8. On each main distribution pipeline immediately downstream of the branch connection to each existing or future operating storage facility served by the pipeline.

9. On the aboveground piping at each tank car or tank truck off-loading connection, and at each inlet to the gravity drop tank.

10. On the aboveground piping at each tank car and tank truck loading connection.

11. At critical roadway, runway and taxiway crossings, consider isolation valves on both sides of runway/taxiway to facilitate hydrostatic testing and isolation.

j. Other Valves – Check Valves, V-Port Ball Valves, and Thermal Relief Valves

k. Diaphragm Control Valves

l. Thermometers

m. Provide thermometers in Burner Fuel No. 5 and No. 6 distribution piping systems at each loading and receiving point and on the inlet and outlet of each heater.

n. Fuel Hoses – Loading and Off-Loading Fuel Hoses

3-7 CONTROLS.

3-7.1 Control System Philosophy.

Fuel systems that includes pumps to receive, transfer, and issue fuel may be provided with an Automatic Pump Control system with a programmable logic controller (PLC) driven Pump Control Panel (PCP) to control the system. Provide an Automatic Pump Control system when required by Service Headquarters. All systems must be designed to perform all of their functions manually in the event the PCP is down. The PCP must:

a. Start and stop issue and transfer pumps.

b. Provide permissive interface to off-loading system receipt pump(s). Receipt pump must not start or continue to operate when receipt tank high-high level is reached or emergency system activation occurs. Local control will start or stop receipt pump.

c. Provide start and stop or permissive interface to drop tank off-loading system receipt pump(s). Receipt pump must not start or continue to operate when receipt tank high-high level is reached or emergency system activation occurs. PCP control via tank level sensors or local start/stop control of the receipt pump(s) is acceptable.

3-7.2 Exceptions.

The exceptions for systems covered in Chapter 3 where a PCP is not required are:

a. Pumps serving miscellaneous use tanks (see Chapter 8 for definition).

b. Isolated miscellaneous pumps that are not part of a larger system. These 5 horsepower or less size pumps act as sump pumps, pier stripping pumps, truck unloading pumps such as those required for off-loading small vacuum trucks, waste oil trucks, etc.

3-7.3 Design Requirements.

Automatic controls at any facility may include temperature, pressure, fuel level and pump controls, automatic flow controls, alarm and limit switches, motor operated isolation valves, solenoid pilot actuated diaphragm control valves, and remote system condition indicators. Other forms of automatic controls are remote meter indication, electronic access control, data logging, and application of computer techniques. Base the selection of advanced automation and telemetry systems on a study of the particular application with consideration of possible economic justification, operational, and security requirements.

3-7.4 Flow Controls

Where it is possible to achieve flow rates which exceed system component ratings, provide an adjustable flow control valve on the outlet connection of each meter or filter-separator. Use a diaphragm control valve controlled by the pressure differential across an orifice plate in the valve or a venturi in the main line. Where necessary, provide remote-operated valves on storage tank inlet and outlet lines, suction and discharge of transfer pumps, and transfer lines at fuel piers and other locations.

3-7.5 Pump Controls.

Operation of pump suction and discharge valves may be a part of the automatic sequence for the starting of a centrifugal pump and for shutting it down, remotely, locally, or by a protective shutdown device. Remote-operated valves on the discharge side of the pump can be either motor-operated or the solenoid pilot-type, hydraulically operated diaphragm control valves. Remote control valves on the suction side of the pump can be motor-operated valves only. Equip these valves with green and red (open and closed) indicating lights at their pushbutton control locations.

3-7.5.1 All Pumps.

Provide the following controls:

a. A keyed hand/auto button at each pump and a keyed hand-off-auto switch at the motor starter for each remotely operated pump. Both devices will use the same key.

b. Indicator lights at the control station to give positive indications both when a pump is operating and when it is not energized. Use the "push-to-test" type.

c. A signal light or alarm to indicate pump failure when a pump is controlled automatically.

d. Reduced voltage starting if required by electric utility supplier or for all pump motors greater than 50 horsepower (37 kW) and all vertical pumps.

e. Emergency fuel shut-off (EFSO) pushbutton stations, between 100 and 200 feet (30 m and 60 m) from the pump in the expected ingress and egress direction, with maintained contacts. Provide additional EFSO pushbutton stations at the point of fuel delivery or receipt (fillstands, piers, tanks, etc.) using the same spacing and location requirements.

3-7.5.2 Multi-Functions Pumps.

Multi-function pumps are typically used at small facilities and are designed and arranged to be able to perform different functions such as fuel loading, off-loading, or transfer depending on how valves are aligned. Provide each function with the control system requirements for each function described elsewhere in this chapter. For each multi-task pump provide a manual selector switch to choose which set of control and set points the pump is to "look at" when performing a particular function.

3-7.5.3 Transfer Pumps.

Transfer pumps are used to supply fuel to a tank truck loading facility, tank car loading facility, or transfer fuel from one place on the installation to another (e.g., bulk storage tank facility to operating storage tank). If these pumps exceed 150 horsepower (112 kW), comply with the paragraph titled “Pipeline Pumps” in this Chapter. In addition to requirements in the paragraph titled “Pipeline Pumps” in this Chapter, provide transfer pumps with push button start/stop stations. Where these pumps are used for truck and/or car loading, provide push button controls adjacent to the pumps and at each loading station. Use programmable logic controllers (PLC) where multiple pumps supply header loading multiple trucks or cars to obtain desired flow rate to each loading station.

3-7.5.4 Pipeline Pumps.

For pumps over 150 horsepower (112 kW), provide protective shutdown devices with alarm at central supervisory control station in the event of the following:

a. High pump case temperature due to blocked discharge.

b. Excessive pump vibration.

c. Mechanical seal or packing gland failure.

d. High discharge pressure or loss of discharge pressure.

e. Excessive motor vibration.

f. High motor winding temperature.

g. Electrical interlocks which will prevent starting a pump if certain key valve settings are not correct and which will cause a pump shutdown if a key valve setting is changed.

h. Loss of pump suction pressure.

i. High bearing temperature and/or loss of cooling water flow.

3-7.5.5 Temperature Controls.

Provide temperature controls at all fuel oil heaters to control the outlet oil temperature within safe limits. Provide a sensing element in the fuel outlet line which activates a thermostatic valve in the heating medium supply connection to the heater. Use a self-actuating control valve that requires no external power for closure. Use a manually adjustable set point for each temperature variable over the desired temperature range. Provide a bypass around the control valve with a V-port globe or ball valve for manual operation.

\1\ /1/

3-8 PRODUCT RECOVERY SYSTEMS.

Provide a product recovery system to collect and store usable aviation turbine fuel that would otherwise become waste from operational or maintenance activities. Consider a product recovery system for other products. See Chapter 8 of this UFC for product recovery systems.

3-9 FUEL ADDITIVES.

If directed by DLA-Energy , provide bulk storage facilities which store aviation turbine fuels and diesel fuels with the system components to inject fuel additives. This will require proportional injectors, storage of additives, and capability of recirculating tanks through piping with injectors. If the additives have a corrosive characteristic, construct the system, including storage tanks, tank appurtenances, pumps, if required, piping and associated fittings, valves, and injector assemblies of stainless steel components.

CHAPTER 4 AIRCRAFT FUELING FACILITIES

4-1 INTRODUCTION.

This chapter provides guidance for the design of aircraft fueling facilities, including operating storage tanks and those components normally located within a typical compound. These components include pipeline receiving facilities, tank truck and tank car receiving facilities, refueler truck fillstands, type III, IV, and V aircraft direct fueling systems, and associated piping and system components. Fuel storage tanks are discussed in Chapter 8 and piping systems in Chapter 9 of this UFC. Systems used to receive fuels from barges and ships are discussed in Chapter 5. Pipelines that transport fuel from off base and pipelines between bulk tanks and operating storage tanks are discussed in Chapter 6 of this UFC.

Note: If aviation fuel can be pumped directly from a tank into an aircraft, aircraft direct fueling system or a refueler, treat the tank as an operating storage tank regardless of size and location and meet the applicable requirements for aviation turbine fuel operating tanks. The exception is bulk storage tanks that are configured to fill refuelers on an emergency basis only.

4-1.1 Function.

Aircraft fueling facilities, as discussed in this chapter, are designed for ground fueling of fixed and rotary wing aircraft. Two methods are used for refueling aircraft: refueler trucks and aircraft direct fueling systems (e.g., hydrant system). The preferred method of fueling used at most Navy, Marine Corps, and Army small aircraft bases is by refueler trucks. For Air Force transport, tanker, cargo, bomber, and other large aircraft, the preferred method of fueling is by hydrant system where the aircraft are fueled on the apron in their parked positions. Where operational/mission requirements dictate a quick return to the air, small-frame aircraft, both fixed and rotary wing, are refueled with the engines running via aircraft direct fueling systems under a "gas and go" or hot pit refueling concept. Install aircraft direct fueling systems only when specifically authorized by Service Headquarters.

4-1.2 Aviation Turbine Fuels.

The fuels covered in this chapter are JP-4, JP-5, JP-8, JPTS, Jet A, additized Jet A (F-24), and Jet A-1. Because of the critical nature of the end use of the fuel, protection of fuel quality, dependability of the system, and safety are very important. Refer to Chapter 2 of this UFC for information on fuel properties.

4-1.3 Special Precautions for Aviation Turbine Fuel Quality.

Take extra care to prevent the contamination of aviation turbine fuels by dirt, water, and other fuels. For additional information, refer to Chapter 2 of this UFC. Aircraft fueling system must be designed with capability to generate sufficient turbulent flow to flush sediment and condensed water from all portions of piping systems. Refer to Chapter 9 of this UFC for fuel velocity criteria.

4-2 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, contains information on fueling facilities. Do not begin the design on any fueling system without first becoming completely familiar with Chapters 2 and 9 of this UFC and with the airfield clearance requirements found in UFC 3-260-01.

4-3 RECEIVING FACILITIES.

Fuel deliveries to a military aviation activity are normally made by tank truck, railroad tank car, barge, or pipeline. A secondary method of delivery is normally required. Service Headquarters, with concurrence from the DLA-Energy, will determine the appropriate type of delivery method based on mission requirements and an economic analysis.

4-3.1 Pipeline Receiving Facilities.

4-3.1.1 General Criteria.

Petroleum fuels may be supplied to aviation turbine fuel storage tanks by interterminal pipelines or installation pipelines. Interterminal pipelines may be dedicated to serving the particular facility or may be commercial pipelines handling a number of types or grades of fuel for more than one user. Installation pipelines will normally be a pipe from the bulk facility to the aircraft fueling facility. Provide for separate receiving and distribution piping for each grade of aviation turbine fuel unless otherwise approved by Service Headquarters. Exercise extreme care to avoid designing a system that could create damaging surges in the pipeline created by quick closing valves.

4-3.1.2 Required System Components.

a. Provide pressure-regulating diaphragm control valves to reduce pipeline pressures to the design pressure of the facility's piping and system components. Provide a manual isolation valve at both the upstream and downstream side of each diaphragm control valve. Prior to designing any features into the system which might affect the flow from a pipeline, contact the operator of the pipeline to ascertain the current operating conditions, evaluate the use of diaphragm control valves, conduct a surge analysis of the pipeline, and determine whether the use of diaphragm control valves is appropriate.

b. Provide a meter at the receiving end of the line to measure quantities of fuel received. Turbine-type meters are commonly used for pipeline receipt above 1200 gpm because of the cost of large positive displacement meters. However, positive displacement meters are acceptable if available at the required flow rate. Compensate for fuel temperature at the point of custody transfer. Provide two parallel basket strainers with double block and bleed isolation valves immediately upstream of the meter and connections for proving the meter with a portable prover. A meter prover connection consists of a manual isolation valve in the main pipeline with a tee on both the upstream and downstream sides of the valve. The branch of each of the tees has a manual isolation valve and a hose connection. The master meter can be attached to the hose connections.

c. Provide a means for sampling each pipeline product at a breakout manifold.

d. Provide provisions for maintenance and ILI pigging on interterminal pipeline receipt location. Consult Service Headquarters for arrangements required to meet commercial pipeline agreements. Provide ILI launcher and receiver on government owned interterminal pipelines. Arrange pig receiving connections to avoid introducing pipeline sludge and sediment into the tanks. Pig launching and receiving provisions are required for interterminal (cross-country) and installation (as described in Chapter 6 of this UFC) underground pipelines. See Chapter 9 for pigging requirements.

e. Provide an interface tank to receive mixed fuels at the beginning and ending of a shipment unless the commercial pipeline company can provide this service satisfactorily.

f. Provide a breakout tank only if pipeline flow cannot be stopped due to pipeline operational requirements. Provide valves to divert the flow of fuel from the pipeline to the breakout tank in the event fuel transfer is blocked by a manual or automatic valve within the fuel facility system such that the fuel facility system would be overpressurized from transient surge or high pressure from deadheading a pipeline supply pump. Provide appropriate breakout tank overfill alarms and alarm breakout operation so fuel facility operators can take necessary steps to stop pipeline flow. Provide means of transferring fuel out of breakout tank back to fuel systems after a breakout event. Conduct a thorough review with the pipeline operator and perform a transient surge analysis to determine if surge pressure reduction methods are required to avoid damage to the pipeline. Consider multiple factors when determining size of breakout tank. Factors shall include ability of receiving facility to recognize excursion (over pressure event), ability to notify source of transfer to shutdown pipeline pumps, impact of deadheading pipeline pump, and factor of safety. Increased confidence of ability to shutdown pumps, via receipt pressure sensors with rate of rise PLC assessment, communication to transfer source via fiber optics communication, and automatic transfer pump shutdown will lead to smaller sized breakout tanks. Whereas reliance on receipt staff to respond to alarm and notify source pumpstation via telephone will lead to larger sized breakout tank. Consideration shall also be given to type of surge breakout system, such as side stream pressure relief versus rapid full opening surge dump valve. As a minimum, the surge breakout tank must be sized such that its ullage volume, above a minimum heal level, can safely store not less than two times the volume of fuel resulting from a release event, but not less than two times the receipt volume for a 10-minute flow at normal pipeline flow. When sizing breakout tanks also consider using aboveground shop fabricated UL listed tanks, and that increasing the tank size (and thus safety factor of release) very often is a small cost, compared to the cost of release cleanup. Contact Service Headquarters for design considerations and approval of surge breakout tank system approval.

g. Provide means of inbound filtration for all products. The selection of filtration depends on anticipated impurities, the source of fuel, and the shipping methods. Avoid the use of water slug shutoff diaphragm control valves or other rapid-closing valves on pipeline receipt facilities. See the "Special In-Bound Filtration" paragraph and Table 4-1 of this Chapter of the UFC for details. When a water slug shutoff is not provided, provide sump water detector and alarm panel.

h. Provide manual isolation valves to isolate system components for service.

i. Provide basket strainers immediately upstream of pumps, meters and receipt filtration. On piggable pipeline receipt, provide 2 parallel strainers with isolation valves so pigging can continue while cleaning one strainer.

j. Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

k. Provide a concrete housekeeping pad, and a canopy for protection from the elements of fixed facility assets and system components in accordance with paragraph 2-22.

4-3.2 Tank Truck and Tank Car Off-Loading Facilities.

4-3.2.1 General Criteria.

Fuel system operating tanks may be supplied with fuel by tank truck or tank car or both. At facilities with pipeline or water transport as their principal supply source, provide tank truck or tank car deliveries as a secondary supply source. Tank truck deliveries are the most common method. However, special transportation considerations or changing circumstances may make the use of rail facilities desirable. Therefore, at an activity with railroad service, arrange a tank truck receiving facility so that the system can be easily and economically extended to the existing rail spur. See Facility Plate 002.

a. The preferred off-loading method is into a drop tank off-loading system. See Facility Plate 003.

b. Provide a packaged off-loading system when a drop tank type off-loading system is not practical for off-loading tank trucks or tank cars due to environmental concerns, site limitations, or cost considerations, and/or when directed by Service Headquarters. See Facility Plate 004.

c. Provide a direct off-loading system when only an occasional tank truck requires off-loading and when directed by Service Headquarters. See Facility Plate 005.

d. Do not locate tank truck or tank car receiving facilities closer than 50 feet (15 m) from buildings, roads, overhead power lines, pad-mounted transformers, and installation property lines, and 25 feet (7.6 m) from the installation interior fence surrounding the fuel farm. See Chapter 8 of this UFC for clearance from tanks. Comply with NFPA 30 and assume that the property line is the fuel farm fence. Use the criteria for Class I liquids regardless of product and do not take a reduction for fixed fire protection.

e. Provide an adequate number (minimum two) of positions to off-load the daily fuel requirements of the facility in an 8-hour period without causing detention or demurrage of delivery conveyances.

f. Provide separate off-loading connections for each type of fuel to be handled. To facilitate the use of tank trucks with multiple independent compartments, provide a hose manifold with a minimum of two connections per tank truck. A manifold with hose connections equal to the number of truck compartments is recommended for quick turnaround. If less than five connections are provided, provide a blind flange on the end of the manifold to accommodate additional connections.

g. Provide a containment area at each truck off-loading position consisting of an impermeable retention and controlled drainage system leading to a concrete remote spill containment system. Pave the containment area consisting of the islands, the spaces between islands and on each side of the outer islands, with concrete pitched a minimum of one percent toward catch basins or trench drains. Design the containment area in accordance with UFC 1-200-01, federal, state and local regulations. Do not use asphalt within a spill containment area. The maximum slope of any paving within a truck movement or parking area must not exceed 2 percent excepting ramps. If a ramp is provided, the sum of the vertical entrance and exit grades must not exceed 8 percent and the ramp must be aligned perpendicular with direction of truck movement. The designer must assure that adequate ground clearance is achieved for all vehicles utilizing the containment areas.

h. Provide spill containment at each rail tank car off-loading position consisting of an impermeable containment system surrounding the rail car with drainage leading to a concrete remote spill containment basin. Pave the offload equipment area and space between the offload equipment and rail car containment system with concrete sloped a minimum of one percent toward a drainage collection system that leads to the concrete remote spill containment basin.

i. Provide a concrete remote spill containment system for each containment area. Design the remote spill containment system in accordance with UFC 1-200-01, federal, state, and local regulations. Provide the remote spill containment system with capacity greater than the volume of the largest tank truck or tank car compartment to be off-loaded. The top elevation of the remote spill containment basin must not be set less than 6-inches above the top of the refueler truck parking area's maximum ponding elevation. This will prevent overflow of the remote spill containment basin during a heavy rain event. A curbed truck position may be provided in addition to a remote system. Twenty-five percent or more of the total required containment volume must be directed to, and stored at, the remote system before any of the shared containment volume will pond at the truck stand area. Provide a lockable eccentric plug valve with indicator post located outside the containment area at a location that will be safely accessible during a fire. The valve must be lockable and normally closed to allow for containment during fueling operations and which can be opened to drain area when necessary. Tank trucks can be as large as 10,000 gallons (38,000 L) in capacity and tank cars as large as 40,000 gallons (151,000 L). Consider combining the remote spill containment system with other spill containment systems on-site, except with tank containment systems. However, take the level of contamination in each containment area into consideration.

j. Construct the drain piping between the containment area and the remote spill containment system, and between the remote spill containment system and lockable plug valve of petroleum-resistant, impermeable materials with water-tight joints such as ductile iron or HDPE pipe with fusion welded joints. Do not use clay, concrete, or fiberglass piping materials.

k. For off-loading tank trucks, arrange the flow of traffic to permit continuous forward movement of trucks at all times. Commercial tank trucks off-load on the passenger side.

l. Tank truck configurations vary. Key variables are: the number of compartments per tank, single or multiple trailers, location of connections on each trailers, height of trailer connections, etc. Designer must coordinate with the installation and Service Control Point regarding the type of delivery trucks used at the installation.

m. To determine the number of connections needed for off-loading tank cars, consult with Service Headquarters and consider minimizing tank car movements, tank car shipping schedules, conveyance turn-around times, local rail switching capabilities, and quantity of fuel needed for one day's fuel supply.

n. Provide an electrical design that meets the minimum requirements of NFPA 70, NFPA 77, and NFPA 780. Treat combustible liquids under pressure as a flammable liquid.

o. Provide a canopy for protection from the elements of fixed facility assets and system components **\1** in accordance with paragraph 2-22. **/1/**

p. Provide a canopy to preclude rain from the containment area **\1** in accordance with paragraph 2-22. **/1/**

q. Provide for egress and entrance of emergency response vehicles. The egress and entrance routes need to be large enough to allow both, trucks and emergency vehicles to leave and enter the facility simultaneously.

r. Provide means of inbound filtration for all products. The selection of filtration depends on anticipated impurities, the source of fuel, and the shipping methods. See "Special In-Bound Filtration" paragraph and Table 4-1 in this chapter of this UFC.

4-3.2.2 Tank Truck and Tank Car Drop Tank Off-Loading System.

The introduction of air into a fuel receiving system poses extreme hazards which can result in fire and/or explosion. Hazards are compounded when an air/fuel mixture is passed through receipt filter-separators where static electricity is generated and ignition can occur. Design off-loading facilities so air is not introduced into the system. For facilities with the capability to off-load several tank trucks at once or where newer tank trucks with multiple hoses are connected to multiple isolated compartments, consider providing an underground, gravity-type, receiving tank with submersible transfer pumps and level controls. For smaller systems of one or two tank trucks, consider providing a low profile, aboveground, receiving tank with a centrifugal transfer pump. For either case, provide level sensors to control the transfer flow rate. Provide a temperature compensated meter on the receipt line to the tank at points of custody transfer and when directed by Service Headquarters. For materials of construction for off-loading drop tanks, refer to Chapter 8. See Facility Plate 003.

4-3.2.3 Tank Truck and Tank Car Packaged Off-Loading System.

For tank truck or tank car off-loading an off-loading drop tank may not be practical due to environmental concerns, site limitations, or cost considerations. In these instances, provide a 600 gpm (38 L/s) packaged off-loading system. Provide one packaged system, including vertical inline centrifugal pump, diaphragm control valves to control flow, meter, and multiple hose connections (one for each tank truck compartment), for each tank truck or tank car receiving station. Provide an air eliminator tank to remove air from the system, reducing the risk of an air/fuel mixture passing through receipt filter-separators and preventing the metering of air. Level sensors in the air eliminator tank control the pump discharge diaphragm control valves, modulating the flow rate based on the level in the air eliminator tank. Refer to DoD Standard Design AW 078-24-28 and Facility Plate 004.

4-3.2.4 Tank Truck and Tank Car Direct Off-Loading System.

Use when only an occasional tank truck requires off-loading and when directed by Service Headquarters. Refer to Facility Plate 005.

4-3.2.5 Required System Components.

a. When tank trucks or tank cars are off-loaded with a drop tank off-loading system, do not provide an off-loading pump. Provide at least two pumps in the drop tank to transfer fuel to the storage tank.

b. When tank trucks or tank cars are off-loaded with packaged off-loading systems, provide one system for each tank truck or tank car that is to be off-loaded simultaneously, at an average capacity of 600 gpm (38 L/s) each. The number of systems will be determined by Service Headquarters but must be a minimum of two. The capacity of the systems may be reduced to 300 gpm (19 L/s) each only when directed by Service Headquarters.

c. When tank trucks or tank cars are off-loaded with direct off-loading systems, provide centrifugal pumps configured to provide automatic air elimination as shown on Facility Plate 005. Provide at least two pumps to allow continued operation if one is out of service. The capacity of the pumps may be increased to 600 gpm (38 L/s) each only when directed by Service Headquarters. The centerline height of suction line from manifold to pump usually should not exceed 23.25 inches (591 mm) above truck unloading, parked position. Confirm this with the activity; in western CONUS, trucks tend to have lower connections. Locate the pump as close as possible to the off-load point to prevent suction problems.

d. Provide lightweight reinforced vacuum rated off-loading hoses and covered hose storage racks for each hose connection at each off-loading position. Eliminate covered hose storage rack if off-load rack is to be covered by a canopy. Ensure that all swivels are non-lubricated aluminum or stainless steel in-line repairable type. Consult with activity to verify the need for hoses, since at some locations, the fuel hauling contractor provides the hoses.

e. Equip each tank truck off-loading position with an electronic, intrinsically safe, automatic, self-monitoring ground verification unit with a lockable bypass. If grounding is not verified and there is an off-loading pump dedicated to that position, ensure the unit prevents the pump from starting. If the pump is not dedicated, ensure an alarm sounds if the off-loading valve is opened prior to grounding verification. Include a separate grounding reel to accommodate vehicles without grounding system components.

f. Provide emergency fuel shutoff (EFSO) pushbutton stations. For truck off-loading stations with multiple positions, an EFSO pushbutton station is required for each position and along routes of personnel ingress and egress between 100 and 200 feet (30 m and 60 m) from the off-loading position. Design in such a manner that activation of the emergency stop will shut off all fueling in the off-loading area and/or the associated pumphouse or pump pad.

g. Provide fuel sampling connections at each position for each product line for collecting test samples.

h. Provide pressure gauges on both sides of each strainer or a differential type gauge across each strainer. Where a strainer is upstream of a pump, the pump suction gauge may function as the strainer downstream gauge.

i. Provide a compound (pressure/vacuum) gauge on the inlet side of the pumps and a pressure gauge on the outlet side of pumps.

j. If system is for JP-5 or other fuel that does not have a static dissipater additive which provides a conductivity level greater than 50 conductivity units (50 picosiemens per meter), and a 30-second retention time is not provided between filter-separator and receiving tank, provide a relaxation tank downstream of the filter-separator or design the piping layout to provide the required 30-second relaxation time downstream of the filter-separator.

k. Provide basket strainers immediately upstream of pumps, meters and receipt filtration.

l. Provide a combination flow control and non-surge check diaphragm control valve on all off-loading pumps except positive displacement types. If a bulk air eliminator with automatic air release head is included, provide a means of closing the diaphragm control valve with a solenoid pilot.

m. Provide a positive displacement or turbine meter. Provide meter with temperature compensation capability and meter proving connections at each offload position (custody transfer location). Provide a basket strainer immediately upstream of the meter.

n. On each off-loading connection or on the off-loading riser, install a visual fuel flow indicator (maximum pressure 275 psi (1900 kPa) at 100 degrees F (38 degrees C), with Viton Seals with a maximum temperature rating of 350 degrees F (177 degrees C)). This will allow visual quality assurance and provide the operator with a backup system to shut off the pumps when off-loading is complete to prevent air build-up in the receipt lines.

o. Provide filter-separators and other filtration devices as described in Table 4-1 to filter fuel before it enters the storage tank.

p. Provide manual isolation valves to isolate system components for service.

q. Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

r. For JP-8 systems, provide a capability to defuel JP-8 refueler trucks back into operating storage as described in the paragraph titled “Defueling and Return-to-Bulk Systems” in this chapter.

s. Where tank trucks or tank cars are off-loaded into drop tanks, provide meters on the downstream side of the drop tank pumps.

4-3.3 Marine Off-Loading Facilities.

See Chapter 5 of this UFC.

4-3.4 Special In-Bound Filtration.

Where fuel is transferred to the base fuel system operating tanks from tankers, barges, or directly from the supplier (off base) by a multi-product pipeline, pass the fuel through strainers, then pre-filtration, then fine filtration. In other cases, pass the fuel through strainers and fine filtration only. See Table 4-1 of this chapter for details.

4-4 DISPENSING FACILITIES.

4-4.1 Refueler Truck Fillstands.

Mission and turn-around times will establish the number of fill positions, with two being the minimum. Service Headquarters can assist in determining the number. See Facility Plates 006 and 007 for general design guidance and also DoD Standard Design AW 078-24-29, Type IV/V. Provide a separate loading system for each grade or type of fuel to be handled.

4-4.1.1 General Criteria.

a. Locate the refueler loading facility as close as practical or permissible to the location of the aircraft to be fueled but not less than 50 feet (15 m) from buildings, roads, overhead power lines, pad-mounted transformers, and installation property lines and 25 feet (7.6m) from the installation interior fence surrounding the fuel farm. See Chapter 8 of this UFC for clearance requirements from tanks.

b. For aircraft direct fueling systems, the fuel supply piping to the refueler truck loading facility may be a spur or extension from that system and constructed of the same material as that system. In this case, the filter-separators are not required since they are provided as part of the aircraft direct fueling system. Where filtration is downstream of the pump house and the spur connects prior to the filtration system components, a filtered lateral is required.

c. Arrange fuel loading system components on one or more concrete islands configured for refueling on one side only. Make the direction of traffic appropriate for the location of the loading connections on the refueler, located on the driver's side. When more than one island is required because of the volume or number of fuel grades to be handled, arrange them in a parallel fashion with approximately 15 feet (4.6 m) between adjacent sides. Arrange the islands and approaches to allow forward motion for all trucks at all times with ample room for turning. Allow for egress and entrance of emergency response vehicles.

d. Provide a containment area at each truck loading position, consisting of an impermeable retention and controlled drainage system leading to a concrete remote spill containment system. Pave the containment area consisting of the islands, the spaces between islands and on each side of the outer islands, with concrete pitched a minimum of one percent toward catch basins or trench drains. Design the containment areas in accordance with UFC 1-200-01, federal, state, and local regulations. Do not use asphalt within a spill containment area. The maximum slope of any paving a within truck movement or parking area must not exceed 2 percent excepting ramps. If a ramp is provided, the sum of the vertical entrance and exit grades must not exceed 8 percent, and the ramp must be aligned perpendicular with direction of truck movement. The designer must assure that adequate ground clearance is achieved for all vehicles utilizing the containment areas.

e. Provide spill containment at each rail tank car loading position consisting of an impermeable containment system surrounding the rail car with drainage leading to a concrete remote spill containment basin. Pave the offload equipment area and space between the offload equipment and rail car containment system with concrete sloped a minimum of one percent toward a drainage collection system that leads to the concrete remote spill containment basin.

f. Provide a concrete remote spill containment system for each containment area. Design the remote spill containment system in accordance with UFC 1-200-01, federal, state, and local regulations. Provide the remote spill containment system with capacity greater than the volume of the largest refueler to be loaded. The top elevation of the remote spill containment basin must not be set less than 6-inches above the top of the refueler truck parking area's maximum ponding elevation. This will prevent overflow of the remote spill containment basin during a heavy rain event. A curbed truck position may be provided in addition to a remote system. Twenty-five percent or more of the total required containment volume must be directed to, and stored at, the remote system before any of the shared containment volume will pond at the truck stand area. Provide a lockable eccentric plug valve with indicator post located outside the containment area at a location that will be safely accessible during a fire. The valve on the drain system must be lockable and normally closed to allow for containment during fueling operations and which can be opened to drain the area when necessary. Tank trucks can be as large as 10,000 gallons (38,000 L) in capacity. Consider combining the remote spill containment systems with other spill containment systems on site, except with tank containment systems. However, take the level of contamination in each containment area into consideration.

g. Construct the drain piping between the containment area and the concrete remote spill containment system, and between the remote spill containment system and lockable eccentric plug valve of petroleum-resistant, impermeable materials with water-tight joints such as ductile iron or HDPE pipe with fusion welded joints. Do not use clay, concrete, or fiberglass piping materials.

h. Load aircraft refueler trucks by bottom loading only. Design the system to deliver a refueling nozzle pressure of 35 psig (240 kPa) with a flow range of 50 to 560 gpm. System design must take into consideration pressure and flow settings to prevent damage to bottom loader. Contact Service Headquarters for further direction.

i. Provide a canopy for protection from the elements of fixed facility assets and system components **\1** in accordance with paragraph 2-22. **/1/**

j. Provide a canopy to preclude rain from the containment area **\1** in accordance with paragraph 2-22. **/1/**

k. Design all electrical systems and apparatus for use in Class I, Division 1, Group D, hazardous areas in accordance with NFPA 70, regardless of the type of fuel dispensed.

l. Provide for egress and entrance of emergency response vehicles. The egress and entrance routes need to be large enough to allow both, trucks and emergency vehicles, leaving and entering the facility.

m. For JP-8 systems, provide a capability to defuel JP-8 refueler trucks back into operating storage as described in the paragraph titled "Defueling and Return-to-Bulk Systems" in this chapter.

4-4.1.2 Required System Components.

\3 Provide separate piping, pumps, loading connections, and controls for each different type or grade of fuel. Provide an individual isolation valve for each fill connection. Include the following system components in each refueler truck fillstand: **/3/**

a. Self-closing emergency valve with 165 degrees F (74 degrees C) fusible link (These valves are neither required nor permitted on Air Force projects).

b. Provide manual isolation valves to isolate system components for service.

c. Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

d. Provide filter-separator, unless fillstand is supplied from an aircraft direct fueling system via a non-ferrous branch connection downstream of the issue filter-separator. Ensure that the piping downstream of the filter-separator is non-ferrous or interior coated.

e. Positive displacement or turbine meter with rated capacity equal to the maximum flow of the loading station and the following accessories:

  1. If custody transfer point: a combination ticket printer and large numeral zero reset counter with self-closing weatherproof cover. Ticket printer not required on Army or Air Force projects.

  2. Pulse transmitter of the photoelectric, high resolution type required for projects which employ electronic data acquisition systems.

  3. Temperature compensation if at a custody transfer point.

f. Provide relaxation tank or piping configuration with sufficient capacity to retain the maximum flow of the loading station for 30 seconds from the time the fuel leaves the last piece of filtration system component to the fuel reaching the loading pressure refueling nozzle. Applies to JP-5, Jet A, and other fuels which do not have a static dissipation additive that provides a conductivity level greater than 50 picosiemens per meter.

g. Mechanical loading arm. The preferred device is a non-lubricated, swiveled, stainless steel, counterbalanced mechanical loading arm. As an option, with the approval of Service Headquarters, use a loading hose approximately 10 feet (3 m) long, 3 or 4-inch (75 or 100 mm) nominal diameter, and meeting requirements of EI Std 1529. A spiral protective device (slinky) may be installed around the hose. House the hose in a covered hose tray to protect from ultraviolet damage. Install with a non-lubricated stainless steel in-line repairable swivel.

h. SAE AS5877 pressure refueling nozzle of size and type compatible with truck-loading connections (coded for product use, if more than one type of fuel is issued at the fillstand). Connect the pressure fueling nozzle to the loading arm or hose with a dry-break quick disconnect.

i. Provide a sample outlet with probe, ball valve, and quick disconnect at each position for each product line.

j. Make provisions to start and stop the pumps with start and stop pump control stations at each position. Include pump status indicator light on control box.

k. A hydraulically operated diaphragm control valve with the following functions (care must be taken to select system components which are compatible with electronic or mechanical meter stacks):

  1. Adjustable rate of flow control if fillstand is on a branch line from an aircraft direct fueling system or other multiple pump arrangement which could result in issue exceeding 600 gpm (38 L/s).

  2. Pressure regulating to maintain desired upstream or downstream pressures.

  3. Adjustable time delay for opening and closing speed control.

  4. Control valve to close in the event of diaphragm failure.

5. Thermal relief to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points.

6. Position indicator.

7. Solenoid Shutoff. Interlock the solenoid with the electronic high-level shutoff and electronic ground verification control systems.

l. Provide each fill position with an electronic high-level shutoff, electronic ground verification, and hydraulic or electronic deadman control system. The system must be intrinsically safe and self-checking. Interlock the system with either the solenoid operated truck loading diaphragm control valve or the pump such that the valve cannot remain open or the pump cannot operate if the tank truck compartment is full, the tank truck is not bonded to the fueling system components, or the deadman is released. Ensure the system is compatible with both electronic and fiber optic sensors with manual-keyed bypass. (May require a parallel effort beyond the project scope to ensure that all trucks using the facility have compatible connections. If facility has trucks that do not have fixed probes, use cane probes instead.) (This unit is optional on Army projects with only tactical refuelers. Contact the Service Headquarters for guidance.)

m. Provide emergency fuel shutoff (EFSO) pushbutton stations. For fillstands with multiple positions, an EFSO pushbutton station is required for each position and along routes of personnel ingress and egress between 100 and 200 feet (30 m and 60 m) from the fillstand. Design in such a manner that activation of the emergency stop will shut off all fueling at that pump house or pump pad.

n. Low-intensity area lighting, in accordance with API RP 540, to permit full visibility of all system components and controls during night operations.

o. Refer to Chapter 2 of this UFC for information on vapor collection and recovery or disposal systems.

p. If pumps are dedicated to fillstands, make provisions to start and stop the pumps with start and stop pump control stations at each position. Include pump status indicator light on control box. Grounding reel and grounding plate as detailed in Standard Design AW 078-24-29, Type III with multiple connections.

q. Provide basket strainer immediately upstream of pumps, meters, and where a filter-separator is not provided at the load rack.

r. Pressure gauge.

s. Maintenance drains.

t. Vents.

u. Provide hydraulic shock surge suppressors (if required).

v. For JP-8 systems, to allow defueling of refueler trucks, provide a Return-To-Bulk (RTB) station by providing a MIL-STD MS 24484 aircraft refueling adapter a point upstream of receipt filtration. Acceptable locations include the return line at a truck fillstand, the return line at a hydrant hose truck check-out station, the return line at a pantograph flush station, the product recovery tank, or at a truck off-load station. Provide one single point receptacle (SPR) connection per group of fillstands or truck off-load stations. If into a product recovery tank, do not bypass the level control valve.

w. Provide meter proving connections as described in the paragraph titled “Pipeline Receiving Facilities”, unless local procedure provides an alternative.

4-4.2 Aircraft Direct Fueling Systems.

Aircraft direct fueling systems are fuel systems that deliver fuel directly into an aircraft and require additional fueling hardware, such as a hydrant hose truck, pantograph, or hydrant hose cart. These may be Type III hydrant systems (DoD Standard Design AW 078-24-28) for portable pantographs or hydrant servicing trucks/carts; or may be hard piped with fixed pantographs, which is usually the case for Type V in-shelter fueling (DoD Standard Design AW 078-24-29) and Type IV hot fueling stations (DoD Standard Design AW 078-24-29). For facilities being constructed OCONUS NATO refer to DoD Standard Design STD 121-122-01 USAFE/NATO, Airfield Standard Design US, Jet Fuel Storage Dispensing Systems for Tactical and Wide Body Aircraft for design guidance. While individual components may vary slightly between the various aircraft fueling systems, the basic philosophy of a system configured in a loop with no dead ends, is followed by all the services. The loop is made up of the supply/return piping with a flushing/back pressure control valve that maintains a constant pressure on the supply side piping and relieves excess fuel not taken on by the aircraft(s) into the return portion of the piping and back to the tank. The lead pump is turned on either automatically by a drop in the system pressure or manually by an on/off switch at each direct fueling station. A venturi in the supply piping senses flow rate in the loop and works in conjunction with a venturi in the return loop. Depending on the flow demand, the return venturi turns on/off additional pumps as required. If return flow is below a preset limit (indicating that fuel is being dispensed), a low flow is sensed and additional pump(s) are turned on, one at a time, until a steady flow condition is reached. Conversely, if the return flow is above a preset limit (indicating less fuel is being dispensed), the return venturi senses high flow conditions and turns the pump(s) off, one at a time, until the system is brought to rest. The continued circulation of the fuel not only provides a self-cleaning action but when properly adjusted, the system is able to more closely match the varying fuel filling rates of aircraft. This provides smooth operation and helps eliminate destructive surge pressure spikes. In order to ensure the highest quality of fuel, contact with bare carbon steel is limited to an absolute minimum prior to filtration and is not permitted downstream of the issue filter-separators, unless specifically authorized by Service Headquarters.\

4-4.2.1 General Requirements.

Install aircraft direct fueling systems only when specifically authorized. Service Headquarters assist in determining the number and type of stations required by the activity and with locating hydrant pits in aircraft parking ramps. Construct new facilities only for issuing aviation turbine fuels through pressurized refueling nozzles and closed circuit fueling nozzles. Locate fueling stations at the edge of the aircraft parking apron or taxiways or at apron parking spots for large frame aircraft. Size and configure these systems based on the types of aircraft to be refueled, aircraft fuel capacity, and the number and types of aircraft to be simultaneously refueled. A parking plan must be approved before proceeding with the hydrant pit layout design. Some aircraft, such as fighters and some helicopters, may be refueled with engines running. See Facility Plates 008, 009 and 010. For additional guidance on Air Force projects, refer to **\2** AFMAN 32-1084 **/2/.**

4-4.2.2 Fixed-Wing Small-Frame Aircraft.

Locate aircraft direct fueling stations for small-frame aircraft (carrier aircraft, patrol aircraft, fighter aircraft, and small transports) along the edge of designated access ramps, aprons, or fueling lanes with easy access by aircraft and as close to their normal taxi routes as practical while still meeting centerline clearance requirements. Provide facilities for fueling aircraft with engines or support equipment running. These systems are installed where the mission dictates a continuing need for rapid turnaround without shutting engines down and are located to permit quick return to the runway. Configure taxi patterns to and from fueling stations to keep jet blast away from people. Refer to DoD Standard Design AW 078-24-29 . Use the following design criteria:

a. Outside of the limits prescribed for clear areas by UFC 3-260-01 and UFC 3-260-02, locate the system components aboveground on a concrete slab adjacent to the edge of an access ramp, apron, or fueling lane. Ensure that the width of the slab and location of the system components, including the pantograph when retracted, with respect to the ramp, apron, or fueling lane, does not interfere with any part of the aircraft on its approach to or departure from the fueling station. Equip Army and Navy hot fueling stations with an emergency dry breakaway coupling.

b. Limit the height of the system components, including lighting, on the slab to approximately 30 - 36 inches (762 - 914 mm) above nominal grade. For official height constraints, contact Airfield Manager or the authority having jurisdiction.

c. Provide a nominal maximum flow rate for each direct fueling station of 600 gpm (38 L/s). However, design the system to deliver 400 gpm (25 L/s) with a nozzle pressure of 35 psig (240 kPa). Ensure adequate pump design for 600 gpm flowrate. (In general, systems designed to deliver 400 gpm at 35 psig have been shown to be fully capable of delivering 600 gpm with a nozzle pressure reading of 10 to 20 psig.) Actual fueling rates for small-frame aircraft range from 250 to 550 gpm (16 to 35 L/s). Since the actual flow rate will vary as the nozzle back pressure varies, it is necessary to limit the maximum nozzle pressure to 55 psig (380 kPa) at the skin of the aircraft to protect the aircraft. The issue venturi in a pantograph is a critical component of the aircraft direct fueling system and must be able to correctly simulate nozzle pressure and compensate for all pressure losses up to and including the fueling nozzle. Use maximum rates and the number of required simultaneous refuelings for system sizing.

d. Provide at least two fueling stations, with the system sized for a minimum flow rate of 1,200 gpm (76 L/s). Where more than two fueling stations are required, increase the total system rate by 600 gpm (38 L/s) for every three additional fueling stations. Service Headquarters approval is required for systems exceeding 2400 gpm and less than 1200 gpm. However, systems are not recommended to exceed 3,000 gpm (including spare pump).

e. DOD has two variations of the standard design for fixed-wing, small frame aircraft direct fueling stations – Type IV (DoD Standard Design AW 078-24-29) and Type V (DoD Standard Design AW 078-24-29). Both variations use pantographs for fueling the aircraft. The Type V is the same as the Type IV except that the refueling points are located in hardened aircraft shelters. The Type V variation is also known as in-shelter refueling.

f. Both hose-end and hoseless pantographs can be used with either Type IV or Type V aircraft direct fueling systems. Contact the Service Headquarters for which type of pantograph to use. Use SAE AS5877 pressure refueling nozzles on pantographs.

g. Provide two separate pressure control devices for every aircraft direct fueling station: an aircraft refueling control valve and a hose end pressure regulator. Equip the aircraft refueling control valve with a pressure control pilot set at 45 psig and a surge shutdown pilot set at 50 psig on the fixed station. The hose end pressure regulator is located just before the aircraft refueling nozzle and is set at 55 psig. The hose end regulator is required unless specifically directed otherwise by the Service Headquarters. Refer to DoD Standard Design AW 078-24-29, Type IV/V.

h. In order to ensure that the control valve is always in control and modulating and thus able to protect the aircraft, provide a differential pressure pilot with a set point of 15 psi (100 kPa).

4-4.2.3 Large-Frame Aircraft.

Locate aircraft direct fueling stations for large aircraft (transports, cargo planes, tankers, long-range patrol planes, and bombers) adjacent to their normal parking positions. Use the following design criteria:

a. Individually determine the number of fueling stations required for each activity. This depends on the number of large aircraft based at the activity or the number of aircraft that will need refueling as transients. To accommodate the fueling of a number of aircraft within a given time span without moving them, more fueling stations are normally required than would actually be used at one time.

b. Provide flow rate criteria for each aircraft direct fueling station of 600 gpm (38 L/s) or 1,200 gpm (76 L/s) at 45 psig (310 kPa) nozzle pressure. The selection of 600 gpm (38 L/s) or 1,200 gpm (76 L/s) is based on aircraft. Contact Service Headquarters for guidance. Size combined system requirements in multiples of 600 gpm (38 L/s), starting at a minimum flow rate of 1,200 gpm (76 L/s) up to a maximum flow rate of 2,400 gpm (152 L/s).

c. The default hydrant control valve size for new aircraft direct fueling hydrant systems is 4-inch (nominal 600 gpm flowrate, potential maximum 900 gpm flowrate). Mission requirements of flowrates in excess of that are rare but may occur. In that case the larger 6-inch valve (nominal 1200 gpm delivery flowrate) may be used in new systems. The 6-inch valve may not be used in new systems without Service Headquarters approval. The 6-inch valve may be used in new hydrant pits added to existing systems, if the existing pits retain their existing 6-inch hydrant valves. Alternatively, the new pits can be provided with 4-inch hydrant control valves and the existing 6-inch hydrant valves replaced with 4-inch valves with 6-inch flanges and a spacer plate; contact the Service Headquarters for guidance. Each hydrant pit control valve is equipped with a pressure control and surge shutdown pilot. These pilot controls are set at 45 psig (310 kPa) and 50 psig (345 kPa), respectively. In order to ensure that the control valve is always in control and modulating and thus able to protect the aircraft, provide a differential pressure pilot with a set point of 15 psi (100 kPa).

d. Design the piping, hydraulics, materials, and pumps in accordance with other paragraphs in this chapter.

e. Large aircraft (bombers, transports, tankers, cargo planes, etc.) are typically fueled from flush-mounted in-apron hydrant pits (preferred method for Air Force projects) that conform to DoD Standard Design AW 078-24-28 for Type III hydrant systems.

f. Large aircraft can also be fueled from fixed pantograph assemblies when normal aircraft parking positions are located adjacent to edge of the ramp (fixed long-reach pantographs have a maximum reach of 135 feet (41 m)). This type system is equipped with Type IV (DoD Standard Design AW 078-24-29) pantograph stations. This system has a pantograph station mounted control valve that is hydraulically actuated and operated. In order to ensure that the control valve is always in control and modulating and thus able to protect the aircraft, provide a differential pressure pilot with a set point of 15 psi (100 kPa).

g. Use self-propelled hydrant hose trucks, Type III hydrant hose carts, or detachable pantograph assemblies to provide the connection from the flush-mounted in-apron hydrant pits to the aircraft and the necessary controls. Provide a hydrant control valve in the hydrant pit that is hydraulically or pneumatically actuated and operated, depending on the type of mobile refueling equipment used.

h. Provide two separate pressure control devices for every aircraft direct fueling station. This will either be two control valves in series or a control valve plus a hose end pressure regulator. Use of only a single control valve with two pilots does not meet this requirement, there must be two separate devices.

1. For flush-mounted in-apron hydrant pits with hydrant control valves in the pit, and that are served by self-propelled hydrant hose trucks, Type III hydrant hose carts, or detachable pantograph assemblies with a control valve on the pantograph, use the two control valves method, with a hydrant valve in the pit, and a control valve on the mobile equipment.

2. For flush-mounted in-apron hydrant pits served by detachable pantograph assemblies that do not have a control valve on the pantograph, use the hydrant control valve in the pit plus a hose end pressure regulator on the pantograph method.

3. For apron edge mounted Type IV fixed pantograph assemblies, use the control valve on the fixed pantograph plus hose end pressure regulator on the pantograph method.

4. Hose end pressure regulators are set at 55 psi and located just before the refueling nozzle. Refer to DoD Standard Design AW 078-24-29, Type IV/V.

i. Equip pantographs in accordance with DoD Standard Designs. When incorporating the detachable pantograph into the design, follow USAFE/NATO specifications in which the swivels contain in-line repairable roller bearings. In addition, include the pantograph(s) as part of the construction project. Normally, the number of pantographs required equals the number of simultaneous refuelings to be performed.

j. The Air Force large-frame aircraft direct fueling system is referred to as a Type III pressurized fueling system. The Type III fueling system, or the constant pressure system, is the standard hydrant fueling system for large-frame aircraft. It is comprised of two operating storage tanks, a pump house, a hydrant loop, and hydrants at each parking position. The system is controlled by two redundant programmable logic controllers (PLC) and is constantly pressurized when in operation. Fuel is pumped from the tanks, through filter-separators and a supply venturi into the hydrant loop. It flows through the appropriate hydrant valve, through a hydrant servicing vehicle or mobile pantograph, into the aircraft if refueling is underway. A back pressure control valve keeps system pressure at a pre-set level and a return venturi measures flow back to the storage tank. Working in conjunction with the return venturi, pumps are turned on and off depending on refueling requirements. This system is sized in 600 gpm (38 L/s) increments up to 2,400 gpm (152 L/s). Issue pumps are sized to provide a minimum of 100 psi (690 kPa) at the outlet of the most distant hydrant adapter. The piping has to be non-ferrous or interior coated carbon steel (for the Air Force) from downstream of the issue filter-separators all the way to final hose or hard piped aircraft or refueler nozzle connection. For a Type III fueling system, there are two stages of filtration – fuel is filtered into the tank on receipt and out of the tank on issue. Contact Service Headquarters for specific guidance and sizing of the hydrant control valve. Refer to DoD Standard Design AW 078-24-28 for Type III hydrant systems.

4-4.2.4 Helicopters.

Refer to DoD Standard Design AW 078-24-29, Type IV, and use the following design criteria for designing direct fueling systems for helicopters:

a. Design piping, pumps, controls, accessories, and auxiliary systems in accordance with other applicable paragraphs of this chapter. For each direct fueling station, provide a nominal maximum flow of 300 gpm (19 L/s). Design system to be capable of delivering 275 gpm (17 L/s) at 35 psig (240 kPa) nozzle pressure. Make the minimum size system 600 gpm (38 L/s) with at least two fueling stations. For diversity usage, increase by 300 gpm (19 L/s) for every three additional fueling stations. At outlying fields and with Service Headquarters' approval, a single fueling station may be used.

b. Provide aboveground direct fueling stations equipped identical to fixed-wing small-frame aircraft fueling stations. Design the horizontal position and vertical projection of fueling system components to avoid interference with the helicopters' blades when in the drooped attitude.

c. Coordinate the type of pressure refueling nozzle, SAE AS5877 or closed-circuit, with the end user. In order to ensure that the control valve is always in control and modulating and thus able to protect the aircraft, provide a differential pressure pilot with a set point of 15 psi (100 kPa).

4-4.2.5 Surface Effect Hovercraft.

Turbine-powered, surface-effect hovercraft can be fueled on the parking apron with aircraft direct fueling systems. Use a 200 gpm (13 L/s) maximum fueling rate at 30 psig (207 kPa) nozzle pressure. The fueling hardware components are similar to those required for aircraft direct fueling with JP-5. Orient fueling stations so that the blast generated from the turbine engine does not damage the direct fueling station components. Refer to DoD Standard Design AW 078-24-29, Type IV.

4-4.3 Marine Loading Facilities.

See Chapter 5 of this UFC.

4-5 PIPING SYSTEMS.

Refer to Chapter 9 of this UFC for information and guidelines regarding piping systems.

4-5.1 Product Segregation.

Except as otherwise approved by Service Headquarters, prevent contamination of aviation turbine fuel by providing separate receiving, storage, and distribution systems for each product. Except as otherwise approved by Service Headquarters prevent misfueling (transferring a type of fuel other than that intended) by using different size piping, valves, adaptors, nozzles, etc.

4-5.2 Pigging.

Hydrant loop piping and long runs of truck fillstand piping (runs over one-half mile in length) must be smart piggable including 1.5 diameter (D) elbows and barred tees unless otherwise directed by Service Headquarters in accordance with Chapter 9.

4-6 DESCRIPTION OF SYSTEMS COMPONENTS.

The appropriate guide specifications and/or standard design will provide specific information for selection of system components. Make provisions to drain system components for maintenance. Provide hard piped drains when a system component holds more than 5 gallons (19 L) of fuel or when a pipe which drains to the product recovery tank is within 12 feet (3.7 m) of the system component. Unless otherwise indicated below, refer to Chapter 15 for description of system components. The following system components are typically used in aircraft fueling facilities:

a. Bulk Air Eliminators

b. Meters – Positive Displacement and Turbine

c. Pressure Gauges

d. Strainers

e. Surge Suppressors

f. Filtration – Filter-Separators

g. Pumps – Centrifugal, Vertical Turbine, Rotary, and Jockey

h. Manual Valves – Isolation Valves

i. Manual Valves – Isolation Valve Locations

Provide isolation valves in product piping systems to control flow and to permit isolation of system components for maintenance or repair. Provide additional valves at required locations necessary to conduct a valid hydrostatic test. Require manually operated valves, except where motor operators are specifically authorized by applicable standard drawings or technical specifications. Use double block and bleed type isolation valves for separation of product services, on tank shell connections (ASTs over 12,000 gallons (45,800 L) only), when piping goes aboveground or underground, between pier and tank storage, and other locations critical to periodic pressure-testing of piping. Quick opening/frequent opening type isolation valves may be used for less critical applications where double block and bleed shutoff is not required. As a minimum requirement, provide isolation valves at the following locations:

1. Provide double block and bleed valves where piping goes below/aboveground and requires periodic pressure testing.
2. At all subsurface and aboveground piping connections to storage tanks.
3. On each branch line at the point of connection to the main product pipeline or header.
4. On the product pipeline or header just before the line leaves a pumping station.
5. On the suction side and discharge side of each pumping unit, except the suction side of vertical centrifugal pumps installed in underground tanks.
6. At all aircraft fuel dispensing points.
7. On the inlet and outlet connection of each line strainer, filter-separator, meter, diaphragm control valve, and other system components that requires periodic servicing. One inlet valve and one outlet valve may be used to isolate more than one piece of adjacent system components which are connected in series.
8. On the aboveground piping at each tank car or tank truck off-loading connection. This requirement does not apply to gravity off-loading lines unless isolation valves are specifically called for on applicable drawings.
9. On the aboveground piping at each refueler loading connection.
10. At critical points where pipes cross runways, roads, and taxiways.

j. Other Valves – Check Valves, V-Port Ball Valves, and Thermal Relief Valves

k. Diaphragm Control Valves

l. System Components for Pigging

Equip all piggable pipelines with pig launchers and receivers, kicker lines into launcher, and receipt by-pass piping from receiver. Where directed by Service Headquarters, design pipelines for bi-directional pigging. Design pigging barrels so that they can accommodate internal nondestructive inspection trains. Provide sufficient curvature of bends in the pipeline to permit free passage for such equipment. Back to back 1.5 diameter (D) elbows must not be provided. If back to back direction changes are required, use 3 D sweeps. Provide tees with internal guide bars, at branch connections where indicated. See Chapter 9.

m. Fuel Hoses – Loading and Off-Loading Fuel Hoses

4-7 CONTROLS.

4-7.1 Control System Philosophy.

a. Fuel systems that include pumps to receive, transfer, and issue fuel must be provided with an Automatic Pump Control system with a programmable logic controller (PLC) driven Pump Control Panel (PCP) to control the system. All systems must be designed to perform all of their functions in the event the PCP is down. The PCP must:

b. Control hydrant systems as per the DoD Standard Designs AW 078-24-28 and AW 078-24-29.

c. Control truck fillstand systems that are designed with a pumphouse that operates in a fashion similar to hydrant systems as per the hydrant system DoD Standard Design AW 078-24-28.

d. Control cut and cover tank pumphouses per the DoD Standard Design AW 078-24-33.

e. Start and stop issue and transfer pumps.

f. Provide permissive interface to off-loading system receipt pump(s). Receipt pump must not start or continue to operate when receipt tank high-high level is reached or emergency system activation occurs. Local control will start or stop receipt pump.

g. Provide start and stop or permissive interface to drop tank off-loading system receipt pump(s). Receipt pump must not start or continue to operate when receipt tank high-high level is reached or emergency system activation occurs. PCP control via tank level sensors or local start/stop control of the receipt pump(s) is acceptable.

4-7.2 Exceptions.

The exceptions for systems covered in Chapter 4 where a PCP is not required are:

a. Pumps serving miscellaneous use tanks (see Chapter 8 for definition).

b. Isolated miscellaneous pumps that are not part of a larger system. These 5 horsepower or less size pumps act as sump pumps, pier stripping pumps, truck unloading pumps such as those required for off-loading small vacuum trucks, waste oil trucks, etc.

4-7.3 Design Requirements.

Automatic controls at any facility may include temperature, pressure, fuel level and pump controls, automatic flow controls, alarm and limit switches, motor operated isolation valves, solenoid pilot actuated diaphragm control valves, and remote system condition indicators. Other forms of automatic controls are remote meter indication, electronic access control, data logging, and application of computer techniques. Base the selection of advanced automation and telemetry systems on a study of the particular application with consideration of possible economic justification, operational, and security requirements.

4-7.4 Flow Controls.

Where it is possible to achieve flow rates which exceed system component ratings, provide an adjustable flow control valve on the outlet connection of each meter or filter-separator. Use a diaphragm control valve controlled by the pressure differential across an orifice plate in the valve or a venturi in the main line. Where necessary, provide remote-operated valves on storage tank inlet and outlet lines, suction and discharge of transfer pumps, and transfer lines at fuel piers and other locations.

4-7.5 Pump Controls.

Operation of pump suction and discharge valves may be a part of the automatic sequence for the starting of a centrifugal pump and for shutting it down, remotely, locally, or by a protective shutdown device. Remote-operated valves on the discharge side of the pump can be either motor-operated or the solenoid pilot-type, hydraulically operated diaphragm control valves. Remote control valves on the suction side of the pump can be motor-operated valves only. Equip these valves with green and red (open and closed) indicating lights at their pushbutton control locations.

4-7.5.1 All Pumps.

Provide the following controls:

a. A keyed hand/auto button at each pump and a keyed hand-off-auto switch at the motor starter for each remotely operated pump. Both devices will use the same key.

b. Indicator lights at the control station to give positive indications both when a pump is operating and when it is not energized. Use the "push-to-test" type.

c. A signal light or alarm to indicate pump failure when a pump is controlled automatically.

d. Reduced voltage starting if required by electric utility supplier or for all pump motors greater than 50 horsepower (37 kW) and all vertical pumps.

e. Emergency fuel shut-off (EFSO) pushbutton stations, between 100 and 200 feet (30 m and 60 m) from the pump in the expected ingress and egress direction, with maintained contacts. Provide additional EFSO pushbutton stations at the point of fuel delivery or receipt (fillstands, piers, tanks, etc.) using the same spacing and locations requirements.

f. Equip pantographs with 55 psi hose end pressure regulators located just before the refueling nozzle as described previously, unless directed otherwise by the Service Headquarters.

4-7.5.2 Multi-Function Pumps.

Multi-function pumps are typically used at small facilities and are designed and arranged to be able to perform different functions such as fuel loading, off-loading, or transfer depending on how valves are aligned. Provide each function with the control system requirements for each function described elsewhere in this chapter. For each multi-task pump provide a manual selector switch to choose which set of control and set points the pump is to "look at" when performing a particular function.

4-7.5.3 Transfer Pumps.

Parallel transfer pumps supplying an issuing facility with varying demand flow rates must be sequenced automatically by flow-sensing sequence equipment. Lead pumps can be started by a pushbutton at an issuing facility, or automatically by a pressure switch actuated by a decrease in system pressure as might be caused by opening a valve at the issuing facility. This method requires the system to be pressurized at all times and is normally incorporated in the Type III hydrant system design. Incorporate the following control features:

a. Automatically controlled pumps with emergency stop buttons with lock-key reset at issuing stations and at the central supervisory control station.

b. Automatic shut-off of transfer pumps on loss of suction or no flow for more than 3 minutes. Upon automatic shut-off, a corresponding alarm at the central supervisory control station is activated.

4-7.5.4 Pipeline Pumps.

For pumps over 150 horsepower (112 kW), provide protective shutdown devices with alarm at central supervisory control station in the event of the following:

a. High pump case temperature due to blocked discharge.

b. Excessive pump vibration.

c. Mechanical seal or packing gland failure.

d. High discharge pressure or loss of discharge pressure.

e. Excessive motor vibration.

f. High motor winding temperature.

g. Electrical interlocks which will prevent starting a pump if certain key valve settings are not correct and which will cause a pump shutdown if a key valve setting is changed.

h. Loss of pump suction pressure.

i. High-bearing temperature and/or loss of cooling water flow.

\1\ /1/

4-8 FUEL ADDITIVES.

Provide storage facilities which store aviation turbine fuels with the system components to inject fuel additives if directed by Service Headquarters. This will require proportional injectors with manual bypass, storage of additives, and recirculation of tanks through piping with injectors. If the additives have a corrosive characteristic, construct the system, including storage tanks, tank appurtenances, pumps if required, piping and associated fittings, valves, and injector assemblies of stainless steel components. Consult Service Headquarters for guidance as to which additives must be included.

4-9 DEFUELING AND RETURN-TO-BULK (RTB) SYSTEMS.

4-9.1 General Criteria.

Acceptable locations for defueling and RTB Systems include the return line at a truck fillstand, the return line at a hydrant hose truck check-out station, the return line at a pantograph flush station, the product recovery tank, or at a truck off-load station.

4-9.2 JP-5 Systems.

4-9.2.1 Hydrant Systems.

Because the degradation of flash point below the minimum JP-5 requirement can occur when other than JP-5 is defueled from aircraft directly into operating tanks, ensure that JP-5 direct fueling systems are not capable of defueling an aircraft back into hydrant systems and operating storage. Defuel aircraft into mobile tanker vehicles or into fixed dedicated defuel tanks.

4-9.2.2 Other.

Do not provide a capability to defuel JP-5 refueler trucks back into storage unless directed by Service Headquarters.

JP-5 systems do not use fuel bowsers (mobile defuel tanks).

4-9.3 JP-8 Systems.

4-9.3.1 Hydrant Systems – Hydrant Loop.

Provide JP-8 hydrant systems with capability to defuel aircraft back into the hydrant systems and operating storage through the hydrant pit diaphragm control valves.

4-9.3.2 Hydrant Systems – Other.

To allow defueling of refueler trucks provide a Return-To-Bulk (RTB) station on the return line of a hydrant hose truck check-out station or a pantograph check-out station, or a pantograph flushing station. Provide one adapter per group.

4-9.3.3 Tank Truck and Tank Car Off-Loading.

To allow defueling of refueler trucks, provide a Return-To-Bulk (RTB) station by providing a MIL-STD MS 24484 aircraft refueling adapter at a tank truck or tank car off-loading station. Provide one adapter per group of tank truck or tank car off-load stations. If defueling into a product recovery tank, do not bypass the level control valve.

4-9.3.4 Refueler Truck Fillstands.

To allow defueling of refueler trucks, provide a Return-To-Bulk (RTB) station by providing a MIL-STD MS 24484 aircraft refueling adapter at a point upstream of receipt filtration when the fillstand has a return line. Provide one adapter per group of refueler truck fillstands. If defueling into a product recovery tank, do not bypass the level control valve.

4-9.3.5 Fuel Bowsers (Mobile Defuel Tanks).

Provide a capability to empty JP-8 fuel bowsers mobile defuel tanks by providing a gravity drain connection on underground product recovery tanks, or by providing a pump at aboveground product recovery tanks. Do not bypass the product recovery tank level control valve.

4-10 PRODUCT RECOVERY SYSTEMS.

Provide a system with pumps, piping, valves, and tanks to collect and store usable aviation turbine fuel which would otherwise become waste from operational or maintenance activities. See Chapter 8 of this UFC.

4-10.1 Tank Trucks and Fuel Bowsers.

Provide a capability to receive fuel from JP-8 tank trucks and JP-8 fuel bowsers into the product recovery tank, either at the product recovery tank location, the truck fillstands, or through a connection at the fuel receipt facility.

4-10.2 Return to Bulk.

Provide a capability to return aviation turbine fuel from JP-5 and JP-8 product recovery tank back into operating storage by pumping the fuel into the receipt piping upstream of receipt filtration.

CHAPTER 5 MARINE AND DISPENSING FACILITIES

5-1 FUNCTION.

Design marine fuel receiving and dispensing facilities for the purpose of receiving fuel and/or loading fuel aboard ships, barges and boats for consumption or as cargo. In many cases, the marine receiving and dispensing facilities will be combined. Special requirements for aviation turbine Fuels are in Chapter 4 of this UFC.

5-2 FUEL PIERS AND WHARVES.

Ensure that the structural design of fuel piers and wharves is in accordance with UFC 4-152-01. When required and approved by the appropriate Service Headquarters, design fuel piers for dispensing and receiving fuel. Ensure that the size of the facility is compatible with the fuel requirements of the activity and the number of simultaneous loadings and off-loadings to be accommodated. For dispensing of fuel, consider the number, type, and size of vessels to be fueled or loaded to provide the required number and locations of fuel outlets. In most cases, use dedicated fuel piers and wharves for fuel receipt. Include in the design an energy absorbing fender system. Refer to NAVFAC Definitive Drawings **\2** 10009724 through 10009734 **/2/**.

5-3 BERTHING PIERS.

In some cases, permanent fuel piping and system components may be installed on berthing piers which were not primarily designed for handling fuel. Design such piers in accordance with UFC 4-152-01. These facilities are normally used only for dispensing fuel to surface combatants for consumption. Operational requirements usually dictate a clear berthing pier surface area. This imposes restrictions on the use of loading arms and above deck piping. For these areas, trench-contained piping may be considered. Prior to designing facilities on berthing piers for receiving and/or dispensing of bulk fuel for transport, review plans with appropriate port operations agency.

5-4 OFFSHORE MOORINGS.

When operations of an activity do not warrant construction of fuel piers, provide offshore moorings for vessels to discharge or receive fuel through underwater pipelines connecting to the shore facility. Clearly mark the moorings so that the vessel, when moored, will be in the proper position to pick up and connect to the underwater connection. Coordinate offshore mooring systems with Naval Facilities Engineering and Expeditionary Warfare Center, Oceans Technical Department (NAVFAC EXWC, OC).

5-5 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, of this UFC contains important information on fueling facilities. Do not start the design of any fueling system without first becoming completely familiar with Chapter 2 of this UFC. In particular, refer to Chapter 2 for guidance on spill prevention, air quality control, and other environmental, safety and fire protection issues.

5-6 GENERAL LAYOUT.

Provide pier loading and off-loading connections, with blind flange and with ball valve for throttling and isolation, at the pier edge for each product to be transported. The intent is for a loading arm manifold with a separate manual isolation plug valve for each product connection. This will allow simultaneous loading and off-loading of different products, each through a dedicated arm. Provide a double block and bleed plug valve at the point which the line is being stripped. Use the following criteria:

a. Provide each branch line to the pier edge with a manual isolation valve located at the main line. Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

b. Do not provide a gauge outboard of the hose connection shutoff valve because hose movement will indicate the presence or absence of pressure in the hose.

c. If required, provide one or more loading arms at each station.

d. Provide a liquid-filled pressure gauge for each loading arm, located to be easily read from the operator position. This gauge is provided because the drybreak check valve at the end of the loading arm and the rigid piping will not intuitively indicate the presence or absence of pressure at the loading arm.

e. Provide for venting and draining of the branch lines and loading arm manifolds. Provide for manual venting of the branch lines, connect the vents to the oil waste line, similar to a sanitary vent system to avoid spillage. When pier drain lines cannot be sloped back to the pierhead stripping pumps, a design including separate oil waste drain lines, holding tank and dedicated stripping pump is a viable alternative.

f. Provide segregated handling of multiple products through the loading arms, while allowing easy selection of the products to be transported. Double block and bleed valves can be used for this application.

g. Provide a separate pipe and connection for ballast water or offspec fuel if the size of the facility and level of activity warrants it.

h. Provide each hose handling and loading arm area with fixed spill containment as defined in 33 CFR Part 154.

i. Provide hydraulic shock surge suppressors (if required).

5-7 PIPING SYSTEMS.

Refer to Chapter 9 of this UFC for information regarding piping systems.

5-7.1 Piping Arrangement.

In addition to complying with Chapter 9, use the following criteria:

a. Where simultaneous deliveries of the same fuel may be made by more than one vessel, size fuel headers and related system components for the total flow rates of all vessels discharging into the headers. Ensure that flow rates are in accordance with Chapter 2 of this UFC.

b. Place pier piping above the pier deck within a containment area for fueling piers and within a trench on berthing piers. Slope piping toward shore to permit stripping. Use gratings as required to allow access across the piping.

c. Provide flexibility in the piping between the pier and the shore to allow for small movement of the pier relative to the shore. Use a suitable pipe bend or offset configuration, preferably in a horizontal plane, that will allow three-dimensional movement. If vertical bends are used, install vents and drains.

d. Provide flexibility in the piping along the pier to allow for pipe growth due to thermal expansion. Horizontal expansion loops are preferred. In cases where space is tight provide vertical expansion loops or bellows expansion joints where necessary. Where practical provide vertical expansion loops with vents and drains.

e. Include in the pier facilities, pipe manifolds for each fuel type arranged parallel to the face of the pier.

f. Pipe hangers are not allowed.

5-8 DESCRIPTION OF SYSTEMS COMPONENTS.

Unless otherwise indicated below, refer to Chapter 15 for description of system components. The following system components are typically used in marine receiving and dispensing facilities:

a. Loading/Off-Loading Arms

Provide articulated marine loading arms for receiving and shipping fuel cargoes so that the connected vessel can move 15 feet (4.6 m) forward, 15 feet (4.6 m) aft, and 10 feet (3 m) off the face of the pier and vertically as caused by loading or off-loading of the vessel and tidal changes, without damage to the arm. Provide a hydraulic power assist system for operating loading arms larger than 8-inch (200 mm) nominal size. Equip the end of the loader to be connected to the ship's manifold with an insulating section, a standard ANSI forged steel flange, and a steel quick coupling device, manually or hydraulically operated. Refer to NAVFAC Drawings. 2\10009724 through 10009734/2/.. Consider breakaway couplings for locations with strong current.

b. Fuel Hoses – Submarine Fuel Hoses

c. Meters – Positive Displacement and Turbine

d. Strainers

e. Surge Suppressors

f. Filtration – Filter-Separators, Micronic Filters, and Haypack Coalescers

g. Manual Valves – Isolation Valves

h. Manual Valves – Isolation Valve Locations

1. Provide an isolation valve on each line at the shore end. For piping used only for receiving fuel, also provide a check valve at the shore end. Use double block and bleed type, which may be motor-operated with remote control. To minimize surge potential, use a slow-closing speed, if possible.

2. Provide double block and bleed isolation valves on the aboveground piping at each barge or tanker off-loading and loading connection.

3. Provide double block and bleed isolation valves near the shoreline of a submerged pipeline to offshore moorings.

4. Provide double block and bleed isolation valves on the inlet and outlet connection of each line strainer, filter-separator, meter, diaphragm control valve, and other system components that requires periodic servicing. One inlet valve and one outlet valve may be used to isolate more than one piece of adjacent system components which are connected in series.

i. Other Valves – Check Valves and Thermal Relief Valves

j. Pressure Gauges

k. Pumps – Stripper Pumps

l. Excess Flow Sensors

In piping used for both loading and off-loading, provide a sensor that will alarm both the control room and at the pier to detect excess flow that might occur in the event of a line break.

m. Solid Cyclonic Separators

In facilities which receive product by tankers or barge, consider the use of solid separators in the receiving lines as part of pre-filtration to remove gross impurities from the incoming product. In systems equipped with filter-separators in the receiving lines, locate strainers or cyclonic separators upstream of the filter-separator. Ensure that there is no slug valve feature on the filter-separator. Consider the use of automatic water drains. Do not allow reverse flow thru cyclonic separators.

5-8.1 Grounding Systems.

Provide grounding systems for barges in accordance with **\1** paragraph 2-11.3. **/1/**

5-8.2 Special Considerations for Aviation Turbine Fuels.

For inbound filtration of aviation turbine fuels, refer to Chapter 4 of this UFC.

5-9 CONTROLS.

5-9.1 Control System Philosophy.

Fuel systems that includes pumps to receive, transfer, and issue fuel must be provided with an Automatic Pump Control system with a programmable logic controller (PLC) driven Pump Control Panel (PCP) to control the system. All systems must be designed to perform all of their functions manually in the event the PCP is down.

5-9.2 Exceptions.

The exceptions for systems covered in Chapter 5 where a PCP is not required are:

a. Pumps serving miscellaneous use tanks (see Chapter 8 for definition).

b. Isolated miscellaneous pumps that are not part of a larger system. These 5 horsepower or less size pumps act as sump pumps, pier stripping pumps, etc.

5-10 PRODUCT RECOVERY SYSTEMS.

Provide a product recovery system to collect and store usable aviation turbine fuel that would otherwise become waste from operational or maintenance activities. Consider a product recovery system for other products. See Chapter 8 of this UFC for product recovery systems.

5-11 WEATHER SHEDS.

Provide adequate shelter for personnel, as well as for spill containment booms, absorbent material, and other weather-sensitive system components.

5-12 CANOPIES.

\1 Provide a canopy for protection from the elements of fixed facility assets and system components in accordance with paragraph 2-2**. /1/**

5-13 SPECIAL CALCULATIONS.

Calculate pipeline filling/venting times and draining/stripping times. The larger and the longer the pipeline, the greater the volume of fuel required to fill the line and, therefore, the greater the volume of air required to be vented. Undersized vent lines will delay filling the lines and delay changeover of products in multiproduct lines. Size the vent lines to allow filling of the line at not more than four times the design transit time of the line. Connect vent line to the drain line to avoid spills to the environment. Check vent line air velocity, which must not exceed the allowable air velocity to avoid electrostatic buildup, in accordance with API RP 2003. Vent rate must be not less than the lowest allowable pumping rate from ship or shore. Vent rate must be less than the design transit velocity to minimize hydraulic shock.

5-14 EMERGENCY SHOWERS AND EYEWASH STATIONS.

Provide manual shutoff valves on the potable water branch to the emergency shower and eyewash station. Provide a means to seal shutoff valve in the open position. This will ensure operation in an emergency, yet allow for servicing a single shower without shutting off potable water to the whole pier. Design for freeze protection in climates subject to freezing. **\1\ /1/**

5-15 TRAFFIC BOLLARDS.

Provide traffic bollards to protect fueling piping and system components on piers and wharves. Utilize concrete-filled steel pipe of minimum 4-inch (100 mm) diameter and 4-foot (1.2 m) height, embedded in concrete or welded to a steel plate mounted on the structure.

5-16 SPECIAL DRAINAGE FOR FUELING PIERS.

a. Provide an intercept system to collect oil spills. Place pipes on piers in a curb containment area with a drain system independent of the deck drainage. Provide containment also for loading arms and risers. Provide locking valves in normally closed positions on all containment areas along with sump pumps or other means of removing the spilled fuel to a collection point or tank.

b. In cases where the stormwater collected in the intercept system is contaminated, the water/fuel mixture should be treated as an oil spill as described previously.

5-17 BALLAST RECEIVING AND SLUDGE REMOVAL.

5-17.1 Ballast Receiving and Treatment Facilities.

5-17.1.1 Design Requirements.

It is the policy of the United States that there should be no discharge of oil or hazardous substances into or upon the navigable waters of the United States, adjoining shorelines, or into or upon the waters of the contiguous zone. For OCONUS, follow the most stringent of the United States policy or local national regulations. Petroleum fuel facilities, which transfer fuel by barge or tanker or which fuel large ships, require ballast water collection and treatment facilities to receive and treat oily ballast from cargo or fuel tanks. Also:

a. Blend the fuel oil which has been reclaimed from the ballast water during the collection and treatment process with boiler fuel oil for use in shoreside boilers. Perform a quality assurance check on the reclaimed fuel oil to ensure that it meets the minimum requirements for shoreside boiler fuel. Dispose of sludge accumulated during the collection and treatment of ballast water in accordance with applicable hazardous waste management disposal procedures.

b. Select and design the appropriate treatment system based on an evaluation of the types of oil/water mixtures that may be encountered at the particular facility. If possible, base the evaluation on samples of typical ballast water receipts and tank washings including the following:

   1. Whether they are simple mixtures, simple gravity suspensions, or chemically stable emulsions.

   2. The specific gravity and viscosity of the oil in the mixture.

   3. Whether other substances, such as chemicals or bacteria, in the mixtures must be removed.

   4. The general condition of the ship's tanks expected to be discharged (e.g., new, clean, coated, well maintained, or dirty and normally full of sludge, scale, and rust).

   5. Whether ballast water is clean sea water or polluted harbor water.

   6. Whether the treatment system proposed ("ship's waste off-load barge" or fixed shore-based facilities) meets the standards of effluent water quality established by local environmental regulations.

c. If it is determined that both simple mixtures and emulsions are present, consider the possibility of using two segregated separate systems, one for gravity separation and the other for breaking emulsions. Avoid mixing the two types of suspensions when possible. For bilge water and other contaminated oily wastes which require additional treatment, refer to UFC 4-832-01N, Industrial and Oily Wastewater Control or for Army and Air Force projects **\2** UFC 3-240-01. ***/2/***

d. For typical schematic arrangement of ballast water treatment and disposal systems, refer to UFGS 46 25 14.

5-17.1.2 Receiving and Settling Tanks.

The minimal ballast water receiving facility usually requires two storage tanks, usually of equal capacity, to be used alternately as receiving and settling tanks. If these tanks are sized to allow 4 to 5 days undisturbed settlement, separation of simple suspensions of light oils in water can be achieved. Use welded steel vertical aboveground storage tanks designed and constructed in accordance with Chapter 8 of this UFC. In addition to complying with Chapter 8 of this UFC for construction appurtenances, provide the following fittings and appurtenances:

a. An automatic float gauge suitable for use with transmitting device for remote readout.

b. One cable-operated swing-line assembly on the oil outlet pipe.

c. One shell fill nozzle.

d. Valved sample connections in the shell, having nonfreezing-type valves in cold climates, every 2 feet (0.6 m) vertically, easily accessible from the ladder or stairway.

e. When chemical feed is provided, a chemical feed inlet valve, to be nonfreezing type in cold climates.

f. When air blowing is provided, a perforated pipe air sparger for mixing. Make the perforations in the sides of the pipe to avoid plugging by settling solids. Use nonfreezing-type air inlet valve(s) in cold climates.

g. Sight glass or look box on oil outlet line.

h. Sight glass or look box on water outlet line.

i. Oil sump tank with high-level alarm.

j. Water and oil pumps as required to move fluids from receiving tanks or from oil sump tanks. For transfer of oily water, use low-speed-type pumps to minimize emulsification.

k. If heaters are required to reduce oil viscosity and promote separation, use either tank wall heaters or internal pipes. Keep internal pipes at least 2 feet (0.6 m) above the tank floor.

l. Insulation for tanks that will be regularly heated.

m. Provide automatic temperature controls and thermometers for all heated tanks.

5-17.1.3 Oil/Water Separators.

Separate water/fuel mixtures from storage or settling tanks with an API oil/water separator. Recycle the fuel portion and pass the water portion to another treatment process. Do not discharge water drawn from tanks to surface water without additional treatment and permits. Chapter 2 of this UFC contains design information for an API oil/water separator.

5-18 SLUDGE REMOVAL SYSTEMS.

5-18.1 Design Requirements.

Install sludge removal systems where the accumulation of sludge in substantial quantities is likely to occur on a regular basis. Sources of such sludge are a ballast water treatment system, a contaminated fuel recovery system, or frequent cleaning of shore or ships' tanks. If routine cleaning of clean product storage tanks occurs on an irregular basis, sludge removal systems are not required.

5-18.2 Sludge Disposal.

a. Where possible, provide pumps, tanks, and piping to return sludge containing recoverable oil to the contaminated oil recovery system. If this is not possible, consider transferring the sludge to a refinery or waste oil treatment facility. For additional details, refer to **\2** UFC 3-240-01 **/2/**

b. Provide a tank or tanks with transfer pump(s) for pumpable sludges that are unreclaimable. Include piping for receiving sludge and for mixing other low viscosity waste oils for thinning as required. Ensure that tanks are dike-enclosed and have cone bottoms.

c. Provide tank heating where climate conditions prove necessary.

d. Coordinate sludge disposal method and design with facility environmental office.

e. Enclose the sludge disposal facility with a security fence to prevent unauthorized entry. Do not use this facility for disposal of sand, gravel, rust scale, or other solid nonpumpable matter found on tank bottoms

5-18.3 Piping Materials.

Refer to Chapter 9 of this UFC for information regarding piping materials.

This Page Intentionally Left Blank

CHAPTER 6 INTERTERMINAL AND INSTALLATION PIPELINES

6-1 INTRODUCTION.

This chapter provides guidance for the design of pipelines. Military pipelines are typically either interterminal pipelines which are cross country and connect government installations, or installation pipelines which connect POL facilities within an installation. The primary differences are that interterminal pipelines cross public and private properties, streets, highways, railroads, and utility rights-of-way, whereas installation pipelines do not. Interterminal pipelines may be dedicated lines connecting two or more facilities or privately owned common carrier lines serving several commercial or military shippers. In some cases, the shipping facility may consist of a relatively short spur which delivers the fuel to the suction side of a pumping station which is part of the main line of a larger pipeline system. Interterminal pipeline receipt and transfer facilities are normally part of a bulk fuel storage facility, which is discussed in Chapter 3 of this UFC. Installation pipelines are usually for aviation turbine fuels. Special requirements for aviation turbine Fuels are in Chapter 4 of this UFC.

6-2 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, contains important information on fueling facilities. Do not start the design of any fueling system without first becoming completely familiar with Chapter 2 of this UFC.

6-3 DESIGN REQUIREMENTS.

6-3.1 Fuel Segregation.

Clean products, such as diesel fuel and distillate-type burner fuels, may be shipped in the same system without segregation. Batches are usually pumped product to product, but they may be separated by fresh or suitably treated water. Separate piping systems are required for residual fuels. For DoD projects, provide a dedicated pipeline for aviation turbine fuels.

6-3.2 Applicable Regulations.

Interterminal and installation pipelines must be designed as described below. Where federal, state, or local regulations are more restrictive than the requirements indicated, the more restrictive requirements must apply.

6-3.2.1 Installation Pipelines.

All installation pipelines must be designed in accordance with ASME B31.3.

6-3.2.2 Interterminal Pipelines.

The U.S. Department of Transportation regulates the design, construction and operation of commercially-owned interterminal pipelines for liquid petroleum. Intrastate interterminal pipelines must be designed in accordance with ASME B31.4. Interstate interterminal pipelines, must be designed in accordance with the requirements of 49 CFR Part 195.

6-3.3 Sampling.

\3 Provide a means for taking samples of the products shipped. ***/3/***

6-3.4 Pigging.

Pipelines must be smart piggable including 1.5 diameter (D) elbows and barred tees (where indicated) unless otherwise directed by Service Headquarters in accordance with Chapter 9. Provide permanent launchers and receivers suitable for smart pigging.

6-3.5 Surge Suppressions.

Provide surge suppressors for hydraulic shock when required by results of a computer based dynamic transient surge analysis.

6-3.6 Filtration.

When directed by Service Headquarters, provide means of filtration for all products. The selection of filtration depends on anticipated impurities, the source of fuel, and the shipping methods. Consider the use of filter-separators, micronic filters and Haypack coalescers as possible filtration devices. For filtration of aviation turbine fuels, refer to Chapter 4 of this UFC.

6-4 PIPING SYSTEMS.

Refer to Chapter 9 of this UFC for information regarding piping systems.

6-5 DESCRIPTION OF SYSTEMS COMPONENTS.

The appropriate guide specification and/or standard design provides specific information for selection of system components. Make provisions to drain and vent piping for maintenance. Unless otherwise indicated below, refer to Chapter 15 for description of system components. The following system components are typically used in interterminal and installation pipelines:

a. Meters – Positive Displacement and Turbine

b. Pressure Gauges

c. Manual Valves – Isolation Valves

d. Manual Valves – Isolation Valve Locations

   Provide valves in product piping systems to control flow and to permit isolation of system components for maintenance or repair. Provide additional valves at required locations necessary to conduct a valid hydrostatic test. Provide manually operated valves, except where motor operators are specifically authorized by applicable standard drawings or technical specifications. Use double block and bleed type isolation valves for separation of product services, on tank shell connections (ASTs over 12,000 gallons (45,800 L) only), when piping goes aboveground or underground, between pier and tank storage, and other locations critical to periodic pressure-testing of piping. Quick opening/frequent opening type isolation valves may be used for less critical applications where double block and bleed shutoff is not required. Before adding isolation valves, evaluate piping system and make modifications to prevent pressure buildup caused by thermal expansion. Review paragraph on "Thermal Relief Valves" in Chapter 9 of this UFC. As a minimum requirement, provide isolation valves at the following locations:

1. Provide a double block and bleed isolation valve on each branch line at the point of connection to the main product pipeline or header.

2. Provide a double block and bleed isolation valve on the product pipeline or header just before the line leaves a pumping station.

3. Provide a double block and bleed isolation valve at the inlet and outlet connection of each line strainer, filter-separator, meter, diaphragm control valve, thermal relief valve, and other system components that requires periodic servicing. One inlet and one outlet double block and bleed isolation valve may be used to isolate more than one piece of adjacent system components which are connected in series.

4. Provide a double block and bleed isolation valve on the upstream and downstream side of each line blind at connections to cross country pipelines.

5. Provide a double block and bleed isolation valve on each main distribution pipeline immediately downstream of the branch connection to each existing or future operating storage facility served by the pipeline.

6. Provide full-bore double block and bleed isolation valve at intermediate points of approximately 10 miles (16 km) in cross country distribution pipelines to facilitate isolation of a section of the line for maintenance and repair.

7. Provide a double block and bleed isolation valve on each side of water crossing exceeding 100 feet (30 m) in width, and near the shoreline of a submerged sea pipeline.

8. Provide a double block and bleed isolation valve at critical points where pipes cross under runways, taxiways, and roadways.

9. For low-point drains and high-point vents.

e. Other Valves – Check Valves and Thermal Relief Valves

f. Diaphragm Control Valves

g. Strainers

h. Surge Suppressors

i. Filtration – Filter-Separators, Micronic Filters, and Haypack Coalescers

j. System Components for Pigging

Provide all piggable pipelines with pig launchers and receivers, kicker lines into launcher, and receipt by-pass piping from receiver. Where directed by Service Headquarters, design pipelines for bi-directional pigging. Design pigging barrels so that they can accommodate internal nondestructive inspection trains. Provide sufficient curvature of bends in the pipeline to permit free passage for such equipment. Back to back 1.5 diameter (D) elbows must not be provided. If back to back direction changes are required, use 3 D sweeps. Provide tees with internal guide bars, at branch connections where indicated. See Chapter 9.

k. Pumps

Primary pumping facilities are discussed in Chapter 3 of this UFC. If multiple pump stations are required to keep pipeline pressure within safe limits, provide them at appropriate locations. Chapter 3 also provides guidance for those pumping facilities.

l. Sampling Connections

Provide connections for sampling fuels on each section of a fuel transfer piping system. Install sampling and testing connections at receiving points, tank outlets, inlet and outlet sides of filter-separators, fuel dispensing points, truck off-load header, and between isolation valves so that remaining fuel in each portion of a fuel transfer pipeline can be sampled. Where possible, install sampling connections in vertical runs. Provide a 1/4-inch (8 mm) diameter sample point with a probe, ball valve, and quick disconnect with dust cap.

6-6 CONTROLS.

6-6.1 Control System Philosophy.

Fuel systems that includes pumps to receive, transfer, and issue fuel must be provided with an Automatic Pump Control system with a programmable logic controller (PLC) driven Pump Control Panel (PCP) to control the system. All systems must be designed to perform all of their functions manually in the event the PCP is down.

6-6.2 Exceptions.

The exceptions for systems covered in Chapter 6 where a PCP is not required are:

a. Pumps serving miscellaneous use tanks (see Chapter 8 for definition).

b. Isolated miscellaneous pumps that are not part of a larger system. These 5 horsepower or less size pumps act as sump pumps, pier stripping pumps, etc.

6-7 PRODUCT RECOVERY SYSTEMS.

Provide a product recovery system to collect and store usable aviation turbine fuel that would otherwise become waste from operational or maintenance activities. Consider a product recovery system for other products. See Chapter 8 of this UFC for product recovery systems.

\1\ /1/

6-8 SPECIAL CALCULATIONS.

Calculate pipeline filling/venting times and draining/stripping times. The larger and the longer the pipeline, the greater the volume of fuel required to fill the line and, therefore, the greater the volume of air required to be vented. Undersized vent lines will delay filling the lines and delay changeover of products in multiproduct lines. Size vent lines to allow filling of the line at not more than four times the design transit time of the line. Where applicable, connect vent lines to system drain lines to avoid spills to the environment. Check vent line air velocity, which must not exceed the allowable air velocity to avoid electrostatic buildup, in accordance with API RP 2003. Vent rate must be not less than the lowest allowable pumping rate from ship or shore. Vent rate must be less than the design transit velocity to minimize hydraulic shock.

This Page Intentionally Left Blank

CHAPTER 7 GROUND PRODUCTS FUELING FACILITIES

7-1 INTRODUCTION.

This chapter provides guidance for the design of ground products (gasoline, diesel, biodiesel, and E-85)) fueling facilities and covers government vehicle motive fuel filling stations and tactical refueler truck loading facilities. Private vehicle filling stations, such as exchange service stations, are not included. Refer to DoD Standard Design STD 123-335-03 for Military Service Station and Factory Fabricated Tank Engineering Standard.

7-1.1 Types of Facilities.

The following three types of ground products fueling facilities may be required (see Facility Plates 011, 012 and 013):

a. A filling station for dispensing motive fuel gasoline, diesel, biodiesel, and E-85 into government (commercial type) sedans, vans, and small trucks. See Facility Plate 011.

b. A filling station for dispensing motive fuel gasoline, diesel, biodiesel, and E-85 into tactical vehicles. See Facility Plate 011.

c. A truck loading facility for loading gasoline, diesel, biodiesel, and E-85 into tactical refueler vehicles. See Facility Plates 012 and 013.

7-2 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, contains important information on fueling facilities. Do not start design of any fueling system without first becoming completely familiar with Chapter 2 of this UFC.

7-3 DESIGN REQUIREMENTS.

7-3.1 Fuel Segregation.

Provide separate receiving, storage and distribution systems for each grade or type of fuel. Except as otherwise approved by Service Headquarters, prevent misfueling (transferring a type of fuel other than the type intended) by using different size piping, valves, adaptors, nozzles, etc.

In the CONUS, use color coding in accordance with API RP 1637. In non-CONUS facilities, use host nation standard if it is different than API RP 1637. Use API RP 1637 if no other standard is in effect. For Air Force projects to refer to 37-1-1.

7-3.2 Facility Size.

In each filling station, provide one commercial-type dispensing unit which displays volume only for each 100 vehicles assigned to the activity. The total amount of storage capacity in each station should be approximately twice the capacity of all vehicle fuel tanks, by grade or type of fuel, assigned to the activity. Minimum storage capacity for any grade or type of fuel is 5,000 gallons (19,000 L) unless approved by Service Headquarters. For tactical refueler truck loading facilities, see Chapter 3 of this UFC.

7-3.3 Facility Configurations.

In general, for control and safety, separate the three types of filling stations. For a relatively small installation or one on which there is a limited amount of activity expected at one time, it may not be practical to provide totally separate facilities. In those cases, separate the functions as much as possible to minimize mixing traffic of commercial-type vehicles from tactical vehicles and, more importantly, from mixing tactical refuelers which are being loaded with relatively large quantities of fuel from other vehicles which are being fueled for their own engine (motive fuel). Filling stations must be configured to comply with all NFPA 30A siting and storage requirements.

7-3.4 Bulk Operations.

A motive fuel filling station located at a bulk plant must be separated from areas in which bulk plant operations are conducted by a fence or another approved barrier. Dispensing devices at the motive fuel filling station must not be supplied by aboveground tanks located in the bulk plant. Storage tanks at motive fuel filling station must not be connected by piping to aboveground tanks located in the bulk plant. Tactical refueler truck loading may be conducted at a motor fuel dispensing facility. Filling stations must be configured to comply with NFPA 30A.

7-3.5 Shelters.

For staffed facilities, provide a shelter for personnel, records, and tools.

7-3.6 Concrete Fueling Area – Filling Stations.

Create a fueling area constructed of concrete by surrounding fueling islands with a concrete slab graded at a minimum of 1 percent away from the islands.

7-3.7 Canopies.

7-3.7.1 Canopies to Protect Fixed Assets from Extreme Weather Conditions.

\1 Provide a canopy for protection from the elements of fixed facility assets and system components in accordance with paragraph 2-22**. /1/**

7-3.7.2 Canopies to Reduce Stormwater of Filling Stations.

Do not provide a canopy to preclude rain from reaching the concrete fueling area unless it is required by federal, state, or local regulations or if directed by Service Headquarters. Ensure structural design is in accordance with UFC 1-200-01 and UFC 3-301-01.

7-3.8 Regulations.

Design must comply with 40 CFR Part 112, NFPA 30, NFPA 30A, and API RP 1615.

7-3.9 Bottom Loading.

The bottom loading of refuelers is required if the refuelers are equipped for it. However, there are Army refuelers which are not equipped for bottom loading and which will be in inventory for several years. Therefore, provide top loading racks with elevated steel platforms at tactical refueler fillstands, when approved by Service Headquarters.

7-3.10 Truck Offload and Loading Facilities.

Design of service station truck offload and loading facilities must comply with NFPA 30, NFPA 30A and 40 CFR Part 112. Also, do not locate truck offload or tactical refueler loading facilities/vehicles closer than 25 feet (7.6 m) from above ground tanks, buildings, roads, overhead power lines, pad-mounted transformers, and installation property lines with the following exceptions:

a. The minimum separation distance from truck offload facilities/vehicles governed by NFPA 30A may be reduced as allowed by NFPA 30A.

b. The minimum separation distance from overhead power lines may be reduced to 15 feet (4.6 m) for Class II or III liquids.

7-3.11 Tactical Refueler Truck Loading Facilities.

Equip similar to truck loading facilities covered in Chapter 3 of this UFC except provide a grounding reel in lieu of the high-level shutoff/ground detecting system. Verify with the user, the type of nozzle required.

7-3.12 Spill Containment.

All areas subject to fuel spills or drips must be concrete surfaced, including truck offload and fuel dispenser areas.

a. Tactical Refueler Truck Loading Facilities: Provide sized concrete spill containment areas and a concrete remote spill containment system as described for truck loading facilities in Chapter 3 of this UFC.

b. Other Fuel Transfer Areas: General spill containment, as defined by 40 CFR Part 112.7, must be provided for all other fuel transfer areas at a military service station. General secondary containment requires controls to address typical failures and the most likely spill volume to occur and to size a secondary containment system to prevent a release of spilled fuel to the environment before cleanup occurs. Fuel transfer areas must be provided with general spill containment including truck offload and vehicle dispensing areas. General spill containment should also be provided around double wall ASTs to capture leaks from vents, fittings and other devices on the tanks or fuel lines within the immediate area of the tank. A simple system typically consists of a 6-inch high concrete curb around the perimeter of a concrete pad with a 2-inch stainless steel pipe and lockable stainless steel ball valve located at a low point that discharges to grade.

c. Drainage: Storm water runoff from spill containment areas should be collected separately from general runoff and controlled by a lockable containment drain valve. Design the spill containment drainage system in accordance with federal, state, and local regulations.

7-4 STORAGE TANKS.

Chapter 8, Atmospheric Storage Tanks, contains information on aboveground and underground storage tanks. For ground products fueling facilities underground, horizontal tanks are preferred. Follow federal, state, and local regulations when determining use of AST or UST.

7-4.1 Distance from Power Lines.

Minimum separation of underground and aboveground tanks from overhead electric power transmission, pad-mounted transformers, and distribution wires must be 25 feet (7.6 m), with the exception that these minimum separation distances may be permitted to be reduced to 15 feet (4.6 m) for Class II or III liquids.

7-5 PIPING SYSTEMS.

7-5.1 Piping System – Tactical Refueler Facilities.

For systems serving tactical refueler fillstands see the requirements for tank truck loading facilities in Chapter 3 of this UFC.

7-5.2 Aboveground Piping System – Filling Stations.

Follow state or local regulations when they exceed these requirements. When they do not exceed them, provide as described in Chapter 9 of this UFC with the following exceptions:

a. Piping 2-1/2 inches (65 mm) and larger must be butt welded. Use flange connections for joining pipe to system components.

b. Piping smaller than 2-1/2 inches (65 mm) may be butt welded or socket welded. Use flange connections or socket weld connections with unions for joining pipe to system components. Threaded end connections may be used only where butt welded or socket welded connections cannot physically be provided.

c. Branch outlet fittings do not have to be designed to be radiographed.

7-5.3 Underground Piping System – Filling Stations.

Follow state or local regulations when they exceed these requirements. When they do not exceed them, provide as described in Chapter 9 of this UFC with the following exception:

a. Use of double wall flexible piping (≤ 4 inches (100 mm)) in conformance with UL971 is permitted. Use of FRP piping is discouraged because of issues with underground joints and requires Service Headquarters approval.

7-6 CONTROLS.

7-6.1 Control System Philosophy.

Fuel systems that includes pumps to receive, transfer, and issue fuel must be provided with an Automatic Pump Control system with a programmable logic controller (PLC) driven Pump Control Panel (PCP) to control the system. All systems must be designed to perform all of their functions manually in the event the PCP is down.

7-6.2 Exceptions.

a. The exceptions for systems covered in Chapter 7 where a PCP is not required are:

b. Motive fuel filling stations that only dispense motive fuel into vehicles.

c. Motive fuel filling stations that also include attached tactical refueler truck loading station(s) whose flowrate is under 200 gpm for each station.

d. Pumps serving miscellaneous use tanks (see Chapter 8 for definition).

e. Isolated miscellaneous pumps that are not part of a larger system. These 5 horsepower or less size pumps act as sump pumps, pier stripping pumps, etc.

7-6.3 Card and Key Locks.

Provide an electronic card or key system which permits 24-hour unmanned operation of the facility. These types of systems are comprised of a card/key reader which is located near the service pump. The reader is activated by a card or key and accumulates issues and customer data which is downloaded to a central computer on a periodic basis.

7-7 DESCRIPTIONS OF SYSTEM COMPONENTS.

Unless otherwise indicated below, refer to Chapter 15 for description of system components. For systems serving tactical refueler fillstands see the requirements for tank truck loading facilities in Chapter 3 of this UFC. The below requirements apply to filling stations only. The following system components are typically used in ground product fueling facilities:

a. Fuel Dispensers – Filling Stations

Use a commercially available dispenser with a self-contained electric motor and pumping unit or a remote pumping type where the pump and motor are located in the storage tank. If an in-tank type of pump is used, ensure that it is equipped with a reduced start volume as a leak check. Provide a meter for each dispenser. Dispenser flow rates are typically a maximum of 10 gpm (0.6 L/s); follow state and local regulations for actual maximum. Designer must check with state and local regulations for limitations on dispenser flowrates. Dispensing system will include management control system, printers, computers, and microprocessors. Equip fuel dispensers with an inline filtration system with 5-micron or smaller porosity filters for gasoline and ethanol products, and 25-micron or smaller porosity filters for diesel and biodiesel products. Add emergency break-away hose connections at each fuel dispenser in accordance with NFPA 30A. Where liquid is supplied to the dispenser under pressure, provide an emergency shutoff valve, incorporating a fusible link, in the supply line at the base of each dispenser as required by NFPA 30A. Equip dispensing islands with impervious spill containment pans under the dispensers.

b. Manual Valves – Isolation Valves

Materials of Construction – Require valves to have carbon steel bodies and bonnets. Do not allow valves with aluminum, cast iron, or bronze materials. Use only API fire-safe valves complying with API Std 607.

c. Manual Valves – Isolation Valve Types

1. Ball Valves: These are the only approved quick opening/frequent opening isolation valves.

2. Double Block and Bleed Isolation Valves: Do not provide unless directed by Service Headquarters or required to perform hydrostatic test.

3. Lubricated Plug Valves: Lubricated plug valves are not allowed.

4. Gate Valves: Gate valves are not allowed.

5. Butterfly Valves: Butterfly valves are not allowed.

d. Manual Valves – Isolation Valve Operators

Manually operate valves not specified for remote, automatic, or emergency operation. Use geared operators for ball valves larger than 6 inches (150 mm). Provide locking tabs on isolation valves to allow padlock to be used to lock out the valves during maintenance. Provide chain operators on valves which are located 72 inches (1800 mm) or higher above grade.

e. Manual Valves – Isolation Valve Locations

Provide isolation valves in piping systems to control flow and to permit isolation of system components for maintenance or repair, or as necessary to conduct a valid hydrostatic test. As a minimum requirement, provide isolation valves at the following locations:

1. Where piping goes underground or comes aboveground and requires periodic pressure testing.
2. At all subsurface and aboveground piping connections to storage tanks.
3. On the suction side and discharge side of each pumping unit, except the suction side of vertical centrifugal pumps installed in underground tanks.
4. On the inlet and outlet connection of each line strainer, meter, diaphragm control valve, and other system components that requires periodic servicing. One inlet valve and one outlet valve may be used to isolate more than one piece of adjacent system components which are connected in series.

f. Diaphragm Control Valves

These valves are not required in filling stations.

g. Anti-Siphon Valve

Use anti-siphon valves to prevent release of fuel by siphon flow from an aboveground storage tank. These valves are generally installed on the tank drain lines.

h. Solenoid-Controlled Anti-Siphon Ball Valve

Use solenoid controlled anti-siphon ball valves to prevent release of fuel by siphon flow from an aboveground storage tank. These valves are generally installed on the discharge side of the fuel dispenser pumps. These valves are normally closed and open upon an electronic signal when a dispenser pump is turned on.

i. Other Valves – Check Valves

Use check valves to prevent backflow through pumps, branch lines, meters, or other locations where runback or reverse flow must be avoided. Check valves may be of the swing disk, globe, dual plate hinged disk, spring-loaded poppet, ball, or diaphragm-actuated types. Use checks of soft-seated non-slamming type with renewable seats and disks. Ensure check valves conform to API Spec 6D.

j. Other Valves – Thermal Relief Valves

7-8 VAPOR RECOVERY.

Provide vapor recovery in accordance with guide specifications unless there are more stringent federal, state, and local codes or regulations. If gasoline is being handled, refer to 40 CFR Part 63 Subpart CCCCCC. Per 40 CFR Part 63 Subpart CCCCCC, gasoline storage tanks located at gasoline dispensing facilities with a monthly throughput of 100,000 gallons or more are required to be equipped with a vapor balance system. The vapor balance system needs to be tested at the time of installation and every three years thereafter. Only install Stage II vapor recovery piping if required by local or state regulations at time of installation.

CHAPTER 8 ATMOSPHERIC STORAGE TANKS

8-1 INTRODUCTION.

This chapter provides guidance for the design of bulk storage tanks, operating storage tanks, ground vehicle fueling tanks, miscellaneous use tanks, product recovery system tanks, contaminated fuel storage tanks, and jet engine test cell fuel storage tanks. Design guidance on issues related to storage tanks such as protection, location, coatings, product recovery, and spill containment systems are also covered in this chapter. Ballast water storage tanks are covered in Chapter 5 and pressurized tanks for storage of LPG are covered in Chapter 10 of this UFC. This chapter generally applies to new tanks. Refer to Chapter 12 for repair or refurbishment of existing tanks.

8-2 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, contains important information on fueling facilities. Do not start design of any fueling system without first becoming completely familiar with Chapter 2 of this UFC.

8-3 GENERAL CRITERIA.

Design liquid fuel storage tanks to comply with the operational requirements of the particular Command having jurisdiction of the facility. Ensure that the design is appropriate for the mission of the facility. Consider the operational requirements of the users of the fuel.

8-3.1 Materials.

All aboveground storage tanks must be constructed of steel or concrete encased steel.

8-3.2 Protection.

Provide protection to preserve product quality and ensure minimal losses by evaporation, dilution, leakage, substitution, theft, contamination, attack, sabotage, fire, and damage to the environment. Use aboveground steel tanks unless the mission of the facility or other practical considerations dictate that underground tanks be used. Cut and cover (buried vertical) tanks are not normally used in the CONUS. Cut and cover tanks may be required if the dispensing system is located in clear zones or explosive cordon areas. Conduct economic, operational, and mechanical analyses of remotely locating the pump house/system from the hydrant system versus constructing cut and cover tanks. For all fuel storage tanks, design in accordance with NFPA 30, NFPA 30A, and this document.

8-3.3 Design Requirements.

Fuel storage facilities provide an operating and reserve supply of fuel. The types and sizes of storage tanks depend on safety, economics, terrorist activity, locality, and intended service. Provide separate storage for each type and grade of fuel.

8-3.4 Storage Capacity.

The capacity or size of each fuel storage tank is based upon the logistical and mission requirements for the facility and any other facility to be supported from it. For a stated volume of each fuel, fewer tanks of larger size will result in maximum economy. The appropriate Service Headquarters with DLA-Energy approval will determine the number and size of tanks required. Rule of thumb guidance for operating storage and bulk storage capacity is available in Navy UFC 2-000-05N/P-80. Provide a minimum of two tanks for each type of fuel to receive and isolate new receipts until tested and checked for quality and quantity while the facility continues to function with stocks on hand. The exception to this is at military service stations where one tank for each product is usually acceptable. In general, capacities of individual tanks should not exceed 50 percent of the total storage volume required for each type and grade of aviation fuel. Do not provide tanks with capacities greater than 100,000 barrels (16,000,000 L) except when larger tanks are specifically authorized by Service Headquarters.

8-3.5 Tank Spacing.

8-3.5.1 Vertical Tanks.

\3 Provide a minimum distance between the shells of vertical tanks, both aboveground and underground, of not less than one diameter. ***/3/***

8-3.5.2 Horizontal Underground Tanks.

Provide a minimum clearance between shells of adjacent horizontal underground tanks of 3 feet (0.9 m).

8-3.5.3 Horizontal Aboveground Tanks (Single Wall and Double Wall Steel) (Non-Fire Resistant and Non-Protected).

Provide a minimum clearance between **\2** the shells of ***/2/*** aboveground horizontal tanks with capacities 50,000 gallons (189,300 L) or under as follows:

a. Arrange tanks in pairs with a minimum of 5 feet (1.5 m) between **\2** the shells of the ***/2/*** tanks in each pair and 10 feet (3 m) between **\2** the shells of the ***/2/*** adjacent tanks of two pairs in the same row.

b. Space adjacent groups of more than two pairs in a single row with at least 20 feet (6 m) between **\2** the shells of ***/2/*** the nearest tanks of the groups.

c. Provide a minimum end-to-end spacing between **\2** the shells of ***/2/*** tanks in longitudinal rows of 20 feet (6 m).

d. Provide a UL nameplate on tanks stating that the tanks are approved for that material and service.

e. In addition to requirements listed in this paragraph, tanks located in facilities governed by NFPA 30A, such as marine/motor fuel dispensing facilities, must comply with NFPA 30A.

8-3.5.4 Horizontal Aboveground Tanks (Fire Resistant).

Provide minimum clearance and spacing between **\2** the shells of **/2/** fire resistant, secondarily contained aboveground horizontal tanks in compliance with NFPA 30 and NFPA 30A as applicable.

8-3.5.5 Horizontal Aboveground Tanks (Protected).

Provide minimum clearance and spacing between **\2** the shells of **/2/** protected, secondarily contained aboveground horizontal tanks in compliance with NFPA 30 and NFPA 30A as applicable.

8-3.6 Distance from Buildings and Property Lines.

Locate tanks a sufficient distance from buildings and property lines to prevent the ignition of vapors from the tank and to protect buildings and their occupants or contents from damage by a tank fire. Ensure that the maximum internal pressure in a fire exposure will not exceed 2.5 psig (17 kPa). As a minimum, comply with requirements of the following paragraphs.

8-3.6.1 Underground Tanks.

Locate underground tanks with respect to buildings or similar structures so that the soil pressure created by the building foundations will not be transmitted to the tank. Pumping facilities which are often located directly above underground tanks are accepted. Locate **\2** the shell of **/2/** horizontal cylindrical tanks less than or equal to 12 feet (3.7 m) in diameter not less than 10 feet (3 m) from the nearest point of an adjacent building or property line. Locate **\2** the shell of **/2/** vertical underground tanks, **\2** or the vent if the vent is located away from the shell of the tank, **/2/** at least 25 feet (7.6 m) from the nearest point of an adjacent building and 50 feet (15 m) from the nearest property line.

8-3.6.2 Aboveground Tanks.

Locate aboveground tanks with consideration of fire safety. The first consideration is to prevent the ignition of vapors from the tank, and the second consideration is to protect the building and its occupants or contents from damage by a tank fire. As a protective measure, provide all aboveground tanks with some form of emergency relief venting for fire exposure in accordance with NFPA 30. Required minimum distances **\2** between the normal vent, emergency vent, or the overflow vent (for tanks with floating roofs) **/2/** for aboveground tanks from buildings and property lines are as follows:

a. Tanks, all sizes and types, not protected or fire-resistant, containing petroleum fuels with a flash point less than 100 degrees F (38 degrees C), 100 feet (30 m) or one tank diameter, whichever is greater, with the exception that tanks located in facilities governed by NFPA 30A, such as marine/motor fuel dispensing facilities, must comply with NFPA 30A guidelines.

b. Tanks, not protected or fire-resistant, containing petroleum fuels with a flash point of 100 degrees F (38 degrees C) or greater in accordance with the following:

Tank Capacity gallons (L)	Minimum Distance from Nearest Property Line Feet (m)	Minimum Distance from Nearest Building Feet (m)
275 or less (1040 or less)	10 (3.0)	5 (1.5)
276 to 750 (1041 to 2800)	20 (6.0)	10 (3.0)
751 to 12,000 (2801 to 45 400)	30 (10)	15 (4.5)
12,001 to 30,000 (45 401 to 113 500)	40 (12)	20 (6.0)
30,001 to 50,000 (113 501 to 189 000)	60 (18)	60 (18)
50,001 to more (189 001 or more)	100 (30)	100 (30)

c. For aboveground, fire-resistant tanks, use NFPA 30 guidelines. Fire-resistant tanks located in facilities governed by NFPA 30A, such as marine/motor fuel dispensing facilities, must comply with NFPA 30A criteria.

d. For aboveground, protected tanks, use NFPA 30 guidelines. Protected tanks located in facilities governed by NFPA 30A, such as marine/motor fuel dispensing facilities, must comply with NFPA 30A criteria.

8-3.7 Distance from Roadway, Railroads and Power Lines.

For tanks located in facilities governed by NFPA 30A, use NFPA 30A guidelines and Chapter 7 of this UFC. For all other storage tanks, the minimum distances **\2** between the normal vent, emergency vent, or the overflow vent (for tanks with floating roofs) and ***/2/*** adjacent roadways, railways, railroads, and overhead electric power lines are as follows:

8-3.7.1 Underground Tanks.

Spacing and clearances for underground tanks must be:

a. A minimum of 25 feet (7.6 m) from regularly traveled roads and highways, not including tank farm utility and fire access roads.

b. 25 feet (7.6 m) from railroad spur tracks not used for through traffic.

c. No less than 100 feet (30 m) from main railroad tracks carrying through traffic.

d. 50 feet (15 m) from overhead electric power transmission and distribution wires.

8-3.7.2 Aboveground Tanks.

a. The greater of 100 feet (30 m) or one tank diameter from regularly traveled roads and highways, not including tank farm utility and fire access roads. For protected and fire-resistant tanks, roads and highways must match the clearance provisions specified in paragraph 8-3.6.2.

b. 50 feet (15 m) from railroad spur tracks not used for through traffic.

c. 200 feet (60 m) from main railroad tracks carrying through traffic.

d. 50 feet (15 m) from overhead electric power transmission and distribution wires.

8-3.8 Distance from Tank Truck and Tank Car Off-Loading and/or Loading Facilities.

For tanks located in facilities governed by NFPA 30A, such as marine/motor fuel dispensing facilities, use NFPA 30A guidelines and Chapter 7 of this UFC. For all other tanks, use guidelines indicated within this UFC and NFPA 30. For fire resistant or protected horizontal aboveground tanks and underground tanks, provide a minimum separation of 25 feet (7.6 m) from tank truck and tank car off-loading and loading facilities, including tanker trucks. For all other tanks, provide a minimum separation of 50 feet (15 m) from tank truck and tank car off-loading facilities**\2** and tank truck and tank car loading facilities ***/2/***. **\2**

8-3.9 Distance and Location of Tanks from Photovoltaic Arrays

Provide a minimum separation of 100 feet (30 m) between the normal vent, emergency vent, or the overflow vent (for tanks with floating roofs) for above and under ground tanks and the photovoltaic array and components (batteries and inverters). The photovoltaic array must not be accessible to or from the tank farm, or located in the tank farm. The photovoltaic array must not restrict emergency assess to the tank farm. ***/2/***

8-3.10 Interior Coatings.

To extend the life of steel storage tanks, coat new tanks according to the following guidelines:

a. Vertical tanks

1. All aviation, diesel fuel marine (F-76), additive, and lube oil tanks. Except for stainless steel tanks referenced in paragraph 3-10, interiors must be 100 percent coated, including floor, shell, and underside of the roof.

2. Other products. Coat the floor, the underside of the fixed roof, and the bottom 40 inches (1000 mm) of the tank shell. Additional coating of up to 100 percent requires economic justification and Service Headquarters approval. Tanks containing E85 are not to be coated internally unless otherwise approved by Service Headquarters.

b. Horizontal tanks

1. For all products, tank interiors must be 100 percent coated. Tanks containing E85 are not to be coated internally unless otherwise approved by Service Headquarters.

c. For all products, coat the interior of 3 inch and larger carbon steel piping and exterior of all carbon steel piping located inside the tank, and steel appurtenances inside all tanks. Carbon steel piping, and carbon steel appurtenances located inside of tanks containing E85 are not to be coated internally unless otherwise approved by Service Headquarters.

8-3.11 Exterior Coatings.

a. Protect the exterior surface of all aboveground steel tanks by coating in accordance with appropriate guide specifications.

b. Protect the exterior surfaces of all underground horizontal steel tanks with a factory-applied coating specified in the appropriate guide specifications.

c. For protected tanks, with exterior steel containment, consider exterior fiberglass cladding for extremely corrosive atmospheres or seaside locations.

8-3.12 Fill Piping.

Size the pipe so that the velocity does not exceed 12 feet (3.7 m) per second at maximum flow rate. Provide a means for reducing the velocity of flow of the receipt pipeline to 3 feet (0.9 m) per second until the filling inlet nozzle is completely submerged and/or the floating pan has lifted off its legs.

8-3.13 Vapor Emission Control Systems.

Provide a vapor emission control system for tanks that store products having a true vapor pressure of 0.75 psia (5 kPa) or more located in air pollution control areas in which the discharge of petroleum vapors is controlled or prohibited. Ensure that the system has sufficient capacity to control the vapor discharged from the tank vents at maximum filling rate in conformance with local air quality regulations. If gasoline is being handled, provide, as a minimum, Stage I vapor recovery and the piping for Stage II. If not required by local or state regulations at time of construction, connect the Stage II piping to the tank and cap it at the dispenser.

8-3.14 Strapping Tables.

Provide two certified strapping tables for all tanks. Provide one of the tables in U.S. Customary units reading in 1/16-inch increments, gallons and barrels and one in metric units reading in 2mm increments, liters and cubic meters. Provide electronic media data files. Determine strapping table volumes for all field fabricated tanks using the procedures stated in API MPMS Chapter 2. The tables are to be calibrated for critical measurement **\1\ /1/**. Determine strapping table volumes for all factory fabricated tanks of 5,000 gallons (19,000 L) and larger using physical measurements, not calculated values. For factory fabricated tanks of less than 5,000 gallons (19,000 L), provide strapping tables certified by the tank manufacturer.

8-3.15 Product Recovery Systems.

8-3.15.1 General Design Considerations.

Provide pumps, piping, valves, and tanks to collect and store usable aviation turbine fuel which would otherwise become waste from operational or maintenance activities. Consider a product recovery system for other products. Include a tank to collect fuel/water mixtures from tank and system component sumps, system component drains, product saver tanks, high point vents, low point drains, and any other system components from which fuel/water mixtures can be collected. Separate the fuel and water portions. Filter the fuel portion and return to operating storage tanks. Do not discharge the water portion to surface water or treat the water portion as wastewater without additional treatment and permits. Refer to Chapter 2 of this UFC for information on handling of wastewater. Product recovery systems are included in DoD Standard Design AW 078-24-28.

8-3.15.2 Product Recovery Tanks.

For hydrant and aircraft direct fueling systems provide the tank indicated in DoD Standard Design AW 078-24-28. For other systems equipped with product recovery tanks, provide a tank with, at a minimum, the following appurtenances:

a. Level gauge.

b. Overfill protection level control valve.

c. High and low level switches with alarms and controls.

d. A motor driven fuel transfer pump that returns recovered fuel back to the system through a hard piped connection.

e. A motor driven sump pump for emptying the tank.

f. Manual gauging hatch.

g. Vent.

h. ATG system for aboveground product recovery tanks having a capacity more than or equal to 4,000 gallons (15,000 L).

i. Do not allow sight flow indicators to be installed on product recovery tanks.

8-3.15.3 Product Saver Tanks.

In addition to the product recovery tank(s) for the facility, all vertical storage tanks storing aviation turbine fuel should include a product saver tank with electric pump, unless the tank is equipped with a filter-separator to remove water from the sump. A product saver tank is a small aboveground tank piped and valved to allow drawing water from the bottom of the storage tank and returning the product after the water has been separated and disposed of in accordance with environmental regulations.

8-3.16 Registration.

Register all tanks with the appropriate state and local agencies as required.

8-3.17 Nameplates.

All tanks must have a nameplate installed in accordance with the standard of construction.

8-4 HORIZONTAL ABOVEGROUND TANKS (SINGLE WALL STEEL).

8-4.1 General Design Considerations.

If small factory-built aboveground storage tanks are required, use horizontal tanks. Limit tank diameter to 12 feet (3.7 m) or less and capacity to 50,000 gallon (191,000 L) or less. Require tank to be of welded steel construction in accordance with UL 142. Plastic and/or fiberglass aboveground storage tanks are not allowed. Requirements for all horizontal aboveground storage tanks must comply with NFPA 30. However, tanks located in facilities governed by NFPA 30A, such as marine/motor fuel dispensing facilities, must comply with NFPA 30A guidelines.

8-4.2 Tank Design Requirements.

a. Install tanks 5,000 gallons (19000 L) and less on a level surface. Install tanks greater than 5,000 gallons (19000 L) so that the bottom slopes downward toward one end at a slope of 1 percent. Locate transfer pumps or suction piping at the high end of the tank; locate water draw-off at low end of the tank.

b. Provide water draw-off lines in each tank. For aviation fueling systems, arrange piping so that the fuel in the tanks may be recirculated through the filter-separators.

c. Provide steel tanks with steel saddles or skids in accordance with UL 142. Mount steel supports on a reinforced concrete foundation.

d. Tanks must be inspected in accordance with STI SP001 by a STI certified inspector prior to commissioning.

8-5 HORIZONTAL ABOVEGROUND TANKS (DOUBLE WALL STEEL).

8-5.1 General Design Considerations.

Limit tank diameter to 12 feet (3.7 m) or less and capacity to 50,000 gallon (191,000 L) or less. Require tank to be of welded steel construction in accordance with UL 142. No fiberglass aboveground storage tanks are allowed. The main advantage of double wall steel storage tanks over single wall steel storage tanks is that separate spill containment may not be required. Secondary containment-type tanks can be used to provide spill control per NFPA 30, if the capacity of the tank is no more than 50,000 gallons (191,000 L). All of the criteria in the NFPA regulations for the appropriate application must be met before a secondary containment-type tank is used without separate spill containment. Requirements for double wall steel horizontal aboveground storage tanks must comply with NFPA 30. However, tanks located in facilities governed by NFPA 30A, such as marine/motor fuel dispensing facilities, must comply with NFPA 30A guidelines.

8-5.2 Tank Requirements.

a. For flammable liquid installations, require additional curbing containment based on tank filling rates if there is a chance of a fuel spill entering a critical area.

b. Install tanks 5,000 gallons (19000 L) and less on a level surface. Install tanks greater than 5,000 gallons (19000 L) so that the bottom slopes downward toward one end at a slope of 1 percent. If there is to be a product recovery and/or water draw-off, locate transfer pumps or suction piping at the high end of the tank; locate water draw-off at low end of the tank. Otherwise, locate transfer pumps at the low end.

c. Provide water draw-off lines in each tank. For aviation fueling systems, arrange piping so that the fuel in the tanks may be recirculated through the filter-separators.

d. Provide protective bollards for tanks not surrounded by a dike. Bollards must not be less than four (4) feet (1.2 m) high and 4-inches (100 mm) in diameter, of steel construction, filled with concrete, and spaced not more than four (4) feet (1.2 m) on center.

e. Provide steel tanks with steel saddles or skids in accordance with UL 142. Mount steel supports on a reinforced concrete foundation. Mount rectangular (flat bottomed) tanks of 4,000 gallons (15,100 L) or greater 12 inches (300 mm) above grade to allow inspection and maintenance of the tank bottom.

f. Require the tank to be tested after installation in accordance with STI SP001 and STI R912 accepted air test and manufacturer's instructions.

g. Require tanks to be inspected in accordance with STI SP001 by a STI certified inspector prior to commissioning.

h. A primary tank constructed of stainless steel is permitted when required.

i. Require support channels with anchor holes for earthquake/hurricane/flood restraint tie down.

j. Require steel thickness to be in accordance with UL142 but not less than a minimum thickness of 3/16-inch (5 mm) for interior carbon steel tank.

8-6 HORIZONTAL ABOVEGROUND TANKS (FIRE-RESISTANT).

8-6.1 General Design Considerations.

When small (250 to 50,000 gallon (900 to 191,000 L) capacity) aboveground storage tanks are required and there are clearance or fire exposure problems and the additional cost can be justified, consider the use of fire-resistant storage tanks. The main advantage of fire-resistant tanks over the single wall steel tanks is that separate spill containment may not be required and the vault system provides an added measure of fire protection.

a. Secondary containment-type tanks can be used to provide spill control per NFPA 30, if the capacity of the tank is no more than 50,000 gallons (191,000 L).

b. All of the criteria in the NFPA regulations for the appropriate application must be met before a secondary containment-type tank is used without separate spill containment.

c. Require tanks to be factory-constructed with a UL 142 welded steel primary tank.

d. Tanks may be used in applications where, in addition to the above considerations, construction of a separate spill containment system for secondary containment purposes would have a negative impact on operations and/or aesthetics.

e. Tanks located close to buildings or with integral fuel dispensers must be UL-listed secondary containment tanks, utilizing steel inner and outer tanks that can provide interstitial containment which is both pressure testable and verifiable.

   1. Such tanks usually have a fill of regular or insulating concrete or may be encased in a reinforced monolithic concrete vault.

   2. Do not provide rectangular UL2080 tanks that are greater than 5,000 gallons (19,000 L) except when approved by Service Headquarters.

f. Ensure the two-hour fire rating meets or exceeds all requirements of NFPA 30A for “fire resistance” tanks and provides a minimum two-hour fire rating in accordance with UL 2080.

8-6.2 Tank Design Requirements.

a. For flammable liquid installations, require additional curbing containment based on tank filling rates if there is a chance of a fuel spill entering a critical area.

b. Install tanks 5,000 gallons (19000 L) and less on a level surface. Install tanks greater than 5,000 gallons (19000 L) so that the bottom slopes downward toward one end at a slope of 1 percent. Locate transfer pumps or suction piping at the high end of the tank; locate water draw-off at low end of the tank.

c. Provide water draw-off lines in each tank. For aviation fueling systems, arrange piping so that the fuel in the tanks may be recirculated through the filter-separators.

d. A primary tank constructed of stainless steel is permitted when required.

e. Require support channels with anchor holes for earthquake/hurricane/flood restraint tie down.

f. Require steel thickness to be in accordance with UL142 but not less than a minimum thickness of 3/16-inch (5 mm) for the interior carbon steel tank.

g. Mount rectangular (flat bottomed) tanks of 4,000 gallons (15,100 L) or greater 12 inches (300 mm) above grade to allow inspection and maintenance of the tank bottom.

h. Provide protective bollards in traffic areas. Bollards must be not less than four (4) feet (1.2 m) high and 4-inches (100 mm) in diameter, of steel construction, filled with concrete and spaced not more than four (4) feet (1.2 m) on center.

i. Require the tank to be tested after installation in accordance with STI SP001 and STI R912 accepted pressure test.

j. Tanks must be inspected in accordance with STI SP001 by a STI certified inspector prior to commissioning.

8-7 HORIZONTAL ABOVEGROUND TANKS (PROTECTED TANKS).

8-7.1 General Design Considerations.

When small (250 to 50,000 gallon (900 to 191,000 L) capacity) aboveground storage tanks are required and there are clearance or fire exposure problems and the additional cost can be justified, consider the use of protected storage tanks. The main advantages of protected tanks over the single wall steel tanks are that a separate dike (containment) may not be required and the vault system provides an added measure of fire protection.

a. Secondary containment-type tanks can be used to provide spill control per NFPA 30, if the capacity of the tank is no more than 50,000 gallons (191,000 L).

b. All of the criteria in the NFPA regulations for the appropriate application must be met before a secondary containment-type tank is used without separate spill containment.

c. Additional benefits include added protection from ballistic and vehicular impact and reduced evaporation of volatile fuels in warm climates.

d. Require tanks to be factory-constructed with a UL 142 welded steel primary tank.

e. Tanks may be used in applications where, in addition to the above considerations, construction of a separate dike for secondary containment purposes would have a negative impact on operations and/or aesthetics.

f. Tanks located close to buildings or with integral fuel dispensers must be UL-listed secondary containment tanks, utilizing steel inner and outer tanks that can provide interstitial containment which is both pressure testable and verifiable.

1. Such tanks usually have a fill of regular or insulating concrete or may be encased in a reinforced monolithic concrete vault.

2. Do not provide rectangular UL 2085 tanks that are greater than 5,000 gallons (19,000 L) except when approved by Service Headquarters.

g. Ensure the two-hour fire rating meets or exceeds all requirements of NFPA 30A for "fire resistance" tanks, meets the requirements of UFC 3-600-01 and provides a minimum two-hour fire rating in accordance with UFC 3-600-01 and UL 2085.

8-7.2 Tank Design Requirements.

a. For flammable liquid installations, require additional curbing containment based on tank filling rates if there is a chance of a fuel spill entering a critical area.

b. Install tanks 5,000 gallons (19000 L) and less on a level surface. Install tanks greater than 5,000 gallons (19000 L) so that the bottom slopes downward toward one end at a slope of 1 percent. Locate transfer pumps or suction piping at the high end of the tank; locate water draw-off at low end of the tank.

c. Provide water draw-off lines in each tank. For aviation fueling systems, arrange piping so that the fuel in the tanks may be recirculated through the filter-separators. Locate the water draw-off piping at the low end of the tank.

d. A primary tank constructed of stainless steel is permitted when required.

e. Require support channels with anchor holes for earthquake/hurricane/flood restraint tie down.

f. Require steel to be a minimum thickness of 3/16-inch (5 mm) for the interior carbon steel tank.

g. Mount rectangular (flat bottomed) tanks of 4,000 gallons (15,100 L) or greater 12 inches (300 mm) above grade to allow inspection and maintenance of the tank bottom.

h. Provide protective bollards in traffic areas. Bollards must be not less than 4 feet (1.2 m) high and 4-inches (100 mm) in diameter, of steel construction, filled with concrete, and spaced not more than four (4) feet (1.2 m) on center.

i. Require the tank to be tested after installation in accordance with STI SP001 and STI R912 accepted air test and manufacturer's instructions.

j. Tanks must be inspected in accordance with STI SP001 by a STI certified inspector prior to commissioning.

8-8 ABOVEGROUND VERTICAL STORAGE TANKS.

8-8.1 General Design Considerations.

Provide cylindrical single wall steel aboveground vertical storage tanks meeting one of the following criteria (as approved by Service Headquarters):

a. Factory-fabricated tanks complying with UL 142 criteria. The diameter of the tanks is limited by transportation restrictions. Although these tanks are fabricated in sizes up to 50,000 gallon (191,000 L), they become quite tall due to the diameter limitation. Give special consideration to height/diameter ratio to ensure tank stability.

b. Field-erected tanks not requiring an internal pan must comply with DoD Standard Design AW 078-24-27 and the design considerations included herein for tanks without a floating pan. Tanks must be site-adapted by the designer. The standard design includes tanks ranging in capacity from 5,000 barrels (800,000 L) through 100,000 barrels (16,000,000 L). For tanks larger than 100,000 barrels (16,000,000 L), use the multicolumn API Std 650 design.

c. Field-erected tanks requiring an internal floating pan must comply with DoD Standard Design AW 078-24-27. The standard design includes tanks ranging in capacity from 5,000 barrels (800,000 L) through 100,000 barrels (16,000,000 L) with internal pan and requires site-adapting by the design team. For tanks larger than 100,000 barrels (16,000,000 L), use the multicolumn API Std 650 design.

8-8.2 Tank Roofs.

For tanks with internal floating pans, design the roofs in conformance with DoD Standard Design AW 078-24-27.

8-8.3 Internal Floating Pans.

a. Field-erected tanks containing Class I flammable fuels or mission-critical Class II combustible fuels, such as JP-8, must be equipped with a full contact, aluminum honeycomb floating pan. Other Class II fuels require a floating pan if the tank does not comply with the spacing and diking requirements of this UFC. Tanks storing mission-critical Class III fuels, such as JP-5 and diesel fuel marine (F-76), if located in hot (desert-like) climate, also require a floating pan to eliminate the fuel/air interface. A single slotted stilling well, that penetrates the floating pan, has a maximum diameter of 8 inches (250 mm) and is used for the automatic tank gauge system, is allowed to be provided without a vapor sleeve (bellow). The slotted well used for manual measurements must be equipped with a floating plug. The 8 inch (200 mm) slotted stilling well for the automatic tank gauge system level sensing device and the 6-inch (150 mm) minimum nominal size slotted stilling well for the automatic tank gauge system water probe are allowed to be provided without floating plugs.

b. For cone roof tanks with floating pans, provide roof vent/inspection hatches in the fixed roof and overflow port/vents near the top of the shell near a device(s) in the floating pan which is (are) sized by the tank erector to evacuate air and gases from underneath the pan when the pan is on its supports during filling operations.

c. Provide grounding bonds between the floating pan and shell as follows:

 1. Two lengths of bare, 1/8-inch (3 mm) diameter, stranded, extra-flexible, stainless steel wire rope, each extending from the top of the floating pan to the underside of the fixed roof.

 2. Attach two of the wires near the tank periphery, 180 degrees apart. Attach an additional third wire from the floating pan to the floating pan manhole cover.

 3. Securely connect the wires to the pan and extend vertically to the tank roof. Ensure wires are accessible for inspection.

 4. Ensure wires are long enough to accommodate the full travel of the pan. Locate wires to miss all interior tank appurtenances and structure.

d. Provide anti-rotation cables in accordance with DoD Standard Design AW 078-24-27.

e. For cone roof tanks with floating pans, provide gauge and sampling hatches in accordance with DoD Standard Design AW 078-24-27.

f. Provide a 36-inch (900 mm) diameter covered manhole in the floating pan.

g. Provide a pressure/vacuum vent sized by the internal floating pan manufacturer.

8-8.4 Tank Bottoms.

Slope the tank bottoms downward in accordance with DoD Standard Design AW 078-24-27. A slope of 5 percent is required for positive drainage and self-cleaning action for tanks storing fuels. After tank construction is complete perform a hydrostatic test prior to tank coating. In addition, conduct all tests in accordance with DoD Standard Design AW 078-24-27.

8-8.5 Foundations.

Design tank foundations on the basis of a soils exploration program including preliminary exploration as a minimum and detailed exploration and testing, if existing soil data is not available and/or inadequate. Refer to UFC 3-220-10N. Analyze the results of the exploration program to determine the most practical and economical design to provide a stable foundation for the tank. See DoD Standard Design AW 078-24-27. As a minimum, use the following criteria for all tank designs:

a. Prevent external corrosion of tank bottoms by locating the tank bottom perimeters well above the general tank field grade, provide adequate tank field drainage away from the tank, and construct the foundation pad as specified in AW 078-24-27.

b. Ensure a minimum electrical resistance of 35,000 ohm-cm. Foundation material should be neutral or alkaline with a pH greater than 7, a chloride concentration less than 300 ppm, and a sulfate concentration less than 150 ppm as specified by DoD Standard Design AW 078-24-27 and UFGS 33 56 13.15. The sand may be washed and the pH may be raised to meet the requirements. Include cathodic protection to prevent external corrosion of the tank bottoms. Do not use oil in the sand under the tank. Do not use dredge material or beach sand.

c. Provide good drainage under the tank.

d. Provide a reinforced concrete ringwall foundation. Locate the top of the foundation a minimum of 12 inches (300 mm) above the dike basin.

e. Cover the area beneath the tanks with a fuel-impermeable liner complying with DoD Standard Design AW 078-24-27, UFGS 33 56 13.15 and meeting local and state requirements. Install all liners according to the manufacturer's requirements.

f. Over the liner, provide a minimum of 12 inches (300 mm) of compacted clean sand or similar material as described above. Securely attach and seal the liner to the inside of the concrete foundation ring wall beneath the tank shell.

g. Provide a leak detection system for the tank bottom by installing a pipe or pipes through the concrete foundation ring wall as a telltale for tank bottom leaks in accordance with DoD Standard Design AW 078-24-27. These pipes will also permit water beneath the tank to escape by gravity.

h. Perform subsurface investigation in sufficient detail to determine if any compressible, weak, organic, or otherwise objectionable soils exist within a distance of two tank diameters below ground surface.

i. Estimate the magnitudes and rates of settlement (uniform, differential, and seismic induced) as part of the design. Provide adequate flexibility in piping, appurtenances, and other systems to accommodate anticipated settlements. Accomplish flexibility by using pipe offsets or ball joints. Do not use corrugated or bellows type expansion compensators. Do not exceed differential settlement values given in UFC 3-220-10N.

j. Where objectionable materials exist or magnitudes of anticipated settlement are sufficient to cause damage or unacceptable distortion, consider subsurface improvement. Potential improvement techniques may include removal of objectionable materials and replacement with clean compacted granular fill, preloading or surcharging in conjunction with drainage wicks, deep dynamic compaction, vibrocompaction, stone columns, compaction grouting, or similar techniques.

k. Where justified by subsurface conditions and economics, consider using deep foundations such as driven piling or drilled shafts. Design foundation in accordance with UFC 3-220-01N.

8-8.6 Post Installation Inspection.

Require tanks to be inspected by a STI Registered Inspector or an API Std 653 Certified Inspector, where applicable, prior to the tanks being put into service.

8-9 UNDERGROUND HORIZONTAL STORAGE TANKS.

8-9.1 General Design Considerations.

Where underground storage tanks of 50,000 gallon (191,000 L) or less capacity are required, use factory-built horizontal cylindrical double wall tanks (welded steel or fiberglass reinforced plastic (FRP)). Ensure that the design and installation are in accordance with 40 CFR Part 280 and NFPA 30 or any more stringent state or local criteria. Require separation of exterior tank walls from the interior walls with standoffs, thus creating an open space, or interstitial, for monitoring of leaks. UL 58 defines this type of tank as a Type II tank. Ensure that factory-fabricated tanks comply with UL 58 and STI P3 criteria.

8-9.2 Installation.

a. Install tanks in accordance with NFPA 30 and also in strict accordance with the manufacturer's installation instructions.

b. Install the tank so that the bottom slopes downward toward one end at a slope of 1 percent. If there is to be a product recovery and/or water draw-off, locate transfer pumps and suction piping at the low end of the tank; locate water draw-off at low end of the tank. Otherwise, locate the transfer pumps at the low end.

c. Provide straps and anchors designed to prevent flotation of tanks located in areas with high groundwater levels or subject to flooding. **\2** Design the concrete anchor pad with a factor of safety of 1.50 for resisting buoyant forces. ***/2/*** Provide electrical isolation strips between hold-down straps and metal tanks. Anchors may be a concrete anchor slab under the tank or concrete deadmen.

d. Place tanks on a uniform bed of homogeneous granular material at least 12 inches (300 mm) thick. If a concrete anchor slab is used, place a minimum of 6 inches (150 mm) of bedding for steel tanks and 12 inches (300 mm) of bedding for fiberglass tanks between the tank and the concrete anchor slab. Do not use blocks, chocks, or rocks.**\2**

e. All fuel storage tank nozzle fittings must be located above ground. If the tank nozzle penetrates a manway, the nozzle must be flanged so that the manway can be removed without requiring the nozzle piping to be cut. If any product recovery tank nozzle fittings are direct buried, the fittings are to be coated and wrapped with appropriate materials (i.e., anticorrosion tape wrap). Contact the appropriate Service Headquarters SME for approval. **/2/**

f. The tank must be installed by state-certified contractor, if state has a certification program.

g. The tank must be installed by a contractor that is certified by the tank manufacturer.

h. Tanks must be inspected in accordance with STI SP131 by a STI certified inspector prior to commissioning.

8-10 UNDERGROUND VERTICAL STORAGE TANKS (CUT AND COVER).

Underground vertical storage tanks are steel-lined reinforced concrete with leak monitoring capability. These tanks may be completely buried, surface-constructed and then covered with embankment, or any variation in between. OCONUS Pacific they are only required in high threat areas or when tanks are required to be constructed within the explosive cordon area or clear zone. Tanks being constructed OCONUS NATO refer to Standard Design STD 121-122-01 USAFE/NATO, Airfield Standard Design US, Jet Fuel Storage Dispensing Systems for Tactical and Wide Body Aircraft for design guidance. They are not used within CONUS except when tanks are required to be constructed within clear zones or explosive cordon areas. Design underground vertical steel storage tanks in accordance with DoD Standard Design AW 078-24-33 Aircraft Fueling System with Underground Vertical Storage Tanks (Cut and Cover), except as modified herein. These standards include tank sizes of 10,000 through 100,000 barrels (1,600,000 L through 16,000,000 L) capacity. In general, do not exceed 100,000 barrels (16,000,000 L) capacity. Alternative designs using prefabricated/pre-stressed tank sections must be approved by the appropriate Service Headquarters. Provide leak detection for underground storage tanks in accordance with federal, state, and local regulations.

8-11 APPURTENANCES.

Table 8-1 describes appurtenances for atmospheric storage tanks larger than 12,000 gallons and identifies the type of tank to which they should be mounted. Full seal weld all tank attachments to prevent moisture/water from corroding the tank shell and attachments. Threaded connections must not be used for mounting of any appurtenances to the tank (i.e. thread-o-let).

8-12 HEATERS.

8-12.1 General Design Considerations.

Provide tank heaters and controls for tanks intended for storage of high viscosity products, such as lube oils, or burner fuels No. 4, No. 5, and No. 6, in climates where the ambient tank temperature would be less than 20 degrees F (11 degrees C) above the fuel's pour point temperature. Heat heavy burner fuel oils and lube oils to a temperature of 20 degrees F (11 degrees C) above the fuel's pour point prior to pumping. Use one of the types of heaters listed below.

8-12.2 Heating Medium.

Use the appropriate heating medium for the particular application based on temperature, pressure, and availability. Saturated steam is the preferred heating medium, but consider using hot oil, hot water, and electric heating where steam is not available from existing sources.

8-12.3 Convection-Type.

Use convection-type heaters installed inside a storage tank and capable of passing through a 36-inch (900 mm) diameter manhole with a capacity to raise the temperature of a full tank of burner fuel oil approximately 60 degrees F (33 degrees C) in 24 hours. The appropriate Service Headquarters and/or DLA-Energy will determine if the capacity of the heater could be reduced if it is not necessary to heat a full tank of fuel within 24 hours.

8-12.4 In-Line Type.

In-line heaters consist of two general types: tank suction and straight tube. All in-line heaters are of the shell and tube construction. A tank suction or suction in-line heater is installed inside the tank on the tank issue line. The fuel oil enters the exchanger at the end within the tank and exits at the opposite end outside of the tank. The steam or another heating medium enters and exits the exchanger at the end outside of the tank. A straight tube or pipe in-line heater is installed directly into the pipeline. The fuel oil enters the exchanger at one end and exits from the other. The entry and exit points for the steam side can vary. The following criteria applies to in-line heaters:

a. Capable of heating fuel oil passing through them from the ambient tank temperature to a minimum of 20 degrees F (11 degrees C) above the fuel oil's pour point temperature at required flow rate.

b. If installed in tanks, allow removal of heater tube bundles without emptying the tank.

c. If multipass in-line heaters are used, do not allow the oil temperature rise to exceed 30 degrees F (17 degrees C) per pass.

d. Use carbon steel shells designed for a minimum 175 psig (1210 kPa) cold working pressure on both steam and oil sides.

e. Do not exceed 0.2 psig (1.4 kPa) for the pressure drop on the oil side of pump suction line nor exceed 10 psig (70 kPa) of pressure drop for heaters installed on pump discharge.

8-12.5 Insulation and Tracing.

In cases where fuels are heated, examine the possible economic incentives for insulating heated storage vessels and piping. In many cases, piping carrying heated products must be heat traced to prevent possible solidification of the fuel during a shutdown period. Insulate traced lines. Consider possible incentives for installing a condensate collection and return system. If a condensate return system is installed, include a monitor to detect oil in the condensate.

8-13 UNDERGROUND STORAGE TANK SPILL CONTAINMENT SYSTEMS.

8-13.1 General Design Considerations.

Provide drainage structures to impound escaping fuel where rupture of an underground tank in a hillside location would endanger other activities and structures at elevations lower than the tank.

8-14 ABOVEGROUND TANK SPILL CONTAINMENT SYSTEMS.

Provide a spill containment system for all aboveground tanks to prevent spilled petroleum from leaving the property.

8-14.1 General Design Considerations.

Tank Capacity barrels (L)	Method of Spill Containment
Individual Single Wall Tanks larger than 10,000 barrels (1,600,000 L)	Individual Diked Enclosure
Group of Single Wall Tanks with - no tank larger than 10,000 barrels (1,600,000 L), and - not exceeding 15,000 barrels (2,400,000 L) in aggregate capacity	Single Diked Enclosure with subdivisions between each tank 2,000 barrels or larger
Double Wall Tanks	Exempt by exception granted by NFPA 30 or NFPA 30A, if all provisions of that document are met and if local, state, and federal regulations permit

Refer to DoD Standard Design AW 078-24-27. Use the following criteria for tank spill containment systems:

a. The preferred method of containment is by diked enclosure (impounding spilled fuel around the tank by means of dikes) to prevent the accidental discharge of petroleum.

b. As an alternative to diked enclosures, use a remote impoundment spill collection system consisting of a series of drains leading from storage tank areas to a remote containment or impoundment designed to prevent the accidental discharge of petroleum. This is not the preferred method and requires approval of Service Headquarters. Generally, this system is used for tanks on a hillside.

c. Slope the area within the containment at no less than 1 percent to carry drainage away from the tank to a sump located at the low point of the enclosure.

d. Construct the drain line from the sump of petroleum-resistant, impermeable material with water-tight joints such as ductile iron or HDPE pipe with fusion welded joints. Do not use clay, concrete, or fiberglass piping materials.

e. Control drainage from the sump to the outside of the enclosure by an eccentric plug valve with indicator post located outside of the enclosure in an area that will be safely accessible during a fire.

f. Do not allow fuel to run off or escape from the containment area under any circumstances. Provide means for disposing or for treating contaminated water from the containment to meet the most stringent of applicable federal, state, or local requirements.

g. When subdividing is required, use subdivisions not less than 18 inches (450 mm) in height.

8-14.2 Spill Containment System Capacity.

8-14.2.1 Diked Enclosures.

Design diked enclosures in accordance with the most stringent of NFPA 30, 40 CFR Part 112, and other federal, state and local regulations. Additionally, ensure that the capacity of the diked enclosure is, at a minimum, greater than the largest tank volume located within the diked enclosure, plus sufficient freeboard equal to the greater of a 24-hour, 25-year storm or one foot (0.3 m) over the entire area of containment, or the flow of the water from firefighting activities. In appropriate environmental climates, consider snow and ice accumulation as well. Limit dike heights to 6 feet (1.8 m) or less, if possible. If dike height is higher than 6 feet (1.8 m) follow the requirements of NFPA 30 and confined space requirements.

8-14.2.2 Remote Impoundments.

If approved by Service Headquarters, design remote impoundments in accordance with the most stringent of NFPA 30, 40 CFR Part 112, and other federal, state and local regulations. Additionally, ensure the capacity of the remote impoundment is, at a minimum, greater than the largest tank volume located within the area of containment plus sufficient freeboard equal to the greater of a 24-hour, 25-year storm or one foot (0.3 m) over the entire area of containment or the flow of water from firefighting activities on neighboring storage tanks sharing the same spill collection system. When sizing the remote impoundment consider the total drainage area from all tanks that are included within the spill collection system. In appropriate environmental climates, consider snow and ice accumulation as well.

8-14.3 Remote Containment/Impoundment Spill Collection Systems.

Construct the remote impoundment as generally described for diked enclosures and in accordance with UFC 1-200-01.

8-14.4 Diked Enclosure – Earthen Dike Type.

Construct earthen dikes of earthen materials with fuel impermeable liner cover. Where space is a premium, construct dikes of vertical concrete walls. For earthen dikes, make the minimum distance from the toe of the dike to the tank foundation 5 feet (1.5 m) and provide a flat surface on the top of the dike at least 3 feet (0.9 m) wide. Do not make earthen dike slopes steeper than 2.5 horizontal to 1 vertical. If space is restricted, dike slopes may be increased to 2 horizontal to 1 vertical if the sloped dikes are concrete surfaced. Cover the sides and top of the earthen dike and the floor around the tank with one of the following materials (Refer to AW 078-24-27):

a. A fuel impermeable liner. If liner is exposed, the exposed areas must be resistant to the effects of direct sunlight and to wind uplift. Provide sandbags in accordance with the appropriate UFGS, or other means approved by the liner manufacturer, to assure the liner is resistant to wind uplift. Follow the liner manufacturer's recommendations for protecting the liner by the use of geotextile cover or other recommended means. Provide a concrete maintenance pad for personnel access to the tank and for work areas around tank manholes and valves.

b. Do not use Bentonite or a Bentonite composite material in the construction of dikes or basins.

c. Do not use asphalt.

8-14.5 Diked Enclosure – Reinforced Concrete Dike Type.

Design reinforced concrete (prefabricated or cast-in-place) dikes and their foundations to resist and contain the full hydrostatic load when filled to capacity. Use vertical reinforced concrete dikes where space is a premium. Seal all concrete surfaces with a flexible, UV-resistant, fuel-resistant coating if required by local or State regulations. Use a fuel impermeable liner as described above for the dike floor. When concrete is used as the secondary containment system, it must meet American Concrete Institute (ACI) 350 Code Requirements for Environmental Engineering Concrete Structures.

8-14.6 Diked Enclosure – Combination Dike Type.

A vertical concrete wall backed by an external earthen berm may be used. Design the combined earthen and concrete unit and its foundation to resist and contain the full hydrostatic load when filled to capacity. Use a fuel impermeable liner as described above for the dike floor.

8-14.7 Stormwater Collection Systems.

Design a stormwater collection system to contain, transport, treat, and discharge any stormwater that collects in the tank enclosure. Refer to Chapter 2 of this UFC. Review state and local regulations for design requirements and permitting of stormwater treatment systems.

8-14.8 Dike Access.

Provide concrete, steel, or aluminum steps with pipe handrails for passage across a dike. Steps and handrails must comply with 29 CFR Part 1910.36. Include a removable section of the handrail to provide access to the flat top of earthen dikes. If steel steps are used, they should be hot-dipped galvanized after fabrication. Provide a minimum of two access locations for safe emergency egress and for normal operation. This will normally include steps over the dikes separating adjacent tanks, as well as on one wall without an adjacent tank. Locate steps at the most accessible points, preferably on the same side as the access stairs to a tank roof. For tanks 20,000 barrels (3,200,000 L) and larger, consider providing earth-filled ramps to permit vehicle access into the dike when approved by Service Headquarters. If there is sufficient need to provide vehicle access into diked areas, provide a concrete paved road and/or earth-filled ramp for vehicle travel-ways. Where the vehicle access road crosses the dike, provide a security gate and prominent sign indicating that access is limited to a light duty vehicle that is rated for use in NFPA 70 Class I, Group D, Division 2 hazardous locations.

8-15 MISCELLANEOUS USE TANKS.

This paragraph provides design guidance for miscellaneous use tanks. These tanks are typically less than 550 gallons (2,100 L) in capacity. Check state and local regulations before beginning design. If a miscellaneous use tank has a capacity greater than 12,000 gallons (45,800 L), follow the requirements of Table 8-1. Otherwise, use the standards described below. For interior and exterior protective coating systems, consider using manufacturer's standard coating systems. Ensure coating system is compatible with application and products being stored.

8-15.1 Installation.

Install the tank in conformance with the requirements of NFPA 30. The exception used in NFPA 30 for the deletion of dike containment is acceptable if all of the criteria associated with that exception are met. Provide containment for all tanks, regardless of size, except small residential heating oil tanks, by complying with the paragraph titled "Aboveground Tank Spill Containment Systems" in this chapter of this UFC or by using properly installed aboveground concrete-encased tanks in accordance with the paragraph titled "Horizontal Aboveground Tanks (Protected Tanks)" in this chapter of this UFC.

8-15.2 Heating Oil Tanks.

Comply with NFPA 31.

8-15.3 Generator Fuel Tanks.

Comply with NFPA 31, NFPA 37, and NFPA 110.

8-15.4 Fire Pump Fuel Tanks.

Comply with NFPA 20, NFPA 30, and NFPA 31.

8-15.5 Waste Oil Tanks.

Check local and state environmental regulations for any additional requirements for storage of waste oil.

8-15.6 Containment.

As discussed previously in this chapter, provide containment, under and around all aboveground tanks except home heating oil tanks.

8-15.7 Underground Tanks.

Ensure all underground tanks are double-walled and have overfill protection, as described previously in this chapter.

8-16 SHIPBOARD OFF-LOAD FUEL STORAGE TANKS.

8-16.1 Function

In addition to regular storage, consider a storage tank for fuel removed from ships that may be off-specification or otherwise not satisfactory for its intended use. This fuel may be downgraded to heating oil or diesel fuel marine.

8-16.2 General Design Considerations.

Determine the volume requirements of the contaminated fuel storage tank by an activity survey. Provide bottom loading facilities for tank truck loading and off-loading of contaminated fuel.

8-16.3 Locations.

Locate the contaminated fuel storage tank(s) in or near the facility tank farm. Clearly mark the tank(s) as to the type or grade of fuel.

8-17 JET ENGINE TEST CELL FUEL STORAGE TANKS.

Design jet engine test cell fuel storage and issue systems to the same standards as operating storage tank fuel systems (e.g., high level alarms, gauging, shut-offs, etc.). Normally, tanks are refilled using station aircraft refueling trucks through aircraft single-point refueling adaptors.

8-18 FUELS AUTOMATED SYTEM.

The Defense Logistics Agency's Business System Modernization (BSM Enterprise Resource Programs (ERP) - Fuels section) is an Automated Information System (AIS) designed to support the DLA-Energy and the Military Services in performing their responsibilities in fuel management and distribution. FAS is a multi-functional AIS which provides for point of sale data collection, inventory control, finance and accounting, procurement, and facilities management. BSM-ERP is composed of an integrated set of commercial off the shelf (COTS) software applications, based around an oracle relational database management system (RDBMS), which is hosted on commercially available computer hardware. The system will provide interfaces to existing logistics/financial AIS's or to be used only when directed by DLA-Energy.

Table 8-1 Appurtenances

Item	Appurtenance	V-A	H-A	H-U	F-A	P-A	V-U
Manhole							
a	A 30-inch (750 mm) diameter manhole, a minimum of one manhole for tanks between 1,000 gallons (4,000 L) and 5,000 gallons (19,000 L) capacity, and a minimum of two manholes (both are to be at least 36 inches (900 mm), for tanks larger than 5,000 gallons (19,000 L) capacity.		✓	✓	✓	✓	✓
b	A dedicated manhole, other than required above, as the primary point for piping penetrations into a tank (may be as small as 22 inches (559 mm)). * For horizontal underground tanks located at military service stations, refer to DoD Standard STD 123-335-03. Diesel and bio-diesel tanks at military service stations are to be provided with a 32-inch access manway in addition to Item a above.			✓ *			
c	A shell manhole located above the internal floating pan's high position to aid in venting the tank during cleaning and to provide access to the floating pan's elastomeric wiper seals as required by DoD Standard AW 078-24-27.	✓					
d	Containment sumps and extension manhole.			✓			
e	Internal ladder access hatch in accordance with API Std 650. Locate the internal ladder access hatch near the perimeter of the roof.	✓					
f	Shell manholes in accordance with API Std 650. Two 36-inch (900 mm) shell manholes 180 degrees from each other. Align shell manholes parallel with prevailing wind direction. Support shell manhole covers by davits.	✓					
g	A bolted cover in the roof for installation and removal of the internal floating pan as required by the tank supplier based on the pan manufacturer.	✓					
Inspection Hatches							
h	A minimum of four roof perimeter vents/inspection hatches on fixed roof tanks with floating pans. Inspection hatches are not required for tanks without floating pans.	✓					
Ladder/Stairs							
i	Internal ladders (in accordance with OSHA criteria) for tanks of 5,000 gallons (19,000 L) or larger. * with floating pans. ** Ladders are optional per STD 123-335-03.	✓ *	✓ **	✓ **	✓ **	✓ **	✓
j	An external ladder and platform with safety railing for gauging and sampling in accordance with 29 CFR Part 1910.23 (if height justifies it).		✓		✓	✓	

Item	Appurtenance	V-A	H-A	H-U	F-A	P-A	V-U
k	Ladders, railings, toe boards, a spiral stairway, bottom platform (for internal floating roof only), intermediate platform, top platform, and handrail in accordance with API Std 650 and OSHA requirements. Provide stairways and platform to access high level shut-off and alarms. Provide bar grating stair tread and platforms. Provide stair tread with non-slip nosings. **\2** In locations where there is severe corrosion, these components may be fabricated from nonmetallic composite material (e.g. fiberglass reinforced plastic, carbon fiber, or other nonmetallic composite). Stair treads may be bolt-on type to facilitate replacement when required. ***/2/***	✓					
Item	**Appurtenance**	**V-A**	**H-A**	**H-U**	**F-A**	**P-A**	**V-U**
Level Alarms							

Item	Appurtenance	V-A	H-A	H-U	F-A	P-A	V-U
I	1. Tanks Greater ≥ 30,000 gallons (112 500L): 1. An individual automatic level alarm system, independent of the gauging device or system for each tank. Include high, high-high, low and low-low level alarms. On aboveground tanks: provide a means to manually test each alarm sensor to ensure system operability without a full tank; locate level alarm system component for ready access from ground level, stairway platforms, or roof access. On aboveground vertical tanks set level alarms as defined in AW 078-24-27. On tanks without floating pans, set the low level alarm to actuate 5 minutes above the low-low level alarm, and the low-low level alarm as defined in AW 078-24-27. **\2** On Cut and Cover tanks, set level alarms as defined in AW 078-24-33. For horizontal underground tanks and aboveground tanks, high and high-high will be 90 and 95 percent, respectively (although this may have to be adjusted downwards for horizontal tanks). **/2/** In determining the low level, consider the time it would take for the pump or system to shut down. Provide both audible and visible alarms in a manned area responsive to the alarm. Review facility size and operating method to determine the most desirable location for audible and visible alarms, this will usually be in the tank farm or near the operations building. Interface the alarm output to stop issue pump on low level alarm and receipt pump/valve on high-high level alarm. Install alarms on winter sun side of the tank. Comply with most stringent of federal, state, or local regulations.	✓ *	✓ *	✓ *	✓	✓	✓

Item	Appurtenance	V-A	H-A	H-U	F-A	P-A	V-U
I (cont)	2. Tanks < 30,000 gallons (112,500 L): An automatic level alarm system for each tank to include high, high-high, low and low-low level alarms. On aboveground tanks: provide a single multi-set point Automatic Tank Gauge (ATG) level probe with continual/dynamic testing for both gauging and alarm; locate ATG level alarm system component for ready access from roof or platform access. Additional redundancy level sensors or switches that interface with the ATG may be added. On aboveground vertical tanks, in general conformance with API RP 2350, set high-level at 95 percent and high-high at 98 percent; on tanks with floating pans locate the low level alarm to actuate 5 minutes above the low-low level alarm and locate the low-low level alarm at 2 percent above the low level of the floating pan. For underground tanks and horizontal aboveground tanks, high and high-high will be 90 and 95 percent, respectively (although this may have to be adjusted downwards for horizontal tanks). On all tanks without floating pans, set the low level alarm 5 percent before loss of suction, and the low-low level alarm 2 percent before loss of suction to avoid pump cavitation. In determining the low level, consider the time it would take for the pump or system to shut down. Provide both audible and visible alarms in a manned area responsive to the alarm. Review facility size and operating method to determine the most desirable location for audible and visible alarms, this will usually be in the tank farm and in or near the operations building. Interface the alarm output to stop issue pump on low-low level alarm and receipt pump/valve on high-high level alarm. Comply with most stringent of federal, state, or local regulations. For vertical aboveground tanks, refer to AW 078-24-27 or STD 123-335-03 as applicable.	✓ *	✓ *	✓ *	✓	✓	✓

Item	Appurtenance	V-A	H-A	H-U	F-A	P-A	V-U
l (cont)	3. Product Recovery Tanks (PRT): An automatic level alarm system for each tank to include high and high-high level alarms. On aboveground tanks: provide a single multi-set point Automatic Tank Gauge (ATG) level probe with continual/dynamic testing for both gauging and alarm; locate ATG level alarm system component for ready access from ground level or stairway platforms. Additional redundancy level sensors or switches that interface with the ATG may be added. On aboveground tanks, in general conformance with API RP 2350, set high-level at 95 percent and high-high at 98 percent. For underground tanks, high and high-high will be 90 and 95 percent, respectively (although this may have to be adjusted downwards for horizontal tanks). **\1** On cut-and-cover tanks, set level alarms as defined in AW 078034-33. **/1/** Provide both audible and visible alarms in a manned area responsive to the alarm. Review facility size and operating method to determine the most desirable location for audible and visible alarms, this will usually be in the tank farm and in or near the operations building. Interface the alarm output to receipt pump/valve on high-high level alarm. Comply with most stringent of federal, state, or local regulations. Refer to STD 123-335-03.	✓ *	✓ *	✓ *	✓	✓	✓
***Note:** State and local regulations may be more restrictive. Because underground and aboveground horizontal tanks will fill extremely fast in the last 5 percent, values of high level alarm positions should be chosen based on filling rate, tank size, and time needed to respond to the alarm condition. Adjust values as well for extremely large vertical tanks with small receipt rates and extremely small vertical tanks with high receipt rates.							
Vents							
m	Open atmospheric vents with weather hoods and bird screens for tanks to be used for products with true vapor pressure of 0.75 psia (5 kPa) or less, when a full contact internal floating pan is provided.	✓	✓	✓	✓	✓	✓
n	For higher vapor pressure, or if a vapor recovery system is used, provide pressure/vacuum vents in lieu of open vents. Consider using pressure/vacuum vents if product quality is at risk by blowing sand, dust, or snow. Comply with NFPA 30, host nation requirements, Chapter 2 of this UFC, API Std 650, API Std 2000, 29 CFR Part 1910.106, and DoD Standard Design AW 078-24-27, where applicable.	✓	✓	✓	✓	✓	✓

Item	Appurtenance	V-A	H-A	H-U	F-A	P-A	V-U
o	Do not use flame arrestors unless required by host-nation and/or NATO regulations.	✓	✓	✓	✓	✓	✓
p	Emergency relief venting with capacity in accordance with NFPA 30 and UL 142, as applicable. For vertical aboveground tanks, a floating roof or weak roof-to-shell seam, as specified in API Std 650, may be used to fulfill emergency relief requirements.	✓	✓		✓	✓	✓
	Gauge/Gauge Hatch/Stilling Wells						
q	A mechanical tape level gauge calibrated in 1/16-inch (2 mm) graduations mounted at 60 inches (1500 mm) above the walking surface. For tanks with internal floating pans, attach mechanical tape level gauge to the manufacturer provided floating roof anchor weight that rests on top of the floating pan.	✓					✓
r	A clock-type mechanical gauge. Gauge must be accurate to plus or minus 1/4 inch (6 mm) and must measure the liquid level over the full range of a tank's height. See DoD Standard Design STD 123-335-03.		✓	✓	✓	✓	
s	Automatic Tank Gauging (ATG) for all tanks with fuel managed through the Defense Logistics Agency's Business Modernization {BSM Enterprise Resource Programs (ERP) - Fuels section}, that complies with API MPMS Chapter 3. Key features include: measures fluid level to ±0.05 inch (1 mm); measures standard volume ±0.1 percent; measures average product temperature ±1 F (0.5 C); measures product density ±1 percent; detects water in the tank sump to a level equal to or slightly above the water draw-off pipe; converts volume to API standard conditions; local tank readout; For tanks that are 30K gallons or less certain ATG systems (Veeder-Root and Ronan) can provide backup alarms for high, high-high, low, and low-low level conditions; meet American Standard Code for Information Interchange (ASCII) interface.	✓	✓	✓	✓	✓	✓
t	A 4-inch (100 mm) gauge hatch with drop tube to within 3 inches (75 mm) of the bottom of the tank.* * Lowest point in the tank not the sump.						✓
u	A 4-inch (100 mm) opening without a drop tube or gauge hatch.		✓	✓	✓	✓	✓
v	One 10-inch (250 mm) roof flanged nozzle with an 8-inch (200 mm) aluminum, fully slotted, stilling well for ATG near the edge of the roof near the top of the stairway platform.	✓					✓

Item	Appurtenance	V-A	H-A	H-U	F-A	P-A	V-U
w	One 8-inch (200 mm) roof flanged nozzle with a 6-inch (150 mm) aluminum, fully slotted, stilling well for temperature and water bottom sensor, as close to or in the tank sump as possible. See DoD Standard Design AW 078-24-27.	✓					✓
x	One 10-inch (250 mm) roof nozzle and an aluminum, slotted stilling well for gauging and sampling. A datum plate to establish a gauging zero point. See DoD Standard Design AW 078-24-27.	✓					✓
Piping Connection							
y	Inlet fill connection. Refer to AW 078-24-27 or STD 123-335-03 as applicable.	✓	✓	✓			
z	Main suction and low suction. See DoD Standard Design AW 078-24-27.	✓					
aa	Inlet fill pipe with horizontal exit perpendicular to a tank radial. Discharge is approximately 4 inches (100 mm) above tank floor and enlarged to reduce fuel velocity. An u-trap is placed in the line to serve as a liquid lock to prevent entry of fire or an explosion from outside the fill pipe.						✓
Overfill Protection							
bb	Overfill protection with a hydraulically operated diaphragm control valve. Tanks connected to commercial pipelines or marine offload systems with restrictions on shut-off may require diversion to additional tankage. On vertical tanks, valve typically closes midway between high and high-high levels, but ensure valve closes no later than on high-high level. For underground tanks, (per NFPA 30) and in aboveground horizontal tanks, automatically shut off the flow into the tank when the tank is no more than 95 percent full. Comply with most stringent of federal, state, or local regulations. Use API RP 2350 to establish the proper overfill level setting. On gravity drop fills, horizontal aboveground storage tanks, fire resistant aboveground storage tanks, and protected aboveground storage tanks, replace valve with an integral high level shut-off valve in the drop tube. Prior to designing automatic valve closure features, conduct a surge analysis on pressure filled systems. Refer to AW 078-24-27 or STD 123-335-03 as applicable. * If pressure-filled.	✓	✓	✓ *	✓	✓	✓
cc	A lockable, welded steel overfill protection box (5 gallon (20L) minimum) and a manual drain valve to return spills to the inner tank (omit the drain feature on aviation turbine fuel tanks).				✓	✓	

Item	Appurtenance	V-A	H-A	H-U	F-A	P-A	V-U
Water Draw-off							
dd	A 2-inch (50 mm) double block and bleed, plug valve at the low end of the tank, unless tank contains aviation turbine fuels with icing inhibitors. In those cases, the water draw-off valve may be a ball valve.		✓				
ee	Water draw-off connections. See DoD Standard Design AW 078-24-27.	✓					
ff	A 1-inch (25 mm) connection from the low end of the tank to approximately 3.5 feet (1.1 m) above the ground and equipped with a positive displacement-type, hand-operated pump for water draw-off. For Air Force projects, use electrical pumps only.			✓			
gg	A water removal suction tube at low end of tank with connection for water removal by truck. Consider installing a fixed, hand-operated pump as an alternative.		✓	✓	✓	✓	
hh	A central sump pump.						✓
Ball Joints							
ii	Ensure that contract specifications do not allow piping connections to be made until after the tank has been completely tested and allowed to settle. As an alternative, ball joints on pipes to relieve strain caused by tank settling or seismic activity or settlement calculations can be made, and piping flexibility can be designed to account for settling and pipe can be connected prior to testing. * May be required on tanks 25,000 gallons (94,600 L) and larger.	✓	✓ *				
Cable Supports							
jj	On the fixed roof of all tanks, provide two scaffold cable supports in accordance with API Std 650. Locate the supports near the center of the tank so that supported cables will have maximum range and flexibility of operation with minimum interference with other tank fittings.	✓					
Striker Plates							
kk	Striker plates under all openings used for manual gauging in steel tanks and all openings in fiberglass tanks.	✓	✓	✓	✓	✓	✓
Monitoring Port							
ll	A 2-inch (50 mm) monitoring port including a tube which provides a means to detect product leakage from the primary tank into the secondary tank.				✓	✓	

V-A = Vertical Aboveground Storage Tank
H-A = Horizontal Aboveground Storage Tank
H-U = Horizontal Underground Storage Tank
F-A = Fire-Resistant Aboveground Storage Tank
P-A = Protected Aboveground Storage Tank
V-U = Vertical Underground Storage Tank

CHAPTER 9 PIPING SYSTEMS

9-1 INTRODUCTION.

This chapter provides guidance for the design of new piping portions of fueling systems, as discussed in other chapters of this UFC. The criteria provided is intended to be general in scope except where specific criteria are necessary for given situations.

9-2 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, contains important information on fueling facilities. Do not start design of any fueling system without first becoming completely familiar with Chapter 2 of this UFC. Follow the requirements listed in Chapter 13, when connecting a new system to an existing system, to prevent contamination of the new system.

9-2.1 Design Requirements.

Ensure that piping design, materials, fabrication, assembly, erection, inspection, and pressure tests for fuel piping systems are in accordance with ASME B31.3. See Chapter 6 of this UFC for design requirements for interterminal and installation pipelines. Follow appropriate guide specifications for piping design and materials selection. Use the following design criteria for piping systems:

a. Unless otherwise specified by Service Headquarters, provide underground piping systems in and around areas subject to aircraft ground movements. When directed by Service Headquarters, install piping in concrete trenches. When trenches are employed, comply with NFPA 415. The use of common trenches for more than one utility is prohibited. Fueling system components may be aboveground where it does not interfere with aircraft or service vehicle movements. Design all clearances in accordance with UFC 3-260-01 and DoD Standard Design AW 078-24-28.

b. In other cases, aboveground piping is preferred where it is not aesthetically objectionable or not exposed to accidental damage, vandalism, blast damage, or sabotage. Small diameter (≤4 inches (100mm)) pipe associated with the aboveground storage of petroleum, oil, and lubricants must be single wall aboveground piping. Exemptions may be granted by the Service Headquarters in cases where routing aboveground could result in catastrophic damage to the pipe. If an exemption is granted, double wall piping must be installed in accordance with the paragraph titled “Double Wall Piping” in this chapter of this UFC.

c. The preferred method of routing aboveground piping out of a diked area is over the top of the dike. However, avoid creating an inverted “U” on the suction side of a pump to avoid an air trap. Provide high point vents and low point drains as required, refer to AW 078-24-27.

d. Steel reinforced, high-density polyethylene (HDPE) flexible piping manufactured in accordance with API 17J may be used in underground piping systems. Service Headquarters approval is required prior to use of this material in place of carbon or stainless steel piping. It is preferred that all underground piping end connections are located within service pits. However, if it is not feasible, piping connections can be direct buried. Direct buried piping connections must be liquid-tight and provided with an adjacent monitoring well and a suitable pipeline marker above the connections. Steel reinforced, high-density polyethylene (HDPE) flexible piping is not to be used as aboveground piping.

e. Provide thermal relief devices around all installed double block and bleed valves and other isolation valves within the piping system.

f. Refer to UFC 3-130 series for construction of aboveground and underground piping in arctic and subarctic conditions.

9-2.1.1 Hydrostatic Testing Requirements.

a. Hydrostatically test new piping systems in accordance with ASME B31.3 and the UFGS specification appropriate for the system service. During testing, disconnect system components such as storage tanks or system components which were not designed for the piping test pressure or protect them against damage by over-pressure. Hydrostatically test aboveground piping systems to the maximum allowable working pressure of the ASME B16.5 piping system flanges at 100 degrees F (38 degrees C). Hydrostatically test underground piping systems to 1.5 times the maximum allowable working pressure of the ASME B16.5 piping system flanges at 100 degrees F (38 degrees C). See Table 9-1 for the maximum allowable maximum_allowable_working_pressure.

b. **\1** Hydrostatically test **/1/** fuel systems and pipelines with the fuel that will be used in the system or pipeline or, at a minimum, a fuel with the same minimum specification flashpoint as the fuel that will be used when the piping is in service, except as may be allowed in the following paragraph. The temperature of the fuel used for testing, and the ambient temperature, must be at least 20 degrees F (11 degrees C) below its flashpoint throughout the test.

c. Hydrotesting with water requires explicit, written Service Headquarters approval except in the case of fuel piping systems containing fuels with a flash point of less than 100 degrees F (i.e., JP-4, mogas, avgas, etc.); without that approval, hydrotesting with water is forbidden. When water is authorized for hydrostatic testing of fuel piping, ensure that all water is removed from the piping by a combination of pigging the piping, followed by dehydrating the line either with dehumidified air or vacuum extraction. Verification of pipeline dehydrating must be confirmed by measuring dew point of exhausted air. Do not allow water to remain in piping for more than 48 hours after testing. Schedule hydrotesting such that the pipeline can be filled with fuel as soon as possible (no more than two weeks) after testing is complete as it is nearly impossible to assuredly remove all water and corrosion can occur if the time to fuel introduction is extended. Considerations when deciding when to hydrotest with water include the following. As noted previously, except for JP-4, mogas, and avgas piping, all require Service Headquarters approval:

1. Fuel piping systems must be hydrotested with water for pipelines containing fuels with a flash point of less than 100 degrees (i.e. JP-4, mogas, avgas, etc.)

2. Interterminal pipelines that are constructed piggable should be hydrotested with water if permitted by the Service Headquarters in order to avoid exposing off-Base personnel and property to the risks inherent in pressure testing with fuel. Test prior to tie-in to piping at point of receipt complex and pumphouses that cannot be readily dewatered. This can be the point of connection between new and existing transfer piping, or the system connection at the receipt pig barrel.

3. Installation pipelines that are constructed piggable may be tested with water if permitted by the Service Headquarters. Test prior to tie-in to piping at point of receipt complex and pumphouses that cannot be readily dewatered. This can be the point of connection between new and existing transfer piping, or the system connection at the receipt pig barrel.

4. Hydrant systems that have been identified as having been contaminated by solids/soil during assembly should be hydrotested with water if permitted by the Service Headquarters.

5. Hydrant systems may be hydrotested with water if permitted by the Service Headquarters.

6. Determine required water discharge permitting requirements and provide a water handling/cleanup/disposal system to meet those requirements.

9-2.1.2 Pipeline Flushing Requirements.

a. Flush fuel system and pipelines with the fuel that will be used in the system or pipeline, except as may be allowed in the following paragraphs.

b. Flushing with water requires explicit, written Service Headquarters approval. Without that approval, flushing with water is forbidden. Approval must be obtained as a part of the original project programming and reconfirmed as a part of the 35% project design submission. The engineering design must include confirmation of water source, and impact on installation water distribution from high velocity water flushing as well as means of preventing particulates present in water distribution systems from being introduced into the hydrant loop. When water is authorized for flushing of fuel piping, ensure that all water is removed from the piping by a combination of pigging the piping, followed by dehydrating the line either with dehumidified air or vacuum extraction. Verification of pipeline dehydrating must be confirmed by measuring dew point of exhausted air. Determine required water discharge permitting requirements and provide a system to meet it. Do not allow water to remain in piping for more than 48 hours after testing. Schedule flushing such that the pipeline can be filled with fuel as soon as possible (no more than two weeks) after testing is complete as it is nearly impossible to assuredly remove all water and corrosion can occur if the time to fuel introduction is extended. As always, without explicit Service Headquarters approval, fuel must be used for flushing.

c. Flushing of soil contaminated hydrant loops with water requires explicit, written Service Headquarters approval. Without that approval, flushing with water is forbidden. In cases where a hydrant loop is contaminated during construction with trench soil having characteristics of clay, it is impossible to remove the clay with any form of fuel flushing and pigging. The contamination will only be pushed further into the system and then into the pumphouse. If complete hydrant loop flushing with water per above is not feasible, consider batch water pigging using fuel as propulsion. Considerations for removing clay and other solids from hydrant loop piping with water include:

1. This is a specialty operation and should only be conducted by organizations having specific prior experience in this type of effort. It is suggested that the project Systems Supplier be engaged in the process.

2. Batches of water, between batch pigs (or defueling pigs) will need to be run multiple times until foam pigs are no longer fouled with particulate contamination.

3. Water from installation water supply systems may not have sufficient pressure to seat a pig. It may be necessary to momentarily pressurize pig barrel with fuel and hydrant system pumps to move the batch pig into the head of the launcher.

4. The water batch must be diverted to a product reclaim tank and not be through filter-separators.

5. All flushing water should be considered fuel contact water and must be properly stored, tested, treated, and/or disposed.

6. It is recommended that the system be drained after flushing with water and then inspected by video equipment where possible. Tractor driven tethered cameras can be introduced at loop access point at the pumphouse, and by removal of isolation valves in the loop. The distance a tractor driven camera can progress is limited by slopes and bends but can be up to several hundred feet. In

hydrant systems, pushrod cameras can be introduced through the hydrant laterals (if no pig bars installed on branch tee) and then used to investigate the primarily loop several hundred feet in each direction.

9-2.1.3 Pipeline Pigging Requirements.

a. Design interterminal and installation pipelines between piers and storage tanks, cross-country pipelines, and between bulk storage and operating tanks to accommodate maintenance pigging and ILI smart pigging operations. Use 1.5 diameter (D) elbows, or 3 D sweeps, full port valves, barred tees where indicated. Do not design with back to back 1.5 D elbows as they can restrict smart pig trains. If back to back elbows are required, provide 3 D sweeps. Provide permanent launchers and receivers suitable for smart pigging. Provide associated launcher kicker piping and receipt bypass piping, not less than 3-inch in size for 6-inch lines and 4-inch for up to 10-inch and 6-inch for up to 14-inch pipelines. Launcher and receiver configuration must be able to accommodate current technology in ILI tools that assess piping for geometry, corrosion loss (UT and MFL) and X-Y-Z orientation as a minimum as directed or approved by Service Headquarters. For general guidance review pig barrel design in Type III Standard Design AW 078-24-28 .

b. Design aircraft hydrant system piping to accommodate maintenance pigging and ILI smart pigging operations. Provide piggable design and pig launchers and receiver as noted above for Installation and Interterminal pipelines.

c. Design long runs of truck fillstand piping (runs over one-half mile in length) to accommodate maintenance pigging and ILI smart pigging operations. Provide piggable design and pig launchers and receiver as noted above for Installation and Interterminal pipelines.

d. Provide barred tees on piggable systems using the following guidelines. Barred tees are required for all branch outlets 2-inch and larger when within 20 feet of pig launcher or receiver barrel, including the barrels. Barred tees are required on all outlets on the bottom half of the pipe, greater than 2-inch in size. Barred tees are required on all branch connections equal to or greater than 50% of piggable line size. Barred tees should not be provided on 4, 6, and 8-inch hydrant laterals so that video equipment can be inserted into the main hydrant loop from the hydrant pit. For details on barred tees, refer to Facility Plate 014.

9-2.1.4 Certified Inventory.

DLA-E requires that a fuel system volume be calculated using as-constructed pipe lengths, internal diameters, fittings, and components of a system i.e. all items containing fuel with the exception of tanks. A detailed list with sizes, lengths, quantity, and volumes must be provided for each of the systems.

9-2.1.5 Hydraulic Design.

In general, provide a hydraulic design with a velocity of 7 to 12 feet per second (2.1 to 3.7 m/s) on pump discharge and 3 to 5 feet per second (0.9 to 1.5 m/s) on pump suction at full flow. If project-specific conditions make it advisable to exceed these values, consult the appropriate Service Headquarters. Consult with appropriate Service Headquarters for outlet pressure requirements. Design suction piping to ensure that the net positive suction head required by the pumps is available under all conditions of operation. Consider the following factors in selecting pipe sizes:

a. Operating requirements of the facility to be served.

b. Capital cost of the pipe

c. Capital cost of pumping stations and attendant facilities

d. Operating cost of the system

e. Harmful effects of excessive velocity of flow including hydraulic shock and static generation.

f. Fatigue failure cause by cyclic loading

9-2.2 Piping Arrangement.

Wherever possible, arrange piping in parallel groups to facilitate multiple use of supports, to minimize the amount of trenching for underground piping, and to minimize the number of steps or stiles needed across pipe runs. For underground applications, consider constructability when determining amount of spacing between pipes. Use the following criteria:

a. Provide looped piping systems whenever practical. Loops add to the flexibility and reliability of the system, contribute to product cleanliness by making circulation possible, and can be used to reduce the magnitude of hydraulic shock. Sectionalize loops by double block and bleed valves to provide verifiable isolation and to facilitate pressure testing. All line valves on piggable lines must be true full port through conduit opening without protrusions that could impede pig passage.

b. Between mains, install cross connections for flexibility of operation and as an auxiliary means of continuous operation in emergency situations. In addition, permit the use of full thickness line blinds where space limitations preclude the use of removable pipe sections or fittings. Provide a separate piping system for each grade of fuel to be handled. Do not provide cross connections between grades except when approved by Service Headquarters; typically for large Defense Fuel Support Points and other large multi-fuel depot style bulk fuel farm installations.

c. As described under "Pipeline Pigging Requirements" paragraph 9-2.1.3, lay out the following underground piping systems to accommodate maintenance pigging and ILI smart pigging operations:

1. Interterminal and installation pipeline piping between piers and storage tanks, cross-country pipelines, and between bulk storage and operating tanks.

2. Aircraft direct fueling system piping hydrant loops.

3. Truck fillstand piping runs that are over one-half mile in length.

d. For short runs of piping, provide a line slope of at least 0.2 percent. For long runs of piping (except **hydrant systems** and long runs of truck fillstand piping, see below), make line slope sufficient to establish positive drainage by gravity, but without excessive bury depth. Make gradients uniform between high point vents and low point drains. Traps are undesirable because they provide a place for water and sediment to accumulate. High points are undesirable because they trap air in the piping affecting their hydraulic performance; install high point vents to remove trapped air. Install low point drains at all low points to allow for removal of any water from condensation. These low point drains also provide the capability to remove fuel for line maintenance. For piggable **installation pipelines**, the low point drains and high point vents may be deleted when approved by **Service Headquarters**. Low point drains are not required on **interterminal pipelines**.

e. To help maintain fuel quality, design aircraft **hydrant system** piping and long runs of truck fillstand piping with as steep a slope a possible (0.5 percent or greater) to allow for better draining capability. This is typically done by following the slope of the terrain in order to minimize the number of high point vent and low point drain pits. In no case slope the pipe less than 0.2 percent without **Service Headquarters** approval.

f. As a general rule of thumb, provide spacing between aboveground piping and piping in valve pits that will allow a minimum clearance of 3 inches (75 mm) between adjacent flanges. In certain situations, such as in a piping trench or other restrictive location, it may be necessary to reduce the spacing. A minimum of 12 inches (300 mm) or one pipe diameter, whichever is greater, should still be maintained between pipe walls.

9-2.3 Surge Analysis.

Conduct a complete surge analysis of system operation using a computer simulation program for all systems with quick closing valves and for aircraft hydrant and direct fueling systems with more than two outlets. Give full consideration to the causes and effects of hydraulic shock. This is especially important in closed fueling systems such as aircraft fueling systems where the receiving tanks or dispensing system components may be damaged by shock pressure. Reduce the possibility of shock by limiting flow velocity and avoiding the use of quick opening/closing valves except where required for system operation such as hydrant pit valves. Do not reduce flow velocities below minimum velocity indicated in the paragraph titled “Hydraulic Design” in this chapter of the UFC. Every reasonable effort must be made to control hydraulic surge or shock within acceptable limits by the design of the piping system rather than by the use of surge suppressors. Surge suppressors are strictly a last resort solution and require the approval of Service Headquarters prior to designing into a system. For all aircraft direct fueling/hydrant system designs, the loop back pressure control valve is critical in preventing excessive hydraulic shock. Use the following design criteria and Table 9-1 for piping design pressures:

a. For all complex piping systems (main header, several laterals, mobile equipment), employ computer modeling techniques to determine if surge suppression is required. Conduct a run at steady state flow conditions to establish system flow rates for the scenario being modeled. After that, conduct a transient surge analysis imposing worst-case operating conditions on the system. For hydrant systems incorporating the use of a back pressure control valve, simulate this valve as an active modulating valve. If acceptable peak pressures are exceeded, discuss the results with the Service Headquarters fuels engineer to review parameters used and consider alternatives. If this consultation produces no workable solution, perform a second surge analysis to model the use of surge suppressors in the system. This analysis must indicate that damaging peak pressures are not exceeded. Do not use manual surge calculations, except as found under (c) below, because they do not account for dampening effects of the system and yield overly conservative results.

b. Most systems designed in accordance with this manual will have ANSI Class 150 flanges and the maximum allowable operating pressures seen in Table 9-1. Design the system such that the total pressure including surge, pump shutoff pressure, thermal fuel expansion effects, and static pressure in any part of the system never exceeds the maximum allowable operating pressure. Other equipment items such as tank trucks, aircraft fuel tanks, or shipboard fuel tanks which may be damaged by shock pressures may require lower maximum surge pressure. Assume a near instantaneous shut-off by the aircraft in the design of aircraft hydrant systems.

c. Do not use manual calculations instead of computer modeling when system surge pressures are crucial and the piping system is complex. However, for simple piping systems that operate under 80 psi (550 kPa) the manual calculations contained in Appendix A can be used to ascertain if surge will be a problem.

Table 9-1 Allowable Pressure Table – ANSI Class 150 Flanged Joints

	ASTM A 105	ASTM A 182 Gr. F304
Maximum Allowable Working Pressure	285 psig (1970 kPa)	275 psig (1900 kPa)
Maximum Hydrostatic Test Pressure	450 psig (3100 kPa)	425 psig (2930 kPa)
Minimum Hydrostatic Test Pressure	425 psig (2930 kPa)	400 psig (2760 kPa)
Maximum Allowable Operating Pressure	285 psig (1970 kPa)	275 psig (1900 kPa)
Maximum Allowable Surge Pressure	380 psig (2620 kPa)	366 psig (2525 kPa)

Notes:
(1) All pressure values are taken from ASME B16.5, ASME B16.47 and ASME B31.3 at 100 degrees F (38 degrees C).
(2) Values are presented for information only. Confirm actual values with ASME B16.5, latest edition, based on actual temperatures, bolting and gasket materials, etc.
(3) For other materials, see ASME B16.5 and ASME B31.3.
(4) For lower hydrostatic test pressures, the maximum allowable operating pressure will be lower than indicated. See ASME B31.3.

9-3 ABOVEGROUND PIPING.

Support aboveground piping so that the bottom of the pipe is a minimum of 18 inches (450 mm) above the ground surface or higher if required to service valves and system components. In areas subject to flooding, greater clearance may be desirable. At intersections with roadways, allow enough clearance for the passage of tank trucks, cranes, and similar heavy vehicles. In areas subject to seismic activity, provide the piping configuration and support in accordance with the seismic design criteria in **\3** UFC 3-301-01. Refer to 3-301-01 **/3/** for considerations in extremely cold climate. Wherever possible, arrange piping in parallel groups to facilitate multiple uses of supports, to minimize the amount of trenching for underground piping, and to minimize the number of pipe stiles needed. Consider constructability and maintenance in spacing of piping.

9-3.1 Identification.

Identify piping in accordance with Chapter 2 of this UFC. In addition, mark fuel lines at head of fueling pier near valves, and mark valve “open” and “close" positions.

9-3.2 Pipe Supports.

Provided engineered pipe supports for all aboveground piping systems must meet the applicable requirements of ASME B31.3 or ASME B31.4. All supports must be to the bottom of the pipe. Rest piping on supports, both insulated and uninsulated, preferably on a steel shoe (tee) welded to the bottom of the pipe. Leave the shoe free to move on the support when both in-line and lateral motion of the pipe is acceptable (no restraint). Where guides are designed with lift control, hold down brackets must be of welded construction, not bolted. Facility Plate 015 shows the design of typical "slide/guide" pipe supports for use when in-line flexibility is required, and vertical or lateral motion must be restrained. Facility Plate 017 shows the design of typical pipe supports with U-bolt restraints with a half round slide surface when use of a welded steel shoe is not required. Facility Plate 018 shows the design of a typical pipe support with U-bolt restraints with a half round slide surface that can be used for smaller piping systems (≤ 4 inches). Construct the portion of pipe supports in contact with the ground with concrete. Use of concrete piers is preferred over structural steel supports whenever feasible. Other support configurations are acceptable provided the support does not contain rollers**,** does not allow movement of the pipe on a metal surface**,** and does not include hangers. See AW 078-24-27, AW 078-24-28, AW 078-24-29, and STD 123-335-03 for specialized pipe supports particular to system layout requirements. General guidelines for pipe supports include:

a. Ensure that support shoe is the same as the pipe material (carbon steel or stainless steel).

b. Welded pipe shoes must be fully seal welded to prevent moisture pockets.

c. Pipe shoes may be manufactured products or custom designed and fabricated. Pipe static loads as well as dynamic loads must be addressed with a safety of factor not less than 4.

d. Strap-on, bolt on pipe attachments must not be used.

e. Cradle type supports must not be used when subject to weather or condensing climates due to water collection and increase in corrosion.

f. Welded carbon steel pipe shoe (tee), and shoe base must be hot dipped galvanized for all waterfront facilities and facilities located in the tropics with a condensing chloride climate. Special procedures for welding are required to remove the galvanization at the pipe to shoe weld. Galvanized shoes must receive proper surface preparation, then coated with the intermediate and topcoat system specified for piping.

g. Selection of pipe support type, vertical only support, pipe shoe with restraints, pipe shoe with no restraints, restrained or loose U-bolt on slide half round must consider all load factors (thermal, wind, seismic) and flexibility (thermal). Avoid excessive restraint supports that can result in damaged pipe, pipe shoes and supports. Avoid lack of restraint in high seismic regions that can lead to excessive pipe motion and failure.

9-3.3 Arrangement.

Arrange pipes to provide for expansion and contraction caused by changes in ambient temperature. Where possible, accommodate expansion and contraction by changes in direction in piping runs, offsets, loops, or bends. Where expansion loops or off-sets are not possible, use flexible ball joint offsets or bellows style expansion joints. Provide in-line restrained sliding (guided slide) pipe supports or other method of maintaining alignment on each side of the expansion joint. Do not use expansion devices which employ packings, slip joints, friction fits, or other non-fire resistant arrangements. Use ball-type offset joints to accommodate possible settlement of heavy structures such as storage tanks, if piping design cannot provide enough flexibility. Design expansion bends, loops, and offsets within stress limitations in accordance with ASME B31.3 and/or ASME B31.4. Thermal expansion of pipes should also be calculated based on the pipe being empty to include considerations for when the pipe is being installed or drained. For complex systems, computerized code compliant pipe stress analysis programs must be used to assure proper pipe support selection for load conditions.

9-3.4 Anchors.

Anchor aboveground piping at key points so expansion will occur in the desired direction. Anchors and guides may also be required to control movement in long runs of straight pipe or near a connection to fixed system components such as a pump or filter. See **Facility Plate 016**. Space anchors to provide maximum amount of straight runs of piping from expansion points to the anchors. In general, place anchors at all points of the system where only minimum piping movement can be tolerated, such as at branch connections and system component connections. Key locations are pump houses or other buildings, manifolds, at changes of direction if not used as an expansion joint, at points where the pipe size is drastically reduced related to adjacent piping, and at all terminal points. Limit the use of anchors to the situations described above. Thrust anchors must be directly welded to the pipe and must not include strap or bolt restraints. Where an anchor is welded directly to a pipe, ensure that the anchor material is compatible with the pipe material (carbon steel and stainless steel). Welded carbon steel pipe anchors must be hot dip **galvanized** for all waterfront facilities and facilities located in the tropics with a condensing chloride climate. Special procedures for welding are required to remove the **galvanization** at the pipe to shoe weld. **Galvanized** shoes must receive proper surface preparation, then coated with the intermediate and topcoat system specified for piping. Anchors must be designed for engineered load case and must take into account the type of expansion control device/concept. Pipe hold-down restraints are considered a form of anchors and are only suitable for use when in-line forces are limited, and not suitable for thrust restraint.

9-3.5 Thermal Relief Valves.

The coefficient of expansion of liquid petroleum in the range of 35 degrees to 60 degrees API (0.8498 to 0.7389) at 60 degrees F (16 degrees C) is 0.0005 gallon per gallon per degree F (0.0009 L per L per degree C). The total volume generated in most cases is very small, but the pressure increase resulting from this expansion can equate to as much as 75 psi for every degree rise in the fuel temperature if not relieved. For this reason, provide any section of pipe that has the potential to be isolated by a shut-off valve or other means with a thermal relief valve to relieve the isolated piping section. Provide a thermal relief of the internal cavity of valves where pressure is trapped when the valve is in the closed position (double block and bleed plug valves for example).

9-3.5.1 Construction of Thermal Relief Valves.

The thermal relief valves must match the material of the piping in which it is installed. When a stainless steel valve is provided, all components including bonnet and adjustments must also be stainless steel. Carbon steel components are not acceptable in a stainless steel thermal relief valve.

There are two types of thermal relief devices that can be used to protect a piping system: Balanced type thermal relief valves or ASME type thermal relief valves. Valves used for relief of thermal expansion must be not less than 3/4-inch (20 mm) nominal pipe size. Valve nameplate must list liquid flow capacity in gpm only. **\2** Provide with testing tees and isolation ball valves with removable handles, on the inlet and outlet sides of the valve. ***/2/*** The set pressure of the relief valve will vary, but consider a set pressure of about 10 percent above the dead-head pressure of the pump. This should keep the valve from opening during normal fueling operations. Ensure the set point is within the design limitations of the piping. Do not provide thermal relief piping with sight flow indicators.

9-3.5.2 Discharge of Thermal Relief Valves.

Thermal relief valves should never discharge to grade or to a stormwater drainage system. Ideally, the relief valve should discharge to a header which is piped directly to an atmospheric source such as a storage tank or product recovery tank; in this situation, consider using ASME Type relief valves. Often, the practical alternative is to use the balanced type relief valve (in lieu of the ASME type) arranged into a cascading system, where each relief valve bypass the shut-off valve that is isolating the piping section and discharges back into the main product piping. The excess volume may pass through two or more relief valves before finally making its way back to an atmospheric source. Caution must be taken to ensure that the relief valves have the capacity to handle the additive relief flows this type of system creates and that the total relief pressure does not exceed that system maximum allowable operating pressure. Balanced type relief valves limit pressure buildup that is created in a cascading system, because the balanced type relief valves relieve at a point independent of downstream pressure.

In some cases, a small atmospheric tank may need to be placed to properly relieve a piping system. This may be the case if a system component has a lower maximum allowable pressure then the rest of the system or in a remote location where a cascading system will not work. Equip the tank with self-checking high level alarms and containment. See Facility Plates 020, 021, 022 and 023.

9-4 UNDERGROUND PIPING.

Provide underground piping which passes under public roadways or railroad tracks in accordance with Department of Transportation regulations 49 CFR Part 195 and API RP 1102. Refer to Chapter 2 of this UFC for corrosion protection and for environmental protection. Before installing underground pipelines, review all federal, state, and local regulations for double wall pipe, leak detection, and corrosion protection requirements.

9-4.1 Depth of Cover.

Use the following criteria for depth of cover over buried fuel pipelines:

a. Locate top of lines at a minimum of 3 feet (0.9 m), except that less cover is permissible for occasional stretches where overriding conditions exist, such as the need to pass over a large culvert or beneath drainage ditches. At such locations, build sufficient slack into the line to allow for vertical and lateral movement due to frost heave. Refer to UFC 3-130 series for additional guidance. Protective measures, such as the installation of reinforced concrete slabs above the pipe, may also be required where depth is less than required under Paragraph (b) below.

b. Subject to Paragraph (a), provide minimum depths in accordance with 49 CFR Part 195 and federal, state and local regulations. Under roadways and shoulders of roadways, provide a minimum depth of 4 feet (1.2m).

9-4.2 Parallel and Crossing Pipes.

Provide a minimum clearance of 12 inches (300 mm) between the outer wall of any buried POL pipe and the extremity of any underground structure including other underground pipe. Where pipelines cross and a minimum clearance of 12 inches (300 mm) cannot be achieved, provide an insulating mat between the pipes and centered vertically and on the point of intersection. Insulating mat must be constructed of neoprene or butyl rubber and must be 36 inch (900 mm) by 36 inch (900 mm) and 1/8 inch (3 mm) thick. Provide a test station with two test leads from each pipe. See UFC 3-570-01, Electrical Engineering Cathodic Protection for more information. Where non-government and government owned pipe cross or are in proximity of less than 150 feet, contact owner of non-government pipe for coordination to prevent/mitigate cathodic protection interference. In areas where multiple utilities are routed in the same area (e.g., a utility corridor), make sure electrical and communication ducts/conduits are kept a minimum of 36 inches (900 mm) from all other underground utilities especially fuel, steam, and high-temperature water pipes. Refer to IEEE C2, ASME B31.4, and 49 CFR Part 195 for additional requirements. For pipes in concrete trenches, provide a minimum clearance of 6 inches (150 mm) between flanges and the trench wall and between adjacent flanges. If there are no flanges, provide a minimum clearance of 12 inches (300 mm) or one pipe diameter (based on largest pipe), whichever is greater, between the pipe and the trench wall and between adjacent pipes within the concrete trench.

9-4.3 Casing Sleeves.

The use of casings on underground pipelines is highly discouraged due to increase problems with pipe corrosion and inability to provide cathodic protection to the pipe in the sleeve. Use steel casing sleeves only for those crossings where sleeves are required by authorities having jurisdiction (i.e.: Airfield Managers), or where it is necessary to place stainless steel lines under the roadway or railroad tracks while avoiding interference with traffic. Consider installing carbon steel and stainless steel pipelines under roadways by the traditional trenching method, or use alternative trenchless pipe construction methods for carbon steel pipelines to avoid the need for a casing. Do not use directional drilling for stainless steel lines. When using alternative trenchless methods for carbon steel lines, provide supplemental abrasion resistant coatings applied in addition to the fusion bonded epoxy exterior pipe coating. When required to construct open trench cased crossings, consider the economics of installing spare casing sleeves to eliminate excavating for future fuel lines. Ensure that the casing design electrically isolates fuel-carrying pipes from contact with the casing pipes. Require a seal of the annular space at each end of the casing and spacers properly spaced in the casing, and within 12-inches of casing ends. Include a vent on the higher end of each casing and a low point drain on the lower end of the casing. Locate crossings at a minimum depth of 36 inches (900 mm) beneath the bottom of drainage ditches. If this depth cannot be obtained, install above, but not in contact with, the casing or pipe, a 6-inch (150 mm) thick reinforced concrete slab of adequate length and width to protect the casing or pipe from damage by equipment such as ditch graders and mowers. In areas with high normal or seasonal groundwater tables consider the use of a water excluding casing fill material. Refer to API RP 1102 for additional information on the use of casings. Provide cathodic protection test leads to the pipe and casing to monitor for electrical isolation.

9-4.4 Line Markers.

Except where prohibited by national security considerations, install line markers over each buried line and allow for maintenance provisions in accordance with 49 CFR Part 195.

9-4.5 Warning Tapes.

Provide buried warning tape for all underground pipelines as required by the appropriate guide specification.

9-4.6 Thermal Relief Valves.

The isolation valves installed in underground piping are generally located aboveground or underground in valve pits. Because these segments of underground piping are open to the atmosphere, they are subjected to the effects of atmospheric temperature changes and therefore, require thermal relief. Provide any section of underground piping that can be isolated by a shut-off valve (or other means) with a thermal relief valve to relieve the isolated piping section. Provide also a thermal relief of the internal cavity of valves where pressure is trapped when the valve is in the closed position (double block and bleed plug valves for example). Refer to Paragraph 9-3.5 for more details on materials, discharge, and operation of thermal relief valves.

9-4.7 Double Wall Piping.

Provide double wall piping for Ground Vehicle Fueling Facilities and any other small diameter (< 4 inches (100 mm)) underground pipe installations. For other applications (pipes ≥ 4 inches (100 mm)) in diameter do not use double wall piping unless required by state or local regulations, and approved by Service Headquarters. Service Headquarters approval to use large diameter (≥ 4 inches (100 mm)) double wall pipe must be obtained at the programming level and at the 35 percent design level. Low point drains and high point vents associated with large diameter piping systems must not be double-walled, unless required by state or local regulations, and approved by Service Headquarters. Use of FRP piping as part of double wall piping (or as single wall) is discouraged because of issues with underground joints and requires Service Headquarters approval.

9-4.8 Single Wall Piping Leak Detection Systems.

For all single wall buried pipe not used in aircraft direct fueling systems, consider providing a leak detection system similar to leak detection for aircraft direct fueling systems when approved by Service Headquarters. Do not use cable type leak detection systems for single wall piping unless required by state and local regulations.

9-4.8.1 Leak Detection for Aircraft Direct Fueling Systems.

For aircraft direct fueling systems, provide an automatic leak detection system approved by Service Headquarters, to test all buried portions of the piping system. Automatic leak detection systems measure changes in either the volume or pressure of the fuel in a fixed piping system, while accounting for variations in ambient temperature. The pressure type leak detection system works by measuring the time rate of change of line pressure at two different pressures. The volume type leak detection system works by measuring the amount of fuel required to maintain a constant pressure in a line, also at two different pressures. The system must detect leaks as required by regulations or as listed with the National Work Group on Leak Detection Evaluations (NWGLDE).

9-4.9 Double Wall Piping Leak Detection Systems for Ground Vehicle Fueling Facilities.

For all underground double wall pipe used in ground vehicle fueling facilities, provide automatic line leak detector systems that continuously and automatically monitor piping for leaks. Automatic line leak detector systems are to be provided for pressurized piping only. Detector must detect a minimum leak rate of 3 gallons per hour (0.003 L/s) at 10 psig (69 kPa) line pressure within 1 hour. Detector must detect leaks against a minimum 6 feet (1.8 m) of head pressure. Detector must detect leaks from any portion of the underground product piping. In conjunction with the automatic line leak detector system, the use of double wall piping and a continuous monitoring/alarm system must be considered. Slope double wall piping from containment sump to dispenser sump and provide leak sensors for immediate notification of piping failure. Do not use cable type leak detection systems for double wall piping unless required by state and local regulations.

9-4.10 Double Wall Piping Leak Detection Systems for Non-Ground Vehicle Fueling Facilities.

For leak detection of double wall piping at locations other than the ground vehicle fueling facilities, contact Service Headquarters for direction.

9-4.11 Service Pits.

Grading around service pits (hydrant pits, isolation valve pits, low point drain pits, high point vent pits, transition sumps, etc.) must be designed to prevent water intrusion into the pits. The pits and pit lids must be designed and constructed to be liquid tight. Concrete pits must be constructed in accordance with ACI-350. Where required by federal, state, and/or local regulations, provide leak detection systems within service pits.

9-5 UNDERWATER PIPING.

To receive fuel from offshore moorings, provide one or more underwater pipelines from the shore facility to the mooring. Limit the design of these systems to engineers with this type of experience. Coordinate offshore piping systems with Naval Facilities Engineering and Expeditionary Warfare Center, Oceans Technical Department (NAVFAC EXWC, OC).

9-5.1 Special Arrangements.

At the mooring end of each pipeline, provide lengths of submarine fuel hose equal to 2.5 times the depth at high water. At the pipe end of the hose, provide a flanged removable section of hose 10 feet (3 m) long. At the free end of the hose, provide a steel valve with a marker buoy attached to a cable or chain which has sufficient strength and suitable fittings for the vessel to lift the hose and valve aboard.

9-5.2 Connections.

Lay out multiple fuel lines and connections so that they correspond to the layout of the ship’s discharge manifold.

9-5.3 Unique Considerations.

In piping design, consider fuel characteristics as they may be affected by the sea water temperature, particularly in cold water. For diesel fuel, aviation turbine fuel, or other light fuels, small individual lines are preferable as follows:

a. Minimum nominal pipe size of 6 inches (150 mm).

b. For transfers of fuels exceeding 3,000 gpm (189 L/s), use 12-inch (300 mm) to 16-inch (400 mm) diameter pipe.

c. Instead of pipes larger than 16 inches (400 mm) in diameter, consider using two smaller diameter pipes.

d. At an accessible upland location, as close to the water entry as practical, provide a double block and bleed valve and a manually operated check valve or bypass to allow reversal of flow when required.

e. Provide a dependable means of communication between the vessel in the offshore berth and the shore facility.

9-5.4 Corrosion Protection.

Wrap, coat, and cathodically protect underwater pipelines in accordance with Chapter 2 of this UFC.

9-5.5 Depth of Burial.

Provide sufficient burial depth of underwater pipelines to prevent damage by dredging of the waterway, by ships' anchors, trawls, or by scouring action of the current. Specifically, ensure depth conforms to the requirements of 49 CFR Part 195. Where lines cross ship channels or anchorages, ensure the top of the pipe is at least 12 feet (3.7 m) below the theoretical, present or planned future bottom elevation, whichever is deeper. Recommended backfill in such areas is 2 feet (0.6 m) of gravel directly over the pipe, followed by stones weighing 50 to 60 pounds (23 kg to 27 kg) up to the bottom elevation.

9-5.6 Pipe Thickness and Weight.

Provide sufficient pipe wall thickness to keep stresses due to maximum operating pressure and other design loads within design limits. Include full consideration to extra stresses which may occur in laying the pipe. It is common practice to use heavier wall pipe for water crossings of more than 200 feet (60 m) from bank to bank at normal water level. This affords greater stiffness and resistance to buckling during handling of the assembled crossing pipe and requires less weighting material to obtain the necessary negative buoyancy to keep the line in place while empty or containing a light product. Reinforced sprayed-on concrete is an acceptable weighting material. Use of "river weights" is discouraged. Hydrostatically test assembled crossing pipe before placing, unless crossing pipe is too long for prior assembly in one segment. In this case, separately test each segment as described.

9-6 PIPING MATERIALS.

9-6.1 Non-Aviation Systems.

Use carbon steel piping material for interterminal pipelines (regardless of product) and for all portions of non-aviation turbine fuel systems. FRP is not to be used in aviation turbine fuel system applications. The appropriate Unified Federal Guide Specification (UFGS) includes the necessary requirements. See Facility Plate 019.

9-6.2 Aviation Systems.

New aviation turbine fuel systems must use stainless steel issue piping downstream of the last issue filter-separator all the way to the final hose or hard piped aircraft or refueler nozzle connection. Interior coated carbon steel may be used downstream of the last issue filter-separator only with the approval of the Service Headquarters. Return piping must be interior coated carbon steel, unless stated otherwise. Return piping on Navy/Marine Corps systems must be stainless steel, unless authorized by Service Headquarters. Give special consideration to the pressure rating of both the pipe and fittings to ensure adequacy to accommodate surge pressure. See Facility Plate 019 for piping material options.

9-7 WELDING CRITERIA.

Ensure that the contract requires welding and welding inspections in accordance with appropriate guide specifications and/or standard design. Proper welding, done in accordance with the guide specifications, will prevent loose and adhered slag on the inside of the pipeline. Use 100 percent radiographed weld joints meeting the standards for severe cyclic service contained in ASME B31.3 for piping downstream of the pump in hydrant systems. For all other underground steel pipes, use 100 percent radiographed weld joints meeting the requirements of ASME B31.3. Use of alternates to radiography must be approved by Service Headquarters and should be considered where radiography is prohibited or impractical (off shore). If used, Phase Array UT (PAUT) with permanent digital recording/record must be used.

9-8 PIPING CONNECTIONS.

a. For steel piping systems, use weld neck forged flanges with raised faces having a modified spiral serrated gasket surface finish, except for piping 2-inch (50 mm) and less located in contained pumphouses, contained truck offloads, contained truck fillstands, and other visibly contained areas, where socket weld flanges may be used. Slip-on flanges are not permitted in new systems. Use of slip on flanges may be considered in connections between new and existing systems/components only when dimensional factors prevent the effective use of weld neck flanges. Use flat face flange and gasket only when connecting to flat face system component flange, such as aluminum vessels and some pump flanges.

b. Do not use cast iron flanges.

c. Do not use grooved pipe type couplings or similar fittings in permanent fixed piping systems.

d. Do not direct bury flanges, valves, mechanical couplings, threaded fittings, or any mechanical system component. If they must be used in an underground system, enclose them in an accessible pit.

e. Use welded connections for joining steel pipe. Use flange connections for joining pipe to system components. Use threaded connections only where unavoidable such as on differential pressure gauges, pressure snubbers, and fuel sample connections. Do not back weld threaded piping.

f. Use carbon steel bolts, studs, and nuts with carbon steel flanges. Use stainless steel bolts, studs, and nuts with stainless steel flanges. Stainless steel bolts may be used on carbon steel flanges in corrosive environments. Select stainless steel bolts, studs, and nuts based on seizing and elongation. Coordinate both strength with force needed to compress selected gasket. In locations where severe corrosion (typically chloride laden salt air) on carbon steel piping is susceptible use flange protectors and bolt seals (caps), filled with non-expansive grease preservative, as required to prevent and control corrosion.

g. In steel piping systems, use socket weld joints on 2-inch (50 mm) diameter nominal size and smaller pipe, except underground low point drains must be butt welded only.

h. Make branch connections with butt welded tees except where the branch is at least two pipe sizes smaller than the run, in which case the branch connection can be made with a forged or seamless branch outlet fitting. The branch outlet fitting must be designed in such a way that the connection can be radiographed. The branch outlet fittings may be a non-radiographicable if: the piping it is connected to is aboveground, the branch outlet size is 2.5-inches or less in diameter, and the branch outlet is located either in a pumphouse or on a system component pad equipped with containment curb.

i. Do not use wrinkle bends or mitered bends for changes in direction.

j. Except for unions and control tubing couplings, do not use threaded joints in stainless steel systems. Socket weld stainless steel drain, vent, and thermal relief valve lines 2-inch (50 mm) in diameter or less. If aboveground, flanges may be used.

k. Provide over-voltage protection (OVP) devices for all above grade flanges with insulating flange kits. Provide insulating flange kits elsewhere where electrical isolation is needed as specifically required by DoD Standard Designs, such as in hydrant pits.

l. Provide insulating flange kits at locations required for the proper performance of cathodic protection systems on underground piping. This is to include insulating gaskets, bolt sleeves and washers of compatible materials, matching the flange types and ratings. Attention must be given to electrically isolating alternate ground paths such as thermal relief lines, instruments and conduit brackets. Insulating sleeves must pass through all bolt washers and OVP brackets. Washers must be assembled in the proper sequence and bolts tightened to recommended torque.

9-9 INTERIOR PIPE COATINGS.

To protect aviation fuel quality and extend the life of the piping, minimize bare carbon steel piping (except interterminal pipeline) which comes in contact with aviation turbine fuels especially downstream of initial filtration system components. Maximize the use of internally coated pipe. This is not intended to allow the use of lined carbon steel piping as a substitute for areas requiring non-ferrous piping. Comply with other paragraphs of this chapter for material selection. Interior pipe coating is not required on non-aviation piping except for carbon steel piping that connects to the tank within the lower 36 inches (900 mm) of aboveground vertical storage tanks, and ballast lines on piers.

9-10 EXTERIOR PIPE COATINGS.

a. Protect the exterior surfaces of all aboveground and underground steel piping systems in accordance with applicable service requirement.

b. For coating of underwater piping, coordinate with Naval Facilities Engineering and Expeditionary Warfare Center, Oceans Technical Department (NAVFAC EXWC, OC).

9-11 SAMPLING FACILITIES.

Provide connections for sampling fuels on each section of a fuel transfer piping system. Install sampling and testing connections at receiving points, tank outlets, inlet and outlet sides of filter-separators, all fuel dispensing points, and between isolation valves so that the remaining fuel in each portion of a fuel transfer pipeline can be sampled. Where possible, install sampling connections in vertical runs. Provide a sample point with a probe, ball valve, and quick disconnect with dust cap.

CHAPTER 10 ALTERNATE POL FACILITIES

10-1 INTORDUCTION.

This chapter provides guidance for design of alternate POL facilities. The alternate fuels discussed are: LPG, CNG, hydrazine, and OTTO fuel. This chapter contains information on products which are unique. Therefore, some special considerations are discussed, in addition to information provided in Chapter 2, General Design Information, which contains important information on fueling facilities. Do not start the design of any fueling system without first becoming completely familiar with Chapter 2 of this UFC.

10-2 LIQUEFIED PETROLEUM GAS (LPG).

10-2.1 Uses.

The uses for which LPG fuel is procured and the methods of transportation of the fuel are as follows:

a. LPG fuel is used for general heating, metal cutting and brazing, and in laboratories. LPG is procured in cylinders or for bulk storage by tank car or tank truck. Cylinders usually contain 100 pounds (45 kg) of gas, in a liquid state.

b. Fuel supply for firefighting trainers and crash and rescue training facilities.

c. Where economically justified, LPG facilities supplement utility-supplied gas systems for meeting peak loads and as a standby where interruption to a supply is possible.

    1. Standby LPG facilities serving large capacity system components, such as boilers of 200,000 British thermal units (Btu's) per hour (58 000 W) and above, may consist of a separate gas system to an alternate set of burners on the system components.

    2. For a gas system serving multiple small appliances, provide the standby equipment with means for air mixing to dilute the LPG with the proper amount of air to match combustion characteristics of either natural or manufactured gas serving the system in place of the utility-supplied gas, or in conjunction with it to reduce utility peak loads.

10-2.2 General Design Considerations.

LPG is odorless, colorless, non-toxic, heavier than air, and explosive. To permit easier leak detection, an artificial odor may be introduced when shipped from a refinery. Under standard atmospheric conditions, LPG is in a vapor phase, but it is liquefied under moderate pressure for shipping and storage. The maximum vapor pressure for LPG design is 215 psig (1480 kPa) at 100 degrees F (38 degrees C). All LPG purchased by the military should emit a distinct odor at a concentration required by NFPA 58. See Facility Plates 024, 025, 026 and 027.

10-2.2.1 Fire Hazards.

In the vapor phase, LPG is a hazard comparable to flammable natural or manufactured gas. The explosive range is 2.16 to 9.6 percent by volume of air-gas mixture.

a. Provide ventilation in accordance with NFPA 58.

b. In the liquid phase, LPG is a highly volatile, flammable liquid. Because of rapid vaporization, an LPG fire is basically a gas fire. Therefore, in the event of a fire, provide means to automatically shut off the LPG supply feeding the fire.

c. Provide emergency shut-off consisting of the combination of three modes: manual shut-off, remote shut-off, and thermal shut-off. Remote shut-off normally consists of a nitrogen system with plastic tubing at the controlled point so that the pressure holds open the valve. The plastic tubing acts as a fusible link. Provide a cable release shut-off with remote shut-off for combination shut-off. Refer to UFC 4-179-01 and API Std 2510.

d. Provide leak detection in accordance with NFPA 59.

e. For LPG system component located inside buildings where there is a potential for loss of LPG, provide an alarm/detection system with local and remote alarms (audible and visual), high and low ventilation, doors with panic hardware, a leak detector readout with the readout outside, and a leak detector kit located outside.

10-2.2.2 Refrigerating Effects.

At normal atmospheric pressure, the boiling point of propane is -45 degrees F (-43 degrees C). Propane in a liquid state and open to the atmosphere will evaporate (not boil).

a. Provide means to address operational concerns as described in the following paragraph. When LPG is expanded through a regulator from its vapor pressure to normal service pressures, the cooling effect may freeze the regulator if water is present in the LPG. Freeze-up can also occur on system components which accumulates water such as strainers and control valves. The freezing effect can also result in exterior ice formations which disrupts the valve operator. Freeze-ups can be avoided by cleaning and nitrogen-purging the system.

b. Although it is dehydrated at the refinery, provide a means to keep LPG dry.

c. In flashing to vapor from the liquid phase, the refrigerating effect can be severe if an abrupt pressure drop occurs. Therefore, design a system which provides means to avoid this problem.

10-2.2.3 Design Standards.

Use the following references for general design and safety standards for all LPG facilities. (Follow particular sections of standards applicable to types of facilities. Where conflicts occur, use the more stringent requirements.) Appropriate standards are as follows:

a) Factory Mutual Engineering Corp. (FM), Loss Prevention Data, Liquid Petroleum Gas, Section 7-55.

b) NFPA 54, NFPA 58, and NFPA 59.

c) API Std 2510.

d) Gas Processors Association Standard 2140.

e) Commercial Item Description A-A-59666, Sections ICC 4BW, ICC 4E, and ICC 4BA.

f) UFC 4-179-01.

10-2.3 Receiving Facilities.

10-2.3.1 General Design Considerations.

LPG may be received by truck, rail, or water for either cylinder (bottled gas) or bulk systems.

10-2.3.2 Transfer Methods.

\3 Design the facility to accommodate one of the following transfer methods: ***/3/***

a. No pumping or pressurizing facilities are required for small bulk systems utilizing truck delivery. Use pumping system components provided on trucks instead of stationary pumps.

b. Provide LPG vapor piping, pumps, and compressors for off-loading tank cars or waterborne LPG tanks to operate, as follows:

    1. Provide compressor and piping to take suction from the vapor space of the storage tanks to be filled through an equalizing line and pressurize the tank to be off-loaded. This forces the LPG out through the liquid off-loading line into the storage tank.

    2. Arrange the piping so that after all liquid has been evacuated, the compressor suction can be reversed to pump the LPG gas from the delivery tank to the storage tank through a subsurface dip tube.

    3. Provide connections and valving to allow bleeding of the liquid propane from the connection after shutting off the valve at both the

hose end and at the off-loading piping. This is done after off-loading the liquid from either a transport truck or a tank car. Provide a bleed attachment built into the off-loading system components for this purpose.

4. See Facility Plates 024, 025, 026 and 027 for typical installation. Provide liquid pumps as standbys for compressors.

c. Provide the transfer point from trucks or tank cars with a substantial concrete bulkhead. Anchor the piping in the bulkhead. Do not use pipe sleeves. Provide with the bulkhead hose or swivel-type piping connections. The bulkhead provides a breakaway point if the truck or tank car moves away without first disconnecting the hoses. Also provide emergency shut-off and excess flow valves. Refer to NFPA 58 and UFC 4-179-01 for additional information.

10-2.3.3 Flow Rates.

Use the following flow rates:

a. Provide flow rates commensurate with the storage capacity and the size of pumps, compressors, and loading devices.

b. Provide flow rates that allow operators adequate time to shut down facilities before tanks or trucks are filled beyond maximum allowable. Limit flow rates from tanks by setting excess flow valves.

c. Provide off-loading lines with manually operated throttle valves so operators can adjust flow rates to points below shut-off settings of excess flow valves.

10-2.4 Storage Facilities.

10-2.4.1 Types of Storage.

Types of storage facilities include cylinders or bulk storage tanks.

a. Provide cylinders or containers conforming to ASME and/or DOT criteria as described in guide specifications. Used tanks are not allowed. The number of cylinders at a facility depends on the maximum required flow rate and the vaporization rate per cylinder at the minimum operating temperatures.

b. Provide bulk storage tanks as follows:

1. For storage tanks up to 30,000 gallons (114,000 L) capacity, use horizontal steel tanks.

2. For storage tanks above 30,000 gallons (114,000 L) capacity, use spherical or spheroidal steel tanks.

3. Do not use underground tanks for LPG.

10-2.4.2 Number and Size of Bulk Tanks.

Storage capacity depends on requirements, frequency of deliveries, and dependability of supply. Consider a multi-tank system for more dependability.

10-2.4.3 Design Requirements.

Design requirements are as follows:

a. Tanks and tank appurtenances require conformance with NFPA 58 and API Std 2510. Design LPG tanks for a minimum working pressure of 250 psig (1700 kPa).

b. Tank spacing requires conformance with UFC 4-179-01 and FM criteria. See Facility Plates 026 and 027.

c. Provide sufficient flexibility in piping connections to tanks to allow for differential settlement of tank and system components.

d. Provide cathodic protection in accordance with Chapter 2 of this UFC.

e. If using compressor transfer systems, fit tanks with dip pipes a minimum of 3/4 inches (20 mm) diameter, and gas inlet lines from compressors, so that gas pumped into storage tanks from empty delivery vessels is bubbled through liquid LPG to prevent overpressuring tanks.

f. Provide float-actuated high-level alarms set at maximum permissible filling level of 80 percent on all tanks of 3,000 gallon (11,000 L) capacity and above.

g. If using installed transfer systems, provide pressure switches on tanks set to open at pressures 5 psig (35 kPa) below set pressures of safety valves to stop compressor pumps transferring LPG to tanks.

h. Ensure that tanks are ASME coded and have the ASME national registration number.

i. Size storage tanks for 120 percent of required storage volume.

j. Electrically ground all storage tanks.

10-2.4.4 Inspections, Testing, and Certifications

Inspect, test, and certify all new unfired pressure vessels prior to placing into operation. Do not operate the unfired pressure vessel (UPV) without a valid certificate. Perform the following tests on the UPV:

a. A general UPV site inspection

b. An external UPV inspection

c. An internal UPV inspection

d. A hydrostatic test (strength and tightness tests)

e. An operational test

The inspector must be registered by the National Board of Boiler and Pressure Vessel Inspectors (NBBI) and must possess a Certificate of Competency and a NBBI National Board Inspection Code (NBIC) Commission. Upon completion and passing of the inspections and tests, the tank will be certified. Post a current, valid certificate on or near the UPV under a protective coating.

10-2.5 Distribution Facilities.

See Facility Plates 024, 025, 026 and 027.

10-2.5.1 General Design Considerations.

The following distribution system requirements apply to the transfer of both the gas and liquid phases of LPG:

a. Lay all distribution piping underground when practicable.

b. Provide the required flow rates.

c. Install electrical system components in accordance NFPA 70 and API RP 500. Use only system components approved for each classified area. Ensure electrical design conforms to API RP 540.

d. Ground and bond all piping, tanks, and system components in accordance with API RP 2003, API Std 2510, API RP 540, and NFPA 70.

e. Refer to Chapter 2 of this UFC for corrosion protection requirements of underground pipe.

10-2.5.2 Piping Materials.

Provide pipe, valves, and fittings in accordance with applicable sections of API Std 2510. Use Schedule 80 welded carbon steel. Threaded connections are only allowed for valves and system components. Provide design characteristics and features for gas and liquid pipelines in accordance with Chapter 9 of this UFC. The minimum design pressure for liquid LPG piping is 350 psig (2400 kPa) as required by NFPA 58. Use Class 300 ANSI flanges as a minimum.

10-2.5.3 Accessories.

a. Provide totalizing-type meters, pressure gauges, thermometers, strainers, and surge suppressors.

b. Ensure that meters are turbine-type with pressure and temperature compensation and have electronic/digital readout capability.

c. Install meters, if required, in accordance with requirements of API MPMS Chapter 5.

d. Provide pressure gauges of suitable range on all tanks, on suction and discharge of pumps and compressors, on inlet and outlet of vaporizers and on downstream of throttle valves.

e. Provide thermometers on all tanks, in all transfer lines for both liquid and gas, and on inlet and outlet of vaporizers.

f. Provide strainers in compressor suctions, upstream of meters and control valves.

g. Provide surge suppressors on liquid lines, if required.

h. Provide knock-out drums or scrubbers of suitable capacities in suction lines of compressors to remove entrained liquid. Provide drums with high level, shut-down devices, automatic liquid drainers, glass gauges, and drains.

i. Ensure all valves are UL listed or FM approved for LPG service. At a minimum, use Class 300 valves.

j. Provide equipment to inject alcohol into the LPG off-loading line. Provide equipment capable of injecting alcohol at a rate of 1:800 alcohol to LPG by volume.

10-2.5.4 Pumps and Compressors.

Design and install pumps and compressors in accordance with API Std 2510 and NFPA 58.

10-2.5.5 Vaporizers.

Provide vaporizing system component for distribution facilities as follows:

a. Provide vaporizers at locations where liquid temperatures are too low to produce sufficient vapor pressure to meet the maximum required flow rate.

b. Use vaporizers that are indirect fired-type utilizing steam or hot water as a heating medium or direct fire waterbath-type.

c. Size vaporizers to provide at least 125 percent of expected peak load.

d. Design and install vaporizers in accordance with NFPA 58.

e. Use waterbath vaporizers approved by Factory Mutual.

f. Space waterbath vaporizers in accordance with FM Section 7-55, except provide a minimum of 75 feet (23 m) between truck off-load stations and tank storage. Where space is limited, provide a blast wall at the truck off-load stations.

g. When using waterbath vaporizers, provide fire-safe fusible link shut-off valves in LPG supply piping at the vaporizers. Provide remote shut-off capability and 24-hour remote monitoring.

h. When using waterbath vaporizers, provide an automatic excess flow/emergency shut-off valves in LPG supply lines to vaporizers. Use a hydraulically operated diaphragm control valve and locate at tank storage.

10-2.5.6 Controls.

Provide the following controls.

a. Use pumps and/or compressors that can be started and stopped by manual pushbutton.

b. Provide automatic limit switches as follows:

   1. Pressure switches on storage tanks set 5 psig (35 kPa) below relief valve settings.

   2. Liquid level switches on storage tanks set at maximum filling levels.

   3. Liquid level switches on knock-out drums set to shut off compressor at high liquid levels.

   4. High pressure switches in compressor discharges to shut off compressor at safe pressure levels.

c. Provide manually operated throttle valves in liquid off-loading lines to adjust flow rates below excess flow valve settings on delivery tanks.

d. Provide a sight flow indicator in liquid lines near throttle valves.

e. Provide automatic temperature, pressure, and limit controls on vaporizers in accordance with NFPA 58.

10-2.6 Air Mixing Facilities.

10-2.6.1 Pressure Controls.

Provide pressure control valves in both air and gas lines to air mixing system component. Provide a low pressure alarm in both lines to shut-off air and gas in the event of low pressure.

10-2.6.2 Volumetric Controls.

Provide volumetric controls at all distribution facilities as follows:

a. Provide displacement-type or flow-type meters in both air and gas lines to maintain a proportional flow of air and gas.

b. Use a venturi-type proportioner where the variation in demand flow rate does not exceed the limited range of the venturi proportioner. Where the demand flow rate varies excessively, use a venturi-type proportioner in conjunction with a downstream storage tank, if economically justified. The storage tank will permit a varying rate of flow to the system while being filled continually or intermittently at a constant rate of flow through the proportioner.

10-2.6.3 Specific Gravity Indication.

Provide a specific gravity indicator and recorder with high and low-limit switches to sound an alarm if the variation of specific gravity of an air-gas mixture exceeds acceptable limits of the system. For air mixing systems using LPG with a propane content of 90 percent and above, the specific gravity of the air-gas mixture is a sufficiently accurate index of its Btu or joule (J) content, so calorimetric controls and indication are not required.

10-2.6.4 Calorimetric Controls.

Where economically justified, provide an automatic calorimeter to indicate and record the Btu or J content of the air-gas mixture. Provide high- and low-limit switches to calorimeter to sound an alarm if the variation of Btu content exceeds acceptable limits of the system.

10-3 COMPRESSED NATURAL GAS (CNG).

Design CNG storage and dispensing facilities to comply with NFPA 52 and appropriate sections of NFPA 55.

10-3.1 Uses.

CNG is primarily used as an alternative fuel in light duty vehicles although it and its cryogenic counterpart liquid natural gas are gaining acceptance in heavy duty applications. Energy policy has mandated with certain reservations that by fiscal year 2000 and thereafter, 75 percent of the light-duty vehicles purchased by the government will use alternative fuels. Therefore, there will be a significant increase in alternative fuel consumption.

10-3.2 General Design Considerations.

10-3.2.1 System Sizing.

To size the system, determine the total daily fuel consumption of base liquid natural gas vehicles. Based on daily miles driven, determine the number to be refueled each day. The number of vehicles refueled during surges limits the capacity of most fast fill (3 to 6 minutes) operations. Scheduling vehicles to refuel through the day will effectively increase system capacity. Use a computer program to size the system because manual calculations usually result in larger systems than needed. Refer to the Gas Technology Institute GTI-02/0136 in the References section of this UFC for ordering information of one possible program. Use the latest version.

10-3.2.2 Future Requirements.

Anticipate future requirements when sizing the system but normally limit the project to 100 to 150 standard cubic feet per minute (scfm) (47 to 71 L/s). If additional capability will be needed in the future, plan a second system later or consider other options such as slow fill systems for overnight fueling. This will provide redundancy and reduce initial cost. Usually, surge requirements drive machine size and can be controlled by management actions. Additionally, boosters operating from system pressure or special control systems may increase surge handling capacity (e.g., 25 to 30 percent of the gas in a cascade system is available for fast fill operations. A booster or special control system can increase it to 60 percent.) The combination of these actions could delay installing a second system many years at most installations.

10-3.2.3 Pressures.

Most vehicle conversions use 3,000 psig (21 000 kPa) storage systems while original system component manufacturers use 3,600 psig (25 000 kPa) systems. The compressors should operate up to 5,000 psig (35 000 kPa) to refuel at either pressure.

10-3.2.4 Connections.

Design the systems to be skid-mounted with compressor system, cascade storage, and controls. Limit field tie-ins to connecting electricity and high and low pressure gas.

10-3.2.5 Compressors.

Use crosshead guide type compressors for CNG service. Although more expensive, the design life of these units is significantly longer. Another option is a conventional style compressor designed specifically for CNG service. Do not use modified air compressors. Choose the type compressor after comparing maintenance and reliability data. Test all compressors at the factory with natural gas before shipping.

10-3.2.6 Compressor Drives.

Use either electric or engine-driven compressor drives. Gas engine drives are less expensive to operate, but maintenance costs are higher. Use a life cycle cost analysis to determine which compressor drive is best. Although an engine-driven compressor is more expensive than an electric motor, electrical upgrade costs may be reduced. It also may be able to operate during power outages.

10-3.2.7 Compressor Inlet Pressure.

Suction pressure is a key factor in selecting a compressor. Use high pressure gas mains to reduce both initial and operating costs. Avoid pressures less than 20 psig (140 kPa). If high and low pressure lines are near each other and the pressure differential is at least 150 psig (1030 kPa), 250 psig (1720 kPa) is preferred, and the low pressure line has a continuous load, a system can be installed and powered by the differential pressure. Such systems are extremely effective and have low initial and operating costs. Where a high pressure differential exists, another option is a turbine to drive the compressor.

10-3.2.8 Storage.

Install a cascade system using ASME vessels; either tubes or spheres. Avoid banks of DOT cylinders since they must be inspected every 5 years.

10-3.2.9 Controls.

Use either pneumatic or electronic controls depending on local practices. Electronic controls are preferred in most areas because they provide more accurate compensation for temperature effects. Pneumatic controls are simpler, but do not fill tanks to their limits. Normally, this is not a problem, since base vehicles do not normally operate to their maximum range in one day. Since vehicle tank pressures are rated at 70 degrees F (21 degrees C), tanks will fill to a higher pressure when outside temperatures are warmer and to a lower pressure when temperatures are cooler.

10-3.2.10 Dispensers.

Although more expensive, provide conventional rather than post style dispensers. To reduce installation costs, use dispensers with the electronics internally mounted and calibrated at the factory. A dispenser makes CNG refueling similar to conventional refueling. Depending on funds, a post style dispenser is an option.

10-3.2.11 Nozzles.

Use the industry standard nozzle. It comes in three pressure ranges: 2,400 psig (16 500 kPa), 3,000 psig (21 000 kPa), and 3,600 psig (25 000 kPa). These nozzles are designed so that a fill system cannot connect to a vehicle tank with a lower pressure rating, yet it can connect to vehicle tanks with higher ratings.

10-3.2.12 Environmental Considerations.

a. The compressor unit’s receiver is usually blown-down automatically, releasing about 0.06 gallons (0.2 L) of oil to the base and subsequently the ground. Discharges from other components, such as intercoolers, add to the contamination. Therefore, drip gutters with drains are required at each corner of the base. Develop a means of collection and retention of these wastes. Deactivating the automatic dump features and manually draining is an alternative to a collection system.

b. Provide gas recovery system as part of the compressor package to recover gas into an ASME recapture tank when off-loading the compressor.

c. At the dispenser, provide a vent 8 feet (2.4 m) to 10 feet (3 m) above ground level to discharge vent gas from dispenser hoses. Oversize the conduit from the dispenser to the cascade for a vent line to a future gas recovery system.

d. Locate units with care because of noise. Use landscaping to conceal units and attenuate the sound.

e. Natural gas engine drives, if used, may require an air emissions permit.

10-3.2.13 Weather.

As a minimum, protect compressor units from the weather with a canopy. In colder climates, use a heated shelter/enclosure with sound attenuation. Some vendors have enclosures as normal options. Costs vary widely depending on the degree of protection. Enclosures may require ventilation and Class I, Division 1 classified electrical components. They should also be accessible by inspectors and servicing personnel. In lieu of a heated facility/enclosure, crankcase heaters and/or circulating block heaters may be suitable in moderately cold climates.

10-3.2.14 Coatings.

The CNG system component comes factory-painted. Specify special coatings where climatic conditions warrant. Select a color from the base color scheme. Light beige is a practical choice. White is a poor choice since the heat of operation discolors it. Storage containers may have to be painted white with blue letters to meet codes.

10-3.2.15 Water Content.

Water content in natural gas varies with region. Gas in the Southeast United States is usually dry, while gas from West Virginia is very wet. Provide dryers to dry the gas to a pressure (storage pressure) dew point (PDP) at least 10 degrees F (6 degrees C) below the winter design dry bulb temperature.

10-3.2.16 Design Standards.

Design CNG systems to NFPA 52. Use NFPA 54 for the gas supply to the compressor. Use the ASME Boiler and Pressure Vessel Code (BPVC) for cascade storage. Electrical work must conform to NFPA 70. When collocating CNG and gasoline stations, also use NFPA 30A.

10-3.3 Warning.

During peak demand periods, some suppliers mix propane air mixtures with natural gas. When the amount added exceeds 10 percent by volume, the CNG produced from this gas will normally not perform properly in CNG vehicles because propane becomes a permanent liquid in storage tanks. Oxygen sensors can be installed to shut down the station during such periods. Installations with this situation should use dual fuel vehicles.

10-4 HYDRAZINE STORAGE AND SERVICING FACILITIES.

10-4.1 Uses.

A blend of 70 percent hydrazine and 30 percent water, known as H-70 fuel, is used to operate the F-16 emergency power unit (EPU). The F-16 H-70 tank carries 56 pounds (25 kg) of fuel and requires servicing after the fuel has been used. The H-70 tanks are removed from the aircraft when the fuel is depleted below a level specified by the using activity. The tanks are delivered to the servicing facility where any remaining fuel is drained into a closed 55-gallon (210 L) stainless steel drum. The aircraft H-70 tank is filled using a closed system charging unit and is either returned to the aircraft or placed in a handling/storage container for future use. The bulk H-70 storage tank is a 55-gallon (210 L) stainless steel drum containing approximately 51 gallons (190 L) of H-70. Nitrogen gas is used as an inert pressure head in the bulk drum to transfer H-70 to the charging unit. The charging unit is 75 inches (1900 mm) long by 36 inches (900 mm) wide by 92 inches (2340 mm) high and weighs approximately 475 pounds (216 kg). An F-16 tactical wing is expected to use approximately 100 gallons (380 L) of H-70 per 20,000 flight hours with an additional minimum of 150 gallons (570 L) held in reserve to handle deployment/safety stock requirements.

10-4.2 General Design Considerations.

a. H-70 carries the compatibility group designation of Group C.

b. Separate H-70 fuel storage and liquid/gaseous oxygen storage in accordance with AFMAN 91-201. Locate the facility a minimum of 50 feet (15 m) from aboveground explosive storage in accordance with AFMAN 91-201.

c. Locate the facility a minimum of 100 feet (30 m) from public highways; civilian or government living areas; public facilities such as schools, churches, clubs, sewage treatment plants; or rivers, lakes, or streams because of bio-environmental considerations.

d. Segregate the servicing and storage facility from large population concentrations within the confines of a military installation and subject to the criteria stated above.

e. Store 55-gallon (210 L) drums of hydrazine in facilities no less than 80 feet (24 m) apart. The spacing is also subject to the other criteria stated in this chapter. This criterion is limited to ten 55-gallon (210 L) drums and 20 EPU tanks (provided the tanks are stored inside an approved shipping container).

f. Refer to Air Force TO 42B1-1.

10-4.3 Construction Concepts.

Provide the H-70 facility with space for tank servicing, storage, and personnel hygiene.

10-4.3.1 Access.

a. Provide security fencing with a vehicle entrance gate surrounding the facility to restrict access.

b. Provide a doorway leading into storage areas to allow for forklift access.

10-4.3.2 Architectural.

a. The total area recommended for the facility is 783 square feet (73 m2) with H-70 and N2 bulk storage occupying 210 square feet (20 m2), a servicing and storage area of 449 square feet (42 m2), and a personnel area of 124 square feet (12 m2).

b. Provide ceiling height of 12 feet (3.7 m) in storage and servicing areas and 8 feet (2.4 m) in personnel areas.

c. Provide hollow, metal, exterior and interior doors with panic hardware and automatic closure. Provide double doors, 6 feet (1.8 m) wide to allow for system component movement. Ensure single doors are standard size.

d. Provide a rack in the servicing and storage area for vertical drum storage (bung side up) to allow for drainage of flush water. Construct storage rack of hydrazine compatible materials such as stainless steel, plastic, or high-density polyethylene (HDPE).

e. Design floors to permit drainage and prevent collection of liquids on any floor surface.

10-4.3.3 Fire Protection Systems.

A wet pipe sprinkler system is recommended. Consider above-ceiling detectors, as well as room detectors. Provide fire extinguishers of a type approved for use in combating hydrocarbon fuel fires in regulated areas. **\1\ /1/** Do not use halogens or CO_2 extinguishers. Refer to Air Forces TO 00-25-172.

10-4.3.4 Spill Containment.

a. Provide spill containment in the H-70 storage area with a capacity equal to the larger of 110 percent of the largest drum present or 10 percent of the total volume present.

b. Spill containment for facilities which store only one or two drums of H-70 can be individual containers for each drum.

c. Provide a diked containment area for facilities which store multiple drums of H-70.

   1. Provide ramps for vehicle access.

   2. Provide a coating or liner for concrete containment areas. Do not allow exposed iron or rebar in the containment area.

10-4.3.5 Floor Drains.

a. Provide a concrete floor in the regulated areas, sloped to floor drains which lead to a containment tank.

b. Provide a floor trench drain 18 inches (450 mm) wide by 6 inches (150 mm) deep by 9 feet (2.7 m) long, covered with an open stainless steel grate in the H-70 fuel tank servicing area. The trench is required to contain any possible H-70 spillage and periodic draining of the H-70 servicing stand. Construct the trench parallel to the wall separating the storage area from the servicing area. Locate the servicing stand so the drain spigot from the scrubber is in-line with the trench drain. A polypropylene or polyethylene elbow connection directly from the drain spigot to the trench drain is required.

c. Ensure emergency shower and eyewash station in the servicing area drain into the containment tank.

d. Ensure industrial sink in the protective system component room drains into the containment tank.

e. Equip drains leading to the containment tank with traps to prevent vapors from contaminating the area.

f. Provide access to the sanitary sewer for both clean change room and shower facilities.

g. Construct floor drains which are subject to carrying H-70 residue of polypropylene or polyethylene.

10-4.3.6 Collection Tank and Piping.

a. Provide a collection tank and piping of materials compatible with hydrazine, water, and neutralizer.

b. Size the collection tank to contain 100 times the maximum quantity of H-70 that could spill with a minimum capacity of 1,000 gallons (4,000 L).

c. Provide piping of 304 stainless steel, HDPE, or to a limited extent, galvanized steel.

d. Provide gaskets of suitable materials such as Viton.

e. Test the system annually with water.

10-4.3.7 Grounding.

In the storage area, provide a ground strap or grounding point system to ground each drum of H-70. Locate the grounding strap around the interior walls of the storage room, 54 inches (1370 mm) above the floor. The grounding system must have a resistance of 25 ohms or less. The facility must also have an approved lightning protection system.

10-4.3.8 Hygiene Support Criteria.

a. Provide lavatory washing facilities in a non-regulated area close to the exit from the regulated area and contiguous to the clean change room.

b. Provide shower facilities for each 10 or less workers.

c. Provide a clean change room. Provide a separate area for the removal of contaminated clothing to prevent the spread of potential contamination from the regulated area.

d. Provide toilet facilities if the H-70 facility is isolated from other buildings where toilet facilities are available.

e. Post signs which state that consumption of food, beverages, cosmetics, tobacco products, and chewing materials are prohibited.

10-4.3.9 Lighting.

Provide lighting intensities of 50 foot-candles (540 lux) in the servicing area and 30 foot-candles (320 lux) in the remainder of the facility. Provide exterior lighting at all entrances and security lighting as required.

10-4.3.10 Safety.

a. Provide vapor sniffers for use in the H-70 fuel drum storage area and servicing area to alert personnel to excessive levels of H-70 fuel vapors. Provide sniffers capable of detecting 10 ppb of H-70.

b. A facility respirator air system is recommended. Breathing air must meet at least the minimum Grade D breathing air requirements of 29 CFR Part 1910.134 and Compressed Gas Association (CGA) Pamphlet G-7.1.

c. Provide an explosion-proof observation window (4 feet (1.2 m) by 4 feet (1.2 m)) between the H-70 fuel drum storage area and the tank servicing area.

d. All lighting fixtures, electrical outlets, and electrical components located within the storage and servicing area should be explosion-proof.

e. Provide emergency shower and eyewash station within sight of and on the same level as locations where direct exposure to H-70 might occur. Pipe eyewash and showers to the H-70 collection tank.

f. Post signs at entrances to all areas. Signs should warn personnel that “H-70 is a cancer suspect agent,” “Authorized Personnel Only,” and “No Smoking.”

g. All tools and system components must be constructed of hydrazine compatible, rust-free, corrosion-resistant materials.

10-4.3.11 Utilities.

a. For electricity, provide 120-VAC, 60-Hz, single phase, three-wire, 20 amperes, duplex convenience outlets in each area of the facility (minimum six outlets). Two-way switching is preferred to control lighting in the H-70 fuel drum storage area from the H-70 fuel tank servicing area. Provide explosion-proof, Class I, Division 2, Group C electrical fixtures.

b. Provide 15 gpm (1.0 L/s) hose bibb water outlets with backflow prevention. Size hose bibb for standard lawn hose connections. Locate the hose bibb to provide water to service stand on the inside of the exterior wall, on the center of the servicing trench, about 2.5 feet (0.8 m) above the finished floor (below the 4-inch (100 mm) pipe sleeve). Water with a reduced pressure-type backflow preventer will also be required for the fire suppression system and potable water systems.

10-4.3.12 Ventilation.

a. Segregate mechanical ventilation for regulated versus non-regulated areas. Exhaust regulated areas through a common manifold. Evaluate the need for an air pollution control system on a case-by-case basis and consider federal, state, or local emissions criteria applicable to the construction location.

b. Design ventilation systems for regulated areas to maintain a negative pressure of 0.05 to 0.1 inches of water (12 to 25 Pa) with respect to adjacent non-regulated areas.

c. Design ventilation for servicing and storage areas to provide a minimum of 20 air changes per hour.

d. Design the ventilation system for automatic shutdown in the event of a fire within the facility.

e. Use flexible exhaust vent of the “elephant trunk” type to exhaust vapors that are released when full hydrazine drums are opened. Design for air flow at the vent nozzle to be approximately 150 cfm (71 L/s). Refer to American Conference of Governmental Industrial Hygienists (ACGIH), Industrial Ventilation: A Manual of Recommended Practice for Design.

f. Place exhaust ports at approximately 18 inches (450 mm) above the floor. To avoid exhausting H-70 vapors into areas where personnel are present, such as walkways or escape paths, consider placing exhaust ports above the roof line.

g. Place a switch on the outside of the building, near an entrance that will allow personnel to turn on all exhaust fans prior to entering the facility. This will purge the facility of any H-70 vapors that may have collected in the facility while not in use.

h. Maintain temperature in regulated areas below 120 degrees F (49 degrees C). Provide environmental controls consistent with ventilation for personnel comfort.

10-4.3.13 Waste Product Disposal.

a. Add water to H-70 spills in a 100 to 1 ratio to reduce the H-70 concentration to less than 1 percent. Size collection tank accordingly.

b. Use neutralizers, such as 65 percent granular calcium hypochlorite (HTH), 14 percent bleach, and 5 percent bleach to stabilize the H-70/water mixture.

c. Provide storage for HTH away from hydrazine and other potentially reactive materials. HTH is extremely corrosive.

d. Consult with local base bio-environmental engineer as to procedures for emptying the collection tank.

10-5 OTTO FUELS.

Information on OTTO fuels is contained in NAVSEA S6340-AA-MMA-010. Distribution of this document is restricted. Requests for information are handled by Naval Sea Systems Command. Refer to Chapter 2 of this UFC for additional information.

CHAPTER 11 SUPPORT FACILITIES

11-1 INTORDUCTION.

This chapter provides design criteria for facilities which may be required to support fueling activities. Specifically, operations buildings, contaminated fuel recovery systems, roads, utilities, and aircraft refueler parking areas are detailed in this chapter.

11-2 OPERATIONS BUILDING.

Review the fueling activity to establish a need for each component of this building. Factors which will affect these reviews are number of people required for fueling activity, level of activity, types of fuels handled, on-site quality control, availability of replacement parts, availability of maintenance support, and level of training required.

11-2.1 Design Standards.

The support facilities must be designed in accordance with UFC 1-200-01, General Requirements. See UFC 3-600-01 for fire protection requirements.

11-2.2 Fuel Office.

Provide a fuel office with sufficient space to perform the necessary planning, administrative, and management functions associated with the accomplishment of the fuel division's mission. Refer to **\2** AFMAN 32-1084 **/2/** for size on Air Force projects.

11-2.3 Training/Conference Room.

Provide a multipurpose room with system components for training, conferences, and briefings. Design this room to accommodate furniture and have built-in features such as markerboard, tack board, book shelves, screen, clock, coat hooks, and storage cabinets.

11-2.4 Fuel Maintenance Workshop.

Provide a fuel maintenance workshop with an adequately sized and convenient work bench with compressed air and electrical outlets available. Provide slip and fuel-resistant floor, emergency shower and eyewash station, and adequate storage space adjacent to the workbench for frequently used tools, spare hardware items and accessories. If facility is large enough and mission warrants, consider overhead crane, laundry facility, and shower facility. Refer to Chapter 2 of this UFC for electrical hazard classification and requirements and NFPA for ventilation requirements.

11-2.5 Storeroom.

Provide an adequate storeroom for spare hoses, nozzles, filtration elements, special tools, special clothing, test equipment, and fuel spill clean-up equipment. Determine size and location of each facility to provide sufficient space for orderly storage and location for ready access to needed material by fuels division personnel.

11-2.6 Laboratory.

\2 Laboratories must comply with the general facility requirements of UFC 4-310-03. DoD Fuels Laboratory Standards and UFC 3-600-01 Fire Protection Engineering for Facilities. **/2/**

11-2.7 System Components for Miscellaneous Safety.

Provide firefighting, fire alarm, and emergency shower and eyewash station system components. Provide emergency shower and eyewash station with tempered water in cold weather climates. Also see applicable service-specific guidelines.

11-2.8 Control Room.

Where computerized control system components are anticipated, provide a control room of adequate size and with a maximum view of outside activities. Allow extra space along the ceiling/wall interface for future installation of security monitors. Consider electrical receptacles and data outlets for future use.

11-2.9 Miscellaneous Spaces.

Provide toilets, shower facilities, lockers, dressing rooms, mechanical room, electrical room, janitor closet, break room, etc. based on the size of the facility and the planned activities. Provide exhaust for locker rooms through the back or top of the lockers.

11-2.10 Communications.

Make provisions for telephone, data transmission, and other planned communications system components.

11-3 ROADS.

Design roads within a fueling facility to accommodate maintenance activities, operations personnel, and fuel delivery and/or issues. In addition, evaluate the roads leading to the facility for their adequacy of width, access, geometrics, and weight restrictions. For vehicle access roads in diked areas around tanks, see Chapter 8 of this UFC. Refer to **\2** UFC 3-201-01 **/2/** and **\2** UFC 3-250-01 **/2/** for design guidance.

11-4 UTILITIES.

In most cases, a fueling facility requires water (domestic and fire protection), sanitary sewer, storm sewer, communications, and electricity.

11-5 AIRCRAFT REFUELER AND FUEL DELIVERY VEHICLE PARKING.

11-5.1 General.

Ensure aircraft refueler and ground fuel delivery vehicle parking areas meet the following criteria at a minimum. For additional design guidance, refer to NAVAIR 00-80T-109 and Air Force TO 00-25-172.

11-5.2 Clearances.

a. Provide a minimum of 25 feet (7.6 m) between the centerlines of adjacent aircraft refueler trucks and ground fuel delivery vehicles when in the parked position or 10 feet (3 m) minimum of clear space between parked trucks, whichever is greater.

b. Provide a minimum of 50 feet (15 m) between aircraft refueler/ground fuel delivery vehicle parking area and the following:

1. Low Occupancy buildings as defined in Appendix A of UFC 4-010-01.
2. Taxiing aircraft.
3. Fence, if space is a limitation (100 feet (30 m), if space is available).
4. Roads outside of a security fence.
5. Overhead power and communication lines.
6. Pad-mounted transformers.
7. Parked aircraft.

c. Provide a minimum of 100 feet (30 m) between aircraft refueler/ground fuel delivery vehicle parking area and the following:

1. POL Operations Buildings and Inhabited Buildings
2. Aboveground Storage Tanks
3. Truck or tank car off-loading station.
4. Truck fillstand.
5. Property lines.
6. Highways.
7. Airport surface detection radar system components.

d. Provide a minimum of 300 feet (90 m) between an aircraft refueler/ground fuel delivery vehicle parking areas and the following:

1. Aircraft warning radar antennas.
2. Areas where airborne surveillance radar may be operated.

e. Provide a minimum of 500 feet (150 m) between an aircraft refueler/ground fuel delivery vehicle parking areas and airport ground approach and control system components.

f. Provide a distance as great as practically possible between an aircraft refueler/ground fuel delivery vehicle parking areas and radio transmitting antennas.

g. Contact the installation safety office to obtain distance criteria from an aircraft refueler/ground fuel delivery vehicle parking areas to aircraft carrying explosive materials.

11-5.3 Arrangement.

The preferred arrangement is parallel positions, but "front-to-back" and variations of the two are acceptable. Provide "front-to-back" clearance between vehicles such that the aircraft refueler/ground fuel delivery vehicle in the "back" position would not have to back up to pull out of the parking position. This distance will vary according to the turning radius of each aircraft refueler/ground fuel delivery vehicle. Arrangement should satisfy functional requirements of users and provide for safe operation and efficient use of available space. Provide for parking of all refueling vehicles expected to use this facility and include identification of positions.

11-5.4 Ingress/Egress.

Provide for "drive-ahead" motion of vehicles at all stages to avoid backing up vehicles under normal circumstances. Provide for smooth and efficient movement from the truck fillstand area to the parking positions and from the parking positions to the aircraft apron. Where necessary, provide adequate markings to ensure safe and efficient vehicle movements. At a minimum, provide two means of ingress/egress.

11-5.5 Paving.

Use concrete pavement, capable of withstanding design vehicle wheel loads. Seal joints with fuel-resistant materials. For circulation pavements, provide bituminous flexible pavements unless an economic analysis shows rigid concrete is more cost-effective. Use concrete pavement in aircraft refueler/ground fuel delivery vehicle parking areas.

11-5.6 Containment Area.

Provide a containment area consisting of an impermeable retention and controlled drainage system leading to a concrete remote spill containment system. Pave the area with concrete pitched a minimum of 1 percent toward catch basins or trench drains. Design the containment area in accordance with UFC 1-200-01, federal, state, and local regulations. Do not use asphalt within a spill containment area. The maximum slope of any paving within a truck movement or parking area must not exceed 2 percent except ramps. If a ramp is provided, no single slope must exceed 8 percent and the ramp must be aligned perpendicular with direction of truck movement. The designer must assure that adequate ground clearance is achieved for all vehicles utilizing the containment areas.

11-5.7 Remote Spill Containment System.

Design the spill containment system in accordance with UFC 1-200-01, federal, state, and local regulations. Provide the spill containment system with capacity not less than the volume of the largest refueler to be parked since this is most likely the maximum spill volume to occur for unattended vehicles. Precipitation is not required to be accounted for in the volume calculations. The top elevation of the remote spill containment basin must not be set less than 6-inches above the top of the refueler truck parking area's maximum ponding elevation. This will prevent overflow of the remote spill containment basin during a heavy rain event. Twenty-five percent or more of the total required containment volume must be directed to, and stored at, the remote system before any of the shared containment volume will pond at the truck parking area. Provide a lockable eccentric plug valve with indicator located outside the containment area at a location that will be safely accessible during a fire.

Consider combining the remote spill containment system with other remote spill containment systems on site, except with tank containment systems. Construct the drain lines between the containment area and the remote spill containment system, and between the remote spill containment system and the lockable eccentric plug gate valve of petroleum-resistant, impermeable material with water-tight joints such as ductile iron or HDPE pipe with fusion welded joints. Do not use clay, concrete, or fiberglass piping materials.

11-5.8 Fire Protection.

Refer to Chapter 2 of this UFC for fire protection requirements.

11-5.9 Security.

Provide fencing and lighting for security as required in Chapter 2 of this UFC.

11-5.10 Lighting.

Provide a minimum of 1-footcandle (10 lux) lighting with a uniformity ratio of 15:1 maximum/minimum to ensure that a fuel leak from the refueler is seen.

11-5.11 Block Heater Connections.

At facilities where aircraft refuelers/ground fuel delivery vehicles have engine block heaters, provide connections for those heaters.

This Page Intentionally Left Blank

CHAPTER 12 MAJOR REHABILITATION

12-1 INTORDUCTION.

Decisions concerning major rehabilitation will be based on economics, mission, safety, or environmental factors. It is not the intent of this chapter to mandate rehabilitation, but only to provide guidance if the decision is made. The most common reasons for rehabilitation are to meet environmental needs or to extend the usable life of the facility. If a tank or major component is taken out of service for rehabilitation, review other chapters of this UFC. However, consider each change based on its merits and its compliance with this UFC. It is not the intent of this UFC to initiate changing and upgrading of existing facilities. Before initiating a facility improvement or major rehabilitation fuel project, it is recommended that a Physical Condition Survey be conducted to survey the condition of the facility with the goal of identifying major deficiencies and prioritizing the work required. Contact the appropriate Command Fuels Engineer, Naval Facilities Engineering Component Commands and the Naval Facilities Engineering and Expeditionary Warfare Center, or Army Corps of Engineers regional design office. For Naval Air Stations and Marine Corps Air Stations, include a representative from NAVAIR on the survey team. In most cases, coordinate major rehabilitation proposals with the base master plan.

12-2 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, contains important information on fueling facilities. Do not begin the design or modification of any fueling system without first becoming completely familiar with Chapter 2 of this UFC.

12-3 ABOVEGROUND FUEL STORAGE TANK REHABILITATION.

Existing aboveground storage tanks can be modified to meet fuel quality standards, safety requirements, and environmental regulations. To maintain the structural integrity of aboveground storage tanks and to ensure a complete and usable facility, ensure all designs are accomplished by an engineering firm regularly engaged in tank modification or have all plans and specifications reviewed by an API Std 653 certified inspector. Complete all tank modifications, repairs, alterations, or inspections in accordance with API Std 653 and API Std 650. Require a new strapping table after any major tank rehabilitation.

12-3.1 Aboveground Vertical Tank Inspections.

Prior to modifying the tank**,** conduct a thorough inspection consistent with the requirements of API Std 653. This inspection will reveal any repairs that need to be made in order to comply with current regulations. If the tank is suspected of leaking, a helium test may be conducted.

12-3.2 Increase Manhole Sizes.

Many older aboveground vertical tanks have inadequately sized shell manholes. The ventilation and system components requirements for maintenance have created a need for 36-inch (900 mm) diameter manholes. If they do not exist, consider rehabilitation. Provide in accordance with Chapter 8 of this UFC. When considering the increase in manhole size, the risk of damaging the tank must be taken into account. Also the need for stress relieved manhole inserts must be considered (larger tanks). Indiscriminate installation of larger manholes has been known to severely damage tanks.

12-3.3 Replace Tank Floors.

Replace existing tank floors only when an API Std 653 inspection (including a magnetic flux leakage test) indicates that the useful life of the bottom has expired, or that the bottom requires more than minor repairs or upgrades, or if significant fuel quality problems due to ponding water exist. Contact Service Headquarters for guidance. Whenever a tank bottom is replaced it must comply with current design standards including either a double bottom or single bottom with liner. In no case must a tank with a single bottom remain in service when the bottom warrants replacement, unless other provisions such as a programmed MILCON or SRM project has been approved to replace the tank and/or bottom. Conduct an analysis of the existing tank and local conditions to determine the most desirable approach. The type of new bottom to be installed depends upon a number of factors, including: condition of the existing bottom, tank foundation, shell condition, and amount of tank capacity which can be "lost." Install double bottoms or replacement bottoms in accordance with API Std 653. Install sloped bottoms (3 to 5 percent) either above the existing bottom if the user can accept the resulting loss in tank capacity or remove the existing bottom and install a new sloped bottom in its place. A slope of 5 percent is preferred, but not required. If conditions and cost make the recommended slope impractical, provide a minimum slope of 2 percent. The installation of a new cone up floor above an existing cone up floor may be considered only for large (80,000 Bbl and larger) bulk storage tanks, and must be approved by the Service Headquarters. In either case, install an impermeable liner in accordance with DoD Standard Design AW 078-24-27, as well as leak detection between the two floors. The technology exists and it may be cost effective to raise the tank off its foundation to accomplish under tank modifications or repairs (e.g., adding containment liner/tell-tale system, cathodic protection, ringwall, etc.).

12-3.3.1 Double Bottom with Washed Sand Layer and Liner.

Clean and repair the existing tank bottom, install a liner on top of the existing tank bottom, add a 4- to 6-inch (100 to 150 mm) silica sand layer on top of the liner, and install the new steel tank bottom on top of the sand layer. Refer to Chapter 8 of this UFC for suitable sand criteria. Leak detection consists of tell-tale slotted **\3** pipes within the sand layer at regularly spaced intervals and extending out through the outer shell of the tank. PVC pipe materials are not allowed. **/3/** Provide cathodic protection by sacrificial anodes or impressed current close to the liner to allow maximum clearance from the new tank bottom. Install adequate numbers of a cathodic protection reference cells between the two bottoms.

12-3.3.2 Double Bottom with Concrete Layer and New Steel Bottom.

Clean and repair the existing tank bottom, install a liner on top of the existing tank bottom, pour 4 to 6 inches (100 to 150 mm) of fiber reinforced (low slump mix - typically 3,000 psig (21 000 kPa)) concrete over the liner and existing bottom, shape the concrete to provide adequate slope, and install the new steel tank bottom on top of the concrete. Slope the concrete towards a sump and form with a series of grooves along the top surface to collect any product which may leak through the new bottom. Slope the channels to a collection point with a pipe extending to an observation well. Provide concrete with an alkalinity of 13 or higher.

12-3.3.3 Double Steel Bottom.

Clean and repair the existing tank bottom, place a structural support system on top of the existing tank bottom, and install the new tank bottom. Design the structural support system to prevent excessive deflections resulting from loads on the primary (new) tank bottom. Allow for an interstitial space between the two tank bottoms to detect and collect any product from a leak. Purge the interstitial space between the two bottoms with nitrogen to remove the oxygen, thus creating a non-corrosive, non-combustible environment. The elimination of condensation and oxygen within the space minimizes corrosion formation for the upper (new) bottom. Provide leak detection with sensors which can detect pressure changes within the space. A pressure increase results from a leak in the upper tank bottom as product enters the space. A decrease in pressure indicates a leak or steel failure has occurred in the lower tank bottom.

12-3.3.4 Single Bottom with Liner.

Remove the existing tank bottom and prepare the sub-base for bearing capacity. Place sand layer on the sub-base to support the primary tank bottom, install a liner with a slope to a center liner sump, place a minimum 12-inch layer of sand on top of the liner, and install a new tank bottom on top of the sand layer. The liner sump is the collection point for any leaks from the bottom and consists of a drain pipe leading to an observation well. An alternative method is to use tell-tale slotted **\3** pipes in accordance with DoD Standard Design AW 078-24-27. PVC pipe materials are not allowed. **/3/** Provide cathodic protection by sacrificial anodes or impressed current close to the liner to allow maximum clearance from the new tank bottom. Install adequate numbers of a cathodic protection reference cells between the two bottoms. Place cathodic protection in the sand layer approximately 6 inches (150 mm) below the new tank bottom and above the liner.

12-3.4 Replace Floating Roof tank with Fixed Roofs.

If an external floating roof requires significant repair work, is corroded beyond economic repair, or for any reason is considered unserviceable (by an API Std 653 inspection), consider replacing it with a fixed cone roof and internally sealed honeycomb cell floating pan, as required in the "Protection of Aboveground Storage Tanks" paragraph of Chapter 2. When a fixed cone roof is added to an existing tank the roof manufacturer and the designer must determine that the tank has sufficient strength to support the new roof. If the shell is structurally insufficient, a geodesic dome may be considered. Install structural supported roofs in accordance with API Std 650, API Std 653, and DoD Standard Design AW 078-24-27. In general, all open top, floating roof tanks containing aviation fuel should be programmed to receive a cover, as should all tanks in northern climates where snow and ice is a problem.

12-3.5 Product Recovery Systems.

Provide storage tanks with pumps, piping, valves, and tanks to collect, recover, and return usable aviation turbine fuel which would otherwise become waste. Include a tank(s) to collect fuel/water mixtures from tank and system component sumps, system component drains, high point vents, low point drains, and any other system components from which fuel/water mixtures can be collected. Separate the fuel and water portions. Filter the fuel portion and return to bulk storage tanks. Do not discharge the water portion to surface water without additional treatment and permits or treat the water portion as wastewater. Refer to Chapter 2 of this UFC for information on handling of wastewater. Design in accordance with DoD Standard Design AW 078-24-27.

12-3.6 Coatings.

In tank coating projects, minimize the generation of hazardous waste associated with coating removal. Some alternatives to traditional sand blasting include shot "blasting", chemical stripping, high pressure water, carbon dioxide, or chemical stabilizer additive process. Designs for maintenance painting, both interior and exterior, should be based on a coating condition survey, as discussed in the notes to UFGS 09 97 13.15, 09 97 13.17, and 09 97 13.27. An evaluation of shell coating should be based not only on condition but on the need for coating the shell and an evaluation of apparent corrosion pressures on the shell. Corrosion pressure on shell coatings is generally fairly low; therefore, there is not the same need for coating thickness and integrity that is required for floors and ceilings. Refer to Chapter 8 of this UFC for additional information on interior and exterior coatings for storage tanks. Re-coat the portion of the tank that is already coated. When tanks are taken out of service for inspection or repairs, inspect the underside of the roof for rust. If conditions merit, coat the underside of the roof in conformance with Chapter 8 of this UFC.

12-3.7 Isolation Valves.

Require tank isolation valves to prevent the accidental release of fuel into the environment. On aboveground tanks larger than 12,000 gallons (45,800 L), provide double block and bleed tank shell valves located between the tank shell and the high level shut-off valve.

12-3.8 Alarms and High Level Shut-off Valves.

Equip storage tanks with a means to prevent accidental overfill. Remove solenoid pilots, if present, on high level shut-off valves. Design in accordance with DoD Standard Design AW 078-24-27. Refer to Chapter 8 of this UFC for applicable requirements for alarm and valve installation.

12-4 UNDERGROUND OPERATING TANKS.

If major rehabilitation is required, upgrade existing underground operating tanks to conform with 40 CFR Part 280 and 40 CFR Part 281 and applicable state and local underground storage tank regulations. As a minimum, provide leak detection, cathodic protection, and overfill protection. Careful study of cut and cover tanks is necessary since construction features may make it impossible to comply.

12-4.1 Manholes.

Provide a 36-inch (900 mm) diameter manhole for tanks. Extension necks and internal ladders are required for cleaning and inspection. Provide a minimum of one manhole for tanks between 1,000 gallons (4,000 L) and 5,000 gallons (19,000 L). Provide a minimum of two manholes for tanks larger than 5,000 gallons (19,000 L). Provide manhole containment sumps for all manholes.

12-4.2 Interior Coatings.

Coat underground operating tanks in accordance with Chapter 8 of this UFC.

12-5 HYDRANT SYSTEMS.

Decisions concerning major rehabilitation of existing direct aircraft refueling systems will be made by Service Headquarters. This paragraph addresses existing direct aircraft refueling systems (Type I and Type II) which can be rehabilitated or modified to meet fuel quality standards, safety requirements, mission requirements, and environmental regulations. All designs should be accomplished by an engineering firm regularly engaged in the design of direct aircraft fueling systems. The provisions of Chapter 4 of this UFC are applicable.

12-5.1 Pumps.

Repair or replace existing pumps to meet increased fuel demands. Rebuild pumps including complete bearing replacement, additional bowls or increased impeller size, replacement of mechanical seals, shaft lengthening or shortening to match replacement tanks, etc. In some cases, additional capacity can only be achieved by total pump replacement or rearrangement of piping. Consider pump replacement where, due to system component age or condition, it is more economical to replace than to rebuild. Pump and motor replacement may also result in higher efficiency units with lower power demands and increased spare part availability.

12-5.2 Filter-Separators.

Existing filter-separators must be capable of meeting requirements of EI Specification 1581 (Edition 5). Existing filter-separator vessels built to earlier editions of API 1581 may be able to be reutilized with EI Specification 1581 (Edition 5) coalescer and separator elements. Where possible, the replacement elements must be of the same size as other elements at the activity. Contact the Service Headquarters for guidance. Replace existing vessels if they cannot be converted to use EI Specification 1581 (Edition 5) elements or if the vessel with EI Specification 1581 (Edition 5) elements fails to meet quality standards. Issue filter-separators should be given priority for upgrade on a stand-alone project. Upgrade of all filter-separators is mandatory on any major rehabilitation project.

12-5.3 Fuel Quality Monitors.

Existing fuel quality monitors will be removed. Fuel quality monitor elements degrade when they come in contact with fuel additives (FSII) in aviation turbine fuel causing fuel quality issues.

12-5.4 Control Systems.

Pump houses and hydrant systems typical of the Panero (circa 1952) and Pritchard (circa 1958) designs utilize hard-wired, high-voltage mechanical relays. Control systems installed from the pump house to the lateral control pits, emergency stops, and pit activation switches are typically high voltage. Age, elements, and exposure to fuels may deteriorate control system wiring and render it no longer reliable or safe to operate. Consider control system replacement whenever a significant portion of the pump house is repaired or when fire, safety, or electrical codes indicate a hazard exists. Generally, hard-wired relay logic systems are expensive to build and maintain and do not offer the flexibility of programmable logic controller (PLC) based systems. Control systems should be of low voltage design incorporating industry standard programmable logic controllers (PLC). If control facilities are isolated from the pump house (not subject to atomized fuel) and the facility has positive ventilation, then non-explosion-proof fixtures may be incorporated into the design. Existing control wiring has probably deteriorated and numerous conduits are no longer intrinsically safe. Replace control wiring and wherever possible run control wiring in overhead conduit. If necessary, replace kill switch and emergency stop circuits as part of the pump house rehabilitation. Cable wiring systems are easier to install and troubleshoot and should be considered whenever the wiring to hydrant system is replaced.

12-5.5 Electrical Systems.

Replace secondary electrical systems, including lighting and motor conductors and motor control centers, as part of pump house repairs. Ensure circuits within the pump house, exposed to the possibility of atomized fuel, comply with the provisions of NFPA 30 and are classified Class I, Division 1. If the motor control center is isolated from the pump house (not subject to atomized fuel) and the facility has positive ventilation, then the area may be derated and non-explosion-proof lighting fixtures may be incorporated into the design. Existing secondary wiring has probably deteriorated and numerous conduits are no longer intrinsically safe. Replace motor wiring and wherever possible run control wiring in overhead conduit.

12-5.6 Lateral Control Pits.

Lateral control pits are typically concrete structures with heavy metal-hinged lids containing valves, pumps, filters, and piping associated with the supply of fuel from a pump house to a hydrant outlet. Repair or replace pits to prevent the accidental release of aviation turbine fuel to the environment and water infiltration. Slope pit floors to a sump and provide manually operated sump pumps to aid in water removal. Use either rolling or light-weight hinged aluminum pit lids with a water-tight design. Comply with DoD Standard Design AW 078-24-28.

12-5.7 Distribution Piping.

Minimize the use of unlined carbon steel pipe, especially with jet aircraft. A number of alternatives exist which reduce the exposure of aviation turbine fuel to unlined carbon steel pipe. One option is to internally coat existing systems without pipe removal. In-situ coatings can prevent fuel degradation; however, final filtration must still be provided at the aircraft by either a mobile or fixed filter-separator. Another option is to sleeve the piping with a non-ferrous material (stainless steel). Consider this option if reduced flow rates are acceptable.

12-5.8 Diaphragm Control Valves.

Consider reusing existing diaphragm control valves wherever possible. Diaphragm control valves can typically be refurbished by either the original manufacturer or by a factory authorized repair facility for less than the replacement cost. Ensure refurbishers modify, remove, or replace pilot assemblies, tubing, and solenoids to meet specifications as outlined in DoD Standard Design AW 078-24-28. As a minimum, replace non-ferrous pilot tube assemblies with a stainless steel unit. Provide stainless steel control tubing and replace all internal valve components. If the valve body is carbon steel, request Service Headquarters to determine if the valve body should be sand-blasted and cleaned or replaced. Coat or plate carbon steel bodies to meet DoD Standard Design AW 078-24-28.

12-5.9 Hydrant Control Valve Differential Pressure Control Pilots.

If the aircraft direct fueling system hydrant control valves (including the one at a hydrant hose truck (HHT) or pantograph checkout stand do not have a differential pressure control pilot (maintains a minimum differential pressure across the valve to ensure it remains in control) modify or replace the control valve to provide one. Set it for 15 psig differential pressure and verify it at flowrates from 50 to 600 gpm.

12-5.10 Hydrant Outlets.

Remove and replace existing hydrant outlets and connections (e.g., Buckeye) with API adapters. Conversion to API adapters ensures compatibility with all refueling system components. If adequate pressure control (regulating and surge) in accordance with DoD Standard Design AW 078-24-28 does not exist at the hydrant pit or at the lateral control pit, then install a control valve at either location.

12-6 DIKES, LINERS, AND BASINS.

If dikes, liners, and basins do not comply with the requirements of this UFC, 40 CFR Part 112, state, or local spill containment regulations and the potential for accidental fuel discharges exists, repair or replace the existing structures. The provisions of Chapter 8 of this UFC are applicable. In general, if the dike does not retain rainwater, improvements are necessary.

12-7 LEAK DETECTION.

When rehabilitating fuel facilities, install leak detection, if necessary, as detailed in Chapter 2 of this UFC.

12-8 CATHODIC PROTECTION.

When rehabilitating any fuel facility, install or upgrade cathodic protection. Ensure cathodic protection systems are designed by a NACE certified Corrosion Specialist or Cathodic Protection Specialist or a registered professional Corrosion Engineer. Install cathodic protection on all steel structures including, but not limited to, aboveground storage tanks, underground storage tanks, and underground piping systems. The provisions of Chapters 2 and 8 of this UFC are applicable.

In the event it is determined the tank floor cathodic protection system has failed, or is non-existent, and evidence is produced that floor backside corrosion is occurring (from an API 653 out-of-service floor scanning inspection), consider the use of Vapor Corrosion Inhibitors (VCI) to reduce the potential for backside corrosion. As the use of VCI is not as effective as original studies reported, and it is not possible to test their performance, any application of VCI must only be with the approval of the Service Specific Fuels Subject Matter Expert (SME) for Cathodic Protection from each Service. If the backside corrosion is of a low level, and projections of remaining useful life of the floor do not indicate the need for a floor replacement, the use of VCI may be indicated. If the API 653 Inspection is not finding low level backside corrosion, the use of VCI may not be warranted.

12-9 ISOLATION VALVES.

Provide valves in product piping systems to control flow and to permit isolation of system components for maintenance or repair. Provide additional valves at required locations necessary to conduct a valid hydrostatic test. Provide manually operated valves, except where motor operators are specifically authorized by applicable standard drawings or technical specifications. Use double block and bleed type isolation valves for separation of product services, on tank shell connections (ASTs over 12,000 gallons (45,800 L) only), when piping goes aboveground or underground, between pier and tank storage, and other locations critical to periodic pressure-testing of piping. Quick opening/frequent opening type isolation valves may be used for less critical applications where double block and bleed shutoff is not required. Before adding isolation valves, evaluate piping system and make modifications to prevent pressure buildup caused by thermal expansion. Review paragraph on "Thermal Relief Valves" in Chapter 9 of this UFC. Except for those serving tactical refueler fillstands, this paragraph does not apply to systems covered by Chapter 7 of this UFC unless otherwise directed by Service Headquarters.

12-10 SOIL AND GROUNDWATER REMEDIATION.

Monitor, store, and dispose of petroleum-contaminated soil disturbed during rehabilitation in accordance with state and local environmental regulations. Collect, test (if appropriate), and treat petroleum-contaminated groundwater removed during dewatering by one of the following methods:

a) Off-site disposal at an industrial waste facility.

b) On-site treatment with a portable groundwater treatment system.

c) Treatment through an oil/water separator.

d) Treatment through the sanitary sewer.

Prior to selecting a treatment method, review state and local environmental regulations and consult the facility for acceptable alternatives and permits required for on-site treatment and disposal.

12-11 LIQUEFIED PETROLEUM GAS (LPG) FACILITIES.

When rehabilitating an LPG facility, back weld (seal weld) all existing threaded piping.

12-12 PIPELINE INSPECTION.

12-12.1 Inspection.

Conduct pipeline inspections in accordance with API 570 and NACE SP0169.

12-12.2 In-Line Inspections (Smart Pigging).

To determine if or how a pipeline requires rehabilitation, information on the pipeline's structural integrity is essential. One method to survey the condition of the pipeline is to use smart pigs.

12-12.2.1 General.

An in-line inspection (ILI), or “smart” or “intelligent” pig is one of a variety of instrumented tools using one or more physical or electro-mechanical principles for recording and measuring information for positioning and relative severity of anomalies in a pipeline. Different configurations of ILI tools can detect cracks, metal loss, geometry (ovality, curvature, bends) and even geoposition. Other types available can map and profile pipe, detect leaks, perform photographic inspection, and sample product. Use of smart pigs may require modifying the pipeline to increase the radius of sharp elbows and eliminate obstructions caused by valves that are not full port type.

12-12.2.2 Types.

The three basic types of smart pigs are ultrasonic, magnetic flux leakage (MFL), and eddy current. Ultrasonic, MFL, and eddy current pigs can be used in liquid pipelines. An alternative form of ultrasonic inspection is an electromagnetic acoustic transducer (EMAT). An EMAT can be used in either a liquid or gas pipeline. MFL can also be used in gas pipelines. Prior to choosing a smart pig, consider expected results, cost of various options, and expected pipeline condition.

In order to consider the use of ILI tools, an engineer specializing in the execution of ILI inspections must prepare a piggability assessment that determines if it is feasible to pig the lines, and what changes may be necessary to make the line piggable. The piggability assessment must also include an assessment of fuels management from the perspective of fuel source, and ullage required at receipt tank. Preservation of fuel quality as well as minimizing loss of product must also be considered, including the installation of filtration at point of receipt prior to introduction into the installation tank. Fuel filtration has been found to be far more preferable than introducing dirty fuel into an installation tank.

12-13 PIPELINE REPAIRS.

Pipeline repairs must be identified as part of the pipeline inspection. Any areas of pipe where defects or anomalies exceed the limits outlined in the API 570 assessment must be repaired. Pipeline repairs must be made in accordance with API 570, ASME B31.3, and/or ASME B31.4 as applicable.

12-13.1 Pipeline Repair Methods.

All permanent pipeline repairs must be engineered. Where possible the preferred method of repair is to remove the section of defective pipe and provide a like-for-like replacement pup. Reinforcing the deficient piece of pipe with an encircling repair sleeve or other repairs are acceptable provided they are in accordance with applicable codes.

12-13.2 Pipe Support Upgrades.

Pipe support repairs requiring replacement of the support must be engineered. Where possible updating supports with galvanized metal support steel and updating support type to a U-bolt and half round slide pad must be considered. Any changes to support type must be accompanied by a seismic and thermal flexibility analysis. For complex systems, computerized code compliant pipe stress analysis programs must be used to assure proper pipe support selection for load conditions.

12-14 CHECKLIST.

The following is a checklist of items to be considered in a major rehabilitation.

a. Aboveground storage tank rehabilitation

1. API Std 653 inspection.
2. 36 inch (900 mm) diameter manholes for maintenance.
3. Add double bottom.
4. Repair and slope tank floor.
5. Repair or replace floating roof.
6. Product recovery system.
7. Internal and external coating systems.
8. Tank isolation valves.
9. Fill and overfill protection.
10. Corrosion protection to tank bottom.
11. Leak detection.
12. Automatic tank gauging system.
13. Thermal expansion relief.

b. Underground storage tank rehabilitation

1. 36 inch (900 mm) diameter manhole(s).
2. Leak detection.
3. Corrosion protection.
4. Overfill protection.
5. Interior coating.

c. Aviation/Hydrant system rehabilitation

1. Repair or replace pumps to API Std 610.
2. Upgrade filter-separators to comply with EI Specification 1581 (Edition 5).
3. Remove automatic water drains from filter-separators.
4. Repair or replace control systems.
5. Repair or replace electrical systems.

6. Repair or replace lateral control valve pits and lids, including an impervious liner.
7. Internal coating to carbon steel distribution pipe.
8. Refurbish diaphragm control valves.
9. Provide hydrant control valve differential pressure control pilots
10. Hydrant outlets to API adapters.
11. Replace lubricated valves and swivels with non-lubricated.

d. Truck fill/off-load stands

1. Grounding, deadman, and high level shut-off systems.
2. Pantographs - convert from 3-inch **\1** off-loading pantographs and hoses **/1/** to 4-inch (75 mm to 100 mm).
3. Low profile filters.
4. Fusible link butterfly valves (These valves are not required nor permitted on Air Force projects).
5. Piping of thermal reliefs to contained tank.
6. Updated meters and meter diaphragm control valves.
7. Adequacy of piping and system grounding.
8. Adequacy of spill collection and containment.
9. Upgrade military specification filter-separators to comply with EI Specification 1581 (Edition 5). (Issue filters have priority over receipt filters.)
10. Remove automatic water drains on filter-separators and ensure that any liquid drained from separators is properly handled.
11. Convert top loading to bottom loading fillstands.

e. Add isolation valves and blind flanges throughout system.

f. Use smart pigging to determine the condition of the distribution piping.

g. Monitor, remove, and dispose of petroleum-contaminated soil and groundwater.

h. Spill Containment and collection.

1. Concrete containment areas for dikes, system component pads, fillstands, etc.
2. Impervious lining system for dikes, containment areas, and catch basins.
3. When required to meet federal, state, and local regulations, refer to Chapter 2 of this UFC for information on design and sizing of oil/water separators for treatment of stormwater discharges from

containment areas (e.g., dike areas, fillstands, system component pads, etc.).

i. Pipeline Inspections

1. Areas of metal to metal contact should be noted.

j. Pipeline Repairs

1. Eliminate metal to metal contact.
2. Complete seismic and thermal flexibility analysis to verify support type and location.
3. Repair pipe anomalies or defects with engineered repairs only.

This Page Intentionally Left Blank

CHAPTER 13 FUELING FACILITY TEMPORARY DEACTIVIATION

13-1 INTRODUCTION.

Follow the more stringent of local, state, or applicable guidelines of this chapter during the initial deactivation of a fueling facility. Follow the applicable subsection when temporarily deactivating a fueling facility for three months or more. The requirements of this chapter are also applicable when connecting a new system to an existing system to prevent contamination of the new system. For continuing maintenance issues and reactivation of a deactivated facility, refer to inactive document UFC 4-911-01N, which is required for these circumstances. Additional guidelines for the deactivation of storage tanks and pipes are provided in API Std 2610 and Appendix C of NFPA 30,. Federal regulations addressing out-of-service underground storage tank systems are in 40 CFR Part 280.

13-2 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, contains important information on fueling facilities. Do not begin the design of any deactivation plan without first becoming completely familiar with Chapter 2 of this UFC.

13-3 FUEL STORAGE AND DISTRIBUTION FACILITIES.

13-3.1 Tanks.

The following items apply to deactivation of all tanks in general.

a. Empty and clean tanks in accordance with API Std 2015 and UFGS 33 65 00

b. Provide water ballast with a copper sulphite solution (1 part copper sulphite to 3 million parts water) to discourage organic growth. Verify compatibility with environmental regulations prior to employing this solution.

c. Follow the procedures of UFC 3-460-03 and 29 CFR Part 1910 when entering tanks or performing maintenance on tanks.

d. For tanks equipped with cathodic protection systems, inspect for proper operation and repair if necessary. For tanks not equipped with cathodic protection systems, investigate the economic trade-offs of installing those systems at deactivation versus the associated caretaker maintenance costs and various environmental protection concerns.

e. Mark each tank clearly with its status. Place a warning sign on the tank to indicate its current and former contents.

f. If required by state or local regulatory agencies, submit required documentation for “out-of-service” storage tanks.

13-3.1.1 Aboveground Tanks.

a. Empty and evaluate for hazardous atmosphere as defined by 29 CFR Part 1910.146.

b. Wash and dry tank interior until visibly clean in accordance with API Std 2015.

c. Physically disconnect all fuel connections.

d. Treat the interiors of tanks that have been used to store fuel oil with a corrosion-preventive compound. For all other steel tanks, coat the unpainted interior surfaces with a preservative lubricating oil.

e. Close vents on lubricating oil tanks. Vents on other tanks should remain open.

f. Partially fill tanks subjected to high winds to prevent overturning. Use water except where there is the possibility of it freezing and rupturing the tanks. In those environments, use kerosene. Add caustic soda to the water to obtain a pH of 10 or a corrosion inhibitor. Determine the amount of liquid ballast required based on the expected winds, size of the tank, and specific gravity of the liquid used.

g. Comply with API Std 2015.

h. Comply with state and local environmental requirements.

13-3.1.2 Underground Tanks.

a. Empty, evaluate for hazardous atmosphere as defined by 29 CFR Part 1910.146, and clean underground metal and concrete tanks.

b. Partially fill tanks insufficiently anchored against flotation with water to prevent buoyancy. Provide adequate safeguards where there is danger of the water freezing.

c. Provide a minimum of 12 inches (300 mm) of water in rubber-lined concrete tanks.

d. Leave vent lines on underground tanks open and make sure the vents are adequately screened.

e. Tightly cap or plug all other tank openings after removal of system components.

f. Provide release detection where fuel is left in the tank.

g. Comply with 40 CFR Part 280 and any applicable state and local environmental regulations.

3-3.1.3 Tank Level Controls.

a. Remove controls such as float control valves, float-operated gauges, low level cutoffs, water detector locks, and probes from tanks.

b. Clean, treat with corrosion-preventive compound, and store controls in a dry place.

13-3.2 Pipelines.

a. Drain and vacuum extract all fuel from the pipeline.

b. If possible, pig the pipeline to remove any residual fuels.

c. Blind all flange connections and vents.

d. Charge the line with nitrogen gas.

e. Continue to provide cathodic protection and maintain the nitrogen charge.

f. Externally coat unpainted and unwrapped lines exposed to the weather with a corrosion-preventive compound.

13-3.2.1 Pipeline System Components.

a. Remove, clean, coat inside and outside with a light oil, and reinstall strainers.

b. Remove, clean, treat with corrosion-preventive compound, and store meters in a dry place.

c. Keep gaskets tight to prevent dirt and water from entering.

d. Remove, clean, grease, and store hydraulically operated diaphragm control valves in a dry place.

e. Paint exterior or treat with a corrosion-preventive compound and leave all other valves, such as plug valves and check valves in place.

f. Lubricate plug valves and leave in an open position.

g. Remove, tag, date, and store hoses in dry storage.

13-3.2.2 Fueling Pits.

a. Inspect, tag, and secure fueling pits.

b. Make provisions for pumping pits dry.

13-4 FACILITIES.

13-4.1 General Considerations.

a. Make arrangements to retain the minimum amount of maintenance equipment.

b. Check and label all keys to all doors, gates, hatches, and other moving items.

c. Clean and repair as necessary all storm sewers, drainage ditches, and other drainage structures to prevent flooding and storm damage to roads, runways, tracks, and structures.

13-4.2 Fencing.

a. Tighten connections at gates, posts, braces, guys, and anchorages to ensure stability and correct alignment.

b. Clean and lubricate all hinges, latches, locking devices, and all other alignment hardware.

c. Confine painting to those parts of fences and gates that show signs of corrosion.

13-4.3 Paved Surfaces.

a. Unpaved shoulders

1. Provide unpaved shoulders with only the repairs necessary to ensure positive drainage of surface water from the adjoining pavement.
2. Fill holes and ruts and blade ridges to eliminate standing water.
3. Backfill depressions when the undermining of pavement is threatened.
4. When possible, retain existing ground cover.

b. Concrete pavements

1. Repair concrete pavements only as required to perform service activities and to prevent severe disintegration.
2. Patch bituminous surfaces of depressed or broken slabs to prevent ponding of water and the resultant saturation of the subgrade.
3. Seal joints and cracks in concrete pavement with bituminous material.

c. Bituminous pavements

1. Limit surface repairs of bituminous pavements to the repair of holes, raveled areas, edge failures, and open cracks.
2. Repair unused surfaces only as necessary to maintain drainage and to prevent the ponding of surface water.

CHAPTER 14 FUELING FACILITY CLOSURE

14-1 CLOSURE REQUIREMENTS.

Follow the more stringent of local, state, or applicable guidelines in this chapter when permanently closing a fuel facility or a portion of a fuel facility. Additional guidance on closure and disposal of storage tanks is available in Appendix C of NFPA 30 and API Std 2610.

14-1.1 Aboveground Tanks.

a. Physically disconnect all fuel connections.

b. Remove fuel.

c. Clean tank in accordance with API Std 2015.

d. Dismantle the tank and dispose of as scrap steel.

e. Comply with API Pub 2202.

f. Comply with state and local environmental requirements.

14-1.2 Underground Tanks.

a. Perform a soil and groundwater analysis to determine if a fuel release occurred.

b. Review and comply with 40 CFR Part 280 and any applicable state and local environmental regulations.

c. If allowed by federal, state and local regulations, perform closure in place, as outlined in API RP 1604. However, this alternative may be more expensive than removal for small volume tanks. Abandoning in place also impedes soil clean-up and future land use.

d. If removal is required, excavate and dispose of the tank in accordance with API RP 1604.

e. Comply with applicable guide specifications and EM 1110-1-4006.

14-1.3 Pipelines.

a. Physically disconnect the pipeline from any active fuel systems.

b. Drain and vacuum extract all residual liquids from the pipeline.

c. Remove all fuel and pig to remove any residual fuel.

d. Purge the pipeline to remove all vapors. Do not use water as flushing media because it will typically generate large quantities of hazardous waste with high disposal costs.

e. Excavate the line only if required by federal, state, or local regulations or if deemed necessary by Service Headquarters for land reuse.

f. Report any contaminated soil or groundwater discovered during excavation to the appropriate state and local environmental authorities.

g. If excavation is not performed, fill the pipeline with cellular concrete or other acceptable inert solid material allowed by regulations requiring the filling. Consider the lowest cost from the acceptable materials list. As an option, the pipeline can be capped, where it meets environmental regulations and with approval from Service Headquarters.

14-2 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, contains important information on fueling facilities. Do not begin the design or modification of any closure plan without first becoming completely familiar with Chapter 2 of this UFC.

14-3 INVENTORY.

Prepare an inventory of valuable fueling hardware which could be easily salvaged and reused at another base. System components such as pantographs, control valves, pumps, and filtration system component are always in demand. Submit list to your Command Fuels Engineer.

CHAPTER 15 FUEL SYSTEM COMPONENTS

15-1 INTRODUCTION.

This chapter contains the descriptions of various fueling system components used in DoD fuel facilities such as bulk storage facilities (See Chapter 3), aircraft fueling facilities (See Chapter 4), marine receiving and dispensing facilities (See Chapter 5), ground product fueling facilities (See Chapter 7), and interterminal and installation pipelines (See Chapter 6).

15-2 BULK AIR ELMINATORS.

Use flange-connected, steel bodied bulk air eliminator of the appropriate pressure and flow rating to meet applicable service requirements. Include an automatic air release head and interlock the system component with a float or solenoid-operated hydraulically operated diaphragm control valve. Provide discharge piping to the product recovery tank or other safe means of containment.

15-3 METERS.

15-3.1 Custody Transfer versus Non-Custody Transfer Meters.

Meters are used to quantify the amount of fuel that is transferred between two points or systems. They can be of the custody transfer or the non-custody transfer type. The meters that are not designed for custody transfer are used for operational control and to determine approximately how much fuel is being transferred. The meters designed for custody transfer are used for inventory transfer and financial accounting control and require an accuracy of plus or minus 0.5 percent or better. Positive displacement and turbine meters can be used as custody transfer meters with the addition of temperature compensation.

15-3.2 Meters – Positive Displacement.

Use flange-connected, cast steel bodied (aluminum or stainless steel, only if downstream of the issue filter-separator in aircraft fueling facilities) positive displacement meters of the appropriate pressure and flow rating to meet applicable service requirements. Ensure meter has case drain and register. Provide each meter with temperature compensation and adjustable calibration where there is custody transfer. Ensure meter accessories are compatible with either the mechanical or electronic support system component selected. For positive displacement meters, the measurement error in the normal flow direction must be within plus or minus 0.3 percent of actual quantity delivered. Consult the appropriate Service Headquarters for requirements for the meter to communicate to a remote location or system component. Consider the use of a card-operated or key-operated data acquisition system. Cards or keys, as appropriate, are coded to identify the receiver of the fuel and to allow access to the fuel. The quantities taken are transmitted to a data-receiving device by electronic pulse transmitters mounted on each meter, and each transaction is automatically recorded. For bulk storage facilities, refer to “Cards and Key Locks” under “Controls” paragraph of Chapter 3. For ground product fueling facilities, refer to “Cards and Key Locks” under “Filling Stations” paragraph of Chapter 7.

15-3.3 Meters – Turbine.

Use flange-connected carbon steel bodied (stainless steel, if used in aircraft fueling facilities) turbine meters of the appropriate pressure and flow rating to meet applicable service requirements. Provide a flow straightener before turbine meters or provide a straight length of pipe at a minimum of ten pipe diameters upstream and five pipe diameters downstream of all turbine meters, or as required by manufacturer. Ensure meter has case drain and register. Provide each meter with temperature compensation and adjustable calibration where there is custody transfer. For turbine meters, the measurement error in the normal flow direction must be within plus or minus 0.5 percent of actual quantity delivered. Ensure all supporting system components for meter is compatible with the turbine meter selected. Consult the appropriate Service Headquarters for requirements for the meter to communicate to a remote location or system components. Consider the use of a card-operated or key-operated data acquisition system. Cards or keys, as appropriate, are coded to identify the receiver of the fuel and to allow access to the fuel. The quantities taken are transmitted to a data-receiving device by electronic pulse transmitters mounted on each meter, and each transaction is automatically recorded. For bulk storage facilities, refer to “Cards and Key Locks” under “Controls” paragraph of Chapter 3. For ground product fueling facilities, refer to “Cards and Key Locks” under “Filling Stations” paragraph of Chapter 7.

15-3.4 Meters – Orifice.

Use this type of meter only where custody transfer or accounting/inventory control is not required. Provide with flange connections. Provide a flow straightener before orifice meters or provide a straight length of pipe at a minimum of ten pipe diameters upstream and five pipe diameters downstream of all orifice meters, or as required by manufacturer. Indicate the date of calibration, temperature, and flow on the meter.

15-4 PRESSURE GAUGES.

Use liquid-filled gauges of range and dial size, as necessary, but not less than 0 to 160 psig (0 to 1100 kPa) pressure range and 4.5-inch (115 mm) diameter dial. Gauges must be all stainless steel construction, with black graduations on a white face. For locations where the temperature exceeds 100 degrees F (38 degrees C), consult Service Headquarters for direction on the possible use of gas-filled gauges. For locations where the temperature is less than -40 degrees F (-40 degrees C), use an appropriate gauge liquid that will not freeze to prevent damaging the gauge.

a. Consider the location, year-round weather conditions, and service requirements for the type of liquid filling to be used.

b. Install compound (pressure/vacuum) gauges on the suction side of each pump at fuel storage tanks.

c. Gauge liquids and service ranges:

Liquid	Range
Glycerin	0F to 400F (-18C to 204C)
Silicone	-40F to 600F (-40C to 316C)

d. Provide a lever handle gauge cock and pressure snubber in each pressure gauge connection.

e. Provide indicating and recording pressure gauges on suction and discharge lines for interterminal pipeline pumping stations and on the incoming line at the delivery terminal of each such pipeline, if required by Service Headquarters.

f. Pressure gauges must be installed so that they are testable without removing them from the piping.

g. Use pressure gauges upstream and downstream of strainers and filter-separators. A differential pressure gauge may be used in lieu of gauges on each side.

For marine receiving and dispensing facilities (See Chapter 5), provide the following in addition to the above requirements:

a. Provide a pressure gauge on each side of the pipeline shutoff valve at the shore end of each pier-mounted pipeline. Provide the indicating pointer with a high-pressure-reading tell-tale indicator suitable for reporting the highest pressure experienced since last reset. Provide for non-contact resetting of the tell-tale by means of a small magnet.

b. Provide a pressure gauge on each branch line at each fueling station on each pier-mounted pipeline. Ensure that the pressure gauge is legible from the fuel hose connection array and from the pantograph loading arm location (if provided).

c. Provide a pressure gauge on each marine loading arm assembly (if provided). Ensure that the gauge is visible by the operator.

15-5 STRAINERS.

Require a strainer to protect centrifugal pumps, unless it precludes meeting the net positive suction head of the pump. Whether or not strainers are installed on the suction side of centrifugal pumps, install a spool piece so that temporary strainers can be installed during startup of the system. Strainers are required on the suction side of all pumps, meters, and receipt filtration. Strainers are not required upstream of issue filter-separators or diaphragm control valves.

a. Use flanged basket strainers constructed of steel and fitted with removable baskets of stainless steel mesh with large mesh reinforcements. Provide quick opening, single screw type with a drain connection on the bottom.

b. Unless otherwise specified, provide a fine screen mesh as follows:

	Mesh	Size of Opening
Pump suctions (Centrifugal)	7	0.108 inch (2.74 mm)
Pump suctions (Positive Displacement)	40	0.016 inch (0.40 mm)
Receipt Filtration	40	0.016 inch (0.40 mm)
Meter inlets (unless downstream of a filter-separator)	40	0.016 inch (0.40 mm)

c. In all cases, ensure the effective screen area is not less than three times the cross-sectional area of the pipe.

d. Provide pressure gauges on both sides of the strainer or a differential type gauge across the strainer.

e. Consider providing a manifold with two individual strainers and isolation valves for pipeline receipt, marine receiving facilities, and any other locations where uninterrupted flow is required for extended periods of time.

15-6 SURGE SUPPRESSORS.

Every effort should be made to control hydraulic surge or shock to acceptable limits by the design of the piping system rather than by the use of surge suppressors. Where this is not possible or becomes extremely impractical, surge suppressors may be incorporated. Use the diaphragm or bladder type equipped with a top-mounted liquid-filled pressure gauge, wafer-style check valve at the bottom, drain above the check valve, and isolation valve. Provide a needle valve around the check valve to permit controlled bleed back of the surge suppresser without rebounding. Locate surge suppressors as close as possible to the point of shutoff that is expected to cause the shock. Surge suppressors can reduce shock pressure but will not eliminate it entirely. The preferred solution to hydraulic shock is conservative piping design, use of loops, and slow-closing valves. Surge suppressors are strictly a last resort solution and require the approval of Service Headquarters prior to designing into a system.

15-7 FILTRATION.

The common contaminants for every fuel are water, solids, surfactants, micro-organisms, and miscellaneous contaminants. Solid contaminants are generally those which are insoluble in fuel, most common are iron rust, scale, sand, and dirt. However, metal particles, dust, lint from filter material and rags, gasket pieces, and even sludge produced by bacterial action are included. The maximum amount and size of solids that an engine can tolerate vary by engine type and fuel system. Ensure that the design provides the filtration for the fuel as required before reaching any truck fillstand or the motive fuel tank on the vehicle being refueled, hydrant pit, or aircraft direct fueling station.

The most common filtration equipment are filter separators. Less common are micronic pre-filters and hay packs.

15-7.1 Aviation Turbine Fuel Filter-Separators.

Filter-separators remove the common contaminants from aviation turbine fuel in three steps using two separate elements:

a. Removal of solid contaminant in the filter portion of the coalescer cartridge.

b. Removal of large particles of free water in the second stage of the coalescer cartridge.

c. Removal of fine particles of water in the separator cartridge.

The maximum amount and size of solids that an aircraft can tolerate vary by aircraft type and fuel system. Close Tolerance mechanisms in turbine engines can be damaged by particles as small as 1/20th the diameter of a human hair. Filter-separators continually remove dirt and free water from aviation turbine fuels. Ensure that the design requires two separate filtrations using two separate filter separators (or banks of filter-separators) prior to the fuel reaching the refueler truck fillstand, hydrant pit, or aircraft direct fueling station.

15-7.1.1 Design Requirements.

All aviation turbine fuels received into an operating tank must pass through a filter-separator. All aviation turbine fuels issued from an operating tank must pass through a second filter-separator. Filter-separators are required for all aviation turbine fuel systems in facilities where the fuel is dispensed directly to aircraft or is loaded on refuelers that eventually dispense the fuel to aircraft. Refer to aviation turbine fuel receipt filtration table, Table 4-1. As a minimum for such facilities, provide filter-separators as follows:

a. Design and construct filter-separators in accordance with EI Specification 1581 (Edition 5).

b. Elements for filter-separators should be of the same size as other elements at the activity.

c. Provide horizontal filter-separators. Provide vertical filter-separators only where space constraints prohibit horizontal units. Provide access to at least one side of every vertical unit via a separate (not attached to the filter-separator), stand alone, fixed platform.

d. Design and construct filter-separators in accordance with the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC). Construct metal parts which will be in contact with the fuel, including the shell, head, and internal attachments of 3003 or 5083 aluminum alloy, stainless steel, or interior epoxy-coated carbon steel. Include the following accessories:

1. Piston-type differential pressure gauge with 1 psi (5 kPa) graduations across the elements. Pressure gauge must be testable without removal from the piping.

2. Sight glass on the water sump.

3. Hydraulically operated diaphragm control valve in the main discharge piping with rate of flow and water slug features.

4. Include a manual check mechanism external to the filter-separator to check the float. (The water slug feature must not be included on pipeline, barge, or tanker receipt lines. In those cases, use a differential pressure alarm and a differential pressure-actuated bypass valve.)

5. Only at barge-receiving locations or where large quantities of water are expected, automatic water drain valve connected to the bottom of the water sump.

6. Manual water drain valve from the bottom of the water sump.

7. Safety relief valve in accordance with the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC).

8. Thermal relief valves. Provide a thermal relief valve on the vessel or integrate thermal relief via piloting on the filter-separator control valve.

9. Automatic air release with check valve.

10. Basket strainers immediately upstream of all receipt filter-separators.

11. Connect automatic water drains, manual drains, safety relief valve, and air releases to a permanently installed product recovery tank as described in Chapter 8 of this UFC or a suitable other container if a product recovery tank is not directly accessible.

12. Fuel sample connections upstream and downstream.

e. Do not provide sight gauges (sight flow indicators) on drain piping and thermal relief valves. Do not allow sight flow indicators to be installed on any filtration device.

f. Do not allow reverse flow thru filter-separators or any other filtration devices.

g. **\2** Provide a means for slow filling through the sump, to prevent static discharge when first filling empty filter-separator vessels. Slow filling through the sump may be bypassed, depending on the type of system, fuel type, and Service Headquarters requirements. ***/2/*** DoD Standard Design AW 078-24-28 gives details for this design feature.

15-7.1.2 Arrangement.

Arrange the system piping so that fuel from the discharge side of the fueling system transfer pumps can be recirculated back through the inlet filter-separators into the operating storage tank. Inlet filter-separators may serve more than one operating storage tank. In aircraft direct fueling systems on the downstream side of operating storage tanks, arrange the piping so that the fuel can be circulated from the operating storage tanks, through the filter-separators, to each aircraft fixed fueling station and back through the inlet filter-separators to the operating storage tanks. Provide dispensing filter-separators of the same number and capacity as the transfer pumps; that is, for three 600 gpm (38 L/s) pumps, provide three 600 gpm (38 L/s) filter-separators.

15-7.2 Micronic Pre-Filters.

Many aviation turbine fuel systems receive such a large amount of solid contaminants that the filter-separator coalescer elements are frequently changed out because the filter portion of the coalescers is loaded up with dirt and other solids. In such a case, it is often more economical to provide micronic pre-filters (with cheaper paper elements) ahead of the filter-separators to take out the majority of the solid contaminants before they reach the filter-separators. These devices are most often associated with intrastate interterminal and interstate interterminal pipelines as these lines generally have the largest amounts of solid contaminants in them. Contact Service Headquarters for guidance on when to use them as these will be installed only selectively. As a minimum for such facilities, provide micronic filters as follows:

a. Design and construct vessels in accordance with EI Specification 1590.

b. Provide horizontal vessels. Provide vertical units only where space constraints prohibit horizontal units. Provide access to at least one side of every vertical unit via a separate (not attached to the filter-separator), stand alone, fixed platform.

c. Design and construct vessels in accordance with the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC). Construct metal parts which will be in contact with the fuel, including the shell, head, and internal attachments of 3003 or 5083 aluminum alloy, stainless steel, or interior epoxy-coated carbon steel. Include the following accessories:

1. Piston-type differential pressure gauge with 1 psi (5 kPa) graduations across the elements. Pressure gauge must be testable without removal from the piping.
2. Hydraulically operated diaphragm control valve in the main discharge piping with rate of flow features.
3. Manual drain valve.
4. Safety relief valve in accordance with the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC).
5. Thermal relief valves. Provide a thermal relief valve on the vessel or integrate thermal relief via piloting on the filter-separator control valve.
6. Automatic air release with check valve.
7. Connect manual drains, safety relief valve, and air releases to a permanently installed product recovery tank as described in Chapter 8 of this UFC.
8. Fuel sample connections upstream and downstream.

d. Do not provide sight gauges (sight flow indicators) on drain piping and thermal relief valves. Do not allow sight flow indicators to be installed on any filtration device.

e. Do not allow reverse flow thru any filtration devices.

15-7.3 Haypack Coalescers.

Many aviation turbine fuel systems receive such a large amount of water that the filter-separators in the receiving lines would be quickly overwhelmed. In such a case, it is often economical to provide Haypack coalescer vessels ahead of the filter-separators to take out the majority of the gross water before it reaches the filter-separators. These devices are most often associated with barge and ship marine receipt systems as these generally have the largest amounts of water contamination. Contact Service Headquarters for guidance on when to use them as these will be installed only selectively.

Haypack coalescers are single-stage water coalescers with horizontal, cylindrically shaped housings designed to protect filtration systems from gross amounts of water and some of the larger solid contaminants. The media is excelsior (stranded wood fiber) although coarse fiberglass is also sometimes used. As a minimum for such facilities, provide Haypack coalescers as follows:

a. Provide horizontal vessels. Provide vertical units only where space constraints prohibit horizontal units. Provide access to at least one side of every vertical unit via a separate (not attached to the filter-separators), stand alone, fixed platform.

b. Use wafer style repack coalescers since they allow the first two sections to be replaced when required. The third and successive sections require fewer change outs since they may remain relatively free of solids. Coalescing first starts as the product enters the vessel. Due to the substantially reduced velocity, free water will fall out by gravity. While the product progresses through the mass packed media, further coalescing occurs by impingement of water droplets on the media. At the same time, solids tend to fall out as the liquid enters the housing at a reduced velocity, but are further removed by filtration as the flow continues through the mass media.

c. Design and construct vessels in accordance with the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC). Construct metal parts which will be in contact with the fuel, including the shell, head, and internal attachments of 3003 or 5083 aluminum, stainless steel, or interior epoxy-coated carbon steel. Include the following accessories:

1. Piston-type differential pressure gauge with 1 psi (5 kPa) graduations across the elements. Pressure gauge must be testable without removal from the piping.

2. Hydraulically operated diaphragm control valve in the main discharge piping with rate of flow features.

3. Manual drain valve.

4. Safety relief valve in accordance with the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC).

5. Thermal relief valves. Provide a thermal relief valve on the vessel or integrate thermal relief via piloting on the filter-separator control valve.

6. Automatic air release with check valve.

7. Connect manual drains, safety relief valve, and air releases to a permanently installed product recovery tank as described in Chapter 8 of this UFC.

8. Fuel sample connections upstream and downstream.

d. Do not provide sight gauges (sight flow indicators) on drain piping and thermal relief valves. Do not allow sight flow indicators to be installed on any filtration device.

e. Do not allow reverse flow thru any filtration devices.

15-8 PUMPS.

15-8.1 Design Requirements.

Design pumps to deliver the full range of operating conditions anticipated with flow rates as presented in Chapter 2 and Chapter 4 of this UFC. Ensure pumps develop sufficient head to overcome the friction and static head losses in the system at the rated flow. Consider the specific gravity, temperature, viscosity, vapor pressure, corrosive, and solvent properties of the fuel. If a range is given for the specific gravity, etc., in the "Fuel Properties and Additives" paragraph of Chapter 2, use the larger value for the purpose of calculations. For any single grade of fuel, connect pumps in parallel. Select according to the type most suitable for the particular application.**\2** Do not use positive displacement or reciprocating pumps for aircraft, truck or vessel product issue or product issue or installation pipelines. Positive displacement pumps can be used for product recovery return. ***/2/***. For bulk storage facilities, provide enough pumps to allow the system to operate at full capacity with the largest pump out-of-service. For aircraft fueling systems, provide at least two separate pumps for each type of aviation turbine fuel and at least two transfer pumps, each capable of delivering the required system capacity.

15-8.2 Centrifugal Pumps.

Use API Std 610 centrifugal pumps to pump from aboveground tanks with continuously flooded suctions.

15-8.3 Vertical Turbine Pumps.

Use API Std 610 vertical turbine pumps to pump from underground tanks. Do not use horizontal transfer pumps in a pit alongside the underground tank. Provide a foot valve on all vertical turbine pumps on Navy and USAFE Projects.

15-8.4 Jockey Pumps.

Use jockey pumps when tightness testing of underground pipelines is required. These pumps are ANSI type centrifugal pumps.

15-8.5 Rotary Pumps.

Use rotary self-priming pumps for applications such as stripping pipelines, direct off-loading stations, or similar service where the pump may frequently lose its prime. There are two main types of self-priming pumps permitted.

15-8.5.1 Positive Displacement Pumps.

Positive displacement pumps do not require prime but are required to be equipped with a pressure relief valve to prevent damage to the pump if the pump is started against a closed valve. If the positive displacement pump is used with a flow control valve, then an additional modulating pressure relief valve must be included at the discharge of the pump. This modulating pressure relief valve must not be used to modulate the pump discharge pressure as this will void the pump warranty.

15-8.5.2 Self-Priming Centrifugal Pumps.

Self-Priming centrifugal pumps are not completely self-priming, as they cannot pump only air; they require a mixture of fluid and air for priming. These pumps do not need a pressure relief valve at the discharge of the pump as they function like a standard centrifugal pump. These pumps require proper air venting at the pump discharge.

15-8.5.3 Stripper Pumps.

Provide positive displacement stripper pumps for emptying loading arms, hoses, and manifolds. Provide a stripper pump to reclaim each clean product from each main product line, or connect the product lines to the oil waste drain line. Conduct an economic analysis of the two alternatives to determine the appropriate choice. Larger, longer, or more frequently drained lines will favor the stripper pump choice. Use a stripper pump on multi-product lines, but do not exceed acceptable limits of cross contamination. Provide a dedicated stripper pump to each separate product line, such as aviation turbine fuels.

15-8.6 Drivers.

Drive permanently installed pumps by an electric motor which is properly classified in accordance with NFPA 70. Size drivers to be non-overloading at any point on the curve. Provide anti-reversing ratchets on all vertical turbine pump motors.

15-8.7 Materials of Construction.

For bulk fuel storage facilities, use carbon steel or nodular iron casings and components. For aviation turbine fuels, use cast steel or nodular iron casings and stainless steel impellers and trim. Consider nonferrous materials in severe corrosive environments and consult Service Headquarters.

15-8.8 Installation.

Mount permanently installed pumps on substantial foundations of reinforced concrete, designed in accordance with Hydraulic Institute Standards.

15-9 MANUAL VALVES.

15-9.1 Material of Construction – General Service.

Valves are required to have carbon steel bodies and bonnets except for aviation turbine fuels (see below). Valves in general service may be internal nickel plated, or internal epoxy-coated. Do not allow valves with aluminum, cast iron, or bronze materials. Use only API fire-safe valves complying with API Std 607.

15-9.2 Materials of Construction – Aviation Turbine

Fuel service valve materials in contact with aviation turbine fuel must either be stainless steel, chrome plated carbon steel, or electroless nickel plated carbon steel. Do not allow zinc, zinc-coated, copper, or copper bearing materials in contact with the fuel. Do not allow internally epoxy-coated valves. Manual valves in aviation turbine fuel systems are required to have stainless steel bodies and bonnets. Carbon steel bodied valves are permitted provided they are internally plated with nickel plating. Do not allow aluminum, cast iron, or bronze bodied valves. Use only API fire-safe valves complying with API Std 607.

15-9.3 Isolation Valves Types.

15-9.3.1 Double Block and Bleed Isolation Valves.

Except for those serving tactical refueler fillstands, double block and bleed valves are not allowed in systems covered by ground product fueling facilities in Chapter 7 of this UFC unless otherwise directed by Service Headquarters.

a. Plug Valves (Double Block and Bleed): Use lockable, double-seated, tapered lift, plug type valves with an automatic body bleed between the seats (double block and bleed) in critical applications such as separation of product services, on each line at the shore end, when piping goes aboveground or underground, between pier and tank storage, and other locations critical to pressure-testing of piping. Valves must be designed so that if the synthetic seating material is burned out in a fire, a metal-to-metal seat will remain to ensure closure and comply with API Std 607. Lubricated plug valves are not allowed. Include integral body cavity thermal relief valve.

b. Ball Valves (Double Block and Bleed): Use double-seated, trunnion mounted, lockable, ball type valves with a body bleed between the seats (double block and bleed). These will be very rarely used but are acceptable as an alternative to double block and bleed plug valves in applications where the valve is operated very infrequently. Examples are isolation valve pits or isolation valves in the middle of piers, where they are only closed to perform pressure testing of piping. Valves must be designed so that if the synthetic seating material is burned out in a fire, a metal-to-metal seat will remain to affect closure and comply with API Std 607. Include integral body cavity thermal relief valve.

c. Gate Valves (Double Block and Bleed): Use double-seated, lockable, gate type valves with a body bleed between the seats (double block and bleed). These will be very rarely used but are acceptable as an alternative to double block and bleed plug valves and double block and bleed ball valves only when other double block and bleed valves will not physically fit. Valves must be designed so that if the synthetic seating material is burned out in a fire, a metal-to-metal seat will remain to affect closure and comply with API Std 607. Single seated gate valves are not allowed. Include integral body cavity thermal relief valve.

15-9.3.2 Quick Opening/Frequent Opening Isolation Valves.

Use full port valves with exact same diameter of the pipe when line pigging is required.

a. Ball Valves: Ball type valves may be used as valves for quick or frequent opening applications when a double block and bleed valve is not required. Ball type, lockable, valves must be designed so that if the synthetic seating material is burned out in a fire, a metal-to-metal seat will remain to affect closure and comply with API Std 607. Use Teflon or Viton synthetic seals or seating material. Use full port ball valves with exact same diameter of the pipe within ten pipe diameters upstream and/or five pipe diameters downstream of a flow or pressure control valve, or a flow-sensing device such as a venturi. Valves should comply with API Std 608.

b. Butterfly Valves: High-performance wafer trunnion butterfly type valves designed so that if the synthetic seating material is burned out in a fire, a metal-to-metal seat will remain to affect closure and comply with API Std 607. Use Teflon or Viton synthetic seals or seating material. Use valves of high performance type with eccentric disc shaft and clamping action for bubble-tight shutoff. Provide only at inlet to truck fillstand and on supply and return risers at aircraft direct fueling stations with fusible link set to release at 165 degrees F (74 degrees C). These valves are not required nor permitted on Air Force projects. Butterfly valves are not allowed in aircraft fueling facilities, marine receiving and dispensing facilities, and filling stations at ground product fueling facilities.

15-9.4 Isolation Valve Operators.

Provide manually operated valves not specified for remote, automatic, or emergency operation. Double block and bleed gate, ball, and plug valves specified for remote, automatic, or emergency service may have electric motor operators with suitable torque limiting controls, if approved by Service Headquarters. For remote valves, consider using solar battery packs to reduce cost of routing power for the motor operators. Provide geared operators for ball and double block and bleed valves larger than 6 inches (150 mm). Provide locking tabs on isolation valves to allow padlocks to be used to lock out valves during maintenance. Provide chain operators on valves which are located 72 inches (1800 mm) or higher above grade.

15-9.5 Isolation Valve Pits.

Provide fiberglass or concrete pits with a rolling or hinged cover designed in accordance with the DoD Standard Design AW 78-24-28 for all isolation valves installed in nontraffic areas on underground fuel systems. Design valve pits and valve operators so that the valves can be operated by personnel, without confined space entry.

15-10 OTHER VALVES.

15-10.1 Check Valves.

Use check valves to prevent backflow through pumps, branch lines, meters, or other locations where runback or reverse flow must be avoided. Check valves may be of the swing disk, globe, dual plate hinged disk, spring-loaded poppet, ball, or diaphragm-actuated types. Use checks of soft-seated non-slamming type with renewable seats and disks. Ensure check valves conform to API Spec 6D. Use non-surge check diaphragm control valves with flow control feature on the discharge of all pumps. When using non-surge check diaphragm control valves on pump discharge, consider the use of a spring type wafer check before the diaphragm control valve to prevent sudden flow reversals during shutdown from passing back through the pump before the diaphragm control valve diaphragm chamber is filled and reacts by closing the valve.

15-10.2 V-Port Ball Valves.

Valve must conform to requirements as specified for “Ball Valves” paragraph in this section. Valve must be provided with characterized linear v-port for flowrate control, and with infinite position lever bracket with locking bolt for set position. These valves are to be used only in packaged off-loading systems.

15-10.3 Thermal Relief Valves.

Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

15-11 DIAPHRAGM CONTROL VALVES.

Hydraulically operated, single-seated, globe type, diaphragm actuated control valves are used extensively in fueling systems as control valves. These valves consist of a main valve and a pilot control system. The main valve consists of body, diaphragm, and cover and is operated by varying the amount of pressure above the diaphragm. Since the chamber above the diaphragm exposes a greater area of the diaphragm to chamber pressure than the area of the disc exposed to line pressure, an equal pressure in the chamber and pipeline results in a greater force being applied to the top of the disc. This forces the disc against the seat, thus closing the valve. By selecting the proper pilot control system, these valves can be used in numerous ways to control flow, pressure, and level within fueling systems. Use extreme care when including these valves on pipelines as they can significantly contribute to surge potential, if closing time is too short. When properly adjusted, they can reduce surges.

15-11.1 Open/Close Operation.

This is the most basic function of hydraulically operated diaphragm control valves. The operation is accomplished by applying pressure above the diaphragm to close the valve and relieve that pressure to allow line pressure to open the valve. The pilot trim used to perform this operation is a three-way valve which can be controlled by a solenoid, hand, pressure, pressure differential, or a float.

15-11.2 Throttling Operation.

This is the other main method of controlling the hydraulically operated diaphragm control valve. In this case, the valve modulates to any degree of opening, in response to changes in the throttling control. The throttling control reacts to a pressure, or a pressure differential across the main valve, or pressure differential across an orifice plate to regulate the position of the disc in the main valve. For proper operation these valves should be installed with straight pipe on both sides of the valve. Ten pipe diameters on the upstream side and five pipe diameters on the downstream side is sufficient; provide full port manual isolation valves if they are placed within these limits.

15-11.3 Check Valve Function.

This is a unique function of a control valve. In this case, the main valve outlet pressure is connected to the diaphragm cover. Therefore, if the downstream outlet pressure exceeds the inlet pressure, which normally holds the valve open, the valve will close and prevent backflow. Note: In order for the valve to close, it must backflow, sometimes for a substantial amount of time. Consider putting a regular check valve in series with this valve in cases where this is a concern.

15-11.4 Remote Operations.

Hydraulically operated diaphragm control valves can be operated remotely. This is accomplished by installing tubing from the point of pressure sensing to the valve or by using remote-controlled solenoids within the trim.

15-11.5 Materials of Construction.

Use stainless steel pilot control valves and stainless steel tubing. Use bodies, bonnets, and covers made of stainless steel, internally plated (chrome) steel, or internally plated (nickel) nodular iron. Provide Viton or Buna-N diaphragm and disc ring. Enclose all electrical apparatus according to classification of the area in which they are installed. Provide a means to wire seal all adjustable pilots. Do not use aluminum valves.

15-11.6 Applications.

These valves are not required in filling stations at ground product fueling facilities (Chapter 7). Use hydraulically operated diaphragm control valves in the following applications:

a. Water slug shutoff.

b. Rate of flow control.

c. Pressure reduction.

d. Pressure relief.

e. Liquid level control.

f. Non-surge check control.

g. Deadman control.

h. Electrical block control.

i. Excess flow shutdown.

15-11.7 Combinations.

A combination of these controls is also possible. A typical use of these controls is on a filter-separator for water slug shutoff and rate of flow control.

15-12 FUEL HOSES.

Use sizes as required for design flow rates. For hose flanges and nipples, use carbon steel or brass, except at aviation turbine fuel issue points use brass, stainless steel, or aluminum where metal parts contact the fuel.

15-12.1 Loading Fuel Hoses.

Provide pressurized loading hoses and connections complying with EI Std 1529.

15-12.2 Off-Loading Fuel Hoses.

Provide lightweight, flexible, non-pressurized off-loading hoses constructed of nitrile rubber, rigid polyvinyl chloride (PVC) helix, synthetic braiding, smooth bore, and corrugated outer diameter. Provide non-pressurized hoses with a 65 psi (450 kPa) rating at 72 degrees F (22 degrees C) and 27 in Hg (90 kPa) vacuum rating.

15-12.3 Submarine Fuel Hoses.

Loading/off-loading arms are the preferred method to be used. Provide a facility for storing and protecting the hose as near as practical to the pier if hose is provided in lieu of loading/off-loading arm.

Provide submarine fuel hose where offshore moorings are used. Use heavy duty, smooth bore, oil and gasoline, marine cargo, discharge hose rated for a working pressure of not less than 225 psig (1550 kPa) and built-in nipples with Class 300 flanges with stainless steel bolts and Monel nuts. **\2** Hoses must meet U. S. Coast Guard requirements. ***/2/***

\2\

CHAPTER 16 AUSTERE LOCATION FUEL SYSTEM REQUIREMENTS

16-1 INTRODUCTION.

This chapter provides guidance for the design of fuel systems in austere locations. An austere location is an installation where real property infrastructure is present, but does not have any permanently assigned operational assets such as aircraft, ships, tanks, or other weapons systems. These locations are typically maintained in a caretaker status. If DLA fuel system capitalization is required, DLA must be included during the decision making to provide approval of designing the fuel system in accordance with this chapter. Approval by the Service Headquarters Subject Matter Expert (SME) is required to use the sections in this chapter. The Mission Owner described in this chapter is combatant or supporting command unit that is requiring the fuel system. Approval may be given on a line item basis.

16-1.1 Qualifications.

To use this chapter, one or more of the following qualifications must be met.

a. The location is geographically separated from other installations.

b. The location does not have assigned operational assets.

c. The location does not have assigned personnel. Personnel required to maintain the installation in a caretaker status may be present.

d. Ability to connect to local utility services is restricted.

16-2 GENERAL REQUIREMENTS (REF. CHAPTER 2).

Chapter 16 provides supplemental guidance for locations that meet the qualifications outlined in paragraph 16-1.1 and have written Service Headquarters Subject Matter Expert approval. Designers must follow UFC 3-460-01 Chapters 1 through 15 except when approval to follow chapter 16 has been provided by the Service Headquarters Subject Matter Expert.

16-2.1 Operational Capabilities (Ref. Paragraph 2-1).

Design austere fuel systems to meet the specified mission requirement as coordinated with the SCP. This may include a certain amount of redundancy for various reasons to include continued operation due to natural disaster, attack, or continued operation. However, these systems are not required to have the same redundancies typically seen in primary fuel systems.

16-2.2 Transfer Flow Rates (Ref. Paragraph 2-5).

The receipt and transfer flow rates established in Table 2-4 are a guide and not required. Greater or slower flow rates may be acceptable depending on the mission. The issue flow rates are well established and should be followed.

16-2.3 Voice Communications (Ref. Paragraph 2-8).

Where possible, provide a direct line for voice communications between separated areas such as receiving, dispensing, pump stations, and fuel storage areas to coordinate operations involved in fuel transfer. Where not possible, ensure a reliable form of communication is established and the Service Control Point (SCP) concurs with the selected solution.

16-2.4 Safety Showers and Eyewash Fountains (Ref. Paragraph 2-10.1).

The designer is to review the availability of existing utilities and evaluate individual circumstances at these locations. At a minimum, showers are required within 15 second reach of any corrosive chemicals, such as hydrazine and some additives, IAW OSHA and service safety requirements. At all other fuel facilities, either a fixed or portable eyewash is required. Coordinate with the SCP if portable eyewash units are planned to be used.

16-2.5 Corrosion Control.

Corrosion control is extremely important in these types of facilities. Corrosion prevention strategies should be based on the climate of the location. Refer to UFC 1-200-01 for Environmental Severity Classification and humidity design requirements for these locations and their corrosion prevention requirements. Every effort should be made to prevent corrosion by material selection, construction practices and standard corrosion prevention practices.

16-2.6 Cathodic Protection (Ref. Paragraph 2-12).

In addition to paragraph 2-12, the use of cathodic protection in these facilities should be minimized to the maximum extent possible through material selection and other mitigating measures.

16-2.7 Fire Protection (Ref. Paragraph 2-14).

In many of these locations, adequate utilities to support water based fire protection measures will not be available. A fire prevention and protection strategy needs to be established for the entire fuels related compound, including tanks, pump facilities, filtration facilities, tank truck and tank car facilities, aircraft parking and fueling facilities, refueler vehicle facilities, fuel testing laboratories, support facilities, and fuel piers to prevent the spread of fire beyond the level of an acceptable risk. The Mission Owner, Subject Matter Expert and host installation (if applicable) need to agree to the level of risk and cost of protection that is acceptable.

- Alternate forms of fire protection should be considered such as fire valves, fire breaks, and fire barriers. Distance remains the best method to prevent fire from spreading to other assets and should be carefully considered.

- Fuel driven pumps should be rated for the fuel that is available at the location. A separate logistical trail should be avoided.

16-2.8 Emergency Fuel Shut-Off (Ref. Paragraph 2-15).

Follow paragraph 2-15 to the maximum extent possible. The installation of an emergency fuel shut-off may be problematic due to system configuration or extensive maintenance. A request to install emergency bypass to the emergency fuel shut-off switch or to deviate from the prescribed EFSO switch locations must be submitted to the Service SME for review and approval. This approval will only be for a specific location and fuel system.

16-2.9 Material Acquisition.

Material acquisition, such as sand for under the tank bottoms, in these environments can be extremely difficult. Where possible, procure locally available materials that meet the technical requirements and comply with federal and host nation regulations.

16-3 BULK FUEL STORAGE FACILITIES (REF. CHAPTER 3).

16-3.1 Tank Truck and Tank Car Off-loading Facilities (Ref. Paragraph 3-3.1.3).

a. Where possible, do not locate tank truck or tank car receiving facilities closer than 50 feet (15m) from buildings, roads, overhead power lines, pad-mounted transformers, and installation property lines, and 25 feet (7.6m) from the installation interior fence surrounding the fuel farm. Where tank truck or tank car receiving facilities need to be closer than the prescribed distances, determine potential ignition risks and install other means of fire protection to mitigate the risk. The mitigation measure must be approved by the Service Headquarters Subject Matter Expert. Receiving facilities should maintain as much distance as possible if they are unable to meet the recommended stand-off distances.

b. Provide a spill containment system in accordance with Chapter 3 if possible. Alternate methods of containment must be approved by the Service Headquarters Subject Matter Expert on a case-by-case basis.

c. For off-loading tank trucks, arrange the flow of traffic to permit continuous forward movement of tank trucks. If space does not permit this, the tank truck off-loading area will be limited to two truck positions per lane, with space behind the second truck to back up.

d. Provide for adequate response of emergency vehicles. This is to be determined by the site layout and in conjunction with representatives of the emergency vehicle community.

16-3.2 Tank Car and Tank Truck Off-loading Facility Required System Components (Ref. Paragraph 3-3.1.7).

a. Provide an emergency fuel shutoff (EFSO) at the ingress and egress of the truck off-loading stations in accordance with paragraph 16-2.8.

b. Follow the recommended system components. Any requested changes must be submitted to the Service Headquarters Subject Matter Expert for review and approval.

16-3.3 Pipeline Pumping Facilities Required System Components (Ref. Paragraph 3-4.1.2).

Follow the required system components. Any requested changes must be submitted to the Service Headquarters Subject Matter Expert for review and approval.

16-3.4 Controls (Ref. Paragraph 3-7).

Controls for these type of systems must be simplified versions. Use the control scheme that provides the greatest reliability and the lowest maintenance for the mission of the location.

16-4 AIRCRAFT FUELING FACILITIES (REF. CHAPTER 4).

16-4.1 Pipeline receiving Facilities Required System Components (Ref. Chapter 4.3.1.2).

Follow the required system components. Any requested changes must be submitted to the Service Headquarters Subject Matter Expert for review and approval.

16-4.2 Tank Truck and Tank Car Off-Loading Facilities (Ref. Paragraph 4-3.2).

a. Use an alternate receipt mode where ever practical. It is not required to have two methods of receipt.

b. Where possible, do not locate tank truck or tank car receiving facilities closer than 50 feet (15m) from buildings, roads, overhead power lines, pad-mounted transformers, and installation property lines, and 25 feet (7.6m) from the installation interior fence surrounding the fuel farm. Where tank truck or tank car receiving facilities need to be closer than the prescribed distances, determine potential ignition risks and install other means of fire protection to mitigate the risk. The mitigation measure must be approved by the Service Headquarters Subject Matter Expert. Receiving facilities should maintain as much distance as possible if they are unable to meet the recommended stand-off distances.

c. Provide a spill containment system in accordance with 4-3.2.1 if possible. Alternate methods of containment must be approved by the Service Headquarters Subject Matter Expert on a case-by-case basis.

d. For off-loading tank trucks, arrange the flow of traffic to permit continuous forward movement of tank trucks. If space does not permit this, the tank truck off-loading area will be limited to two truck positions per lane, with space behind the second truck to back up.

e. Provide access for adequate response of emergency vehicles. This is to be determined by the site layout and in conjunction with representatives of the emergency vehicle community.

f. For tank truck and tank car off-loading facilities, follow the required system components. Any requested changes must be submitted to the Service Headquarters Subject Matter Expert for review and approval.

16-4.3 Dispensing Facilities (Ref. Chapter 4-4).

16-4.3.1 Refueler Truck Fillstands (Ref. Chapter 4-4.1).

a. Mission and turn-around times will establish the number of fill positions. There are no minimum number of positions.

b. Where possible, do not locate the refueler loading facility closer than 50 feet (15m) from buildings, roads, overhead power lines, pad-mounted transformers, and installation property lines, and 25 feet (7.6m) from the installation interior fence surrounding the fuel farm. Where tank truck or tank car receiving facilities need to be closer than the prescribed distances, determine potential ignition risks and install other means of fire protection to mitigate the risk. The mitigation measure must be approved by the Service Headquarters Subject Matter Expert. Receiving facilities should maintain as much distance as possible if they are unable to meet the recommended stand-off distances. Do not locate closer than allowed per NFPA.

c. Provide a spill containment system in accordance with 4-4.1.1 if possible. Alternate methods of containment must be approved by the Service Headquarters Subject Matter Expert on a case-by-case basis.

d. Provide access for adequate response of emergency vehicles. This is to be determined by the site layout and in conjunction with representatives of the emergency vehicle community.

e. For refueler truck fillstands, follow the required system components. Any requested changes must be submitted to the Service Headquarters Subject Matter Expert for review and approval.

16-4.3.2 Aircraft Direct Fueling Systems (Ref. Chapter 4-4.2).

a. Aircraft Direct Fueling Systems in austere environments are based on the Type III, IV and V hydrant systems. Systems in austere environments may be simplified versions of the highly controlled standard systems. Additionally, modifications can be made to improve reliability but may sacrifice some operational capability as long as it is acceptable to the

Mission Owner and the Fuels Operators. An example of this is using commercial pits, which improve reliability but eliminate the ability to defuel the aircraft through the hydrant system.

b. For dual pressure control, a single device can be used. The single device must be a combination of the HSV and a pressure control coupler when commercial pits are used. Hose end couplers provide pressure control but do not have surge features.

16-4.4 Description of System Components (Ref. Chapter 4-6).

For dispensing facilities, follow the required system components. Any requested changes must be submitted to the Service Headquarters Subject Matter Expert for review and approval.

16-4.5 Controls (Ref. Paragraph 4-7).

Controls for these type of systems must be simplified versions. Use the control scheme that provides the greatest reliability and the lowest maintenance for the mission of the location.

16-4.6 Aviation Turbine Fuel Receipt Filtration Table (Ref Table 4-1).

Use Table 4-1 as a guide. The designer will need to analyze the particular situation and determine the most appropriate fuel cleaning methodology.

16-5 MARINE RECEIVING AND DISPENSING FACILITIES (REF. CHAPTER 5).

16-5.1 Controls (Ref Paragraph 5-9).

Controls for these type of systems may be simplified versions, for example Programmable Logic Controller (PLC), electro-mechanical relay or manual operation. Use the control scheme that provides the greatest reliability and the lowest maintenance for the mission of the location.

16-6 INTERTERMINAL AND INSTALLATION PIPELINES (REF. CHAPTER 6).

16-6.1 Controls (Ref Paragraph 6-6).

Controls for these type of systems may be simplified versions, for example Programmable Logic Controller (PLC), electro-mechanical relay or manual operation. Use the control scheme that provides the greatest reliability and the lowest maintenance for the mission of the location.

16-7 GROUND PRODUCTS FUELING FACILITIES (REF. CHAPTER 7).

16-7.1 Stand-off Distances (Ref. throughout Chapter 7).

Where possible, follow the prescribed stand-off distances prescribed in Chapter 7. Where facilities need to be closer than the prescribed distances, determine potential ignition risks and install other means of fire protection to mitigate the risk. The mitigation measure must be approved by the Service Headquarters Subject Matter Expert. Ground Products Fueling Facilities should maintain as much distance as possible if they are unable to meet the recommended stand-off distances. At a minimum, federal, state, and local regulations must be followed.

16-7.2 Spill Containment (Ref. Paragraph 7-3.12).

Provide a spill containment system in accordance with Chapter 7 if possible. Alternate methods of containment must be approved by the Service Headquarters Subject Matter Expert on a case-by-case basis.

16-7.3 Controls (Ref. Paragraph 7-6).

Controls for these type of systems may be simplified versions. Use the control scheme that provides the greatest reliability and the lowest maintenance for the mission of the location.

16-8 ATMOSPHERIC STORAGE TANKS (REF. CHAPTER 8).

16-8.1 General Criteria (Ref. Chapter 8-3).

a. Any deviation to tank materials must be submitted to the Service Headquarters Subject Matter Expert for review and approval.

b. Provide a minimum of two tanks for each type of fuel to ensure the tanks can be maintained appropriately. A single tank option may be used if the mission supports it.

c. Follow tank spacing, as prescribed in paragraph 8-3.5, as much as possible. In austere locations, cost and available land may force the tanks to be placed closer together. In these circumstances, the tank spacing must not be less than the spacing requirements stated in NFPA 30. Where facilities need to be closer than the prescribed distances, determine potential ignition risks and install other means of fire protection to mitigate the risks. The mitigation measure must be approved by the Service Headquarters Subject Matter Expert. Tanks should maintain as much distance as possible if they are unable to meet the recommended stand-off distances. At a minimum, federal, state and local regulations must be followed.

16-8.2 Horizontal Aboveground Tanks (Double Wall Steel) (Ref. Chapter 8-5).

Tank dimensions and capacity may be exceeded. However, the tanks must be UL listed or equivalent. Tanks larger than those prescribed in paragraph 8-5 may be difficult to transport. Logistical challenges must be accounted for. At a minimum, host nation, federal, state, and local regulations must be followed.

16-8.3 Aboveground Vertical Storage Tanks (Ref. Chapter 8-8).

a. If use of sand beneath the tank bottom is impractical, alternative methods may be considered. The mitigation measure must be approved by the Service Headquarters Subject Matter Expert.

b. Alternatives to hydrostatic testing may be required for austere environments. If deviating from a standard practice, the revised procedures must be submitted to the Service Headquarters Subject Matter Expert for review and approval.

16-8.4 Underground Horizontal Storage Tanks (Ref. Chapter 8-9).

Tank dimensions and capacity may be exceeded. However, the tanks must be UL listed or equivalent. Tanks larger than those prescribed in paragraph 8-5 may be difficult to transport. Logistical challenges must be accounted for. At a minimum, host nation, federal, state, and local regulations must be followed.

16-8.5 Appurtenances (Ref Chapter 8-11).

For tanks, follow the appurtenances as outlined in Table 8-1. Any requested changes must be submitted to the Service Headquarters Subject Matter Expert for review and approval.

16-8.6 Aboveground Tank Spill Containment Systems (Ref. Chapter 8-14).

Use Chapter 8-14 as a guide to design containment systems for aboveground tanks. For austere systems, alternative methods of containment may be considered. This includes alternative tank dike, remote impoundment, and remote containment design. Key considerations for designing the tank containments are safety of operators who may be in the tank containment area, fire prevention, and the ability to contain a fuel spill.

APPENDIX A MANUAL SURGE CALCULATIONS FOR SIMPLE PIPING SYSTEMS

1. Determine the critical time of the system. This is defined as the time it takes for the first increment of the pressure wave to travel upstream, reflect, and return to the valve. Use the following equation:

EQUATION (1):

$$T_c = \frac{2L}{a}$$

Where:
T_c = critical closure time of system(s)
L = length of pipe (ft or m)
a = surge pressure wave velocity (fps or m/s)

Values for "a" for liquid petroleum in schedule 40 steel pipe are as follows. These values are based on hydrocarbons with a specific gravity of 0.8 at a temperature of 68 degrees F (20 degrees C):

Nominal Pipe Size inches (mm)	Surge Pressure Wave Velocity, "a" ft/s (m/s)
2 (50)	3,771 (1149.4)
3 (75)	3,763 (1147.0)
4 (100)	3,736 (1138.7)
6 (150)	3,692 (1125.3)
8 (200)	3,663 (1116.5)
10 (250)	3,639 (1109.2)
12 (300)	3,599 (1097.0)

2. If valve closure time (T) is less than Tc, it is equivalent to instantaneous closure and will result in maximum surge pressure. The equation used to calculate surge pressure rise for this situation is:

EQUATION (2):

$$P_1 - P = (V_1 - V_0)(\rho)(a)$$ ***(Metric Units)***

$$P_1 - P = [(V_1 - V_0)(\rho)(a)] / [(C)(g_c)]$$ ***(English Units)***

Where:
P_1 = maximum pressure (psig or Pa)
P = pump shutoff pressure (psig or Pa) (equal to system static pressure)
V_1 = initial velocity (fps or m/s)
V_0 = final velocity (fps or m/s)
ρ = density of the fluid (lbm/ft^3 or kg/m^3)
a = surge pressure wave velocity (fps or m/s)

C = unit conversion factor (144 in^2/ft^2)
g_c = gravitational unit conversion constant (32.17 ft · lbmass / (lbforce · sec^2))
Metric units require no conversion. 1 Pa = 1 N / m^2 = 1 kg / (m · sec^2)

3. For example, a fuel storage facility has a truck loading rack located 2,000 feet (610 m) away. The load rack is fed by a 600 gpm (38 L/s) pump located at the storage facility. The load rack is equipped with a deadman apparatus which is tied to a hydraulically operated diaphragm control valve at the rack. The valve has a closure time of 1.0 seconds. The pipe is 6-inch (150 mm) diameter carbon steel, Schedule 40, with Class 150 flanges. The pump shutoff pressure is 60 psig (410 kPa). Find the critical time of the system if the loading rack control valve closes.

$$T_c = 2L/a = 2 \times 2{,}000/3{,}692 = 1.08\, seconds$$

From the table of values for "a", the surge pressure wave velocity (a) is 3,692 fps (1125.3 m/s). The maximum pressure in any pipeline occurs when the total discharge is stopped in a period of time equal to or less than the critical time. Since the valve will theoretically close prior to this, Equation (2) should be used to determine the pressure rise. In this case, the final velocity (V_o) will be assumed to be zero because the critical time is greater than the valve closure time.

$$P_1 - P = [(V_1)(\rho)(a)] / [(144)(g_c)]$$

$$= [(6.81 \times 51.5 \times 3{,}692)] / [(144 \times 32.2)] = 279\, psig\ (1925\, kPa)$$

$$P_1 = P + 273 = 60 + 279 = 339\, psi\ (2337\, kPa)$$

Initial velocity (V_1) was found by dividing the given flow rate of 600 gpm (38 L/s) by the cross sectional area of the 6-inch (150 mm) diameter, Schedule 40 pipe. Considerations will have to be made for this system to deal with the maximum predicted pressure.

4. When the valve closure time is longer than the critical time, the surge will be less than predicted by Equation (2). The equation used to calculate surge pressure rise for this situation is:

EQUATION (3):

$$P_1 - P = [2(L)(\rho)(V_1 - V_c)] / [1.3\,(T)] \qquad \textit{(Metric Units)}$$

$$P_1 - P = [2(L)(\rho)(V_1 - V_c)] / [1.3\,(C)(g_c)(T)] \qquad \textit{(English Units)}$$

Where:
P_1 = maximum pressure (psig or Pa)
P = pump shutoff pressure (psig or Pa) (equal to system static pressure)
V_1 = initial velocity (fps or m/s)
V_0 = final velocity (fps or m/s)

ρ = density of the fluid (lbm/ft^3 or kg/m^3)
a = surge pressure wave velocity (fps or m/s)
C = unit conversion factor (144 in^2/ft^2)
g_c = gravitational unit conversion constant (32.17 ft · lbmass / (lbforce · sec^2))
Metric units require no conversion. 1 Pa = 1 N / m^2 = 1 kg / (m · sec^2)

Determination of V_c is too complex for simple calculation. Therefore, for the conditions where $T > T_c$, use a computer modeling program.

APPENDIX B CHARTER OF DOD FUELS DISCIPLINE WORKING GROUP (FDWG)

B-1 INTRODUCTION.

To benefit from Department of Defense (DoD) wide petroleum, oils, and lubricants (POL) expertise and apply it to fuel facilities issues facing the DoD, the Engineering Senior Executive Panel (ESEP) approved (2018) the establishment of the Fuels Discipline Working Group, previously known as the Fuels Facility Engineering Panel (FFEP). The FDWG consists of recognized POL experts, primarily from the engineering community, to establish the criteria for the DoD community on ways to provide safe, operationally effective, and economic fuel facilities systems to meet the mission requirements. The FDWG will examine, develop, recommend and provide design features for the standardization of facilities and equipment, and procedures used in fuel handling systems for storage, distribution, maintenance and dispensing of aircraft, marine, and ground fuels. The FDWG will evaluate facility component parts on DoD installations and will serve as a pool of expertise to assist in resolving systemic fuel handling facility problems. FDWG meetings will also serve as a forum to update members on new equipment, DoD or service-specific programs, and changes affecting the fuels facility maintenance, repair and construction community.

B-2 COMPOSITION.

B-2.1 FDWG Members.

a. Air Force Fuels Facility Subject Matter Expert (AFCEC/COSM)

b. NAVFAC Fuels Facility Subject Matter Expert (NAVFAC EXWC)

c. HQ Army Corps of Engineers Technical POC, POL Facility Criteria (CECW-EC)

B-2.2 Associate member:

a. Defense Logistics Agency Installation Support for Energy – Facilities Engineer (DLA-DF-FEI)

B-2.3 Coordinating members.

a. Defense Logistics Agency (Installation Management; Installation Operations)

b. Defense Logistics Agency Energy (SRM; Quality)

c. Defense Fuel Region Facility Managers

d. AF MAJCOM Fuels Engineers

e. AF Petroleum Agency Fuels Facilities Team

f. NAVPETOFF Fuels Facility Engineers

g. NAVAIR Fuels Engineers

h. NAVFACENGCOM, Fuels Facility Engineers

i. Army Petroleum Center Fuel Facility Team Members

j. Army Corps of Engineers, Omaha District, POL Mandatory Center of Expertise (POL-MCX)

k. Space and Naval Warfare Systems Center Atlantic (SPAWAR Atlantic)

B-3 TASKS.

Tasks of the FDWG include but are not limited to:

1. Develop and maintain standardized designs for receipt, storage, and dispensing fuel facilities and fuel systems.
2. Periodically review and update UFC 3-460-01 and UFC 3-460-03, including referenced DoD fuel handling facility criteria, and fuel system maintenance and repair criteria, and fuel facility assessment criteria (FUELER).
3. Perform technical review and provide approval of new or proposed design standards or concepts.
4. Review fuel system operational challenges, including system components and materials, and recommend corrections.
5. Cross-feed information such as problems and solutions, new missions and equipment, needed modifications to equipment, and new DoD or Service-wide programs and periodically communicate this information in a newsletter.
6. Provide a means of communication among the Air Force, Army, Navy, and DLA Energy to reduce duplication and institutionalize DoD-wide Standardization for fuel facilities.
7. Evaluate changes to fuel facilities that enhance training and efficient use of operation and maintenance personnel.
8. Provide information to fueling operations personnel to assure proper operation of equipment.
9. Assess the impact of mission demand, environmental, health and fire safety, energy, economic, and other drivers on fuel facilities design, and develop criteria that will address these impacts.

B-4 MEETINGS.

1. The Chairperson will be rotated biennially among the FDWG and Associate members.

2. The FDWG will meet at the call of the Chairperson but not less than once per year. FDWG members may request a meeting at any time. A quorum consists of not less than three FDWG/Associate members, and no more than one Proxy.

3. Decisions of the FDWG will be by consensus among the FDWG/Associate members.

4. When a FDWG/Associate member cannot attend a meeting, the member shall appoint a proxy for meeting attendance. The FDWG must be advised of the proxy prior to the meeting.

B-5 CHARTER REVIEW.

1. The FDWG will review the Charter at least once per year, and update as required.

H-U	Horizontal Underground Storage Tank
ICC	International Code Council
IESNA	Illuminating Engineering Society of North America
JPTS	Jet Propellant Thermally Stable Fuel
LPG	Liquefied Petroleum Gas; Propane, Butane
MFL	Magnetic Flux Leakage
MIL	A unit of length equal to one thousandth of an inch, especially used to measure the thickness of paints and coatings
Mogas	Common contraction of Motor Gasoline, referring to fuel for land vehicles

NACE	National Association of Corrosion Engineers
NATO	North Atlantic Treaty Organization
NAVAIR	Naval Air Systems Command
NBBI	National Board of Boiler and Pressure Vessel Inspectors
NBIC	National Board Inspection Code
NAVFAC EXWC	Naval Facilities Engineering and Expeditionary Warfare Center
NAVFAC EXWC, OC	Naval Facilities Engineering and Expeditionary Warfare Center, Oceans Technical Department
NFPA	National Fire Protection Association
NPDES	National Pollutant Discharge Elimination System
OCONUS	Outside of the Continental United States
OMSI	Operation and Maintenance Support Information
OSHA	Occupational Safety and Health Act of 1970
OVP	Over-Voltage Protection
P-A	Protected Aboveground Storage Tank
PDP	Pressure Dew Point
pH	A number assigned to indicate whether a substance is acidic or alkaline (pH 7 is considered neutral, less than 7 is acidic and more than 7 is alkaline)
PLC	Programmable Logic Controller
POL	A commonly used abbreviation which broadly refers to all Petroleum, Oils, and Lubricants
PSI or PSIG	Pounds per Square Inch, the unit of pressure measurement; gauge pressure above atmospheric
PSIA	Pounds per Square Inch absolute; pressure above an absolute vacuum
PVC	Polyvinyl Chloride

RDBMS	Relational Database Management System
SAE	Society of Automotive Engineers, used in conjunction with specification for viscosity of lubricating oils
SPCC	Spill Prevention Control and Countermeasure
SPR	Single Point Receptacle
STANAG	Standardization Agreement (NATO term)
UFGS	Unified Facilities Guide Specifications
ULSD	Ultra Low Sulfur Diesel
UPV	Unfired Pressure Vessel
UST	Underground Storage Tank
USAFE	United States Air Forces in Europe
V-A	Vertical Aboveground Storage Tank
VOC	Volatile Organic Compound
V-U	Vertical Underground Storage Tank

D-2 DEFINITION OF TERMS

Additive. Chemical added in minor proportions to fuels or lubricants to create, enhance or inhibit selected properties; example, fuel system icing inhibitor (FSII).

Aircraft Direct Fueling System. Method used to refuel aircraft by issuing fuel directly to the aircraft from the tank farm without first transferring the fuel to a refueler truck. Also known as a hydrant system.

Aircraft Refueling Adapter. A device, mounted on an aircraft, that combines with a pressure refueling nozzle mounted on a refueling vehicle or station to form a quick disconnect connection for the purpose of refueling or defueling aircraft. It can also be used for refueling and defueling refuelers.

Ambient. Encompassing on all sides, as temperature.

Anode. The positively charged electrode of an electrolytic cell.

API Gravity. Petroleum industry scale for measuring the density of oils.

ASME Type Thermal Relief Valve. Thermal relief valve that is labeled in accordance with ASME BPVC SEC VIII D1.

Atmospheric Pressure. The pressure exerted by the earth's atmosphere, when measured at sea level under standard conditions is equal to 14.7 pounds per square inch (101 kPa).

Atmospheric Tank. Storage tank which operates at or near atmospheric pressure (14.7 psi (101 kPa) at sea level).

Balanced Type Thermal Relief Valve. Thermal relief valve that is a fully balanced (back pressure will not affect relief pressure) regulator-type valve.

Ballast Water. Water carried in ship's fuel tanks or cargo tanks to improve the vessel's stability when empty of petroleum.

Barrel. Measure of volume as used in the petroleum industry, equivalent of 42 U.S. gallons (0.16 m^3).

Blind Flange. Piping flange with no passage through the center.

Boiler Fuel Oil. Fuel oil that is burned in furnaces to create steam or hot water, also called fuel oil.

Boiling Point. The temperature at which the vapor pressure of a liquid is equal to the pressure of the vapor above the liquid, usually atmospheric pressure. The temperature increases as the atmospheric pressure increases.

Bollard. A heavy solid post used to protect equipment from an impact. Also used on docks and ships for mooring.

Bond. Electrical connection between two objects which equalizes their potential.

Boom. Flexible floating barrier consisting of linked segments designed to contain free oil on the surface of a body of water.

Bottom Loading. Method of filling tank trucks or tank cars through a tight connection at the bottom.

Breakaway Coupling. Coupling designed to part easily with a moderate pull with a dry-break from both directions.

Bulk Storage Tank. Storage tank for fuel normally received by pipeline, tank truck, or tank car. For aviation turbine fuel, configure tank to supply fuel to operating storage tanks, either directly tank-to-tank, or indirectly by issuing fuel to tank trucks, tank cars, barges, ships, or pipelines.

Bunkers. Common expression referring to heavy residual boiler fuel.

Calibration. Adjustment of the scale of a graduated device to meet an established standard, especially applicable to the adjustment of meter registers to indicate true volume as determined by a standard measure.

Cathodic Protection. A method for preventing the corrosion of metals by electrolysis.

Centistokes. A centistoke (cSt) is equal to 1 millimeter squared per second.

Centrifugal Pump. A rotating device which moves liquids and develops liquid pressure by imparting centrifugal force.

Clean Product. Refined light petroleum products such as gasoline or distillates, as differentiated from residuals or black oils.

Coalescer. A porous substance through which a liquid is passed to remove unwanted water from fuel by causing very small drops of water to form larger drops (coalesce) which will separate from fuel by gravity.

Coalescer Vessel. A pre-filtration vessel designed to remove gross amounts of water and, to a lesser degree, particulate water. Types include Haypack coalescers.

Combustible Liquid. Any liquid having a flash point at or above 100 °F (38 °C).

Contaminated Fuel. Petroleum fuel containing suspended or emulsified water, cleaning chemicals; or other foreign matter such as iron scale, dust, or other solid particles; or containing an unacceptable percentage of noncompatible fuel or other liquids; or containing more than one, or all of these classes of contaminants.

Contamination. The accidental addition to a petroleum fuel of some foreign material (contaminant) such as dirt, rust, water, or accidental mixing with another grade of petroleum.

Corrosion. The process of dissolving, especially of metals due to exposure to electrolytes.

Crude Oil. Petroleum in its natural state prior to refining.

Cut and Cover. Refers to underground vertical storage tanks.

Cyclonic Filter. A filter used to remove gross amount of particulate matter using the principle of centrifugal force to separate solid particles from a liquid.

Deadman Control. A control device, such as a switch or valve, designed to interrupt flow if the operator leaves his station.

Density. The mass per unit volume of a substance.

Dike. An embankment or wall, usually of earth or concrete, surrounding a storage tank to impound the contents in case of a spill.

Distillate. Common term for any of a number of fuels obtained directly from distillation of crude petroleum, usually includes kerosene, JP-5, light diesel, and light burner fuels. Does not include any grades of gasoline.

Double Block and Bleed Valve. A valve with two seats with a cavity in between them which can be drained while the valve is closed to prove the valve is not leaking.

Downgrade. To use a fuel for a lesser purpose than originally specified, often because of contamination.

Effluent. Stream flowing; discharge.

Electrode. Electrical conductor through which an electric current enters or leaves an electrolyte.

Electrolysis. Chemical change, especially decomposition, produced in an electrolyte by an electric current.

Electrolyte. A substance capable of forming solutions with other substances which produce ions and thereby permit the flow of electric currents.

Electrical Conductor. A substance which permits the flow of electric currents without permanent physical or chemical change; copper, aluminum.

Element. Term used to describe the ‘disposable’ part of a filter vessel such as a filter-separator, micronic filter, or Haypack coalescer. Also referred to as a cartridge.

Emulsion. A suspension of small globules of one liquid in a second liquid with which the first will not mix.

Epoxy Coating. A coating of thermosetting resins having strong adhesion to the parent structure, toughness, and high corrosion and chemical resistance, also used as an adhesive.

Explosion-proof. Classification of electrical enclosures for use in hazardous areas designed to prevent the passage of internal arcs, sparks or flames.

Fender. Part of a pier structure designed to absorb the impact of a moving vessel.

Fiberglass. Composite material consisting of glass fibers in a matrix of resin such as epoxy.

Filling Station. A facility designed to fill vehicles with gasoline or diesel as motive fuel.

Filter. A porous substance through which a liquid is passed to remove unwanted particles of solid matter. Types include cyclonic filters and micronic filters.

Filter/Coalescer Elements. A type of coalescer that removes water and particulate matter from fuel. Used as the first element in filter-separators. Also to as coalescer elements or coalescers.

Filter-separator. A filtration vessel consisting of two separate element types (also called stages). The first stage consists of filter/coalescer elements to remove fine particulate matter and to remove entrained water by coalescing it; the second stage consists of separator elements to prevent fine droplets of water (caused by the coalescing process) from reaching the vessel outlet. It removes dirt and free water down to the very low levels required for aircraft operations. Filter-separators are the only approved vessels for use in fine filtration; they are occasionally used for pre-filtration as well.

Fine Filtration. A term used to refer to filtration vessels used to remove dirt and free water down to the very low levels required for aircraft operations. Fine filtration vessels are always filter-separators.

Fire Resistant Tank. Aboveground storage tank that is listed in accordance with UL 2080, that consists of a primary tank that is protected or insulated from a 2-hour fire exposure.

Flammable Liquid. Any liquid having a flash point below 100 degrees F (38 degrees C) and a vapor pressure not exceeding 40 psia (275 kPa) at 100 degrees F (38 degrees C).

Flash Point. The lowest temperature at which a combustible or flammable liquid produces enough vapor to support combustion.

Floating Roof Tank. Petroleum storage tank with a roof that floats on the liquid surface and rises and falls with the liquid level.

Free Water. Undissolved water content in fuel.

Freeze Point. The temperature at which wax crystals form in distillate fuels and aviation turbine fuels.

Fuel Oil. See Boiler Fuel Oil.

Fuel Quality Monitor. A special type of filter designed to interrupt the flow of fuel when dirt r water content becomes too great.

Galvanizing. Rust inhibiting zinc coating applied to iron and steel.

Ground. An electrical connection to earth.

Haypack Coalescer. A type of coalescer that uses hay, straw, or excelsior as a medium to remove large slugs of water.

Hazardous Area. Electrical classification for areas where flammable or combustible liquids or vapors may be present.

Hot Refueling. Refueling of aircraft when one or more engines are running.

Housekeeping Pad. Concrete pad usually installed on concrete slabs or floors to elevate and anchor equipment. Housekeeping pads aid in maintenance and keep equipment clear of debris.

Hydrant System. Distribution and dispensing system for aviation turbine fuels consisting of a series of fixed flush type outlets or hydrants connected by piping. It issues fuel directly to the aircraft from the tank farm without first transferring the fuel to a refueler truck. Also known as an aircraft direct fueling system.

Hydrocarbon. A compound made up exclusively of hydrogen and carbon in various ratios and molecular arrangements.

Hydrostatic Head. Pressure caused by a column of liquid.

Hydrostatic Test. A test for leaks in a piping system using liquid under pressure as the test medium.

Hydrostatic Test Pressure. The pressure in the system while it is undergoing a hydrostatic leak test as defined by ASME B31.3. For the purpose of this document, set at 1.5 times the maximum allowable working pressure.

Ignition Temperature. The minimum temperature required to initiate or cause self-sustained combustion independent of any heating or heated element.

Impervious. Not easily penetrated. The property of a material that does not allow, or allows only with great difficulty, the movement or passage of a fluid. Also referred to as impermeable.

Impressed Current System. A cathodic protection system using an outside source of electric power.

Inert Material. Any solid, liquid, or gaseous substance not combustible or fire-producing when exposed to the atmosphere under ordinary climatic conditions; it includes common metals, packing materials, ceramic materials, construction materials such as concrete, mineral aggregates, and masonry.

Installation Pipelines. Pipelines which connect POL facilities within an installation such as a barge pier to a bulk facility and a bulk facility to an operating (ready-issue) tank. These pipelines do not cross property lines and, therefore, do not leave the government facility and control.

Interterminal Pipelines. Pipelines which connect two government installations such as a Defense Energy Supply Center depot to a military installation. These pipelines cross property lines and cross public and/or private properties, streets, highways, railroads, and utility rights-of-way.

Intrastate Interterminal Pipelines. Interterminal pipelines that do not cross state lines.

Interstate Interterminal Pipelines. Interterminal pipelines that cross state lines.

JP Fuel. Military designation applied to aviation turbine fuels (e.g., JP-4, JP-5, and JP-8).

Kerosene. A general term covering the class of refined petroleum which boils between 370 degrees F and 515 degrees F (188 degrees C and 268 degrees C). Mostly used in oil lamps and cooking stoves.

Kerosene Type Aviation Turbine Fuel. JP fuel derived from kerosene without the addition of naphthas; characterized by a flash point of 100 degrees F (38 degrees C) or more.

Kinematic Viscosity. The ratio of viscosity of a liquid to its specific gravity at the temperature at which the viscosity is measured.

Lead Hazard. Poisonous contamination of the atmosphere, sludge, or other surroundings, particularly in petroleum storage tanks caused by tetraethyl lead or its residues.

Line Blind. A solid flat plate used to obtain absolute shut-off of flow. Also, referred to as spectacle plates or flanges, blinding plate, figure eights and paddle blinds.

Lube Oil. Common contraction for lubrication oil; used to reduce friction and cool machinery.

Maximum Allowable Working Pressure. The maximum allowable pressure of a fuel system or component will see. For the purposes of this document, set at the pressure rating of a flanged joint per ASME B16.5.

Maximum Allowable Operating Pressure. The maximum pressure at which a system is to operate. For the purposes of this document set at 2/3 of the hydrostatic test pressure, not to exceed the maximum allowable working pressure.

Maximum Allowable Surge Pressure. The maximum pressure allowed during a surge event. For the purposes of this document, set the pressure at 133% of the qualified maximum allowable operating pressure.

Micron. A unit of length equal to one millionth of a meter, especially used as a measure of the size of very fine particles found as contaminants in fuel.

Micronic Filter. A type of pre-filter vessel equipped with paper filter elements, designed to remove particulate matter from a fuel stream. Will not remove water.

Military Specifications. Guides for determining the quality requirements for materials and equipment used by the military services.

Motive Fuel. Any fuel that is used to power vehicles, aircraft, or vessels.

Naphthas. Refined petroleum which boils at 800 degrees F (427 degrees C) to 4400 degrees F (2427 degrees C), used as a component of gasoline and solvents.

Nipple. Short length of pipe, usually used to make side branch connections.

Nondestructive Testing. A method of inspecting materials without cutting, drilling or otherwise destroying the material; usually used to examine steel plates, pipes, and welds.

Nozzle. A spout or connection, usually with a control valve through which fuel is discharged into a receiving container.

Octane Number. A numerical measure of the antiknock properties of automotive gasoline as measured against standard reference fuels, under controlled laboratory conditions. Iso-octane is a reference fuel whose octane number is given a value of 100.

Off-Specification. Usually referring to fuel which is contaminated or otherwise deficient in quality. Commonly used contraction for off-specification is “off-spec”.

Oil/water Separator. A device used to separate mixtures of oil and water, usually by the difference in specific gravity and usually to protect the environment from contamination by the oil.

Oily-water Mixture. Mixture in which water comprises more than half the total volume. Most such untreated mixtures contain less than 15 percent oil, some of which may be in emulsified form.

Operating Storage Tanks. Storage tank for aviation turbine fuel configured to issue fuel directly to an aircraft, hydrant system, or refueler. A tank configured to issue aviation turbine fuel to a refueler only in an emergency is considered a bulk storage tank.

Orifice Plate. A plate with a hole in the center held between two flanges in a pipeline, used to create a drop in pressure which is proportional to flow and can be used to measure the flow or to modulate control devices.

Pantograph. A series of pipes, joined by flexible joints, used to connect fueling equipment to aircraft.

Parallel Pumps. Two or more pumps having common suction and discharge connections.

Particulate Matter. Solid particles such as dirt, grit, and rust, which contaminate fuel.

Pigging. The use of internal pipe tools, called pigs, to clean the inside of the pipe, determine the geometry of the pipe, and determine the location and magnitude of any internal or external corrosion occurring on the pipe.

Pig Launcher. An arrangement of valves and closure devices to launch pigs at the beginning of their run through a pipeline.

Pig Receiver. An arrangement of valves and closure devices to trap pigs at the end of their run through a pipeline.

Pile Cluster. A group of pilings driven close together and usually wrapped with wire rope to act as fender or mooring for small vessels.

Pour Point. The lowest temperature at which an oil will pour or flow without disturbance.

Pontoon Roof. A type of floating roof for a storage tank having liquid-tight compartments for positive buoyancy.

Pre-filter. A term used to refer to any filtration vessel used immediately upstream of a fine filtration filter-separator in a fuel storage/delivery system. They are used to remove gross amounts of particulates and/or free water from a fuel stream in order to prolong the life of the elements used in the fine filtration filter-separator. Typically cyclonic or micronic filters are used as pre-filters although Haypack coalescers or even filter-separators may also be used in this role.

Pre-Filtration. Pre-filters or coalescers vessels placed ahead of additional, more sophisticated, fine filtration vessels for the gross removal of solids and/or free water.

Pressure Drop. The loss in pressure of a liquid flowing through a piping system caused by friction of pipe and fittings, velocity, and change in elevation.

Pressure Refueling Nozzle. A device, mounted on a refueling vehicle or station, that combines with an aircraft refueling adapter mounted on an aircraft to form a quick disconnect connection for the purpose of refueling or defueling aircraft. It can also be used for refueling and defueling refuelers.

Product Recovery Tank. Tank used to collect and store aviation turbine fuel that would otherwise become waste fuel. It is part of a closed system that, either manually or automatically, pumps the fuel back into the system through a hard piped connection. Tanks that do not have this hard piped connection are not product recovery tanks.

Protected Tank. Aboveground storage tank that is listed in accordance with UL 2085, that consists of a primary tank that is protected or insulated from a 2-hour fire exposure and protected from physical damage.

Pump Pad. A facility housing one or more pumps with no roof or canopy.

Pump Shelter. A facility housing one or more pumps with a roof, at least one wall completely open with adequate fire department access, and a total open wall area of 50 percent or more.

Pumphouse. A facility housing one or more pumps with a roof, and a total open wall area of less than 50 percent.

Radiograph. An image produced on radiosensitive film by invisible radiation such as X-ray, specifically the image produced by radiographic inspection of welds and plates.

Ready-Issue Tank. See operating storage tank.

Recoverable Fuel. That portion of the fuel which may be separated and collected from a given lot of contaminated fuel, by proper processing in the treating facility in question.

Recovered Oil. Used to denote untreated petroleum fuel removed from oil/water separators or picked up after being spilled on land or water. Also used to mean oil which has been separated from and collected from a given lot of contaminated fuel by processing in a treating facility.

Refueler. Except for tactical refuelers, tank truck vehicles used to resupply aircraft with fuel. Tactical refuelers may transport ground products (gasoline, diesel) or aviation turbine fuel.

Reid Vapor Pressure. Vapor pressure measured under controlled conditions with the liquid temperatures at 100 °F (38 °C).

Residual Fuel Oil. Topped crude petroleum from refinery operations. Commercial grades of Burner Fuel No. 5, No. 6, and bunker fuels are residual fuel oils.

Relaxation Tank. Small tank in a fuel dispensing piping system downstream of filter-separators designed to remove static electricity from the liquid stream before discharge into a receiving tank.

Rotary Pump. A positive displacement pump which operates in rotary fashion such as a vane, gear, bucket, lobe, or screw pump; not centrifugal, turbine, or propeller pumps.

Rust. Ferric oxide, a reddish-brown scaly or powdery deposit found on the surface of steel and iron as a result of oxidation of the iron.

Safety Relief Valves. Valves that are installed on pressurized vessels to relieve pressure in access of the maximum allowable working pressure of the vessel. Safety valves are provided to protect people, equipment, and property.

Scraper. A type of cleaning pig used in pipelines.

Secondary Containment-Type Tank. A tank that has an inner and outer wall with an interstitial space (annulus) between the walls and that has a means for monitoring the interstitial space for a leak.

Service Headquarters. Defined as follows: Army – Headquarters, U.S. Army Corps of Engineers Technical POC, POL Facility Criteria (CECW-CE); Air Force - The Air Force Fuels Facilities Subject Matter Expert (HQ AFCEC/COS); Navy/Marine Corps: NAVFAC POL Facility Subject Matter Expert (NAVFAC EXWC, SH25)

Service Provider. Defined as follows: Defense Logistics Agency (DLA) – DLA Facilities Engineer, DLA Installation Support for Energy (DLA DS-FEI)

Single Point Receptacle. Point at which fueling hose is attached to skin of aircraft during aircraft refueling operations.

Skimmer. A device used to collect thin layers of oil floating on a body of water.

Slop Oil. Oil or fuel which has become contaminated with other oils or substances, often requiring separation or treatment before it is fit for use.

Sludge. Heavy viscous oily mass found in the bottom of storage tanks and treatment vessels, often contains rust, scale, dirt, lead additives, wax, gum, or asphalt.

Specific Gravity. The ratio of the weight in air of a given volume of a substance to the weight in air of an equal volume of distilled water (62.4 lb/ft^3) (1000 kg/m^3), both taken at the same temperature, usually 39.2 °F (3.98 °C).

Static Electricity. Accumulation of electric charge on an insulated body; also the electrical discharge resulting from such accumulation.

Strapping. The process of determining the volume of a storage tank or cargo hold by measuring its linear dimensions.

Stripper Pump. A pump used to strip or remove the last bit of liquid from a tank or pipe.

Subdivision. A physical structure that divides a secondary containment area. Also known as intermediate curb.

Sump. A low area or depression which receives drainage.

Surge. Sudden increase in fluid pressure caused by sudden stopping of a moving stream as by a quick closing valve; hydraulic shock; also the sudden, brief increase in voltage or current in an electrical circuit.

Surge Arrestor. A protective device for limiting surge voltages by discharging or bypassing surge current, and it also prevents continued flow of follow current while remaining capable of repeating these functions. Designed primarily for connection between a conductor of an electrical system and ground to limit the magnitude of transient (surge) overvoltages on equipment. Also known as arrestor or arrester, surge arrester, lightning arrestor or arrester.

Surge Suppressor. Device designed to control or reduce surges; hydraulic shock absorber.

Thermal Relief Valves. Valves that are installed around isolation valves to relieve excessive pressure caused by thermal expansion of the fuel in the pipe.

Tolerance. An allowable variation from a specified standard of measurement, commonly applied to the accuracy of meters.

Top Loading. Method of filling tank cars and trucks through an opening in the top.

True Vapor Pressure. Vapor pressure measured at actual liquid temperature.

Vapor Lock. Malfunction of an engine fuel system or of a pumping system caused by vaporization of the fuel, usually associated with gasoline.

Vapor Pressure. Internal pressure of vapor in a liquid usually in pounds per square inch; an indication of volatility.

Viscosity. Measure of the internal resistance of a fluid to flow or movement, most commonly measured in centistokes.

Volatility. Measure of the tendency of a liquid to vaporize; vapor pressure.

Waste Oil. Oil from which the water and other contaminants cannot be removed by the available treating facilities, and hence is unfit for further use. This term is also loosely used for contaminated oil which may contain recoverable fuel collected at facilities having no treatment facility for fuel reclamation.

Water Bottom. Free water which has settled to the bottom of a storage tank.

Water Draw-off. A valve or similar device used to remove water from the bottom of a tank.

Water Slug Shutoff. A valve in the discharge piping from a filter-separator which closes automatically when the water in the unit rises above a set level.

Wax. Viscous or solid high molecular weight hydrocarbon substance; paraffin.

Weatherproof. Type of enclosure for electrical apparatus for outdoor service in nonhazardous areas.

Wharf. A landing place where vessels tie up to load or unload; pier.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	29 April 2021	Chapter 1, 2, 3, 4, 5, 6, 7, 8, 11, Appendix A, Appendix, B, Appendix C, Appendix G, Appendix I, Appendix J. Changes incorporated CCR and administrative changes.
2	24 August 2023	Chapter 1, 2, 3, 6, Appendix A, Appendix, B, Appendix C, Appendix I, Appendix J. Changes incorporated CCR and administrative changes. Added Two-Person Rule in Chapter 2. Changed several maintenance tasks in Appendix C between OM and SM.

This UFC supersedes UFC 3-460-03, dated 21 January 2003.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), host nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source: Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)

CHANGE SUMMARY SHEET

Document: UFC 3-460-03, *Petroleum Fuel Systems, Maintenance*

Superseding: UFC 3-460-03, dated 21 January 2003

Description: Unified Facilities Criteria (UFC) 3-460-03 contains general inspection and maintenance criteria for military land-based liquid petroleum fuel facilities. It also applies to facilities dispensing Liquefied Natural Gas (LNG) and Compressed Natural Gas (CNG) for ground vehicle fueling. These criteria are applicable to all branches of the Department of Defense (DoD) and the Defense Logistics Agency (DLA).

Reasons for Document: UFC 3-460-03 was developed to harmonize requirements and guidance documents from the Army, Navy, U.S. Marine Corps, Air Force, industry guidelines, standards and codes. Creating a true unified criteria allows military services to define the required tasks for contractors and government personnel in maintaining petroleum fuel facilities.

Other military publications reviewed during the update to UFC 3-460-03 include United States Air Forces in Europe (USAFE) *Volume 1 General Description and Operation*; USAFE *Volume 2 Maintenance and Repair*; Standardization Agreement (STANAG) 3609 *Standards for Maintenance of Fixed Aviation Fuel Receipt, Storage and Dispensing Systems*; United States Air Force (USAF) Air Force Instruction (AFI) 23-204 *Organizational Fuel Tanks*; USAF Technical Order (TO) 37-1-1 *General Operation and Inspection of Installed Fuel Storage and Dispensing Systems*; and Unified Facilities Guide Specifications (UFGS).

Several industry standards, recommended practices, and codes have been incorporated into UFC 3-460-03 criteria including: American Petroleum Institute (API), Airlines for America (A4A), Energy Institute (EI), National Association of Corrosion Engineers (NACE) International, Petroleum Equipment Institute (PEI), Society of Automotive Engineers (SAE) International, and the Steel Tank Institute (STI).

Impact:

- Provides the requirements for tasks and frequencies for the inspection and maintenance of Petroleum Fuel Systems and components such as aircraft hydrant systems, tanks, and pipelines.
- Provides checklists for the inspection and maintenance of Petroleum Fuel Systems.
- Provides fuel quality, safety, environmental, fire protection guidance to follow during the inspection and maintenance of Petroleum Fuel Systems.

Unification Issues: The Army, Navy, U.S. Marine Corps, and Air Force could not unify on tank cleaning requirements listed in Section 8-7. The Air Force will require fuel tanks above 20,000 gallon in capacity to be cleaned on a 10 year cycle. The Army, Navy, and U.S. Marine Corps will require tanks to be cleaned during out of service inspections. The period of out of service inspections may vary depending on the type and condition of each tank.

This Page Intentionally Left Blank

TABLE OF CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

1-1.1 Introduction.

Clean, water-free fuel of the correct grade is essential to the safety of vehicles, ships and aircraft, and their operators and personnel. This manual emphasizes inspection and preventive maintenance to avoid system shutdowns, prevent fuel contamination, and decrease fire, safety, and health hazards. Periodic inspections and maintenance are essential to continue efficient safe operations and reduce major repairs.

1-1.2 Applicability.

UFC 3-460-03 applies to all real property facilities used for storing, distributing, and dispensing fuels for reciprocating and jet engine aircraft, automotive fuels, lubricating oils, and diesel fuel.

1-1.3 Scope.

This manual establishes the minimum inspection and maintenance standards for fueling systems and applies to all active installations. If the installation is in an inactive or surplus status, reduce maintenance standards to a point consistent with the anticipated mission.

1-1.4 Design Criteria.

This is not a design manual. Refer to UFC 3-460-01 for current design and construction standards.

1-2 ROLES AND RESPONSIBILITIES.

A role is a position or job defined by a set of responsibilities. A responsibility is a task or duty required of a designated party. Military services delegate tasks differently to military service-specific petroleum fuel personnel, contracted operations personnel, or maintenance contractors.

UFC 3-460-03 defines minimum maintenance tasks and their frequency. The criteria outlined within UFC 3-460-03 must be accomplished by DoD personnel (active duty/civilian) and/or DoD contractors.

The Command Authority (i.e., Army, Navy, U.S. Marine Corps, Air Force, and/or DLA) defines how tasks are divided among personnel at each facility. DoD 4140.25-M provides requirements applicable to all DoD fuel facilities.

1-2.1 Operational Tasks.

Operational tasks are actions taken to control and run the petroleum fuel system on a day-to-day basis. These tasks include monitoring control systems, bulk issue and receipt, and storage of petroleum fuel. Operating tasks help ensure the safety of personnel and the environment. Operating tasks often include specific measures to maintain petroleum fuel quality.

1-2.2 Maintenance Tasks

Maintenance tasks are recurring, daily, periodic, or scheduled work required to: preserve a facility, prevent deterioration, prevent component failure, prevent unscheduled outages, and identify components requiring replacement or repair. Maintenance tasks involve: routine inspection, testing of petroleum fuel systems, and identifying required repairs. Maintenance tasks help ensure product quality, safe working conditions, and environmental safety.

Maintenance tasks are separated into Operator Maintenance (OM) and Systems Maintenance (SM). OM is normally performed by facility operator personnel as part of normal use. SM is normally performed by trained personnel of base facility maintenance, facility operating contracts, or maintenance contracts for recurring maintenance and repair. Military services can delegate maintenance tasks between OM and SM differently. Appendix C includes a list of maintenance tasks included in this UFC and their associated designation as OM or SM for the Army, Navy and U.S. Marine Corps, and the Air Force.

1-3 DEPARTMENT OF DEFENSE FUELS \1\ DISCIPLINE WORKING GROUP /1/.

UFC 3-460-03 was updated by the DoD Fuels **1**\ Discipline Working Group (FDWG) /**1**/. For more information on the **1**\ FDWG /**1**/ refer to UFC 3-460-01, Appendix **1**\B/**1**/.

1-4 SERVICE HEADQUARTERS SUBJECT MATTER EXPERTS.

Policies, obligations, and responsibilities vary between DoD components. For interpretation of components required in petroleum fuel systems, consult the applicable Service Headquarters Subject Matter Expert (SME). For interpretation, the SME at the appropriate Service Headquarters is defined as follows:

- Army – Headquarters, US Army Corps of Engineers, POL Facilities Proponent (CECW-EC).
- Air Force – The Air Force Fuels Facilities Subject Matter Expert (**1**\/**1**/ AFCEC/COS) through the applicable **1**\ Regional Fuels Engineer (USAFE/PACAF) /**1**/.
- Navy/Marine Corps: NAVFAC POL Facility Subject Matter Expert (NAVFAC EXWC, CI11).

1-5 SERVICE CONTROL POINTS.

Service Control Points (SCP) have been established for each of the military services. SCPs serve as the central management function in coordinating requirements, technical issues, and supply actions with military units and DLA Energy. For interpretations on operation and maintenance requirements of fuel systems, consult the applicable SCP as defined in DoD 4140.25-M, Volume 1, Chapter 1, Section C1.3.1.5.

1-6 REGULATORY COMPLIANCE.

Inspection and maintenance activities must meet the most stringent of UFC and Military Specific requirements as well as applicable host nation, Federal, state, and local codes and regulations. For example, Ramstein Air Base must comply with the more stringent maintenance criteria of UFC 3-460-03, the applicable NATO STANAG, USAFE documents, or German law.

1-7 WAIVERS AND EXEMPTIONS.

Recommended UFC 3-460-03 language generated from recurring waivers and exemptions will be considered by the DoD **1**\ FDWG /**1**/ with supporting rationale for inclusion on **1**\ FDWG /**1**/ voting agendas. Recommended changes to UFC 3-460-03 are reviewed and approved by the voting members of the DoD **1**\ FDWG /**1**/, preferably in a normal recurring meeting.

1-7.1 Waivers.

Waivers are temporary deviations from the stated criteria within UFC 3-460-03. Waivers are valid for up to one year or as stated on the waiver and are submitted to the military service-specific SCP for review. Refer to Military Standard (MIL-STD)-3007G for the waiver process.

1-7.2 Exemptions.

In contrast to waivers, exemptions are permanent deviations from the stated criteria within UFC 3-460-03. Exemption requests must be submitted through the military service-specific SCP for review. Refer to Military Standard (MIL-STD)-3007G for the exemption process. The **1**\ FDWG /**1**/ must be advised when an exemption is granted.

1-8 REFERENCES.

Other sources for criteria related to petroleum fuel facilities are identified in **1**\ Appendix J. /**1**/ Any reference noted is the latest edition (as of the publication of this document) unless otherwise stated. Many of these documents are available within the public domain and can be found on the Internet; others require purchase. Before purchasing copies of referenced documents, contact the military service-specific SME to determine the need to have a complete copy of the referenced document versus obtaining the specific data needed from the referenced document from the SME.

1-9 CAPITALIZED FUEL SYSTEMS.

SM is normally eligible for DLA Energy funding at facilities that contain, handle, or distribute DLA Energy capitalized fuel under the Sustainment, Restoration, and Modernization (SRM) program. Proper coordination and scheduling with facility operators is necessary before conducting SM to ensure minimal mission impact.

DLA Energy also funds other inspection and maintenance programs at petroleum fuel facilities that contain, handle, or distribute DLA Energy capitalized fuel. See **1**\ Appendix A /**1**/ for a list of current maintenance and inspection programs that are funded by DLA Energy.

1-10 MAINTENANCE AND INSPECTION FREQUENCIES.

The maintenance and inspection frequencies provided in this UFC are strict guidelines and are based on regulatory requirements and commercial practices. The military service-specific SCP can authorize deviations and alternate equivalent methodologies for specific individual tasks and only as needed to support the mission requirements. For example, the military service-specific SCP can authorize deviations to delay or accelerate an out of service inspection of a fuel storage tank to coincide with other work to avoid reducing mission capabilities.

CHAPTER 2 GENERAL

2-1 GENERAL MAINTENANCE INFORMATION.

This chapter contains information general to all chapters of UFC 3-460-03. This chapter includes health and safety information, information related to fuel quality, and general practices and requirements.

2-2 HEALTH AND SAFETY.

Personnel must comply with the measures outlined in this chapter. Petroleum fuel products are hazardous because of their toxic and flammable nature. Health and safety precautions are required and must be strictly adhered to in order to prevent incidents and accidents to personnel and Government property. Before initiating maintenance work on petroleum fuel facilities, a hazard analysis must be completed and procedures must be established to assure recognized hazards have been controlled, items to be serviced are properly isolated and adequate light is available for the task. Only properly trained and authorized personnel are permitted to operate and perform maintenance on petroleum fuel system components. Breaches of safety standards may result in disciplinary action and possible injury or death. Safe efficient maintenance activities require cleanliness, neatness, and order. Each individual is expected to recognize and correct hazardous situations promptly, if qualified, and/or report them to supervisors.

2-2.1 Safety References.

Military service-specific health and safety procedures and information listed in USACE EM 385-1-1, **2**\ **1**\ DAFMAN 91-203 /**1**/ /**2**/, Navy Occupational Safety & Health (NAVOSH) and Occupational Safety and Health Administration (OSHA) regulations, NFPA 2112, NFPA 2113, and ASTM F1449 must be followed as applicable. Refer to Installation Safety Office for additional local and Installation specific safety requirements and procedures.

2-2.2 Personal Protective Equipment.

1\

a. The purpose of this section is to reduce the health and safety risks associated with the incorrect selection and use of personal protective equipment when personnel are potentially exposed to petroleum fuels and associated fire hazards. Each facility is responsible for performing a hazard analysis in accordance with NFPA 2113 to identify, eliminate, and control recognized and identified hazards. Personnel Protection Equipment (PPE) will be selected to provide the user with the appropriate personal protection. Personnel will be trained in the proper selection, use, care and maintenance of their PPE in accordance with the Installation’s written PPE program. Installations that determine there is the potential for a fire to exist from flammable vapors must utilize PPE that meets the minimal standards of NFPA 2112. Installations must reassess the hazard analysis at least every 5 years, or when a significant change is made to the work environment.

b. Any type of clothing may be worn as outer garments when working with high-flashpoint petroleum fuel (e.g., JP-5, JP-8, JP-10, Jet A, Jet A-1, additized Jet A (F-24) or diesel). However, personnel working with low-flashpoint petroleum fuel (e.g., JP-4, Jet B, aviation gasoline, or motor gasoline) must utilize PPE that meets the requirements of NFPA 2112 where the petroleum fuel facility hazard analysis has demonstrated that flammable materials or vapors are present in quantities that may result in a fire or endanger personnel. Wool socks, wool glove inserts, woolen caps, and underwear of nylon, silk, or polyester pose no significant hazard and are acceptable. Appropriate weather gear is allowed for personnel who are subject to outside work during inclement weather.

c. Conventional 50% polyester and 50% cotton-blend coveralls are adequate for routine maintenance work in petroleum fuel facilities that do not pose a fire hazard potential. When completing tasks in petroleum fuel facilities where petroleum fuel is present (e.g., tank cleaning), the use of disposable protective coveralls having a static-dissipating coating may be necessary. Disposable coveralls may be worn alone or over polyester/cotton-blend coveralls. Replace fuel-contaminated clothing.

/**1**/

2-2.3 Health Hazards.

The following paragraphs describe health hazards of exposure to petroleum fuel vapors, liquid petroleum fuels, and solids. The paragraphs also provide guidance on administering appropriate types of first aid for personnel exhibiting symptoms resulting from petroleum fuel exposure. Review and become familiar with the health and exposure hazards listed on Safety Data Sheets (SDSs) for the types of fuel stored and handled in fuel systems to be maintained.

2-2.3.1 Petroleum Fuel Vapors.

Petroleum fuel vapors within a confined space, regardless of their toxicity and explosive potential, will displace oxygen and may cause suffocation. Petroleum fuel vapors can be harmful even at concentrations with a Lower Explosive Limit (LEL) of 0 (zero) unless the area has been completely freed of vapor. The Permissible Exposure Limit (PEL) of petroleum fuel vapors that can be safely inhaled is lower than the LEL. To reduce the potential for personnel exposure to hazardous petroleum fuel vapor concentrations, a facility industrial hygiene survey should be completed and safety controls implemented in accordance with applicable military service requirements as well as OSHA requirements and American Conference of Governmental Industrial Hygienists guidelines.

2-2.3.1.1 Petroleum Fuel Vapor Inhalation First Aid.

Safely remove all persons from the work area who exhibit adverse symptoms of exposure to petroleum fuel vapors to include dizziness, nausea, or headache. If a person is overcome by petroleum fuel vapors, first aid should be administered at once by someone trained in first aid, and the person exhibiting symptoms should get prompt medical attention. Recovery from initial exposure to vapors is usually prompt after exposure to fresh air. If breathing has stopped, Cardiopulmonary Resuscitation (CPR) should be administered by a person trained in CPR. Promptly report all incidents or accidents potentially resulting from petroleum fuel vapor inhalation to supervisors.

2-2.3.2 Liquid Petroleum Fuel.

Avoid getting liquid petroleum fuel on skin or clothing. Liquid petroleum fuel products remove protective oils from the skin, causing drying, chapping, and cracking. Swallowed liquid petroleum fuel products may cause central nervous system depression and pneumonia.

2-2.3.2.1 Liquid Petroleum Fuel Contact/Ingestion First Aid.

External Contact: Remove contaminated clothing at once and avoid any source of ignition. Remove liquid petroleum fuel products from the skin by washing with soap and water as soon as possible after contact. Remove liquid petroleum fuel that comes in contact with eyes immediately with an eyewash or other available means of flushing the eye with water. Obtain medical attention as soon as possible after exposure to liquid petroleum fuel. Do not expose a person to flame producing activities once they have been contaminated with liquid petroleum fuel.

Ingestion: Do not induce vomiting except as directed by physician, as uncontrolled vomiting may cause liquid petroleum fuel to go into the lungs. A person that has ingested liquid petroleum fuel should be taken to a medical facility at once. Be sure to inform medical administrators of the type and approximate amount of liquid petroleum fuel ingested.

2-2.3.3 Solids.

Dusts are formed by additives in petroleum fuel products remaining after the volatile liquids have evaporated. Solid particles in sludge may be dispersed as the sludge dries. Dust can also result from scale, sandblast, and rust particles removed from tank walls and strainers during cleaning operations. Consult the Installation Environmental Office for proper procedures for sludge and solid waste cleaning and disposal.

2-2.3.3.1 Solids Contact/Inhalation First Aid.

Solids will enter the body through inhalation of contaminated dust particles. Treat bodily contact with dust as you would with liquid petroleum fuels (Section 2-2.3.2.1) and inhalation of dust as you would with petroleum fuel vapors (Section 2-2.3.1.1). Seek immediate medical attention.

\1

2-2.4 Confined Spaces.

A confined space is a space large enough and configured so personnel can bodily enter and perform assigned work, has limited or restricted means for entry or exit, and is not designed for continuous human occupancy. Examples include tanks, pits, manholes, etc.

2-2.4.1 Construction Activities.

Employees engaged in construction activities at a worksite with one or more confined spaces must comply with 29 CFR 1926, Subpart AA, state, local and installation requirements.

2-2.4.2 Hazards.

Personnel entering or working in confined spaces may encounter a number of potentially serious hazards. These hazards may include atmospheric hazards such as oxygen deficiency insufficient to support life, oxygen-enriched levels that increase the danger of fire or explosion, flammable or explosive atmospheres and materials, or toxic gases or materials. In addition, the confined space may include electrical, mechanical, engulfment or entrapment hazards that must be locked out, or controlled by other means of securing hazardous energy. Many of these hazards are not readily apparent, nor detectable by odor, or by sight, which may result in workers entering confined spaces without adequate consideration of potential dangers. Workers must consider that all confined spaces may contain unfavorable and unsafe conditions and must not enter or work in these spaces until tests, evaluation, and locally-developed procedures are performed to ensure safe conditions exist prior to entry and are maintained during the entire work period. **/1/**

\2

2-2.4.3 Two-Person Policy.

Ensure two people are present when entering confined spaces, performing maintenance on fuel systems and tanks, or in and around fuel facilities. /**2**/

2-3 ELECTRICAL SAFETY.

This section provides general information related to electrical safety with regard to maintenance operations, static electricity, stray electric currents, hazardous locations, and power generators. These hazards must be considered when handling and dispensing petroleum products. See National Fire Protection Association (NFPA) 70, National Electrical Code, for the practical safeguarding of persons and property from hazards arising from the use of electricity. See NFPA 70E, *Standard for Electrical*

Safety in the Workplace, for electrical safety requirements for employee workplaces that are necessary for the practical safeguarding of employees in their pursuit of gainful employment. See NFPA 77, for additional guidance on static electricity hazards.

2-3.1 Lockout/Tagout.

An electrically safe work condition must be established while operating or performing maintenance on electrical equipment, regardless of whether the equipment is energized or de-energized. NFPA 70E includes detailed information on safety-related work practices, safety-related maintenance requirements, and installation safety requirements.

Establishing and following lockout/tagout procedures is essential for the safe execution of maintenance work on electrical equipment. While specific lockout/tagout procedures can differ from site to site, they must abide by the general principles outlined in NFPA 70E, Article 120, Section 120.2(B). In general, all sources of electrical energy must be controlled in such a way as to minimize personnel exposure to electrical hazards. NFPA 70E also includes Annex G, “Sample Lockout/Tagout Procedure,” which can be used as a basis for establishing a site specific procedure.

2-3.2 Static Charges.

Low-conductivity liquids, such as jet fuel and gasoline, become electrostatically charged while flowing through petroleum fuel systems and during transport in barges, tanker trucks, rail cars and other fuel transport systems. This can produce enough electrical energy to cause ignition, fire, or explosion of petroleum fuel vapor-air mixtures above the liquid petroleum fuel surface.

Grounding and bonding components of petroleum fuel facilities are important to prevent ignition, fire and explosion. All petroleum fuel system components must be bonded and grounded to dissipate static electric charges and stray electrical currents that can discharge in the form of an electric arc. Bonding across flanges is not required provided they are not electrically insulated. UFC 3-460-01, Section **\1** 2-11.3 **/1/,** includes information on grounding petroleum fuel system equipment in order to prevent the accumulation of static electricity.

2-3.2.1 Personnel Static Prevention Requirements.

Personnel must periodically ground themselves to pump house structures, tanks, and equipment by making firm contact with attached grounding bars or approved grounding points. Personnel must not put on or remove garments while conducting petroleum fuel handling operations.

Personnel must ground sampling devices to grounding bars or approved grounding points before collecting petroleum fuel samples.

2-3.3 Electrical Currents.

Electrical currents originate in generators, transmission systems, wiring, and electrical devices. They are more dangerous than static electric charges because of the continuous electric spark that can be created versus the brief electric spark created by a static electric discharge. Verify all electrical work on petroleum fuel storage and dispensing systems complies with NFPA 70, 501, Class I Locations to reduce electrical current hazards.

2-3.3.1 Stray Currents.

Stray currents flow through unintended paths or are extraneous current in the earth. Sources of stray currents include electric railways, electric power systems, electric welders, cathodic protection systems, and aircraft aeronautics electrical equipment malfunctions. Since many fixed petroleum fuel systems are in intimate earth contact, stray currents can take paths through the conducting parts of petroleum fuel systems. Stray currents can cause electric arcs that may ignite combustible petroleum fuel vapor-air mixtures.

\1

2-3.3.1.1 Fuel System Grounding Requirements.

Ground systems used to dissipate static electric charges also reduce stray electric current hazards. These systems provide a path to conduct stray electric currents into the earth without arcing.

2-3.3.1.2 Tank Car Loading and Unloading Requirements.

Railroad spurs used for loading and unloading tank cars should be insulated from the main line rails, ensuring isolation from stray currents that may flow in the main line rails.

2-3.3.1.3 Marine Terminal Requirements.

Stray currents from cathodic protection systems at marine terminals require special attention. These systems protect piping and steel piers and cause current flow in the water. Steel hull vessels act as a conductor of these currents. The ship-to-shore fuel-handling hose will act as a conductor and will complete a low-resistance circuit from the vessel to shore-side piping. Arcs may occur between the vessel and the hose when the hose is connected, disconnected, or brought into contact with the vessel's deck. Arcing can be prevented by connecting a bonding cable between shore-side piping and the vessel before operations begin. A switch on the shore side wired inline with the bonding cable must be closed after the cable connection is made and before the petroleum fuel handling hose is taken aboard the vessel.

2-3.3.1.4 Piping Requirements.

Stray current may flow through petroleum fuel piping systems because their electrical resistance is low compared to the surrounding earth. Removal of piping or components will interrupt the continuity of the petroleum fuel system. A bonding jumper wire must be installed prior to removal of piping or components and must remain in place until the items are replaced. Installing a jumper will prevent an arc when the piping or components are removed or replaced.
/1/

2-3.4 Hazardous Location Classification.

NFPA 70 defines hazardous locations including areas where fire or explosion hazards may exist due to flammable gases or vapors, flammable liquids, flammable liquid produced vapors, combustible liquids produced vapors, and combustible dust. Hazardous locations are classified in three ways: Type (Class), Condition (Division), and Nature (Group). Petroleum fuel facilities are Class 1 where flammable gases or vapors may be present in the air in sufficient quantities to be explosive or ignitable. Class 1 is divided into two divisions. Division 1 areas include environments where the hazard is to be expected under normal operating conditions, and Division 2 areas include environments where the hazard is not normally present in an explosive concentration or present only through accidental rupture, breakage or unusual faulty operation. The National Electrical Code (NEC) further defines the nature or “group” of the hazardous substance. Most petroleum fuel facilities will fall under Group D: hydrocarbons, fuels, solvents. Personnel must ensure that all electrical components and equipment installed, operated or replaced meet the required hazardous classification for the intended environment. Refer to UFC 3-460-01 for additional hazardous location information.

2-4 PETROLEUM FUEL QUALITY.

Every type and grade of petroleum fuel or lubricant has been specifically formulated to provide the most satisfactory and economic performance possible for a particular engine, under the operating conditions for which it was designed. Petroleum fuels or lubricants that have become contaminated or have degraded, can cause fires, explosions, injuries, loss of life, and loss of valuable machinery and equipment. Petroleum fuel product suspected of being contaminated must be reported to the military service-specific SCP.

2-4.1 Water Contamination.

Water contamination usually occurs during the transportation and storage of petroleum fuel. Water contamination is the most common form of contamination and may take one of the following three forms.

\1

2-4.1.1 Free Water.

Free water consists of relatively large drops of water which, if left undisturbed, will settle to the bottom of the container. In low density petroleum fuel products with low viscosity, free water settlement can be quite rapid, but in higher density or more viscous petroleum fuel products, settlement will take longer. Some petroleum fuels contain anti-corrosive or cleaning agents otherwise known as surfactants, which tend to prevent the settlement of free water.

2-4.1.2 Dissolved Water.

In this state, the water is invisible, and the petroleum fuel appears to be clear; but a drop in temperature may cause dissolved water to separate from the petroleum fuel in tiny droplets that remain suspended and give the petroleum fuel a cloudy appearance.

2-4.1.3 Emulsified Water.

Emulsions are mechanical dispersion of petroleum fuel and water having a frothy appearance. Emulsions can be very stable and hard to separate. Separation may require special mechanical and chemical treatments.
/1/

2-4.2 Prevention and Removal of Water Contamination.

a. Operate sump drains on tanks, filter separators, and other vessels and equipment and check for free water on a daily basis when the systems are operated.

b. During petroleum fuel flow operations, observe filter separator differential pressure gauges and be sure units are functioning properly.

c. Ensure that operator and system maintenance is properly performed.

d. Newly received aviation petroleum fuels must be allowed to stand undisturbed in receiving tanks to permit settlement of free water before product is dispensed. Aviation petroleum fuel must be allowed to stand for 1 hour per 1 foot (0.31 m) of liquid level rise in storage tanks up to a maximum standing time of 24 hours or in accordance with undisturbed standing time allowed by military service-specific established procedure or policy. Ground vehicle petroleum fuels do not require settlement time before they are dispensed.

e. When field fabricated aboveground vertical tanks are available for entry, they must be inspected for unintended low spots and repaired as required to eliminate unintended low spots which could collect free water.

f. Tank roofs, seals, and fittings of all types must be maintained in good, weather-tight condition.

g. Testing and inspections required for tanks and underground piping must be followed and documented. If unexplained accumulation of water is detected, the underground petroleum fuel tank(s) suspected of leaking must be tested using a temperature-controlled, hydrostatic stand-pipe test. Underground petroleum fuel piping suspected of leaking must be isolated and subjected to the applicable underground piping annual test as described in Appendix G - Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria.

2-4.3 Solid Matter Contamination.

Iron rust, scale, sand, and airborne dirt are examples of solid matter contamination most prevalent in petroleum fuel. The principal source of iron rust is corrosion in pipelines, storage tanks, or other inline steel components. Sand and dirt are particularly serious in extremely sandy or dusty areas where they may accumulate around tank gauge hatches, tank manways, or other openings and enter the tank when the covers are removed. The presence of large amounts of particulate matter in petroleum fuel results in restricting or clogging of filter separators, silting and plugging of fuel control components and nozzles, and wear and scoring of petroleum fuel system components by abrasion.

2-4.4 Prevention and Removal of Solids Contamination.

a. Brush away or remove accumulated dirt or sand around fill covers, manholes, and other covered openings before removing them.

b. Whenever petroleum fuel tanks, piping, or equipment are open for construction, repairs, or inspection, ensure they are protected against entry of dirt and foreign objects. Normally closed tank openings not required to be open for ventilation or access must remain closed. Open ends of piping and equipment such as pumps and meters must be sealed by temporary closures when they are not required to be open for inspection or repair.

c. Do not operate petroleum fuel handling equipment unless all filters, strainers, screens, and nozzle spout caps are properly installed.

d. Never remove filter, strainer basket, or strainer screens for any purpose, other than cleaning or maintenance. Filters, strainers baskets, and strainer screens must always be replaced immediately after cleaning or maintenance.

e. Observe water that is drained from filter separator sumps and report unusual accumulation of foreign matter to supervisors.

f. The inside of new petroleum fuel pipe must be carefully inspected for loose scale, dirt, or rust. Debris must be removed by brushes, swabs, plugs, or pigs before installation. New piping and pipeline systems must be thoroughly flushed according to UFGS 33 08 55. Temporary strainers installed at strategic points to remove trapped matter will assist with removal of solids.

g. When changing grades of petroleum fuel in a tank, piping or pipeline, the penetrating action of the new grade may loosen existing scale or rust. Prior to changing petroleum fuel grade, the tank, piping or pipeline may need to be thoroughly mechanically or chemically cleaned. Even if a good cleaning job is done, loosened scale or rust can continue to appear in the product for several weeks after starting the new operation. Extra precautions such as more frequent sampling, circulating of petroleum fuel product, temporary use of strainers, frequent cleaning of strainers, and use of cleaning pigs may need to be taken. See Section 2-5 Changes in Tank Product for additional information related to changing grades of petroleum fuel product in tanks.

h. Ensure replacement parts or equipment, such as hoses, packing, gaskets, O-rings, seals, and pipe compounds, are made from materials compatible with the petroleum fuel type and grade.

i. Do not allow petroleum fuel systems to lie unused for long periods of time. Inactive systems may accumulate water at low points and cause corrosion or biological activity leading to solids contamination.

2-4.5 Microbiological Contamination

\1

a. When water and petroleum fuels exist together, yeast, fungus, and, bacteria may be present at the interface of the two fluids or at the water-steel interface. These organisms live in water and feed on petroleum fuel. Only a small amount of water, such as a puddle in a tank bottom, is required to support large colonies of these organisms.

b. Microbiological contamination usually appears as a brown, black, or gray slime-like deposit that adheres to the inner surface of fuel tanks. This results in corrosion of fuel system components also known as Microbial Induced Corrosion (MIC), clogging of filters, and erratic operation of petroleum fuel quality indicating systems. Microbiological contamination is most severe in high temperature/high humidity environments and in alternative ground vehicle fuel products. Damage from microbiological induced corrosion is caused by hydrogen sulfide that is produced as waste by micro-organisms as they metabolize petroleum fuel in the absence of sufficient oxygen and can cause significant damage to tanks and piping and environmental problems in very short periods of time.

c. The presence of microbiological contamination in petroleum fuel is a reliable indication of failure of petroleum fuel filtration equipment, inadequate water stripping of petroleum fuel storage tanks and a need for more frequent cleaning of petroleum fuel storage tanks. **/1/**

2-4.5.1 Prevention of Microbiological Contamination.

To prevent microbiological contamination, remove water from petroleum fuel systems by the use of sumps on tanks, filter vessels and low point drains. The use of biocides in aviation fuels and F-76 is prohibited under current product specifications. Biocides are allowed on a case-by-case basis on rare occasions and require extensive justification and approval by the military service-specific SCP.

2-4.6 Other Product Contamination.

The properties of one type or grade of petroleum fuel can be greatly changed by mixing it with another grade or type of petroleum fuel. Some causes of cross contamination between petroleum fuels are leaky bulkheads between tanks, leaky valve manifolds separating product systems, use of multiproduct pipelines, delivery of improper petroleum fuel grade, and improper cleaning of a tank compartment or pipeline prior to changing petroleum fuel product service.

“Jelly” or “Apple Jelly” is a contaminant found in petroleum fuel systems, specifically filtration equipment, resulting from media migration. “Apple Jelly” occurs when free water particles in the petroleum fuel react with small quantities of super-adsorbent polymers that pass or migrate into the petroleum fuel as it flows through water adsorption media filter and/or monitors. The mixture creates an aggressive solvent that when mixed with other particulates and debris creates a thick “jelly-like” substance. Fuel System Icing Inhibitor (FSII – Diethylene Glycol Monomethyl Ether (DiEGME)) has been shown to increase the rate of media migration, and as a result, water adsorption media filters and/or monitors are no longer used in systems that handle petroleum fuel containing FSII.

2-4.6.1 Prevention of Other Petroleum Fuel Contamination.

Clear identification of petroleum fuel systems and equipment by product type and grade is essential to operational safety and product quality protection. Systems must be clearly identified in accordance with Section 2-7.

a. Be sure that system flow diagrams are available to all operators. Use arrows to indicate the direction of petroleum fuel flow within pipes. Include petroleum fuel product labeling on all petroleum fuel tanks, piping, and load and offload points.

b. Do not begin petroleum fuel transfer operations until markings of all needed petroleum fuel equipment has been checked and found to agree.

c. Ensure valves in valve manifolds are positively shut-off and locked out between petroleum fuel products. Do not depend solely on single valves to separate petroleum fuel products as they may leak. Install spectacle blinds, blind flanges, or use double block and bleed valves in manifolds where petroleum fuel product is to be separated.

d. Be sure that newly arrived petroleum fuel products were not contaminated during shipment. Take samples per military service-specific quality control directives or MIL-STD-3004, and if possible, do not ship or use a petroleum fuel product until test results are confirmed acceptable.

e. Use separate pipelines and equipment for each petroleum fuel product. Unless designed to act as a multi-product line, or required as an alternative capability in a contingency, pipelines should never be used for more than one type of petroleum fuel. Common piping systems must never be used for incompatible petroleum fuel products.

2-4.7 Special Considerations for Biodiesel Blend B20.

Biodiesel Blend B20 is 20 (±1) volume percent biodiesel conforming to specifications ASTM 6751 and 80 volume percent petroleum diesel fuel conforming to ASTM D975.

a. Biodiesel fuel is comprised of mono-alkyl esters of long chain fatty acids derived from vegetable oils or animal fats. Biodiesel is meant to be used in standard diesel engines and should not be confused with the vegetable and waste oils used to fuel converted diesel engines.

b. A B20 product must be pre-blended prior to delivery. It is not acceptable to attempt blending into a Government tank during the delivery.

c. DoD Components and Federal agencies must not order B20 where projected consumption and product storage duration exceeds three months, due to extended and unresolved product stability concerns.

d. B20 may be stored in tanks and handled with equipment used for diesel service. Nevertheless, Defense Energy Support Points (DFSPs) must comply with standard military service-specific procedures and directives regarding tank cleaning prior to converting existing storage tanks from diesel to B20 service.

e. A generally higher cloud point than standard diesel may occasionally affect B20 cold flow properties. DoD Components and Federal agency customers should order more frequent, smaller B20 quantities to achieve advantage of seasonal diesel cloud point adjustments that minimize potential vehicle and equipment cold weather operation problems.

f. DoD only allows the use of B20 biodiesel in non-tactical equipment.

2-4.8 Special Considerations for Fuel Ethanol Blend E85.

Fuel Ethanol Blend E85 is 75 to 85 volume percent fuel ethanol blended with 25 to 15 volume percent hydrocarbon fuel, usually unleaded gasoline. ASTM 5798 governs E85 procurement as fuel ethanol intended for use in ground vehicles with spark-ignition engines.

a. DoD Components and Federal agencies must ensure material compatibility with storage tanks and dispensing equipment prior to converting facilities to E85 service.

b. Special materials requirements are described in DOE's "Handbook for Handling, Storing, and Dispensing E85." Pre-1992 fiberglass tanks may not be suitable to convert to E85 service.

c. Three vapor pressure classes of fuel ethanol (Ed75 – Ed85) with ethanol content varying between 75 and 85 percent for different seasonal conditions and geographic regions serve to ensure proper vehicle operation throughout the year in all locations.

d. High E85 ethanol content may reduce lubricating properties as well as increase water tolerance. Decreased temperature and increased water content may reduce hydrocarbon fuel solubility in fuel ethanol.

e. Monitor and keep water content to a minimum, due to water's miscibility in fuel alcohol, to minimize performance degradation.

f. Ethanol is not compatible with aluminum, and all aluminum products must be removed from a gasoline dispensing system that will be used to dispense E85.

g. In accordance with EPA regulations, all commercial grades of gasoline must contain certain additives, detergents, and corrosion inhibitors. In a finished blend of E85, any additive that was found previously in gasoline is now contained in E85 (although at reduced levels). While adding detergent to the hydrocarbon component of E85 is necessary, it is not necessary to add detergent based on the alcohol portion of the product. Overuse of additives with E85 may result in poor vehicle operation.

2-5 CHANGES IN TANK PRODUCT.

Changes of petroleum fuel product in tank and piping systems must be conducted in accordance with the more stringent of military service-specific quality control directives and MIL-STD-3004.

2-6 ENVIRONMENTAL PROTECTION.

The DoD is actively committed to protecting quality of the environment by preventing and controlling pollution resulting from use and operation of petroleum fuel facilities. The DoD is required to comply with environmental laws and regulations. Individuals who violate environmental regulations may be subject to serious civil and criminal penalties, including fines and jail terms. Significant precautions as listed in UFC 3-460-01, such as petroleum fuel storage tank, load, and offload secondary containment systems, are used to prevent the discharge of petroleum fuel products to sanitary and storm sewer systems, ground water systems, local streams and waterways.

2-6.1 Spill Planning.

Facilities containing or handling petroleum fuel products are designed and constructed in a manner that should prevent spillage. Should a spill occur, the facilities should prevent the spill from leaving the property and/or entering a waterway or ground water table. Installations must have a Spill Prevention Control and Countermeasure (SPCC) plan or, for overseas sites, the spill response document required by the Overseas Environmental Baseline Guidance Document or Environmental Final Governing Standards, as applicable. Refer to UFC 3-460-01, and included references for SPCC requirements. Personnel should be familiar with SPCC requirements specific to the petroleum fuel facility where they are preforming inspections and maintenance.

While performing maintenance activities where a petroleum fuel release is imminent, a drip pan or other suitable means must be utilized to contain petroleum fuel that may be released from a system. Spill pads must also be readily available. Bonding the drip pan to the petroleum fuel system or a grounding rod will reduce the risk of a static electric discharge. Bonding points for drip pans should be provided where they are put into regular use.

2-6.1.1 Reference of UFC 3-460-03 in SPCC Plans.

Spill plans, response plans, operational plans, or other plans required by law should not include UFC 3-460-03 by title for complete inclusion. Only specific items from the document should be included when required.

2-6.2 Containment.

Secondary containment should be provided for petroleum fuel systems and components as required by UFC 3-460-01. These systems may include earthen berms, containment paving, spill kits, and/or liners.

2-6.3 Containment Drain Valves.

Containment areas must be drained as frequently as required to maintain them in a clean, dry, and accessible state. Debris caught in the drainage inlet grate must be removed after each draining. Containment drain valves must be maintained as outlined in Section 6.6 Valves. Coordinate containment area draining with operational personnel.

2-6.4 Waste Disposal.

To ensure waste is disposed of properly, check that adequate waste disposal containers are available and disposal procedures are identified. Coordinate waste disposal procedures with the Installation Environmental Office. Coordination must include strict adherence to the most stringent of host nation, Federal, state, or local hazardous waste regulations to include permitting.

2-7 SIGNAGE AND MARKINGS.

Signs and marking require periodic inspections and maintenances to ensure that important information is easily accessible.

2-7.1 Inspection and Maintenance - Signage and Markings.

a. Check permanent signs and markings for adequacy and readability. Repair or replace deteriorated or illegible signs and markings.
Frequency: Weekly

b. Inspect the location of Department of Transportation (DOT) regulated underground petroleum fuel pipelines and ensure they are marked in accordance with 49 Code of Federal Regulations (CFR) 195.410.
Frequency: Monthly

c. Check that petroleum fuel pipelines, tanks, valves, pumps, meters, and other equipment are marked in accordance with UFC 3-460-01 Section 2-**\1** 17 /**1**/. If markings are missing or insufficient, repair or add markings in accordance with UFC 3-460-01.
Frequency: Monthly

d. Ensure petroleum fuel system Emergency Fuel Shutoff (EFSO) pushbuttons are properly identified at each location. Ensure that signage is properly secured and that the lettering is legible from 25 feet (7.5 meters) away and not faded.
Frequency: Monthly

e. Verify enough movable or temporary signs are maintained in good condition to serve anticipated needs; for example: "DANGER," "CLOSED TO TRAFFIC," “KEEP FLAMES AWAY," "MEN WORKING,” "NO SMOKING,” "DANGER NO OPEN FLAME OR IGNITION SOURCE BEYOND THIS POINT.” Use bilingual signs when appropriate.
Frequency: Annually

2-8 FIRE PROTECTION.

\1

- Three simultaneous conditions are necessary to create petroleum fuel fires: the petroleum fuel product must be in the form of vapor; petroleum fuel vapor-air mixture must be present in correct proportions to support combustion or explosion; and the combustible mixture of petroleum fuel vapor and air must be raised to its ignition temperature or subjected to a source of ignition. The absence of any one of these conditions prevents occurrence of a fire.

- It is not practical to eliminate air completely or to control petroleum fuel vapor-air proportions where petroleum fuel is handled and dispensed, and temperatures cannot be controlled to the point where petroleum fuel vapors are not possible. Therefore, the elimination of sources of ignition is the primary controllable factor for the prevention of petroleum fuel fires.

- NFPA 10 details the number and types of portable fire extinguishers that should be located around petroleum fuel areas and storage locations.

/1/

2-8.1 Petroleum Fuel Vapor Sources for Fires and Explosions.

Petroleum fuel vapors escaping to atmosphere are quickly diluted to within the flammable or explosive limit, and if ignited will cause fire. Eventually the petroleum fuel vapor concentration within a tank or vessel is diluted, creating an explosive hazard within the tank. Petroleum fuel vapors are heavier than air and can travel long distances before they dissipate into the atmosphere. Any source of ignition may ignite petroleum fuel vapors causing a fire or explosion.

2-8.2 Solid Sources for Fires and Explosions.

Sludge and other petroleum fuel saturated material (such as sediment, hollow roof supports, sidewall scale, foam pan seals, and oil-soaked wooden structures) emit petroleum vapors which can accumulate to the flammable or explosive limit.

2-8.3 Ignition Sources for Fires and Explosions.

Primary causes and sources of ignition are poor maintenance or defective electrical equipment, negligence, relaxed disciplinary action to violations of safety regulations, and static or stray electrical currents.

2-8.3.1 Maintenance Tools.

\1

- Non-sparking tools provide protection against fires and explosions in petroleum fuel product environments. Non-sparking tools should be used for operation and maintenance work on highly volatile petroleum fuels with flash points below 100 °F (38 °C) unless the environment has been certified to be vapor free. Common non-sparking tool materials are brass, bronze, copper-nickel alloy, copper-beryllium alloy and copper-aluminum alloy. Ensure non-sparking tools are kept clean of ferrous or other contaminants which have sparking properties.

- Electric tools must have a three-wire cord with a ground and be plugged into a grounded receptacle, be double insulated, or be powered by a low-voltage isolation transformer. Electric tools must be protected by a ground-fault circuit interrupter or an assured equipment-grounding conductor program. All electric power tools, battery or corded, and electrical extension cords must be intrinsically safe and Underwriters Laboratory (UL) listed for the intended hazardous location.

- Refer to OSHA Booklet 3080 *Hand and Power Tools* (based upon 29 CFR, Part 1910, Subpart P) or military service-specific directives for additional safety and guidance regarding the appropriate tools for work to be performed.

/1/

2-8.3.2 Power Generators.

Diesel and gasoline engine-powered generators and other internal combustion powered tools (e.g. internal combustion engine driving pumps) must only be used in close proximity to petroleum fuel systems if equipped with spark arrestors. The equipment must be located outside of petroleum fuel tank containment areas and upwind of petroleum fuel tanks and at least 50 feet (15.2 meters) from the nearest petroleum fuel tank manhole or vent.

2-8.3.3 Smoking Clearances.

"No Smoking" signs must be placed conspicuously around petroleum fuel systems. Smoking must only be permitted in designated smoking areas outside of petroleum fuel vapor clearances.

2-8.4 Fire and Explosion Preventative Measures.

a. Provide proper ventilation for pump houses, pits, and other enclosed spaces where petroleum fuel vapors may accumulate.

b. Take precautions to prevent leakage or spillage of petroleum fuel products.

c. When spillage is expected from petroleum fuel pipes, hoses connections, or opened equipment, ventilate the area and eliminate sources of ignition. Direct the expected spillage to an approved container or a drip pan as applicable. Bonding the drip pan to the petroleum fuel system or a grounding rod will reduce the risk of a static electric discharge. Bonding points for drip pans should be provided where they are put into regular use.

d. If a small amount of petroleum fuel spills on the ground, asphalt or concrete, cover it with dry absorbent. Remove used absorbent once petroleum fuel has been absorbed.

e. Where major operations raise a possibility of sizeable petroleum fuel spills, call fire department authorities for possible standby.

f. Be familiar with local petroleum fuel spill contingency plans and the proper contact information for the local fire department.

g. Do not start or run a vehicle in an area where petroleum fuel has been spilled until all flammable or combustible liquid is removed and the area is freed of petroleum fuel vapors unless the vehicle is required to clean up the spill (e.g., vacuum truck or skimmer boat).

h. Do not weld, cut, rivet, do mechanical or other hot work on out of service petroleum fuel storage tanks, pipe, or other equipment that has contained flammable or combustible substances until the equipment has been properly ventilated and certified vapor free. In limited cases, hot work can be performed safely on in-service equipment with an approved plan. Always obtain a hot work permit before hot work is conducted on petroleum fuel systems.

i. Only allow personnel that meet the requirements of UFGS 33 52 90.00 20 to conduct welding on petroleum fuel tanks or vessels that have contained flammable or combustible liquids or petroleum fuel vapors.

j. Drain, purge, and ventilate petroleum fuel tanks or other equipment brought back to maintenance buildings for repair and keep them outside of buildings, well away from open flames and other sources of ignition.

k. Do not allow open flames near Class 1 hazardous areas as established in NFPA 70.

l. Artificial light and power tools must meet the requirements of Section 2-8.3.1, “Maintenance Tools.”

m. Immediately dispose of petroleum fuel soaked rags or waste, or place them in approved closed noncombustible containers. Refer to Section 2-6.4 Waste Disposal for waste disposal procedures.

2-9 EMERGENCY ACTION PLANS.

Agencies that operate and/or maintain petroleum fuel infrastructure must be knowledgeable of their applicable emergency action plans that include measures to address a variety of emergency responses including but not limited to natural disasters, terrorist threat conditions, and environmental protection.

2-10 SITE MAINTENANCE PROGRAM.

Facility maintainers (e.g., Base Civil Engineering, Department of Public Works, contractors, operators) have the primary responsibility for maintaining and repairing petroleum fuel infrastructure (e.g., petroleum fuel or lubricant receipt, issue and storage systems) under their stewardship. DoD petroleum fuel sites may have more than one facility maintainer depending on the type of mission, the facility owner, or other contractual relationship. Military services can delegate maintenance tasks between operator maintenance and system maintenance differently. See Section 1-2.2, “Maintenance Tasks,” for more information on the delegation of maintenance tasks.

Agencies responsible for infrastructure maintenance must develop site maintenance programs that include:

- List and details of petroleum fuel equipment requiring maintenance.
- Coordination requirements and points of contact for other agencies that may support or provide input on maintenance activities (e.g., cathodic protection, electrical, environmental, fire department, plumbing, and safety).
- Documentation and record retention procedures.
- Details for maintaining infrastructure as-built information.
- Details for developing and submitting projects to maintain, repair or upgrade existing infrastructure and details for coordination with agencies on requirements for new infrastructure.
- Quality assurance requirements for contractors working on petroleum fuel infrastructure.

2-10.1 Maintaining Petroleum Fuel Infrastructure.

Petroleum fuel facility maintainers should utilize recurring maintenance systems to track inspections, scheduled and unscheduled maintenance actions, and equipment serviceability.

Petroleum fuel facility maintainers and operators must coordinate requirements and schedule maintenance actions to minimize mission impact.

2-10.2 Documentation and Record Retention.

\1

a. Petroleum fuel system documentation and record retention must include maintenance records in sufficient detail to identify each real property or equipment item’s current maintenance status (e.g., tanks, pumps, valves, piping). These records must be maintained at the Installation and should be used to justify recommendations for repair, upgrade, and replacement.

b. Each Installation must develop and have site-specific maintenance manuals such as Operation and Maintenance Support Information (OMSI) or Operation, Maintenance, Environmental, and Safety Plan (OMES). These manuals must include manufacturer’s operation and maintenance information for the specific equipment and components installed. The Installation-specific OMSI or OMES manuals must be used in conjunction with the inspection and maintenance criteria of UFC 3-460-03.

c. Unless otherwise specified by military service-specific or contract requirements, maintenance agencies must retain petroleum fuel infrastructure records of tests and inspections (e.g., API Standard 570 and

API 653). Copies of these records must be issued to the Installation for official record retention.

d. Environmental regulations typically require retention of records for a minimum of three to five years. In some cases environmental regulations require record retention for the life of the system (e.g., tanks). Records must be maintained for a minimum of three years unless more stringent military service, Federal, state, host nation, or local requirements apply.

e. For agencies that are responsible for maintenance of DOT regulated petroleum fuel pipelines, additional inspection and repair information is required and must comply with 49 CFR 195.310, 195.404, 195.507 and 195.589.

f. For agencies that are responsible for maintenance of underground storage tanks inspection and repair recordkeeping must comply with 40 CFR 280.34.

g. For agencies that are responsible for maintenance of hose and pipelines near, over, or through navigation and navigable waters, inspection and repair recordkeeping must comply with 33 CFR 154.740.

/**1**/

2-10.3 As-built Information.

Available as-built information for petroleum fuel systems must be preserved and protected. As-built information must be updated when projects that change the configuration of the system are executed at petroleum fuel facilities. An accurate process flow diagram of each petroleum fuel system is the minimum amount of documentation that must be maintained. Copies of as-built information must be maintained at the Installation's petroleum fuel facility operations building and permanent Installation files.

As-built information required for DOT regulated pipelines must comply with 49 CFR 195.404.

2-10.4 Operation and Maintenance Support Information.

Each Installation must maintain a current library or access to manufacturer's operation and maintenance manuals for all equipment that is associated with petroleum fuel infrastructure under the Installation's responsibility.

Operation and maintenance information required for DOT regulated pipelines must comply with 49 CFR 195, Section 402. Operation and maintenance information required for facilities that conduct petroleum fuel transfer to or from marine vessels must comply with 33 CFR Part 154 Sections 300 to 325.

2-10.5 Safety Reports.

All petroleum fuel facilities must follow military service or contract requirements when reporting safety and risk assessments on infrastructure.

Facilities regulated by DOT have additional reporting requirements that are governed by 49 CFR 195 Subpart B. The facility operators or maintainers must copy DLA Energy and/or military service commands when notifying the Pipeline and Hazardous Materials Safety Administration (PHMSA) of a regulated pipeline incident.

This Page Intentionally Left Blank

CHAPTER 3 BULK TRANSFER FACILITIES

3-1 INTRODUCTION.

This chapter applies to permanent petroleum fuel infrastructure and is not intended for contingency or mobility equipment or temporary petroleum fuel receipt or issue systems.

3-2 TRUCK RECEIPT.

Major components of petroleum fuel truck offloading facilities include offloading hoses, piping, basket strainers, air eliminator tanks, pumps, meters, pre-filters, filter separators, grounding systems, ground verification systems and control panels.

a. Piping used to distribute petroleum fuel from truck offloading positions to petroleum fuel tanks may be installed underground, aboveground, or in a combination of aboveground and underground segments.

b. Sometimes these systems use drop tanks which can be underground, vaulted, or low-profile equipped with submerged turbine pumps.

c. Pumps are typically self-priming centrifugal or rotary vane positive displacement.

d. Underground or low-profile petroleum fuel tanks typically receive fuel by gravity offload.

3-2.1 Inspection and Maintenance - Truck Receipt.

a. Refer to Section 3-9.2, “Offloading Fuel Hoses,” for inspection and maintenance requirements of offloading hoses.

b. Refer to Section 6-1, “Pipe Testing And Inspections,” for inspection and maintenance requirements of pipelines and piping.

c. Refer to Section 3-6.4, “Basket Strainers, “for inspection and maintenance requirements of basket strainers.

d. Refer to Section 3-10.1, “Air Eliminator Tanks,” for inspection and maintenance requirements of air eliminator tanks.

e. Refer to Section 3-8, “Pumps,” for inspection and maintenance requirements of petroleum fuel pumps.

f. Refer to Section 3-7, “Meters,” for inspection and maintenance requirements of petroleum fuel meters.

g. Refer to Section 3-6.1, “Pre-Filters,” for inspection and maintenance requirements of pre-filters.

h. Refer to Section 3-6.2, “Filters Separators,” for inspection and maintenance requirements of filter separators.

i. Refer to Section 9-1.6, “Grounding Systems,” for inspection and maintenance requirements of grounding systems.

j. Refer to Section 9-5, “Ground Verification Systems,” for inspection and maintenance requirements of ground verification systems.

k. Refer to Section 9-1.9, “Electronic Equipment,” for inspection and maintenance requirements of control panels.

3-3 PIPELINE RECEIPT.

Fuel can be supplied to petroleum fuel storage tanks from on-base or off-base pipelines. These pipelines can be Government Owned/Government Operated (GOGO), Government Owned/Contractor Operated (GOCO), or Contractor Owned/Contractor Operated (COCO).

Major components of pipeline receipt systems include piping, basket strainers, automatic air vents, meters, pre-filters, filter separators, grounding systems, and control panels.

3-3.1 Inspection and Maintenance – Pipeline Receipt.

a. Refer to Section 6-1, “Pipe Testing and Inspections,” for inspection and maintenance requirements of pipelines and piping.

b. Refer to Section 3-6.4, “Basket Strainers,” for inspection and maintenance requirements of basket strainers.

c. Refer to Section 3-10.2, “Automatic Air Vents,” for inspection and maintenance requirements of automatic air vents.

d. Refer to Section 3-7, “Meters,” for inspection and maintenance requirements of petroleum fuel meters.

e. Refer to Section 3-6.1, “Pre-Filters,” for inspection and maintenance requirements of pre-filters.

f. Refer to Section 3-6.2, “Filter Separators,” for inspection and maintenance requirements of filter separators.

g. Refer to Section 9-1.6, “Grounding Systems,” for inspection and maintenance requirements of grounding systems.

h. Refer to Section 9-1.9, “Electrical Equipment,” for inspection and maintenance requirements of control panels.

3-4 RAIL RECEIPT.

Rail receipt systems use components that are similar to the components used for truck receipt. Refer to Section 3-2 Truck Receipt for a list of typical components that should be expected in a rail receipt system and associated maintenance requirements.

3-5 BULK ISSUE.

3-5.1 Truck Issue.

The preferred connection system for jet fuel issue is a metal, counterbalanced, swivel type pantograph constructed of aluminum or stainless steel; although an approved loading fuel hose is acceptable. Loading fuel hoses, if provided, must be stored away from direct sunlight.

Major components of petroleum fuel truck issue facilities include piping, basket strainers, pumps, filter separators, meters, Truck Fill Valve (TFV), loading fuel hoses, fixed pantographs, fueling nozzles, grounding systems, ground verification equipment, electronic overfill protection systems, and control panels.

3-5.1.1 Inspection and Maintenance – Truck Issue.

a. Refer to Section 6-1, “Pipe Testing and Inspections,” for inspection and maintenance requirements of pipelines and piping.

b. Refer to Section 3-6.4, “Basket Strainers,” for inspection and maintenance requirements of basket strainers.

c. Refer to Section 3-8, “Pumps,” for inspection and maintenance requirements of petroleum fuel pumps.

d. Refer to Section 3-6.2, “Filter Separators,” for inspection and maintenance requirements of filter separators.

e. Refer to Section 3-7, “Meters,” for inspection and maintenance requirements of petroleum fuel meters.

f. Refer to Section 6-6.5.1, “Truck Fill Valves,” for inspection and maintenance requirements of TFVs.

g. Refer to Section 3-9.1, “Loading Fuel Hoses,” for inspection and maintenance requirements of loading fuel hoses.

h. Refer to Section 4-7.1.1, “Fixed Pantographs,” for inspection and maintenance requirements of fixed pantographs.

i. Refer to Section 4-7.3, “Fueling Nozzles,” for inspection and maintenance requirements of fueling nozzles.

j. Refer to Section 9-1.6, “Grounding Systems,” for inspection and maintenance requirements of grounding systems.

k. Refer to Section 9-5, “Ground Verification Systems,” for inspection and maintenance requirements of ground verification systems.

l. Refer to Section 9-6, “Electronic Overfill Prevention Systems,” for inspection and maintenance requirements of electronic overfill prevention systems.

m. Refer to Section 9-1.9, “Electrical Equipment,” for inspection and maintenance requirements of control panels.

3-5.2 Pipeline Issue.

Major components of pipeline issue systems include piping, basket strainers, automatic air vents, pumps, filter separators, meters, grounding systems, and control panels.

3-5.2.1 Inspection and Maintenance – Pipeline Issue.

a. Refer to Section 6-1, “Pipe Testing and Inspections,” for inspection and maintenance requirements of pipelines and piping.

b. Refer to Section 3-6.4, “Basket Strainers,” for inspection and maintenance requirements of basket strainers.

c. Refer to Section 3-10.2, “Automatic Air Vents,” for inspection and maintenance requirements of automatic air vents.

d. Refer to Section 3-8, “Pumps,” for inspection and maintenance requirements of petroleum fuel pumps.

e. Refer to Section 3-6.2, “Filter Separators,” for inspection and maintenance requirements of filter separators.

f. Refer to Section 3-7, “Meters,” for inspection and maintenance requirements of petroleum fuel meters.

g. Refer to Section 9-1.6, “Grounding Systems,” for inspection and maintenance requirements of grounding systems.

h. Refer to Section 9-1.9, “Electrical Equipment,” for inspection and maintenance requirements of control panels.

3-5.3 Rail Issue.

Counterbalanced articulated (swivel-type) tank car loading pantographs or loading fuel hoses are used to load railcars.

Major components of rail issue facilities include piping, basket strainers, pumps, filter separators, meters, TFV, loading fuel hoses, fixed pantographs, fueling nozzles, grounding systems, ground verification systems, electronic overfill protection, and control panels.

3-5.3.1 Inspection and Maintenance – Rail Issue.

a. Refer to Section 6-1, “Pipe Testing and Inspections,” for inspection and maintenance requirements of pipelines and piping.

b. Refer to Section 3-6.4, “Basket Strainers,” for inspection and maintenance requirements of basket strainers.

c. Refer to Section 3-8, “Pumps,” for inspection and maintenance requirements of petroleum fuel pumps.

d. Refer to Section 3-6.2, “Filter Separators,” for inspection and maintenance requirements of filter separators.

e. Refer to Section 3-7, “Meters,” for inspection and maintenance requirements of fuel meters.

f. Refer to Section 6-6.5.1, “Truck Fill Valves,” for inspection and maintenance requirements of TFVs.

g. Refer to Section 3-9.1, “Loading Fuel Hoses,” for inspection and maintenance requirements of loading fuel hoses.

h. Refer to Section 4-7.1.1, “Fixed Pantographs,” for inspection and maintenance requirements of fixed pantographs.

i. Refer to Section 4-7.3, “Fueling Nozzles,” for inspection and maintenance requirements of fueling nozzles.

j. Refer to Section 9-1.6, “Grounding Systems,” for inspection and maintenance requirements of grounding systems.

k. Refer to Section 9-5, “Ground Verification Systems,” for inspection and maintenance requirements of ground verification systems.

l. Refer to Section 9-6, “Electronic Overfill Prevention Systems,” for inspection and maintenance requirements of electronic overfill prevention systems.

m. Refer to Section 9-1.9, “Electrical Equipment,” for inspection and maintenance requirements of control panels.

3-6 FILTRATION.

3-6.1 Pre-Filters.

\1\

a. Micronic pre-filters meeting the requirements of UFGS 33 52 43.28 are sometimes installed upstream of filter separators to extend the life of coalescer cartridges in filter separators. Pre-filters remove particles that cause contamination. Petroleum fuel to be filtered enters the lower part of the housing and flows through the filter cartridges from outside to inside. Coarse dirt particles settle immediately; finer particles are absorbed by the pleated paper type filter cartridges.

b. An elevated differential pressure measurement indicates dirty filter cartridges. Investigate sudden drops or spikes in differential pressure measurement reading. A drop in the flow rate or an increase in pressure of a system may indicate filters cartridges are fouled with debris or contaminants. A sudden increase in flow rate or decrease in pressure may indicate that the filter cartridges are damaged or torn. Replacement filter cartridges must meet the filter cartridge requirements of UFGS 33 52 43.28.

c. The Installation must maintain an inventory of filter cartridges. The inventory must be sufficient to allow the Installation to change the filter cartridges of all pre-filters at an Installation once. The inventory must be kept in a temperature controlled environment in accordance with manufacturer recommendations.

/1/

Figure 3-1 Pre-Filter

3-6.1.1 Inspection and Maintenance – Pre-Filters.

Stencil pre-filters in accordance with Section 3-6.1.3 Stenciling of Pre-Filters when filter cartridges are changed. Pre-filters require the following inspection and maintenance:

a. Open drains under flow conditions until clear fuel is observed from the drain valve.
Frequency: Daily

b. Monitor differential pressure in filter cartridges. Chart differential pressure measurements from readings taken during normal operations.
Frequency: Daily

c. Operate pre-filter isolation valves.
Frequency: Quarterly

d. Replace filter cartridges when the acceptable maximum differential pressure is reached, the maximum in-service duration has passed, or the fuel becomes visibly dirty or discolored. Acceptable maximum differential pressure for a specific pre-filter is dependent on the system flow rate. The military service-specific SCP may extend in-service duration filter cartridge replacement period based on differential pressure for high throughput systems. Check expiration date of replacement filter cartridges before installation.
Frequency: When differential pressure has reached the lower of manufacturer's recommendation or 20 psid (140 kPa), filter cartridge in-service period of 24 months has expired, or when fuel becomes visibly dirty or discolored.

e. Refer to Section 6-7.2, "Differential Pressure Gauges," for inspection and maintenance requirements of differential pressure gauges.

f. Refer to Section 3-10.2, "Automatic Air Vents," for inspection and maintenance requirements of automatic air vents.

g. Refer to Section 6-6.3, "Thermal and Pressure Relief Valves," for inspection and maintenance requirements of thermal and pressure relief valves.

h. Conduct inspections of code rated vessels in accordance with UFC 3-430-07.

3-6.1.2 Pre-Filter Waste Disposal.

Refer to Section 2-6.4 Waste Disposal for proper disposal of filtered waste and used filter cartridges.

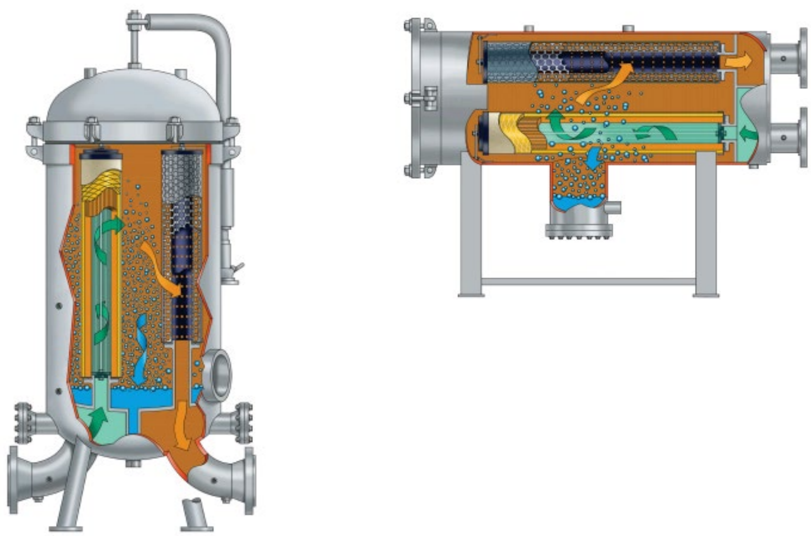
3-6.1.3 Stenciling of Pre-Filters.

Use stencils or embossing tape (0.75 to 1-inch (19 to 25 mm) letters) to permanently mark pre-filters when filter cartridges are changed with date changed, due date for next change, and maximum differential pressure.

3-6.2 Filter Separators.

Filter separators meeting which meet the requirements of UFGS 33 52 43.28 remove undissolved (free) water and solids from petroleum products. Very fine water particles pass through coalescer cartridges from inside to outside and grow in size (coalesce) into larger droplets that fall to the water collection sump.

Figure 3-2 Filter Separator



Second-stage Teflon or nylon coated screens or treated paper cartridges (separator) repels water droplets and prevents them from leaving the filter separator and cause them to fall to the water collection sump. The solids in the fuel are trapped in the coalescer cartridges and build up a differential pressure across the filter separator. Water accumulated in the water collection sump at the bottom of the filter separator is typically removed manually under flow conditions. Additional important notes for filter separators are as follows:

a. Filter separators must be equipped with coalescer and separator cartridges that meet the requirements of UFGS 33 52 43.28. Older units must be modified to accept these cartridges or must be replaced with modern units.

b. If installed, remove automatic water drain option from filter separators at the first opportunity, unless they are installed on a receipt system that must handle excessive water, or if waived by the military service-specific

SME. If automatic water drains are to remain they must be piped to a product recovery or drain tank.

c. Filter separators are equipped with differential pressure gauges to indicate when coalescer cartridges should be changed. The piston-type differential pressure gauge is preferred for petroleum fuel systems. Replace individual gauges with the piston-type as soon as practical.

d. Filter separators have a sampling port in the outlet pipe used to obtain petroleum fuel quality samples. Check the flow direction arrow on sample probes to ensure they are installed in the proper orientation.

e. The Installation must maintain an inventory of coalescer and separator cartridges. The inventory must allow the Installation to change the coalescer and separator cartridges of all filter separators at an Installation once. The inventory must be kept in a temperature controlled environment in accordance with manufacturer recommendations.

3-6.2.1 Inspection and Maintenance – Filter Separators.

Stencil filter separators in accordance with Section 3-6.2.4 Stenciling of Filter Separators when coalescer cartridges are changed. Filters separators require the following inspection and maintenance:

a. Open drain under flow conditions until clear fuel is observed from the drain valve.
Frequency: Daily

b. Monitor differential pressure of coalescer cartridges. The acceptable maximum differential pressure for a specific filter separator is dependent on the system flow rate. Monitor and chart differential pressure measurements of filter separators from readings taken during normal operations. Investigate sudden drops or spikes in differential pressure measurement readings.
Frequency: Daily

c. Operate filter separator isolation valves.
Frequency: Quarterly

d. Inspect components and check operation of water shutoff system.
Frequency: Quarterly

e. Change coalescer cartridges. Refer to Section 3-6.2.2 Replacement of Coalescer Cartridges for general instructions on replacement of coalescer cartridges. Military service-specific SCP may extend the coalescer cartridge replacement frequency based on differential pressure if filters separators are used on high throughput systems. Check expiration date of replacement coalescer cartridges before installation.
Frequency: Every 36 months or sooner if required by differential pressure.

f. Inspect and clean separator cartridges at time of coalescer cartridge change in accordance with Section 3-6.2.3 Separator Cleaning. Worn or damaged separator cartridges must be replaced.
Frequency: Every 36 months or sooner if required by differential pressure.

g. Refer to Section 6-7.2, "Differential Pressure Gauges," for inspection and maintenance requirements of differential pressure gauges.

h. Refer to Section 3-10.2, "Automatic Air Vents," for inspection and maintenance requirements of automatic air vents.

i. Refer to Section 6-6.3, "Thermal and Pressure Relief Valves," for inspection and maintenance requirements of thermal and pressure relief valves.

j. Refer to Section 4-4.2.2, "Filter Separator Control Valves," for inspection and maintenance requirements of filter separator control valves.

k. Conduct inspections of code rated vessels in accordance with UFC 3-430-07.

3-6.2.2 Replacement of Coalescer Cartridges.

General instructions for the replacement of filter separator coalescer cartridges are included in Appendix D. Refer to manufacturer's maintenance and operation manual for additional guidelines.

3-6.2.3 Separator Cleaning.

Separator cartridges, when new, operate in a satisfactory manner, but over time they gradually become less effective. Every time the coalescer cartridges are changed, the separator cartridges must be inspected and cleaned. Typical instructions for cleaning separator cartridges are included in Appendix D. Refer to manufacturer's operation and maintenance manual for additional guidelines.

3-6.2.4 Stenciling of Filter Separators.

Use stencils or embossing tape (0.75 to 1-inch (19 to 25 mm letters) to permanently mark filter separators when coalescer cartridges are changed with date changed, due date for next change, and maximum differential pressure.

3-6.2.5 Initial Filling of Filter Separators.

Internal flash fires have occurred within filter separators. In some cases, there were no audible sounds or immediate indications of a problem. These incidents are mainly due to electrostatic ignition of the petroleum fuel vapor-air mixture during the initial filling operation. Ignition inside filter separators is possible regardless of the type of petroleum fuel handled (e.g., JP-4, JP-5, JP-8, Jet A, additized Jet A (F-24)). Filling a filter separator must take a minimum of ten minutes to perform. Slow filling is the only authorized method of refilling an empty filter separator. This slows buildup of static electricity in fuel, reducing the possibility of a spark igniting the explosive atmosphere inside the vessel. In most cases, coalescer elements cannot be grounded or bonded to dissipate the static electric charge that is generated during filling.

3-6.3 Haypack Filters.

Haypack filters are typically only used for marine barge and tanker offloading where large amounts of water are expected to be present in the fuel.

3-6.3.1 Inspection and Maintenance – Haypack Filter.

Refer to manufacturer's operation and maintenance manual for inspection and maintenance requirements of haypack filters. Refer to Section 2-6.4 Waste Disposal for disposal of requirements.

3-6.4 Basket Strainers.

Basket strainers, which meet the requirements of UFGS 33 52 43.13, remove large particulate matter from petroleum fuel streams. Basket strainers are typically equipped with 60 mesh (0.25 mm sieve) wire strainer screens. In most cases basket strainers are equipped with differential pressure gauges that can be used to measure the differential pressure across the strainer. The maximum retaining capacity of rust and sediment in the basket strainer is reached when the acceptable maximum differential pressure is indicated across the strainer. The acceptable maximum differential pressure for a specific basket strainer is dependent on the size of the strainer and the system flow rate. Reference the manufacturer's data sheet for the maximum differential pressure of a particular basket strainer.

Dirty strainer screens can be washed (using air jets or pressurized liquid streams) and reused as long as they are not ruptured or otherwise damaged. Gum or tar can be removed by soaking strainer screens in a high flash point petroleum fuel, such as kerosene. In order to reduce shutdown time, it is advisable to have extra strainer screens on hand.

3-6.4.1 Inspection and Maintenance - Basket Strainers.

a. Monitor and chart differential pressure measurements of basket strainers from readings taken during normal operations. Investigate sudden drops or spikes in differential pressure measurement reading.
Frequency: Daily

b. Clean and inspect basket and strainer screen. Basket strainer isolation valves must be closed and the strainer body must be drained before removing the cover. After cleaning, the strainer screen must be inserted in the strainer body, and the head tightened and checked for leakage. If strainer is not equipped with means to measure differential pressure, unit must be opened monthly and inspected.

Frequency: Semi-annually if basket strainer is equipped with means to measure differential pressure; otherwise monthly.

c. Refer to Section 6-7.2, Differential Pressure Gauges, for inspection and maintenance requirements of differential pressure gauges.

3-6.5 Filter Separator Sump Heaters.

Heaters are used in sumps to prevent freezing of separated water during winter months in cold climates. Sump heaters are not approved for DoD systems. If heaters are installed contact the military service-specific SCP for guidance. Existing heaters installed in systems must be maintained.

3-6.5.1 Inspection and Maintenance – Filter Separator Sump Heaters.

a. Inspect filter separator sump and drain line heater elements for proper operation per manufacturer's operation and maintenance manual. Ensure heater elements meet manufacturer's requirements by measuring resistance of heater elements with an ohm meter.
Frequency: Semi-annually.

3-7 METERS.

3-7.1 Positive Displacement Meters.

\1
Positive displacement meters that meet the requirements of **\1** UFGS 33 57 55 **/1/** are used to record the amount of petroleum fuel received, transferred, or issued. Flow control devices and strainers are sometimes installed upstream of meters to help ensure accuracy and protect meter internals.

Truck and railcar loading meters may be equipped with a preset feature. This feature is used to slow the petroleum fuel flow to a predetermined rate when the preset petroleum fuel total is approached. Slower fill rates allow a more accurate final fill and reduce the likelihood of hydraulic shock to the system once flow of petroleum fuel is stopped. Meters installed at custody transfer points may be equipped with temperature compensation. This feature allows the meter to adjust the measurement of the flow rate to a standard temperature.

/1/

Figure 3-3 Positive Displacement Meter

3-7.1.1 Inspection and Maintenance – Positive Displacement Meters.

Component wear and accumulation of solids make periodic calibration necessary. Certified master meters or volumetric prover tanks are used for calibration. Master meters must have been certified within a year of calibration operations. Master meters are tested at a predetermined flow rate. Master meters must be calibrated within ±10% of the normal operating flow rate through the inline positive displacement meter. Volumetric prover tanks must have been certified within the last five (5) years of calibration operations.

a. Inspect counter head for unusual noises and smooth operation.
Frequency: Monthly

b. Positive displacement meters must be inspected and calibrated semi-annually or when improper performance is suspected; when unusual sounds or register actions develop; or after repairs have been made which may affect performance. Positive displacement meters are satisfactory when the measurement error in the normal flow direction is within ±0.3% of actual quantity delivered (e.g., ±1.8 gallons for a 600-gallon test (±6.8 liters for a 2275-liter test)). Adjustment of the meter's register will be in accordance with manufacturer's instructions. Identify the next calibration date on meters (example: Mar 14 for March 2014). Use weather resistant label that will remain legible and affixed for at least one year.
Frequency: Semi-annually or as required

c. **\2** Positive displacement meters with temperature compensator feature must be inspected and calibrated semi-annually. Calibration procedures will be followed according to manufacturer's recommendation.
Frequency: Semi-annually /2/

d. Inspect temperature element operation of meters equipped with temperature compensation feature per manufacturer’s operation and maintenance manual.
Frequency: Semi-annually

3-7.2 Turbine Flow Meters

Turbine flow meters that meet the requirements of UFGS 33 52 43.11 utilize an axially aligned rotor to measure fluid flow. Clearances between the rotor and housing allow some slippage which can reduce the accuracy of the flow meter.

Figure 3-4 Turbine Flow Meter

3-7.2.1 Inspection and Maintenance- Turbine Flow Meters.

Component wear makes periodic calibration necessary. Certified master meters or volumetric prover tanks are used for calibration of turbine flow meters in accordance with API *Manual of Petroleum Measurement Standards*. Master meters must have been certified within a year of calibration operations. Master meters are tested at a predetermined flow rate. Master meters must be calibrated within ±10% of the normal operating flow rate through the turbine meter. Volumetric prover tanks must have been certified within the last five (5) years of calibration operations. Refer to the manufacturer’s operation and maintenance manual for turbine flow meter-specific calibration procedures.

a. **\2** Turbine flow meters must be inspected and calibrated semi-annually or when improper performance is suspected, when unusual sounds or register actions develop, or after repairs have been made which may affect performance. /**2**/ Turbine flow meters are satisfactory when the measurement error in the normal flow direction is within ±0.5% of actual quantity delivered (e.g., ±3 gallons for a 600-gallon test (±11 liters for a 2275-liter test)). Adjustment of the meter's register will be in accordance with the manufacturer's instructions. Identify the next calibration date on meters (example: Mar 14 for March 2014). Use weather resistant label that will remain legible and affixed for at least one year.
Frequency: Semi-annually or as required

b. **\2** Turbine flow meters with temperature compensator feature must be inspected and calibrated semi-annually. Calibration procedures will be followed according to manufacturer's recommendation
Frequency: Semi-annually /2/

c. Inspect temperature element operation of meters equipped with temperature compensation feature per manufacturer's operation and maintenance manual.
Frequency: Semi-annually

3-7.3 Orifice Flow Meters.

Orifice flow meters that meet the requirements of UFGS 33 52 43.11 typically do not require calibration. Orifice flow meters are customized to a specific flow rate and are only accurate over a small range.

3-7.3.1 Inspection and Maintenance - Orifice Flow Meters.

Refer to manufacturer's operation and maintenance manual for unit-specific maintenance requirements.

a. Refer to Section 6-7.2, Differential Pressure Gauges, for inspection and maintenance requirements of differential pressure gauges.

b. Refer to Section 6-7.4, Differential Pressure Transmitters, for inspection and maintenance requirements of differential pressure transmitters.

3-8 PUMPS.

3-8.1 Centrifugal Pumps.

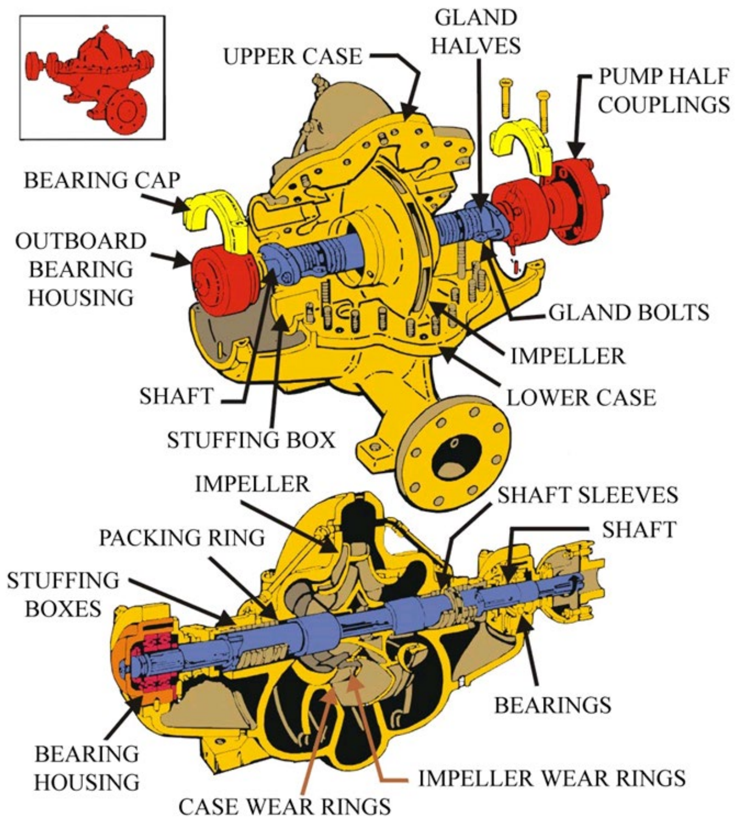
\1

a. Centrifugal pumps work best if the impeller is completely immersed in liquid. It is important to prevent air pockets from delivery trucks and hoses from entering pumps. If air gets into a pump the performance can be drastically reduced. Air eliminator tanks and automatic air vents are used to release air from the suction lines of pumps. In some cases air eliminators are attached directly to the housing of pumps.

b. Centrifugal pumps must have proper shaft alignment with the motors. The pumps must also be properly shimmed and mounted securely. Both inlet and outlet pipe connections should be made with vibration dampeners. The bearings must be adequately lubricated and the mechanical seals should show no signs of leaks.

c. Mechanical seals require maintenance, but they provide reliable service if properly installed on a true shaft. Frequent trouble is usually caused by shaft vibration, wear, or improper installation. It is most important to protect seal faces from contact with skin, grease, or metal particles, which can contaminate the seal and cause premature seal failure./**1**/

Figure 3-5 Split-Case Centrifugal Pump



3-8.1.1 Inspection and Maintenance - Centrifugal Pumps.

Refer to manufacturer’s operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of pump. Follow applicable general maintenance and safety requirements listed in the manufacturer’s operation and maintenance manual.

a. Check for proper operations while pump is in use. Check suction and discharge pressure gauges for abnormal readings.
Frequency: Quarterly

b. Check for unusual noise, vibration, and overheating of bearings or case.
Frequency: Quarterly

c. If equipped with lubricating oil charge, check oil level and adjust as necessary.
Frequency: Quarterly

d. Tighten or replace loose, missing or damaged nuts, bolts, or screws.
Frequency: Quarterly

e. Inspect suction and discharge isolation dampeners for misalignment and wear.
Frequency: Quarterly

f. Inspect mechanical seals, if possible, for proper operating temperature, drips, leaks and dirt.
Frequency: Quarterly

g. Check for alignment, clearances, and rotation of shaft and coupler (requires removal of coupler shroud or cover).
Frequency: Annually

h. Lubricate pump bearings.
Frequency: Annually

i. If equipped with lubricating oil charge, drain old oil, and fill with new oil to full mark on sight indicator (also fill bulb).
Frequency: Annually

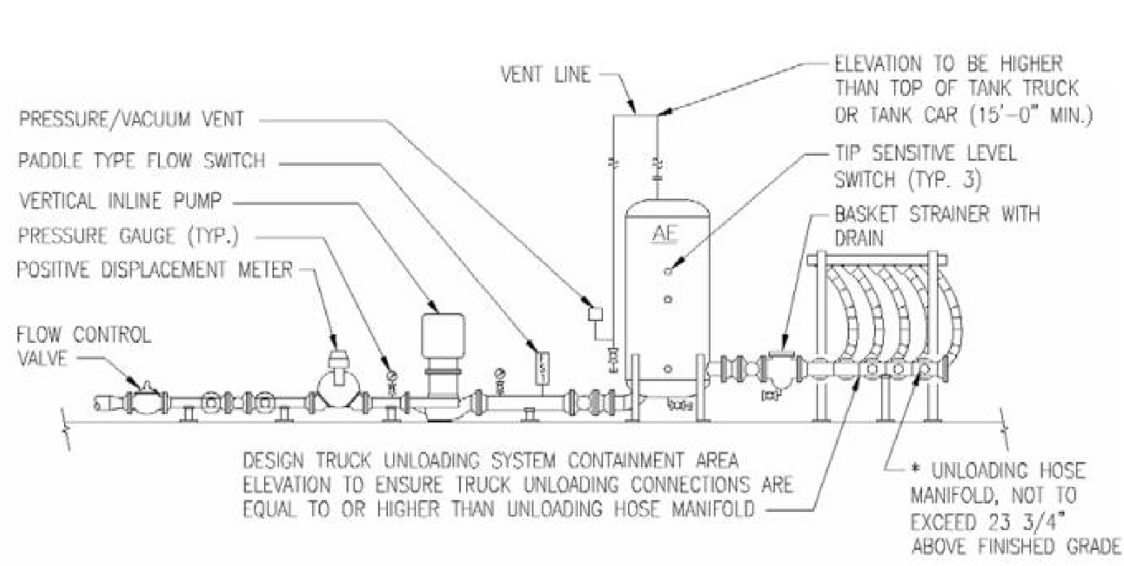
j. Refer to Section 9-1.7, “Electric Motors,” for inspection and maintenance requirements of electric motors.

\1

3-8.2 /1/ Vertical Inline Pumps.

Vertical inline pumps should meet the requirements of **1**\ UFGS 33 52 43.23 /**1**/. Off-loading pump can operate at lower liquid levels than similarly sized end suction pumps due to the geometry of the impeller location and are used frequently in petroleum fuel offloading applications. Vertical inline pumps must be properly supported to prevent unnecessary stress on inlet and outlet piping.

Figure 3-6 Vertical Inline Pump



\1
3-8.2.1 /1/ Inspection and Maintenance – Vertical Inline Pumps.

Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of pump. Follow applicable general maintenance and safety requirements listed in the manufacturer's operation and maintenance manual.

a. Check for proper operations while pump is in use. Check suction and discharge pressure gauges for abnormal readings.
Frequency: Quarterly

b. Check for unusual noise, vibration, and overheating of bearings.
Frequency: Quarterly

c. Tighten or replace loose, missing or damaged nuts, bolts, or screws.
Frequency: Quarterly

d. Inspect suction and discharge isolation dampeners for misalignment and wear.
Frequency: **Quarterly**

e. Inspect mechanical seals, if possible, for proper operating temperature, drips, leaks and dirt.
Frequency: Quarterly

f. Check for alignment, clearances, and rotation of shaft and coupler (requires removal of coupler shroud or cover).
Frequency: Annually

g. Lubricate pump bearings.
Frequency: Annually

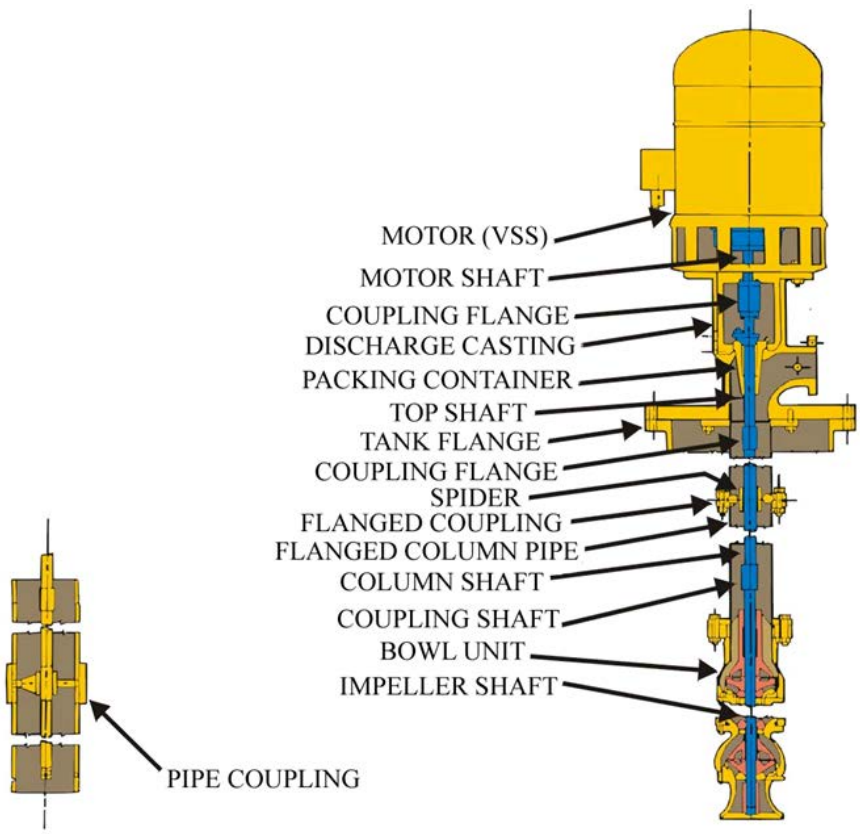
h. Refer to Section 9-1.7 Electric Motors for inspection and maintenance requirements of electric motors.

\1\
3-8.3 /1/ Vertical Turbine/Submerged Turbine Pumps.

Submerged turbine pumps that meet the requirements of UFGS 33 52 43.23 are used to pump from aboveground, underground, and cut and cover tanks. This type of pump is also used to transfer fuel from drop tanks used in some petroleum fuel truck offloading systems. A "can" pump is another type of vertical turbine pump.

Submerged turbine pumps are sometimes used in military service station applications to supply fuel to vehicle fuel dispensers and petroleum fuel truck loading positions. Refer to manufacturer's operation and maintenance manual for more information on each type of pump.

Figure 3-7 Vertical Turbine Pump



\1

3-8.3.1 /1/ Inspection and Maintenance – Vertical Turbine/Submerged Turbine Pumps.

Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of pump. Follow applicable general maintenance and safety requirements listed in the manufacturer's operation and maintenance manual.

a. Check for proper operation while pump is in use. Check discharge pressure gauge for abnormal readings.
Frequency: Quarterly

b. Check for unusual noise, vibration, and overheating of bearings or case.
Frequency: Quarterly

c. If equipped with lubricating oil charge, check oil level and adjust as necessary.
Frequency: Quarterly

d. Tighten or replace loose, missing or damaged nuts, bolts, or screws.
Frequency: Quarterly

e. Inspect mechanical seals, if possible, for proper operating temperature, drips, leaks and dirt.
Frequency: Quarterly

f. Inspect anti-rotation device for proper operation.
Frequency: Semi-annually

g. Check for alignment, clearances, and rotation of shaft and coupler (requires removal of coupler shroud or cover).
Frequency: Annually

h. Lubricate pump bearings.
Frequency: Annually

i. If equipped with lubricating oil charge, drain old oil, and fill with new oil to full mark on sight indicator (also fill bulb).
Frequency: Annually

j. Refer to Section 9-1.7 Electric Motors for inspection and maintenance requirements of electric motors.

\1

3-8.4 /1/ Positive Displacement Pumps.

Positive displacement pumps have an expanding cavity on the suction side and a decreasing cavity on the discharge side. Liquid flows into the pumps as the cavity on the suction side expands and the liquid flows out of the discharge as the cavity collapses. The pumped volume is constant given each cycle of operation.

\1
3-8.5 /1/ Sliding Vane Pumps.

Sliding vane pumps (sometimes referred to as rotary vane pumps) are self-priming positive displacement pumps used where suction lifts are high or where the pump may frequently lose prime such as petroleum fuel truck offload systems. These pumps must have internal or downstream pressure relief.

\1
3-8.5.1 /1/ Inspection and Maintenance – Sliding Vane Pumps.

Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of pump. Follow applicable general maintenance and safety requirements listed in the manufacturer's operation and maintenance manual.

a. Inspect pump for unusual noise, vibrations, and overheating of bearings and case.
Frequency: Quarterly

b. Inspect mechanical seals, if possible, for drips or leaks and dirt.
Frequency: Quarterly

c. Lubricate pump bearings.
Frequency: Quarterly

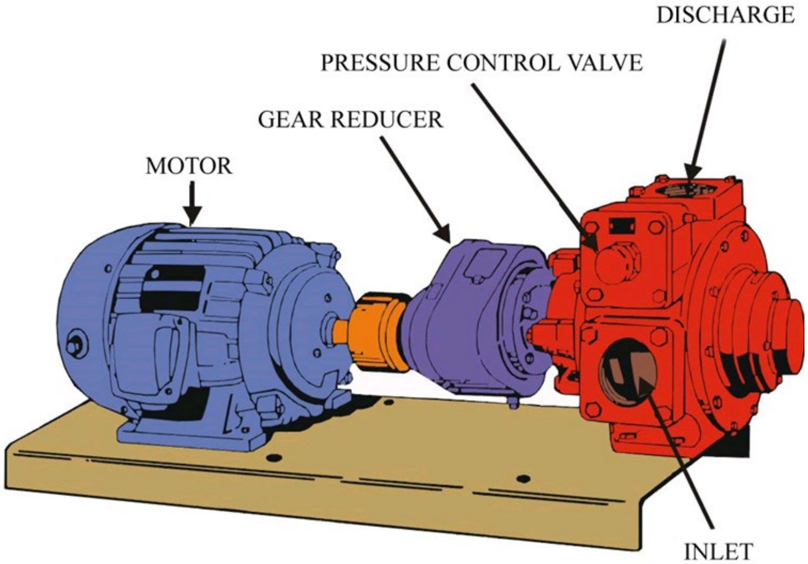
d. Inspect pump and motor coupling for proper alignment.
Frequency: Annually

e. Refer to manufacturer's operation and maintenance manual for internal pressure relief testing and calibration procedures.
Frequency: Annually

f. Refer to Section 3-8.4 Gearboxes for inspection and maintenance of reduction gearboxes.

g. Refer to Section 9-1.7 Electric Motors for inspection and maintenance requirements of electric motors.

Figure 3-8 Rotary Vane Pump



\1
3-8.6 /1/ Gear Pumps.

Gear pumps may be used to transfer petroleum fuel at moderate flow rates and can operate at high pressures.

\1
3-8.6.1 /1/ Inspection and Maintenance – Gear Pumps.

Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of pump. Follow applicable general maintenance and safety requirements listed in the manufacturer's operation and maintenance manual.

a. Inspect pump for unusual noise, vibrations, and overheating of bearings and case.
Frequency: Quarterly

b. Inspect mechanical seals, if possible, for drips or leaks and dirt.
Frequency: Quarterly

c. Lubricate pump bearings.
Frequency: Quarterly

d. Inspect pump and motor coupling for proper alignment.
Frequency: Annually

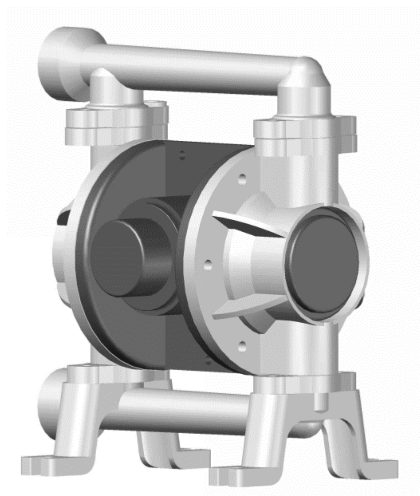
e. Refer to Section 3-8.4 Gearboxes for inspection and maintenance of reduction gearboxes.

f. Refer to Section 9-1.7 Electric Motors for inspection and maintenance requirements of electric motors.

\1
3-8.7 /1/ Diaphragm Pumps.

Diaphragm pumps are relatively low maintenance pumps that provide good performance for transferring high viscosity liquids such as petroleum sludge left in a tank.

Figure 3-9 Diaphragm Pump



\1
3-8.7.1.2 /1/ Inspection and Maintenance – Diaphragm Pumps

Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of pump. Follow applicable general maintenance and safety requirements listed in the manufacturer's operation and maintenance manual. Ensure pump, hoses, and fittings are kept clean and are stored in a protected area out of the elements when is not in use.

a. Inspect hoses for cracks or dry rot.
Frequency: Quarterly

b. Inspect compressed air connections and hose couplings for signs of leaks.
Frequency: Quarterly

c. Inspect compressed air hose coupling safety pins or safety wires for wear and damage. Replace damaged components.
Frequency: Quarterly

d. Diaphragm pumps should have the internal diaphragm replaced if the pump shows decreased performance. Also check operation of actuator valve and ensure ball checks seat properly.
Frequency: As required

\1
3-8.8 /1/ Internal Combustion Drives.

Internal combustion drives are used where equipment is needed on a temporary or portable basis such as temporary pumps or power generators. Internal combustion drives are also used to operate permanent power generators when standard power is interrupted such as emergency backup generators, and where large power feeds for large equipment is not available or cost effective to install such as petroleum fuel transfer pumps installed in remote locations.

\1
3-8.8.1 /1/ Inspection and Maintenance – Internal Combustion Drives.

a. Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of internal combustion drive. Follow all applicable general maintenance and safety requirements listed in the manufacturer's operation and maintenance manual.
Frequency: As required

\1
3-8.9 /1/ Gearboxes.

Gearboxes transmit power from motors to pumps and other rotating equipment. Gearboxes must be monitored for proper alignment and oil level. Do not overfill gearboxes during maintenance.

\1
3-8.9.1 /1/ Inspection and Maintenance – Gearboxes.

When replacing lubricating oil, verify metal shaving content is within manufacturer's recommendations. Refer to manufacturer's operation and maintenance manual for oil testing procedures, proper oil levels, and proper type of oil which should be used. Refer to the applicable manufacturer's operation and maintenance manual for specific maintenance procedures and schedules, and follow applicable general maintenance and safety requirements.

a. Inspect gearboxes for signs of smoke near shaft connections or discoloration of the gearbox from overheating.
Frequency: Quarterly

b. Verify that the oil in the sight glass is not dark or appears to have foam. Adjust oil level if required.
Frequency: Quarterly

c. Lubricate bearings per manufacturer's recommendations.
Frequency: Semi-annually

d. Check motor and gear box and gear box and pump couplers for wear and alignment.
Frequency: Semi-annually

e. Inspect gear alignment within gearbox.
Frequency: Annually

f. Replace lubricant oil in accordance with manufacturer's specifications and recommendations.
Frequency: Annually

3-9 HOSES.

3-9.1 Loading Fuel Hoses.

Loading fuel hoses must meet the requirements of aviation fueling hoses listed in **\1** UFGS 33 57 55 **/1/**. General requirements for loading fuel hose use are as follows:

a. Hoses must be stored away from direct exposure to sun and extreme weather such as rain and snow in a hinged enclosure when not in use.

b. Dust covers or other protective devices must be used to keep out dirt and water.

d. Hoses must be installed within 2 years of the date of the hose's manufacture, and have a maximum service life of 10 years from the date of manufacture.

3-9.1.1 Inspection and Maintenance – Loading Fuel Hoses.

a. Visually inspect hoses for loose covers, cracks, brittle surface coatings, exposed wire braids, exposed reinforcement, flattening, kinks, and bulges or soft spots which might indicate broken or displaced reinforcement.
Frequency: Monthly

b. Pressurize hose to normal working pressure. Check flanged and threaded connections for leaks and inspect hose couplers for fluid seepage by pushing at the base of the coupling with thumbs. A hose softened by petroleum fluid seepage must be replaced.
Frequency: Monthly

c. Check for coupling slippage. Replace hose that shows signs of coupling slippage.
Frequency Quarterly

d. **\1\ /1/**

e. Conduct test of petroleum fuel hose electrical resistivity using an electrostatic meter in accordance with NFPA 77 and API 2003.
Frequency: Annually

3-9.2 Offloading Fuel Hoses.

Offloading petroleum fuel hoses meeting the requirements of UFGS 33 52 43.11 are used for offloading operations. Offloading petroleum fuel hoses must be stored away from direct sunlight in a hinged enclosure when not in use or must be purchased with ultraviolet (UV) light protection.

3-9.2.1 Inspection and Maintenance - Offloading Fuel Hoses.

a. Visually inspect hoses for cracks, brittle surface coatings, exposed wire braids, exposed reinforcement, flattening, kinks, and bulges or soft spots which might indicate broken or displaced reinforcement.
Frequency: Monthly

b. Check flanged and threaded connections for leaks and inspect hose couplers for fluid seepage by pushing at the base of the coupling with thumbs. A hose softened by petroleum fluid seepage must be replaced. Damaged or leaking hoses must be replaced immediately or isolated and taken out of service. **Frequency: Quarterly**

c. Conduct test of offloading petroleum fuel hose electrical resistivity as directed in NFPA 77 and API 2003.
Frequency: Annually

3-10 AIR ELIMINATORS.

Air eliminators are used to remove non-condensing gases such as air from petroleum fuel systems.

3-10.1 Air Eliminator Tanks.

\1

a. Air eliminator tanks meeting the requirements of UFGS 33 52 43.11 are used to remove air from petroleum fuel offloading systems. Air eliminator tanks should include a sight gauge, float vent valve, level sensors, and a pressure/vacuum vent.

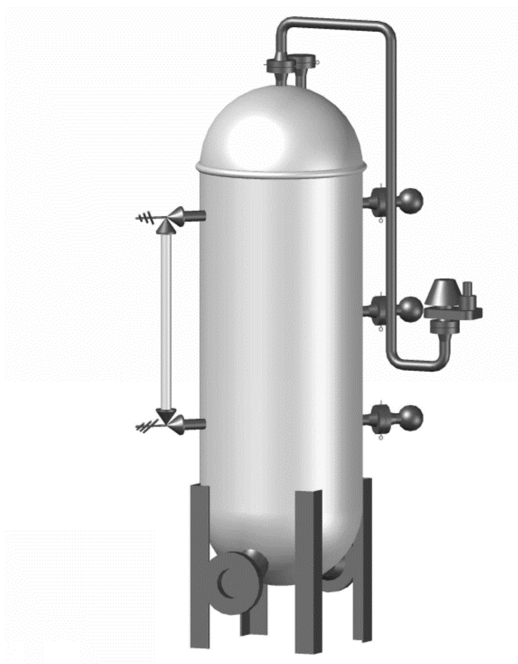
b. A float vent valve is installed at the top of air eliminator tanks in an extractor fitting at the base of the vent pipe. The float and body of the valve are suspended from the extractor fitting inside the air eliminator tank. The float of the valve is buoyant in petroleum fuel and rises to close the float vent valve and block off the vent pipe when the air eliminator tank is full of petroleum fuel. When the level of petroleum fuel in the air eliminator tank drops, the float of the float vent valve drops and opens the vent pipe.

c. A pressure/vacuum vent is installed at the end of the vent pipe. The pressure/vacuum vent allows air to vent from the tank when a small positive pressure is developed in the air eliminator tank and allows air to enter the vent line when a small negative pressure is developed inside the air eliminator tank.

d. Level sensing probes are installed at two or three locations in the air eliminator tank. The level probes are used by the offloading control system to control the operation of the offloading pump.

/1/

Figure 3-10 Air Eliminator Tank



3-10.1.1 Inspection and Maintenance - Air Eliminator Tanks.

a. Inspect operation of petroleum fuel level probes. Ensure probes operate correctly when the level of petroleum fuel in the tank rises to the level of the probe sensing unit.
Frequency: Annually

b. Remove the float vent valve from the air eliminator tank. Clean and inspect the sealing surfaces of the float vent valve. Ensure the float is buoyant in petroleum fuel and test the valve to ensure it closes properly.
Frequency Annually

c. Refer to Section 8-9.3 Tank Pressure/Vacuum Vents for inspection and maintenance requirements of pressure vacuum vents.

3-10.2 Automatic Air Vents.

Automatic air vents meeting the requirements of UFGS 33 52 43.13 automatically vent air under pressure and prevent a vacuum when pressure drops below positive pressure. The vents are operated by a float ball that is buoyant in petroleum fuel. When air is present the float will drop allowing air to escape, and when petroleum fuel is present the ball will float and seal the vent opening. In most cases, automatic air vents are piped to a tank such as a product recovery tank.

Figure 3-11 Automatic Air Vent

3-10.2.1 Inspection and Maintenance - Automatic Air Vents.

a. Check for proper operation of the automatic air vent. Ensure the vent opens to allow air to escape and ensure the float of the vent is buoyant in petroleum fuel and rises to close the vent when the float is suspended in petroleum fuel.
Frequency: Annually

3-11 FUEL ADDITIVE INJECTORS.

Fuel additive injectors are used to inject additives into fuel to change its grade such as a change from Jet A to F-24.

3-11.1 Inspection and Maintenance – Fuel Additive Injectors.

Refer to the manufacturer's operation and maintenance manual for specific calibration and maintenance procedures and schedules and follow all applicable general maintenance and safety requirements.

a. Inspect injectors to ensure they are operating properly.
Frequency: When system has flow through it, inspect injectors weekly. When system is idle, inspect injectors monthly.

b. Calibrate injector to ensure proper additive to fuel ratio.
Frequency: Annually

3-12 CODED VESSELS.

Coded vessels such as filter separators, filters, and relaxation tanks are used when spaces larger than standard piping is required to conduct operations such as filtering or static dissipation in petroleum fuel systems.

3-12.1 Inspection and Maintenance – Coded Vessels.

Pressure vessels used in petroleum fuel system are built to applicable pressure vessel codes and stamped with plates that provide information on the coded vessel. These vessels must follow inspection and maintenance requirements included in UFC 3-430-07.

This Page Intentionally Left Blank

CHAPTER 4 AIRCRAFT FUELING FACILITIES

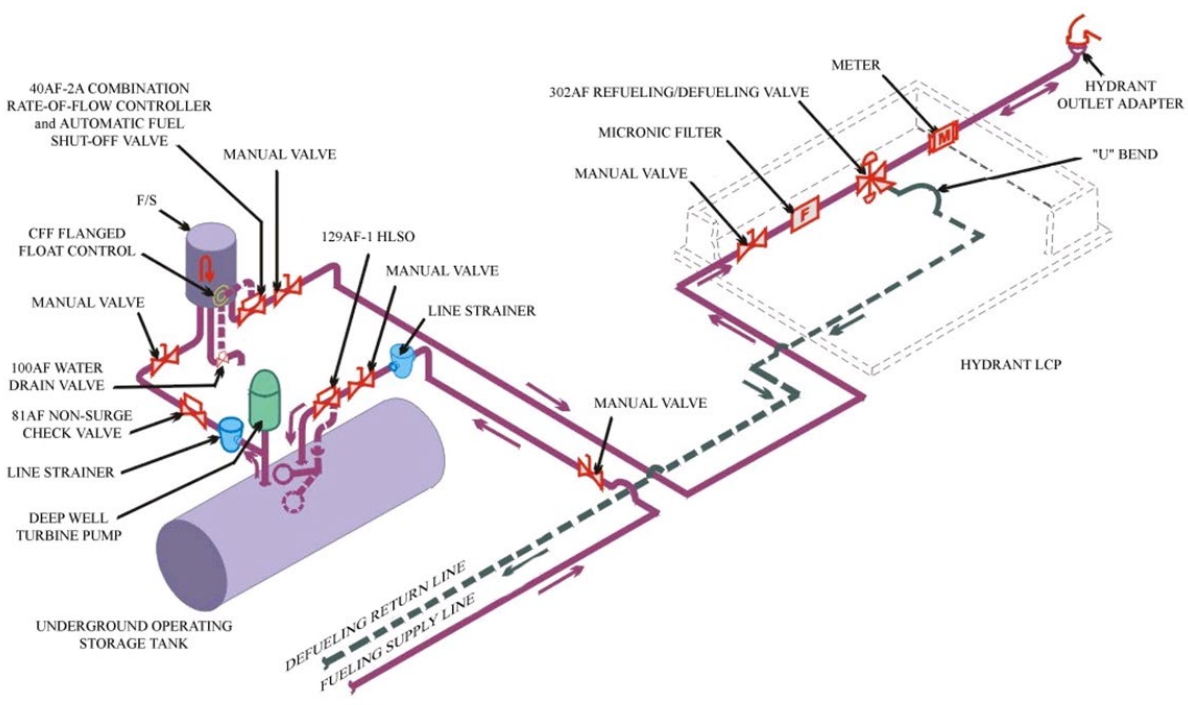
4-1 INTRODUCTION.

This chapter contains a brief operational description of each type of hydrant system and the major components included in each system. Hydrant systems are site-specific. The settings provided within this manual are derived from standard designs and may vary due to configuration, climate, and location of an installed system. Before systems or components are calibrated or maintained, personnel should consult as-built and start up data and must be familiar with proper settings of the specific system.

4-2 HYDRANT SYSTEM – TYPE I.

Type I hydrant systems are known as Panero systems. Panero systems were built in the 1940's and 50's, and were the first hydrant system used by the DoD. Panero systems have been superseded by more modern hydrant systems, but a limited number are still in use. Panero systems pump petroleum fuel to refueling outlets, and aircraft are moved to outlets to conduct refueling operations. These systems typically use vertical turbine pumps and underground horizontal storage tanks. Original Panero systems had automatic control valves on the issue and defuel lines in filter/meter pits. Major modifications to the original Panero created the Modified Panero system. The Modified Panero system uses one automatic control valve to perform both issue and defuel operations and uses MH-2 hose carts instead of filter/meter pits. With these systems defuel operations are conducted by gravity to a dedicated defuel tank.

Figure 4-1 Modified Panero, Type I Hydrant System



4-3 HYDRANT SYSTEM – TYPE II.

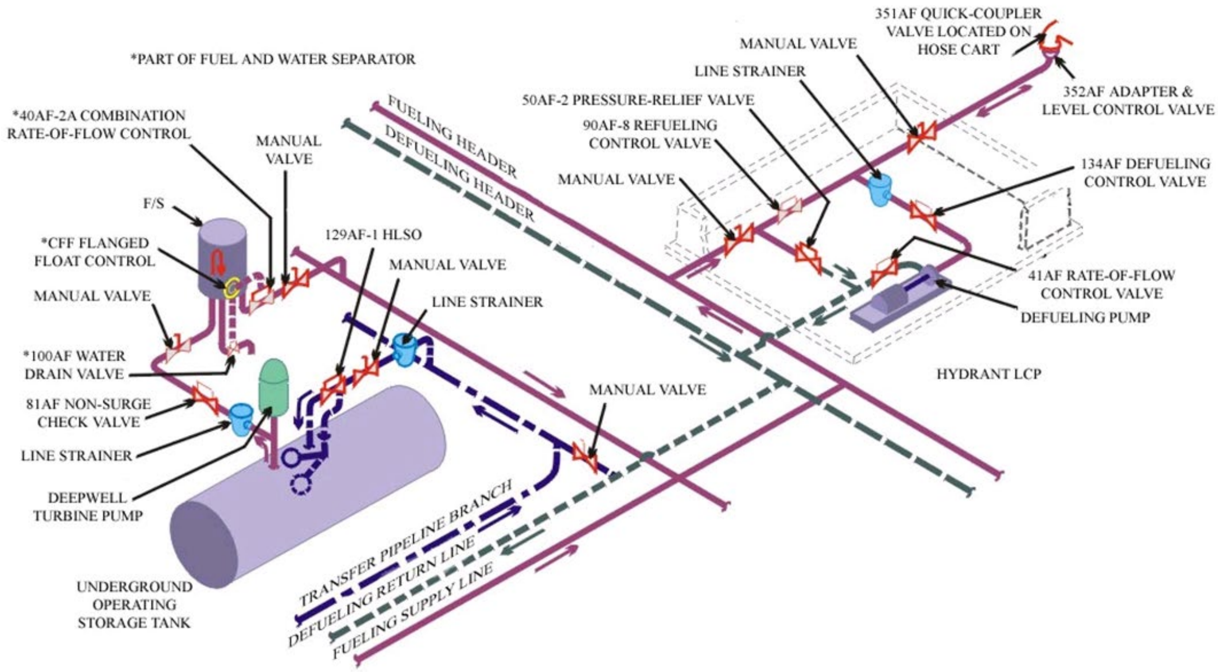
4-3.1 General Description.

Type II hydrant systems are known as Pritchard systems. Pritchard systems were developed in 1955 to improve hydrant refueling operating characteristics. These systems employ Lateral Control Pits (LCPs) and typically use vertical turbine pumps and underground horizontal storage tanks. Pritchard systems can service multiple hydrant outlets per LCP. This system allows flexibility in hydrant outlet locations and enables aircraft to be refueled at parking positions. The Type II Pritchard pumphouse is similar to the Type I, but the Type II Pritchard pumphouse does not include a separate defuel tank. Instead, one of the system operating tanks is designated as the defuel tank on a rotational basis. LCPs include a defueling pump and automatic valves. The MH-2 hose cart equipped with a filter separator, meter, and hoses is used for connecting hydrant outlets to aircraft, and as a result, filtration or meters are not required in LCPs. The following is a simplified description of operation:

a. Fuel Issue: When fuel is required at a hydrant outlet, the operator places a magnet on the refueling magnetic control assembly. This causes a preselected pump in the pumphouse to start and energizes a solenoid on the refueling control valve in the LCP that supplies the activated hydrant outlet. Fuel moves from the pumphouse into the fueling manifold and to the LCP. Fuel enters the refueling control valve and causes it to open. The refueling control valve provides pressure reduction, non-surge, pressure relief, excess flow shutoff, and emergency shutoff capabilities. Fuel flows through the hydrant outlet adapter and to the MH-2 hose cart and into the aircraft. During fuel issue operations, the defueling valve solenoid is de-energized and the defuel valve is held closed. The pressure relief valve relieves excess pressure from the upstream side of the refueling control valve into the defuel line if required.

b. Defueling: When a defuel operation is required the operator places the magnet on the defuel refueling magnetic control assembly switch. This causes a solenoid on the defueling valve connected to the hydrant pit to energize and the associated defuel pump to start. When the defuel solenoid energizes the defuel valve opens and fuel is drawn through the defuel pump and forced through the rate-of-flow control valve into the defuel line at a rate of 200 gallons per minute (gpm) (12.5 Liters per Second (lps)). Fuel flows to the operating tank designated to receive defuel product.

Figure 4-2 Pritchard, Type II Hydrant System



4-3.2 System Specific Control Valves.

4-3.2.1 General System Control Valves.

Petroleum fuel system control valves use hydraulic pressure from the upstream side of petroleum fuel piping connected to the valve to open or close the valve. The valves are equipped with flexible diaphragms and control pilots that are used to operate the valves. The valves can be used to perform many functions. The functionality of the valve is dependent on the type of control pilot that is installed on the valve and the orientation of flow through the valve.

4-3.2.1.1 Inspection and Maintenance - General System Control Valves.

a. Verify operating settings of valve. Valve adjustment must be in accordance with manufacturer's operation and maintenance manuals and final start-up and commissioning set points. Use of DoD standard set points should only be used as a reference starting point as pipe size and other hydraulic factors influence final system settings.
Frequency: Quarterly

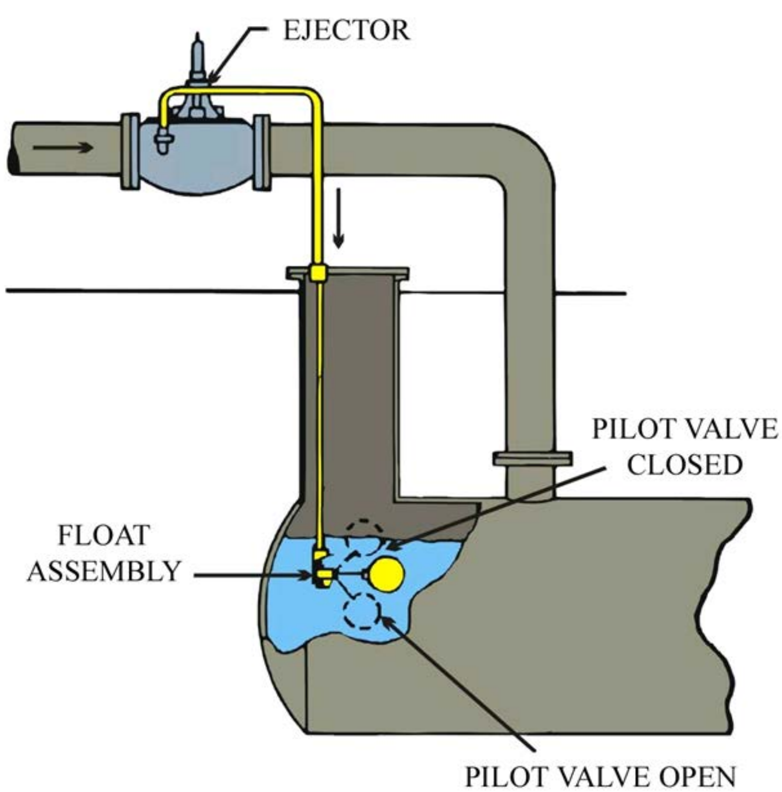
b. Remove and clean strainer installed in the petroleum fuel supply line to the pilot and main valve diaphragm. This strainer is provided to prevent clogging of the orifice in the supply line. Clogging of the screen will cause malfunctioning of the valve.
Frequency: Annually for unfiltered systems and as required for filtered systems.

c. Diaphragms must be removed and inspected for deterioration and breaks at the flexing joint. Damage is often caused by pipe scale, pipe tape, and thread sealant compound that collect above the diaphragm and become lodged between the diaphragm and bonnet of the valve. Damage may also be caused by a change of operational petroleum fuel type or grade (such as a change from JP-4 to JP-8).
Frequency: Every 10 years

4-3.2.2 High Level Shut-off Valve.

For information on the operation and maintenance of a High Level Shut-Off (HLSO) valves, refer to Section 8-9.6 High Level Shut-off Valve (HLSO).

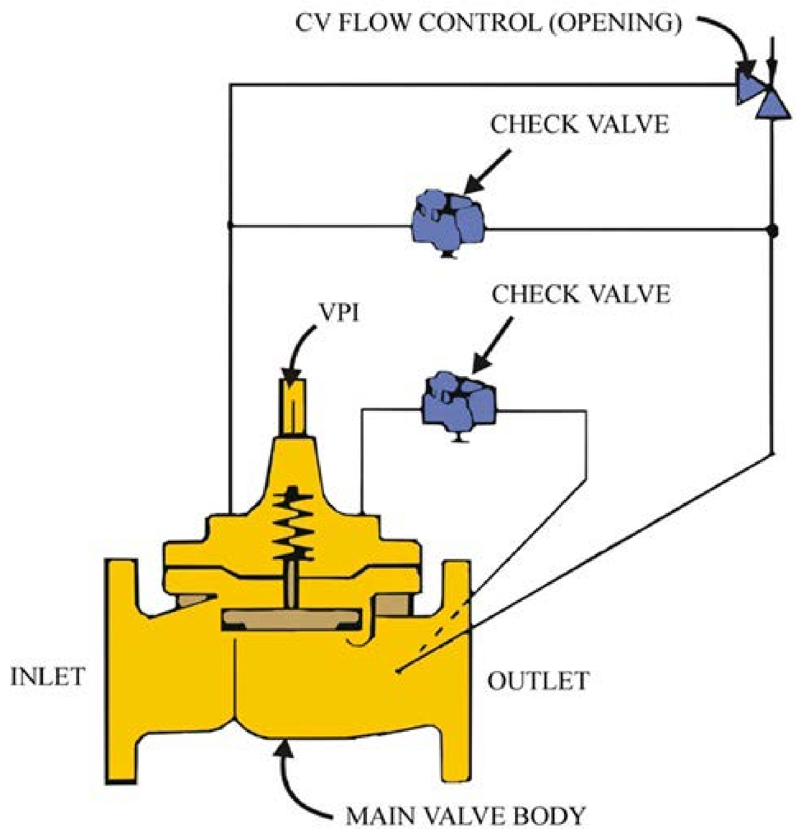
Figure 4-3 High Level Shut-off Valve (Type II)



4-3.2.3 Non-Surge Check Valves.

Type II system non-surge check valves are similar in design and operation to Type III non-surge check valves. Refer to Section 4-4.2.1 Non-Surge Check Valves for information on inspection and maintenance of non-surge check valves.

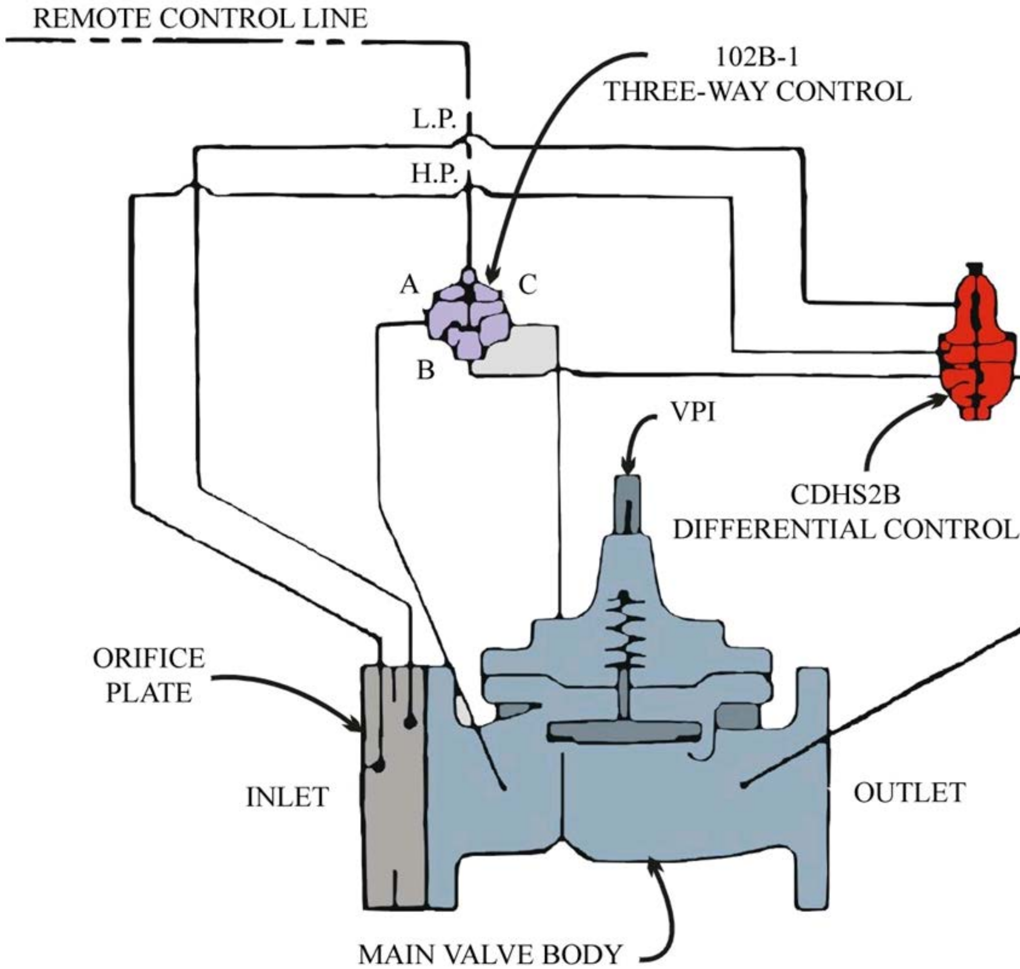
Figure 4-4 Non-Surge Check Valve (Type II)



4-3.2.4 Filter Separator Control Valves.

Type II system filter separator control valves are similar in design and operation to Type III filter separator control valves. Refer to Section 4-4.2.2 Filter Separator Control Valves for information on inspection and maintenance of filter separator control valves.

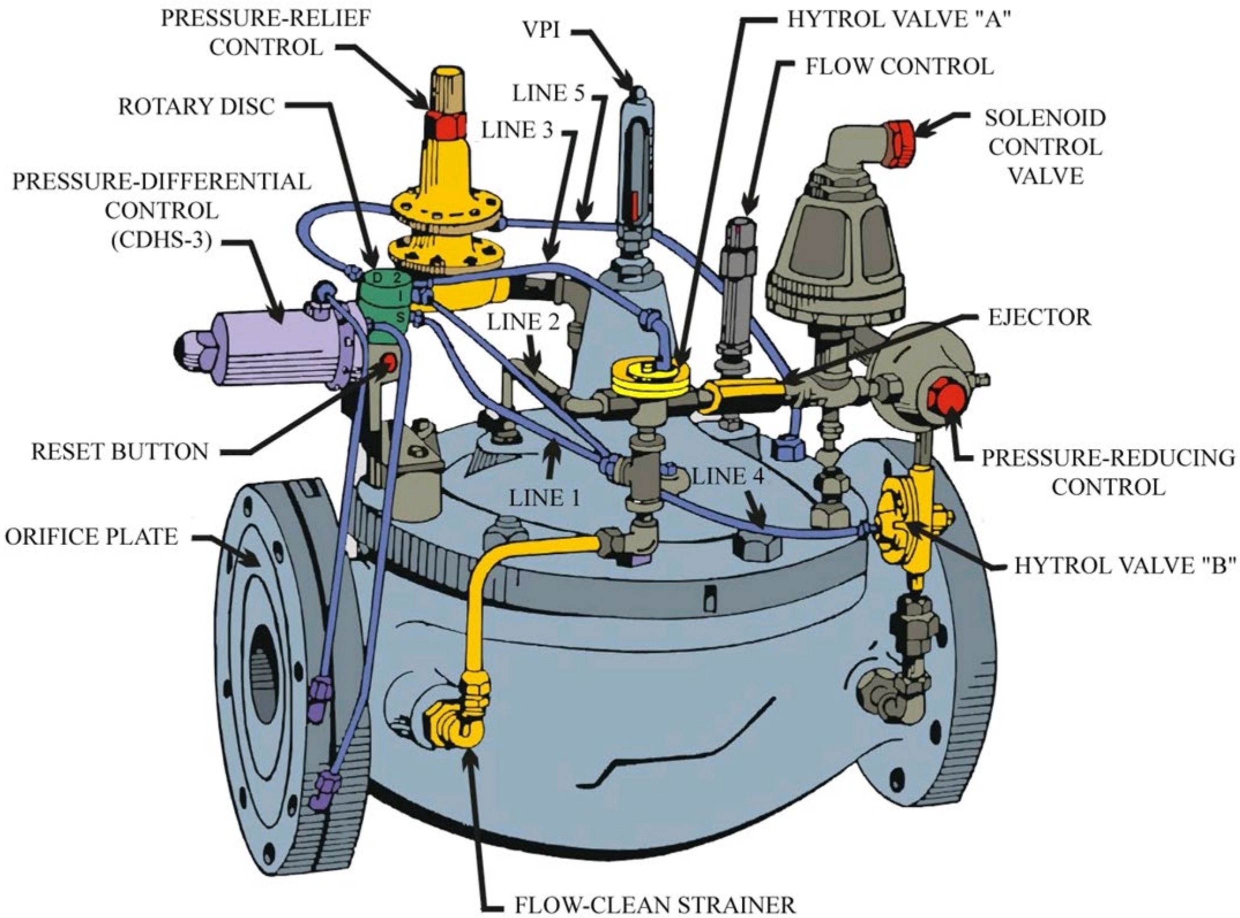
Figure 4-5 Filter Separator Control Valve (Type II)



4-3.2.5 Refuel Control Valves.

The diaphragm actuated refuel control valve provides five functions: pressure reduction; non-surge; pressure relief; excess flow shutoff; and emergency shutoff for Type II systems.

Figure 4-6 Refueling Control Valve (Type II)



4-3.2.5.1 Inspection and Maintenance – Refuel Control Valves.

a. Verify refuel control valve is set to maintain 100 psig (690 kPa) (typical operating pressure) as measured at the furthest hydrant outlet.
Frequency: Quarterly

b. Verify pressure-reducing control will open at 5 psig (35 kPa) above normal operating pressure (typically 105 psig (725 kPa) as measured at the farthest hydrant outlet).
Frequency: Quarterly

c. Verify refueling control valve opening rate is set between 15 and 20 seconds. The valve should open as quickly as possible without tripping the pressure differential control shut-off.
Frequency: Quarterly

d. Verify operation of excess flow shutoff function.
Frequency: Quarterly

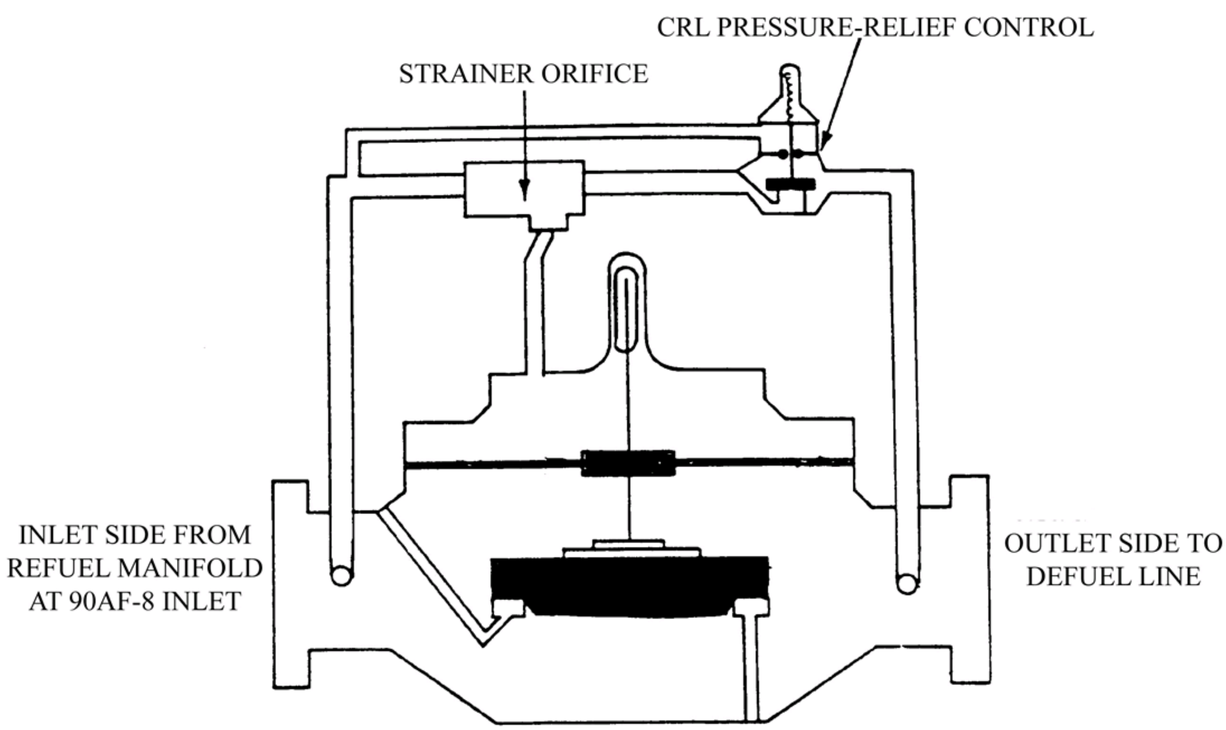
e. Verify operation of solenoid.
Frequency: Quarterly

f. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-3.2.6 Pressure Relief Valves.

The pressure relief valve is installed in the LCP between the fuel issue line and the defueling line. Pressure relief valves are provided to relieve excessive pressure caused by closing a downstream valve or thermal expansion in a closed section of pipeline. This valve is designed for petroleum fuel to flow under the seat disc inside the valve so that it "fails safe" in the open position if the main valve diaphragm fails.

Figure 4-7 Pressure Relief Valve (Type II)



4-3.2.6.1 Inspection and Maintenance – Pressure Relief Valves.

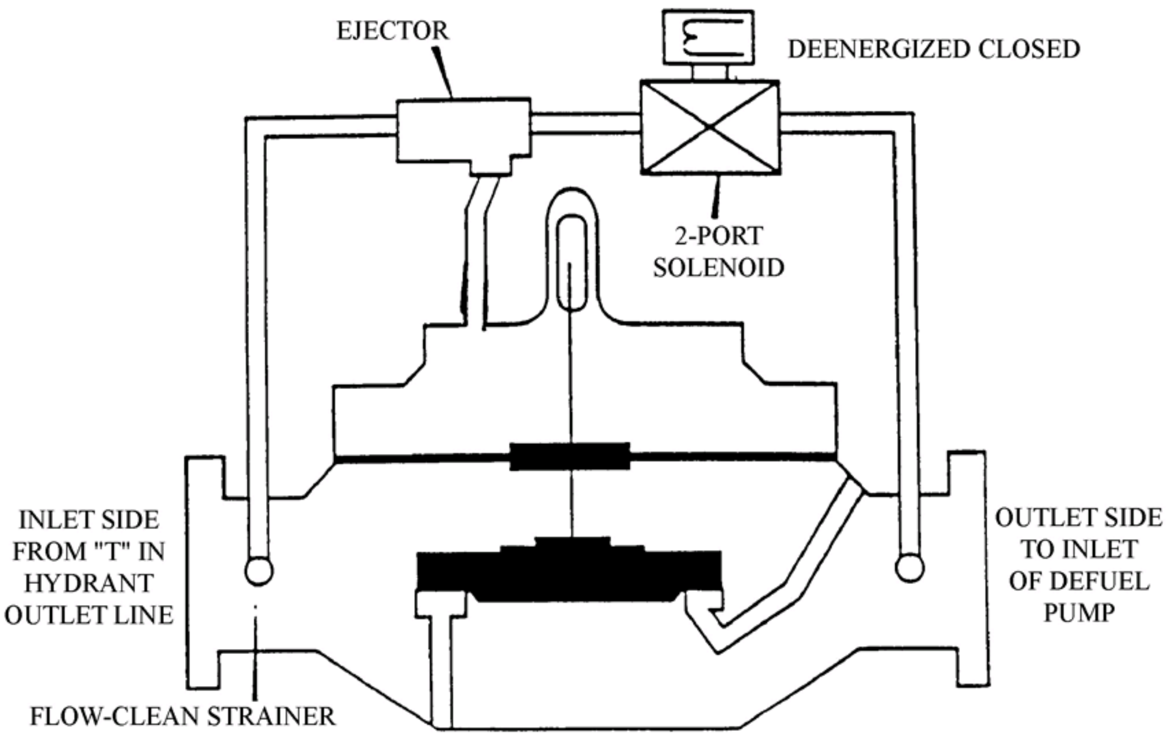
a. Verify pressure relief valve will open at 10 psig (69 kPa) above normal inlet pressure to the refuel control valve.
Frequency: Semi-annually

b. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-3.2.7 Defuel Control Valve.

The defueling control valve is a diaphragm-actuated solenoid shutoff valve. This valve and the defueling pump energize simultaneously. When the solenoid valve on the defuel control valve is energized, it allows the defuel control valve to open and permit defueling through the system.

Figure 4-8 Defuel Control Valve (Type II)



4-3.2.7.1 Inspection and Maintenance – Defuel Control Valves.

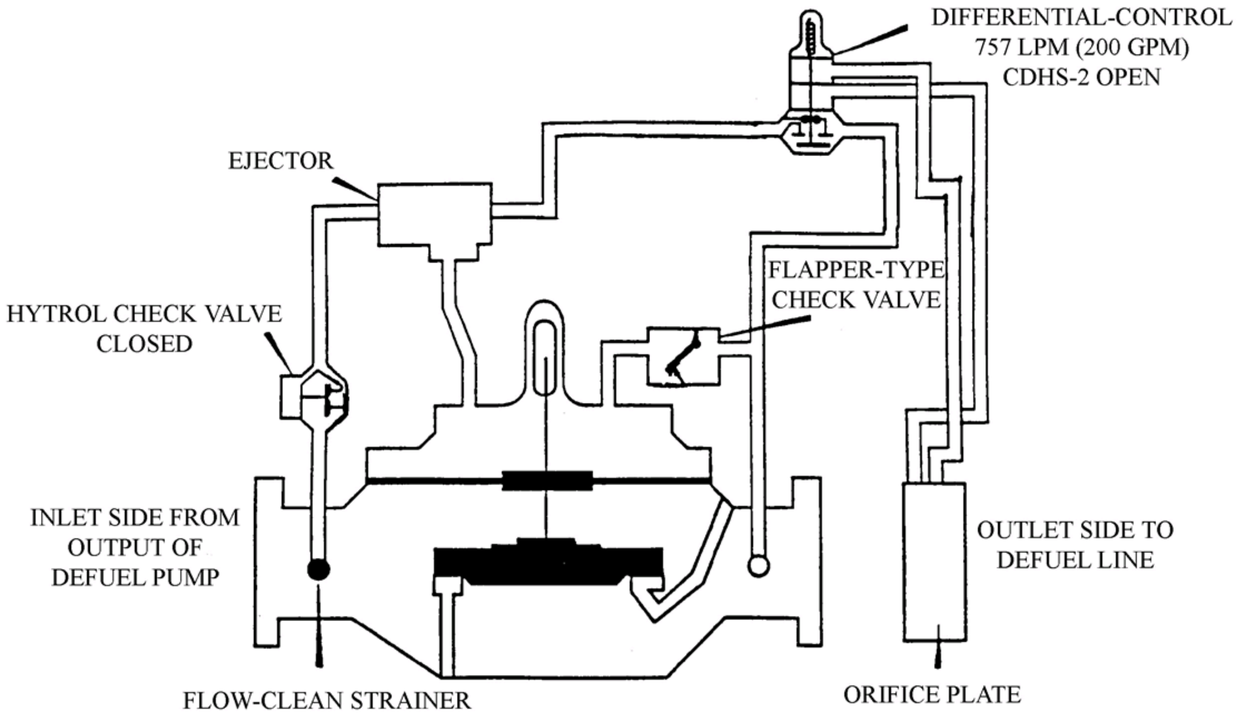
a. Verify the defuel control valve opens when the solenoid on the defuel control valve is energized.
Frequency: Quarterly

b. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-3.2.8 Dual Rate-of-Flow Control Valves.

The dual rate-of-flow control valve is a combination rate-of-flow control valve and fast closing, hydraulically operated check valve that closes the main valve against reverse flow. It performs two distinct functions: maintaining a preset flow rate (typically set at 200 gpm (12.5 lps)), and acting as a check valve to prevent reverse flow.

Figure 4-9 Dual Rate-of-Flow Control Valve (Type II)



4-3.2.8.1 Inspection and Maintenance – Dual Rate-of-Flow Control Valves.

a. Verify dual rate-of-flow control valve is set to maintain a flow rate of 200 gpm (12.5 lps).
Frequency: Quarterly

b. Verify operation of check valve feature.
Frequency: Quarterly

c. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

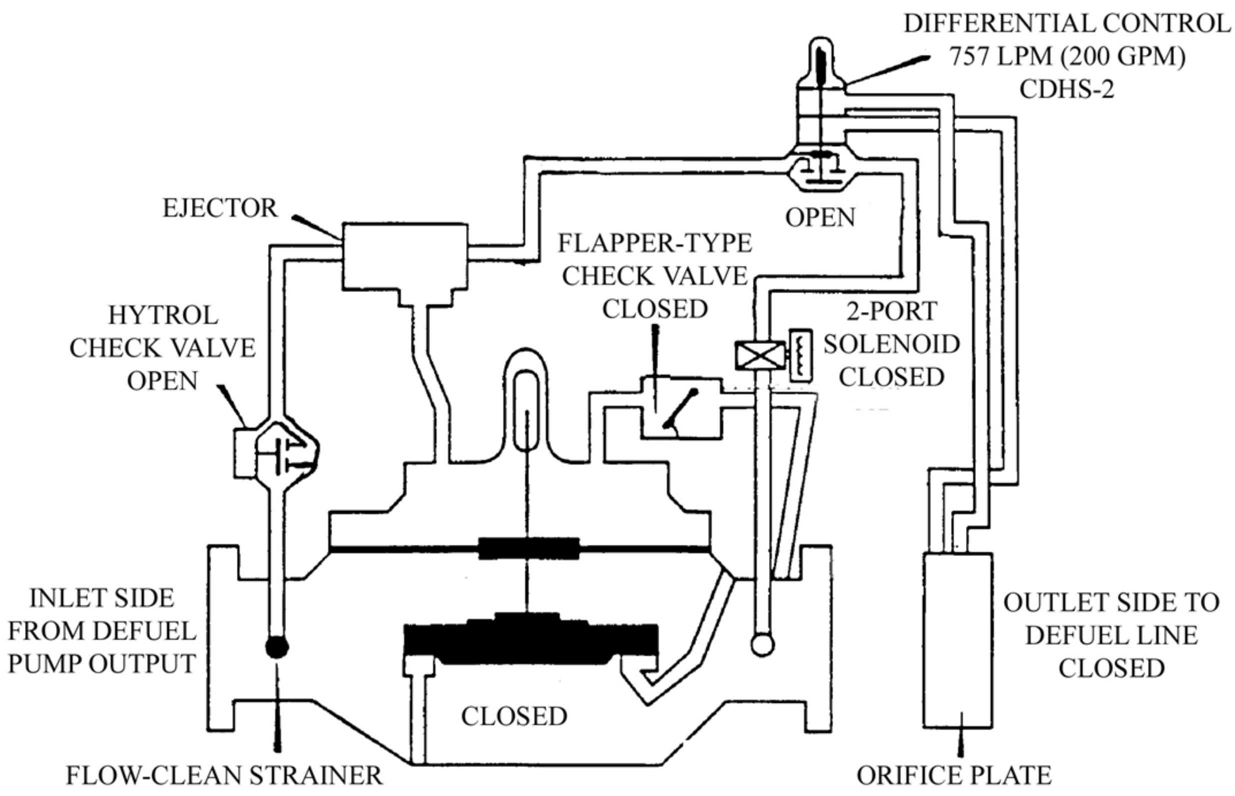
4-3.3 Type II Modified Control Valves (Rapid Flow).

The rapid flow modification was done on some Type II systems to increase defuel rates from 200 to 300 gpm (12.5 to 19 lps). A pump on the aircraft is used to transfer petroleum fuel from the aircraft through the LCP and into the designated defuel tank. The defueling pump in the LCP is only used to evacuate the hose cart after the aircraft pump is de-energized. Two modified control valves are used in the rapid flow system (combination dual rate-of-flow control valve and solenoid valve and dual pressure relief, solenoid shutoff, and check valve).

4-3.3.1 Combination Dual Rate-of-Flow Control and Solenoid Valves.

Combination dual rate-of-flow control and solenoid valves operate like the standard dual rate-of-flow control valves, with the addition of a solenoid for remote-control operations. All settings and functions are the same as the standard dual rate-of-flow control valve.

Figure 4-10 Combination Dual Rate-of-Flow Control and Solenoid Valve (Type II)



4-3.3.1.1 Inspection and Maintenance – Combination Dual Rate-of-Flow Control and Solenoid Valves.

a. Verify valve is set to maintain a flow rate of 300 gpm (19 lps).
Frequency: Quarterly

b. Verify operation of check valve feature.
Frequency: Quarterly

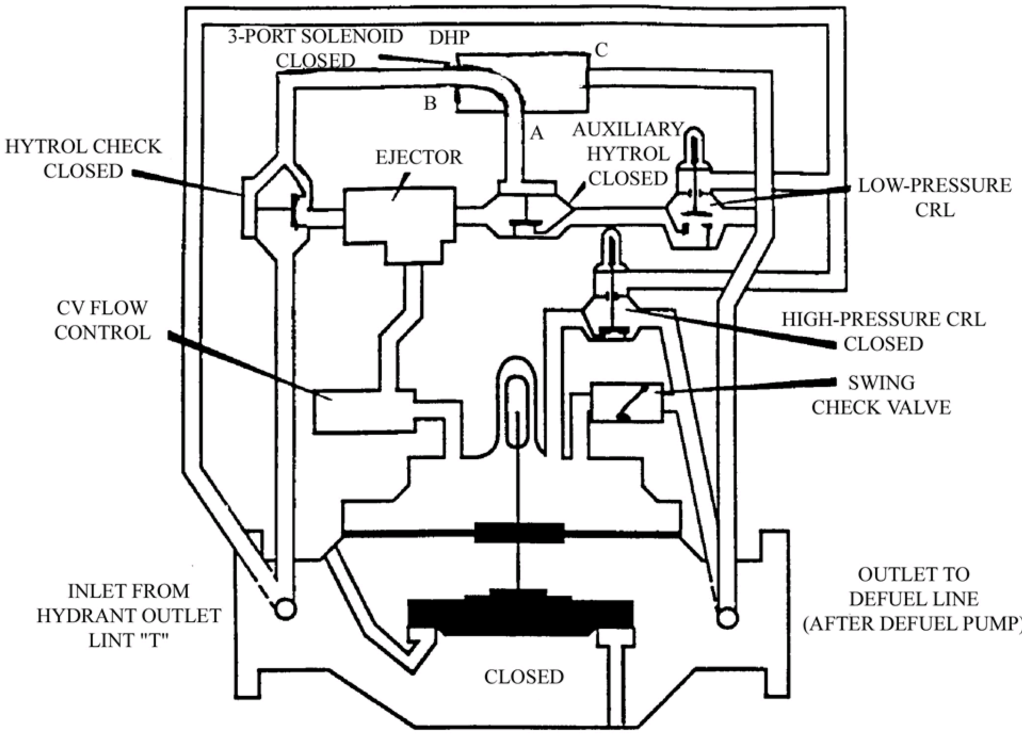
c. Verify solenoid operation.
Frequency: Quarterly

d. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-3.3.2 Dual Pressure Relief, Solenoid Shutoff, and Check Valves.

The dual pressure relief, solenoid shutoff, and check valve is installed in the modified hydrant lateral control pit downstream of the refueling control valve between the issue and defuel line. This relief valve performs two functions: relieves excess pressure in the issue line caused by quick-closing valves during the refueling operation; and maintains a minimum pressure of 5 psig (35 kPa) on the issue line piping when the refueling pumps are not in operation. This valve also has a flow control used to slowly close the valve during rapid defuel operations.

Figure 4-11 Dual Pressure Relief, Solenoid Shutoff, and Check Valve (Type II)



4-3.3.2.1 Inspection and Maintenance – Dual Pressure Relief, Solenoid Shutoff, and Check Valves.

a. Verify high pressure relief control will open at 5 psig (35 kPa) above the refuel control valve pressure relief control set point (typically set at 110 psig (760 kPa)).
Frequency: Quarterly

b. Verify low pressure relief control will open at 5 psig (35 kPa) when refueling pumps are stopped.
Frequency: Quarterly

c. Verify closing speed provides a smooth; pulsation free operation.
Frequency: Quarterly

d. Verify operation of solenoid valve.
Frequency: Quarterly

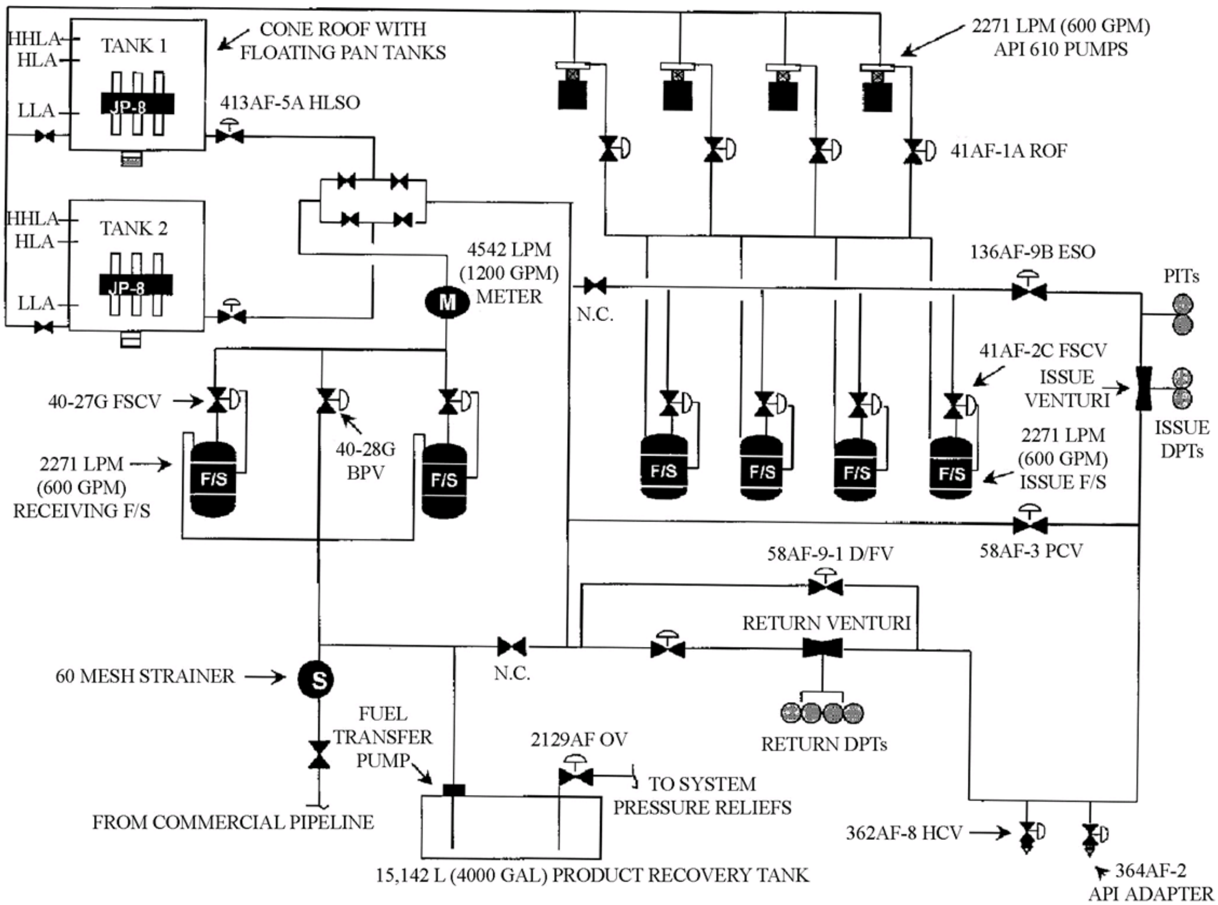
e. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-4 HYDRANT SYSTEM – TYPE III.

4-4.1 General Description.

The DoD large-frame aircraft direct fueling system is referred to as the Type III pressurized fueling system. This system is generally comprised of two operating storage tanks, a pumphouse, a hydrant loop, and hydrant outlets at aircraft parking positions. Two redundant Program Logic Controllers (PLCs) are used to control the operation of the system including the pumps and control valves. The system is constantly pressurized when operating. Petroleum fuel is pumped from the tanks, through filter separators and an issue venturi into the hydrant loop. The petroleum fuel flows through the appropriate hydrant valve, through a hydrant servicing vehicle or mobile pantograph and into the aircraft. A backpressure control valve keeps the hydrant loop at a pre-set pressure and a return venturi measures flow back to the storage tank. Working in conjunction with the return venturi, pumps are turned on and off depending on petroleum fuel issue requirements. Systems are generally sized in 600 gpm (38 lps) increments up to 2,400 gpm (152 lps). Issue pumps are sized to provide a minimum of 100 psig (690 kPa) at the furthest hydrant outlet. Each hydrant pit control valve is equipped with a pressure control and surge shutdown pilot and newer systems also include a differential pilot. (See UFGS 33 52 43.14 for more information). The pilot controls are set at 45 psig (310 kPa) and 50 psig (345 kPa), respectively. Hydrant control valves allow flow rates up to 900 gpm (57 lps) using 4-inch (DN100) valve bodies. Hydrant control valves are typically set to 600 gpm (38 lps). Flow rates of up to 1,200 gpm (76 lps) are possible using 6-inch (DN150) hydrant control valve bodies.

Figure 4-12 Type III Hydrant System Diagram

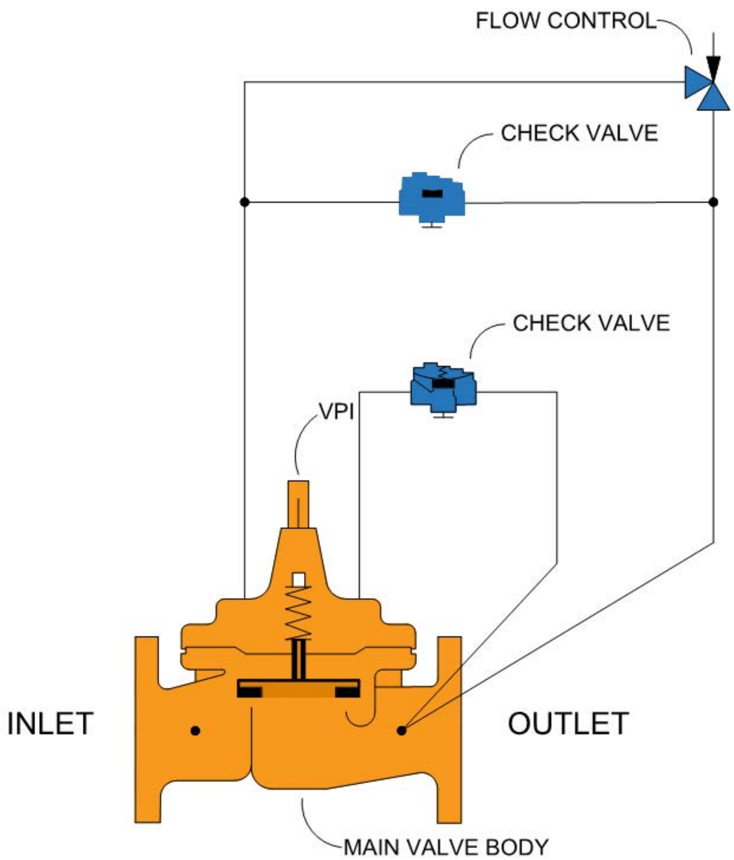


4-4.2 System-Specific Control Valves.

4-4.2.1 Non-Surge Check Valves.

Diaphragm non-surge check valves that meet the requirements of UFGS 33 52 43.14 are used as a flow control feature on the discharge of pumps. A non-surge check valve is used to prevent a pump from running out of its curve when petroleum fuel is flowing through multiple filter separators and to prevent backflow through the pump.

Figure 4-13 Non-Surge Check Valve



4-4.2.1.1 Inspection and Maintenance – Non-Surge Check Valves.

For more information on features, valve settings, and replacement, refer to commissioning documents, as-builts, and manufacturer's operation and maintenance manuals.

a. Verify main valve opening speed (typically 20 seconds). Adjust if required.
Frequency: Semi-annually

b. Verify valve maintains 650 gpm (41 lps) flow rate (some instances 950 gpm (60 lps) flow rate). Adjust if required.
Frequency: Semi-annually

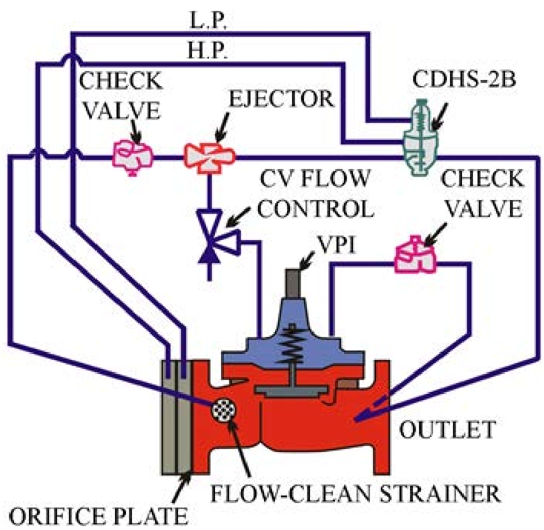
c. Ensure the check valve function is operating properly.
Frequency: Semi-annually

d. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-4.2.2 Filter Separator Control Valves.

Filter Separator Control Valves (FSCVs) that meet the requirements of UFGS 33 52 43.14 are used to control the rate of flow through filter separators, prevent reverse flow, prevent water discharge when the water level float control reaches the high position, and act as an emergency shutoff valve when equipped with an emergency stop solenoid valve. Most FSCVs operate at 600, 900 or 1,200 gpm (38, 57 or 76 lps) based on the rated flow capacity of the filter separator.

Figure 4-14 Filter Separator Control Valve (Type III)



4-4.2.2.1 Inspection and Maintenance – Filter Separator Control Valves.

a. Test FSCV emergency shut off solenoid under flow conditions and ensure that valve closes within 10 seconds of EFSO button activation. Coordinate with overall EFSO test listed in Section 9-1.2.1 Inspection and Maintenance - Electrical Equipment.
Frequency: Quarterly

b. Operate test button (if installed) to ensure the FSCV closes at high water level. Physically press the test button, while recirculating fuel, and ensure the FSCV closes. Note: closing speed is a function of the number of open filters separators and the number of pumps operating. With all filters open and only one pump operating, the valve will close very slowly.
Frequency: Quarterly

c. Verify valve maintains flow rate (typically 600 gpm (38 lps), operating range based on commissioning documentation). Adjust flow rate if required. Flow rate is determined by filter separator vessel gpm (lps) rating, or element flow rate, whichever is less. Use return venturi to measure and confirm flow rate during valve testing and adjustment.
Frequency: Annually

d. Ensure the check valve function is operating properly.
Frequency: Annually

e. Test buoyancy of water level float. Remove the ball or float assembly and place it in a bucket of water. Correctly operating ball or float will float at the top of the water's surface.
Frequency: When coalescer cartridges are changed

f. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-4.2.3 Defuel/Flush Valves.

\1

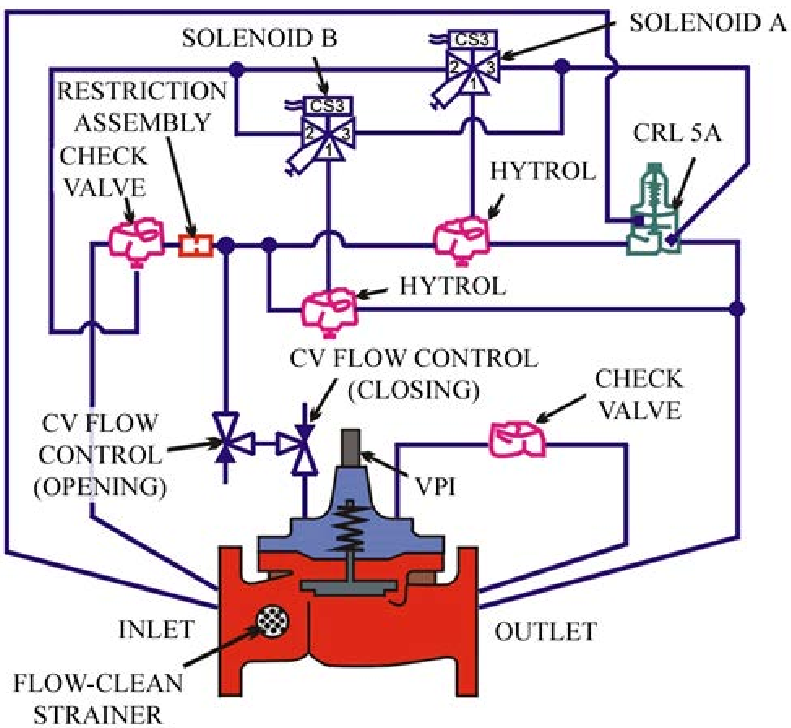
a. Defuel/Flush Valves (D/FV) that meet the requirements of UFGS 33 52 43.14 are controlled by two different solenoids. Solenoid A controls the defuel portion of the main valve and holds the valve closed any time a fuel pump is running. Solenoid B controls the flush portion of the main valve and functions only when the system is placed in flush mode. When the lead pump de-energizes, solenoid A energizes, allowing the valve to open and drop the system pressure to 80 psig (550 kPa) (typical set pressure). While the system is in the idle position, the valve will open to allow defueling when the hydrant loop pressure rises above 80 psig (550 kPa) (typical set pressure).

b. Defueling can be conducted using a Hydrant Hose Truck (HHT) to pump fuel off aircraft and force fuel into the hydrant loop. The HHT pump will overcome the 80 psig (550 kPa) setting of the D/FV and open the valve.

c. Solenoid B energizes only when the system is placed in flush mode. Flush mode is used to move fuel through the system in order to clean the loop. Flushing procedures vary based on system design and should be approved by the military service-specific SME.

/1/

Figure 4-15 Defuel/Flush Valve (Type III)



4-4.2.3.1 Inspection and Maintenance – Defuel/Flush Valves.

For more information on features, settings, and replacement, refer to commissioning documents, as-builts, and manufacturer's operation and maintenance manuals.

a. Ensure Solenoids A and B are de-energized with system in automatic mode and lead pump operating.
Frequency: Quarterly

b. Ensure Solenoid A is energized and Solenoid B is de-energized to allow main valve to open and drop system pressure to 80 psig (550 kPa) (typical set pressure) with system in automatic mode and lead pump off.
Frequency: Quarterly

c. Ensure Solenoid A is de-energized and Solenoid B is energized when system is in flush mode.
Frequency: Quarterly

d. Ensure Solenoids A and B are de-energized when system is in tightness test mode.
Frequency: Quarterly

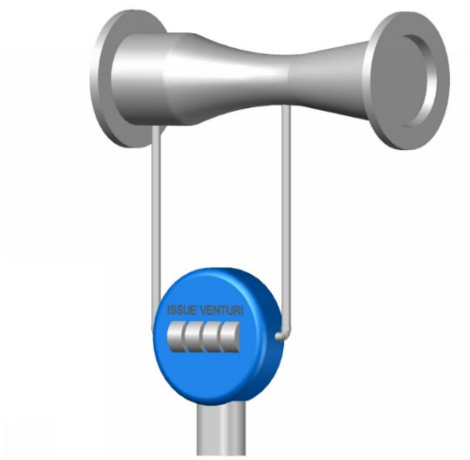
e. Check opening and closing speed. Speed should be as fast as possible while still maintaining smooth operation.
Frequency: Quarterly

f. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-4.2.4 Issue Venturi.

The issue venturi is downstream of the issue filter separator manifold and is typically rated at 2,400 gpm (151 lps). The venturi has upstream and downstream sensing line connections for two redundant Differential Pressure Transmitters (DPTs). The control PLCs determines the flow rate using electronic signals from the DPTs.

Figure 4-16 Issue Venturi



4-4.2.4.1 Inspection and Maintenance - Issue Venturi.

a. Ensure issue venturi DPTs are reading the same value within ± 2% full scale.
Frequency: Semi-annually

b. Refer to Section 6-7.4 Differential Pressure Transmitters for inspection and maintenance requirements of DPTs.

4-4.2.5 Return Venturi.

The return venturi is located upstream of the Back-Pressure Control Valve (BPCV). It is similar to the issue venturi but is typically rated at 800 gpm (50 lps).

4-4.2.5.1 Inspection and Maintenance - Return Venturi.

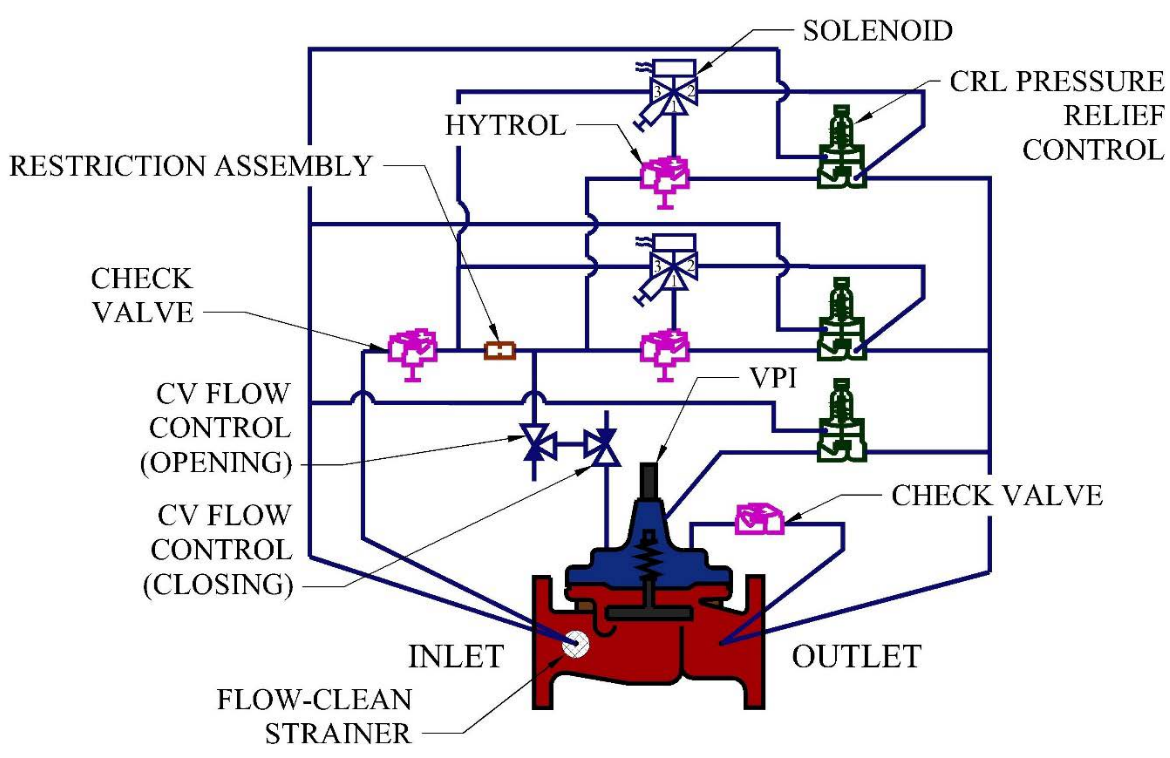
a. Ensure return venturi DPTs are reading the same value within ±2% full scale.
Frequency: Semi-annually

b. Refer to Section 6-7.4 Differential Pressure Transmitters for inspection and maintenance requirements of DPTs.

4-4.2.6 Back Pressure Control Valves.

Back Pressure Control Valves (BPCVs) that meet the requirements of UFGS 33 52 43.14 are used to maintain a constant hydrant loop pressure. The valve is typically 6-inch (DN 150), and the valve is typically set to maintain 100 psig (690 kPa) fuel pressure at the furthest hydrant outlet.

Figure 4-17 Back Pressure Control Valve (Type III)



4-4.2.6.1 Inspection and Maintenance – Back Pressure Control Valves.

For more information on features, valve settings, and replacement, refer to commissioning documents, as-builts, and manufacturer's operation and maintenance manuals.

a. Verify constant upstream pressure is maintained at the set point established and listed in the system commissioning documents. Adjust setting of BPCV as necessary.
Frequency: Quarterly

b. Ensure Solenoid A is energized and Solenoid B is de-energized while lead pump is operating in automatic mode.
Frequency: Quarterly

c. Ensure Solenoids A and B are de-energized prior to lead pump shutdown and system going to stand-by.
Frequency: Quarterly

d. Ensure Solenoids A and B are de-energized while system is in flush mode.
Frequency: Quarterly

e. Ensure that Solenoid A is de-energized and Solenoid B is energized while system is in tightness test mode.
Frequency: Quarterly

f. Verify closing speed control. Valve should close as fast as possible while still maintaining smooth operation.
Frequency: Quarterly

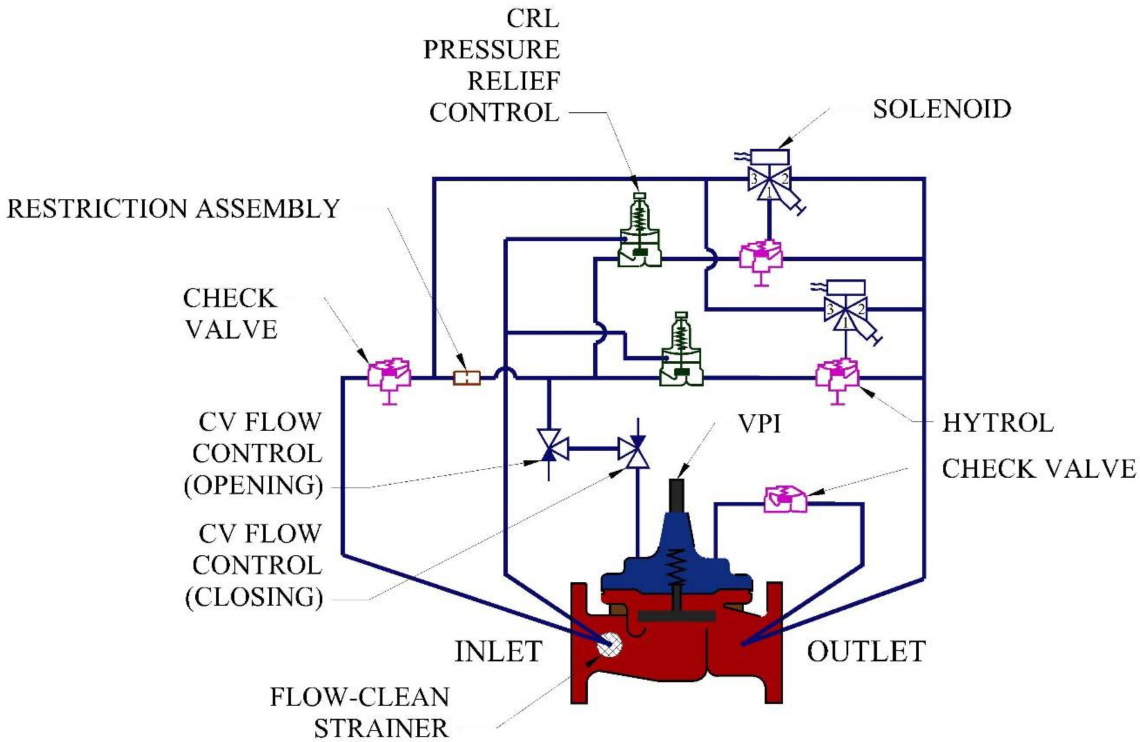
g. Check solenoid EFSO feature when equipped. Coordinate test with overall EFSO test listed in Section 9-1.2.1 Inspection and Maintenance - Electrical Equipment.
Frequency: Quarterly

h. Refer to Section 4-4.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-4.2.7 Pressure Control Valves.

Pressure Control Valves (PCV) meeting the requirements of UFGS 33 52 43.14 reduce system pressure down to 75 psig (515 kPa) during system shutdown process and provide thermal relief during idle periods. The valves are typically 2-inch (DN50). A solenoid installed on the valve energizes to close the valve when the lead pump is operating and de-energizes when the lead pump stops. When the solenoid is de-energized, the valve opens to reduce the system pressure to 75 psig (515 kPa) and the thermal relief function is operable. If the pressure rises above 75 psig (515 kPa), the valve opens and excess pressure flows to the operating storage tank. The valve opening and closing speed controls are typically set at three (3) seconds. In some cases, to prevent valve chattering, the PCV pressure-sensing line is connected to the large defuel/flush line.

Figure 4-18 Pressure Control Valve (Type III)



4-4.2.7.1 Inspection and Maintenance – Pressure Control Valves.

For more information on features, valve settings, and replacement refer, to commissioning documents, as-builts, and manufacturer’s operation and maintenance manuals.

a. Ensure Solenoid A is energized and Solenoid B is de-energized while system is in automatic mode and lead pump is operating.
Frequency: Quarterly

b. Ensure Solenoids A and B are de-energized while system is in automatic mode and lead pump is off. Verify valve opens to maintain system pressure at 75 psig (515 kPa).
Frequency: Quarterly

c. Ensure Solenoid A is energized and Solenoid B is de-energized while system is in flush mode and lead pump is operating.
Frequency: Quarterly

d. Ensure Solenoids A and B are de-energized while system is in flush mode and pumps are off.
Frequency: Quarterly

e. Ensure Solenoids A and B are energized while system is in tightness test mode.
Frequency: Quarterly

f. Verify closing speed control. Valve should close as fast as possible while still maintaining smooth operation.
Frequency: Quarterly

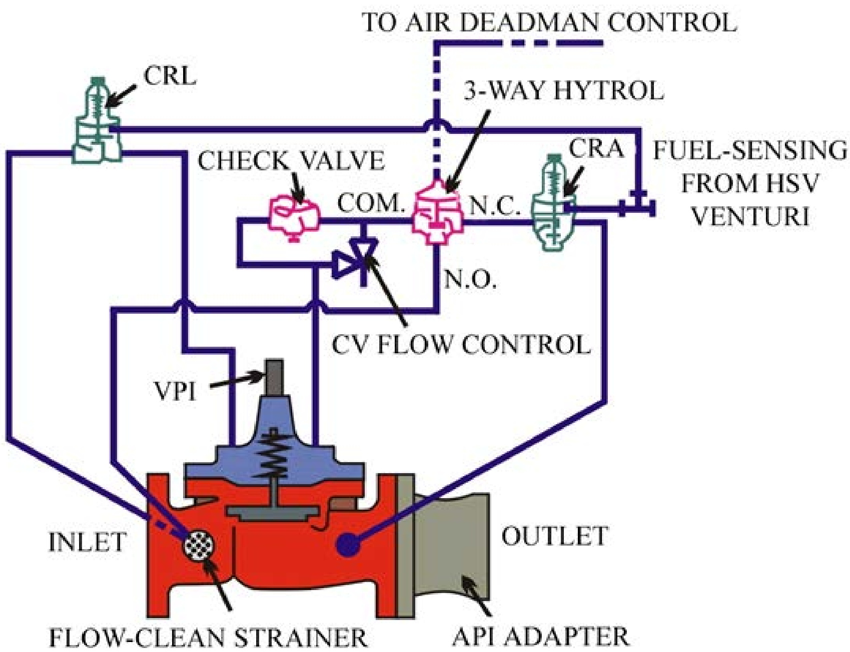
g. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-4.2.8 Hydrant Control Valves.

Hydrant Control Valves (HCV) meeting the requirements of UFGS 33 52 43.14 provide constant nozzle pressure and relieve excess pressure. An air-sensing line is connected from the HHT to the HCV three-way hydraulically operated/diaphragm actuated globe valve. When the HHT's pneumatic deadman is depressed, air is supplied to the three-way valve, allowing the valve to open. A fuel-sensing line is connected from the HHT venturi to the Pressure-Reducing Control (CRA) and the Pressure-Relief Control (CRL) on the HCV. The venturi is calibrated to provide the same pressure as the actual nozzle pressure at the skin of the aircraft. The CRA maintains 45 psig (310 kPa) at the nozzle. The HCV is designed to close rapidly when the nozzle pressure exceeds the 50 psig (345 kPa) setting of the CRL. It reopens when the pressure drops below the 50 psig (345 kPa) set point.

Some Type III systems use towable pantographs instead of HHTs. The operation of a towable pantograph with a HCV is similar to the operation with a HHT.

Figure 4-19 Hydrant Control Valve (Type III)



4-4.2.8.1 Inspection and Maintenance – Hydrant Control Valves.

For more information on features, valve settings, and replacement, refer to commissioning documents, as-builts, and manufacturer's operation and maintenance manuals.

a. Verify HCV maintains 45 psig (310 kPa) nozzle pressure at a flow of 50 to 600 gpm (3 to 38 lps).
Frequency: Quarterly

b. Verify HCV closes when nozzle pressure exceeds 50 psig (345 kPa).
Frequency: Quarterly

c. Verify HCV opening speed is set at a minimum of 20 seconds.
Frequency: Quarterly

d. Verify HCV opens when the deadman control lever is pressed.
Frequency: Quarterly

e. Verify HCV closes within two to five seconds after the deadman lever is released.
Frequency: Quarterly

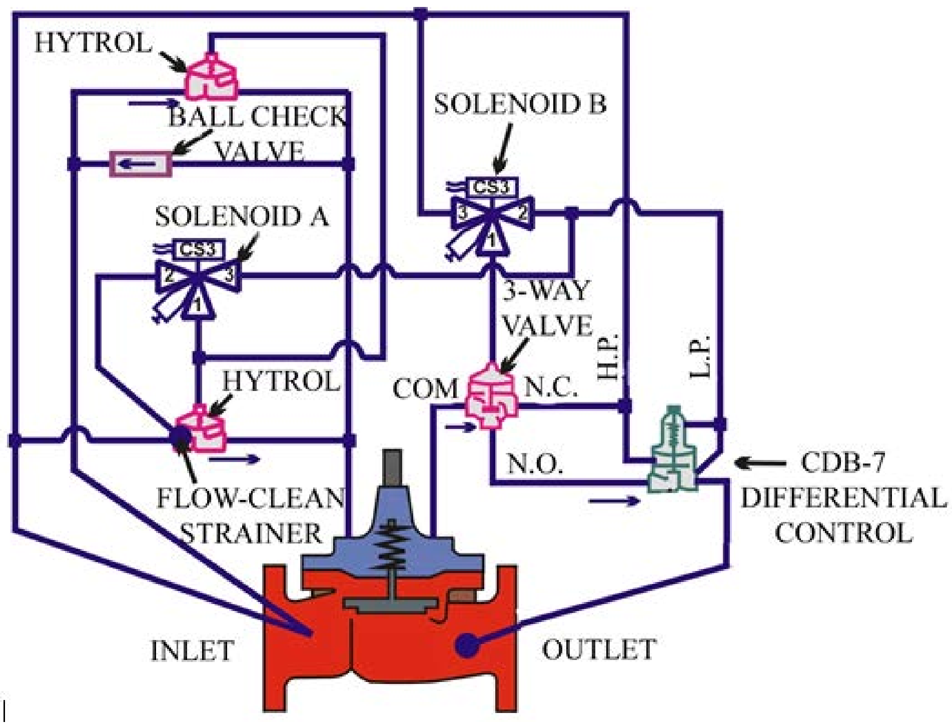
f. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-4.2.9 Emergency Shut-off Valves.

This valve has been removed from the standard Type III design, but it still exists in some systems. New Type III systems achieve the same function as the emergency shut-off valve by including a similar function on the FSCVs.

Emergency Shut-Off (ESO) valves that meet the requirements of UFGS 33 52 43.14 have two solenoids that are energized when power is on, enabling the main valve to open when fuel is flowing. Should power fail or an emergency stop button be pushed, the solenoids will de-energize and the main valve will close within 10 seconds. The valve also has a thermal relief feature that relieves excess cover chamber pressure back to the valve inlet, and a differential control is used to maintain a relatively constant differential pressure between the inlet and outlet of the main valve.

Figure 4-20 Emergency Shut-Off Valve (Type III)



4-4.2.9.1 Inspection and Maintenance – Emergency Shut-off Valves.

For more information on features, valve settings, and replacement, refer to commissioning documents, as-builts, and manufacturer's operation and maintenance manuals.

a. Ensure Solenoids A and B are energized under normal operations.
Frequency: Quarterly

b. Ensure Solenoids A and B are de-energized during emergency stop conditions.
Frequency: Quarterly

c. Test emergency stop function of the valve under flow conditions. Ensure the valve closes within 10 seconds of EFSO button activation. Coordinate test with overall EFSO test listed in Section 9-1.2.1 Inspection and Maintenance - Electrical Equipment.
Frequency: Quarterly

d. Verify differential control maintains a constant seven psig (48 kPa) differential pressure between the inlet and outlet of the valve.
Frequency: Quarterly

e. Ensure thermal relief function (ball check valve) relieves excess pressure when cover chamber pressure exceeds inlet pressure. **Frequency: Quarterly**

f. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-5 HYDRANT SYSTEM – TYPE IV.

4-5.1 General Description.

Type IV hydrant systems are similar in function to the Type III systems except that the Type IV system uses fixed pantographs, designed for fixed-wing, small frame aircraft direct fueling stations. Type IV systems are often designed to support hot refueling operations.

4-5.2 System-Specific Control Valves.

4-5.2.1 High Level Shut-off Valve (HLSO).

Refer to Section 8-9.6 High Level Shut-off Valves (HLSO) for inspection and maintenance requirements of Type IV HLSOs.

4-5.2.2 Non-Surge Check Valves.

Refer to Section 4-4.2.1 Non-Surge Check Valves for inspection and maintenance requirements of non-surge check valves.

4-5.2.3 Filter Separator Control Valve (FSCV).

Refer to Section 4-4.2.2 Filter Separator Control Valves for inspection and maintenance requirements of Type IV FSCVs.

4-5.2.4 Defuel/Flush Valve (D/FV).

Refer to Section 4-4.2.3 Defuel/Flush Valves for inspection and maintenance requirements of Type IV D/FV. Ignore the maintenance and inspection requirements for Type IV systems that are not equipped with a defuel/flush valve.

4-5.2.5 Flush Valves.

Refer to Section 4-4.2.3 Defuel/Flush Valves for inspection and maintenance requirements of Type IV flush valve. Ignore the maintenance and inspection requirements for Type IV systems that are not equipped with a flush valve.

4-5.2.6 Issue Venturi.

Refer to Section 4-4.2.4 Issue Venturi for inspection and maintenance requirements of issue venturi.

4-5.2.7 Return Venturi.

Refer to Section 4-4.2.5 Return Venturi for inspection and maintenance requirements of return venturi.

4-5.2.8 Back Pressure Control Valves.

Refer to Section 4-4.2.6 Back Pressure Control Valves for inspection and maintenance requirements of back pressure control valves.

4-5.2.9 Pressure Control Valves.

Refer to Section 4-4.2.7 Pressure Control Valves for inspection and maintenance requirements of pressure control valves.

4-5.2.10 Hydrant Control Valve (HCV).

Refer to Section 4-4.2.8 Hydrant Control Valves for inspection and maintenance requirements of Type IV HCVs.

4-5.2.11 Emergency Shut-off Valve (ESO).

Refer to Section 4-4.2.9 Emergency Shut-off Valves for inspection and maintenance requirements of Type IV ESOs.

4-5.2.12 Pantograph Control Valves.

The Pantograph Control Valve (PTCV) is used to control flow and pressure of fuel through the pantograph. The unit operates in conjunction with a pantograph venturi installed downstream of the PTCV. The valve is equipped with a deadman control lever.

4-5.2.12.1 Inspection and Maintenance – Pantograph Control Valves.

a. Verify PTCV maintains 55 psig (380 kPa) nozzle pressure at a flow of 50 to 600 gpm (3 to 38 lps).
Frequency: Quarterly

b. Verify PTCV opens when the deadman control lever is pressed.
Frequency: Quarterly

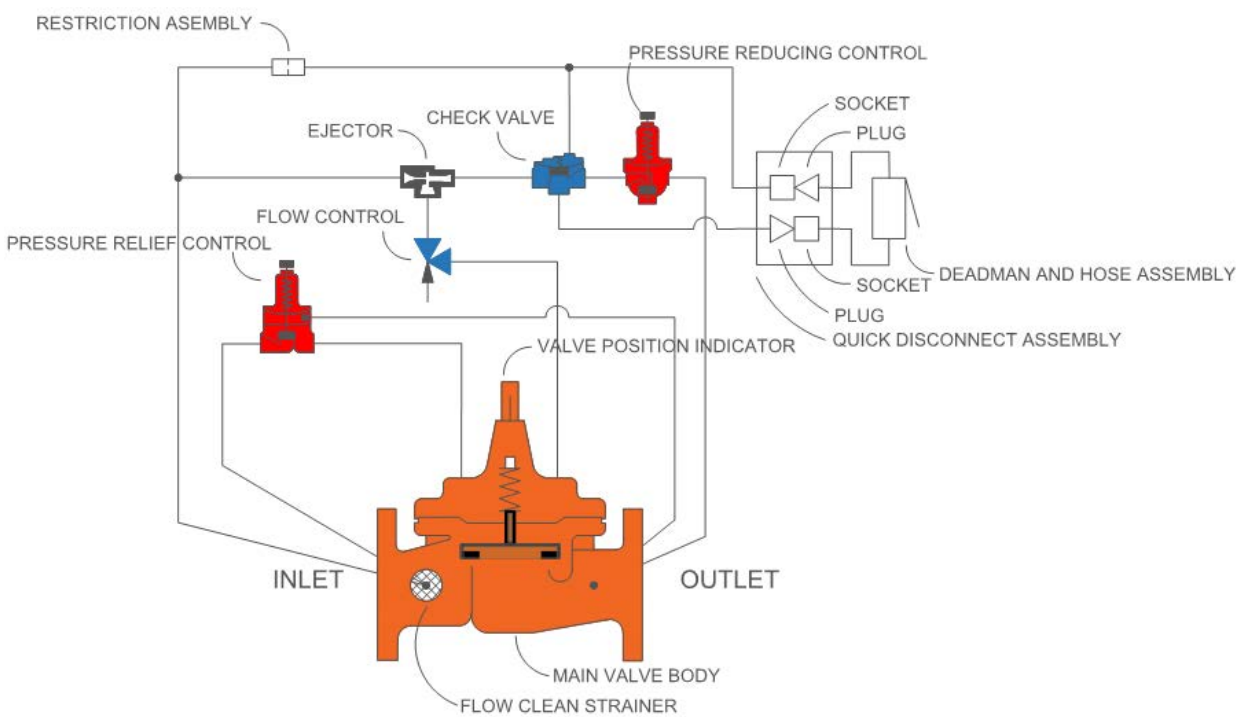
c. Verify PTCV closes in a maximum of 10 seconds after deadman lever is released.
Frequency: Quarterly

d. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

4-5.2.13 Pantograph Pressure Control Valves.

The Pantograph Pressure Control Valve (PPCV) relieves pressure from the pantograph downstream of the PTCV. The PPCV is set to open at 75 psig (515 kPa) and prevents excessive pressure from reaching the aircraft fuel tank.

Figure 4-21 Pantograph Pressure Control Valve



4-5.2.13.1 Inspection and Maintenance – Pantograph Pressure Control Valves.

a. Verify PPCV opens at 75 psig (515 kPa).
Frequency: Quarterly

b. Verify PPCV opening and closing speed are three seconds maximum.
Frequency: Quarterly

4-6 HYDRANT SYSTEM – TYPE V.

4-6.1 General Description.

Type V hydrant systems are similar to the Type IV systems except that the refueling points are located in hardened aircraft shelters.

4-7 HYDRANT SYSTEM GENERAL EQUIPMENT.

4-7.1 Pantographs.

Pantographs that meet the requirements of UFGS 33 52 43.12 are used in aircraft fueling facilities. Pantographs can be fixed at a single location or mounted on a towable frame to make them mobile. Pantographs have a number of swivel joints. The focus of a pantograph's maintenance centers on the care of the joints. Most pantographs have a sufficient number of swivel joints to prevent excessive strain. The movable joints require periodic lubrication when equipped with lubricated swivels and replacement of packings, seals, or O-rings. Once existing lubricated swivels show signs of leaks and failure, they should be replace with stainless steel non-lubricated type swivels.

Care must be taken to ensure that grounding or bonding wire is not damaged during maintenance or allowed to deteriorate. Pantographs are treated roughly during refueling operations. Personnel who perform preventive maintenance must be alert for leaks, wet spots, and erratic mechanical operation.

4-7.1.1 Fixed Pantographs.

Fixed pantographs are connected to piping at a single location and are not relocated.

4-7.1.1.1 Inspection and Maintenance – Fixed Pantographs.

a. Place entire pantograph under static pump head pressure and check for leaks, ease of movement, and damaged grounding or bonding wire.
Frequency: Monthly

b. Inspect wheels (if equipped) for warping, cracking, and uneven wear.
Frequency: Quarterly

c. Inspect exposed piping and components for corrosion.
Frequency: Quarterly

d. Refer to Section 4-7.3 Fueling Nozzles for inspection and maintenance requirements of fueling nozzle.

Figure 4-22 Fixed Pantograph

4-7.1.2 \1\ Detachable /1/ Pantographs.

Mobile pantographs are used in locations that are not equipped with fixed pantographs or hydrant hose trucks. These pantographs are mounted on wheels and can be towed to the use point. Each pantograph is equipped with a hydrant adaptor used to connect to a HCV and a fueling nozzle used to connect to the aircraft receiving fuel.

4-7.1.2.1 Inspection and Maintenance – \1\ Detachable/ 1/ Pantographs.

a. Place pantograph under static pump head pressure and check for leaks, ease of movement, and damaged grounding or bonding wire.
Frequency: Monthly

b. Inspect exposed piping and components for corrosion.
Frequency: Quarterly

c. Lubricate wheels.
Frequency: Quarterly

d. Inspect wheels for warping, cracking, and uneven wear.
Frequency: Quarterly

e. Refer to Section 4-7.2 Hydrant Adapters for inspection and maintenance requirements of pantograph hydrant adapters.

f. Refer to Section 4-7.3 Fueling Nozzles for inspection and maintenance requirements of fueling nozzles.

4-7.2 Hydrant Adapters.

Hydrant adaptors are used to connect to hydrant control valves. Hydrant adaptors are installed on hydrant hose trucks and mobile pantographs.

4-7.2.1 Inspection and Maintenance – Hydrant Adapters.

a. Inspect hydrant adapter for proper operation, damage, and wear.
Frequency: Quarterly

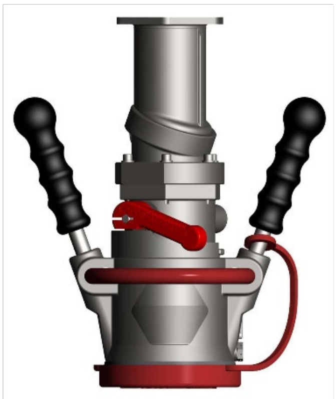
b. Test operation of dry break system.
Frequency: Quarterly

Figure 4-23 Hydrant Adapter

4-7.3 Fueling Nozzles.

Fueling nozzles are used to connect issue systems to refueler trucks and aircraft. They are installed on fuel issue hoses, pantographs, R-11 refuelers, R-12 hydrant hose trucks, and other systems that issue fuel. The fueling nozzle is equipped with 60-100 wire mesh screen (0.25-0.15 mm sieve) to trap particulates from the issue system.

Figure 4-24 Fueling Nozzle



4-7.3.1 Inspection and Maintenance – Fueling Nozzles.

a. Inspect the condition of the dust cap at the aircraft adapter end and ensure it is in good working order. Dust caps must be attached to nozzles when they are not is use.
Frequency: Monthly

b. Test leak resistance of poppet valve against full pump pressure. Unusual conditions found during this test indicate that repair is necessary and the nozzle must be removed from service.
Frequency: Monthly

c. Inspect storage racks for moisture or dirt accumulation. Correct conditions that may be attributing to accumulation of moisture or dirt in the storage racks.
Frequency: Monthly

d. Remove nozzle for inspection of content impinged upon the mesh screen. Clean and dry screens before nozzles are returned to service. If a strainer ball valve is installed upstream of the nozzle only the strainer in the strainer ball valve needs to be check. Nozzles should not be used while strainers are removed from upstream strainer ball valves.
Frequency: Monthly

e. Tests nozzle interlocks. Ensure interlocks prevent release of fuel when the fueling nozzle is not properly connected. Adjust the seating of the poppet valve if required.
Frequency: Monthly

f. Check the operation of the manual valve crank assembly for smooth and positive motion on a special test stand.
Frequency: Monthly

4-7.4 Surge Suppressors.

If the flow of liquid in a pipeline is suddenly stopped, a high pressure wave can be created as kinetic energy of flow is converted to pressure. The resulting pressure spike can cause leaks and damage to connected equipment. A common device designed to decrease pressure spikes in pipelines is a surge suppressor. Surge suppressors can reduce pressure spikes but will not eliminate them entirely.

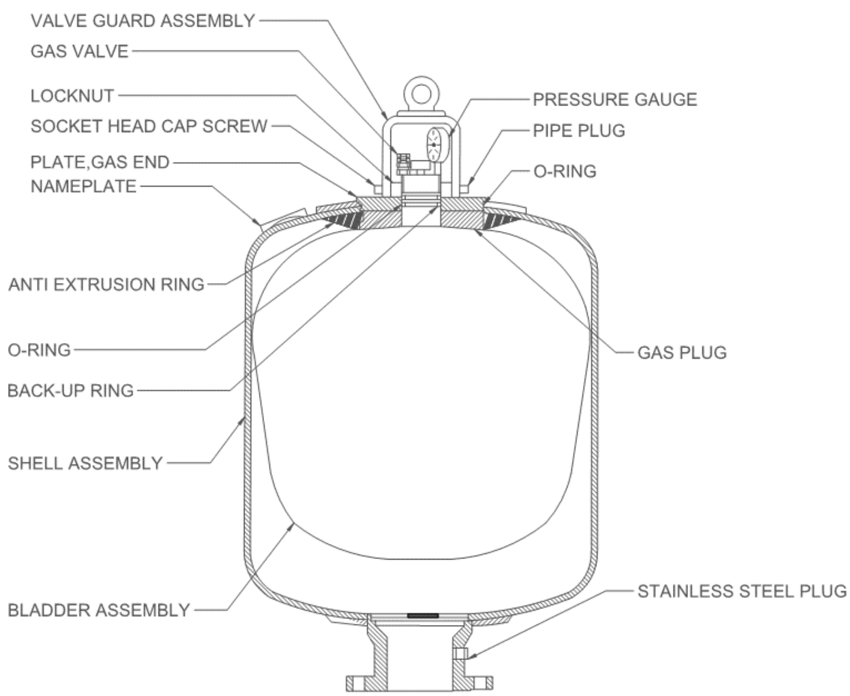
Surge suppressors can be constructed with diaphragms or bladders. Surge suppressors are equipped with a top-mounted pressure gauge, isolation valve, limited bleed-back check valve, and drains.

4-7.4.1 Inspection and Maintenance - Surge Suppressors.

a. Inspect for nitrogen leaks.
Frequency: Quarterly

b. Bladder pressure inside surge suppressors must be validated and recharged as needed with nitrogen. Some surge suppressors are also equipped with needle valves. Settings established in the startup and commissioning documents should be maintained. Adjust nitrogen charge per manufacturer’s recommendations.
Frequency: Quarterly

Figure 4-25 Surge Suppressor



\1

4-7.5 Aircraft Fueling Hoses.

Fuel issue hoses must meet the requirements of aviation fueling hoses listed in UFGS 33 52 43.12.

4-7.5.1 Inspection and Maintenance - Fuel Issue Hoses.

a. Visually inspect hoses for loose covers, cracks, brittle surface coatings, exposed wire braids, exposed reinforcement, flattening, kinks, and bulges or soft spots which might indicate broken or displaced reinforcement.
Frequency: Monthly

b. Pressurize hose to normal working pressure. Check flanged and threaded connections for leaks and inspect hose couplers for fluid seepage by pushing at the base of the coupling with thumbs. A hose softened by petroleum fluid seepage must be replaced.
Frequency: Monthly

c. Check for coupling slippage. Replace hose that shows signs of coupling slippage.
Frequency Quarterly

d. For hot pit refueling hoses only, refer to Appendix D, Section D-2.1 Loading Hose Hydrostatic Test for loading hose hydrostatic testing requirements and procedures.
Frequency: Annually

e. Conduct test of petroleum fuel hose electrical resistivity using an electrostatic meter in accordance with NFPA 77 and API 2003.
Frequency: Annually /1/

4-8 HYDRANT SYSTEM PRODUCT RECOVERY.

This system stores fuel from drain lines, filter separator drains, thermal relief valves and other components. It permits fuel and water to separate, the water to be drained off, and fuel to be returned to storage tanks.

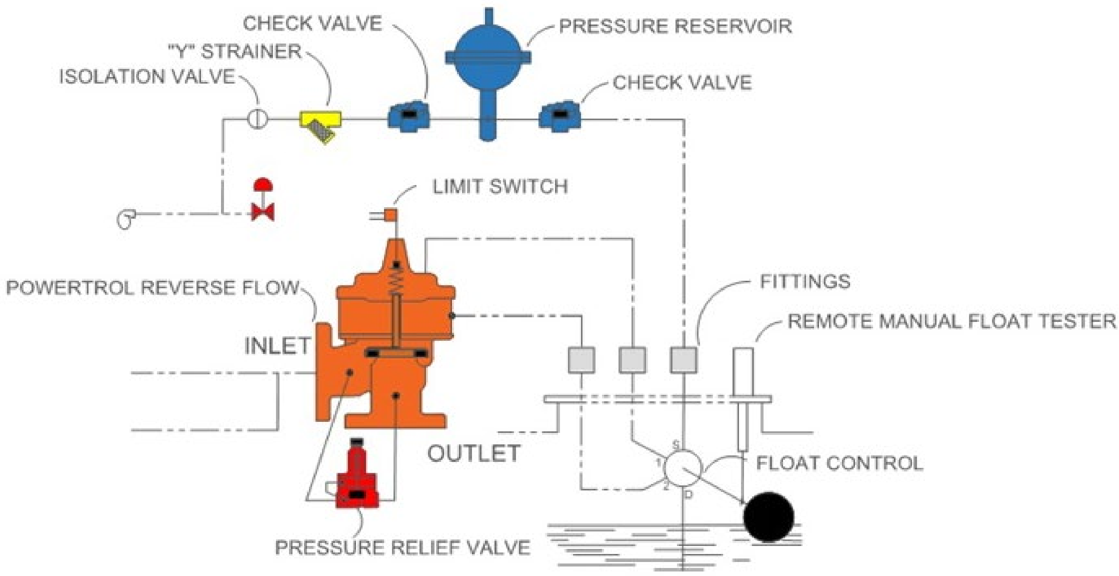
4-8.1 Overfill Valve for Product Recovery Tanks.

Overfill Valves (OVs) that meet the requirements of UFGS 33 52 43.14 are installed on product recovery tanks. Overfill valves are used to stop flow of fuel into product recovery tanks when the product recovery tanks reach a high level condition. A high-level alarm is activated at 85% full capacity, a high-high level alarm is activated at 90% full capacity, and the OV closes at 95% full capacity.

The valve is equipped with a pressure reservoir which supplies hydraulic pressure required to operate the valve. Reservoir pressure is supplied by the Fuel Transfer

Pump (FTP) installed on the product recovery tank. When the FTP operates, pressurized fuel is supplied to the reservoir. The reservoir utilizes a check valve to isolate the pressure in the reservoir. Automatic opening and closing of the OV is controlled by a float installed in the product recovery tank. The OV will close upon loss of reservoir pressure.

Figure 4-26 Overfill Valve for Product Recovery Tank



4-8.1.1 Inspection and Maintenance - Overfill Valve for Product Recovery Tanks.

For more information on features, valve settings, and replacement, refer to commissioning documents, as-builts, and manufacturer's operation and maintenance manuals.

a. Verify that a green light is illuminated on the pump control panel graphic display when OV is open.
Frequency: Semi-annually

b. Ensure pressure reservoir bladder is charged with 13 to 15 psig (90 to 103 kPa) of nitrogen and that the reservoir holds fuel pressure.
Frequency: Semi-annually

c. Verify that the OV closes when the control float is lifted (normally 95% full). Use the manual tester to lift the float. NOTE: When the float in the product recovery tank rises and the OV closes, the pressure in the pressure reservoir tank will decrease.
Frequency: Semi-annually

d. Verify that a red light is illuminated and that an alarm is activated on the pump control panel graphic display when OV is closed. Alarm is activated by a limit switch installed on the OV.
Frequency: Semi-annually

e. Ensure the pressure reservoir tank holds FTP deadhead pressure when the pump is deactivated.
Frequency: Semi-annually

f. Open and clean reservoir inlet strainer.
Frequency: Semi-annually

g. Refer to Section 6-6.3 Thermal and Pressure Relief Valves for inspection and maintenance requirements of thermal and pressure relief valves.

4-8.2 Product Recovery Tank Release Detection.

Underground double-walled product recovery tanks are provided with release detection in the annular space between the inside and outside walls of the underground tank.

4-8.2.1 Inspection and Maintenance - Product Recovery Tank Release Detection.

Refer to Section 8-9.13 Release Detection Monitoring for inspection and maintenance requirements of product recovery tank release detection systems.

4-8.3 Product Recovery Tank Automatic Tank Gauges.

Underground product recovery tanks are typically equipped with automatic tank gauges that are similar to underground storage tanks equipped with automatic tank gauges.

4-8.3.1 Inspection and Maintenance - Product Recovery Tank Automatic Tank Gauges.

Refer to Section 8-9.8 Automatic Tank Gauges for inspection and maintenance requirements of product recovery tank automatic tank gauges.

4-8.4 Product Recovery Tank Fuel Transfer Pump.

Product recovery tanks are equipped with transfer pumps that are used to transfer recovered fuel back to store tanks for use.

4-8.4.1 Inspection and Maintenance - Product Recovery Tank Fuel Transfer Pump.

Refer to Section 3-8.1.3 Vertical Turbine/Submerged Turbine Pumps for inspection and maintenance requirements of product recovery tank fuel transfer pumps.

This Page Intentionally Left Blank

CHAPTER 5 MARINE RECEIVING AND DISPENSING FACILITIES

5-1 PIERS AND WHARVES.

A pier is a deck structure supported above the water on piles (open type), a solid fill structure retained by bulkheads (closed type with apron), or a combination of the two. It extends outward from the shore into a harbor or other navigable waters to permit berthing along one or both sides of its length.

A wharf is a deck structure supported above the water on piles (open type), a solid-fill structure retained by bulkheads (closed), or a combination of the two. It runs parallel to the shore and is connected to it at more than one point (usually continuously) to provide berthing along one side.

5-1.1 Inspection and Maintenance – Piers and Wharves.

Refer to UFC 4-150-07 for inspection and maintenance requirements of piers and wharves.

\1

5-1.2 Inspection and Maintenance – Fuel Containment Systems

a. Containment systems on piers and wharves degrade and will collect debris, which can clog drainage inlets or prevent drain valves from sealing properly. Hydrostatically test the secondary containment and associated drainage systems to include containment concrete/sealant, drain inlets, drain lines and containment drain valves to ensure containment is liquid tight. This test may use opportune rainfall by holding rainwater in the containment system for one hour. Where evaporation is a concern, conduct the testing when this concern would be minimized, such as at night/early morning or during a time of year when this would not be as much of an issue. Record the water level at the start of the 60 minute (minimum) hold period. If the water level drops by 1/8 inch or more, perform and record an investigation to determine the cause and any required repairs. Once repairs are completed, a new test must be completed. Refer to Appendix B for testing procedures and to document the testing.
Frequency: Every 3 Years

/1/

5-2 MARINE RECEIPT.

These facilities include piers or wharves equipped with petroleum fuel transfer piping. Major components of marine receipt systems include marine hoses, marine loading arms, piping, strainers, fuel meters, stripper pumps, and grounding systems.

5-2.1 Inspection and Maintenance – Marine Receipt.

a. Conduct a shore side inspection of the pier or wharf for signs of damage as soon as marine barge or tanker disembarks.
Frequency: After each use

b. Inspect the ground switch used between the marine barge or tanker and the petroleum fuel receipt piping.
Frequency: Monthly

c. Inspect mooring lines, cleats, bollards, bitts, pulley blocks, steel wire ropes, and winches. Use UFC 4-150-08 as a guide when conducting inspections. Repair or replace damaged components as required.
Frequency: Monthly

d. Refer to Section 6-1 Pipe Testing and Inspections for inspection and maintenance requirements of petroleum fuel pipelines installed above water surfaces. These pipelines are regulated under 33 CFR 154 and 156. Any additional requirements listed under 33 CFR 154 and 156 must also be followed.

e. Refer to Section 5-1.1 Marine Transfer Hoses for inspection and maintenance requirements of petroleum fuel marine hoses.

f. Refer to Section 5-4 Marine Loading Arms for inspection and maintenance requirements of petroleum fuel marine loading arms.

g. Refer to Section 3-6.4 Basket Strainers for inspection and maintenance requirements of basket strainers.

h. Refer to Section 3-7 Meters for inspection and maintenance requirements of petroleum fuel meters.

i. Refer to Section 3-8.2 Positive Displacement Pumps for inspection and maintenance requirements of stripper pumps.

j. Refer to Section 9-1.6 Grounding Systems for inspection and maintenance requirements of grounding systems.

5-3 MARINE ISSUE.

Marine petroleum fuel issue systems are used to transfer petroleum fuel from shore storage systems to marine barges and tankers.

5-3.1 Inspection and Maintenance – Marine Issue.

Major components of marine petroleum fuel issue systems include piping, basket strainers, pumps, meters, marine hoses, marine loading arms, stripper pumps, and grounding systems.

a. Inspect pier or wharf for signs of damage as soon as marine barge or tanker disembarks.
Frequency: After each use

b. Inspect the ground switch used between the marine barge or tanker and the petroleum fuel issue piping.
Frequency: Monthly

c. Inspect mooring lines, cleats, bollards, bitts, pulley blocks, steel wire ropes, and winches. Use UFC 4-150-08 as a guide when conducting inspections. Repair or replace damaged components as required.
Frequency: Monthly

d. Refer to Section 6-1 Pipe Testing and Inspections for inspection and maintenance requirements of petroleum fuel pipelines installed above water surfaces. These pipelines are regulated under 33 CFR 154 and 156. Any additional requirements listed under 33 CFR 154 and 156 must also be followed.

e. Refer to Section 3-6.4 Basket Strainers for inspection and maintenance requirements of basket strainers.

f. Refer to Section 3-8 Pumps for inspection and maintenance requirements of marine loading and stripper pumps.

g. Refer to Section 3-7 Meters for inspection and maintenance requirements of petroleum fuel meters.

h. Refer to Section 5-5.1 Marine Transfer Hoses for inspection and maintenance requirements of petroleum fuel marine hoses.

i. Refer to Section 5-4 Marine Loading Arms for inspection and maintenance requirements of petroleum fuel marine loading arms.

j. Refer to Section 9-1.6 Grounding Systems for inspection and maintenance requirements of grounding systems.

5-4 MARINE LOADING ARMS.

\1

a. Marine loading arms are used to connect shore based petroleum fuel receipt and issues systems to marine barges and tankers.

b. The swivel, or swing joint attaching the arm to supply piping can be a source of leaks, especially if the arm is subject to stress when attached to the vessel. A program of periodic lubrication and inspection will ensure longer swivel life. If seals leak in spite of lubrication and seal replacement, complete refurbishment of the swivel may be required and the reason for the recurring failures should be identified. Non-lubricated swivels should not be lubricated.

c. A common cause of failure is inadequate support for the arm. Fully stocked kits are available to complete seal or joint renewal. Non-lubricated type swivels must be refurbished or replaced by the original equipment manufacturer.

d. Additional information pertinent to loading arms can be found in UFC 3-460-01 Section 5-8.a.

/1/

5-4.1 Inspection and Maintenance – Marine Loading Arms.

Signs of leaking lubricant or grease contaminated with fuel are clear signs of swivel joint failure. Refer to the manufacturer's operation and maintenance manual for specific maintenance procedures and schedules and follow applicable general maintenance requirements.

a. Check swivel for smooth operation. Check seals for signs of wear and discoloration which may indicate a seal or ball bearing failure.
Frequency: Quarterly

b. Inspect ball bearings when accessible. Rough and/or uneven wear on the surface are indications of swivel joint failure.
Frequency: Annually

c. Conduct pressure test of marine loading arms in accordance with 33 CFR 156.170 *Equipment Tests and Inspections*, Section (f)(1).
Frequency: Annually

5-5 MARINE AND UNDERWATER HOSES.

5-5.1 Marine Transfer Hoses.

\1

a. Many fueling operations are completed between piers and smaller vessels with non-buoyant hoses because the distance between the vessel and pier is minimal, and because the fuel hose will never touch the water during these fueling operations. Hose sizes can range from 2 to 6 inches (50 to 150 mm) in diameter and range in length from 25 to 100 feet (7.5 to 30.5 meters). These hoses are used to issue and receive petroleum products. The hoses must meet the requirements of 33 CFR 154.500.

b. In some cases floating hoses are used to attach between shore-based facilities and marine barges and tankers. Floatation buoyancy is typically built into the petroleum fuel hose string components, but it can also be externally attached. Hose strings are made up of 30 to 40-foot (9 to 12 m) long sections of individual hose lengths bolted together by steel flanges built into the ends of each floating hose. Each hose connection should have a drain connection on the marine barge or tanker side of the block valve.

c. Floating petroleum fuel hose diameters are standardized, in accordance with Oil Companies International Marine Forum (OCIMF) best practices, and range from 6-inch (DN150) to a maximum of 24-inch (DN600) internal diameter. The hose string length is determined by mooring equipment, marine barge or tanker size, and manifold location. Floating petroleum fuel hose strings will typically end in a blind flange that must be removed by the marine barge or tanker crew before the petroleum fuel hose can be connected to the marine barge or tanker. Floating petroleum fuel hose strings include a pick-up line which is attached to the marine barge or tanker end of the petroleum fuel hose. This pick-up line is used to bring the petroleum fuel hose onto the marine barge or tanker and is connected to a marker buoy which makes the free end of the petroleum fuel hose pick-up line easier to locate.

/**1**/

5-5.1.1 Inspection and Maintenance – Marine Transfer Hoses.

a. Visually inspect petroleum fuel marine transfer hoses. Transfer hoses must have no loose covers, kinks, bulges, soft spots, and no gouges, cuts or slashes that penetrate the hose reinforcement. Hoses must also have no external deterioration.
Frequency: Before each use

b. Visually survey petroleum fuel marine hoses. Observe the general condition and look for fluid puddles, fine mists, physical damage such as jacket abrasion or deformation, and deteriorated joints. Use sense of smell to detect petroleum vapor. Look for improper hose handling that may overstress the hose by stretching, relative movement, or kinking.
Frequency: During each use

c. Refer to Appendix D, Section D-2.2 Marine and Underwater Transfer Hose Hydrostatic Test for marine transfer hose hydrostatic testing requirements and procedures.
Frequency: Annually or not less than 30 days prior to the first transfer conducted past one year from the date of the last test and inspection.

5-5.2 Underwater Hoses.

Underwater petroleum fuel hoses are similar in construction to petroleum fuel marine transfer hoses but may have additional chafing gear covering some sections. External reinforcements may also be added to prevent kinking due to tidal motion when they are used in petroleum fuel transfer service in offshore moorings. Experience has shown that some sections of the underwater hose consistently wear more than others. Hose life can be extended by periodically changing the position of individual sections in the hose string. Ensure that the proper stainless steel bolts and Monel nuts are used to reassemble the string.

5-5.2.1 Inspection and Maintenance – Underwater Hoses.

It is recommended that, when equipment is available to lift buoys, anchors, chains, and other offshore mooring equipment, an effort be made to schedule hose inspection and testing concurrently, regardless of the duration since the last test. Work on the mooring systems can cause additional strain and wear on hoses.

a. Refer to Appendix D, Section D-2.2 Marine and Underwater Transfer Hose Hydrostatic Test for underwater hose hydrostatic testing requirements and procedures.
Frequency: Annually or not less than 30 days prior to the first transfer conducted past one year from the date of the last test and inspection.

5-6 DISPENSERS.

Dispenser systems located at marine facilities are similar to military service station type dispensers and typically include hose reels to refuel various types of watercraft. Hoses are routinely pulled across concrete and other abrasive surfaces that can cause damage to hoses. Automatic nozzle shut-off clips must be removed from marine fuel dispensing nozzles.

5-6.1 Inspection and Maintenance – Dispensers.

a. Refer to Section 7-2 Dispenser Nozzles for inspections and maintenance of requirements of dispenser nozzles.

b. Refer to Section 7-3 Dispenser Hoses for inspections and maintenance requirements of dispenser hoses.

c. Refer to Section 7-4 Breakaways for inspections and maintenance requirements of dispenser hose breakaways.

d. Refer to Section 7-5 Swivels for inspections and maintenance requirements of dispenser hose swivels.

e. Refer to Section 7-8 Dispenser Meters for inspections and maintenance requirements of dispenser meters.

f. Refer to Section 7-9 Dispenser Filters for inspections and maintenance requirements of dispenser filters.

g. Refer to Section 7-10 Dispenser Strainers for inspections and maintenance requirements of dispenser strainers.

h. Refer to Section 7-12 Emergency Shutoff Valves for inspections and maintenance requirements of emergency shutoff valves installed in the petroleum fuel supply line at the base of dispensers.

i. Refer to Section 7-15 Dispenser Pumps for inspections and maintenance requirements of dispenser pumps.

5-7 OFFSHORE MOORING SYSTEMS.

Offshore moorings designed in accordance with UFC 4-159-03 are located out of navigable shipping lanes with necessary anchorage suitable for holding specific capacity marine tankers. Typically a single steel pipeline connected to the shore petroleum fuel storage system extends underwater from the shore to the area of the mooring. This pipeline is used to handle all petroleum fuel products. Underwater petroleum fuel hose, flanged to the underwater pipeline provides a flexible connection to marine tankers. The mooring anchors installed for marine tankers are marked with buoys. The underwater petroleum fuel hose is equipped with a spool piece and a chain at the marine tanker end. The chain is connected to a marker buoy and is used to lift the petroleum fuel hose from the sea bottom for connection to the marine tanker.

Inspection and maintenance of offshore mooring systems focuses on buoy coatings, anchors, and chains. Cathodic protection systems are used to protect the anchors and chains and require routine inspection and replacement of sacrificial anodes.

5-7.1 Single Point Mooring Systems.

Single point moorings (monobuoys) consist of a single buoy. The buoy is attached to marine tankers by means of bow lines or anchor chain. The ship is free to swing 360 degrees around the buoy as it responds to environmental loading conditions (weather vane). This type of mooring may use either a riser or non-riser buoy system.

A diesel engine-driven air compressor is located in the interior of the buoy; its purpose is to provide compressed air displacement for the float/sink hoses. The product hoses are packed at all times, either with petroleum product or water, depending on the operational requirements.

5-7.1.1 Inspection and Maintenance – Single Point Mooring Systems.

2\ Refer to UFC 4-159-03 for frequencies of inspection and additional maintenance required for mooring systems. /**2**/ Required underwater inspections and testing must be performed by experienced professional divers.

a. Inspect and, if necessary, repair or replace all mooring hawsers or lines, deck hose, chain, chair stoppers, flange adaptors, gaskets or other gear used in mooring the marine tanker and in connecting hoses.
Frequency: Monthly

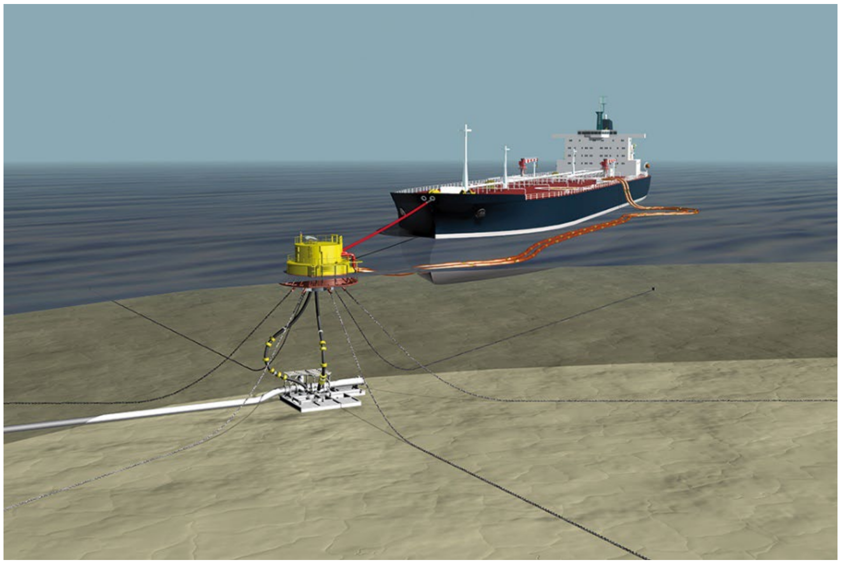
b. Inspect air-compressor for proper operation.
Frequency: Annually

c. **2**\\ Inspect navigation aids and mooring buoys in accordance with UFC 4-159-03 for evidence of damage and possible movement or dragging by marine tankers, current or winds. /**2**/
Frequency: Annually

d. Divers must conduct underwater inspections of mooring chains, shackles and anchors attaching buoys to bay/harbor floors.
Frequency: Annually

e. Conduct overhaul of single point mooring buoys every 3 to 5 years. Single point mooring buoys must be brought ashore for repair in these instances.
Frequency: Every 5 years

Figure 5-1 Single Point Mooring System



5-7.2 Multi-point Mooring Systems.

Multi-point moorings are designed for use by a single ship secured by its bow and stern lines to buoy systems. This mooring is normally installed near a shoreline, parallel to the direction of water current, and outside the normal navigational channel. Riser buoy systems are normally used in this type of mooring.

5-7.2.1 Inspection and Maintenance – Multi-point Mooring Systems.

2\\ Refer to UFC 4-159-03 for frequencies of inspection and additional maintenance required for mooring systems. /**2**/ Required underwater inspections and testing must be performed by experienced professional divers.

a. Inspect and, if necessary, repair or replace all mooring hawsers or lines, deck hose, chain, chair stoppers, flange adaptors, gaskets or other deck gear used in mooring the marine tanker and in connecting underwater hoses.
Frequency: Monthly

b. Inspect navigation aids and mooring buoys, in accordance with NAVFAC MO- for evidence of damage and possible movement or dragging by marine tanker, current or winds.
Frequency: Annually

c. Divers must conduct underwater inspections of mooring chains, shackles and anchors attaching buoys to bay/harbor floors.
Frequency: Annually

5-8 SUBMERGED PIPING SYSTEMS.

Submerged piping is used to connect shore based petroleum fuel systems to mooring locations of marine tankers. A hose is typically installed to connect the submerged piping to the moored marine tanker.

5-8.1 Inspection and Maintenance – Submerged Pipelines.

Required underwater inspections and testing must be performed by experienced professional divers.

a. Inspect water above submerged pipelines and their seaward end for tell-tale petroleum fuel slicks indicating leakage from pipes or underwater hoses.
Frequency: Weekly

b. If equipped, electrically check the cathodic protection rectifier for proper performance.
Frequency: Six times each calendar year with intervals not exceeding 2½ months.

c. Divers must inspect submerged pipe and hoses for signs of incipient failure or indications of rapid wear of parts subject to wave motion or abrasion on the ocean floor.
Frequency: Semi-annually

d. Conduct annual pipe test as specified in Appendix G – Petroleum Fuel Pipeline Pressure testing Guidelines and Criteria. Testing requirements of marine pipelines are regulated under 33 CFR 154 and 156, particularly 33 CFR 156 Section 170.
Frequency: Annually

e. Conduct cathodic protection tests on the protected pipeline as specified in Section 9.2.1 Cathodic Protection at least once each calendar year with

intervals not exceeding 15 months between tests from consecutive years.
Frequency: Annually

5-9 BOOM REELS.

Boom reels are hydraulic or manually operated. They are used to store floating spill containment booms that are used to surround marine barges and tankers and contain spills.

5-9.1 Inspection and Maintenance – Boom Reels.

a. Visually inspect hydraulic drives and hose connections for leaks.
Frequency: Quarterly

b. Grease bearings.
Frequency: Quarterly

c. Inspected boom reel for signs of corrosion. Inspect breaking system and ensure it is in good working order.
Frequency: Quarterly

d. Inspect boom for wear, rips, and tears. Repair or replace as required to ensure containment of petroleum fuel in the event of a spill.
Frequency: Annually

CHAPTER 6 PIPING SYSTEMS

6-1 PIPE TESTING AND INSPECTIONS.

This chapter includes information on testing and inspection requirements of pipelines and piping.

6-1.1 On-Base Pipelines.

On-base pipelines are routed exclusively within an Installation's property and do not pass outside of Installation boundaries. The pipelines are not regulated by the Department of Transportation (DOT). Where more than one type of petroleum fuel is transferred, separate pipelines are typically provided for each type of petroleum fuel. These pipelines include transfer lines between petroleum fuel truck and rail offloading and storage tanks, pump houses and petroleum fuel truck and rail loading systems, transfer lines between storage areas, and hydrant supply and return lines.

6-1.1.1 Inspection and Maintenance – On-Base Pipelines.

a. Conduct petroleum fuel pipeline visual Inspection of aboveground piping in accordance with Section 6-1.5 Pipeline Visual Inspection.
Frequency: Monthly

b. Conduct line walk in areas of petroleum fuel piping in accordance with Section 6-1.6 Line Walk.
Frequency: Conduct during transfer operations, or monthly, at a minimum.

c. Conduct annual test as specified in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria.
Frequency: Annually

d. Conduct cathodic protection tests as specified in Section 9.2.1 Cathodic Protection on protected petroleum fuel pipelines at least once each calendar year, but with intervals not exceeding 15 months.
Frequency: Annually

e. Conduct five year test as specified in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria.
Frequency: Every 5 years

f. Conduct petroleum fuel pipeline API 570 inspection in accordance with Section 6-1.9 API 570 Inspections.
Frequency: Every 5 or 10 years depending on API class piping or in accordance with Pipeline Integrity Management Plan (PIMP).

g. Conduct petroleum fuel pipeline cleaning in accordance with Section 6-2 General Pipeline Cleaning.
Frequency: As required to ensure fuel quality.

6-1.2 Inter-Terminal Pipelines.

\1

a. Inter-terminal petroleum fuel pipelines which cross outside of an Installation's property for more than one mile and are operated by non-government personnel are regulated by the DOT. Operation and maintenance of DOT regulated pipelines must comply with 49 CFR 195. Inter-terminal pipelines which cross outside of an Installation's property for more than one mile and are operated by government personnel are currently exempt from 49 CFR 195 requirements. Although government operated pipelines are not subject to DOT regulations, certain states may regulate or force an activity to adhere to a standard such as 49 CFR 195.

b. Inter-terminal pipelines supplying petroleum fuels to DoD petroleum fuel facilities may be dedicated to serving a single facility or may handle several types or grades of petroleum fuel for more than one user. These pipelines may be owned, operated, and maintained by DoD or commercial agencies; however, only those operated by contractors or non-government entities are potentially DOT regulated.

c. Inter-terminal pipelines owned, operated, and maintained by commercial agencies delivering petroleum fuel to DoD petroleum fuel facilities may be constructed on DoD property in order for the inter-terminal pipelines to reach the DoD petroleum fuel facilities located on DoD property. Responsibility of commercial agencies for maintaining inter-terminal pipelines owned and operated by commercial agencies usually terminates at the custody transfer point located on the DoD Installation. The custody transfer point is typically located close to the location where the commercial inter-terminal pipeline crosses into the Installation and is usually demarcated by a custody transfer valve.

d. In some cases supplier and operator contracts allow the responsible Installation activity to perform emergency maintenance on on-base segments of commercial inter-terminal pipelines, if necessary, to protect against environmental damage to public property or meet emergency wartime mission requirements.

/1/

6-1.2.1 Inspection and Maintenance – Non-DOT Regulated Inter-Terminal Pipelines (Operated by DoD).

a. Conduct petroleum fuel pipeline volume check in accordance with Section 6-1.8 Volume Check.
Frequency: Monthly

b. Conduct line patrol in areas of underground petroleum fuel pipeline in accordance with Section 6-1.7 Line Patrol.
Frequency: Annually

c. Government operated inter-terminal petroleum fuel pipelines must follow the maintenance requirements listed in Section 6-1.1.1 On-Base Pipelines.

6-1.2.2 Inspection and Maintenance – DOT Regulated Inter-Terminal Pipelines.

DOT regulated petroleum fuel pipelines must be maintained and operated in accordance with the provisions of 49 CFR 195. This includes but is not limited to O&M Plans, Integrity Management Plans, and Operator Qualification Plans, which are outside the scope of this document.

6-1.3 Aboveground Piping.

Aboveground piping includes visible piping installed outside and inside of buildings. This piping is supported on aboveground pipe supports or in open trenches or trenches with removable covers.

6-1.3.1 Inspection and Maintenance – Aboveground Piping.

a. Conduct petroleum fuel piping visual Inspection in accordance with Section 6-1.5 Pipeline Visual Inspection.
Frequency: Weekly

b. Conduct petroleum fuel piping annual test as specified in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria.
Frequency: Annually

c. Conduct petroleum fuel piping API 570 inspection in accordance with Section 6-1.9 API 570 Inspections.
Frequency: Every 5 or 10 years depending on API class piping or in accordance with Pipeline Integrity Management Plan (PIMP).

d. Conduct cleaning of petroleum fuel piping in accordance with Section 6-2 General Pipeline Cleaning.
Frequency: As required to ensure fuel quality.

6-1.4 Double-Wall Piping.

Double-wall piping is required by some states or host nations. In the event that the carrier pipe develops a leak, there are techniques for detecting the presence of fuel in the interstitial space of the double-wall piping. See Section 6-13.1 General Inspection of Release Detection Systems for more information on systems used for monitoring the interstitial space.

6-1.4.1 Inspection and Maintenance – Double-Wall Piping.

a. Conduct petroleum fuel pipeline visual Inspection of aboveground piping in accordance with Section 6-1.5 Pipeline Visual Inspection.
Frequency: Monthly

b. Conduct line walk in areas of petroleum fuel piping in accordance with Section 6-1.6 Line Walk.
Frequency: Conduct during transfer operations, or monthly, at a minimum.

c. Conduct annual carrier pipe test as specified in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria.
Frequency: Annually

d. Conduct cathodic protection tests as specified in Section 9.2.1 Cathodic Protection on protected petroleum fuel pipelines at least once each calendar year, but with intervals not exceeding 15 months.
Frequency: Annually

e. Conduct containment pipe test as specified in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria.
Frequency: Every three years

f. Conduct petroleum fuel pipeline API 570 inspection in accordance with Section 6-1.9 API 570 Inspections.
Frequency: Every 5 or 10 years depending on API class piping or in accordance with Pipeline Integrity Management Plan (PIMP).

g. Conduct petroleum fuel pipeline cleaning in accordance with Section 6-2 General Pipeline Cleaning.
Frequency: As required to ensure fuel quality.

6-1.5 Pipe Visual Inspection.

Visually inspect aboveground petroleum fuel piping for leaks (e.g., drips, mist spray). Repair identified leaks. Some leaks can be repaired by replacing or repairing mechanical components. Other leaks will require welding of the pipe for permanent repair. Approval through local work management processes is required before beginning welding or hot work in connection with repairs. The following list is a baseline for petroleum fuel pipeline operability:

a. Visually inspect piping and coatings for signs of corrosion or damage. Schedule maintenance or repair as necessary.

b. Inspect flanges and gaskets.

c. Inspect pipe supports to ensure pipe is properly supported without binding, misalignment, or tipping. Ensure insulating or sliding material between the supports and piping is securely fastened and not missing or deteriorated. Ensure contact points between support and pipe are not corroded.

d. Inspect pipe support anchor bolts and grout for signs of cracking, corrosion, or missing fasteners. Repair as required.

e. Visually inspect expansion bellows for cracks, tears, leaks, or misalignments. Expansion bellows cannot be repaired and must be replaced if damaged.

f. Inspect braided hoses and vibration dampeners for wear and damage to braiding. Also check for compression or tension that could indicate improper loading on the hose or dampener.

g. Visually inspect grounding wires and connection points between pipes and grounding rods.

6-1.6 Line Walk.

Line walkers or vehicle patrols must make detailed inspections of area conditions around aboveground petroleum fuel piping and above underground petroleum fuel piping. Inspections must include general condition of the right-of-way, valves in remote areas, and conditions that may indicate a leak. Leaks in underground pipelines can be detected by fuel surfacing on the ground, fuel runoff in storm drainage systems, fuel in underground pits or manholes, dead vegetation, or the continuous odor of fuel in a particular area. Investigate suspicious circumstances.

Inspections of DOT regulated petroleum fuel pipelines must be in accordance with 49 CFR 195, Subpart F, Section 195.402 , which requires inspections of right-of-way conditions at intervals not exceeding 3 weeks, but at least 26 times each calendar year.

6-1.7 Line Patrol.

Line patrols should occur on sections of petroleum fuel pipelines not easily accessible by vehicle or foot. Line patrols are conducted by observations from aircraft. Line patrols should be flown at an elevation of less than 500 feet (152 meters) from the ground and at speeds from 65 to 80 miles per hour (105 to 130 kilometers per hour). Petroleum fuel pipelines must be marked with posts or signs at 1 mile (1.6 kilometer) intervals and at bends. During line patrols the pilot acts as an observer who checks for unnatural changes in vegetation color and oil slicks on lakes and streams, which are evidence of leaking petroleum fuel pipelines; area construction work (e.g., roads, sewers) that could cross and possibly damage the petroleum fuel pipeline; and the overall condition of the right-of-way.

6-1.8 Volume Check.

Compare records kept on volume and temperature of petroleum fuel that has passed through each pumping station. Differences in meter readings not accounted for by temperature corrections between two stations may indicate a leak, but could also indicate theft, out-of-calibration meters, faulty temperature sensors, or human error.

6-1.9 API 570 Inspections.

Periodic inspections by an API 570 certified inspector must provide documentation of remaining pipeline life; recommended repairs; and/or need for replacement. Intervals for inspection are based on the class of piping and corrosion rate of the piping.

- Class 1: Over water – 5 years maximum.
- Class 2: Natural Gas – 10 years maximum.
- Class 3: Aboveground and underground petroleum fuel piping – 10 years maximum.

6-2 GENERAL PIPELINE CLEANING.

Petroleum fuel pipelines designed as suitable for pigging may be cleaned using various cleaning pigs. Intervals between cleanings are based on site conditions and the type of petroleum fuel. A drop in the flow rate; the continual presence of dirt, rust, or particulate in basket strainers; and/or shortened filter life may indicate a need for cleaning.

6-2.1 Cleaning Operations.

\1

a. Decide on the cleaning tool best suited for the pipe system and operation. For most petroleum fuel applications, a foam pig may be sufficient. For heavier petroleum fuel applications, or extensive cleaning requirements, brush and magnet pigs may be required. Verify operational specifications to be sure the pig will pass through all valves and bends.

b. Keep accurate time records of run start and quantity of petroleum fuel pumped to trace pig progress and determine its arrival at the receiving station. Meters must be bypassed during cleaning operations to avoid fouling. Cleaning pigs must be run at the manufacturer's suggested minimum velocity with no shutdowns while the pig is in the line. Shutdowns cause debris to settle in front of the pig and may cause it to become stuck.

c. Pigging operations may produce debris in the pipe system and extensive flushing and filtering should be performed once a pigging operation is completed. Flushing and filtering should be continued until all debris is removed from the pipe system.

6-3 PIPE SYSTEM REPAIRS.

a. Temporary repairs are defined as repairs made to piping systems that restore sufficient integrity to continue safe operation until permanent repairs can be scheduled and accomplished. The military service-specific SCP must be notified of temporary repairs and must have jurisdiction on how long a temporary repair may stay in place. The military service-specific SCP may require increased inspection while temporary repairs are in place.

b. Permanent repairs generally require planning and potentially welding or patching of the pipeline. Approvals through local work management processes are required before beginning welding or hot work in connection with repairs. All welding pipe repairs must meet the requirements of UFGS **\1**33 52 23.15**/1/** including documentation of welding procedures and welder qualifications before welding repairs are conducted.

c. Pipeline failures can create a welding safety hazard due to fuel-soaked soil in the area of the leak. Temporary pipeline repairs can be accomplished by clamping a steel plate of the same curvature as the pipe over the damaged area (i.e., clockspring repair) and using petroleum-resistant rubber, epoxy compounds, or gaskets for a seal. Once a temporary repair is in place, the area should be cleared of hazards. Permanent repairs may require replacement of failed sections.

/1/

6-3.1 Pits and Small Leaks.

Pitting on pipeline exterior surface is caused by corrosion and can lead to pipeline failure. Pitting can be repaired in a number of ways, but severe pitting must be repaired by either a patch plate or pipe replacement. In some cases, a full encirclement sleeve should be considered. All pipeline welded repairs must meet the requirements of UFGS **\1** 33 52 23.15 **/1/** including documentation of welding procedures and welder qualifications before welding repairs are conducted.

6-4 PIPELINE INTEGRITY MANAGEMENT PLAN.

Each petroleum fuel pipeline facility should have a Pipeline Integrity Management Plan (PIMP) to assist with and guide pipeline integrity maintenance. PIMPs improve the integrity management of piping systems and help prevent leaks or pipeline failures. The plans are developed based on the principles of API Standard 570 Federal, state, host nation, and local codes and regulations.

\1

6-4.1 Certified Pipeline Inventory.

DLA-E requires that a fuel system volume be calculated using as-constructed pipe lengths, internal diameters, fittings, and components of a system; i.e., all items containing fuel with the exception of tanks. If the inventory does not exist, record and provide a detailed list with sizes, lengths, quantity, and volumes for each of the systems inspected or repaired. **/1/**

6-5 FLANGE GASKETS.

When installing a gasket, measure the gap between the flanges to ensure consistent dimensions around the circumference of the connection. The faces of each flange must be inspected for scratches, burs, or other signs of damage before gaskets are installed. Pipe can expand and contract during temperature changes and gaskets should be replaced during consistent temperature conditions.

6-6 VALVES.

6-6.1 Valve Tagging.

\1 Mark valves, pumps, meters, and other system components with easily discernible painted numbers or numbered corrosion-resistant metal or plastic tags attached with a suitable fastener. Ensure numbers correspond to those on the schematic flow diagrams and other drawings for the installation. **/1/**

6-6.2 Manual Valves.

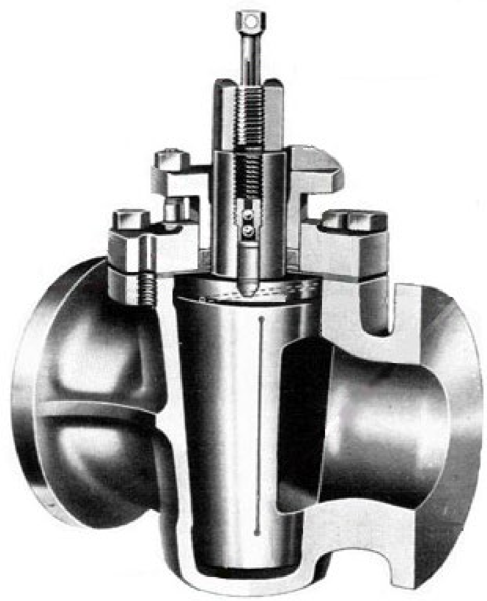
Manual valves are used to isolate portions of fuel systems and equipment, to control flow, or to direct the flow of fuel to a desired location.

6-6.2.1 Plug Valves – Lubricated.

Lubricated plug valves are not allowed in aircraft petroleum fuel systems and must be replaced. If lubricated plug valves are installed in other systems and cannot be replaced, they must be inspected regularly for proper operation.

Lubricated plug valves require lubrication and occasional flushing to keep them working properly. The valves require lubrication through a grease fitting on top of the valve that forces grease into feed channels within the valve plug. The plug is lubricated so that it passes freely over the seats without binding.

Figure 6-1 Lubricated Plug Valve



6-6.2.1.1 Inspection and Maintenance – Plug Valves – Lubricated.

a. Open and close valve to check for ease of operation.
Frequency Quarterly

b. Lubricate valve operator stems and grease fittings.
Frequency: Semi-annually

c. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.
Frequency: Semi-annually

6-6.2.2 Plug Valves – Non-lubricated.

Non-lubricated plug valves use cylindrical or conically shaped plugs that are rotated within the valve body. They are used as block valves, or where shut-off is required in various parts of the system. Plug valves can be either reduced port or full port depending on the location.

6-6.2.2.1 Inspection and Maintenance – Plug Valves – Non-Lubricated.

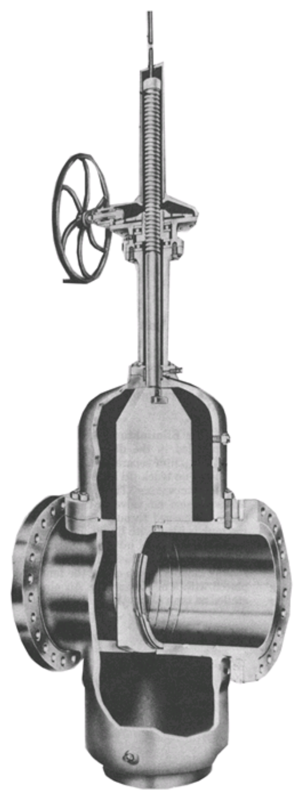
a. Open and close valve to check for ease of operation. Adjust or replace packing as needed.
Frequency Quarterly

b. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.
Frequency: Semi-annually

6-6.2.3 Gate Valves.

A gate valve is equipped with a round or rectangular wedge that is lifted out of the path of fluid to allow flow, and lowered back to its seat to block flow. Gate valves are not designed for throttling. They are designed to be either fully open or fully closed. Gate valves are either of the rising stem type, to visually see that the gate is opening or closing as the stem rises and falls; or of the non-rising stem type, where the hand wheel is fixed and the stem threads are internal to the valve. Rising stem gate valves are preferred in order to keep the stem threads out of the fluid. Gate valves should be equipped with a stem position indicator to indicate the open or closed position. Gate valves are equipped with a bonnet to ensure leak-proof closure of the valve body and are equipped with a valve stem packing tightening mechanism.

Figure 6-2 Gate Valve



6-6.2.3.1 Inspection and Maintenance – Gate Valves.

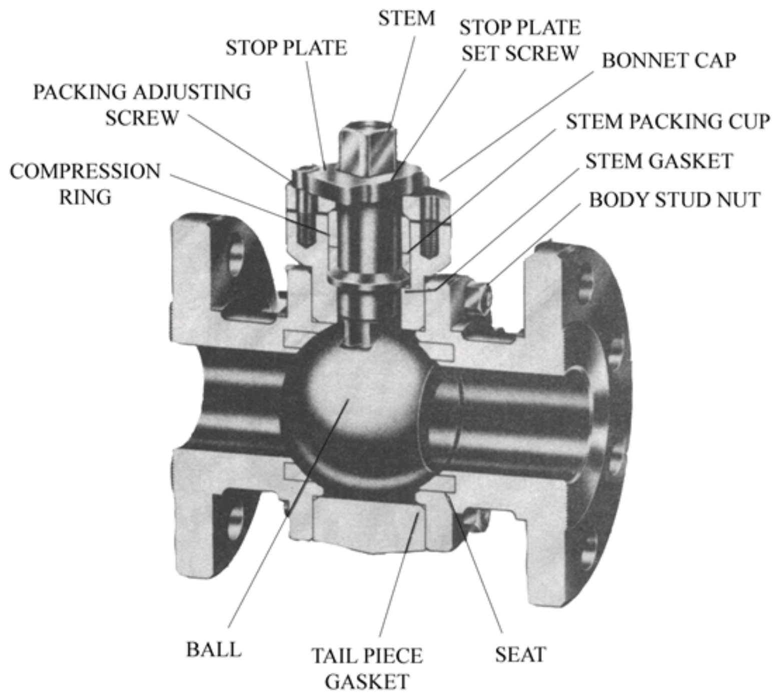
a. Open and close valve to check for ease of operation. Adjust or replace packing as needed.
Frequency Quarterly

b. Lubricate valve operator stem.
Frequency: Semi-annually

c. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.
Frequency: Semi-annually

6-6.2.4 Ball Valves.

Figure 6-3 Ball Valve



Ball valves are used as quick shut-off (block) valves in applications such as piping to hydrant outlets, between pumps and headers, and between pumps and filter separators. They are quarter turn, 0 to 90 degree, open to close type valves consisting of a solid metal ball with either reduced or full port, usually of stainless steel, and tetraflouroethylene (TFE) or fluoroelastetomer (FKM, commonly referred to as Viton) seats, body seals and stem seals. When the valve ball is in its open position (0 degrees) flow is through the open port. When the valve is in its closed position the port is 90 degrees perpendicular to the flow, allowing no flow through the valve. The valves are lever operated or gear operated, depending on the size.

6-6.2.4.1 Inspection and Maintenance – Ball Valves.

a. Open and close valve to check for ease of operation.
Frequency Quarterly

b. Lubricate overhead valve chain operator gears.
Frequency: Quarterly

c. Adjust packing per manufacturer's specifications as needed.
Frequency: Quarterly

d. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.
Frequency: Quarterly

e. Refer to Section 6-6.2.10 Manual Valve Gear Operators for inspection and maintenance of gear operators if equipped.

6-6.2.5 Double Block and Bleed Valves.

Double block and bleed (DBB) valves provide positive shutoff that can be verified by opening the cavity between the two blocks. They are used as positive isolation valves around tanks and in piping runs. They comply with API Specification 6D. Refer to UFC 3-460-01 for recommended locations.

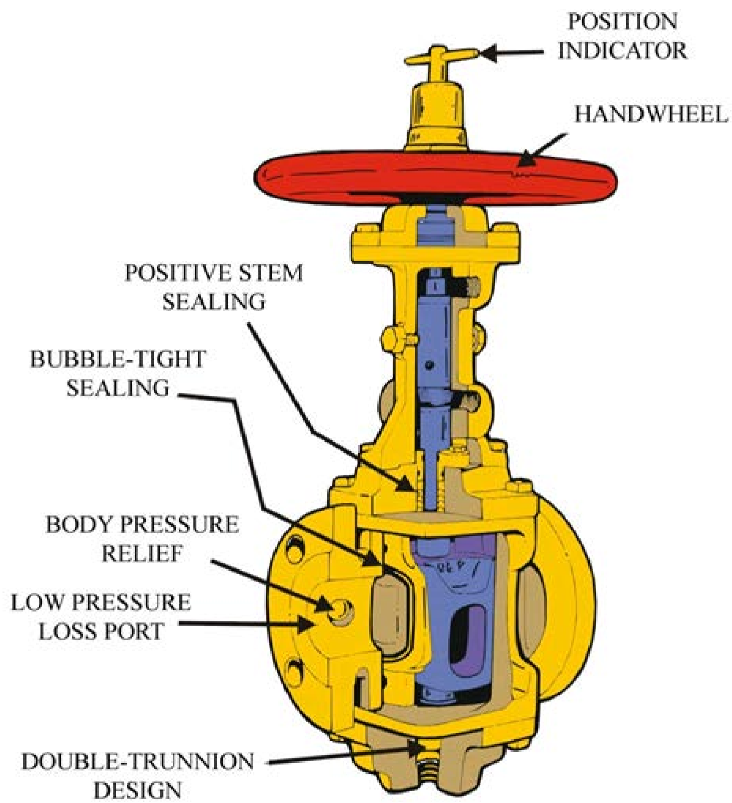
DBB valves can be plug, ball, or gate type, and reduced or full port depending on the location. Typically reduced port plug type DBB valves are used around tanks and in piping systems that do not require periodic pigging. Full port ball DBB valves are required in pipelines that require pigging.

a. Plug type DBB valves are equipped with non-lubricated, resilient, double-seated, trunnion-mounted, tapered lift plugs capable of two-way shutoff. The tapered plug is usually of ductile iron with chrome or nickel plating with the plug supported on upper and lower trunnions. Sealing slips are usually of steel or ductile iron with Viton seals which are held in place by dovetail connections. The sealing slips are removable and replaceable from the bottom of the valve while the valve is mounted in the pipeline in the open position. The valve hand wheel operates the valve from fully closed to fully open by first lifting the plug off the seats and then turning the plug so that the valve is in the fully open position.

b. Ball type DBB valves are equipped with non-lubricated, trunnion-mounted independent spring and hydraulically actuated, floating, single piston effect, self-relieving seat rings with bi-directional sealing. The ball is solid with a flow through conduit opening, suitable for the passage of pipeline pigs. The stems are anti-static, blow-out-proof design with O-ring seals and are provided with an emergency sealant injection fitting. The valves are 3-piece, bolted body design with flanged connections and are equipped with body drain, bleed valve and vent fitting.

c. Gate type DBB valves, when applicable per UFC 3-460-01 are non-lubricated with a bolted bonnet using an expanding gate which does not require pressure to produce a proper two-way seal. These valves are intended for fully open or fully closed operation and must not be used to throttle. The gate segments are usually of ductile iron with chrome or nickel plating. The hand wheel operates the valve from fully open to fully closed by moving the expanding gate into position then wedging the segments against the seats. The valves use flanged connections and are equipped with a body drain, bleed valve and vent fitting.

Figure 6-4 Double Block and Bleed Plug Valve



6-6.2.5.1 Inspection and Maintenance – DBB Valves.

Refer to valve manufacturer's operation and maintenance manual for disassembly, parts, additional maintenance for specific models, reassembly parts, and repair of DBB valves.

a. Open and close valve to check for ease of operation.
Frequency Quarterly

b. Lubricate overhead valve chain operator gears if equipped.
Frequency: Quarterly

c. Adjust packing per manufacturer's specifications as needed.
Frequency: Quarterly

d. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.
Frequency: Quarterly

e. Operate the body cavity drain when the valve is in the closed position to ensure that the valve is closing properly.
Frequency: Quarterly

\1

f. Keep the valve operator housing full of lubricant to displace and prevent moisture from accumulating and freezing, in accordance with manufacturer's recommendations.
Frequency: Semi-annually

g. Remove bottom drain plug and drain valve.
Frequency: Annually

h. Refer to Section 6-6.2.10 Manual Valve Gear Operators for inspection and maintenance of gear operators if equipped.

i. Some double block and bleed valves are equipped with integrated pressure/thermal relief valves. Refer to Section 6-6.3 Thermal and Pressure Relief Valves for inspection and maintenance requirements of pressure/thermal relief valves

/1/

6-6.2.6 Butterfly Valves.

\1

a. UFC 3-460-01 does not allow butterfly valves to be used as isolation valves in the construction of new petroleum fuel systems, as they are not considered positive shut-off valves. However, UFC 3-460-01 does specify that high-performance wafer trunnion butterfly type valves with synthetic seating material and a metal-to-metal seat that comply with API Std 607, equipped with a self-closing mechanism and a fusible link, must be used in two locations on Army and Navy projects. These locations are the inlet to truck fillstands, and on supply and return risers at aircraft direct fueling stations.

b. A butterfly valve is a short face to face valve incorporating a trunnion mounted flat disc that when closed is held tight against a synthetic seating material. Butterfly valves meeting the requirements of API Std 607 include a metal-to-metal seat as a back-up to the synthetic seat which enables the valve to continue to block flow in the closed position if the synthetic seat is burned out in a fire.

c. Butterfly valves are available in flanged, wafer, and lug style configurations. The wafer configuration does not include flanges on the valve body and fits between mating flanges installed in piping. A wafer style valve is centered inside the flange bolts of mating flanges when installed. Lug style valves include threaded lug bolts holes on the body of the valve. A lug style valve can be bolted to mating flanges from either side. For example, a lug style butterfly valve can be used at the end of a pipeline on a single mating pipe flange with the other end open, such as on a drain line.

d. Existing butterfly valves installed in petroleum fuel systems must be inspected and maintained.

/1/

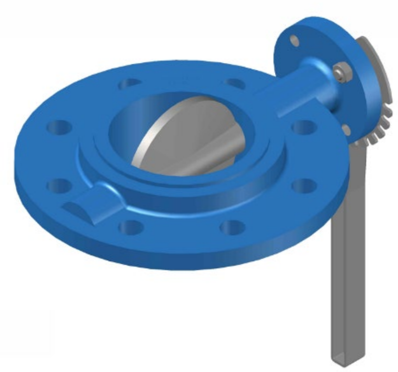
6-6.2.6.1 Inspection and Maintenance – Butterfly Valves.

a. Open and close valve to check for ease of operation. Ensure that lever operators and locking mechanisms are in place and working properly.
Frequency Quarterly

b. Adjust packing per manufacturer's specifications as needed. If butterfly valves are leaking or not shutting off flow, tightening the gland flange to tighten the stem packing or remove the valve from service and replace the seats as necessary.
Frequency: Quarterly

c. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.
Frequency: Quarterly

Figure 6-5 Butterfly Valve



6-6.2.7 Globe Valves.

Globe valves are used for isolation and throttling purposes. Hand wheel operated globe valves consist of a disc that is tightened via the hand wheel against a seat. These valves are equipped with a gland seal mechanism to seal the packing against the valve stem. The valve stem packing is accessible through a gland seal on top of the valve, and the valve seat is typically accessible through the valve bonnet.

Figure 6-6 Globe Valve

6-6.2.7.1 Inspection and Maintenance – Globe Valves.

a. Open and close valve to check for ease of operation.
Frequency Quarterly

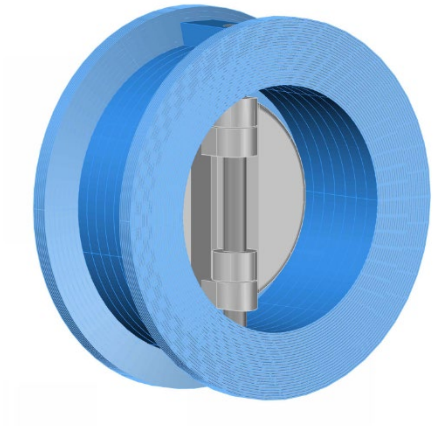
b. Adjust packing per manufacturer's specifications as needed.
Frequency: Quarterly

c. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.
Frequency: Quarterly

6-6.2.8 Check Valves.

Check valves are used to prevent backflow through pumps, branch lines, meters, or other locations where reverse flow must be prevented. Check valves may be of the swing disk, globe, dual plate hinged disk, spring-loaded poppet, ball, or diaphragm-actuated types. Check valves require upstream pressure in order for the check valve mechanism to close. Check valves must conform to API Specification 6D.

Figure 6-7 Check Valve



6-6.2.8.1 Inspection and Maintenance – Check Valves.

Refer to the particular check valve manufacturer's operation and maintenance manual for additional maintenance and parts.

a. Use external test lever to make sure the valve is not sticking if equipped. If a check valve is suspected of not checking and cannot be serviced in place, it must be removed from the piping system and serviced in a shop.
Frequency: Quarterly

b. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.
Frequency: Quarterly

6-6.2.9 Line Blanks, Ring Spacers, and Spectacle Blinds.

\1

a. A line blank is a flat plate designed to fit between two flanges as an isolation device. They are designed to fit between flanges inside the bolt circle with gaskets on either side. For example, blanks may be used at tank connections to isolate a tank from an active system while the tank is being cleaned or inspected. Line blanks are equipped with a handle that protrudes between flange bolts and is visible when it is installed. The handle should be stamped with information about the design of the blank. These are often referred to as blinds or skillets.

b. A ring spacer is a metal ring with gasket seating surfaces with an inner open hole matching the inner diameter of the pipe flanges where it is installed. Ring spacers are used to allow flow in a location where a blank may be installed to block flow. The ring spacer and the associated blank should have the same take-out dimensions and both should fit in the gap installed between the associated pipe flanges. Ring spacers should be equipped with a handle that protrudes between flange bolts and is visible when it is installed. The handle should be stamped with information about the design of the ring spacer.

c. Spectacle blinds include a blank and a ring spacer in one unit. They look like a pair of round eye glasses with one side open to flow and one side blanked off to prevent flow. These allow a line to be drained and the spectacle blind to be flipped to allow flow or provide isolation.

/1/

Figure 6-8 Line Blank

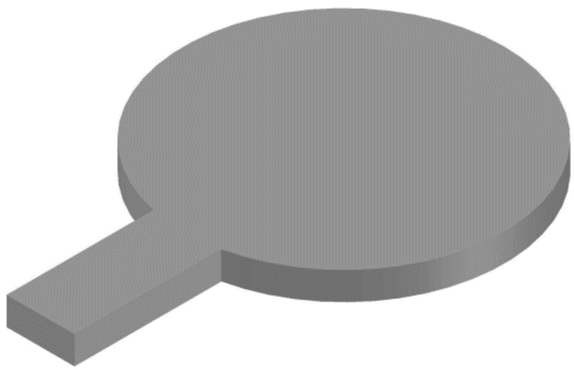


Figure 6-9 Ring Spacer

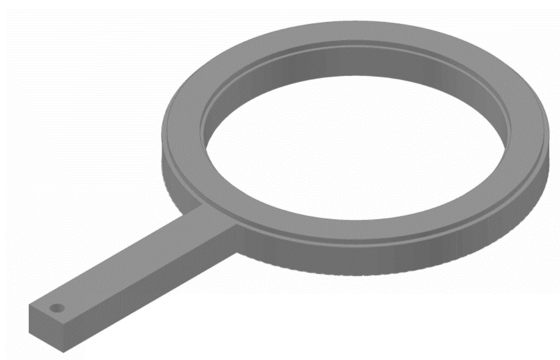

Figure 6-10 Spectacle Blind

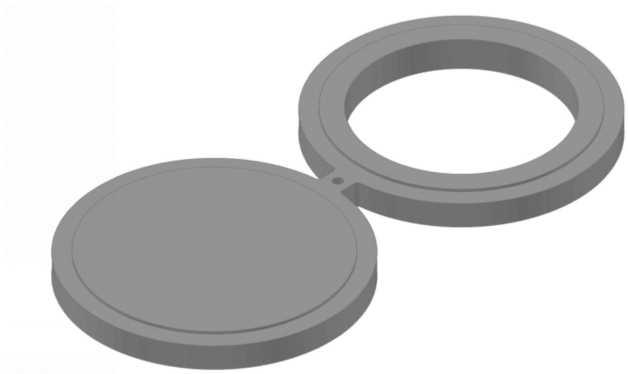


6-6.2.9.1 Inspection and Maintenance – Line Blanks, Ring Spacers, and Spectacle Blinds.

a. Inspect exposed side of spectacle blinds. The exposed side must be kept clean and free of corrosion.
Frequency: Quarterly

b. Spectacle blinds should be inspected to ensure they are installed with the correct orientation for the desired flow or no-flow condition.
Frequency: Quarterly

6-6.2.10 Manual Valve Gear Operators.

Gear operators are used to open and close large valves. Gear operators can be installed on most types of large valves.

6-6.2.10.1 Inspection and Maintenance – Manual Valve Gear Operators.

a. Lubricate gear driven operators and check for smooth operation.
Frequency: Quarterly

6-6.3 Thermal and Pressure Relief Valves.

\1

a. Thermal and pressure relief valves are used to relieve high pressures in piping and system components. Thermal and pressure relief valves are factory set to relieve at a specified pressure and are furnished with certified test paperwork. Pressure relief valves are typically sized for an operating pressure and a flow rate. The flow rate required for a pressure relief valve will be dependent on the system that it is used to protect and may be based on vessel size, vessel surface area, pump operating capacity, or piping flow rate. Thermal relief valves are typically only sized for operating pressure and the flow rate is not specified.

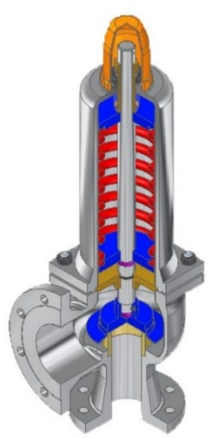
b. Thermal relief valves are used to relieve relatively small volumes of fluid from static or blocked-off systems that may develop high pressures do to thermal heating of the petroleum fuel isolated in piping or a pressure vessel. The coefficient of expansion of liquid petroleum fuel at 60 °F (16 °C) is 0.0005 gallon per gallon per degree F (0.0009 L per L per degree C). The total volume generated in most cases is very small, but the pressure increase resulting from this expansion can equate to as much as 75 psi (515 kPa) for every degree rise in the fuel temperature if not relieved. Therefore, it is absolutely essential that all closed systems have a pressure relief bypass system (thermal release by-pass valve and or check valve). Relieved fuel should be directed to a tank vented to atmosphere.

c. There are two primary types of thermal and pressure relief valves: conventional and balanced type. Conventional spring-loaded relief valves are affected by back pressure. For these valves an increase in downstream back pressure is applied to the seating mechanism and increases the valve opening relief pressure setting. Balanced relief valves are designed so that the downstream back pressure is not applied to the valve seating mechanism and the opening relief pressure setting is not impacted by the back pressure.

d. Thermal and pressure relief valves must be replaced with models that match the type, size, flow rate, and function of valves they are replacing.

/1/

Figure 6-11 Thermal and Pressure Relief Valve



6-6.3.1 Inspection and Maintenance – Thermal and Pressure Relief Valves.

a. Thermal and pressure relief valves must be inspected for signs of leak-by. Inspect relief valves for leaks by visually inspecting downstream flow indicators (if installed) for flow. If no flow indicators are installed listen for

possible leaks. If suspect: isolate and test the relief valve; check opening pressure; and verify re-seating. Malfunctioning valves must be repaired or replaced.
Frequency: Monthly

b. Ensure manual isolation valves installed upstream and downstream of thermal and pressure relief valves are open with valve handles removed, wired open or locked.
Frequency: Monthly

c. Inspect exterior of thermal and pressure relief valves for corrosion. Repaint as required. Information plates attached to thermal and pressure relief valves must not be painted over.
Frequency: Quarterly

d. **\2** Visually inspect and verify thermal and pressure relief valve setting by consulting as-built and historical data. **/2/**
Frequency: Annually

e. Thermal and pressure relief valves must be validated for proper calibration by isolating the valve and using the test connection provided on the piping in conjunction with a hand pump and portable reservoir. The operating pressure must be checked against the set pressure listed on the stamped information plate attached to the valve. The operating pressure must be adjusted to the stamped set pressure if necessary. **\1** If there is no test connection provided, isolate the relief valve and remove the valve to test. If there is no valve isolation or test connection, consider adding these to simplify future testing. **/1/**
Frequency: \2\ Test every five years /2/

6-6.4 Semi-Automatic Valves.

6-6.4.1 Fire Valves.

Fire valves are spring loaded to close in case of a fire to prevent fuel flow. The valves usually incorporate a fusible link that holds the valve open until it melts at 165 °F (74 °C) and allows the valve to close. Fusible link check valves are installed at some locations to close against the flow of fuel when the fusible link melts.

Fire-safe ball valves are sometimes used with a fusible link and a spring actuated closing mechanism.

6-6.4.1.1 Inspection and Maintenance – Fire Valves.

a. Ensure the fusible link mechanism is attached properly to actuate in case of a fire and that it has not been by-passed, blocked, or damaged in any manner. Ensure the fusible link is not filled with debris or paint which could impact operation. **\1** Maintain fusible links per manufacturer's

recommendation. /**1**/
Frequency: Quarterly

b. Check the closing mechanism to ensure that it closes the valve properly.
Frequency: Annually

6-6.4.2 Fusible Link Butterfly Valves.

Fusible link butterfly valves must be fire rated for use on petroleum fuel systems.

6-6.4.2.1 Inspection and Maintenance - Fusible Link Butterfly Valves.

Fusible links are designed to yield under heat generated by a nearby fire. Once the fusible link breaks a spring operated actuator closes the butterfly valve.

a. Ensure the fusible link mechanism is attached properly to actuate in case of a fire and that it has not been by-passed, blocked, or damaged in any manner. Ensure the fusible link is not filled with debris or paint which could impact operation. **1**\ Maintain fusible links per manufacturer's recommendation. /**1**/
Frequency: Quarterly

b. Test the operation of spring closure unit. Ensure that the spring actuator closes the valve and that the valve closes securely against the seat.
Frequency: Annually

c. Refer to Section 6-6.2.6 Butterfly Valves for additional inspection and maintenance requirements of butterfly valves.

6-6.5 Automatic Control Valves.

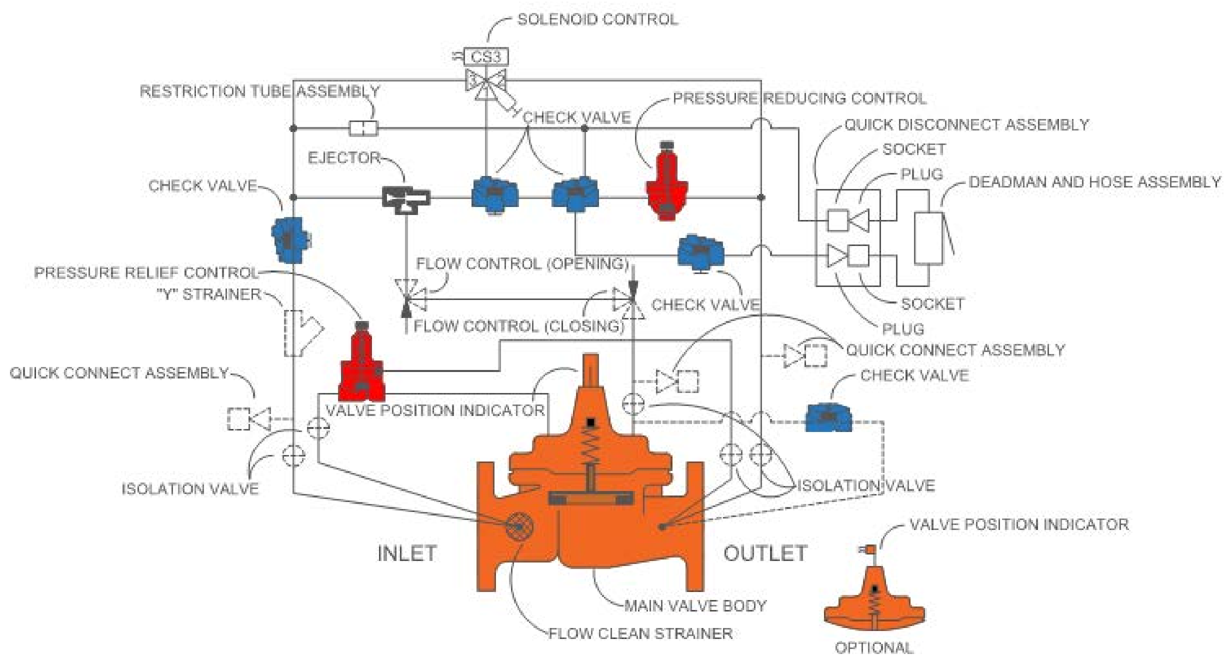
Automatic valves that meet the requirements of UFGS 33 52 43.14 are found throughout fuel systems and are typically of the diaphragm actuated globe type design. Flow through the valve can be either up and over the seat or under the seat and out, depending on the configuration and function of the control valve. The diaphragm is actuated by hydraulic pressure that forces the valve disc against the seat to close the valve or to open or throttle the valve for flow control purposes. An orifice plate is installed with the valve in some instances to control flow based on pressure differential. In other cases a separate float mechanism is installed to actuate the valve, such as in high-level shutoff valves. Almost all fuel control valves are installed in a fail-safe position (i.e., if the main valve diaphragm ruptures the valve will close or open to a safe operating position). Automatic valves can be installed in either a Normally Open (NO) or Normally Closed (NC) position.

Due to the many types of diaphragm-operated automatic valves in service, it is best to consult the particular valves schematic flow diagram and related parts list to understand the parts involved and to maintain and troubleshoot the valve if service is needed.

6-6.5.1 Truck Fill Valves.

Truck fill valves (TFV) meeting the requirements of UFGS 33 52 43.14 are used for petroleum fuel truck loading. TFVs include a deadman feature that is used to start and stop flow through the valve.

Figure 6-12 Truck Fill Valve



6-6.5.1.1 Inspection and Maintenance - Truck Fill Valves.

Deadman control is used to open and close TFVs on fillstands. Deadman controls may be hydraulic or electric. If deadman control fails functional check, remove deadman control from service and repair.

a. Verify TFV maintains 35 psig (240 kPa) nozzle pressure at a flow range of 50 to 600 gpm (3 to 38 lps).
Frequency: Quarterly

b. Verify TFV closes rapidly when outlet pressure exceeds control set point.
Frequency: Quarterly

c. Verify TFV opens when the deadman control lever is pressed.
Frequency: Quarterly

d. Verify TFV closes after the deadman control lever is released.
Frequency: Quarterly

e. If equipped, verify operation of solenoid connected to grounding verification system. Ground verification system should energize solenoid when an acceptable ground is detected by the ground verification unit.
Frequency: Quarterly

f. Systems that have overflow protection systems must be inspected and maintained concurrently with the inspection and maintenance of TFVs.
Frequency: Quarterly

g. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.

6-6.6 Motor Operators.

Motor operators provide electrical actuation of valves for open or closed service.

6-6.6.1 Inspection and Maintenance – Motor Operators.

Refer to the motor operator manufacturer's operation and maintenance manual for particular repair instructions and additional maintenance and parts.

a. Visually inspect motor operators to ensure smooth movement during opening and closing operation and adjust, if necessary, to ensure that they are opening and closing fully. Listen for and investigate unusual noises during operation.
Frequency: Quarterly

b. Lubricate mechanical overrides (if equipped).
Frequency: Quarterly

c. Refer to Section 9-1.7 Electric Motors for inspection and maintenance requirements of electric motors.

6-7 PRESSURE AND VACUUM INSTRUMENTATION.

6-7.1 Pressure and Pressure/Vacuum Gauges.

Round scale type pressure gauges are used to directly indicate line pressure. In some cases these gauges are liquid filled with a silicon based oil.

6-7.1.1 Inspection and Maintenance – Pressure and Pressure/Vacuum Gauges.

Refer to the manufacturer's operation and maintenance manual for specific calibration procedures.

a. Check operation of gauge. Ensure gauge is indicating pressure of the system.
Frequency: Monthly

b. Clean outside of gauge glass.
Frequency: Quarterly

c. Inspect liquid filled gauges for leakage, refill or replace as needed.
Frequency: Semi-annually

d. Conduct calibration check by comparing readings of the process gauge with the readings of a certified master calibration gauge which has been calibrated within the last year. The process gauge and the master calibration gauge must be connected to the same pressure source for testing. Verify accuracy of gauge is within ±2% of full scale. Calibrate gauge if required.
Frequency: Annually

6-7.2 Differential Pressure Gauges.

Differential pressure gauges are used to measure the difference in pressure between two sensing points.

6-7.2.1 Inspection and Maintenance - Differential Pressure Gauges.

Refer to the manufacturer's operation and maintenance manual for specific calibration procedures.

a. Verify proper operation of differential gauge in accordance with gauge manufacturer's procedures.
Frequency: Monthly

b. Clean outside of gauge glass.
Frequency: Quarterly

c. Conduct calibration check by comparing readings of the differential process gauge with the readings of a certified differential master calibration gauge which has been calibrated within the last year. The differential process gauge and the differential master calibration gauge must be connected to the same pressure source for testing. Verify accuracy of gauge is within ±2% of full scale. Calibrate if required.
Frequency: Annually

d. Some differential pressure gauges have a small gauge protection filter located at the high pressure inlet of the gauge that must be checked and replaced as needed. Filters need to be replaced if the indicator is moving slow or sluggishly inside the sight glass or if the sight glass is dirty. Refer to manufacturer's operation and maintenance manual for filter replacement procedures.
Frequency: Annually for inspections and maximum 5 years of service between filter replacements.

6-7.3 Pressure Transmitters.

Pressure transmitters are used to measure pressure at sensing points. These units transmit a 4 to 20 mA (common in US installations) or 0 to 20 mA (common in European installations) electrical signal to a display or a PLC to indicate pressure.

6-7.3.1 Inspection and Maintenance - Pressure Transmitters.

a. Inspect the exterior of the transmitter enclosure for accumulated oil, dust, and dirt. Clean if required.
Frequency: Quarterly

b. Check that both enclosure caps are fully threaded onto the enclosure, compressing the O-ring between the cap and the enclosure. The O-ring must not be cracked, broken, or otherwise damaged.
Frequency: Quarterly

c. Inspect the display viewing glass for cleanliness and damage. Replace the enclosure cap assembly if the glass is damaged or missing. No accumulation of dust, dirt, or water (condensate) should be present inside the enclosure.
Frequency: Quarterly

d. Inspect transmitter and mounting bracket hardware for tightness. Tighten loose hardware as necessary.
Frequency: Quarterly

e. Inspect for loose, bent, or cracked sensing lines. Replace damaged sensing lines.
Frequency: Quarterly

f. Check operation of transmitter. Ensure transmitter is indicating accurate pressure of the system.
Frequency: Quarterly

g. Bleed sensing lines between the transmitter and the main line to ensure they are clean and free of suspended solids and air.
Frequency: Semi-annually

h. Check that all wire connections inside enclosure are tight.
Frequency: Annually

i. Pressure transmitters (PTs) and pressure indicating transmitters (PITs) must be calibrated mechanically and electrically with test equipment and adjusted if applicable. The presence of air in the sensing line of a pressure transmitter is a common cause for failure. Conduct calibration check by comparing readings of the PT or PIT with the readings of a certified master calibration gauge which has been calibrated within the last year. The PT or PIT and the master calibration gauge must be connected

to the same pressure source for testing. Verify accuracy of PT or PIT gauge is within ±2% of full scale. Calibrate in accordance with manufacturer's operation and maintenance manual if required.
Frequency: Annually

6-7.4 Differential Pressure Transmitters.

Differential pressure transmitters (DPT) are used to measure the difference in pressure between two sensing points. These units transmit a 4 to 20 mA (common in US installations) or 0 to 20mA (common in European installations) electrical signal to a display or a PLC to indicate differential pressure. These same signals can also be used to determine flow rate measurements using a function that correlates pressure differential to flow.

6-7.4.1 Inspection and Maintenance - Differential Pressure Transmitters.

a. Inspect the exterior of the transmitter enclosure for accumulated oil, dust, and dirt. Clean as required.
Frequency: Quarterly

b. Check that both enclosure caps are fully threaded onto the enclosure, compressing the O-ring between the cap and the enclosure. The O-ring must not be cracked, broken, or otherwise damaged.
Frequency: Quarterly

c. Inspect the display viewing glass for cleanliness and damage. Replace the enclosure cap assembly if the glass is damaged or missing. No accumulation of dust, dirt, or water (condensate) should be present inside the enclosure.
Frequency: Quarterly

d. Inspect transmitter and mounting bracket hardware for tightness. Tighten loose hardware as necessary.
Frequency: Quarterly

e. Inspect for loose, bent, or cracked sensing lines. Replace damaged sensing lines.
Frequency: Quarterly

f. Check operation of transmitter. Ensure transmitter is indicating accurate differential pressure measurement.
Frequency: Quarterly

g. Bleed sensing lines between the transmitter and the main line to ensure they are clean and free of suspended solids and air.
Frequency: Semi-annually

h. Check that all wire connections inside enclosure are tight.
Frequency: Annually

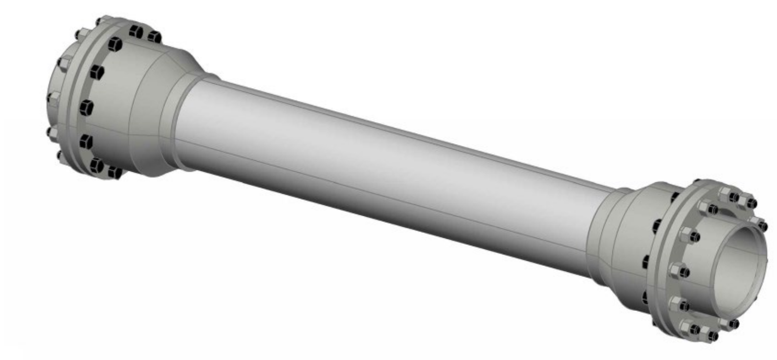
i. DPTs must be calibrated mechanically and electrically with test equipment and adjusted, if applicable. The presence of air in sensing lines of differential pressure transmitters is a common cause for failure. Conduct calibration check by comparing readings of the DPT with the readings of a certified differential master calibration gauge which has been calibrated within the last year. The DPT and the differential master calibration gauge must be connected to the same pressure source for testing. Verify accuracy of DPT is within ±2% of full scale. Calibrate in accordance with manufacturer's operation and maintenance manual if required.
Frequency: Annually

6-8 FLEXIBLE BALL JOINTS.

6-8.1 Flexible Ball Joints.

Flexible ball joints are used to provide flexibility in connections between petroleum fuel tanks and pipelines. These joints may also be used in other areas where flexibility is required.

Figure 6-13 Flexible Ball Joint



6-8.1.2 Inspection and Maintenance – Flexible Ball Joints.

Flexible ball joints can be a source of leaks, especially if the piping is subject to stress when it mates to a tank or coupling adapter. A program of periodic lubrication and inspection will ensure longer joint life, since a fully lubricated joint will not allow dirt to enter. However, if seals leak despite lubrication and seal replacement, the entire joint must be replaced.

a. Lubricate ball joints and inspect for wear and stress.
Frequency: Monthly

6-9 THERMOMETERS.

Thermometers are used to measure temperature at the sensing point.

6-9.1 Dial Thermometers.

Dial thermometers indicate the temperature on the face of a dial.

6-9.1.1 Inspection and Maintenance – Dial Thermometers.

Thermometers are typically bi-metallic or volatile fluid based, and must be periodically inspected.

a. Inspect thermometer for cracked face and proper operational condition. Replace if damaged.
Frequency: Quarterly

b. Check accuracy of thermometer against calibrated master thermometer. Ensure process and calibrated master thermometers are reading the same heat source. Verify accuracy of thermometer is within ±2% of full scale. Calibrate process thermometer if required.
Frequency: Annually

6-10 PIPE AND EQUIPMENT COATINGS.

This section includes information related to periodic inspection of external coating systems that are typically applied to DoD piping systems.

6-10.1 Aboveground Piping and Equipment Coatings.

A three coat system (primer, intermediate, and top coat) is the primary protective coating system for aboveground piping. The primer and intermediate coats should be a two component epoxy-polyamide system and the topcoat should be a UV resistant polyurethane. Refer to UFGS 33 52 43.13 or UFGS 09 97 13.27 for current aboveground exterior pipe coating system requirements. Do not paint stainless steel, aluminum or galvanized surfaces.

6-10.1.1 Inspection and Maintenance – Aboveground Piping and Equipment Coatings.

Coating repairs of aboveground piping, piping in pits, equipment, pipe supports, filter separators, and miscellaneous metal should match color of finish and reflectivity of existing, consistent with the Installation’s Architectural Standards.

Maintenance personnel must determine existing external coating type prior to repairs to ensure proper adhesion. It is recommended to protect surrounding areas of repair by squaring off with masking tape. Ensure the area to be repaired is clean and dry. All surface corrosion or damage coating must be removed per coating manufacturer’s requirements. In addition, abrade immediate area surrounding repair to feathered edge to allow proper adhesion of repair coating layers. Remove all dust particles by brush or vacuum and clean surface with appropriate solvents to prepare area for coating system. Apply coating system in accordance with manufacturer’s instructions. The protective coatings section of UFGS 09 97 13.27 includes coating information and application instructions that should be followed.

a. Visually inspect coatings for signs of deterioration, corrosion or damage. Repair damaged or deteriorated coatings.
Frequency: Quarterly

6-10.2 Underground Piping Coating Repairs.

\1

a. Three coating types have recently been used for underground piping: 2-layer extruded polyolefin coating over soft adhesive per AWWA C215, fusion-bonded epoxy coatings per AWWA C213, and Federal Specification L-C-530C. Refer to UFGS 33 52 80 or UFGS 33 52 43.13 for current underground exterior coating requirements.

b. Maintenance personnel must determine existing coating type prior to repairs to ensure proper adhesion and longevity of repairs. Polyolefin (AWWAC215), fusion-bonded epoxy (AWWA C213), and Federal Specification L-C-530C are common, but other types of coatings may be encountered. Some older pipes may be coated with a coal tar asbestos wrap. Ensure the coating is identified and that proper procedures are used to handle the hazard level associated with the identified coating. Contact the military service-specific SME with questions regarding coating types and appropriate repair methods.

c. In all cases, surfaces must be clean, dry, grease-free, dust-free, free of rust and damaged coatings and prepared in accordance with repair method chosen and the manufacturer’s published procedures. UFGS 33 52 80 includes additional coating information and application instructions that should be followed.

/1/

6-10.2.1 Two-Layer Extruded Polyolefin Coating Repairs.

The following repair methods must be used for two-layer extruded polyolefin coating:

- Coal Tar Enamel per AWWA C203, Type II enamel, Type III outer wrap.
- Coal Tar Tape per AWWA C203.
- Cold Applied Tape per AWWA C209.
- Petroleum or Petroleum Wax Tape Coating per AWWA C217.
- Heat Shrink Sleeve per AWWA C216.

The military service-specific SME must determine the best repair method for the type of repair required. Weld beads must be covered with one wrap of tape prior to spiral wrapping. Fittings must be wrapped spirally beginning with one complete wrap three inches back from each edge of the coating. For pipe less than 4-inches (100 mm) in diameter, one layer half-lapped must be used. For pipe 4-inches (100 mm) and larger in diameter, two layers half-lapped must be used with the second layer wrapped opposite hand of the first.

6-10.2.2 Fusion-Bonded Epoxy Repairs.

Fusion-bonded epoxy must be repaired with a fusion-bonded epoxy coating per NACE Recommended Practice (RP) 0402 to match existing coating or Liquid-Epoxy Coating System per AWWA C210.

Maintenance personnel must coordinate with military service-specific SME to determine best repair method for the type of repair required.

6-10.2.3 Federal Specification L-C-530C Coating Repairs.

Coatings that meet the requirements of Federal Specification L-C-530C have been used on underground fuel piping. The coating is no longer covered by a UFGS specification but it has continued to be used on a case by case basis. Repair of these coatings must be in accordance with manufacturer's instructions.

6-10.3 Internal Carbon Steel Pipe Coatings.

Epoxy coatings systems meeting the requirements of MIL-PRF-4556 (two component epoxy system) or AWWA C213 (fusion bonded epoxy system) are sometimes used on the interior of carbon steel piping used for the transport of petroleum fuels. These coatings are applied to the piping at the factory and are not typically repaired in the field. The inside edges of each pipe segment is left uncoated 1 to 1.5-inches (25 to 40 mm) from each end to prevent coating damage during welding operations. The inside areas of the welds are left uncoated after welding is complete.

6-11 UNDERGROUND FUEL PITS.

Fuel pits such as low point drain pits, high point vent pits, lateral control valve pits, isolation valve pits, and hydrant pits are included in many fueling systems.

6-11.1 Isolation Valve Pits.

Isolation valve pits are buried fiberglass or concrete pits with a rolling or hinged cover designed in accordance with the DoD Standard Design AW 78-24-28 for isolation valves installed in non-traffic areas on underground petroleum fuel piping systems. Valve pits and valve operators are typically designed so that valves can be operated by personnel without confined space entry.

6-11.1.1 Inspection and Maintenance – Isolation Valve Pits.

a. Isolation valve pits should be inspected to ensure that the pits are dry and clean and that all components within the pit are clean and in good working order. Maintain seals and boot seals as appropriate. Obtain necessary confined space entry permits before entry. Inspect the pit for signs of fuel or water. Water or fuel should be removed from the pit as soon as possible and the source of water infiltration or fuel leak determined.
Frequency: Monthly, or more often based on local conditions.

b. Check for cracks in concrete and check piping penetrations through pit wall or bottom to ensure that mechanical seals and boot seals are in good working condition and are allowing no seepage of water into the pits. Make note of cracks in concrete and schedule maintenance as necessary. Check for fuel leaks at all flanged and other piping connections. Check for rusted or deteriorated ladders or grating platforms that might make entry unsafe. Check pit lids for proper sealing. Check rolling pit covers for ease of operation and signs of deterioration, damage or corrosion. Make sure required locks are in place and locking mechanisms are not broken.
Frequency: Monthly, or more often based on local conditions.

6-11.2 Hydrant Fuel Pits.

Hydrant fuel pits are located close to the aircraft parking positions. Hydrant fuel pits contain fuel block valves, pressure gauges, and hydrant control valves. The pits are equipped with counter-weighted lids. A sump out connection is provided to sump collected water or fuel from the pit. Grating installed in the pit provides access to valves and is removable to allow close inspecting of pit pipe penetration seals and general maintenance.

6-11.2.1 Inspection and Maintenance – Hydrant Fuel Pits.

a. Hydrant fuel pits must be inspected to ensure that they are dry and clean and that all fueling components within the pit are clean and in good working order. Obtain necessary confined space entry permits before entry. Inspect the pit for fuel or water. Fuel or water found in the pit must be sumped out as soon as possible.
Frequency: Monthly, or more often based on local conditions.

b. Check pipe penetrations through pit walls or bottom to ensure that mechanical and boot seals are in good working condition and are allowing no water seepage into the pits.
Frequency: Monthly

c. Check for fuel leaks at all flanged and other piping connections.
Frequency: Monthly Check pipe penetrations through pit walls or bottom to ensure that mechanical and boot seals are in good working condition

and are allowing no water seepage into the pits.
Frequency: Monthly

d. Check pit lids to ensure that seals are in good working order and are preventing water entry into the pits.
Frequency: Monthly, or more often based on local conditions.

e. Inspect hydrant fuel pit bonding cables for corrosion and ensure electrical continuity between bonded equipment.
Frequency: Monthly

6-11.3 High Point Vent Pits.

High point vent pits are located throughout fueling systems. High point vents are used to vent air from fuel lines during start-up and operation.

6-11.3.1 Inspection and Maintenance – High Point Vent Pits.

a. Inspect high point vent pits to ensure they are dry and free of water and other debris and that pit and piping components are leak free and in good working condition. Inspect the pit for fuel or water. Fuel or water found in the pit must be sumped out as soon as possible
Frequency: Monthly

b. Check pipe penetrations through pit walls or bottom to ensure that mechanical and boot seals are in good working condition and are allowing no water seepage into the pits.
Frequency: Monthly

c. Check pit lid seals for deterioration and replace as necessary.
Frequency: Monthly

d. Ensure that high point vent valves, quick-disconnect couplings or pit lids are lockable and that locking mechanisms are in good working order.
Frequency: Monthly

e. Inspect high point vent pit bonding cables for corrosion and ensure electrical continuity between bonded equipment.
Frequency: Monthly

6-11.4 Low Point Drain Pits.

Low point drain pits are located throughout fueling systems. Low point drains are used to sump fuel piping where water in the fuel may settle and for draining the pipeline.

6-11.4.1 Inspection and Maintenance – Low Point Drain Pits.

a. Inspect low point drain pits to ensure they are dry and free of water and other debris and that all pit and piping components are leak free and in

good working condition. Inspect the pit for fuel or water. Fuel or water found in the pit must be sumped out as soon as possible.
Frequency: Monthly

b. Check pipe penetrations through pit wall or bottom to ensure that mechanical seals and boot seals are in good working condition and are allowing no water seepage into the pits.
Frequency: Monthly

c. Check pit lid seals for deterioration and replace as necessary.
Frequency: Monthly

d. Ensure that low point vent valves, quick-disconnect couplings or pit lids are lockable and that locking mechanisms are in good working order.
Frequency: Monthly

e. Inspect low point drain pit bonding cables for corrosion and ensure electrical continuity between bonded equipment.
Frequency: Monthly

6-11.5 Lateral Control Pits.

Lateral control pits are buried fiberglass or concrete pits with rolling or hinged covers. Valve operators installed in lateral control pits are typically designed so that the valves can be operated by personnel without confined space entry. Lateral control pits may include isolation valves and hydrant system automatic control valves.

6-11.5.1 Inspection and Maintenance – Lateral Control Pits.

a. Inspect lateral control pits to ensure they are dry and free of water and other debris and that all pit and piping components are leak free and in good working condition. Inspect the pit for fuel or water. Fuel or water found in the pit must be sumped out as soon as possible.
Frequency: Monthly

b. Check pipe penetrations through pit wall or bottom to ensure that mechanical seals and boot seals are in good working condition and are allowing no water seepage into the pit.
Frequency: Monthly

c. Check pit lid seals for deterioration and replace as necessary.
Frequency: Monthly

d. Check for fuel leaks at all flanged and other piping connections.
Frequency: Monthly

e. Ensure that pit lids are lockable and that locking mechanisms are in good working order.
Frequency: Monthly

f. Inspect lateral control pit bonding cables for corrosion and ensure electrical continuity between bonded equipment.
Frequency: Monthly

6-12 MINOR PIPING SYSTEMS.

6-12.1 Low Point Drains.

Water and other fuel contaminants that are not removed by filtration tend to end up at low points in a fuel system. Low point drains are provided at low points in a fuel system to allow water and contaminants to be removed.

6-12.1.1 Inspection and Maintenance – Low Point Drains.

a. Visually inspect low point drains. Ensure that quick-disconnect dust caps are in place and that valves are locked closed.
Frequency: Weekly

b. Operate low point drains when system is not under operating pressure. If there is an absence of sufficient line pressure close the low point drain and pressurize the system. Once adequate pressure is available, continue draining until the piping fuel sample is clear and bright with no visible water.
Frequency: Monthly or as required by local conditions. Verify low point drains are closed after maintenance.

6-12.2 High Point Vents.

High point vents are provided in fuel systems to provide a means of venting trapped air.

6-12.2.1 Inspection and Maintenance – High Point Vents.

a. Inspect high point vents. If fuel leaks are observed they should be repaired as soon as possible. Ensure that quick-disconnect dust caps are in place and that high point vent valves are locked.
Frequency: Weekly

6-12.3 Sight Flow Indicators.

Sight flow indicators are used to visually confirm that fuel is flowing through a system. These devices use a wheel installed in the fluid stream behind a transparent glass or plastic film. Flow is indicated when the wheel turns.

6-12.3.1 Inspection and Maintenance - Sight Flow Indicators.

a. Verify there are no leaks around pipe connection fittings and glass seals. Also check glass for indications of cracks.
Frequency: Daily or **at each use**

6-13 ELECTRONIC RELEASE DETECTION MONITORING.

6-13.1 General Inspection of Release Detection Systems.

Piping release detection systems are designed to quickly detect fuel leaks from concealed and underground portions of fueling systems. A licensed and/or certified technician is required to troubleshoot or inspect leak/release sensors for operation. If an issue is suspected, appropriate military service-specific SCP or Installation Environmental Office personnel should be contacted for support. Refer to SPCC plan for further direction on who to contact.

Host nation, state, and local agencies may have additional design, inspection, and maintenance requirements that may be more stringent than DoD or Federal guidance. Facility operators and maintainers must be familiar with the site’s SPCC plan in order to comply with all inspection and recordkeeping requirements

6-13.1.1 Rope Sensor Systems.

Rope sensors are installed along the length of underground piping, either within the interstice of double-wall piping (common) or direct buried (uncommon). Rope sensors can be installed in service pits and sumps as well. This system uses a discrete sensor built along the length of a rope. Rope sensors send a signal to a monitoring panel indicating the location of the detected liquid within a few feet. Rope sensors are sensitive to the presence of any petroleum based product and care should be taken when handling the rope sensor. A licensed and/or certified technician is required to troubleshoot or inspect rope sensors for operation.

6-13.1.1.1 Inspection and Maintenance - Rope Detector Systems.

a. Ensure the monitoring panel associated with the rope sensor(s) is powered on and no alarms are present.
Frequency: Daily

b. Test rope sensor system and ensure it is functional.
Frequency: Annually

6-13.1.2 Point Sensor – Dry.

Dry point sensors are installed at the lowest point within the space between the fueling system and secondary barrier. Dry point sensors send a signal to a monitoring panel indicating liquid detection. Dry point sensors may include float switches, or electrical resistor switches. A licensed and/or certified technician is required to troubleshoot or inspect dry point sensors for correct operation.

In double-wall piping systems these sensors are placed in the low points of the piping and continuously monitor for the presence of fuel in the annulus of the double-wall pipe.

6-13.1.2.1 Inspection and Maintenance - Point Sensor – Dry.

a. Ensure the monitoring panel associated with the point sensor(s) is powered on and no alarms are present.
Frequency: Daily

b. Ensure monitoring space is clear and free of debris and liquid.
Frequency: Monthly

c. Test sensor and ensure it is functional.
Frequency: Annually

6-14 VISUAL RELEASE DETECTION MONITORING.

6-14.1 Visual Monitoring.

Release detection method utilizing inspection ports to visually inspect for the presence of liquids.

6-14.1.1 Inspection and Maintenance – Visual Monitoring.

a. Visually inspect ports for signs of leaks. Remove debris or foreign objects obstructing the view.
Frequency: Weekly

This Page Intentionally Left Blank

CHAPTER 7 GROUND VEHICLE FUEL FACILITIES

7-1 GENERAL.

This chapter contains inspection and maintenance information associated with ground vehicle fuel systems.

7-2 DISPENSER NOZZLES.

Dispenser nozzles that meet requirements of **1**\UFGS 33 57 55/**1**/are designed to automatically close when the dispenser nozzle handle is released. When the dispenser nozzle vacuum sensing port is blocked by petroleum fuel it will cause the internal poppet valve to close. This feature helps prevent overfilling vehicle tanks. Dispenser nozzles can also be equipped with automatic nozzle shut-off clips to allow the operator to latch dispenser nozzles open during fuel dispensing. When the dispenser nozzle senses fuel at the vacuum sensing port, the shut-off clip disengages and the nozzle closes. Do not remove automatic shut-off clips on ground vehicle fuel dispenser nozzles. Dispenser nozzles should have splash guards in case of overfill.

Figure 7-1 Dispenser Nozzle

7-2.1 Inspection and Maintenance – Dispenser Nozzles.

a. Inspect dispenser nozzle spout. Ensure it is tight, round, has no cracks, or excessive wear. Inspect automatic shutoff hole. Ensure the hole is open and free of obstructions. Inspect nozzle hold-open latch. Ensure the latch is straight, moves freely, and the return spring operates correctly. Inspect body of nozzle. Ensure the body is in good condition and that the valve stem is clean and free of fuel. Inspect the nozzle to hose connection and ensure it is clean and free of fuel.
Frequency: Daily

b. **1**\ /**1**/

c. Test automatic shutoff feature and ensure it is operating properly. Test automatic shutoff at all nozzle hold-open latch positions.
Frequency: Annually

7-3 DISPENSER HOSES.

Dispenser hoses that meet requirements of **1**\UFGS 33 57 55/**1/**are designed to transfer petroleum fuel from dispensers to motor vehicle fuel tanks. Hoses must be reinforced with metallic mesh that prevents kinks and collapse. Reinforcement mesh also provides a conductive path to direct static charges to ground. The outer surface of hoses must be resistant to abrasion, cuts, and degradation from the surrounding environment. No more than 6 feet (1.8 meters) of the dispenser hose may touch the ground. Hose retractors may be installed to elevate long dispenser hoses. Dispenser hoses with a working pressure under 20 psi (138 kPa) do not require annual pressure testing.

Dispenser systems equipped for Stage II vapor recovery require coaxial hoses which are used to provide a path for reclaimed fuel vapors to return to the petroleum fuel storage tank.

7-3.1 Inspection and Maintenance – Dispenser Hoses.

a. Inspect dispenser hoses and hose whips for gouges, cuts, blisters, or outside wear that may lead to rupture during use. Replace hose or hose whips that show signs of wear. Inspect connection points of hoses and hose whips to the dispenser, breakaways, swivels, and the nozzle and ensure the connection points are clean and free of fuel.
Frequency: Daily

7-4 BREAKAWAYS.

Fuel hose breakaways that meet requirements **1**\UFGS 33 57 55/**1**/are used to connect dispenser hoses to dispensing units. Breakaways are designed to disconnect hoses from dispensers if hoses are subjected to strong tensile stresses such as strong pulling forces. Breakaways are double bonnet systems designed to close off fuel flow.

7-4.1 Inspection and Maintenance – Breakaways.

a. Inspect breakaways for loose connections and signs of damage to poppets. Ensure breakaways are clean and free of fuel.
Frequency: Daily

b. Inspect breakaway for an expiration date established by the manufacturer. Breakaways must be replaced before the indicated expiration date.
Frequency: Monthly

7-5 SWIVELS.

Fuel hose swivels are installed between dispenser nozzles and hoses. They provide flexibility and reduce strain on hoses by allowing nozzles to rotate around the swivel. They also make it easier for operators to handle hoses during fuel dispensing.

7-5.1 Inspection and Maintenance – Swivels.

a. Inspect swivel for loose connections and signs of damage. Ensure swivel rotates easily and is clean and free of fuel.
Frequency: Daily

b. Inspect swivel for expiration date established by manufacturer. Swivels must be replaced before the indicated expiration date.
Frequency: Monthly

7-6 HOSE RETRIEVER.

Hose retrievers support the hose and limit contact of the hose with the ground.

7-6.1 Inspection and Maintenance – Hose Retriever

a. Test hose retriever and ensure it is operating correctly and supporting the hose.
Frequency: Monthly

7-7 DISPENSER CABINET.

Dispenser cabinets enclose the inner components of fuel dispensers. The cabinets protect the inner components from the elements and protect the connection points of the underground supply piping.

7-7.1 Inspection and Maintenance – Dispenser Cabinet.

a. Inspect outside of cabinet and ensure it is free of damage. Inspect for fuel stains on the concrete island around the cabinet and on the outside of the cabinet. Ensure the cabinet is free of dirt and fuel.
Frequency: Monthly

b. Open both sides of the cabinet and inspect the inside of the cabinet. Ensure the inside of the cabinet and all of the components inside the cabinet are clean and free of fuel.
Frequency: Monthly

c. Ensure door panels and locks operate easily. Inspect anchor bolts of cabinet to dispenser island and ensure the bolts are in good condition.
Frequency: Annually

7-8 DISPENSER METERS.

Dispenser meters allow operators to monitor the amount of fuel dispensed into a given vehicle fuel tank. Intelligent dispenser meters can reconcile all fuel dispensed against the operating storage tank level readings to verify usage. Meters are able to constantly recalibrate due to changes in temperature that affect the volumetric flow rate.

7-8.1 Inspection and Maintenance – Dispenser Meters.

a. Inspect meter and ensure meter is clean and free of fuel. Ensure calibration mechanism is sealed.
Frequency: Monthly

b. Since moving parts inside meters are subject to wear, periodic calibration is necessary. Meters must be recalibrated utilizing a certified 5 gallon (20 liter) prover can or other approved method. Meters are considered satisfactory for further operation when the error does not exceed ±0.2% of actual quantity delivered.
Frequency: Annually

7-9 DISPENSER FILTERS.

Dispenser filters that meet requirements of **1**\UFGS 33 57 55/**1**/are used to collect particulates in fuel systems. **1**\ Depending on the fuel type different filter strategies may be recommended. Refer to UFC 3-460-01 for filter strategies for each fuel type**.** /**1**/

7-9.1 Inspection and Maintenance – Dispenser Filters.

a. Inspect filter and ensure filter is clean and free of fuel and that filter is labeled with a legible installation date.
Frequency: Monthly

b. Replace dispenser filters annually or when a change in flow rate is noted.
Frequency: Annually or as needed

7-10 DISPENSER STRAINERS.

Dispenser strainers are designed to capture particulates and protect dispenser pumps and meters in self-contained units or meters in remote units.

7-10.1 Inspection and Maintenance – Dispenser Strainers

a. Inspect and clean strainers. Inspect strainer cover gasket for cracks, distortion, and dry rot. If breaks are detected in strainer mesh, replace the strainer.
Frequency: Annually

7-11 GROUND VEHICLE FUEL PIPING.

Underground lines for ground vehicle petroleum fuel products must be constructed in accordance with UFC 3-460-01 and 40 CFR Part 280.

In addition to 40 CFR Part 280, host nation, state, and local regulations may have additional design, inspection, and maintenance requirements that may be more stringent than DoD or Federal guidance. Facility operators and maintainers must be familiar with the site's SPCC plan in order to comply with all inspection and recordkeeping requirements.

7-11.1 Inspection and Maintenance – Ground Vehicle Fuel Piping.

a. Visually inspect aboveground lines for leaks. Shut down systems that are found with leaks and repair.
Frequency: Daily

b. Visually inspect leak detection systems installed on underground piping. Inspections include line leak detectors and leak detection sensors installed in transition sumps and dispenser sumps. Perform leak testing on pressurized underground piping with installed leak detection equipment and record results.
Frequency: Monthly

c. Test leak detection systems installed on underground piping used for ground vehicle petroleum fuel products. Underground leak detection systems include discrete detection sensors installed in transition and dispenser sumps, and line leak detectors installed at the outlet of pumps used to supply pressurized liquid petroleum fuel to underground lines. Repair faulty components. Execution of this work may require state certification or license.
Frequency: Annually

d. Conduct service station aboveground piping annual test as outlined in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria. Execution of this work may require state certification or license.
Frequency: Annually

e. Conduct service station underground piping annual test outlined in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria. Execution of this work may require state certification or license.
Frequency: Annually

f. Refer to Section 2.7 Signage and Markings for inspection and maintenance requirements of ground vehicle petroleum fuel pipe markings.

g. Refer to Section 6-10.1 Aboveground Piping and Equipment Coatings for inspection and maintenance requirements of ground vehicle petroleum fuel pipe coatings.

7-12 EMERGENCY SHUTOFF VALVES (SHEAR VALVES).

Emergency shutoff valves that meet the requirements of **1**\ UFGS 33 57 55 /**1**/ are located at the base of ground vehicle fuel dispensers and are designed to close if the dispenser is struck or exposed to a fire. Emergency shutoff valves are securely mounted to stabilizer bars installed in the containment sumps mounted under dispensers. The valve is designed to break at a weak point in the body of the valve if the dispenser is struck and dislodged. The valve is also designed to close if the valve is subjected to shock of an impact to the dispenser. In addition, the valve is equipped with a fusible link that will melt in the event of a fire and cause the valve to close.

Figure 7-2 Emergency Shutoff Valve

7-12.1 Inspection and Maintenance – Emergency Shutoff Valves (Shear Valves).

a. Inspect stabilizer bar to ensure that it is securely mounted below the base of the dispenser. Inspect the mounting bolts that secure the emergency shutoff valve to the stabilizer bar.
Frequency: Monthly

b. Inspect fusible link and ensure it is not obstructed. Ensure valve body is clean and free of fuel.
Frequency: Monthly

c. Inspect mechanical links of the valve for correct operation. Conduct test of valve to ensure it operates correctly. Execution of this work may require state certification or license.
Frequency: Annually

7-13 DISPENSER SUMPS.

Dispenser sumps are used to protect and provide access to valves and fuel pipe installed below dispensers.

7-13.1 Inspection and Maintenance – Dispenser Sumps.

a. Inspect for signs of water, fuel, trash, and debris inside sumps. Remove and properly dispose of collected water, fuel, trash, and debris. Visually inspect penetration fittings. If fuel or water is detected investigate the source and repair.
Frequency: Monthly, or more often based on local conditions.

b. Inspect sump pipe transition fittings for tears, cracks, or other signs of deterioration. Check hose clamp seals to ensure they are securely tightened.
Frequency: Quarterly

c. Test dispenser sumps and ensure they are liquid tight by using vacuum, pressure, or liquid testing in accordance with 40 CFR 280, Section 43.
Frequency: Every three years

7-14 TRANSITION SUMPS.

Transition sumps are used to protect piping as it transitions from aboveground to below ground. In many cases the piping will change configuration as it transitions from aboveground pipe to underground pipe.

7-14.1 Inspection and Maintenance – Transition Sumps.

a. Inspect for signs of water, fuel, trash, and debris inside sumps. Remove and properly dispose of collected water, fuel, trash, and debris. Visually inspect penetration fittings. If fuel or water is detected investigate the source and repair.
Frequency: Monthly, or more often based on local conditions.

b. Inspect sump pipe transition fittings for tears, cracks, or other signs of deterioration. Check hose clamp seals to ensure they are securely tightened.
Frequency: Quarterly

c. Test sumps and ensure they are liquid tight by using vacuum, pressure, or liquid testing in accordance with 40 CFR 280, Section 43.
Frequency: Every three years

7-15 DISPENSER PUMPS.

Dispenser pumps are either installed as an integral unit to the fuel dispenser or as a remote pump. Integral pumps are typically sliding vane pumps installed in the base of the dispenser unit. Remote pumps are typically submerged turbine pumps mounted on petroleum fuel storage tanks.

7-15.1 Remote Dispenser Pumps.

Fuel dispensers in remote pump systems do not house pumps. Remote dispenser pumps are typically tank mounted submerged turbine pumps. The manufacturer's instructions for installation, operation, and maintenance will further describe pumping unit and parts requiring periodic inspection and maintenance.

7-15.1.1 Inspection and Maintenance – Remote Dispenser Pumps.

a. Refer to Section 7-19.1.2 Automatic Line Leak Detector for maintenance and inspection requirements of automatic line leak detectors installed on submersible turbine pumps.

b. Refer to Section 3-8.1.3 Vertical Turbine/Submerged Turbine Pumps for inspection and maintenance requirements of remote dispenser pumps.

7-15.2 Self-Contained Dispenser Pumps.

Self-contained dispenser pumps are typically belt-driven, sliding vane type positive displacement pumps mounted within the dispenser housing. The pumps draw fuel to the dispenser by creating suction on the fuel line attached to the petroleum fuel storage tank.

7-15.2.1 Inspection and Maintenance – Self-Contained Dispenser Pumps.

a. Inspect self-contained dispenser pump v-belt drives for proper tension and excess wear. Replace belt as recommended by manufacturer.
Frequency: Monthly

b. Inspect pump body. Ensure pump body is clean and free of fuel. Inspect air eliminator. Ensure air eliminator is clean and free of fuel and that the vent tube is not obstructed.
Frequency: Monthly

7-16 EFSO SYSTEMS.

Emergency Fuel Shut-Off (EFSO) systems disable power to dispensers at service stations. Typically military service stations are unattended and require keys or cards to operate the dispensers. EFSO buttons to deactivate the dispensers are typically installed in close proximity to dispensers and at a distance of between 20 and 100 feet (6 to 30 meters) away from dispensers. EFSO systems can be activated by pushing one of the EFSO buttons.

7-16.1 Inspection and Maintenance – EFSO Systems.

a. Check the operation of the EFSO system by activating the fueling system and then pressing each of the EFSO buttons. Ensure that each button disables power to all of the dispensers and fuel pumps installed at the service station.
Frequency: Quarterly

b. Refer to Section 2-7 Signage and Markings for inspection and maintenance requirements of EFSO pushbutton signs.

7-17 VAPOR RECOVERY.

Vapor recovery at service stations is typically classified as Stage I or Stage II. These types of systems are required on fuels with high vapor pressures in many states. For military service station applications this is usually limited to Motor Gasoline (MOGAS).

7-17.1 Stage I Vapor Recovery.

Stage I Vapor Recovery is used for bulk receipt and issue operations and typically includes a vapor balance pipe. The vapor balance pipe is used to connect the head space of the fuel storage tank to the head space of the fuel truck. This allows vapors to move between the fuel storage tank and the fuel truck during receipt and issue operations.

7-17.1.1 Inspection and Maintenance - Stage I Vapor Recovery.

a. Inspect vapor recovery hoses for gouges, cuts or outside wear that may result in vapor leaks.
Frequency: Daily or before each use

b. Inspect caps and camlock fittings for tightness and leaks.
Frequency: Quarterly

c. Refer to Section 7-11 Ground Vehicle Fuel Piping for inspection and maintenance requirements of Stage I vapor recovery piping.

7-17.2 Stage II Vapor Recovery.

Stage II vapor recovery includes the collection of vapors at the dispenser nozzle and may also include the collection of vapors developed from normal tank operations. In most cases these systems include vacuum pumps mounted in dispensers that collect and transfer vapors to petroleum fuel storage tanks. Stage II vapor recovery is no longer a Federal requirement but may still be required by some states. Existing Stage II vapor recovery systems may be phased out in accordance with state regulations. Stage II vapor recovery systems that have not yet been decommissioned (whether required or not) must still be maintained and inspected in accordance with state regulations.

7-17.2.1 Inspection and Maintenance - Stage II Vapor Recovery.

There are several approved vendors for Stage II Vapor Recovery systems. Consult the manufacturer's operation and maintenance manual that was provided with the system for periodic maintenance requirements.

7-17.3 Vapor Burners.

Vapor burners are used to combust vapors from tanks that would otherwise be vented to atmosphere.

7-17.3.1 Inspection and Maintenance - Vapor Burners.

Consult the manufacturer's operation and maintenance manual that was provided with the system for specific periodic maintenance requirements of the unit that is installed.

a. Inspect vapor burners to ensure that the pilot flame system is operating properly. Fans, duct work, and dampeners must also be inspected to ensure proper air to fuel vapor mixtures allow for complete burns.
Frequency: Quarterly

b. Inspect burner knock out pots for condensed fuel vapors and water if equipped.
Frequency: Quarterly

c. Inspect thermowells and gas detection monitors for operability.
Frequency: Quarterly

7-18 TACTICAL REFUELER LOADING.

Tactical refueler loading operations at military service stations are similar to petroleum fuel truck issue systems. Refer to Section 3-5.1 Truck Issue for inspection and maintenance requirements of tactical refueler loading equipment.

7-19 ELECTRONIC RELEASE DETECTION MONITORING.

7-19.1 General Inspection of Release Detection Systems.

Release detection systems are designed to quickly detect fuel leaks from concealed and underground portions of fueling systems. A licensed and/or certified technician is required to troubleshoot or inspect leak/release sensors for operation. If an issue is suspected, appropriate military service-specific SCP or Installation Environmental Office personnel should be contacted for support. Refer to Installation SPCC plan for further direction on who to contact.

7-19.1.1 Point Sensor – Dry.

Dry point sensors are installed at the lowest point within the space between the fueling system and secondary barrier. Dry point sensors send a signal to a monitoring panel indicating liquid detection. Dry point sensors may include float switches or electrical resistor switches. A licensed and/or certified technician is required to troubleshoot or inspect dry point sensors for operation.

These sensors are placed in the low points of the dispenser sumps and fuel pipe transition sumps and continuously monitor for the presence of fuel or water in the sumps.

7-19.1.1.1 Inspection and Maintenance - Point Sensor – Dry.

a. Ensure the monitoring panel associated with the point sensor(s) is powered on and no alarms are present.
Frequency: Daily

b. Ensure monitoring space is clear and free of debris and liquid.
Frequency: Monthly

c. Test sensor and ensure it is functional.
Frequency: Annually

7-19.1.2 Automatic Line Leak Detector.

Automatic line leak detector systems are used on underground pressurized piping to alert the operator to the presence of a leak by restricting or shutting off the flow through the piping or visual alarm. Automatic line leak detectors are commonly installed on submersible turbine pumps and less commonly installed remotely on other pump types.

7-19.1.2.1 Inspection and Maintenance – Automatic Line Leak Detector.

a. Ensure the monitoring panel associated with the detector(s) is powered on and no alarms are present.
Frequency: Daily

b. Simulate a 3 gallons per hour leak at 10 pounds per square inch; the automatic line leak detector must activate within one hour. A licensed and/or certified technician is required to, test, troubleshoot, or calibrate for operation.
Frequency: Annually

7-20 VISUAL RELEASE DETECTION MONITORING.

7-20.1 Visual Monitoring.

Release detection method utilizing inspection ports to visually inspect for the presence of liquids.

7-20.1.1 Inspection and Maintenance – Visual Monitoring.

a. Visually inspect at inspection ports for signs of leaks. Remove debris or foreign objects obstructing the view.
Frequency: Weekly

CHAPTER 8 PETROLEUM STORAGE TANKS

8-1 GENERAL INFORMATION.

\1

a. This chapter includes information on inspection and maintenance of petroleum fuel storage tanks and associated equipment for the purpose of maintaining mechanical and operational integrity.

b. Commercial codes API 653 and STI SP001 have been used to determine baseline inspection requirements for DoD-owned petroleum fuel tanks. API 653 has been used for field-erected tanks and STI SP001 has been used for shop-fabricated tanks. In some cases API 653 and STI SP001 can be applied to field erected tanks. In cases where API 653 or STI SP001 could be applied, the option to use either protocol has been provided. After a tank's inspection protocol has been set, it should continue following that inspection protocol unless the change is approved by the military service-specific SCP or SME. Contact the military service-specific SCP or SME for guidance if unsure of proper inspection protocol.

c. In some cases API 653 and STI SP001 do not directly apply to a type of petroleum fuel tank installed in the field (e.g. cut and cover tanks). In these cases the requirements of the codes must be adjusted to fit the actual tank installed in the field. Contact military service-specific SCP or SME for guidance.

d. Multi-compartment petroleum fuel tanks are a special case of shop-fabricated tank. Each compartment within a multi-compartment tank should be treated as a separate/individual tank, even though they may share components and secondary containment systems.

/1/

8-2 CONTAMINATION PREVENTION.

Petroleum fuel storage tanks are environments where water can promote microbiological growth which can damage inner tank surfaces, restrict flow, damage downstream components, and degrade petroleum fuel product stability. Though water or other debris are inherent to petroleum fuel handing operations, maintaining petroleum fuel tank (e.g., floating roof seals, vent screens) integrity is critical to preventing additional contamination from entering tanks. Water is typically removed via draw off systems or draining directly from petroleum fuel tank sumps.

8-3 TANK SURFACE COATINGS.

Only coating touch-up repair is performed by staff maintenance personnel on petroleum fuel tanks. Coating repair or replacement for an entire petroleum fuel tank is usually performed under contract.

Interior coating systems are programmed for replacement at 20 year intervals. Exterior coatings may fail more rapidly due to weathering and microbial growth. Numerous factors including surface preparation can lead to failure of the coating material. If inspection shows coating is in acceptable condition, the life may be extended past 20 years. There is generally no need to recoat the interior of petroleum fuel tanks unless the coating has failed or a significant change of petroleum fuel service type is planned. The condition of the internal coatings can only be determined during out-of-service internal tank inspections.

8-3.1 External Tank Coating Repairs.

\1

a. The external surfaces of petroleum storage tanks are protected with coatings that meet the requirements of UFGS 09 97 13.27. Existing tanks may be protected by alternative coating systems not listed in UFGS specifications. Questions regarding alternative coatings that are encountered in the field should be directed to the military service-specific SME.

b. Maintenance personnel must determine existing external coating type prior to repairs to ensure proper adhesion. It is recommended to protect surrounding areas of repair by squaring off with masking tape. Ensure the area to be repaired is clean and dry. All surface corrosion or damage coating must be removed per coating manufacturer's requirements. In addition, abrade immediate area surrounding repair to feathered edge to allow proper adhesion of repair coating layers. Remove all dust particles by brush or vacuum and clean surface with appropriate solvents to prepare area for coating system.

c. Application information and instructions provided in UFGS 09 97 13.27 must be strictly adhered to when this type of coating system is applied to the exterior of tanks.

8-3.1.1 Vapor Corrosion Inhibitors.

Vapor Corrosion Inhibitors (VCI) technology has potential. VCIs are acceptable for tanks where the underbottom cathodic protection has failed. The tank's ringwall and liner system must not be compromised, such as drilling thru the concrete and flexible membrane liner, for the injection of the VCI. The amount of VCI must be checked annually to determine if additional VCI is required. VCI is not considered as a permanent repair. The cathodic protection system should be repaired during the tank's next out-of-service inspection. **/1/**

8-3.2 Internal Tank Coating Repairs.

There are two primary coating system types used for tank interiors: low VOC epoxy novolac polysulfide coatings that meet the requirements of UFGS 09 97 13.15, and two component epoxy coatings that meet the requirements of UFGS 09 97 13.17. Existing tanks may be protected by alternative coating systems not listed in UFGS. Questions regarding alternative coatings that are encountered in the field should be directed to the military service-specific SME.

\1
8-3.2.1 Low VOC Epoxy Novolac Polysulfide Interior Coating.
/1/

Epoxy novolac polysulfide interior coating systems are comprised of primer or base coat and top coat that are identical in material except for contrasting colors to allow for identification. When applied correctly, this coating system will last approximately 50 years.

Application information and instructions provided in UFGS 09 97 13.15 must be strictly adhered to when this type of coating system is applied to the interior of tanks.

\1
8-3.2.2 Two Component Epoxy Interior Coating.
/1/

Two component epoxy coating systems are comprised of an epoxy polyamide primer or base coat in accordance with MIL-DTL-24441/29, and epoxy polyamide intermediate and top coats in accordance with MIL-DTL-24441/31. All primer and intermediate coating materials are supplied by one supplier. When applied correctly, this coating system will last approximately 20 years.

Application information and instructions provided in UFGS 09 97 13.17 must be strictly adhered to when this type of coating system is applied to the interior of tanks.

8-4 ABOVEGROUND FIELD-ERECTED TANKS.

\1

a. The majority of the above ground field-erected tanks used for petroleum products are built and/or repaired in accordance with API-650 and DoD Standard Design AW 78-24-27.

b. A baseline internal inspection must be conducted on aboveground field-erected tanks before they are placed into service. The baseline inspection must include floor, shell, and roof wall-thickness measurements. These initial measurements will be used by later inspectors to monitor and evaluate corrosion rates of specific tanks.

c. Military service-specific, host nation, state or local regulations may require additional inspections or increased frequency of inspections of field-erected tanks. The Installation must follow the more stringent of this UFC or military service-specific, host nation, state, or local regulations.

/1/

8-4.1 Inspection and Maintenance – Aboveground Field-Erected Tanks.

a. Visually inspect for evidence of leaks; shell distortions; signs of settlement; corrosion, condition of tank foundation, condition of coating, insulation systems, and appurtenances. Inspection must include all components and equipment located inside the containment area such as piping, pipe supports, containment valves, and product saver tanks. Items noted during the inspection will be documented for follow-up action by an authorized inspector. See Appendix F for the Field-Erected Tank Monthly Inspection Checklist.
Frequency: Monthly

b. Visually inspect **1**\ bottom edge projection (chime) /**1**/ to ringwall sealant. Seal should be maintained in good working order to prevent corrosion of the underside of the tank bottom.
Frequency: Monthly

c. Visually inspect the exterior of the tank for leaks, corrosion, or irregularities such as tilting, settling, or out-of-roundness. Give special attention to seams and anchor bolts. Visual inspection must include all components and equipment located inside the tank containment area such as piping, pipe supports, containment valves, and product saver tanks. Retain records of inspections reports for five years. See Appendix F for the Field-Erected Tank Annual Inspection Checklist.
Frequency: Annually

d. Perform a formal in-service external inspection of the tank in accordance with API 653 or STI SP001 to evaluate the tank for conditions which may affect the operational integrity of the storage tank, including minimum shell thickness measurements. This inspection must be performed by an applicable certified inspector. Inspection must include all components and equipment located inside the tank containment area such as piping, pipe supports, containment valves, and product saver tanks.
Frequency: Every five years or as required by an appropriately certified tank inspector in the previous API 653 or STI SP001 inspection report.

e. Perform an out-of-service API 653 or STI SP001 inspection to evaluate the tank for conditions which may affect the operational integrity of the tank floor, shell, roof and floating roof or pan. API 653 or STI SP001 provides a checklist to be used as part of the assessment. This inspection must be performed by an appropriately certified API 653 or STI SP001 inspector. Inspection must include all components and equipment located inside the tank containment area such as piping, pipe supports, containment valves, and product saver tanks. **1**\ The API 653 or STI SP001 inspector must recommend the date of the next inspection. The inspection interval must be based on the date the Suitability for Service

Letter is issued immediately prior to when the tank is returned to service. Frequency: As recommended by the API 653 or STI SP001 inspector. If there is not a previous recommendation, the inspection must be performed within ten years after the tank was placed into operation. /**1**/

8-4.2 Geodesic Dome Roofs.

Geodesic dome roofs for aboveground vertical petroleum fuel storage tanks are constructed of aluminum and either welded or bolted to the vertical wall of the petroleum tank or wind girder and are self-supporting. Geodesic dome roofs are typically installed on petroleum fuel tanks originally constructed with external floating roofs to reduce infiltration of rainwater into the petroleum fuel tank, to protect the floating roof, seals, and internal coatings from the effects of weather, and to help reduce emissions and fuel odors.

8-4.2.1 Inspection and Repair – Geodesic Dome Roofs.

Internal geodesic dome inspections are most effective when the petroleum fuel in the tank is near or at high level and the floating roof is close to its highest position. Access to an internal floating roof is considered a permit required confined space, therefore all military service-specific safety procedures must be followed.

a. Conduct external inspection of geodesic dome roofs, where accessible, for corrosion of tank-to-shell bolts, gasket connections, visible signs of corrosion, apparent roof leaks, clogging or deterioration of vent screens, and damage to the structure or panels.
Frequency: Monthly

b. Conduct internal inspection of geodesic dome roofs from the floating roof, where accessible, for corrosion of tank-to-shell bolts, gasket connections, visible signs of corrosion, apparent roof leaks, clogging or deterioration of vent screens, and damage to the structure or panels.
Frequency: Annually

8-4.3 Foundations.

Field erected petroleum fuel tanks are generally constructed on a concrete ring wall foundation. In some cases tanks are constructed on a concrete mat foundation. Typically the tank is elevated and the tank containment floor is sloped away from the tank shell.

8-4.3.1 Inspection and Repair – Foundations.

a. Inspect visible components of tank foundations for signs of erosion due to heavy rains, wash-down, etc. and repaired as necessary. Also inspect tank foundations for structural cracks, signs of settlement, spalling, or general deterioration. Remove vegetation found around the tank foundation.
Frequency: Monthly

8-5 SHOP-FABRICATED TANKS.

\1

a. The most common types of shop fabricated tanks for petroleum fuel storage are horizontal cylindrical tanks; however, there are also vertical and rectangular tanks (e.g., Lube Cube® lube oil tanks and ConVault tanks). Shop-fabricated tanks can be constructed with integral secondary containment and fire protection. The most common tanks used for fuel service are described in the sections that follow.

b. A baseline internal inspection must be conducted on shop-fabricated tanks before they are placed into service. The baseline inspection must include, floor, shell, roof, and end wall-thickness measurements as applicable for a specific type of tank. These initial measurements will be used by later inspectors to monitor and evaluate corrosion rates of specific tanks.

c. Military service-specific, host nation, state or local regulations may require additional inspections or increased frequency of inspections of shop-fabricated tanks. The Installation must follow the more stringent of this UFC or military service-specific, host nation, state, or local regulations.

/1/

8-5.1 Aboveground Shop-Fabricated Tanks.

\1

a. UFC 3-460-01 Section 8-4 limits shop-fabricated tank size diameters to 12 feet (3.66 meter) and maximum capacities of 50,000 gallons (190,000 liters). Aboveground single-wall tanks are designed and constructed to meet the requirements of UL 142.

b. Double-wall tanks are designed with a UL 142 compatible inner tank. Fire resistant doubled-walled tanks are equipped with an outer tank design to meet UL 2080. Protected double-walled tanks are equipped with an outer tank designed to meet UL 2085 requirements. Additional considerations and guidance are specified in NFPA 30. NFPA 30A should be consulted for requirements of tanks used to dispense fuel to ground vehicles or watercraft.

c. In general, inspections fall into the categories of internal (first or subsequent), external (periodic or formal), and leak test. Unless more frequent inspection and testing is specified by military service-specific directives, host nation, state or local regulations or certified inspector as a result of the previous inspection, the inspection and testing protocol defined by STI SP001 based on the classification system shown in **1**\ STI SP001 /**1**/ must be used to determine inspection and testing requirements of aboveground shop fabricated tanks.

d. Inspection protocols must be assigned by the military service-specific SCP or SME. Where multiple inspection protocols could be applied, once selected, the initial inspection protocol should not be changed without prior coordination with the military service-specific SCP or SME. Prior inspection history is key to subsequent inspections being able to identify issues. Each tank's inspection protocol should be clearly documented and used as the basis for future projected inspections.

e. When applying STI SP001 formal testing schedules, select the internal inspection option if the tank is physically able to be entered. Otherwise select the leak test option**1**\/**1**/. Only tanks equipped with a manway at least 18 inches wide (455 mm) should be entered.

f. For multi-compartment tanks, the "tank size" is equivalent to the individual compartment that is being inspected.

/**1**/

1\ /**1**/

1\ /**1**/

8-5.1.1 Inspection and Maintenance – Aboveground Shop Fabricated Steel Tank Inspections.

a. Monthly External Inspection (Identified as P in **1**\ STI SP001)/**1**/: Visually inspect for exterior signs of corrosion or coating deterioration. Visually inspect weld seams, tank-to-saddle connections, tank supports, tank anchors, foundation and anchor bolts, overfill valves and alarms, normal vents, emergency vents, leak detection probe or water/petroleum accumulation in the interstice on double-walled tanks, leaking valves, fittings, or components, spill containment systems and release prevention barriers. Leaking valves, fittings or components must be repaired immediately or immediately removed from service and isolated to prevent further discharge. Any irregularities, (e.g., missing valve handles, bolts, nuts, screens) will be assessed for priority and repaired as soon as possible or as required depending on the nature of the defect (see Appendix E for an example of the STI SP001 Standard Monthly Inspection Checklist).
Frequency: Monthly

b. Annual External Inspection (Identified as P in **1**\ STI SP001 /**1**/): A more detailed examination of the tank and appurtenances must be performed on an annual basis (See Appendix E for an example of the STI SP001 Standard Annual Inspection Checklist).
Frequency: Annually

c. Formal External Inspection (Identified as E in **1**\ STI SP001 /**1**/): A formal external inspection as defined in STI SP001 must be conducted by certified STI SP001 inspector.
Frequency: As established by SCP based on tank size and category \1\ as defined in STI SP001. /1/

d. Formal Internal Inspection (Identified as I in **1**\ STI SP001 /**1**/): A formal internal inspection as defined in STI SP001 must be performed by a certified STI SP001 inspector. **1**\ The API 653 or STI SP001 inspector must recommend the date of the next inspection. The inspection interval must be based on the date the Suitability for Service Letter is issued immediately prior to when the tank is returned to service. /**1**/
Frequency: As established by SCP based on tank size and category \1\ as defined in STI SP001. **/1/**

e. Leak Test (Identified as L in **1**\ STI SP001 /**1**/): A leak test as defined in STI SP001 must be performed in accordance with STI SP001.
Frequency: As established by SCP based on tank size and category\1\ as defined in STI SP001. /1/

8-5.2 Self-Diking or Vaulted Tanks.

Self-diking tanks are designed to UL142 can be of either single or double-wall construction and are designed to sit within a fabricated steel containment dike. The dike is designed to contain small spills or the entire tank contents in the event of a major leak or rupture. These tanks usually range in size from 250 to 12,000 gallons (946 to 45,424 liters) but can be larger. NFPA 30 and NFPA 30A have specific criteria that must be met before using this type of tank. Secondary containment dikes may only be opened for draining purposes and performed in accordance with the Installation's SPCC plan. At a minimum, secondary containment drain valves will be monitored during draining, closed and locked after use.

8-5.2.1 Inspection and Maintenance – Self Diking or Vaulted Tank Inspections.

a. Monthly External Inspection (Identified as P in **1**\ STI SP001 /**1**/): Visually inspect for exterior signs of corrosion or coating deterioration. Visually inspect weld seams, tank-to-saddle connections, tank supports, tank anchors, foundation and anchor bolts, overfill valves and alarms, normal vents, emergency vents, leak detection probe or water/petroleum accumulation in the containment area, leaking valves, fittings, or

components. Leaking valves, fittings or components must be repaired immediately or immediately removed from service and isolated to prevent further discharge. Any irregularities, (e.g., missing valve handles, bolts, nuts, screens) will be assessed for priority and repaired as soon as possible or as required depending on the nature of the defect (See Appendix E for an example of the STI SP001 Standard Monthly Inspection Checklist).
Frequency: Monthly

b. Annual External Inspection (Identified as P in **1**\\ STI SP001 /**1**/): A more detailed examination of the tank and appurtenances must be performed annually. (See Appendix E for an example of the STI SP001 Standard Annual Inspection Checklist).
Frequency: Annually

c. Formal External Inspection (Identified as E in **1**\\ STI SP001 /**1**/): A formal external inspection as defined in STI SP001 must be conducted by certified STI SP001 inspector.
Frequency: As established by SCP based on tank size and category \1\ as defined in STI SP001. /1/

d. Formal Internal Inspection (Identified as I in **\1** STI SP001 **/1/**): A formal internal inspection as defined in STI SP001 must be performed by a certified STI SP001 inspector.
Frequency: As established by SCP based on tank size and category \1\ as defined in STI SP001. /1/

e. Leak Test (Identified as L in **1**\\ STI SP001 /**1**/): A leak test as defined in STI SP001 must be performed in accordance with STI SP001.
Frequency: As established by SCP based on tank size and category \1\ as defined in STI SP001. /1/

8-5.3 Rectangular Concrete-Encased Tanks.

Concrete-encased tanks are constructed in accordance with UL 2085 (e.g., ConVault Tanks). The tank by design has an integral secondary containment in the form of a petroleum resistant plastic sheet encased in concrete. The concrete surface is exposed on the exterior of the tank as opposed to a steel shell. These tanks are maintained and inspected in a similar manner as a double-wall or protected steel tanks. Any formal testing of the primary (interior) tank or interstice must be conducted in accordance with manufacturer’s instructions.

8-5.3.1 Inspection and Maintenance – Concrete-Encased Tank Inspections.

a. Monthly External Inspection (Identified as P in **1**\\ STI SP001 /**1**/): Visually inspect tank supports, anchors and anchor bolts, overfill valve and alarms, normal vent, emergency vent, leaking valves, fittings or other components. In addition the exterior concrete must be visually inspected for cracking,

degradation, excessive calcareous deposits or signs of damage. Leaking valves, fittings or components must be repaired immediately or isolated to prevent further discharge. Any other deficiencies or irregularities noted must be repaired as soon as possible or as required depending on the nature of the defect (See Appendix E for an example of the STI SP001 Standard Monthly Inspection Checklist).
Frequency: Monthly

b. Annual External Inspection (Identified as P in **1**\ STI SP001 /**1**/): A more detailed examination of the tank and appurtenances must be performed on an annual basis (See Appendix E for an example of the STI SP001 Standard Annual Inspection Checklist).
Frequency: Annually

c. Formal External Inspection (Identified as E in **1**\ STI SP001 /**1**/): A formal external inspection must be conducted by certified STI SP001 inspector.
Frequency: As established by SCP based on tank size and category \1\ as defined in STI SP001 /1/.

d. Formal Interior Inspection **1**\ STI SP001 /**1**/: A modified formal internal inspection as defined in manufacturer's instructions or STI SP001 must be performed on concrete-encased tanks by a certified STI SP001 inspector if the tank interior is accessible.
Frequency: As established by SCP based on tank size and category \1\ as defined in STI SP001 /1/.

8-5.4 Underground Shop-Fabricated Tanks.

\1

a. UFC 3-460-01 requires tanks to be constructed to meet requirements of NFPA 30 and, if required, NFPA 30A.

b. Underground steel horizontal cylindrical storage tanks are constructed in accordance with UL-58 and conform to environmental requirements of 40 CFR 280.

c. Underground fiberglass horizontal cylindrical storage tanks are constructed in accordance with UL 1316 and also meet requirements of 40 CFR 280.

d. Military service-specific, host nation, state or local regulations may require additional inspections or increased frequency of inspections of shop-fabricated underground tanks. The Installation must follow the more stringent of this UFC or military service-specific, Host

e. Nation, state, or local regulations.

/1/

8-5.4.1 Single-walled Underground Shop-Fabricated Tanks.

\1

a. Underground shop-fabricated tanks for fuel and oil service installed or replaced after April 11, 2016 must be secondarily contained and use interstitial monitoring in accordance with 40 CFR 280 Section 43. The use of existing single-walled tanks that have been upgraded and are maintained in accordance with 40 CFR 280 Section 21 Upgrading of Existing UST Systems is allowed to continue.

b. In general, inspections fall into the categories of internal, external (monthly and annual), and tightness test. Unless more frequent inspection and testing is specified by military service-specific directives, host nation, state or local regulations or certified inspector as a result of the previous inspection, the inspection and testing protocol defined in \1\ Table 8-1 /1/ must be used to determine inspection and testing requirements of single-walled underground shop fabricated tanks.

c. Strong consideration should be given to the replacement of single-walled underground tanks that are over 30 years old with double-walled tanks equipped with interstitial monitoring that meet the requirements of 40 CFR 280 Section 43.

/1/

\1\

Table 8-1 /1/ Single-walled Underground Shop Fabricated Tank Inspection and Testing Schedules*

Tank Size [1] (Gallons)	Release Detection Type	Steel with Cathodic Protection[2]	Fiberglass or Steel with Interior Lining[3]	Steel with Cathodic Protection and Interior Lining[2,3]	Aviation Fuel Tank
111 - 1000	RD-1	P	P	P	P
1001 - 50,000	RD-2	I(10), P	I(INT-1), P	I(15), P	I(10), P
1001 - 50,000	RD-3	I(10), T(INT-2), P	I(INT-1), T(INT-2), P	I(15), T(INT-2), P	I(10), T(INT-2), P

P = periodic inspection (monthly and annual) Use PEI 900 checklists.

I = formal internal inspection by certified inspector. If tank cannot be entered, tanks should be cleaned and inspected with lights and/or cameras through existing openings as deemed practical by a certified tank inspector.

T = tightness test.

( ) = maximum inspection interval, in years.

1 = single-walled tank installed on or before April 11, 2016, that meet the requirements of 40 CFR 280 Section 21 for internal lining, cathodic protection, or both.

2 = Cathodic Protection: At time of cathodic protection installation the integrity of the tank must have been ensured using one of the following methods:

1) The tank was internally inspected and assessed to ensure that the tank was structurally sound and free of corrosion holes prior to installing the cathodic protection system; or
2) The tank had been installed for less than 10 years and has been monitored monthly for releases by automatic tank gauging, vapor monitoring, groundwater monitoring, or statistical inventory reconciliation as defined in 40 CFR 280 Section 43; or
3) The tank had been installed for less than 10 years and was assessed for corrosion holes by conducting two tightness tests. The first tightness test must have been conducted prior to installing the cathodic protection system. The second tightness test must have been conducted between three and six months following the first operation of the cathodic protection system.

3 = interior lining in accordance with 40 CFR 280 Section 33 or constructed of fiberglass.

RD-1 = monitored for release at least every 30 days by automatic tank gauging, vapor monitoring, groundwater monitoring or manual tank gauging as detailed in 40 CFR 280 Section 43.

RD-2 = monitored for release at least every 30 days by automatic tank gauging, vapor monitoring, or groundwater monitoring as defined in 40 CFR 280 Section 43.

RD-3 = monitored for leak detection by inventory control and manual tank gauging as defined in 40 CFR 280 Section 43.

INT-1 = within 10 years after lining, and every 5 years thereafter.

INT-2 = at least every 5 years until 10 years after the tank was installed.

---

* Military service-specific, host nation, state, or local regulations may require additional inspections or increased frequency of inspections. The installation must follow the more stringent of this UFC or military service-specific, host nation, state, or local regulations.

8-5.4.1.1 Inspection and Maintenance – Single-walled Underground Shop-Fabricated Tanks.

a. Monthly External Inspection (Identified as P in **1**\ Table 8-1 /**1**/): Ensure all tank port covers are present, are in good condition, and seated firmly on the correct tank. Inspect tank stick gauge and ensure markings are legible and that the stick gauge is not warped or broken. Inspect tank for water using ATG or stick gauge with water-finding paste. Remove water found in tank. Open and inspect tank-top containment sumps and ensure no fuel or water is collected in the sumps. Check for and remove obstructions in tank fill pipe.
Frequency: Monthly

b. Annual External Inspection (Identified as P in **1**\ Table 8-1 /**1**/): Inspect electrical connections and junction boxes in underground sumps and access ports on tank. Ensure boxes are sealed, and that boxes, conduit, and electrical fittings are not corroded. Inspect submerged turbine pumps if present. Ensure pumps are in good condition and that pumps and fittings show no signs of leaking. Inspect tank top containment sumps for cracks, holes, and budges. Ensure tank top containment sump electrical and pipe penetrations are intact and secured. For double-walled piping systems that drain into the tank top containment sump, ensure interstitial space of piping is open and that sump sensor is properly mounted at the bottom of the sump. Ensure tank top containment sump lid gasket and seals are in good condition. Inspect road access covers. Ensure covers are in good condition, that all bolts are present and that handles and lift mechanism is in good condition as applicable. Inspect concrete installed over tank and ensure there is no significant cracking.
Frequency: Annually

c. Tank Tightness Test (Identified as T in **1**\ Table 8-1 /**1**/): Perform test in accordance with 40 CFR 280, Section 43.
Frequency: As established by SCP based on tank size and release detection type listed in \1\ Table 8-1 /1/.

d. Formal Internal Inspection (Identified as I in **1**\ Table 8-1 /**1**/): A formal modified internal inspection in accordance with STI must be conducted by a certified STI SP001 inspector if the interior is accessible. The inspector will need to supplement and/or adapt portions of STI SP001 to evaluate the specific concerns of an underground tank. Check the tank for settlement and ensure that the tank slopes towards the water drain.
Frequency: As established by SCP based on tank size and release detection type listed in \1\ Table 8-1 /1/ or as recommended by an STI SP001 certified tank inspector in the previous inspection report.

e. Test tank-top containment sumps and ensure they are liquid tight by using vacuum, pressure, or liquid testing in accordance with 40 CFR 280, Section 43.
Frequency: Every three years

8-5.4.2 Double-walled Underground Shop-Fabricated Tanks.

Underground shop-fabricated tanks for fuel and oil service installed or replaced after April 11, 2016 must be secondarily contained and use interstitial monitoring in accordance with 40 CFR 280 Section 43.

In general, inspections fall into the categories of internal and external (monthly and annual) inspections. Unless more frequent inspection and testing is specified by military service-specific directives, host nation, state or local regulations or certified inspector as a result of the previous inspection, the inspection protocol defined in **1**\ Table 8-2 /**1**/ must be used to determine inspection requirements of double-walled underground shop fabricated tanks.

\1

Table 8-2 /1/ Double-walled Underground Shop Fabricated Tank Inspection and Testing Schedules*

Tank Size[4] (Gallons)	Release Detection Type	Aviation Fuel Tank[6]	Double-wall Steel Non-aviation Interior Coated[5]	Double-wall Steel with no Interior Coating	Double-wall Fiberglass
111 - 1000	RD-4	P	P	P	P
1001 - 50,000	RD-5	I(10), P	I(20), P	I(20), P	I(20), P

P = periodic inspection (monthly and annual) Use PEI 900 checklists.

I = formal internal inspection by certified inspector. If tank cannot be entered, tanks should be cleaned and inspected with lights and/or cameras through existing openings as deemed practical by a certified tank inspector.

( ) = maximum inspection interval, in years.

4 = double-walled tank that meets the requirements of 40 CFR 280 Section 20.

5 = interior epoxy coating.

6 = operating tank that issues fuel to aircraft.

RD-4 = monitored for release at least every 30 days by automatic tank gauging, vapor monitoring, groundwater monitoring, interstitial monitoring or manual tank gauging as detailed in 40 CFR 280 Section 43.

RD-5 = tank installed on or before April 11, 2016, monitored for release at least every 30 days by automatic tank gauging, vapor monitoring, groundwater monitoring, interstitial monitoring, or statistical inventory reconciliation or tanks installed after April 11, 2016 monitored for release at least every 30 days by interstitial monitoring as defined in 40 CFR 280 Section 43.

* Military service-specific, host nation, state, or local regulations may require additional inspections or increased frequency of inspections. The installation must follow the more stringent of this UFC or military service-specific, host nation, state, or local regulations.

8-5.4.2.1 Inspection and Maintenance – Double-Walled Underground Shop-Fabricated Tanks.

a. Monthly External Inspection (Identified as P in **1**\ Table 8-2 /**1**/): Ensure all tank port covers are present, are in good condition, and seated firmly on the correct tank. Inspect tank stick gauge and ensure markings are legible and that the stick gauge is not warped or broken. Inspect tank for water using ATG or stick gauge with water-finding paste. Remove water found in tank. Open and inspect tank-top containment sumps and ensure no fuel or water is collected in the sumps. Check for and remove obstructions in tank fill pipe.
Frequency: Monthly

b. Annual External Inspection (Identified as P in **1**\ Table 8-2 /**1**/): Inspect electrical connections and junction boxes in underground sumps and access ports on tank. Ensure boxes are sealed, and that boxes, conduit, and electrical fittings are not corroded. Inspect submerged turbine pumps if present. Ensure pumps are in good condition and that pumps and fittings show no signs of leaking. Inspect tank top containment sumps for cracks, holes, and budges. Ensure tank top containment sump electrical and pipe penetrations are intact and secured. For double-walled piping systems that drain into the tank top containment sump, ensure interstitial space of piping is open and that sump sensor is properly mounted at the bottom of the sump. Ensure tank top containment sump lid gasket and seals are in good condition. Inspect road access covers. Ensure covers are in good condition, that all bolts are present and that handles and lift mechanism is in good condition as applicable. Inspect concrete installed over tank and ensure there is no significant cracking.
Frequency: Annually

c. Formal Internal Inspection (Identified as I in **1**\ Table 8-2 /**1**/): A formal modified internal inspection in accordance with STI must be conducted by a certified STI SP001 inspector if the interior is accessible. The inspector will need to supplement and/or adapt portions of STI SP001 to evaluate the specific concerns of an underground tank. Check the tank for settlement and ensure that the tank slopes towards the water drain.
Frequency: As established by SCP based on tank size and release detection type listed in \1\ Table 8-2 /1/ or as recommended by an STI SP001 certified tank inspector in the previous inspection report.

d. Test tank-top containment sumps and ensure they are liquid tight by using vacuum, pressure, or liquid testing in accordance with 40 CFR 280, Section 43.
Frequency: Every three years

8-6 UNDERGROUND FIELD-CONSTRUCTED TANKS (CUT AND COVER TANKS).

\1

a. Underground field-constructed tanks are vertical or horizontally constructed and can be constructed of welded steel or welded steel interior with concrete exterior. The tanks are covered with soil or buried in the ground.

b. The tank design includes manways that extend to grade level for access to the interior of the tank for inspection and cleaning purposes. Deep-well vertical turbine pumps are mounted to the top of the tank and are enclosed in a small pump house or vault, or tanks are gravity fed and tunnels are used to access tank connections and skin valves. The fill connection extends to the bottom of the tank and is usually equipped with a splash deflector or diffuser. The tank is equipped with a sump pump to remove water from the tank, pressure-vacuum vents, level indicators and transmitters, and level switches.

c. A baseline internal inspection must be conducted on underground field-constructed tanks before they are placed into service. The baseline inspection must include, floor, shell, and roof wall-thickness measurements. These initial measurements will be used by later inspectors to monitor and evaluate corrosion rates of specific tanks.

d. Military service-specific, host nation, state or local regulations may require additional inspections or increased frequency of inspections of underground field-constructed tanks. The Installation must follow the more stringent of this UFC or military service-specific, host nation, state, or local regulations.

/1/

8-6.1 Inspection and Maintenance – Underground Field-Constructed Tanks (Cut and Cover Tanks).

a. Check the level gauge records and interstitial monitoring ports to determine if the tank is leaking.
Frequency: Daily

b. Apply field-erected tank monthly external inspection to the maximum extent possible. Visually inspect tank and appurtenances for evidence of leaks, shell distortions, signs of corrosion, and settlement at accessible locations. Items noted during the inspection will be documented for follow-up action by an authorized inspector (See Appendix F for the Field-Erected Tank Monthly Inspection Checklist).
Frequency: Monthly

c. Check tank under static storage conditions for 24 hours using existing inventory management system to determine if petroleum losses are occurring. If leakage is noted, further investigation must be conducted in accordance with military service-specific guidelines.
Frequency: Monthly

d. Apply field-erected tank annual external inspection to the maximum extent possible. Visually inspect tank and appurtenances for evidence of leaks, shell distortions, signs of corrosion, and settlement at accessible locations. Visually inspect pump/equipment vaults for leaks and cracking in concrete walls and floors. Retain records of inspections reports for five years (See Appendix F for the Field-Erected Tank Annual Inspection Checklist).
Frequency: Annually

e. Perform a modified out-of-Service API 653 internal inspection to evaluate the tank for conditions which may affect the operational integrity of the tank floor, shell, columns and roof by certified API 653 inspector. API 653 provides a checklist to be used as part of the assessment; however the certified API 653 inspector must modify this checklist to incorporate specific needs of underground field-constructed tanks. **1**\\ The API 653 or STI SP001 inspector must recommend the date of the next inspection. The inspection interval must be based on the date the Suitability for Service Letter is issued immediately prior to when the tank is returned to service.
Frequency: As recommended by the API 653 or STI SP001 inspector. If there is not a previous recommendation, the inspection must be performed within ten years after the tank was placed into operation.
/**1**/

8-7 TANK CLEANING.

Tank cleaning operations are detailed in Appendix H for government personnel. Contractors must utilize UFGS**1**\\33 01 50.65/**1**/for cleaning requirements of tanks. Appendix H provides the minimum standards for safe entry of petroleum tanks.

a. Conduct Tank Cleaning: Unless otherwise mandated by operational concerns or military service directives, schedule and conduct tank cleaning based upon the frequency listed below. After cleaning tanks must be stenciled in accordance with Section 8-8.1 Tank Stenciling Requirements.
Frequency:

- **Air Force – Tanks above 20,000 gallon (75,700 liters) in capacity - Every 10 years unless required more frequently due to fuel quality issues. Contact AFPET and AF Fuel SME for deviations on schedule. Schedule changes are typically accepted based on TO 42B1-1 requirements.**

- **Air Force – Tanks 20,000 gallon (75,700 liters) in capacity and under - During out of service inspection cycle unless required more frequently due to potential fuel quality issues.**
- **Army, Navy, U.S. Marine Corps – During out-of-service inspection cycle unless required more frequently due to potential fuel quality issues.**

8-8 RETURNING TO SERVICE AFTER FORMAL OUT OF SERVICE INSPECTION/REPAIR.

\1

- Re-install all valves, piping, and manhole covers using new non-asbestos gasket material compatible with the product being stored. Gasket thickness must not be less than the thickness of the gasket replaced. Restore the entire area to its original condition. Reconnect and activate cathodic protection system.
- Limit the fill line and discharge velocity in the piping of the incoming liquid stream into petroleum fuel tanks to 3 feet per second (fps) (0.9 meter per second (mps)) until the fill pipe is submerged in fuel by either two pipe diameters or 2 feet (60 cm), whichever is less. In the case of a floating-roof or pan equipped tank, observe the 3 fps (1 mps) velocity limitation until the roof or pan becomes buoyant. For additional information, see API 2003.

NOTE: Wait thirty minutes after loading or unloading an aboveground fuel tank before gauging a tank. Wait at least 18 hours before attempting entry onto a floating roof or pan after an initial fill.

- At the completion of a tank inspection or cleaning operation, ensure the tank is stenciled in accordance with Section 8-8.1 Tank Stenciling Requirements.
- Documentation that should be provided before a tank is placed back into service after a formal out of service inspection or repair includes the following:

/1/

- A statement signed by an applicable code certified tank inspector indicating the tank is suitable for return to service including any caveats, clarifications, or limitations that would affect tank operations after return to service. The statement must include due dates for the next applicable formal inspections (internal, external, and leak test) and any repairs required prior to those next inspections. Next inspection due dates must be the maximum allowable by code, calculated from the latest of the inspection or repair completion dates.

- A completed inspection report compliant with the applicable code including all required calculations and analysis. Preliminary or field reports cannot be substituted for this requirement.
- A list of repairs identified during the inspection, including completed repairs and repairs that are still pending. All pending repairs must be annotated with a due date.
- Third-party certified calibration ("strapping") charts when a tank is first placed in service, when certified calibration charts did not previously exist, or when repairs were made that would be reasonably expected to change the tank's calibration. For shop-fabricated tanks, manufacturer-provided calibration charts require third-party certification before they can be accepted.
- A statement signed from the Execution Agent and repair contractor that custody of the tank is returned to the Installation and that items listed above have been delivered to the Government.

8-8.1 Tank Stenciling Requirements.

Tank stencils should be 0.75 to 1-inch (19-25 mm) height letters. The information must be stenciled on or next to the manhole covers for aboveground tanks, or stenciled on the manhole cover or tank pit wall for underground tanks. The following information must be stenciled if known:

- Date of the tank cleaning (Month/Year).
- Cleaning completed by (i.e., in-house or contractor's name).
- Name of the individual certifying the cleaning.
- If applicable, the address or contact information for the contractor.
- Date of last formal internal inspection (Month/Year).
- Date of next formal internal inspection (Month/Year).

8-9 TANK APPURTENANCES.

8-9.1 Floating Roofs and Pans.

\1

a. Floating roofs and pans rest directly on the petroleum surface, minimizing vapor space directly above the petroleum surface when storing light-weight volatile liquids and jet fuels. Floating roofs and pans also minimize water and contaminant infiltration into the petroleum and mitigate fire risks.

b. Floating pans can be constructed of steel or aluminum. Pans float by displacement and are not equipped with large voids or hollow compartments to help provide buoyancy. When aluminum is used the design can include an internal honeycomb in the sheet material. This internal honeycomb includes small void spaces that give the pan additional buoyancy.

c. Pontoon floating pans can be constructed of steel or aluminum. Pontoon floating pans use hollow compartments to provide buoyancy. Typically the hollow compartments are constructed in a circle on the outside diameter of the pontoon floating pan. The compartments or pontoons are individually sealed.

d. Floating roofs are installed on tanks that are not equipped with a sealed cone type roof. In most cases these tanks have been retrofitted with geodesic domes or steel framed roofs to mitigate water entrance into the tank through the open top. Floating roofs are typically constructed of steel and include pontoons for buoyancy. These type roofs are typically equipped with a drain system that will allow rain water that collects on the top of the roof to drain to a point outside of the tank. These roofs drain by sloping to a center sump. The center sump is connected to a hose or multi-jointed pipe extending through the fuel to an outside water draw-off valve.

e. Tanks are typically equipped with internal ladders that can be used to access the top of the floating roof or pan from the top of the tank. In some cases these ladders are installed on rollers and the angle of the ladder changes as the floating roof or pan changes elevation. In other cases these ladders are vertical and penetrate the floating roof or pan and a rubber seal is installed on the floating pan or roof to close the annular space between the ladder and the metal of the floating roof or pan.

f. Floating roofs or pans are equipped with anti-rotation cables or pipes. These anti-rotation devices keep the floating roof or pan in position as the elevation of the floating roof or pan changes due to fuel level changes. They also prevent the floating roof or pan from rotating due to currents produced from fuel receipt or issue operations.

g. Most petroleum fuel tanks are equipped with gauge wells. These wells are used for temperature and level measurement devices. The wells are constructed of vertical pipes that penetrate the floating roof or pan. A rubber seal is installed on the floating roof or pan to close the annular space between the gauge wells and the floating roof or pan. In some cases the vertical risers of vertical ladders are also used as gauge wells.

/1/

Figure 8-1 Floating Roof Seal

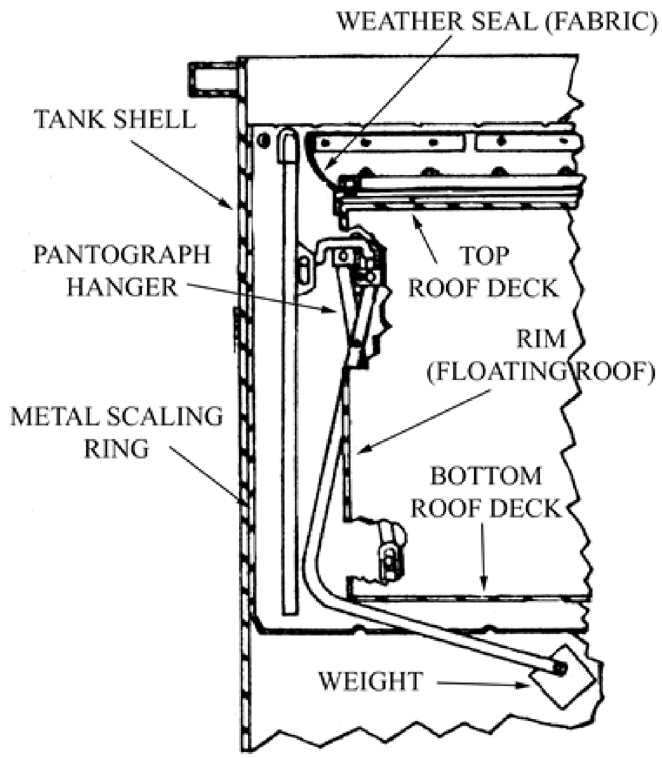


Figure 8-2 Floating Roof Detail

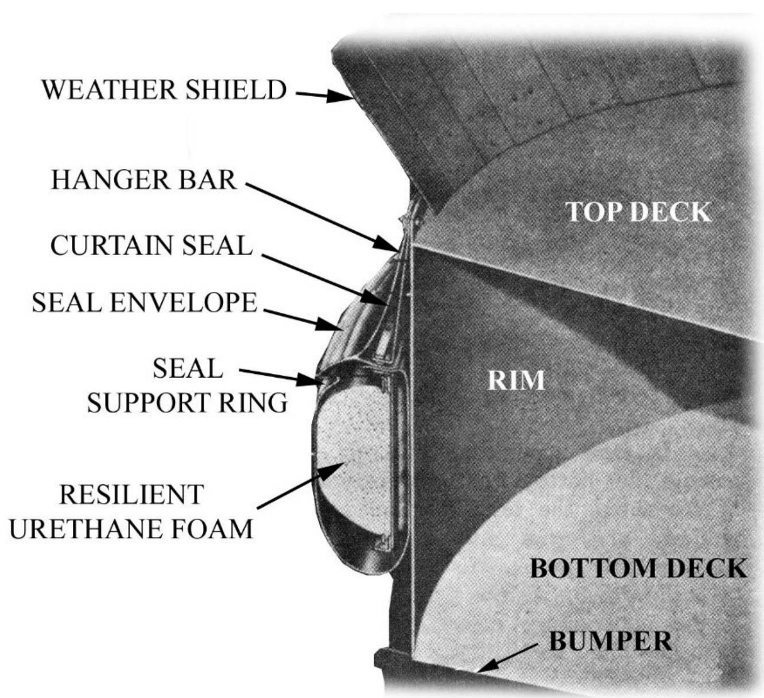

Figure 8-3 Standard Tank Seal on Aluminum Honeycomb Pans

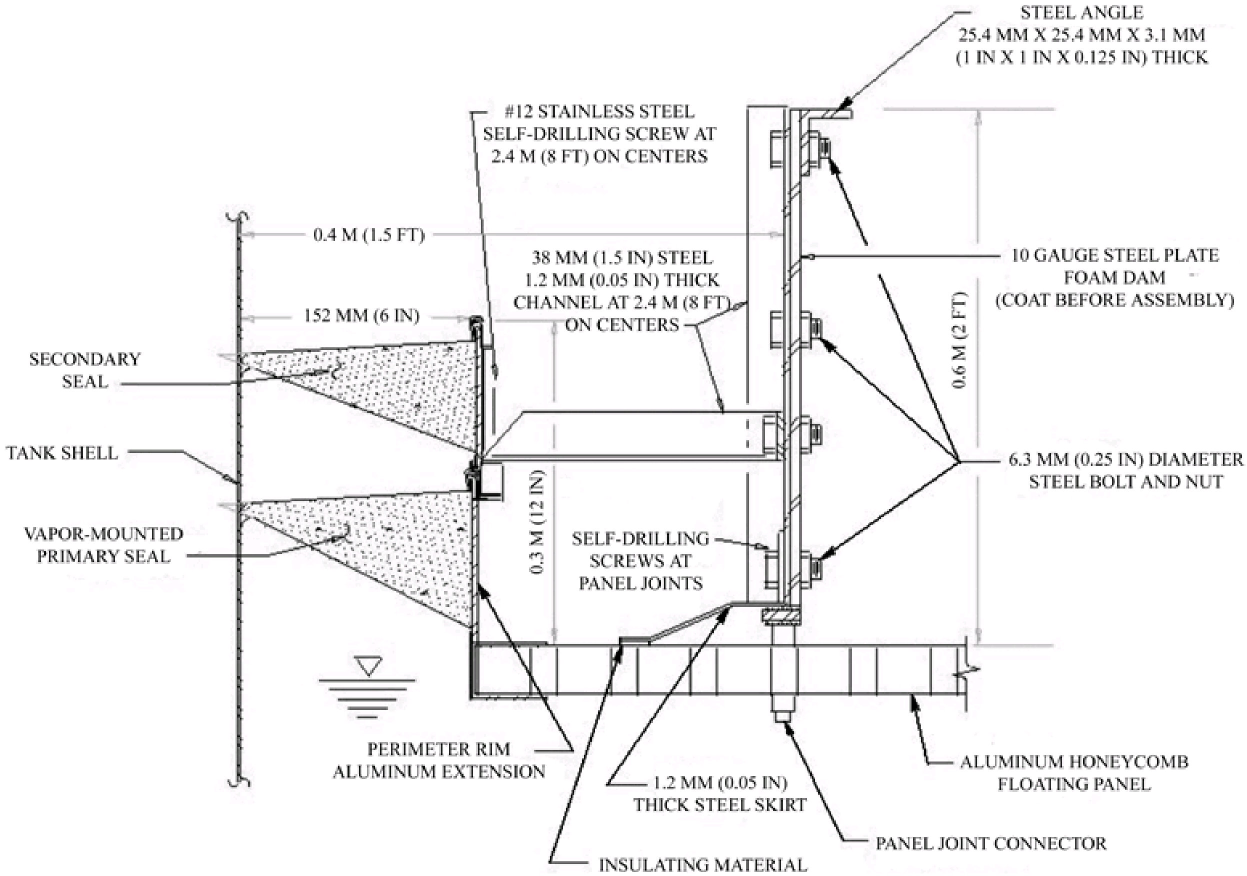


8-9.1.1 Inspection and Maintenance - Aluminum Honeycomb Floating Pans.

Perform visual inspections from fixed roof hatch. Access to internal floating pans is considered a permit-required confined space, therefore all appropriate safety procedures must be followed before conducting internal inspections.

a. Visually inspect pan guide/anti-rotation cables and centering of pan.
Frequency: Monthly

b. Visually inspect pan grounding cables for proper attachment and wear or binding.
Frequency: Monthly

c. Visually inspect for buckling or damage to the pan.
Frequency: Monthly

d. Inspect grounding cables for proper attachment and wear or binding.
Frequency: Annually

e. Inspect all floating roof penetration seals, such as ladder seals, stilling well seals, and other seals to ensure that they are in good working condition.
Frequency: Annually

f. Clean and inspect perimeter tank/pan seals.
Frequency: At time of out of service internal inspection.

g. Refer to Section 8-9.1.5, "Floating Roof and Pan Pressure/Vacuum Vents," for inspection and maintenance requirements of floating pan pressure/vacuum vents.

h. Refer to Section 8-9.1.6, "Floating Roof and Pan Legs," for inspection and maintenance requirements of floating pan legs.

8-9.1.2 Inspection and Maintenance – Steel Floating Pans.

Perform visual inspections from fixed roof hatch. Access to internal floating pans is considered a permit-required confined space, therefore all appropriate safety procedures must be followed before conducting internal inspections.

a. Visually inspect pan guide/anti-rotation cables or pipe and centering of pan.
Frequency: Monthly

b. Visually inspect pan grounding cables for proper attachment and wear or binding.
Frequency: Monthly

c. Visually inspect for buckling or damage to the pan.
Frequency: Monthly

d. Visually inspect for damage or deflection in the rolling ladder (if equipped).
Frequency: Monthly

e. Inspect grounding cables for proper attachment and wear or binding.
Frequency: Annually

f. Inspect all floating pan penetration seals, such as gauge well seals to ensure that they are in good working condition.
Frequency: Annually

g. Inspect gauge wells for abrasions that might indicate out of roundness, or improper centering.
Frequency: Annually

h. Inspect vertical ladder for abrasions that might indicate out of roundness, or improper centering (if equipped).
Frequency: Annually

i. Inspect for damage or deflection in the rolling ladder (if equipped).
Frequency: Annually

j. Clean and inspect perimeter tank/pan seals.
Frequency: At time of out of service internal inspection

k. Refer to Section 8-9.1.5, "Floating Roof and Pan Pressure/Vacuum Vents," for inspection and maintenance requirements of floating pan pressure/vacuum vents.

l. Refer to Section 8-9.1.6, "Floating Roof and Pan Legs," for inspection and maintenance requirements of floating pan legs.

8-9.1.3 Inspection and Maintenance – Pontoon Floating Pans.

Perform visual inspections from fixed roof hatch. Access to pontoon floating pans is considered a permit-required confined space, therefore all appropriate safety procedures must be followed before conducting internal inspections.

a. Visually inspect pan guide/anti-rotation cables or pipes and centering of pan.
Frequency: Monthly

b. Visually inspect grounding cables for proper attachment and wear or binding.
Frequency: Monthly

c. Visually inspect for buckling or damage to the pan.
Frequency: Monthly

d. Visually inspect for damage or deflection in the rolling ladder (if equipped).
Frequency: Monthly

e. Inspect pontoons for standing liquid and presence of strong vapors.
Frequency: Annually

f. Remove mechanical gauge float cover and ensure float is securely fastened to gauge tape. Check gauge tape for ease of movement.
Frequency: Annually

g. Inspect for damage or deflection in the rolling ladder (if equipped).
Frequency: Annually

h. Inspect vertical internal ladder and internal ladder/pan seals for abrasions that might indicate out of roundness, or improper centering (if equipped).
Frequency: Annually

i. Inspect gauge wells and gauge well/pan seals for abrasions that might indicate out of roundness, or improper centering.
Frequency: Annually

j. Inspect steel floating pan coatings for corrosion. Touch up with compatible coating if required (aluminum pans do not require coatings).
Frequency: Annually

k. Clean and inspect perimeter tank/pan seals.
Frequency: At time of out of service internal inspection.

l. Refer to Section 8-9.1.5, "Floating Roof and Pan Pressure/Vacuum Vents," for inspection and maintenance requirements of floating pan pressure/vacuum vents.

m. Refer to Section 8-9.1.6, "Floating Roof and Pan Legs," for inspection and maintenance requirements of floating pan legs.

8-9.1.4 Inspection and Maintenance – Floating Roofs.

Perform visual inspections from fixed roof hatch. Access to floating roofs is considered a permit-required confined space, therefore all appropriate safety procedures must be followed before conducting internal inspections.

a. Visually inspect the center primary roof drain system. Confirm it is water-free.
Frequency: Monthly

b. Visually inspect anti-rotation pipes/roof guides and centering of roof.
Frequency: Monthly

c. Visually inspect grounding cables for proper attachment and wear or binding.
Frequency: Monthly

d. Visually inspect for buckling or damage to the roof.
Frequency: Monthly

e. Visually inspect for standing water on roof deck.
Frequency: Monthly

f. Visually inspect for damage or deflection in the rolling ladder (if equipped).
Frequency: Monthly

g. Ensure that the drip-tight plug is placed in the roof drain opening.
Frequency: Annually

h. Ensure that the roof drain valve is closed. The drain valve is kept in the closed position except after each rain or snowfall when it is opened just long enough to drain the roofline. Tanks with retrofitted geodesic domes or metal roofs may have had the floating roof drain line removed, so before opening the roof drain valve ensure the roof drain line has not been removed.
Frequency: Annually

i. Inspect pontoons for standing liquid and presence of strong vapors.
Frequency: Annually

j. Remove mechanical gauge float cover and ensure float is securely fastened to gauge tape. Check gauge tape for ease of movement.
Frequency: Annually

k. Ensure emergency drain is not blocked with debris (if equipped).
Frequency: Annually

l. Inspect for damage or deflection in the rolling ladder (if equipped).
Frequency: Annually

m. Inspect vertical internal ladder and internal ladder/roof seals for abrasions that might indicate out of roundness, or improper centering (if equipped).
Frequency: Annually

n. Inspect gauge wells and gauge well/roof seals for abrasions that might indicate out of roundness, or improper centering.
Frequency: Annually

o. Inspect the floating roof coating for corrosion. Touch up with compatible coating if required.
Frequency: Annually

p. Clean and check perimeter tank/roof seals.
Frequency: At time of out of service internal inspection.

q. Refer to Section 8-9.1.5, "Floating Roof and Pan Pressure/Vacuum Vents," for inspection and maintenance requirements of floating roof pressure/vacuum vents.

r. Refer to Section 8-9.1.6, "Floating Roof and Pan Legs," for inspection and maintenance requirements of floating roof legs.

8-9.1.5 Floating Roof and Pan Pressure/Vacuum Vents.

Floating roof and pan pressure/vacuum vents are used to relieve vacuum pressure on the floating roof or pan when the legs of the floating roof or pan make contact with the tank bottom and a vapor space is created between the surface of the liquid and the bottom of the floating roof or pan as the liquid level continues to drop. The pressure/vacuum vent also relieves positive pressure as the fluid below the floating roof or pan rises before the surface of the liquid makes contact with the bottom of the floating roof or pan.

8-9.1.5.1 Inspection and Maintenance - Floating Roof and Pan Pressure/Vacuum Vents.

a. Inspect the floating roof or pan pressure/vacuum vent to ensure that the seats and retaining straps or guides are in good working order and that the pressure/vacuum vent is not stuck to its seats, but instead lift easily off of its seats and reseats properly. Inspect gaskets for wear and replace as required. Refer to the manufacturer's operation and maintenance manual

provided with the floating roof or pan for additional guidance on servicing the pressure/vacuum vent.
Frequency: At time of out of service internal inspection.

8-9.1.6 Floating Roof and Pan Legs.

Floating roof and pan legs support the floating roof or pan in its high position for maintenance (approximately 6 foot-3 inch (1.9 meter) clearance from bottom of floating roof or pan to tank bottom), and limit the low position of the floating roof or pan when fuel is drawn down to approximately 2 foot 5-inches (0.7 meter) of clearance from bottom of floating roof or pan to tank bottom or minimum of 6-inch (150 mm) from the top of any internal nozzle flange to the bottom of the floating roof or pan, whichever is higher.

8-9.1.6.1 Inspection and Maintenance - Floating Roof and Pan Legs.

a. Inspect the floating roof or pan legs and tank bottom striker plates for wear; inspect the seals where the legs penetrate the floating roof or pan for leaks; inspect the low leg position stops to make sure they are securely fastened to the legs and will stop the floating roof or pan at the low position; inspect the leg keeper straps to make sure they are securely fastened to the legs to prevent the legs from falling off or through the floating roof or pan; inspect the threaded keeper caps or high position locking mechanisms to ensure they are in proper working order for securing the floating roof or pan in the high position. Refer to the maintenance manual provided with the floating roof or pan for additional guidance on floating roof or pan legs and associated hardware.
Frequency: At time of out of service internal inspection.

8-9.2 Secondary Tank Bottoms.

Secondary tank bottoms are installed to repair original tank bottoms that degraded. Secondary tank bottoms are installed approximately 1-foot (300 mm) above the existing tank bottom. In most cases sand is installed between the original and secondary bottom, although in some cases a new release protection barrier is installed between the original and secondary tank bottom. Tanks equipped with secondary tank bottoms can be identified by the presence of a second chime about 1-foot (300 mm) above the original chime at the tank to concrete foundation interface.

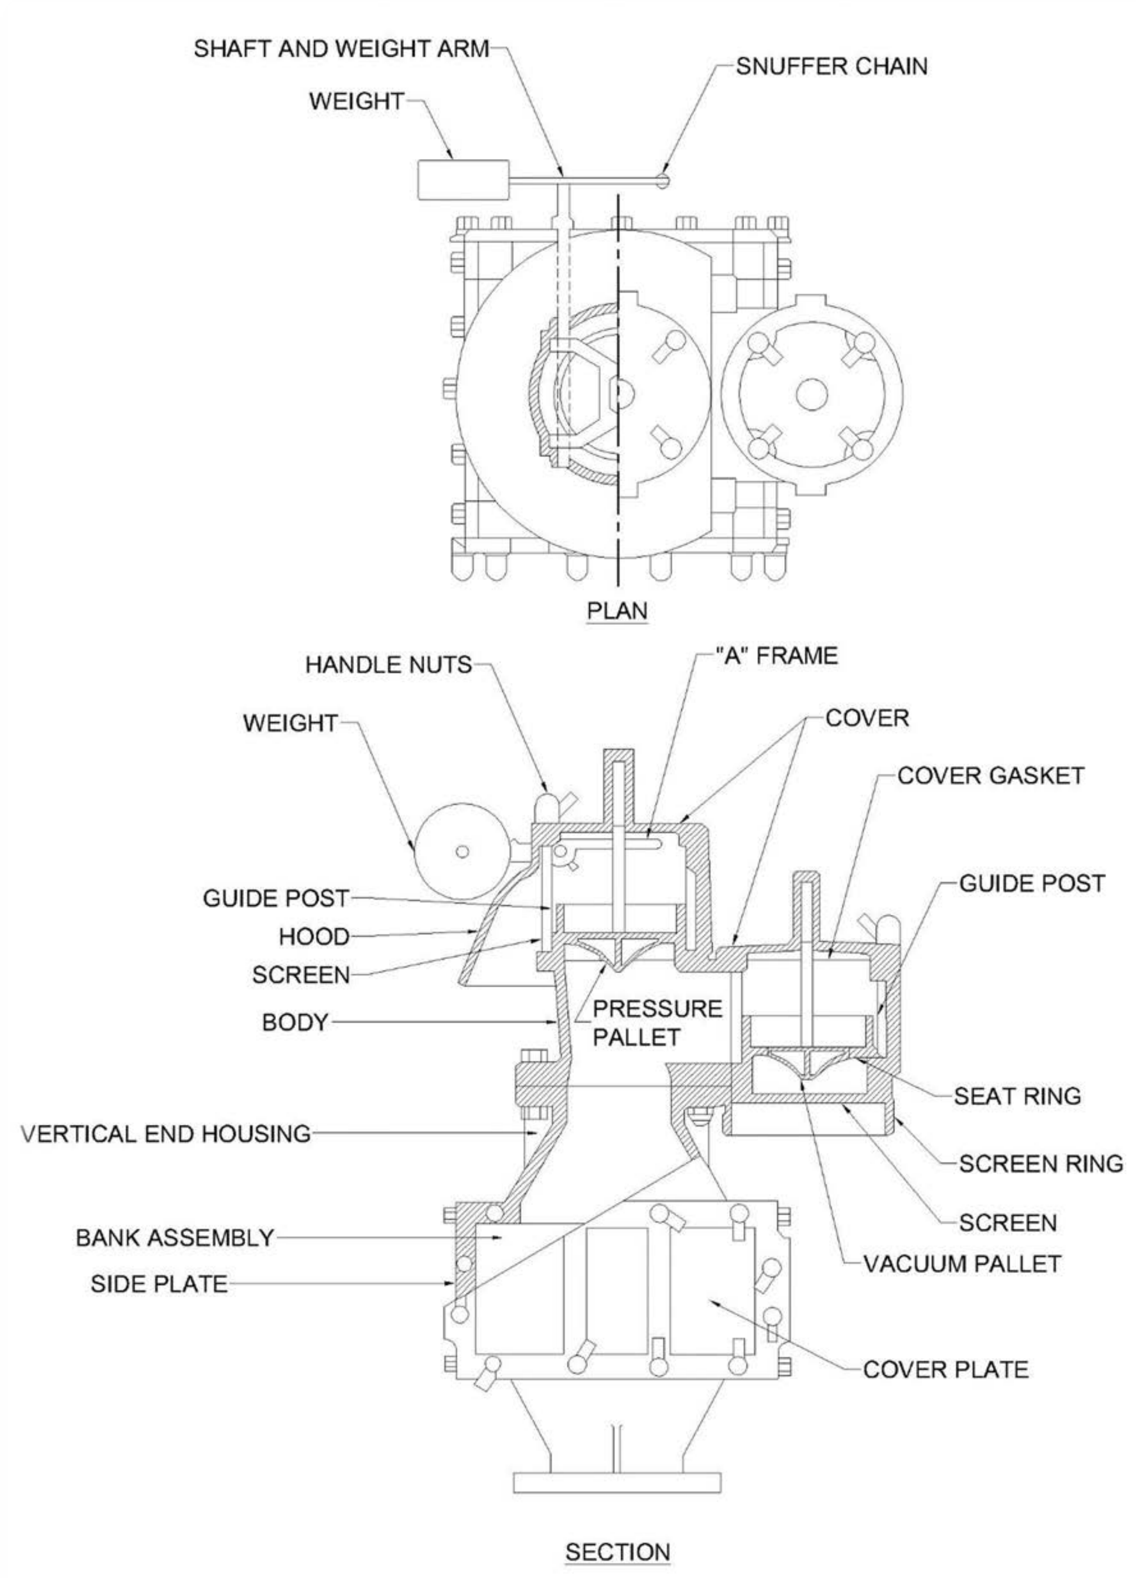
8-9.2.1 Inspection and Maintenance - Secondary Tank Bottoms.

a. Tanks designed with secondary tank bottoms should have tell-tale devices (leak detection ports) to allow for monitoring of the tank’s floor integrity. The tell-tale devices are typically configured as valves or inspection ports to allow for visual monitoring of liquid that may be present between the foundation and the tank floor. The presence of water would indicate a breach in the foundation seals or flooring while the presence of petroleum would indicate integrity loss in the tank floor. Open and check tell-tale valves or inspection ports. Verify the absence of water or petroleum. **Frequency: Monthly**

8-9.3 Tank Pressure/Vacuum Vents.

The pressure/vacuum vent allows air to escape when filling the tank and allows air to enter the tank when the tank is being emptied, or drawn down, in order to keep from damaging the tank and to keep fuels with high vapor pressures from evaporating from the tank. Pressure/vacuum vents are typically installed on petroleum fuel storage tanks storing petroleum fuels with vapor pressures exceeding 0.75 psi (5 kPa). They are not usually installed on API 650 tanks with floating roofs and atmospheric vents. The type and size of vent used can vary greatly.

Figure 8-4 Pressure Vacuum Vent



8-9.3.1 Inspection and Maintenance – Tank Pressure/Vacuum Vents.

a. On underground shop fabricated tanks, ensure tank pressure/vacuum vent is present and that the riser pipe is securely supported and vertical.
Frequency: Monthly

b. Inspect vent settings. Pressure and vacuum settings for pressure/vacuum vents are usually specified on the vent nameplate or in the manufacturer's manual for the vent.
Frequency: Annually

c. Clean the pressure/vacuum vent. Information on the type of pressure/vacuum vent and procedures for the removal of covers, hoods and/or pallet removal and reinstallation should be found in the manufacturer's operation and maintenance manual. Before removing the pallets, brush all accumulations from the protecting screens, the pallets, and all surfaces of the valve. Brush the screens from inside the valve so that dirt and other objects fall to the outer sides. Remove heavy loading weights prior to removing the pallet assembly. Remove deposits or foreign matter using reasonable care not to damage diaphragms or seats.
Frequency: Annually

d. Inspect gaskets, seats, diaphragm, pallet stems and stem guides. Check all mating surfaces which must be free of nicks, cuts, cracks or deposits that might interfere with the proper seating or tightness of the valve. Test the pallets to ensure they move freely up and down over the full range of travel.
Frequency: Annually

8-9.4 Emergency Vents.

Emergency vents are installed on most tanks built to UL 142, UL 2080, UL 2085 and API 650 standards. The type and size of the vent used can vary greatly and is determined by the wetted surface (square feet) or venting capacity (cubic feet per hour) of the tank.

8-9.4.1 Inspection and Maintenance – Emergency Vents.

a. Inspect emergency vents for external damage, such as dents, rusting, severe pitting or obstruction by other equipment, piping or conduits.
Frequency: Annually

b. Remove the vent, if possible, and inspect the seals and diaphragms for cracking or breakdown. Inspect retaining cables to ensure they are fastened to the vent and the manway or tank. Inspect guides to ensure emergency vents can function properly and re-seat.
Frequency: Annually

c. Verify that emergency vents have not been removed or modified. Emergency vents should not be replaced with ATGs, manual sample ports, level alarms, etc.
Frequency: Annually

d. Tanks that are equipped with manways for emergency vents must be inspected for appropriate type, length, number of bolts, and lift clearance of the manway in accordance with UL-142, Sections 8 and 9.
Frequency: Annually

8-9.5 Flame Arrestors.

Flame arrestors are intended to provide a positive flame-stop and prevent a fire from spreading to the interior of storage tanks and are typically installed in conjunction with a pressure/vacuum vent. Flame arrestors normally utilize a tube bank consisting of alternate flat and corrugated metal sheets around a solid core of like material sandwiched between two end sections with uniform precision-ground faces to ensure a tight seal.

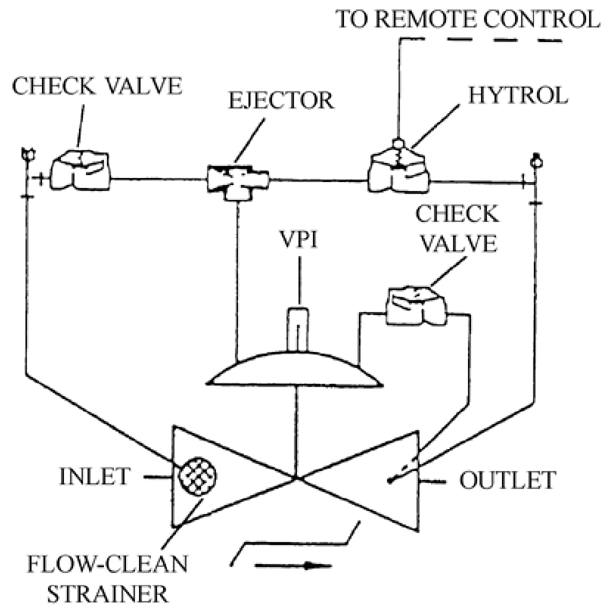
8-9.5.1 Inspection and Maintenance – Flame Arrestors.

a. The tube bank must be removed and cleaned of foreign matter by immersing in an approved solvent solution, taking care not to damage the tube bundle. Gaskets must be inspected and replaced as necessary.
Frequency: Annually

8-9.6 High Level Shut-off Valve (HLSO).

High level shut-off valves are designed to shut off receipts into the tank when a predetermined level is reached.

Figure 8-5 External High Level Shut-off Valve



8-9.6.1 External High Level Shut-off Valves (HLSO).

\1

a. External High Level Shut-off (HLSO) valves are installed in the receipt piping of tanks. Tanks are configured for the HLSO valve to close at the high alarm level or between the high and high-high alarm level. In most cases, these valves use hydraulic pressure from the upstream side of the fuel piping connected to the valve to open. The valves are equipped with flexible diaphragms and control pilots used to operate the valves. In other cases the valves are solenoid operated and require power to open.

b. Hydraulic actuated valves are controlled by a separate float valve assembly. The float valve can be installed in a sensing chamber on the outside of the tank, or internally installed. The float of the float valve is buoyant in fuel and will rise up to activate the float valve when fuel in the tank reaches the predetermined high level.

c. External float valve sensing chambers are usually accessible from stairs or a platform installed on the outside of tanks. Internal floats are installed in manway covers or tank nozzles at the top of tanks. Tubing from the inlet side of a hydraulic HLSO valve is routed to the float valve and back to both the outlet side of the HLSO valve and to the diaphragm of the HLSO valve. When the level float valve is activated it relieves hydraulic pressure from the diaphragm of the HLSO valve and causes the valve to close.

d. Some newer hydraulic HLSOs are equipped with a solenoid valve that will activate to relieve pressure from the diaphragm of the HLSO valve and cause it to close if the fuel in the tank reaches the high-high level. This solenoid is interlocked with the high-high level alarm. The solenoid feature is installed as a backup to the primary float valve closing feature.

/1/

8-9.6.1.1 Inspection and Maintenance – External HLSO Valve.

a. Activate the tank high-high level alarm and ensure the solenoid valve (if equipped) activates on the HLSO valve. Ensure the HLSO valve closes when the solenoid valve is activated.
Frequency: Quarterly

b. Isolate, drain, and then vent the external float valve chamber (if equipped). Refill (either manually or via the storage tank product saver tank pump) the float chamber to test the float valve. Ensure the HLSO closes when the float is raised.
Frequency: Annually

c. Lift the manual test lever of internally mounted float valve (if equipped). Ensure that the HLSO closes when the float of the float valve is raised.
Frequency: Annually

8-9.6.2 Internal HLSO Valve.

Internal HLSO valves are installed in the internal fill tube of tanks. Internal HLSO valves incorporate a float that closes the valve when the float rises. In some cases these valves also include a by-pass valve mechanism. When the level in the tank reaches a pre-determined height, approximately 90%, the float of the HLSO valve rises and closes the main valve. When the main valve closes at the 90% level the by-pass valve (if equipped) opens and allows approximately 5 gpm (0.3 lps) to enter the tank. If the level in the tank continues to rise and reaches the 95% level the by-pass valve will close and prevent additional fuel from entering the tank.

8-9.6.2.1 Inspection and Maintenance – Internal HLSO Valves.

a. Inspect and test the high level shut-off valve and float mechanism, counter-weights, float rods, and floats to ensure the float mechanism is moving freely and functioning properly to close the high level shut-off valve. If valve is not equipped with a manual test mechanism the level of the tank must be raised to the high level shutoff valve set point in order to test the valve. Ensure valve is installed at a proper height.
Frequency: Annually

8-9.7 Mechanical Tape Gauges.

The mechanical tape gauge readout window is typically mounted in a convenient location on the side of the tank and is visible to the tank operator. On aboveground vertical storage tanks, the tape gauge readout device is typically mounted near the base of the tank stairs. The other end of the tape is attached via a stainless steel cable or tape, enclosed in a conduit with sheaves and pulleys, either to a float that rides on the petroleum fuel surface inside the tank or to a weight that rests directly on top of the floating roof or pan. Note: When attached to a weight that rests on top of the floating roof or pan, the petroleum fuel level will not read below the setting of the floating roof or pan legs.

8-9.7.1 Inspection and Maintenance - Mechanical Tape Gauges.

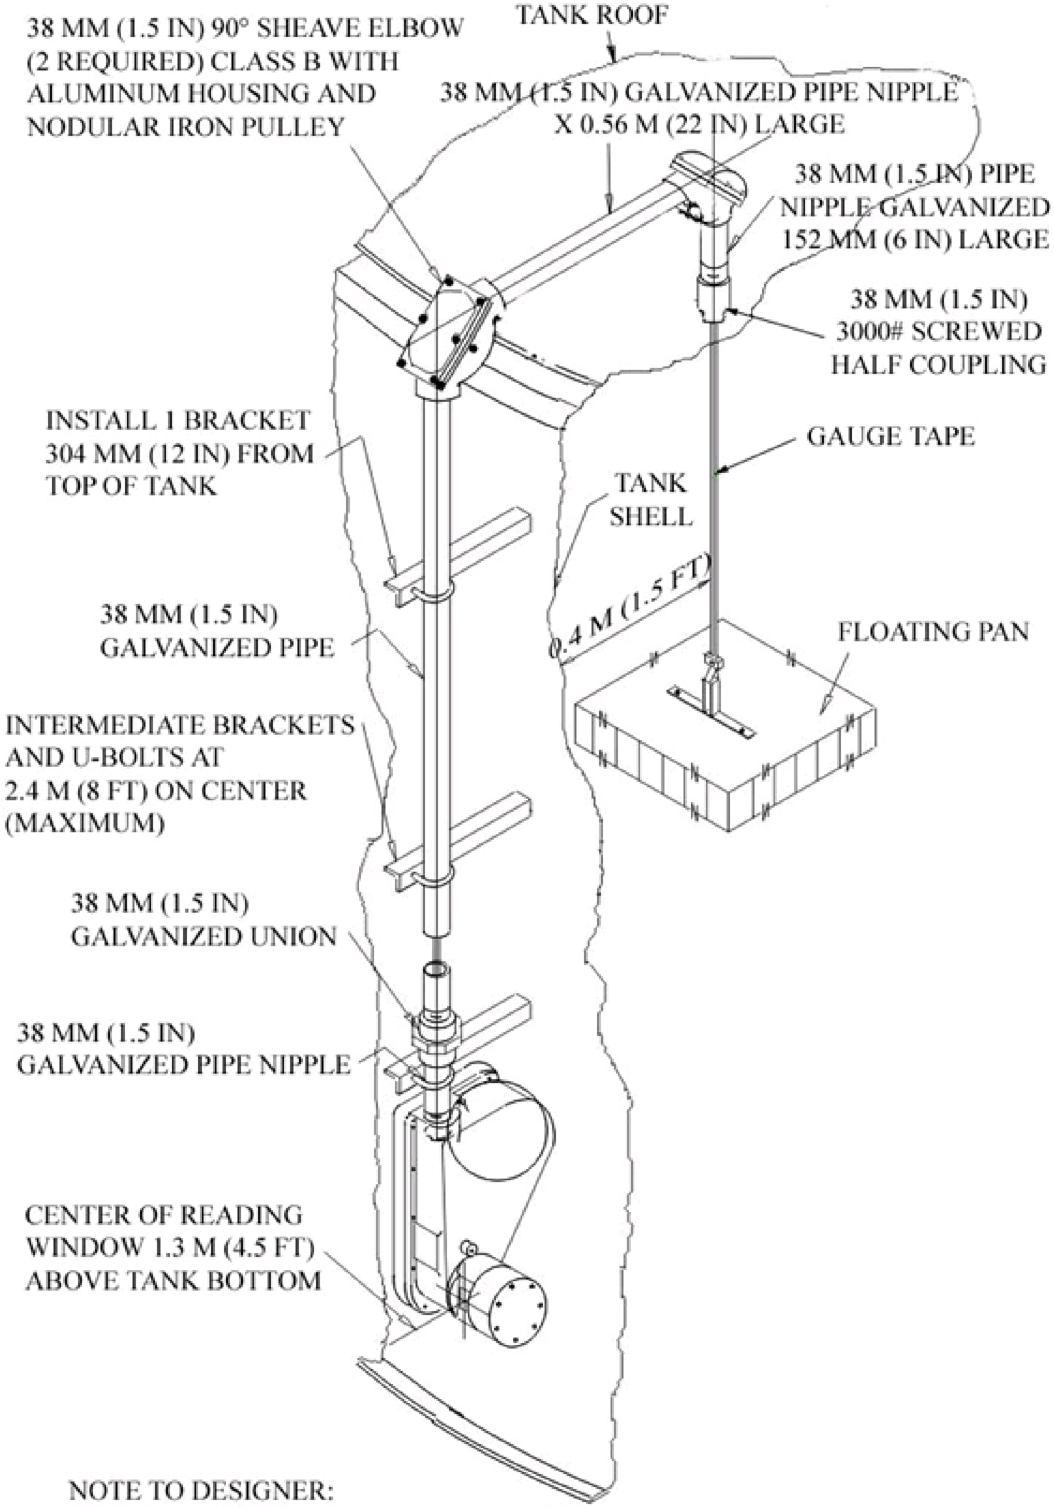
a. Visually check that a liquid level is indicated and that the measurement appears to be accurate.
Frequency: Daily

b. Check the mechanical tape gauge against the automatic electronic tank gauge (if installed) or by manually gauging the tank for relative accuracy and proper working condition. Consult the manufacturer's operation and maintenance manual for additional maintenance and inspection requirements.
Frequency: Quarterly

8-9.8 Automatic Tank Gauges

Automatic Tank Gauges (ATG) are used to measure the fuel level in petroleum fuel tanks.

Figure 8-6 Mechanical Tape Gauge



NOTE TO DESIGNER:
PROVIDE EITHER A SERVO LEVEL GAUGE OR
MECHANICAL TAPE GAUGE BASED ON
USER REQUIREMENTS

8-9.8.1 Mechanically Operated Tape Gauge.

The gauge can be installed on the tank roof or the side of a tank. The level measurement is displayed using a mechanical dial and counter built into the gauge head. An incrementally perforated tape runs from the gauge head through a conduit down into the tank with a float attached at the end. The float moves up and down with the petroleum fuel level. Petroleum fuel level data is electronically transmitted by a level transmitter fitted to the gauge.

The end of the tape should never be attached directly to a floating roof or pan. This type of installation may result in damage to the gauge head or the tape. Existing installations that are currently attached directly to the floating roof or pan should be retrofitted by attaching the tape to a weight placed on top of the floating roof or pan. Varec recommends a ten pound (4.5 kg) weight, and Sand and Jurs recommends a six pound (2.7 kg) weight.

8-9.8.1.1 Inspection and Maintenance – Mechanically Operated Tape Gauge.

Refer to manufacturer’s operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of mechanical float, tape gauge, and electronic level transmitter.

a. Visually inspect the gauge to ensure the power is on, there are no warning alarms or lights and a liquid measurement is indicated and the tank level reading appears to be accurate.
Frequency: Daily

b. Inspect gauge head for buildup of sediment.
Frequency: Quarterly

c. Inspect tape conduit for deformations that would inhibit movement of tape up and down.
Frequency: Quarterly

d. Gauge level accuracy must be checked against a hand dip measurement of the tank. Calibrate as required.
Frequency: Semi-annually

e. Inspect float and guide cable through an opened manway or access cover. Verify that the guide wire is taut and free of kinks. Verify that the float is buoyant and free of sludge or sediment build up.
Frequency: Semi-annually

f. Inspect power and control wires for damage.
Frequency: Semi-annually

g. Inspect wire connection termination points for damage or loose connections.
Frequency: Semi-annually

h. Lubricate moving parts of the gauge head with recommended lubricant.
Frequency: Annually

8-9.8.2 Magnetostrictive Probes.

Magnetostrictive probes are tank gauges that use floats to detect fuel and water levels in tanks. These gauges do not require a stilling well and are typically used on horizontal tanks.

Figure 8-7 Magnetostrictive Probe

8-9.8.2.1 Inspection and Maintenance – Magnetostrictive Probes.

Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of probe and electronic level transmitter.

a. Visually inspect the gauge to ensure the power is on, there are no warning alarms or lights and a liquid measurement is indicated and the tank level reading appears to be accurate
Frequency: Daily

b. Inspect probe assembly for buildup of sediment.
Frequency: Quarterly

c. Inspect probe assembly and probe shaft for deformations that would inhibit movement of probe.
Frequency: Quarterly

d. Level probe accuracy must be checked against a hand dip measurement of the tank. Calibrate as required.
Frequency: Semi-annually

e. Verify that the probe float is buoyant and free of sludge or sediment build up.
Frequency: Semi-annually

f. Inspect power and control wires for damage.
Frequency: Semi-annually

g. Inspect wire connection termination points for damage or loose connections.
Frequency: Semi-annually

8-9.8.3 Servo Gauge.

Servo gauges are tank top mounted, requiring a stilling well for the gauge's float to follow the fuel level up and down the tank.

Figure 8-8 Servo Gauge

8-9.8.3.1 Inspection and Maintenance – Servo Gauge.

Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of servo gauge and electronic level transmitter.

a. Visually inspect the gauge to ensure the power is on, there are no warning alarms or lights and a liquid measurement is indicated and the tank level reading appears to be accurate.
Frequency: Daily

b. Inspect gauge head for buildup of sediment.
Frequency: Quarterly

c. Gauge level accuracy must be checked against a hand dip measurement of the tank. Calibrate as required.
Frequency: Semi-annually

d. Inspect float and guide cable through an opened manway or access cover. Verify that the guide wire is taut and free of kinks. Verify that the float is buoyant and free of sludge or sediment build up.
Frequency: Semi-annually

e. Inspect power and control wires for damage.
Frequency: Semi-annually

f. Inspect all wire connection termination points for damage or loose connections.
Frequency: Semi-annually

g. Inspect stilling well. Ensure the stilling well is straight and vertical with no dents so that the float can move freely.
Frequency: Annually

h. Lubricate moving parts of the gauge head.
Frequency: Annually

8-9.9 Level Alarms.

Alarms can include high-high, high, low, and low-low level alarms. On small or underground tanks the level alarms may be suspended inside the tank. On field-erected vertical tanks the alarm switches are typically mounted in chambers mounted to the outside of the tank.

8-9.9.1 Externally Mounted Level Alarms.

Externally mounted level alarm switches are installed in sensing chambers mounted to the outside of the tank. Manual valves are installed at the sensing chamber tank connection points. These valves are used to isolate the chambers in order to perform periodic maintenance and testing of the switches without increasing or decreasing the fuel level within the storage tank.

On newer installations, the product saver system pump is configured to supply fuel to the sensing chambers and to drain fuel back to the product saver tank to facilitate alarm switch testing. Vent valves are also provided on the sensing chambers.

8-9.9.2 Inspection and Maintenance – Externally Mounted Level Alarms.

a. Test level alarm switches by isolating the chambers from the tank using the sensing chamber isolation valves. Vent and drain the chambers. Slowly pour product into the chambers through a funnel on top of the chamber to test the level switch at the specified level setting.
Frequency: Semi-annually

8-9.9.3 Internally Mounted Level Alarms.

Internal level alarms are suspended inside the tank.

8-9.9.4 Inspection and Maintenance – Internally Mounted Level Alarms.

a. Test level alarm switches by activating manual testing levers, if equipped. If alarms switches are not equipped with manual testing levers, adjust the level of fuel in the tank to the alarm points in order to test the alarm switches. If it is not feasible to adjust the level of the fuel in the tank to all of the alarm set points, remove the alarm switches from the tank and test the alarms externally. Reinstall alarm switches in the tank once testing is complete.
Frequency: Annually

8-9.10 Product Saver Tanks.

Product saver tanks are used to remove water from tank bottoms and return useable fuel back to the tank. The product saver tank typically consists of a 55 gallon (208 liter) tank with a cone down bottom and removable top. The tank includes a sight glass with density ball to monitor the fuel to water interface. The tank is equipped with a water draw-off connection and either an electric pump or a hand pump to return useable fuel to the storage tank and/or pump water off to a portable container. Some product saver tanks are configured to pump fuel to the external high level switch chambers and external high level shut-off valve float chambers to facilitate testing those devices.

8-9.10.1 Inspection and Maintenance – Product Saver Tanks.

a. Inspect the product saver tank to ensure all valves are working properly, sight level gauges with density balls are working properly and are not broken, and hand pumps or electric pumps are working properly and are not leaking.
Frequency: Quarterly

8-9.11 Sidestream Filtration Systems.

Sidestream filtration systems are used to filter or polish fuel stored in tanks. Typically, the system consists of a 100 gpm (6.3 lps) pump that draws fuel from the tank low suction line, which extends to the center sump, and then pumps the fuel through a 100 gpm (6.3 lps) filter separator back to the tank's fill line. A connection is sometimes provided downstream of the filter separator to pump fuel off to a tank truck or bowser. The filter separator will polish the fuel, but will also remove water from the bottom of the tank. The filter separator is equipped with a water level conductance probe and a float control pilot to shut the filter separator flow control valve if too much water is present in the filter separator sump. In this case, the product recovery system should first be utilized to draw as much water off the tank bottom as possible before the sidestream filtration operation is continued.

8-9.11.1 Inspection and Maintenance – Sidestream Filtration Systems

a. Check filter separator vent tank (typically 5 gallon (19 liters), if incorporated) and ensure it is empty.
Frequency: Monthly

b. Refer to Section 6-1 Pipe Testing and Inspections for inspection and maintenance requirements of piping.

c. Refer to Section 3-6.4 Basket Strainers for inspection and maintenance requirements of basket strainers.

d. Refer to Section 3-8 Pumps for inspection and maintenance requirements of fuel pumps.

e. Refer to Section 3-6.2 Filter Separators for inspection and maintenance requirements of filter separators.

f. Refer to Section 4-4.2.2 Filter Separator Control Valves for inspection and maintenance requirements of filter separator control valves.

g. Refer to Section 9-1.6 Grounding Systems for inspection and maintenance requirements of grounding systems.

h. Refer to Section 9-1.9 Electronic Equipment for inspection and maintenance requirements of control panels.

8-9.12 Fill Ports.

Fill ports are used to protect tank fuel receipt and vapor balance connection points. They are typically installed on underground and aboveground horizontal tanks. The fill ports can be installed in a pit installed above the tank (underground storage tanks) or on stands installed in close proximity to the tanks (aboveground storage tanks). They also provide a small volume of containment below the receipt connection points. In some cases the fill port is equipped with a small pump or valve that can be used to transfer fuel that collects in the fill port containment area into the receipt line of the respective tank.

8-9.12.1 Inspection and Maintenance - Fill Ports.

a. Ensure fill port covers are installed and are not damaged or broken. Ensure fill port covers are identified by fuel type and are installed on the correct tank. Visually inspect the fill port spill bucket to ensure there are no cracks, budges, or holes. Ensure the spill bucket is clean of dirt, trash, water, and fuel.
Frequency: Daily

b. Inspect drain valve in spill bucket and ensure it is in good condition. Ensure the caps installed on the receipt connection points are vapor tight and are not broken, cracked, or chipped. Ensure the poppet valve of the

vapor recovery port seals tightly and no vapor is escaping from the tank when the valve is closed.
Frequency: Monthly

c. **1**\ Hydrostatically test fill-port to ensure containment is liquid-tight. This test may use opportune rainfall by holding rainwater in the fill-port containment area for one hour. Where evaporation is a concern, conduct the testing when this concern would be minimized, such as at night/early morning or during a time of year when this would not be as much of an issue. Record the water level at the start of the 60 minute (minimum) hold period and if the water level drops by 1/8 inch or more, perform and record an investigation to determine the cause and any required repairs. Once repairs are completed, a new test must be completed. Refer to Appendix B for testing procedures and to use to document the testing. /**1**/ Ensure secondary containment area of fill port is fuel tight. Ensure the manual transfer pump or drain valve is operational.
Frequency: \1 \Every 3 years /1/

8-9.13 Release Detection Monitoring.

Release detection is installed on aboveground and underground petroleum fuel storage tanks. Release detection measures vary based on the age and type of tank.

In addition to 40 CFR Part 280, host nation, state, and local regulations may have additional design, inspection, and maintenance requirements that may be more stringent than DoD or Federal guidance. Facility operators and maintainers must be familiar with the Installation’s SPCC plan in order to comply with all inspection and recordkeeping requirements

8-9.13.1 Point Sensor – Dry.

Dry point sensors are installed at the lowest point within the space between the fueling system and secondary barrier. Dry point sensors send a signal to a monitoring panel indicating liquid detection. Dry point sensors may include float switches, or electrical resistor switches. A licensed and/or certified technician is required to troubleshoot or inspect dry point sensors for operation.

Underground and aboveground double-wall tanks (such as product recovery tanks) often have point sensor(s) installed through a connection on top of the tank that extends down near the bottom of the interstitial space between the primary and secondary tank shells. The sensor is used to determine if the primary tank is leaking into the interstitial space between the shells or if groundwater is leaking into the interstitial space. The point sensor is typically of the continuous surveillance type and provides an audible and visible alarm at the operator control panel.

8-9.13.1.1 Inspection and Maintenance – Point Sensor – Dry.

a. Ensure the monitoring panel associated with the point sensor(s) is powered on and no alarms are present.
Frequency: Daily

b. Ensure monitoring space is clear and free of debris and liquid.
Frequency: Monthly

c. Test sensor and ensure it is functional.
Frequency: Annually

8-9.13.2 Point Sensor – Wet.

Wet point sensors are installed within liquid reservoirs that monitor the liquid filled space between the primary tank and secondary barrier (USTs only). A licensed and/or certified technician is required to troubleshoot or inspect wet point sensors for operation.

8-9.13.2.1 Inspection and Maintenance – Point Sensor – Wet.

a. Ensure the monitoring panel associated to the wet point sensor(s) is powered on and no alarms are present.
Frequency: Daily

b. Ensure level of monitoring fluid is within normal range.
Frequency: Monthly

c. Test sensor and ensure it is functional.
Frequency: Annually

8-9.13.3 Point Sensor – Pressure/Vacuum.

Pressure/vacuum point sensors are installed at points within the space between a fueling system and secondary barrier. This space may be under pressure or a vacuum depending on the configuration. Pressure/vacuum point sensors send a signal to a monitoring panel indicating loss of pressure or loss of vacuum. A licensed and/or certified technician is required to troubleshoot or inspect pressure/vacuum point sensors for operation.

8-9.13.3.1 Inspection and Maintenance – Point Sensor – Pressure/Vacuum.

a. Ensure the monitoring panel associated with the pressure/vacuum point sensor(s) is powered on and no alarms are present.
Frequency: Daily

b. Test vacuum sensor for proper operation.
Frequency: Annually

8-9.13.4 Visual Leak Detection.

\1

a. Visual leak detection systems include the use of tell-tale holes and leak detection ports.

b. Reinforcement plate tell-tale holes are present in reinforcement plates used on steel storage tanks at pipe connection points and appurtenance connection points. The tell-tale holes allow for leaks that form in the interstitial space between the reinforcement plate and tank shell to be seen through visual inspection by leaking of fuel through the tell-tale hole. Never install plugs in reinforcement plate tell-tale holes.

c. Leak detection ports (tell-tales) are present on storage tank structures with ring wall foundations and are located around the perimeter of the ring wall foundations or at a single collection point. Leak detection ports can be manually opened to inspect for leaks.

/1/

8-9.13.4.1 Inspection and Maintenance – Visual Leak Detection.

a. Visually inspect leak detection ports (tell-tales) for signs of leaks. If there are debris or objects obstructing the view, appropriate measures must be taken to remove the debris or remedy the obstructions.
Frequency: During routine inspection of other components or monthly, whichever comes first.

b. Visually inspect reinforcement plate tell-tale holes for signs of leaks. Ensure tell-tale holes have not been plugged by debris or a cap. Pack reinforcement plate tell-tales with white grease to prevent insect nesting and buildup of debris.
Frequency: Quarterly

8-9.14 Floating Suction Lines.

Floating suction lines are used to pull petroleum from a predetermined level below the petroleum liquid surface. The suction line is typically suspended by pontoon-type floats. A cable system connected to the suction arm moves a visual target external to the tank for visual confirmation that the arm is moving properly.

8-9.14.1 Inspection and Maintenance - Floating Suction Lines.

a. Check external floating suction line position indicator to ensure floating suction line is moving freely as the level in the tank rises or falls.
Frequency: Quarterly

b. Inspect cables, floats, and swing joint. Ensure interior of floats have not collected fuel. Ensure cables are securely fastened to anchor points and

are in good working order. Ensure the suction pipe flange used to support the swing joint is level and true and that swing joint moves freely up and down and does not bind.
Frequency: When tank is taken out of service for internal cleaning or inspection.

8-9.15 Foam Fire Protection Systems.

Aqueous Film Forming Foam (AFFF) systems are sometimes installed on petroleum fuel storage tanks. When equipped, AFFF spray nozzles are installed at the top of the tank and, when activated, spray foam into the interior vapor space of the tank. When the foam is sprayed it forms an aqueous film that floats at the top of the petroleum fuel and separates the petroleum fuel from atmospheric oxygen.

8-9.15.1 Inspection and Maintenance - Foam Fire Protection Systems.

Refer to UFC 3-601-02 for inspection and maintenance requirements of tank foam fire protection systems.

8-9.16 Heating Coils.

Some petroleum storage tanks in heavy fuel or lube oil service are equipped with heating coils or heaters to warm the petroleum and lower the viscosity for transfer operations. Coils may also be present on storage tanks for other types of petroleum in cold climates.

8-9.16.1 Steam Type Heating Coils.

Steam is a very effective means of heating heavy petroleum fuel and lube oils. Steam coils are typically installed in the bottom of tanks and can be in a variety of different configurations. Internal corrosion of the coils due to the presence of condensate in the heater coils or tubes is a primary problem in these systems. Depending on the type of heater used, this corrosion can lead to oil in the steam heating system or water in the petroleum. To avoid corrosion, steam coils must be shut off at the tank connections when not in use. Inactive coils must be plugged or removed from tanks. The flow of steam to the heating coil is typically controlled by an automatic temperature-regulating valve to prevent overheating the petroleum in the tank.

8-9.16.1.1 Inspection and Maintenance – Steam Type Heating Coils.

a. Observe the regulating valve and check it against a thermometer to be sure that it controls the tank temperature within a safe range, usually not over 150 °F (65 °C) for No. 6 burner fuel oil. Steam traps must be inspected for proper operation to ensure condensate is evacuated from the steam coil.
Frequency: At each operation

b. Pressure check heating coils to 10% above normal operating pressure.
Frequency: Annually

c. Steam coils must be cleaned and inspected for visible signs of corrosion or wear when the tank is emptied and cleaned for inspection. All components of the steam heating coils, such as weld joins, support points, valves, temperature wells, control valves, and steam traps must be inspected and checked for proper operation and visible wear or damage. The coil may be carefully pressurized with steam and visually checked for leaks if necessary. Leaks or damage found must be repaired.
Frequency: When the tank is taken down for formal internal inspection or sooner if steam heating coil damage is suspected.

8-9.16.2 Thermal Fluid Type Heating Coils.

Thermal fluids are sometimes used instead of steam in tank heating coils for heavy lube oils and other fuel oils. Thermal fluids do not pose the corrosion problems associated with steam and condensate, but do require inspection and maintenance for proper operation. Thermal heating coils are typically installed in the bottom of the tank and can be in a variety of configurations. The flow of thermal fluid to the heating coil is typically controlled by an automatic temperature-regulating valve to prevent overheating the fuel oil in the tank.

8-9.16.2.1 Inspection and Maintenance – Thermal Fluid Type Heating Coils.

a. Observe the regulating valve and check it against a thermometer to be sure that it controls the tank temperature within a safe range, usually not over 150 °F (65 °C) for No. 6 burner fuel oil. All external valves, fittings, and other components must be inspected for visible signs of leaks during operation.
Frequency: At each operation

b. Pressure check heating coils to 10% above normal operating pressure.
Frequency: Annually

c. When tanks are emptied and cleaned for inspection, the heating coils must be cleaned and inspected for visible signs of corrosion, wear, or damage. The coils can be pressurized and checked for leaks at that time with the thermal heating fluid at normal operating pressure, but at ambient temperature to alleviate possible burns to personnel. Leaks must be repaired.
Frequency: When the tank is taken down for formal internal inspection or sooner if thermal heating coil damage is suspected.

8-9.16.3 Electric Rod Type Heating.

Electric rod type heaters are sometimes used to heat liquids directly or they are inserted into sealed pipes that extend into tanks to indirectly heat the fluid. Typically, electric heaters are controlled by a thermostat in conjunction with a thermometer for a visual check to regulate the heat in the tank and turn the electric heater on and off as required.

8-9.16.3.1 Inspection and Maintenance – Electric Rod Type Heating.

Refer to the manufacturer's operation and maintenance manual for additional maintenance requirements.

a. Inspect heater to ensure no fluid leakage around the heater to tank connection and that the heater is performing properly.
Frequency: At each operation.

8-9.17 Stilling Wells.

Stilling wells are used to minimize movement of level and temperature sensing probes and floats in petroleum fuel tanks. Stilling wells are constructed of vertical pipe and are slotted with holes to ensure that the level of fuel in the stilling well matches the level of petroleum fuel in the tank.

8-9.17.1 Inspection and Maintenance - Stilling Wells.

a. Stilling wells must be visually inspected to be vertically straight and free of dents or indentations. Sometimes tank stilling wells are made of bare carbon steel pipe. In these instances the stilling wells must be replaced with aluminum.
Frequency: At time of out of service internal inspection.

b. Inspect floating seals inside stilling wells to ensure they are not worn and are sealing the inside of the stilling well property.
Frequency: At time of out of service internal inspection.

8-10 CONTAINMENT SYSTEMS.

Petroleum storage tanks have various types of secondary containment to protect surrounding areas from petroleum contamination. Secondary containment systems include metal enclosures, diked/bermed areas and remote impounding systems. Secondary containment systems can be made of metal, concrete, concrete with liner, brick, or earthen material equipped with an impervious liner.

Military services typically assign draining of containment areas to various organizations; in all cases, removing of water must be conducted in accordance with the Installation's SPCC or other stormwater pollution prevention plan to ensure only water without sheen is released. Secondary containment areas must be drained based upon local requirements or monthly, whichever comes first.

8-10.1 Inspection and Maintenance – Containment Systems (General).

a. Inspect containment systems for cleanliness, if accessible.
Frequency: Daily

b. Secondary containment systems degrade and will collect debris, which can clog drainage inlets or prevent drain valves from sealing properly. **\1** Hydrostatically test the drainage systems to include containment drain inlets, drain lines and containment drain valves to ensure the containment is liquid tight. This test may use opportune rainfall by holding rainwater in the containment system for one hour. Where evaporation is a concern, conduct the testing when this concern would be minimized, such as at night/early morning or during a time of year when this would not be as much of an issue. Record the water level at the start of a 60-minute (minimum) hold period and if the water level drops by 1/8 inch or more, perform and record an investigation to determine the cause and any required repairs. Once repairs are completed, a new test must be completed. Refer to Appendix B for testing procedures and to use to document the testing

American Concrete International (ACI) Standards 224R “Control of Concrete Cracking” and ACI’s Concrete Repair Manual are two standards that owners/operators can follow to maintain the integrity of the concrete secondary containment. **/1/**
Frequency: \1\ Every 3 years /1/

8-10.2 Concrete and Cement Brick Dike/Berm Walls and Floors.

Aboveground petroleum tanks that have containment system walls constructed of concrete or cement brick must be maintained and inspected to ensure containment system integrity.

8-10.2.1 Inspection and Maintenance – Concrete and Cement Brick Dike/Berm Walls.

a. Inspect for vegetation that has taken root in seals or cracks. All vegetation must be removed in all cases to prevent penetration of seals, joints or cracks in the concrete.
Frequency: Daily

b. Inspect walls constructed of bricks for signs of deterioration (e.g., spalling caused by freeze-thaw conditions, cracks, and joint cracks between bricks). Walls constructed of bricks must be patched immediately to prevent further penetration of the wall structure.
Frequency: Daily

c. Inspect walls constructed of concrete for signs of deterioration (e.g., spalling caused by freeze-thaw conditions and cracks). Clean and seal

cracks with a fuel resistant sealant.
Frequency: Semi-annually

d. Inspect seals and joints in concrete walls. Joint sealant that has retracted from the joint or become unbonded with the joints must be removed and replaced with fuel resistant sealant.
Frequency: Semi-annually

8-10.2.2 Inspection and Maintenance – Dike/Berm Floors.

a. Inspect for vegetation that has taken root in seals or cracks. All vegetation must be removed in all cases to prevent penetration of seals, joints or cracks in the concrete.
Frequency: Daily

b. Inspect floors made of concrete for signs of deterioration (e.g., spalling caused by freeze-thaw conditions and cracks). Clean and seal cracks with a fuel resistant sealant.
Frequency: Semi-annually

c. Inspect joints and seals. Joint sealant that has retracted from the joint or become unbonded with the joints must be removed and replaced with a fuel resistant sealant.
Frequency: Semi-annually

8-10.3 Earthen Dike Walls.

Earthen dike wall secondary containment systems typically include sloped walls with a level surface at the top.

8-10.3.1 Inspection and Maintenance – Earthen Dike Walls.

a. Inspect for vegetation that has taken root. All vegetation must be removed in all cases.
Frequency: Daily

b. Prevent the growth of vegetation inside the containment area. Use fireproof chemicals for sterilization. Only herbicides approved by the Installation Environmental Office must be used.
Frequency: Monthly

c. Inspect for signs of erosion. Inspections should be performed particularly after heavy rains or storms. Repair areas that have deteriorated due to erosion.
Frequency: Quarterly

8-10.4 Self-Diking or Vaulted Tank Containment.

Tanks built using self-diking or vaulted secondary containment features must meet NFPA 30 and in cases where the tank is used for dispensing to vehicles or watercraft, the tank must meet requirements detailed in NFPA 30A. Additional requirements are specified in NFPA 1: Chapter 20, NFPA 1: Chapter 66, and UL 2085.

8-10.4.1 Inspection and Maintenance – Self-Diking or Vaulted Tank Containment.

a. Secondary containment structures on self-diking or vaulted tanks must be inspected visually for integrity breaches with special attention given to pipe penetrations and interstitial drain valves.
Frequency: Daily

8-10.5 Flexible Membrane Liners.

Flexible Membrane Liners (FML) are sometimes installed under concrete in storage tank secondary containment areas and over earthen dikes used as secondary containment. Typically FML is installed over geotextile membranes and the FML is brought up and sealed to the concrete tank foundation on the inside of the secondary containment area and to concrete dike walls that enclose the perimeter of the secondary containment area. Pipe penetrations through the secondary containment area, such as piers and pipe supports, are also sealed to the FML, preventing product from seeping through the liner along the pipe.

8-10.5.1 Inspection and Maintenance – Flexible Membrane Liners.

a. Remove vegetation growing in the gravel and dirt, taking note if the roots have penetrated the FML.
Frequency: Daily

b. Visibly inspect FMLs where attached to ringwalls, dike walls, concrete piers and other projections for deterioration due to weather or wear and repair as necessary.
Frequency: Quarterly

c. Visually inspect FMLs covered with smooth rock or gravel for bare spots where the gravel has been washed away due to storms or heavy rains for tears. Replace gravel taking care not to puncture the liner.
Frequency: Quarterly

d. Visually inspect exposed FML for tears or punctures and repair.
Frequency: Quarterly

8-10.6 Pipe Penetrations.

Some pipe penetrations through containment walls incorporate a pipe sleeve through which the carrier pipe is placed. The carrier pipe is sealed to the pipe sleeve with a link-type mechanical compression seal at both ends. Boot seals between the end of the pipe sleeve and the carrier pipe are sometimes added as an additional containment measure.

In some cases the carrier pipe directly penetrates concrete containment paving and walls. In these cases, the space between the carrier pipe and the concrete paving or wall is sealed with fuel resistant sealant.

8-10.6.1 Inspection and Maintenance – Pipe Penetrations.

a. Inspect boot seals and mechanical link-type seals for wear and cracking. Ensure the seals are in good working order to seal out water or retain the petroleum product as intended. Repair or replace defective boot and link-seals.
Frequency: \2\ Monthly /2/

b. Inspect sealant between pipes and concrete walls, berms, and floors. Sealant that has retracted from the concrete or pipe surfaces must be removed and replaced with new fuel resistant sealant.
Frequency: Semi-annually

8-11 MISCELLANEOUS USE TANKS.

8-11.1 Miscellaneous Use Tanks.

Miscellaneous tanks include electric generator tanks, fire pump tanks, waste oil tanks, ballast water tanks, lube oil tanks, and others. In most cases standalone tanks are below 10,000 gallon (37,850 liter) capacity and fall into the shop fabricated category and are designed and built to UL 142, UL 2080 or UL 2085 standards. However, in some cases the tanks are large field erected tanks and fall into the vertical or cut and cover category. In some cases the tanks are integrated into the system or skid and are built to the skid manufacturer's specifications. This occurs with generator or fire pump belly tanks.

8-11.1.1 Inspection and Maintenance – Miscellaneous Use Tanks.

a. Standalone aboveground tanks that fall into the vertical field erected category must follow the inspection and maintenance requirements listed in Section 8-4 Field-Erected Tanks.

b. Standalone tanks that fall into the shop fabricated tank category must follow the inspection and maintenance requirements listed in Section 8-5 Shop-Fabricated Tanks.

c. Standalone tanks that fall into the cut and cover category must follow the inspection and maintenance requirements listed in Section 8-6 Underground Field-Constructed Tanks.

d. Integrated tanks that are supplied as part of an equipment skid or system must follow manufacturer's inspection and maintenance recommendations.

8-11.1.2 Generator Tanks and Fire Pump Tanks.

These tanks typically hold diesel or kerosene-based fuel use with piston driven engines to operate electrical generators and fire water pumps.

8-11.1.3 Waste Oil Tanks.

Waste oil tanks store petroleum products that are not suitable for use or reclamation. This product is typical stored until appropriate quantities are accumulated for economical sale or disposal. Waste oil tanks take on many types of configurations, and for integrity testing and maintenance, are considered petroleum tanks.

8-11.1.4 Ballast Water Tanks.

Ballast water tanks are used to store water-fuel mixtures that are pumped from marine vessel fuel tanks.

8-11.1.5 Lube Oil Tanks.

Lube oil tanks are used to store and distribute lube oil for turbines and gears, hydraulic equipment and general mechanical lubrication.

8-11.1.6 Additive Tanks.

Additive tanks store bulk additives used to additize jet fuel. They are typically small aboveground tanks.

8-11.1.7 Heating Oil Tanks.

These tanks typically include heating coils which are used to preheat oil before it can be used. These tanks may be field erected tanks, shop fabricated, or cut and cover tanks.

8-11.1.7.1 Inspection and Maintenance – Heating Oil Tanks.

Refer to Section 8-9.16 Heating Coils for inspection and maintenance requirements of heating coils.

CHAPTER 9 ELECTRICAL SYSTEMS

9-1 ELECTRIC CONTROL SYSTEMS AND EQUIPMENT.

9-1.1 Scope and Limitations.

The intent of this section is to provide guidelines for maintenance of electrical equipment rated for up to 1,000 V. The intended audience is electrical maintenance staff or electrical contractors who are engaged in performance of electrical maintenance. Electrical work must be completed by qualified/licensed electricians equipped with the proper PPE (e.g., Arc Flash, CPR, First Aid) for the type of work conducted. The recommended procedures are not intended to contradict electrical codes. The main objectives of this section are:

- To outline procedures to maintain optimal operating conditions of the electrical equipment.
- To establish a system for early detection of potential faults in electrical equipment in an effort to plan repair or replacement before catastrophic failure occurs.

If in the process of implementing the outlined procedures it is determined that more extensive testing is required, then such tests should be performed in accordance with the applicable codes. Due to safety concerns, the maintenance of equipment rated above 1,000 V is not addressed. This equipment must be maintained only by specially trained personnel in accordance with manufacturer's recommendations.

9-1.2 Electrical Equipment.

Maintenance procedures for electrical equipment usually require enclosures to be opened, inspected and cleaned. This poses higher risk of injury than during normal operation and basic rules for electrical safety should be followed:

- Always follow approved lockout/tagout procedures.
- Never work alone when testing electrical equipment. A second person who is First Aid and CPR qualified should be present.
- Never work on energized equipment. Tests that require energized equipment should be performed by specially trained and licensed personnel.
- Use V-rated tools and V-rated gloves. V-rated tools are tools rated and tested for the maximum line-to-line voltage upon which work will be done. V-rated gloves are gloves rated and tested for the maximum line-to-line voltage upon which work will be done.
- Use appropriately rated Personal Protective Equipment (PPE) as indicated by arc flash hazard warning labels as required by NFPA 70E. If such labels are not installed, perform arc flash hazard analysis before

implementing electrical maintenance procedures to determine the appropriate level of PPE.

The preceding list is not exhaustive and does not intend to contradict safety requirements mandated by codes or regulations.

\2
9-1.2.1 Inspection and Maintenance – Electrical Equipment.
/2/

a. Electrical control systems include: deadman control; ground verification systems; EFSO operation; control panels, motor control, and pump start/stop buttons. These systems must be tested on a periodic basis to ensure proper operation and functionality. In addition, control system Uninterruptible Power Supplies (UPS) must be inspected and replaced as necessary.
Frequency: Quarterly

9-1.3 Power Cables.

The assessment of cable condition is performed mainly by visual inspections. Based on the observations, certain cables may be scheduled for dielectric testing. Visual inspection is usually done while inspecting the equipment to which the cable is connected. Moving or touching of the cables must only be done when the system is de-energized and locked out.

9-1.3.1 Inspection and Maintenance – Power Cables.

a. Visual inspection: Verify that there are no sharp bends. Verify that the cable insulation is intact. Verify that cables are appropriately tagged or otherwise identified. Verify that all connections are tight and not corroded. Open manholes and handholes. Verify that they are not flooded, clogged with debris or infested by pests.
Frequency: Annually

b. Insulation resistance test: This test measures the resistance of the insulation with an Insulation Resistance Tester. During the test, the cable will be disconnected from both ends. Acceptable test values are 100 megaOhms for cables rated between 120 V to 1,000 V. Insulation resistance testing for voltages higher than 1,000 V is to be performed by specialized testing company.
Frequency: As needed based on visual inspection

9-1.4 Motor Controls.

Motor control equipment generally refers to the following: across the line motor starters, reduced voltage auto transformer starters, wye delta starters, partial winding starters, solid state starters, reversing starters, and adjustable frequency drives. All motor control equipment has common components which can be classified as:

a. Overcurrent and overload protective device – circuit breaker or fuse.

b. Electromagnetic contactor.

c. Control logic elements (e.g., relays, switches, pushbuttons).

The motor control equipment may be installed in a motor control center (MCC) or in a standalone enclosure dedicated to a single starter. Usually this equipment is installed in electrical rooms and is protected from the elements. However, standalone enclosures are sometimes located in close proximity to the driven equipment and are exposed to the elements. In such cases special attention should be paid to the physical condition of the enclosure. The maintenance of motor control equipment should be performed together with the maintenance of the motor.

9-1.4.1 Inspection and Maintenance - Motor Controls.

a. Verify the labeling is consistent with the drawings and specifications.
Frequency: Semi-annually

b. Verify that pushbuttons are easy to operate and are not stuck. Verify that there is no grease accumulation around the seating.
Frequency: Semi-annually

c. Verify that indicating lights are functional and replace as needed.
Frequency: Semi-annually

d. Verify that electrical and mechanical interlocks operate according to the design intent. In case of key interlocks, ensure that the number of keys corresponds to the interlock intent. Having more keys than required defeats the intent of the interlocking and poses danger to the service personnel and equipment. If extra keys are found, they should be removed from the equipment.
Frequency: Semi-annually

e. Inspect the enclosure for visible signs of corrosion.
Frequency: Interior annually/exterior semi-annually

f. Open the enclosure – be mindful of insects, rodents and reptiles, particularly if located outdoors. Look for signs of corrosion, dust accumulation, spider webs, etc. Clean the enclosure with compressed air and apply rust inhibitors and paint as needed.
Frequency: Annually

g. Inspect the overcurrent protective devices for proper seating. Verify that rating is appropriate for the motor. Look for signs of attached wire and device overheating.
Frequency: Annually

h. Inspect the arch shoots of contactors and clean as needed. Check that partitions are not burned.
Frequency: Annually

i. Inspect contactors for abnormal wear. Check contacts for pitting, roughness and oxidation. Verify that contact gap, alignment and pressure are in accordance with manufactures recommendations.
Frequency: Annually

j. When contactors are used, listen for the chatter of contacts or buzzing noise. These are indicative of a faulty contactor.
Frequency: Annually

k. Verify that relays and switches are firmly seated in their bases and there are no signs of overheating or vibration.
Frequency: Annually

l. Look for frayed or broken strands in the flexible control wiring and replace if such are found.
Frequency: Annually

m. Perform a functional test of protective devices if they are equipped with self-testing circuits or switches.
Frequency: Annually

n. Perform a functional test of all manual switches and verify proper operation against intended design logic. Replace switches and relays if operation is not satisfactory.
Frequency: Annually

o. Perform insulation resistance test for the control wiring.
(Note: Testing of the control wires may require substantial down time. Therefore, this should only be performed on a case by case basis if there are reasons to suspect that the insulation of the control wiring is deteriorating.)
Frequency: As required

9-1.5 Panelboards.

Panelboards are used to control power supply to equipment, buildings, and structures.

9-1.5.1 Inspection and Maintenance – Panelboards.

Conduct the following actions to complete the inspection:

a. Verify that there are no physical obstructions blocking access to the panelboard. Remove physical obstructions.
Frequency: Quarterly

b. Inspect the enclosure and the surrounding area for water damage and corrosion.
Frequency: Annually

c. Verify that all breakers are either in the “On” or the “Off” position. If there are tripped breakers, investigate the cause of the trip.
Frequency: Annually

d. Verify that there is a breaker schedule. If there is no breaker schedule or the schedule is worn and out-of-date, create and post a new one.
Frequency: Annually

e. Verify that the breaker operation matches the description on the panel schedule.
Frequency: Annually

f. Observe breakers, wires and terminals for signs of overheating or short circuiting.
Frequency: Annually

g. Verify that all breakers are firmly seated and locked in place by slightly shaking them.
Frequency: Annually

h. Verify that all grounding wires are firmly connected to the grounding bar.
Frequency: Annually

i. If a breaker malfunction is identified, leave breaker in the open position and replace as soon as possible. If a breaker cannot disconnect its circuit, the entire panelboard must be switched off using its main disconnecting means and locked out until the breaker is repaired.
Frequency: Annually

9-1.6 Grounding Systems.

Visual inspection of the integrity of the grounding should be performed together with the visual inspection of the grounded equipment, such as motors, motor control centers, piping, filter vessels, petroleum fuel tanks, and transformers. A typical facility will include two types of grounding systems: power grounding and static grounding. Power grounding provides a low-impedance path for the fault current in case of equipment, conductor, and raceway failures. Static grounding provides a path for static electricity discharge to dissipate static electricity build up on equipment.

9-1.6.1 Inspection and Maintenance – Power Grounding Systems.

a. The connections to the grounding system must be surveyed and verified for continuity. If a connection is suspected to be loose, perform further testing. In some occasions, it is more cost effective to replace the suspected connection instead of performing diagnostic tests.
Frequency: Annually

b. Measure the voltage between the equipment grounding conductor and the electrode grounding conductor (usually bare copper). Investigate test results above 3 VAC for a potential ground fault.
Frequency: Annually

c. Measure the voltage between the chassis of the equipment and the electrode grounding conductor. Investigate if the readings exceed 2 VAC.
Frequency: Annually

d. Facility ground resistance check: This type of testing is performed with a four lead, low resistance ohmmeter or digital ohmmeter. Recommended values are between 3 and 5 ohms. In no case should the grounding resistance be higher than 25 ohms.
Frequency: Every five years

9-1.6.2 Inspection and Maintenance – Static Grounding Systems.

a. Inspect ground reels for corrosion. Ensure ground reels are securely mounted to a rigid base. Inspect clamps for serviceability. Replace clamp if jaws are deformed or corroded, spring is weak, or other defects are evident that would prevent a good connection. Inspect cable wires. Replace if more than one-third of the cable wires are broken.
Frequency: Quarterly

b. The connections to the grounding system must be surveyed and verified for continuity. If a connection is suspected to be loose, perform further testing. In some occasions it is more cost effective to replace the suspected connection instead of performing diagnostic tests.
Frequency: Annually

c. Resistance measurement on static grounds: Measure static ground resistance of new and damaged ground rods. Static ground with a resistance greater than 10,000 ohms will be removed or replaced. Static ground mechanically damaged will be repaired and retested.
Frequency: When observed to be physically damaged.

9-1.7 Electric Motors.

a. Based on the operational parameters, motors can be classified as:

- Induction (squirrel cage or asynchronous) motors: These are the most common type and widely used in pumps, fans and other industrial equipment.
- Synchronous motors: These are usually relatively large (500 hp and above) and are used when constant speed is required regardless of the torque on the shaft or power factor correction needed.

- DC motors: These type of motors are rare in industrial applications and are used mainly in traction, cranes and sometimes in elevators.

b. Depending on the applied voltage, motors can be:

- Low voltage (< 1,000 V).
- Medium voltage (2,300 V to 6,000 V). These motors are usually rated 300 hp to 15,000 hp (225 kW to 11.2 MW).

c. Depending on the number of phases, motors are:

- Single phase: Usually small motors less than 10 hp (7.5 kW) and often less than 3 hp (2.2 kW).
- Three phase: Most commonly used for industrial applications larger than 0.5 hp (375 W).

d. The maintenance of synchronous and DC motors should be performed by specialized companies and in accordance with the written instructions of the motor manufacturer.

9-1.7.1 Inspection and Maintenance – Electric Motors.

Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of motor. Follow all applicable general maintenance and safety requirements listed in the manufacturer's operation and maintenance manual.

a. Lubricate motor bearings and inspect for vibration and overheating.
Frequency: Quarterly

b. Check for debris and other foreign material in the fan housing.
Frequency: Semi-annually

c. Check motor ground wires. Ensure they are firmly connected to the housing or the junction box.
Frequency: Annually

d. If the motor is installed in a hazardous location, verify that the seals of the connection boxes and conduits are intact.
Frequency: Annually

9-1.8 Lighting.

The purpose of the lighting maintenance is to ensure a relatively constant illumination level and lighting quality for internal and external lighting systems. Most often, the lighting maintenance involves lamp replacement. There are two possible approaches for regular lamp replacement:

1. Spot re-lamping is performed when the lamps in a light fixture are replaced on an as-needed basis. If there is more than one lamp in the light fixture, it is recommended to replace all of the lamps at the same time. This ensures more uniform light output and equal utilization of the lamps.
2. Group re-lamping involves simultaneous replacement of all lamps in a given area regardless of whether they are operational or not.

9-1.8.1 Inspection and Maintenance – Lighting.

a. Verify proper operation of light switch, lighting contactor, photocell or timer as appropriate. If a lighting contactor is used, listen for the chatter of contacts or buzzing noise. These are indicative of a faulty contactor. Replace if required.
Frequency: Annually

b. With the lights turned on, observe individual luminaries for flicker or lights turning on and off. The former is indicative of a faulty choke. The latter is indicative of a faulty starter. Replace the faulty components as required.
Frequency: Annually

c. When light fixtures are located in hazardous areas, verify that the seals are intact and the hazardous rating of the fixture is maintained.
Frequency: Annually

d. Thoroughly clean dust, bugs, and debris from the luminaires. Light solvents or cleaning agents may be used.
Frequency: Annually (in dusty areas the luminaries may require cleaning at shorter intervals)

e. Re-Lamping: With the lights turned off, replace the lamps. In order to prevent accidental turning on of the lights, it is mandatory to switch off and lockout the breaker of the lighting circuit. Ensure the replacement lamps are the same type as those they are replacing. Verify the proper operation of all light fixtures after the lamp replacement.
Frequency: Annually or as required

9-1.9 Electronic Equipment.

Electronic equipment usually operates at voltages less than 120 V and does not have rotating components. As a result, electronic equipment tends to accumulate dust, which interferes with cooling. Overheating is the most likely cause for failure of electronic equipment.

9-1.9.1 Inspection and Maintenance - Electronic Equipment.

If the inspection and maintenance of the equipment does not require functional and operational testing, de-energize and lockout the power source to the equipment.

a. Inspect the outside of the equipment enclosures for dust and evidence of corrosion. Vacuum clean the dust to ensure unobstructed air circulation.
Frequency: Annually

b. Open the enclosure and vacuum clean the dust to ensure unobstructed air circulation. Pay particular attention to fans and air passages. If there is evidence of corrosion, verify that there is no water damage on printed circuit boards or contacts. If water or humidity damage is observed, the electronic components may not work properly and further testing is required.
Frequency: Annually

c. Verify proper operation of the space heater if one is installed.
Frequency: Annually

d. Check fans for proper operations and rotation.
Frequency: Annually

e. Look for signs of overheating such as discoloration and charring.
Frequency: Annually

f. Replace air filters.
Frequency: Annually or more frequently based on local environmental conditions.

g. Verify connection tightness. Lightly pull wires on soldered and terminal screws and ensure the wires are not loose.
Frequency: Annually

h. Verify that circuit boards are properly seated. Ensure that board locking tabs are fully engaged. Do not unplug and plug connectors to verify seating. This will wear out the pins. Unplug only if connector malfunction is suspected.
Frequency: Annually

i. Observe wires for excessive strain, braiding, or wear due to vibration. Replace as required.
Frequency: Annually

9-2 CATHODIC PROTECTION SYSTEMS.

9-2.1 Cathodic Protection.

Cathodic protection must be maintained by appropriately trained personnel (NACE CP tester certified). Personnel must ensure the cathodic protection system is maintained in accordance with UFC 3-570-06 and the most stringent of applicable host nation, Federal, state or local regulations.

Cathodic protection systems are installed on underground piping systems, at the bottom of steel tanks, on underground steel tanks, and on marine pier and anchor systems.

Cathodic protection systems are used to prevent corrosion of these systems and are specifically designed for the system that they are intended to protect.

9-2.1.1 Inspection and Maintenance - Cathodic Protection.

a. Inspect rectifiers in in accordance with UFC 3-570-06.
Frequency: \2\ Monthly /2/

b. Inspect cathodic protection systems in accordance with UFC 3-570-06.
Frequency: Annually

9-2.2 Electrical Isolation.

Electrical isolation components and lightning surge arresters are installed on underground piping systems as part of a complete corrosion protection system.

9-2.2.1 Lightning Surge Arresters.

Lightning surge arresters are devices that protect dielectric insulating flanges from over-voltage transients. These transients are caused by lightning or AC fault currents. The arresters block AC and DC voltages up to a predetermined voltage threshold. Upon voltage exceeding the threshold, the arrester allows the current to safely pass around the insulating flange.

9-2.2.1.1 Inspection and Maintenance – Lightning Surge Arresters.

a. Newer lightning surge arresters are designed to withstand unlimited surges at 50,000 amperes; however, manufacturers of older surge arresters may provide a maximum number of surge events that can occur before it must be replaced. If surge arresters include a maximum number of surge events, a spare arrester must be kept on hand. Refer to the surge arrester manufacturer's operation and maintenance manual for particular inspection instructions and parts. Inspect as part of an overall cathodic protection system inspection.
Frequency: Annually

9-3 CARD AND KEY LOCKS.

Card and proximity readers are used at Automated Fuel Service Station (AFSS) to activate the systems. Card and key lock system issues must be called into the Business System Modernization-Energy (BSME) Help Desk for all issues outside of the annual preventive maintenance visits.

9-3.1 Inspection and Maintenance - Card and Key Locks.

a. Conduct operational check of card and key lock system and ensure that all features provided with the installed system are operational.
Frequency: Annually

9-4 LIGHTNING PROTECTION SYSTEMS.

Lightning protection systems are typically designed to \1\/1/UFC 3-575-01. The systems include air terminals that are installed on top of buildings, canopies, or tall equipment. The air terminals are connected together with heavy-gauge copper or aluminum wires. These copper or aluminum wires are also attached to grounding loops or ground rods installed at the base of the building, canopy, or equipment.

9-4.1 Inspection and Maintenance – Lightning Protection Systems.

a. Inspect air terminals to make sure they are securely attached to the roof of the building, canopy, or the piece of equipment. Check all connections between the air terminals and the grounding loop or grounding rods. Repair damaged or loose connections and perform continuity check after repairs.
Frequency: Annually

9-5 GROUND VERIFICATION SYSTEMS.

Ground verification systems are used in petroleum fuel truck and rail offloading and loading systems. The systems are used to verify that the trucks or rail cars are grounded. In most cases, the systems are interlocked with the receipt or issues controls and will prevent the receipt or issue system from operating if an acceptable ground connection between the truck or rail car and the fueling system is not detected.

9-5.1 Inspection and Maintenance – Ground Verification Systems.

a. Conduct an operational check of the ground verification system and ensure that all features provided with the installed system are operational. Inspect the plug for corrosion, weakness, or loose nuts and replace if heavily dented or deformed.
Frequency: Quarterly

9-6 ELECTRONIC OVERFILL PROTECTION SYSTEMS.

Overfill protection systems are used on petroleum fuel truck and rail issue systems. In some cases, overfill protection switches are permanently installed on petroleum fuel trucks or rail cars. In other cases, probes from the system are applied to the trucks or rail cars at the time of petroleum fuel issue. The overfill protection systems are interlocked with petroleum fuel issues systems and will stop the issue process if a high petroleum fuel level is detected in a truck or rail car.

9-6.1 Inspection and Maintenance – Electronic Overfill Prevention Systems.

a. Conduct operational check of overfill prevention system and ensure that all features provided with the installed system are operational.
Frequency: Quarterly

This Page Intentionally Left Blank

CHAPTER 10 ALTERNATE POL FACILITIES

10-1 LIQUEFIED PETROLEUM GAS.

This section includes inspection and maintenance information related to Liquefied Petroleum Gas (LPG) storage and distribution systems. These systems differ from typical fuel systems due to the pressures involved and are covered by additional regulations. LPG systems must follow the equipment, installation and maintenance requirements listed in NFPA 58*.* Operation and maintenance manuals required for LPG systems by NFPA 58 must be developed for each installation.

10-1.1 Liquefied Petroleum Tanks.

Liquefied petroleum tanks are pressure vessels with typical maximum allowable working pressure of 250 psig. These tanks are built to ASME standards for non-fired pressure vessels. These tanks follow the requirements listed in NFPA 58 and API 2510.

10-1.1.1 Inspection and Maintenance – Liquefied Petroleum Tanks.

a. Inspect fuel tank for leaks. If a leak is occurring, the odorizing agent of the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. Systems that are found with leaks must be taken out of service.
Frequency: Monthly

b. Test operation of emergency shutoff valves. Ensure the fusible link mechanism is attached properly to actuate in case of a fire and that it has not been by-passed, blocked, or damaged in any manner. Ensure the fusible link is not filled with debris or paint which could impact operation.
Frequency: Semi-annually

c. Check settings of tank safety valves and calibrate if required.
Frequency: Every 5 Years

10-1.2 Liquefied Petroleum Pipelines.

Liquefied petroleum lines transfer liquefied petroleum gas between the delivery vehicle and the storage tanks, and between vaporizers and other equipment and storage tanks. These lines operate at the storage pressure of the tank.

10-1.2.1 Inspection and Maintenance – Liquefied Petroleum Pipelines.

a. Conduct visual inspection of pipelines for potential damage and leak points. Use a soap and water solution to spray on areas suspected of leaks. Systems that are found with leaks must be taken out of service and repaired.
Frequency: Monthly

b. Inspect coatings and markings on piping. Repair coating deterioration and replace labels that are fading and are difficult to read.
Frequency: Semi-annually

10-1.3 Liquefied Petroleum Vapor Lines.

Liquefied petroleum vapor lines are used to transfer vaporized petroleum gas between the delivery vehicle and the LPG tank and from the LPG tank to use points. Vapor transfer between the LPG tank and the delivery vehicle is at the tank operating pressure and transfer from the tank to the use points is typically at a reduced pressure.

10-1.3.1 Inspection and Maintenance – Liquefied Petroleum Vapor Lines.

a. Inspect vapor lines for leaks. If leaks are occurring, the odorizing agent in the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. Systems that are found with leaks must be taken out of service and repaired.
Frequency: Monthly

b. Inspect coatings and markings on piping. Repair coating deterioration and replace labels that are fading and are difficult to read.
Frequency: Semi-annually

10-1.4 LPG Vaporizers.

At large use points, vaporizers are used to vaporize the pressurized liquid into gas for use.

10-1.4.1 Inspection and Maintenance – LPG Vaporizers.

a. Inspect vaporizers for leaks. If leaks are occurring, the odorizing agent in the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. Systems that are found with leaks must be taken out of service and repaired.
Frequency: Monthly

b. The manufacturer maintenance schedules and recommendations provided with the LPG vaporizer must be followed.
Frequency: As required

10-1.5 Petroleum Gas Regulators.

Regulators are used to reduce the pressure of petroleum gas before it is used or transferred to the use point.

10-1.5.1 Inspection and Maintenance – Petroleum Gas Regulators.

a. Inspect petroleum gas regulators for leaks. If leaks are occurring, the odorizing agent in the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. Systems that are found with leaks must be taken out of service and repaired.
Frequency: Monthly

10-1.6 Liquefied Petroleum Gas Hoses.

Liquefied petroleum gas hoses are used to transfer liquid and vapor between LPG storage tanks and delivery vehicles.

10-1.6.1 Inspection and Maintenance – Liquefied Petroleum Gas Hoses.

a. Inspect hoses for damage and leaks. If leaks are occurring, the odorizing agent in the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. If leaks are detected from a hose discontinue use of the hose and remove it from service. Inspect for damage to outer cover that exposes reinforcement. Inspect for kinks or flattened areas, soft spots or bulges. Inspect couplings and ensure they have not slipped on the hose or been damaged.
Frequency: Annually

10-2 COMPRESSED NATURAL GAS (CNG).

This section includes inspection and maintenance information related to compressed natural gas systems. These systems used compressed gas at pressures up to 5,000 psig (34.5 MPa). CNG systems must follow the equipment, installation and maintenance requirements listed in NFPA 52. Operation and maintenance manuals required for CNG stations by NFPA 52 must be develop for each installation.

10-2.1 CNG Piping.

CNG piping is used between the natural gas source and the compressor. It is also used between the compressor and the CNG tubes or storage tanks and storage and the CNG dispenser. The lines vary from low pressure to high pressure. Some CNG lines may have pressure ratings as high as 5,000 psig (34.5 MPa).

10-2.1.1 Inspection and Maintenance – CNG Piping.

a. Inspect CNG lines for leaks. Inspection of high-pressure CNG lines and equipment must be conducted using proper PPE including but not limited to safety glasses, a face shield, hard hat and fire resistant clothing. If leaks are occurring, the odorizing agent in the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. Systems

that are found with leaks must be taken out of service and repaired.
Frequency: Daily

b. Inspect coatings and markings on piping. Repair coating deterioration and replace labels that are fading and are difficult to read.
Frequency: Semi-annually

10-2.2 CNG Compressors.

Compressors are used to boost the pressure of natural gas from the supply pressure to the high-pressure tube storage pressure. The compressors include up to four stages of compression and are driven by electrical motors or natural gas engines. Designs of compressors and compressor drivers vary by manufacturers.

10-2.2.1 Inspection and Maintenance – CNG Compressors.

a. Compressors will require maintenance based on the model included in the system. Consult the compressor manual for manufacturer’s maintenance requirements.
Frequency: As required

10-2.3 CNG Storage.

High-pressure tubes or spherical storage tanks are used to store CNG at pressures of up to 5,000 psig (34.5 MPa). The tubes and tanks should be ASME stamped pressure vessels. The tubes are typically assembled in bundles of twenty (20).

10-2.3.1 Inspection and Maintenance – CNG Storage.

a. Inspect CNG tubes and tanks for leaks. Inspection of high-pressure CNG lines and equipment must be conducted using proper PPE including but not limited to safety glasses, a face shield, hard hat and fire resistant clothing. If leaks are occurring, the odorizing agent in the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. Systems that are found with leaks must be taken out of service and repaired.
Frequency: Daily

b. Inspect coatings and markings on storage tubes or tanks. Repair coating deterioration and replace labels that are fading and are difficult to read.
Frequency: Semi-annually

c. Check operation and calibration of safety valves on tubes and tanks.
Frequency: Every 3 years

10-2.4 CNG Dispensers

Dispensers (Vehicle Fuel Appliances) are used to transfer CNG between storage tubes or tanks and CNG vehicle storage tanks. The system uses a series of valves to cascade the compressed gas from the tubes or tanks into the vehicle storage tank.

10-2.4.1 Inspection and Maintenance – CNG Dispensers

a. Dispensers are listed for service with CNG and will vary by manufacture. Consult the maintenance manual that was supplied with the system for manufacturer's maintenance required for the CNG dispenser.
Frequency: As required

10-2.5 CNG Dispenser Hoses.

Hoses and fill adaptors are used to make the connection between the CNG dispenser and the vehicle storage tank.

10-2.5.1 Inspection and Maintenance – CNG Dispenser Hoses.

a. Inspect hoses for damage, leaks, and cracks. If leaks are occurring, the odorizing agent in the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. If leaks are detected from a hose, discontinue the use of the hose and remove it from service.
Frequency: Monthly

b. Test hoses for leaks following manufacturer recommended frequencies and procedures.
Frequency: As required

10-3 HYDRAZINE CHARGING UNITS.

Hydrazine is transferred from 55 gallon (208 liter) drums to small aircraft holding tanks by a closed system charging unit.

10-3.1 Inspection and Maintenance – Hydrazine Charging Units.

a. Hydrazine charging units are self-contained factory fabricated systems. Refer to the manufacturer's maintenance manual that was provided with the system for required periodic maintenance.
Frequency: As required

10-4 JP-10.

JP-10 is a gas turbine fuel developed for missiles. Maintenance for JP-10 system components should follow maintenance requirements for fuel system components listed in this document.

10-5 OTTO.

Information on OTTO fuels is contained in Naval Sea Systems Command (NAVSEA) S6340-AA-MMA-010. Distribution of this document is restricted. Requests for information are handled by Naval Sea Systems Command.

CHAPTER 11 SUPPORT FACILITIES

11-1 SECONDARY CONTAINMENT.

The military services assign responsibility for inspection, maintenance, and draining of secondary containment structures to various organizations (including contractors).

Those organizations or contractors must inspect and maintain secondary containment structures in accordance with military service-specific directives or applicable contract requirements. Refer to Section 8-10 Containment Systems for tank secondary containment inspection and maintenance procedures.

11-1.1 Fuel Truck \1\ and Rail Car /1/ Containment Areas.

Fuel truck **1**\ and rail car /**1**/ containment areas such as refueler parking areas, refueler loading areas, and commercial truck offloading **\1** and loading areas, rail car loading and offloading /**1**/ areas are equipped with secondary containment. Typically these areas are provided with security fence and overhead lighting.

11-1.1.1 Inspection and Maintenance – Fuel Truck \1\ and Rail Car /1/ Containment Areas.

a. Remove debris from around security fence.
Frequency: Monthly

b. Inspect fence grounding points. Ensure connections are not loose or damaged.
Frequency: Monthly

c. Inspect the parking area for cracks in the concrete containment paving and curbs. Remove vegetation that may have established roots in the buildup of dirt or from exposed earth under cracks. Thoroughly clean and seal cracks with a fuel resistant sealant.
Frequency: Quarterly

d. **1**\ Secondary containment systems degrade and will collect debris which can clog drainage inlets or prevent drain valves from sealing properly. Hydrostatically test secondary containment and associated drainage systems to include containment concrete/sealant, drain inlets, drain lines and containment drain valves to ensure containment is liquid tight. This test may use opportune rainfall by holding rainwater in the containment system for one hour. Where evaporation is a concern, conduct the testing when this concern would be minimized, such as at night/early morning or during a time of year when this would not be as much of an issue. Record the water level at the start of a 60-minute (minimum) hold period and if the water level drops by 1/8 inch or more, perform and record an investigation to determine the cause and any required repairs. Once repairs are

completed, a new test must be completed. Refer Appendix B for testing procedures and to document the testing. /**1**/
Frequency: \1\ Every 3 years /1/

e. Verify continuity of vehicle grounding system connections. If a connection is suspected to be loose, perform further testing. In some occasions it is more cost effective to replace the suspected connection instead of performing diagnostic tests.
Frequency: Annually

f. Inspect pavement markings and vehicle movement lines for wear and fading. Repair faded or worn pavement markings.
Frequency: Annually

g. Inspect security fence for wear and rust. Inspect barbed wire and ensure it is adequately secured to outriggers. Repair loose fencing components and coatings at areas that show rust.
Frequency: Annually

h. Refer to Section 9-1.8 Lighting for inspection and maintenance requirements of area lighting.

11-1.2 Remote Spill Containment.

Fuel truck parking, loading and offloading areas **\1** and rail car loading and offloading areas, **/1/** are typically equipped with remote containment basins. These basins are used to increase the overall containment volume of the system. The basins are constructed of concrete walls and a concrete floor.

11-1.2.1 Inspection and Maintenance – Remote Spill Containment.

a. Inspect the remote containment basin for cracks in the concrete containment paving, walls, and curbs. Remove vegetation that may have established roots in the buildup of dirt or from exposed earth under cracks. Thoroughly clean cracks with a water spray or air jet. Seal cracks with a fuel resistant sealant.
Frequency: \2\ Monthly /2/

b. If equipped, inspect spill containment sump pump for proper operation.
Frequency: \2\ Monthly /2/

c. **\1** Secondary containment systems degrade and will collect debris which can clog drainage inlets or prevent drain valves from sealing properly. Hydrostatically test secondary containment and associated drainage systems to include containment concrete/sealant, drain inlets, drain lines and containment drain valves to ensure containment is liquid tight. This test may use opportune rainfall by holding rainwater in the containment system for one hour. Where evaporation is a concern, conduct the testing when this concern would be minimized, such as at night/early morning or during a time

of year when this would not be as much of an issue. Record the water level at the start of a 60-minute (minimum) period and if the water level drops by 1/8 inch or more, perform and record an investigation to determine the cause and any required repairs. Once repairs are completed, a new test must be completed. Refer Appendix B for testing. **/1/**.
Frequency: \1\ Every 3 years /1/

11-2 PROTECTIVE SHELTERS.

11-2.1 Pumphouse/Filter Buildings.

Pump and filter equipment is typically enclosed within a building or covered by a shelter. These buildings can be constructed of pre-engineered metal or concrete. The floors of these areas should provide secondary containment for the piping and equipment that is installed in the building or under the shelter.

11-2.1.1 Inspection and Maintenance – Pumphouse/Filter Buildings.

a. Inspect the floor and containment curbs for cracks. Thoroughly clean cracks with a water spray or air jet. Seal cracks with a fuel resistant sealant.
Frequency: Annually

b. Refer to **\1** UFC 3-110-03 **/1/** for inspection and maintenance requirements of pumphouse and filter building roof systems.

11-2.2 Canopies.

Canopies are used to cover service station dispensers, containment basins, fuel truck loading and offloading equipment, and equipment installed in remote areas.

11-2.2.1 Inspection and Maintenance – Canopies.

a. Inspect and maintain canopies in accordance with **\1** UFC 3-110-03 **/1/**.

11-3 SAFETY SHOWERS AND EYEWASH FOUNTAINS.

Emergency safety showers and eyewash fountains are installed around fueling areas and pumphouses. They are typically equipped with an activation alarm that energizes a strobe light and horn. In some cases emergency eyewash/showers are equipped with tempered water systems that supply warm water to the emergency eyewash/shower.

11-3.1 Inspection and Maintenance – Emergency Eyewash/Showers.

a. Test operation of the emergency eyewash/shower by pushing on the activation handles. Ensure the water is not brown in color, due to rust in the piping or dirt seeping in from a hole in the buried piping. For systems with tempered water, ensure that the water that is being supplied by the emergency eyewash/shower is between 60 and 100 °F (16 and 39 °C).

For systems with a horn and strobe light, ensure that the horn and strobe light activate when the activation lever on the emergency eyewash/shower is pushed. For systems that interface with Installation or fire emergency systems, pre-coordinate before testing. At some Installations emergency eyewashes and showers act as EFSOs and are tied into the fire alarm systems.
Frequency: Weekly

b. Inspect portable/packaged safety showers and eyewash stations for proper operation. Check fluid levels. Where tap water is used, fluid must be replaced monthly. Less frequent intervals of fluid change, as recommended by the manufacturer, are acceptable where a solution or water additive is used. Ensure packaged eyewash supplies are within the listed expiration date. Tags or labels must be attached to the unit or adjacent to it, indicating the fluid change schedule.
Frequency: Monthly

c. Inspect the exterior coatings of permanently installed units and repair damaged coatings or rust.
Frequency: Quarterly

d. For systems with tempered water systems inspect components of the water heater for correct operation and temperature control. Ensure that the safety valve on the hot water heater tank is not leaking.
Frequency: Semi-annually

e. Inspect signage and labels on the emergency eyewash/shower. Replace missing labels or signage that has become loose. Signs that are faded must be replaced.
Frequency: Annually

11-4 FUELS LABORATORIES.

Fuels laboratories are typically equipped with ventilation hoods. These systems will be periodically inspected to ensure proper operation. Laboratories must comply with the general facility requirements of UFC 3-600-01 and NFPA 45.

11-4.1 Ventilation Hoods.

Ventilation hoods are used to prevent the buildup of flammable and noxious vapors inside of fuels laboratories. The hoods are typically equipped with sliding or rollup doors that can be used to reduce the opening area of the hood. Additional ventilation hood designs employed include laminar flow, elephant trunk and canopy hoods. The systems pull air from inside of the lab through the hood and exhausts outside of the lab through a ventilation stack. Fume hoods must comply with military service-specific directives and/or 29 CFR 1910.1450, and ANSI (American National Standards Institute)/AIHA *Laboratory Ventilation Z9.5*.

11-4.1.1 Inspection and Maintenance – Ventilation Hoods

a. Inspect the operation of the doors. Ensure that they close and open smoothly.
Frequency: Quarterly

b. Inspect the lights inside of the hood to make sure they are operating properly. Replace light bulbs that are no longer working.
Frequency: Semi-annually

c. Verify that all electrical equipment is properly classified in accordance with NFPA 70.
Frequency: Annually

d. Inspect the ventilation system (ductwork, fans, etc.) for signs of disrepair and air leakage and ensure it is operational and pulling air through the hood. Inspect and assure that the lab hood air measuring device for assuring proper air flow is permanently attached and working properly. The ventilation hood must be inspected and **\1** approved by a service specific industrial hygienist or bioenvironmental engineer **/1/** in accordance with OSHA, 29 CFR 1910.1450, and ANSI/AIHA *Laboratory Ventilation Z9.5*.
Frequency: Annually

e. Verify negative pressure is present through the ventilation hood to the exhaust.
Frequency: Annually

11-5 OIL/WATER SEPARATORS.

Oil/water separators are used to remove water from oil/water mixtures. Oil/water separators are sized for a maximum flow rate and this maximum flow rate must not be exceeded. Inspections and maintenance must be conducted in accordance with the regulating authority for the particular location (e.g., Federal, host nation, state and local) and in accordance with the OEM specifications so as not to void warranty.

11-5.1 Inspection and Maintenance – Oil/Water Separators.

a. Inspect the oil/water separator for the buildup of collected petroleum fuel or oil. Remove and properly dispose of accumulated petroleum fuel or oil.
Frequency: Quarterly or as needed based on precipitation events.

b. Drain, clean, and inspect the interior of the oil/water separator. Ensure all divider plates and screens are in good working order. Replace or repair damaged components.
Frequency: Annually or more frequently based on local environmental conditions.

11-6 CRANES AND HOISTS.

Cranes and hoists are used inside of pumphouses and maintenance areas to assist in the removal and installation of petroleum fuel system components.

11-6.1 Inspection and Maintenance – Cranes and Hoists.

a. Inspect cranes and hoists for smooth operation. If the crane or hoist is equipped with electronic controls, check power supply and operational control cords for nicks or damage. A crane service technician must correct binding that may prevent smooth operation and repair damage to power cords.
Frequency: Before each use

b. Apply lubricant or grease to areas that require periodic greasing.
Frequency: Annually

c. Military services-specific, host nation, state, and/or local regulations require cranes and hoists to be certified for operation. Follow the more stringent of military services-specific, host nation, state or local regulations.
Frequency: Annually

CHAPTER 12 FUEL FACILITY TEMPORARY DEACTIVATION OR CLOSURE

12-1 DEACTIVATION OF FUELING FACILITIES.

Prior to deactivation of a fuel facility, maintainers must contact the Installation's Environmental Office to review the requirements and coordinate to ensure that the deactivated facility remains in regulatory compliance throughout the deactivation period. Note: USTs deactivated for an extended period of time may be subject to closure notifications per Federal, state, and local requirements. Contact Installation Environmental Office for further information.

12-2 DEACTIVATED PETROLEUM FUEL TANKS

Deactivated petroleum fuel tanks that require ballast must be filled with a water or anti-corrosion solution to protect against floatation and overturning. Piping connections of tanks must be disconnected and blind flanged. Remaining active pressure relief systems attached to deactivated tanks must be reconnected to active tanks. Tanks must be labeled to indicate the present status of the tanks and the previous contents. Cathodic protection systems on deactivation tanks must continue to be used and maintained.

12-2.1 Inspection and Maintenance – Deactivated Petroleum Fuel Tanks.

a. Inspect water or anti-corrosion level in tank. If level has dropped, investigate potential leak points such as blind flanges. Repair leaks that are detected and refill to appropriate level.
Frequency: Quarterly

b. Check exterior coatings and labels. Repair peeling coatings and/or rusting areas and replace or repair labels which have become faded and difficult to read.
Frequency: Quarterly

c. Inspect cathodic protection system on deactivated tanks for proper operation.
Frequency: Annually

12-3 DEACTIVATED PETROLEUM FUEL PIPELINES.

Deactivated petroleum fuel pipelines must be drained of fuel, vapor freed and isolated by the use of blind flanges, blanks, or spectacle blinds. Once the petroleum fuel pipeline is isolated it must be charged with nitrogen to a pressure of 10 psig (69 kPa), or as otherwise determined based on the size and thickness of the pipe material. Pipeline cathodic protection systems must remain in operation and in good working order throughout the deactivation period.

Inter-terminal pipelines regulated by the DOT must have a written deactivation plan describing the process to be used. The deactivation plan must be submitted to the

Installation Environmental Office and the Pipeline Regulatory Compliance Agency for review and approval prior to taking the inter-terminal pipeline out of service and reclassifying the pipeline into inactive status. Refer to 49 CFR 195 for additional information on closure of DOT regulated pipelines.

12-3.1 Inspection and Maintenance – Deactivated Petroleum Fuel Pipelines.

a. Inspect the pressure of the nitrogen charge applied to the petroleum fuel pipeline with a pressure gauge. If the pressure of the charge has dropped investigate and repair leak points. Once leak points are repaired, recharge with nitrogen.
Frequency: Quarterly

b. Check exterior coatings and labels. Repair peeling coatings and/or rusting areas and replace or repair labels which have become faded and are difficult to read.
Frequency: Quarterly

c. Inspect cathodic protection system for proper operation.
Frequency: Annually

12-4 DEACTIVATED PETROLEUM FUEL PUMPS.

Deactivated petroleum fuel pumps must be disconnected from supply and discharge piping and the interior of the pumps must be treated with a light corrosion-inhibiting oil. The suction and discharge ports of the pump must be equipped with blind flanges or plugs.

12-4.1 Inspection and Maintenance – Deactivated Petroleum Fuel Pumps.

a. Manually rotate pump through several rotations. Ensure that the pump turns freely.
Frequency: Quarterly

b. Check exterior coatings. Repair peeling coatings and/or rusting areas and replace or repair labels which have become faded and are difficult to read.
Frequency: Quarterly

c. Remove isolation flanges and recoat interior of pump with light corrosion-inhibiting oil.
Frequency: Annually

12-5 MISCELLANEOUS DEACTIVATED COMPONENTS.

Deactivated control valves and specialized components must be removed from piping and tanks. The connection ports of the removed components must be equipped with blind flanges, dust caps, or plugs in order to protect the internal surfaces and working parts of the components from environmental exposure. The pipe or tank connection points of the removed components must also be equipped with blind flanges or plugs in order to protect the internal surfaces of the piping or tanks from environmental exposure. The removed components must be stored in a clean dry area protected from the elements.

12-5.1 Inspection and Maintenance – Miscellaneous Deactivated Components.

a. Ensure that blind flanges are tight. Inspect exterior coatings and labels. Repair peeling coatings and/or rusting areas and replace or repair labels that have become faded and are difficult to read.
Frequency: Annually

12-6 TANKS AND PIPELINES.

Refer to Chapter 14 of UFC 3-460-01 for facility closure requirements.

12-7 DOCUMENTATION/RECORDKEEPING.

Refer to Section 14-3 of UFC 3-460-01 for inventory requirements of closed systems.

\1

APPENDIX A DLA ENERGY PROJECT PROGRAMING

A-1 PROJECT PLANNING STUDIES.

The Planning Study Program is a fence-to-fence analysis of Installation-level infrastructure holding DLA Energy capitalized fuel to identify deficiencies. They are scheduled in 5 year intervals. The program has three over-arching phases:

- Planning Study Site Visit. This phase involves an on-location site visit to identify deficiencies in the fuels infrastructure.
- Planning Study Design Package Development. This phase involves the creation and refinement of the report used to document deficiencies that will be compiled into projects for funding.
- Planning Study Construction Project. This phase involves the construction required to rectify deficiencies identified during the planning study site visit phase.

A-2 RECURRING MAINTENANCE MINOR REPAIR PROGRAM.

The DLA Energy Recurring Maintenance Program is a contract vehicle which provides quarterly, semi-annual, and annual maintenance service for capitalized Installation level real property. Also included is a minor repair and emergency response services for mission essential repairs of a non-technical nature within an established dollar amount. This program is currently executed by the United States Army Corps of Engineers (USACE); however, other executing agencies may be used to address recurring maintenance requirements not covered by this contract.

A-3 FILTER REPLACEMENT PROGRAM.

For facilities eligible for DLA Energy SRM Program, funds have been made available to purchase replacement filter separator cartridges and associated parts such as O-rings and gaskets. **2**\ Refer to the current DLA energy filter requisitioning policy document for further guidance in accordance with DLA-Energy P-22, *Procedures for Requisition, Funding Requests, or Reimbursement of Filter/Coalescer Elements*. /**2**/

A-4 DLA CENTRALLY MANAGED PROGRAMMING.

The Centrally Managed Program (CMP) manages regulatory, compliance, and best practice maintenance processes for deficiencies on assets that are common to all Services.

A-4.1 Tank Integrity Management Program.

The Tank Integrity Management Program for DLA Energy capitalized tanks uses industry standard API 653, *Tank Inspection, Repair, Alteration, and Reconstruction* document or STI SP001, *Standard for the Inspection of Aboveground Storage Tanks*, as the basis of meeting regulatory requirements included in 40 CFR 112 *Oil Pollution Prevention* and state regulations. Many military tanks, such as cut and cover and mined styles, do not fit well into the API 653 standard so the code is applied to the maximum extent possible. It is the policy of DLA Energy to require professional engineering oversight of all inspection and repair programs.

DLA Energy sanctions the use of STI *Standard for the Inspection of Aboveground Storage Tanks*, SP001 as the inspection standard for small shop fabricated DLA Energy capitalize tanks, typically aboveground, horizontal, and up to 45,000 gallons in size. Host nation standards, such as the German TUEV (Technischer Ueberwachungsverein [German safety and standards institution]), are addressed as an “add-on” to the base inspection program.

Military service-specific SCP identifies tanks coming due, are past due or are without a record of inspection and coordinates inspections with DLA Energy. Inspection frequencies are in accordance with applicable standards and codes.

A-4.2 Pipeline Integrity Management Program.

The Pipeline Integrity Management Program provides for the development of Pipeline Integrity Management Plans (PIMPs) and funds API 570 inspections of piping systems.

A-4.3 Pressure Vessel Integrity Management Program.

The Pressure Vessel Integrity Management Program provides for the physical inspection of pressure vessels (e.g., filter separators, micronic or cyclonic separators, relaxation chambers, and air eliminators tanks) in accordance with API 510. Its goal is to reduce the risk of failure, thereby reducing potential environmental damage and/or mission readiness consequences.

A-4.4 Cathodic Protection System Integrity Management Program.

The Cathodic Protection System Integrity Management Program provides for the annual inspection, repair and maintenance of cathodic protection systems. Cathodic protection is a form of corrosion protection applied to underground or underwater metallic structures. Cathodic protection usually works in conjunction with protective coatings on steel/stainless steel structures. Common applications include buried pipelines, underground fuel storage tanks, and the bottom of aboveground fuel storage tanks. Other applications include water storage tanks, and submerged pilings/fender piles on piers and wharves. Federal and state regulations require cathodic protection for many fuel related applications and UFC 3-570-06 requires cathodic protection for all metallic fuel containing structures in direct contact with soil and water.

Corrosion inhibitors are another form of corrosion control covered under this program. Corrosion inhibitors are used in areas where cathodic protection is not possible, usually due to space requirements. A typical inhibitor project would replace a failed or absent cathodic protection system where anode replacement or installation is not economical or feasible. These systems follow the same guidelines and inspection cycle as cathodic protection systems.

A-4.5 Maritime Fuel Facilities/Piers Program.

The Maritime Fuel Facilities/Piers Program provides for the inspection and repair of piers. Routine pier inspections are conducted to identify, quantify, and document deficiencies observed on marine fuel facility structural, electrical, and mechanical systems. The results from inspections are utilized by professional engineers to assess a facility's overall condition and operational readiness (fit for purpose), and to produce maintenance plans and specifications for repairs.

A-4.6 Marine Loading Arm Program.

The Marine Loading Arm (MLA) Program provides for the inspection and repair of loading arms used in Defense Working Capital Fund (DWCF) loading/unloading operations at fixed real property energy infrastructure.

A-4.7 Underwater Hose Program.

Only underwater hoses used in Defense Working Capital Fund (DWCF) loading/unloading operations are eligible for DLA Energy SRM funds. This funding is provided by the Underwater Hose Program.

A-4.8 Dredging Program.

The Dredging Program provides funds for dredging projects. Deficiencies are identified by the Installation. Dredging of dedicated waterways used for vessel movement and delivery of DWCF products is eligible for DLA Energy funding consideration under this program. Dredging of shared-use waterways is cost shared based on a benefit assessment involving all users or in accordance with established Energy Infrastructure Facility Sustainment Model (FSM) rules.

A-4.9 Rails Program.

The Rails Program provides for the maintenance and sustainment of railcar loading/off-loading infrastructure and rail spurs from the Installation fence line. The program covers these systems when they are used for the DWCF fuel mission and coded for DLA Energy sustainment.

A-4.10 Demolition Program.

The Demolition Program provides funds for demolition projects when the real property is no longer required by DLA Energy or the applicable military service. Deficiencies are identified by the Installation. DLA Energy will fund demolition of real property infrastructure if the facility last contained DLA Energy owned product and for which DLA

Energy had SRM funding responsibility. DLA Energy may, depending on the situation, also fund facility demolition using Military Construction (MILCON) appropriation when the MILCON project involves demolition of existing energy infrastructure.

A-4.11 Automated Fuel Handling Equipment/Automatic Tank Gauging Program.

The Automated Fuel Handling Equipment (AFHE)/Automatic Tank Gauging (ATG) Program provides for installation and maintenance of automation systems. Professional engineering assessments, which are required by DLA Energy on capitalized fuel systems, are conducted under this program. These assessments improve overall fuel facility controls, improve inventory accountability, provide fail-safe engineering for spill prevention, increase efficiency, and execute routine maintenance.

This program supports automation programs for AFHE, Automated Fuel Service Station (AFSS), ATG, ATGR, Hydrant Automation Monitoring System (HAMS), Independent Alarm System (IAS), Overfill Protection Equipment (OPE) and Temperature Compensating Meter (TCM). The DLA Energy Installation Support Automation Branch coordinates with the military service-specific SCPs, the Space and Naval Warfare System Center (SPAWAR), and Installations to identify needed projects.

This program also supports automation maintenance programs for AFHE, ATG, IAS, AFSS, OPE, and Hydrant Fueling Automation Maintenance (HFAM). The life cycle maintenance support includes annual preventative maintenance and as-needed corrective maintenance support. Maintenance activities follow an annual cycle, are initiated after the warranty period, have an indefinite duration, and are reviewed annually. This program is also used to provide system support which includes on-call technical support, logistics support, configuration management, system enhancements and modifications.

Deficiencies are grouped into projects based on several factors such as geographic location and the preferences of the executing agents, military service-specific SCPs or other affected parties. Capital automation projects require the development of a Business Case Analysis (BCA), must be included in the Capital Budget 5-Year Plan, listed on the annual Master Operating Plan (MOP) and have the approval of a Capital Execution Package.

A-4.12 Leak Detection Program.

The Leak Detection Program is an Environmental managed and funded program to execute annual, biennial, and quarterly testing and monthly monitoring of DLA capitalized underground fuel storage and distribution systems worldwide for storage tanks, transfer and distribution piping, hydrant systems and ground fuel facilities. Testing is performed to meet environmental regulatory requirements and DLA best management practice testing requirements. The program encompasses leak detection testing, leak confirmation, location and/or inspection and rapid response of suspect leaks at DLA capitalized fuel facilities worldwide.

The Leak Detection program also includes support for permanently installed leak detection systems. This includes the maintenance, repair and certification of the permanently installed leak detection systems and the installation of new permanent leak detection systems at DLA capitalized fuel facilities worldwide.

A-5 REPAIR PROJECTS.

Provide adequate information for input of a deficiency into the DLA Energy Enterprise Business System (EBS) database. Required information for project development include: a cost estimate, justification, impact if not provided, and project description as well as an indication of the expected funding type. The funding types that are available include: Minor Construction (MC), Maintenance and Repair (MR), Maintenance (M) and Environmental (E).

A-6 CAPITALIZED ENVIRONMENTAL FUNDING.

DLA Energy also has an Environmental Managed and Funded Program for the development and revisions of environmental documents and will also support environmental compliance and restoration funding of capitalized fuel facilities for sampling and testing of petroleum, oil, and lubricants (POL) emissions and discharges, removal and disposal of POL wastes (except consumables), fees for spill cooperatives, permit fees, fines and penalties, spill cleanup, removal and disposal of POL wastes associated with facility maintenance projects and update of environmental compliance documents.

APPENDIX B CONTAINMENT INTEGRITY TESTING CHECKLIST

Secondary Containment/Drainage System Integrity Testing			
UST Facility		**Person Conducting Test**	
Facility Name	Facility ID#	Tester's Name:	
Physical Address		Testing Company:	
City	State	City	State

Testing Requirements	
Type of Test	□ Code of practice developed by a nationally recognized association or independent testing
Purpose of Test	□ Notice of Alleged Violation
	□ Required Annual Test
	□ Post Repair Test

Liquid Tight Test Procedure

1. Clean containment of any debris.
2. Visually exam containment area for problem areas (gaps, cracks, sealant failure, etc.)
3. Make sure drainage valve is completely closed, *IF* adding water.
4. Add water to observe standing water at a highest point within the containment area (or conduct this test after a rain event where water has filled the secondary containment area).

2\ 4a. Fill all containments other than truck fill stands to minimum 1 inch water depth. /**2**/

5. Ensure water is calm (i.e. it is not still raining), and mark and record the high water line (e.g. using a tape measure with 1/16-in increments).
6. Leave water in containment, undisturbed for one hour (i.e. no operations are taking place).
7. Compare the starting water level to the ending level:
   - If the water level is the same or changed less than 1/8th (vertical) inch, the containment passed the test.
   - If the water level has dropped 1/8th inch or more, an investigation must be conducted.
8. After the investigation, justify why this is not a leak or identify the leak and necessary repairs.

Test Data Table						
Test Date						
Containment Item ID No.						
Test Start Time						
Test End Time						
Test Beginning Water Level						
Test Ending Water Level						
Test Result (P/F)						
Comments:						

I hereby certify that all the information contained in this report is true, accurate, and in full compliance with legal requirements. Maintain six (6) years of test records. (Two Test Periods)

Tester's Signature: ______________________________________ Date:______________________

Secondary Containment Drainage System Integrity Testing

General Guidance

Who must complete this form?
Any person or their authorized representative (such as a tester or contractor) that conducts the secondary containment liquid tight testing.

What sites must complete this testing?
All underground secondary containment drainage systems to include bulk fuel storage, aircraft fueling systems, truck and railcar loading & unloading areas, marine facilities, and ground vehicle fuel facilities.

Petroleum Equipment Institute (PEI) Recommended Practice 1200-17: *Recommended Practices for the Testing and Verification of Spill, Overfill, Leak Detection and Secondary Containment Equipment at Underground Storage Tank Facilities* is an acceptable protocol.

Instructions for Completing the Fill-Port Containment Integrity Form:

UST Facility Information: Enter name and complete address of the facility, and the permit identification number for the facility.

Person Conducting the Test: Enter the tester's name and their company (if not completed by site operator) including the city and state from which they operate.

2) Purpose of the Test: Indicate by checking the box why the test is being done. Note: Testing must occur after repairs or replacement of parts connected to secondary containment.

Liquid Tight Test Procedure: Please review the methodology (if this is the desired test) before conducting the test.

Test Data Table:
1) Test Date: Indicate the date YYYYMMDD the test was completed
2) Indicate the starting and ending time for each Fill-Port Containment being tested.
3) Indicate the starting and ending water level for each Fill-Port Containment being tested.
4) Indicate if the test passed (P) or failed (F).
5) Comments: Add any comments or notes, particularly if there were any failing results.

Tester's Signature: The person conducting the test must sign and date the test.

/**1**/

APPENDIX C MAINTENANCE TABLE

Inspection and maintenance tasks listed below are the minimum required. Additional operation and maintenance tasks may be performed based on specific installation requirements set by facility command.

OM stands for Operator Maintenance, and SM stands for System Maintenance. See Section 1-2 for more information on roles and responsibilities.

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
SIGNAGE AND MARKINGS					
Signage and Markings (Section 2-7)					
Signage and Markings	A. Check permanent signs and markings for adequacy and readability. Repair or replace deteriorated or illegible signs and markings. B. Inspect the location of Department of Transportation (DOT) regulated underground pipelines and ensure they are marked in accordance with 49 Code of Federal Regulations (CFR) 195.410. C. Check that all non-DOT regulated pipelines, tanks, valves, pumps, meters, and other equipment are marked in accordance with UFC 3-460-01. Section **1**\\ 2-17 /**1**/. If markings are missing or insufficient, repair or add markings in accordance with UFC 3-460-01. D. Ensure petroleum fuel system Emergency Fuel Shutoff (EFSO) push buttons are properly identified at each location. Ensure that signage is properly secured and that the lettering is legible from 25 feet (7.5 meters) away and not faded.	Monthly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	E. Verify enough movable or temporary signs are maintained in good condition to serve anticipated needs; for example: "DANGER," "CLOSED TO TRAFFIC," “KEEP FLAMES AWAY," "MEN WORKING,” "NO SMOKING,” "DANGER NO OPEN FLAME OR IGNITION SOURCE BEYOND THIS POINT.” Use bilingual signs when appropriate.	Annually	OM	OM	OM
FILTRATION					
Pre-Filter Vessels (Section 3-6.1)					
Pre-Filter Vessels	A. Open drains under flow conditions until clear fuel is observed from the drain valve. B. Monitor differential pressure in filter cartridges. Chart differential pressure measurements from readings taken during normal operations.	Daily	OM	OM	OM
	C. Operate pre-filter isolation valves.	Quarterly	SM	**2**\\ OM /**2**/	SM
	D. Replace filter cartridges when the acceptable maximum differential pressure is reached, the maximum in-service duration has passed, or the fuel becomes visibly dirty or discolored. Acceptable maximum differential pressure for a specific pre-filter is dependent on the system flow rate. The military service-specific SCP may extend in-service duration filter cartridge replacement period based on differential pressure for high throughput systems. Check expiration date of replacement	When differential pressure has reached the lower of manufacturer’s recommendation or 20 psid (140 kPa), filter cartridge in-service period of 24 months has expired, or when fuel becomes visibly dirty or discolored. 	B. Inspect mechanical seals, if possible, for drips or leaks and dirt. C. Lubricate pump bearings				
	D. Inspect pump and motor coupling for proper alignment.	Annually	SM	SM	SM
	E. Refer to Section 3-8.4 Gearboxes for inspection and maintenance of reduction gearboxes. F. Refer to Section 9-1.7 Electric Motors for inspection and maintenance requirements of electric motors.	As required	SM	SM	SM
Diaphragm Pumps (Section 3-8.2.3)					
Diaphragm Pumps	A. Inspect hose for cracks or dry rot. B. Inspect compressed air connections for signs of leaks. C. Inspect compressed air hose coupling safety pins or safety wires for wear and damage. Replace damaged components.	Quarterly	SM	SM	SM
	D. Diaphragm pumps should have the internal diaphragm replaced if the pump shows decreased performance. Also check operation of actuator valve and ensure ball checks seat properly.	As required	SM	SM	SM
Internal Combustion Drives (Section 3-8.3)					
Internal Combustion Drives	A. Refer to manufacturer's operation and maintenance manual for specific maintenance procedures and schedules associated with a specific model of internal	As required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	combustion drive. Follow all applicable general maintenance and safety requirements listed in the manufacturer's operation and maintenance manual.				
Gearboxes (Section 3-8.4)					
Gearboxes	A. Inspect gearboxes for signs of smoke near shaft connections or discoloration of the gearbox from overheating. B. Verify that the oil in the sight glass is not dark or appears to have foam. Adjust oil level if required.	Quarterly	SM	SM	SM
	C. Lubricate bearings per manufacturer's recommendations. D. Check motor and gear box and gear box and pump couplers for wear and alignment.	Semi-annually	SM	SM	SM
	E. Inspect gear alignment within gearbox. F. Replace lubricant oil in accordance with manufacturer's specifications and recommendations.	Annually	SM	SM	SM
HOSES					
Loading Fuel Hoses (Section 3-9.1)					
Loading Fuel Hoses	A. Visually inspect hoses for loose covers, cracks, brittle surface coatings, exposed wire braids, exposed reinforcement, flattening, kinks, and bulges or soft spots which might indicate broken or displaced reinforcement.	Weekly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	B. Pressurize hose to normal working pressure. Check flanged and threaded connections for leaks and inspect hose couplers for fluid seepage by pushing at the base of the coupling with your thumbs; a hose softened by fluid seepage must be replaced.	Monthly	OM	OM	OM
	C. Check for coupling slippage. Replace hose that shows signs of coupling slippage.	Quarterly	SM	**\2** OM **/2/**	SM
	D. **\1\/1/** E. Conduct test of fuel hose electrical resistivity using an electrostatic meter in accordance with NFPA 77 & API 2003.	Annually	SM	SM	SM
Offloading Fuel Hoses (Sections 3-9.2)					
Offloading Fuel Hoses	A. Visually inspect hoses for cracks brittle surface coatings, exposed wire braids, exposed reinforcement, flattening, kinks, and bulges or soft spots which might indicate broken or displaced reinforcement.	Weekly	OM	OM	OM
	B. Check flanged and threaded connections for leaks and inspect hose couplers for fluid seepage by pushing at the base of the coupling with thumbs; a hose softened by petroleum fluid seepage must be replaced. Damaged or leaking hoses must be replaced immediately or isolated and taken out of service.	**\2** Monthly **/2/**	**\2** OM **/2/**	**\2** OM **/2/**	**\2** OM/ **2/**
	C. Conduct test of offloading fuel hose electrical resistivity as	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	directed in NFPA 77 and API 2003.				
AIR ELIMINATOR TANKS					
Air Eliminator Tanks (Section 3-10.1)					
Air Eliminator Tanks	A. Inspect operation of fuel level probes. Ensure probes operate correctly when the level of fuel in the tank rises to the level of the probe sensing unit. B. Remove the float vent valve from the air eliminator tank. Clean and inspect the sealing surfaces of the float vent valve. Ensure the float is buoyant in fuel and test the valve to ensure it closes properly.	Annually	SM	SM	SM
	C. Refer to Section 8-9.3 Tank Pressure/Vacuum Vents for in- spection and maintenance require- ments of pressure vacuum vents.	As required	SM	SM	SM
Automatic Air Vents (Section 3-10.2)					
Automatic Air Vents	a. Check for proper operation of the automatic air vent. Ensure the vent opens to allow air to escape and ensure the float of the vent is buoyant in petroleum fuel and rises to close the vent when the float is suspended in petroleum fuel.	Annually	SM	SM	SM
FUEL ADDITIVE INJECTORS					
Fuel Additive Injectors (Section 3-11)					
Fuel Additive Injectors	a. Inspect injectors to ensure they are operating properly.	When fuel system has flow through it, inspect weekly. When fuel system is sitting idle, inspect	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
		injectors monthly.			
	b. Calibrate injector to ensure proper additive to fuel ratio.	Annually	SM	SM	SM
CONTROL VALVES – TYPE II HYDRANT SYSTEM					
General System Control Valves (Section 4-3.2.1)					
General System Control Valves	A. Verify operating settings of valve. Valve adjustment must be in accordance with manufacturer's operation and maintenance manuals and final start-up and commissioning set points. Use of DoD standard set points should only be used as a reference starting point as pipe size and other hydraulic factors influence final system settings.	Quarterly	SM	SM	SM
	B. Remove and clean strainer installed in the petroleum fuel supply line to the pilot and main valve diaphragm. This strainer is provided to prevent clogging of the orifice in the supply line. Clogging of the screen will cause malfunctioning of the valve	Annually for unfiltered systems and as required for filtered systems.	SM	SM	SM
	C. Diaphragms must be removed and inspected for deterioration and breaks at the flexing joint. Damage is often caused by pipe scale, pipe tape, and thread sealant compound that collect above the diaphragm and become lodged between the diaphragm and bonnet of the valve. Damage may also be caused by a change of operational petroleum fuel type	Every 10 years	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	or grade (such as a change from JP-4 to JP-8).				
Refuel Control Valves (Section 4-3.2.5)					
Refuel Control Valves	A. Verify refuel control valve is set to maintain 100 psig (690 kPa) (typ- ical operating pressure) as meas- ured at the furthest hydrant outlet. B. Verify pressure-reducing control will open at 5 psig (35 kPa) above normal operating pressure (typ- ically 105 psig (725 kPa) as meas- ured at the farthest hydrant outlet) C. Verify refueling control valve opening rate is set between 15 and 20 seconds. The valve should open as quickly as possible without tripping the pressure differential control shut-off. D. Verify operation of the excess flow shut-off function. E. Verify operation of solenoid.	Quarterly	SM	SM	SM
	F. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Pressure Relief Valves (Section 4-3.2.6)					
Pressure Relief Valves	A. Verify pressure relief valve will open at 10 psig (69 kPa) above normal inlet pressure to the refuel control valve.	Semi-annually	SM	SM	SM
	B. Refer to Section 4-3.2.1 General System Control Valves for	As required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	additional inspection and maintenance requirements.				
Defuel Control Valves (Section 4-3.2.7)					
Defuel Control Valves	A. Verify the defuel control valve opens when the solenoid on the defuel control valve is energized.	Quarterly	SM	SM	SM
	B. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Dual Rate-of-Flow Control Valves (Section 4-3.2.8)					
Dual Rate-of-Flow Control Valves	A. Verify dual rate-of-flow control valve is set to maintain a flow rate of 200 gpm (12.5 lps). B. Verify check valve feature is operational.	Quarterly	SM	SM	SM
	C. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Combination Dual Rate-of-Flow Control and Solenoid Valves (Section 4-3.3.1)					
Combination Dual Rate-of-Flow Control and Solenoid Valves	A. Verify valve is set to maintain a flow rate of 300 gpm (19 lps). B. Verify operation of check valve feature. C. Verify solenoid operation.	Quarterly	SM	SM	SM
	D. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Dual Pressure Relief, Solenoid Shutoff, and Check Valves (Section 4-3.3.2)					

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Dual Pressure Relief, Solenoid Shutoff, and Check Valves	A. Verify high pressure relief control will open at 5 psig (35 kPa) above the refuel control valve pressure relief control set point (typically set at 110 psig (760 kPa)). B. Verify low pressure relief control will open at 5 psig (35 kPa) when refueling pumps are stopped. C. Verify closing speed provides a smooth, pulsation free operation. D. Verify operation of solenoid valve.	Quarterly	SM	SM	SM
	E. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
CONTROL VALVES – TYPE III HYDRANT SYSTEM					
Non-Surge Check Valves (Section 4-4.2.1)					
Non-Surge Check Valves	A. Verify main valve opening speed (typically 20 seconds). Adjust if required. B. Verify valve maintains 650 gpm (41 lps) flow rate (some instances 950 gpm (60 lps) flow rate). Adjust if required. C. Ensure the check valve function is operating properly.	Semi-annually	SM	SM	SM
	D. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements .	As required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Filter Separator Control Valves (Section 4-4.2.2)					
Filter Separator Control Valves	A. Test FSCV emergency shut off solenoid under flow conditions and ensure that valve closes within 10 seconds of EFSO button activation. Coordinate with overall EFSO test listed in Section 9-1.2.1 Inspection and Maintenance - Electrical Equipment. B. Operate test button (if installed) to ensure the FSCV closes at high water level. Physically press the test button, while recirculating fuel, and ensure the FSCV closes. Note: closing speed is a function of the number of open filters separators and the number of pumps operating. With all filters open and only one pump operating, the valve will close very slowly.	Quarterly	SM	SM	SM
	C. Verify valve maintains flow rate (typically 600 gpm (38 lps), operating range based on commissioning documentation). Adjust flow rate if required. Flow rate is determined by filter separator vessel gpm (lps) rating, or element flow rate, whichever is less. Use return venturi to measure and confirm flow rate during valve testing and adjustment. D. Ensure check valve function is operating properly.	Semi-annually	SM	SM	SM
	E. Test buoyancy of water level float. Remove the ball or float assembly and place it in a bucket of water. Correctly operating ball or float will float at the top of the water's surface.	When coalescer cartridges are changed.	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	F. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Defuel/Flush Valves (Section 4-4.2.3)					
Defuel/Flush Valves	A. Ensure Solenoids A and B are de-energized with system in automatic mode and lead pump operating. B. Ensure Solenoid A is energized and Solenoid B is de-energized to allow main valve to open and drop system pressure to 80 psig (550 kPa) (typical set pressure) with system in automatic mode and lead pump off. C. Ensure Solenoid A is de-energized and Solenoid B is energized when system is in flush mode. D. Ensure Solenoids A and B are de-energized when system is in tightness test mode. E. Check opening and closing speed. Speed should be as fast as possible while still maintaining smooth operation.	Quarterly	SM	SM	SM
	F. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Issue Venturi (Section 4-4.2.4)					
Issue Venturi	A. Ensure issue venturi DPTs are reading the same value within ± 2% full scale.	Semi-annually	SM	SM	SM
	B. Refer to Section 6-7.4 Differential Pressure Transmitters for inspection and	As required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	maintenance requirements of DPTs				
Return Venturi (Section 4-4.2.5)					
Return Venturi	A. Ensure return venturi DPTs are reading the same value within ± 2% full scale.	Semi-annually	SM	SM	SM
	B. Refer to Section 6-7.4 Differential Pressure Transmitters for inspection and maintenance requirements of DPTs.	As required	SM	SM	SM
Back Pressure Control Valves (Section 4-4.2.6)					
Back Pressure Control Valves	A. Verify constant upstream pressure is maintained at the setpoint established and listed in the system commissioning documents. Adjust setting of BPCV as necessary. B. Ensure Solenoid A is energized and Solenoid B is de-energized while lead pump is operating in automatic mode. C. Ensure Solenoids A and B are de-energized prior to lead pump shutdown and system going to stand-by. D. Ensure Solenoids A and B are de-energized while system is in flush mode. E. Ensure that Solenoid A is de-energized and Solenoid B is energized while system is in tightness test mode. F. Verify closing speed control. Valve should close as fast as possible while still maintaining smooth operation.	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	G. Check solenoid EFSO feature when equipped. Coordinate test with overall EFSO test listed in Section 9-1.2.1 Inspection and Maintenance - Electrical Equipment.				
	H. Refer to Section 4-4.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Pressure Control Valves (Section 4-4.2.7)					
Pressure Control Valves	A. Ensure Solenoid A is energized and Solenoid B is de-energized while system is in automatic mode and lead pump is operating. B. Ensure Solenoids A and B are de-energized while system is in automatic mode and lead pump is off. Verify valve opens to maintain system pressure at 75 psig (515 kPa). C. Ensure Solenoid A is energized and Solenoid B is de-energized while system is in flush mode and lead pump is operating. D. Ensure Solenoids A and B are de-energized while system is in flush mode and pumps are off. E. Ensure Solenoids A and B are energized while system is in tightness test mode. F. Verify closing speed control. Valve should close as fast as possible while still maintaining smooth operation.	Quarterly	SM	SM	SM
	G. Refer to Section 4-3.2.1 General System Control Valves for	As required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	additional inspection and maintenance requirements.				
Hydrant Control Valves (Section 4-4.2.8)					
Hydrant Control Valves	A. Verify HCV maintains 45 psig (310 kPa) nozzle pressure at a flow of 50 to 600 gpm (3 to 38 lps). B. Verify HCV closes when nozzle pressure exceeds 50 psig (345 kPa). C. Verify HCV opening rate is set at a minimum of 20 seconds. D. Ensure HCV opens when the deadman control level is pressed. E. Verify HCV closes in five seconds maximum after the deadman lever is released.	Quarterly	SM	SM	SM
	F. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Emergency Shut-off Valves (Section 4-4.2.9)					
Emergency Shut-off Valves	A. Ensure Solenoids A and B are energized under normal operations. B. Ensure Solenoids A and B are de-energized during emergency stop conditions. C. Test emergency stop function of the valve under flow conditions. Ensure the valve closes within 10 seconds of EFSO button activation. Coordinate test with overall EFSO test listed in Section 9-1.2.1 Inspection and Maintenance - Electrical Equipment.	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	D. Verify differential control maintains a constant seven psig (48 kPa) differential pressure between the inlet and outlet of the valve. E. Ensure thermal relief function (ball check valve) relieves excess pressure when cover chamber pressure exceeds inlet pressure.				
	F. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
CONTROL VALVES – TYPE IV AND V HYDRANT SYSTEMS					
Pantograph Control Valves (Section 4-5.2.12)					
Pantograph Control Valves	A. Verify PTCV maintains 55 psig (380 kPa) nozzle pressure at a flow of 50 to 600 gpm (3 to 38 lps). B. Verify PTCV opens when the deadman control lever is pressed. C. Verify PTCV closes in a maximum of 10 seconds after deadman lever is released.	Quarterly	SM	SM	SM
	D. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Pantograph Pressure Control Valves (Section 4-5.2.13)					
Pantograph Pressure Control Valves	A. Verify PPCV opens at 75 psig (515 kPa). B. Verify PPCV opening and closing speed are three seconds.	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Hydrant Adapters	A. Inspect hydrant adapter for proper operation, damage, and wear. B. Test operation of dry break system.	Quarterly	SM	SM	SM
Fueling Nozzles (Section 4-7.\1\3/1/)					
Fueling Nozzles	A. Inspect the condition of the dust cap at the aircraft adapter end and ensure it is in good working order. Dust caps must be attached to nozzles when they are not is use. B. Test leak resistance of poppet valve against full pump pressure. Unusual conditions found during this test indicate that repair is necessary and the nozzle must be removed from service. C. Inspect storage racks for moisture or dirt accumulation. Correct conditions that may be attributing to accumulation of moisture or dirt in the storage racks. D. Remove nozzle for inspection of content impinged upon the mesh screen. Clean and dry screens before nozzles are returned to service. If a strainer ball valve is installed upstream of the nozzle only the strainer in the strainer ball valve needs to be check. Nozzles should not be used while strainers are removed from upstream strainer ball valves. E. Tests nozzle interlocks. Ensure interlocks prevent release of fuel when the fueling nozzle is not properly connected. Adjust	**1**\Monthly/**1**/	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	the seating of the poppet valve if required. F. Check the operation of the manual valve crank assembly for smooth and positive motion on a special test stand.				
SUPPRESSORS					
Surge Suppressors (Section 4-7.**1**\\4/**1**/)					
Surge Suppressors	A. Inspect for nitrogen leaks. B. Bladder pressure inside surge suppressors must be validated and recharged as needed with nitrogen. Some surge suppressors are also equipped with needle valves. Settings established in the startup and commissioning documents should be maintained. Adjust nitrogen charge per manufacturer's recommendations.	Quarterly	SM	SM	SM
2\\ Aircraft Fueling Hoses (Section 4-7.5)					
Aircraft Fueling Hoses	A. Visually inspect hoses for loose covers, cracks, brittle surface coatings, exposed wire braids, exposed reinforcement, flattening, kinks, and bulges or soft spots which might indicate broken or displaced reinforcement.	Monthly	OM	OM	OM
	B. Pressurize hose to normal working pressure. Check flanged and threaded connections for leaks and inspect hose couplers for fluid seepage by pushing at the base of the coupling with thumbs. A hose softened by petroleum fluid seepage must be replaced.	Monthly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force

Marine Loading Arms (Section 5-4)					
Marine Loading Arms	A. Check swivel for smooth operation. Check seals for signs of wear and discoloration which may indicate a seal or ball bearing failure.	**\2** Monthly **/2/**	**\2** OM **/2/**	**\2** OM **/2/**	**\2** OM **/2/**
	B. Inspect ball bearings when accessible. Rough and/or uneven wear on the surface are indications of swivel joint failure C. Conduct pressure test of marine loading arms in accordance with 33 CFR 156.170 *Equipment Tests and Inspections*, Section (f)(1).	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Marine Bulk Transfer Hoses (Section 5-5.1)					
Marine Bulk Transfer Hoses	A. Visually inspect transfer hoses. Transfer hoses must have no loose covers, kinks, bulges, soft spots, and no gouges, cuts or slashes that penetrate the hose reinforcement. Hoses must also have no external deterioration.	Before each use	OM	OM	OM
	B. Visually survey petroleum fuel marine hoses. Observe the general condition and look for fluid puddles, fine mists, physical damage such as jacket abrasion or deformation, and deteriorated joints. Use sense of smell to detect petroleum vapor. Look for improper hose handling that may overstress the hose by stretching, relative movement, or kinking.	During each use	OM	OM	OM
	C. Refer to Appendix D, Section D-2.2 Marine and Underwater Transfer Hose Hydrostatic Test for marine transfer hose hydrostatic testing requirements and procedures.	Annually or not less than 30 days prior to the first transfer conducted past one year from the date of the last test and inspection.	SM	SM	SM
Underwater Hoses (Section 5-5.2)					
Underwater Hoses	A. Refer to Appendix D, Section D-2.2 Marine and Underwater Transfer Hose Hydrostatic Test for underwater hose hydrostatic testing requirements and procedures.	Annually or not less than 30 days prior to the first transfer conducted past one year from the date of the last test and inspection.	SM	SM	SM
Single Point Mooring Systems (Section 5-7.1)					
	A. Inspect and, if necessary, repair or replace all mooring hawsers or lines, deck hose, chain, chair	Monthly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Single Point Mooring Systems	stoppers, flange adaptors, gaskets or other gear used in mooring the marine tanker and in connecting hoses.				
	B. Inspect air-compressor for proper operation. C. Inspect navigation aids and mooring buoy, in accordance with NAVFAC MO-124 *Mooring Maintenance Manual*, for evidence of damage and possible movement or dragging by vessels, current or winds. D. Divers must conduct underwater inspections of mooring chains, shackles and anchors attaching buoys to bay/harbor floors.	Annually	SM	SM	SM
	E. Conduct overhaul of single point mooring buoys every 3 to 5 years. Single point mooring buoys must be brought ashore for repair in these instances.	Every 5 years	SM	SM	SM
Multi Point Mooring Systems (Section 5-7.2)					
Multi Point Mooring Systems	A. Inspect and, if necessary, repair or replace all mooring hawsers or lines, deck hose, chain, chair stoppers, flange adaptors, gaskets or other deck gear used in mooring the marine tanker and in connecting underwater hoses.	Monthly	OM	OM	OM
	B. Inspect navigation aids and mooring buoys, in accordance with NAVFAC MO-124 *Mooring Maintenance Manual*, for evidence of damage and possible movement or dragging by vessels, current or winds. C. Divers must conduct underwater inspections of mooring chains, shackles and anchors attaching	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	buoys to bay/harbor floors.				
SUBMERGED PIPING SYSTEMS					
Submerged Piping Systems (Section 5-8)					
Submerged Piping Systems	A. Inspect water above submerged pipelines and their seaward end for tell-tale petroleum fuel slicks indicating leakage from pipes or underwater hoses.	Weekly	OM	OM	OM
	B. If equipped, electrically check the cathodic protection rectifier for proper performance.	Six times each calendar year with intervals not exceeding 2½ months	SM	**2**\\ OM /**2**/	SM
	C. Divers must inspect submerged pipe and hoses for signs of incipient failure or indications of rapid wear of parts subject to wave motion or abrasion on the ocean floor.	Semi-annually	SM	SM	SM
	D. Conduct annual pipe test as specified in Appendix G – Petroleum Fuel Pipeline Pressure testing Guidelines and Criteria. Testing requirements of marine pipelines are regulated under 33 CFR 154 and 156, particularly 33 CFR 156 Section 170. E. Conduct cathodic protection tests on the protected pipeline as specified in Section 9.2.1 Cathodic Protection at least once each calendar year with intervals not exceeding 15 months between tests from consecutive years.	Annually	SM	SM	SM
Boom Reels (Section 5-9)					
Boom Reels	A. Visually inspect hydraulic drives	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	and hose connections for leaks. B. Grease bearings. C. Inspected boom reel for signs of corrosion. Inspect breaking system and ensure it is in good working order.				
	D. Inspect boom for wear, rips, and tears. Repair or replace as required to ensure containment of petroleum fuel in the event of a spill.	Annually	SM	SM	SM
ON-BASE PIPELINES					
On-Base Pipelines (Section 6-1.1)					
On-Base Pipelines	A. Conduct petroleum fuel pipeline visual Inspection of aboveground piping in accordance with Section 6-1.5 Pipeline Visual Inspection.	Monthly	\2\ OM /2/	\2\ OM /2/	SM
	B. Conduct line walk in areas of petroleum fuel piping in accordance with Section 6-1.6 Line Walk..	Conduct during transfer operations, or monthly, at a minimum	OM	OM	OM
	C. Conduct annual test as specified in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria.	Annually	SM	\2\ OM /2/	SM
	D. Conduct cathodic protection tests as specified in Section 9.2.1 Cathodic Protection on protected petroleum fuel pipelines at least once each calendar year, but with intervals not exceeding 15 months.	Annually	SM	SM	SM
	E. Conduct five year test as specified in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria.	Every five years	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	F. Conduct petroleum fuel pipeline API 570 inspection in accordance with Section 6-1.9 API 570 Inspections.	Every 5 or 10 years depend-ing on API class piping or in accordance with Pipeline Integ-rity Manage-ment Plan (PIMP).	SM	SM	SM
	G. Conduct petroleum fuel pipeline cleaning in accordance with Section 6-2 General Pipeline Cleaning.	As required to ensure fuel quality.	SM	SM	SM
INTER-TERMINAL PIPELINES					
Non-DOT Regulated (Section 6-1.2.1)					
Non-DOT Regulated	A. Conduct petroleum fuel pipeline volume check in accordance with Section 6-1.8 Volume Check.	Monthly	OM	OM	OM
Non-DOT Regulated	B. Conduct line patrol in areas of underground petroleum fuel pipeline in accordance with Section 6-1.7 Line Patrol.	Annually	OM	OM	OM
Non-DOT Regulated	C. Government operated inter-terminal petroleum fuel pipelines must follow the maintenance requirements listed in Section 6-1.1.1 for On-Base Pipelines.	As required	SM/OM	SM/OM	SM/OM
Aboveground Piping (Section 6-1.3)					
Aboveground Piping	A. Conduct petroleum fuel piping visual Inspection in accordance with Section 6-1.5 Pipeline Visual Inspection.	Weekly	OM	OM	OM
Aboveground Piping	B. Conduct petroleum fuel piping annual test as specified in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria.	Annually	SM	SM	SM
Aboveground Piping	C. Conduct petroleum fuel piping API 570 inspection in accordance with Section 6-1.9	Every 5 or 10 years depend-ing on API class piping or	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
		Plan (PIMP).Management Plan (PIMP).			
	F. Conduct petroleum fuel pipeline cleaning in accordance with Section 6-2 General Pipeline Cleaning.	As required to ensure fuel quality.	SM	SM	SM
MANUAL VALVES					
Plug Valves – Lubricated (Section 6-6.2.1)					
Plug Valves - Lubricated	A. Open and close valve to check for ease of operation.	Quarterly	SM	SM	SM
	B. Lubricate valve operator stems and all grease fittings. C. Inspect valve exterior for corrosion and tightness of bolts. Repaint/tighten as required.	Semi-annually	SM	SM	SM
Plug Valves – Non-lubricated (Section 6-6.2.2)					
Plug Valves Non-Lubricated	A. Open and close valve to check for ease of operation. Adjust or replace packing as needed.	Quarterly	SM	SM	SM
	B. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.	Semi-annually	SM	SM	SM
Gate Valves (Section 6-6.2.3)					
Gate Valves	A. Open and close valve to check for ease of operation. Adjust or replace packing as needed.	Quarterly	SM	SM	SM
	B. Lubricate valve operator stem.	Semi-annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	C. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.				
Ball Valves (Section 6-6.2.4)					
Ball Valves	A. Open and close valve to check for ease of operation. B. Lubricate overhead ball valve chain operator gears. C. Adjust packing per manufacturer's specifications. D. Inspect valve exterior for corrosion and tightness of bolts. Repaint/tighten as required.	Quarterly	SM	SM	SM
	E. Refer to Section 6-6.2.10 Manual Valve Gear Operators for inspection and maintenance of gear operators if equipped.	As required	SM	SM	SM
Double Block and Bleed Valves (Section 6-6.2.5)					
Double Block and Bleed Valves	A. Open and close valve to check for ease of operation. B. Lubricate overhead valve chain operator gears if equipped. C. Adjust packing per manufacturer's specifications. D. Inspect valve exterior for corrosion and tightness of bolts. Repaint and tighten as required. E. Operate the body cavity drain when valve is in closed position to ensure that the valve is closing properly.	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	F. **2**\ Keep the valve operator housing full of lubricant to displace and prevent moisture from accumulating and freezing, in accordance with manufacturer's recommendations.	Semi-Annually	SM	SM	SM
	G. Remove bottom drain plug and drain valve.	Annually	SM	SM	SM
	H. Refer to Section 6-6.2.10, Manual Valve Gear Operators, for inspection and maintenance of gear operators, if equipped. I. Some double block and bleed valves are equipped with integrated pressure/thermal relief valves. Refer to Section 6-6.3, Thermal and Pressure Relief Valves, for inspection and maintenance requirements of pressure/thermal relief valves. /**2**/	As required	SM	SM	SM
Butterfly Valves (Section 6-6.2.6)					
Butterfly Valves	A. Open and close valve to check for ease of operation. Ensure that lever operators and locking mechanisms are in place and working properly. B. Adjust packing per manufacturer's specifications as needed. If butterfly valves are leaking or not shutting off flow, tightening the gland flange to tighten the stem packing or remove the valve from service and replace the seats as necessary. C. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Globe Valves (Section 6-6.2.7)					
Globe Valves	A. Open and close valve to check for ease of operation. B. Adjust packing per manufacturer's specifications as needed. C. Inspect valve exterior for corrosion and tightness of bolts. Repaint/tighten as required	Quarterly	SM	SM	SM
Check Valves (Section 6-6.2.8)					
Check Valves	A. Use external test lever to make sure the valve is not sticking if equipped. If a check valve is suspected of not checking and cannot be serviced in place, it must be removed from the piping system and serviced in a shop. B. Inspect valve exterior for corrosion and tightness of bolts. Repaint and retighten as required.	Quarterly	SM	SM	SM
Line Blanks, Ring Spacers, and Spectacle Blinds (Section 6-6.2.9)					
Line Blanks, Ring Spacers, and Spectacle Blinds	A. Inspect exposed side of spectacle blinds. The exposed side must be kept clean and free of corrosion. B. Spectacle blinds should be inspected to ensure they are installed with the correct orientation for the desired flow or no-flow condition.	Quarterly	SM	SM	SM
Manual Valve Gear Operators (Section 6-6.2.10)					
Manual Valve Gear Operators	A. Lubricate gear driven operators and check for smooth operation	Quarterly	SM	SM	SM
RELIEF VALVES					

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Thermal and/or Pressure Relief Valves (Section 6-6.3)					
Thermal and Pressure Relief Valves	A. Thermal and pressure relief valves must be inspected for signs of leak-by. Inspect relief valves for leaks by visually inspecting downstream flow indicators (if installed) for flow. If no flow indicators are installed listen for possible leaks. If suspect: isolate and test the relief valve; check opening pressure; and verify re-seating. Malfunctioning valves must be repaired or replaced. B. Ensure manual isolation valves installed upstream and downstream of thermal and pressure relief valves are open with valve handles are removed, wired open or locked.	Monthly	OM	OM	SM
	C. Inspect valve exterior of thermal and pressure relief valves for corrosion. Repaint as required. Information plates attached to thermal and pressure relief valves must not be painted over.	Quarterly	SM	SM	SM
	D. Verify thermal and pressure relief valve setting by consulting as-built and historical data. E. Thermal and pressure relief valves must be validated for proper calibration by isolating the valve and using the test connection provided on the piping in conjunction with a hand pump and portable reservoir. The operating pressure must be checked against the set pressure listed on the stamped information plate attached to the valve. The operating pressure must be adjusted to the	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	stamped set pressure if necessary.				
SEMI-AUTOMATIC VALVES					
Fire Valves (Section 6-6.4.1)					
Fire Valves	A. Ensure the fusible link mechanism is attached properly to actuate in case of a fire and that it has not been by-passed, blocked, or damaged in any manner. Ensure the fusible link is not filled with debris or paint which could impact operation. **1**\\ Maintain fusible links per manufacturer's recommendation./**1**/	Quarterly	SM	SM	SM
	B. Check the closing mechanism to ensure that it closes the valve properly.	Annually	SM	SM	SM
Fusible Line Butterfly Valves (Section 6-6.4.2)					
Fusible Link Butterfly Valves	A. Ensure the fusible link mechanism is attached properly to actuate in case of a fire and that it has not been by-passed, blocked, or damaged in any manner. Ensure the fusible link is not filled with debris or paint which could impact operation. **1**\\ Maintain fusible links per manufacturer's recommendation./**1**/	Quarterly	SM	SM	SM
	B. Test the operation of spring closure unit. Ensure that the spring actuator closes the valve and that the valve closes securely against the seat.	Annually	SM	SM	SM
	C. Refer to Section 6-6.2.6 Butterfly Valves for additional inspection and maintenance requirements of butterfly valves.	As required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
AUTOMATIC VALVES					
Truck Fill Valves (Section 6-6.5.1)					
Truck Fill Valves	A. Verify TFV maintains 35 psig (240 kPa) nozzle pressure at a flow range of 50 to 600 gpm (3 to 38 lps). B. Verify TFV closes rapidly when outlet pressure exceeds control set point. C. Verify TFV opens when the deadman control lever is pressed. D. Verify TFV closes after the deadman control lever is released. E. If equipped, verify operation of solenoid connected to grounding verification system. Ground verification system should energize solenoid when an acceptable ground is detected by the ground verification unit. F. Systems that have overflow protection systems must be inspected and maintained concurrently with the inspection and maintenance of TFVs.	Quarterly	SM	SM	SM
	G. Refer to Section 4-3.2.1 General System Control Valves for additional inspection and maintenance requirements.	As required	SM	SM	SM
Motor Operators (Section 6-6.6)					
Motor Operators	A. Visually inspect motor operators to ensure smooth movement during opening and closing operation and adjust, if	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	necessary, to ensure that they are opening and closing fully. Listen for and investigate unusual noises during operation. B. Lubricate mechanical overrides (if equipped).				
	C. Refer to Section 9-1.7 Electric Motors for inspection and maintenance requirements of electric motors	As required	SM	SM	SM
PRESSURE/VACUUM INSTRUMENTATION					
Pressure and Pressure/Vacuum Gauges (Section 6-7.1)					
Pressure and Pressure/ Vacuum Gauges	A. Check operation of gauge. Ensure gauge is indicating pressure of the system.	Monthly	OM	OM	OM
	B. Clean outside of gauge glass.	Quarterly	SM	SM	SM
	C. Inspect liquid filled gauges for leakage, refill/replace as needed.	Semi-annually	SM	SM	SM
	D. Conduct calibration check by comparing readings of the process gauge with the readings of a certified master calibration gauge which has been calibrated within the last year. The process gauge and the master calibration gauge must be connected to the same pressure source for testing. Verify accuracy of gauge is within ±2% of full scale. Calibrate gauge if required.	Annually	SM	SM	SM
Differential Pressure Gauges (Section 6-7.2)					
Differential Pressure Gauges	A. Verify proper operation of differential gauge in accordance with gauge manufacturer's procedures.	Monthly	**\2** OM **/2/**	**\2** OM **/2/**	**\2** OM **/2/**
	B. Clean outside of gauge glass.	Quarterly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	C. Conduct calibration check by comparing readings of the differential process gauge with the readings of a certified differential master calibration gauge which has been calibrated within the last year. The differential process gauge and the differential master calibration gauge must be connected to the same pressure source for testing. Verify accuracy of gauge is within ±2% of full scale. Calibrate if required.	Annually	SM	SM	SM
	D. Some differential pressure gauges have a small gauge protection filter located at the high pressure inlet of the gauge that must be checked and replaced as needed. Filters need to be replaced if the indicator is moving slow or sluggishly inside the sight glass or if the sight glass is dirty. Refer to manufacturer’s operation and maintenance manual for filter replacement procedure.	Annually for inspections and maximum 5 years of service between filter replacements.	SM	SM	SM
Pressure Transmitters (Section 6-7.3)					
Pressure Transmitters	A. Inspect the exterior of the transmitter enclosure for accumulated oil, dust, and dirt. Clean if required. B. Check that both enclosure caps are fully threaded onto the enclosure, compressing the O-ring between the cap and the enclosure. The O-ring must not be cracked, broken, or otherwise damaged. C. Inspect the display viewing glass for cleanliness and damage. Replace the enclosure	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	cap assembly if the glass is damaged or missing. No accumulation of dust, dirt, or water (condensate) should be present inside the enclosure. D. Inspect transmitter and mounting bracket hardware for tightness. Tighten loose hardware as necessary. E. Inspect for loose, bent, or cracked sensing lines. Replace damaged sensing lines. F. Check operation of transmitter. Ensure transmitter is indicating accurate pressure of the system.				
	G. Bleed sensing lines between the transmitter and the main line to ensure they are clean and free of suspended solids and air.	Semi-annually	SM	SM	SM
	H. Check that all wire connections inside enclosure are tight. I. Pressure Transmitters (PTs) and Pressure Indicating Transmitters (PITs) must be calibrated mechanically and electrically with test equipment and adjusted if applicable. The presence of air in the sensing line of a pressure transmitter is a common cause for failure. Conduct calibration check by comparing readings of the PT or PIT with the readings of a certified master calibration gauge which has been calibrated within the last year. The PT or PIT and the master calibration gauge must be connected to the same pressure source for testing. Verify accuracy of PT or PIT	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	gauge is within ±2% of full scale. Calibrate in accordance with manufacturer's operation and maintenance manual if required.				
Differential Pressure Transmitters (Section 6-7.4)					
Differential Pressure Transmitters	A. Inspect the exterior of the transmitter enclosure for accumulated oil, dust, and dirt. Clean as required. B. Check that both enclosure caps are fully threaded onto the enclosure, compressing the O-ring between the cap and the enclosure. The O-ring must not be cracked, broken, or otherwise damaged. C. Inspect the display viewing glass for cleanliness and damage. Replace the enclosure cap assembly if the glass is damaged or missing. No accumulation of dust, dirt, or water (condensate) should be present inside the enclosure. D. Inspect transmitter and mounting bracket hardware for tightness. Tighten loose hardware as necessary. E. Inspect for loose, bent, or cracked sensing lines. Replace damaged sensing lines. F. Check operation of transmitter. Ensure transmitter is indicating accurate pressure of the system	Quarterly	**2**\\ OM /**2**/	SM	**2**\\ OM /**2**/
	G. Bleed sensing lines between the transmitter and the main	Semi-annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	line to ensure they are clean and free of suspended solids and air.				
	H. Check that all wire connections inside enclosure are tight. I. DPTs must be calibrated mechanically and electrically with test equipment and adjusted, if applicable. The presence of air in sensing lines of differential pressure transmitters is a common cause for failure. Conduct calibration check by comparing readings of the DPT with the readings of a certified differential master calibration gauge which has been calibrated within the last year. The DPT and the differential master calibration gauge must be connected to the same pressure source for testing. Verify accuracy of DPT is within ±2% of full scale. Calibrate in accordance with manufacturer's operation and maintenance manual if required.	Annually	SM	SM	SM
FLEXIBLE BALL JOINTS					
Flexible Ball joints (Section 6-8)					
Flexible Ball Joints	A. Lubricate ball joints and inspect for wear and stress.	Monthly	**2**\\ OM /**2**/	**2**\\ OM /**2**/	SM
THERMOMETERS					
Dial Thermometer (Section 6-9.1)					
Dial Thermometer	A. Inspect thermometer for cracked face and proper operational condition. Replace if damaged.	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	B. Check accuracy of thermometer against calibrated master thermometer. Ensure process and calibrated master thermometer are reading the same heat source. Verify accuracy of thermometer is within ±2% of full scale. Calibrate process thermometer if required.	Annually	SM	SM	SM
PIPE COATINGS					
Aboveground Piping and Equipment Coatings (Section 6-10.1)					
Aboveground Piping and Equipment Coatings	A. **2**\\ Visually inspect coatings for signs of minor deterioration, corrosion, or damage. Repair damaged or deteriorated coatings. B. Coatings needing major repairs will be accomplished by system maintainers. /**2**/	**2** \\Monthly /**2**/	**2**\\ OM /**2**/	**2**\\ OM /**2**/	SM
UNDERGROUND FUEL PITS					
Isolation Valve Pits (Section 6-11.1)					
Isolation Valve Pits	A. Isolation valve pits should be inspected to ensure that the pits are dry and clean and that all components within the pit are clean and in good working order. Main- tain seals and boot seals as appro- priate. Obtain necessary confined space entry permits before entry. Inspect the pit for signs of fuel or water. Water or fuel should be removed from the pit as soon as possible and the source of water infiltration or fuel leak determined. B. Check for cracks in concrete and check piping penetrations through pit wall or bottom to ensure that mechanical seals	Monthly, or more often based on local conditions	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	and boot seals are in good working condition and are allowing no seepage of water into the pits. Make note of cracks in concrete and schedule main- tenance as necessary. Check for fuel leaks at all flanged and other piping connections. Check for rusted or deteriorated ladders or grating platforms that might make entry unsafe. Check pit lids for proper sealing. Check rolling pit covers for ease of operation and signs of deterioration, damage or corrosion. Make sure required locks are in place and locking mechanisms are not broken.				
Hydrant Fuel Pits (Section 6-11.2)					
Hydrant Fuel Pits	A. Hydrant fuel pits must be inspected to ensure that they are dry and clean and that all fueling components within the pit are clean and in good working order. Obtain necessary confined space entry permits before entry. Inspect the pit for fuel or water. Fuel or water found in the pit must be sumped out as soon as possible. B. Check pipe penetrations through pit walls or bottom to ensure that mechanical and boot seals are in good working condition and are allowing no water seepage into the pits. C. Check for fuel leaks at all flanged and pipe connections. D. Check pit lids to ensure that seals are in good working order	Monthly, or more often based on local conditions	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	and are preventing water entry into the pits. E. Inspect hydrant fuel pit bonding cables for corrosion and ensure electrical continuity between bonded equipment.				
High Point Vent Pits (Section 6-11.3)					
High Point Vent Pits	A. Inspect high point vent pits to ensure they are dry and free of water and other debris and that pit and piping components are leak free and in good working condition. Inspect the pit for fuel or water. Fuel or water found in the pit must be sumped out as soon as possible. B. Check pipe penetrations through pit walls or bottom to ensure that mechanical and boot seals are in good working condition and are allowing no water seepage into the pits. C. Check pit lid seals for deterioration and replace as necessary. D. Ensure that high point vent valves, quick-disconnect couplings or pit lids are lockable and that locking mechanisms are in good working order. E. Inspect high point vent pit bonding cables for corrosion and ensure electrical continuity between bonded equipment.	Monthly	OM	OM	OM
Low Point Drain Pits (Section 6-11.4)					
Low Point Drain Pits	A. Inspect low point drain pits to ensure they are dry and free of water and other debris and that	Monthly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	all pit and piping components are leak free and in good working condition. Inspect the pit for fuel or water. Fuel or water found in the pit must be sumped out as soon as possible. B. Check pipe penetrations through pit wall or bottom to ensure that mechanical seals and boot seals are in good working condition and are allowing no water seepage into the pits. C. Check pit lid seals for deterioration and replace as necessary. D. Ensure that low point vent valves, quick-disconnect couplings or pit lids are lockable and that locking mechanisms are in good working order. E. Inspect low point drain pit bonding cables for corrosion and ensure electrical continuity between bonded equipment.				
Lateral Control Pits (Section 6-11.5)					
Lateral Control Pits	A. Inspect lateral control pits to ensure they are dry and free of water and other debris and that all pit and piping components are leak free and in good working condition. Inspect the pit for fuel or water. Fuel or water found in the pit must be sumped out as soon as possible. B. Check pipe penetrations through pit wall or bottom to ensure that mechanical seals	Monthly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	and boot seals are in good working condition and are allowing no water seepage into the pit. C. Check pit lid seals for deterioration and replace as necessary. D. Check for fuel leaks at all flanged and other piping connections. E. Ensure that pit lids are lockable and that locking mechanisms are in good working order. F. Inspect lateral control pit bonding cables for corrosion and ensure electrical continuity between bonded equipment.				
MINOR PIPING EQUIPMENT					
Low Point Drains (Section 6-12.1)					
Low Point Drains	A. Visually inspect low point drains. Ensure that quick-disconnect dust caps are in place and that valves are locked closed.	Weekly	OM	OM	OM
	B. Operate low point drains when system is not under operating pressure. If there is an absence of sufficient line pressure close the low point drain and pressurize the system. Once adequate pressure is available, continue draining until the piping fuel sample is clear and bright with no visible water.	Monthly or as required by local conditions. Verify low point drains are closed after maintenance	OM	OM	OM
High Point Vents (Section 6-12.2)					

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
High Point Vents	A. Inspect high point vents. If fuel leaks are observed they should be repaired as soon as possible. Ensure that quick-disconnect dust caps are in place and that high point vent valves are locked.	Weekly	OM	OM	OM
Sight Flow Indicators (Section 6-12.3)					
Sight Flow Indicators	A. Verify there are no leaks around pipe connection fittings and glass seals. Also check glass for indications of cracks.	Daily or at each use	OM	OM	OM
ELECTRONIC RELEASE DETECTION MONITORING					
Rope Sensor Systems (Section 6-13.1.1)					
Rope Sensor System	A. Ensure the monitoring panel associated with the rope sensor(s) is powered on and no alarms are present.	Daily	OM	OM	OM
	B. Test rope sensor system and ensure it is functional.	Annually	SM	SM	SM
Point Sensor - Dry (Section 6-13.1.2)					
Point Sensor - Dry	A. Ensure the monitoring panel associated with the point sensor(s) is powered on and no alarms are present.	Daily	OM	OM	OM
	B. Ensure monitoring space is clear and free of debris and liquid.	Monthly	OM	OM	OM
	C. Test sensor and ensure it is functional.	Annually	SM	SM	SM
Visual Monitoring (Section 6-14.1)					
Visual Monitoring	A. Visually inspect ports for signs of leaks. Remove debris or foreign objects obstructing the view.	Weekly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
FILLING STATION DISPENSERS					
Dispenser Nozzles (Section 7-2)					
Dispenser Nozzles	A. Inspect dispenser nozzle spout. Ensure it is tight, round, has no cracks, or excessive wear. Inspect automatic shutoff hole. Ensure the hole is open and free of obstructions. Inspect nozzle hold-open latch. Ensure the latch is straight, moves freely, and the return spring operates correctly. Inspect body of nozzle. Ensure the body is in good condition and that the valve stem is clean and free of fuel. Inspect the nozzle to hose connection and ensure it is clean and free of fuel.	Daily	OM	OM	OM
	B. \1/	\1/	\1/	\1/	\1/
	C. Test automatic shutoff feature and ensure it is operating properly. Test automatic shutoff at all nozzle hold-open latch positions	Annually	SM	SM	SM
Dispenser Hoses (Section 7-3)					
Dispenser Hoses	A. Inspect dispenser hoses and hose whips for gouges, cuts, blisters, or outside wear that may lead to rupture during use. Replace hose or hose whips that show signs of wear. Inspect connection points of hoses and hose whips to the dispenser, breakaways, swivels, and the nozzle and ensure the connection points are clean and free of fuel.	Daily	OM	OM	OM
Breakaways (Section 7-4)					
Breakaways	A. Inspect breakaways for loose connections and signs of	Daily	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	damage to poppets. Ensure breakaways are clean and free of fuel.				
	B. Inspect breakaway for an expiration date established by the manufacturer. Breakaways must be replaced before the indicated expiration date	Monthly	OM	OM	OM
Swivels (Section 7-5)					
Swivels	A. Inspect swivel for loose connections and signs of damage. Ensure swivel rotates easily and is clean and free of fuel.	Daily	OM	OM	OM
	B. Inspect swivel for expiration date established by manufacturer. Swivels must be replaced before the indicated expiration date.	Monthly	OM	OM	OM
Hose Retriever (Section 7-6)					
Hose Retriever	A. Test hose retriever and ensure it is operating correctly and supporting the hose.	Monthly	OM	OM	OM
Dispenser Cabinet (Section 7-7)					
Dispenser Cabinet	A. Inspect outside of cabinet and ensure it is free of damage. Inspect for fuel stains on the concrete island around the cabinet and on the outside of the cabinet. Ensure the cabinet is free of dirt and fuel. B. Open both sides of the cabinet and inspect the inside of the cabinet. Ensure the inside of the cabinet and all of the	Monthly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	components inside the cabinet are clean and free of fuel.				
	C. Ensure door panels and locks operate easily. Inspect anchor bolts of cabinet to dispenser island and ensure the bolts are in good condition.	Annually	SM	SM	SM
Dispenser Meters (Section 7-8)					
Dispenser Meters	A. Inspect meter and ensure meter is clean and free of fuel. Ensure calibration mechanism is sealed.	Monthly	OM	OM	OM
	B. Since moving parts inside meters are subject to wear, periodic calibration is necessary. Meters must be recalibrated utilizing a certified 5 gallon (20 liter) prover can or other approved method. Meters are considered satisfactory for further operation when the error does not exceed ±0.2% of actual quantity delivered.	Annually	SM	SM	SM
Dispenser Filters (Section 7-9)					
Dispenser Filters	A. Inspect filter and ensure filter is clean and free of fuel and that filter is labeled with a legible installation date.	Monthly	OM	OM	OM
	B. Replace dispenser filters annually or when a change in flow rate is noted.	Annually or as needed	SM	SM	SM
Dispenser Strainer (Section 7-10)					
Dispenser Strainers	A. Inspect and clean strainers. Inspect strainer cover gasket for cracks, distortion, and dry rot. If breaks are detected in strainer mesh, replace the strainer.	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
GROUND FUEL PIPING					
Ground Vehicle Fuel Piping (Section 7-11)					
Ground Vehicle Fuel Piping	A. Visually inspect aboveground lines for leaks. Shut down systems that are found with leaks and repair.	Daily	OM	OM	OM
	B. Visually inspect leak detection systems installed on underground piping. Inspections include line leak detectors and leak detection sensors installed in transition sumps and dispenser sumps.**2**\\ /**2**/	Monthly	**2**\\ OM /**2**/	**2**\\ OM /**2**/	**2**\\ OM /**2**/
	C. Perform leak testing on pressurized underground piping with installed leak detection equipment and record results. D. Test leak detection systems installed on underground piping used for ground vehicle petroleum fuel products. Underground leak detection systems include discrete detection sensors installed in transition and dispenser sumps, and line leak detectors installed at the outlet of pumps used to supply pressurized liquid petroleum fuel to underground lines. Repair faulty components. Execution of this work may require state certification or license. E. Conduct service station aboveground piping annual test as outlined in Appendix G – Petroleum Fuel Pipeline Pressure Testing Guidelines and Criteria. Execution of this	Annually	SM	SM	SM

	snowfall when it is opened just long enough to drain the roofline. Tanks with retrofitted geodesic domes or metal roofs may have had the floating roof drain line removed, so before opening the roof drain valve ensure the roof drain line has not been removed. I. Inspect pontoons for standing liquid and presence of strong vapors. J. Remove mechanical gauge float cover and ensure float is securely fastened to gauge tape. Check gauge tape for ease of movement. K. Ensure emergency drain (if equipped) is not blocked with debris. L. Inspect for damage or deflection in the rolling ladder (if equipped). M. Inspect vertical internal ladder and internal ladder/roof seals for abrasions that might indicate out of roundness, or improper centering (if equipped). N. Inspect gauge wells and gauge well/roof seals for abrasions that might indicate out of roundness, or improper centering. O. Inspect the floating roof coating for corrosion. Touch up with compatible coating if required.				
	P. Clean and inspect perimeter tank/pan seals.	At time of out of service internal inspection	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	Q. Refer to Section 8-9.1.5 Floating Roof and Pan Pressure/Vacuum Vents for inspection and maintenance requirements of floating roof pressure/vacuum vents. R. Refer to Section 8-9.1.6 Floating Roof and Pan Legs for inspection and maintenance requirements of floating roof legs.	As required	SM	SM	SM
Floating Roof and Pan Pressure/Vacuum Vents (Section 8-9.1.5)					
Floating Roof and Pan Pressure/ Vacuum Vents	A. Inspect the floating roof or pan pressure/vacuum vent to ensure that the seats and retaining straps or guides are in good working order and that the pressure/vacuum vent is not stuck to its seats, but instead lift easily off of its seats and reseats properly. Inspect gaskets for wear and replace as required. Refer to the manufacturer's operation and maintenance manual provided with the floating roof or pan for additional guidance on servicing the pressure/vacuum vent.	At time of out of service internal inspection	SM	SM	SM
Floating Roof and Pan Legs (Section 8-9.1.6)					
Floating Roof and Pan Legs	A. Inspect the floating roof or pan legs and tank bottom striker plates for wear; inspect the seals where the legs penetrate the floating roof or pan for leaks; inspect the low leg position stops to make sure they are securely fastened to the legs and will stop the floating roof or pan at the low position; inspect the leg keeper straps to make sure they are securely fastened to the legs to prevent the legs from falling off or through the	At time of out of service internal inspection	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	floating roof or pan; inspect the threaded keeper caps or high position locking mechanisms to ensure they are in proper working order for securing the floating roof or pan in the high position. Refer to the maintenance manual provided with the floating roof or pan for additional guidance on floating roof or pan legs and associated hardware.				
Secondary Tank Bottoms (Section 8-9.2)					
Secondary Tank Bottoms	A. Tanks designed with secondary tank bottoms should have tell-tale devices (leak detection ports) to allow for monitoring of the tank's floor integrity. The tell-tale devices are typically configured as valves or inspection ports to allow for visual monitoring of liquid that may be present between the foundation and the tank floor. The presence of water would indicate a breach in the foundation seals or flooring while the presence of petroleum would indicate integrity loss in the tank floor. Open and check tell-tale valves or inspection ports. Verify the absence of water or petroleum.	Monthly	OM	OM	OM
Tank Pressure/Vacuum Vents (Section 8-9.3)					
Tank Pressure/ Vacuum Vents	A. On underground shop fabricated tanks, ensure tank pressure/vacuum vent is present and that the riser pipe is securely supported and vertical.	Annually	OM	OM	OM
	B. Inspect vent settings. Pressure and vacuum settings for pressure/vacuum vents are	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	usually specified on the vent nameplate or in the manufacturer's manual for the vent. C. Clean the pressure/vacuum vent. Information on the type of pressure/vacuum vent and proced- ures for the removal of covers, hoods and/or pallet removal and reinstallation should be found in the manufacturer's operation and maintenance manual. Before removing the pallets, brush all accumulations from the protecting screens, the pallets, and all surfaces of the valve. Brush the screens from inside the valve so that dirt and other objects fall to the outer sides. Remove heavy loading weights prior to removing the pallet assembly. Remove deposits or foreign matter using reasonable care not to damage diaphragms or seats. D. Inspect gaskets, seats, diaphragm, pallet stems and stem guides. Check all mating surfaces which must be free of nicks, cuts, cracks or deposits that might interfere with the proper seating or tightness of the valve. Test the pallets to ensure they move freely up and down over the full range of travel.				
Emergency Vents (Section 8-9.4)					
Emergency Vents	A. **2**\\ Inspect emergency vents for external damage, such as dents, rusting, severe pitting, or obstruction by other equipment, piping, or conduits.	Annually	OM	OM	SM /**2**/

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	B. Remove the vent, if possible, and inspect the seals and diaphragms for cracking or breakdown. Inspect retaining cables to ensure they are fastened to the vent and the manway or tank. Inspect guides to ensure emergency vents can function properly and re-seat. C. Verify that emergency vents have not been removed or modified. Emergency vents should not be replaced with ATGs, manual sample ports, level alarms, etc. D. Tanks that are equipped with manways for emergency vents must be inspected for appropriate type, length, number of bolts, and lift clearance of the manway in accordance with UL 142 Standard for *Steel Aboveground Tanks for Flammable and Combustible Liquids*, Section 8 and 9.	Annually	SM	SM	SM
Flame Arrestors (Section 8-9.5)					
Flame Arrestors	A. The tube bank must be removed and cleaned of foreign matter by immersing in an approved solvent solution, taking care not to damage the tube bundle. Gaskets must be inspected and replaced as necessary.	Annually	SM	SM	SM
External High Level Shutoff Valves (HLSO) (Section 8-9.6.1)					
External High Level Shutoff Valves (HLSO)	A. Activate the tank high-high level alarm and ensure the solenoid valve (if equipped) activates on the HLSO valve. Ensure the HLSO valve closes when the solenoid valve is activated.	Quarterly	SM	SM	SM
	B. Isolate, drain, and then vent the external float valve chamber (if equipped). Refill (either	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	manually or via the storage tank product saver tank pump) the float chamber to test the float valve. Ensure the HLSO closes when the float is raised. C. Lift the manual test lever of internally mounted float valve (if equipped). Ensure that the HLSO closes when the float of the float valve is raised.				
Internal HLSO Valve (Section 8-9.6.2)					
Internal HLSO Valves	A. Inspect and test the high level shut-off valve and float mechanism, counter-weights, float rods, and floats to ensure the float mechanism is moving freely and functioning properly to close the high level shut-off valve. If valve is not equipped with a manual test mechanism the level of the tank must be raised to the high level shutoff valve set point in order to test the valve. Ensure valve is installed at a proper height.	Annually	SM	SM	SM
Mechanical Tape Gauges (Section 8-9.7)					
Mechanical Tape Gauges	A. Visually check that a liquid level is indicated and that the measurement appears to be accurate.	Daily	OM	OM	OM
	B. Check the mechanical tape gauge against the automatic electronic tank gauge (if installed) or by manually gauging the tank for relative accuracy and proper working condition. Consult the manufacturer's operation and maintenance manual for additional maintenance and inspection requirements	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Automatic Tank Gauges					
Mechanically Operated Tape Gauge (Section 8-9.8.1)					
Mechanically Operated Tape Gauge	A. Visually inspect the gauge to ensure the power is on, there are no warning alarms or lights and a liquid measurement is indicated and the tank level reading appears to be accurate.	Daily	OM	OM	OM
	B. Inspect gauge head for buildup of sediment. C. Inspect tape conduit for deformations that would inhibit movement of tape up and down.	Quarterly	SM	SM	SM
	D. Gauge level accuracy must be performed against a hand dip measurement of the tank. Calibrate as required. E. Inspect float and guide cable through an opened manway or access cover. Verify that the guide wire is taut and free of kinks. Verify that the float is buoyant and free of sludge or sediment build up. F. Inspect power and control wires for damage. G. Inspect wire connection termination points for damage or loose connections.	Semi-annually	SM	SM	SM
	H. Lubricate moving parts of the gauge head	Annually	SM	SM	SM
Magnetostrictive Probes (Section 8-9.8.2)					
Magnetostrictive Probes	A. Visually inspect the gauge to ensure the power is on, there are no warning alarms or lights and a liquid measurement is	Daily	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	indicated and the tank level reading appears to be accurate.				
	B. Inspect probe assembly for buildup of sediment. C. Inspect probe assembly and probe shaft for deformations that would inhibit movement of probe.	Quarterly	SM	SM	SM
	D. Level probe accuracy must be performed against a hand dip measurement of the tank. Calibrate as required. E. Verify that the probe float is buoyant and free of sludge or sediment build up. F. Inspect power and control wires for damage. G. Inspect wire connection termination points for damage or loose connections.	Semi-annually	SM	SM	SM
Servo Gauge (Section 8-9.8.3)					
Servo Gauge	A. Visually inspect the gauge to ensure the power is on, there are no warning alarms or lights and a liquid measurement is indicated and the tank level reading appears to be accurate.	Daily	OM	OM	OM
	B. Inspect gauge head for buildup of sediment.	Quarterly	SM	SM	SM
	C. Gauge level accuracy must be performed against a hand dip measurement of the tank. Calibrate as required. D. Inspect float and guide cable through an opened manway or access cover. Verify that the	Semi-annually	SM	SM	SM

	guide wire is taut and free of kinks. Verify that the float is buoyant and free of sludge or sediment build up. E. Inspect power and control wires for damage. F. Inspect all wire connection termination points for damage or loose connections.				
	G. Inspect stilling well to be straight and vertical with no dents so that the float can move freely. H. Lubricate moving parts of the gauge head.	Annually	SM	SM	SM
Level ALARMS					
Externally Mounted Level Alarms (Section 8-9.9.1)					
Externally Mounted Level Alarms	A. Test level alarm switches by isolating the chambers from the tank using the sensing chamber isolation valves. Vent and drain the chambers. Slowly pour product into the chambers through a funnel on top of the chamber to test the level switch at the specified level setting.	Semi-annually	SM	SM	SM
Internally Mounted Level Alarms (Section 8-9.9.3)					
Internally Mounted Level Alarms	A. Test level alarm switches by activating manual testing levers, if equipped. If alarms switches are not equipped with manual testing levers, adjust the level of fuel in the tank to the alarm points in order to test the alarm switches. If it is not feasible to adjust the level of the fuel in the tank to all of the alarm set points, remove the alarm switches from the tank and test	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	the alarms externally. Reinstall alarm switches in the tank once testing is complete.				
PRODUCT SAVER TANKS					
Product Saver Tanks (Section 8-9.10)					
Product Saver Tanks	A. Inspect the product saver tank to ensure all valves are working properly, sight level gauges with density balls are working properly and are not broken, and hand pumps or electric pumps are working properly and are not leaking.	Quarterly	SM	SM	SM
SIDESTREAM FILTRATION SYSTEMS					
Sidestream Filtration Systems (Section 8-9.11)					
Sidestream Filtration Systems	A. Check (typically 5 gallon (19 liters), if incorporated) filter separator vent tank and ensure it is empty.	Monthly	OM	OM	OM
	B. Refer to Section 6-1 Pipe Testing and Inspections for inspection and maintenance requirements of piping. C. Refer to Section 3-6.4 Basket Strainers for inspection and maintenance requirements of basket strainers. D. Refer to Section 3-8 Pumps for inspection and maintenance requirements of fuel pumps. E. Refer to Section 3-6.2 Filter Separators for inspection and maintenance requirements of filter separators. F. Refer to Section 4-4.2.2 Filter Separator Control Valves for inspection and maintenance	As required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	requirements of filter separator control valves. G. Refer to Section 9-1.6 Grounding Systems for inspection and maintenance requirements of grounding systems. H. Refer to Section 9-1.9 Electronic Equipment for inspection and maintenance requirements of control panels.				
FILL PORTS					
Fill Ports (Section 8-9.12)					
Fill Ports	A. Ensure fill port covers are installed and are not damaged or broken. Ensure fill port covers are identified by fuel type and are installed on the correct tank. Visually inspect the fill port spill bucket to ensure there are no cracks, budges, or holes. Ensure the spill bucket is clean of dirt, trash, water, and fuel	Daily	OM	OM	OM
	B. Inspect drain valve in spill bucket and ensure it is in good condition. Ensure the caps installed on the receipt connection points are vapor tight and are not broken, cracked, or chipped. Ensure the poppet valve of the vapor recovery port seals tightly and no vapor is escaping from the tank when the valve is closed.	Monthly	**2**\\ OM /**2**/	**2**\\ OM /**2**/	SM
	C. **1**\\Hydrostatically test fill-port to ensure containment is liquid-tight. Where evaporation is a concern, conduct the testing when this concern would be minimized, such as at	**1**\\Every 3 Years/**1**/	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	night/early morning or during a time of year when this would not be as much of an issue. Record the water level at the start of the 60-minute (minimum) hold period. If the water level drops by 1/8 inch or more, perform and record an investigation to determine the cause and any required repairs. Once repairs are completed, a new test must be completed. Refer to Appendix B for testing procedures and to use to document the testing.**/1/** Ensure secondary containment area of fill port is fuel tight. Ensure the manual transfer pump or drain valve is operational.				
LEAK DETECTION					
Point Sensor - Dry (Section 8-9.13.1)					
Point Sensor - Dry	A. Ensure the monitoring panel associated with the point sensor(s) is powered on and no alarms are present.	Daily	OM	OM	OM
	B. Ensure monitoring space is clear and free of debris and liquid	Monthly	**\2** OM **/2/**	**\2** OM **/2/**	**\2**OM**/2/**
	C. Test sensor and ensure it is functional	Annually	SM	SM	SM
Point Sensor - Wet (Section 8-9.13.2)					
Point Sensor - Wet	A. Ensure the monitoring panel associated to the wet point sensor(s) is powered on and no alarms are present.	Daily	OM	OM	OM
	B. Ensure level of monitoring fluid is within normal range.	Monthly	**\2** OM **/2/**	**\2** OM **/2/**	SM

Point Sensor – Pressure/Vacuum (Section 8-9.13.3)					
Point Sensor – Pressure/ Vacuum	A. Ensure the monitoring panel associated with the pressure/vacuum point sensor(s) is powered on and no alarms are present.	Daily	OM	OM	OM
	B. Test vacuum sensor for proper operation	Annually	SM	SM	SM
Visual Leak Detection (Section 8-9.13.4)					
Visual Leak Detection	A. Visually inspect leak detection ports (tell-tales) for signs of leaks. If there are debris or objects obstructing the view, appropriate measures must be taken to remove the debris or remedy the obstructions.	During routine inspection of other components or monthly, whichever comes first.	OM	OM	OM
	B. Visually inspect reinforcement plate tell-tale holes for signs of leaks. Ensure tell-tale holes have not been plugged by debris or a cap. Pack reinforcement plate tell-tales with white grease to prevent insect nesting and buildup of debris	Quarterly	OM	OM	OM
FLOATING SUCTION LINES					
Floating Suctions Lines (Section 8-9.14)					
Floating Suction Lines	A. Check external floating suction line position indicator to ensure floating suction line is moving freely as the level in the tank rises or falls.	Quarterly	SM	SM	SM
	B. Inspect cables, floats, and swing joint. Ensure interior of floats have not collected fuel. Ensure cables are securely fastened to	When tank is taken out of service for internal	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	anchor points and are in good working order. Ensure the suction pipe flange used to support the swing joint is level and true and that swing joint moves freely up and down and does not bind.	cleaning or inspection			
HEATING COILS					
Steam Type Heating Coils (Section 8-9.16.1)					
Steam Type Heating Coils	A. Observe the regulating valve and check it against a thermometer to be sure that it controls the tank temperature within a safe range, usually not over 150 °F (65 °C) for No. 6 burner fuel oil. Steam traps must be inspected for proper operation to ensure condensate is evacuated from the steam coil.	At each operation	OM	OM	OM
	B. Pressure check heating coils to 10% above normal operating pressure.	Annually	SM	SM	SM
	C. Steam coils must be cleaned and inspected for visible signs of corrosion or wear when the tank is emptied and cleaned for inspection. All components of the steam heating coils, such as weld joins, support points, valves, temperature wells, control valves, and steam traps must be inspected and checked for proper operation and visible wear or damage. The coil may be carefully pressurized with steam and visually checked for leaks if necessary. Leaks or damage found must be repaired.	When the tank is taken down for formal internal inspection or sooner if steam heating coil damage is suspected.	SM	SM	SM
Thermal Fluid Type Heating Coils (Section 8-9.16.2)					

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Thermal Fluid Type Heating Coils	A. Observe the regulating valve and check it against a thermometer to be sure that it controls the tank temperature within a safe range, usually not over 150 °F (65 °C) for No. 6 burner fuel oil. All external valves, fittings, and other components must be inspected for visible signs of leaks during operation.	At each operation	OM	OM	OM
	B. Pressure check heating coils to 10% above normal operating pressure.	Annually	SM	SM	SM
	C. When tanks are emptied and cleaned for inspection, the heating coils must be cleaned and inspected for visible signs of corrosion, wear, or damage. The coils can be pressurized and checked for leaks at that time with the thermal heating fluid at normal operating pressure, but at ambient temperature to alleviate possible burns to personnel. Leaks must be repaired.	When the tank is taken down for formal internal inspection or sooner if thermal heating coil damage is suspected.	SM	SM	SM
Electric Rod Type Heating (Section 8-9.16.3)					
Electric Rod Type Heating	A. Inspect heater to ensure no fluid leakage around the heater to tank connection and that the heater is performing properly.	At each operation	OM	OM	OM
STILLING WELLS					
Stilling Wells (Section 8-9.17)					
Stilling Wells	A. Stilling wells must be visually inspected to be vertically straight and free dents or indentations. Sometimes tank stilling wells are made of bare carbon steel pipe. In these	At time of out of service internal inspection	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	instances the stilling wells must be replaced with aluminum. B. Inspect floating seals inside stilling wells to ensure they are not worn and are sealing the inside of the stilling well property.				
CONTAINMENT SYSTEMS					
Containment Systems (General) (Section 8-10.1)					
Containment Systems (General)	A. Inspect containment systems for cleanliness, if accessible.	Daily	OM	OM	OM
	B. Secondary containment systems degrade and will collect debris which can clog drainage inlets or prevent drain valves from seating properly. **1**\\Hydrostatically test the drainage systems to include containment drain inlets, drain lines and containment drain valves to ensure the containment is liquid tight. This test may use opportune rainfall by holding rainwater in the containment system for one hour. Where evaporation is a concern, conduct the testing when this concern would be minimized, such as at night/early morning or during a time of year when this would not be as much of an issue. Record the water level at the start of the 60-minute (minimum) hold period. If the water level drops by 1/8 inch or more, perform and record an investigation to determine the cause and any required repairs Record the water level at the start of the 60 minute (minimum) hold period. ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	retracted from the concrete or pipe surfaces must be removed and replaced with new fuel resistant sealant.				
ELECTRICAL CONTROL SYSTEMS AND EQUIPMENT					
Electrical Equipment (Section 9-1.2)					
Electrical Equipment	A. Electrical control systems include: deadman control; ground verifica- tion systems; EFSO operation; con- trol panels, motor control, and pump start/stop buttons. These sys- tems must be tested on a periodic basis to ensure proper operation and functionality. In addition, con- trol system Uninterruptible Power Supplies (UPS) must be inspected and replaced as necessary.	Quarterly	SM	SM	SM
Power Cables (Section 9-1.3)					
Power Cables	A. Visual inspection: Verify that there are no sharp bends. Verify that the cable insulation is intact. Verify that cables are appropriately tagged or otherwise identified. Verify that all connections are tight and not corroded. Open manholes and handholes. Verify that they are not flooded, clogged with debris or infested by pests.	Quarterly	SM	SM	SM
	B. Insulation resistance test: This test measures the resistance of the insulation with an Insulation Resistance Tester. During the test, the cable will be disconnected from both ends. Acceptable test values are 100 megaohms for cables rated between 120 V to 1000 V. Insulation resistance testing for voltages higher than 1000 V are to be performed by specialized testing company.	As needed based on visual inspection	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Motor Controls (Section 9-1.4)					
Motor Controls	A. Verify that the labeling is consistent with the drawings and specifications. B. Verify that pushbuttons are easy to operate and are not stuck. Verify that there is no grease accumulation around the seating Verify that indicating lights are functional and replace if required. C. Verify that indicating lights are functional and replace as needed. D. Verify that electrical and mechanical interlocks operate according to the design intent. In case of key interlocks, ensure that the number of keys corresponds to the interlock intent. Having more keys than required defeats the intent of the interlocking and poses danger to the service personnel and equipment. If extra keys are found, they should be removed from the equipment.	Semi-annually	SM	SM	SM
	E. Inspect the enclosure for visible signs of corrosion.	Interior annually/ exterior semi-annually	SM	SM	SM
	F. Open the enclosure – be mindful of insects, rodents and reptiles, particularly if located outdoors. Look for signs of corrosion, dust accumulation, spider webs, etc. Clean the enclosure with compressed air and apply rust inhibitors and paint as needed. G. Inspect the overcurrent protective devices for proper seating. Verify that rating is	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	appropriate for the motor. Look for signs of attached wire and device overheating. H. Inspect the arch shoots of contactors and clean as needed. Check that partitions are not burned. I. Inspect contactors for abnormal wear. Check contacts for pitting, roughness and oxidation. Verify that contact gap, alignment and pressure are in accordance with manufactures recommendations. J. When contactors are used, listen for the chatter of contacts or buzzing noise. These are indicative of a faulty contactor. K. Verify that relays and switches are firmly seated in their bases and there are no signs of overheating or vibration. L. Look for frayed or broken strands in the flexible control wiring and replace if such are found. M. Perform a functional test of protective devices if they are equipped with self-testing circuits or switches. N. Perform a functional test of all manual switches and verify proper operation against intended design logic. Replace switches and relays if operation is not satisfactory.				
	O. Perform insulation resistance test for the control wiring. (NOTE: Testing of the control wires may require substantial down time. Therefore, this should only be performed on a case by case basis if there are	As required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	reasons to suspect that the insulation of the control wiring is deteriorating.)				
Panelboards (Section 9-1.5)					
Panelboards	A. Verify that there are no physical obstructions blocking access to the panelboard. Remove physical obstructions	Quarterly	OM	OM	OM
	B. Inspect the enclosure and the surrounding area for water damage and corrosion. C. Verify that all breakers are either in the “On” or the “Off” position. If there are tripped breakers, investigate the cause of the trip. D. Verify that all breakers are either in the “On” or the “Off” position. If there are tripped breakers, investigate the cause of the trip. E. Verify that the breaker operation matches the description on the panel schedule. F. Observe breakers, wires and terminals for signs of overheating or short circuiting. G. Verify that all breakers are firmly seated and locked in place by slightly shaking them. H. Verify that all grounding wires are firmly connected to the grounding bar. I. If a breaker malfunction is identified, leave breaker in the open position and replace as soon as possible. If a breaker cannot disconnect its circuit, the	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	entire panelboard must be switched off using its main disconnecting means and locked out until the breaker is repaired.				
Grounding Systems (Section 9-1.6.1)					
Power Grounding Systems	A. The connections to the grounding system must be surveyed and verified for continuity. If a connection is suspected to be loose, perform further testing. In some occasions, it is more cost effective to replace the suspected connection instead of performing diagnostic tests. B. Measure the voltage between the equipment grounding conductor and the electrode grounding conductor (usually bare copper). Investigate test results above 3 VAC for a potential ground fault. C. Measure the voltage between the chassis of the equipment and the electrode grounding conductor. Investigate if the readings exceed 2 VAC.	Annually	SM	SM	SM
	D. Facility ground resistance check: This type of testing is performed with a four lead, low resistance ohmmeter or digital ohmmeter. Recommended values are between 3 and 5 ohms. In no case should the grounding resistance be higher than 25 ohms	Every five years	SM	SM	SM
Grounding Systems (Section 9-1.6.2)					
	A. Inspect ground reels for corrosion. Ensure ground reels	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Static Grounding Systems	are securely mounted to a rigid base. Inspect clamps for serviceability. Replace clamp if jaws are deformed for corroded, spring is weak, or other defects are evident that would prevent a good connection. Inspect cable wires. Replace if more than one-third of the cable wires are broken.				
	B. The connections to the grounding system must be surveyed and verified for continuity. If a connection is suspected to be loose, perform further testing. In some occasions it is more cost effective to replace the suspected connection instead of performing diagnostic tests.	Annually	SM	SM	SM
	C. Resistance measurement on static grounds: Measure static ground resistance of new and damaged ground rods. Static ground with a resistance greater than 10,000 ohms will be removed or replaced. Static ground mechanically damaged will be repaired and retested.	When observed to be physically damaged.	SM	SM	SM
Electric Motors (Section 9-1.7)					
Electric Motors	A. Lubricating motor bearings and inspect for vibration and overheating.	Quarterly	SM	SM	SM
	B. Check for debris and other foreign material in the fan housing	Semi-annually	SM	SM	SM
	C. Check motor ground wires. Ensure they are firmly	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	connected to the housing or the junction box. D. If the motor is installed in a hazardous location, verify that the seals of the connection boxes and conduits are intact.				
Lighting (Section 9-1.8)					
Lighting	A. Verify proper operation of light switch, lighting contactor, photocell or timer as appropriate. If a lighting contactor is used, listen for the chatter of contacts or buzzing noise. These are indicative of a faulty contactor. Replace if required. B. With the lights turned on, observe individual luminaries for flicker or lights turning on and off. The former is indicative of a faulty choke. The latter is indicative of a faulty starter. Replace the faulty components as required. C. When light fixtures are located in hazardous areas, verify that the seals are intact and the hazardous rating of the fixture is maintained.	Quarterly	SM	SM	SM
	D. Thoroughly clean dust, bugs, and debris from the luminaire. Light solvents or cleaning agents may be used.	Annually (in dusty areas the luminaries may require cleaning at shorter intervals)	SM	SM	SM
	E. Re-Lamping: With the lights turned off, replace the lamps. In order to prevent accidental turning on of the lights, it is mandatory to switch off and lockout the breaker of the	Annually or as required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	lighting circuit. Ensure the replacement lamps are the same type as those they are replacing. Verify the proper operation of all light fixtures after the lamp replacement.				
Electronic Equipment (9-1.9)					
Electronic Equipment	A. Inspect the outside of equipment enclosures for dust and evidence of corrosion. Vacuum clean the dust to ensure unobstructed air circulation. B. Open the enclosure and vacuum clean the dust to ensure unobstructed air circulation. Pay particular attention to fans and air passages. If there is evidence of corrosion, verify that there is no water damage on printed circuit boards or contacts. If water or humidity damage is observed, the electronic components may not work properly and further testing is required. C. Verify proper operation of the space heater if one is installed. D. Check if fans for proper operations and rotation. E. Look for signs of overheating such as discoloration and charring. F. Replace air filters. G. Verify connection tightness. Lightly pull wires on soldered and terminal screws and ensure the wires are not loose. H. Verify that circuit boards are properly seated. Ensure that	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	board locking tabs are fully engaged. Do not unplug and plug connectors to verify seating. This will wear out the pins. Unplug only if connector malfunction is suspected. I. Observe wires for excessive strain, braiding, or wear due to vibration. Replace as required.				
CATHODIC PROTECTION SYSTEMS					
Cathodic Protection (Section 9-2.1)					
Cathodic Protection	A. Inspect rectifiers in in accordance with UFC 3-570-06	**2**\\ Monthly /**2**/	**2**\\ OM /**2**/	**2**\\ OM /**2**/	SM
	B. Inspect cathodic protection systems in accordance with UFC 3-570-06	Annually	SM	SM	SM
Lightning Surge Arresters (Section 9-2.2.1)					
Lightning Surge Arresters	A. Newer lightning surge arresters are designed to withstand unlimited surges at 50,000 amperes; however, manufacturers of older surge arresters may provide a maximum number of surge events that can occur before it must be replaced. If surge arresters include a maximum number of surge events, a spare arrester must be kept on hand. Refer to the surge arrester manufacturer's operation and maintenance manual for particular inspection instructions and parts. Inspect as part of an overall cathodic protection system inspection.	Annually	SM	SM	SM
Card and Key Locks (Section 9-3)					

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Card and Key Locks	A. Conduct operational check of card and key lock system and ensure that all features provided with the installed system are operational.	Annually	SM	SM	SM
Lightning Protection Systems (Section 9-4)					
Lightning Protection Systems	B. Inspect air terminals to make sure they are securely attached to the roof of the building, canopy, or the piece of equipment. Check all connections between the air terminals and the grounding loop or grounding rods. Repair damaged or loose connections and perform continuity check after repairs.	Annually	SM	SM	SM
Ground Verification System (Section 9-5)					
Ground Verification System	A. Conduct an operational check of the ground verification system and ensure that all features provided with the installed system are operational. Inspect the plug for corrosion, weakness, or loose nuts and replace if heavily dented or deformed.	Quarterly	SM	SM	SM
Electronic Overfill Protection Systems (Section 9-6)					
Electronic Overfill Protection Systems	A. Conduct operational check of overfill prevention system and ensure that all features provided with the installed system are operational.	Quarterly	SM	SM	SM
ALTERNATE POL FACILITIES					
Liquefied Petroleum Tanks (Section 10-1.1)					
Liquefied Petroleum Tanks	A. Inspect fuel tank for leaks. If a leak is occurring, the odorizing agent of the gas should be detectable. Use a soap and	Monthly	OM	OM	OM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	water solution to spray on areas suspected of leaks. Systems that are found with leaks must be taken out of service.				
	B. Test operation of emergency shutoff valves. Ensure the fusible link mechanism is attached properly to actuate in case of a fire and that it has not been by-passed, blocked, or damaged in any manner. Ensure the fusible link is not filled with debris or paint which could impact operation.	Semi-annually	SM	SM	SM
	C. Check settings of tank safety valves and calibrate if required	Every 5 years	SM	SM	SM
Liquefied Petroleum Pipelines (Section 10-1.2)					
Liquefied Petroleum Pipelines	A. Conduct visual inspection of pipelines for potential damage and leak points. Use a soap and water solution to spray on areas suspected of leaks. Systems that are found with leaks must be taken out of service and repaired.	Monthly	OM	OM	OM
	B. Inspect coatings and markings on piping. Repair coating deterioration and replace labels that are fading and are difficult to read.	Semi-annually	SM	SM	SM
Liquefied Petroleum Vapor Lines (Section 10-1.3)					
Liquefied Petroleum Vapor Lines	A. Inspect vapor lines for leaks. If leaks are occurring, the odorizing agent in the gas should be detectable. 	the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. Systems that are found with leaks must be taken out of service and repaired.				
	B. Inspect coatings and markings on storage tubes or tanks. Repair coating deterioration and replace labels that are fading and becoming difficult to read.	Semi-annually	SM	SM	SM
	C. Check operation and calibration of safety valves on tubes or tanks.	Every 3 years	SM	SM	SM
CNG Dispensers (Section 10-2.4)					
CNG Dispensers	A. Dispensers are listed for service with CNG and will vary by manu- facturer. Consult the maintenance manual that was supplied with the system for manufacturer's maintenance required for the CNG dispenser.	As Required	SM	SM	SM
CNG Dispenser Hoses (Section 10-2.5)					
CNG Dispenser Hoses	A. Inspect hoses for damage, leaks, and cracks. If leaks are occurring, the odorizing agent in the gas should be detectable. Use a soap and water solution to spray on areas suspected of leaks. If leaks are detected from a hose, discontinue the use of the hose and remove it from service.	Monthly	OM	OM	OM
	B. Test hoses for leaks following manufacturer recommended frequencies and procedures.	As required	SM	SM	SM
Hydrazine Charging Units (Section 10-3)					
Hydrazine Charging Units	A. Hydrazine charging units are self-contained factory fabricated systems. Refer to the	As Required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	manufacturer's maintenance manual that was provided with the system for required periodic maintenance.				
SUPPORT FACILITIES					
	Fuel Truck **1**\\and Rail/**1**/ Containment Areas (Section 11-1.1)				
Fuel Truck Containment Areas	A. Remove debris from around security fence. B. Inspect fence grounding points. Ensure connections are not loose or damage. C. **2**\\ Inspect the parking area for cracks in the concrete containment paving and curbs. Remove vegetation that may have established roots in the buildup of dirt or from exposed earth under cracks. /**2**/	Monthly	OM	OM	OM
	D. Inspect the parking area for cracks in the concrete containment paving and curbs. Remove vegetation that may have established roots in the buildup of dirt or from exposed earth under cracks. Thoroughly clean and seal cracks with a fuel resistant sealant.	Quarterly	SM	SM	SM
	E. **1**\\ Secondary containment systems degrade and will collect debris which can clog drainage inlets or prevent drain valves from sealing properly. Hydrostatically test secondary containment and associated drainage systems to include containment concrete/sealant, drain inlets, drain lines and containment drain valves to ensure containment is liquid tight. This test may use opportune rainfall by holding	**1**\\Every 3 Years/**1**/	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	rainwater in the containment system for one hour. Where evaporation is a concern, conduct the testing when this concern would be minimized, such as at night/early morning or during a time of year when this would not be as much of an issue. Record the water level at the start of the 60-minute (minimum) hold period. If the water level drops by 1/8 inch or more, perform and record an investigation to determine the cause and any required repairs. Once repairs are completed, a new test must be completed. Refer Appendix B for testing procedures and to document the testing. /**1**/. F. Verify continuity of vehicle grounding system connections. If a connection is suspected to be loose, perform further testing. In some occasions it is more cost effective to replace the suspected connection instead of performing diagnostic tests. G. Inspect pavement markings and vehicle movement lines for wear and fading. Repair faded or worn pavement markings. H. Inspect security fence for wear and rust. Inspect barbed wire and ensure it is adequately secured to outriggers. Repair loose fencing components and coatings at areas that show rust.				
	I. /**2**/Refer to Section 9-1.8 Lighting for inspection and maintenance requirements of area lighting	As required	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Remote Spill Containment (Section 11-1.2)					
Remote Spill Containment	A. Inspect the remote containment basin for cracks in the concrete containment paving, walls, and curbs. Remove vegetation that may have established roots in the buildup of dirt or from exposed earth under cracks. **2**\ /**2**/ B. If equipped, inspect spill containment sump pump for proper operation.	**2**\Monthly/**2**/	**2**\OM/**2**/	/**2**/OM/**2**/	**2**\OM/**2**/
	C. **2**\ Inspect the remote containment basin for cracks in the concrete containment paving, walls, and curbs. Thoroughly clean cracks with a water spray or air jet. Seal cracks with a fuel-resistant sealant. /**2**/	Quarterly	SM	SM	SM
	D. **1**\ Secondary containment systems degrade and will collect debris which can clog drainage inlets or prevent drain valves from sealing properly. Hydrostatically test secondary containment and associated drainage systems to include containment concrete/sealant, drain inlets, drain lines and containment drain valves to ensure containment is liquid tight. This test may use opportune rainfall by holding rainwater in the containment system for one hour. Where evaporation is a concern, conduct the testing when this concern would be minimized, such as at night/early morning or during a time of year when this would not be as much of an issue. Record the water level at	**1**\Every 3 Years/**1**/	**2**\ SM /**2**/	**2**\ SM /**2**/	**2**\ SM /**2**/

	the start of the 60-minute (minimum) hold period. If the water level drops by 1/8 inch or more, perform and record an investigation to determine the cause and any required repairs. Once repairs are completed, a new test must be completed. Refer Appendix B for testing. /**1**/.				
Pumphouse/Filter Buildings (Section 11-2.1)					
Pumphouse/ Filter Buildings	A. Inspect the floor and containment curbs for cracks. Thoroughly clean cracks with a water spray or air jet. Seal cracks with a fuel resistant sealant.	Annually	SM	SM	SM
	B. Refer to UFC **1**\\ 3-110-03 /**1**/ for inspection and maintenance requirements of pumphouse and filter building roof systems	As required	SM	SM	SM
Canopies (Section 11-2.2)					
Canopies	A. Inspect and maintain canopies according to UFC **1**\\ 3-110-03 /**1**/.	As required	SM	SM	SM
Emergency Eyewash/Showers (Section 11-3)					
Emergency Eyewash/ Showers	A. Test operation of the emergency eyewash/shower by pushing on the activation handles. Ensure water is not brown in color, due to rust in the piping or dirt seeping in from a hole in the buried piping. For systems with tempered water, ensure that water that is being supplied by the emergency eyewash/shower is between 60 and 100 °F (16 and 39 °C). For systems with a horn and strobe light, ensure that the horn and strobe light activate	Weekly	**1**\\OM/**1**/	**1**\\OM/**1**/	**1**\\OM/**1**/

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	when the activation lever on the emergency eyewash/shower is pushed. For systems that interface with Installation or fire emergency systems, pre-coordinate before testing. At some Installations emergency eyewashes and showers act as EFSOs and are tied into the fire alarm systems.				
	B. Inspect portable/packaged safety showers and eyewash stations for proper operation. Check fluid levels. Where tap water is used, fluid must be replaced monthly. Less frequent intervals of fluid change, as recommended by the manufacturer, are acceptable where a solution or water additive is used. Ensure packaged eyewash supplies are within the listed expiration date. Tags or labels must be attached to the unit or adjacent to it, indicating the fluid change schedule.	Monthly	**1**\OM/**1**/	**1**\OM/**1**/	**1**\OM/**1**/
	C. Inspect the exterior coatings of permanently installed units and repair damaged coatings or rust.	Quarterly	SM	SM	SM
	D. For systems with tempered water systems inspect components of the water heater for correct operation and temperature control. Ensure that the safety valve on the hot water heater tank is not leaking.	Semi-annually	SM	SM	SM
	E. Inspect signage and labels on the emergency eyewash/shower. Replace missing labels or signage that	Annually	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	has become loose. Signs that are faded must be replaced				
Ventilation Hoods (Section 11-4.1)					
Ventilation Hoods	A. Inspect the operation of the doors. Ensure that they close and open smoothly.	Quarterly	SM	SM	SM
	B. Inspect the lights inside of the hood to make sure they are operating properly. Replace light bulbs that are no longer working.	Semi-annually	SM	SM	SM
	C. Verify that all electrical equipment is properly classified in accordance with NFPA 70 *National Electrical Code*. D. Inspect the ventilation system (ductwork, fans, etc.) for signs of disrepair and air leakage and ensure it is operational and pulling air through the hood. Inspect and assure that the lab hood air measuring device for assuring proper air flow is permanently attached and working properly. The ventilation hood must be inspected and **\1**approved by a service specific industrial hygienist or bioenvironmental engineer**/1/** in accordance with OSHA, 29 CFR 1910.1450 *Occupational Exposure to Hazardous Chemicals in Laboratories*, and ANSI/AIHA *Laboratory Ventilation Z9.5*. E. Verify negative pressure is present through the ventilation hood to the exhaust.	Annually	SM	SM	SM
Oil/Water Separators (Section 11-5)					

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Oil/Water Separators	A. Inspect the oil/water separator for the buildup of collected petroleum fuel or oil. Remove and properly dispose of accumulated petroleum fuel or oil.	Quarterly or as needed based on precipitation events	SM	SM	SM
	B. Drain, clean, and inspect the interior of the oil/water separator. Ensure all divider plates and screens are in good working order. Replace or repair damaged components.	Annually or more frequently based on local environmental conditions.	SM	SM	SM
Cranes and Hoists (Section 11-6)					
Cranes and Hoists	A. Inspect cranes and hoists for smooth operation. If the crane or hoist is equipped with electronic controls, check power supply and operational control cords for nicks or damage. A crane service technician must correct binding that may prevent smooth operation and repair damage to power cords.	Before each use	OM	OM	OM
	B. Apply lubricant or grease to areas that require periodic greasing. C. Military services-specific, host nation, state, and/or local regulations require cranes and hoists to be certified for operation. Follow the more stringent of military services-specific, host nation, state or local regulations.	Annually	SM	SM	SM
FUEL FACILITY TEMPORARY DEACTIVATION OR CLOSURE					
Deactivated Fuel Tanks (Section 12-2)					
Deactivated Fuel Tanks	A. Inspect water or anti-corrosion level in tank. If level has dropped, investigate potential leak points such as blind flanges. Repair leaks that are	Quarterly	SM	SM	SM

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
	detected and refill to appropriate level. B. Check exterior coatings and labels. Repair peeling coatings and/or rusting areas and replace or repair labels which have become faded and difficult to read.				
	C. Inspect cathodic protection system for proper operation.	Annually	SM	SM	SM
Deactivated Pipelines (Section 12-3)					
Deactivated Pipelines	A. Inspect the pressure of the nitrogen charge applied to the petroleum fuel pipeline with a pressure gauge. If the pressure of the charge has dropped investigate and repair leak points. Once leak points are repaired, recharge with nitrogen. B. Check exterior coatings and labels. Repair peeling coatings and/or rusting areas and replace or repair labels which have become faded and are difficult to read.	Quarterly	SM	SM	SM
	C. Inspect cathodic protection system for proper operation.	Annually	SM	SM	SM
Deactivated Pumps (Section 12-4)					
Deactivated Pumps	A. Manually rotate pump through several rotations. Ensure that the pump turns freely. B. Check exterior coatings. Repair peeling coatings and/or rusting areas and replace or repair labels which have become faded and difficult to read.	Quarterly	SM	SM	SM
	C. Remove isolation flanges and recoat interior of pump with light corrosion-inhibiting oil.	Annually	SM	SM	SM
Miscellaneous Deactivated Components (Section 12-5)					

ITEM	PARAGRAPH	FREQUENCY	Army	Navy/ USMC	Air Force
Miscellaneous Deactivated Components	A. Ensure that blind flanges are tight. Inspect exterior coatings and labels. Repair peeling coatings and/or rusting areas and replace or repair labels that have become faded and are difficult to read.	Annually	SM	SM	SM

<u>Note:</u> Follow manufacturer's recommendation and published operation and maintenance manuals for items and equipment not discussed in this document.

This Page Intentionally Left Blank

APPENDIX D MAINTENANCE PROCEDURES

D-1 D-1 FILTER SEPARATOR COALESCER CARTRIDGE REPLACEMENT AND SEPARATOR CARTRIDGE CLEANING.

D-1.1 Coalescer Cartridge Replacement in Vertical Filter Separator.

a. Drain the filter separator completely.

b. Raise the cover. CAUTION: Do not touch new coalescer cartridges or the separator cartridges with your bare hand. The oil on your hand will cause damage to the water-removal capability of these components.

c. Where there is an outer separator cartridge, remove, clean (D-1.3), and set it aside for reuse.

d. Remove and discard the old coalescer cartridges in an approved manner. Coordinate disposal of coalescer cartridges with Installation Environmental Office.

e. Check the adapter gasket and adapter to make sure the gasket and adapter threads are clean.

f. Complete the installation of the coalescer cartridge assemblies by lowering each of the coalescer cartridge assemblies onto one of the deck plate nipples. Make sure that each of the coalescer cartridge assemblies is screwed down onto its deck plate nipple and the gasket is seated properly and seals tightly. Next, apply the procedures in items (1) through (6) below:

1. Replace the cover gasket with a new gasket of the same grade and manufacturer as the old one.
2. Swing the cover back into place, lowering the lifting handle as you do so.
3. Swing the eyebolts up into place and tighten the nuts using the crisscross method. Do this so that the cover gasket and cover are seated properly. When tightening cover bolts and nuts, use a torque wrench. Tighten nuts just enough to prevent leaking through the dome cover seal (refer to manufacturer's instructions for torque requirements) and to eliminate possible damage to the vessel.
4. Close the manual water drain valve.
5. Slowly fill the separator. Filling a filter separator must take a minimum of ten minutes to perform. Conduct slow filling by use of the slow fill valve on the filter separator, if equipped, or by filling all of the filter separators on a system at one time. Slow filling is the

only authorized method of refilling an empty filter separator. This slows buildup of static electricity in fuel, reducing the possibility of a spark igniting the explosive atmosphere inside the vessel. In most cases, coalescer elements cannot be grounded or bonded to dissipate the static electric charge that is generated during filling.

6. Pressurize the vessel to inspect all gaskets and screwed connections for leaks; tighten all loose connections.

g. Note: Remember, once a system is opened for any reason it must be sampled before aircraft are serviced.

h. Notify the facility supervisor that the filter separator is ready to be put back into service and is awaiting QC flushing and sampling. (This is necessary to ensure the fuel meets quality requirements.)

i. After the coalescer cartridges have been replaced and the filter separator is ready to be put back into service, follow the steps below:

1. Stencil the filter separator in accordance with Section 3-6.2.4.

2. Set up and keep a logbook or wall chart in the maintenance shop. Record the following information in this book or chart: pumphouse facility number; filter separator number; month and year replacement coalescer cartridges were installed; serial number of the coalescer cartridges; number of coalescer cartridges; and manufacturer’s coalescer cartridge lot number, if available.

D-1.2 Coalescer Cartridge Replacement in Horizontal Filter Separator.

a. After the vessel has been drained thoroughly, remove the head flange bolts and open the vessel. For the original KMU-416/F modification kit, use the following method:

1. Starting with the bottom (left) coalescer cartridge, loosen the 0.5-inch (12.7-millimeter) nut on the adapter mounting rod. Slowly drain the fuel trapped in the manifold by loosening the bottom coalescer cartridge.

2. After the fuel has been drained from the manifold, remove the fifteen coalescer cartridges on the outlet side of the manifold.

3. To remove the coalescer cartridge hold-down plate, use a screwdriver for leverage to pry the seals outward from the cartridge. The O-ring seals on the cartridge mounts may be removed more easily by applying a slight twisting motion instead of a direct pull.

4. Loosen and remove the Victaulic coupling from the inlet pipe, sliding the sealing gasket down on the manifold pipe section. Be sure to use a static bonding wire.

5. Remove the manifold. This requires two people to slide the manifold forward, using the protruding coalescer cartridge hold-down rods as handles to help in removing the manifold. CAUTION: Have a container available to place the manifold in and catch fuel that might spill out of the manifold. Dispose of the used coalescer cartridges in an approved manner. Do not allow fuel-soaked coalescer cartridges to be left in the area or disposed of in a manner that can create a safety or fire hazard. Be careful when handling used coalescer cartridges because they are toxic and combustible or flammable, depending on the fuel's flashpoint.

6. Remove the separator cartridges and follow the steps outlined in Section D-1.3 when cleaning.

7. Clean the inside of the filter separator with rags.

8. Install new coalescer cartridges and cleaned separator cartridges on the manifold and reinstall the manifold.

9. Align and bolt in the Victaulic coupling.

10. Replace cover and tighten bolts using the crisscross method. Tighten nuts just enough to prevent leaking through the dome cover seal (refer to manufacturer's instructions for torque requirements) to eliminate possible damage to the vessel.

b. For modified KMU-416/F (300 gallons per minute (1135 liters per minute) kits with nine additional coalescer cartridges on the back side of the manifold, remove only the bottom front six coalescer cartridges instead of all fifteen. This will balance the manifold, and make it easier to remove. Remove the manifold from the vessel.

c. For KMU-417/F kits (600 gallons per minute (2271 liters per minute), leave all coalescer cartridges in place when removing the manifold. This provides balance and lets you remove the manifold easily.

D-1.3 Separator Cartridge Cleaning, Repairing, and Handling.

a. Cleaning: Separator cartridges, when new, operate in a satisfactory manner, but after processing millions of gallons of fuel that contain additives and contaminants they gradually become less effective. Every time the coalescer cartridges are changed the separator cartridges should be inspected and cleaned according to the following procedure:

1. Connect a water hose to a hot water supply. Attach a nozzle to the hose and direct a high-velocity stream of water at a downward angle against the outer surface of the separator cartridge. Hold the separator cartridge assembly vertically by the end to avoid touching the cartridge surface. Begin at the top and work downward along

the length of the separator cartridge. Rotate the separator cartridge slowly so the entire surface is subject to the jet of hot water. Repeat as necessary until the separator cartridge is clean.

2. After cleaning, shake excess water from the separator cartridge and allow the remaining water to evaporate, or use clean, dry, oil-free compressed air. Air quality must be very clean. If the air quality is doubtful, do not use.

3. After each separator cartridge is dry, hold it horizontally and pour tap water onto the cartridge from a height of 1 to 2 inches (25 to 50 millimeters) above the cartridge. Pour water along the entire length of the separator cartridge while slowly rotating the cartridge. Under test, observe the way the water appears on the surface of the separator cartridge. If the water soaks through the separator cartridge instead of beading up or rolling off, the cartridge must be recleaned.

4. The Teflon or nylon coating of the separator cartridge must be visually inspected for small cuts and breaks. Small breaks in the Teflon or nylon coating of the separator cartridge can be repaired for temporary service by patching with a fuel-resistant sealant, epoxy adhesive, or epoxy-base putty. If major holes appear in the Teflon or nylon coating of the separator cartridge, rendering it impracticable to repair, the separator cartridge should be replaced.

b. Installation and Handling: Just before installing separator cartridges, agitate the cartridges briefly in a container of clean fuel to flush off all remaining water. (Use the same type of fuel being filtered). Extra care must be taken during installation to ensure separator cartridges are not damaged. Separator cartridges must be installed very carefully to prevent physical damage to the Teflon or nylon coating. When installing the separator cartridge assembly, the securing nut should not be over torqued, as this can damage the cartridge assembly.

D-2 D-2 HOSE HYDROSTATIC TEST.

D-2.1 Loading Hose Hydrostatic Test.

a. Prior to hydrostatic test of fuel loading hose, determine the maximum allowable pressure rating of attached valves, meters, or swivels to prevent possible injury to personnel or damage to the equipment. It may be necessary to remove the fueling hose prior to testing.

b. Test fluid may be water or liquid petroleum fuel with a flash point of 100 °F (37.7 °C) or more. If liquid petroleum fuel is used as the test medium, the test should be conducted in a place where contamination of adjacent waters will not occur if there is spillage.

c. Provide blind flanges, nipples, valves, pressure gauges, and pumps of appropriate size and rating for the test to be performed.

d. Lay the hose out flat and straight, uniformly supported.

e. Fill the hose with test fluid, expel all air and raise the pressure to 10 psig (69 kPa).

f. Hold the pressure for at least five minutes. During the test interval, measure the length of the hose, end-of-rubber to end-of-rubber. Record the measured length as original length.

g. If the hose is maintaining 10 psig, raise the pressure to the lower of 1.5 times the pump deadhead pressure or the maximum allowable working pressure of the hose and hold the pressure for a minimum of 15 minutes. Measure the length of the hose, end-of rubber to end-of-rubber and record the measured length as test pressure length.

h. During the test the hose must not burst, bulge, leak, or abnormally distort under static liquid pressure.

i. Calculate the elongation as a percentage of original length versus test pressure length. If the elongation of the hose exceeds 15% it is an indication that there is a serious internal weakness and the hose should be removed from service and retired.

D-2.2 Marine and Underwater Transfer Hose Hydrostatic Test.

a. Hydrostatic testing of marine and underwater petroleum fuel transfer hose must meet the requirements of 33 CFR 156, Section 170.

b. Prior to hydrostatic test the hose must meet the following requirements:

1. Have no unrepaired loose covers, kinks, bulges, soft spots or other defects which would permit the discharge of fuel through the hose material, and no gouges, cuts, or slashes that penetrate the first layer of the hose reinforcement.
2. Have no external deterioration and, to the extent internal inspection is possible with both ends of the hose open, no internal deterioration.

c. Test fluid may be water or liquid petroleum fuel with a flash point of 100 °F (37.7 °C) or more. If liquid petroleum fuel is used as the test medium, the test should be conducted in a place where contamination of adjacent waters will not occur if there is spillage.

d. Provide blind flanges, nipples, valves, pressure gauges, and pumps of appropriate size and rating for the test to be performed.

e. Lay the hose out flat and straight, uniformly supported.

f. Fill the hose with test fluid, expel all air and raise the pressure to 10 psig (69 kPa).

g. Hold the pressure for at least five minutes.

h. If the hose is maintaining 10 psig, raise the pressure to 1.5 times the maximum allowable working pressure of the hose and hold the pressure for a minimum of 15 minutes.

i. During the test the hose must not burst, bulge, leak, or abnormally distort under static liquid pressure.

APPENDIX E TANK INSPECTION CHECKLISTS

STI SP001 MONTHLY INSPECTION CHECKLIST

General Inspection Information:

Inspection Date: ____________________ Prior Inspection Date: ______________________ Retain Until Date: ______________________

Inspector Name (print): ______________________________________ Title: ______________________________________

Inspector's Signature: ____

Tanks Inspected (ID #'s): ____

Regulatory facility name and ID number (if applicable) ____

Inspection Guidance:

- This checklist is intended as a model. Locally developed checklists are acceptable as long as they are substantially equivalent (as applicable). Inspections of multiple tanks may be captured on one form as long as the tanks are substantially the same.
- For equipment not included in this Standard, follow the manufacturer recommended inspection/testing schedules and procedures.
- The periodic AST Inspection is intended for monitoring the external AST condition and its containment structure. This visual inspection does not require a Certified Inspector. It must be performed by an owner's inspector per paragraph 4.1.2 of the standard.
- Upon discovery of water in the primary tank, secondary containment area, interstice, or spill container, remove promptly or take other corrective action. Inspect the liquid for regulated products or other contaminants and dispose of properly.
- Non-conforming items important to tank or containment integrity require evaluation by an engineer experienced in AST design, a Certified Inspector, or a tank manufacturer who will determine the corrective action. Note the non-conformance and corresponding corrective action in the comment section.
- Retain the completed checklists for at least 36 months.
- **After severe weather (snow, ice, wind storms) or maintenance (such as painting) that could affect the operation of critical components (normal and emergency vents, valves), an inspection of these components is required as soon as the equipment is safely accessible after the event.**

ITEM		STATUS	COMMENTS/DATE CORRECTED
Tank and Piping			
1	Is tank exterior (roof, shell, heads, bottom, connections, fittings, valves, etc.) free of visible leaks? **Note:** *If "No", identify tank and describe leak and actions taken.*	□Yes □No	

ITEM		STATUS	COMMENTS/DATE CORRECTED
2	Is the tank liquid level gauge legible and in good working condition?	□Yes □No □N/A	
3	Is the area around the tank (concrete surfaces, ground, containment, etc.) free of visible signs of leakage?	□Yes □No	
4	Is the primary tank free of water or has another preventative measure been taken? NOTE: Refer to paragraph 6.10 and 6.11 of the standard for alternatives for Category 1 tanks. N/A is only appropriate for these alternatives.	□Yes □No □N/A	
5	For double-wall or double bottom tanks or CE-ASTs, is interstitial monitoring equipment (where applicable) in good working condition?	□Yes □No □N/A	
6	For double-wall or double bottom tanks or CE-ASTs, is interstice free of liquid? Remove the liquid if it is found. If tank product is found, investigate possible leak.	□Yes □No □N/A	
Equipment on Tank			
7	If overfill equipment has a "test" button, does it activate the audible horn or light to confirm operation? If battery operated, replace battery if needed.	□Yes □No □N/A	
8	Is overfill prevention equipment in good working condition? If it is equipped with a mechanical test mechanism, actuate the mechanism to confirm operation.	□Yes □No □N/A	
9	Is the spill container (spill bucket) empty, free of visible leaks and in good working condition?	□Yes □No □N/A	
10	Are piping connections to the tank (valves, fittings, pumps, etc.) free of visible leaks? **Note:** *If "No", identify location and describe leak.*	□Yes □No	
11	Do the ladders/platforms/walkways appear to be secure with no sign of severe corrosion or damage?	□Yes □No □N/A	
Containment (Diking/Impounding)			
12	Is the containment free of excess liquid, debris, cracks, corrosion, erosion, fire hazards and other integrity issues?	□Yes □No □N/A	
13	Are dike drain valves closed and in good working condition?	□Yes □No □N/A	

ITEM		STATUS	COMMENTS/DATE CORRECTED
14	Are containment egress pathways clear and any gates/doors operable?	□Yes □No □N/A	
	Concrete Exterior AST (CE-AST)		
15	Inspect all sides for cracks in concrete. Are there any cracks in the concrete exterior larger than 1/16"?	□Yes □No □N/A	
16	Inspect concrete exterior body of the tank for cleanliness, need of coating, or rusting where applicable. Tank exterior in acceptable condition?	□Yes □No □N/A	
17	Visual inspect all tank top openings including nipples, manways, tank top overfill containers, and leak detection tubes. Is the sealant between all tank top openings and concrete intact and in good condition?	□Yes □No □N/A	
	Other Conditions		
18	Is the system free of any other conditions that need to be addressed for continued safe operation?	□Yes □No

APPENDIX F TANK INSPECTION CHECKLISTS

Field Erected Tank Monthly Inspection Checklist

General Inspection Information:

Inspection Date: ____________________ Retain Until Date: ______________________ (36 months from inspection date)

Prior Inspection Date: ____________________ Inspector Name: ____________________________________

Tanks Inspected (ID #'s): ____

Item	Task	Status	Comments
1.	Inspect the reinforcement plate weep holes for signs of fuel and remove pipe plugs if installed.	☐Yes ☐No ☐N/A	
2.	Inspect all tank bottom tell tales and monitoring wells. Remove any water if present.	☐Yes ☐No ☐N/A	
3.	For tanks equipped with floating-roof ensure the center primary roof drain system is free of water, the drip-tight plug is placed in the roof drain opening, and drain valve is closed.	☐Yes ☐No ☐N/A	
4.	Inspect floating roof systems for:		
	4.1. Inspect the roof for buckling or damage.	☐Yes ☐No ☐N/A	
	4.2. Inspect for standing water on the roof deck.	☐Yes ☐No ☐N/A	
	4.3. Ensure the roof drain system is water-free.	☐Yes ☐No ☐N/A	
	4.4. Check the floating roof guides.	☐Yes ☐No ☐N/A	
	4.5. Visually inspect the roof for centering.	☐Yes ☐No ☐N/A	
5.	Check the product recovery system for; proper pump operation; sight glass is clear; float assembly is functioning.	☐Yes ☐No ☐N/A	

Item	Task	Status	Comments
6.	Ensure the ladders, platforms, handrails, and stairs are secured to the structure and inspect for signs of corrosion.	☐Yes ☐No ☐N/A	
7.	Visually check the exterior of the tank (i.e., welds, plates, bolts, fill ports, appurtenances) for leaks, corrosion.	☐Yes ☐No ☐N/A	
8.	Visually inspect tank foundation berms for signs of erosion, and irregularities such as tilting, settling, out-of-roundness, and growth of vegitation.	☐Yes ☐No ☐N/A	
9.	Visually inspect tank concrete ring wall foundations for cracks or signs of settlement.	☐Yes ☐No ☐N/A	
10.	Inspect and clean the protective screens at pressure and vacuum ports and tank exterior.	☐Yes ☐No ☐N/A	
11.	Inspect the manual liquid level gauge for proper operation. If installed verify manual gauge to the ATG.	☐Yes ☐No ☐N/A	
12.	If applicable; inspect swing lines for fraying and operability.	☐Yes ☐No ☐N/A	
13.	Check all signs and markings for adequacy and readability.	☐Yes ☐No ☐N/A	
14.	If additional maintenance actions are required, compile list of discrepancies and submit for correction.	☐Yes ☐No ☐N/A

Item	Task	Status	Comments
1.	Pack the reinforcement plate weep holes with white grease to prevent water and/or dirt infiltration	☐Yes ☐No ☐N/A	
2.	Inspect floating roof seals for:		
	2.1. Inspect and clean perimeter tank seals.	☐Yes ☐No ☐N/A	
	2.2. Roof guide cables for wear, fraying, and corrosion.	☐Yes ☐No ☐N/A	
	2.3. Roof grounding cables for binding and secure attachment.	☐Yes ☐No ☐N/A	
	2.4. Inspect the ladder for damage and deflection (if equipped).	☐Yes ☐No ☐N/A	
	2.5. Check interior shell for abrasions that may indicate shell out of roundness or improper centering.	☐Yes ☐No ☐N/A	
	2.5.1. If abrasions are discovered, inspect seals for wear.	☐Yes ☐No ☐N/A	
	2.6. Check floating roof for corrosion, apply touch up with compatible coating.	☐Yes ☐No ☐N/A	
	2.7. Inspect pontoons for standing liquid and presence of vapors.	☐Ye* ☐No ☐N/A	
3.	Ensure the ladders, platforms, handrails, and stairs are secured to the structure and inspect for signs of corrosion.	☐Yes ☐No ☐N/A	

Item	Task	Status	Comments
4.	Visually check the exterior of the tank (i.e., welds, plates, bolts, appurtenances) for leaks, corrosion, or irregularities such as tilting, settling, or out-of-roundness.	☐Yes ☐No ☐N/A	
5.	Inspect, clean, and repair tank vacuum and pressure vents as follows:		
	5.1. Clean seating surfaces of pallets and valve seats carefully with an approved suitable cleaning solvent.	☐Yes ☐No ☐N/A	
	5.2. Inspect seating surfaces for damage or undue wear.	☐Yes ☐No ☐N/A	
6.	Inspect and clean the protective screens at pressure and vacuum ports and tank exterior.	☐Yes ☐No ☐N/A	
7.	Remove mechanical gauge float cover and ensure float is securely fastened to gauge tape. Check gauge tape for ease of movement.	☐Yes ☐No ☐N/A	
8.	Check all signs and markings for adequacy and readability.	☐Yes ☐No ☐N/A	
9.	If additional maintenance actions are required, compile list of discrepancies and submit for correction.	☐Yes ☐No ☐N/A	

Additional Comments:

APPENDIX G PETROLEUM FUEL PIPELINE PRESSURE TESTING GUIDELINES AND CRITERIA

G-1 INTRODUCTION.

G-1.1 Scope.

This appendix contains general criteria and standard guidelines for Petroleum, Oil, and Lubricant (POL) pipeline pressure testing. These procedures are based on current codes and criteria in addition to field experience and best management practices. This appendix clarifies the requirements for the procedures, frequency, duration, and test pressures for POL pipeline integrity testing. This appendix also provides a consistent definition of many of the terms used for pressure testing guidelines and procedures. In addition, an overall criteria list surrounding pipeline pressure testing is provided, along with a statement on the impact to the guidance given.

G-2 PIPELINE PRESSURE TESTING GUIDELINES.

G-2.1 Introduction.

G-2.1.1 Best Management Practice.

Testing criteria is to be adopted on a best management practice basis, with overall guidelines and minimum criteria established for a broad range of piping, with exceptions and special cases noted where required.

G-2.1.2 Regulations.

Host nation, Federal, state and local regulations with jurisdiction must be followed when more stringent than criteria outlined herein.

G-2.1.3 New Pipelines.

Testing of new pipelines, segments of existing pipelines after major repairs, or segment replacement must be in accordance with current piping codes and UFGS specifications.

G-2.1.4 Existing Pipelines.

Testing of existing pipelines must be in accordance with site specific criteria developed to provide integrity management consistent with the published guidelines and the procedures stated in Sections G-2.2 thru G-2.5.

G-2.2 GENERAL REQUIREMENTS.

G-2.2.1 Aboveground Pipe Testing.

Aboveground pipe testing should be based on the premise that it can be visually inspected on a regular basis, and is observable during the testing process. Overwater or near overwater piping is a special case and should receive a higher level of integrity testing due to the consequence of failure (and in some cases higher risk of failure due to increased corrosion).

G-2.2.2 Underground Pipe Testing.

Underground pipe testing should be based on the premise that it cannot be visually inspected during the test. The testing program needs to address greater safety factors, frequency of testing, and procedures to minimize the impact of temperature change of fuel during testing to assure integrity of testing.

G-2.2.3 Overall Testing Methodology Criteria.

The following items apply to all integrity pressure testing.

a. A job-specific written procedure (pressure test plan) must be used when performing a pressure test. Detailed procedures must be developed to address safety, procedural, and equipment issues for each pipeline segment.

b. Periodic testing must determine both long term safety of operation, as well as determining if the pipeline is currently leaking.

c. Preferred testing is via increasing pressure to a level consistent with reasonably predictable peak pressures, plus a comfort factor that reflects time between testing, future risk of failure, and consequence of failure.

d. Integrity testing using a fuel inoculant (e.g. tracer additive) can be considered in certain cases. In order to qualify as an integrity test, the procedure should utilize a pressure consistent with integrity management principles, instead of the minimum pressure required to conduct the test.

e. Integrity testing using a third-party certified, National Work Group on Leak Detection Evaluations (NWGLDE) listed, short duration proprietary procedure is acceptable in principle. Selected method must be certified for system parameters such as pipe size and liquid volume. To qualify as an integrity test the procedure must utilize a pressure consistent with integrity management principles, instead of the minimum pressure required to conduct the test. Alternatively, a lower pressure third-party certified leak test can be conducted after a strength test meeting the requirements of Section G-2.2.11 has been conducted.

G-2.2.4 Test Fluid.

Test fluid should be the system fuel such as DF-2, JP-5, JP-8, or F-76 when testing is within normal ANSI Class 150 ranges, and stress does not exceed 50% of Specified Minimum Yield Stress (SMYS) of the pipe. Table G-2.1 provides examples of maximum test pressures for a selection of frequently used carbon and stainless steel pipe based on

SMYS calculations (pipe only, not flanges, components). Testing with fuel with a pressure that induces a yield greater than 50% of SMYS is possible but factors such as pipe location (off-base or on-base) and proximity to occupied structures must be carefully considered. The method of calculating the pipe pressure properties for off base pipelines may require a slight variation and therefore should use the appropriate design code.

\1

Table G-1 /1/ Pipe Properties

Pipe Size (D) x (t)	Material	SMYS / allowable stress (S) psi (kPa)	Max Design Pressure psi (kPa) (note 1)	Pressure @ SMYS psi (kPa) (note 1)	Pressure @ 50% of SMYS psi (kPa)
8.625 dia. x .322	ASTM A 53/A 53M, Type S Grade B	35,000/20,000 (241,316.5/137,895.	1,539 (10611.0)	2,614 (18022.9)	1,307 (9011.4)
10.75 dia. x .365	ASTM A 53/A 53M, Type S Grade B	35,000/20,000 (241,316.5/137,895.	1,396 (9625.1)	2,376 (16381.0)	1,188 (8191.0)
12.75 dia. x .375	ASTM A 53/A 53M, Type S Grade B	35,000/20,000 (241,316.5/137,895.1)	1,205 (8308.1)	2,058 (14189.4)	1,029 (7094.7)
14.00 dia. x .250	ASTM A 358/A 358M, Grade 304L	25,000/16,700 (172,368.9/115,142.1)	605 (4171.3)	892 (6150.0)	446 (3075.1)
16.00 dia. x .250	ASTM A 358/A 358M, Grade 304L	25,000/16,700 (172,368.9/115,142.	528 (3640.4)	781 (5384.8)	390 (2689.0)
20.00 dia. x .250	ASTM A 358/A 358M, Grade 304L	25,000/16,700 (172,368.9/115,142.	422 (2909.6)	625 (4309.2)	312 (2151.2)

Note 1: P= 2SEt/D, E=1 for seamless and ERW pipe (ASME B31.3 Barlow equation). Consult ASME B31.3 and/or API 570 for other pipe materials, quality factors and wall thickness

G-2.2.5 Exceptions to Test Fluid.

Testing with water should be limited as much as possible to high pressure testing (greater than 450 psig (3102.6 kPa), testing over water, testing at high pressures outside of military property, and where mandated by regulatory jurisdiction (when waiver cannot be obtained). Testing with JP-8 which has a minimum flash point of 100 °F (37.8 °C) may require special permission when regulations permit testing with the fuel only when the associated flash point is above 120 °F (48.9 °C). Testing of motor gasoline lines must use potable water due to its low flash point and associated safety concerns.

G-2.2.6 Thermal Relief and Surge Considerations.

All testing programs need to consider system pressures that may be developed by thermal relief valve settings and possible dynamic transient surge (water hammer) conditions. Testing at a pressure less than these potential conditions will not provide adequate assurances of system integrity.

Pressure relief valve settings should be confirmed prior to pressurization to ensure correct test pressure and relief valve operation.

G-2.2.7 Dynamic Surge.

Evaluate the maximum surge pressure for systems known to have dynamic surge potential. The test pressure must be such that the qualified maximum operating pressure is high enough to support predictable surge pressure. (Under ASME B31.3 max surge = 133% of qualified maximum allowable operating pressure, under ASME B31.4 max surge = 110% of qualified maximum operating pressure).

G-2.2.8 System Components.

Testing programs need to consider all components within the test segments, such as strainers, sight glasses, meters, pressure gauges, pressure transmitters, check valves, instrumentation fittings and filter separators. Testing at 150% of the maximum operating pressure may overpressure system components and must be accordingly considered. Removal of lower pressure components from test segments by valve closure or blinding should be considered rather than reducing test pressure. In accordance with API RP 1110, these components should be identified with information from the component manufacturer such as maximum operating pressure, serial numbers, and other pertinent information. These components and manufacturer’s information should be listed in the pressure test plan.

Special consideration must be given to systems having non-standard fittings such as mitered elbows, orange peel reducers, stab-in connections, and similar. Note that under ASME B31.3, some of these fittings are acceptable when operation pressure results in stress less than 20% of SMYS.

G-2.2.9 Pressure Test Plan.

For all pressure class systems, a specific plan must be developed for pressure testing. For pressure class systems greater than ANSI Class 150, prepare a very detailed site specific engineering evaluation and code documentation to assure adequate and safe pressure testing. Some systems can contain more than one class of flange, so the pressure test plan must be based on the lowest class of flange present. For OCONUS locations, confirm pressure class of non-ASME components. Some OCONUS locations may incorporate a lower pressure class of flanges/components.

Any test section that includes an elevation difference of over 100 feet (30.5 meters) requires a pressure versus elevation plot and associated calculations to ensure that the lower points in the piping are not over pressurized and the highest points are subjected to the proper test pressure. These calculations and plot must be included in the pressure test plan.

G-2.2.10 Conventional Leak Test.

A conventional leak test as used in this report is a temperature compensated and volume/pressure change reconciled pressure test at not less than 150% of pump deadhead pressure by a qualified individual/organization with API 1110 developed procedures.

G-2.2.11 Strength Test.

A strength test as used in this report is a pressure test at not less than the greater of 150% of pump deadhead pressure or thermal pressure relief valve resultant pressure, including cascade, conducted with a calibrated pressure gauge, for a duration of not less than four (4) hours. The strength test does not attempt to reconcile pressure change with fuel temperature change as required by the conventional leak test. As a result, low volume leaks may go unrecognized when conducting this test.

G-2.2.12 US Coast Guard Criteria for Marine Pipelines.

Testing of lines under USCG criteria needs to carefully consider required test pressure, and jurisdiction of testing (i.e., how much of system). Testing to 150% of “tanker rail” pressure may not be high enough. USCG rules require consideration of either pump deadhead pressure, safety shutoff, or over pressure thermal relief settings as the basis for the 150% test. Commonly this may result in a test pressure requirement of 225 psig (1550 kPa). Another factor with USCG jurisdiction systems is possible deadhead pressure when pumping to tankers, which may exceed tanker offload pressures, and thus may require a test pressure higher than 225 psig (1550 kPa). The governing worst case scenario may be the dynamic surge possible when outloading with terminal pumps and a pier side emergency stop valve is rapidly closed.

G-2.2.13 Off-Base Systems.

Receipt pipelines from or connected to commercial off-base systems must be tested at a pressure that recognizes deviations or maximum system capability within flange ratings, which are normally much higher than pressures from normal receipt operations. Many off-base pipelines are constructed to ANSI Class 300 standards and connect to ANSI Class 150 systems at the point of pipeline ownership change. Discussions with off-base pipeline operators is important to determine operating characteristics, including pump deadhead pressure, safety shutdown considerations, and protection of lower pressure class piping. Federal regulations (49 CFR 195) mandate that a means of “over pressure prevention” is required if a higher pressure class pipeline is connected to a lower pressure class pipeline.

An overpressure condition can be caused by rapidly closing a Base valve, or startup of a receipt operation against a closed Base valve.

G-2.2.14 Minimum Test Pressure.

The test pressure for all pipelines subject to pump discharge pressure must not be less than 100 psig (689.4 kPa). The test pressure for pump suction lines may be between 50 psig (344.7 kPa) to 100 psig (689.4 kPa).

G-2.2.15 Maximum Test Pressures.

G-2.2.15.1 General Requirements.

Ensure that the flanges are stamped with B16.5, otherwise the flange may not conform to B16.5. Additionally, prior to testing, verify that all the nuts and bolts are properly engaged with sufficient threads past the nut.

G-2.2.15.2 ASME B16.5 Flange Ratings.

Test must not exceed test pressures permitted by ASME B16.5 (Flange Ratings) as follows:

- Carbon Steel, ANSI Class 150: 450 psig (3102.6 kPa)
- Stainless Steel, ANSI Class 150, with 304 or 304/304L flanges: 425 psig (2930.3 kPa)
- Stainless Steel, ANSI Class 150, with 304L flanges: 350 psig (2413.2 kPa)
- Carbon Steel, ANSI Class 300: 1050 psig (7239.5 kPa)
- No ANSI Class Flange: As noted by code authority

G-2.2.16 Service Station Piping.

Service station piping is considered a special case and is discussed in Section G-2.5, with separate criteria for integrity testing.

G-2.2.17 Non-metallic Piping.

Systems containing non-metallic piping such as fiberglass or coaxial flexible systems must be evaluated for pressure rating, or practical pressure limits based on historical failures of these types of piping systems.

\1\ G-2.2.18 Small Bore Piping.

Small bore piping, less than 4 inches (100 mm) in diameter, typically leading to and from small fuel tanks should be run aboveground. Inspection of these lines is required per Service Station Piping as discussed in Section G-2.5. Do not remove paint as part of the visual inspection. If the piping is in a containment area, such as a tank dike, the piping is not required to be pressure tested. In addition, if the piping cannot be pressure tested due to no means (tank valve) of isolation, a visual inspection for exterior pipe corrosion will satisfy integrity requirements. **/1/**

G-2.3 DEPARTMENT OF DEFENSE (DoD) PETROLEUM FUEL PIPELINES.

G-2.3.1 General.

Consistent with API 570, underground systems should undergo periodic pressure tests above normal operating pressures, whereas fully inspectable aboveground piping should undergo periodic pressure testing at normal operating pressure. Note that the Service Control Points can authorize deviations and alternate equivalent testing methodologies from these criteria. Section G-5 provides a summary of pipeline pressure testing guidelines.

G-2.3.2 On-Base Aboveground Piping Annual Test.

The test pressure for the annual test must not be less than pump deadhead pressure, the pressure resulting from thermal relief valve settings, or 100 psig (689.4 kPa) (whichever is greater) for a duration of two hours minimum. The duration of the test may extend longer to allow time to inspect the entire aboveground piping section being tested. When piping is not subject to pump discharge pressures a minimum test pressure of 100 psig (689.4 kPa) is required for the annual test. The pressure for the annual test may be reduced to 50 psig (344.7 kPa) for systems not subject to pump discharge pressure that contain threaded components. All components undergoing the annual test must be visually inspected for leaking during the test. Addition or withdrawal of fuel during the annual test is permitted due to loss of pressure from valve seat bypass or to prevent overpressure (thermal gain). On-Base aboveground piping does not require a five year test, as long as annual testing is conducted.

G-2.3.3 On-Base Single-Wall Underground Piping Annual Test.

G-2.3.3.1 Pressure Testing Options.

The options to complete the test include:

a. Annual Option 1: The test pressure for the annual test must not be less than pump deadhead pressure, or the pressure resulting from thermal relief valve settings (whichever is greater) for duration of two hours minimum. Perform accurate pressure and ambient temperature monitoring. All instrumentation should be of sufficient quality to Ensure accurate test data collection. The pressure change, if any, must be within a small range and/or reconciled with fuel temperature change. To minimize the effect of changing temperature, the fuel should be allowed to reach equilibrium, and testing is to occur at time of day with little solar influence or rapid temperature change. The acceptable pressure deviation or pressure change criteria are to be established by the Service Control Point. The allowable pressure change is to be based on installation’s location, size of system, and historical testing results.

b. Annual Option 2: Perform annual test at not less than pump deadhead pressure or the pressure resulting from thermal relief valve settings (whichever is greater), with third-party certified NWGLDE listed leak test. By doing annual third-party certified test at NOT LESS THAN the pump deadhead pressure or the pressure resulting from thermal relief valve settings (whichever is greater), the requirement for a five-year test is waived.

G-2.3.4 On Base Double-Wall Underground Carrier Piping Annual Test.

Test the carrier pipe using piping test methods, as applicable, as described in Section G-2.3.3 **\1\/1/**. After testing, confirm that there is no product at all low point locations in the secondary containment system. If the “double wall” system cannot be tested for both pressure integrity and presence of fuel leaks or water intrusion the system must be treated as a single-walled pipe and the requirements listed in section G-2.3.6 for the five-year test must be conducted in addition to the tests required in this section.

G-2.3.5 \1\ On /1/ Base Double-Walled Underground Containment Piping Test.

Interstitial Breach of Integrity testing must take place at three to five year intervals, depending on regulatory requirements and local practice.

The containment pipe of a double-wall pipe system must have the ability to be check for leakage thru low point check points. In addition, the annular space between the containment pipe and the carrier pipe must have the ability to be air-tested for the presence of hydrocarbon vapor with a calibrated atmospheric meter. Most secondary containment piping is equipped with test ports at each end and may be equipped with low point drains.

In the event that the pipeline is located in a jurisdiction that requires double wall systems, and the secondary system fails, then the system will be considered out of compliance. The system should then either be repaired or taken out of service.

G-2.3.5.1 Interstitial Breach of Integrity Testing Three-to-Five-Year Test.

Conduct a containment interstitial space breach of integrity test per manufacturer’s instructions. This test pressure is normally 5-10 psig (34.4-68.9 kPa) and held for two hours. The test could be a vacuum test if leaks are suspected as a safe alternative. All test equipment should be calibrated and suitable for the low pressure. A failure of the containment pipe test and a successful carrier pipe test would indicate defective end seals (depending on the type of containment piping: i.e.: FRP, SS, CS, etc.) or a breach in the wall of the containment pipe. The acceptable pressure deviation or pressure change criterion is 0%.

G-2.3.6 On Base Single-Wall Underground Piping Five-Year Test.

G-2.3.6.1 Test Pressure.

The test pressure for the five-year pressure test must be 150% of pump deadhead pressure minimum (including elevation difference from base of tank to pump plus full tank fuel level). Preferably, perform a pump deadhead test to confirm peak pressure, and adjust for fuel level in tank. Reasonable consideration should be taken to assure that selected test pressure is not less than 110% of pressures resulting from thermal pressure relief valve settings, which may be much higher than pump deadhead pressure (such as Type III Hydrant Systems).

G-2.3.6.2 Pressure Testing Options.

The options to complete the test include:

a. Five-year Option 1: Perform a strength test and conventional leak test at not less than 150% of pump deadhead or at 110% of the pressure resulting from thermal relief valve settings (whichever is greater). The testing must be executed by a qualified individual/organization experienced with using procedures meeting API 1110 procedures and performing pressure/temperature compensation calculations. Test duration must be a minimum of four hours for the strength test and four hours for the conventional leak test. The conventional leak test must immediately follow the strength test. A thorough visual inspection during the strength test should identify leaking flanges, instrument fittings, relief lines, valve stems, valve seats, etc. These deficiencies should be corrected prior to the conventional leak test by removing the components, installing flange skillets, plugging, or other methods of isolation or repair.

b. Five-year Option 2A: Perform a four hour strength test at not less than 150% of pump deadhead pressure or 110% of the pressure resulting from thermal relief valve settings (whichever is greater), and monitor calibrated gauges for potential leak causing pressure decay. Immediately follow the strength test by a third-party certified NWGLDE listed leak test at a pressure consistent with the certification of the system, and optimum for testing (generally 120 psig (827.4 kPa) to 150 psig (1034.1 kPa)).

c. Five-year Option 2B: Pressurized to the test pressure, and hold the pressure for two hours prior to a third-party certified test. Next, perform a third-party certified NWGLDE listed leak test at a pressure not less than 150 % of pump deadhead pressure or 110% of the pressure resulting from thermal relief valve settings (whichever is greater).

If the pipeline has been tested ANNUALLY by a third-party certified test at a pressure NOT LESS THAN pump deadhead pressure or the pressure resulting from thermal relief valve settings (whichever is greater), the requirement for a five-year test is waived.

G-2.3.7 Third Party Certified “Leak Detection” Systems.

Monthly testing with permanently installed proprietary vendor third-party certified “leak detection” systems that have received listing by the NWGLDE organization can be substituted for on base underground single-walled piping five year test as noted in Sections G-2.3.6.2(e) and G-2.3.3.1(b). Test must be conducted at NOT LESS THAN the pump deadhead pressure or the pressure resulting from thermal relief valve settings (whichever is greater). These systems are required to receive annual re-certification by the equipment vendor.

G-2.3.8 Off-Base Transfer or Supply Pipeline Annual Test.

An engineering assessment must be made to determine appropriate annual test pressure. In most cases, provide annual pump deadhead pressure test as noted for on-base pipeline systems in Section G-2.3.3, so long as flange ratings are not exceeded. Note that this will result in portion of the piping on longer pipelines being subject to test pressures considerably higher than normal operating pressures and thus is most appropriate when the system is constructed as an ANSI Class 150 system with a maximum allowable operating pressure of 275 psig (1896.1 kPa), and maximum test pressure of 450 psig (3102.6 kPa). For systems of higher ANSI pressure class construction and operating characteristics, a testing program must be developed and consider actual operating pressures along the pipeline, type of development along pipeline, age of system, history of cathodic protection, results from in-line intelligent pigging program and test liquid (fuel or water).

G-2.3.9 Off-Base Transfer or Supply Pipeline Five Year Test.

An engineering assessment must be made to determine appropriate five-year test pressure, or equivalent means of integrity management. Perform five-year test regime as follows:

a. Provide five-year strength and conventional leak test at a pressure higher than operating conditions ***only*** when required by state or Federal regulations or Service Control Point. Particular attention needs to be given to actual test pressures based on pipeline pumping operations, elevation changes along the pipeline, surge potential and type of development and population density along the pipeline. Test media (water or fuel) must be determined in accordance with regulatory and criteria documents. Testing with fuel is the preferred method.

b. Test methods as noted in Section G-2.3.6 for on-base pipeline systems can be considered, and must be coordinated with the Federal, state, and local regulations, and the Service Control Point.

c. For piggable off base pipelines, the use of in-line intelligent pigging on periodic basis (10 years maximum) to monitor corrosion and mechanical damage can significantly improve integrity management and eliminate the need for a 5-year pressure test regime, except when required by state or local regulatory body. Note that a written integrity management plan using in-line intelligent pigging has resulted in some regulatory bodies waiving the need for a 150% pump deadhead pressure test.

d. Note that under 49 CFR 195.452, if a pipeline is located in a "High Consequence Area," use of intelligent pigging on a five year increment is mandatory, (when the pipeline is considered regulated) and recommended otherwise, as a powerful threat assessment approach. The five year smart pigging interval will satisfy the need to perform a five-year pressure test, and has the added advantage of not resulting in testing of a pipeline with fuel at pressures far above normal operating pressure.

G-2.4 MARINE PIPELINES.

This section applies to areas under direct United States Coast Guard (USCG) jurisdiction, and Outside Continental United States (OCONUS) Installations with over-the-water fuel transfers.

G-2.4.1 33 CFR 154 and 33 CFR 156.

Marine facilities (or installation components that fall under marine conditions) must be tested in accordance with USCG regulations 33 CFR 154 and 33 CFR 156.

G-2.4.2 Piping Over Water.

Piping over water and not having a secondary containment system should consider testing with water when testing is above the maximum normal operating pressure. Pressure testing at maximum normal operating pressure may be with fuel. Where testing with fuel the use of spill containment booms around the test area is encouraged.

G-2.4.3 Tanker Offload Pressure.

The test pressure for the annual pressure test must be not be less than 150% of maximum delivery tanker pressure at the tanker rail before loading arm or hose, taking into consideration the pressure relief valve setting or high pressure cut off switch setting. It is recommended that the test pressure be not less than 225 psig (1551.3 kPa) based on most tankers' shutdown pressure setting of 150 psig (1034.1 kPa).

G-2.4.4 Barge Offload Pressure.

The test pressure for the annual pressure test must not be less than 150% of maximum delivery barge pressure at the barge rail before loading arm or hose, taking into consideration the pressure relief valve setting or high pressure cut off switch setting. It is recommended that the test pressure be not less than 175 psig (1206.6 kPa) based on most barges' shutdown pressure setting of 115 psig (792.9 kPa).

G-2.4.5 Issue Pressure.

When issuing to tankers and barges is possible, issue test pressure must be evaluated. The issue test pressure must consider the deadhead pressure of installation pumps, the static elevation difference, and the dynamic surge caused by pier emergency stop valves. It is possible for the issue test pressure to exceed the tanker/barge offload test pressure. When such conditions exist, use the issue test pressure for all piping, loading arm and hoses up to the point of connection to the receiving tanker/barge.

G-2.4.6 Aboveground Marine Piping Annual Test.

The test pressure for the annual pressure test must be derived from paragraphs G-2.4.3, G-2.4.4 and G-2.4.5 for duration of two hours minimum. All components must be visually inspected for leaking. Addition or withdrawal of fuel during testing is permitted due to loss of pressure from valve seat bypass or to prevent overpressure (thermal gain). Addition or withdrawal of fuel during testing is only permitted if entire system is aboveground. If any portion of the piping is underground and cannot be visually inspected, underground pipeline testing procedures must apply.

G-2.4.7 Underground Marine Piping Annual Test.

The options to complete the test include:

a. Annual Option 1: Perform a strength test and conventional leak test at a pressure derived from paragraphs G-2.4.3, G-2.4.4, or G-2.4.5 as appropriate. The testing must be executed by a qualified individual/organization experienced using procedures meeting API 1110 procedures and performing pressure/temperature compensation calculations. Test duration must be a minimum of four hours for the strength test and four hours for the conventional leak test. The leak test must immediately follow the strength test. A thorough visual inspection during the strength test should identify leaking flanges, instrument fittings, relief lines, valve stems, valve seats, etc. These deficiencies should be corrected prior to the conventional leak test by removing the components, installing flange skillets, plugging, or other methods of isolation or repair.

b. Annual Option 2: Conduct a two hour pressure soak at a pressure derived in paragraphs G-2.4.3, G-2.4.4, or G-2.4.5 as appropriate, and monitor calibrated gauges for potential leak causing pressure decay, followed by third-party certified NWGLDE listed leak test, at the same pressure, with the permission of the USCG Captain of the Port (COTP). Note: During a pressure soak, the tester blocks in the pressure and does not allow for volume change. During the test, pressure is relieved to prevent over-pressurizing if required.

G-2.5 SERVICE STATION PIPELINES.

G-2.5.1 General Requirements.

Due to the multiple types of piping system materials, single or double-wall pipe, piping components (line leak detectors, leak detection systems), fiberglass and coaxial piping, small bore piping (2 inch and less) and low operating pressures (less than 50 psig (344.7 kPa)), the annual and 5-year testing requirements as described in Section G-2.3 do not translate well for this type of system. Wherever possible, the requirements of state or host nation rules must be utilized to satisfy pipe integrity investigation to maintain consistency on regulated tank and connected piping installations. When specific state or host nation rules are lacking, the piping integrity must be considered. The use of a third-party certified NWGLDE listed leak test (see NWGLDE website, many vendors and systems are approved) may be appropriate. Even when tanks are aboveground, if underground piping is used to service dispensers, the use of a NWGLDE vendor and procedure is still appropriate.

G-2.5.2 Service Station Aboveground Piping Annual Test.

The test pressure for the annual pressure test must be not less than pump deadhead pressure for duration of two hours minimum. All components must be visually inspected for leaking. Addition or withdrawal of fuel during testing is permitted due to loss of pressure from valve seat bypass or to prevent overpressure (thermal gain). Note that in very small systems receiving fuel from delivery vehicle pump, observation of the receipt line under pressure is sufficient when there is no means (tank valve) to otherwise test the receipt line. When a small system consists of a suction withdrawal from the tank, with closely positioned dispenser with pump, and the suction line cannot be tested when there is no means (tank valve) of isolation, a visual inspection for exterior pipe corrosion will satisfy integrity requirements.

G-2.5.3 Service Station Underground Piping Annual Test.

The test pressure for the annual pressure test must be not less than pump deadhead pressure for duration of two hours minimum unless being tested in combination with an attached UST. The test procedure must be as required and approved by the host nation, state or local regulatory jurisdiction.

G-2.5.4 Service Station Combined Aboveground and Underground Annual Test.

When testing aboveground and underground piping together due to configuration of system, use of a third-party certified and NWGLDE procedure is encouraged, or utilizes a pump deadhead pressure test only when the underground piping is in secondary containment. The test must include a check of secondary containment for fuel after the pressure test.

G-3 CRITICAL TERM DEFINITION.

G-3.1 Introduction.

This section provides guidance on the definition of terms normally used in developing pressure testing documentation. Several of the guidance/criteria documents use poorly defined terms. Table G-3.1 summarizes what can be determined or inferred from the available information. Unfortunately, mixing the definition of the terms, or applying them too loosely may result in inappropriate conclusion

\1

Table G-2 /1/ Definition of Terms

Item	Term	Abbreviation For	Definition and Commentary
A	MOP, MAOP	"Colloquial version" Maximum Operating Pressure, or Maximum Allowable Operating Pressure	Must be the worst case sustained internal pressure under the worst combination of internal and external pressure at a given point on a pipeline, and must consider deadhead of pumping, static head, and resultant pressure from thermal relief conditions (and cascade). Some exceptions apply depending on frequency and duration. Pressure must be supported by a qualifying hydrostatic test at 125% (B31.4) or 150% (B31.3).Does not include transient pressure, such as a surge event, which can exceed (to a limit) MOP under many codes.
B	MAWP	Maximum Allowable Working Pressure API 570 §3.1.49	"The maximum internal pressure permitted in the piping system for continued operation at the most severe condition of coincident internal or external pressure and temperature (minimum or maximum) expected during service. It is the same as the design pressure, as defined in ASME B31.3 and other code sections, and is subject to the same rules relating to allowances for variations of pressure or temperature or both."
C	NOP	"Colloquial version" Normal Operating Pressure	Generally considered the pressure of dynamic operations, such as the pressure gauge on a pump discharge, or the pressure at any point on a pipeline taking into consideration elevation and pressure gradient.
D		From ASME B31.4 § 400.2	"*internal design pressure:* internal pressure used in calculations or analysis for pressure design of a piping component (see para. 4-1.2.2): Comment: Internal design pressure must be not less than maximum steady state operating pressure.
E	MOP	Maximum Operating Pressure defined under 40 CFR 195 § 195.2	*"Maximum operating pressure (MOP)* means the maximum pressure at which a pipeline or segment of a pipeline may be normally operated under this part." (Similar to ASME B31.4 definition for NOP)

Item	Term	Abbreviation For	Definition and Commentary
F	NOP	NOP from ASME B31.4 § 400.2	"*maximum steady state operating pressure:* Maximum pressure (sum of static head pressure, pressure required to overcome friction losses, and any back pressure) at any point in a piping system when the system is operating under steady state conditions.
G	MAWP	Maximum Allowable Working Pressure 33 CFR 154.500	"(b) The maximum allowable working pressure (MAWP) for each hose assembly must be more than the sum of the pressure of the relief valve setting (or the maximum pump pressure when no relief valve is installed) plus the static head pressure of the transfer system, at the
H		design pressure API 570 § 3.1.18	"The pressure at the most severe condition of coincident internal or external pressure and temperature (minimum or maximum) expected during service."
I		overwater piping API 570 § 3.1.60	"Piping located where leakage (liquid or solids) would result in discharge into streams, rivers, bays, etc., resulting in a potential environmental incident." *(Note, does not require pipe to be physically over the water)*

G-4 CRITERIA SURROUNDING PIPELINE PRESSURE TESTING.

G-4.1 INTRODUCTION.

This section provides the current criteria for pipeline pressure testing and the discussion of its applicability to the Department of Defense POL pipelines and methods of testing and determination for integrity assessment. Tables G-4.1 and G-4.2 lists the criteria and provides a discussion of its applicability to the guidelines stated in Section G-2.

\1\

Table G-2 /1/ Military Requirements

Item		Issue - Parameter	Testing Requirement
i	1	Testing Requirement – UFGS 33 52 43	UFGS Specification Section 33 52 43 "Aviation Fuel Distribution Systems," May 2011. This specification is to be used for new piping or major renovated piping systems. Extract of pressure testing requirements follows: 3.2.2.4 Hydrostatic Test Hydrostatically test product piping with the system operating fuel. Test at the corresponding pressures identified in Table 2 for the corresponding product piping material type. Maintain the pressure within the piping for 4 hours with no leakage or reduction in gauge pressure. If leaks are discovered, repair the leaks accordingly and retest. Table 2. Hydrostatic Test Pressures Product Piping Material Type / Min Test Pressure / Max Test Pressure Carbon Steel / 2930 kPa 425 psig / 3103 kPa 450 psig Stainless Steel (1) / 2758 kPa 400 psig / 2930 kPa 425 psig Stainless Steel (2) / 2241 kPa 325 psig / 2413 kPa 350 psig Aluminum / 1724 kPa 250 psig / 1896 kPa 275 psig Notes: 1. Grade F304 Flanges Used 2. Grade F304L Flanges Used
	2	Waivers and Deviations to Criteria	The Air Force, Army, and Navy Criteria specialists (Service HQ) are able to grant waivers or deviations.
	3	Comment and Recommendation	Pressures stated in the UFGS were derived from ASME B16.5. Water can be used and easily disposed of if the piping is new and no part of it has ever had fuel in it, and it can be thoroughly drained from the pipeline. ASTM B31.3 permits testing with fuels having a flash point of 120 °F (48.9 °C). Testing with fuel is acceptable in special cases (i.e., when draining of water is not obtainable). Obtain waiver for testing with JP-8 (100° minimum flash point) when needed.

Notes:

1. Pump deadhead pressure is the maximum pressure at no flow with fuel level at or near high condition in source tank. For the purposes of the pressure determination, do not use normal operating pressure. Dead head pressure is normally 10% to 25% above normal operating pressure. Determine deadhead pressure by starting pump and slowly closing discharge valve and reading the maximum discharge pressure. Do not operate at no flow for more than a minute.
2. Most thermal pressure relief valves associated with pump discharge piping in the pumphouse in particular must be set above pump deadhead otherwise they would discharge every time the pump deadheads. Normally they should be set a minimum of 10% above system deadhead pressure. If system testing is only to pump deadhead, it is not as high as the relief valve settings. For annual testing this is generally considered acceptable. For periodic integrity testing (i.e. five-year test), the test pressure should exceed the thermal relief valve pressure, in order to provide a valid strength test. This is the case with a five-year test at 150% of pump

deadhead. As thermal relief most likely is 10%-20% above pump deadhead, a test at 150% above deadhead will be above peak pressure of thermal relief valves.

3. ANSI Class 150 systems may be tested to the limit of flanges, per ASME B16.5 as follows:

Pipe Class and Material	Maximum Operating Pressure	Maximum Test Pressure
Class 150 Carbon Steel	285 psig 1965.0 kPa	450 psig 2102.6 kPa
Class 150 Stainless Steel (with 304 or 304/304L flanges)	275 psig 1896.1 kPa	425 psig 2930.3 kPa
Class 150 Stainless Steel (with 304L flanges)	230 psig 1585.8 kPa	350 psig 2413.2 kPa

\1

Table G-3 /1/ Commercial and Industrial Guidelines

ITEM		ISSUE - PARAMETER	TESTING REQUIREMENT
A	1	Testing protocol & Requirement – API 570	API 570 Piping Inspection Code, Third Edition (11-2009)
	2	Test Pressure Criteria and duration- aboveground piping.	The majority of API 570 addresses aboveground piping. API 570 5.8 states "Pressure tests are not normally conducted as a part of routine inspection", but when performed, must be completed in accordance with ASME B31.3 requirements.
	3	Test Pressure Criteria, modified systems	8.2.7 covers pressure testing after making system repairs or modifications that include welding of the pipe, in accordance with ¶5.8. When pressure testing is not practical, certain NDE steps may be substituted for the pressure test so long as other installation requirements are met.
	4	Pressure Testing Alternatives	5.8.5 Addresses special cases: "Appropriate NDE must be specified and conducted when a pressure test is not performed after a major repair or alteration. Substituting NDE procedures for a pressure test after an alteration is allowed only after the engineer and inspector have approved the substitution. For cases where UT is substituted for radiographic inspection, the owner/user must specify industry-qualified UT shear wave examiners or the application of ASME B31 *Code Case* 179/181, as applicable, for closure welds that have not been pressure tested and for welding repairs identified by the engineer or inspector.

<table>
<tr><th>ITEM</th><th></th><th>ISSUE - PARAMETER</th><th>TESTING REQUIREMENT</th></tr>
<tr><td></td><td>5</td><td>Test Pressure Criteria and duration- underground piping (Section 9 specifically deals with underground piping)</td><td>9.3.7 Indicates that a pressure test may be used as an integrity management tool in lieu of other methods. The pressure test is a leak test at not less than 110% of the maximum operating pressure, at an interval shown in Table 9-1 for a cathodically protected system and at ½ the interval for an underground system that is not cathodically protected.
The test must be 8 hours in duration, with the first 4 hours to stress the system, and the last 4 hours being the actual data collection period.
If the pressure drops more than 5% over the course of the test, an investigation must be conducted, including internal and external evaluation of corrosion.</td></tr>
<tr><td></td><td>6</td><td>Comment:</td><td>Table 5 below is primarily the intervals indicated for smart pigging or direct excavation, when deemed important for determining integrity of system, but is also used for the intervals for pressure testing as noted above.</td></tr>
<tr><td></td><td>7</td><td>Table 5 from API 570</td><td>Table 5—Frequency of Inspection for Buried Piping Without Effective Cathodic Protection
<table>
<tr><th>Soil Resistivity (ohm-cm)</th><th>Inspection Interval (years)</th></tr>
<tr><td><2,000</td><td>five</td></tr>
<tr><td>2000 to 10,000</td><td>10</td></tr>
<tr><td>>10,000</td><td>15</td></tr>
</table></td></tr>
<tr><td></td><td>8</td><td></td><td>API 570 9.3.7 also recognizes the use of other testing procedures including temperature corrected volumetric, pressure, and addition of a tracer inoculant.</td></tr>
<tr><td></td><td>9</td><td>Comment and Interpretation</td><td>API 570 supports the premise that a leak, pressure or hydrostatic test provides satisfactory investigation into the integrity of underground piping. Note that API 2611 (draft) calls for 150% testing of MOP, not 110% of MOP as in API 570. This may be a result of pressure testing of terminal piping that may not be done to a standard as high as in a refinery.
Lacking other evidence (such as leak history) or direct knowledge on pipe surface condition from excavation or smart pigging, use of pressure/leak testing is the appropriate degree of investigation necessary. Use of smart pigging, LRUT, or excavation is not a mandatory API requirement. As API 570 does not clearly identify what is “maximum operating pressure”. This document defines it to be the greater of maximum system deadhead, or thermal relief valve setting.</td></tr>
<tr><td></td><td>10</td><td>Test Fluid</td><td>5.8.1 states that test fluid must be water, unless damage may occur due to freezing, or unless contamination presents unacceptable environmental risk. If tested with fuel, the flash point must be 120 °F (48.9 °C) or greater.</td></tr>
</table>

ITEM		ISSUE - PARAMETER	TESTING REQUIREMENT
	11	Comment and Interpretation	JP-8 (100 °F (37.8 °C) flash point) is regularly used in the military for pipeline pressure and hydrotesting due to the greater risk of product contamination from testing with water. JP-5 (140 °F (60 °C) flash point) meets the criteria. The military has accepted the risk of using JP-8 for testing. Need to confirm state requirements as well to see if a waiver is needed. Some states, such as CA, mandate water but have permitted using JP-5 on some tests.
B	1	Testing protocol & Requirement – API RP 2611	API RP 2611 1st Edition, June 01, 2011, *Terminal Piping Inspection – Inspection of In-Service Terminal Piping Systems*. *Note, the document is in response to the industry needing a companion to API 570 that better reflects operating conditions, risk and consequence of terminal operations, as compared to refinery operations covered under API 570.*
	2	Test Pressure Criteria and duration- aboveground piping.	API RP 2611 5.5.5 states that leak testing is not a stand-alone integrity test, but should be performed in conjunction with other integrity tests such as corrosion under insulation and wall thickness analysis.
	3	Test Pressure Criteria and duration - underground piping.	§ 7 addresses the overall assessment of underground piping and stresses use of both knowledge of the age and history of a system, cathodic testing and coating testing procedures, but does not specifically call for pressure testing. However pressure testing is noted as a viable means of integrity assessment, with little stated on its pressure levels or duration. The frequency of testing is dependent on a variety of factors noted, and ranges from 5 to 25 years.
	4	Frequency of Inspection	Table 6-1 in API RP 2611 is primarily the intervals indicated for smart pigging or direct excavation, when deemed important for determining integrity of system, but is also used for the intervals for pressure testing as noted.
	5	Comment and interpretation	• API RP 2611 supports the premise that a leak, pressure or hydrostatic test provides satisfactory investigation into the integrity of underground piping. • Lacking other evidence (such as leak history) or direct knowledge on pipe surface condition from excavation, use of pressure/leak testing is an appropriate degree of investigation necessary. Use of smart pigging, Long-Range Ultrasonic testing (LRUT), or excavation is not a mandatory API requirement. As API RP 2611 does not clearly identify what is "maximum operating pressure". This document defines it to be the greater of maximum system deadhead, or thermal relief valve setting.
C	1	Testing protocol & Requirement -ASME B31.3	ASME B31.3 Process Piping, 2012

ITEM		ISSUE - PARAMETER	TESTING REQUIREMENT
	2	Test Pressure Criteria and Duration	345.4.2 states that pipe must be tested to not less than 1.5 times the maximum design pressure. "Design Pressure is the most severe combination of internal and external pressure expected during service" (ASME B31.3 Par 301.2.1). Note that the test pressure is limited to the maximum rating for flange testing per ASTM B16.5, Flanges. Per 345.2.2, the minimum test duration for examination of connections and joints is 10 minutes. Most systems will take longer to physically inspect. 345.2.1 (b) permits the use of a pneumatic test at up to 25 psig (172.4 kPa) to find major leaks, prior to the liquid hydrotesting.
	3	Comment and Interpretation	ASME B31.3 was written for new piping installation into a new, or modified system. It was not written for periodic integrity testing. Several codes, such as API 570, reference ASME B31.3 as the governing document for pressure testing in certain circumstances.
	4	Test Fluid	345.4.1 states that test fluid must be water, unless damage may occur due to freezing, or unless contamination presents unacceptable environmental risk. If tested with fuel, the flash point must be 120 °F (48.9 °C) or greater.
	5	Comment and Interpretation	JP-8 (100 °F (37.8 °C) flash point) is regularly used in the military for pipeline pressure and hydrotesting due to the greater risk of product contamination from testing with water. JP-5 (140 °F (60 °C) flash point) meets the criteria.
	6	Closure Weld Testing	345.2.3 Addresses testing of closure welds (tie-in welds). So long as the components/piping being installed into the system have been pre- tested, the final closure or tie-in weld need not be leak tested provided the weld is examined in-process in accordance with 344.7 and passes with 100% radiography or 100% ultrasonic examination in accordance with 344.6.
	7	Comment and Interpretation	This paragraph is important as it validates not hydrotesting an existing system, when a change or repair is made, so long as more rigorous examinations are made of the tie-in weld, and the new components are pretested.
	8	Testing of Vessels and piping together	345.4.3 addresses the testing of vessels and pipe together so long as the following is met: If the test pressure of the pipe is equal or less than test pressure of the vessel, testing to the piping test pressure is permitted. If the test pressure of the pipe exceeds the test pressure of the vessel, combined testing is permitted at the vessel test pressure, provided the owner approves of the reduced test pressure, and the pressure is not less than 77% of the piping test pressure calculated in accordance with 345.4.2(b)
	9	Comment and Interpretation	Testing together simplifies many testing scenarios.

ITEM		ISSUE - PARAMETER	TESTING REQUIREMENT
D	1	Testing protocol & Requirement - ASME B31.4	ASME B31.4 Pipeline Transportation for Liquid Hydrocarbons – 2012 Although commonly applied to cross country pipelines, ASME B31.4 can also be applied to connected terminals, in lieu of ASME B31.3, although there is no particular advantage in doing so.
	2	Test Pressure Criteria and duration	437.4.1 states that piping systems operated at a hoop stress of more than 20% of Specified Minimum Yield Strength (SMYS) must be proof tested to not less than 1.25 times the internal design pressure at that point per 401.2.2. The test duration is not less than 4 hours. 401.2.2 "Internal Design Pressure" is not less than the steady state operating pressure at that location, or static pressure when higher. Per 437.4.1(2) if the line undergoing testing is not fully inspectable for leaks, the proof test must be followed by a leak test at not less than 1.10 times the internal design pressure, for not less than an additional 4 hours.
	3	Comment and Interpretation	This piping code was written for long transportation pipelines with potential large grade and hydraulic grade changes. Once placed in operation these lines have a greater predictable operating pressure range, thus the less conservative 1.25 test as compared to ASME B31.3 with a 1.5 times pressure test.
	4	Test Fluid	437.l.1(c) Test fluid must be water, except liquid petroleum that does not vaporize rapidly may be used provided: The pipeline is outside of a city and populated area, and is not underwater. All buildings within 300 ft (91.5 meters) of the pipeline are unoccupied during the test when the pressure produces a hoop stress exceeding 50% of SMYS.
	5	Comment and Interpretation	JP-8 (100 °F (37.8 °C) flash point) meets the criteria of permissible petroleum for testing.
	6	Tie-in Weld Testing	437.1.4 Addresses testing of closure welds (tie-in welds). So long as the components/piping being installed into the system have been pre-tested, the final closure or tie-in weld need not be leak tested provided the weld is examined in- process and passes with 100% radiography or 100% ultrasonic examination in accordance with 434.8.5(a)(4).
	7	Comment and Interpretation	This paragraph is important as it validates not hydrotesting an existing system, when a change or repair is made, so long as more rigorous examinations are made of the tie-in weld, and the new components are pretested.
E	1	Testing Protocol & Requirement - 49 CFR 195	Subpart E – Pressure Testing

ITEM		ISSUE - PARAMETER	TESTING REQUIREMENT
	2	Test Pressure Criteria and duration	§ 195.304 "…maintain for 4 hours at a pressure equal to 125%, or more, of the operating pressure and, in the case of a pipeline that is not visually inspected for leakage during the test for at least an additional 4 continuous hours at a pressure equal to 110% or more, of the ***maximum operating pressure***. (Nov. 4, 1998).
	3	Comment and Interpretation	"Maximum Operating Pressure is defined in § 195.2 "Definitions" as: *Maximum operating pressure (MOP)* means the maximum pressure at which a pipeline or segment of a pipeline may be normally operated under this part. B31.4 uses the term "maximum internal design pressure" as the basis for design, as well as the starting point for the 125% test pressure. B31.4 further states that the maximum internal design pressure must not be less than the steady state operating pressure at any point on a pipeline. Taking the above into consideration, the design engineer may use steady state operating pressure or deadhead pressure as the basis for the 125% pressure test. Presumably, if the steady state pressure is used, there must be operational controls that are failsafe in not permitting a pipeline to deadhead at a higher pressure than steady state pressure. For typical short military pipelines this report recommends using deadhead as the basis for any pressure testing due to any means of preventing a dead head (such as startup) is an unrealistic expectation.
	4	Test Fluid	§195.306 Requires water to be used for testing but permits the use of a flammable liquid if the pipeline is not offshore and is outside of cities and populated areas, the fluid does not rapidly vaporize, and if the test pressure results in a hoop stress greater than 50% of SMYS, all buildings must be unoccupied within 300 feet (91 meters) of the pipeline under test, and there is continuous communication along the entire test section.
	5	Comment and Interpretation	The use of water and fuel as a test medium is similar in nature to ASME B31.3, except an actual flash point of the fuel is not noted.
F	1	Testing protocol & Requirement - 33CFR Part 154 and Part 156	33 CFR Part 154 Facilities Transferring Oil or Hazardous Material in Bulk 33 CFR Part 156 Oil and Hazardous Material Transfer Operations (i.e., USCG regulations for ports)
	2	Test Pressure Criteria and duration- aboveground piping and equipment.	§156.170, Equipment Tests and Inspections, (c)(iii) requires that hose and loading arms not burst at 1½ times the Maximum Allowable Working Pressure (MAWP). The Operations Manual must indicate per §154.310(a)(16) "The maximum allowable working pressure (MAWP) of each loading arm, transfer pipe hose assembly required to be tested by §156.170 of this chapter, including the maximum relief valve setting (or maximum system pressure when relief valves are not provided) for each transfer system."

ITEM		ISSUE - PARAMETER	TESTING REQUIREMENT
	3	Test Pressure Criteria and duration-	§156.170 (f)(1) Requires the tests to have been accomplished within the last 12 months prior to a transfer ¶(h) permits alternative compliance testing when approved by the Captain of the Port (COTP). §154.105 "Definitions" defines "Marine Transfer Area" to be the part of the waterfront area between the vessel and the first valve inside a containment required by 40 CFR 112 or 49 CFR 195, or if no containment area, to the valve on the receiving tank.
	4	Comment and Interpretation	The requirements for testing of piping and systems under USCG jurisdiction is not clear, and requires a read of various sections as noted above. Traditionally the maximum over the water transfer pressure is limited to 150 psig (1034.1 kPa) by agreement or mandate of the COTP. This does vary. Traditionally the maximum over the water transfer pressure at government facilities is 100 psig (689.4 kPa). This has been attributed to tradition or in some cases, the contract maximum under the MSLC tanker contracts, but has not been verifiable. Traditionally the required test pressure in many ports has been 150 psig x 150% = 225 psig (1034.1 kPa x 150% = 1551.3 kPa). This however can be deficient when a variety of factors and system features could lead to a higher surge pressure that is within the capability of a properly tested ANSI Class 150 system. It is clear testing is required annually. It is not clear what the duration or test standard requirement is. Traditionally the test is for one hour, with procedures left up to the local region and owner. Consideration must be given to issue to ships and barges operations having higher deadhead conditions than a delivery tanker, thus hydrotesting must be accomplished to a higher pressure.
	5	Test Fluid	§156.170 (c)(iv) The test medium does not need to be water.
	6	Comment and Interpretation	This paragraph is discussing the testing of hoses, which is normally done above deck, within a contained area, thus testing with fuel is possible if deemed appropriate. This paragraph should not be considered a justification to test over the water piping with fuel. That decision is best made based on the risk of failure and consequential spill to the water.

This Page Intentionally Left Blank

G-5 PIPELINE PRESSURE TESTING GUIDELINES AND CRITERIA SUMMARY TABLE

Pipeline Pressure Testing Guidelines and Criteria SUMMARY TABLE				
Pipe Location/Test	**Basis of Test Pressure**	**Duration**	**Type of Testing**	**Comments**
USCG/Marine Service, Over water/aboveground - Annual Pressure Test	150% of highest delivery pressure (relief valve or pressure switch)	2 hr	100% observation for leaks (1)	225 psig (1551.3 kPa) test suggested in most cases (based on tankers with 150 psig (1034.1 kPa) relief/shutdown) or 175 psig (1206.6 kPa) (based on barges with 115 psig (792.9 kPa) relief/shutdown). Also, the issue pressure must be calculated as this pressure may exceed offload pressures.
USCG/Marine Service, Underground - Annual Pressure Test	150% of highest delivery pressure (relief valve or pressure switch)	2 hr (min)	Accurate pressure monitor, reconcile temperature-pressure change (2) 5-year Option 1 testing meets criteria. 5-year Option 2B acceptable with permission of the USCG COTP	225 psig (1551.3 kPa) test suggested in most cases (based on tankers with 150 psig (1034.1 kPa) relief/ shutdown) or 175 psig (1206.6 kPa) (based on barges with 115 psig (792.9 kPa) relief/shutdown). Also, the issue pressure must be calculated as this pressure may exceed offload pressures.
Base Piping, Aboveground - Annual	Greater of pump deadhead, or PSV setting/cascade	2 hr	100% observation for leaks (1)	Suggest not less than 50-100 psig (344.7-689.4 kPa) for pump suction lines not subject to discharge pressure.
Base Piping, Underground - Annual (Annual Option 1)	Greater of pump deadhead, or PSV setting/cascade	2 hr (min)	Accurate pressure monitoring, pressure change, if any, must be within small range and or reconciled with fuel temperature change (2)	To minimize effect of changing temperature, fuel should be allowed to reach equilibrium, and testing occur at time of day with little solar influence or rapid temperature change.
Base Piping, Underground - Annual (Annual Option 2)	Test at greater of deadhead or PSV setting/cascade using third- party certified procedure	Per certs	Third-party certified and NWGLDE listed and DLA-E approved procedure (6)	If conducted ***every year*** this procedure, with lower pressure testing also satisfies the 5-year 150% testing requirement.
Base Piping, Double Wall Underground – Annual (with air testable and low point checking secondary containment capability) (8)	Test carrier pipe using USCG or non-USCG annual piping (as applicable)	Per above	Per above procedure selected	After testing, confirm no product at all low points in secondary containment system. **Every 5 years provide secondary containment integrity test per manufacturer's instructions, normally a 2 hour 10-15 psig (68.9-103.4 kPa) test.**
Base Piping, Underground - (5-year Option 1)	Greater of 150% of deadhead or 110% of PSV setting/cascade	8 hr	Precision temperature and pressure measurement and reconciliation of temperature-pressure change (3)	Minimum 4 hour analysis period over test cycle.
Base Piping, Underground - (5-year Option 2A)	Strength test at greater of 150% of deadhead or 110% of PSV setting/ cascade, followed by third-party certified leak test	4 hr strength	Strength (4) Leak – Third-party certified and NWGLDE listed (5)	Acceptable even when 150% strength test pressure is above leak test pressure.

Pipeline Pressure Testing Guidelines and Criteria SUMMARY TABLE				
Pipe Location/Test	**Basis of Test Pressure**	**Duration**	**Type of Testing**	**Comments**
Base Piping, Underground - (5-year Option 2B)	Test at greater of 150% of deadhead or 110% of PSV setting/cascade using third-party certified leak test	2 hr soak	2 hr "soak" at test pressure to bring to equilibrium, followed by third-party certified and NWGLDE listed (5) (10)	Generally appropriate only when the 150% test pressure is within the third-party certified test protocol limits.
Base Piping, Underground - with in- situ leak detection system	Per third-party certification, scheduled for testing on monthly frequency minimum	Per certs	Third-party certified and NWGLDE listed (5)	Annual recertification required.
Off Base, Underground - Annual	Greater of pump deadhead, or PSV setting/cascade	2 hr	Accurate pressure monitor, reconcile temperature-pressure change (2)	Actual test pressure needs to be validated and to consider resultant pressure along entire pipeline, test media (flash point restrictions), and density/type of population.
Off Base, Underground - Annual (Alternative)	Leak test	Per certs	Leak – Third-party certified and NWGLDE listed (5)	An engineering review required to determine appropriate test pressure.
Off Base, Underground - 5-year	Higher then operating-deadhead conditions, but must be assessed. In some cases use of high pressure shutdown is acceptable. (may be up to 150%)	Per reg	Precision temperature and pressure measurement and reconciliation of temperature-pressure change (3)	Only required when mandated by regulations. (Not a normal requirement) Consider intelligent pigging as integrity management tool (7).
Off Base, Underground - 5-year -Alternative	Equal to or higher then operating-deadhead conditions, but must be assessed. In some cases use of high pressure shutdown is acceptable.	Per reg	Strength (4) Leak – Third-party certified and NWGLDE listed (5)	Only required when mandated by regulations or Service Control Point. (Not a normal requirement) Consider intelligent pigging as integrity management tool (7).
Service Station, Above and Underground - Annual or Periodic	Pump deadhead, or per state Regulations	Per reg	If all aboveground, visual. If above and underground, precision test as required/approved by local/state regulatory jurisdiction (9)	Meet UST regulations.

Pipeline Pressure Testing Guidelines and Criteria

SUMMARY TABLE

Pipe Location/Test	Basis of Test Pressure	Duration	Type of Testing	Comments

1. Visual test, maintain pressure over duration and inspect 100% of system for weeps and leaks.
2. Acceptable pressure deviation or pressure change criteria established by Service Control Point, taking into consideration installation location, size of system, and historical testing results.
3. A conventional pressure test as used in this Table is a temperature compensated and volume/pressure change leak test at not less than 150% of pump deadhead by a qualified individual/organization with API 1110 developed procedures. Use of the California State Fire Marshall's procedure is acceptable, but not necessarily conclusive in all cases.
4. A strength test as used in this Table is a pressure test at not less than 150% of pump deadhead, conducted with a calibrated pressure gauge, for a duration of not less than 4 hours, but does not attempt to reconcile pressure change with fuel temperature change as is required by conventional pressure test. Low volume leaks may go unrecognized. To qualify for integrity testing, a strength test must be followed by a conventional leak test.
5. Integrity testing using a third-party certified and National Work Group on Leak Detection Evaluations (NWGLDE) listed short duration proprietary procedures are acceptable in principle. Selected method must be certified for system parameters such as pipe size and liquid volume. To qualify as an integrity test the procedure ***must utilize a pressure consistent with integrity management principles***, not just a minimum pressure required to conduct the test. Alternatively, a lower pressure third-party certified leak test can be conducted after a strength test.
6. Note that a third-party certified NWGLDE listed procedure, if conducted every year ***at not less than greater of pump deadhead or PSV settings*** is an acceptable means of meeting the 5-year testing requirement (without requiring a 5-year 150% test).
7. For piggable off base pipelines, the use of in-line intelligent pigging on periodic basis (10 years maximum) to monitor corrosion and mechanical damage can significantly improve integrity management and eliminate the need for any 5-year testing regime, except when required by local or state regulatory body.
8. If secondary containment is not air pressure testable and capable of being checked at all low points for liquid, the primary carrier piping system must be tested using any one of the appropriate underground pipe testing methods.
9. Due to the myriad of piping system materials, single or double wall pipe, and piping components (line leak detectors, leak detection systems), fiberglass and coaxial piping, the annual and 5-year testing requirements do not translate well for this type of system, with small bore piping (2" and less) and low operating pressures (less than 50 psig (344.7 kPa)), thus use of a certified testing procedure and company is more appropriate company is more appropriate. Even when tanks are aboveground, if underground piping used to service dispensers, the use of UST testing organizations still is appropriate.
10. It is the intent that the 2-hour "soak" permit the piping segment under test be visually inspected for leaks and weeps, and to stretch to test pressure, thus improving testing accuracy. This 2-hour soak can be coincident with a similar purpose procedure of the testing organization,

This Page Intentionally Left Blank

APPENDIX H TANK CLEANING GUIDANCE

This Appendix provides minimum standards for safe entry, inspection, and cleaning guidance of liquid petroleum fuel tanks for DoD personnel.

H-1 RESPONSIBILITY.

Military services will comply with their respective safety equipment certification (e.g., respirator) and task training certification (e.g., confined space entry, tank cleaning, medical) programs.

H-2 COORDINATION.

Coordinate with facility agencies (i.e., tank operators, Installation Environmental Office, Installation Safety Office, local fire department, and military service-specific headquarters), when applicable, to facilitate lowering product levels in tanks, alternate tank use during cleaning, hot work permits, disposal of waste, and coordination of safety related procedures (i.e., egress, rescue, and fire).

H-3 TANK CLEANING PREPARATION.

H-3.1 Unless superseded by Military service-specific directives, the following guidance details the minimum requirements for tank preparation prior to cleaning.

H-3.2 Secure (e.g., fence, rope, tape) and clear the work areas of all non-essential personnel. Isolate tank openings by establishing a perimeter of 50 feet (15.2 meters) and post warning signs (e.g., Do Not Enter Tank Entry in Progress) to identify the work being accomplished. If the area is subject to high foot or vehicle traffic; tank cleaning team members should be posted to ensure that unauthorized personnel and vehicles do not enter the established perimeter.

H-3.3 Consider projected weather conditions to ensure a safe working environment throughout the cleaning process. The potential of electrical storms, severe weather, or changes in the direction may produce hazardous conditions that could impact the cleaning process.

H-3.4 Remove all ignition sources from surrounding areas.

H-3.5 Move all flame-producing devices to a designated safe area prior to entry.

H-3.6 Inspect equipment and tools for serviceability and hazards. Complete necessary adjustments and calibrations prior to entry. Cleaning equipment and tools should be placed upwind of tank openings and at the highest elevation possible to minimize hazards. Cleaning equipment and tools should never be placed in an area lower than the surrounding terrain.

H-3.7 Inspect grounding and bonding cable connection points, wires, and clips for serviceability. In addition, check wire and connections for electrical continuity with an ohmmeter. Replace damaged and broken items prior to beginning tank cleaning operations.

H-3.8 Turn off cathodic protection systems prior to disconnecting pipelines from tanks.

H-3.9 Verify PPE is in proper working order.

H-3.10 Test the area around the tank for explosive vapors using a combustible gas detector before equipment is started which may be a source of ignition.

H-3.11 Ensure an emergency shower/eyewash is available and serviceable in the immediate area. Portable emergency eyewash units are acceptable if approved by the facility's authorizing agency.

H-4 TANK PREPARATION.

H-4.1 Isolate the tank to ensure product does not reenter the tank once draining procedures have commenced.

H-4.2 Tank isolation must be conducted in accordance with military service or contract lockout/tagout procedures. Ensure tank isolation is established to prevent product from reentering the tank.

H-4.3 Lockout/tagout all electrical equipment and necessary valves. Isolate all piping by removing valves and installing blind flanges, spectacle blinds, or skillet flanges to prevent fuel or vapors from returning to the tank.

H-4.4 Blind and spectacle flanges must be able to withstand any pressure the system is able to produce. If spectacle blinds are used, insert the blind between the tank valve and the flange nearest the tank.

H-4.5 No valve or piping is to be disconnected from any tank component until it is verified that the line has been emptied of product and a bonding cable has been installed between pipe flanges.

H-4.6 Tanks with floating roofs or pans pose additional inspection requirements. All applicable military service directives or industry standards will apply when inspecting floating roofs or pans (e.g. harness, confined space, atmospheric testing).

H-4.7 Qualified personnel must visually inspect the floating roof or pan to ensure the roof or pan is safe for inspection. Personnel will ensure the roof or pan support legs and sleeves (to the extent possible) have the ability to support the roof or pan.

H-4.8 Inspect the roof or pan pontoons, buoyant foam panels, and seals for fuel and water and drain as necessary to facilitate vapor and gas freeing of the tank space.

H-4.9 Qualified personnel must inspect anti-rotation pipes and guide cables to ensure proper function as the roof or pan descends.

H-4.10 Floating roof or pan leg pins must be placed in the high roof or pan position to allow for maximum space under the roof or pan to facilitate tank cleaning operations.

H-4.11 If the tank has a double bottom, a qualified individual must inspect the bottom annular space to ensure the space is free of petroleum product or vapors.

H-4.12 Ensure tank operators or responsible organizations have removed petroleum from the tank to the lowest point possible using installed pumps. Extra precautions such as gravity flow and reduced pumping rates must be considered to ensure the floating roof or pan settles and rests on legs as the fuel level drops below the high leg position of the roof or pan. If applicable use secondary pumps (i.e., air-operated, double-diaphragm pumps, explosion proof electric) to remove remaining petroleum fuel once the petroleum fuel level drops below the installed pumps suction point. Secondary pumps must be located upwind of the tank and at least 50 feet (15.2 meters) from the farthest manhole or vent.

H-5 VAPOR FREEING.

H-5.1 The tank must be ventilated using air-operated eductors, such as COPIS or Lamb air movers. The roof and shell manhole covers must be removed to allow air to circulate freely by natural ventilation to aid in removing vapors. Do not use air moving systems that would blow air into the tank.

H-5.2 Consider local conditions when placing ventilating equipment. Ventilation discharge locations must be selected to maximize diffusion of vapors into the surrounding air. This will minimize the possibility of a flammable mixture forming at ground level. Position ventilating equipment to push vapor through roof manholes.

H-5.3 Petroleum vapors are heavier than air and usually accumulate in the bottom of tanks. Blowing air into a tank can dilute the vapors, but it may take longer for the vapor-air ratio to drop to an acceptable level. Eductor-type air movers with a flexible oil-proof hoses inserted near the bottom of the tank will remove vapors in a shorter period of time.

H-5.4 The primary goals of tank preparation prior to entry are to eliminate sources of ignition and reduce the amount of fuel sludge. A near vapor free work area will drastically reduce the possibility of hazardous conditions (toxicity, asphyxiation, fire, explosion) inside the tank and in the surrounding area.

H-5.5 Eductors must be operated for at least one hour or until LEL and oxygen are within safe limits. Test the tank for LEL and oxygen immediately prior to entry and throughout the operation to ensure a safe atmosphere.

H-5.6 The interior of the tank is considered an explosive atmosphere until all sludge and loosely adhering rust and scale has been removed, regardless of the type of petroleum stored.

H-5.7 All personnel entering the tank prior to and during cleaning must wear authorized PPE including supplied air respirator (SAR) with emergency egress SCBA until the tank is declared hazard-free in accordance with military service-specific directives.

H-5.8 Before entry to the tank without PPE, the LEL reading must be zero, oxygen levels between 19.5% and 23.5%, and lead, benzene, and other toxic material levels within safe limits. Refer to API Standard 2015 for additional information.

H-5.9 The tank being cleaned will be considered leaded unless positive proof exists that the tank has never contained leaded fuel, or the tank has been coated.

H-5.10 Vapors will be present as long as petroleum product, scale, or sludge are inside the tank. Operate air eductors continuously until all these materials have been removed.

H-6 ATMOSPHERIC TESTING.

H-6.1 Tank entrants will follow military services directives detailing specific safety, medical, certification, and testing procedures for confined spaces and safe atmospheric standards.

H-6.2 Personnel will not enter a tank without proper respiratory protection unless the LEL is zero, the oxygen level is within tolerances (19.5% to 23.5%), and the facility’s authorized agency has determined that airborne benzene and other toxic vapors are within permissible exposure limits. Personnel may enter the tank when vapor levels are below 10% of LEL if they are equipped with approved SAR with emergency SCBA.

H-6.3 Provided personnel are wearing appropriate PPE based upon the current LEL, toxicity, and oxygen levels, eductors may be shutdown while workers are in the tank if the eductors impair the ability of personnel to communicate.

H-6.4 If vapor levels cannot be reduced below the 10% LEL, or in some cases below 20% LEL, the following situations may exist:

H-6.4.1 Insufficient time has passed to reduce vapor concentrations (which in turn can affect facility mission requirements and maintenance costs).

H-6.4.2 The amount of remaining fuel and solid sludge has not been reduced to an appropriate level.

H-7 TANK CLEANING.

H-7.1 All entrants must be equipped with approved PPE. In addition, the entry supervisor (or Military service equivalent) must be aware of equipment that is used inside the tank and ensure equipment (where applicable) is explosion proof, has ground fault interrupters and is bonded to the tank. If pressure washers are used, the washer nozzle must be electrically bonded to the tank.

H-7.2 Tanks must be cleaned from the outside first. Ventilation and vapor readings at the manhole must continue during cleaning from the outside. Entry is authorized once the flammable atmosphere tester registers 10% LEL or less. Since vapors will be present as long as fuel, scale, or sludge remains inside the tank, continue forced ventilation until all such material has been removed.

H-7.3 Maintain an uninterrupted air supply until all persons are out of the tank and have removed their face pieces. Personnel who are inside the tank while wearing PPE that detect an odor (such as petroleum products) must leave the tank immediately and not re-enter until the cause has been determined and equipment repaired or replaced.

H-7.4 Unless otherwise directed by military service-specific directives, continue testing for explosive vapors at fifteen-minute intervals while personnel are in the tank. Stirring sludge releases vapors and increases the vapor concentration. Remove puddles of fuel-water sludge to keep vapor readings below 20% LEL.

H-7.5 Personnel will continue to remove sludge from the tank by scraping the bottom of the tank and 3 feet (0.9 meters) up the sides of the tank until all loosely adhering rust and scale have been removed.

H-7.6 Wash down the remainder of the tank with high-pressure hoses. Include the metal supports, braces, the upper portion of horizontal tanks, and the decks (tops) of vertical tanks. Wash these areas until the water pumped out of the tank is clean.

H-7.7 Water discharged from the tank must be contained and disposed of as instructed by the authorized facility environmental agency.

H-7.8 Remaining non-recoverable sludge residue and deposits may be removed by several different methods, including, but not limited to:

H-7.8.1 Wash brush, squeegee, and sweep material (i.e., sludge, deposits) into portable containers.

H-7.8.2 Spray or wash down material with water hose streams and remove by pump or vacuum. If additional liquids are needed to reduce tank material (e.g., sludge, deposits) the use of diesel, solvent, or approved chemicals can be used in accordance with military service-specific directives.

H-7.9 Use of solvents and soap can create additional undesired reactions if used incorrectly, the tank cleaning team must only use approved substances in accordance with manufacturer's instructions.

Solvents and soaps reactions can range from polymerization (depletion of inhibitor or excessively high temperature), saponification (creation of hard soap forming a layer on the tank requiring acid cleaning or even removal by hydroblasting), or drying/hardening (formation of hard debris that is no longer soluble, requiring treatment with a solvent).

H-7.10 Once washing is completed, allow the floor to dry. When interior tank vapor readings are 0% of the LEL on unleaded tanks, personnel may enter the tank without protective equipment if the testing required by API Standard 2015 has been done, and the facility's authorized agent determines that airborne benzene and other toxic vapors are below the permissible exposure limits.

A clean dry tank that has been ventilated overnight will provide the best atmosphere for entry without protective gear.

H-7.11 Pipes used for center poles and braces, pontoons, and leaking bottoms are potential sources of explosive vapors even after the tank is cleaned. In as little as one to two hours a safe tank may reach the explosive range because of these sources. While unprotected personnel are in the tank, take hazardous atmosphere readings at least every fifteen minutes. Where pontoon-type floating roofs or pans are installed in aboveground tanks, check each pontoon with a hazardous atmosphere tester.

H-7.12 Petroleum products irritate and burn the skin and may cause serious discomfort and injury. Promptly remove clothing that becomes splashed with sludge or fuel to prevent contact with the skin. Before continuing work, wash the affected area with soap and water (if a small area), or shower and put on a fresh change of clothing. Clothing contaminated by petroleum products must be kept away from any source of ignition.

H-7.13 Unless a full-face respirator is worn, wear goggles during scraping and spreading loose absorbent material. If hands are frequently wet with fuel and it is not practical to wear protective gloves, the hands may be coated with commercial non-greasy cream that gives the desired protection. NOTE: If work site has contained leaded gasoline, approved protective gloves or other impermeable gloves must be worn throughout the operation.

H-7.14 Keep manholes and adjacent areas clear of equipment or material that would hamper rescue operations in an emergency situation.

H-8 MATERIAL TREATMENT AND DISPOSAL.

Residue (i.e., sludge, deposits) will be treated and disposed of in accordance with Military service-specific environmental directives or contract requirements.

H-9 RETURNING TANK TO SERVICE.

H-9.1 The tank cleaning team supervisors must inspect the tank after cleaning to evaluate the condition of the tank for any follow-on repairs.

H-9.2 Once the inspection is complete and any necessary work completed, the tank must be brought back into service by reinstalling all valves, piping, and manhole covers using new non-asbestos gasket material compatible with the product being stored. The gasket thickness must not be less than the thickness of the gasket that is being replaced.

H-9.3 Refer to UFC 3-460-03 Section 8-8, "Returning to Service after Formal Out of Service Inspection/Repair," for maximum fuel line velocities for initial fills of petroleum fuel tanks that will be returned to service.

H-9.4 Petroleum fuel tanks must be stenciled before they are returned to service after cleaning. Refer to UFC 3-460-03 Section 8-8.1, "Stenciling Requirements."

H-10 TANK CLEANING EQUIPMENT AND PROTECTIVE CLOTHING.

H-10.1 Tank cleaning equipment must meet the following requirements:

H-10.1.1 All electrical equipment and conductors used within 50 feet (15.2 meters) of petroleum pipes or storage tanks, or where a hazardous accumulation of flammable vapors may exist, will be NFPA 70 for Class 1, Division 1, Group D (or higher) (or Class 1, Zone 0, or Zone 1) locations. The maximum temperature rating will be "T2D" – 419 °F (215 °C), as defined in the NEC for use in hazardous (explosive) areas.

H-10.1.2 Hazardous atmosphere detectors must meet military service requirements.

H-10.1.3 Air movers will be of the eductor type capable of educting vapors from the tank, and will be either air-driven or explosion-proof electrically operated. Electrically operated air movers must meet the minimum requirements of NFPA 70 for Class 1, Division 1, Group D (or higher) (or Class 1, Zone 0, or Zone 1) locations.

H-10.2 Tank cleaning personnel must be equipped and trained to use protective clothing (i.e., impervious coveralls, gloves, footwear, head coverings, face shields) that is compliant with safety related military service directives.

H-10.2.1 The tank cleaning team will review the Safety Data Sheets of the petroleum product to select the type of respirator that is applicable with the type of tank and petroleum product used. Caution must be exercised to select a respirator that will not deteriorate or corrode when exposed to the petroleum product or solvents used in the tank cleaning process.

This UFC supersedes UFC 3-470-01, dated May 2012.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-470-01 *Utility Monitoring and Control System (UMCS) Front End and Integration,* formerly *"LonWorks® Utility Monitoring and Control System (UMCS)*

Superseding: UFC 3-470-01, dated May 2012

Description: UFC 3-470-01 is revised throughout to address changes in UFGS 25 10 10 and to add support for the BACnet® protocol, Modbus® protocol, DNP®, Niagara Framework® and OPC®. Changes include:

- Changes to the UFC title including removal of the word "LonWorks" and clarification that the UFC covers the UMCS front-end and integration
- Removal of "educational" text not needed to support "instructive" text
- Removal of some LonWorks-specific information
- Addition of information on BACnet, Modbus, DNP®, Niagara Framework and OPC
- Explanation of the difference between utility control systems and building control systems
- Removal or updating of out-of-date information

Reasons for Document: The changes to UFC 3-470-01 (and to UFGS 25 10 10) were required as a result of the requirements contained in the National Defense Authorization Act of FY2010 (NDAA 2010).

Impact: There are no direct cost impacts to the changes to this UFC. The changes will support the proper design and implementation of UMCS in accordance with UFGS 25 10 10 in support of meeting NDAA 2010 requirements and the procurement of open control systems.

Unification Issues: Due to differences in approach, structure, procurement processes, and technical capabilities some requirements differ between the services. These differences have been documented in this UFC and in UFGS 25 10 10 (using Tailoring Options) and do not pose a barrier to unification.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Designers, installers, and operation and maintenance (O&M) staff have struggled with the complexities and incompatibilities of multi-vendor direct digital control (DDC) systems almost since they were introduced in the 1980s. DDC systems are routinely designed and procured on a building-by-building or sub-system by sub-system basis, a process that in the past has often resulted in multiple proprietary systems that will not interoperate with each other. In the absence of specifications and criteria for Open systems, Government procurement rules that require competitive bidding make it extremely difficult if not impossible to procure new DDC systems that are interoperable with existing ones while also being compatible with a base-wide or campus-wide supervisory system.

The introduction of "LonTalk®" and "BACnet®" Open control protocols in the early 1990's allowed for the procurement of Open and interoperable DDC systems.

1-1.1 History.

In 2004, Unified Facilities Guide Specifications (UFGS) 23 09 23 specifying Open building control systems based on LonWorks technology and a UFGS 25 10 10 specifying a LonWorks-based utility monitoring and control system (UMCS) were released. These specifications covered the use of LonWorks® technology to specify and procure an Open building automation system. In 2010, HR2647, the National Defense Authorization Act of 2010 (NDAA 2010) was passed. Section 2841 of this legislation called for "adoption of an open protocol energy monitoring and utility control system specification" by the Department of Defense. The specification was further required to cover seven different types of systems:

- Utilities and energy usage, including electricity, gas, steam and water usage
- Indoor environments, including temperature and humidity levels
- Heating, ventilating, and cooling components
- Central plant equipment
- Renewable energy generation systems
- Lighting systems
- Power distribution networks

Some of these systems are traditionally considered part of the building automation system (BAS) while others are generally considered to be utility control systems. In order to meet these NDAA 2010 requirements, this UFC and UFGS 25 10 10 -

previously LonWorks only - was revised to incorporate support for BACnet®, Modbus®, DNP®, Niagara Framework® and OPC®.

1-1.2 Field Control System Types.

Generally speaking, there are two basic categories of field control system (FCS): building control systems (BCS) and utility control systems (UCS). BCS systems are generally considered "commercial grade" and are used for applications such as heating and air conditioning, metering, or lighting control. UCS systems are generally considered "industrial grade" and are used for applications where a higher level of reliability and performance (e.g. response time) can justify a higher cost, such as for industrial processes or power distribution. BACnet and “LonTalk” are primarily BCS protocols, Modbus and DNP are primarily UCS protocols and OPC is used for integration of UCS or BCS systems but is not generally considered a “field protocol”. While the Niagara Framework is focused at the UMCS front end, it also provides support for field devices and field protocols within BCSs and UCSs using a variety of protocols.

1-1.3 Monitoring and Control Software Protocol Support.

Note there is no front end monitoring and control (M&C) software that natively (without some 3rd party hardware device) supports both BACnet and DNP, or both LonWorks and DNP. Because UFGS 25 10 10 must address the integration of HVAC systems using BACnet or LonWorks, there is no option to select DNP as a protocol supported by the front end. As described later in this UFC, DNP systems will be supported through the use of gateways. Of the seven systems required by NDAA 2010, renewable energy generation systems and power distribution networks are expected to use UCS protocols. Central plant equipment and utility metering may use either UCS or BCS protocols, and the remaining systems are expected to use BCS protocols.

1-1.4 Open System Definition and Considerations.

Generally, an Open system is one where there is no future dependence on any one contractor or controls vendor:

- It’s One system - Multiple field systems with controls installed by multiple vendors are integrated into one system

- There is one common front-end that provides users with the capability to interface with all field systems (monitoring, supervisory control, etc.)

- There are a minimum number of vendor-proprietary (software) tools (ideally zero, in practice, a small number) which are required to operate, maintain and modify the system.

- There is no future need for the original (installing) contractor or any particular device manufacturer to perform work on the system

- There is no need for coordination between the installer of the field system and the installer or (or integrator to) the front-end. As long as each contractor follows the appropriate specification the systems will interoperate.

It's important to note, however, that Openness is not black or white. There is no such thing as a 100% open control system, but UFG 25 10 10 and this UFC, in concert with the building level UFC and specifications (UFC 3-410-02, UFGS 23 09 00, UFGS 23 09 23.01, and UFGS 23 09 23.02) are intended to procure the most open system practical. Further, an Open system can contain some proprietary components and can have fees, provided the components are a small part of the system and the fees are reasonable

1-1.4.1 Open Building Control Systems.

For building control systems, a flat (one protocol at all levels of the system) single multi-vendor system from the front-end down to the field device can be achieved using LonWorks or BACnet, and UFGS 25 10 10 includes requirements for "top-to-bottom" Openness using these protocols. This includes requirements in the UMCS specification that need complementary requirements in the building control system specification. For example:

- To integrate with a UMCS (front end) based on LonWorks, the building control system has to use only SNVTs and provide an LNS Database.

- To integrate with a UMCS (front end) based on BACnet, the building control system must use only standard BACnet Services and must support a number of BIBBs to allow for configuration of scheduling, alarming and trending functionality from the UMCS.

Niagara Framework does not provide a flat system since the Niagara Framework Supervisory Gateways[1] used in the field control systems act as gateways, but it can provide a single multi-vendor system. To integrate with a UMCS (front end) based on the Niagara Framework, a building control system should ideally be installed using the Niagara Framework components. All Niagara components must use an open license which allows multiple vendors to interoperate freely with Niagara components from other vendors.

1-1.4.2 Open Utility Control Systems.

For UCS, Openness from the UMCS all the way to the field controller is not as achievable, and may not be not desirable in some cases. Instead UCS systems are often integrated as distinct "complete systems" (with their own front-end) and use UMCS as a common supervisory front-end. UFGS 25 10 10 can accommodate using the UMCS as the primary front-end for UCS, but the general assumption is that it will serve as a supervisory system in most cases. This is due to many factors, including the increased reliability requirements of the UCS, difference in cybersecurity requirements

[1] This device is more commonly known as a "JACE", which is the name for a specific version of this device. The term "Niagara Framework Supervisory Gateway" is used to remain vendor-neutral.

for the UCS and the UMCS, and because the UCS are often operated by a different organization or group at the garrison than the BCS. In addition, integration of the field control system (with no front-end) to a UMCS is more difficult with utility control systems than with building control systems since the UCS protocols lack data exchange standards compared to LonWorks or BACnet.

1-2 PURPOSE AND SCOPE.

This document describes the design of an Open UMCS Front End and the integration of field control systems into the UMCS, both in accordance with UFGS 25 10 10. This includes hardware, software and, in some cases, networking for the UMCS Front End. With few exceptions, requirements for field control systems, including controllers, networking, and sequences of operation, are not included in this criteria or UFGS 25 10 10 and are addressed by the relevant field control system criteria and specifications.

The UMCS front end required by this criteria and specified in UFGS 25 10 10 will openly interoperate with systems and subsystems installed in accordance with the building control system specifications (UFGS 23 09 00 Instrumentation and Control for HVAC, UFGS 23 09 23.01 LonWorks® Direct Digital Control for HVAC and UFGS 23 09 23.02, BACnet Direct Digital Control for HVAC). UFGS 23 09 23.01 contains specific requirements, such as the use of LonWorks Network Services (LNS), which provide for open integration to a UMCS installed using the complementary options contained in UFGS 25 10 10. UFGS 23 09 23.02 contains similar specific requirements for a BACnet-based system. Both UFGS 23 09 23.01 and UFGS 23 09 23.02 contain options for use of the Niagara Framework.

1-3 APPLICABILITY.

This UFC and accompanying UFGS 25 10 10 'Utility Monitoring and Control System Front End and Integration' are for use on all Department of Defense projects. At the discretion of and with approval from the assigning government agency (such as the responsible Corps of Engineers District), the design of the UMCS may deviate from the standards defined in this UFC. When deviating from the guidance, systems based on an Open communications protocol are recommended and proprietary procurement or single-vendor systems are discouraged. Without this specific approval, use of both this UFC and the accompanying guidance in UFGS 25 10 10 is mandatory.

UFGS 25 10 10, and the Division 23 controls specifications referenced within, have been adopted in accordance with 10 USC 2867, and exceptions to the requirement for use of these specifications require a waiver from the Secretary of the relevant Service.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety.

Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 REFERENCES.

APPENDIX A contains a list of references used in this document.

1-6 GLOSSARY.

APPENDIX C contains acronyms, abbreviations, and terms.

This Page Intentionally Left Blank

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 USE OF UFGS 25 10 10.

The implementation of a UMCS Front End and the successful integration of field control systems requires highly specific and prescriptive specifications. UFGS 25 10 10 incorporates these requirements, and makes use of SpecsIntact Tailoring Options and designer options (bracketed text with notes) to allow for project-specific editing.

Unless specifically indicated in this UFC or with specific written permission from the authority having jurisdiction, the design of a UMCS front end and the specification of integration of field control systems into a UMCS front end must use UFGS 25 10 10 without edits beyond the use of the included tailoring options and designer options.

2-2 TAILORING OPTIONS AND DESIGNER OPTIONS IN UFGS 25 10 10.

The use of tailoring options and designer options in UFGS 25 10 10 must be in accordance with this UFC.

This Page Intentionally Left Blank

CHAPTER 3 UMCS ARCHITECTURE

3-1 GENERAL.

As illustrated in Figure 3-1, a basewide UMCS consists of a UMCS front end (specified by UFGS 25 10 10) connected to one or more field control systems. These field control systems (FCS) may be building control systems (BCS) – which are generally DDC systems for the control of HVAC, lighting and other building systems - or utility control systems – which vary in composition from “smart relays” to DDC controls to programmable logic controllers (PLC) for control of power distribution or other “industrial” systems. The network architecture consists of a base-wide IP network connected to one or more field control networks. In general, field control networks themselves may use a wide variety of media and protocols, but building control networks for systems based on LonWorks should be a combination of IP, TP/FT-10, and possibly TP/XF-1250. Building control networks for systems based on BACnet should be IP and/or MS/TP. In each case a field point of connection (FPOC) provides an interface between the UMCS IP network and the field control network (FCN).

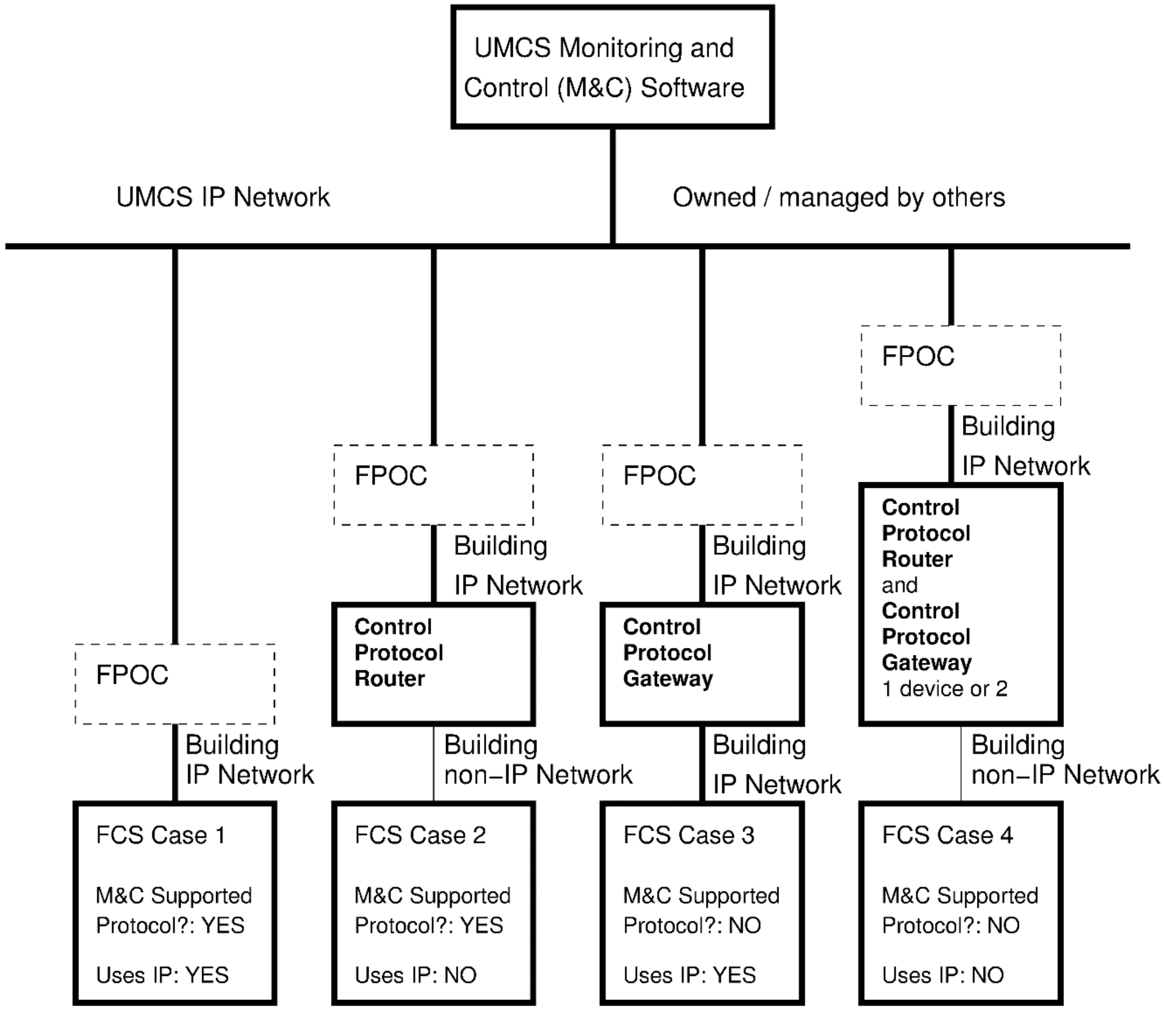
Generally, the UMCS will be a base-wide system, but it may initially consist of very few, or even only one, field control systems. The UMCS may later be expanded to include additional field control systems. A single UMCS is expected to connect to many field control systems from several or many different vendors, where the field control systems are procured separately and then integrated into the UMCS front end.

3-2 UMCS IP NETWORK.

As specified by UFGS 25 10 10 and as illustrated in Figure 3-1, the UMCS uses a base-wide IP network to support inter-building communication and to serve as the communications link between the field control system(s) and the UMCS computers.

Although this UMCS IP network could be contractor-installed, it will generally be Government Furnished, and this UFC and UFGS 25 10 10 assume the latter. Note that coordination with the installation IT group is critical to ensure that the IP network usage is approved and that cybersecurity for the UMCS has been addressed.

Figure 3-1 UMCS Architecture



Notes:
1) All FCS may have a non–IP network in addtion to any IP network
2) All buildings installed under UFC 3–410–02 / UFGS 23 09 23 are Case 1. Cases 2–4 should only be for legacy
3) M&C Protocols include those selected via tailoring options in UFGS 25 10 10 and others that may be supported by that vendor's M&C software.
4) Note that in Cases 2 – 4, the UMCS integrator may need to install Control Protocol Router and/or Gateway and also install/extend the building IP and/or non–IP networks.

3-3 KEY REQUIREMENTS FOR INTEGRATION.

A successful connection between the FCS and the UMCS front end requires two things:

- The UMCS and FCS must use the same protocol (e.g. BACnet, "LonTalk", other)
- The UMCS and FCS must use the same media. While this is often associated with the protocol (e.g. TP/FT-10 is a LonWorks media type), they are not the same. BACnet uses both IP and MS/TP, and a successful connection requires that both sides use one or the other. Similarly, many incompatible protocols use (can be carried over) IP, so although IP is a protocol, the relevant question isn't

"use of IP", but rather "what protocol is being carried over IP". IP is treated as simply another media type in UFGS 25 10 10 and this UFC.

3-4 FIELD CONTROL SYSTEM CONNECTION TO UMCS FRONT END.

Depending on the FCS, the connection between the FPOC and the FCS may be made via many different means. The primary means of connection are shown in Figure 3-1 and described in the following sub-paragraphs, but there are other, less common possibilities which are not described in this UFC. In addition, there may be additional complexities within the building, additional gateways and control protocol routers. These details are also not described here – the focus here is how the FCS presents itself to the UMCS.

In some cases, specific hardware may be required for the connection. This hardware may be provided as part of the FCS (case 1, sometimes case 2), otherwise it must be procured as part of integration of the FCS to the UMCS (cases 3 and 4, sometimes case 2). As part of UMCS design, the location and source of this hardware must be determined and shown on the drawings, as well as whether or not the hardware must be provided as part of integration.

3-4.1 Direct Connection (Figure 3-1 Case 1).

When the field control network uses IP (as a media type) and the field control system protocol is supported by the UMCS M&C software, no additional hardware is required and the two systems can be directly connected together.

Strictly speaking, a Niagara building could be considered to be as Case 3 or 4, as the Niagara Framework Supervisory Gateway converts between the building protocol and the UMCS protocol. However, since the Niagara Framework Supervisory Gateway is furnished as part of the building, this detail can be ignored from the perspective of the UMCS, and a Niagara FCS is integrated as in Case 1.

3-4.2 Control protocol router (Figure 3-1, Case 2).

When the field control system protocol is supported by the UMCS M&C software but the field control network does not use IP, a control protocol router (**not** an IP router) is required to convert the media from the field control network media to IP.

3-4.3 Control protocol gateway (Figure 3-1, Case 3).

When the field control system uses IP but its protocol is not supported by the UMCS M&C software, a gateway is required to convert the FCN protocol to one supported by the UMCS M&C Software.

3-4.4 Control protocol gateway (Figure 3-1, Case 4).

When the field control system does not use IP and its protocol is not supported by the UMCS M&C software, a gateway is required to convert the FCN protocol to one supported by the UMCS M&C Software.

- (Single Device) If a gateway is available that can connect to the field control network media, then a single device may convert both the protocol and the media.

- (Two Devices) If there is no gateway available that can connect to the field control network media, then both a gateway and a control protocol router must be used.

3-5 FIELD POINT OF CONNECTION (FPOC).

A key point in the overall system architecture is the Field Point Of Connection (FPOC), which is the connection point between the portion of the network that is physically dedicated to the control system and the portion of the network that is shared with other applications. The FPOC is important because it:

- Serves as a demarcation point between field-installed network and the UMCS IP network. In many cases, this is also the demarcation point between network owned/managed by the organization operating the facility (Army DPW or other equivalent organization) and the installation IT staff.

- Is a device that, in order to meet cybersecurity requirements, should be secured to limit traffic between the two network pieces.

The FPOC is typically a switch owned and managed by the installation IT staff. As such, it is largely transparent to the UMCS; it is part of the IP network provided by the installation IT staff. It is included here because of its important role in cybersecurity for the system.

3-6 FIELD CONTROL SYSTEM.

A Field Control System (FCS) is a networked system of controllers operating to control a building, a portion of a building, or a utility system. The terms Field Control System and Field Control Network refer to both Building Control Systems/Networks and Utility Control Systems/Networks. A FCS is generally installed as a single project and is intended to provide a complete stand-alone solution for the control of the underlying equipment, though it may lack a full-featured operator interface. From the perspective of integration to the UMCS front end, the underlying details of the FCS are not important; the integration of a FCS into the UMCS will be accomplished using one of the cases discussed above and shown in Figure 3-1.

3-6.1 Building Control Systems.

Building control systems installed in accordance with UFGS 23 09 00 (and UFGS 23 09 23.01 or UFGS 23 09 23.02) are described in those specifications and in UFC 3-410-02.

3-6.2 Other Field Control Systems.

Other field control systems, whether they are building control systems using other protocols or utility control systems, will generally not result in a flat network. In these cases it is generally expected that the connection between the UMCS and FCS will be through a gateway or through a supervisory controller/interface provided as part of the field control system. For Niagara Framework based UMCS, it is expected that these control systems will be integrated through the use of Niagara Framework Supervisory Gateways. Ideally, the gateways are installed as part of the FCS project, otherwise they must be installed during integration.

Note that for some systems, the connection between the FCS and UMCS may be via a FCS local front-end; for example, a FCS which uses a protocol not supported by the UMCS front end may have a FCS front end that has a software driver for BACnet, LonTalk, or OPC.

3-7 BASEWIDE UMCS IP NETWORK.

3-7.1 Cybersecurity.

Cybersecurity is an ever-changing area, and the guidance provided here may no longer be current or applicable. Further, the different Services have different approaches to cybersecurity for UMCS and it's vital to coordinate cybersecurity requirements with the respective Service or agency for each project. UFC 4-010-06, *Cybersecurity of Facility-Related Control Systems* provides guidance on incorporating cybersecurity into the design of UMCS. For the Army, UMCS design, including cybersecurity, should be coordinated with the UMCS Mandatory Center of Expertise (MCX) at Huntsville.

In general, the UMCS front end will not be considered a mission critical system to the installation. Individual controls within a building control system are designed to run stand-alone without intervention from a UMCS front end. Guidance on handling critical systems as part of a UMCS is in UFC 4-010-06, *Cybersecurity of Facility-Related Control Systems*.

3-7.1.1 [Army] Certificates of Networthiness.

Army regulations require that any application or system connected to the basewide network have a Certificate of Networthiness (CoN). Installations may reference a pre-existing Networthiness certificate developed by another installation as long as the application is the same (vendor and release) and the existing certificate is not of the "limited" type and therefore can be used Army-wide. UFGS 25 10 10 includes a requirement for the contractor to either provide a valid CoN or submit a completed CoN application for use by the installation in obtaining a CoN. Further information is available at the Networthiness website[2] at: https://army.deps.mil/netcom/sites/nw/CoNApproval/Lists/Networthiness%20Data/NWPublicView.aspx.

[2] This website requires CAC authentication.

The UMCS Mandatory Center of Expertise (MCX) at Huntsville can assist with addressing CoN and should be contacted for advice and support during UMCS design.

3-7.2 IT Group Coordination.

Coordination with the IT Group is critical to address cybersecurity as well as other aspects of UMCS operation. Some key points of coordination are described here.

3-7.2.1 Computer Selection, Administration and Maintenance.

It may be advantageous (or in some cases required) for the IT group to manage day-to-day operation of UMCS computer servers including backups, account management, operating system and security updates, and other administration tasks. At the very least, the IT group will likely have specific requirements for computers connected to the basewide network

Some UMCS software, the M&C Software in particular, will have specific requirements for the configuration of the computers it operates and may also have certain requirements or limitation on the upgrades and patches that can be applied to the operating system without also updating the software. In addition, there may be certain patches or updates that cause the web browser based client to fail when they are applied to client machines. Coordination with the IT group to ensure that computers vital to the operation of the UMCS aren't patched or updated without coordination between the organization operating the UMCS and the IT group is critical.

3-7.2.2 UMCS Network Bandwidth.

A properly designed UMCS Network will require minimal network bandwidth as compared to many IT applications and compared to the bandwidth typically available on a modern basewide IT backbone. The IT group, however, will likely require assurances of this. UFGS 25 10 10 requires that the contractor provide a network bandwidth estimate. The purpose of this estimate it to provide documentation of a "ballpark" for bandwidth use that can be provided to the IT group. The UFGS does not provide specific guidance on how to calculate this estimate and instead require the contractor to use their understanding of the M&C Software they are installing and the M&C Software licensing and performance requirements to estimate the overall bandwidth usage.

CHAPTER 4 COMPUTER SOFTWARE

4-1 MONITORING AND CONTROL SOFTWARE.

The Monitoring and Control (M&C) software uses a client-server model with web-browser based clients. The UFGS specifies M&C Software functionality. Some vendors cannot implement all of this functionality in their standard server-based software, and the UFGS permits some functionality – specifically point calculations and demand limiting – to be performed by controller hardware. The software operating on the controller hardware to perform these functions is still considered M&C Software and is included in all M&C Software requirements such as licensing. In addition, any software required to set up this controller hardware must be provided.

4-1.1 M&C Software Protocol Requirements

UFGS 25 10 10 makes use of SpecsIntact Tailoring Options which allow for customization by the designer of requirements for protocol support by the Monitoring and Control (M&C) Software. Including a tailoring option – BACnet, LonWorks, Modbus, OPC, or Niagara Framework - will require support for that protocol or technology by the UMCS M&C Software. Careful consideration must be used in determining which tailoring options to include:

- Selection of a specific protocol will require that the M&C software support that protocol and that integration of buildings supporting that protocol be via that protocol (there could be cases where there are multiple options for integration).
- Any protocol (whether selected or not) may always be integrated, either by direct support of that protocol by the M&C software (e.g. integration of a Modbus FCS where the front end was required to support LonWorks but also provided a Modbus driver) or through the use of a hardware gateway.

Careful selection of appropriate tailoring options is critical to avoid creating conflicting, confusing or impossible to meet requirements. Additional guidance on the selection of tailoring options can be found in 0 *This Page Intentionally Left Blank*

UMCS DESIGN AND IMPLEMENTATION.

4-1.2 M&C Software Licensing Requirements

M&C software packages have upper capacity limits on the number of points, alarms, etc. that the package can accommodate. In addition, many packages have licenses that further limit the capacity to less than the maximum supported by the software. The designer must specify the number of network points and number of alarms, trends, and occupancy schedules required for the installation. These requirements are determined by two factors:

- The number of points, alarms, trends, and schedules required for a specific system or sequence of operation and

- The number of systems to be ultimately integrated into the UMCS

The former number can be calculated quite accurately (e.g. "this AHU needs 37 points"), however this is seldom worth the effort given the large uncertainties in the ultimate size of the UMCS (e.g. will the UMCS contain 200 AHUs, or 2000?).

4-1.2.1 Number of Points

Table 4-1 provides very rough estimates of the number of points and long-term trends for typical HVAC systems.

Table 4-1 Number of Points and Trends in Typical HVAC Systems

System	Points	Trends
Terminal unit (fan coil, VAV box, etc.)	5 - 15	1 - 5
Small packaged AHU	20 -30	4 - 8
Medium built-up AHU	25 – 50	10 - 15
Large complex AHU	30 – 60	15 - 20
Small package chiller or boiler	10 – 20	5 – 15
Large central plant chiller	30 – 60	20 – 30
Large central plant boiler	20 – 40	15 - 25
Hydronic pumping system	15 – 25	5 - 10

More accurate numbers could be obtained from sequence specific point schedules, but effort should be focused on determining the actual number of systems as that will drive the licensing requirements.

4-1.2.2 Number of schedules

If the only protocol tailoring option selected is BACnet or Niagara Framework there is no need for a requirement in the UFGS relating to number of schedules since scheduling occurs within the building control system. Similarly, if only the LonWorks tailoring option is used and the UMCS is connecting only to new building control systems installed in accordance with UFGS 23 09 00 and UFGS 23 09 23.01, scheduling will be performed within the building control system and there is no need to require that the UMCS front end perform scheduling.

When using other tailoring options (or when using LonWorks to connect to older building control systems which do not use the “Simple Scheduler” functional profile), specify the required number of schedules. A very conservative estimate would be one schedule per system (AHU, or AHU and its associated VAV boxes) and one schedule per X number of stand-alone terminal units which can operate on a common schedule, where X is determined from the design. In practice, though, it is expected that multiple systems (in multiple buildings) will operate from a common schedule so the total required number of schedules should be much less than this conservative estimate. Coordinate with the site to determine their approach to scheduling. If the site indicates they operate systems according to common schedules, the “default” recommendation in the guide spec should be more than sufficient.

4-1.2.3 Number of clients

An important decision that the designer must make in coordination with the installation (customer) is the number of client seats desired. Most M&C software will be licensed as a single server but with varying numbers of client (these may be referred to as client “seats”). UFGS 25 10 10 requires web-browser based clients, so the limit on the number of clients is the total number of simultaneous clients.

4-1.3 System display graphics requirement.

The term Graphical User Interface (GUI) is somewhat a misnomer. An operator thinks of a GUI as providing a graphical representation of systems (i.e. pictures) whereas vendors use the term GUI in the same sense that Microsoft® describes Excel®, as providing a GUI for a spreadsheet (tool bars, pull down menus, mouse driven, etc.). This can potentially lead to a Contractor providing a GUI without graphics. Most vendors offer some level of graphical representation of systems; whether these graphics are included in the base-level product offering depends on the vendor. Most vendors also offer animation, 3-D graphics, links to AutoCAD or PDF documents, and links to GIS (Geographical Information Systems).

4-1.3.1 System display graphics detail level.

UFGS 25 10 10 requires a moderate level of graphics including building floor plans and either one-line or 3-D representation of HVAC systems. These requirements must be edited in accordance with the specific site requirements. It’s important to consider the effect that detailed graphics have on the performance of the user interface; the more complex the graphic, particularly interactive graphics, the longer it will take for the page to load.

4-1.3.2 Cybersecurity issues related to graphics.

It is important to note that many vendors make extensive use of Java, JavaScript, Flash, Shockwave, Silverlight, and ActiveX controls; all of these technologies have important IA ramifications. UFGS 25 10 10 requires that the system function using only Java, Shockwave, Silverlight, Flash, and specifically prohibits use of ActiveX. These issues should be carefully coordinated with site cybersecurity personnel and with the requirements of UFC 4-010-06 and UFGS 25 05 11.

4-1.4 Standard reports.

UFGS 25 10 10 requires an extensive list of reports. Coordinate with the installation and edit these requirements as needed.

4-1.5 Demand limiting.

UFGS 25 10 10 requires that the M&C Software be capable of performing electrical demand limiting. While the installation may not implement demand limiting immediately, trends in energy pricing and government energy targets make its eventual use likely.

The UFGS includes a designer option to require the use of real time pricing data for demand limiting. While most vendors provide some demand limiting functionality, it may be difficult to get demand limiting incorporating real time pricing at this time. In addition, the use of real time pricing requires a connection to an external server (via the Internet), which introduces vulnerabilities into the system and makes meeting cybersecurity requirements more difficult. Unless specifically required by the site, it is recommended that the requirement for real time pricing ***not*** be included.

4-1.6 User account management for M&C software.

UFGS 25 10 10 requires that the M&C Software includes the ability to create and manage user accounts for itself. In addition, it includes a requirement that the M&C Software support a Common Access Card (CAC) login, although implementation of this may not be required for all projects.

4-2 USER ACCOUNT MANAGEMENT FOR OTHER COMPUTER SOFTWARE.

While other computer software required by UFGS 25 10 10 may have user accounts and privileges similar to the M&C software, more often the full capabilities of the software will be available to anyone with access to the software (i.e. there may not be a specific login screen within the software package). For example, an in general, anyone who can run the LNS Network Configuration Tool or ASHRAE-135 Network Browser will be able to perform any operation allowed by that software. For this reason, care should be taken when assigning Microsoft® Windows® user accounts to machines that contain this software to prevent an unauthorized user from being able to damage the system.

4-3 LNS NETWORK CONFIGURATION TOOL (LONWORKS).

The LNS network configuration tool is used to configure communication between controllers and to set device configuration properties such as PID loop settings and setpoints. So that the installation can become proficient with one tool and to avoid multiple tools, UFGS 25 10 10 requires the tool be provided as a part of UMCS contract rather than asking for a tool from each building control system contractor.

Coordinate with the site to determine how many copies of the LNS Network Configuration Tool are required and where they are to be installed. In general, one copy of the LNS Network Configuration Tool should always be installed on the M&C Software Server, but additional installation on laptops may be needed by the maintenance staff. Show these requirements on the UMCS Equipment Schedule.

4-4 BACNET NETWORK BROWSER (BACNET)

The BACnet Network Browser provides the capability to look at, read values from and write values to a BACnet network. While the M&C Software will also have this functionality, the BACnet Network Browser can be installed on a laptop and used by maintenance staff in the field even when the building control system is not connected to the UMCS IP network, or when a local interface is beneficial.

Coordinate with the site to determine how many copies of the BACnet Network Browser are required and where they are to be installed. Show these requirements on the UMCS Equipment Schedule.

4-5 NIAGARA FRAMEWORK ENGINEERING TOOL

The Niagara Framework engineering tool is software used to program and configure all aspects of the Niagara Framework including both Niagara Framework Supervisory Gateways and the Niagara Framework M&C software. It also provides network management and device configuration capabilities for Niagara Framework devices. It is available from multiple vendors, but requires additional licensing requirements for an open implementation (to ensure a tool from one vendor will function with Niagara Framework components from a different vendor). The tool, along with the specific licensing requirements, is specified in UFGS 25 10 10, as well as UFGS 23 09 23.01 and UFGS 23 09 23.02 (though it will typically be procured under UFGS 25 10 10).

This Page Intentionally Left Blank

CHAPTER 5 DRAWINGS

5-1 UMCS DRAWINGS OVERVIEW.

This chapter describes typical UMCS design drawing requirements and how to edit them to be project-specific. CHAPTER 6 UMCS DESIGN AND IMPLEMENTATION provides an overview of the project-specific drawing requirements detailed in this chapter. Example drawings in Microsoft Excel format can be found at the “UFGS Forms, Graphics and Tables” page of the Whole Building Design Guide (WBDG) website: http://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables

5-1.1 CONTRACT DRAWING SET.

5-1.1.1 Contract drawing set contents.

A set of Contract drawings must include:

- Points Schedule(s)
- Points Schedule - Contractor Instructions
- Alarm Contact Schedule
- Alarm Routing Group Schedule
- UMCS Equipment Schedule
- Demand Limiting Schedule (if demand limiting is implemented)
- Occupancy Schedules

5-1.1.2 Editing contract drawings.

As part of the editing process to make the sample drawings project-specific, the sample drawings use the following conventions:

- Entries required of the designer are shown bracketed as: [___]
- Entries required of the UMCS Contractor are shown bracketed as: < ___ >
- Spaces where no entry is ordinarily required contains a tilde: “ ~ “ (equivalent to an “n/a” or null value)

The bracketed ([__]) designer entries in the sample drawings are provided as a guide to the designer, and must be verified or changed during design. When editing the drawings, delete the brackets after verifying/providing the entry. Contract drawings must contain no designer brackets [___]; entries requiring information from the contractor are shown in “<___>” brackets. When appropriate, designer brackets may be replaced with contractor brackets during design. Do not leave cells blank. Instead, show the tilde ("~") to indicate a null value or that no further entry is required.

5-2 POINTS SCHEDULE.

The most common task to be performed under UFGS 25 10 10 is integration of one or more field control systems into a UMCS (new or existing), and the designer must include Points Schedule drawing(s) in the UMCS contract package to specify integration requirements. Whenever possible, these Points Schedules should be obtained from the as-built submittals of completed field control system projects, particularly when UFGS 23 09 23.01 or UFGS 23 09 23.02 was used.

Detailed point schedule instructions are in UFC 3 410 02 Direct Digital Control for HVAC and Other Local Building Systems.

5-2.1 ALARM CONTACT AND ALARM ROUTING GROUP SCHEDULES.

The M&C software will route alarms according to the alarm routing group shown on the Points Schedule. The alarm routing group is defined by the use of two separate schedules: an Alarm Contact Schedule that lists information on specific individuals and an Alarm Routing Group Schedule that defines the actions to be taken for each “route”.

5-2.2 Alarm contact schedule.

The Alarm Contact Schedule, shown in Table 5-1, defines alarm recipient information. The designer must either complete this schedule or specify that the Contractor must complete this schedule. In either case, customer input is required to identify appropriate entries.

Table 5-1 Alarm Contact Schedule

PERSONS NAME	EMAIL ADDRESS	TEXT MESSAGE ADDRESS	DESCRIPTION
[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]

5-2.3 Alarm routing group schedule.

The Alarm Routing Group Schedule (shown in Table 5-2), defines actions to be taken for an alarm based on alarm routing groups. Each alarm routing group specifies the destinations for the alarm message and is some combination of the following:

- Pop-up a message on all open clients
- Send as email to one or more individuals
- Send a text message via email to one or more individuals
- Print to one or more printers

The designer must either complete this schedule or specify that the Contractor must complete this schedule. In either case, input from the project site is required to identify appropriate entries. Each row in this schedule specifies a unique alarm routing group, and each group may be used by multiple alarms. Individual cells may have multiple entries (e.g. one routing group may email to multiple individuals). Alarms are assigned to routing groups in the M&C Routing column of the Points Schedule.

Table 5-2 Alarm Contact Schedule

ROUTING NAME	EMAIL TO	TEXT MESSAGE TO	POP-UP	PRINT TO PRINTERS
[_____]	[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]	[_____]
[_____]	[_____]	[_____]	[_____]	[_____]

5-3 UMCS EQUIPMENT SCHEDULE.

The UMCS Equipment Schedule, Table 5-3, shows requirements for UMCS equipment such as FPOCs (routers, gateways), Control Protocol Network Hardware, computer servers, computer workstations and printers. The schedule contains the following information (by column heading):

- Reference: Complete this field by entering an equipment identifier.
- Hardware: Complete this field for each piece of hardware furnished by the Government or required of the Contractor.
    - Computer: List each Server and each Workstation (Desktop or Laptop).

  - Printer: List each printer by type - Alarm (continuous feed is default), Laser (B&W), or Color.
  - FPOC: List each Control Protocol Router and each Gateway.
  - The Contractor will add entries for other hardware such as each M&C Software Controller Hardware and each BACnet Supervisory Controller Hardware.

- Hardware Provided By: Complete this field to indicate whether the hardware is contractor-provided or Government-furnished.
- Hardware Location: Show the location the hardware is installed or must be installed in.
- Network Name: The Contractor completes this field.
- IP Address: The Contractor completes this field.
- Media Size or Monitor Size: Show the display monitor size for computers or non-standard media size for printers. UFGS 25 10 10 requires all printers be able to print on 8.5 inch by 11 inch portrait mode media. List any other media sizes required here.
- Note that the following three columns are protocol specific – their use must be coordinated with tailoring options in UFGS 25 10 10.
  - Install LNS Network Configuration Tool: Designate each workstation that must be provided with LNS network configuration tool (NCT) software.
  - Install BACnet Network Browser: Designate each workstation that must be provided with BACnet Network Browser software.
  - Install Niagara Framework Engineering Tool: Designate each workstation that must be provided with Niagara Framework Engineering Tool software.
- Reference Sheet Number: The Contractor completes this field. If there is a UMCS riser diagram, this may be used to indicate a reference to the sheet number (of that riser diagram) on which the equipment is shown.

Table 5-3 UMCS Equipment Schedule

REFERENCE	HARDWARE	HARDWARE PROVIDED BY	HARDWARE LOCATION (BLDG & RM)	NETWORK NAME	IP ADDRESS	MEDIA SIZE OR MONITOR SIZE	LNS NETWORK CONFIGURATION TOOL	BACNET NETWORK BROWSER	REFERENCE SHEET No.

CHAPTER 6 UMCS DESIGN AND IMPLEMENTATION

6-1 INTRODUCTION

This chapter describes the planning and design of a UMCS project and is largely constrained to the case where a new UMCS is being designed, including integration of an initial set of field control systems. In addition to the guidance contained in this UFC the design should be based on site-specific planning documents. Designs must be accomplished in accordance with the customer's site specific requirements, such as those in the Installation Design Guide (IDG) for an Army garrison, Master Planning documents, and a UMCS/DDC Implementation Plan. To help obtain maximum benefit of Open DDC systems, designers should encourage their customers to develop a UMCS/DDC Implementation Plan as described in ERDC/CERL Technical report TR-08-12 'IMCOM LonWorks® Building Automation Systems Implementation Strategy' available at: http://dtic.mil/dtic/tr/fulltext/u2/a492015.pdf.

Note that while this report may be outdated, it still contains useful information on how best to obtain an Open DDC system.

6-2 UMCS DESIGN CONSIDERATIONS.

6-2.1 Protocol advantages and disadvantages.

Each of the three protocol options – BACnet, LonWorks and the Niagara Framework protocol - has its own strengths and weaknesses. None of them stand head and shoulders above the others; as discussed below, the decision of which protocol to require should be driven by other factors.

6-2.1.1 BACnet.

BACnet has good support for Scheduling, Alarming, and Trending in an Open standard way at the building. On the other hand, BACnet lacks a system-wide network database, and requires more proprietary software tools for device configuration. While buildings can be competed openly, the front end is generally proprietary.

6-2.1.2 LonWorks (LNS-based).

LonWorks (LNS-based) has an open system-wide database standard allowing the use of a single tool for network management and device configuration. Widespread use of ASCs reduces the need for proprietary programming tools. Scheduling, Alarming, and Trending are not supported in a standard manner, requiring custom solutions. While buildings can be competed openly, the front end is generally proprietary.

6-2.1.3 Niagara Framework.

Niagara Framework has good support for Scheduling, Alarming, and Trending in a standard way at the building. The Niagara Framework toolset and system database is more standard than BACnet, but less standard than LonWorks. Building competition is somewhat less open than for LonWorks or BACnet. The front end is non-proprietary (supported by multiple vendors), but has a larger footprint due to the common approach of installing Niagara Framework Supervisory Gateways in buildings. The biggest single downside of the Niagara Framework is that, while it meets the government procurement definition of non-proprietary, it is not an Open technology, but is wholly owned and licensed by Tridium (a subsidiary of Honeywell). Unlike BACnet and LonWorks, in theory there is no guarantee that support for the technology will continue into the future.

6-2.1.3.1 Niagara Framework as LonWorks or BACnet front end.

Note that a Niagara vendor can meet the UFGS 25 10 10 requirements for either a LonWorks or BACnet front end (even in the case where Niagara Framework was not selected). This is not the "standard" installation of that product and is not desired.

6-2.1.3.2 Standardization of building control system protocol for Niagara Framework UMCS.

When implementing the Niagara Framework it is strongly recommended to standardize on either LonWorks or BACnet for building control systems. This will help provide a more maintainable system for the installation operation and maintenance staff as they will not have to understand both protocols and can reduce the number of software tools the installation has to maintain.

6-2.1.4 Other protocols.

Note that most vendors have a great deal of flexibility in integration and that most field control protocols (for example, DNP, JCI N2, or IEC-61850) can be integrated to most front end via ***some*** method – the real issue is "how easy and seamless is the integration". Even when protocols are different, a gateway is generally available that will allow for integration (Figure 3-1, case 3 or case 4). This is often a reasonable approach towards integrating UCS which generally have their own dedicated front end and where the integration requirements are not as stringent.

6-2.2 Determine the BCS protocol requirements.

In order to support the procurement of open building control systems, the UMCS must support at least one of BACnet, LonWorks, or the Niagara Framework. In general, do ***not*** require support for more than one. The only possible exception would be an installation with a large established base of both Niagara Framework and BACnet buildings and the installation wishes to continue to add both Niagara and BACnet buildings and wishes to have a ***single*** UMCS (an installation wishing to support multiple protocols could simply have multiple UMCS).

6-2.3 Determine the UCS protocol requirements.

The primary driver behind protocol selection must be the needs of the BCS. Only if there are a large number of UCS to be integrated and they use a common protocol should the UCS requirements impact the overall choice of protocol. Even then, BCS protocol compatibility should not be sacrificed for UCS protocol compatibility. Most BCS vendors make hardware gateways that support Modbus, some BCS vendor's front end support Modbus and/or OPC.

6-2.4 Selection of UMCS protocol.

Some key considerations in making this decision are:

- Availability of local vendor support. This is the number one concern; the best protocol and software in the world will not make up for poorly trained installers and contractors. To some extent, this also depends on level of complexity in the specification and level of enforcement – both the LonWorks and BACnet specifications tend to push vendors out of their comfort zone. Selecting the Niagara Framework option will result in a somewhat more "normal" installation.

- The extent and type of existing legacy systems. This is important, but for most installations, no single legacy system has a clear majority of buildings when compared to the eventual size of a site-wide BAS. However, the existence of a large quantity of a specific legacy system is generally an indicator of local vendor support.

- The particular strengths and weaknesses of each option should be considered where there is no clear preference between LonWorks, BACnet, or Niagara Framework based on local support or existing legacy buildings.

- The need to support large numbers of Modbus and/or OPC UCS systems, which might eliminate some BACnet vendors from consideration since many BACnet vendor's front ends do not support Modbus and/or OPC.

This selection of Niagara Framework, LonWorks, or BACnet is a difficult choice, and must be carefully considered and closely coordinated with the installation. There is a lot of information available to help with this decision – unfortunately while some of it is good, much of it is not so good and a surprising amount of it is just plain wrong. Before proceeding, coordinate with the project site. For Army projects, also coordinate with the UMCS MCX at Huntsville. **It is strongly recommended that a) only one of Niagara Framework, LonWorks, or BACnet be selected and b) if BACnet is selected, do NOT select Modbus or OPC.**

6-2.5 Services tailoring option recommendations.

In addition to the protocol tailoring options, UFGS 25 10 10 contains tailoring options for the different services, with "Air Force", "Army", "Navy" and "Service Generic" tailoring options. When designing a project for the Air Force, Army or Navy use the appropriate tailoring option. Otherwise use the "Service Generic" tailoring option

6-3 UMCS DESIGN IMPLEMENTATION.

The designer is responsible for designing the UMCS using the guidance in this UFC and according to the requirements in UFGS 25 10 10. This design responsibility requires producing a design package consisting of a specification and a set of drawings. Although many implementation details are left to the Contractor, the designer must not depend on the UMCS Contractor or vendor for the preparation of the contract package.

The resultant project-specific specifications will require the UMCS Contractor to produce shop drawings, schedules, test plans, test procedures, and other documents showing the application of products to implement the UMCS design. The specification further requires the Contractor to define and install the interface to the field control network in a manner that is consistent with performance requirements defined in the specification and that the Contractor conducts a performance verification test of the UMCS to show that the UMCS functions as designed.

6-3.1 Design package requirements.

The UMCS design must include a tailored specification and contract drawings. All bracketed options in the UFGS must be addressed - included, removed or edited - as required by this UFC, the UFGS designer notes and the needs of the project. The contract drawing package must include the following drawings:

- Points Schedule(s): Points Schedules for the UMCS should derive from the As-Built Points Schedules for the FCS to be integrated. When FCS as-builts are not available, create Points Schedules for the FCS to show the UMCS integration requirements such as graphic display, overrides, and alarming.
- Points Schedule - Contractor Instructions
- Alarm Contact Schedule
- Alarm Routing Group Schedule
- Computer Equipment Schedule
- System Occupancy Schedule: The system occupancy schedule should be based on the FCS as-built drawings. If as-built drawings are not available for the FCS create a system occupancy schedule to show the required operation schedule for each system.
- Demand Limit Schedule (when demand limiting is used)

All drawings must be complete, with all information provided or shown as requiring a contractor entry.

6-3.2 Contracting mechanisms.

While procurement of building level controls is relatively straightforward, procurement of a UMCS is more complex. There are two main issues to be considered:

- UMCS work is an ongoing process. While the UMCS Front End is procured once, building integration to the UMCS is a process that can span many years. The question of how to accomplish future integration work should be addressed prior to initial procurement. As an extreme example, there are “mom-and-pop” shops that can install a custom UMCS that they have developed themselves. However, use of such a UMCS essentially guarantees that future integration work will have to be performed by the “mom-and-pop” shop.

- Contractually, it might be easiest to procure the initial UMCS Front End from a building level DDC Contractor as part of a building level DDC controls project. The danger in this approach is that allowing the same Contractor to install both requires extra vigilance on the part of the government to ensure that the interface between the UMCS Front End and the building is fully compliant with UMCS UFGS 25 10 10. As an extreme case, the Contractor might install a UMCS that works fine with the Contractor’s controls, but will not work with other building control systems that are compliant with the DDC specification.

There are a number of contracting mechanisms that can be used, including (a) IDIQ or services contract, (b) As part of a building level DDC contract, and (c) As a separate contract for either UMCS procurement or integration services. A detailed discussion of contracting methods and the pros and cons of each can be found in ERDC/CERL Technical Report TR-08-12 'IMCOM LonWorks® Building Automation Systems Implementation Strategy' available at: http://dtic.mil/dtic/tr/fulltext/u2/a492015.pdf.

UMCS	Utility Monitoring and Control System
USACE	U.S. Army Corps of Engineers
VAV	Variable Air Volume

C-2 DEFINITION OF TERMS

Several terms are defined in this appendix for ease of reference, but UFC 4-010-06 contains a more extensive, and definitive, list of terms. Should the definitions provide here and in UFC 4-010-06 conflict, the definitions in UFC 4-0101-06 should be used, and a Criteria Change Request (CCR) should be submitted to update the definitions in this UFC.

C-2.1 Field Control System (FCS) and Field Control Network (FCN).

A Building Control System or Utility Control System. The network used by the field control system is called the field control network (FCN).

C-2.1.1 Building Automation System (BAS).

The system consisting of the UMCS Front-End and connected building control systems which provides for control of the building electrical and mechanical systems as well as a user interface and supervisory capability (i.e. the portion of the UMCS for building control and excluding any connected UCS).

C-2.1.2 Building Control System (BCS) and Building Control Network (BCN).

One type of Field Control System. A control system primarily for building electrical and mechanical systems, typically HVAC (including central plants) and lighting. Building Control Systems are generally composed of direct digital controls (DDC) and do not have a full-featured user interface. They may have some local user interface such as “local display panels” but rely on the UMCS for the full user interface functionality. The network used by the building control system is called the building control network (BCN).

C-2.1.3 Utility Control System (UCS) and Utility Control Network(UCN).

One type of Field Control System. Used for control of utility systems such as an electrical substation, sanitary sewer lift station, water pump station, etc. Building controls are excluded from a UCS, however it is possible to have a Utility Control System and a Building Control System in the same facility, and for those systems to share components such as the Field Point of Connection (FPOC). A UCS may include its own local front-end.

C-2.2 Field Point of Connection (FPOC).

The connection point between the field control network (installed by the controls contractor) and the UMCS network (generally owned and installed by the installation IT staff). The FPOC device is typically on the IP network – usually a managed switch, owned and managed by the installation IT staff, and a focal point for Cybersecurity. Note that this definition has evolved over time and may be at variance with older usage of the term.

C-2.3 Industrial Control System (ICS).

One type of control system. Most specifically a control system which controls an industrial (manufacturing) process. Sometimes also used to refer to other types of control systems, particularly utility control systems such as electrical, gas, or water distribution systems.

Note than ICS is at times used to mean “all control systems”, so care must be taken to interpret the term in the appropriate context.

C-2.4 Utility Monitoring and Control System (UMCS)

The system consisting of one or more field control systems connected to a UMCS Front-End which provides for control of the electrical and mechanical systems as well as a user interface and supervisory capability. (i.e. the complete system consisting of the UMCS Front-End with all connected BCS and UCS systems). Note that in the past the term “UMCS” has sometimes been used to mean just “the UMCS front end”, but is no longer used in this manner.

C-2.5 Utility Monitoring and Control System (UMCS) Front End

The portion of the UMCS consisting primarily of computers running software to provide a full-featured user interface. In addition to providing a full user interface, this system performs functions such as alarming, scheduling, data logging, electrical demand limiting and report generation. The front end does not directly control physical systems; it interacts with them only through field control systems.

C-2.6 Utility Monitoring and Control System (UMCS) IP Network

The IP network used by the UMCS Front End for communication between Field Control Systems. This includes the IP infrastructure components only. The UMCS IP network is often also referred to as the “platform enclave” for cybersecurity purposes.

C-3 TERMS SPECIFICALLY NOT USED BY THIS UFC

The term SCADA (Supervisory Control And Data Acquisition) is not used as the definition can vary depending on context. In general usage, however, “SCADA” can be taken to mean “UCS”.

NDAA 2010 uses the term Energy Monitoring and Utility Control System to refer to a Utility Monitoring and Control System (UMCS). This term is not a standard term used by the controls industry, so this UFC and UFGS 25 10 10 do not use this term.

C-4 OTHER TERMINOLOGY

Other terminology related to control systems is defined in UFGS 25 10 10 and in the field control system specifications (e.g. UFGS 23 09 00, UFGS 23 09.01, and UFGS 23 09.02).

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
SUMMARY SHEET

Document: UFC 3-490-06: *Elevators*

Superseding: NAVFAC ITG 2013-01, NAVFAC Elevator Design Criteria

Description: This UFC 3-490-06 incorporates tri-service requirements into one unified document and provides design and construction requirements for elevators in DOD facilities.

Reasons for Document:

- References industry standards to meet DOD requirements.
- Identifies consistent and uniform design and methodology to be used for effective compliance with National Building and Safety Codes that apply to elevator installations.
- Provides direction for the most effective application of standard elevator types to the majority of typical DOD facility sizes and configurations.

Impact:

- Design requirements presented herein will reduce design costs by providing standard design requirements utilizing industry standards. Requirements for design and construction of elevators support competition and capture energy savings over the lifecycle of the elevator systems.

Unification Issues: None.

TABLES

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Non-Governmental building and safety codes identify absolute minimum design and operational requirements for elevator systems and for the building systems that interface with the elevator microprocessor controllers. The performance language used in the codes results in a multitude of different, and often conflicting, interpretations. This UFC was developed to provide the authority having jurisdiction (AHJ) with consistent and uniform methods to be used to comply with the performance language used in the building and safety codes.

While safety codes are designed to achieve safe operation and usage, they do not address reliability and sustainability. The NAVFAC ITG 2013-01, Elevator Design Guide, was originally developed to ensure safety, sustainment, and effective elevator performance. This concept was endorsed by USACE and ITG 2013-01 was adopted by USACE in October 2014. This UFC builds on the holistic design criteria approach and establishes uniform quality and performance requirements for specific elevator components and systems, to ensure safety code compliance, effective performance, sustainability, energy efficiency, and optimum life-cycle costs.

1-2 PURPOSE AND SCOPE.

This UFC provides minimum technical requirements and guidance for new construction and modernization of elevator systems, and their supporting structure, building systems, and components.

1-3 APPLICABILITY.

This UFC applies to all planning, design and construction, modernization, repair, maintenance and operation, and equipment installation in new and existing buildings, regardless of funding source. Certain specialized facilities, such as health facilities, may have more stringent requirements. Project conditions and geographic locations may dictate the need for designs that exceed these requirements.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, DoD Building Code (General Building Requirements). UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 CYBER SECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06 and as required by individual Service Implementation Policy.

1-6 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise stated, the latest available issuance of the reference is used. References to other publications, standards, and technical data referenced herein form a part of the UFC requirements to the extent referenced.

1-7 ADDITIONAL REQUIREMENTS.

When performing work within the U.S., verify if there are additional State requirements that apply to elevator design and operation. Confirm with the DOD Service agency as to the applicability of any state requirements.

1-8 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

CHAPTER 2 PLANNING AND DESIGN REQUIREMENTS

2-1 PLANNING AND PRELIMINARY DESIGN.

Coordinate elevator planning and design with facility operational requirements, DOD policy, UFCs and requirements referenced herein. The project planning and preliminary design process must determine the need for elevators based on facility operational requirements as well as DOD Policy and UFC compliance. Requirements and considerations addressing the need for elevators include the following:

- Operational requirements
- ABA Accessibility Standard for Department of Defense Facilities
- DEPSECDEF Memo: Access for People with Disabilities
- UFC or FC addressing facility type design requirements

2-2 CLIENT SURVEY AND TRAFFIC STUDY.

To determine the elevator types, service, size, capacity, speed, quantity, and operational systems necessary for effective elevator service, the preliminary design process must include a client survey and traffic study of the proposed facility design.

2-2.1 Traffic study factors.

For facilities not covered by a UFC or FC specific to a facility type where elevator requirements have been predetermined, obtain the services of an elevator consultant to conduct a traffic study. Utilize the following factors in the traffic analysis:

- Type and Use of Building
- Size and Height of Building
- Building Population
- Exterior Personnel Traffic Considerations
- Anticipated Personnel Traffic Flow

2-2.2 Passenger or freight classification.

The two categories of service that are recognized by ASME A17.1, Safety Code for Elevators and Escalators, are Passenger and Freight. For each elevator, the designer and client must decide whether the elevator will be designated as a passenger elevator or freight elevator, based on the anticipated usage of the elevator. An elevator that will be used for the movement of personnel must be designed as a passenger elevator, and must comply with DEPSECDEF Memo "Access for People with Disabilities" dated October 31, 2008. An elevator that will be used exclusively for the movement of material may be classified and designed as a freight elevator.

2-2.2.1 Platform Loading.

Passenger elevators may be utilized for movement of furniture, office equipment, and other material. A passenger elevator that will be used to transport material that exceeds 25% of the capacity of the elevator must be designed with a minimum of ASME A17.1 Class C-3 loading.

2-2.3 Emergency Medical Services (EMS) Elevator.

Where elevators are provided in a building, design a minimum of one passenger elevator to accommodate EMS access to all floors of the building. Design elevator to accommodate a 24-inch by 84-inch (610mm by 2134mm) ambulance stretcher **1**\ with not less than 5-inch (127 mm) radius corners, /**1**/ in the horizontal, open position. Identify the elevator with the international symbol for emergency medical services (star of life). Design facility to ensure EMS access from EMS response area to the EMS-designated elevator.

1\ Note: Existing building elevator modernizations are exempt if reusing the existing hoistways/shafts. However, if a new elevator shaft/hoistway is part of the renovation project, then it must comply with this requirement. /**1**/

2-3 BUILDING SYSTEMS INTERFACE.

Building utility systems that interface with elevator design and control systems include electrical, mechanical, communication, fire protection, and fire alarm. For modernization projects, verify that existing building systems are compliant with current safety code requirements and are compatible with proposed elevator systems.

2-3.1 Firefighters' Emergency Operation (FEO).

All elevators with a travel distance greater than 80 **1**\ inches /**1**/ must be designed with Firefighters' Emergency Operation (FEO). For modernization projects, verify existing building fire alarm system is compatible with elevator operational controller and compliant with current safety and building codes.

2-3.2 Emergency Power.

For new construction and modernization of buildings equipped with an emergency power generator, the emergency power system must provide, at a minimum, the capability for the normal operation of the EMS elevator on emergency **1**\ standby /**1**/ power. **1**\ All elevators in the same control group as the EMS elevator must be capable to operate on standby power. /**1**/ In addition, the designer must determine if the client requires additional elevators to be powered by the facility emergency power generator.

2-3.2.1 Emergency Power Design Considerations.

The design of elevator emergency power operation must address the following:

- Identify the number of elevators to run simultaneously.
- Identify elevators and elevator groups to be designed with sequential return operation.

2-3.2.2 Auxiliary Power Operation.

Elevators not designed for building emergency power generator operation must be equipped with an auxiliary power operating system that provides the following operation:

- Electric Traction elevators must run to the next available landing, open **\1\ /1/** the doors, and be removed from service.
- Hydraulic elevators must lower to the FEO Designated Landing, open and close the doors, and be removed from service. If elevator is below the FEO Designated Landing when normal power fails, elevator must open and close the doors at first available landing and be removed from service.

2-3.3 Energy Efficiency.

Energy-efficient technologies are available for new construction and modernization of elevator installations and can be effective in buildings with 10 stories or greater. “Regenerative Drive” motor control systems have been developed for use with gearless traction elevators. This motor control system uses the energy that is developed when the elevator is running in an overhauling load condition. The drive converts the mechanical energy into electrical energy and feeds it back to the facility power grid. The use of gearless traction machines and regenerative drive motor control should be considered for **\1** mid-rise **/1/** and high-rise elevator installations.

2-3.4 Telephone and Communication Systems.

The elevator emergency communication phone line must provide the capability for the elevator cab automated communication system to connect to an emergency response desk that is manned 24 hours a day by authorized personnel. **\1** The phone line must provide the elevator cab communication system to automatically identify the location of the elevator, elevator number and provide the capability for voice communication between the elevator passenger and authorized personnel. The phone line must be capable to provide two-way voice communication between the elevator machine room/control room and the elevator cab. **/1/**

2-3.4.1 Secondary Call Capability.

The emergency communication line must provide the capability for the elevator cab communication device to accomplish the elevator safety code required secondary phone call in the event that the initial call is not answered within 45 seconds.

2-4 ELEVATOR TYPES AND USAGE.

2-4.1 Hydraulic Elevators.

Direct Plunger Hydraulic Elevators may be used for 2 to 4 stories. Roped hydraulic elevators may be used for specific, approved applications, as incorporated into DoD UFC Criteria for approved building types and designs. Telescopic plunger, and inverted cylinder/plunger elevator designs are not permitted in DOD facilities.

2-4.1.1 Speed and Travel Requirements.

- In-ground Direct Plunger: For an elevator travel distance of **1**\ less than 16 feet (4.9 m), rated speed must be 125 feet per minute (fpm) (38.1 m/min). For a travel distance between 16 feet (4.9 m) and 44 feet (13.4 m), the rated speed must be 150 fpm (45.7 m/min). Do not exceed a travel length of 44 feet (13.4 m) or a maximum of four floors for this type of elevator. Do not exceed rated speed of 150 feet per minute (45.7 m/min). /**1**/
- Hole-less Direct Plunger: Rated speed must be 125 fpm (38.1 m/min) for this type of elevator. Elevator travel distance is limited by the depth of the hoistway pit and the overhead clearance in the top of the hoistway.
- Roped-hydraulic: A roped-hydraulic elevator is allowed for Air Traffic Control Towers (ATCT). When used for ATCT facilities, elevator travel distance must not exceed 48 feet (14.6 m). This is intended to equate to an ATCT tower cab floor elevation of 60 ft (18.3m) or less as the elevator stops at the floor below the tower cab. **1**\ For rated speed, follow speed requirements of "In-ground Direct Plunger" paragraph above. /**1**/ See section 2-5 Exceptions for other uses of roped-hydraulic elevators.

  1\ NOTE: An overspeed valve is not to be used on a Roped-hydraulic system. /**1**/

2-4.1.2 Unified Facilities Guide Specifications (UFGS).

Hydraulic elevator equipment requirements are specified in the following UFGS:

- UFGS 14 24 13: Hydraulic Freight Elevators
- UFGS 14 24 23: Hydraulic Passenger Elevators

2-4.2 Electric Traction Elevators.

1\ Provide in the design of the hoistway, a minimum of 18 inches of counterweight runby to allow for rope stretch and adjustability. /**1**/

2-4.2.1 Minimum Travel and Speed Requirements.

- Geared Traction Machine: This type of elevator may be used for **1**\ elevators with a travel of 100 feet or less. For a travel distance of less than 16 feet (4.9 m), the rated speed must be a minimum of 125 fpm (38.1 m/min). For a travel distance of 16 feet (4.9 m) to 24 feet (7.31 m), the rated speed must be a minimum of 150 fpm. For a travel distance of greater than 24 feet (7.3 m), up to 44 feet (13.4 m), the rated speed must be a minimum of 200 fpm (61 m/min). For a travel distance of 44 feet (13.4 m) /**1**/ - 100 feet (30.5 m), the rated speed must be a minimum of 350 fpm (106.7 m/min).
- Gearless Traction Machine: This type of electric traction elevator may be used for all applications and must be used for **1**\ elevators with a travel of greater than 100 feet (30.5 m). For a travel distance of less than 16 feet (4.9 m), rated speed must be a minimum of 125 fpm (38.1 m/min). For a travel distance of 16 feet (4.9 m) to 24 feet (7.3 m), the rated speed must be a minimum of 150 fpm. For a travel distance of greater than 24 feet (7.3 m), up to 44 feet (13.4 m), rated speed must be a minimum of 200 fpm (61 m/min). For a travel distance of 44 feet (13.4 m) - 100 feet (30.5 m), rated speed must be a minimum of 350 fpm (106.7 m/min). For a travel distance of greater than 100 feet (30.5 m), rated speed must be a minimum of 500 fpm (152.4 m/min). For elevators with a travel distance of greater than 200 feet (61 m), utilize elevator traffic study to determine appropriate speed. /**1**/

2-4.2.2 Unified Facilities Guide Specifications (UFGS).

Electric Traction elevator equipment requirements are specified in the following UFGS:

- UFGS 14 21 13: Electric Traction Freight Elevators
- UFGS 14 21 23: Electric Traction Passenger Elevators

Table 2-1 Elevator Types and Usage

Elevator Type	\1\ Approximate Number of /1/ Landings	Travel	Minimum Speed
Hydraulic Traction Geared Traction Gearless	2	Up to 15’	125 ft/min
1\ Hydraulic	2 - 4	16’ - 44’	150 ft/min /**1**/

\1\ /1/ Traction Geared Traction Gearless	2 - 4	16’ - **\1** 24’ **/1/**	150 ft/min
Traction Geared Traction Gearless	2 - 5	24’ - 44’	200 ft/min
Traction Geared Traction Gearless	**\1** 2 **/1/** - 10	45’ - 100’	350 ft/min
Traction Gearless	> 10	> 100’	500 ft/min

2-5 EXCEPTIONS.

Submit written UFC exception requests to the responsible Service elevator program SME. For an individual project design, the SME is authorized to grant an exception for the following conditions:

- Use of a roped-hydraulic elevator for a new construction or modernization project (except as allowed for ATCT)
- elevator speed and travel requirements for special purpose, special application, and high capacity freight elevator installations

CHAPTER 3 ARCHITECTURE

3-1 ELEVATOR MACHINE ROOM.

For building design with elevator machine room, provide one elevator machine room (MR) for each elevator or elevator group. Locate the elevator machine and elevator controller in the machine room.

3-1.1 Machine Room Size.

For a single electric traction elevator, provide a minimum machine room (MR) size of 120 sq. ft., with a minimum interior wall length of 10 feet. For a single hydraulic elevator, provide a minimum MR size of 72 sq. ft., with a minimum wall length of 8'-0". For MR with multiple elevators, increase MR size to accommodate elevator and elevator utilization equipment and to comply with all applicable codes and standards.

3-1.2 Machine Room Location.

Locate elevator MR directly adjacent to the elevator hoistway. For electric traction elevator installations, locate MR directly above hoistway or directly beside the elevator hoistway. Locate hydraulic elevator MR on the lowest landing served by the elevator, except as noted in Paragraph "Flood Zone Restrictions".

3-1.2.1 Flood Zone Restrictions.

For all elevators, design elevator system, and all related components, in accordance with the Elevator Section in the current edition of ASCE 24, Flood Resistant Design and Construction.

3-1.3 Machine Room Plans.

Provide the following:

- a. Design building and elevator systems so that access panels are not installed in walls or ceiling of the MR.
- b. Provide maximum ceiling height of 15 feet (4.6 m).
- c. For overhead traction elevator, provide interior width of elevator MR a minimum of 16 inches wider than the interior width of the elevator hoistway **1**\\ for clearance to service and test governor /**1**/.
- d. Provide minimum clearance of 18 inches (450 mm) between any building component and a traction elevator drive machine.
- e. Provide minimum clearance of 10 inches (254 mm) between over-speed governor and any building component.
- f. Provide minimum clearance of 10 inches (254 mm) between any building component and a hydraulic elevator pump unit.

g. Provide minimum 3 feet wide X 6 feet 8inches high MR entry door.

h. Provide **1**\ an out-swing, /**1**/ self-closing MR door with lever handle on MR side of door equipped with a self-locking spring-type lock arranged to permit the door to be opened from inside the MR without a key.

i. **1**\ Provide 84 inches of unobstructed vertical clearance. (headroom) /**1**/

3-1.4 Machine Room Sound Transmission Limits.

Provide elevator MR with a sound transmission coefficient design to not exceed 65 decibels of audible elevator machine room equipment noise, measured at any location outside of the elevator MR.

3-1.5 Machine Room Access.

Provide a permanent and unobstructed personnel and material access route from building entrance to the elevator MR door. The access route must have a continuous minimum width of 3 feet (914 mm) and minimum height of 7 feet (2133 mm).

3-1.5.1 Stairway Access.

When the floor level of the access route is greater than 8" above or below the floor of the MR, provide a stairway **1**\ that is IBC compliant, minimum inclination of 30 degrees and maximum inclination of 50 degrees. Vertical ladders, ships ladders, and alternating step tread designs are not permitted for MR access. Provide maximum riser height of 7 inches (178 mm) and a minimum step tread depth of 11 inches (279 mm) /**1**/, as measured from each adjoining step, nose to nose. Provide maximum height of the access stairs 12 feet (3.6 m) without an intermediate landing.

1\ Exception: For building stair designs that cannot comply with IBC, this UFC allows designers to use OSHA requirements for step riser height of 7 ½ inches and minimum step tread of 10 inches. /**1**/

3-2 ELEVATOR CONTROL ROOM AND ELEVATOR MACHINERY SPACE.

For building design that does not have an elevator machine room, provide an elevator Control Room (CR) for the elevator controller and an elevator machinery space (MS) for the elevator drive machine and speed governor. For building design with elevator CR and MS, provide one CR and one MS for each elevator or elevator group. Design CR and MS for full bodily entry. Locate elevator controller in CR and elevator drive machine in MS.

3-2.1 Control Room Location and Size.

Locate elevator CR directly adjacent to, and outside of, the elevator hoistway. For a single elevator, provide a minimum CR size of 40 sq. ft., with a minimum of one interior wall length of 7 feet. For CR with multiple elevators, increase CR size to accommodate elevator controls, elevator utilization equipment, hydraulic MS access panel, maintenance and service, and all applicable codes and standards.

1\ [C] 3-2.1 The elevator CR provides a dedicated space to facilitate maintenance associated with the elevator controller while minimizing disruption to building users (elevator operation and access to common areas). /**1**/

3-2.2 Machinery Space Location and Size.

For electric traction elevator, locate MS directly above the hoistway, directly adjacent to the side of the hoistway, or in the top of the hoistway. For a single elevator, provide a minimum MS size of 36 sq. ft. For MS with multiple elevators, increase MS size to accommodate elevator equipment, maintenance and service, and all applicable codes and standards. For hydraulic elevator, locate MS in the elevator hoistway pit or directly adjacent to the hoistway on the lowest landing served by the elevator, except as required by ASCE 24, Flood Resistant Design and construction.

1\ [C] 3-2.2 The elevator MS provides a dedicated, fixed space to facilitate ease of maintenance and testing associated with the elevator mechanical equipment. /**1**/

3-2.2.1 Flood Zone Restrictions.

For all elevators, design elevator and all related components in accordance with the Elevator Section in the current edition of ASCE 24, Flood Resistant Design and Construction.

3-2.3 Control Room Plans.

Provide the following:

a. Design building and elevator systems so that access panels are not installed in walls or ceiling of the CR. Exception: Hydraulic elevators with MS in the elevator hoistway.

b. For hydraulic elevator with MS in the elevator hoistway, provide access panel in CR that provides all necessary access to the elevator pump unit and drive machine for maintenance, service, inspection, and testing of the elevator. Maximum allowable height of access panel is 6’ above finished CR floor.

c. Provide maximum ceiling height of 12 feet (3.6 m).

d. Provide minimum clearance of 10 inches (254 mm) between over-speed governor and any building component.

e. Provide minimum 3 feet wide X 6 feet 8 inches high CR entry door.

f. Provide **1**\ an out-swing, /**1**/ self-closing CR door with lever handle on CR side of door equipped with a self-locking spring-type lock arranged to permit the door to be opened from inside the CR without a key.

3-2.4 Machinery Space Plans.

Provide the following:

a. Design building and elevator systems so that access panels are not installed in walls or ceiling of the MS.
b. Provide minimum headroom clearance of 78 inches (1981 mm) in the MS.

c. Provide minimum clearance of 18 inches (450 mm) between any building component and a traction elevator drive machine.

d. Provide minimum clearance of 10 inches (254 mm) between over-speed governor and any building component.

e. Provide minimum clearance of 10 inches (254 mm) between any building component and a hydraulic elevator pump unit located in a MS outside of the elevator hoistway.

f. Provide minimum 3 feet wide X 6 feet high MS entry door.

g. Provide self-closing MS door with lever handle on MS side of door equipped with a self-locking spring-type lock arranged to permit the door to be opened from inside the MS without a key.

h. Where MS is located in the top of the hoistway, provide solid flooring, excluding holes required for hoist and governor ropes.

3-2.5 Machinery Space Sound Transmission Limits.

Provide elevator MS with a sound transmission coefficient design to not exceed 65 decibels of audible elevator machine room equipment noise, measured at any location outside of the elevator MS, including all building interior areas and the interior of the elevator cab.

3-2.6 Control Room and Machinery Space Access.

Provide a permanent and unobstructed personnel and material access route from building entrance to the elevator CR and MS door. The access route must have a continuous minimum width of 3 feet (914 mm) and minimum height of 7 feet (2133 mm).

3-2.6.1 Stairway Access.

When the floor level of the access route is greater than 8 inches above or below the **1**\ floor of CR or MS, provide a stairway that is IBC compliant, minimum inclination of 30 degrees and maximum inclination of 50 degrees. Vertical ladders, ships ladders, and alternating step tread designs are not permitted for CR or MS access. Provide maximum riser height of 7 inches (178 mm) and a minimum step tread depth of 11 inches (279 mm) /**1**/, as measured from each adjoining step, nose to nose. Provide maximum height of the access stairs 12 feet (3.6 m) without an intermediate landing.

1\ Exception: For building stair designs that cannot comply with IBC, this UFC allows designers to use OSHA requirements for step riser height of 7 ½ inches and minimum step tread of 10 inches. /**1**/

3-3 ELEVATOR HOISTWAY.

3-3.1 Hoistway Pit Entrapment Protection.

Provide a minimum horizontal clearance of 20 inches (508 mm) between the side of the elevator platform/cab and any one wall of the elevator hoistway. A horizontal clearance of 20 inches (508 mm) wide X 36 inches long (915 mm) must be maintained for the entire height of the hoistway. Elevator and building components must not encroach on the minimum clearances or block personnel passage from the elevator pit to the **1**\ pit entrapment area.

A secondary push-to-stop pit stop switch must be provided within the hoistway pit entrapment protection egress area, at a height between 50 inches (1270 mm) and 60 inches (1524 mm) above the pit floor. /**1**/

NOTE: For the restoration or modernization of an elevator with an existing hoistway, comply with this requirement if practicable.

3-3.2 Elevator Hoistway Plans.

Develop detailed plan and section drawings for elevator hoistway. Provide all layout drawing information required by ASME A17.1. Comply with the following:

a. Elevator hoistway layout and dimensions must take into consideration the size and configuration of the elevator landing entrances.

b. Locate only access panels or doors in the walls or ceiling that are necessary for the operation, maintenance, service, inspection, and testing of the elevator.

c. Provide plumb hoistway walls with flush surfaces on the hoistway side.

d. For hoistway pit with a depth exceeding 35 inches (889 mm), provide fixed ladder on the hoistway side closest to the hoistway entrance.

e. Provide only mechanical equipment and systems directly related to the installation, operation and maintenance of the elevator. Pipes, ducts, and conduit not related to the elevator system must not penetrate the hoistway.

f. **1**\ Provide in the design of the hoistway, a minimum of 18 inches of counterweight runby to allow for rope stretch and adjustability. /**1**/

3-4 ELEVATOR HOISTWAY PIT.

3-4.1 Hoistway Pit Waterproofing.

Provide water stops in the walls and waterproofing for elevator pit floor and walls.

1\ NOTE: Waterproofing to be white or gray in color. Clear finish is not allowed. /**1**/

3-4.2 Sump and Sump Pump.

Provide elevator hoistway with a sump pit, submersible sump pump, and permanent discharge piping to a point outside of the elevator hoistway and MR. Coordinate discharge location with installation environmental department and local laws and statutes. Comply with the following:

a. Provide sump pit with fully supported and removable sump pit grate cover, with top of grate flush with pit floor.

b. Provide sump pit large enough to fully enclose submersible sump pump and control sensors below the bottom of the sump pit grate cover.

NOTE: For existing facilities that are not equipped with a sump pit, the sump pit is not required. All other requirements of **1**\ 3-4.2 /**1**/ must be met.

3-5 ELEVATOR LANDING.

Fill elevator landing doorway entrance frames **1**\ completely /**1**/ with grout to a height of 60 inches (1524 mm). Design interface between elevator landing doorway entrance frame and elevator hoistway wall to facilitate effective installation of grout in the door frame.

3-5.1 Emergency Lock Box.

For each individual elevator or for each elevator group, a keyed lockbox must be provided at the FEO Designated Landing. The lockbox must be flush mounted in the wall, adjacent to and within 20 inches (508 mm) of the hoistway entrance assembly. Locate lockbox recess in the elevator lobby wall, at a height of 60 inches (1524 mm) above the landing sill. The lockbox must have a minimum size of 6 inches (152 mm) W X 8 inches (203 mm) H X 1.25 inches (32 mm) D. The locking mechanism must utilize the ASME A17.1 FEO key.

3-5.2 Exterior Elevator Lobby Enclosure.

For exterior elevator landing entrances, provide elevator lobby enclosure or vestibule to protect elevator entrance, elevator hoistway, and elevator equipment from snow, ice, and wind driven rain.

3-6 \1\ CORROSION PROTECTION. /1/

1\ All ferrous metal elevator equipment and building components in the elevator hoistway, machine room, and machinery spaces must be painted with a minimum of one coat of enamel paint. /**1**/

This Page Intentionally Left Blank

CHAPTER 4 STRUCTURAL

4-1 ELEVATOR MACHINE ROOM AND ELEVATOR MACHINERY SPACE.

Design elevator machine beams, sheave beams, **1**\ lifting beams, /**1**/ floor, and supporting structure in accordance with the concentrated load and live load requirements of ASME A17.1. Do not support elevator **1**\ machine beams or /**1**/ machine room floors located over elevator hoistway with cast-in-place or post installed anchors loaded in shear. Instead, design **1**\ all /**1**/ said **1**\ systems /**1**/ to be supported by direct bearing on hoistway walls or on structural beams pocketed in hoistway walls.

4-2 ELEVATOR HOISTWAY.

Design elevator hoistway to provide adequate support for the elevator guide rail and rail bracket connection to the building structure. For hydraulic elevators, design hoistway pit floor in accordance with the concentrated load and live load requirements of ASME A17.1.

4-2.1 Hoistway Wall Construction.

1\ All hoistway walls must comply with UFC 3-301-01. /**1**/ This applies to both load bearing and non-load bearing conditions. Additionally, elevator guide rails, rail brackets, hoist beams, and load reaction points must be supported and backed with fully grouted and reinforced cells. Do not use clay tile or brick for the construction of elevator hoistway walls.

4-3 MACHINE ROOM, MACHINERY SPACE, AND HOISTWAY PLANS.

Develop detailed plan and section drawings for elevator MR, MS, and hoistway. Show location of all support beams in the MR, MS, and hoistway. For multiple elevators in the same hoistway, provide divider beams for guide rail support brackets. Provide all layout drawing information required by ASME A17.1.

4-3.1 Structural Design Submittal.

Elevator design submittal must include a design analysis with calculations for the total static loads, impact loads, and horizontal and vertical reaction loads that will be transmitted to machine beams, sheave beams, supports, floors, walls, and foundations.

4-3.2 Lifting Beam.

For hydraulic elevator installations, provide a lifting beam at the top of the hoistway for installation of elevator equipment. The bottom of lifting beam must **1**\ not encroach on any code required clearances. /**1**/

This Page Intentionally Left Blank

CHAPTER 5 MECHANICAL

5-1 ELEVATOR MACHINE ROOM, CONTROL ROOM, AND MACHINERY SPACE.

5-1.1 Elevator MR, CR, AND MS Temperature and Humidity Control.

For each elevator MR, CR, and MS, provide an independent, dedicated **1**\ Heating and Cooling system. Design Heating and Cooling system to maintain MR or CR temperature between 70 and 90 degrees F (21 to 32 degrees C) and relative humidity between 35% and 60% at all times and in all weather conditions. Design /**1**/ system to include the BTU heat load generated by operation of the elevator equipment.

5-1.2 Mechanical Equipment Installation.

Comply with the following:

a. Provide **1**\ 84 inches of unobstructed vertical clearance (headroom) where installed mechanical and electrical system components are located. /**1**/

b. Do not locate HVAC equipment above elevator equipment.

c. Provide a minimum of 18 inches (450 mm) horizontal clearance between elevator drive machine and any mechanical or electrical equipment in the elevator MR.

d. Drain AC condensate to a location outside of elevator MR and hoistway.

5-1.3 Machine Room and Machinery Space Sound Level.

Limit maximum acoustic output to 85 dBA at any point in the MR and MS.

5-2 ELEVATOR HOISTWAY PIT.

5-2.1 Hoistway Pit Sump and Sump Pump.

Provide sump pump, automatic sump pump controls, and permanent discharge piping that complies with the following:

a. Provide sump pump discharge capacity of 50 gallons per minute (189 lit/min), per elevator. Sump pump and piping must be sized to accomplish this output, regardless of head pressure or piping run.

b. Discharge to an approved location, outside of the elevator hoistway, MR, CR, and MS, that will accommodate full pump output and comply with all applicable discharge permits, regulations, and statutes.

c. Coordinate sump pump size with Architect to ensure that the sump pump and control sensors will fit completely within the sump.

d. Coordinate power requirements with electrical engineer.

5-2.1.1 Hydraulic Elevator Requirement.

For hydraulic elevator, in addition to the requirements of 5-3.1, provide a sump pump oil sensing control system designed to allow water to be pumped out of the sump without pumping oil/hydraulic fluid from the elevator hoistway pit. The sump pump control system must include an audible alarm and visual indicators for water and oil. Install alarm indicators and controls in the elevator MR **1**\ or CR. The system must alarm with high water level and the presence of oil in the sump. /**1**/

5-3 HYDRAULIC ELEVATOR CYLINDER PIPING.

5-3.1 In-Ground Cylinder Well Casing.

A dry, plumb, steel well casing must be provided for every in-ground cylinder assembly. The well casing must be located according to the elevator manufacturer's design. The well casing must have a minimum ¼ inch (6 mm) thick wall and a welded 1/2 inch (13 mm) thick steel bottom.

5-3.2 Hydraulic Oil Supply Piping.

Hydraulic oil lines must remain in or under conditioned space from end to end and remain within the building footprint. For all buried hydraulic lines between hoistway and MR or MS, provide straight pipe run in PVC pipe sleeves. Inside diameter of the PVC must be a minimum of 4 inches (102 mm) larger than the outside diameter of the supply line fittings.

CHAPTER 6 ELECTRICAL

6-1 ELEVATOR MACHINE ROOM, CONTROL ROOM, AND MACHINERY SPACE.

6-1.1 Elevator Power Supply.

For each elevator group, provide electrical power service from the main building electrical distribution panel to the elevator machine room. Designer must consider type of elevator drive specified and design accordingly. Coordinate with Designer of Record for elevator power requirements.

6-1.2 Elevator Disconnecting Means.

Provide elevator disconnecting means on the wall inside the MR and CR, on the strike jam side of the entrance door, within sight of the elevator equipment it controls.

6-1.2.1 Shunt Trip Disconnect.

For elevators with fire protection sprinklers in the elevator MR, CR, MS, or top of hoistway, provide a shunt trip circuit breaker in the elevator MR or CR for each individual elevator main power, and emergency power if provided. Shunt trip breaker design must comply with the following:

a. Shunt trip breaker must be designed to be operated by actuation of the sprinkler flow switch(s) designed to automatically open the power supply to the elevator. Power must be restored manually.

b. Breaker enclosure must include a safety-switch type handle for manual operation of the breaker.

c. Breaker handle must be capable of being locked in the open position only.

6-1.2.2 Sprinkler Line Flow Switch.

Provide sprinkler line flow switches as required by Chapter 7, Fire Protection. Provide an electrical circuit for actuation of the elevator main-line shunt trip disconnect. The sprinkler line flow switch control circuit must be monitored for the presence of operation voltage. Loss of voltage must cause actuation of a supervisory signal **\1** **/1/** at the building fire protection panel.

6-1.2.3 Auxiliary Contact.

Hydraulic elevators that are not designed for building emergency power generator operation must be designed and equipped with auxiliary power lowering operation for the purpose of lowering the car in the case of failure of the main power supply. When an elevator is equipped with auxiliary power lowering operation, the main line disconnect must be designed with an auxiliary contact to prevent automatic lowering operation when the main line disconnect is in the open position.

6-1.3 MR, CR, and MS Lighting and Receptacles.

Provide a separate 120 VAC branch circuit for each elevator MR, CR, and MS lighting and receptacles. Provide a minimum of two 2-light, 4 feet (1.2 m) long fluorescent, LED, or equivalent energy efficient lighting fixtures for illumination. Provide lighting fixture housings that are dust tight and rated for damp locations. Lighting must provide a minimum of 19 fc at floor level, in all areas of the MR, CR, and MS. The lighting must not be equipped with automatic controls or be fed from the load side of a GFCI circuit.

6-1.4 Dedicated Branch Circuits.

For each of the following circuits, provide a separate, dedicated branch circuit with a fused disconnect or breaker in the elevator MR or CR. Disconnects and breakers must be designed to be lockable in the open position only.

a. Elevator 120 VAC circuit for elevator cab lighting and receptacles.

b. Elevator cab HVAC equipment circuit **1**\ (if provided)

c. Elevator hoistway pit sump pump power and control system.

d. Elevator door controller (if provided)

e. Pit & hoistway lighting

f. MR, CR, or MS lighting

g. Pit GFCI receptacles

h. MR, CR, or MS GFCI receptacles

i. MR or CR Heating and Cooling system

j. Oil Cooler

k. Oil Heater /**1**/

6-1.5 Emergency Power.

Design power and control circuits to accomplish automatic transfer of power from normal building power to emergency power operation for elevators that will operate on emergency power. Coordinate elevator emergency power design with designer of record and the results of the client survey, as detailed in Par 2-4.2. Design requirements include the following:

a. Design electrical power circuit from emergency buss to elevator mainline disconnect(s) for all elevators that will operate on emergency power.

b. Determine which elevators will operate simultaneously on emergency power. Design emergency power system capacity to operate these elevator(s), simultaneously, at rated speed with rated load.

c. Coordinate design of the Automatic Transfer Switch (ATS) electrical control circuit with the elevator controller manufacturer's requirements.

d. Verify location of elevator MRs and CRs for potential control wiring interconnections for sequential elevator return operation.

e. Provide manual selector switch in main elevator lobby area(s) to allow emergency personnel to override the automatic emergency power selection.

f. Provide emergency power for MR, CR, and MS lighting and HVAC equipment.

g. Provide emergency power for Cab lighting and Cab HVAC equipment.

h. Provide emergency power for hoistway pit sump pump operation.

6-1.6 Emergency Communication Systems.

For elevator emergency phone in the elevator cab, provide a dedicated elevator communication service line for each **1**\ group that enables emergency response personnel to call back to any one of the individual elevators in the group and identify their location. /**1**/ Locate elevator communication line outlet adjacent to each elevator controller. Indicate outlets on telephone riser.

6-1.6.1 Fire Command Center.

For all elevators with a travel of 60 feet (18.3 m) or greater, provide emergency communication between the elevator cab and the building Fire Command Center.

6-1.7 Firefighters' Emergency Operation (FEO).

Design building fire detection and alarm system for an effective interface with the elevator controller for actuation of Fire Fighter's Emergency Operation (FEO). For FEO actuation, detail ceiling mounted fire alarm initiating devices in elevator lobbies, elevator MR or CR, and elevator hoistway where required, in conformance with UFC 3-600-01. Indicate devices on electrical drawings unless there are separate fire protection drawings. Coordinate with Fire Protection Engineer.

6-1.7.1 FEO Relay Modules.

Mount FEO operation modules on the wall inside the elevator MR or CR. Coordinate with Designer of Record for identification of FEO Designated and Alternate Landings.

\1\ /**1**/

6-2 ELEVATOR HOISTWAY.

\1\ /1/

6-2.1 \1\ Hoistway and Pit Lighting. /1/

Design hoistway **\1** and **/1/** pit lighting to provide a minimum of 10 fc at the pit floor in all areas of the pit. Hoistway lighting design must include a minimum of two lighting fixtures for lighting of the elevator hoistway pit. The fixtures must have a one piece, molded, high-impact clear acrylic diffuser with a secure seal against dust and moisture. A similar fixture must be provided at a minimum of every 10 feet (3 m) vertically up the hoistway. The fixture at the top of the hoistway must be mounted on the ceiling. For control of the hoistway lighting circuit, provide two 3-way switches inside the elevator hoistway, at a height of 4 feet (1.2 m) above the top and bottom elevator landings. Mount the switches on the hoistway wall, adjacent to the hoistway entrance strike jamb. The lower level lighting switch must be located adjacent to the hoistway pit access ladder.

6-3 ELEVATOR HOISTWAY PIT.

6-3.1 Sump Pump Receptacles.

Provide a separate branch circuit supplying power to the hoistway pit sump pump. Provide a dedicated simplex receptacle, **\1\ /1/** to supply the permanently installed sump pump. Mount sump pump receptacle 5 feet (1524 mm) above elevator pit floor. Provide LED indicator light to verify circuit is energized. For hydraulic elevators, provide an additional GFCI duplex receptacle in the elevator MR, CR, or MS to supply power to the sump pump control system.

6-3.2 Hoistway Pit GFCI Receptacles.

Provide a separate branch circuit supplying the hoistway pit **\1** receptacles with **/1/** a minimum of two duplex GFCI receptacles in the pit. Locate one receptacle on each side wall of the hoistway, at 3 feet (915 mm) above pit floor. For hydraulic elevators, provide one additional receptacle on the rear wall of the hoistway at a height of 3 feet (915 mm) above the pit floor for elevator oil-scavenger-pump power.

6-3.3 NEMA 4 Electrical Enclosures.

Provide NEMA Type 4 electrical enclosures per NEMA ICS6 for all electrical equipment located less than 4 feet (1219 mm) above the pit floor. Electrical enclosures must be water-tight, dust-tight, and identified for use in wet locations in accordance with the requirements in NFPA 70. Hydraulic elevator scavenger pump receptacle must be provided with an in-use cover.

6-4 \1\ GENERAL WIRING REQUIREMENTS.

Only electric wiring, raceways, and cables used directly in connection with the elevator are permitted inside the elevator MR, CR, Hoistway, and MS. All conductors and optical fibers except traveling cables must be in conduits.

6-4.1 Allowable electrical wiring and cables.

Allowable wiring includes wiring for elevator power control and operation, elevator communication, fire alarm and fire protection signals, lighting, receptacles, sump pump, and elevator MR, CR, and MS heating and cooling systems.

6-4.2 Separate raceways and conduits.

Provide separate electrical raceways and/or conduits for each building trade discipline; separate electrical raceways and/or conduits must be provided for:

a) Elevator contractor’s power and control wiring for operation of elevator system.

b) Fire alarm and fire protection signals and controls for the interface with the elevator system.

c) Electrical contractors power and control wiring for the lighting, receptacles, heating and cooling, and sump pump power in the MR, CR, MS, and Hoistway. /**1**/

This Page Intentionally Left Blank

CHAPTER 7 FIRE PROTECTION

7-1 FIRE ALARM SYSTEM.

Design all elevator installations with Firefighters' Emergency Operation (FEO). Provide fire alarm detection and alarm system for actuation of elevator FEO and automatic elevator operational response to fire alarm initiating devices located in the elevator machine room, elevator lobbies, and elevator hoistway, as required by UFC 3-600-01 Fire Protection.

7-1.1 Elevator Controller Interface.

Utilize FEO operation relay modules for the interface between the building fire alarm panel and the elevator controller. Indicate fire alarm initiating devices, FEO relay modules, and connections on fire protection drawings or on electrical drawings if fire protection drawings are not provided. Coordinate with Electrical Engineer.

7-1.2 FEO Designated and Alternate Landings.

Determine FEO designated and alternate landings during the facility design process and identify same in the design submittal package. Coordinate FEO landing designations with the base or local fire department that will respond to a fire alarm at the facility.

7-2 FIRE PROTECTION SYSTEM.

In buildings protected with an automatic sprinkler system, comply with UFC 3-600-01, applicable codes, and the following.

7-2.1 Machine Room and Hoistway Sprinkler Protection.

For elevator MR and hoistway sprinklers located more than 2 feet (610 mm) above the pit floor, design for a supervised shut-off valve, check valve, flow switch, and test valve in the dedicated sprinkler line feeding the elevator MR and/or hoistway. Locate these items outside of and adjacent to the MR and/or hoistway. Actuation of the flow switch must remove power to the elevator by shunt trip breaker operation. Shunt trip actuation must be instantaneous; the flow switch must not have time delay capability.

7-2.2 Hoistway Pit Sprinkler Protection.

In buildings protected with an automatic sprinkler system, provide sprinkler in the pit for hydraulic elevators (except in Italy). Locate sprinkler head no more than 2 feet (609 mm) above the pit floor. Actuation of a pit sprinkler within 24 inches (610mm) of the pit floor must not remove power to the elevator.

7-2.3 Machine Room Fire Extinguisher.

On MR drawings, indicate fire extinguisher on the wall, inside the elevator machine room, on the strike-jam side of the MR door.

APPENDIX B BEST PRACTICES

This appendix identifies and describes standard elevator systems that are available in the elevator industry and best practices associated with each type of elevator. The best practices represent design concepts adopted by the DOD to address typical facility types, proven facility solutions, lessons learned, facility system safety, and total ownership cost.

B-1 ELEVATOR MACHINE ROOM.

The elevator Machine Room is the most critical building component of an elevator installation. The elevator machine room is the one functional area in the building that is designed and designated for the safe and effective maintenance, service, repair, and safety code mandated inspection and testing of the elevator system. During diagnostic evaluation and testing of the elevator, the certified elevator technician must operate the elevator from the elevator controller and simultaneously observe and evaluate the operation of the elevator drive machine. In addition, the certified elevator inspector is required to observe the operation of the elevator drive machine and overspeed governor during safety code mandated annual performance tests of the elevator car speed, safeties, hoist ropes, drive sheave, and overspeed governor. Performance of service, repair, inspection, and testing is more effective and more efficient when the elevator controller, the elevator drive machine, and the overspeed governor are all located in the same functional area, the elevator MR. For DoD facilities, elevator systems with a machine room for each elevator or elevator group, and the elevator controller and drive machine in the MR, are the preferred design approach.

B-1.1 Safety.

Elevator systems are comprised of complex and sophisticated mechanical, electrical, hydraulic, and electronic systems that require diagnostic evaluation, maintenance, service, repair, inspection, and testing. Elevator service personnel utilize mechanical tools and electronic equipment to perform the repair, and replacement of elevator components, including the microprocessor controller, drive machine, drive motor, over-speed governor, safeties, rope-gripper, hoist ropes, traction drive sheave, machine brake, and hydraulic elevator control valve. In addition, elevator safety code officials conduct periodic inspection and testing of the elevator system. The elevator machine room is the one functional area in the building that provides a suitable area for the staging of personnel, components, service manuals, tools, and equipment and for the safe and effective performance of these critical functions.

The elevator controller, electric motor, and motor drive, are powered by electrical power circuits that range from 30 VAC to 480 VAC. During elevator service, repair, and testing, elevator personnel are exposed to electrical safety hazards that include both electric shock and arc flash. Safety hazard exposure to any other occupants of the building is minimized by locating the elevator controller, electric motor, and motor drive in the machine room vice public space areas of the facility.

B-1.2 Clearances.

Elevator machine room minimum clearances, between elevator equipment and the MR building components, are provided to facilitate maintenance, replacement, inspection, and testing of elevator components within the machine room. While these clearances may slightly exceed the ASME A17.1 code requirements, they are designed to maximize effective lifecycle sustainment of the elevator system by DOD maintenance personnel and/or contracted services.

B-1.3 \1\ Hoistway Pit Entrapment Area.

The ASME A17.1 provides a minimum standard for refuge area and accepts the potential temporary entrapment of elevator personnel under a car in the pit. Should elevator personnel become trapped and this occurs concurrently with fire sprinkler discharge and/or catastrophic hydraulic fluid line rupture in the hoistway, entrapped personnel would be at risk of drowning.

This UFC provides egress from the pit in this scenario by requiring a hoistway pit entrapment area. DoD considers the benefit of providing egress from the pit in this scenario to outweigh its additional cost. The purpose of this area is that if an entrapment occurs emergency personnel could lower a ladder in the entrapment area to rescue trapped personnel. If the pit starts flooding before emergency personnel arrives at the scene, the entrapped personnel will have an area to self-rescue by floating up the side of the elevator. /**1**/

B-2 MACHINE-ROOM-LESS ELEVATOR DESIGN.

ASME A17.1 requires an elevator drive machine to be located in either an elevator Machine Room (MR) or an elevator Machinery Space (MS). When the elevator drive machine is not located in the machine room, the elevator is referred to as a Machine-Room-Less (MRL) elevator.

B-2.1 Location and Access.

In an MRL elevator design, the elevator drive machine is relocated from the elevator machine room (MR) to the elevator hoistway. For MRL electric traction elevators, the MRL machine is typically located in the top of the hoistway. For hydraulic elevators, the hydraulic pump unit is relocated to a position along the side wall of the hoistway pit. For both types, the elevator operation controller will be located in what is then referred to as the Control Room (CR).

Machine-Room-Less (MRL) elevator design may be utilized in the design and construction of DoD Facilities. ASME A17.1 requires elevators to be designed and constructed with an accessible machinery space whenever the elevator drive machine is located within the elevator hoistway. This UFC provides specific direction for the location and access to the MS and for clearances around mechanical and electrical equipment in the MS. These safety code and criteria design requirements are intended to facilitate the safety code mandated safe and effective maintenance, service, repair, and safety code certification inspection and testing of the elevator system.

B-2.2 Construction Cost and Leasable Space.

The construction cost and leasable space benefit of using an MRL design is that the size of the elevator equipment room can be reduced since it no longer contains the elevator drive machine. Instead of having a 72 sq ft MR, the elevator equipment room can be reduced to a 40 sq ft Control Room.

However, this perceived advantage is offset by the fact that the building must also be designed with an additional mechanical area, the machinery space described in Par B-2 and B-2.1, above. For an electric traction elevator, a typical machinery space will require approximately 36 sq ft. In developing the building design, and determining the associated costs, designers must take into consideration the duplicate electrical, mechanical, and fire protection utility systems that are required for both the CR and the MS. Building and safety codes require both the CR and the MS to be equipped with lighting, electrical disconnects, fire alarm and fire protection systems, and independent HVAC systems for each area. For electric traction elevators, electrical design considerations must also include the additional run of electrical power conductors from the CR to the MS in the top of the elevator hoistway.

B-2.3 \1\ Sustainment (maintenance) Costs.

Although often costing more initially than MRL designs, machine room designs can realize lower maintenance costs over an expected building service life when considering operating costs, preventative maintenance, testing, repair, and modernization. These avoided costs can make machine-room designs life-cycle cost effective over a building service life in most applications. /**1**/

B-3 HYDRAULIC ELEVATORS.

The conventional hydraulic elevator consists of an elevator machine room (MR) located adjacent to elevator hoistway, with the elevator operation controller and hydraulic pump unit located in the elevator MR. The hydraulic pump unit consists of a hydraulic fluid reservoir, an electric motor and hydraulic pump, and control valves that regulate the movement of hydraulic fluid in and out of the pump unit. The hydraulic cylinder/plunger assembly is located in the elevator hoistway and is fully supported by the pit floor. Hydraulic fluid supply piping is installed from the pump unit to the hydraulic cylinder/plunger assembly in the elevator hoistway. When the pump unit supplies hydraulic fluid to the cylinder, the hydraulic plunger is forced up and out of the cylinder, driving the elevator up the hoistway. Downward movement of the elevator is powered by gravity and controlled by the elevator control valve in the pump unit. Current hydraulic elevator control valve technology that controls elevator acceleration, deceleration, and leveling, limits effective hydraulic elevator speed to a maximum of 150 fpm. At higher speeds, excessive slowdown and leveling time and travel distances are required for acceleration and deceleration.

B-3.1 Restricted Designs and Technology.

Roped hydraulic elevators and hydraulic elevators with a telescopic cylinder/plunger assembly (jack) are available in the elevator industry to allow the use of hydraulic elevator systems for higher rise applications. However, the acquisition and sustainment cost of these systems, including cost of equipment, installation, maintenance, and service, is comparable to electric traction elevators without the benefits of greater speed, efficiency, and performance offered by electric traction elevators. There are some, limited, applications where a roped hydraulic elevator can be the best choice, including Air Traffic Control Tower (ATCT) installations and modernizations of existing buildings that cannot support an electric traction elevator.

A non-standard, inverted hydraulic cylinder/plunger design is also available from a limited number of hydraulic cylinder manufacturers. In this design, the hydraulic cylinder is attached to the elevator cab in an upside-down configuration. The plunger protrudes from the bottom of the cylinder and presses against the pit floor. There is no inherent cost or performance benefit to this design and the sustainment cost is much greater than for a standard hydraulic cylinder design.

B-4 ELECTRIC TRACTION ELEVATORS.

Electric traction elevators may be used for all buildings. The traditional overhead-traction elevator consists of an elevator machine room (MR) located above the elevator hoistway. The elevator operation controller and drive machine are located in the elevator MR. Steel hoist ropes (cables) are suspended on the elevator machine drive sheave and the ends of the hoist ropes hang down into the elevator hoistway. In the hoistway, the elevator cab is fastened to one end of the hoist ropes and the elevator counterweight is fastened to the other end of the hoist ropes. The counterweight is used to counterbalance the weight of the elevator cab and the load in the cab, thereby reducing required motor torque and increasing energy efficiency. Alternative roping configurations are also used (e.g. 2:1) for greater energy efficiency and to allow a smaller drive machine to support a higher capacity load than it could otherwise. As identified in Section 2-4, speed limitations are directly related to the height of the building and the number of landings served by the elevator.

B-4.1 Drive Machines.

There are two types of electric traction hoist machines, geared and gearless. Elevator travel and car speed typically determine the most effective application of each type.

- Geared Traction Machine: The elevator drive motor drives a worm and ring gear assembly in the elevator drive machine. The ring gear turns the drive sheave, which moves the hoist ropes that raise and lower the elevator cab in the hoistway.
- Gearless Traction Machine: The gearless drive machine consists of an electric motor that connects directly to the elevator drive sheave; there is no gear reduction unit. Gearless machines are available with a

conventional asynchronous induction AC motor with electrically excited fields or with the more energy efficient AC Permanent Magnet (PM) motor. Rapid advances in AC PM motor and machine technology have made this a standard option for electric traction elevator drive machines. The PMAC motor, drive, and machine technology provides the same energy efficiency whether it is located in the elevator machine room or in a machinery space in the top of the elevator hoistway.

B-4.2 Energy Efficiency.

Electric motor and motor-drive energy-efficient technologies are available in the elevator industry for electric traction elevators. High-efficiency alternating current (AC) permanent magnet (PM) gearless machines have been incorporated into elevator design in the elevator industry and can provide up to 30 - 40% efficiency gains over standard geared traction drive machines. The machine utilizes an electric motor design with permanent magnets, in lieu of electrically energized field coils, to increase energy efficiency of the drive machine. In addition, “Regenerative Drive” motor control systems have been developed for use with the AC PM motor drives. This motor control system uses the energy that is developed when the elevator is running in an overhauling load condition and converts the mechanical energy into electrical energy which is fed back to the building power grid.

Electric motor and motor-drive energy-efficient technologies should be considered for all buildings. However, the current AC PM motor and drive technology provides a service life of only 35% - 60% of the standard geared traction machine. Prior to providing direction for use of regenerative elevator motor drives, additional research and cost analysis is required, with regard to a comparison of motor drive energy savings versus excessive cost of replacement of elevator motor and motor drive systems.

B-4.3 Suspension Means.

Elevator traction-steel wire rope is the industry standard for elevator suspension means (hoist ropes). Non-coated steel hoist ropes are specified for use in UFGS 14 21 13: Electric Traction Freight Elevators and UFGS 14 21 23: Electric Traction Passenger Elevators. Elevator certifying officials are required to verify safety code compliance with minimum hoist rope diameters and maximum allowable number of broken wires in the strands of the rope. The use of non-coated steel hoist ropes provides for the effective application of elevator safety code inspection and certification requirements related to hoist rope wear and fatigue. In addition, in the event that the elevator runs past a terminal landing and bottoms out on the car or counterweight buffer, non-coated steel wire rope can slip traction with the drive sheave without damaging the wire rope.

B-4.4 Cost, Performance, and Safety.

Electric Traction vs Hydraulic

Section 2-4 of this UFC provides direction for the application of elevator types to building design, based on the length of travel and number of landings served by the elevator. These limitations are driven by several factors, including effective elevator performance, cost of the elevator system, and safety of the elevator occupants.

When an electric traction elevator is included in the design of a building, building design and construction is more expensive than for buildings with hydraulic elevators. The primary reason is that, for electric traction elevators, the building structure must be designed and constructed to support the weight of the elevator equipment, the elevator capacity, and the vertical and lateral reaction loads associated with elevator operation. In addition, the costs for the electric traction elevator equipment, installation, and sustainment are greater than the associated costs for hydraulic elevators.

B-4.4.1 Application.

For lower rise buildings, hydraulic elevators were developed as an economic alternative to electric traction elevators. By using a hydraulic elevator, cost savings are realized in the design and construction of the building since the building structure does not have to support the weight of the elevator equipment, the elevator capacity, and vertical reaction loads associated with elevator operation. The elevator is supported by the hydraulic cylinder/plunger (jack) which is supported by the elevator hoistway pit floor. All vertical loading is transferred directly to the pit floor. For low rise applications, the costs for the elevator equipment, installation, and sustainment **1**\ in most cases are /**1**/ lower for hydraulic elevators than the cost of these items for a comparable electric traction elevator.

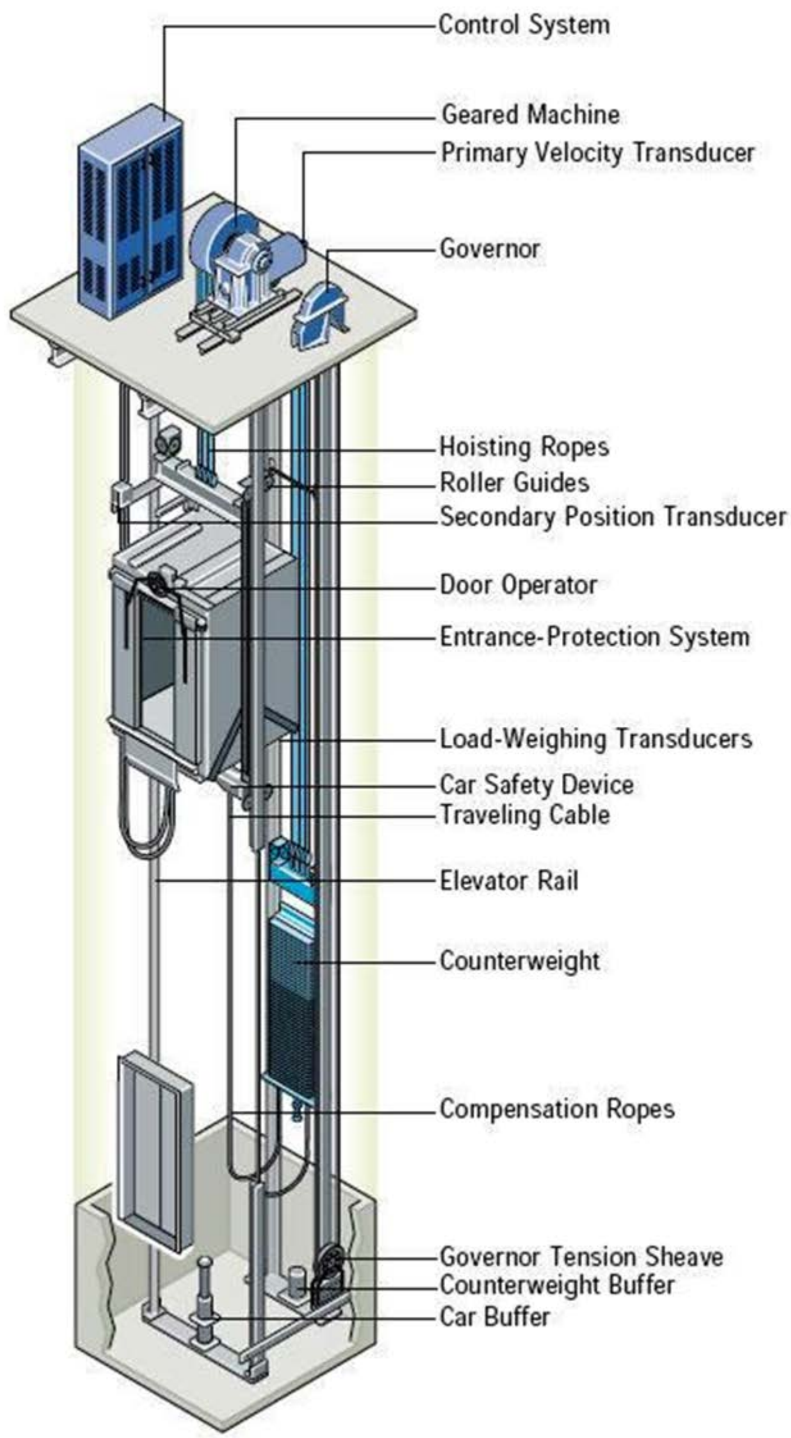
The selection of a hydraulic elevator is effective for buildings of 2 to 4 stories. For buildings of 5 stories and greater, however, the cost of the elevator equipment, the installation cost, and the cost of sustainment begin to rise substantially for hydraulic elevator systems. In addition, the speed limitations associated with hydraulic elevators has a detrimental impact on traffic flow within the building and results in excessive wait times for elevator response to hall calls and car calls. For these reasons, an electric traction elevator is the more appropriate choice for higher rise applications.

B-4.4.2 Safety.

One other critical consideration, for hydraulic elevators, has to do with safety of personnel who will be using the elevator for the life of the building. The ASME A17.1, Safety Code for Elevators & Escalators, requires all elevators suspended by wire rope to be equipped with a speed governor and elevator car safeties. The speed governor monitors the speed of the elevator and actuates elevator car safeties in the event that the elevator accelerates to an over-speed condition. These safety devices are designed to bring the elevator to a sliding stop and are effective for over-speed emergency actuation in both the up and down directions. However, ASME A17.1 does not require direct plunger hydraulic elevators to be equipped with a speed governor or safeties. The travel limitation of 44’ for hydraulic elevators serves to minimize the risk associated with catastrophic failure of the hydraulic cylinder/plunger or the hydraulic oil supply line.

Figure B-1 Electric Traction Elevator with Geared Machine

Elevator Machine Room is located Directly Over the Elevator Hoistway.



B-5 HYDRAULIC ELEVATORS.

The hydraulic drive system consists of a hydraulic fluid reservoir, hydraulic pump, and hydraulic piping from the elevator MR to the cylinder/plunger assembly located in the elevator hoistway. There are two types of cylinder/plunger configurations: direct plunger and indirect plunger.

B-5.1 Direct Plunger Hydraulic Elevator.

There are two types of direct plunger hydraulic elevators: in-ground and hole-less. The use of one or the other is governed the building design characteristics and site conditions.

B-5.1.1 In-ground Direct Plunger.

An elevator cylinder and plunger assembly is installed in the ground, below the elevator cab. The elevator cab frame is connected to the top of the plunger and moves up as hydraulic fluid is pumped into the cylinder from the hydraulic elevator pump-unit reservoir.

B-5.1.2 Hole-less Direct Plunger.

Either one or two hydraulic cylinder/plunger assemblies are installed vertically, in the elevator hoistway, with the bottom of the cylinder supported by the hoistway pit floor. The cab frame is attached to the top of the plunger and moves up as hydraulic fluid is pumped into the cylinder from a reservoir.

B-5.2 Indirect Plunger Hydraulic Elevator.

B-5.2.1 Roped Hydraulic Elevator.

The roped design is similar to the standard hole-less elevator design. The difference is that a wire rope sheave is mounted to the top of the hydraulic plunger and steel hoist ropes are attached to the cylinder base, run over the sheave, and down to the cab frame. As the cylinder runs up, the 1:2 roping moves the elevator cab twice the distance of the plunger travel. The cost of acquisition, maintenance, and service for a roped-hydraulic elevator is substantially greater than for the direct plunger types and is not permitted in DOD facilities except in the event of compelling design conditions.

Figure B-2 In-ground Direct Plunger Hydraulic Elevator

Elevator Machine Room is located Directly Adjacent to the Elevator Hoistway

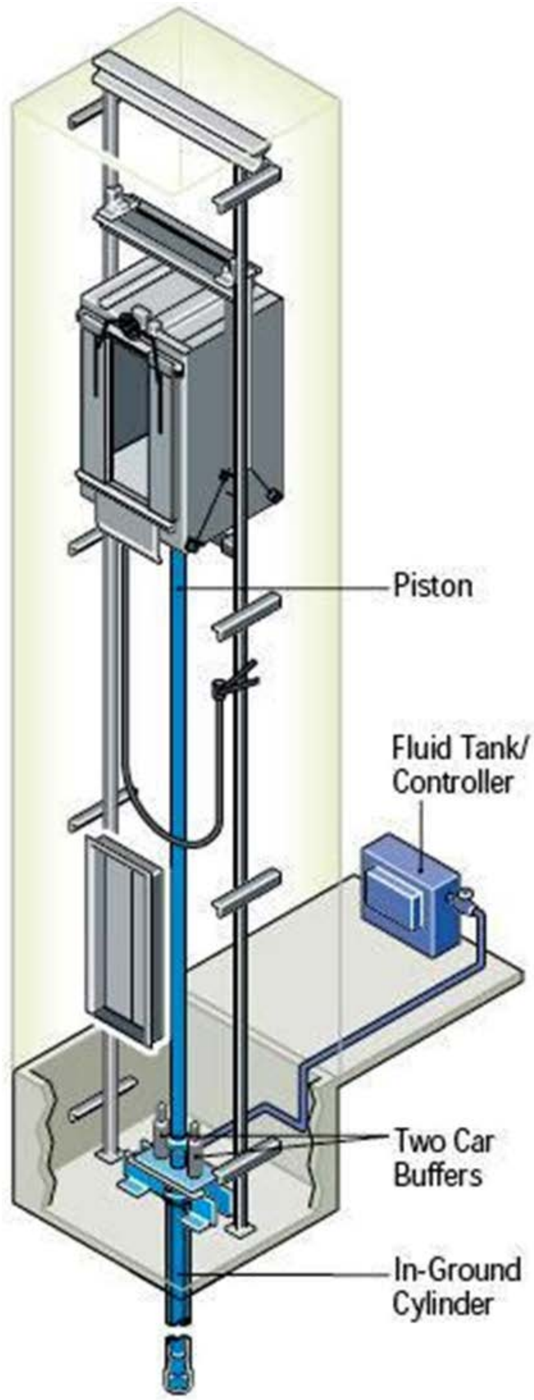


Figure B-3 Hole-less, Dual Post, Direct Plunger Hydraulic Elevator

Elevator Machine Room is located Directly Adjacent to the Elevator Hoistway.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

The purpose of this UFC is to provide technical requirements for general aspects of the electrical design of projects. Apply the criteria provided in this UFC for the development of the plans, specifications, calculations, and Design/Build Request for Proposals (RFP). It serves as the minimum electrical design requirements for design-build and design-bid-build projects. Project conditions may dictate the need for a design that exceeds these minimum requirements.

1-1.1 UFC Hierarchy.

This UFC provides the top-tier baseline requirements for electrical UFCs and is intended as a reference for all electrical work on projects. All electrical UFCs listed in Appendix E rely on this UFC for overall requirements regarding design analysis and documentation.

1-1.2 Upgrades and Modifications to Existing Systems.

Modernization of electrical systems solely for the purpose of meeting design criteria in UFCs is not required. Upgrades or modifications to electrical systems should consider the design criteria in this UFC, but it is not intended that an entire facility or system require modernization solely because of a minor modification.

For minor projects, determine if the project will affect existing electrical system calculations such as by modifying circuit breaker settings. If any electrical system calculations are affected by the modification, update the calculations, including the arc flash calculation, as part of the project.

Note: Arc flash calculation updates are necessary for electrical safety.

1-2 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 3-501-01, *Electrical Engineering*, dated 06 October 2015.

1-3 APPLICABILITY.

This UFC applies to the planning, design, construction, sustainment, restoration, and modernization of DoD-owned facilities. It is applicable to all methods of project delivery and levels of construction as defined by UFC 1-200-01 section 1-3.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 WAIVER AND EXEMPTIONS PROCESS.

The waiver and exemption process is provided in MIL-STD 3007.

1-6 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-7 PERMITS – CONSTRUCTION, ENVIRONMENTAL, AND OTHER.

Identify the permits and fees necessary for environmental, construction, and operation of facilities.

1-8 GLOSSARY.

APPENDIX D contains acronyms, abbreviations, and terms.

1-9 REFERENCES.

APPENDIX E contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies. If dates are not indicated in the contract or in the absence or other direction, the issue/version of publication in effect at the time the design started is to be used. Designs that have been started and then delayed will need to evaluate which version is applicable and may have to update to the newer version if considerable time has gone by. This may require some redesign.

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 GENERAL.

Design electrical systems to meet the needs of the activity and supporting facilities in accordance with this document.

Provide electrical equipment that is the manufacturer's standard catalog products, conforming to the latest published industry and technical society standards at the date of contract award. Underwriters Laboratories (UL) listing or third-party certification is required for all basic equipment. Use of shop or field fabricated electrical equipment assemblies that are not manufacturer's standard catalog products or do not conform to the industry and technical society standards are not acceptable.

2-1.1 Removal of Existing Cables and Conductors.

When a project requires disconnection of existing cables and conductors enclosed in either duct or conduit, physically remove the existing cables and conductors. Associated ducts or conduits may be abandoned in place only for the following conditions:

- They are planned for re-use.
- Removal will cause substantial facility damage.
- Conduits are inaccessible.

On duct systems between underground structures (handholes, manholes, and vaults), provide a pull wire (string or rope) for future use, and seal both ends of duct. Apply label to each end of the pull rope noting the location of the other end of the conduit.

2-1.2 Hot Caps and Removal of T-Splices Inside Manholes.

Regardless of voltage, do not hot cap conductors in a manhole or handhole as part of demolition.

If the conductor is part of a T-splice or Y-splice that is being removed, remove the splice and install an in-line splice for the remaining conductors. For the Army and Navy, if the conductor is part of a T-splice or Y-splice that is being re-used, a hot cap is allowed during construction to maintain an energized circuit.

Note: Hot caps are only allowed as a temporary method during construction to maintain an energized circuit.

2-1.3 Modification to Existing Electrical Equipment.

Uniquely identify equipment to be "Modified" or "Added to" and include the manufacturer's name and other pertinent manufacturer's identification (e.g., serial number, model number, style), if such information exists.

2-1.4 Salvaged Materials and Equipment.

Demolition projects may require equipment or material to be salvaged for, or by the Government. Uniquely identify all salvageable equipment or material. Include the manufacturer's name and other pertinent manufacturer's identification including serial number, model number, style, physical dimensions, and weight if such information exists. Indicate who is responsible for removal, storage, and transportation.

2-1.5 Scheduling and Sequencing Outages.

Designer of Record must:

- Determine and address scheduling, sequencing, and outage requirements including anticipated outage durations as a part of contract design documents. Provide a specific and detailed suggested sequence of construction. Identify any temporary requirements, including the need for emergency generators for backup power during construction-related outages.
- Require the contractor to review all identified requirements and submit outage requests for approval by the Government prior to initiating the specific work task.
- Require that all work complies with the electrical safety requirements contained in UFC 3-560-01 for government workers and EM 385-1-1 for contractor work.

Note: UFC 3-560-01 is usually more stringent than EM 385-1-1. However, it may be invoked on contractor work when desired and agreed to by the Activity. In that case, include the appropriate requirements during the design phase in the contract documents.

2-1.6 Energy Efficiency and Sustainable Design.

Comply with UFC 1-200-02.

2-1.7 Antiterrorism and Physical Security.

UFC 4-010-01 is a multidiscipline document which contains several standards that may impact electrical system design. Electrical designers must be familiar with UFC 4-010-01 and how it may affect the design of utilities, service entrance equipment, emergency backup systems, and bracing of electrical equipment. Incorporate the minimum standards into the design of all new construction and major renovations of inhabited DoD buildings. UFC 4-020-01 supports the planning of DoD facilities that include requirements for security and antiterrorism. Use in conjunction with UFC 4-010-01 to establish the security and antiterrorism design criteria that will be the basis for DoD facility designs.

2-1.8 Facility Systems Safety.

Incorporating safety into the engineering and design process is an important part of designing, constructing and maintaining safe facilities for use by U.S. Military, U.S. Government, and Contractor personnel. To the extent practicable and feasible, incorporate the safety engineering practices delineated under the Facilities Systems Safety (FASS) program as prescribed under OPNAV M-5100.23 Chapter 38 and DA PAM 385-16.

Ensure systems safety engineering related to equipment access and proper equipment clearances are addressed during a FASS review at the earliest phases of project development when remedies and solutions are more easily addressed rather than during construction or after facility turnover.

2-1.9 Corrosive and High Humidity Areas.

The special design requirements listed below apply when electrical equipment is routinely subjected to salt spray (such as installations at piers and wharves) or is installed in locations exposed to condensing humidity that has historically caused premature rusting and degradation of equipment enclosures. Coordinate with local Activity to obtain historical information and documentation to validate requirements.

- Provide an entire corrosion resistant transformer assembly, fabricated of stainless steel.
- Use stainless steel cabinets and hardware for pad-mounted switchgear, switchboards, and sectionalizing termination cabinets.

Note: When feasible, sectionalizing termination cabinets can be designed to comply with NEMA 4X non-metallic enclosure requirements instead of stainless steel if the enclosures are not subject to physical or structural integrity damage.

- Use stainless steel enclosures and hardware for exterior safety switches and other electrical equipment.
- Do not use aluminum-conductor steel-reinforced (ACSR) overhead conductors.
- Use weatherproof stainless steel or aluminum enclosures for outdoor engine generator applications.
- Use corrosion-resistant materials for other electrical components, such as conduit, conduit supports, couplings, fittings, plugs, connectors, receptacles, equipment supports, and luminaires.

2-1.10 Arc Flash Warning Labels.

Refer to UFC 3-560-01 for arc flash label requirements.

2-1.11 NFPA 70 (NEC) / IEEE C2 (NESC) Design Interface Points.

Design buildings and similar support structures such as piers, wharfs, parking structures, sewage pump stations, and fueling facilities in accordance with the general requirements of NFPA 70:

a. Services. Apply the following:

- The location for the "service point" (for clarification of the NFPA 70 Article 100 and IEEE C2 Section definitions): at the building/similar support structure service equipment which contains the main incoming overcurrent protective device.
- The demarcation between NFPA 70 and IEEE C2 for electrical power design purposes: is always the secondary terminal of the building/support structure utilization electric supply system.
- The demarcation between NFPA 70 and IEEE C2 for communication and security systems design purposes: is always the incoming service interface equipment including the five-foot raceway extension outside the building/support structure.

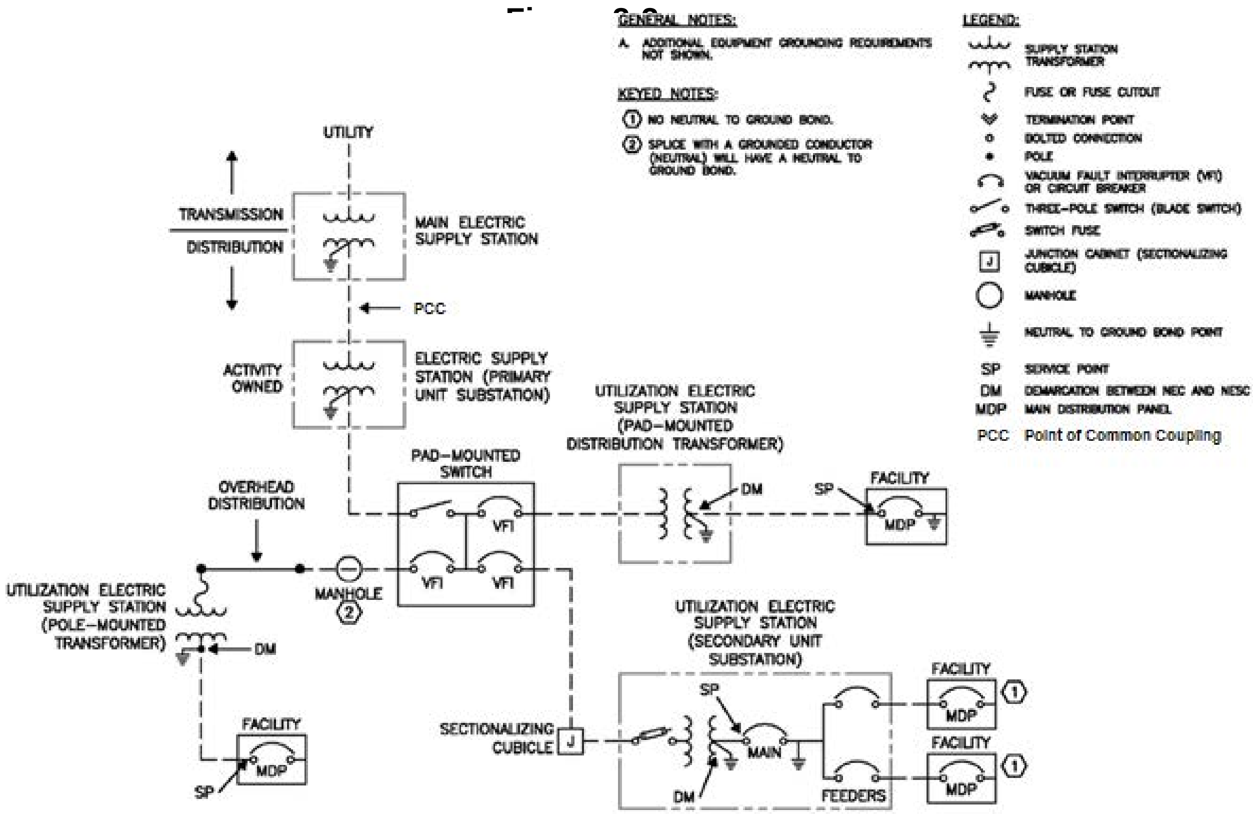
  Figure 2-1 illustrates the above in graphic form.

b. Exterior branch circuits. Design the following in accordance with the general requirements of NFPA 70:

- Exterior lighting systems (parking lot, roadway, security, and sports).
- Exterior branch or feeder circuits originating from building/support structure service equipment.
- Wiring from and connections to non-utility equipment supplying power to the wiring system of the facility or the low-voltage terminals of the medium-voltage distribution system, including engine-generator sets, photovoltaic power systems, wind turbines, and fuel cells.

c. Design all exterior underground and overhead, medium, and low voltage systems not specifically associated with a building/support structure in accordance with the general requirements of IEEE C2 except utilize the NFPA 70 ampacity and conduit fill tables for all designs.

Figure 2-1 Illustration of NFPA 70 Service Point and NFPA 70 / IEEE C2 Demarcation



2-2 SITE EXTERIOR POWER DISTRIBUTION SYSTEMS..

Provide the site utility distribution system that is compatible with the existing system and comply with UFC 3-550-01. Where the site service is derived from an existing primary feeder, the designer of record must coordinate with the government authority and receive direction regarding point of connection and concurrence that existing circuit can support the new loads.

Coordinate remote monitoring and control requirements for exterior distribution system equipment with the Activity.

2-2.1 Exterior Power Distribution Systems, Including Housing.

Comply with UFC 3-550-01.

2-2.2 Dockside Utilities for Ship Service.

Comply with UFC 4-150-02.

2-2.3 Exterior Lighting Systems.

Comply with UFC 3-530-01.

2-2.4 Airfield Lighting.

Comply with UFC 3-535-01.

2-2.5 Cathodic Protection Systems.

Comply with UFC 3-570-01

2-2.6 High-Altitude Electromagnetic Pulse (HEMP) Shielded Systems – Exterior.

Comply with MIL-STD-188-125-1A and MIL-HDBK-423. In lieu of concrete encasement for medium voltage direct buried metal conduits (ductbank), utilize a sand bed (minimum thickness of 3” (75 mm)) and topped with a minimum of 3” (75 mm) of sand. Provide a 2” (50 mm) thick concrete cap, the width of the trench atop the sand encasement. Place detectable warning tape above the concrete cap, 12” (300 mm) below finished grade to provide easy identification for future excavations.

2-2.7 Generators.

Comply with UFC 3-540-01.

2-2.8 Renewable Energy Systems.

Comply with UFC 3-540-08.

2-2.9 Microgrids.

Comply with UFC 3-550-04.

2-3 INTERIOR DISTRIBUTION SYSTEMS.

2-3.1 Interior Electrical Systems.

Comply with UFC 3-520-01.

For Army Civil Works funded projects, the requirements of NFPA 70 Article 240.2(A)(4) do not apply if all the following conditions are met.

a. The molded-case circuit breaker (MCCB) is considered mission critical.

b. A new replacement for the MCCB is not commercially available.

c. The replacement MCCB is refurbished in accordance with ANSI/PEARL Electrical Equipment Reconditioning Standard for Electrical Apparatus and Equipment used in Commercial and Industrial Applications (EERS).

d. Any equipment requiring the use of a refurbished MCCB must be prioritized for replacement.

2-3.2 Interior Lighting Systems.

Comply with UFC 3-530-01.

2-3.3 Emergency and Standby Systems.

2-3.3.1 Exit and Emergency Lighting.

Comply with UFC 3-530-01.

2-3.3.2 Fire Alarm Systems.

Comply with UFC 3-600-01.

2-3.3.3 Generators.

Comply with UFC 3-540-01.

2-3.4 Sensitive Compartmented Information Facilities (SCIF).

Comply with UFC 4-010-05.

2-3.5 Hazardous Locations.

Show boundaries of hazardous locations on the plans and identify the type of hazard by class, division, and group.

2-3.6 Stationary and Mission Batteries.

Comply with UFC 3-520-05.

2-3.7 HEMP Shielded Systems – Interior.

Comply with MIL-STD-188-125-1A and MIL-HDBK-423.

2-3.8 Renewable Energy Systems.

Comply with UFC 3-440-01.

2-3.9 Mission Critical Power, Cooling, and Control Systems.

Comply with UFC 3-520-02.

2-4 COMMUNICATIONS AND SECURITY.

2-4.1 Telecommunication Systems.

2-4.1.1 General.

Comply with UFC 3-580-01 for interior and exterior information communications technology.

2-4.1.2 Outside Plant.

Provide underground telecommunications wiring in conduit to a depth of 24 in (610 mm). Specify concrete encased conduits for telecommunications systems in accordance with UFC 3-550-01. Unless directed otherwise by the BCO, size outside category 3 copper cable for a minimum of one pair per 100 ft^2 (9 m^2) of building and provide a minimum of one 12 strand single-mode fiber optic cable for each facility. Coordinate cable selection and point of connection with the BCO and specify using RUS specifications.

Provide solid-state type primary communication circuit protectors with sneak current protection for all twisted pair media terminating inside a building from an overhead or underground outside plant.

2-4.1.3 BEQ/BOQ Housing.

Completely wire the building interior conforming to UFC 3-580-01.

2-4.1.4 Family Housing.

Provide a complete structured telecommunications system in accordance with UFC 3-580-01.

2-4.2 Television Systems.

Coordinate television system requirements with the activity.

2-4.3 Community Antenna Television (CATV) Systems.

Comply with UFC 3-580-01. Coordinate exterior cable installation with the local service provider and Base Communications Officer (BCO). Provide a conduit and pull wire from a point of connection to the base system and the main distribution equipment.

2-5 ELECTRONIC SECURITY SYSTEMS (ESS).

Comply with UFC 4-021-02.

2-6 MASS NOTIFICATION SYSTEMS.

Comply with UFC 4-021-01.

CHAPTER 3 DESIGN ANALYSIS AND DOCUMENTATION

3-1 GENERAL.

This chapter defines the minimum information to be provided at the various design submittal levels. During the design submittal process, the Designer of Record must clarify comments with the appropriate Government reviewer rather than wait until the next submittal to respond. Whenever possible, the Designer of Record is encouraged to meet with the reviewer to discuss comments.

3-2 DESIGN ANALYSIS.

The Design Analysis is a presentation of facts to demonstrate the concept of the project is fully understood and the design is based on sound engineering principles. As a minimum, include the following information in the Design Analysis.

3-2.1 Basis of Design.

Document design decisions throughout the design process. List any special features and alternatives that were considered. Provide a written narrative accurately addressing the electrical and telecommunication design. Describe the design approach to all electrical systems. Include the method used for sizing conductors, conduit, protective devices, and other equipment. Show all calculations used in determining capacities of electrical systems. When tables from industry standards are used in the design, indicate the title, source, and date of the document. Include a complete list of all design standards and references used for the design.

Update the Basis of Design for each submittal to accurately show the current state of the design. Include the information in the following sub-paragraphs as a minimum.

3-2.1.1 Exterior Primary Power Distribution Systems.

- Existing Primary Power Source – Identify the location of the point of connection into the existing primary system. Address the characteristics of this primary system, including ANSI voltage designation, phase, number of conductors, available fault current, and the circuit grounding classifications (ungrounded, uni-grounded, resistance grounded, or multi- grounded). Address the adequacy of the primary system; if inadequate, state measures proposed to correct the inadequacy.
- Estimated Electrical Project Load – Provide an estimate of total connected load (kVA) and the resulting demand load (kVA), transformer size, and service size.
- Voltage Selection – Provide basis for selection of primary and secondary voltages.
- Conductors – Include conductor size, type, number of conductors, insulation voltage rating, and insulation level.

- Standards of Design – Describe pertinent standards of design, such as voltage drop, and equipment ratings.
- Materials – Provide manufacturer's data sheets and product data for selected equipment.

3-2.1.2 Other Exterior Systems.

- Telecommunications (including voice, video and data) System – Identify point of connection into base system. Describe modifications, if required, to existing base system.
- Special Systems – Identify any special systems, such as Electronic Security Systems (ESS) or Cable Television (CATV). Describe how and where the facility will connect to the basewide Mass Notification System.
- Exterior Lighting Systems – Describe types of luminaires and illuminance values.
- Alternate Energy Sources – Describe alternate energy systems such as engine-generator sets, photovoltaic power systems, wind turbines, and fuel cells.
- Metering – Determine installation specific metering requirements as part of the electrical distribution system connection during design.
- Conductors – Include conductor type and number of conductors.
- Standards of Design – Describe pertinent standards of design, such as voltage drop and equipment ratings.
- Materials – Provide manufacturer's data sheets and product data for selected equipment.

3-2.1.3 Interior Distribution Systems.

Describe the electrical systems including the following: lighting systems; power systems; alternate energy systems, emergency lighting; emergency/standby power; grounding systems; telecommunications system; other systems such as television; physical and electronic security features such as ESS or TEMPEST. Refer to NSTISSI 7000, TEMPEST Countermeasures for Facilities, for TEMPEST criteria.

a. Electrical Characteristics – Describe the electrical system to be provided and justify its selection. Indicate ANSI voltage designation, phase, and number of conductors.

b. Switchgear and Switchboards – Provide specific design information for the following:

   - Nominal system voltage.
   - Short circuit ratings.
   - Maximum voltage ratings.

- Basic impulse level (BIL).
- Main bus ampacity.

c. Estimated Electrical Loads – Provide a breakdown, by category, of the estimated loads (kVA). Include lighting, convenience outlet, mechanical equipment, special operating equipment, user equipment, and miscellaneous load categories.

d. Wiring Methods – Indicate the type of wiring method, such as rigid conduit, electrical metallic tubing, cable tray, nonmetallic sheathed cable, and where proposed to use.

e. Conductors – Indicate the type of conductors and insulation material such as CU, AL, THW, XHHW, and where proposed to use.

f. Standards of Design – Describe the proposed standards of design, such as voltage drop, illuminance values, type of light sources, and energy conserving features.

g. ASHRAE compliance – Describe the approach for compliance with UFC 1-200-02 and its ASHRAE 90.1 requirements.

h. Special Systems – Describe the proposed type of systems. Indicate each system's function and the interrelationships between systems, when applicable. Identify government-furnished equipment, if any. Special systems include such systems as CATV, Closed Circuit Television (CCTV), Intercom, Sound, Nurse Call, Security, or Uninterruptible Power Supplies (UPS). Identify special security requirements. Identify special physical security requirements.

i. Telecommunications Systems – Identify space required for telecommunication equipment, and size of incoming duct/conduit. Include documentation concerning telecommunications room sizes, to accommodate interface equipment provisions for multi-use systems (i.e. special use systems, such as voice, video, and data).

j. Materials – Where appropriate, like for design build, provide manufacturer's data sheets and product data for selected equipment.

3-2.1.4 System Maintainability.

Design the system in a manner that facilitates safe periodic maintenance of the equipment in accordance with Section 2-1.8.

3-2.1.5 Instrumentation and Controls.

Coordinate all interfaces with instrumentation and control systems provided by other disciplines, and provide required connections, either empty conduits or power wiring as required. Normally, the designer for the discipline that is responsible for the process (such as electrical, mechanical, or civil) is also responsible for the instrumentation and controls design of that system.

3-2.2 Electrical Calculations – Overview.

The Designer of Record (DOR) is responsible for providing calculations (in accordance with the associated follow-on paragraphs) to verify proper design and operation of the facility to the point of connection to the existing electrical systems.

Note: There can be differences in how the required electrical analyses are handled, depending on whether the project is design-build or design-bid-build. Army projects might also use UFGS 26 05 73, Power System Studies, as the method for specifying requirements associated with the coordination study during the construction phase.

The DOR is also responsible for:

- Contacting and obtaining all utility data required to complete the relay coordination study from the respective Base Electric Utility Department or Private Utility Company including existing upstream protective device types and settings. The information needed for the electrical analysis depends on the point of connection to the primary distribution system and the scope of the project.
- Determining the different operational configurations. If the facility or system has various operational configurations (such as different transformer supplies, emergency generator operation, UPS bypass, or microgrid) or operational modes (such as normal parallel mode, transition-to-island mode, island mode, and reconnection mode), evaluate each possible operating configuration and each operational mode, and provide the results for each case.
- Providing analyses and calculations that are described fully, written clearly, and lead the reviewer through the design by stating all assumptions and design inputs. Computer printouts are acceptable only if accompanied by explanations to allow adequate independent review of calculation methods and results.

3-2.2.1 Electrical Analysis Software.

Most electrical-related calculations for significant projects will be completed with software tools; hand calculations are typically only acceptable for minor modifications to an existing system. For power systems analyses, coordinate with the base to determine if specific software tools are required for the analyses. Whenever software tools are used to perform analyses, provide the electronic software files with each submittal. Electronic software files must be in a format compatible with the analysis software used at the Government's facility. Before using any software tools, identify any base or service-specific limitations regarding which software packages can be used.

Note: The Navy Network is only able to utilize ETAP, SKM software modules and EasyPower for electrical analysis. If project calculations are done using any other software, they must also be provided in either ETAP, SKM or EasyPower so that they *are usable by Navy personnel on the Navy Network. The designer performing the calculations shall verify with the Navy which software package they are using at that facility and provide there database calculations to the Navy in that software database.*

Note: For the Air Force, only EasyPower is certified in accordance with AFI 33-210 for use on standard desktop systems connected to the Air Force Global Information Grid and placed on the Air Force Evaluated/Approved Products List. Other software products can be used on standard desktop systems connected to the Air Force Global Information Grid after they have been certified in accordance with AFI 33-210 and placed on the Air Force Evaluated/Approved Products List.

3-2.2.2 Electrical Calculation Summary.

Provide calculations that include a complete analysis with supporting data. Address system arrangement; voltage selection; and major equipment selections including load analysis and equipment sizing calculations. Whenever sizing electrical equipment, such as transformers, breakers, or electric cables, provide calculations to demonstrate proper facility design. Provide the following calculations unless the Basis of Design clearly explains why a particular calculation type is not applicable:

a. Load analysis.

b. Short circuit analysis, including protective device interrupting rating.

c. Protective device time-current coordination study.

d. Arc flash analysis.

e. Voltage drop.

f. Motor starting analysis.

g. Lighting.

h. Underground structure design.

i. Cable pulling tension.

j. Directional Boring

k. Sag, tension, and guying analysis.

l. Cathodic protection calculation.

m. Lightning protection analysis.

n. CATV network loss calculations.

o. ESS calculations.

p. Alternate energy system calculations.

q. Utility interactive systems and distributed resources island systems evaluation.

r. ASHRAE 90.1 calculations.

Detailed requirements for each calculation item in the list are contained in the following paragraphs.

3-2.3 Load Analysis.

3-2.3.1 Preliminary Basis of Design.

a. Load Analysis for Service Entrance Equipment, Including Feeders:

- Complete a preliminary load analysis (Basis of Design). Base calculations on NFPA 70 and use load information provided in Appendix B or ASHRAE 90.1 as applicable. Use Appendix C to apply demand and load factors when sizing the service entrance transformer only. Do not apply these factors to distribution equipment downstream of the service entrance transformer.

b. Load Analysis for Service Entrance Transformer:

- Select appropriately sized transformer based on:
  i. The standard available ratings and
  ii. The calculated demand load which is connection to each transformer.
- Apply the demand and diversity factors from Appendix C to the preliminary load analysis to determine the transformer size.
- For building designs, do not exceed a service transformer size greater than 12 VA/square foot (130 VA/square meter) of facility gross floor area or 70% of the total connected load on installations served by transformer rated 300 kVA or greater. Any design calculations exceeding these requirements must be specifically approved by the technical reviewing authority.

Note: The above check is intended to serve as a simple confirmation that the facility transformer is not oversized.

c. Load Analysis for Emergency/Standby Generator:

- Provide sizing calculations including starting kVA.
- Refer to UFC 3-540-01 for additional load analysis requirements, including the effect of UPS systems on generator sizing.

d. Load Analysis for Alternate Energy Systems:

- Provide maximum power calculations applicable to the type of alternate energy system. This includes:
  i. DC systems, including 270 VDC charging systems.
  ii. Frequency conversion equipment.
  iii. Renewable energy systems.

e. Load Analysis for Uninterruptible Power Supply (UPS):

- Provide sizing calculations in accordance with UFC 3-520-01, section entitled “Stationary Batteries and Battery Chargers”.

f. Load Analysis for utility interactive systems and distributed resource island systems (microgrids). Provide a load analysis in accordance with IEEE Std 1547.4 Clause 5. Include a system one-line diagram with system interconnection points. Evaluate historical demand profiles (real and reactive) and identify any large motor loads. Include in the load analysis a calculation of real and reactive power requirements in normal and island mode of operation.

Note: Microgrids are not included with all projects. When required by the project scope of work to install a new system or to incorporate a microgrid into an existing system, provide a complete description of the microgrid including its connection points to the system and how the system will operate.

g. ASHRAE 90.1 calculations:

- Power allowance for lighting.
- If the design methodology requires additional receptacles to satisfy the ASHRAE 90.1 automatic receptacle control criteria, identify as a line item in the system load analysis.

3-2.3.2 Follow-On Submittals.

a. Load Analysis for Service Entrance Equipment, Including Feeders:

- Complete a load analysis (Basis of Design). Base calculations on NFPA criteria.

b. Load Analysis for Service Entrance Transformer:

- Apply the demand and diversity factors from Appendix C to the final total connected load analysis to determine the transformer size. For example, Diversity Factor - A distribution feeder serves 4 buildings, each has a peak demand of 25 KW. The feeder peak demand is equal to 80 KW. The diversity is equal to 80/100 or .8. Demand Factor - a residence having 12,000W of total connected load has a maximum demand load of 9,000W. The demand factor is 9,000/12,000= 75%.
- For building designs:
    - For all transformers, do not exceed a service transformer size greater than 12 VA/square foot (130 VA/square meter) of facility gross floor area.
    - For a transformer rated 300 kVA and larger, do not exceed a service transformer size of 70% of the total connected load.

- Validate that transformer size has not been increased by the design approach taken to comply with ASHRAE 90.1.

Any design calculations exceeding these requirements must be specifically approved by the Technical Reviewing Authority.

c. Load Analysis for Emergency/Standby Generator:

- Provide sizing calculations including starting kVA.
- Refer to UFC 3-540-01 for additional load analysis requirements, including the effect of UPS systems on generator sizing.

d. Load Analysis for Alternate Energy Systems:

- Provide maximum power calculations applicable to the type of alternate energy system. Identify actual power delivered from source.

e. Load Analysis for Uninterruptible Power Supply (UPS):

- Provide sizing calculations in accordance with UFC 3-520-01, section entitled “Stationary Batteries and Battery Chargers”.

f. Load Analysis for utility interactive systems and distributed resource island systems (microgrids) in accordance with the criteria provided in Section 3-2.3.1.f.

g. ASHRAE 90.1 calculations in accordance with the criteria provided in Section 3-2.3.1.g.

3-2.3.3 Load Analysis Criteria.

Use the following additional criteria for the load analysis:

- Assign a “0%” demand factor for fire pump loads in demand calculations.
- Design underground service entrance distribution using commercially-available thermal analysis software based on Neher-McGrath or finite element methods. Assume a load factor of 100%.
- Size the service entrance conductors for a continuous load current not less than the ampacity of the main bus in the service entrance equipment. For example, provide conductors sized for 1200 amperes with 1200 ampere rated equipment which is protected with a 1000 ampere device. Listed conductor size adapters are acceptable. Design main service equipment to provide a minimum of approximately 15% combination of spare devices/space to accommodate future work. Include this 15% spare capacity in the demand load calculations for future or anticipated load growth.

Note: Consideration for spare device/space above 15% should be addressed during the scoping of the project.

- Select size of service entrance transformers based on the standard available ratings.

Note: This criterion does not apply to secondary substation transformers, dedicated site lighting transformers, etc.

For small systems 225 amps or less, or for small modifications to large systems, the load analysis can be performed manually using the above criteria. For larger systems, a load analysis using computer software tools is necessary to evaluate properly all of the possible facility modes of operation.

3-2.4 Short Circuit Analysis.

Complete a short circuit analysis in accordance with IEEE 3002.3 and include the following in the analysis:

a. Include the utility system data as well as data for the distribution system. Contact the Contracting Officer or technical reviewing authority for the utility system data and available fault current on the primary side of medium voltage equipment. When accurate data does not exist, assume that maximum available fault exists, up to a possible infinite bus on the primary side of the upstream transformer, and design the system assuming such conditions.

b. Calculate the available short circuit and ground fault currents at each bus. Incorporate any motor contribution in determining the momentary and interrupting ratings of the protective devices.

c. Use a commercially available software program designed for the type of required analysis. Incorporate pertinent data and the rationale employed in developing the calculations in the introductory remarks of the study. Comply with IEEE C37.06, IEEE C37.13.1, or UL 489 criteria, as applicable, for equipment interrupting capability evaluations.

d. Where diagrams will not fit on standard letter size paper, present the data determined by the short circuit study in a tabular format. Include the following:

    - Device identification
    - Operating voltage
    - Protective device
    - Device rating
    - Calculated short circuit current

e. Coordinate the calculated short circuit current at the service entrance with the available fault current labeling required by NFPA 70 for the service entrance equipment (switchgear, switchboard, or panelboard).

3-2.5 Protective Device Time-Current Coordination Study.

3-2.5.1 Selective Coordination.

Design the electrical system such that any fault in the system will be preferentially isolated by the selective operation of only the overcurrent protective device closest to the faulted condition. If required by the contract, perform a coordination study at the design stage to establish the basis for the system design and to enable completion of an initial arc flash analysis. Provide a final coordination study based on the as-built configuration of the system. Identify locations where selective coordination is not achievable, such as with instantaneous trips on molded case circuit breakers.

The Designer of Record is responsible for the selective coordination of overcurrent protective devices, including protective relays and medium voltage protective devices, high side transformer protection for distribution transformers, main secondary breakers, and secondary feeder protective devices. Ensure coordination between the new equipment design and the existing distribution system.

Selective coordination shall not be required between two overcurrent devices located in series if no loads are connected in parallel with the downstream device.

Any permanently installed backup power source required by published DoD or agency-specific criteria shall be considered a legally required standby system or emergency system.

3-2.5.2 Required Time-Current Data.

The Designer of Record is responsible for ensuring that construction contract documents require the Contractor to submit the transformers' inrush current and damage curve and the manufacturer's published time-current curves for primary fuses, relays, main secondary breakers, and secondary feeder protective devices. This information is required during the submittal process. Using the time-current curve data, perform a coordination study in accordance with the following paragraphs to ensure that protective devices are properly coordinated.

3-2.5.3 Coordination Study.

If required by the contract, provide a complete coordination study that includes a system one-line diagram, short circuit and ground fault analysis, and protective coordination plots.

The Designer of Record is responsible for providing to the Contractor settings for relays, main secondary breakers, secondary feeder protective devices, and any other protective devices in the circuit. Base the final coordination study and the specified setting information on the as-built configuration.

3-2.5.4 One-Line Diagram(s).

Show on the one-line diagram all electrical equipment and wiring to be protected by the overcurrent devices including breakers and fuses. Multiple one-line diagrams may be used if required to clearly present all the required data. Also, show on the one-line diagram the following specific information:

a. Calculated short circuit values and X/R ratios at the project utility point of connection.

b. Breaker and fuse ratings.

c. Transformer kVA and voltage ratings, percent impedance, and wiring connections.

d. Identification and voltage at each bus.

e. Identify feeder cable sizes and conduit sizes. Identify configuration such as 4-#2 AWG, 1-#4 AWG ground in 1-1/2" conduit. (Use worst case fill based on allowed materials.) Where limitations on materials and insulation are specifically required due to special environments, clearly identify this when applicable.

3-2.5.5 Coordination Curves.

Prepare the coordination curves to determine the required settings of protective devices to assure selective coordination. Graphically illustrate on a log-log scale that adequate time separation exists between series devices, including the utility company upstream devices where applicable. Plot the specific time-current characteristics of each protective device in such a manner that all applicable upstream devices will be clearly shown on one sheet. Include the following information on the coordination curves:

a. Device identification.

b. Voltage and current ratios for curves.

c. 3-phase and 1-phase ANSI damage points for transformers directly fed from the switchgear.

d. Minimum melt and total clearing curves for fuses.

e. Cable damage curves.

f. Transformer inrush points.

g. Maximum short circuit current.

3-2.5.6 Settings.

Develop a table to summarize the settings selected for each protective device. Low voltage protective devices less than 225 amperes, unless adjustable trip, are not required to be included. Address all relays and relay functions. Include in the table the following:

a. Device identification and breaker or load controlled.

b. Relay CT ratios and electronic set point equivalents for relay tap, time dial, and instantaneous pickup points.

c. Circuit breaker sensor rating.

d. Fuse rating and type.

e. Ground fault pickup and time delay.

f. Differential relay settings.

3-2.5.7 Coordination Study Report.

Include the following in each coordination study report:

a. A narrative describing the analyses performed, the methods used, and the desired method of coordinated protection of the power system.

b. Descriptive and technical data for existing devices and new protective devices. Include the manufacturers' published data, nameplate data, and definition of the fixed or adjustable features of the existing or new protective devices.

c. Documentation of the utility company data including system voltages, fault MVA, system X/R ratio, time-current characteristic curves, current transformer ratios, and protective device settings.

d. Fully coordinated composite time-current characteristic curves to ensure coordinated power system protection between protective devices or equipment. Include recommended ratings and settings of all protective devices in tabulated form.

e. Evaluation of the total feeder inrush current with respect to relay or circuit breaker overcurrent trip settings. Power restoration following an outage should not cause a feeder trip on overcurrent.

3-2.6 Arc Flash Analysis.

Complete an arc flash evaluation in accordance with NFPA 70E, IEEE C2 and IEEE Std 1584 (including Amendments 1 and 2), and IEEE Std 1584.1 as applicable.

Note: Nominal system voltages over 15 kV must follow IEEE C2 (NESC) instead of NFPA 70E and IEEE Std 1584.

Note: Provide PPE criteria in accordance with Chapter 4 of UFC 3-560-01.

Complete an arc flash evaluation on direct current (DC) systems analysis in accordance with NFPA 70E. Include the following:

a. Description of the software used to perform the evaluation, including an explanation of software-specific user adjustable analysis settings that were used for the study.

b. Scope of analysis. When switchgear, switchboards, and panelboards are equipped with main circuit breakers, provide both “Line Side” and “Bus Side” results for each item. If the facility or system has different operational configurations, such as different transformer supplies, emergency generator operation, or UPS bypass, evaluate each possible operating configuration and provide the arc flash results for each case. When equipment design includes dual protective device settings for the purpose of equipment maintenance (non-coordinated system), provide the arc flash result for that scenario. Summarize all data and include the worst-case results in terms of arc flash levels.

c. Assumed working distance in feet. For low voltage systems, assume a working distance of 18 in. For medium voltage systems, assume a minimum working distance of 4 ft. For high voltage systems, assume a minimum working distance of 6 ft.

d. For medium voltage and high voltage systems, credit can be taken for the associated distribution feeder circuit breaker as the upstream device if:

- Existing circuit breakers – documented maintenance and testing of the circuit breaker and relay is less than five years old.
- New circuit breakers – the circuit breaker and relay commissioning process confirm functionality in accordance with NETA ATS.

e. For existing low voltage systems, credit can be taken for the main breaker as the upstream protection device if one of the following configurations apply:

- The main breaker is located remotely (separate enclosure) from the feeder breakers.
- The main breaker is located in its own sealed compartment, such as a switchgear.

f. For existing low voltage systems, an upstream circuit breaker can be credited to clear the arcing fault if:

- There is documented maintenance and testing for the circuit breaker.

Note: Maintenance confirms the functional capability and physical condition. Testing confirms that the circuit breaker can respond to and clearing an overcurrent event in accordance with its published time-current curves.

- Documented maintenance and testing is less than five years old.

g. For new low voltage systems, an upstream circuit breaker can be credited to clear the arcing fault if the circuit breaker commissioning process confirms functionality of the trip unit in accordance with NETA ATS.

h. Calculated energy in cal/cm^2 at each evaluated location. The design goal is to establish arc flash levels that result in 8 cal/cm^2 or less. Consider remote racking mechanisms to rack breakers in and out to limit personnel exposure to an arc flash event. Specifically identify locations where this energy level cannot be achieved, such as upstream of a main breaker (between the breaker and an upstream transformer) or downstream of UPS systems.

i. Specified protective device settings to achieve the arc flash results. Reconcile arc flash protective device setting recommendations with the protective device time-current coordination study.

j. List of work locations exceeding 40 cal/cm^2.

3-2.7 Voltage Drop.

The following voltage drop requirements apply to AC and DC constant voltage systems 1000V or less unless more stringent criteria apply. The following does not apply to constant current systems or distribution systems over 1000V. In situations where the voltage within a facility's distribution system is increased over this threshold, the voltage drop requirements shall restart assuming nominal voltage when transformed below the threshold.

400Hz systems must be designed for voltage drop in accordance with UFC 3-555-01N requirements.

If the phase conductor size is increased for voltage drop, increase the size of the equipment grounding conductor proportional to the circular mil increase of the phase conductor in accordance with NFPA 70 Section 250.122.

3-2.7.1 Permitted Voltage Drop.

The maximum voltage drop permitted must not exceed 5%. Unless stricter requirements apply as adopted by this or other UFCs, feeders and service conductors must be limited to 3% voltage drop and branch circuits must be limited to 3% voltage drop, with no greater than 5% total. The starting point for this calculation is defined below.

Calculation limits must be based on the cumulative amount of voltage drop seen at a given location in the distribution system from the start of calculation identified below, not on an individual basis by circuit.

3-2.7.2 General Voltage Drop Mitigation Strategies and Impacts.

Voltage drop can be mitigated through various strategies, including increasing conductor size, reducing the circuit's load, decreasing the conductor's length, decreasing conductor temperature, and improving power factor. When establishing distribution equipment placement within a facility, locate panelboards relatively central to the loads supplied to minimize circuit lengths. Likewise, routing the majority of the distribution at 480/277V and stepping down to 208/120V more locally to the loads served will yield a lower voltage drop to the end devices; this strategy needs to evaluate a balance between transformer and circuit costs, as well as requirements to submeter different load types when applicable.

Note increased conductor sizes will yield lower conductor resistances, lead to increased fault current values, and impact arc flash values at the equipment buses, potentially leading to protection coordination issues. Designers must ensure all conductor sizes are established prior to performing final fault current and arc flash calculations, and update safety calculations when modifying existing systems.

3-2.7.3 Voltage Drop Relationship with Utilization Voltage.

Voltage drop calculations focus on energy loss through conductors, and voltage drop contributes to utilization voltage for end users. However, voltage drop and utilization voltage, which is the actual voltage seen at end-use devices and equipment, are not synonymous. Devices and equipment have acceptable utilization voltage ranges within which operation can occur, the lower bound of which can be of a lower voltage than yielded by the maximum permitted voltage drop alone. Other system losses occur throughout the distribution system, most notably through transformers, and the voltage delivered by the utility service may deviate from the nominal voltage assumed in calculations. Transformer tap settings aid in providing appropriate downstream utilization voltage, however, the use of transformer taps does not negate energy losses incurred through conductor impedance voltage drop.

Design and construction personnel must remain cognizant of the utilization voltage requirements for the equipment and appliances served. Adjustments to the distribution system, such as the use of transformer taps and/or an increase in conductor sizes, must be performed accordingly to ensure proper utilization voltage is provided to the end use devices while simultaneously satisfying the voltage drop energy conservation requirements.

Practices used to boost utilization voltage at the load must not be used as a method to comply with voltage drop requirements.

3-2.7.4 Calculation Assumptions and Procedures.

3-2.7.4.1 Initial Voltage.

The use of service transformer taps must not be assumed to compensate for voltage drop on the service-entrance equipment side of the calculation start point. Calculations must assume the nominal system voltage (i.e., 208V, 240V, 480V) is present at the location described for the calculation starting point.

3-2.7.4.2 Starting Point.

Voltage drop calculations must start at the point of government ownership (i.e., transformer, disconnect switch, meter cabinet, or similar). Where the government owns the exterior distribution upstream of the service transformer, the calculation must start at the service transformer secondary lugs. Where the facility is without a service transformer and supplied by independent generator or energy storage system, the calculation must start at such power supply's output terminals.

3-2.7.4.3 Load Estimations.

3-2.7.4.3.1 Capacity.

The capacity must be 100% of a circuit breaker or fuse device's nominal rating (e.g., 100A standard (80%) devices and 100A continuous (100%) devices are both considered 100A capacity) for voltage drop calculation purposes. See UFC 3-520-01 regarding Adjustable-Trip Devices.

3-2.7.4.3.2 Feeder Loads.

Size feeders to accommodate the maximum permitted load based on the circuit ampacity. Exceptions to this are as follows:

a. **Transformer Feeders.** Per ANSI C57.96, transformers complying with the ANSI standard are designed for continuous operation at the specified temperature rise for normal life expectancy at the rated kVA. The rated kVA may be different than the nameplate or nominal kVA value based upon insulation temperature rating, ambient temperature, altitude, and other operating conditions.

   For voltage drop purposes, a transformer's secondary feeders must assume a load equivalent to the transformer's nominal output rating.

   For voltage drop purposes, a transformer's primary feeders must assume the same load as identified above for the secondary feeders PLUS 6% transformer loss load.

b. **Motor Feeders.** Motor overcurrent protection is located at the overloads and NFPA 70 categorizes the circuits from the circuit breakers to the overcurrent protection as feeders. As on transformer primary circuits, circuit breakers are sized to account for inrush. Utilize the circuit's total full-load amps (FLA) based on NFPA 70 Article 430 tables for voltage drop calculations. Additionally, this circuit must be considered a "branch circuit" for voltage drop compliance purposes only.

Fire pumps must comply with the voltage drop requirements identified in NFPA 70 Article 695 in lieu of the limits stated in this section.

c. **Air-Conditioning and Refrigerating Equipment Feeders.** The voltage drop load must be the rated-load current or full-load current marked on the nameplate as identified in NFPA 70 Article 440. Additionally, this circuit must be considered a “branch circuit” for voltage drop compliance purposes only.

d. **Variable Frequency Drives/Adjustable Speed Drive Feeders.** Feeders to variable frequency drives, adjustable speed drives, and similar must be sized for voltage drop based on the drive’s maximum input current, including any drive losses. Additionally, this circuit must be considered a “branch circuit” for voltage drop compliance purposes only.

e. **Other Feeders Directly Supplying Motor-Based Equipment.** Where NFPA 70 categorizes conductors as feeders, but the conductors supply dedicated motor-based equipment or equipment assemblies such as cranes and elevators, the voltage drop calculation load must be the total FLA. Application-specific NFPA 70 demand factors may be applied to the loads when used for voltage drop calculations. Additionally, this circuit must be considered a “branch circuit” for voltage drop compliance purposes only.

3-2.7.4.3.3 Branch Circuit Loads.

a. **Lighting Circuits.** Lighting circuits must utilize the total full load of all luminaire and non-luminaire devices connected. Where the lighting circuit contains non-luminaire components such as room controllers or power packs, ensure such loads are captured.

b. **Receptacle Circuits.** Receptacle circuits (including circuits where a dedicated receptacle is provided for a single device, appliance, or equipment) must use 80% of the circuit’s capacity for voltage drop calculations.

c. **Systems Furniture Circuits.** Systems furniture circuits must use 80% of the circuit’s capacity for voltage drop calculations.

d. **Hard-Wired Appliance and Other Non-Receptacle Circuits.** Hard-wired appliance and other non-receptacle circuits must utilize the total connected load on the circuit for voltage drop calculations.

3-2.7.4.4 Circuit Lengths.

3-2.7.4.4.1 Methods.

See UFC 3-520-01 for routing estimation instructions, and utilize the applicable method as described and assigned below.

a. **End-of-Line Method.** Loads on circuits must be at the end of the circuit for voltage drop calculations unless otherwise indicated below.

b. **Point-to-Point Method.** Calculate the load contributions to voltage drop as a function of the load experienced for a given portion of the circuit except as identified in the subsequent entries of this section. That is, the entire load on the circuit is experienced to the first device, be it a load, splicing/junction point, etc. Beyond that point, the load is diminished for the next series or parallel lengths, and only those loads contribute to the voltage dropped in the associated circuit length.

The totality of the voltage dropped on any given path must be evaluated in determining a satisfactory conductor size (i.e., the path to one end device may experience less voltage drop than the path to a different end device), and the more severe condition in a comparison of multiple paths must be used for the entire circuit size.

3-2.7.4.4.2 Feeders.

The entire feeder conductor lengths from the start of calculation described above to the last circuit breaker or fuse for a given portion of the distribution system must be used in the voltage drop calculation using the End-of-Line method.

3-2.7.4.4.3 Branch Circuits.

As with feeder conductors, the entire length of the branch circuit conductors (End-of-Line) must be used in the calculation except as follows for the purposes of the voltage drop load location:

a. **Lighting Circuits.** Lighting circuits may use the Point-to-Point Method.

Where the lighting circuit contains non-luminaire components such as room controllers, power packs, or other line-voltage control devices, ensure the lengths used and loads associated used in the voltage drop calculation capture these portions of the circuit, including travelers between three- and four-way switches.

b. **Receptacle Circuits.** The load identified above must be at the farthest receptacle (End-of-Line) as routed through other receptacles, junction boxes, control devices, etc.

c. **Systems Furniture Circuits.** The load identified above must be at the point of connection to the assembly (End-of-Line) as routed through junction boxes, control devices, etc., prior to the point of systems furniture connection.

d. **Hard-Wired Appliances and Other Non-Receptacle Circuits.** Hard-wired appliances and other non-receptacle circuits may use the Point-to-Point Method.

3-2.7.4.5 Additional Calculation Considerations.

3-2.7.4.5.1 Circuit Breakers in Series for Singular Loads or Set of Receptacles.

In situations where a circuit supplies a singular load or set of receptacles but is provided with an additional overcurrent protective device local to the load, the two portions of the distribution system may collectively be considered as part of the "branch circuit" for voltage drop calculations. For example, if an interior panelboard circuit breaker supplies an exterior pedestal-mounted receptacle with a local circuit breaker, the combined length of the circuits from the panelboard circuit breaker to the pedestal circuit breaker and from the pedestal circuit breaker to the receptacle may be sized using the branch circuit requirements for voltage drop (rather than the circuit from the panelboard circuit breaker to the pedestal circuit breaker being considered part of the feeder portion of the distribution system).

3-2.7.4.5.2 Branch Circuits Containing a Mix of Load Types.

Use the worst-case load assignment for the voltage drop calculation. Where portions of the circuit are distinguishable by load type, the worst-case voltage drop calculation may be performed for each full path from source to end device and the worst-case of the comparative results must be used.

For example, a branch circuit is routed to a junction box, where the circuit is split into separate circuit paths ('A') for a set of receptacles and ('B') for a set of luminaires. The entirety of the circuit load must be included from the source to the divergent point at the junction box; include the voltage drop to this point in the sizing for the comparative calculations. Then use the sizing results from the comparative calculations between 'A' and 'B' to establish a circuit size.

3-2.7.4.5.3 Voltage Drop through Transformers.

Voltage drop through transformers due to transformer losses for design calculation purposes must be zero. When modeling, configure transformers such that the voltage drop percentages relative to the values identified in section "Initial Voltage" above on the transformer primary and secondary buses match. That is, if the totality of the voltage dropped to the transformer primary terminations is, for example, 1.50% of the nominal system primary voltage, the calculation for the start of the conductors at the transformer secondary lugs must be at 1.50% of the nominal system secondary voltage. The aforementioned load associated with transformer losses are to be accounted for in the voltage drop calculations for the distribution system upstream of the transformer.

Voltage drop mitigation measures must be through conductor size increases only, and through strategic selection of voltage systems and locations of transformation equipment.

Transformer taps must not be used in voltage drop design calculations and must be used for field adjustments only, including to account for voltage lost through the transformer or longer conductor routing lengths than estimated in design. Note the output voltage of a transformer will drop as the load increases or the power factor decreases.

3-2.7.4.5.4 Voltage Drop Allowances Addressed by Industry Standards.

For specific applications whereby a published industry standard establishes a voltage tolerance wider than the requirements of this section, the requirements of this section will end at the point at which the facility distribution system interfaces with the specific appliance, equipment, or similar system. For example, the voltage drop limits provided by this section must be met for crane systems to the point of connection at the runway electrification system, however, the voltage drop experienced through the runway and subsequent conduction paths to the eventual loads may adhere to CMAA-70 instead.

Similarly, the additional voltage drop experienced through appliance cord and plug connections are not covered under this section's requirements, which end at the receptacle connection point.

3-2.7.4.6 Power Factor.

For applications where power factor is known or can be easily estimated based on industry standards or approved sole-source equipment, utilize such information. The following are typical power factors and must be used as estimations where the specific power factor is unknown:

	208/120V	480/277V
Fluorescent Lighting	0.95	0.95
Compact Fluorescent Lighting (hardwired)	0.90	0.90
Compact Fluorescent Lighting (GU-24)	0.50	0.30
LED Lighting	0.90	0.90
Incandescent Lighting	1.00	---
High-Intensity Discharge Lighting	0.90	0.90
HVAC Package Units	0.85	0.90
Other Motors Less than 5HP	0.80	0.80
Other Motors Greater than or Equal to 5HP	0.85	0.85
Electric Resistance Heating (including Hot Water)	1.00	1.00
Kitchen Equipment	0.90	0.90
Receptacles	0.85	0.85
Other	0.85	0.85

Table adapted from California Title 24.

Unity power factor must not be used for loads other than electric resistance heating and incandescent lighting.

3-2.8 Motor Starting.

Account for both starting and running current in motor calculations.

Refer to IEEE C37.96 for calculating motor inrush and how to place the knee point from starting to running on a Time Current Curve.

3-2.9 Lighting.

Provide calculations for interior and exterior lighting systems in accordance with UFC 3-530-01.

3-2.10 Underground Structures Design.

Provide sizing and cable bending radius calculations for underground structures (manholes and handholes) with cable sizing exceeding 500 kcmil. Verify design requirements of UFC 3-550-01 are met. Coordinate with the Activity on the naming convention for underground structure identification on the drawings.

3-2.11 Cable Pulling Tension Calculations.

Provide cable pulling tension and sidewall pressure calculations for medium voltage cable in conduit. Compare the calculations to the rating of the cable.

3-2.12 Calculations for Directional Boring.

Provide calculations in accordance with UFC 3-550-01, Appendix B.

3-2.13 Sag, Tension, and Guying Analysis.

Provide calculations in accordance with UFC 3-550-01.

Crane trolley contact conductors are exempted from this requirement due to excessive enveloping of the conductor.

3-2.14 Cathodic Protection Calculations.

Provide calculations in accordance with UFC 3-570-01.

3-2.15 Lightning Protection Calculations.

Provide a lightning risk assessment in accordance with NFPA 780 Annex L and document the required level of protection.

If lightning protection is a design requirement, provide a lightning protection system in accordance with UFC 3-575-01. Provide side flash calculations as required by NFPA 780. Provide calculations for alternative grounding methods when required by the design.

3-2.16 ESS Calculations.

Provide calculations in accordance with UFC 4-021-02.

3-2.17 Renewable Energy System Calculations.

Provide calculations for renewable energy system project requirements. As a minimum, incorporate the requirements of criteria under development in accordance with Section 2-1.8. Calculations can vary with the types of renewable energy system, but typically include:

- Predicted power generation – kW and kVAR.
- Predicted energy production – kWh per year.
- IEEE Std 1547 interface compliance.
- Voltage drop.
- Ampacity requirements.
- Site orientation and safety considerations, including glare analysis for photovoltaic systems.
- Electrical protection and coordination.

3-3 DRAWING REQUIREMENTS.

Provide adequate plans, including demolition, existing conditions, and new work, legends, details, and diagrams to clearly define the work to be accomplished. Coordinate construction drawings and specifications; show information only once to avoid conflicts. For the Navy, additionally comply with FC 1-300-09N for specific drawing requirements and drawing phases.

Utilize electrical design "Best Practices Information" located at https://www.wbdg.org/dod/supp-tech-documents to facilitate drawing requirements and related equipment detail required by the remaining paragraphs of this UFC.

Provide a General Note at the beginning of the Electrical Drawings clarifying the work to be accomplished. The following note is required unless directed or approved by the government:

"ELECTRICAL WORK AND MATERIAL IS NEW AND PROVIDED BY THE CONTRACTOR UNLESS INDICATED OTHERWISE".

a. Arrangement. Arrange the Electrical Drawings in accordance with the National CAD standards at https://www.nationalcadstandard.org/ncs6/. Provide drawings that are clear and consistent in presentation and format. Follow the NFPA 70 Metric Designations (mm) and Trade Sizes (in) for conduit.

b. Multiple Conduit/Cable Runs. To avoid misinterpretation as to the quantity of cables and conduit required in multiple conduit and cable runs, use one of the following acceptable descriptions:

- Acceptable: Two 4-inch conduits, each containing four 500 kcmil and one #2 Gnd.
- Acceptable: Two 4-inch conduits, each with four 500 kcmil and one #2 Gnd
- Acceptable: Two 4-inch conduits, with four 500 kcmil and one #2 Gnd in each conduit
- Unacceptable: Two sets of four 500 kcmil and one #2 Gnd in 4-inch conduit
- Unacceptable: Parallel Service: Four 500 kcmil and one #2 Gnd in 4-inch conduit

3-3.1 Legends and Abbreviations.

Define all symbols used in the drawings in the legend. Locate legend on the first electrical sheet using multiple legends where required and identifying the specific use of each legend. Use different legends for new and existing work. Avoid using composite legends that include all symbols but fail to indicate which symbols are to be used on which drawings.

Refer to electrical technical paper TSEWG TP-12: Appendices for typical illustrations of how to properly display legends on the contract drawings. Refer to Appendix A for more information.

3-3.2 Site Plans.

Show utility point of common coupling to the base power and telecommunications systems on the site plan. Provide explicit direction on method of entering existing manholes. Provide all details including composition of duct banks and depth and configurations of the duct banks.

3-3.2.1 Coordination with Other Utilities.

Provide Electrical Site Plans that are separate and distinct from other utility site plans. Include with the electrical drawings. Electrical and civil site plans may be combined only when the project requires minor utility work. Coordinate with the electrical engineering reviewer before combining the electrical and civil site plans.

Provide the orientation of electrical drawings consistently with the civil drawings. In addition, provide the orientation of partial building or site plans identical to the orientation of the larger plan from which the partial was taken. Indicate the exact title of each detail, partial plan or elevation as identified on the cross-referenced sheet.

3-3.2.2 Overhead Distribution.

For overhead distribution use a separate symbol for each individual circuit; define each circuit by voltage level as well as number, size, and type of conductors. Coordinate guying and conductor sag information shown on the drawings with that shown in the specifications.

3-3.2.3 Pole Details.

Indicate overhead distribution pole details on the drawings. Identify pole number assignment consistent with installation standards on the site plan and require pole identifier number to be installed on pole matching installation standard.

3-3.2.3.1 Format.

NAVFAC pole details are available in Adobe PDF format and in AutoCAD format on the WBDG website at https://www.wbdg.org/dod/ufgs/forms-graphics-tables.

Provide details in situations where an applicable pole detail has not been developed. Designer developed details must contain the same level of detail equivalent to the NAVFAC pole details and include material requirements.

Review the information contained on Details OH-1.1 through OH-1.5a for examples of how to show overhead distribution work. Do not describe proposed work by referencing sketch numbers instead of pole detail designation symbols. Do not use pole detail designation symbols to describe existing facilities to be removed. To maintain the integrity of the pole details, do not modify pole details; include any required exceptions or modifications as supplemental information with the pole detail designation symbols. When using pole details, place a note referencing the pole detail designation symbols (like the following) on the drawings:

> “XFB, 15FR3-N are pole detail designation symbols. Refer to Sketches OH-1.1 through OH-41 on Sheets [TBD] for an explanation of the use and description of equipment provided by these symbols.”

3-3.2.3.2 Conductor Sag.

Indicate conductor initial sag values. Provide initial sag values at ambient temperatures in 18 degrees F (10 degrees C) increments for a temperature range, which includes the outside summer and winter design temperature values. Clearly indicate each different calculated ruling span on the plans and provide initial sag for one span in the calculated ruling span.

3-3.2.3.3 Fusing.

Provide appropriate symbol and detail indicating the use of backup current limiting fuses with the device being protected. Indicate the fuse type and ampere rating as well as the voltage rating and current designation of the backup current limiting fuse.

3-3.2.4 Transformer Details.

Indicate transformer details on the drawings. Transformer details are available in a PDF format and an AutoCAD format on the WBDG website at https://www.wbdg.org/dod/ufgs/forms-graphics-tables.

3-3.2.4.1 Descriptive Information.

Provide the following transformer descriptive information:

- Transformer type (e.g., pad-mounted, pole mounted, station type, unit-sub)
- kVA, single or three phase
- Voltage ratings per IEEE C57.12.00 (e.g., 11.5KV – 208Y/120 volts)
- Primary and secondary connection (when using single-phase units for three-phase service; specifically indicate how the units are to be connected, i.e., connect delta-wye grounded for 208Y/120-volt secondary service)

3-3.2.4.2 Surge Arresters and Fused Cutouts.

Include the following information for surge arresters and fused cutouts:

- Surge arrester kV rating.
- Cutout kV, continuous ampere, and interrupting ampere rating.
- Fuse link type and ampere rating.

3-3.2.5 Underground Distribution.

3-3.2.5.1 Required Information.

Profiles may be required for ductbank runs. Discuss profile requirements with the electrical reviewer. Indicate structure (manhole and handhole) tops, ductbank elevations, slopes, and diameters. Coordinate structure numbers with plan sheets. Show and label all crossing utility lines, both existing and new. If depths of existing utilities are unknown, indicate the horizontal location of the utility and indicate the vertical location with a line representing the anticipated range of elevations where the utility will be found in the field. Indicate the method of new utility installation routing above or below conflicts. Notes can be used to identify parts.

Provide cable/ductbank information indicating cable identification, description, conduit size, and remarks for any special instructions. Where four or more conduits are to be installed, provide in schedule format. For smaller applications, schedule or notational conveyance is acceptable.

3-3.2.5.2 Detail Drawings.

Provide manhole foldout details or exploded views for all multiple-circuit primary systems and all primary systems requiring splices. Indicate the entrance of all conduits and the routing of all conductors in the manholes.

Manhole details are available in Adobe PDF format and in AutoCAD format on the WBDG website at https://www.wbdg.org/dod/ufgs/forms-graphics-tables.

3-3.3 Demolition Plans.

3-3.3.1 Required Information.

Provide “Demolition” plans separate and distinct from “New Work” plans, except where only minor demolition work is required. Clearly show what is to be demolished, at an appropriate scale. Indicate the beginning and ending points of circuit removals.

For modification of or additions to existing equipment, provide the manufacturer’s name and other pertinent manufacturer’s identification (e.g., serial number, model number, style, and any other manufacturer’s identifying markings).

3-3.3.2 Demolition Sequence.

Provide a sequence of demolition; if necessary, include any known requirement for continuous operation and limited shutdown requirements. Identify these in the special scheduling paragraphs of the specifications.

3-3.3.3 Lighting Demolition.

Indicate the quantity of lighting ballasts that contain PCBs and the quantity of lamps that contain mercury.

3-3.4 Lighting Plans and Details.

Do not show lighting and power on the same floor plan, unless the scale of the plan is 1:50 (¼ in = 1 ft – 0 in) or larger. "Provide a photometric layout plan as an appendix to the design analysis. The photometric layout plan may also be a for-information-only (FIO) drawing but may not be a contract drawing.

Provide luminaire (lighting fixture) details, separate luminaire schedule, controls, and control strategies for each space. Details and a luminaire schedule are available in Adobe PDF format and in AutoCAD format on the WBDG website at https://www.wbdg.org/dod/ufgs/forms-graphics-tables. To maintain the integrity of the details, do not modify details; make any required exceptions or modifications in the remark’s column of the luminaires schedule and not on the details themselves. Provide applicable luminaires type symbol(s) with each luminaire sketch/detail. When using luminaire(s) not included in the database, detail the luminaire(s) on the drawings providing the following minimum information:

- Luminaire type (e.g., high bay, fluorescent, industrial, downlight, roadway type, floodlight).
- Physical construction including housing material and fabrication method, description of lens, reflector, refractor.
- Electrical data including number of lamps, lamp type, ballast data, operating voltage.
- Mounting (surface, suspended, flush) and mounting height.
- Special characteristics such as wet label, specific hazardous classification, or air handling.

3-3.5 Power Plans.

Show all power requirements and points of connections. Specifically identify each piece of equipment including HVAC and mechanical equipment (e.g., unit heater No. 1, unit heater No. 2).

Typical illustrations showing proper methods for displaying equipment on the contract drawings are provided in a PDF format within the electrical technical paper TSEWG TP-12: Appendices. Refer to Appendix A for more information.

3-3.6 Telecommunication Plans.

Show locations of voice and data outlets in each room, closets, and equipment spaces. Detail all outlet, cable tray, backboard or distribution frames, and grounding bus bars.

Note: Power and telecommunication systems may be shown on the same drawings provided the design is small, the electrical designer and the telecommunications registered communications distribution designer (RCDD) are the same person, and combining the drawings is approved by the Contracting Officer or technical reviewing authority.

For larger designs where power and telecommunications plans are not shown on the same drawings, provide telecommunications drawings stamped by an RCDD. Refer to UFC 3-580-01 for telecommunications requirements.

3-3.7 Grounding Plan.

Provide grounding plans and details at an appropriate scale.

3-3.8 Roof Plan.

When roof mounted equipment, including HVAC equipment, cannot be adequately shown on the Power Plan, provide an appropriately scaled roof plan.

3-3.9 Lightning Protection Plan.

Provide lightning protection plan and details at an appropriate scale. Indicate locations and number of system components required. Show air terminal installation details, roof and wall penetration details, and details to show concealed components of the system.

Coordinate roof and wall penetrations with other disciplines to ensure that the integrity of the facility envelope is not compromised.

3-3.10 Hazardous Location Plan.

Provide on the drawings the boundaries and classifications of all hazardous locations in accordance with NFPA 70.

3-3.11 Power One-Line/Riser Diagrams.

Provide a power one-line (single-line) diagram for:

- Medium-voltage distribution systems, including substations and switching stations.
- Systems involving generation, either low voltage or medium voltage.
- Building switchgear, switchboards, and main distribution panels (MDPs).

3-3.11.1 Content and Format.

The one-line diagram must show all components (including metering and protective relaying). Indicate sizes of bus, feeders and conduits. Show connections of transformers, PTs, CTs, and capacitors on the one-line diagram by means of the proper symbol. Show potential and current transformer ratios. Indicate relay quantity and function (overcurrent, voltage, differential) using ANSI designation numbers.

On most facility-related projects, it is acceptable to combine the one-line diagram with a riser diagram. The one-line diagram would begin with the medium voltage system and continue through the transformer up to and including the main breaker and feeder breakers within the MDP. Sub-panels beyond the MDP may be shown in the riser diagram format.

3-3.11.2 Electrical Equipment.

Indicate kV ratings for surge arresters, and kV and ampere rating for cutouts. Indicate fuse link type and ampere rating. For capacitors indicate kVAR per unit, number of units per bank, voltage (voltage rating of units, not the system voltage), phase (e.g., three-phase or single-phase units), fuse size, and fuse type.

3-3.11.3 Transformer Information.

Show the following on the one-line diagram when a transformer is indicated, as applicable.

- Primary switches.
- Wye or delta connection.
- Loadbreak elbows.
- Lightning arresters.
- kVA rating.
- Rated voltage (primary & secondary).
- Transformer identification number.
- Industry standard impedance.
- Meter type.
- CT and PT sizes.
- Fuse sizes.

Show all pertinent transformer information on the one-line diagram as opposed to the specifications. Items that are common to all transformers can be indicated by notes on the one-line diagram if a typical detail drawing is provided.

3-3.11.4 Pad-Mounted Switchgear Information.

Show the following on the one-line diagram when pad-mounted switchgear is indicated:

- Spare ways (cubicles).
- Protective devices.
- Loadbreak elbows.
- Switch identification number.

3-3.11.5 Primary Distribution.

Show the following on the one-line diagram when a new primary is indicated:

- In-line splices in manholes.
- Normally open points.
- Number and sizes of phase, neutral and ground cables.
- Conduit sizes.

3-3.11.6 One-Line Diagram for Demolition.

If there is demolition involved or work is to be done to existing equipment, provide an existing one-line diagram showing the current arrangement of the gear and then show a new one-line diagram indicating by line weights what is existing or new.

3-3.11.7 Format.

Ensure that information shown on the one-line diagram is not duplicated elsewhere in the construction package, as this will likely cause conflicts if changes are necessary. Indicate on the electrical legend the exact nomenclature used to indicate conductor and conduit sizing. Provide a schedule for feeder runs. Provide medium voltage one-line diagrams for stations and distribution systems that have a geographic affiliation to the actual constructed distribution system.

Typical illustrations showing proper methods for displaying one-line and power riser diagrams on the contract drawings are provided in a PDF format within the electrical technical paper TSEWG TP-12: Appendices. Refer to Appendix A for more information.

3-3.12 Telecommunications Riser Diagram.

Clearly indicate service entrance cable and duct, entrance protector assemblies, and connections to existing outside cable plant. Include the following:

- Cross-connects. Indicate by notation that voice and data cables terminate in separate fields. Indicate method of cross connecting – patch panel or connector block.
- Telecommunications outlets, including room numbers.
- Cable for building backbone and horizontal distribution system.
- Pathway, including conduit and cable tray for backbone and horizontal distribution system.
- Telecommunications grounding system.

3-3.13 Intercommunication/Paging Riser Diagram.

Show power source, master station with associated equipment, speakers, and outlets. Include room numbers, wiring/conduit between components.

3-3.14 Fire Alarm Riser Diagram.

If required, fire alarm riser diagrams, including mass notification system, will be provided by the fire protection engineer.

3-3.15 Special Systems Riser Diagrams.

Provide other riser diagrams like those developed for telecommunications or intercommunication/paging.

3-3.16 Schedules and Elevations.

Provide elevations, sections, and details to clearly identify space constraints, unique conditions, design intent, or to ensure a specific method is implemented.

3-3.16.1 Panelboards.

Provide schedules for all panelboards. Provide the panelboard schedule reflecting the actual circuit breaker and bus arrangement. Include the following:

- Panelboard designation and location (i.e. room number).
- Voltage, phase, frequency, number of poles, and minimum interrupting rating.
- Main amperes indicating main breakers or lugs only.
- Surface or flush mounting.
- Circuit number, wire size, breaker trip, connected load, and identification of load associated with each branch or feeder. Provide the specific identification of load. For example, do not merely indicate “Lighting,” but rather “Lighting, Room 102” for the directory marking.
- Total connected load (calculated load) including demand factors of all circuits.
- Any special breaker requirements such as GFCI, AFCI, SWD, adjustable trip, 100% rated.

  Note: many manufacturers require minimum 400A panel frames for 100% breakers to be used.
- Neutral bus size (100% or 200%).
- See UFC 3-520-01 for additional values to be included in panelboard schedules and drawings.

Additionally, consider the following:

- Other conductor sizing factors specific to a given circuit such as anticipated ambient temperature on the assumed routing path, whether the load is nonlinear, and the number of current-carrying conductors for purposes of re-sizing should circuits be consolidated into a common raceway during construction.

Show all circuiting (identifying conduit and wiring back to specific panels but not identifying the exact routing required during construction) on the design drawings exactly as they are to be installed.

3-3.16.2 Switchboards and Switchgear.

Provide plan and elevation or isometric drawings for switchboards and switchgear, showing compartments, their intended use, and instruments, relays, and controls. Clearly show contents of all sections including whether breakers are individually, or group mounted. Indicate that switchboards and switchgear are mounted on 4 in (100 mm) elevated concrete pads. Coordinate design of pad with structural engineer.

3-3.16.3 Motor Control Centers.

Provide plan and elevation or isometric drawings for Motor Control Centers (MCCs) identifying compartments. Provide schedule listing each compartment. Include on the schedule (for each compartment) the description of load, load in amperes, load in horsepower, NEMA size and type of starter, breaker size, conductor and conduit size, control devices, and other special requirements.

- Indicate, on plans or in specifications, enclosure type, bus rating, bus material, bus bracing, NEMA class and wiring type, service voltage, control voltage and source, and top or bottom feed.
- Indicate on the drawings that MCCs are mounted on 4 in (100 mm) elevated concrete pads. Coordinate design of pad with structural engineer.
- Provide elevation of control panels, indicating front panel devices, such as indicator lights, pushbuttons, gauges, and switches.

3-3.17 Details/Diagrams.

Detail all telecommunications outlets, cable tray, and backboard/distribution frames. Provide elevations of pertinent communication room walls. Indicate additional details as required. Provide a junction box detail on the drawings showing the interface between the Systems Furniture wiring harness and the branch circuit wiring.

3-3.18 Grounding Diagrams.

Provide grounding diagrams with explicit grounding and grounded conductor requirements beginning with the medium-voltage system and continuing through the transformer up to and including the Service entrance equipment, step down transformers, sub-panels, and telecommunications systems grounding.

The service entrance grounding electrode systems and interconnections with other system grounding electrodes must be clearly shown and identified on the grounding plan. The main bonding jumper connection must be indicated and system bonding jumper connections for separately derived systems must be clearly indicated. Automatic Transfer switches must be identified indicating 3-pole design for single-phase systems and 4-pole design for three-phase systems. Coordinate this UFC with TSEWG TP-19 and clarify when ATS with unswitched neutral be used in lieu of ATS with switched neutral. Typical illustrations showing proper methods for displaying grounding diagrams on the contract drawings are provided in a PDF format within the electrical technical paper TSEWG TP-12: Appendices. Refer to Appendix A for more information.

3-3.19 Cathodic Protection Plans and Details.

Provide cathodic protection plans and details at appropriate scales. Indicate on the drawing the location of all rectifiers, anode beds, structures, elevators, and overhead cranes protected by cathodic protection system(s). Include all structures, elevators, and overhead cranes that may be affected by stray current corrosion because of cathodic protection of the specific structure within the affected area of cathodic protection. A NACE-certified Cathodic Protection Specialist must prepare or review cathodic protection design. Follow the requirements of UFC 3-570-01.

This Page Intentionally Left Blank

APPENDIX A TRI-SERVICE ELECTRICAL WORKING GROUP TECHNICAL PAPERS

The Tri-Service Electrical Working Group (TSEWG) has developed technical white papers to provide additional information on certain topics. Some of these papers contain information that was provided in earlier versions of the UFCs, which was considered important to maintain for reference. The following white papers are located at https://www.wbdg.org/dod/supp-tech-documents:

- **TP-01: Electrical Calculation Examples** – provides example calculations for a variety of electrical equipment.
- **TP-02: Capacitors for Power Factor Correction** – provides information regarding capacitor application, sizing, and design.
- **TP-03: Surge Protector Performance and Evaluation Criteria** – provides information for low voltage surge protection.
- **TP-04: Stationary Battery and Charger Sizing** – provides different sizing techniques for stationary applications.
- **TP-05: Interior Transformer Ratings and Installation** – discusses transformer application, rating, and installation criteria.
- **TP-06: Low-Voltage Breaker Interrupting Ratings** – explains how low-voltage circuit breakers are rated and tested.
- **TP-07: Protection System Design** – provides electrical analysis criteria for relays, fuses, and circuit breakers.
- **TP-08: Electrical Equipment Enclosures and Hazardous Locations** – provides NEMA and NFPA guidance regarding enclosure designs and hazardous location classifications.
- **TP-09: Automatic Transfer Equipment** – provides information regarding automatic transfer switch application and design.
- **TP-10: Arc Flash Levels for Fused Voltage Inputs to Electricity Meters** – provides an arc flash analysis for arcing faults downstream of protective fuses on an electricity meter.
- **TP-11: UFC 3-500-10N Best Practices** – UFC 3-500-10N was developed by NAVFAC and was superseded by the initial issue of UFC 3-501-01. TP-11 provides the best practices information that was contained in UFC 3-500-10N.
- **TP-12: UFC 3-500-10N Appendices** – UFC 3-500-10N was developed by NAVFAC and was superseded by the initial issue of UFC 3-501-01. TP-12 provides appendices that were not included in UFC 3-501-01.
- **TP-13: UFC 3-501-03N Load Demand Analyses** – UFC 3-501-03N, Electrical Engineering Preliminary Considerations, was superseded by the initial issue of UFC 3-501-01. UFC 3-501-03N contained in its entirety MIL-HDBK 1004/1, Electrical Engineering Preliminary Design

Considerations. TP-13 was issued to retain the load demand analysis information originally contained in MIL-HDBK 1004/1.

- **TP-14**. Reserved
- **TP-15: Arc Flash Calculations and Detailed Arc Flash Warning Labels** – NFPA 70E requires a detailed arc flash warning label that specifies either the available incident energy in cal/cm^2 or the required level of personal protective equipment (PPE) that must be worn at a particular work location. TP-15 explains why detailed arc flash warning labels might be inappropriate for many military installations.

APPENDIX B DESIGN DATA TABLES

Table B-1 Typical Loading for Personal Computer Systems

Component	Measured Load
Dell Precision T5400 Desktop (Max)	2.4A
15.6", 2.6 GHz Dell Inspiron Laptop	0.75A
24" Dell Monitor	0.58A
HP LaserJet Pro P1102w printer	0.22A idle, 3A printing

Table B-2 Load Data for Preliminary Demand Calculations

Facility Type	VA/m^2	VA/ft^2
BEQ	21-64	2-6
Commissary/Exchange	75- 97	7-9
Cafe/Mess Hall	75-108	7-10
Administration Building	64-108	6-10
Craft/Hobby/Golf Pro	43-54	4-5
Shore Intermediate Maintenance Activity (SIMA)	64-108	6-10
BOQ	22-64	2-6
Warehouse/Exchange	43	4
Child Care	64	6
Chapel	54-75	5-7
Applied Instruction Building	64-108	6-10

Use the above information to aid in estimating demand for transformer sizing for preliminary calculations. As the design progresses, update demand calculations to reflect actual load of the building.

Dwelling Unit Demand Data for Electrical Calculations.

Note: These Tables are provided to aid the Designer of Record in estimating the total demand for "ALL ELECTRIC" dwelling units (including diversity). Size all distribution systems for dwellings for "ALL ELECTRIC". Use the data below for sizing distribution transformers, service lateral voltage drops and flicker calculations. These tables are not to be used for sizing the service laterals or service entrance conductors.

Table B-3 Dwelling Demand kVA per A/C Size

# of Units	HVAC Diversity	2 Tons		2.5 Tons		3 Tons		3.5 Tons		4 Tons	
		FE	Total	FE	Total	FE	Total	FE	Total	FE	Total
1	1.0	3.89	6.42	4.09	7.25	4.29	8.08	4.93	9.35	5.67	10.72
2	0.85	6.61	10.91	6.95	12.33	7.29	13.74	8.38	15.9	9.64	18.22
3	0.82	8.64	14.91	9.08	16.95	9.52	18.96	10.94	21.95	12.59	25.16
4	0.80	10.27	18.37	10.8	20.91	11.33	23.45	13.02	27.16	14.97	31.13
5	0.77	11.86	21.61	12.47	24.64	13.08	27.68	15.04	32.05	17.29	36.74
6	0.75	13.3	24.69	13.99	20.21	14.67	31.73	16.86	36.75	19.39	42.12
7	0.73	14.7	27.63	15.46	31.61	16.22	35.58	18.64	41.22	21.43	47.24
8	0.72	16.2	30.76	17.01	35.22	17.85	39.68	20.51	45.97	23.59	52.68

Table B-4 Typical A/C Size for Dwelling Units

Dwelling Type	A/C (Tons)	Typical (m^2)	Typical (ft^2)
Mobile Home, Small House	2.0	93	1000
Townhouse, House	2.5	116	1250
Townhouse, Condominium	3.0	140	1500
Condo, House	3.5	163-186	1750-2000
House	4.0	186-279	2000-3000

Table B-5 Demand for Electric Strip Heat

kW Rating of Strip	kVA Demand
5	5.0
10	8.0
15	10.5
20	14.0

FE (Full Electric) is the demand value (with diversity pre-calculated) of the load **without** a summer (air conditioning) or winter (heat strip) HVAC mechanical load included.

"Total" is the demand which **includes** a summer air conditioner load (**Total = FE + air conditioning load**). "Total" does not include the demand associated with resistive heat elements (which may drive the need for larger transformers). **HVAC diversity** = the diversity factor to use for winter HVAC unit demand calculations. It is incumbent on the electrical designer to address loads that are larger than those associated with the summer load. Size the transformer for the summer load unless the winter load calculation is more than 140% of the summer calculation.

Example: A new underground distribution system is being designed for a housing development of duplexes. Each dwelling unit is 1500 ft^2 (140 m^2) with a 3-ton heat pump and 5 kW of strip heat. "Total" load for 8 dwellings (maximum 4 duplexes per transformer – See paragraph “Housing Distribution” in UFC 3-550-01) and 3-ton units = 39.68 kVA (Table B-3). A check of the winter load = FE (Table B-3) + # of strip units x heat strip demand (Table B-5) x HVAC diversity (Table B-3). Winter load = 17.85 + 8 x 5 kW x 0.72 or 46.65 kVA. Summer to Winter load ratio = 46.65/39.68 or 1.18. Size the transformer for the summer load (39.68 kVA). Thus, each 50 kVA pad-mounted transformer must feed 4 duplexes.

This Page Intentionally Left Blank

APPENDIX C ELECTRICAL ENGINEERING PRELIMINARY CONSIDERATIONS

Appendix C provides the preliminary design considerations information previously contained in UFC 3-501-03N, *Electrical Engineering Preliminary Considerations*, which has been superseded by UFC 3-550-01. UFC 3-501-03N contained MIL HDBK 1004/1, *Electrical Engineering Preliminary Design Considerations*.

C-1 PRELIMINARY DATA

C-1.1 Load Data.

Before specific electric power sources and distribution systems can be considered, realistic preliminary load data must be compiled. The expected electric power demand on intermediate substations, and on the main electric power supply, shall be calculated from the connected load by applying appropriate factors. Determine these factors by load analysis and by combining loads progressively. To combine the loads, start at the ends of the smallest feeders and work back to the electric power source. Because all loads must be on a common kilowatt (kW) or kilovolt-ampere (kVA) basis, it is necessary to convert motor horsepower ratings to input kilowatts or kilovolt- amperes before combining them with other loads already expressed in those terms. Preliminary electric power load estimates can be made by using the approximate value of one kilovolt-ampere of input per horsepower (hp) at full load. Preliminary estimates of lighting loads may be made by assuming watts per ft^2 (m^2) of building area.

C-1.2 Load Analysis.

To determine appropriate load estimating factors, using the tables and factors below as guides analyze the characteristics of each load. Consider items such as environmental conditions of weather, geographical location, and working hours, as the situation dictates. Notice that when the load densities in w/ft^2 (m^2) are used only in preliminary estimates, the demand and load factors will be used in the final designs.

C-1.3 Terminology.

Five terms are essential to the analysis of load characteristics: demand factor, coincidence factor, diversity factor, load factors and maximum demand. These terms are defined in paragraphs C-1.3.1 through C-1.3.5.

C-1.3.1 Demand Factor.

The demand factor is the ratio of maximum demand of a system to the total connected load of the system or

Equation: Demand factor = Maximum demand load / Total load connected

C-1.3.2 Coincidence Factor.

The coincidence factor is the ratio of the maximum demand of a system, or part under consideration, to the sum of the individual maximum demands of the subdivisions or

Equation: Coincidence factor = Maximum system demand / Sum of individual maximum demands

C-1.3.3 Diversity Factor.

The diversity factor is the reciprocal of the coincidence factor or

Equation: Diversity factor = Sum of individual maximum demands / Maximum system demand

C-1.3.4 Load factor.

The load factor is the ratio of the average load over a designated period, usually 1 year, to the maximum load occurring in that period or

Equation: Load factor = Average load / Maximum load

Load factors in Table C-1 are not to be used when sizing the service conductors.

C-1.3.5 Maximum Demand.

The maximum demand is the integrated demand for a specified time interval, i.e., 5 minutes, 15 minutes, 30 minutes, or other appropriate time intervals, rather than the instantaneous or peak demand.

Table C-1 Factors for Individual Facilities by Navy Category Code (See Note 1)

Navy Code	Description	Demand Factor (%)	Load Factor (%)
100	**Operational and Training Facilities:**		
121	Aircraft fueling/dispensing facility	40-60	16-20
122	Marine fuel dispensing	40-60	16-20
123 10	Filling station	40-60	13-17
125 16	Miscellaneous POL pipeline facilities	100	13-17
126	Liquid fueling and dispensing-other	40-60	3-7
131	Communications – buildings	60-65	70-75
131 40	Telephone exchange building	55-70	20-25
133 75	Air surveillance radar building	55-70	70-75
137 40	Port control office	55-70	20-25
141 11	Air passenger terminal building	65-80	28-32
141 20	Aircraft fire and rescue station	25-35	13-17
141 30	Aircraft line operations building	65-80	24-28
141 40	Aircraft operations building * EXC 141-70*	65-80	28-32
141 60	Photographic building	65-80	16-20
171 10	Academic instruction building	40-60	22-26
171 20	Applied instruction building	35-65	24-28
171 40	Drill Hall	75-85	3-7
200	**Maintenance and Production Facilities:**		
211 05	Maintenance Hangar O/H space (high bay)	45-50	28-30
211 06	Maintenance Hangar – 01 space (crew equipment)	45-50	28-30
211 07	Maintenance Hangar – 02 space (administrative)	45-50	28-30
211 10	Aircraft overhaul and repair shop (NARF)	32-38	25-30
211 12	Paint/finishing hangar	65-75	25-27
211 20	Engine overhaul shop (NARF)	32-38	20-25
211 30	Aircraft/engine accessories overhaul shop (NAR)	32-38	25-30
211 75	Parachute/survival equipment	60-65	23-28
211 81	Engine test cell (Non-NARF)	42-48	25-30
211 96	Maintenance, aircraft spares storage (Miscellaneous)	58-63	23-28

890 20	Compressed air plant	60-65	20-25

Note 1: Demand factors include allowance for system loss.

C-2 ESTIMATION OF LOADS.

C-2.1 Preparation of Load Data.

Load data are generally computed in steps such as:

a. individual loads,

b. area loads, and

c. activity loads.

A particular design problem may be limited to step a), to steps a) and b), or may encompass steps a), b), and c). This section outlines each step as a separate entity, dependent only on previous steps for data. Paragraphs C-2.2 through C-2.4.4 describe the three loads.

C-2.2 Individual Loads.

Individual loads are those with one incoming service supplying utilization voltage to the premises. In general, these loads would comprise single structures. Large structures could contain more than one function: for example, aircraft operations, aircraft fire and rescue stations, and photographic buildings. Under this condition, factors that have been developed and keyed to Navy category codes (refer to Table C-1) would be used. In this case, the factors listed under Navy category Code 141 40, 141-20, and 141-60, respectively, would be combined to obtain the total load.

C-2.2.1 Lighting.

To eliminate lighting loads, divide a facility area into its significant components by function (for example, office, storage, mechanical, and corridor). Determine the average lighting level and type of light source for each area. Consider requirements for supplementary lighting (for example, floodlighting, security lighting, and special task lighting). Preliminary load estimates may be made based on applicable ASHRAE 90.1 lighting power allowances.

C-2.2.1.1 Small Appliance Loads.

Small appliance loads shall include those served by general purpose receptacles. In general, the dividing of areas by function for estimating lighting loads will serve for estimating small appliance loads. The determination of loads requires not only the knowledge of the function of an area, but to what extent its occupants use small appliances. For example, an office area demand may average about 1 W/ft^2 (10.76 W/m$^{2)}$ but could vary from a low of 0.5 W/ft^2 (5.38 W/m$^{2)}$ to a high of 1.5 W/ft^2 (16 W/m^2), depending on the specific tasks to be performed. A minimum of 0.1 W/ft^2 (1 W/m^2) for auditoriums to a maximum of 2.5 W/ft^2 (27 W/m^2) for machine shops is possible, although the upper limit would occur very rarely. Mechanical spaces in building storage areas and similar spaces in which outlets are provided but infrequently used are usually neglected in computing loads, except for special cases.

C-2.2.1.2 Electric Power Loads.

Electric power loads shall include all loads other than lighting loads and those served by general purpose receptacles. Electric power loads comprise the environmental system electric power requirements and the facility occupancy equipment electric power requirements.

C-2.2.1.3 System Loss.

A system loss of approximately 6 percent, based on calculated maximum demand, should be added to the building load.

C-2.2.2 Demand and Load Factors.

The demand and load factors for a specific facility will vary with the division of load and hours of usage. Refer to Tables C-2 and C-3 for values that can be applied to determine demand and load factors. Table C-4 is included as a guide and an aid in illustrating the method of determining loads, which are calculated for a particular type of building, such as an academic and general instruction building (Navy Code 171-10). The values given are empirical and will vary from activity to activity and may vary from one facility to another within an activity. Annual hours use of demand must be determined for each case in accordance with methods of operation and characteristics of the installation. Demand factors and load factors for individual facilities by the Navy category code given in Table C-1 are based on a survey of existing Navy facilities and past experience. Such factors should be used for quick estimating purposes and as a check when a more precise calculation is undertaken (refer to Table C-4).

C-2.2.2.1 Guides for Demand Factors.

For guides on selection of demand factors, refer to Table C-5.

C-2.2.2.2 Guides for Load Factors.

Guides for the selection of load factors indicate the need for special considerations (refer to Table C-6). Factors in the middle of the range are for the average facility at the peacetime shore establishment and should be used unless the guides in Table C-6 indicate otherwise.

Table C-2 Demand Factors for Specific Loads (See Note 1)

Types of Loads	Estimated Range of Demand Factor (%)	Quick Estimating Demand Factor (%)
Motors: General purpose, machine tool, cranes, elevators, ventilation, compressors, pumps, etc.	20–100	30
Motors: Miscellaneous, fractional, and small appliances	10–50	25
Resistance ovens, heaters, and furnaces	80–100	80
Induction furnaces	80–100	80
Lighting	65–100	75
Arc welders	25–50	30
Resistance welders	5–40	20
Air-conditioning equipment	60–100	70
Refrigeration compressors	40–100	60

Note 1: Demand factors include allowance for system loss.

Table C-3 Annual Hours of Demand Usage for Specific Loads

Types of Loads	Quick Estimating Hours of Use		
	1-Shift Operation	2-Shift Operation	3-Shift Operation
Motors: General purpose	1,200	1,600	2,000
Motors: Miscellaneous, fractional, and small appliances	1,500	1,800	2,100
Resistance ovens, heaters, and furnaces	1,000	1,300	1,600
Induction furnaces	900	1,200	1,500
Lighting	2,200	2,800	3,500
Arc welders	500	700	900
Resistance welders	500	700	900
Air-conditioning equipment			
Less than 1,500 cooling degree days	1,200	1,400	1,600
1,500 to 2,500 cooling degree days	1,600	1,800	2,000
More than 2,500 cooling degree days	2,200	2,500	2,800

Table C-4 Academic Building (Code 171-10) Demand and Load Factor Calculations (See Note 1)

		Motors				
		General	Miscellaneous Fractional & Small Appliances	Lighting	Air Conditioning	Total
1.	Watts/square foot (Watts/square meter)	1.0 (10)	1.0 (10)	2.7 (26.5)	4.5 (45)	9.2 (91.5)
2.	Connected load	100 kW	100 kW	265 kW	450 kW	915 kW
3.	Specific load demand factor	30%	10%	75%	70%	
4.	Maximum demand load (line 2 x line 3)	30 kW	10 kW	200 kW	315 kW	555 kW
5.	Annual operating (1-shift) usage	1,200 hrs.	1,500 hrs.	2,200 hrs.	1,600 hrs.	
6.	Annual usage in megawatt hours (line 4 x line 5)	36	15	440	504	995
7.	Demand factor Formula = Line 4 / Line 2 (1)	-	-	-	-	60%
8.	Load factor Formula = Line 6 / (Line 4 x 8760 hours) (4)	-	-	-	-	20%

Note 1: Calculated for a 100,000 square-foot (10,000 square meter) building. See Tables C-2 and C-3 for data used for lines 3 and 5 respectively. Load growth is included in connected load. Maximum demand load includes allowance for system loss. For this illustration, the coincidence factor occurring when individual demand loads are added is considered to be 1.00 and has not been shown.

Table C-5 Guides for Selection of Demand Factors

Select factors in upper half of range for conditions described below	Select factors in lower half of range for conditions described below
GENERAL GUIDES	
Facilities in active use and approaching maximum capacity. Loads predominantly lighting. Loads predominantly heating. Loads dominated by one or two large motors.	Facilities of intermittent use or not being fully utilized. Motor loads made up of a number of independently operated small motors. Motor loads controlled automatically unless control depends upon weather conditions.
OPERATIONAL AND TRAINING FACILITIES	
Instruction buildings with little or no electric equipment. Communications buildings with telephonic equipment only.	Large instruction buildings with electrical demonstration and training equipment.
MAINTENANCE AND PRODUCTION FACILITIES	
Shops and facilities when engaged in mass production of similar parts.	No special guides.
RESEARCH, DEVELOPMENT, AND TEST FACILITIES	
Facilities used for repetitive testing of material or equipment.	No special guides.
SUPPLY FACILITIES	
Refrigerated warehouses in South. Dehumidified warehouses in Mississippi Valley and along seacoasts. Warehouses for active storage.	Warehouses with many items of electric materials handling equipment, including cranes and elevators.
HOSPITAL AND MEDICAL FACILITIES	
No special guides.	No special guides.
ADMINISTRATIVE FACILITIES	
Large administrative buildings with mechanical ventilation and air conditioning. Note: Group large administrative buildings separately only when administration is a significant part of total activity load.	Casual offices, offices used infrequently by foremen and supervisors, or offices in which there is little prolonged desk work.
HOUSING AND COMMUNITY FACILITIES	
Enlisted barracks at training centers. Public quarters where less than 25 family units are involved. Restaurants, exchanges, cafeterias, and other food service facilities when gas or steam is primary fuel.	Food service facilities where load is primarily cooking and baking.
UTILITIES AND GROUND IMPROVEMENTS	
Central heating plants serving extended areas and buildings. Water pumping stations serving extended areas or carrying most of load of water systems. Central station compressed air plants.	No special guides.

Table C-6 Guides for Selection of Loads Factors

Select factors in upper half of range for conditions described below	Selection factors in lower half of range for conditions described below
GENERAL GUIDES	
Facilities operated on two or more shifts. Loads that are primarily fluorescent or high intensity discharge lighting. Many small independently operated motors. Electronic equipment continuously operated for immediate use. Cooling and dehumidification loads for year-round climate control in southern climates. Retail-type service loads and loads that are in active use.	Facilities used intermittently. Inactive facilities. Large motor loads when the load consists of relatively small numbers of motors. Wholesale-type service facilities.
OPERATIONAL AND TRAINING FACILITIES	
Large, permanent instruction buildings in active use.	Special-purpose instruction and training facilities not regularly used.
MAINTENANCE AND PRODUCTION FACILITIES	
Shops with battery charging equipment operated after hours. Active shops at full employment. Mass production shops.	Welding loads or loads made up primarily of welding equipment. Job-order workshops. Shops with large, heavy special function machines. Large induction or dielectric heating loads.
RESEARCH, DEVELOPMENT, AND TEST FACILITIES	
No special guides.	No special guides.
SUPPLY FACILITIES	
Refrigerated and dehumidified warehouses in South or in humid climates. Warehouses for active storage and in continuous use.	Refrigerated warehouses in North. Warehouses with large materials handling equipment loads.
HOSPITAL AND MEDICAL FACILITIES	
Clinics and wards with daily operating hours and in active use.	No special guides.
ADMINISTRATIVE FACILITIES	
Large, active, well-lighted offices with ventilation and air-conditioning equipment.	No special guides.
HOUSING AND COMMUNITY FACILITIES	
Navy exchanges with food service facilities. Gymnasiums used in connection or with physical therapy. Barracks at schools and training centers.	Restaurants and exchanges serving only one meal a day. Restaurants and exchanges with gas steam food preparation equipment. Chapels used primarily on Sundays. Subsistence buildings serving less than four meals a day. Laundries with dry cleaning plants. Exchanges operated less than 8 hrs/day Gatehouses operated less than 24 hrs/day
UTILITIES AND GROUND IMPROVEMENTS	
Heating plants that supply both heating and process steam. Water plants with little power load. Air-conditioning plants for year-round control of environment in South. Compressed air plants consisting of many banked compressors operating automatically.	Heating plants in South.

C-2.2.3 Load Growth.

Determine the requirements for load growth for anticipated usage and life expectancy with particular attention to the possibility of adding heavy loads in the form of air conditioning, electric heating, electric data processing and electronic communication equipment. Before determining the size of service and method of distribution to a facility, an economic analysis shall be made to determine the most feasible way of serving this future load. This analysis shall include the effect on the existing installation if future loads require reinforcing or rehabilitation of the service system.

C-2.2.4 Emergency Loads.

The determination of emergency electric power requirements is based on three types of loads (refer to Section 3 for types of loads to be included in each category):

- Minimum essential load,
- Emergency load for vital operations, and
- Uninterruptible (no-break) load.

When the three categories of emergency electric power requirements have been ascertained, determine where local emergency facilities are required, where loads may be grouped for centralized emergency facilities, and what loads are satisfied by the reliability of the general system. Base the above determinations on safety, reliability, and economy, in that order.

C-2.3 Area Loads.

Area loads consist of groups of individual facility loads served by a subdivision of the electric distribution system. The term “area” applies to the next larger subdivision of an overall distribution system. Demand loads for an area must be known for sizing the distribution wiring and switching, and in a large installation will be required for the design of substations serving the area. Table C-7 gives an example of how the coincident peak demand is calculated.

C-2.3.1 General Loads.

To obtain the general load, add roadway lighting, area lighting, obstruction lighting, and other loads not included in individual facility loads.

C-2.3.2 Coincidence Factor.

Determine the maximum expected demands, taking into consideration whether loads within the area peak at the same or at different times.

C-2.3.2.1 Relationships.

Figure C-1 indicates the relationship that exists between the load factor of individual facility loads and the coincidence of their peak demands with the peak demand of the group. This relationship was developed by a study of the loads of selected naval shore activities and by the application of factors developed to the formulas published by IEEE. For collateral reading on this subject, refer to IEEE Technical Paper 45-116 Coincidence-Factor Relationship of Electric Service Load Characteristics. Table C-8 is Figure C-1 in tabular form with values shown to the nearest whole dollar, except for low load factors.

C-2.3.2.2 Selection.

Areas with relatively insignificant residential type loads, where the load curve indicates that most of the electric power consumed in the area is used during the 40 normal working hours of a week, have coincidence factors at the higher end of the range.

C-2.3.2.3 Electric Power Consumption.

In general, areas where large amounts of electric power are consumed outside the usual 40 working hours a week have a coincidence factor at the lower end of the range (examples are hospitals, areas operated on two or more shifts, or large barracks type activities). The upper limit of the range is for the 40 hour per week operation; the lower limit is for a 60 hour per week operation.

C-2.3.2.4 Influencing Factors.

The number of individual loads in a group and their load factors influence the individual load coincidence factor. The coincidence factors in Table C-8 apply for groups of 100 or more individual loads. These coincidence factors can also be used for groups of as few as 30 to 50 individual loads if their load factor is 0.30 or greater. For areas of fewer individual loads, the mathematical relationship from IEEE Technical Paper 45-116 provides a basis for estimating the connected coincidence factor as shown by the following equation:

Equation: $En = Et + (1 – Et)1/n$

Where:

En = The individual load coincidence factor applied with a given number of consumers.

Et = The coincidence factor as given in Table C-8 in hundredths.

n = The number of individual loads in a group.

C-2.3.2.5 Individual loads.

The coincidence factors in Table C-8 are based on the individual loads in a group being substantially the same size. If a single load or small group of loads in an area represent a substantial percentage of overall load, the coincidence factors as given in Table C-8 will no longer apply. With an individual load, increase the coincidence factor to a value commensurate with its effect on the overall area load. This is not in addition to, but in place of, the normal coincidence factor. Determine this value by considering intergroup coincidence factors given in paragraph C-2.3.2.

An example of facility Navy Code 211-70 is presented in Table C-7.

For a small group, determine the coincidence peak load, and to this apply the appropriate intergroup coincidence factor to obtain the coincidence peak load for the area.

C-2.3.2.6 Groups of Loads or Areas.

Where groups of loads within an area, or areas within a facility are combined, an additional intergroup coincidence factor will exist. For loads of similar nature, the intergroup coincidence factor should be in the range 0.93 to 1.00. If loads of a varying nature (evening loads and daytime loads) are combined, the intergroup coincidence factor should be in the range of 0.70 to 1.00. The lower values will occur when magnitudes of the loads are nearly balanced, and the higher ones when the combined load is predominantly one type.

Table C-7 Method of Calculating Coincident Peak Demand

Navy Code		Description	Total Connected Load (kW)	Demand Factor (%)	Maximum Demand (%)	Load Factor (%)	Coincidence Factor (%)	Coincidence Peak (kW)

							Total	3,325
						System loss (6%)	194	
							Grand total	3,429

(1) The coincidence factor has been increased to allow for low load factor and number of facilities in the area. Refer to paragraph C-2.3.2.4, Influencing Factors, of this handbook.

(2) The coincidence factor has been increased because of the relative magnitude of the load. Refer to paragraph C-2.3.2.5, Individual Loads, of this handbook.

49	73	69	99	99	99
50	73	69	100	100	100

C-2.3.3 Load Growth.

In addition to planned expansion, increased application of electric equipment will generate an increase in load. When sizing components, such as transformers or feeders for the area system, consider possible load growth in addition to that included in determination of individual loads.

C-2.3.4 System Losses.

Add distribution system losses to estimated area demands. For a good approximation, use 6 percent of the calculated maximum demand.

C-2.3.5 Emergency Loads.

Review the overall emergency requirements for the area, based on criteria for the facility or as furnished by the using agency, to determine the following:

a. The emergency loads that may be combined in groups to take advantage of the coincidence factor.

b. The type of distribution system needed for reliability and to economically satisfy at least the less critical emergency load requirements. This reliability can be provided only if the source of electric power is not the determining factor.

c. Area loads that must be added to individual emergency loads, for example, security lighting and minimum roadway lighting.

C-2.3.6 Expansion.

The planned development of the area, as shown on the activity general development map, shall be considered for requirements of future expansion.

C-2.4 Activity Loads.

Activity Loads are loads that consist of two or more area loads served from a single electric power source and an integrated distribution system.

C-2.4.1 General Loads.

Follow the approach used in paragraph C-2.3 for area loads. Area loads used for determining activity coincidence demand should be the area coincident demand exclusive of allowance for load growth.

C-2.4.2 Coincidence Factor.

Refer to paragraph C-2.3.2 for the necessary approach. Where dissimilar areas, whether residential, administrative, or industrial, are part of an activity, make a careful analysis of the coincidence factor used.

C-2.4.3 Load Growth.

As for an area, components should be sized after due consideration has been given to load growth. Apply this increase to the coincident demand of the activity.

C-2.4.4 Expansion.

The planned development of the activity, as shown on its general development map, shall be considered for requirements of future expansion.

APPENDIX D GLOSSARY

D-1 ACRONYMS.

AC	Alternating Current
ACSR	Aluminum Conductor Steel-Reinforced
AFI	Air Force Instruction

D-2 DEFINITION OF TERMS.

Activity: The end user of a base or facility.

Base Communications Officer (BCO): The person(s) responsible for the telecommunications and data infrastructure for a base or facility.

Closed Circuit Television (CCTV): A network of cables and equipment to monitor and transmit video signals throughout a facility.

Community Antenna Television System (CATV): A network of cables, headend and electronic components that process and amplify television and frequency-modulated (FM) radio signals for distribution from one central location to outlets throughout a facility.

Contractor: Person(s) doing actual construction portion of a project.

Corrosive Area: An area identified by the Technical Reviewing Authority as requiring special equipment corrosion mitigation methods.

Designer of Record: The engineer responsible for the actual preparation of the construction documents.

Distribution Device: A facility located within a dwelling unit for interconnection or cross connection of interior telecommunications wiring. Passive cross connect facilities enable the termination of cable elements and their interconnection or cross-connection by means of jumpers and patch cords.

Ductbank: Two or more conduits (or ducts) routed together in a common excavation with or without concrete encasement.

Electric Supply Station: A station that transforms the energy level (voltage) for further bulk distribution at medium voltage levels.

Hot Cap: A sealed insulated cover over the end of a bare energized conductor.

Low Voltage System: An electrical system having a maximum root-mean-square (rms) voltage of less than 1,000 volts.

Medium Voltage System: An electrical system having a maximum RMS AC voltage of 1,000 volts to 34.5 kV. Some documents such as ANSI C84.1 define the medium voltage upper limit as 100 kV, but this definition is inappropriate for facility applications.

Non-Linear Loads: Loads that convert AC to DC and contain some kind of rectifier.

Service: The conductors and equipment for delivering electrical energy from the serving utility or Government-owned system to the wiring system of the premises served.

Service Point: Demarcation for the “service point” (for clarification of the NFPA 70 Article 100 definition): at the building/similar support structure service equipment line side connection.

Site Electrical Utilities: Site Electrical Utilities are the primary electric power distribution to the facilities and other electrical loads, exterior lighting not attached to the building; and telecommunication services (such as fiber optic, copper cable, CATV) required by the Facilities.

Systems Furniture: Modular prewired office furniture.

Technical Reviewing Authority: The “discipline specific” person at the DoD organization who is responsible for signing the project design documents. This is different than the authority responsible for waivers and exemptions required by Mil Std 3007.

Telecommunications Room: An enclosed space for telecommunications equipment, terminations, and cross-connect wiring for horizontal cabling.

TEMPEST: The unclassified name for the studies and investigation of compromising emanations (communications security).

Utilization Electric Supply Station: Equipment such as pole or pad-mounted transformers or secondary unit substations that transforms the energy level (voltage) to a utilization voltage for consumer use.

This UFC supersedes TM 5-688, dated 12 November 1999. The format of this UFC does not conform to UFC 1-300-01; however, the format will be adjusted to conform at the next revision. The body of this UFC is a document of a different number.

FOREWORD

\1\
The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Center for Engineering and the Environment (AFCEE) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current. /1/

LIST OF TABLE

CHAPTER 1

INTRODUCTION

1-1. Purpose.

This manual provides guidance required to identify the voltage and frequency standards of various foreign countries for both medium and low voltage systems. It also identifies the classes of equipment that are sensitive to voltage and frequency differences. Foreign countries around the world use different electrical standards for voltage and frequency than those of the United States. Some electrical equipment will operate properly at an electrical frequency of either 50 or 60 Hz. Equipment designed for 60 Hz that will not operate properly at 50 Hz is termed "50 Hz sensitive," and equipment designed for 50 Hz that will not operate properly at 60 Hz is termed "60 Hz sensitive."

1-2. Scope.

This manual identifies the classes of electrical equipment that are sensitive to frequency and voltage variations. Appendix B covers identification of various low and medium voltage levels, along with the system frequencies, used by countries around the world. Derating factors are discussed and developed for the six generic types of equipment in chapter 3. Appendix C summarizes the derating factors presented in chapter 3 for different voltage and frequency environments.

1-3. References.

Appendix A contains a list of publications referenced in this manual.

CHAPTER 2

EQUIPMENT SENSITIVE TO FREQUENCY AND VOLTAGE LEVELS

2-1. Theoretical overview.

Equipment sensitive to frequency and or voltage is designed to operate within certain tolerances. Most equipment is sensitive to large changes in the supply voltage level because more current will flow through a device when the voltage level of the supply is increased (the current through the device is equal to the voltage across the device divided by the impedance of the device). When a larger current flows, the heat dissipated in the device increases (the heat dissipated by the device is proportional to the square of the current). Thus, doubling the voltage will typically double the current, resulting in the device dissipating four times the heat. Most devices cannot tolerate this amount of heat and cannot operate reliably with a supply voltage level more than 10 percent or so higher than their rated voltage.

a. An additional complication arises in the case of devices that use magnetic coupling. Since most electrical equipment depends on a magnetic field as the medium for transferring and converting energy, the following paragraphs discuss a basic transformer to explain how the magnetic circuit depends on the frequency and amplitude of the applied voltage.

b. A transformer enables electrical energy to be transferred with high efficiency from one voltage level to another at the same frequency. Consider a simplified view of a transformer with a sinusoidal voltage source, *v*, applied to the primary circuit and the seconday circuit open, as shown in figure 2-1. The operation of the transformer depends on several natural laws including the following—

(1) A sinusoidal, time-varying flux, Φ, linking a conducting circuit produces a voltage, *e*, in the circuit proportional to $d\Phi/dt$ (i.e., Faraday's law of induction).

(2) The algebraic sum of the voltages around any closed path in a circuit is zero (i.e., Kirchhoff's voltage law).

(3) The voltage, *v*, in a circuit induced by a changing flux is always in the direction in which current would have to flow to oppose the changing flux (i.e., Lenz's law).

c. When the sinusoidal voltage, *v*, is impressed onto the primary electrical winding of N_1 turns, it is expected that a sinusoidal current, *I*, will begin to flow in the circuit, which in turn will produce a sinusoidally varying flux, Φ. For simplicity, it is assumed that all of the flux set up by the primary circuit lies within the transformer's iron core and it therefore links with all the turns of both windings. If the flux at any instant is represented by the equation:

$$\Phi = \Phi_m \sin 2\pi ft$$

where:

Φ_m = the maximum value of the flux
f = the frequency
t = time,

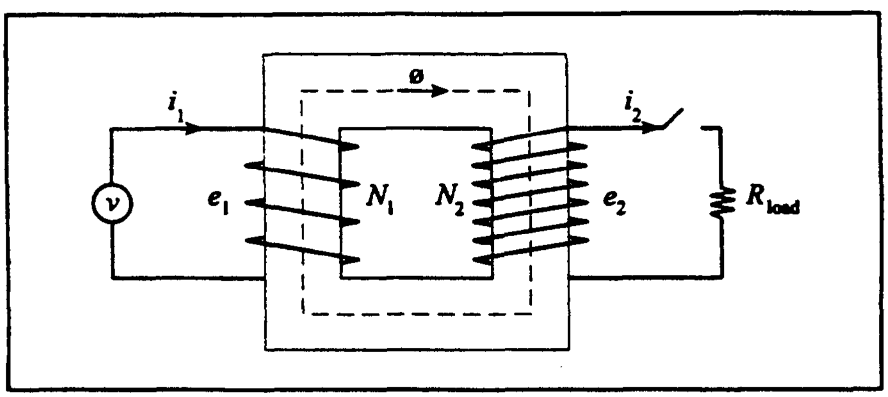

Figure 2-1 Simplified two-winding transformer

it follows from Faraday's law (i.e., $e = N\, d\Phi/dt$) that the instantaneous voltage e_1 induced in the primary winding is:

$$e_1 = 2\pi f N_1 \Phi_m \cos 2\pi f t$$

The polarity of e_1 will be according to Lenz's law, and hence will be in opposition to the impressed voltage, v (figure 2-1). The root mean square (rms) value of e_1 is

$$E_1 = (2\pi/\sqrt{2}) f N_1 \Phi_m = 4.44 f N_1 \Phi_m$$

d. Remembering Kirchhoff's voltage law, and assuming that the winding resistance is relatively small, E_1 must be approximately equal to V, where V represents the rms value of the applied voltage. One important result from this equation is that the value of the maximum flux, Φ_m, is determined by the applied voltage. In other words, for a given transformer, the maximum value of the flux is determined by the amplitude and frequency of the voltage applied to the primary winding. The same flux that caused E_1 in the primary winding will also induce a voltage across the terminals of the secondary winding. Thus, the only difference in the rms values of the two voltages will come from the difference in the number of turns. If the secondary winding has N_2 turns, the seconday voltage can be written as:

$$E_2 = 4.44 f N_2 \Phi_m$$

Dividing Equation 3 by Equation 4 gives the familiar relationship:

$$E_1/E_2 = N_1/N_2$$

e. Consider next when the transformer is loaded with a resister R_{load} by closing the switch in the secondary circuit. If the core flux is in the direction indicated (with the flux increasing), then by Lenz's law, the polarity of E_2 will be such that current I_1 will flow in the secondary winding in attempt to decrease the core flux. The amount of secondary current that will flow will depend on the value of R_{load} (that is, $I_2 = E_2/R_{load}$), and the power delivered to the load will equal $E_2 I_2$. It is important to understand the mechanism by which the power is transferred from the primary circuit to the load. Consider a situation when current is suddenly allowed to flow in the secondary winding by closing the switch. As mentioned previously, the action of this current will be to decrease the core flux. Decreasing the core flux would lower the value of E_1, which would be in violation of Kirchhoff's voltage law (KVL). Since KVL must be satisfied, more current must flow in the primary winding. The steady-state result is that the primary current will increase to the value sufficient to neutralize the demagnetizing action of the secondary current. It is important to realize that the resultant flux in the core remains the same regardless of the loading on the transformer. If the level of core flux were to vary with load, then E_1 and E_2 would also vary, which is contrary to what is observed in practice.

f. An iron core is used in transformers because it provides a good path for magnetic flux and directs the flux so it predominantly links all of the turns in each winding. However, the core has its limitations and can carry only so much flux before it becomes saturated. Core saturation occurs when all of the magnetic domains of the iron align, resulting in a condition in which no further increase in flux density over that of air can be obtained. Consider the magnetizing curve in figure 2-2, showing flux versus magnetizing current, where the magnetizing current i_m is the steady-state component of current

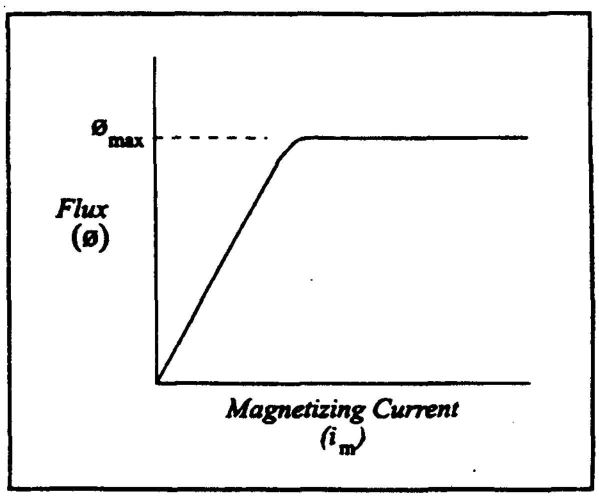

Figure 2-2. Magnetization curve for the transformer's iron core

required to establish the resultant flux level in the iron core for the transformer. It is typical for a transformer, or any other magnetic circuit, to be designed for operation close to the "knee" of this curve (i.e., Φ_{max}) to use as much of the iron core as possible. Beyond Φ_{max}, the iron saturates and it becomes extremely difficult to further increase the flux level. The curve implies that forcing the iron core into saturation can result in a significant increase in the value of the magnetizing current, and hence, can cause the windings to become overloaded and the transformer to overheat.

g. This study is concerned primarily with equipment sensitive to 50 Hz and voltage levels since the equipment will be used overseas where voltage frequencies and levels typically are different from those in the United States. This equipment could be listed by item, but a more useful format results when it is divided into classes and subclasses of equipment from which manufacturers for specific pieces of equipment can be easily selected. Following this format, listed below are the broad classes of equipment sensitive to 50 Hz and building voltage levels. Each section contains specific classes and subclasses of equipment. Additionally, each section describes why the equipment is sensitive to voltage frequency and or level. Equipment that does not readily fit into any other category is listed in paragraph 2-8.

2-2. Heating, ventilation, and air-conditioning (HVAC).

HVAC equipment includes boilers, furnaces, water chillers, humidifiers, fans, compressors, evaporators, and related equipment. Certain issues must be considered when using HVAC equipment in 50 Hz and alternate voltage environments, including the motor speed and step-down transformers for power supplies.

a. The objective of an HVAC system is to provide the necessary heating and cooling to a building according to the design specifications. Typically, alternating current (AC) motors are used in HVAC systems to drive fans, pumps, and compressors. When 60 Hz motor is run off a 50 Hz supply, the shaft speed of the motor is reduced by 5/6 since the motor speed is directly related to the frequency of the applied voltage. This speed will affect all direct-drive applications. For example, a pump that is directly coupled to the motor shaft will transfer less fluid over time if the shaft speed is reduced. Consequently, direct-drive HVAC applications must be derated to account for the reduced motor speed. However, for driven equipment that is tied to the motor through adjustable pulleys, the speed of the driven device can be increased to the necessary level.

b. Regardless of how the driven equipment is coupled to the motor, the 60 Hz motor must still operate within its rating in the 50 Hz environment. For the motor to deliver the same mechanical power at a lower speed, it must deliver more torque since output power equals torque times the shaft speed. If the motor delivers more torque, more current will flow in the motor and an overloaded condition may result. Hence, a 60 Hz motor may have to be derated to handle the extra current flow.

c. Another concern with operating a 60 Hz motor with a 50 Hz voltage source is with saturating the iron core of the motor. Like the transformer, the maximum value of flux in the core depends directly on the amplitude of the applied voltage and inversely on the frequency. Assuming that the same voltage level is applied to the 60 Hz motor in the 50 Hz environment, the reduction in frequency to 50 Hz would require an increase in core flux of 20 percent (that is, 6/5 of its 60 Hz level). If the iron core of the motor is unable to provide the extra flux, the core will saturate, and a significant increase in the stator currents can result, causing the motor to overheat.

d. Step-down transformers typically are needed to transform local voltage levels to the levels the equipment is designed for. In most cases, the equipment contains some sort of step-down transformer that typically has to be changed to convert the higher input voltage to the same output voltage. In cases where no step-down transformer is in the equipment, one must be added to avoid burning out components by subjecting them to a higher supply voltage. Determining the need for a step-down transformer and adding it to the equipment is easily accomplished, and is discussed further in chapter 3. Equipment that cannot be purchased with the precise specifications needed must be purchased in U.S. specifications and then derated as described in chapter 3.

2-3. Electrical distribution and protection.

Electrical distribution equipment includes transformers, panelboards and switchboards, generators, transfer switches, capacitors, and related equipment. Electrical protection devices include fuses, circuit breakers, relays, reclosers, and contactors. The devices have different sensitivities to supply voltage and frequency, and are discussed below.

a. Electrical distribution. As mentioned earlier, transformers are sensitive to the frequency and amplitude of the supply voltage. Using a 60 Hz transformer in a 50 Hz electrical environment can cause the core of the transformer to saturate, overheating the transformer. Other than the potential problem with saturation, the transformer should be fully capable of supplying the nameplate rated load. Most transformers are available in 50 Hz or 50/60 Hz configurations, so saturation should not be a problem.

(1) Panelboards, switchboards, and load centers are generally not sensitive to supply frequency, except when protective devices such as circuit breakers are included in them. These items can be acquired readily in a wide variety of voltage ratings; therefore, supply voltage does not pose a problem.

(2) General output voltage can be increased or decreased by using an appropriate transformer. However, since generators are typically used to supply backup power when the utility power source fails, and or are used in addition to the utility power source, it is necessary for the generator to provide a 50 Hz voltage source to match the utility supply. Therefore the user must purchase a generator configured for 50 Hz operation.

(3) Automatic source transfer switches are sensitive to supply voltage frequency and amplitude because they are electronically controlled and have power supplies that expect to operate on 60 Hz and rated voltage. Once again, supply voltage level is not a problem since transformers are available to adapt voltage levels. Supply frequency, however, may be a problem depending on the type of power supply the electronics use.

(4) Related equipment includes meter centers, and sockets or receptacles. Meter centers are sensitive to voltage level and frequency. Consequently, using a 60 Hz meter center in a 50 Hz environment may result in inaccurate readings. However, meters are readily available in a variety of voltage levels and 50 Hz configurations.

(5) Sockets or receptacles are needed when foreign consumer products are to be used with the power system. Receptacles are configured for different voltage levels, and these configurations vary in different countries. It is important that the standard receptacle style for a given voltage be used to avoid confusing the user and creating a potential safety hazard.

(6) Capacitors are used in an electrical distribution system to adjust the power factor or phase angle between the voltage and current waveforms. It is desirable to have a phase angle close to zero, or a power factor close to one so that most of the power transferred to the load is real power. Real power is the only part of the total kilovolt-amperes transferred that can do work. The balance is called reactive power and cannot do any useful work. The operation of a capacitor depends on the supply frequency, since a capacitor's impedance, X_C, is related to the capacitance and frequency of the current passing through it by the equation $X_C = 1(j2\pi f C)$, where C is the capacitance in farads and j equals the square root of -1.

b. Electrical protection. Electrical protection devices vary in their sensitivity to supply frequency. All protection devices are available in a wide range of voltage ratings so the level of the supply voltage is not a concern. The main concern with protection devices is the change in response time from 60 Hz to 50 Hz. These devices are coordinated to protect the distribution system from faults (shorts or spikes) but are connected so they do not trip when anticipated voltage spikes (that is, motor starting) occur. The power system design engineer must be sure to use the proper trip curves for the environment when coordinating protective devices. Trip curves for 50 Hz are readily available from vendors contacted in this study. The only device designed differently for 50 Hz and 60 Hz is the circuit breaker.

2-4. Medium voltage distribution equipment: 50 Hz → 60Hz.

In this section medium voltage transformers, switchgear and associated auxiliary devices will be examined with respect to frequency and voltage changes.

a. Medium voltage distribution transformers. Distribution transformers are key components in any electric power distribution system. It is important that they are properly matched to their environment. Issues related to operating a 60 Hz transformer from a 50 Hz power source were discussed earlier in this manual. The emphasis here will be on discussing issues concerning operating 50 Hz transformers in a 60 Hz environment.

(1) An important parameter to consider when operating a transformer, or other iron core-based devices, is the ratio of amplitude to frequency of the applied voltage. The ratio obtained using the nameplate rated voltage and frequency should be compared with the ratio available at the proposed site. If the ratio is less than or equal to that obtained using the nameplate quantities, magnetic saturation will not be a problem at the new site. Any time the ratio is higher than nameplate, the manufacturer should be contacted to ensure that the transformer has enough reserve available to accommodate the increase in operating magnetic flux density.

(2) For example, consider a transformer that is brought over from Germany where it was used on a 10 kV, 50 Hz distribution system. It was determined that the electrical insulation system of the transformer was rated for 15 kV. It is desired to use the transformer on a 13.8 kV, 60 Hz system. Considering the magnetic circuit, the volts-per-hertz ratio of the 50 Hz transformer is 200 (i.e., 10 kV/50 Hz). On the new supply the ration would be increased to 230 (that is, 13.8 kV/60 Hz), requiring a higher magnetic flux density in the iron core. This increase could potentially saturate the iron core and overheat the transformer. Alternatively, this

transformer could be used on a 7.2 kV/60 Hz system (120 volts-per-hertz ratio), where saturation would not be a problem.

(3) A few words should be mentioned concerning iron core loss in transformers. The two primary components of core loss are eddy-current loss and hysteresis loss. Eddy-current loss is the term used to describe the power loss associated with circulating currents that are found to exist in closed paths within the body of a iron material and cause undesirable heat production. Hysteresis loss represents the power loss associated with aligning and realigning the magnetic domains of iron in accordance with the changing magnetic flux. Both components are dependent on the frequency, as shown in the following equations:

$$P_{eddy\text{-}current} = K_e f^2 B^2_m \tau^2 v$$

$$P_{hysteresis} = K_h f B^2_m v$$

where,

K = constant value dependent upon material
f = frequency of variation of flux
B = maximum flux density
v = total volume of the material
τ= lamination thickness.

(4) It should be noted that, even though frequency increases when using 50 Hz transformers on a 60 Hz-based system, the voltage-to-frequency ratio will typically be lower, and hence, the maximum flux densities B will be lower. The result is that core-losses will generally not increase as a result of the higher frequency used.

(5) Other key parameters are voltage and current. To maintain insulation system integrity, rated voltage and/or current for the transformer should not be exceeded. A transformer can be operated on lower than rated voltage; however, its current rating must not be violated. Also, the secondary voltage must be matched to the proper voltage levels.

(6) In addition to having an iron core, windings, and insulation system, distribution transformers may include tap changers and auxiliary devices. Auxiliary devices might include fans, current transformers, pressure relief devices, and lighting arresters. Once again, attention should be focused on devices that use a magnetic field for transferring or converting energy, such as instrument transformers and small motor drives. Even if the voltage-to-frequency ratio is found to be lower, manufacturers should be contacted to make sure that all linear and rotating drive mechanisms will develop adequate force and torque to function properly.

b. Medium voltage switchgear. Switchgear is a general term covering switching and interrupting devices alone, or their combination with other associated control, metering, protective, and regulating equipment. Common switchgear components include the power bus, power circuit breaker, instrument transformers, control power transformer, meters, control switches, protective relays and ventilation equipment. The ratings of switchgear assemblies are designations of the operational limits under specific conditions of ambient temperature, altitude, frequency, duty cycle, etc. For example, the performance of some 50 Hz magnetic type circuit breakers may be altered slightly when operated on a 60 Hz power system. Switchgear manufacturers should always be consulted to identify the frequency response of circuit breakers and all auxiliary devices.

2-5. Safety and security equipment.

Safety and security equipment includes fire detection systems, burglar alarm systems, doorbells, and surveillance systems. This equipment typically operates on low voltage, either alternating current (AC) or direct current (DC), generated initially by a power supply. Acquiring the proper power supply to convert from the supply voltage to the low voltage that these systems expect (typically 6 to 12 VAC or VDC) is the key to proper operation of these systems in foreign environments. Power supplies of 50 Hz/120 VAC usually are available from vendors of these systems, and a transformer can be used to step a 240 VAC supply down to a 120 VAC foreign environment. Therefore, derating is not necessary for these items, although a transformer may be needed to step high voltage supply levels down to 120 VAC for the power supplied to these systems. Most vendors of safety and security equipment can configure their equipment to 50 Hz and a variety of voltage levels.

2-6. Communication equipment.

Communication equipment encompasses public address systems and sound systems, both of which operate on a low-voltage DC supply generated by a power supply. Power supplies are available to operate on 50 Hz and 240 V supply voltages. In cases where only 120/50 Hz supplies are available, a step-down transformer can be used to step a 240 V supply down to 120 V. The vendors contacted in this study have stated that they provide 50 Hz power supplies.

2-7. Lighting.

Lighting can be divided into incandescent, fluorescent, and high intensity discharge (HID) categories. Incandescent lighting is not frequency-sensitive, whereas fluorescent and HID lights are started by a ballast that is sensitive to voltage level and frequency.

All types of lighting are sensitive to the supply voltage level and cannot be derated for voltage. For example, subjecting a 120 V incandescent lamp to a 240 V source will result in the lamp burning twice as hot, causing rapid lamp failure. Subjecting the iron core ballast use in many HID and fluorescent fixtures to twice its rated voltage will saturate the ballast and will subject the fixture to much more than its rated current. As with transformers and motors, 60 Hz iron-core ballasts can also be saturated when operated at 50 Hz. At first thought, frequency dependence may not be os much of a problem with electronic ballasts since, in most cases, the AC voltage source is first converted back to a high frequency AC source, and therefore, the voltage source that is actually impressed across the lamp is decoupled from the 60 Hz AC source. However, the power supply used to power the electronics in these ballasts must be capable of 50 Hz operation.

2-8. Other electrical equipment.

Other electrical equipment includes motors, motor starters, computer power supplies, and clocks.

a. Typically, motor starters are sensitive to both supply voltage level and frequency. The most commonly used motor starters consisters of a coil, thermal overloads, and a set of contactors (contacts). The thermal overloads, which are essentially circuit breakers, and the contactors are rated to handle a certain amount of current. Since at 50 Hz, a motor of a given horsepower rating will draw more current than an identically-rated motor would draw at 60 Hz, the thermal overloads and the contactors must be sized accordingly.

b. Computer power supplies include voltage regulators, isolation transformers, transient voltage suppressor transformers, computer regulator transformers, and power conditioning transformers. Computer power supplies are sensitive to both frequency and voltage level.

c. Clocks are sensitive to supply frequency and voltage. Clocks rely on the frequency of the supply voltage to keep correct time, so a clock designed for 60 Hz will not keep correct time at 50 Hz. The motor that runs the clock is also sensitive to supply voltage level. Therefore, a clock must either be purchased configured for the supply voltage level, or a transformer must be used to convert the supply voltage level to the clock's rated voltage level. Clocks cannot be derated for frequency, and therefore clocks designed for 50 Hz must be purchased.

CHAPTER 3
EQUIPMENT DERATING

3-1. Derating under 50 Hz conditions.

Derating factors for 50 Hz operation are developed differently for different types of equipment. Derating factors for HVAC, electrical distribution and protection, safety and security equipment, communication equipment, lighting, and other electrical equipment are discussed below.

3-2. Heating, ventilating, and air conditioning (HVAC) for derating.

The frequency of the supply voltage affects two types of components in HVAC systems: motors and controls. From the discussion in paragraph 2-2, for the same mechanical load and voltage level, a 60 Hz motor will draw 20 percent more current when supplied from a 50 Hz voltage source. This assumes the iron core of the motor does not saturate. Therefore, a 60 Hz motor would have to be capable of handling the increase in current level. However, as was also mentioned in the previous chapter, saturation can be a serious problem when running a 60 Hz motor off a supply frequency of 50 Hz. Developing a derating factor to account for saturation is not possible, since the motor designs vary from vendor to vendor, and hence, the degree of saturation that would occur, if any, would be impossible to predict. Consequently, it is recommended that no horsepower derating be performed, and a 50 Hz motor be purchased.

a. However, if the vendor can guarantee the user that a given 60 Hz motor would not saturate at 50 Hz, then the motor would need only to be derated to handle the 20 percent increase in current level. The amount of horsepower derating required would depend on the motor's mechanical load, service factor, and thermal limit. The service factor is a measure of how much the motor can be overloaded continuously without exceeding safe temperature limits. The thermal limit is the minimum speed at which an AC motor can be operated with rated amperes, without exceeding safe temperature rise. The thermal limit is important because the motor's ability to cool itself will be reduced at lower speeds unless, of course, some sort of auxiliary cooling is used. In most cases, however, the minimum shaft speed necessary to exceed the thermal limit is much lower than 1500 revolutions per minute (RPM, for example, for a 4-pole motor), so 50 Hz operation should not be a problem, although the vendor should be contacted for verification. A 60 Hz motor with a 1.20 service factor can be operated safely while overloaded continuously by 20 percent. The same motor can be operated safely with a rated mechanical load and a 50 Hz power supply with no horsepower derating, assuming saturation is not an issue, the thermal limit of the motor is not exceeded, and the same voltage amplitude is applied. However, a 60 Hz motor, with a 1.0 service factor, driving a rated mechanical load would have to be derated for horse power by 20 percent, since it is not capable of handling greater than the rated current. In summary, the user should find out the service factor and thermal limit of the motor to determine the amount of horsepower derating required, and to ensure that the 20 percent increase in current level in the motor does not exceed the motor's rating (again, assuming saturation is not a concern].

b. Another issue to be considered when purchasing HVAC equipment for a 50 Hz environment is that the motor's shaft will spin 5/6 as fast as it would with a 60 Hz supply. For a 4-pole motor, the shaft will rotate at roughly 1500 RPM when run off a 50 Hz supply, where as with a 60 Hz voltage source it will rotate at about 18OO RPM. Consequently, equipment that is directly coupled to the shaft of the motor will rotate at 5/6 the speed it would in a 60 Hz environment. Hence, direct-drive equipment must be derated to account for the change in speed. In cases where the equipment is indirectly coupled to the motor shaft, through the use of adiustable pulleys for example, the reduction in shaft speed is not as much of a problem since the required speed of rotation can be obtained through the proper adjustment or selection of the pulleys.

c. Additionally, electronic HVAC controls that contain their own power supply may be 50 Hz sensitive. Most of the vendors contacted stated that this typically is not a problem because most controls are frequency-sensitive. If the control are 50 Hz sensitive, they must be purchased in a 50 Hz configuration. The HVAC vendor must be consulted on a case-bycase basis to determine if the controls can be used in 50 Hz environments.

3-3. Electrical distribution and protection.

In general, a 60 Hz transformer should not be used with a 50 Hz voltage source because of the potential saturation problem. As with motors, a derating factor cannot be developed to account for saturation because of the many different transformer designs on the market. It is recommended that a 50 Hz transformer be purchased for use with a 50 Hz voltage source. However, if a 60 Hz transformer vendor can ensure that a transformer will not saturate when operated at 50 Hz, the transformer should be fully capable of safely supplying its nameplate rated load (that is, no horsepower derating is required). In terms of the transformer's equivalent impedance, sometimes used for power system studies (for example, short-circuit and load-flow analysis), the 60 Hz value should be derated by 5/6 to account for the reduction in system frequency.

a. Power factor capacitors rated at 60 Hz must also be derated to 50 Hz. Capacitors do not consume any real power, but they do consume reactive power. The rating given to power factor capacitors is given in units of kilovolt-amperes reactive (KVAR), which indicates the amount of reactive power the capacitor will consume at the rated frequency. As mentioned in chapter 2, the capacitor's impedance, X_c, is inversely related to frequency. If the frequency drops from 60 to 50 Hz, the impedance will increase to 6/5 of its 50 Hz value. Since the KVAR rating equals V^2/X_c, if X_c at 50 Hz increases to 6/5 of its 60 Hz rating, the KVAR rating will decrease to 5/6 of its 60 Hz rating when the capacitor is used in a 50 Hz environment. Therefore, a 60 Hz-rated capacitor must have the KVAR rating multiplied by 5/6 to yield its 50 Hz KVAR rating.

b. Other electrical protection and distribution equipment either cannot or should not be derated. Electrical protection devices are generally able to be used at either 50 Hz or 60 Hz, but a different trip curve needs to be used by the power system designer for 50 Hz. These 50 Hz trip curves are readily available from vendors of this equipment, so no derating is necessary. The only exception is that some circuit breakers are designed differently at 50 Hz and 60 Hz.

c. Voltage, current, and power meters can be derated, but this practice is not recommended. A meter should display the true value it is supposed to measure to ensure that the readings are interpreted correctly and that no dangerous situations result. Meters, therefore, should not be derated. Automatic transfer switches use power supplies that may or may not be frequency-sensitive. Vendors must be contacted regarding 50 Hz configuration of these devices. Electrical generators must be purchased already configured to provide a 50 Hz voltage source.

3-4. Safety and security equipment for derating.

Safety and security equipment operate on a low-voltage AC or DC source that is generated by a power supply. Some power supplies are sensitive to frequency; others are not. In either case, derating is not necessary since power supplies sensitive to frequency cannot be derated, and power supplies insensitive to frequency do not need to be derated. In cases where the power supplies are sensitive to 50 Hz, vendors are able to ship the equipment with a 50 Hz-compatible power supply.

3-5. Communication equipment for derating.

Communication equipment operates on a low-voltage DC supply and does not need to be derated for frequency. Vendors will either ship the units with frequency-insensitive power supplies, or they will configure the units for 50 Hz operation before shipping.

3-6. Lighting for derating.

Incandescent lighting is not frequency-sensitive since this type of lighting consists of a resistive element (the filament), which is not frequency-sensitive. Fluorescent and high intensity discharge (HID) lighting, on the other hand, use a ballast to generate the proper lamp voltage and to limit the current flowing through the lamp. These ballasts are sensitive to frequency. Because of the numerous ballast designs and styles on the market, and the potential saturation problem, a simple derating factor cannot be developed and it is recommended that a vendor supplying 50 Hz-rated ballasts be located.

3-7. Other electrical equipment for derating.

Other electrical equipment consists of motors, motor starters, computer power supplies, and clocks. Motor derating was mentioned earlier in the HVAC section of this chapter. Motor starters are sensitive to frequency as well, but indirectly so. Since a 60 Hz motor will draw 20 percent more current when operated off a 50 Hz voltage source, assuming the same voltage amplitude is applied and there is no saturation problem, the motor starter current rating must be derated by 20 percent to account for the increase in current. Clocks and computer supply equipment are sensitive to frequency and cannot be derated. Clocks rely on the frequency of the supply to keep correct time, so a 60 Hz clock will not keep correct time at 50 Hz. Although derating factors could be developed for clocks, they would be meaningless. Computer power supply equipment cannot be derated due to the way the equipment is constructed.

3-8. Derating under alternate voltage conditions.

As appendix B shows, standard one-phase voltages around the world are either in the range of 100-127 VAC or 220-240 VAC. Voltage variations within about 10 percent of an equipment's rated voltage are acceptable, so derating for voltage will only be necessary when a piece of equipment rated for U.S. voltage (approximately 120 VAC) needs to be operated in an environment using 220-240 VAC. This would be a doubling of rated voltage. None of the equipment sensitive to voltage level is capable of surviving this increase without rapid failure. Thus, no derating factors for voltage level are offered. Instead, it is recommended that transformers be used to step the higher voltage level down to a voltage level in the range of 100-127 VAC, which U.S. equipment can tolerate. It has been found, however, that most vendors of voltage-sensitive equipment are able to configure the equipment for 220-240 VAC and corresponding threephase voltage levels.

3-9. Recommendations.

Derating factors were discussed and developed for the six generic types of equipment. Appendix C, which summarizes the discussion of derating factors presented in this chapter, is useful in identifying derating factors quickly and easily. Although this chapter presents derating factors for equipment, it is recommended that, whenever a piece of equipment is to be derated, the vendor be contacted to discuss the derating. It is always preferable to locate a vendor that will supply the equipment with the desired ratings before derating is attempted. The majority of vendors contacted are able to supply equipment rated at 50 Hz and a variety of voltage levels, so derating should be necessary in only a few cases.

3-10. Summary.

Appendix B can be used to rapidly identify the standard frequency and voltage levels in other countries. In cases where cities within a country differ in their electrical standards, the cities are listed separately. For countries in which all cities have the same electrical standards, typically only the capital city is listed. In these cases, assume that all cities in the country have the same electrical standards.

APPENDIX B

Frequency and Single- and Three-Phase Voltage Levels by Country

This appendix covers identification of various low and medium voltage levels, along with the system frequencies, used by countries around the world.

Table B-1. Frequency and Single and Three-Phase Voltage Levels by Country

Country/City	Frequency (Hz)	Number of Phases	Low Voltage (V)	Medium Voltage (kV)
Afghanistan	50	1,3	220/380	3.2, 6, 10, 15, 20
Algeria	50	1,3	127/220 220/380	5.5, 6.6, 10, 30
American Samoa	60	1,3	120/240 240/480	NA
Angola	50	1,3	220/380	NA
Antigua	60	1,3	230/400	NA
Argentina	50	1,3	220/380	6.6, 13.2, 33
Australia	50	1,3	240/415	6.6, 7.6, 11, 12.7, 19, 22, 33, 66
Austria	50	1,3	220/380	3, 5, 6, 10, 20, 25, 28, 30
Azores				NA
Ponta Delgada	50	1,3	110/190 220/380	
All Others	50	1,3	220/380	
Bahamas	60	1,3	120/240 120/208	7.2, 11
Bahrain				11
Awali	60	1,3	230/400	
All Others	50	1,3	230/400	
Bangladesh	50	1,3	220/380	11, 33 (various seasonally)
Barbados	50	1,3	115/230 115/200	11,24
Belgium				6.6, 10, 15, 36, 70*
Anderlecht	50	1,3	220	
Antwerpen	50	1,3	127/220 220/380	
Brugge	50	1,3	220/380	
Brussels	50	1,3	127/220 220/380	
Charlerio	50	1,3	230/400	
Gentbrugge	50	1,3	220/380	
Hasselt	50	1,3	130/220 220/380	
Hoboken	50	1,3	127/220 220/380	
Huy	50	1,3	220	

*Voltages listed are country-inclusive, all voltages listed for the country may not be found in individual cities listed.

Table B-1. Frequency and Single and Three-Phase Voltage Levels by Country–Continued

Country/City	Frequency (Hz)	Number of Phases	Low Voltage (V)	Medium Voltage (kV)
Belgium *(continued)*

APPENDIX C
Derating Factors

C-1. Heating, ventilation, and air conditioning (HVAC).

a. 50 Hz. The output of directlycoupled, motordriven equipment must be derated to account for the reduction in shaft speed to 5/6 the 60 Hz value. Otherwise, the mechanical coupling used between the motor and driven equipment should be purchased to give the required rotating speed. HVAC controls that are frequency dependent must be purchased in 50 Hz configurations.

b. Voltage. Derating for voltage is not an option.

C-2. Electrical distribution and protection for transformers.

a. 50 Hz. In general, derating for frequency is not recommended. See chapter 3 for details.

b. Voltage. Derating for voltage is not recommended. Vendors can provide almost any needed input voltage rating. Consult vendor regarding derating possibility if derating is absolutely necessary.

C-3. Electrical distribution and protection for power factor capacitors.

a. 50 Hz. Derate kilovolt-amperes reactive (KVAR) rating by multiplying 60 Hz KVAR rating by 5/6 to yield 50 Hz WAR rating.

b. Voltage. Derating for voltage is not recommended. Vendors can provide almost any needed voltage rating. Consult vendor regarding derating possibility if derating is absolutely necessary.

C-4. Electrical distribution and protection for protection equipment.

a. 50 Hz. Different trip curves may be needed. Consult vendor for these curves.

b. Voltage. Derating for voltage should not be needed. Verify with vendor since special protection equipment may need derating.

C-5. Other electrical distribution and protection.

Derating either cannot or should not be performed. Contact vendors to purchase appropriately rated equipment.

C-6. Safety and security equipment.

a. 50 Hz. Depends on type of power supply. Derating is either not necessary or not possible. Contract vendor to purchase appropriately configured power supply.

b. Voltage. Derating far voltage is not recommended. Contact vendor to purchase appropriately configured power supply, or use transformer to convert supply voltage level to power supply input level.

C-7. Communication equipment.

a. 50 Hz. Depends on type of power supply. Derating is either not necessary or not possible. Contact vendor to purchase appropriately configured power supply.

b. Voltage. Derating for voltage is not recommended. Contact vendor to purchase appropriately configured power supply, or use transformer to convert supply voltage level to power supply input level.

C-8. Incandescent lighting.

a. 50 Hz. No derating necessary. Incandescents are frequency insensitive.

b. Voltage. Not possible. Bulb life will suffer drastically. Contact vendor to purchase high voltage bulbs, or use transformer to convert supply voltage to lamp voltage.

C-9. Fluorescent and high intensity discharge (HID) lighting.

50 Hz. Derating is not recommended. Fixtures configured for 50 Hz should be purchased.

C-10. Motors.

a. 50 Hz. In general, derating a 60 Hz motor is not recommended. See chapter 3 for exceptions

b. Voltage. Derating for voltage is not recommended. Contact vendor to purchase appropriately configured equipment, or use transformer to convert supply voltage to motor's rated voltage level.

C-11. Motor Starters.

a. 50 Hz. Derate by multiplying 60 Hz horsepower rating by 4/5 to yield the 50 Hz horsepower rating.

b. Voltage. Derating for voltage is not possible. Contact vendor to purchase appropriately configured equipment, or use transformer to convert supply voltage to motor starter's rated voltage level.

C-12. Clocks.

a. 50 Hz. Derating is possible but meaningless since 60 Hz clock will not keep correct time in 50 Hz environment

b. Voltage. Derating for voltage is not recommended. Contact vendor to purchase appropriately configured clocks, or use transformer to convert supply voltage to clock's rated voltage level.

C-13. Computer power supplies.

a. 50 Hz. Derating is not possible due to equipment construction. Contact vendor to purchase 50 Hz rated equipment.

b. Voltage. Derating for voltage is not possible. Contact vendor to purchase appropriately configured equipment, or use transformer to convert supply voltage to equipment's rated voltage level.

The proponent agency of this publication is the Chief of Engineers, United States Army. Users are invited to send comments and suggested improvements on DA Form 2028 (Recommended Changes to Publications and Blank Forms) directly to HQUSACE, (ATTN: CEMP-SP), Washington, DC 20314-1000.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) has been issued to provide guidance for the design of interior electrical systems. The criteria contained herein are intended to ensure economical, durable, efficient, and reliable systems and installations. Whenever unique conditions and problems are not specifically covered by this UFC, use the applicable referenced industry standards and other documents for design guidance.

UFC 3-501-01 provides the governing criteria for electrical systems, explains the delineation between the different electrical-related UFCs, and refers to UFC 3-520-01 for interior electrical system requirements. Modernization of electrical systems within existing facilities solely for the purpose of meeting design criteria in this UFC is not required. Upgrades or modifications of existing facilities must apply the design criteria in this UFC, but it is not intended that an entire facility require modernization solely because of a minor modification to a part of the facility.

1-2 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 3-520-01, dated 06 October 2015.

1-3 APPLICABILITY.

This UFC applies to planning, design, construction, sustainment, restoration, and modernization of DoD-owned facilities. It applies to all methods of project delivery and levels of construction as defined by UFC 1-200-01, Section 1-3.

1-3.1 UFC Scope.

Compliance with this UFC is mandatory for the design of interior electrical systems at all facilities and bases. This UFC typically applies up to 5 feet beyond the facility envelope. It also applies to:

- Service(s) supplying power from the utility system utilization transformer to the wiring system of the facility.
- Circuits originating from within the facility that extend beyond the facility envelope.
- Wiring and connections for supplemental grounding systems.
- Wiring from and connections to non-utility equipment supplying power to the wiring system of the facility, including engine-generator sets, photovoltaic power systems and fuel cells.

Refer to UFC 3-550-01 for exterior electrical systems.

1-3.2 Host Nation Standards.

In addition to NFPA 70 requirements, facilities located outside of the United States must also comply with the applicable host nation standards. Host nation voltage and frequency as defined in UFC 3-510-01 generally applies. Different wiring and grounding conventions usually apply in other host nations; however, follow the design principles provided in this UFC to the extent practical.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

Cybersecurity is implemented to mitigate vulnerabilities to all DoD real property facility-related control systems to a level that is acceptable to the System Owner and Authorizing Official. UFC 4-010-06 provides requirements for integrating cybersecurity into the design and construction of control systems.

1-6 DESIGN STANDARDS.

Comply with the requirements of National Fire Protection Association (NFPA) 70, National Electrical Code, and the requirements herein. Electrical safety requirements, including the types of energized work permitted, approval process for energized work, and Personal Protective Equipment (PPE), applicable to the design, installation, and operation of electrical systems are provided in UFC 3-560-01.

Note: When a project, or portion of a project, has been designated as requiring Critical Operations Power Systems (COPS) treatment as a Designated Critical Operations Area (DCOA) per NFPA 70 Article 708, those requirements identified in the Unified Facility Criteria that are more stringent than NFPA 70 requirements take precedence over NFPA requirements. This UFC does not address COPS requirements.

1-7 GLOSSARY.

APPENDIX C contains acronyms, abbreviations, and terms.

1-8 REFERENCES.

APPENDIX D contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

References applicable to a specific topic are also listed and described in the appropriate sections of this UFC. Codes and standards are referenced throughout this UFC. Follow the guidance provided in UFC 1-200-01, Section 1-3.1 to establish the issue/version of the publication effective for the project.

This Page Intentionally Left Blank

CHAPTER 2 GENERAL POWER SYSTEM CRITERIA

2-1 VOLTAGE.

Refer to UFC 3-550-01 for voltage criteria associated with the primary distribution supply voltage.

Unless there are specialty voltage requirements, base the facility system voltage on the interior load requirements as follows:

- Apply 240/120V for facilities with only single-phase loads.
- Apply three-phase, four-wire, 208Y/120V systems for lighting and power demand loads less than 150 kVA.
- Apply three-phase, four-wire, 480Y/277V systems for lighting and power demand loads greater than 150 kVA unless 208Y/120V systems are shown to be more cost-effective. Use step-down transformers inside the facility as required to obtain lower voltages.
- For facilities with demand loads less than or equal to 150 kVA in which potential voltage drop issues have been identified, evaluate the life cycle cost effectiveness of installing larger conductor sizes and/or buck-boost transformers on a 208Y/120V system against the use of a 480Y/277V service utilizing step-down transformers. If determined that the life cycle cost is effective, the use of a 480Y/277V service shall be used in lieu of a 208Y/120V service.

2-2 FREQUENCY.

Apply a frequency of 60 Hz for distribution and utilization power.

In locations in which the commercially supplied frequency is other than 60 Hz, such as 50 Hz, use the available supplied frequency to the extent practical. Where frequencies other than that locally available are required for technical purposes, frequency conversion or generation equipment can be installed. The facility user will normally provide this equipment.

This Page Intentionally Left Blank

CHAPTER 3 POWER DISTRIBUTION AND UTILIZATION

3-1 TRANSFORMERS.

The transformer design criteria provided herein apply to interior applications and to dry-type transformers fed by distribution traditionally placed in/for the facility downstream of the main service. Most facilities will be supplied by an exterior utility system pad-mounted transformer.

Interior transformers shall be sized according to the NEC.

3-1.1 Low Voltage Transformers.

Specify dry-type transformers in accordance with NEMA ST 20 and the following:

- For transformers rated for 15 kVA or larger, use transformers with a 428 degrees F (220 degree C) insulation system not to exceed a 239 degrees F (115 degree C) rise capable of carrying continuously 115 percent of nameplate kVA without exceeding insulation rating at a maximum ambient temperature of 104 degrees F (40 degrees C). Provide a transformer of 80 degrees C temperature rise capable of carrying continuously 130 percent of nameplate kVA without exceeding insulation rating when additional overload capacity is required.
- Transformers rated less than 15 kVA can use a 356 degrees F (180 degree C) insulation system not to exceed an 176 degrees F (80 degree C) rise at a maximum ambient temperature of 104 degrees F (40 degrees C).
- When the transformer is located in areas where noise is a factor, specify sound levels at least 3 decibels below recommended values established by NEMA ST 20.
- Derate the transformer in accordance with the manufacturer’s guidance for locations with a maximum ambient temperature above 104 degrees F (40 degrees C) and in accordance NEMA ST 20 for altitudes higher than 3,300 feet (1,000 meters).

Include the following as part of the installation:

- Design system such that transformer vibrations are not transmitted to the surrounding structure. Small transformers can usually be solidly mounted on a reinforced concrete floor or wall. Flexible mounting will be necessary if the transformer is mounted to the structure in a normally low-ambient noise area.
- Use flexible couplings and conduit to minimize vibration transmission through the connection points.

- Locate the transformer in spaces where the sound level is not increased by sound reflection. For example, in terms of sound emission, the least desirable transformer location is in a corner near the ceiling because the walls and ceiling function as a megaphone.
- Provide adequate ventilation in transformer spaces to prevent the temperature rise from exceeding the transformer rating.

Refer to TSEWG TP-05, Interior Transformer Ratings and Installation, at https://wbdg.org/dod/supp-tech-documents for additional information regarding transformers and transformer ratings.

3-1.2 Other Transformer Types.

Do not use unless justified and documented in the design analysis. Refer to Appendix B for additional guidance for applications involving significant harmonic distortion.

3-2 SERVICE ENTRANCE AND DISTRIBUTION EQUIPMENT.

Locate service entrance equipment and other major electrical equipment in a dedicated electrical space. Provide a main breaker on each service entrance either outside of a building or structure or inside nearest the point of entrance of the service conductors in accordance with NFPA 70. Service feeders may be installed under the building only when necessary or for optimal routing. Distances shall be minimal. Locate other electrical equipment, such as electrical panels, in dedicated spaces.

Note: Identify when 100 percent rated circuit breakers are included in the design.

Size circuit breaker interrupting ratings based on the available short circuit current; however, do not select circuit breakers less than 10 kA symmetrical interrupting rating for voltages 240V and below and 14 kA symmetrical interrupting rating for 480V applications. The use of series-rated combinations of breakers to clear a fault that utilize an individual breaker rated at less than the available fault current is prohibited.

Do not use fusible overcurrent devices except when non-fusible overcurrent devices will not comply with NFPA 70 requirements for selective coordination.

3-2.1 Spare Capacity.

Provide a minimum of 15% empty space and 15% spare capacity (ampacity) for all switchgear, switchboards, panelboards, and load centers. For flush-mounted equipment, provide spare conduits extending up above the ceiling and down below raised floors when applicable. For panelboards, provide one spare conduit, minimum of ¾-inch (20 mm), for every three spare circuit breakers and for every three empty pole positions. Round up the sum of spare breakers and empty pole positions to the nearest multiple of three.

Note: Do not use spare capacity as part of the demand calculations specified in UFC 3-501-01. The overall calculations already account for this spare capacity with the 15% allowance for future load growth specified in UFC 3-501-01 load analysis calculations for the service entrance.

3-2.2 Selection.

Select equipment as follows:

- Specify metal-enclosed switchgear when the equipment is 1200A or larger, and branch and feeder circuits are above 400A or if any branch or feeder circuits is larger than 800A.
- Specify switchboards when the equipment feeds circuit breakers 800A or larger. Utilize switchboards throughout the distribution system where equipment is 1200A or larger.
- Specify distribution system type panelboards when the equipment is 800 – 1200A. Utilize panelboards up to 600A if they can be accommodated in one enclosure.

For all circuit breakers where the continuous current trip setting for the actual overcurrent device in the circuit breaker is rated for or can be adjusted is 1,200 amperes or higher, select the method used to reduce the clearing time for arc energy reduction:

- Zone-selective interlocking, or
- Differential relaying, or
- Energy-reducing maintenance switching with local status indicator, or
- Energy-reducing active arc flash mitigation system or
- An approved equivalent means.

3-2.3 Switchgear.

Design metal-enclosed switchgear per IEEE C37.20.1 and UL 1558. Provide electrically operated circuit breakers. The switchgear and circuit breakers must be the product of the same manufacturer.

Evaluate the following options as part of the switchgear design:

- Arc-resistant switchgear tested and certified to IEEE C37.20.7 to provide added protection for internal arcing faults.
- Infrared viewing windows to allow the use of an infrared camera or thermal imager direct line of site to inspect electrical connections without requiring the opening of panels and doors.
- A remote racking mechanism to allow an operator to rack a circuit breaker in or out at least 20 feet from the front of the equipment.

- Drawout compartment shutters to protect operators from accidental contact with breaker stabs when a circuit breaker is withdrawn from its cubicle.
- Evaluate medium-voltage gas-insulated switchgear (GIS) with vacuum circuit breakers when the facility owner requires more than 99.9% availability, or the switchgear must fit in a small footprint. GIS switchgear must be tested and certified per IEEE C37.20.9

3-2.4 Switchboards.

Design switchboards per NEMA PB2 and UL 891. Devices must be front accessible and must be completely isolated between sections by vertical steel barriers. Switchboards should have hinged fronts to allow safer maintenance access for electrical safety.

3-2.5 Panelboards.

3-2.5.1 Configuration.

Equip panelboards and load centers with separate ground bus bars and insulated neutral bus bars to isolate the bus bar, when required by code. Circuit breakers must be bolt-on type unless where specifically indicated otherwise for load center type panelboards. Do not use dual section panelboards.

Do not use panelboards or load centers with more than 54 poles unless any of the following conditions are met.

- All of the loads are served by a redundant source, or
- The customer accepts in writing the risk of larger outages and the AHJ approves the larger panelboard or load center.

Distribution and branch circuit panelboards should be of the wall-mounted, dead-front type, equipped with bolt-on circuit breakers. Load center style panelboards, with plug-in breakers should be used only where authorized for military family housing. Each panelboard and load center style panelboard must be fed from a dedicated circuit and circuit breaker.

3-2.5.2 Location and Design.

Place panelboards as close as possible to the center of the loads to be served. Provide panelboards with hinged fronts to allow safer maintenance access for electrical safety. Clearly fill out panelboard circuit directories indicating the specific load and location, such as “Lights, Room 102”.

Optimize equipment layout and circuit arrangement. Optimization shall include grouping together circuits going to the same space or area of the building. The phase loading on panelboards shall be balanced as much as practical by the type of loads on the panel.

Take into consideration circuit breaker frame size mismatching when arranging circuits across from each other, as well as additional pole spaces required for specialty features such as 3-pole GFCI electronics and shut trip devices.

3-2.5.3 BEQ/BOQ Facilities and Housing.

Use panelboards for service entrance equipment and electrical distribution in BEQ/BOQ facilities. Load center style panelboards, with plug-in breakers, can be used in housing units and BEQ/BOQ rooms.

3-2.5.4 Arc-Fault Circuit Interrupters.

Provide arc-fault circuit interrupter protection for branch circuits supplying 120V, single-phase,15A and 20A outlets installed in dwelling units as specifically required by NFPA 70.

3-2.6 Motor Control Centers (MCCs).

Comply with UL 845 and NEMA ICS 2.

3-2.7 Power for Fire Protection Systems.

Fire pump and fire pump controller power supply shall satisfy the requirements of NFPA 70 and UFC 3-600-01 rather than the requirements of this subpart.

Provide power for the remainder of the fire protection systems, including fire alarm and mass notification systems, suppression and containment control panels, line voltage indicator systems (such as beacons), transmitter panel, and similar monitoring, control, and reporting equipment but excluding fire pumps and fire pump controllers in accordance with NFPA 72, NFPA 70 Article 760, and as follows:

a. Distribution Configuration(s). A dedicated distribution leg (or multiple legs) shall be supplied from the main distribution equipment to support the fire protection system components described above if either of the following conditions are present:

   1. The building area exceeds 25,000 square feet.

   2. Six or more circuits are required to supply the fire protection system components on a given voltage system (i.e., 208/120V, 480/277V, etc.).

   Circuits for components directly supporting the fire protection components, such as surge protective devices and receptacles in the immediate vicinity of and whose purpose is to perform maintenance on the fire protection components, shall be permitted to be supplied from the dedicated equipment.

   In all other cases, the fire protection system components may be suppled from the portions of the distribution equipment present for other building electrical support, and such distribution components must comply with the succeeding requirements of this section.

Where multiple fire protection circuits are supplied from the same panel not dedicated exclusively to fire protection systems described above, connect the fire protection circuits to physically adjacent pole locations.

Where fire protection circuits for larger equipment (such as nitrogen generators or jockey pumps) are connected to the building main distribution equipment or the main distribution equipment for a backup power system, such circuits do not contribute toward the number of circuits in the threshold listed above. The succeeding requirements apply to the circuits connected directly to the main distribution equipment described in the paragraph.

b. Protection and Control Features. Provide lock-on circuit breakers for all feeders and branch circuits supplying fire protection system components described above. Start providing the lock-on circuit breakers from the load side of the service disconnecting means. Permanently identify in red the lock-on breakers in the branch panelboards, distribution equipment, and dedicated panelboards without obstructing manufacturer's markings on the breakers.

c. Distribution System Identification. At the distribution equipment, including panelboards, distribution panels, switchboards, switchgear, transformers, enclosed circuit breakers, disconnect switches, transfer switches, and similar equipment which are part of the electrical supply to components described above, provide a label with the following inscription in addition to the equipment nameplate: "Fire Protection/Life safety Equipment." Construct and fasten the label identical to the panelboard nameplate, except the label must be red laminated plastic with white center core. The service disconnecting means shall not require this supplemental nameplate.

d. Backup Power Sources. For facilities which are provided with emergency power supplies (i.e., engine-driven generator, energy storage system, etc.) supporting life safety functions, fire protection described above must be powered by the backup power supply system. Do not power fire protection systems from UPS systems dedicated to specific compartmentalized functions such as individual telecommunications rooms.

3-2.8 Disconnect Switches.

Fusible disconnect switches should be used only where special considerations require their use. Provide heavy duty type safety switches on systems rated for greater than 240V. Use fused switches that utilize Class R fuseholders and fuses. Use NEMA 4X stainless steel switch enclosures for switches located on building exteriors in areas where salt spray or extended high humidity is a concern.

Utilize non-fused disconnect switches as local disconnects only, properly protected by an upstream protective device.

Note: Selection of disconnect switches must be coordinated with the short circuit calculations. Non-fused disconnects are typically rated to only 10kAIC. In cases where the fault current at a disconnect location is greater than 10KAIC, provide one of the following solutions:

a. Fused disconnect.

b. Enclosed circuit breaker.

c. If NFPA 70 permits for a given application, eliminate the local disconnecting means and provide a lockable circuit breaker at the panel.

3-2.9 Circuit Lockout Requirements.

Circuit breakers, disconnect switches, and other devices that are electrical energy-isolating must be lockable in accordance with NFPA 70E and OSHA 1910.303.

3-2.10 Signage.

Place a safety sign on any cubicles containing more than one voltage source. Refer to ANSI Z535.4 for safety sign criteria.

3-2.11 Interrupting Ratings.

Refer to TSEWG TP-06, Low Voltage Breaker Interrupting Ratings, at https://wbdg.org/dod/supp-tech-documents for additional information regarding low voltage breaker interrupting ratings.

3-2.12 Load Balancing by Phase.

Arrange circuits throughout the distribution system with 5% or less design load imbalance for both single- and three-phase systems. Show load imbalance by phase as a percentage on the panel, switchboard, switchgear, and motor control center schedules. Larger facilities generally will be capable of better phase balancing than smaller facilities. Document within the design analysis the instances where phase balancing below the imbalance threshold is not possible and state the reasons, tradeoffs, and/or broader remedies.

3-2.13 Adjustable Trip Devices.

Where adjustable-trip devices are used and NFPA 70 does not permit use of the maximum trip setting, conductors must be sized with the rated capacity equal to the actual device setting. Perform arc flash calculations based on the actual device setting. In design-bid-build projects, provide contract language requiring the contractor to adjust conductor sizes at the direction of the designer of record should the trip setting on the adjustable devices deviate from the rating indicated on the plans in cases such as complying with selective coordination requirements.

Note: NFPA 70 limits the maximum trip rating for equipment such as transformers and motors. It is also possible for the circuit breaker's trip setting to exceed the bus rating.

Provide labeling on the adjustable-trip device indicating the maximum value to which the conductors are capable of safely carrying after all applicable correction and adjustment factors were applied and voltage drop calculations performed. Additionally, provide warning of the potential for different arc flash conditions should the adjustable trip rating be altered.

Size equipment grounding conductors and perform voltage drop calculations based on the respective approach used: Where the rating is based on restricted access, use the actual setting; where the rating is based on unrestricted access, use the maximum setting possible.

3-3 MOTORS AND MOTOR CONTROL CIRCUITS.

3-3.1 Basic Motor Criteria.

3-3.1.1 Efficiency.

Apply premium efficiency ratings per the Energy Policy Act of 2005 (EPACT 2005) to all motors.

3-3.1.2 Application.

Use three-phase motors if more than 0.5 horsepower rating when such service is available. If three-phase service is not available or if three-phase motor is not available, operate motors larger than 0.5 horsepower at phase-to-phase voltage rather than phase-to-neutral voltage. Motors 0.5 horsepower and smaller must be single phase.

Do not use 230V motors on 208V systems because the utilization voltage will commonly be below the -10% tolerance on the voltage rating for which the motor is designed (a 230V motor is intended for use on a nominal 240V system).

3-3.2 Motor Control Circuits.

3-3.2.1 Motor Controllers.

Provide motor controllers (starters) for motors larger than 1/8 horsepower (93.25 watts) and apply the design criteria of NEMA ICS 1 and NEMA ICS 2.

3-3.2.2 Motor Starting.

Use full voltage-type starting unless the motor starting current will result in more than a 20% transient voltage dip or if the analyzed voltage dip is otherwise determined to be unacceptable. For other than full voltage starting, apply one of the following methods for motor starting:

- Reduced Voltage Starters.
- Adjustable Speed Drives (ASDs) are also referred to as Variable Frequency Drives (VFDs). If an ASD is required for other reasons, it can also address motor starting current design needs. Refer to NEMA ICS 7 for design criteria related to the selection and design of ASDs. Appendix A provides additional information regarding the sizing and operational design of ASDs.

3-3.2.3 Manual Control.

Provide manual control capability for all installations having automatic control that operates the motor directly. Use a double-throw, three-position switch or other suitable device (marked MANUAL-OFF-AUTOMATIC) for the manual control. Confirm that all safety control devices, such as low- or high-pressure cutouts, high-temperature cutouts, and motor overload protective devices, remain connected in the motor control circuit in both the manual and automatic positions.

3-4 SURGE PROTECTIVE DEVICES (SPDS).

Provide SPDs for surge protection of sensitive or critical electronic equipment, as required by the activity or equipment manufacturer.

The design criteria provided here apply to permanently installed, hard-wired surge protectors and should not be applied to plug-in type surge protectors (Type 3). Use point-of-use (plug-in type) surge protectors to protect specific critical equipment that plugs into wall receptacles.

3-4.1 Power System Surge Protection.

Use Type 1 or Type 2 SPD and connect on the load side of a dedicated main circuit breaker of the associated equipment. Where multiple service main disconnects are used the device(s) should be placed as recommended by the manufacturer to protect the circuits. Locate as close as practical to the breaker with a maximum lead length of 3 ft (900 mm). Integral SPDs with surge counters visible from the dead front of the panelboard and manufactured by the panelboard manufacturer are permitted. The SPDs must be rated as Type 1 or Type 2 and comply with UL 1449. The SPDs must include the thermal protection measures and overcurrent protection per UL 1449.

For buildings with high concentrations of electronics equipment, employ a multi-level or cascaded system. Coordinate multiple stage surge protection.

Note: Type 1 SPDs are allowed to be installed ahead of the service entrance MCB when other equipment is required to be connected ahead of the MCB.

3-4.1.1 Service Entrance Surge Protection.

Provide the following specification requirements for SPD on the service entrance equipment

a. Use SPD to protect the electrical service entrance equipment.

b. The SPD must meet or have a voltage protection rating that is less than the UL 1449 voltage protection ratings listed below. If surge protection is required as part of a lightning protection system, comply with the more stringent voltage protection ratings specified in NFPA 780.

System Voltage	Protection Modes	Voltage Protection Rating
208/120 or 240/120	L-N	700
	L-G	700
	N-G	700
	L-L	1,200
480/277	L-N	1,200
	L-G	1,200
	N-G	1,200
	L-L	2,000

c. Per mode single pulse surge current rating for an 8x20 ms waveform must be no less than:

L-N 40kA

L-G 40kA

N-G 40kA

L-L 80kA

d. Protection Mode: Provide the following six modes (additional modes are permitted):

Line-to-line

Line-to-ground or line-to-neutral

Wire SPDs at grounded service entrances in a line-to-ground (L–G) or line-to-neutral (L–N) configuration. For services without a neutral, connect the SPD elements line-to-ground (L–G).

e. MCOV for L-N and L-G modes of operation: 120% of nominal voltage for 240 volts and below; 115% of nominal voltage above 240 volts to 480 volts.

f. Surge Life: Greater than 5000 surges of repetitive sequential IEEE C62.41 Category C3 waveforms with less than 10% degradation of measured limiting voltage.

g. Listing: The total unit as installed must be UL 1283 and UL 1449 listed, and not merely the components or modules.

h. Warranty: Not less than a 5-year warranty and include unlimited free replacements of the unit if destroyed by lightning or other transients during the warranty period.

i. Diagnostics: Visual indication unit has malfunctioned or requires replacement. Provide Form C dry contacts for remote monitoring.

3-4.1.2 Branch Panelboard Surge Protection.

Provide the following specification requirements for SPD on all the branch panelboards for facilities requiring cascaded suppression system protection.

a. Use SPD to protect the distribution branch panelboards.

b. The SPD must meet or have a voltage protection rating that is less than the UL 1449 voltage protection ratings listed below.

System Voltage	Protection Modes	Voltage Protection Rating
208/120 or 240/120	L-N L-G N-G L-L	700 700 700 1,200
480/277	L-N L-G N-G L-L	1,200 1,200 1,200 2,000

c. Per mode single pulse surge current rating for an 8x20 ms waveform must be no less than:

L-N 40kA

L-G 40kA

N-G 40kA

L-L 80kA

d. Protection Mode: Provide the following six modes (additional modes are permitted):

Line-to-line

Line-to-ground or line-to-neutral

Wire SPDs at grounded service entrances in a line-to-ground (L–G) or line-to-neutral (L–N) configuration. For services without a neutral, connect SPD elements line-to-ground (L–G).

e. MCOV for L-N, L-G, and N-G modes of operation: 120% of nominal voltage for 240 volts and below; 115% of nominal voltage above 240 volts to 480 volts.

f. Surge Life: Greater than 5000 surges of repetitive sequential IEEE C62.41 Category B3 waveforms with less than 10% degradation of measured limiting voltage.

g. Listing: The total unit as installed must be UL 1283 and UL 1449 listed, and not merely the components or modules.

h. Warranty: Not less than a 5-year warranty and include unlimited free replacements of the unit if destroyed by lightning or other transients during the warranty period.

i. Diagnostics: Visual indication unit has malfunctioned or requires replacement. Provide Form C dry contacts for remote monitoring.

3-4.1.3 Dwelling Unit Surge Protection.

Install as close as practical to the main breaker/lugs. All leads must be as short as possible, with no leads longer than 24 in (610 mm). Provide protection in accordance with branch panelboard surge protection criteria listed above.

3-4.2 Surge Protection for Communications and Related Systems.

3-4.2.1 Systems Requiring Protection.

Provide surge protection for the following systems, including related systems:

- Fire alarm systems.
- Telephone systems.
- Computer data circuits.
- Security systems.
- Television systems.
- Coaxial cable systems.
- Intercom systems.
- Electronic equipment data lines.

3-4.2.2 Protection Levels.

Provide surge protection equipment used for communications and related systems as follows:

- If surge protection is required as part of a lightning protection system, comply with the more stringent voltage protection ratings specified in NFPA 780.

- If surge protection is not required as part of a lightning protection system, provide the following protection UL Listed and tested to UL 497A, or third party verified and tested to UL 497A:
    - o Telephone communication interface circuit protection – provide a minimum surge current rating of 9,000A.
    - o Central office telephone line protection – provide multi-stage protection with a minimum surge current rating of 4,000A.
    - o Intercom circuit protection – provide a minimum surge current rating of 9,000A. Provide protection on points of entry and exit from separate buildings.
- Provide fire alarm and security alarm system loops and addressable circuits that enter or leave separate buildings, UL Listed or third-party verified and tested to UL 497B, with a minimum of 9,000A surge current rating.
- Protect coaxial lines at points of entry and exit from separate buildings.
- Single stage gas discharge protectors can be used for less critical circuits. Multistage protectors utilizing a gas discharge protector with solid-state secondary stages should be used to obtain lower let-through voltages for more critical equipment.

3-4.3 Acceptance Tests.

Perform the following installation checks:

- Inspect for physical damage and compare nameplate data with drawings and specifications.
- Verify that the surge protector rating is appropriate for the voltage.
- Inspect for proper mounting and adequate clearances.
- Verify that the installation achieves the minimum possible lead lengths. Inspect the wiring for loops or sharp bends that add to the overall inductance.
- Check tightness of connections by using a calibrated torque wrench. Refer to the manufacturer’s instructions or Table 10-1 of International Electrical Testing Association (NETA) ATS for the recommended torque.
- Check the ground lead on each device for individual attachment to the ground bus or ground electrode.
- Perform insulation resistance tests in accordance with the manufacturer’s instructions.

- For surge protectors with visual indications of proper operation (indicating lights), verify that the surge protector displays normal operating characteristics.
- Record the date of installation.

3-5 METERING.

Provide advanced metering systems (e.g., with remote reading, monitoring, or activation capabilities) in accordance with service-specific criteria and the DoD directives to comply with EPACT 2005 requirements. Coordinate meters, system components, and meter locations to be compatible with the Activity's central system.

Upon Activity request, limit housing units to meter sockets only. Sockets must be single phase, four terminal, and ring-less with manual bypass device and polycarbonate blank cover plate.

3-6 RACEWAY AND WIRING.

3-6.1 Wiring Devices.

Wiring devices and faceplate colors must match and be consistent with the interior wall types and colors. Use grounding type wiring devices. Outlet boxes must not be placed back-to-back. Provide a minimum of 12 inch (300 mm) of separation between outlet boxes located on opposite sides on common walls.

3-6.1.1 Switches.

Toggle switches must be specification grade, quiet type, and rated minimum 120/277V, 20A, totally enclosed with bodies of thermoplastic and/or thermoset plastic and mounting strap with grounding screw. Use silver-cadmium contacts and one-piece copper alloy contact arm.

When specified, pilot lights must be integrally constructed as a part of the switch's handle.

3-6.1.2 Receptacles.

Provide general purpose convenience outlets that are specification grade, 20 A, 120 V, duplex. Identify locations where split receptacles will be used with one receptacle controlled by a separate manual or automatic switching device. Provide GFI and AFCI protection in accordance with NFPA 70.

Where required by ASHRAE 90.1, all workstations and work areas must have controlled and non-controlled outlets. For non-systems furniture, duplex receptacles must be split yoke with controlled and non-controlled outlets. Duplex receptacle outlets must be fed from the same circuit. Double duplex receptacles must have controlled and non-controlled outlets fed from the same circuit, but split yoke outlets are not required. Note that GFCI receptacles typically cannot be split wired where both split wiring and GFCI are required. Provide either a GFCI device ahead of the wiring split (such as at the panelboard) or provide a double duplex arrangement where each yoke has a GFCI feature.

In addition to the location requirements specified by NFPA 70, locate general purpose, and dedicated (on an individual circuit) outlets in accordance with the following:

a. Mechanical equipment: Provide receptacle within 25 ft (7.6 m) of mechanical equipment on the interior and exterior of buildings, including roof mounted mechanical equipment.

b. Office, staff-support spaces, and other workstation locations: Minimum of two duplex receptacles, one double duplex, or one quadraplex receptacle for each workstation. Where systems furniture is not to be provided, provide double duplex receptacles a minimum of every 20-ft (5.2 m) of wall space at the floor line. Where there is less than 20-ft (5.2 m) of wall at the floor line in offices and where there are no other provisions for powering workstations (such as with systems furniture), provide a minimum of two duplex receptacles spaced appropriately to anticipate furniture relocations. Limit loads to a maximum of four (4) workstations per 20A circuit.

c. Conference rooms and training rooms: One for every 12 ft (3.6 m) of wall space at the floor line. Ensure one receptacle is located next to each voice/data outlet in all areas of the room (floor, wall, and ceiling). Provide one receptacle in the ceiling, faceplate flush with ceiling, to support video projection device, if necessary, and one receptacle in the wall to support a wall mounted monitor. Extend circuit to wall location for connection to motorized screen. When it is expected that a conference room table will be specifically dedicated to floor space in a conference room, ensure not less than one (1) floor-mounted receptacle is located under the table. This receptacle may be part of combination power/communications outlet. Ensure signal pathway exists between conference room table and wall or ceiling mounted displays.

d. Provide power outlets throughout the building to serve all proposed equipment, including government furnished equipment, and allow for future reconfiguration of equipment layout. Provide power connections to all ancillary office equipment such as printers, faxes, plotters, and shredders. Provide dedicated circuits where warranted.

e. In each telecommunications room provide a dedicated 20A circuit with a receptacle adjacent to each rack or backboard for each of the following:

   - CCTV for training systems
   - CCSTV for security systems
   - CATV

- Voice systems
- Data systems.

f. Provide receptacles supplying television monitors on circuits dedicated for such equipment and associated specialty equipment. Multiple receptacles, television monitors, and associated specialty equipment receptacles may be connected to the same circuit dedicated to this purpose provided the total connected load satisfies the limits permitted by NFPA 70 for a standard 15- or 20-amp receptacle circuit as applicable. These outlets will typically be located near the ceiling level for wall mounted television monitors.

g. Corridors: One every 50 ft (15 m) with a minimum of one per corridor.

h. Janitor’s closet and toilet rooms: One GFI receptacle per closet. Provide GFI receptacles at counter height for each counter in toilets such that there is a minimum of one outlet for each two sinks.

i. Space with counter tops: One for every 4 ft (1.2 m) of countertop, with a minimum of one outlet.

j. Building exterior: GFCI protected, weather-resistant (WR) and identified as extra-duty, within 25 ft (7.5 m) of each exterior door and near HVAC equipment in accordance with NFPA 70 requirements. An exception to the requirement for a receptacle in proximity to each exterior door is permitted for doors providing direct entrance into living units for barracks and dormitories. In such cases, one is to be provided for every 50 ft (15 m) wall length with a minimum of one per exterior wall; additionally, one is to be installed within 10 ft (3m) of each exterior door which does not provide direct entrance into a living unit.

k. Kitchen non-residential: One for each 10 ft (3 m) of wall space at the floor line.

l. Dwelling units, Child Development Centers, and other child occupied spaces (including toilets): Provide listed tamper-resistant receptacles.

m. All other rooms: One for every 25 ft (7.6 m) of wall space at the floor line. When 25 ft (7.6 m) or less of wall at the floor line exists in a room, provide a minimum of two receptacles spaced appropriately to anticipate furniture relocations.

n. Special purpose receptacles: Coordinate with the user to provide any special purpose outlets required. Provide outlets to allow connection of equipment in special use rooms.

o. Permanently installed equipment: Do not use cord and plug connections for permanently installed equipment in areas requiring GFI-protected receptacles. Provide hard-wired connections instead.

3-6.2 Cable and Raceway Criteria.

3-6.2.1 Installation.

Minimum permitted size conduit permitted is 1/2 in (15 mm). Provide an insulated green equipment grounding conductor or supply-side bonding jumper for all circuit(s) installed in raceways. Do not rely on the metallic raceway as the only boding path. Conceal raceways above ceilings and in finished areas that have finished walls or finished surfaces.

The above minimum conduit size does not apply to conduit that is part of a factory installed assembly, such as lighting fixtures.

3-6.2.2 Approved Cable and Raceway Types.

Specify cables and raceway in accordance with NFPA 70 as follows:

- The Uses Permitted are as modified by Table 3-1.
- The Uses Not Permitted are:
    - As specified in NFPA 70.
    - When restricted by other UFCs for specific types of buildings such as medical facilities.

For instances where NFPA 70 does not allow an installation based on “subject to physical damage” or “subject to severe physical damage,” refer to Appendix C-2 for baseline definitions of these conditions.

Provide a plan in the contract documents that graphically depicts the areas subject to physical damage or subject to severe physical damage along with the descriptions (such as the heights given in Appendix C-2) for installation purposes. Alternatively, as another option, provide a narrative list in the specifications indicating such descriptions in the portion of the specifications pertaining to areas subject to physical damage and subject to severe physical damage, respectively.

Table 3-1 Authorized Cable and Raceway Types

NFPA 70 Article	Raceway/Cable Type	Authorization
320	AC – Armored Cable	Prohibited for feeder circuits. Prohibited for embedded locations. Allowed for branch circuits only in the following dry locations: • New construction in exposed locations. • Renovations in exposed locations. • Concealed in renovations in existing areas where walls and ceilings are not disturbed. • Cable trays.
322	FC – Flat Cable Assemblies	Authorized.
324	FCC – Flat Conductor Cable	Authorized.
326	IGS – Integrated Gas Spacer Cable	Prohibited.
328	MV – Medium Voltage Cable	Authorized. For interior applications, MV cable must be installed in raceway or a fully enclosed cable tray. Refer to UFC 3-550-01 for additional applications.

NFPA 70 Article	Raceway/Cable Type	Authorization
330	MC – Metal-Clad Cable	Prohibited for feeder circuits other than feeder circuits for aerial messengers between buildings. Prohibited for embedded or direct buried locations. Prohibited for concealed locations, except as allowed below. Allowed for branch circuits only in the following dry locations: • New construction in exposed locations. • Renovations in exposed locations. • Concealed in renovations in existing areas where walls and ceilings are not disturbed. • Cable trays.
332	MI – Mineral-Insulated, Metal-Sheathed Cable	Authorized.
334	NM, NMC, NMS – Nonmetallic-Sheathed Cable	Allowed only in one- and two-family dwellings and their attached or detached garages, and their storage buildings.
336	TC – Power and Control Tray Cable	Authorized.
338	SE, USE – Service-Entrance Cable	Authorized.
340	UF – Underground Feeder and Branch-Circuit Cable	Prohibited.
342	IMC – Intermediate Metal Conduit	Authorized.
344	RMC – Rigid Metal Conduit	Authorized. Only threaded-type fittings are allowed for wet and damp locations.

NFPA 70 Article	Raceway/Cable Type	Authorization
348	FMC – Flexible Metal Conduit	Flexible metal conduit can be used, limited to 6 ft length, for recessed and semirecessed lighting fixtures; for equipment subject to vibration; and for motors other than pumps. Use liquidtight flexible metal conduit in damp and wet locations and for pumps.
350	LFMC – Liquidtight Flexible Metal Conduit	Use LFMC where authorized for FMC in damp and wet locations and for pumps.
352	PVC – Rigid Polyvinyl Chloride Conduit	Authorized. Minimum allowed size is PVC Schedule 40. For exterior use, comply with UFC 3-550-01.
353	HDPE – High Density Polyethylene Conduit	For exterior use only. Comply with UFC 3-550-01.
354	NUCC – Nonmetallic Underground Conduit with Conductors	Authorized only for exterior branch circuits and for feeder circuits between buildings.
355	RTRC – Reinforced Thermosetting Resin Conduit	Authorized.
356	LFNC – Liquidtight Flexible Nonmetallic Conduit	Prohibited.
358	EMT – Electrical Metallic Tubing	Specify EMT for branch circuits and feeders above suspended ceilings or exposed where not subject to severe physical damage. Only steel or stainless steel EMT may be used where subject to physical damage. Do not use EMT underground, encased in concrete, mortar or grout, in hazardous locations, where exposed to physical damage, outdoors or in fire pump rooms.
360	FMT – Flexible Metallic Tubing	Prohibited.
362	ENT – Electrical Nonmetallic Tubing	Prohibited.
366	Auxiliary Gutters	Authorized and must be listed for the application.

NFPA 70 Article	Raceway/Cable Type	Authorization
368	Busways	Authorized. For low voltage busway, provide UL 857 listed busway. For medium voltage busway, comply with IEEE C37.23.
370	Cablebus	Authorized.
372	Cellular Concrete Floor Raceways	Authorized. Requires a unique Unified Facilities Guide Specification to be developed as part of any design.
374	Cellular Metal Floor Raceways	Authorized. Requires a unique Unified Facilities Guide Specification to be developed as part of any design.
376	Metal Wireways	Authorized and must be listed for the application.
378	Nonmetallic Wireways	Authorized. *Note: The UFC definition of "subject to physical damage" prohibits the use of nonmetallic wireways for exterior applications installed less than 8 ft above finished grade or 8 ft above floor elevation for raceways on elevated platforms, loading docks, or stairwells.*
380	Multioutlet Assembly	Authorized for building improvements or renovations, or for applications where a variety of cord-and-plug connected equipment will be utilized in a limited space, such as in some areas of medical facilities, shops, and laboratories. Authorized for Sensitive Compartmented Information Facilities (SCIF) to limit the number of electrical penetrations through the SCIF boundary.
382	Nonmetallic Extensions	Prohibited.
384	Strut-Type Channel Raceway	Authorized.

NFPA 70 Article	Raceway/Cable Type	Authorization
386	Surface Metal Raceways	Authorized for use only for building improvements or renovations, or for applications where a variety of cord-and-plug connected equipment will be utilized in a limited space, such as in some areas of medical facilities, shops, and laboratories. Authorized for Sensitive Compartmented Information Facilities (SCIF) to limit the number of electrical penetrations through the SCIF boundary.
388	Surface Nonmetallic Raceways	Prohibited.
390	Underfloor Raceways	Authorized for listed underfloor raceways.
392	Cable Trays	Authorized. Provide and maintain a minimum of 12 inches (300 mm) access headroom above a cable tray system and a minimum of 18 inches (450 mm) side access clearance on one side of the cable tray system. The AHJ may approve side and top encroachments totaling up to 3 feet (914 mm) in a 20-foot (6096 mm) section of cable tray provided the encroachments do not prohibit access to raceways that feed into the tray.
393	Low-Voltage Suspended Ceiling Power Distribution Systems	Authorized.
394	Concealed Knob-and-Tube Wiring	Prohibited.
396	Messenger-Supported Wiring	Authorized only for exterior applications.
398	Open Wiring on Insulators	Prohibited.
399	Outdoor Overhead Conductors over 1000 Volts	Authorized.

3-6.2.3 Enclosures and Hazardous Locations.

Refer to TSEWG TP-08, Electrical Equipment Enclosures and Hazardous Locations, at https://www.wbdg.org/dod/supp-tech-documents

3-6.3 Conductors.

3-6.3.1 Baseline Requirements.

Specify conductors in accordance with NFPA 70 and the following:

- Conductors #6 AWG and smaller must be copper. Aluminum conductors of equivalent ampacity can be used instead of copper for #4 AWG and larger sizes.
- Feeder and branch circuit conductors, including power and lighting applications, will in no case be less than #12 AWG. Provide branch circuit breakers rated for 20 amperes minimum, except where lesser ratings are required for specific applications, such as fractional horsepower motor circuits.
- Circuit conductors must be sized based on the 60 degrees C ampacity for circuits rated 100 amperes or less (#12 AWG through #1 AWG) and the 75 degrees C ampacity for circuits rated over 100 amperes (larger than #1 AWG).
    - Higher temperature ampacity ratings for conductors may only be used for ampacity adjustment or correction as permitted by NFPA 70.
    - Where conductor sizing for ambient temperature correction is based on an insulation value greater than 60 degrees C for circuits rated 100 amperes or less (#12 AWG through #1 AWG) and greater than 75 degrees C ampacity for circuits rated over 100 amperes (larger than #1 AWG), explicitly indicate such in the contract documents for the circuits deviating from this convention.
    - All sizing for ampacity shall incorporate ambient temperature corrections and current-carrying conductor adjustments. Indicate whether neutral conductors are current-carrying elements.

3-6.3.2 Conductor Sizing Adjustment.

- Adjust conductor size and/or insulation type based on the ambient temperature anticipated to be encountered on the logical circuit routing path. Utilize NFPA 70 correction factors and exceptions in conductor sizing determinations. Utilize information from the Air Force Engineering Weather Data website (https://climate.af.mil/) or similar data sources such as ASHRAE for location-specific historical temperature information.

Coordinate with the HVAC designer to determine expected maximum ambient temperatures in each building space, including ceiling cavities and plenums where conductors will be routed, perimeter walls, and the building exterior. Do not assume less than 78 degrees F (25 degrees C) for ambient temperature correction factors.

Note: Recommend documenting these determinations graphically on a plan using the applicable temperature ranges for which adjustments are made in NFPA 70 Article 310 for graphical depiction. Require further adjustments to be made during construction based on the contractor exercising their routing discretion for routing not explicitly shown. Indicate on the contract documents the ambient temperature the design considered for sizing conductors and require further adjustments should the contractor's final routing path traverse an area of higher ambient temperature.

Note: Circuits are typically sized individually and consolidation of circuits into a common raceway may occur during construction, requiring further adjustments to be made during construction based on the contractor exercising their discretion to consolidate multiple circuits into a common raceway for lengths exceeding the exception threshold for adjustments and corrections in NFPA 70. Indicate on the contract documents the number of conductors the design considered to be current carrying. This information is useful when resizing conductors due to potential circuit consolidation.

- For voltage drop requirements, see UFC 3-501-01.
- For ambient temperature and voltage drop calculations, include anticipated routing of circuits in all directions (lateral and vertical). Unless explicitly identified to be installed in such a manner, do not assume underground routing will occur for conductor sizing factor purposes; overhead routing will typically require additional circuit lengths. Assume conduit routing at right angles to the building structure unless specifically shown on the plans; diagonal routing may be used for calculations only if indicated on the plans.

  Note: Routing concept adapted from the ASHRAE 90.1 User's Manual. This estimate should account for any known conditions shown on the plans including room and structure geometry.
- Where conductor size increases to mitigate voltage drop exceed the maximum permitted by a given device termination, the conductor size may be reduced to terminate properly in accordance with manufacturer requirements. Select splice kits, junctions, cable-reducing adapters, etc., to accommodate the increased wire size. Where a conductor size has been adjusted to mitigate voltage drop and conductor size reduction is required, the following restrictions will apply:

- The total length of conductor to be reduced below the size adjusted to mitigate voltage drop must not exceed 10 feet or 10 percent of the circuit length, whichever is less.
- Conductors must not be reduced below the maximum size permitted by the terminations in question.
- Conductors must not be reduced in size smaller than required by ambient temperature and current-carrying conductor ampacity corrections and adjustments; utilize increased conductor insulation as necessary.
- Alternatively, increase the equipment frame size to a class that will accommodate the termination of larger conductor sizes. This strategy may be used in combination with adapters for conductors whose size was increased to account for voltage drop, ampacity correction, or adjustment factors. Do not adjust the overcurrent protection ratings as a result of the frame size increase.

3-6.4 Wiring Annotation.

When using homerun symbols, point the homerun symbol in the general direction of the source equipment. Combine one-pole branch circuits to minimize number of homeruns.

3-7 LIGHTING.

Design lighting, including ASHRAE 90.1 criteria, in accordance with UFC 3-530-01.

3-8 GENERATORS.

Comply with UFC 3-540-01.

Coordinate with the Activity to establish marking requirements for receptacles and panelboards served by backup power systems.

3-9 AUTOMATIC TRANSFER EQUIPMENT.

Comply with UFC 3-540-01. Refer to NFPA 99 for any transfer switch applications involving medical facilities.

Refer to TSEWG TP-09, Automatic Transfer Equipment, at https://www.wbdg.org/dod/supp-tech-documents for additional information regarding ATS design and application.

3-10 UNINTERRUPTIBLE POWER SUPPLY.

Uninterruptible power supply (UPS) selection and sizing information is in TSEWG TP-19, Static Uninterruptible Power Supply, at the following site: https://www.wbdg.org/dod/supp-tech-documents

3-11 STATIONARY BATTERIES AND BATTERY CHARGERS.

3-11.1 Selection.

3-11.1.1 Vented Lead Acid Batteries.

Use vented lead acid batteries preferentially for switchgear control power and UPS applications. Batteries for switchgear or backup power applications should be rated for general purpose, switchgear, or utility use. Batteries for UPS applications should be rated for UPS or high-rate use.

3-11.1.2 Valve-Regulated Lead Acid Batteries.

As a general practice, do not use a valve-regulated lead acid (VRLA) battery if a vented lead-acid battery will satisfy the design and installation requirements. VRLA batteries have exhibited a shorter service life than vented equivalents and have shown a tendency to fail without warning. Refer to IEEE Std 1189 for additional information regarding the unique failure modes and shorter service life of this battery type. For the Air Force, refer also to AFPAM 32-1186 for additional information regarding VRLA batteries.

3-11.1.2.1 Allowed Applications.

VRLA batteries are allowed to be used in the following types of applications:

- Installations with small footprints such that a vented battery with adequate power density will not fit within the available space.
- Locations in which the consequences of electrolyte leakage cannot be allowed. UPS systems are often located in areas that necessitate the use of a VRLA battery.

3-11.1.2.2 Prohibited Applications.

Do not use VRLA batteries in the following types of applications:

- Unregulated environments that can experience abnormally high and low temperatures.
- Unmonitored locations that seldom receive periodic maintenance checks. VRLA batteries have shown a tendency to fail within only a few years after installation.

- Critical applications, unless the installation location requires the features available only in a VRLA battery.

3-11.1.3 Nickel-Cadmium Batteries.

Nickel-cadmium batteries are often more expensive than vented lead-acid batteries and should be considered primarily for extreme temperature environments or engine-starting applications. Nickel-cadmium batteries are preferred for engine starting applications because of their high-rate discharge capability and their more predictable failure modes.

3-11.1.4 Lithium Batteries.

Do not use lithium-ion, lithium metal polymer, or other lithium-based batteries for stationary applications in occupied buildings.

3-11.1.5 Battery Life for Life-Cycle Cost Analyses.

Apply the following service life for life-cycle cost comparisons of stationary batteries (small would be facility generators and large would be facility energy storage systems):

- Small VRLA batteries – 3 years.
- Large VRLA batteries – 7 years.
- Small vented lead acid batteries – 10 years.
- Large vented lead acid batteries – 15 years.
- Nickel-cadmium batteries – 15 years.

3-11.2 Battery Areas and Battery Racks.

Comply with UFC 3-520-05.

3-11.3 Installation Design.

3-11.3.1 Industry Standards.

Review the following IEEE standards, as applicable for the battery type, prior to the installation:

- IEEE Std 450—provides maintenance and test criteria for vented lead acid batteries.
- IEEE Std 484—provides installation criteria for vented lead acid batteries.
- IEEE Std 485—defines battery sizing requirements for lead acid batteries.

IEEE Std 1106—provides maintenance and test criteria for nickel cadmium batteries.

- IEEE Std 1115—defines battery sizing requirements for nickel cadmium batteries.
- IEEE Std 1184—provides application and sizing criteria for UPS applications.
- IEEE Std 1187—provides installation criteria for valve-regulated lead acid batteries.
- IEEE Std 1188—provides maintenance and test criteria for valve-regulated lead acid batteries.
- IEEE Std 1189—explains application limitations for valve-regulated lead acid batteries.

Note: the above industry standards apply to lead acid and nickel cadmium batteries. There are no industry standards available yet for the selection, specification, sizing, design, installation, maintenance, and testing of lithium-ion, lithium metal polymer, or other lithium-based batteries for stationary applications.

3-11.3.2 Design Requirements.

Size the battery in accordance with IEEE Std 485, IEEE Std 1115, or IEEE Std 1184 as appropriate for the selected battery type and application.

Refer to TSEWG TP-04, Stationary Battery and Charger Sizing, at https://www.wbdg.org/dod/supp-tech-documents for additional information regarding battery sizing principles.

3-11.3.3 Installation Requirements.

Design and install the battery in accordance with IEEE Std 484, IEEE Std 1187, or IEEE Std 1106 as appropriate for the selected battery type. Refer to the above industry standards and NETA ATS for acceptance test criteria.

3-11.3.4 Battery Chargers.

Use single-phase chargers for smaller applications. Rate single-phase battery chargers for 240V single phase, unless only 120V is available. Use three-phase chargers if the charger’s dc output current rating will be greater than 75A. Unless the battery has specific requirements to the contrary, all chargers should be of the constant voltage type.

3-11.3.5 Battery Protection.

Install a circuit breaker or fused protection device as close to the battery as possible.

Provide overcurrent protection for each string in a parallel battery system. Refer to IEEE Std 1375 for additional guidance.

3-12 GROUNDING, BONDING, AND STATIC PROTECTION.

The below requirements apply for the identified subset of acceptable techniques.

3-12.1 Ground Rods.

3-12.1.1 Design.

For ground rod composition, minimum spacing requirements and connections, conform to requirements of NFPA 70 Article 250 except that minimum ground rod dimensions are 10 feet (3.0 m) in length and ¾ inch (19 mm) diameter. Provide copper-clad steel, solid copper, or stainless steel ground rods.

3-12.1.2 Connections.

All connections to ground rods below ground level must be by exothermic weld connection or with a high compression connection using a hydraulic or electric compression tool to provide the correct circumferential pressure. Accessible connections above ground level and in test wells can be accomplished by clamping.

3-12.1.3 Spacing and Location.

Spacing for driving additional grounds must be a minimum of 10 ft (3.0 m). Bond these driven electrodes together with a minimum of 4 AWG soft drawn bare copper wire buried to a depth of at least 12 in (300 mm).

Install ground rods (and ground ring, if applicable) 3 ft to 8 ft (0.9 m to 2.4 m) beyond the perimeter of the building foundation and at least beyond the drip line for the facility. If another UFC requires the installation of one or more ground rods inside a facility, follow the requirements specified in that UFC.

3-12.2 Ground Rings.

Coordinate requirements for the ground ring of a lightning protection system with UFC 3-575-01. Provide a ground ring (counterpoise) for facilities with sensitive electronic equipment or other applications when identified by project requirements.

Provide a ground ring with at least two ground rods located diagonally at opposite corners. When required by a specific activity or facility, provide a ground rod at each change in direction of the ground ring and install test wells for at least two of the corner ground rods to allow for testing of the system. Assemble test wells with bolted connections to facilitate future testing.

3-12.3 Communication-Electronics Facilities.

Provide grounding electrode systems for Communications-Electronics (C-E) facilities in accordance with MIL-HDBK 419A when identified by project requirements.

3-12.4 Static Electricity Protection.

Comply with UFC 3-575-01 for static protection requirements.

3-12.5 Aircraft Hangars.

Refer to UFC 3-575-01 for grounding criteria for power systems and static electricity protection for aircraft hangars.

3-12.6 Ammunition and Explosive Storage Magazines.

Refer to UFC 4-420-01 and NAVSEA OP 5 for Navy project for grounding, bonding, and lightning protection criteria.

3-13 LIGHTNING PROTECTION SYSTEMS.

Provide lightning protection systems in accordance with UFC 3-575-01.

3-14 400-HERTZ DISTRIBUTION SYSTEMS.

Design 400 hertz power systems in accordance with UFC 3-555-01.

3-15 270-VOLT DC DISTRIBUTION SYSTEMS.

System requirements are specified in UFGS 26 35 44.

3-16 POWER FACTOR CORRECTION.

The power factor within a facility is normally 0.9 lagging or greater; therefore, power factor correction is not routinely required for interior electrical systems. However, if the facility design incorporates large motor applications or other specific loads that may adversely affect the power factor, provide an evaluation that includes the considerations identified in TSEWG TP-02, Capacitors for Power Factor Correction, at https://www.wbdg.org/dod/supp-tech-documents.

If the evaluation supports the need for power factor correction, contact the AHJ for authorization prior to providing power factor correction equipment.

3-17 POWER QUALITY.

Design secondary electrical systems to mitigate the harmonic effects of non-linear loads as a result of connections to electronic loads, including computer work stations, file servers, UPS, and electronic ballasts. Refer to Appendix B for power quality design criteria.

3-18 SYSTEMS FURNITURE.

3-18.1 Planning.

When systems furniture is utilized, the electrical designer, the architect, and the interior designer must coordinate during the design process. Systems furniture is typically specified and ordered when construction is nearing completion; therefore, if proper coordination has not occurred earlier in the design process, field interface problems will occur.

3-18.2 Design.

Systems furniture is pre-wired to a wiring harness. Unless specified otherwise, select a standard wiring harness that meets one of the following configurations:

- 8-wire harness consisting of 3 circuit conductors, 3 neutral conductors and 2 equipment grounding conductors.
- 10-wire harness consisting of 4 circuit conductors, 4 neutral conductors and 2 separate equipment grounding conductors.

Serve 8-wire harnesses with 2 separate circuits and 10-wire harnesses with 4 separate circuits. Provide harnesses that have a neutral conductor per phase conductor and a green ground conductor. Balance loads between circuits and phases. A single circuit must not serve more than 4 workstations under any circumstances.

3-19 ASHRAE COMPLIANCE.

Verify per UFC 1-200-02 the version of ASHRAE 90.1 that is currently used.

Provide automatic receptacle control in accordance with ASHRAE 90.1. The detailed electrical energy monitoring requirements of ASHRAE 90.1are permissible on projects when authorized in writing by the activity in order to coordinate with their existing industrial controls program.

3-20 ELECTRIC VEHICLE SUPPLY EQUIPMENT.

Provide Electric Vehicle Supply Equipment (EVSE) for Government Owned Vehicle (GOEV) for Type 1, Type 2, and Type Direct Current (dc) Fast Charging complying with requirements of NFPA 70.

3-20.1 Site and Equipment Considerations.

The following are some of the site and equipment issues that must be considered when designing for a EVSE installation.

3-20.1.1 Physical Protection of EVSE.

Provide wheel stops or bollards for physical protection in front of EVSE when curbing of sidewalks is not present.

3-20.1.2 Signage for EVSE.

Provide signage as indicated by Manual on Uniform Traffic Control Devices (MUTCD), that indicates EVSE.

3-20.1.3 Avoiding Hazards.

Cords and wires associated with EVSE should not interfere with pedestrian traffic or present tripping hazards. Charging spaces should not be located near potentially hazardous areas.

3-20.1.4 Ventilation.

When EVSE is located in an enclosed space, there must be adequate ventilation, which may include installation of fans, ducts, and air handlers. Verify the installation and ventilation requirements with the manufacturer's documentation.

3-20.1.5 Battery Temperature Limits.

Because some EV batteries have operating and charging temperature limits, EVSE may need to be located within an enclosed, climate-controlled area in extreme climates. Verify resulting installation environment is compatible with EVSE manufacturer's installation requirements.

3-20.1.6 Metering.

Separate or sub-metering for electricity used by EVSE may be a requirement so that vehicle charging can be isolated from the rest of a building or structure's energy usage. Verify if metering is a requirement with the activity.

APPENDIX A ADJUSTABLE SPEED DRIVES

A-1 ADJUSTABLE SPEED DRIVES (ASD).

A-1.1 ASD Sizing.

At the rated full load of the driven equipment, the output voltage and frequency of the ASD should be the same as the motor's rating. Note that this design requirement places limits on the motor design; the motor should not have a significantly higher full load horsepower or speed rating than the driven load. Mismatches can easily cause operational problems, including efficiency losses and increased ASD input current. In extreme cases, a mismatch can cause the ASD to trip on overcurrent during motor starting or cause the ASD input current to be substantially higher than the design without the ASD.

The ASD short term current rating should be adequate to produce the required motor starting torque, including loads with high starting torque.

A-1.2 Motor Considerations.

Specify a motor with a minimum 1.15 service factor or ensure the motor is rated well above the actual load it will carry. Verify with the manufacturer that the motor is capable of acceptable operation with an ASD. Standard motors can often operate down to 50% of rated speed, high efficiency motors can often operate down to 20% of rated speed, and "inverter duty" motors can operate below 20% of rated speed without problems in a variable load application.

A-1.3 Power Quality.

Ensure that the final installation does not create voltage or current harmonic distortion beyond acceptable limits. Take power quality field measurements after installation to confirm that the system total harmonic distortion is not degraded beyond acceptable levels. If the ASD can be provided power from a standby generator upon loss of normal commercial power, the harmonic distortion evaluation must include the system effects when powered from the standby generator.

Voltage sags can cause nuisance tripping. Ensure that the ASD either has a minimum of 3 cycle ride-through capability or automatic reset circuitry.

A-1.4 Capacitor Switching Effects.

Nearby capacitor switching can cause transient overvoltages, resulting in nuisance tripping. In this case, ensure the ASD either has input filtering to reduce the overvoltage or automatic reset circuitry.

A-1.5 Bypass Capability.

Important applications should include bypass operation capability to allow motor operation independent of the ASD.

APPENDIX B POWER QUALITY

B-1 INTRODUCTION.

Unlike other electrical design requirements, power quality design solutions are very dependent on the types of transients and disturbances that can and will occur in power systems. In many cases, it will be easier to provide protection and power quality design features to specific equipment rather than generically throughout the facility.

B-2 UNBALANCED VOLTAGES.

Evaluate the loading on each phase and balance the loads as well as possible. As part of acceptance testing, monitor the degree of unbalance and make corrections if necessary.

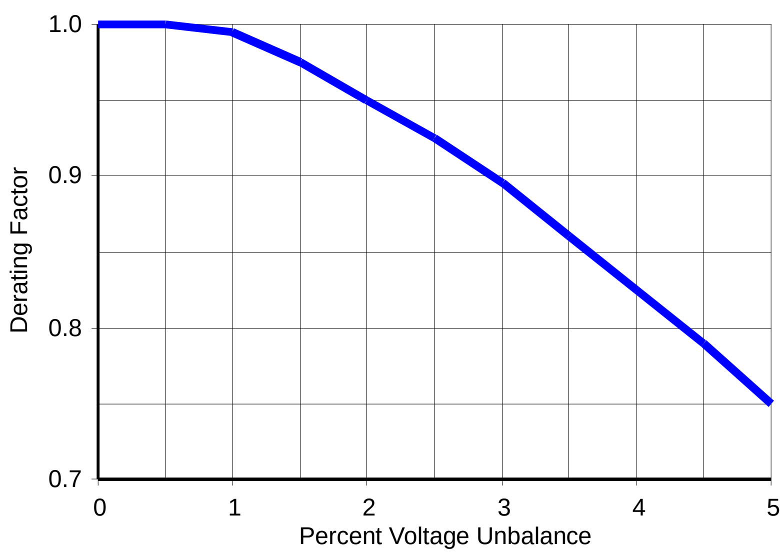
B-2.1 Calculation.

Calculate voltage unbalance as follows:

B-2.2 Effect on Motors.

The rated load capability of three-phase equipment is reduced by voltage unbalance. Figure B-1 shows a typical derating factor for three-phase induction motors as a function of voltage unbalance.

Figure B-1 Typical Derating Factor for Three-Phase Induction Motors



B-3 HARMONIC DISTORTION EVALUATION.

If a significant number of nonlinear loads are installed in the facility, perform a harmonic distortion evaluation during the facility design phase. If the effect of nonlinear loads is expected to be minor, a detailed harmonic distortion evaluation is not required.

IEEE Std 519 provides the industry-accepted method of evaluating harmonic voltages and currents. IEEE Std 519 provides system level guidance, not equipment specific guidance; harmonic distortion limits are established for the facility and the installation of any equipment should not degrade the system to beyond acceptable levels

B-4 DERATING TRANSFORMERS FOR HARMONIC CURRENT EFFECTS.

Whenever significant nonlinear loads are expected in a facility, evaluate the system in accordance with IEEE C57.110 to determine if transformer derating will be required. For transformers without a k-factor rating, derating must be used to determine the maximum fundamental load current that the transformer can maintain with the additional harmonic currents.

Note: Derating applies to the full-load capability of the transformer when applied in an environment containing significant harmonic distortion. If the transformer is not fully loaded, the derating process might have little or no practical significance unless it is expected that the transformer will eventually be fully loaded. Nationwide surveys indicate average loading levels for dry-type transformers of between 35% for commercial facilities and 50% for industrial facilities. Military facilities are commonly loaded to less than 25% of the service entrance transformer full-load capability during periods of peak demand.

If it is determined that a transformer will require derating because of harmonic distortion, perform the following additional reviews:

- Verify the expected transformer loading assumptions for a new design or actual metering data for an existing design to confirm that the transformer is fully loaded; most transformers are never fully loaded.
- Determine if the harmonic distortion environment can be improved by design changes for the most offending loads.
- If the transformer requires more than 10% derating, evaluate the feasibility of installing a new transformer designed for a harmonic distortion environment (harmonic mitigating transformer). Include delivery and replacement time scheduling as well as cost in the evaluation.
- If transformer derating is the selected option, annotate the percent derating on the applicable design drawings and install a label near the transformer nameplate indicating that the transformer has been derated. The purpose of these actions is to prevent inadvertent overloading of the transformer in the future.

B-5 NONLINEAR LOAD DESIGN CONSIDERATIONS.

Analyze planned electrical loads on new projects to determine whether or not they are considered potential nonlinear loads with high harmonic content. The following guidelines are provided if nonlinear loads are a significant portion of the total load.

- Derate transformer, motor, and generator outputs if necessary to prevent overheating or burnout. Ensure that design documents and equipment nameplates reflect the derated capability.
- If standby generators represent the only power source upon loss of normal power, the generator design must account for nonlinear loads.
- Use a single three-phase transformer with common core, delta connected primary and wye connected secondary instead of three single-phase transformers connected for three-phase service. Evaluate the use of a harmonic mitigating transformer if a standard transformer has to be derated by more than 10%.

  Note: Refer to TSEWG TP-05, Interior Transformer Ratings and Installation, at https://www.wbdg.org/dod/supp-tech-documents *for additional information regarding harmonic mitigating transformers.*

- Specify harmonic filters as necessary to minimize the localized effects of harmonics. If separate harmonic filters are installed specifically to protect against offending loads, locate each filter as close to each load as practical.
- Specify true RMS sensing meters, relays, and circuit breaker trip elements.

Analysis alone will not always adequately predict power quality problems. Refer to IEEE Std 1159 for additional information regarding power quality monitoring.

B-6 NEUTRAL CIRCUIT SIZING FOR NONLINEAR LOAD CONDITIONS.

Minimize neutral circuit overheating by specifying separate neutral conductors for line-to-neutral connected nonlinear loads with high harmonic content. Treat the neutral conductors as current carrying conductors in the design analysis. When a shared neutral conductor must be used for three-phase, four-wire systems, size the neutral conductor to have an ampacity equal to at least 1.73 times the ampacity of the phase conductors.

Two paralleled, full size neutral conductors can be used to obtain the required neutral ampacity for conductors sized #1/0 AWG and larger. Size the neutral conductor between the transformer and all downstream distribution equipment to be a minimum of 1.73 times the ampacity of the phase conductors. Select panelboards that have been rated for nonlinear loads.

APPENDIX C GLOSSARY

C-1 ACRONYMS.

A	Amperes
AC	Alternating Current
AC	Armored Cable
AFCI	Arc Fault Current Interrupter
AFPA	Air Force Pamphlet
AHJ	Authority Having Jurisdiction
ANSI	American National Standards Institute
ASD	Adjustable Speed Drive
ATS	Automatic Transfer Switch
AWG	American Wire Gauge
BEQ	Bachelor’s Enlisted Quarters
BOQ	Bachelor’s Officer Quarters
CCTV	Closed Circuit Television
CATV	Cable Television
CFR	Code of Federal Regulations
COPS	Critical Operations Power System
Dc	Direct Current
DCOA	Designated Critical Operations Area
EGSA	Electrical Generating Systems Association
EMT	Electrical Metallic Tubing
ENT	Electrical Non-Metallic Tubing
EV	Electric Vehicle
EVSE	Electric Vehicle Supply Equipment

FC	Flat Cable Assemblies
FCC	Flat Conductor Cable
FMC	Flexible Metal Conduit
FMT	Flexible Metallic Tubing
Ft	Feet
GFI	Ground Fault Circuit Interrupter
GRS	Galvanized Rigid Steel
HDPE	High Density Polyethylene Conduit
HID	High Intensity Discharge
Hz	Hertz
IEEE	formerly Institute of Electrical and Electronics Engineers
IMC	Intermediate Metal Conduit
kA	Kilo-Amperes
kVA	Kilo-Volt-Amperes
kW	Kilowatt
LFMC	Liquidtight Flexible Metal Conduit
LFNC	Liquidtight Flexible Nonmetallic Conduit
M	Meter
MCC	Motor Control Center
MCOV	Maximum Continuous Overvoltage Rating
Mm	Millimeter
MC	Metal-Clad Cable
MI	Mineral-Insulated, Metal-Sheathed Cable
MV	Medium Voltage Cable
NAVFAC	Naval Facilities Engineering Systems Command

NEC	National Electrical Code
NEMA	National Electrical Manufacturers Association
NETA	International Electrical Testing Association
NFPA	National Fire Protection Association
NM, NMC, NMS	Nonmetallic-Sheathed Cable
NUCC	Nonmetallic Underground Conduit with Conductors
OSHA	Occupational Safety and Health Administration
PVC	Rigid Polyvinyl Chloride Conduit
RMC	Rigid Metal Conduit
RMS	Root-Mean-Square
RTRC	Reinforced Thermosetting Resin Conduit
SCIF	Sensitive Compartmented Information Facilities
SE, USE	Service-Entrance Cable
SPD	Surge Protective Devices
SWD	Switching Duty
TC	Power and Control Tray Cable
TSEWG	Tri-Service Electrical Working Group
UF	Underground Feeder and Branch-Circuit Cable

VFD	Variable Frequency Drive (see ASD)
VRLA	Valve-Regulated Lead Acid

C-2 DEFINITION OF TERMS

Note: The terms listed here are provided for clarification of the design criteria provided in this UFC. Refer to IEEE Std 100 for additional electrical-related definitions.

Automatic Transfer Switch (ATS): A switch designed to sense the loss of one power source and automatically transfer the load to another source of power.

Branch Circuit: The circuit conductors and components between the final overcurrent device protecting the circuit and the equipment.

Closed Transition Switch: Transfer switch that provides a momentary paralleling of both power sources during a transfer in either direction. The closed transition is possible only when the sources are properly interfaced and synchronized.

Existing Facility: A facility is existing if changes to be made are cosmetic or minor in nature.

Harmonic: A sinusoidal component of a periodic wave or quantity having a frequency that is an integral multiple of the fundamental frequency.

Linear Load: An electrical load device that presents an essentially constant load impedance to the power source throughout the cycle of applied voltage in steady-state operation.

Listed: Applies to equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction. The organization periodically inspects production and certifies that the items meet appropriate standards or tests as suitable for a specific use.

Low Voltage System: An electrical system having a maximum root-mean-square (rms) voltage of less than 1,000 volts.

Medium Voltage System: An electrical system having a maximum RMS AC voltage of 1,000 volts to 34.5 kV. Some documents such as ANSI C84.1 define the medium voltage upper limit as 100 kV, but this definition is inappropriate for facility applications.

Molded Case Circuit Breaker: A low voltage circuit breaker assembled as an integral unit in an enclosing housing of insulating material. It is designed to open and close by nonautomatic means, and to open a circuit automatically on a predetermined overcurrent, without damage to itself, when applied properly within its rating.

Motor Control Center: A piece of equipment that centralizes motor starters, associated equipment, bus and wiring in one continuous enclosed assembly.

New Construction: A facility is considered new if changes to be made are more than cosmetic or minor, such as major renovations, additions, or new facilities.

Nonlinear Load: A steady state electrical load that draws current discontinuously or has the impedance vary throughout the input ac voltage waveform cycle. Alternatively, a load that draws a nonsinusoidal current when supplied by a sinusoidal voltage source.

Power Quality: The concept of powering and grounding sensitive equipment in a manner that is suitable to the operation of that equipment.

Service Voltage: Voltage at the facility service entrance location.

Short Circuit: An abnormal condition (including an arc) of relatively low impedance, whether made accidentally or intentionally, between two points of different potential.

Subject to Physical Damage (or Subject to Severe Physical Damage): Locations that are subject to physical damage or severe physical damage include:

- Exposed interior raceways installed less than 6 ft above finished floor elevation where personnel are operating mechanized equipment on a recurring basis. Mechanized equipment that might be operated on a recurring basis includes vehicles, carts, forklifts, and pallet-handling units.
- Exposed exterior raceways installed less than 8 ft above finished grade or 8 ft above floor elevation for raceways on elevated platforms, loading docks, or stairwells.
- Exposed raceways where personnel operate mobile or fixed-in-place hoisting equipment.

Surge Protector: A device composed of any combination of linear or nonlinear circuit elements and intended for limiting surge voltages on equipment by diverting or limiting surge current; it prevents continued flow of current and is capable of repeating these functions as specified.

Transfer Switch: A device for transferring one or more load conductor connections from one power source to another.

Uninterruptible Power Supply System: A system that converts unregulated input power to voltage and frequency controlled filtered ac power that continues without interruption even with the deterioration of the input ac power.

Utilization Voltage: The voltage at the line terminals of utilization equipment.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Unified Facilities Criteria (UFC) documents provide planning, design, construction, sustainment, restoration, and modernization criteria. They also apply to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. The United States Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC) and the Office of the Air Force Civil Engineer are responsible for administration of the UFC system. This is one of those documents.

Resilience is “the ability to anticipate, prepare for, and adapt to changing conditions and withstand, respond to, and recover rapidly from disruptions.” When applying resilience principles to the design and operation of critical facilities, it is useful to incorporate tools for evaluating the effectiveness of existing and proposed system designs or upgrades. The purpose of this document is to describe quantitative methods for evaluating the resilience of an existing or proposed designs for the electrical, Mechanical and Controls for Critical Facilities.

1-2 PURPOSE AND SCOPE.

This document summarizes current knowledge, research related to backup power system reliability, and identified best cost options in areas for R&D investment. The scope of this document is electrical systems, cooling systems (chilled water systems, condenser water systems, and all other aspects for facility cooling) and control systems.

1-3 APPLICABILITY.

This UFC follows the same applicability as UFC 1-200-01, APPLICABILITY for C5ISR facilities.

\1\ See UFC 4-141-03 for specific design requirements for new C5ISR facilities. /1/

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-6 GLOSSARY.

APPENDIX E contains acronyms, abbreviations, and terms.

1-7 REFERENCES.

APPENDIX F contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 RESILIENCE

2-1 RESILIENCE.

2-1.1 Prepare, Absorb, Recover and Adapt.

RESILIENCE is the ability to anticipate, prepare for, and adapt to changing conditions and withstand, respond to, and recover rapidly from disruptions. When applying resilience principles to the design and operation of critical facilities, it is useful to incorporate tools for evaluating the effectiveness of existing and proposed system designs or upgrades. The purpose of this chapter is to describe quantitative methods for evaluating the resilience of an existing or proposed design.

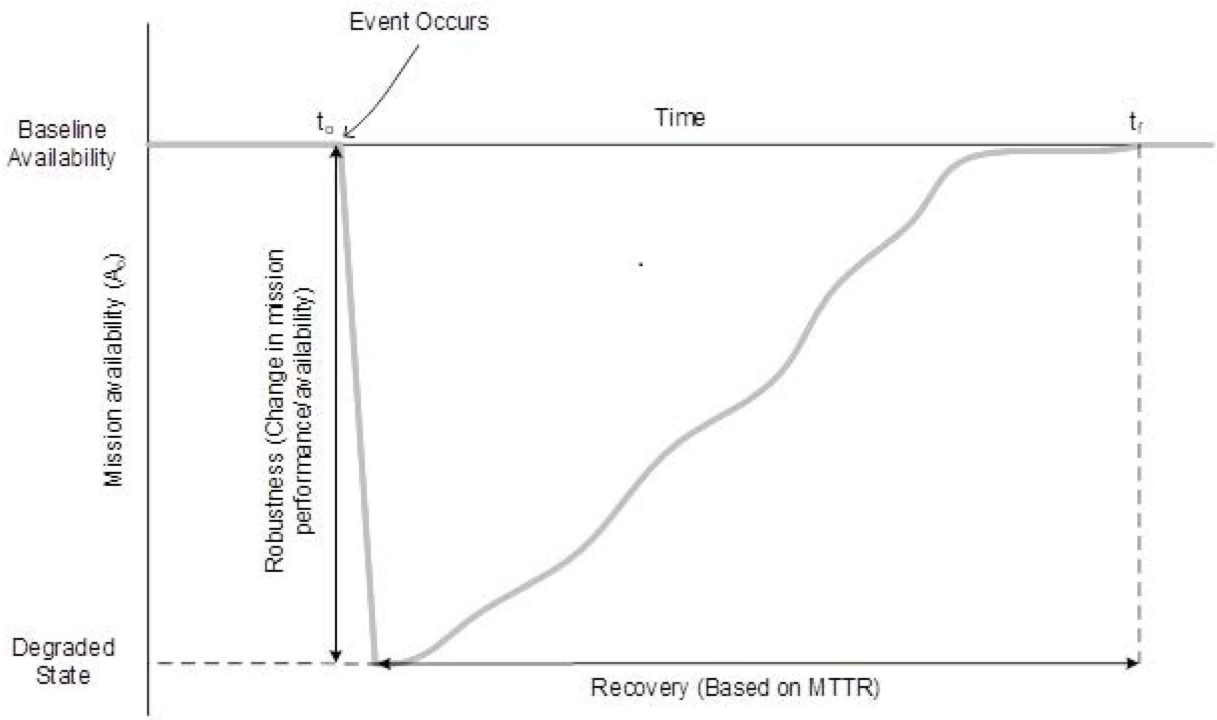
2-1.2 Considerations.

System operational considerations and the nature of events to be considered may dictate the preferred measure of availability for evaluating a given event. For example, hurricanes are often closely tracked and forecasted, allowing for several days or even weeks of advance notice prior to arrival. This can provide time for workers to delay or back out of planned maintenance tasks. In this situation, the availability of the system is more representative of its inherent availability. For disturbances which occur without warning such as seismic events, it may be more useful to consider operational availability as this is more representative of normal day-to-day operations. For the purposes of this discussion, the following examples will refer to operational availability.

2-1.3 Absorption and Recovery.

Using availability concepts, the overall resilience of a system can be quantified in two phases: absorption of the event, and recovery. Consider an event occurring as shown in Figure 2-1.

Figure 2-1 System Response to a Disruptive Event



Immediately following the event, there is a sharp drop in mission availability. The change in mission availability from the baseline to the degraded state represents the robustness of the system to that particular event. The lower the change in mission availability, the more robust the system. The time required to restore the system to its baseline state is referred to as recovery. This is based on the mean-time-to-repair (MTTR) of any assets affected by the event and may be affected by several factors including site remoteness, event severity, and environmental conditions. The overall resilience, R(t) of the system to any particular event can be quantified according to the area under the curve as shown in Equation 2-1. By this model, a perfectly resilient system would have resilience index value of zero.

Equation 2-1. Resilience

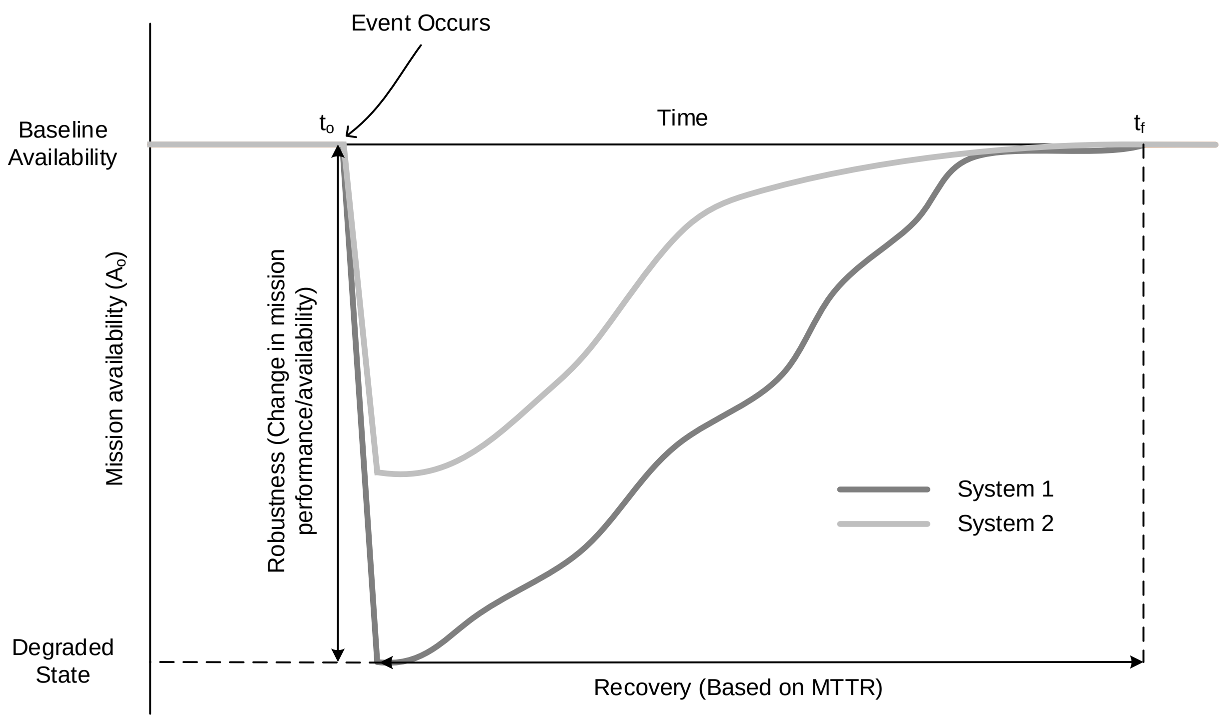
$$R(t) = \int_{t_o}^{t_f} A_o(t)dt$$

Where:
R(t) = resilience
t_f = time required to restore (hours)
t_o = time event occurs (hours)
A_o = mission availability
(t) = time (hours)
dt = downtime (hours)

2-1.4 Prioritizing Robustness or Recovery.

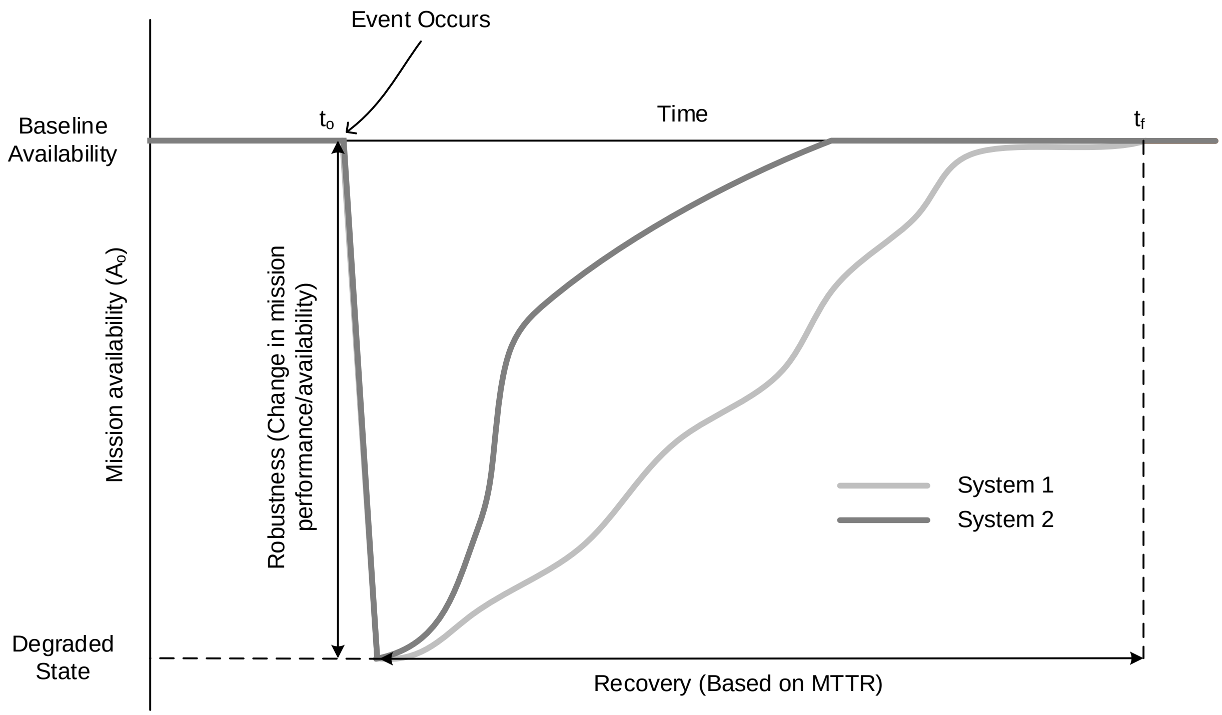
Depending on mission needs, it may be more important to prioritize either robustness or recovery. For those installations with limited availability of repair parts and personnel, consider prioritizing robustness. Where resources are more readily available, consider prioritizing recovery, provided that the minimum requirements for mission functions are satisfied. Figure 2-2 shows two systems with different levels of resilience. The two systems have the same recovery time, but System 2 has a lower initial decrease in mission availability. System 2 is more resistant to the postulated event and is more resilient than system 1 despite having the same recovery time. This may be beneficial for improving overall resilience at remote sites where recovery time is limited by the physical demand of getting replacement parts to the site.

Figure 2-2 Two System with Different Robustness



In other cases, it may be more important to prioritize recovery from an event as opposed to robustness. Figure 2-3 shows two systems with similar robustness to an event, but different recovery times. Though both systems have the same ability to absorb the shock from the event, the shorter recovery time for System 2 yields less area under the curve. Accordingly, System 2 can be said to be more resilient than System 1. The difference between the system responses shown in Figure 2-2 and Figure 2-3 demonstrate that similar improvements in overall resilience can be achieved by improving either robustness or recovery. Consider site-specific factors such as duration of backup power supplies and minimum equipment requirements when determining an optimal resilience improvement strategy.

Figure 2-3 Two Systems with Different Recovery Time



2-1.5 Availability Definitions.

Availability is defined as the percentage of time that a system is available to perform its required function(s). It is measured in a variety of ways, but it is principally a function of downtime. Availability can be used to describe a component or system, but it is most useful when describing the nature of a system of components working together. Because it is a fraction of time spent in the “available” state, the value can never exceed the bounds of $0 < A < 1$. Thus, availability will most often be written as a decimal, as in 0.99999, as a percentage, as in 99.999%, or equivalently spoken, “five nines of availability.” Chapter 5 contains a detailed discussion of availability.

2-1.5.1 Operational Availability (A_O).

Another equation for availability directly uses parameters related to the reliability and maintainability characteristics of the item as well as the support system. Equation 2-2 reflects this measure.

Equation 2-2. Operational Availability

$$A_0 = \frac{MTBM}{MDT + MTBM}$$

Where:
A_o = operational availability
MTBM = mean time between maintenance (hours)

MDT = mean downtime (hours)

2-1.5.2 Inherent Availability (A_i).

In Equation 2-2, MTBM includes all maintenance required for any reason, including repairs of actual design failures, repairs of induced failures, cases where a failure cannot be confirmed, and preventive maintenance. When only maintenance required to correct design failures are counted and the effects of the support system are ignored, the result is inherent availability, which is given by Equation 2-3.

Equation 2-3. Inherent Availability

$$A_i = \frac{MTBF}{MTTR + MTBF}$$

Where:
A_i = *inherent availability*
MTBF = mean time between failure
MTTR = mean time to repair

2-1.6 Reliability.

Reliability is concerned with the probability and frequency of failures (or more correctly, the lack of failures). A commonly used measure of reliability for repairable systems is the mean time between failures (MTBF). The equivalent measure for non-repairable items is mean time to failure (MTTF). Reliability is more accurately expressed as a probability of success over a given duration of time, cycles, etc. For example, the reliability of a power plant might be stated as 95% probability of no failure over a 1000-hour operating period while generating a certain level of power. (Note that the electrical power industry has historically not used the definitions given here for reliability. The industry defines reliability as the percentage of time that a system is available to perform its function, such as, availability. The relationship between reliability and availability is discussed in paragraph 2-1.8.)

2-1.7 Maintainability.

Maintainability is defined as the measure of the ability of an item to be restored or retained in a specified condition. Maintenance should be performed by personnel having specified skill levels, using prescribed procedures and resources, at each prescribed level of maintenance and repair. Simply stated, maintainability is a measure of how effectively and economically failures can be prevented through preventive maintenance and how quickly system operation can be restored following a failure through corrective action. Note that maintainability is not the same as maintenance. Maintainability is a design parameter, while maintenance consists of actions to correct or prevent a failure event.

2-1.8 Relationship Among Reliability, Maintainability, and Availability.

Perfect reliability (such as, no failures, ever, during the life of the system) is difficult to achieve. Even when a "good" level of reliability is achieved, some failures are expected. The effects of failures on the availability and support costs of repairable systems can be minimized with a "good" level of maintainability. A system that is highly maintainable can be restored to full operation in a minimum of time with a minimum expenditure of resources.

2-1.8.1 Inherent Availability.

Inherent availability is when only reliability and corrective maintenance or repair (such as, design) effects are considered. This level of availability is solely a function of the inherent design characteristics of the system.

2-1.8.2 Operational Availability.

Availability is determined not only by reliability and repair, but also by other factors related to preventative maintenance and logistics. Operational availability is when the effects of preventative maintenance and logistics are included. Operational availability is a "real-world" measure of availability and accounts for delays such as those incurred when spares or maintenance personnel are not immediately at hand to support maintenance.

2-1.9 Factors Influencing Availability.

Availability of a system in actual field operations is determined by the following.

2-1.9.1 The Frequency of Occurrence of Failures.

These failures may prevent the system from performing its function (mission failures) or cause a degraded system effect. This frequency is determined by the system's level of reliability.

2-1.9.2 Restoration and Maintenance Time.

The time required restoring operations following a system failure or the time required to perform maintenance to prevent a failure. These times are determined in part by the system's level of maintainability.

2-1.9.3 Logistics Delays.

The logistics provided to support maintenance of the system. The number and availability of spares, maintenance personnel, and other logistics resources combined with the system's level of maintainability determine the total downtime following a system failure.

2-1.9.4 Reliability Impact.

Reliability is a measure of a system's performance that affects availability, mission accomplishment, and operating and support (O&S) costs. Too often performance is only thought of in terms of voltage, capacity, power, and other "normal" measures. However, high frequency of system failures can be overshadowing the importance of more typical system metrics.

2-1.9.5 Impact of Failures and Costs.

Reliability also affects the costs to own and operate a system. Using an example of a critical DoD facility, Reliability determines how often repairs are needed. The less often the facility has a failure, the less it will cost to operate over its life. The reliability of any repairable system is a significant factor in determining the long-term costs to operate and support the system. For non-repairable systems, the cost of failure is the loss of the function (for example, the missile misses its target, the fuse fails to protect a circuit, etc.). In addition, the mission plays a part in the overall operation of the facility. The objective is to run as efficient as possible while still maintaining mission requirements.

2-1.9.6 Improving Availability of Failures.

Regardless of how reliable a system may be, failures will occur. An effective maintenance program applied to a system that has been designed to be maintainable is necessary to deal with the certainty of failure. Even when several redundant items are installed to decrease the chance of a mission failure, when any one item fails, it must be repaired or replaced to retain the intended level of redundancy.

2-1.10 Improving Availability of C5ISR Facilities.

The decision on which methods to use for improving availability depends on whether the facility is being designed and developed or is already in use.

2-1.10.1 Existing C5ISR Facilities.

For a facility that is being operated, three basic methods are available for improving availability when the current level of availability is unacceptable:

- Selectively adding redundant units, such as: (e.g., generators, chillers, fuel supply, etc.) to eliminate sources of single-point-failure
- Optimizing maintenance using a reliability-centered maintenance (RCM) approach to minimize downtime
- Redesign subsystems to replace components and subsystems with higher reliability items.

2-1.10.2 New C5ISR Facilities.

The opportunity for designing high availability and reliability systems is greatest when designing a new facility. A highly available facility will result from the following: applying an effective RAM strategy, modeling, and evaluating the systems, designing for maintainability, and ensuring that manufacturing and commissioning do not negatively affect the inherent levels of reliability, availability, and maintainability. \1\ See UFC 4-141-03 for details on specific design requirements /1/. Upon completion, an RCM program should be employed to cultivate the opportunities for high RAM success. Although the primary focus of this UFC is on improving the availability of current facilities, a brief discussion of the approach used when designing a new facility is provided in the next paragraphs to give the reader an appreciation of an effective design and development program.

2-1.10.2.1 RAM Strategy.

A RAM strategy describes how an organization approaches reliability for all systems and services it develops and provides to its customers. The strategy can be considered as the basic formula for success, applicable across all types of systems and services. A reliability strategy that has proved successful in a variety of industries and in government is shown in Figure 2-4.

2-1.10.2.2 RAM Program.

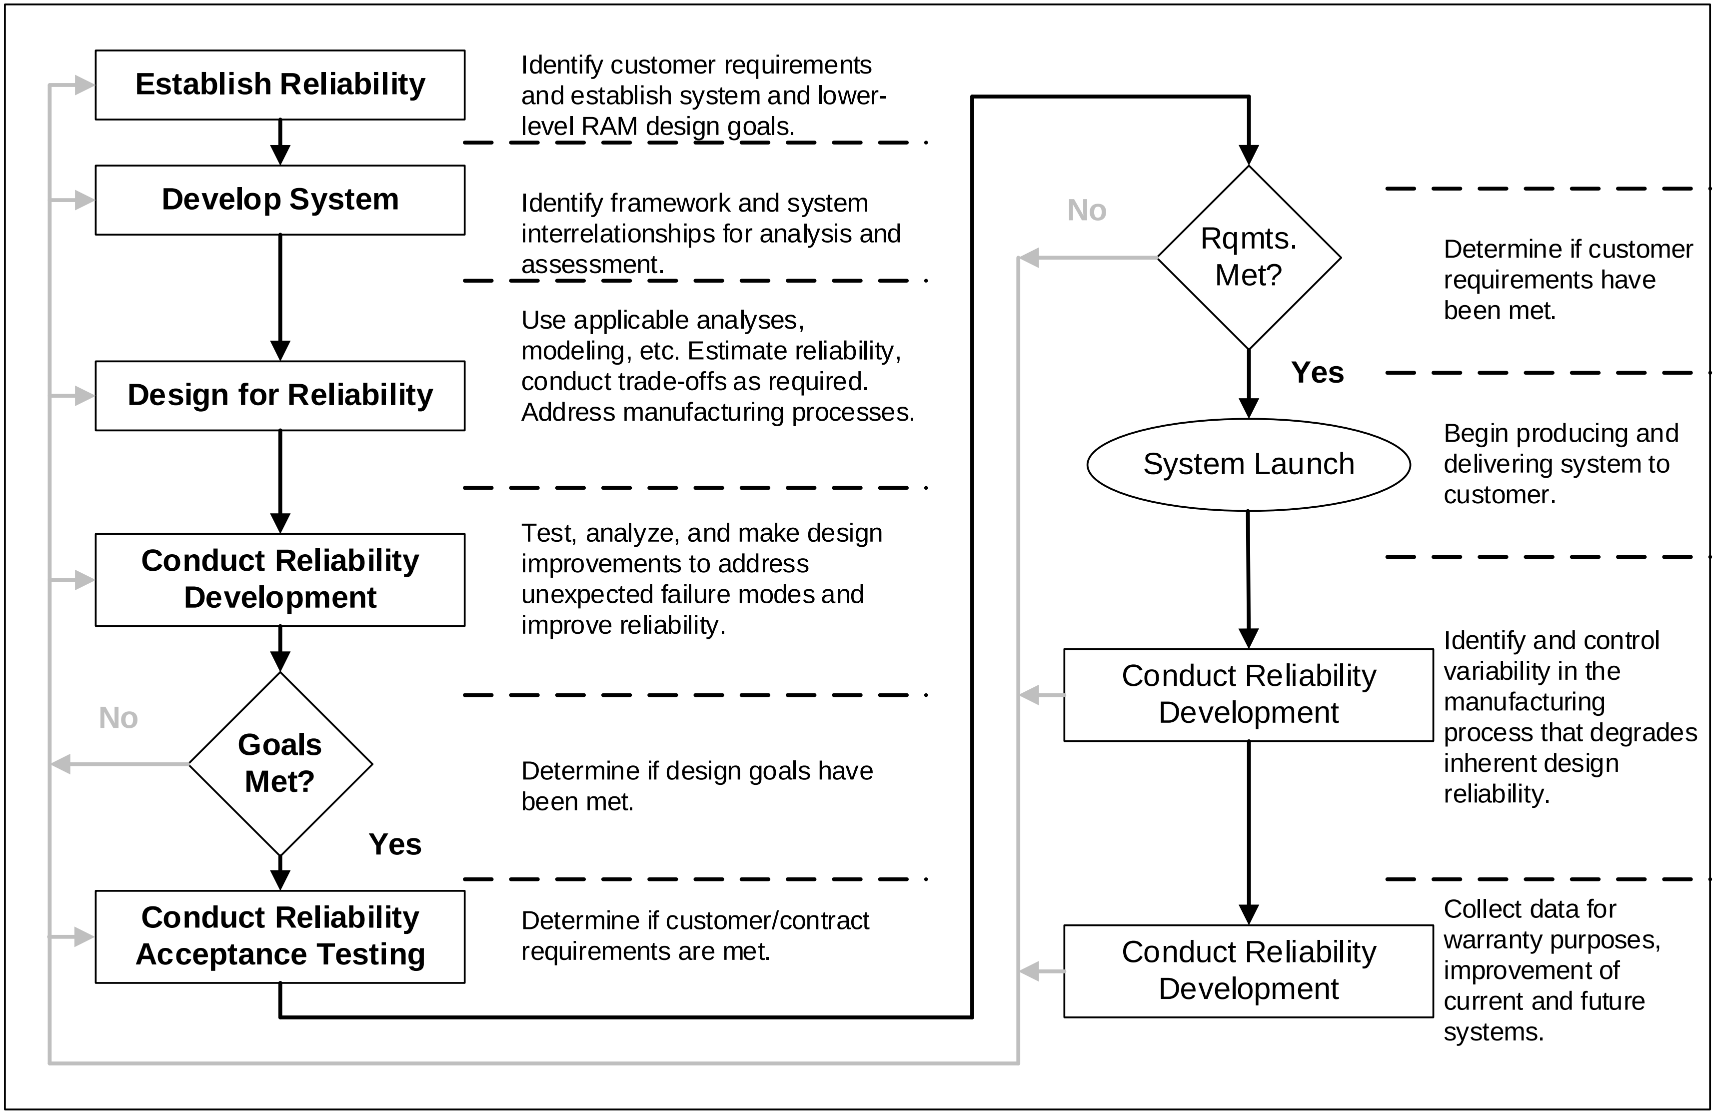
A RAM program is the application of the RAM strategy to a specific system or process. As can be inferred from Figure 2-4, each step in the strategy requires the selection and use of specific methods and tools. For example, various methods can be used to develop requirements or evaluating potential failures.

(a) Developing Requirements. Translations and analytical models can be used to derive requirements. Quality Function Deployment (QFD) is a technique for deriving more detailed, lower-level requirements from one level of indenture to another, beginning with customer needs. It was developed originally as part of the Total Quality Management movement. Translations are parametric models intended to derive design RAM criteria from operational values and vice versa. Analytical methods include:

- thermal analysis
- durability analysis
- predictions, etc.

They are used to make accommodations for special considerations to system design, such as environmental concerns.

Figure 2-4 A Sound Reliability Strategy addresses All Phases of a System's Life Cycle



(b) Evaluate possible failures. Failure Modes and Effects Analysis (FMEA) and Fault Tree Analysis (FTA) are two different methods for evaluating possible failures. The reliability engineer must determine which one to use, or whether to use both. Chapters 5, 6 and 7 will address these and other methods and how to determine which are applicable to a specific situation. Selecting the specific tasks to accomplish each step of the strategy results in a tailored system program. Figure 2-5 shows some of the factors that must be considered in selecting tasks to implement the reliability strategy.

Figure 2-5 Factors Selecting Tasks for a Specific Program

Effectiveness and applicability of tasks vary depending on:

- Production runs (total population) – limits use of system-level statistical analysis
- Critical functions/cost of failure – may require exhaustive analysis
- Technology being used – may require new models
- Nature of development (such as evolutionary vs. revolutionary) experience of much less value when breaking new ground

Selection of tasks is also a function of past experience, budget, schedule, and the amount of risk commanders and facility managers are willing to accept

2-1.10.2.3 Reliability Requirements.

The entire effort of designing for reliability begins with identifying the customer's reliability requirements. These requirements are stated in a variety of ways, depending on the customer and the specific system. Table 2-1 lists some of the ways in which a variety of industries measure reliability. Note that in the case of the oil & gas and communications industries, availability is the real requirement. The reliability and maintainability requirements must then be derived based on the availability requirement.

Table 2-1 Typical Reliability-Related Measures

Customer	System	Measure of Reliability
Airline	Aircraft	On-time departure
Consumer	Automobile	Frequency of Repair
Hospital	Medical	Availability& Accuracy
Military	Weapon	Mission Success Probability
Highway Department	Bridge	Service Life
Oil & Gas	Sub-sea	Availability
Communications Organization	Utilities	Availability

2-2 PROGRAM ELEMENTS.

The essential elements of a system’s engineering program are described below. They must be considered in light of the organization’s mission and function, the availability of existing natural and manmade resources and the security necessary for a new or existing facility.

2-2.1 RAM Requirements Implementation.

The designer must implement reliability, availability, and maintainability (RAM) to achieve the required availability of the C5ISR utility systems.

2-2.2 Human Factors Engineering (HFE).

Human factors engineering (HFE) activities will ensure that reliability, availability, and safety of the C5ISR power system are not degraded through human activities during operation or maintenance. The design agency must accomplish the HFE program requirements using established standard HFE design criteria and practices based on MIL-STD-1472, Human Engineering.

2-2.3 Power System Safety Program.

The C5ISR power system safety program must ensure that the design incorporates, within program restraints, the highest attainable level of inherent safety. It must eliminate or reduce the probability of events that can cause injury or death to personnel, or damage to or loss of equipment or property. For example, pipes, lines, and tanks must be placed away from high-traffic areas. Safety documentation must be provided for safety items that require designation or may cause action during subsequent program phases. The design agency system safety program must be based on a philosophy that the most effective actions to control potential hazards are those taken early in the design process.

2-2.3.1 Special Operating Procedures.

When hazards cannot be controlled by design measures, including safety and warning devices, special operating procedures must be developed and documented. The safety program must provide support to the systems engineering (SE) program and must ensure that the applicable requirements of MIL-STD-882, System Safety, are met.

2-2.3.2 System Safety Analyses.

The systems safety program must define and address the system safety analyses that must be performed during development of design. During the early design phase, an analysis that identifies conditions that may cause injury or death to personnel and damage or loss to equipment and property must be performed. Prior to the final safety design review, the design agency must perform a second systems safety analysis to determine adherence of the design to all required safety standards and criteria, and to ensure avoidance or reduction of identified hazards. Operating and maintenance procedures must also be reviewed for compliance with all required safety standards and criteria.

2-2.3.3 Safety Hazards Identified.

The systems safety program must include procedures to ensure that safety hazards identified by the systems safety analyses are eliminated or reduced to acceptable levels of risk, and that those actions taken are fully documented.

2-2.3.4 Safety Program Documentation.

The design agency must prepare specific safety program documentation. This documentation must include, but not be limited to, safety analysis reports and the final systems safety report.

2-2.4 Consolidation Systems Test Program.

The design agency must develop a consolidated systems test program that covers all phases of testing, develops confidence in the system, and provides means for interim and final acceptance of equipment and systems. The design agency must minimize cost through elimination of testing duplication and by maximizing the collection of data for each test. Successful completion of these tests must be accomplished prior to final acceptance.

2-2.5 Standardization Program.

The design agency must develop and implement a standardization program to minimize equipment and component stockage. Redundant systems must be of the same design.

2-2.6 Configuration Management (CM) Program.

The configuration management (CM) program must maintain effective control over design from criteria development through design, construction, and installation of the equipment. The design agency should work with maintenance staff supervisor to determine maintenance capabilities and any training or funding requirements. A government configuration control procedure must be developed by the design agency for use in the C5ISR utility systems configuration control program.

2-2.7 Operations and Maintenance Planning.

Operations and maintenance (O&M) planning will be done by the design agency and must identify and recommend essential items of the program during the design phase. The design agency should work with maintenance staff supervisors to determine maintenance capabilities and any training or funding requirements. An RCM program should be implemented to identify single point failures and identify the critical systems. Basic elements of the program are as follows.

2-2.7.1 Data Requirements.

As part of the SE database, data requirements must be identified for preparation of O&M manuals. Systems functional descriptions must be developed. Requirements must be developed for data collection, including spare parts list, calibration requirements, special tools and test equipment, spare parts stockage level, and shelf-life data. Spare parts list, spare parts stockage level, test equipment, and test frequency must be provided for the using government agency. For a resilient C5ISR facility, spare parts for critical equipment are necessary to make the facility complete and usable, because they impact the required resilience of the facility design.

2-2.7.2 Complex Systems and Equipment.

Systems and equipment of high complexity or peculiarity must be identified, and special training for personnel who operate and maintain such systems and equipment must be identified.

2-2.7.3 Identify Critical Items.

The design agency must identify those items critical to accuracy and repeatability and must recommend calibration requirements. Unique calibration requirements and procedures must be provided whenever necessary.

2-2.7.4 Systems Test and Checkout.

Systems test and checkout requirements to be performed following major maintenance activities must be developed during design to ensure safe and normal operation of the system.

CHAPTER 3 DESIGN CONSIDERATIONS

3-1 \1\ RELIABILITY/AVAILABILITY REQUIREMENTS FOR EXISTING C5ISR FACILITIES. /1/

3-1.1 Availability Requirements.

The availability will initially be set to at least 0.999 (99.9%, approximately 8 hours and 45 minutes of downtime a year). The criticality of the mission will determine if a higher availability is required but must not be required to exceed 0.999999 (99.9999%, approximately 31 seconds of downtime a year). The utility systems must be evaluated using the standard R/A analysis techniques to determine if goals are met.

3-1.2 Responsibilities for Determining Availability Requirements.

\1\ The Component Technical Representative is responsible for determining if the availability requirements for their mission and facility should be set higher than 0.999 (99.9%). Section 3-1.3 covers specific mission and facility types that have an availability requirement higher than 0.999 (99.9%). See UFC 1-200-01 for the definition of the CTR. /1/

3-1.3 Availability Requirements for Specific Facility Types.

There are some missions and facilities that are critical enough to require a higher availability requirement. \1\ If the Component Technical Representative (CTR) does not provide availability requirements, achieve the following availability levels for the listed missions and facilities. /1/

The criticality of the following missions and facilities is sufficiently high they should be designed and constructed to have a minimum availability of at least 0.99999 (99.999%, approximately five minutes of downtime a year). This availability requirement applies to any operational headquarters facility, airfield and supporting infrastructure, harbor facility supporting naval vessels, munitions production and storage facility, radar, space launch facility, or operational communications facility that is determined to be a critical mission.

The criticality of the following missions and facilities is sufficiently high they should be designed and constructed to have a minimum availability of at least 0.999999 (99.9999%, approximately 31 seconds of downtime a year). This availability requirement applies to any missile field, ballistic missile early warning radar, satellite control facility, cyber operations facility, or biological defense facility that is determined to be a critical mission.

3-2 GENERAL DESIGN REQUIREMENTS \1\ FOR UPGRADING EXISTING SYSTEMS. /1/

The design agency's role in the O&M concept is to establish the foundation for stable C5ISR utility systems that must provide continuous operation incorporating redundancy (dual systems), readiness (standby systems), flexibility (multiple modes of operations), and standardization (parts and equipment). Power plant facilities, systems, and O&M documentation must be designed to permit rapid startup and repair of equipment under emergency conditions. O&M functions must be enhanced through the application of these guidelines by the C5ISR utility systems designer.

\1\ The availability requirement for upgrade and renovation projects will initially be set to at least 0.999 (99.9%, approximately 8 hours and 45 minutes of downtime a year). The Component Technical Representative is responsible for determining if the availability requirements for their mission and facility should be set higher than 0.999 (99.9%). See section 3-1.3 for specific mission and facility types that have an availability requirement higher than 0.999 (99.9%).See UFC 1-200-01 for the definition of the CTR. /1/

3-2.1 Historical Records.

A recording device must be included in the design to provide a log of facility performance. This recorder must accept either analog or digital signals (such as input and output parameters for generators, main switchgear feeders, uninterruptible power supply (UPS) systems, power distribution units, chillers, etc.), convert them to numerical data, scale them to useful values and store them in electronic storage. The signals should be stored at intervals of 15 minutes or other specified preset time intervals. The recorder must have the capability to record critical signal values more frequently than the preset recording rate (for example, every five seconds) when prompted by a signal from the operator or operating equipment. The recorder must automatically return to its primary recording when system operation returns to normal. Records must be maintained on-site for a minimum of five years. A supervisory control and data acquisition (SCADA) system should be incorporated into the design of the systems.

3-2.2 Control Systems.

Control systems are the third major component making a C5ISR facility as reliable as possible with electrical systems being the first major component and mechanical systems being the second major component. Control systems are the brains behind the operational characteristics during normal and abnormal conditions. Control systems are commonly identified as SCADA systems and are designed to monitor conditions and react in a manner to maintain a set point. Typical SCADA systems are comprised of a series of sensors sending signals to a central command center where the signals are interpreted. A data communication protocol will be required for the signals between the central command center and the sensors to be interpreted and acted upon. \1\ To achieve maximum reliability/availability for a facility consideration should be given to the reliability/availability of the SCADA system when it participates in the control of the facility systems. If the monitoring and control station is located outside of the facility, then the reliability/availability of the communication pathways should be analyzed and improved as needed. /1/

Some examples of common data communication protocols include \1\ MIL-STD-3071, Lonworks, and BACNet. /1/ There are other data communication protocols available and the protocol providing the most robust solution should be used. Signals are sent from the command center to actuators to throttle input conditions and provide the necessary environmental condition required for the mission operations. Typical components for a SCADA system are:

- Computer access panel
- Digital drivers
- Power supplies
- Programmable Logic Controller (PLC)
- Interface devices such as control panels or circuit breakers

3-2.3 Maintenance Concepts.

The design outputs prepared by the design agency must reflect the following maintenance concepts.

3-2.3.1 Equipment Standardization Program.

The design agency must develop and implement an equipment standardization program to simplify equipment maintenance.

3-2.3.2 Modular Designed Subassemblies.

The design agency must specify modular designed subassemblies which will permit rapid repair.

3-2.3.3 Built-in Test Modules/Fault Sensors.

The design agency must specify that manufacturers provide built-in test modules/fault sensors. Selector switches that allow personnel to access and sequentially monitor operating variables within an assembly must be provided.

3-2.3.4 Equipment Tag.

The design agency must specify that a plate with an equipment tag number be attached to the equipment by the construction contractor. The design agency must specify a method for identifying and numbering wires and cables, for marking cable termination strips, and for uniformly interconnecting equipment of different manufacturers. Corresponding identity codes must be used for termination strips and wiring. The design agency must specify that if a manufacturer changes the characteristics of a purchased component for use in a composite item, the true source identity of the originally purchased part will remain intact.

3-2.4 Evaluations.

The following evaluations must be an integral part of the design process.

3-2.4.1 Operations Evaluations.

Operations evaluations must consider both user and system requirements.

(1) The design agency must evaluate user requirements to determine operating parameters and the effect that these parameters will have on system operation, output efficiency, and personnel safety. The design agency must determine if limits need to be placed on manual control and, if so, must specify those limits.

(2) The design agency must evaluate the system requirements as to the operational effects produced by changing power by switching the source of electrical power and maintenance or repair activities within the facility. System designers must identify critical mission variables subject to O&M schedules and incorporate equipment and/or operational redundancies to perform maintenance without disruption to critical operations. The design agency must specify areas in the control system that should allow automatic adjustments to system equipment to aid the operator when events occur that demand immediate operator intervention.

3-2.4.2 Evaluate User Constraints and Parameters.

The design agency must evaluate user constraints and parameters to ensure maintainability of the C5ISR utility systems.

3-2.4.3 Perform a Hazard Evaluation.

The design agency must perform a hazard evaluation to ensure adherence to Occupational Safety and Health Administration (OSHA), National Electrical Code (NEC), and other locally binding safety standards.

3-2.5 Operations and Maintenance Documentation.

The design agency must perform an O&M analysis to identify the equipment in the C5ISR utility systems that contributes significantly to the maintenance burden of the system and the O&M data required to support maintenance of this equipment by the using government agency. This analysis must be coordinated with the using government agency to determine maintenance parameters and O&M data that are available to the using government agency.

3-2.5.1 Identify O&M Data Requirements.

The design agency must identify O&M data requirements on an individual basis for all maintenance-significant equipment. Typical data requirements include the following items.

- Minimum spare parts list.
- Recommended spare parts list.

- Recommended onsite test equipment.
- Recommended O&M training.

3-2.5.2 Specify Functional Areas of Operating System.

The design agency must specify functional areas of the operating system and/or equipment where a technical representative will be furnished by the manufacturer for training, test, checkout, validation, or pre-operational exercises.

3-2.6 Verification.

A verification of O&M procedures and data manual content must be performed by the using government agency to demonstrate technical accuracy, fulfillment of intent, and applicability to the performance of O&M within the facility. A review of the verification process may necessitate that additional information be obtained from the equipment manufacturer.

3-2.6.1 Verification Process.

Verification should begin during the equipment acceptance process and continue as the using government agency applies the instructions, data, and technical manuals to the continuous routines of equipment operation and repair.

3-2.6.2 Verification Support.

The design agency must support the user's verification process by:

(1) Specifying acceptance test procedures which the contractor must be expected to fulfill during facility acceptance. The format should contain adequate sign-off routines to verify the performance of equipment in accordance with design specifications.

(2) Requiring that, for specially designed equipment that does not fit well into a standard acceptance format, the contractor must submit an acceptance plan in lieu of the designer-specified acceptance test procedures.

This Page Intentionally Left Blank

CHAPTER 4 ACCEPTABLE METHOD FOR EVALUATING SYSTEM RESILIENCE

4-1 ROBUSTNESS.

Robustness is defined as "the ability to absorb shocks and continue operating." (North American Electric Reliability Corporation - NERC) For many critical facilities, there may be many mission assets which are considered uninterruptible. Since it is imperative to the mission that these assets remain on-line, any downtime or outage for such assets would be considered mission failure; the shock has not been absorbed. When evaluating missions for which any interruption is unacceptable, component failure or degradation should be considered as reducing the probability of mission success. Component failures or degradations should be considered as eliminating equipment redundancies or reducing individual component reliability. In these cases, it is appropriate to evaluate the performance of the system as the resulting operational availability for the mission. For example, if an event occurs which reduces the mission availability to 0.999, then the average expected weekly downtime of the mission is about 10 minutes. If a more resistant system is only reduced to an availability of 0.9999, the expected weekly downtime for the mission is approximately one minute. This essentially represents a 10-fold difference in system performance during the recovery period.

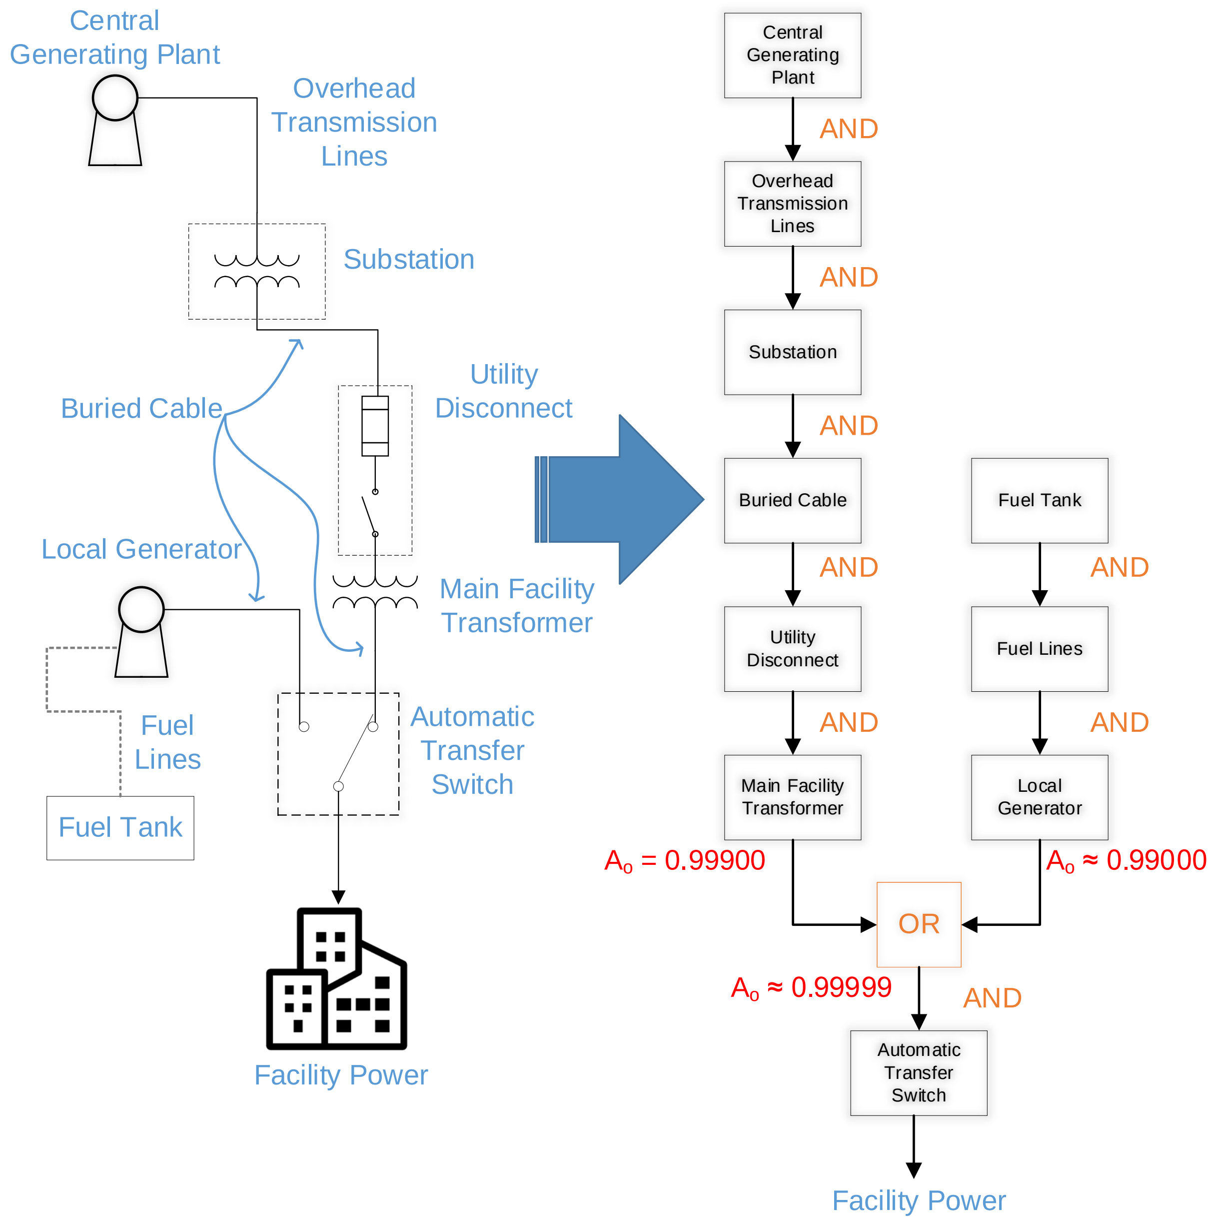
4-1.1 Evaluating Robustness.

As discussed, robustness may be quantified as a change in mission availability caused by the occurrence of a postulated event. Traditional reliability and availability analysis methods such as reliability block diagrams (RBDs), state-space modeling, or Monte Carlo simulations, may be used to evaluate mission availability during base-case and contingency operations. For the purposes of evaluating resilience, the following paragraphs will focus on the reliability RBD/Boolean algebra methodology.

4-1.1.1 Constructing an RBD.

Constructing a RBD requires translating the system topology into a set of discrete elements and logic gates. Items connected in series are typically combined with AND operators; parallel objects and strings are typically combined with OR operators. Depending on system configuration and redundancy parallel objects and strings may be combined using AND or OR operators. Each element in the block diagram has an associated availability statistic, which is derived from statistical data collected from similar components. Figure 4-1 shows an example of a typical utility system translated into an RBD. Note that combining redundant paths with an OR operator significantly increases the mission availability.

Figure 4-1 RBD for a Typical Distribution System



4-1.1.2 Contingency Event Data.

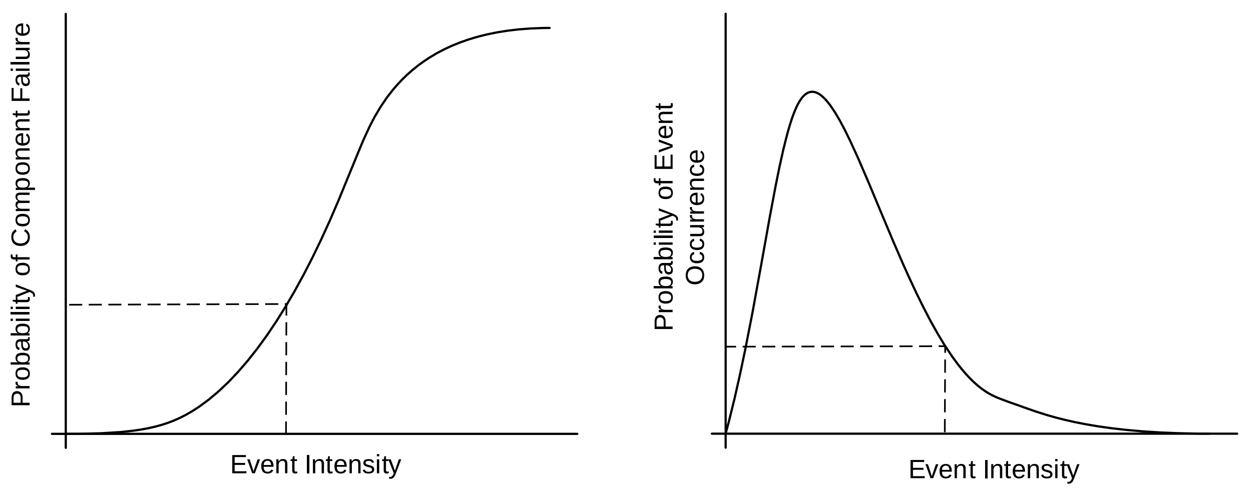
Incorporating contingency event data into availability modeling allows for a quantifiable difference in performance between base-case and contingency operations. There are two primary ways through which this is accomplished. The first, and most intuitive method, involves a deterministic approach, and is similar to traditional Failure Modes, Effects and Criticality Analysis (FMECA) analysis. This method assumes that an event of a certain magnitude has occurred and evaluates the effect that the event has on overall system availability. The following steps outline the deterministic method for Robustness evaluation:

4-1.1.2.1 Determine Events for which the Robustness of the System should be Assessed.

When applying the deterministic method, only a particular event or set of related events should be evaluated at a time. When selecting scenarios for evaluation, the probability and severity of the event should be considered. As a starting point, consider key components in the system where, as determined by baseline availability studies, failure is likely to significantly impact the performance of the system. Chapter 5 will discuss how to perform/create the baseline availability analysis.

In cases where reliable statistics exist to determine the probability that a particular event may occur, it is possible to select events based on the conditional probability of component failure given the occurrence of the event. In general, higher intensity events have a greater chance of causing component failure, but also occur less frequently. This can be seen in the two graphs in Figure 4-2. The graph on the left shows the fragility curve for a particular component; this shows the probability of component failure according to the intensity of an event. The graph on the right shows the probability density function (PDF) for a particular event based on event intensity.

Figure 4-2 Fragility Curves vs Event Probability



From these graphs, it can be see that an event of a given intensity has a corresponding probability of causing component failure (P(failure)), and an independent probability that it will occur (P(event)). Combining these two probabilities in Equation 4-1 yields the conditional probability of failure given the occurrence of the event.

Equation 4-1. Conditional Probability of Failure Given Occurrence of the Event

$$P(failure\ given\ event) = \frac{P(failure)\ \cap P(event)}{P(event)}$$

Where:

P = probability
∩ = the probability that Events A and B both occur is the probability of the intersection of A and B. The probability of the intersection of Events A and B is denoted by P(A ∩ B). If Events A and B are mutually exclusive, P(A ∩ B) = 0.

4-1.1.2.2 Conditional Probability of Failure.

The conditional probability of failure given event occurrence can be used to evaluate the relative risk associated with an event and determine whether further evaluation of that event is justified. For example, a site in Utah may not need to evaluate its response to a hurricane. If fragility data and event data indicate that event occurrence does not significantly increase the risk of component failure (such as the conditional probability of failure is within one order of magnitude of inherent failure rate), that scenario does not necessarily require further evaluation.

For other events, the severity of risk may be more subjective. For contingencies such as HEMP events, wildlife damage, cyber-attacks, or terrorist attacks, the probability of occurrence may be unknown or is subject to change. Consequently, a threshold value for conditional probability of failure may not exist, and a different means of event selection is warranted.

4-1.1.2.3 Determine what Components are likely to Fail as a Result of the Event.

All components in a system are uniquely vulnerable to a set of events. For example, exterior generators may be vulnerable to flooding, whereas SCADA controlled switchgear may be more vulnerable to cyber-attacks. If fragility curves for individual components are available, then the probability of component failure associated with an event can be incorporated into the system availability model. Consider using an analysis tool such as HAZUS, as developed by the Federal Emergency Management Agency (FEMA), to assess the overall risk of component failure due to specific events. HAZUS is an example of a risk assessment tool that utilizes both fragility and event data in its analysis. Where event and fragility data are unavailable, it may be more practical to assume certain key components as having failed due to a postulated event. This deterministic approach clearly identifies single points of failure or areas that require additional hardening measures.

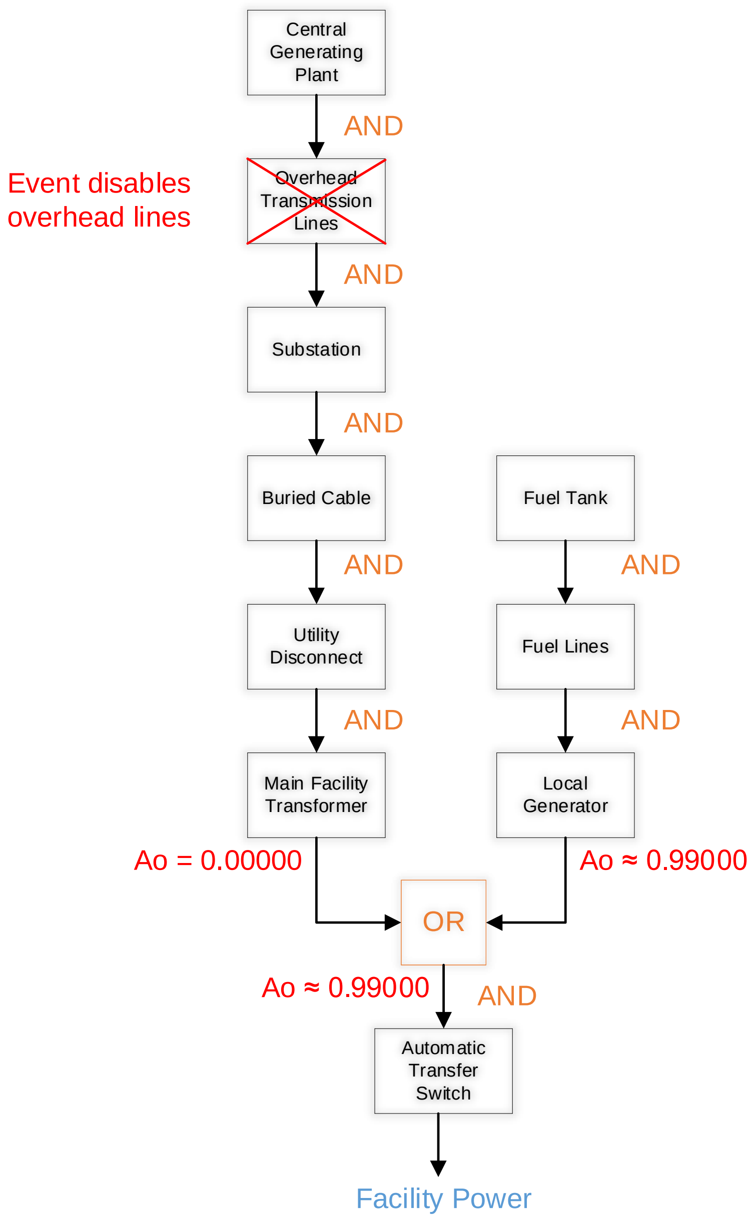
4-1.1.2.4 Analyze the Degraded System State.

As previously mentioned, functionality for critical missions that are considered uninterruptible must be maintained. In these cases, the change in system performance can be measured by the change in mission availability from the baseline state. In other words, a contingency event is considered to affect mission availability, not overall mission success. For example, in the postulated power system in Figure 4-3, a wind event disables only overhead transmission lines. Since backup power can be immediately supplied by emergency generators, mission loads can continue to operate.

However, until the transmission lines are restored, the likelihood of failure is significantly increased.

Similar methods can be used to evaluate the degraded mission availability as for the baseline case (for example RBDs, Monte Carlo, state space). More information on each of these methods is provided in Chapter 5. To evaluate the degraded state, the input data used for the analysis must be modified to reflect the impact of the event being considered. The simplest method is to consider failed components as having an availability of zero. If equipment fragility curves are available, the resulting equipment reliability can be incorporated into the existing availability model.

Figure 4-3 Distribution System Model in Degraded State



4-2 RECOVERY.

Operations in the recovery phase have stabilized, and no further damage or degradation is expected. The system may be operating in alternate or emergency modes with a reduced availability. Power may be provided to critical systems via stand-by generators, alternate utility feeds, or distributed energy resources. In this phase, the emphasis is on restoring the system to its baseline operation.

4-2.1 Recovery Time.

As previously discussed, the shorter the recovery time, the more resilient the system. Recovery time is determined by the average length of time required to return damaged components to service. In general, the availability of the system increases as assets are recovered. For large or complex systems, availability during the recovery phase may change continuously. For smaller systems, or where fewer redundant paths exist, it can be more useful to consider the change in availability during the recovery phase as a step function. That is, there are discrete step changes in availability as components or success paths are returned to service.

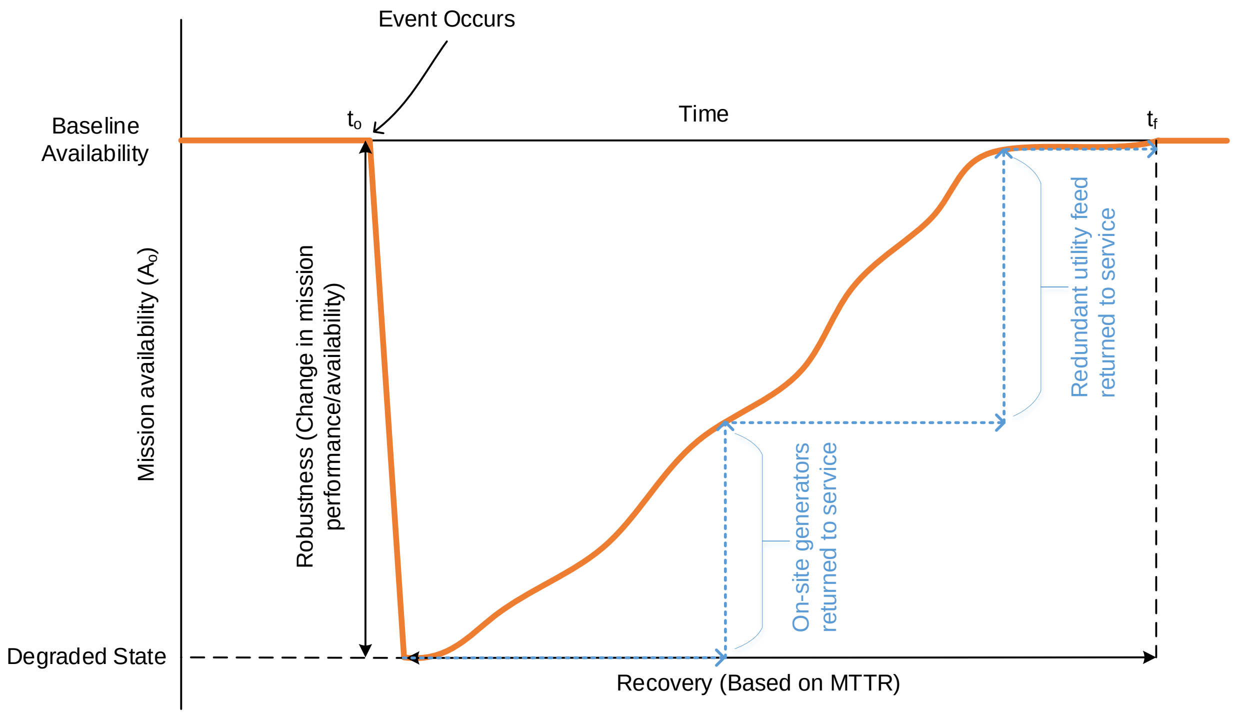
4-2.2 Stepped Recovery of Power System Assets.

Figure 4-4 provides an example of this concept. In this example, an event has disabled both the on-site generation as well as one of two redundant utility feeders. The on-site generators are quickly returned to service, resulting in a large step increase in availability. After some time, the redundant utility feed is returned to service, resulting in a second step increase in availability. It is important to note that for a single success path to be restored, all series components must be fully restored before improvements in availability are realized. For example, if an event disables a backup generator, its associated fuel tank and fuel lines, all these assets must be repaired before that feed is considered back on-line.

The step-change model in Figure 4-4 indicates the recovery time for the system can be approximated using the mean-time-to-repair (MTTR) for the various affected components. However, designers, planners, and facility managers must use caution when using MTTR to anticipate recovery time following a contingency event. MTTR data is typically based on failure modes that occur during normal operation. Contingency events may cause different failures to occur, and additional logistics delays must be considered based on the nature of the event and the location of the site. To determine the recovery time for a system, MTTR data should be used as an input to evaluate a disaster recovery plan.

Following a contingency event, the facility or site should have a plan in place to adapt to and recover quickly from its affects. Due to limitations of personnel, resources, and logistics, repairs for all components cannot occur simultaneously. It may also be required that some assets be restored in sequence. The following steps provide an outline for considerations when developing a recovery plan:

Figure 4-4 Stepped Recovery of Power System Assets



4-2.2.1 Identify the Components that are likely to have Failed.

This step may already have been completed as part of evaluating system robustness. Fragility curves and unique factors such as site geography are used to identify those components and success paths which may be inoperable following the event.

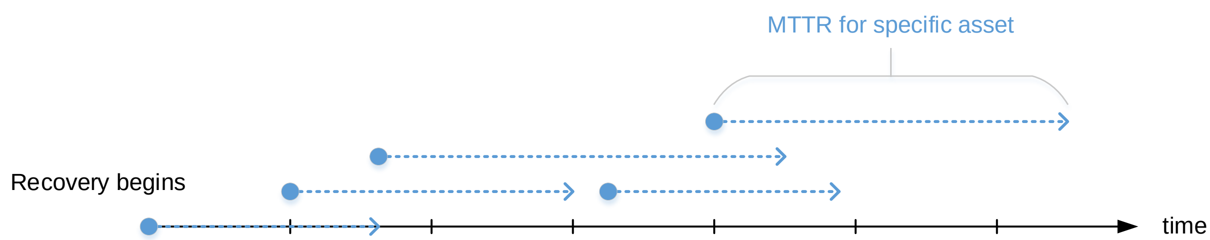
4-2.2.2 Evaluate Repair Priorities.

The RBD can be used to evaluate the effectiveness of individual repair activities based on what effect they have on mission availability and the time it takes to execute the repair. For example, when comparing two repair activities which have similar execution times, the activity which results in a larger improvement in mission availability should be prioritized. Typical MTTR values can be used as an input to evaluate the time requirements for each activity, but event-specific failure modes, and additional logistical delays should also be evaluated. In this step it is important to consider any repairs that, due to operational or resource limitations, may need to be executed in sequence.

4-2.2.3 Determine the Overall Time to Return to Baseline Operations.

Once the overall structure of the recovery plan is in place, the timeline for recovery should be evaluated. The result should be a site-specific, and event-specific number representing the required execution time for the planned series of repair activities. The result should be evaluated against operational limitations such as fuel reserves to determine whether the recovery time is adequate. Figure 4-5 shows an example of how the timeline for a typical recovery plan may look. Each arrow represents the repair time for a specific asset. Note that individual repair events are staggered to optimize personnel and equipment resources throughout the recovery phase.

Figure 4-5 Sample Recovery Timeline



4-3 DETERMINING OPERATIONAL REQUIREMENTS FOR RESILIENCE METRICS.

Requirements for resilience metrics can vary from site to site and depend on a multitude of factors. As previously discussed, certain sites may want to prioritize either robustness or recovery depending on their specific needs.

4-3.1 Evaluate the Needs of the System.

To evaluate the needs of the system, it is important to apply a realistic time scale to the baseline and degraded availability states. Typically, availability is related to equipment downtime on a yearly scale; a “six-nines” system relates to about 30 seconds of downtime per year. However, contingency scenarios are more likely measured in weeks. Table 4-1 shows the corresponding weekly downtime for various levels of availability.

Table 4-1 Average Weekly Downtime Based on Availability

Availability	Average Weekly Downtime (Minutes)
0.9	1008
0.99	100.8
0.999	10.08
0.9999	1.008
0.99999	0.1008
0.999999	0.01008

4-3.2 Availability Requirements.

There are certain mission types with specific availability requirements. These requirements come from a memorandum from the Office of the Under Secretary of Defense dated 20 May 2021. The subject of the memorandum is Metrics and Standards for Energy Resilience at Military Installations. The availability requirement for the following mission types must be 99.999% or five-9's:

- Operational Headquarters Facility
- Airfield and Supporting Infrastructure
- Harbor Facility Supporting Naval Vessels
- Munitions Production and Storage Facility
- Radar
- Space Launch Facility
- Operational Communications Facility that is determined to be a critical mission

The availability requirement for the following mission types must be 99.9999% or six-9's:

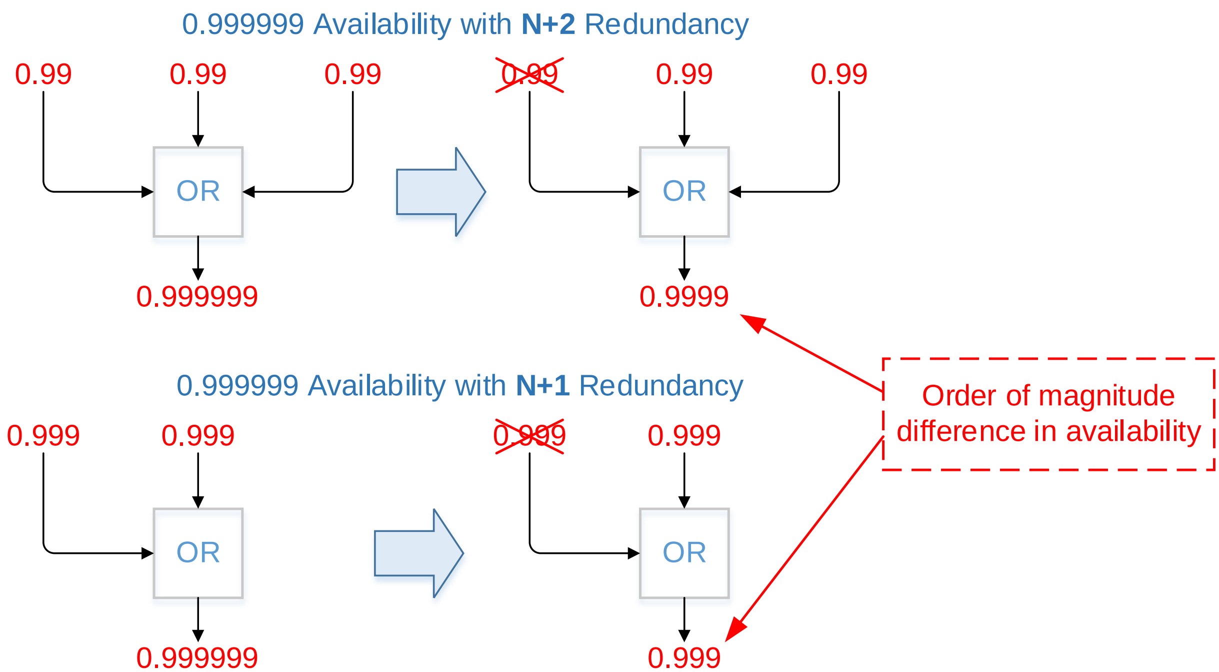
- Missile Field
- Ballistic Early Warning Radar
- Satellite Control Facility
- Cyber Operations Facility
- Biological Defense Facility that is determined to be a critical mission

A critical mission that does not fit these mission types is allowed to have an availability range from 99.9% (three-9's) to 99.9999% (six-9's) depending on the criticality of the mission.

4-3.3 Minimum Acceptable Level of Degraded State Availability.

When assessing the minimum acceptable level of degraded state availability, it is also important to consider the site-specific requirements for availability, as well as requirements for system topology. For example, a baseline availability requirement of six nines (0.999999) can be achieved using an N+2 redundant arrangement of three elements each with an availability of 0.99, or an N+1 redundant arrangement of two elements each with an availability of 0.999. If an event occurs which incapacitates only one feed, the N+2 system will have a degraded state availability a full order of magnitude higher than the N+1 system. Naturally, systems with a higher level of required redundancy should have more stringent requirements for resilience than those with less design redundancy. This is shown in Figure 4-6.

Figure 4-6 N+2 vs N+1 System Resilience



Site-specific requirements for resilience should also be decided by weighing several major factors. Ultimately, the required level of resilience is based on the level of mission criticality, the remoteness of the site, and whether the mission is duplicated and can be executed at any other sites.

4-3.3.1 Criticality.

Many DoD installations serve a range of critical missions. In a perfect world, designers would be able to protect all levels of critical missions from the effects of any possible event. However, due to funding and design constraints, some assets must be prioritized over others. Ultimately, the assets should be prioritized according to the DoD Mission-Based Critical Asset Identification Process (CAIP, DoD Inst 3020.45). To simplify the decision process for resilience planning, missions and supporting assets can also be categorized as having low, medium, or high criticality. Criticality in this context refers to the impact that incapacity or destruction of a mission would have on the physical or economic security or public health or safety.

This criticality level can be assigned based on national priorities, or within the scope of a local project. For example, when considering resilience improvements for only a single installation or facility, it may be useful to consider the low-medium-high scale as spanning the range of criticality present at that installation. In many cases, specific details related to the level of criticality of a mission may be classified.

4-3.3.2 Remoteness.

Critical facilities and other critical assets exist in a variety of locations. This can have a significant effect on recovery of a mission following an extreme event. Remoteness is primarily related to the geographical location of a facility or installation but can be further influenced by other accessibility factors. Topographic features such as bodies of water or mountainous terrain, as well as the number and condition of access roads can also impact the remoteness of a site. For example, if a site can only be accessed via a single bridge, it would be considered as more remote than a similar site with several access points.

Like the level of criticality, the remoteness of a site can be categorized in relative terms. For the purposes of resilience planning, sites should be considered to have low, medium, or high remoteness. Typically, more remote sites should prioritize the robustness phase of resilience as recovery may be limited by physical constraints. This maximizes overall resilience by prioritizing the ride-through ability for these missions.

4-3.3.3 Duplicated Missions.

Some missions can be carried out at geographically diverse sites such that a contingency event at one is unlikely to affect mission success at any of the other sites. This creates additional mission redundancy and can reduce resilience requirements at an individual site. It is important to evaluate the practical considerations in mission duplication; several questions must be answered. Will the mission be transferred to an alternate site automatically? Will personnel be available at the alternate site to process the mission? Can the mission be transferred in anticipation of a foreseen event? In the interest of simplicity, the ability of a mission to be carried out at alternate sites should be considered as a simple yes or no.

Once these three factors have been evaluated, the results can be used to determine the requirement categories for both Robustness and Recovery. As previously discussed, these two aspects of resilience should be considered independently due to the unique needs of individual sites. Using Table 4-2 below, the three factors can be applied to place a mission or asset in prioritized categories for both Robustness and Recovery. The result is a low-medium-high index for each resilience phase. For example, a mission with medium criticality, high remoteness, and no mission duplication would have a High Robustness requirement and a Medium recovery requirement.

Table 4-2 is designed to provide a simple framework to assign independent requirements for both robustness and recovery. This should be used as a tool to determine the relative need for prioritizing either phase of the system response to a given event. In some cases, a single facility may have different required levels of robustness and recovery.

Table 4-2 Determine Resilience Requirements

		Resilience Phase	
		Robustness	Recovery
Resilience Metric Requirement	Low	Criticality: **Low-Med** Remoteness: **Low** Duplicated Missions: **Yes**	Criticality: **Low** Remoteness: **Low-Med** Duplicated Missions: **Yes**
	Medium	Criticality: **Low-Med-High** Remoteness: **Med** Duplicated Missions: **Yes**	Criticality: **Low-Med** Remoteness: **Low-Med-High** Duplicated Missions: **No**
	High	Criticality: **Med-High** Remoteness: **Med-High** Duplicated Missions: **No**	Criticality: **High** Remoteness: **Low-Med-High** Duplicated Missions: **No**

CHAPTER 5 RELIABILITY/AVAILABILITY

5-1 BASIC RELIABILITY AND AVAILABILITY CONCEPTS.

5-1.1 Probability and Statistics

This chapter provides the reader with an overview of the mathematics of reliability theory. It is not presented as a complete (or mathematically rigorous) discussion of probability theory and statistics but should give the reader a reasonable understanding of how reliability is calculated. Before beginning the discussion, a key point must be made. Reliability is a design characteristic that indicates a system's ability to perform its mission over time without failure or without logistics support. In the first case, a failure can be defined as any incident that prevents the mission from being accomplished; in the second case, a failure is any incident requiring unscheduled maintenance. Reliability is achieved through sound design, the proper application of parts, and an understanding of failure mechanisms. Estimation and calculation techniques are necessary to help determine feasibility, assess progress, and provide failure probabilities and frequencies to determine spare part requirements and other analyses.

5-1.1.1 Uncertainty.

Uncertainty - at the heart of probability. The mathematics of reliability is based on probability theory. Probability theory, in turn, deals with uncertainty. The theory of probability had its origins in gambling.

(1) Simple examples of probability in gambling are the odds against rolling a six on a die, of drawing a deuce from a deck of 52 cards, or of having a tossed coin come up heads. In each case, probability can be thought of as the relative frequency with which an event will occur in the long run.

(a) Tossing an honest coin will result in heads (or tails) 50% of the time, this does not mean it will necessarily toss five heads in ten trials. It only means that in the long run, it is expected to be 50% heads and 50% tails. Another way to look at this example is to imagine a very large number of coins being tossed simultaneously; again, it is expected to be 50% heads and 50% tails.

(b) Rolling an honest die, it is expected the chance of rolling any possible outcome (one, two, three, four, five, or six) is one in six. It is possible to roll a given number, say a six, several times in a row. However, in a large number of rolls, it is expected to roll a six (or a one, or a two, or a three, or a four, or a five) only 1/6 or 16.7% of the time.

(c) Drawing from an honest deck of 52 cards, the chance of drawing a specific card (an ace, for example) is not as easily calculated as rolling a six with a die or tossing a heads with a coin. First it must be recognized that there are four suits, each with a deuce through ace (ace being high). Therefore, there are four deuces, four tens, four kings, etc. So the chance of drawing any ace is four in 52 since there are only four aces. It is instinctively known that the chance of drawing the ace of spades, for example, is less than four in 52. Indeed, it is one in 52 (only one ace of spades in a deck of 52 cards).

(2) Why is there a 50% chance of tossing a head on a given toss of a coin? It is because there are two results, or events, which can occur (assume that it is very unlikely for the coin to land on its edge) and for a balanced, honest coin, there is no reason for either event to be favored. Thus, the outcome is random, and each event is equally likely to occur. Hence, the probability of tossing a head (or tail) is one of two equally probable events occurring = 1/2 = 0.5 = 50% of the time. On the other hand, one of six equally probable events can result from rolling a die: it can be a one, two, three, four, five, or six. The result of any roll of a die (or of a toss of a coin) is called a discrete random variable. The probability that on any roll this random variable will assume a certain value, call it x, can be written as a function, f(x). The probabilities of f(x), specified for all values of x, are referred to as the values of probability function of x. For the die and coin, the function is constant. For the coin, the function is f(x) = 0.5, where x is either a head or tail. For the die, f(x) = 1/6, where x can be any of the six values on a die.

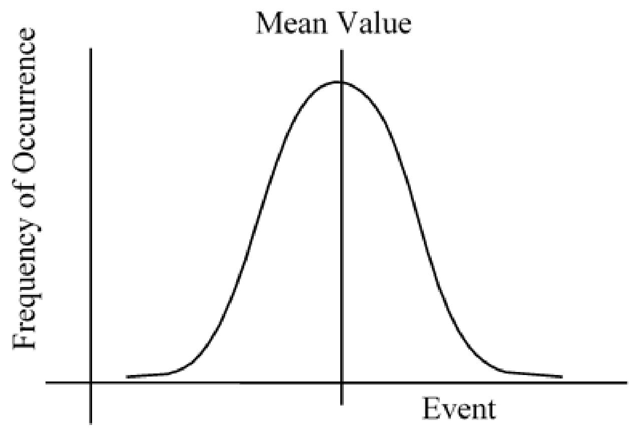
5-1.1.2 Probability Functions.

All random events have either an underlying probability function (for discrete random variables) or an underlying PDF (for a continuous random variable).

(1) The results of a toss of a coin or roll of a die are discrete random variables because only a finite number of outcomes are possible; hence these events have an underlying probability function. When the probability of each event is equal, underlying probability function is said to be uniform.

(2) The number of possible heights for American males is infinite (between 5 feet – 8 inches (1.72 meters) and 6 feet (1.83 meters), for example, there are an infinite number of possible heights) and is an example of a continuous random variable. The familiar bell-shaped curve describes most natural events, such as the height of a person, intelligence quotient of a person, errors of measurement, etc. The underlying PDF represented by the bell-shaped curve is called normal or Gaussian. Figure 5-1 shows a typical normal distribution. Note that the event corresponding to the midpoint of the curve is called the mean value. The mean value, also called the expected value, is an important property of a distribution. It is like an average and can be compared with the center of mass of an object. For the normal distribution, half the events lie below the mean value and half above. Thus, if the mean height of a sample of 100 Americans is 5 feet -9 inches (1.75 meters), it is expected that half the sample would be less than 69 inches (1.75 meters) tall, and half would be taller. It is also expected that most people would be close to the average with only a few at the extremes (very short or very tall). In other words, the probability of a certain height decreases at each extreme and is “weighted” toward the center, hence, the shape of the curve for the normal distribution is bell-shaped.

Figure 5-1 Typical Normal Distribution Curve



(3) The probability of an event can be absolutely certain (the probability of tossing either a head or a tail with an honest coin), absolutely impossible (the probability of throwing a seven with one die), or somewhere in between. Thus, a probability always can be described with Equation 5-1.

Equation 5-1. Probability of an Event

$$0 \leq P \leq 1$$

Where:
P = probability of an event

(4) Determining which distribution best describes the pattern of failures for an item is extremely important, since the choice of distributions greatly affects the calculated value of reliability. Two of the continuous distributions commonly used in reliability are shown in Table 5-1. Note that f(t) is called the probability density function (PDF). Reliability is usually concerned with the probability of an unwelcome event (failure) occurring.

Table 5-1 Commonly Used Continuous Distributions

Distribution	Probability Density Function	Most Applicable to
Exponential	$f(t) = \eta e^{-\lambda t}$	Electronic parts and complex systems
Weibull (2-parameter)	$f(t) = \frac{\beta}{\eta}\left(\frac{t}{\eta}\right)^{\beta-1} e^{(\frac{t}{\eta})^{\beta}}$	Mechanical Parts

Where:
f(t) = probability density function
η = scale
e = the base of natural logarithms
λ = the failure rate (inverse of MTBF)

t = time (hours)

Where:
f(t) = probability density function
β = shape parameter/Weibull slope
η = scale
t = time (hours)
e = the base of natural logarithms

(a) The underlying statistical distribution of the time to failure for parts is often assumed to be exponential. A glance at the equation of the PDF explains why. It is easy to work with and has a constant mean, λ. Rather than assuming a distribution, one should determine the most appropriate one using various techniques for analyzing time-to-failure data.

(b) When the exponential distribution is applicable, the rate at which failures occur is constant and equal to λ. For other distributions, the rate at which failures occur varies with time. For these distributions, a Hazard Function is used, which is a function that describes how the rate of failures varies over time.

(c) Note that different types of parts (such as, items that fail once and then are discarded and replaced with a new item) may have different underlying statistical distributions of the time to failure. The times to failure of electronic parts, for example, often follow the exponential distribution. The times to failure for mechanical parts, such as gears and bearings, often follow the Weibull distribution. Of course, the parameters for the Weibull for a gear will most likely will be different from the parameters for a ball bearing. The applicability of a given distribution to a given part type and the parameters of that distribution are determined, in part, by the modes of failure for the part.

(d) By their very nature, systems consist of many, sometimes thousands, of parts. Since systems, unlike parts, are repairable, they may have some parts that are very old, some that are new, and many with ages in between these extremes. In addition, each part type will have a specific distribution of times to failure associated with it. The consequence of these part characteristics together within a system is that systems tend to exhibit a constant failure rate. That is, the underlying statistical distribution of the time to failure for most systems is exponential. This consequence is extremely significant because many reliability prediction models, statistical demonstration tests, and other system analysis are predicated on the exponential distribution.

5-1.1.3 Determining Failure Rate or Hazard Function.

How is the failure rate (or Hazard Function) of a specific system or component determined? Two methods are used.

(1) In the first method, use failure data for a comparable system or component already in use. This method assumes that the system in use is comparable to the new system

and that the principle of transferability applies - this principle states that failure data from one system can be used to predict the reliability of a comparable system.

(2) The other method of determining failure rate or the Hazard Function is through testing of the system or its components. Although, theoretically, this method should be the "best" one, it has two disadvantages. First, predictions are needed long before prototypes or pre-production versions of the system are available for testing. Second, the reliability of some components is so high that the cost of testing to measure the reliability in a statistically valid manner would be prohibitive. Usually, failure data from comparable systems are used in the early development phases of a new system and supplemented with test data when available.

5-1.2 Calculating Reliability.

If the time (t) over which a system must operate and the underlying distributions of failures for its constituent elements are known, then the system reliability can be calculated by taking the integral (essentially the area under the curve defined by the PDF) of the PDF from t to infinity, as shown in Equation 5-2.

Equation 5-2. Reliability

$$R(t) = \int_{t}^{\infty} f(t)\, dt$$

Where:
R(t) = reliability over time t
t = time (hours)
f(t) = probability density function
dt = downtime (hours)

5-1.2.1 Exponential Distribution.

If the underlying failure distribution is exponential, Equation 5-2 becomes Equation 5-3.

Equation 5-3. Exponential Distribution

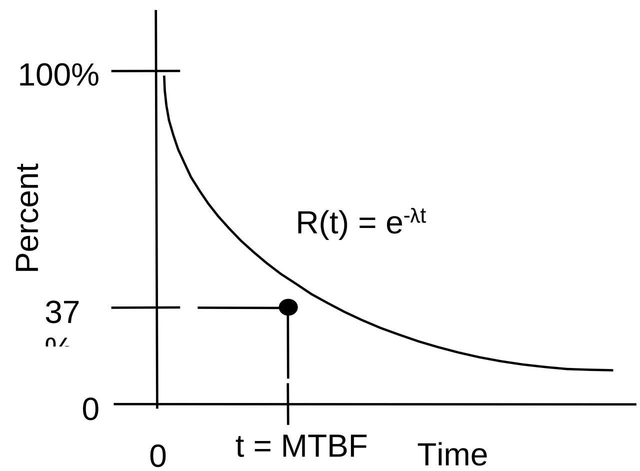
$$R(t) = e^{-\lambda t}$$

Where:
λ = the failure rate (inverse of MTBF)
t = the length of time the system must function
e = the base of natural logarithms
R(t) = reliability over time t

(1) Figure 5-2 shows the curve of Equation 5-3. The mean is not the "50-50" point, as was true for the normal distribution. Instead, it is approximately the 37-63 point. In other words, if the mean time between failures of a type of equipment is 100 hours, it is expected that only 37% (if t = MTBF = 1/λ, then $e^{-\lambda t} = e^{-1} = 0.367879$) of the population

of equipment to still be operating after 100 hours of operation. Put another way, when the time of operation equals the MTBF, the reliability is 37%.

Figure 5-2 Exponential Curve Relating Reliability and Time

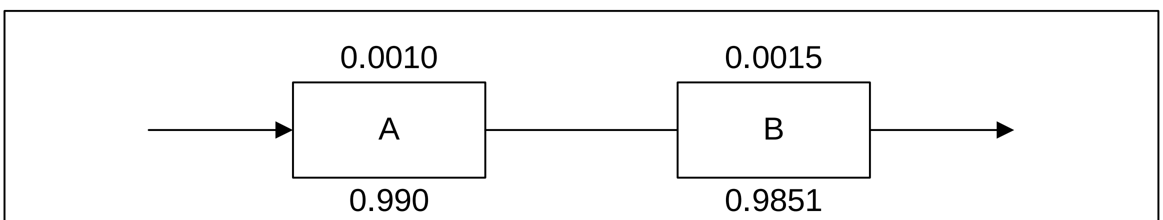


(2) If the underlying distribution for each element is exponential and the failure rates (λ_i) for each element are known, then the reliability of the system can be calculated using Equation 5-3.

5-1.2.2 Series Reliability.

Consider the system represented by the RBD in Figure 5-3.

Figure 5-3 Example RBD



1. The number above each block is the failure rate in failures per million hours.
   The inverse of the failure rate is the mean time to failure (exponential failure rate assumed).
2. The number below each block is the reliability calculated using equation 5-3 with t = 10 hours.

(1) Components A and B in Figure 5-3 are said to be in series, which means all must operate for the system to operate. Since the system can be no more reliable than the least reliable component, this configuration is often referred to as the weakest link configuration.

(2) Since the components are in series, the system reliability can be found by adding together the failure rates of the components and substituting the result as seen in

Equation 5-4. Furthermore, if the individual reliabilities are calculated (the bottom values,) the system reliability can be found by multiplying the reliabilities of the two components as shown in Equation 5-5.

Equation 5-4. System Reliability

$$R(t) = e^{-(\lambda_A+\lambda_B)t} = e^{-0.0025x10} = 0.9753$$

Where:
R(t) = system reliability
λ = the failure rate (inverse of MTBF)
t = the length of time the system must function
e = the base of natural logarithms

Equation 5-5. System Reliability

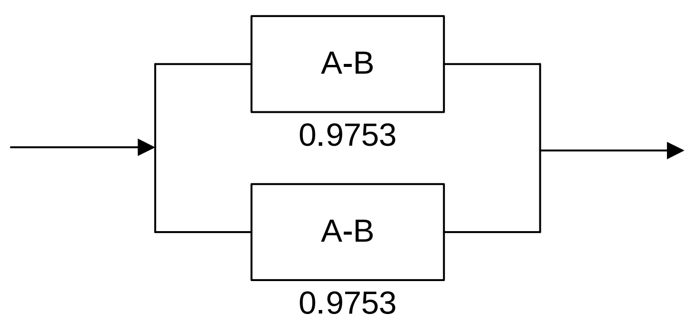
$$R(t) = R_A(t)\ x\ R_B(t) = 0.99000\ x\ 0.98510 = 0.9753$$

Where:
R(t) = system reliability
$R_A(t)$ = system A reliability
$R_B(t)$ = system B reliability

5-1.2.3 Reliability with Redundancy.

Now consider the RBD shown in Figure 5-4.

Figure 5-4 RBD of a System with Redundant Components



1. Each block represents the series configuration of components A and B.
2. The number below each block is the reliability calculated using equations 5-3 and 5-4 with t = 10 hours.

(1) The system represented by the RBD in Figure 5-4 has the same components (A and B in series denoted by one block labeled: A-B) used in Figure 5-3, but two of each component are used in a configuration referred to as redundant or parallel. Two paths of operation are possible. The paths are top A-B and bottom A-B. If either of two paths is intact, the system can operate. The reliability of the system is most easily calculated by

(Equation 5-6) finding the probability of failure (1 - R(t)) for each path, multiplying the probabilities of failure (which gives the probability of both paths failing), and then subtracting the result from 1. The reliability of each path was found in the previous example. Next, the probability of a path failing is found by subtracting its reliability from 1. Thus, the probability of either path failing is 1 - 0.9753 = 0.0247. The probability that both paths will fail is 0.0247 x 0.0247 = 0.0006. Finally, the reliability of the system is 1 - 0.0006 = 0.9994, about a 2.5% improvement over the series configured system.

Equation 5-6. System Reliability of Figure 5-4

$$R(t) = 1 - \left(1 - R_T(t)\right) x \left(1 - R_B(t)\right) = 1 - (0.0274\ x\ 0.0274) = 0.9994$$

Where:
R(t) = system reliability
R_T = the reliability of the top path
R_B = the reliability of the bottom path

(2) Two components in parallel may always be on and in operation (active redundancy) or one may be off (standby redundancy). In the latter case, failure of the primary component must be sensed to indicate that the standby module should be activated. Standby redundancy may be necessary to avoid interference between the redundant components. If the redundant component is normally off, reduces the time over which the redundant component will be used (it's only used from the time when the primary component fails). Of course, more than two components can be in parallel. Paragraph 5-2.4.1 discusses the various types of redundancy and how they can be used to improve the availability of current C5ISR facilities.

(3) Adding a component in parallel, such as, redundancy, improves the system's ability to perform its function. This aspect of reliability is called functional or mission reliability. Note, however, that in Figure 5-4 another set of components with its own failure rate has been added. To calculate the total failure rate for all components, they are add together. The result is 5000 failures per million operating hours (0.005000). The failure rate for the series-configured system in Figure 5-3 was 2500 failures per million operating hours. Although the functional reliability of the system improved, the total failure rate for all components increased. This perspective of reliability is called basic or logistics reliability. When standby redundancy is used, the sensing and switching components add to the total failure rate.

5-1.2.4 Logistics Reliability.

Whereas functional reliability only considers failures of the function(s), logistics reliability considers all failures because some maintenance action will be required. Logistics reliability can be considered as either the lack of demand placed on the logistics system by failures or the ability to operate without logistics. If standby redundancy is used with the redundant component not on, the apparent failure rate of the standby component will be less than that of its counterpart (it will likely operate less than ten hours), but the failure rate of the switching circuits must now be considered.

5-1.3 Calculating Availability.

For a system such as an electrical power system, availability is a key measure of performance. An electrical power facility must operate for very long periods of time, providing power to systems that perform critical functions, such as C5ISR. Even with the best technology and most robust design, it is economically impractical, if not technically impossible, to design power facilities that never fail over weeks or months of operation. Although forced outages are never welcome and power facilities are designed to minimize the number of forced outages, they still occur. When they do, restoring the system to operation as quickly and economically as possible is paramount. The maintainability characteristics of the system predict how quickly and economically system operation can be restored.

5-1.3.1 Reliability, Availability, and Maintenance.

Reliability and maintainability (R&M) are considered complementary characteristics. Looking at a graph of constant curves of inherent availability (A_i), one can see this complementary relationship. A_i is defined by Equation 5-7 and reflects the percent of time a system would be available if delays due to maintenance, supply, etc. are ignored.

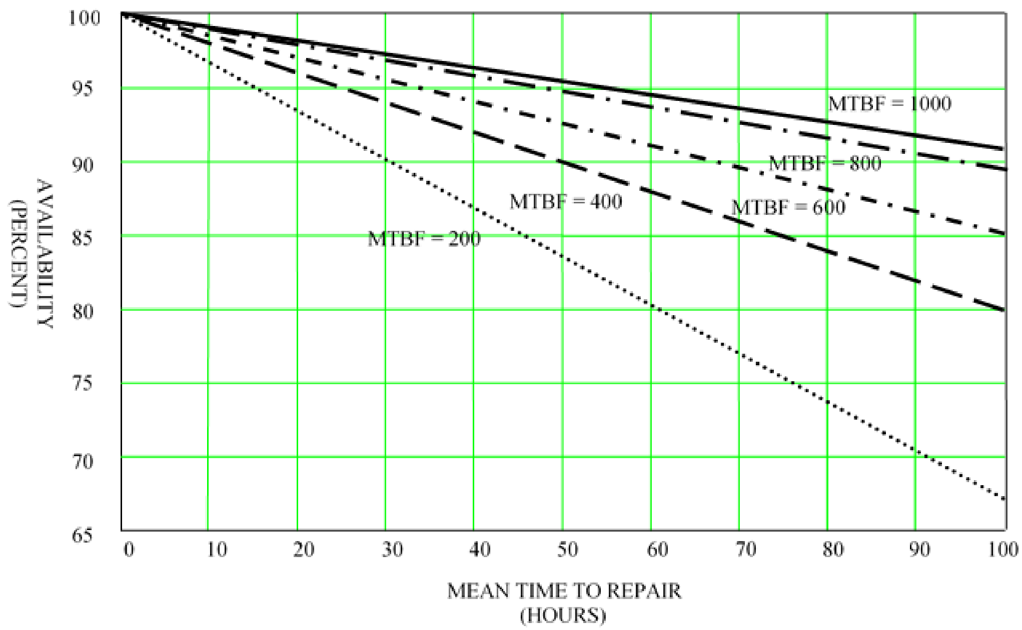
Equation 5-7. Inherent Availability

$$A_i = \frac{MTBF}{MTBF + MTTR} \; x \; 100\%$$

Where:
A_i = inherent availability
MTBF = mean time between failure
MTTR = mean time to repair

As seen in Equation 5-7, if the system never failed, the MTBF would be infinite, and A_i would be 100%. Or, if it took no time at all to repair the system, MTTR would be zero and again the availability would be 100%. Figure 5-5 is a graph showing availability as a function of reliability and maintainability (reliability is calculated using Equation 5-6). Note that the same availability with different values of R&M can be achieved. With higher reliability (MTBF), lower levels of maintainability are needed to achieve the same availability and vice versa. It is very common to limit MTBF, MTTR, or both. For example, the availability requirement might be 95% with an MTBF of at least 600 hours and a MTTR of no more than 3.5 hours.

Figure 5-5 Different Combinations of MTBF and MTTR Yield Same Availability



5-1.3.2 Other Measures of Availability

Availability is calculated through data collection by two primary methods:

(1) Operational availability includes maintenance and logistics delays and is defined using Equation 5-8:

Equation 5-8. Operational Availability

$$A_0 = \frac{MTBM}{MTBM + MDT}$$

Where:
A_o = operational availability
MTBM = mean time between all maintenance
MDT = mean downtime for each maintenance action

(2) Availability is also a function of raw uptime and downtime as seen in Equation 5-9:

Equation 5-9. Availability

$$A = \frac{Uptime}{Uptime + Downtime}$$

Where:
A = availability

where uptime is the time during which the system is available for use and downtime is the time during which the system is not available for use. Given that the sum of uptime and downtime is equal to the total system run time, this calculation is simply a ratio, indicating the percentage of the time that the system is up (or available).

(3) Note that A_o and A_i are probabilistic measures, while *A* is a deterministic measure. MTBF, MTBM, MTTR, and MDT are measures of reliability and maintainability (R&M). By designing for appropriate levels of R&M and ensuring statistically appropriate calculations, a high confidence in the availability can be obtained. However, that confidence can never be 100%. Measuring *A* is done by measuring the amount of uptime in a given total time and then calculating the observed availability using Equation 5-9. For this measure of availability, the time interval for the measurement is extremely important. Its importance can be understood by considering an availability requirement of 95% with a maximum downtime of ten hours. Table 5-2 shows the effect of varying intervals of time for measuring *A*.

Table 5-2 Effect of Measurement Interval on Observed Availability

Total Time	Actual Downtime	Actual Uptime	Measured Availability	Maximum Downtime to Meet Requirement (Using Equation 5-9)
1 hours	0.5 hours	0.5 hour	50%	0.05 hours (3 minutes)
8 hours	1 hour	7 hours	87.5%	0.4 (24 minutes)
24 hours	2 hours	22 hours	91.67%	1.2 hours
240 hours	10 hours	230 hours	95.83%	10 hours
7200 hours	10 hours	7190 hours	99.86%	10 hours

(a) Very short intervals make it increasingly difficult, if not impossible, to meet an availability requirement. It is very possible that a failure could occur in the first hour of operation. If that were the case, the system would pass the 95% availability test only if the repair could be made in 3 minutes or less. For many systems, it may be impossible to correct any failure in three minutes or less. So even if it is unlikely that a failure will occur in the first hour of operation (such as, the system is highly reliable), the probability of such a failure is not zero. If a failure occurs in the first hour and requires more than three minutes to repair, the system will have failed to meet an availability requirement of 95%. Yet, if the system is truly reliable, it may experience no more failures (and no more downtime) in the next 24 hours of operation, in which case the measured availability will be greater than the requirement.

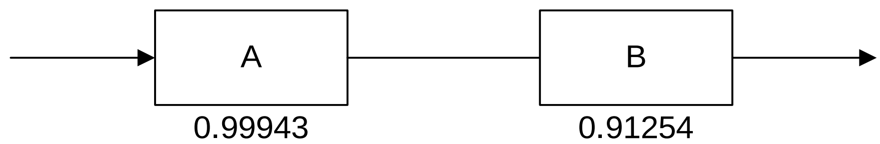
(b) Since A_o, A_i, and A are not measured in the same way, it is extremely important in contractual form to state clearly (for example, in a step-by-step, deductive manner) how availability will be measured during acceptance or qualification testing.

5-1.3.3 Calculating Simple System Availabilities.

Calculating simple system availability measures is similar to the reliability calculations in paragraphs 5.1-2.2 and 5.1-2.3.

(1) For series availability, consider the system represented by the block diagram in Figure 5-6.

Figure 5-6 Example Availability Block Diagram



1. The number below each block is availability of the component.

(a) Since the components are in series, the system availability can be found by multiplying the availabilities of the two components as shown in Equation 5-10.

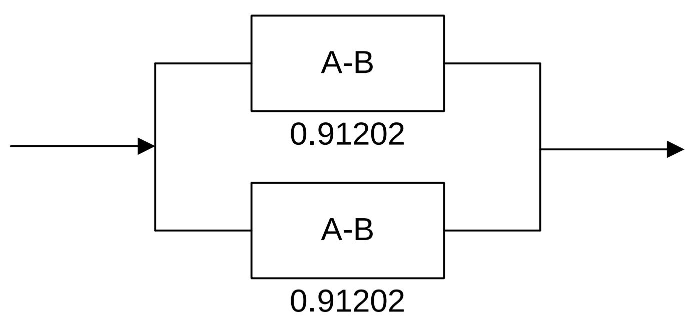
Equation 5-10. Series Availability

$$Series\ Availability = A_A\ x\ A_B = 0.99943\ x\ 0.91254 = 0.91202$$

Where:
A_A = component A availability
A_B = component B availability

(2) For parallel availability, consider the system represented by the block diagram in Figure 5-7.

Figure 5-7 Availability Block Diagram of a System with Redundant Components



1. The number below each block is the availability of the set of components.

(a) Since the components are parallel, the system availability can be found as shown in Equation 5-11.

Equation 5-11. Parallel Availability

$$\textit{Parallel Availability} = 1 - (1 - A_T)\ x\ (1 - A_B)$$

$$\textit{Parallel Availability} = 1 - (0.08798) \times (0.08798)$$

$$\textit{Parallel Availability} = 0.99226$$

Where:
A_T = *the availability of the top path*
A_B = *the availability of the bottom path*

5-1.4 Predictions and Assessments.

Predictions and assessments refer to the process of evaluating the RAM calculations, system weaknesses, and areas offering opportunities for improvement. Quantitative numbers are a usual byproduct of a prediction or assessment. Such numbers are necessary for calculating spares requirements, probability of success, and other purposes.

5-1.4.1 Reliability Predictions.

In a new development program, reliability predictions are a means of determining the feasibility of requirements, assessing progress toward achieving those requirements, and comparing the reliability impact of design alternatives. Predictions can be made through any appropriate combination of reliability models, historical data, test data, and engineering judgment. The choice of which prediction method to use depends on the availability of information. That choice can also be a function of the point of the system life cycle at which the prediction is performed. Considerations in performing predictions include that correct environmental stresses are used, the reliability model is correct, the correct part qualities are assumed, and that all operational and dormancy modes are reflected.

5-1.4.2 Reliability Assessments.

Predictions are one method of assessing the reliability of an item. At the onset of a new development program, the prediction is usually purely analytical. As the program progresses, other methods become available to improve or augment the analytical prediction. These methods include testing, design reviews, and others. For existing systems, reliability assessments include analyzing field data to determine the level of reliability being achieved and identify weaknesses in the design and opportunities for improvement.

5-1.4.2.1 Common Techniques.

Table 5-3 lists some common techniques that can be used for assessing reliability and guidance for their use. Some of these methods provide a numerical value that is representative of the system reliability at a point in time; all provide a valuable means of better understanding the design's strengths and weaknesses so that it can be changed accordingly.

5-1.4.2.2 Assessment Methods.

The assessment methods chosen should be appropriate for the system and require only a reasonable level of investment given the value of the results. The failure of some components, for example, may have little impact on either system function, or on its operating and repair costs. A relatively costly analysis may not be justified. For other systems, a thermal analysis may not be needed, given the nature of the system and its operating environment. When the consequences of failure are catastrophic, every possible effort should be made to make the system fail-safe or fault tolerant.

Table 5-3 Methods for Assessing Reliability

Method	Application
Accelerated Life Testing	Effective on parts, components, or assemblies to identify failure mechanisms and life limiting critical components.
Critical Item Control	Apply when safety margins, process procedures and new technology present risk to the production of the system.
Design of Experiments (DOE)	Use when process physical properties are known, and parameter interactions are understood. Usually done in early design phases, it can assess the progress made in improving system or process reliability.
Design Reviews	Continuing evaluation process to ensure details are not overlooked. Should include hardware and software.
Dormancy Analysis	Use for products that have “extended” periods of non-operating time or unusual non-operating environmental conditions or high cycle on and off periods.
Durability Analysis	Use to determine cycles to failure or determine wear out characteristics. Especially important for mechanical products.
Failure Modes, Effects and Criticality Analysis (FMECA)	Applicable to equipment performing critical functions (for example control systems) when the need-to-know consequences of lower-level failures is important
Failure Reporting Analysis and Corrective Action (FRACAS)	Use when iterative tests or demonstrations are conducted on breadboard, or prototype products to identify mechanisms and trends for corrective action. Use for existing systems to monitor performance.
Failure Tree Analysis (FTA)	Use for complex systems evaluations of safety and system reliability. Apply when the need to know what caused a hypothesized catastrophic event is important.
Finite Element Analysis (FEA)	Use for designs that are unproven with little prior experience/test data, use advanced/unique packaging/design concepts, or will encounter severe environmental loads.
Life Cycle Planning	Use if life limiting materials, parts or components are identified and not controlled.
Parts Obsolescence	Use to determine need for and risks of application of specific parts and lifetime buys.
Prediction	Use as a general means to develop goals, choose design approaches, select components, and evaluate stresses. Equally useful when redesigning or adding redundancy to an existing system.
Reliability Growth Test (RGT)/Test Analyze and Fix (TAAF)	Use when technology or risk of failure is critical to the success of the system. These tests are costly in comparison to alternative analytical techniques.

Sneak Circuit Analysis (SCA)	Apply to operating and safety critical functions. Important for space systems and others of extreme complexity. May be costly to apply.
Supplier Control	Apply when high volume or new technologies for parts, materials or components are expected.
Test Strategy	Use when critical technologies result in high risk of failure
Thermal Analysis (TA)	Use for products with high power dissipation, or thermally sensitive aspects of design. Typical for modern electronics, especially of densely packages products.
Worst Case Circuit Analysis (WCCA)	Use when the need exists to determine critical component parameters variation and environmental effects on circuit performance.

5-2 IMPROVING AVAILABILITY.

5-2.1 Overview of the Process.

Facility managers are faced with the responsibility of providing the proper utilities (electrical, chilled water, steam, etc.) at the needed levels (power levels, voltage, pressure, etc.) to their customers when needed to support an end mission. The steps for improving the availability of new facilities in design and facilities already in use are shown in Table 5-4. The steps for each situation will be discussed in this chapter. \1\ See UFC 4-141-03 for specific design requirements. /1/

Table 5-4 The Process for Improving Facility Availability

New Facilities Being Designed	Facilities Already in Use
1. Determine system availability requirements 2. Derive reliability and maintainability requirements from availability requirement 3. Develop one-line diagrams 4. Conduct analyses to predict availability, reliability, and maintainability and to determine weaknesses in design based on failure criteria and cost/benefit analysis 5. Conduct testing to validate analytical results 6. Update assessment of availability, reliability, and maintainability based on test results 7. Revise design as necessary based on test results 8. Construct facility and continuously assess performance and identify opportunities for improvement 9. Continuously assess performance and identify opportunities for improvement	1. Determine system availability requirements 2. Derive reliability and maintainability requirements from availability requirement 3. Develop one-line diagrams 4. Collect data for availability assessment 5. Assess availability, reliability, maintainability, and logistics performance being achieved for each system (this establishes the baseline performance) 6. Identify shortfalls (differences between required level of performance and baseline performance) 7. Perform cost-benefit analysis to prioritize improvement efforts 8. Design and develop system changes 9. Assess improvement in availability, reliability, and maintainability based on analyses and test 10. Implement design changes 11. Continuously assess performance and identify opportunities for improvement

5-2.2 New Facilities

Since reliability and maintainability, and hence availability, are predominantly affected by design, it is essential that these system characteristics be addressed in the design of a new system. It is during design, that these characteristics can be most effectively and positively influenced at the least cost.

5-2.2.1 Determine System Availability Requirements.

Establishing clear, comprehensive, and measurable requirements is the first and most important step in designing and developing systems. The design requirements must allow the user needs to be met. User needs are often stated in non-design terms. For facilities, these might include operational availability, readiness, mean time between maintenance (where maintenance includes all maintenance actions, including those to repair operator-induced failures), and total downtime (including the time to order and ship parts if necessary). Designers must have requirements that they can control. For a facility, these may include inherent availability, mean time between design failures, and mean time to repair (includes only the actual "hands on" time to make a repair). The facility availability requirement should be included in the specifications for a new facility.

5-2.2.2 Derive Reliability and Maintainability Requirements from Availability Requirement.

Based on the user need (for example, operational availability), the reliability and maintainability design requirements (for example, mean time between failure and mean time to repair) must be derived. This derivation of lower-level requirements is usually done by the design organization and continues throughout the development effort until design requirements are available at the lowest level of indenture (subsystem, assembly, subassembly, part) that makes sense.

5-2.2.3 Develop One-line Diagrams.

One-line diagrams will be instrumental in the creation of all models concerning RAM criteria and analysis. It is critical that diagrams are accurate and up to date. Paragraph 5.3-5 of this UFC demonstrates how one-line diagrams are used in modeling and calculation.

5-2.2.4 Conduct Analyses.

Conduct analyses to predict availability, reliability, and maintainability and to determine weaknesses in design and redesign based on failure criteria and cost/benefit analysis. Some of the pertinent analyses are summarized in Table 5-5.

5-2.2.5 Conduct Testing to Validate Analytical Results.

No matter how diligently the models are developed, and the analytical tools are used, all variations and factors cannot be accounted for. By testing a given design, unexpected problems will be uncovered. These problems can include new types of failures, more frequent than expected failures, different effects of failures, and so forth. Problems discovered during test provide opportunities for improving the design and models and tools.

5-2.2.6 Update Assessment of Availability, Reliability, and Maintainability Based on Results.

Based on the results of testing, the analytical assessments of reliability made earlier should be updated. Adding the results of testing provides higher confidence in the assessment than is possible using analytical results alone.

Table 5-5 Analyses Helpful in Designing for Reliability

Analysis	Purpose	Applications	When to Perform
FEA	• Computer simulation technique for predicting material response or behavior of modeled device • Determine material stresses and temperature • Determine thermal and dynamic loading	• Use for devices that: - Are unproven with little prior experience/data - Use advanced/unique packaging/design concepts - Will encounter severe environmental loads - Have critical thermal/mechanical constraints	• In design phase when candidate devices can be selected using selection criteria
TA	• Calculate junction temperatures • Calculate thermal gradients • Calculate operating temperatures	• For integrated circuits • For electronics and electrical devices	• During circuit design • Prior to design of cooling systems
Dormancy Analysis	• Calculate failure rates of devices in dormancy or storage	• Use for devices identified to have periods of dormancy	• During design
FTA	• Top-down approach to identify effects of faults on system safety or reliability • Address multiple failure	• Can be applied when FMECA too expensive • To address effects of multiple failures	• Early in design phase, in lieu of FMECA
FMECA	• Bottom-up approach to identify single failure points and their effects • To assist in the efficient design of BIT and FIT • To establish and rank critical failures • To identify interface problems	• More beneficial if performed on newly designed equipment • More applicable to equipment performing critical functions (for example, control systems)	• Early in design phase
SCA	• To identify failures not caused by part failures • To reveal unexpected logic flows that can produce undesired results • To expose design oversights that create conditions of undesired operation	• Mission and safety critical functions • Hardware with numerous interfaces • Systems with high testing complexities • Use selectively due to high testing complexities	• Later in design stage but prior to CDR
WCCA	• To evaluate circuits for tolerance to “drift” • When time dependency is involved • To evaluate the simultaneous existence of all unfavorable tolerances • Single failures	• Assesses combined effect of parts parameters variation and environmental effects on circuit performance • Not often applied • Use selectively	• Later design stage as required

LEGEND: Finite Element Analysis (FEA); Thermal Analysis; Fault Tree Analysis (FTA); Failure Modes, Effects and Criticality Analysis (FMECA); Sneak Circuit Analysis (SCA); Worst Case Circuit Analysis (WCCA); Build-in-Test (BIT); Framework for Integrated Test (FIT); Critical Design Review (CDR)

5-2.2.7 Revise Design as Necessary Based on Test Results.

If the updated assessment indicates the design is falling short of the RAM requirements, the design must be revised to improve the reliability. Even when the updated assessment indicates the design is close to meeting the requirements, design changes should be considered referencing cost-benefit considerations.

5-2.2.8 Construct Facility and Continuously Assess Performance and Identify Opportunities for Improvement.

Once the RAM requirements are satisfied by the facility design, the facility is constructed. The inherent levels of reliability must be sustained over time. To that end, data needs to be collected continuously to assess the availability performance of the facility. This operational, field data should be archived for use in designing new facilities.

5-2.3 Existing Facilities.

For facilities in use, the process for improving availability is somewhat different than that discussed for new systems. It is different for two major reasons. First, improvements must be made by modifying an existing design, which is usually more difficult than creating the original design. Second, the improvements must be made with as little disruption to the facility as possible since it is supporting an ongoing mission. Although design changes are usually the primary focus of improvement efforts, changes in procedures or policy should also be considered. Not only are such changes usually much easier and economical to make, but they may also be more effective in increasing availability.

5-2.3.1 Determine System Availability Requirements.

As was the case for a new system, the requirements must be known. For existing facilities, it may be difficult to find the original user needs or design requirements. Even when the original requirements can be determined, the current requirements may have changed due to mission changes, budget constraints, or other factors.

5-2.3.2 Derive Reliability and Maintainability Requirements from the Availability Requirement.

After the system availability requirements are determined, it is necessary to translate them into reliability and maintainability requirements.

5-2.3.3 Develop One-line Diagrams.

This step can be bypassed if original one-lines are still current.

5-2.3.4 Collect Data for Availability Assessment.

Ideally, a data collection system was implemented when the facility was first put into operation. If that is not the case, one should be developed and implemented. The data to be collected includes the category of failures, causes of failures, date and time when failures occur, mechanisms affected, and so on. A substantial byproduct of an RCM program is the generation of such unique, facility data.

5-2.3.5 Assess Performance.

Assess the availability, reliability, maintainability, and logistics performance being achieved for each system. Performing this step establishes the baseline performance for the facility.

5-2.3.6 Identify Shortfalls.

Shortfalls are the differences between the required level of performance and baseline performance.

5-2.3.7 Performance Cost-Benefit Analysis to Prioritize Improvement Efforts.

Many potential improvements will be identified throughout the life of a facility. Those that are safety-related or are essential for mission success will always be given the highest priority. Others will be prioritized based on the costs to implement compared with the projected benefits. Those that have only a small return for the investment will be given the lowest priority.

5-2.3.8 Design and Develop System Changes.

The process for improving the availability, reliability, and maintainability performance of an existing facility is essentially the same as for designing new facility.

5-2.3.9 Assess Improvement.

Assess improvement in reliability, availability, and maintainability based on analyses and tests. Before implementing any potential improvements, some effort must be made to ensure that the design changes must be validated. All too often, a change that was intended to improve the situation makes it worse. Through careful analyses and appropriate testing, one can determine that the proposed change results in some level of improvement.

5-2.3.10 Implement Design Changes.

Those design changes that are validated as improving availability must be implemented in a way that minimizes the downtime of the facility. Perhaps they can be made during scheduled maintenance periods. Or perhaps there are times of the day, month, or year when downtime is less critical to the mission than at other times. Careful planning can minimize the impact on the mission. Also, the procedures, tools, training, and materials needed for the design change must be in place and validated prior to starting the facility modification.

5-2.3.11 Monitor Performance.

Continuously assess performance and identify opportunities for improvement. Continuous improvement should be the goal of every facility manager. As the facility ages, the cost-benefits of what were low-priority improvements may change, new problems may be introduced, and new mission requirements may arise. By collecting data and maintaining a baseline of the facility availability performance, the facility manager will be able to make future improvements as they become necessary or economical.

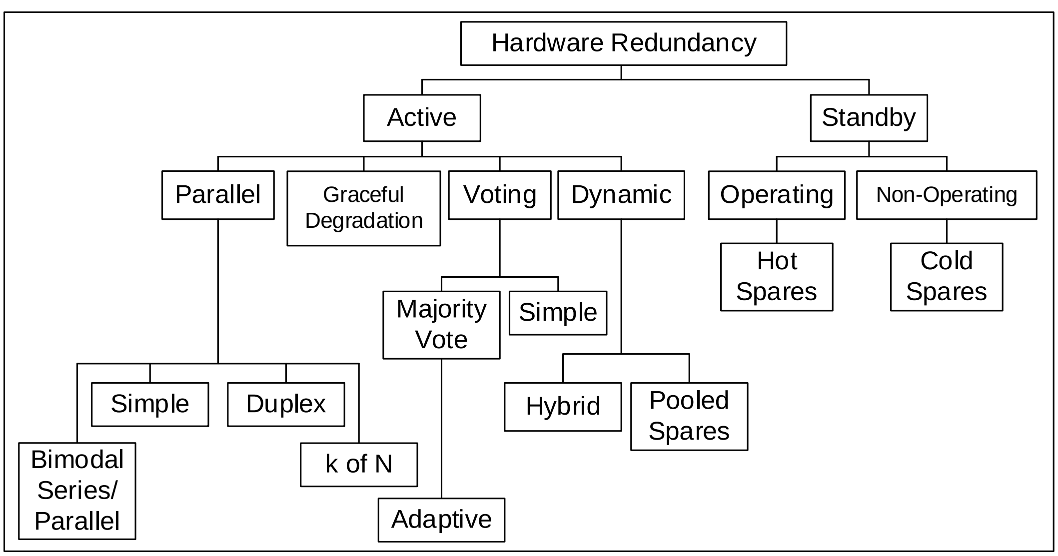
5-2.4 Improving Availability Through Addition of Redundancy.

Redundancy is a technique for increasing system reliability and availability by making the system immune to the failure of a single component. It is a form of fault tolerance – the system can tolerate one or more component failures and still perform its function(s).

5-2.4.1 Types of Redundancy.

There are essentially two kinds of redundancy techniques employed in fault tolerant designs, space redundancy and time redundancy. Space redundancy provides separate physical copies of a resource, function, or data item. Time redundancy, used primarily in digital systems, involves the process of storing information to handle transients, or encoding information that is shifted in time to check for unwanted changes. Space, or hardware, redundancy is the approach most commonly associated with fault tolerant design. Figure 5-8 provides a simplified tree-structure showing the various types of hardware redundancy that have been used or considered in the past.

Figure 5-8 Types of Redundancy



5-2.4.2 Impact on Testability.

Many of today's more sophisticated systems not only require an ability to detect faults but also to diagnose or isolate them. It may even be desirable for a system to have the ability to reconfigure itself to avoid system failure. Automated fault detection and isolation has therefore become an essential means of obtaining highly fault tolerant systems. Because of this, the design of the diagnostic system, including any built-in-test (BIT) features and the overall testability of the design are important tradeoffs that need to be made as part of the fault tolerant design process. Table 5-6 presents a sample list of hardware fault tolerant design approaches, and their impact on diagnostic approaches and BIT.

(1) No matter which technique is chosen to implement fault tolerance in a design, the ability to achieve fault tolerance is becoming increasingly dependent on the ability to detect, and isolate malfunctions as they occur or are anticipated to occur. Alternate maintainability diagnostic concepts must be carefully reviewed for effectiveness before committing to a final design approach. BIT design has become very important to achieving a fault tolerant system. When using BIT in fault tolerant system design, the BIT system must do the following:

(a) Maintain real-time status of the system's assets (on-line and off-line, or standby, equipment).

(b) Provide the operator with the status of available system assets.

(c) Maintain a record of hardware faults for post-mission evaluation and corrective maintenance.

(2) The essence of fault tolerance is that the system is able to perform its mission despite experiencing some failures. In systems where redundancy is used, this fault tolerance is achieved by one or more redundant units taking over the function previously being performed by another unit. When standby redundancy is used, the failed unit must be detected and the standby unit "brought online." In still other cases principally involving electronics, failures can be repaired by rerouting signals or functions to other units. These repairs can be done upon a failure or in anticipation of a failure. In such cases, the BIT should, in addition to the actions identified in paragraph 5-2.4.2; maintain a record of any reconfiguration events that were required for system recovery during the mission.

(3) For fault tolerant systems, it is important that the design's inherent testability provisions include the ability to detect, identify, recover, and if possible, reconfigure, and report equipment malfunctions to operational personnel. The RBDs for fault tolerant systems are complex, with non-serial connections. Fault tolerant systems often have a multitude of backups with non-zero switch-over time and imperfect fault detection, isolation, and recovery. Therefore, it is imperative that effective testability provisions be incorporated in the system design concept. If they are not, the fielded design will exhibit long troubleshooting times, high false alarm rates, and low levels of system readiness.

Table 5-6 Diagnostic Implications of Fault Tolerant Design Approaches

Fault Tolerant Design Technique	Description	Diagnostic Design Implications	BIT Implications
Active Redundancy simple parallel	All parallel units are on whenever the system is operating. K of the N units are needed, where 0<k<N. External components are not required to perform the function of detection, decision and switching when an element or path in the structure fails. Since the redundant units are always operating, they automatically pick up the load of the failed unit. An example is a multi-engine aircraft. The aircraft can continue to fly with one or more of engines out of operations	Hardware/Software is more readily available to perform multiple functions.	N/A
Active Redundancy with voting logic	Same as Active Redundancy but where a majority of units must agree (for example, when multiple computers are used)	Performance/status-monitoring function assures the operator that the equipment is working properly: failure is easily isolated to the locked-out branch by the voting logic	N/A
Stand-by redundancy (Non-operating)	The redundant units aren't operating and must be started if a failure is detected in the active unit (for example a spare radio is turned on when the primary radio fails.)	Test capability and diagnostic functions must be designed into each redundant or substitute functional path (on-line AND off-line) to determine their status.	Passive, periodic, or manually initiated BIT
Stand-by redundancy (Operating)	The redundant units are operating but not active in system operation; must be switched "in" if a failure is detected in the active unit (for example a redundant radar transmitter feeding a dummy load is switched into the antenna when the main transmitter fails)	N/A	Limited to passive BIT (such as, continuous monitoring) supplemented with periodic BIT

5-2.4.3 Role of RAM Concepts in the Fault Tolerant Design Process.

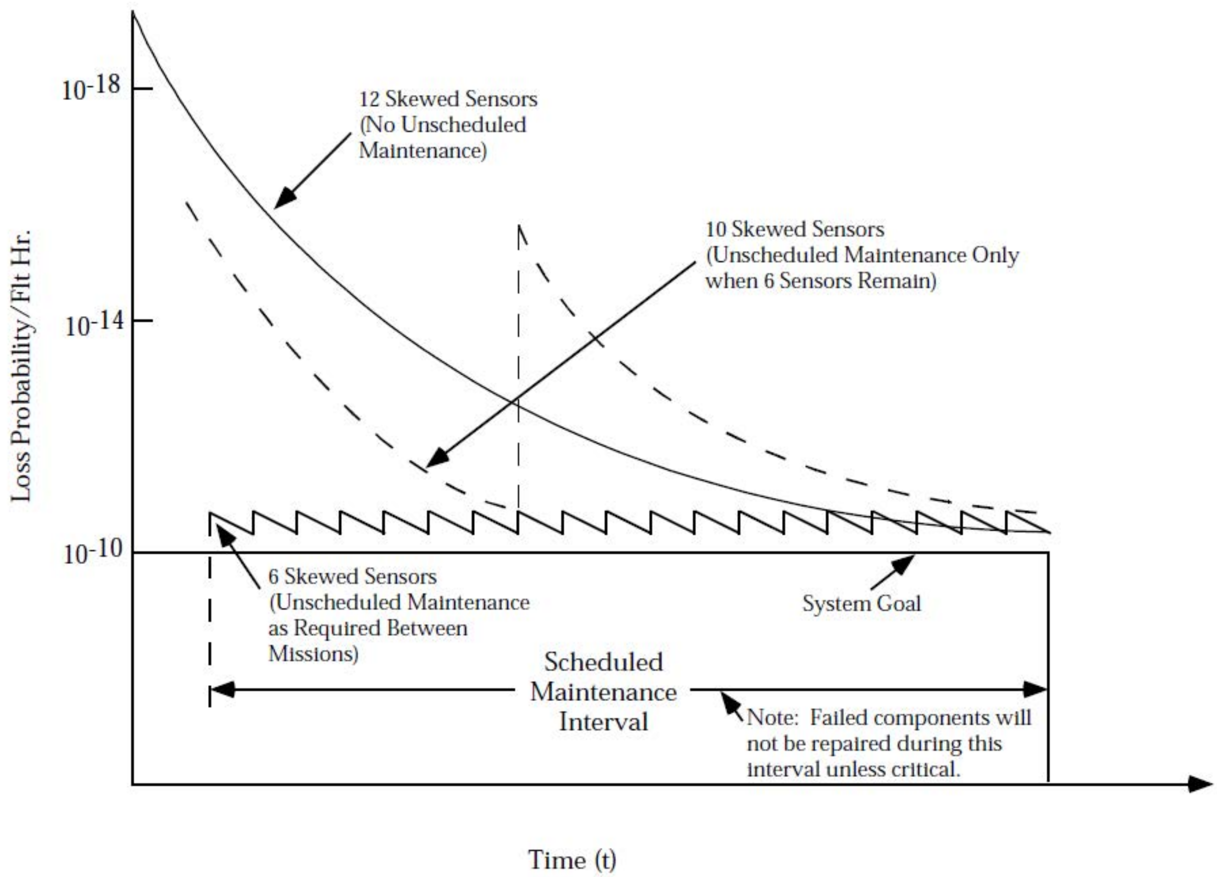
The role of the reliability engineer in regard to fault tolerant design requirements is to ensure that system RAM requirements are achievable for each of the fault tolerant design approaches being considered. Furthermore, to properly design a fault tolerant system, including a diagnostic scheme, the designer needs to understand the modes in which the system can fail, and the effects of those failure modes. This requires that a failure mode and effects analysis (FMEA) be performed, as a minimum. The FMEA will identify which faults can lead to system failure and therefore must be detected, isolated, and removed to maintain system integrity. In general, the reliability design manager must ask a series of questions, as listed below. Additionally, the RCM process helps to direct RAM concepts throughout the facility life cycle. The applicability of that process is further described in Chapter 7.

1. How do the system fault tolerance requirements impact the overall reliability, maintainability, and availability requirements?
2. Where should fault tolerant design methods be applied?
    - Which functions involve the most risk to mission success?
    - What is the effect of the operating environment?
    - What maintenance strategy/policy needs to be considered?
3. What is the effect of maintainability and testability?
4. What are the constraints that affect fault tolerance?
    - Cost
    - Size & Weight
    - Power
    - Interface Complexity
    - Diagnostic Uncertainties

5-2.4.4 Fault Tolerance and Tradeoffs.

The designer needs to consider each of the questions, listed above, and others as part of the overall fault tolerant design process. Other reliability tradeoffs to be considered involve analysis of the redundancy approaches being considered for the fault tolerant design. In addition to reliability concerns, fault tolerance also requires analysis of the impacts on maintainability and testability. As an example, consider Figure 5-9. This figure illustrates a design vs. corrective maintenance tradeoff analysis performed early in the product development phase. In particular, the figure shows the tradeoff of restoration frequency versus the number of sensors being used to meet requirements. This program requires a time period for allocating a scheduled maintenance activity and a probability of less than one in 10 billion per flight hour that a total loss of the skewed sensor function would occur. The tradeoff is made between the number of sensors and the cost of unscheduled maintenance activity associated with each approach. Other tradeoffs, such as cost, power, weight, etc. are also necessary. In general, as in any design analysis support function, an analysis of the impacts on reliability, availability, and maintainability (including support for system testing) of a chosen fault tolerant design approach must be performed.

Figure 5-9 Effect of Maintenance Concept on Level of Fault Tolerance



Note: More Frequent Restoration of Redundancy Lowers Fault Tolerance Requirements, But Results in Higher Maintenance Manhours

5-2.4.5 General Rules in Applying Redundancy.

In applying redundancy to a C5ISR facility, the following general rules should be followed:

5-2.4.5.1 Rule 1.

Determine the weak links in the system to know where to add redundancy. These weak links may be portions of the system prone to single point failures or, where redundancy is already used, the reliability is still too low to meet availability requirements.

(a) As an example of applying Rule 1, consider the simple system shown in Figure 5-10.

This system has five subsystems (lettered) with seven major components (numbered). The MTBF and MTTR for each component are shown. Using these figures, the overall system availability can be calculated using Monte Carlo simulation (see paragraph 5-3 for methods of calculating complicated system availability models). The results of a Monte Carlo simulation of the system yielded the results shown in Table 5-7. The areas of weakness from an availability perspective can be determined from simply looking at the relative contribution to system unreliability as summarized in Table 5-8 (also resultants from a Monte Carlo simulation). Note that subsystem C is the weakest link, even though it is not subject to a single point failure. Subsystem D is the next weakest link; it is subject to a single point failure. It may have been obvious that D, representing a potential single point failure, is a weak link. It may not have been as obvious that C, even though it already incorporates redundancy, is a weak point. Looking at the relative availability of component 3, we see that it is much less reliable than the other components. Even dual redundancy is insufficient to compensate for the low MTBF. As this example shows, although it may be tempting to always add redundancy to those portions of a system subject to single point failures, it is sometimes more effective to add it elsewhere.

Figure 5-10 Analyzing the Contribution to System Reliability Helps Determine Where Redundancy is Needed

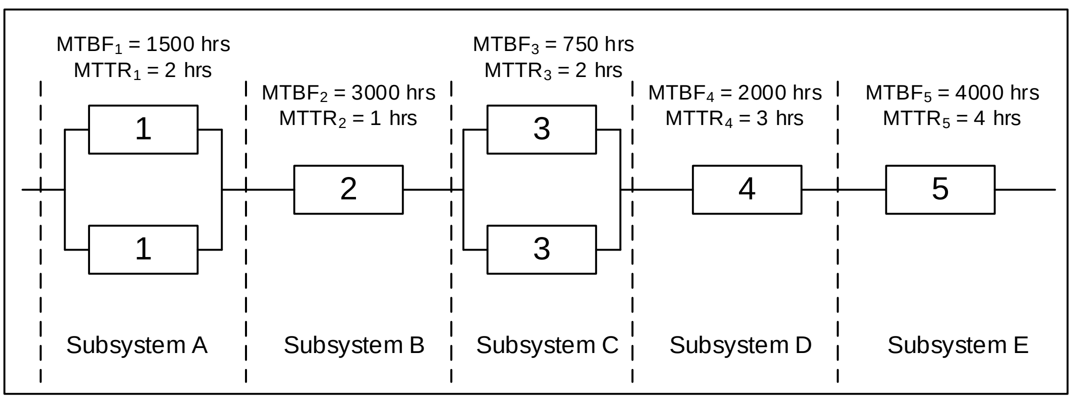


Table 5-7 Availability of System Depicted in Figure 5-10

MTBM	Mean System Failures	MTTR	Availability %
258.77	1.0658	2.5695	99.7236

Notes:

1. For ease of calculation, the times to failure and the times to repair were assumed to be distributed exponentially.
2. 10,000 simulation trials were run using an operating time of 1,000 hours.

Table 5-8 Relative Unreliability of Subsystems (Repairs Ignored)

Subsystem	Reliability in 1000 hours	Expected Failures per 1000 Hours	% Contribution to System Unreliability	Contribution to System Unreliability Ranking
A	0.7632	0.2368	14.12	4
B	0.7165	0.2835	16.90	3
C	0.4577	0.5423	32.33	1
D	0.6065	0.3935	23.46	2
E	0.7788	0.2212	13.19	5
SYSTEM	0.1182	1.6773	-	-

5-2.4.5.2 Rule 2.

Add redundancy in a way that avoids undesirable interactions. Rule 2 implies that some components cannot be used in some forms of redundancy, depending on the failure modes, application, and other factors. The type of redundancy shown in Figure 5-10 is active redundancy, in which all components are on all the time that the system is operating. In some cases, such a redundant configuration would result in undesired interactions or interference among the redundant units. As will be seen later in this chapter, certain forms of redundancy are preferable to others in a given application.

5-2.4.5.3 Rule 3.

Adding redundancy increases support requirements and costs. Rule 3 refers to the added costs incurred with redundancy. The most obvious increase is because more components must be purchased and installed. An additional cost comes from an increase in the total failures within the system. The increase in complexity results in an increase in unscheduled maintenance. If nothing is done to improve the reliability of the individual components in a system, but additional components are added to provide redundancy, the total failure rate of the components will increase. System reliability will improve but more component failures will occur. These failures will increase support requirements and costs. Redundancy also increases weight, space requirements, complexity, and time to design. Thus, safety and mission reliability are gained at the expense of adding an item(s) in the unscheduled maintenance chain.

(a) The decision to use redundant design techniques must be based on analysis of the tradeoffs involved. Redundancy may prove to be the only available method, when other techniques of improving reliability (for example, derating, simplification, better components) have been exhausted, or when methods of item improvement are shown to be more costly than duplications.

(b) When preventive maintenance is planned, the use of redundant equipment can allow for repair with no system downtime. Occasionally, situations exist in which equipment cannot be maintained. In these cases, redundant elements may be the best way to significantly prolong operating time.

5-2.4.5.4 Rule 4.

Ensure that any one redundant unit can be maintained without shutting down the other redundant units. Assume that two generators, for example, are sharing a load. If one fails and the operators must shut the other generator down to either gain access to or repair the failed generator, then there is no effective redundancy. An implicit assumption in using redundancy is that availability increases because a failed component can be repaired while the remaining redundant components continue to operate. If this assumption is violated, redundancy will not increase availability.

5-2.4.6 Design Considerations.

The FMEA is a primary reliability analysis, critical to the fault tolerant design process. The reliability engineer will use additional techniques as well for analyzing a fault tolerant design to verify that it meets reliability requirements. However, many of the evaluation tools used in the past are no longer adequate to deal with more sophisticated fault tolerant designs that include more complex fault handling capabilities. Because fault handling methods include the use of fault detection and fault recovery approaches, any evaluation tool must include the ability to properly account for the effects of imperfect fault detection and fault recovery.

5-2.4.6.1 Monte Carlo Simulation and Markov Techniques.

Monte Carlo simulation and Markov techniques continue to be used as the primary means of analyzing highly sophisticated fault tolerant designs. These approaches have been modified to incorporate situations where the sequence of failure is important, where the failure is transient or intermittent, or where the response to failure (such as, detection, isolation, recovery, and reconfiguration) is imperfect. In these situations, Markov methods continue to lead the way in evaluation methods. In general, the Markov approach, which is used to define the specific states that a system can occupy, has been used to incorporate fault handling and recovery. A major limitation to the Markov approach is that the number of system states that must be defined to comprehensively describe a large system and model the behavior of complex fault management schemes can become very large (approaching 105 system states for highly complex systems). A common solution to this problem is to partition the system into smaller systems, evaluate each partition separately, and then combine the results at the system level. However, such an approach is only exact when each partitioned subsystem's fault tolerant behavior is mutually independent of each other. If subsystem dependencies do exist, then an assumption of independence will result in only an approximate solution.

5-2.4.6.2 Other Approaches.

Other approaches that are now becoming more common involve decomposing the system into separate fault-occurrence and fault handling submodels. However, the inputs for this type of approach require knowledge of the distribution and parameter values of detection, isolation, recovery, rates, etc. The following is a list of assumptions, limitations and sources of error found in existing reliability models:

(a) Solving a fault-handling model in isolation and then reflecting its results in an aggregate model is, itself, an approximation technique. The assumptions necessary to determine a solution typically result in a lower bound (conservative) approximation of the system reliability.

(b) Separate fault-handling models have been assumed to be independent of system state. This requires that the same fault-handling model and choice of parameters be used irrespective of the system's level of degradation. This ignores the fact that for many systems the recovery process is faster if the number of active units is smaller or that the recovery process may be different, depending on the sequence of events in different subsystems.

(c) The common technique of partitioning the system into independent functional subgroups for computational ease is a potential source of error. The magnitude and direction of the error is a function of how truly independent/dependent the subgroups are of each other. If subgroups are assumed independent when in fact they are not, the effect is an overstatement of system reliability/availability. If subgroups are assumed completely dependent when some degree of independence exists, the effect is an understatement of the system's RAM capabilities.

(d) Some models assume a constant instantaneous fault-protection coverage factor in lieu of a separate fault handling model. These fail to recognize that during time spent in the intermediate fault-handling states to detect, isolate, and recover/reconfigure, a second item failure could result in system failure. Further, as with fault handling models, these times are generally not constant, but depend on the current state of the system.

(e) Most models require the assumption that the system is perfect at the mission start. Therefore, they cannot evaluate the effects of latent defects (for example, handling, manufacturing, transportation, and prior mission), nor assist in determining the testability payoff or requirements for detection and removing them before the start of the mission. Models with this limitation cannot be used to evaluate alternate maintenance concepts that include degradation between missions as an acceptable strategy.

(f) Some models require that spares be treated exactly like active units, irrespective of their actual utilization in the system mechanization. This requires that spares are assumed to be "hot" and have the same failure rates and failure modes as the active units. This assumption will cause the model to understate the system reliability in those situations where spares are "cold" or in "stand-by" and/or where their failure rates may be less that those of the active units.

(g) As indicated previously, some models require the assumption that item failure rates are constant throughout time. This will result in an overstatement of system reliability if the items have failure rates that increase with mission time. Some models remove this restriction and permit time-varying failure rates. However, the solution algorithms employed require the use of global time (as opposed to local time of entry into a state), thus precluding the use of the model for repairable systems and availability analysis.

5-3 ASSESSING RELIABILITY AND AVAILABILITY.

5-3.1 Purpose of the Assessment.

As systems become more and more complex, good methods for specifying and analyzing the systems and their sub-systems become more important. Reliability modeling (including prediction, evaluation, and control) is vital for proper design, dependable operation, and effective maintenance of systems. The popularity of designing redundancy into systems poses additional challenges to reliability professionals. For the various kinds of redundant systems, the reliability and availability are extremely sensitive to even small variations in certain parameters; thus, precise understanding and insight can be gained only by modeling.

The need to assess the reliability, availability, and maintainability of a system is becoming more important as organizations understand the potential effects of failures and downtime for the systems. Regardless of what mission is being served, or who the intended customer may be, it should be a reasonable assumption to state that the degree of product/service success is directly related to the ability of that product/service to meet or exceed customer expectations.

The eight-step process shown below should be adhered to during a reliability study. Validation is essential throughout the eight-step process.

1. **Problem Definition**: define problem and its objectives.
2. **Model Building**: description of system’s entities and their interaction.
3. **Data Collection**: quantify probability distributions for system’s entities.
4. **Program**: select programming language or software package to execute.
5. **Verification**: check that code is achieving expected results.
6. **Experimental Design**: determine initial conditions, simulation period and number of runs (must be statistically valid).
7. **Implementation**: run model and test its sensitivity to variations.

8. **Documentation**: document reliability study to verify problem definition objectives are reached (document enough for functional model in future).

5-3.2 Prediction.

There are many valid reasons for predicting reliability. One purpose for reliability prediction is to assess the reliability of a proposed design and to provide a quantitative basis for selection among competing approaches or components. In addition, prediction results can be used to rank design problem areas and assess trade study results. A combination of prediction methods should be used to assess progress in meeting design goals, identifying environmental concerns, controlling critical items, and determining end-of-life failure mechanisms. Making predictions should be an ongoing activity that starts with the initial design concept and continues through the evaluation of alternate design approaches, redesigns, and corrective actions. Each iteration of prediction should provide a better estimate of system reliability as better information on the system design approach becomes available.

5-3.3 Analytical Methodologies.

Analytical methods of evaluating systems are based on a variety of logical and mathematical principles. Some utilize logical algebraic formulas to arrive at a closed-form, exact, solution to a model of a system. Others use simulation processing to empirically arrive at model solutions. Simple systems can be calculated with pencil and paper. Those exercises grow linearly as the model grows linearly. Several techniques/software algorithms streamline the process of calculating availability for large systems.

5-3.3.1 Cut Set.

The cut-set method can be applied to systems with simple as well as complex configurations and is a very suitable technique for the reliability analysis of power distribution systems. A cut-set is a “set of components whose failure alone will cause system failure,” and a minimal cut-set has no proper subset of components whose failure alone will cause system failure. The components of a minimal cut-set are in parallel since all of them must fail to cause system failure and various minimal cut-sets are in series as any one minimal cut-set can cause system failure.

5-3.3.2 Network Reduction.

The network reduction method is useful for systems consisting of series and parallel subsystems. This method consists of successively reducing the series and parallel structures by equivalent components. Knowledge of the series and parallel reduction formulas is essential for the application of this technique.

5-3.3.3 Boolean Algebra and Block Diagrams.

One of the most useful tools in evaluation methods has been the use of a combination of block diagrams and Boolean algebra. The use of software to these analyses is critical given that the logic and algebra become immense as systems grow. The GO algorithm is one such instrumental method.

5-3.3.3.1 GO Algorithm.

The GO algorithm, a success-oriented system analysis technique, was originally developed for defense industry applications in the early 1960s. The capability of the GO methodology was drastically improved under the sponsorship of the Electric Power Research Institute (EPRI) with the development of additional analytical techniques (such as system interactions, system dependencies, and man-machine interactions) and improved computer software reliability. The popularity of the GO method can be linked to basic characteristics that fault trees do not possess. The hardware is modeled in a manner more or less the same way as in the system drawings, model modifications can be easily introduced to reflect configuration changes, and the modeling capability is extremely flexible. GO's success-oriented technique analyzes system performance through straightforward inductive logic. The GO representation of a system, or GO model, can often be constructed directly from engineering drawings, which makes GO a valuable tool for many applications, since it is relatively easy to build and review models.

5-3.3.3.2 System Model.

A system model is first constructed within the GO methodology using a top-down (forward-looking) approach to identify the functions required for successful operation following normal process flow or operational sequences. Secondly, in the GO methodology each of the systems that provide the functionality is modeled to the required level of detail. The level of detail may be at the system, subsystem, or component level depending upon the type of information required and the plant specific information available. The GO models determine all system-response modes: successes, failures, prematures, etc.

5-3.3.3.3 Go Models.

GO models consist of arrangements of GO operator symbols and represent the engineering functions of components, subsystems, and systems. The models are generally constructed from engineering (one-line) drawings by replacing engineering elements (valves, motors, switches, etc.) with one or more GO symbols that are interrelated to represent system functions, logic, and operational sequences. The GO software uses the GO model to quantify system performance. The method evaluates system reliability and availability, identifies fault sets, ranks the relative importance of the constituent elements, and places confidence bounds on the probabilities of occurrence of system events reflecting the effects of data uncertainties. Some key features of the GO method are:

- Models follow the normal process flow
- Most model elements have one-to-one correspondence with system elements
- Models accommodate component and system interactions and dependencies
- Models are compact and easy to validate
- Outputs represent all system success and failure states
- Models can be easily altered and updated
- Fault sets can be generated without altering the basic model
- System operational aspects can be incorporated
- Numerical errors due to pruning are known and can be controlled

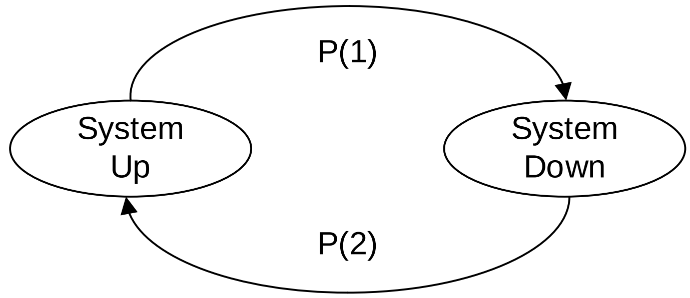
5-3.3.3.4 Go Procedure.

The GO procedure uses a set of seventeen standard logical operators to represent the logic operation, interaction, and combination of physical equipment and human actions. For example, a type 1 operator represents the logical operation of equipment which either performs, or fails to perform, its function given a proper input or stimulus. The type 2 operator performs the logical OR gate operation where a successful response is generated if any of several inputs is proper, etc. The Random variables of the GO methodology include operator inputs called stimuli (S1, S2…Sn) and outputs referred to as responses (R1, R2…, Rn). An operator, which represents equipment responses or human actions, and which may itself have associated performance probabilities, process the input random variable in a prescribed and well-defined way to generate the output random variables. These random variables are given the electrical term “signals” in the GO models.

5-3.3.4 State Space.

The State Space methodology is founded on a more general mathematical concept called Markov Chains. Markov Chains employ a modeling technique that describes a system by the possible states in which it can possess (such as State Space). For this purpose, a system essentially resides in two distinct states: up or down. The probability of transitioning from one state to the other in a given time period is the critical reliability metric used. Figure 5-11 shows this simple Markov model.

Figure 5-11 Simple Markov Model

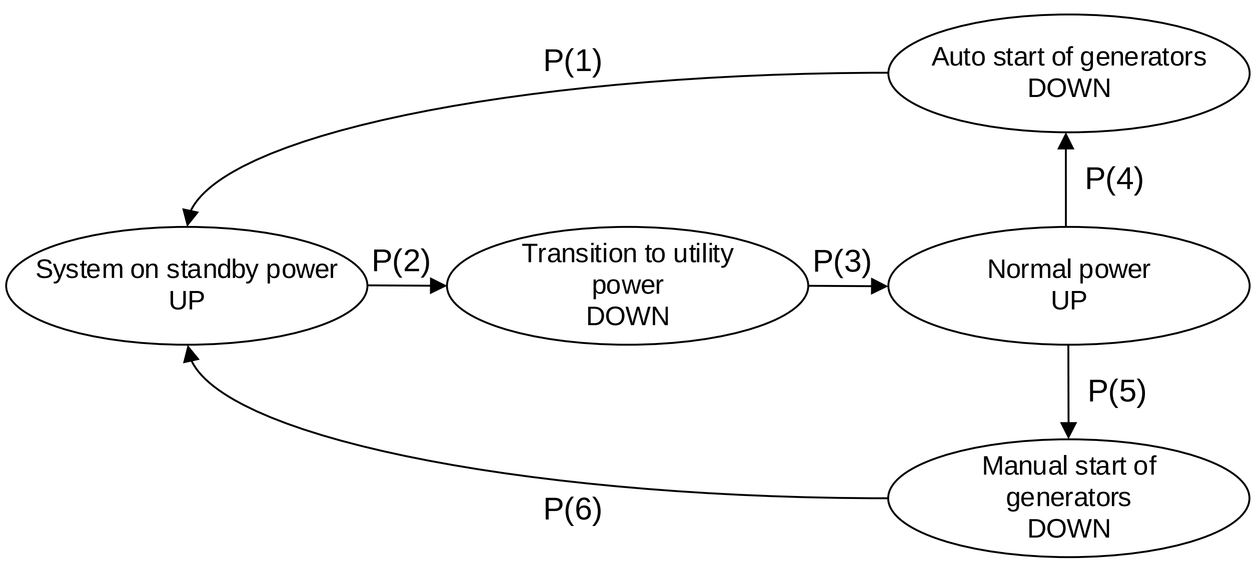


Where
P(1) is the probability of the system going down in time t
P(2) probability of the system coming up in time t

(1) However, the true goal of availability analysis is to determine the probability of being in the up state – or the time spent in the up state for an indefinite time period. To show this, consider a simple scenario including only a system with backup generation. Given loss of utility power, the generators will either start automatically or, if that functionality fails, the generators can be started manually. In those starting phases, the system is 'down.' Once started, the system is 'up.' The system will then switch to utility power once available. The system could be down during that switching.

(2) Figure 5-12 shows the associated Markov model for this system. Between each of the possible states are state transitional probabilities that must be known. The solution to the model will be the system's time spent in the up states vs. the down states.

Figure 5-12 Less Simple Markov Model



(3) Solving Markov models is simple only for very simple models, by solving a set of linear equations. The complexity solving these models grows exponentially as the sizes of the models grow linearly. Solutions can be found by using complex Numerical Analysis methods involving Linear Algebraic matrix operations, etc. Markov models can also be solved by Monte Carlo techniques described below.

5-3.3.5 Monte Carlo Simulation.

Monte Carlo Simulation is the most versatile modeling methodology available. The methodology can be implemented in many forms from simple models in a spreadsheet environment to complex models that are ‘hand crafted’ in a programming language of choice. There are also a variety of simulation software packages that provide drag-and-drop environments that can automate the creation of simulated models for the casual analyst.

(1) The Monte Carlo Simulator operates on an iterative process where each ‘iteration’ represents a description of what the system could experience through a set mission life. For instance, consider the past experience of a system, including what really failed, that experience was only one of infinite possible outcomes that depended on the failure characteristics of that system.

(2) Thus, Monte Carlo Simulation looks forward by considering possible scenarios that could occur in the future – and those scenarios, with their associated likelihoods, are dependent on the failure characteristics applied to the system components. For each iteration, failure times and the associated repair attributes are picked for each component in the system. The simulation will then implement the logical relationships of the system to determine:

(a) If a failure has occurred in the system prior to the defined mission life.

(b) If a failed component(s) takes the system down, what is the duration of downtime?

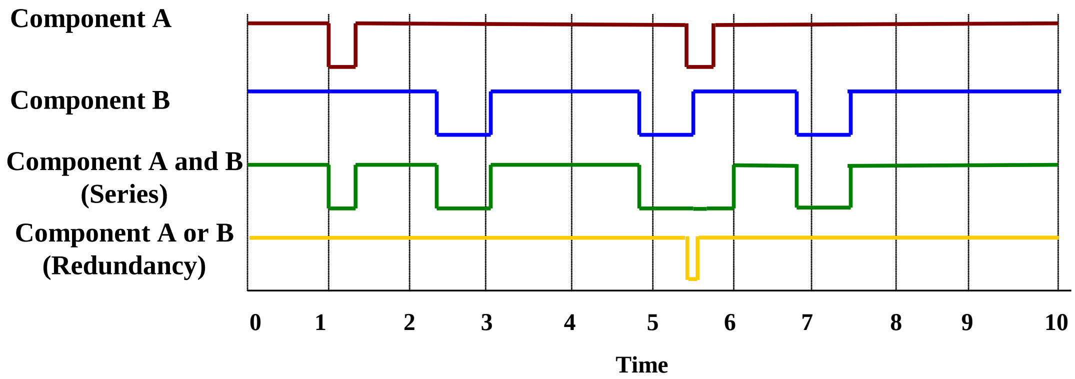
(3) With these items determined, the availability for the system in that particular iteration can be calculated. Then, as this single iteration is repeated, an average is tabulated of uptime vs. downtime, and duration of downtime. The average of all the iterations yields expected system availability.

(4) This method is extremely useful in calculating downtime based on different types of failure distributions. A component in a system may be repaired or replaced upon failure. Because many components that are replaced have failure distributions that are based on time in service, calculations must incorporate time-based failure distributions to accurately predict system availability.

(5) Figure 5-13 shows a sample timeline of the operation of two components. In this example, both components start in the available state. As the simulated time progresses, component failures are randomly generated based on that component’s

operational RAM statistics. The figure shows the difference in series and redundant component orientation. In series, downtime occurs when either component fails; with redundancy, both components are required to fail to incur downtime.

Figure 5-13 Timeline of a Monte Carlo Simulation



5-3.4 Analysis Considerations.

The results of availability analyses are extremely sensitive to factors such as underlying assumptions, techniques for calculating availability, and the data used to support the analysis. No results of an analysis should be distributed – let alone trusted – without documentation supporting those attributes. Subtle differences in those attributes can produce drastically different results – results that might be used to drive design decision making. It is the ultimate responsibility of the analyst to be aware of those sensitivities and perform and present analyses with integrity.

5-3.4.1 Modeling Limitations.

Cut set, State Space, Network Reduction and Boolean algebra are techniques that lend themselves to the casual reliability engineer to analyze small systems; primarily because they can all be accomplished with common desktop PC tools such as spreadsheets, etc. A series of studies recently performed on the IEEE Gold Book (IEEE 493-2007) standard network have shown that, provided that the assumptions are held equal, each technique produces similar results. However, model size and data sophistication make algebraic methods more complicated and therefore, more difficult to use.

5-3.4.1.1 Large Systems.

As larger systems are modeled, the sheer size of the analysis becomes burdensome for the analyst. Furthermore, ‘what-if’ sensitivity analyses also become impractical because models must be redrawn and formulas, rewritten. For the number of formulas and conditions that can be involved, peer reviews are of utmost importance to compensate for the high probability of error involved in such an extensive effort.

5-3.4.1.2

Data collection efforts have expanded the analysts' tools beyond the classical 'MTBF' analysis. MTBF relies on the exponential distribution, sometimes referred to "point estimates." These estimates give the average MTBF (such as one point). Failure distributions such as the Normal, Lognormal, Weibull, etc. are being fitted to common failure modes of many critical components in electrical and mechanical distribution networks. These distributions capture the fact that the failure rate of a component likely changes over time, capturing initial and wear-out failure modes. These distributions require more precise data collection: time-to-failure data. With point estimates, the data collector need only count operational hours and failure events for a component. For time-to-failure data, each interval of time between installation and failures, making the data collection and processing effort extremely challenging, but extremely valuable.

5-3.4.1.3 Time-To-Failure Data.

Time-to-failure data has become substantially important to system analyses. For many components such as belts, valves, and batteries, availability figures may not be specific enough to characterize the likelihood of failure. In these cases, failures are more likely to occur toward the end of a component's life – not evenly throughout its life. Simulation methods provide the means to include these considerations.

5-3.4.2 Modeling Hurdles.

There are several system attributes that are challenging to model. UPS battery life, for instance, had historically been assumed to be limitless in many analyses – whereas their contribution to power availability is not. Furthermore, data has shown that standby equipment has differing distributions from their primary counterparts. Spare parts availability, human factors, etc. are difficult to capture with the classical approaches to availability analysis.

5-3.4.3 Modeling Data.

The underlying data that supports a reliability assessment can be as important as the model itself. Data must be scrutinized to ensure that the results are realistic and defendable. There are a variety of sources of component reliability data. \1\ Appendix D of this UFC /1/ contains data collected by the US Army Corps of Engineers. This dataset was collected and summarized for the distinct \1\ purpose /1/of modeling C5ISR facilities.

5-3.4.4 Modeling Solutions.

The typical engineer can perform 'back of the envelope' analyses easily. Results from these analyses are only as good as the assumed ground rules and the data used. Experience has shown that analysts who wish to perform availability studies often and consistently should choose a software package to aid in this effort. Packages exist that perform analyses via most of the described methodologies. Once a package is selected, the user should become familiar with the package behavior, the analytical or numerical methodology used, and the underlying limitations of that package.

5-3.5 Modeling Examples.

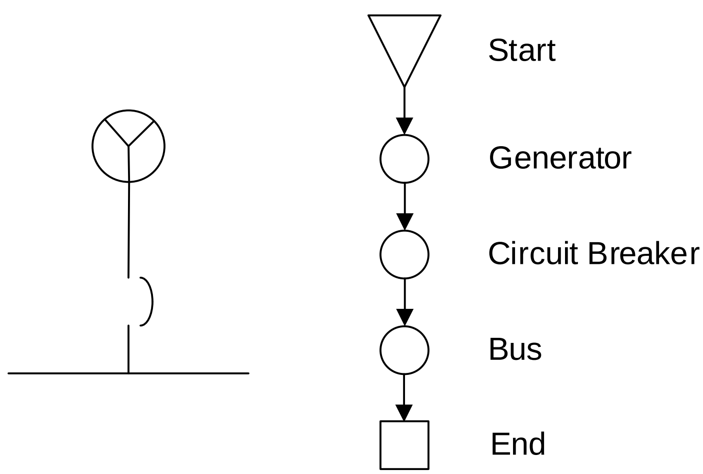
No matter what methodology is chosen for a reliability analysis, the expected results, provided that the underlying assumptions are held fixed, should be consistent across all methods. The analyst should develop a sense of the expected results of small systems and have a feel for the effects of increments changes to a system when made. Below are a series of small examples that will illustrate typical results in simple models.

5-3.5.1 Modeling Basics.

Reliability modeling generally begins with referring to a one-line drawing for the electrical, mechanical, and control systems. In addition to these resources, the analyst should have a firm understanding of the theory of operation of the system to be modeled. These sources of information will form the basis for the structure and behavior of the system that is to be modeled.

(1) For this UFC, a pseudo diagramming technique is adopted that can be applied to, or converted to, whichever modeling technique is chosen. The convention can be most accurately described as an RBD. Figure 5-14 shows a typical one-line diagram representation of a generator/bus and its corresponding RBD representation.

Figure 5-14 Simple Series Model



(2) Figure 5-14 represents a typical series diagram – the most common scenario observed in electrical and mechanical one-line drawings and can be solved simply by series calculations, such as for power to be available at the bus, the following must be available: generator, breaker, and the bus.

(3) Assume that the generator has an availability of 0.99, the breaker is 0.9999, and the bus is 0.99999. Then the series can be calculated by the following equation:

Equation 5-12. Availability for Figure 5-14

$$A = 0.99 \times 0.99999 \times 0.9999 = 0.989891$$

Where:
A = Availability

(4) Typical generator models often require an N of M calculation. If, for example a plant has three generators, of which two are required to carry the critical load, then a 2 of 3 generator availability calculation must be made. The calculation for this can be quite complex, but is reasonable for small values of M:

Equation 5-13. Availability for Typical Generator Models

$$A = \sum_{k=m}^{n} \frac{n!}{k!\,(n-k)!}(A')^{k}(1-A')^{(N-K)}$$

Where:
A = Availability
n = the total number of components
m = the required components

(5) Figure 5-15 represents a simplistic parallel-redundant system commonly found in C5ISR facilities. Note that the model consists of series calculations and parallel calculations. This model implies that there is a pure redundancy, where switching between A and B happens without risk of failure. In most cases, there are reliability considerations in the switching between redundant systems.

(6) The model described by Figure 5-15 can also be solved with simple calculations. Assume that the bus has an availability of 0.99999, the breakers are 0.9999, and the UPS is 0.999. To determine the system availability, one must reduce the network to simpler series and parallel models. The general sequence is to reduce the breaker-UPS-breaker series to one value. Then calculate the redundant OR operator followed by treating that result as a value in series with the bus. The breaker-UPS-breaker series can be computed by

Equation 5-14. Breaker-UPS-Breaker Reduction for Figure 5-15

$$A_{UPS} = 0.9999 \times 0.999 \times 0.9999 = 0.9988002$$

Where:
A_{ups} = the UPS Availability

Now, with that reduction, the model can be represented by Figure 5-16.

Figure 5-15 Simple Parallel Model

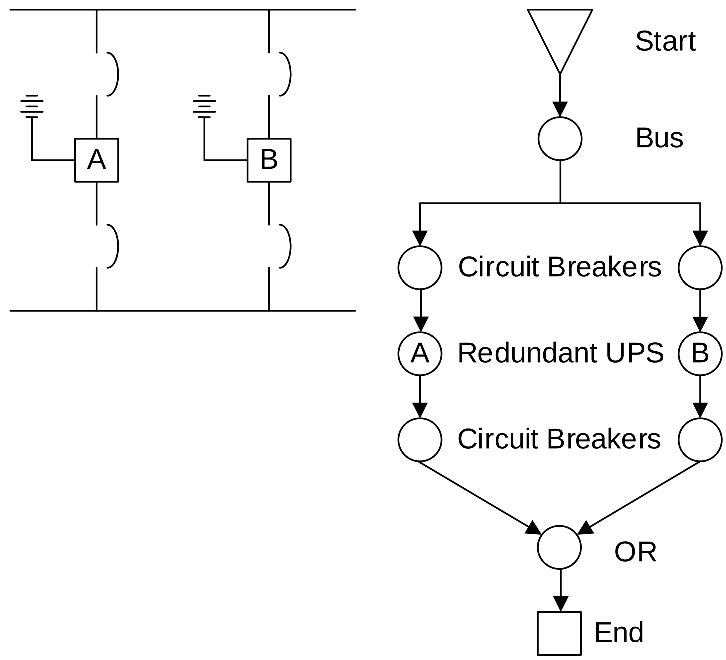


Figure 5-16 Simple Parallel Model, First Reduction

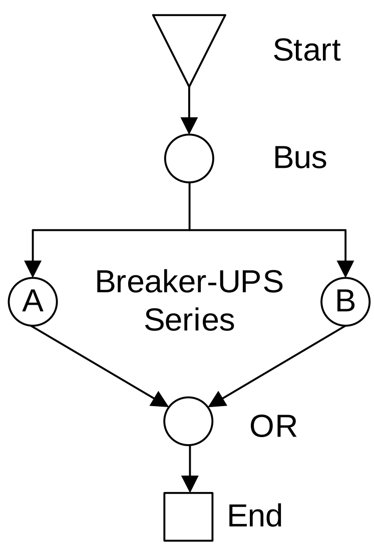


Next reduce the OR calculation to one availability value:

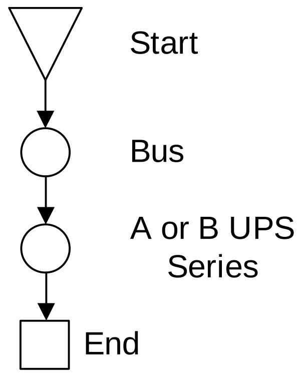
Equation 5-15. OR Availability for Figure 5-16

$$A_{OR} = 1 - [(1 - 0.9988002) \times (1 - 0.9988002)] = 0.99999856$$

Where:
A_{OR} = *OR Availability*

Figure 5-17 shows this further reduction.

Figure 5-17 Simple Parallel Model, Second Reduction



Then, this system, now reduced to a series system, can be easily calculated by

Equation 5-16. Final Availability for Figure 5-17

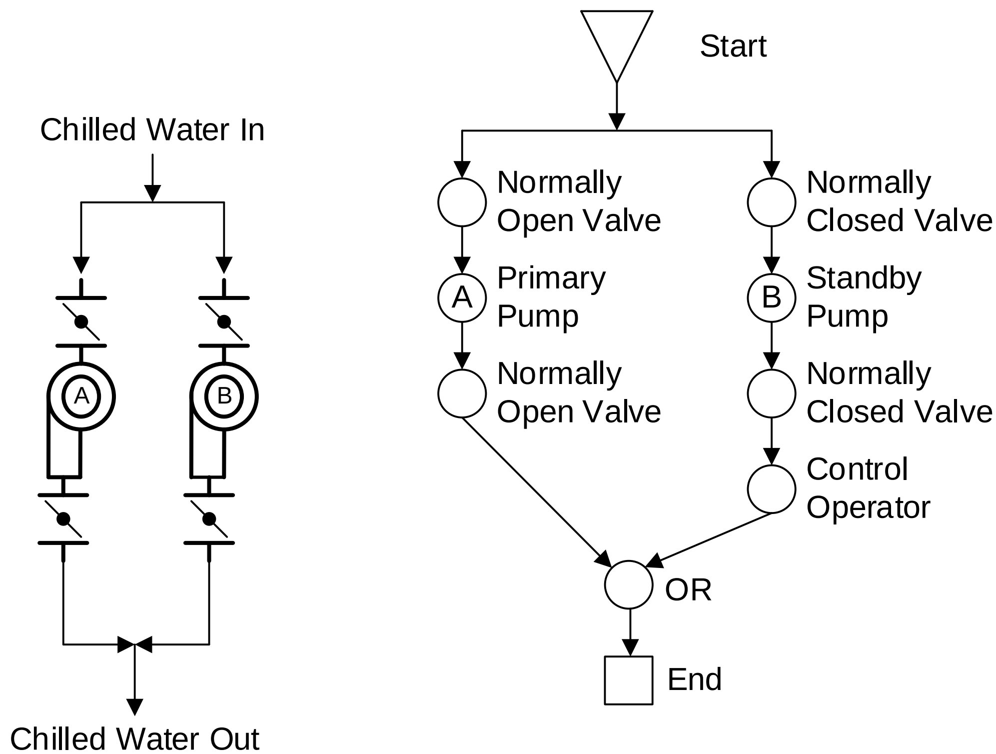
$$A_{Final} = 0.99999 \times 0.99999856 = 0.99998856$$

Where:
A_{Final} = *Final Availability*

(7) Building controls contingencies into reliability models is prudent. Often pure OR gates result in availability values that are inflated because they do not include the probability of the switching action itself. Whether the control is automatic via PLC or SCADA, or requires maintenance personnel to manually make the switch, the redundancy is limited by that switching action.

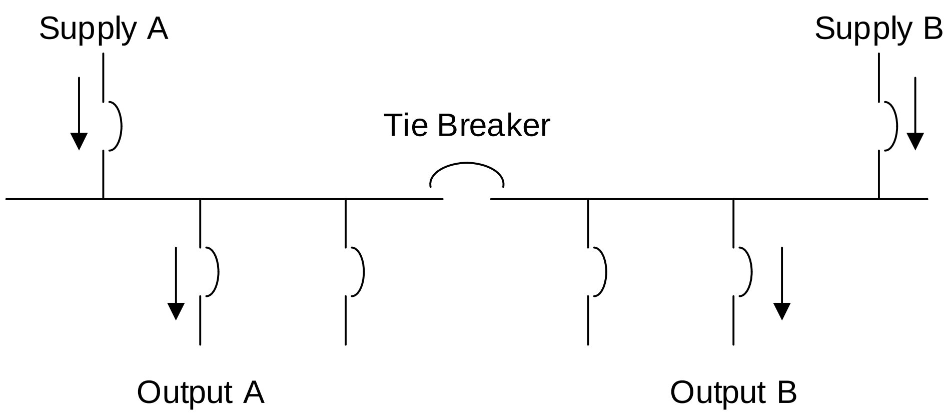
(8) Consider Figure 5-18 where a facility utilizes dual chilled water pumps. If Pump A fails (or is taken down for maintenance) the valves supporting Pump A must be closed and the valves supporting Pump B must be opened. The model shows a control node with the B series to represent the reliability of the switching. Note that the A path, the ‘normal day’ operating mode, has no controls contingency. Only when path B is required does the availability of the system need to be reduced due to the switching function.

Figure 5-18 Parallel Model with Controls Contingency



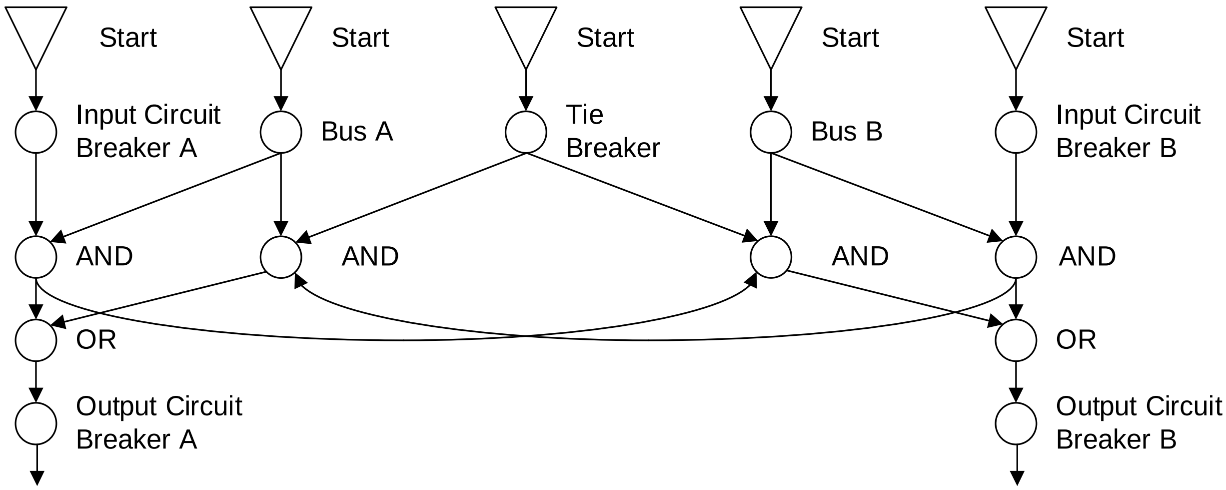
(9) Modeling becomes significantly more complicated when redundant paths are added. Even the most common scheme found in C5ISR facilities, the Double-Ended Bus with a tie, can begin to complicate modeling. Consider Figure 5-19. The gear essentially receives power from two sources and passes it through via two paths (thus retaining the redundancy). If one source is lost, then the Tie, which is normally open, closes to provide power to both output paths.

Figure 5-19 Double Ended Bus



A typical model of this system is illustrated in Figure 5-20

Figure 5-20 Model of Double Ended Bus



(10) The key to the logic lies in the fact that typical modeling cannot readily emulate that power can pass through the tie in both directions. Thus, the availabilities of the tie and the busses are created independently and used within the logic where required.

(11) If one looks at the logic behind the availability of power out of a breaker on bus A, then the critical ‘OR’ statement is joining the following two scenarios:

(a) Power available from source A

(b) Power required from source B

(12) In case (a), the only required components are the incoming breaker, (on side A) the Bus A, and the outgoing breaker A. Case (b) requires much more. In order of how the power will flow if source A is unavailable: Input Breaker B, Bus B, Tie, Bus A, output Breaker A. Figures 5-21 and 5-22 show these two cases, with the pivotal OR block shaded black.

Figure 5-21 Model of Double Ended Bus, Case 1

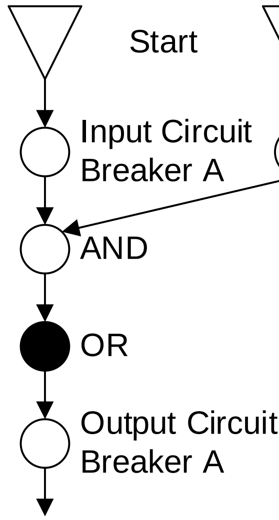


Figure 5-22 Model of Double Ended Bus, Case 2

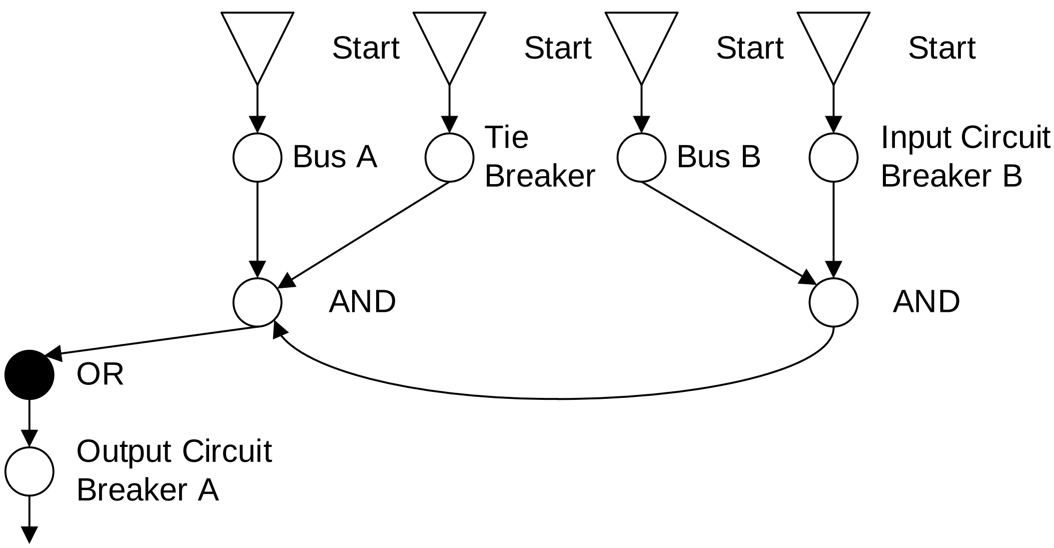


5-3.6 Modeling Complexities.

The modeling examples discussed previously represent a top-down style of modeling and is the most common type of modeling. The model has a beginning and an end. Failures within the model interrupt the availability of downstream components. This style has a variety of advantages, one being that it loosely follows the intuitive paths of, say, power or chilled water. There are some disadvantages and limitations to top-down modeling: upstream effects of failures, loop systems, and UPS systems. In most cases, advanced simulation methods need to be employed to capture these complexities.

5-3.6.1 Effects of Unique Failure Modes.

The failure of a component in a system typically influences the remainder of the system downstream of the failure only. Unfortunately, there are some failures, or failure modes of a component, that can have effects on the system upstream. For example, if a circuit breaker fails to open on command, such as there is a downstream fault that the breaker is intended to protect against but doesn't. That fault can be passed upstream and influence a much larger portion of the entire system than just those components downstream of the fault. The sequence of Figure 5-23 shows how a downstream fault can affect other sub-systems.

5-3.6.2 Interdependencies and Loop Systems.

Interdependencies and loop systems are common in C5ISR facilities. Two scenarios often create a modeling hurdle. One instance is the interdependency between power, chilled water, and controls. The mechanical systems are dependent on power and the controls system, the power system depends on the controls system, and the control system requires power. These interdependencies are possible to model, though typically only through special means, such as Monte Carlo Analysis.

5-3.6.3 UPS Systems.

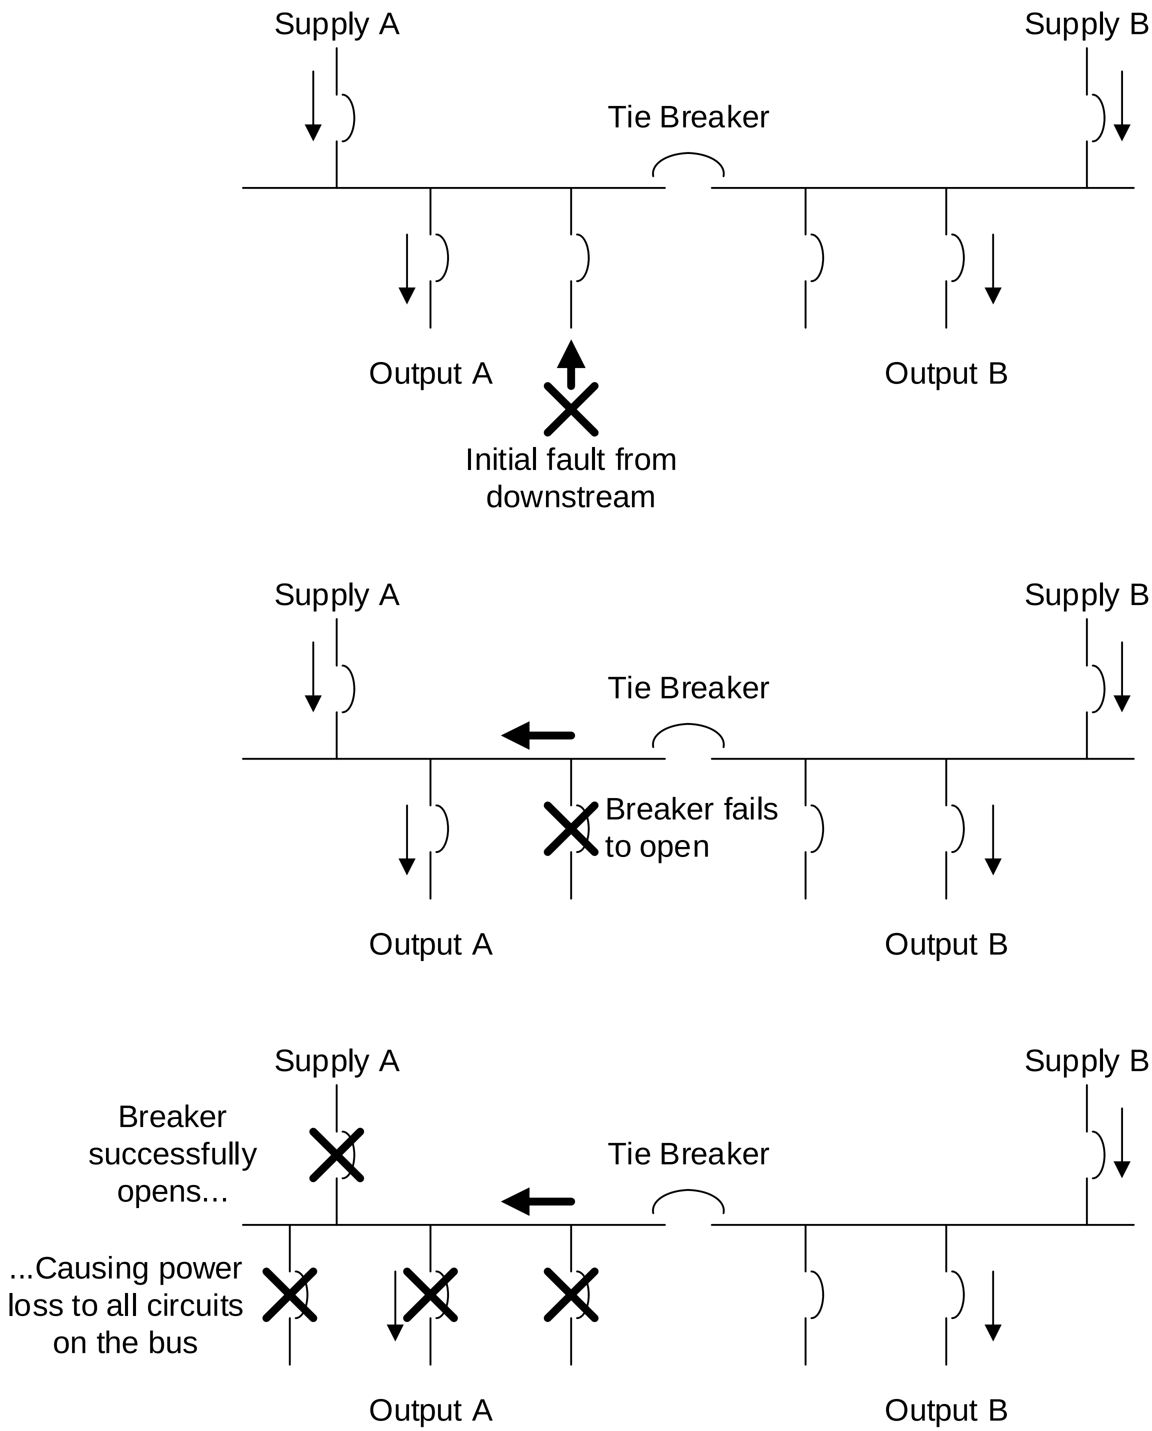
Uninterruptible power supply systems present a unique challenge to the analyst because capturing the effects on availability from the added battery backup can be difficult. The concept of operation for a UPS is limited to the fact that the battery has a limited life. If, for instance, a UPS has 45 minutes of ride-through time, then any upstream interruption less then 45 minutes will essentially be mitigated. However, if an interruption lasts longer then 45 minutes, the total interruption time is essentially shortened by 45 minutes before the downstream mission is lost. Below are two simple cases to illustrate this point.

Assume that over the course of one year, a system experiences a failure upstream of the UPS:

Case 1: the failing component is repaired within 30 minutes. In this case the UPS provides sufficient downstream power and the mission remains available. This case yields an availability of 8766/8766 = 1. Availability is retained.

Case 2: the failing component requires 24 hours to repair. In this case the UPS merely reduces the downtime of the mission to 24 hrs – 45 minutes, or 23.25 hrs. In this case the availability for the case-year is (8766-23.25)/8766 or 0.9973.

Figure 5-23 Downstream Fault



5-3.6.4 Conclusion of Complexities.

Complex modeling scenarios need complex modeling techniques. In most cases Monte Carlo methods need to be employed. Monte Carlo methods capture true operating scenarios, one iteration at a time, as set up by the analyst. Simulation allows the analyst to interject nearly any conceivable operating anomaly that might occur in a facility.

5-3.7 Conclusion.

RAM studies should be conducted with the intent of capturing the actual behavior of the facility. This goal will force the analyst to continually seek better data and better modeling techniques. Although, in design, RAM can not be perfectly captured; it is still just a prediction. Refined assessment techniques can uncover previously unforeseen contingencies that may cause a mission to be lost.

5-3.7.1 RAM Analysis.

RAM analysis must be continuously improved to converge with the behavior of a system. As systems become more complex, the methods will undoubtedly become more complex as well. The analyst should always compare their modeling assumptions and attributes captured to the actual operation of the system being modeled. New techniques must continuously be explored to see that the gap between the models and the true system narrows.

5-3.7.2 Verification.

Facility managers must verify that the model is valid – capturing their system accurately. They must also be aware of the reliability data that supports the model. The model is only as good as the data that it uses. In a sense, the data is a single-point vulnerability for the accuracy of the model. Facility managers and reliability analysts alike should always consult the most recent IEEE DOT STD 3006.8 for reliability data. Further, adoption of a continuous RAM process such as RCM will provide actual system behavior data that will continue to serve the reliability, availability, and maintainability goals over the life of the system.

CHAPTER 6 FAILURE MODES, EFFECTS AND CRITICALITY ANALYSIS

6-1 BACKGROUND ON FMECA.

6-1.1 Define FMECA.

The FMECA is composed of two separate analyses, the Failure Mode and Effects Analysis (FMEA) and the Criticality Analysis (CA). The FMEA analyzes different failure modes and their effects on the system while the CA classifies or prioritizes their level of importance based on failure rate and severity of the effect of failure. The ranking process of the CA can be accomplished by utilizing existing failure data or by a subjective ranking procedure conducted by a team of people with an understanding of the system. Although the analysis can be applied to any type of system, this \1\ UFC /1/ will focus on applying the analysis to a C5ISR facility.

6-1.1.1 Initiating a FMECA.

The FMECA should be initiated as soon as preliminary design information is available. The FMECA is a living document that is not only beneficial when used during the design phase but also during system use. As more information on the system is available the analysis should be updated to provide the most benefit. This document will be the baseline for safety analysis, maintainability, maintenance plan analysis, and for failure detection and isolation of subsystem design. Although cost should not be the main objective of this analysis, it typically does result in an overall reduction in cost to operate and maintain the facility.

6-1.2 FMECA Benefits.

The FMECA will:

- Highlight single point failures requiring corrective action.
- Aid in developing test methods and troubleshooting techniques.
- Provide a foundation for qualitative reliability, maintainability, safety, and logistics analyses.
- Provide estimates of system critical failure rates.
- Provide a quantitative ranking of system and/or subsystem failure modes relative to mission importance; and identify parts & systems most likely to fail.

6-1.2.2 Developing a FMECA.

Developing a FMECA during the design phase of a facility, the overall costs will be minimized by identifying single point failures and other areas of concern prior to construction, or manufacturing. The FMECA will also provide a baseline or a tool for troubleshooting to be used for identifying corrective actions for a given failure. This information can then be used to perform other analyses such as a FTA or an RCM analysis.

6-1.2.3 FTA.

The FTA is a tool used for identifying multiple point failures; more than one condition to take place for a particular failure to occur. This analysis is typically conducted on areas that would cripple the mission or cause a serious injury to personnel.

6-1.2.4 RCM Analysis.

The RCM analysis is a process that is used to identify maintenance actions that will reduce the probability of failure at the least amount of cost. This includes utilizing monitoring equipment for predicting failure and for some equipment, allowing it to run to failure. This process relies on up-to-date operating performance data compiled from a computerized maintenance system. This data is then plugged into a FMECA to rank and identify the failure modes of concern.

6-1.2.5 Additional Analysis Information.

For more information regarding these types of analyses refer to the following publications:

(1) Ned H. Criscimagna, Practical Application of Reliability Centered Maintenance Report No. RCM, Reliability Analysis Center, 201 Mill Street, Rome, NY, 2001.

(2) David Mahar, James W. Wilbur, Fault Tree Analysis Application Guide, Report No. FTA, Reliability Analysis Center, 201 Mill St., Rome, NY: 1990

(3) NASA's Reliability Centered Maintenance Guide for Facilities and Collateral Equipment, February 2000.

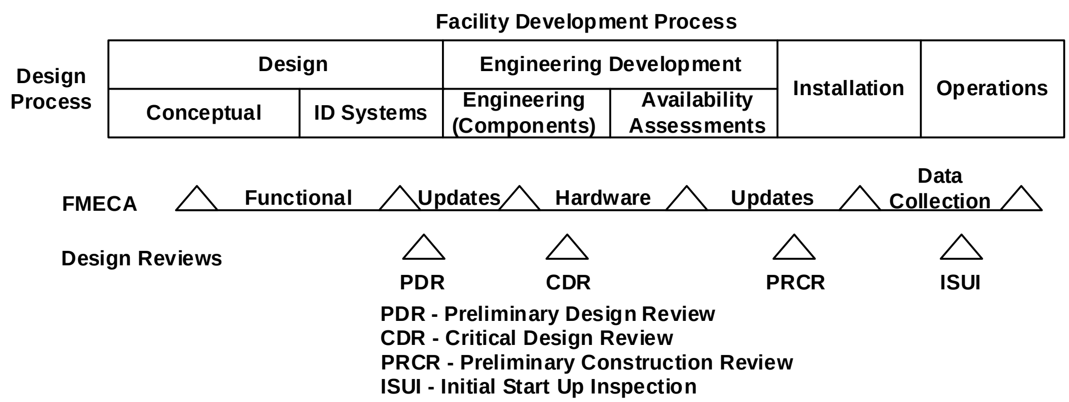
6-1.3 Team Effort.

The FMECA should be a catalyst to stimulate ideas between the design engineer, operations manager, maintenance manager, and a representative of the maintenance personnel (technician). The team members should have a thorough understanding of the systems operations and the mission's requirements. A team leader should be selected that has FMECA experience. If the leader does not have experience, then a FMECA facilitator should be sought. If the original group of team members discovers that they do not have expertise in a particular area during the FMECA then they should consult an individual who has the knowledge in the required area before moving on to the next phase. The earlier a problem in the design process is resolved, the less costly it is to correct it.

6-1.4 FMECA Characteristics.

The FMECA should be scheduled and completed concurrently as an integral part of the design process. Ideally this analysis should begin early in the conceptual phase of a design, when the design criteria, mission requirements and performance parameters are being developed. To be effective, the final design should reflect and incorporate the analysis results and recommendations. However, it is not uncommon to initiate a FMECA after the system is built to assess existing risks using this systematic approach. Figure 6-1 depicts how the FMECA process should coincide with a facility development process.

Figure 6-1 Facility Development Process



Since the FMECA is used to support maintainability, safety, and logistics analyses, it is important to coordinate the analysis to prevent duplication of effort within the same program. The FMECA is an iterative process. As the design becomes mature, the FMECA must reflect the additional detail. When changes are made to the design, the FMECA must be performed on the redesigned sections. This ensures that the potential failure modes of the revised components will be addressed. The FMECA then becomes an important continuous improvement tool for making program decisions regarding trade-offs affecting design integrity.

6-1.5 Requirements.

To perform an accurate FMECA, the team must have some basic information to get started.

a. The basic information is:

- Schematics or drawings of the system.

- Bill of materials list (for hardware only)

- Block diagram which graphically shows the operation and interrelationships between components of the system defined in the schematics.
- Knowledge of mission requirements
- An understanding of component, subsystem, & systems operations

b. Once the team has all the information available to them, the analysis can proceed. The team leader should organize a meeting place for all team members with enough space to display schematics, block diagrams or bill of materials for all members to view. Setting the ground rules and establishing the goals of the mission should be discussed at the first meeting.

6-1.6 Goals.

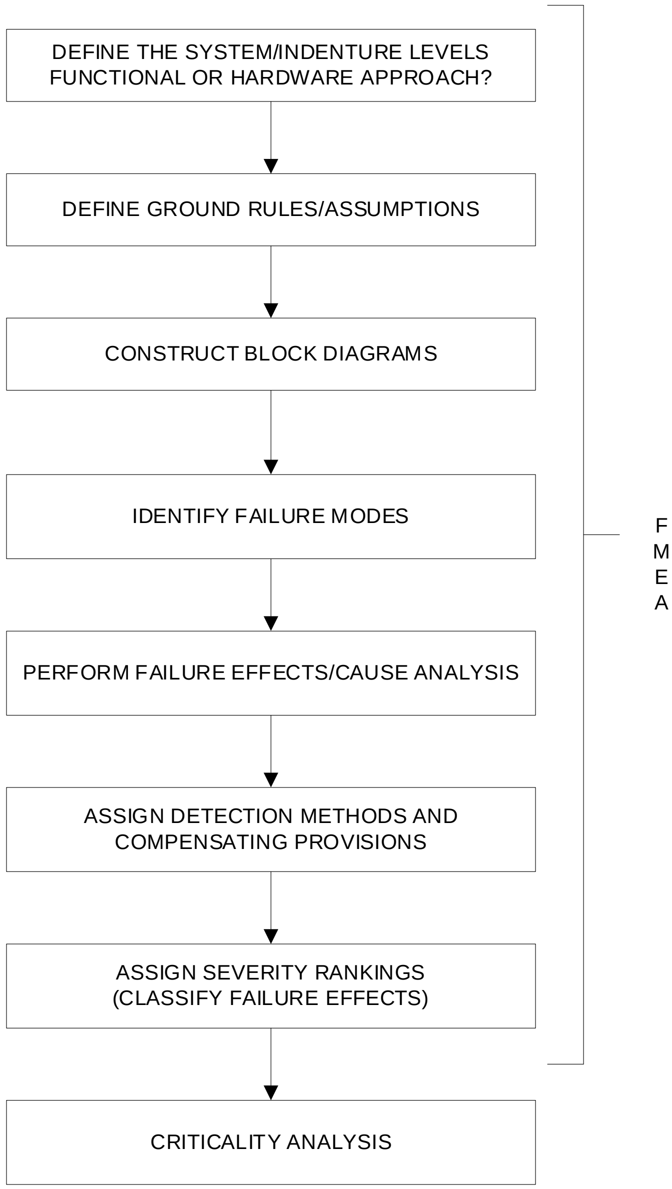
Questions from all participants should be addressed. It is essential to the analysis that all "gray" areas concerning the goal(s) of the analysis should be clarified early on. For the analysis to be successful, all team members must be cooperative and have a positive outlook regarding the goals of the analysis.

6-2 FAILURE MODES AND EFFECTS ANALYSIS (FMEA) METHODOLOGY.

6-2.1 Methodology – Foundation.

To perform a FMECA the analysts must perform a FMEA first then the CA. The FMEA will then be used as the foundation of the CA. This paragraph will discuss the process flow of a FMEA, see Figure 6-2, and explain when and how to perform a FMEA at an upper system level and lower system level approach. The FMEA will identify systems and/or components and their associated failure modes. This part of the analysis will also provide an assessment of the cause and effects of each failure mode.

Figure 6-2 Typical FMEA Flow



6-2.2 Define the System to be Analyzed (Functional/Hardware Approach)

Provide schematics and operational detail of the system. Clarify the mission of the system or the goal of the system. The mission may be to provide emergency power or maintain a certain temperature to the facility. Whatever it is, it must be identified prior to analysis. Identify failure definitions, such as conditions which constitute system failure or component failure.

6-2.2.1 System Indenture Levels.

The system indenture levels must be identified. Figure 6-3 depicts typical system indenture levels. At these system indenture levels; a functional approach is usually applied. Each system's function is known and possibly the major pieces of equipment are known. However, it is possible to conduct a hardware analysis to these levels as well. But they must begin at the lower levels and propagate them up to the higher system levels. An example of the hardware approach is shown in Figure 6-4.

Figure 6-3 Functional Method

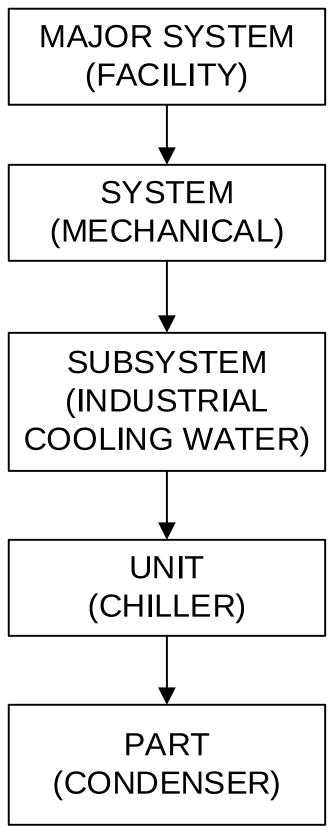


Figure 6-4 Hardware Method

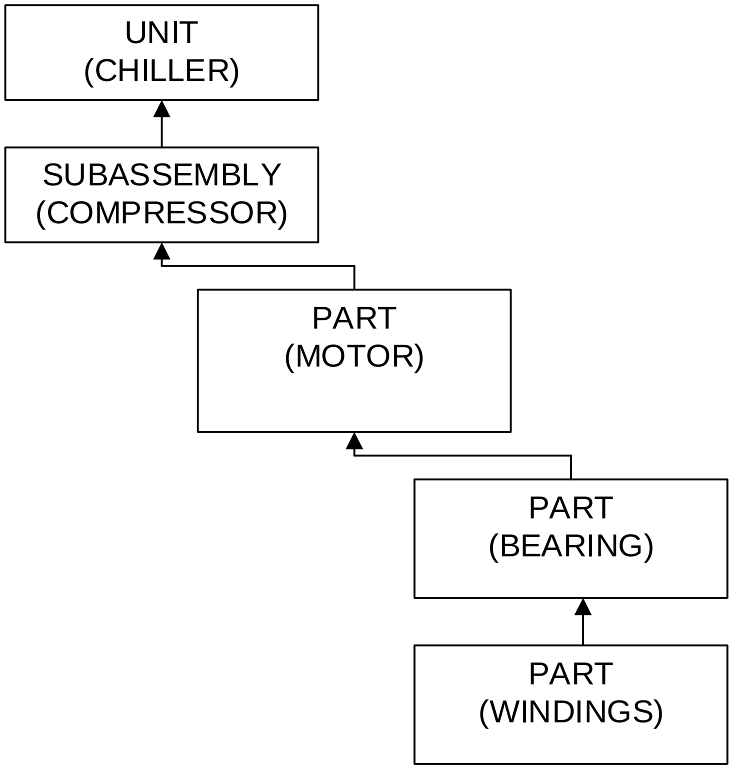


6-2.2.2 Functional Approach.

Early in a design, the functional approach will be used to analyze a system's or sub-system's affects on the specified mission. This approach is performed from the upper system level down to quickly provide a general assessment of the major system's requirements to meet mission objectives. Specific parts or components are initially unknown. Once the major components are known a hardware approach can be conducted as well. This type of analysis is conducted at the indenture levels shown in Figure 6-4. To perform a functional FMEA the analyst will need:

- System definition and functional breakdown
- Block diagrams of the system
- Theory of operation
- Ground rules and assumptions including mission requirements
- Software specifications

6-2.2.3 Define and Identify.

The analyst performing a functional FMEA must be able to define and identify each system function and its associated failure modes for each functional output. Redundant components are typically not considered at the upper levels. The failure mode and effects analysis is completed by determining the potential failure modes and failure causes of each system function. For example, the possible functional failure modes of a pump are pump does not transport water; pump transports water at a rate exceeding requirements; pump transports water at a rate below requirements.

6-2.2.4 Failure Mechanisms or Causes.

The failure mechanisms or causes would be motor failure; loss of power; over voltage to motor; degraded pump; motor degraded; and, under voltage to motor.

6-2.2.5 Observing.

The functional approach should start by observing the effects of each major system, heating, ventilation, and air conditioning (HVAC) and power generation/distribution, has on each other. The next level down would analyze either just the required components within the HVAC or the required components of the power generation/distribution.

6-2.2.6 Functional FMEA.

The functional FMEA is crucial to the success of understanding the equipment and to determine the most applicable and effective maintenance. Once failure rates on each component within each system can be established, they are added up to assign a failure rate of the system. This failure rate will aid in determining where redundant components are required.

6-2.2.7 Hardware Approach.

The hardware approach is much more detailed. It lists individual hardware or component items and analyzes their possible failure modes. This approach is used when hardware items, such as what type of motors, pumps, cooling towers, or switchgear, can be uniquely identified from the design schematics and other engineering data.

6-2.2.8 Hardware Failures.

The possible hardware failure modes for a pump could be pump will not run; pump will not start; and, pump is degraded. The mechanisms would be motor windings are open; a coupling broke; starter relay is open; loss of power; impeller is worn; and, seal is leaking.

6-2.2.9 Bottom-Up.

The hardware approach is normally used in a bottom-up manner. Analysis begins at the lowest indenture level and continues upward through each successive higher indenture level of the system. This type of analysis is usually the final FMEA for the design. To perform a hardware FMEA the analyst will need:

- Complete theory or knowledge of the system
- RBDs/functional block diagrams
- Schematics
- Bill of materials/parts list
- Definitions for indenture levels
- Ground rules and assumptions including mission requirements

6-2.2.10 Utilizing Both Hardware and Functional Approaches.

Depending on the complexity of the system under analysis, it is sometimes necessary to utilize both the hardware and functional approach. The major difference between the two approaches is the amount of “parts” the component has and the descriptions of the failure modes. The failure mode description for a functional approach is a functional description whereas the hardware approach may identify a particular part that failed.

6-2.2.11

To help the reader understand the FMEA and FMECA results, the analyst must clearly document the ground rules and/or assumptions made when performing each part of the analysis. The ground rules generally apply to the system/equipment, its environment, mission, and analysis methods. Ground rules require customer approval and generally include:

a. The mission of the item being analyzed (example: Power-Electricity)

b. The phase of the mission the analysis will consider (example: Main Power Outage)

c. Operating time of the item during the mission phase (example: Run Time of Generators)

d. The severity categories used to classify the effects of failure

e. Derivation of failure mode distributions (vendor data, statistical studies, analyst's judgment)

f. Source of part failure rates when required (nonelectronic parts reliability data (NPRD), vendor data, Power Reliability Enhancement Program (PREP) data)

g. Fault detection concepts and methodologies (SCADA, alarms, warnings)

6-2.2.12 Block Diagrams.

A functional and RBD representing the operation, interrelationships, and interdependencies of functional entities of the system should be constructed. The block diagrams provide the ability to trace the failure mode effects through each level of indenture. The block diagrams illustrate the functional flow sequence as well as the series or parallel dependence or independence of functions and operations.

6-2.2.12.1 Item Input and Output.

Each input and output of an item should be shown on the diagrams and labeled. A uniform numbering system which is developed for the functional system breakdown order is essential to provide traceability through each level of indenture.

6-2.2.12.2 Functional Block Diagram.

The functional block diagram shows the operation and interrelationships between functional parts of the system as defined by the schematic drawings and engineering data. It depicts the system functional flow, the indenture level of analysis, and the present hardware indenture level. This type of diagram should be used for hardware and functional FMEAs.

6-2.2.12.3 Functional Block Diagram Subsystems.

The functional block diagram in Figure 6-5 would be used at the earliest part of a design. It indicates what subsystems a facility will need to supply a room with temperature control. These subsystems are:

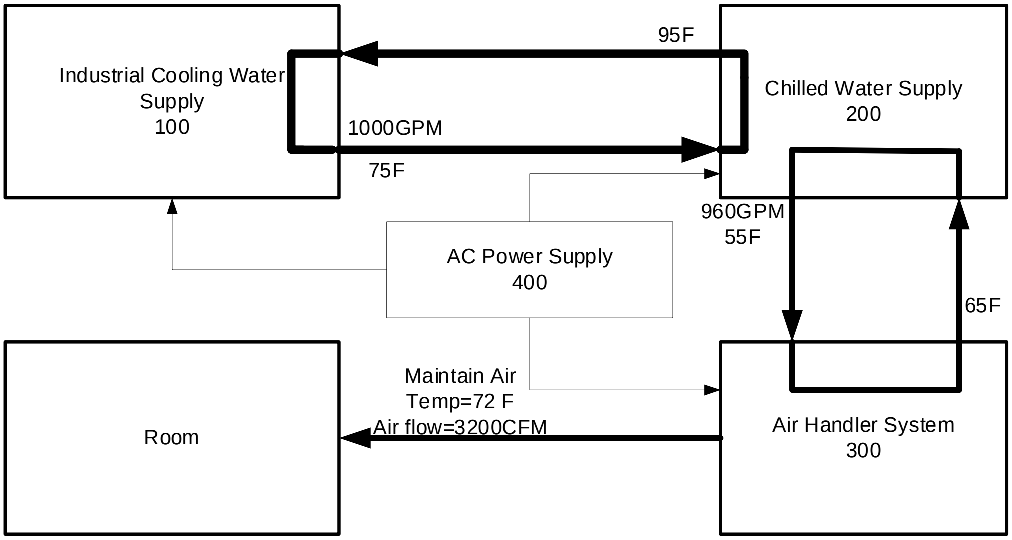
(1) The Industrial Cooling Water system; used to remove the heat generated by the chiller.

(2) The Chilled Water Supply; used to supply water at a temperature of 55°F to the Air Handling System.

(3) The Air Handling system; used to provide air flow at 3200cfm to the room and maintain a temperature of 72°F.

(4) AC Power Supply; used to provide power to each of the above subsystems.

Figure 6-5 Functional Block Diagram of System



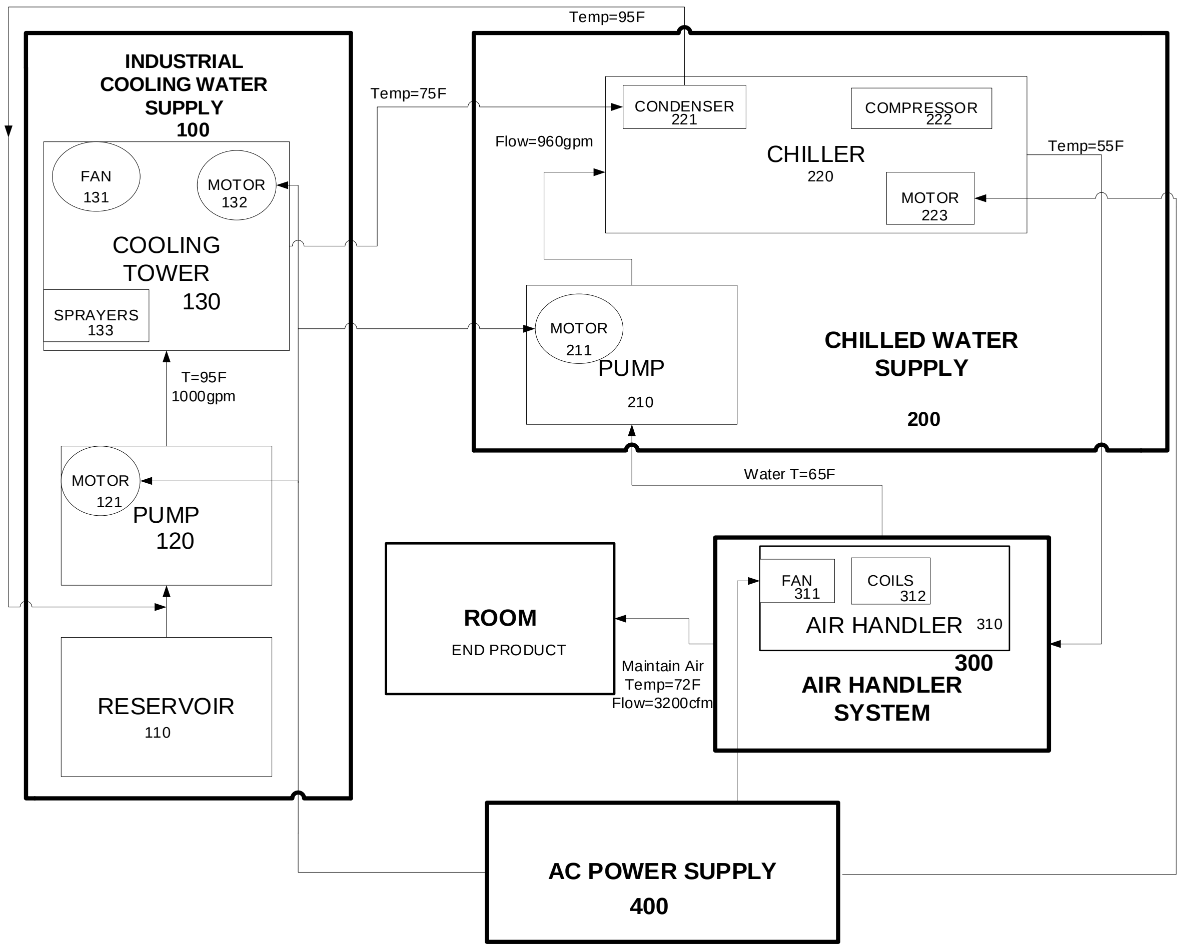
6-2.2.12.4 Functional Block Diagram Subsystem Components.

The next step is to provide a functional diagram within each sub-system indicating what types of components are required and their outputs. Figure 6-6 is an example of the same system but provides the basic components and their relationship within their system and other systems.

6-2.2.12.5 Functional or Hardware FMEA.

If a functional or hardware FMEA is to be conducted, a reliability diagram should be constructed down to the component level after the functional diagram of the system is completed. This will visually provide information to the team of any single point failures at the component level.

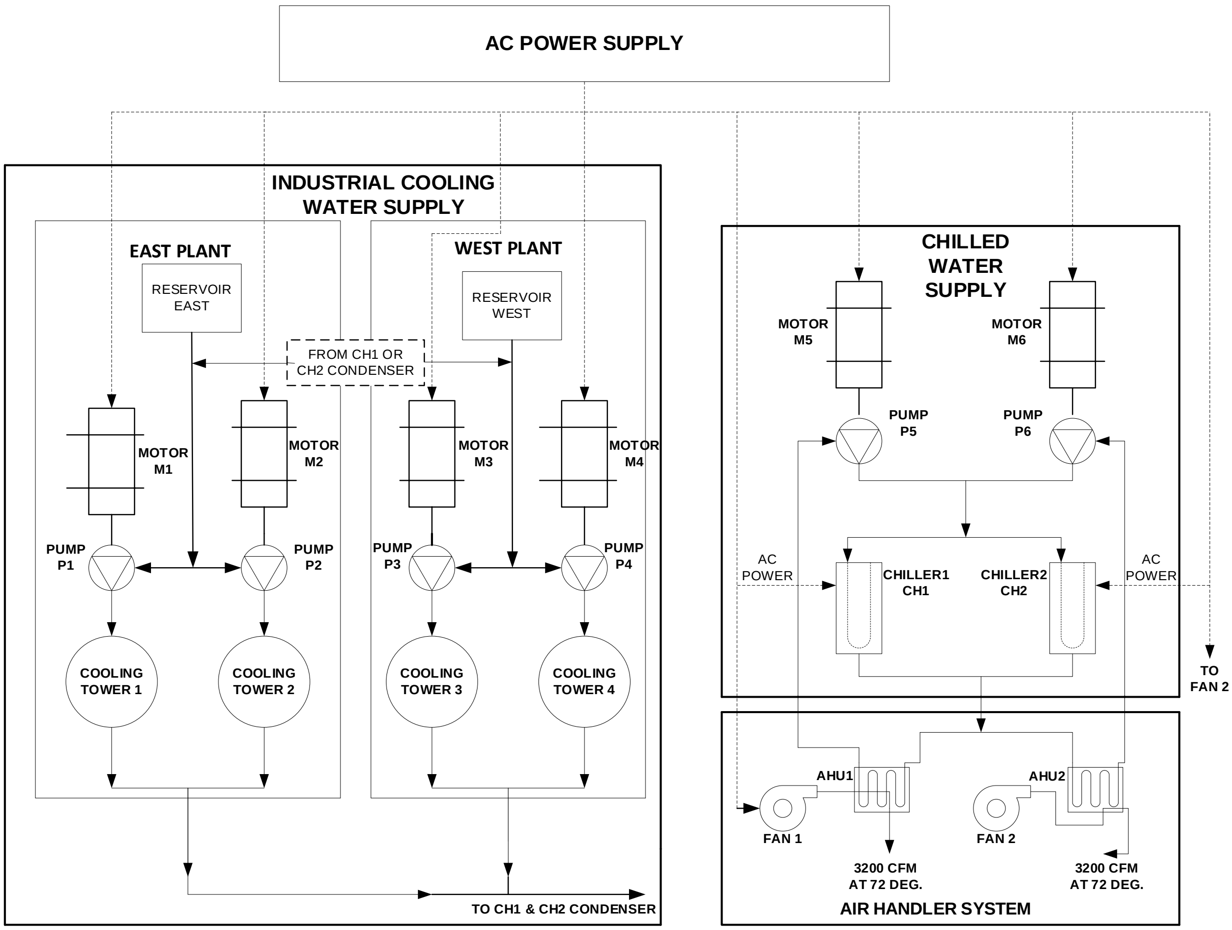
Figure 6-6 Functional Block Diagram of the Sub-Systems



6-2.2.12.6 Reliability Diagram.

The RBD of the same system is shown in Figure 6-7. It is used to illustrate the relationship of all the functions of a system or functional group. All the redundant components should be shown. This diagram should also indicate how many of the redundant components are required for the whole system to be operational. In other words, it should be stated that there may be four pumps but only two are required to accomplish the mission.

Figure 6-7 Reliability Block Diagram



6-2.2.12.7 Reliability Block Diagram Figure 6-7 Case.

In this case: one cooling tower is required from either the East or West Plant Industrial Cooling Water Supply. Either the East Plant or the West Plant is sufficient enough with one cooling tower operational for mission success.

6-2.2.12.8 Reliability Block Diagram Figure 6-7 Chilled Water and Air Handling System.

Within the Chilled Water Supply and the Air Handling System, one pump, one chiller, and one air handling unit is required to supply enough air flow and heat exchange (cooling) to the room.

6-2.2.12.9 Reliability Block Diagram Figure 6-7 AC Power Supply.

The AC Power Supply is not shown broken down for clarity reasons. This system should also be broken down similar to the “Mechanical Systems” in the HVAC. When conducting the HVAC analysis, the AC power supply should be referenced to for possible failure mechanisms.

6-2.2.12.10 Reliability Block Diagram Figure 6-7 Blocks.

The example shown provides symbols for components, but "blocks" clearly labeled are all that is necessary to be effective. There are numerous software programs available to aid in the construction of these diagrams.

6-2.2.12.11 Entering Reliability Block Diagram Information into FMEA Sheet.

From the reliability or functional block diagram, each system, component, part number and name under analysis can now be entered in the corresponding columns of the FMEA sheet (Table 6-1, DA Form 7610). Important: The FMEA should be filled out in a column-by-column manner. Never go across the sheet. Start by filling in all the item numbers and the item names/functions before identifying the failure modes. Using this method will allow the team to stay focused and consistent when assigning inputs into each category. This should be repeated across the worksheet.

6-2.2.12.12 Entering Reliability Block Diagram Information into FMEA Sheet Exception.

The only exception to this rule is when it comes time to assign item numbers for failure modes/mechanisms. Each failure mode/mechanism identified should have its own unique number that can associate it to the component. For example, if the component number is 100 then a number assigned to the mechanism should be 100.1 or 100.01 depending on how many failure modes/mechanisms are possible for the item. This is shown in Table 6-2.

6-2.2.12.13 HVAC System Components.

The components that make up the HVAC system in a typical facility are AC power; industrial cooling water; chilled water supply; and, air handling/heat exchanger.

6-2.2.12.14 Industrial Cooling Water Sample FMEA Worksheet.

A sample FMEA worksheet for just the industrial cooling water is presented in Table 6-1 to indicate the flow of the process using DA Form 7610, Failure Modes and Effects Analysis.

Table 6-1 Example of DA Form 7610 (AUG 2006), FMEA Worksheet Flow (One Column at a Time)

FAILURE MODES AND EFFECTS ANALYSIS (FMEA) For use of this form, see TM 5-698-4; the proponent agency is USACE.

SYSTEM: Mechanical System — DATE (YYYYMMDD): 20050819

PART NUMBER: Industrial Water Supply — SHEET: 1 of 1

REFERENCE DRAWINGS: — COMPLIED BY: AAA

MISSION: Provided Temperature Control to Room — APPROVED BY: BBB

ITEM NUMBER	ITEM/FUNC-TIONAL ID	POTENTIAL FAILURE MODES	FAILURE MECHANISM	FAILURE EFFECTS			DETECTION METHOD	COMPEN-SATING PROVSION	SEVERITY CLASS	REMARKS
				LOCAL EFFECTS	NEXT HIGHER LEVEL	END EFFECTS				
100.0	Ind cool water /supply water to condenser at 75° F & 1000GPM	Provide water greater than 75° F	Cooling tower malfunction, pump degraded, fan will not start							
100.1		Provide water less than 75° F	Fan will not turn off							
100.2		Provide water less than 1000GPM	Degraded pump							
100.3		Provide no water	Broken pipe							
100.4			Blockage in pipe or pump failure							

6-2.3 Failure Mode Identification.

The failure mode is the manner that a failure is observed in a function, subsystem, or component. There are many modes a component or system may fail. Failure modes of concern depend on the specific component, system, environment, and history of failures in similar systems. All probable independent failure modes for each item should be identified.

6-2.3.1 Conditions to be Examined.

To assure that a complete analysis has been performed, each component failure mode and/or output function should be examined for the following conditions:

- Failure to operate at the proper time
- Intermittent operation
- Failure to stop operating at the proper time
- Loss of output
- Degraded output or reduced operational capability

6-2.3.2 Functional Approach of Analyzing System.

The example used in Table 6-6 is a functional approach of analyzing the upper system level's ability to perform its intended function. The systems were identified in the functional block diagram as: industrial cooling water supply; chilled water system; air handling system; and the AC power supply. All failure modes of specific components are not analyzed. Only the system's ability to perform a function is evaluated. As the analysis steps down a level, a specific component can be identified and then a failure mechanism(s) associated with the component can be analyzed as is shown in Table 6-7.

6-2.3.3 Failure Mode Cause or Failure Mechanism.

The cause or failure mechanism of a failure mode is the physical or chemical processes that cause an item to fail. It is important to note that more than one failure cause is possible for any given failure mode. All causes should be identified including human induced causes. These can occur more frequently when initiating a redundant system upon a failure of the primary system. When analyzing the cause of each failure mode one should be careful not to over analyze why a part failed. For example, failure mode-bearing seized:

(1) Why did it seize? – Contamination was in the bearing.

(2) Why was there contamination? – Seal was cracked.

(3) Why was the seal cracked? – Scheduled PM could not be completed.

(4) Why was seal not replaced? – Because there were none in stock.

6-2.3.4 Root Cause.

The root cause should be the "seal was cracked". By analyzing further, the cause can be chased "out of bounds". The analysts must use their judgment to decide how far to investigate root causes while considering economical constraints and probability of failure vs mission criticality and acceptable risks.

6-2.4 Failure Effects Analysis.

A failure effects analysis is performed on each item of the RBD. The consequence of each failure mode on item operation, and the next higher levels in the block diagram should be identified and recorded. The failure under consideration may affect several indenture levels in addition to the indenture level under analysis. Therefore, local, next higher and end effects are analyzed. Failure effects must also consider the mission objectives, maintenance requirements and system/personnel safety.

6-2.4.1 Failure Effect Levels.

Example failure effect levels are shown in Table 6-3 and are defined as follows:

(1) Local effects are those effects that result specifically from the failure mode of the item in the indenture level under consideration. Local effects are described to provide a basis for evaluating compensating provisions and recommending corrective actions. The local effect can be the failure mode itself.

(2) Next higher-level effects are those effects which concentrate on the effect of a particular failure mode has on the operation and function of items in the next higher indenture level.

(3) End effects are the effects of the assumed failure on the operation, function and/or status of the system.

6-2.4.2 Item Failures.

Example end or system level effects of item failures are also shown in Table 6-3 and generally fall within one of the following categories:

(1) System failure where the failed item has a catastrophic effect on the operation of the system.

(2) Degraded operation where the failed item has an effect on the operation of the system, but the system's mission can still be accomplished.

(3) No immediate effect where the failed item causes no immediate effects on the system operation.

6-2.4.3 Assigning the Effect.

Try to be specific when assigning the effect. The above items are just categories and are not intended to be the only input for "end effect". Detailed effects will provide the analyst the most useful information later in the analysis.

6-2.4.4 System Level Failures.

Failures (shown in Table 6-3) at the system level are those failures which hinder the performance or actual completion of the specified mission. Failures at each indenture level is defined below.

(1) A major system failure would be failure in the main mission of the facility. A failure at the major system level would be defined as the inability to command, control, & communicate.

(2) A system failure of a mechanical system. A failure at the system level would be defined as the inability of the mechanical system to cool the facility to within a minimally acceptable temperature range allowed for the computers.

(3) A subsystem failure would be failure of the industrial cooling water. A failure at the subsystem level would be defined as the inability to provide cooling water to the facility.

(4) A component failure would be failure of a chiller. A failure at the system component level could be defined as the inability of the chiller to provide chilled water.

(5) A sub-component failure would be the failure of a condenser. A failure at the sub-component level would be defined as the inability of the condenser to remove heat from the water supply.

6-2.4.5 Typical Entries into the Failure Effects Categories.

Table 6-3 provides an example of typical entries into the failure effects categories. Remember to be as specific as necessary so that anyone who reads this will be able to decipher what the effects are without asking questions. Note the progression of one column at a time.

Table 6-3 Example of DA Form 7610 (AUG 2006), FMEA Progression

FAILURE MODES AND EFFECTS ANALYSIS (FMEA)

For use of this form, see TM 5-698-4; the proponent agency is USACE.

SYSTEM: Mechanical System | DATE (YYYYMMDD): 20050819

PART NUMBER: Industrial Water Supply | SHEET: 1 of 1

REFERENCE DRAWINGS: | COMPLIED BY: AAA

MISSION: Provided Temperature Control to Room | APPROVED BY: BBB

ITEM NUMBER	ITEM/FUNC-TIONAL ID	POTENTIAL FAILURE MODES	FAILURE MECHANISM	FAILURE EFFECTS			DETECTION METHOD	COMPEN-SATING PROVSION	SEVERITY CLASS	REMARKS
				LOCAL EFFECTS	NEXT HIGHER LEVEL	END EFFECTS				
100.0	Ind cool water /supply water to condenser at 75° F & 1000GPM	Provide water greater than 75° F	Cooling tower malfunction, pump degraded, fan will not start	The required amount of heat is not removed from water	Condenser not efficient, Chiller will use more energy $$	Air temp may rise but not significant				
100.1		Provide water less than 75° F	Fan will not turn off	Too much cooling will take place	Chiller will be less efficient and use more energy	No effect to air temp				
100.2		Provide water less than 1000GPM	Degraded pump	Pump will not be able to provide enough flow or pressure	Condenser not efficient, Chiller will use more energy	Air temp may rise but not significant				
100.3		Provide no water	Broken pipe	Excess water consumption, isolation actions will be required	Condenser in chiller will not function, Chiller will overheat	Air temp will rise above maximum allowed mission				
100.4			Blockage in pipe or pump failure	No water will be provided through the system	Condenser in chiller will not function, Chiller will overheat	Air temp will rise above maximum allowed mission				

6-2.5 Failure Detection Methods.

The FMEA identifies the methods by which occurrence of failure is detected by the system operator. Visual or audible warnings devices and automatic sensing devices, such as a SCADA system, are examples of failure detection means. Any other evidence to the system operator that a system has failed should also be identified in the FMEA. If no indication exists, it is important to determine if the failure will jeopardize the system mission or safety. If the undetected failure does not jeopardize the mission objective or safety of personnel and allows the system to remain operational a second failure situation should be explored to determine whether an indication will be evident to the operator or maintenance technician.

6-2.5.1 Failure Detection Methods – Indications.

These indications can be described as follows:

(1) A normal indication is an indication to the operator that the system is operating normally.

(2) An abnormal indication is an indication to the operator that the system has malfunctioned or failed. (alarm-chiller overheated)

(3) An incorrect indication is an erroneous indication to the operator that a malfunction has occurred when there is no fault. Conversely, an indication that the system is operating normally when, in fact, there is a failure.

6-2.5.2 Periodic Testing.

Periodic testing of stand-by equipment would be one method used to detect a hidden failure of the equipment. This testing helps to assure that the stand-by equipment will be operational at the inopportune time the primary equipment fails. The ability to detect a failure to reduce the overall effect will influence the severity of the failure. If the detection method does not reduce the overall effect, then the severity will not be influenced. The analysts should explore an alternative method for detection if this is the case.

6-2.5.3 Failure Mode Detection Prior to Occurring.

Typically, if the failure mode can be detected prior to occurring, the operator can prevent further damage to the system or take some other form of action to minimize the effect. An "over-temperature" alarm for a compressor would be an example. If the compressor had a loss of lubrication and was overheating, the alarm/SCADA would shut that chiller down prior to seizure. If the compressor were allowed to run to seizure, costly damage would occur, and the system would not be able to function.

6-2.6 Compensating Provisions.

Compensating provisions are actions that an operator can take to negate or minimize the effect of a failure on the system. Any compensating provision built into the system that can nullify or minimize the effects of a malfunction or failure must be identified.

6-2.6.1 Examples of Design Compensating Provisions.

Examples of design compensating provisions are:

(1) Redundant item that allows continued and safe operation.

(2) Safety devices such as monitors or alarm systems that permit effective operation or limit damage.

(3) Automatic self-compensating devices that can increase performance as unit degrades such as variable speed drives for a pump.

(4) Operator action such as a manual over-ride.

6-2.6.2 Multiple Compensating Provisions.

When multiple compensating provisions exist, the compensating provision which best satisfies the fault indication observed by the operator must be highlighted. The consequences of the operator taking the wrong action in response to an abnormal indication should also be considered and the effects of this action should be recorded in the remarks column of the worksheet.

6-2.6.3 Ability to Detect a Failure and React.

To be able to detect a failure and react correctly can be extremely critical to the availability of the system. For example, if a failure is detected in the primary pump (no flow) then the operator/technician must know what buttons and/or valves to actuate to bring in the backup pump. If by chance the operator/technician inadvertently actuates the wrong valve, there may be undesirable consequences because of their actions. This is a basic example but should be considered in the analysis on all failure modes.

6-2.7 Severity Rankings.

After all failure modes and their effects on the system have been documented in the FMEA the team now needs to provide a ranking of the effect on the mission for each failure mode. Make sure that prior to assigning these rankings that all prior columns of the FMEA are filled in. This will help the analyst in assigning each severity ranking relative to each other. This ranking will be used later in the CA to establish relative "severity" rankings of all potential failure modes.

6-2.7.1 Evaluating Item Failure Mode.

Each item failure mode is evaluated in terms of the worst potential consequences upon the system level which may result from item failure. A severity classification must be assigned to each system level effect. A lower ranking indicates a less severe failure effect. A higher ranking indicates a more severe failure effect. Severity classifications provide a qualitative measure of the worst potential consequences resulting from an item failure.

6-2.7.2 Assigning Severity Classification.

A severity classification is assigned to each identified failure mode and each item analyzed in accordance with the categories in Table 6-4.

Table 6-4 Severity Ranking Table

Ranking	Effect	Comment
1	None	No reason to expect failure to have any effect on Safety, Health, Environment or Mission.
2	Very Low	Minor disruption to facility function. Repair to failure can be accomplished during trouble call.
3	Low	Minor disruption to facility function. Repair to failure may be **longer** than trouble call but does not delay mission.
4	Low to Moderate	Moderate disruption to facility function. Some portion of Mission may need to be reworked or process delayed.
5	Moderate	Moderate disruption to facility function **100%** of Mission may need to be reworked or process **delayed**.
6	Moderate to High	Moderate disruption to facility function. Some portion of Mission is lost. **Moderate** delay in restoring function.
7	High	High disruption to facility function. Some portion of Mission is lost. **Significant** delay in restoring function.
8	Very High	High disruption to facility function. **All** of Mission is lost. Significant delay in restoring function
9	Hazard	Potential Safety, Health, or Environmental issue. Failure will occur with warning
10	Extreme Hazard	Potential Safety, Health, or Environmental issue. Failure will occur without warning

6-2.7.3 Items with High Severity.

Although this chart can be used for a qualitative (without data) analysis or a quantitative (with data) analysis, some facilities may choose the following categories to assign another familiar format of severity classifications for the quantitative CA, Table 6-5. These categories are used to "flag" the analysts to items with high severity.

6-2.7.4 Items with High Severity.

Although this chart can be used for a qualitative (without data) analysis or a quantitative (with data) analysis, some facilities may choose the following categories to assign another familiar format of severity classifications for the quantitative CA, Table 6-5. These categories are used to "flag" the analysts to items with high severity.

Table 6-5 Severity Classification for Qualitative CA

Category	Effect	Comment
I	Minor	A failure not serious enough to cause injury, property damage or system damage, but which will result in unscheduled maintenance or repair.
II	Marginal	A failure which may cause minor injury, minor property damage, or minor system damage which will result in delay or loss of availability or mission degradation.
III	Critical	A failure which may cause severe injury or major system damage which will result in mission loss. A significant delay in restoring function to the system will occur.
IV	Catastrophic	A failure which may cause death or lack of ability to carry out mission without warning (power failure, over-heating).

6-2.7.5 Exception when using Qualitative Analysis.

Do not use this method to categorize severity in a qualitative analysis. The qualitative analysis requires an equal scale (such as 1 through 10, or 1 through 5) for both severity and occurrence. If they are not equal, one category will hold more "weight" than the other in the CA.

6-2.7.6 System Level vs Component Level Severity.

A FMEA at the component level will have high severity rankings because there is no redundancy at that level. At the system level, however, the severity may decrease because when there is loss of one component in the system, there is a backup in place. The mission of the system at this indenture level is not compromised assuming the backup component or system is functional.

6-2.7.7 Special Remarks or Components.

If there are any special remarks or comments that need to be recorded should be included in the "REMARKS" category at the end of the FMEA. This should include specific hazards or explanations of the failure mode effects or other categories associated with it.

6-2.7.8 Example of a Completed FMEA.

An example of a completed functional FMEA of only the Industrial Cooling Water Supply is provided in Table 6-6. Hardware FMEA’s on all the systems are shown in Table 6-7. Notice that the functional FMEA did not include any redundancy as a consideration when assigning the effects.

6-2.8 Results of FMEA.

The team should now review the information on the FMEA to determine if any changes should be made. It is not uncommon for people to think of more failure modes or detection methods on items during the process. Make these changes or additions prior to proceeding on to the CA.

6-2.8.1 Critical Analysis Foundation.

Once all the information has been entered into the FMEA, the foundation for the CA has been established. The FMEA sheet will be referenced while creating the CA. Due to the amount of information on the FMEA, it is not feasible to include all of it on the CA.

6-2.8.2 FMEA on Subsystems Example.

In this example, a FMEA should also be conducted on the remaining systems of the HVAC System: the chilled water supply; the air handling system; and the AC power supply system.

6-2.8.3 Applying Critical Analysis to Example.

Once they are completed the steps discussed in the next paragraph for the CA should be applied to complete the FMECA process.

Table 6-6 Example of DA Form 7610 (AUG 2006), Completed FMEA (functional) for Industrial Water Supply

FAILURE MODES AND EFFECTS ANALYSIS (FMEA)

				LOCAL EFFECTS	NEXT HIGHER LEVEL	END EFFECTS				
130.2		Fan failure	Motor winding open, No supply voltage to motor	Low evaporative cooling will take place	Lower condenser efficiency. Chiller uses more energy	Slight rise in air temp. No severe effect. Mission compromised	Flow sensor	Redundant system	4	
210.0	Pump #5/ Transport Industrial water supply at 960GPM	Degraded operation – produce water at rate less than 960GPM	Impeller degraded, gasket leak, motor degraded	Pump can-not produce required rate of water	Chiller needs to decrease water temp to satisfy air handler	No effect	Flow sensor	Redundant system	4	
210.1		Produce no water flow	Broken coupling, leak on suction line, motor inoperable	Damage to motor or pump shafts	Chiller will not be able to remove heat from water	No air-cooling Room temp above max. Mission failure.	Flow sensor	Redundant system	5	
220.0	Chiller/ Remove heat(10°F) from chilled water supply	Degraded operation – remove less than 10°F	Refrigerant leak degraded compressor, tube leak, dirty coil	Compressor will cycle on frequently/ chiller will be less efficient	Air handling unit will run continuously trying to meet demand	Air temp will rise but not above maximum allowed.	Temp sensor	Redundant chiller	5	
200.1		Remove no heat	Compressor seizure, motor failure	Chiller will be unable to function	Air handling unit will run continuously trying to meet demand	Minimal air cooling-temp rise above max. Mission failure	Temp sensor	Redundant chiller	7	This failure is costly and time consuming to repair.

6-3 CRITICALITY ANALYSIS (CA) METHODOLOGY.

6-3.1 Methodology – Moving into Criticality Analysis.

The FMECA is composed of two separate analyses, the FMEA and the CA. The FMEA must be completed prior to performing the CA. It will provide the added benefit of showing the analysts a quantitative ranking of system and/or subsystem failure modes. The CA allows the analysts to identify reliability and severity related concerns with particular components or systems. Even though this analysis can be accomplished with or without failure data, there are differences on each approach which are discussed in the following paragraphs. Figure 6-8 shows the process for conducting a FMECA using quantitative and qualitative means.

6-3.2 Criticality Analysis.

The CA provides relative measures of significance of the effects of a failure mode, as well as the significance of an entire piece of equipment or system, on safe, successful operation and mission requirements. In essence, it is a tool that ranks the significance of each potential failure for each component in the system's design based on a failure rate and a severity ranking. This tool will be used to prioritize and minimize the effects of critical failures early in the design.

6-3.2.1 Quantitative or Qualitative Approach.

The CA can be performed using either a quantitative or a qualitative approach. Tables 6-8 and 6-9 identify the categories for entry into their respective CA using DA Forms 7611 and 7612, respectively. Availability of part configuration and failure rate data will determine the analysis approach. As a general rule, use Table 6-8 when actual component data is available and use Table 6-9 when no actual component data or only generic component data is available.

6-3.2.2 Levels of Data.

Figure 6-9 is a representation of the different levels of data that a facility may have. Depending on the level of data available, the analysts must determine which approach they will use for the CA. The areas where there are overlaps between quantitative and qualitative, the analyst will have to assess what the expectations are for conducting the analysis to determine which approach will be used.

Figure 6-8 FMECA Flow

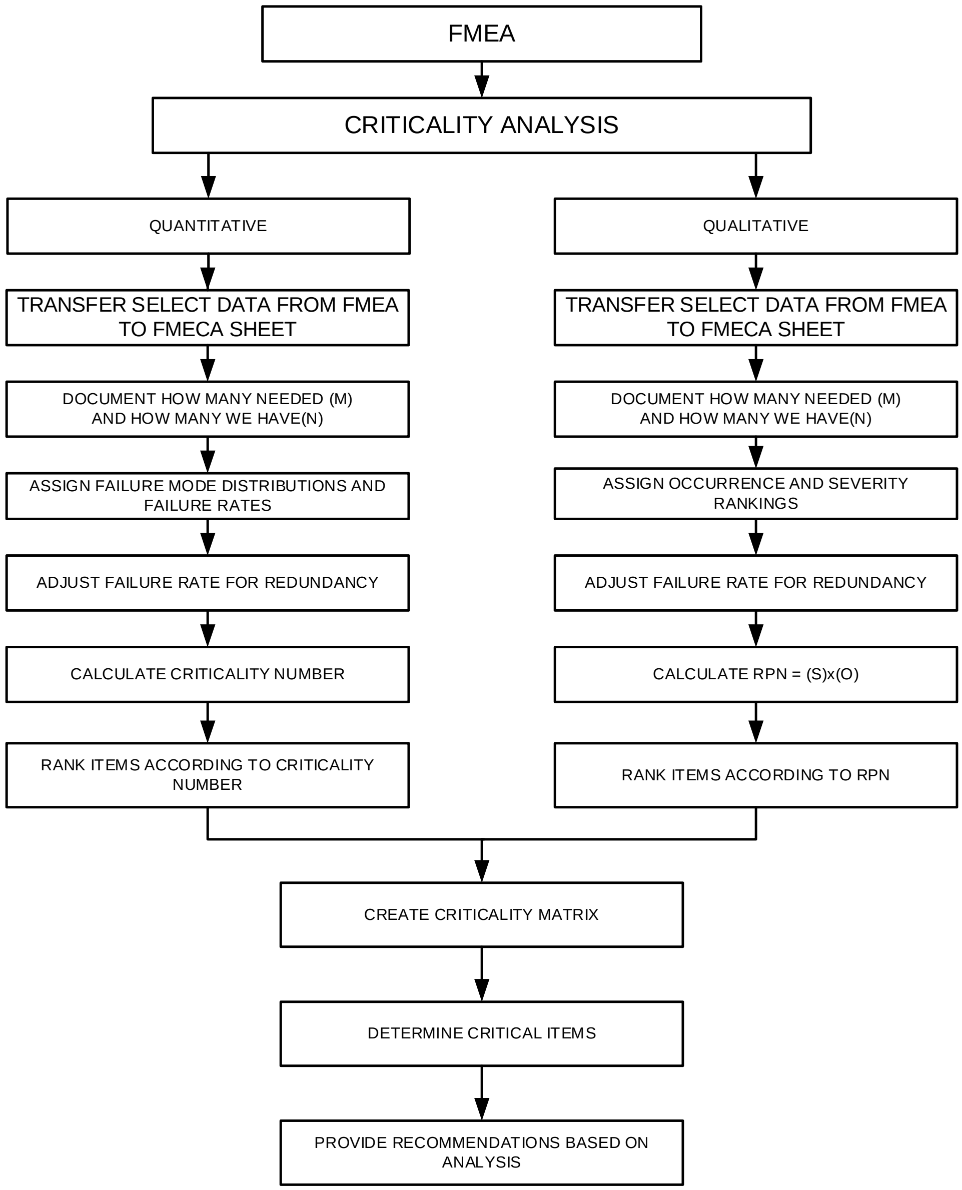

Table 6-8 Example of DA Form 7611 (AUG 2006), FMECA Worksheet – Quantitative

QUANTITATIVE FAILURE MODES, EFFECTS AND CRITICALITY ANALYSIS (FMECA)

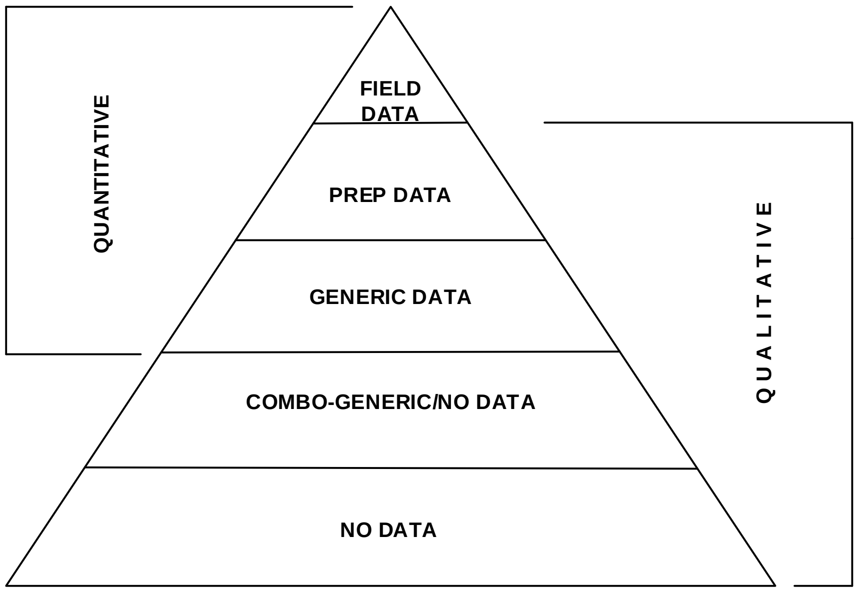
					OCCUR	SEVER-ITY	RPN (O)X(S)	HAVE (N)	NEED (M)	OCCUR	SEVER-ITY	RPN (O)X(S)	

Figure 6-9 Data Triangle



(1) Quantitative method is used when failure rates, failure modes, failure mode ratios, and failure effects probabilities are known. These variables are used to calculate a "criticality number" to be used to prioritize items of concern. This is used typically after the design has been completed when confident data on the system can be collected. However, in certain instances data may be available from other sources. This type of analysis will provide concrete figures which can be used for other types of analyses including FTA and RCM program.

(2) Qualitative method is used when no known failure rates and failure modes are available. The criticality or risk associated with each failure is subjectively classified by the team members. The use of a subjective ranking system is applied to the severity, and occurrence of the failures. This method will provide a relative ranking of item failure mode's effects for identifying areas of concern and for initiating other analyses such as RCM, fault tree, and logistics. As the system matures it is recommended that data be collected to enhance the analysis through a quantitative method.

6-3.3 Transfer Select Data from FMEA.

The information from the FMEA sheet that will be used in the FMECA worksheet will aid in developing the CA. Given the fact that not all the information will be shown on the FMECA sheet, does not mean that the excluded information will be ignored. The FMEA sheet will still be referenced frequently for data.

(1) All of the information on the FMEA can sometimes be difficult to read. This can be a major contributing factor to not include all information. This is just a suggestion that may or may not be desirable at every facility. In fact, some facilities may choose to add more

categories. Keep in mind, this UFC is just a guide and is meant to be flexible to achieve the objective of the analysis.

(2) Once it is determined which type of analysis will be conducted, qualitative or quantitative, the appropriate FMECA worksheet can be chosen. Examples of FMECA sheets for the two different types of analyses are provided in Tables 6-8 and 6-9.

(3) The following categories will be transferred from the FMEA sheet:

- Item Number
- Item/Functional ID
- Failure Modes
- Failure Mechanisms
- Failure Effects (qualitative only due to space limitations)
- Severity Classification/Ranking

(4) All other categories from the FMEA will be referenced during the CA.

6-3.4 Quantitative Criticality Analysis.

Once it is determined that sufficient failure rate data and failure mode distributions are available, a criticality worksheet for conducting a quantitative analysis that looks like Table 6-8 will be used. Note that some of the categories are derived from the FMEA sheet. The additional categories will be used to calculate the criticality number. Traditional methods will be used to derive this number except where redundant components are used, which is typical with a C5ISR facility. The required number of components necessary (M) to perform the function and the amount of components that are redundant (N) should be recorded. The effect of redundancy will be discussed in paragraph 6-3.5. A description of each category and variable used in the CA is listed below.

6-3.4.1 Beta.

Beta (β) is defined as the failure effect probability and is used to quantify the described failure effect for each failure mode indicated in the FMECA. The beta (β) values represent the conditional probability or likelihood that the described failure effect will result in the identified criticality classification, given that the failure mode occurs. The β values represent the analyst's best judgment as to the likelihood that the loss or end effect will occur. For most items the failure effect probability (β) will be one. An example would be if the generator engine shuts down (failure mode), it can be confidently stated that 100% of the time the effect will be loss of power.

(1) However, if the failure mode was that the generator produces low voltage (brown out condition), the end effect could vary. Effects such as degraded motor function or motor

burns up condition on various pieces of equipment could occur. Therefore, there are two possible effects for the generator's failure mode low voltage: degraded motor function and motor burns up.

(2) Now the analyst must make a judgment call of what percentage of time or probability each effect may occur. If the analyst determined that 80% of the time the motor is degraded, then beta (β) for that effect would be (.80). This would leave 20% of the time the effect would be motor burns up and would be assigned a beta (β) of (.20).

6-3.4.2 Alpha.

Alpha (α) is the probability, expressed as a decimal fraction, that the given part or item will fail in the identified mode. If all the potential failure modes for a device are considered, the sum of the alphas will equal one. Determining alpha is done as a two-part process for each component being analyzed. First, the failure modes are determined and secondly, modal probabilities are assigned.

(1) Modal failures represent the different ways a given part is known, or has been "observed", to fail. It is important to make the distinction that a failure mode is an "observed" or "external" effect so as not to confuse failure mode with failure mechanism. A failure mechanism is a physical or chemical process flaw caused by design defects, quality defects, part misapplication, wear out, or other processes. It describes the basic reason for failure or the physical process by which deterioration proceeds to failure.

(2) For example, when there is no air flow from an air handling unit caused by a broken belt. In this example, the failure mode would be the "no air flow from air handling unit" while the failure mechanism would be the "broken belt". Another failure mode could be low air flow and the mechanism would be belt slippage (loose belt).

(3) Once common part failure modes have been identified, modal probabilities (α) are assigned to each failure mode. This number represents the percentage of time, in decimal format, that the device is expected to fail in that given mode. This number is given as a percentage of the total observed failures. Using the air handler example, the probabilities of occurrence for each failure mode are shown in Table 6-10.

Table 6-10 Failure Mode Ratio (α)

Part Failure Modes	Failure Mode Ratio (α)
Blows to little air	0.55 or 55%
Blows too much air	0.05 or 5%
Blows no air	0.40 or 40%
The sum of modal probabilities is	1.00 or 100%

Note: These are hypothetical failure mode ratios.

(4) Alpha and beta are commonly confused. It is best to memorize that alpha is the failure mode ratio, the percentage of time how or in what manner an item is going to fail. However, beta is the conditional probability of a failure effect occurring given a specific failure mode; when a failure mode occurs, what percentage of time is this going to be the end effect. Beta typically is assigned 1 to only consider the worst possible end effect as a result of a failure mode.

6-3.4.3 Failure Rate.

The failure rate (λp) of an item is the ratio between the numbers of failures per unit of time and is typically expressed in failures per million hours or failures/10^6 hours. Although failure data compiled from actual field test are recommended, other sources for failure information are available for use until actual field data can be obtained.

(1) When analyzing system failure rates where redundant like components are used to accomplish a mission, the failure rate must be adjusted to reflect the “system failure rate”. This is explained in paragraph 6-3.5. When entering in the failure rate on the FMECA sheet, in parentheses it should identified that the failure rate is the single item component failure rate or the failure rate of the redundant system. The example in this chapter provides an example of how to show this. It indicates the single failure rate and the redundant failure rate.

(2) The source of the failure rate should also be noted in this category as well so that anyone who looks at the analysis will know if the data was derived by field data or some other source for reference purposes. This will be important if someone does question the validity of the data.

6-3.4.4 Modal Failure Rate.

The modal failure rate is the fraction of the item’s total failure rate based on the probability of occurrence of that failure mode. The sum of the modal failure rates for an item will equal the total item failure rate providing all part failure modes are accounted for. If there are three different failure modes, then all three failure rates (modal failure rates) will equal the item failure rate. The modal failure rate is given by the equation:

Equation 6-1. Modal Failure Rate

$$\lambda m = \alpha \, \lambda p$$

Where:
λm = the modal failure rate
α = the probability of occurrence of the failure mode (failure mode ratio)
λp = the item failure rate

6-3.4.5 Failure Mode (Modal) Criticality Number.

The failure mode criticality number is a relative measure of the frequency of a failure mode. In essence it is a mathematical means to provide a number to rank importance based on its failure rate. The equation used to calculate this number is as follows:

Equation 6-2. Failure Mode Criticality Number

$$C_m = (\beta \alpha \lambda_p t)$$

Where:
Cm = Failure mode criticality number
β = Conditional probability of the current failure mode's failure effect
α = Failure mode ratio
λ_p *= Item failure rate*
t = Duration of applicable mission phase (expressed in hours or operating cycles)

(1) This number is derived from the modal failure rate which was explained in paragraph 6-3.4.4. It also takes into consideration of the operating time that the equipment or system is running in hours or operating cycles.

(2) Below is an example of a centrifugal pump used for condenser water circulation. The failure rates were derived from the Non-electric Parts Reliability Data-95 (NPRD-95) publication and the failure mode probability was derived from the Failure Mode/Mechanism Distribution-97 (FMD-97) publication. The failure effect probability (β) will equal 1.

Failure mode criticality:

Component type: Centrifugal pump condenser circulation

Part number: P1

Failure rate (λ_p): 12.058 failures per million hours
Source: NPRD-95

Failure Mode probability (α):
- No output (0.29)
- Degraded (0.71)

Source: FMD-97

Time (t): 1 hour

Failure effect probability (β): 1

Failure mode criticality (C_m):

$C_m = \beta\ \alpha\ \lambda_p$ t

C_m (No output) = (1 x .29 x 12.058 x 1)

C_m (No output) = 3.5 x 10^{-6}

C_m (Degraded) = (1 x .71 x 12.058 x 1)

C_m (Degraded) = 8.56 x 10^{-6}

6-3.4.6 Item Criticality Number.

Item criticality number. The item criticality number is a relative measure of the consequences and frequency of an item failure. This number is determined by totaling all the failure mode criticality numbers of an item with the same severity level. The severity level was determined in the FMEA. The equation used to calculate this number is as follows:

Equation 6-3. Item Criticality Number

$$C_r = \sum (C_m)$$

Where:
C_r = Item criticality number
C_m = Failure mode criticality number

(1) If an item has three different failure modes, two of which have a severity classification of 3 and one with a classification of 5, the sum of the two "failure mode criticality numbers" (C_m) with the severity classification of 3 would be one "item criticality number" (C_r). The failure mode with the severity classification of 5 would have an "item criticality number" equal to its "failure mode criticality number".

(2) The example below was used in the failure mode criticality example. Both failure modes for this example have the same severity classification of 3. If the severity classifications were different, then the item criticality numbers would be calculated as separate items. In this case, since there are only two failure modes, the item criticality number for each severity level would equal the failure mode criticality number.

Item criticality:
Component type: Centrifugal pump condenser circulation

Part Number: P1

Failure rate (λ_p): 12.058 failures per million hours
Source: NPRD-95

Failure mode probability (α):
No output (0.29)
Degraded (0.71)
Source: FMD-97

Time (*t*): 1 hour

Failure effect probability (*β*): 1

Item criticality (C_r):

$$C_r = \sum_{n=1}^{j} (\beta \alpha \lambda_p t)_n \quad n = 1,2,3 \ldots j \; or \; C_r = \sum_{n=1}^{j} (C_m)_n$$

$C_r = (1 \times .29 \times 12.058 \times 1) + (1 \times .71 \times 12.058 \times 1)$

$C_r = 12.058$

6-3.5 Effects of Redundancy – Quantitative.

When redundancy is employed to reduce system vulnerability and increase uptime, failure rates need to be adjusted prior to using the preceding formula. This can be accomplished by using formulas from various locations depending on the application. Below are a few examples from the Reliability Toolkit: Commercial Practices Edition, page 161, which is based on an exponential distribution of failure (constant time between failures).

6-3.5.1 Failure Rate with Repairs.

Example 1: For a redundant system where all units are active "on-line" with equal failure rates and (n-q) out of n required for success. This equation takes repair time into consideration.

Equation 6-4. Failure Rate with Repairs

$$\lambda_{(n-q)/n} = \frac{n!\,(\lambda)^{q+1}}{(n-q-1)!\,(\mu)^{q}}, with\ repairs$$

Where:
n = number of active online units; n! is n factorial.
λ = failure rate for on-line unit (failures/hour)
q = number of online units that can fail without system failure
μ = repair rate (μ=1/MTTR; where MTTR is the mean time to repair (hour).

6-3.5.2 Failure Rate with Repairs Example.

Therefore, if a system has five active units, each with a failure rate of 220 f/10^6 hours, and only three are required for successful operation. If one unit fails, it takes an average of three hours to repair it to an active state. What is the effective failure rate of this configuration?

6-3.5.3 Failure Rate with Repairs Example Inputs.

Substituting the following values into the equation:

$$n = 5,\ q = 2,\ \mu = 1/3$$

$$\lambda(5-2) / 5 = \lambda 3 / 5$$

$$\lambda_{3/5} = \frac{5!\,(220x10^{-6})^3}{(5-2-1)!\,(1/3)^2} = 5.75x10^{-9} failures/hour$$

$$\lambda_{3/5} = .00575 \text{ failures}/10^6 \text{ hours}$$

6-3.5.4 Determining Criticality Number of Example.

Then this new failure rate ($\lambda_{3/5}$) would be substituted for (λ_p) to determine criticality numbers of the system.

6-3.5.5 Failure Rate without Repairs Example.

Example 2: If by chance in the above sample, the unit was never repaired then the formula to use would be:

Equation 6-5. Failure Rate without Repairs

$$\lambda_{(n-q)/n} = \frac{\lambda}{\sum_{i=n-q}^{n} \frac{1}{i}}, without\ repairs$$

Where:
n = number of active online units; n! is n factorial
λ = failure rate for on-line unit (failures/hour)
q = number of online units that can fail without system failure

6-3.5.6 Failure Rate without Repairs Example Inputs.

Using the same problem from above and substituting into this formula

$$\lambda_{3/5} = \frac{200x10^{-6}}{\left(\frac{1}{3}\right) + \left(\frac{1}{4}\right) + \frac{1}{5}} = \frac{220x10^{-6}}{\frac{47}{60}}$$

$\lambda_{3/5} \approx 280x10^{-6}$ *failures/hour*

$\lambda_{3/5} \approx 280$ *failures/*10^6 *hours*

6-3.5.7 Failure Rate with Repairs vs without Repairs.

A noticeable increase in failure rate because the components are not repaired.

6-3.5.8 Other Failure Rate Formulas.

Other useful failure rate formulas used for redundant systems are as follows:

6-3.5.8.1 Active Units and Standby Units.

Example 3 & 4: One standby off-line unit with n active on-line units required for success. Off-line spare assumed to have a failure rate of zero. On-line units have equal failure rates.

Equation 6-6. Example 3

$$\lambda_{\frac{n}{n+1}} = \frac{n[n\lambda + (1-P)\mu]\lambda}{\mu + n(P+1)\lambda}, with\ repair$$

Equation 6-7. Example 4

$$\lambda_{\frac{n}{n+1}} = \frac{n\lambda}{P+1}, without\ repair$$

Where:
n = number of active online units; n! is n factorial.
λ = failure rate for on-line unit (failures/hour)
q = number of online units that can fail without system failure
μ = repair rate (μ=1/MTTR; where MTTR is the mean time to repair (hr).
P = probability that the switching mechanism will operate properly when needed (P=1 with perfect switching)

6-3.5.8.2 Active Units with Different Failure and Repair Rates.

Example 5 & 6: Two active on-line units with different failure and repair rates. One of two is required for success.

Equation 6-8. Example 5

$$\lambda_{1/2} = \frac{\lambda_A + \lambda_B[(\mu_A + \mu_B) + (\lambda_A + \lambda_B)]}{(\mu_A)(\mu_B) + (\mu_A + \mu_B)(\lambda_A + \lambda_B)}, with\ repair$$

Equation 6-9. Example 6

$$\lambda_{1/2} = \frac{{\lambda_A}^2\lambda_B + {\lambda_B}^2\lambda_A}{{\lambda_A}^2 + {\lambda_B}^2 + \lambda_A\lambda_B}, without\ repair$$

Where:
λ = failure rate for on-line unit (failures/hour)

6-3.5.9 Calculating Criticality Number for Examples 5 and 6.

These new failure rates (λ) should then be placed back in the equation,

$$C_{rc} = \sum_{n=1}^{j} (\beta\alpha\lambda_p t)_n$$

to calculate the new Criticality Number which accounts for redundancy.

6-3.5.10 Additional Redundancy Reference Material.

There is a technical publication that exclusively addresses various redundancy situations that may be of use, Rome Air Development Center, RADC-TR-77-287, A Redundancy Notebook, Rome Laboratory, 1977.

6-3.5.11 Additional Relative Ranking Approach.

If the facility does have failure rate data but does not have failure mode distribution data, a relative ranking can still be achieved, allowing for redundancy, by using the method described in the qualitative analysis, paragraph 6-3.6.

6-3.6 Qualitative Criticality Analysis.

Qualitative analysis will be used when specific part or item failure rates are not available. However, if failure rates are known on some components and not known on others, the failure rate data can be used to support the rankings below. This will provide a relative ranking between all the components. Failure mode ratio and failure mode probability are not used in this analysis. This analysis will allow the analysts the ability to subjectively rank each failure modes level of severity in relationship to its probability of failure. The items of most concern will be identified and evaluated to decrease the negative impact on the mission.

6-3.6.1 Criticality Worksheet.

Once it is determined that a qualitative approach will be used the Criticality worksheet that looks like Table 6-9 will be used. Note that some of the categories are derived from the FMEA sheet. The information from the FMEA should be transferred into the respective columns of the criticality worksheet. The additional categories will be used to support and calculate the Risk Priority Number (RPN), which will be explained in paragraph 6-3.6.7. Adjustments to occurrence rankings to compensate for redundant components within a typical C5ISR facility must be addressed as well and will be discussed in paragraph 6-3.7. Therefore, it is essential that the required amount of components necessary (M) to perform the function and the amount of components that are redundant (N) should be recorded in the respective categories of the criticality worksheet. Table 6-11 is an example of the quantitative FMECA worksheet with redundant components.

6-3.6.2 Occurrence Ranking.

The occurrence ranking is a method used to subjectively assign a failure rate to a piece of equipment or component. Each step in the ranking will correspond to an estimated failure rate based on the analyst's experience with similar equipment used in a similar environment. As mentioned previously, a known failure rate can be cross referenced to an occurrence ranking thereby allowing a complete analysis of a system that does not have failure rate and failure mode information on every item or component. When known failure rate data is used in this type of analysis, it not only adds merit to the ranking for the equipment with failure data, but also adds merit to the occurrence rankings of unknown equipment by providing benchmarks within the ranking scale. These values will establish the qualitative failure probability level for entry into a CA worksheet format. Rates can be hours, days, cycles …etc.

Table 6-11 Example of DA Form 7611 (AUG 2006), Quantitative FMECA with Redundant Components

QUANTITATIVE FAILURE MODES, EFFECTS AND CRITICALITY ANALYSIS (FMECA)

6-3.6.3 Qualitative Occurrence Rankings.

Possible qualitative occurrence rankings (O) are shown in Table 6-12.

Table 6-12 Occurrence Rankings

Ranking	Failure Rate	Comment
1	1/10,000	Remote probability of occurrence; unreasonable to expect failure to occur
2	1/5,000	Very low failure rate. Similar to past design that has had low failure rates for given volume/loads
3	1/2,000	Low Failure rate based on similar design for volume/loads
4	1/1,000	Occasional failure rate. Similar to past design that has similar failure rates for given volume/loads.
5	1/500	Moderate failure rate. Similar to past design having moderate failure rates for given volume/loads.
6	1/200	Moderate to high failure rate. Similar to past design having moderate failure rates for given volume/loads.
7	1/100	High failure rate. Similar to past design having frequent failures that caused problems
8	1/50	High failure rate. Similar to past design having frequent failures that caused problems
9	1/20	Very high failure rate. Almost certain to cause problems
10	1/10+	Very high failure rate. Almost certain to cause problems

6-3.6.4 Severity Ranking.

The severity ranking, as mentioned in paragraph 6-2.7, is also important in determining relative concerns amongst failure modes. The severity of the consequences of the failure effect is evaluated in terms of worst potential consequences upon the system level which may result from item failure. A severity classification must be assigned to each system level effect. A lower ranking indicates a less severe failure effect. A higher ranking indicates a more severe failure effect. Severity classifications provide a qualitative measure of the worst potential consequences resulting from an item failure.

6-3.6.5 Severity Rankings Table.

The severity rankings (S) from Table 6-4 are again shown here in Table 6-13.

Table 6-13 Severity Rankings

Ranking	Effect	Comment
1	None	No reason to expect failure to have any effect on Safety, Health, Environment or Mission
2	Very Low	Minor disruption to facility function. Repair to failure can be accomplished during trouble call
3	Low	Minor disruption to facility function. Repair to failure may be **longer** than trouble call but does not delay mission.

4	Low to Moderate	Moderate disruption to facility function. Some portion of Mission may need to be reworked or process delayed.
Ranking	**Effect**	**Comment**
5	Moderate	Moderate disruption to facility function **100%** of Mission may need to be reworked or process **delayed**.
6	Moderate to High	Moderate disruption to facility function. Some portion of Mission is lost. **Moderate** delay in restoring function.
7	High	High disruption to facility function. Some portion of Mission is lost. **Significant** delay in restoring function.
8	Very High	High disruption to facility function. **All** of Mission is lost. Significant delay in restoring function
9	Hazard	Potential Safety, Health, or Environmental issue. Failure will occur with warning
10	Extreme Hazard	Potential Safety, Health, or Environmental issue. Failure will occur without warning

6-3.6.6 Risk Priority Number.

The Risk Priority Number (RPN) is the product of the Severity (1-10) and the Occurrence (1-10) ranking.

Equation 6-10. Risk Priority Number

$$RPN = (S) \times (O)$$

Where:
RPN = Risk Priority Number
S = Severity Ranking
O = Occurrence Ranking

6-3.6.7 Risk Priority Number – Identify the Concerns or Risks.

The Risk Priority Number is used to rank and identify the concerns or risks associated with the operation due to the design. This number will provide a means to prioritize which components should be evaluated by the team to reduce their calculated risk through some type of corrective action or maintenance efforts. However, when severity is at a high level, immediate corrective action may be given regardless of the resultant RPN.

6-3.6.8 Automotive Industry Action Group Risk Priority Number.

This method was developed by the Automotive Industry Action Group (AIAG) and can be found in the reference manual titled Potential Failure Mode and Effects Analysis – FMEA. However, this \1\ UFC /1/ also considers detection to determine the Risk Priority Number.

Equation 6-11. Risk Priority Number

$$RPN = (S) \times (O) \times (D)$$

Where:
RPN = Risk Priority Number
S = Severity Ranking
O = Occurrence Ranking
D = Detection Ranking

6-3.6.9 Detection Rankings.

Where detection is ranked (1-10), shown in Table 6-14, in a similar fashion as severity and occurrence.

Table 6-14 Detection Rankings

Ranking	Detection	Comment
1	Almost Certain	Current control(s) almost certain to detect failure mode. Reliable controls are known with similar processes.
2	Very High	Very high likelihood current control(s) will detect failure mode.
3	High	High likelihood current control(s) will detect failure mode.
4	Moderately High	Moderately high likelihood current control(s) will detect failure mode.
5	Moderate	Moderate likelihood current control(s) will detect failure mode.
6	Low	Low likelihood current control(s) will detect failure mode.
7	Very Low	Very low likelihood current control(s) will detect failure mode.
8	Remote	Remote likelihood current control(s) will detect failure mode.
9	Very Remote	Ver remote likelihood current control(s) will detect failure mode.
10	Almost Impossible	No known control(s) available to detect failure mode.

6-3.6.10 Excluding Detection.

Detection was not included in the examples because in mission critical facilities, the team considers detection of a failure mode when assigning a severity ranking. They also consider a compensating provision such as redundancy. The end effect is altered due to these two contributing factors, therefore changing the severity of the consequences of this failure by design of the facility.

6-3.6.11 Severity Ranking vs Occurrence Ranking based on System.

Given the scenario that a compressor overheats due to the lack of lubrication, the effects would be "compressor seizes, room temperature rises, and computers malfunction". This would produce a severity ranking of "7" or "8". But due to the ability of the system to detect a problem, shut down the one component, and activate a redundant component in its place, a severity of "2" or "3" may be assigned for the failure mode. Note that it is also possible that the occurrence ranking will also be altered as well due to the redundant system. Even if there was no redundant component the end effect is altered because the ability to detect and shut down the compressor will prevent it from seizing thus saving repair or replacement costs and shortening the duration of down time by minimizing the damage.

6-3.6.12 C5ISR vs Auto Industry Goals.

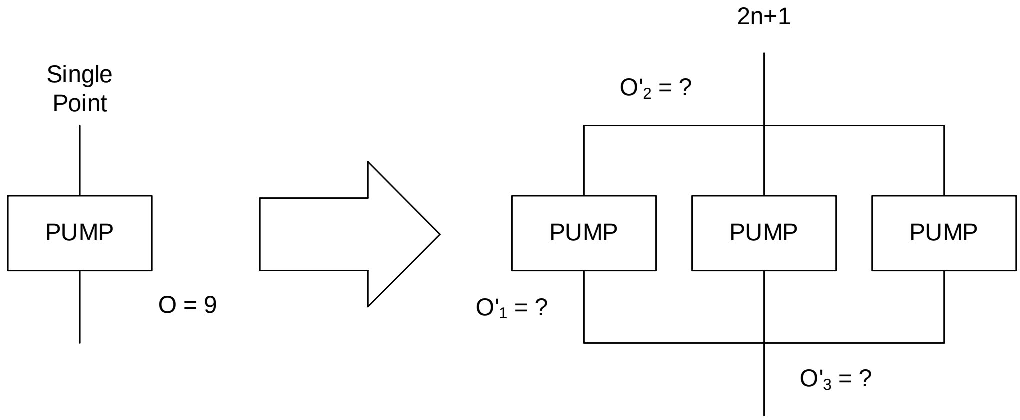
In addition, a C5ISR facility has a different "product" than the auto industry. The auto industry is producing parts and designers of the C5ISR facilities are primarily concerned with producing consistent temperature control and high-quality electricity. The auto industry does not want, under any circumstance, to allow a defective part out of their facility. If it does, the consequences would cost them immensely on recalls or warranty work. Therefore, it makes sense that they would consider detection of a faulty part prior to leaving their facility as important as severity in their analysis. This is not the case with a C5ISR facility. The designer’s goal in producing a C5ISR facility is to be available without interruption. Just because a failure has been detected does not necessarily mean that the end level effect is prevented. However, it may minimize the downtime, thus increasing availability. When severity is assigned, this would be taken into consideration. For that reason, even though detection is considered in classifying severity, it does not hold the same relative importance.

6-3.7 Effects of Redundancy – Qualitative.

Traditional methods for dealing with redundancy's effect on failure rate are rather lengthy and difficult to apply to a qualitative analysis. Therefore, further explanation is required for how to deal with criticality rankings for like components within a single redundant system.

For example, consider an occurrence ranking of 9 for a chilled water supply pump (see Figure 6-10). In essence, the analysis is ranking the failure rate associated with the loss of function of that component relative to the equipment operation, or mission as a whole, and not the component itself. So, the question becomes "how to subjectively, but meaningfully, rank like redundant components with the same system function?"

Figure 6-10 Single Point System vs Redundant System



6-3.7.1 Redundant Systems.

By design, a redundant system is more reliable and less vulnerable than a single component, with respect to system function and mission requirements. So, it makes sense that qualitative ranking of redundant components should take such concepts as degree of redundancy and presumed individual component reliability into consideration.

As a result of decreased system vulnerability, each individual component is less critical to the system function and mission requirement. Therefore, it is evident that O'_1, O'_2, and O'_3 should not all have the same ranking number as the single component system (9). Furthermore, the relationship between degree of redundancy and occurrence is not linear. So, it is also evident that the value for O'_1, O'_2, and O'_3 cannot be a strict division by n of the ranking number assigned to the redundant system's function (3, 3, and 3). This is supported with the redundancy formula in the quantitative criticality analysis in paragraph 6-3.5.1, Equation 6-4.

6-3.7.2 Occurrence Rankings.

The occurrence ranking number for a single component function must be weighted to reflect the operation, presumed reliability, and severity of loss of function of the redundant component system as accurately as possible. Furthermore, it should be observed that for mission critical facilities, the presence of one more component than needed is not sufficient to confidently assure mission availability. Therefore, a conservative factor should also be observed when determining individual occurrence rankings of redundant components, relative to the single point function.

6-3.7.3 Adjusted Occurrence Level.

The following mathematical equations can be used to emulate a non-linear redundancy/occurrence relationship while introducing a conservative mission critical factor:

Equation 6-12. Adjusted Occurrence Level

$$O' = Ox\frac{M}{N-1}$$

Where:
O = Occurrence level for loss of subsystem / system function, reliability data
O' = The adjusted occurrence level for the current redundant component being analyzed
M = The minimum number of components necessary
N = The number of components available

6-3.7.4 N+1 Occurrence Ranking.

Using this formula with only one redundant component will result in an occurrence ranking equal to the original. This formula reinforces the importance of having at least one extra component than necessary in a mission critical facility. The only way to decrease the occurrence ranking is to have 2 or more additional components than required.

$$O' = Ox\frac{M}{N-1}$$

Using:

M=2
N=3

$$O' = Ox\frac{2}{3-1}$$

$$O' = Ox\frac{2}{2}$$

$$O' = Ox1$$

Where:
O = Occurrence level for loss of subsystem / system function
M = The minimum number of components necessary
N = The number of components available
O' = The adjusted occurrence level for the current redundant component

6-3.7.5 Risk Priority Number.

If only two items are needed and four are available and the occurrence is nine:

M=2
N=4

$$O' = Ox\frac{2}{4-1}$$

$$O' = 9x\frac{2}{3}$$

$$O' = 6$$

Insert O' into the equation RPN = O'×S using the new severity ranking since the consequences of a failure of one component is not as severe to the end failure effect.

Original: $RPN = O \times S = 9 \times 8 = 72$

New: $RPN = O' \times S = 6 \times 5 = 30$

When sufficient failure rate data is available it is always recommended that quantitative CA be conducted through calculation or modeling. However, when a complete and detailed quantitative analysis is not necessary, realistically feasible, or desirable, the use of Equation 6-12 can be incorporated to quickly emulate the redundancy/occurrence relationship as part of a qualitative analysis.

6-3.7.6 Combined Method.

This “combined” method allows for an analysis to be conducted using the qualitative (subjective) approach and using supportive data to rank occurrence. Ranking occurrence with supportive data not only provides more merit to the results but offers flexibility by allowing the analyst to use data for components when available in the same analysis as other components that may not have any supportive data.

This is accomplished by allowing the failure rate (λ), failure mode probability (α), and the failure effect probability (β) to be multiplied to determine a failure rate for a particular failure mode. This rate can then be cross referenced in the occurrence ranking chart and assigned a new ranking (O'). Substituting in the formula:

$$RPN = (O') \times (S)$$

6-3.7.7 Adjusted Risk Priority Number.

This adjusted RPN will then be used in the final ranking process. Table 6-15 is an example of a FMECA using the qualitative method utilizing the redundancy formula to adjust the occurrence ranking. After the redundancy formula was applied, the number was rounded to the nearest whole number for this example. The components that only had one additional backup component did not have their occurrence rankings altered by this equation. Note: Rounding is not mandatory. This was done in the example for simplicity.

6-4 RANKINGS.

6-4.1 Criticality Rankings.

A criticality ranking is a list used to rank the failure modes of most concern first, down to the least concern, at the bottom. This procedure is essentially conducted in the same fashion whether it is a quantitative analysis or the more widely used qualitative (subjective) analysis.

6-4.1.1 Analyzing Failure Modes in Terms of RPN.

When failure modes are analyzed in terms of RPN, the highest RPN must be listed first (qualitative analysis). When failure rate data is used to calculate criticality numbers (quantitative analysis) the highest criticality number should be listed first. See Table 6-16 for an example failure mode criticality ranking using DA Form 7613. Table 6-17 using DA Form 7614 is another type of ranking that only ranks the item criticality number (Equation 6-3) that was discussed in paragraph 6-3.4.6. This is called an item criticality ranking. Both rankings have advantages, but the failure mode criticality ranking provides the most detail regarding failure rates and failure modes and is therefore the preferred type when conducting a quantitative analysis.

Table 6-16 Example of DA Form 7613 (AUG 2006), Failure Mode Criticality Rankings

FAILURE MODE CRITICALITY RANKING (QUANTITATIVE)
For use of this form, see TM 5-698-4; the proponent agency is USACE.

6-4.1.2 Failure Mode Criticality, Item Criticality and RPN Ranking.

The failure mode criticality ranking, item criticality ranking, and RPN ranking lists can be useful tools but should not be solely used to determine which items are of most concern. Where these rankings fall short are their inability to allow the analyst to be judgmental to determine higher risk or higher consequences of failures. It is quite possible that two or more failure modes have similar RPN's or criticality numbers, but one has a much higher severity or consequence of the failure. These items typically need to be addressed first. Therefore, it is highly suggested that this ranking should be complimented by developing a criticality matrix. The matrix is explained in paragraph 6-4.2.

6-4.1.3 Not Constructing a Criticality Matrix Approach.

If the analysts do not wish to construct a criticality matrix, the next best approach would be to organize the Criticality Ranking by not only the Criticality Number or RPN, but also list the items by severity. This can be accomplished quite easily in an Excel program sorting first by severity and then by Criticality Number or RPN. The analysts can then review all the higher severity items first and make sound judgments regarding what type of actions, if any, should be taken to decrease the severity. This critical ranking list is to be used in a flexible manner according to the best judgment of the analysts. If done correctly it will aid in safety, maintainability, and FTA, thereby enabling improvements in the design.

6-4.2 Criticality Matrix.

The Criticality Matrix is a graphical or visual means of identifying and comparing failure modes for all components within a given system or subsystem and their probability of occurring with respect to severity. It is used for quantitative and qualitative analyses. The matrix can be used along with the Critical Item List or by itself to prioritize components.

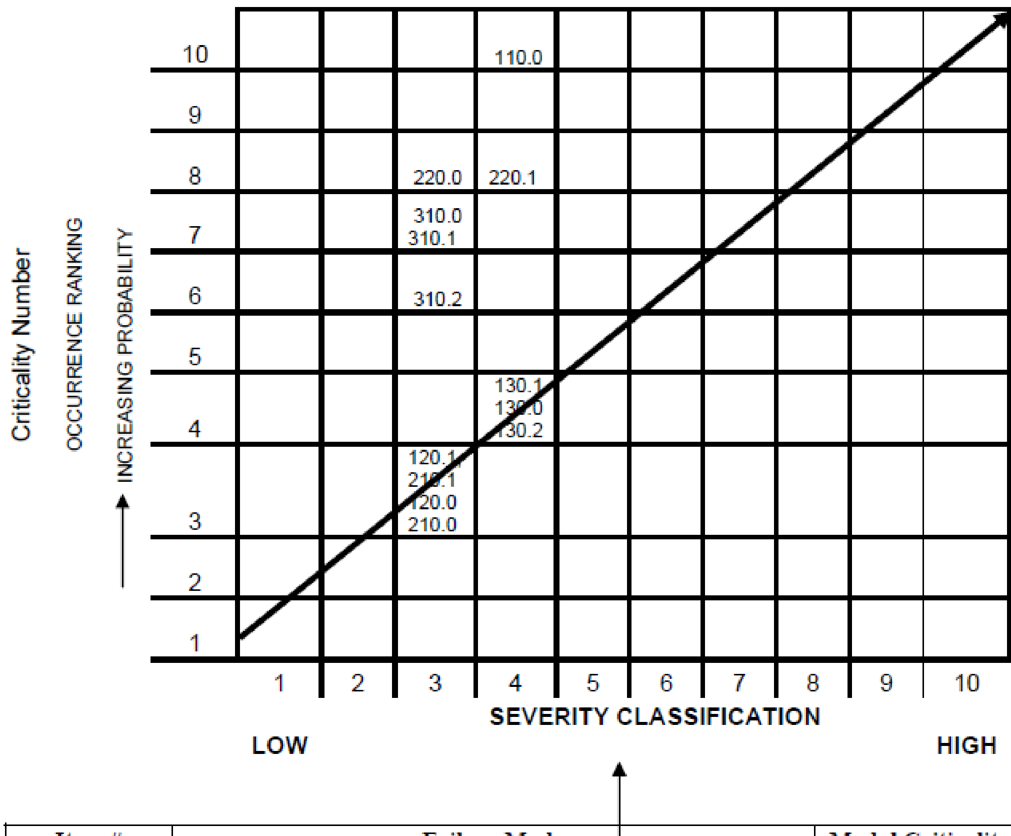
6-4.2.1 Differentiate Criticality of Components.

The matrix has the distinctive ability to differentiate criticality of components with the same or similar RPN and criticality number. For example: two components could have the same RPN, one with the severity of three and an occurrence ranking of ten, the other with a severity of ten and an occurrence ranking of three, thus producing a RPN of 30. Consequently, listing them only by RPN would produce an equal ranking. By placing them in the matrix it becomes very evident that an item that is in the severity category of "ten" should take priority for some type of corrective action.

6-4.2.2 Criticality Matrix Construction.

The matrix is constructed by inserting the assigned Item number, or other indicator, for each failure mode into matrix locations which represent the severity classification and probability of occurrence ranking. The criticality matrix example shown in Figure 6-11 is representative of the HVAC system FMECA example in Table 6-11. If there is not sufficient space available in the matrix to paste the Item number, then an alternative method to represent each failure mode should be used. The resulting matrix shows the relative ranking of criticality for each item's failures.

Figure 6-11 Criticality Matrix



Item #	Failure Mode	Modal Criticality Number
110.0	leak	$6.38x10^{-4}$
120.0	Transport water at a rate below 1000 gpm	$3.00x10^{-13}$
120.1	produce no water flow	$5.58x10^{-13}$
130.0	Scaling(deposits) on media	$2.87x10^{-12}$
130.1	Clogged sprayers	$3.51x10^{-12}$
130.2	Fan failure	$1.54x10^{-12}$
210.0	Degraded operation-produce water at a rate less than 960gpm	$3.00x10^{-13}$
210.1	produce no water flow	$5.58x10^{-13}$
220.0	Degraded operation-remove less than 10°F	$9.70x10^{-6}$
220.1	remove no heat	$8.45x10^{-6}$
310.0	Maintain air at a temp higher than 72°F	$1.34x10^{-7}$
310.1	Provide airflow at a rate less than 3200cfm	$1.53x10^{-7}$
310.2	Provide no air flow	$9.56x10^{-8}$

6-4.2.3 Criticality Matrix Item Numbers.

Item number's displayed in the upper most right-hand corner of the matrix require the most immediate attention. These failures have a high probability of occurrence and a catastrophic effect on system operation or personnel safety. Therefore, they should be evaluated first to determine if a redesign (such as, design in redundancy) is an alternative approach. Moving diagonally towards the lower left-hand corner of the matrix, the criticality and severity of potential failures decreases. In cases where failures display the same relative severity and criticality, it must be determined whether safety/mission success or cost is the driving factor of the analysis. If safety/mission success is of more concern, items shown on the right of the diagonal line require the most re-design attention, because the effects of their failures are more severe even though their criticality ranking may be less. If cost is a major concern, items to the left of the diagonal line require attention, because the high criticality numbers (occurrence rankings) reflect higher failure probability.

6-4.2.4 Criticality Matrix with Redundant System.

By employing redundancy, a duplicate system is constructed such that it serves as a backup for a critical single point failure. Though the initial failure of the component or system cannot be avoided, the effect of the failure will no longer be catastrophic since a compensating provision (the redundant system) will serve to operate in its place. If redundancy cannot be employed, then a more robust component with a lower failure rate may be an option. Every means possible should be evaluated to lower the failure rate on any high severity classification failure mode. If this cannot be accomplished, then a reaction plan must be developed to minimize the downtime of the system.

6-5 RESULTS.

6-5.1 Overview.

At the conclusion of the FMECA, critical items/failure modes are identified, and corrective action recommendations made based on the criticality list and/or the Criticality Matrix generated by the CA.

6-5.1.1 Utilizing the Criticality List.

Utilizing the criticality list, the items with the highest criticality number or RPN receive attention first. Utilizing the Criticality Matrix (recommended), items in the upper most right-hand quadrant will receive attention first. Typical recommendations call for design modifications such as the use of higher quality components, higher rated components, design in redundancy or other compensating provisions.

6-5.1.2 Recommendations.

Recommendations cited must be fed back into the design process as early as possible to minimize iterations of the design. The FMECA is most effective when exercised in a proactive manner to drive design decisions, rather than to respond after the fact.

6-5.2 Recommendations – from the Criticality Matrix Example.

Once the items are assigned their respective "squares" in the criticality matrix, the team now has the ability to rank which components need further review. From the above example the items can be quickly judged. If there are items that have similar RPNs and fall in the roughly the same vicinity in the matrix, then the team will have to determine which item should be addressed first. Remember, as the design matures and information is collected, this tool will be able to identify more clearly which items should take priority.

6-5.2.1 Item Number 110.0.

Item number 110.0 is the reservoir and has a high failure rate. Possibly another choice for a reservoir with a lower failure rate and an annual inspection/evaluation of condition of reservoir should be considered.

6-5.2.2 Item Number 220.1.

Item number 220.1 is the inability of the chiller to remove any heat from the chilled water supply. This has a relatively high failure rate and severity. The chiller should have inspections at specified intervals including eddy current testing annually to monitor breakdown of tubes. Motor should be tested annually as well for breakdown of windings. Because there is a redundant component this can be done at a predetermined time. Continuous monitoring of temperature with existing sensors and alarms should prevent catastrophic failure of the chiller. These procedures should address item 220.0 as well.

6-5.2.3 Item Numbers 310.0, 310.1, and 310.2.

Item numbers 310.0, 310.1, & 310.2 are all associated with the air handler system. Number 310.0 and number 310.1 have a higher failure rate and are therefore more likely to occur and possibly predict due to their nature of failure mechanisms which are a “wear out” type mechanism. Therefore, typical preventative maintenance actions at manufacture’s recommendations should be employed initially. This interval can be adjusted according to inspection reports from the maintenance actions. The fan should not be driven by one belt. Use a sheave with three grooves for three belts to decrease the chance that one broken belt will make the item fail. A spare motor should be on hand to quickly replace the existing motors in the event one fails. Bearings should be greased quarterly (do not over grease) and air filter(s) changed semiannually.

6-5.2.4 Item Numbers 130.0, 130.1, and 130.2.

Item numbers 130.0, 130.1, and 130.2 have relatively high severities and average failure rates. These items are all related to the cooling towers. Most of the failures associated with this item are related to contamination of the water, therefore monitoring the condition of the water through water analysis and changing the filters at a regular interval (again, adjust this as needed) should also be implemented. An annual inspection should be done as well. Replacement sprayers and fan motors should be readily available to quickly respond to a spontaneous failure in these locations.

6-5.2.5 Remaining Failure Modes.

The final four failure modes are associated with the pumps in both the chilled water supply and the industrial cooling water supply. The chilled water supply ranks higher because in the event of no chilled water there will be no heat removed from the room and therefore would lead to computer failure. This is an immediate effect versus the industrial cooling water system which will affect the efficiency of the chiller and possibly lead to a failure over time. Therefore, if a priority were to be in place,
the chilled water pump should take precedence. In either case, the recommendations for both pumps are the same. Along with the manufacture’s recommended PM in place for rebuilding the pump and periodic inspections, then a vibration analysis and an electrical test on the motor could be conducted at a semiannual basis. In the event of a spontaneous failure the redundant pump can be transferred over while the failed pump is repaired. It should be noted however, that if the power supply is disrupted to the first pump then there is a possibility that the second pump will also be unable to start. This means there better be a separate power feed line to the secondary pumps.

6-5.3 Incentives.

The FMECA is a valuable tool that can be utilized from early design to functional use of a system. It is most beneficial when initiated early in the design process by providing engineers a prioritized list of areas in the design that need attention. This early assessment will minimize costs associated with constructing a facility and maintaining it. To develop strategies after the facility is built not only costs more but will typically be compromised due to physical restraints.

6-5.3.1 Identifying Critical Items.

Due to the continuous challenge to provide clean reliable power and precise temperature control to a mission critical facility, it is somewhat intimidating to attempt to assess which items should be more critical to mission success. The effects of redundancy, failure rates and severity on this assessment of each component/subsystem can be complex and time consuming when using a pure statistical approach. However, the alternative method explained in this \1\ UFC /1/ should provide a simpler means to make this assessment or ranking possible, with or without failure data.

6-5.3.2 Method Modifications.

The method used in this \1\ UFC /1/ should be used as a guide and tailored to a facility's specific need. It is important that the user makes modifications to the forms to meet those needs. This \1\ UFC /1/is meant to be used as a tool and must be flexible to accomplish a meaningful analysis at different facilities.

6-5.4 Results.

6-5.4.1 Comparison of Single Component Failures.

The results from this type of analysis are for comparison of single component failures only. The information derived from this analysis will provide a baseline to conduct other analyses. For simultaneous multiple failure event analysis, other techniques, such as FTA, should be used. The FTA is very extensive and is usually applied to areas of concern that are identified through the FMECA process or from prior experience.

6-5.4.2 Strength and Weaknesses of FMECA.

It is very important to know the strengths and weaknesses of this analysis. The FMECA is a living document and should be updated on a continual basis as more and more information is collected on the system. It should provide a valuable resource to support reliability, corrective maintenance actions, and safety.

6-5.4.3 Effects of Redundancy.

The effects of redundancy should be taken into consideration when calculating criticality numbers or assigning occurrence rankings because redundancy reduces the failure rate, thus increasing the availability. After all, availability is the prime objective of the C5ISR facility.

CHAPTER 7 RELIABILITY CENTERED MAINTENANCE (RCM)

7-1 RCM.

7-1.1 The RCM Concept.

Prior to the development of the RCM methodology, it was widely believed that everything had a "right" time for some form of preventive maintenance (PM), usually replacement or overhaul. A widespread belief among many maintenance personnel was that by replacing parts of a product or overhauling the product (or reparable portions thereof), that the frequency of failures during operation could be reduced. Despite this previous commonly held view, the results seemed to tell a different story. In far too many instances, PM seemed to have no beneficial effects. Indeed, in many cases, PM made things worse by providing more opportunity for maintenance-induced failures.

7-1.1.1 Airline Study.

When the airline companies in the United States observed that PM did not always reduce the probability of failure and that some items did not seem to benefit in any way from PM, they formed a task force with the Federal Aviation Administration (FAA) to study the subject of preventive maintenance. The results of the study confirmed that PM was effective only for items having a certain pattern of failures. The study also concluded that PM should be required only when required to assure safe operation. Otherwise, the decision to do or not do PM should be based on economics.

7-1.1.2 RCM Approach.

The RCM approach provides a logical way of determining if PM makes sense for a given item and, if so, selecting the appropriate type of PM. The approach is based on the following precepts.

(1) The objective of maintenance is to preserve an item's function(s). RCM seeks to preserve system or equipment function, not just operability for operability's sake. Redundancy improves functional reliability but increases life cycle cost in terms of procurement and life cycle cost.

2) RCM focuses on the end system. RCM is more concerned on maintaining system function than individual component function.

(3) Reliability is the basis for decisions. The failure characteristics of the item in question must be understood to determine the efficacy of preventive maintenance. RCM is not overly concerned with simple failure rate; it seeks to know the conditional probability of failure at specific ages (the probability that failure will occur in each given operating age bracket).

(4) RCM is driven first by safety and then economics. Safety must always be preserved. When safety is not an issue, preventive maintenance must be justified on economic grounds.

(5) RCM acknowledges design limitations. Maintenance cannot improve the inherent reliability – it is dictated by design. Maintenance, at best, can sustain the design level of reliability over the life of an item.

(6) RCM is a continuing process. The difference between the perceived and actual design life and failure characteristics is addressed through age (or life) exploration.

7-1.1.3 RCM Concept.

The RCM concept has completely changed the way in which PM is viewed. It is now a widely accepted fact that not all items benefit from PM. Moreover, even when PM would be effective, it is often less expensive (in all senses of that word) to allow an item to "run to failure" rather than to do PM. In the succeeding discussions, the RCM concept will be examined in more detail. The meaning of terms that are central to the RCM approach will be explored. These terms include failure characteristics, efficiency, run to failure, cost, and function.

7-1.2 Benefits of RCM.

7-1.2.1 Reduced Costs.

A significant reason for creating the joint airline/FAA task force was the new Boeing 747 (B747) jumbo jet. Boeing and United Airlines, the initial buyer of the aircraft, were already considering the development of the PM program for the B747. This new airliner was vastly larger and more complex than any ever built. Given the cost of maintenance on smaller aircraft already in service, the maintenance costs for the B747, using the traditional approach to PM, would have threatened the profitability, and hence the viability, of operating the new aircraft. Examples of the ultimate savings achieved in using RCM to develop the PM program for the B747 and other aircraft are shown in Table 7-1. Similar savings have been achieved by other industries for other equipment when going from a traditional to an RCM-based PM program. It is important to note that these costs savings are achieved with no reduction in safety, an obvious requirement in the airline industry.

Table 7-1 Cost Benefits of using RCM for Developing PM Program

Type of PM	Required Using Traditional Approach	Required Using RCM
Structural Inspections	4,000,000 hours for DC-8	66,000 hours for B747
Overhaul	339 items for DC-8	7 items for DC-10
Overhaul of turbine engine	Scheduled	On-condition (cut shop maintenance costs by 50% compared with DC-8)

7-1.2.2 Increased Availability.

For many systems, including C5ISR facilities, availability is of primary importance. Availability was defined in paragraph 2-1.5. As indicated in the definition, the level of availability achieved in actual use of a product is a function of how often it fails and how quickly it can be restored to operation. The latter, in turn, is a function of how well the product was designed to be maintainable, the amount of PM required, and the logistics resources and infrastructure that have been put in place to support the product. RCM directly contributes to availability by reducing PM to that which is essential and economic.

7-1.3 Origins of RCM.

7-1.3.1 Airlines.

As stated earlier, RCM had its origins with the airline industry. Nowhere had the then prevailing philosophy of maintenance been challenged more. By the late 1950's, maintenance costs in the industry had increased to a point where they had become intolerable. Meanwhile, the Federal Aviation Agency (FAA) had learned through experience that the failure rate of certain types of engines could not be controlled by changing either the frequency or the content of scheduled fixed-interval overhauls. As a result of these two factors, a task force consisting of representatives of the airlines and aircraft manufacturers was formed in 1960 to study the effectiveness of PM as being implemented within the airline industry.

(1) The task force. The task force developed a rudimentary technique for developing a PM program. Subsequently, a maintenance steering group (MSG) was formed to manage the development of the PM program for the new Boeing 747 (B747) jumbo jet. This new airliner was vastly larger and more complex than any ever built. Given the cost of maintenance on smaller aircraft already in service, the maintenance costs for the B747, using the traditional approach to PM, would have threatened the profitability, and hence the viability, of operating the new aircraft.

(2) MSG-1. The PM program developed by the steering group, documented in a report known as MSG-1, was very successful. That is, it resulted in an affordable PM program that ensured the safe and profitable operation of the aircraft.

(3) MSG-2. The FAA was so impressed with MSG-1 that they requested that the logic of the new approach be generalized, so that it could be applied to other aircraft. So, in 1970, MSG-2, Airline Manufacturer Maintenance Program Planning Document, was issued. MSG-2 defined and standardized the logic for developing an effective and economical maintenance program. MSG-2 was first used on the L1011, DC10, and MD80 aircraft. In 1972, the European aviation industries issued EMSG (European Maintenance System Guide), which improved on MSG-2 in the structures and zonal analysis. EMSG was used on the Concorde and A300 Airbus.

7-1.3.2 Adoption by Military.

The problems that the airlines and FAA had experienced with the traditional approach to maintenance were also affecting the military. Although profit was not an objective common to both the airlines and military, controlling costs and maximizing the availability of their aircraft were. Consequently, in 1978, the DOD contracted with United Airlines to conduct a study into efficient maintenance programs. The study supplemented MSG-2 by emphasizing the detection of hidden failures and moved from a process-oriented concept to a task-oriented concept. The product of the study was MSG-3, a decision logic that was called RCM.

7-1.3.3 Use for Facilities and Other Industries.

Although created by the aviation industry, RCM quickly found applications in many other industries. RCM is used to develop PM programs for public utility plants, especially nuclear power plants, railroads, processing plants, and manufacturing plants. It is no overstatement to say that RCM is now the pre-eminent method for evaluating and developing a comprehensive maintenance program for an item. Today, a variety of documents are available on RCM.

7-1.4 Relationship of RCM to Other Disciplines.

7-1.4.1 Reliability.

It is obvious why the first word in the title of the MSG-3 approach is reliability. Much of the analysis needed for reliability provides inputs necessary for performing an RCM analysis, as will be seen in succeeding paragraphs. The fundamental requirement of the RCM approach is to understand the failure characteristics of an item. As used herein, failure characteristics include the underlying failure rate, the consequences of failure, and whether the failure manifests itself and, if it does, how. Reliability is measured in different ways, depending on one's perspective: inherent reliability, operational reliability, mission (or functional) reliability, and basic (or logistics) reliability. RCM is related to operational reliability.

(1) Inherent versus operational reliability. From a designer's perspective, reliability is measured by "counting" only those failures that are design related. When measured in this way, reliability is referred to as "inherent reliability." From a user's or operator's perspective, all events that cause the system to stop performing its intended function is a failure event. These events certainly include all design-related failures that affect the systems' function. Also included are maintenance-induced failures, no-defect found events, and other anomalies that may have been outside the designer's contractual responsibility or technical control. This type of reliability is called "operational reliability."

(2) Mission or functional reliability versus basic or logistics reliability. Any failure that causes the product to fail to perform its function or mission is counted in "mission reliability." Redundancy improves mission reliability. Consider a case where one part of

a product has two elements in parallel where only one is needed (redundant). If a failure of one element of the redundant part of the product fails, the other continues to function allowing the product to do its job. Only if both elements fail will a mission failure occur. In "basic" reliability, all failures are counted, whether a mission or functional failure has occurred. This measure of reliability reflects the total demand that will eventually be placed on maintenance and logistics.

7-1.4.2 Safety.

Earlier, it was stated that one of the precepts on which the RCM approach is that safety must always be preserved. Given that the RCM concept came out of the airline industry, this emphasis on ensuring safety should come as no surprise. In later paragraphs, the way the RCM logic ensures that safety is ensured will be discussed. For now, it is sufficient to note that the RCM specifically addresses safety and is intended to ensure that safety is never compromised. In the past several years, environmental concerns and issues involving regulatory bodies have been accorded an importance in the RCM approach for some items that is equal (or nearly so) to safety. Failures of an item that can cause damage to the environment or which result in some Federal or state law being violated can pose serious consequences for the operator of the item. So, the RCM logic is often modified, as it is in this UFC, to specifically address environmental, mission, or other concerns.

7-1.4.3 Maintainability.

RCM is a method for prescribing PM that is effective and economical. Whether or not a given PM task is effective depends on the reliability characteristics of the item in question. Whether or not a task is economical depends on many factors, including how easily the PM tasks can be performed. Ease of maintenance, corrective or preventive, is a function of how well the system has been designed to be maintainable. This aspect of design is called maintainability. Providing ease of access, placing items requiring PM where they can be easily removed, providing means of inspection, designing to reduce the possibility of maintenance-induced failures, and other design criteria determine the maintainability of a system.

7-2 MAINTENANCE.

Maintenance is defined as those activities and actions that directly retain the proper operation of an item or restore that operation when it is interrupted by failure or some other anomaly. Within the context of RCM, proper operation of an item means that the item can perform its intended function. These activities and actions include fault detection, fault isolation, removal and replacement of failed items, repair of failed items, lubrication, servicing (includes replenishment of consumables such as fuel), and calibrations. Other activities and resources are needed to support maintenance. These include spares, procedures, labor, training, transportation, facilities, and test equipment. These activities and resources are usually referred to as logistics. Although some organizations may define maintenance to include logistics, it will be used in this document in the more limited sense and will not include logistics.

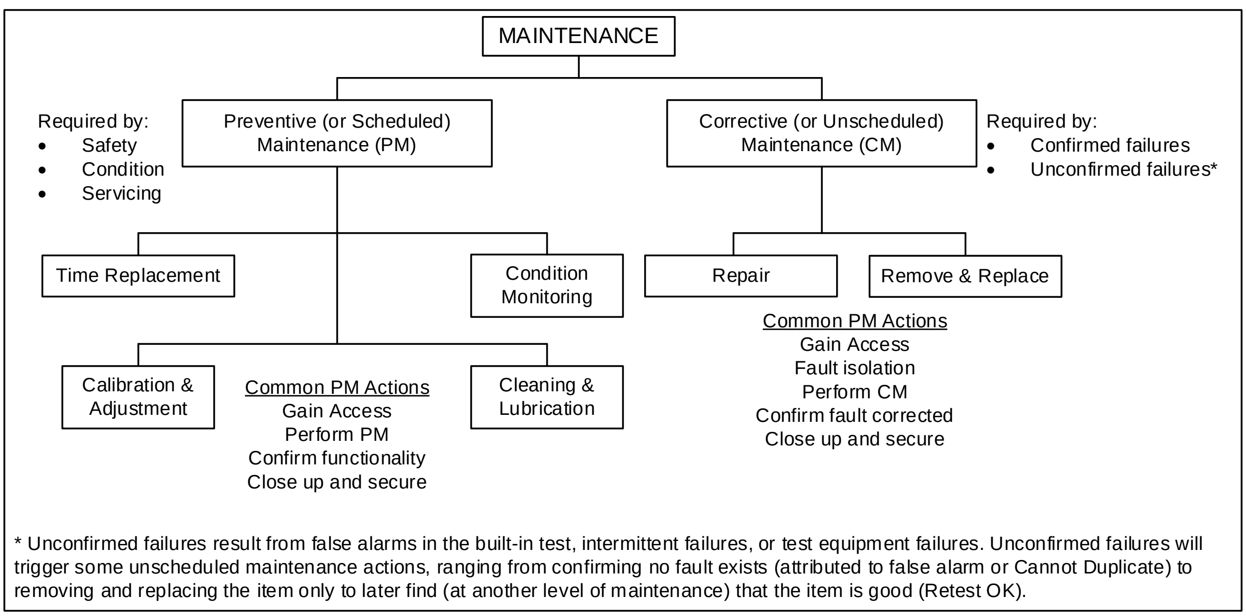
7-2.1 Categories of Maintenance.

Maintenance is usually categorized by either when the work is performed or where the work is performed.

7-2.1.1 Categorizing by when Maintenance is Performed.

In this case, maintenance is divided into two major categories: preventive and corrective. Figure 7-1 illustrates how these two categories are further broken down into specific tasks. These categories of maintenance, corrective and preventive, are further subdivided in some references into reactive, preventive, predictive, and proactive maintenance.

Figure 7-1 Major Categories of Maintenance by when Performed.



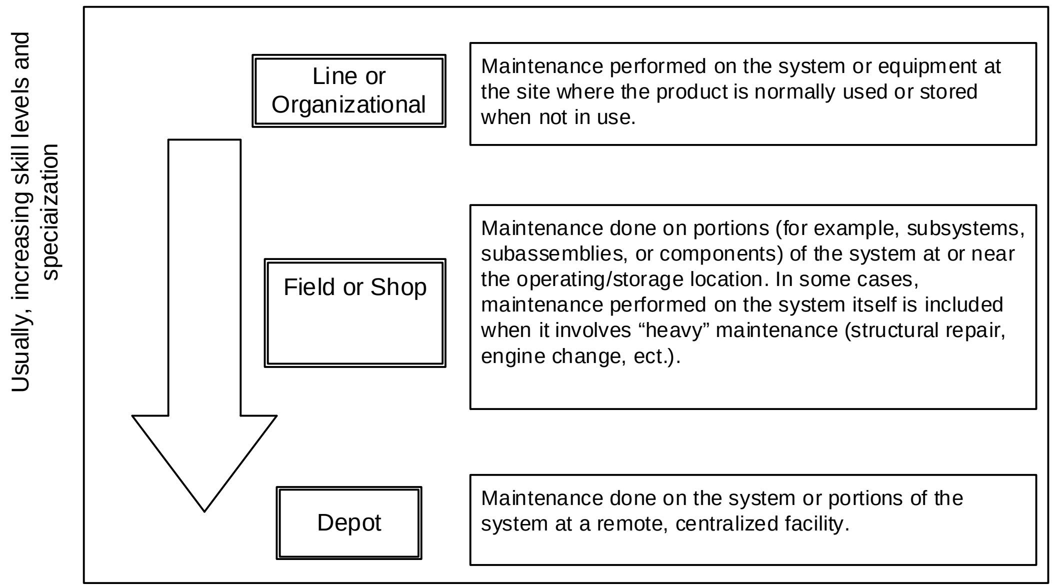
(1) Reactive maintenance. This term is equivalent to corrective maintenance, and both are also referred to as breakdown, repair, fix-when-fail, or run-to-failure maintenance.

(2) Proactive maintenance. Includes actions intended to extend useful life, such as root-cause failure analysis, continual improvement, and age exploration. Proactive and predictive are treated herein as categories of preventive maintenance, with proactive included under Scheduled, predictive under Condition-based, and age exploration as a separate step in the RCM process.

7-2.1.2 Categorizing by where Maintenance is Performed.

Maintenance can also be categorized by where the work is performed. These categories are referred to as levels of maintenance. The categories most often used are shown in Figure 7-2.

Figure 7-2 Typical Approach to Categorizing Maintenance by where it is Performed.



7-2.2 Categorization by when Maintenance is Performed.

7-2.2.1 Preventative Maintenance.

Preventive maintenance (PM) is usually self-imposed downtime (although it can be done while corrective maintenance is being performed and it may even be possible to perform some PM while the product is operating). PM consists of actions intended to prolong the operational life of the equipment and keep the product safe to operate. This UFC defines two types of PM: Scheduled and Condition-based. In both cases, the objectives of PM are to ensure safety, reduce the likelihood of operational failures, and obtain as much useful life as possible from an item. Table 7-2 has examples of each type of PM.

(1) Scheduled maintenance. When a specified interval between maintenance is required, the maintenance is referred to as scheduled preventive maintenance. The interval may be in terms of hours, cycles, rounds fired, or other measure meaningful to the way the item is operated. Note that with scheduled PM, no attempt is made to ascertain the condition of the item. Scheduled maintenance may also consist of recalibrations or adjustments made at regular intervals. Some texts categorize inspections as scheduled PM. Certainly, inspections are based on some periodic interval or event (for example, inspection of an aircraft prior to and after each flight).

However, since the purpose of an inspection is to ascertain the condition of the item, it has been included under the next category of PM, Condition-based.

Table 7-2 Examples of Tasks under Two Categories of Preventive Maintenance

Category	Tasks	Examples	Notes
Scheduled [1]	Remove and replace (R&R)	R&R batteries in smoke alarm twice annually	Maintenance is performed without regard to actual condition of item. Interval based on useful life and other factors. Includes all lubrication and servicing.
		R&R gun barrel after 5,000 rounds have been fired	
		Change oil every 3,000 miles	
		Lubricate bearings every 25,000 shaft revolutions	
	Overhaul or recondition	Overhaul transmission every 100,000 miles	Item is overhauled or reconditioned without regard to actual condition. Interval based on useful life and other factors.
		Refinish blades every 2,000 operating hours	
	Recalibrate	Recalibrate depth setting on drill press daily	Compensate for changes in calibration due to vibration and other conditions of use.
		Recalibrate gage against standard at beginning of each shift	
Condition[2]	Inspect item or area	Visually inspect belts and pulleys for excessive wear prior to starting machine	Inspections can be performed using human senses (e.g., visually check belts for wear), using non-destructive inspection (NDI) techniques (e.g., inspect for corrosion using dye penetrant), or special measuring equipment (check tread depth using gage). Can also include functional check to determine proper operation.
		Inspect for corrosion every 2 weeks	
		Inspect for delamination or disbond weekly	
		Inspect tires for cuts and proper tread depth before and after each flight	
		Inspect for hidden failure of redundant item	
	Monitor condition	Continuously monitor vibration profile and R&R bearing when limits reached	Objective is to act before useful life has been reached or a functional failure has occurred. Parameter limits and profiles based on analysis, test, and field experience. Monitoring can but does not need to be continuous.
		Check sample of oil every 50 operating hours for presence of wear metals and overhaul engine when limits reached	

1. Based on time.
2. Based on observed or measured condition.

(2) Condition-based maintenance. Preventive maintenance performed to ascertain the condition of an item, detect, or forecast an impending failure, or performed because of such actions is referred to as Condition-based PM.

(a) A hidden failure of an item is one that has already occurred, has not affected performance of the end system, but will if another item fails. Ideally, through some form of warnings or monitoring device, no failure will be "hidden." It is impractical and not always feasible to detect every failure of every item in a system and alert the operator or maintainer that the failure has occurred. Inspections are therefore needed to detect such failures. See paragraph 7-4.3.1.3 for a more complete discussion of hidden failures. Maintenance that is required to correct a hidden failure condition is, of course, corrective maintenance.

(b) Some texts use terms such as predictive maintenance and on-condition. The definition of condition-based PM used herein includes these concepts. In summary, the objectives of condition-based PM are to first evaluate the condition of an item, then, based on the condition, either determine if a hidden failure has occurred or a failure is imminent, and then take appropriate action.

7-2.2.2 Corrective Maintenance and Run-to-Failure.

As already alluded to, corrective maintenance (CM) is required to restore a failed item to proper operation.

(1) Restoration. Restoration is accomplished by removing the failed item and replacing it with a new item, or by fixing the item by removing and replacing internal components or by some other repair action.

(2) When CM is required. CM can result from system failures or from condition based PM.

(a) When system operation is impaired by the failure of one or more items, the operator is usually and immediately alerted to the problem. This alert may come from obvious visual or sensory signals (such as, the operator can see, hear, or feel that a problem has occurred) or from monitoring equipment (indicators, built-in diagnostics, annunciator lights, etc.). When the alert comes from the latter, it is possible that a system failure has in fact not occurred. That is, the detecting equipment itself has failed or a transient condition has occurred resulting in an indication of system failure that is false or cannot be duplicated. Whether or not an actual system failure has occurred, any indication that one has will necessitate CM. The CM may result in a Cannot Duplicate (CND) or Retest OK (RTOK), in-place repair, or replacement. CNDs and RTOKs are serious problems in very complex systems for two reasons. First, they consume maintenance time and can cause unnecessary loss of system availability. Second, without in-depth test and analysis, one cannot be certain whether the detecting equipment failed, the system did fail, or transients caused the failure (and is not evident except under those transient conditions).

(b) When inspection or condition monitoring detects a hidden or failure, then some form of corrective maintenance is required.

(c) If the only concern were to obtain the greatest possible amount of life from an item, it would be allowed to run-to-failure. Under a run-to-failure approach, only CM would be required. No PM would be performed. However, the consequences on economics, safety, and mission requirements of some failures make a run-to-failure approach untenable. Consequently, most practical maintenance programs consist of a combination of PM and CM. Determining what combination is "right" for an item is one of the objectives of the RCM process.

7-2.3 Maintenance Concepts.

7-2.3.1 Level of Maintenance.

In considering how maintenance can be categorized, the idea of levels of maintenance was introduced. The term "levels of maintenance" has traditionally been used by the military services, although its use is not unknown in commercial industry. Within the services, the norm was once three levels of maintenance (line or organizational, field or shop, and depot). Under a 3-level concept, items are either repaired while installed on the end product or are removed and replaced. Various terms are used to refer to an item that is removed and replaced and include Line Replaceable Unit (LRU) and Weapon Replaceable Assembly (WRA). For convenience, LRU will be used in this document to refer to items that are normally removed from and replaced on the end product.

(1) The benefits of a 2-level maintenance concept. To reduce costs and increase availability, the services have been working for several years to implement a 2-level maintenance concept. Under this concept, repairs made on the system are kept to a minimum and, whenever possible, consist of remove and replace (R&R) actions. The idea is that by making R&R the preferred maintenance on the product, the downtime of the system can be kept to a minimum. Failed items are then sent back to the second level of maintenance, usually a depot or original equipment manufacturer (OEM).

(2) Making a 2-level concept work. A 2-level maintenance concept will only be affordable and practical if three criteria are met. First, each LRU's reliability must be "sufficiently high" given the item's cost. If not, availability will suffer, due to an excessive number of high-cost spares failing, and the supply "pipeline" will be expensive. Second, the integrated diagnostic capability (Built-in Test, Automatic Test Equipment, manual methods, etc.) must be very accurate and reliable. Otherwise, the supply pipeline to the second level of maintenance will be filled with good LRUs mistakenly being sent for repair – CNDs and RTOKs are a serious problem under any maintenance concept but spell disaster for a 2-level maintenance concept. Finally, a responsive and cost-effective means of transporting LRUs between the field and the depot must be available.

7-2.3.2 Centralized Versus De-Centralized.

When maintenance at a given level is performed at several locations located relatively close to the end user, a decentralized maintenance concept is being implemented. For example, suppose a 3-level maintenance concept is being used. When an LRU fails at an operating location, it is removed and replaced with a good LRU. The operating location sends the failed LRU to a co-located field repair activity (FRA) where it is repaired. Such repair can consist of either in-place repair or R&R of constituent components often called Shop Replaceable Units. Under a centralized concept, each operating location would not have a co-located FRA. Instead, one or more centralized FRAs would be strategically located throughout the geographic operating area (such as, country, continent, hemisphere, etc.). Each operating location would ship its failed LRUs to the nearest centralized FRA. Such a concept is most effective when the LRUs are highly reliable. If the reliability is high, then few failures will occur at any given operating location making it difficult to keep the technicians proficient in repairing the LRUs. Also, with few failures, the technicians and any support equipment (for example, automatic test equipment) will be under utilized. Under such conditions, it is difficult to justify a co-located FRA.

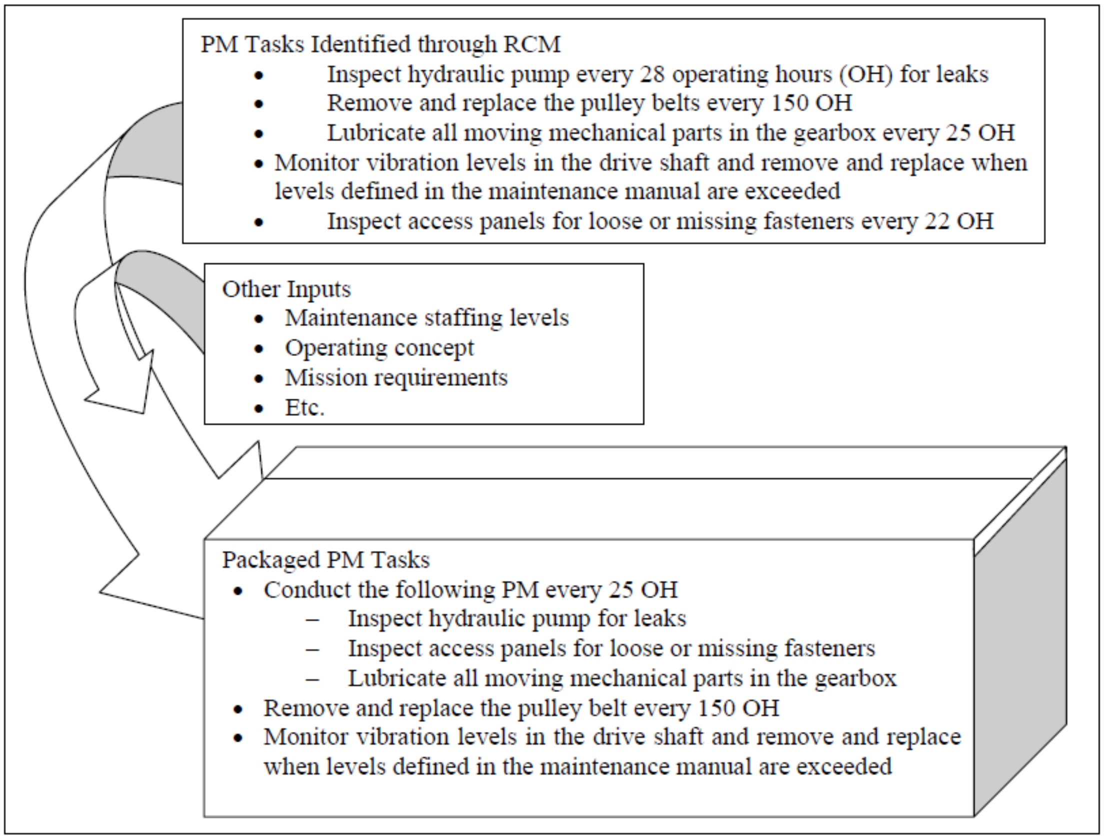
7-2.4 Packaging a Maintenance Program.

The total maintenance requirements for a product will dictate a set of preventive maintenance (PM) tasks and a set of corrective maintenance (CM) tasks. The latter tasks are essentially "maintenance on demand" and cannot be predicted. PM, as discussed previously, will consist of on-condition and scheduled maintenance. Once all PM tasks have been identified, they must be grouped, or packaged. By packaging PM tasks, maintenance resources can be used more effectively and minimize the number of times that the system will be out of service for PM.

7-2.4.1 Packaging Example.

An example is shown in Figure 7-3. The pump inspection could be conducted at 28 hours, the panel inspection at 22 hours, and lubricated the gearbox at 25 hours. But it is much more efficient to "package" the tasks as shown in the example.

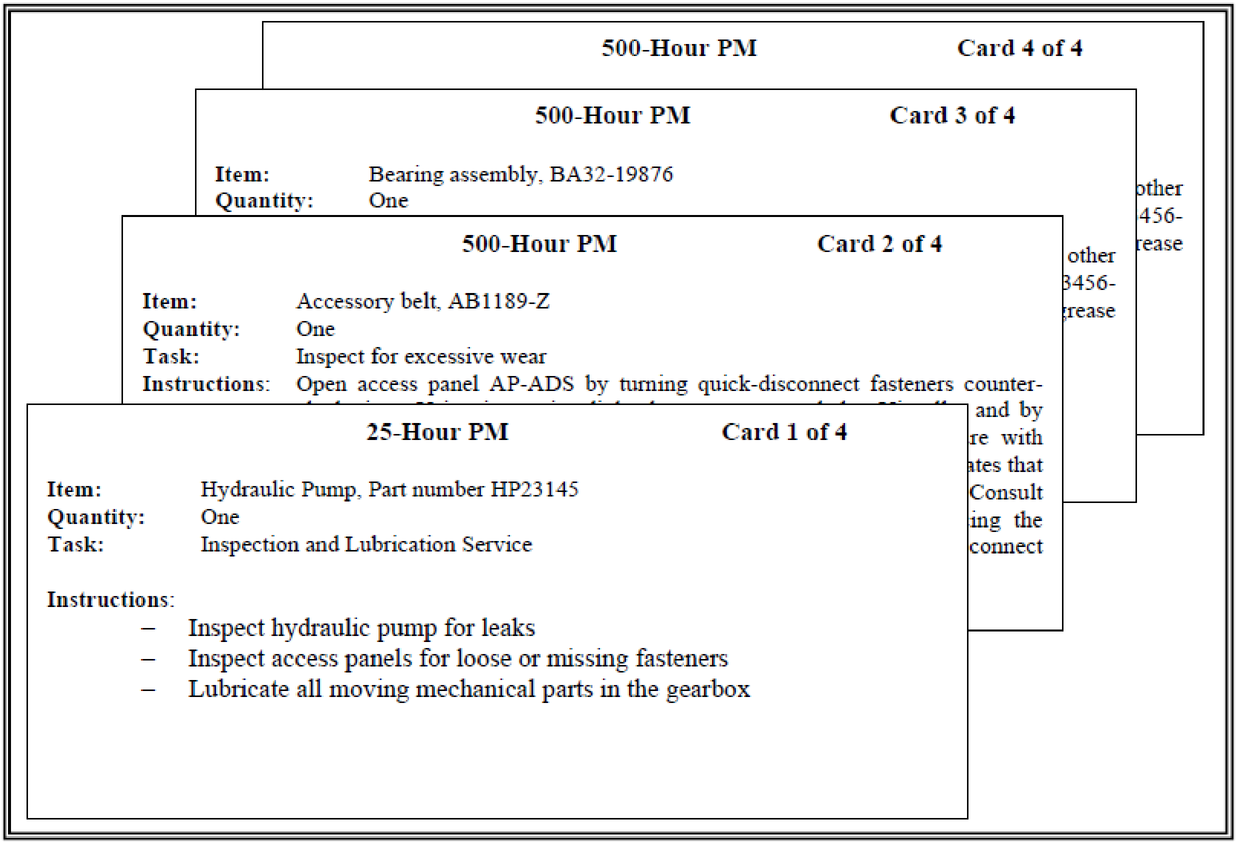
Figure 7-3 An Example of Packaging PM Tasks



7-2.4.2 Document the Packaging for Maintenance Personnel.

One method of documenting the packaging of PM tasks is to create inspection cards. For a given point in time (calendar time, number of operating hours, etc.), a set of cards defines the PM tasks to be performed. Figure 7-4 illustrates this approach.

Figure 7-4 Example of how PM Cards can be used to Document Required PM Tasks

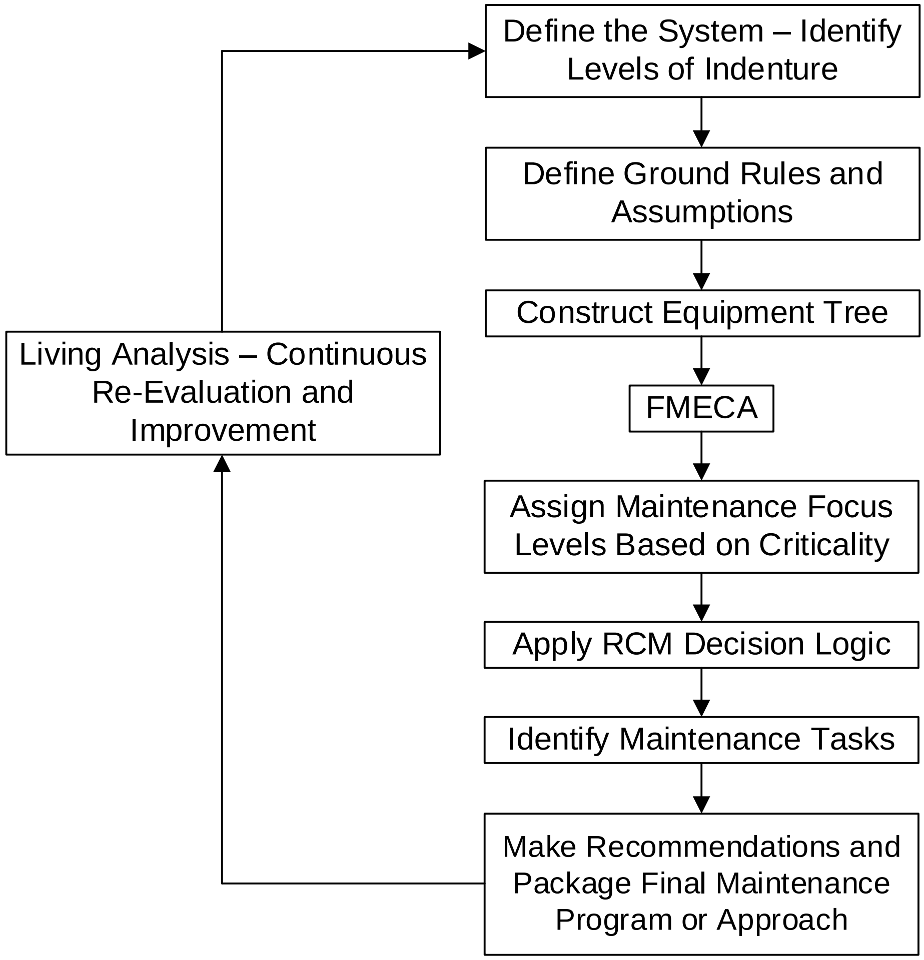


7-3 ELEMENTS OF RCM PROGRAM.

7-3.1 RCM Implementation Plan.

An overview of steps of the RCM process is shown in Figure 7-5.

Figure 7-5 The RCM Process Starts in the Design Phase and Continues for the Life of the System



7-3.1.1 Major Tasks.

As shown in Figure 7-5, several major tasks are required to implement the RCM concept.

- Define the System – Identify and document the boundaries of the analysis
  - Identify and document equipment included in the analysis
  - Identify and document the indenture level the analysis is intended to extend to
- Define Ground Rules and Assumptions – Identify and document ground rules and assumptions used to conduct the analysis

- Construct Equipment Tree – Construct equipment block diagrams to indicate equipment configuration, down to the lowest indenture level intended to be covered by the analysis
- Conduct FMECA – Analyze failure modes, effects and criticality
- Assign Maintenance Focus Levels – Classify maintenance focus levels based on criticality rankings
- Apply RCM Decision Logic – Apply RCM logic trees for items, especially those identified as being critical
- Identify Maintenance Tasks – Identify maintenance tasks to be performed on the given item
- Package Maintenance Program – Develop a maintenance tasking schedule for the analyzed equipment

Note: RCM Analysis is intended to be a living analysis. Effort should be made to continue to collect more complete information and add it to the analysis, to continue to provide a foundation for effective continuous improvement. Results and recommendations should be periodically reviewed and reevaluated, taking into consideration additional information of any kind.

(1) Conduct supporting analyses. RCM is a relatively information-intensive process. To provide the information needed to conduct the RCM analysis, several supporting analyses are either required, often as prerequisites to beginning the RCM analysis, or desirable. These supporting analyses include the FMEA, FTA, functional analysis, and others.

(2) Conduct the RCM analysis. The RCM analysis consists of using a logic tree to identify effective, economical, and, when safety is concerned, required PM. (As will be seen, PM is required when safety is involved; if no PM is effective, then redesign is mandatory).

7-3.1.2 The Implementation Plan.

Planning to implement an RCM approach to defining the PM for a system or product must address each of the tasks noted in the preceding paragraph. The plan must address the supporting design phase analyses needed to conduct an RCM analysis. Based on the analysis, an initial maintenance plan, consisting of the identified PM with all other maintenance being corrective, by default, is developed. This initial plan should be updated through Life Exploration during which initial analytical results concerning frequency of failure occurrence, effects of failure, costs of repair, etc. are modified based on actual operating and maintenance experience. Thus, the RCM process is iterative, with field experience being used to improve upon analytical projections.

7-3.2 Data Collection Requirements.

7-3.2.1 Required Data.

Since conducting an RCM analysis requires an extensive amount of information, and much of this information is not available early in the design phase, RCM analysis for a new product cannot be completed until just prior to production. The data falls into four categories: failure characteristics, failure effects, costs, and maintenance capabilities and procedures.

7-3.2.1.1 Failure Characteristics.

Studies conducted by the MSGs and confirmed by later studies showed that PM was effective only for certain underlying probability distributions. Components and items, for example, for which a constant failure rate applies (for example, the underlying probability distribution is the exponential) do not benefit from PM. Only when there is an increasing probability of failure should PM be considered.

7-3.2.1.2 Failure Effects.

The effects of failure of some items are minor or even insignificant. The decision whether to use PM for such items is based purely on costs. If it is less expensive to allow the item to fail, and to perform CM, than it is to perform PM, then the item is allowed to fail. As stated earlier, allowing an item to fail is called run to failure.

7-3.2.1.3 Costs.

The costs that must be considered are the costs of performing a PM task(s) for a given item, the cost of performing CM for that item, and the economic penalties, if any, when an operational failure occurs.

7-3.2.1.4 Maintenance Capabilities and Procedures.
