONUS	Continental United States
CSRA	Cost and Schedule Risk Analysis
DC	design contingency
GRT	gross receipts tax
GSF	gross square feet
GUC	guidance unit cost
HR	historical requirement factor
LID	low impact development
MEC	munitions and explosives of concern
MILCON	military construction
MLE	material/labor/equipment
NWC	new work cost
O&M	operation and maintenance
OMSI	operations and maintenance support information
PACES	Parametric Cost Engineering System
PAX	Programming Administration and Execution
PCAS	post-construction award services
PDT	Project Delivery Team
RDC	removal/demolition cost

RDF	removal/demolition factor
RNF	replacement new factor
S	size factor
SAF	special adjustment factor
SIOH	supervision, inspection, and overhead
SS	site sensitivity factor
TU	technological updating factor
WBS	Work Breakdown Structure

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Costs estimates are to be prepared as though the Government were a prudent and well-equipped contractor estimating the project. Therefore, the total construction costs, which a prudent, experienced contractor would expect to incur, are to be included in the cost estimate. This philosophy prevails throughout the entire project cycle -- from programming through completion of construction.

1-2 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 3-740-05, 8 November 2010.

1-3 PURPOSE AND SCOPE.

This document establishes uniform guidance to describe methods, procedures, and formats for the preparation of cost estimates and associated analyses (price/cost). This guidance applies where services have common requirements, however, for instances where there are differences, use the policies and procedures of the cognizant design agency.

This document addresses the various phases of cost estimating from the initial start of design through modification cost estimates during construction. UFC 3-730-01 - PROGRAMMING COST ESTIMATES FOR MILITARY CONSTRUCTION provides guidance for cost estimating during the initial planning, programming, and budget review phases. The term construction includes remedial action environmental projects, dredging and other construction type work often implemented as service contracts. For the purposes of this document, the term cost engineer applies to qualified individuals, whether employed by the Government or under contract to the Government, who are routinely engaged in the preparation or review of cost estimates.

1-4 APPLICABILITY.

This UFC applies to Military Construction (MILCON) and Military Operations and Maintenance (O&M) projects. “Construction” is defined as construction, alteration, or repair (including dredging, excavating, and painting) of buildings, structures, or other real property. See FAR 2.101.

1-5 GLOSSARY.

APPENDIX C contains acronyms.

1-6 REFERENCES.

APPENDIX D contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

The samples and data referenced in this UFC are found under "Related Materials" accompanying this UFC on the (WBDG) Web site: https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05.

CHAPTER 2 GENERAL

2-1 COST ESTIMATING PHILOSOPHY.

Per Government Accountability Office (GAO-20-195G), the four key elements of a reliable cost estimate are (1) Comprehensive; (2) Well Documented; (3) Credible and (4) Accurate. Therefore, all costs, which a prudent, experienced contractor would expect to incur, are to be included in the cost estimate. Each cost estimate is to be developed as accurately as possible, in as much detail as can be assumed, and be based upon the best information available. This objective is to be maintained during the programming, design, and construction phases of the project. Cost estimating in the Federal government does not intend to be the low bidder but to represent a fair and reasonable cost of a prudent, well equipped contractor.

2-2 RESPONSIBILITY FOR PREPARATION, REVIEW AND PRESENTATION.

2-2.1 General.

Preparation and review of cost estimates through project completion is the responsibility of an independent centralized Cost Engineering Office within the design agency. The Cost Engineering Office will provide independence and consistency with training, software, and cost estimating practices. In concert with this responsibility, the cost engineer must be accountable for the comprehensiveness, documentation, credibility and accuracy completeness, quality, accuracy and the reasonableness of the cost estimate. The project manager (PM) will disclose to the cost engineer the intended recipient(s) of the cost estimate and the reason the cost estimate is being produced.

2-2.2 Preparation.

Cost estimates may be prepared in-house or by contract. When it is necessary to contract services for the preparation of cost estimates, such services will be provided by competent firms experienced in cost engineering. Other specific needs, submittals, and requirements are to be provided to insure a complete understanding of the cost engineering requirements. These supplementary requirements are to be included as part of a comprehensive contract scope of work.

2-2.3 Review.

Cost estimates, whether prepared in-house or by contract, will be given an independent review by government cost engineers as prescribed by the cognizant agency review procedures. The cost estimate is to be reviewed for the purpose of confirming the validity of the assumptions and the logic used in estimating the cost of construction tasks. The review is to include a check of the quantities, unit prices, arithmetic, and include a comparison to any other available historical data. It is important that the reviewer develops and completes a review checklist to assure that important considerations have not been overlooked (see sample checklist provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05). The review checklist may be customized based on the nature of the work and the design stage. Cost estimates are not to be released until receiving review and approval.

2-2.4 Presentation to Management.

A cost estimate is not considered complete until management, as defined by the cognizant agency, has approved it. Refer to the cognizant agency for specific requirements. Because many cost estimates are developed to support a budget request or make a decision between competing alternatives, it is vital that management is presented with information on how the cost estimate was developed, including risks associated with the underlying assumptions, data, and methods. Therefore, the cost estimator presents management with enough detail to easily defend the cost estimate by showing how it is complete and high in quality. The information in a cost estimate presentation succinctly illustrates the main cost drivers and the final cost estimate, and is to match the information in the cost estimate documentation.

2-3 TEAM INVOLVEMENT.

Cost engineers are important members of the project delivery team (PDT). The cost engineer is expected to have a clear understanding of those responsibilities and areas where contributions can be made. It is imperative that the team concept be enhanced and supported by each member. As such, the cost engineer is encouraged to lead in cost issues and provide ideas for cost control and sharing measures. The cost engineering team will develop a cost estimating plan. The plan will state who is on the cost engineering team and the schedule for completion dates of the cost engineering products at each design stage.

2-4 PROGRAM SPECIFIC REQUIREMENTS.

In the MILCON and O&M programs, cost estimates are prepared throughout the planning, design, and construction phases of a construction project. These cost estimates may be categorized as follows: Programming & Budgetary, Current Working Estimate (CWE), and Independent Government Estimate (IGE).

2-4.1 Programming and Budgetary Estimates.

In the planning phase, the cost estimate is called a programming estimate and is prepared on a Department of Defense form, DD Form 1391. Develop this programming estimate based on preliminary construction scope or mission requirements. Refer to UFC 3-730-01 for criteria and standards for development and preparation of programming cost estimates for constructing military facilities.

2-4.2 Current Working Estimates.

Current working estimates for projects may be categorized as 15%, 35%, 50%, 65%, 95%, or 100% stages of design as examples. For Design-Bid-Build (DBB) projects the CWE’s are refined more during their respective phases, in order to match the increased definition of the design criteria and project requirements. CWE’s for Design-Build (DB) projects are based upon RFP performance and prescriptive specifications. A technical baseline document will be developed by the design team at the earliest possible design phase to define the project. The technical baseline document describes the acquisition strategy, the work breakdown structure, and how the project will perform its purpose.

2-4.3 Independent Government Estimate.

The last stage of development is the IGE. For DBB projects the IGE is based on the Ready to Advertise (RTA) set of the plans and specifications and contract amendments. The RTA set of plans and specification is typically considered the corrected final incorporating all back checked review comments. For DB projects the IGE is based upon the final RFP performance and prescriptive specifications and contract amendments. The IGE is the cost estimate that is provided for procurement.

2-4.4 Independent Cost Estimate.

An Independent Cost Estimate (ICE), is conducted by an organization independent of the cognizant design agency, it is based on the same construction scope used for the cost estimate. ICEs are used primarily to validate cost estimates and are reconciled with them. Because the team performing the ICE is independent, the ICE provides an unbiased test of whether the cost estimate is reasonable. The ICE is also used to identify risks related to budget shortfalls or excesses.

2-5 LIFE CYCLE COST (LCC) STUDY SUPPORT.

Quality management policy requires LCC studies to be performed to evaluate system alternatives. The alternative analyses are the responsibility of the design team. Cost engineering provides the cost estimating input for the LCC analyses. As preparation to such responsibility, the cost engineer is to be familiar with the LCC procedures.

2-6 COST ESTIMATE FORMAT STRUCTURE.

It is important that the format of the cost estimate be as consistent as possible. UNIFORMAT II (ASTM Standard E1557-09) has been established for this purpose: This is a hierarchical presentation of the scope of work. It provides a common, ordered hierarchy framework for summarizing information and for quantitative reporting to customers and management. The purpose of this format is to: (1) provide an organized manner of collecting project cost data in a standard format for cost reporting and cost tracking; (2) provide a checklist for categorizing costs; and (3) provide a basis to maintain historical cost data in a standard format.

2-7 WORK BREAKDOWN STRUCTURE (WBS).

2-7.1 Military Construction Program.

The MILCON process is formally structured to comply with the DOD’s Planning, Programming, Budgeting, and Execution (PPBE) process for resource allocation.

The common elements of the MILCON program are as follows:

- Planning and Programming: All effort of technical and functional activities associated with identifying the requirement, prioritizing, justification, and requesting funds for a project.
- Program Management: The business and administrative of planning, organizing, coordinating, tracking and controlling the overall program objectives as they apply to a specific program.
- Design and Construction: Develop plans, specifications, cost estimate, solicit bidders, execute the contract and construct the project. This UFC is focused on the design and construction component.
- Delivery: Provide final product to the owner/stakeholder.

2-7.2 Facility Construction WBS.

The goal of this work breakdown structure (WBS) is to establish a standardized classification of building elements and related sitework. These elements are major components to most facilities and perform a given function, regardless of the design specification, construction method, or materials used. Using the WBS ensures consistency in project management, data collection, and economic evaluation of projects over time and from project to project.

UNIFORMAT II (ASTM International E1557-09) provides a common framework for preparing cost estimates, developing models, and collecting cost data for Department of Defense (DOD) military construction projects. It is to be used for categorizing facility costs and associated supporting facility costs for conventional military construction projects. This WBS is comprised of a collection of six building related elemental system classifications, and a collection of one sitework elemental building classification system. Each system is organized in a hierarchical structure with multiple sub-elements. Detail items or assemblies can be entered at an appropriate level within the hierarchy. An example of the UNIFORMAT II WBS structure is shown to Level 4 below:

Level 1 – Major Group Elements
Example: A - SUBSTRUCTURE
    Level 2 – Group Elements
    Example: A10 - Foundations
        Level 3 – Individual Elements
        Example: A1010 – Standard Foundations
            Example Level 4 Elements from Appendix X1.1 of E1557-09
            Example: A101001 – Wall Foundations

Table A-1 in Appendix A lists the UNIFORMAT II elements to Level 3.

2-7.2.1 Measure.

A unit of measure is associated with each level of the WBS and must be followed in every cost estimate to facilitate the estimating review process. This will allow cost estimates to be compared to other similar project cost estimates.

2-7.2.2 Numbering Structure.

The complete hierarchical structure is defined in ASTM Standard E1557-09. An example is shown in Appendix A, Table A-1.

2-8 DEGREE OF DETAIL.

2-8.1 Construction Tasks.

Cost estimates within the scope of this manual will be prepared on the basis of calculated quantities and unit prices that are commensurate with the degree of detail of the design known or assumed. This is accomplished by separating construction into its incremental parts. These parts are commonly referred to as construction tasks and are the line-by-line listings of every cost estimate. Each task is then defined and priced as accurately as possible. Tasks are seldom spelled out in the contract documents, but are necessary for evaluating the requirements and developing their cost.

2-8.2 Analyzing Construction Tasks.

When analyzing construction tasks in a cost estimate, the cost engineer identifies the tasks that account for the major costs in the cost estimate. These tasks can be identified by applying the Pareto Principle (80/20 rule), which states that approximately 80% of the project cost is contained in 20% of the items. Because these significant items account for most of the project cost, they receive prime emphasis and effort in both preparation and review.

2-8.3 At the Most Detailed Level.

At the most detailed level; each task is usually related to and performed by a crew. The cost engineer develops or selects the task description by defining the type of effort or item to be constructed. Task descriptions are to be as complete and accurate as possible to lend credibility to the cost estimate and aid in later review and analysis. An example of a detailed manually prepared cost estimate is provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05. Whenever a significant amount of design assumptions are necessary such as in design-build process, the cost engineer leverages cost data from previous similarly designed projects or use parametric estimating models.

2-9 RELIABILITY.

GAO uses the term "reliable" to describe the standard in quality for cost estimating. A reliable cost estimate is defined as well documented, comprehensive, accurate, and credible.

Accuracy and completeness are critical factors in cost estimates. An accurate and complete cost estimate establishes accountability with the cost engineer and enables management to place greater confidence in the cost estimate. Given the probabilistic nature of cost estimating, a point estimate does not provide the best picture of the accuracy of the estimate. That requires accounting for the amount of variation inherent in the cost estimate. A given point estimate is one cost estimate in a range of cost estimates. A more complete understanding of accuracy, therefore, is provided by indicating where a given point estimate falls in a range of possible cost estimates.

2-10 ROUNDING FIGURES.

For preliminary or alternative cost estimates, when design details are limited, the cost estimate may be rounded based on the experience of the cost engineer, whereby the end cost is not significantly affected.

Rounding the total cost of military construction projects to the nearest thousand dollars for design estimates and Independent Government Estimates (IGE) is acceptable for reporting purposes.

2-11 SAFEGUARDING COST ESTIMATES.

Although not required by regulations, cost estimates based on less than completed design must be handled in a discretionary manner. Access to each cost estimate and its contents will be limited to those persons whose duties require knowledge of the cost estimate. Cost estimates prepared by A-E's will also be similarly handled. Architect-Engineer (A-E) contracts must provide a letter of transmittal that includes the following statement: "To the best of my knowledge the confidential nature of this cost estimate has been maintained." for each cost estimate submitted to the Government. This statement must be signed, dated, and maintained until the official markings have been removed. Any request by the public for information and pricing in the cost estimate will not be provided until coordination, verification of data, and approvals have been given by the commander or designated authority. Procedures for safeguarding the cost estimate are to be in accordance with the design agency's requirements.

2-12 SECURITY AND DISCLOSURE OF INDEPENDENT GOVERNMENT ESTIMATE.

2-12.1 Contents of the Independent Government Estimate.

The Independent Government Estimate (IGE) normally consists of a title page, signature page, and bid schedule. Supporting documents that are publicly available as parts of the solicitation (such as plans, specifications, and project descriptions) are not part of the IGE. IGEs for contract awards and contract modifications are treated the same.

2-12.2 Access to the Independent Government Estimate.

Access to the IGE and its contents will be limited to personnel whose duties require they have knowledge of the subject. When an A-E is responsible for preparing any such IGE, the A-E submittal includes a list of individual's names that have had access to the total amount of the IGE. Government personnel also sign the same or a similar list. A list similar to the "Sample Control Record for IGE", provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05 is filed with the IGE.

2-12.3 Marking the Independent Government Estimate.

The IGE will be marked in accordance with DODINST 5200.48 and cognizant design agency requirement. The IGE will ensure that the protective marking "Controlled Unclassified Information" (CUI) is properly applied to pertinent documents, computer files, compact discs (CDs), printouts, and other documents prepared manually or electronically for incorporation into the IGE.

2-12.4 Disclosure Outside of the Government.

After contract award, ordinarily, only the title page, signature page, and bid schedule are disclosed outside the Government. The IGE back-up data is not released since it contains sensitive cost data (e.g., contractor quotes, crews and productivity) that are proprietary or might compromise cost estimates for future similar procurement.

2-12.5 Bid Protests and Litigation.

During bid protests and litigation, if appropriate and to the extent possible, Counsel should have the IGE and the IGE back-up data placed under a "protective order." There are valid reasons for not releasing the IGE back-up data supporting the IGE to the contractors. In the case of a bid protest, there is a possibility that the contract could be re-advertised or converted to a negotiated procurement. Release of the IGE back-up data would provide bidders with the detailed cost data that supports the IGE. If, however, the apparent low bidder protests the details of the IGE, the Command may provide the IGE and IGE back-up data, to the protestor only, upon receipt of complete details of the protestor's cost estimate. If the protest is not sustained and the proposal is re-advertised, bidders are entitled to have the same information as the protestor.

2-13 RELEASE OF INDEPENDENT GOVERNMENT ESTIMATES UNDER THE FREEDOM OF INFORMATION ACT (FOIA).

The IGE and IGE back-up data, prepared for construction contracts and modifications, are sensitive procurement information and in many cases are withheld under the FOIA.

2-13.1 Definitions.

- The IGE consists of a title page, signature page, and bid schedule.
- The IGE back-up data is the detailed cost data, which includes production and crew development methodology, labor, equipment and crew back-up files, subcontractor quotes and other data identified on agency approved cost estimating software as detail sheets.
- Fair market price determinations, under the Small Business Program, Federal Acquisition Regulations (FAR) 19.202-6, will be treated as the IGE for purposes of this guidance.
- Supporting documents that are publicly available as part of the solicitation, such as plans, specifications and project description, or that contains no

cost information, such as sketches, soil borings and material classifications, are not part of the IGE or back-up data.

2-13.2 Requests for Independent Government Estimates and Back-Up Data.

IGE's and IGE back-up data are intra-agency memoranda, which may be withheld under FOIA Exemption 5, "confidential commercial information" and "deliberative process" privileges. Proper use of Exemption 5, however, requires a showing that release of information will harm the Government's interests. Therefore, requests for IGE and back-up data will be reviewed on a case-by-case basis, based on the following guidance, to determine whether release will harm the interests of the Government. In reviewing requests, the FOIA Officer will seek the assistance of the cost engineer. If the FOIA Officer determines that release will harm the interests of the Government, the information will be withheld.

2-13.2.1 Sealed Bid Procurement.

When sealed bidding is used, neither the IGE nor the IGE back-up data is to be released prior to bid opening. See FAR 36.203(c), 36.204. It is well established that release of IGE's and back-up data before contract award would harm the interests of the Government. Refer to FAR 36.203, Federal Open Market Committee v. Merrill, 443 U.S. 340 (1979), Morrison-Knudson v. Department of the Army, 595 F. Supp. 352 (D.D.C. 1984), aff'd 762 F.2d 138 (D.C. Cir 1985).

2-13.2.2 Post Bid.

The IGE will normally be released when bids are opened. In some instances, however, the IGE will not be released at that time, such as when bids received are non-responsive and a re-procurement is envisioned.

2-13.2.3 Negotiated Procurement.

In negotiated procurement for construction under FAR Parts 15 and 36, the IGE will not be released prior to contract award, except that Government negotiators may disclose portions of the IGE in negotiating a fair and reasonable price, see FAR 36.203(c).

2-13.2.4 Back-Up Data.

The IGE back-up data will not be released. Release of IGE back-up data after contract award and before completion of a construction contract may also result in harm to the Government. The IGE back-up data is used to develop cost estimates for modifications and claims. Release of the backup data prior to contract completion provides the contractor with the details of the Government's position and would allow the contractor to develop a biased price proposal. This could harm the Government's ability to negotiate a fair and reasonable price for the modification or claim, putting the Government at a serious commercial disadvantage. Moreover, knowledge of the construction methods contemplated by the Government might reduce the contractor's incentive to discover less expensive methods. This could also reduce the contractor's incentive to locate and charge out materials at a lower cost, or to achieve project goals using less labor and equipment. See Quarles v. Department of the Navy, 983 F.2d 390, (D.C. Cir 1990). Taylor Woodrow International, Ltd. V. Department of the Navy, No. 88-429R, (W.D. Wash. Apr 6, 1989).

CHAPTER 3 BASICS FOR PREPARATION OF COST ESTIMATES

3-1 GENERAL.

This chapter establishes uniform guidance to be used prior to cost estimate preparation. In the normal sequence of events toward the preparation of any cost estimate, it is of utmost importance to understand basic fundamental principles and responsibilities. Cost estimates consist of:

- Descriptions of work elements to be accomplished (tasks).
- A quantity of work required for each task.
- A cost for each task quantity.

A unit cost for each task is developed to increase the accuracy of the estimating procedure and to provide a reference comparison to historic experience. Lump sum cost estimating when used at the task level must be fully documented to show the intent and extent of the item.

3-2 PLANNING THE WORK.

The cost engineer must thoroughly understand the construction scope of work and the biddability, constructability, operability, environmental, sustainability (BCOES) aspects of the project being estimated. The cost engineer must review available resources including design analysis, drawings, and specifications. The cost engineer must also consider construction sequences, durations, and site conditions to determine total construction costs. A site visit is strongly recommended to enable the cost engineer to relate the physical characteristics of the project to the available design parameters and details. This is particularly important on projects with difficult site conditions, major maintenance and repair projects, and alteration/addition projects. The construction sequence must be developed as soon as possible and used to provide a checklist of construction requirements throughout the cost estimating process. The overall format of major cost elements in a cost estimate must be compatible with current standards, management needs, the anticipated bidding schedule, and the appropriate WBS.

3-3 QUANTITIES.

The quantity “take-off” is an important part of the cost estimate. It must be as accurate as possible, and be based on available engineering and design data.

- After the scope has been analyzed and broken down into the construction tasks, each task must be quantified prior to pricing. Equal emphasis is placed on both accurate quantity calculation and accurate pricing. Quantities are to be shown in standard units of measure and consistent with design units. Assistance for preparing “take-off's” may be provided by others within the organization in support of cost engineering or by A-E contracts; however, the responsibility for the accuracy of the quantities remains with the cost engineer.

- The detail to which the quantities are prepared for each task is dependent on the level of design detail. Quantity calculations beyond design details are often necessary to determine a reasonable price to complete the overall scope of work for the cost estimate. Project notes will be added at the appropriate level in the cost estimate to explain the basis for the quantity calculations, to clearly show contingencies, and to note quantities determined by cost engineering judgment that will be reconciled upon design refinement.
- For Design-Build contracts the cost engineer is provided a proof of concept (pilot project design, which demonstrates that a design concept is feasible) from the design team in which reasonable quantities and scope can be derived to establish the baseline cost estimate. The proof of concept addresses the RFP requirements so that the project delivery team can verify the scope can be built within budget.

3-4 TYPES OF COSTS.

Various types of cost elements must be evaluated in detail.

- Direct costs are those costs, which can be attributed to a single task of construction work. These costs are usually associated with a construction labor crew performing a task using specific equipment and materials for the task. Labor foreman cost is normally considered a direct cost. Subcontracted costs are considered as direct costs to the prime contractor in cost estimates.
- Indirect costs are those costs which cannot be attributed to a single task of construction work. These costs could include but are not limited to mobilization, demobilization, supervision, overhead, profit, and bond. Indirect costs are also referred to as distributed costs. When a percentage factor is used, an engineer’s cost estimate is developed to verify the adequacy of the percentage factor used. For example, thru the use of an estimated construction schedule, the superintendents, quality control manager, safety officer, and trailers monthly costs multiplied by the number of required months from the schedule is compared to the resultant of the percentage factor used for JOOH to verify if the percentage used is in the right order of magnitude.
- Cost estimates based on detailed design will be developed from separate direct cost pricing of labor, material, construction equipment, and supplies. Applicable indirect costs will be added to reflect the total construction cost. Other costs, including escalation, design contingencies, design-build design costs, building commissioning, sustainment, construction contingencies, construction supervision, inspections and overhead (SIOH), and Operation and Maintenance (O&M) Manuals, may be added to the cost estimate to determine the total project cost as required by program specific requirements. These costs are often applied as multipliers at various levels in the cost estimate and distributed across the

items within that level. In some cases, there may be specific tasks costs developed for such items. For Design/Construction Contingency and DB Design Costs a cost estimate is developed to verify the adequacy of the percentage factor used.

3-5 COST SOURCES.

Typically, there are various cost sources available to the cost engineer. In obtaining costs from any source, experience and ability to relate data in hand to a specific circumstance is important. The following discussion is provided on commonly used sources and source development.

3-5.1 Cost Book

The Cost Book is the common name for the Tri-Services construction direct costs database. It contains repetitive construction tasks with direct cost pricing (labor, equipment, material) based on a typical crew and production rate for new construction. Some Cost Book line items may include quotes for work that is fully provided and installed by subcontractor. Quotes for work fully priced by subcontractor must be clearly identified. Each office is encouraged to use this cost source and to refine the project database to more accurately reflect local costs at the project site (i.e., obtain quotes, adjust productivity, assess crew makeup).

3-5.2 Historical Data.

Historical costs from past similar work are excellent pricing sources when adequate details have been saved and adjustment to project specifics can be defined. Portions of other cost estimates having similar work can be retrieved and repriced to the current project rates. Automated historical databases are discussed in Appendix B. Historical data is consistently gathered, organized for ease of access, and analyzed for trends. MILCON historical data is utilized to develop the guidance unit costs provided in Chapter 2 of UFC 3-701-01.

3-5.3 Parametric Database.

A parametric database of predefined assemblies for buildings and sitework has been developed and is discussed in Appendix B.

3-5.4 Development of Specific Tasks.

When Cost Book items do not meet project needs, specific new cost tasks may need to be developed. Such development requires experience. Descriptions developed must adequately define the scope and material requirement for each task. Unit cost for each task is developed as a direct cost with separate costing for the labor, equipment, and material components. Notes, which explain key factors in the pricing and methodology, accompany the task development. Comparison with existing pricing guides is recommended.

- Labor unit cost - This cost is based on a defined crew from the Cost Book or on a newly developed crew, which performs the tasks at an assigned production rate. Hourly rates for each craft are applied to the crew labor to arrive at the hourly crew labor cost. The total crew labor cost/hour is divided by the expected production rate (units/hour) to derive the labor cost/unit.
- Equipment unit cost - This cost is derived similar to labor unit cost. Hourly equipment rates are obtained from the appropriate regional manual, entitled, Construction Equipment Ownership and Operating Expense Schedule (herein referenced as, Equipment Ownership Schedule), Engineer Pamphlet (EP) 1110-1-8 or developed according to the methodology as described in this pamphlet.
- Material unit cost - This cost is developed using vendor quotes, historical costs, commercial pricing sources, or component calculations. The price is to include delivery to the project site.
- Commercial unit cost books - These common sources are typically available through subscription or purchase. Basis of costs shown are typically explained along with adjustment methodology. Such publications are valuable for verification and appropriate for commercial type work item pricing.

3-6 COSTS AND PRICING.

The cost for each task is developed by summing the direct cost elements for materials, labor, and equipment. The indirect costs and other markups associated with each task or work item are identified and are considered separately for the specific project.

3-6.1 Minor Direct Costs.

The direct cost on construction tasks of minor overall cost significance and of a repetitive nature can normally be priced from any of those sources discussed above.

3-6.2 Historical Pricing.

When using historical pricing, adjustments must be made for project location, work methodology, quantity of work, and escalation to current price level, and other dissimilarities, which affect prices.

3-6.3 Lump Sum Items.

Use of lump sum items is discouraged. If lump sum items are used in the cost estimate, they must have backup cost data relating to their tasks and source of the data.

3-6.4 Detailed Backup of Cost.

As a general rule-of-thumb, it is highly recommended that when a task extended direct cost is 5 percent or more of the total direct cost, a detailed backup for the cost is prepared or vendor quotations obtained as pricing support to the cost estimate. Use of the Pareto Principle should be considered.

3-6.5 Predetermined Bid Items.

Applying a similar rule-of-thumb, in some instances, unit price bid items for IGEs may be based on suitable experienced bid prices or historical cost data, i.e., predetermined bid item does not exceed 5 percent or more of the estimated total cost a detailed backup for the cost is prepared as pricing support to the IGE. For cost estimates prepared during preliminary or planning phases, where design is limited or not available, predetermined unit prices adjusted to current pricing level may be used by the cost engineer. Use of predetermined prices are to consider any necessary adjustments in prime contractor's profit or distributed costs appropriate to the contract requirements. The cost engineer must use extreme care and sound judgment when using predetermined unit costs. The basis for the unit costs is to be well documented and included in the supporting data of the cost estimate. Where a bid item consists mostly of equipment and labor costs, with very little materials and supplies, it is advisable to develop the cost as indicated above, even though the item may fall under this rule-of-thumb.

3-7 COST ESTIMATE FORMAT AND SUPPORTING DOCUMENTATION.

Cost estimates are generally composed of contract costs and other allowable project costs authorized by directives or regulations. The overall format of the cost estimate must be in accordance with the appropriate WBS as described in Chapter 2. The cost engineer is to be aware of the documentation necessary to support the cost estimate submission requirements specified for each phase of project development. Support documentation such as project narrative, bid schedule, estimated construction schedule, backup data, and drawings and sketches are further discussed in Chapter 4.

3-8 MILITARY CONSTRUCTION PROGRAM SPECIFIC REQUIREMENTS.

In addition to costs described in this chapter, the cost estimate for Military Construction projects are to include other costs authorized by directive to be charged to construction as funded cost. These costs include installation costs or installed equipment in place to be furnished by the using service or other agency, and the cost of Government-Furnished Materials (GFM) or Government-Furnished Equipment (GFE) purchased with construction funds and furnished to the contractor without reimbursement.

3-9 UPDATING COST ESTIMATE.

At each project development milestone including solicitation amendments, the cost estimate must be updated with current costs so that it is always relevant and current. The continual updating of the cost estimate as the project matures not only results in a more accurate cost, but also gives opportunities to incorporate lessons learned. Future cost estimates can benefit from the new knowledge. For example, cost or schedule variances resulting from incorrect assumptions are thoroughly documented so as not to repeat those mistakes on future cost estimates. Finally, actual cost is collected and archived in the Historical Analysis Generator Second Generation (HAG/HII) historical database for use in supporting new cost estimates.

CHAPTER 4 COMPOSITION OF INDEPENDENT GOVERNMENT ESTIMATES

4-1 GENERAL.

Well-documented cost estimates are considered a best practice for high-quality cost estimates for several reasons.

- First, thorough documentation is essential for validating and defending a cost estimate. That is, a well-documented cost estimate can present a convincing argument of a cost estimate's validity and can help answer decision-makers' and oversight groups' probing questions.
- Second, documenting the cost estimate in detail, step by step, provides enough information so that someone unfamiliar with the program could easily recreate or update it.
- Third, good documentation helps with analyzing changes in program costs and contributes to the collection of cost and technical data that can be used to support future cost estimates.
- Finally, a well-documented cost estimate is essential, if an independent review or audit is performed, to ensure that it is valid and reliable. It also supports reconciling differences with an independent cost estimate, if performed, by improving understanding of the cost elements and their differences so that decision-makers can be better informed.

Documentation provides total recall of the cost estimate's detail so that it can be replicated by someone other than those who prepared it. It also serves as a reference to support future cost estimates. Documenting the cost estimate makes available a written justification showing how it was developed and aiding in updating it as key assumptions change and more information becomes available.

The IGE is the final approved cost estimate submitted to the Contracting Officer to support contract award. Each Agency may have its own requirements and procedures. The presentation format for this type of IGE generally is: Independent Government Estimate of Construction Cost, Basis of Estimate (BOE), IGE back-up data, and miscellaneous support data. Sample IGE sheets are provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05. Security and control of the IGE is described in Chapter 2.

4-2 INDEPENDENT GOVERNMENT ESTIMATE OF CONSTRUCTION COST.

The Independent Government Estimate (IGE) of Construction Cost is to be submitted as required by procurement regulations. It includes the protective cover page, title page, signature page, and bid schedule.

4-2.1 CUI Cover Page.

The IGE must include a CUI cover page per section 2-8.3.

4-2.2 Title Page.

The title page must include the name and location of the project, the office responsible for the project design, the cost engineer responsible for preparation of the IGE, and the submittal date.

4-2.3 Signature Page.

The signature page contains the names and signatures of those individuals responsible for the preparation, review, submittal, and approval of the IGE. It is necessary that the signature page contain the total amount of the estimated costs so that there will be no question as to the approved total amount. The number of amendments included in the IGE appears on the same page so that there will be no question whether the IGE accounts for all amendments.

4-2.4 Bid Schedule.

The bid schedule required by the solicitation documents must be completed as part of the IGE. As part of the design team, the cost engineer is involved in the development of the bid schedule. The format of the bid schedule must be anticipated and discussed as early in the planning process as possible. It is important that the bid schedule includes meaningful scopes of work elements structured to aid in evaluation and historical data collection. When the bid schedule is finalized for procurement, it must show unit prices, quantities, extension of unit prices, lump sum items, and total costs. Rounding off is not permitted on the bid schedule between the unit price and extension. Refer to Price Schedule (https://www.wbdg.org/ffc/navy-navfac/project-information-form-specifications-cover-sheet/price-schedule) for the minimum bid schedule items.

4-3 BASIS OF ESTIMATE (BOE).

Two important criteria are to be kept in mind when generating high-quality cost estimate documentation. First, document the cost estimating process, data sources, and methods. Second, present the results of the estimating process in a format that makes it easy to prepare reports and briefings to upper management and stakeholders.

Cost estimators document the steps used to develop the cost estimate. As a best practice, the cost estimate documentation addresses how the cost estimate satisfies the guidance used to govern the creation, maintenance, structure, and status of the cost estimate. It contains discussions, considerations, and the developed construction plan.

4-3.1 Cover Page and Table of Contents.

This page denotes the project name, date, milestone, names of the cost estimators and the organization they belong to.

4-3.2 Executive Summary.

This section provides at the minimum the following information:

- Summarizes clearly and concisely the cost estimate results, with enough information about cost drivers and high-risk areas for management to make informed decisions
- Identifies critical ground rules and assumptions
- Identifies data sources and methods used to develop major WBS cost elements and reasons for each approach
- Discusses independent cost estimate (ICE), if performed, results and differences and explains whether the point estimate can be considered reasonable
- Discusses the results of a sensitivity analysis, the level of uncertainty associated with the point estimate, and any contingency recommendations

4-3.3 Cost Estimate Purpose.

This section provides the cost estimates purpose, need, and submittal. If the cost estimate needed to be revised, note and identify the purpose of the revision.

4-3.4 Construction Scope and Assumptions.

The construction scope description provides detail to give a clear understanding of the scope of work. The construction scope description defines the assumptions made during the preparation of the cost estimate. It describes the project requirements that must be performed in sufficient detail to give a clear understanding of the scope of work. It also describes project details including length, width, height and shape of primary features, special problems that will be encountered in performing the work, site conditions affecting the work, reasons for selection of major plant and equipment, method and time for mobilization and demobilization of equipment, and the reasons for unusually high or low unit prices. Each cost estimate will include a statement, which relates both the development of design, as appropriate, and date of effective pricing.

The construction scope description defines the assumptions made during the preparation of the cost estimate. Assumptions represent a set of judgments about past, present or future conditions postulated as true in the absence of positive proof. It is important that assumptions developed by the cost estimator are based on input from the technical team.

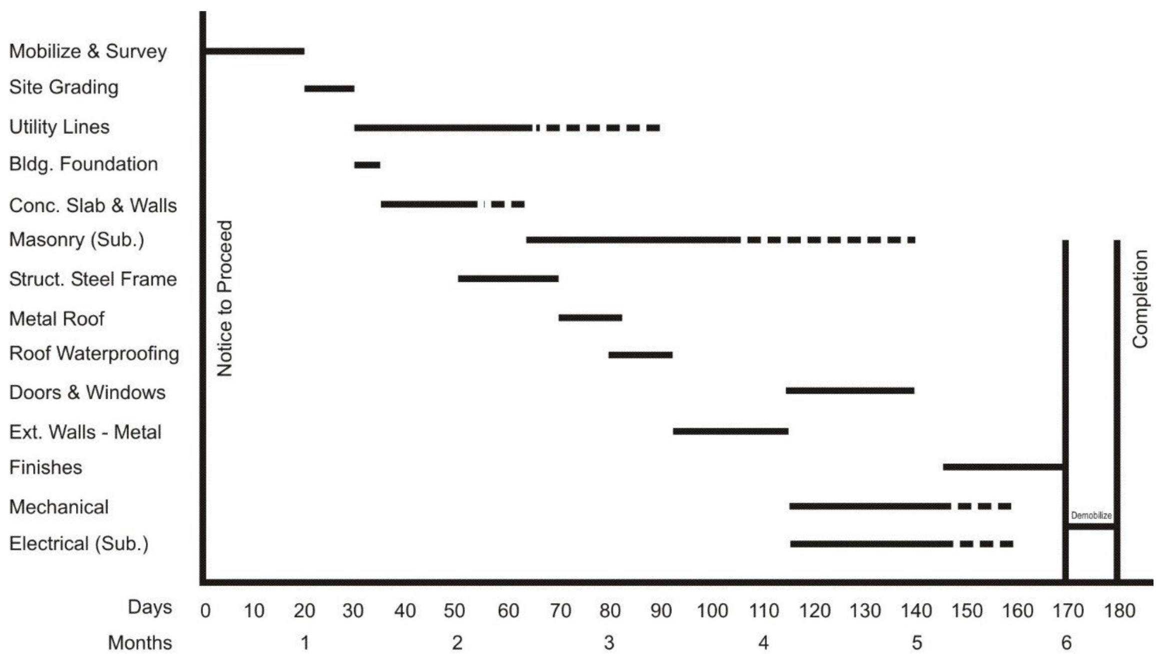
Other factors to be considered in the construction scope description include:

- Construction schedule, use of overtime, construction windows, phasing, acquisition plan and subcontracting.
- Project related details including site access, borrow areas, construction methodology, unusual conditions (soil, water or weather), unique techniques of construction, equipment/labor availability and distance traveled, environmental concerns, contingencies by feature or sub feature, if appropriate, and effective dates and sources for labor, equipment and material pricing.

4-3.5 Estimated Construction Schedule.

The cost engineer prepares a construction schedule to support the cost estimate that is consistent with the schedule for completion of the project. It may be in the form of a bar chart or network analysis system (see Figure 4-1 for an example). It must identify the sequence and duration of the tasks upon which the cost estimate is developed. The schedule considers holidays, non-workdays, and weather days as supplied in the specifications. The schedule must be prepared in sufficient detail to adequately develop the required labor, equipment, crew sizes, and production rates required for each of the identified construction tasks. In addition, it will support the development of the duration of the job office overhead. The construction schedule is reviewed by the project delivery team.

Figure 4-1 Construction Schedule Example



4-3.6 Sensitivity Analysis.

- Describe the effect of changing key cost drivers and assumptions independently
- Identify the major cost drivers that to be closely monitored

4-3.7 Risk and Uncertainty Analysis.

- Discuss sources of risk and uncertainty, including critical assumptions, associated with the cost estimate as developed by the CSRA
- Document the effect of uncertainty associated with the point estimate is quantified with probability distributions, and the resulting S-curve; the

method for quantifying uncertainty is discussed and backed up by supporting data

- Discuss risk distributions and correlation between WBS elements
- Describe the basis for contingency and how it was calculated.

4-3.8 Equipment and Materials Utilization.

On those projects involving considerable heavy construction equipment, it is necessary to sufficiently plan the equipment usage against the construction work schedule to identify the actual number of cranes, dozers, and allow for proper mobilization to assure that demand for the equipment is not over or understated. Equipment references are to be provided which indicate the region and date of the equipment library used for pricing the equipment. Materials, which require long lead-time and can become critical to the construction schedule are to be noted, planned, and adequately considered.

4-3.9 Labor Discussion and Utilization.

The cost estimate clearly states the sources for the various labor classifications and rates and include tabulation by crafts of the various composite wage rates used. When extensive overtime beyond the normal workday is used in the cost estimate, an explanation is to be included.

4-4 INDEPENDENT GOVERNMENT ESTIMATE BACKUP DATA.

This part of the IGE consists of the support and backup documentation. The various categories of support documentation contained in this part are:

- Cost estimate summary sheets. The automated or manually prepared summary sheets for direct, indirect and owner costs are used to summarize cost components for each bid item and by the appropriate Work Breakdown Structure. Distribution of overhead and profit is shown on this sheet.
- Mobilization, preparatory work, and demobilization. These costs are to be itemized and costed separately. These costs may be combined at summary level with overhead if these costs are not paid as a separate bid item.
- Profit computation sheet. When profit is included, the weighted guidelines will be used to compute the profit and will be part of the cost estimate backup.
- Overhead costs. The itemization and calculations of overhead costs, both job site and home office, are to be accomplished in accordance with Chapter 10.
- Bond costs. Bond costs are to be calculated in accordance with Chapter 12. Distribution is made to bid items similar to or as part of overhead costs distribution.

- Automated detail sheets. The completed direct costs are to be organized in the proper sequence by the appropriate Work Breakdown Structure for each bid item.
- Production rates. The automated or manually prepared details are used to express production rate analysis of crews. See Chapter 6 for further discussion.
- Crew, labor, equipment rates. These automated or manually prepared details are used to express the crew composition, and associated rates for labor and equipment costs. The information contained on these sheets provides the backup support for the task unit labor and equipment costs shown.
- Quantity computations. The quantity takeoff computations for the tasks estimated, are organized by task for the bid items and kept as backup. The takeoff references the drawing and clearly explain the computation.
- Quotations. Quotations are to be collected and compiled by task or bid item into an organized reference. When quotations were not obtained for significant material and supply items, the basis for the cost used is fully described. Quotations are considered proprietary information and kept confidential to protect the information entrusted to the cost engineer.

Projects outside continental United States (OCONUS) are to include International Balance of Payment (IBOP) analysis under normal or revised procedures. Cost estimates will not include the IBOP statement but the documentation will be retained at the cognizant design agency office. The projects will be evaluated for IBOP impact in accordance with DODI 7060.2, Federal Acquisition Regulation (FAR) 25-300 and Defense Federal Acquisition Regulation Supplement (DFARS) 225.75. Countries exempt from IBOP analysis are listed in DFARS 225.872-1.

4-5 MISCELLANEOUS SUPPORT DATA.

Include other information pertinent to the cost estimate such as drawings, sketches, and a listing of similar projects that may be relevant for comparison, which were used as the basis of the cost estimate. Drawings may include a project map showing the location of the work with respect to principal cities, roads, railways, and waterways; a site map showing the location of the work, borrow, quarry, and spoil areas, and existing work access roads; any existing facilities usable by the contractor; a general plan and elevation, or profile of the work with typical sections; and a construction layout.

Supporting documents that are publicly available as parts of the solicitation, such as plans, specifications and project description, or that contain no cost information, such as sketches, soil boring and material classifications, are not part of the IGE or back-up.

4-6 REQUIREMENTS FOR REVISION TO INDEPENDENT GOVERNMENT ESTIMATE.

The IGE may be changed or revised as a result of errors, differing conditions or additional information. Approval authority for revision to the IGE remains the responsibility of the Contracting Officer or authorized original IGE-approving official. Each office assures that appropriate justification is attached to the revised IGE. Any revision to the IGE must be clearly indicated, dated, justified, and approved. A copy of each IGE that has been approved is included in a file along with the details and circumstances reflecting the revisions.

This Page Intentionally Left Blank

CHAPTER 5 LABOR

5-1 GENERAL.

5-1.1 Direct Labor Costs.

Direct labor costs are defined as base wages plus labor cost additives including payroll taxes, fringe benefits, travel, and overtime allowances paid by the contractor for personnel who perform a specific construction task. In addition to the actual workers, there are generally working crew foremen who receive an hourly wage and are considered part of the direct labor costs.

5-1.2 Indirect Labor Costs.

Indirect labor costs are wages and labor cost additives paid to contractor personnel whose effort cannot be attributed to a specific construction task. Personnel such as superintendents, engineers, clerks, and site cleanup laborers are usually included as indirect labor costs (overhead).

5-2 CREWS.

Direct labor cost requirements are broken into tasks of work. Since each task is usually performed by a labor crew including equipment, the crew must be defined, costed, and a production rate established for the task. Crews may vary in size and mix of skills. The number and size of each crew are to be based on such considerations as having sufficient workers to perform a task within the construction schedule and the limitation of workspace. Once the crews have been developed, the task labor costs can be determined based on the production rate of the crew and the labor wage rates.

5-3 WAGE RATES.

A wage rate must be developed for each labor craft, which will represent the total hourly cost rate to the construction contractor. This total rate will include the base wage rate plus labor overtime, payroll taxes and insurance, fringe benefits, and travel or subsistence costs as further described in this chapter. The composite wage rate for each craft will be used for development of the cost estimate. The computation will be prepared on the “Wage Rate Calculations” for provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05 or similar local forms, or cognizant design agency approved cost estimating software.

Wage rates are generally well defined. The Davis-Bacon Act, PL 74-403, requires a contractor performing construction in the United States for the Government to pay not less than the prevailing rates set by the Department of Labor. Information on prevailing rates can be found at sam.gov. A schedule of minimum rates is included in the project specifications and is normally kept on file for each location by each local Office of Counsel. The cost engineer consults with the Contracting Officer on any questions regarding determination coverage, specific definitions, or concerns. Where labor is in short supply for certain crafts in the area, or the work is in a remote area, or it is well known that rates higher than the set rate scale will be paid, these higher wage rates are used instead of the minimum wage since this would be required of the contractor in order to attract labor to the job. The wage rate is adjusted to include travel time or night differential where these are a customary requirement.

For projects in locations not contiguous to the United States and its territories the wage rates are to reflect the prevailing wages being paid for construction labor in the host nation. These are to be fully burdened wage rates, including fringes, insurance and taxes.

5-3.1 Long Duration Projects.

For a long duration project, where future wage rates (i.e., Union Agreements) are known and used, care must be taken to avoid duplication by not applying an escalation rate to such costs.

5-4 OVERTIME AND SHIFT DIFFERENTIAL.

The cost engineer is to carefully consider the available working time in the construction schedule for each task accomplishment in a normal time period. The efficiency of both the second and third shifts are to be adjusted to recognize that production will not be as high as the day shift for most types of construction operations. A three-shift operation is normally avoided due to lower labor efficiency and the requirement to include equipment maintenance.

5-4.1 Overtime.

Overtime is to be included in the labor cost computation when work in excess of regular time is required by the construction schedule or is the custom of labor in the local vicinity. Overtime labor cost is normally calculated as a percentage of the base wage rate. It is usually based on time and one-half, but may be double time depending on the existing labor agreements. Tax and insurance costs are applied to overtime, but fringe benefits and travel and subsistence costs are not. Figure 5-1 shows an example of overtime calculation for 40 hours regular time, plus 8 hours overtime at time and one half:

Figure 5-1 Overtime Calculation

OVERTIME CALCULATION EXAMPLE	
48 hours at Straight Time	= 48.00 hours
8 hours at ½ Time	= 4.0 hours paid
Equivalent Straight Time	=52.00 hours
(52 hours paid/48 hours worked = 1.0833) - 1 x 100% = 8.33%	
Note: Refer to the Related Material on WBDG.org for example estimate sheets for method of application	

5-4.2 Shift Operations.

Many construction projects utilize multiple shift operations. When estimating direct labor costs for multiple shift operations, the cost engineer estimates the number of hours to be worked (include shift differential work loss) and the number of hours to be paid for each shift based upon the construction schedule. Differential shift premiums may need to be added to the hourly rate.

5-4.3 Tabulation of Overtime Percentages.

A tabulation of overtime percentages for most conditions is provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05. The percentage also includes an allowance for the direct work loss of multiple shift or shift differential, where applicable.

5-5 TAXES AND INSURANCE.

5-5.1 Rates.

Rates for taxes and insurance are to be verified prior to computation.

5-5.2 Workman's Compensation.

Workman's compensation and employer's liability insurance costs applicable for the state in which the work is performed are to be included in the composite wage rate. Insurance rates may be obtained from the state if the state law provides a monopoly or from insurance companies providing this type insurance. The project compensation rate is based on the classification of the major construction work and applies to every craft employed by the contractor.

5-5.3 Unemployment Compensation Taxes.

Unemployment compensation taxes are composed of both state and Federal taxes. Unemployment compensation tax will vary with each state while the Federal unemployment tax will be constant for every project. Insurance rates can be obtained from the state unemployment office, commercial publications, or the Bureau of Labor Statistics.

5-5.4 Social Security Tax Rates.

The social security tax rates and the income ceilings on which social security taxes must be paid vary from year to year. Therefore, the cost engineer must verify the rate to be used in the cost estimate. Current and future rates can be obtained from the Social Security Administration.

5-5.5 Total Percentage of Taxes and Insurance.

The total percentage of the above taxes and insurance is summed and then applied to the basic hourly wage rate plus overtime for the various crafts. Figure 5-2 illustrates the method for deriving the total tax and insurance percentage. Since rates are subject to change and in some cases vary by region, the calculations shown are presented as an example only. Actual values must be determined by the cost engineer for the specific project.

Figure 5-2 Total Taxes and Insurance Percentage

TOTAL TAXES AND INSURANCE PERCENTAGE	
Workman's compensation and employer/s liability (varies with state and contractor)	7.60%
State unemployment compensation (varies with each state)	3.20%
Federal unemployment compensation	0.80%
Social Security & Medicaid	7.65%
Total taxes and insurance	19.25%
Note: Foreman and overhead labor rates must also include these applicable costs. Refer to the Related Material on WBDG.org for example estimate sheets for method of application	

5-6 FRINGE BENEFITS AND TRAVEL/SUBSISTENCE.

5-6.1 Fringe Benefits.

Fringe benefits may include health and welfare, pension, apprentice training, depending on the craft and the location of the work. These summed costs are usually expressed as an hourly cost with the possible exception of vacation, which may be easily converted to an hourly cost. The type of fringe and the amount for the various crafts can usually be found with the Davis-Bacon Act wage determination in the specifications. Non-union contractors pay comparable fringe benefits directly to their employees.

Figure 5-3 illustrates the calculations for fringe benefits. Since the values change and vary by region and union agreement, the calculations shown are presented as an example only. Actual values must be determined by the cost engineer.

Figure 5-3 Fringe Benefits

FRINGE BENEFITS EXAMPLE	
Health and Welfare	$0.70/hr
Pension	$0.75/hr
Apprentice Training (N/A in this case)	$0.00/hr
Total Fringe Benefits	$1.45/hr

5-6.2 Travel and Subsistence.

Travel and subsistence (per diem) costs are normally expressed as a daily or weekly cost. Travel and subsistence may be converted to an hourly cost and excluded from an overtime premium unless travel and subsistence are part of an increased hourly wage. See example estimates provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05 for methodology.

Some fringe benefits and travel/subsistence are subject to payroll taxes. For example, vacation benefits are taxable and added to the basic wage rate.

This Page Intentionally Left Blank

CHAPTER 6 LABOR PRODUCTIVITY

6-1 GENERAL.

Estimating labor productivity is subject to many diverse and unpredictable factors. There is no substitution for the knowledge and experience of the cost engineer when estimating labor productivity. For some types of work, the task productivity of crew members such as equipment operators, helpers, or oilers is determined by the productivity of the equipment. For some labor based crews, the task productivity of craftsman such as carpenters, steel workers, and masons may be based on average experience in the Cost Book, tempered with the experience of the cost engineer, historical records, or other appropriate reference manuals.

6-1 PRODUCTIVITY ADJUSTMENT CONSIDERATIONS.

6-1.1 Labor Effort.

The labor effort needed to perform a particular task varies with many factors, such as the relative experience, capability and morale of the workers, the size and complexity of the job, site specific security requirements, the climatic and topographic conditions, the degree of mechanization, the quality of job supervision, amount of similar task repetition, and the existing labor-management agreements and trade practices. The effort from these labor efficiency factors and work practices that exist in the project locality must be considered in each productivity assignment.

6-1.2 Complexity of the Variable.

The complexity of the variables affecting productivity makes it difficult to estimate a production rate. Therefore, production rates are based on averaging past production rates for the same or similar work. The cost engineer must incorporate particular job factors and conditions to adjust historical data to the project being estimated. Other sources for production rates include reference manuals, field office reports, construction logbooks, and observation of ongoing construction.

This Page Intentionally Left Blank

CHAPTER 7 CONSTRUCTION EQUIPMENT AND PLANT

7-1 GENERAL.

Construction plant and equipment refers to the tools, instruments, machinery, and other mechanical implements required in the performance of construction work. Construction plant is defined as concrete batch plants, aggregate processing plants, conveying systems, and any other processing plants which are erected in place at the job site and are essentially stationary or fixed in place. Equipment is defined as items, which are portable or mobile, ranging from small hand tools through tractors, cranes, and trucks. For estimating purposes, plant and equipment are grouped together as equipment costs.

7-2 SELECTION OF EQUIPMENT.

An important consideration in the preparation of a cost estimate is the selection of the proper equipment to perform the required tasks. The cost engineer is to carefully consider number, size, and function of equipment to arrive at optimum equipment usage. Some factors to consider during the selection process are: conformance to specification requirements; job progress schedule (production rate); magnitude of the job; type of materials; availability of space; mobility and availability of equipment; suitability of equipment for other uses; equipment capabilities; number of shifts; distances material must be moved; steepness and direction of grades; weather conditions; hauling restrictions; standby time; and mobilization and demobilization costs.

The cost engineer preparing the cost estimate must be familiar with construction equipment and job-site conditions. The selected equipment conforms to contract requirements and be suitable for the materials to be handled and conditions that will exist on the project.

7-3 ESTIMATING METHODOLOGY.

The "crew concept" discussed in Chapter 5 for cost estimates requiring detailed estimating of labor, materials, and equipment is to also be considered in costing equipment. For each significant work task, workers and equipment are expressed in the hourly cost and expected production rate. Where a major piece of equipment serves more than one crew, the total equipment time is prorated between both crews.

7-4 PRODUCTION RATE.

After determining the type of equipment to be employed, the cost engineer selects the specific equipment size which has a production rate suited to the efficient and economical performance of the work. The size and number of units required will be influenced by equipment production rate, job size, availability of space for equipment operations, the project construction schedule for the various work tasks, number of shifts to be worked, and the availability of equipment operators. Emphasis must be placed on the importance of establishing a reasonable production rate. Production may be based on actual performance data, commercial manufacturer tables or rates from Micro Computer-Aided Cost Engineering System 2nd Generation

(MCACES/MII)/historical equipment models and assemblies, adjusted for project conditions.

7-5 MOBILIZATION AND DEMOBILIZATION.

Mobilization costs for equipment include the cost of loading at the contractor's yard, transportation cost from the yard to the construction site, including permits, unloading at the site, necessary assembly and testing, and standby costs during mobilization and demobilization. Trucks for the project capable of highway movement are usually driven to the site and are often used to transport minor items. Labor, equipment, and supply costs required to mobilize the equipment are to be included in the mobilization cost. When the equipment location is unknown, the mobilization and demobilization distance should be based on a circular area around the project site, which will include a reasonable number of qualified bidders. Demobilization costs are based on that portion of the equipment that would be expected to be returned to the contractor's storage yard and may be expressed as a percentage of mobilization costs. Labor, equipment, and supply costs required for cleaning/prepping the equipment so that it is in the same condition as it was when it arrived at the site is to be included in the demobilization cost. Transportation rates should be obtained periodically from qualified firms normally engaged in that type work.

Mobilization and demobilization costs for plant are based on the delivered cost of the item, plus erection, taxes, and dismantling costs minus salvage value at the end of the project. Maintenance and repair are operating costs that are distributed throughout work accomplishment.

7-6 EQUIPMENT OWNERSHIP AND OPERATING EXPENSE COST RATES.

The EP 1110-1-8 Construction Equipment Ownership and Operating Expense (includes 12 volumes) determines the hourly rates for equipment ownership and operating expense by region. These regional rates are incorporated into the Cost Book and are to be used in the preparation of cost estimates for owned equipment. These volumes have been developed for different geographic regions in the United States, and the appropriate volume is to be used based upon project location. Rented and leased equipment is also discussed in the EP and is appropriate for inclusion in the cost estimate at competitive rates if judgment determines this to be a reasonable approach.

When the cost engineer develops costs for the actual equipment being used at a job site exceeding 40 hours per week, the rates must be adjusted as described by EP 1110-1-8.

7-7 PLANT COST.

In cases of highly specialized plant, 100 percent write-off of the total value of the plant may be justified for a particular project. For less highly specialized plant, some salvage may be anticipated, depending on storage cost, resale value, and probability of sale or reuse in the immediate future. The total project charge including operation, maintenance, and repair are distributed in proportion to the time and item the plant is used on the various contract items. Cost of plant required for the production of concrete, aggregates, ice or heat for cooling or heating of concrete, etc., is to be included in the cost estimate as part of the cost of these materials or supplies manufactured or produced at the site.

7-8 SMALL TOOLS.

The cost of small power and hand tools and miscellaneous non-capitalized equipment and supplies are estimated as a percentage of the labor cost. The allowance must be determined by the cost engineer in each case, based upon experience for the type of work involved. Unit prices based on historical data already include a small tools allowance. The small tool cost will be considered as part of equipment cost. Such allowance is typically 2 percent of direct labor cost. The cost engineer must ensure that this cost is not duplicated in the overhead rate percentages. The crews in the Cost Book do not contain a small tools allowance.

This Page Intentionally Left Blank

CHAPTER 8 MATERIALS AND SUPPLIES

8-1 GENERAL.

Materials and supplies are defined below, and for the purpose of cost estimating, both can be considered materials unless they need to be separated because of different tax rates.

8-1.1 Materials.

Those items which are physically incorporated into and become part of the permanent structure.

8-1.2 Supplies.

Those items which are used in construction but do not become physically incorporated into the project such as concrete forms.

8-2 SOURCES OF PRICING DATA.

8-2.1 General.

Prices for materials and supplies may be obtained from pricing services, the Cost Book, catalogs, quotations, and historical data records. Each office should review the source of the pricing contained in these publications and assess the reasonableness prior to use. Standard unit prices from these sources are considered satisfactory only after an applicability determination has been made. Care is to be taken when using this type of cost data to make proper allowances for quantity discounts, escalation, and other factors affecting contractor cost.

8-2.2 Quotes from Manufacturers and Suppliers.

Quotes are to be obtained for significant materials and installed equipment and for specialized or not readily available items. Use the Pareto Principle to determine the number of quotes required. Quotations may be received either in writing, electronically, or by telephone. It is preferable to obtain quotes for each project to ensure that the cost is current and that the item meets specifications. If possible, more than one quote is to be obtained to be reasonably sure the prices are competitive. The cost engineer should attempt to determine and ensure that contractor discounts are considered in the cost estimate. Quotes are kept proprietary to preserve the confidentiality entrusted. A sample telephone quotation data sheet similar to that provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05 is utilized for recording quoted information. The cost engineer is to also take into consideration FAR Subpart 25.2 Buy American Act-Construction Materials and FAR Subpart 6.1 Full and Open Competition for the materials specified.

8-3 WASTE ALLOWANCE.

Waste and loss considerations may be included in material unit price computations. This methodology when computing material costs results in a quantity takeoff of work placement, which is not altered to reflect material losses. However, the alternative methodology of increasing the measured quantity by waste and loss quantity is acceptable if the excess quantity will not be used for any other purpose. The preferred methodology used by the cost engineer is not to charge labor on the excess quantity. In either case, a note statement is required in the cost estimate explaining the methodology used.

8-4 FORWARD PRICING.

Sometimes quotes are requested in advance of the expected purchase date. However, suppliers are reluctant to guarantee future prices and often will only quote current prices. It may therefore be necessary to adjust current prices to reflect the cost expected at the actual purchase date. This cost adjustment, if required, is not to be included as a contingency, but clearly and separately defined in each cost estimate. Adjust current pricing to future pricing using program specific escalation factors. Computations of adjustments are to be clear and maintained as cost estimate backup support. The cost engineer is to ensure that this cost is not duplicated in the escalation to midpoint of construction percentages.

8-5 FREIGHT.

The cost engineer checks the basis for the price quotes to determine if they include delivery. If they do not include delivery, freight costs to the project site must be determined and included. The supplier can usually furnish an approximate delivery cost. For delivery charge, Free/Freight on Board (FOB) refers to the point to which the seller will deliver goods without additional charge to the buyer.

8-5.1 FOB Factory or Warehouse.

If the materials or supplies are FOB factory or warehouse, freight costs to the construction site are to be added to the cost of the materials or supplies.

8-5.2 Unloading and Transporting the Materials or Supplies.

If the cost of materials or supplies includes partial delivery, FOB to the nearest rail station, the cost of unloading and transporting the materials or supplies is to be included in the cost estimate.

8-5.3 Large Quantity in Bulk.

If the materials or supplies are a large quantity in bulk, which would require extensive equipment for unloading and hauling, it may be desirable to prepare a labor and equipment cost estimate for the material handling and delivery.

8-6 HANDLING AND STORAGE.

The contractor is usually required to off-load, handle and stockpile, or warehouse materials on site. These costs are to be included in the cost estimate. An item of electronic equipment requiring special low-humidity storage might have this special cost added to the direct cost of the equipment. For common items, such as construction materials or equipment needing secure storage, the cost for the security fencing, temporary building and material handling are considered as an indirect cost and be included in the job-site overhead cost.

8-7 TAXES.

When applicable, state and local taxes (i.e., sales, excise) are to be added to the materials or supplies cost. In some states, material incorporated into Federal construction is exempt, but supplies are not. Care is to be taken, therefore, that the sales tax rate is applied as required. The cost engineer is to verify the tax rates and the applicability of these rates for the project location. Sales tax is considered a direct cost of the materials and supplies.

8-8 MATERIALS OR SUPPLIES MANUFACTURED OR PRODUCED AT THE SITE.

If it is likely the contractor will manufacture or produce materials or supplies at the project site, a separate cost estimate component (i.e., batch plant) is to be developed for this work. This cost estimate includes a detailed equipment, labor, materials, and supplies estimate, and concludes with a unit cost of material or supply delivered to the stockpile, storage yard, or other end point.

8-9 GOVERNMENT-FURNISHED MATERIALS (GFM) OR EQUIPMENT (GFE).

On some projects, the Government may provide some of the project materials. Government-furnished materials and equipment are to be estimated in the same manner as other materials, except that the purchase price is not included. The cost estimate includes an allowance for transporting, handling, storage from point of delivery and assembly, sales tax, and installation if applicable. There may be special costs associated with Government-furnished materials such as insurance to cover loss until final installation, special storage costs, or special security measures. Note that these materials and procurement costs are normally to be included as part of the total project cost.

This Page Intentionally Left Blank

CHAPTER 9 SUBCONTRACTED WORK

9-1 GENERAL.

In construction, specialty work such as plumbing, heating, electrical, roofing, plastering, and tile work are usually more effectively performed by subcontract. With so many specialties being performed, subcontract work becomes a very significant portion of the total costs of construction. Since each cost estimate is prepared as practically and as realistically as possible, subcontract costs become a necessary consideration.

9-1.1 Parts of Work to be Subcontracted.

The cost engineer must first determine those parts of the work that will probably be subcontracted. When the work to be subcontracted has been determined, those items will be identified in the cost estimate. The appropriate subcontractor overhead and profit costs are to be applied to subcontractor direct cost items in addition to the appropriate prime contractor overhead and profit.

9-1.2 Cost of Subcontracted Work.

The cost of subcontracted work is the total cost to the prime contractor for the work performed. Subcontractor's costs include direct labor, materials and supplies, equipment, second tier subcontracts, mobilization and demobilization, transportation, set-up, and charges for overhead and profit. Particular attention is given to large items such as turbines, generators, and incinerators. The total subcontract cost is considered a direct cost to the prime contractor.

9-1.3 Construction Contractual Methods.

The cost engineer should be aware of the type of contractual method for which the solicitation is being issued. Limited competition contractual procurement methods may result in multiple compounded levels of subcontracted work, e.g., compounded subcontractors' markups passed on to the prime contractor. Some examples of limited contractual procurement methods are 8-A Sole Source RFP, MATOC sole source task order, POCA sole source task order, etc. The prime contractor is required per the contract to perform a minimum amount of work, but the remaining work may be performed by subcontractors. If possible, particular attention is to be given to the workload capacity and workforce capability of the prime contractor. If the prime contractor already is at full capacity in performing other work, or their own workforce resources are at maximum usage, then the prime contractor will likely subcontract to the maximum extent allowable. Also, the same scenario would occur for the subcontractors if they are at their maximum capacities.

9-2 USE OF QUOTATIONS.

Potential prime contractors are not to be utilized for quotes. The cost engineer may utilize quotes for the expected subcontracted work when reviewed and verified as reasonable. In lieu of a quotation, each task of the subcontract is priced as a direct cost with an appropriate rate of subcontractor's overhead and profit added.

This Page Intentionally Left Blank

CHAPTER 10 OVERHEAD COSTS

10-1 GENERAL.

Overhead costs are those costs, which cannot be attributed to a single task of construction work. Costs, which can be applied to a particular item of work is to be considered a direct cost to that item and are not to be included in overhead costs. The overhead costs are customarily divided into two categories:

- General home office overhead (HOOH) commonly referred to as General and Administrative (G&A) costs.
- Job office overhead (JOOH) also referred to as General Conditions or Field Office Overhead (FOOH).

10-1.1 Duplication of Overhead Costs.

The cost engineer must be sure that overhead costs are not duplicated between the two categories (JOOH/HOOH). Because of the nature of overhead costs, it is not practical to discuss all overhead items. Specific considerations must be carefully evaluated for each project. The cost engineer must use considerable care and judgment in estimating overhead costs. Many indirect cost items are frequently described in the General Requirements Section (Construction Specification Institute (CSI) Division 01) of the contract specifications. If not related to a specific work task, these costs must be identified and appropriately assigned as overhead costs.

Beyond ensuring there is no duplication of costs, the General Requirements Section of the contract specifications can also impact specific adjustments to costs, such as number of project offices, utility requirements/coverage’s, contractor quality control matrices, allowances or restrictions against multiple roles for a single supervisory role, etc.

10-1.2 Previously Determined Overhead Rates.

The application of a previously determined overhead rate may be used for early design stages, but it is not an accurate or reliable method of forecasting costs. Overhead will vary from project to project and may even vary from month to month within any given project. Job overhead items for the prime contractor are estimated in detail for projects at final design requiring a cost estimate. Detailing of overhead costs for subcontract work is recommended when the impact of these costs is significant.

10-2 GENERAL HOME OFFICE OVERHEAD (G&A/HOOH).

Home office overhead expenses are those incurred by the contractor in the overall management of the business. Since they are not incurred for any one specific project, they must be apportioned to all the projects. Many expenses such as interest and entertainment are not allowable. Construction equipment depreciation is included in the EP 1110-1-8, Construction Equipment and Operating Expense Ownership Schedule cost rates and are not included in the G&A rate. An accurate percentage of G&A can only be determined by an audit. On major changes requiring an audit, it is important to request that the G&A rate be determined.

Of all the categories of costs, the contractor's G&A costs are the least definable. Each contractor organizes his company differently from any other. Each incurs costs differently from varying sources and manages operations of that home office by their own methodology. It is important to understand that home office costs are not standard and fixed. Even though the cost for a specific contractor varies from period to period, a rate is normally averaged as a computation of total home office costs over a sufficient period divided by the total volume of business during that specific period. This rate computation methodology allows distribution and projection to future project cost estimates. When more specific data is not available, the cost engineer may include empirical rates. Empirical G&A rates typically range from three percent for large contractors to ten percent for small contractors. Home office costs are typically included in the estimate of overhead as the product of an average experienced percentage rate times the expected contract amount. Typical categories of home office overhead are:

- Main office building, furniture, equipment.
- Management and office staff, salary and expense.
- Utilities.
- General communications and travel.
- Supplies.
- Corporate vehicles.
- General business insurance.
- Taxes.

10-3 JOB OFFICE OVERHEAD.

Job overhead costs are those costs at the project site, which occur specifically as a result of that particular project. Some examples of job overhead costs are:

- Job supervision and office personnel.
- Engineering and shop drawings/surveys.
- Site security.
- Temporary facilities, project office.
- Temporary material storage.
- Temporary utilities.
- Preparatory work and laboratory testing.
- Transportation vehicles.
- Supplies and maintenance facilities.

- Temporary protection and Occupational Safety and Health Administration (OSHA) requirements.
- Telephone and communications.
- Permits and licenses.
- Insurance (project coverage).
- Schedules & reports.
- Quality control.
- Cleanup.
- Taxes.
- Fuel.
- Support Equipment utilized for general use on site
- Operation and maintenance of temporary job-site facilities.
- Project specific travel
- Relocation of key personnel

10-3.1 Mobilization and Preparatory Work.

The costs of mobilization and preparatory work, including the setup and removal of construction facilities and equipment are part of overhead costs unless there is a specific bid item. For large projects, the cost for each part of this initial work is to be estimated on a labor, materials, and equipment basis. For smaller projects, these costs may be estimated based on experience.

10-4 DURATION OF OVERHEAD ITEMS.

After the overhead items have been listed, a cost must be determined for each. Each item is to be evaluated separately. Some items such as erection of the project office may occur only once in the project. The cost engineer utilizes the construction schedule (see paragraph 4-3.5) in estimating requirements based on duration. Costs reflective of each particular item during the scheduled period are to be applied.

10-5 SOURCES FOR PRICING.

The cost engineer must rely on judgment, historical data, and current labor market conditions to establish overhead costs. Sources for information can be obtained from current or past contractors bid data and audits. Some contractors will informally discuss and furnish information for overhead items and audit reports of previous similar projects. Other sources include previously negotiated modifications and review of organizational charts of construction firms for staffing and overhead costs evaluation. Overhead salaries are to include an allowance for payroll taxes and fringes such as Federal Insurance Contributions Act (FICA), health benefits, and vacation.

10-6 DISTRIBUTION OF OVERHEAD.

The prime contractor's overhead costs, which have been costed in an organized format, are to be summed and distributed proportionally to the Contract Line Item (CLIN) items. A proportional distribution is commonly made by percentage ratio of total direct costs to those direct costs in each item. When options, additive, or split-bid items are included, only those job office overhead costs, which relate directly to the work, are to be distributed to those items.

Job office overhead costs which the contractor will incur regardless of whether the item is optional, additive, or split is distributed to base bid schedule items only. Selective distribution ensures recoupment of costs if only the basic contract scope is awarded. Regardless of the method of distribution, the cost estimates are to clearly demonstrate the procedures and cost principles applied.

For modifications that extend the baseline contract duration, the estimated job office overhead requirements are to be itemized and costed to reflect the actual net change in cost of overhead, that is, costs before and after the modification work. As a refinement to distribution, the cost engineer may reasonably and justifiably reduce the prime job office overhead distribution on subcontract work items. The balance of the total prime job office overhead are then distributed as discussed above to the remaining prime items of work.

CHAPTER 11 PROFIT

11-1 GENERAL.

Profit is defined as a return on investment. It is what provides the contractor with an incentive to perform the work as efficiently as possible.

11-2 WEIGHTED GUIDELINES METHOD.

Profit and weighted guideline methods determining profit are discussed in the FAR and its supplements. There are various types of weighted guideline methods for determining profit according to DFARS 215.404-4. The proper weighted guideline method to use will depend on the type of contractual acquisition action and the supplemental regulations that apply to the contracting activity. Reference FAR Sub-part 15.404-4 concerning the use of profit when price is based on a negotiated firm fixed price construction contracts. The use of the weighted guideline method when price is negotiated will be per the cognizant design agency guidance. The determination of profit, as appropriate for each procurement action, may be determined and submitted on the sample worksheet identified as Figure 11-1 which applies to the weighted guidelines alternate structured approach DFARS 215.404-4 (b)(1)(C) “Alternate Structured Approach”. Explanation of the factors to be used in calculating profit, are described below, and provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05.

11-2.1 Weighted Guidelines Method.

The weighted guidelines method yields a reasonable profit value and are to be used to determine profit for contracts that include profit. This methodology is also be used wherever a detailed direct costing method is used for preparing cost estimates. A rate of profit may be used based on historical experience for early stage cost estimates prepared for programming, budgeting, reconnaissance, or concept design.

11-2.2 Weighted Guideline Factors for the Alternate Structured Approach.

Based on the circumstances of each procurement action, each of the factors listed in the “Guidelines for Weighted Factors Profit Determination” at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05. will be weighted from 0.03 to 0.12 as discussed in the following text. Statements in sufficient detail to explain the reasons for assigning the specific weights shall be included on the profit computation sheet. The value will then be obtained by multiplying the rate column by the weight column. The value column when totaled indicates the fair and reasonable profit percentage.

- Degree of Risk. Where the work involves no risk or the degree of risk is very small, the weighting is 0.03; as the degree of risk increases, the weighting is increased up to a maximum of 0.12. Lump sum items will have, generally, a higher weighted value than unit price items for which quantities are provided. Other things to consider include ; the nature of work; where the work is to be performed; the reasonableness of negotiated costs; the amount of labor included in the costs; and whether the negotiation occurs before or after the period of performance of work.

- Relative Difficulty of Work. If the work is difficult and complex, the weighting is 0.12 and is proportionately reduced to 0.03 on the simplest of jobs. This factor is tied in to some extent with the degree of risk. Some things to consider include technical nature of the work; by whom work is to be done; location of work; and time schedule.
- Size of the Job. Work not in excess of $100,000 will be weighted at 0.12. Work estimated between $100,000 and $5,000,000 will be proportionately weighted from 0.12 to 0.05. Work from $5,000,000 to $10,000,000 shall be weighted at 0.04 and work in excess of $10,000,000 at 0.03.
- Period of Performance. Jobs in excess of 24 months are to be weighted at 0.12. Jobs of lesser duration are to be proportionately weighted to a minimum of 0.03 for jobs not to exceed 30 days. No weight is given for modification cost estimates when additional performance time is not required.
- Contractor’s Investment. Jobs are to be weighted from 0.03 to 0.12 on the basis of below average, average to above average of contractor investment. Things to consider include amount of subcontracting; mobilization payment item; Government-furnished property; method of making progress payments; and front-end requirements of the job.
- Assistance by Government. Jobs are to be weighted from 0.12 to 0.03 on the basis of below average to above average. Things to consider include use of Government-owned property, equipment and facilities, and expediting assistance.
- Subcontracting. Jobs are to be weighted inversely proportional to the amount of subcontracting. Where 80 percent or more of the work is to be subcontracted, the weighting is to be 0.03 and such weighting proportionately increased to 0.12 where work is performed by the contractor's own forces.

11-2.3 Separate Profit Calculation.

A separate profit calculation is to be performed for the prime contractor and for each subcontractor. When the subcontractor assumes the risk and responsibility for portions of the work, the prime contractor's profit rate on that work is decreased. As a general rule, profit is applied as a percentage rate to the total of costs required by the contract or modification scope. For early design stage cost estimates, a rate of profit may be assumed based on past historical experience.

Figure 11-1 Profit Computation Sheet using the Alternate Structure Approach

PROFIT COMPUTATION SHEET

Project:	Estimated By:
Contract No:	Checked By:
Change Order No:	Date: XX/XX/XX

Profit Objective For: (Prime Contractor, Subcontractor)

Factor	Rate (%)		Weight (0.03-0.12)		Value
1. Degree of Risk		X		=	
2. Difficulty of Work		X		=	
3. Size of Job		X		=	
4. Period of Performance		X		=	
5. Contractor's Investment		X		=	
6. Assistance by Government		X		=	
7. Subcontracting		X		=

CHAPTER 12 SURETY BONDS

12-1 GENERAL.

Surety bonds are three-way agreements between a bidder or contractor (the principal), and a second party (the surety), to assure fulfillment of the principal's obligations to a third party (the obligee). If the principal obligations are not met, the bond assures payment to the extent stipulated of any loss sustained by the obligee.

In most Government construction contracts, these three parties are as follows:

Three Party	Under a General Contract	Under a Subcontract
The Principal	Contractor	Subcontractor
The Obligee	Government	Contractor
The Surety	Surety	Surety

12-2 PURPOSE OF BONDS.

The purpose of surety bonds varies with the type of bond.

12-2.1 Bid Bonds or Bid Guarantee.

Bid bonds or bid guarantee provides an assurance that the bidder will not withdraw his bid within the specified period for acceptance and will execute a written contract and furnish the required bonds if the bid is accepted.

12-2.2 Payment Bonds.

Payment bonds protect subcontractors, suppliers, and laborers against nonpayment by the prime contractor.

12-2.3 Performance Bonds.

Performance bonds ensure the contractor will complete the project as specified and for the agreed price. It does not shift responsibility for administering the contract to the surety. A performance bond provides a financial guaranty for the work and provides the contractor with a method of freeing his working capital and other assets, which might otherwise be tied up by other forms of surety such as certified checks, retainage, or deposits.

12-3 AMOUNT OF REQUIRED SURETY BONDS.

The amount included in the cost estimate is based on the contract requirements, the bond rules, premium rates, and, if known, the actual contractor bond cost. Performance and payment bonds are required for construction contracts of $150,000 or more (FAR 28.102-1). Payment bonds are required for construction contract values from $35,000 to $150,000 or some form of payment guarantee (FAR 28.101-1 and 28.101-2).

Performance bonds may not be required for construction contract values of less than $150,000. The cost of performance bonds, payment bonds, and other types of bonds determined to be appropriate by the cost engineer are allowable costs.

12-4 RULES GOVERNING THE APPLICATION OF BOND RATES.

Bonds are classified as Class A, Class B, or Class A-1, depending on the type of construction to be performed. If the contract is susceptible to two classifications, normally the higher rate is applicable. Bond rates tables are provide at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05.

12-4.1 Separate Contracts.

Separate contracts take the same classification as a general contract. Neither the classification nor the rate is changed by subdividing the work or by the Government's providing certain materials.

12-4.2 Subcontracts.

Subcontracts take the same classifications and rates as general contracts.

12-4.3 Non-Deviating States Exceeding 12 Months Stipulated Time.

For states in conformance (non-deviating) with the Surety Association of America (SAA) rates (Bond Rates Table) where the construction time exceeds the bond stipulated time of 12 months, add 1 percent of the bond premium for each month in excess of 12 months.

12-4.4 Non-Deviating States Exceeding 24 Months Stipulated Time.

For states in conformance (non-deviating) with the SAA rates (Bond Rates Table) where the construction time exceeds the bond stipulated time of 24 months, add 1 percent of the basic premium for each month in excess of 24 months.

12-4.5 Deviating States Exceeding Stipulated Time.

For states not conforming (deviating) with the SAA rates where the construction time exceeds the bond stipulated time of 12 months, add ½ percent of the basic premium for each month in excess of 12 months up to 24 months and 1 percent of the basic premium for each month in excess of 24 months.

12-4.6 Consent of the Surety Not Required.

If the consent of the surety is not required and given for changes or extras, first and renewal premiums for the additional cost thus caused are computed at manual rates from the date of the bond.

12-4.7 Consent of the Surety Required.

If the consent of the surety is required and given for changes or extras, premium for the additional cost thus caused is computed at manual rates from the date of such surety's cost.

12-5 COST OF PERFORMANCE AND PAYMENT BONDS.

Performance and payment bonds are normally obtained as a single package. The premium is the same as for the performance bond alone. Rates vary with the type of the contract work, the dollar value, and the length of the contract.

The development of costs for surety bonds is to be in accordance with the design agency requirements.

12-5.1 Coverage Limit of Performance Bonds.

The coverage limit of performance bonds is specified in each contract and is usually for the full amount of the contract price (bid amount). The premium is adjusted at the completion of the work for any modification changes in the contract price other than changes due to time bonuses or penalties. If the original contract price is increased through change order, the contractor must pay an additional premium. Conversely, if any part of the original work is deleted and the original price thereby reduced, the contractor will receive a refund from the surety.

12-5.2 SAA Issues Advisory Rates.

It should be noted the surety industry has become a state regulated industry. The SAA issues advisory rates, but these rates may or may not be accepted by the state involved. Therefore, actual rates charged by surety corporations may vary from state to state.

12-5.3 Types and Classes of Bonds.

Contract Bonds Rate Classifications tables provided on https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05 shows the various types and classes of bonds.

12-5.4 Calculation of Bond Premium Cost.

Figure12-1 illustrates the calculation of bond premium cost. Since the rates are subject to change and may vary by state, the calculations are to be used as a sample only. The cost engineer is responsible for ensuring the rates used are accurate and current. This example assumes a canal excavation project in Tennessee to be accomplished at an estimated cost of $2.5 million, including profit, with a duration of 20 months. From the Contract Bond Rates Classification tables, excavation is found in Class B. Referring to the Class B rate schedule in the Bond Rates table, the premium for a performance-payment bond written in the full amount of the contract price (including bond) and by a non-deviating Surety Association Company would be calculated as follows:

Figure 12-1 Bond Premium Calculation

BOND PREMIUM CALCULATION					
Estimated Bond Amount x Rate = Premium					
First	$100,000	@	$25.00/M	=	$2,500
Next	$400,000	@	$15.00/M	=	$6,000
Next	$2,000,000	@	$10.00/M	=	$20,000
Anticipated Estimated Amount (inc. bond)					
	$2,500,000		$28,500		
(20 mos - 12 mos = 8 mos surcharge)					
Eight additional months @ 1%/Month					
(8 mos x 1% x $28,500)		=	$2,280		
TOTAL PREMIUM		=	$30,780		

CHAPTER 13 OTHER COSTS

13-1 GENERAL.

This chapter provides guidance regarding other costs not specifically identified in previous chapters, but costs that must be included in the preparation of detailed project cost estimates.

13-2 CONTRACTOR COMPETITION AND MARKET ANALYSIS.

Each IGE for procurement will reflect the fair and reasonable cost for performing the scope specified. Although contractor bids will reflect the anticipated competitiveness, the IGE must remain the "yardstick" against which cost reasonableness is judged.

During development of the design-stage, market competitiveness may be considered for funding and design alternatives. When competition is included in the cost estimate, it must be clearly defined and documented in the BOE.

13-3 OTHER PROJECT COSTS.

13-3.1 Design Costs

Design costs for Design Build projects may not be included in the cost estimate for all agencies. Refer to cognizant design agency guidance for clarity.

13-3.1.1 SIOH.

An allowance or cost calculation for construction management is normally included in each Budgetary estimate. Budgetary estimates must include SIOH, a factor expressed as a percentage applied to the total of the construction contract including construction contingency. The rate of SIOH and its application is further discussed in the specific program regulation. The current cognizant design agency's authorized SIOH percentage for the continental United States (CONUS) and outside the continental United States (OCONUS) must be used.

13-3.1.2 Other Project Costs.

In order for a total project cost estimate to be prepared, other project costs identified in project requirements and per cognizant design agency guidance need to be estimated. These costs, such as as-built drawing preparation, O&M manual preparation, need to be identified and included as determined by the PM and specific program requirements.

13-4 COST ESCALATION.

Cost estimates, when finalized, must reflect cost escalation due to inflation. This cost escalation must be identified as a separate element within the cost estimate. This allows the cost engineer the ability to easily adjust the cost estimate to reflect schedule changes. The usual method of applying cost escalation is to use the midpoint of construction as the end date of the escalation.

13-4.1 Military Programs.

The Selling Price Index (SPI) will be used for bringing cost estimates from a historical date to the current date. The forecasted SPI is provided by Table 4.2 of UFC 3-701-01. Refer to cognizant design agency guidance for clarity.

13-5 CONTINGENCIES.

Contingencies are used to cover unknowns, unforeseen uncertainties, and unanticipated conditions that are not possible to adequately evaluate from the data on hand at the time the cost estimate is prepared, but must be represented by a sufficient cost to cover the identified risks. Contingencies relate to a known and defined construction scope and are not a prediction of future construction scope or schedule changes. Contingency allocations are specifically related to the project uncertainties and are not to be reduced without appropriate supporting justification. Contingencies are normally separated into two elements - design contingencies and construction contingencies.

13-5.1 Design Contingencies.

Design contingencies are assigned to cover construction cost increases due to design incompleteness, detail changes, alternative design changes, and associated costing inaccuracy. Design contingencies are used to cover known costs that are not yet well-defined (or defined at all) in the design. Design contingencies will normally decrease, as design information becomes known. The magnitude of design contingency is determined by the level of technical complexity of the project for which the cost estimate is being prepared. Cost Engineers use experience and reliable data in order to make assumptions that will cover those costs until they are defined appropriately in the design documents.

13-5.2 Construction Contingencies.

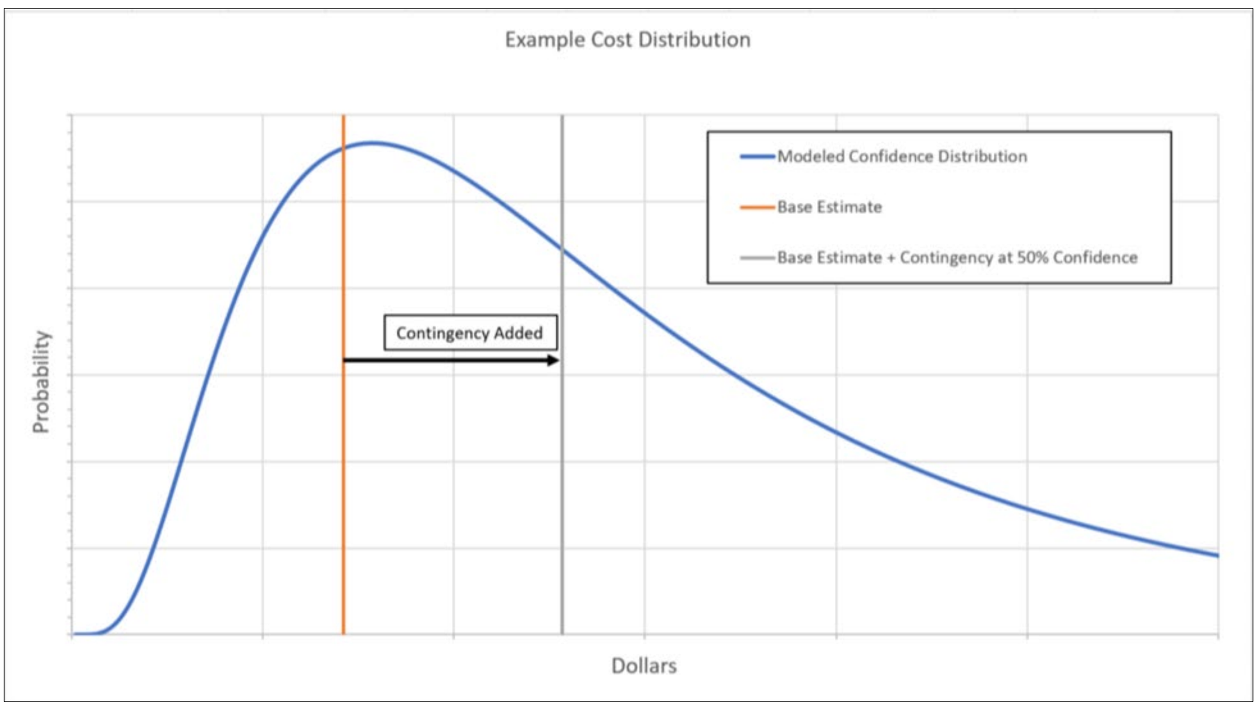
Construction contingencies are a reserve for construction cost increases due to adverse or unexpected conditions such as unforeseeable relocations; foundation conditions; utility lines in unknown locations; quantity overruns; or other unforeseen problems beyond interpretation at the time of or after contract award. Construction Contingency percentages for military projects may be applied in accordance with cognizant agency requirements.

CHAPTER 14 COST AND SCHEDULE RISK ANALYSIS

14-1 GENERAL.

Construction projects face uncertainties from design through construction that need to be addressed through risk management measures. Because the project scope definition is developed in an iterative fashion over time, the development of the associated cost and schedule for a project are based on iterative improvements in project scope definition. This iterative process drives the need for determining the appropriate contingency required at each cost and schedule estimate milestone for the uncertainties. The base estimate will reflect the anticipated value and the contingency will cover uncertainties for a total project cost and schedule or as defined by the cognizant agency procedures. The cost estimate can best be understood in the context of a range of possible cost (Figure 14-1). The contingency due to risks and unknowns will typically be highest at concept design and typically reduce over time as the scope matures and construction is completed. These considerations will minimize the likelihood that a project will experience funding-related issues. The iterative development of project scope definition gives rise to risks and opportunities that need to be managed.

Figure 14-1 Range of Cost



Cost and Schedule Risk Analysis (CSRA) is the process by which cost and schedule risks/opportunities are identified, documented, qualified, quantified and managed. Monte Carlo simulation is employed to determine the contingency needed to achieve any level of confidence. The output of the CSRA process includes a risk register and contingency models that provides a defensible contingency value.

The CSRA process was developed by the US Army Corps of Engineers in 2007 with the help of AACE and follows the best practices from range estimating techniques with adaptation to general DOD principles of cost estimating. Do not use "expected value" type modeling for construction risks.

The CSRA process provides many benefits, including:

- Communicating as a team regarding scope, status, cost, schedule and risk concerns
- Understanding the potential risks and opportunities that could impact the project
- Establishing contingencies supported by project team involvement and studies
- Defining and targeting high risk areas for management and risk reduction
- Realizing cost and schedule opportunities similar to the value engineering process
- Increasing the probability of successful completion of the project
- Understanding where the base estimate fall within possible ranges
- Informing decision makers by providing the context in which to consider a base estimate

The risk management process is incorporated as a risk management plan, (RMP) and included within the project management plan (PMP). The four main building blocks of the risk management process include:

- Risk Identification
- Risk Assessment
- Risk Response
- Risk Documentation

14-1.1 CSRA Stages.

CSRA is a dynamic, ongoing effort that can be useful at any given stage of project development and execution.

14-1.1.1 Budgeting.

The early stages of project development often focus on systemic risks. AACE Recommended Practice (RP) 10S-90 describes these types of risks as those that are artifacts of such things as an organization's project system, strategy, or culture. Systemic risk are often understood well by the project team and even by some of the project's stakeholders. Project specific risks must be considered at this level where available.

14-1.1.2 Design.

When the project team begins developing the project technical documents. Many if not most of the systemic risks will likely be mitigated or eliminated. At this stage systemic risks will typically give way to project-specific risks – those specific events, actions and other conditions associated with the project's scope (as per AACE RP 10S-90).

14-1.1.3 Construction.

The DOD Construction Agent (DCA) may choose to continue the use of the CSRA, developed in support of the IGE, as an in-house tool to assist the government's construction managers in tracking the project. This is not to be confused with the Contractor's own risk management tools. Any CSRA information developed in support of the IGE must not be disclosed to those without a need to know.

14-1.2 Terminology and Definitions.

It is helpful to consider the use of terminology in the context of the CSRA process. AACE RP 10S-90, Cost Engineering Terminology provides useful concepts for defining risks as used in this context:

- Allowance: A quantity of resources added to cost or schedule estimate to cover known but undefined requirements for specific items to be included in the cost or schedule.
- Confidence Interval: The probability that a specified range along the continuum of possible values will include the actual value of the quantity of resources being estimated.
- Confidence Level: The probability that the actual value of the quantity of resources being estimated is equal to or less than a specified point along the continuum of possible values.
- Contingency: A quantity of resources to be added to cost or schedule estimate to achieve a specified confidence level.
- Estimate: A prediction of the quantity of resources (material, labor, costs, time) required to achieve an agreed upon scope of work, at an agreed upon location, within an agreed upon period of performance. Note that cost and schedule are a type of estimate in this context.
- Risk: Any uncertain event that could affect a project objective or business goal such as cost, schedule or scope.
- Uncertainty: The total range of events that may arise and produce risks. These events are neither 0% nor 100% likely to occur. Risks may be favorable (opportunities) or unfavorable (threats). Considered collectively, Uncertainty = threats + opportunities.

14-2 RESPONSIBLITIES.

The CSRA requires the active participation of the project team. As members of the project team, the Cost Engineer and Risk Analyst play key roles in facilitating the process and in preparing the risk register, developing and running the risk models, and analyzing the results. However, the necessary familiarity with and detailed knowledge of the project resides with the PM and other project team members. In addition, the PM and other members project team also are in the best position not only to identify and qualitatively assess the risks, but they are also in a position to be able to provide potential risk mitigation measures.

14-2.1 Project Team.

The project team assists in identifying risk likelihood and their potential impacts to cost and schedule. The project team includes stakeholders that have knowledge of the project and critical responsibility for development and management of the total project. Project team members typically include representatives from but not limited to:

- Project and planning management
- Contracting and acquisition
- Real estate and relocations
- Environmental
- Technical design
- Cost estimators and schedulers
- Risk analyst
- Construction
- Operations
- Host installation public works personnel
- Sponsors
- Project End User

14-2.2 Project Manager (PM).

The PM is responsible for leading the project. Since CSRA is instrumental for successful project completion, the PM's engagement is critical in the following tasks:

- Developing a PMP that addresses risk management, the CSRA requirements and its execution.
- Supporting the CSRA process related to budgeting, scheduling, and team formulation to accomplish the CSRA.
- Participation in the identification of risk mitigation measures.

- Monitoring and managing recognized risk events that may impact successful execution of the budget and schedule.
- Evaluating the need for follow-on CSRAs.
- Validate that the CSRA results are appropriately captured in the project cost and schedule estimate.

14-2.3 Cost Engineer/Risk Analyst.

The experienced cost engineer or seasoned risk analyst will perform key roles in the CSRA process. One individual may be responsible for both functions or if multiple individuals are involved then effective coordination is required.

A cost engineer is typically assigned the role as the risk analyst and many times serves as the CSRA meeting facilitator to lead the project team through the CSRA process i.e., project team discussions to develop the initial risk register and establish the resulting CSRA conclusions. A confident facilitator, knowledgeable with the type of project work, is needed to actively engage and encourage communication amongst the project team.

The cost engineer/risk analyst is tasked to lead the CSRA and report the results. Typically, a risk analyst is responsible for developing and running the CSRA models to develop project contingencies. Additional responsibilities include:

- Sharing the contents, assumptions, and accepted risks of the base estimate.
- Updating the cost estimate as information is gathered from the project team.
- Sharing the contents and assumptions of the schedule.
- Updating the schedule as information is gathered from the project team.
- Record/document team comments and determinations in the risk register.
- Leading the market analysis to quantitatively bracket the variances with regards to cost and schedule.
- Facilitating the identification of risk events.
- Facilitating the qualitative assessment of risk levels.
- Create, run, document and summarize cost and schedule risk models.
- Collaborating with the PM the results of the CSRA.
- Incorporate the contingency results from CSRA model into the total project cost and schedule.

14-3 SUPPORTING DOCUMENTATION.

Applicable documents recommended for the CSRA process and deliverables include*:

- Current project scope
- Quality base cost estimate excluding contingency
- Quality Basis of Estimate
- Quality base schedule estimate correlating with the project scope and base cost estimate
- Agency specific guidance
- Risk presentation to educate the project team
- Risk checklist presenting typical risks considered
- Risk register
- Cost and schedule risk templates/models
- A table of recommended risk mitigation measures for the project
- Report of the process, outcome, and recommendations

14-3.1 Tri-Service CSRA Template.

The Tri-Service CSRA template is located at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05 and is to be used for MILCONs that require a CSRA. The CSRA Template is to be used unless otherwise approved by the cognizant design agency. The template includes several tabs that are summarized below:

- Tab A-Quick Instructions: Provides instructions on how to use the template.
- Tab B-Meeting Agenda: Provides a sample agenda for the initial risk discussion.
- Tab C-Risk Checklist (MILCON): Provides a sample risk checklist for common risk events related to MILCON projects. The checklist is not all-inclusive and risks are to be added as necessary.
- Tab D-Project Data: Input project details and scope of work.
- Tab E-Cost & Schedule Summary: Input base cost and schedule estimate.
- Tab F-Meeting Attendance: Input list of attendees from initial risk discussion.
- Tab G-Assumptions: Provides a summary of the risk range assumption development for qualitatively analyzing the risks.

- Tab H-Risk Register-Model: List identified risks associated with the project. Provide qualitative and quantitative analysis and run the model.

- Tab I-Project Contingency: Provides a summary of the model contingency results for cost and schedule.

- Tab J-Sensitivity Chart: Provides a summary of the risks sensitivity analysis.

- Tab K-Dashboard Template: Provides a summary of the model contingency results and a table to itemize risks used in the model and identify suggested risk reduction measures.

14-4 CSRA PROCESS.

CSRA uses risk identification processes common in the industry. It is a formally documented process of the project team's efforts, considerations, and concerns. The CSRA process combines two powerful risk-management tools, a well-developed risk register and an integrated cost/schedule risk analysis model.

The CSRA identifies risks including but not limited to variances in the base estimate, then qualitatively assesses the risk. It then quantifies the risks related to the project cost and schedule. This is accomplished through collaborative meetings. The results are expressed in terms of cost and schedule contingency amounts, which are measured in both dollars and time. It also expresses the level of confidence in the ability to successfully execute the project.

CSRA is an ongoing and iterative process. Risks are to be considered from budgeting to construction, maintaining a broad view of risks and opportunities avoids leaving many of them unidentified and unmanaged. As the project evolves, new risks may be identified and previously identified risks may be accepted into the project scope and cost and schedule estimate, mitigated or retired. The CSRA must reflect the latest project scope and base estimate. CSRA could be continued through design, procurement and post award. The CSRA should be updated at each submittal.

The outcome of the CSRA includes:

- A risk register including current and historical known risks, team discussions regarding those risks, and recommended actions necessary to manage, eliminate, reduce or plan for known risk events and opportunities. This is best accomplished through the use of a risk breakdown structure that categorizes risks consistently.
- A well-documented, tailored project cost contingency at various confidence levels.
- A well-documented tailored project schedule contingency at various confidence levels.
- Common understanding of the project and the scope.

14-4.1 CSRA Determination.

The Monte Carlo CSRA is recommended for projects that are large, complex, of long duration, or critical funding constraints. Regulations, policy and guidance play a large role in establishing mandatory CSRAs. The PM must follow their agency requirements, but also consider whether other project milestones warrant a CSRA update based on scope, cost, schedule, and risk changes. This is a critical step in quality project management processes. The PM may directly consult leadership, but generally the regulations and intent are fairly clear.

14-4.2 Preparation.

The cost and schedule estimate based on the current project scope are prepared to support the CSRA process as the base estimate and base schedule. The total project scope must be reflected within the two products. During the early stages of the project, the base estimate may not be available at the beginning of the CSRA process, but the risk identification may be started and later quantified once cost and schedule estimate are available. Care is to be taken when design contingency is applied within the base estimate and if the CSRA includes risks focused on incomplete design scope to avoid overstating contingency. A best practice would be to include design contingency at the system level within the base estimate and model the variation with the CSRA.

The PM typically establishes the project team. The project team is comprised of experienced members and project stake holders with knowledge of the project scope and criteria, potential risks, opportunities, and unknowns.

In preparation for the initial risk discussions that prepare the first risk register (the document used to support the CSRA), it is recommended that the Risk Analyst distribute to the project team a list of potential risks that are commonly encountered for MILCON projects. A sample risk checklist is available as part of the CSRA template. The sample risk checklist is not intended to be exhaustive but serve to stimulate the team in the brainstorming of each project’s specific applicable risks. The project team is encouraged to examine lessons learned for inclusion in the risk checklist. After reviewing the checklist, the project team members will be better prepared to present their risk concerns at the brainstorming meeting where the risks are discussed and captured within the initial risk register.

14-4.3 Initial Risk Discussion.

The project team brainstorming session is the first step in developing the risk register that serves as the basis for the CSRA. In order to prepare the initial risk register supporting the CSRA, the following coordination steps are recommended.

14-4.3.1 Project Team Coordination and Assembly.

The PM coordinates the brainstorming session with the project team. This is the first meeting where the project team attempts to collectively capture the total project risks and place them into the risk register.

14-4.3.2 CSRA Presentation.

It is recommended that the designated facilitator begin with a CSRA presentation in order to explain the process and expected outcomes with the project team. A confident facilitator, knowledgeable with the type of work, is needed to actively engage and encourage discussion and communication among the project team members.

14-4.4 Project Scope and Cost Presentation.

Next, it is highly recommended that the PM or technical design lead and the lead cost engineer for the project present the project scope and related cost and schedule. The presentation includes the major construction features and assumptions in the design, base estimate, and schedule. Oftentimes it is discovered that the base estimate and assumptions do not match current understood scoping and construction elements. As a rule, well-defined scope is the critical element that then establishes the current cost and schedule estimate. Less defined scoping documents will generally lead to the development of more severe risks and higher contingency values. As scope is improved and more confident designs are developed, contingencies normally decrease. Risk analysis cannot overcome significant omissions or errors in scope of the project. If something significant is missing, the CSRA model may not provide an adequate contingency. It is also recommended that the risk analyst discuss the parameters related to likelihood of occurrence, cost impact ranges, and schedule impact ranges to better aide in risk identification.

14-4.5 Brainstorming Session.

The brainstorming session is the opportunity for the project team to qualitatively define the risk concerns, as well as potential opportunities. It is highly recommended that the brainstorming session include the major project team members because the dialogue between the members typically results in scope clarification or change, findings of new risks, and possible revision of the cost and schedule estimate. The potential variances to the base estimate that are identified in the brainstorming session are the basis for further study and modeling in the analysis. This stage is considered the qualitative stage that lacks the studies to establish cost and schedule impacts or variances. This period is more speculative, pre-study.

To guide the project team through the discussions, refer to the risk checklist for ideas. As previously mentioned, this list is not intended to be exhaustive. Each project team member is provided an opportunity to address their concerns. As concerns are discussed, the facilitator or risk analyst begins developing the initial risk register that supports the CSRA, capturing the project teams concerns and discussions. Like a value engineering study, any concern is valid, considered, and captured within the risk register—even lower risks, because they serve as record of discussion. This session can result in revised cost and schedule estimate.

Generally, the project team must address the key risks listed below:

- Potential scope growth

- Acquisition strategy
- Construction elements
- Design quantities
- Special fabrication and equipment
- Market/bidding conditions
- Escalation
- Cost estimate assumptions
- Schedule estimate assumptions
- External Risk
- Assumed Funding Strategy (MILCON, O&M, Other Appropriations)
- Design Confidence
- Project Management Plan (Pre & Post Design)
- Potential for unknown-unknown risks (risks unforeseen by the team that have an unknown likelihood of occurrence)
- Change management approach of the agency. Managing customer requested changes beyond the scope.
- Potential mitigation efforts for identified risks

14-4.6 Completing the Initial Risk Register.

A well-developed risk register captures the identified risks along with a qualitative risk assessment (in a range from “low risk” to “high risk”) that combines their probability of occurrence and their range of impact on project cost and schedule. It serves to document the risks considered throughout the design development (and potentially beyond), including mitigation measures.

Within the model, the risk register (Tab H) will serve as the basis for the CSRA model. When referring to the risk register, the project team focuses on the following fields:

- REF – Risk ID (typically numerical)
- Risk Type – Technical, External, etc. (drop down list)
- Risk/Opportunity – Event (simple clear title)
- Risk Event Description (clearly written specific concerns)
- PDT Discussion on Impact and Likelihood (decision justifying chosen risk levels)
- Project Cost: Likelihood, Impact, and Risk Level as a result.
- Project Schedule: Likelihood, Impact, and Risk Level as a result.
- Responsibility/POC

- Suggested Risk Reduction Measures

The project team attempts to capture concerns for project features, even if the risk level is considered low. The register serves as an archive of discussions and there is potential that those low-level risks may become higher following market studies, improved information being made available, or through time during the risk management and risk mitigation processes.

Within the risk register, the project team's concerns and discussions must be adequately and clearly captured because the logic presented in those discussions must support the "likelihood" and "impact" decisions reflected within the risk register. While this product is the initial risk register, it has already captured the project team's greater concerns. The project team can begin using this data to prepare for project risk management. The cost estimator/risk analyst is to send out a copy of the initial risk register to the project team to make sure their comments are adequately captured from the brainstorming session.

14-4.7 Modeling and Output.

The next steps in the CSRA process are to review the base estimate and schedule, conduct market research, develop and run the models, and analyze the model output. These steps are detailed in subsequent sections.

14-5 COST AND SCHEDULE ESTIMATE INDEPENDENT REVIEW AND ADJUSTEMENT.

The CSRA can begin before the cost and schedule estimate have received an adequate review, whether it is by QC check, agency technical review, or by external agencies. This may be a reasonable approach if the PM is keenly interested in quantifying the potential impacts from the established risk events. However, if later reviews determine that sufficient changes in the cost and schedule estimate are needed, the base estimate and CSRA may have to be adjusted prior to finalization of the analysis.

Once the initial risk register is complete, the PM and cost engineer, responsible for the cost and schedule estimate, must consider whether the base estimate truly represent the most likely project scope. Often times, project team discussions will present scope changes or processes that may impact the current cost and schedule estimate. There could be a different construction approach. There could be items such as revised productivity or crew makeup. Important assumptions and quantities may not yet be confident.

Other project team members may choose to revise their portions of the featured costs and schedules that reside within their area of responsibility. The cost engineer is responsible for the costs and schedules. Other project team members are responsible for the cost and schedule estimate of their project areas/efforts, such as project management, contract acquisition, design studies, construction management, etc. The PM must confirm from the project team whether these areas must be further developed or improved to reflect the most likely base estimate that serve as the basis for the market studies and the CSRA product.

14-6 MARKET ANALYSIS.

Once the initial risk register is completed and the project team is confident that the cost and schedule reflect the base estimate conditions, the initial risk register is ready for the risk analyst to begin the market analysis. Risks qualitatively determined to be medium to high will be moved forward for quantitative analysis. This classification is made using a likelihood vs impact matrix. It is recommended to carefully review the qualitative assessment of each risk to ensure that it is accurately characterized as only the moderate and high risks will move forward for Monte Carlo analysis in the risk model. Any risks misclassified are to be corrected in the risk register.

The market analysis supports the quantitative portion of the CSRA, establishing estimate values or ranges in cost and schedule impacts. It is intended to validate the presumed risk levels within the initial risk register for both cost and schedule. The market analysis will help establish the “most optimistic” (or “low variance”), and the “worst case” (also referred to as the “high variance”). These two data points or values will be used within the risk model to evaluate the range of costs and schedule from the base estimate. A key concept is that potential variances from the base estimate and schedule are studied. Risks that can be tied directly to base estimate and schedule are defined as the “likely” value as zero and model low, and high variance accordingly. For risks that do not have a direct link to the base estimate, define the three values (low variance, likely, high variance) according to market analysis.

The study and quantification of risks may require project team interviews, historical data research, internet searches, etc. Issues may include items such as real estate fluctuations, land acquisition and easements, construction productivity concerns, fuel pricing, construction modifications, specialized equipment and material availability, local labor resources and rates, potential scope growth, bidding competition, effects resulting from the acquisition strategy, economic trends, etc.

14-7 FINALIZING THE RISK REGISTER.

This section describes the completion of the risk register for the current submittal. A logical flow must occur between risk events, concerns, discussions, and reasoning for the chosen likelihood and impact values that result in the risk level of low-moderate-high.

To finalize the risk register, market analysis may result in revising the risk register as needed. Refinement may reveal similar risk events that could be duplicates or double-counted as a risk impact. It may result in adding risk/opportunity events not previously captured. It may result in revising the “likelihood” and “impact” values to support a revised risk level that reflects the research findings. If the likelihood and impact values is revised, the project team concerns and discussions may have to be reevaluated to ensure that they logically support the revised risk register. The final risk register must reflect the correct final risk classification of low, medium, or high based on the revised “likelihood” and “impact”.

The market analysis will enable the risk analyst to complete the risk model fields:

- Cost Impacts
- Cost Variations (low variance, likely, and high variance)
- Schedule Impacts
- Schedule Variations (low, likeliest and high)
- Correlation of Risks to One Another
- Cost Impacts due to Schedule Variations

The model focuses on certain risk register categories and the market analysis values related to low, likeliest, and high. The entire risk register can be included in the model; however, it can be cumbersome when producing paper documents and reports. The key risk register fields required to be completed are:

- REF (Risk number)
- Risk Type
- Risk/Opportunity Event
- Risk Event Description
- Likelihood-Impact-Risk level (Cost and Schedule)
- Variance Distribution (Cost and Schedule)
- Risk Correlation to Other(s)
- Suggested Risk Reduction Measures
- Cost and Schedule Variances (Low, likeliest, high)

14-7.1 Cost Impacts and Distribution.

The market analysis will help establish the input probability distribution parameters (low, likeliest and high values). These parameters may be used within the risk model to determine the input probability distribution. The impacts can be indicated in dollars or percent.

14-7.2 Schedule Impacts and Distribution.

The market analysis will help establish the input probability distribution parameters (low, likeliest and high values). These parameters may be used within the risk model to determine the input probability distribution. The impacts can be indicated in months or percent. Additionally in investigating the schedule risks often these risks will imply an additional cost may be incurred due to the schedule risk. In the recommended standard template there is to be a separate group of columns to include/model any specific risks due to schedule. This technique allows the cost due to schedule risks to be modeled. These risks sum into the overall cost risk forecast in the template. In general, most schedule risks will have some cost risk such as but not limited to time related cost impacts such as extended Field Office Overhead, support crews, and special monitoring. Often this cost risk is below the threshold for modeling and is evaluated case by case.

14-7.3 Correlations.

Many times risk events have a correlation or relationship to one another. A positive correlation occurs when one risk goes higher and the other must also go higher. A negative or adverse correlation occurs when one risk increases and the other risk must decrease. To complete the risk register, note the assumed correlations and include in the model development. When preparing the model, it is highly recommended to review correlations before running the risk model because they may significantly alter the output. Many times assumed correlations are actually restatements of the same risk and are best combined into one variable.

14-7.4 Risk Register Quality Control Check.

Upon completion of the market analysis, the cost engineer/risk analyst completes the risk register, confident that the:

- Project team risk/opportunity events are adequately captured/conveyed
- Project team discussions support the "likelihood" and "impact" decisions especially after updating cost or schedule impacts from modeling because it could change your impact rating.
- Market analysis supports the risk level assigned
- Current cost and schedule estimate serve as the base estimate for the CSRA
- Correlations and event duplication are minimized and addressed
- Market analysis adequately defines the cost and schedule variations

14-8 COST AND SCHEDULE RISK MODEL DEVELOPMENT.

The integrated cost/schedule risk model is developed by the cost engineer or risk analyst experienced with the CSRA process. The model includes the key risk drivers and a Monte Carlo computer simulation tool is utilized to produce the probability distribution of likely cost and schedule variances. These then become the basis for developing contingencies required to provide a given level of confidence. Cost and schedule processes are separated since each requires a separate analysis - though the results of each may impact each other. On larger projects, the CSRA process may require additional members to study the initial risk register, evaluate the concerns captured within the brainstorming session(s), perform market analysis of those risk events, and validate whether the project team's risk level assignments are accurate.

14-8.1 Risk Model Template.

The risk model utilizes the risk register as its basis within the spreadsheet format. The cost engineer/risk analyst and the project team must determine the best modeling method that provides adequate model output for the project. The result is a customized model specifically related to the project. The final product must present contingencies in the desired format for the total project cost and schedule. For example, CSRAs can be performed on each contract (assuming several contracts), on assumed funding cycles, on each project feature, or on the total project. The use of the standard risk model template is recommended as it provides a common platform for development, review, analysis and future data collection efforts.

14-8.1.1 Establishing the Risk Events for Study.

The CSRA process relies on the Pareto Principle that in construction projects 20% of the risks will cause 80% of the impacts. This is akin to the “Few Risk Items” approach outlined in the current DOD Joint Cost Schedule Risk and Uncertainty Handbook. Practice has shown that risk events evaluated as having lower than a moderate level of risk have a negligible impact on CSRA results and are therefore not considered to be materially beneficial to the process.

It is recommended that moderate and high-risk events be further studied and included in the model. Large and complicated projects may have considerably more identified risks meeting the threshold for modeling. Identified risks are examined to make certain of their overall risk rating. Often events may be qualitatively assessed in error by the team and a small effort of further study could indicate it is overall a low risk (not modeled) or a moderate to high risk (included in the model). If the risk analysis later determines a risk was either not identified or was not qualitatively assessed correctly by the team it is added/noted in the risk register and the proper classification entered to ensure the model and the risk register match.

The risk register depicts only the risk events under study; however, the cost engineer/risk analyst documents identified risk events within the model, simply indicating that the risk is not modeled and is not assigned a variance distribution.

14-8.1.2 Incorporating Market Analysis into Model.

Once the determination of which risk events will be incorporated into the model has been completed, the market analysis findings can be added. Values are then input into the model to support the variance distribution. When assigning the distributions, the likeliest value must be a hard value with no equations or links to other data. Remember that the likeliest value is generally be zero indicating that the base estimate value is the likeliest value for this model. If the likeliest value is nonzero this can indicate that the base estimate may be deficient in the costing/duration of this variable. It is recommended to correct deficiencies in the base estimate prior to modeling the project.

14-8.1.3 Establishing Variance Distribution.

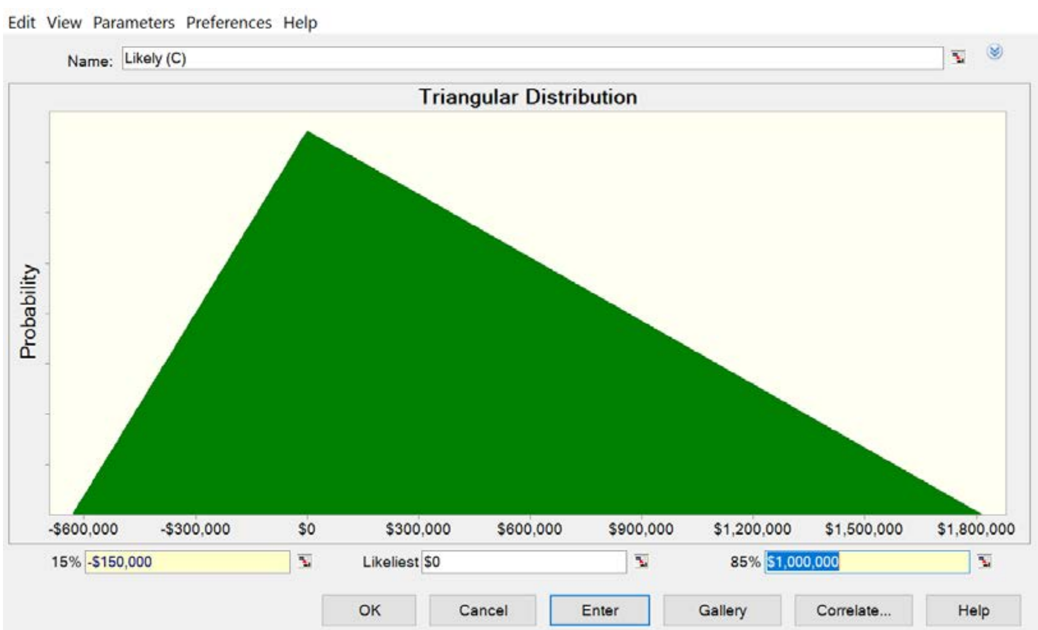
The variance distribution within the model must only address those risk events under study. The value in the base estimate establishes what is most likely to occur and the risk study is based on how the cost/duration within the estimate could vary. Most risks in the model will have zero for the likeliest value.

Within the model, the distribution gallery provides more than 20 diagrams or distribution choices that can represent the market analysis data related to low, likeliest and high value. The most commonly utilized distributions are the triangular and the uniform distributions. Other distributions may better address certain risks where better data exists and considered more appropriate. This is very rarely the case.

When modeling assumptions (risks) within the model, for each assumption (risk event), the cost engineer/risk analyst must properly name the risk event, enter the low, likeliest (usually zero), and high values and address any correlations, both positive and negative, between the respective risk events.

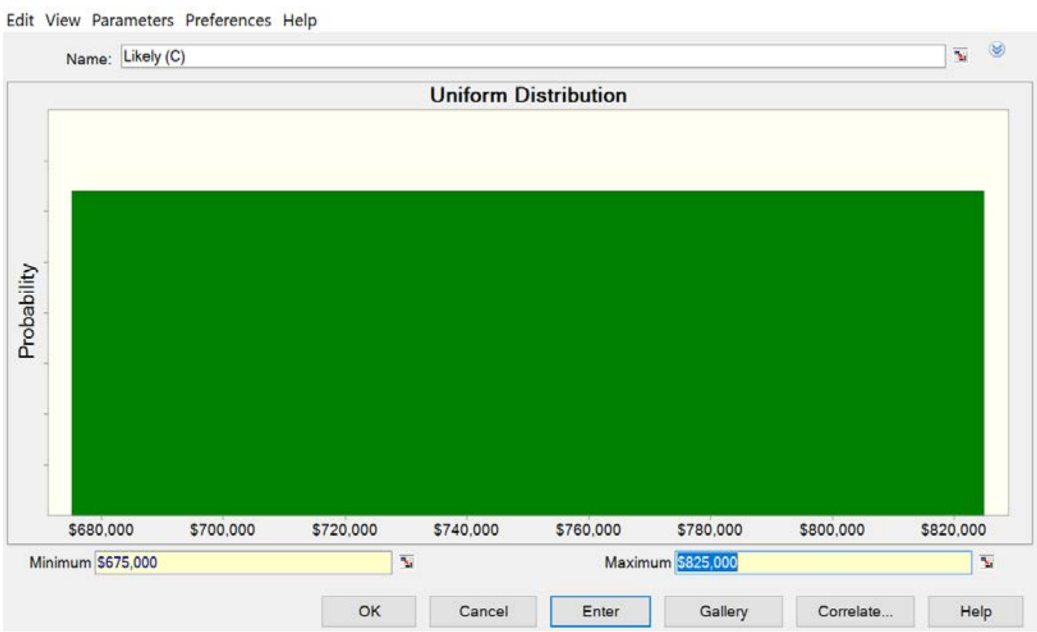
The triangular distribution (Figure 14-2) is commonly used for construction. The cost or schedule estimate generally will have likeliest value and the ranges of low and high values that are determined by market analysis. This distribution is recommended for the risk events that impact specific areas or details of the cost or schedule estimate. It is recommended to set the default parameters to low, likeliest (typically 0), and high value. It is also recommended and a GAO best practice that the low value be set to the 15th percentile and the high value be set at the 85th percentile when utilizing the triangular distribution. Lessons learned indicate that often the teams are too optimistic in the high value and underestimate the high value of the risk. There is research that shows that even the most experienced subject matter experts' opinion on the impact rarely if ever exceeds the 85th percentile.

Figure 14-2 Example of Triangular Distribution



The uniform distribution (Figure 14-3) is used when any value between the low and high value is equally likely to occur. In these instances, only two points are needed, the low and high value. A second variable of Probability of Occurrence could be added to the equation for events with discrete causal effect such as a storm or overtopping event. Caution must be exercised to use this approach to ensure the modeling is correct. Often a triangular distribution may be more appropriate.

Figure 14-3 Example of Uniform Distribution



14-8.1.4 Forecast.

The input risk distributions are used by the model to develop the forecast. The cost engineer/risk analyst needs to understand what the summation of the assumption represents. Simply summing the assumption cells and creating a forecast on a formula cell will yield the variance of the model. The creation of confidence tables and charts are not an automatic function but instead are created using the outputs of the forecast cell.

The cost engineer/risk analyst must set the model parameters related to desired reports, decision variables, defining the forecast, establishing precisions, etc. Once the model includes the risk events under study, distribution variances have been assigned, duplications and correlations have been addressed, and the base estimate captured, the cost engineer/risk analyst is ready for the initial model run.

14-8.1.5 Model Execution and Evaluation.

By this time, the cost engineer/risk analyst has a feel for the quality of the scope, base estimate, and market analysis. It will be of value when reviewing the initial output data. The cost engineer/risk analyst evaluates the initial reports, reviewing areas of potential conflict or inaccuracy. Even if the contingency values appear reasonable, a QC check must still be performed.

Generally, several iterations will be performed as the model is studied for logic, assumptions, and values. Through several iterations, the model is corrected and improved; however, care must be taken to ensure the model is not arbitrarily adjusted to present preferred results. Ultimately, the final product and report must reflect logic and pass the scrutiny of independent review.

14-8.1.6 Model Results Quality Control (QC).

A QC is required to validate reasonableness after the initial model/first trial has been run. Contingency calculations may seem too low or too high, based on the cost engineer/risk analyst's knowledge of the scope and cost and schedule estimate quality. If the contingency data falls significantly outside the anticipated range, there may be errors within the model, the base estimate, or market analysis. Within the sensitivity chart (Figure 14-5), the order of high-risk events may seem unlikely or out of expected order.

Common mistakes include:

- Poor project scoping. Risk analysis cannot overcome significant omissions or errors in scope of the project. If something significant is missing, the CSRA may not provide an adequate contingency.

- Base estimate is too optimistic or too conservative. A conservative base estimate could result in the outcome of negative contingency or an optimistic base estimate could result in the base estimate falling below zero percentage of occurrence.

- Double counting of risks - There may be similar risk events that are listed separately within the risk register, thereby measuring the risk twice. This is especially common on schedule risks since some activities may be on the same critical path and one risk event could help mitigate another.

- Omissions of risks- There may be critical risks absent from the modeling, especially external risks.

- Risk Mitigation measures assumed to be 100% effective prior to execution and or no consideration for second and third order effects of mitigation. The second and even third level effects of risk mitigation could be more severe than the original perceived risk.

The initial output may cause a change in the risk discussions on the risk register. The discussions are to be clear and explain the logic for the chosen likelihood and impact values.

Failure to update the project CWE with the correct risk percentage or amount to show the project's overall total cost correctly will have an impact on the fixed rate costs such as SIOH that grow linearly with the construction cost.

14-8.1.7 Risk Model Output.

There are numerous model outputs that are helpful in presenting data as well as supporting the CSRA report. While not all are portrayed in this document, the more common figures used to support the final report are presented in the following paragraphs. This data is obtained from the output after the risk simulation is run.

14-8.1.7.1 Sensitivity Chart.

The sensitivity chart (Figure 14-4 and Figure 14-5) ranks risk events by way of variability. It is similar to a tornado chart, but a tornado chart does not include any effects of modeling and simply shows the absolute value of the ranges of the modeled variables from highest to lowest. These charts can be very misleading as to the true contribution of contingency to the project. The risks with the largest ranges of cost or schedule typically show up at the top of the chart. This may or may not indicate their actual contribution to project contingency. High cost or time impacts with small ranges of variance can contribute substantially to the overall contingency but may not show up on the sensitivity chart. For example consider the following two risk events:

Risk 1. A risk with a low of -$4M(savings), a likely of $0, and a high of $4M (cost increase has a variance of $8M).

Risk 2. It is determined that most likely an event of $5M is missing from the base estimate, and it is added to the risk analysis with a low of $5M, a likely of $5M, and a high value of $6M.

From a sensitivity analysis point, Risk 1 has an $8M range and will show higher than Risk 2 ($1M range) on the sensitivity chart. Understanding and analysis of the model is required to determine the truly critical risk drivers that need to be addressed. It is recommended to compare the sensitivity results to a sorting of the risks based on the likely and high-risk values for comparison to identify additional critical risks beyond the sensitivity analysis. This is often referred to as a "Pareto ranking." Sensitivity analysis alone is not adequate for the ranking of risks in priority and the cost engineer/risk analyst must examine the risks, effects of modeling, and communicate the key risk drivers within the analysis.

Figure 14-4 Sensitivity Chart for Cost

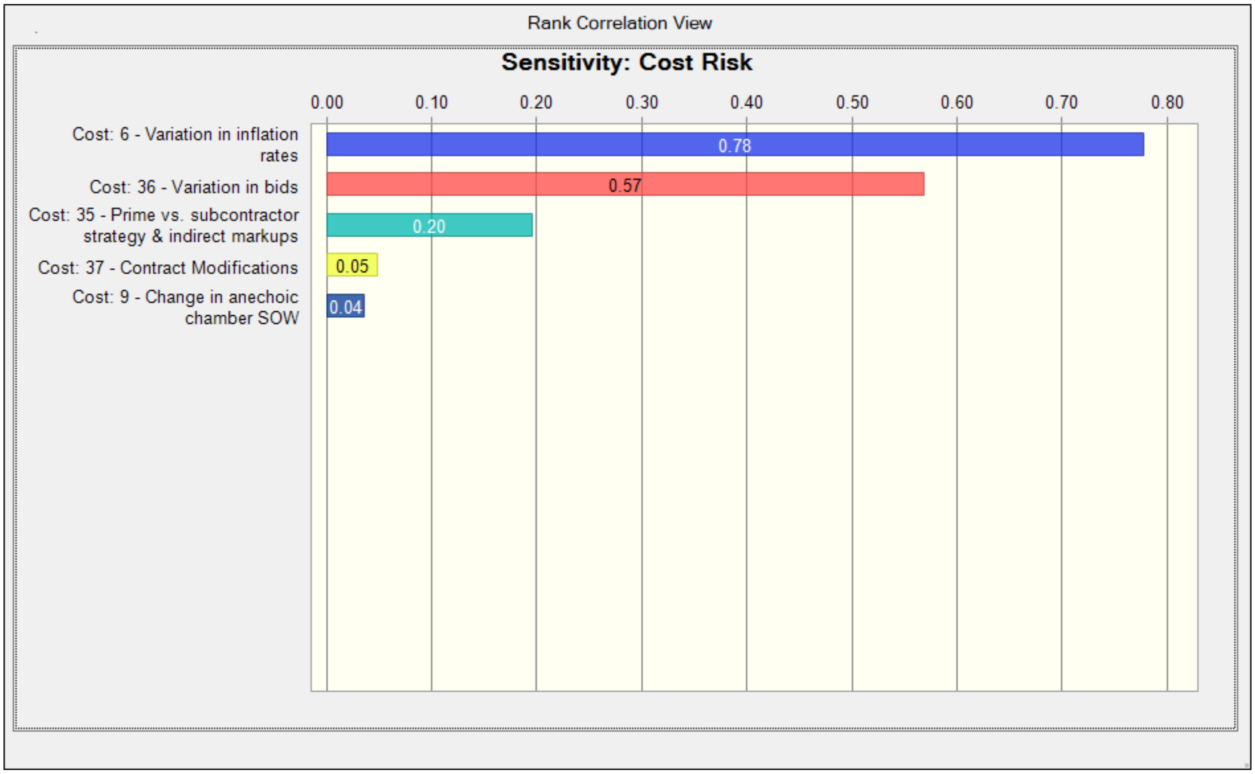


Figure 14-5 Sensitivity Chart for Schedule

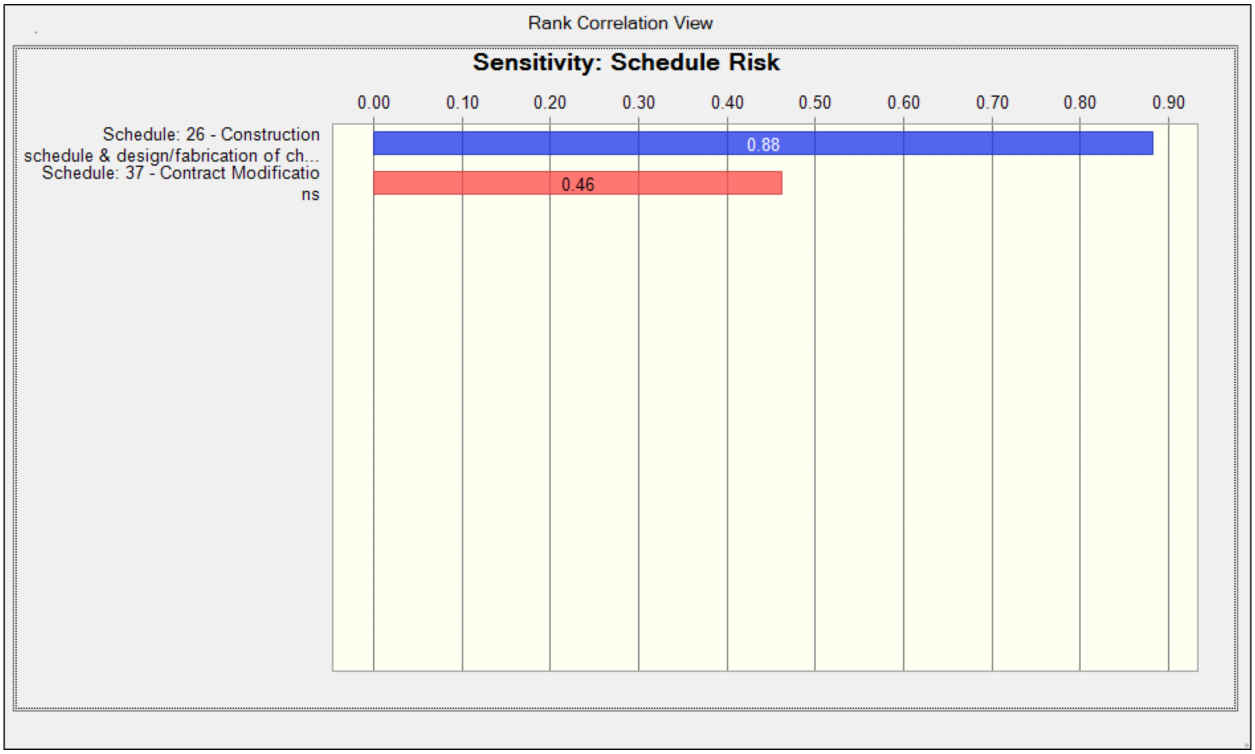

14-8.1.7.2 Contingency Analysis.

A contingency analysis is measured against the base estimate and schedule in dollars and months. The model output creates tables and figures summarizing the cost and schedule values with associated confidence level for successful project execution. It can be presented in tabular form and graphically as a confidence curve. Each agency is left to decide what confidence level they will use. It is recommended that the project contingencies be presented with confidence levels and associated contingencies in 5-10 percent confidence increments from 0-100%. Events to consider in the confidence level chosen could be life safety, project complexity, national priority, project status, and likelihood of mitigating risks. In any case, the chosen value is justified within the CSRA and main reports.

Tables 14-1, 14-2 and 14-3, and Figures 14-6 and 14-7 are an example of the final CSRA outputs.

Table 14-1 Contingency Analysis Output for Cost

Base Estimate ->	$30,889,900	
Confidence Level	Contingency Value	Contingency
0%	-4,942,384	-16%
10%	617,798	2%
20%	1,853,394	6%
30%	2,780,091	9%
40%	3,706,788	12%
50%	**4,633,485**	**15%**
60%	5,560,182	18%
70%	6,486,879	21%
80%	7,722,475	25%
90%	9,266,970	30%
100%	15,444,950	50%

Figure 14-6 Cost Contingency Analysis

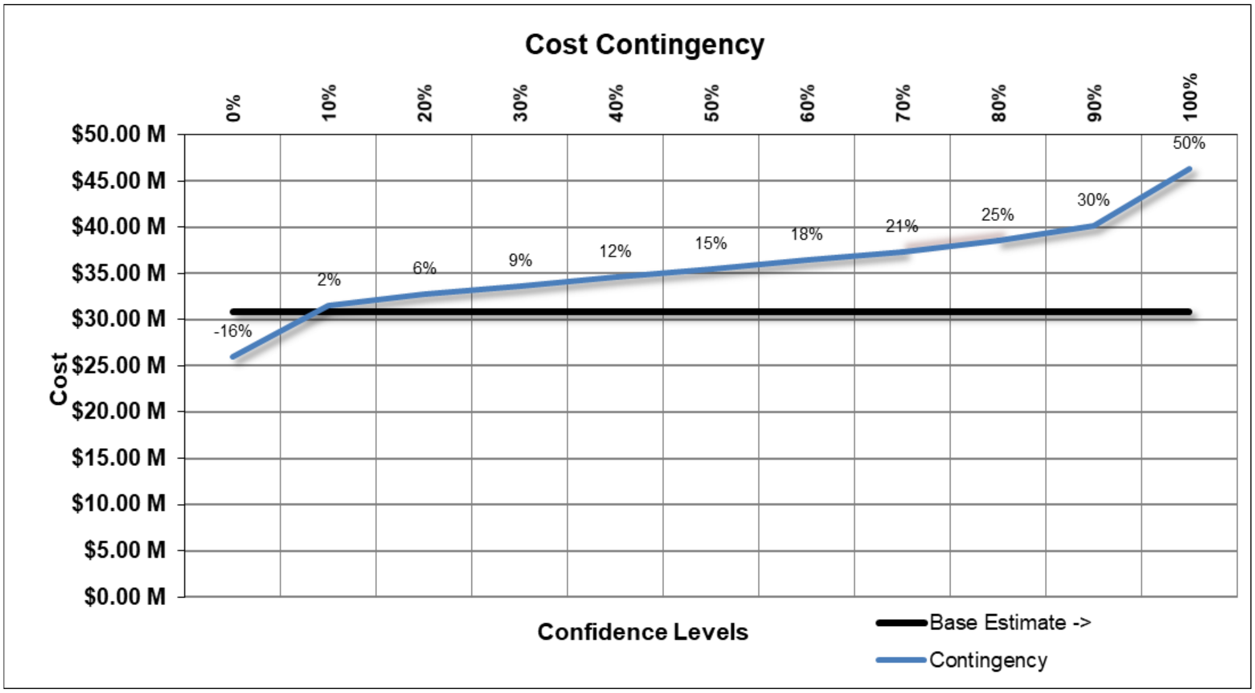

Table 14-2 Contingency Analysis Output for Schedule

Base Schedule Duration ->	53.0 Months	
Confidence Level	**Contingency Value**	**Contingency**
0%	0.5 Months	1%
10%	1.1 Months	2%
20%	1.6 Months	3%
30%	2.1 Months	4%
40%	2.6 Months	5%
50%	**2.6 Months**	**5%**
60%	3.2 Months	6%
70%	3.7 Months	7%
80%	4.2 Months	8%
90%	4.8 Months	9%
100%	6.9 Months	13%

Figure 14-7 Schedule Contingency Analysis

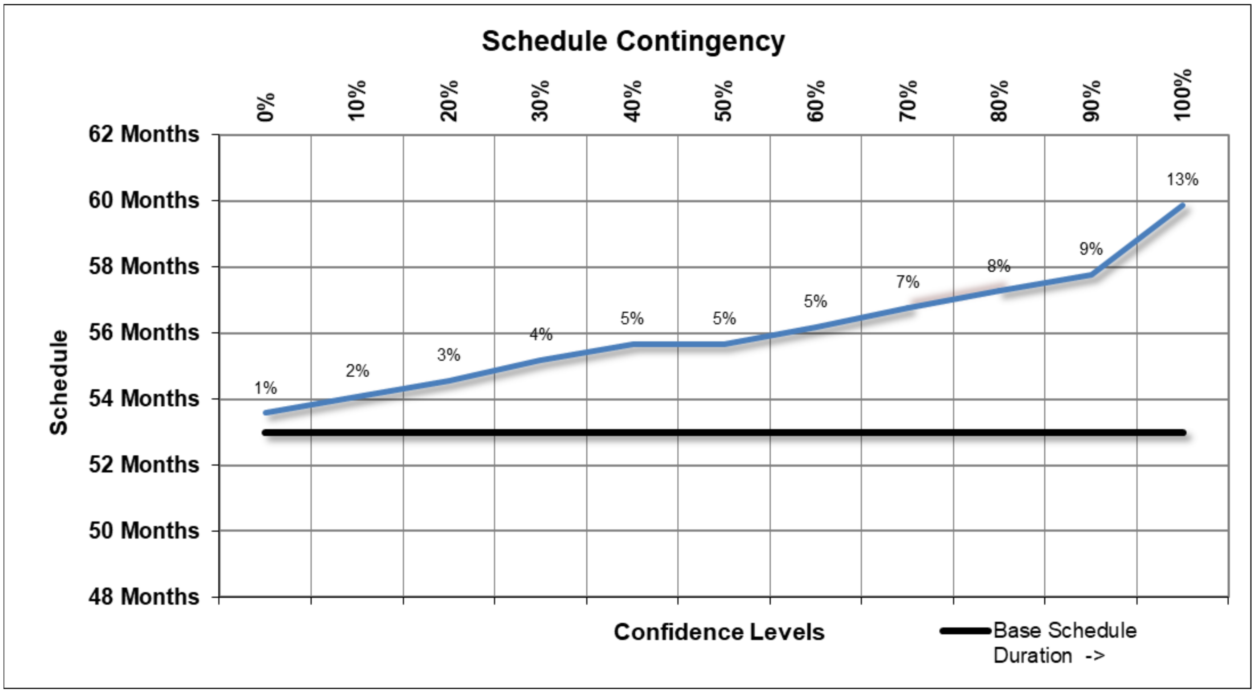

Table 14-3 Contingency Analysis Output for Cost and Schedule

Contingency on Base Estimate	50% Confidence Project Cost	
Base Estimate ->	$30,889,900	
Estimate Contingency ->	$4,633,485	15%
Base Estimate w/ Contingency (50% Confidence) ->	$35,523,385	

Contingency on Base Schedule	50% Confidence Project Schedule	
Base Schedule Start Date ->	October 1, 2021	
Base Schedule Finish Date ->	March 1, 2026	
Base Schedule Duration ->	53.0 Months	
Schedule Contingency Duration ->	2.6 Months	5%
Base Schedule w/ Contingency (50% Confidence) ->	55.6 Months	
Base Finish Date w/ Contingency (50% Confidence) ->	May 22, 2026	

14-9 CSRA DELIVERABLES.

Finally, the CSRA results are included within a report (A sample CSRA report is available on https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05). The CSRA report can be added to the cost report or it can remain a standalone report. The report is a result focused document and not include common methodology/process related discussion on CSRA. These deliverables are to be updated at each submittal as required by the inclusion of CSRA.

Include the following:

- Title page with project name, date, and author
- Executive Summary with the following points: project scope, key assumptions, major findings, observations and risk reduction recommendations.
- Tab K- Dashboard Template from CSRA model
- CSRA Model Excel file

CHAPTER 15 SENSITIVITY ANALYSIS

15-1 GENERAL.

As a best practice, a sensitivity analysis should be included in cost estimates because it examines the effects of changing cost estimate inputs, or parameters, and underlying assumptions. Sensitivity analysis involves recalculating the cost estimate with different quantitative values for selected inputs to compare the results with the original cost estimate. If a small change in the value of a factor yields a large change in the overall cost estimate, the results are considered sensitive to that factor.

Typically performed on high-cost and high-risk elements, sensitivity analysis examines how the cost estimate is affected by a change in a parameter or assumption. For example, it might evaluate how the point estimate varies with different assumptions about system reliability values, or how costs vary in response to system weight growth.

15-2 PROCESS STEPS.

For sensitivity analysis to reveal how the cost estimate is affected by a change in a single parameter or assumption, the cost estimator must examine the effect of changing one factor at a time while holding all others constant. This allows for an understanding of which factor most affects the cost estimate. By examining each factor independently, the cost estimator can evaluate the results to discover which parameters or assumptions most influence the cost estimate.

A valid sensitivity analysis typically has five steps:

1. Identify assumptions and parameters, including key cost drivers, as factors for sensitivity testing
2. Re-estimate the total cost of the program by varying one of these factors between two set amounts
3. Document the results
4. Repeat steps 2 and 3 until factors identified in step 1 have been tested independently
5. Evaluate the results to determine which factors affect the cost estimate most and document the results

15-3 IDENTIFY FACTORS.

The first step of a sensitivity analysis requires analysts to identify the factors to be varied. The sources of variation are to be well documented and traceable. Simply varying factors by a subjective plus or minus percentage is not useful and does not constitute a valid sensitivity analysis.

Uncertainty about the values of some, if not most, of the technical parameters is common early in a program’s design and development. Many assumptions made at the start of a program turn out to be inaccurate. Therefore, once the point estimate has been developed, it is important to determine how sensitive the total cost estimate is to changes in the factors. Some factors that are often varied in a sensitivity analysis are:

- Variations in specific material pricing
- Labor Rates of specific trade
- Escalation rates

In a sensitivity analysis, the cost estimator includes the factors that are most likely to change, such as an assumption that was made for lack of knowledge or one that is outside the project team's control.

Another method for identifying parameters is to examine artifacts from related analyses, such as cost and schedule risk analysis. One such artifact is a tornado chart, a special type of bar chart that shows which parameters have the greatest effect—positive or negative—on the overall point estimate.

Determining which parameters are key cost drivers can be done in several ways. One way to determine key cost drivers is to calculate the proportion of each cost element to the total cost. Those input variables affecting the highest proportion cost elements are varied in a sensitivity analysis. However, analysts may want to consider the parameters contributing to high-risk cost elements as well, even if they are not cost drivers, because these elements may become schedule drivers.

15-4 LIMITATIONS.

A sensitivity analysis reveals critical factors that most affect the cost estimate results and can sometimes yield surprises. Therefore, the value of sensitivity analysis to decision-makers lies in the additional information and understanding it brings.

However, sensitivity analysis does not yield a comprehensive sense of the overall possible range of the cost estimate. Rather, it examines only the effect of changing one factor at a time. In some cases, a sensitivity analysis can be conducted to examine the effect of multiple factors changing in relation to a specific scenario. But the risk of several factors varying simultaneously and the effect on the overall point estimate should be understood. Whether the analysis is performed on only one cost driver or several within a single scenario, sensitivity analysis tries to isolate the effects of changing one variable at a time, while risk and uncertainty analysis examines the effects of many variables changing at once.

CHAPTER 16 COMPETED PROCUREMENTS

16-1 GENERAL.

FAR 36.203 requires an IGE for contracts in excess of the Simplified Acquisition Threshold.

16-2 DIRECTIVES.

Those responsible for the preparation of IGEs for contracts should be thoroughly familiar with the requirements set forth in FAR, DFARS, their supplements, and per guidance of the cognizant design agency. The acronyms for the Federal Acquisition Regulations are listed in the Glossary.

16-3 SEALED BID ABSTRACTS.

A bid/proposal abstract are prepared on invitation for bid (IFB) procurements. The bid/proposal abstract is simply a table comparing each bidders/proposers pricing vs the IGE. An analysis is performed on the bid/proposal abstracts by the cost engineer.

16-4 PRICE ANALYSIS.

The cost engineer who prepared the IGE should be a member of the Price Evaluation Team (PET) for RFP's. A price analysis is to be developed by the PET on RFP competed procurements. The price analysis will compare the bottom line cost of each offer with the market average and IGE to provide the PET's evaluation of reasonableness. The PET notes in the price evaluation any unbalanced contract line item numbers (CLIN's) that may be considered detrimental to the government.

16-5 COST ANALYSIS.

The cost engineer who prepared the IGE should perform the cost analysis for RFP's. The cost analysis includes a technical reviewer who was part of the scoping team. A cost analysis is developed on non-competed procurements as well as on cost reimbursable procurements. For firm fixed price non-competed contracts, the cost analysis will compare individual aspects of the proposal to the IGE including labor, equipment, materials, and other markups and costs to evaluate reasonableness. For cost reimbursable projects, a cost realism analysis will determine the probable cost for each proposal given the proposal technical approach and the elemental costs of labor, material, equipment, and other markups and costs.

This Page Intentionally Left Blank

CHAPTER 17 CONTRACT MODIFICATIONS AND OTHER NEGOTIATED PROCUREMENTS

17-1 GENERAL.

FAR Subpart 36.203 requires an IGE for modifications in excess of the Simplified Acquisition Threshold. IGEs are required for unilateral modifications. For contract modifications, the amount refers to the sum of the absolute value of increases and decreases. For example, if the SAT is $250,000 a modification containing an increase of $160,000 and decrease of $145,000 has an absolute value of $305,000, and therefore an IGE will be required.

17-2 DIRECTIVES.

Those responsible for the preparation of IGEs for contract modifications should be thoroughly familiar with the requirements set forth in FAR, DFARS, their supplements, and per guidance of the cognizant design agency. The acronyms for the Federal Acquisition Regulations are listed in the Glossary.

17-3 NEGOTIATED PROCUREMENTS AND CONTRACT MODIFICATIONS.

The cost engineer has several important tasks to perform prior to actually preparing the IGE. Some of the major activities to be considered in preparing the IGE are technical and cost analysis in addition to labor, material, equipment and construction techniques include:

17-3.1 Review of Available Documents.

Reviewing available documents and becoming thoroughly familiar with the scope and requirements of the changed work. This will perhaps entail a comparison, analysis, and discussions with the designer or field office to ensure common understanding of the scope of work. The cost engineer must assure that the proposed modification or procurement action is clearly defined with regard to specified work requirements, proposed measurement, and payment.

17-3.2 Determine Status of Construction.

Determining the status of construction and how the changed work will impact the construction schedule. This will require obtaining progress reports, schedules, and discussion with the field office responsible for the construction. For major or complex changes, a visit to the construction site is required.

17-3.3 Contractor’s Existing Methods, Capabilities and Rates.

The cost engineer must be fully aware of the contractor's existing methods, capabilities, and rates of accomplishment. The IGE is not to include arbitrarily methods and capabilities different from the method in which the contractor is performing the ongoing work. The cost engineer bases the change on existing contractor operations for similar work. When work is anticipated to be subcontracted, the IGE is prepared to include subcontractor costs.

17-3.4 Current Labor and Equipment Rates.

The cost engineer must obtain current labor and equipment rates for the work force and work actually ongoing. These rates are usually available from labor reports or from the contractor upon request. Suppliers for materials are not to be contacted for quotes. The price, which the contractor is expected to pay, is the basis for estimating material costs. A list of equipment on the job is to be obtained and equipment rates determined in accordance with EP 1110-1-8, Construction Equipment Ownership and Operating Expense Schedule for owned equipment. If rental equipment is being used onsite, contact the equipment supplier for current rental rates.

17-4 PREPARATION OF COST ESTIMATES FOR NEGOTIATION.

The cost estimate can be prepared after the information has been collected and analyzed, and the cost engineer decides upon the format to present the change. It is important to have a prior agreement and discussion as previously indicated with the contractor. Generally, successful negotiations depend on agreement in scope of work and accurate quantity take-off and a detailed cost estimate supported by accurate cost data for each element. General guidance for the calculation of direct costs is as follows:

17-4.1 Additional Work.

For additional work, items and format is priced similar to a new contract as performed by the known contractor. New work is to be priced at the rates anticipated to be in effect at the time the work will be performed.

17-4.2 Changed Work.

For changed work, a separate quantity takeoff for each item directly affected will be required for both before and after the change. Each item is to be priced at the rates, which would be in effect at the scheduled time of accomplishment. Typically, each item of changed original work is priced, and each comparable item of revised work is priced at the applicable rates. The net cost (or credit) would be obtained by subtracting the total of the original work from the total of the revised work. It is important that the cost engineer maintain a comparable scope of work for both cost estimates. When an item of work will be performed as originally specified, except for a revision in quantity, the net quantity may be estimated directly for that item.

17-4.3 Deleted Work.

For deleted work, the item and format is priced similar to a new procurement as performed by the current contractor. Current labor, equipment, and material rates at the time of the modification are to be used instead of rates used in the contractor's original bid/proposal or original IGE. In addition to the direct cost of the work, overhead, profit, and bond costs are included for credit on the deleted work.

17-4.4 Impact Related Costs.

Impact related costs, if applicable, are clearly described and included as a part of each cost estimate.

17-4.5 Detail of Cost Estimate.

The cost estimate for a modification is prepared in as much detail (inclusive of detailed notes) as required to clearly cost the change for negotiations. In many instances, even more detail is required to negotiate the lowest reasonable price. The cost estimate is, however, be modified to reflect a negotiated procurement in lieu of an advertised procurement. It includes a general summary sheet relating the major categories of cost of the modification, both for increases and for decreases. Revised construction drawings and specifications are included in the modification supporting documents. When the cost engineer prepares the cost estimate, the effort is to be the same as the contractor acting prudently under the given conditions. The results will generally provide an accurate cost estimate, which can be used as a firm basis for negotiation. The cost estimate does not rely on past generalized rates and settlements unless actually appropriate to the specific modification under consideration.

17-5 COST CONSIDERATIONS.

The cost estimate should be based on the data actually collected and experienced from the project. Time motion studies are important, and periodic field visits and log records can provide this data. Previous modifications can also provide valuable data. Valuable cost data is often available from past audit reports on other modifications. With the assistance of the auditor, many costs can be readily obtained and may be directly applicable to the present modification. The cost engineer must exercise judgment in the use of audit information from a specific report, which may not be released.

17-6 TIMELINESS OF PREPARATION.

Timeliness of the cost estimate for modification is as important as its accuracy. Procurement requirements stress the importance of settlement prior to commencing the work. Therefore, the cost engineer should immediately proceed to obtain the necessary data for the modification and notify the appropriate authorities of the earliest date that the cost estimate can be completed. It is generally understood that the larger and more complex the change, the longer the time requirement for the initial preparation of an accurate cost estimate.

17-7 IMPACT COSTS.

When a modification is initiated, the settlement of that modification includes not only the cost and time change of the work directly affected but also the cost and time impact on the unchanged work. The impact portion of a modification is very important to be estimated accurately. The scope of impact may be broad and susceptible to a large variety of situations. The following discussion will provide guidance and understanding of impact cost considerations.

17-7.1 Acceleration or Delay.

Generally, the greatest portion of impact costs results from acceleration or delays due to changes. When delays due to a change can be minimized, impact costs are reduced. Impact costs are normally determined on a case-by-case basis for each particular situation. The determinations have been based on interpretation of the Contract Clauses and on Board of Contract Appeals and court decisions.

17-7.2 Comparative Review.

Impact costs are generally presented by the contractor as part of the proposal. The existing construction schedule furnished by the contractor must be analyzed to determine the actual construction and the extent of the impact at the time of the change. The modification work must be superimposed upon the original schedule in such a position to determine and minimize the delay. The revised plan must then be thoroughly reviewed relative to the existing job plan. This comparative review indicates those areas, which have been affected by the modification.

17-7.3 Factual or Judgmental Costs.

Once the extent of impact has been determined, each cost claimed must be classified as either factual or judgmental. The factual costs are those which are fixed and established and can be determined directly from records. These include rental agreements, wage rate agreements, and purchase orders. Once the item has been determined valid as a factual impact, the item cost may be directly calculated. The amount of cost change is stated on the certified document or can be determined from the scheduled time change of the construction progress plan. Judgmental costs are those, which are dependent on variable factors such as performance, efficiency, or methodology and cannot be stated factually prior to actual accomplishment. These must be negotiated and based upon experienced judgments. In actual practice, most factual costs are based to varying degrees upon judgment.

17-7.4 Cost of Impact.

The cost estimate of impact is to be prepared for each activity affecting the change. In some cases, the impact items are typically so interrelated that it is often best to develop a detailed plan for accomplishing the remaining work. Each item in this plan would be estimated at the productivity and rate in effect at the time the work is to be accomplished. The same items of work under the original plan would also be estimated at the productivity and rate in effect at the originally scheduled time. The comparison of these two cost estimates yields the cost of impact. Impact costs determined to be valid must be estimated by the most accurate method available and included in the modification.

17-7.5 Impact Factors or Conditions.

The following impact factors or conditions play a recurring role in determining impact costs. Each modification must be evaluated separately and impact costs considered especially for the implications of the particular change. Impact costs are only included by detailed itemization and only after having been found to be valid.

17-7.5.1 Factual.

Impact costs considered factual include escalation of material and labor wage rates, and change in equipment rates.

17-7.5.2 Judgmental.

Impact costs considered judgmental include change of efficiency resulting from rescheduling; loss of labor efficiency resulting from longer work hours; loss of efficiency caused by disruption of the orderly existing processes and procedures; inefficiency from tearing out completed work and the associated lowering of morale; loss of efficiency during rescheduling of manpower; inefficiency incurred from re-submittal of shop drawings, and sample materials; additional costs resulting from inability to transfer manpower expertise to other work; and change in management for the revised work.

17-7.5.3 Factual Based on Judgmental.

Impact costs considered factual but are based on judgmental decisions including increase from extending the storage period for materials and equipment; increase from extending the contract for labor cost and subsistence; increase from a longer period of equipment rentals or use; increase from a longer period of utilizing overhead personnel, materials, and utilities; and increase from a longer period of providing overhead and project office services.

17-8 SUPPORT FOR THE NEGOTIATIONS.

Before participating as part of a negotiating team, the cost engineer must become thoroughly familiar with negotiating requirements and techniques. The expertise and support of the cost engineer can be very beneficial in major and complex changes.

17-8.1 Review for Allowability.

Many of the costs that are presented in the contractor's proposal breakdown must be reviewed for allowability. Of those costs found allowable, each item must further be reviewed for applicability for that portion relevant to the particular change. The auditor has primary responsibility for this determination and should advise the negotiation team accordingly. For those cases where the auditor is not directly involved, the negotiation team must base their decisions on regulatory guidance and the best expertise available. In accomplishing the review of the proposal, the cost engineer should remain constantly aware of the contractor's profit motivation. The Government must consider all reasonable costs anticipated to be incurred by the contractor.

17-8.2 Settlement of Disputed Work Items.

In some cases, portions of the cost estimate may be revealed only to the extent determined necessary by the negotiator to settle disputed items of work. The total of the IGE will not be released during negotiations. On occasion, important information has been revealed through negligence by allowing the IGE to lay open upon the negotiation table. During negotiations the IGE including backup support is considered CUI and protected accordingly.

17-8.3 Technical Evaluation.

A technical analysis, as performed by the technical team, is the evaluation of the contractor's proposal for scope differences from the IGE. The technical evaluation also may include questions asked during negotiations. This performed prior to negotiations will help expedite the negotiation process.

17-8.4 Teaming with Negotiator.

The cost engineer should be on the negotiation team. As a team member working with the negotiator, coordinate with the contractor to agree on scope of work and format prior to preparation of the IGE and submittal of the contractor's proposal. This discussion will assist both the Government and contractor in reaching a mutually accepted scope of work to eliminate unnecessary effort for both parties during negotiations.

17-8.5 Cost Analysis.

A cost analysis is the evaluation of the contractor's proposal for cost reasonableness which is typically determined after negotiations. The cost analysis must address the cost elements within the proposal, not just the bottom line cost. This is performed prior to award of the contract or modification.

17-8.6 Revision of the Independent Government Estimate.

Revision of the IGE may be necessary as a result of an error, changed conditions, or additional information. Approval authority for revisions to the IGE remains the responsibility of the Contracting Officer or authorized original IGE-approving official. When the IGE is changed during or subsequent to conferences or negotiations, the details of the basis for the revision or changes in price must be fully explained and documented in the price negotiation memorandum. A copy of each IGE that has been approved is included in the official modification file along with the details and circumstances causing the revisions.

CHAPTER 18 LITIGATION CONCERNING THE INDEPENDENT GOVERNMENT ESTIMATE

18-1 GENERAL.

There are two major situations in which the cost engineer may become involved in litigation concerning the IGE. These situations include:

- A bid protest when bids are opened;
- A proposed change order/modification is not accepted by a contractor and the contractor pursues the dispute.

The procedure to process the issues are the same for the many types of projects or contracts associated to military programs. When either of the above occurs, the cost engineer has a major role in reviewing the IGE and evaluating the Government's position.

18-1.1 Bid/Proposals.

During the bidding process, and upon receipt of bids/proposals, if bids/proposals are significantly higher than the IGE, the Contracting Officer should verify the reasonableness of the IGE. The cost engineer is a key resource for assisting the Contracting Officer in determining reasonableness. The allowed award percentage above the IGE must be in accordance with the design agency regulations.

18-1.2 Contract Modifications/Change Orders.

During the on-going construction, changes will occur; including over-runs of quantities, and disagreements may occur between the contractor and the Government. If a dispute does arise, it generally concerns a disagreement between what the government considers a fair and reasonable cost as compared to the proposal offered by the contractor. In the event, an agreement can’t be reached between the contractor and the Government, a dispute, or claim may result.

18-2 PREPARATION OF TECHNICAL AND COST ANALYSIS BY COST ENGINEER.

The cost engineer should prepare a technical and cost analysis evaluation for documentation of the contract file. Additional information concerning factors to be considered in the technical and cost analysis is presented in Chapter 17. Reference is made to FAR sub-part 15.404 for proposal evaluation.

18-3 REVIEW OF THE INDEPENDENT GOVERNMENT ESTIMATE.

18-3.1 Bid Protests.

If there is a bid protest concerning the reasonableness of the IGE, i.e., a bidder is claiming the IGE is too low, the cost engineer conducts a review of the IGE for missing scope, site conditions, quantities, market conditions, etc.

18-3.1.1 Independent Government Estimate Evaluation.

The cost engineer reviews the IGE to be sure that it does not contain mistakes. This evaluation must be completed as soon as possible to provide timely advice to the cognizant agency's staff to preclude delay in award. If the IGE is revised, and the revised IGE brings an offeror's price within the range of a fair and reasonable price, award will be made provided funds are available. The revised IGE requires the same approval authority as the original IGE.

18-3.1.2 Fair and Reasonable Determination.

When the IGE is reviewed and has been determined to be fair and reasonable for the intended scope of work, unless the protester withdraws the bid protest, the usual procedure will require a Contracting Officers Decision (COD) in the form of a (letter) memorandum of denial of the protest unless the protestor withdraws the bid protest.

18-3.1.3 Meetings.

Meetings may be held with the apparent low bidder or contractor prior to issuance of the COD memoranda to ensure that both the Government and the protestor have the opportunity to review the project and agree to the scope of work as specified by the plans and specifications. Meetings will also allow discussion whether there are unusual conditions or circumstances that may affect or complicate the work. If a meeting reveals an error or omission in the IGE, it may be revised as previously discussed.

18-3.1.4 Resolution Assistance.

The protest/dispute may take several months to resolve. The Government's position may be reviewed and evaluated at the appropriate agency office, as well as by the General Accounting Office, a court, or a board of contract appeals. During each of these reviews, questions will arise, and the cost engineer will be called on to support the IGE. The cost engineer(s) responsible for preparing the IGE are most familiar with the IGE, as such, should be prepared to assist counsel, contracting, and other staff to resolve the issue; and be prepared to testify in court and certify the validity of the IGE.

18-3.2 Contract Modifications/Change Orders.

The cost engineer may also be required to prepare cost estimates for major or complex changes; or design change orders for on-going construction projects; major or extensive quantity overrun bid items; or even assisting in evaluating claims occurring during construction whereby an IGE is required.

18-3.2.1 Independent Government Estimate Agreement.

Prior to the cost engineer finalizing the IGE, it is important to meet with the contractor to agree on the scope of work concerning change orders for on-going construction. The cost engineer will prepare the IGE as detailed in Chapter 17. On occasion, disputes arise between the Government and the contractor, primarily due to a very wide variance between the value of work estimated by the contractor and the IGE being on the low side. When a dispute arises, meetings are necessary in an attempt to resolve the difference in cost between the contractor and the Government. Even when the scope may be in general agreement, the cost may be in dispute. The Contracting Officer may issue a unilateral modification establishing the cost and the modification may result in litigation. The procedure upon encountering an impasse generally results in the Government issuing a COD, and the process is the same as previously discussed for a bid protest.

18-3.2.2 Independent Government Estimate Revision.

It is possible that not all of the facts of a claim, change, or major overrun of quantities have been provided or verified by the cost engineer. In those cases where the cost engineer was unable to meet with the contractor, and additional facts are discovered by other means, the cost engineer may revise the IGE as appropriate, provided an original IGE was prepared. The revised IGE requires the same approval authority as the original IGE. Upon revising the IGE and mutual agreement by the contractor and Government, a modification is processed.

18-3.2.3 Revision Documentation.

When the IGE is changed during or subsequent to conferences or negotiation, the basis for the revision or changes in price must be fully explained and documented in the price negotiation memorandum. Judgment in making this type of decision is to be based on the circumstances of a particular issue, not all-encompassing, and recommendations made to the Contracting Officer. For major differences in cost, disputes or claims not resolved, a revised IGE is recommended, supported by a technical and cost analysis of the dispute in litigation.

18-4 SECURITY AND DISCLOSURE OF INDEPENDENT GOVERNMENT ESTIMATES.

Security and disclosure of the revised IGE must be handled in the same manner as the original IGE. Procedures for handling the IGE are described in Chapter 2.

18-5 MISTAKE IN BIDS.

After the opening of bids, contracting officers examine bids for mistakes. In cases of apparent mistakes and in cases where the contracting officer has reason to believe that a mistake may have been made, the contracting officer requests from the bidder a verification of the bid, calling attention to the suspected mistake. Any clerical mistake, apparent on its face in the bid, i.e., obvious misplacement of a decimal point, may be corrected by the contracting officer before award, after first receiving verification of the bid intended.

18-5.1 Before Award in Sealed Bidding.

For other mistakes disclosed before award in sealed bidding, the bidder must provide clear and convincing evidence to establish both the existence of the mistake and the bid actually intended. The contracting officer must make a determination as to the circumstances to verify the mistake; to allow the bidder to withdraw the bid; or make a determination that the bid be neither withdrawn nor corrected. The cost engineer may be part of the team of specialists to provide an analysis and a recommendation to the contracting officer. For the cost engineer, the evaluation could be the verification of a quantity as related to a unit price bid item; or determination of a fair and reasonable cost for a service or product. The cost engineer may refer to FAR part 14 for the appropriate definitions, discussions and overview of the acquisition requirements pertaining to sealed bidding.

18-5.2 Before Award in Negotiated Procurement.

The process for determination of a mistake in bid when the solicitation of a project is contracted by negotiated procurement is similar to the procedure as for sealed bidding. Additional tools are available to the Government to amend a solicitation before award as compared to sealed bidding. Clarification may be used to communicate with an offeror for the sole purpose of eliminating minor irregularities, informalities, or apparent clerical mistakes in the proposal. In negotiated procurement, discussions mean any oral or written communications between the Government and an offeror that involves information essential to determine the acceptability of a proposal or provides the offeror an opportunity to revise or modify its proposal. When, either before or after receipt of proposals, the government changes, relaxes, increases, or otherwise modifies its requirements, the contracting officer issues a written amendment to the solicitation. In the event evaluation factors are selected to evaluate proposals, price or cost to the Government is included as an evaluation factor in every source selection. If a mistake in a proposal is suspected, the contracting officer advises the offeror or otherwise identifying the area of the proposal where the suspected mistake is and request verification. If the offeror verifies its proposal, award may be made. If an offeror alleges a mistake in its proposal, the contracting officer advises the offeror that it may withdraw the proposal or seek correction by submitting clear and convincing evidence and a determination is made by agency. The cost engineer may also be involved in providing support to the contracting officer if any mistake concerns scope, quantity or prices in the IGE. The cost engineer may refer to FAR part 15 for the appropriate definitions, discussions and overview of the acquisition requirements pertaining to negotiated procurement. In the event negotiations are conducted with offeror’s in the competitive field, the cost engineer should be a member of the negotiation team.

CHAPTER 19 STANDARD COST ESTIMATING FORMS

19-1 GENERAL.

This chapter contains a discussion of the standard cost estimating forms with a brief explanation of their use in presenting manually prepared cost estimates. A Basis of Estimate is to be provided for each cost estimate prepared using these forms. Refer to Chapter 4-3 for factors to be considered when preparing the BOE.

19-1.1 Completed Examples.

Completed examples of these forms are provided in this chapter. Cost estimates developed using these forms may be prepared in an electronic format or pencil format. For uniformity in form completion, the following general guidance is given:

Each original sheet is to be in reproducible quality.

- Once the cost estimate has been completed, checked, and approved, the desired number of copies is reproduced from the original.
- For Architect-Engineer prepared cost estimates, the original is included with the final submittal.
- Originals are normally retained by the cost engineering office preparing the cost estimate.
- A cover sheet is to be initialed by both the preparer and the reviewer.

19-2 FORMS.

Although no forms are mandatory for use in preparing early cost estimates, it is recommended that the cost engineer consider using forms expressing unit price and extended price in columns. The following standard cost estimating forms may be used in preparing detailed cost estimates for military projects. Sample forms for use in development of cost estimates are provided at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-740-05 and are discussed in paragraphs 19-2.1 through 19-2.5.

19-2.1 Cost Estimate Detail Summary Sheet.

Cost Estimate Detail Summary Sheet is used to summarize project costs, to relate the method of distribution of overhead and profit to the various bid items, and to determine the overall price for each bid item. For unit price bid items, calculations, results, and rounding may be shown on the line following the total bid item price calculation. Rounding of Lump Sum bid items may also be shown similarly. The total cost, or adjusted cost, is transferred to the bidding schedule.

19-2.2 Cost Estimate Analysis.

Cost Estimate Analysis is used to itemize and quantify work tasks and to calculate the direct cost for each task. The form follows, column by column, the format shown in the

Cost Book. It is also intended as the direct cost summary sheet for each bid item. Items of significant cost are related to other detailed backup sheets with analysis or quotations.

19-2.3 Cost Estimate Worksheet.

Cost Estimate Worksheet is used for miscellaneous cost items. Common uses include quantity takeoff, description and discussion pages, and price quotations.

19-2.4 Crew and Productivity Worksheet.

Crew and Productivity Worksheet is used to develop a crew analysis and task unit cost for labor and equipment. This is necessary for significant and unusual construction tasks. The "CREW REF NO" can be completed similar to the crew names described in the Cost Book.

19-2.5 Wage Rate Calculations.

Wage Rate Calculations, is used to calculate hourly cost for laborers.

APPENDIX A BEST PRACTICES

A-1 WORK BREAKDOWN STRUCTURE.

The information contained in this appendix is to aid in the presentation of cost estimates for military programs. The structure outlined in this appendix is described in Chapter 2.

A-1.1 Uniformat II.

Military Construction Uniformat II Structure, see Table A-1.

Table A-1 Uniformat II Structure

PRIMARY FACILITIES			
Section A	Substructure		
	A10	Foundation	
		A1010	Standard Foundations
		A1020	Special Foundations
		A1030	Slab On Grade
	A20	Basement Construction	
		A2010	Basement Excavation
		A2020	Basement Walls
Section B	Shell		
	B10	Superstructure	
		B1010	Floor Construction
		B1020	Roof Construction
	B20	Exterior Closure	
		B2010	Exterior Walls
		B2020	Exterior Windows
		B2030	Exterior Doors
	B30	Roofing	
		B3010	Roof Coverings
		B3020	Roof Openings
Section C	Interiors		
	C10	Interior Construction	
		C1010	Partitions
		C1020	Interior Doors
		C1030	Fittings
	C20	Stairs	
		C2010	Stair Construction
		C2020	Stair Finishes
	C30	Interior Finishes	
		C3010	Wall Finishes
		C3020	Floor Finishes
		C3030	Ceiling Finishes

Section D	Services

Note: These item (*) are not part of the Uniformat II Structure, but are required in order to produce a complete cost estimate with markups.

APPENDIX B AUTOMATION

B-1 PURPOSE.

This appendix provides general information on using this automation and an overview of existing systems. Detailed guidance on the use of each system can be found in the appropriate system user manual for each software program. The appropriate policy guidance on the use of automation in developing cost estimates is provided in the specific Agency cost engineering regulations.

B-2 USE OF COST ENGINEERING AUTOMATED SYSTEMS.

The use of cost engineering automated systems enhances the efficiency, accuracy and credibility of project cost estimates. Automation assists in the standardization of cost estimating procedures and provides cost estimates that are easily reviewed, revised and adapted to new projects or situations. Standardization assists in collection and analysis of historical costs that can be used to develop budget estimates, for cost comparison purposes, for reporting and tracking of project cost data, and for the building of parametric models.

B-2.1 Software Updates and New Systems.

Automation continues to develop at a rapid pace. Minor upgrades may occur annually and major system changes can occur every two or three years. Major new systems may be fielded at any time. Cost engineers should insure that they are using the latest available version of the software.

B-2.2 Limitations on the Use of Automation.

Automation is just a tool and cannot take the place of professional cost engineering knowledge or judgment. The cost engineer should always be knowledgeable of the system's capabilities and limitations in relation to a project. The cost engineer must be especially careful using models and in adapting existing cost estimates to new projects to insure that there are neither duplications nor omissions in the cost estimate. Output is to be checked for reasonableness and assumptions and methodology verified and documented. The best cost automated system is not a replacement for good cost engineering judgment.

B-2.3 Automation Proponent.

The Tri-Service Committee on Cost Engineering is the proponent for all the major components of the Tri-Service Cost Engineering Systems (TRACES).

B-3 OVERVIEW OF TRI-SERVICE AUTOMATED COST ENGINEERING SYSTEMS (TRACES).

TRACES is the umbrella linking automated cost engineering systems and their associated databases. The entire system seeks to provide a user friendly cost engineering platform in a standard environment that will provide the cost engineer the tools to prepare, review, and maintain types of cost estimates.

TRACES includes the following major systems/modules: a detailed quantity take-off cost engineering system (MCACES/MII); a parametric systems for the preparation of less than fully detailed design cost estimates for military construction projects Parametric Cost Engineering System (PACES); a historical cost analysis generator (HAG/HII) to collect, store, and analyze historical cost data for facilities, and site work; a location cost factors system to adjust average historical facility cost to a specific project location (ACF) ; a dredge cost engineering system (CEDEP); a life-cycle cost (LCC) module (ECONPACK) for analysis of system design alternatives; a parametric system for preparation of Formerly Used Defense Sites (FUDS)/Cost to Complete (CTC) estimates (RACER); a scheduling software program (i.e., Microsoft Project, P2, Primavera); and risk analysis software (i.e., Oracle Crystal Ball).

B-3.1 Other Systems.

Other systems/modules which are specific to each Service's requirement include: PC-Cost, DD Form 1391 for Army users. EPG Electronic Project Generator to develop DD Form 1391 for NAVFAC users.

B-3.2 Micro Computer-Aided Cost Engineering System 2nd Generation (MCACES/MII).

MCACES/MII is a multi-user software program used for the preparation of detailed construction cost estimates for military, civil works, and HTRW programs. The system also includes a project database and supporting databases. The supporting databases include Cost Book, crews, assemblies, labor rates, equipment ownership schedule costs and models. Databases work in conjunction with each other to produce a detailed cost estimate. The databases are described in the MCACES/MII user's manual.

B-3.3 Parametric Cost Engineering System (PACES).

PACES is a parametric cost estimating system which is used primarily for development of programming or budgetary cost estimates in support of MILCON Program such as military facilities, family Housing, medical, and operation and maintenance projects. The PACES is a comprehensive program incorporating cost models for new construction, alteration, and renovation. The system uses a parametric methodology adjusting cost models for estimating project costs. The cost models are based on generic engineering solutions for building and site work projects, technologies, and processes. The generic engineering solutions were derived from historical project information, government laboratories, construction management agencies, vendors, contractors, and engineering analysis. PACES provides the capability to prepare cost estimates of military projects based on past designs on less than fully detailed design information. It uses the appropriate Work Breakdown Structure (WBS), a database of models and assemblies from historic projects, and a series of detailed linking algorithms used to develop a cost estimate. The cost estimate can then be transferred to

MCACES/MII for task-by-task analysis of the cost estimate. PACES is the Air Force's primary tool for preparing programming estimates.

B-3.4 Historical (Cost) Analysis Generator (HAG/HII).

HAG/HII is a stand-alone software/module which is used to collect and display historical cost data from awarded projects. HAG/HII uses the standard WBS structure to track historical bid costs by type, location, size and time, and has the capability of automatically normalizing and adjusting awarded costs. The HAG/HII system also provides a vehicle to retrieve selected statistical cost information from the historical cost database for use in the preparation of programming or budgetary estimates.

B-3.5 Area Cost Factor (ACF).

The ACF program calculates the area cost factor index for each specific location based on material, labor, and equipment index and matrix factors. At a given installation, the combination of local labor, material and equipment (LME) costs has the largest impact on total construction cost. Therefore, a comparison of the local LME project costs for typical military construction at different cities would give a comparison of relative construction costs. A market basket of 8 labor crafts, 18 materials and 4 pieces of construction equipment, and seven matrix factors for each location are used in the calculation of the ACF index.

B-3.6 Life Cycle Cost (LCC) Module.

The LCC module called ECONPACK is a stand-alone program designed primarily to conduct life-cycle cost (LCC) analyses among competing design alternatives for a given project providing a record of the results. The program comes with an extensive maintenance and repair (M&R) database tailored for Army buildings. The most prominent capabilities are: (a) to conduct LCC analyses in accordance with the provisions of statutes, regulations, and requirements; (b) to calculate the present worth of individual building or facility components; and (c) to compare M&R costs for building components in the M&R database.

B-3.7 Oracle Crystal Ball.

The Oracle Crystal Ball software program provides the capability to assess risk and uncertainty associated with any Military, Civil Works or HTRW project cost estimate, at any time during the project life cycle period. This process of "probability based" estimating can be used to revise cost and schedule estimates based on "confidence levels," and can assist in the evaluation of project contingency funds. The Oracle Crystal Ball software performs cost and schedule risk analyses on cost and schedule estimates using Monte Carlo simulation techniques as the basis of its calculations.

B-3.8 Other TRACES System/Module.

The need to integrate cost estimating tools with Agency specific program/project management systems has led to the development of several cost estimating tools and models. Some of these tools are stand-alone programs designed primarily for a specific requirement and for use by base/installation personnel.

B-3.8.1 PC-Cost.

PC-Cost is a comprehensive software package that allows the user to prepare and submit programming or budgetary cost estimates based on the Department of Defense Facilities Pricing Guide and Army specific HAG/HII data. PC-Cost also allows the user to create an cost estimate from an existing detailed or parametric cost estimate, download a DD Form 1391 cost estimate for revisions (for Army users of PAX System), or create a new DD Form 1391 estimate from a template. PC-Cost also provides a mechanism for a user interface access capability with MCACES/MII and PACES.

B-3.8.2 DD Form 1391 Estimate Generator.

The DD Form 1391 Estimate Generator is one of the modules within the Army's DD 1391 Processor. It is an interactive computer program which assists users in preparing the programming cost estimate shown on the DD Form 1391, Military Construction Project Data. (The DD Form 1391 is used by DOD agencies to justify the need of a military project and serves as a funding request for the Authorization and Appropriation of Military Construction funds by Congress.) The cost estimate generator of the DD Form 1391 Processor has capabilities for automatic computation of area cost factor adjustments, size factor adjustments, and automatic escalation computation. It uses the cost data from the DOD Facilities Pricing Guide and HAG/HII to generate costs of facilities.

B-3.8.3 Electronic Project Generator (EPG).

EPG, the Electronic Project Generator, is a web-based software system that supports the development, review, and approval of Navy MILCON and SRM projects. It is the paperless vehicle by which DD 1391 supported projects are entered into the NAVFAC planning, programming, and budgeting process.

B-4 OVERVIEW OF TRACES DATABASES AND FILES.

Databases and files used by the TRACES modules are as follows:

B-4.1 Cost Book Database.

The Cost Book database is a collection of common construction detail line item tasks used in developing project cost estimates for military, civil works, and HTRW programs. The Cost Book is organized in accordance with the Construction Specification Institute (CSI) numbering system. These material costs can be modified to reflect localized costs for other locations. Each task listed provides unit costs for labor, equipment, and materials. Localized Cost Books can be developed by modifying the key rates in the national Cost Book.

B-4.2 Models Database.

This database contains groupings of assemblies for a whole facility or sitework entity. Linkage between assemblies and assemblies to tasks are by WBS or as exists in a historic cost estimate. Linkage algorithms are provided to the cost engineer for project-specific cost estimate refinement. At the heart of the detail pricing is the Cost Book task costs. Using models can reduce the time for cost estimate preparation but relies heavily on past designs using default linkages.

B-4.3 Assemblies Database.

The Assemblies database stores common groupings of related work tasks, each representing a composite cost required to create a larger piece of a project rather than a single task. The individual cost items within each assembly are either extracted from the Cost Book or from the labor and equipment databases. The database is broken down according to the WBS. Each assembly includes parameter worksheets, requiring only that you input the parameters appropriate for your specific job. Using assemblies can greatly reduce the amount of data entry required to build a project.

B-4.4 Other Databases.

Other TRACES databases include the crews' database, labor rates database, and equipment rates database.

B-4.5 Work Breakdown Structure (WBS).

This data file provides a separate hierarchical work breakdown master structure for use as a template in formatting cost estimates for military projects.

B-4.6 Cost Escalation Index.

The cost escalation index provides a historic and projected cost index for cost escalation adjustment due to inflationary factors.

B-4.7 Area Cost Factor (ACF) Index.

The ACF index is used in adjusting estimated costs to a specific geographical area. The factors reflect the average surveyed difference for each location in direct costs between that location and the national average location.

B-4.8 Department of Defense Facilities Pricing Guide.

This guide is published yearly as an update to UFC 3-701-01. The guide provides unit cost factors intended for macro-level analysis and planning in tools such as the Sustainment Cost Factors which are generally not suitable for individual facilities or projects. The guide also provides unit cost data and related adjustment factors for selected DoD facility types and is intended for use in developing project-level cost estimates and preparing MILCON project documentation (DD Forms 1391 cost estimate).

B-4.9 Army Facilities Pricing Guide ($/SF).

This index is a listing of facility unit costs normalized to a geographical location factor of 1.00. Unit prices reflect costs forecast on the basis of an assumed midpoint of construction date. This guide is published via PAX Newsletter.

B-5 ASSIGNED AGENCY.

The Assigned Responsible Agency (ARA) for TRACES is the U.S. Army Engineering and Support Center, Automated Systems Branch, TRACES group, Huntsville, Alabama. The ARA serves as the focal point for support usage of these software programs by providing operation, maintenance, and "Hot-Line" telephone support.

APPENDIX C GLOSSARY

C-1 ACRONYMS.

ACF	Area Cost Factor
ACO	Administrative Contracting Officer
A-E	Architect-Engineer
AFARS	Army Federal Acquisition Regulation Supplement
AFCEC	Air Force Civil Engineer Center
AR	Army Regulation
ARA	Assigned Responsible Agency
ASA(CW)	Assistant Secretary of the Army (Civil Works)
ASTM	American Standards for Testing and Material
AT/FP	Anti-Terrorism/Force Protection
BIA	Bilateral Infrastructure Agreement
BOE	Basis of Estimate
CACES	Computer Aided Cost Engineering System
CD	Compact Disc
CE	Cost Engineer
CLIN	Contract Line Item Numbers
COD	Contracting Officers Decision
CONUS	Continental United States

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	7/1/2017	• Added paragraph 1.5 Safety. • Minor revisions to paragraphs 1-4, 2-4.1, 2-5, 2-5.3, 2-6.3, 2-6.3.1, 2-12, 2-17, 3-1, 3-2.5 and Appendix A, B-6 and C-1. • Added requirements for final drawings and specifications to be attached to Design Build RFP. See paragraphs 3-2.1 and 3-2.2. • Added requirements and best practices as they relate to Beryllium. See paragraphs 2-6.3, Section 2-7, 2-15.1.1, 3-1, 3-1.6, 3-2.3, 3-2.4.1, Section 3-2.7, and Appendix B-4.
2	7/1/2021	• Added reference to EM 385-1-1 in paragraph 2-3 Design Criteria. • Minor revisions to paragraphs 2-6.3, 3-2.4.1, 3-2.5, 3-2.5.1, 3-2.5.2, 3-2.6, 3-2.6.1, 3-2.6.2, and Appendix A. • Minor revisions to the titles of paragraphs 3-2.5 and 3-2.6 in the Table of Contents. • Added additional certified professionals that meet the requirements to prepare final drawings and specifications for paint in industrial and commercial facilities. See paragraph 3-2.6.
3	12/1/2021	• Added reference to DoD Environmental Laboratory Accreditation Program in paragraph 2-17.2.

This UFC supersedes UFC 3-800-10N, Final Draft dated July 2006.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 3-810-01N, *Navy and Marine Corps Environmental Engineering for Facility Construction*

Superseding: UFC 3-800-10N, Final Draft, *Environmental Engineering for Facility Construction.*

Description: This UFC provides specific criteria on environmental engineering design topics as they relate to project development of demolition, renovation and site development projects. In these situations, it is primarily intended to address hazardous waste management. It is organized into technical requirements and design deliverables. Requirements for design deliverables beyond or in more detail of what is already required by a Core UFC or by FC 1-300-09N and are provided for NAVFAC-only.

Reasons for Document:

- Provide criteria for meeting \1\ DoDI 6055.01 and applicable Occupational Safety and Health Act (OSHA) Standards/1/, U.S. Environmental Protection Agency (EPA) requirements, and other Federal, state, and local laws and regulations.
- Provide technical requirements for hazardous waste field investigation and design criteria in the development of reports, specifications, and drawings.
- Establish minimum technical requirements and deliverables, including environmental reports, specifications and drawings, in support of design activities.
- Define minimum requirements for specifications and contract drawings as they relate to hazardous materials.

Impact: By providing standardized criteria for the identification of hazardous materials during design it is expected that construction schedules and cost for change orders will be reduced by having adequate hazardous waste information included in the contract documents during the bidding process.

Unification Issues: Requirements in this FC conform to Navy instructions and manuals. These requirements include NAVY specific requirements that have not been unified. These Navy requirements may not work for Army and Air Force operations because of their organizational and operational differences.

TABLE OF CONTENTS

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Environmental Engineering combines the principles of engineering and science to protect the environment, preserve resources, and enhance public health. Congress has enacted various acts to improve or protect the natural environment, clean up polluted sites, and protect human health by providing requirements for drinking water, wastewater management, clean air, and various other issues that affect public health. This legislation establishes conditions requiring Federal agencies to implement projects in a manner that maintains or enhances the environment and public health.

1-2 PURPOSE AND SCOPE.

This document provides technical criteria and outlines technical requirements for the more typical aspects of the Environmental Engineering. It is not intended to cover all aspects of Environmental Engineering. It is primarily intended for building demolition and building renovation projects. It does introduce other topics such as cultural resources preservation, wetlands protection, and remediation of contaminated soil and groundwater. While topics such as contaminated soil and groundwater are introduced, this UFC is not intended to cover the remediation of all hazardous materials. Where remediation of specific hazardous materials not covered in this criteria is warranted, contact the appropriate Environmental Engineering media manager. Many of these topics are considered during the National Environmental Policy Act (NEPA) process. This UFC assumes that appropriate NEPA actions have been accomplished prior to committing resources to any proposed activity. Many facilities were constructed with materials that are now considered hazardous to worker safety and the environment. Removal and disposal of these materials requires a complex analysis of Federal, state, and local regulations to determine the appropriate methods for removing and disposing of these hazardous materials. Use this UFC to determine the minimum environmental engineering design requirements. State and local regulations may be more stringent. Where other state or local criteria regulatory requirements exist, comply with the more stringent requirements.

1-3 APPLICABILITY.

This UFC applies to all military service elements and contractors involved in the planning, design, and construction of Navy and Marine Corps facilities worldwide.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, \1\DoD Building Code (*General Building Requirements*)/1/. UFC 1-200-01 provides applicability of model building codes and unique government criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and other UFCs and Government criteria referenced therein.

1-5 SAFETY.

\1\All DoD facilities must comply with DoDI 6055.01 and applicable Occupational Safety and Health Administration (OSHA) safety and health standards./1/

1-6 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-7 GLOSSARY.

Appendix C contains acronyms and abbreviations used in this document.

CHAPTER 2 TECHNICAL REQUIREMENTS

Identification and compliance with all Federal, state and local environmental regulations requires comprehensive environmental investigations, analysis, design and engineering. A lack of these comprehensive environmental tasks and efforts leads to increased project schedules and costs, and potential Notices of Violations (NOV) and fines.

2-1 PERMITS.

Identify, assist or provide, as applicable, all permits, approvals and fees required for the design, construction and operation of the proposed project from Federal, state and local regulatory authorities or overseas equivalent. Comply with FC 1-300-09N for professional registration requirements. Licensure in the state where the project is located may be required to obtain permits and approvals. Coordinate with the Installation Environmental (EV) staff to obtain the project NEPA documentation, as applicable, for project specific requirements. For areas outside of the United States and its territories and possessions with host nation agreements, follow design approval procedure as directed in project scope and by the Government Project Manager. For areas outside of the United States and its territories and possessions without Host nation agreements, the Government will review and approve environmental plans.

2-2 REGULATORY NOTIFICATIONS.

Identify all regulatory notification requirements in accordance with Federal, state, and local regulations. Where the Navy needs to provide public notification, coordinate with the Government Project Manager and the Installation EV staff. Require the Contractor to provide copies of all regulatory notifications to the Government Project Manager and the Installation EV staff. Typically, regulatory notifications are provided for the following (this listing is not all inclusive): demolition, renovation, national pollutant discharge elimination system defined site work, or remediation of hazardous materials (such as asbestos, hazardous waste, and lead-based paint).

2-3 DESIGN CRITERIA.

Contact the Installation EV program staff for specific environmental requirements for the project location. Design projects in accordance with applicable requirements of the local regulatory agency with jurisdiction over the installation and the criteria in this UFC; whichever is more stringent.

Provide design in accordance with the following criteria precedence:

- Federal regulations required for installations in the United States, U.S. Territories, and U.S. Possessions governed by U.S. law

- Department of Defense Policies

- Department of the Navy Policies

- State and local regulations for the project location
- \2\EM 385-1-1 *Safety and Health Requirements*/2/
- Final Governing Standards (FGS) and Overseas Environmental Baseline Guidance Document (OEBGD)
- Protection of natural resources and minimization of potential environmental impacts

2-4 FIELD INVESTIGATION.

Comply with EM 385-1-1 and all safety and environmental regulations during field investigations, surveys, sampling, abatement and removal procedures, material management, and waste management. Take precautions to protect human health and the environment as required by Federal, state, and local regulations and DoD policy. Ensure that the contract documents include information and survey data sufficient to identify and quantify the materials listed in the following paragraphs.

Complete all field investigations (e.g., information gathering, surveys, sampling and testing), for the environmentally sensitive materials indicated below. Each Installation maintains record files pertaining to the environmental aspects of previously constructed projects. Contact the Installation EV program staff and obtain all existing surveys, test reports and drawings prior to beginning field investigations.

2-4.1 Safety.

Comply with \1\DoDI 6055.01 and the applicable Occupational Safety and Health (OSHA) Standards./1/ Verify that all preconstruction work performed and construction contract requirements, such as facility surveys, sampling, testing, and field investigations, comply with \1\ DoDI 6055.01 /1/ for respiratory protection, noise exposure, permit-required confined-space entry, personal protective equipment, protection of building occupants, and similar.

2-5 ASBESTOS-CONTAINING MATERIALS.

\1\These requirements apply to sites and projects where existing buildings or structures will be renovated, altered, repaired, or demolished as part of the scope of work. /1/Navy policy requires elimination of the asbestos hazard. Refer to OPNAV M-5090.1 Section Asbestos.

Do not remove installed RACM that are in good condition for the sole purpose of eliminating asbestos. Identify RACM that will not be disturbed or do not have the potential to be disturbed during the construction activities, and manage in place.

2-5.1 Conducting Field Investigations, Surveys and Sampling – Asbestos-Containing Materials.

Perform facility asbestos investigation, survey and sampling in accordance with 40 CFR 763 prior to any renovation, alteration, repair, or demolition project that will disturb building materials regardless of the age of the existing construction. For Federal requirements, refer to http://www2.epa.gov/asbestos/building-owners-and-managers#renovations. Data from previous asbestos surveys may be available from the Installation EV staff. Earlier surveys may not have included all suspect RACM that will be impacted by the project. This may include, but is not limited to, roofing materials, crawl-space soils, and confined utility chases. Provide personnel who are currently Environmental Protection Agency (EPA) accredited asbestos inspectors to perform ACM sampling.

2-5.2 Laboratory – Asbestos-Containing Materials.

Use laboratories that are fully equipped and proficient in conducting analyses of suspect RACM bulk samples in accordance with 40 CFR 763, are accredited by the National Institute of Standards and Technology/National Voluntary Laboratory Accreditation Program (NIST/NVLAP), and are a successful participant and maintain proficiency in the NIST/NVLAP sponsored quality assurance program for asbestos identification.

2-5.3 Control of Regulated Asbestos-Containing Materials.

Federal law defines demolition activities and renovation activities, and establishes different requirements for each one. Identify what requirements apply to the project, based on the National Emission Standards for Hazardous Air Pollutants (NESHAP) compliant survey, and\1\ include in the specifications. Before beginning any demolition or renovation activities, determine the potential for releasing asbestos. /1/ Identify the requirements for notification to the regulatory agency and include in the specifications.

2-6 PAINT.

2-6.1 Lead-Based Paint in Target Housing and Child-Occupied Facilities.

These requirements apply to projects involving the renovation, alteration, or repair of any target housing or child-occupied facility. Child-occupied facilities may include, but are not limited to, daycare centers, preschools, or kindergarten classrooms.

Federal regulations include specific requirements for any work in a child-occupied facility under EPA Title X and EPA RRP Rule. EPA Title X is not limited to residential units, and also applies to child-occupied facilities. Design and perform all phases of work relating to Lead-Based Paint in accordance with EPA Title X and EPA RRP Rule.

2-6.1.1 Conducting Field Investigations, Surveys, and Sampling – Lead-Based Paint in Target Housing and Child-Occupied Facilities.

Evaluate all surfaces impacted by the project for lead-based paint, including, but not limited to, painted surfaces (interior and exterior), dust, and soil. Perform all sampling and testing in accordance with EPA Title X and EPA RRP Rule. Sampling and testing will include x-ray fluorescence (XRF), bulk, wipe, water, and soil sampling as required by EPA Title X and EPA RRP Rule. Provide EPA accredited professionals to perform the lead-based paint field work, sampling, and risk assessment.

2-6.1.2 Laboratory – Lead-Based Paint in Target Housing and Child-Occupied Facilities.

Use laboratories that meet all the requirements of EPA Title X, EPA RRP Rule, and laboratories performing analysis for lead-based paint chip, air, water, soil, or wipe samples. Laboratories must be fully accredited by the EPA National Lead Laboratory Accreditation Program (NLLAP) and rated proficient in the EPA Environmental Lead Proficiency in Analytical Testing (ELPAT) Program. The EPA list of accredited laboratories is available on the following website: http://www2.epa.gov/lead/national-lead-laboratory-accreditation-program-nllap.

2-6.1.3 Removal of Lead-Based Paint in Target Housing and Child-Occupied Facilities.

Abatement is a lead-based paint hazard-reduction method that is designed to permanently eliminate lead-based paint or lead-based hazards. Permanent removal is defined as having a 20-year expected life. Require abatement to be performed by certified abatement workers who successfully completed an EPA accredited abatement worker course and who are supervised by an abatement supervisor certified under EPA or under a state program authorized by EPA. Abatement activities include:

- Removing lead-based paint and its dust.
- Permanently encapsulating or enclosing the lead-based paint.
- Replacing components with lead-based paint.
- Removing or permanently covering lead-contaminated soil.

Prior to clearing an area in which lead-based paint abatement has been performed, collect and analyze a representative clearance sample by a certified individual and an accredited laboratory, in accordance with the EPA RRP Rule. Require the Contractor to comply with the EPA RRP Rule in the specifications.

Residential lead-based paint may be disposed of in construction and demolition (C&D) landfills in accordance with 66 FR 53535 in addition to being disposed of in municipal solid waste landfills.

2-6.2 Lead-Based Paint in Commercial or Industrial Facilities.

In order to dispose of lead-based paint waste from industrial or commercial sources, take a representative sample of the waste material and require analysis using the toxicity characteristic leaching procedure (TCLP). Samples equal to or greater than 5.0 milligrams per liter (mg/L) TCLP are considered hazardous and need to be disposed of in an approved hazardous waste landfill. Samples less than 5.0 mg/L TCLP are considered nonhazardous and may be disposed of in a municipal solid waste landfill or a C&D landfill. Indicate final disposition of the waste material in accordance with the test results.

2-6.3 Paint – Lead, Cadmium, Chromium, and Other Hazardous Metals.

\2\ Refer to 2-6.1 Lead-Based Paint in Target Housing and Child-Occupied Facilities for any work being performed in target housing or child-occupied facilities/2/. Paints containing lead, cadmium and chromium are often found as protective coatings on structural steel, tanks, piping, metal building components, or exterior coatings on metal surfaces and are used in current operational processes in various facilities, such as aircraft maintenance hangars, ship maintenance and repair facilities, and similar types of facilities. Require control and management of dust and particulates containing lead, cadmium, chromium, and other hazardous metals generated from construction activities in accordance with \2\29 CFR 1926.62, 1910.1026, and 1910.1027 and OPNAVINST 5100.23G/2/, to avoid contaminated indoor air or contaminated dust on building surfaces.

Identify the potential factors that affect the thresholds and exposures to building occupants and construction workers in accordance with \1\DoDI 6055.01/1/ and state codes and laws. Require facility engineering controls, building occupant protection, construction activity requirements for worker protection, and any additional requirements for safe environmental conditions in the specifications.

2-6.3.1 Conducting Field Investigations, Surveys, and Sampling – Paint.

Monitor worker exposure in accordance with \1\DoDI 6055.01/1/. Use ASTM Standards and EPA or HUD Guidelines for air monitoring criteria. Evaluate anticipated waste materials as part of the field investigation and sampling. Refer to paragraph entitled “Control and Management of Solid and Hazardous Waste” for additional requirements.

2-6.3.2 Laboratory – Paint.

Use laboratories that are fully accredited by the EPA NLLAP and rated proficient in the National Institute for Occupational Safety and Health; EPA ELPAT to perform analysis for air samples. Refer to the paragraph entitled “Laboratory - Lead-Based Paint in Target Housing and Child-Occupied Facilities” for a link to the EPA website to verify the list of accredited laboratories.

2-7 BERYLLIUM.

\1\These requirements apply to sites and projects where any existing buildings or structures will be renovated, altered, repaired, or demolished. Beryllium can be found in the air and on surfaces where beryllium is used as either a pure metal, as beryllium oxide, as an alloy with copper, aluminum, magnesium, or nickel and in certain types of slags. Facilities that have the potential to contain beryllium include:

- Primary Beryllium Production,
- Processing Beryllium Metal/Alloys/Composites,
  - Foundries,
  - Furnace Shops,
  - Machine Shops,
  - Metal Fabricating Shops,
  - Welding Shops,
  - Dental Labs,
- Secondary smelting and refining work areas (recycling electronic and computer parts, metals),
- Abrasive Blasting Shops (slags).

If not properly controlled and managed, dust or particulates containing beryllium may be deposited on building surfaces. Facility types that may contain beryllium (dust and particulates) include areas such as aircraft maintenance hangars, ship maintenance and repair facilities, automotive repair facilities, dental labs and similar types of facilities.

2-7.2 Conducting Field Investigations and Surveys – Beryllium.

Perform a beryllium investigation and survey where beryllium is known to have been used or processed. Where beryllium has been used or processed, test all surfaces impacted by the project for beryllium dust. Perform all sampling and testing in accordance with applicable ASTM and industry standards.

When investigation and sampling are performed, there are hazards associated with the generation of dust. OSHA Standards cite action levels and exposure limits with regard to worker protection. Wherever employees are, or can reasonably be expected to be, exposed to airborne beryllium at levels above the time weighted standard permissible exposure limits or short-term exposure limit; monitor worker exposure and designate a competent person to perform the investigation and sampling in accordance with 29 CFR 1910.1024, 29 CFR 1915.1024 and 29 CFR 1926.1124.

2-7.3 Laboratory – Beryllium.

Use laboratories that are fully accredited by Industrial Hygiene Laboratory Accreditation Program.

2-7.4 Management – Beryllium.

Require control and management of beryllium during construction in accordance with 29 CFR 1910.1024, 29 CFR 1915.1024 and 29 CFR 1926.1124. Areas with beryllium dust may be cleaned by high-efficiency particulate air (HEPA) filter vacuuming in accordance with 29 CFR 1910.1024./1/

2-8 RADON.

2-8.1 Radon Mitigation.

Implement a radon mitigation system design in new or renovated, altered, or repaired occupied facilities as described in UFC 3-101-01. For any occupied building renovation, alteration, or repair, identify the levels of indoor radon. In addition, comply with ASTM E2121, Navy Radon Assessment and Mitigation Program – Guidance Document for Navy Family Housing, Navy Radon Assessment and Mitigation Program – Guidebook for Naval Shore Installations, and state specific documents from the EPA for additional information concerning radon zones, and level of risk (low, medium, high), whichever is more stringent.

2-8.2 Conducting Field Investigations, Surveys, and Sampling – Radon.

Use short-term testing detectors or long-term alpha tracking detectors to determine if radon is present at the project site. The short-term test is typically 90 days and the long-term test can be up to one year. Confirm with the Installation's EV staff that the radon detection devices and the sampling strategies and procedures comply with the Navy Radon Assessment and Mitigation Program (NAVRAMP). Obtain all existing radon test information from Installation EV staff.

2-9 POLYCHLORINATED BIPHENYLS.

Eliminate Polychlorinated Biphenyls (PCB) containing materials from all Navy equipment and all electrical distribution systems. Refer to OPNAV M-5090.1, Section, Polychlorinated Biphenyls.

2-9.1 Conducting Field Investigations, Surveys, and Sampling – Polychlorinated Biphenyls.

Obtain a current environmental survey from Installation EV staff that indicates the status of PCB in the building to be renovated, repaired, altered, or demolished. Provide an inspector who is familiar with the various uses of PCB. Based on the age of the facility and the extent of the project, determine the potential PCB sources. During the field survey, the inspector is to examine the potential PCB sources for labeling and manufacturer information. If there is no label that states “non-PCB”, contact the manufacturer for more information or assume the source contains PCB.

2-9.2 Management of Polychlorinated Biphenyls.

Manage and dispose of PCB in accordance with the Toxic Substance Control Act (TSCA) and with state and local requirements. Dispose of PCB materials at facilities meeting the requirements of incineration or in a chemical waste landfill as required by 40 CFR 761 Subpart D. Contractors are required to comply with all Navy-applicable PCB requirements while performing work onsite.

2-10 LOW-LEVEL RADIOACTIVE COMPONENTS.

Components that may contain low-level radioactive (LLR) material include thermostats, switches, smoke detectors, High Intensity Discharge (HID) lamps and exit signs. If there is no label or a warning on the label that states the contents of the source, assume it contains LLR material.

2-10.1 Conducting Field Investigations and Surveys – Low-Level Radioactive Components.

Obtain a current environmental survey from Installation EV staff that indicates the status of LLR components in the building to be altered, renovated, repaired, or demolished. Provide an inspector familiar with the various building components that could contain LLR material. Based on age of the facility and the extent of the project, determine potential sources. During the field survey, the inspector is to examine the potential sources for labeling. If there is no label that states the contents contain potential LLR material, contact the manufacturer for more information or assume the source contains LLR material.

2-11 ANIMAL DROPPINGS.

2-11.1 Conducting Field Investigations and Surveys – Animal Droppings.

Testing soil and air samples for Histoplasma is not likely to be useful because the fungus is thought to be common in the environment in certain areas, and positive or negative results in soil samples does not mean the soil is a source of infection or that the fungus is not there. Treat soils, buildings, or other areas with bat droppings or bird manure as containing the Histoplasma virus. Use best practice document DHHS 2005-109 when conducting surveys or preparing specification for building renovation, alteration, or demolition projects. Do not stir up dust by sweeping or vacuuming areas containing rodent droppings or nesting material as it may contain Hantavirus. Use Centers for Disease Control and Prevention (CDC) cleaning up after rodents for cleanup requirements. http://www.cdc.gov/rodents/index.html

2-12 MOLD AND SPORES.

These requirements apply to sites and projects where any existing building(s) or structure(s) will be renovated, altered, repaired, or demolished. \1\/1/ Design moisture barriers and retarders as defined in UFC 3-101-01. Additional requirements can be found in EPA 402-K-01-001.

2-12.1 Conducting Field Investigations, Surveys and Sampling – Molds and Spores.

During field investigations for hazardous constituents, areas with chronic moisture may be found and recognized as potentially containing harmful molds. Renovations, alterations, or repairs that involve unoccupied areas of a building often include significant water damage and fungal growth, which could pose a hazard to construction workers, the design team, and to occupants of other parts of the building. Complete the Microbial Assessment Survey and Report prior to the preparation of the project specifications. Provide a qualified microbial assessor that meets at least one of the following criteria to complete the survey:

- Bachelor's degree from an accredited university or college with a major in engineering, architecture, building construction, occupational health, microbiology, occupational safety, or a related natural or physical science. An additional 2 years' experience in conducting microbial investigations is required.

- Associates degree from an accredited university or college with a concentration in environmental, natural, or physical sciences. An additional 4 years' experience in conducting microbial investigations is required.

- Certification as an industrial hygienist as certified by the American Board of Industrial Hygienists, safety professional as certified by the Board of Certified Safety Professionals or engineer. An additional one year of experience in conducting microbial investigations is required.

- Certification by the American Council for Accredited Certification as a Council-Certified Indoor Environmental Consultant, Council-Certified Indoor Environmentalist, Council-Certified Mold Consultant, Council-Certified Microbial Investigator, Council-Certified Residential Mold Inspector, Council-Certified Mold Remediation Supervisor, or Council-Certified Mold Remediator.

Provide a microbial assessor familiar with signs of potential mold problems, including stains or discoloration of walls, ceilings, or carpets; swelling or sagging of building components; standing or dripping water; rot (wet or dry); and musty odors. Types of samples include air samples, bulk samples (chunks of carpet, wallboard, insulation, and similar), and water samples from drains and cooling pans. Collect samples using sterile materials and containers, and ship overnight for next day delivery in accordance with instructions provided by the laboratory. Use a laboratory with special expertise in mold analysis. Longer shipping time must be approved by the laboratory.

2-12.2 Laboratory – Molds and Spores.

Use laboratories that are fully accredited by the Environmental Microbiology Proficiency in Analytical Testing program of the American Industrial Hygiene Association to perform analyses for fungi (molds) or bacteria.

2-13 STORAGE TANKS.

These requirements apply to hazardous waste storage tanks regulated under 40 CFR 264 Subpart J and 40 CFR 265 Subpart J. UFC 3-460-01 covers the general environmental criteria and standards for storage tanks containing regulated substances subject to the provisions of the Resource Conservation and Recovery Act (RCRA) Part 280. Evaluate sites with known tanks, known soil, or groundwater contamination at the beginning of the design of facility renovations, repairs, demolition, and construction so appropriate precautions can be taken to protect workers and the environment prior to excavation.

2-13.1 Tank Installation.

Projects that include the installation of new storage tanks, including reinstalled tanks or replaced tanks, used to contain hazardous waste at treatment, storage, and disposal facilities are subject to Federal regulation and are to comply with the requirements set forth in 40 CFR 264 Subpart J and 40 CFR 265 Subpart J. Design storage tanks to meet Federal regulation for tank location, secondary containment, cathodic protection, leak-detection system, leak-detection testing, and similar.

2-13.2 Tank Removal.

These requirements apply to sites and projects where aboveground storage tanks (AST) or underground storage tanks (UST) are known to exist. Obtain copies of available reports, such as tank integrity assessment reports, groundwater sampling and testing, contaminated soil sampling and testing, and Closure Reports from the Installation EV staff. Coordinate with the Installation EV staff in order to determine the requirements to initiate a permanent closure process of the storage tank as applicable. Closure activities are regulated at the state level. Storage tanks and piping systems may be permanently closed by removing them from the ground, or by decontaminating and filling the empty tanks with an inert solid material, which is referred to as being “closed in-place”. Dispose of AST or UST following the hazardous waste requirements discussed in the paragraph entitled “Hazardous Waste”.

2-13.2.1 Conducting Field Investigations, Surveys, and Sampling – Storage Tanks.

Where the construction site contains tanks, a site inspection must be performed. Before performing field investigations and sampling, obtain all available information regarding AST and UST from the Installation EV staff. Develop a soil and groundwater sampling and testing plan. See paragraph entitled “Conducting Field Investigations, Surveys and Sampling – Contaminated Soil and Groundwater". Encompass all tank system components. Include information such as the age of the unit, corrosions-protection measures in place, and results of prior leak tests or inspections of the tank. See information required in the paragraph entitled "Report - Tanks".

2-13.2.2 Laboratory – Storage Tanks.

Use laboratories to analyze potentially contaminated soils, free product, or sludge that are fully equipped and proficient in conducting analysis in accordance with EPA SW-846, EPA 540/R-99/008, EPA-540-R-014-002, EPA-540-R-04-004, and certified by the National Environmental Laboratory Accreditation Conference (NELAC).

2-14 CONTAMINATED SOIL OR GROUNDWATER.

These requirements apply to sites and projects where contaminated soil or groundwater is known to exist. Evaluate sites with known soil or groundwater contamination during the planning phase and before initiating any facility design work. Obtain copies of available reports, such as groundwater sampling and testing, contaminated soil sampling and testing, and remediation reports, from the Installation EV staff. Coordinate with the Installation EV staff to identify permit conditions applicable to soil, restrictions on land development, and other requirements that must be considered for the project. Prepare specifications and construction documents that accurately convey existing site conditions as they pertain to soil and groundwater contamination. Manage and dispose of contaminated soils and groundwater in accordance with the requirements described in the paragraph entitled "Hazardous Waste".

2-14.1 Conducting Field Investigations, Surveys, and Sampling – Contaminated Soil or Groundwater.

When the construction site is known to contain contaminated soil or groundwater and no determination actions have been started, perform a site inspection. Before field investigation and sampling, obtain all available information regarding contaminated soil or groundwater from the Installation EV staff. Develop a soil and groundwater sampling and testing plan that contains, at a minimum, the procedure for collecting samples, the frequency of the sampling events, the test methods that will be employed, type of sampling design and sampling density, error Type, confidence level and procedure for handling samples. Follow EPA Soil Screening Guidance (SSG). The SSG presents a framework for developing risk-based, soil screening levels (SSL) for protection of human health. Screening levels are not national cleanup levels; instead, they are intended to streamline the evaluation and cleanup of site soils by helping site managers eliminate areas, pathways and chemicals of concern at National Priority List sites. See information required in the paragraph entitled "Report - Contaminated Soil or Groundwater".

2-14.2 Laboratory – Contaminated Soil or Groundwater.

Use laboratories that are fully equipped and proficient in conducting analysis in accordance with EPA SW-846, EPA 540/R-99-008, EPA-540-R-04-004, and certified by the NELAC to analyze potentially contaminated soils or groundwater.

2-15 CONTROL AND MANAGEMENT OF SOLID AND HAZARDOUS WASTE.

Disposal or ultimate disposition of waste materials is performed on all projects. Waste reduction in the form of recycling or reuse is encouraged. Require the Contractor to develop a waste management and reduction plan to be used during construction. Coordinate with the Installation EV staff and identify materials suitable for recycling or reuse, taking into account the Installation's recycling program. If disposal or ultimate disposition of hazardous or contaminated materials, soils, or groundwater are part of the project a waste characterization is required. Consult regional, state, and local regulations for more stringent threshold levels. To determine whether a waste fails the toxicity characteristic, perform a TCLP analysis on the waste. Note the TCLP analysis differs from total constituent laboratory analysis; TCLP analysis is only for disposal needs. However, total analysis may also be needed. Solid or nonhazardous waste accumulation requirements can be found, if regulated, within state-specific regulations and should follow industry standard.

2-15.1 Hazardous Waste Accumulation.

Require accumulation and storage of contaminated media and any debris according to applicable requirements while awaiting transportation and disposal. Require coordination with the Installation EV staff to determine what quantity may be stored on-site. Accumulate and manage any hazardous waste generated in accordance with 40 CFR 262, 40 CFR 264, and 40 CFR 265, Installation, state-specific and local requirements, whichever are more stringent.

2-15.1.1 Hazardous Waste.

Federal regulations define waste as hazardous when it exhibits a hazardous characteristic (such as ignitability, corrosivity, reactivity, or toxicity) as specified in 40 CFR 261, Subpart C, or when the waste contains a listed hazardous waste as identified in 40 CFR 261, Subpart D. RCRA requires that solid wastes be properly characterized at the point of generation. RCRA regulates "cradle to grave" control over hazardous wastes. Request recycling and reuse of waste classified as hazardous, in accordance with the requirements in 40 CFR 261.6.

Require treatment of hazardous wastes in accordance with 40 CFR 268. This section identifies treatment standards for hazardous waste that must be met before waste may be disposed (placed on the land). Follow the requirements of 40 CFR 262, 40 CFR 264, and 40 CFR 265 when accumulating hazardous waste onsite. Coordinate with the Installation EV staff for generator status of the Installation and applicability, including instances when an EPA identification (ID) number is required, accumulation requirements regarding quantities and time allowed, inspections, required documentation and labeling, reporting, training, and contingency planning. Table 2-1 identifies regulatory references that provide requirements for each of these. States may have more stringent requirements than Federal regulations provide. Determine state requirements for hazardous wastes prior to generation, characterization, classification, and disposal to determine the most stringent requirement.

Table 2-1 Regulatory References

	Conditionally Exempt Small Quantity Generators	**Small Quantity Generators**	**Large Quantify Generators**
Quantity Limits	≤100 kilogram (kg) per month ≤1 kg per month of acute hazardous waste ≤100 kg per month of acute spill residue or soil §§261.5(a) and (e)	>100 <1,000 kg per month §262.34(d)	≥1,000 kg per month >1 kg per month of acute hazardous waste >100 kg/month of acute spill residue or soil Part 262 and §261.5(e)
EPA ID Number	Not required	Required §262.12	Required §262.12
On-Site Accumulation Quantity	≤1,000 kg ≤1 kg acute ≤100 kg of acute spill residue or soil §§261.5(f)(2) and (g)(2)	≤6,000 kg §262.34(d)(1)	No limit
Accumulation Time Limits	None	≤180 days or ≤270 days (if greater than 200 miles) §§262.34(d)(2) and (3)	≤90 days §262.34(a)
Storage Requirements	None	Basic requirements with technical standards for tanks or containers §§262.34(d)(2) and (3)	Full compliance for management of tanks, containers, drip pads, or containment buildings §262.34(a)

	Conditionally Exempt Small Quantity Generators	Small Quantity Generators	Large Quantify Generators
Sent To:	State-approved or RCRA permitted/ interim status facility §§261.5(f)(3) and (g)(3)	RCRA permitted/interim status facility §262.20(b)	RCRA permitted/ interim status facility §262.20(b)
Manifest	Not required	Required §262.20	Required §262.20
Biennial Report	Not required	Not required	Required §262.41
Personnel Training	Not required	Basic training required §262.34(d)(5)(iii)	Required §262.34(a)(4)
Contingency Plan	Not required	Basic plan §262.34(d)(5)(i)	Full plan required §262.34(a)(4)
Emergency Procedures	Not required	Required §262.34(d)(5)(iv)	Full plan required §262.34(a)(4)
Department of Transportation (DOT) Transport Requirements	Yes (if required by DOT)	Yes §§262.30-262.33	Yes §§262.30-262.33

2-15.1.2 Universal Waste.

The regulations govern the collection and management of batteries, pesticides, mercury-containing equipment, and lamps, thus facilitating environmentally sound collection and proper recycling or treatment. Comply with the Federal universal waste regulations set forth in 40 CFR 273. States may modify the universal waste rule and add additional universal waste(s) in individual state regulations. Coordinate with the Installation EV staff and research the specific state for additional regulations that apply.

Universal waste may be accumulated for up to one year from the date when the waste is generated. In most cases, universal waste (such as, lamps and batteries) are “generated” when they are removed from service.

2-15.1.3 Beryllium.

\1\Comply with 29 CFR 1910.1024, 29 CFR 1915.1024 and 29 CFR 1926.1124./1/

2-15.1.4 Used Oil.

Comply with EPA required practices in 40 CFR 270, called "management standards," developed for used oil. These include proper labeling, proper and maintained containers, spill and leak prevention, and proper recordkeeping. Comply with additional, more stringent state requirements, if applicable. States may have additional more stringent requirements.

2-15.2 Conducting Field Investigations, Surveys, and Sampling– Solid and Hazardous Waste.

Require a waste characterization study (including solid and liquids) before disposing of potentially unknown hazardous or contaminated wastes. In order to determine if anticipated construction waste (solid or liquid) is within regulatory limits for disposal and ultimate disposition as a nonhazardous material, request the analysis of a representative sample of the waste stream in accordance with Federal regulations using the appropriate EPA analytical methods. Perform this sampling in accordance with RCRA procedures, state, and local regulations and with EPA and state guidelines for avoiding exposure to human health and the environment. Establish a health and safety program to be followed during the sample collection process, select the statistical method to be followed, and set a quality control procedure for the data collection in accordance with EPA 530-D-02-002. Collect a representative sample of the anticipated waste stream; it may be necessary to collect subsamples of various materials to collect an accurate heterogeneous waste stream sample. To accomplish the analysis of a heterogeneous waste stream, collect a composite sample that can be analyzed in accordance with Federal regulations, EPA protocols, and ASTM Standards. The representative composite sample should be prepared from samples of each of the different building material categories, and then mixed in proportion to the percentage by weight of the different components in the anticipated waste stream. Patch and repair sample locations with suitable materials. Consult a qualified laboratory for required sample quantities to obtain accurate analysis. Should other sampling methodologies be used, request coordination with onsite personnel before sample collection and analysis.

2-15.3 Laboratory – Solid and Hazardous Waste.

Use laboratories that are fully equipped and proficient in conducting analysis in accordance with EPA SW-846, EPA 540/R-99-008, EPA-540-R-04-004, and NELAC certified to perform analysis for potential hazardous waste.

2-16 OTHER ENVIRONMENTAL REQUIREMENTS.

2-16.1 National Environmental Policy Act.

NEPA and 40 CFR Parts 1500-1508, require Federal agencies to assess and consider the potential impacts to the environment by their proposed actions that occur within the United States. Executive Order (EO) 12114, requires similar assessment and consideration as NEPA, but applies to proposed actions occurring outside the United States. A NEPA analysis should be completed prior to beginning design. NEPA is prepared based on previous findings, anticipated building use and planned building locations. NEPA documentation addresses the requirements in Federal statute or EO that applies to the resources found within the project area.

Obtain the NEPA documentation prepared for the project from the Installation EV staff. The NEPA documentation identifies any sensitive resources that exist within or adjacent to the site and any mitigation or avoidance measures that are required. Comply with measures identified in the NEPA documentation and include them as contract requirements. If conditions change from what was analyzed in the NEPA document, such as a change in use, location on the site, the addition of or change in location of supporting facilities, or discovery of new information about the site, contact the Installation EV staff to determine if a modification to the NEPA document is required.

2-16.2 Cultural Resources.

Section 106 of the National Historic Preservation Act of 1966 (NHPA) requires Federal agencies to consider the effects of actions they fund or approve on any district, site, building, structure, or object that is listed in or eligible for listing in the National Register of Historic Places (NRHP). The primary agency for enforcement of NHPA is the State Historic Preservation Officer (SHPO). Federal agencies must comply with Section 106 of the NHPA by adherence to the regulations found at 36 CFR 800. The Native American Graves Protection and Repatriation Act of 1990 (NAGPRA); 43 CFR 10 provides a process for Federal agencies and museums to return certain Native American cultural items -- human remains, funerary objects, sacred objects, or objects of cultural patrimony -- to lineal descendants and culturally affiliated Indian tribes. NAGPRA includes provisions for unclaimed and culturally unidentifiable Native American cultural items, intentional and inadvertent discovery of Native American cultural items on Federal and tribal lands, and penalties for noncompliance and illegal trafficking. NAGPRA outlines the treatment, repatriation, and disposition of such resources and ensures consultation with associated tribes or lineal descendants.

Obtain documentation from Installation EV staff regarding any known historic properties or the potential to discover historic properties within the project site and any mitigation required to avoid an adverse effect to historic properties. Comply with state and local preservation laws in addition to Section 106 of the National Historic Preservation Act (NHPA).

2-16.2.1 Archaeology.

Comply with the Archaeological Resource Protection Act of 1979; 16 U.S.C. 470aa-470mm. The Act defines regulations for excavating archaeological sites and requires that a permit be obtained from the Federal land manager when excavation or the removal of any archaeological resource occurs on public or Native American lands.

Obtain from Installation EV staff any measures, such as buffer areas, that were agreed upon during the Section 106 process. Include these measures and the necessary language to ensure protection of any archaeological resources, as contract requirements.

2-16.2.2 Architectural.

Obtain information on historic architectural resources from the Installation EV staff and include any mitigation measures as contract requirements. Refer to UFC 3-101-01 for projects involving historic architectural resources.

2-16.2.3 Inadvertent Discoveries.

These requirements apply to all projects that include ground disturbance. Include procedures for the Contractor to follow should an archaeological site be discovered during construction. If any previously unidentified prehistoric- or historic-period archaeological sites (for example, human skeletal remains or burials and artifacts) are discovered during construction activities, suspend all ground-disturbing activities and then notify the Installation EV staff and Contracting Officer. Consultation with SHPO, interested Native American tribes, and other interested parties should occur as appropriate regarding the site’s eligibility for listing in the NRHP, project impacts, necessary mitigation, and other treatment measures.

2-16.2.4 Tribal Consultation.

Obtain from the Installation EV staff any measures, such as buffer areas that were agreed upon during tribal consultation. Include these measures as contract requirements.

2-16.3 Air Quality.

These requirements apply to sites and projects with new or existing facilities and with new or existing stationary air emissions sources. Comply with Clean Air Act (CAA) requirements and state and local regulations. Coordinate with the Installation EV staff and provide the necessary information and require purchased equipment meets the necessary regulations. The National Ambient Air Quality Standards (NAAQS) include air quality standards that are implemented at the state level in the State Implementation Plan required under Section 110 of the CAA. Verify whether the project is located in an EPA nonattainment area for criteria pollutants and identify in the construction documents how this affects the project construction schedule and cost. Provide the

Installation EV staff with the information necessary for obtaining a new or updating the existing air permits.

Verify whether asphalt pavement plants in the project area have production limitations due to what is called “summer ozone season” and design accordingly. These limitations will affect the Contractor’s schedule and construction phasing.

Permanent equipment such as new boilers and emergency power generators must be added to the Installation’s air permit as required by applicable regulations. Coordinate with the Installation EV staff to determine conditions that require adding emission sources used during construction to the air permit, and require the Contractor to comply with these requirements.

2-16.4 Wetlands/Waters of the United States.

These requirements apply to project sites where there are wetlands and other waters of the United States (streams, rivers, and bays). The discharge of dredged or fill material into waters of the United States is regulated under Section 404 of the Clean Water Act. Comply with Section 404 of the Clean Water Act. Obtain documentation from the Installation EV staff to identify the location of wetlands or other waters of the United States on or adjacent to the project area. Avoid impacts to jurisdictional wetlands or waters of the United States to the maximum extent practicable or minimize impacts if they are unavoidable. Coordinate with the Project Manager to determine if alternative sites may be explored to minimize wetland impacts. Notify the Installation EV staff to determine if the NEPA documentation requires an amendment. If impacts to the jurisdictional wetlands or waters of the United States cannot be avoided, obtain all Federal and state permits before initiating any land-disturbance activities. Require the Contractor to comply with all wetland permit conditions. Coordinate with the Installation EV staff to determine suitable mitigation options.

2-16.5 Natural Resources.

Obtain documentation from the Installation EV staff to identify what natural resources are located on or within the project area.

2-16.5.1 Threatened and Endangered Species/Critical Habitat.

Require compliance with the Endangered Species Act and protect threatened and endangered species and the habitat upon which these species rely. Obtain the documentation from Installation EV staff, to include mitigation measures, as contract requirements, to protect threatened and endangered species and critical habitat that could be located on or in the vicinity of the project area. Implement and monitor mitigation measures. Provide implementation or monitoring reports, as necessary, to the Installation EV staff.

2-16.5.2 Migratory Bird Treaty Act.

Design in compliance with the Migratory Bird Treaty Act (MBTA) between the United States, Canada, Japan, Mexico, and Russia. The MBTA makes it unlawful to take, kill, or possess listed birds, unless permitted by regulation. Implement measures identified by the Installation EV staff to ensure compliance with MBTA requirements.

2-16.5.3 Essential Fish Habitat.

The Magnuson-Stevens Fishery Conservation and Management Act requires Federal agencies to consider impacts to essential fish habitat (EFH) from projects they authorize, fund, or undertake. EFH is defined as those waters and substrates necessary to fish for spawning, breeding, feeding, or growth to maturity. These requirements apply to projects in or adjacent to EFH. In accordance with 50 CFR 600, Subpart J, Federal agencies must consider impacts to EFH from projects they authorize, fund, or undertake. Obtain the EFH assessment from the Installation EV staff and include the conservation recommendations made by the National Marine Fisheries Service as contract requirements.

2-16.5.4 Marine Mammal Protection Act.

The Marine Mammal Protection Act; 50 CFR 18 prohibits, with certain exceptions, the take of marine mammals in United States waters. These requirements apply to projects in or adjacent to the marine environment (oceans or seas). Obtain the documentation from Installation EV staff to determine what mitigation measures are required as contract requirements to protect marine mammals.

2-16.5.5 Bald and Golden Eagle Protection Act.

The Bald and Golden Eagle Protection Act; 50 CFR 22 requires the protection of the bald eagle and the golden eagle by prohibiting, except under certain specified conditions, the taking, possession, and commerce of bald and golden eagles. Obtain the documentation from Installation EV staff to determine if bald or golden eagles are located on or in the vicinity of the project area and include the mitigation measures as contract requirements to ensure their protection.

2-16.5.6 Stormwater Management and Erosion and Sediment Control.

Projects with land disturbance activities greater than one acre require coverage under the National Pollutant Discharge Elimination System (NPDES) permit program. Most states are authorized to implement the NPDES permitting program. Refer to the EPA website for the list of states authorized to implement this permitting program: http://water.epa.gov/polwaste/npdes/basics/State-and-Tribal-Program-Authorization-Status.cfm. Obtain the NPDES permit through EPA for all other states. Obtain from the Installation EV staff the regional permitting requirements and copies of all existing stormwater and erosion and sediment control permits that affect or encompass the project site. Identify all permit conditions that affect the design and include them in the specifications or on the drawings. Design stormwater management facilities and erosion and sediment controls in accordance with UFC 3-201-01.

2-17 CHLORDANE.

These requirements apply to sites and projects where existing building(s) or structure(s) will be renovated, altered, repaired, or demolished as part of the scope of work. \1\/1/ Specification preparation must comply with the applicable requirements of 40 CFR 260 – 40 CFR 270, Resource Conservation and Recovery Act.

2-17.1 Conducting Field Investigations, Surveys – Chlordane.

Prior to demolition of structures, it may be necessary to determine if chlordane was used to prevent termites. If adequate pesticide application records exist, it may be possible to confirm or rule out the use of chlordane or similar products. If adequate records do not exist, sample the soil around the foundation of a building scheduled for demolition. Chlordane was typically applied in a swath approximately 12-18 inches (300 to 450 mm) below the surface of the ground and approximately 12-18 inches (300 to 450 mm) away from the foundation. It may also have been injected through boreholes into the subsurface soil under concrete slab foundations. Sampling and analysis of the soil may be necessary along the foundation of suspect buildings.

2-17.2 Laboratory – Chlordane.

Laboratories performing analysis for chlordane in soil must be fully equipped and proficient in conducting analyses according to RCRA and SW-846, and accredited by \3\a recognized DoD Environmental Laboratory Accreditation Program /3/.

2-17.3 Control of Chlordane.

Chlordane is very stable and does not readily degrade or migrate in the environment. It is highly insoluble in water and if left undisturbed it will continue to serve its intended purpose for many years. Properly applied chlordane tends to only become a problem when disturbed, as in building demolition. Under RCRA regulations, as long as the soil remains undisturbed chlordane does not present a regulatory issue. It may even be acceptable to excavate chlordane contaminated soil to remove the foundation and place the soil back in the excavation site provided there is not subsequent disturbance or construction on the site. However, if the soil will be moved to another location or disturbed as part of new construction efforts, chlordane may present a hazardous waste disposal issue or costly environmental cleanup. It is very important that steps be taken prior to demolition to minimize the risk to the environment, site workers, or future users of the site.

CHAPTER 3 DELIVERABLES

This chapter identifies the expected level of detail and quality of all deliverables. The following information is critical to ensure contract documents are complete and biddable. Provide all deliverables in accordance with FC 1-300-09N and the following requirements.

3-1 FIELD INVESTIGATION REPORT.

Each Installation maintains record files pertaining to the environmental aspects of previously constructed projects. Utilize these resources and include applicable record files as an attachment to the required reports. Submit separate reports, including drawings, addressing each of the following environmentally sensitive materials:

- \1\Asbestos-Containing Materials/1/
- Paint - Lead-Based Paint in Target Housing and Child-Occupied Facilities
- Paint – Lead, Cadmium, Chromium, and other Hazardous Metals
- \1\Beryllium/1/
- Radon
- Polychlorinated Biphenyls
- Low-Level Radioactive Components
- Animal Droppings
- Molds and Spores
- Tanks
- Contaminated Soil or Groundwater
- Waste Characterization
- Chlordane

\1\When final drawings and specifications are not required for Design Build projects, provide field investigation reports in Part 6 of the Request for Proposal (RFP)/1/.

3-1.2 Drawings.

Provide scaled and dimensioned drawings, within the reports, showing existing site conditions and existing buildings or structures. Drawings must contain enough information to do quantity takeoffs for cost estimating purposes. Indicate project location and facility number. For buildings, provide drawings showing floor plans, and interior and exterior sections as applicable. Provide dimensions (e.g., building, rooms, halls) and room numbers to allow for easy alignment in the field. Include drawing notes indicating:

- type and location of the work associated with the project
- sample locations
- extents of environmentally sensitive materials
- condition, and form of environmentally sensitive materials
- extents of environmentally sensitive materials in poor condition requiring removal
- extents of environmentally sensitive materials in good condition that may remain if not disturbed
- components (e.g., mercury tubes, ballasts) containing environmentally sensitive materials; show locations and indicate the number of components to be removed
- access restrictions, utilities, and equipment that hinder access or egress (include dimensions for the restricted openings)
- components or environmentally sensitive materials to be removed or segregated prior to mass demolition

3-1.3 Report – Asbestos-Containing Materials.

Provide an asbestos report when asbestos field investigation work has occurred or when a prior asbestos report has been used to identify ACM and include the following information: a narrative summary of the work that identifies the project description, location, previous survey data, and additional ACM identified. List the areas, types, locations, and quantities of ACM and any contamination that will affect the project. Provide sample descriptions, results, locations, location maps, and photographic documentation. Obtain a copy of the Asbestos Survey Data Template located at http://www.wbdg.org/references/pa_dod_ntools.php. Include copies of the EPA asbestos inspector and the laboratory accreditation that performed the work.

3-1.4 Report – Lead Based Paint in Target Housing and Child-Occupied Facilities.

Provide a lead-based paint report and include a narrative summary of the work that identifies the project description, test results (including negative results), location, previous survey data, components with lead-based paint, and rationale for removal or abatement. Include all the requirements of EPA Title X and EPA RRP Rule. Include copies of all EPA lead accreditation certificates for the professionals that performed the sampling and analytical work, including the risk assessor, lead workers, samplers, and laboratory.

3-1.5 Report – Paint.

Provide a paint report and include a narrative summary of the work that identifies the project description, location, previous survey data, additional lead, cadmium or chromium paint identified, sample descriptions, results, locations, location maps, and photographic documentation. Include a description and full characterization of all waste streams (that is, hazardous, to include all waste codes, or nonhazardous). List the areas, types, and locations of paint and any contamination that will affect the project, including soil and dust. Include copies of all accreditation certificates, licenses, certificates, sampling plans, and analyses and test reports identified above.

3-1.6 Report – Beryllium.

\1\ Provide a beryllium report and include a narrative summary of the work that identifies project description, location and location of beryllium identified. Provide sample descriptions including test results, locations, location maps, and photographic documentation of each sample taken. List the areas and locations of any beryllium that will affect the project, including airborne particles and dust. Include copies of laboratory accreditation certificate, sampling plans, method of analyses and test reports./1/

3-1.7 Report – Radon.

Provide a radon report and include a narrative summary of the work that identifies the project description, location, and test results provided by onsite personnel. Provide research on potential radon in the area in the report. Briefly summarize precautions that need to be taken to address radon. Refer to EPA Radon Mitigation Standards (RMS) and radon-resistant new construction techniques.

3-1.8 Report – Polychlorinated Biphenyls.

Provide a PCB report and include a narrative summary of the work that identifies the project description, location, previous survey data, and additional PCB identified. List the areas, types, and location of PCB-containing lighting ballasts and all other PCB-containing equipment and any contamination that will affect the project. Summarize state or local laws that affect PCB removal and disposal and ultimate disposition for the project, such as project size, limitations on removal methods, and monitoring requirements. Include notification requirements, permit fees, licensing, or other specialized requirements.

3-1.9 Report –Low-Level Radioactive Components.

Provide a LLR components report and include a list of the areas surveyed, types of LLR components, location of LLR components, method of disposal and any additional information that may impact the project. Provide photographic documentation of LLR components.

3-1.10 Report – Animal Droppings.

Provide animal droppings report and include a narrative summary of the work that identifies the project description, location, and conditions found at the site. Provide photographic documentation of contaminated areas. Briefly summarize precautions that need to be taken to protect workers, building occupants, and the environment.

3-1.11 Report – Molds and Spores.

Provide a mold (microbial) assessment survey report and include a narrative summary of the work that identifies the project description, location, previous survey data, and additional mold identified. Determine the quantities, classification, and location of mold and any contamination that will impact the project. Briefly summarize precautions that need to be taken to protect workers, building occupants, and the environment. Provide copies of laboratory testing and classification reports and laboratory certifications.

3-1.12 Report – Tanks.

Provide a tank report and include the following information: contents of tank, size of tank, approximate location of tank, associated pipelines (including construction, size, and linear footage per diameter), existing soil conditions associated with tank, age of tank, and tank construction material. Document the quantity of remaining hazardous or toxic waste products in AST and UST. Coordinate with Installation EV staff to determine all requirements associated with removal, disposal, and ultimate disposition of the remaining product in a tank. Provide copies of laboratory certification and state or local accreditation certificates with the report. Include copies of all certificates of analyses or test reports with the report, including but not limited to NELAC certification under EPA program.

3-1.13 Report – Contaminated Soil or Groundwater.

Provide a contaminated soil or groundwater report and include the following information: type of hazardous constituents, approximate location of the contamination on the site, approximate depth of contamination, existing soil and site conditions, approximate quantities of contaminated soil or groundwater, and calculations with assumptions made in determining the estimated quantities. Include copies of all certificates of analyses or test reports with the report, including but not limited to NELAC certification under EPA program.

3-1.14 Report – Waste Characterization.

Provide a waste characterization report and include the following information: sample methodology, descriptions, results, locations, location maps, and photographic documentation. Specifically itemize anticipated waste materials to be generated during construction and provide the method of disposal and ultimate disposition for hazardous and nonhazardous wastes. Provide copies of laboratory certification and state and local accreditation certificates with the report. Include copies of all certificates of analyses or test reports with the report, including but not limited to NELAC certification under EPA program.

3-1.15 Report – Chlordane.

Provide a chlordane report when chlordane field investigation work has occurred or when a prior chlordane report has been used to identify contaminated soil and include the following information: a narrative summary of the work that identifies the project description, location, previous survey data, and additional contaminated areas identified. List the areas, types, locations, and quantities of contaminated soil that will affect the project. Provide sample descriptions, results, locations, location maps, and photographic documentation.

3-2 SPECIFICATIONS AND DRAWINGS.

3-2.1 Design Build Request for Proposal (Pre Award).

\1\Include final drawings and specifications for the control, removal, abatement, storage and disposal of:

- Asbestos-Containing Materials
- Paint - Lead-Based Paint in Target Housing and Child-Occupied Facilities
- Paint – Lead, Cadmium, Chromium, and other Hazardous Metals
- Polychlorinated Biphenyls
- Low-Level Radioactive Components
- Chlordane

For Design Build projects, provide field investigation reports in Part 6, specifications in Part 5 and drawings in Part 6 of the RFP./1/

3-2.2 Design Build Design Submittals (Post Award).

The Contractor's Designer of Record (DOR) is responsible for verifying all site information furnished in the Government issued Design Build RFP. The Contractor's DOR must verify existing site conditions and provide any additional field investigation needed to support the development of the final design and construction of the project. When the Contractor \1\conducts additional sampling, the Government furnished drawings and specifications provided in the RFP must be revised by the Contractor's DOR and used /1/ for final design and construction of the project.

3-2.3 Specifications.

Edit UFGS 01 57 19 to include paragraphs for asbestos, lead-based paint, \1\beryllium, /1/ polychlorinated biphenyls, or low-level radioactive components when those materials or components are part of the project. Specify disposal requirements based on project location. Review Federal, state and local disposal regulations before specifying disposal of any type of waste and comply with the most stringent requirement.

UFGS 01 57 19.01 20 is a regional supplement to UFGS 01 57 19 and contains state and local requirements applicable to the project for specific project locations. Review and edit UFGS 01 57 19.01 20 as applicable.

3-2.4 Asbestos-Containing Materials.

Provide an EPA accredited Asbestos Project Designer to prepare asbestos specifications and drawings.

3-2.4.1 Specifications for Asbestos-Containing Materials.

\1\Prepare specifications in accordance with the applicable requirements of 40 CFR 61.145, Subpart M, for any project that involves disturbance or removal of regulated asbestos-containing materials (RACM). Describe the applicable RACM control methods, notification requirements, and workers' minimum certification requirements. NESHAP classifies RACM into three categories: friable, Category I nonfriable, and Category II nonfriable. Identify the NESHAP categories that apply to the project. Identify which non-friable RACM have a potential to become friable during demolition and renovation activities and require those materials to be removed using friable control methods./1/

Edit the guide specification for asbestos removal using \2\UFGS 02 82 00/2/. Indicate the type and location of the asbestos and to provide a description and rationale for removal. Identify conditions that affect access or egress for workers and equipment, such as confined spaces, crawl spaces, or elevated working surfaces. Identify utility systems (HVAC, steam, electrical, and similar) required to be shut down during the project. Where the building is to remain partially occupied during construction, temporary utilities may be required. Where the building is to remain partially occupied by the Government during construction, specifically identify utility shutdowns to the project manager, in writing. Indicate work area isolation requirements. Indicate disposal and ultimate disposition requirements. Summarize conditions that affect asbestos removal and disposal or ultimate disposition for the project, such as project size, limitations on removal methods, and air monitoring requirements. Include notification requirements, permit fees, licensing, or other specialized requirements. Some jurisdictions may require third-party monitoring during the construction phase for asbestos abatement activities. Depending on the regulatory requirement, a separate contract to the third party (that is, a contact separate from the construction contract) may be required. Consult a local asbestos manager or regulatory expert. If replacement materials are required, coordinate with the architect.

3-2.4.2 Drawings for Asbestos.

Provide scaled and dimensioned drawings for floor plans or building sections showing all ACM. Provide building and room dimensions allowing easily established alignment in the field. If asbestos is present and will not be disturbed by the project, provide a drawing note indicating the type and location of the ACM with a note that the material is not to be disturbed by project work. For ACM impacted by the project, indicate location, condition, and form of all ACM to be removed, as well as the structures, utilities, and equipment that hinder access or egress. Provide dimensions for access or egress to crawl spaces, attics, chases, or restrictive areas that affect asbestos removal personnel or equipment. Identify rooms by name and number.

3-2.5 Lead-Based Paint \2\in Target Housing and Child-Occupied Facilities /2/.

Provide an EPA accredited Lead Paint Project Designer in accordance with EPA Title X and EPA RRP Rule to prepare the lead-based paint removal specifications \1\ and /1/ drawings.

3-2.5.1 Specifications for Lead-Based Paint \2\in Target Housing and Child-Occupied Facilities/2/.

Edit the guide specification for lead-based paint using \2\UFGS 02 83 00/2/. Indicate building components with lead-based paint that will be affected by the work. Identify conditions that affect access or egress for workers and equipment, such as confined spaces, crawl spaces, or elevated working surfaces. Identify utility systems (HVAC, steam, electrical, and similar) that may require shutdown during the project. Where the building is to remain partially occupied by the Government during construction, identify utility shutdowns to the Government's project manager, in writing. Indicate work area isolation requirements. Summarize state or local laws that affect child-occupied facilities and lead-based paint removal, containment, disposal, or ultimate disposition for the project, such as project size, limitations on removal methods, and air monitoring requirements. Include notification requirements, permit fees, licensing, final clearance criteria (dust wipes, soil sampling, and similar), disposal and ultimate disposition requirements, or other specialized requirements. Indicate disposal and ultimate disposition requirements. If replacement materials are required, coordinate with architect.

3-2.5.2 Drawings for Lead-Based Paint \2\in Target Housing and Child-Occupied Facilities/2/.

Information regarding paint as it pertains to child-occupied facilities may be detailed on the demolition drawings by adding notes indicating that lead-based paint abatement activities be conducted in accordance with the appropriate corresponding specification section and EPA Title X and EPA RRP Rule. Indicate existing lead-based paint affected by the project on the drawings using a chart or some other method to display the laboratory results of the lead analysis. For abatement drawings, provide scaled and dimensioned drawings and floor plans or building sections showing all items from which the hazardous paint will be removed, replaced, or encapsulated. Indicate all locations of hazardous paint to be removed, as well as structures, utilities, and equipment that hinder access or egress. Provide dimensions for access or egress to crawl spaces, attics, or restrictive areas that affect removal personnel or equipment.

3-2.6 Paint \2\in Commercial or Industrial Facilities/2/.

Provide \2\a certified industrial hygienist certified by the American Board of Industrial Hygiene, a certified safety professional certified by the Board of Certified Safety Professionals, or/2/ an EPA accredited, \2\or equivalent State certified/2/, Lead Project Designer to prepare lead, cadmium, and chromium specifications and drawings. \2\Refer to 3-2.5 Lead-Based Paint in Target Housing and Child-Occupied Facilities for any work being performed in target housing or child-occupied facilities./2/

3-2.6.1 Specifications for Paint \2\in Commercial or Industrial Facilities/2/.

Edit \2\UFGS 02 83 00/2/ to include requirements for the removal of paint containing lead cadmium, and chromium. Describe all the different scenarios that will be encountered in the project (that is, “tasks” per OSHA). Clearly identify all the areas with paint on the construction documents and outline the protocol for providing protection of workers and the environment during all construction activities \2\in accordance with DODI 6055.01, EM 385-1, and OPNAVINST 5100.23G/2/. Identify conditions that affect access or egress for workers and equipment, such as confined spaces, crawl spaces, or elevated working surfaces. Identify utility systems (HVAC, steam, electrical, and similar) that may require shutdown during the project. Where the building is to remain partially occupied by the Government during construction, identify utility shutdowns to the Government’s project manager, in writing. Indicate work area isolation requirements. Include state and local regulations, notification requirements, permit fees, licensing, or other specialized requirements. Identify the appropriate clearance level required for the Contractor to attain when finishing the construction activities that generate dust, fumes, or debris. Thoroughly research the clearance level for each type of construction project and the differences established based upon the nature of the project. Indicate disposal and ultimate disposition requirements and any special waste segregation requirements.

3-2.6.2 Drawings for Paint \2\in Commercial or Industrial Facilities/2/.

Information regarding paint as it pertains to demolition work may be detailed on the demolition drawings by adding notes indicating that specific requirements and demolition activities must be conducted in accordance with the appropriate corresponding specification section and title. Indicate on the drawings all existing paint determined from the field survey to contain detectable levels of lead, cadmium, and chromium using a chart or some other method to display the laboratory results of the lead analysis. For abatement drawings, provide scaled and dimensioned drawings and floor plans or building sections showing all items from which the hazardous paint (lead, cadmium, or chromium containing) will be removed (and hence abated). Examples of this include wood molding or steel structures that are to be salvaged and reused in the finished project but are coated with paints that contain the identified hazardous metal. Indicate all locations of hazardous paint to be removed, as well as structures, utilities, and equipment that hinder access or egress. Provide dimensions for access or egress to crawl spaces, attics, or restrictive areas that affect removal personnel or equipment.

3-2.7 Beryllium.

\1\Provide a Certified Industrial Hygienist to prepare beryllium specifications and drawings./1/

3-2.7.1 Specifications for Beryllium.

\1\Edit UFGS 01 57 19 to include requirements for beryllium abatement, containment, storage and disposal. Identify conditions that affect access or egress for workers and equipment, such as confined spaces, crawl spaces, or elevated working surfaces. Identify utility systems (HVAC, steam, electrical, and similar) required to be shut down during the project. Where the building is to remain partially occupied during construction, temporary utilities may be required. Where the building is to remain partially occupied by the Government during construction, specifically identify utility shutdowns to the project manager, in writing. Indicate work area isolation and disposal requirements. Summarize conditions that affect beryllium abatement and disposal for the project, such as project size, removal method, and air monitoring requirements. Include any specialized requirements that may be applicable. Outline the protocol for providing protection of workers and the environment during all construction activities in accordance with 29 CFR 1910.1024, 29 CFR 1915.1024 and 29 CFR 1926.1124./1/

3-2.7.2 Drawings for Beryllium.

\1\Clearly identify all areas where beryllium is present on the drawings and indicate beryllium work isolation zones. Provide scaled and dimensioned drawings and floor plans or building sections showing all areas from which the beryllium will be abated. Indicate all locations where beryllium particles and dust must be abated, as well as structures, utilities, and equipment that hinder access or egress. Provide dimensions for access or egress to crawl spaces, attics, or restrictive areas that affect removal personnel or equipment./1/

3-2.8 Radon.

3-2.8.1 Specifications for Radon.

Edit the guide specifications for radon mitigation using UFGS 31 21 13. A licensed professional mechanical consultant must handle specifications for radon remediation. Develop specifications in accordance with EPA RMS and radon-resistant new construction techniques.

3-2.9 Polychlorinated Biphenyls.

3-2.9.1 Specifications for Polychlorinated Biphenyls.

Edit the guide specification for PCB removal using UFGS 02 84 16 or UFGS 02 84 33. Indicate existence of PCB and detail equipment that contains PCB. Provide description of how PCB containing materials will be handled. Indicate the disposal and ultimate disposition requirements, which may include recycling.

3-2.9.2 Drawings for Polychlorinated Biphenyls.

Provide drawings that indicate the PCB-containing component to be removed, including locations and quantities. Indicate in the notes how the Contractor is to distinguish between PCB and PCB-free components. For light fixtures, provide exact number of lighting fixtures to be removed. Drawing notes or symbols allow the Contractor to do an accurate takeoff of the number of ballasts to be removed. As an alternative, if Electrical Demolition drawings are part of the same contract and they have sufficient detail to show all electrical fixtures, then the lamps and ballasts may be shown on these drawings. Clearly indicate in the notes the components to be removed prior to any additional demolition.

3-2.10 Low-Level Radioactive Components.

3-2.10.1 Specifications for Low-Level Radioactive Components.

Comply with OPNAV M-5090.1 Low-Level Radioactive Waste Disposal Program and contact Naval Sea Systems Command Detachment (NAVSEADET), Radiological Affairs Support Office (RASO) to determine the requirements applicable to the project. Edit UFGS 01 57 19 to include requirements for LLR component removal, containment, storage and disposal. If any LLR components are indicated in the Low-Level Radioactive Components Report, provide requirements for removal, containment, storage and disposal. Indicate disposal and ultimate disposition requirements, including information such as notification requirements, permit fees, licensing, or other specialized requirements.

3-2.10.2 Drawings for Low-Level Radioactive Components.

If LLR components are indicated in the Low-Level Radioactive Components Report, provide drawings that indicate the LLR components to be removed, including locations and quantities. Indicate disposal and ultimate disposition requirements. As an alternative, use Electrical and Fire Protection Demolition drawings; provide sufficient detail on these drawings to show all components. Clearly indicate in the notes the LLR components to be removed prior to facility demolition.

3-2.11 Mercury.

3-2.11.1 Specifications for Mercury.

Edit the guide specification for mercury removal using UFGS 02 84 16. If mercury tubes or the other items listed are present, indicate their existence. Provide a description and the methodology for removal, containment, and sampling. Summarize state or local laws that affect removal and disposal or ultimate disposition for the project, such as project size, limitations on removal methods, and monitoring requirements. Include notification requirements, permit fees, licensing, or other specialized requirements. Indicate disposal and ultimate disposition requirements. Investigate companies that recycle used mercury-containing devices and require recycling to the extent practical.

3-2.11.2 Drawings for Mercury.

Provide drawings that indicate the mercury tubes to be removed, including locations and quantities. As an alternative, use Electrical Demolition drawings that have sufficient detail to show all components. Clearly indicate in the notes the components to be removed before any additional demolition.

3-2.12 Animal Droppings.

3-2.12.1 Specifications for Animal Droppings.

Edit UFGS 01 57 19 to include requirements to for the removal of animal droppings. Identify conditions that affect access or egress for workers and equipment, such as confined spaces, crawl spaces, or elevated working surfaces. Identify utility systems (HVAC, steam, electrical, and similar), required to be shut down during the project. Where the building is to remain partially occupied during construction, temporary utilities may be required. Indicate work area isolation requirements. Include requirements for disposal, ultimate disposition, project size, and limitations on removal methods. A certified industrial hygienist must review the specifications.

3-2.12.2 Drawings for Animal Droppings.

If animal droppings are present, indicate their existence, location, and approximate quantity. Provide removal notes that describe equipment, precautions for removal personnel (such as using personal protection equipment), precautions for protecting occupants, and techniques for removal. Indicate disposal and ultimate disposition requirements.

3-2.13 Molds and Spores.

3-2.13.1 Specifications for Molds and Spores.

Edit the guide specification to address mold and spore remediation using UFGS 02 85 00.00 20. Identify conditions that affect access or egress for workers and equipment, such as confined spaces, crawl spaces, or elevated working surfaces. Identify utility systems (HVAC, steam, electrical, and similar) required to be shut down during the project. Where the building is to remain partially occupied during construction, temporary utilities may be required. Indicate work area isolation requirements. Indicate disposal and ultimate disposition requirements. Summarize state or local laws that affect removal and disposal or ultimate disposition for the project, such as project size, limitations on removal methods, and air monitoring requirements. A certified industrial hygienist must review the specifications.

3-2.13.2 Drawings for Molds and Spores.

Indicate the areas where mold is located and include a description or listing of all affected building components. Provide removal notes that describe equipment, precautions for removal personnel (such as using personal protection equipment), precautions for protecting occupants, and techniques for removal.

3-2.14 Tank Removal.

The drawings and specifications together must provide the Contractor with sufficient information to determine quantities of materials, material classification (hazardous, nonhazardous, and special waste), and regulatory testing requirements.

3-2.14.1 Specifications for Tank Removal.

Edit the guide specification for tank removal using UFGS 02 65 00. Several environmental issues must be addressed when removing and disposing of AST or UST. Determine the correct collection and disposal and ultimate disposition procedures for items, such as cleaning water, rinse water, and existing sludge or product in the tank. Require that the Construction Contractor certify that the removed tanks were rendered unusable before transportation to the disposal or ultimate disposition site. Incorporate any specific confirmatory soil samples to prove clean conditions. Include state and local environmental requirements relative to tank closure and removal in the specifications. Describe tanks, including their type, size, contents, and piping. Describe how much product will be left in the tank and who will be responsible for removing any existing product. Describe all required construction activities, such as gas-free tank, cleaning, removing fuel lines, draining fuel lines, and testing of cleaning residue, sludge, water and product for disposal and ultimate disposition purposes. A registered Professional Engineer or Professional Geologist must prepare the specification.

3-2.14.2 Drawings for Tank Removal.

Provide separate Tank Removal drawings or use civil drawings to indicate aboveground storage tanks (AST) or underground storage tanks (UST) that are to be removed or cleaned. Clearly indicate tank contents and the quantity of remaining product, water, or sludge in the notes. Provide an overview of the steps to cleaning and removing the tank. Indicate the disposal and ultimate disposition requirements for the product in the tank. Coordinate closely with Installation EV staff to determine if the tank product may be disposed of on Base; if so, clearly indicate on the drawings where the disposal and ultimate disposition facilities are located. Include photographs of the removed tank to show it has been rendered unusable, as contract requirements.

3-2.15 Contaminated Soil or Groundwater.

The drawings and specifications together must provide the Contractor with sufficient information to determine type and quantities of materials, disposal and ultimate disposition classification (hazardous, nonhazardous, special waste), and regulatory testing requirements.

3-2.15.1 Specifications for Contaminated Soil or Groundwater.

Edit the guide specification for contaminated soil or groundwater using UFGS 02 61 13, UFGS 02 61 23. Provide detailed requirements for worker protection, collecting groundwater, stockpiling contaminated soil, testing, and disposing of the wastes. For any new construction that requires dealing with contaminated soil or groundwater, clearly state all information pertaining to the existing conditions at the site. Comply with regulations regarding worker protection and additional requirements defined by EPA, the regulating authority for the site, or as applicable per EM 385-1-1. Indicate the existence of contaminated soil and groundwater and source of information. List all reports that contain existing analytical information on the existing site conditions. Describe which site controls will be used during construction (e.g. the use of organic vapor analytes or meters and equipment to test and monitor atmosphere), and all analytical requirements for testing and disposal and ultimate disposition of the contaminated material. Indicate the handling and disposal or ultimate disposition procedures.

3-2.15.2 Drawings for Contaminated Soil or Groundwater.

Provide separate drawings or use civil drawings that indicate the extent of known or suspected soil or groundwater contamination. Indicate the type and level of contamination.

3-2.16 Specifications for Waste.

Waste requirements are handled within various design specification sections. Refer to previous design specification requirements, see paragraph entitled “Control and Management of Solid and Hazardous Waste” and the applicable portions of this Chapter.

3-3 COST ESTIMATES.

Coordinate with the lead discipline to determine the extent of the work and develop cost estimates. Include estimated quantities, unit costs and total costs for each type of environmentally sensitive material, such as floor tile containing asbestos, insulation containing asbestos and lead-contaminated soil. Do not provide lump-sum quantities and costs. Provide unit pricing for each type of environmentally sensitive material encountered during field investigation or previously known to exist in UFGS 01 20 00.00 20.

CHAPTER 4 HANDLING AND STORAGE

Use the following information to assist in the preparation of the project specifications.

4-1 HANDLING AND STORAGE OF HAZARDOUS MATERIAL.

Properly store, manage, and maintain hazardous materials, such as fuels. Provide storage in accordance with Safety Data Sheets. Storage and handling of hazardous materials are regulated under 29 CFR, National Fire Protection Association and the American Petroleum Institute. Small flammable containers must be stored within a proper flammable storage cabinet. Fuel storage at quantities greater than 1,320 gallons require the preparation and implementation of a Spill Prevention, Control, and Countermeasures Plan, as described in 40 CFR 112. Certain hazardous materials may also be regulated under the Department of Homeland Security, Title 6 CFR 27.

4-2 HAZARDOUS MATERIAL TRANSPORTATION.

Hazardous material; 49 CFR 171.8, is a substance or material that the Secretary of Transportation has determined is capable of posing an unreasonable risk to health, safety, and property when transported in commerce, and has designation as hazardous under the Federal Hazardous Materials Transportation Law; 49 U.S.C. 5103. The term includes hazardous substances, hazardous wastes, marine pollutants, elevated temperature materials, materials designated as hazardous in the Hazardous Materials Table 49 CFR 172.101, and materials that meet the defining criteria for hazard classes and divisions in 49 CFR 173.

4-2.1 Department of Transportation Requirements.

Requirements under 49 CFR 171-180 apply to all offsite shipments of hazardous materials. Provide a DOT-trained individual to verify that the requirements of 49 CFR 171-180 are met.

4-2.2 Shipping Name.

Material that exhibits one of the nine DOT hazard class characteristics (for example, explosives, gases, flammable liquids, flammable solids, oxidizing substances, toxics or poisons, radioactive materials, corrosive substances, or miscellaneous hazards) is regulated under DOT rules for the transportation of hazardous material. Provide a proper shipping name for each shipment of a suspected hazardous material using the Hazardous Materials Table in 49 CFR 172.101. DOT-trained personnel must make all determinations.

4-2.3 Packaging, Marking, and Labeling.

Mark the shipping name, hazard class, identification number, technical names (if applicable), EPA markings and waste code numbers, and consignee or consignor designations on packages for shipment 49 CFR 172.301. Once a waste is characterized, determine the appropriate label in accordance with the Hazardous Materials Table in 49 CFR 172.101.

4-2.4 Placards.

Provide DOT-trained personnel to determine the appropriate placards. Specific placard descriptions are found starting at 49 CFR 172.521. If a placard is required, it must be affixed on each side and each end of the vehicle.

4-2.5 Proper Container.

Use the appropriate United Nations (UN) approved container in accordance with 49 CFR 172.101, 49 CFR 172.102, and 49 CFR 173.

APPENDIX B BEST PRACTICES

The best practices detailed herein apply to all sites and each project should be evaluated individually (if they are governed by regulation then they are a requirement and not a best practice). Neglecting to address the items listed below may result in unnecessary exposure to human health and the environment, changes in the project scope and be potentially subject the Government to regulatory notice of violations.

B-1 ASBESTOS.

RACM are commonly found in building materials and related products. Asbestos-containing products are available today and are often used in the form of tars, sealants, caulks, coatings, insulation, and roofing materials.

B-2 LEAD BASED PAINT IN TARGET HOUSING AND CHILD-OCCUPIED FACILITIES.

When dealing with target housing and child-occupied facilities, lead-based paint is defined by EPA and the U.S. Department of Housing and Urban Development (HUD) as any paint, varnish, shellac, or other coating that contains lead equal to or greater than 1.0 milligram per square centimeter (mg/cm^2) as measured by XRF analyzer or laboratory analysis, or 0.5 percent by weight as measured by laboratory analysis. This is not the OSHA definition of lead-containing paint.

A child-occupied facility is defined as a building, or portion of a building, constructed prior to 1978, visited regularly by the same child (6 years of age or younger) on at least two different days within any week (Sunday through Saturday period), provided that each day’s visit lasts at least 3 hours, the combined weekly visits last at least 6 hours, and the combined annual visits last at least 60 hours.

B-3 PAINT – LEAD, CADMIUM, CHROMIUM, AND OTHER HAZARDOUS METALS.

Many painted surfaces contain lead, cadmium, chromium, and other hazardous metals that may be regulated by the RCRA when these coated surfaces are disturbed by renovation, alteration, repair, or demolitions activities. These coatings are commonly found in buildings and steel structures, and on fuel piping and on every type of surface that can be painted or coated. Thresholds, exposures, and engineering controls for paint containing lead, cadmium, chromium, or other hazardous metals differ depending on a variety of factors including, but not limited to, whether or not these paints are used in operational processes, are painted surfaces of building components or exterior coatings, and are disturbed during construction activities. When investigation, sampling, renovation or demolition occurs, there are hazards associated with the generation of dust, debris, and fumes. The OSHA Standards cite requirements for work activities that can create an unsafe condition with regards to worker protection. These include, but are not limited to manual demolition, paint scraping, heat-gun applications, power tooling with dust collection, power tooling without dust collection, rivet busting, cleanup activities with dry abrasives, movement or removal of enclosures, abrasive blasting, welding, cutting, and burning on steel structures.

B-4 BERYLLIUM.

\1\Beryllium is a grey metal that is stronger than steel and lighter than aluminum. Its physical properties of great strength-to-weight, high melting point, excellent thermal stability and conductivity, reflectivity, and transparency to X-rays make it an essential material in industry. Workers in industries where beryllium is present may be exposed to beryllium by inhaling beryllium dust in the air or by dermal contact. Workers who come in contact with beryllium are at an increased risk of developing cancer; lung effects (CBD and acute beryllium disease); beryllium sensitization; skin sensitization; and skin, eye, and respiratory tract irritation.

B-4.1 Beryllium Uses and Products.

Beryllium is used in:

- Aerospace (aircraft braking systems, engines, satellites, space telescope),
- Automotive (anti- lock brake systems, ignitions),
- Ceramic manufacturing (rocket covers, semiconductor chips)
- Defense (components for nuclear weapons, missile parts, guidance systems, optical systems),
- Dental labs (alloys in crowns, bridges, and dental plates),
- Electronics (x- rays, computer parts, telecommunication parts, automotive parts),
- Energy (microwave devices, relays),
- Medicine (laser devices, electro-medical devices, X-ray windows),
- Nuclear energy (heat shields, reactors),
- Sporting goods (golf clubs, bicycles),
- Telecommunications (optical systems, wireless base stations)./1/

B-5 RADON.

Radon is a colorless, odorless, tasteless gas that is a byproduct of naturally decaying uranium. The amount of uranium beneath the earth’s surface varies greatly with geographic location and soil type. As the uranium decays below a building surface, it creates a radon gas that may penetrate through cracks and openings in the building’s foundation or basement. Buildings that have a tight shell have increased chances for radon being trapped within the structure.

B-6 POLYCHLORINATED BIPHENYLS.

Polychlorinated biphenyls\1\, commonly referred to as PCB or PCBs,/1/ are a group of toxic substances with chlorinated compounds that are either oily liquids or solids. PCB are typically colorless or light yellow. Some common PCB manufacturer product trade names are as follows: Apirolio, Aroclor, Asbestol, Bakola 131, Chlorextol, Clophen, Inerteen, Kanechlor, No-Flamol, Pyralene, Pyranol, Saf-T- Kuhl and Sovol. PCB were used for many years in electrical equipment as coolants and lubricants because they are good insulators that tend not to burn. The EPA banned the manufacturing of PCB in 1977 and regulated PCB as a toxic substance under the Toxic Substance Control Act (TSCA). Current PCB regulations can be found in 40 CFR 761.

Products manufactured prior to 1977 that may contain PCB include light ballasts, transformers, capacitors, heat transfer fluids, lubricants, hydraulic fluids, compressor oil, paints, plastics, asphalt roofing materials, paints, and caulk.

B-7 ANIMAL DROPPINGS.

B-7.1 Histoplasmosis.

Histoplasmosis is an infectious disease caused by inhaling the spores of a fungus called *Histoplasma capulatum*. The fungus is most associated with bird manure or bat droppings. The organism can be carried on the wings, feet, and beaks of birds and infected soil under roosting sites or manure accumulations inside or outside buildings. The fungus also grows in soils with high nitrogen content, especially those enriched with bird manure or bat droppings. Histoplasmosis is most commonly transmitted when the spores become airborne, often during cleanup or demolition projects. Areas with an increased number of infections are located in central and eastern states, along the valleys of the Ohio, Mississippi, and St. Lawrence Rivers and the Rio Grande.

B-7.2 Hantavirus.

Hantavirus is carried by rodents, especially mice and rats. The virus is found in their urine, droppings, and saliva. Potential sites where people may be exposed to the virus are outbuildings or sheds located in forests and fields that offer a suitable habitat for the virus’s rodent hosts. The virus is mainly transmitted to people when they breathe in air contaminated with the virus. When fresh rodent urine, droppings, or nesting materials are stirred up, tiny droplets containing the virus get into the air.

B-8 MOLDS AND SPORES.

Thousands of different types or species of fungi or "molds" are normally present in the environment, and many can grow within a building and cause occupants and workers discomfort or harm. Some fungi are toxic (that is, they secrete mycotoxins, which are harmful if inhaled or ingested), and many can cause allergic reactions of various types in susceptible people. Internal infections can also be caused by fungi, but are rare in people with normal immune systems. Fungi are commonly found in buildings that have flooding or long-term water damage from broken pipes, roof leaks, sewage backups, poor drainage, condensation, or inadequate HVAC system design. Because leaks can occur inside walls, in crawl spaces, in ventilation systems, or in enclosed ceiling areas, they may not be visible to the occupants.

B-9 STORAGE TANKS.

The majority of AST or UST contain petroleum products or other hazardous substances. Until the mid-1980s, most UST were made of bare steel that could corrode over time and allow the contents to leak into the surrounding soils and groundwater, causing harm to the environment and human health. Similar conditions are associated with AST.

B-10 CONTAMINATED SOIL OR GROUNDWATER.

There are instances where construction will occur on sites that are known to have contaminated soil or groundwater. The area could also be classified as a “past hazardous waste site” or “Installation Restoration” (IR) site. IR is a comprehensive program to identify, investigate, and clean up hazardous substances, pollutants, and contaminants at Installations. Sites include those contaminated by past defense activities that require clean up under the Comprehensive Environmental Response, Compensation, and Liability Act as amended by Superfund Amendments and Reauthorization Act, and certain corrective actions required by RCRA.

B-11 SOLID AND HAZARDOUS WASTE.

Solid waste is defined as a solid, liquid, semi-solid, or contained gaseous waste. A solid waste may be a hazardous waste or a nonhazardous waste.

B-11.1 Nonhazardous Waste.

Nonhazardous waste is solid waste that does not meet the RCRA or state criteria for hazardous waste. Nonhazardous wastes are regulated for disposal and may contain toxic chemicals or physically hazardous components. Some materials may be assumed nonhazardous because of the nature of the waste and the waste generation process. Examples include petroleum-contaminated soil and C&D debris.

Nonhazardous waste is a broad category that includes a range of materials with various management requirements. Nonhazardous wastes are generally regulated under state solid waste regulations. Some states call nonhazardous waste solid waste, special waste, industrial waste, or non-RCRA regulated waste. Review state solid waste regulations and determine state specific definitions. Nonhazardous waste classifications include waste that is excluded from, or does not meet, hazardous waste criteria, waste containing contaminants at concentrations less than hazardous waste thresholds (for example, ignitability, corrosivity, reactivity, or toxicity), or wastes that are prohibited from being disposed of at a subtitle D municipal solid waste landfill.

Nonhazardous waste may consist of contaminated environmental media, debris, or wastes. These wastes generally have less stringent storage, transport, and disposal requirements than hazardous wastes. Consider managing these wastes through waste minimization, reuse or recycling, and cost control.

B-11.2 Universal Waste.

Prior to demolition, facility should be cleared of any potential universal wastes, specifically fluorescent lamps and mercury containing electrical equipment such as thermostats or switches. EPA universal waste regulations streamline hazardous waste management standards for federally designated "universal wastes," which include:

- Batteries: “Battery” means a device consisting of one or more electrically connected electrochemical cells that are designed to receive, store, and deliver electric energy. An electrochemical cell is a system consisting of an anode, cathode, and an electrolyte, plus such connections (electrical and mechanical) as may be needed to allow the cell to deliver or receive electrical energy. The term battery also includes an intact, unbroken battery from which the electrolyte has been removed.
- Pesticides: “Pesticide” means any substance or mixture of substances intended for preventing, destroying, repelling, or mitigating any pest, or intended for use as a plant regulator, defoliant, or desiccant, other than any article that:
    - Is a new animal drug under Federal Food, Drug and Cosmetic Act (FFDCA) section 201(w), or
    - Is an animal drug that has been determined by regulation of the Secretary of Health and Human Services not to be a new animal drug, or
    - Is an animal feed under FFDCA section 201(x) that bears or contains any substances described by the paragraphs above.
- Mercury-containing equipment: “Mercury-containing equipment” means a device or part of a device (including thermostats, but excluding batteries and lamps) that contains elemental mercury integral to its function.
- Lamps: A “lamp” is the bulb or tube portion of an electrical lighting device that may contain hazardous materials such as mercury or lead. Examples of common types of lamps containing hazardous materials include fluorescent, high-intensity discharge (HID), neon, mercury vapor, high-pressure sodium, and metal halide. Many lighting companies produce "low-level" mercury-containing lamps and claim they do not constitute a hazardous waste for disposal. In accordance with Federal law, the generator must prove that the lamps are nonhazardous if they choose to manage and dispose of them as such. Testing of the lamps may be

performed if it will result in a cost-saving solution. Otherwise, consider the lamps as hazardous, and properly manage and dispose them. The ultimate responsibility lies in the waste generator to determine the proper management and disposal of this waste.

B-11.3 Used Oil.

Used oil is any petroleum-based or synthetic fluid that has been used and is regulated under 40 CFR 279. During normal use, impurities such as dirt, metal scrapings, water, or chemicals may get mixed in with the oil, so that in time, the oil no longer performs well. Eventually, this used oil is replaced with virgin or re-refined oil to perform correctly. To meet EPA's definition of used oil, a substance must meet three criteria:

Origin: The first criterion for identifying used oil is based on the origin of the oil. Used oil must have been refined from crude oil or made from synthetic materials. Animal and vegetable oils are excluded from EPA's definition of used oil.

Use: The second criterion is based on whether and how the oil is used. Oils used as lubricants, hydraulic fluids, heat transfer fluids, buoyants, and for other similar purposes are considered used oil. Unused oil such as bottom clean-out waste from virgin fuel oil storage tanks or virgin fuel oil recovered from a spill, do not meet EPA's definition of used oil because these oils have never been "used." EPA's definition also excludes products used as cleaning agents or solely for their solvent properties, as well as certain petroleum-derived products like antifreeze and kerosene.

Contaminants: The third criterion is based on whether or not the oil is contaminated with either physical or chemical impurities during use. In other words, to meet EPA's definition, used oil must become contaminated as a result of being used. This aspect of EPA's definition includes residues and contaminants generated from handling, storing, and processing used oil. Physical contaminants could include metal shavings, sawdust, or dirt. Chemical contaminants could include solvents, halogens, or saltwater.

B-12 CULTURAL RESOURCES.

The term “cultural resources” includes archaeological sites, Native American and other traditional cultural resources, historic buildings and structures, significant objects, planned landscapes, and historic districts. The term “historic properties” is a technical term from the National Historic Preservation Act of 1966 (NHPA) to denote properties that have recognized public significance. The NHPA, 54 United States Code U.S.C. 300101 et seq., is one of the primary Federal statutes designed to protect cultural resources. The implementing regulation for NHPA is the Protection of Historic Properties; 36 CFR 800. Historic properties are defined in 36 CFR 800.16 as places listed in or eligible for listing in the National Register of Historic Places (NRHP). These properties may include districts, sites, buildings, structures, objects, and landscapes significant in American history, prehistory, architecture, archaeology, engineering, and culture. They include properties that belong to the prehistoric era as well as the historic era. Generally, properties must be at least 50 years of age to be eligible for the NRHP, unless they are proven to have exceptional importance. The NHPA also provides for consultation with Native American groups when a proposed project might affect cultural or traditional places or resources that have value to a Native American tribal group derived from the role the property plays in the community's historically rooted beliefs, customs, and practices.

B-12.1 Archaeology.

The Archaeological Resource Protection Act of 1979 recognizes that archaeological resources are an irreplaceable component of the heritage of the United States. Prehistoric archaeological resources are physical properties resulting from human activities that predate written records and generally are identified as isolated finds or sites. Prehistoric resources may include areas such as village sites, temporary camps, lithic scatters, roasting pits or hearths, milling features, petroglyphs, rock features, and burial sites. Historic archaeological site types, which result from human activities that occurred after European settlement, include town sites, homesteads, agricultural or ranching features, mining-related features, refuse concentrations, and features or artifacts associated with early military use of the land.

B-12.2 Architectural.

Historic architectural resources include fabricated, aboveground resources resulting from human activities that occurred after European settlement. These resources may include buildings such as houses, churches, barns, and lighthouses; early military buildings such as hangars, administration buildings, barracks, officers' quarters, warehouses, and guardhouses; and structures such as roads, bridges, and culverts.

B-13 CHLORDANE.

Chlordane was used extensively as an insecticide in the United States. It was sold from 1948 to 1988, both as a dust and an emulsified solution. The most common use of chlordane was for termite control. It was poured or injected around foundations to protect homes and buildings from termite damage. Its use was especially high in areas where termites caused structural damage, such as the southern U.S. Though banned for use on crops by 1978, its use for protection of buildings continued for another 10 years. In 1988, all commercial and domestic use of chlordane in the U.S. was banned by the EPA. Chlordane, heptachlor, and similar products can be expected to be found around the foundation of wooden (and possibly other) structures constructed prior to 1988. It is linked to various health effects on humans. Chlordane and similar products may still be in use in other countries.
