Change No.	**Date**	**Location**
1	09 Jan 2024	Updated ASHRAE 90.1 reference in paragraph 1-1; paragraph 2-10.1.3; and Appendix A References.
2	20 Sep 2024	Updated ASCE/SEI 7 reference in paragraph 2-2.6.4.3 and Appendix A References.

This UFC supersedes UFC 3-400-02, dated February 2003.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source: Whole Building Design Guide website http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-400-02, *DESIGN: ENGINEERING WEATHER DATA*

Superseding: UFC 3-400-02, dated 28 February 2003

Description: The purpose of this document is to provide an overview of and instructions for access to climate data available for use by engineers designing government structures. Final selection of sites was based upon availability of climate data. Most are located at military installations supporting airfield operations, or at local airports/airfields. This UFC is applicable to all service elements and contractors involved in the planning, design and construction of DoD facilities worldwide.

Reasons for Document:

- To update document to include new procedures for accessing weather data, new selection sites, new design values and new format.

Impact:

- There are no impacts.

Unification Issues

None.

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

The purpose of this document is to provide an overview of and instructions for access to climate data available for use by engineers designing government structures.

The 14th Weather Squadron (14 WS), formerly AFCCC, compiled Engineering Weather Data (EWD) at the request of the Air Force Civil Engineering Center (AFCEC). Sites were identified by AFCEC, US Army Corps of Engineers (USACE), and the Naval Facilities Engineering Command (NAVFAC). Final selection of sites was based upon availability of climate data. Most are located at military installations supporting airfield operations, or at local airports/airfields. Non-DoD requests may be satisfied from a private consulting meteorologist or from NOAA's National Centers for Environmental Information (NCEI, formally the National Climatic Data Center). Each site's EWD is presented as a PDF. To comply with **1**\ ASHRAE Standard 90.1, *Energy Standard for Buildings Except Low-Rise Residential Buildings* (Refer to UFC 1-200-02, for applicable publication date) /**1**/, the 14 WS has added a separate comma separated values file containing all cooling degree-day data based on 50°F for all sites. Paragraph in Chapter 2 entitled "Alternate Cooling Degree-Days Calculation" covers the use of this file in more detail. Bin Temperature Data .csv files are suitable for importing into Microsoft® Excel.

1-2 APPLICABILITY.

This UFC is applicable to all service elements and contractors involved in the planning, design and construction of DoD facilities worldwide.

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

1-5 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

1-6 ACCESSING EWD.

1-6.1 Retrieving data for .mil domain users.

1. Access https://www.climate.af.mil/.
2. A Common Access Card (CAC) is required to access the 14th Weather Squadron's web site. If you do not have one, call 828-271-4291 to request an EWD or send an email request to 14WS_SAR@us.af.mil.
3. A CAC user can also electronically submit a Support Assistance Request by clicking on the "Request Support" tab at the top of the 14 WS website.

1-6.2 Retrieving Data for Non-DoD (non CAC) Users.

Non-DoD users (e.g., contractors) may access data from the 14 WS if they are working on a DoD contract. If so, follow these instructions:

1. Fill out the Sample SAR Form in Appendix D, and send an email requesting support to 14WS_SAR@us.af.mil. This email inbox is monitored Monday –Friday 0730-1630 with the exception of holidays.
2. Pay particular attention to the fields requesting a complete description of the information being requested (e.g., site location and coordinates), a suspense date, a statement about how the data applies to the mission and the contract number.
3. The 14 WS must be able to verify that the contractor is working on a valid DoD contract before providing the information. The 14 WS will then e-mail the appropriate PDF file for the site requested. Non-DoD contractors and vendors must contact the National Centers for Environmental Information (NCEI, formally NCDC) to purchase the Engineering Weather Data (EWD).
4. Retrieving data for unlisted sites. If a station is not in the EWD list, fill out the 14 WS Support Assistance Request (SAR) form (example in Appendix D) and pay particular attention to the fields requesting a complete description of the information being requested (e.g., site location and coordinates), a suspense date, a statement about how the data applies to the mission, and the contract number.

CHAPTER 2 DATA DESCRIPTION AND APPLICATIONS

2-1 INTRODUCTION.

This chapter summarizes each page in a typical site data set and provides guidance for using the data.

2-2 DATA SET PAGE 1: CLIMATE SUMMARY.

Figure 2-1 is a sample of Data Set Page 1, which summarizes the site's climate.

2-2.1 Location Information.

This section of Data Set Page 1 contains a summary table that includes site name, location, elevation (above mean sea level), period of record (POR), and average (atmospheric) pressure not corrected to sea level (higher elevations result in lower pressures). The POR is the time frame over which the data used to compute the statistics in this document were compiled.

2-2.2 Design Values.

2-2.2.1 Explanation of Design Values.

Design values are provided for dry bulb temperature, wet bulb temperature, and humidity ratio at specific percentile frequencies of occurrence. The design values of 0.4%, 1%, and 2% are based on the entire year. The winter design values of 99.6%, 99%, and 97.5% are also based on the entire year. In other words, the design values are annual values, not seasonal values. These design values were instituted for several reasons. At some locations, the warmest or coldest months of the year do not fall into the months listed above. It is easier to compare locations that are in tropical or marine climates where there is less seasonal variability. It is also more straightforward to compare southern hemisphere locations.

SCOTT AFB MIDAMERICA IL Page (1 of 18)

2-2.2.2 Dry Bulb Temperature.

2-2.2.2.1 Median of Extreme Highs (or Lows).

The dry bulb temperature extreme high (or low) is determined for each calendar year of the POR along with the coincident values for wet bulb temperature, humidity ratio, wind speed, and prevailing wind direction. Median values are determined from the distribution of extreme highs (or lows).

2-2.2.2.2 0.4%, 1.0%, 2.0%, 97.5%, 99.0%, and 99.6% Dry Bulb Design Values.

Listed is the dry bulb temperature corresponding to a given annual cumulative frequency of occurrence and its respective mean coincident values for wet bulb temperature, humidity ratio, wind speed, and prevailing wind direction. The dry bulb temperature listed represents the value that was exceeded for the respective percent of time over the entire POR. For example, the 1.0% occurrence design value temperature (92 °F) has been exceeded only 1 percent of the time during the entire POR. All the observations occurring within one degree of the design value are grouped, and the Mean Coincident (Average) Values for Wet Bulb Temperature, Humidity Ratio, and Wind Speed are calculated. The prevailing wind direction (the “mode” of the wind direction distribution) is also calculated.

2-2.2.2.3 Mean Daily Range.

The mean daily range (difference between daily maximum and daily minimum temperatures) is the average of all daily dry bulb temperature ranges for the POR.

2-2.3 Wet Bulb Temperature.

2-2.3.1 Median of Extreme Highs.

The Median of Extreme Highs value for wet bulb temperature is the highest annual extreme wet bulb temperature averaged over the POR. The corresponding Mean Coincident (Average) Values are determined the same way as for the respective values for dry bulb temperature.

2-2.3.2 0.4%, 1.0 %, 2.0% Wet Bulb Temperature Design Values.

The design values listed and the corresponding Mean Coincident (Average) Values are determined the same way as for dry bulb temperature, described in 2-2.2.2.2.

2-2.4 Humidity Ratio.

2-2.4.1 Median of Extreme Highs.

The value for humidity ratio is the highest annual extreme averaged over the POR. The corresponding Mean Coincident (Average) Values are determined the same way as described in 2-2.2.2.2.

2-2.4.2 0.4%, 1.0%, and 2.0% Humidity Ratio Design Values.

Design values are provided for humidity ratio and the corresponding Mean Coincident (Average) Values for dry bulb temperature, vapor pressure, wind speed, and wind prevailing direction.

2-2.5 Air Conditioning/Humid Area Criteria.

These are the number of hours, on average, that dry bulb temperatures of 34 °C (93 °F) and 27 °C (80 °F) and wet bulb temperatures of 23 °C (73 °F) and 19 °C (67 °F) are equaled or exceeded during the year.

2-2.6 Other Site Data.

This information is provided **for general reference only, and should not be used as the basis for design**. There are some locations for which this data is not available. In these cases, that portion of the table will be left blank.

2-2.6.1 Weather Region.

Eleven weather regions have been developed by the Department of Energy. They are defined by the range of cooling-degree days and heating-degree days based on 65 °F. ASHRAE/IESNA Standard 90.1 of 2001 uses annual HDD65 (Heating Degree Days based on 65 °F) and CDD50 (Cooling Degree Days based on 50 °F) to select the appropriate Building Envelope Requirements table for energy conservation design. Refer to paragraph 2-10 for further explanation of this data.

2-2.6.2 Ventilation Cooling Load Index.

The Ventilation Cooling Load Index (VCLI) is a two-part index that defines the total annual cooling load for ventilation air by calculating sensible heat load separately from the latent heat load (moisture). The results are expressed in ton-hours per cubic feet per minute per year of latent and sensible load. Values for sensible heat load are calculated by comparing the outdoor temperature to indoor conditions (75 °F and 60% relative humidity [RH]), and calculating how much energy is required to bring the outdoor air to the indoor temperature. The latent load is calculated similarly. Separate calculations are made for each hour of the year and then summed to form the annual VCLI.

2-2.6.3 Average Annual Freeze-Thaw Cycles.

This value is the average number of times per year that the air temperature first drops below freezing and then rises above freezing, regardless of the duration of either the freezing or thawing. The number of cycles is summed per year and averaged over the entire POR. Days with high temperatures or low temperatures at 0 °C (32 °F) are not counted for a freeze- thaw cycle. A cycle is counted only when the temperature drops below freezing (-0.5 °C [31 °F] or colder) or goes above freezing (0.5 °C [33 °F] or warmer).

2-2.6.4 Other Values.

The following values are derived from sources other than the 14 WS. Engineers and architects should review the publications listed below and contact the organizations for current values, including background information and complete guidelines for use of these data elements.

2-2.6.4.1 Groundwater.

National Ground Water Research and Educational Foundation
601 Dempsey Road
Westerville OH 43081-8978
(800) 551-7379
http://www.ngwa.org/

NOTE: Average groundwater temperature parallels long-term average air temperature, because soil at a depth of 15 meters (50 feet) does not undergo significant temperature change over the course of a year. Soil temperature at 15 meters stays slightly warmer than average annual air temperature by approximately 1.4 °C (2.5 °F).

2-2.6.4.2 Rain Rate.

International Plumbing Code
International Code Council
4051 West Flossmoor Road
Country Club Hills IL 60478
(888) 422-7233
http://www.iccsafe.org/

2-2.6.4.3 Frost Depth, Basic Wind Speed, Ground Snow Loads.

2\ ASCE/SEI 7-16, *Minimum Design Loads and Associated Criteria for Buildings and Other Structures* /***2***/
American Society of Civil Engineers
1801 Alexander Bell Drive
Reston, VA 20191
(800) 548-2723
http://www.asce.org/

NOTE: Use UFC 3-301-01, *Structural Engineering*, for reference on some frost depth and ground snow load values.

2-2.7 Suggestions for Use.

The dry bulb, wet bulb, and humidity ratio values in Figure 2-1 are peak load conditions and are used for sizing mechanical equipment. Design guidance determines the frequency of occurrence design is to be based upon.

2-2.7.1 Dry Bulb Temperature.

The 0.4% dry bulb temperature value is seldom used for sizing conventional comfort control systems but is sometimes appropriate for mission-critical systems where equipment failure due to high heat would be unacceptable. Using the 0.4% value for equipment sizing requires that the engineer consider its operation at less-than-peak design conditions. In the past, oversized cooling equipment has been incapable of modulating during the more common range of operating conditions, yielding comfort control problems. Also, over-sized equipment cycles on and off more frequently, increasing maintenance costs and failing to remove enough moisture to maintain humidity control.

2-2.7.1.1 Design for Extreme Conditions.

Similar special considerations apply to the extreme low dry bulb temperature. Heating equipment designed for extreme conditions must be evaluated carefully to ensure that it will modulate properly to maintain comfort at less extreme outdoor temperatures that occur in 99.6% of the hours during the year.

2-2.7.1.2 Design of Humidity Control Systems.

The mean coincident value for humidity at the 0.4% peak dry bulb temperature is not the highest moisture value and must not be used for design of humidity control systems. The mean coincident value is the arithmetic average of all the moisture levels that occur when the dry bulb temperature is high; however, the highest moisture values typically occur when the dry bulb temperatures are lower.

2-2.7.2 Wet Bulb Temperature.

High wet bulb temperature is used for sizing cooling towers and other evaporative equipment.

2-2.7.3 Peak Humidity Ratio.

Peak humidity ratio is used for sizing dehumidification systems. Peak moisture condition usually represents a higher enthalpy (total heat) than peak dry bulb condition. Consequently, engineers use the peak moisture condition to cross-check operation of a system that may be primarily intended to control temperature.

2-2.7.4 Coincident Wind Speed.

Coincident wind speed allows the engineer to accurately estimate latent loads due to infiltration of humid air in the summer and of dry air in the winter.

NOTE: The same precautions that apply to heating and cooling equipment also apply to dehumidification and humidification systems. Oversized equipment may not control properly under typical operating conditions without special attention from the engineer.

2-3 DATA SET PAGE 2: AVERAGE ANNUAL CLIMATE.

Figure 2-2 is an example of Data Set Page 2, a graph summarizing the site’s average annual climate.

2-3.1 Explanation of Graph.

The graph on Data Set Page 2 shows the site’s monthly mean temperature, dew point, and precipitation. The bar graph representing precipitation uses the scale on the right side of the chart (inches or centimeters). Lines of temperature and dew point use the scale on the left side of the chart (degrees Fahrenheit or Celsius). These charts have fixed maximum and minimum values on their axes for easy comparison between different sites. The precipitation chart is capped at a maximum of 45 centimeters (15 inches) per month. A few sites may exceed this value, but to keep the graph readable, a fixed maximum value was used. For a number of sites, no accurate precipitation data was available. In those cases, no bars appear on the chart.

2-3.2 Suggestions for Use.

2-3.2.1 Comparisons.

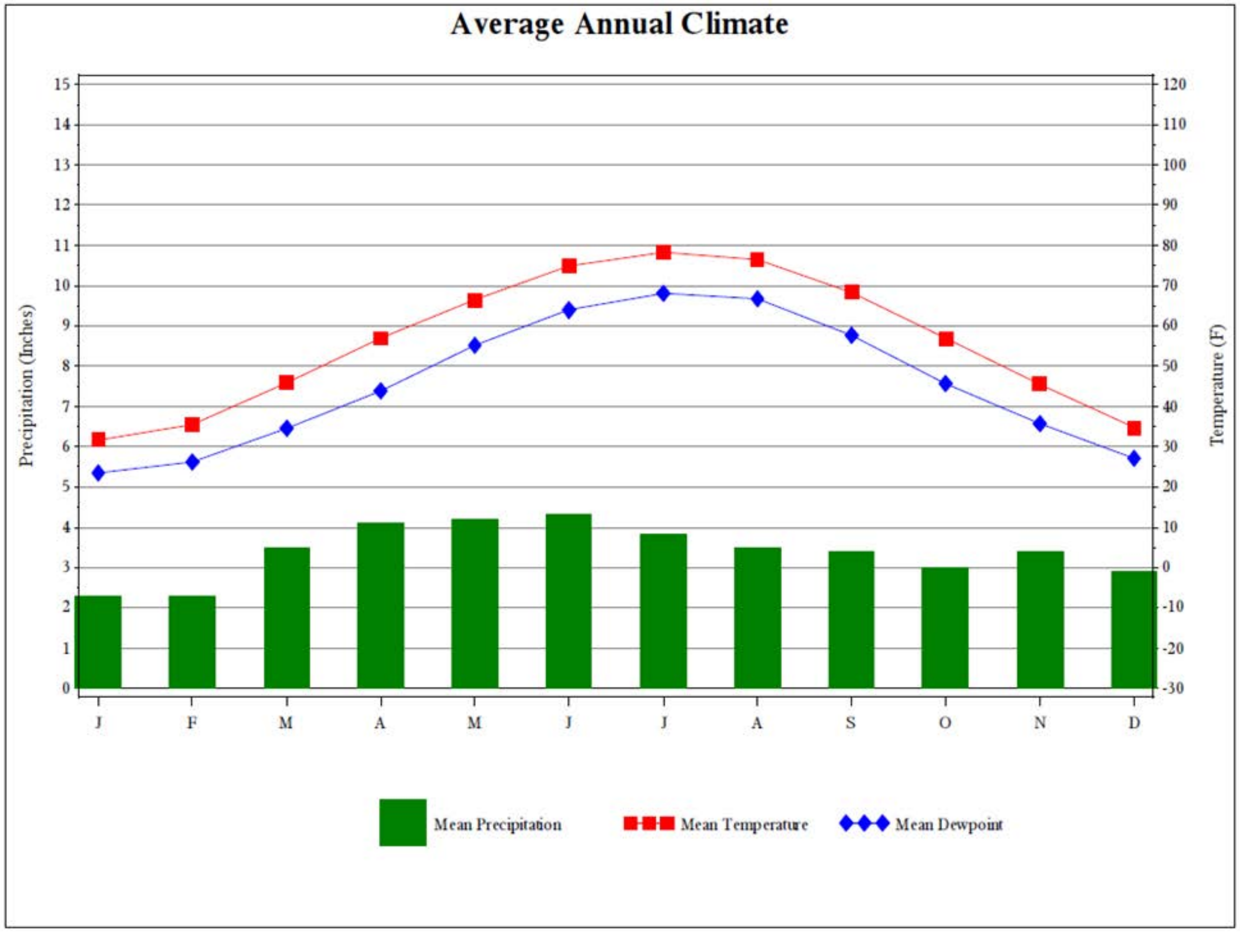
The Data Set Page 2 graph displays the average behavior of weather over a single year. An architect can compare rainfall patterns at one station with another and also the relative importance of water resistance for the exterior envelope. An engineer can compare the temperature and moisture patterns to understand the relative importance of sensible heat loads rather than latent loads at this location.

2-3.2.2 Seasonal Variations.

With averages displayed by month, it is relatively easy to comprehend seasonal variation of each variable, and also to understand which specific months are likely to be hot or cold, humid or dry, or have high precipitation. This can be helpful for mission planning, as well as for planning construction and building operation.

NOTE: This graph displays averages, not design or extreme values. Data shown should not be used to determine equipment capacities or thermal characteristics of building envelopes.

Figure 2-2 Sample Data Set Page 2



SCOTT AFB MIDAMERICA IL Page (2 of 18)

2-4 DATA SET PAGE 3: 30-YEAR PSYCHROMETRIC SUMMARY.

Figure 2-3 is an example of Data Set Page 3, a graph summarizing the site's psychrometric data.

2-4.1 Explanation of Graph.

2-4.1.1 Joint-Frequency Table.

The graph displays the joint cumulative percent frequency of temperature and humidity ratio. Hourly observations are grouped into bins of 5 Fahrenheit degrees and 10 grains per pound (gr/lb) (or 3 Celsius degrees and 1.5 grams per kilogram [g/kg]), centered on each value of temperature or humidity ratio. For example, the 70 °F temperature bin collects all observations between 67.5 °F and 72.5 °F. The bin is depicted as a gridline on the chart; the vertical lines represent the temperature bins and the horizontal lines represent the humidity ratio bins. The intersection of temperature and humidity ratio lines represent a further subdivision of the observations into groups meeting both temperature and humidity ratio criteria. For example, the intersection of the 70 °F bin line and the 40 gr/lb bin line represent the observations when temperature was between 67.5 °F and 72.4 °F and the humidity ratio was between 35 gr/lb and 44 gr/lb. Thus, a joint-frequency table is created for all temperature and humidity ratio bin combinations.

NOTE: The psychrometric graph is intended as a visual tool only. Its purpose is to allow a quick visual comparison between climates at different locations. Extrapolation of data directly from the graph is not advised due to the approximate plotting routine used to generate the graph from the binned data. This is evident where values of humidity appear past their saturation point. This discrepancy between the actual data and the graph is the result of the plotting routine used to generate the graph and not from errors in the original hourly data used to create the binned summary.

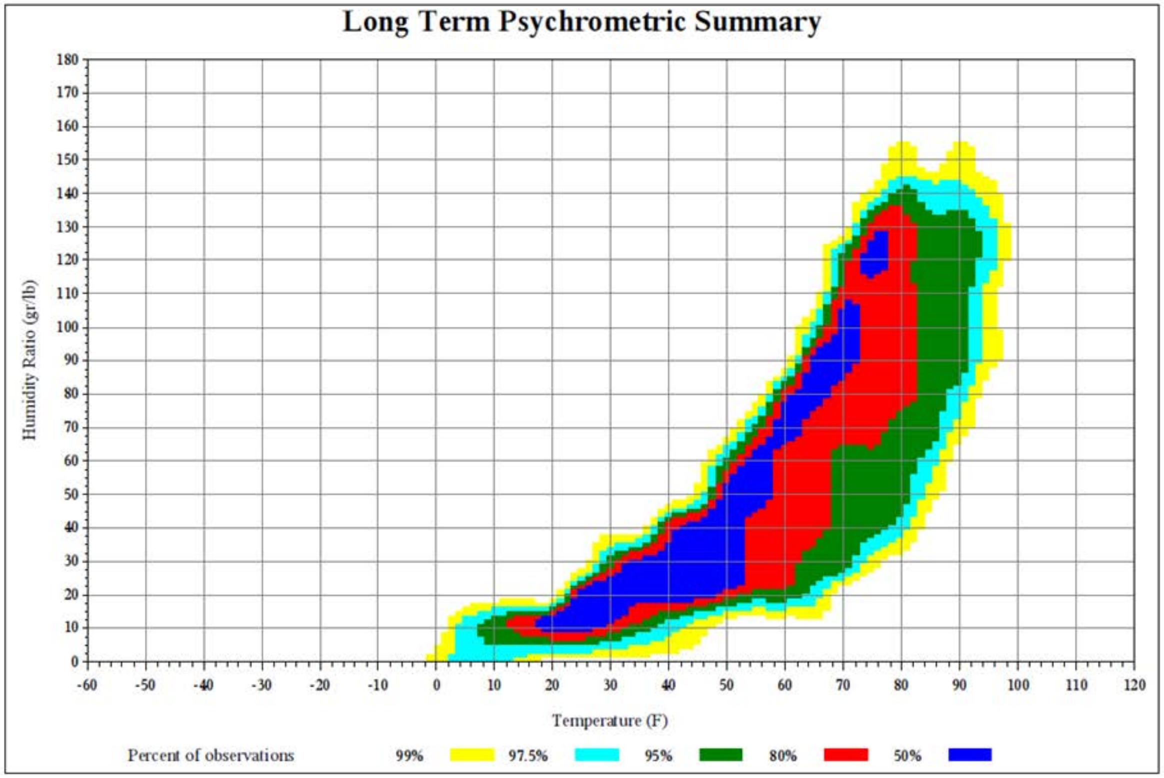
2-4.1.2 Contours.

The contours on this chart represent the areas containing 99%, 97.5%, 95%, 80%, and 50% of all observations (cumulative percent frequency or percentiles). The contours are centered on the most frequently occurring bins (50% contour), spreading outward until almost all observations (99%) are grouped. Contours are defined by calculating a percent frequency for each bin (relative to the others), and then accumulating these percent frequencies (from most frequent to least frequent) until the 50% value is passed, and thus the first set of bins is grouped. The accumulating continues until the 80% value is passed, and the second group of bins is grouped. This process continues until the 95%, 97.5%, and 99% values are passed.

2-4.1.3 Least Frequent (Most Extreme) Bins.

Consequently, the least frequent (most extreme) bins, which when accumulated amount to less than 1 percent of the total observations, are outside of the 99% contour. Any bins outside the 99% contour thus have either not occurred, or have occurred so infrequently that they should not be taken into consideration for sizing equipment.

Figure 2-3 Sample Data Set Page 3



SCOTT AFB MIDAMERICA IL Page (3 of 18)

2-4.2 Suggestions for Use.

2-4.2.1 Most Common Temperature and Moisture Conditions.

The Data Set Page 3 graph displays the long-term history of temperature and moisture at each station (a total of 262,800 hourly observations if the POR is 30 years and if the data is complete over that period). The engineer can use this graph to ascertain the most common temperature and moisture conditions that will be encountered over the operating life of the mechanical equipment.

2-4.2.2 Ensure Modulation and Control Capability.

It is often useful to calculate the behavior of the proposed system at “most common” conditions and assess these calculations in addition to the traditional peak design calculations. This will help ensure that the selected equipment and controls are capable of modulation and control at all points of operation rather than simply at extreme conditions.

2-5 DATA SET PAGE 4: PSYCHROMETRIC DISPLAY OF DESIGN VALUES.

Figure 2-4 is an example of Data Set Page 4, a psychometric display of the site’s design values.

2-5.1 Saturation Curve.

Similar to Data Set Page 3, this chart depicts the saturation curve (when RH = 100%) along with peak design values. The design values are calculated as in the table on Data Set Page 1 (Figure 2-1), but this chart shows their relationships graphically, depicting their position relative to each other and relative to the saturation curve.

2-5.2 Observations.

Above and to the left of the saturation curve, RH would be greater than 100% (not possible). The area below and to the right of the curve (including the points on the curve itself) represent the area where RH is less than or equal to 100%, and thus where all observations occur. Note that since the humidity ratio is a function of pressure, and pressure varies with elevation, different sites will have different saturation curves.

2-5.3 Scatter Plot.

The dry bulb temperature is the horizontal coordinate on this scatter plot, and the humidity ratio is the vertical coordinate. Peak design values are depicted by the red square (1.0% Temperature [dry bulb]), the green circle (1.0% Humidity Ratio), and the blue diamond (99% Temperature [dry bulb]).

2-5.4 Table.

The table below the chart shows the exact values of 99% dry bulb temperature, 1.0% humidity ratio, and 1.0% dry bulb temperature, along with calculated values of enthalpy, mean coincident wet bulb temperature, and humidity ratio (as applicable). The value of enthalpy coincident to each temperature/humidity ratio is created using the psychrometric functions provided by the Linric Company, Bedford, New Hampshire. The dry bulb temperature and humidity ratio are used to calculate enthalpy using the Linric algorithms.

Figure 2-4 Sample Data Set Page 4

	(°F) / (gr/lb)	MCDB (°F)	MCWB (°F)	MCDP (°F)	MCHR (gr/lb)	Enthalpy (btu/lb)
1.0% Dry Bulb	93.0		77		116.0	40.6
99.0% Dry Bulb	11.0				7.0	3.6
1.0% Humidity Ratio	141.0	83.0	78.5	76.7		42.1

SCOTT AFB MIDAMERICA IL Page (4 of 18)

2-6 DATA SET PAGES 5 THROUGH 9: TEMPERATURE BIN DATA.

Figures 2-5 through 2-9 are examples of Data Set Pages 5 through 9, respectively. These tables show the number of hours that temperatures occur in 5 Fahrenheit degree (3 Celsius degree) bins of specific 8-hour daily periods during a given month. The 8-hour periods are based upon a 24-hour clock and displayed in Local Standard Time (LST). For each month, the number of observations for each temperature bin during each of the specific 8-hour periods of the day appear in a column under the specific Hour Group (LST). The total number of observations (hours) in each temperature bin is displayed in the “Total Obs” column for the month. The mean coincident wet bulb temperature is the mean value of all those wet bulb temperatures that occur coincidentally with the dry bulb temperatures in the particular 5° temperature bin. At the upper, or warmer, end of the mean coincident wet bulb distribution, the values occasionally reverse their trend because the highest wet bulb temperatures do not necessarily occur with the highest dry bulb temperatures. There are 13 such tables, one for each month and one representing the overall annual summary (Data Set Page 9).

2-6.1 Suggestions for Use.

Binned summaries are used by many different technical disciplines for different purposes. They are useful in making informal estimates of energy consumption by cooling and heating equipment, and for gaining a general understanding of patterns of temperature and moisture at different times of the day, month, and year.

NOTE: Do not use these binned summaries to calculate design moisture loads.

2-6.2 Comments.

These particular binned summaries are based on the dry bulb temperature. After each observation has been placed into a dry bulb bin, the average humidity ratio is calculated for all observations in each bin. Consequently, dry bulb bins underestimate the magnitude of dehumidification and humidification loads because the averaging calculation “flattens” the peaks and valleys of humidity ratios. The amount of the underestimation varies according to the intended humidity control level.

Figure 2-5 Sample Data Set Page 5

Dry-Bulb Temperature Hours For An Average Year

-15/-11	1	0	0	1	-12.6
-20/-16	0			0	-15.5

Caution: This summary reflects the typical distribtion of temperature in a typical year. It does not reflect the typical mositure distribution. Because wet bulb temperatures are averaged, this summary understates the annual moisture load. For accurate moisture load data, see the long-term humidity summary and the ventilation and infiltration load pages in this manual.

2-7 DATA SET PAGE 10: ANNUAL TEMPERATURE SUMMARY.

Figure 2-10 is an example of Data Set Page 10. This chart shows a week-by-week summary of dry bulb temperatures for the given site. The observations are grouped into 7-day periods (approximate calendar weeks). For example, observations from January 1 through 7 from all years are grouped, observations from January 8 through 14 from all years are grouped, and so on, overlapping the end of one month and beginning of the next month where necessary. The following statistics are shown for each of the 7-day periods:

- *1% Dry Bulb Temp* is the dry bulb temperature that is exceeded 1% of the time during that calendar week.
- *MCWB (1% Dry Bulb)* is the mean of wet bulb temperatures coincident with 1% dry bulb temperatures during the same week.
- *Mean Max Temp* is the daily maximum dry bulb temperature, averaged by week over the POR.
- *Mean Min Temp* is the daily minimum dry bulb temperature, averaged by week over the POR.
- *99% Min Dry Bulb Temp* is the daily dry bulb temperature that is at or above this value 99% of the time, or below this value 1% of the time.

NOTE: The information in this chart is calculated on a weekly basis; information on a climate summary (Data Set Page 1) is calculated on an annual basis.

2-7.1 Suggestions for Use.

The weekly 1% and 99% temperatures are useful for understanding the probable temperature extremes that can occur during a given week of the year. The weekly dry bulb temperatures are useful for understanding the change of seasons at a given location. The display is helpful for mission planning and construction project planning.

2-7.2 Special Considerations.

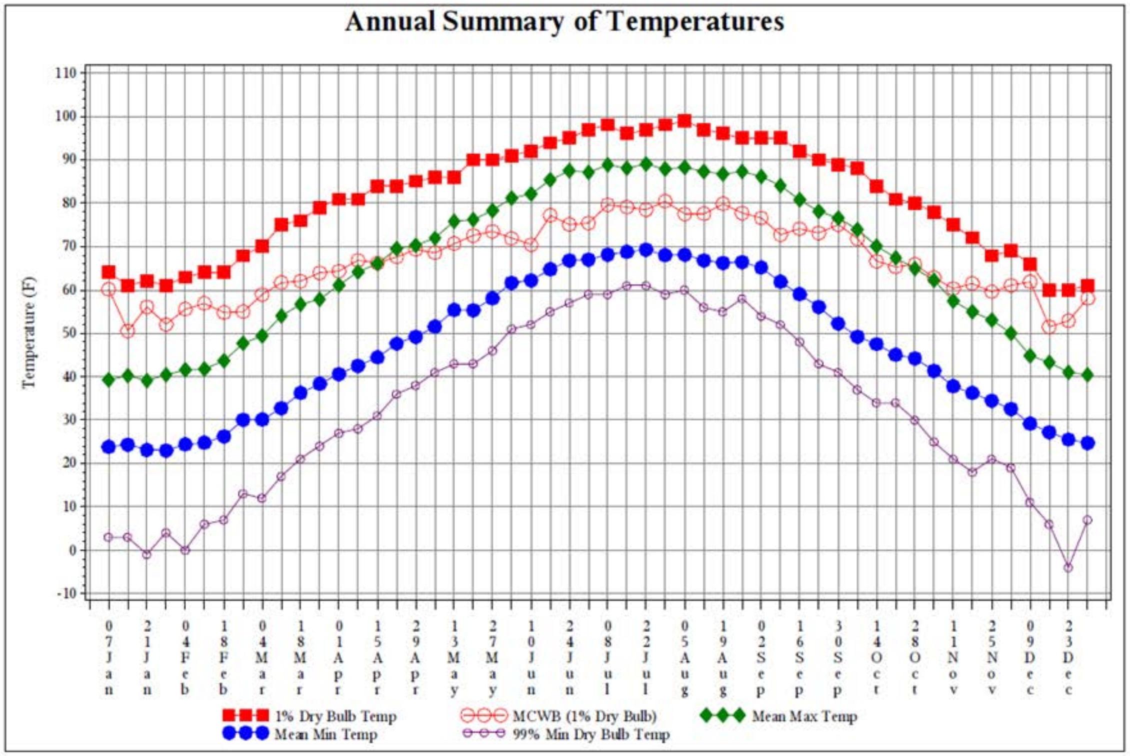
2-7.2.1 Designers.

The values displayed here are based on the 30-year record. It is important that designers **not** base equipment selection on the “highest” or “lowest” recorded temperature at the station. That error would result in selecting equipment extremely costly to install, which would operate inefficiently for all but the very hottest or coldest single hour in 30 years. See the Design Criteria Data section on Sample Data Set Page 1 (see Figure 2-1) in this document for appropriate maximum and minimum temperatures for sizing equipment.

2-7.2.2 Construction and Operation Planners.

The mean maximum and minimum temperatures shown for each week seldom occur in the same year. Keep in mind that these are mean values that are useful for understanding the **typical** range of temperatures in a given week. The difference does **not** represent the **actual** day-night temperature swing in a given week.

Figure 2-10 Sample Data Set Page 10



SCOTT AFB MIDAMERICA IL Page (10 of 18)

2-8 DATA SET PAGE 11: ANNUAL HUMIDITY SUMMARY.

Figure 2-11 is an example of Data Set Page 11. Similar to the annual temperature summary (see Sample Data Set Page 10, Figure 2-10), this chart depicts mean maximum and minimum values of humidity ratio, plus the 1% maximum humidity ratio, along with its mean coincident dry bulb temperature, summarized by calendar week. The chart uses two vertical axes: on the left are the humidity ratio values and on the right is a temperature scale for the mean coincident dry bulb temperature.

2-8.1 Suggestions for Use.

Weekly humidity ratios are useful for understanding the change of seasons at a given location and the probable high and low moisture levels during a given week of the year. The display is helpful for planning humidity- controlled storage projects and for understanding factors contributing to atmospheric corrosion. Humidity also affects the deterioration rate of building materials and the weathering of military equipment and structures exposed to the elements.

2-8.2 Special Considerations.

2-8.2.1 Designers.

The values displayed here are based on the 30-year record. It is important that designers **not** base equipment selection on the “highest” or “lowest” recorded humidity at the station. That error would result in selecting oversized equipment, which would increase costs and might result in control problems at other than extreme conditions. Use design values on Data Set Page 1 (Figure 2-1) for equipment sizing.

2-8.2.2 Construction and Operation Planners.

The high and low humidity ratios shown for each week seldom occur in the same year. Keep in mind that these are mean values that are useful for understanding the typical range of humidity ratio in a given week. The difference does **not** represent the **actual** day-night humidity ratio swing in a given week.

2-9 DATA SET PAGE 12: ANNUAL DRY BULB TEMPERATURE AND HUMIDITY SUMMARY TABLES.

Figure 2-12 is an example of Data Set Page 12. Data Set Page 12 consists of tables containing the values used to plot the charts on Data Set Page 10 and Data Set Page 11. The left half of the table uses Data Set Page 10 and the right half uses Data Set Page 11.

SCOTT AFB MIDAMERICA IL   Page (12 of 18)

2-10 DATA SET PAGE 13: BUILDING ENVELOPE LOADS.

Figure 2-13 is an example of Data Set Page 13. Data Set Page 13 consists of charts summarizing a site's mean heating and cooling degree days.

2-10.1 Explanation of Charts.

2-10.1.1 Calculation of Cooling Degree-Days.

Cooling degree-days are derived by multiplying the number of hours that the outdoor temperature is above the base temperature of 65 °F (18 °C) times the number of degrees of that temperature difference. For example, if 1 hour was observed at a temperature of 78 °F, that observation adds 13 degree-hours to the annual total. The sum of the degree-hours is divided by 24 to yield degree-days.

2-10.1.2 Calculation of Heating Degree-Days.

Heating degree-days are calculated similarly, against the base temperature of 65 °F, so a 1-hour outside temperature observation of 62 °F adds 3 degree-hours to the annual total. Heating degree-days are summed separately from the cooling degree-days. Heating and Cooling degree-hours do not cancel each other out, since both heating and cooling conditions may occur over the course of a given day.

2-10.1.3 Alternate Cooling Degree-Days Calculation.

A separate file has been added to the 14 WS Web site to include the cooling degree-days based upon a base temperature of 50 °F. This file is located on the Engineering Weather Data page under the Standard EWD Package file. This data is intended to allow selection of the proper Building Envelope Requirements table from within **1**\ ASHRAE Standard 90.1, *Energy Standard for Buildings Except Low-Rise Residential Buildings* (Refer to UFC 1-200-02, for applicable publication date) /**1**/ for energy conservation design. The cooling degree-days based on 65 °F tabulated and graphed here are historically used to estimate loads as suggested in paragraph 2-10.2 below.

2-10.2 Suggestions for Use.

Degree-days are used to estimate the sensible heat and sensible cooling loads on the building envelope. Degree-day loads can be used to estimate the annual energy consumption of a building, provided that the loads from ventilation and infiltration air are also considered (see paragraph 2-11).

SCOTT AFB MIDAMERICA IL Page (13 of 18)

2-11 DATA SET PAGE 14: VENTILATION AND INFILTRATION LOADS.

Figure 2-14 is an example of Data Set Page 14. Data Set Page 14 consists of a graph and table that display the independent loads imposed by heating, cooling, humidifying, and dehumidifying outside air as it is brought into a building. The calculation assumes that air inside the building is maintained at conditions between 68 °F (20 °C)/30% RH and 75 °F (24 °C)/60% RH. For the purposes of these calculations, when the outside air is within that range of temperature and moisture, any incoming air is assumed not to impose any load.

These values are calculated with the methodology used to calculate the annual VCLI on Data Set Page One, except that values on this page are computed by month and the result is displayed as British thermal units per cubic foot per minute (Btu/cfm) rather than as ton-hours per CFM per year. The heating and humidifying loads are shown as negative values. Cooling and dehumidifying loads are displayed as positive values.

2-11.1 Suggestions for Use.

Bringing fresh ventilation air into a building or allowing air to infiltrate into buildings through cracks imposes heating, cooling, dehumidification, and humidification loads on the mechanical system. The information on this data set page helps the architect, engineers, and operating personnel understand the nature and magnitude of those loads on an annual basis. It also shows how the loads vary from month to month throughout the year.

2-11.2 Comments.

These calculations are based on the load created when 1 cubic foot of outside air is brought into the building each minute. The results of the calculation include the moisture load or deficit, and the sensible heat load or deficit created by that cubic foot of air during each month of the year. Note that most months have both a load and a deficit for temperature and moisture. The monthly deficit and load do not “cancel” from the perspective of the mechanical system, because temperature and moisture loads will often occur at different times of the day.

NOTE: The values displayed here assume that the inside air is maintained between 68 °F/30% RH and 75 °F/ 60% RH. If the inside conditions are held in a different range of temperature or moisture, the loads will be different. For example, in calculating loads for humidity-controlled but unheated storage, the loads vary according to the change in both temperature and humidity, since the inside temperature varies but the inside humidity is held constant. For estimating loads in that or similar applications, the engineer may obtain better results by using the average maximum weekly humidity data shown on Data Set Pages 11 and 12 (Figures 2-11 and 2-12).

Figure 2-14 Sample Data Set Page 14

SCOTT AFB MIDAMERICA IL Page (14 of 18)

2-12 DATA SET PAGES 15 AND 16: SOLAR RADIATION DATA.

Figures 2-15 and 2-16 are samples of Data Set Page 15 and Data Set Page 16, respectively.

2-12.1 Explanation of Charts.

2-12.1.1 Data Source.

This data is reproduced courtesy of the National Renewable Energy Laboratory (NREL). The data were first published in the NREL's *Solar Radiation Data Manual for Buildings* (1995). The user should refer to that publication for a complete description of how to use this data. The manual can be accessed online at http://www.osti.gov/bridge by searching for "NREL/TP--463-7904."

2-12.1.2 Site Location.

The site used in each station record is the nearest NREL-published site available within a 1.5° latitude radius from the requested location. Consequently, some sites may be several miles away, and in some cases, the NREL location may be in a neighboring state. Use caution when the nearest site available is not in the same city as the requested location, since significant differences in cloud climatology can exist over short distances.

2-12.1.3 Site Availability.

When this document was prepared, the only sites available from NREL were Puerto Rico, Guam, and the 50 states. For locations where solar radiation data is not available, Data Set Pages 15 and 16 are blank. For these locations, users may wish to contact NREL directly to obtain advice concerning data not published in the NREL solar radiation data manual.

2-12.2 Suggestions for Use.

The solar data presented here can be used for calculating solar radiation cooling loads on building envelopes, and also for estimating the value of solar illumination for daylighting calculations. Again, the user should refer to the *Solar Radiation Data Manual for Buildings* for a complete description of how to use this data.

NOTE: The data source for the NREL reports comes from the National Solar Radiation Database—not the data set used to calculate peak design values and other monthly temperature and moisture data in this document. The two data sets will differ for many reasons, including different POR, measurement locations, sampling methodology and frequency, and differences in calculation methodology. Consequently, the user should expect differences in degree-days, minimum and maximum temperatures, and humidity values between this data and that calculated by the 14 WS. For design criteria, use the temperature and moisture values presented on the Design Criteria Data section of Data Set Page 1 (see Figure 2-1) of this document. These were calculated more recently and used a longer POR. Also, they are taken from records at DoD locations rather than from civilian locations near—but not always identical to—the military data collection points.

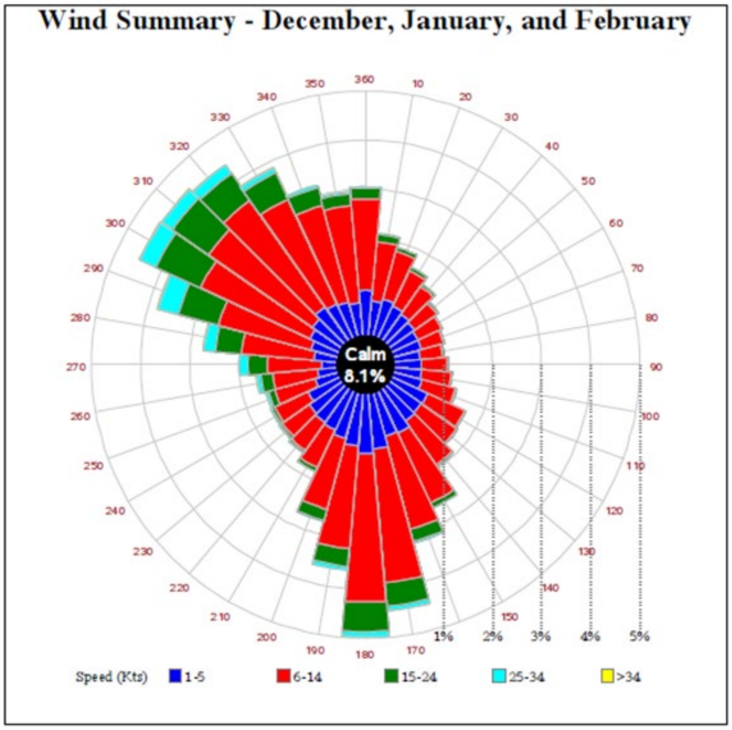
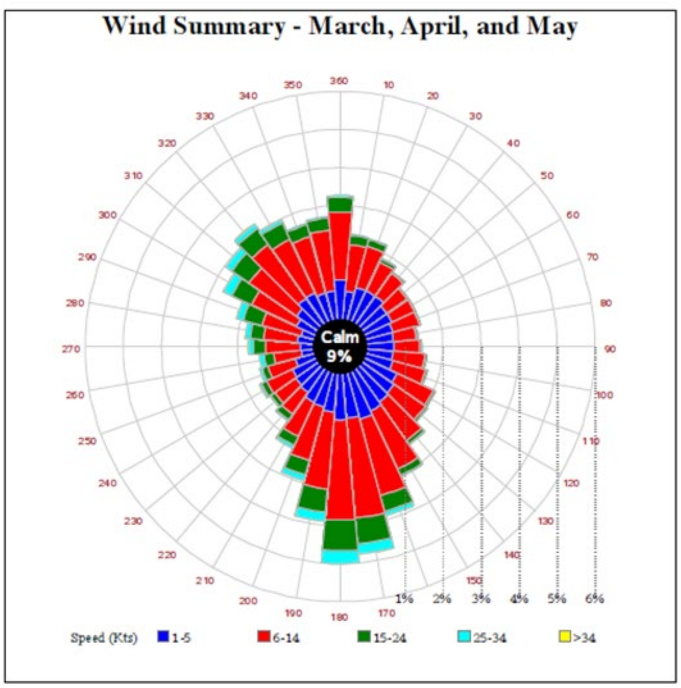
SCOTT AFB MIDAMERICA IL Page (16 of 18)

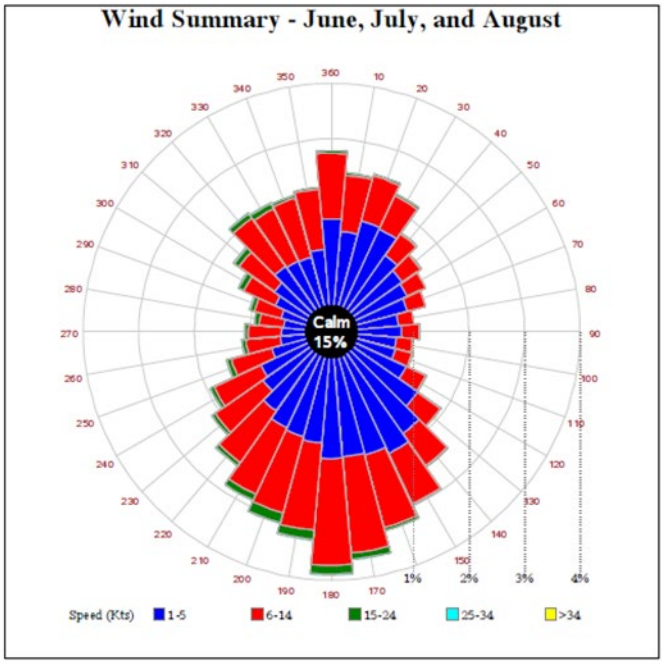
Figure 2-17 Sample Data Set Page 17

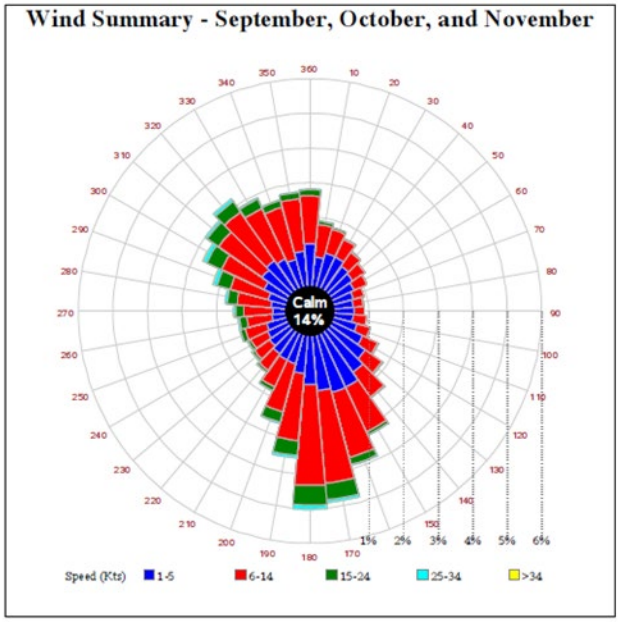




SCOTT AFB MIDAMERICA IL Page (17 of 18)

Figure 2-18 Sample Data Set Page 18





SCOTT AFB MIDAMERICA IL Page (18 of 18)

2-13 DATA SET PAGES 17 AND 18: WIND SUMMARY.

Figures 2-17 and 2-18 are samples of Data Set Page 17 and Data Set Page 18, respectively.

2-13.1 Explanation of Charts.

2-13.1.1 Depiction.

These charts depict the frequency of different wind direction and wind speed combinations. The observations are binned into 36 compass directions and 5 speed categories (1 to 5 knots, 6 to 14 knots, 15 to 24 knots, 25 to 34 knots, and greater than 34 knots). The frequency of direction and the tick marks indicate that values lie along each “spoke” of the wind chart. The wind speed bins for each direction are color coded by the legend at the bottom of the chart.

2-13.1.2 Percent Frequency.

To determine the percent frequency of a particular wind direction, look for the tick mark bounding the outer edge of a colored (wind speed) area. In the case of the first wind speed bin (1 to 5 knots), the percent frequency is simply the value of the tick mark on the outer edge of the 1 to 5 knot region. For the higher speed bins (6 to 14 knots or greater), subtract the earlier spoke values from the value shown to get the frequency for the speed bin in question.

2-13.1.3 Total Percent Frequency.

The values for percent frequency have been summed by direction, so to determine the total percent frequency for all speeds from a particular direction, look up the tick mark (or interpolated value) bounding the outermost colored area along that spoke. That tick mark represents the total percent frequency of wind from that direction.

2-13.1.4 Calm Conditions.

Since the calm condition has no direction, the percent occurrence of calm conditions is displayed at the center of the chart.

2-13.2 Wind Summary Chart Example.

The wind summary charts are prepared by 3-month seasons, over all hours (e.g., December, January, February for northern hemisphere winter or southern hemisphere summer; March, April, May for northern hemisphere spring or southern hemisphere fall). See the December through February sample wind summary chart in Figure 2-17 for an example of determining percent frequencies.

2-13.2.1 December through February.

From the December through February sample wind summary chart, the percent frequency of wind between 1 to 5 knots and from the north (N) is about 1%. The percent frequency of wind between 6 to 14 knots and from the south (S) is about 3% (~4.25% minus ~1.25%). The percent frequency of all wind speeds from the south (S) is about 5%. The percent frequency of all wind directions from the west through north (270° - 360°) is about 35% (2% + 2.75% + 3.875% + 4.5% + 4.5% + 4.25% + 3.875% + 3.25% + 3% + 3%, respectively – all values approximated). It is easy to determine that wind speeds greater than 34 knots almost never occur (or are such a small frequency from any direction) because the colored area (yellow) is not shown or is indistinguishable because it is extremely small.

2-13.2.2 Calm Wind.

The percent of time the wind is calm is indicated in the center of the chart—in this case, 8.1%. When the outermost value from each of the 36 directions are summed and added to the percent calm, the result is 100% (allowing for rounding). Occurrences of variable wind direction are omitted from the sample before computing percent frequency by direction.

2-13.3 Suggestions for Use.

Knowing the probable wind speed and direction in a particular month can be helpful in construction and mission planning as well as in designing structures that experience severe wind-driven rain or drifting snow. Engineers designing outside air intake and building exhaust vents for heating and air conditioning systems can use these data to minimize the potential for cross-contamination between supply and exhaust air streams. Also, when drifting snow accumulation on roofs is likely, the information on these data set pages can be helpful for locating inlet and exhaust ducts so they are less likely to be obstructed by snowdrifts.

NOTE: The wind currents around any building are strongly affected by the geometry of the building and the topography of the site as well as those of any surrounding buildings. The wind data used for these wind summaries are typical of flat and open airfields where there are no obstructions near the observation point.

F	Fahrenheit
gr/lb	Grains per pound (humidity ratio, grains of water vapor per pound of air)

g/kg	Grams per kilogram (humidity ratio, grams of water vapor per kilogram of air)
in. Hg	Inches of mercury (atmospheric pressure)
in.	Inches (frost depth)
in./hr	Inches per hour (rain rate)
klux-hr	Thousands of lux-hours (average incident illuminance)
lb/ft2	pounds per square foot (snow load)
LST	Local Standard Time
MCAS	Marine Corps air station
MCB	Marine Corps base
MC Dewpt	Mean Coincident Dewpoint
MCDB	Mean of dry bulb temperatures
MCHR	Mean Coincident Humidity Ratio
MCWB	Mean of wet bulb temperatures
mph	Miles per hour (wind speed)
NAS	Naval Air Station
NAF	Naval Air Facility
NAVFAC	Naval Facilities Engineering Command
NCDC	National Climatic Data Center
NRC	Naval Reserve Center
NREL	National Renewable Energy Laboratory
NS	Naval Station
NSA	Naval Support Activity
POR	Period of record
RH	Relative humidity
ton-hr/cfm/yr	Ton-hours of load per cubic foot per minute per year (Btu÷12,000)

USACE	US Army Corps of Engineers
VCLI	Ventilation Cooling Load Index
WBAN No	Weather Bureau Army Navy number, an identification number for solar radiation data stations in NREL's *Solar Radiation Data Manual for Buildings*
WS	Weather Squadron
BIA	Bilateral Infrastructure Agreement
DoD	Department of Defense
HQUSACE	Headquarters, U.S. Army Corps of Engineers
HNFA	Host Nation Funded Construction Agreements
SOFA	Status of Forces Agreements
UFC	Unified Facilities Criteria
U.S.	United States

APPENDIX D SAMPLE 14 WS SUPPORT ASSISTANCE REQUEST (SAR) FORM

14WS SUPPORT ASSISTANCE REQUEST (SAR)

SUBJECT

CONTACT INFORMATION

RANK/TITLE | FULL NAME

TELEPHONE NUMBER | E-MAIL

ORGANIZATION	STATION
ORGANIZATION TYPE:	LOCATION
Are you Meteorological or Oceanographic Personnel?	
Are you a part of the Air Force Weather community?	

REQUEST

When do you need your data?

Describe what you need, include specific locations, if applicable and all pertinent details:

Who will receive the information? What it will be used for? Include any tangible benefits or expected impacts. If classified, contact via classified email.

IF DOD CONTRACTOR
MILITARY POINT OF CONTACT

RANK/TITLE | FULL NAME

APPENDIX E LIST OF AVAILABLE EWD SITES

E-1 REGULARLY UPDATED SITES.

Table E-1 is a list that consists of the Site Name, 4-letter Station ID, Latitude/Longitude, and Country for each Engineering Weather Data (EWD) site available at the 14th Weather Squadron. Note that the sites are regularly updated and the latest list should be retrieved at https://www.climate.af.mil.

Table E-1 List of Available EWD Sites

Site Name	Station ID	Lat	Lon	Country
BAGRAM	KQSA	34.94	69.26	AFGHANISTAN

Change No.	Date	Location
1	October 2015	Changes to Chapters 1, 2 and Appendix A in response to Criteria Change Requests (CCRs) and Tri-Service reviews.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force \2\ Civil Engineer Center (AFCEC) /2/ are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

(Installations and Environment)

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 3-401-01, *Mechanical Engineering*

Superseding: None

Description: This UFC is the core document for the mechanical discipline. It is intended as a reference for all mechanical work. It is organized to provide the top-level minimum mandatory mechanical design and analysis requirements and refers to other criteria as appropriate.

Reasons for Document:

- This new UFC provides a central point reference for all mechanical design criteria.
- Establishes minimum design analysis and drawing requirements in support of design activities
- Helps direct designers to the appropriate mechanical discipline criteria document.

Impact:

- There are negligible cost impacts. Creation of a single-source reference for mechanical design discipline helps clarify requirements for the design of DoD facilities.

Unification Issues:

- The Navy uses MO-230, *Petroleum Fuel Facilities* for maintenance of petroleum fuel systems while the Air Force and Army use UFC 3-460-03, *O&M: Maintenance of Petroleum Systems*. There is a project pending by the tri-service Fuel Facility Engineering Panel to unify these documents.
- The Navy uses UFC 3-430-08N, *Central Heating Plants* for design of central heating plants while the Army and Air Force use 3-430-02FA, *Central Steam Boiler Plants*. There is an ongoing Army project to update and unify these documents.

TABLE OF CONTENTS

TABLES

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facility Criteria (UFC) provides requirements and guidance for mechanical systems designed and constructed for the Department of Defense (DoD) together with criteria for selecting mechanical system materials and equipment. This information must be used by mechanical engineers to develop design calculations, specifications, plans, and design-build Requests for Proposal (RFPs) and must serve as the minimum mechanical design requirements.

This UFC is provided to ensure quality and consistency in design of mechanical systems with minimum life cycle costs which satisfy the functional and operational requirements of DoD facilities and which provide a healthy and safe environment for facility occupants. This UFC is intended as a reference for all mechanical work. Figure 1-1 shows the relationship of this UFC to other related mechanical UFCs.

1-2 APPLICABILITY.

This UFC is applicable to all service elements and contractors involved in the planning, design and construction of Department of Defense (DoD) facilities worldwide.

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, General Building Requirements. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance, sustainability, and safety. Use this UFC in addition to UFC 1-200-01 and the government criteria referenced therein.

1-4 REFERENCES.

Appendix A contains a list of references used in this document.

1-5 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

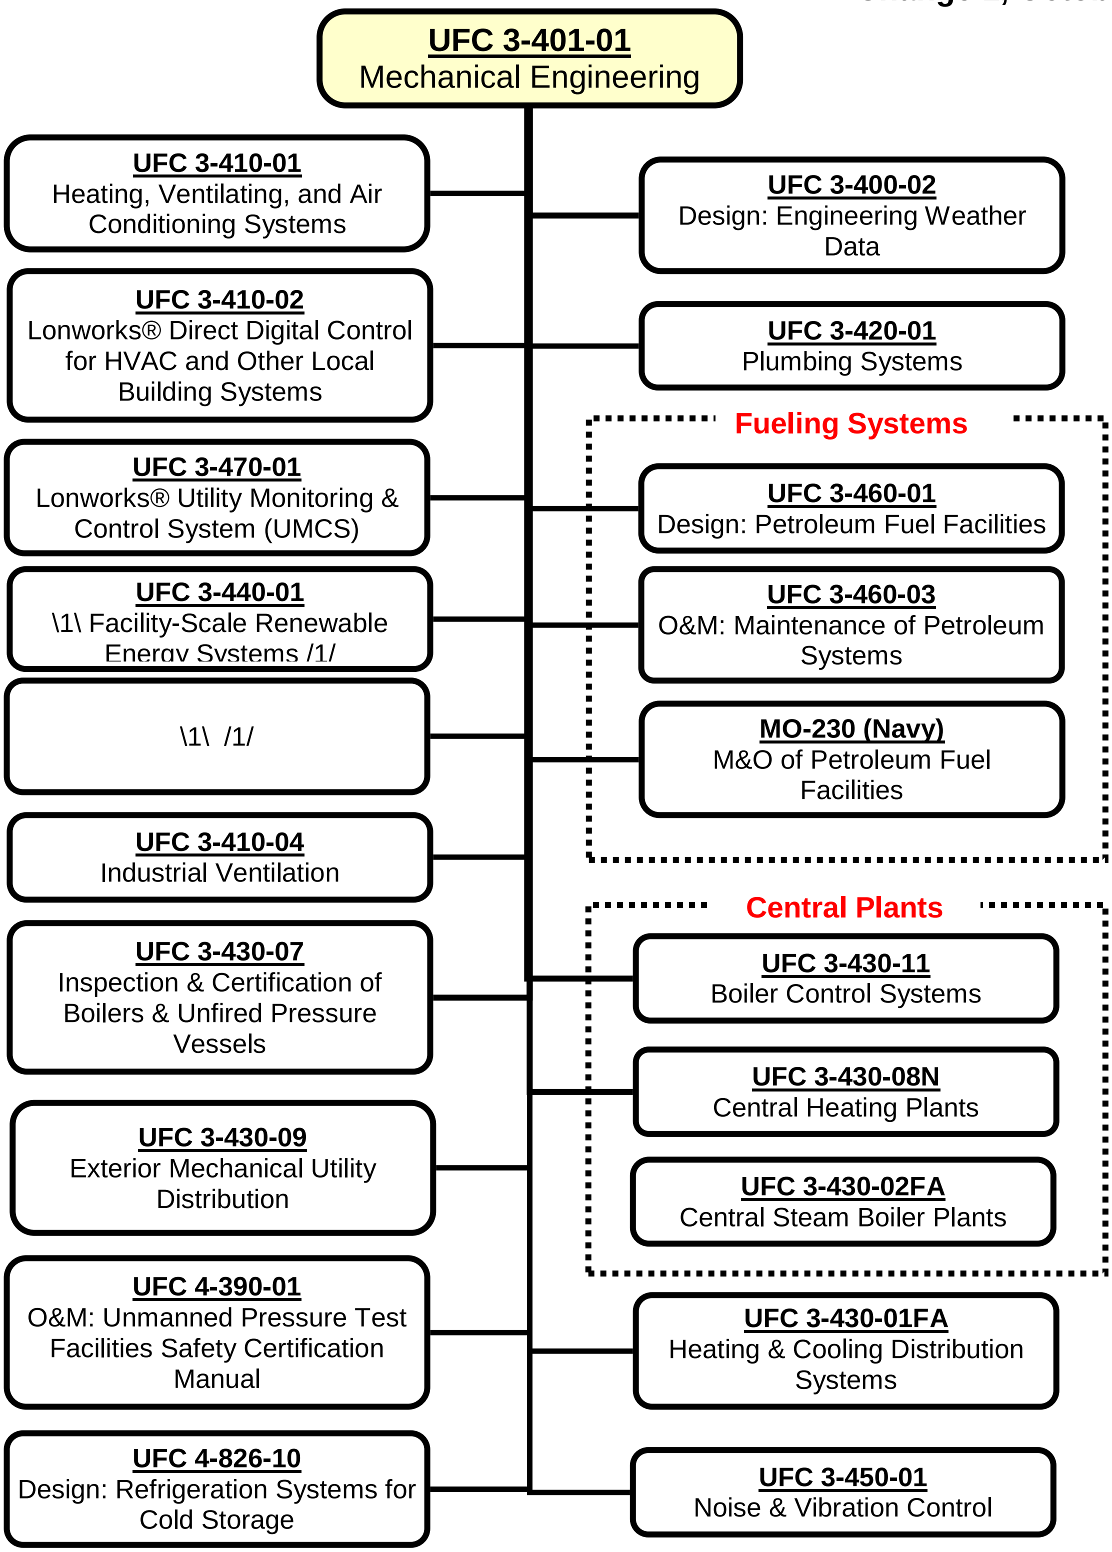

Figure 1-1 Mechanical UFC Delineation

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 BASIC PRINCIPLES.

2-1.1 Life Cycle Considerations.

Energy and water-efficient and sustainable design attributes for military construction must be based on the cost-benefit analysis, return on investment, total ownership costs, and demonstrated payback. Provide mechanical systems based on achieving the lowest life cycle cost of the approved alternatives. Ensure that all operation and maintenance costs are included in any life cycle cost analysis. Follow procedures for Life Cycle Cost Analysis (LCCA) stated in UFC 1-200-02. HVAC system (including fuel source) preliminary design must be determined at the concept stage justified by a LCCA.

2-1.2 Maintainability.

Maintainability and reliability are paramount to the operation of DoD buildings. Mechanical equipment not required to be located outside must be located in an equipment room. All mechanical equipment must be based on a minimum of three manufacturers. Catalog cuts from those three manufacturers must be included in the mechanical design analysis. Size the mechanical room to accommodate the space required to house all equipment and piping. A three dimensional envelope must be shown on the mechanical drawings for each item of equipment showing the maximum dimensions of those three manufacturers including the space necessary for maintenance and replacement. Verify adequate door dimensions to permit passage of equipment into mechanical spaces. Provide system designs with the features necessary for easy access for maintenance and for successful testing, adjusting, balancing, and system commissioning. Provide protection for equipment materials located in corrosive environments.

2-1.3 Seismic Protection

Design mechanical systems with respect to seismic protection in accordance with UFC 3-310-04. Provide details to structural engineer for support verification and sizing.

2-1.4 Weather Data

Weather data needed for design calculations and analysis must be obtained from UFC 3-400-02.

2-1.5 Conflicts in Design

Avoid conflicts with other disciplines and building features.

2-1.6 Conflicts in Criteria.

Where, in any specific case, different sections of any mechanical UFC or referenced standards specify different materials, methods of construction or other requirements, the most restrictive requirement will govern.

2-1.7 Specifications

All projects including DBB and DB will use the applicable UFGS as part of the design and construction documentation. \1\ Construction specifications projects shall require all materials to be protected from moisture and conditions that have potential to result in deterioration of material properties or in mold growth during site storage and construction. Protective measures must be taken to ensure that the construction process adequately shelters the materials to prevent mold growth and material degradation during construction. /1/

2-2 ASSOCIATED MECHANICAL SYSTEMS CRITERIA.

2-2.1 Facility Plumbing Systems

Design and construct plumbing systems for facilities in accordance with this document and the current issue of UFC 3-420-01. \1\ When solar preheat and heating of domestic hot water is shown to be LCC effective, systems must be in accordance with UFC 3-440-01. /1/

2-2.2 Facility HVAC Systems and Controls.

Design and construct Heating, Ventilating, and Air Conditioning (HVAC) systems for facilities in accordance with this document and the current issues of UFC 3-410-01. \1\ Insulate piping with an operating temperature below dewpoint with jacketed insulation meeting the cold piping requirements. The insulation jacket must be sealed to provide an exterior vapor barrier. /1/

2-2.3 Utility Monitoring and Control Systems.

Utility Monitoring and Control System Front Ends must be designed and constructed in accordance with UFC 3-470-01 and UFGS 25 10 10*.*

2-2.4 Exterior Mechanical Distribution Systems.

Design and construct all exterior steam, chilled water, and hot water distribution systems in accordance with this document and UFC 3-430-01FA.

2-2.5 Petroleum Fuel Systems.

Design and construct petroleum fueling systems in accordance with this document and the current issue of UFC 3-460-01. Provisions for maintenance of fueling facilities must be provided in accordance with UFC 3-460-03 for the **Air Force** and **Army**. The maintenance aspects of Navy fuel facilities must follow MO-230.

2-2.6 Industrial Ventilation Systems.

Design industrial ventilation systems in accordance with UFC 3-410-04. Provide air flow and static pressure calculations with each design.

Mechanical requirements for stationary battery installations that do not perform battery maintenance must be designed in accordance with UFC 3-520-05.

2-2.7 Compressed Air Systems.

Design and construct exterior compressed air distribution systems in accordance with this document and the current issue of UFC 3-430-09. Interior distribution must be designed and constructed in accordance with the Compressed Air and Gas Institute's Compressed Air and Gas Handbook and the ASME BPVC (Boiler and Pressure Vessel Codes)***.***

2-2.8 Refrigeration Systems for Cold Storage Facilities.

Design and construct refrigeration systems for cold storage facilities in accordance with this document, UFC 3-410-01 and the current issue of UFC 4-826-10.

2-2.9 Central Plants.

Design and construct central heating plants in accordance with this document and the current issue of UFC 3-430-08N for the **Navy** or 3-430-02FA for the **Army** and **Air Force**.

When a central plant is provided to serve multiple buildings, meter all utility services (gas, oil, steam, chilled, and hot water) at the central plant (both supply and return) and at each building served (supply only). Provide flow and temperature measurement for steam, chilled and hot water demand and measure BTU for energy consumption.

2-2.10 Mechanical Systems for Health Care Facilities.

Mechanical system designs for health care facilities will be in accordance with the current issue of UFC 4-510-01.

This Page Intentionally Left Blank

CHAPTER 3 DOCUMENTATION REQUIREMENTS

3-1 DESIGN ANALYSIS.

The Design Analysis must be submitted at a preliminary design stage equivalent to 35% design for concurrence of the results. The Design Analysis must consist of a Basis of Design Narrative and Calculations. The analysis must be updated as necessary as the design progresses. The results of this analysis are used for design decision-making in reducing total life cycle cost, while meeting mission objectives.

3-1.1 Basis of Design Narrative.

Provide a Basis of Design narrative as part of all design analysis.

3-1.1.1 User Requirements.

Document ventilation, temperature and humidity requirements, occupancies, functions, usage schedules, equipment loads, and exhaust requirements by space.

3-1.1.2 Criteria / Codes.

Identify the governing codes and criteria utilized for the design. Include the titles and the date of the applicable edition or publication.

3-1.1.3 Site Conditions.

Conduct detailed field investigation and interview the appropriate field personnel. Do not rely solely on the as-built drawings.

Determine energy sources available at the project site. Describe the source of thermal energy that will be used (i.e. Extension of central high pressure steam, hot water, natural gas, or stand alone heat source with the type of fuel utilized). Use fuel conversion factors provided in Appendix B for the analysis.

3-1.1.4 System Selection.

Provide a narrative description of all system alternatives considered. Describe in detail all systems and components selected at a preliminary design stage equivalent to 35% design to include the results of the LCCA and modeled energy use.

3-1.1.5 Special Mechanical Systems

Provide a description of special mechanical systems such as compressed air, hydraulic, nitrogen, lubrication oil, etc.

3-1.1.6 Other Basis of Design Narrative Requirements.

Provide any additional basis of design documentation as required by the specific mechanical UFCs.

3-1.2 Calculations and Analysis.

Show calculations and assumptions supporting equipment selections in a clear and organized manner. When charts or tables are used in the design analysis, cite the source and date of the publication.

3-1.2.1 Sizing Calculations.

Provide calculations for sizing equipment, piping, ductwork and all accessories. Provide the model number and manufacturer of each major piece of equipment used as the basis for the design.

3-1.2.2 LCCA.

Provide LCCA on optimized system level alternatives modeled in accordance with UFC 1-200-02. Provide energy model, including model inputs and outputs, on optimized system level alternatives by energy type in accordance with UFC 1-200-02.

3-1.2.3 Energy Compliance Analysis (ECA).

If required by UFC 1-200-02, provide a computerized Energy Compliance Analysis. The ECA is a building level analysis which takes into account the interaction between architectural, electrical and mechanical components of the facility design and confirms compliance with the energy reduction goals.

3-1.2.4 Other Calculation Requirements.

Provide any additional calculation documentation as required by the specific mechanical UFCs.

3-2 FINAL DRAWING REQUIREMENTS.

Drawings must be accurate and to scale. Drawings must show equipment, ductwork, and piping sufficiently to indicate all aspects of installation. Where practical, group all notes, legends, and schedules at the right of the drawings above the title block.

3-2.1 Drawing Units.

Unless otherwise authorized, the IP System of measurement must be used on CONUS projects and the SI system of measurement must be utilized on OCONUS projects. Metric and English pipe sizes are listed in Appendix C.

3-2.2 Legend.

Provide legends to clarify all symbols and abbreviations used on the drawings.

3-2.3 Seismic.

Show all pertinent seismic detailing for the mechanical systems on the contract drawings.

3-2.4 Demolition Plans.

“Demolition” plans should be separate and distinct from “new work” plans.

3-2.5 Floor Plans and Site Plans.

Exercise judgment to avoid overly congested drawings. Provide north arrows an all building and site plans. The orientation of drawings must be arranged with the north arrow toward the top of the plotted sheets, unless overriding circumstances dictate otherwise. The orientation of all partial building or site plans must be identical to that of the larger plan from which it is derived or referenced. Consistency in drawing orientation must be maintained with all disciplines. Enlarged plans must be drawn at no less than 1:50 (¼” = 1’-0”).

3-2.6 Sections and Elevations.

Provide as required to supplement plan views.

3-2.7 Access Space.

Identify space necessary to access and replace items that require maintenance, such as filters, coils, heat exchangers, tube bundles, strainers, and chillers on the drawings in three-dimensions.

3-2.8 Special Detailing

Provide details on the drawings necessary to ensure drainage for “winterizing” equipment where appropriate.

3-2.9 Equipment Schedules.

The equipment actually installed on a project may be different from that used as your basis of design. Therefore, mechanical equipment schedules must reflect actual required equipment capacities as calculated, not capacities provided by manufacturers' catalog data. This helps ensure that the installed equipment is optimally sized for the application.

3-2.10 Other Drawing Requirements.

Provide any additional drawing requirements indicated in the specific mechanical UFCs.

APPENDIX B STANDARD CONVERSIONS AND TABLES

Table B-1 - Fuel Conversion Factors

Type of Fuel	Conversion Factors (See note (a))	Notes
Anthracite Coal	28.4 Million Btu/Short Ton	
	29.9 kJ/kg	
Bituminous Coal	24.6 Million Btu/Short Ton	
	25.9 kJ/kg	
Electricity	3413 Btu/KWH	
	12.3 MJ	
No. 2 Distillate Fuel Oil	138,700 Btu/Gallon	
	38.7 MJ/L	
Residual Fuel Oil	149,700 Btu/Gallon	
	41.8 MJ/L	
Kerosene	135,000 Btu/Gallon	
	37.7 MJ/L	
LP Gas	95,500 Btu/Gallon	
	26.6 MJ/L	
Natural Gas	1,031 Btu/Cubic Foot	
	38.5 MJ/L	
Purchased or Steam from Central Plant	1,000 Btu/Pound	See note (b)
	2.3 MJ/kg	

Notes:

(a) At specific installations where the energy source Btu content is known to vary consistently by 10% or more from the values given below, the local value may be used provided there is adequate data on file for two years or more to justify the revision and that this value is expected to hold true for at least five years following building occupancy.

(b) High temperature, medium temperature, or chilled water from a central plant must use the heat value of fluid based on the actual temperature and pressure delivered to the 1.5 m (5 ft) line.

Table B-2. Metric Pipe Size Equivalence

NPS (Inches)	DN (mm)	NPS (Inches)	DN (mm)
1/8	6	2-1/2	65
3/16	7	3	80
1/4	8	3-1/2	90
3/8	10	4	100
1/2	15	4-1/2	115
5/8	18	5	125
3/4	20	6	150
1	25	8	200
1-1/4	32	10	250
1-1/2	40	12	300
2	50		

Notes:
1. NPS is the inch-pound designation for “nominal pipe size”.
2. DN is the metric designation for “diameter nominal”.
3. For pipe sizes over 12 inches, use the conversion factor of 25 mm per inch.

Table B-3. Metric Ductwork Dimensions

Inches	mm
3	80
4	100
5	130
6	150
7	180
8	200
10	250
12	300

Notes:
1. For dimensions over 12 inches, increase mm size in increments of 50

FOREWORD

Facilities Criteria (FC) provide functional requirements (i.e., defined by users and operational needs of a particular facility type) for specific DoD Component(s), and are intended for use with unified technical requirements published in DoD Unified Facilities Criteria (UFC). FC are applicable only to the DoD Component(s) indicated in the title and do not represent unified DoD requirements. Differences in functional requirements between DoD Components may exist due to differences in policies and operational needs.

All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the contracting team must ensure compliance with the most stringent of the FC, the SOFA, the HNFA, and the BIA, as applicable.

Because FC are coordinated with unified DoD technical requirements, they form an element of the DoD UFC system applicable to specific facility types. The UFC system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applicable to the Military Departments, Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) memorandum dated 29 May 2002. The UFC System also includes technical requirements and functional requirements for specific facility types, both published as UFC documents and FC documents.

FC are living documents and will be periodically reviewed, updated, and made available to users as part of the Service's responsibility for providing criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

FC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

42 USC 8253, as modified by the Energy Independence and Security Act of 2007 (EISA 2007) and the Energy Act of 2020, requires a comprehensive energy and water evaluation be completed on Federal buildings that constitute at least 75 percent of building energy use every four years; these evaluations include identifying and assessing recommissioning or retrocommissioning measures. For Navy and Marine Corps buildings, the NAVFAC publication P-602, *3 Pillars of Energy Security (Reliability, Resilience, & Efficiency)*, aligns with the prior mandates in requiring comprehensive energy and water evaluations be conducted on covered facilities once every four years.

1-2 PURPOSE AND SCOPE.

This FC provides a process standard that aligns best practices with ASHRAE and industry standards for existing building commissioning (EBCx). EBCx includes both recommissioning and retrocommissioning. It is written for use by building maintenance engineers and program professionals. This document has been developed to ensure consistency of efforts and resulting deliverables from performance of EBCx services. This document outlines requirements for building systems commonly included in EBCx efforts and excludes those systems typically covered by other required inspections and not included in an EBCx scope of work (such as fire protection/sprinkler systems, fire alarm systems, cable television and closed circuit television systems, conveying systems, and cybersecurity systems).

1-3 ORGANIZATION.

This document breaks the overall EBCx process down into phases, generally following those outlined in ASHRAE 0.2 as well as BCxA Existing Building Commissioning Best Practices. The EBCx phases work together; as an example, Assessment Phase results suggest the appropriate tasks in the Investigation Phase, which reveal the most beneficial Implementation Phase actions. Chapters 3 thru 8 cover each phase in depth. This document is organized as follows:

- CHAPTER 1 introduces the scope of this document and overall requirements
- CHAPTER 2 provides an overview of EBCx
- CHAPTER 3 contains the steps within the Planning Phase
- CHAPTER 4 details the steps within the Assessment Phase
- CHAPTER 5 contains the Investigation Phase steps
- CHAPTER 6 details the Implementation Phase steps
- CHAPTER 7 details the steps within the Hand-off Phase
- CHAPTER 8 contains the steps within the Ongoing Commissioning Phase

1-4 APPLICABILITY.

This document applies to DoD building assets equal to or greater than 25,000 square feet (2,323 square meters) and buildings which house energy intensive operations (such as data centers, health facilities or utility plants). This document applies where DoD is performing or managing the performance of EBCx efforts on existing buildings or systems. Existing building commissioning pays benefits on buildings where there is a focus on energy efficiency, reliability of systems, building size, greenhouse gas emissions, decarbonization, facility resiliency, buildings with subpar performance (excessive trouble calls), and mission criticality. Resiliency performance impacts include robustness, durability, maintainability, and rapid recovery following a disruption. This document does not apply to a construction project; follow the requirements of UFC 1-200-02 and related UFGS guide specifications for commissioning which seeks to verify design and performance of new construction or renovation projects.

Commissioning of existing buildings assists in enhancing “military installation resilience”; as defined in 10 USC 101(e), this term means the capability of a military installation to avoid, prepare for, minimize the effect of, adapt to, and recover from extreme weather events, or from anticipated or unanticipated changes in environmental conditions or energy disruptions. This FC document relies on existing standards, guidelines and best practices recognized by firms and individuals that are certified to perform commissioning services. These are consensus documents developed by organizations such as the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE), the Building Commissioning Association (BCxA), and the National Environmental Balancing Bureau (NEBB).

1-5 GENERAL BUILDING REQUIREMENTS.

For design and construction project-related efforts, comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety.

1-5.1 Required Upgrades in Corrosive Environments.

When upgrades resulting from EBCx efforts are implemented, incorporate in the design systems and details to meet the environmental corrosivity conditions for the specific project location, as defined by its Environmental Severity Classification (ESC). See UFC 1-200-01 for determination of ESC for project locations. Design upgrades may also be required due to the humidity conditions; humid locations are those in ASHRAE climate zones 0A, 1A, 2A, 3A, 3C, 4C, and 5C (as identified in ASHRAE 90.1).

Required corrosion-related upgrades to building systems are identified in UFC 1-200-01 and “Core” UFC’s. UFC 1-200-01 contains general requirements for corrosion-related upgrades covering multiple disciplines; UFC 3-410-01 includes requirements for heating, ventilating, and air-conditioning (HVAC) system components and UFC 3-501-

01 includes requirements for electrical system components. Upgrade requirements for other systems are found in their related UFC documents.

1-6 CYBERSECURITY.

To maintain proper cybersecurity measures, facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-7 BEST PRACTICES.

APPENDIX A contains best practices which are not required but have shown to produce the best results and ensure EBCx efforts are consistent and comprehensive.

1-8 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-9 REFERENCES.

APPENDIX C contains a list of references used in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 OVERVIEW

2-1 EBCx DEFINED.

Existing building commissioning (EBCx) is a quality-focused process for attaining the current facility requirements (CFR) of an existing building and its systems and assemblies. The process focuses on planning, investigating, implementing, verifying, and documenting that the building and its systems and assemblies are operated and maintained to meet the CFR, with a program in place to maintain the enhancements for the remaining life of the building. EBCx includes both recommissioning and retrocommissioning. Recommissioning is the application of the commissioning (Cx) process to an existing building or system that underwent the Cx Process during project delivery. Retrocommissioning applies the Cx Process to an existing building or system that was not previously commissioned.

EBCx is a process of inspecting, testing, analyzing, adjusting, and optimizing existing building systems to improve how building equipment and systems function together. EBCx often resolves problems that occurred during design or construction, or addresses expected building system performance degradation problems that have developed throughout the building's life. Properly executed, EBCx improves a building's operations and maintenance procedures and enhances overall building performance while meeting the Government's and occupant needs.

2-1.1 Scope.

The scope of EBCx may be either comprehensive or targeted on specific known issues or underperforming building systems. The building systems which may be included in comprehensive EBCx efforts are further outlined in paragraph titled Comprehensive Commissioning. Clearly outline the extent of the scope in the Request for Proposal (RFP) to a Cx Provider, or in a scoping document when utilizing a Government EBCx team.

If the EBCx efforts are being undertaken to achieve compliance with the 42 USC 8253 requirements, which require a comprehensive evaluation be completed on each Federal building every four years, the scope of the EBCx must include the energy- and water-consuming building systems at a minimum. EBCx efforts targeted on only specific problematic building systems do not qualify as a comprehensive building energy evaluation required by 42 USC 8253 every four years.

2-1.2 Purpose/Intent.

The intent of EBCx is to identify a corrective process for repairing equipment and optimizing building systems and operations for energy efficiency, occupant comfort, air quality, enhanced building resiliency and extended equipment useful life. EBCx applies to buildings with no prior commissioning or where building systems no longer meet or exceed minimum requirements due to equipment failure or work-arounds, improper system adjustments, renovations or significant changes in building space utilization.

The goal of EBCx is to make building systems perform interactively to meet the Current Facility Requirements (CFR) and provide the tools to maintain the system performance over time.

2-1.3 Benefits.

Typical benefits of EBCx efforts include:

- Reduces energy and water usage
- Reduces the number of system deficiencies and inefficiencies and better focuses the maintenance efforts and resources to meet the needs of end users.
- Improves the building system's overall performance by optimizing energy-efficiency and system integration.
- Reduces building operating expenses.
- Identifies potential indoor environmental quality issues and ensures indoor air quality meets the minimum American Society of Heating, Refrigeration and Air Conditioning Engineers (ASHRAE) requirements.
- Improves thermal comfort and reduces occupant complaints.
- Ensures that system operations meet building manager's expectations.
- Improves equipment performance and extends equipment life expectancy.
- Through training, enhances operations and maintenance (O&M) staff capabilities and expertise to operate and maintain the equipment more effectively and efficiently.
- Reduces service calls and demands on O&M staff.
- Identifies safety hazards such as unprotected electrical wiring, fall hazards, and other dangerous conditions.
- Discovers unique design and historic information about the building uncovered during drawing research.
- Identifies deficiencies in building enclosure water barrier, air barrier, thermal barrier and vapor retarder.
- Improves/updates building documentation.
- Ensures compliance with Federal building policies and directives.
- Ensures compliance with energy goals and mandates.
- Improves building resiliency by enhancing robustness, durability, maintainability, and ability to recover following a disruption.

2-2 TEAM ROLES AND RESPONSIBILITIES

The personnel required and the extent of their responsibilities differ depending on whether the EBCx is being performed by a consultant firm or an in-house Government EBCx team, as well as which building systems are included. Where EBCx is provided by a Contractor/consultant, Government personnel have support roles in assisting with coordination of the process.

2-2.1 EBCx Team Members.

The EBCx Team is responsible for executing the EBCx scope of work. Roles and responsibilities within the team may include:

- Commissioning (Cx) Provider – oversees and executes EBCx phases.
- Commissioning specialists – specialty team members based on the scope of the EBCx, such as Testing, Adjusting and Balancing (TAB) Contractor, controls specialists, equipment support vendors, energy consultant, and other specialized testing providers.
- Facilities management specialists - assists in selection of buildings, researches past/future building projects and work orders, and coordinates efforts with building manager.

2-2.2 EBCx Support.

Support roles and responsibilities to allow for completion of EBCx efforts include:

- Facilities management leadership – decision-making to assist in selection of buildings and establish EBCx goals and objectives.
- Existing building commissioning (EBCx) program management personnel – when a formalized EBCx program is in place, provides program objectives, tracks funding, and assists with selecting EBCx candidate buildings.
- Utilities management personnel – provides utility-related data for buildings, including meter data and utility rates.
- Regional Energy Program Manager (REPM) – assists with central funding and with selection of buildings.
- Installation Energy Manager (IEM) – often the primary point of contact for EBCx at the installation; coordinates public works resources.
- Building manager – acts as building representative and provides data and other requested information.
- Public works personnel – supports implementation of EBCx measures.

- Architectural and engineering technical support personnel – provides reachback support for complex technical concerns.
- Installation shops maintenance personnel – provides access to secured mechanical spaces, assists with location and operational condition of equipment, and assists in identification of known deficiencies.
- Preventive maintenance (PM) personnel – assists with deferred maintenance; provides maintenance logs.
- Controls shop – responsible for proper operations of energy and water control systems (Cx Provider will need to coordinate with this shop when testing control sequences)

2-3 REQUIRED CERTIFICATIONS AND TRAINING.

2-3.1 Lead EBCx Specialist Certification Requirements.

Individuals that serve as a Lead EBCx Specialist and are in responsible charge of executing EBCx efforts, either in-house or as part of a consultant team, must have obtained one of the commissioning professional certifications identified in Table 2-1; individuals with certifications that are not specific to Existing Building Commissioning must have five years of experience in leading efforts on commissioning existing buildings of similar size and complexity. Individuals which assist with EBCx activities are not required to have these certifications but must be directly supervised by a certified individual.

Table 2-1 Lead EBCx Specialist Required Certification

Organization	Certification
National Environmental Balancing Bureau (NEBB) (www.nebb.org)	Retro-Commissioning of Existing Buildings Certified Professional (RCx CP)
Association of Energy Engineers (AEE) (www.aeecenter.org)	Certified Building Commissioning Professional (CBCP®)
Association of Energy Engineers (AEE) (www.aeecenter.org)	*Existing Building Commissioning Professional (EBCP®)
Associated Air Balancing Council (AABC) Commissioning Group (ACG) (www.commissioning.org)	Certified Commissioning Authority (CxA)
American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) (www.ashrae.org)	Building Commissioning Professional (BCxP)
University of Wisconsin-Madison (www.pdc.wisc.edu)	Qualified Commissioning Process Provider (QCxP)
Building Commissioning Certification Board (www.bccbonline.org)	Certified Commissioning Professional (CCP)

*Note: EBCP certifications are no longer being issued but are still active.

2-3.2 Building Enclosure Commissioning Certification Requirements.

Individuals that perform EBCx activities on the building enclosure system, either in-house or as part of a consultant team, must have obtained one of the professional certifications listed in Table 2-2.

Table 2-2 Building Enclosure Required Certification

Organization	Certification
National Environmental Balancing Bureau (NEBB) (www.nebb.org)	Building Enclosure Testing Certified Professional (BET CP)
University of Wisconsin-Madison (www.pdc.wisc.edu)	Building Enclosure Commissioning Process Provider (BECxP)
	Accredited Commissioning Authority + Building Enclosure (CxA+BE)
International Institute of Building Enclosure Consultants (IIBEC) (www.iibec.org)	Certified Building Enclosure Commissioning Provider (CBECxP®)

2-3.3 Training Resources.

For individuals who desire to increase their knowledge on specific EBCx processes and activities, training is available from the organizations listed in Table 2-3.

Table 2-3 Training Resources

International Facility Management Association (IFMA)	www.ifma.org or www.fm.training

International Institute of Building Enclosure Consultants (IIBEC)	www.iibec.org
American Society for Health Care Engineering (ASHE)	www.ashe.org

2-4 EXTENT OF COMMISSIONING.

Existing building commissioning may be either comprehensive or targeted on specific known issues or underperforming systems. In either case, the funding and level of effort is based on the building systems that need to be evaluated or improved to meet the goals and objectives of the tenant organization. The most common EBCx scope focuses on the energy- and water-consuming systems in a building, plus other systems that are known to have documented operational or maintenance issues.

2-4.1 Targeted Commissioning.

In existing buildings, not every system requires commissioning to provide a return on the investment. Additionally, the level of effort and the associated cost to carry out the EBCx process on all building systems could exceed the funding available. Thus, in many instances, the EBCx process is targeted on specific systems within a building to address specific known issues and to meet the specified goals or objectives of the tenant organization. It should be noted that EBCx efforts targeted on only specific problematic building systems do not qualify as a comprehensive building energy evaluation required by 42 USC 8253 every four years.

2-4.2 Comprehensive Commissioning.

A comprehensive EBCx task order might include the following building systems:

- HVAC and refrigeration systems and associated controls
- Air-curtain systems
- Domestic water heating and distribution systems
- Domestic water treatment systems
- Sanitary sewer systems
- Building envelope (walls and roofing)
- Structural system
- Electrical power distribution systems (panelboards/switchgear plus known problem areas)
- Emergency and standby power
- Energy storage systems
- Lighting and control systems

- Solar photovoltaic and renewable energy systems
- Security and intrusion detection systems
- Landscape watering systems
- Telephone and intercommunications systems

The following systems are typically covered by other required inspections and are not included in an existing building commissioning scope of work:

- Fire protection/sprinkler system
- Fire alarm system
- Cable television (TV) and closed-circuit television (CCTV) systems
- Conveying systems
- Cybersecurity systems

2-5 THE COMMISSIONING TEAM SKILLS.

The EBCx Team must be led by a certified individual as outlined in paragraph titled Required Certifications and Training. The overall assembled EBCx team must have the following skills and experience:

- Project management
- Project team supervision
- System testing techniques and use of instrumentation
- System troubleshooting
- System analysis
- Energy and water conservation techniques
- Energy and water calculation procedures
- Working knowledge of control systems and sequence strategies
- Capability to train operators
- Good communication skills

2-6 COMMISSIONING EQUIPMENT.

The National Environmental Balancing Bureau (NEBB) maintains an Approved Instruments Requirements list for performing EBCx services (https://nebb.org/firm-certification/instrument-requirements/). This list includes the range and accuracy requirements for instruments based on their testing function, and also designates calibration intervals for these instruments. Duplicate equipment may be required for some items to allow for periods when equipment fails or is not available while being calibrated. Firms or Government teams that conduct EBCx efforts must provide proof to the Government Project Manager that equipment being used has been calibrated according to the manufacturer's or industry standards for each piece of equipment and the date it was last calibrated.

2-7 PHASES OF COMMISSIONING.

The EBCx process as outlined in this document is broken down into phases, generally following those outlined in ASHRAE 0.2 as well as BCxA Existing Building Commissioning Best Practices. The Phases may be performed by separate entities, as described in this document. The remaining Chapters in this document are organized by these Phases, which are as follows:

- Planning
- Assessment
- Investigation
- Implementation
- Hand-off
- Ongoing Commissioning

CHAPTER 3 PLANNING PHASE

3-1 OBJECTIVES.

The Planning Phase is implemented when the EBCx process is being considered for a single building or multiple buildings. When considering EBCx for multiple buildings, this Phase assists in identifying the buildings that are the best candidates for benefitting from the EBCx process. When a decision has been made to perform EBCx on a single building (the building has been confirmed as a good candidate for these services), the Planning Phase is abbreviated. While each phase could be contracted, it is recommended that the Planning Phase and a portion of the Assessment Phase be performed in-house to better establish the scope for execution in subsequent phases. The objectives of this phase are to clarify the scope and expectations of the EBCx process, and to develop a strategy to guide the execution of the efforts.

3-2 PLANNING PHASE FOR MULTIPLE BUILDINGS.

When considering the application of EBCx on multiple buildings, follow these Planning Phase steps:

a. Assemble EBCx program planning team

b. Conduct program planning meeting and workshop (develops EBCx goals and screens buildings)

c. Gather documents

d. Building walk-through

e. Engage a Cx Provider

f. Develop EBCx program plan

3-3 PLANNING PHASE FOR A SINGLE BUILDING.

When a decision has been made to perform EBCx on a single building (the building has been confirmed as a good candidate for these services), the Planning Phase is somewhat shortened as follows:

a. Confirm/Document EBCx goals and objectives

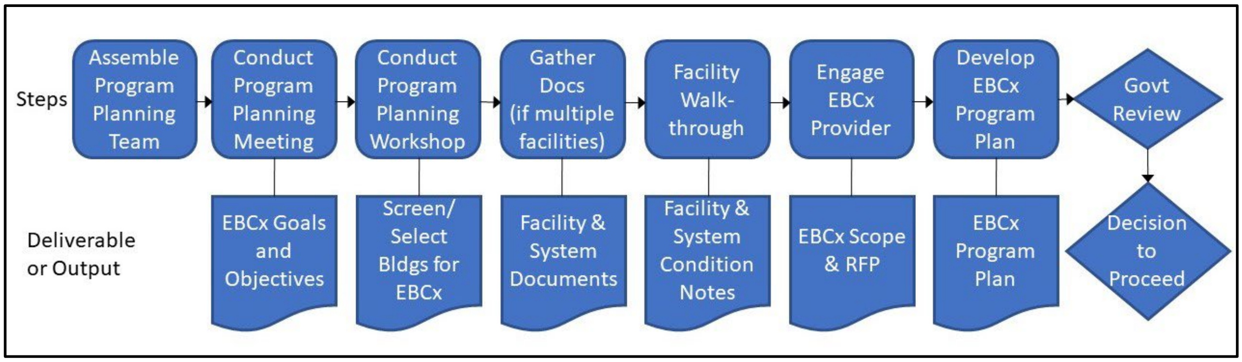
b. Initial walk-through of building

c. Engage a Cx Provider

3-4 PLANNING PHASE STEPS.

The following planning phase steps are undertaken to clarify the scope and expectations of the EBCx process. Some of these are only undertaken when considering multiple buildings, and others are undertaken when planning EBCx for a single building or multiple buildings.

Figure 3-1 Planning Phase Process and Deliverables/Outputs



3-4.1 EBCx Program Planning Team.

An installation may have a formal program and organization for conducting EBCx. If no formal program exists, a program is defined within the Planning Phase when conducting EBCx on multiple buildings. When conducting planning sessions on EBCx for multiple buildings, assemble an EBCx Program Planning Team. This Planning Team consists of facilities management leadership, utilities management personnel, engineering management staff, the installation energy managers and the facility-related control systems (FRCS) manager. As a part of initiating the planning process, this team conducts the following primary activities:

- Determine funding availability for EBCx efforts and develop a funding plan based on the funding source.
- Determine contract availability if aspects of the work are to be performed through an outside contractor. Determine whether in-house Cx resources are available or if an outside Contractor is required.

3-4.2 EBCx Program Planning Meeting and Workshop.

When considering EBCx on multiple buildings, conduct a planning workshop to discuss/confirm the overall goals of the program and orient the team on the EBCx process. An overview meeting is conducted to review the concepts listed below, then an extended workshop is held to complete these steps after information is compiled, such as the data required to conduct the building screening/selection process. Cover the following topics at a minimum (see ASHRAE 0.2 Multiple-Facility Planning Phase section titled "Conduct EBCx Program Planning Meeting" for information to discuss on each of these topics):

- EBCx goals and objectives (see paragraph titled EBCx Goals and Objectives)
- EBCx process overview, including types of systems included, and potential benefits expected.
- Identify buildings considered as candidates for the program.

- What building systems are included in EBCx assessments.
- The building screening/selection process (see paragraph titled Screen/Select Buildings for EBCx Viability)
- Determine measurement and verification (M&V) standards and performance metrics
- Identify the training needed for building managers and O&M staff
- Confirm personnel resources available in-house for EBCx efforts vs. those that need to be performed via outside contract
- Confirm funding sources, contract mechanisms and available funds
- Expected benefits of EBCx
- Preferred timeframe for EBCx execution

3-4.2.1 EBCx Goals and Objectives.

For single buildings or multiple-building EBCx efforts, the Planning Team confirms the desired objectives of the EBCx efforts so these expectations can be conveyed to all parties involved. Objectives may include one or more of the following:

- Bring equipment to its proper operational state.
- Reduce energy and demand cost, increase equipment life.
- Improve indoor environmental quality and increase tenant satisfaction.
- Improve building operation and maintenance.
- Reduce overall complaints.
- Reduce staff time spent on emergency calls.

The Government Project Manager must convey assessment parameters for specialized objectives other than energy and water savings. Objectives beyond traditional EBCx might include system expansion capability, enhanced building resiliency, emissions reduction, or enhanced electrification. EBCx teams are made up of disciplines which can assess these issues; however, it is important to clearly state these objectives in the EBCx scope of work.

3-4.2.2 Screen/Select Buildings for EBCx Viability.

When considering multiple buildings for EBCx, some existing buildings or groups of buildings make better candidates for EBCx than others. Assemble the EBCx Program Planning Team and the Building Managers for the buildings under consideration for EBCx to screen the buildings and identify those that are the preferred candidates for the EBCx Program. The goal of the screening process is to perform EBCx efforts on those buildings which provide the highest returns, such as reductions in energy or operational costs, as well as ensuring continuity of operations for those buildings which are deemed as mission critical. These efforts require compiling data on each candidate building, such as checking planned project lists and reviewing maintenance records; to gain the best information; a brief walk-through of each building and talking with occupants and maintenance personnel are best practices.

Follow these steps in screening buildings for the EBCx Program (see Appendix A, paragraph titled Navy and Marine Corps Templates for location of a best practice template available for use in the screening process):

- Step 1 – Confirm it is a “building” and it is a DoD asset:
  - Per UFC 1-300-08, a building is “A roofed and floored facility enclosed by exterior walls and consisting of one or more levels that is suitable for single or multiple functions.”
  - Through available asset data, confirm the building is a DoD asset (and not locally owned).
- Step 2 – Consider the following criteria when making a building selection:
  - Buildings equal to or greater than 25,000 square feet (2,323 square meters) and buildings which house energy intensive operations (such as data centers, health facilities or utility plants).
  - Buildings which are not scheduled for demolition.
  - Buildings with prior energy audits that recommend EBCx as an Energy Conservation Measure (ECM) (note: A building is not required to have a prior energy audit to be considered a good candidate for EBCx).
  - Buildings with a Condition Index (CI) greater than 60.
  - Buildings with high energy use index (EUI) that cannot be explained or unexplained increases in energy consumption. Compare the EUI for the candidate building to similar buildings using benchmarking. Benchmarking can be done using a tool such as the Commercial Buildings Energy Consumption Survey (CBECS): www.eia.gov/consumption/commercial/
  - Buildings with persistent failure of building equipment, control systems, or both (note: failed control systems make it difficult to diagnose systems and test performance).
  - Buildings with access to a Direct Digital Control (DDC) operator workstation, where DDC controls are present
  - Buildings whose current use or configuration have been modified from the original design intent.
  - Buildings with occupant complaints about temperature, airflow, and comfort.

   - Buildings that do not have deferred maintenance based on Preventive Maintenance (PM) and Service Call records to ensure that important maintenance tickets have been addressed.
   - Buildings that are not scheduled for capital improvements (which replace EBCx systems before the payback period had elapsed and equipment has reached its useful life).
   - Buildings with Building Automation System (BAS) control systems or complex mechanical systems.
   - Buildings with unexplained increases in numbers of work orders/services requests.
   - Buildings with meters (electric, water, gas, or steam) installed prior to EBCx.
- Step 3 – Where funding is not available to perform EBCx on all candidate buildings, prioritize buildings by mission criticality and known issues affecting resiliency:
   - Prioritize buildings which are critical to performing the Installation's mission. For additional information on criticality, contact Installation Facilities Management (IFM) or the Installation Energy Management (IEM) office for a list of existing critical buildings that may require commissioning.
   - Prioritize buildings with known issues affecting their resiliency, defined as having lessened ability to provide for mission in the face of all hazards, including extreme weather events or changes in environmental conditions, or recover operations quickly after a disruption in operation (such as having known power reliability issues, a mission critical building with an inoperable backup power generation system, HVAC systems with difficulties operating in expected extreme hot or cold conditions, building enclosures in occupied spaces with gaps which allow external air flows in extreme conditions).

3-4.3 Gather Documentation.

When considering multiple buildings for EBCx, gather documentation during the follow-on Assessment Phase. For EBCx on an individual building, obtain documentation in the Planning Phase to understand the condition of the systems, where potential issues exist, and to establish the scope of work for the Cx Provider, whether they are in-house or contracted. Gather the following documents:

- Original "as-built" construction drawings
- Original construction specifications
- Renovation construction drawings

- Minimum one year of utility bills or usage and cost data (including electrical, natural gas, water, wastewater, fuel, steam Hot Water (HW) or Chilled Water (CW))
- Utility rates
- Previous energy audit, commissioning, or EBCx reports
- TAB reports for HVAC system
- Existing equipment submittals or shop drawings
- Controls systems “as-built” submittals
- Copies of written control sequences or diagrams
- Copies of existing building operations and maintenance guides
- One-year summary report of maintenance and repair records
- Six months of HVAC BAS/DDC trend data alarms as available
- Equipment replacement records

3-4.4 Building Initial Walk-through.

The initial walk-through of the building helps to gain an understanding of the condition of the spaces and state of the building and systems. Collect information on the types and quantities of equipment, and if there is pending corrective repair work. Discuss with the maintenance personnel where known issues are and speak with occupants regarding current thermal comfort issues.

3-4.5 Engage Commissioning Provider.

While each phase could be contracted, it is recommended that the Planning Phase and a portion of the Assessment Phase be performed in-house to better establish the scope for execution in subsequent phases. Performing a portion of the Assessment Phase will help to understand enough about the building(s) to develop an initial scope and budget for the EBCx task. For the EBCx Team, whether being performed in-house or via Contractor personnel, clearly define the scope of the EBCx assessment, the parameters of the building(s) being evaluated, and assistance being provided by installation or building personnel. Parameters needed to enable a well-defined scope of work include the following at a minimum (see Appendix A, paragraph titled Navy and Marine Corps Templates, for the location of a best practice template for the EBCx Contractor scope of work):

- EBCx project objectives
- Whether Government provides the CFR or Contractor develops
- List and quantity of building equipment and systems to be evaluated
- Condition of equipment and known outstanding repairs

- List of problem areas or known issues
- State if electrical, gas and water meters are installed and operational
- State if approximate costs for energy and water use are available
- Specific procedures required, or emphasis on specific spaces (such as systems supporting data/IT systems or mission critical spaces)
- Existing controls systems; capabilities of the BAS for trending and reporting
- Clarify if Cx Provider provides controls Contractor or Government
- Allowed work hours
- Instructions for coordination of building availability
- List of documents that will be provided, and whether they'll be provided electronically or may only be viewed on-site
- Description of support to expect from operations staff for interviews and answering questions
- Required sample size and pass rate
- List the installation security access requirements
- List the building access requirements (badging, escort)
- Identify security requirements regarding use of cell phone cameras, standalone cameras, and thermal imaging cameras
- Requirements for deliverables, including draft and final reports
- What extent, if any, of Implementation Phase or Ongoing Commissioning Phase activities are conducted by the Cx Provider
- Desired schedule, including milestones or check-in points
- Potential measurement and verification (M&V) plan
- Which party develops Performance Verification Tests
- List of deliverables required and format
- Requirement for out-briefing or Post-EBCx presentation
- List of points of contact (building utilities, control system vendors, building access coordination, building maintenance)

3-4.6 EBCx Program Plan.

For Planning Phases when considering multiple buildings for EBCx, develop the information resulting from the EBCx Program Planning Meeting and Workshop in a cohesive planning document (see paragraph titled EBCx Program Planning Meeting and Workshop. Topics in this plan include the following at a minimum:

- EBCx goals and objectives
- Buildings considered as candidates for the program.
- Building systems included in EBCx assessments.
- The building screening/selection process utilized, including ranking metrics
- Prioritized/selected list of buildings
- Measurement and verification (M&V) requirements
- Training needed for building managers and O&M staff
- Personnel resources available in-house for EBCx efforts and those that require performance via outside contract
- Budget, funding sources, and contract mechanisms
- Expected benefits of EBCx
- Schedule for EBCx execution
- EBCx program planning team

3-4.7 Government Review and Decision to Proceed.

For Planning Phases when considering multiple buildings for EBCx, submit the developed EBCx Program Plan for review and approval. This review evaluates the process followed for screening the buildings and the decision/selection of buildings planned for EBCx. Additionally, the planned method of performing EBCx efforts is assessed, whether through in-house teams or contracted resources; potential contracting mechanisms are also confirmed.

3-5 PLANNING PHASE DELIVERABLES.

The Planning Phase deliverables consist of the following:

- EBCx Program Plan
- Compiled building documentation
- Contractor RFP scope of work

CHAPTER 4 ASSESSMENT PHASE

4-1 OBJECTIVES.

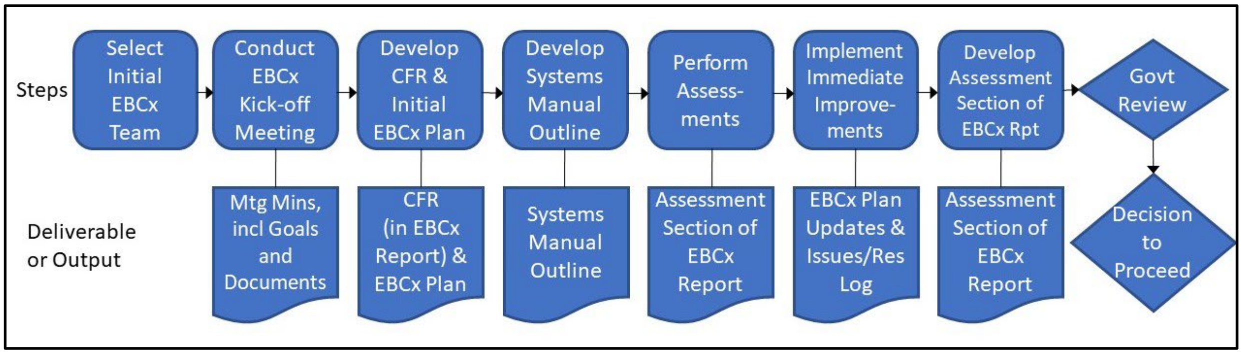
The Assessment Phase consists of performing preparatory activities in developing the Current Facility Requirements (CFR) and an EBCx Plan for a single building, and performing an assessment of the building. It is not a full evaluation but rather a cursory data gathering and brief walk-through of the building. The goal of the on-site Assessment Phase is to record building system conditions, identify obvious performance issues, and flag potential opportunities for more in-depth analysis. The Assessment Phase approach must align with the Government's objectives and goals for the overall EBCx efforts (such as energy reduction, enhancing occupant comfort, or reducing service calls). The objectives of this phase are to gain enough of an understanding about the individual building to develop an initial scope, schedule, budget, and approach for the follow-on Investigation Phase, as well as an estimate of the potential improvements to the building's performance.

4-2 ASSESSMENT PHASE STEPS.

There is some overlap in the Planning and Assessment Phases. And Assessment Phase steps may be performed by a different entity than the Planning Phase, thus some initial steps are used to confirm the scope and expectations for the EBCx process. Assessment Phase steps are as follows:

a. Select the initial EBCx Team
b. Conduct an EBCx kick-off meeting
c. Develop CFR
d. Develop the initial EBCx Plan
e. Establish the Systems Manual outline
f. Perform assessments
g. Implement immediate improvements
h. Develop Assessment Report portion of EBCx Report
i. Obtain Government review and decision to proceed

Figure 4-1 Assessment Phase Process and Deliverables/Outputs



4-2.1 The Initial EBCx Team.

Define the EBCx Team to oversee and accomplish the Cx activities. To what extent a Contractor is responsible for the activities is affected largely by the resources available at the installation. The initial team consists of the Government representatives, the Commissioning Provider, and additional team members based on the EBCx goals and the building systems included in the scope. After responses are received from Contractor support requests, decisions are made for securing the services of the most appropriate team and procuring these services utilizing available contracting mechanisms.

4-2.2 Kick-off Meeting.

Following issuance of Notices to Proceed to Contractors, or an agreement to utilize a Government in-house team, conduct a kick-off meeting to develop an understanding of the planned EBCx processes and coordinate the work activities. The focus of this pre-assessment meeting is to determine which EBCx members are required to support the assessment, which requested documents remain outstanding, and what the access needs will be during the assessment. Also review assessment strategies and deliverables during the meeting. Required attendees include Government and Contractor personnel playing a key role in the EBCx activities. Topics for the kick-off meeting include the following:

- Confirm EBCx goals and objectives
- Confirm documentation requested
- Introduce EBCx team members
- Confirm EBCx roles, including local support
- Communication and coordination plan
  - Site visit security requirements and coordination
  - Planned meetings
- Specific EBCx plan/activities

  - Outline of activities
  - Building systems being evaluated
  - Approach to measurement and verification
  - Planned assessments/tests
  - Access required
  - Impacts to operations
  - Government staff participation/assistance
  - Training approach
  - Deliverables/Submittals
- Planned EBCx schedule

Following the meeting, develop formal meeting minutes and issue to attendees as well as stakeholders who were unable to attend.

4-2.2.1 EBCx Goals and Objectives.

If a different entity is involved in the Assessment Phase from the Planning Phase, confirm the goals and objectives of the EBCx efforts. Confirmation of the goals and objectives as designated in the scope of work is important prior to proceeding with the activities of this phase because these determine the appropriate assessment methods and level of testing. A list of potential objectives for EBCx efforts is included in Chapter 3 of this document.

4-2.2.2 Documentation Requested.

At the kick-off meeting, confirm if the list of documentation from Chapter 3 has been provided. The Government identifies items that do not exist for the building being assessed.

4-2.3 Current Facility Requirements (CFR).

The CFR is the foundational information for the EBCx efforts in that it defines the specific operating parameters for the building to support its' mission. Establishing these CFR parameters is critical to understanding how an existing building is performing when compared to its' intended design, and establishes the targets for successful EBCx results. A CFR must reflect the current needs and requirements of the users or occupants. For example, functional uses may have changed since the building was originally constructed; these space renovations may have resulted in revising the operation of building systems. For buildings that were commissioned during construction/renovation, or that have had prior retrocommissioning efforts, the EBCx efforts involve updating the Owner's Project Requirements (OPR) established during the original commissioning process. For existing buildings with no prior commissioning efforts, developing the requirements defined within the CFR require input from building staff, occupants, users, maintenance personnel and management; thus, obtaining this information typically requires facilitation of a series of meetings or a workshop as well as interviews and surveys.

The minimum content requirements for the CFR are stated in ASHRAE 0.2, Assessment Phase section titled “Develop CFR”. ASHRAE 1.2 provides an in-depth outline of CFR information for HVAC systems; provide similar information for other building systems included in the scope. Annex I of ASHRAE 0.2 provides a best practice approach for conducting a workshop to obtain information for the CFR; the Commissioning Provider facilitates this workshop. Annex J of ASHRAE 0.2 provides an example format for the CFR.

4-2.4 The Initial EBCx Plan.

The EBCx Plan outlines a strategic method of assessment that attempts to identify indicators of poor performance and opportunities for improved building system optimization. This plan provides the basis from which the follow-on Investigation and Implementation Phases proceed. The minimum content requirements for the EBCx Plan are stated in ASHRAE 0.2, Assessment Phase section titled “Develop the EBCx Plan”. This same section in ASHRAE 1.2 provides an in-depth outline of EBCx Plan information for HVAC systems; provide similar information for other building systems included in the scope. Include strategies and activities in the EBCx Plan to meet each CFR item.

4-2.5 Systems Manual Outline.

The Systems Manual contains the information needed to understand, operate and maintain the building systems that are included in the EBCx scope. If the building has not been commissioned in the past, the Assessment Phase efforts include beginning to develop the sections for the complete Systems Manual. If a Systems Manual exists from prior commissioning efforts, the Cx Provider reviews it for accuracy and completeness, and updates and adds information as necessary. ASHRAE 0.2, Assessment Phase section titled “Establish the Systems Manual Outline”, identifies required topics in the Systems Manual, with an example outline included in Annex M of ASHRAE 0.2.

4-2.6 Building and System Assessments.

The assessment of the building provides the first opportunity for the EBCx Team to document baseline performance of the systems and assemblies. Baselines are documented assessments of current operation for items such as energy use, energy demand reduction, ability to provide occupant comfort, frequency and type of service calls, and reliability of building systems and equipment. Utilize the assessment strategies as outlined in the EBCx Plan. This assessment seeks to provide a good understanding of the building systems and assemblies, their state and condition, and the operational parameters currently in place. Ensure this information is well documented as it provides the initial comparison of building performance against the criteria defined in the CFR. This baseline information is used to measure anticipated benefits and performance improvements obtained through the EBCx process. Where needed, these assessments are performed in more detail during the follow-on Investigation Phase.

4-2.6.1 System Assessments.

Perform the following assessment activities on systems in the EBCx scope (additional details on specific building systems are included below):

a. Determine if assessments will address all equipment or a sample of equipment.

b. Identify procedures, requirements, and schedule, to gain access to areas of the building. Determine accessibility to equipment, systems, and components for inspection and testing.

c. Perform a visual inspection of major equipment. Review documents as needed (such as O&M records and on-site systems documents).

d. Document observed deferred maintenance and O&M issues.

e. Evaluate building performance in accordance with benchmarking methods defined in the CFR and document maintenance and operational issues.

f. Determine change of use or function of systems, assemblies, or components with initial design.

g. Document occupant and user issues discovered during walk-throughs or surveys.

h. Document safety hazards observed during building walk-throughs (such as unprotected electrical wiring, fall hazards, and other dangerous conditions).

i. Identify known resources, such as operations and maintenance support personnel.

j. Identify subject areas where additional training needs are necessary, based on both the complexity of systems and the personnel’s expertise in operating and maintaining them.

k. Record the general condition of the systems, including age, maintenance issues, observed damage, and design or installation flaws.

l. Perform additional walk-through observations or interviews/surveys as necessary to gain a general understanding of the baseline condition of existing building systems and assemblies.

4-2.6.2 HVAC & Refrigeration System Assessments.

Perform Assessment Phase activities on HVAC&R systems in accordance with ASHRAE 1.2, Assessment Phase Section titled “Perform Assessment”.

4-2.6.3 Building Enclosure System Assessments.

Perform initial assessment of building enclosure systems through review of documentation, interviews, and visual assessments as follows.

4-2.6.3.1 Review of Building Enclosure Documentation.

Review the original design plans of the building and renovation drawings, as well as records of changes or previous condition surveys, to assess the following which may affect the performance of the building enclosure:

- Air barrier continuity
- Materials used and known life cycle issues
- Original performance expected
- Inherent thermal bridging issues
- Identify clearly the four control layers for the building enclosure: a) rain/moisture control layer, b) air control layer, c) vapor control layer, and d) thermal control layer
- Determine if non-occupied areas such as crawl spaces and attics are designed as vented or non-vented spaces, or the design is unclear and they are operating as unintended hybrid systems (which harm building performance).

4-2.6.3.2 Interviews with Building Manager and Occupants.

Interview the building manager, maintenance personnel and building occupants regarding the following issues:

- Changes to purpose or function of the building (such as warehouse to office space)
- Known water penetration issues, observed high humidity, or deteriorated interior finishes
- Air movement detected around windows or doors
- Glare problems
- Temperature issues in spaces
- Unpleasant odors
- Excessive background noise in spaces

4-2.6.3.3 Visual Inspections of Building.

Perform visual inspection of the building to assess the following for conditions adversely affecting building performance:

- Topography slopes with the potential for ponding water against the building
- Deterioration issues (such as sealants, masonry pointing and spalling, window gaskets)
- Evidence of excessive dampness, vegetative growth, or staining on the building exterior
- Roof issues (such as deterioration of membranes or flashings, poor adhesion, tenting of membranes, ponding, vegetative growth, or evidence of roof drain overflows)
- Corrosion issues
- Evidence of foundation movement (such as cracks or displaced or out of plane elements)
- Obvious changes of cladding materials or changes in building footprint as compared to record original and renovation construction drawings
- Crawl space issues:
  - Evidence of condensation or water penetration into the space
  - For ventilated crawl spaces, check sub-floor insulation for continuity
  - At a minimum, crawl spaces must have a vapor barrier sealed at laps, exterior walls, and penetrations.
- Evidence of exterior wall issues observed from the interior:
  - Obvious signs of water entry, especially around windows, doors, foundation walls, and at the roof-to-wall connection. Signs may include stains, mold, peeling paint, efflorescence, peeling drywall tape, or standing water or dampness.
  - Fogging on the inside of insulated glass panels.
  - Dark stains on the exterior wall around light switches and receptacles and other penetrations in the drywall (common indications of air infiltration).
  - “Ghosting” (dark stains) at drywall screw heads or metal studs, resulting from drywall with a high moisture content. This is often caused by thermal bridging, by a lack of exterior insulation, or incorrectly installed vapor barrier resulting in a dew point condition within the wall cavity. A lack of an air barrier also results in dew point issues in the wall cavity.
  - Check seals around windows and doors for continuity and resilience.
- Evidence of issues above ceilings:
  - Stains on the ceiling drywall or acoustical tile (caused by roof leaks or by condensation dripping from building systems above the ceiling).

  - Excessive rusting on bar joists or structural steel (may indicate condensation caused by air infiltration, often at the roof-to-wall interface).
- Carpet or floor tile may indicate the presence of water by discoloration or loss of adhesion (caused by water infiltration or condensation on insufficiently insulated slabs-on-grade).
- Air curtains with operational issues

4-2.6.4 Electrical System Assessments.

Perform initial assessment of electrical systems through review of documentation and interviews as follows.

4-2.6.4.1 Review of Electrical System Documentation.

Review the original design plans of the building and renovation drawings, as well as records of changes or previous condition surveys, to assess the following which may adversely affect the performance of the electrical systems:

- Current systems installed
- Materials used and known life cycle issues
- Original performance expected
- Inherent increased energy usage issues
- Current stage in life cycle of existing equipment for continued use opportunity
- Bulb/lamp type replacement vs. fixture replacement

4-2.6.4.2 Interviews with Building Manager and Occupants.

Conduct interviews to determine how the building is being used, identify known system issues, and confirm how the building is serving the occupant’s needs. Interview the building manager, maintenance personnel and building occupants regarding the following issues:

- Past changes to purpose or function of the building (such as warehouse to office space)
- Known electrical issues, or high cost of maintenance on equipment
- Nuisance tripping of circuit breakers
- Generator (Emergency Power)
  - Excessive fuel costs (equipment running poorly)
  - Nuisance breakdowns (frequency of and cost for repairs)

   - Life Cycle (expected equipment life vs. current age)
   - Adequacy of fuel storage capacity (if function/mission of building has changed, new function may have additional energy demand that requires increased fuel storage)
- Current Lighting Systems
   - Fixture types (examples include incandescent, fluorescents, and light-emitting diode (LED))
   - Lighting Controls (examples include switches, occupancy sensors, time clocks, and building management system (BMS))
- Renewable Energy Systems
   - Solar Arrays, wind turbines
   - Life cycle (expected equipment life vs. current age)

4-2.7 Issues and Resolution Log.

Create an initial Issues and Resolution Log which contains detailed descriptions of the findings and recommendations from the initial assessments. This log contains information outlined in the ASHRAE 0.2, Assessment Phase section titled “Issues and Resolution Log”. The log contains issues found, recommendations for corrective actions, estimated costs and benefits, implementation actions and status, and hand-off activities such as training and actions for maintaining performance improvements. Maintain/update this log through the entire EBCx process.

4-2.8 Implement Immediate Improvements.

Bring to the attention of the Building Manager issues found, especially those related to safety, security, health, or operational issues that can be easily remedied and do not require further evaluation (will obviously not adversely impact other systems). Corrective actions that do not incur costs and provide immediate payback can be implemented during the EBCx process; however, do not implement corrective actions without coordinating with maintenance staff responsible for upkeep on the building due to the possibility of creating unintended adverse issues (for example, opening a valve may improve the operation of the mechanical system, but the maintenance staff may have closed the valve temporarily until repairs can be performed on a system leak).

For minor improvements that require installation maintenance staff involvement, coordinate with installation personnel such that work orders are submitted for correcting these issues. Document and include in both the EBCx Report and the Issues and Resolution Log these immediately implemented modifications and corrective actions, along with their projected benefits.

4-2.9 Assessment Report Portion of EBCx Report.

The EBCx Report begins with the creation of the Assessment Report. The Assessment Report becomes the initial chapter of the EBCx Report and documents the findings and results of the Assessment Phase activities. The minimum content requirements for the Assessment Report portion of the EBCx Report are stated in ASHRAE 0.2, Assessment Phase section titled "Initiate EBCx Report with Assessment Report". This same section in ASHRAE 1.2 identifies information required for HVAC systems. Provide the information outlined in ASHRAE 0.2 for the building systems included in the EBCx scope.

4-2.10 Government Review and Decision to Proceed.

Government representatives will review the Assessment Phase deliverables to determine if the Assessment Phase activities are complete and they concur with the planned approach for proceeding into the Investigation Phase. Review comments are submitted to the Cx Provider and submittals are revised and re-submitted as necessary. For projects considering multiple buildings for EBCx, the Government will review the revised EBCx Program Plan for concurrence with recommendations on the buildings planned for subsequent evaluation.

4-3 ASSESSMENT PHASE DELIVERABLES.

The Assessment Phase deliverables consist of the following:

- CFR (included in EBCx Report)
- EBCx Plan
- Initial EBCx Report, including the Assessment Section
- Systems Manual Outline
- Updated EBCx Program Plan (if applicable to multiple building projects)
- Initial Issues and Resolution Log

4-3.1 EBCx Plan.

The fully developed EBCx Plan has multiple report sections which outline the strategies for executing the EBCx phases. Sections are initially developed in one phase and are updated as the EBCx efforts progress into subsequent phases. The minimum content requirements for the EBCx Plan are stated in ASHRAE 0.2, Assessment Phase section titled "Develop the EBCx Plan". Sections of the overall EBCx Plan and the phase in which they are developed are as follows (refer to the referenced phase within this document for the requirements of plan report section contents; see Appendix A for the location of best practice templates for the EBCx Program Plan and the EBCx Plan):

- EBCx Program Plan – developed for multiple-building EBCx efforts; initially developed in Planning Phase and updated in Assessment Phase

- Initial EBCx Plan – created in the Assessment Phase
- Measurement and Verification (M&V) Plan – initial approach is developed in Initial EBCx Plan during Assessment Phase, then plan is updated in subsequent phases for the detailed M&V of the recommendations that are implemented. M&V Plan includes the details for both baseline and post-implementation performance period testing required for quantifying the performance and achieved benefits of the process.
- Training Plan – included in the Initial EBCx Plan during Assessment Phase, then plan is updated in subsequent phases based on personnel needs and system complexity
- Investigation Plan – added to the EBCx Plan during the Investigation Phase
- Implementation Plan – added to the EBCx Plan during the Implementation Phase
- OCx Plan – developed in the Hand-off Phase, then updated in the OCx Phase.

4-3.2 EBCx Report.

The full EBCx Report has multiple report sections which document the activities undertaken and results of the EBCx process. Sections of the overall EBCx Report and the phase in which they are developed are as follows (refer to the referenced phase within this document for the requirements of the report section contents; see Appendix A for the location of best practice templates for the EBCx Report):

- Initial EBCx Report with Assessment Report – created in the Assessment Phase, includes initially recommended CFR and initial Issues and Resolution Log.
- Investigation Report section – added to EBCx Report during Investigation Phase, including results and findings, and updated content.
- Implementation Report section – added to EBCx Report during Implementation Phase, including work undertaken and implementation results. Other content includes test documentation, updated Issues and Resolution Log, site visit records, verification documentation, M&V documentation, and training documentation.
- Final EBCx Report, including Lessons Learned Report section – created in the Hand-off Phase to include lessons learned, necessary updates to prior content, final training and verification documentation.

The OCx Report is a separate report from the EBCx Report and is developed during the OCx Phase. It is most common for the Government to be responsible for OCx Phase efforts, either utilizing installation maintenance resources or installation support contracts.

This Page Intentionally Left Blank

CHAPTER 5 INVESTIGATION PHASE

5-1 OBJECTIVES.

The Investigation Phase consists of detailed site investigations, which compare the actual as-is building conditions and system performance with the Current Facility Requirements (CFR). This phase reveals existing conditions in the building, evaluates the need for change, and identifies requirements for additional systems, assemblies, or additions. The benefits and expected payback of each recommended change are derived. The objectives of the Investigation Phase are to understand and document existing conditions and performance to identify improvements needed to bring the building into compliance with the CFR.

This phase concludes with the completion of the Investigation Report section of the EBCx Report, which identifies scope and benefits of recommended building modifications and improvements as well as quick fix improvements already implemented during the Investigation. This is the data intensive portion of EBCx and may be most appropriate for contracting to EBCx specialists. When contracting, the issues and opportunities identified in the Assessment Phase determine the type of specialist needed; for example, if issues are broad and widespread across systems, an Energy Services Contractor (ESCO) may be the best fit, but if the issues are controls-specific a local controls vendor/Contractor may be the right team member.

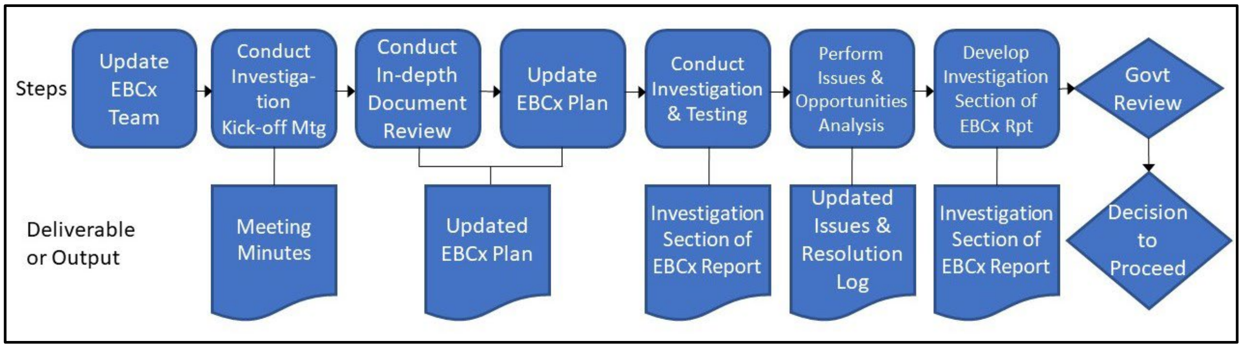
5-2 INVESTIGATION PHASE STEPS.

The Investigation Phase involves performing detailed testing and analysis of specific building systems, discovering operational characteristics, verifying needed modifications, and quantifying implementations needed and improvements expected.

Investigation Phase steps are as follows:

a. Update EBCx Team
b. Conduct Investigation Phase kick-off meeting
c. Conduct in-depth building documentation review
d. Update EBCx Plan
e. Perform site Investigations and testing
f. Perform issues and opportunities analysis
g. Update EBCx Report with Investigation Report
h. Present recommendations to Government and adjust plans
i. Obtain Government review and decision to proceed

Figure 5-1 Investigation Phase Process and Deliverables/Outputs



5-2.1 Updated EBCx Team.

Based on the results of the evaluations conducted in the Assessment Phase, which identify the testing and inspections required in the Investigation Phase, the EBCx Team may require additional specialists or support. Identify these new team members and their roles and responsibilities in a revised version of the EBCx Plan.

5-2.2 Investigation Phase Kick-off Meeting.

Conduct an Investigation Phase kick-off meeting to provide an overview of the EBCx Plan, review findings from the Assessment Phase, and coordinate the upcoming work activities. Also review investigation tests/inspections and deliverables during the meeting. Required attendees include Government and Contractor personnel playing a key role in the Investigation Phase activities, as well as building operations and maintenance staff. Topics for this meeting include the following:

- EBCx goals and objectives
- Introduction of new EBCx team members
- Confirmation of EBCx roles, including local support
- Review of communication and coordination plan
  - Security requirements and coordination
  - Planned meetings
- Specific Investigation Phase Plan/Activities
  - Outline of activities
  - Building systems being evaluated
  - Approach to measurement and verification (M&V), with special focus on baseline testing
  - Planned Functional Performance Tests (FPT's)/inspections
  - Access required

- Impacts to operations
- Government staff participation/assistance
- Training approach
- Deliverables/Submittals

- Planned EBCx schedule

Following the meeting, develop formal meeting minutes and issue to attendees as well as stakeholders who were unable to attend.

5-2.3 In-Depth Building Documentation Review.

Conduct a more detailed review of the documentation gathered during the Assessment Phase. This detailed review and analysis assists in identifying which tests and inspections are the most appropriate for the Investigation Phase efforts. This review seeks to reveal information about the intended original basis of design, the existing baseline design, as well as the current operational procedures. With this information, the Cx Provider seeks to determine the deviations between current operations, the original building/systems design, and the current facility requirements (CFR). Goals of this review include:

- Gaining a complete picture of equipment and assemblies included in the EBCx scope
- Identifying potential problem areas to investigate
- Understanding the intended design of building systems and assemblies
- Creating a list of specific equipment and assemblies to evaluate during the Investigation Phase and the appropriate methods of testing and inspection

At a minimum, the detailed review includes the following:

- Evaluation of original and new drawings, specifications, historical utility records, and previous CFRs and commissioning records
- Interactions between building systems and assemblies (such as building envelope components that impact HVAC system performance)
- Prior building evaluation reports, such as energy performance analysis, roof inspections, architectural studies, energy audit reports, TAB reports, capital planning documents, sustainability assessments, safety/health reports, Cx reports, or similar documents to determine what has already been evaluated, recommended for improvements, improved, or not yet implemented
- Building/systems operations and maintenance manuals, with special focus on controls systems (such as those related to HVAC, lighting, security, and fire alarm)

- Maintenance records to assess preventive maintenance and identify potential systems issues

5-2.4 Updated EBCx Plan.

Update the EBCx Plan to include an Investigation Plan. The Investigation Plan is a detailed outline of the planned processes for analyzing existing building conditions and identifying upgrades and improvements needed to meet the Government's CFR. The plan addresses every system and assembly included in the EBCx scope of work. The Government will review and accept the Investigation Plan prior to on-site investigation activities being performed.

The Investigation Plan must include, at a minimum, the information outlined in ASHRAE 0.2 Investigation Phase section titled "Update EBCx Plan".

5-2.5 Site Investigations and Testing.

Carry out physical inspections and tests to evaluate condition and performance as detailed in the reviewed and accepted EBCx Investigation Plan, and record observations and data. The two elements of physical site investigation are condition evaluation and performance evaluation. Condition evaluation includes an assessment of the installed condition of the equipment, systems, and assemblies, such as appearance, physical damage, deterioration of condition, upgraded features, and change of use. Performance evaluation includes an assessment of how the equipment, systems, and assemblies are operated and how they are performing relative to expected performance and the CFR.

During the physical site investigation, evaluate and document the condition and performance of the equipment, systems, and assemblies, as identified in the Investigation Plan. Performance evaluation may include active and passive testing. Execute the tests and repeat as necessary to obtain conclusive information about the performance of systems. During execution of the Investigation Plan, issues may be uncovered that lead to expansion of the plan or to the elimination of specific planned activities. When revisions of an accepted Investigation Plan are required, submit the revised plan to the Government for formal acceptance before proceeding with execution of an altered plan. Conduct on-site investigations in accordance with ASHRAE 0.2 Investigation Phase section titled "Perform Site Investigation and Testing", as well as additional information contained within this document.

5-2.5.1 Detailed Site Survey.

The detailed site survey involves evaluating and documenting the condition and performance of the equipment, systems, and assemblies, as included in the EBCx scope of work and identified in the Investigation Plan. This survey focuses on areas of concern revealed from interviews/surveys, document reviews, and prior brief walk-throughs of the building. The detailed site survey includes assessments to evaluate condition and performance, involving the following actions at a minimum:

- Assess condition, including damage, and noting age of equipment and expected remaining life
- Identify indications of deferred maintenance which could be affecting performance
- Note new features or changes in use of equipment
- Denote issues that affect the equipment's ability to be appropriately operated or maintained (such as lack of adequate access)
- Compare how system/components are operated vs. CFR or good practice
  - Set-points
  - Modes of operation (such as daytime, 24/7, or seasonal)
  - Load

5-2.5.2 Calibrations of BAS-Trended Points.

If BAS systems are operating, verify the accuracy of sensors, valves and actuators and statuses to ensure precision of BAS screen shots and trend data. At a minimum, perform this on the devices that impact control and BAS points. Complete calibration prior to initiating trends – coordinate with building manager prior to performing calibration.

If controls are obsolete or non-functioning, include in the EBCx improvements corrective actions to repair or replace the controls. If the BAS/DDC system has been modified from the original design, interview the O&M staff to investigate why the change was made.

5-2.5.3 Energy Usage and Building Performance Baseline.

Establish an energy usage baseline early in the project and track improvements as corrective actions are identified and implemented. Compare this current energy usage to benchmark buildings to identify the potential for improvement. In addition to energy use, available performance data may also include maintenance work orders, comfort complaint logs, indoor air quality parameters, occupant/user satisfaction survey results, and BAS trend data or data logger data. Obtaining this information establishes a performance baseline prior to implementation actions and helps determine the positive impact of EBCx efforts and the benefits gained.

5-2.5.4 System and Equipment Performance Monitoring.

The EBCx Team executes the system and equipment monitoring as outlined in the Investigation Plan section of the EBCx Plan. This involves gathering data through diagnostic monitoring methods to identify poor performance and potential improvements. For example, to monitor HVAC systems, diagnostic monitoring methods include BAS trending, portable data logger trending, and energy and weather data collection. Perform similar diagnostic testing to assess performance of other building systems included in the EBCx scope.

5-2.5.5 Additional Building Personnel and Occupant Interviews.

Conduct additional interviews with the Building Manager, O&M personnel and building occupants to gain a more in-depth picture of the current use of the building and operation of its systems. While surveys can serve the purpose of gathering initial feedback from the building occupants/users, also conduct formal interviews with building managers and O&M personnel. The goals of obtaining this information are to identify current problem issues, uncover potential improvement opportunities and confirm the CFR. See Appendix A for the location of best practice templates for the building occupant questionnaire.

5-2.5.6 Building Automation Controls System Reviews.

Conduct a thorough and detailed review of the building automation system, focusing on establishing the current sequence of operations, identifying/confirming accurate graphics, and evaluating unit alarms/settings. Review building automation system graphic screens, alarm logs, and schedules for each piece of HVAC equipment, including a complete review of setpoints or reset parameters. Identify conditions which result in wasted energy use. Document the "as-found" conditions and the current operation of the systems (information is critical for subsequent measurement and verification activities). Record identified problems and improvement recommendations to the sequence of operations in the Issues and Resolutions Log.

5-2.5.7 Functional Performance Test (FPT) Procedures.

Develop functional performance test (FPT) procedures for the systems identified in the EBCx scope of work. Functional testing is often necessary to determine how systems react to key operating conditions. Test plans for energy efficiency focused projects both confirm existing system operation to identify improvements, and test or confirm ideas for improvement. Develop the FPT's with the goal of verifying that EBCx efforts, after system improvements, aid in the building achieving the CFR parameters. The information to be included in a thorough test procedure and test form is outlined in ASHRAE 0.2 Investigation Phase section titled "Update EBCx Plan". The developed FPT's are included in the Investigation Phase portion of the EBCx Plan which is submitted to the Government for acceptance of the procedures prior to scheduling testing.

5-2.5.8 System Functional Testing.

Following Government acceptance of the FPT's, functional testing is conducted to evaluate existing systems performance and identify areas requiring improvements to meet the CFR. Issues identified in the Assessment Phase or early in the Investigation Phase are considered for more in-depth evaluation during system testing to determine root causes and potential solutions. Ensure required equipment and personnel, both

EBCx Team and Government support, are on-site prior to commencing testing. Schedule tests with building management staff so that disruptions to normal operations are avoided or minimized. Schedule testing which requires outages or operations impacts with adequate notice and communicate to the building manager, O&M personnel, and occupants/users. Testing may need to be deferred based on climate conditions, occupancy situations or planned events. Additional testing guidelines for specific systems are included below.

5-2.5.8.1 HVAC & Refrigeration System Investigation and Testing.

Perform testing of HVAC&R systems in accordance with ASHRAE 1.2, Investigation Phase section titled “Perform Site Investigation and Testing”.

5-2.5.8.2 Building Enclosure Investigation and Testing.

Conduct further investigation and testing of building enclosure issues in accordance with the following:

- Test for air movement through the enclosure in accordance with ASTM E1186. This standard covers multiple test methods. For initially testing large surface areas, infrared scanning allows for rapid surveying; for follow-up leak detection testing of local areas, the smoke tracer, theatrical fog, anemometer, sound detection, bubble detection, and tracer gas techniques are typically more appropriate methods.
- Test for air leakage in accordance with either ASTM E779 or ASTM E1827.
- Test for water infiltration through building walls in accordance with ASTM E2128.
- Test for continuity of insulation by use of infrared imaging in accordance with ASTM C1060.
- Test for roof leaks in accordance with ASTM D8231 and ASTM C1153.

5-2.5.8.3 Electrical Systems Investigation and Testing.

Conduct further investigation and testing of electrical systems in accordance with the following (Note: It is important to note that the local Authority Having Jurisdiction may have more stringent requirements for operational requirements; these must be confirmed.):

- Emergency and Stand-by Power Systems:
  - Perform inspections and operational testing in accordance with UFC 3-540-07, NFPA 110 section titled “Operational Inspection and Testing”, and the manufacturer’s instructions.

- Lighting Control Systems:
  - Test lighting controls in accordance with IECC (C405 & C408.3 – Lighting system functional Testing), NEMA 410 – (Performance testing for lighting controls and switching devices), and manufacturer's installation and operation instructions (sequence of operations).
- Power and distribution systems:
  - Conduct infrared camera thermography tests on equipment in accordance with ISO 18251-1: Non-destructive Testing – Infrared Thermography – Part 1, Characteristics of System and Equipment; and ANSI/NETA MTS, Standard for Maintenance Testing Specifications for Electrical Power Equipment and Systems. Follow the required safety protocols of NFPA 70E, Standard for Electrical Safety in the Workplace.
- Renewable energy systems:
  - Photovoltaic (solar arrays): test functionality in accordance with NFPA 70; and IEC (International Electrotechnical Commission) 62446-1, Photovoltaic systems – Requirements for testing, documentation, and maintenance Part 1: Grid connected systems – documentation, commissioning tests, and inspection.
- Energy storage systems:
  - Uninterruptable power supply (UPS): test functionality in accordance with NFPA 70; and IEC (International Electrotechnical Commission) 62040-3 Uninterruptable Power Systems – Part 3 Performance and testing requirements – UPS.

5-2.5.9 Data for Energy Calculations and Implementation.

Gather data for savings calculations and detailed implementation recommendations. This includes documenting current energy usage for a system or piece of equipment being recommended for repairs or replacement. If electrical data measurement is not allowed or practical, electrical usage may be derived using data such as equipment sizes and run times.

5-2.5.10 Simple Repairs.

Corrective actions that are discovered by the EBCx Team during the Investigation Phase and provide immediate payback through no or low costs can be implemented during the EBCx process; however, do not implement corrective actions without coordinating with maintenance staff responsible for upkeep on the building due to the possibility of creating unintended adverse issues (for example, opening a valve may improve the operation of the mechanical system, but the maintenance staff may have closed the valve temporarily until repairs can be performed on a system leak). For minor improvements that require installation maintenance staff involvement, coordinate with installation personnel such that work orders are submitted for correcting these issues. Document and include in both the EBCx Report and the Issues and Resolution Log these immediately implemented modifications and corrective actions, along with their projected benefits. ASHRAE 1.2 lists examples of these quick fixes as follows:

- Systems control calibration/repairs: air-distribution component repairs, water/steam distribution component repairs, variable air volume (VAV) or constant volume (CV) box calibration
- Mechanical system repairs: blockage from air-distribution devices, connecting broken flex duct from a duct tap or diffuser, replacing a broken fan belt, damper linkage, resetting dampers, resetting air handling unit (AHU) or fan coil unit (FCU) air flows with significant variance from design
- Plumbing systems: fixture and appliance repair, water system repair, water pressure and hot water temperature adjustment corrections
- Electrical repairs: such as loose terminations or lighting repairs, lighting schedule adjustments
- Correcting systems operating schedules: system running 24/365
- Turning off equipment that does not need to be operating.
- Releasing overridden control set points and parameters.
- Returning equipment to automatic mode
- Deferred maintenance issues: filter replacement, coil cleaning, clean pipe strainers/tower screens, adjust fan belts, replace failed components

5-2.6 Issues and Opportunities Analysis.

Analyze issues, conditions, and performance information acquired from site investigation and testing to identify possible solutions and corrective action recommendations. Review information gathered from previous commissioning activities to increase understanding of issues that adversely affect the building and system conditions and performance. Update the Issues and Resolution Log with identified issues and related recommendations for improvement.

5-2.6.1 Data Analysis.

The off-site portion of the Investigation Phase involves evaluating the data collected during on-site inspections and tests to draw conclusions about existing or potential system performance. Data analysis forms the basis for the recommendations for improving the building and systems condition and performance. Keep in mind that these recommendations must, at a minimum, identify those improvements required to achieve the CFR, plus those corrective actions required to address poor conditions and are leading to subpar performance of the building and its' systems.

5-2.6.2 Energy Impacts and Cost Calculations.

During the Investigation Phase, each recommendation which impacts energy usage included in the Issues and Resolution Log requires developing a simplified Life Cycle Cost Analysis (LCCA). While some commissioning activities will result in reduced energy usage, some activities will increase energy usage. A negative payback or LCCA may result from these situations and should be captured. The LCCA requires development of the cost of repairs/upgrades and the expected annual energy impacts. Develop the estimated construction costs for each recommendation utilizing traditional cost estimating techniques (as outlined in UFC 3-740-05) and include the mark-ups necessary to reflect a total cost if undertaken as a standalone project. The construction costs developed during the Investigation Phase can be rough order of magnitude costs based on the EBCx Team's recent projects; the follow-on Implementation Phase requires more detailed costing efforts of each accepted recommendation prior to procuring the upgrades.

The LCCA requires comparing the current energy usage to the energy use estimated for the new equipment, or estimating the change in energy use resulting from the current condition being corrected. Obtain the local installation's utility rates to derive the energy costs. Develop a simple payback period, in years, for each energy saving recommendation to identify the time required to recover the initial costs of the recommended improvement. For the simple payback, divide the total cost of the improvement recommendation by the projected annual energy savings. The Federal Energy Management Program (FEMP) has online energy- and water-savings calculators that are simple to use and cover specific types of equipment (such as boilers, water heaters, and lighting fixtures). These calculators and other resources can be found at https://www.energy.gov/femp/federal-energy-management-tools. See Appendix A for best practice template for performing savings calculations.

5-2.6.3 List of Findings and Recommendations.

Using the Investigation Phase results, including on-site testing/inspections and analysis of the data, create a list of recommendations. This list is derived from the Issues and Resolution Log. The list includes key information useful for the Government to select recommendations for implementation. The in-depth supporting data is included in the Issues and Resolution Log (included in the Investigation Report portion of the EBCx Report). For the content of the List of Findings and Recommendations, include the information outlined in ASHRAE 0.2 Investigation Phase section titled "List of Findings and Recommendations". Include separate recommendation lists for those that are quick fixes and can be implemented by O&M personnel or installation work orders, and others that are more extensive and require execution as capital projects.

As a basis for classifying recommendations, ASHRAE 1.2 recommends that improvements with a simple payback of less than two years be implemented, and those with a simple payback greater than two years be considered for implementation as a capital improvement project. Keep in mind that some recommendations may be more attractive based on qualitative impacts, rather than their savings gained from the improvement; for example, a key qualitative benefit often achieved is the ability for the tenant to fully support its' mission. The list of findings and recommendations must clearly identify qualitative benefits. Additionally, state the associated greenhouse gas emissions impact related to the implementation of each energy-saving recommendation (in tons of CO_2 emissions avoided). Coordinate with the Installation Energy Manager for local greenhouse gas conversion factors to utilize; in the absence of specific direction from the Installation Energy Manager, utilize the regional conversion factors published on the U.S. Environmental Protection Agency's Avoided Emissions and Generation Tool (AVERT) website (https://www.epa.gov/avert/avoided-emission-rates-generated-avert).

5-2.7 Investigation Report Portion of EBCx Report.

Develop and add to the EBCx Report the Investigation Report portion which documents the findings and results of the Investigation Phase activities. The minimum content requirements for the Investigation Report portion of the EBCx Report are stated in ASHRAE 0.2, Investigation Phase section titled "Update EBCx Report with Investigation Report". This same section in ASHRAE 1.2 identifies information required for HVAC systems. Provide the information outlined in ASHRAE 0.2 for the building systems included in the EBCx scope.

5-2.8 Recommendations and Plan Adjustments.

Conduct a meeting to present the recommendations resulting from the Investigation Phase. Based on these discussions, make adjustments based on the most likely means of implementing the recommendations. For example, at an installation with sufficient resources and access to contracting mechanisms to implement specific types of repairs or upgrades, those recommendations could be prioritized for early completion and other recommendations deferred to a later timeframe. These deferred recommendations could be implemented as a capital project involving similar upgrades at other buildings.

Recommendations may be prioritized for early implementation based on the following parameters, from highest to lowest priority:

- Life safety or code compliance issue that requires immediate action (note: safety evaluations are not included in the scope of standard EBCx efforts, but identify safety issues discovered in the normal course of EBCx activities in the corrective actions list; examples include electrical boxes with exposed faceplates, exposed wiring, and obvious fall hazards).
- Deferred maintenance issue with easy implementation
- No cost to implement
- Common repair/adjustment through installation work order or service contract

- Corrective action that enhances resiliency of a mission critical building (such as an inoperable backup power generation system), or reduces the risk of a building being able to support its' mission
- Corrective action that provides quality of life improvement (such as restoring operations of the HVAC system to provide proper occupant comfort or indoor environmental quality)
- Capital improvement project (requires design and construction) with high energy savings, low cost, or short payback period
- Capital improvement project with higher cost or extended payback period

5-2.9 Government Review and Decision to Proceed.

Government representatives will review the Investigation Phase deliverables to determine if the activities are complete and they concur with the planned approach for proceeding into the Implementation Phase. Review comments are submitted to the Cx Provider and submittals are revised and re-submitted as necessary.

When a recommendation involves design and construction efforts such as replacement of an entire building system, these are not performed as part of EBCx efforts but follow the Government's design process. Follow-on commissioning efforts to verify design and performance of new construction or renovation projects will then follow the requirements of UFC 1-200-02 and related UFGS guide specifications.

5-3 INVESTIGATION PHASE DELIVERABLES.

The Investigation Phase deliverables consist of the following:

- Updated EBCx Plan
- Updated EBCx Report, including the Investigation Report

CHAPTER 6 IMPLEMENTATION PHASE

6-1 OBJECTIVES.

During the Implementation Phase, the Government decides which Investigation Phase recommendations to implement and how they will be accomplished. The selected recommendations are implemented and evaluated to verify they achieve the expected benefits and satisfy the Current Facility Requirements (CFR). The objectives of the Implementation Phase are to execute the recommendations selected from the Investigation Phase, verify performance meets the CFR, and report the results of implementation. It is important to emphasize that the main benefits of EBCx, such as achieving energy savings and optimizing system performance, are not realized until corrective actions are implemented.

The Assessment, Investigation, and Implementation Phases are typically iterative processes. If during investigation it is found that a repair can be easily made, or a change/repair is required to complete the investigation, this item can be implemented during the Investigation Phase. An iterative implementation might occur when a repair needs to take place before the system can be fully investigated or when changes made need verifying and modifying multiple times before the targeted results are achieved. This phase concludes with the verification of the system's performance and the updating of the Systems Manuals.

6-2 IMPLEMENTATION PHASE STEPS.

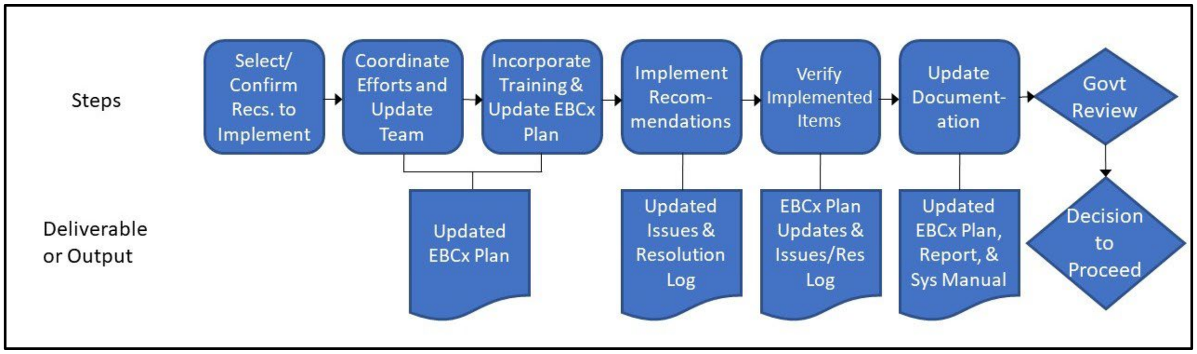
Recommendations from the Investigation Phase can be grouped into Implementation Phase packages completed through different execution routes. Depending on their complexity and cost, these can be executed through installation public works resources, installation service contracts, or if extensive and costly, may require some level of design and construction procurement. Thus, the Implementation Phase involves oversight of construction or service contract work in the building(s). The goals of the Implementation Phase are to select the most beneficial recommendations to achieving the established goals and objectives of the EBCx project, select the execution route, implement the selected measures, and verify or performance test that these measures achieve the expected benefits. The Implementation and Hand-off Phases are conducted by the same project delivery team whether it is an in-house or contracted group.

Implementation Phase steps are as follows:

a. Select/Confirm recommendations to implement
b. Coordinate implementation
c. Update EBCx Team
d. Incorporate informal training
e. Update EBCx Plan

f. Implement recommendations
g. Verify completed recommendations and performance
h. Update EBCx documentation
i. Obtain Government review and decision to proceed

Figure 6-1 Implementation Phase Process and Deliverables/Outputs



6-2.1 Implementation Recommendations Selection/Confirmation.

This step involves identifying those improvements planned for the Implementation Phase and others deferred with a timetable for planned implementation as capital improvement projects. The ultimate goal of this phase is having the systems perform efficiently to meet the CFR. Involve the O&M staff in the implementation decision process. At the completion of the prior Investigation Phase, a meeting is held to review recommendations and set priorities for implementation based on the installation resources and contracting mechanisms available. The Implementation Phase then begins with reviewing these priorities and timeframes and confirming the recommendations that were selected for implementation.

6-2.2 Implementation Coordination.

The Cx Provider assists with coordinating the completion of the selected recommendations. For recommendations that can be handled through installation resources or service contracts, or through a modification to the EBCx contract, the Cx Provider acts as a third-party commissioning resource to ensure the resulting improvements meet the CFR (provided if Implementation Phase services are included in the Cx Provider's scope of work).

Recommendations from EBCx efforts requiring involvement of design and construction are typically handled as projects separate from the EBCx process. However, these projects require third-party commissioning efforts in accordance with UFGS 01 91 00.15 BUILDING COMMISSIONING.

6-2.3 Updated EBCx Team.

The EBCx team members for the Implementation Phase typically change based on the recommendations planned for implementation. The team may include building operations staff, installation O&M personnel, subcontractors, system vendors, or other specialists contracted directly to the Government or to the Cx Provider.

6-2.4 Informal Training.

The Cx Provider coordinates the Implementation Phase to allow for involvement in implementation and verification testing by the installation or building O&M staff (depending on which party is responsible for maintaining the system). This involvement serves as informal hands-on training for operating and maintaining the systems after the improvements are in place. This involvement also establishes an understanding of the expected system performance and aids in identifying performance degradation and ensuring extended equipment life. The level of involvement depends on the types of recommendations implemented and the methods chosen for implementation (contracted vs. in-house implementation).

6-2.5 Updated EBCx Plan.

This step involves developing the portions of the EBCx Plan associated with the Implementation Phase. The EBCx Plan portions developed or updated in this phase are as follows:

- Implementation Plan
- Implementation Verification Plan
- Updated Training Plan
- Updated Measurement and Verification (M&V) Plan

6-2.5.1 Implementation Plan.

Develop an Implementation Plan containing the detailed roles and responsibilities of EBCx team members, including identification of new team members. Include a communication plan for the new team structure. In addition, incorporate any necessary Plan changes to the execution process based on updates to local resource availability conveyed from the Government to the Cx Provider. Also include the details of the planned implementation of recommendations. Submit to the Government for review and acceptance. Once the Implementation Plan is accepted by the Government, implementation activities can be performed.

For each recommendation accepted by the Government for implementation, the Implementation Plan includes the following information:

a. EBCx team members involved in the implementation and their roles and responsibilities.

b. Planned schedule of implementation as coordinated with occupants, building security, custodians, and utility services. Clearly communicate and coordinate any operational impacts including outages and shutdowns.

c. Detailed scope of work, including implementation methods, work required for sustained performance improvement, and verification procedures with roles/responsibilities. Implementations involving HVAC systems must include additional scope actions as outlined in ASHRAE 1.2, Implementation Phase section titled “Create Implementation Plan”

6-2.5.2 Implementation Verification Plan.

Update the EBCx Plan to include an Implementation Verification Plan. This outlines the detailed implementation verification tests and physical inspection procedures, as well as forms and checklists utilized for each selected recommendation. These tests and inspections represent those required to ensure that corrections and improvements were successfully implemented such that systems meet the CFR. Submit the Plan to the Government for review and acceptance. Once the Implementation Verification Plan is accepted by the Government, verification activities can be performed.

The Implementation Verification Plan includes the following information:

a. Roles and responsibilities of EBCx team members, including new verification specialists.

b. Verification tests and inspection procedures are required to ensure that implemented recommendations are installed and functioning in accordance with the CFR. Verification Plans for implementations involving HVAC systems must follow ASHRAE 1.2, Implementation Phase section titled “Develop Implementation Verification Plan”. Plans for other building systems must include similar information, with tests and inspections following the standards for those systems as outlined in Chapter 5 of this document.

6-2.5.3 Updated Training Plan.

Update or further develop the formal Training Plan developed in prior phases to include necessary changes based on Implementation Phase activities. Ensure the training addresses the implemented recommendations and changes to the operating procedures.

6-2.5.4 Updated Measurement and Verification (M&V) Plan.

Update the M&V Plan based on the known scope of work for recommendations planned for implementation. While the Implementation Verification Plan included the test and inspection procedures required for verification of the implemented recommendation, this updated M&V Plan includes the details for both baseline and post-implementation performance period testing required for quantifying the performance and achieved benefits of the process. Where specific M&V protocols are required, include the specific means and methods necessary to comply with the requirements of the chosen protocol. Submit to the Government for review and acceptance. Once the updated M&V Plan is accepted by the Government, implementation activities can be performed.

6-2.6 Recommendations Implementation.

The Cx Provider implements those recommendations selected and within their scope of work. When recommendations are being performed by resources not under the Cx Provider's contract, the Provider serves as a third-party to verify proper implementation such that CFR are achieved. Implementation activities by the Cx Provider include:

- Verifying design and submittals related to recommendations
- Conduct an implementation kick-off meeting
- Conduct site visits for verification
- Update Issues and Resolution Log

The minimum requirements for the Cx Provider during implementation are outlined in ASHRAE 0.2, Implementation Phase section titled "Implement Recommendations". Implementations involving HVAC systems must follow ASHRAE 1.2 Implementation Phase section titled "Implement Recommendations" and subsections; similar actions are required for the other systems included in the scope of work.

6-2.7 Completed Recommendations and Performance Verification.

Once installation is complete, the Cx Provider tests and inspects the completed recommendations to confirm the CFR are achieved; tests and inspections are conducted in accordance with the accepted EBCx Plan and Implementation Verification Plan. Document verification tests and physical inspections as outlined in the EBCx Plan, including tests and physical inspection data records, capture test data, observations, and M&V data. ASHRAE 1.2 Implementation Phase section titled "Verify Completed Recommendations" includes requirements specific to HVAC systems, including situations when deferred testing of systems may be necessary.

6-2.8 Documentation.

Develop or update the following documentation during the Implementation Phase:

- Update EBCx Plan on completion of tests
- Update EBCx Report to include the Implementation Report
- Update Systems Manual
- Update CFR (in EBCx Report)
- Update list of findings and recommendations (in EBCx Report)
- Test and inspection documentation (in EBCx Report)

- Update Issues and Resolution Log (in EBCx Report)
- Site visit records (in EBCx Report)
- Verification documentation (in EBCx Report)
- M&V documentation (in EBCx Report)
- Training documentation (in EBCx Report)

The minimum Implementation Phase documentation requirements are outlined in ASHRAE 0.2, Implementation Phase section titled “Update the EBCx Documentation”.

6-2.9 Government Review and Decision to Proceed.

Government representatives will review the Implementation Phase deliverables to determine if the activities were completed. The EBCx Plan and EBCx Report sections for this Phase are initially developed by the Cx Provider and submitted to the Government for review and acceptance. Review comments are submitted to the Cx Provider and submittals are revised and re-submitted as necessary. Once the EBCx Plan and EBCx Report sections for this Phase are accepted by the Government, Hand-off Phase activities may proceed.

6-3 IMPLEMENTATION PHASE DELIVERABLES.

The Implementation Phase deliverables consist of the following:

- Updated EBCx Plan
- Updated EBCx Report, including the Implementation Report
- Updated Systems Manual materials

CHAPTER 7 HAND-OFF PHASE

7-1 OBJECTIVES.

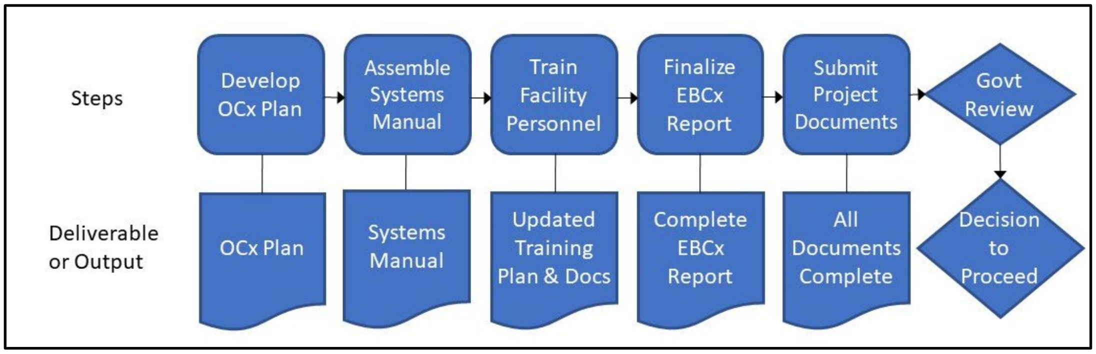
The Hand-off Phase represents the transition between the EBCx Team and the personnel responsible for operating and maintaining the systems. The goals are to provide the O&M team with the information, training, and procedures to ensure persistence of benefits. While many phases of EBCx may be independently performed by in-house or contractor teams, the Implementation and Hand-off of individual upgrade measures must be conducted by the same project delivery team whether it is an in-house or contracted group. During the Hand-Off Phase, the EBCx Team works to ensure the required documentation in the EBCx Report has been completed and is aligned with the EBCx Program (if one exists) and the EBCx Plan. This phase includes the development of the Ongoing Commissioning (OCx) Plan, the finalizing of the required systems documentation, and the submittal of completed deliverables. The objectives of the Hand-Off Phase are to provide the completed documents from the Cx Provider to the Government and provide training to the Government's personnel.

7-2 HAND-OFF PHASE STEPS.

Hand-Off Phase steps are as follows:

a. Develop OCx Plan
b. Assemble Systems Manual
c. Train building personnel
d. Finalize EBCx Report
e. Provide project documents to Government
f. Obtain Government review and decision to proceed

Figure 7-1 Hand-off Phase Process and Deliverables/Outputs



7-2.1 OCx Plan.

The OCx Plan documents how the building performance will be monitored going forward, what systems are included, what parameters are tracked, and how identified issues are corrected. It is most common for the Government to be responsible for ongoing commissioning activities, either utilizing installation maintenance personnel or installation support contracts. Develop the OCx Plan based on the knowledge of which resources will be utilized. The minimum content required in the OCx Plan is outlined in ASHRAE 0.2, Hand-off Phase section titled “Develop OCx Plan”.

7-2.2 Systems Manual.

Assemble the Systems Manual to incorporate changes to assemblies and systems that occurred during EBCx activities. Also incorporate documentation generated during and after the Implementation Phase into the Systems Manual. Update the Facility Guide, a component of the Systems Manual, to reflect changes to assemblies and systems. Add training documentation to the Systems Manual as training is performed. A comprehensive list of requirements for the Systems Manual is outlined in ASHRAE 0.2, Assessment Phase section titled “Establish the Systems Manual Outline”. Annex M of ASHRAE 0.2 provides an example outline of a Systems Manual.

7-2.3 Building Personnel Training.

Train building personnel based on the Training Plan developed as a part of the EBCx Plan. Training is most effective when consisting of a combination of classroom style and in-the-field type instruction. Training sessions are separated into topics targeted for building staff and O&M personnel. Refer to ASHRAE 0.2, Hand-off Phase section titled “Train Facility Personnel” for procedures and the training topics required for each personnel group.

7-2.4 Final EBCx Report.

Update the EBCx Report to reflect necessary changes to the EBCx Program Plan and OCx Plan. Update the EBCx Report to include the final training documentation and verification.

7-2.5 Government Review and Decision to Proceed.

Government representatives will review the Hand-Off Phase deliverables to determine if the Hand-Off Phase activities are complete and they concur with the planned approach for proceeding into the Ongoing Commissioning Phase (if the EBCx Contract includes the OCx Phase). Review comments are submitted to the Cx Provider and submittals are revised and re-submitted as necessary.

7-3 HAND-OFF PHASE DELIVERABLES.

The Hand-Off Phase deliverables consist of the following:

- Updated EBCx Report
- Systems Manual, including the Facility Guide
- OCx Plan

This Page Intentionally Left Blank

CHAPTER 8 ONGOING COMMISSIONING PHASE

8-1 OBJECTIVES.

Whether this phase is included in the initial EBCx contract is resource-dependent. The Ongoing Commissioning (OCx) phase is typically conducted with separate resources from the EBCx Team involved in prior phases, either utilizing installation maintenance resources or contracted through installation support contracts.

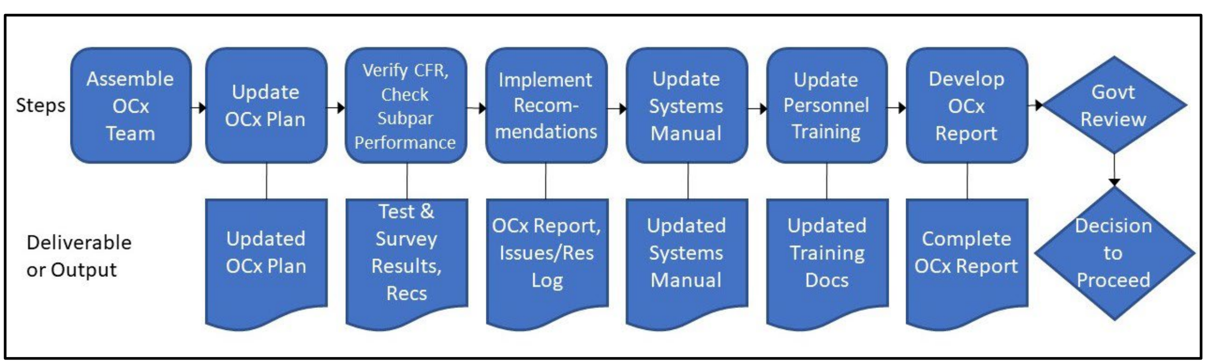
The OCx Phase is a program that consists of Cx Process activities that repeat regularly throughout the life of the building subsequent to the Hand-Off Phase. An OCx program repeats the EBCx activities on a scheduled, periodic basis to ensure the systems are continuously evaluated against the updated CFR. This phase is ongoing and involves developing an OCx Plan, continuously verifying the achievement of CFR's, and updating Systems Manuals and personnel training as needed. The overall objective of the OCx Program is to ensure that the benefits obtained from the EBCx Plan and other building improvements are sustained over time and improved if possible.

8-2 ONGOING COMMISSIONING PHASE STEPS.

Ongoing Commissioning Phase steps are as follows:

a. Assemble the OCx Team
b. Update the OCx Plan
c. Verify achievement of CFR
d. Investigate unacceptable performance or outcome
e. Implement recommendations
f. Update Systems Manual
g. Update building personnel training
h. Develop OCx Report
i. Obtain Government review

Figure 8-1 OCx Phase Process and Deliverables/Outputs



8-2.1 OCx Team.

The OCx Phase tasks may be performed in-house or contracted utilizing a service or Indefinite Delivery Indefinite Quantity (IDIQ) contract. It is most common for the Government to be responsible for OCx activities, either utilizing installation maintenance personnel or installation support contracts. The make-up of the OCx Team varies based on which building systems require ongoing commissioning. The Government must identify a person with clear responsibility for ensuring the OCx efforts are carried out on the building systems included in the scope and take place at the required intervals to ensure sustained optimal performance of the systems.

8-2.2 Updated OCx Plan.

Update the OCx plan as developed in the Hand-off Phase with the knowledge of the resources planned for these efforts. OCx Plan updates are made to ensure parameters which require monitoring are defined along with metrics for determining compliance with the CFR. The minimum content required in the OCx Plan is outlined in ASHRAE 0.2, Hand-off Phase section titled “Develop OCx Plan”. OCx Plan updates include:

- Review scope of OCx activities, including determining that assigned resources have the availability and capabilities needed for each activity.
- Ensure frequency of OCx activities are clearly defined and reviewed by the OCx Team.
- Clearly define remaining scope items from the EBCx Report, including deferred inspections/testing and recommendations that have not yet been implemented.

8-2.3 CFR Verification.

The initial iteration of the OCx process includes verifying that the building and system performance is acceptable to the Government, as defined during Implementation and Hand-off Phases, is still being achieved and is correctly defined. Sustaining this performance becomes the primary focus of the ongoing OCx Program and can be demonstrated by defining, tracking, and evaluating various aspects of building condition or performance, such as operations, maintenance procedures, and occupant/user satisfaction and needs. Thus, these OCx Program activities involve monitoring the actual condition or performance of the defined CFR parameters and providing feedback to the OCx Team of deviations that require corrective action.

The OCx Team may conduct periodic workshops to update information in the CFR to identify improvement opportunities and select the appropriate corrective actions. To gain feedback, the OCx Team may also conduct periodic interviews with O&M personnel and building occupant/user surveys. These OCx efforts seek to measure the current building performance against the CFR with the goal of sustaining the improvements gained through the EBCx process.

8-2.4 Unacceptable Performance Investigation.

Whenever the OCx process discovers significant negative deviations from the intended CFR baseline or parameters, the cause of the performance or condition degradation must be identified to specify a solution. This requires condition assessment, testing, and analysis of the results to determine the extent of the subpar performance or degree of deviation from desired results. The OCx Team follows the same activities as outlined in the Assessment and Investigation Phases of this document, including on-site detailed inspections and performance testing of the systems and assemblies.

Once the issue is confirmed and the appropriate corrective actions are identified, enter this information on the Issues and Resolution Log, including the estimated costs and expected resulting benefits. Similar to the approach for the EBCx Implementation Phase, include methods in the recommendations to maintain the improvements made and benefits realized.

8-2.5 Recommendations/Corrective Action Implementation.

The OCx Team develops a written plan for implementing the recommendations, including planned schedules and responsible parties. Clearly identify corrective actions which require outages or building operations impacts. Following coordination with the building manager and building occupants, implement the accepted recommendations in accordance with that plan. Upon completion of the corrective action, verify that the expected improvements have been achieved. Document lessons learned to prevent a recurrence of the issue, develop a cost-benefit analysis, and include these in the OCx Report.

Bring to the attention of the Building Manager issues, especially those related to safety, security, health, or operational issues, that can be easily remedied and do not require further evaluation (will obviously not adversely impact other systems). Those Corrective actions that do not incur costs and provide immediate payback can be implemented during the OCx process; however, do not implement corrective actions without coordinating with maintenance staff responsible for upkeep on the building due to the possibility of creating unintended adverse issues (for example, opening a valve may improve the operation of the mechanical system, but the maintenance staff may have closed the valve temporarily until repairs can be performed on a system leak). For minor improvements that require installation maintenance staff involvement, coordinate with installation personnel such that a work order is submitted for correcting these issues. Document and include in both the OCx Report and the Issues and Resolution Log these immediately implemented modifications and corrective actions, along with their projected benefits.

8-2.6 Updated Systems Manual.

Review the building Systems Manual at regular intervals and make updates to ensure information is current. Update the Systems Manual with key performance parameters and building operating procedures whenever they are changed. Establish monitoring procedures to compare building performance against the baseline at frequent intervals to ensure performance improvements are maintained. In addition, revise the Systems Manual when changes in occupancy, use, or renovations require changes to the CFR.

8-2.7 Updated Building Personnel Training.

Include in the OCx Program updated or refresher training of operations and maintenance personnel at regular intervals to ensure the procedures required to maintain building performance are followed to meet the CFR and ensure persistence of benefits. Prior training sessions may require updating in the case of building/system or operational changes. Additionally, ensure training addresses implemented recommendations, lessons-learned, and changes to the operating procedures.

8-2.8 OCx Report.

Develop and update the OCx Report at regular intervals to document the performance of the building/systems and the benefits/results of the OCx efforts. The OCx Report must contain, at a minimum, the content outlined in ASHRAE 0.2, OCx Phase section titled “Write/Deliver OCx Report”.

8-2.9 Government Review.

Government representatives will review the OCx Phase deliverables to determine if activities are complete. Review and acceptance of the OCx Plan takes place before the EBCx efforts proceed further into the OCx Phase (note that the Government is most often responsible for the OCx Phase). Review comments are submitted to the Cx Provider and submittals are revised and re-submitted as necessary.

8-3 ONGOING COMMISSIONING PHASE DELIVERABLES.

The OCx Phase deliverables consist of the following:

- Updated OCx Plan
- Updated CFR
- Updated Systems Manual
- OCx Report (submitted periodically)

APPENDIX A BEST PRACTICES

A-1 EBCx TEMPLATES.

The following templates are available for use and should be utilized to ensure efforts are consistent and comprehensive.

A-1.1 Industry Templates

The following templates or formats are available for use from industry resources and can be utilized for EBCx efforts:

- EBCx Program Plan: Annex H of ASHRAE 0.2 includes planning templates for multiple-building EBCx efforts.
- EBCx Plan: sections are outlined in ASHRAE 0.2, Assessment Phase section titled "Develop the EBCx Plan". Annex G attachments to ASHRAE 0.2 contains example EBCx Plans.
- EBCx Report: Annex L attachments to ASHRAE 0.2 contains example EBCx Reports.
- EBCx building occupant questionnaire form – can utilize the template developed by the Army and posted on the WBDG website (https://www.wbdg.org/building-commissioning/additional-commissioning-resources/army-templates).

A-1.2 Navy and Marine Corps Templates

The following templates have been developed specifically for Navy and Marine Corps EBCx efforts:

- Navy and Marine Corps EBCx building selection and scoring or ranking
- Savings calculations for repair, replacement or maintenance items
- Navy and Marine Corps EBCx contractor support contract scope of work

These are available on the Whole Building Design Guide (WBDG) website resource page for "Building Commissioning" under "Additional Commissioning Resources (https://www.wbdg.org/building-commissioning/additional-commissioning-resources).

A-2 BEST PRACTICES FOR ENHANCED RESILIENCY.

Building resiliency is defined in this document as the ability to provide for mission in the face of all hazards or recover operations quickly after a disruption in operation (such as having known power reliability issues, HVAC systems with difficulties operating in expected extreme hot or cold conditions, or building enclosures in occupied spaces with gaps which allow external air flows in extreme conditions). Where the EBCx scope includes assessment for building resiliency, efforts should include the following systems issues at a minimum.

A-2.1 Mechanical Systems.

Assess mechanical systems for issues such as the following:

- HVAC systems with difficulties operating in expected extreme hot or cold conditions
- Ensuring controls are designed for systems to return to operation following non-normal operating conditions or power outage
- Verifying that support systems operate in non-normal operations (such as chillers or boilers not operating to support air handler requiring chilled or hot water)
- Other mechanical, controls or plumbing systems issues that are adversely impacting the occupant’s ability to perform their mission

A-2.2 Electrical Systems.

Assess electrical systems for issues such as the following:

- Testing backup generators, including “black start”
- Load bank testing
- Power monitoring (to determine the presence of, or need for, surge protection to address “dirty power” issues)
- Assessing that critical issues for mission are on backup power

A-2.3 Building Enclosure Systems.

Assess building enclosure systems for issues such as the following:

- Building enclosures in occupied spaces with gaps which allow external air flows in extreme weather conditions
- Leaks from roofs or exterior walls affecting use of occupied spaces

A-3 ADDITIONAL RESOURCES.

The following organizations have developed additional resources such as templates and other guidelines for conducting EBCx efforts:

- ASHRAE (www.ashrae.org)
- BCxA (www.bcxa.org)
- NEBB (www.nebb.org)

A-4 LESSONS LEARNED.

The following are lessons learned which can provide benefits in ensuring a comprehensive evaluation of systems and lead to optimized performance of building systems.

A-4.1 Hand-off Phase Best Practices.

The following have shown to provide improved training results and retention of information, as well as improving future EBCx efforts through incorporating lessons learned.

A-4.1.1 Training Effectiveness Verification.

Verify the effectiveness of training within a reasonable period of the completion of each training program. The intent of this testing is to verify that the trainees were provided with pertinent information and can demonstrate their ability to operate and maintain the building to meet the CFR and ensure persistence of benefits. Example training verification methodologies are provided in Annex L5 of ASHRAE 0.2.

A-4.1.2 Lessons-Learned Workshop.

Conduct a lessons-learned workshop after the completion of the training and the update of the Systems Manual. The intent of the discussion is to determine improvements in both the EBCx process and building operations. These lessons learned are recorded in the EBCx Report, especially when the EBCx efforts may have corrected issues resulting from an action during the planning, design, or construction phases – recording this information allows the EBCx Report to serve as a feedback loop to allow for avoiding future deficiencies in design and construction.

Attendees of the lessons-learned workshop include the key participants and stakeholders of the EBCx process. Example approaches to the lessons-learned workshop are provided in Annex L6 of ASHRAE 0.2.

A-4.2 BCxA Existing Building Commissioning Best Practices.

The BCxA document titled “Existing Building Commissioning Best Practices” contains content resulting from lessons learned on conducting EBCx efforts. It is recommended that EBCx teams utilize it as a resource when conducting EBCx on Government buildings.

A-4.3 ANSI/NEBB Standard S120.

ANSI/NEBB S120, Appendix H, includes lessons learned on areas that commonly present issues on a typical EBCx project. It is recommended that EBCx teams review these areas in projects.

VAV	Variable Air Volume

B-2 DEFINITION OF TERMS.

Except where indicated otherwise, definitions below match those used in ASHRAE documents for Commissioning and Existing Building Commissioning.

Acceptance: a formal action taken by a person with appropriate authority (which may or may not be contractually defined) to declare that some aspect of the project meets defined requirements, thus permitting subsequent activities to proceed.

Commissioning (Cx): a quality-focused process for enhancing the delivery of a project. The process focuses on verifying and documenting that the facility and all of its systems and assemblies are planned, designed, installed, tested, operated, and maintained to meet the Owner's Project Requirements (OPR).

Current Facility Requirements (CFR): a written document in which the Owner details the current functional requirements of a facility and the expectations of how it should be used and operated. This may include goals, measurable performance criteria, cost considerations, benchmarks, success criteria, and supporting information to meet the requirements of occupants, users, and Owner(s) of the facility.

Existing Building Commissioning (EBCx) Plan: a document that outlines the organization, goals, schedule, allocation of resources, and documentation requirements of the EBCx Process.

Existing Building Commissioning (EBCx) Process: a quality-focused process for attaining the CFR of an existing building and its systems and assemblies. The process focuses on planning, investigating, implementing, verifying, and documenting that the facility and its systems and assemblies are operated and maintained to meet the CFR, with a program in place to maintain the enhancements for the remaining life of the facility. Existing Building Commissioning includes both Recommissioning and Retrocommissioning.

Existing Building Commissioning (EBCx) Team: individuals who through coordinated actions are responsible for implementing the EBCx Process.

Facility guide (FG): a basic building systems description and operating plan with general procedures and confirmed facility operating conditions, setpoints, schedules, and operating procedures to properly operate the facility.

Functional test procedures (FPT): a written collection of tests that, when executed in the test process, allow verification of the performance of a system or assembly.

Issues and Resolution Log: a formal and ongoing record of problems or concerns and their resolution that have been raised by members of the Cx Team during the course of the Cx Process.

Measurement and Verification (M&V) Plan: a plan for gathering relevant data over time to evaluate performance and benefits. M&V Plan includes the details for both baseline and post-implementation performance period testing required for quantifying the performance and achieved benefits of the process.

Ongoing Commissioning (OCx) Process: a continuation of the Cx Process after the Hand-Off Phase to verify that a facility continues to meet current and evolving CFR (OPR for new construction). OCx Process Activities occur throughout the life of the facility; some of these will be close to continuous in implementation and others will be either scheduled or unscheduled (as needed).

Recommissioning: an application of the Cx Process requirements to an existing facility or system that underwent the Cx Process during project delivery (see Existing-Building Commissioning [EBCx] Process).

Retrocommissioning: the Cx Process applied to an existing building or system that was not previously commissioned (see Existing Building Commissioning [EBCx] Process).

Simple Payback: as used in NIST Handbook 135, “simple payback” is a measure of the length of time required for the cumulative savings from a project to recover its initial investment cost and other accrued costs, without considering the time value of money.

Systems Manual: a system-focused composite document that includes the design and construction documentation, FG and operation manual, maintenance information, training information, Cx Process records, and additional information of use to the Owner during occupancy and operation.

Test procedure: a written protocol that defines methods, personnel, and expectations for tests conducted on components, equipment, assemblies, systems, and interfaces among systems.

Training Plan: a written document that details the expectations, schedule, budget, and deliverables of EBCx process activities related to training of project operations and maintenance personnel, users, and occupants.

Verification: the process by which specific documents, components, equipment, assemblies, systems, and interfaces among systems are confirmed to comply with the criteria described in the CFR.

Record of Changes (changes are indicated by **\1**\ ... /**1**/)

Change No.	Date	Location
1	October 2014	Numerous clarifications, corrections, additions and deletions throughout the document in response to Criteria Change Requests (CCRs) and Tri-Service reviews; the addition of Appendices E, F and G.
2	October 2015	Changes to Chapters 3, 4, 5 and Appendix A in response to CCRs and Tri-Service reviews.
3	January 2017	Criteria Change Request to address variable refrigerant flow (VRF) systems.
4	November 2017	Changes to Chapters 3 and 4 and Appendices A and B in response to CCRs and Tri-Service reviews.
5	November 2019	Added Environmental Severity Classification and humidity design requirements and updated corrosion prevention requirements in 1-3.1, 3-6.11, 3-6.11.1, 4-2.4.5, 5-2.25, B-12 and B-13.
6	March 2020	Changes to Chapter 3 for VRF requirements and Chapter 4 for referencing IMC-2018. Numerous clarifications, corrections, additions and deletions throughout the document in response to Criteria Change Requests (CCRs) and Tri-Service reviews.
7	February 2021	Change in 3-6.17.3 Design Requirements for VRF Systems paragraph no. 3, and 3-7.6 Electric Resistance Heating.
8	July 2021	Criteria Change Requests to address variable refrigerant flow (VRF) systems.

9	09 January 2024	Updated ASHRAE 90.1 reference in Appendix A References. Updated Summary Sheet stating no revision will be made to this UFC concerning variable refrigerant flow (VRF) systems without Federal Register notification. Updated ASHRAE 62.1 reference in Appendix A References.

This UFC supersedes UFC 3-400-10N, dated July 2006; UFC 3-410-01FA, dated 15 May 2003; MIL-HDBK-1190, Chapter 10, dated 1 September 1987; and TI 800-01, Chapter 13, dated 20 July 1998.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*

Superseding: This UFC supersedes UFC 3-400-10N, *Mechanical Engineering*; UFC 3-410-01FA, *Heating, Ventilating, and Air Conditioning*; MIL-HDBK-1190, *Facility Planning and Design*, Chapter 10; and TI 800-01, *Design Criteria*, Chapter 13.

Description: This UFC provides requirements for the design of facility heating, ventilating, and Air Conditioning systems. It incorporates the provisions of the International Code Council's International Mechanical Code (IMC) and ASHRAE design guidance to the greatest extent possible. This UFC is to be applied in conjunction with the core mechanical UFC 3-401-01. **\9** No revision will be made to this UFC concerning variable refrigerant flow (VRF) systems without Federal Register notification. **/9/**

Reasons for Document:

- To unify Department of Defense facility HVAC criteria and create more consistency in DoD designs.
- To incorporate and modify the provisions of the IMC to meet DoD needs.
- To update existing criteria to reflect new and revised industry standards.

Impact:

- Standardized guidance for facility HVAC design among the Services.
- Provides more detail on documentation requirements for design analysis and drawing requirements.
- Incorporates lessons learned from issues which occurred in previous construction contracts.

Unification Issues

- The Navy uses UFC 3-430-08N, *Central Heating Plants* for design of central heating plants while the Army and Air Force use 3-430-02FA, *Central Steam Boiler Plants*. There is an ongoing Army project to update and unify these documents.
- ASHRAE's BACnet® protocol is the preferred control system architecture for Navy & Marine Corp facilities. LonWorks® protocol is the preferred control system architecture for Army facilities. The Army uses UFC 3-410-02 for LonWorks® protocol control systems design.

TABLE OF CONTENTS

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides requirements and guidance in the design of heating, ventilating, and air-conditioning (HVAC) systems, together with the criteria for selecting HVAC materials and equipment.

1-2 APPLICABILITY.

This UFC is applicable to all service elements and contractors involved in the planning, design and construction of DoD facilities worldwide. Where conflicts in requirements appear between sections of any mechanical UFC or applicable codes or laws, the most restrictive requirement will govern.

1-3 GENERAL BUILDING REQUIREMENTS.

\6 Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, physical security, cybersecurity, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein. **/6/**

1-3.1 \5\ Environmental Severity and Humid Locations.

In corrosive and humid environments, provide design detailing, and use materials, systems, components, and coatings that are durable and minimize the need for preventative and corrective maintenance over the expected service life of the component or system. UFC 1-200-01, section titled “Corrosion Prone Locations” identifies corrosive environments and humid locations requiring special attention. UFC 1-200-01, section titled “Requirements for Corrosion Prone Locations” provides examples of necessary actions. To determine Environmental Severity Classifications (ESC) for specific project locations refer to UFC 1-200-01 Appendix titled “Environmental Severity Classifications (ESC) for DoD Locations”. **/5/**

1-4 \6\ CYBERSECURITY.

All control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06 and as required by individual Service Implementation Policy.

Cybersecurity is implemented to mitigate vulnerabilities to all DoD real property facility-related control systems to a level that is acceptable to the System Owner and Authorizing Official. UFC 4-010-06 provides requirements for integrating cybersecurity into the design and construction of control systems. **/6/**

1-5 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-6 BEST PRACTICES.

Appendix B contains information that is not requirements but is considered best practices based on experience and lessons learned.

1-7 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

1-8 \8\ OPEN CONTROL SYSTEM REQUIREMENTS.

10 USC 2867 requires the adoption of a “Department-wide, Open Protocol, Energy Monitoring and Utility Control System Specification” for use in military construction and military family housing activities. Public law (10 USC 2867) states: “The Secretary of Defense shall adopt an open protocol energy monitoring and utility control system specification for use throughout the Department of Defense in connection with a military construction project, ...” It continues: “The energy monitoring and utility control system specification ... shall cover: (A) ... (B) Indoor environments, including temperature and humidity levels. (C) Heating, ventilation, and cooling components. ...” DoD has published the following control system specifications to meet this requirement:

1. UFGS 25 10 10 Utility Monitoring and Control System (UMCS) Front End and Integration

2. UFGS 23 09 00 Instrumentation and Control for HVAC

3. UFGS 23 09 23.01 LonWorks Digital Control for HVAC and Other Building Control Systems

4. UFGS 23 09 23.02 BACnet Digital Control for HVAC and Other Building Control Systems

All HVAC control systems must meet the requirements of UFGS 23 09 00 and either UFGS 23 09 23.01 or UFGS 23 09 23.02 These specifications require the installation of non-proprietary control networks down to the level of each individual device in the system.

1-9 EPA HFC-REFRIGERANT REGULATIONS.

Beginning 1-Jan-2019, the EPA implemented new rules to regulate HFC refrigerant systems including those used for comfort cooling. This regulation includes R-410A, a common HFC refrigerant used in DX systems. The new rules lowered the threshold leak rate to 10% loss annually. Systems exceeding this rate must be repaired within 30-days or else face mandatory system shutdown, costly retrofits, or replacement. (The Services estimate a current annual refrigerant leak rate of 25%.) **/8/**

This Page Intentionally Left Blank

CHAPTER 2 MECHANICAL CONSENSUS STANDARDS

2-1 PRIMARY VOLUNTARY CONSENSUS STANDARD REFERENCE.

The DoD uses the International Code Council™ International Mechanical Code© as the primary voluntary consensus standard for DoD facility HVAC systems. The scope of the IMC is stated as:

> "*This code must regulate the design, installation, maintenance, alteration and inspection of mechanical systems that are permanently installed and utilized to provide control of environmental conditions and related processes within buildings.*"

2-1.1 International Mechanical Code© Copyright.

The International Mechanical Code© is copyrighted by International Code Council, Inc., Falls Church, Virginia, U.S.A. Without advance written permission from ICC or its duly authorized agent, no portion of the IMC may be reproduced, distributed, or transmitted in any form or by any means, including, without limitation, electronic, optical, or mechanical means (by way of example and not limitation, photocopying, or recording by or in an information storage and retrieval system). For information on permission to copy IMC material exceeding fair use, please contact the International Code Council, Inc.

2-1.2 IMC Additions, Deletions, and Revisions.

The additions, deletions, and revisions to the IMC sections listed in Chapter 4 "Supplemental Technical Criteria" of this document preserve the appropriate supplemental technical criteria for use in current and future designs of DoD facilities. When and if these supplemental technical criteria are adopted into the IMC, they will be removed from this document. When interpreting the IMC, the advisory provisions must be considered mandatory; interpret the word "should" as "must." The format of Chapter 4, including English and metric unit references, does not follow the UFC format, but instead follows the format established in the IMC, to the extent possible.

This Page Intentionally Left Blank

CHAPTER 3 GENERAL DESIGN REQUIREMENTS

3-1 \1\ HVAC /1/ SYSTEM SELECTION \1\ AND LIFE CYCLE COST ANALYSIS CONSIDERATIONS.

\6 The designer must develop three energy efficient solutions for each individual energy system and prepare a LCCA to determine the heating and cooling systems, fuel sources and major system components. Designers should follow Appendix E - HVAC Systems Selection Flow Chart for this selection process. The analysis must conform to the life cycle cost and energy criteria specified in UFC 1-200-02 **/6/**. For Army projects only: Centralized versus De-centralized Plants - De-centralized plants may be a more cost effective alternative for a new or replacement project. The designer must follow the "Evaluation of District and Islanded/Decentralized Utility Options with Life-Cycle Cost Analysis Guidance" in Appendix G to determine which alternative is most life cycle cost effective. **/1/**

3-2 \6\ [FOR NAVY PROJECTS ONLY] VENTILATION AIR.

\4 These requirements apply to Navy projects. Final determination of equipment's dehumidification capabilities is subject to approval by the Navy based on submitted equipment selections, control sequences, and psychrometrics. **/6/**

A Dedicated Outdoor Air System (DOAS) is the only allowed method for providing dehumidification of ventilation air (outside air) when replacing an existing DOAS delivering any quantity of ventilation air or when the sum of all ventilation air into facility is greater than 750 cfm (354 lps) and either of the following conditions apply:

- Design includes any direct-expansion or chilled water equipment such as heat pumps, packaged terminal air conditioners, split systems, and fan coil units delivering any quantity of outside air with limited dehumidification capability referred to below as light-duty equipment
- Design includes any direct-expansion equipment delivering any quantity of outside air with cycling refrigeration circuit(s) not manufactured and controlled for continuous dehumidification referred to below as medium-duty equipment

3-2.1 DOAS Associated with Light-Duty Equipment.

DOAS's associated with light-duty equipment must be selected, designed, and controlled as follows:

- Cooling coil must be selected to meet outside air sensible and latent loads plus space latent load
- Cooling coil must be selected and controlled to maintain a continuous coil leaving air temperature no greater than 55.0 °F for applications requiring

space conditions of 78.0 °F dry-bulb / 57.9 °F dewpoint / 50-percent relative humidity

- Cooling coil must be selected and controlled to maintain a continuous coil leaving air temperature suitable for applications requiring space conditions more stringent than 78.0 °F dry-bulb / 57.9 °F dewpoint / 50-percent relative humidity
- Reheat coil must be selected and controlled to maintain a unit discharge air temperature equivalent to the facility average design temperatures for comfort cooling and comfort heating

  (73.0 °F for 78.0 °F comfort cooling / 68.0 °F comfort heating)
- DOAS must not be subject to intermediate season (no-heat / no-cool) shutdown
- DOAS must distribute airflow directly to zones without passing through light-duty equipment
- DOAS air inlets and outlets must deliver airflow quantities equal to or greater than 50 cfm (24 lps) through each device to allow for proper system balancing

3-2.2 DOAS Associated with Medium-Duty Equipment.

DOAS's associated with medium-duty equipment must be selected, designed, and controlled as follows:

- Cooling coil must be selected to meet outside air sensible and latent loads, but not space loads
- Cooling coil must be selected and controlled to maintain a continuous coil leaving air temperature no greater than 58.0 °F for applications requiring space conditions of 78.0 °F dry-bulb / 57.9 °F dewpoint / 50-percent relative humidity
- Cooling coil must be selected and controlled to maintain a continuous coil leaving air temperature suitable for applications requiring space conditions more stringent than 78.0 °F dry-bulb / 57.9 °F dewpoint / 50-percent relative humidity
- Reheat coil must be designed and controlled to maintain a unit discharge air temperature equivalent to DOAS's coil leaving air setpoint temperature plus 5.0 °F to maintain discharge ductwork relative humidity less than 90-percent to help prevent ductwork microbial growth
- DOAS must distribute airflow directly into inlet of associated equipment and must not distribute airflow directly into zones

3-2.3 DOAS Associated with Light-Duty or Medium-Duty Equipment.

DOAS's associated with light-duty or medium-duty equipment, in addition to other requirements, must be selected, designed, and controlled as follows:

- DOAS must be provided with energy recovery devices in accordance with ASHRAE 90.1
- Energy recovery devices must be controlled to never increase energy (enthalpy) of outside air when energy of outside air upstream of energy recovery device is greater than energy of outside air immediately downstream of DOAS's cooling coil
- Energy recovery devices must be controlled to never decrease dry-bulb temperature of outside air when dry-bulb temperature of outside air upstream of energy recovery device is less than dry-bulb temperature of outside air immediately downstream of DOAS's cooling coil
- DOAS must be designed and controlled to be in operation during all occupied periods, but not necessarily unoccupied periods
- Ventilation air does not require humidification regardless of how it is provided into facility
- System controls must monitor the DOAS cooling coil leaving air temperature and unit discharge air temperature regardless of which point is used for control
- A visual alarm must be initiated upon detection of cooling coil leaving air temperature being equal to or greater than 5° F above design dew point temperature at the Operator work station (OWS) or at DOAS for construction without an OWS

3-2.4 Additional Requirements.

Additional requirements are as follows:

- Zone terminal heating / cooling equipment must have occupant control and may be subject to intermediate season heating / cooling curtailment as directed by installation or command policy
- A vapor transmission (hygrothermal) analysis must be provided in accordance with UFC 3-101-01 **/4/**

3-3 \6\ [FOR AIR FORCE PROJECTS ONLY] VENTILATION AIR.

These requirements apply to Air Force projects. Final determination of equipment's dehumidification capabilities is subject to approval by the Air Force subject matter expert (SME) as applicable based on submitted equipment selections, control sequences, and psychrometrics.

A Dedicated Outdoor Air System (DOAS) is the only allowed method for providing dehumidification of ventilation air (outside air) when replacing an existing DOAS delivering any quantity of ventilation air or when the sum of all ventilation air into facility is greater than 750 cfm (354 L/sec) and the 1% occurrence humidity ratio (as documented in the official engineering weather data, or EWD) is above the inside cooling load design dew-point temperature of 57.9°F.

3-3.1 DOAS Requirements.

Systems must be selected, designed, and controlled as follows:

- Cooling coil must be selected to meet outside air sensible and latent loads plus space latent load
- Cooling coil must be selected and controlled to maintain a continuous coil leaving air temperature no greater than 55.0 °F
- Reheat coil must be selected and controlled to maintain a unit discharge air temperature equivalent to the facility average design temperatures for comfort cooling and comfort heating

  (73.0 °F for 78.0 °F comfort cooling / 68.0 °F comfort heating)
- DOAS must not be subject to intermediate season (no-heat / no-cool) shutdown
- DOAS must distribute airflow directly to zones
- DOAS air inlets and outlets must deliver airflow quantities equal to or greater than 50 cfm (1400 L/min) at flow velocities between 400 – 800 ft/min (2 – 4 m/sec) through each device to allow for proper system balancing
- DOAS cooling coil leaving air temperature must be reset to 73°F and reheat coil de-energized when dew-point of outdoor air is at or below 57.9°F
- DOAS must be provided with energy recovery devices in accordance with ASHRAE 90.1
- Energy recovery devices must be controlled to never increase energy (enthalpy) of outside air when energy of outside air upstream of energy recovery device is greater than energy of outside air immediately downstream of DOAS's cooling coil
- Energy recovery devices must be controlled to never decrease dry-bulb temperature of outside air when dry-bulb temperature of outside air upstream of energy recovery device is less than dry-bulb temperature of outside air immediately downstream of DOAS's cooling coil
- DOAS must be designed and controlled to be in operation during all occupied periods

- Ventilation air does not require humidification regardless of how it is provided into facility
- System controls must monitor the DOAS cooling coil leaving air temperature and unit discharge air temperature regardless of which point is used for control
- A visual alarm must be initiated upon detection of cooling coil leaving air temperature being equal to or greater than 5° F above design dew point temperature at the Operator work station (OWS) or at DOAS for construction without an OWS
- A vapor transmission (hygrothermal) analysis must be provided in accordance with UFC 3-101-01

3-3.2 General Ventilation Requirements.

If a DOAS is not required, ventilation air may be brought in through the primary HVAC system only if the system is configured to continuously supply ventilation air. **/6/**

3-4 \4\ \2\ [FOR ARMY PROJECTS ONLY] VENTILATION AIR AND USE OF DOAS.

\6 When the 1% occurrence humidity ratio (as documented in the official engineering weather data, or EWD) for the outside air (OA) is greater than the inside cooling load design set-point (78°F, 57.9°F dew-point) humidity ratio, dehumidification of outdoor air is necessary and a Dedicated Outdoor Air System (DOAS) must be one of the three solutions included by the designer as described in the Appendix E - HVAC System Selection Flow Chart to address the humidity. Conditioning more humid air to design set points and the associated reheat can result in a DOAS being more Life Cycle Cost Effective (LCCE).

The DOAS must also be one of the three solutions included when the ventilation air for the building is 1000 CFM or greater. When larger volumes of ventilation air are required the DOAS may be more LCCE.

The required DOAS solution must apply to new and renovation projects.

Life cycle cost analyses (LCCA) must be performed to include a DOAS. The calculations must show the Energy Use Index (EUI) for the DOAS as well as the other solutions.

For buildings that may be unoccupied for extended periods of time, a DOAS may be necessary to maintain humidity conditions in the building to avoid mold growth or moisture damage during such time periods. An example building would be a barracks for which the assigned unit deploys. Coordinate with the installation Directorate of Public Works or component equivalent to determine when this is necessary. When this is required, ensure that the DOAS is designed, including capacity and controls, to properly dehumidify the building.

The DOAS coils must be designed to condition OA, occupant and space loads.

An alarm must be included with the HVAC controls that would indicate if the outside air damper failed to open during occupied period.
A DOAS is required whether or not life cycle cost effective per the following paragraphs:

When zone sensible cooling systems (e.g. fan coil units, chilled beams, heat pumps, etc.) are employed, Dedicated Outdoor Air Systems (DOAS) must be utilized to dehumidify all outside air for conditioned spaces. Use of DOAS may be applicable for use with central air handling systems when LCCE. The DOAS will separate the ventilation function from the space air conditioning function, (refer to Appendix F). Size the DOAS to condition the ventilation air necessary to remove the latent heat from the ventilation air and the latent heat from the space. The DOAS cooling coil must be sized using the 0.4 outdoor peak dew point design value and it's Mean Coincident Dry Bulb (MCDB) for the outside air conditions in accordance with ASHRAE Fundamentals Handbook. Coil loads must be checked against peak conditions. **/6/**

On DOAS units, system controls must monitor the discharge temperature to prevent condensation in the space or zone. Provide energy recovery devices where life-cycle cost-effective or where required by ASHRAE 90.1.

Consider the following when completing your Life Cycle Cost Analysis (LCCA) of your HVAC systems selection:

- The additional outside air required per ASHRAE 62.1 for VAV systems that condition ventilation air (multiple space equation).
- Fan coil unit maintenance considering the available capacity of maintenance staff
- Cost saving from the energy savings of fan coil unit or VAV (recirculated air) cycling (as stated above)
- The HVAC system application, (e.g. fan coil units may not be practical for a large open- space layouts or mission applicable).
- The loss of the ability to provide air-side economizer to include the added cost (incl. maintenance) for water side economizer.

/2/ /4/

3-5 HEATING AND COOLING LOAD CALCULATIONS.

Heating and cooling system design loads for the purpose of sizing systems, appliances and equipment must be determined in accordance with the following requirements.

\2 The HVAC design analysis for new facilities or renovation of existing facilities must include a psychrometric analysis documenting that the system meets design criteria. The analysis must provide calculations of system cooling load, energy/mass transfer through conditioning equipment and fans, and a system schematic indicating state point dry bulb and wet bulb temperatures (or humidity ratios) of outside air, mixed air, supply air, and return air flow streams. The system must provide the capability to condition ventilation air and maintain space relative humidity over the full range of cooling load.
/2/

3-5.1 Load Calculations.

Heating and cooling system design loads must be determined in accordance with the calculation procedures described in the ANSI/ASHRAE/ACCA Standard 183 unless otherwise specified herein.

Provide no more than a **\1** 1.15 **/1/** safety factor for heating equipment and distribution sizing to account for morning warm-up.

3-5.2 Outdoor Design Conditions.

Use UFC 3-400-02 for outdoor design conditions **\2** for **Navy** projects. For **Army** and **Air Force** projects, use ASHRAE Fundamentals Handbook or UFC 3-400-02. **/2/**

3-5.2.1 \1\ Spaces /1/ Conditioned for Comfort Cooling.

Size equipment and all system components to maintain and control indoor design conditions at each of the following: (1) the 1.0 percent dry bulb and the corresponding mean coincident wet bulb (MCWB) temperature and (2) the 1.0 percent humidity ratio and corresponding mean coincident dry bulb (MCDB) temperature.

3-5.2.2 \1\ Spaces /1/ Conditioned for Specialized Technical Requirements.

Size equipment and all system components to maintain and control indoor design conditions at each of the following: (1) the 0.4 percent dry bulb temperature and the corresponding MCWB temperature and (2) the 1.0 percent humidity ratio and corresponding MCDB.

3-5.2.3 \1\ Spaces /1/ Conditioned for Comfort Cooling Using Evaporative Equipment.

Size equipment and all system components to maintain and control indoor design conditions at each of the following: the 1.0 percent wet bulb temperature and corresponding MCDB.

3-5.2.4 \1\ Spaces /1/ Conditioned for Comfort Heating.

Size equipment and all system components to maintain and control indoor design conditions at the 99 percent dry bulb temperature.

3-5.2.5 Condensers and condensing units.

For **\1** sizing condensers and condensing units, add 5°F (3°C) to the outdoor dry bulb temperature. **/1/**

3-5.3 Indoor Design Conditions.

Indoor cooling and heating conditions are determined as follows **\1** unless specified in a facility type UFC or as approved by the authority having jurisdiction (AHJ). **/1/**

3-5.3.1 \1\ Spaces /1/ Conditioned for Comfort Cooling.

\4 78.0° F (25.6 °C) dry-bulb / 57.9° F (14.4 °C) dewpoint / 50-percent relative humidity. **/4/** The design must take into account the moisture gain in the space.

3-5.3.2 \1\ Spaces /1/ Conditioned for Comfort Cooling Using Evaporative Equipment.

80°F (26.7°C) dry bulb and a maximum of 55°F (12.8°C) dew point.

3-5.3.3 \1\ Spaces /1/ Conditioned for Comfort Heating.

68°F (20°C) dry bulb.

During unoccupied hours, temperatures must be set no higher than 55°F (12.8°C).

\1 Provide humidification where the indoor relative humidity for comfort heating is expected to fall below 30 percent at design conditions. **/1/** Coordinate with the architect to design the building envelope to prevent condensation in the wall/roof systems during the time humidification is in operation. Include in the design analysis a dew point analysis profile (ASHRAE Fundamentals Chapter 23) for winter design conditions, showing condensation boundaries. The dew point analysis must consider the effect of air movement into the walls for buildings under positive pressurization relative to the outdoors.

3-5.3.4 \1\ Spaces /1/ Conditioned for Heating - High to Moderate Physical Activity.

55°F (12.8°C) dry bulb. Examples of these facilities include areas in maintenance shops where engines are rebuilt and aircraft shops where instrumentation is repaired, warehouses areas where there are forklift loading operations, and aircraft hangars with high bay areas and limited amounts of people.

3-5.3.5 \1\ Spaces /1/ Conditioned for Heating - Freeze Protection.

40°F (4.5°C) at the 99.6 percent dry bulb outdoor design temperature.

3-5.3.6 \1\ Spaces /1/ Which are Naturally or Mechanically Ventilated Only \1\ for Comfort. /1/

80°F (26.7°C) dry bulb and 55°F (12.8°C) dew point maximum and 68°F (20°C) dry bulb minimum.

3-5.3.7 \1\ Spaces /1/ Conditioned for Process Cooling and Heating.

Process cooling and heating indoor design conditions are determined by the respective process requirements.

3-6 SPECIFIC FACILITY-TYPE HVAC REQUIREMENTS.

3-6.1 Facility Air Conditioning Eligibility.

Facilities are eligible for air conditioning where facilities of similar structure and function in the local private sector are equipped with air conditioning.

\6 Air conditioning for comfort cooling is not allowed for the following facilities **\1** unless approved by the AHJ for Army and Air Force projects. **/1/** Air conditioning for comfort cooling is not allowed for the following facilities unless required to meet ASHRAE 55 for occupied spaces and work areas for Navy projects. **/6/** Comfort conditioning is allowed in administrative areas of these facilities.

- Motor vehicle storage garages
- Aircraft maintenance facilities & hangars
- Special areas requiring high ventilation rates (i.e., woodshops, paint booth) **\1** unless approved by the AHJ **/1/**
- Vehicle storage areas of crash and fire stations
- Boiler plants and rooms
- Greenhouses
- General Warehouses

\6 For Navy projects only: Evaluate air conditioning for work areas to determine most life cycle cost effective approach. Include equipment that will contribute to generating heat loads when sizing air conditioning equipment. Consult with end user on operations that will occur in work areas that may also contribute to sizing air conditioning equipment.

For Army projects only: Manufacturing or maintenance processes may require temperature and humidity air conditions that need to be considered when determining the eligibility for comfort cooling. Cooling can be provided if the 1% occurrence temperature or humidity set point is above the temperature or humidity set point required by the equipment manufacturer or maintenance process. Comfort cooling for the aforementioned facilities can be considered on a case by case basis if cooling is common in industry for that type of facility but must still be approved by the AHJ. **/6/**

3-6.2 Natural or Mechanical Ventilation Requirements.

In areas where mechanical or natural ventilation may be feasible, evaluate the use of these methods in lieu of other air conditioning methods to meet interior design conditions. Ambient noise levels and the availability of prevailing winds should be addressed in the evaluation. Include the effect of outdoor humidity levels when designing the mechanical ventilation systems.

3-6.3 Nonpermanent Construction.

The design of air conditioning for semi-permanent or temporary facilities must be on a minimum cost basis with exposed duct work, electrical work, and refrigerant or water piping and all other possible economies used. See UFC 1-201-01 for temporary contingency operations facility requirements.

3-6.4 Intermittent Occupancy Facilities.

Facilities such as reserve centers, chapels, auditoriums, and theatres are occupied at irregular or infrequent intervals. Typically, only a small portion of a reserve center is occupied during normal working hours, while the balance of the facility is used primarily for weekends only. Consider the anticipated occupancy pattern when developing equipment layout and sequence of operation in order to ensure that overall life cycle cost is minimized. Evaluate opportunities such as thermal storage systems and demand controlled ventilation by occupancy sensors for these facility types. **\6\ /6/**

3-6.5 Vestibules.

Vestibules must be heated to 50°F (10°C) to melt tracked-in snow in locations where conditions warrant. Otherwise, vestibules must not be heated or air conditioned.

3-6.6 Closets and Storage in Air Conditioned Facilities.

These areas must be either directly air conditioned (greater than 50 sq. ft (4.6 sq. meters) of floor space) or provided with exhausts to transfer conditioned air from adjacent spaces (lesser than 50 sq. ft (4.6 sq. meters) of floor space).

3-6.7 Aircraft Maintenance Shops.

Provide air conditioning for those functional areas where required for quality control of equipment, material, and task. **\1** Localized or spot air conditioning is allowed at individual workstations. **/1/**

3-6.8 Data Processing Centers and \1\ Server Rooms. /1/

HVAC designs for data processing centers **\1** and server rooms must follow DOE-FEMP “Best Practices Guide for Energy-Efficient Data Center Design unless specific manufacturer’s guidance exceeds the criteria contained within. **/1/**

3-6.9 Health Care Facilities.

HVAC designs for health care facilities will be in accordance with the current issue of UFC 4-510-01.

3-6.10 Laboratories.

The design of HVAC systems must provide control over space temperature conditions including contaminants and fume control appropriate to the space function. **\1\ /1/**Exhaust systems must be provided with fume hoods to remove toxic substances as near to the source of the fumes as practical. Hood and system design must follow the recommendations of the following manual from the American Conference of Government Industrial Hygienists (ACGIH): ACGIH Industrial Ventilation: A Manual of Recommended Practice. Where laboratories are required to be under a negative pressure relative to other areas in the facility, coordinate with the architect to locate these spaces in the interior to prevent negative pressure induced infiltration of outdoor air into exterior wall cavities. Medical labs must meet the requirements of UFC 4-510-01.

3-6.11 Fitness Centers.

HVAC designs for Fitness Centers will be in accordance with this document and the current issue of **\6** UFC 4-740-02 **/6/**.

3-6.12 General Purpose Aircraft Hangars.

\6 HVAC designs for general purpose aircraft hangars will be in accordance with the current issue of UFC 4-211-01. **/6/**

3-6.13 Aircraft Fire and Rescue and Fire Station.

\1 Provide fire apparatus vehicle exhaust removal systems in all new, rehabilitated, or self-help Aircraft Fire and Rescue Station and Fire Stations. Projects must prevent exposure of fire fighters and contamination of living and sleeping areas to exhaust emissions. **/1/** As required by NFPA 1500, such systems must permit the operation of the apparatus with the apparatus doors closed. **\6** Refer to UFC 4-730-10. **/6/**

3-6.14 \6\ Telecommunications Rooms.

HVAC designs for telecommunications rooms will be in accordance with UFC 3-580-01. **/6/**

3-6.15 Laundries and Dry Cleaners.

Mechanical ventilation will generally be the primary method of heat dissipation. Evaporative cooling may be provided where effective. Spot air conditioning or general air conditioning must be provided to keep the temperature in the work areas from exceeding 85°F (29°C). Coil discharge temperatures used in spot cooling must be 50°F (10°C) dry bulb maximum for maximum dehumidification. Where life cycle cost effective, use heat recovery equipment on exhaust air to temper makeup air in cold weather **\2** to reduce the energy consumption **/2/**. **\1** Provide a readily accessible clean-out in all dryer exhaust ducts. **/1/**

3-6.16 Dining Facilities.

HVAC designs for Dining Facilities will be in accordance with this document, the following requirements, and the current issue of FC 4-722-01N and FC 4-722-01F. Provide fire suppression system for hoods in accordance with UFC 3-600-01.

3-6.16.1 Kitchen Ventilation.

Comply with NFPA 96. No air must be returned from the kitchen to the HVAC system. Generally, air flows from the dining areas to the kitchen areas to provide make-up air for kitchen exhausts. Maximize the use of dining area make-up air to the kitchen as this will provide secondary cooling for the kitchen staff. Kitchen hoods with built-in make-up air must be of the horizontal face discharge type.

Localized air conditioning or general air conditioning must be provided to keep temperature in the work areas from exceeding 85°F (29°C) dry bulb, if the main portion of the facility is air conditioned and the criteria for exhaust ventilation are met. Provide a separate ventilation system for the dishwashing area. Furnish tempered 65°F DB minimum (18°C DB minimum) makeup air for the range hood exhaust. The design must not allow recirculation of more than 75 percent of air (excluding hood exhausts) in the kitchen at any time. Kitchen canopy hood exhaust ventilation rates must be 75 fpm (0.4 m/s) for grease filter sections, and 50 fpm (0.25 m/s) for open hood section, measured at the horizontal hood opening. As an alternative, internal baffle-type canopy hood with peripheral slot and a slot velocity of 500 fpm (2.5 m/s) must be provided. Electrically interlocked supply and exhaust air fans must be designed for **\1** at least **/1/** 2-speed operation. **\1** Commercial kitchen Type I or Type II hoods for systems over 1000 CFM must be provided with variable speed, demand control for exhaust air. **/1/** Provide control interlocks for supply and exhaust fans to ensure that the HVAC system balance is maintained and that the proper direction of airflow is maintained during normal operations. Do not use evaporative coolers on kitchen supply air in humid areas

If additional make-up air is required for kitchen exhausts, provide push-pull kitchen hoods with built-in heated make-up air supply.

3-6.16.2 Ductwork for Humid Dishwasher Room Exhaust.

Dishwasher room exhaust ducts must be as short as possible with direct runs to outside of building. Ductwork must **\1** be aluminum or stainless steel and **/1/** have watertight joints, and must have a drain line from the low point. Approximately 25 percent of the exhaust air must be exhausted from the ceiling level.

3-6.16.3 Heat Recovery for Kitchens.

When heat in kitchens rejected by refrigeration equipment exceeds 10,551 W (36,000 Btuh), heat recovery systems must be used **\1** unless not **/1/** life cycle cost effective.

\4\ \3

3-6.17 Variable Refrigerant Flow (VRF) Systems.

VRF systems are a relatively new technology with design considerations and requirements that may differ from traditional HVAC systems.
\8\ /8/

\8 See paragraph 1-8 for Open Control System Requirements. **/8/ \6** As of the publication date for this UFC, all known commercially-available VRF systems rely on a proprietary network with a gateway to provide Open protocol interface; this arrangement does not comply with the UFGS requirements for open protocols. UFC 3-410-02 includes a process by which specific systems can be excepted from some of the open protocol requirements and permitted to use proprietary communications between system components with a gateway or interface meeting the open protocol requirements. **/6/**

3-6.17.1 Design Requirements for VRF Systems.

1. **\6** VRF systems must meet the control system specifications, or the system must be identified for an exception in accordance with UFC 3-410-02. **/6/**

2. The design must not preclude competition between vendors:
    a. Since VRF systems from different manufacturers require different mechanical designs, provide a design with necessary design allowances to permit multiple manufacturers to meet the design. For example, piping designs differ between VRF manufacturers so do not require specific VRF piping design, but rather indicate where piping may be installed.

    b. Edit project specifications and requirements to include contractor design drawings as additional pre-construction drawing SD-02 Shop Drawing submittals. These drawings must document the details of the VRF design, including but not limited to piping layout.

3. Designs must require that the system be configured and installed strictly in accordance with the manufacturer's installation requirement **\7** with the exception of press-fittings, which are not permitted per paragraph #5 below. **/7/**

4. Include and require refrigerant line vibration isolation at all connections to motorized equipment, including but not limited to the refrigerant line connections at each fan coil unit.

5. VRF systems piping/tubing must have all brazed connections that meet ASME B31.5 requirements and the manufacturer's installation requirements. The list of fittings and joints that are prohibited include but are not limited to the following: push-on fittings, extruded fittings, flare fittings, press-connect

fittings, mechanical joints and groove joints. The VRF system must be pressure tested and vacuum tested.

6. VRF systems must be provided to meet ASHRAE 15 and IMC safety requirements pertaining to leakage to rooms and spaces. Calculations must be performed per IAW ASHRAE 15 and IMC and must be provided to demonstrate these requirements are met.

7. The total refrigerant charge of the independent VRF system must be **\8** in compliance with the latest EPA Section 608 Refrigerant Management Regulations. (See paragraph 1-9 EPA HFC-Refrigerant Regulations **/8/** for more information on EPA regulation and refrigerant leakage concerns.)

3-6.17.2 Additional Considerations for VRF Systems.

3-6.17.2.1 Life-Cycle Cost Analysis.

Life Cycle Cost analysis comparing VRF with traditional systems can be difficult given the relative newness of VRF systems, and given that many VRF systems can only be serviced by factory-trained technicians which affects the maintenance costs for the system compared to more traditional systems. When performing life cycle cost analysis for VRF systems use care to properly identify all operation and maintenance costs. See APPENDIX B for more information on considerations regarding life-cycle costs.

3-6.17.2.2 Coordination with Project Site.

As with any system, coordinate the design of a VRF system with the government representative for the project. This is particularly important for VRF systems because their complexity can introduce operational, maintenance and cybersecurity challenges that are not necessarily experienced by traditional HVAC systems. For example: a higher level of training and expertise required to repair the system; differences in capability to operate the system in a degraded or manual mode; safety and operational considerations of running refrigerant lines through occupied spaces.

/3/ /4/

3-7 OTHER HVAC DESIGN CONSIDERATIONS.

3-7.1 Latent Load Considerations.

The design must take into account the moisture gain in the space.

3-7.2 Reheat.

When reheat is required to control indoor relative humidity, use energy recovery where feasible.

3-7.3 Economizer.

\1\ \6 For Army and Air Force projects, water economizer must be used in lieu of air economizers where practicable. The prohibition of air side economizers as stated in this UFC must be followed. **/6/** For Navy projects, use waterside economizers in lieu of airside economizers when applicable and life cycle cost effective. **/1/** Where air economizers are used, provide separate dampers for ventilation air and minimum outdoor air requirements. **\1** For Army and Air Force projects, air economizers must not be used in ASHRAE climate zones 1, 2, 3a, and 4a. For Navy projects, air economizers must be designed with controls and alarms to indicate economizer malfunction. **/1/**

3-7.4 Redundant Systems.

When a system failure would result in unusually high repair costs, or replacement of process equipment, or when activities are disrupted that are mission critical, the designer must submit a request for approval to the applicable AHJ in accordance with MIL-STD-3007, to provide redundant HVAC systems. No exemption is required where redundant HVAC systems are specified by other applicable criteria.

3-7.5 Humidification.

\1\ /1/Use of district steam is prohibited as a humidification method. Use of wetted pad type or water spray type humidifiers is prohibited since these have the potential to inject Legionnaire bacillus as well as other pathogenic organisms into the air stream.

3-7.6 Electric Resistance Heating.

Electric resistance heating must not be used for heating or reheat except where **\4** life cycle cost effective. \7\ Electric resistance heating must follow ASHRAE 90.1 and use of the unburdened rate for life cycle cost calculation. Electric resistance heating is permitted in the following circumstances for Family Housing and Small Remote Facilities whether or not life cycle cost effective. **/4/ /7/**

3-7.6.1 Family Housing.

Electric resistance heating may be used where a bathroom has been added and the existing heating system is inadequate to heat the addition, or where a bathroom has been added and it is unreasonable from an engineering or economic position to extend the existing heating system to the new area. An occupant-activated time switch with a maximum time setting of 30 minutes must be used for electric resistance or infrared heaters in family housing bathrooms. Thermostats must have a maximum setting of 75°F (24°C).

3-7.6.2 Small Remote Facilities.

Electric resistance heating may be used where all of the following criteria are met. Otherwise, use air source heat pumps where life cycle cost effective.

- The individual facility (total building) heating load is less than 15,000 Btu per hour (4 kW) provided natural gas is not available within a reasonable distance.
- The facility has a maximum total energy consumption of less than 60,000 Btu per square foot (190 kilowatt-hrs per square meter) per year (nominal 40-hour week use) or less than 118,000 Btu per square foot (1,340,00 kJ per square meter) per year (around-the-clock use).
- The facility is equipped with thermostats with a maximum setting of 75°F (24°C) and a positive cutoff above 65°F (18°C) outdoor temperature
- All facilities occupied less than 168 hours per week must be equipped with a temperature setback to a maximum of 50°F (10°C) during all unoccupied periods. Small offices or duty stations located within larger unheated or partially heated buildings (e.g., warehouse office, dispatch office in a motor pool, duty room in an armory or reserve facility) requiring less than 15,000 Btu per hour (4kW) may use electric resistance heating under the conditions outlined above.

3-7.6.3 \1\ Non-occupied Spaces.

\6 Electric resistance heating is permitted in the following non-occupied spaces where life cycle cost effective: **/6/**

- In non-occupied spaces in facilities without hot water heating systems.
- Electrical rooms. **/1/**

3-7.7 Steam Systems.

Single-pipe systems must not be used for comfort heating. For safety purposes, low-pressure steam 15 psig (100 kPa gage) and below must be used where terminal equipment is installed in occupied areas. High- **\1** or medium-pressure above 15 psig (100 kPa gage) steam unit heaters may **/1/** be used for space heating in areas such as garages, warehouses, and hangars where the discharge outlets are a minimum of 13 feet (4 meters) above floor level.

3-7.8 Fan Coil Applications for Ventilation Air.

Fan-coil units must not be used for conditioning ventilation loads.

3-7.9 Ground Coupled Heat Pumps.

3-7.9.1 Sizing.

For projects which are considering Ground Coupled Heat Pumps (GCHP), field test the ground heat transfer capacity at the proposed well field site prior to design. **\6** Follow the requirements of ASHRAE and ANSI/CSA C448. If any conflict occurs between the two standards, the more stringent direction must be followed. **/6/** Nonresidential, commercial scale ground source heat pump systems require the utilization of computer design software. Such software **\1** must consider the interaction with adjacent loops and minimum 40 years **/1/** buildup of rejected heat in the soil.

3-7.9.2 Regulatory Requirements.

Regulatory requirements for vertical wells vary widely among States. Some regulations require partial or full grouting of the borehole. Confirm requirements with the Activity and current state and federal regulations, as well as relevant building codes.

3-7.9.3 Borehole Grouting.

The thermal conductivity of grouting materials is typically low when compared to the conductivity of native soils. Grout acts as an insulator and will, thus, hinder heat transfer to the well field. When governing regulations permit, consider the following alternatives:

1. Reduce the quantity of grout to an absolute minimum. Fine sand may be used as backfill where permitted, but caution must be exercised to ensure the interstitial space between pipe and borehole is filled to enhance conductivity.

2. Use thermally enhanced grout. Consult ASHRAE Ground Source Heat Pumps: Design of Geothermal Systems for Commercial and Institutional Buildings. Reduce the borehole diameter as much as possible to reduce the insulating effects of grout or backfill.

3-7.9.4 Piping.

Provide a bypass line around each heat pump unit to facilitate flushing and purging the condenser loop without subjecting the heat pump to residual construction debris. Provide test ports (sometimes referred to as “Pete’s plugs”) on the inlet and outlet to each heat pump unit, circulating pump and desuperheater, if incorporated. Provide isolation valves and valved tee connections for flushing and purging of the well field independently from the building condenser water system.

The design and installation of the ground loop heat exchanger (GLHX) must be with future maintenance and troubleshooting in mind. No fittings other than the supply and return takeoffs into a single vertical well are be allowed to be buried. **\6** Use reverse return circuits and headers in large well fields. No more than 20 wells may be allowed on a single branch circuit with a maximum of 20% of the total number of wells for an entire system on a single branch circuit. **/6/** Each individual supply and return loop length from the mechanical room or manifold must be within 15 percent **\1** of each other **/1/** for hydronic balancing purposes. Each supply and return loop off a GLHX manifold must have a shut-off valve and a balancing valve. For heat pumps with reduced flow requirements of 2 GPM/ton or less, consider series return in order to maintain fluid velocities necessary to foster good heat transfer. Base the decision to commit to reverse return on installed cost, pumping costs and the system flow requirements.

Each manifold header must have both a visual temperature gauge and a visual pressure gauge. Each manifold header must have a shut-off valve on both the main supply and return header piping between all field loops and the building. All system manifolds must be within the building or in a vault with adequate room for a person.

3-7.9.5 Heat Exchangers.

Use cupronickel refrigerant-to-water heat exchangers in open condenser loops only.

3-7.9.6 Make-up Water.

Do not provide automatic water makeup in residential GCHP systems. Reserve the added complexity and cost to larger, non-residential systems of 10 tons or larger.

3-7.9.7 Freeze Protection.

In geographic areas with heating dominated climates, an antifreeze solution may be required if condenser loop temperatures are expected to drop below 41°F (5°C). **\1** Minimize use of antifreeze, but if necessary, use propylene glycol **/1/** and keep concentrations to a minimum. Use condenser water circulating pumps with high efficiency **\1** or premium efficiency **/1/** motors. Design them to operate near their peak of maximum efficiency.

3-7.10 Variable Air Volume (VAV) Cooling.

- Do not oversize the system. Do not add safety factors in the load calculations. Size all central air handling equipment and central plant equipment for “block” loads. Design for both peak and part load conditions (minimal wall transmission load, low occupancy, etc.). Submit part load design calculations. Verify proper fan operating characteristics throughout the range from the minimum to the maximum flow conditions that will be experienced.
- For systems using a dedicated outdoor air handler for ventilation air directly connected to a VAV air handler, provide controls to ensure ventilation air requirements are maintained over all load conditions.
- Select the minimum primary air requirements of the VAV terminal units to maintain at least the minimum outside air ventilation requirements.
- **\1** Provide a low velocity filter module upstream of the outdoor air flow monitoring station to prevent dust/dirt build up that may clog the pitot tubes associated with the sensor. **/1/** Provide a duct access door at the inlet to the **\1** sensor **/1/** for periodic inspection and cleaning.
- Do not use discharge dampers or inlet vanes **\1** on VAV air handler for air volume **/1/** modulation. Provide variable frequency drives for air volume modulation.

- **\1** For high-ceiling areas, use a maximum of ten foot ceiling height for air change calculations. **/1/**
- Locate the static pressure sensor for modulating fan capacity two-thirds to three-quarters the distance from the supply fan to the end of the main trunk duct. Locate in a straight run of ductwork. Provide static pressure reset **\1** based on zone requirements **/1/** in accordance with ANSI/ASHRAE/IESNA Standard 90.1 **\1** paragraph in Chapter 6 entitled, “Setpoint Reset”. **/1/** Provide protection against over pressurization of the supply duct system. Use pressure independent (PI) terminal units.
- Use either the Static Regain or the T-Method method to design **\1** primary **/1/** ducts for VAV systems. Equal friction method must be used for VAV return ducts **\1** and ductwork downstream of VAV terminal units. **/1/** Use round and oval prefabricated duct for the primary air distribution to reduce both leakage and friction losses. Primary air connections to VAV terminals must always be made with a rigid duct to avoid high turbulence in the proximity of the VAV terminal flow sensor. Design the primary air duct connections to the VAV terminals with a straight duct section of at least 6 to 8 duct diameters (more if required by specific manufacturers). Reducer and increaser duct fittings installed immediately upstream of the VAV terminal connection collars are prohibited. If the branch duct size is other than the VAV terminal connection collar size, install the reducer or increaser fitting upstream of the aforementioned straight duct section. If a section of flexible duct, or a flexible connection, is required for vibration control, limit the length to no more than **\6** 150 mm (6 inches) **/6/**, and ensure that it is placed at least 6 to 8 duct diameters upstream of the VAV box collar connection/flow sensor.
- Minimum primary airflow rates must be established to attain minimum velocity pressures of no less than 0.03-inch w.g. (7.45 Pa). Do not use system-powered (also called "pressure dependent") terminal units. Discharge dampers must be installed in the supply duct from all series fan-powered VAV boxes (SFPVAV), regardless of the type of fan speed control utilized (3-speed fan switch or solid state speed control).
- When fan-powered VAV terminal boxes are used, perform an acoustic analysis to ensure designs are within acceptable NC criteria noise levels. Pay particular attention to noise attenuation in locations where the boxes are installed in spaces without dropped ceilings. Provide attenuation as required. Acoustical duct liner is not permitted for attenuation.
- Direct expansion equipment must be specifically designed and manufactured for VAV applications. **\1** For Army and Air Force projects, **/1/** the same manufacturer must provide central air handling units, VAV boxes/zone dampers and zone controls.

- When installing VAV terminals at heights in excess of 3.6 m (12 feet) above finished floors, special maintenance accommodations are necessary:

    1. Do not use fan-powered VAV boxes in such locations, since there are many serviceable components involved.

    2. When DDC controls are installed, specify the location of the DDC digital controller to facilitate ease of access.

    3. Ensure floor area likely to remain clear of permanent or semi-permanent equipment is available below the VAV boxes to facilitate the means of access (i.e. scaffolding, etc.).

    4. Specify the ability to monitor VAV box hot water control valve position (if provided with hot water coils), control damper position, primary airflow, flow sensor pressure differential, and box leaving supply air temperature.

    5. Specify the integral mounting of communication ports for the VAV box digital controllers to the room zone temperature sensor. When occupied/unoccupied modes of control are required of the VAV system, specify remote momentary override switch mounted integral to the room zone temperature sensors to permit non-standard schedule operation during unoccupied modes

3-7.11 \1\ Corrosion.

Provide corrosion resistant coatings or materials for any exterior air-conditioning (including heating and ventilating) equipment and equipment handling outside air that is to be installed. **\6** This includes any coils exposed to outside air. Coatings must be factory applied. Any reduction in heat transfer due to coil coatings must be taken into account when selecting equipment. **/6/ \5** Use upgraded materials/coatings in humid locations or project locations with Environmental Severity Classifications (ESC) of C3 thru C5. Humid locations are those in ASHRAE climate zones 0A, 1A, 2A, 3A, 3C, 4C and 5C (as identified in ASHRAE 90.1). See UFC 1-200-01 for determination of ESC for project locations. For example, use stainless steel, fiberglass, or ceramic in lieu of galvanized steel for cooling towers, and aluminum in lieu of steel for exhaust fans. **/1/ /5/**

3-7.11.1 \5\ Areas Prone to Hurricanes and Typhoons.

Locate HVAC equipment indoors whenever possible. Roof-mounted equipment is not recommended in areas prone to hurricanes and typhoons. Hurricane and typhoon prone areas include: The U.S. Atlantic Ocean and Gulf of Mexico coasts where the basic wind speed for Risk Category II buildings is greater than 115 miles/hour (185 km/hour); Hawaii, Puerto Rico, Guam, Virgin Islands, and American Samoa; other Pacific Ocean islands and other coastal areas in the Pacific and Asia with design wind speeds greater than 115 miles/hour (185 km/hour). Additionally, roof-mounted equipment creates roof construction and maintenance problems. Where roof mounting is unavoidable, evaluate the cost effectiveness of providing roof-top equipment rooms. If locating equipment on exterior is unavoidable, the equipment should be located on the leeward side of the facility to protect from wind.**/5/**

3-7.12 Sound and Vibration Control.

The design of HVAC systems to maintain noise levels below those recommended for the proposed occupancy in accordance with the ASHRAE Handbook and SMACNA guidelines. Preferably, locate sound sensitive rooms away from air handlers and mechanical equipment. Acoustical duct liner is not allowed. Use double wall acoustic duct where sound attenuation cannot be accomplished by other methods and the duct is not serving occupancies that are sensitive to particulates. Increase the outside duct dimensions as required to maintain adequate internal cross sections.

Use ASHRAE Applications Handbook Chapter 48 “Selection Guide for Vibration Isolation” or manufacturers recommendations for vibration isolation design requirements.

3-7.13 Radon.

Provisions for the prevention and mitigation of indoor radon must comply with UFC 3-101-01.

3-7.14 HVAC System Testing & Balancing.

Testing and Balancing of HVAC systems must follow the requirements in UFGS 23 05 93.

\1 Do not exceed nameplate motor amperage in normal operating conditions. **/1/**

3-7.14.1 Balancing Valves and Cocks.

Provide **\1\ /1/** balancing valves for hydronic balance. The designer must specify the size of the balancing valves required in each application, cognizant of the required differential pressure requirements in the pipe systems. A balancing device is required in coil bypasses only when coil drops are in excess of 2 feet w.g. (6 kPa).

3-7.14.2 Flow Control Balancing Valves.

Provide flow control balancing valves in the discharges of all closed circuit pumps and at all hydronic terminal units. For pipe sizes larger than 3 inches (80 mm), a flow orifice combined with a butterfly valve must be specified. Install all flow control balancing valves in accordance with the manufacturer’s recommendations regarding the minimum straight lengths of pipe up and downstream of the device. Designers must select the proper size flow control-balancing valve for each application to ensure the devices are not oversized; valves must be selected using the median flow rating indicated in the manufacturer’s published performance data. Oversized flow control balancing valves yield inaccurate flow readings. Do not use automatic flow control balancing valves. **\1** Do not use triple duty valves. **/1/**

3-7.14.3 Balancing Dampers.

Except for primary VAV supply ductwork **\1** from air handling unit outlet to air terminal unit inlet, **/1/** provide manual volume dampers for all main and branch ducts; these should include all supply, return, and exhaust ducts. Do not use splitter dampers or air extractors for air balancing. Provide opposed blade manual balancing damper for outside air. Indicate opposed blade manual balancing dampers for both the main supply and return duct and the main relief duct on all return air fans; dampers must be in close proximity to the automatic return and relief dampers.

3-7.14.4 Duct Leakage and Testing.

All new duct systems must be constructed no less than a 1-inch (2.5 cm) pressure class and must be leak tested. Refer to Table 6-2 for a duct pressure table example which must be edited and included on the mechanical construction contract drawings. **\1** Provide seal class A on all ductwork. **/1/**

TAB contractors must not be allowed to sum the inlets or supplies to exhaust, return, and supply systems without accurately measuring the total flow rate at the fan for comparison and determination of approximate leaking rates.

3-7.14.5 Variable Speed Drives.

\6 Variable speed drives on pumps or fans must not be manually or automatically adjusted to achieve system balance. Balance systems to deliver design flows with variable speed drives operating at between 55 and 60 Hz so that maximum operational flexibility is maintained. Design conditions for variable speed drives to exceed 60 Hz is prohibited. **/6/** Replace or adjust fan drive sheaves and throttle pump discharges to achieve system balance. Consider trimming pump impellers on larger systems. Verify pump performance at minimum and maximum operating points.

3-7.15 Commissioning Requirements.

Commissioning must be provided as required by UFC 1-200-02. After the successful completion of the Test and Balance activities and prior to final acceptance of the HVAC systems, provide a minimum of four days of trends measured with data loggers **\1** or from the Building Automation System (BAS) **/1/** while the equipment is in full automatic mode to ensure that all systems are working properly under all conditions. **\1** Include the following trending requirements:

- Points to be trended must be the same or similar to App. D, Minimum Control Points List.
- Data points must be at the same time increment.
- Provide trends in graphic format.
- Clearly identify all trend data. **/1/**

CHAPTER 4 SUPPLEMENTAL IMC TECHNICAL CRITERIA

(Note: Chapter and paragraph numbers reference **\6** IMC-2018 ***/6/***)

4-1 GENERAL SUBSTITUTIONS.

All references to “approved” materials must be materials allowed by the applicable Unified Facilities Guide Specification (UFGS).

All references in the International Mechanical Code to the International Building Code must be considered to be references to UFC 1-200-01.

All references in the International Mechanical Code to the International Fuel Gas Code must be considered to be references to NFPA 54 and NFPA 58.

All references in the International Mechanical Code to the International Plumbing Code must be considered to be references to UFC 3-420-01.

All references in the International Mechanical Code to the International Energy Conservation Code must be considered to be references to UFC 1-200-02.

All references in the International Mechanical Code to the International Fire Code must be considered to be references to UFC 3-600-01

All references in the International Mechanical Code to NFPA 70 must be considered to be references to UFC 3-501-01.

4-2 IMC SUPPLEMENTARY PARAGRAPHS.

4-2.1 IMC CHAPTER 1 “*SCOPE AND ADMINISTRATION*” SUPPLEMENTS.

Delete Chapter 1 in its entirety. The administrative requirements are covered by the applicable Federal Acquisition Regulations (FAR) and by the authority granted to the Contracting Officer in administering the contract.

4-2.2 IMC CHAPTER 2 “*DEFINITIONS*” SUPPLEMENTS.

4-2.2.1 Definition Replacements.

Replace the definitions published in Chapter 2 with the following definitions:

APPROVED. Acceptable to the code official or other authority having jurisdiction. “Approved” materials must be materials allowed by the applicable Unified Facilities Guide Specification (UFGS).

CODE OFFICIAL. The Code Official is the authority having jurisdiction as described in UFC 1-200-01.

4-2.2.2 Definition Additions.

Add the following definitions to Chapter 2:

OWNER OR OWNER'S REPRESENTATIVE. For Government-owned facilities, the Contracting Officer assigned by the Government to administer the construction contract. For leased facilities, the leaser of the facility.

PERMIT HOLDER. The contractor accomplishing the project.

4-2.3 IMC CHAPTER 3 "G*ENERAL REGULATIONS*" SUPPLEMENTS.

4-2.3.1 Addition - Section 304.1 "General"

Insert after the last sentence of Section 304.1:

"All equipment mounted on a roof must be detailed by the structural engineer. Ductwork must be connected to equipment with flexible connections and supported to ensure proper alignment."

\6

4-2.3.2 Addition - Section 306.5 "Equipment and appliances on roof or elevated structures"

Insert after the last sentence of Section 306.5:

"The means to access the equipment must be shown on the mechanical drawings." **/6/**

\2

4-2.3.3 Addition - Section D306.6 "Mechanical Equipment installed in excess of 12 feet above finished floors"

Add the following section to Chapter 3:

D306.6 Mechanical Equipment installed in excess of 12 feet above finished floors. When mechanical equipment are installed at heights in excess of 12 feet, provide special maintenance accommodations such as a service platform, railings, catwalk with railings, and a permanent ladder or stairs for access of maintenance, repair, and replacement. **/2/**

4-2.3.4 Addition - Section 307.2.1 "Condensate disposal"

Insert after the last sentence of Section 307.2.1:

"Terminate condensate drain lines in accordance with the IMC and local direction."

4-2.3.5 Replacement – Section 309 "Temperature Control"

Replace Section 309 with the following:

Section 309
HVAC CONTROL

309.1 HVAC Control. Follow the mandatory requirements of the section titled "Controls" of ANSI/ASHRAE/IESNA Standard 90.1 as modified below. All air distribution systems must be capable of shutdown to meet the requirements of Standard 18 of UFC 4-010-01 "DoD Minimum Antiterrorism Standards for Buildings". **\2\ /2/**

\4\ 309.2 Control Protocol. ASHRAE's BACnet® protocol is the preferred control system architecture for **Navy** & **Marine Corp** facilities. LonWorks® protocol is the preferred control system architecture for **Army** facilities. Facility HVAC control systems based on the BACnet® protocol must be designed and constructed in accordance with ANSI/ASHRAE Standard 135, UFGS 23 09 00, UFGS 23 09 23.02 and UFGS 23 09 13. LonWorks® items in UFC 3-410-02 are not applicable when identified in UFGS 23 09 00, UFGS 23 09 23.02 and UFGS 23 09 13 for **Navy** & **Marine Corps** projects. Facility HVAC control systems based on the LonWorks® (ANSI/CEA-709.1 and related technologies) must be designed and constructed in accordance with UFC 3-410-02, UFGS 23 09 00, UFGS 23 09 23.01 and UFGS 23 09 13. **/4/**

309.3 Networked Controls. Prior to designing the DDC system, confirm whether an existing energy management network is available for interface on the Base. Provide DDC equipment which is compatible with existing systems to the maximum extent practicable. Where use of a specific DDC system is mandatory, a Justification and Authorization (J&A) for the utilization of proprietary DDC equipment must be provided by the Government.

309.4 Minimum Control Points. \6 Provide a control system with at least the minimum points as indicated in Appendix D. Develop point schedules and required naming conventions in accordance with UFC 3-410-02. For Navy projects, provide DDC BACnet® system in accordance with UFC 3-410-02. **/6/**

309.5 DDC Accreditation. \6 Provide hardware equipment utilizing the latest technology which will accomplish the desired control and will meet the Risk Management Framework (RMF) plan developed to comply with UFC 4-010-06. **/6/**

309.6 DDC Training. Require the DDC installer to provide training for government facility personnel on all new DDC equipment.

309.7 Hot Water System Modulation. Systems using hot water as a heat source will be controlled by a master outdoor temperature sensing unit that modulates the hot water temperature according to the outdoor temperature with a positive cut-off above 65°F (18.3°C) **\1** except when hot water is approved for reheat. **/1/**

4-2.3.6 Deletion - Section 312 "Heating and Cooling Load Calculations"

Delete Section 312 in its entirety.

4-2.4 IMC CHAPTER 4 "*VENTILATION*" SUPPLEMENTS.

4-2.4.1 Replacement – Section 401 "GENERAL"

\6 Replace Section 401.1 through 401.4 and 401.6 content with the following: **/6/**

> **401.1 Scope.** Every occupied space is to be ventilated in accordance with ANSI/ASHRAE Standard 62.1. **\6** Use the "ventilation rate procedure" in calculating minimum outdoor air requirements. **/6/** **\1** For Army and Air Force projects, **/1/** use of CO2 sensors for ventilation control is prohibited unless approved by AHJ.
>
> Maintain toilets, lockers, and utility closets at a negative pressure relative to adjacent areas during occupied periods by exhausting air transferred from these adjacent areas to the outdoors.
>
> **\2** Closets and storage or utility rooms smaller than 4.64 square meters (50 square feet) of floor space within conditioned spaces must have undercut doors allowing airflow through these spaces. Closets and storage or utility spaces larger than 4.64 square meters **\6** (50 square feet) **/6/** of floor space must be supplied with conditioned air. **/2/**
>
> For industrial applications not covered by ANSI/ASHRAE Standard 62.1 use the UFC 3-410-04.

4-2.4.2 Replacement – Section 402 "NATURAL VENTILATION"

Replace all Section 402 content with the following:

> **402.1 Scope.** Natural ventilation systems are to be in accordance with ANSI/ASHRAE Standard 62.1.

4-2.4.3 Replacement – Section 403 "MECHANICAL VENTILATION"

Replace all Section 403 content with the following:

> **403.1 Scope.** **\6** "Mechanical ventilation systems are to be in accordance with facility criteria or ANSI/ASHRAE Standard 62.1." **/6/**

4-2.4.4 Addition - Section 406 "Ventilation of Uninhabited Spaces"

Insert after the last sentence of Section 406:

"All air conditioned facilities with uninhabited spaces outside the air/moisture barrier must be designed to achieve maximum natural ventilation of the uninhabited space. "

\6

4-2.4.5 Replacement - Section 407 "Ambulatory Care Facilities and Group I-2 Occupancy"

Replace Section 407 with the following:

"Ambulatory Care Facilities and Group I-2 occupancy must be designed in accordance with UFC 4-510-01." **/6/**

4-2.4.6 Addition - Section D408 "Equipment Rooms"

Add the following section to Chapter 4:

D408.1 Equipment Spaces. \6 All equipment rooms must have exterior access sized to accommodate all maintenance and equipment replacement throughout the life of the building. Incorporate provisions for future equipment removal and replacement. Provide fall protection as required. Hand rails must be removable.

Equipment rooms on grade must be provided with door(s) on the building exterior.

Equipment rooms above grade must be provided with exterior access that will allow crane or mobile lift access to equipment. Provide fall protection as appropriate. Hand rails must be removable. Coordinate with the Architect on this requirement since it may have historical preservation impacts.

Equipment rooms below grade must be provided with pit access with floor drains, stairs and exterior double door(s) at a minimum. Provide fall protection as required. Hand rails must be removable.

For supplemental mechanical spaces with equipment weighing 125 lbs or less, verify if exterior access is required by the Installation Commander. **/6/**

D408.2 Equipment Room Ventilation. Where a refrigerating system is housed within the equipment room, the design of the room must comply with ASHRAE Standard 15.

D408.3 Equipment Room Ventilation Design. Equipment rooms will usually be ventilated using outside air intake louvers and a thermostatically controlled exhaust fan. Use a supply fan in lieu of an exhaust fan in rooms where atmospheric burners are located. The ventilation fan will have a two-speed motor, which is sized, at the high speed, to have adequate capacity to limit the room dry bulb temperature to a maximum of 10°F (6°C) above the outdoor dry bulb temperature when both equipment and ambient loads are at their maximum peaks. The high speed will be activated 10°F (6°C) below the maximum temperature at which the most sensitive item of equipment in the room can operate. The low speed will operate at 20°F (11°C) below that of the high speed.

D408.4 Equipment Room Air Conditioning. Air conditioning may be provided **\5\ /5/** to prevent severe corrosion **\5** in areas with an Environmental Severity Classification (ESC) of C4 and C5 and in high humidity areas identified in ASHRAE 90.1 as climate zones 0A, 1A, 2A, 3A, 3C, 4C and 5C. See UFC 1-200-01 for determination of ESC for project locations. In project locations as described above, seal the mechanical equipment rooms from air leakage. **/5/\1** Return air must not be taken from equipment rooms by air handlers serving occupied spaces. **/1/**

4-2.5 IMC CHAPTER 5 "*EXHAUST SYSTEMS*" SUPPLEMENTS.

4-2.5.1 Replacement – Section 501.1 "Scope"

Replace Section 501.1 with the following:

501.1 Scope. This chapter governs the design, construction and installation of mechanical exhaust systems, including exhaust systems serving clothes dryers and cooking appliances; hazardous exhaust systems; dust, stock and refuse conveyor systems; subslab soil exhaust systems; smoke control systems; energy recovery ventilation systems and other systems specified in Section 502. Use this chapter and UFC 3-410-04. If any conflict occurs between this chapter and UFC 3-410-04, the requirements of UFC 3-410-04 take precedence. **\6** The mechanical gases must meet the requirements in UFC 4-510-01. **/6/** Mechanical ventilation and exhaust systems for flammable, hazardous, grease laden, or toxic vapors, gases or fumes must follow the codes of practice of NFPA.

4-2.5.2 Addition - Section D501.6 "Roof Fans"

Add the following section to Chapter 5:

D501.6 Roof Fans. Roof exhaust fans should be avoided due to maintenance access restrictions and roof leak potential. If provided and where feasible, use direct drive fan motors with speed controllers to reduce maintenance requirements.

4-2.5.3 Replacement – Section 502.3 "Battery-charging areas for powered industrial trucks and equipment"

Replace Section 502.3 with the following:

502.3 Battery-charging areas for powered industrial trucks and equipment. Ventilation must be provided in an approved manner in battery-charging areas for powered industrial trucks and equipment to prevent a dangerous accumulation of flammable gases. Mechanical ventilation systems are to be in accordance with UFC 3-410-04.

4-2.5.4 \1\ Addition /1/ – Section 502.4 "Stationary storage battery systems"

\1 Insert after sentence of Section 502.4:

/1/ Design stationary secondary battery installations in accordance with UFC 3-520-05. For battery maintenance and repair facilities, use UFC 3-410-04 for design criteria.

\1\ /1/

4-2.5.5 \1\ Addition /1/ – Section 502.5 "Valve-regulated lead-acid batteries in cabinets"

\1 Insert after sentence of Section 502.5:

/1/Valve-regulated lead-acid (VRLA) batteries installed in cabinets must be provided with ventilation in accordance with UFC 3-520-05 and UFC 3-410-04.

4-2.5.6 Replacement – Section 502.13 "Public garages"

Replace Section 502.13 with the following:

502.13 Public garages. Mechanical exhaust systems for public garages must be in accordance with the applicable provisions of NFPA 88A.

4-2.5.7 Replacement – Section 502.19 "Indoor firing ranges"

Replace Section 502.19 with the following:

502.19 Indoor firing ranges. Mechanical ventilation systems must be provided in accordance with MIL-HDBK-1027/3B.

4-2.5.8 Addition - Section 506.1 "General"

Insert after the last sentence of Section 506.1:

"Evaluate the use of heat recovery in kitchens where heat rejected by refrigeration equipment is 50,000 Btuh (15 kW) or more."

4-2.5.9 Replacement – Section 507.3 "Type II hoods"

Replace Section 507.3 with the following:

507.3 Type II hoods. Type II hoods must be installed above dishwashers and appliances that produce heat or moisture and do not produce grease or smoke as a result of the cooking process, except where the heat and moisture loads from such appliances are incorporated into the HVAC system design or into the design of a separate removal system. Type II hoods must be installed above all appliances that produce products of combustion and do not produce grease or smoke as a result of the cooking process. Spaces containing cooking appliances that do not require Type II hoods must be ventilated in accordance with Section 403.3 and ANSI/ASHRAE Standard 62.1. If any conflict occurs between ANSI/ASHRAE Standard 62.1 and Section 403.3, the requirements of ANSI/ASHRAE Standard 62.1 take precedence. For the purpose of determining the floor area required to be exhausted, each individual appliance that is not required to be installed under a Type II hood must be considered as occupying not less than 100 ft^2 (9.3 m^2). Such additional square footage must be provided with exhaust at a rate of 0.70 cfm per square foot [.00356 $m^3/(s\text{-}m^2)$].

4-2.5.10 Replacement – Section 510.2.1 “Lumber yards and woodworking facilities”

Replace Section 510.2.1 with the following:

510.2.1 Lumber yards and woodworking facilities. Equipment or machinery located inside buildings at lumber yards and woodworking facilities which generates or emits combustible dust must be provided with an *approved* dust-collection and exhaust system. The systems must be in conformance with section 510 and UFC 3-600-01. Woodworking exhaust systems must be designed in accordance with UFC 3-410-04N.

4-2.5.11 Addition - Section 513.1 “Scope and purpose”

Insert before the first sentence of Section 513.1:

“Use Section 513 and UFC 3-600-01. If any conflict occurs between Section 513 and UFC 3-600-01, the requirements of UFC 3-600-01 take precedence.”

4-2.6 IMC CHAPTER 6 “*DUCT SYSTEMS*” SUPPLEMENTS.

4-2.6.1 Addition - Section 601.2 “Air movement in egress elements”

Insert after the last sentence of Section 601.2:

“Corridors in all new construction must conform to NFPA 90A.”

4-2.6.2 Addition - Section 603.1 "General"

Insert after the last sentence of Section 603.1:

"Design air distribution systems for central HVAC systems to maintain a slightly positive pressure (0.02"w.g.) relative to the outdoors within the area served in order to reduce or eliminate infiltration unless there is a valid need to maintain a negative pressure in that area. Maintain pressure relationships in each pressure zone (defined by full height interior walls, fire/smoke barriers, and external walls) and not exclusively calculated for the building as a whole."

Construct all ductwork to meet SMACNA seal class A. **\2** For **Navy** and **Air Force** projects, use round **\1** or **/1/** oval prefabricated duct to reduce both leakage and friction losses on duct systems above 1.5"w.g. static pressure. For **Army** projects, use round **\1** or **/1/** oval prefabricated duct to reduce both leakage and friction losses on duct systems per ASHRAE Handbook. **/2/**

Consider **\1** round or oval duct **/1/** for all other positive pressure applications. The additional material cost for round or oval prefabricated duct is often offset by reduced installation cost and time and reduced fan energy consumption and air leakage.

Provide air flow measuring devices as a means of determining outside air flow amounts. If an air flow measuring station is provided in the outside air duct, the equipment layout must allow for the straight duct length and size requirements of the air flow measuring station in accordance with the manufacturer's recommendations. **\1** Ensure all outside air entering air flow measuring stations has been filtered. **/1/**

Provide ducted returns from the occupied space for each zone to the air handler on all HVAC systems. **\6** UFC 3-600-01 does not override this requirement. **/6/**

Where negative pressure of indoor spaces relative to other indoor spaces is required, the building layout must place those spaces on the interior to minimize the possibility for negative pressure induced infiltration of the exterior wall cavity.

Ensure that duct design incorporates all features necessary to accommodate testing, adjusting, and balancing (TAB). TAB specifications must call for a plus 10%/minus 0 (zero)% on the outdoor air supply and a plus 0 (zero)%/minus 10% on the exhaust systems to prevent inadvertent building negative pressure after TAB."

4-2.6.3 Addition - Section D603.1.1 "Prohibited construction"

Add the following section to Chapter 6:

> **D603.1.1 Prohibited construction.** Do not use the following types of duct construction where the potential for subterranean termite infestation is high:
>
> - Sub-slab or intra-slab HVAC ducts.
> - Plenum-type, sub-floor HVAC systems, as currently defined in Federal Housing Administration minimum acceptable construction criteria guidance.
> - HVAC ducts in enclosed crawl spaces that are exposed to the ground.
> - HVAC systems where any part of the ducting is in contact with or exposed to the ground.

4-2.6.4 Deletion - Section 603.5 “Nonmetallic ducts”

Delete Section 603.5 in its entirety. **\1** Fiber or gypsum board **/1/** ducts are prohibited.

4-2.6.5 Replacement – Section 603.6.1.1 “Duct length”

Replace Section 603.6.1.1 with the following:

> **603.6.1.1 Duct length.** Flexible air ducts must not exceed **\2** 5 **/2/** feet in length. Do not use flexible duct for offsets greater than 45 degrees or connections to diffusers, registers or grilles greater than 45 degrees.

\6

4-2.6.6 Replacement – Section 603.6.2.1 “Connector length”

Replace Section 603.6.2.1 with the following:

> **603.6.2.1 Connector length.** Flexible air connectors must not exceed 5 feet in length. **/6/**

4-2.6.7 Replacement – Section 603.8 “Underground ducts”

Replace Section 603.8 with the following:

> **603.8 Underground ducts.** The use of underground ducts **\1** for general comfort conditioning **/1/** is prohibited, except for sub slab soil exhaust systems, per Section 512, which are allowed.

4-2.6.8 Addition - Section D603.19 “Control Dampers”

Add the following section to Chapter 6:

> **D603.19 Control Dampers.** Provide parallel blade dampers for two-position, on/off control. Provide opposed blade dampers for

modulating applications, but for best performance, their pressure drop should be between 5% and 20% of the total system pressure drop. They are effective for two-position, on/off applications as well, but are more expensive than parallel dampers. Outside air intakes must be equipped with low leakage dampers which have a maximum leakage rate of 3 CFM/ft^2 at 1"w.g. static pressure.

4-2.6.9 Replacement – Section 604.1 "General"

Replace Section 604.1 with the following:

604.1 General. Duct insulation must conform to the requirements of Sections 604.2 through 604.13 with the following exceptions. Spray polyurethane foam insulation, foam plastic insulation and internal duct insulation is prohibited. **\2** Duct insulation must be external, and duct board or internal duct liner is not allowed. **/2/**

4-2.6.10 Deletion - Section 604.7 "Identification"

Delete Item Number 4 in Section 604.7 in its entirety.

4-2.6.11 Replacement – Section 606.1 "Controls required"

Replace Section 606.1 with the following:

606.1 Controls required. Air distribution systems must be equipped with smoke detectors listed and labeled for installation in air distribution systems as required by Section 606 and UFC 3-600-01. If any conflict occurs between Section 606 and UFC 3-600-01, the requirements of UFC 3-600-01 take precedence. Duct smoke detectors must comply with UL 268A. Other smoke detectors must comply with UL 268. **\1** Locate smoke detectors on plans in accordance with manufacturer's recommendations and downstream from the fan discharge, downstream of the air filters, ahead of any branch connections, and at the center of the duct. **/1/**

4-2.6.12 Replacement – Section 607.1 "General"

Replace Section 607.1 with the following:

607.1 General. The provisions of Section 607 and UFC 3-600-01 must govern the protection of duct penetrations and air transfer openings in assemblies required to be protected. If any conflict occurs between Section 607 and UFC 3-600-01, the requirements of UFC 3-600-01 take precedence.

\6 (IMC CHAPTER 7 "COMBUSTION AIR" SUPPLEMENTS Addition to Section 701 "General" was deleted because it was incorporated into IMC-2015.) **/6/**

4-2.7 IMC CHAPTER 8 "*CHIMNEYS & VENTS*" SUPPLEMENTS.

4-2.7.1 Addition - Section 801.2 "General"

Insert after the last sentence of Section 801.2:

> "See ASHRAE HVAC Systems and Equipment Chapter entitled "Chimney, Vent, and Fireplace Systems" for general chimney & vent design information and Table 2 for estimates of typical chimney flow rates. Where natural-draft stacks would be a hazard to aircraft or otherwise objectionable, use mechanical-draft fans discharging into short stub stacks. Equipment spaces equipped with natural draft stacks must not be operated at a negative pressure.

4-2.8 IMC CHAPTER 9 "SPECIFIC APPLIANCES, FIREPLACES AND SOLID FUEL-BURNING EQUIPMENT" SUPPLEMENTS.

4-2.8.1 Addition - Section D901.5 "Combustion equipment"

Add the following section to Chapter 9:

> **D901.5 Combustion equipment.** The installation of combustion equipment, including burners and draft fans, must be in accordance with ASHRAE Handbook, Underwriters Laboratory (UL), National Fire Protection Association (NFPA), and the recommendations of equipment manufacturers. Direct-fired heaters must not be used in areas subject to hazardous concentrations of flammable gas, vapors, or dust. Locate fuel burning equipment; such as packaged slab-mounted HVAC units away from windows, doors or outside air intakes. Gravity flow warm air furnaces must not be used.
>
> **D901.5.1 Gas burners.** All gas-fired equipment must be equipped with a burner, which can be readily converted to burn an alternate fuel.
>
> **D901.5.2 Oil burners.** The selection of oil burners must depend on the grade of the oil being burned, the size of installation, and the need for modulating control. For light oil, atomizing must be accomplished using oil pressure, air, or steam atomizing burners. For heavy oil, atomizing must be accomplished using air or steam atomizing burners.

4-2.8.2 Addition - Section 908.5 "Water supply"

Insert after the last sentence of Section 908.5:

> "Provide automatic blowdown and chemical feed provisions to all cooling towers to maintain cleanliness."

4-2.8.3 Addition - Section D912.4 "Installation"

Add the following section to Chapter 9:

D912.4 Installation. "When using non-condensing gas infrared heaters, the length of the exhaust flue should be minimized. To minimize condensation, run the flue horizontally with a slight pitch down from the heater to a sidewall exit. Heaters should be properly braced where excessive movement, such as by wind through an open hangar bay door, may cause separation of radiant pipe sections and rupture of gas connections. Consider condensing type IR heaters for larger applications. Provide ducted combustion air intake through roof or exterior wall. Direct vents for condensing type IR heaters to carry water vapor and exhaust out of the building.

4-2.8.4 Addition - Section 918.2 "Heat pumps"

Add the following section to Chapter 9:

D918.2.1 Application. Water source units may be used in heating the perimeter spaces of buildings that have interior spaces that must be cooled concurrently. Air-to-air heat pumps must be used only in locations with heating design temperatures (99 percent basis) greater than 12°F (-11.1°C). This restriction must not apply to those locations in which 30 percent or more of the total annual heating hours below 65°F (18°C) occur during the period of May through October. Heating only air-to-air heat pumps may be used in facilities not air-conditioned based on the lowest life cycle cost analysis. When applied to heat pump applications, auxiliary electric heat must be limited to the capacity needed to supplement the heat pump. Larger systems, including built-up systems, may be used where economically feasible.

D918.2.2 Capacities. Air-to-air heat pumps up to 39,565 W (135,000 Btuh) cooling capacity must be certified under the Heat Pump Certification Program of the Air Conditioning, Heating, and Refrigeration Institute (AHRI), unless a detailed life cycle cost analysis indicates selection of a less efficient unit would be more cost-effective. Larger systems, including built-up systems, must be used where economically feasible.

4-2.8.5 Replacement – Section 928 "Evaporative Cooling Equipment"

Replace Section 928 with the following:

Section 928
EVAPORATIVE COOLING EQUIPMENT

928.1 Applications. Evaporative cooling must only be used where the facility in question is eligible for air conditioning, and evaporative cooling can provide the required indoor design conditions based on the appropriate outdoor design conditions. A life cycle cost analysis must be used to determine if evaporative cooling is appropriate for the facility. In many locations where evaporative cooling cannot provide the required indoor conditions year-round, consideration must be given to its use as a supplement to the primary cooling system when preliminary life cycle calculations show the supplementary system to be cost effective. For special applications where close temperature or humidity control is required, consideration must be given to two-stage evaporative cooling or indirect evaporative cooling in the life cycle cost analysis as a supplement to, not in lieu of, the primary cooling system.

928.2 Design Evaporative cooling equipment must:

1. Be installed in accordance with the manufacturer's instructions

2. Be installed on level platforms in accordance with Section 304.10.

3. Have openings in exterior walls or roofs flashed in accordance with UFC 1-200-01.

\6 4. Be sized and provided with potable water backflow protection in accordance with UFC 3-420-01. **/6/**

5. Have air intake opening locations in accordance with Section 401.4.

4-2.9 IMC CHAPTER 10 “BOILERS, WATER HEATERS AND PRESSURE VESSELS” SUPPLEMENTS.

4-2.9.1 Replacement – Section 1001.1 “Scope”

Replace Section 1001.1 with the following:

1001.1 Scope. This chapter governs the installation, alteration and repair of boilers, water heaters and pressure vessels. Use Chapter 10, UFC 3-430-08N, UFC 3-430-02FA, and UFC 3-430-11 for boilers; and Chapter 10 and UFC 3-430-07 for the inspection and certification of boilers and unfired pressure vessels. If any conflict occurs between Chapter 10 and the above UFCs, the requirements of the UFCs take precedence.

4-2.9.2 Addition - Section 1004.2 “Installation”

Insert after the last sentence of Section 1004.2:

“**\6\ /6/** During heating season, multiple boilers should be kept warm and ready should the lead boiler fail to operate. On multiple boiler installations with the largest boiler off line, the remaining boiler(s) must be capable of carrying not less than 65 percent of the maximum winter design load. Where the smallest boiler installed has a capacity of more than twice the minimum summer load, provide an additional boiler or hot water heater sizes for the anticipated summer load."

4-2.9.3 Replacement – Section 1004.3 "Working clearance"

Replace **\1\ /1/** Section 1004.3 with the following:

\1 "Clearance around boilers must be per ANSI/NB23, National Board Inspection Code, Part 1, Sections 2 and 3, each with respective paragraphs entitled, 'Clearances'." **/1/**

4-2.9.4 Addition - Sections D1005.3 – D1005.4

Add the following sections to Chapter 10:

D1005.3 Feedwater systems. Provide heaters for the de-aeration of feedwater for all boiler installations with steam capacities in excess of 20,000 MBtuh (6,000kW). Install feedwater heaters above the boiler feed pump suction at a height sufficient to prevent flashing at the pump inlet at the design feedwater temperature. Provide a bypass and isolation valves for each feedwater heater to permit operation of the boilers at times when the heater is being serviced.

D1005.3.1 Feedwater pump requirements. Feedwater flow rate to the heater must equal the boiler demand. Size feedwater pumps 10 percent larger than the capacity calculated to allow for pump cooling requirements. **\1** Boiler feedwater pumps discharge pressure must conform with National Board Inspection Code, Part 1, Section 2, paragraph entitled, "Pumps". **/1/**

D1005.3.2 Surge tanks. Install the surge tanks upstream of the feedwater heaters where the space-heating load predominates, where large quantities of condensate are returned by condensate pumps, and where steam-driven auxiliaries are used. Size surge tanks for 20 minutes of condensate storage based on boiler steaming capacity.

D1005.4 Boiler auxiliaries. Boiler plant auxiliaries must be electrically driven; however, whenever an uninterrupted supply of steam is essential, provide one of the boilers with steam-driven auxiliaries. Provide individual forced or induced-draft fans with each boiler unit. Provide necessary standby equipment to maintain essential operations.

4-2.9.5 Addition - Section 1009.2 "Closed Type Expansion Tanks"

Insert after the last sentence of Section 1009.2:

"Use diaphragm type expansion tanks. Size the expansion tank according to the latest edition of the ASHRAE Systems Handbook.

Indicate the acceptance volume, nominal dimensions, configuration (i.e. horizontal or vertical) and pre-charge air pressure."

\6

4-2.9.6 Deletion - Section 1009.3 "Open Type Expansion Tanks"

Delete Section 1009.3 in its entirety.

4-2.9.7 Addition - Section 1011.1 "Tests"

Insert after the last sentence of Section 1011.1:

"Provide testing and certifications in accordance with UFC 3-430-07."
/6/

4-2.10 IMC CHAPTER 11 "*REFRIGERATION*" SUPPLEMENTS.

4-2.10.1 Addition - Section D1101.11 "Refrigerant oil"

Add the following section to Chapter 11:

D1101.11 Refrigerant oil. Compressors operating in parallel must have the normal oil level at the same elevation for all machines and the crankcases of these compressors must be provided with gas and oil equalizing lines. When compressors are connected in parallel, arrange the hot-gas discharge lines so that the oil from the common discharge line must not collect in an idle unit while the other units are running, and size the lines to provide an equal pressure drop between each machine and its respective condenser. The suction lines must return refrigerant gas and oil from the evaporator to the compressor during operation of the system, and must not allow oil or liquid refrigerant to be returned as slugs at any time. Provide means for trapping oil in the common suction header to prevent oil slugs from collecting in the idle compressor.

4-2.10.2 Replacement – Section 1102.2 "Refrigerants"

Replace section 1102.2 with the following (subparagraphs must remain to be enforced)

1102.2 Refrigerants. **\6** Refrigerants for new equipment must have an Ozone Depletion Potential (ODP) no greater than 0.0. **/6/**

4-2.10.3 Addition - Sections D1102.3 - D1102.6

Add the following sections to Chapter 11:

D1102.3 Absorption refrigeration. Use absorption equipment only where waste steam from incineration of solid wastes, heat recovery engine or gas turbine exhausts, or exhaust from steam turbine drives for refrigeration compressors or electric generators are available. Absorption chillers must have the capability of operating at variable condenser water temperature without crystallization. Use a throttling valve to modulate flow to the absorbent generator with chilled water temperature, as well as an automatic steam valve that reduces steam pressure and temperature, for energy efficient part load capacity control. Use two-stage absorption refrigeration whenever high-pressure steam or high-temperature water is available.

D1102.4 Reciprocating refrigeration. For reciprocating chillers over 10 tons (35 kW), use capacity control that reduces the power requirement as the load varies. Individual reciprocating machines must not exceed 200 tons (700 kW) capacity, and the total capacity of all reciprocating machines or packaged air-conditioning units equipped with reciprocating compressor used for air conditioning a single facility must not exceed 400 tons (1400 kW). A single packaged unit must not contain more than eight compressors.

D1102.5 Centrifugal refrigeration. When a two-stage centrifugal compressor is selected, a refrigerant intercooler must also be required. For low-temperature applications, where compressors with four or more stages are used, two-stage intercoolers must be used. Use capacity control methods to reduce energy consumption as the load is reduced to minimize life cycle costs. Use variable frequency drives; inlet vane control is not allowed.

D1102.6 Multiple chillers. Where multiple chillers are specified, provide a chilled water pump and a condenser pump for each chiller. With the exception of the criteria listed herein, the number of chillers specified must be optimized in the life cycle cost analysis. In multiple chillers installations the sequence of operation should ensure that the chillers are loaded and unloaded optimally for best performance and energy efficiency. Provide connection and communication between the chiller panels and the DDC system.

4-2.10.4 Addition - Sections 1107.2 “Piping location”

Insert after the last sentence of Section 1107.2:

“For refrigerant piping runs longer than 15 m (50 ft), size refrigerant piping in accordance with manufacturer requirements.”

4-2.11 IMC CHAPTER 12 “*HYDRONIC PIPING*” SUPPLEMENTS.

4-2.11.1 Addition - Sections 1201.2 “Sizing”

Insert after the last sentence of Section 1201.2:

”Provide back-up or standby pumps with lead/lag controls so that the total system capacity is available with any one pump out of service.

On variable flow systems, maintain a minimum system flow of 20-30% of peak flow to avoid pump dead-head and overheating."

4-2.11.2 Addition - Sections D1201.4 – D1201.7

Add the following sections to Chapter 12:

D1201.4 System types. Hydronic systems for comfort applications must be four pipe **\4** hydronic heat cool system (4-pipe independent load system) **/4/**. Piping material for hydronic systems must be either copper or steel. "Triple duty" or "multi- purpose" valves which combine a check valve, throttling valve, and shut-off valve must not be used in piping systems.

D1201.5 Safety. For safety purposes, low-temperature hot water [250°F (120°C) and below] must be used where terminal equipment is installed in occupied areas. Medium-temperature [250 to 350°F (120 to 175°C)] hot water or high-temperature [350 to 400°F (175 to 200°C)] hot water unit heaters **\1** may **/1/** be used for space heating in areas such as garages, warehouses, and hangars where the discharge outlets are a minimum of 13 ft (4 m) above floor level.

D1201.6 Freeze protection. Freeze protection must be provided by automatic circulation of hydronic pumps when the outside temperature drops below 35°F (2°C) , or by the addition of an appropriate antifreeze solution, or design of a pipe temperature maintenance systems (i.e. heat trace) based on the lowest recorded temperature in UFC 3-400-02.

\4 1. For hydronic systems not needed for winter months, freeze protection may also be accomplished by draining the system prior to seasons that may experience freezing temperatures.

2. Look at the cost effectiveness when using antifreeze solutions considering the labor, material cost and the de-creased capacity. If used due to possible extended power outages or other, be aware that many manufacturers warn against dropping below 20% due to a quicker degradation of corrosion inhibitors. **/4/**

D1201.7 Chilled water systems. Provide a dedicated primary pump and condenser water pump for each chiller. **\6\ \1** Provide backup or standby pump for each chiller and cooling tower. **/1/ /6/** Provide piping and valve configuration that allows each chiller to operate **\1\ /1/** with any condenser water pump. The optimum supply and return water temperature differential must be determined by life cycle cost analysis.

4-2.11.3 Replacement – Section 1204.2 "Required thickness"

Replace Section 1204.2 with the following: Add

1204.2 Required thickness. Hydronic piping must be insulated to a minimum thickness as required by ANSI/ASHRAE/IESNA Standard 90.1. Follow the MICA National Commercial & Industrial Insulation Standards for proper installation of field applied insulation."

4-2.11.4 Replacement – Section 1205.1.5 "Equipment and Appliances"

Replace the last sentence of Section 1205.1.5 with the following:

"Provide shutoff valves to isolate all pumps."

4-2.11.5 Addition - Section 1206.1 "General"

Insert after the last sentence of Section 1206.1:

"Conceal piping in permanent-type structures. Exposed piping attached to or near equipment, or subject to high heat or frequent washing, must be copper, brass, or chromium plate. Prime other exposed piping with paint suitable for metal surfaces and finish-paint with color to match background. Arrange piping runs to minimize interference with personnel and equipment. Provide pressure and temperature taps ("Pete's Plugs") on the inlets and outlets of all coils, pumps, chillers, heat exchangers, and other equipment. Provide expansion loops and/or devices as required for proper piping protection. Detail and dimension loops and schedule joints indicating minimum total traverse and installed expansion traverse. Indicate guide spacing. Avoid the use of expansion joints where possible due to the high resultant thrust. Instead use geometry and ball joints where possible. Where chemical feeders are provided, fill openings should be no higher than 4 feet (1.2 meters) above the finish floor for ease of filling. **\2** Hydronic piping is not permitted to be installed within or pass through electrical or communication rooms. **/2/**"

4-2.11.6 Addition - Section 1206.2 "System drain down"

Insert after the last sentence of Section 1206.2:

"Provide drain lines from air handling units, fan coil units, pressure relief valves, backflow preventers, etc. Provide a water seal on drains as required. Pipe drain valves to floor drains where possible. Where not possible, provide hose connection. Provide manual type air vents. "

4-2.11.7 Addition - Section 1207.2 "Makeup water"

Insert after the last sentence of Section 1207.2:

"Provide automatic makeup water system for each hydronic system in accordance with UFC 3-420-01. Provide pressure gauges up and downstream of the PRV. Provide bypass line with a globe valve for each PRV.

4-2.12 IMC CHAPTER 13 "*FUEL OIL PIPING AND STORAGE*" SUPPLEMENTS.

4-2.12.1 Replacement – Section 1301.1 "Scope"

Replace section 1301.1 with the following:

1301.1 Scope. This chapter governs the design, installation, construction and repair of fuel-oil storage and piping systems. Use Chapter 13 and UFC 3-460-01. If any conflict occurs between Chapter 13 and UFC 3-460-01, the requirements of UFC 3-460-01 take precedence.

4-2.13 IMC CHAPTER 14 "*SOLAR SYSTEMS*" SUPPLEMENTS.

4-2.13.1 Replacement – Section 1401.1 "Scope"

Replace section 1401.1 with the following:

1401.1 Scope. This chapter governs the design, construction, installation, alteration and repair of systems, equipment and appliances intended to use solar energy for space heating or cooling, domestic hot water heating, swimming pool heating or process heating. **\2** Additional guidance is provided in UFC 3-440-01. If any conflict occurs between Chapter 14 and the above UFC, the requirements of the above UFC takes precedence. ***/2/***

CHAPTER 5 DESIGN ANALYSIS AND DRAWING REQUIREMENTS

5-1 DESIGN ANALYSIS.

The Design Analysis must consist of a Basis of Design Narrative and Calculations demonstrating compliance with all UFC requirements.

5-1.1 Basis of Design Narrative Requirements.

In addition to the Basis of Design Narrative requirements indicated in 3-401-01, provide the following:

5-1.1.1 \1\ /1/Design Conditions.

Provide the interior design conditions, including temperature, humidity, filtration, ventilation, air changes, etc., that are used for the design. Provide a tabulation of the design indoor and outdoor heating and cooling conditions for all occupied and unoccupied areas. **\6\ \2** For **Navy** projects, maintain a minimum airflow of four air changes per hour or in accordance with ASHRAE 55 in all regularly occupied spaces during occupied hours. The term “air change” in this particular instance means “air movement” calculated on the basis of four air changes per hour. An example that can satisfy this requirement is the use of ceiling fans. Another example would be for VAV systems where four air changes per hour can be satisfied with the use of fan-powered terminals. **/2/ /6/**

5-1.1.2 Base Utilities.

Describe the source of thermal energy that will be used (i.e. extension of central high pressure steam, hot water, natural gas, or stand-alone heat source with the type of fuel utilized). Where more than one source of thermal energy is considered economically feasible, or where a facility is deemed appropriate for study as defined under the heading entitled “Energy Computations”, include a computerized Life Cycle Cost Analysis to justify the selection.

5-1.1.3 Sustainable Design.

Briefly describe all energy and water conservation features, systems, and components used in the project and the expected energy savings in accordance with UFC 1-200-02 calculation requirements. Describe all features being used for sustainability credits and include the applicable completed forms.

5-1.1.4 Heating System.

Provide a description of the heating system proposed, including an explanation and cost analysis of why this system is preferred over other alternatives. Indicate locations of major components of the system.

5-1.1.5 Cooling System.

Provide a description of the cooling system proposed including an explanation and cost analysis of why this system is preferred over other alternatives. Indicate locations of major components of the system. Identify special humidification or dehumidification requirements. Indicate ASHRAE Standard filter efficiencies and any other special filtration requirements.

5-1.1.6 Ventilation System.

Provide a brief description of the ventilation system proposed. Indicate the outside air ventilation rates in cfm/person (L/s/person) and cfm/ft^2 (L/s/m^2) for various room types. The prescribed rates must be in compliance with ANSI/ASHRAE Standard 62.1. Describe the operation of the ventilation system in summer and winter modes.

5-1.1.7 HVAC Control System.

Briefly describe the HVAC control system type and its functions. If applicable, indicate a requirement to tie into an existing Base-wide EMCS or UMCS/BAS.

\1

/1/

5-1.2 Calculations and Analysis Requirements.

In addition to the calculations and analysis requirements indicated in UFC 3-401-01, provide the following. Identify the source of each calculation including date of reference and chapter, paragraph or section.

5-1.2.1 \1\ Energy Compliance Analysis (ECA).

Provide a Preliminary ECA as required by UFC 3-401-01 and UFC 1-200-02. Provide an updated Final ECA at final submittal. **/1/**

5-1.2.2 "U" Factor Calculations.

Follow the building envelope thermal requirements of UFC 3-101-01, Architecture, Chapter 3. Calculate "U" factors, including thermal bridging, for all composite wall and roof systems using the latest edition of ASHRAE Fundamentals. Include cross sections drawings of all wall and roof systems to supplement the calculations.

5-1.2.3 Heating and Cooling Load Calculations.

Use of professionally recognized, nationally used computerized load calculating program is required. Load calculations are required for each room or zone by the ASHRAE method indicated in the latest edition of the Fundamentals Handbook. Copies of input and output data are required. Psychrometric calculations of each air-conditioning process must be illustrated on psychrometric charts and submitted with the

100% submittal. Clearly identify all points in the conditioning process on the psychrometric chart and verify the sensible, the latent, and the total cooling capacity using the appropriate data from the chart. **\2** Performance requirements should include total cooling capacity, sensible capacity, coil design entering and leaving air conditions (wet and dry bulb temperatures), design airflow rate, face velocities, coil sensible heat ratio, and entering chill water temperature. **/2/** Outputs should demonstrate that indoor design conditions are continuously maintained at both outdoor design criteria.

5-1.2.4 \1\ /1/Outside Air Requirements/Calculations.

Calculate the outside air ventilation requirements as prescribed by the latest edition of ANSI/ASHRAE Standard 62.1. Calculations must consider the factors of "Multiple Spaces", "Ventilation Effectiveness" and "Intermittent or Variable Occupancy" as specified in ANSI/ASHRAE Standard 62.1. Optimize zoning where possible to reduce overall ventilation requirements. Evaluate cost effectiveness of exhaust air and condenser heat recovery. Provide a summary analysis showing compliance with the ventilation requirements. The analysis narrative must document a summary of all factors considered when making design choices regarding IAQ, including alternative ventilation solutions considered and reasons for the selection of the solution chosen. The analysis must also include a room-by-room breakdown of the anticipated **\1** or actual **/1/** number of occupants, the amount of ventilation air required, and any applicable adjustments such as multiple spaces factor, intermittent or variable occupancy factor, the ventilation effectiveness factor, and any other factors such as high relative humidity.

5-1.2.5 Building Air Balance Calculations.

Provide air balance calculations addressing the relationship between supply, return, outside air, and exhaust air quantities and indicating pressurization. Special requirements for space pressurization must be reflected and referenced in the air balance calculations.

5-1.2.6 Duct Pressure Drop Calculations.

Provide pressure drop calculations for all supply, return, outside and exhaust air systems.

5-1.2.7 Hydronic System Pressure Drop Calculations.

Provide pressure drop calculations for all supply and return piping systems.

5-1.2.8 Pipe Expansion Calculations.

Provide pipe stress calculations for all low-pressure 15 psig (103 kPa) steam, condensate and hot water piping systems where pipe diameters exceed 4 inches (100 mm) and/or the length exceeds 100 linear feet (30m) without a directional change. Provide pipe stress calculations for all medium and high-pressure steam and high temperature hot water systems.

5-1.2.9 Equipment Sizing Calculations.

Provide equipment sizing calculations and psychometric calculations and charts, if applicable, to justify the selection of equipment, including the following:

a. Terminal equipment including VAV boxes, fan coil units, etc.

b. Pumps.

c. Control valves and dampers.

d. Meters and metering devices.

e. Fans.

f. Air Handling Units.

g. Chillers.

h. Boilers.

i. Closed Circuit Coolers and Cooling Towers.

5-2 FINAL DRAWING REQUIREMENTS.

In addition to the final drawing requirements indicated in 3-401-01, provide the following:

5-2.1 Site Work.

Show the type and routing of the heat source conveyance system on the drawings. Exterior above and below grade steam and condensate distribution and below grade chilled and hot water distribution plans must be accompanied by profile drawings. Profile drawings must clearly depict all other utilities in the proximity of the new work.

5-2.2 Floor Plans.

When drawing congestion is likely, ductwork and piping should not be shown on the same plan. Single line ductwork layouts are not allowed on final drawings. A two line ductwork layout to scale **\1** must **/1/** be provided. Show thermostat locations on the plans **\1** with clear indication of associated terminal equipment (as applicable). **/1/** Show locations of humidistats on floor plans, when required. Show location of door louvers on floor plans or coordinate with architectural drawings. **\2** Ductwork must not be installed within or beneath slab-on-grade floors. **/2/**

5-2.3 Enlarged Plans.

Provide large-scale details of congested areas on the drawings, with dimensions locating all work relative to structural features of the building.

5-2.4 Mechanical Room Plans.

Mechanical rooms must be drawn at no less than ¼” = 1’-0” (1:50). Congested mechanical rooms must be drawn at no less than ½” = 1’-0” (1:20). Mechanical room plans should be supplemented by at least one section; at least two sections for more complex, congested applications.

5-2.5 Schematic Diagrams.

Provide a 3-dimensional isometric diagram representing the mechanical room piping or a 2-dimensional diagram indicating the entire system. Indicate shutoff valve locations to allow replacement of control valves and system components.

5-2.6 Design Conditions.

Provide a schedule indicating indoor and outdoor design temperatures for each room type.

5-2.7 Equipment Schedules.

Provide an equipment schedule on the drawings indicating actual design conditions, not manufacturer’s catalog data. Include as a minimum:

- Air flow quantities (maximum and minimum if applicable) and static pressure requirements.
- Coil water flow quantities and entering and leaving temperatures.
- Heating and cooling coil sensible and latent capacities including the sensible heat ratio.
- Coil entering and leaving air conditions. For cooling coils include wet bulb **\1** and dry bulb ***/1/*** temperatures at the design flow rate. Ensure these conditions adequately cover the design latent load. For heating coils provide entering and leaving air temperature. Include face velocity for coil selection. **\2** To preclude moisture carryover, coil face velocities must not exceed 167.6 meters per minute (550 feet per minute). ***/2/***
- Coil maximum allowable air side and water side pressure drops.
- Motor electrical characteristics including horsepower, voltage, RPM, and NEMA motor starter size.

5-2.8 Control Valves Schedule.

Provide flow rates, minimum Cv or maximum pressure drop, nominal valve size, service (i.e. steam, hot water, etc.), configuration (i.e. 2-way or 3-way), and action (i.e. modulating or 2-position).

5-2.9 Metric Valve Coefficient.

The metric version of the valve coefficient, Kv, is calculated in cubic meters per second at 1 kPa pressure drop. Do not use Cv, the English version, on a metric project.

5-2.10 Outdoor Air Schedule.

Provide an outdoor air schedule on the drawings. List the outdoor air to each zone with the number of anticipated **\1** or actual **/1/** occupants. Add a footnote to each schedule indicating that the number of occupants listed is for information purposes only.

5-2.11 Vibration Isolator Schedule.

Where vibration and/or noise isolation is required, provide a vibration isolator schedule on the drawings indicating type of isolator, application, and deflection in inches (mm).

5-2.12 Fouling Factors.

Indicate fouling factors for all water-to-air and water-to-water heat exchangers (i.e. coils, converters, chillers, etc). Indicate in the appropriate equipment schedule. Fouling factors must be accompanied with their appropriate **\6** Inch-Pound **/6/** or SI units.

5-2.13 Details.

Details must be edited to reflect the configurations and construction materials shown on the plans.

5-2.14 Access Panels.

Indicate location and size of access panels in floors, walls, and ceilings (except in lay-in tile applications) as required to access valves, smoke dampers, fire dampers, balancing dampers, balancing valves, air vents, drains, duct coils, filters, air flow monitoring stations, equipment, **\1** duct access doors, **/1/** etc. on drawings. **\2** Ensure adequate access for servicing, filter replacements, and coil removal. Sufficiently sized, safe access must be provided for the maintenance of valves, variable air volume (VAV) boxes, dampers, controls, and other HVAC components. **/2/**

5-2.15 Sequence of Operations.

The designer must provide a sequence of operations that includes a step by step instruction for all anticipated modes of heating and cooling system operations to include unoccupied periods. Sequence of operation must include control provisions to maintain **\1** conditions as listed in Chapter 3 of this UFC in paragraph entitled, “Indoor Design Conditions”. **/1/**

5-2.16 Control Diagrams.

Provide for all HVAC systems. Show system control schematics for the sequence of operation specified above on the drawings for each HVAC system. Show controller functions, such as normally open (NO), normally closed (NC), common (C), etc. Indicate all set points. Describe all controlled equipment operating modes, sequence of events, set points, and alarms. For Direct Digital Control (DDC) systems, include an input/output points list and a system architecture schematic.

5-2.17 Roof Fans.

Details of roof exhaust fans must include a requirement for airtight seals between the fan frame and the wood nailer of the roof curb. The details must require the duct of ducted exhaust fans to extend up through the fan curb to a flanged and sealed termination at the top of the curb.

5-2.18 Equipment Supports.

Show hanger rods and structural supports for all ceiling or roof-mounted air handling units, heating/ventilating units, fan coil units, exhaust or supply fans, expansion tanks, etc. in drawing details.

5-2.19 Drain Lines.

Show condensate drain lines from air handling units, fan coil units, etc. Indicate required depth of water trap. Show slope from drain pan.

5-2.20 Balance Dampers.

All dampers and their intended locations must be clearly delineated on the floor plans.

5-2.21 Ductwork Testing.

Indicate those HVAC duct systems to be leak tested on the contract drawings. Specify the test type and test pressure for each duct system (supply air, return air, exhaust air, and outside air ductwork) subject to testing.

5-2.22 Duct Construction Classifications.

Indicate duct static pressure, seal and leakage classifications on the drawings in accordance with SMACNA-HVAC Air Duct Leakage Test Manual. Include a completed “Ductwork Construction and Leakage Testing Table” on the drawings. Table 6-2 provides an example of this table.

5-2.23 \1\ Make-up Water. /1/

Detail all accessories, to include pressure reducing valves (PRV), relief valves, and backflow preventers. Show pressure reducing and relief valve pressure settings. **\1** Provide separate make-up water piping specialties for chilled and hot water systems. **/1/**

5-2.24 Flow and Slope Arrows.

Indicate the flow direction of pipe on the drawings. Show slope direction and rate of slope on all piping systems. **\1** Piping systems also include sanitary, steam, compressed air, condensate drain, and any other gravity drained systems. **/1/**

5-2.25 Guides for Piping.

Show pipe guide locations on all aboveground anchored piping. **\2** Route chilled water piping through pipe chases. Route chilled water piping through hallways where feasible. Conceal piping in the walls or ceilings of occupied spaces where it is not feasible to route through pipe chases and hallways. **/2/ \5** Route chilled water piping in accessible locations to the maximum extent possible for ease of maintenance or replacement. **/5/**

5-2.26 Pipe Anchors.

Show anchor locations on plans. Provide anchor detail(s).

5-2.27 Pressure Gauges.

Indicate pressure gauge ranges; system operating pressures should be midrange on the graduated scale.

5-2.28 Air Vents.

Show location of air vents required in piping systems.

5-2.29 Balance Valves.

Contract drawings must specify the valve size and flow for each application. When an existing system is modified, provide all information required for re-balancing in the construction documents. Detail installation of all flow control balancing valves.

5-2.30 Kitchen Hood Diagram.

Provide a detailed air balance diagram on the drawings for every kitchen/dining facility design to show compliance with the ventilation requirements. Indicate required capture velocities and capture distances for all hoods on the drawings. Provide notes and contractor instructions on plans indicating that fan airflows shown for hoods are approximate and requiring the contractor to balance the system to achieve the capture velocities indicated. The scheduled fan and motor size must allow for adjustment of the airflow.

Table 6-2 Ductwork Construction and Leakage Testing Table Example

System	Duct Pressure Class				Supply				Return/ Outside Air		Duct Test Pressure: Inches of Water Column	Notes
	Inches of Water Column				Round/Oval		Rectangular					
	Supply Duct	Return Duct	Exhaust Duct	Outside Air Duct	Duct Seal Class	Duct Leak Class	Duct Seal Class	Duct Leak Class	Duct Seal Class	Duct Leak Class		
Packaged Rooftop - VAV	4	-	-	-	A	3	A	6	-	-	4.0	1
	-	-2	-	-	-	-	-	-	A	24	2.0	1
Packaged Rooftop -CV	2	-	-	-	-	-	A	12	-	-	2.0	1
	-	-1	-	-	-	-	-	-	A	24	1.0	1
Air Handling Unit with Economizer-Constant Volume	2	-	-	-	A	6	A	12	-	-	2.0	1
	-	-1	-	-	-	-	-	-	A	24	1.0	1
	-	-	-1	-	-	-	A	24	-	-	1.0	1
	-	-	-	-1	-	-	-	-	A	24	1.0	1
Series VAV Terminal Boxes	2	-	-	-	-	-	A	12	-	-	2.0	1
	-	-1	-	-	-	-	-	-	A	24	1.0	1
Exhaust Duct	-		-1	-	-	-	A	24	-	-	1.0	1

Notes:

1. Test in accordance with UFGS 23 05 93, Testing, Adjusting, and Balancing for HVAC and the procedures in SMACNA HVAC Air Duct Leakage Test Manual

2. Each piece of air moving equipment on the project must be shown in the schedule and the required pressure class, duct seal class, duct leak class and test pressure must be indicated. Duct seal class A is required on all duct systems.

APPENDIX B BEST PRACTICES

B-1 OUTSIDE AIR INTAKES.

Locate outdoor air intakes in areas where the potential for air contamination is lowest. Basic guidelines include the following:

- Maximize distance between intakes and cooling towers, plumbing vents, loading docks, traffic, etc.
- Maintain a minimum distance of 10 meters (30 feet) between intakes and exhausts, more if possible.
- Locate intakes and exhausts on different building faces.

B-2 INDEPENDENT VENTILATION SYSTEMS.

Ventilation systems that are independent of the primary air supply and distribution systems can provide benefits such as increased humidity control, reduced amount of ventilation air than may be otherwise required, and increased equipment operating efficiency.

B-3 PURGE MODE.

Where desirable, the designer may incorporate a purge mode into system design. This mode could be used, for example, to purge the building with outside air during off-hours or to purge an area of the building undergoing maintenance, such as painting.

B-4 FILTRATION.

For administrative facilities, commercial facilities, and similar facility occupancy classifications where indoor air quality is of primary concern, filter the combined supply air, including return and outside air, with a combination of prefilter(s) with a MERV of 8 and final filter(s) with a MERV of 13 when tested in accordance with ASHRAE Standard 52.2. Where the use of extended surface nonsupported pocket (bag) or cartridge filters is unacceptable and satisfactory indoor quality can be achieved using extended surface filters, the use of prefilters is not required. Where practical, provide separate filtration or other means to clean the outdoor air, typically equivalent to that used for the combined air stream, prior to mixing it with the return air. **\1** Provide separate static pressure switch for each filter bank. **/1/** Due to the decrease in system airflow as the pressure drop across the filter increases, size fans for the “dirty” filter condition. This will ensure that each fan has adequate capacity to deliver the design airflow as the filter becomes loaded.

B-5 COMFORT VENTILATION.

Gravity ventilation is rarely adequate as a reliable source for comfort ventilation. It can be used in high-bay areas that are rarely occupied, such as storage buildings, or in areas that are difficult to ventilate, such as hangars. Consider nighttime air flushing of spaces, multi-speed fans, increased insulation, improved shading, and building site to improve the effectiveness of comfort ventilation.

B-6 FAN COIL UNITS.

The limitations of fan-coil units with regards to latent loads associated with simply providing adequate ventilation for occupancies such as living quarters make them unsuitable as the only means of cooling and dehumidification in most locations and for most occupancies, unless the fan coil unit is equipped with a split coil to allow for the continuous conditioning of outside air.

B-7 \1\ DEDICATED OUTSIDE AIR SYSTEM (DOAS). /1/

Consider using a separate system for outdoor air where necessary to maintain a sensible heat ratio of the mixed air entering the primary air-conditioning unit within the required limits of commercially available equipment and/or to reduce corrosive, salt-laden air from entering the primary air distribution system.

B-8 INFRARED HEATING.

Consider infrared radiant heating for high-bay areas or where spot heating is required. Gas, oil, and electricity may be considered as fuel sources.

B-9 RELIABILITY.

For Data Processing and Electronic Office areas use two or more smaller units to satisfy the required cooling capacity. This will generally reduce energy consumption at partial cooling loads and will also increase overall system reliability.

B-10 PHOTOCOPIERS & LASER PRINTERS.

If possible, locate photocopiers and laser printers in a separate room or group them together and provide local exhaust. Maintain the separate room at a negative pressure relative to adjacent areas by transferring air from these adjacent areas to the separate room. Do not add the air exhausted from the separate room or local exhaust to the return air or transfer it to any other areas. Coordinate with the architect to place areas requiring negative pressure relative to other spaces in the interior of the building to minimize the chances for negative pressure induced infiltration.

\4

B-11 VRF SYSTEMS.

A variable refrigerant flow (VRF) system is defined as any system containing two or more interconnected DX refrigerant coils that are designed for installation within a facility's occupied space. They are 'ductless' A/C or heat pump systems in which refrigerant is moved from fan-coil unit to fan-coil unit within the occupied facility spaces.

DoD has placed special requirements on these systems due to their inherent risks. Three primary risk areas have been identified: 1) VRF systems currently contain proprietary hardware and software in conflict with 10 USC 2867, 2) VRF systems increase the risk of adverse mission impacts due to **\8** EPA leak-rate rules on HFC refrigerant systems **/8/** and the challenge of locating and repairing a leak in often hard to access areas, and 3) VRF systems have uncertain life-cycle costs (LCC) making comparisons with traditional HVAC systems difficult.

1. **Proprietary Systems: \8** See paragraph 1-8 for Open Control System Requirements. **/8/** To our knowledge, all VRF systems currently in production use a proprietary control network and thus fail to meet the requirements of **\8** specifications UFGS 25 10 10, UFGS 23 09 00, UFGS 23 09 23.01 and UFGS 23 09 23.02. **/8/** The adoption and use of systems with proprietary control networks is in conflict with the legal requirement of adopting systems with an 'open protocol'. While many VRF systems can connect to a LonWorks or BACnet DDC system through a Gateway device, this does not meet the requirements of an Open system and installation of proprietary networks communicating through a gateway is not permitted by the specifications **\8** unless the system meets the specific requirements and approvals for an exception defined in UFC 3-410-02. **/8/** Further, the facility owner remains dependent upon the original vendor for maintenance and support which also violates the Open system requirements of the specifications. **\8\ /8/**

2. **\8\ EPA HFC-Refrigerant Regulations:** See paragraph 1-9 for EPA HFC-Refrigerant Regulations. **/8/** VRF systems have attributes that significantly increase DoD exposure to adverse impacts **\8** concerning refrigerant. **/8/** For instance, VRF systems have refrigerant line lengths much greater than traditional DX systems. These lines extend through the occupied space and are mounted above ceilings and through walls. Tracing and repairing a leak on a VRF system is many times more difficult with an additional access requirement of maintenance crews to the workspace environment. In classified workspaces, shut down of the mission may be necessary to affect repairs.

3. **Uncertain Life-Cycle Costs:** Currently, VRF systems have an above-average initial capital cost. However, the out-year maintenance costs and labor man-hours are uncertain as VRF systems are relatively new within the U.S. For instance, there is a lack of information on the rate of component wear to predict replacement intervals. ASHRAE Handbooks show a service life of 15-yrs for DX systems yet some life-cycle cost studies indicate a VRF expected life of 30-yrs. In addition, the proprietary nature of VRF systems implies a disproportionate reliance on contract repair and proprietary parts vice in-house maintenance.

The DoD will continue to monitor and/or investigate these risk elements and update the UFC as appropriate.

/4/

B-12 \5\ CAPACITY OF EQUIPMENT.

Select air conditioning equipment to ensure the minimum anticipated cooling load is larger than the capacity of the lowest stage of the equipment. Use multiple air conditioning units if this is not possible. **/5/**

B-13 \5\ LOCATION OF EXHAUST REGISTERS FOR MOISTURE REMOVAL.

Locate exhaust registers as close as possible to the source of the moisture being exhausted. **/5/**

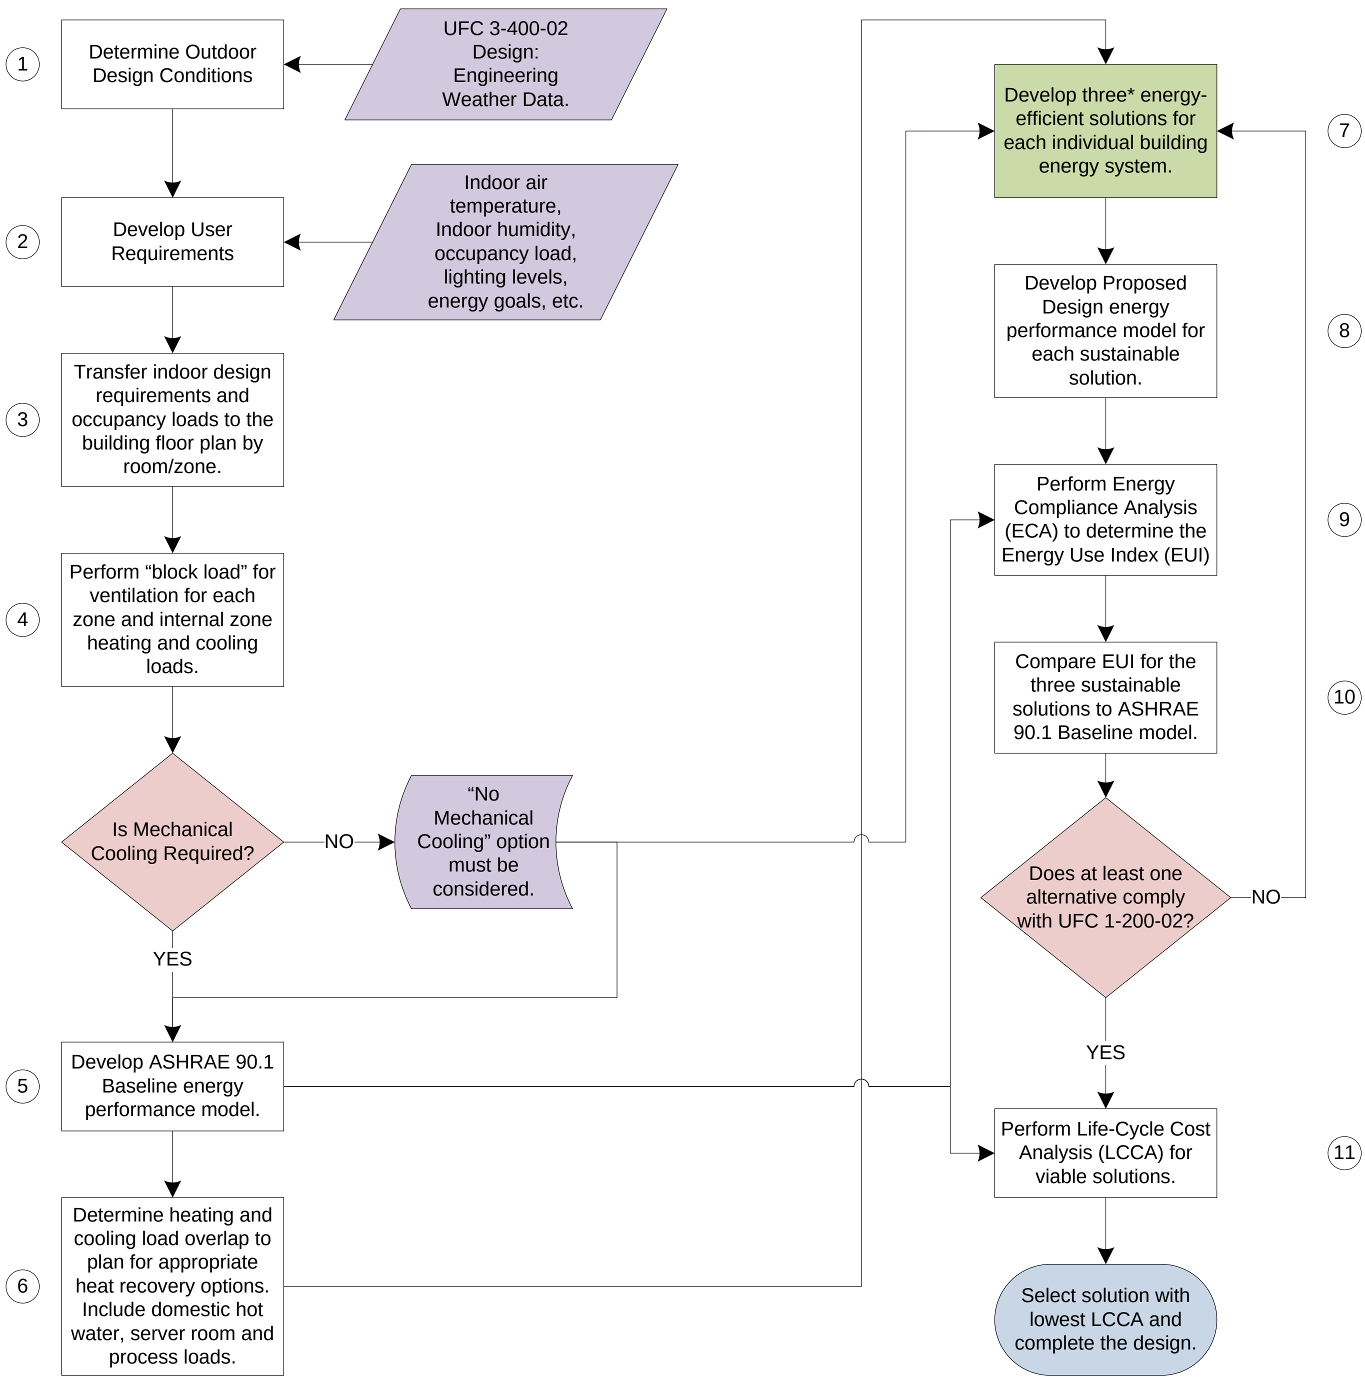
\6\ *For Navy projects: Metering for the building (facility wide consumption) needs to be coordinated with the RFP and base utilities. DDC monitoring, accumulating, and totalizing is not required for utilities connected to the AMI metering system or if the base has a base wide utilities smart metering system. Sub metering for the different utilities shall be connected to the DDC as required per the RFP and ASHRAE 90.1 requirements. /6/

APPENDIX E – HVAC SYSTEM SELECTION FLOW CHART

\1\



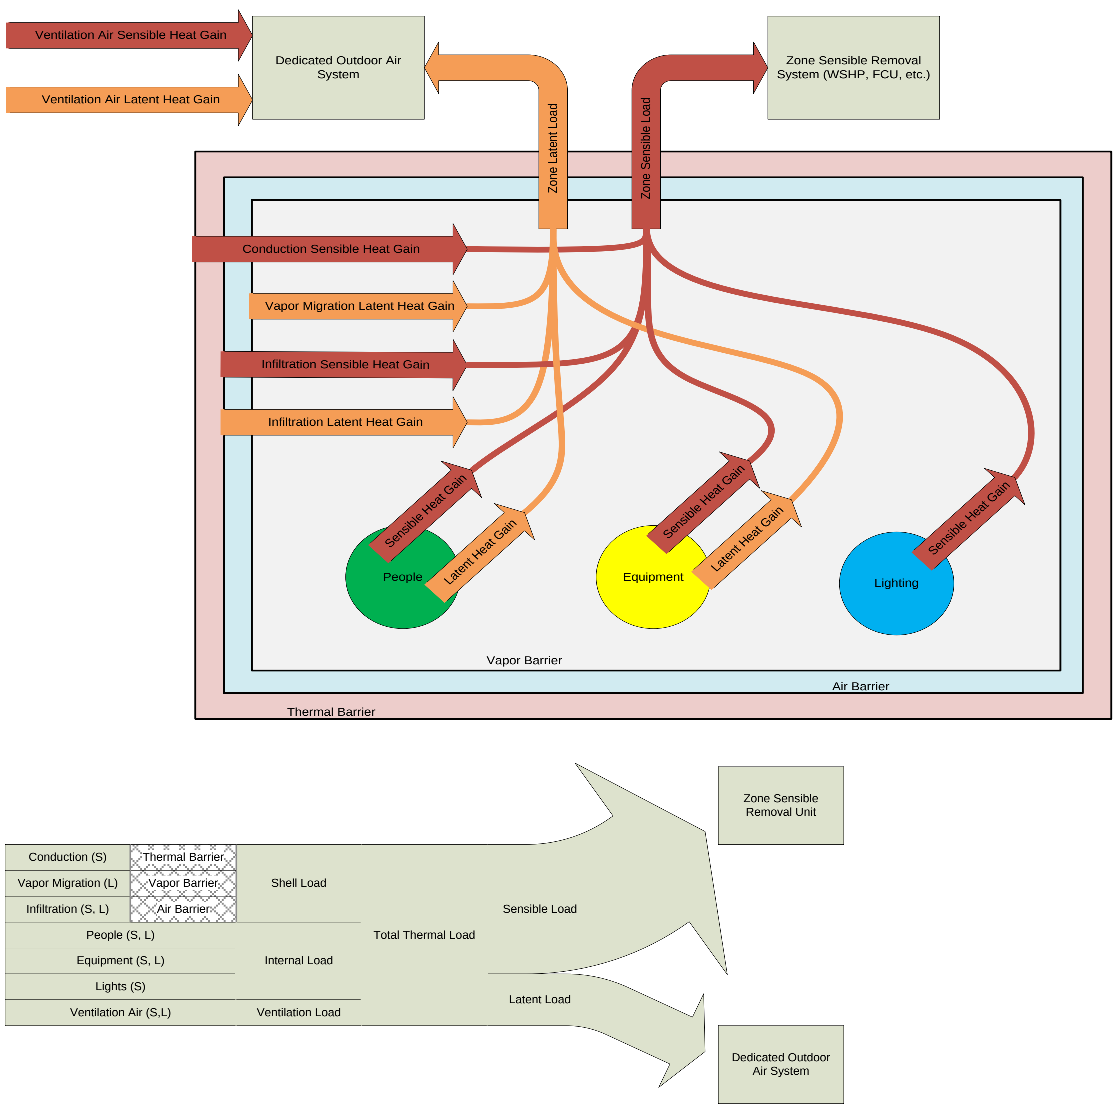
This diagram is interactive with the rest of this UFC. The reader may navigate to the section of the UFC governing each step by clicking on that step.

*For some applications, three technically-feasible solutions may not exist. Develop as many solutions as are practical for these applications. Use Appendix F for Army projects only for examples of 90% energy-efficient HVAC system solutions. **/1/**

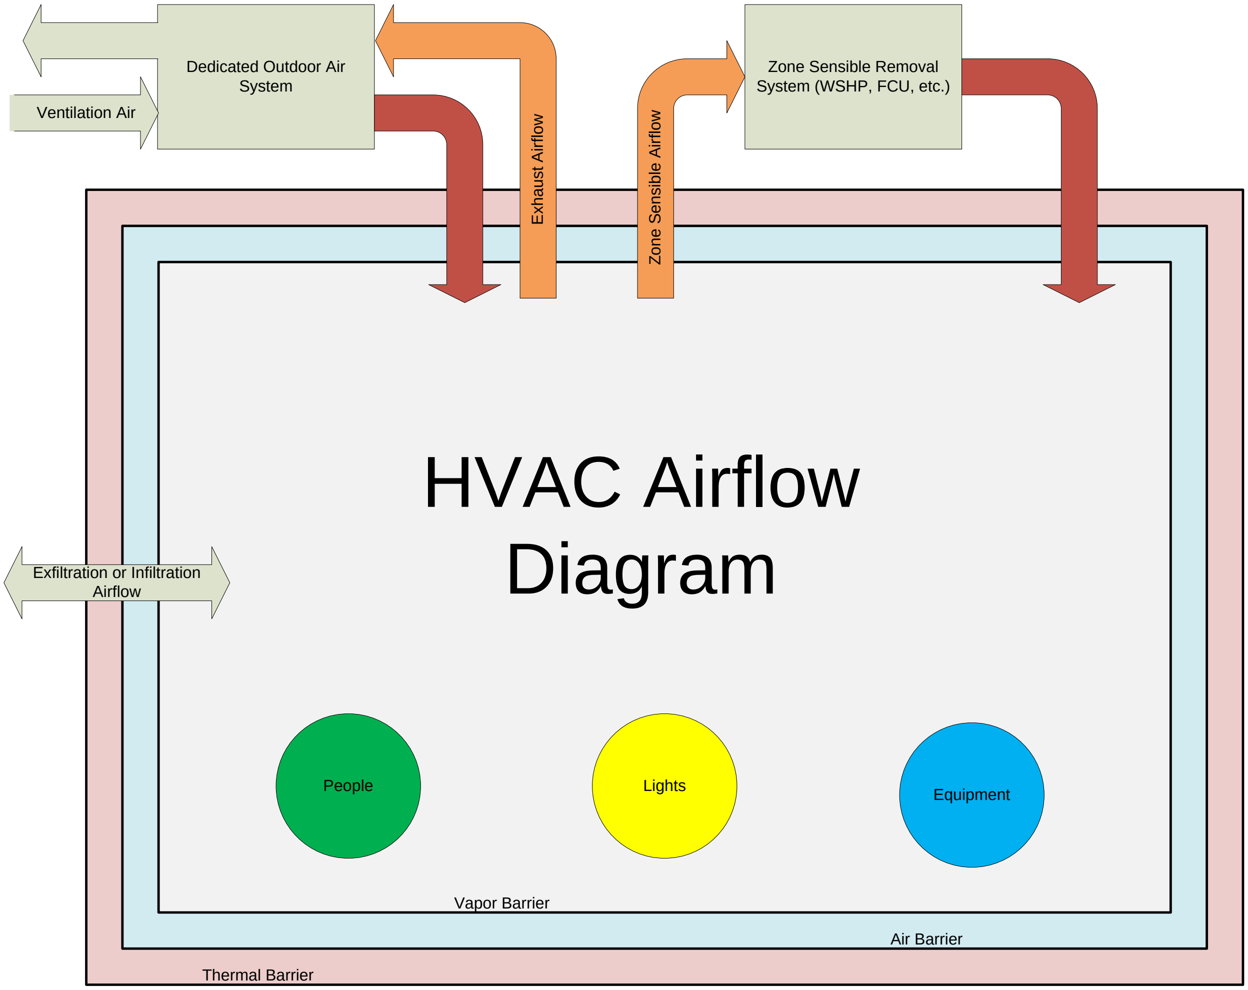
APPENDIX F – 90% ENERGY-EFFICIENT HVAC SOLUTIONS (FOR ARMY PROJECTS ONLY)

\1 The following present schematic solutions that have proven to be energy-efficient solutions for HVAC systems. The generic load-flow and airflow schematics are presented first, followed by specific equipment-based schematic examples.

HVAC Load Flow Diagram



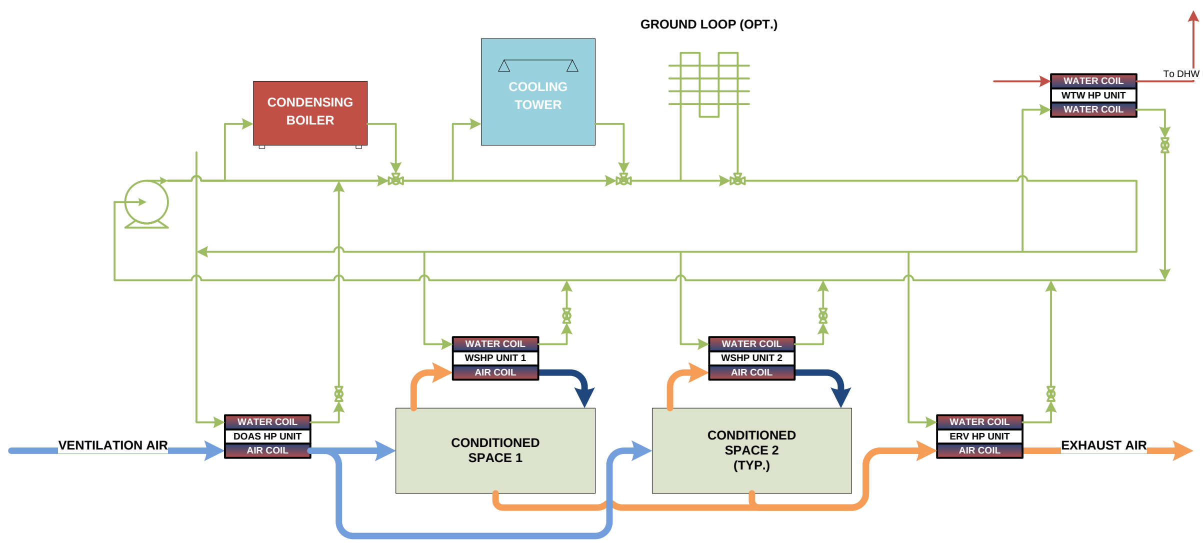
The HVAC Load Flow Diagram shows the components of HVAC load that are typically considered in an HVAC System Analysis. Per this UFC, the Dedicated Outdoor Air System (DOAS) should handle the latent loads for both the Ventilation Air and the Zone. The DOAS is typically a stand-alone, constant-pressure Variable Air Volume (VAV) system. The DOAS supplies each zone with outside air through a two-position VAV box that is operated in accordance with the sequence of operation. The Zone Sensible Removal System will maintain the zone temperature.



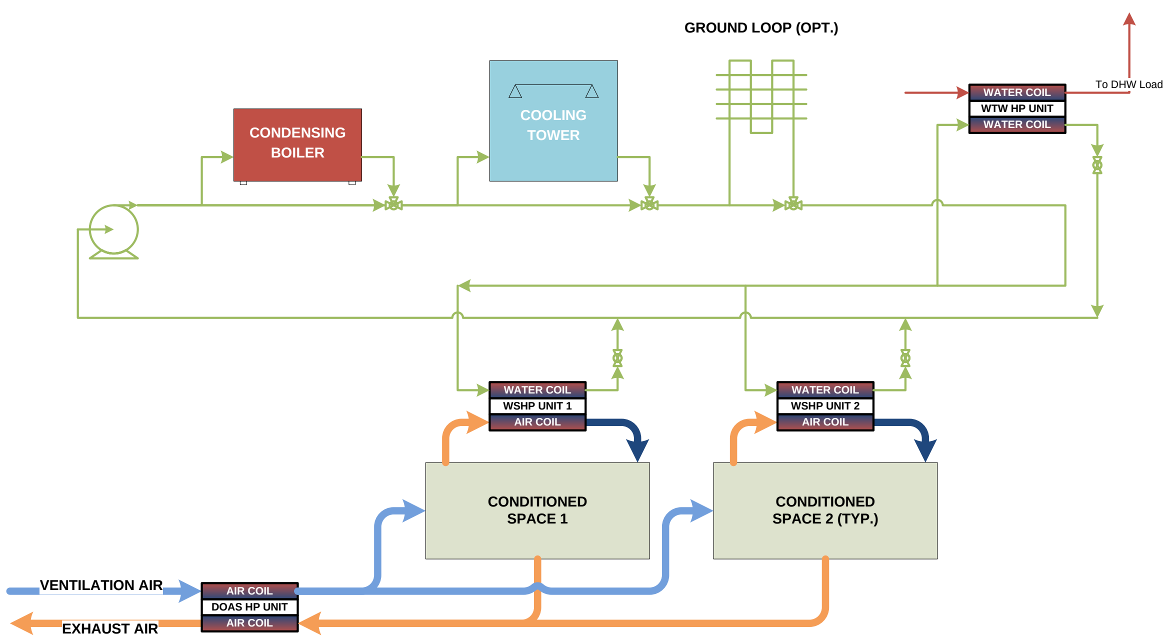
The HVAC Airflow Diagram shows the typical airflow considerations for a design. HVAC designs should provide a one-line diagram of the air flow to each zone, within each zone and, where there is a required pressure differential, between zones. The peak sensible and latent load for each zone should be indicated on the diagram and assigned to the appropriate system.

The diagrams on the following pages present equipment-based schematics for energy-efficient systems.

Energy Recovery Loop with separate DOAS and Exhaust ERV



Energy Recovery Loop with integrated DOAS and Exhaust ERV



Fan Coil Units with conventional DOAS
(optional Heat Pump Chiller)

Evaluation of District and Islanded/Decentralized Utility Options with Life-Cycle Cost Analysis Guidance

Enclosure

DEPARTMENT OF THE ARMY
U.S. ARMY CORPS OF ENGINEERS
441 G STREET, NW
WASHINGTON, DC 20314-1000

CEMP-NWD

DEC 18 2012

MEMORANDUM FOR Director of Operations, MG Aycock, Office of the Assistant Chief of Staff for Installation Management (DAIM-OD), 600 Army Pentagon, Washington, DC20310-0600

SUBJECT: District and Islanded/Decentralized Heating Systems selection evaluation with Life Cycle Cost Analysis Guidance

1. This is in response to your request to update technical guidance on "district and islanded/decentralized" heating systems selection resulting from our studies of Joint Base Lewis McCord and Fort Carson. The guidance will help to bring consistency and alignment across the Army.

2. The attached enclosure of the "Evaluation of District and Islanded/Decentralized Utility Options with Life Cycle Cost Analysis Guidance" is ready for distribution. This guidance has been coordinated with Headquarters, Installation Management Command (IMCOM) and your staff, and they are in agreement with its content. We will now commence coordination with the Air Force and Navy to incorporate this checklist into the existing UFC, Central Heating Plants, UFC 3-430-08N.

3. The study that produced the attached checklist concluded that recapitalization of existing central plants in kind are often not the most life-cycle cost effective solution. New technologies, strategies and alternative fuels may result in lower life cycle costs, and efficiency of central plants improves when distribution networks are minimized through denser development and infill of existing sites. Care must be exercised when completing the checklist to ensure that alternatives systems are considered appropriately.

4. Request your office establish policy and distribute to all Landholding Commands. Upon your approval of the policy, USACE will follow through with implementing guidance in the UFC and to our Districts.

5. Questions regarding the interim guidance should be directed to Mr. Robert Rizzieri, HQUSACE, 202-761-7769, Robert.rizzieri@us.army.mil.

LLOYD C. CALDWELL, P.E.
Director of Military Programs

Evaluation of District and Islanded/Decentralized Utility Options

with Life-Cycle Cost Analysis Guidance

Army Installations are under increasing pressures to ensure capability to meet their designated missions while reducing their overall energy footprint within the local community in a fiscally responsible manner. This guidance is intended to be applied to District and Islanded/Decentralized systems such as District hot water or steam distribution systems, Islanded hot water distribution systems, and District co-generation systems, among others. Definitions of District and Islanded/Decentralized systems can be found at the end of this guidance. This guidance shall be applied to all new construction projects and projects where capital expenditures are being used to replace generation equipment and/or the distribution network for the purpose of rehabilitation. Emergency repairs are excluded from the studies described herein.

1. Evaluations to determine the most cost effective method for delivering utilities to facilities shall follow this decision making process:
    a. Define scope and system requirements
    b. Define alternatives to be considered
    c. Develop Life-Cycle Cost Analysis
    d. Determine most cost effective option

2. Questions to consider when evaluating how utilities will be delivered to facilities include:
    a. Is this a new construction project or project expending capital to replace generation equipment and/or the distribution network for the purpose of rehabilitation?
    b. What fuel sources are available?
    c. What is the required output (heat, hot water, electricity)?
    d. What is the anticipated utility load factor?

3. Evaluations to determine the most cost effective method for delivering utilities to facilities shall comply with the following minimum requirements:
    a. Be completed in the context of the broader Federal and Army energy mandates.
        i. Energy Policy Act of 2005
        ii. Energy Independence and Security Act of 2007
        iii. National Defense Authorization Act
        iv. Office of The Assistant Secretary of the Army for Installations and Environment Strategic Plan
        v. Army Installation Management Community Campaign Plan
        vi. Other: ________________________

    b. Include alternatives to the base case that each meets the defined utility needs using different technologies or bundling of technologies. Although a multi-step transition plan may be used to modernize existing legacy equipment, it is imperative that the alternatives under comparison each meet the defined utility needs. A minimum of three alternatives shall be considered in each study.
        i. Alternative 1 (Base Case): ________________________
        ii. Alternative 2: ________________________
        iii. Alternative 3: ________________________
        iv. Alternative 4: ________________________
        v. Alternative 5: ________________________

Evaluation of District and Islanded/Decentralized Utility Options

with Life-Cycle Cost Analysis Guidance

c. Include a Life-Cycle Cost Analysis (LCCA) which has been conducted for each alternative under consideration. Major LCCA criteria are described in Paragraph 5 and LCCA procedures are described in Paragraph 6.
   i. LCCA Completed by: ___________________________

d. Include sufficient detailed information such that an independent technical review (ITR) can duplicate the results. Assumptions made for the required end state and base and comparison cases shall be clearly identified and documented.
   i. Assumptions have been clearly documented in evaluation

e. Receive an independent technical review (ITR). The ITR shall be a formal review of the study to ensure that planned and completed work complies with predetermined requirements, industry standards, and engineering practices. The ITR team shall be comprised of qualified individuals who have technical expertise applicable to the technologies being studied and shall not have been directly involved in generating the study under review.
   i. USACE is available to support Installations or other Army Offices in validating the qualifications of the ITR team under consideration. Contact HQUSACE, Chief Installation Support, CEMP-CI, at 202-761-5763 for assistance in confirming that the firm or organization being considered to perform the ITR is fully qualified.
   ii. USACE has qualified offices that can perform the described ITRs upon request.
   iii. ITR Conducted by: ___________________________

f. Include a narrative describing which alternative was determined to be most cost effective. This decision will be guided by the results of the LCCA.
   i. Most cost effective option identified and explained

g. Include a narrative describing the appropriate programming course of actions required to implement the recommended alternative. Programming course of action shall consider Army regulations on project programming and work classification.

h. Army shall review new laws and policies to determine if study re-evaluations are warranted. Army and installations shall review mission changes to determine if study re-evaluation is warranted.

4. At a minimum, the following alternatives shall be considered where applicable:
   a. Base case. When there is an existing system the base case alternative shall assume no change to the system.

   b. Completely Decentralized. New or renovated solution that meets individual utility needs of buildings using local, dedicated equipment at each facility. Example: Heating and domestic hot water needs of buildings are met using local dedicated boilers at each facility.

   c. Completely District. New or renovated solution that meets individual utility needs of buildings using one district energy plant (which may or may not include co-generation or tri-generation) with supply and return

Evaluation of District and Islanded/Decentralized Utility Options

with Life-Cycle Cost Analysis Guidance

lines between the buildings and district plant. Example: Heating and domestic hot water needs of buildings are met using a single district heating plant with supply and return lines between the buildings and district heating plant.

d. Island. New or renovated solution that meets individual utility needs of buildings using a combination of decentralized solutions in clusters larger than individual buildings. Example: Heating and domestic hot water needs of buildings are met using a combination of decentralized solutions in clusters larger than individual buildings.

5. The following factors have been determined as having primary influence in LCCA outcomes for provision of building utilities. It is imperative that sound economic and engineering data be developed to support each of the following factors and all calculations and assumptions be clearly documented:
    a. First costs of installation
        i. Capital cost of new equipment: Pricing shall be based on quotations received from manufacturers. Where quotations from manufacturers are not available pricing shall be based on RS Means data. Costs shall be comprehensive and include all components required for a complete and usable system to include distribution network costs.
        ii. Distribution network costs: These are often a significant percentage of capital costs and should be clearly identified for District and Islanded system analyses.
        iii. Labor for installation priced per location: Pricing shall be based on data from recent projects at the Army Installation on projects of comparable scope and scale. Where such projects do not exist pricing shall be based on RS Means data.
    b. Maintenance costs
        i. Required Maintenance: Hours shall be based on manufacturer provided component and system maintenance requirements and life expectancies. If components and/or systems are recommended to be replaced within the 40 year study period the manufacturer's recommendations shall be accounted for in the LCCA.
        ii. Labor Rates: Pricing shall be based on data from existing Army Installation maintenance contracts of comparable scope and scale. Where such contracts do not exist pricing shall be based on RS Means data.
    c. Operations cost
        i. Energy and fuel prices including consideration for interruptible opportunities: Pricing shall be based on current prices experienced at the Installation. Escalation rates shall be determined using the most current version of the Annual Supplement to NIST Handbook 135 and NBS Special Publication 709, titled "Energy Price Indices and Discount Factors for Life-Cycle Cost Analysis" and using information from the Department of Energy, Energy Information Administration.
        ii. Energy and fuel used by system: Usage data shall be based on measured use for existing facilities. If measured data does not exist, usage shall be estimated using engineering analysis. For planned projects consumption rates shall be estimated using engineering analysis. Fuel consumption rates shall be obtained from the manufacturer for the life of the equipment being considered. Occupancy schedules and heating/cooling degree days shall be used to determine an average system load factor.

Evaluation of District and Islanded/Decentralized Utility Options

with Life-Cycle Cost Analysis Guidance

System load factor and equipment fuel consumption rates shall be used to estimate the total fuel consumption and thus the life-cycle cost for fuel use.

iii. Labor for operation priced per location: Pricing shall be based on data from existing Army Installation operation contracts of comparable scope and scale. Where such contracts do not exist pricing shall be based on RS Means data.

Primary Factor	Alternative 1 (Base Case)	Alternative 2 (New, Completely Decentralized)	Alternative 3 (New, Completely District)	Alternative 4 (Hybrid)	Alternative 5 (______)
Capital cost of new equipment ($)					
Capital cost of distribution network ($)					
Labor for installation of new equipment ($)					
Manufacturer recommended maintenance (hours)					
Labor required for maintenance ($)					
Fuel price ($)					
Fuel usage (appropriate units for fuel used)					
Labor required for operations ($)					

d. Note: The factors above are not all inclusive factors for a comprehensive LCCA on provision of building utilities. Additional factors identified in NIST Handbook 135 which shall be considered in the LCCA include but are not limited to the following:

i. Renovation and demolition costs: Pricing shall be based on data from recent projects at the Army Installation on projects of comparable scope and scale. Where such projects do not exist pricing shall be based on RS Means data.

ii. Costs for water treatment: Pricing shall be based on data from recent projects at the Army Installation on projects of comparable scope and scale. Where such projects do not exist pricing shall be based on RS Means data.

Evaluation of District and Islanded/Decentralized Utility Options

with Life-Cycle Cost Analysis Guidance

iii. Costs associated with concurrent applicable projects: Ensure cost savings associated with concurrent projects that open roads, trenches, or accomplish other projects that would support the alternative under consideration are adequately captured.
iv. Requirements for equipment redundancy: Costs shall be included when backup equipment is required to meet statutory standby requirements (Example: generator for critical hospital loads).
v. Salvage value at end of useful life: Pricing shall be based on data from recent projects at the Army Installation on projects of comparable scope and scale. Where such projects do not exist pricing shall be based on RS Means data.

6. The Life-Cycle Cost Analysis identified above shall be conducted in accordance with the most current version of the National Institute of Standards and Technology (NIST) Handbook 135, "Life-Cycle Costing Manual for the Federal Energy Management Program", associated supplements and U.S. Army Corps of Engineers Engineering and Construction Bulletin 2012-13, "Energy Implementation Guidance Update, ASHRAE 189.1, Life-Cycle Cost Analysis Requirements". The study period shall be set at 40 years. Final LCCA documentation shall include a comprehensive summary that defines each alternative considered with assumptions and references provided for each parameter; the assumptions shall be clear and of a level of detail sufficient to be used by a third party to duplicate the results of the LCCA. LCCAs shall be completed using the same matrix of information consistently across alternatives to ensure a fair comparison is made between alternatives. For example, building loads and cost of fuel shall be consistent between base and alternatives.
   a. LCCA complies with NIST Handbook 135
   b. LCCA study period set at 40 years
   c. Comprehensive summary defining alternatives considered with assumptions and references for each parameter is provided
   d. Alternatives use same matrix of information
   e. LCCA for each alternative reflects all costs associated with meeting the identified long term energy goals

7. The alternative whose LCCA has the lowest life cycle cost is considered the most cost effective solution. Further guidance on analyzing the results of LCCAs can be found in NIST Handbook 135.

8. Definitions
   a. **District System**. A community scale utility system connecting multiple users through a distribution network that provides heating, domestic hot water, and/or electricity to facilities.

   b. **Islanded/Decentralized System**. A utility system for providing heating, domestic hot water, and/or electricity to one or more co-located buildings at or near the point of use with a limited distribution network.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	2 March 2020	Changed Preparing Activity from Navy to Army. Added paragraph 2-4 USE OF PROPRIETARY NETWORKS, to accommodate new requirements for an exception to the use of open protocols within specific system types when certain criteria are met.
2	1 April 2021	Changed “UFC 3-401-01” to UFC 3-470-01” in paragraphs 1-2.1.3 and 1-3.2.3. Changed “APPENDIX A” to “APPENDIX D” in paragraph 5-4.2. Deleted first sentence of paragraph 6-6.1.

This UFC supersedes UFC 3-410-02, dated 5 2012.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-410-02 *Direct Digital Control for HVAC and Building Control Systems,* formerly *LonWorks® Direct Digital Control for HVAC and Other Local Building Systems*

Superseding: None

Description: Design guidance and requirements for Open Direct Digital Control Systems. The guidance is particularly detailed due to the complex and definitive requirements required for the design of a digital control system and for the procurement of an Open system that supports integration into a multi-vendor system.

Reasons for Document: Initial version of this UFC covered LNS-Based LonWorks only. Extensive revisions were required to accommodate BACnet and the Niagara Framework.

Impact: There are negligible cost impacts; however, these benefits should be realized:

- The ability to procure systems competitively that can be integrated into a single supervisory system rather than requiring the procurement of several supervisory systems.

- Competitive procurement of control systems will result in cost savings. . Describe the impact. This should describe impact on design cost, initial cost, energy savings, or life cycle costs.

Unification Issues: None

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Designers, installers, and operations and maintenance (O&M) staff have struggled with the complexities and incompatibilities of multi-vendor building automation direct digital control (DDC) systems almost since they were introduced in the 1980's. DDC systems are routinely designed and procured on a building-by-building or sub-system by sub-system basis, most notably for heating, ventilating, and air-conditioning (HVAC) systems. In the absence of specifications and criteria for Open systems, Government procurement rules which require competitive bidding make it extremely difficult if not impossible to procure new DDC systems that are compatible with existing ones and that are also compatible with a basewide or campus-wide supervisory system.

In the absence of sole-source procurement, new but incompatible DDC systems result at best in inefficiencies and at worst in complex and non-functioning systems. This is a problem with system-to-system data sharing and is a problem where multiple individual systems need to communicate with a supervisory monitoring and control (front-end) system such as a Utility Monitoring and Control System (UMCS) specified by UFGS 25 10 10. This inability to interoperate is a result of Closed systems due to vendor-specific proprietary elements. In contrast, Open DDC systems are now available. An Open DDC system is characterized by the ability for any qualified entity to readily modify, operate, upgrade, and perform retrofits on the DDC system. An Open system:

- Permits multiple devices from multiple vendors to readily exchange information.
- Provides the capability to easily replace any device with another device procured from multiple sources.
- May have proprietary components within devices, but these proprietary components must be a small percentage of the overall device.
- May have fees associated with use of certain components.

In short, an Open system is one (integrated, multi-vendor) system where there is no future dependence on any one Contractor or controls vendor.

1-1.1 Open system benefits and capabilities.

Open communications and data sharing between multi-vendor systems and with a third party supervisory system is necessary to achieve effective system operation. Some of the benefits and capabilities of Open multi-vendor DDC systems include:

- Competitive procurement, most notably at the building and sub-system level.
- An operator workstation/user interface that provides for the same look and feel for monitoring and control regardless of which vendor's DDC system or sub-

system an operator is viewing. As a result, system operators need only become proficient with one user interface.

- An operator workstation/user interface (software) that provides for management of base-wide system operations such as: remote alarm reporting, remote scheduling (on/off control), remote set point override, data logging and reports, energy management including load shedding, utilities monitoring/measurement for the purpose of monitoring energy performance contracts, and initial diagnosis of service calls. The ability to monitor multiple vendor's systems from a single Operator Workstation/User Interface (OWS/UI) with the same look and feel across all vendor's systems. As a result, through a single user interface, system operators and managers are afforded the means to efficiently and effectively manage base-wide operations.

- A whole-building approach to systems integration. This includes the efficient inter-connection of HVAC control sub-systems. For example, terminal unit equipment, such as VAV boxes can be readily interfaced to the servicing air handler to provide a call for cooling. In addition, the whole-building approach provides the capability for integrating non-HVAC sub-systems such as fire and security

- (For a LonWorks system) groundwork for establishment of a non-proprietary and openly accessible 'point-database' in support of communications-network management requirements.

1-1.2 References to UFGS 23 09 23.XX.

This UFC is intended to be used with UFGS 23 09 00 (Instrumentation and Control for HVAC), UFGS 23 09 23.01 (LonWorks® Direct Digital Control for HVAC and Other Building Systems), and UFGS 23 09 23.02 (BACnet Direct Digital Control for HVAC and Other Building Systems). This document will often use "UFGS 23 09 23.XX" when the intent is to refer to both the LonWorks and BACnet UFGS.

1-2 OPEN SYSTEM TECHNOLOGIES.

The Open systems approach described in this UFC is based on several possible technologies: BACnet, LONWORKS, or Niagara Framework.

1-2.1.1 BACnet.

The term "BACnet" is used in this UFC as the shorthand reference to the ANSI/ASHRAE Standard 135, specifically referring to the communications protocol specified there-in. The term "BACnet" is also used in this UFC to loosely describe a collection of technologies, including hardware, and software, vendors and installers relating to or based on the ASHRAE Standard 135 communications protocol. While every attempt has been made to distinguish which meaning is intended, in some cases the reader must make the determination from context

1-2.1.2 LONWORKS®

ANSI/CEA standard 709.1-C communications protocol (sometimes referred to as LonTalk®) and on LONWORKS® Network Services (LNS®) network operating system. The standard protocol supports Open communications while LNS supports Open network management. 'CEA 709.1' is used in this UFC as the shorthand reference to the ANSI/CEA standard 709.1-C communications protocol. In this UFC the term LONWORKS® is used to loosely describe a collection of technologies (including hardware, and software), vendors and installers relating to or based on the CEA 709.1 communications protocol

1-2.1.3 Niagara Framework.

The Niagara Framework is a protocol and set of technologies developed and owned by Tridium Inc. which is licensed to multiple vendors. Different vendors provide this system under different product names, but the overall term used by Tridium is “Niagara”. The Niagara Framework may be used in conjunction with either the BACnet or LonWorks option to design a system using BACnet or LonWorks that also can interoperate with a Niagara Framework front end installed in accordance with UFGS 25 10 10 and/or **\2** UFC 3-470-01, Utility Monitoring And Control System (UMCS) Front End and Integration ***/2/***. Note that use of Niagara Framework will override/trump some design options that would normally be used in a BACnet or LonWorks system.

1-2.2 Control system types

The combination of technologies result in 4 possible building control system types:

- A BACnet building using the BACnet standard
- A BACnet building using both the BACnet standard and the Niagara Framework
- A LonWorks building using CEA 709.1 and LNS
- A LonWorks building using both CEA 709.1 and the Niagara Framework

1-2.3 Open system design complexity

The design of an Open system is not simple. It requires attention to a great deal of detail. This UFC, the specifications, and accompanying drawings were developed to minimize the time and effort required on the part of the designer.

The level of detail contained in the guide specification and this UFC is necessary because of the variety of approaches that can be used to implement BACnet, or CEA 709.1-C, or Niagara Framework where, in the absence of this detail, would very likely result in incompatible systems.

1-3 PURPOSE AND SCOPE.

1-3.1 Purpose

The design concept described in this UFC provides definitive guidance intended to streamline DDC system design and installation leading to maintainable, interoperable, extensible, and non-proprietary control systems. This UFC also contains minimal project requirements. The purpose of this UFC is two-fold, to provide for commonality and compatibility of control systems:

- Commonality. Describes a definitive methodology for the design of building-level control systems and strategies (primarily for HVAC) where the intent is to achieve at least a degree of commonality in systems designed and procured through different channels. Common sequences of operation are specified in UFGS 23 09 93.

- Compatibility. Describes a definitive methodology to obtain multi-vendor systems that can communicate and interoperate with each other and with a supervisory monitoring and control system such as a basewide UMCS through the use of an Open communications protocol.

1-3.2 Scope.

This UFC describes the design of HVAC control systems and the associated building control network that can interface to a UMCS in an Open and non-proprietary manner.

1-3.2.1 HVAC control sequences and instrumentation.

These topics are covered in UFGS 23 09 13, UFGS 23 09 93.

1-3.2.2 Building controllers and control network.

This UFC describes designer selections for DDC hardware and software as well as the Building Control Network (BCN) communications including data exchange, architecture, and cabling.

1-3.2.3 UMCS interface.

The DDC system can function as a stand-alone system with reduced functionality (limited user interface, no trending etc.) but is intended to be integrated into a UMCS in accordance with the UMCS guidance (UFC 3-401-01 and UFGS 25 10 10) to provide for remote supervisory monitoring and control of the DDC system. This UFC (3-410-02) and UFGS 23 09 23.XX helps to ensure that the building-level control system is capable of being interconnected with a UMCS installed in accordance with UFGS 25 10 10 and/or **\2** UFC 3-470-01, Utility Monitoring And Control System (UMCS) Front End and Integration **/2/**. Even in the absence of a UMCS, this UFC describes the methodology for designer selection and specification of data exchange parameters including requirements that will facilitate subsequent non-proprietary UMCS interface.

1-3.2.4 Other systems.

Although not directly addressed or specified in the UFC or UFGS the methodology, approach, and many of the requirements defined in this UFC and UFGS 23 09 23.XX can be used in the design of other (non-HVAC) Open DDC systems such as water and sanitary sewer systems, electrical systems, lighting, and other utility systems and equipment.

1-4 APPLICABILITY.

This UFC is applicable to all HVAC control system design, both for new construction and renovation. This UFC and the guide specifications may also be applied to other non-HVAC building control when those systems use LonWorks or BACnet.

1-5 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, DoD Building Code (General Building Requirements). UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-6 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

1-7 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms. In addition, UFGS 23 09 00 contains an extensive list of definitions.

This Page Intentionally Left Blank

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 USE OF UFGS 23 09 XX SERIES OF SPECIFICATIONS.

Unless specifically indicated in this UFC or with specific written permission from the authority having jurisdiction, the design of a building control system must use UFGS 23 09 00 and either UFGS 23 09 23.01 or UFGS 23 09 23.02 (as appropriate) without edits beyond the use of tailoring options and designer option.

2-2 USE OF UFGS 23 09 23.XX.

The implementation of a building control system requires highly specific and prescriptive specifications. UFGS 23 09 23.01 (for LonWorks based BCS) and UFGS 23 09 23.02 (for BACnet based BCS) incorporates these requirements, and makes use of SpecsIntact Tailoring Options and designer options (bracketed text with notes) to allow for project-specific editing.

Unless specifically indicated in this UFC or with specific written permission from the authority having jurisdiction, the design of a building control system must use either UFGS 23 09 23.01 or UFGS 23 09 23.02 (as appropriate) without edits beyond the use of tailoring options and designer options.

2-3 TAILORING AND DESIGNER OPTIONS IN UFGS 23 09 23.XX.

The use of tailoring options and designer options in either UFGS 23 09 23.01 or UFGS 23 09 23.02 must be in accordance with this UFC.

2-4 \1\ USE OF PROPRIETARY NETWORKS. /1/

\1\ The use of multiple devices communicating on a proprietary networks is allowed as an exception to the open protocol requirements of UFGS 23 09 23.01 or UFGS 23 09 23.02 only when the specific requirements in the following paragraphs are met. Note that internal communications within a single piece of packaged equipment (package unit) need not meet the open protocol requirements, but the packaged equipment must be provided with an interface meeting the open protocol requirements.

When including proprietary networks in a design as permitted in this UFC, the systems specifically permitted to use proprietary networks must be indicated in UFGS 23 09 00. /**1**/

2-4.1 \1\ Proprietary Networks for Simple Split Systems. /1/

\1\ A simple split (DX) system consisting of a single indoor unit and a single outdoor unit from the same manufacturer is always permitted to use a proprietary network between the two units provided that one unit has an open protocol interface meeting the requirements of the UFGS. Include a Points Schedule in the design package for the split system at the system interface. /**1**/

2-4.2 \1\ Proprietary Networks for Multi-Split Systems (Including Variable Refrigerant Flow (VRF) Systems). /1/

\1 Multi-split (including variable refrigerant flow (VRF)) systems using proprietary networks connecting multiple units which operate together must meet the following requirements:

- A gateway must be provided between the proprietary network and the open protocol control system required by UFGS 23 09 23.01 or UFGS 23 09 23.02 to provide a functional interface between the two networks. The open protocol side of the gateway must meet the requirements of UFGS 23 09 23.01 or UFGS 23 09 23.02.
- A Point Schedule for the system must be included in the design package to define the functional interface of the system to the open protocol control system.
- All units must be products of a single manufacturer.
- The units must operate using a common sequence of operation which operates the units in a manner that requires operational parameters be shared between them. The units must use a factory provided program for the sequence of operation; this program may be field configurable but units must not be field programmed.
- The solution using the proprietary network must have a lower life-cycle cost than at least two (2) alternate solutions not using proprietary networks.
- The System Owner receiving the control system must approve of and accept the use of the system. When a System Owner does not accept a system using a proprietary network it must not be used regardless of other factors.
- For USACE projects, the Utility Monitoring and Control System Mandatory Center of Expertise (UMCS MCX) must review the design, life cycle cost analysis, and System Owner approval and concur prior to specifying a system using a proprietary network.

When allowing proprietary networks for multi-split systems, the life cycle cost analysis, System Owner approval, and UMCS-MCX concurrence (for USACE projects) must be included in the design documents. The systems specifically permitted to use proprietary networks must be indicated in the table provided in UFGS 23 09 00. /**1**/

2-4.3 \1\ Proprietary Networks for Chiller and Boiler Plants. /1/

\1 Boilers or chillers using proprietary networks connecting multiple units which operate together must meet the following requirements:

- A gateway must be provided between the proprietary network and the open protocol control system required by UFGS 23 09 23.01 or UFGS 23 09 23.02 to provide a functional interface between the two networks. The open protocol side of the gateway must meet the requirements of UFGS 23 09 23.01 or UFGS 23 09 23.02.

- A Point Schedule for the system must be included in the design package to define the functional interface of the system to the open protocol control system.

- All units must be from the same manufacturer.

- All units must be co-located in the same room, and the network connecting them must be fully contained in that room.

- The units must operate using a common "plant" sequence of operation which stages the units in a manner that requires operational parameters be shared between them and which cannot be accomplished with a single lead-lag command from a third-party controller.

- The design must include specific model chiller and boilers. If the design is not specifying the exact equipment, do not include the exception as part of the design; UFGS 23 09 00 includes a mechanism by which the installing contractor can request the exception if needed. (In most cases, this means that this exception will apply primarily to design-build projects and not design-bid-build.)

When allowing proprietary networks for chiller or boiler plants, the design documents must include a statement that the system meets the necessary requirements for use of a proprietary networks and the systems specifically permitted to use proprietary networks must be included in the table provided in UFGS 23 09 00. /**1**/

2-4.4 \1\ All Other Systems. /1/

1\\ The specific exceptions defined in this UFC were determined as warranted based on implementation and maintenance considerations, and on industry capabilities to provide solutions meeting open systems requirements and apply only to the indicated systems. For all other systems, the use of multiple devices communicating on a proprietary networks requires a waiver from UFC requirements.

To suggest additional systems for consideration for establishing exception procedures, submit a Criteria Change Request (CCR) to this UFC. /**1**/

This Page Intentionally Left Blank

CHAPTER 3 DESIGN

3-1 INTRODUCTION.

This chapter describes building-level Open-communications control system architecture, device functionality, and control devices for HVAC and other building-level monitoring and control applications. The communications network and devices are based on one of:

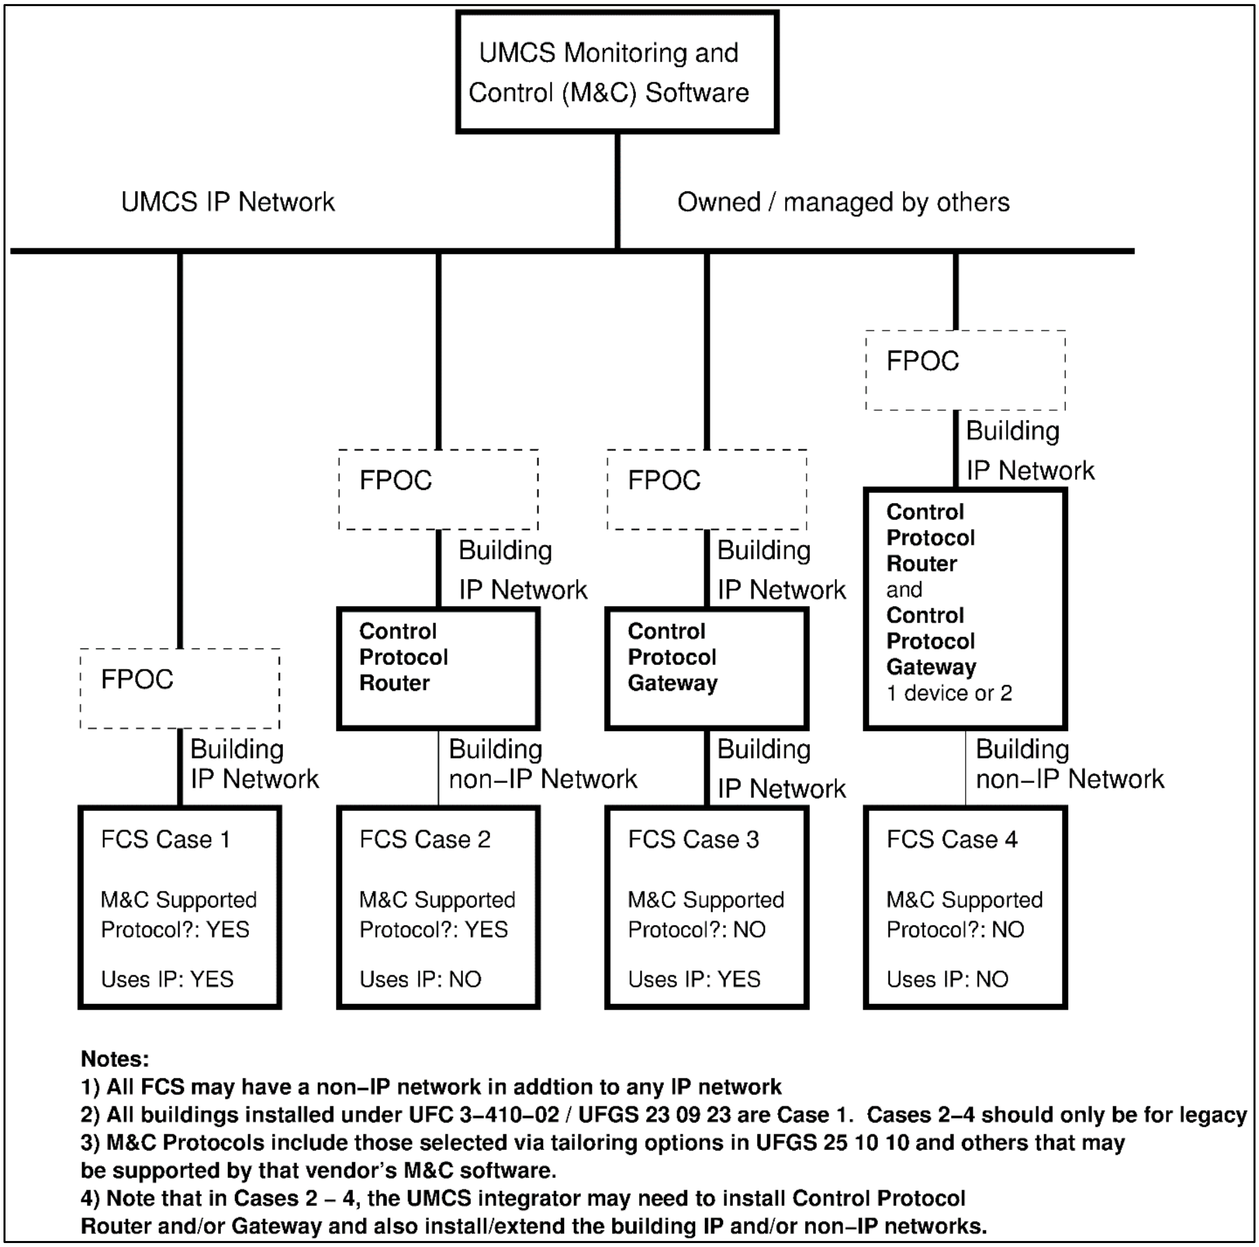
- LonWorks® technology and CEA 709.1 communications protocol with LNS
- LonWorks and the Niagara Framework
- BACnet, ASHRAE-135
- BACnet and the Niagara Framework

This UFC will primarily focus on either the LonWorks or BACnet option, with supplemental material provided to cover the Niagara Framework variant. Design of an Open-communications building-level control system does not require an extensive familiarity with CEA 709.1 protocol, BACnet, or the Niagara Framework, but it is critical that the designer understand that these protocols can be implemented in a manner that is not Open and thus can lead to incompatible systems. Therefore, this chapter contains supplemental information to be used in conjunction with UFGS 23 09 23.XX.

3-2 BASEWIDE UMCS ARCHITECTURE.

As illustrated Figure 3-1, a basewide system consists of a UMCS (specified by UFGS 25 10 10) containing to one or more building-level DDC systems (specified by UFGS 23 09 00 and UFGS 23 09 23.XX). The network architecture consists of a basewide IP network and one or more building-level networks. DDC UFGS 23 09 23.XX refers to the building-level network as the Building Control Network (BCN). A field point of connection (FPOC) provides an interface between the basewide IP and BCN networks. Since the FPOC is the location where the contractor-installed Building Control Network (BCN) meets the basewide IP network, the location of the FPOC must be coordinated with the base IT/networking staff.

Figure 3-1 UMCS Architecture



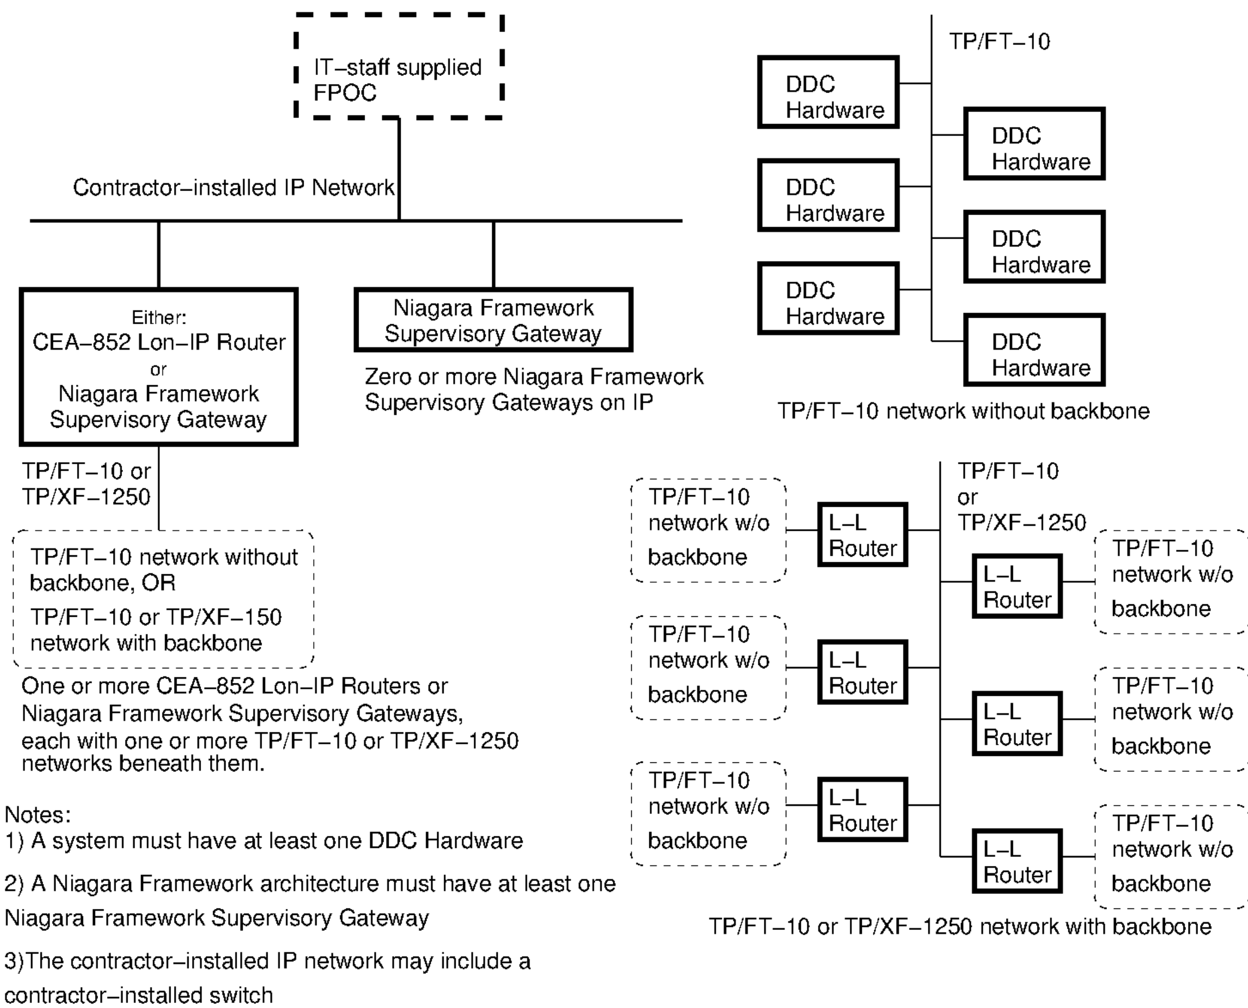
3-3 LONWORKS BCN ARCHITECTURE.

3-3.1 General.

As illustrated in Figure 3-2, a LonWorks (with or without Niagara Framework) BCN consists of an IP network with one or more (in the case of LonWorks with LNS) CEA 852 routers or (in the case of LonWorks with Niagara) Niagara Framework Supervisory Gateways. Beneath each CEA 852 router or Niagara Framework Supervisory Gateway is either TP/XF-1250 media or TP/FT-10 media (not all Niagara Framework Supervisory Gateways will necessarily have a network beneath them). TP/XF-1250 media functions as a non-IP network backbone and will only have Lon-to-Lon routers connected to it. Each Lon-to-Lon router will, in turn, have TP/FT-10 media connected, with individual DDC Hardware connected to the individual TP/FT-10 networks.

TP/FT-10 media directly connected to a CEA 852 router or Niagara Framework Supervisory Gateway may have DDC Hardware connected to it, or it may be used as a non-IP network backbone (identical to the use of TP/XF-1250 media). When used as a non-IP network backbone it will only have Lon-to-Lon routers connected to it (with TP/FT-10 networks and DDC Hardware connected to the individual Lon-to-Lon routers). The LNS-based LonWorks architecture produces a logically flat network in the building where each node can communicate directly with any other node without the intervention of another controller.

Figure 3-2 LonWorks Building Network Architecture



3-3.2 CEA 709 Media selection.

UFGS 23 09 23.01 specifies the use of one of: IP, TP/XF-1250, or TP/FT-10 media; each has advantages and disadvantages:

- IP is necessary because the UMCS uses IP, so at some point the network needs to connect to IP. For a smaller building, this may as simple as a single IP port on a CEA 852 router or Niagara Framework Supervisory Gateway. Larger buildings will likely have multiple devices on IP and a contractor-installed IP network. IP also has by far the greatest bandwidth of the media types. IP does have the downside of having the most IA (Information Assurance) issues. Future management of the IP network will vary from service to service and possibly even from site to site, but all IP networks will be required to meet some level of Information Assurance (IA) requirements.

- TP/XF-1250 communicates at 1250 kbps, which is considerably faster than TP/FT-10, but not as fast as IP. TP/XF-1250 is not part of the CEA 709 standard, but it is a de-facto standard for a high-speed Lon media. There are very few DDC Hardware devices using TP/XF-1250, so its use is limited to that of a backbone media. TP/XF-1250 must be installed in a doubly-terminated bus configuration.

- TP/FT-10 communicates at 78 kbps, which is the slowest of the 3 but still sufficiently fast to allow its use as the main media type in fairly large installations. It is covered by CEA 709 and is universally supported; almost all devices support TP/FT-10 and in these specifications it is the only media that can be connected to DDC Hardware (other than Niagara Framework Supervisory Gateways). TP/FT-10 must be installed in a doubly-terminated bus configuration

Use of other media types may limit future competition by giving an advantage to the limited number of vendors whose products support the non-standard media. Therefore use of alternative media is prohibited by the guide specifications. There may be some situations where a different CEA 709 media is needed – such the use of Power Line for retrofits where it is impossible to run new media or fiber optic for inter-building runs where electrical isolation is required. Do not specify or permit alternate media without written authorization from the AHJ.

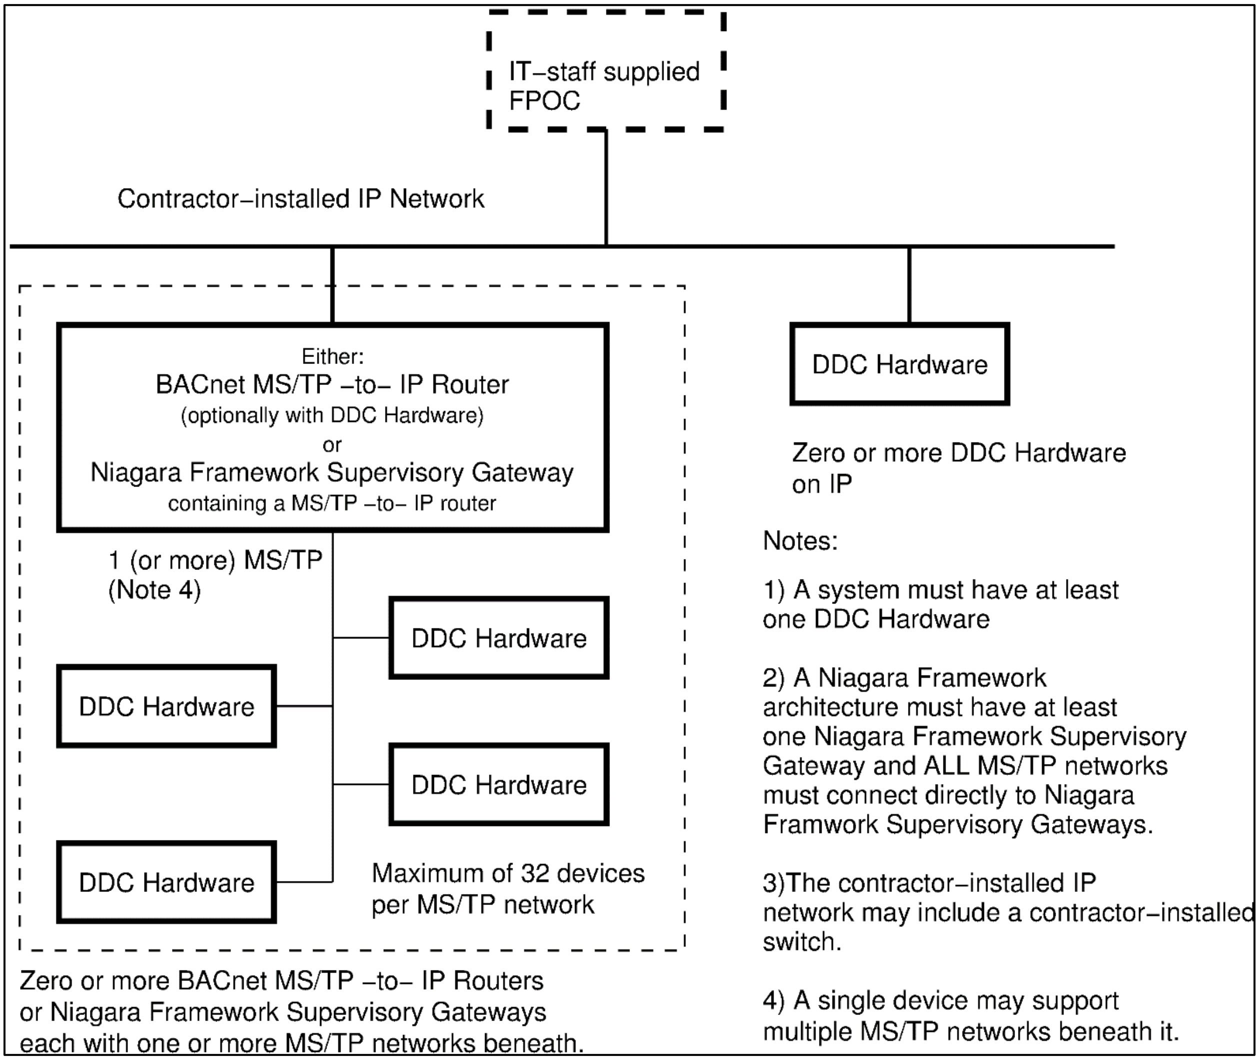
3-4 BACNET BCN ARCHITECTURE.

BACnet uses the term internetwork to refer to the entire connected BACnet system, consisting of one or more interconnected individual BACnet networks. A particular site may have multiple disconnected internetworks; each would be a separate BACnet system.

As illustrated in Figure 3-3, a BACnet (with or without Niagara Framework) BCN consists of an IP network with a mixture of DDC Hardware (including, in the case of the Niagara Framework, Niagara Framework Supervisory Gateways) and BACnet MS/TP –

to- BACnet IP routers (which may be furnished as part of DDC Hardware). Each MS/TP –to- IP router or Niagara Framework Supervisory Gateway may have MS/TP networks beneath it, with DDC Hardware on the individual MS/TP networks. Each project will have a single Field Point of Connection (FPOC) which provides an interface between the basewide IP network and the BCN network installed by that project.

Figure 3-3 BACnet Building Network Architecture



3-4.1 Device and network addressing.

BACnet addressing uses two pieces of data which must be unique throughout the Internetwork - Device IDs and Network Numbers. Unlike Lon-based systems installed under UFGS 23 09 23.01, BACnet does not provide a mechanism to globally manage this data across multiple vendors ***and the installation must manually manage these numbers***:

- Network Number. The network number is assigned to every BACnet network and must be unique across the entire BACnet internetwork. The network number is between 1 and 65,535.
  - The basewide BACnet internetwork should have a single BACnet/IP network; all BACnet devices residing on the IP network should have the same BACnet network number. While this network may well span multiple IP subnets, from the perspective of BACnet, it will logically consist of a single BACnet/IP network and only use a single Network Number. This network must be assigned Network Number=1.
  - Each MS/TP network (of which large projects will have several) also needs a site-wide number. Since network numbers can range from 1 – 65,535, and most sites have at most a few thousand buildings, one option is to assign a range of network numbers to each building by building number. So, for example, building 2705 might have network numbers in the range 27,050 – 27,059. Another option is to assign each vendor a range of network numbers and force the vendors to keep track (site-wide) which numbers they have used. Finally, network numbers could simply be assigned site-wide in increasing consecutive order. This requires some care when multiple independent BACnet projects are underway at the same time.
- Device Object Identifier. Every device on the internetwork must have a unique Object identifier for the Device Object, this is often referred to as the Device ID. This number can be any value between 1 and 4,194,302. Similar to Network Numbers, Device IDs must be globally unique within a site (the BACnet internetwork). The same methods suggested for managing MS/TP network numbers can be used for managing Device IDs, with the additional complication that a single project may include devices from multiple vendors and projects using devices from multiple vendors will need multiple tools to manage Device IDs on a single project

Within a specific project, installers will have some method to maintain unique Device Object Identifiers within the device manufacturer’s product lines. This however does not guarantee unique Device Object Identifiers across manufacturers. ***It also does not ensure unique Device IDs and Network Numbers when a specific project is later integrated into a basewide BACnet internetwork.*** Coordination with the project site concerning their management procedure for these values is critical. If the project site does not have an existing procedure for managing these values coordinate with them to develop one. For the Army, assistance with the resolution of this issue can be obtained from the UMCS MCX at Huntsville Center.

3-4.2 Media selection.

UFGS 23 09 23.02 specifies the use of either MS/TP or IP.

- Master-Slave/ Token Passing (MS/TP) is a data link protocol as defined by the BACnet standard and the majority of DDC controllers used will communicate BACnet MS/TP over a doubly terminated field bus network compliant with EIA/TIA-485. In order to avoid interoperability issues, MS/TP media shall operate at 38.4 kbps, use 3 wire (twisted pair with reference) with shield media and shall be installed with 2 sets of network bias resistors and no more than 32 nodes per segment. MS/TP is by far the slowest of any media types in either UFGS 23 09 23.01 or UFGS 23 09 23.02.

- Some BACnet controllers will likely use BACnet/IP in accordance with ASHRAE-135 (2012) Annex J. While installation of this media is the responsibility of the controls contractor, this network will, when integrated into a basewide UMCS, connect to the basewide IP network. Future management of the IP network will vary from service to service and possibly even from site to site, but all IP networks will be required to meet some level of Information Assurance (IA) requirements.

Use of other media types may limit future competition by giving an advantage to the limited number of vendors whose products support the non-standard media. Therefore use of alternative media should generally be avoided, though there may be cases (retrofits where it is impossible to run new media) where Zigbee (wireless – but carefully coordinate wireless with the site IT and RF management groups) is desired, or inter-building runs where fiber optic should be considered for its electrical isolation characteristics.

3-5 NIAGARA FRAMEWORK NETWORK.

The Niagara Framework provides an overlay system. At the bottom level of the architecture, there are non-Niagara Framework controllers based on either LonWorks or BACnet. Above those controllers are Niagara Framework Supervisory Gateways which connect the individual building to a Niagara Framework UMCS Front End. These devices function as gateways because the protocol for devices under them is either LonWorks or BACnet, while the protocol above these devices (connecting to the UMCS Front End) is the Fox protocol. In most aspects, the architecture when the Niagara Framework is selected is similar to the base (non-Niagara) architectures discussed above. Differences are discussed below.

3-5.1 Niagara Framework and LonWorks.

The Niagara Framework Supervisory Gateway will take the place of the CEA 852 router to provide a connection to the IP network. The Niagara Framework Supervisory Gateway is a gateway and does not route CEA 709.1 to the IP network. The Niagara Framework Supervisory Gateway is DDC hardware and may be connected directly to the IP network.

The Niagara Framework engineering tool will be used for network management instead of an LNS-based tool. For many requirements, an LNS-based requirement is replaced with a similar requirement based on the Niagara Framework engineering tool. The communication between the building control system and the front end will be via Fox, not CEA 709.1

3-5.2 Niagara Framework and BACnet.

The Niagara Framework Supervisory Gateway will function as the BACnet MS/TP–to-IP Router. The Niagara Framework Supervisory Gateway does route BACnet, and all MS/TP networks must be connected to a Niagara Framework Supervisory Gateway.

The communication between the building control system and the front end will be via Fox, not BACnet. Non-Niagara devices on the IP network must use the Niagara Framework Supervisory Gateway to communicate with the Niagara Framework front end.

3-6 CONNECTION TO A UMCS.

The building control system will perform all necessary control functionality in a stand-alone mode but does not provide an operator interface (other than local display panels) for monitoring and control of the network. If the building is to be operated in a stand-alone mode for an extended period and monitoring and control functionality are required, use the applicable portions of UFGS 25 10 10 to obtain a local monitoring and control system. Integration of the building control system to the UMCS is specified in UFC 3-470-01 and UFGS 25 10 10.

3-7 NETWORK HARDWARE.

In addition to media, the control network may contain the following types of hardware.

- Repeaters: A repeater is a device that connects two (or more) pieces of media, and passes all traffic between the two pieces of media. Repeaters may allow for longer cable runs in some cases, but not others. The BACnet specification does not allow the use of repeaters. The LonWorks specification allows the use of routers which are configured as repeaters (but prohibits “physical layer” repeaters).

- Media Converter: A media converter is a repeater that changes media types. The network architecture defined in UFGS 23 09 23.XX does not use media converters, but they may be needed if non-standard media was authorized.

- Router: A router is similar to a repeater, but performs the additional function of packet filtering based on destination address. A router will only pass traffic that needs to be sent to another output port. Routers may also convert between media types. Both UFGS 23 09 23.01 and UFGS 23 09 23.02 specify the use of routers.

- Gateway: A gateway translates from one protocol to another. The use of gateways, other than Niagara Framework Supervisory Gateway in a Niagara Framework project, is severely restricted in UFGS 23 09 23.XX.

3-8 NETWORK DESIGN AND LAYOUT.

Network layout is left largely to the building-level controls Contractor as specified in UFGS 23 09 23.XX.

While the Contractor is responsible for selecting the details of the architecture and ensuring that the proposed system does not saturate the network, UFGS 23 09 23.XX provide specific additional requirements to help ensure those limits are not exceeded:

- Use of higher speed media and use of a backbone architecture

- Group devices that need to communicate often on a common local control bus

- Limit the amount of information sent to the UMCS. A modern UMCS can easily demand data from the local controls faster than the building network can deliver the data. Coordinate with the UMCS installer to limit “always-active” data requests from the UMCS such as trending to those really required by the installation.

- Ensure the Contractor is careful in selecting data transfer rates and integrity methods. Use “Send on Change” with reasonable change values to avoid sending data more often than required. Except for critical data, do not require an acknowledgement or confirmation that data was received.

3-8.1 Data transmission methods.

There are two primary mechanisms through which data transfer data occurs; polling and send on change. These data transfer aspects of the protocol along with the quantity of data transferred govern how much bandwidth is used. Polling occurs when a receiver of data requests data from a transmitter. This is generally a periodic event with a defined period. Polling can occur at any time and a device can always poll another device for data. Send on change, often referred to as Change Of Value (COV), is another form of data transfer where a data source sends (on its own initiative) data to a recipient. In most cases, the specifications require the use of COV.

3-8.2 Data integrity.

DDC networks are not 100% reliable. While proper network design, media selection and installation can improve network reliability, some dropped data packets are inevitable. Both LonWorks and BACnet have mechanisms to ensure reliable data transmission even when the underlying network is unreliable and the specification requires these methods where appropriate.

3-8.3 Number of controllers per system or sequence.

Although sequences are generally implemented in a single controller with sufficient inputs and outputs, the specifications allow a single sequence or system to be split across multiple controllers. There are designer options in the UFGS to select a preference for one approach over the other. Discuss this with the installation to determine if they have a preference. UFGS 23 09 23.XX places the burden on the Contractor to decide when distributed control should be used.

3-9 CYBERSECURITY.

Cybersecurity is an ever-changing area, and it's vital to coordinate IA requirements both with the site networking personnel and with the respective service or agency for each project. UFC 4-010-06, *Cybersecurity of Facility-Related Control Systems* provides guidance on incorporating cybersecurity into the design of control systems, and includes points of contact for each Service. For the Army, control system design, including cybersecurity, should be coordinated with the UMCS Mandatory Center of Expertise (MCX) at Huntsville.

CHAPTER 4 DIRECT DIGITAL CONTROL HARDWARE AND CONTROL DEVICES

4-1 INTRODUCTION.

This chapter describes control devices and the DDC Hardware specified in UFGS 23 09 23.XX including the extended requirements needed to implement an Open system. It also describes the related terms and concepts pertaining to LONWORKS, BACnet, and the Niagara Framework.

4-2 LONWORKS REQUIREMENTS.

4-2.1 General.

Any device, other than network hardware, that communicates over the CEA 709.1 network is considered DDC Hardware. In general, the term DDC Hardware is used interchangeably with the term controller, but there are devices such as smart sensors and actuators that communicate on the network and are considered DDC Hardware but are not traditionally called controllers even though they may in fact have control functionality (like a feedback control loop). All DDC Hardware must:

- Communicate only using CEA 709.1C using a TP/FT-10 transceiver for use on a TP/FT-10 network at 78.1 kbps.

- Use Standard Network Variable Types (SNVTs). SNVTs provide a common set of standards defining how data is sent over the network, including engineering units

- Meet the LonMark Interoperability guidelines. These guidelines provide a foundation for interoperability and devices meeting these guidelines are readily available.

- Be provided with an external interface file (XIF file). This is a text file that tells a Network Management Tool what the interface (inputs, outputs, configuration settings) of the controller is.

Some of these requirements may be difficult to confirm for some devices, specifically programmable controllers. Product data sheets can provide a good indication of whether a device, particularly an application specific controller, meets LonMark Guidelines. In addition, LonMark International has a self-certification checklist that vendors can use to certify that a device meets the LonMark Guidelines.

Where Lonworks falls short is in defining a standard interface between the BCS and the UMCS front end. In particular, there is no well-supported standard for either alarming or trending; therefore these functions are not specified in UFGS 23 09 23.01 (they are specified in UFGS 25 10 10 if the LonWorks tailoring option is selected). DDC Hardware is further broken down into three categories, Application Specific Controllers, Application Generic Controllers, and General Purpose Programmable Controllers, each of which has additional requirements it must meet.

4-2.2 Application specific controller.

An application specific controller (ASC) is supplied with a factory-installed (and fixed) application program. Example ASCs include VAV box controllers, fan coil unit controllers, 'smart' actuators and 'smart' sensors. An ASC is configured for the specific application in which it is used. UFGS 23 09 23.01 requires, with rare exceptions, that ASCs be LonMark Certified to meet a specific Functional Profile. Functional Profiles describe standard node communications and consists of mandatory and optional input and output SNVTs, mandatory and optional configuration properties, and finally a manufacturer specific section. UFGS 23 09 23.01 also requires, with rare exceptions that ASCs be provided with an LNS® Plug-in to provide a semi-standard GUI for device configuration

4-2.3 Application generic controller.

An application generic controller (AGC) is similar to an ASC, but has a limited programming capability. Programming these controllers does not change the controller ProgramID, so these controllers can be (and often are) programmed through an LNS plug-in. UFGS 23 09 23.01 has specific requirements for AGCs which includes a mix of ASC and GPPC requirements. These controllers are capable of executing most of the sequences specified in UFGS 23 09 93. Further, since they can be re-programmed remotely and without changing the ProgramID, they are often preferred to GPPCs.

4-2.4 General purpose programmable controller.

A general purpose programmable controller (GPPC) comes from the factory without a fixed application program and must be programmed for the application in which it is used. This makes the GPPC more flexible and powerful than an ASC, but more complicated and costly as well. UFGS 23 09 23.01 requires the GPPC to conform to the LonMark Interoperability Guide. It also requires that the programming software be provided and that a source-code version of the actual program installed in the GPPC be provided as well.

4-3 BACNET REQUIREMENTS.

4-3.1 General.

Any device, other than network hardware, that communicates over the BACnet network is considered DDC Hardware. In general, the term DDC Hardware is used interchangeably with the term controller – this includes smart sensors and actuators that use the network. Another term commonly used is "device", where a BACnet device is any device that resides on the BACnet network and communicates via the BACnet ASHRAE Standard 135 protocol. All DDC Hardware must:

- Communicate only using BACnet ASHRAE Standard 135.
- Use standard Objects, Properties, and Services. UFGS 23 09 23.02 requires the use of specific Object types to support specific point types.
- Do not use Proprietary Objects or Proprietary Properties. In addition, UFGS 23 09 23.02 places severe restrictions on the use of Proprietary Services.
- Provide Commandable Objects to support overrides.
- Be Listed by BACnet Testing Labs (BTL) (http://www.bacnetinternational.net/btl/). For some applications, devices must be listed as either B-BC (BACnet Building Controllers) or B-OD (BACnet Operator Displays).
- Be installed in a manner consistent with both their BTL listing and with the BTL Implementation Guidelines.

Some of these requirements may be difficult to confirm; the PICS is a good place to start for devices. Note, however, that the PICS only describes capabilities, a particular usage of the device may not implement or support every capability described in the PICS. BACnet provides a fairly extensive range of standards defining the interaction between a UMCS front end (specifically a B-AWS) and a BCS, because of this, UFGS 23 09 23.02 has requirements for scheduling, alarming, and trending in the BCS. When BACnet is selected via tailoring option in UFGS 25 10 10, that specification requires that the front end be BTL listed as a BACnet Advanced Workstation (B-AWS).

4-3.2 Scheduling.

UFGS 23 09 23.02 has specific requirements for scheduling, including that scheduling must be performing using Schedule Objects in B-BC devices with support for Schedule creation/modification/deletion from a B-AWS. This last requirement can be partially offset by the provision of extra blank Schedule Objects.

4-3.3 Alarm generation.

The BACnet standard supports 2 primary forms of alarm generation: Intrinsic, where the Object itself incorporates logic to determine if an alarm condition exists, and Algorithmic, where an Event Enrollment Object contains the alarm generation logic. Algorithmic is in turn broken down into Local -- where the Event Enrollment Object is in the same device as the alarm point and Remote – where the Event Enrollment Object is in a different device. In all cases, a Notification Class Object is also required to send the Event Notification associated with the alarm generation to the B-AWS front end. In order to allow the use of all three types of alarm generation and also ensure that Alarm Generation functionality may be created/modified/deleted from a B-AWS, UFGS 23 09 23.02 has extensive and complex requirements for alarm generation.

4-3.4 Trending.

The BACnet standard provides a Trend Log Object and a Trend Log Multiple Object to support trending. A Trend Log Object supports a single trend; the Trend Log Multiple Object can contain multiple trends. UFGS 23 09 23.02 requires the use of Trend Log and/or Trend Log Multiple Objects and also has additional requirement to support trend creation/modification/deletion from a B-AWS.

4-3.5 Engineering units.

BACnet data does not have pre-determined engineering units and UFGS 23 09 23.02 requires the use of specific engineering units. The choice of either SI or inch-pounds should be coordinated with the site and used on all BACnet projects at that site.

4-4 NIAGARA FRAMEWORK REQUIREMENTS.

4-4.1 General.

Selection of the Niagara Framework is via a tailoring option to either UFGS 23 09 23.01 or UFGS 23 09 23.02. In either case, the requirements normally found in these specification remain largely intact; the tailoring options make specific modifications to support the Niagara Framework. Use of Niagara Framework in the building must be accompanied by selection of the Niagara Framework tailoring option in UFGS 25 10 10.

4-4.2 Niagara Framework and LonWorks (UFGS 23 09.01).

The most significant changes that will result from use of the Niagara Framework tailoring option in UFGS 23 09 23.01 are:

- Network configuration and network management will be via the Niagara Framework Engineering tool rather than an LNS-based tool. Similarly, Niagara Framework Wizards may be required rather than LNS-plugins
- Connections to the IP network will be via Niagara Framework Supervisory Gateways rather than CEA 852 Lon-to-IP routers.
- Scheduling, Alarming, and Trending will be via Niagara Framework Supervisory Gateways located in the building.
- Some DDC Hardware requirements, as they apply to Niagara Framework Supervisory Gateways, are depreciated in favor of Niagara-specific requirements.

4-4.3 Niagara Framework and BACnet (UFGS 23 09.02).

The most significant changes that will result from use of the Niagara Framework tailoring option in UFGS 23 09 23.02 are:

- Niagara Framework Engineering tool will be used for some aspects of device configuration. Note that vendor specific tools will likely still be required for many aspects

- Connections to the IP network will be BACnet MS/TP-to-IP routers in Niagara Framework Supervisory Gateways

- Scheduling, Alarming, and Trending will be via Niagara Framework Supervisory Gateways rather than the normal BACnet implementation methods.

- Some DDC Hardware requirements, as they apply to Niagara Framework Supervisory Gateways, are depreciated in favor of Niagara-specific requirements.

4-5 OTHER ISSUES.

4-5.1 Expansion modules and tethered hardware.

UFGS 23 09 23.XX considers hardware expansion modules and tethered hardware to be part of a single piece of DDC Hardware. Expansion modules typically provide additional I/O and are designed to connect directly to the base (main) DDC Hardware. Tethered hardware is functionally similar to expansion modules, but is connected to the base unit by a cable. The intent of the requirements is to allow a single device to be split among multiple physical pieces of hardware, not to allow multiple devices to be connected together using a proprietary protocol.

4-5.2 Building management interface.

A building-level project might call for a local building management interface. This should only be used in the absence of a UMCS, and is not specified in either UFGS 23 09 23.XX or UFGS 25 10 10. This interface provides web services and can also perform scheduling, logging (trending), alarming, and other supervisory interface functions. Note that if it is later decided to connect the building to a UMCS, the interface will need to be replaced and any functionality in it will need to be accomplished in an Open manner in accordance with UFGS 23 09 23.XX or UFGS 25 10 10. On the other hand, a Niagara Framework Supervisory Gateway can provide this interface and can later be integrated into a Niagara Framework front end. UFGS 23 09 23.XX has a designer option to require serving web pages from the Niagara Framework Supervisory Gateway. Any web server within the building should be carefully coordinated with the site IT staff.

4-5.3 Local Display Panel.

The local display panel (LDP) is a device with a small display screen and some navigational buttons used to view and/or change the value of network variables. Although the functionality of an LDP is limited as compared to an operator workstation computer, it can be a useful diagnostic tool for maintenance staff and can often be used as a limited building interface until the building can be integrated into a UMCS. Coordinate with the site O&M staff regarding number and location of LDPs desired.

Note that there may be drawbacks to allowing overrides from both the M&C software and from an LDP. The value of specifying LDP override capability may be sufficiently beneficial to compensate for the potential confusion, but this should be coordinated with the project site.

4-5.4 Networked sensors and actuators.

Sensors and actuators may be networked devices. A common example would be a variable frequency drive unit containing a network interface. The choice of whether to provide a so-called “smart” sensor or actuator is left to the contractor. These “smart” devices are considered DDC Hardware and must meet both the DDC Hardware requirements as specified in UFGS 23 09 23.XX and any sensor or actuator requirements as specified in UFGS 23 09 13.

4-5.5 Hand-Off-Auto (H-O-A) Switches.

UFGS 23.09.23.XX has a number of general designer options for requiring Hand-Off-Auto switches. These are in addition to those already required by specific sequences of operation. In general, it is preferable to use overrides rather than H-O-A switches and the design should reflect this preference.

CHAPTER 5 CONTROL SYSTEM DRAWINGS

5-1 CONTROL SYSTEM DRAWINGS OVERVIEW.

A complete design must include the following project drawings:

- Index (title sheet)
- Symbols and Legend drawing
- Points Schedule Instructions for the Installing Contractor

as well as the following HVAC system-specific drawings as applicable to the HVAC system:

- Control Schematic
- Ladder Diagram
- Control Logic Diagram (OPTIONAL)
- Sequence of Operation
- Points Schedule
- Thermostat and Occupancy Sensor Schedule
- Occupancy Schedule
- Control Damper Schedule
- Control Valve Schedule

5-2 SAMPLE DRAWINGS.

Sample drawings are available online at the "UFGS Forms, Graphics and Tables" page at the Whole Building Design Guide at https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables. The use of the sample drawings is recommended. Points Schedule drawings must contain all fields in the sample drawing which are relevant to the project, and the use of the sample Points Schedule drawings as a template is strongly recommended.

5-2.1 Brackets in sample drawings.

As part of the editing process to make the sample drawings project-specific, the sample drawings use the following conventions:

- Entries required of the designer are shown bracketed as: [___]

- Entries required of the Contractor are shown bracketed as: < ___ >
- Spaces where no entry is ordinarily required contains a tilde: " ~ " (equivalent to an "n/a" or null value)

The bracketed [___] designer entries in the sample drawings are shown/provided as a guide to the designer. These entries must be verified or changed by the designer. When editing the drawings, delete the brackets after verifying/providing the entry. Contract drawings should contain no designer brackets [___]. Do not leave cells blank. Instead show the tilde ("~") to indicate a null value or that no further entry is required.

5-3 UNIQUE IDENTIFIERS.

Use unique identifiers to identify components across control systems drawings. APPENDIX E describes the point naming convention used in the sample drawings. Unless otherwise required, use the point naming convention in the sample drawings for the project drawings.

5-4 POINTS SCHEDULE.

5-4.1 Overview.

The Points Schedule drawing conveys a great deal of information critical to the design, installation, and subsequent performance of the control system. It includes hardware input/output information, device ranges and settings, and protocol specific information. It also includes information about data that is to be accessible at the operator workstation by the UMCS UFGS 25 10 10 Monitoring and Control software.

5-4.2 Responsibilities.

The designer is responsible for the initial set of Points Schedule entries and for creating the Points Schedule Instructions drawing (using the Instructions in **\2** APPENDIX D ***/2/*** of this UFC) . The Building Controls Contractor is responsible for the bulk of the entries and submits the Points schedule as a Design Drawing for government approval and then finalizes it as an As-Built submittal. The As-Built is then used as a Contract Drawing by the UMCS Contractor. Finally, the completed Point Schedule is submitted by the UMCS Integration Contractor as an As-Built submittal.

Detailed responsibilities for each column in the Point Schedule are shown under the description for each column.

5-4.3 UMCS content shown on UFGS 25 10 10 points schedules.

Some columns in the Points Schedule (labeled "M&C") pertain to functionality provided by the Monitoring and Control (M&C) Software specified in UFGS 25 10 10. These columns include information that the building controls system must provide for present or future use by the UMCS. Then, as stated in the Points Schedule Instructions drawing, when the building control system is integrated into a UMCS, these columns tell the UMCS Contractor what functionality to configure in the M&C Software.

If the building will be 'stand-alone' and M&C functionality is required at the building level (to be provided by the DDC building control system contractor), certain requirements from UMCS UFGS 25 10 10 must be added to the building controls specification or an edited version of UMCS UFGS 25 10 10 must be used in conjunction with the building controls specification. Note that in the absence of adequate documentation on the Points Schedule by the DDC Contractor, the UMCS Contractor will be unable to integrate the building into the UMCS.

5-4.4 Points Schedule Description and Instructions.

APPENDIX D contains a detailed description of the Points Schedule and instructions for its use.

5-5 CONTROL SYSTEM SCHEMATIC.

The control system schematic provides a functional representation of the control system. It shows control loops, control system devices, their symbols, unique identifiers, and associated input and output signals. It also contains space for designer notes. Depending upon the particular system, the control system schematic might also show Sequencing Diagrams. It is used to complement the sequence of operation, along with the other control system drawings, and must be coordinated with the sequence of operation and the devices and signals shown in the other drawings.

5-5.1 Loops and devices.

Each control system schematic consists of one or more loops with associated control hardware and devices including DDC hardware, input devices (sensors and other instrumentation), output devices (valves/dampers/fans/pumps), and multi-function devices. With few exceptions, such as valves, dampers, fans, and pumps, all control devices and signals shown in the Control Schematic should also be shown in the Points Schedule. Valve and damper details are shown in their respective schedules.

The control system schematic must be edited to be project specific and consistent with the other Contract drawings:

- Edit the border as required.
- Provide/show an identifier for the 'system'.
- Add or delete loops and devices as required.
- Show other points (sensors) that will be used for monitoring purposes only and show these Other Points in the Points Schedule.
- Show pneumatic actuation if desired, including positive positioners. By default, valve and damper actuators will use electric actuation.

- Where applicable, show the locations of permanent instrumentation in coordination with other drawings (M-plates).

5-5.2 Sequencing diagrams.

A Sequencing Diagram shows the heating, deadband, and cooling temperature ranges for controlled devices and equipment. Default Sequencing Diagrams are shown on the sample control drawings and must be edited to be project specific. Show device sequencing for primary equipment such as single-zone air handlers, multizone zone temperature controls and terminal unit equipment, such as VAV boxes and fan coil units on the Control Schematic. In most cases, the sequencing is dependent upon the mode of operation such as occupied, unoccupied, and warm-up/cool-down. Sequencing is further described in the respective written Sequence of Operation and, when used, the Control Logic Diagram.

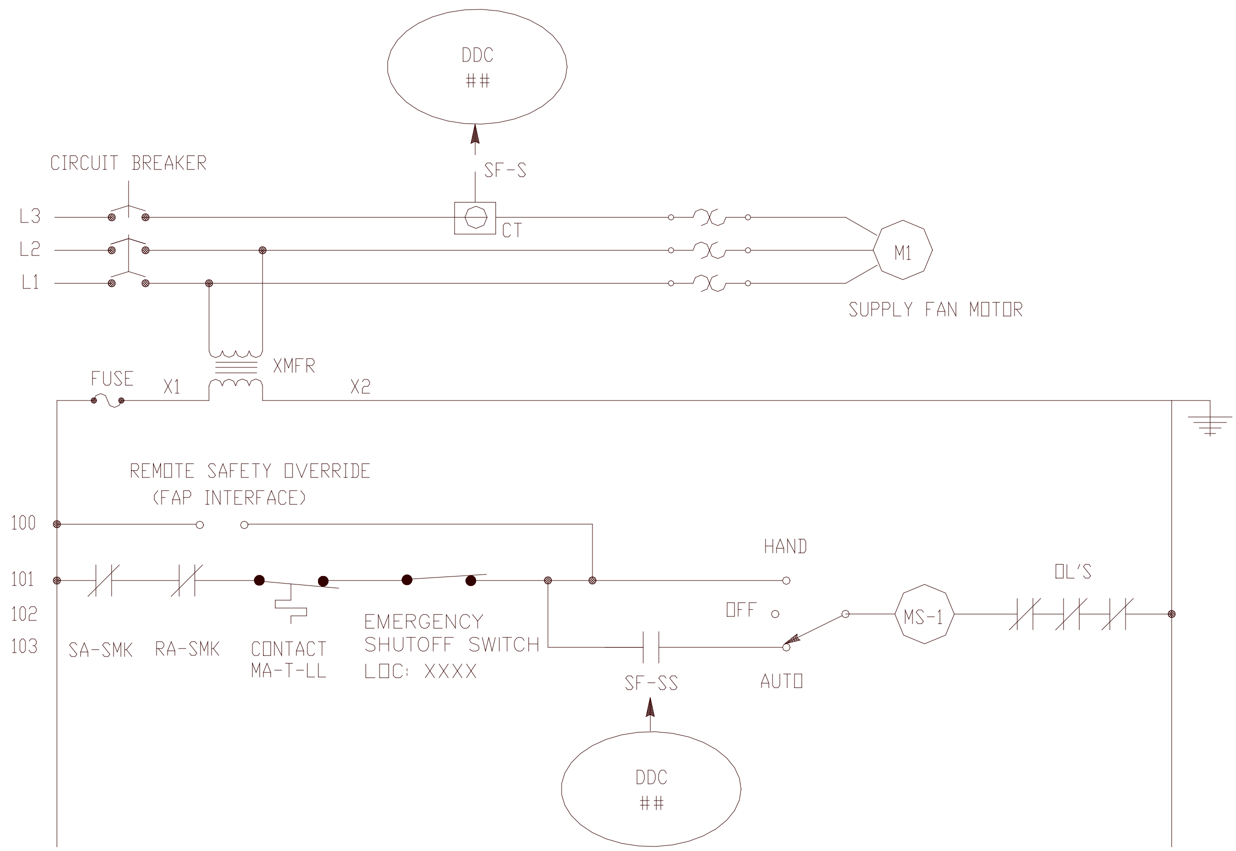
5-5.3 Designer notes.

The Control System Schematic has space provided for designer notes including pre-defined/default notes.

5-6 LADDER DIAGRAM.

The ladder diagram, sometimes referred to as a fan or pump starter circuit or wiring diagram, shows control system equipment interlocks and interfaces. In most cases, these interlocks will be with fan and pump motor starters or variable frequency drive units. In the case of HVAC system equipment, the interlocks will usually include hand-off-auto switches, freeze stats, smoke detectors, fire alarm panel interface, and the emergency shutdown switch. Default Ladder Diagrams are shown on the sample control drawings and should be edited to be project specific.

Figure 5-1 Sample Ladder Diagram



5-7 CONTROL LOGIC DIAGRAM.

The control logic diagram (CLD) drawing is intended to be an unambiguous graphical description of the control system sequence of operation. It provides detail that may not be evident in the written sequence. The focus of the CLD is on control logic, not on a particular hardware implementation. Inclusion of a CLD in the Contract drawing package is optional depending on the desired degree of specificity in the design. Use of a CLD is recommended where precise implementation of a particular control sequence is needed. It is also beneficial as part of project quality verification as it can be used as a tool to verify proper implementation of the control sequence.

The CLD must be edited to be project specific and consistent with the other Contract drawings. A control logic diagram overview is contained in APPENDIX F

5-8 SEQUENCE OF OPERATION.

The sequence of operation drawing shows a written description of the control logic. Example written sequences are in UFGS 23 09 93. To avoid confusion, these sequences were not repeated on the sample control drawings. The sequence must be edited to be project specific and consistent with the other Contract drawings and be copied onto the Sequence of Operation drawing.

5-9 THERMOSTAT AND OCCUPANCY SENSOR SCHEDULE.

The Thermostat and Occupancy Sensor Schedule (Figure 5-2) shows requirements for space mounted devices.

Figure 5-2 Thermostat and Occupancy Sensor Schedule.

SYSTEM SERVICE (AHU)	TERMINAL UNIT IDENTIFIER	SPACES SERVED	STAT LOCATION	ZN-T	ZN-T-SP ADJUST	UNOCC OVERRIDE PUSHBUTTON	UNOCC OVERRIDE TIME	OCC SENSOR
[____]		RM-[____] RM-[____]	RM-[____]	[_]	[_]	[_]	[____]	[_]
[____]		RM-[____] RM-[____] RM-[____]	RM-[____]	[_]	[_]	[_]	[____]	[_]
[____]		RM-[____]	RM-[____]	[_]	[_]	[_]	[____]	[_]

5-9.1 Thermostats.

Note that the definition of a thermostat (STAT) is used somewhat loosely here in that (contrary to the historical definition, but in line with current usage) the thermostat does not necessarily provide a control output (to modulate or position an end device). Instead, the thermostat will contain a temperature sensor and one or more of an occupant adjustable setpoint input, an occupancy sensor, or an unoccupied mode override (manual pushbutton). The intent and application of a thermostat, along with the technical requirements, are clear in the drawings and specifications (including ‘User Input Devices’ and ‘Multifunction Devices’).

5-9.2 Occupancy sensors.

Space occupancy input(s) may consist of an occupancy sensor and/or a local push-button. Occupancy sensor location, within the room/space, is left up to the Contractor. If ceiling mount sensors are preferred, edit the sequences and/or indicate in the Thermostat and Occupancy Sensor Schedule.

5-9.3 Schedule entries.

Show project specific entries in the Thermostat and Occupancy Sensor Schedule columns:

- System Service: Show an identifier for the system, such as the air handler, that services/supplies the space. Ensure coordination/consistency with other mechanical system drawings.
- Terminal Unit Identifier: Show an identifier when applicable, such as in a VAV system. Ensure coordination/consistency with other mechanical system drawings.
- Spaces Served: Show the room or rooms serviced by the thermostat and/or occupancy sensor. In general, all stats and occupancy sensors for a given terminal unit should be shown on the same line. However, there may be cases where additional rows may be required. For example, if a VAV zone consists of multiple spaces, a single thermostat but multiple occupancy sensors (one in each space/room) may be desired. The designer might choose to show a separate row for each occupancy sensor. Alternatively, a comment could be added to the column entitled 'Other' to clarify the requirement for a single thermostat with multiple space occupancy sensors.
- STAT Location: Show the physical location of the thermostat.
- ZN-T: Thermostats should always include a temperature sensor, so there should always be an 'X' in this column.
- ZN-T-SP Adjust: Show an 'X' if the thermostat is to include an occupant adjustable setpoint (thumb wheel or sliding bar). Where a non-(occupant)-adjustable setpoint is specified, show the (configured) setpoint in the Points Schedule. When using non-adjustable setpoints, be sure to indicate on the Points Schedule that the setpoint must be capable of being overridden from the M&C Software or an LDP.
- OCC Pushbutton: Show an 'X' if the thermostat is to include an occupant accessible pushbutton to override the unoccupied mode and start the servicing system for a duration shown under the UNOCC Override Time.
- OCC Pushbutton Time: If an 'X' is shown in the UNOCC Override Pushbutton column, show the time duration that the system will remain in Occupied mode after pressing the UNOCC Override Pushbutton.
- OCC Sensor: Show an 'X' if the space is to include an occupancy sensor. The occupancy sensor specification requires a 15 minute off-mode delay prior to leaving the occupied mode. If a different time is desired, show it in the thermostat schedule and ensure that it is consistent with the specifications.

5-10 OCCUPANCY SCHEDULE.

The Occupancy Schedule shows the system modes (Occupied, Unoccupied, and Warm-Up/Cool-Down) and when the system should be in each mode. Two sets of times are shown. One for the normal operating schedule set at the UMCS and one for the default schedule in the building which is active if connection to the UMCS is lost. In addition, the number of occupancy sensors that are required to be reporting as 'occupied' before the system air handler is put into occupied mode is shown on this schedule

5-10.1 System default schedule.

The System Default Schedule is configured in the System Scheduler by the controls Contractor. This schedule is a '7-day' schedule. In other words, the schedule can differ by day of the week but not day of the year. This schedule should be as simple as possible with one set of times for weekdays and one for weekends. An extended Occupied mode is recommended and should encompass warm-up/cool-down times. For example, if the building is normally in Warm-Up from 0700-0800 and Occupied mode from 0800-1800, a reasonable default schedule might be for the building to be in Occupied mode from 0530-1930. When choosing times for the default schedules for systems with occupancy sensors, the Occupied mode times can be shorter since the occupancy sensors (or override buttons) can still put the system into an Occupied mode.

5-10.2 Supervisory monitoring and control schedule.

The Supervisory Monitoring and Control (M&C) Schedule is configured at the M&C software by the UFGS 25 10 10 Contractor. Once a building is connected to the UMCS, this is the schedule that systems in the building will use. Although this schedule can include exceptions for holidays, it is recommended that the designer coordinate with the project site before requiring the implementation of these exceptions. Since the date of most holidays needs to be adjusted year-by-year, the project site O&M staff will need to reconfigure them yearly. As with the default schedule, the presence of Occupancy Sensors should be considered when choosing Occupied mode times.

5-10.3 Number of occupancy sensors to put AHU in occupied mode.

Systems with occupancy sensors (or override buttons) can be placed into the Occupied mode by the occupancy sensors when a minimum number of occupancy sensors detect that the space they serve is occupied. Indicate the required number of occupancy sensors in this column.

CHAPTER 6 BUILDING CONTROL SYSTEM DESIGN AND IMPLEMENTATION

6-1 INTRODUCTION.

This chapter describes the planning and design of a DDC project.

6-2 PLANNING.

In addition to the guidance contained in this UFC, the design should be based on site-specific planning documents. Designs must be accomplished in accordance with the customer's site specific requirements such as, in the case of a Corps of Engineers project, the Installation Design Guide (IDG), Master Planning documents, and the UMCS/DDC Implementation Plan. To help obtain maximum benefit of Open DDC systems, designers should encourage their customers to develop a UMCS/DDC Implementation Plan. Development of an Implementation Plan is recommended in Engineering Construction Bulletin (ECB) 2007-8 and is described in ERDC/CERL Technical report TR-08-12 'IMCOM LONWORKS® Building Automation Systems Implementation Strategy'. This Technical Report is available at: http://dtic.mil/dtic/tr/fulltext/u2/a492015.pdf

6-3 CHOICE OF SPECIFICATION AND PROTOCOL.

The first decision that must be reached for the building is the choice of protocol, one of:

- LonWorks with LNS (use UFGS 23 09 23.01 with the LNS tailoring option),
- LonWorks with Niagara Framework (use UFGS 23 09 23.01 with the Niagara Framework tailoring option),
- BACnet (use UFGS 23 09 23.02 with the non-Niagara tailoring option), or
- BACnet with Niagara Framework (use UFGS 23 09 23.02 with the Niagara Framework tailoring option).

In most cases, selection of protocol will be dictated by the need to integrate to a specific UMCS. Selection of protocol is extensively described in UFC 3-470-01.

6-4 INTEGRATION TO UMCS.

Most buildings will eventually be integrated to a UMCS. Even if, at the time, it seems like the project is for a stand-alone building, the realities of O&M staffing at most installations make it advantageous to integrate buildings into a single UMCS and the decision to procure a building with no planning for future integration is generally very short-sighted. There are legitimate exceptions for buildings that will not (and likely will never) be maintained by the installation staff – e.g. hospitals and other tenants who have their own O&M staff. In many cases, it is desirable to perform this integration as part of the building project. In this case, use DDC UFGS 23 09 23.XX for the present building-level project and use an edited version of UMCS UFGS 25 10 10 to specify the integration of the building system to the UMCS (UMCS UFGS 25 10 10 is designed to make this editing task straightforward). If integration is not performed as part of the building project, an integration project will be necessary later using an edited version of UFGS 25 10 10. If there will be a significant time lapse between building construction and integration, the building controls project may wish to include additional LDP functionality.

One possible issue is that the site may not have a UMCS that the project can integrate to, in which case the site should consider adding requirements for a UMCS to the building control project. This can often be an effective approach, particularly if the building project spans multiple buildings. See UFC 3-470-01 and UFGS 25 10 10 for guidance and requirements on procuring a UMCS.

6-5 PROCUREMENT CONSIDERATIONS.

6-5.1.1 Non-proprietary procurement.

Unless there is specific written authorization from the Project Manager or Authority Having Jurisdiction, the project shall use non-proprietary procurement using requirements in UFGS 23 09 23.XX.

6-6 DDC DESIGN.

6-6.1 General.

\2\ /2/

Much of the needed detail was attended to during the development of the UFGS and UFC criteria. Still, project specific requirements must be defined by the designer and the specifications and drawings edited accordingly. This notably includes, but is not limited to, editing the Points Schedule drawing to show critical Open system requirements.

The resultant project-specific specification will require the control system Contractor to produce shop drawings, schedules, instructions, test plans, test procedures, testing procedures, and other documents showing the application of products to implement the control system design. The specification will require the Contractor to implement the building-level network in a manner that is consistent with performance requirements defined in the specification. The specification will further require that the Contractor perform calibration, adjustments, and testing of the control system and document the testing to show that the control system functions as designed.

6-7 DRAWING PACKAGE.

Assemble and edit the drawing package as described in CHAPTER 5 CONTROL SYSTEM DRAWINGS.

APPENDIX C GLOSSARY

C-1 ACRONYMS

BCN	Building Control Network
BCS	Building Control System
CCR	Criteria Change Request
DDC	Direct Digital Control
FPOC	Field Point of Connection
HVAC	Heating Ventilating and Air Conditioning
IDG	Installation Design Guide
IP	Internet Protocol
IT	Information Technology
LNS	LonWorks Network Services
M&C	Monitoring and Control
MCX	Mandatory Center of Expertise
NCT	Network Configuration Tool
NDAA	National Defense Authorization Act
O&M	Operations and Maintenance
PDF	Portable Document Format
PID	Proportional, Intergal, Derivative
UFC	Unified Facilities Criteria
UFGS	Unified Facilities Guide Specification
UMCS	Utility Monitoring and Control System
USACE	U.S. Army Corps of Engineers
VAV	Variable Air Volume

C-2 DEFINITION OF TERMS

Several terms are defined in this appendix for ease of reference, but UFC 4-010-06 contains a more extensive, and definitive, list of terms. Should the definitions provide here and in UFC 4-010-06 conflict, the definitions in UFC 4-0101-06 should be used, and a Criteria Change Request (CCR) should be submitted to update the definitions in this UFC.

C-2.1 Field Control System (FCS) and Field Control Network (FCN).

A Building Control System or Utility Control System. The network used by the field control system is called the field control network (FCN).

C-2.1.1 Building Automation System (BAS).

The system consisting of the UMCS Front-End and connected building control systems which provides for control of the building electrical and mechanical systems as well as a user interface and supervisory capability (i.e. the portion of the UMCS for building control and excluding any connected UCS).

C-2.1.2 Building Control System (BCS) and Building Control Network (BCN).

One type of Field Control System. A control system primarily for building electrical and mechanical systems, typically HVAC (including central plants) and lighting. Building Control Systems are generally composed of direct digital controls (DDC) and do not have a full-featured user interface. They may have some local user interface such as “local display panels” but rely on the UMCS for the full user interface functionality. The network used by the building control system is called the building control network (BCN).

C-2.1.3 Utility Control System (UCS) and Utility Control Network(UCN).

One type of Field Control System. Used for control of utility systems such as an electrical substation, sanitary sewer lift station, water pump station, etc. Building controls are excluded from a UCS, however it is possible to have a Utility Control System and a Building Control System in the same facility, and for those systems to share components such as the Field Point of Connection (FPOC). A UCS may include its own local front-end.

C-2.2 Field Point of Connection (FPOC)

The connection point between the field control network (installed by the controls contractor) and the UMCS network (generally owned and installed by the installation IT staff). The FPOC device is typically on the IP network – usually a managed switch, owned and managed by the installation IT staff, and a focal point for Cybersecurity. Note that this definition has evolved over time and may be at variance with older usage of the term.

C-2.3 Industrial Control System (ICS)

One type of control system. Most specifically a control system which controls an industrial (manufacturing) process. Sometimes also used to refer to other types of control systems, particularly utility control systems such as electrical, gas, or water distribution systems.

Note than ICS is at times used to mean "all control systems", so care must be taken to interpret the term in the appropriate context.

C-2.4 Utility Monitoring and Control System (UMCS)

The system consisting of one or more field control systems connected to a UMCS Front-End which provides for control of the electrical and mechanical systems as well as a user interface and supervisory capability. (i.e. the complete system consisting of the UMCS Front-End with all connected BCS and UCS systems). Note that in the past the term "UMCS" has sometimes been used to mean just "the UMCS front end", but is no longer used in this manner.

C-2.5 Utility Monitoring and Control System (UMCS) Front End

The portion of the UMCS consisting primarily of computers running software to provide a full-featured user interface. In addition to providing a full user interface, this system performs functions such as alarming, scheduling, data logging, electrical demand limiting and report generation. The front end does not directly control physical systems; it interacts with them only through field control systems.

C-2.6 Utility Monitoring and Control System (UMCS) IP Network

The IP network used by the UMCS Front End for communication between Field Control Systems. This includes the IP infrastructure components only. The UMCS IP network is often also referred to as the "platform enclave" for cybersecurity purposes.

C-3 TERMS SPECIFICALLY NOT USED BY THIS UFC

The term SCADA (Supervisory Control and Data Acquisition) is not used as the definition can vary depending on context. In general usage, however, "SCADA" can be taken to mean "UCS".

NDAA 2010 uses the term Energy Monitoring and Utility Control System to refer to a Utility Monitoring and Control System (UMCS). This term is not a standard term used by the controls industry, so this UFC and UFGS 25 10 10 do not use this term.

C-4 OTHER TERMINOLOGY

Other terminology related to control systems is defined in UFGS 25 10 10 and in the field control system specifications (e.g. UFGS 23 09 00, UFGS 23 09.01, and UFGS 23 09.02).

This Page Intentionally Left Blank

APPENDIX D POINTS SCHEDULE IINSTRUCTIONS

D-1 USE OF BRACKETS IN THE POINTS SCHEDULE

As with guide specifications, the Points Schedule uses brackets to indicate where entries or selections are required. Unlike with the guide specifications, however, two types of brackets are used in the Points Schedule. “Square brackets” (“[___]”) are used to indicate selections or entries made by the designer, while “angle brackets” (“<___>”) are used to indicate selections or entries that must be made by the building control system contractor.

The building control system contractor is responsible for completing the entire Points Schedule regardless of the presence or absence of “angle brackets”. “Angle brackets” are used in sample drawings to indicate to the designer information they would not typically provide. They may also be used by the designer to highlight specific information they have decided not to provide or have determined must be provided by the Contractor.

D-2 POINTS SCHEDULE DESCRIPTION AND INSTRUCTIONS

Points Schedule columns and entries are described below along with the Designer and Contractor responsibilities related to that column. For each column in the point schedule, the instructions below provide the following data:

APPLICABILITY: Not all columns are used for all protocols. This entry defines which protocol(s) (SpecsIntact tailoring options) the column is used with. “Any” means “use this column regardless of the protocol tailoring option chosen”.

PURPOSE: The intent of the column; why it is necessary

VALID ENTRIES: What are the allowed entries for this column? Note that these are given for a “complete” table, while a designer might, for example, enter “<___>” to indicate that this information will be provided later by the Building Contractor, this is not regarded as a “Valid Entry”. If the information is not needed, then the valid entries are “~” or “N/A” (Note that, to avoid confusion, a blank entry is not a valid entry – do not leave cells blank.):

- An “N/A” (or a greyed out cell, or a combination of N/A and a greyed out cell) is used when there is no possibility of a valid entry for that particular cell.
- A tilde (“~”) is used in a cell where there could be a valid entry, but no entry is required (i.e. it’s specifically used to mean “I could have put a value here but I chose not to enter one”).

DESIGNER: Describes designer responsibilities associated with the entry.

BUILDING CONTRACTOR: Describes building contractor responsibilities associated with the entry.

UMCS CONTRACTOR: Describes UMCS contractor responsibilities associated with the entry.

In some cases, the contractor instructions are further divided by protocol. “Other” means “a protocol other than the ones specifically enumerated”, while “All” means “any and all protocols, including those specifically enumerated”.

Note that while these instructions are complete and authoritative, they may omit some details which are covered either elsewhere in this UFC or the relevant UFGS. In all cases, the designer and contractor are responsible for implementing the requirements of the UFC and UFGS.

D-2.1 General Columns

D-2.1.1 Function

APPLICABILITY: Any protocol

PURPOSE: Describe the functionality of this group of points

VALID ENTRIES: Functional blocks from sequence of operation

DESIGNER: Provide this information

BUILDING CONTRACTOR: None, informational only

UMCS CONTRACTOR: None, informational only

D-2.1.2 Point Name

APPLICABILITY: Any protocol

PURPOSE: The point name

VALID ENTRIES: As shown on sample Points Schedules, or using the point naming convention in APPENDIX E

DESIGNER: Provide this information

BUILDING CONTRACTOR: Provide this information for any additional points needed or where designer did not provide an entry.

UMCS CONTRACTOR: Show these point names on graphic displays

D-2.1.3 Description

APPLICABILITY: Any protocol

PURPOSE: The point description

VALID ENTRIES: Functional description of the point.

DESIGNER: Provide this information

BUILDING CONTRACTOR: Provide this information for any additional points needed or where designer did not provide an entry.

UMCS CONTRACTOR: These values should be displayed on a graphic when an operator requests additional details ("Properties") for a point

D-2.1.4 DDC Hardware ID

APPLICABILITY: Any protocol

PURPOSE: The unique identifier used in the documentation for the DDC Hardware containing the point. This is the identifier for the device used across all drawings.
VALID ENTRIES: Unique Identifier from the Equipment Schedule

DESIGNER: None

BUILDING CONTRACTOR: Provide this information

UMCS CONTRACTOR: None, informational only

D-2.1.5 Setting

APPLICABILITY: Any protocol

PURPOSE: This shows all settings related to the point, such as setpoints and configuration parameters. These are values established in the controller by the building control system contractor, either by dip switches, hardware settings, or engineering software such as controller programming or configuration software.

VALID ENTRIES: Typical values are shown in the sample drawings

DESIGNER: Show setpoints and settings, including appropriate engineering units, as required.

BUILDING CONTRACTOR: Use these settings when configuring devices and provide the setting used where the design did not show or specify one.

UMCS CONTRACTOR: None, informational only

D-2.1.6 Range

APPLICABILITY: Any protocol

PURPOSE: Shows the range of values associated with the point. For example, it could be a zone temperature setpoint adjustment range, a sensor measurement range, occupancy values for an occupancy input, or the status of a safety.

VALID ENTRIES: In general, provide values for the following types of points:

- Zone setpoints
- Switch settings
- Occupancy modes

Note that ranges must meet UFGS 23 09 13 (e.g. permissible range of a temperature sensor). For sensors, show the actual sensor range, which must at least encompass the range specified in section 23 09 13. For actuators show the actual range over which the valve or damper is actuated and indicate whether the maximum value corresponds to a more open or more closed damper or valve.

DESIGNER: Provide this information, including engineering units, or use "< >" to indicate that the building control system contractor is to provide this information

BUILDING CONTRACTOR: Use these ranges when configuring devices, and document the ranges used when designer did not provide an entry.

UMCS CONTRACTOR: None

D-2.1.7 I/O Type

APPLICABILITY: Any protocol

PURPOSE: Shows the input/output signal type (if any) associated with the point.

VALID ENTRIES: One or more of:

- AI: The value comes from a hardware (physical) Analog Input
- AO: The value is output as a hardware (physical) Analog Output
- BI: The value comes from a hardware (physical) Binary Input
- BO: The value is output as a hardware (physical) Binary Output
- PULSE: The value comes from a hardware (physical) Pulse Accumulator Input
- NET-IN: The value is provided from the network (generally from another device)
- NET-OUT: The value is provided to another controller over the network

Note that NET-IN and NET-OUT entries are not used for all values that exist on the network, but rather only when the value is specifically input from or output to another device which uses the value as part of its sequence. Network values used only for trending, alarming, overrides or display at a workstation should not use NET-IN or NET-OUT entries. In other words, absence of a "NET-IN" or "NET-OUT" tag does not mean that the point does not need to be exposed on the network, merely that the point is not shared as part of a sequence.

Note that a point might require two entries, for example an AI that is also used by another device ("AI / NET-OUT").

DESIGNER: In some cases, provide this information to meet specific requirements.

BUILDING CONTRACTOR: Provide this information

UMCS CONTRACTOR: None

D-2.1.8 HOA Required

APPLICABILITY: Any protocol

PURPOSE: Indicates which hardware outputs require HOA switches.

VALID ENTRIES: "Y" to require HOA

DESIGNER: Provide this information

BUILDING CONTRACTOR: Provide HOAs as required

UMCS CONTRACTOR: None – unless monitoring of HOA status is required by specification.

D-2.1.9 Config Type (Configuration Type)

APPLICABILITY: Any protocol

PURPOSE: For points requiring configuration, indicate the type of configuration required for the point

VALID ENTRIES:

- H = Hardware (via switches or adjustments directly on the device).
- C = Configurable
- O or OC = Operator Configurable

(where Configurable and Operator Configurable are defined in the specification)

DESIGNER: Provide this information

BUILDING CONTRACTOR: Provide the appropriate configuration capability in accordance with the specification.

UMCS CONTRACTOR: Provide a means for configuration (such as a configuration page on the system graphic) for each point that is "Operator Configurable" in accordance with the integration requirements.

D-2.1.10 M&C View and Ovrd

APPLICABILITY: Any protocol

PURPOSE: This column indicates whether a point is to be displayed on a workstation via Monitoring and Control (M&C) software, and whether the point must be overridable from the M&C display.

VALID ENTRIES:

- V: View. The point must be displayed on the system graphics
- O: Override. The point must be displayed and overridable via the system graphics
- VO: View and Override. The point must be displayed and overridable via the system graphics (functionally equivalent to "O")

DESIGNER: Provide an entry for each row

BUILDING CONTRACTOR: For V, expose the point to the network so it will be visible to the UMCS. For O, or VO, provide both the value on the network and an override for the value in accordance with the specification points and override capability. Note that additional columns providing protocol specific point details will need to be filled out as well.

UMCS CONTRACTOR: For V, display the point on the system graphic. For O, or VO, display the value on the system graphic and provide the capability to override the point using the override capability provided by the Building Contractor.

D-2.1.11 LDP View and Ovrd

APPLICABILITY: Any protocol

PURPOSE: This column indicates whether a point is to be displayed on an LDP, and whether the point must be overridable from the LDP.

VALID ENTRIES:

- V: View. The point must be displayed on the LDP
- O: Override. The point must be displayed and overridable via the LDP
- VO: View and Override. The point must be displayed and overridable via the LDP (functionally equivalent to "O")

DESIGNER: Provide an entry for each row. Note that there may be conflicts if points are overridden from both the M&C software and from an LDP. For Army projects, do not require overrides from both without specific guidance from the UMCS MCX.

BUILDING CONTRACTOR: For V, display the value on the LDP. For O, or VO, both display the value on the LDP and provide the capability to override the point from the LDP. Note that, depending on how the overrides are implemented, a requirement for Overrides from both the M&C Server and an LDP may require additional configuration in the device as well as additional points in the device and multiple entries in the Points Schedule.

UMCS CONTRACTOR: None

D-2.1.12 Trend Required

APPLICABILITY: Any protocol

PURPOSE: Indicate whether the point should be trended

VALID ENTRIES: “Y”

DESIGNER: Provide this information. Note that all trended points should also have a “V” in the M&C View and Override column.

BUILDING CONTRACTOR: For each point with a “Y” set up a trend in accordance with the specification. Note there is no building contractor action required for in an LNS-based LonWorks system.

UMCS CONTRACTOR: For each point with a “Y”, perform the following in accordance with the specification:

> **LNS-based LonWorks**: Set up a trend
>
> **Other:** Provide trend data upload capability
>
> **All:** Provide a M&C Software interface to access the trend information.

D-2.1.13 Alarming: Alarm condition

APPLICABILITY: Any protocol

PURPOSE: Show the conditions under which an alarm occurs, including any time delays.

VALID ENTRIES: The conditions which, when TRUE, will cause an alarm to be generated. See sample drawings for examples.

DESIGNER: Provide this information

BUILDING CONTRACTOR: Perform alarm generation in DDC Hardware in accordance with the specification. Note there is no building contractor action required for in an LNS-based LonWorks system.

UMCS CONTRACTOR:

LNS-based LonWorks: Perform alarm generation in M&C software in accordance with the specification.

Other: None (but note requirements for ALARM PRIORITY and M&C ROUTING columns).

D-2.1.14 Alarming: Alarm priority

APPLICABILITY: Any protocol

PURPOSE: Indicates which alarms are Informational (in alarm until acknowledged or the condition clears itself) and which are Critical (in alarm until acknowledged and the condition clears itself).

VALID ENTRIES: INFO or CRIT

DESIGNER: Provide this information

BUILDING CONTRACTOR: Configure hardware to assign this priority as part of alarm generation. Note there is no building contractor action required for in an LNS-based LonWorks system.

UMCS CONTRACTOR:

LNS-based LonWorks: Configure M&C Software to assign this priority as part of alarm generation.

All: Take appropriate action at M&C Software based on incoming alarm priority.

D-2.1.15 Alarming: M&C routing

APPLICABILITY: Any protocol

PURPOSE: Show the name of the alarm routing group that is to be used for each alarm to be handled by the UMCS. The routing group defines the destinations for each alarm message and, as specified in UMCS UFGS 25 10 10, each group requires some combination of a pop-up message for a user session, an email to one or more individuals, email to SMS for one or more individuals, or printing to one or more printers.

VALID ENTRIES: Name of a valid alarm routing group as defined on UMCS Contract Drawing.

DESIGNER: Provide this information where integration to a UMCS is planned and the alarm routing groups are known. Otherwise, enter "[___]" indicating that this information will be provided as part of integration.

BUILDING CONTRACTOR: None

UMCS CONTRACTOR: Provide alarm routing in accordance with the routing definition for that alarm routing group.

D-2.2 Protocol-Specific Columns

D-2.2.1 Primary Point Information: Object Type & Instance Number

APPLICABILITY: BACnet, Niagara BACnet

PURPOSE: Document the BACnet Object used for the point, if any. Any point (except for points only used within Niagara Framework) that is displayed at the front end, displayed on an LDP, is trended, is used by another device on the network, or has an alarm condition must have a BACnet Object associated with it and be documented here.

If the Property of interest is not Present_Value, also document the Property that contains the value (for example, a LOOP Object may use the Setpoint Property). In that case, add the Property Identifier after the Object Type / Instance Number.

VALID ENTRIES: BACnet Object Type and Object Instance Number (e.g. AO-8). Typical Object Types are:

- Analog Input (AI)
- Analog Value (AV)
- Analog Output (AO)
- Binary Input (BI)
- Binary Value (BV)
- Binary Output (BO)
- Multi-state Value (MSV)
- Loop (LOOP)

This is not a complete list of Object Types which may be used. In many cases, the specification and sample drawings require specific points use specific Object Types.

DESIGNER: None

BUILDING CONTRACTOR: Provide this entry.

UMCS CONTRACTOR: Use this information when accessing the point over the network.

D-2.2.2 Primary Point Information: SNVT Name

APPLICABILITY: LNS, Niagara LonWorks

PURPOSE: Document the name of the SNVT used for the point. Any point (except for points only used within Niagara Framework) that is displayed at the front end, displayed on an LDP, is trended, is used by another device on the network, or has an alarm condition must be documented here.

VALID ENTRIES: SNVT Name used by the point.

DESIGNER: None

BUILDING CONTRACTOR: Provide this entry.

UMCS CONTRACTOR: Use this SNVT Name when accessing the point over the network.

D-2.2.3 Primary Point Information: SNVT Type

APPLICABILITY: LNS, Niagara LonWorks

PURPOSE: For any point with an entry in the SNVT Name column, document the SNVT Type used for the point.

VALID ENTRIES: Allowed SNVT Types are generally defined in the specification or on the sample drawings.

DESIGNER: If requiring a specific SNVT Type indicate the Type here.

BUILDING CONTRACTOR: When a SNVT Type is shown, provide a SNVT of the indicated type for the point. Otherwise provide this entry.

UMCS CONTRACTOR: Use this SNVT Type when accessing the point over the network

D-2.2.4 Primary Point Information: Niagara ID

APPLICABILITY: Niagara BACnet, Niagara LonWorks

PURPOSE: List the Niagara station ID of the Niagara Framework Supervisory Gateway that the point is mapped into.

VALID ENTRIES: Valid Niagara Station IDs

DESIGNER: None

BUILDING CONTRACTOR: Provide this information

UMCS CONTRACTOR: Use this information when obtaining data from the control system.

D-2.2.5 Network Data Exchange: Gets Data From and Sends Data To

APPLICABILITY: BACnet, Niagara BACnet

PURPOSE: Document other BACnet devices that this point is shared with. This specifically is for <NET-IN> and <NET-OUT> points, but may include other points as well. Do not include the front end as a possible device, but do include all other DDC Hardware such as LDPs that view or override the point.

BACnet provides multiple methods for data to be exchanged between devices.

Any point with a value that is obtained from other DDC Hardware, regardless of method used, must have an entry in the Gets Data From column. Likewise, any point with data that is provided to other DDC Hardware, regardless of method used, must have an entry in the Sends Data To column.

VALID ENTRIES: DDC Hardware IDs of devices obtaining or providing information with the point. Examples are given below in Points Schedule Application Notes.

DESIGNER: None

BUILDING CONTRACTOR: Provide this entry.

UMCS CONTRACTOR: None.

D-2.2.6 Overrides: Object Type and Instance Number

APPLICABILITY: BACnet, Niagara BACnet

PURPOSE: For any point (except for points within a Niagara Framework Supervisory Gateway) requiring an override, document the Object used for overriding the point

VALID ENTRIES:

- “Commandable”: Indicates that the point’s Object is Commandable (Overridable via use of the Priority Array)
- Object Type and Instance Number: If the point is not Commandable, specify the (other) Object, that when written to, will override the point.

DESIGNER: None

BUILDING CONTRACTOR: Provide this entry.

UMCS CONTRACTOR: Use this information / Object ID when overriding the point over the network.

D-2.2.7 Overrides: SNVT Name

APPLICABILITY: LNS, Niagara LonWorks

PURPOSE: For any point (except for points within a Niagara Framework Supervisory Gateway) requiring an override, document the SNVT used for overriding the point

VALID ENTRIES: SNVT Name of point, that when written to, will override the point

DESIGNER: None

BUILDING CONTRACTOR: Provide this entry.

UMCS CONTRACTOR: Use this SNVT Name when overriding the point over the network.

D-2.2.8 Overrides: SNVT Type

APPLICABILITY: LNS, Niagara LonWorks

PURPOSE: For any point with an entry in the Overrides: SNVT Name column, document the SNVT Type used for overriding the point

VALID ENTRIES: SNVT Type used for overriding the point. Note that UFGS 23 09 23.01 has requirements regarding this SNVT type.

DESIGNER: None

BUILDING CONTRACTOR: Provide this entry.

UMCS CONTRACTOR: Use this SNVT Type when overriding the point over the network.

D-2.2.9 Trend Object Location, Type and Instance Number

APPLICABILITY: BACnet

PURPOSE: Indicates the Object ID of the Trend Log Object and whether the Object is local or remote to the device containing the point.

VALID ENTRIES: "~" when no trend was required, otherwise an "L" or "R" and the Object Type and Instance number for the Trend Log (or Trend Log Multiple) Object. Use "L" (Local) when the Object is in the same device as the point and an "R" (Remote) when it's in a different device.

DESIGNER: None.

BUILDING CONTRACTOR: Provide this information. If the Trend is Remote, include the DDC Hardware ID for the remote device in the Notes. Configure TrendLog Object and configure BUFFER_FULL event to request trend upload.

UMCS CONTRACTOR: Provide on-request (via BUFFER_FULL Event) uploading of trend data from this Object.

D-2.2.10 Alarm Information: Alarm Type

APPLICABILITY: BACnet, Niagara BACnet

PURPOSE: Indicates how alarm generation is performed.

VALID ENTRIES:

- “Intrinsic”: Alarm is generated using Intrinsic Reporting
- “Local Algorithmic”: Alarm is generated using Algorithmic Reporting with an Event Enrollment Object in that device
- “Remote Algorithmic”: Alarm is generated using Algorithmic Reporting with an Event Enrollment Object in a different device
- “Niagara Framework”: Alarm is generated using the Niagara Framework

Note that “Niagara Framework” is only allowed if the Niagara Framework is used by the project. Note that “Local Algorithmic” and “Remote Algorithmic” are prohibited if the Niagara Framework is selected.

DESIGNER: None

BUILDING CONTRACTOR: Provide this information. When “Local Algorithmic” or “Remote Algorithmic” fill out the Event Enrollment Object Instance Number column as well. If “Remote Algorithmic” is used, indicate the DDC Hardware ID of the device containing the Event Enrollment Object in the Notes.

UMCS CONTRACTOR: None

D-2.2.11 Alarm Information: Notification Class Object Instance Number

APPLICABILITY: BACnet, Niagara BACnet

PURPOSE: For Intrinsic and Algorithmic alarms, indicates the Notification Class Object used for alarm generation.

VALID ENTRIES: Notification Class Object Instance Number

DESIGNER: None

BUILDING CONTRACTOR: Provide as required.

UMCS CONTRACTOR: Use the Notification Class Object when configuring alarm notifications at the Front End.

D-2.2.12 Alarm Information: Event Enrollment Object Instance Number

APPLICABILITY: BACnet

PURPOSE: Indicates the Event Enrollment Object used for algorithmic alarm generation

VALID ENTRIES: Event Enrollment Object Instance Number.

DESIGNER: None

BUILDING CONTRACTOR: Provide as required.

UMCS CONTRACTOR: None

D-2.3 Configuration Information

APPLICABILITY: Any protocol

PURPOSE: Indicate the means of configuration associated with the point

VALID ENTRIES: The valid entries depend on the configuration requirements for the point:

BACnet:

- Operator Configurable Points: BACnet Object and Property information (Name, Type, Identifiers) containing the configurable value. Indicate whether the property is writable always, or only when Out_Of_Service is TRUE.
- Configurable Points: Indicate one of:
  - BACnet Object and Property information as for Operator Configurable points.
  - The configurable settings from within the engineering software for the device
  - The hardware settings on the device

LonWorks:

Indicate one of:

- “Plug-In” if the point is configurable via an LNS plug-in or Niagara Wizard.

- The network variable or configuration property used to configure the value.
- The hardware settings on the device.

Niagara Framework Supervisory Gateways:

Indicate the point within the Niagara Framework Supervisory Gateway used to configure the value.

DESIGNER: None.

BUILDING CONTRACTOR: Provide this information.

UMCS CONTRACTOR: Use this information when providing configuration screens for Operator Configurable points.

D-2.4 Point Schedule Application Notes

D-2.4.1 Use of BACnet "Gets Data From" and "Sends Data To" Columns

Example 1:

- DDC #1 is the controller for a VAV Air Handler.
- DDC #2 is a Smart Sensor reading the supply air pressure (SA-P)
- There is both an AI Object in DDC #2 for Supply Air Pressure, and an AV Object in the AHU controller (DDC #1) for this value. Note that UFGS 23 09 23.02 requires the use of either the AI Object in the sensor or the AV object in the AHU, it does not require the presence of both Objects.
- The relevant entries are highlighted (cells are filled, text is bolded) in the following Points Schedule excerpt:

POINT NAME	DDC HARDWARE ID	IO Type	OBJECT TYPE AND INSTANCE NUMBER (AND PROPERTY ID)	DATA FROM	DATA TO
SF-C	DDC #1	AO	AO 2		
SA-P-SP	DDC #1	~	AV 8		
SA-P	**DDC #2**	**AI, NET-OUT**	**AI 3**		**DDC #1**
SA-P	**DDC #1**	**NET-IN**	**AV 9**	**DDC #2**	

Example 2:

- DDC #1 is the controller for a VAV Air Handler.
- DDC #2 is a Smart Sensor reading the supply air pressure (SA-P)
- There is an AI Object in DDC #2 but there is no BACnet Object in DDC #1 for

supply air pressure.

- The appropriate entries are highlighted (cells are filled, text is bolded) in the following Points Schedule excerpt:

POINT NAME	DDC HARDWARE ID	IO Type	OBJECT TYPE AND INSTANCE NUMBER (AND PROPERTY ID)	DATA FROM	DATA TO
SF-C	DDC #1	AO	AO 2		
SA-P-SP	DDC #1	~	AV 8		
SA-P	**DDC #2**	**AI, NET-OUT**	**AI 3**		**DDC #1**

Example 3:

- DDC #1 is the controller for a VAV Air Handler.
- DDC #2 is a Smart Sensor reading the supply air pressure (SA-P)
- There is NOT an AI Object in DDC #2 for Supply Air Pressure, but there is an AV Object in the AHU controller (DDC #1) for this value.
- The appropriate entries are highlighted (cells are filled, text is bolded) in the following Points Schedule excerpt:

POINT NAME	DDC HARDWARE ID	IO Type	OBJECT TYPE AND INSTANCE NUMBER (AND PROPERTY ID)	DATA FROM	DATA TO
SF-C	DDC #1	AO	AO 2		
SA-P-SP	DDC #1	~	AV 8		
SA-P	**DDC #1**	**NET-IN**	**AV 9**	**DDC #2**	

APPENDIX E POINT NAMING CONVENTION

E-1 POINT SCHEDULE APPLICATION NOTES.

This appendix defines a point naming convention consisting of abbreviations and acronyms (W-X-Y-Z and ##) that describe the device or signal. Note that a signal can be a hardwired input or output to or from a device as shown in a control schematic or can be a logical constant or variable as shown in a control logic diagram:

- W - Device descriptor; Describes the device, physical location of the device, source of the signal, destination of the signal, or the apparatus/function being controlled. In some cases, a two-part device descriptor is used. For example, MA-FLT is used to describe the mixed air filter.

- X - Measured variable or controlled device; In the case of a sensor or measurement instrument, it is temperature (T), relative humidity (RH), pressure (P), etc. In the case of an output, it can describe the actuated device such as a valve (V) or damper (D).

- Y - Modifier; In some cases, a modifier is required, such as indicating that a signal is a low-limit (LL) or high-limit (HL) input. Alternatively, the modifier may be used to describe the type of control signal such as a modulating command (C), start/stop (SS), enable (ENA), or disable (DIS) signal.

- Z - In some cases, an additional modifier is required, such as indicating that a signal is a setpoint (SP).

- Device or signal number; When there are multiple identical control devices or signals, sequential numbering is used to avoid duplicate unique identifiers. All DDC controllers are numbered (by the Contractor), even if there is only one. The intent is to be able to show a single (common) DDC controller multiple times on a drawing. This can help simplify the control drawings by showing fewer signal lines connected to several DDC controllers instead of showing numerous signal lines connect to a single DDC controller. It also provides leeway to the Contractor to use multiple controllers where project application requirements dictate the need.

E-2 DEVICE DESCRIPTORS.

The following are typical device descriptors (W):

Table E-1 Typical Device Descriptors

Name	Description	Comment
BA	BYPASS AIR	
BLR	BOILER	

Name	Description	Comment
CD	COLD DECK	
CF	CONDENSER FAN	
CHLR	CHILLER	
CLG	COOLING	
CDWR	CONDENSER WATER RETURN	
CDWR	CONDENSATE WATER RETURN	
CDWS	CONDENSER WATER SUPPLY	
CT	COOLING TOWER	
CTF	COOLING TOWER FAN	
CHWR	CHILLED WATER RETURN	
CHWS	CHILLED WATER SUPPLY	
CHW	CHILLED WATER	
DA	DISCHARGE AIR	
DT	DUAL TEMP	
DTWR	DUAL TEMP WATER RETURN	
DTWS	DUAL TEMP WATER SUPPLY	
DX	DIRECT EXPANSION (UNIT)	
EA	EXHAUST AIR	
EF	EXHAUST FAN	

Name	Description	Comment
FAP	FIRE ALARM PANEL	
HD	HOT DECK	
HTG	HEATING	
HTHW	HIGH TEMPERATURE HOT WATER	
HUM	HUMIDIFIER	
HW	HOT WATER	
HWR	HOT WATER RETURN	
HWS	HOT WATER SUPPLY	
HX	HEAT EXCHANGER	
MA	MIXED AIR	
MINOA	MINIMUM OUTSIDE AIR	
OA	OUTSIDE AIR	
PC	PRE-COOLING	
PCHW	PRIMARY CHILLED WATER	
PCHWR	PRIMARY CHILLED WATER RETURN	
PCHWS	PRIMARY CHILLED WATER SUPPLY	
PH	PREHEAT	
PRI	PRIMARY	To distinguish from Secondary
RA	RETURN AIR	
RF	RETURN FAN	
RLA	RELIEF AIR	

Name	Description	Comment
RM	ROOM	Generally, use Zone instead
SA	SUPPLY AIR	
SEC	SECONDARY	To distinguish from Primary
SF	SUPPLY FAN	
STM	STEAM	
SCHD	SCHEDULER	
ZN	ZONE	May use Room instead

E-3 TYPICAL VARIABLES OR CONTROLLED DEVICES.

The following are typical measured variables or controlled devices (X):

Table E-2 Typical Measured Variables or Controller Devices

Name	Description
CO2	CARBON DIOXIDE
D	DAMPER
ECO	ECONOMIZER
F	FLOW
FLT	FILTER
P	PRESSURE
PMP	PUMP
RH	RELATIVE HUMIDITY
SMK	SMOKE
T	TEMPERATURE
V	VALVE

WB	WET BULB (TEMPERATURE)

E-4 TYPICAL MODIFIERS.

The following are typical modifiers (Y and Z):

Table E-3 Typical Modifiers

Name	Description	Comment
2P	TWO-POSITION	Indicates a 2-position output
ADJ	ADJUSTABLE	Indicates a value is to be adjustable
ALM	ALARM	Indicates an alarm annunciation point
C	COMMAND	Indicates an analog output
DB	DEADBAND	
DIFF	DIFFERENCE	
DIS	DISABLE	
ENA	ENABLE	
HL	HIGH LIMIT	
LL	LOW LIMIT	
OCC	OCCUPIED	
RQST	REQUEST	
RTN	RETURN	
S	STATUS	
SPLY	SUPPLY	
SP	SETPOINT	

Name	Description	Comment
SS	START/STOP COMMAND	
SYS	SYSTEM	
UNOCC	UNOCCUPIED	

E-5 EXAMPLE POINT NAMES.

For example, here are the standard point names used in the Points Schedule for VAV AHU with Return Fan:

Table E-4 Example Point Names

Name	Description
MINOA-F	MINIMUM OUTSIDE AIR FLOW
MINOA-D-C	MINIMUM OUTSIDE AIR DAMPER COMMAND
MINOA-F-SP	MINIMUM OUTSIDE AIR FLOW SETPOINT (SETTING)
OA-T	OUTSIDE AIR TEMPERATURE
MA-T	MIXED AIR TEMPERATURE
MA-D-C	MIXED AIR DAMPER COMMAND
ECO-HL-SP	ECONOMIZER HIGH LIMIT SETPOINT
ECO-LL-SP	ECONOMIZER LOW LIMIT SETPOINT
MA-T-SP	MIXED AIR TEMPERATURE SETPOINT
SA-T	SUPPLY AIR TEMPERATURE
CLG-V-C	COOLING VALVE COMMAND
SA-T-SP	SUPPLY AIR TEMPERATURE SETPOINT
RA-T	RETURN AIR TEMPERATURE

Name	Description
MA-FLT-P-HL	MIXED AIR FILTER PRESSURE HIGH LIMIT SWITCH
OA-FLT-P	OUTSIDE AIR FILTER PRESSURE
OA-FLT-P-LL	OUTSIDE AIR FILTER PRESSURE LOW LIMIT
SF-S	SUPPLY FAN STATUS
RF-S	RETURN FAN STATUS
SA-SMK	SUPPLY AIR SMOKE
RA-SMK	RETURN AIR SMOKE
CLG-DA-T-LL	COOLING COIL DISCHARGE AIR TEMP LOW LIMIT
SA-P-HL	SUPPLY AIR PRESSURE HIGH LIMIT
RST-BUT	SYSTEM RESET BUTTON (FOR SAFETIES)
SYS-OCC-SCHED	SYSTEM OCCUPANCY SCHEDULE
UNIT STATUS	UNIT STATUS (HTG AND/OR CLG REQUEST) (SEE NOTES)
SYS-OCC-C	OCCUPANCY COMMAND
SYS-OCC	SYSTEM OCCUPANCY (ACTUAL)
SF-SS	SUPPLY FAN START/STOP
RF-SS	RETURN FAN START/STOP
BLDG-T	BUILDING TEMPERATURE (NIGHT STAT)
BLDG-T-LL	BUILDING TEMPERATURE LOW LIMIT
SF-C	SUPPLY FAN COMMAND
SA-P	SUPPLY AIR PRESSURE
SA-P-SP	SUPPLY AIR PRESSURE SETPOINT

Name	Description
SA-F	SUPPLY AIR FLOW
RA-F	RETURN AIR FLOW
RF-C	RETURN FAN COMMAND
F-DIFF-SP	FLOW DIFFERENCE SETPOINT

E-6 OTHER ABBREVIATIONS.

Other Abbreviations that are often encountered in HVAC controls, but would not normally appear in a Point Name in a Point Schedule are:

Table E-5 Other Abbreviations

Name	Description	Comment
AFMA	AIRFLOW MEASUREMENT ARRAY	
BLDG	BUILDING	
BUT	BUTTON	
COM	COMMON	
COMP	COMPARATOR	
COMP	COMPRESSOR	
CP	CONFIGURATION PROPERTY	
CSR	CURRENT SENSING RELAY	
DDC	DIRECT DIGITAL CONTROL(LER)	
DIR	DIRECT (CONTROL ACTION)	
DISP	DISPLAY	
EP	ELECTRIC TO PNEUMATIC TRANSDUCER	
EPS	ELECTRIC TO PNEUMATIC SWITCH	
I/O	INPUT/OUTPUT	

Name	Description	Comment
IR	INFRARED	
LDP	LOCAL DISPLAY PANEL	
M	MOTOR or MAIN	
M&C	MONITORING & CONTROL (SOFTWARE)	
MS	MOTOR STARTER	
N/A	NOT APPLICABLE	
NC	NORMALLY CLOSED	
nci	NETWORK CONFIGURATION INPUT	
NO	NORMALLY OPEN	
ODT	ON DELAY TIMER	
OL	OVERLOAD	
OWS	OPERATOR WORKSTATION	
PID	PROPORTIONAL INTEGRAL DERIVATIVE	
PP	POSITIVE POSITIONER	For pneumatic actuators
R	RELAY	
REV	REVERSE (CONTROL ACTION)	
RST	RESET	
RT	RATE	
SNVT	STANDARD NETWORK VARIABLE TYPE	
STAT	THERMOSTAT	
TAP	TAP, PRESSURE	
VAV	VARIABLE AIR VOLUME	
VFD	VARIABLE FREQUENCY DRIVE	

Name	Description	Comment
XFMR	TRANSFORMER	

This Page Intentionally Left Blank

APPENDIX F CONTROL LOGIC DIAGRAM (CLD) OVERVIEW

F-1 INTRODUCTION

The control logic diagram (CLD) is an unambiguous graphical description of the control system sequence of operation. The focus of the CLD is on control logic, not on a particular hardware implementation. In particular, the CLD does not distinguish between normally open or normally closed contacts, valves, or dampers; these details should instead be indicated on the appropriate wiring diagram, valve/damper schedule, or control schematic drawing. The CLD is concerned with whether a given signal is TRUE or FALSE.

For example, a typical sequence calls for a 'fan status' input (to be used in a fan-proof logic block). The actual hardware could be implemented in a variety of ways, -- a current-sensing-relay on the fan motor, a DP switch across the fan, or an air flow proof switch. The actual hardware used is irrelevant to the CLD. Any one of these possible hardware devices would be shown as a simple binary input to the sequence. Another example would be the freeze stat (CooLinG-Discharge-Air-Temp-LowLimit; CLG-DA-T-LL) which is TRUE when the freeze stat trips; whether that's from a set of NO or NC contacts is a detail for the wiring diagram. Finally, the Controller hardware implementation is not shown; while a given functional block is probably implemented in one controller, a build-up system (such as a RF VAV system with MA Economizer and Ventilation Demand control) may be in one or more controllers – the CLD does not make that distinction.

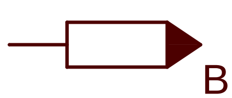
F-2 FUNCTIONAL BLOCKS USED IN CONTROL LOGIC DIAGRAMS.

In the following descriptions, logical values are always referred to as TRUE or FALSE. Synonyms for these names include ON and OFF, as well as 1 and 0.

F-2.1 Signal.

A line represents a signal path within the logic, either analog or binary. This line shows signal inputs and/or outputs to and from functional blocks.

F-2.2 Actuator Output.



2-Position Actuator Output

Modulating Actuator Output

This block represent a physical output from the system, an actuator or valve. It accepts a binary (B) or analog (A) signal and drives a piece of hardware. Since the CLD shows the control logic without reference to the hardware implementation, the actual hardware is unspecified.

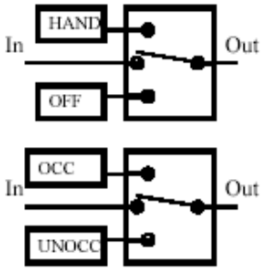
F-2.3 Sensor Input.

Binary Sensor Input

Analog Sensor Input

This block represents a hardware sensor input to the system. It may provide either an analog (A) or binary (B) signal. Again, the exact hardware type is unspecified.

F-2.4 Hand-Off-Auto (H-O-A) Switch.



H-O-A Switch

This represents a HAND-OFF-AUTO switch. Sometimes, a H-O-A switch will be shown differently; for example where the position of the H-O-A switch would select some input to control logic. This block is generally used when the output of a control block is selected. The top block shows a normal H-O-A switch, the bottom shows a variant where the manually selected values are OCCUPIED or UNOCCUPIED.

F-2.5 Constant Value.

This logic block represents a constant value, either analog or binary and is usually provided as an input to another logic block.

F-2.6 Signal I/O.

Signal Input

Signal Output

These blocks represent a named signal path within the logic. These are functionally identical to the symbols described earlier, except that this signal is given a name, which allows it to be defined or used elsewhere in the logic.

F-2.7 Logical AND.

Logical AND Function

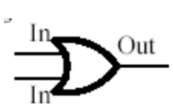
This logic block represents the logical AND function. It takes two or more binary inputs and produces a binary output. Its output is TRUE if and only if all of its inputs are TRUE. If any of its inputs are FALSE, then its output is FALSE.

F-2.8 Logical NOT.

Logical NOT Function

This logic block represents the logical NOT function. It has one binary input and one binary output. Its output is TRUE if and only if its input is FALSE. If its input is TRUE, its output is FALSE.

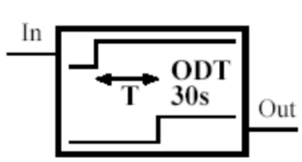
F-2.9 Logical OR.



Logical OR Function

This logic block represents the logical OR function. It has two or more binary inputs and one binary output. Its output is TRUE if any of the inputs are true. If all the inputs are FALSE, the output is FALSE.

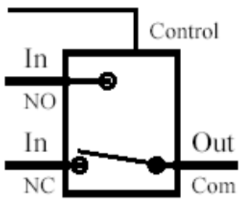
F-2.10 On Delay Timer.



On Delay Timer

This logic block represents an On Delay Timer. It has one binary input and one binary output. In addition it has one parameter, a time (T) value. The output is always equal to the input, except when the input changes value from FALSE to TRUE. In this case, the transition of the output from FALSE to TRUE is delayed by the value of the time parameter. This time value has no effect on the transition from TRUE to FALSE, it only affects the output when the input becomes TRUE.

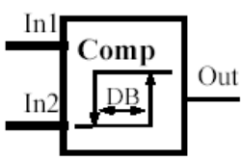
F-2.11 Switch.



Switch

This block represents an analog switch with 2 analog inputs, one analog output, and a binary control input. When the control input is false, the output is the value of the analog signal at the Normally Closed (NC) input. When the control input is true, the output is the value of the analog signal at the NO (Normally Open) input. Note that this convention for NC and NO follows the electrical switch convention; it is opposite from that used for pneumatic switches.

F-2.12 Comparator with Deadband.



Comparator with Deadband

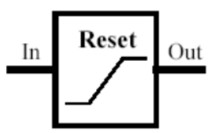
This logic block represents a comparator function with hysteresis. It takes two analog inputs and produces a binary output. It also has one parameter, deadband (DB). As shown in Comparator Table below the output value only changes if the difference between the inputs exceeds half the deadband, if the difference in inputs is less than half the deadband, the output remains at its present value.

Comparator Input and Corresponding Output

Input Conditions	Output Value
(*In1*–*In2*) < -*deadband*/2	FALSE
-*deadband*/2 ≤ (*In1*–*In2*) ≤ *deadband*/2	Output does not change; remains fixed
(*In1*–*In2*) > +*deadband*/2	TRUE

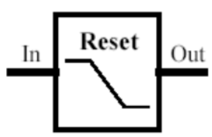
For example, if *In1*=75, *In2*=68 and the *deadband*=4, the output would be TRUE. As *In1* fell, the output would remain TRUE until *In1* went below 66 (68–66=4/2). Essentially, the output of this block is TRUE if the top value is greater than the bottom value and FALSE if the bottom value is greater than the top value (neglecting the deadband).

F-2.13 Reset Schedule.



Reset Schedule

(output increases as input increases)

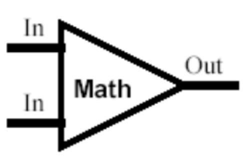


Reset Schedule

(output decreases as input increases)

This block represents a reset schedule. It has one analog input, one analog output, and 4 parameters: InputMin, InputMax, OutputMin, and OutputMax. For the first reset schedule shown, the output increases as the input increases; as the input ranges from InputMin to InputMax, the output varies linearly from OutputMin to OutputMax. Inputs below InputMin or above InputMax result in the output going to OutputMin or OutputMax, respectively. For the second reset schedule shown, the output decreases as the input increases. The reset schedule block can be thought of as a graph, with the input variable on the X-axis and the output variable on the Y-axis.

F-2.14 Math Function.



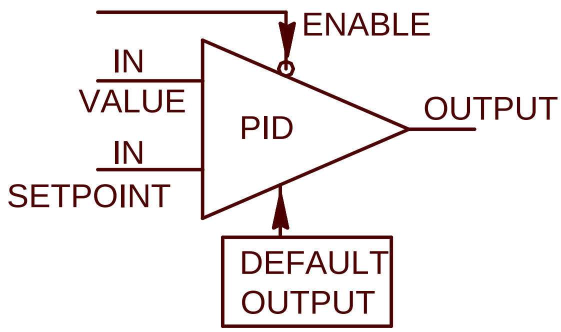
Math Function

This logic block represents a variety of mathematical functions. It takes two or more analog inputs and produces an analog output. Some common functions for this block are shown in the table below.

Common Math Block Functions

Name	Function
Minus	Subtraction
Minimum	Select the minimum value from the input values
Maximum	Select the maximum value from the input values
Plus	Addition

F-2.15 PID Loop with Enable.



This function block represents a proportional-integral-derivative (PID) loop with an Enable input. It has 2 analog inputs (a value and a setpoint), an analog output, a binary enable input, and default output. The DEFAULT OUTPUT is the OUTPUT when the ENABLE is false.

F-2.16 IF Block.

The IF Block is TRUE if the input meets the condition inside the block, otherwise the IF Block’s output is FALSE.

F-2.17 Set/Reset Latch.

This function block represents a latch. The latch has 2 binary inputs, a set input and a reset input, as well as a single binary output. Once set (by a TRUE value at the Set input), the latch's output remains TRUE until reset (by a TRUE value at the reset input). Likewise, once reset, the output remains FALSE until set by a TRUE value at the set input. Essentially, the latch remembers whether it was last Set or Reset.

Record of Changes (changes are indicated by **\1** ... **/1/**)

Change No.	Date	Location

This UFC supersedes UFC 3-410-04N, *Industrial Ventilation, dated* 21 October 2004.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force \2\ Civil Engineer Center (AFCEC) /2/ are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW DOCUMENT SUMMARY SHEET

Document: UFC 3-410-04, *Industrial Ventilation, 13 December 2017*
Superseding: UFC 3-410-04N, *Industrial Ventilation, 21 October 2004*

Description: This UFC provides criteria for the design of ventilation systems that control contaminants generated from industrial processes.

Reasons for Document: This is a new Joint Service document. This new document represents another step in the Joint Services effort to bring uniformity to the planning, design and construction of military facilities. This UFC was developed to provide design requirements to accomplish the following:

- Assist designers in understanding the system requirements for ventilation systems.
- Provide architects, engineers, and construction surveillance personnel with the essential, minimum requirements for the design of ventilation systems that control contaminants generated from industrial processes.
- Clarify the operational intent of the system design.

Impact: The following will result from the publication of this UFC:

- This UFC creates a single source for common DoD industrial ventilation system criteria and an accurate reference to individual Service-specific documents.
- This UFC facilitates updates and revisions and promotes agreement and uniformity of design and construction between the Services.

Non-Unification Issues: The following are issues that remain non-unified and the reasoning for each:

- Section 2-1 identifies different safety standards for each Service. These standards are operational in nature and have not been unified.

CHAPTER 1 INTRODUCTION

1-1 SCOPE.

This Unified Facilities Criteria (UFC) provides criteria for the design of ventilation systems that control contaminants generated from industrial processes.

1-2 PURPOSE OF CRITERIA.

Criteria are developed to define requirements during the design of industrial ventilation systems. Chapter 2 provides general criteria and Chapters 3 through 10 provide criteria for specific processes. Use the general criteria presented in Chapter 2 along with the applicable specific criteria presented in Chapters 3 through 10 to design the ventilation system. For all other ventilation applications, use the criteria in Chapter 2.

Criteria contained in this UFC should be interpreted as the minimum required and should be improved where current technology or situation warrants. Users of this UFC are advised to consult the most current edition of the standards.

This UFC does not incorporate individual state and local environmental requirements. It is the sole responsibility of the cognizant design personnel to design an industrial ventilation system that complies with state and local environmental requirements. It is also the responsibility of the cognizant design personnel to design an industrial ventilation system that is energy efficient.

1-3 SPECIFIC PROCESSES.

The specific processes addressed in this UFC are asbestos delagging, torpedo refurbishing (Otto Fuel II), composites fabrication and repair, abrasive blasting, woodworking, battery maintenance, and paint spray booths. Requirements for aircraft corrosion control facilities are located in UFC 4-211-02, *Aircraft Corrosion Control and Paint Facilities*.

1-4 APPLICABILITY.

This UFC is applicable to all service elements and contractors involved in the planning, design and construction of DoD facilities worldwide. Where conflicts in requirements appear between sections of any mechanical UFC or applicable codes or laws, the most restrictive requirement will govern.

1-5 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-6 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with DoD Instruction 8500.01, DoD Instruction 8510.01, and as required by individual Service Implementation Policy

This Page Intentionally Left Blank

CHAPTER 2 GENERAL REQUIREMENTS

2-1 GENERAL CRITERIA.

Installing engineering controls is the preferred method of controlling hazardous processes as specified in 29 CFR 1910.1000(e), *Air Contaminants* and OPNAVINST 5100.23, *Navy Occupational Safety and Health Program Manual*, AFOSHSTD 91-501 Air Force Consolidated Occupational Safety standard, and EM 385-1-1 *USACE Safety and Health Requirements Manual*. Properly designed industrial ventilation systems are the most common form of engineering controls.

2-2 COORDINATION.

Form a project design team to direct the design of industrial ventilation projects. Include in the design team representatives from:

- Affected industrial shop.
- Public Works or Base Civil Engineer.
- Health and Safety Office.
- Cognizant Regional Engineering Office (REO) (for example: Navy Facility Engineering Command, Army Corps of Engineers District, and Air Force major command engineering office). The REO representative establishes a design team and acts as the team leader in all cases, except when the cognizant REO grants a variance.
- Industrial Hygiene (IH) Offices.

NOTE U.S. NAVY: BUMED or activity IH. Use Navy and Marine Corps Public Health Center as a back-up.

- Systems or major command program manager (where applicable).
- System safety engineer.
- Environmental manager.

2-3 DESIGN PROCEDURE.

Refer to the ACGIH, *Industrial Ventilation; A Manual of Recommended Practice for Design (IV Design Manual)*, Chapter 9, “Local Exhaust Ventilation System Design Calculation Procedures” for system design calculations. In addition, design all industrial ventilation systems in accordance with Steps 1-9 in the paragraphs below.

2-3.1 Step 1.

Identify all significant contaminant sources that require ventilation control. Request the local industrial hygiene office to provide a source characterization with area diagrams of the contaminant sources, and employee work areas. Also, consider how the system being designed might affect the performance of any existing processes, industrial ventilation systems or HVAC systems.

2-3.2 Step 2.

Coordinate with permitting agencies to determine specific permitting requirements. Also determine documentation and system monitoring requirements.

2-3.3 Step 3.

Consider how the facility is to be used or expanded in the future. It may be possible to initially specify fans that are capable of handling future needs at minimal increased cost.

2-3.4 Step 4.

Select or design the exhaust hood that best suits the work piece or operation. Design the exhaust hood to enclose the work piece or operation as much as possible. This will reduce the ventilation rates required to provide contaminant control. This UFC provides optimum exhaust hood designs for many of the operations covered.

2-3.5 Step 5.

Determine the capture velocity required to control generated contaminants. Capture velocities in this UFC are specified assuming there are no cross drafts or turbulence that adversely affects the capture efficiency. Reduce potential for cross drafts or turbulence near a given exhaust hood by properly locating and designing the hood with baffles, and also by designing the replacement air system to complement the exhaust system. Pay close attention to how air diffuses into the room near the local exhaust ventilation system.

2-3.6 Step 6.

Determine the exhaust volumetric flow, in cubic feet per minute (cfm) [cubic meters per second (m^3/s)], required to maintain the capture velocity determined in previous step.

2-3.7 Step 7.

Create a line drawing of the proposed system. Include plan and elevation dimensions, fan location and air cleaning device location. Identify each hood, branch duct and main duct sections.

2-3.8 Step 8.

Size ductwork using the balance by design or the blast gate method. Maintain the required minimum transport velocity throughout the system.

2-3.9 Step 9.

Determine requirements for replacement air. Based on the process, determine if the room must be slightly negative or neutral pressure with respect to the surrounding area. The surrounding area can be either outside the building envelope or an adjacent room or hallway. Determine if tempered replacement air is needed.

2-4 DESIGN CRITERIA.

Several design criteria are common to all industrial ventilation systems; use the ACGIH IV Design Manual and this document for primary guidance. If conflicts exist, this UFC takes precedence. See the following paragraphs in Chapter 2 for general requirements, plus Chapters 3 through 9 for design requirements on specific types of facilities. Incorporate the guidelines provided in UFC 1-200-02, *High Performance and Sustainable Building Requirements*, for system design and equipment selection.

2-4.1 Ductwork.

In addition to the recommendations of the *ACGIH IV Design Manual* and requirements of NFPA 91 section on Duct Materials and Construction, consider the following when designing a ventilation system.

a. Specify duct gage, reinforcement schedule and hanger design and spacing, in accordance with SMACNA RIDCS, *Round Industrial Duct Construction Standards* for round duct and SMACNA RTIDCS, *Rectangular Duct Construction Standards* for rectangular duct.

b. Install clean-out doors in ductwork that conveys particulate material such as wood dust or blasting grit. Mount clean-out doors on top half of horizontal runs near elbows, junctions, and vertical runs.

2-4.2 Fans.

2-4.2.1 Selection.

Except where specified below, fan selection criteria for replacement air fans and exhaust air fans are identical.

a. Select exhaust system industrial fans that meet design pressure and volume flow rate requirements and have the AMCA-certified performance seal. The design pressure requirement must account for any system effects caused by non-uniform airflow into or out of the fan. See AMCA 201, *Fans and Systems* for more information on system effects. Specify a fan class that is appropriate for the design operating point. Do not select fans with forward curved blades for exhaust or recirculating replacement air-systems.

b. When selecting fan capacity, consider if the process room pressure will be positive, negative or neutral with respect to the external areas. Select a fan that will provide the necessary volumetric flow rate to maintain the desired process room pressure. Ensure that all sources of exhaust air are considered when selecting fan capacity. See the paragraph in Chapter 2 entitled, “Replacement Air” for more details.

c. Specify fan shafts that have a uniform diameter along the entire length. Use bearings that are rated with an average life of 200,000 hours.

d. Select only energy efficient motors. If available, select “*NEMA Premium Efficiency* “motors per NEMA MG-1 for motors and generators. Select the motor to handle cold startup amperage for nonstandard air processes.

e. Specify vibration-isolating couplings at the fan inlet and outlet. Mount all fans on vibration isolating bases.

f. If the planner's forecasts change in the processes to occur within the next couple of years, which would require an increase in the amount of replacement or exhaust air, then consider purchasing a larger capacity fan and oversized wiring.

g. Additional fan specification data such as spark resistant construction, drive arrangement, etc. is available in ANSI/AMCA Standards 99-10, *“Standards Handbook”*.

2-4.2.2 Location.

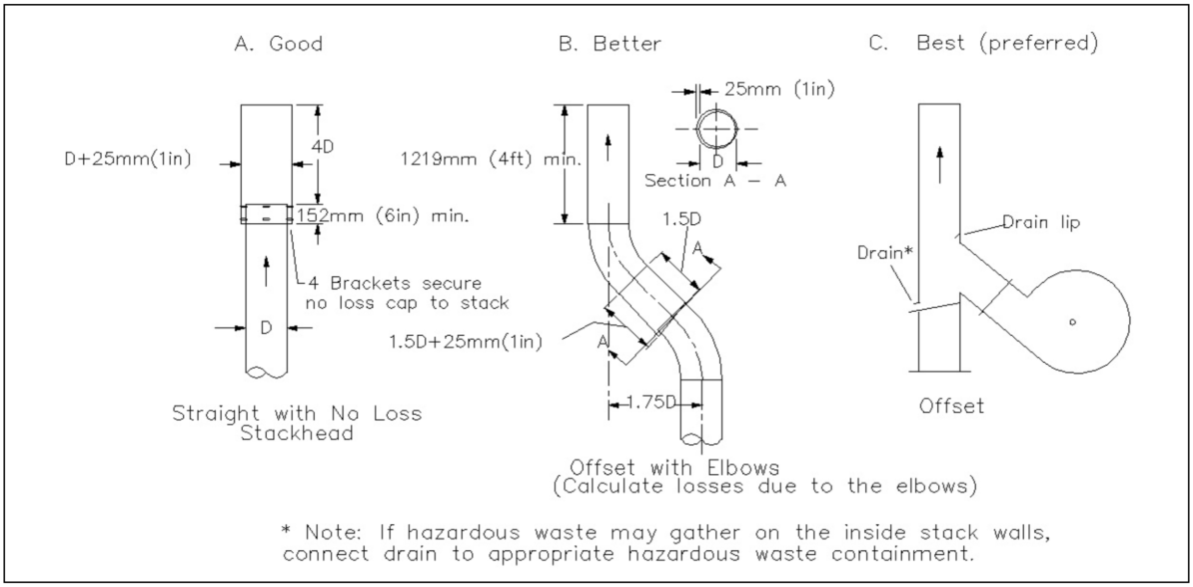
Locate the exhaust fan after the air pollution control equipment to protect fan blades from contaminated air-stream. Provide access for maintenance to all fans, including ladders and guardrails where necessary. Refer to NFPA 70, *National Electrical Code* for motor controller and disconnect location requirements. In all cases, install exhaust fans outside the building that they serve. Installing the fan outside the building envelope will isolate the working space from contaminants during fan maintenance, minimize noise inside the building, and ensure that ductwork within the building envelope is under negative pressure.

2-4.3 Exhaust Stacks.

2-4.3.1 Design Considerations.

Refer to the ACGIH IV Design Manual for exhaust stack design criteria. The best designs are cylindrical, vertical discharge stacks as shown in Figure 2-1. The best protection from rain, when the ventilation system is not running, is the “offset stack” design C, as shown in Figure 2-1. Water may still enter the system with straight stack design A. Provide a means to drain water from the fan housing.

Figure 2-1. Exhaust Stack Designs.



2-4.3.2 Location and Structural Considerations.

Refer to ASHRAE Handbook, *Fundamentals* for information on airflow around buildings. Do not select stack locations based exclusively on prevailing winds. A stack must provide effluent dispersion under all wind conditions. Refer to UFC 1-200-01, *General Building Requirements* for exhaust stack structural design considerations. Some structural considerations are wind load, lightning protection, and stack support. Refer to SMACNA GSSDC, *Guide for Steel Stack Design and Construction* for additional information.

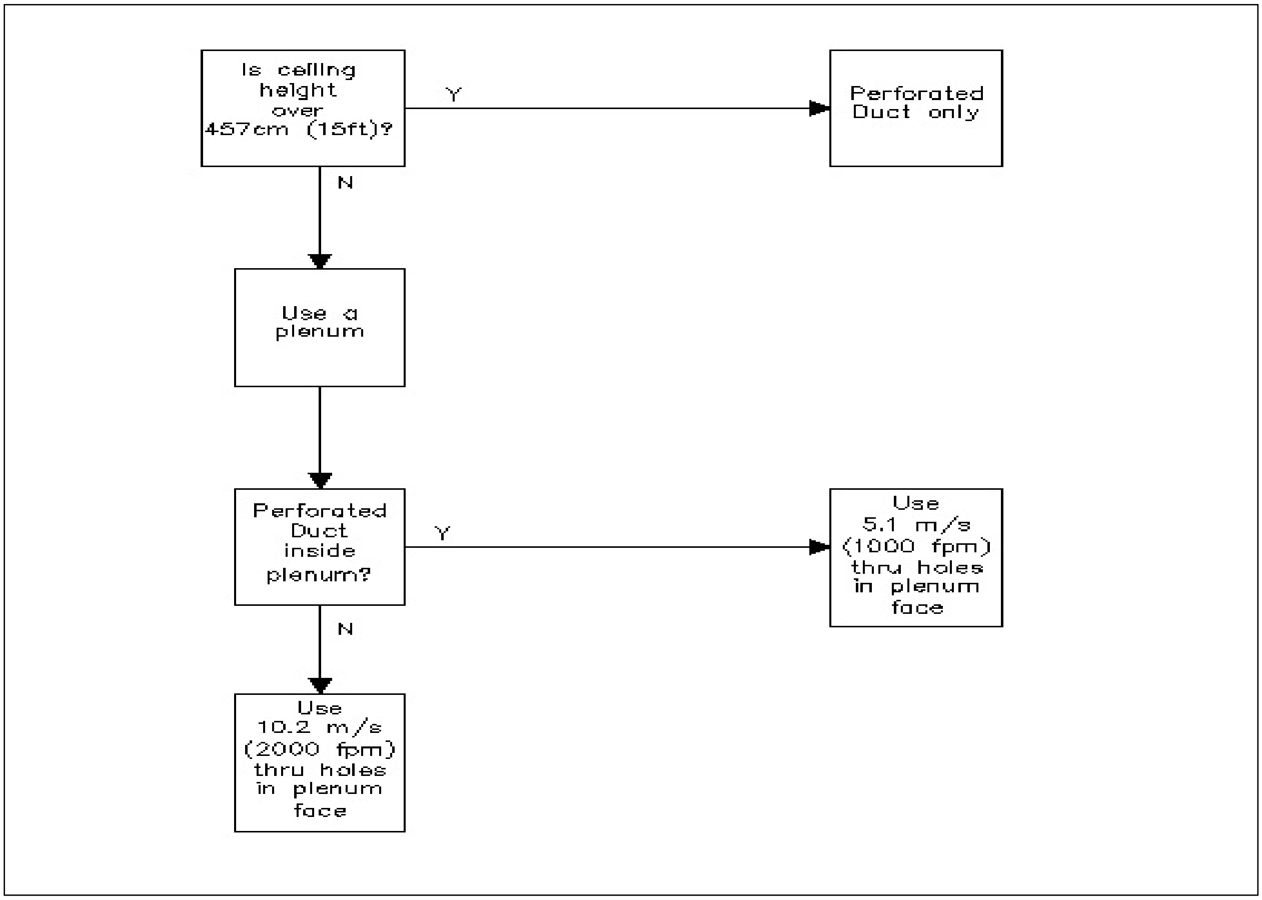
2-4.4 Air Pollution Control Equipment.

Requirements for air pollution equipment vary by process and geographical region in the United States. Contact the local activity environmental manager to determine the pollution control requirements for the process.

2-4.5 Replacement Air.

Replacement air is as important as exhaust air in controlling industrial process contaminants. The quantity and, in particular, the distribution of the replacement air profoundly affects the exhaust hood performance. Properly designed replacement air will (1) ensure that exhaust hoods have enough air to operate properly, (2) help to eliminate cross-drafts through window and doors, (3) ensure proper operation of natural draft stacks, (4) eliminate cold drafts on workers, and (5) eliminate excessive differential pressure on doors and adjoining spaces. (6) Ensure that replacement air does not draw from a loading dock or parking lot area or where exhaust air could be drawn into the system. Design the replacement air system in accordance with the decision tree shown in Figure 2-2.

Figure 2-2. Decision Tree For Replacement Air Design.



2-4.5.1 Space Pressure Modulation.

Modulate the replacement air to maintain the required space pressure differential between the process area and adjacent spaces, while maintaining the exhaust flow. Operate all process areas and/or buildings at a slight negative pressure to prevent the controlled contaminant from migrating into clean areas and prevent fugitive emissions to the atmosphere. Use a variable frequency drive (VFD) motor to control the fan speed. Do not use barometric dampers or sensor controlled transfer grilles to control replacement air quantity.

Exhaust hoods require a specific amount of exhaust air to control the contaminant. Certain conditions (e.g., paint curing or unattended lab hood processes) may permit an exhaust flow reduction. Worker protection takes precedence over energy savings.

2-4.5.2 Plenum Design.

The replacement air configuration which provides the most operational flexibility and worker protection is a down flow design, with the replacement air being delivered from the ceiling. The following discussion is based primarily on a down flow system, although a cross flow system may be utilized if the down flow arrangement proves to be impractical. Consider worker breathing zone when designing and balance the energy usage with worker protection.

Use perforated plate to cover as much of the ceiling (or wall opposite the exhaust hood(s)) as practical. The diameter of the perforation should be between 1/4 in and 3/8 in (6.3 mm and 9.5 mm). Perforated plenums work best when ceiling height is less than 15 ft (4.58 m). Use either of the following two choices for replacement air plenum design:

a. Design for 1,000 fpm (5.1 m/s) replacement air velocity through the open area of the perforated plate if perforated duct is used inside the plenum as shown in Figure 2-3.

b. Design for 2,000 fpm (10.2 m/s) replacement air velocity through the open area of the perforated plate if the plenum is served with ducts using diffusers, grills or registers as shown in Figure 2-4.

Figure 2-3. Plenum Design With Perforated Duct.

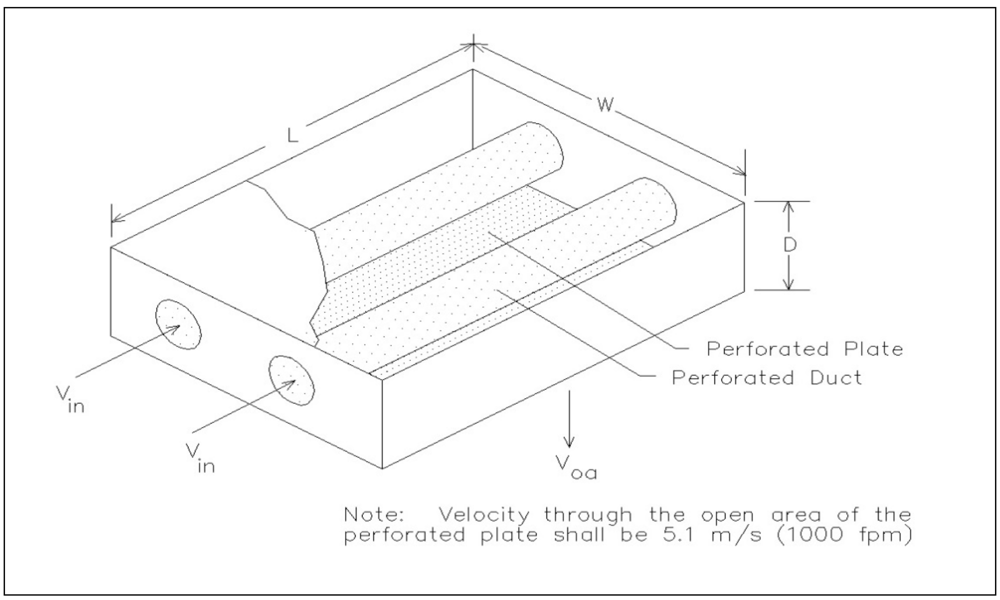


Figure 2-4. Plenum Design Without Perforated Duct.

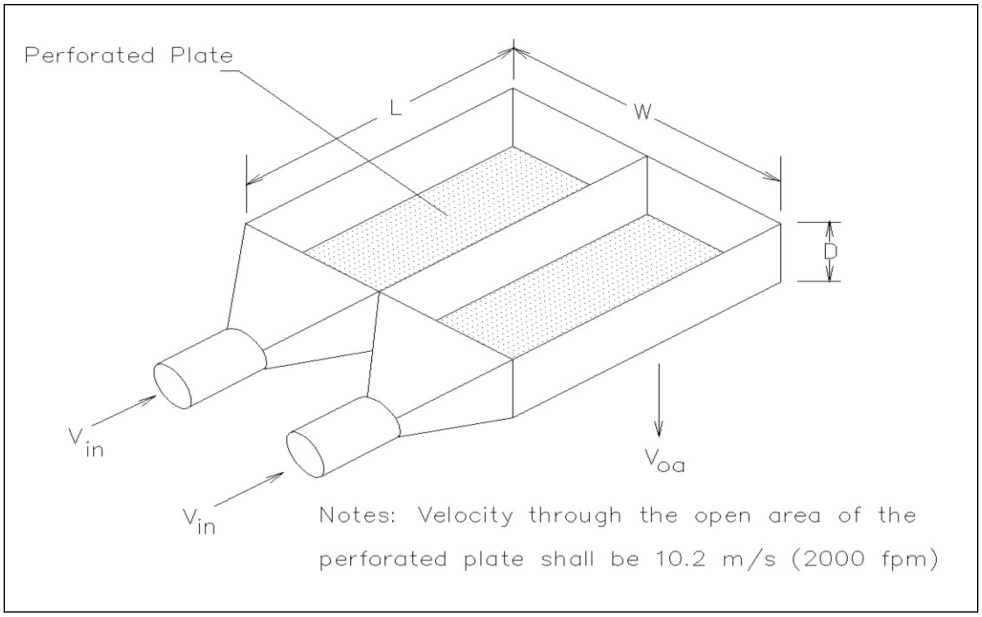


2-4.5.3 Perforated Duct Design.

Use perforated duct to evenly distribute the flow of replacement air inside a plenum or use alone when ceiling height is greater than 15 ft (4.58 m). Manufacturers provide several different types and sizes of perforated duct. Use recommendations from the manufacturer for duct design. The manufacturer will not only recommend the size, shape, and type of the required perforated duct, but also the location of the orifices and reducers to distribute the air properly.

2-5 CONTROLS.

Provide industrial ventilation system controls and associated alarms to ensure contaminant control, space specific balance and conditioning, a safe and healthy work environment, and system malfunction notification.

Comply with Standard 18, Emergency Air Distribution Shutoff, found in UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*. A hazardous exhaust system may continue to operate if de-energizing the system will violate building codes, fire codes, create an unsafe condition or imperils life safety.

2-5.1 Gauges and Sensors.

Specify gauges and sensors to provide continuous monitoring of system performance. The minimum requirements are:

2-5.1.1 Differential Pressure Sensors

Provide differential pressure sensors, with gauge readouts, across each replacement air filter section and the exhaust air cleaning sections. Program control system alarm set points for each filter differential sensor to indicate when the filter pressure drop falls below the initial “clean” filter differential pressure or rises beyond the final “dirty” filter differential pressure. Provide text and graphical representation for the low pressure alarm and the high pressure alarm indications.

2-5.1.2 Replace Fan Motor Sensors

Operating light on replacement air system fan motor.

2-5.1.3 Static Pressure Sensors

Static pressure sensor at the outlet of the replacement air fan with a gauge readout. Alarms must be triggered when the pressure is lower than the recommended range (as determined by baseline testing).

2-5.1.4 Hood Static Pressure Sensors

Hood static pressure sensor, for critical processes or process where extremely toxic substances are used, with a gauge mounted in a conspicuous place near the hood. An alarm must be triggered when the static pressure is lower or higher than the recommended range (as determined by baseline testing). Do not use the type of inline flow sensor, which measures the pressure drop across an orifice plate. Use only a static pressure tap and differential pressure gauge.

2-5.1.5 Fan Static Pressure Sensors

Static pressure sensor at the exhaust fan inlet with gauge readout. An alarm must be triggered when the pressure is lower than the recommended range (as determined by baseline testing).

2-5.1.6 Exhaust Air Motor Sensor

Operating light on exhaust air system motor. When a sensor indicates a malfunction, trigger an alarm that is both audible and visible in the shop space.

2-5.1.7 Gauge Operating Range

Operating ranges on all gauges clearly marked. Locate gauges on an annunciator panel (except hood static pressure gauges). Provide a 3-way valve at each gauge connection for cleanout and calibration; see Figure 2-5.

2-5.1.8 Differential Pressure Sensor Location

Place room differential pressure sensors away from doors, windows, and replacement air discharge.

2-5.2 Interlocks.

Provide an interlocked on-off switch so that the replacement air and exhaust air systems operate simultaneously. When there are multiple fans, clearly label which exhaust fan is interlocked with which supply fan.

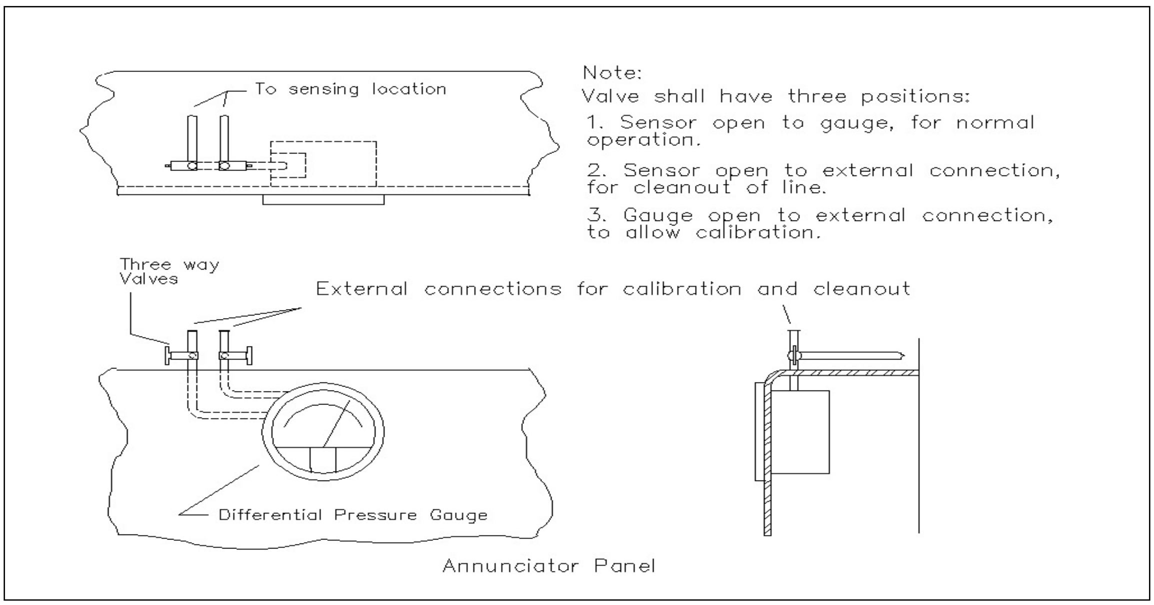
2-5.3 Annunciator Panel.

Provide an annunciator panel to allow for continuous monitoring of ventilation system performance. Locate the panel so it is accessible to shop personnel. The panel must include, but is not limited to, all gauges (except hood static pressure gauges) described in the paragraph in Chapter 2, entitled, “Gauges and Sensors”. Mount fan motor operating lights and interlocked ON/OFF switch on the panel. The interlocked switches must clearly show which exhaust and supply fans are interlocked, where multiple fans are used. The panel must indicate what action to take when operation falls outside the prescribed ranges. For example, “examine/replace filter on R.A. unit when this gauge reads outside indicated range.” Connect sensor outputs to building DDC systems when available.

2-5.4 Security.

Any networked communications from controls must meet the Information Assurance security requirements of the Activity served.

Figure 2-5. Annunciator Panel.



2-6 OPERATIONAL CONSIDERATIONS.

2-6.1 Provision for System Testing.

Provide access to the fan and motor to measure voltage, amperage, and fan speed. Evaluate and incorporate the use of guard rails, working platforms, and OSHA ladders into the design where equipment is located at elevation. Specify that all testing will be done in accordance with the ACGIH *Industrial Ventilation, A Manual of Recommended Practice for Operation and Maintenance (IV O&M) Manual*, Chapter 3, “Testing and Measurement of Ventilation Systems.”

2-6.2 Energy Conservation.

Incorporate applicable energy conservation measures in the design of all industrial ventilation systems. Criteria herein minimize volume flow rates through appropriate designs. Evaluate life cycle costs for heat recovery systems and specify when appropriate. For HVAC-related issues use UFC 3-410-01, *Heating, Ventilation, and Air Conditioning Systems.*

2-6.3 Recirculation.

Industrial ventilation systems use a large quantity of air. Exhaust air recirculation is discouraged for most industrial processes and prohibited by OPNAVINST 5100.23, *Navy Occupational Safety and Health Program Manual* for processes generating lead and asbestos. Follow the re-circulated air guidelines set forth in NFPA 654, *Standard for the Prevention of Fire and Dust Explosions from the Manufacturing, Processing, and Handling of Combustible Particulate Solids* for fire protection; the *ACGIH IV Design Manual*, Section 10.8, and ANSI AIHA/ASSE Z9.7, *Recirculation of Air from Industrial Process Exhaust Systems* for health protection, and the applicable OSHA standards when recirculation is included in the design.

2-6.4 Maintenance.

Require the contractor provide an operation and maintenance manual for the system and also provide hands-on training for maintenance and shop personnel. Ensure safe and sufficient maintenance access to the system components.

2-7 SAFETY AND HEALTH CONSIDERATIONS.

2-7.1 Posting.

For those systems where the replacement air is critical to the proper operation of the system, consider posting the following sign at each entrance to the ventilated space:

KEEP DOOR CLOSED
THIS DOOR MUST BE CLOSED FOR EFFECTIVE CONTROL OF CONTAMINANTS

2-7.2 Noise.

Use engineering controls as the primary means of protecting personnel from hazardous noise. It is cheaper to eliminate potential noise problems during the design or procurement stages, than it is to retrofit or modify after installation. Determine the acoustic environment in advance, both to fulfill the design goals and prevent the need for corrections at a later stage.

2-7.2.1 Criteria.

Determine the sound power levels for each piece of equipment used for industrial ventilation. Use this information to predict the acoustic characteristics and the resulting ambient noise level. Refer to UFC 3-101-01, *Architecture*.

Also refer to the appropriate facility-type UFC's for sound transmission requirements (STC's) into adjacent building spaces.

For additional information on noise control refer to UFC 3-450-01, *Noise and Vibration Control*; and OSHA 3048, *Noise Control, A Guide for Workers and Employees*.

2-7.3 Respiratory Protection.

29 CFR 1910.134(d), *Respiratory Protection* specifies requirements for respiratory protection. Consult with an industrial hygienist (IH) or occupational health specialist to determine the appropriate type of respiratory protection required for each process.

2-7.3.1 Breathing Air.

Breathing air for supplied air respirators must meet grade D standards as required by 29 CFR 1910.134(d) and defined in Compressed Gas Association Specification for Air G-7.1. Make up air for the breathing air compressor must be from outside and upwind of any potential exhaust sources. Breathing air couplings must not be compatible with outlets for non-respirable worksite air or other gas systems. Consider providing multiple connection ports for airline respirator hoses to allow worker mobility. Provide a means to permit the IH to test air quality on a routine basis.

2-7.3.2 Air Compressors.

Breathing air systems require a high temperature, carbon monoxide and Oxygen alarm. Alarms must be located where the respirator user and helper can see and hear them. Compressors must have the carbon monoxide level monitored to ensure the air supplied contains below 10 ppm CO. Compressors used to supply breathing air must be constructed and situated with a 30 foot separation from sources of contamination (e.g., exhausts, plumbing vents, loading docks) to prevent entry of contaminated air into the air supply system. The breathing air compressor must minimize moisture content so that the dew point is 10 degrees F (5.56 degrees C) below the ambient temperature. The breathing air system must have suitable in-line air-purifying sorbent beds and filters. Sorbent beds and filter must be maintained per manufacturer's instructions.

2-7.4 Emergency Showers and Eyewash Stations.

Provide in accordance with UFC 3-420-01, *Plumbing Systems*, Appendix D.

2-7.5 Hygiene Facilities.

These facilities are adjacent to or nearby the operation when employees are exposed to certain stressors such as asbestos, cadmium, lead, etc. The facilities may be as simple as a hand washing station or as complicated as multiple clean/dirty rooms in an asbestos delagging shop or a facility using metals such as cadmium, lead or hexavalent chromium. Consult with the local industrial hygiene department to determine the extent of and location for these facilities.

2-8 COMMISSIONING.

This process begins before the conceptual design is complete. It is a strategy that documents the occupants' needs, verifies progress and contract compliance and continues throughout the design, build and acceptance process. DOD projects and construction offices have long used parts of the commissioning process for military construction (MILCON) and some smaller projects. To ensure that issues specific to ventilation are not overlooked, use ASHRAE Guideline 1.1, *HVAC &R Technical Requirements for the Commissioning Process*.

This Page Intentionally Left Blank

CHAPTER 3 ASBESTOS DELAGGING FACILITIES

3-1 FUNCTION.

An asbestos delagging facility provides a complete workshop to remove asbestos material from piping, mechanical and structural equipment during ship repair and demolition. The ventilation system design discussed in this section is for activities with extensive asbestos removal operations. The design includes: shop and equipment space, clean and dirty locker rooms for men and women, and administrative space to support the coordination and monitoring of facility operation.

3-2 OPERATIONAL CONSIDERATIONS.

3-2.1 Airborne Contamination.

When asbestos material is removed, the asbestos fibers are dispersed into the air, creating a health hazard. 29 CFR 1910.1001, *Asbestos, General Industry* and 29 CFR 1915.1001, *Asbestos, Shipyards* dictate protective measures for workers in these facilities, including respiratory protection and impermeable outerwear. The regulations also prescribe wetting the asbestos material with amended water (water containing a surfactant), if practicable, to reduce the potential for asbestos fibers to become airborne.

3-2.2 Heat Stress.

The physical nature of the work and impermeable outer garments worn by the workers creates heat stress conditions. Provide supplied air respirators with vortex tubes as specified in EPA-560-OPTS-86-001, *A Guide to Respiratory Protection for the Asbestos Abatement Industry*. Consider cooling the replacement air when supplied air respirators are not available. Consider using "micro climate cooling" or "cool suits," mechanically cooled garments, for individual workers.

3-2.3 Employee Workflow.

Workers enter the clean locker rooms through the control point area. They put on protective outerwear and proceed to the work area. After performing asbestos work, workers remove the outer set of disposable booties as they step in to the decon area.

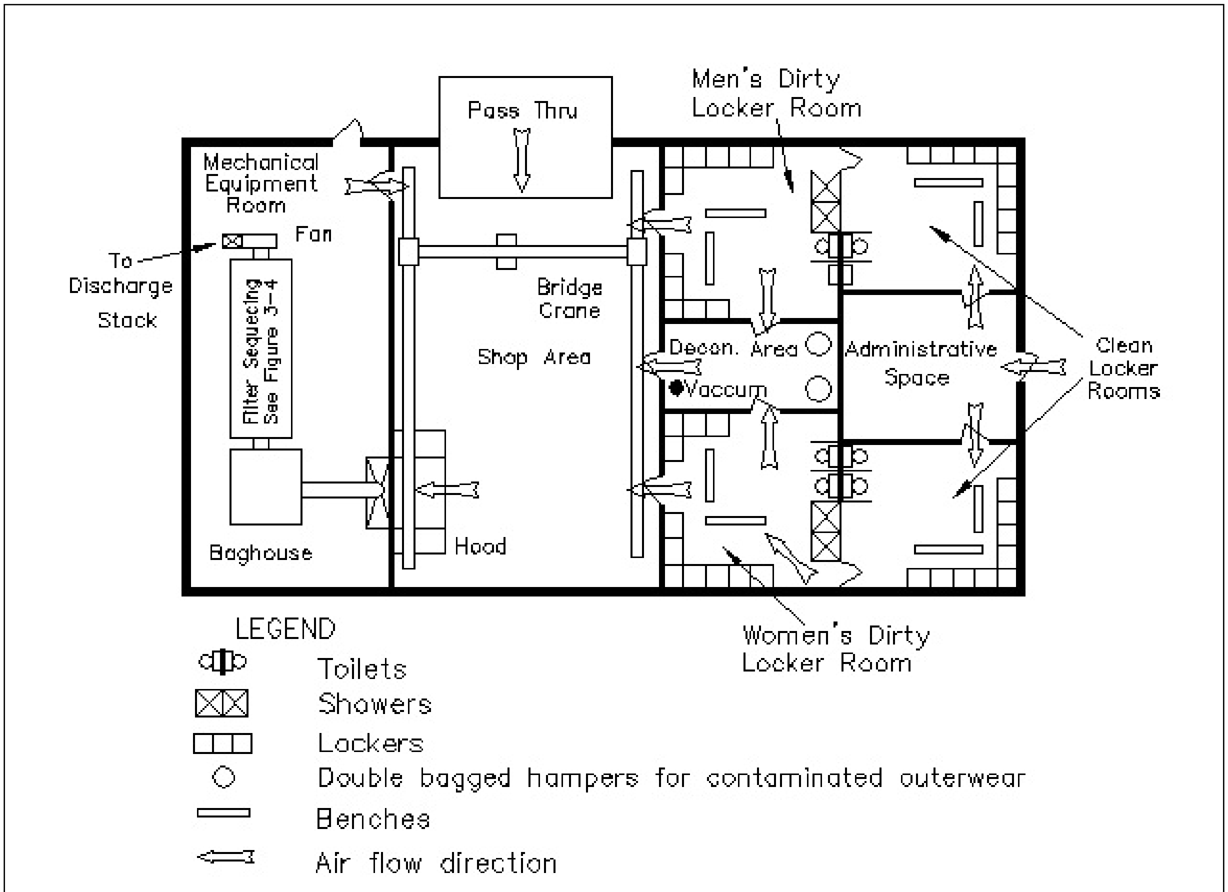
In the Decon room, the workers will vacuum their protective outerwear and dispose of them in containers provided. They enter the dirty locker rooms and remove the remainder of their work garments. Workers then proceed to the clean locker rooms via the showers, which act as a barrier to the migration of asbestos fibers.

In the shower, the worker can remove and wash their respirator and proceed to the clean room to get dressed in their personal clothing and exit to the control point.

3-3 TYPICAL FLOOR PLANS.

Design floor plans to meet the requirements of 29 CFR 1910.1001 and 29 CFR 1915.1001 and the paragraph in Chapter 3 entitled, “Employee Workflow”. Figure 3-1 shows a sample delagging facility floor plan.

Figure 3-1. Delagging Facility Floor Plan.



3-4 DESIGN CRITERIA.

Design the facility using general technical requirements in Chapter 2 of this UFC and the specific requirements in this Chapter.

3-5 EXHAUST AIR.

Design the exhaust air system to generate 4 exchanges of air/hour and .02 inches (0.5 mm) of water column.

3-5.1 Hood Design.

Design asbestos delagging hood to enclose the work piece as much as possible. Do not use small portable hoods with flexible ductwork because they do not provide consistent capture.

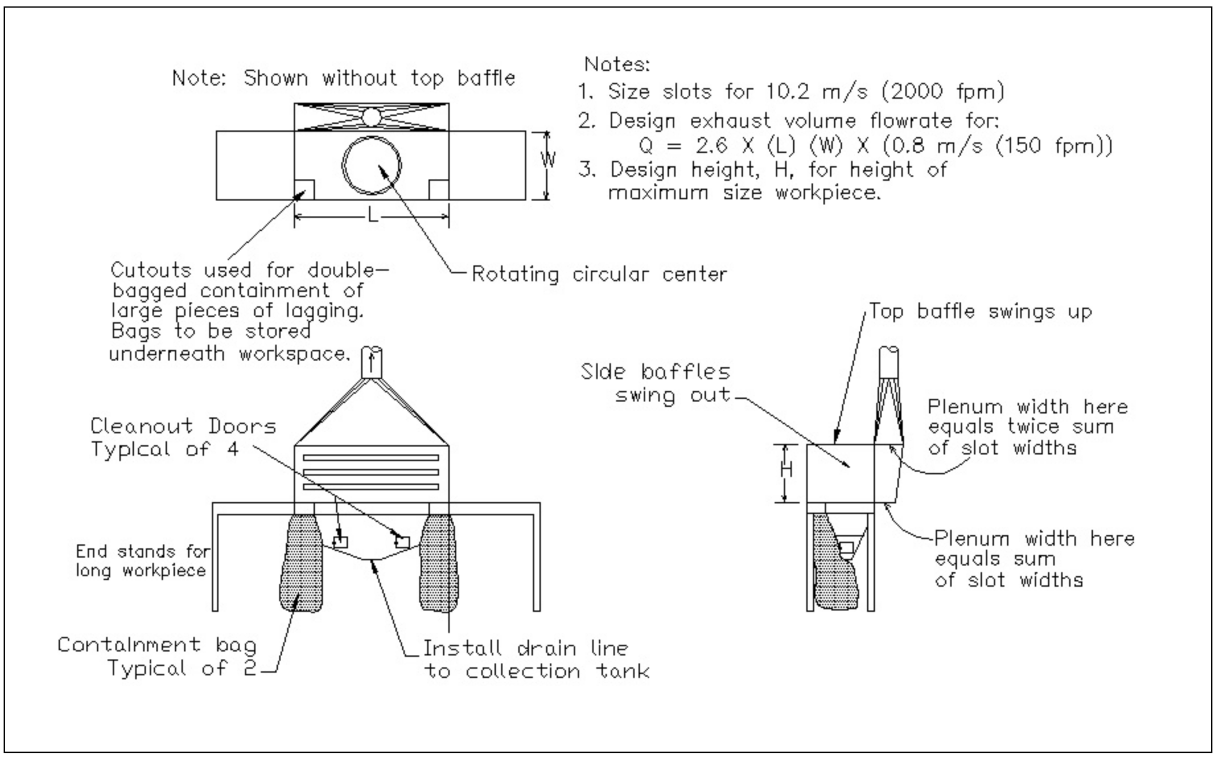
3-5.1.1 Typical Hood Design for High Profile Work Pieces.

Figure 3-2 shows a hood design consisting of a workbench with a central, circular area. Mount the circular area on sealed bearings to allow easy turning of heavy work pieces. This design is best for high profile work pieces (for example, boilers, pumps). The hood captures contaminants through the slots into an exhaust plenum. Design each hood with:

a. Two cleanout doors on the front and two doors on the sides of the hood for easy access to asbestos debris. Provide two small cutouts in the outer corners of the workbench to place large pieces of lagging in double bagged containment.

b. The top baffle swings up to allow access to overhead cranes.

Figure 3-2. Exhaust Hood For High Profile Work Pieces.



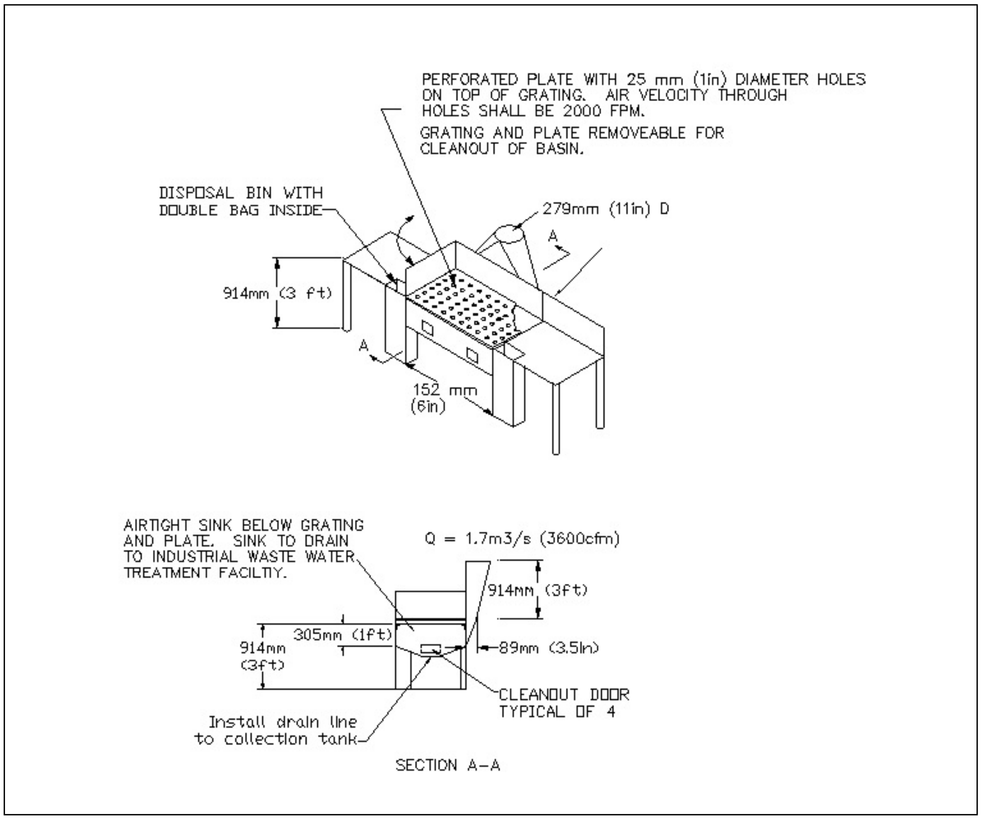
3-5.1.2 Typical Hood Design for Low Profile Work pieces.

Figure 3-3 shows a hood design consisting of a workbench with a grating strong enough to support the heaviest expected work piece. This is a downdraft hood that draws small pieces of lagging through the grating. The perforated plate below the grating creates even airflow over the grating. This design is best for low profile work pieces such as piping. Design each hood with stands and swinging baffles on each end to accommodate long work pieces (e.g., pipes).

3-5.2 Ductwork.

Size the exhaust ductwork to provide a minimum transport velocity of 5,000 fpm (25.4 m/s). The high velocity is necessary because the practice of wetting the fibers makes them heavier and more difficult to transport. See the paragraph in Chapter 2 entitled, “Ductwork” for general duct considerations.

Figure 3-3. Exhaust Hood For Low Profile Work Pieces.



3-5.3 Fans.

See the paragraph in Chapter 2 entitled, “Fans” for general fan considerations.

3-5.4 Weather Stack Design and Location.

See the paragraph in Chapter 2 entitled, “Exhaust Stacks”.

3-5.5 Air Cleaning Devices.

A delagging facility requires multistage filtering, which consists of a fabric filter collector, prefilters, a mist eliminator, and high efficiency particulate air (HEPA) filters. Prefilters extend the life of the HEPA filters. Use "bag in, bag out" styles of HEPA filters, which allow for safe replacement of the filter element without exposure to asbestos. A mist eliminator before the HEPA filter protects it from the moisture generated during asbestos removal.

a. Have all collectors deliver the collected asbestos to a common pickup point to minimize the risk of exposure. Provide a double acting valve at each collector hopper throat, in accordance with the ACGIH IV Design Manual, Chapter 8, Air Cleaning Devices.

b. Use a single chamber, shaker type collector to minimize the number of collection points.

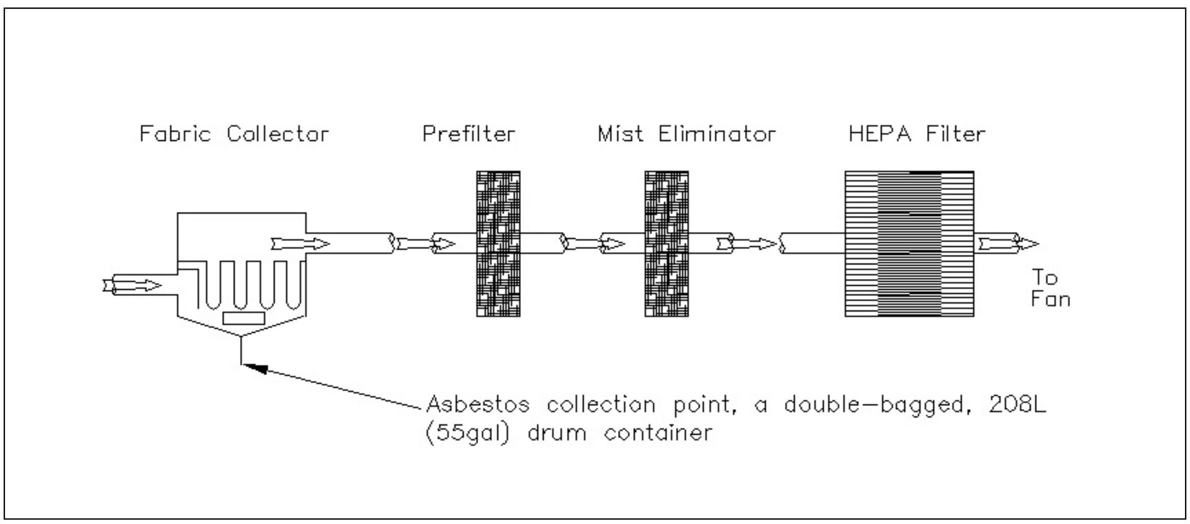
3-5.5.1 Filter Efficiency.

The fabric filter collector requires a minimum efficiency reporting value (MERV) of not less than 15 in accordance with ASHRAE 52.2, *Method of Testing General Ventilation Air Cleaning Devices for Removal Efficiency by Particle Size*.

3-5.5.2 Sequencing.

Figure 3-4 illustrates the required sequence of air cleaning devices.

Figure 3-4. Sequence Of Air Cleaning Devices For Asbestos Delagging.



3-5.6 Industrial Vacuum System.

Provide a low volume, high velocity (LVHV) central vacuum system at delagging shops to exhaust fibers and dust from power tools (e.g., grinders and saws) when they are used, as specified in 29 CFR 1910.1001.

3-5.6.1 Central Vacuum System

Design a central vacuum cleaning system, which consists of a motor driven exhauster interconnected with bag type separators.

3-5.6.2 Ductwork

Connect the separator to rigid hose or duct, which extends throughout the plant. Terminate the rigid hose or duct with inlet valves at the various workstations. Provide flexible hose connections to allow workers to do shop cleanup and to decontaminate their protective outerwear.

3-5.6.3 Exhaust Tools and Hoods

Use local exhaust hoods and high velocity exhaust takeoffs for each hand tool. Table 3-1 of this UFC and the ACGIH IV Design Manual provide examples of tools and exhaust system for specific operations.

3-5.6.4 Contaminant Capture Distance

Ensure proper capture velocity is produced at each local exhaust hood. Design vacuum systems to reach within 1/2 inch (12.7 mm) of the contaminant source.

3-5.6.5 Pick-up Velocity

Design the pickup air-stream to have a velocity of two to three times the generation velocity for particle sizes from 20 to 30 micrometers (20 to 30 micron.) Design for an additional velocity of: (1) four to five times the generation velocity to pull the particles up through 300 U.S. standard mesh, or (2) six to eight times the generation velocity to pull the particles up through a 20 U.S. standard mesh.

Table 3-1. Minimum Volumes And Vacuum Hose Size For Asbestos Operations.

Hand Tool	Flow rate cfm (m^3/s)	Hose Size in. (mm)
Pneumatic chisel	125 (0.06)	1.5 (38)
Hand wire brush, 3 x 7 inches	125 (0.06)	1.5 (38)
Rip out knife	175 (0.08)	1.5 (38)
Rip out cast cutter	150 (0.07)	1.5 (38)
Saber saw	150 (0.07)	1.5 (38)
Saw abrasive, 3 inch	150 (0.07)	1.5 (38)
General vacuum	200 (0.09)	2.0 (51)

Adapted from: Hoffman Air and Filtration Systems, “Design of Industrial Vacuum Cleaning Systems and High Velocity, Low Volume Dust Control.”

3-5.6.6 Air to Asbestos Ratio

Design the air volume for no less than two parts of air to one part of asbestos to be captured by weight.

3-5.6.7 Hose Lengths and Locations

Design the vacuum hose length less than 25 ft (7.6 m). Locate inlet valves 30 to 35 feet (9 to 10.7 meters) apart when a 25 ft (7.6 m) length of hose is used. Locate tool vacuum hose connection on the ends of the workbench underneath the stands. Size the hose based on: (1) air volume per hose, (2) number of hoses to be used simultaneously, and (3) air velocity required to convey the material to the separators.

3-5.6.8 PVC Hoses

Use single-ply, lightweight thermoplastic or polyvinyl chloride (PVC) flexible hose, but limit the usage whenever possible.

3-5.6.9 Multi-stage Blower

Use a multistage centrifugal blower for the vacuum system. Size the blower for: (1) total system pressure loss associated with the total number of hoses to be used simultaneously, and (2) maximum exhaust flow rate entering the inlet of the blower.

3-5.6.10 Blower to Bag House Relationship

Feed the blower directly into the bag house used by the industrial exhaust system to minimize the number of asbestos collection points.

3-5.6.11 Filters and Location

Install a prefilter and a HEPA filter in front of the blower to prevent it from becoming contaminated.

3-5.6.12 Balance by Design

Design the vacuum system duct to balance with the exhaust system duct where the two systems connect.

3-5.6.13 Noise

Use manufacturer guidance to design vacuum system and UFC 3-450-01, *Noise and Vibration Control* as preliminary guidance.

3-5.7 Replacement Air.

Design replacement air systems with fan inlet guide vanes, variable speed motors, or "eddy current clutch" units to maintain a pressure (relative to the atmosphere) ranging from -0.02 to -0.05 inches wg (12.4 to 24.9 Pa scale) in the shop spaces.

a. Maintain the pressure in decontamination areas, the equipment room, and dirty locker rooms within a range of -0.01 to -0.04 inches wg (-2.49 to -9.96 Pa). Maintain the pressure in clean spaces within a range of (+0.02 to +0.05 inches wg (+4.98 to +12.4 Pa).

b. For further replacement air system criteria, see the paragraph in Chapter 2, entitled, “Replacement Air”.

3-5.8 System Controls.

Design system controls in accordance with the paragraph in Chapter 2 entitled, “Controls” and the following:

a. Position the annunciator panel at the entrance to the dirty space so operators can monitor operating gauges.

b. Install static pressure sensors at locations that are representative of average static pressure in each controlled space. This will ensure that desired differential pressures are maintained.

c. Trigger a timer if pressure varies from the specified range. Select timer that automatically resets if the problem is corrected within 60 seconds.

d. Trigger both visible and audible alarms if the system cannot correct the difficulty within allotted time. Install multiple alarm beacons if operator's view is obscured during delagging. Monitor the shop's negative pressure continuously, using strip chart recorder, so the operator can detect any pressure changes.

e. Interlock the hand tool power supply with the ventilation system's on-off switch. This will prevent the use of hand tools without ventilation controls.

3-6 TREATMENT OF WASTE EFFLUENT.

All waste water generated in the facility must be considered contaminated effluent and must be filtered to remove solid particulate contaminants prior to entry into the Industrial Waste stream.

Notify and comply with any pretreatment requirements as required by the POTW, state and local authorities prior to discharging any waste water from the facility.

3-7 SAFETY AND HEALTH CONSIDERATIONS.

Consult the local industrial hygienists (IH) for required respiratory protection in accordance with 29 CFR 1910.1001 (f) and (g), 29 CFR 1915.1001(g) and (h). See the paragraph in Chapter 2 entitled, “Respiratory Protection” for additional information.

This Page Intentionally Left Blank

CHAPTER 4 OTTO FUEL II FACILITIES

4-1 FUNCTION.

MK-46 and MK-48 torpedo facilities maintain, prepare, and test torpedoes. MK-46 and MK-48 torpedoes use Otto Fuel II, a toxic monopropellant. Further best practices and reference documents can be found in the inactive UFC 4-216-02, *Design: Maintenance Facilities for Ammunition, Explosives, and Toxins*.

4-2 OPERATIONAL CONSIDERATIONS.

Operations in a torpedo facilities create a potential for personnel exposure to one or more of the following: (1) Otto Fuel II, (2) Agitene - parts cleaning solvent used in MK-46 shops, (3) hydrogen cyanide - a product of combustion in torpedoes, and (4) mineral spirits - parts cleaning agent used in MK-48 shops.

4-3 DESIGN CRITERIA.

Design the facilities using general technical requirements in Chapter 2 of this UFC and the specific requirements in this Chapter. Torpedo size differences and maintenance procedures dictate the use of different floor plans and exhaust hood designs for the two types of facilities. Refer to NAVSEA OP5, Volume 1, *Ammunition and Explosives Ashore Safety Regulations for Handling, Storing, Production, Renovation and Shipping* for the specific order of operations. In all cases, the industrial ventilation systems must remove hazardous vapor (from Otto Fuel II, and part cleaning solvent) and products of combustion.

4-3.1 Exhaust Air for MK-46 Ventilated Spaces.

The MK-46 floor plan in Figure 4-1 optimizes the workflow while allowing the ventilation system to control airborne contaminants. Figure 4-2 shows an elevation view of this floor plan.

Figure 4-1. Layout for the MK-46 Fuel/Defuel and Afterbody Breakdown Room.

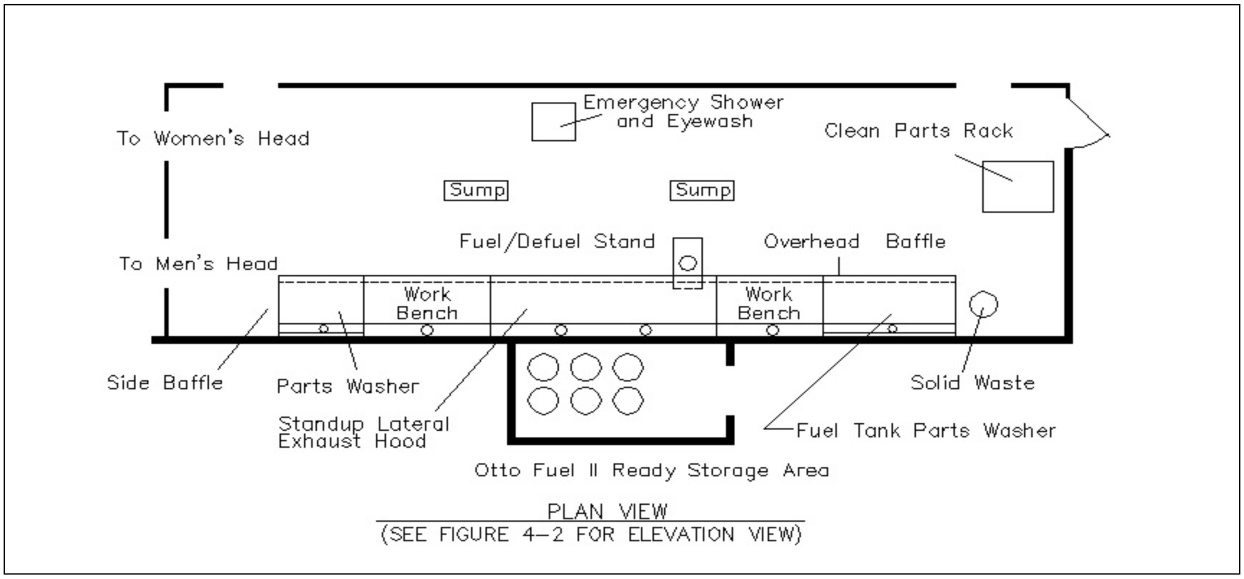


Figure 4-2. Series of Hood in the MK-46 Shop.

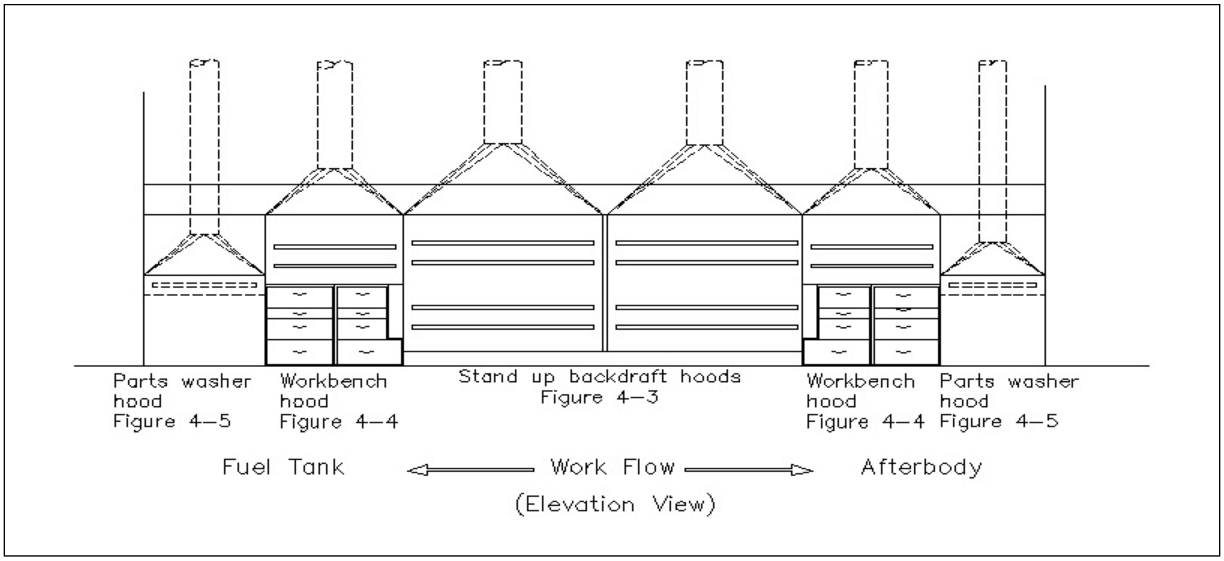
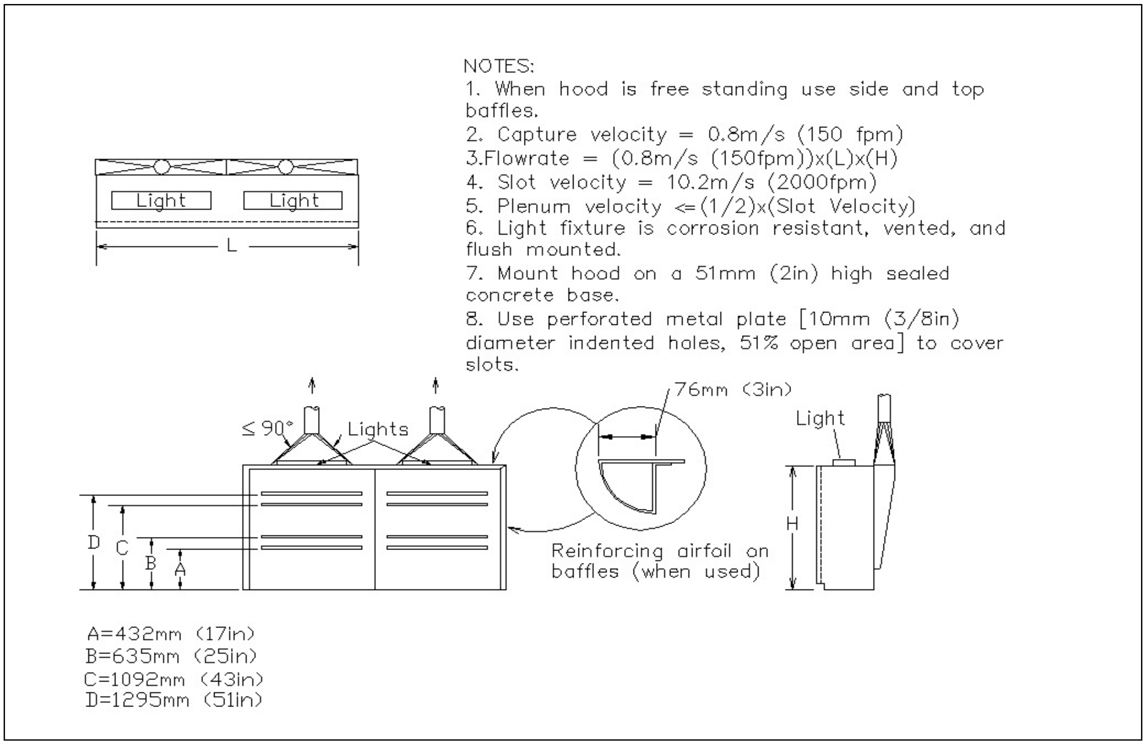


4-3.1.1 MK-46 Standup Backdraft Hood.

Workers uncouple the fuel section and the engine section of the torpedo in teardown operations. During these operations, Otto Fuel II remains in the lines, in the components of the engine section, and in the fuel tank. The residual fuel releases vapor into the air. The defueling and refueling processes also release Otto Fuel II vapor. Use the standup backdraft hood as shown on Figure 4-3 to capture Otto Fuel II vapor in afterbody teardown, fueling, and defueling operations.

Figure 4-3. MK-46 Standup Backdraft Hood.



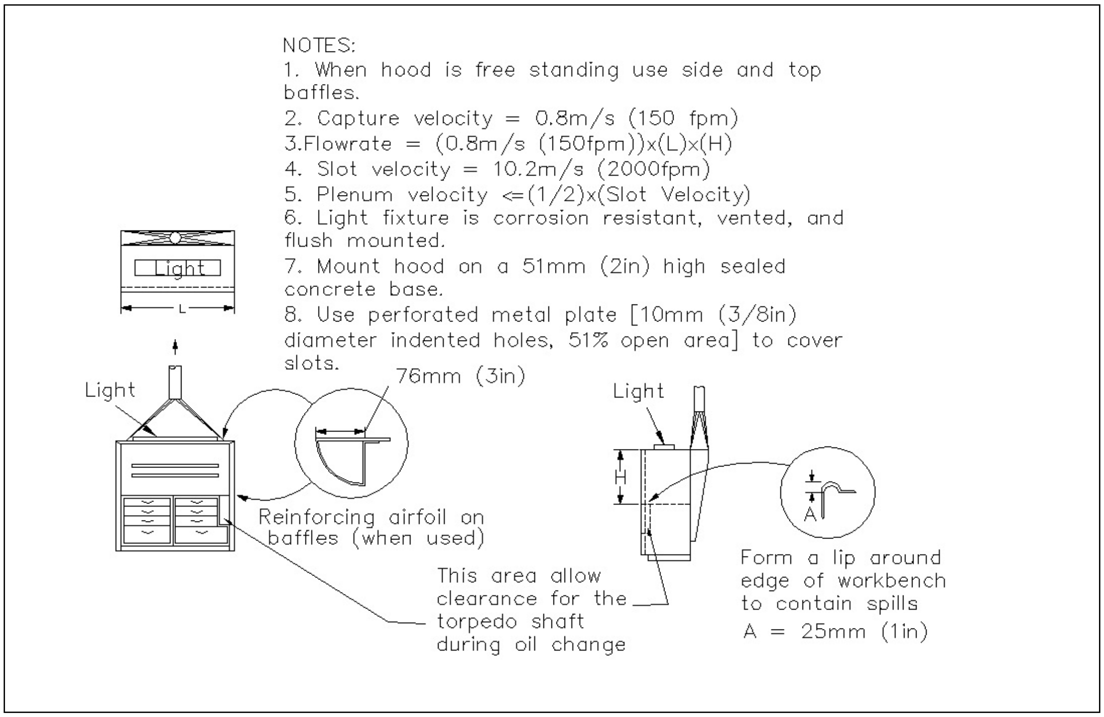
a. Hood transitions (takeoffs) with an included angle no greater than 90 degrees. Length of the hood, served by an exhaust plenum, is not to exceed 8 ft (2.44 m). For example, hoods between 8 and 16 ft (2.44 and 4.88 m) in length have two exhaust takeoffs.

b. Baffles to control airflow from the sides and top of the hood bank as shown on Figure 4-3.

4-3.1.2 MK-46 Workbench Hood.

After defueling and decoupling, workers lift the fuel and engine sections onto two different ventilated workbenches. They remove the stabilizing baffles in the fuel section, inspect, and wipe them clean before loading the baffles into the parts washer. Personnel also dismantle the engine section to inspect the engine, fuel pump, and seawater pump before loading them into the parts washer. Design a backdraft exhaust hood, as illustrated in Figure 4-4, to control contaminants generated by these workbench operations.

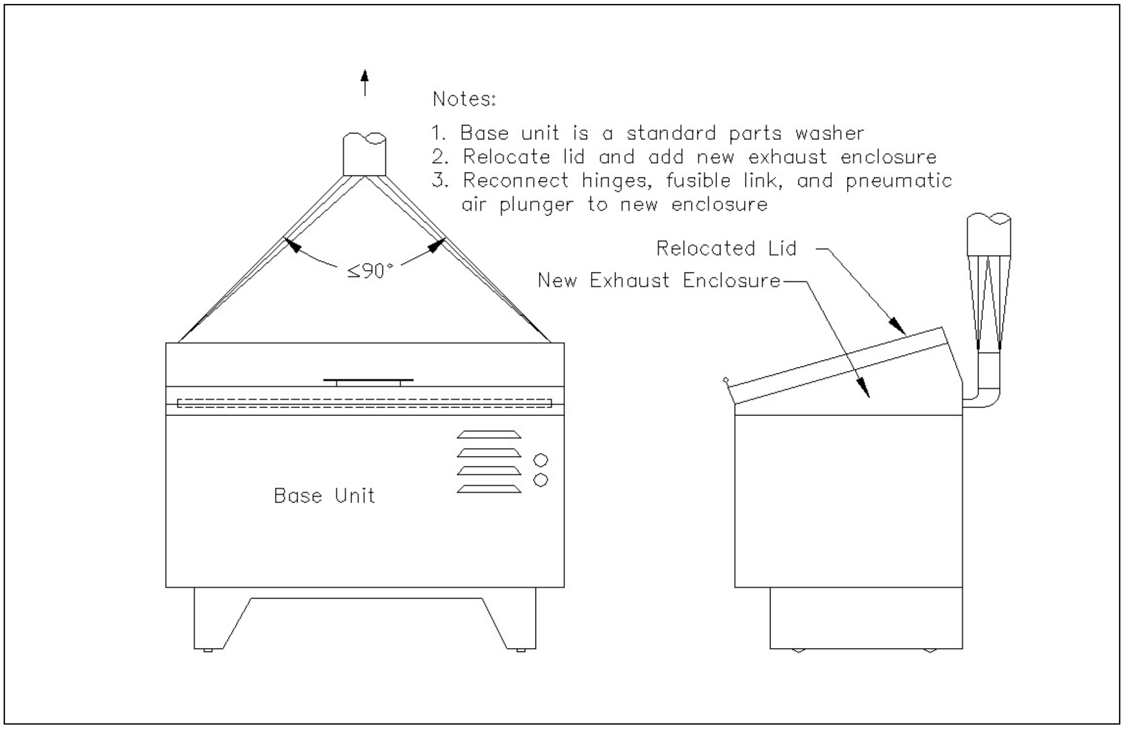
Figure 4-4. MK-46 Workbench Hood.



4-3.1.3 MK-46 Parts Washer Hood.

Design parts washer as shown on Figure 4-5 to clean off oils and excess Otto Fuel II from torpedo components. The parts washer cover must automatically close in case of fire in accordance with NFPA 34, *Standard for Dipping Coating and Printing Processes Using Flammable or Combustible Liquids*. Design the parts washer large enough to completely enclose the work piece. Design the parts washer deep enough to allow a minimum clearance of 6 in (153 mm) between the liquid level and the exhaust slot when the tank is full of parts. Position the parts washer next to the workbenches to shorten the work path and optimize ventilation control.

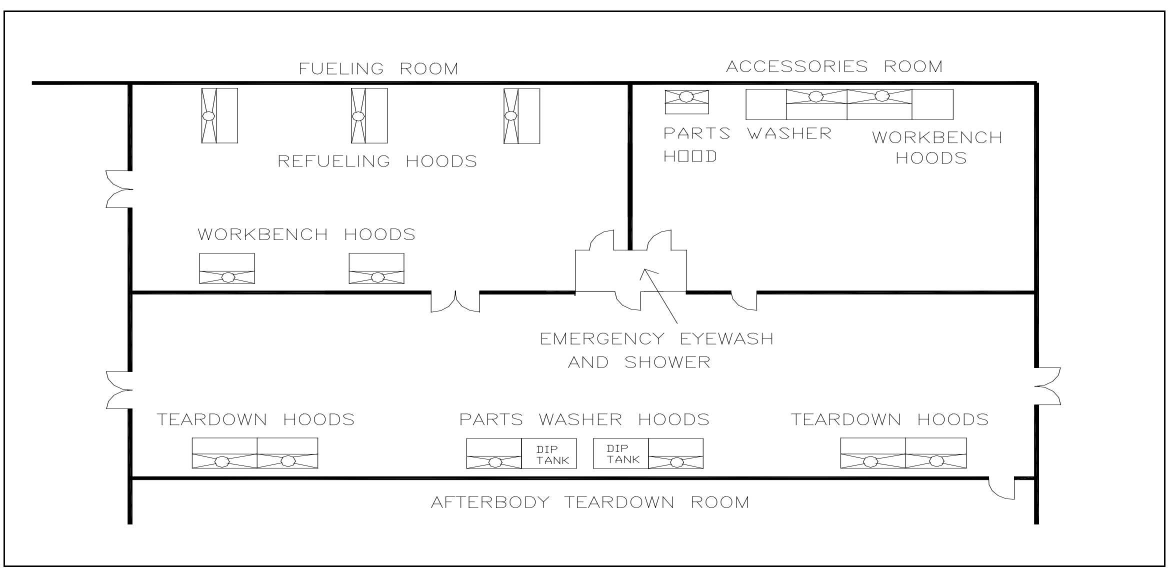
Figure 4-5. MK-46 Parts Washer Hood.



4-3.2 Exhaust Air for MK-48 Ventilated Spaces.

The floor plan shown in Figure 4-6 optimizes the work path while allowing the ventilation system to control airborne contaminants. Obtain detailed MK-48 exhaust hood drawings from Naval Underwater Systems Center.

Figure 4-6. Typical MK-48 Ventilated Space Layout.



4-3.2.1 MK-48 Afterbody Teardown Hood.

Workers uncouple the fuel section and the engine section of the torpedo in the teardown operations. During these operations, Otto Fuel II remains in the lines and the components of the engine section, and in the fuel tank. The residual fuel releases vapor into the air. Design the afterbody teardown hood as shown in Figure 4-7 to capture Otto Fuel II vapor. Design the hood using the following criteria.

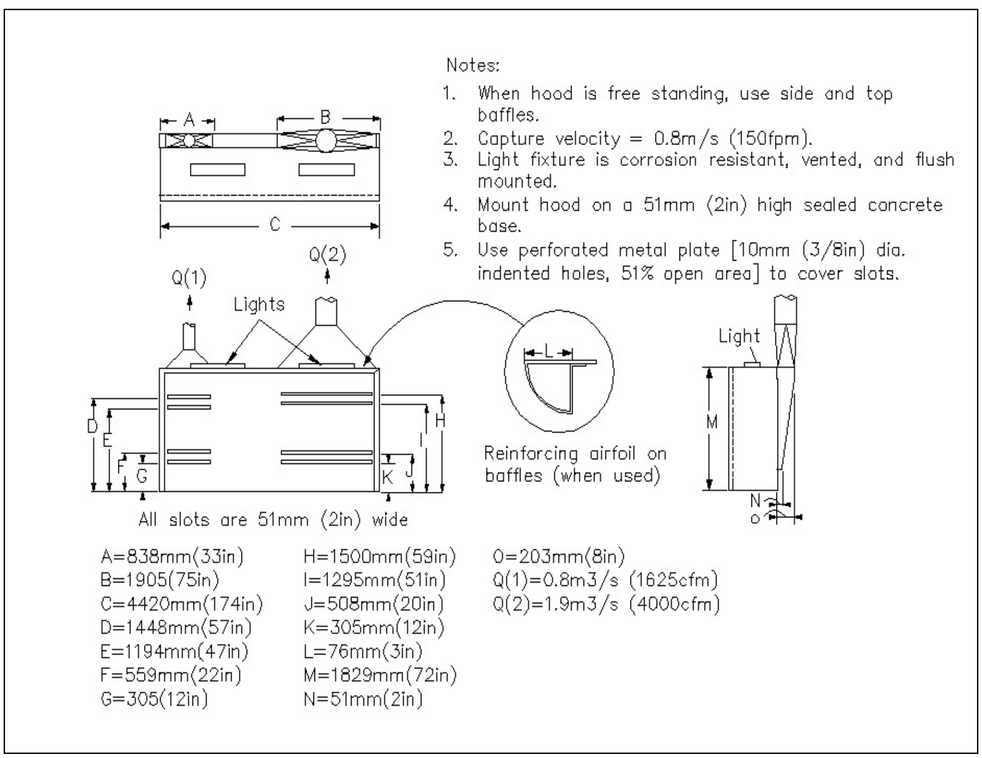
a. Install baffles on the top and side of the hood forming a booth.

b. Install a 3 in (7 mm) airfoil on the outer edge of the hood. The airfoil, bent inward from the baffle, must provide an airfoil effect and prevent turbulence and backflow.

c. Install lighting that is vented and flush mounted in the overhead baffle as shown on Figure 4-7.

d. Bolt the hood to the floor, using a continuous natural rubber gasket on hood bottom to create a seal between the hood and the floor.

Figure 4-7. MK-48 Afterbody Teardown Hood.



4-3.2.2 MK-48 Workbench Hood.

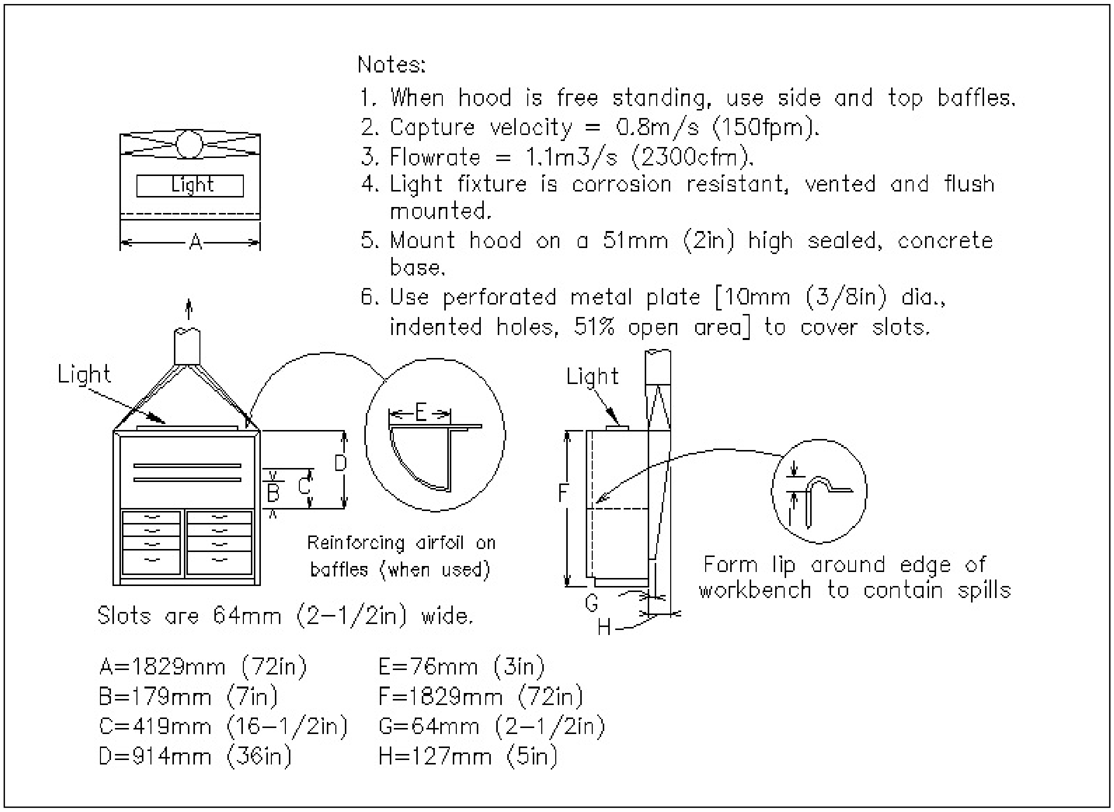
After defueling and decoupling, personnel dismantle and inspect the fuel tank and the engine section. They then load components of the fuel tank and the engine section into the parts washer. Design a backdraft exhaust hood as illustrated in Figure 4-8 to control contaminants generated by these workbench operations. Specify the following criteria for workbench hoods:

a. A 72- by 24-in (1850- x 600-mm) stainless steel workbench top to support the whole exhaust hood. See Figure 4-8 for dimensions of the hoods.

b. A 3-in (76-mm) airfoil rotated inward to prevent turbulence and backflow.

c. Lighting that is vented and flush mounted in the top of the exhaust hood.

Figure 4-8. MK-48 Workbench Hood.



4-3.2.3 MK-48 Parts Washer Hood.

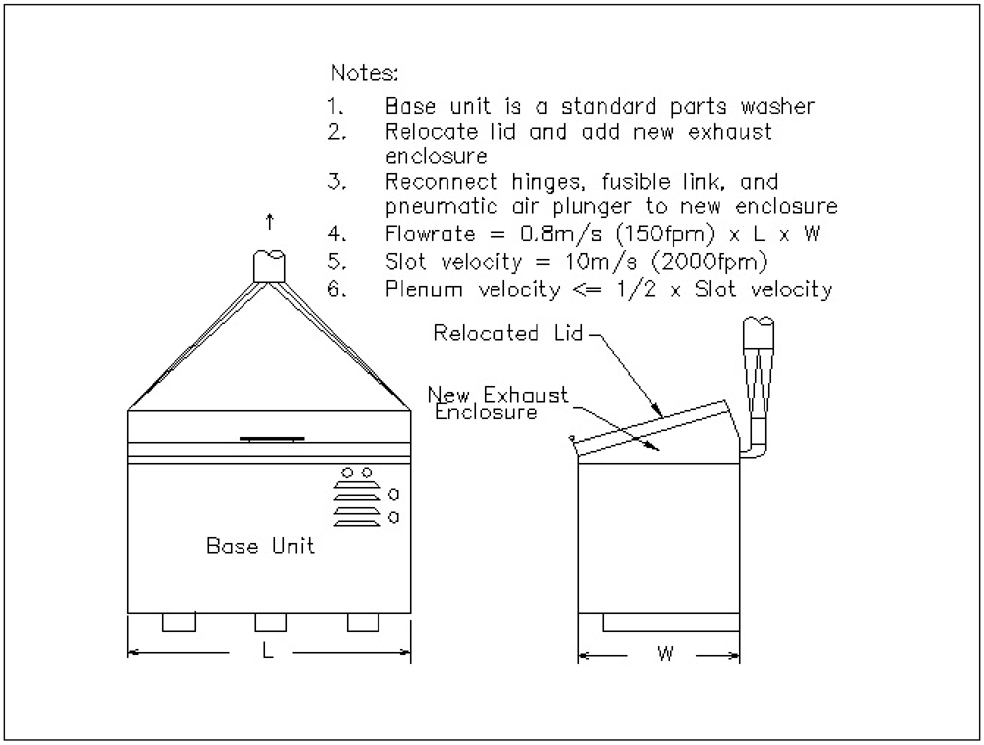
Design or modify the parts washers as shown on Figure 4-9. Specify the following criteria for the parts washers:

a. Fabricate a new enclosure to mount on top of the parts washer.

b. Relocate the cover with a pneumatic plunger and a fusible link assembly.

c. Install an automatic switch to turn on the exhaust fan when the cover is opened and to turn off the exhaust fan when the cover is closed.

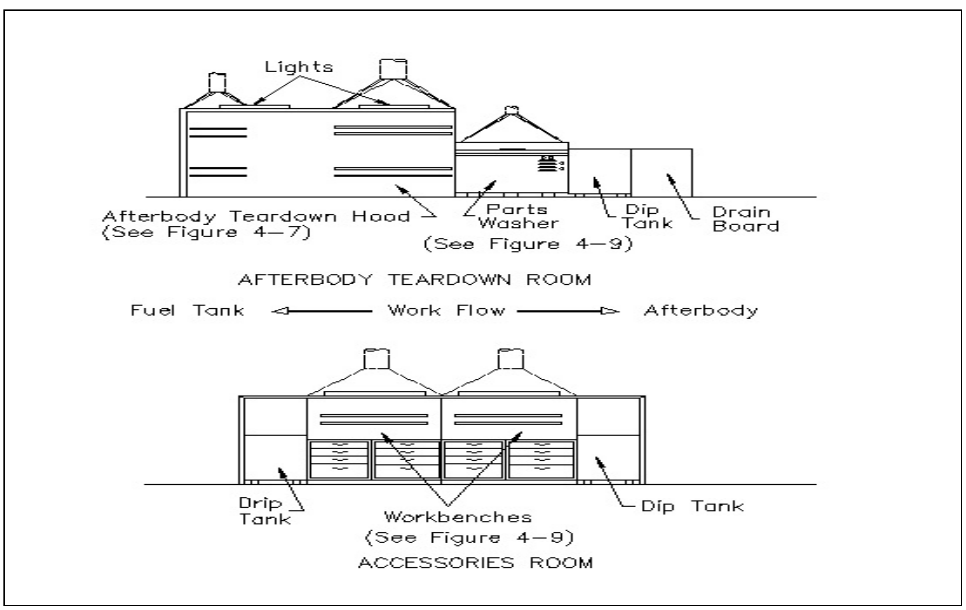
Figure 4-9. MK-48 Parts Washer Hood.



4-3.2.3 Workflow in Afterbody Teardown Room and Accessories Room.

Figure 4-10 illustrates the workflow in both the afterbody teardown room and the accessories room with the proper sequence of hoods.

Figure 4-10. MK-48 Hood Sequence Afterbody Teardown and Accessories Rooms.



4-3.2.4 MK-48 Refueling Hood.

Before refueling, personnel connect the hoses from the fueling equipment to the fuel tank. Once the fueling operation has begun, the operator does not need access to the fuel tank, except to see the hose connections. Therefore, design an enclosing hood to reduce ventilation rates and decrease the potential for exposure to a spill during fueling. Design the hood as illustrated in Figure 4-11. Specify the following criteria for the refueling hoods.

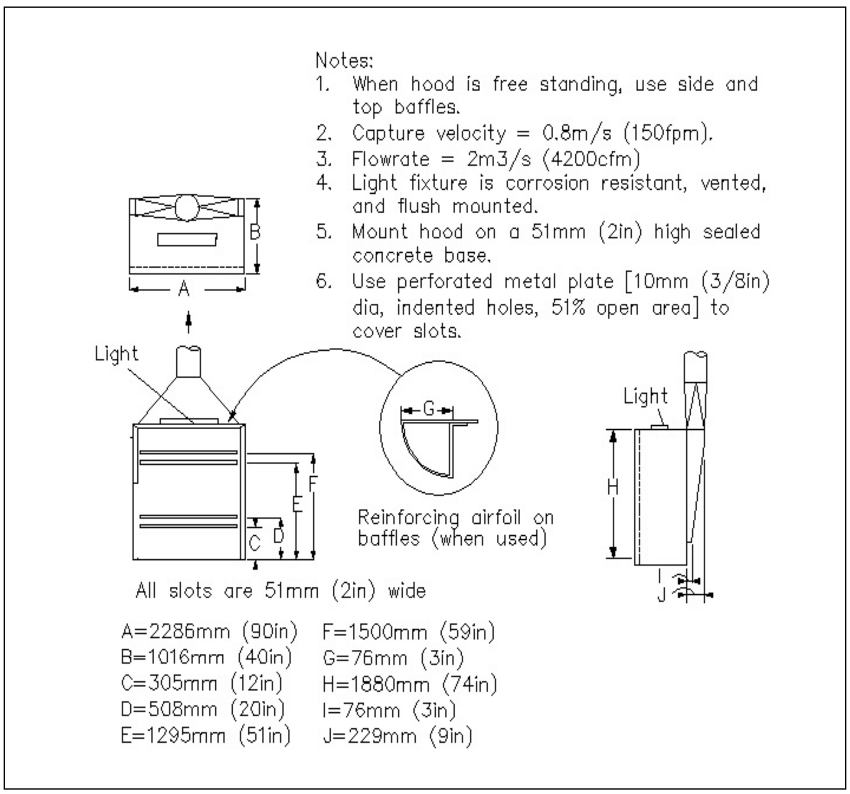
a. A 3-in (76 mm) airfoil rotated inward to prevent turbulence and backflow.

b. Lighting that is vented and flush mounted in the top of the exhaust hood.

c. Hood that bolts the floor, using a continuous natural rubber gasket on hood bottom to create a seal between the hood and the floor.

d. Design the exhaust such that the dip tank can be cleaned using the work station exhaust.

Figure 4-11. MK-48 Refueling Hood.



4-3.2.5 Ductwork.

Follow criteria as specified in the paragraph in Chapter 2 entitled, “Ductwork” for both MK-46 and MK-48 shops and the following:

a. Fabricate all ductwork in contact with Otto Fuel II vapors with (black) carbon steel. Require all joints be either butt welds or flanges.

b. Size the duct to maintain a minimum transport velocity of 2,500 fpm (12.7 m/s).

4-3.2.6 Fans.

Select fans as specified in the paragraph in Chapter 2 entitled, “Fans”.

4-3.3 Weather Stack Design and Location.

Proper dispersion from the stack is critical because Otto Fuel II exhaust is not filtered. See the paragraph in Chapter 2 entitled, “Exhaust Stacks”.

4-3.4 Air Cleaning Devices.

Due to the quantities and types of contaminants generated by these processes, there is no requirement for air pollution control equipment.

4-3.5 Replacement Air.

Design replacement air systems to maintain a pressure (relative to the atmosphere) ranging from -0.02 to -0.06 inches wg (-5.0 to -14.9 Pa) in the spaces with a potential for personnel exposure. Maintain the spaces with a low potential for personnel exposure at a differential pressure ranging from +0.01 to +0.05 inches wg (2.49 to 12.4 Pa).

4-3.5.1 Quantity and Distribution.

Distribute air to produce laminar flow of air from supply to exhaust in the workspace. Use vertical supply distribution method as shown on Figure 4-12. Horizontal supply distribution method as shown on Figure 4-13 is adequate if, and only if, all exhaust hoods are located on the wall opposite the supply plenum. See the paragraph in Chapter 2 entitled, “Replacement Air” for detailed criteria.

Figure 4-12. Vertical distribution method.

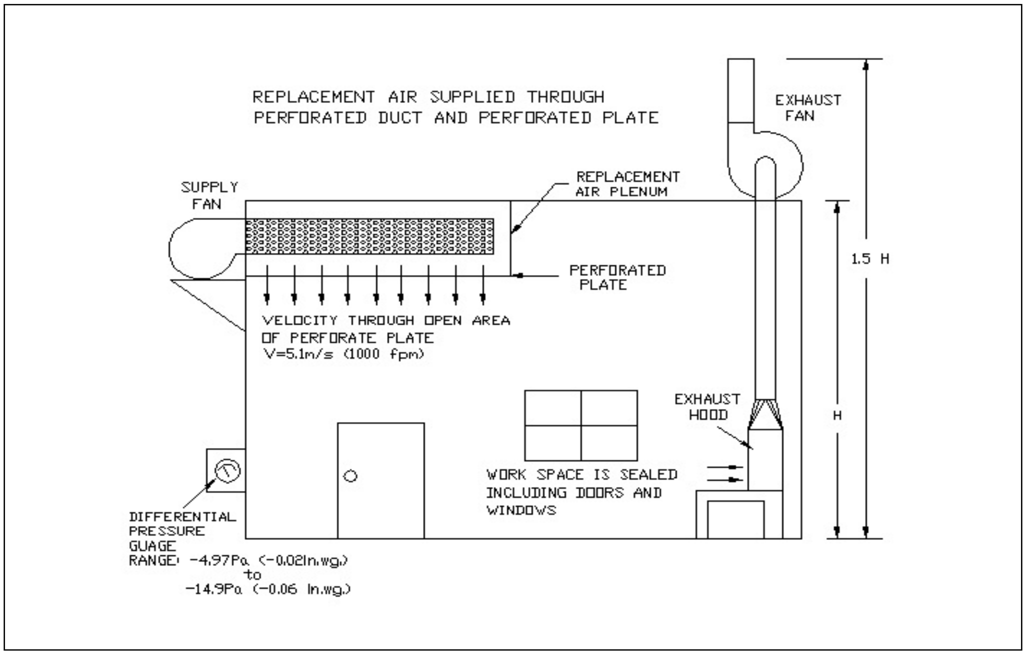


Figure 4-13. Horizontal Distribution Method.

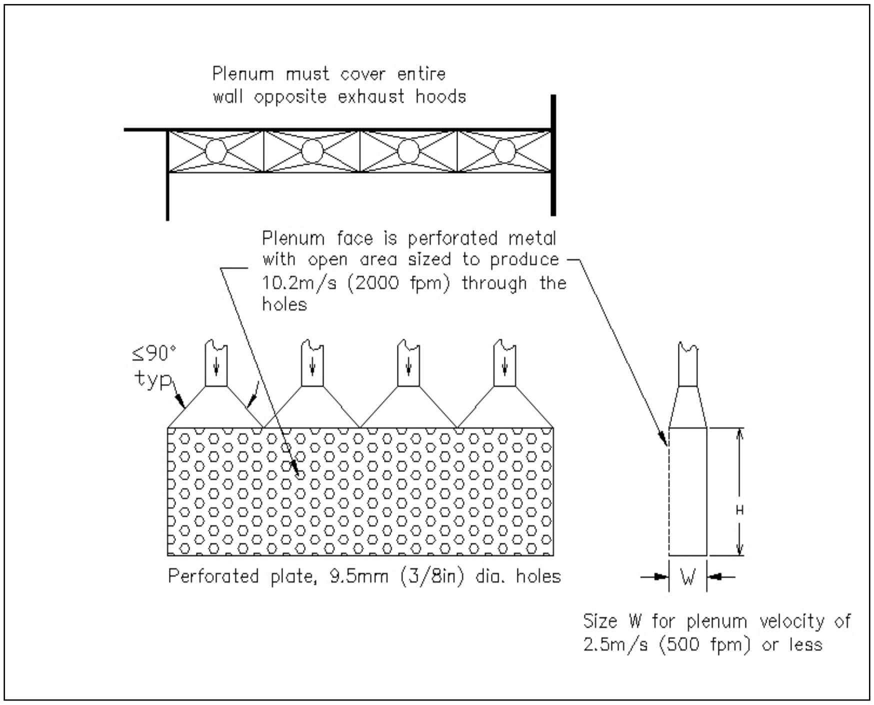


4-3.5.1.1 Vertical Distribution Method.

Design a drop ceiling with perforated plate to form a plenum in accordance with the paragraph in Chapter 2 entitled “Plenum Design”.

4-3.5.1.2 Horizontal Distribution Method.

Design the wall plenum to cover the entire wall opposite the hoods. Size the open area of the perforated sheet for 2,000 fpm (10.16 m/s) through the holes. See Figure 4-13 for more details.

4-3.6 Heating and Air Conditioning.

Design heating, air conditioning, and humidity control according to UFC 3-410-01, *Heating, Ventilation, and Air Conditioning Systems*. Temper the replacement air to provide a minimum winter design temperature of 65 degrees F (18 degrees C) and a maximum summer design temperature of 78° F (25.6° C), with a relative humidity of 50 percent +/- 10 percent. Do not separate the air conditioning system from the replacement air system. See the paragraph in Chapter 2 entitled, “Energy Conservation” for criteria on heat recovery systems. Do not re-circulate exhaust air.

4-4 SYSTEM CONTROLS.

Design system controls in accordance with the paragraph in Chapter 2 entitled, “Controls” and the following:

a. Position an annunciator panel at the entrance to the space with a potential for personnel exposure so operators can monitor operating gauges.

b. Install static pressure sensors at locations that are representative of average static pressure in each controlled space. This will ensure that desired differential pressures are maintained.

c. Trigger a timer if the pressure varies from the specified range. Select a timer that automatically resets if the problem is corrected within 60 seconds.

d. Trigger both visible and audible alarms if the system cannot correct the difficulty within the allotted time.

4-5 SAFETY AND HEALTH CONSIDERATIONS.

29 CFR 1910 requires specific criteria for the safety and health of operators. The physical nature of the work and the use of protective clothing increase the potential for heat stress. Consider cooling the replacement air to reduce this potential. Refer to NAVSEA S6340-AA-MMA-010, *Otto Fuel II Safety, Storage, and Handling Instructions* for complete operational considerations.

4-5.1 Emergency Shower and Eyewash Stations.

Provide combination emergency shower and eyewash stations in the immediate area of Otto Fuel II use. Design in accordance with UFC 3-420-01, *Plumbing Systems,* Appendix D.

CHAPTER 5 COMPOSITE FABRICATION AND REPAIR FACILITIES

5-1 FUNCTION.

Composite shops and facilities primarily fabricate and repair aircraft and shipboard components. Both include a shop area, a mechanical equipment area, and a decontamination area (for protective clothing).

5-2 OPERATIONAL CONSIDERATIONS.

Composite fabrication and repair operations include sanding, buffing, fabric cutting, grinding, lay up, and wet spray up. These operations produce dust and vapor that constitute health hazards. The protective clothing that the workers wear and the physical nature of the work creates a potential for heat stress.

a. Consider using airless spray equipment to reduce hazardous vapors in the shop. Initial cost for this equipment is greater than traditional compressed air systems. Benefits include overspray reduction and less accumulation of resin and fiberglass over the life of the equipment. A disadvantage of these systems is their limited pattern and flow adjustment capability.

b. Consider using low monomer polyester material, closed molding systems or low-VOC resin systems, and airless and air-assisted spray equipment to avoid the need for expensive air pollution devices.

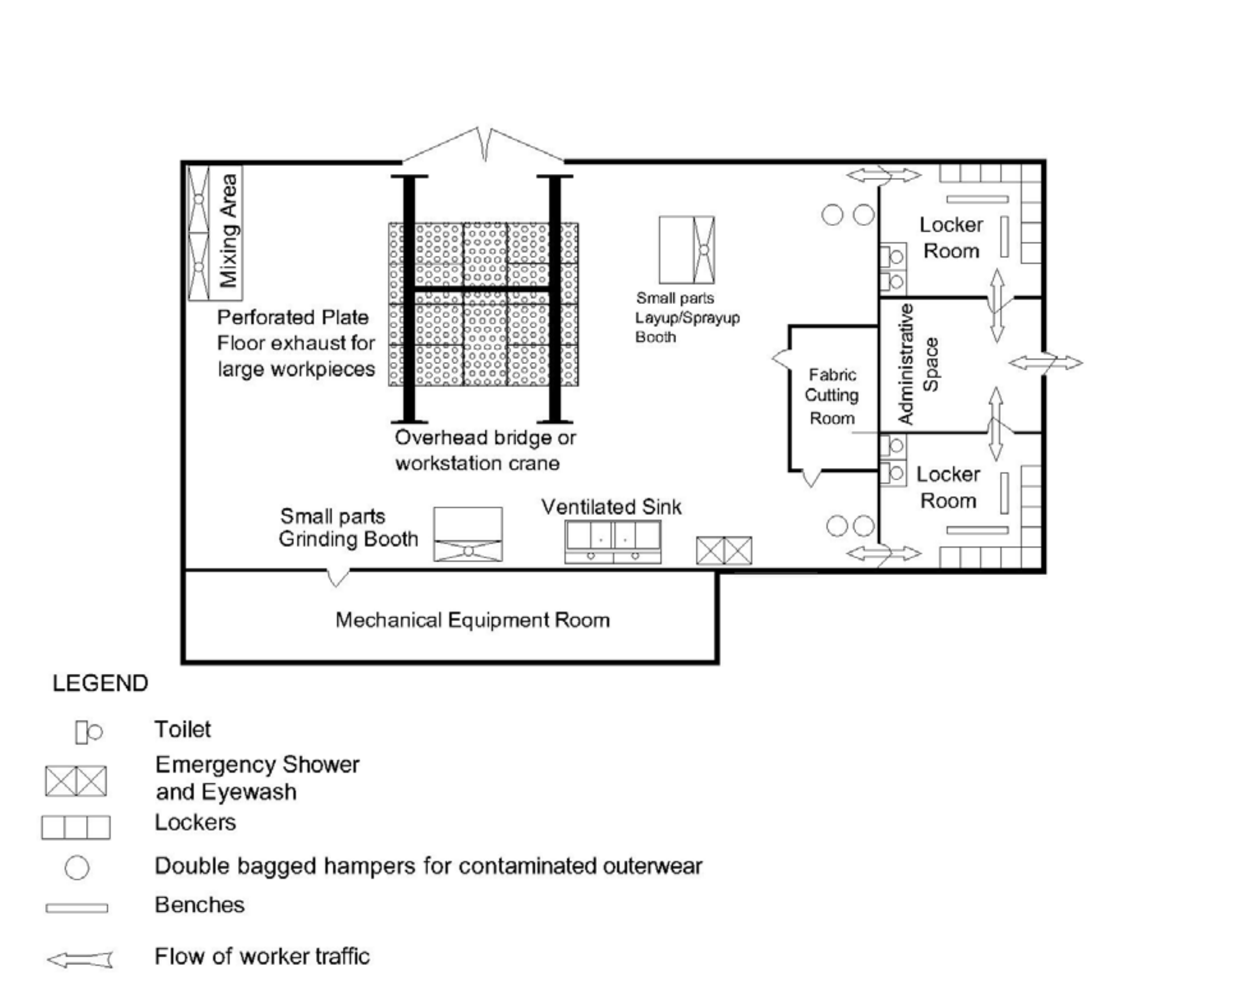
c. Isolate conventional grinding operations from the mixing areas and the lay up and spray up areas. The combined hazard of dust and flammable vapors is potentially explosive. Post signs in the lay up and spray up areas and the mixing area without low volume-high velocity (LVHV) connectors that read:

DANGER
DO NOT GRIND, CUT, OR SAW
FIBERGLASS IN THIS AREA

5-3 FLOOR PLAN.

Figure 5-1 shows typical floor plans for Composite fabrication and repair facility. The workers enter the clean locker rooms through the administrative area. They put on protective outerwear and proceed to the shop area. After performing their work, shop personnel vacuum, then discard their protective outerwear in containers near the entrances to the locker rooms. The workers then enter the locker rooms where they remove the remainder of their work garments.

Figure 5-1 Example Floor Plan for a Composite Facility.



5-4 DESIGN CRITERIA.

Design the facility using general technical requirements in Chapter 2 of this UFC and the specific requirements in this Chapter.

5-4.1 Exhaust Air System.

Provide an exhaust system that captures contaminated air generated during FRP fabrication and repair operations. Refer to Chapter 2 of this UFC; UFC 3-600-01, *Fire Protection Engineering For Facilities*; NFPA 33, *Standard Spray Application Using Flammable or Combustible Materials*; NFPA 68, *Standard on Explosion Protection by Deflagration Venting*; NFPA 91, *Standard for Exhaust Systems for Air Conveying of Vapors, Gases, Mists, and Noncombustible Particulate Solids*; NFPA 654, and the specific requirements of this Chapter.

5-4.2 Hood Design.

The sizes and shapes of work pieces in FRP fabrication and repair facilities vary. Design separate hoods for processes producing only particulate and only vapor, and both particulate and vapor. Consider a molding system that completely encloses the work piece if the facility repeatedly manufactures the same work piece. Design exhaust hoods to enclose all processes to the greatest possible extent without inhibiting operations. Baffle all exhaust hoods to reduce cross drafts and improve hood efficiency. Table 5-1 summarizes recommended exhaust hoods, capture velocities, and air pollution control devices for each operation.

Table 5-1. Recommended Hood, Capture Velocity, and Air Pollution Device

Operation (expected contaminant)	Hood Type	Recommended Capture Velocity (fpm (m/s))	Air Cleaning Device (see notes)
Chemical Mixing (vapors)	Workbench (Figure 5-2)	100 (0.51 m/s)	1
Lay up (Vapors)	Workbench/Floor Exhaust (Figure 5-3)	100 (0.51 m/s)	1
Spray up (Vapors)	Spray up Booth (Figure 5-4)	100 (0.51 m/s)	1
Grind,Cut,Saw (Particulate)	Workbench/Floor Exhaust (Figure 5-3)	150 (0.76 m/s)	2
Cleanup (Vapors)	Ventilated Sink (Figure 5-5)	100 (0.51 m/s)	3 or 1
Hand Tools (Particulate)	LVHV Vacuum System	Not applicable	2

NOTES: (1) Determined by the local air pollution regulatory agency,
(2) fabric collector, and
(3) substitute an aqueous emulsion cleaner for acetone.

5-4.2.1 Plenum Velocity.

Design the plenum velocity at least one-half, but no greater than, the velocity through the perforated plate or layered prefilter to create an even airflow over the hood face. Design the hood-to-duct transition with an included angle of no more than 90 degrees.

5-4.2.2 Hood Length.

Specify that the length of the hood served by each exhaust plenum will not exceed 8 ft (2.44 m). For example, hoods between 8 and 16 ft (2.44 and 4.88 m) in length will have two exhaust takeoffs. Provide cleanout doors in the plenum to allow removal of accumulated particulate.

5-4.2.3 Portable Hand Tools.

Use portable hand tools with Low Volume High Velocity (LVHV) vacuum systems for sawing, cutting, and grinding on all work pieces. Ensure that the tools, with their vacuum hoses, are properly sized for the work piece internal angles and curvature. LVHV systems are described in the paragraph in Chapter 5 entitled, “Industrial Vacuum System”.

Figure 5-2. Workbench Hood.

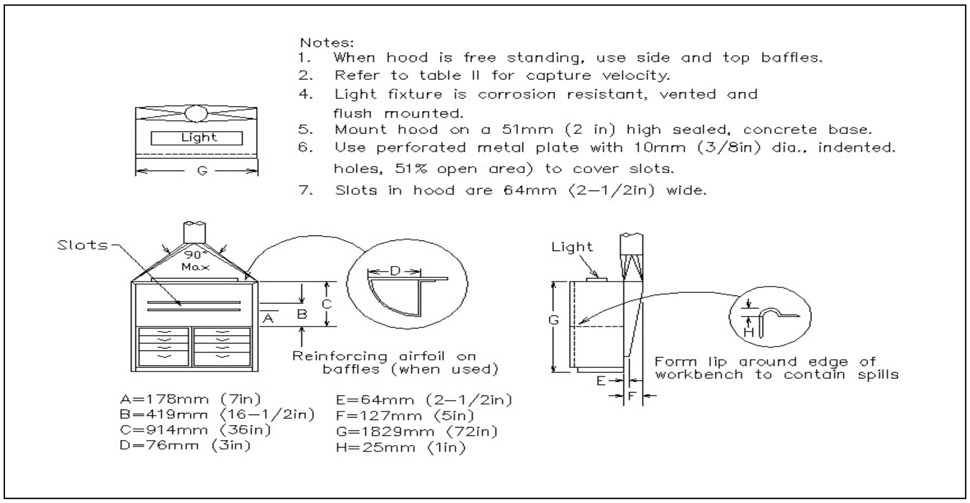


Figure 5-3. Floor Exhaust.

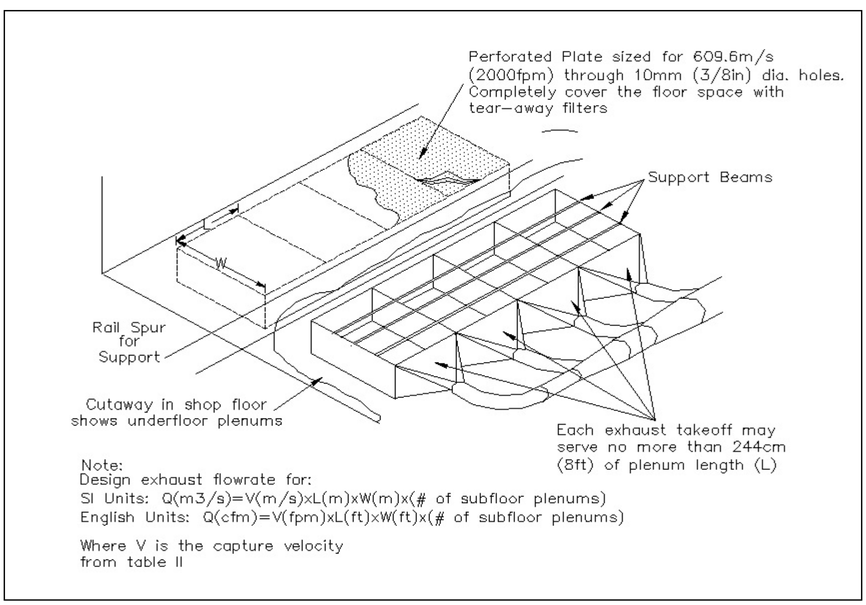

NOTE: Mount the work piece on a mechanism for easy rotation. This will reduce the dead air space that occurs when working on radomes, boat hulls, and other large objects.

Figure 5-4. Spray Up Booth.

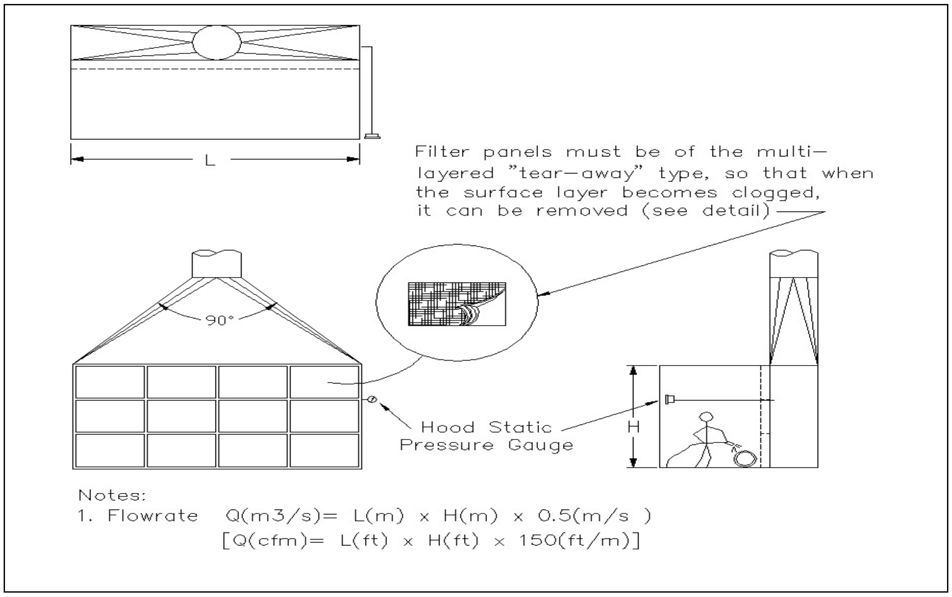

Figure 5-5. Ventilated Sink.

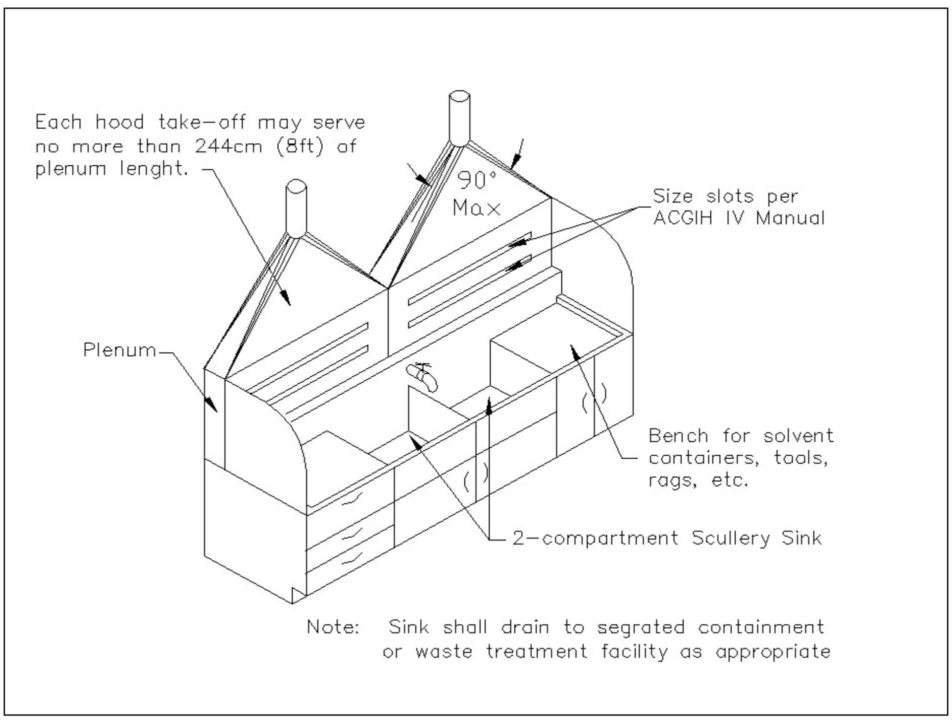


5-4.2.4 Spray Up Booths.

Design a spray up booth as shown on Figure 5-4. Use the spray up hood design in shops where spray up and lay up are performed in the same booth. Separate operations in this booth from any cutting, grinding, and sawing operations when conventional hand tools are used.

5-4.2.5 Ventilated Workbench and Sink.

Design a ventilated workbench as shown in Figure 5-2 for small work pieces. Use a similar workbench for resin preparation and mixing as shown on Figure 5-5. Eliminate the drawers and increase the size of the hood face by extending it to the floor if collection drums are used during resin preparation. Use aqueous emulsion cleaners to reduce styrene and acetone exposure.

5-4.3 Ductwork.

Design a 3,500 fpm (17.8 m/s) minimum transport velocity for LVHV hand tools, and grinding and spray up operations to prevent particulate material from collecting in the ductwork.

a. Size the ductwork carrying vapor generated during lay up and mixing operations for a minimum transport velocity of 2,500 fpm (12.7 m/s). Use sheet metal as duct material since it is non-combustible. Route the ductwork directly to fans located outdoors. See the paragraph in Chapter 2 entitled, “Ductwork” for further information on ductwork.

b. Consult with a fire protection engineer and use UFC 3-600-01, *Fire Protection Engineering For Facilities* to design a fire protection system for the ductwork when required. Condensation of flammable vapors, i.e. styrene and acetone, may occur and pool in the ductwork as it passes through an area with a lower temperature.

5-4.4 Fans.

See the paragraph in Chapter 2 entitled, “Fans” for general considerations.

5-4.5 Weather Stack Design and Location.

See the paragraph in Chapter 2 entitled, “Exhaust Stacks” for exhaust stack design guidance.

5-4.6 Air Cleaning Devices.

Use separate air cleaning devices for grinding, buffing and polishing operations where particulate material is generated. Use separate air cleaning devices for lay up and mixing operations where flammable vapors are generated. Consult the air pollution control authorities for details on local requirement.

5-4.6.1 Grinding Operations and Hand Tools.

Use a fabric collector for grinding operations and LVHV hand tools. Consider using a disposal chute with a motor-driven rotary air lock in shops with a large particulate volume.

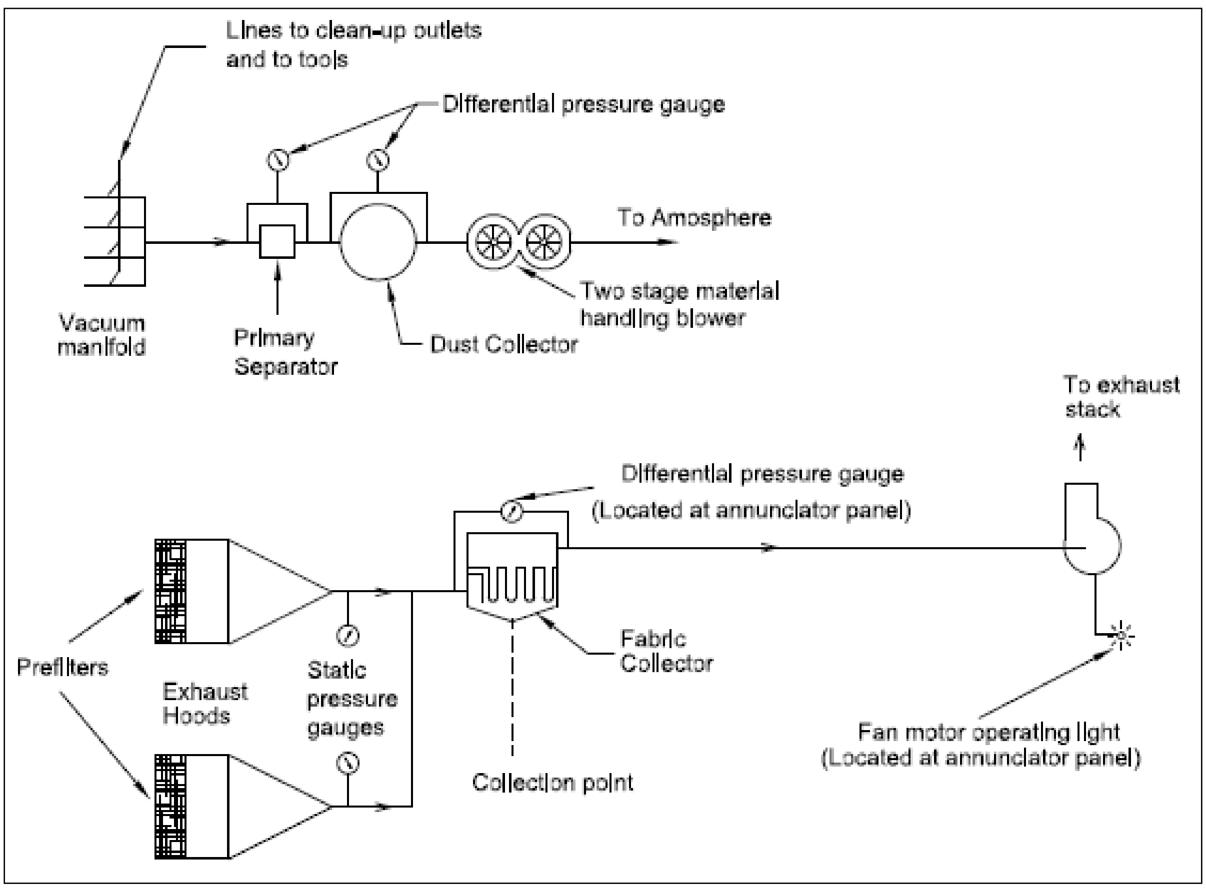
5-4.6.2 Spray Up Operations.

Spray-up operations release a combined contaminant of wet resin laden fiber and organic vapors. Therefore, separate spray up operations from all other operations. Install an air-cleaning device for vapors. Install layered prefilters on the spray up hood face instead of the perforated plate to prevent wet airborne resin from hardening in the ductwork and collectors. Peel off and discard a layer of the prefilter when its surface becomes loaded as indicated by the hood static pressure gauge. This continues until only the base filters remain. After that, replace the entire prefilter section. Specify a filter material that is not damaged by the styrene and acetone vapor produced in Composites facilities.

5-4.7 Industrial Vacuum System.

Install a vacuum system; see Figure 5-6, to exhaust fibers, dry resin and dust from LVHV hand tools when they are used. The vacuum system also allows workers to conduct shop cleanup and to decontaminate their protective outerwear. ACGIH IV Design Manual, Chapter 13, Section 13.40, Low Volume-High Velocity Exhaust Systems, gives design details and illustrates power tools using LVHV vacuum systems. The large size and high terminal velocity of the particulates produced by the hand tools requires a high velocity vacuum take-off hood for each tool. Generally, design the takeoff hood into the tool's safety guard.

Figure 5-6. Exhaust System Schematic.



5-4.7.1 Vacuum System Design.

Design the vacuum system in accordance with the following criteria:

a. Ensure each take-off hood produces the proper capture velocity. This is the most important consideration in designing the vacuum system. Design the hood to capture contaminants as close as possible to the point of generation. Design vacuum systems to capture contaminants within 1/2 inch (12.7 mm) of the source.

b. Design the capture air-stream to have a velocity of two to three times the generation velocity for particles of 20 to 30 micrometers (20 to 30 microns.) Design for an additional velocity of:

   1. Four to five times the generation velocity to pull the particles up through 300 U.S. standard mesh, or

   2. Six to eight times the generation velocity to pull particles up through 20 U.S. standard mesh.

c. Design the air volume for no less than two parts of air to one part of material to be captured by weight.

d. Design the vacuum hose length less than 25 ft (7.6 m). Locate inlet valves 30 to 35 ft (9 to 10.7 m) apart when a 25ft (7.6 m) length of hose is used. Locate the tool vacuum hose connection on the ends of the workbench underneath the stands. Size the hose based on the following:

   1. Air volume per hose.

   2. Number of hoses to be used simultaneously.

   3. Transport velocities.

e. Use either a multistage centrifugal or turbine blower, positive-displacement blower or a regenerative blower for the vacuum system. Size the blower according to the following:

   1. The total system pressure loss associated with the total number of hoses to be used simultaneously.

   2. The maximum exhaust flow-rate entering the inlet of the blower.

f. Place the primary separator and dust collector ahead of the vacuum exhaust blower to minimize wear to the blower.

g. Use the manufacturer's data to complete the design because the LVHV system design data is largely empirical.

5-5 REPLACEMENT AIR.

Design replacement air systems to maintain a pressure (relative to the atmosphere) ranging from -0.02 to -0.06 in wg (-4.97 to -14.9 Pa) in the shop space and the protective clothing decontamination areas. Maintain the clean spaces at a positive pressure differential relative to dirty spaces. See the paragraph in Chapter 2 entitled, “Replacement Air” for further details. Provide each ventilated space with a dedicated replacement air system. Conduct a study of the curing requirements of the resin before specifying temperature and humidity ranges. Do not re-circulate exhaust air.

5-6 SYSTEM CONTROLS.

Design system controls in accordance with the paragraph in Chapter 2 entitled, “Controls” and the following:

a. Position the annunciator panel at the entrance to the dirty space so operators can monitor operating gauges.

b. Install static pressure sensors at locations that are representative of the average static pressure in each controlled space. This will ensure that desired differential pressures are maintained.

c. Interlock the hand tool power supply with the main ventilation system's on/off switch and with the vacuum system. This will prevent the use of hand tools without ventilation controls.

5-7 SAFETY AND HEALTH CONSIDERATIONS.

See the paragraph in Chapter 2 entitled, “Safety and Health Considerations”. Provide combination emergency shower and eyewash stations in the workspace. Design in accordance with UFC 3-420-01, *Plumbing Systems,* Appendix D.

This Page Intentionally Left Blank

CHAPTER 6 ABRASIVE BLASTING FACILITIES

6-1 FUNCTION.

Workers prepare the surface of aircraft, shipboard, mechanical, utility, and other equipment in abrasive blasting facilities for surface coating, welding, and other operations.

This Chapter does not apply to temporary blasting enclosures.

Criteria for the design of Dry Media Blast (DMB) Aircraft Depaint Hangars are contained in UFC 4-211-02, *Aircraft Corrosion Control and Paint Facilities*.

6-2 OPERATIONAL CONSIDERATIONS.

Silica sand is prohibited from use in fixed location enclosures. Avoid using agricultural media (e.g. peach pits, rice hulls, walnut shells). They are particularly susceptible to explosions.

6-3 DESIGN CRITERIA.

Apply the general technical requirements of Chapter 2 and the specific requirements of this Chapter to ensure the proper function, operation and maintenance of an abrasive blasting facility. Use this information when assembling a specification package for an enclosure manufacturer or inspecting an enclosure already in place.

6-3.1 Exhaust Air.

Determine the type of dust hazard and the minimum average air velocity through the blasting enclosure in accordance with 29 CFR 1910.94(a), *Abrasive Blasting*; ANSI/AIHA/ASSE Z9.4, *Abrasive-Blasting Operations– Ventilation and Safe Practices for Fixed Location Enclosures*, sections 4, 5, 6 and A7; NFPA 68, *Standard on Explosion Protection by Deflagration Venting*; NFPA 69, *Standard on Explosion Prevention Systems*; NFPA 70; NFPA 91; NFPA 654; NFPA 484 *Standard for Combustible Metals* when blasting on materials containing aluminum, magnesium, titanium, zirconium and lithium, respectively.

6-3.2 Blasting Cabinets.

Install baffles around air inlets to prevent abrasive material from escaping from the cabinet. Use a minimum inward air velocity of 500 fpm (2.54 m/s) at all operating openings. Discharge the exhaust air outside the building.

6-3.3 Walk-in Blasting Enclosures.

Design the enclosure so that the air flows from either the ceiling to the floor (downdraft), Figure 6-1, or from one wall to the opposite wall (crossdraft), Figure 6-2, and the following:

a. Consider the geometry of the room and how work pieces are positioned within the room, and the number of workers and their locations when selecting a downdraft or a crossdraft design.

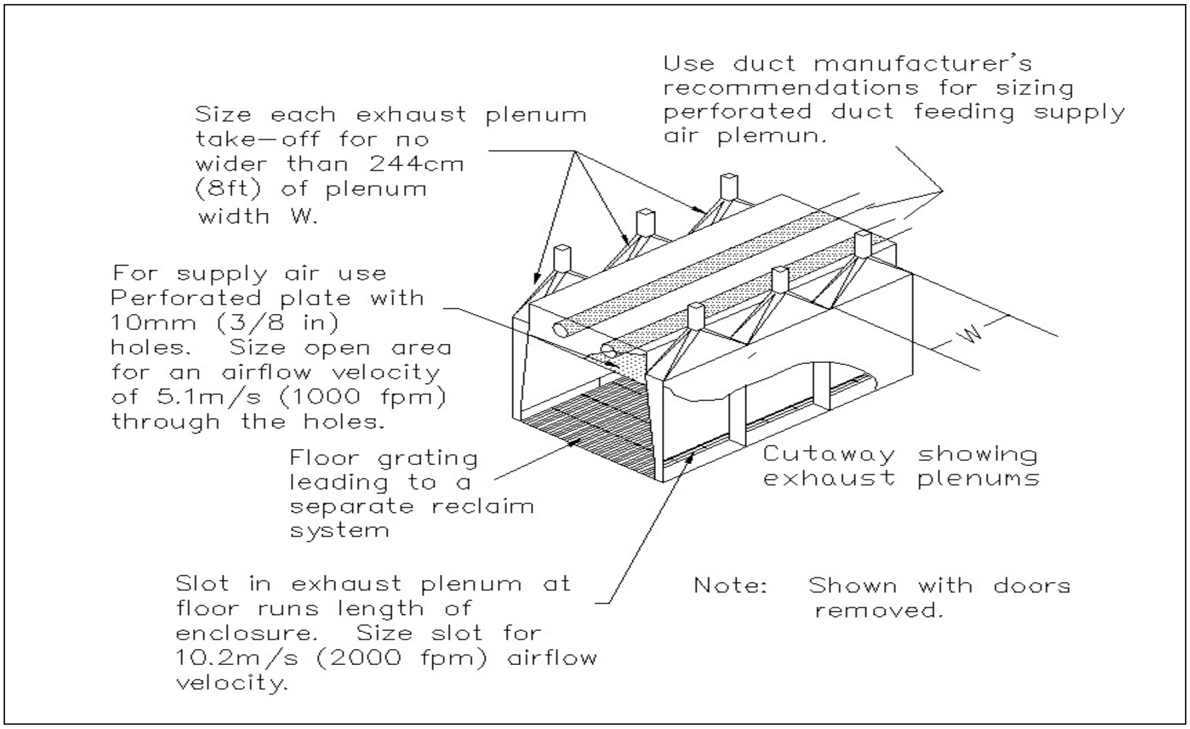
b. Minimize the area of a blasting room to reduce the volumetric airflow rate. Allow at least 4 ft (1.22 m) of clearance between the work piece and the ceiling, walls, and doors of the room. Add extra clearance to accommodate internal fixtures such as tables and hoists.

c. Isolate the abrasive blasting rooms from other processes, functions and activities, whenever possible. Place blasting rooms outside, away from administration and other spaces. Protect the blasting room and related equipment from rainwater and moisture intrusion. As a minimum, put a roof or cover over the blasting room.

6-3.3.1 Downdraft.

The downdraft design provides superior visibility. In addition, a downdraft design is preferred since contaminated air is usually drawn away from the worker's breathing zone. When more than one operator works in an enclosure, contaminated air generated from one operation is less likely to migrate into the other operator's breathing zone. Use a perforated plate with 3/8-in (9.53 mm) diameter holes, as shown in Figure 6-1, to uniformly distribute the airflow over the entire cross-section of the enclosure. Use a perforated duct inside the plenum to help evenly pressurize the plenum.

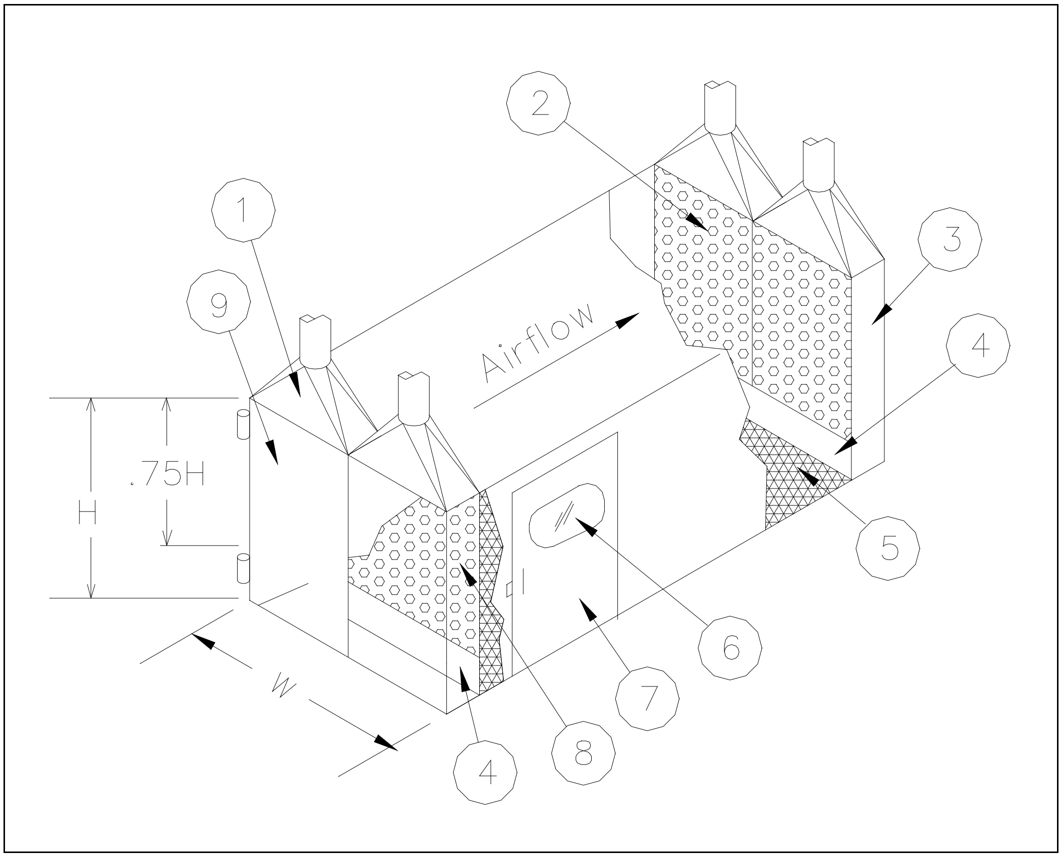
Figure 6-1. Downdraft Blast Enclosure.



6-3.3.2 Crossdraft.

Consider the work locations of operators when positioning the replacement and exhaust air plenums. Do not allow any operator to blast upstream of coworkers. Use a perforated plate with 3/8-in (9.53 mm) diameter holes; see Figure 6-2, to uniformly distribute airflow over the entire cross-section of the enclosure.

Figure 6-2. Crossdraft Blast Enclosure.



NOTES:
1. For mechanically supplied replacement air, use maximum plenum take-off width of 8 ft (2.44 m). Plenum serves as material door.
2. Perforated plate with 3/8-in (9.53 mm) holes. Size open area for an airflow velocity of 2000 fpm (10.16 m/s) through holes.
3. Size the exhaust plenum for a maximum plenum velocity of 1000 fpm (5.08 m/s). Size any supply plenum for a maximum plenum velocity of 500 fpm (2.54 m/s).
4. Lift up flap to remove material from behind plenum.
5. Floor grating.
6. Observation window.
7. Personnel door.
8. Perforated plate, from floor to ceiling and wall-to- wall, with 3/8-in (9.53 mm) holes. Size open area for an airflow velocity of 1000 fpm (5.080 m/s) through holes.
9. Hinged plenum equipment doors.

6-3.4 Access Doors and Observation Windows.

Provide an observation window and an access door in accordance with 29 CFR 1910.94(a)(3)(i)(d) and (e) and ANSI/AIHA/ASSE Z9.4 sections 5.3 and 5.4. Position the observation window in the blast room walls and door as necessary so workers inside the room can be seen from outside the room at all times. Use several doors and windows in large rooms. Provide emergency exits on opposing walls. Make personnel and equipment doors operable from both inside and outside of the room.

6-3.5 Air Cleaning Devices.

See the paragraph in Chapter 2 entitled, "Air Pollution Control Equipment". Design in accordance with 29 CFR 1910.94(a)(4)(iii) and ANSI/AIHA/ASSE Z9.4, section 6.3. Consider using a pulse-jet, pleated paper cartridge type dust collector and the following.

a. Replaceable explosion vents on the collector hoppers in accordance with NFPA 68.

b. Platforms leading to all elevated access hatches.

c. Fan located on the clean side of the collector.

d. Place dust collectors outside of the building for all blasting applications. NFPA 651, *Standard for the Machining and Finishing of Aluminum and the Production and Handling of Aluminum Powders*, specifically requires that the air pollution equipment be located outside when blasting on aluminum or aluminum alloys.

6-3.6 Recirculation.

Do not recirculate exhaust air when operations generate toxic materials. If exhaust air recirculation is permitted, design the system in accordance with the ACGIH IV Design Manual (Section 10.8), ANSI/AIHA/ASSE Z9.4 (section 6.3) and ANSI AIHA/ASSE Z9.7, 29 CFR 1910.1025 (lead), and 29 CFR 1910.1027 (cadmium). The outdoor air volumetric airflow rate must be sufficient to keep the contaminant below 25 percent of the MEC.

6-3.7 Media Reclamation.

Design in accordance with 29 CFR 1910.94(a)(4)(ii) and ANSI/AIHA/ASSE Z9.4, section 6.2. Do not integrate the exhaust ventilation system with the media recovery system.

a. Protect the media recovery system and ductwork from moisture and rainwater intrusion to keep the media from caking and plugging up the system.

b. Use mechanical recovery systems such as rotary screw conveyors for heavy media (steel shot).

c. Consider using pneumatic recovery system instead of mechanical recovery system for plastic media.

6-3.8 Ductwork.

See the paragraph in Chapter 2 entitled, “Ductwork”. Do not use spiral lock seam duct. Size the exhaust ductwork to maintain a minimum transport velocity of 3,500 fpm (17.8 m/s). Specify flat backed elbows per the ACGIH IV Design Manual, Chapter 5, Figure 5-16.

6-3.9 Fans.

See the paragraph in Chapter 2 entitled, “Fans”. Use centrifugal fans with backward curved blades, whenever possible. Centrifugal fans with radial blades are less efficient, but still acceptable. Place the exhaust fan and the outlet ductwork outside of the building.

6-3.10 Weather Stack Design and Location.

See the paragraph in Chapter 2 entitled, “Exhaust Stacks” for design guidance.

6-3.11 Replacement Air Ventilation Systems.

See the paragraph in Chapter 2 entitled, “Replacement Air”. Design dedicated mechanically supplied replacement air systems to maintain room static pressures (relative to the atmosphere) ranging from -0.02 to -0.06 in wg (-4.98 to -14.9 Pa).

Blast booths often do not have mechanical replacement air. In this case, there is no control over the room static pressure for non-mechanical replacement air systems. The extra negative pressure reduces exhaust fan performance. If mechanically supplied replacement air is not feasible, ensure that the room static pressure and the resistance through filters and louvers are included when sizing the exhaust fan.

6-3.12 Heating and Air Conditioning.

For HVAC-related issues use UFC 3-410-01, *Heating, Ventilation, and Air Conditioning Systems.*

6-3.13 System Controls.

Design system controls in accordance with the paragraph in Chapter 2 entitled, “Controls” and the following.

a. Install static pressure sensors at locations that represent the average static pressure in each blasting room. This will enhance monitoring and maintenance of desired blasting room pressures.

b. Interlock the blasting tool power supply with the ventilation system's on-off switch. This will prevent the use of blasting tools without ventilation controls.

6-4 SAFETY AND HEALTH CONSIDERATIONS.

See the paragraph in Chapter 2 entitled, “Safety and Health Considerations”, 29 CFR 1910.94(a)(5), and ANSI/AIHA/ASSE Z9.4, section 7, for general requirements. Consider the following.

6-4.1 Respiratory Protection.

Follow the guidelines in 29 CFR 1910.94(a)(5) for respiratory protection requirements. The operator must wear a continuous-flow, air-line respirator that covers the head, neck, and shoulders. Consider providing each respirator hood with an adjustable, vortex-type climate control system.

6-4.2 Air Supply and Air Compressors.

For large booths, consider providing multiple air hose connection points along the perimeter of the enclosure to accommodate work in various parts of the booth.

6-4.3 Noise.

See the paragraph in Chapter 2 entitled, “Noise”. Carefully select the blast nozzle. Nozzle noise generation depends greatly on the discharge velocity. Consider using sound barriers or dampening materials on enclosure walls. Protect the dampening material from abrasive blast as much as possible. Isolate the air compressor, media recirculation, and air pollution equipment to minimize noise exposure.

6-4.4 Hygiene Facilities.

Provide clean change rooms, shower facilities, and lunchroom facilities in accordance with OSHA regulations.

CHAPTER 7 WOOD SHOP FACILITIES

7-1 FUNCTION.

Wood shops differ in size and function. Use the design criteria in this chapter as a general guideline for developing ventilation systems for wood shops.

7-2 OPERATIONAL CONSIDERATIONS.

A properly designed ventilation system will control the dust level within the shop. Exposure to wood dust may lead to health problems. The accumulation of wood dust can create explosion and fire hazards. Even if a ventilation system is installed to collect most of the dust, manual cleaning at each machine and throughout the shop is still necessary. Restrict woodworking exhaust systems to handling only wood dust. Do not connect any other process that which could generate sparks, flames, or hot material to a woodworking exhaust system.

7-3 FLOOR PLAN LAYOUT.

Contact the shop personnel who will be working with the machinery to get their input on workflow and specific equipment. Design the ventilation system to complement equipment layout and minimize housekeeping.

7-4 DESIGN CRITERIA.

Design the facility using general technical requirements in Chapter 2 of this UFC, NFPA 664, *Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities* and the specific requirements in this chapter.

7-4.1 Dust Collection System.

Calculate the system capacity on the basis that the system operates with all hoods and other openings, such as floor sweeps, open. Refer to the ACGIH IV Design Manual, Chapter 13, (Section 13.95), for determining the exhaust flow rate for specific wood shop machines.

7-4.1.1 System Layout.

Lay out the system to meet the shop requirements. Consider locating machines with the greatest hood resistance as close as possible to the fan. In most cases, ductwork is located along the ceiling and walls; however, running ductwork under removable grates or panels in the floor may reduce duct lengths and leave more working space around machinery. Refer to NFPA 650, *Pneumatic Conveying Systems for Handling Combustible Particulate Solids* and NFPA 664 for information on wall penetrations and clearances.

7-4.1.2 Plenum Exhaust System.

An alternative to the tapered system is a plenum system, described in the ACGIH IV Design Manual, Chapter 5. A plenum system allows equipment to be moved in the shop and may be more efficient. Ducts can be added or removed, as equipment needs change. See the ACGIH IV Manual Chapter 5 (Section 5.5) for further considerations.

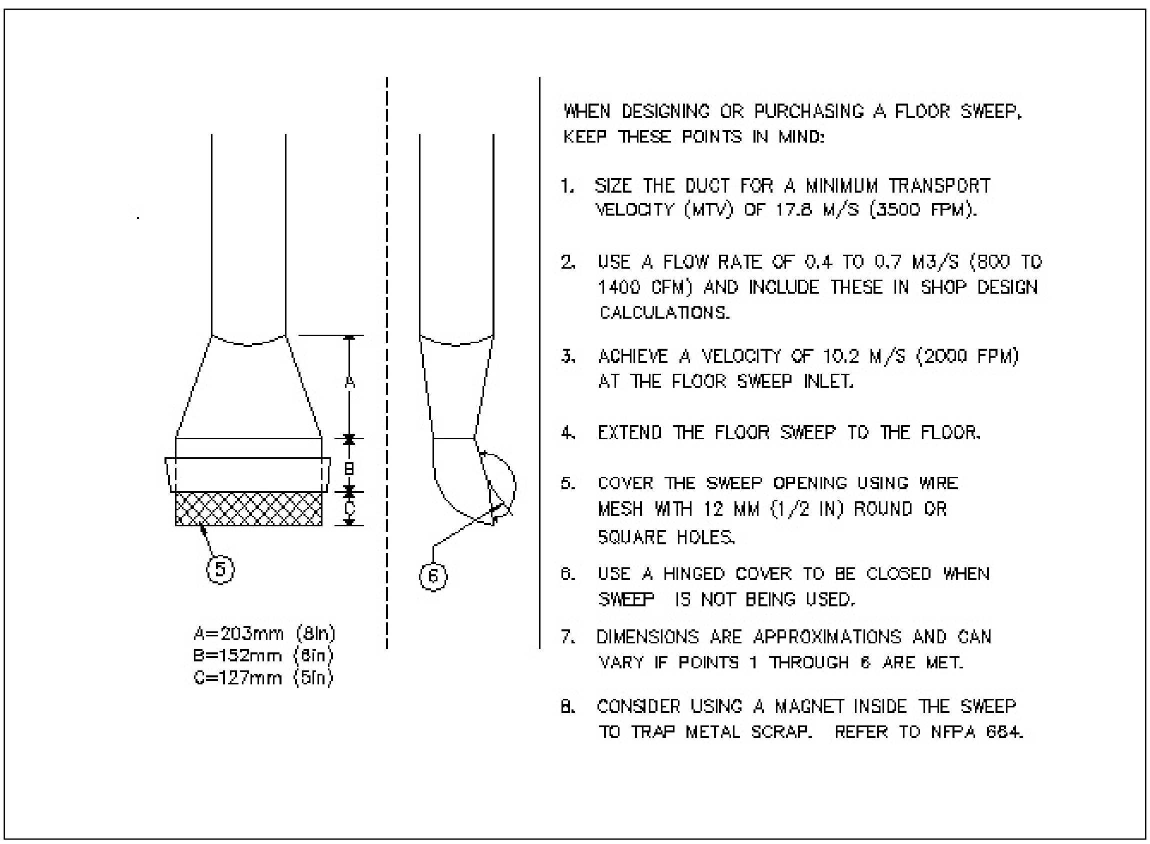
7-4.2 Hood Design.

Provide a hood for each operation that produces dust. This includes sawing, shaping, planing, and sanding operations. Design and position all hoods so the wood dust will fall, be projected, or be drawn into the hood in the direction of the airflow. Construct hoods of noncombustible materials. Ensure the hoods do not interfere with worker operations. In some cases, the exhaust hood may be utilized as a safety guard. Refer to the ACGIH IV Design Manual, Chapter 13 (Section 13.95) for woodworking hood designs. Modify the drawings as necessary to meet the specific equipment and process requirements.

7-4.3 Floor Sweeps.

If the design includes floor sweeps, include a means, such as magnetic separators, to prevent scrap metal from entering the system. Figure 7-1 shows a basic floor sweep design. The floor sweep is only opened during shop clean up. If the system design calculations indicate that, when opened, the floor sweep provides a transport velocity of less than 3,500 fpm (17.78 m/s), design the system to include floor sweeps in the normally opened position without a hinged cover.

Figure 7-1. Floor Sweep



7-4.4 Ductwork.

See the paragraph in Chapter 2 entitled, “Ductwork” for general ductwork design. See NFPA 664 for specific requirements on wood shop ductwork construction. Size the ductwork to maintain a minimum transport velocity as specified in the ACGIH IV Design Manual, Chapter 13.95, Woodworking. Use only metal ductwork and conductive flexible hose. Bond and ground all ductwork in accordance with NFPA 664. The ductwork must be designed on the basis that all hoods and other openings connected to the system are open.

7-4.5 Blast Gates.

Provide blast gates only for the specific purpose of balancing the airflow. Do not use blast gates to isolate equipment from the exhaust system with the intent to reduce the overall airflow requirement. When possible, install blast gates on horizontal runs and orient the gate so the blade is on the top half of the duct and opens by pulling the blade towards the ceiling. When possible, blast gates must be installed at a location not easily accessible to shop personnel. After final balancing and acceptance, secure the blade and mark its position so that it can be returned to the balanced position if inadvertently moved. When the blast gate cannot be placed out of the reach of shop personnel, then lock the blade in position. For example, drill a hole through the body and blade of the gate and then insert a bolt and tack weld it.

7-4.6 Duct Support.

If sprinkler protection is provided in the duct, horizontal ductwork must be capable of supporting the weight of the system, plus the weight of the duct half-filled with water or material being conveyed, whichever has the higher density.

7-4.7 Clean Out Panels.

See the paragraph in Chapter 2 entitled, “Ductwork”.

7-4.8 Exhaust Fans.

See the paragraph in Chapter 2 entitled “Fans”.

7-4.9 Weather Stack Design and Location.

See the paragraph in Chapter 2 entitled, “Exhaust Stacks”.

7-4.10 Air Cleaning Devices.

See the paragraph in Chapter 2 entitled, “Air Pollution Control Equipment”. Locate the air-cleaning device outside the building.

7-4.11 Building Heating and Air Conditioning.

For HVAC-related issues use UFC 3-410-01, *Heating, Ventilation, and Air Conditioning Systems.*

7-5 SAFETY AND HEALTH CONSIDERATIONS.

See the paragraph in Chapter 2 entitled, “Safety and Health Considerations” and the following items.

a. Refer to section 7.2.2 of ANSI O1.1, *Woodworking Machinery, Safety Requirements* for personal protective equipment.

b. Provide a means for separately collecting and disposing of any metal scrap such as nails, band iron, or any wood containing metal. Do not use the woodshop ventilation system to pick up these materials.

c. Avoid the use of wood painted with paints containing lead, hexavalent chromium, cadmium, or coated with wood preservatives. Otherwise, consult an industrial hygienist (IH) to determine the exposure level and the level of respiratory protection needed.

d. Use sharp and clean blades at the correct feed rate to generate less heat. The generated heat can raise the wood or wood-containing product to ignition temperature that could start a fire.

CHAPTER 8 BATTERY MAINTENANCE FACILITIES

8-1 FUNCTION.

Battery maintenance facilities contain space and equipment for receiving, cleaning, testing, charging, and issuing batteries. Sizes range from a small booth to a room with storage area. In these facilities, batteries are not in operation while being charged. Two types of electrochemical battery in general use are lead-acid and nickel-cadmium (NICAD). This chapter does not address battery-post repair operation. For stationary battery installations where batteries are operated on a continuous float charge and no battery maintenance is involved, use UFC 3-520-05 *Stationary and Mission Batteries*.

8-2 OPERATIONAL CONSIDERATIONS.

Batteries generate a small amount of hydrogen and other gases while they are being charged or discharged. Hydrogen build-up could lead to an explosion. Provide ventilation to keep the hydrogen concentration below 25 percent of the LEL (LEL = 4 percent) to prevent an accumulation of an explosive mixture.

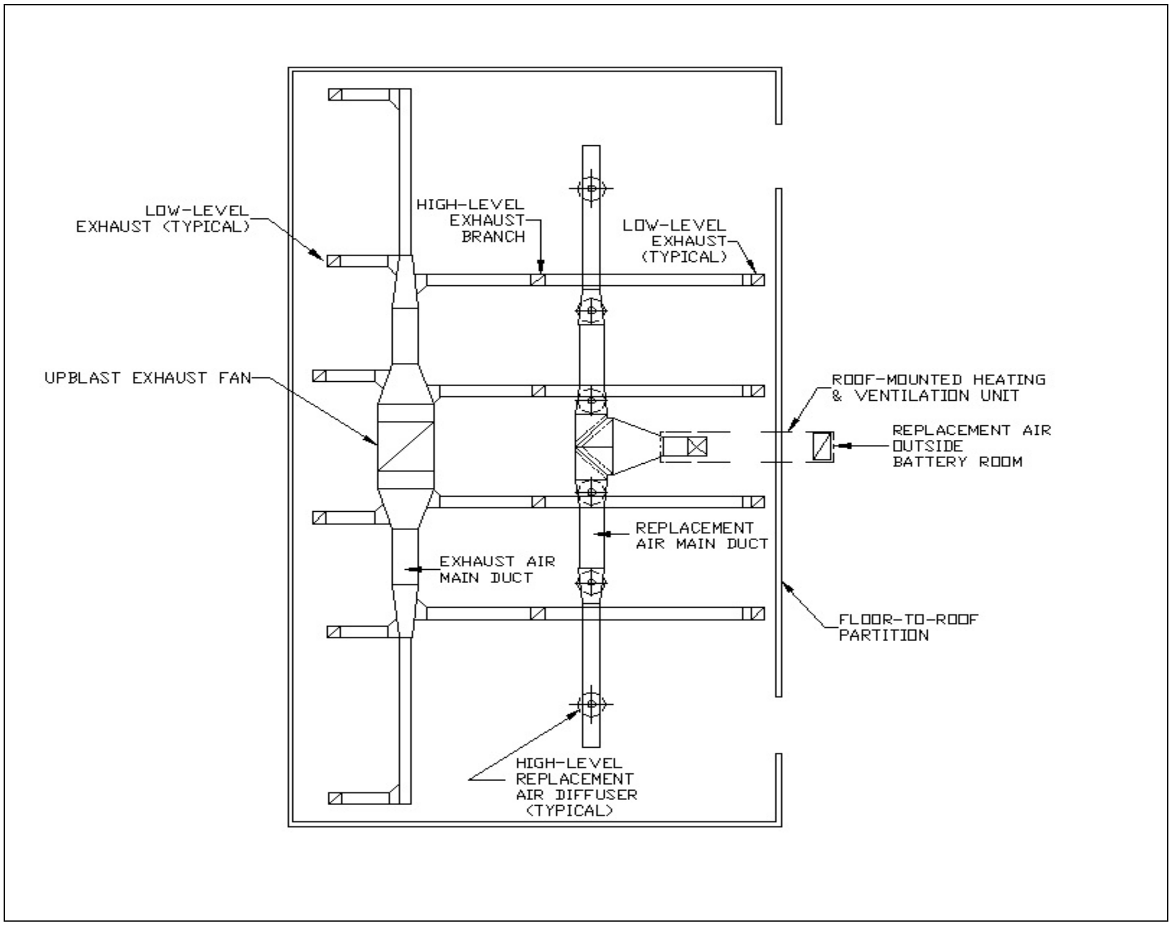
8-3 DESIGN CRITERIA.

Design the ventilation system using general technical requirements in Chapter 2 of this UFC and the specific requirements in this Chapter.

8-3.1 Exhaust System.

Design exhaust ventilation to have both high-level exhaust for hydrogen and low-level exhaust for electrolyte spills (acid mist and odors). Distribute one-third of the total exhaust flow rate to the high-level exhaust to ventilate all roof pockets. Locate low-level exhaust at a maximum of 1-ft (304.8-mm) above the floor. Do not re-circulate exhaust air back to the maintenance facility. Exhaust all air directly to the outdoors through a dedicated exhaust duct system. See Figure 8-1 for a floor plan of a battery maintenance room.

Figure 8-1. Ventilation System for Battery Maintenance Facilities.



8-3.1.1 Minimum Flow Rate Calculation.

To determine the amount of required volumetric airflow rate, the amount of hydrogen produced must be calculated for the total number of battery cells in the room. Hydrogen generation, heat generation and proximity factor into the ventilation calculation. The volume of hydrogen generated is governed by the amount of charging current (ampere) supplied to the fully charged battery by the charger. Significant amounts of hydrogen are evolved only as the battery approaches full charge. Refer to IEEE Standard 1635 / ASHRAE Guideline 21, “Guide for the Ventilation and Thermal Management of Batteries for Stationary Applications”, Section on HVAC System Design for Ventilation.

8-3.2 Ductwork.

Design ductwork in accordance with the paragraph in Chapter 2 entitled, “Ductwork”. Use FRP or PVC ductwork.

8-3.3 Fans and Motors.

Select fans in accordance with the paragraph in Chapter 2 entitled, "Fans". Use AMCA 201, Type B spark resistant construction and explosion proof motors. Fans must have non-sparking wheel. Locate the motor outside of the air stream.

8-3.4 Weather Stack Design and Location.

Avoid re-entry of exhaust air by discharging the exhaust high above the roof line or by assuring that no window, outdoor intakes, or other such openings are located near the exhaust discharge. See the paragraph in Chapter 2 entitled, "Exhaust Stacks" for additional considerations.

8-3.5 Air Cleaning Device.

Due to the quantities and types of contaminants generated by this process, there is no requirement for air pollution control equipment.

8-3.6 Replacement Air.

Design a replacement air system in accordance with the paragraph in Chapter 2 entitled, "Replacement Air". Design the replacement (makeup) air volumetric flow rate equal to 95 percent of the exhaust airflow rate to maintain the space under a negative pressure and prevent the migration of fumes and gases into adjacent areas. Provide means for air flow to ensure a negative pressure relationship. duct system. Makeup air can be transferred from a Class 1 or Class 2 area in the facility as defined in ANSI/ASHRAE 62.1, Ventilation for Acceptable Indoor Quality, or supplied directly. If supplied directly, it must be filtered.

8-3.7 System Controls.

Design system control in accordance with the paragraph in Chapter 2 entitled, "Controls" and the following criteria:

a. Interlock the charging circuit and the exhaust fan in the shop to ensure chargers will not operate without ventilation.

b. Provide indicator light showing that the exhaust system is functioning properly.

8-4 SAFETY AND HEALTH CONSIDERATIONS.

In accordance with 29 CFR 1926.403, *Battery Rooms and Battery Charging*, provide the following.

a. Face shields, aprons, and rubber gloves for workmen handling acids or batteries.

b. Combination emergency shower and eyewash stations within 25 ft (7.6 m) of the work area. Design in accordance with UFC 3-420-01, *Plumbing Systems,* Appendix D.

c. Facilities for flushing and neutralizing spilled electrolyte, and for fire protection.

d. Non-slip rubber insulating matting in front of all charging benches to protect personnel from electric shock and slipping hazards

e. Warning signs, such as: “Hydrogen, Flammable Gas, No Smoking, No Open Flames.”

This Page Intentionally Left Blank

CHAPTER 9 PAINT SPRAY BOOTHS

9-1 FUNCTION.

Paint spray booths provide surface finishing capabilities for a wide range of parts, equipment, and vehicles. Paint spray booth sizes range from bench type units for painting small parts, to large walk-in booths or rooms for painting vehicles, tractors or large equipment.

9-2 OPERATIONAL CONSIDERATIONS.

During paint spray operations, paint is atomized by a spray gun and then deposited on the object being painted. Depending on the application equipment and spray method used, transfer efficiencies vary greatly. Transfer efficiency is the amount of paint solids deposited on a surface divided by the total amount of paint sprayed, expressed as a percentage.

a. Use equipment with a high transfer efficiency, such as electrostatic or high volume low pressure (HVLP) spray guns, to reduce overspray. Overspray is the paint that is sprayed but not deposited on the surface being painted. This equipment not only saves in paint cost, but also reduces volatile organic compound (VOC) emissions and maintenance requirements.

b. Warm the paint before applying, whenever possible. This lowers the paint viscosity enabling spray painting at a lower pressure, thereby minimizing the amount of overspray generated. The lower viscosity also decreases the quantity of solvent used to thin the paint prior to spraying. This results in reduced solvent consumption and VOC emissions.

9-2.1 Painting Equipment Types.

Spray-painting equipment must conform to national, state, and local emission control requirements. One of these requirements is transfer efficiency. Five primary types of paint spraying equipment and their typical transfer efficiencies include:

1. Conventional air spray (25 percent transfer efficiency).
2. Airless spray (35 percent transfer efficiency).
3. Air-assisted airless spray (45 percent transfer efficiency).
4. Electrostatic spray (65 percent transfer efficiency).
5. High volume/low pressure (HVLP) spray (up to 75 percent transfer efficiency).

9-3 DESIGN CRITERIA.

Design or procure paint spray booths in accordance with the general technical requirements in Chapter 2 of this UFC and the specific requirements in this Chapter. Design paint spray booths in accordance with the requirements of NFPA 33, *Standards for Spray Application Using Flammable or Combustible Materials*.

9-3.1 Walk-in Spray Paint Booths.

The ventilation system for a walk-in booth is mainly to prevent fire and explosion. A well-designed ventilation system will also reduce paint overspray, help control workers' exposure, and protect the paint finish. Workers must use appropriate respiratory protection irrespective of the airflow rate.

a. Ensure the ventilation system for a walk-in booth meets the requirements of 29 CFR 1910.94 and 29 CFR 1910.107 and the appropriate guidelines in the painting operations section ACGIH IV manual.

b. Do not re-circulate exhaust air while painting.

9-3.1.1 Exhaust Configurations.

The two main ventilation system configurations are downdraft and crossdraft. In a downdraft booth, air enters through filters in the ceiling of the booth and leaves through filters that cover trenches under a metal grate floor. In a crossdraft booth, air enters through filters in the front of the booth and leaves through filters in the back of the booth. Both configurations are commercially available.

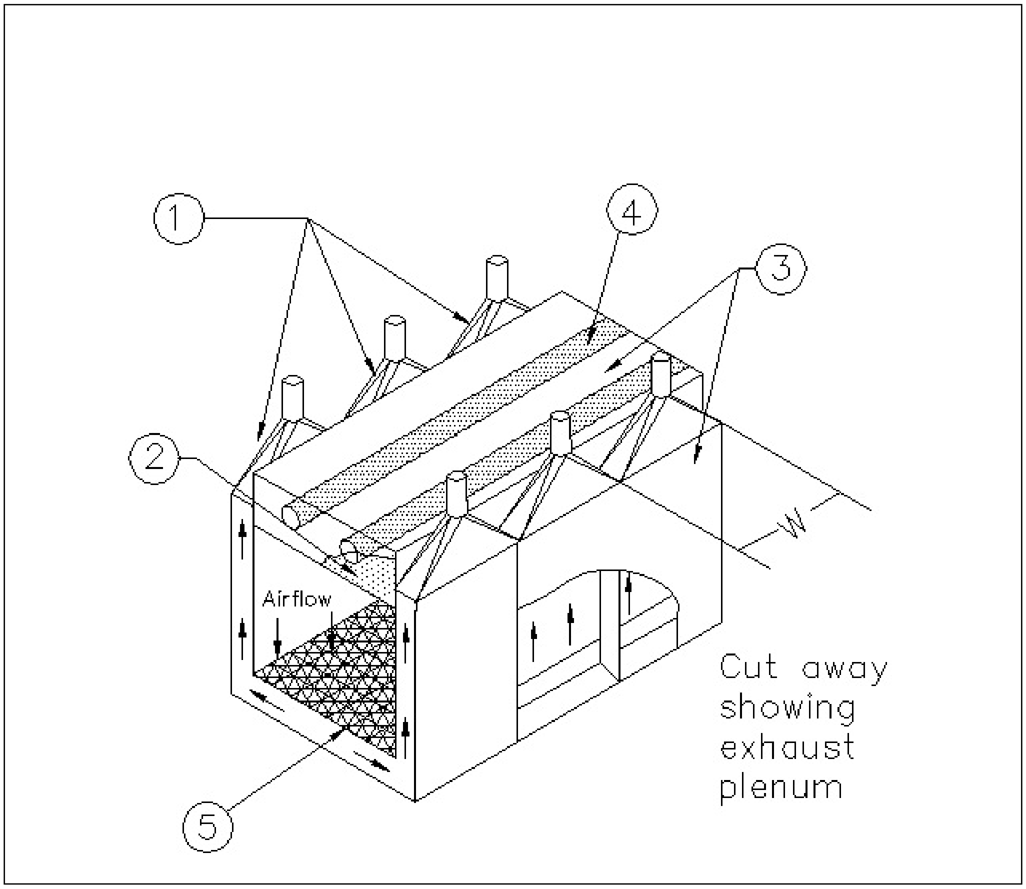
9-3.1.1.1 Downdraft Paint Spray Booths.

Downdraft booth configuration provides a cleaner paint job than the crossdraft booth configuration and controls exposures to workers better than crossdraft booth configuration. Figure 9-1 is an example of a downdraft configuration.

9-3.1.1.2 Crossdraft Paint Spray Booths.

The crossdraft paint spray booth usually requires less total volumetric airflow rate than the downdraft spray paint booth because the vertical cross-sectional area of the booth is often smaller than the booth footprint area. Figures 9-2 and 9-3 are examples of drive-through crossdraft paint spray booth configurations.

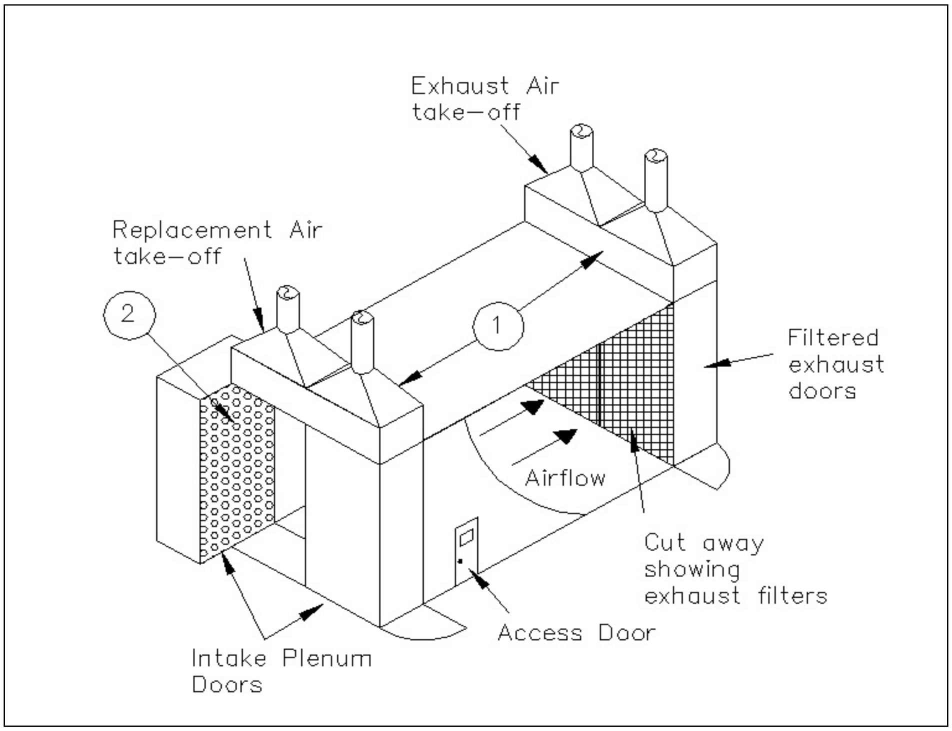
Figure 9-1. Walk-In Downdraft Paint Booth.



Drawing shown with doors removed

NOTES:
1. Size each plenum take-off for no more than 8 ft (2.44 m) of plenum width (W).
2. Perforated plate with 3/8-in (9.53-mm) holes. Size open area for an airflow velocity of 1,000 fpm (5.08 m/s) through holes.
3. Size exhaust plenum for a maximum plenum velocity of 1,000 fpm (5.08 m/s). Size replacement air plenum for a maximum plenum velocity of 500 fpm (2.54 m/s).
4. Use manufacturer's recommendations for sizing perforated ductwork.
5. Removable filters and floor grating.

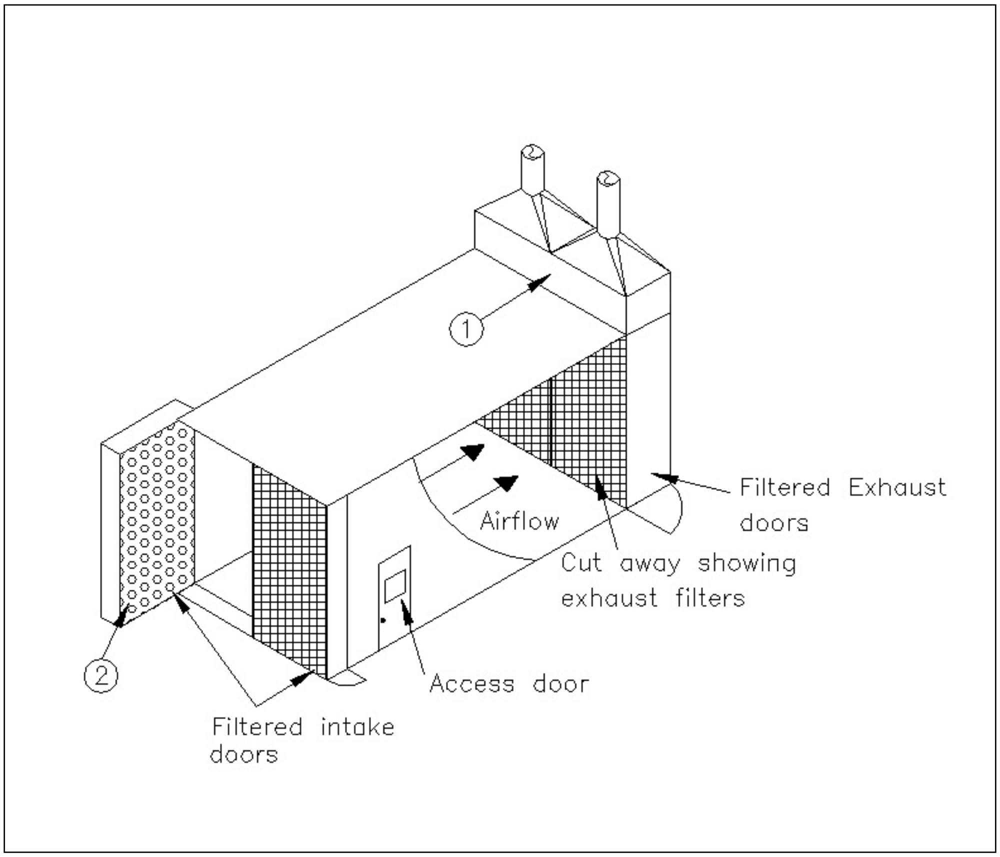
Figure 9-2. Drive-Through Cross Draft Paint Booth with Mechanical Replacement Air.



NOTES:

1. Size each plenum take-off for no more than 8 ft (2.44 m) of plenum width. Size the exhaust plenum for a maximum plenum velocity of 1,000 fpm (5.08 m/s). Size replacement air plenum for a maximum plenum velocity of 500 fpm (2.54 m/s).
2. Perforated plate with 3/8-in (9.53-mm) holes. Size open area for an airflow velocity of 2,000 fpm (10.16 m/s) through holes.

Figure 9-3 Drive-Through Crossdraft Paint Booth With No Mechanical Replacement Air



NOTES:

1. Size each plenum take-off for no more than 8 ft (2.44 m) of plenum width. Size the exhaust plenum for a maximum plenum velocity of 1,000 fpm (5.08 m/s). Size replacement air plenum for a maximum plenum velocity of 500 fpm (2.54 m/s).
2. Perforated plate with 3/8-in (9.53-mm) holes. Size open area for an airflow velocity of 2,000 fpm (10.16 m/s) through holes.

9-3.1.2 Paint Spray Booth Exhaust Filtration System.

There are two types of exhaust air filtration systems. The first type is a water wash system. A water curtain is created at the exhaust plenum by a pump providing continuous circulation of water. The second type is a dry filter system, where the exhaust air passes through filter media. Consider the following.

a. Do not design or purchase the water wash paint spray booths. The water wash system requires more energy to operate than the dry filter system. The wastewater must be treated and the hazardous constituents removed (often at great cost to the generating facility) before it may be discharged to a municipal treatment plant.

b. Neither water wash nor dry filter filtration systems can reduce the concentration of volatile organic compounds in the exhaust air stream. Consult the environmental department for controlling volatile organic compounds.

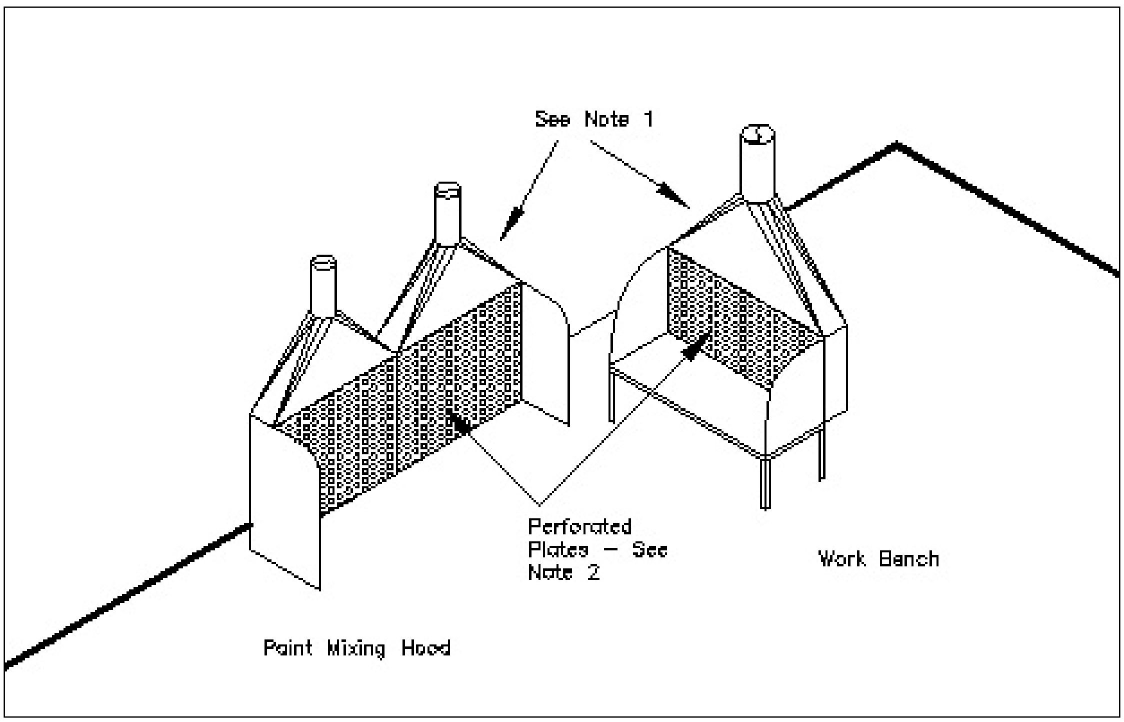
9-3.2 Storage and Mixing Room.

Refer to the ACGIH IV Manual, Paint Mix Storage Room, VS-75-30 for the design of ventilation system.

9-3.3 Small Spray Booths and Paint Mix Hoods.

Refer to the ACGIH IV Design Manual for the design of ventilation system. Figure 9-4 is an example of a workbench and a floor hood designed for paint mixing and small spray applications. ACGIH P.13-120 figure VS-75-02 states that Q=125cfm/ft2 for face area up to 4ft2 and Q=100cfm/ft2 for face area over 4 ft2.

Figure 9-4 Paint Mixing Hood and Work Bench



NOTES:

1. Size each plenum take-off for no more than 8 ft (2.44 m) of plenum width. Size each plenum for a maximum plenum velocity of 1,000 fpm (5.08 m/s).
2. Perforated plate with 3/8-in (9.53 mm) holes. Size open area for an airflow velocity of 2,000 fpm (10.16 m/s) through holes.

9-4 FANS AND MOTORS.

Use explosion proof motor and electrical fixtures for exhaust fan. Do not place electric motors, which drive exhaust fans, inside booths or ducts. See Section 2-4.2 entitled, “Fans” for more detailed information about fan selection.

9-5 REPLACEMENT AIR.

There is no control over the room temperature or room static pressure for non-mechanical replacement air systems. Dust from outside often enters the paint spray booths through cracks and damages the paint finish. If painting operations require neutral air pressure inside the booth, provide a mechanical replacement air system to maintain a neutral air pressure inside the booth and prevent dust from entering the paint spray area. The neutral air pressure will also prevent paint overspray and vapors from escaping the booth and migrating into adjacent work areas.

9-5.1 Air Distribution.

Distribution of replacement air within the spray booth is as significant as the average air velocity through the booth. Distribute the replacement air evenly over the entire cross section of the booth to prevent turbulence or undesirable air circulation. The preferred means of distributing the replacement air is through perforated plate as shown in Figures 9-1, 9-2, and 9-3. See the paragraph in Chapter 2 entitled, “Replacement Air” for additional replacement air design criteria.

9-5.2 Heating and Air Conditioning.

See the paragraph in Chapter 2 entitled, “Replacement Air”. Most new paint spray booth ventilation systems have a painting mode and a curing mode. Do not re-circulate air during the painting mode. About 10 percent of the booth airflow is from outside the booth and 90 percent of the exhaust air is recycled during curing. Review the paint drying requirements before specifying temperature and humidity ranges. Refer to ANSI AIHA/ASSE Z9.7 for exhaust air re-circulation requirements.

9-6 SYSTEM CONTROLS.

Design system controls in accordance with the paragraph in Chapter 2 entitled, “Controls”.

9-7 SAFETY AND HEALTH CONSIDERATIONS.

See the paragraph in Chapter 2 entitled, “Safety and Health Considerations”. Provide combination emergency shower and eyewash stations in the workspace. Design in accordance with UFC 3-420-01, *Plumbing Systems,* Appendix D.

APPENDIX B GLOSSARY

B-1 TERMS

Air cleaner	**A device designed for the purpose of removing atmospheric airborne impurities such as dusts, gases, vapors, fumes, and smoke. (Air cleaners include air washers, air filters, electrostatic precipitators and charcoal filters.)**
Air filter	**An air cleaning device to remove light particulate loadings from normal atmospheric air before introduction into the building. Usual range: loadings up to 3 grains per thousand ft^3 (0.0069 g/m^3). Note: Atmospheric air in heavy industrial areas and in-plant air in many collectors are then indicated for proper air cleaning.**
Air, standard	**Dry air at 70 degrees F, 21.11 degrees C, and 29.92 in. Hg barometer. This is substantially equivalent to 0.075 pounds per cubic feet (lb/ft^3). Specific heat of dry air = 0.24 Btu/lb-F (1.004 kJ/(kg.K).**
Aspect ratio (AR)	**Ratio of the width to the length; AR = W/L.**
Blast gate	**Sliding damper.**
Capture velocity	**Air velocity at any point in front of the hood or at the hood opening necessary to overcome opposing air currents and to capture the contaminated air at that point by causing it to flow into the hood.**
Dust	**Small solid particles created by the breaking up of larger particles by processes crushing, grinding, drilling, explosions, etc. Dust particles already in existence in a mixture of materials may escape into the air through such operations as shoveling, conveying, screening, and sweeping.**
Dust collector	**Air cleaning device to remove heavy particulate loadings from exhaust systems before discharge to outdoors. Usual range: loadings 0.003 grains per cubic foot and higher.**
Fan class	**This term applies to the fan's performance abilities. The required fan class is determined according to the operating point of the ventilation system. AMCA 99-2408 provides a set of five minimum performance limit**

	standards (Class I through V) which manufactures use to apply the correct class to their fans.
FRP	Fiberglass reinforced plastic used in construction of such items as boats and airplanes. It is also used for ductwork in corrosive environments.
Fumes	Small, solid particles formed by the condensation of vapors of solid materials.
Gases	Formless fluids which tend to occupy an entire space uniformly at ordinary temperatures and pressures.
Gravity, specific	Ratio of the mass of a unit volume of a substance to the mass of the same volume of a standard substance at a standard temperature. Water at 39.2 degrees F (4 degrees C) is the standard substance usually referred to for gases, dry air, at the same temperature and pressure as the gas is often taken as the standard substance.
Hood	A shaped inlet designed to capture contaminated air and conduct it into the exhaust duct system.
Humidity, relative	Ratio of the actual partial pressure of the water vapor in a space to the saturation pressure of pure water at the same temperature.
Lower explosive limit (LEL)	Lower limit of flammability or explosiveness of a gas or vapor at ordinary ambient temperatures expressed in percent of the gas or vapor in air by volume. This limit is assumed constant for temperatures up to 250 degrees F (121 degrees C). Above these temperatures, it must be decreased by a factor of 0.7 since explosiveness increases with higher temperatures.
Manometer	An instrument for measuring pressure; essentially a U-tube partially filled with a liquid, usually water, mercury or a light oil, so constructed that the amount of displacement of the liquid indicates the pressure being exerted in the instrument.
Micron	A unit of length; approximately 1/25,000 of an inch (the thousandth part of 1 millimeter or the millionth of a meter).
Mists	Small droplets of materials that are ordinarily liquid at normal temperature and pressure.

Plenum	**A pressure equalizing chamber.**
Pressure, static	**Potential pressure exerted in all directions by a fluid at rest. For a fluid in motion, it is measured in a direction normal to the direction of flow. Usually expressed in inches water gauge when dealing with air. (The tendency to either burst or collapse the pipe.)**
Pressure, total	**The algebraic sum of the velocity pressure and the static pressure (with due regard to sign).**
Replacement air	**Ventilation term used to indicate the volume of controlled outdoor air supplied to a building to replace air being exhausted. It may require heating, cooling, or humidity control.**
Slot velocity	**Linear flow rate of contaminated air through a slot. Usually measured in meters per second (m/s) [feet per minute (fpm)].**
Smoke	**An air suspension (aerosol) of particles, usually not solid, often originating in a solid nucleus, formed from combustion or sublimation.**
Threshold limit values	**Values, established by ACGIH, for airborne toxic materials (TLV) as guidelines in the control of health hazards and represent time-weighted concentrations to which nearly all workers may be exposed 8 hours per day over extended periods of time without adverse effects.**
Transport (conveying))	**Minimum air velocity required to move the particulates in the air stream, measured in fpm (m/s).**
Vapor	**The gaseous form of substances which are normally in the solid or liquid state and which can be changed to these states either by increasing the pressure or decreasing the temperature.**
Work piece	**The item being created or repaired using equipment or machinery that, while operating, generates a fume, gas, vapor, or particulate hazardous to the health of the operator. Landing gear, torpedo parts, cabinetry, lagged piping are examples of work pieces. Parts washers, wood saws, and degrease units are example equipment.**

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	Date	Location

This UFC supersedes UFC 3-420-01, dated 25 October 2004, with Change 10, dated 26 October 2015.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-420-01, *PLUMBING SYSTEMS*

Superseding: UFC 3-410-01, *PLUMBING SYSTEMS*, dated 25 October 2004, with Change 10, dated 26 October 2015.

Description: This UFC is the core document for plumbing design. It is intended as a reference for all plumbing work. It is organized to provide the top-level minimum mandatory plumbing design and analysis requirements and refers to other criteria as appropriate.

Reasons for Document:

- This UFC provides a central point reference for all plumbing design criteria.
- Establishes minimum design analysis and drawing requirements in support of design activities
- Helps direct designers to the appropriate plumbing discipline criteria document.

Impact:

- There are negligible cost impacts. Creation of a single-source reference for mechanical design discipline helps clarify requirements for the design of DoD facilities.

Unification Issues

- There are no unification issues.

TABLE OF CONTENTS

FIGURES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides guidance in the design of plumbing systems, together with the criteria for selecting plumbing materials, fixtures, and equipment and is applicable to all elements of the Department of Defense (DoD) charged with planning military construction. This UFC provides minimum standards to safeguard life or limb, health, property, and public welfare by regulating and controlling the design, construction, installation, quality of materials, location, operation, and use of plumbing systems. It is not the intent of this manual to duplicate information contained in the standards cited herein, but to reference them as appropriate. See Chapter 4.

1-2 APPLICABILITY.

This UFC applies to all service elements and contractors involved in the design and construction of plumbing systems for use in facilities of all branches of service. A plumbing system consists of the water supply distribution system; fixtures, and fixture traps; soil, waste, and vent piping; storm water drainage; acid and industrial waste disposal systems; special gases (medical and oxygen) systems; and water heaters. The plumbing system extends from connections within a structure to a point 5 feet (1.5 m) outside the structure. Additions, alterations, renovations, or repairs to a plumbing system must conform to requirements for a new plumbing system without requiring the existing plumbing system to comply with all the requirements of this manual. Do not execute additions, alterations, or repairs that cause an existing plumbing system to become unsafe, hazardous, or overloaded.

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

Service water heating systems must meet American Society of Heating, Refrigerating, and Air Conditioning Engineers (ASHRAE) 90.1, *Energy Standard for Buildings Except Low-Rise Residential Buildings*. Refer to UFC 1-200-02, *High Performance and Sustainable Building Requirements* for publication year of ASHRAE.

1-3.1 Environmental Severity and Humid Locations.

In corrosive and humid environments, provide design detailing, and use materials, systems, components, and coatings that are durable and minimize the need for preventative and corrective maintenance over the expected service life of the component or system. Follow the guidance of UFC 1-200-01, Chapter 4 to address corrosion control and apply the requirements for the appropriate Environmental Severity

Classification (ESC) for the specific installation as identified in UFC 1-200-01 Appendix A.

1-4 SAFETY.

The Designer of Record must follow the concepts from the most current ANSI/ASSE Z590.3, *Prevention Through Design: Guidelines for Addressing Occupational Hazards and Risks in Design and Redesign Processes*. Through the application of Prevention through Design (PtD) concepts, decisions pertaining to occupational hazards and risks can be incorporated into the process of design and redesign of work premises, tools, equipment, machinery, substances, and work processes, including their construction, manufacture, use, maintenance, and ultimate disposal or reuse. This standard also provides guidance for a life-cycle assessment and design model that balances environmental and occupational safety and health goals over the life span of a facility, process, or product.

All DoD facilities must comply with DoDI 6055.01 and applicable Occupational Safety and Health Administration (OSHA) safety and health standards.

1-5 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, *Cybersecurity of Facility-Related Control Systems* and as required by individual Service Implementation Policy.

1-6 NON-GOVERNMENT STANDARD MODIFICATION.

1-6.1 Primary voluntary consensus standard reference.

The DoD uses the International Code Council™ International Plumbing Code® as the primary voluntary consensus standard for DoD facility plumbing systems.

1-6.1.1 International Plumbing Code® copyright.

1-6.1.2 International Plumbing Code® modifications.

Chapter 4 modifies the IPC and is organized by the chapter of the IPC that each section modifies. The modifications are one of four actions, according to the following legend:

- [Addition] – Add new chapter or section, including new chapter or section numbers.
- [Deletion] – Delete chapter, section, paragraph, or sentence.
- [Replacement] – Delete chapter, section, paragraph, or sentence noted and replace it with the narrative shown.
- [Supplement] – Add narrative shown as a supplement to the narrative shown in the referenced chapter, section, or paragraph.

The format of Chapter 4, including English and metric unit references, does not follow the UFC format, but instead follows the format established in the IPC, to the extent possible.

When and if these supplemental technical criteria are adopted into the IPC, they will be removed from this document. When interpreting the IPC, the advisory provisions must be considered mandatory; interpret the word “should” as “shall”.

1-6.2 Conflicts in criteria.

Where, in any specific case, different sections of this guidance or referenced standards specify different materials, methods of construction, or other requirements, the most restrictive requirement will govern. In leased facilities where the local jurisdiction controlling the lessor has adopted a different plumbing code, the more restrictive requirement will govern.

1-7 GLOSSARY.

Appendix A contains acronyms, abbreviations, and terms.

1-8 REFERENCES.

Appendix B contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This page intentionally left blank

CHAPTER 2 TECHNICAL CRITERIA

Not used.

This page intentionally left blank

CHAPTER 3 GENERAL DESIGN REQUIREMENTS

3-1 GENERAL POLICY.

3-1.1 Energy Efficiency and Water Conservation.

Plumbing system energy usage and equipment efficiencies must comply with UFC 1-200-02. Employ strategies that in aggregate use a minimum of 20 percent less potable water than the indoor water use baseline calculated for the building after meeting the Energy Policy Act of 1992 and the IPC fixture performance requirements. Use ultra-water-efficient plumbing fixtures including low flow faucets, showerheads, and ultra-low consumption (e.g., 1/8 gallon (0.5 liters) per flush) flushing urinals or (if approved) waterless urinals, in accordance with UFC 1-200-02. Mission requirements and operating points to prevent Legionella will take priority over meeting energy and conservation targets.

3-1.2 Reliability.

Provide dual-fuel capability and/or redundant system components to Mission Critical facilities.

3-1.3 Piping Arrangement.

Conceal piping in permanent-type structures. In limited life structures, piping may be installed exposed, except when specific project criteria justify concealment or where concealment does not increase the cost of the project. Exposed piping attached to or near fixtures or equipment, or subject to high heat or frequent washing, must be copper, brass, or chromium plate. Prime other exposed piping with paint suitable for metal surfaces and finish-paint with color to match background. Arrange piping runs parallel or perpendicular to primary walls and to minimize interference with personnel and equipment. For critical piping services such as medical gas systems, route piping so that it is not on exterior walls or walls shared with mailrooms in accordance with UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*. Provide efficient piping designs. Efficient designs consist of, but are not limited to, minimized changes of direction of horizontal sanitary piping and reduced number of vents by use of venting methods that serve multiple fixtures.

3-1.4 Siting.

Whenever possible, site and design buildings, sewers, and water mains to avoid the need for sewage lifts or water booster pumps.

This Page Intentionally Left Blank

CHAPTER 4 SUPPLEMENTAL IPC TECHNICAL CRITERIA

Note: Chapter, section and paragraph numbers reference IPC-2018.

4-1 GENERAL SUBSTITUTIONS.

- All references to “approved” materials must be materials allowed by the applicable Unified Facilities Guide Specification (UFGS).
- All references in the IPC to the IBC must be considered to be references to UFC 1-200-01.
- All references in the IPC to the International Fuel Gas Code must be considered to be references to NFPA 54, *National Fuel Gas Code* and NFPA 58, *Liquefied Petroleum Gas Code*.
- All references in the IPC to the International Mechanical Code must be considered to be references to UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*.
- All references in the IPC to the International Energy Conservation Code must be considered to be references to UFC 1-200-02.
- Where the IPC references the International Fire Code (IFC), the IFC must be replaced with NFPA 1, *Fire Code* except where superseded by UFC 3-600-01, *Fire Protection Engineering for Facilities*.
- All references in the IPC to NFPA 70, *National Electric Code* must be considered to be references to UFC 3-501-01, *Electrical Engineering*.

4-2 CHAPTER 1 - SCOPE AND ADMINISTRATION. [DELETION]

Delete chapter in its entirety. Scope administrative requirements are covered by the applicable Federal Acquisition Regulations (FAR) and by the authority granted to the Contracting Officer in administering the contract and this UFC.

4-3 CHAPTER 2 – DEFINITIONS.

4-3.1 Section 202 - GENERAL DEFINITIONS.

Code [Replacement]

Delete the code definition and replace it with the following:

The IPC, revision year approved by UFC 1-200-01 and subsequent amendments thereto, as modified by this UFC.

Code Official [Replacement]

Delete the code official definition and replace it with the following:

Refer to UFC 1-200-01, paragraph entitled Implementation, Administration, and Enforcement.

Owner or Owner's Representative [Addition]

Add the following definition:

OWNER OR OWNER'S REPRESENTATIVE. For Government-owned facilities, the Contracting Officer assigned by the Government to administer the construction contract. For leased facilities, the leaser of the facility.

Permit Holder [Addition]

Add the following definition:

PERMIT HOLDER. The contractor accomplishing the project.

4-4 CHAPTER 3 - GENERAL REGULATIONS.

4-4.1 Section 301 – GENERAL.

301.6 Prohibited Locations. [Supplement]

Insert the following before the first sentence:

No plumbing system components may be installed within any Air Handling Unit (AHU), ductwork, or room used as a plenum conveying supply air, return air, outside air, or mixed air. This will not prohibit connection of AHU components, such as humidifiers, to the water supply system, nor prohibit connection of trapped condensate pans and humidifier drains indirectly to the drainage system. This will also not prohibit plumbing system components in ceiling spaces used as return air plenums, nor prohibit drains in raised floor supply plenums.

301.8 Protection of Building Materials. [Addition]

Where the seasonal design temperature of the cold water entering a building is below the seasonal design dew point of the indoor ambient air, and where condensate drip will cause damage or create a hazard, insulate plumbing piping with a vapor barrier type of insulation to prevent condensation. All chilled water piping from a central drinking water cooling system should be insulated with vapor barrier type insulation to prevent condensation.

301.9 Protection of Computers, Telephone Switches, Terminal Equipment, Record Storage, and other Electronic Equipment from Water Damage. [Addition]

Neither water nor drainage piping shall be located over electrical wiring or equipment unless adequate protection against water (including condensation) damage has been provided. Insulation alone is not adequate protection against condensation. Locate these areas to minimize exposure to water and other listed hazards from adjoining areas and activities.

301.9.1 Prohibited piping. Water, sanitary, indirect waste, special waste, gas, fuel oil, condensate drain, roof drains, conductors, and other utility piping not serving these areas within building are prohibited.

301.9.2 Restricted piping. Utilities containing water or other fluids, which serve these areas within the building, must not pass directly over electronic equipment, telephone switches, or stored records, whether the utilities are installed over or below the finished ceiling.

301.9.3 Waterproof floor above. The floor above these areas should be waterproofed to prevent passage of accidental spillage. As an alternative, allow no prohibited pipe in the rooms above the electronic equipment and record storage areas.

4-4.2 Section 303 – MATERIALS.

303.3 Plastic pipe, fittings and components. [Supplement]

Add the following after the last sentence:

Installation procedure for plastic piping materials shall be in accordance with the Plastic Pipe Institute (PPI) *Handbook of Polyethylene Pipe*. Design parameters such as thermal movement, chemical resistance, flow characteristics, and pressure ratings are covered in PPI publications. The designer should be aware that some Schedule 40 plastic pipes do not have the strength of a Schedule 40 steel pipe; therefore, the desired working temperature and pressure ratings for any plastic piping specified must be indicated either in the specifications or on the drawings.

4-4.3 Section 305 – PROTECTION OF PIPES AND PLUMBING SYSTEM COMPONENTS.

305.4 Freezing. [Supplement]

Add the following after the last sentence:

Although insulating water pipes, tanks, and cooling towers may not prevent water from freezing, these devices are to be insulated and, if noted on the drawings, heat traced for protection against damage. The proper thickness or conductivity factor for this insulation and the watts/linear foot (watts/linear meter) for heat tracing are to be determined by the design engineer. Do not provide water or waste piping in exterior walls or attic spaces where there is danger of freezing where practicable. Provide proper design to prevent freezing when not practicable.

Section 308 – PIPING SUPPORT.

308.5 Interval Support. [Replacement]

Replace first sentence with the following:

Above ground piping and below ground piping shall be supported from structure in accordance with Table 308.5.

4-4.4 Section 313 – EQUIPMENT EFFICIENCIES.

313.2 Energy conservation. [Addition]

Design systems containing electric water heaters, gas water heaters, solar water heaters, air-to-water heat pump water heaters, and water-to-water heat pump water heaters in accordance with the ASHRAE Handbook Series (appropriate Chapters), ASHRAE Standard 90.1 and Department of Energy – Federal Energy Management Program (DOE-FEMP), *Buying Energy Efficient Products* (appropriate recommendations).

4-4.5 Section 316 – ALTERNATIVE ENGINEERED DESIGN.

316 Alternative engineered design. [Deletion]

Delete section its entirety.

4-5 CHAPTER 4 - FIXTURES, FAUCETS AND FIXTURE FITTINGS.

4-5.1 Section 401 – GENERAL.

401.2 Prohibited fixtures and connections. [Supplement]

Add the following after the last sentence:

Fixtures employing continuous flow devices and fixtures that are subject to backflow are prohibited. Continuous flow devices cannot be used for water conservation reasons.

401.3 Water conservation. [Supplement]

Add the following after the last sentence:

Water conservation fixtures conforming to the IPC shall be used except where the sewer system will not adequately dispose of the waste material on the reduced amount of water. DOE-FEMP water conservation recommendations are, for certain fixtures, more restrictive than Section 604.4. Designers have the option to design to DOE-FEMP water conservation recommendations for areas of the country that restrict water usage. The owner or owner's representative should be consulted before specifying water conservation fixtures that are more restrictive than Section 604.4.

4-5.2 Section 402 – FIXTURE MATERIAL.

402.1 Quality of fixtures. [Supplement]

Add the following after the last sentence:

Fixture materials are to be selected from those specified in UFGS 22 00 00, *Plumbing, General Purpose*. Porcelain-enameled cast-iron lavatories shall be provided in enlisted personnel barracks or dormitories or other gang toilet in similar facilities.

4-5.3 Section 403 – MINIMUM PLUMBING FACILITIES.

403.1 Minimum number of fixtures. [Replacement]

Delete the last sentence and replace with the following:

Use the actual number of occupants for whom each occupied space, floor or building is designed to calculate the design occupant load. The designer must document the calculations for the design occupant load. These calculations must be reviewed and approved for the project to ensure that the number of plumbing fixtures is appropriate.

Table 403.1 Minimum Number of Required Plumbing Fixtures. [Deletion]

Delete the last sentence:

“The number of occupants shall be determined by the *International Building Code*.”

Table 403.1 Minimum Number of Required Plumbing Fixtures. [Supplement]

For the business classification, add the following to the description:

training rooms, support areas (such as for the administrative and supervisory offices for industrial shops and warehouses), and locker rooms in coliseums, arenas, skating rinks, pools, and tennis courts for indoor sporting events and similar activities

4-5.4 Section 404 – ACCESSIBLE PLUMBING FACILITIES.

404.1 Where required. [Replacement]

Replace the first sentence with the following:

Accessible plumbing facilities and fixtures must be provided in accordance with the Architectural Barriers Act (ABA), *Accessibility Standards for Department of Defense Facilities* and the IBC, whichever is more stringent.

4-5.5 Section 405 – INSTALLATION OF FIXTURES.

405.3 Setting. [Supplement]

Add the following after the last sentence:

Lavatories and urinals in enlisted men's barracks or dormitories and in men's gang-toilet facilities (three or more water closets) are subject to heavy damage. Verify wall bolts are tight and properly installed.

405.3.1 Water closets, urinals, lavatories and bidets. [Supplement]

Add the following after the last sentence:

Lavatories provided in enlisted personnel barracks or dormitories or other gang toilet facilities shall be installed to prevent uplifting.

4-5.6 Section 410 – DRINKING FOUNTAINS.

410.6 Central drinking water systems. [Addition]

Central drinking water systems should be evaluated as an alternative to unitary water coolers in facilities where 15 or more drinking stations are required. Evaluation should include potential heat recovery from central condenser, addition of heat to building envelope by unitary condensers, differences in anticipated energy usage, and differences in first cost.

4-5.7 Section 411 – EMERGENCY SHOWERS AND EYEWASH STATIONS.

411.4 Design guidance for emergency shower and eyewash stations. [Addition]

Refer to Appendix C of UFC 3-420-01, *Design: Plumbing Systems* for additional requirements associated with emergency shower and eyewash stations.

4-5.8 Section 413 – FLOOR AND TRENCH DRAINS.

413.5 Required locations and construction. [Addition]

Floor drains are not required in service sink rooms and transformer rooms.

Provide floor drains to serve, but not be limited to, the following areas and equipment:

1. Gang toilets, which are those having three or more water closets; and gang shower drying rooms, which are those serving two or more showers.

2. Subsistence buildings, as follows:

   (a) Dishwashing, scullery or pot washing, and food-cart washing areas.
   (b) Vegetable peelers and vegetable preparation areas.
   (c) Steam table and coffee urn areas.
   (d) Soda fountain area.
   (e) Adjacent areas to ice chests, ice-making machines, and walk-in or reach-in, freezers and refrigerators.

(f) Steam cookers and steam-jacketed kettles.

3. Cold-storage buildings, as follows:

   (a) Fat-rendering, processing, salvage, and receiving rooms.
   (b) Receiving and issuing vestibules.
   (c) Adjacent areas to meat coolers and milk, butter, and egg rooms.

4. Mechanical rooms with steam, condensate, chilled ,or hot water systems.

5. Laundry rooms.

When automatic priming is through a device connected to the water system, ensure that device is equipped with a vacuum breaker.

412.6 Floor drains for emergency shower and eyewash stations. [Addition]

Refer to Appendix C of UFC 3-420-01 for additional requirements for use of floor drains associated with emergency shower and eyewash stations.

4-5.9 Section 416 – FOOD WASTE DISPOSER.

416.5 Food waste disposer design. [Addition]

Food waste disposers are authorized in DoD permanent quarters, hospitals, and dining facilities when the sewage treatment plant can handle the additional load. Design of new sewage treatment plants and additions to existing plants shall be based on the increase in load that will result from food waste disposers installed in hospital, dining facilities, and the ultimate projected number of family quarters to be constructed. Food waste disposers installed in hospital kitchens and dining facilities shall be sized as shown in Table 413.5. Food waste disposers will not discharge into a grease interceptor.

Table 413.5
SIZE OF FOOD WASTE DISPOSERS

PERSONS SERVED	POT WASHER HORSEPOWER	DISHWASHER HORSEPOWER
Up to 200	2	3
200 to 500	3	5
501 to 1,000	5	7-1/2
Over 1,000	7-1/2	10

4-5.10 Section 419 LAVATORIES.

419.6 Tempered water for private hand-washing facilities. [Addition]

Tempered water shall be delivered from lavatories located in private toilet facilities. *Tempered water* shall be delivered through an *approved* water-temperature limiting device that conforms to ASSE 1070/ASME A112.1070/CSA B125.70, *Water Temperature Limiting Devices* or CSA B125.3, *Plumbing Fittings*.

4-5.11 Section 422 - SINKS.

422.4 Tempered water for kitchen sinks. [Addition]

Tempered water shall be delivered from kitchen sinks located in break rooms. *Tempered water* shall be delivered through an *approved* water-temperature limiting device that conforms to ASSE 1070/ASME A112.1070/CSA B125.70 or CSA B125.3.

4-5.12 Section 424 – URINALS.

424.1 Approval. [Supplement]

Add the following after the last sentence:

Waterless/waterfree urinals must conform to American Society of Mechanical Engineers (ASME) A112.19.2, *Vitreous China Plumbing Fixtures and Hydraulic Requirements for Water Closets and Urinals*, but not conform to the hydraulic performance requirements.

Approval for the use of waterless/waterfree urinals is the responsibility of the Facilities Engineering Command (FEC) Technical Discipline Coordinator (TDC), Base Civil Engineer (BCE) or the Department of Public Works and Utilities (DPW) to ensure life cycle costs and operation and maintenance (O&M) requirements are acceptable.

4-6 CHAPTER 5 - WATER HEATERS.

4-6.1 Section 501 – GENERAL.

501.2 Water heater as space heater. [Replacement]

Replace the first sentence with the following:

Where a combination potable water heating and space heating system requires water for space heating at temperatures of 140°F (60°C) or higher, a master thermostatic mixing valve complying with ASSE 1017, *Temperature Activated Mixing Valves for Hot Water Distribution Systems,* must be provided to limit the water to the potable hot water distribution system. The valve must be set to deliver 131°F (55°C) water to the fixtures except where higher temperatures are required by specialized equipment as indicated in ASHRAE Handbook, *Applications*. If the master thermostatic mixing valve is near the point of use at the fixtures, then lower potable domestic hot water distribution temperatures, less than 131°F (54.4°C), may be acceptable.

501.9 Multiple water heaters. [Addition]

Provide hospitals, laundry buildings, subsistence buildings, bachelor officers' quarters with mess, and enlisted men's barracks with mess with multiple water heaters and storage tanks. Provide other facilities with a single water heater and storage tank. Multiple units, however, may be justified by circumstances such as:

1. facility configuration
2. space limitations
3. limited access to tank room
4. hot water requirements necessitating an unusually high capacity heating and storage unit.

When two units are provided for hospitals, laundry buildings, subsistence buildings, bachelor officers' quarters with mess, and enlisted men's barracks with mess, each will have a capacity equal to two thirds of the calculated load. When more than two units are provided, their combined capacity shall be equal to the calculated load.

501.10 Solar water heating. [Addition]

At least 30 percent of domestic hot water demand shall be provided by the use of solar water heating, if life cycle cost effective. Solar water heating systems must be in accordance with UFC 3-440-01, *Facility Scale Renewable Energy Systems*. Conventional back-up heating equipment shall be provided for periods when high demand or an extended period of cloudy days exceeds the capacity of the solar energy system."

4-6.2 Section 502 – INSTALLATION.

502.1 General. [Supplement]

Add the following after the last sentence:

The local Public Works/Base Civil Engineer should be contacted to determine if scale will be an issue based on the chemical analysis of the potable water or historical data. If so, provide a commercial scale prevention system.

4-6.3 Section 504 – SAFETY DEVICES.

504.2 Vacuum relief valve. [Supplement]

Add the following after the last sentence:

Provide a vacuum relief valve on each copper-lined storage tank to prevent the creation, within the tank, of a vacuum which could cause loosening of the lining.

4-6.4 Section 505 – INSULATION.

505.1 Unfired vessel insulation. [Supplement]

Add the following after the last sentence:

The insulation requirements stated in this section are minimum design requirements. The quality of insulation should be upgraded if the designer can show an improvement in the system performance or that insulation improvements are cost effective.

4-6.5 Section 507 – SIZING HOT WATER SYSTEMS.

507.1 Sizing Calculations. [Addition]

Design in accordance with ASHRAE Handbook, *HVAC Applications*, "Service Water Heating" chapter; and in accordance with ASHRAE Standard 90.1. In addition to criteria provided in the ASHRAE Handbook, consideration should be given to differences in costs of building area required to support systems when calculating life cycle costs. For low-rise residential buildings, design in accordance with the ICC International Residential Code. Size domestic hot water system and set service water heater (SWH) storage temperature set point for not less than 140°F (60°C) to limit the potential for growth of *Legionella pneumophila*. Provide temperature control (master mixing valve) to lower temperature to 131°F (55°C) immediately downstream of the SWH storage tank in accordance with ASSE 1017. Where a recirculation pump is required the hot water temperature shall be at least 122°F (50°C) throughout the recirculation piping. Deliver a minimum of 122°F (50°C) water to the fixtures and drop the temperature at the fixture through a water-temperature limiting device in accordance with Section 424, except where higher temperatures are required by specialized equipment as indicated in ASHRAE Handbook, *Applications.*

Take steps to both limit the risk of Legionella bacteria growth and scalding in the domestic water system. Therefore, if the master mixing valve is near the point of use at the fixtures, then lower domestic hot water distribution temperatures, less than 131°F (55°C), and lower recirculation loop temperatures, less than 122°F (50°C), may be acceptable. On existing systems take necessary steps to avoid scalding occupants when distributing at 131°F (55°C). For example, existing lavatories may have to add ASSE 1070 temperature reducing devices at all applicable existing fixtures and shower valve limit stops on all existing showers may have to be adjusted.

507.1.1 Sizing central service water heater systems. [Addition]

Use ASHRAE Handbook, HVAC Applications, “Service Water Heating” chapter, “Hot-Water Demand per Fixture for Various Types of Buildings” table to size central SWH systems, except revise the numbers in row “9. Showers” by multiplying by the correction factor (CF) calculated in Section 507.1.3. The revision reflects Public Law 102-486 maximum fixture flow of 2.5 gpm (9.5 L/s), ASHRAE recommended service water storage temperature minimum of 140°F (60°C), personnel safety maximum fixture delivery temperature of 110°F (43°C), and the appropriate supply design cold water temperature, which varies according to location and season. Use the Hotel column to size central SWH systems for Navy bachelor housing and lodges, due to occupant’s schedules resembling those of hotel and motel occupants – the rooms are inhabited mostly between 5 p.m. and 7 a.m. Use Appendix D of UFC 3-420-01 for sizing the domestic water heaters in Army barracks.

507.1.2 Hot water mixing equation. [Addition]

Conversion Factors: 1 gpm = 3.8 L/s; °F = 9/5 °C + 32

Let:

Q_f = Fixture flow in gpm = 2.5 gpm per Public Law 102-486
Q_s = Flow from SWH storage tank in gpm
Q_c = Flow from cold water supply in gpm
T_f = Temperature at fixture in °F = 110°F for personnel safety
T_s = Temperature at SWH storage tank in °F, 140°F minimum for Legionella
T_c = Temperature at cold water supply in °F, varies due to location and season

Mixing Equation:

$$(Q_f \times T_f) = (Q_s \times T_s) + (Q_c \times T_c)$$

Substituting $Q_c = Q_f - Q_s$ gives the following:

$$\begin{aligned}
(Q_f \times T_f) &= (Q_s \times T_s) + \left((Q_f - Q_s)T_c\right) \\
(Q_f \times T_f) &= (Q_s \times T_s) + (Q_f - T_c) - (Q_s \times T_c) \\
(Q_f \times T_f) - (Q_f \times T_c) &= (Q_s \times T_s) - (Q_s \times T_c) \\
Q_f \times (T_f - T_c) &= Q_s(T_s - T_c) \\
Q_s &= Q_f \times \left(\frac{T_f - T_c}{T_s - T_c}\right)
\end{aligned}$$

Substituting Q_f = 2.5 gpm, T_f = 110°F, T_s = 140°F, and T_c = 50°F gives the following:

$$Q_s = 2.5 \times \left(\frac{110 - 50}{140 - 50}\right)$$

$Q_s = 1.667\ gpm$ of hot water from storage tank

$Q_c = Q_f - Q_s = 2.5\ gpm - 1.667\ gpm = 0.833\ gpm$ of cold water from supply

The mixing equation may be used to evaluate the effect of variation of T_c temperatures on Q_s. At T_s = 140°F, for T_c = 40°F, Q_s = 1.75 gpm; and for T_c = 80 F, T_c = 1.25 gpm.

The mixing equation may also be used to evaluate the required size of SWH storage tanks as T_s varies. Higher storage temperatures allow smaller tank sizes to deliver equal water to fixtures.

507.1.3 ASHRAE Handbook, *HVAC Applications*, "Service Water Heating" chapter, "Hot-Water Demand per Fixture for Various Types of Buildings" table. [Supplement]

Row 9, Showers, indicates 225 gallons per hour (gph) per fixture for hot water flow in Gymnasiums, Industrial Plants, Schools, and YMCA's. Assume this represents continuous flow of shower fixture, what is the design fixture flow rate?

Since 225 gph/60 minutes per hour = 3.75 gpm of hot water flow = Q_s, calculate the fixture flow Q_f from the mixing equation, using T_f = 110°F, T_s = 140°F, and T_c = 50°F. Observe that $Q_f = Q_s + Q_c$, therefore $Q_c = Q_f - Q_s$. Substituting:

$$\begin{aligned} Q_f \times T_f &= (Q_s \times T_s) + (Q_c \times T_c) \\ Q_f \times T_f &= (Q_s \times T_s) + \left((Q_f \times Q_s)T_c\right) \\ Q_f \times T_f &= \left(Q_f \times T_c\right) + \left(Q_f \times T_c\right) - (Q_s \times T_c) \\ \left(Q_f \times T_f\right) - \left(Q_f \times T_c\right) &= (Q_s \times T_s) - (Q_s \times T_c) \\ Q_f \times \left(T_f - T_c\right) &= Q_s(T_s - T_c) \\ Q_f &= Q_s\left(\frac{T_s - T_c}{T_f - T_c}\right) \\ &= 3.75\left(\frac{(140-50)}{(110-50)}\right) \\ &= 5.625 \text{ gpm} \end{aligned}$$

Therefore, the proper CF for Chapter 50, Table 10, Row 9 is equal to 2.5 gpm per fixture (per Public Law 102-486) divided by 5.625 gpm (calculated above), which results in CF = 0.444 for T_c of 50°F. This may also be calculated as Q_s = 1.667 divided by Q_s = 3.75 equals CF = 0.444.

Thus, the gymnasium shower at 225 gph x CF corrects to 225 gph x 0.444 = 100 gph for T_c of 50°F.

507.1.4 Domestic hot water recirculation pumps. [Addition]

See Appendix E-3.2.5 of UFC 3-420-01, *Design: Plumbing Systems*.

507.2 Life cycle cost analysis. [Addition]

Evaluate alternative energy source options, such as electric, steam, oil-fired, and gas-fired SWH. Evaluate SWH storage tank capacity and electric heater element sizing to minimize electric demand charges to the government. Larger storage tanks with smaller heater elements may be cost effective due to reduced demand charges, although the longer storage recovery time and the additional costs for providing non-standard tank and element selections should also be considered. Do not exceed the ASHRAE recommended 8-hour maximum recovery time. Also consider the incremental cost of additional electric service capacity versus the incremental costs of providing steam or gas service or providing fuel oil storage and delivery. Include the costs of providing combustion air and flue gas exhaust for fuel-fired water heaters. Do not consider the cost of the tempering valve in the life cycle costs analysis, it is required by the 140°F (60°C) storage temperature to avoid Legionella. However, since it is required, consider the life cycle cost advantages of storing hot water at higher temperatures, if the source is electric, steam, or natural gas, and the tank insulation is increased to maintain equal total heat loss. A smaller SWH storage tank may reduce the size of the mechanical room and the building, which will reduce the energy and capital costs of the facility. Consider a pre-heat tank upstream of the SHW storage tank for applications recovering heat from refrigerant hot gas, steam condensate, process waste cooling, solar collectors, and diesel engines. Provide a tempering valve for all heat recovery SWH systems to limit the supply temperature, because the recovered heat can heat the storage tank above the normal storage temperature. A pre-heat tank may increase the amount of heat usably recovered prior to allowing the water to be heated by prime energy. Consider sealed combustion chambers for natural gas-fired SWH's, with combustion air ducted directly from and flue gases ducted directly to the outside air. This may reduce the possibility of carbon monoxide poisoning within the occupied spaces. Ensure adequate clearances of inlet and outlet during snow, icing, flood, and heavy wind-driven rain conditions.

507.3 Minimizing the risk of Legionellosis in building water systems [Addition]

The following are suggested references that provide guidance on minimizing the risk of Legionellosis: U.S. Army Corps of Engineers Engineering Manual (EM) 200-1-13, *Environmental Quality: Minimizing the Risk of Legionellosis Associated with Building Water Systems on Army Installations*; ASHRAE Guideline 12-2000, *Minimizing the Risk of Legionellosis with Building Water Systems;* and ANSI/ASHRAE Standard 188-2015, *Legionellosis: Risk Management for Building Water Systems.*

For **Navy** projects only:

For projects that meet the scope as defined by Section 2 "Scope" of the ASHRAE Guideline 12-2000, designs must incorporate the design recommendations in the "Recommended Treatment" paragraphs and the Public Works Department must provide the services to meet the maintenance recommendations in the “Recommended Treatment” paragraphs, for the applicable systems.

For projects that meet the scope as defined by Section 2 “Scope” of the ANSI/ASHRAE Standard 188-2015 designs must incorporate the requirements in Section 4.1 “Building Designer Requirements” and the Public Works Department must provide the services to meet the requirements in Section 4.2 “Building Owner Requirements.”

4-7 CHAPTER 6 - WATER SUPPLY AND DISTRIBUTION.

4-7.1 Section 601 – GENERAL.

601.6 Storage tank materials. [Addition]

Storage tanks shall be constructed of one of the following combinations of materials and methods:

1. Ferrous metals lined with nonferrous metals and provided with cathodic protection.
2. Ferrous metals lined with glass and provided with cathodic protection.
3. Ferrous metals lined with cement and provided with cathodic protection.
4. Fiberglass reinforced plastic for atmospheric pressure applications.

4-7.2 Section 602 - WATER REQUIRED.

602.2 Potable water required. [Supplement]

Add the following after the last sentence:

Exception: A nonpotable water supply, when used in an entirely separate system and when approved by the local health department, may be used for flushing water closets and urinals and for other approved purposes where potable water is not required.

602.2.1 Water for landscaping. [Addition]

Wall faucets, wall hydrants, lawn faucets, and yard hydrants shall be located so that, with 100 feet (30 m) of garden hose, the area can be watered without crossing the main entrance of public buildings or barracks. The branch to the lawn faucets and yard hydrants shall be equipped with stop and waste valves. The means of watering lawn areas, flowerbeds, and gardens shall be provided as follows:

1. Wall faucets with vacuum breaker backflow preventer on outside walls in nonfreezing climates.
2. Non-freeze wall hydrants with vacuum breaker backflow preventer on outside walls in freezing climates.
3. Lawn faucets with vacuum breaker backflow preventer for garden and lawn areas in nonfreezing climates.

4. Yard non-freeze hydrants for garden and lawn areas in freezing climates. Yard non-freeze hydrants have an automatic drain feature that can allow ground water to enter the service line. To protect the water supply the designer can either isolate the supply to the yard non-freeze hydrants with a double check valve backflow preventer, or specify sanitary yard hydrants. Sanitary yard hydrants are self-contained and do not drain to the surrounding ground, eliminating the possibility of cross-contamination. The designer should select the most cost effective option; sanitary yard hydrants are about three times the cost of standard non-freeze yard hydrants.

4-7.3 Section 604 – DESIGN OF BUILDING WATER DISTRIBUTION SYSTEM.

604.1 General [Supplement]

Add the following after the last sentence:

Service lines will enter the building in accessible locations. Large and mission critical facilities shall be provided with two or more water services to ensure constant delivery to all fixtures and equipment. Coordinate with user. A drain valve must be installed inside the building and downstream of both the building backflow preventer and the building service valve. Drain valve must be placed in a location with access to waste drains.

604.3 Water distribution system design criteria [Supplement]

Add the following after the last sentence:

Provide piping water velocities not to exceed 10 feet per second (3.28 m/s).

604.9 Water hammer [Supplement]

Add the following after the last sentence:

Only specify commercial-type water hammer arresters; vertical capped pipe columns are not permitted. Size and locate commercial water hammer arresters in accordance with PDI WH 201, *Water Hammer Arresters Standard* and manufacturer's recommendations. Provide access doors or removable panels when water hammer arresters are concealed.

4-7.4 Section 606 – INSTALLATION OF THE BUILDING WATER DISTRIBUTION SYSTEM.

606.5.11 Sizing booster systems and pumps [Addition]

Water pressure may be increased by using a hydro-pneumatic system consisting of a tank, pumps, compressed air system, and associated control devices.

606.5.11.1 Tank Pressure. The minimum pressure maintained within the tank is at low-water level and is equal to the pressure required to meet the fixture demands. The high pressure at high water level depends on the operating pressure differential selected for the system. A reasonable and most commonly selected pressure differential is 20 psi (138 kPa).

606.5.11.2 Pumps. Provide factory prefabricated pump package. Use variable speed pumping unless approved by the Authority Having Jurisdiction. For mission critical projects or for contingency operations provide triplex pumps, otherwise provide duplex pumps. . Each pump is sized to meet the requirements of the facility. Pump capacities in gallons per minute (L/s) shall be in accordance with Table 606.5.11.2. Pump head is to be equal to the high pressure maintained within the hydro-pneumatic tank.

606.5.11.3 Tank Capacity. For constant speed pumping, tank capacity is to be based upon a withdrawal, in gallons (liters), of 2-1/2 times the gallon per minute (L/s) capacity of the pump and a low water level of not less than 10 percent of total tank capacity or 3 inches (76 mm) above top of the tank outlet, whichever is greater. Table 606.5.11.3 indicates high water levels and withdrawals for efficient operation of tanks with bottom outlets and a 10 percent residual. Using this table, the tank capacity may be determined as per Example 1. Pressure ranges are given in pounds per square inch (psi) and kilopascals (kPa)

Example 1: Determine the tank capacity when pump capacity is 150 gpm and tank operating pressure range is 40 to 60 psi. (Referring to Table 606.5.11.3, the withdrawal from the tank is 24 percent of the tank capacity.)

Total tank capacity = 2.50 x 150 gpm / 0.24 = 1,563 gallons

or

Total tank capacity = 2.50 x 568 L/s / 0.24 = 5916 liters

For variable speed pumping, follow manufacturer's recommendations for tank size or calculate tank size based on 4% minimum flow and a 5-minute minimum off time.

606.5.11.4 Compressed Air. Compressed air is supplied for tank operation according to the tank capacities. Satisfactory operation has been attained by providing 1.5 cubic feet per minute (cfm) for tank capacities up to 500 gallons (1893 L) and 2 cfm (0.0566 cubic meters/min.) for capacities from 500 to 3,000 gallons (1893 to 11 355 L). For each additional 3,000 gallons (11 355 L) or fraction thereof, add 2 cfm (0.0566 cubic meters/min.). (Quantities are expressed in cubic feet (cubic meter) per minute free air at pressure equal to the high pressure maintained within the hydro-pneumatic tank.)

606.5.11.5 Controls. The controls of a hydro-pneumatic system are to maintain the predetermined pressures, water levels, and air-water ratio within the tank. Specify manufacturer's packaged controls. Specify commissioning of booster pump systems to ensure proper on/off set points and pump ramp speed settings under various conditions i.e. high demand/low incoming pressure and low demand/high incoming pressure.

606.5.11.6 Booster Pumps. Booster pumps must be the "on-off".

606.5.11.6.1 On-Off Type. The installation of an "on-off" type of pumping system should be considered when relatively long periods of pump-on or pump-off are anticipated. Pumps are to be activated, only when pressure is inadequate. Flow normally is through a single full-size pump bypass with check valve and two normally open (N.O.) isolating valves, whether the installation has one pump or multiple pumps. Provide each pump with a check valve on the discharge and two N.O. isolating valves.

Table 606.5.11.2
TANK FILL PUMPS

LOCATION	NUMBER OF FIXTURES	FLOW RATE PER FIXTURE gpm (L/s)	MIN. PUMP CAPACITY gpm (L/s)

30-50 (205-345)	38	28
40-60 (275-415)	34	24
50-70 (345-480)	32	22
60-80 (415-550)	28	18
20-45 (140-310)	48	38
30-55 (205-380)	42	32
40-65 (275-450)	37	27
50-75 (345-520)	35	25
60-85 (415-590)	32	22

4-7.5 Section 607 – HOT WATER SUPPLY SYSTEM.

607.1.3 *Legionella pneumophila* (Legionnaires' disease) [Addition]

The bacterium that causes Legionnaires' disease when inhaled has been discovered in the service water systems of various buildings in the United States and abroad. It has been determined that *Legionella pneumophila* can colonize in hot water systems maintained at temperatures of 115°F (46°C) or lower. Service water segments subject to stagnation (e.g., faucet aerators, shower heads and certain portions of storage–type water heaters) could provide an ideal location for bacteria to breed. Service water temperatures in the range of 140°F (60°C) are recommended in order to limit the growth potential of the bacteria. However, care must be taken to avoid scalding. Anti-scald devices must be incorporated in designs in which the service water temperature is in the range described above. For hospital and health care facilities, periodic supervised flushing of fixture heads with water at or above 170°F (77°C) are recommended.

607.2 Hot or tempered water supply to fixtures [Replacement]

Remove the last sentence and replace with the following:

Recirculating system piping shall be considered to be sources of *hot* and *tempered water*.

Size hot water recirculation pump in accordance with ASHRAE Handbook, *HVAC Applications*.

A water distribution system having one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe is prohibited.

607.2.1 Circulation systems and heat trace systems for maintaining heated water temperature in distribution systems. [Replacement]

Delete the first paragraph and replace with the following:

Provide recirculating systems for temperature maintenance. Heat trace systems are not permitted for temperature maintenance.

In buildings operated on a nominal 40-hour week or on a nominal two-shift basis (either a 5- or a 7-day week), a clock or other automatic control will be installed on domestic hot-water circulating pumps to permit operation only during periods of occupancy plus 30 minutes before and after.

607.2.1.2 Demand recirculation controls for distribution systems [Deletion]

Delete section in its entirety.

607.5 Insulation of piping [Supplement]

Add the following after the last sentence:

Insulate service hot water piping to meet the more restrictive minimum requirements of the following:

1. IPC.
2. ASHRAE Standard 90.1
3. UFGS 23 07 00, *Thermal Insulation for Mechanical Systems*.

The insulation requirements are minimum design requirements. The quality of insulation should be upgraded if the designer can show an improvement in the system performance or that insulation improvements are cost effective.

4-7.6 Section 608 – PROTECTION OF POTABLE WATER SUPPLY.

608.1 General [Supplement]

Add the following after the last sentence:

Single check valves are not considered adequate protection against backflow. Backflow prevention devices must be approved by the State/local regulatory agencies. If there is no State/local regulatory agencies requirements, all backflow prevention devices must be listed by the Foundation for Cross-Connection Control & Hydraulic Research, or any other approved testing laboratory having equivalent capabilities for both laboratory and field evaluation of backflow prevention devices and assemblies. Testing frequencies will follow the requirements set forth by the State/local regulatory agencies or DoD policy, whichever is more stringent.

4-7.7 Section 611 – DRINKING WATER TREATMENT UNITS.

611.2 Reverse osmosis systems [Supplement]

Add in front of the first sentence:

Reverse osmosis water treatment systems shall be installed when water of a higher purity than that produced by the domestic water is required, such as for deionized or distilled water systems used in hospitals. A water quality analysis shall be performed and water treatment design shall proceed based on that analysis. Reverse osmosis is a general term covering equipment that can have various types of filter elements and membranes and polishing components. The reverse osmosis membrane selection is critical and the operating pressure depends upon the membrane selected. Pump pressures can range from 80 to 800 psi (552 to 5516 kPa). The reverse osmosis unit is only part of the required treatment systems, which may include pretreatment facilities and organic filters. In some cases, booster pumps may be required for final water distribution. Materials for piping, pumps, valves, and other components must be carefully selected due to the corrosive nature of the high-purity water produced.

4-7.8 Section 614 – ION EXCHANGE WATER SOFTENING TREATMENT EQUIPMENT [ADDITION].

614.1 Ion exchange

Softening requirements are application-specific; it is typically required where precipitation of calcium carbonate can damage boiler/water heating equipment, block conduits or for aesthetic reasons. Ion exchange water softening is a suitable process for these purposes. However, each category has its own recommended limits for maximum hardness. Water hardness for laundries should not exceed 2.5 grains per gallon (43 ppm) and water hardness is usually reduced to zero. Large mess halls should have a water hardness not exceeding that provided for laundries; whereas, hospitals can utilize water of up to 3 grains per gallon (51 ppm) water hardness. Ion exchange water softening equipment consists of a softener unit and a regeneration brine tank utilizing common salt (NaCl) for regeneration of the softener exchange material. Softening units can be multiple units where two or more units utilize the same regenerating brine tank to provide for continuity of treatment during regeneration of a softening unit.

4-8 CHAPTER 7 - SANITARY DRAINAGE.

4-8.1 Section 704 – DRAINAGE PIPING INSTALLATION

704.5 High efficiency water closets [Addition]

For both new construction and renovations, high efficiency flushometer valve water closets with flush valves less than 1.28 gpf must be installed downstream of additional long-duration flows from other water-consuming appliances, plumbing fixtures, (e.g., lavatory faucets, flushing urinals, showerheads), and other devices that are able to assist with the drain line transport of solid wastes. For new construction, drain line slopes of greater than 1% must be provided.

704.6 Waterless/waterfree urinals [Addition]

When multiple waterless/waterfree urinals are ganged together, the most upstream urinal shall not be a waterless/waterfree urinal to assure flushing of the sanitary drain line.

4-8.2 Section 712 - SUMPS AND EJECTORS.

712.3.1 Sump pump [Supplement]

Add the following after the last sentence:

Sump pumps shall be installed in pits below the lowest floor. Subsoil drains may discharge into this pit. Provide a single pump unit where the function of the equipment is not critical, and provide duplex pump units where the function of the equipment is mission critical. When duplex pump units are provided, the capacity of each pump is to be sufficient to meet the requirements of the facility..

712.3.2 Sump pit [Supplement]

Add the following after the last sentence:

Sumps are to contain, in gallons, between the high level and low level operating switch settings approximately twice the capacity of the sump pump, in gallons per minute. The depth of the pit, below the finished floor, shall be in even feet to conform to standard lengths of submerged pump shafts.

712.3.4 Maximum effluent level [Supplement]

Add the following after the last sentence:

A high water alarm actuator is to be installed within sump and operate an audible or visual alarm when the normal high-water level within sump has been exceeded.

712.3.6 Controls [Addition]

Automatic controls are to be provided for each pump. Duplex pump units are to be equipped with controls to alternate the operation of the pumps under normal conditions and to operate pumps simultaneously when one pump cannot handle the flow.

712.4 Sewage pumps and sewage ejectors [Supplement]

Add the following after the last sentence:

Detailed requirements for pumps and ejectors shall be in accordance with the standards of the Hydraulic Institute. Where sewers are not of sufficient depth to drain the lower floor fixtures by gravity, the main toilet rooms should be located on higher floors. Sewage ejectors shall be of the duplex pneumatic type and shall be located in a concrete pit below the lowest floor. Ejectors will utilize a high-velocity steam, air, or water jet for ejecting the sewage. When the sewage must be pumped, duplex units shall be provided below the lowest floor in a concrete sump protected by a safety railing. Duplex sewage pumps shall be installed in a separate pump house when the sewage from a group of buildings must be pumped and where it is not possible to install sewage pumps in the buildings. Pump motors shall be located so as not to become submerged by an electrical service interruption. Packaged pumping systems installed in vertical dry or wet basins with non-clog centrifugal pumps are acceptable, if the influent line leads directly to the discharge line of both pumps and all incoming sewage passes through self-cleaning screens. Auxiliary screens shall be installed in influent lines within wet wells, since built-in, self-cleaning screens of the pump discharge lines may not be able to handle extreme peak flow conditions. Combination "T" and check valve arrangements shall be provided in the influent line to each pump to prevent raw sewage from backing into incoming sewer lines, when pumps are operating.

712.4.2 Capacity [Supplement]

Add the following after the last sentence:

The capacity shall be determined by the fixture unit method described in Section 710.

4-8.3 Section 715 - BACKWATER VALVES.

714.3 Location [Supplement]

Add the following after the last sentence:

A gate valve must be installed on the sewer side of each backwater valve, and both shall be installed in a manhole.

4-8.4 Section 716 – VACUUM DRAINAGE SYSTEMS [DELETE]

Delete section in its entirety.

4-9 CHAPTER 8 - INDIRECT/SPECIAL WASTE.

4-9.1 Section 802 - INDIRECT WASTES.

802.1.5 Nonpotable clear-water waste [Supplement]

Add the following after the last sentence:

Clear water discharge from hydraulic elevator sump pumps shall be connected to the sanitary sewer drainage system through an indirect waste pipe by means of a 2-inch (50 mm) air gap or directly through an oil/water separator to storm sewer, or to grade outside the building, each in accordance with discharge permits, regulations, and statutes.

802.1.9 Arms vault and storage areas [Addition]

Through-the-wall drains with discharge to grade shall be provided in arms vaults and storage areas requiring dehumidification, to dispose of condensate water from dehumidifiers. When such drains are not practicable, floor drains shall be installed inside the vaults or storage areas to provide for water removal.

4-10 CHAPTER 9 – VENTS.

4-10.1 Section 901 – GENERAL.

901.1 Scope [Supplement]

Add the following after the last sentence:

A Philadelphia (one pipe), engineered vent system, or a sovent (aerator) type system are not be permitted.

901.3 Chemical waste vent systems [Replacement]

Replace with the following:

The vent system for a chemical waste system must be independent of the sanitary vent system and must terminate separately through the roof to the open air.

4-10.2 Section 917 - SINGLE STACK VENT SYSTEM [DELETE].

Delete section in its entirety.

4-10.3 Section 918 - AIR ADMITANCE VALVES [SUPPLEMENT].

Add the following before the first sentence:

Air admittance valves may be used on a limited basis for renovation projects only after approval from the FEC, TDC, BCE, or DPW

4-10.4 Section 919 - ENGINEERED VENT SYSTEM [DELETE].

Delete section in its entirety.

4-11 CHAPTER 10 – TRAPS, INTERCEPTORS AND SEPARATORS.

4-11.1 Section 1002 - TRAP REQUIREMENTS.

1002.4 Trap Seals [Supplement]

Add the following after the last sentence:

Where a trap seal is subject to loss by evaporation, the trap seal shall be protected by a deal seal trap consisting of a 4-inch (100 mm) seal and one of the other trap seal protection methods listed in Sections 1002.4.1.1 through 1002.4.1.4.

4-11.2 Section 1003 - INTERCEPTORS AND SEPARATORS.

1003.1 Where required [Supplement]

Add the following after the last sentence:

Interceptors shall be installed underground outside the building. The area surrounding interceptors shall be paved and provided with suitable drainage facilities. Where design temperatures are less than 0°F (–18°C), interceptors should be located within the building, remote from the kitchen area.

4-12 CHAPTER 11 - STORM DRAINAGE.

4-12.1 Section 1101 – GENERAL.

1101.1 Scope [Supplement]

Add the following after the last sentence:

Storm drainage will include roof drains, leaders, and conductors within the building and to a point 5 feet (1.5 m) outside the building.

4-12.2 Section 1104 - CONDUCTORS AND CONNECTIONS.

1104.3 Insulation of rainwater conductors [Addition]

To prevent condensation, insulate horizontal piping runs, roof drains, and roof drain sumps inside the building with a minimum of 1-inch (25 mm) thick insulation.

4-12.3 Section 1107 – SIPHONIC ROOF DRAINAGE SYSTEMS [DELETE]

4-13 CHAPTER 12 - SPECIAL PIPING AND STORAGE SYSTEMS.

1201.1 Scope [Supplement]

Add the following before the last sentence:

Refer to UFC 4-510-01, *Design: Military Medical Facilities,* for additional medical gas systems requirements.

4-14 CHAPTER 15 - REFERENCED STANDARDS.

Delete the last sentence of the first paragraph.

4-15 APPENDIX A.

4-15.1 PLUMBING PERMIT FEE SCHEDULE [DELETE].

Delete appendix in its entirety.

4-16 APPENDIX C.

4-16.1 STRUCTURAL SAFETY [DELETE].

Delete appendix in its entirety.

4-17 APPENDIX D.

4-17.1 DEGREE DAY AND DESIGN TEMPERATURES [SUPPLEMENTAL].

Where data conflicts with UFC 3-400-02, *Engineering Weather Data*, UFC 3-400-02 takes precedence.

CHAPTER 5 DESIGN ANALYSIS

5-1 DESIGN ANALYSIS.

The Design Analysis must be submitted at a preliminary design stage equivalent to 35% design for concurrence of the results. The Design Analysis must consist of a Basis of Design Narrative and Calculations. The analysis must be updated as necessary as the design progresses. The results of this analysis are used for design decision-making in reducing total life cycle cost, while meeting mission objectives.

5-1.1 Basis of Design.

5-1.2 Provide a Basis of Design Narrative.

Include the following:

- Building population (number of males and number of females)
- Plumbing fixture determination, listing quantity and types of fixtures
- Fixture units for drainage, venting, cold and hot water piping
- Roof areas used in determining storm drainage pipe sizes
- Capacities of all equipment and tanks

5-1.2.1 Criteria/Codes.

Identify the governing codes and criteria utilized for the design. Include the titles and the date of the applicable edition or publication.

5-1.2.2 Site Conditions.

Conduct detailed field investigation and interview the appropriate field personnel. Do not rely solely on the as-built drawings.

Determine energy sources available at the project site. Describe the source of thermal energy that will be used (i.e. extension of central high pressure steam, natural gas, or standalone heat source with the type of fuel utilized).

5-1.2.3 System Selection.

Provide a narrative description of all system alternatives considered. Describe in detail all systems and components selected at a preliminary design stage equivalent to 35% design to include the results of the LCCA and modeled energy use.

5-1.2.4 Special Plumbing Systems.

Provide a description of special plumbing systems such as compressed air, medical gas, etc.

5-1.3 Calculations.

Show calculations and assumptions supporting equipment selections in a clear and organized manner. When charts or tables are used in the design analysis, cite the source and date of the publication.

5-1.3.1 Sizing Calculations.

Provide calculations for sizing equipment, piping, and all accessories which includes pressure calculations. Provide the model number and manufacturer of each major piece of equipment used as the basis for the design.

5-1.3.2 LCCA.

Provide LCCA on optimized system level alternatives modeled in accordance with UFC 1-200-02. Provide energy model, including model inputs and outputs, on optimized system level alternatives by energy type in accordance with UFC 1-200-02.

5-1.3.3 Energy Compliance Analysis (ECA).

If required by UFC 1-200-02, provide a computerized Energy Compliance Analysis. The ECA is a building level analysis which takes into account the interaction between architectural, electrical and mechanical components of the facility design and confirms compliance with the energy reduction goals.

5-2 FINAL DRAWING REQUIREMENTS.

The drawings will be accurate, to scale and follow the Tri-Service A/E/C CADD Standard. Drawings must show equipment and piping sufficiently to indicate all aspects of installation. Provide each set of drawings with a legend covering symbols and abbreviations as indicated in ASHRAE Handbook, *Fundamentals*. Where practical, group all notes, legends, and schedules at the right of the drawings above the title block.

5-2.1 Drawing Units.

Unless otherwise authorized, the IP System of measurement must be used on CONUS projects and the SI system of measurement must be utilized on OCONUS projects.

5-2.2 Legend.

Provide legends to clarify all symbols and abbreviations used on the drawings.

5-2.3 Seismic and ATFP Bracing

Show all pertinent seismic and ATFP bracing details for the plumbing systems on the contract drawings.

5-2.4 Demolition Plans.

Demolitions plans must be separate and distinct from new work plans.

5-2.5 Floor and Site Plans.

Exercise judgment to avoid overly congested drawings. Provide north arrows an all building and site plans. The orientation of drawings must be arranged with the north arrow toward the top of the plotted sheets, unless overriding circumstances dictate otherwise. The orientation of all partial building or site plans must be identical to that of the larger plan from which it is derived or referenced. Consistency in drawing orientation must be maintained with all disciplines. Provide drawings with dimensions locating all work relative to structural features of the building. For floor plans show fixtures, equipment, and piping in their proper locations. For site plans show connections to existing systems, location of propane and oil tanks, and layout of ground coupled heat pump well fields. Calculate the grade of drain lines and show established invert elevations.

5-2.6 Enlarged Floor Plans.

Provide large-scale details of congested area on the drawings, with dimensions locating all work relative to structural features of the building. Provide separate waste/vent and domestic water enlarged floor plans. Enlarged floor plans must be drawn at no less than 1/4” = 1’-0” (1:50).

5-2.7 Sections and Elevations.

Provide as required to supplement plan views.

5-2.8 Access Space.

Identify space necessary to access and replace items that require maintenance, such as heat exchangers, on the drawings.

5-2.9 Riser Diagrams

Show riser diagrams of soil, waste, drain, and vent stacks. Indicate cleanouts. Show water risers for all buildings in excess of one story. Indicate shutoff valve and water hammer arrester locations. Indicate pipe sizes.

5-2.10 Water Service.

Unless directed otherwise, place the following note on the applicable drawing: "Water pipe sizes are based on a minimum working pressure of ___ [psig (kPa)] at a flow rate of ___ [gpm (L/s)] at the location where the main service enters the building." When water pressure is not known, it must be measured.

5-2.11 Equipment Schedules.

Unless directed otherwise, include equipment schedules on the drawings. The following are typical schedules and data provided on these schedules:

5-2.11.1 Hot water circulating pump.

Provide a hot water circulating pump schedule. Include as a minimum:

- Capacity in gpm (L/s)
- Total head in feet (m)
- Minimum horsepower
- Volts, phase, hertz
- RPM

5-2.11.2 Ejector or sump pump.

Provide an ejector or sump pump schedule. Include as a minimum:

- Capacity in gpm (L/s)
- Total dynamic head in feet (m)
- Minimum horsepower
- Volts, phase, hertz
- RPM

5-2.11.3 Water heater.

Provide a water heater schedule. Include as a minimum:

- Heating capacity in gph (L/s)
- Temperature rise in degrees Fahrenheit (°F) (Celsius (°C))
- Storage capacity in gallons (liters)
- Energy Factor (defined by Gas Appliance Manufacturers Association (GAMA))

5-2.11.4 Hot water storage tank.

Provide a water heater storage tank schedule. Include as a minimum:

- Dimensions
- Capacity in gallons (liters)
- Minimum insulation

5-2.11.5 Hot water generator.

Provide a hot water generator schedule. Include as a minimum:

- Dimensions
- Storage capacity in gallons (liters)

- Heating surface area
- Design pressure
- Heat source (i.e. steam, HTHW, natural gas, electric)
- GPH @ entering water temperature and leaving water temperature

5-2.11.6 Drinking water dispenser:

Provide a drinking water dispenser schedule. Include as a minimum:

- Cafeteria: Type, size
- Electric drinking water cooler: Type, size (Note: Water coolers must use HFC refrigerants.)

5-2.11.7 Grease interceptor.

Provide a grease interceptor schedule. Include as a minimum:

- Fat capacity in pounds (kilograms)
- Flow rating in gpm (L/s)
- Maximum leaving water grains (ppm)

5-2.11.8 Reverse osmosis water treatment equipment.

Provide a reverse osmosis water treatment equipment schedule. Include as a minimum:

- Minimum flow rating in gpm (L/s)
- Design and operating temperature in °F (°C)
- Maximum leaving water grains (ppm)

5-2.11.9 Water softening treatment equipment.

Provide a water softening treatment equipment schedule. Include as a minimum:

- Minimum flow rating in gpm (L/s)
- Grains (grams) hardness to which water is to be softened
- Amount of water metered in gallons (liters) to start automatic regeneration of a softener unit

5-2.11.10 Booster pump.

Provide a booster pump schedule. Include as a minimum:

- Capacity in gpm (L/s)
- Total head in feet (m)
- Minimum horsepower
- Volts, phase hertz
- RPM

5-2.12 Details.

Details must be edited to reflect the configurations and construction materials shown on the plans.

5-2.13 Access Panels.

Indicate location and size of access panels in floors, walls, and ceilings (except in lay-in tile applications) as required to access valves, wall cleanouts, etc. on drawings. Sufficiently sized, safe access must be provided for the maintenance of valves and other components.

APPENDIX C DESIGN GUIDANCE FOR EMERGENCY SHOWER AND EYEWASH STATIONS

C-1 EMERGENCY SHOWER AND EYEWASH STATION (ES/EWS).

Provide ES/EWS meeting ANSI/ISEA Z358.1, *Emergency Eyewash and Shower Equipment,* where required by Occupational Safety and Health Administration (OSHA) regulations or by other competent authority, such as UFC's, Military Handbooks, or Design Manuals. Consult with the local station and engineering authorities, including the process, environmental, and safety engineers, and the Industrial Hygienist about ES/EWS locations, materials present, waste treatment systems available, and permits required. Locate ES/EWS as close to the hazard as possible, within 10 to 20 feet (3 to 6 m) for highly corrosive chemicals, but not more than 10 seconds or 100 feet (30 m) of unobstructed travel away, whichever is lesser.

For personnel protection within water-reactive hazardous materials storage and handling areas, provide ASSE Z87.1, *Occupational Eye and Face Protection* chemical splash goggles. Consider providing portable ANSI/ISEA Z358.1 personal eyewash protection for use within the water-reactive area. Provide ES/EWS immediately outside the water-reactive area, but not more than the 10 seconds or 100 feet (30 m) away from the work location. Ensure water from ES/EWS will not enter the water-reactive area; this may require provision of partitions, walls, berms, trenches, or curbs. The personal eyewash must be of the smallest reasonable volume necessary to enable initial flushing on the way to the ES/EWS, to minimize the water-reactive hazard due to spillage of the flushing fluid. A water-reactive material spill is the most probable cause of the need for flushing, and the spillage of the flushing fluid provides the other chemical needed to initiate the reaction. Carefully consider whether to provide personal eyewash or not, and document the decision analysis. Personal eyewash fluid presence may increase the risk of a water-reactive chemical event due to risk of accidental personal eyewash fluid spill, and due to valid usage of personal eyewash. Water-reactive materials are defined in UFC 4-440-01, *Warehouses and Storage Facilities*.

C-2 ALARMS.

Provide a water flow-initiated alarm for each ES/EWS. For locations where potable water is not available, provide personal eyewash protection and a manually initiated alarm. Provide a local audible signal device, a silencing switch, and a flashing strobe light for each ES/EWS and for each manual alarm, and optionally provide central reporting of the alarm to a 24 hour per day manned location. Alarm installations must be waterproof per National Electrical Manufacturers Association (NEMA) Class 3. ES/EWS alarm systems in hazardous (classified) locations, per National Electric Code, must be listed and labeled for that purpose. Alarm audible signal devices must have a distinct sound, different from other alarms in this and adjacent facilities. Mount alarm audible signal device, silencing switch, and strobe light on wall or ES/EWS column, immediately above the level of the showerhead.

Alarms protect people by promptly summoning help, and protect stored materials, equipment, and facilities by indicating or reporting ES/EWS activation, with its attendant water flow.

C-3 FLOOR DRAINS.

Floor drains for ES/EWS are not required by the IPC. See Section 411.

C-3.1 Occupant Preference.

Owners and occupants prefer floor drains, for housekeeping and for material and facility protection reasons.

The floor drain may become a source of illicit disposal of prohibited substances. Careful supervision will be necessary.

C-3.2 De Minimis Losses.

Floor drains may be provided. The Environmental Protection Agency regulation, 40 CFR 261, *Identification and Listing of Hazardous Waste*, describes “ ...the following mixtures of solid wastes and hazardous wastes listed in Subpart D are not hazardous wastes...” “...“de minimis” losses include ...” “...discharges from safety showers and rinsing and cleaning of personal safety equipment;...”. Therefore, ES/EWS discharges may be drained to the sanitary sewer system, as they are “de minimis” losses.

C-3.3 Sizing.

C-3.3.1 Capacity.

Minimum capacity 45 gpm (2.8 L/s) water flow, based upon 1.5 times the ANSI/ISEA Z358.1 standard water flow minimum requirement.

The floor drain must accommodate the full flow of the ES/EWS to avoid spilling water over the containment curb, into the hazardous material storage area, and to avoid damage to the material and the facility in case of continuous ES/EWS operation.

C-3.3.2 Traps.

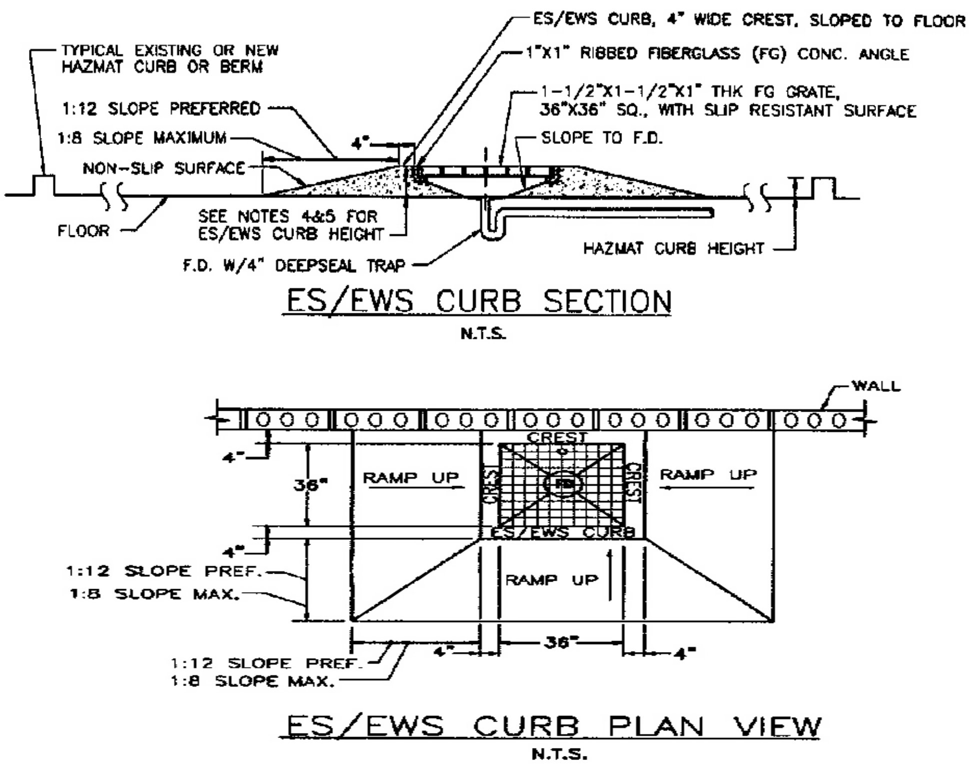
Floor drains must be provided with 4-inch (100 mm) deep seal traps. Frequent testing of the ES/EWS, as required by ANSI/ISEA Z358.1, will refill the trap seal.

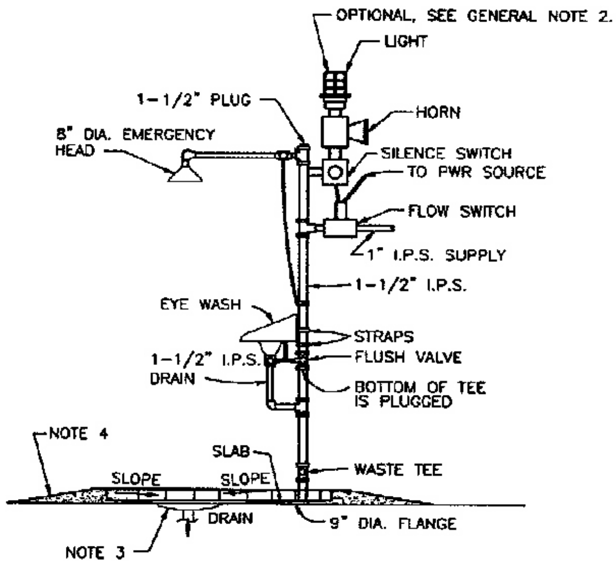
The deep seal trap is provided to reduce the problem of the unused trap drying out and allowing the back flow of sewer gases, fumes, and vermin into the space. Weekly testing of the ES/EWS will be usage enough to refill the trap seal; otherwise, provide an automatic trap priming valve connected to the cold water supply to maintain the trap seal.

C-3.3.3 Containment Curb.

For hazardous material (HAZMAT) areas, provide a 1.5 inch (37 mm) high ES/EWS containment curb completely around the ES/EWS, slope the exterior (approach) face of the curb up at a slope of 1/12 rise, but not more than 1/8 rise per *ABA Accessibility Standards for DoD Facilities*, mark the ES/EWS curb as a trip hazard per OSHA regulations, and inform the personnel that the ES/EWS curb exists. Where ES/EWS with floor drains are located within hazardous material (hazmat) spill containment bermed or curbed areas, provide the crest of the ES/EWS curb to be 1.5 inch (37 mm) higher than the surrounding HAZMAT area curb, to ensure spills do not enter the floor drain. See Figure D-1.

Figure C-1 Emergency Eyewash and Shower Details





EMERGENCY SHOWER & EYE WASH (ES/EWS) DETAIL
N.T.S.

The ES/EWS containment curb protects the floor drain from accidental spills in the surrounding HAZMAT area. The ES/EWS curb also protects the stored HAZMAT materials and facility from accumulated ES/EWS water flow by directing the flow into the floor drain.

C-3.3.4 Placard.

In HAZMAT areas, post a placard at each ES/EWS stating: “NO DUMPING. This drain discharges untreated into the sanitary sewer, contact Activity Environmental Office for proper disposal of spilled material or waste.”

The placard provides the occupants with sufficient information to avoid inadvertent “spills” caused by using the floor drain as a convenient sink for cleanup of spilled materials. Revise the wording to correctly indicate the discharge destination and any treatment system it passes through, such as a neutralization tank or an oil-water separator.

C-3.4 Connection.

All drain connections must comply with all national, State, local, and DoD regulations.

C-3.4.1 Extraordinary hazard materials.

Extraordinary hazard materials - such as poisons, must not discharge into a drain system. Utilize the HAZMAT spill containment curb system to contain the ES/EWS water flow. Provide remote alarm reporting to a central manned station. Immediate action is required to prevent poison contaminated water from spreading throughout the facility.

The floor drain is omitted to prevent inadvertent exposure of persons downstream of the floor drain from unknowingly contacting the potentially poisonous runoff. The hazardous material spill response team answering the alarm will be aware of the hazards and capable of taking appropriate measures for self-protection. If the HAZMAT spill containment curbed area has insufficient volume to hold a minimum of 30 minutes of ES/EWS water flow, provide a floor drain to an above ground holding tank sized to hold at least 30 minutes of flow. Properly label the piping and the tank as holding poisonous fluids. Provide a HAZMAT spill containment berm around the holding tank. Provide an ES/EWS containment curb around the floor drain to preclude fire protection water from flooding the floor drain holding tank and tank berm. ES/EWS curb to be 1.5 inches (37 mm) higher than the HAZMAT curb.

C-3.4.2 Plating shops.

Drain to the proper industrial waste treatment system. Segregate cyanide wastes, including ES/EWS drainage, from all acid wastes. Segregate hexavalent chromium wastes, including ES/EWS drainage, from all caustics and cyanides. Where the shower is located in a multiple use area, such as a material handling or shipping/receiving area, drain to the proper industrial waste treatment system.

C-3.4.3 Battery rooms or shops.

Drain to the proper neutralization tank, if provided; otherwise, drain to the sanitary sewer system. Segregate caustics from the Nickel- Cadmium-Alkali battery area, including ES/EWS drainage, from acids. Segregate acids from the Lead- Acid battery area, including ES/EWS drainage, from caustics. Do not allow mixing of acid and alkali wastes in the drains.

C-3.4.4 Oily waste shops.

Drain to the oil/water separator, if provided; otherwise, drain to the sanitary sewer system. Typical oily waste shops include the following: paint shops and hangers, paint mix rooms, paint equipment rooms, engine shops, ground support equipment shops, refueler shops, Public Works automotive shops, locomotive and crane shops.

C-3.4.5 Miscellaneous materials.

Drain to the sanitary sewer system.

C-3.4.6 Exterior ES/EWS in HAZMAT areas.

Slope impervious-surfaced grade to drain to a bermed or curbed impervious-surfaced area to allow cleanup without “spillage” to the environment; or provide a floor drain connected to an appropriate drain system, and an enclosure with roof to preclude storm water entry into the floor drain. Provide the ramp, curb, and grate around the floor drain, to preclude surface drainage into the floor drain.

C-4 PIPED DRAINS.

Piped drains for eyewash stations (EWS) are not required by the IPC. See Section 411.

C-4.1 Occupant Preference.

Owners and occupants prefer piped drains for EWS for housekeeping purposes.

C-4.2 De Minimis Losses.

Piped drains for EWS may be provided. The Environmental Protection Agency regulation, 40 CFR 261, describes " ...the following mixtures of solid wastes and hazardous wastes listed in Subpart D are not hazardous wastes..." "..."de minimis" losses include ..." "...discharges from safety showers and rinsing and cleaning of personal safety equipment;...". Therefore, EWS discharges may be drained to the sanitary sewer system, as they are "de minimis" losses.

C-4.3 Sizing.

Pipe full size from waste tee. See Figure D-1.

C-4.3.1 Traps.

Piped drains must be provided with 4 inch (100 mm) deep seal traps. Frequent testing of the EWS, as required by ANSI/ISEA Z358.1, will refill the trap seal.

The deep seal trap is provided to reduce the problem of the unused trap drying out and allowing the back flow of sewer gases, fumes, and vermin into the space. Weekly testing of the EWS will be usage enough to refill the trap seal; otherwise, provide an automatic trap priming valve connected to the cold water supply to maintain the trap seal.

C-4.4 Connection.

All drain connections must comply with all national, State, local, and DoD regulations.

C-4.4.1 Extraordinary hazard materials.

Extraordinary hazard materials - such as poisons, must not discharge into a drain system. Utilize the HAZMAT spill containment curb system to contain the EWS water flow. Provide remote alarm reporting to a central manned station. Immediate action is required to prevent poison contaminated water from spreading throughout the facility.

The piped drain is omitted to prevent inadvertent exposure of persons downstream of the piped drain from unknowingly contacting the potentially poisonous runoff. The hazardous material spill response team answering the alarm will be aware of the hazards and capable of taking appropriate measures for self-protection. If the HAZMAT spill containment curbed area has insufficient volume to hold a minimum of 30 minutes of EWS water flow, provide a piped drain to an above ground holding tank sized to hold at least 30 minutes of flow. Properly label the piping and the tank as holding poisonous fluids. Provide a HAZMAT spill containment berm around the holding tank.

C-4.4.2 Plating shops.

Drain to the proper industrial waste treatment system. Segregate cyanide wastes, including EWS drainage, from all acid wastes. Segregate hexavalent chromium wastes, including EWS drainage, from all caustics and cyanides. Where the EWS is located in a multiple use area, such as a material handling or shipping/receiving area, drain to the proper industrial waste treatment system.

C-4.4.3 Battery rooms or shops.

Drain to the proper neutralization tank, if provided; otherwise, drain to the sanitary sewer system. Segregate caustics from the Nickel- Cadmium-Alkali battery area, including EWS drainage, from acids. Segregate acids from the Lead- Acid battery area, including EWS drainage, from caustics. Do not allow mixing of acid and alkali wastes in the drains.

C-4.4.4 Oily waste shops.

Drain to the oil/water separator, if provided; otherwise, drain to the sanitary sewer system. Typical oily waste shops include the following: paint shops and hangers, paint mix rooms, paint equipment rooms, engine shops, ground support equipment shops, refueler shops, Public Works automotive shops, locomotive and crane shops.

C-4.4.5 Miscellaneous materials.

Drain to the sanitary sewer system.

C-4.4.6 Exterior EWS in HAZMAT areas.

Slope impervious-surfaced grade to drain to a bermed or curbed impervious-surfaced area to allow cleanup without “spillage” to the environment; or provide a piped drain connected to an appropriate drain system.

Note: All drain connections must comply with all national, State, local, and DoD regulations. Coordinate this issue with the local authorities per paragraph 1 above.

C-5 ELECTRICAL.

Provide ground fault circuit interrupter (GFCI) protection for dedicated heat tape circuits and for all electrical power outlets within 6 feet (1.8 m) of an ES/EWS and below the elevation of the showerhead.

For heat tape systems, provide a ground fault equipment protection (GFEP) device on each heating cable branch circuit. Conventional circuit breakers may not prevent arcing from damaged or improperly installed heat trace cables. Coordinate heat tape system requirements with electrical engineer.

This Page Intentionally Left Blank

APPENDIX D DOMESTIC WATER HEATER FOR ARMY BARRACKS

D-1 PURPOSE.

This appendix provides basic design guidance for the sizing of domestic water heaters for barracks buildings at Army installations.

D-2 BACKGROUND.

There have been questions regarding the sizing for domestic water heaters for barracks. Designers have often used ASHRAE design criteria for motels or dormitories with some over sizing. However the peak demand for domestic hot water in barracks is significantly larger than motels or dormitories due to the concentrated shower pattern of the occupants. This appendix provides a uniform approach to determine domestic water heating requirements for Army barracks, and will be used for the planning, design and construction of new and renovated facilities.

D-3 GUIDANCE.

D-3.1 General.

D-3.1.1 Storage Temperature.

As with any domestic water heating system, storage tank temperature must be maintained at a minimum of 140°F (60°C) to reduce the potential for *Legionella pneumophila* (Legionnaires' disease). Note that higher storage temperatures will result in a lower recovery rate to satisfy the peak demand. Include a cross connection with a mixing valve between the domestic water supply and hot water supply lines (leaving the storage tank) to control the temperature of water distributed to plumbing fixtures to a minimum of 131°F (55°C). Require a strainer upstream of the thermostatic mixing valve on both the hot- and cold-water connections to protect the small orifice in the mixing valve from debris that may be in either line. Where a recirculation pump is required, the minimum hot water return temperature shall be 122°F (50°C) at the connection to the cold water inlet of the water heater/storage tank, at the master mixing valve. The water temperature shall be reduced at the fixture as required through a water temperature limiting device in accordance with Section 424, except where higher temperatures are required by specialized equipment as indicated in ASHRAE Handbook, *Applications* or Table 506.1.

D-3.1.2 Thermal Expansion.

If a backflow preventer is installed in the domestic water main entering a building or in the line supplying the domestic hot water system, include provisions to accommodate thermal expansion. In barracks this can be critical as occupants often shower at the same time and after this peak usage event, the hot water loop will be at a relatively low temperature. During the subsequent recovery phase the water temperature will rise causing the water to expand. If little hot water is being used, this expansion will cause a pressure increase that may activate a relief valve or rupture the storage tank. The best method to alleviate this excess pressure is to install an expansion tank, sized in accordance with "Hydronic

Heating and Cooling" chapter in the ASHRAE Handbook, *Systems and Equipment*.

D-3.1.3 Central Plant.

Normally if a central energy plant is available it will be life cycle cost effective (an analysis must be performed) to generate domestic hot water using distributed media as the heat source. If there is no central plant or if the plant does not operate during the non-heating season, provide a separate domestic hot water source. If the site consists of several barracks buildings, evaluate the life cycle cost of these alternatives:

- A single boiler to provide low temperature hot water, 200°F (94°C) to heat exchangers in each barracks for domestic hot water generation.
- A single heating source for domestic hot water in each individual barracks separately.

If the barracks building is not part of a building complex and there is no central plant or distribution system available then a single heating source must be provided.

D-3.2 Calculations.

The following information applies to all types of domestic water heating systems for barracks.

D-3.2.1 Peak Demand.

Design for the case where all occupants are taking showers at essentially the same time. Public law limits the maximum flow from of each showerhead and private lavatory faucet to 2.5 gpm (0.16 L/s). It is assumed during peak demand that the shower runs for 7.5 minutes and the lavatory runs for 2 minutes. As a result, the peak domestic hot water demand (at T_s) can be found by the following equation:

$$V_p = (h)(occ)(P)\left(\frac{T_d - T_c}{T_s - T_c}\right)$$ **(Equation E-1)**

where:

V_p = volume of domestic hot water required at peak, L (gal).
h = number of shower heads, ea.
occ = number of occupants using each shower, ea.
T_d = temperature of water delivered to shower valve, 43°C (110°F).
T_s = temperature of water in storage tank, °C (°F).
T_c = temperature of cold water supply.
P = amount of water used per occupant during peak demand, 90.0 L/occupant (23.75 gal/occupant).

Note that there is no diversity in the number of occupants in the building. The peak volume of domestic hot water is calculated assuming 100 percent building occupancy. Also note that Equation E-1 does not take laundry or dining facilities into account. Add additional hot water requirements if laundry or dining facilities will be requiring hot water during the peak demand period.

D-3.2.2 Tank Size.

Once the peak demand is known, the tank capacity and corresponding recovery rate can be determined. Since space in the mechanical room is frequently limited, select the desired tank capacity first. An initial estimate of tank size can be determined by using 12.5 gal per occupant (50 L per occupant). Normally a selection of 12.5 gal (50 L) will provide acceptable operation at a reasonable cost but it must be noted that other factors including larger tank sizes and higher storage temperatures will reduce amount of recovery required. Larger tank sizes and increased storage temperatures will also result in greater heat loss from the storage tank. Compare selected tank size to standard tank capacities available commercially and with the space available in the mechanical room.

D-3.2.3 Recovery Rate.

Once the tank capacity is known, the recovery rate can be calculated. The recovery rate is the quantity of water to be heated from the inlet temperature to the desired storage temperature. The difference between the inlet water temperature and the water storage temperature is often assumed to be 100°F (55°C). However, this temperature difference must be coordinated with local conditions and revised as necessary. The required recovery rate can be found using the following equation:

$$R = \left(\frac{V_p - (MS_t)}{d}\right) \qquad \textbf{(Equation E-2)}$$

where:

R = recovery rate at the required temperature, L/s, (gph).

M = ratio of usable water to storage tank capacity, 60-80%.

S_t = storage tank capacity (initial estimate), L (gal) = $(h)(occ)\frac{50\ L}{occupant}$.

d = duration of the peak, (hours) = $\frac{9.5\ min}{occupant}\ (occ)\ \frac{1\ hour}{60\ min}$.

The duration is calculated assuming that the peak usage period will be 9.5 minutes per occupant. Therefore, if two occupants share a bathroom the duration is 19 minutes, 3 occupants would be 28.5 minutes, etc.

The recovery rate is an output condition. Insure that manufacturer's data for the hot water generation unit indicates sufficient input capacity to satisfy the recovery rate with actual design inlet water and storage temperatures.

The tank size may be adjusted up or down to accommodate available tank sizes or available recovery capacities. A smaller tank size yields a higher recovery rate. Simply enter the desired tank size into Equation E-2 and solve for the required recovery rate. Verify that the combination of tank size and recovery rate is commercially available.

D-3.2.4 Pipe Sizes.

The next component to be sized in the system is the domestic hot water distribution piping. Appendix A of *The National Standard Plumbing Code*, “Service Water Heating” chapter of the ASHRAE Handbook, *Applications,* and “Pipe Sizing” chapter of the ASHRAE Handbook, *Fundamentals* provide an ample set of resources on this topic. Therefore, this appendix will not discuss this process.

D-3.2.5 Domestic Hot Water Circulation Pump.

After the domestic hot water distribution piping has been sized, the domestic hot water circulation pump can be sized. This pump is used to circulate the domestic hot water through the distribution piping system. Size the pump using equation below:

$$Q_p = \frac{q}{c\ \rho\ c_p\ \Delta T}$$ **(Equation E-3)**

where:

Q_p = pump capacity, L/s (gpm).

q = heat loss in the piping system, kW (Btuh).

c = constant, $1\ \frac{kW \cdot sec}{kJ}\left(60\frac{min}{hr}\right)$.

ρ = density of water, $0.9971\frac{kg}{L}\left(8.33\ \frac{lb}{gal}\right)$.

c_p = specific heat of water, $4.18\ \frac{kJ}{kg \cdot K}\left(1\ \frac{Btu}{lb \cdot °F}\right)$.

ΔT = allowable temperature drop through the system, K (°F).

Equation E-3 can be simplified to:

$$Q_p = \frac{q}{\left(4.1679\frac{kW \cdot sec}{L \cdot K}\right)\Delta T}$$ **(Equation E-4 (SI))**

$$Q_p = \frac{q}{\left(500\frac{Btuh}{gpm \cdot °F}\right)\Delta T}$$ **(Equation E-4 (IP))**

Heat loss in the piping system (q) can be calculated using ASHRAE Handbook, *Applications*. However, a common rule of thumb is 0.032 kW/m (30 Btuh/ft.).

The allowable temperature drop through the piping system (ΔT) is usually 2 to 5K (5 to 10°F). It is recommended to use 2K (5°F) to assure that sufficient hot water is provided for all occupants under peak conditions.

D-3.3 Separate Storage Tank.

Systems using a separate hot water generation unit and storage tank: The following information applies to systems using a separate storage tank and forced circulation type water heater, boiler or heat exchanger to generate and store domestic hot water. A forced circulation type water heater is similar to a boiler in that it is designed to heat domestic water as it passes through a series of coils rather than heating water in a storage tank but is designed for generating domestic hot water only.

D-3.3.1 Tank Location

Locate the storage tank and hot water generation unit in the same mechanical room whenever possible. This keeps the head requirements at a minimum for the pump circulating water between the hot water generation unit and the storage tank.

D-3.3.2 Connection

Require the domestic water supply be connected in the line supplying hot water to the storage tank. This allows the cold water to mix with the warmer water in the storage tank before entering the boiler, minimizing problems associated with condensation and thermal stress and improving overall system efficiency. Require a submittal from the manufacturer addressing whether a thermostatically controlled bypass line between the boiler supply and return lines or other means are needed to preclude the possibility of thermal shock to the boiler.

D-3.3.3 Forced Circulation

If a forced circulation type water heater or boiler is used, Equation E-3 again can be used to size the circulation pump between the heater and the storage tank. In this case limit the temperature differential to no greater than 30°F (16K) to minimize problems with condensation and thermal stress and improve overall system efficiency. Also note that the sizing of the circulation pump must account for the heating of the domestic cold water being provided. Therefore, the value of q required to use Equation E-3 can be found using the following equation:

$$q = q_{pipe} + (R\ c\ \rho\ c_p\ \Delta T) \quad \textbf{(Equation E-5)}$$

where:

q_{pipe} = heat loss in the piping between the boiler and the storage tank, kW (Btuh)

ΔT_t = temperature difference between the tank water and the make-up water, K (°F)

Determine actual storage tank and domestic water supply temperatures based on local requirements. If the water in the tank is assumed to be 60°C (140°F) and the make-up water is 4°C (40°F), Equation E-5 can be simplified to:

$$q = q_{pipe} + \left(R \times 233.402 \frac{kW \cdot sec}{L}\right) \qquad \text{(Equation E-6 (SI))}$$

$$q = q_{pipe} + \left(R \times 50{,}000 \frac{Btuh}{gpm}\right) \qquad \text{(Equation E-6 (IP))}$$

The new value of q can then be inserted into Equation E-3 to determine the required flow rate for the pump. Compare this flow rate with the minimum flow rates required for boiler or water heater operation and require the larger of the two values. Once the required flow rate is known, the pressure drop for the circulation pump can be determined. The resources listed in E-3.2.4 (Pipe Sizes) give adequate information on calculating the pressure drop through the piping. However, several manufacturers must be contacted to determine the pressure drop through the water heater or boiler. This value will vary widely between different manufacturers. Therefore, the circulation pump must be sized to overcome the highest pressure drop.

However, flow rates over or under those required by the boiler or water heater manufacturer can reduce the efficiency of the unit. As a result, the drawings must indicate the pump characteristics used for the design. Then add a note indicating that the pump is to be sized by the boiler or water heater manufacturer with the horsepower requirements not to exceed those listed in the schedule.

D-3.3.4 Heat Exchanger.

If a heat exchanger is used, size the circulation pump based on the flow required for the heat exchanger to meet the recovery calculated in Equation E-3 and the heat lost through the piping.

D-3.4 Sample Calculations.

D-3.4.1 Given.

h = 36 shower heads
occ = 2 occupants per shower
T_d = 43°C (110°F)
T_s = 60°C (140°F)
T_c = 4.4°C (40°F)
M = 75% useable tank capacity
ΔT = 5K (9°F) Maximum temperature drop through distribution system.
ΔT_t = 54K (97°F)

Piping system consists of:

- 9 meters of DN50 pipe
- 6 meters of DN25 pipe
- 15 meters of DN20 pipe

A separate tank and hot water boiler will be used.

q_{pipe} = 0.10 kW = 341.18 Btuh

D-3.4.2 Find.

(a) Peak domestic hot water demand, L (gal).
(b) Storage tank size, L (gal).
(c) Recovery rate required given the tank size selected, L/s (gph).
(d) Flow rate required for domestic hot water circulation pump.
(e) Flow rate required for boiler circulation pump.

D-3.4.3 Solution.

(a) Peak Domestic Hot Water Demand:

$$V_p = (h)\ (occ)\ \left(\frac{90}{occupant}\right)\left(\frac{T_d - T_c}{T_s - T_c}\right)$$

$$= (36\ heads)\left(\frac{2\ occupants}{head}\right)\left(\frac{90\ L}{occupant}\right)\left(\frac{43°C - 4.4°C}{60°C - 4.4°C}\right)$$

$$= 4499\ L\ (1{,}188\ gal)$$

(b) Initial Storage Tank Size:

$$S_t = (36\ heads)\left(\frac{2\ occupants}{head}\right)\left(\frac{50\ L}{occupant}\right)$$

$$= 3600\ L\ (951\ gal)$$

Use 2 tanks of 1893 L (500.0 gal) each to fit into the available space.

(c) Initial Recovery Rate:

$$d = \left(\frac{9.5\ min}{occupant}\right)(2\ occupants)\left(\frac{60\ sec}{min}\right)$$

$$= 1140\ sec$$

$$R = \frac{4499L - (75\% \times 2\ each \times 1893L)}{1140\ sec}$$

$$= 1.46\ Lps\ (1{,}388\ gph\ or\ 23\ gpm)$$

(d) Flow rate for domestic hot water circulation pump (heat loss through piping is 0.629 kW):

$$Q_p = \frac{0.629\ kW}{\left(4.1679\ \frac{kW\ \cdot sec}{L\ \cdot K}\right)\ 5K}$$

$$= 0.0302\ L/s\ (0.48\ gpm)$$

(e) Flow rate for boiler circulation pump:

$$q = q_{pipe} + \left(R \times 233.402 \frac{kW\ \cdot sec}{L}\right)$$

$$= 0.1\ kW + \left(1.46 \frac{L}{sec} \times\ 233.402 \frac{kW\ \cdot sec}{L}\right)$$

$$= 340.87\ kW$$

$$Q_p = \frac{340.87\ kW}{\left(4.1679 \frac{kW\ \cdot sec}{L\ \cdot K}\right) 16K}$$

$$= 5.11\ L/s\ (81.0\ gpm)$$

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 REISSUES AND CANCELS

This UFC reissues and cancels UFC 3-420-02FA, 15 May 2003.

1-2 PURPOSE AND SCOPE.

The intention of this UFC is to provide criteria to achieve economical, durable, efficient, and dependable compressed air systems to support Tri-Service facilities. Utilize industry standard practices for sizing and selecting equipment, components, fittings, piping, etc. except as otherwise noted in this UFC. Non-Government standards form the foundation of criteria requirements as represented in MIL-STD-3007G (General Requirements, figure 1). Refer to MIL-STD-3007G as DoD policy authority to adopt non-government standards (NGS).

1-3 APPLICABILITY.

This UFC provides criteria for the provision and design of low pressure compressed air systems with a maximum design operating pressure of 125 psig (8.62 barg), including piping, compressors, aftercoolers, separators, air receivers, and air dryers. For medium and high pressure compressed air systems, refer to CAGI and the ASME Piping Series (B31.1 and B31.3) for further guidance.

This UFC is applicable to all service elements and contractors involved in the planning, design, and construction of DoD facilities worldwide. Where conflicts in requirements appear between sections of any mechanical UFC or applicable codes or laws, the most restrictive requirement will govern.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4.1 Additional Requirements.

Use this UFC in conjunction with UFC 3-401-01 and the UFCs and government criteria referenced therein. This includes, but is not limited to, taking the following into consideration: maintainability; site location (weather, elevation, air cleanliness, etc.); conflicts in design criteria; and control system integration. Please refer to UFC 4-510-01 for Medical Gas Systems, including Dental Compressed Air and Medical Compressed Air.

1-4.2 Environmental Severity and Humid Locations.

In corrosive and humid environments, provide design detailing, and use materials, systems, components, and coatings that are durable and minimize the need for preventative and corrective maintenance over the expected service life of the component or system. UFC 1-200-01, section titled “Corrosion Prone Locations” identifies corrosive environments and humid locations requiring special attention. UFC 1-200-01, section titled “Requirements for Corrosion Prone Locations” provides examples of necessary actions. To determine Environmental Severity Classifications (ESC) for specific project locations refer to UFC 1-200-01 Appendix titled “Environmental Severity Classifications (ESC) for DoD Locations”.

1-5 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

Cybersecurity is implemented to mitigate vulnerabilities to all DoD real property facility-related control systems to a level that is acceptable to the System Owner and Authorizing Official. UFC 4-010-06 provides requirements for integrating cybersecurity into the design and construction of control systems.

1-6 DESIGN GUIDANCE.

The leading compressed air standards organization in the USA is the Compressed Air and Gas Institute (CAGI). Utilize CAGI's Compressed Air and Gas Handbook for design guidance, best practices, and calculation procedures in conjunction with this UFC. Figure 4-1 illustrates the arrangement of a typical compressed air system. As an additional resource of technical information on compressed air systems, please refer to the Army Technical Manual TM-5-810-4/Airforce Manual 88-8, Chapter 3 which can be found on the Whole Building Design Guide (https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-420-02).

1-7 BEST PRACTICES.

APPENDIX A contains information that is considered best practice based on experience and lessons learned.

1-8 GLOSSARY.

APPENDIX B contains acronyms and abbreviations.

1-9 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 BASIC PRINCIPLES.

2-1.1 Life Cycle Consideration.

Energy and water-efficient and sustainable design attributes for military construction must be based on the cost-benefit analysis, return on investment, total ownership costs, and demonstrated payback. Provide mechanical systems based on achieving the lowest life cycle cost of the approved alternatives. Ensure that all operation and maintenance costs are included in any life cycle cost analysis.

Follow procedures for Life Cycle Cost Analysis (LCCA) stated in UFC 1-200-02. In selecting alternatives for analysis, give preference to features and systems with lower complexity and maintenance burden. Do not include alternatives for which it is clear, prior to LCCA that the cost exceeds the potential savings based on historic information or engineering judgment. Where such alternatives were considered, but not analyzed, identify those alternatives and provide an explanation.

2-1.2 Energy Conservation.

Utilize Life Cycle Cost Effective (LCCE) strategies in design and operation of compressed air systems. Energy Conservation Best Practices are discussed further in APPENDIX A.

2-1.3 HVAC Considerations.

Provide heating, ventilating, and air conditioning systems to maintain space temperatures within acceptable ranges for the compressed air systems. Refer to APPENDIX A for design considerations.

2-1.4 Electrical Considerations.

Provide electrical systems for compressed air systems and components thereof in accordance with UFC 3-501-01 & UFC 3-520-01.

2-1.5 Noise and Sound Considerations.

Determine the sound power levels for each piece of equipment used for compressed air systems. Use this information to predict the acoustic characteristics and the resulting ambient noise level. Refer to UFC 3-101-01 and appropriate facility-type UFCs for sound transmission requirements (STCs) into adjacent building spaces.

For additional information on noise control refer to UFC 3-450-01.

2-1.6 Breathing Air Systems

Breathing Air systems must deliver Grade D breathable air in accordance with CGA G-7.1-2018. Table 2-1 is derived from OSHA Standard 29 CFR 1910.134(i)(1) which lists minimum criteria of Grade D air. Coordinate Breathing Air System design with the stakeholders to ensure equipment, materials, design, and configuration comply with local regulations and requirements (for example, Tinker Air Force Base INSTRUCTION 48-103 “RESPIRATORY PROTECTION PROGRAM”).

Table 2-1 Minimum Grade D Breathing Air Characteristics

Component	**Criteria**
Oxygen Content (volume/volume)	19.5% - 23.5%
Hydrocarbon (condensed)	<= 2-gr/ft^3 (5 mg/m^3)
Carbon Monoxide (CO)	<= 10 parts per million (ppm)
Carbon Dioxide (CO2)	<= 1,000 ppm
Odor	Lack of a noticeable odor

CHAPTER 3 COMPRESSED AIR SYSTEM COMPONENTS

3-1 INTRODUCTION.

Compressed air systems are comprised of multiple components, including but not limited to air intakes, intake filters, compressors, aftercoolers, wet receivers, dry receivers, valves, air dryers, condensate removal, regulators, oil separators, and lubricators.

3-1.1 Redundant Systems.

When a system failure would result in unusually high repair costs, or replacement of process equipment, or when activities are disrupted that are mission critical, the designer must provide redundancy requirement analysis to support the justification of redundancy.

3-1.2 Air Intakes.

The intake for a compressor will be located either outdoors or indoors, whichever provides better air quality. All air compressors are sensitive to dust and airborne vapors which can form adhesive, abrasive, and corrosive mixtures within the compressor. These contaminants build up in rotating parts and can induce excessive wear and mechanical unbalance, thereby damaging the compressor.

- Locate air intakes outside of the building where practicable (save for breathing air systems which must always be located outside of the building). Locate the air intake at least 6-feet (2 m) above the ground or roof level. Position intake pipes to prevent entrance of snow or rainwater. If the intake would be subject to adverse weather conditions, provide a hood or louver for protection therefrom. Locate intakes far enough away from steam, gas, or oil engine exhaust pipes to ensure that the intake air is free of moisture or pollution.
- Locate intakes for reciprocating compressors at least 3-feet (1 m) away from any wall to minimize the pulsating effect on the structure. Provide an intake filter silencer or a pulsation damper.
- Do not locate compressor air intakes within an enclosed courtyard.

3-1.2.2 Intake Pipe Materials.

Provide plastic, copper, stainless steel, aluminum, or galvanized steel for air intake pipes. Utilize mechanical couplings for metallic pipe. Welded joints are prohibited.

3-1.2.3 Intake Air Filter.

Select air filters based on manufacturer’s recommendations for the type of compressor (for example, lubricated or non-lubricated) and based on the ambient air quality. Provide the necessary stages of filtration required to ensure the air entering the compressor is within the compressor manufacturer's recommendations, accounting also for the purpose of the compressor (for example, breathing air versus shop air).

3-1.2.4 Pressure Drop.

Provide a means to monitor the pressure drop across the inlet air filters. Coordinate with end user as to the level of detail required (for example, a binary input dirty filter switch versus directly measuring the pressure drop).

3-2 COMPRESSORS.

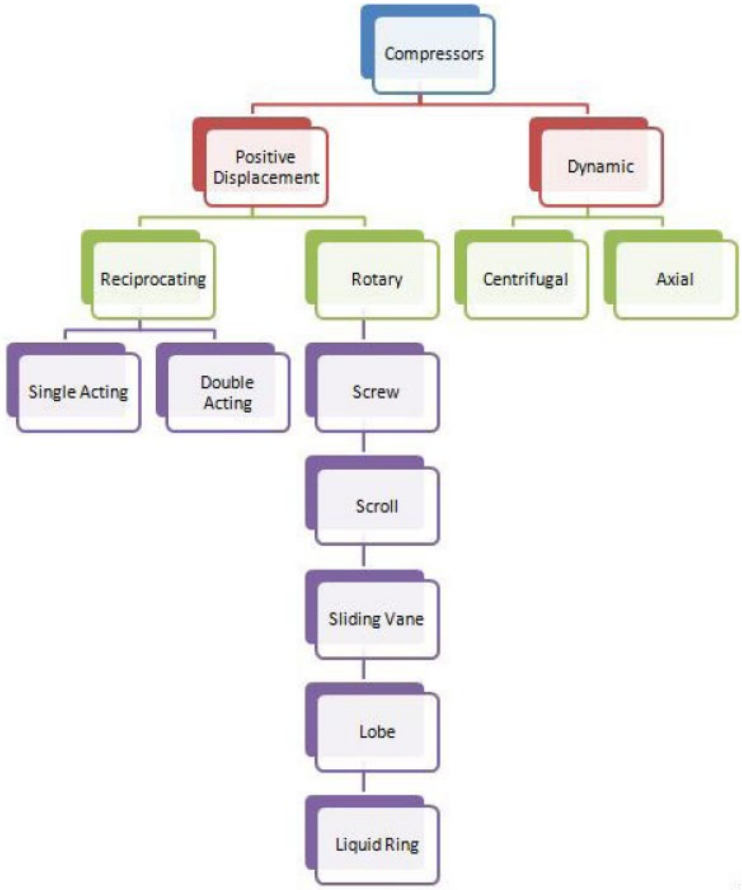
Utilize a central compressed air system whenever it is economically feasible as determined via a Life Cycle Cost Analysis. Compressors and all accessories must conform to ANSI/CAGI B19.1 and ASME B19.3, ASME BPVC Section VIII, PTC-9 & PTC-10, and ISA 7.0.01-1996, as applicable.

Where lubricating oils cannot be tolerated at the point of use, oil-free air compressors must be used. Oil-free air is required for such end uses as food handling, medical and dental application, chemical processing, and instrument air for pneumatic controls. Breathing air must be oil-free unless otherwise permitted by the end-user (for example, Contingency Operations).

3-2.1 Compressor Types.

Perform an analysis for each compressor to ensure that the best value is obtained by comparing such items as brake horsepower (bhp) per 100 cubic feet per minute (cfm) (kilowatt (kW) per cubic meter per minute (m^3/min)), unloaded horsepower (kilowatt), expected compressor life, and expected operation and maintenance costs. See Figure 3-1 for type of compressors. Typical applications for each type of compressor can be found in TM 5-810-4.

Figure 3-1 Types of Compressors



Courtesy of the Compressed Air and Gas Institute (CAGI)

3-2.2 Capacity.

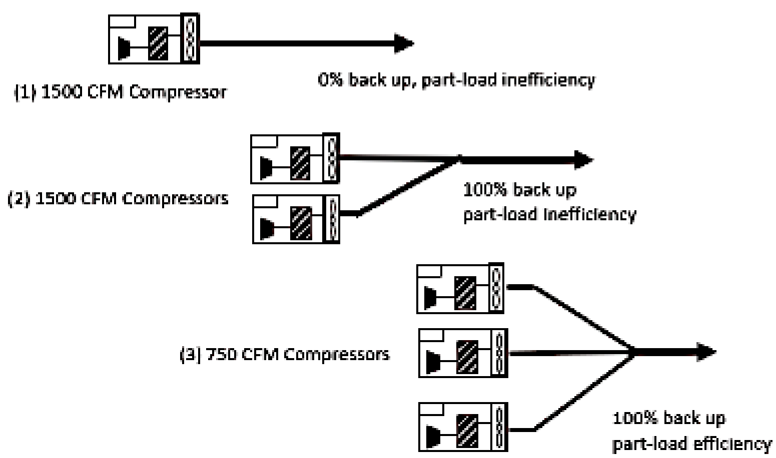
Size compressor based on the sum of the average air consumption of the end use devices, not the sum of the maximum air consumption (that is to say, utilize a load factor in determining compressor capacity). Utilize the CAGI Handbook, along with user input, to determine load factors.

Add an additional 10% to the estimated consumption to account for system leakage.

3-2.3 Multi-staging.

Multistage compressors may be used; however, only if LCCE. If multistage compressors are used, intercoolers must be used. An economic evaluation is necessary to determine whether a central compressed air distribution system or a system of separate compressors located near the point of usage is most cost-effective. Selection of the number of compressors for either situation must be based upon economics and other factors such as system reliability. Seasonal or operational load variations must also be considered. The efficiency of larger compressors is generally higher than that of smaller units but use of smaller air-cooled units permits savings on water, water piping, and system losses. Multiple units with interconnecting piping give flexibility for maintenance shutdown of one compressor. A smaller air compressor to handle requirements for weekends, holidays and other low usage times may also be economical (see Figure 3-2).

Figure 3-2 Multiple Compressor Installation



Courtesy of the Compressed Air and Gas Institute (CAGI)

3-2.4 Location.

Locate compressor(s) in a clean, well-lit, and ventilated area of sufficient size to permit easy access for cleaning, inspection, and any necessary dismantling (for example, removal of pistons, wheels, crankshafts, intercoolers, motors, and drivers). Provide aisle space between equipment for normal maintenance as well as for equipment removal and replacement as recommended by the manufacturer and code.

The temperature of the room in which air-cooled compressors are located must not exceed 100°F (38°C) or the maximum inlet air temperature specified by the compressor manufacturer, whichever is lower.

3-2.5 Automatic Warning and Shutdown.

Protect air compressor systems against high temperature, high pressure, and low oil pressure. In the case of centrifugal compressors, provide protection against excessive vibration. Protective controls will include a fault indicator and a manual reset device.

3-2.6 Vibration Limits.

To obtain guidance for establishing centrifugal compressor vibration levels, please contact manufacturers.

Flexible connectors, such as flexible metal hose, must be used to connect the discharge piping system to the air compressors.

3-2.7 Lubrication System.

System design will be in accordance with the manufacturer's recommendations. Lubricant type will depend on the compressor application:

- Gravity, splash, or pressure petroleum oil must be used where oil contamination of the compressed air at the point of use is not a problem.
- Synthetic liquid lubricants must be used where there is a danger of fire, where the carbonaceous deposits must be reduced, or where lubricant is provided for extended maintenance periods
- Solid lubricants, such as carbon or Teflon piston rings, must be used for oil-free reciprocating compressed air applications.

3-3 AIR DISCHARGE PIPE.

3-3.1 Critical Pipe Length.

Determine critical pipe lengths of the air discharge pipe by coordinating with air compressor manufacturers. Critical pipe lengths must be avoided to prevent resonance.

3-3.2 Surge Volume.

Provide pulsation dampers or surge bottles at the discharge of reciprocating compressors if LCCE.

3-3.3 Safety Provision.

Provide a safety valve between a positive displacement compressor discharge and any isolation valve or other flow restricting device, as well as between the compressor and an internally finned tube aftercooler. The safety valve or valves will have a total capacity sufficient to handle the entire output of the compressor. Connect safety valves directly into the piping without unnecessary additional piping or tubing. Direct safety valve discharge away from personnel areas and traffic lanes.

3-4 AFTERCOOLER AND SEPARATOR.

3-4.1 Circulating Water.

When water-cooling is provided or required, provide the required waterflow through the intercooler, cylinder jacket, and aftercooler for cooling the compressor, cooling the compressed air, and for moisture removal. Provide controls and components to prove waterflow (for example, flow switch or differential pressure sensor) to ensure that sufficient cooling water is flowing before the compressor is allowed to start. Water for the aftercooler for liquid seal rotary compressors must be piped in series with the compressor. Waterflow for rotary screw compressors and rotary lobe compressors is not required prior to startup. Design the pipes to conform to the manufacturer's recommendations. Use a strainer or filter in the piping system to reduce fouling of the cooler system components.

Ensure cooling water temperature entering compressor cylinder jackets is at least 15°F (8.3°C) above the inlet air dew point to prevent condensation from forming in the cylinder inlet ports. Consult with a compressor manufacturer to verify the cooling water requirements for cooling compressor cylinder jackets.

3-5 AIR DRYER.

Provide air dryers where required. Coordinate the required air dew point temperature with customer and as required by the application (for example, very low dew point air for piping exposed to freezing where heat tracing is not practicable.).

3-5.1 Dryer Types.

In determining the type of dryer to be used for a given application, drying requirements, flow pressure, inlet temperatures, and the pressure dew point must be accurately determined. Select the dryer that meets these requirements most economically and efficiently. The various drying methods are as follows:

a. Refrigeration. Refrigeration dryers remove moisture from compressed air by cooling the air in a heat exchanger. This condenses and removes the moisture from the airstream and produces an operating pressure dew point at the dryer outlet in the range of 35°F to 39°F (2°C to 4°C). By adjusting the refrigeration unit operating parameters, these units can produce pressure dew points of 50°F (10°C). Higher dew points are available in either direct refrigeration or chiller-type design. The temperature of the room in which an air-cooled refrigerated dryer is located must not exceed 100°F (38°C) or the maximum inlet air temperature specified by the compressor manufacturer, whichever is lower.

b. Twin-tower regenerative. Regenerative dryers utilize non-consumable desiccants to remove moisture form the inlet air while the other is being regenerated (typical dew point ranges from -150°F up to 33°F (-101°C up to 1°C)). This method of regeneration includes the following dryer classifications:

    (1) Heatless desiccant regeneration passes a quantity of dried (purge) air through the off-stream bed. No external heat is applied. This type, with a field-adjustable purge control must be selected so that purge rate (and therefore pressure dew point) can be adjusted to accommodate seasonal variation in ambient temperatures, thereby reducing operating costs. Provide prefiltering to remove oil from the air stream to minimize future desiccant replacement.

(2) Heat regenerative dryers utilize heat from an external source (either electric or steam) in conjunction with purge air to regenerate the off-stream tower.

c. Deliquescent. Deliquescent (salt pellet) dryers and ethylene glycol stills are mentioned here for general information purposes only and must not be used.

A summary of typical applications for the above dryers are illustrated in Figure 3-3.

Figure 3-3 Air Dryer Types

Type of Dryer	Pressure Dew Point Range	Typical Applications	Initial Cost	Operating Cost	Remarks
DELIQUESCENT					
	12-20°F below inlet temperature	Protection against condensation in indoor air lines.	Lowest	Low to moderate	Causes high maintenance of downstream equipment due to salt solution in air lines.
REFRIGERATED					
	Above 33° F	General plant air, air-operated tools, instruments; materials conveying.	Low	Lowest	Most widely used type of air dryer because of its inherent reliability and low cost factor.
TWIN-TOWER REGENERATIVE					
Heatless Desiccant	Below 33°F (down to minus 150°F)	Outside air lines; chlorine padding; manufacturing processes requiring very dry air such as assembling electronic components and making urethane foam.	Low to moderate	Highest	Inefficient operation due to high purge rate.
Heat Regenerative	Below 33°F (down to minus 150°F)	Outside air lines; chlorine padding; manufacturing processes requiring very dry air such as assembling electronic components and making urethane foam.	Moderate to high	Moderate to high	Minimum air waste for high flow, low dew point applications.

Century Park, New Castle, Delaware

3-5.2 Prefilters and After-Filters.

Consideration must be given to providing a prefilter upstream of the air dryer. A prefilter may be required to remove compressor carry-over oil and other undesirable particles from the air prior to the air entering the air dryer. This filter can extend the life of the air dryer and reduce air dryer maintenance costs. An air filter must be considered to protect the downstream piping system and equipment from impurities and undesirable particles added to the air as a result of passing through the air dryer. Consult the air dryer manufacturers for recommendations and selection of prefilters and after filters for specific air quality requirements.

3-6 AIR RECEIVER.

Air receivers must be constructed in accordance with ASME BPVC Section VIII. Provide both a wet receiver and a dry receiver for applications that require dry air. Tank mounted compressors do not require wet and dry storage.

3-6.1 Determining Receiver Size.

Determine the appropriate receiver size after establishing the air compressor capacity. Size the receiver in accordance with the recommendations of the CAGI Handbook or the compressor manufacturer's recommendations. If the compressor manufacturer's literature recommends a larger air receiver, then provide the larger receiver.

3-6.2 Installation.

Install each receiver on a dry equipment pad. Provide space around each unit to facilitate draining, inspection, and maintenance. When a receiver is located outside, install the safety valve and pressure gauge indoors to prevent freezing. Heat trace the associated outdoor piping and arrange piping to drain back to the receiver. Where an automatic condensate trap is used with a receiver located outdoors, locate the trap indoors and heat trace the outdoor piping, or provide the outdoor trap and piping with electric heat tape to protect them from freezing.

3-7 PIPING.

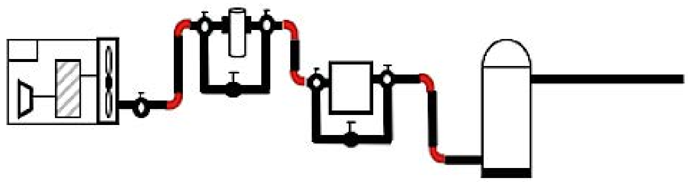
3-7.1 Materials.

- Steel compressed air piping must be a minimum of Schedule 40 and be galvanized, black, or stainless steel. Pipe fittings will be galvanized, black, or stainless steel, to match piping used. Fittings must be threaded, flanged, or welded type. Grooved fittings may only be used if permission is received by the Authority Having Jurisdiction.
- Copper compressed air piping or tubing will be Type K or Type L with brazed joints. Brazing filler metals with melting temperatures between 1,000°F (537.8°C) and 1,600°F (871.1°C) will be used.
- Thermoplastic piping system for transport or storage of compressed air will not be allowed. Safety records show that leaks in this type of pipe (when used for compressed air service) have caused the pipe to rupture, causing serious injury to personnel and/or property damage.

3-7.2 Loss of Air Pressure Due to Friction.

The maximum allowable pressure drop from the compressor to the most distant point of use must not exceed 5 percent. Utilize equivalent lengths of pipe to account for fittings, valves, and other minor losses.

Figure 3-4 Piping Loss Calculation



Pipe length calculation

	Piping and Equivalent Length Fitting Adjustment	
	2" piping and components	3" piping and components
Piping	500'	500'
5 Gate Valves	6.05 equivalent feet 1.21 x 5	8.95 equivalent feet 1.79 x 5
6 Long Radius Elbows	12.42 equivalent feet 2.07 x 6	18.42 equivalent feet 3.07 x 6
Total Piping	**518.47 feet**	**527.37 feet**

Pressure drop calculation

	pressure drop @ 500 cfm with 2" piping and components	pressure drop @ 500 cfm with 3" piping and components
Piping	9.95 psid 518.47/1000 x 19.2 psid	1.23 psid 527.37/1000 x 2.34 psid
Filter	2 psid	2 psid
Dryer	3 psid	3 psid
System Total	**14.95 psid**	**6.23 psid**

System conditions and assumptions

- 500 cfm compressor, fully loaded
- 50' of pipe in compressor room
- 450' of pipe in distribution header
- 5 open gate valves
- 6 long radius elbows
- Pipe is schedule 40 steel
- Filter pressure drop is 2 psid
- Dryer pressure drop is 3 psid

Courtesy of the Compressed Air and Gas Institute (CAGI)

3-7.3 Piping Layout.

Arrange piping system in a closed loop or “ring main” where possible. Provide dedicated main air lines to services requiring heavy air consumption and that are long distances from the compressor unit. Install piping parallel with the lines of the building, with main and branch headers sloping down toward a dead end. Install traps in airlines at all low points and dead ends to remove condensed moisture.

- Branch headers from compressed air mains, and all other takeoffs, must be taken off at the top to avoid picking up moisture.
- A strainer or filter and a lubricator must be provided in piping that serves tools.
- Provide all end points with a filter/strainer, pressure regulator, and dryer/lubricator (depending on end use application). Provide pressure gauges upstream and downstream of pressure regulator if a pressure gauge is not integral to the regulator. Provide filters and dryers with automatic drains.

- Provide service drops with isolation ball valves.
- Provide end point quick connect couplings compatible with end user equipment.
- Coordinate service drop locations and configurations with end user.

3-8 CONTROL SYSTEM.

Compressed air system controllers must be integrated into the building automation system (BAS) where a BAS is available; to the extent of which the compressor controls are capable; and to the extent of the user’s needs. For example, a rotary screw compressor may be provided with web-based controls from the manufacturer that can display operating conditions and permit remote modification and control; however, manufacturers might only offer auxiliary contacts and relays to facilitate remote monitoring for tank mounted reciprocating compressors. Integrate air dryers into the BAS to monitor operating status, faults, alarms, and leaving compressed air dry bulb temperature and dew point.

- Align the control features and needs provided with a compressed air system with the end-user and Installation during design development.
- If a BAS is not available, provide the compressor with the means to facilitate future integration. Compressor controller must natively communicate using open protocols (BACnet, LON, or MODBUS) using standard objects and services, or provide a gateway to facilitate the aforementioned communication.
- Refer to UFC 3-410-02 and UFC 4-010-06 for additional control requirements.
- These requirements do not apply to portable air compressor units.

3-9 SOUND TESTS.

After installation, perform a sound test on all compressors and accessories in accordance with UFGS 22 05 48.00 20. Sound reading test results must not exceed limitations set by OSHA Standard 1910.95.

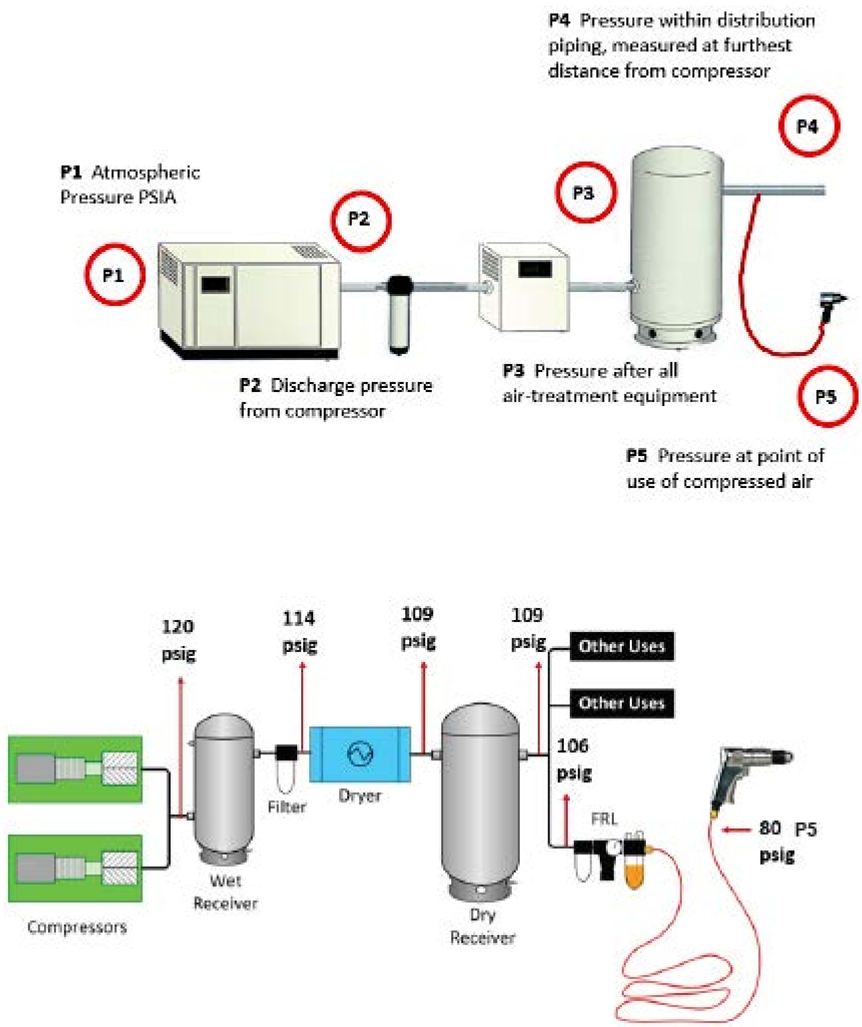
CHAPTER 4 GENERAL DESIGN AND EQUIPMENT SCHEDULES

4-1 DESIGN ANALYSIS.

The following items must be included in the design analysis:

- Equipment redundancy requirements for critical system operation.
- Application (hospital, industrial, etc.)
- Maximum operating pressure required
- Location of air requirement in buildings
- Total compressed air flow and compressor sizing calculation including, but not limited to adjustments for altitude, moisture, temperature, and additional environmental factors that impact the compressed air system design.
- Heat Rejection Rates and rejection methods (for example, heat rejected to space, remote radiator, or other)
- Makeup/intake air system(s) design, including calculations.
- Air usage continuous or intermittent demand
- Operating pressure dew point requirement
- Dryer type selection and justification
- Air filtration needs at points of use
- Need for oil-free air
- Life Cycle Cost Analyses performed in accordance with UFC 1-200-02.
- Pressure drop calculations due to components, fittings, and piping from compressor outlet to end point devices (see Figure 4-1).
- List end point air consumption rates with corresponding minimum operating pressure requirements. If used, provide diversity factors for each corresponding end point load.
- Consider the Best Practices enumerated in APPENDIX A and document in the design narrative/analysis the best practices incorporated into the design. Include justification/rationale in the design narrative when a best practice is not incorporated into the design.

Figure 4-1 Design with the End in Mind



Courtesy of the Compressed Air and Gas Institute (CAGI)

4-2 EQUIPMENT SCHEDULES.

Equipment schedules will be shown on the drawings, including the following:

4-2.1 Air Compressor.

a. Capacity in standard cubic feet of air per minute (SCFM) (standard cubic meters per minute (Standard m^3/min))

b. Inlet air pressure in psia (bar)

c. Discharge pressure in psia (bar)

d. Ambient air temperature range with coincident humidity in gr/lb (g/kg)

e. Heat rejection type (water/oil/air cooled)

f. Heat Rejection characteristics (for example, for air-cooled: btu/h (kW), CFM (m^3/min), and temperature difference).

g. Minimum motor power in horsepower (kW)

h. Volts, phase, frequency

i. Minimum Circuit Ampacity

j. Maximum Overcurrent Protection Device in Amps

k. Type of Compressor

l. Number of Compressors

m. Oil-free or not oil-free

n. Accessory list

o. Spare parts list

4-2.2 Air Receiver.

a. Type (wet or dry)

b. Capacity in ft^3 (m^3)

c. Design Pressure in psia (bar)

d. Orientation: horizonal or vertical

e. Diameter in feet and inches (mm)

f. Length in feet and inches (mm)

g. Accessory list

h. Spare parts list

i. Drain type

j. Accessories

4-2.3 After Cooler-Separator.

a. Water-cooled

  i. Capacity in cfm (m^3/min) and psig (barg)

  ii. Dew point temperature entering and leaving in °F (°C)

  iii. Length in inches (mm)

  iv. Diameter in inches (mm)

  v. Cooling water

    1. Flow rate in gpm (L/s)

    2. Inlet Temperature in °F (°C)

    3. Outlet Temperature in °F (°C)

4. Fluid Type (for example, water, glycol, etc.)
5. Percentage of Glycol or level of freeze protection required

vi. Accessory list

vii. Spare parts list

b. Air-cooled

i. Capacity in cfm (m^3/min) and psig (barg)

ii. Compressed air inlet temperature entering after cooler in °F (°C)

iii. Approach temperature in °F (°C)

iv. Ambient air temperature in °F (°C)

v. Minimum fan motor power in horsepower (kW)

vi. Volts, phase, hertz,

vii. Minimum Circuit Ampacity

viii. Maximum Overcurrent Protection Device in Amps

ix. Accessory list

x. Spare parts list

4-2.4 Air Dryer.

a. Type (for example, refrigerated)

b. Capacity (cfm (m^3/min)) and operating pressure in psig (barg)

c. Dew point temperature entering and leaving in °F (°C)

d. Ambient temperature in °F (°C)

e. Volts, phase hertz (if applicable)

f. Refrigerant Type (if applicable)

g. Approx. Refrigerant Charge (if applicable)

h. Regeneration air flow in cfm (m^3/min)

i. Regeneration air temperature in °F (°C)

j. Regeneration Heater Input in btu/h (W) (if applicable)

k. Accessory list

l. Spare parts list

m. Drain type

APPENDIX A BEST PRACTICES

The Best Practices Appendix is considered to be guidance and not requirements. Its main purpose is to communicate proven facility solutions, systems, and lessons learned, but may not be the only solution to meet the requirement.

A-1 ENERGY CONSERVATION MEASURES.

To the extent practicable and LCCE, consider the following energy conservation measures:

A-1.1 Compressors.

a. Variable speed compressor(s).

b. Multiple compressors versus a single compressor (for example, if demand differs significantly on nights and weekends versus during weekday daytime demand, then multiple small compressors may be a LCCE solution than a single large single speed compressor).

c. Shut down idling compressors.

d. Utilize heat from compressors to provide compressor room heating in winter.

e. Select an air compressor with a pneumatic load- unload feature that, when fully unloaded, consumes approximately 15 percent of the base load horsepower.

f. Use waste heat from the oil cooler to heat makeup air or for building space heating during the heating season.

g. When economically justifiable, use multistage compression with intercoolers.

h. Integral size motors must be the premium efficiency type in accordance with NEMA MG 1.

i. Provide a dedicated room for air compressors.

A-1.2 Aftercooler with Separator.

a. Aftercooler selection must be based on degree of drying required downstream of the aftercooler. Final discharge air temperature of the aftercooler will affect dryer sizing and can reduce both the initial and operating costs of compressed air dryers.

b. Duct air from air cooled aftercoolers to provide space heating in winter and to remove heat form the plant in summer. Pipe coolant water to recycle waste heat.

A-1.3 Filters and Dryers.

a. Improve air quality only to the degree required at the point of use. If air quality requirements differ at various points of use, specify appropriate filters or dryers in applicable branch lines.

b. Accurately determine the dew point required at each point of use since that affects the selected type(s) and size(s) of dryer(s).

c. Room air temperatures will affect drying efficiency. If practicable, locate dryers where ambient temperature will not exceed 100°F (38°C).

d. Select dryer in conjunction with aftercooler so inlet air temperature to the dryer can be as low as feasible. Keep inlet pressure as high as possible. Accurately determine operating temperature and pressure, since even minor changes in either can result in substantial operating costs.

A-1.4 Air Leakage.

a. Maximum acceptable air leakage rate for a compressed air system must not exceed 10 percent of the installed system flow rate. Air leaks occur most often at pipe joints. Hose connections, and equipment connections; and are usually a result of poor maintenance practices and/or inadequately trained maintenance personnel.

b. Specification of quality materials and workmanship are a major contribution the designer of a compressed air system can provide for a safe and relatively leak-free air system. In addition, designing the compressed air system with minimum piping and pipe joints, will reduce potential leakage sources.

A-2 AIR INTAKES.

It is desired that the intake air filter be located on the compressor and piped from the enclosed filter hood to the outside. This method prevents ingestion of foreign material to the internals of the compressor should the piping have a poor joint or other leak upstream of the intake filter.

A-3 AIR COMPRESSORS.

Oil-free air can be obtained by using a centrifugal compressor, which is not lubricated due to its configuration; a water-sealed rotary compressor: or a reciprocating nonlubricated air compressor using carbon or Teflon for piston and packing rings. For isolated cases where oil-free air is required on a compressed air system coalescing filters may be used to remove solids, moisture, and oil from the air stream.

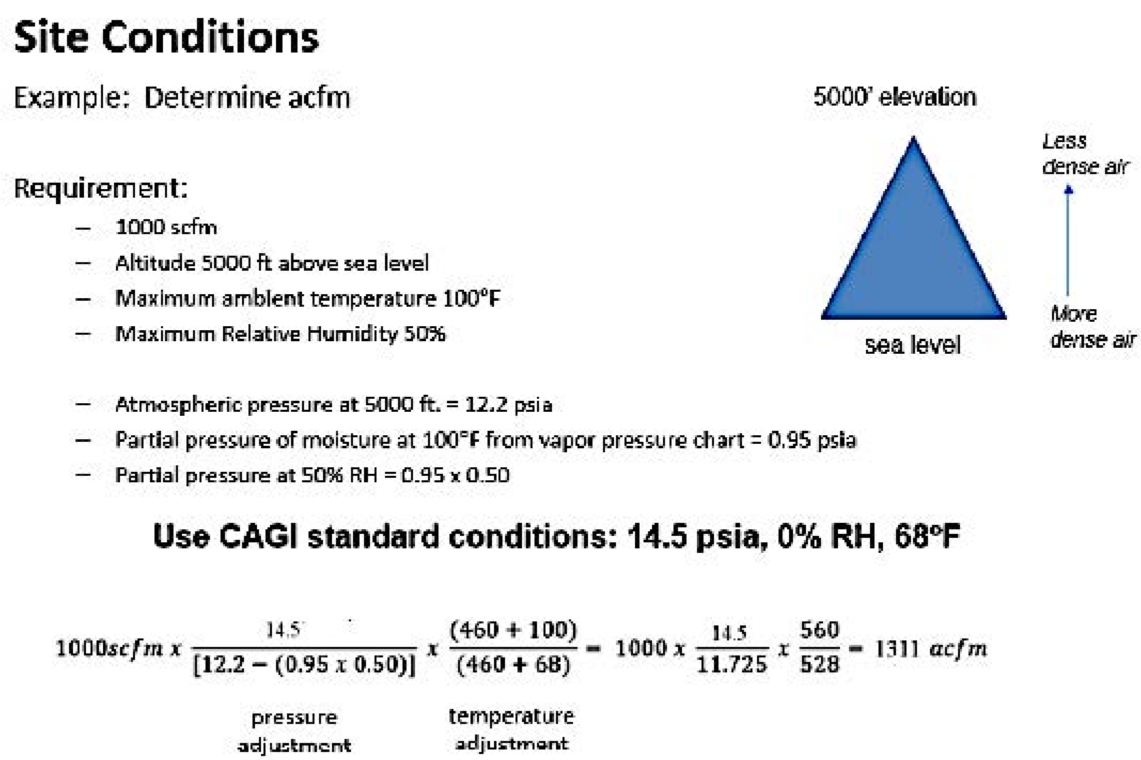
A-4 AIR PRESSURE ADJUSTMENTS.

Converting between actual cubic feet per minute (ACFM) and standard cubic feet per minute (SCFM) can be accomplished using the following equation which is illustrated in Figure A-1 utilizing I-P units of measure.

$$Flow_{act} = (Flow_{std})\left(\frac{P_{std,abs}}{P_{act,abs} - (P_v RH)}\right)\left(\frac{T_{act,abs}}{T_{std,abs}}\right)$$

Where:
$Flow_{act}$ = Actual Flow Rate in CFM (m³/minute)
$Flow_{std}$ = Standard Flow Rate in CFM (m³/minute)
$P_{std,abs}$ = Standard Pressure (Absolute) in PSIA (bar)
$P_{act,abs}$ = Actual Pressure (Absolute) in PSIA (bar)
P_v = Partial Pressure of Moisture in Air at Actual Temperature in PSIA (bar)
RH = Actual Relative Humidity
$T_{act,abs}$ = Actual Temperature (Absolute) in Rankine (Kelvin)
$T_{std,abs}$ = Standard Temperature (Absolute) in Rankine (Kelvin)

Figure A-1 Flow Rate Adjustments



Courtesy of the Compressed Air and Gas Institute (CAGI)

A-5 AIR RECEIVER SIZING.

Oversizing dry receivers by at least 10% may reduce the risk of running out of dry air if an unusual period of high demand exceeds the amount of usable storage.

A-6 AUTOMATIC BLOW DOWNS & DRAINS.

Blow downs and drains must be the automatic type to conserve energy. Typical locations include, but are not limited to, air receivers, filters, and dryers.

APPENDIX B GLOSSARY

B-1 ACRONYMS.

ACFM	Actual Cubic Feet per Minute
AFCEC	Air Force Civil Engineer Center

B-2 DEFINITION OF TERMS.

Actual Cubic Feet Per Minute (Actual Cubic Meters Per Minute): The flow rate of air expressed in terms of actual conditions, that is at non-standard conditions.

Standard Conditions: For the purposes of this UFC, standard conditions are taken to be those of CAGI: Standard Pressure of 14.5 psia (1 bar); Standard Dry Bulb Temperature of 68°F (20°C); Standard Humidity of 0% Relative Humidity.

Standard Cubic Feet Per Minute (Standard Cubic Meters Per Minute): The flow rate of air expressed in terms of standard conditions.

This UFC supersedes TI 810-32 dated 10 January 2002. The text of this UFC is the text of TI 810-32. The format of this document does not conform to UFC 1-300-01; however, it will be reformatted at the next revision.

FOREWORD

\1\
The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Support Agency (AFCESA) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

Reissued 10 January 2002

FOREWORD

These technical instructions (TI) provide design and construction criteria and apply to all U.S. Army Corps of Engineers (USACE) commands having military construction responsibilities. TI will be used for all Army projects and for projects executed for other military services or work for other customers where appropriate.

TI are living documents and will be periodically reviewed, updated, and made available to users as part of the HQUSACE responsibility for technical criteria and policy for new military construction. CEMP-ED is responsible for administration of the TI system; technical content of TI is the responsibility of the HQUSACE element of the discipline involved. Recommended changes to TI, with rationale for the changes, should be sent to HQUSACE, ATTN: CEMP-ED, 20 Massachusetts Ave., NW, Washington, DC 20314-1000.

TI are effective upon issuance. TI are distributed only in electronic media through the TECHINFO Internet site *http://www.hnd.usace.army.mil* /techinfo/index.htm and the Construction Criteria Base (CCB) systems maintained by the National Institute of Building Sciences at Internet Site *http://www.nibs.org/ccb/*. Hard copies of these instructions produced by the user from the electronic media should be checked against the current electronic version prior to use to assure that the latest instructions are used.

CHAPTER 1

GENERAL INFORMATION

1-1. PURPOSE AND SCOPE. This document provides criteria and guidance for the design and construction of heating and cooling distribution systems and supplements information in the "Notes to the Designer" of the guide specifications. These distribution systems include Heat Distribution Systems in Concrete Trenches, Pre-engineered Underground Heat Distribution Systems, Prefabricated Underground Heating/Cooling Distribution Systems, and Aboveground Heat Distribution Systems. The mediums used in these distribution systems, as defined by the Department of Defense (DoD), include:

a. High temperature hot water (HTHW) (251 deg. F to 450 deg. F)

b. Low temperature hot water (LTHW) (150 deg. F to 250 deg. F)

c. Low pressure steam systems (up to 15 psig)

d. High pressure steam systems (over 15 psig)

e. Condensate return systems (up to 200 deg. F)

f. Chilled water systems.

1-2. APPLICABILITY. These instructions are applicable to all **\2** DoD agencies **/2/** and their contractors involved in the design and construction of heating and cooling distribution systems.

1-3. REFERENCES. Appendix A contains a list of references used in these instructions.

1-4. EXCEPTIONS. Generally, this document covers heating and cooling distribution systems most typically installed on United States military installations. However, deviations from the recommendations of this manual may be necessary when unusual site conditions are present or specific using service requirements are encountered. For example, the manual does not discuss design problems associated with arctic and subarctic construction, in which case, the designer should refer to the "Cold Climate Utilities Manual", 1986, Canadian Society of Civil Engineers, Montreal, Quebec.

1-5. DEFINITIONS. The term "designer" used throughout this manual refers to the person or persons responsible for preparing contract drawings and specifications for a heating or cooling distribution design. The main engineering discipline areas of the "designer" are:

a. Mechanical. Includes expansion compensation, stress analysis, piping system design (fittings, valves, insulation), equipment selection and sizing, and pipe sizing and routing.

b. Structural. Includes reinforced concrete design, pipe supports, and valve manhole cover design.

c. Electrical. Includes cathodic protection, electrical service and controls (e.g. sump pumps).

d. Civil. Includes earth work, road crossings (for buried systems), system plans and profiles, and area drainage designs.

CHAPTER 2

SYSTEM SELECTION

2-1. GENERAL. When designing a heating or cooling distribution system, the designer must first select two critical items: media type and system type.

2-2. DISTRIBUTED MEDIA SELECTION.

a. Connecting to an existing system. Almost all heating and cooling distribution systems will be connected to an existing central distribution system. In this case, the designer most often designs for the media to which it is being connected-HTHW, LTHW, steam/condensate, or chilled water.

b. Installation of new system. When no existing system is present, the designer must select the system that is most appropriate for the end user. High temperature hot water and steam/condensate systems are the most common types of distribution systems currently used on military installations. However, a new system should only use the temperatures and pressures necessary to meet the requirements of the installation. For example, the use of high pressure steam sterilizers or steam kettles at several facilities may require the use of a high pressure steam or HTHW system. However, it is usually much more cost effective (on a first cost and life cycle cost basis) to use a low or medium temperature hot water distribution systems whenever possible and to incorporate stand alone high pressure/temperature systems where required. The lower maintenance costs, safer operation, longer life of systems, and simpler system controls for hot water systems often offset the costs of larger piping required. For further assistance for selecting the system type, refer to ASHRAE Handbook, "HVAC Systems and Equipment."

2-3. SYSTEM TYPES. When selecting a distribution system, the designer must determine which system types apply to a particular medium. The designer must also exclude systems which are not appropriate for a particular site or for which the customer has no interest. Examples of this are locating aboveground systems in non-industrial areas where the installation is sensitive to the aesthetic appearance of the area or routing concrete shallow trench systems through drainage swales or flood plains.

a. Heat Distribution Systems in Concrete Trenches (chapter 4). This system is a buried system with its removable concrete cover installed at grade and will typically be used for HTHW and steam/condensate systems. In rare instances, it may also be used for chilled water and LTHW in the event no plastic piping is installed in the same trench as high temperature (greater than 250 degrees F) piping systems. Experience has shown that if insulation of a high temperature system is compromised, temperatures can increase to such a level and cause damage to the plastic piping.

b. Pre-engineered Underground Heat Distribution Systems (chapter 5). This system is designed for higher pressure and temperature applications. The two types of pre-engineered systems are the drainable-dryable-testable (DDT) type which is used for high pressure steam/condensate and HTHW at all sites, and high temperature hot water at any type of site, and the water spread limiting (WSL) type which is used only for steam/condensate systems in bad and moderate sites. HTHW supply and return lines may be provided in a single casing; however, steam and condensate lines must always be provided in separate casings because condensate lines typically last less than half as long as the steam line and are easier to replace when in a separate casing.

c. Prefabricated Underground Heating/Cooling Distribution System (chapter 6). This system is designed for lower temperature and pressure applications. It is typically used for LTHW, chilled water, or combination LTHW/chilled water systems.

d. Aboveground Heat Distribution System (chapter 7). This system may be used for HTHW, steam/condensate, and LTHW systems, and for chilled water systems where freezing is not a concern.

2-4. SYSTEM SELECTION. The system type selected will be based on the type of media that is distributed.

a. High Temperature Water and Steam/condensate Systems. The order of preference for system types for high temperature and high pressure systems are:

(1) Aboveground Heat Distribution System. This is the least expensive system and historically requires the lowest maintenance and operating costs. However, the safety and aesthetics of an aboveground system are not always desirable and must be accepted by the end user.

(2) Heat Distribution Systems in Concrete Trenches. This is the most dependable of the buried distribution systems. The piping is totally accessible through removable concrete covers, the piping does not come in contact with the soil, and ground water is drained away from the piping system to low point drains. Except in rare instances, this is the system that should be selected if aboveground is not acceptable with the end user.

(3) Pre-engineered Underground Heat Distribution System. This type of buried distribution system should be selected as the last option due to very short system lives which are typically caused by poor drainage, poor corrosion protection, and improper installation. Instances where it would be used would be when aboveground is not acceptable with the end user or when drainage swales and high ground water prevent the installation of a concrete trench system.

b. Low Temperature and Chilled Water Systems. The order of preference for system types for hot water, chilled water or combination hot/chilled water are:

(1) Aboveground Heat Distribution System. This is the least expensive system and historically requires the lowest maintenance and operating costs. However, the aesthetics of an aboveground system are not always desirable and must be accepted by the end user. In addition, aboveground systems are typically not used for chilled water because of potential freezing problems in colder climates and heat gain in warmer areas.

(2) Prefabricated Underground Heating/Cooling Distribution System. This buried distribution system is relatively inexpensive and dependable. The non-metallic casing materials provide excellent protection from corrosion and the lower temperatures and pressures allow the system to operate for extended periods of time. It is an excellent application for chilled water since the system is installed underground, limiting the amount of heat gain to the system.

CHAPTER 3

GENERAL DISTRIBUTION SYSTEM DESIGN

3-1. GENERAL. Some aspects of a heating or cooling distribution system design are similar regardless of the system type. These aspects are covered in this chapter.

3-2. SITE SOIL SURVEY. After general routing has been proposed and before specific design has begun, a detailed soil survey will be conducted for all distribution systems.

a. The survey will be made after the general layout of the system has been determined, will cover the entire length of the proposed system, and will be made by a geotechnical engineer. The geotechnical engineer will be a registered professional engineer with a minimum of three years of experience in the field of soil mechanics and foundation design. This engineer must also be familiar with the local soil conditions.

b. If at all possible, the survey should be conducted during the time of the year when the ground-water table is at its highest point; if this is not possible, water table measurements will be corrected, on the basis of professional judgement and local knowledge, to indicate conditions likely to exist at the time of year when the water table is at its highest point. It may be necessary to dig test pits at the worst locations to investigate the soil for evidence of high water table.

c. As a minimum, information on ground-water conditions, soil types, terrain, and precipitation rates and irrigation practices in the area of the system will be collected. This information will be obtained from available records at the installation. In addition, soil resistivity will be determined for the cathodic protection system design for Pre-Engineered Underground Heat Distribution Systems.

d. Information on ground-water conditions and soil types (in most cases not necessary for Prefabricated Underground Heating and Cooling Distribution Systems and Aboveground Heat Distribution Systems) will be obtained through borings, test pits, or other suitable exploratory means. Generally, a boring test pit will be made at least every 100 feet along the line of the proposed system within areas of prior construction. In open undisturbed natural areas the spacing of borings may be increased. Each exploratory hole will extend to a level at least five feet below the anticipated elevation of the bottom of the proposed system. If a significant difference in underground conditions is found at adjacent exploratory points, additional explorations will be made between those points in order to determine more precisely where the change occurs. Upon completion of the survey, each exploration point will be classified on the basis of the criteria presented in the guide specification for Pre-Engineered Underground Heat Distribution Systems or in the guide specification for Heat Distribution Systems in Concrete Shallow Trenches. The classification criteria is different for each system. Note that although classification is not a requirement for design of Prefabricated Underground Heating and Cooling Distribution Systems or Aboveground Heat Distribution Systems, the site survey, except for borings or test pits, must be conducted to ensure that actual site characteristics have been identified so that accurate plan and profile drawings can be generated.

3-3. UTILITY INVESTIGATION. All existing, concurrently constructed and new utilities will be identified if within 25 feet of the proposed distribution system routing. If the proposed routing crosses any utilities, burial depths will be determined. Utility locations and depths can be verified through base personnel familiar with utilities, base/post utility maps and by site visits. The designer is responsible for these site visits to verify locations of utility interferences and to coordinate all other construction items with the user. In the event utility information is not available, utility location consultants may be procured who specialize in the location, identification and depth determination of utilities. If interferences exist, details will be provided in the design to relocate utilities or modify system routing to avoid the interference.

3-4. SYSTEM LAYOUT PLAN/PROFILE. All distribution systems require a layout plan and profile be provided by the designer.

a. Layout plans will include, but not be limited to:

(1) system routing (including expansion loops and bends, manhole locations and anchor locations).

(2) stationing numbering for the system (one dimensional coordinates from the point of origin of the distribution system).

(3) all utilities within 25 feet of the system.

(4) all roads and buildings clearly labeled.

(5) types of surface conditions (asphalt, concrete, seeding, gravel, etc.).

(6) grade contour lines (new and existing).

(7) all dimensions and clearances to ensure accurate routing.

b. A profile of the system will also be drawn and, as a minimum, show:

(1) all system stationing numbering.

(2) system slope drawn to scale (1-inch to 20 feet minimum for all systems) to all low points.

(3) new and existing grade.

(4) all existing or new utilities shown at their actual burial depths.

3-5. EXPANSION COMPENSATION. All expansion systems, loops, and bends, will be sized in order to prevent excessive pipe stresses (due mainly from thermal expansion) from exceeding those allowed by the Power Piping Code, ASME B31.1. Mechanical expansion joints are not recommended for absorbing system expansion. Mechanical expansion joints greatly increase the maintenance requirements of the distribution systems. In the unlikely event that expansion joints must be used, they must be placed in an adequately sized valve manhole. The designer is responsible for expansion calculations for Heat Distribution Systems in Concrete Trenches, Prefabricated Underground Heating/Cooling Distribution Systems, and Aboveground Heat Distribution Systems. The designer is also responsible for the expansion and stress determinations in all the valve manholes, including the location of the equipment/pipe support locations. Even though the manufacturer is responsible for the expansion calculations for Pre-Engineered Underground Heat Distribution Systems, the calculations will be thoroughly reviewed by the designer at the shop drawing review. It is recommended that a three dimensional finite element computer program be used for determining system stresses. Many finite element software packages are available which operate on desktop computers. The temperature differential used in the stress analysis will be the maximum temperature of the media less the minimum temperature the system will encounter during a shutdown. All loops and bends will be sized based on zero percent cold springing. Cold springing effects lessen over time and are difficult to maintain in the event the system is ever cut, and shall therefore not be included in the analysis. However, loops may be installed with cold springing as an added conservative measure.

3-6. VALVE MANHOLES. For all distribution systems, valve manholes will be designed by the project designer. A valve manhole is required for all buried system lateral connections, all below to above ground system transitions, all drain points (low points), all below ground valving, all trap stations, high points for vents of buried systems, and to minimize depth of buried systems. Distance between valve manholes varies with different applications. However, spacing shall never exceed 500 feet with Pre-Engineered Underground Heat Distribution Systems or Prefabricated Underground Heating/Cooling Distribution Systems to minimize excavation when searching for failures and to minimize effects of a failure. To enhance maintainability, avoid valve manholes deeper than 6 feet.

a. Manhole internals. Layout of each manhole will be designed on a case by case basis.

(1) Equipment/valve locations. It is important to first layout, to scale, all manhole piping, insulation, valving (with stems upright 90 degrees or less from vertical), and equipment and then locate the manhole walls around these appurtenances to ensure adequate manhole size and room for maintenance personnel. One line diagrams of piping and equipment are unacceptable. See figure 3-1 for a typical manhole plan. Note that all valve manhole layouts have certain designer requirements in common. The designer will:

(a) Provide main line isolation valves in valve manholes to most efficiently minimize outages to buildings served by the distribution system. When installed, main line isolation valves will be located downstream of the building's service laterals.

(b) Provide lateral isolation valves within the valve manholes for all laterals runs.

(c) Locate all carrier pipe vents and drains needed within the manhole for proper system drainage of the main and lateral lines.

(d) Layout all valve manhole internals (valves and valve stems, pipe w/insulation, access ladders, isolation flanges, and equipment) to scale to ensure adequate clearance has been provided for operation and maintenance within the manhole.

(e) Ensure no non-metallic piping is routed in the manholes (i.e., as allowed with chilled water or condensate return systems) which also serves high temperature mediums that could damage the non-metallic piping. Damage to non-metallic piping is caused when manholes flood and the hot piping boils the flood water. Boiling water can exceed the temperature allowables of many nonmetallic piping materials. Because of this, the designer must transition to steel piping at the manholes (see figure 8-4).

(2) Clearances. Design will provide for clearance around piping and equipment in the manhole in accordance with table 3-1.

(3) Access Ladders. Access ladders will be required on all valve manholes greater than 3 feet in depth. Ladders will be welded steel and will consist of uprights and nonslip steps or rungs. Uprights will be not less than 16 inches apart and steps or rungs will be spaced no greater than 12 inches apart. Ladders will extend not less than 6 inches from the manhole wall and will be firmly anchored to the wall by steel inserts spaced not more than three 3 feet apart vertically. All parts of the ladders will be hot-dipped galvanized after fabrication in conformance with ASTM A 123. The top rung of the ladders shall be not more than 6 inches from the top of the manhole. A typical valve manhole access ladder detail is shown in figure 3-2.

(4) Insulation. Insulation for valves, fittings, field casing closures, and other piping system accessories in valve manholes will be of the same types and thicknesses as those provided in the distribution systems' guide specification. All insulation will be premolded, precut, or job fabricated to fit and will be removable and reusable. Insulation jackets will be provided for all pipe insulation in manholes and will comply with the requirements of the particular distribution system guide specification.

(5) Isolation flanges. Isolation flanges will be provided when connecting to an existing cathodically protected heating or cooling distribution system or to prevent a new system's cathodic protection system from contacting an existing system. The isolation flanges will be installed in the valve manhole and a typical flange detail is shown in figure 3-3.

(6) Valve/piping supports. Piping in valve manholes often will need supports within the manhole especially when larger valves or equipment are attached to the piping. These supports will be located on the manhole plans as determined by the designer's expansion compensation calculations for each manhole valving and equipment layout. Typical valve/piping support details are shown in figure 3-4.

b. Valve manhole construction. Valve manholes will be field constructed of reinforced concrete conforming to the current criteria. Valve manholes will be constructed of 4,000 psi minimum compressive strength concrete. Reinforcing bars will conform to ASTM A 615, grade 60. Typical reinforcing steel details and sizing are shown in figure 3-5 and table 3-2 respectively. Concrete floor slabs and walls will be of sufficient weight to prevent flotation in high water table areas. Floor slabs will be sloped to the drain which will be installed in the floor slab. Concrete wall sections will be not less than 8 inches thick and must meet anticipated load and soil conditions. Side walls will be constructed in a monolithic pour. Water stops will be provided at all construction joints. Do not locate valve manholes in roads or parking areas which create an inadequate amount of manhole ventilation and poor access.

c. Valve manhole covers. The valve manhole cover types discussed here are: raised solid plate, supported cover, and concrete.

(1) Raised solid plate covers. Raised solid plate covers are preferred for HTHW and steam/condensate systems installed in Pre-Engineered Underground Heat Distribution Systems. For shallow concrete trench systems, the raised solid plate cover's raised feature will interfere with the trench's walkway function. When the valve manhole cover must remain flush with the trench top, the supported cover is the preferred type. For the raised solid plate cover, ventilation openings are provided around the entire perimeter below the raised top. The height of the valve manhole wall above grade (6 inches, minimum) shall be sufficient to prevent surface water entry. The solid plate cover assembly is removable. The cover, constructed of aluminum, also provides sectionalized access for inspection and maintenance. The solid plate cover raised frame design and section, lifting lug, and handle details are shown in figure 3-6 through 3-12. Figure 3-13 contains notes for raised solid plate cover figures.

(2) Supported covers. Supported covers may be used for any distribution system covered in this manual. For Pre-engineered Underground or Prefabricated Underground Heat Distribution Systems, design the cover to be at least 6 inches above the surrounding grade. When used for concrete shallow trench systems, the finished top will be flush with the concrete trench top. Required grates or other structural members used for supporting covers to be made of corrosion resistant material such as aluminum or galvanized steel. Details for the supporting cover are shown in figures 3-14 through 3-18. These details are designed for loadings up to 150 psf and must be re-evaluated for larger loadings. Other structural solutions for supporting the checkered plate are acceptable. The checkered plate cover (also referred to as diamond or embossed plate) as shown in figure 3-18, will be installed over grating or other structural supports in most locations to minimize the influx of leaves and other debris. The checkered plate is attached to the grating and is removable.

(3) Concrete covers. The use of concrete covers is discouraged, but, if used, they must be used with 4 x 4 ft. aluminum doors for any distribution system covered in this manual. Concrete covers should only be used if desired by the user or if specific design conditions exist, such as below to aboveground system transitions. When used for Pre-engineered Underground or Prefabricated Underground Heat Distribution Systems, design the top of the concrete cover to be a minimum of 6 inches above the surrounding grade. When used for concrete shallow trenches, design the cover to be flush with the trench top. Concrete requirements for this cover are similar to those required for valve manhole construction. Concrete cover will be designed to support anticipated loadings. Figure 3-19 shows a typical concrete cover plan and figure 3-20

provides construction details for this cover. The concrete cover detailed is designed for loadings up to 150 psf. For greater loadings, the design must be re-evaluated. A disadvantage of concrete covers is the difficulty in providing ventilation. For concrete shallow trench systems, a single 6 inch gooseneck pipe will be used, as detailed in figure 3-21, to allow steam to exit the valve manhole if a leak or excessive heat loss is present. Note that for shallow trench systems, the gooseneck will be installed off to one side of the valve manhole concrete top to minimize pedestrian traffic interference. For Pre-engineered Underground Heat Distribution Systems, two 6 inch goosenecks will be used. One will extend below the top as detailed in figure 3-21. The other will be similar but will extend to within 8 inches of the valve manhole floor on the opposite side of the manhole.

d. Valve manhole drainage. Drainage of water from the valve manhole is mandatory for the successful operation and longevity of buried heating or cooling distribution systems. There are three types of valve manhole drainage systems described in this manual: gravity drainage, pumped drainage from a sump basin, and pumped drainage from the valve manhole.

(1) Gravity drainage. The most cost effective and lowest maintenance system is gravity drainage to a storm drain when location, depth of existing storm drains, and local regulatory requirements allow this possibility. Drainage lines will be 6 inches in diameter minimum and will conform to the latest storm drain criteria and will be sloped at one percent, minimum. Valve manhole outlet will be a floor drain with backflow preventer to prevent storm water inflow from the storm drain (see figure 3-22). Note that valve manhole drain outlets shall be covered with a "hat type" cast iron pipe screen to minimize the accumulation of trash over the drain inlet. Also, the manhole floor will be sloped toward the drain.

(2) Pumped drainage from sump basin. For pumped drainage, a duplex submersible pump system installed in a remote sump basin may be provided as indicated in figures 3-23 and 3-24. The sump basin will be located no more than 10 feet from the valve manhole. Drainage from the valve manhole to the sump basin will be similar to drainage to a storm drain including the valve manhole floor drain (fig 3-22). Discharge from the pumps can be routed to a splashblock at grade or to an adjacent storm sewer. Design of the surrounding grade must ensure drainage away from the sump basin, valve manhole and concrete shallow trench (if used) when discharging to grade. A power pedestal complete with failure warning light will be provided with each basin as shown in figure 3-25. A typical wiring diagram and sequence of operation are shown in figure 3-26. A specification for the sump basin system can be included in the applicable manhole or heat distribution section of the contract specification. The sump basin design has proven to operate well even in the colder climates of the upper tier states in the continental United States. It is also an excellent method to retrofit existing manholes that currently do not drain properly. The remote sump basin increases the life of the systems by removing the sump pump and pump controls from the hot, humid environment of the manhole. Also, pump maintenance will be done outside of the manhole. The pumps are easily disconnected and lifted to grade. The sump pumps used in the sump basin must incorporate the design characteristics listed in table 3-3.

(3) Pumped drainage from valve manhole. Another means to pump water from the manhole is to locate the duplex sump pumps in the valve manhole. Typically, a 2'0" by 2'0" by 1'0" (deep) sump will be provided in a corner of the valve manhole. The duplex sump pumps will be installed to pump out of this sump. Valve manhole sump pump electrical arrangement should be installed as shown in figure 3-27. The control panel with high level warning light will be mounted adjacent to the valve manhole at grade. This keeps the electrical panel out of the hot, humid environment of the manhole. The sequence of operation and wiring diagrams will meet the requirements of figure 3-26. Pump discharge can be routed to a splashblock at grade (similar to the sump basin discharge piping arrangement on figure 3-23) or to an adjacent storm drain. Electric sump pumps used in the valve manholes must incorporate the design characteristics listed in table 3-3. Note that life of the pumps are typically shortened when installed in the hot and humid valve manhole environment.

e. General.

(1) Valve manhole wall penetrations. A design must be provided for the distribution system wall

penetrations. For a shallow trench system, the wall penetrations will typically be the same size as the inside dimension of the shallow trench connecting to the valve manhole. For shallow trench dimensions, refer to chapter 4 of this manual. Structural reinforcement must be designed around this opening. Drainage from the trench will then flow into the manhole. For Pre-engineered or Prefabricated Underground Heat Distribution Systems, sleeved openings will typically be provided with an expandable seal between the casing and the pipe sleeve as indicated on figure 3-28. Structural reinforcement must be designed to avoid contact with the pipe sleeve and water stop to prevent grounding of the system's cathodic protection.

(2) Waterproofing. Waterproof membranes will be placed in or below the concrete bottom slab and continued up the outer sides to the top of the sidewalls in accordance with the valve manhole guide specification.

(3) Pipe anchoring adjacent to valve manholes. Regardless of the buried distribution system, pipe anchors should be provided between 2 to 5 feet of a manhole wall to minimize movement through the manhole. For piping which passes through valve manholes, anchoring on one side only is typically adequate. Anchoring piping on more than one side may restrict piping movement and overstress the piping in the valve manhole. Anchors will typically be provided as part of the distribution system and will not be embedded in the manhole wall. However, if the manhole is used to support an anchor, the manhole must be designed to withstand the forces exerted by the system. Expansion compensation stress calculation will always be conducted to ensure proper anchor locations throughout the distribution system. These calculations must also account for the expansion in the valve manholes.

(4) Piping materials in valve manholes. Nonmetallic piping must not be used in the same valve manholes as piping carrying higher temperature media that could cause the temperature around the non-metallic piping to exceed the allowables and potentially cause permanent damage to the non-metallic piping. In addition, chilled water systems with PVC carrier piping must never be installed in the same valve manhole with any heating system.

CHAPTER 4

HEAT DISTRIBUTION SYSTEMS IN CONCRETE TRENCHES

4-1. GENERAL. The concrete shallow trench (CST) is a system, which allows insulated carrier pipes to be routed underground but yet not have the piping in contact with the soil. The system also provides comparatively easy access for maintenance and repair by means of removable concrete tops. These exposed tops can be used as sidewalks since the system is installed at grade.

4-2. SYSTEM DESIGN. The designer is responsible for conducting a site investigation, designing the distribution system plan and profiles, and designing the valve manholes, as described in chapter 3 of this manual. In addition, the designer will use details and descriptions presented here to design a concrete shallow trench system at a particular site.

a. Trench Systems - General.

(1) Piping and fittings. All carrier piping and pipe fittings will be carbon steel and will be designed to satisfy the temperature and pressure requirements of the system. Materials will conform to the requirements in the guide specification.

(2) Pipe supports. Pipe supports will typically consist of three types: free, guided, and anchor. These supports are detailed in figure 4-1, figure 4-2, and figure 4-3. All of these pipe supports will be mounted on channel supports mounted to the trench walls as detailed in figure 4-4. Supports may be mounted by other means, such as on concrete pedestals, provided that paths for water flow are maintained. Table 4-1 provides guidance for the sizing of the channel supports. Note that the channels for anchor supports in the table are designed for more substantial loads than required for free and guided supports. The anchor support channel in this table is adequate for approximately 1,000 pounds force axially. The designer will determine axial force requirements at all anchor points and design the channels to accommodate these forces. **\1** Maximum distance between support channels shall be as listed in table 4-2. **/1/** These spacings are applicable to long, straight runs of piping only and must be reduced at elbows, vertical risers, valving, and equipment. The actual spacings, in these instances, will be determined by analyzing the pipe stresses with the pipe stress analysis, as described in chapter 3 of this manual. The designer should note that there are other types of supports (such as roller type) that may also be used. However, all supports must be capable of withstanding the thermal stresses and forces exerted on them.

(3) Clearances. Clearances in the trench will be adequate to provide room for expansion, air movement, and a sufficient amount of access for cleaning and maintenance. There must also be a minimum of 4 inches clearance under the support channels to ensure ground water drainage along the trench floor. Figure 4-5 provides a trench cross-section, which corresponds to the table 4-3 trench dimension schedule, which must be filled in by the designer.

(4) Insulation and jacketing. Insulation will be selected in accordance with insulation thickness tables in the guide specification. These insulation thicknesses were developed using a life cycle cost analysis. All insulations used have passed the Federal Agency Committee's boiling test and are listed in the guide specifications. All insulation in the trench will be covered with jacketing material in conformance to the guide specification.

b. Trench System - Structural. The concrete trench will be field constructed of reinforced concrete conforming to the current criteria. Trench walls and floors will be poured in place-they will not be precast. Trench tops will be poured in place or precast. Walls, floors, and tops will be constructed with 4,000 psi minimum compressive strength concrete. Reinforcing bars will conform to ASTM A 615, grade 60. Wall, floor, and top thicknesses shall be 6 inches, minimum. However, thicker sections may be required to accommodate site specific loadings or to prevent flotation. Concrete trench floors shall be sloped at a 1 inch in 20 feet slope toward all low points to ensure proper drainage. Doweled or keyed joints and water stops shall be provided at all construction joints and shall be detailed as shown in figure 4-6. Trench reinforcing details will be provided and will be similar to the section shown in figure 4-7. Note that actual concrete thicknesses and reinforcing bar sizes will be verified by the designer for each project. Trench corners will be constructed as detailed in figure 4-8. Trench tops will be no longer than eight feet to allow easy removal and placement.

c. Trench Top Removal Devices. The most common type of removal devices for the trench tops will be the sling type as detailed in figure 4-9. Four lifting devices are required to lift a trench top. One set of lifting devices will accommodate all trench tops for each contract. In some instances, sling type lifting devices will not be convenient to use (eg. when the trench top butts up against a parallel sidewalk or when the trench is routed through a parking area). In these instances, the designer shall require coil inserts to be cast into the trench cover in four locations that will accommodate threaded lifting eye bolts. When not being used, threaded plugs are inserted into the coil inserts. The lifting devices are also detailed in figure 4-9.

d. Road and Parking Lot Crossings. Road crossing requirements will be designed on a case by case basis and must take into account pavement materials, soils, and frost characteristics of the design site. A typical road crossing is shown in figure 4-10. Figure 4-11 details a concrete trench to curb and gutter system transition and figure 4-12 details a concrete trench to drain pan system transition. In all instances, the crown of the road crossing will be matched and the thickness of the trench top will be designed to accommodate worst case loadings. Parking lot crossings typically will have the trench top exposed at grade as shown in figure 4-13. Exposed tops allow for easier trench top removal over extended lengths of paved areas. If appearance of the crossing is critical, black pigments may be added to the concrete tops at the road crossing to match the surrounding pavement. In rare instances, the trench tops may be covered with asphalt surfacing, as detailed in figure 4-14.

e. Sidewalk Intersections. In the event the trench system intersects an existing sidewalk, the trench system will match the sidewalk as detailed in figure 4-15.

f. Expansion Compensation. Expansion loop and bend design is the responsibility of the designer, and is covered in chapter 3 of this manual. The expansion loop design is critical. Sufficient space needs to be provided in the expansion loop area to ensure that no pipe or insulation interference will occur due to pipe movement as shown in figure 4-16. This detail indicates location of supports and also shows how the piping system will be offset to allow for expansion movement in the trench. Table 4-4 is a typical loop schedule, which corresponds to figure 4-16. The locations of the supports in the expansion loops will be determined from the designer's piping stress analysis and then entered in Table 4-4. All piping stresses will be less than ASME B31.1 allowables for each application. The designer will require inspection ports be provided in the trench tops at each bend in the trench system routing for the purpose of observing pipe movement at the bends during system startup. The inspection port is similar to the access cover detailed in figure 4-18, except the nominal diameter of the lid will be 12 inches.

g. Sealants. The trench will be sealed to minimize the influx of ground water. A 1/4 inch thick neoprene pad will be used between trench tops and tops of trench walls. The pad will have a minimum width of 2 inches. All trench joints must be sealed with elastomeric sealants, which are available as a one or two component system. Asphaltic sealants have not performed as reliably for this application. The elastomeric sealant should be able to resist 50 percent total joint movement. The nonsagging type must be used for vertical joints. The self-leveling type must be used for trench top butt joints as shown in figure 4-17. Other horizontal joints may be sealed with either type of elastomeric sealant, but the sealant used in trench bottoms must finish flush with the floor.

h. Vents and drains. Piping vents and drains will be located at all high and low points, respectively **\1** (see figure 4-19) **/1/**. Piping drains will be provided in valve manholes only where access can be achieved and where system drainage is provided. Piping vents may be located anywhere in the trench piping system with an access cover provided in the trench top, as detailed in figure 4-18 or with an aluminum access door shown in figure 3-19.

4-3. GENERAL CONSIDERATIONS. The designer will address these key areas to ensure a satisfactory shallow trench design.

a. The grading design will ensure ground water will not pond or sit over the trench. The trench will not be routed through existing flood plains, swales, or in areas where seasonal water accumulates. Another distribution system, preferably an Aboveground Heat Distribution System (chap 7), should be used in these areas. In areas where seasonal ground water will cause a trench flotation problem, the design will include a subdrainage system along the trench if thickening of system walls and floor slabs to offset the buoyancy effect is not practical.

b. The trench floors will slope a minimum of 1 inch in 20 feet toward valve manholes and the piping will parallel the trench floor. This will allow the trench to drain off all water that may enter. Drainage will then be provided from the valve manholes as described in chapter 3 of this manual.

c. Valve manholes should be spaced to minimize the depth of the trench system. Additional manholes may be less expensive than excessive trench depths to accommodate the slope while still keeping the trench tops at grade.

Table 4-1. Channel Support Schedule *

LOCATION	PLATE	ANCHOR STUDS	ANGLE	CHANNEL	BOLTS
Free and Guided Supports	1/2" x 10" x 10"	4-1/2" x 4"	2" x 2" x 1/4" x 6" long	MC 6" x 15.3"	1/2"
Anchor Supports	3/4" x 10" x 10"	6-5/8" x 4"	2" x 2" x 1/4" x 6" long	MC 8" x 22.4"	3/4"

* Schedule for channel detailed in Figure 4-4.

NOTE TO THE DESIGNER:
Channels exceeding loadings indicated in manual shall be designed for vertical and axial loadings encountered.

Table 4-2. Support spacing schedule

\1\ MAXIMUM HORIZONTAL PIPE SUPPORT SPACING FOR STEEL /1/ DISTRIBUTION PIPING	
PIPE SIZE (INCHES)	SPACING (FEET)
1	7
1-1/4	7
1-1/2	9
2	10
2-1/2	11
3	12
2-1/2	13
4	14
5	16
6	17
8	19
10	22
12	23
14	25
16	27
18	28
20	30
24	32
30	33

NOTES TO THE DESIGNER: These spacings are maximum for horizontal, straight runs. More closely spaced supports must be provided for bends and risers and at equipment.

Table 4-3. Trench dimension schedule.

TRENCH DIMENSION SCHEDULE											
STANDARD TRENCH INTEM NO.	[PIPE SIZES (INCHES)	A	B_1	B_2	C*	D_1	D_2	E*	F MIN.	H_W MIN.	W
					6”		6”				
					6”		6”				
					6”		6”				
					6”		6”				

NOTES TO THE DESIGNER:

1. CLEARANCES BASED ON THE THICKEST INSULATION, IF LESS INSULATION (LOWER “k”) IS PROVIDED. DIMENSIONS C, D, E AND F WILL BE DIFFERENT THAN SCHEDULED. HOWEVER, OVERALL TRENCH DIMENSIONS SHSALL REMAIN THE SAME. C* & E* DIMENSIONS MUST BE MAINTAINED THROUGHOUT ALL STRAIGHT SECTIONS OF TRENCH TO ALLOW PROPER CLEARANCES FOR EXPANSION.

2. SCHEDULE DESIGNATIONS ARE ASSOCIATED WITH TRENCH DIMENSION SECTION, FIGURE 4-5.

Table 4-4. Expansion Loop Schedule*

Loop Name	Line Sizes	X	Y	YY	Z	ZZ	W	H	U	REMARKS

*See Expansion Loop Detail for Designations (Figure 4-16).

NOTE TO THE DESIGNER:
If only one support is required along parallel leg of loop, ZZ =0. If only one support is required along perpendicular legs of loop, YY = 0.

CHAPTER 5

PRE-ENGINEERED UNDERGROUND HEAT DISTRIBUTION SYSTEM

5-1. GENERAL. Unlike Heat Distribution Systems in Concrete Trenches, which are totally designed by the designer, Pre-engineered Underground Heat Distribution Systems are designed by the system manufacturer. These pre-engineered systems are factory fabricated in lengths, which are transported to the site for field assembly. Other types of systems and materials are continuously being evaluated and will be included in guide specifications and this manual when deemed acceptable. There are two types of these systems. The DDT type is allowed for severe, bad and moderate site conditions. In severe sites allow only drainable-dryable-testable type systems. In bad and moderate sites allow DDT and water spread limiting systems. These **\1** site **/1/** conditions (or classifications) are described in detail in the guide specifications. Although the manufacturer is responsible for the pre-engineered system design, the project designer also has design responsibilities which include establishing the site, soil, and groundwater conditions, pipe sizes, proposed routing (including construction limits) estimated length, elevations, profiles of the system along with existing and finished earth surfaces and obstructions **\1** within **/1/** 8m (25 feet) of the system centerline including adjacent or crossing utilities. The project designer also provides information on location and design of manholes and entrances to buildings and manholes.

5-2. MANUFACTURER'S RESPONSIBILITY.

a. Pre-engineered Underground Heat Distribution System design. The manufacturer is responsible for the Pre-engineered Underground Heat Distribution System. This responsibility includes any or all of the following: insulation types, guided and anchor supports, end seals, casing and piping joint closure, casing type and thickness, and carrier pipe depending on the type of Pre-engineered Underground Heat Distribution System provided. There are two types of Pre-Engineered Underground Heat Distribution Systems. The drainable-dryable-testable system is a factory fabricated system, which includes a water-tight outer protective casing of steel, an air space, and an insulated carrier steel pipe. Casing drains and vents are provided in end plates, which are installed in valve manholes. DDT systems can be used for any heating medium including HTHW, high and low pressure steam, and condensate return and in any site condition (severe, bad or moderate). The water spread limiting systems is also a factory fabricated system, which includes an outer protective casing and an insulated carrier pipe. The system is fabricated in sections, which are independent from each other. Ground water or condensate, which leaks from or into one section, cannot travel into the next section. Field-assembly of the sections requires no welding; the sections are pushed together and are sealed with a system of couplings and seals. WSL systems can be used only in bad and moderate site conditions. The designer must determine the site conditions before a system type is selected. The site conditions will be considered severe, bad or moderate based on the site investigation results. For DDT and WSL systems, steam and condensate lines must always be installed in separate casings, as shown for a DDT system in figure 5-1, due to the corrosion problems associated with condensate return systems. Water systems may use just one casing for both supply and return pipes as detailed for a DDT system in figure 5-2, although installing the pipes in separate casings is preferred by most users because it is less difficult to isolate leaks. The tops of the casings will typically be buried between 2 and 6 feet below grade. However, note that excessive burial depths increase the installation and repair costs and should be avoided where possible.

b. Expansion compensation. The manufacturer is responsible for the system expansion compensation. A detailed stress analysis will be submitted for review as part of the contract requirements. The manufacturer will normally make use of expansion loops and bends to absorb system expansion in DDT systems. For WSL systems, field joints may be used to accommodate expansion. Except in rare instances, expansion joints will not be permitted.

c. Pre-engineered system's representative. The manufacturer is required to ensure that a qualified direct employee of the system manufacturer is present to guarantee proper installation when the following types of work are performed:

(1) inspection, unloading and storage of materials.

(2) inspection of trench prior to laying of casing.

(3) inspection of concrete thrust blocks.

(4) hydrostatic test of all service lines.

(5) field joint closure work.

(6) air test of casing.

(7) coating patch work.

(8) holiday test of casing coating.

(9) initial backfill up to 10 inches above the top of the casing.

(10) radiographic weld examination.

(11) startup and operation tests.

5-3. PROJECT DESIGNER'S RESPONSIBILITY.

a. Site information. As with all buried distribution systems, the site investigation is the responsibility of the designer. As described in chapter 3 of this manual, the designer will obtain soil borings, be responsible for designing the grading in the area, investigate all utilities for possible conflicts, and design for utility relocation as necessary. The designer must then determine the site conditions (severe, bad, or moderate) before a system type (DDT or WSL) is selected. The designer will then provide plans and profiles of the Pre-engineered system routing. The designer will show approximate slope of the system (1 inch in 20 feet is required to ensure drainage). This slope must be maintained in the entire system including through each leg of each expansion loop to ensure proper system drainage.

b. Valve manholes. The designer will design all valve manholes for the system as described in chapter 3 of this manual. The manholes will be no further apart than 500 feet to minimize excavation if a leak in the system must be found. The manholes will also be provided at all high (vent) points and low (drain) points in the system. The valve manholes will include ground water drainage capabilities as explained in chapter 3. Casing vents and drains will be included for maintenance of the casing air space in DDT systems as shown in figure 5-3.

c. Insulation. The insulation types used on the Pre-engineered Underground system will only be those that are listed in the guide specification. The insulation thickness tables in the guide specification will be used in determining required insulation thickness. These insulation thicknesses were developed using life cycle cost analyses.

d. Cathodic protection. The designer will be responsible for the cathodic protection design for all systems with coated steel casings. The designer shall also require that dielectric flanges be provided to isolate the system's cathodic protection system from non protected systems. These dielectric flanges shall always be installed inside valve manholes.

e. Review. The designer will provide a detailed review of the manufacturer's shop drawings to ensure the system meets the requirements of the contract. As a minimum, the following items are required in this review process:

(1) carrier pipe size and thickness.

(2) insulation thickness, type and K-value.

(3) casing material and thickness.

(4) casing coating material and thickness.

(5) verification of constant system slope to all low points (proposed elevations at all casing joints on submitted shop drawing layouts).

(6) cathodic protection design.

(7) manufacturer’s system stress analysis.

CHAPTER 6

PREFABRICATED UNDERGROUND HEATING/COOLING DISTRIBUTION SYSTEM

6-1. GENERAL. This system is similar to Pre-engineered Underground Heat Distribution System (chapter 5) because it is factory fabricated in lengths, which are transported to the site for field assembly. However, the system is not allowed for any high temperature water (greater than 200 deg. F) or steam/condensate systems. The project designer is also responsible for more of the overall design.

6-2. SYSTEM DESIGN.

a. Site information. As with all heat distribution systems, the site investigation is the responsibility of the designer. The designer will obtain soil borings, be responsible for designing all grading in the area, and investigate all utilities for possible conflicts with the system. The designer will provide detailed design plans and profiles of the distribution system routings. The design will ensure a minimum slope of 1 inch in 20 feet is maintained between valve manholes. The site information requirements are covered in detail in chapter 3 of this manual.

b. Valve manholes. The designer will design all valve manholes for the system as covered in chapter 3 of this manual. As with valve manholes for the Pre-engineered Underground Heat Distribution System, manhole spacing will not exceed 500 feet and all manholes will have drainage capabilities. Also, all valves, flanges, unions, and couplings shall be located within the manholes.

c. System Material Selections. Although this system is manufactured in sections in a factory, the designer will specify all materials.

(1) Piping. The piping materials allowed are steel, copper tubing, reinforced thermosetting resin plastic (RTRP), or polyvinyl chloride (PVC). RTRP piping can not be routed through valve manholes with heating systems that could damage the RTRP. PVC piping can not be routed in any valve manhole with any other heating system piping due to its comparatively low temperature tolerance.

(2) Casing. Allowed casing materials are PVC, polyethylene (PE), or RTRP. Because these casing materials are susceptible to damage from high temperatures, they must be installed a minimum of 15 feet from buried HTHW or steam systems to avoid plastic deformation and failures of the casing materials.

(3) Insulation. Insulation type for these systems is typically polyurethane foam. Open cell type insulations, such as fiberglass, mineral wool or calcium silicate, are unacceptable for use with chilled water systems due to the tendency of condensation forming in these insulations. Insulation thickness will be specified in the guide specification.

d. Expansion compensation. The designer will perform expansion compensation calculations as covered in chapter 3 of this manual. When required, based on these calculations, sizes and locations of all expansion loops and bends, and any other expansion-compensating device, will be clearly shown on the contract drawings. The designer shall provide expansion loop details.

CHAPTER 7

ABOVEGROUND HEAT DISTRIBUTION SYSTEMS

7-1. GENERAL. Aboveground distribution systems have the lowest first cost and lowest maintenance costs of any distribution system described in this manual and are completely designed by the project designer. This system is a good application for industrial areas and where water tables are high. Many installations, however, do not desire to have distribution piping above ground for aesthetic reasons.

7-2. SYSTEM DESIGN.

a. Site information. The designer will determine information on the site. The designer will design all grading for the area and investigate all utilities for conflicts. The designer will provide detailed plans and profiles of the above ground distribution system routing. Although this system is aboveground, profiles will indicate system drain and vent points and also potential interferences between the concrete support piers and any buried utilities.

b. Piping and fittings. All carrier piping and pipe fittings will be carbon steel and will be designed to satisfy the temperature and pressure requirements of the system. Materials will conform to the requirements of the guide specification.

c. Pipe supports. The two most common types of aboveground distribution systems are low profile and high profile.

(1) Low profile system. A typical low profile support is shown in figure 7-1. In this system, the distribution piping is mounted to concrete piers by means of pipe supports. Typically, the bottoms of the pipes are mounted no more than 4 feet above grade except at road crossings, which usually incorporate high profile supports. Typical anchor, free, and guided pipe supports mounted to the concrete piers are detailed in figure 7-2, figure 7-3, and figure 7-4. Spacing of supports in straight runs of piping will conform to the support spacing schedule in table 4-2. Provide extra supports, as necessary, at pipe bends and risers. Requirements for concrete piers and pipe supports are included in the guide specification.

(2) High profile systems. High profile systems are routed high enough to cross roads and avoid obstructions. Typically the piping will be installed 14 to 16 feet above grade. The system presented in this manual uses 6-inch concrete-filled pipes embedded in concrete footings as detailed in figure 7-5. The pipe guides are mounted on channels at the top of the support pipe as detailed in figure 7-6. The pipe anchors are also mounted to channels and then stabilized with guy cables as shown in figure 7-7. Structural design for the structural members on these high profile supports in figure 7-6 and 7-7 are for water filled, schedule 40 steel pipes up to 10-inch nominal size. Conditions outside these constraints must be designed on a case-by-case basis. The designer for each anchor application will also size the guy cables. Spacing of supports in straight runs of piping will conform to the support spacing schedule in table 4-2. Extra supports will be added, as necessary, at pipe bends and risers. Concrete footings and high profile supports will conform to the requirements of the guide specification.

c. Insulation and jacketing. All piping on aboveground systems shall be insulated and jacketed. Insulation thicknesses will be determined by insulation tables provided in the guide specification. These insulation thicknesses were developed using life cycle cost analyses. All insulation will be covered with a jacketing material in conformance with the guide specification.

e. Expansion Compensation. Expansion loops and bends will be designed as described in chapter 3 of this manual. Expansion loops will be located to minimize impacts to ground level interferences such as trees and sidewalks. For horizontal expansion loops, pipe supports will be spaced less than the maximums listed in table 4-2 because of the extra bends and associated movement in the loops. In low profile systems, vertical expansion loops may be used as road crossings. Details will be provided indicating support types and locations throughout the loops and bends.

f. Vents and Drains. Provide venting of all piping high points and draining of all low points to allow total drainage of the system. Vent and drain locations will be indicated on the profile drawings. Vents and drains are similar to those used for the concrete shallow trench system, figure 4-15.

g. Transition to Buried Systems. When a buried system transitions to an aboveground system a valve manhole will be provided at that point. A manhole top penetration will be provided to allow expansion of the distribution piping in the man-hole top yet keep rain and ground water out of the manhole. Figure 7-8 shows such a transition in a valve manhole with a concrete cover. The valve manhole used for this transition must be large enough to be accessible and will be designed in accordance with chapter 3 of this manual.

CHAPTER 8

SPECIAL CONSIDERATIONS

8-1. GENERAL. Although it is impractical to cover all special considerations, which arise in heating and cooling distribution designs, this chapter presents typical design problems and solutions associated with steam, high temperature hot water, low temperature hot water and chilled water systems.

8-2. STEAM SYSTEMS.

a. Trap Selection. Steam traps are used to separate the condensate and non-condensable gases from the steam. Many types of traps are used on drip legs for steam distribution systems. Those trap types include float and thermostatic (F&T), inverted bucket, thermostatic and thermodynamic (disc). However, for buried heat distribution drip leg applications, inverted bucket or thermostatic (bimetallic type) should be the trap types selected. For drip leg applications where freezing is a consideration, thermodynamic type (installed vertically) or bimetallic thermostatic type should be selected.

b. Trap Sizing and Location. Trap sizing is important for obtaining an efficient steam distribution system. Condensation in the steam line is caused by heat loss from the steam line. Trap life will be shortened, function affected and excessive energy will be wasted if traps are oversized to handle the higher initial startup condensate flows. Therefore, the traps should be sized for the condensate load seen during the distribution system normal operation. Because the traps are not sized for startup loadings, the bypass must be opened at startup to allow condensate to pass until the steam line has reached normal operating temperatures (see figure 8-1). The designer will calculate heat loss and condensate flow for that particular design using the methods presented in appendix D for determining condensate loads during normal operation. It is critical that the designer calculate trap capacity using the Appendix D method for each trap station in the design to ensure proper steam system operation. In addition to trap capacity, steam trap type, differential pressures, and inlet pressure must always be provided on the contract documents. Do not locate steam drip legs, with associated traps, more than 500 feet apart.

c. Drip Leg Sizing. Drip legs, installed vertically down from the steam pipe, are used to collect condensate. Design all steam lines to slope at 1 inch in 20 feet minimum toward these drip legs. It is preferable to slope the steam lines in the direction of steam flow whenever possible. The steam trap line and bypass line are connected to the drip leg as indicated in figure 8-1. The drip leg will be the same nominal pipe size as the main line (up to a 12-inch line) and will provide a storage capacity equal to 50% of the startup condensate load (no safety factor, one-half of an hour duration) for line sizes 4 inches in diameter and larger and 25% of the startup condensate load (no safety factor, one-half of an hour duration) for line sizes less than 4 inches. In no case will the drip leg be less than 18 inches in length or larger than 12 inches in diameter for all steam line sizes. The designer will calculate startup loads for drip leg sizing using the methods presented in appendix D.

d. Trap Station Layout. All trap stations will be piped as indicated in figure 8-1, as a minimum. Valve and strainer sizes will match the line sizes on which they are installed. Pipe lines to and from the steam trap will be sized based on calculated trap capacity but will be no less than 3/4-inch nominal size (line size "A" on figure 8-1). If reducing fittings are needed at the trap inlet and outlet, eccentric reducers must be used. The bypass line will be sized to accommodate warm-up condensate loads. For steam systems with an operating pressure of 150 psig or less and pipe sizes 12 inches or less, provide a ¾-inch bypass line. If the condensate return main is a low pressure or gravity flow type, the trap discharge line will be routed through an accumulator, as indicated in figure 8-2. The accumulator will lower the trap discharge temperature and minimize flashing when the condensate is introduced into sloped condensate lines which are routed to receiver/pump sets located in valve manholes. The pumps push the condensate back to the central plant in a separate pressurized condensate line. See figure 8-3 for a duplex condensate pump set connection detail.

This type of condensate return system is referred to as a "three pipe" or a "pumped return" system. If the steam pressure is sufficiently high, it may be used to force the condensate through the condensate return system to the central plant as shown in figure 8-1. No accumulator is required for this type system, which is referred to as a "two pipe" system. Sizing of the lines for both of these systems is presented later in this chapter.

e. Condensate Cooling System. Fiberglass reinforced plastic (FRP) piping is usually allowed for most condensate return systems. Since internal corrosion is a frequent problem in steel condensate lines, FRP eliminates this problem. However, the FRP materials cannot withstand as high of pressures or temperatures as steel and often fail when exposed to these conditions. A common temperature in an FRP distribution piping system where damage will occur is 250 deg. F. Condensate temperatures may exceed 250 deg. F. at the outlet of steam drip leg traps on steam systems that have pressures greater than 15 psig. In order to use FRP condensate lines in this case, a condensate cooling system will be employed, as detailed in figure 8-4. In this system, the high temperature condensate is discharged into a cooling tank where it blends with the system condensate. The blended condensate is then routed to the condensate main. Note that the detail shows the FRP (or non-metallic) pipe transitioning to steel inside the valve manhole to avoid burying the transition point. Also, note that nonmetallic piping will not be allowed in a manhole with high temperature hot water or high pressure steam systems due to the potential for this pipe being exposed to damaging temperatures within the manhole if the manhole floods or the carrier pipe on the heating system leaks.

f. Non-metallic Pipe Anchors in Valve Manholes. If anchoring of a non-metallic piping system is required at the valve manhole wall to comply with the distribution system stress analysis, a typical method is as detailed in figure 8-5. If the system is to be anchored at both of the valve manhole wall penetrations, provide adequate piping bends in the manhole to accommodate the expansion between the two anchors. Steel straps and bolts will be sized to accommodate the axial force of that particular piping layout. These sizes will be entered on the detail. Also, valve manhole sizes must be large enough to accommodate the anchors and still allow for maintenance access.

g. Pipe Sizing. Pipe sizing is critical to proper operation of both the steam and the condensate return systems.

(1) Steam. There are several methods to size steam lines. One of the quickest and most popular methods is using pressure drop versus flow rate charts, which provide steam velocities based on the required flow and pressure drops. The American Society of Heating, Refrigeration, and Air Conditioning Engineers (ASHRAE) Fundamentals Handbook, Chapter "Pipe Sizing", is a good source for these steam sizing tables. Recommended velocities for various system pressure ranges are:

0 - 10 psig, saturated - 1,000 to 4,000 fpm
10 - 50 psig, saturated - 4,000 to 8,000 fpm
50 - 150 psig, saturated - 8,000 to 12,000 fpm

In addition, ensure the total pressure drop in the system will not be excessive. Steam pressure must be high enough at the end users to meet all special process requirements.

(2) Condensate. As described previously in this chapter, there are basically two types of condensate return systems used on central heating systems: the two pipe system (which uses steam pressure to force condensate back to the plant) and the three pipe, or pumped return, system. When sizing lines for these condensate return systems, table 8-1 will be used for guidance.

h. Steam System Material Selection.

(1) Valves. For high-pressure steam systems (125 psig or greater), valves will be 300-pound class and

will have welded ends. Steam and condensate valves at lower pressures will be 150-pound class with welded ends. Valves on trap stations, including the bypass valve, will be 150-pound class with threaded ends. Shutoff valves will be gate type.

(2) Fittings. All fittings in the steam distribution system, except as discussed for valves, will be welded except at equipment, traps, strainers, and items which require frequent removal. These items will be threaded or flanged.

(3) Piping. Steam and condensate piping will usually be carbon steel conforming to ASTM A 53, Grade B, Type E or S. Steam piping will be schedule 40. Condensate lines will be schedule 80 as will all welded piping less than 1-1/2 inches. Condensate lines in a pre-engineered underground heat distribution system may be FRP as discussed in chapter 5.

i. Field Joints. Radiographic examination of all carrier pipe field joints is required.

8-3. HTHW SYSTEMS.

a. Pipe Sizing. Sizing lines for HTHW systems is similar to any water system, except at high temperatures water becomes less dense and less viscous, and, therefore, the mass flow rate of the system must be calculated considering the lower density (usually temperatures are around 400 deg. F for HTHW).

$$m = q \times 60 \text{ min/hr} \times 0.1335 \text{ ft}^3\text{/gal} \times ?$$

where

q = system flow in gal/min

m = mass flow rate in lbm/hr

? = density of water at maximum system temperature in lbM/ft^3

Pressure drop versus flow charts may be used to determine line size, such as the chart included in appendix B. This chart takes into account the characteristics of higher temperature water systems. Recommended velocities for various HTHW flows are as follows:

Up to 10,000 lbm/hr	-	1 to 2 feet/sec
10,000 to 30,000 lbm/hr	-	2 to 3 feet/sec
30,000 to 200,000 lbm/hr	-	3 to 5 feet/sec
200,000 lbm/hr on up	-	(use velocity to accommodate 0.50 psi/100 ft., maximum)

b. HTHW System Material Selection

(1) Valves. All valves on HTHW systems will be 300-pound class with welded ends. Shutoff (isolation) valves will be gate type. Valve packings must be capable of handling the pressures and temperatures associated with HTHW systems.

(2) Fittings. All fittings on HTHW systems will be welded. The only exceptions will be specialty equipment such as dielectric flanges used to isolate the piping system from a cathodically protected system.

(3) Piping. HTHW piping will be carbon steel conforming to ASTM A53, Grade B, Type E or S. All piping will be schedule 40 except for welded pipe less than 1-1/2 inches, which will be schedule 80.

8-4. LTHW and CW systems.

a. Pipe Sizing. The most efficient method of determining pipe size for LTHW and CW systems is to use head loss vs. flow rate charts such as those found in ASHRAE Fundamentals, Chapter "Pipe Sizing". These tables are based on 60 deg. F water so for chilled water pipe sizing there is little error introduced using these charts. For LTHW systems, the use of the charts does introduce some error. However, the error is on the conservative side (the charts overstate the pressure drop of LTHW).

b. LTHW and CW Material Selection.

(1) Valves. Typically, valves on either LTHW or CW systems will be 150-pound class and will be located in the valve manholes. Ball valves provide a good means for line isolation. Although nonmetallic valves are sometimes allowed for these systems, metallic valves should be used for durability.

(2) Piping. The most common piping materials used for LTHW and CW systems are steel, copper tubing, reinforced thermosetting resin pipe (fiber- glass) and, for CW only, polyvinyl chloride and polyethylene. However, do not include nonmetallic piping in the same valve manholes with HTHW and steam systems. Chilled water lines using PVC piping must be installed in separate valve manholes since PVC can be thermally damaged at relatively low temperatures. Outside the valve manholes, a separation of 15 feet (minimum) must be maintained between pre-engineered underground HTHW and steam systems and PVC encased, prefabricated underground heating/cooling distribution systems to avoid thermal degradation of the PVC.

Table 8-1. Pipe sizing guidelines for condensate return systems.

TWO-PIPE SYSTEM SIZING GUIDELINES

- ?? DETERMINE CONDENSATE LINE PRESSURE (AS OBSERVED FROM ON-SITE PRESSURE GAGES).
- ?? DETERMINE CONDENSATE LOAD (lbm/hr) FROM CENTRAL PLANT LOGS AND OTHER INPUT.
- ?? ASSUME CONDENSATE AT TRAP DISCHARGE IS A COMBINATION OF CONDENSATE AND FLASH STEAM.
- ?? SIZE LINE TO ACCOMMODATE 5,000 ft/min STEAM AND CONDENSATE MIXTURE VELOCITY AND TO ENSURE MIXTURE PRESSURE IS HIGH ENOUGH TO OVERCOME LINE LOSSES.

THREE-PIPE SYSTEM SIZING GUIDELINES

GRAVITY LINE
- ?? SLOPE AT 1 inch/20 feet (MINIMUM) TOWARD RECEIVER.
- ?? TOTAL PRESSURE DROP LESS THAN 0.25 psi.
- ?? LINE SIZE WILL BE TWO (2) INCHES.

PUMPED LINE
- ?? SIZE PUMPS TO MOVE CONDENSATE TO THE CENTRAL PLANT AT THE REQUIRED HEAD AT 200 deg. F.

APPENDIX C

CONDENSATION LOAD CALCULATIONS (NORMAL)

Step #1 Determine the heat loss per foot of line.

$$Q = 2? \ (T_{st} - T_{out})/(\ln(r_o/r_i)/k_p + \ln(r_{io}/r_o)/k_{in} + 1/3r_{io})$$

Assumptions. This equation models an insulated pipe surrounded by air. The convective resistance between the insulation and the outside of the pipe is assumed to be negligible. Also, the convective heat transfer coefficient outside of the insulation is assumed to be 3 BTU/hr-ft^2 deg. F.

Step #2 Determine the flow of condensate from the heat loss calculated in step #1.

$$m = Q/(h_{st} - h_{con})$$

Step #3 Multiply the flow rate per foot, calculated in step #2, by the total number of feet of steam line that slopes toward the trap in question. The result is the minimum flow capacity of the trap.

where:

- Q = heat loss per foot of pipe; Btu/hr-ft
- T_{st} = temperature of steam; deg. F
- T_{out} = temperature of ambient conditions; deg. F
- r_o = outside pipe radius; feet
- r_i = inside pipe radius; feet
- r_{io} = outside insulation radius; feet
- k_p = thermal conductivity of pipe; Btu/hr-ft- deg. F; (26 Btu/hr-ft-deg. F for steel)
- k_{in} = thermal conductivity of insulation; Btu/hr-ft- deg. F * (see table below)
- m = mass flow rate of condensate; lbm/hr-ft
- h_{st} = enthalpy of saturated steam; Btu/lbm
- h_{con} = enthalpy of condensate; Btu/lbm

\1\ *K-value (Btu/hr-ft-deg. F /1/

Insulation Type	400 deg. F	300 deg. F	200 deg. F
Mineral Fiber	0.034	0.029	0.024
Calcium Silicate	0.042	0.038	0.035

APPENDIX D

CONDENSATION LOAD CALCULATIONS (STARTUP)

Step #1 Determine the heat loss per foot of line.

The startup load can be calculated by determining the amount of heat that is required to heat the steam pipe from an ambient temperature to the saturation temperature of the steam the pipe is to carry. This is done by using the following equation:

$$Q = (v_p * c_p * ?_p \ (t_{st} - T_{out}))/t;\ \text{Btu/ft}$$

where:

$$v_p = ? \ (r_o^2 - r^2);\ \text{in ft}^3/\text{ft}$$

Step #2 Determine the pounds of condensate per foot from the heat loss calculated in step #1.

$$m = Q/(h_{st} - h_{con});\ \text{lbm/ft}$$

Step #3 Multiply the condensate per foot, calculated in step #2, by the total number of feet of steam line that slopes toward the drip leg in question. Then convert the total pounds of condensate to gallons assuming 200 F condensate:

$$\text{Total Condensate Volume (gallons)} = \frac{(m*L)*7.49\ \text{gallons/ft}^3}{60.1\ \text{lbm/ft}^3}$$

where:

Q = heat loss per foot of pipe; Btu/hr-ft
T_{st} = temperature of steam; deg. F
T_{out} = temperature of ambient conditions; deg. F
r_o = outside pipe radius; feet
r_i = inside pipe radius; feet
m = mass flow rate of condensate; lbm/hr-ft
h_{st} = enthalpy of saturated steam; Btu/lbm
h_{con} = enthalpy of condensate; Btu/lbm
c_p = specific heat of pipe (steel); (0.10 to 0.11) Btu/lbm/degrees F
$?_p$ = density of pipe (steel); (489) lbm/ft_3

t = length of time for startup; hrs (typically 0.5 hrs.)

L = total length of pipe draining to drip; ft
v_p = volume of pipe material per foot; ft^3/ft

CEMP-E **TI 810-32**
30 August 1999
Reissued 10 January 2002

FOREWORD

These technical instructions (TI) provide design and construction criteria and apply to all U.S. Army Corps of Engineers (USACE) commands having military construction responsibilities. TI will be used for all Army projects and for projects executed for other military services or work for other customers where appropriate.

TI are living documents and will be periodically reviewed, updated, and made available to users as part of the HQUSACE responsibility for technical criteria and policy for new military construction. CEMP-ED is responsible for administration of the TI system; technical content of TI is the responsibility of the HQUSACE element of the discipline involved. Recommended changes to TI, with rationale for the changes, should be sent to HQUSACE, ATTN: CEMP-ED, 20 Massachusetts Ave., NW, Washington, DC 20314-1000.

TI are effective upon issuance. TI are distributed only in electronic media through the TECHINFO Internet site *http://www.hnd.usace.army.mil* /techinfo/index.htm and the Construction Criteria Base (CCB) systems maintained by the National Institute of Building Sciences at Internet Site *http://www.nibs.org/ccb/*. Hard copies of these instructions produced by the user from the electronic media should be checked against the current electronic version prior to use to assure that the latest instructions are used.

FOR THE COMMANDER:

CHAPTER 1

GENERAL INFORMATION

1-1. PURPOSE AND SCOPE. This document provides criteria and guidance for the design and construction of heating and cooling distribution systems and supplements information in the "Notes to the Designer" of the guide specifications. These distribution systems include Heat Distribution Systems in Concrete Trenches, Pre-engineered Underground Heat Distribution Systems, Prefabricated Underground Heating/Cooling Distribution Systems, and Aboveground Heat Distribution Systems. The mediums used in these distribution systems, as defined by the Department of Defense (DoD), include:

a. High temperature hot water (HTHW) (251 deg. F to 450 deg. F)

b. Low temperature hot water (LTHW) (150 deg. F to 250 deg. F)

c. Low pressure steam systems (up to 15 psig)

d. High pressure steam systems (over 15 psig)

e. Condensate return systems (up to 200 deg. F)

f. Chilled water systems.

1-2. APPLICABILITY. These instructions are applicable to all **\2** DoD agencies **/2/** and their contractors involved in the design and construction of heating and cooling distribution systems.

1-3. REFERENCES. Appendix A contains a list of references used in these instructions.

1-4. EXCEPTIONS. Generally, this document covers heating and cooling distribution systems most typically installed on United States military installations. However, deviations from the recommendations of this manual may be necessary when unusual site conditions are present or specific using service requirements are encountered. For example, the manual does not discuss design problems associated with arctic and subarctic construction, in which case, the designer should refer to the "Cold Climate Utilities Manual", 1986, Canadian Society of Civil Engineers, Montreal, Quebec.

1-5. DEFINITIONS. The term "designer" used throughout this manual refers to the person or persons responsible for preparing contract drawings and specifications for a heating or cooling distribution design. The main engineering discipline areas of the "designer" are:

a. Mechanical. Includes expansion compensation, stress analysis, piping system design (fittings, valves, insulation), equipment selection and sizing, and pipe sizing and routing.

b. Structural. Includes reinforced concrete design, pipe supports, and valve manhole cover design.

c. Electrical. Includes cathodic protection, electrical service and controls (e.g. sump pumps).

d. Civil. Includes earth work, road crossings (for buried systems), system plans and profiles, and area drainage designs.

CHAPTER 2

SYSTEM SELECTION

2-1. GENERAL. When designing a heating or cooling distribution system, the designer must first select two critical items: media type and system type.

2-2. DISTRIBUTED MEDIA SELECTION.

a. Connecting to an existing system. Almost all heating and cooling distribution systems will be connected to an existing central distribution system. In this case, the designer most often designs for the media to which it is being connected-HTHW, LTHW, steam/condensate, or chilled water.

b. Installation of new system. When no existing system is present, the designer must select the system that is most appropriate for the end user. High temperature hot water and steam/condensate systems are the most common types of distribution systems currently used on military installations. However, a new system should only use the temperatures and pressures necessary to meet the requirements of the installation. For example, the use of high pressure steam sterilizers or steam kettles at several facilities may require the use of a high pressure steam or HTHW system. However, it is usually much more cost effective (on a first cost and life cycle cost basis) to use a low or medium temperature hot water distribution systems whenever possible and to incorporate stand alone high pressure/temperature systems where required. The lower maintenance costs, safer operation, longer life of systems, and simpler system controls for hot water systems often offset the costs of larger piping required. For further assistance for selecting the system type, refer to ASHRAE Handbook, "HVAC Systems and Equipment."

2-3. SYSTEM TYPES. When selecting a distribution system, the designer must determine which system types apply to a particular medium. The designer must also exclude systems which are not appropriate for a particular site or for which the customer has no interest. Examples of this are locating aboveground systems in non-industrial areas where the installation is sensitive to the aesthetic appearance of the area or routing concrete shallow trench systems through drainage swales or flood plains.

a. Heat Distribution Systems in Concrete Trenches (chapter 4). This system is a buried system with its removable concrete cover installed at grade and will typically be used for HTHW and steam/condensate systems. In rare instances, it may also be used for chilled water and LTHW in the event no plastic piping is installed in the same trench as high temperature (greater than 250 degrees F) piping systems. Experience has shown that if insulation of a high temperature system is compromised, temperatures can increase to such a level and cause damage to the plastic piping.

b. Pre-engineered Underground Heat Distribution Systems (chapter 5). This system is designed for higher pressure and temperature applications. The two types of pre-engineered systems are the drainable-dryable-testable (DDT) type which is used for high pressure steam/condensate and HTHW at all sites, and high temperature hot water at any type of site, and the water spread limiting (WSL) type which is used only for steam/condensate systems in bad and moderate sites. HTHW supply and return lines may be provided in a single casing; however, steam and condensate lines must always be provided in separate casings because condensate lines typically last less than half as long as the steam line and are easier to replace when in a separate casing.

c. Prefabricated Underground Heating/Cooling Distribution System (chapter 6). This system is designed for lower temperature and pressure applications. It is typically used for LTHW, chilled water, or combination LTHW/chilled water systems.

d. Aboveground Heat Distribution System (chapter 7). This system may be used for HTHW, steam/condensate, and LTHW systems, and for chilled water systems where freezing is not a concern.

2-4. SYSTEM SELECTION. The system type selected will be based on the type of media that is distributed.

a. High Temperature Water and Steam/condensate Systems. The order of preference for system types for high temperature and high pressure systems are:

(1) Aboveground Heat Distribution System. This is the least expensive system and historically requires the lowest maintenance and operating costs. However, the safety and aesthetics of an aboveground system are not always desirable and must be accepted by the end user.

(2) Heat Distribution Systems in Concrete Trenches. This is the most dependable of the buried distribution systems. The piping is totally accessible through removable concrete covers, the piping does not come in contact with the soil, and ground water is drained away from the piping system to low point drains. Except in rare instances, this is the system that should be selected if aboveground is not acceptable with the end user.

(3) Pre-engineered Underground Heat Distribution System. This type of buried distribution system should be selected as the last option due to very short system lives which are typically caused by poor drainage, poor corrosion protection, and improper installation. Instances where it would be used would be when aboveground is not acceptable with the end user or when drainage swales and high ground water prevent the installation of a concrete trench system.

b. Low Temperature and Chilled Water Systems. The order of preference for system types for hot water, chilled water or combination hot/chilled water are:

(1) Aboveground Heat Distribution System. This is the least expensive system and historically requires the lowest maintenance and operating costs. However, the aesthetics of an aboveground system are not always desirable and must be accepted by the end user. In addition, aboveground systems are typically not used for chilled water because of potential freezing problems in colder climates and heat gain in warmer areas.

(2) Prefabricated Underground Heating/Cooling Distribution System. This buried distribution system is relatively inexpensive and dependable. The non-metallic casing materials provide excellent protection from corrosion and the lower temperatures and pressures allow the system to operate for extended periods of time. It is an excellent application for chilled water since the system is installed underground, limiting the amount of heat gain to the system.

CHAPTER 3

GENERAL DISTRIBUTION SYSTEM DESIGN

3-1. GENERAL. Some aspects of a heating or cooling distribution system design are similar regardless of the system type. These aspects are covered in this chapter.

3-2. SITE SOIL SURVEY. After general routing has been proposed and before specific design has begun, a detailed soil survey will be conducted for all distribution systems.

a. The survey will be made after the general layout of the system has been determined, will cover the entire length of the proposed system, and will be made by a geotechnical engineer. The geotechnical engineer will be a registered professional engineer with a minimum of three years of experience in the field of soil mechanics and foundation design. This engineer must also be familiar with the local soil conditions.

b. If at all possible, the survey should be conducted during the time of the year when the ground-water table is at its highest point; if this is not possible, water table measurements will be corrected, on the basis of professional judgement and local knowledge, to indicate conditions likely to exist at the time of year when the water table is at its highest point. It may be necessary to dig test pits at the worst locations to investigate the soil for evidence of high water table.

c. As a minimum, information on ground-water conditions, soil types, terrain, and precipitation rates and irrigation practices in the area of the system will be collected. This information will be obtained from available records at the installation. In addition, soil resistivity will be determined for the cathodic protection system design for Pre-Engineered Underground Heat Distribution Systems.

d. Information on ground-water conditions and soil types (in most cases not necessary for Prefabricated Underground Heating and Cooling Distribution Systems and Aboveground Heat Distribution Systems) will be obtained through borings, test pits, or other suitable exploratory means. Generally, a boring test pit will be made at least every 100 feet along the line of the proposed system within areas of prior construction. In open undisturbed natural areas the spacing of borings may be increased. Each exploratory hole will extend to a level at least five feet below the anticipated elevation of the bottom of the proposed system. If a significant difference in underground conditions is found at adjacent exploratory points, additional explorations will be made between those points in order to determine more precisely where the change occurs. Upon completion of the survey, each exploration point will be classified on the basis of the criteria presented in the guide specification for Pre-Engineered Underground Heat Distribution Systems or in the guide specification for Heat Distribution Systems in Concrete Shallow Trenches. The classification criteria is different for each system. Note that although classification is not a requirement for design of Prefabricated Underground Heating and Cooling Distribution Systems or Aboveground Heat Distribution Systems, the site survey, except for borings or test pits, must be conducted to ensure that actual site characteristics have been identified so that accurate plan and profile drawings can be generated.

3-3. UTILITY INVESTIGATION. All existing, concurrently constructed and new utilities will be identified if within 25 feet of the proposed distribution system routing. If the proposed routing crosses any utilities, burial depths will be determined. Utility locations and depths can be verified through base personnel familiar with utilities, base/post utility maps and by site visits. The designer is responsible for these site visits to verify locations of utility interferences and to coordinate all other construction items with the user. In the event utility information is not available, utility location consultants may be procured who specialize in the location, identification and depth determination of utilities. If interferences exist, details will be provided in the design to relocate utilities or modify system routing to avoid the interference.

3-4. SYSTEM LAYOUT PLAN/PROFILE. All distribution systems require a layout plan and profile be provided by the designer.

a. Layout plans will include, but not be limited to:

(1) system routing (including expansion loops and bends, manhole locations and anchor locations).

(2) stationing numbering for the system (one dimensional coordinates from the point of origin of the distribution system).

(3) all utilities within 25 feet of the system.

(4) all roads and buildings clearly labeled.

(5) types of surface conditions (asphalt, concrete, seeding, gravel, etc.).

(6) grade contour lines (new and existing).

(7) all dimensions and clearances to ensure accurate routing.

b. A profile of the system will also be drawn and, as a minimum, show:

(1) all system stationing numbering.

(2) system slope drawn to scale (1-inch to 20 feet minimum for all systems) to all low points.

(3) new and existing grade.

(4) all existing or new utilities shown at their actual burial depths.

3-5. EXPANSION COMPENSATION. All expansion systems, loops, and bends, will be sized in order to prevent excessive pipe stresses (due mainly from thermal expansion) from exceeding those allowed by the Power Piping Code, ASME B31.1. Mechanical expansion joints are not recommended for absorbing system expansion. Mechanical expansion joints greatly increase the maintenance requirements of the distribution systems. In the unlikely event that expansion joints must be used, they must be placed in an adequately sized valve manhole. The designer is responsible for expansion calculations for Heat Distribution Systems in Concrete Trenches, Prefabricated Underground Heating/Cooling Distribution Systems, and Aboveground Heat Distribution Systems. The designer is also responsible for the expansion and stress determinations in all the valve manholes, including the location of the equipment/pipe support locations. Even though the manufacturer is responsible for the expansion calculations for Pre-Engineered Underground Heat Distribution Systems, the calculations will be thoroughly reviewed by the designer at the shop drawing review. It is recommended that a three dimensional finite element computer program be used for determining system stresses. Many finite element software packages are available which operate on desktop computers. The temperature differential used in the stress analysis will be the maximum temperature of the media less the minimum temperature the system will encounter during a shutdown. All loops and bends will be sized based on zero percent cold springing. Cold springing effects lessen over time and are difficult to maintain in the event the system is ever cut, and shall therefore not be included in the analysis. However, loops may be installed with cold springing as an added conservative measure.

3-6. VALVE MANHOLES. For all distribution systems, valve manholes will be designed by the project designer. A valve manhole is required for all buried system lateral connections, all below to above ground system transitions, all drain points (low points), all below ground valving, all trap stations, high points for vents of buried systems, and to minimize depth of buried systems. Distance between valve manholes varies with different applications. However, spacing shall never exceed 500 feet with Pre-Engineered Underground Heat Distribution Systems or Prefabricated Underground Heating/Cooling Distribution Systems to minimize excavation when searching for failures and to minimize effects of a failure. To enhance maintainability, avoid valve manholes deeper than 6 feet.

a. Manhole internals. Layout of each manhole will be designed on a case by case basis.

(1) Equipment/valve locations. It is important to first layout, to scale, all manhole piping, insulation, valving (with stems upright 90 degrees or less from vertical), and equipment and then locate the manhole walls around these appurtenances to ensure adequate manhole size and room for maintenance personnel. One line diagrams of piping and equipment are unacceptable. See figure 3-1 for a typical manhole plan. Note that all valve manhole layouts have certain designer requirements in common. The designer will:

(a) Provide main line isolation valves in valve manholes to most efficiently minimize outages to buildings served by the distribution system. When installed, main line isolation valves will be located downstream of the building's service laterals.

(b) Provide lateral isolation valves within the valve manholes for all laterals runs.

(c) Locate all carrier pipe vents and drains needed within the manhole for proper system drainage of the main and lateral lines.

(d) Layout all valve manhole internals (valves and valve stems, pipe w/insulation, access ladders, isolation flanges, and equipment) to scale to ensure adequate clearance has been provided for operation and maintenance within the manhole.

(e) Ensure no non-metallic piping is routed in the manholes (i.e., as allowed with chilled water or condensate return systems) which also serves high temperature mediums that could damage the non-metallic piping. Damage to non-metallic piping is caused when manholes flood and the hot piping boils the flood water. Boiling water can exceed the temperature allowables of many nonmetallic piping materials. Because of this, the designer must transition to steel piping at the manholes (see figure 8-4).

(2) Clearances. Design will provide for clearance around piping and equipment in the manhole in accordance with table 3-1.

(3) Access Ladders. Access ladders will be required on all valve manholes greater than 3 feet in depth. Ladders will be welded steel and will consist of uprights and nonslip steps or rungs. Uprights will be not less than 16 inches apart and steps or rungs will be spaced no greater than 12 inches apart. Ladders will extend not less than 6 inches from the manhole wall and will be firmly anchored to the wall by steel inserts spaced not more than three 3 feet apart vertically. All parts of the ladders will be hot-dipped galvanized after fabrication in conformance with ASTM A 123. The top rung of the ladders shall be not more than 6 inches from the top of the manhole. A typical valve manhole access ladder detail is shown in figure 3-2.

(4) Insulation. Insulation for valves, fittings, field casing closures, and other piping system accessories in valve manholes will be of the same types and thicknesses as those provided in the distribution systems' guide specification. All insulation will be premolded, precut, or job fabricated to fit and will be removable and reusable. Insulation jackets will be provided for all pipe insulation in manholes and will comply with the requirements of the particular distribution system guide specification.

(5) Isolation flanges. Isolation flanges will be provided when connecting to an existing cathodically protected heating or cooling distribution system or to prevent a new system's cathodic protection system from contacting an existing system. The isolation flanges will be installed in the valve manhole and a typical flange detail is shown in figure 3-3.

(6) Valve/piping supports. Piping in valve manholes often will need supports within the manhole especially when larger valves or equipment are attached to the piping. These supports will be located on the manhole plans as determined by the designer's expansion compensation calculations for each manhole valving and equipment layout. Typical valve/piping support details are shown in figure 3-4.

b. Valve manhole construction. Valve manholes will be field constructed of reinforced concrete conforming to the current criteria. Valve manholes will be constructed of 4,000 psi minimum compressive strength concrete. Reinforcing bars will conform to ASTM A 615, grade 60. Typical reinforcing steel details and sizing are shown in figure 3-5 and table 3-2 respectively. Concrete floor slabs and walls will be of sufficient weight to prevent flotation in high water table areas. Floor slabs will be sloped to the drain which will be installed in the floor slab. Concrete wall sections will be not less than 8 inches thick and must meet anticipated load and soil conditions. Side walls will be constructed in a monolithic pour. Water stops will be provided at all construction joints. Do not locate valve manholes in roads or parking areas which create an inadequate amount of manhole ventilation and poor access.

c. Valve manhole covers. The valve manhole cover types discussed here are: raised solid plate, supported cover, and concrete.

(1) Raised solid plate covers. Raised solid plate covers are preferred for HTHW and steam/condensate systems installed in Pre-Engineered Underground Heat Distribution Systems. For shallow concrete trench systems, the raised solid plate cover's raised feature will interfere with the trench's walkway function. When the valve manhole cover must remain flush with the trench top, the supported cover is the preferred type. For the raised solid plate cover, ventilation openings are provided around the entire perimeter below the raised top. The height of the valve manhole wall above grade (6 inches, minimum) shall be sufficient to prevent surface water entry. The solid plate cover assembly is removable. The cover, constructed of aluminum, also provides sectionalized access for inspection and maintenance. The solid plate cover raised frame design and section, lifting lug, and handle details are shown in figure 3-6 through 3-12. Figure 3-13 contains notes for raised solid plate cover figures.

(2) Supported covers. Supported covers may be used for any distribution system covered in this manual. For Pre-engineered Underground or Prefabricated Underground Heat Distribution Systems, design the cover to be at least 6 inches above the surrounding grade. When used for concrete shallow trench systems, the finished top will be flush with the concrete trench top. Required grates or other structural members used for supporting covers to be made of corrosion resistant material such as aluminum or galvanized steel. Details for the supporting cover are shown in figures 3-14 through 3-18. These details are designed for loadings up to 150 psf and must be re-evaluated for larger loadings. Other structural solutions for supporting the checkered plate are acceptable. The checkered plate cover (also referred to as diamond or embossed plate) as shown in figure 3-18, will be installed over grating or other structural supports in most locations to minimize the influx of leaves and other debris. The checkered plate is attached to the grating and is removable.

(3) Concrete covers. The use of concrete covers is discouraged, but, if used, they must be used with 4 x 4 ft. aluminum doors for any distribution system covered in this manual. Concrete covers should only be used if desired by the user or if specific design conditions exist, such as below to aboveground system transitions. When used for Pre-engineered Underground or Prefabricated Underground Heat Distribution Systems, design the top of the concrete cover to be a minimum of 6 inches above the surrounding grade. When used for concrete shallow trenches, design the cover to be flush with the trench top. Concrete requirements for this cover are similar to those required for valve manhole construction. Concrete cover will be designed to support anticipated loadings. Figure 3-19 shows a typical concrete cover plan and figure 3-20

provides construction details for this cover. The concrete cover detailed is designed for loadings up to 150 psf. For greater loadings, the design must be re-evaluated. A disadvantage of concrete covers is the difficulty in providing ventilation. For concrete shallow trench systems, a single 6 inch gooseneck pipe will be used, as detailed in figure 3-21, to allow steam to exit the valve manhole if a leak or excessive heat loss is present. Note that for shallow trench systems, the gooseneck will be installed off to one side of the valve manhole concrete top to minimize pedestrian traffic interference. For Pre-engineered Underground Heat Distribution Systems, two 6 inch goosenecks will be used. One will extend below the top as detailed in figure 3-21. The other will be similar but will extend to within 8 inches of the valve manhole floor on the opposite side of the manhole.

d. Valve manhole drainage. Drainage of water from the valve manhole is mandatory for the successful operation and longevity of buried heating or cooling distribution systems. There are three types of valve manhole drainage systems described in this manual: gravity drainage, pumped drainage from a sump basin, and pumped drainage from the valve manhole.

(1) Gravity drainage. The most cost effective and lowest maintenance system is gravity drainage to a storm drain when location, depth of existing storm drains, and local regulatory requirements allow this possibility. Drainage lines will be 6 inches in diameter minimum and will conform to the latest storm drain criteria and will be sloped at one percent, minimum. Valve manhole outlet will be a floor drain with backflow preventer to prevent storm water inflow from the storm drain (see figure 3-22). Note that valve manhole drain outlets shall be covered with a "hat type" cast iron pipe screen to minimize the accumulation of trash over the drain inlet. Also, the manhole floor will be sloped toward the drain.

(2) Pumped drainage from sump basin. For pumped drainage, a duplex submersible pump system installed in a remote sump basin may be provided as indicated in figures 3-23 and 3-24. The sump basin will be located no more than 10 feet from the valve manhole. Drainage from the valve manhole to the sump basin will be similar to drainage to a storm drain including the valve manhole floor drain (fig 3-22). Discharge from the pumps can be routed to a splashblock at grade or to an adjacent storm sewer. Design of the surrounding grade must ensure drainage away from the sump basin, valve manhole and concrete shallow trench (if used) when discharging to grade. A power pedestal complete with failure warning light will be provided with each basin as shown in figure 3-25. A typical wiring diagram and sequence of operation are shown in figure 3-26. A specification for the sump basin system can be included in the applicable manhole or heat distribution section of the contract specification. The sump basin design has proven to operate well even in the colder climates of the upper tier states in the continental United States. It is also an excellent method to retrofit existing manholes that currently do not drain properly. The remote sump basin increases the life of the systems by removing the sump pump and pump controls from the hot, humid environment of the manhole. Also, pump maintenance will be done outside of the manhole. The pumps are easily disconnected and lifted to grade. The sump pumps used in the sump basin must incorporate the design characteristics listed in table 3-3.

(3) Pumped drainage from valve manhole. Another means to pump water from the manhole is to locate the duplex sump pumps in the valve manhole. Typically, a 2'0" by 2'0" by 1'0" (deep) sump will be provided in a corner of the valve manhole. The duplex sump pumps will be installed to pump out of this sump. Valve manhole sump pump electrical arrangement should be installed as shown in figure 3-27. The control panel with high level warning light will be mounted adjacent to the valve manhole at grade. This keeps the electrical panel out of the hot, humid environment of the manhole. The sequence of operation and wiring diagrams will meet the requirements of figure 3-26. Pump discharge can be routed to a splashblock at grade (similar to the sump basin discharge piping arrangement on figure 3-23) or to an adjacent storm drain. Electric sump pumps used in the valve manholes must incorporate the design characteristics listed in table 3-3. Note that life of the pumps are typically shortened when installed in the hot and humid valve manhole environment.

e. General.

(1) Valve manhole wall penetrations. A design must be provided for the distribution system wall

penetrations. For a shallow trench system, the wall penetrations will typically be the same size as the inside dimension of the shallow trench connecting to the valve manhole. For shallow trench dimensions, refer to chapter 4 of this manual. Structural reinforcement must be designed around this opening. Drainage from the trench will then flow into the manhole. For Pre-engineered or Prefabricated Underground Heat Distribution Systems, sleeved openings will typically be provided with an expandable seal between the casing and the pipe sleeve as indicated on figure 3-28. Structural reinforcement must be designed to avoid contact with the pipe sleeve and water stop to prevent grounding of the system's cathodic protection.

(2) Waterproofing. Waterproof membranes will be placed in or below the concrete bottom slab and continued up the outer sides to the top of the sidewalls in accordance with the valve manhole guide specification.

(3) Pipe anchoring adjacent to valve manholes. Regardless of the buried distribution system, pipe anchors should be provided between 2 to 5 feet of a manhole wall to minimize movement through the manhole. For piping which passes through valve manholes, anchoring on one side only is typically adequate. Anchoring piping on more than one side may restrict piping movement and overstress the piping in the valve manhole. Anchors will typically be provided as part of the distribution system and will not be embedded in the manhole wall. However, if the manhole is used to support an anchor, the manhole must be designed to withstand the forces exerted by the system. Expansion compensation stress calculation will always be conducted to ensure proper anchor locations throughout the distribution system. These calculations must also account for the expansion in the valve manholes.

(4) Piping materials in valve manholes. Nonmetallic piping must not be used in the same valve manholes as piping carrying higher temperature media that could cause the temperature around the non-metallic piping to exceed the allowables and potentially cause permanent damage to the non-metallic piping. In addition, chilled water systems with PVC carrier piping must never be installed in the same valve manhole with any heating system.

CHAPTER 4

HEAT DISTRIBUTION SYSTEMS IN CONCRETE TRENCHES

4-1. GENERAL. The concrete shallow trench (CST) is a system, which allows insulated carrier pipes to be routed underground but yet not have the piping in contact with the soil. The system also provides comparatively easy access for maintenance and repair by means of removable concrete tops. These exposed tops can be used as sidewalks since the system is installed at grade.

4-2. SYSTEM DESIGN. The designer is responsible for conducting a site investigation, designing the distribution system plan and profiles, and designing the valve manholes, as described in chapter 3 of this manual. In addition, the designer will use details and descriptions presented here to design a concrete shallow trench system at a particular site.

a. Trench Systems - General.

(1) Piping and fittings. All carrier piping and pipe fittings will be carbon steel and will be designed to satisfy the temperature and pressure requirements of the system. Materials will conform to the requirements in the guide specification.

(2) Pipe supports. Pipe supports will typically consist of three types: free, guided, and anchor. These supports are detailed in figure 4-1, figure 4-2, and figure 4-3. All of these pipe supports will be mounted on channel supports mounted to the trench walls as detailed in figure 4-4. Supports may be mounted by other means, such as on concrete pedestals, provided that paths for water flow are maintained. Table 4-1 provides guidance for the sizing of the channel supports. Note that the channels for anchor supports in the table are designed for more substantial loads than required for free and guided supports. The anchor support channel in this table is adequate for approximately 1,000 pounds force axially. The designer will determine axial force requirements at all anchor points and design the channels to accommodate these forces. **\1** Maximum distance between support channels shall be as listed in table 4-2. **/1/** These spacings are applicable to long, straight runs of piping only and must be reduced at elbows, vertical risers, valving, and equipment. The actual spacings, in these instances, will be determined by analyzing the pipe stresses with the pipe stress analysis, as described in chapter 3 of this manual. The designer should note that there are other types of supports (such as roller type) that may also be used. However, all supports must be capable of withstanding the thermal stresses and forces exerted on them.

(3) Clearances. Clearances in the trench will be adequate to provide room for expansion, air movement, and a sufficient amount of access for cleaning and maintenance. There must also be a minimum of 4 inches clearance under the support channels to ensure ground water drainage along the trench floor. Figure 4-5 provides a trench cross-section, which corresponds to the table 4-3 trench dimension schedule, which must be filled in by the designer.

(4) Insulation and jacketing. Insulation will be selected in accordance with insulation thickness tables in the guide specification. These insulation thicknesses were developed using a life cycle cost analysis. All insulations used have passed the Federal Agency Committee's boiling test and are listed in the guide specifications. All insulation in the trench will be covered with jacketing material in conformance to the guide specification.

b. Trench System - Structural. The concrete trench will be field constructed of reinforced concrete conforming to the current criteria. Trench walls and floors will be poured in place-they will not be precast. Trench tops will be poured in place or precast. Walls, floors, and tops will be constructed with 4,000 psi minimum compressive strength concrete. Reinforcing bars will conform to ASTM A 615, grade 60. Wall, floor, and top thicknesses shall be 6 inches, minimum. However, thicker sections may be required to accommodate site specific loadings or to prevent flotation. Concrete trench floors shall be sloped at a 1 inch in 20 feet slope toward all low points to ensure proper drainage. Doweled or keyed joints and water stops shall be provided at all construction joints and shall be detailed as shown in figure 4-6. Trench reinforcing details will be provided and will be similar to the section shown in figure 4-7. Note that actual concrete thicknesses and reinforcing bar sizes will be verified by the designer for each project. Trench corners will be constructed as detailed in figure 4-8. Trench tops will be no longer than eight feet to allow easy removal and placement.

c. Trench Top Removal Devices. The most common type of removal devices for the trench tops will be the sling type as detailed in figure 4-9. Four lifting devices are required to lift a trench top. One set of lifting devices will accommodate all trench tops for each contract. In some instances, sling type lifting devices will not be convenient to use (eg. when the trench top butts up against a parallel sidewalk or when the trench is routed through a parking area). In these instances, the designer shall require coil inserts to be cast into the trench cover in four locations that will accommodate threaded lifting eye bolts. When not being used, threaded plugs are inserted into the coil inserts. The lifting devices are also detailed in figure 4-9.

d. Road and Parking Lot Crossings. Road crossing requirements will be designed on a case by case basis and must take into account pavement materials, soils, and frost characteristics of the design site. A typical road crossing is shown in figure 4-10. Figure 4-11 details a concrete trench to curb and gutter system transition and figure 4-12 details a concrete trench to drain pan system transition. In all instances, the crown of the road crossing will be matched and the thickness of the trench top will be designed to accommodate worst case loadings. Parking lot crossings typically will have the trench top exposed at grade as shown in figure 4-13. Exposed tops allow for easier trench top removal over extended lengths of paved areas. If appearance of the crossing is critical, black pigments may be added to the concrete tops at the road crossing to match the surrounding pavement. In rare instances, the trench tops may be covered with asphalt surfacing, as detailed in figure 4-14.

e. Sidewalk Intersections. In the event the trench system intersects an existing sidewalk, the trench system will match the sidewalk as detailed in figure 4-15.

f. Expansion Compensation. Expansion loop and bend design is the responsibility of the designer, and is covered in chapter 3 of this manual. The expansion loop design is critical. Sufficient space needs to be provided in the expansion loop area to ensure that no pipe or insulation interference will occur due to pipe movement as shown in figure 4-16. This detail indicates location of supports and also shows how the piping system will be offset to allow for expansion movement in the trench. Table 4-4 is a typical loop schedule, which corresponds to figure 4-16. The locations of the supports in the expansion loops will be determined from the designer's piping stress analysis and then entered in Table 4-4. All piping stresses will be less than ASME B31.1 allowables for each application. The designer will require inspection ports be provided in the trench tops at each bend in the trench system routing for the purpose of observing pipe movement at the bends during system startup. The inspection port is similar to the access cover detailed in figure 4-18, except the nominal diameter of the lid will be 12 inches.

g. Sealants. The trench will be sealed to minimize the influx of ground water. A 1/4 inch thick neoprene pad will be used between trench tops and tops of trench walls. The pad will have a minimum width of 2 inches. All trench joints must be sealed with elastomeric sealants, which are available as a one or two component system. Asphaltic sealants have not performed as reliably for this application. The elastomeric sealant should be able to resist 50 percent total joint movement. The nonsagging type must be used for vertical joints. The self-leveling type must be used for trench top butt joints as shown in figure 4-17. Other horizontal joints may be sealed with either type of elastomeric sealant, but the sealant used in trench bottoms must finish flush with the floor.

h. Vents and drains. Piping vents and drains will be located at all high and low points, respectively **\1** (see figure 4-19) **/1/**. Piping drains will be provided in valve manholes only where access can be achieved and where system drainage is provided. Piping vents may be located anywhere in the trench piping system with an access cover provided in the trench top, as detailed in figure 4-18 or with an aluminum access door shown in figure 3-19.

4-3. GENERAL CONSIDERATIONS. The designer will address these key areas to ensure a satisfactory shallow trench design.

a. The grading design will ensure ground water will not pond or sit over the trench. The trench will not be routed through existing flood plains, swales, or in areas where seasonal water accumulates. Another distribution system, preferably an Aboveground Heat Distribution System (chap 7), should be used in these areas. In areas where seasonal ground water will cause a trench flotation problem, the design will include a subdrainage system along the trench if thickening of system walls and floor slabs to offset the buoyancy effect is not practical.

b. The trench floors will slope a minimum of 1 inch in 20 feet toward valve manholes and the piping will parallel the trench floor. This will allow the trench to drain off all water that may enter. Drainage will then be provided from the valve manholes as described in chapter 3 of this manual.

c. Valve manholes should be spaced to minimize the depth of the trench system. Additional manholes may be less expensive than excessive trench depths to accommodate the slope while still keeping the trench tops at grade.

*See Expansion Loop Detail for Designations (Figure 4-16).

NOTE TO THE DESIGNER:
If only one support is required along parallel leg of loop, ZZ =0. If only one support is required along perpendicular legs of loop, YY = 0.

CHAPTER 5

PRE-ENGINEERED UNDERGROUND HEAT DISTRIBUTION SYSTEM

5-1. GENERAL. Unlike Heat Distribution Systems in Concrete Trenches, which are totally designed by the designer, Pre-engineered Underground Heat Distribution Systems are designed by the system manufacturer. These pre-engineered systems are factory fabricated in lengths, which are transported to the site for field assembly. Other types of systems and materials are continuously being evaluated and will be included in guide specifications and this manual when deemed acceptable. There are two types of these systems. The DDT type is allowed for severe, bad and moderate site conditions. In severe sites allow only drainable-dryable-testable type systems. In bad and moderate sites allow DDT and water spread limiting systems. These **\1** site **/1/** conditions (or classifications) are described in detail in the guide specifications. Although the manufacturer is responsible for the pre-engineered system design, the project designer also has design responsibilities which include establishing the site, soil, and groundwater conditions, pipe sizes, proposed routing (including construction limits) estimated length, elevations, profiles of the system along with existing and finished earth surfaces and obstructions **\1** within **/1/** 8m (25 feet) of the system centerline including adjacent or crossing utilities. The project designer also provides information on location and design of manholes and entrances to buildings and manholes.

5-2. MANUFACTURER'S RESPONSIBILITY.

a. Pre-engineered Underground Heat Distribution System design. The manufacturer is responsible for the Pre-engineered Underground Heat Distribution System. This responsibility includes any or all of the following: insulation types, guided and anchor supports, end seals, casing and piping joint closure, casing type and thickness, and carrier pipe depending on the type of Pre-engineered Underground Heat Distribution System provided. There are two types of Pre-Engineered Underground Heat Distribution Systems. The drainable-dryable-testable system is a factory fabricated system, which includes a water-tight outer protective casing of steel, an air space, and an insulated carrier steel pipe. Casing drains and vents are provided in end plates, which are installed in valve manholes. DDT systems can be used for any heating medium including HTHW, high and low pressure steam, and condensate return and in any site condition (severe, bad or moderate). The water spread limiting systems is also a factory fabricated system, which includes an outer protective casing and an insulated carrier pipe. The system is fabricated in sections, which are independent from each other. Ground water or condensate, which leaks from or into one section, cannot travel into the next section. Field-assembly of the sections requires no welding; the sections are pushed together and are sealed with a system of couplings and seals. WSL systems can be used only in bad and moderate site conditions. The designer must determine the site conditions before a system type is selected. The site conditions will be considered severe, bad or moderate based on the site investigation results. For DDT and WSL systems, steam and condensate lines must always be installed in separate casings, as shown for a DDT system in figure 5-1, due to the corrosion problems associated with condensate return systems. Water systems may use just one casing for both supply and return pipes as detailed for a DDT system in figure 5-2, although installing the pipes in separate casings is preferred by most users because it is less difficult to isolate leaks. The tops of the casings will typically be buried between 2 and 6 feet below grade. However, note that excessive burial depths increase the installation and repair costs and should be avoided where possible.

b. Expansion compensation. The manufacturer is responsible for the system expansion compensation. A detailed stress analysis will be submitted for review as part of the contract requirements. The manufacturer will normally make use of expansion loops and bends to absorb system expansion in DDT systems. For WSL systems, field joints may be used to accommodate expansion. Except in rare instances, expansion joints will not be permitted.

c. Pre-engineered system's representative. The manufacturer is required to ensure that a qualified direct employee of the system manufacturer is present to guarantee proper installation when the following types of work are performed:

(1) inspection, unloading and storage of materials.

(2) inspection of trench prior to laying of casing.

(3) inspection of concrete thrust blocks.

(4) hydrostatic test of all service lines.

(5) field joint closure work.

(6) air test of casing.

(7) coating patch work.

(8) holiday test of casing coating.

(9) initial backfill up to 10 inches above the top of the casing.

(10) radiographic weld examination.

(11) startup and operation tests.

5-3. PROJECT DESIGNER'S RESPONSIBILITY.

a. Site information. As with all buried distribution systems, the site investigation is the responsibility of the designer. As described in chapter 3 of this manual, the designer will obtain soil borings, be responsible for designing the grading in the area, investigate all utilities for possible conflicts, and design for utility relocation as necessary. The designer must then determine the site conditions (severe, bad, or moderate) before a system type (DDT or WSL) is selected. The designer will then provide plans and profiles of the Pre-engineered system routing. The designer will show approximate slope of the system (1 inch in 20 feet is required to ensure drainage). This slope must be maintained in the entire system including through each leg of each expansion loop to ensure proper system drainage.

b. Valve manholes. The designer will design all valve manholes for the system as described in chapter 3 of this manual. The manholes will be no further apart than 500 feet to minimize excavation if a leak in the system must be found. The manholes will also be provided at all high (vent) points and low (drain) points in the system. The valve manholes will include ground water drainage capabilities as explained in chapter 3. Casing vents and drains will be included for maintenance of the casing air space in DDT systems as shown in figure 5-3.

c. Insulation. The insulation types used on the Pre-engineered Underground system will only be those that are listed in the guide specification. The insulation thickness tables in the guide specification will be used in determining required insulation thickness. These insulation thicknesses were developed using life cycle cost analyses.

d. Cathodic protection. The designer will be responsible for the cathodic protection design for all systems with coated steel casings. The designer shall also require that dielectric flanges be provided to isolate the system's cathodic protection system from non protected systems. These dielectric flanges shall always be installed inside valve manholes.

e. Review. The designer will provide a detailed review of the manufacturer's shop drawings to ensure the system meets the requirements of the contract. As a minimum, the following items are required in this review process:

(1) carrier pipe size and thickness.

(2) insulation thickness, type and K-value.

(3) casing material and thickness.

(4) casing coating material and thickness.

(5) verification of constant system slope to all low points (proposed elevations at all casing joints on submitted shop drawing layouts).

(6) cathodic protection design.

(7) manufacturer's system stress analysis.

CHAPTER 6

PREFABRICATED UNDERGROUND HEATING/COOLING DISTRIBUTION SYSTEM

6-1. GENERAL. This system is similar to Pre-engineered Underground Heat Distribution System (chapter 5) because it is factory fabricated in lengths, which are transported to the site for field assembly. However, the system is not allowed for any high temperature water (greater than 200 deg. F) or steam/condensate systems. The project designer is also responsible for more of the overall design.

6-2. SYSTEM DESIGN.

a. Site information. As with all heat distribution systems, the site investigation is the responsibility of the designer. The designer will obtain soil borings, be responsible for designing all grading in the area, and investigate all utilities for possible conflicts with the system. The designer will provide detailed design plans and profiles of the distribution system routings. The design will ensure a minimum slope of 1 inch in 20 feet is maintained between valve manholes. The site information requirements are covered in detail in chapter 3 of this manual.

b. Valve manholes. The designer will design all valve manholes for the system as covered in chapter 3 of this manual. As with valve manholes for the Pre-engineered Underground Heat Distribution System, manhole spacing will not exceed 500 feet and all manholes will have drainage capabilities. Also, all valves, flanges, unions, and couplings shall be located within the manholes.

c. System Material Selections. Although this system is manufactured in sections in a factory, the designer will specify all materials.

(1) Piping. The piping materials allowed are steel, copper tubing, reinforced thermosetting resin plastic (RTRP), or polyvinyl chloride (PVC). RTRP piping can not be routed through valve manholes with heating systems that could damage the RTRP. PVC piping can not be routed in any valve manhole with any other heating system piping due to its comparatively low temperature tolerance.

(2) Casing. Allowed casing materials are PVC, polyethylene (PE), or RTRP. Because these casing materials are susceptible to damage from high temperatures, they must be installed a minimum of 15 feet from buried HTHW or steam systems to avoid plastic deformation and failures of the casing materials.

(3) Insulation. Insulation type for these systems is typically polyurethane foam. Open cell type insulations, such as fiberglass, mineral wool or calcium silicate, are unacceptable for use with chilled water systems due to the tendency of condensation forming in these insulations. Insulation thickness will be specified in the guide specification.

d. Expansion compensation. The designer will perform expansion compensation calculations as covered in chapter 3 of this manual. When required, based on these calculations, sizes and locations of all expansion loops and bends, and any other expansion-compensating device, will be clearly shown on the contract drawings. The designer shall provide expansion loop details.

CHAPTER 7

ABOVEGROUND HEAT DISTRIBUTION SYSTEMS

7-1. GENERAL. Aboveground distribution systems have the lowest first cost and lowest maintenance costs of any distribution system described in this manual and are completely designed by the project designer. This system is a good application for industrial areas and where water tables are high. Many installations, however, do not desire to have distribution piping above ground for aesthetic reasons.

7-2. SYSTEM DESIGN.

a. Site information. The designer will determine information on the site. The designer will design all grading for the area and investigate all utilities for conflicts. The designer will provide detailed plans and profiles of the above ground distribution system routing. Although this system is aboveground, profiles will indicate system drain and vent points and also potential interferences between the concrete support piers and any buried utilities.

b. Piping and fittings. All carrier piping and pipe fittings will be carbon steel and will be designed to satisfy the temperature and pressure requirements of the system. Materials will conform to the requirements of the guide specification.

c. Pipe supports. The two most common types of aboveground distribution systems are low profile and high profile.

(1) Low profile system. A typical low profile support is shown in figure 7-1. In this system, the distribution piping is mounted to concrete piers by means of pipe supports. Typically, the bottoms of the pipes are mounted no more than 4 feet above grade except at road crossings, which usually incorporate high profile supports. Typical anchor, free, and guided pipe supports mounted to the concrete piers are detailed in figure 7-2, figure 7-3, and figure 7-4. Spacing of supports in straight runs of piping will conform to the support spacing schedule in table 4-2. Provide extra supports, as necessary, at pipe bends and risers. Requirements for concrete piers and pipe supports are included in the guide specification.

(2) High profile systems. High profile systems are routed high enough to cross roads and avoid obstructions. Typically the piping will be installed 14 to 16 feet above grade. The system presented in this manual uses 6-inch concrete-filled pipes embedded in concrete footings as detailed in figure 7-5. The pipe guides are mounted on channels at the top of the support pipe as detailed in figure 7-6. The pipe anchors are also mounted to channels and then stabilized with guy cables as shown in figure 7-7. Structural design for the structural members on these high profile supports in figure 7-6 and 7-7 are for water filled, schedule 40 steel pipes up to 10-inch nominal size. Conditions outside these constraints must be designed on a case-by-case basis. The designer for each anchor application will also size the guy cables. Spacing of supports in straight runs of piping will conform to the support spacing schedule in table 4-2. Extra supports will be added, as necessary, at pipe bends and risers. Concrete footings and high profile supports will conform to the requirements of the guide specification.

c. Insulation and jacketing. All piping on aboveground systems shall be insulated and jacketed. Insulation thicknesses will be determined by insulation tables provided in the guide specification. These insulation thicknesses were developed using life cycle cost analyses. All insulation will be covered with a jacketing material in conformance with the guide specification.

e. Expansion Compensation. Expansion loops and bends will be designed as described in chapter 3 of this manual. Expansion loops will be located to minimize impacts to ground level interferences such as trees and sidewalks. For horizontal expansion loops, pipe supports will be spaced less than the maximums listed in table 4-2 because of the extra bends and associated movement in the loops. In low profile systems, vertical expansion loops may be used as road crossings. Details will be provided indicating support types and locations throughout the loops and bends.

f. Vents and Drains. Provide venting of all piping high points and draining of all low points to allow total drainage of the system. Vent and drain locations will be indicated on the profile drawings. Vents and drains are similar to those used for the concrete shallow trench system, figure 4-15.

g. Transition to Buried Systems. When a buried system transitions to an aboveground system a valve manhole will be provided at that point. A manhole top penetration will be provided to allow expansion of the distribution piping in the man-hole top yet keep rain and ground water out of the manhole. Figure 7-8 shows such a transition in a valve manhole with a concrete cover. The valve manhole used for this transition must be large enough to be accessible and will be designed in accordance with chapter 3 of this manual.

CHAPTER 8

SPECIAL CONSIDERATIONS

8-1. GENERAL. Although it is impractical to cover all special considerations, which arise in heating and cooling distribution designs, this chapter presents typical design problems and solutions associated with steam, high temperature hot water, low temperature hot water and chilled water systems.

8-2. STEAM SYSTEMS.

a. Trap Selection. Steam traps are used to separate the condensate and non-condensable gases from the steam. Many types of traps are used on drip legs for steam distribution systems. Those trap types include float and thermostatic (F&T), inverted bucket, thermostatic and thermodynamic (disc). However, for buried heat distribution drip leg applications, inverted bucket or thermostatic (bimetallic type) should be the trap types selected. For drip leg applications where freezing is a consideration, thermodynamic type (installed vertically) or bimetallic thermostatic type should be selected.

b. Trap Sizing and Location. Trap sizing is important for obtaining an efficient steam distribution system. Condensation in the steam line is caused by heat loss from the steam line. Trap life will be shortened, function affected and excessive energy will be wasted if traps are oversized to handle the higher initial startup condensate flows. Therefore, the traps should be sized for the condensate load seen during the distribution system normal operation. Because the traps are not sized for startup loadings, the bypass must be opened at startup to allow condensate to pass until the steam line has reached normal operating temperatures (see figure 8-1). The designer will calculate heat loss and condensate flow for that particular design using the methods presented in appendix D for determining condensate loads during normal operation. It is critical that the designer calculate trap capacity using the Appendix D method for each trap station in the design to ensure proper steam system operation. In addition to trap capacity, steam trap type, differential pressures, and inlet pressure must always be provided on the contract documents. Do not locate steam drip legs, with associated traps, more than 500 feet apart.

c. Drip Leg Sizing. Drip legs, installed vertically down from the steam pipe, are used to collect condensate. Design all steam lines to slope at 1 inch in 20 feet minimum toward these drip legs. It is preferable to slope the steam lines in the direction of steam flow whenever possible. The steam trap line and bypass line are connected to the drip leg as indicated in figure 8-1. The drip leg will be the same nominal pipe size as the main line (up to a 12-inch line) and will provide a storage capacity equal to 50% of the startup condensate load (no safety factor, one-half of an hour duration) for line sizes 4 inches in diameter and larger and 25% of the startup condensate load (no safety factor, one-half of an hour duration) for line sizes less than 4 inches. In no case will the drip leg be less than 18 inches in length or larger than 12 inches in diameter for all steam line sizes. The designer will calculate startup loads for drip leg sizing using the methods presented in appendix D.

d. Trap Station Layout. All trap stations will be piped as indicated in figure 8-1, as a minimum. Valve and strainer sizes will match the line sizes on which they are installed. Pipe lines to and from the steam trap will be sized based on calculated trap capacity but will be no less than 3/4-inch nominal size (line size "A" on figure 8-1). If reducing fittings are needed at the trap inlet and outlet, eccentric reducers must be used. The bypass line will be sized to accommodate warm-up condensate loads. For steam systems with an operating pressure of 150 psig or less and pipe sizes 12 inches or less, provide a ¾-inch bypass line. If the condensate return main is a low pressure or gravity flow type, the trap discharge line will be routed through an accumulator, as indicated in figure 8-2. The accumulator will lower the trap discharge temperature and minimize flashing when the condensate is introduced into sloped condensate lines which are routed to receiver/pump sets located in valve manholes. The pumps push the condensate back to the central plant in a separate pressurized condensate line. See figure 8-3 for a duplex condensate pump set connection detail.

This type of condensate return system is referred to as a "three pipe" or a "pumped return" system. If the steam pressure is sufficiently high, it may be used to force the condensate through the condensate return system to the central plant as shown in figure 8-1. No accumulator is required for this type system, which is referred to as a "two pipe" system. Sizing of the lines for both of these systems is presented later in this chapter.

e. Condensate Cooling System. Fiberglass reinforced plastic (FRP) piping is usually allowed for most condensate return systems. Since internal corrosion is a frequent problem in steel condensate lines, FRP eliminates this problem. However, the FRP materials cannot withstand as high of pressures or temperatures as steel and often fail when exposed to these conditions. A common temperature in an FRP distribution piping system where damage will occur is 250 deg. F. Condensate temperatures may exceed 250 deg. F. at the outlet of steam drip leg traps on steam systems that have pressures greater than 15 psig. In order to use FRP condensate lines in this case, a condensate cooling system will be employed, as detailed in figure 8-4. In this system, the high temperature condensate is discharged into a cooling tank where it blends with the system condensate. The blended condensate is then routed to the condensate main. Note that the detail shows the FRP (or non-metallic) pipe transitioning to steel inside the valve manhole to avoid burying the transition point. Also, note that nonmetallic piping will not be allowed in a manhole with high temperature hot water or high pressure steam systems due to the potential for this pipe being exposed to damaging temperatures within the manhole if the manhole floods or the carrier pipe on the heating system leaks.

f. Non-metallic Pipe Anchors in Valve Manholes. If anchoring of a non-metallic piping system is required at the valve manhole wall to comply with the distribution system stress analysis, a typical method is as detailed in figure 8-5. If the system is to be anchored at both of the valve manhole wall penetrations, provide adequate piping bends in the manhole to accommodate the expansion between the two anchors. Steel straps and bolts will be sized to accommodate the axial force of that particular piping layout. These sizes will be entered on the detail. Also, valve manhole sizes must be large enough to accommodate the anchors and still allow for maintenance access.

g. Pipe Sizing. Pipe sizing is critical to proper operation of both the steam and the condensate return systems.

(1) Steam. There are several methods to size steam lines. One of the quickest and most popular methods is using pressure drop versus flow rate charts, which provide steam velocities based on the required flow and pressure drops. The American Society of Heating, Refrigeration, and Air Conditioning Engineers (ASHRAE) Fundamentals Handbook, Chapter "Pipe Sizing", is a good source for these steam sizing tables. Recommended velocities for various system pressure ranges are:

0 - 10 psig, saturated - 1,000 to 4,000 fpm
10 - 50 psig, saturated - 4,000 to 8,000 fpm
50 - 150 psig, saturated - 8,000 to 12,000 fpm

In addition, ensure the total pressure drop in the system will not be excessive. Steam pressure must be high enough at the end users to meet all special process requirements.

(2) Condensate. As described previously in this chapter, there are basically two types of condensate return systems used on central heating systems: the two pipe system (which uses steam pressure to force condensate back to the plant) and the three pipe, or pumped return, system. When sizing lines for these condensate return systems, table 8-1 will be used for guidance.

h. Steam System Material Selection.

(1) Valves. For high-pressure steam systems (125 psig or greater), valves will be 300-pound class and

will have welded ends. Steam and condensate valves at lower pressures will be 150-pound class with welded ends. Valves on trap stations, including the bypass valve, will be 150-pound class with threaded ends. Shutoff valves will be gate type.

(2) Fittings. All fittings in the steam distribution system, except as discussed for valves, will be welded except at equipment, traps, strainers, and items which require frequent removal. These items will be threaded or flanged.

(3) Piping. Steam and condensate piping will usually be carbon steel conforming to ASTM A 53, Grade B, Type E or S. Steam piping will be schedule 40. Condensate lines will be schedule 80 as will all welded piping less than 1-1/2 inches. Condensate lines in a pre-engineered underground heat distribution system may be FRP as discussed in chapter 5.

i. Field Joints. Radiographic examination of all carrier pipe field joints is required.

8-3. HTHW SYSTEMS.

a. Pipe Sizing. Sizing lines for HTHW systems is similar to any water system, except at high temperatures water becomes less dense and less viscous, and, therefore, the mass flow rate of the system must be calculated considering the lower density (usually temperatures are around 400 deg. F for HTHW).

$$m = q \times 60 \text{ min/hr} \times 0.1335 \text{ ft}^3\text{/gal} \times ?$$

where

q = system flow in gal/min

m = mass flow rate in lbm/hr

? = density of water at maximum system temperature in lbM/ft^3

Pressure drop versus flow charts may be used to determine line size, such as the chart included in appendix B. This chart takes into account the characteristics of higher temperature water systems. Recommended velocities for various HTHW flows are as follows:

Up to 10,000 lbm/hr	-	1 to 2 feet/sec
10,000 to 30,000 lbm/hr	-	2 to 3 feet/sec
30,000 to 200,000 lbm/hr	-	3 to 5 feet/sec
200,000 lbm/hr on up	-	(use velocity to accommodate 0.50 psi/100 ft., maximum)

b. HTHW System Material Selection

(1) Valves. All valves on HTHW systems will be 300-pound class with welded ends. Shutoff (isolation) valves will be gate type. Valve packings must be capable of handling the pressures and temperatures associated with HTHW systems.

(2) Fittings. All fittings on HTHW systems will be welded. The only exceptions will be specialty equipment such as dielectric flanges used to isolate the piping system from a cathodically protected system.

(3) Piping. HTHW piping will be carbon steel conforming to ASTM A53, Grade B, Type E or S. All piping will be schedule 40 except for welded pipe less than 1-1/2 inches, which will be schedule 80.

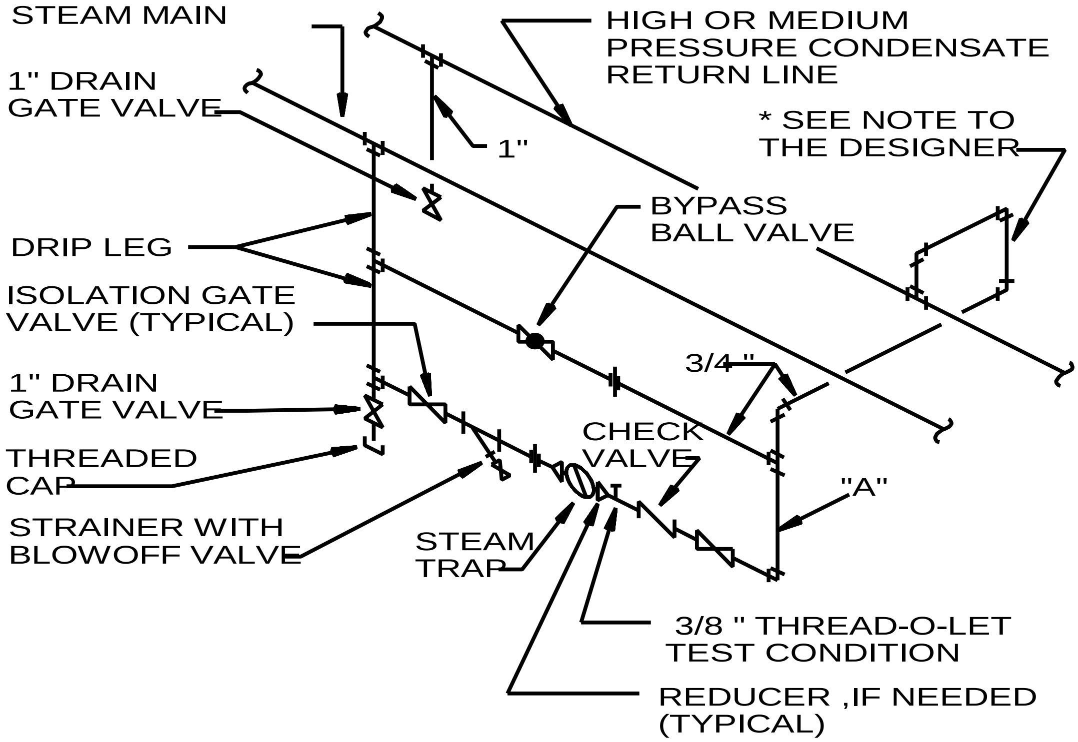
8-4. LTHW and CW systems.

a. Pipe Sizing. The most efficient method of determining pipe size for LTHW and CW systems is to use head loss vs. flow rate charts such as those found in ASHRAE Fundamentals, Chapter "Pipe Sizing". These tables are based on 60 deg. F water so for chilled water pipe sizing there is little error introduced using these charts. For LTHW systems, the use of the charts does introduce some error. However, the error is on the conservative side (the charts overstate the pressure drop of LTHW).

b. LTHW and CW Material Selection.

(1) Valves. Typically, valves on either LTHW or CW systems will be 150-pound class and will be located in the valve manholes. Ball valves provide a good means for line isolation. Although nonmetallic valves are sometimes allowed for these systems, metallic valves should be used for durability.

(2) Piping. The most common piping materials used for LTHW and CW systems are steel, copper tubing, reinforced thermosetting resin pipe (fiber- glass) and, for CW only, polyvinyl chloride and polyethylene. However, do not include nonmetallic piping in the same valve manholes with HTHW and steam systems. Chilled water lines using PVC piping must be installed in separate valve manholes since PVC can be thermally damaged at relatively low temperatures. Outside the valve manholes, a separation of 15 feet (minimum) must be maintained between pre-engineered underground HTHW and steam systems and PVC encased, prefabricated underground heating/cooling distribution systems to avoid thermal degradation of the PVC.



TRAP STATION LAYOUT ISOMETRIC

TWO-PIPE SYSTEM SIZING GUIDELINES

- ?? DETERMINE CONDENSATE LINE PRESSURE (AS OBSERVED FROM ON-SITE PRESSURE GAGES).
- ?? DETERMINE CONDENSATE LOAD (lbm/hr) FROM CENTRAL PLANT LOGS AND OTHER INPUT.
- ?? ASSUME CONDENSATE AT TRAP DISCHARGE IS A COMBINATION OF CONDENSATE AND FLASH STEAM.
- ?? SIZE LINE TO ACCOMMODATE 5,000 ft/min STEAM AND CONDENSATE MIXTURE VELOCITY AND TO ENSURE MIXTURE PRESSURE IS HIGH ENOUGH TO OVERCOME LINE LOSSES.

THREE-PIPE SYSTEM SIZING GUIDELINES

GRAVITY LINE

- ?? SLOPE AT 1 inch/20 feet (MINIMUM) TOWARD RECEIVER.
- ?? TOTAL PRESSURE DROP LESS THAN 0.25 psi.
- ?? LINE SIZE WILL BE TWO (2) INCHES.

PUMPED LINE

- ?? SIZE PUMPS TO MOVE CONDENSATE TO THE CENTRAL PLANT AT THE REQUIRED HEAD AT 200 deg. F.

APPENDIX C

CONDENSATION LOAD CALCULATIONS (NORMAL)

Step #1 Determine the heat loss per foot of line.

$$Q = 2\pi\ (T_{st} - T_{out})/(\ln(r_o/r_i)/k_p + \ln(r_{io}/r_o)/k_{in} + 1/3r_{io})$$

Assumptions. This equation models an insulated pipe surrounded by air. The convective resistance between the insulation and the outside of the pipe is assumed to be negligible. Also, the convective heat transfer coefficient outside of the insulation is assumed to be 3 BTU/hr-ft^2 deg. F.

Step #2 Determine the flow of condensate from the heat loss calculated in step #1.

$$m = Q/(h_{st} - h_{con})$$

Step #3 Multiply the flow rate per foot, calculated in step #2, by the total number of feet of steam line that slopes toward the trap in question. The result is the minimum flow capacity of the trap.

where:

- Q = heat loss per foot of pipe; Btu/hr-ft
- T_{st} = temperature of steam; deg. F
- T_{out} = temperature of ambient conditions; deg. F
- r_o = outside pipe radius; feet
- r_i = inside pipe radius; feet
- r_{io} = outside insulation radius; feet
- k_p = thermal conductivity of pipe; Btu/hr-ft- deg. F; (26 Btu/hr-ft-deg. F for steel)
- k_{in} = thermal conductivity of insulation; Btu/hr-ft- deg. F * (see table below)
- m = mass flow rate of condensate; lbm/hr-ft
- h_{st} = enthalpy of saturated steam; Btu/lbm
- h_{con} = enthalpy of condensate; Btu/lbm

\1\ *K-value (Btu/hr-ft-deg. F /1/

Insulation Type	400 deg. F	300 deg. F	200 deg. F
Mineral Fiber	0.034	0.029	0.024
Calcium Silicate	0.042	0.038	0.035

APPENDIX D

CONDENSATION LOAD CALCULATIONS (STARTUP)

Step #1 Determine the heat loss per foot of line.

The startup load can be calculated by determining the amount of heat that is required to heat the steam pipe from an ambient temperature to the saturation temperature of the steam the pipe is to carry. This is done by using the following equation:

$$Q = (v_p * c_p * ?_p \ (t_{st} - T_{out}))/t; \text{ Btu/ft}$$

where:

$$v_p = ? \ (r_o^2 - r^2); \text{ in ft}^3\text{/ft}$$

Step #2 Determine the pounds of condensate per foot from the heat loss calculated in step #1.

$$m = Q/(h_{st} - h_{con}); \text{ lbm/ft}$$

Step #3 Multiply the condensate per foot, calculated in step #2, by the total number of feet of steam line that slopes toward the drip leg in question. Then convert the total pounds of condensate to gallons assuming 200 F condensate:

$$\text{Total Condensate Volume (gallons)} = \frac{(m*L)*7.49 \text{ gallons/ft}^3}{60.1 \text{ lbm/ft}^3}$$

where:

Q = heat loss per foot of pipe; Btu/hr-ft
T_{st} = temperature of steam; deg. F
T_{out} = temperature of ambient conditions; deg. F
r_o = outside pipe radius; feet
r_i = inside pipe radius; feet
m = mass flow rate of condensate; lbm/hr-ft
h_{st} = enthalpy of saturated steam; Btu/lbm
h_{con} = enthalpy of condensate; Btu/lbm
c_p = specific heat of pipe (steel); (0.10 to 0.11) Btu/lbm/degrees F
$?_p$ = density of pipe (steel); (489) lbm/ft_3

t = length of time for startup; hrs (typically 0.5 hrs.)

L = total length of pipe draining to drip; ft
v_p = volume of pipe material per foot; ft^3/ft

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**

This UFC supersedes UFC 3-430-09, dated January 2004.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-430-05, *Natural Gas and Liquefied Petroleum Gas (LPG) Distribution Pipelines*

Superseding: This change supersedes UFC 3-430-09 Exterior Mechanical Utility Distribution, dated 16 January 2004, with Change 1.

Description: This UFC provides guidance to the design and installation of new or modifications to existing distribution pipelines that convey natural gas, manufactured gas, or LPG in the vapor phase, that are installed on Government owned property. These requirements must be followed by the Government or its contractors when the Government is the responsible operator of the distribution pipeline. Where the Government is not the responsible operator, this UFC is intended to inform Government personnel of the requirements typically implemented by the responsible operator of the distribution pipeline.

Reasons for Document:

- This UFC has been completely rewritten in this change to comply with the Code of Federal Regulations, Title 49, Part 192 (49 CFR 192), Transportation of Natural and Other Gas by Pipeline: Minimum Federal Safety Standards.

Impact:

- This change increases the initial and maintenance costs of gas distribution pipelines but ensures compliance with 49 CFR 192 in support of the requirements for reporting to the Pipeline and Hazardous Material Safety Administration (PHMSA). Proper application of these requirements also supports the transfer of responsible operation of compliant gas distribution pipelines from the Government to a Utility Privatization (UP) contractor or local gas provider.

Unification Issues

There are no unification issues with the guidance written herein.

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC is written to provide guidance for development of distribution pipelines carrying natural gas, manufactured gas or Liquefied Petroleum Gas (LPG) in its vapor phase, that are installed on Department of Defense (DoD) owned property, from the point of delivery by the gas supplier to the points of connection to the buildings' fuel gas piping. This UFC implements the regulations written in the Code of Federal Regulations (CFR), Title 49, Part 192 (49 CFR 192), Transportation of Natural and Other Gas by Pipeline: Minimum Federal Safety Standards. This UFC applies where the DoD is the responsible operator of the distribution pipeline. Where a private utility provider is designated as the responsible operator, this UFC is to inform Government personnel of the requirements that apply to the distribution pipeline.

This document does not cover building fuel gas piping, which is the piping system that connects to the last downstream component of the distribution pipeline, either isolation valve, service regulator or meter, and supplies fuel gas to individual appliances. Refer to National Fire Protection Association (NFPA) 54, the International Code Council (ICC) fuel gas code and Unified Facilities Guide Specifications (UFGS) 23 11 25 Facility Gas Piping for guidance when installing building fuel gas piping.

This document does not cover systems used to convey LPG in its liquid phase. Refer to 49 CFR 195 and UFC 3-460-01 for liquid phase LPG pipelines and transfer systems. Refer to NFPA 58, the ICC fuel gas code and UFGS 23 11 25 Facility Gas Piping for guidance when installing a single LPG storage tank with LPG service to a single building.

1-2 APPLICABILITY.

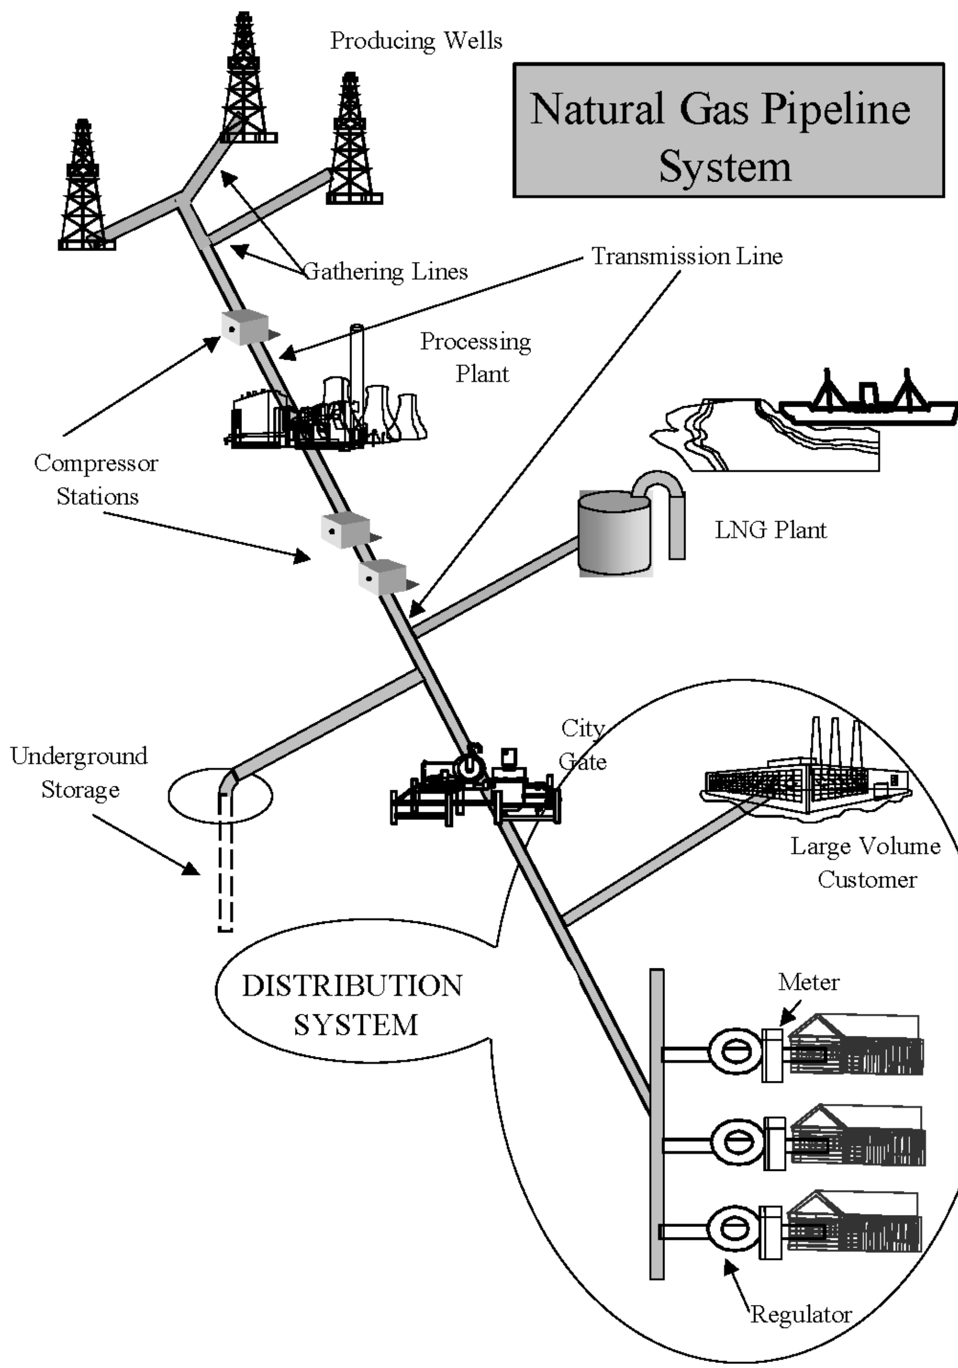
This UFC applies to all planning, design, design, construction, operations and maintenance for the gas distribution pipeline and all of the appurtenances where the DoD is designated as the responsible operator.

1-3 PIPELINE DISTRIBUTION.

1-3.1 Natural and Manufactured Gas.

Regulations written in 49 CFR 192 apply to every part of gas pipelines from the point of gas production to the point of connection of the service line components to a building's fuel gas piping system. An electronic version of 49 CFR 192 can be found at the Electronic CFR website: https://ecfr.io/Title-49/cfr192_main. Within 49 CFR 192, three distinct types of pipelines are described 1) Gathering Pipelines, 2) Transmission Pipelines and 3) Distribution Pipelines. See Figure 1-1 for a graphical representation of the 49 CFR 192 natural gas pipeline system. Gathering pipelines are not under the authority or scope of this UFC. Transmission pipelines typically owned and operated by gas suppliers and not covered by this UFC. Transmission lines installed on DoD installations are under an easement from the DoD to a responsible owner.

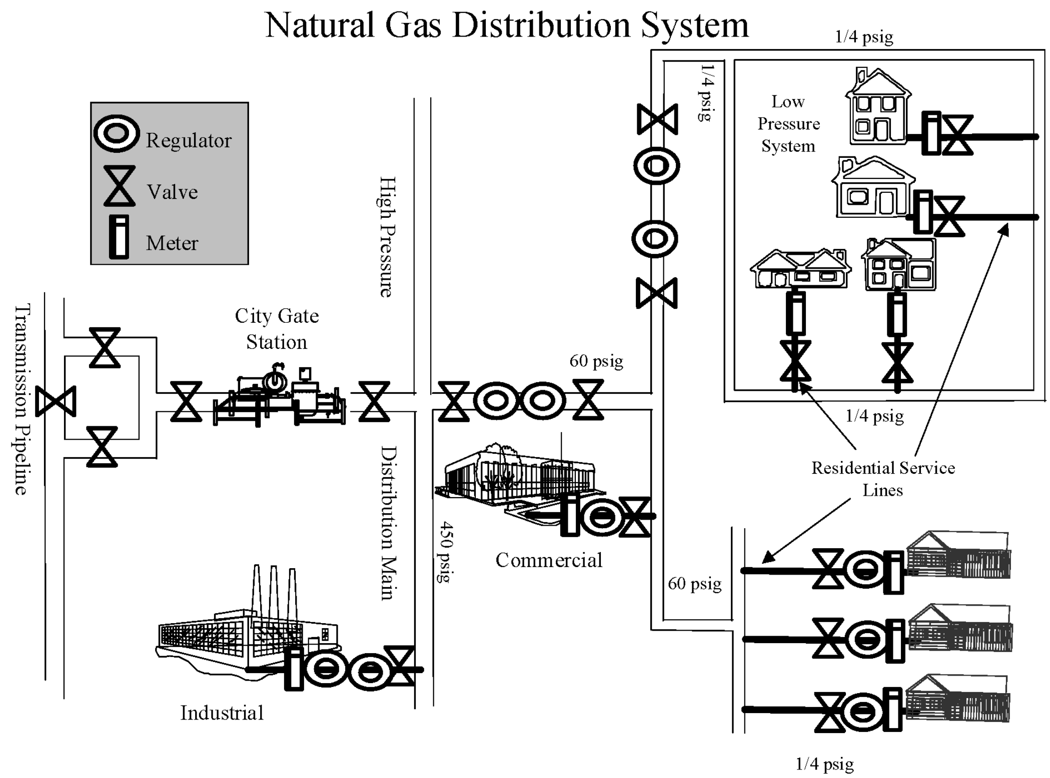
Figure 1-1 Example 49 CFR 192 Natural Gas Pipeline Network



Courtesy of the DOT Guidance Manual for Operators of Small Natural Gas Systems, January 2017

Gas pipelines for which the DoD is the responsible operator are typically classified as Distribution Pipelines and are characterized as a pipeline that receives gas from a gas utility purveyor who delivers, meters, and regulates the pressure of gas supplied to the distribution pipeline that is located on a DoD installation. See Figure 1-2 for a graphical representation of the natural gas distribution pipeline.

Figure 1-2 Example Typical Natural Gas Distribution System



Courtesy of the DOT Guidance Manual for Operators of Small Natural Gas Systems, January 2017

1-3.2 Liquefied Petroleum Gas (LPG).

49 CFR 192 also applies to LPG distribution pipelines that convey LPG in the vapor phase. Piping that conveys liquid LPG is not covered under 49 CFR 192, but is regulated by 49 CFR 195: Transportation of Hazardous Liquids by Pipeline. 49 CFR 195 §195.1 (b) (1) writes an exception to applicability for any hazardous liquid transported in a gaseous state. This exception implements, by default, 49 CFR 192 as the regulating document. 49 CFR 192 §192.11 refers to the vapor phase of LPG as 'petroleum gas' and requires that petroleum gas pipelines comply with 49 CFR 192 and NFPA 58, with NFPA 58 prevailing in the event of conflict. NFPA 58 applies to liquid LPG pipelines, liquid LPG storage containers, and pipelines that convey LPG in the vapor phase. This UFC provides guidance for the vapor phase distribution pipeline and the liquid storage container that serves that distribution pipeline. Please refer to UFC 3-460-01 for guidance on liquid phase LPG piping systems.

49 CFR 192 §192.1 (b) (5) allows two exceptions to applicability for any pipeline system that transports only petroleum gas.

"(5) The regulations of 49 CFR 192 do not apply to a pipeline system that transports petroleum gas or petroleum gas/air mixture to:

(i) Fewer than ten customers, if no portion of the system is located in a public place – or –

(ii) A single customer, if the system is located entirely on the customer's premises (no matter if a portion of the system is located in a public place)."

However, the requirements of NFPA 58 do apply. The exception allowed in paragraph (i) must not be applied on a DoD installation. On DoD installations, there is the likely possibility that a system will expand to include 10 or more customers. These exceptions do not change the materials or installation practices, as these are dictated by NFPA 58. What is exempted is the qualification of installation practices, installer qualifications, and reporting regulations of 49 CFR192. Therefore, the risk is that a system installed that does not comply with 49 CFR 192 regulations is very difficult, if not impossible, to expand into the scope of 49 CFR 192.

1-4 PIPELINE NOMENCLATURE.

Gas pipelines are described in 49 CFR 192 using the following nomenclature.

1-4.1 Gas.

Each time the term 'Gas' is used in this UFC, it is understood that the term applies to natural gas, manufactured gas, liquefied petroleum gas in its vapor phase, and any other flammable gas.

1-4.2 Gathering Lines.

Gathering lines transport gas from a gas production facility to the transmission pipeline or main. Gathering lines are not under the authority or control of DoD installations.

1-4.3 Transmission Lines.

Transmission lines are typically owned and operated by gas suppliers and are not operated by the DoD installation.

1-4.4 Distribution Lines.

Distribution lines transport gas from the transmission line or LPG storage container to each individual customer. Pipeline that operates at a hoop stress of 20% or more of the specified minimum yield stress (SMYS) must also meet the requirements of a transmission line.

1-4.4.1 Main.

A main is defined as a distribution line that serves more than one service line. Note that 49 CFR 192, Subpart G appears to apply only to transmission pipelines because it is entitled ‘General Construction Requirements for Transmission Lines and Mains’. Whenever 49 CFR 192 discusses a Main, the requirement applies to the distribution pipeline.

1-4.4.2 Service Line.

A service line is a distribution line that transports gas from a main to an individual customer’s meter, regulator, or isolation valve upstream of the customer’s piping. Note that this point of connection is the demarcation between the pipeline as governed by 49 CFR 192 and the fuel gas piping governed by NFPA 54.

1-4.4.3 High Pressure Distribution System.

A distribution system that operates with a gas pressure in the main that is higher than the pressure provided to the customer.

1-4.4.4 Low Pressure Distribution System.

A distribution system that operates with a gas pressure in the main that is substantially the same as the pressure provided to the customer.

Refer to 49 CFR 192 §195.3 for the official definition of each of these terms.

1-4.5 Master Meter Operators (MMO).

Small natural gas distribution systems are sometimes designated as Master Meter Systems (MMS). This designation is typically reserved for owners of apartment buildings, trailer parks, or other types of property managers. The 49 CFR 192 refers to MMO, the operator of an MMS, but does not provide clearly defined criteria for determining who is and who is not an MMO. The reporting regulations for an MMO are significantly less than the reporting regulations for the distribution pipeline operator; however, the requirement to obtain and retain complete knowledge of the system operated are nearly equal for each operator.

It is routine for natural gas systems installed on DoD installations to connect to transmission or distribution lines owned and operated by a natural gas purveyor through a metered and pressure regulated connection. Because of this method of connection and the limited reporting responsibility of an MMO, it is tempting for engineers, contractors, and operators to claim a natural gas distribution system to be a master meter system. No natural gas systems that are installed on a DoD installation shall be considered a master meter system without expressed written approval from the authorized administrator(s) of all applicable regulations.

1-4.6 Administering Agencies.

The Pipeline and Hazardous Material Safety Administration (PHMSA) is assigned as the administrator in 49 CFR 192 and is tasked with enforcing the regulations presented therein. Transmission line operators and distribution line operators are required by the regulations to report specific information to PHMSA. The reporting regulations are different and more detailed for the transmission line operator than for the distribution line operator. But, none the less, the distribution line operator is required to report to PHMSA. These reporting requirements create the need for the pipeline operator to obtain and retain complete knowledge of each pipeline segment and component installed in the system that the operator is responsible for. Details of the plans, procedures and reports that must be available for PHMSA review for distribution pipelines are defined in 49 CFR 192, Subparts L and P. A more comprehensive discussion of reporting requirements can be found in the January 2017 revision of "Guidance Manual for Operators of Small Natural Gas Systems", Chapter VIII, authored by the Department of Transportation (DOT). Paragraph 1-3.7 of this UFC briefly describes these reporting requirements to emphasize the importance of the detailed design and construction submittal process necessary to support the DoD installation in complying with the reporting regulations of 49 CFR 192.

State agencies may also enforce pipeline safety regulations that are more stringent than the regulations presented in 49 CFR 192. Local municipalities, gas purveyors, and the transmission line operator may also apply more stringent regulations. The distribution line operator must know the regulations that apply to the distribution pipeline that he operates and should transfer the requirements to design engineers and installing contractors who perform work on this system.

It is necessary that the Designer of Record (DoR) for any distribution pipeline projects such as construction, addition, rehabilitation, and repair on a DoD installation contact the person or department responsible for operating the pipeline to understand the requirements that apply.

1-4.7 Plans and Reports.

All operators of gas pipelines are required to maintain a number of plans for safe operation of the pipeline. Therefore, all information relative to work performed on gas distribution pipelines installed on DoD installations must be provided to the responsible operator through the design and construction process in order to support the ongoing planning and reporting efforts required from that responsible operator. The Department of Public Works (DPW)/Base Civil Engineer (BCE), a Utility Privatization (UP) contractor, or a gas supplier is typically the responsible operator of gas distribution pipelines located on DoD installations and should provide information on the distribution pipeline as it exists and must receive complete information on all work performed.

The plans required from a distribution pipeline operator are listed below to indicate the necessary thoroughness of the information that must be made available. Requirements for developing these plans and reporting the information contained in the plans are defined in 49 CFR 192.

- Operations and Maintenance (O&M) Plan: Subparts L and M, consist of 27 procedures covering all aspects of installing, operating and maintaining each pipe segment and component. These procedures include, but are not limited to, the following:
    - Making construction documents available to operating personnel.
    - Gathering data needed for reporting incidents.
    - Corrosion control.
    - Continued surveillance and damage prevention: §192.613 and 614.
    - Emergency Plan: §192.615.
    - Public Awareness Plan: §192.616.
    - Leak Survey: §192.723.
- Operator Qualification Plan: Subpart N.
- Distribution Integrity Management Plan: Subpart P, consists of 7 required elements.

The information necessary to develop these required plans mostly originates during design and construction of each segment of the pipeline. Therefore, the construction plans and specifications developed by the Designer of Record (DoR) must include appropriate system design and testing parameters as well as requirements for the installing contractor to submit all information necessary, including location, materials, equipment, installation procedures, procedure and personnel qualification, and testing results, for the DoD installation to develop and maintain the required plans and procedures.

1-5 ORGANIZATION OF 49 CFR 192.

49 CFR 192 is divided into Subparts, each describing a specific area of concern. The following sub-parts are not retroactive and apply to pipelines readied for service after 12 March 1971, or were replaced, relocated, or changed after 12 November 1970:

Subpart B – Materials
Subpart C – Pipe Design
Subpart D – Design of Pipeline Components
Subpart E – Welding of Steel in Pipelines
Subpart F – Joining of Materials other than by Welding
Sub part G – General Construction Requirements for Transmission Lines
Subpart H – Customer Meter, Services, Regulators, and Service Lines
Subpart J – Test Requirements
Subpart N – Qualification of Pipeline Personnel

The following subparts are retroactive and apply to all existing pipelines regardless of date of construction:

Subpart A – General
Subpart I – Requirements for Corrosion Control
Subpart K – Uprating
Subpart L – Operations
Subpart M – Maintenance
Subpart O – Gas Transmission Pipeline Integrity Management
Subpart P – Distribution Integrity Management

1-6 USE OF ASME B31.8.

Pipelines on DoD installations must comply with the requirements of 49 CFR 192. A comparable industrial standard is ASME B31.8, Gas Transmission and Distribution Piping Systems. Although ASME B31.8 may appear to be an acceptable piping code for compliant natural gas pipeline construction, it allows materials, components, and construction practices that do not comply with 49 CFR 192. §192.7 specifies that use of ASME B31.8 is approved only as referenced in §192.112(b) and §192.619(a).

As an industry standard, ASME B31.8 provides additional detail that is not found in the Code of Federal Regulations (CFR). Therefore, ASME 31.8 is a very good reference document and is recommended to help the reader better understand the material and construction practices available from the natural gas industry. But 49 CFR 192 is the defining requirements document and any decision made from information presented in ASME B31.8 must be confirmed to comply with the requirements of 49 CFR 192.

1-7 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-8 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 DISTRIBUTION PIPELINE DESIGN

2-1 SYSTEM PLANNING.

2-1.1 System Layout.

Gas distribution pipelines will be planned carefully with due consideration for economy, safety, and uniformity of pressure. The lines will be well-looped within the main area and in all outlying areas whenever practicable and economically feasible to do so. It is not always practicable to loop a supply line to an outlying area and then back into the main system, but in such cases the objectionable effects of dead ends can often be relieved to some extent by looping such line around the area it serves and then back into itself.

2-1.2 Pipeline Location.

Gas distribution pipelines will never be installed under a building. They will not be laid in the same trench with other utilities to preclude the possibility of leaking gas following along or collecting in other conduits and creating an explosion hazard. For the same reason, gas lines will be above other utilities whenever they cross, if practicable. Underground gas pipelines must be installed with the minimum clearance from other underground structures as is specified in §192.325. Gas lines will not be laid under paved streets or in other locations subject to heavy traffic whenever practicably avoidable. Whenever it is necessary to locate gas lines in such locations, the lines will be protected in accordance with (IAW) 49 CFR 192. Sufficient clearance must be maintained between plastic mains and steam, hot water, power lines, and other sources of heat, to avoid temperatures in excess of the rated temperature and pressure combination of the pipe.

2-1.3 Location Classification.

49 CFR 192, §192.5 classifies the location of a gas pipeline based on its proximity to occupied buildings or frequently occupied outdoor locations. The location classification ranges from Class 1 to Class 4 and signifies the level of risk and consequence to human life in the event of pipeline failure. As population density increases, so the location class number increases. The location classification is used in defining several regulatory requirements for a given pipe segment.

The Designer of Record (DoR) of any project that modifies any segment of a gas distribution pipeline on a DoD installation must obtain existing location classifications, verify that the class meets §192.5, and identify the proper location class for all pipeline segments modified or connected to in the project. Design drawings must indicate the location classification for each pipe segment in the distribution pipeline. For projects on DoD installations, all new or modified distribution pipeline must be location Class 3 to minimize the impact that future building construction projects may have on existing pipelines. Where connection is made to a pipe segment designed for a location class other than Class 3, the drawings must identify the location of the change in class.

The pipeline operator is responsible for maintaining the proper location classification for each segment of pipe as additional buildings are constructed on the DoD installation. Therefore, the DoR must coordinate the intended location classification with appropriate DoD installation personnel.

2-2 ENGINEERING ANALYSIS, PLANS, AND SPECIFICATIONS.

The DoR must provide an engineering analysis, plans, and specifications that define the work to be performed and all of the information that the installing contractor is required to provide to the Government for a complete and functional installation that meets the regulatory requirements of 49 CFR 192 and provides the Government Operator with all information needed for proper reporting to the regulatory agency, for example PHMSA, State agency.

2-2.1 Engineering Analysis.

Engineering analysis will be presented in diagram form showing all connected loads, design flow rate, locations of valves, pressure regulators, and other pipeline devices, actual operating pressure before and after each regulator, and any other appurtenance required to control downstream pressure, relieve downstream pressure, or prevent excess flow. A complete set of supporting calculations will be prepared.

2-2.2 Plans.

The plans will include a layout drawing showing the entire distribution system and detail drawings clearly showing pipe sizes, the location of gas mains, service connections, details for abandoning gas piping, mechanical couplings, valves, service taps, regulators, and other appurtenances. ASME B31.8 requires that abandoned gas lines be physically disconnected from gas sources. Shutoff valves are not an acceptable means of disconnect.

2-2.3 Specifications.

2-2.3.1 Required Specifications.

The DoR must use UFGS 33 51 15 Natural-Gas / Liquefied Petroleum Gas Distribution Pipelines to specify gas distribution pipeline work from the gas source (gas purveyor's meter and regulator) and LPG storage tank where applicable, to the point of connection to building fuel gas piping. Be aware that UFGS 23 11 25 Facility Gas Piping specifies the requirements from the point of connection to the distribution system to the appliances.

2-2.3.2 Submittal Description (SD)-11 Close-Out Submittals Required.

Close-out submittals, SD-11, typically include items such as the as-built set of drawings and specifications, test results, and project acceptance documents. Close-out submittals for construction of distribution pipelines are required to include a complete display of all information obtained during the construction process in order to support the ongoing efforts of the DoD Installation to comply with the documentation and reporting tasks required by 49 CFR 192.

The following is a list of information that must be submitted at project close-out in order to support the DoD Installation in obtaining and retaining information pertinent to construction of distribution pipelines for which the DoD Installation is the operator:

- As-built Layout Drawings – Submit drawings that show the geographic information system (GIS) location each newly installed pipe segment, each connection to existing pipe, and each abandoned pipe segment. The drawing must include pipe size, material type, design gas flow capacity, and maximum allowable operating pressure as defined by the operator and specified by the DoR.
- Pipe Materials – Submit for each pipe segment the pipe material specification number (for example ASTM D2513), name of manufacturer, manufacturer's item or part number, length of segment purchased, lot number, date manufactured, and date installed. These material submittals must be keyed to the layout drawing.
- Mechanical Couplings – Submit for each mechanical coupling installed the name of manufacturer, manufacturer's part number, serial number, date manufactured, and date installed. Each mechanical coupling must be keyed to the layout drawing so as to identify the exact location of the particular serial number installed.
- Piping Joints – Layout drawings must identify the GIS location of each joint made in every segment of distribution pipeline. A pipe joint, as used here, is defined as any connection made to join a pipe to another pipe, a fitting, a piece of equipment, or any other appurtenance. The following information regarding each pipe joint must be correlated to the pipe joints shown on the layout drawing.
    - Manufacturer's written procedure for making the identified connection.
    - Name and identifying mark of the person making that connection.
    - Qualification certificate for the person who made the connection.
- Leakage and strength test results.

Geographic Information System (GIS) coordinates must be submitted for the pipeline including all joints in the pipeline, all taps and tee, and all mechanical fittings.

2-3 DISTRIBUTION PIPELINE DESIGN.

The design for any new or modified gas pipeline must comply with 49 CFR 192, Subpart C. For LPG (petroleum gas) pipelines, 49 CFR 192, §192.11 states that the requirements of NFPA 58 prevail in case of conflict.

Subpart C – Pipe Design, prescribes the minimum requirements for pipe design. Pipe must be designed with sufficient wall thickness to withstand the internal pressure of the gas without failure. The wall thickness must be increased or the pipe must be installed with adequate protection to withstand the anticipated external forces and loads without failure.

2-3.1 Load Diversity.

The design of a gas distribution pipeline installed on a DoD Installation will be based on the sum of rated gas load of all connected appliances to the distribution pipeline in the following proportions:

- Natural gas, more than 15 buildings: More than 80 percent of the full connected appliance load.
- Natural gas, 15 buildings or fewer: 100 percent of the full connected appliance load.
- LPG, vapor phase: 100 percent of the full connected appliance load regardless of the system size.

2-3.2 Design Pressure for Steel Pipe.

2-3.2.1 Design Pressure.

The DoR must determine the design pressure of each pipe segment in accordance with 49 CFR 192, Subpart C.

Steel pipe design pressure is calculated using the equation presented in §192.105. This equation uses the basic hoop stress equation with reduction factors for increased temperature, type of longitudinal joint, and location classification. Each of the variables used in the equation are defined in §192.107 through 115.

2-3.2.2 Yield Strength.

The yield strength of pipe is defined in the pipe specifications that are listed in 49 CFR 192, Appendix B, and is the Specified Minimum Yield Strength (SMYS) stated in the Appendix B specification list for the pipe material used. Because pipe specifications not listed in Appendix B are not allowed on Government DoD installations, alternative means of determining yield strength are not allowed for new construction. These alternative means may, however, be required for evaluating the design pressure existing pipe.

Class 3 location is the minimum class allowed for all distribution pipelines on a DoD Installation.

2-3.3 Design Pressure for Plastic Pipe.

The DoR must determine the design pressure of each pipe segment in accordance with 49 CFR 192, Subpart C.

Plastic pipe design pressure is calculated using the equation presented in §192.121. This equation is a modified version of the basic hoop stress equation that uses terms common in the plastic piping industry. The yield strength is the Hydrostatic Design Basis (HDB) at or above the operating temperature of the pipe. The HDB is typically found in the pipe specification that defines the particular type of plastic pipe.

2-3.3.1 Standard Dimension Ratio (SDR).

The maximum allowed Standard Dimension Ratio (SDR) for plastic pipe installed on a DoD installation is SDR-11. The SDR is the diameter of the pipe divided by the wall thickness. SDR-11 represents the minimum wall thickness allowed on DoD installations.

A design factor of 0.32 reduces the design pressure of polyethylene (thermoplastic) and reinforced epoxy resin (thermosetting) pipe. A design factor of 0.40 reduces the design pressure of polyamide-11 (PA-11) pipe.

2-3.3.2 Maximum Design Pressure.

Maximum design pressure for plastic pipe is limited by §192.121. 49 CFR 192 limits the design pressure of plastic pipe to 100 pounds per square inch gauge (psig) with exceptions in specific piping materials to allow higher pressures. These exceptions must be thoroughly investigated and documented prior to providing plastic pipe in systems with greater than 100 psig.

Note that ASTM F2945 for PA-11 states that heat fusion joining of PA-11 pipe and fittings is not allowed to pipes and fittings made from any other thermoplastic materials. Therefore, care should be taken when specifying a different type of plastic than has been previously installed because of the complexity in connecting different plastic materials.

2-3.4 Maximum Allowable Operating Pressure (MAOP).

The MAOP of the distribution pipeline is controlled by the responsible operator of that distribution system, in accordance with 49 CFR 192. The DoR must obtain the MAOP for the existing distribution system from this responsible operator prior to designing work on the distribution pipeline. The MAOP must be included in the design calculations and on the design drawings for each pipe segment connected to or installed in the project.

Maximum Allowable Operating Pressure (MAOP) for steel and plastic pipelines is determined from the requirements stated in §192.619 thru 623, which prescribe the MAOP for distribution mains and service lines respectively. MAOP, as determined under §192.619 thru 623, is generally associated with the lowest of the design pressure or a fraction of the test pressure that the pipe segment was initially tested to after installation. The test pressure for Class 3 locations is 1.5 times the MAOP. Every pipe segment must be tested IAW 49 CFR 192, Subpart J in order to substantiate the MAOP determined under §192.619. It is recommended that new pipe be tested at the highest pressure that is safely practical to set the MAOP of that pipe segment has high as safely possible to prevent having to uprate in the future.

MAOP for distribution mains is limited to 60 psig unless every service line connecting to the distribution main contains devices installed for the purpose of protection against over-pressurization IAW §192.197(c). These devices must limit the inlet pressure to the service regulator by pressure regulation, flow relief, or isolation. ASME B31.8, para. 845 may be used as reference, as this reference provides additional information on these overpressure devices, and all devices listed are included in 49 CFR 192.

2-3.5 Increasing the MAOP by Uprating.

Pipelines may have their pressure increased above a previously determined MAOP by following the requirements of 49 CFR 192, Subpart K and logically determining a new MAOP IAW §192.619. All pipe segments to be uprated must be tested to the requirements of a new pipe of the same material installed in the same location.

The process required by 49 CFR 192, Subpart K is quite detailed, requiring much research and field work before the pipeline pressure increase is allowed. Therefore, it is recommended to initially test all pipelines to the highest test pressure that is safely practical in order to prevent the need for uprating in the future.

2-3.6 Alternative MAOP.

Although 49 CFR 192.619 allows for determining alternative MAOP, this method is difficult to implement due to the vast amount of information necessary to apply the method. An acceptable alternative is to utilize §192.620 which provides the requirements for determining and using an alternative MAOP. §192.620(b) (2) requires that the pipeline segment that uses an alternative MAOP be constructed to meet the additional design requirements of § 192.112. This section stipulates that only pipe manufactured to API SPEC 5L may use the alternative MAOP. The requirements further mandate several documented quality control manufacturing processes, which are typically not available for existing systems and not cost effective for new systems.

2-3.7 Test Requirements.

Every pipe segment must be tested IAW 49 CFR 192, Subpart J in order to substantiate the MAOP determined under §192.619. Tests are required to prove that the pipeline does not leak and in specified cases must be strength tested for a specified duration. For safety reasons, hydrostatic testing is preferred; however, 49 CFR 192 allows air, inert gas, and even the natural gas source to be used under specific constraints. 49 CFR 192 does not allow the use of LPG in the vapor phase, a.k.a. petroleum gas, to be used as a test media.

LPG pipelines operating under 49 CFR 192 must comply with the testing requirements of 49 CFR 192, rather than testing described in NFPA 58.

2-3.7.1 Test Pressure for Steel Pipelines.

The test pressure that applies to most distribution pipelines installed on DoD installation are defined in the 2018 revision of 49 CFR 192 as follows:

- §192.507 for steel pipelines operating at 100 psig or higher and less than 30% SMYS: Leak test between 100 psig and the pressure that creates stress of 20% SMYS. Strength test at leak test pressure for duration of 1 hour.
- §192.509 for steel distribution mains operating below 100 psig: A minimum leak test pressure of 90 psig for operating pressures of 1 psig or greater. A minimum leak test pressure of 10 psig for operating pressures less than 1 psig.
- §192.511 for steel service lines with operating stress less than 20% SMYS: A minimum leak test pressure of 50 psig for operating pressures from 1 to 40 psig. A minimum leak test pressure of 90 psig for operating pressures greater than 40 psig.
- §192.513 for plastic distribution mains and service lines: Leak test pressure at least 150% of the maximum operating pressure. Not less than 50 psig. Refer to §192.513 for further restrictions during testing. Pneumatic leak testing must be performed IAW ASTM F2786. Hydrostatic testing must be performed IAW ASTM F2164

For steel pipelines that operate at or above 100 psig, with a hoop stress less than 30% of the SMYS, the rules presented in §192.507 must be applied using an appropriate test pressure and inspection that discovers all leaks in the segment being tested. In the rare case that a steel distribution pipeline operates with a hoop stress above 30% of the SMYS, the reader should follow §192.505 for hydrostatic strength testing and leak testing requirements.

Please refer to these 49 CFR 192 sections for updates to the required test pressures and more detail of the required tests.

2-3.7.2 Test Pressure for Polyethylene Pipelines.

2-3.7.2.1 Leak Testing.

49 CFR 192 §513 requires that leak test on plastic distribution mains and service lines be performed at a pressure at least 150% of the maximum operating pressure, but not less than 50 psig. Refer to §192.513 for further restrictions during testing.

Leak testing of polyethylene and other plastic pipelines must be specified and performed with an understanding of the effects that pressure has on the plastic material. Pneumatic leak testing of polyethylene pipelines must be performed IAW ASTM F2786. Hydrostatic testing of polyethylene pipelines must be performed IAW ASTM F2164. Both of these documents prescribe procedures that limit the maximum test pressure to 1.5 times the design pressure of the weakest component. This limitation is in contrast 49 CFR 192 §513, which states that the maximum test pressure must not exceed 3 times the design pressure calculated in §192.121. This is because the two documents define ‘design pressure’ differently.

2-3.7.2.2 Hydrostatic Design.

49 CFR 192 §121 uses the Hydrostatic Design Basis (HDB) of the particular material at the testing temperature and a design factor of 0.32 to reduce the pipeline design pressure.

ASTM F2786 uses the Hydrostatic Design Stress (HDS) of the particular material to calculate the pressure rating of the pipeline and a temperature reduction factor to reduce the pipeline maximum test pressure. ASTM F2164 uses the terms ‘design pressure’ and ‘pressure rating’ synonymously.

2-3.7.2.3 Pressure Testing.

It is recommended that the maximum test pressure be determined using the methods presented in ASTM F2786 for pneumatic testing or ASTM F2164 for hydrostatic testing. Although the ASTM and CFR methods produce the same maximum test pressure when the pipe temperature is at 73° F, as the pipe temperature increases, 3 times the design pressure as specified in 49 CFR 192 §513 exceeds the maximum test pressure calculated from the ASTM methods.

Because pipe strength reduces with increasing pipe temperature, it necessary to monitor the pipe temperature during testing. Pipe temperature increases during pneumatic testing due to the heat of compression in the compressible test media, sunlight exposure, and ambient temperature. Contact the manufacturer of pipe, fitting, and components for guidance during pneumatic testing. The cooler temperature and higher heat capacitance of a hydrostatic test media helps to reduce the temperature of the test section.

In both pneumatic testing per ASTM F2786 and hydrostatic testing per ASTM F2164, the length of time that the pipeline is pressurized above its MAOP is limited to 8 hours. Therefore, from the start of pressurizing the pipeline, through the test phase, and ending at depressurization of the pipeline, the total time duration must not exceed 8 hours. If retesting is necessary, the pipeline must be allowed to relax at a pressure less than the operating pressure for a duration of 8 hours before restarting the test.

CHAPTER 3 MATERIALS AND COMPONENTS

3-1 LPG STORAGE CONTAINERS.

Containers used for storage of LPG in the liquid phase must comply with NFPA 58 requirements. Where piping systems are to be designed for filling LPG storage tanks, please refer to UFC 3-460-01 for guidance in design of these specialized, LPG liquid piping systems.

LPG storage containers must be designed, fabricated, tested, and marked in accordance with the regulations of the department of transportation (DOT), ASME Section VIII "Rules for the Construction of Unfired Pressure Vessels, or API-ASME Code for Unfired Pressure Vessels for Petroleum Liquids and Gases. Storage containers having 4,000-gallon water storage capacity or less must include all appurtenances as required by NFPA 58, paragraph 5.9 to include, but not limited to, the following:

- Vapor shutoff valve
- Liquid shutoff valve
- Pressure relief valve
- Fixed maximum liquid level gauge
- Filler valve
- Overfilling protection device
- Actuated liquid withdrawal excess-flow valve for 25-gallon water capacity or more
- Float gauge for 125-gallon water capacity or more

Please refer to NFPA 58, paragraph 5.9.4.2 for connection and appurtenance requirements that apply to LPG storage containers having storage capacity greater than 4,000 gallons of water capacity. Container appurtenances must have a minimum service pressure rating of 250 psig.

3-2 PIPE MATERIAL SELECTION.

Pipe materials used in LPG distribution pipelines installed on a DoD installation must comply with the material specifications listed in NFPA 58, with the exceptions of DoD installations below.

Pipe materials used in natural gas and manufactured gas distribution pipelines installed on a DoD installation must comply with the material specifications listed in 49 CFR 192, Subpart B and Appendix B, with the following exceptions:

3-2.1 Exceptions of DoD Installations.

The following are exceptions to the materials listed in Appendix B of 49 CFR 192:

- It is recommended that steel pipe not be installed below grade due to corrosion. Where a fuel gas compressor is installed on the user's fuel gas supply piping, governed by NFPA 54, a steel service line may be necessary to withstand the forces caused by pressure pulsation and vibration. See API RP 686, ASME B31.8, and 49 CFR 192 for guidance. Steel pipe installed below grade must be coated and cathodically protected from corrosion.
- Polyethylene (PE) piping, ASTM D2513, must be installed below grade, SDR-11 or thicker wall.
- Polyamide-11 (PA-11), SDR-11 or thicker wall, can be installed below grade only to connect to existing PA-11 piping because heat fusion of PA-11 to any other plastic is not qualified. Recommend using ASTM F2945 for specifying PA-11 piping because this material was moved from the PE piping ASTM after 1999.
- Plastic pipe that passes through vaults or is otherwise uncovered by soil, the plastic pipe must be encased in ASTM A53/A53M minimum schedule 40 steel pipe that is properly protected from corrosion and vented. Materials and installation must comply with 49 CFR 192.
- Although ASTM D2517, Standard Specification for Reinforced Epoxy Resin Gas Pipe and Fittings, for example thermosetting plastic, is included in the Appendix B list. Thermosetting plastic material should not be specified unless the existing distribution pipeline is also constructed of this material.
- For LPG, NFPA 58 does not allow ASTM D2517, thermosetting plastic pipe to be used.

3-2.2 Restricted Materials.

Cast iron and ductile iron are restricted materials within 49 CFR 192. Cast and ductile iron should not be used in natural or manufactured gas distribution pipelines on DoD installations. Where existing cast iron or ductile iron pipe is installed, the DoR must make every effort to know all details of its installation and any rehabilitation that has been performed. The construction documents created by the DoR that connect to the existing cast iron or ductile iron pipe must require the installing contractor to perform all inspections and tests and make all necessary enhancements or take all necessary precautions required by 49 CFR 192. The following information is identified from the 2018 revision of 49 CFR 192, but is not inclusive of all restrictions. NFPA 58 does not allow cast iron pipe or pressure containing components constructed from cast iron to be used in LPG pipelines. NFPA 58 does not allow ductile iron pipe to be used in LPG pipelines, but does allow metallic fittings and pressure containing components to be constructed from ductile iron that meets ASTM A395/A395M.

The following apply to existing cast iron or ductile iron natural or manufactured gas pipelines as stated:

- §192.621 limits the operating pressure of cast iron pipe segment with unreinforced bell and spigot connections to 25 psig.
- §192.753 (a) requires all bell and spigot connections in pipe segments operating at pressures higher than 25 psig to be sealed with mechanical leak clamps or equivalent. For pipe segments operating at 25 psig or below, the connection must be sealed IAW §192.753. (b) if the connection is exposed for any reason.
- Existing cast iron connections that are sealed with a gasket and retained by a follower ring are qualified under §192.275 but are restricted in MAOP.
- Cast iron flanges must be cast integrally into the pipe, fitting, or valve and must conform to ASME B16.1.
- Neither cast iron nor ductile iron pipe that is less than 6" nominal pipe size (NPS) may be used as a service line, per §192.373.
- Requirements of §192.557 must be met before the operating pressure of a cast iron or ductile iron pipe segment is increased above its previously established MAOP.
- Ductile iron components are typically allowed to operate at 80% of their rated pressure at temperature.

In addition, §192.489 requires the replacement of cast and ductile iron piping that shows general graphitization might cause the pipe to fracture or leak. Only localized graphitization may be repaired. Several other paragraphs throughout 49 CFR 192 place requirements on construction practices that may be required when modifying a distribution pipeline that is constructed from cast iron or ductile iron. The reader is cautioned to pay particular attention to all design elements when modifying an existing pipeline constructed of these materials.

3-3 DESIGN OF PIPELINE COMPONENTS.

Components installed in distribution pipelines must comply with the requirements of 49 CFR 192, Subpart D, which prescribes the qualification of all valves, fittings, pressure regulators, and other devices installed in a natural gas pipeline.

3-3.1 Fittings.

Fittings used on steel pipe must be butt welded or flanged and be rated for the operating pressure and temperature of the distribution pipeline. Butt weld fittings should be factory made wrought steel per ASME B16.9 with butt weld ends per ASME B16.25. Flanges should comply with ASME B16.5 and MSS SP-44.

3-3.1.1 Threaded Fittings.

Threaded fittings complying with ASME B1.20.1 may be used above ground only, due to the corrosion potential when installed underground. Threaded fittings must have at least the minimum metal thickness required for the operating pressure and temperature of the system.

Threaded fittings may be used on LPG pipelines to connect piping to equipment or appurtenances that are provided from the manufacturer with threaded connections. The proper type of threaded fitting must be specified to make connection to the manufacturer's equipment or appurtenance. Butt weld fittings are preferred to connect lengths of pipe in all sizes. Threaded fittings should not be used to connect lengths of pipe, but where this type of connection is necessary in the construction, specify schedule 80 pipe and back weld at the threaded connection.

3-3.1.2 Socket Weld Fittings.

Socket weld fittings must not be used in natural gas, manufactured gas, or LPG distribution pipelines installed on DoD installations for the reasons listed hereinafter. Socket weld fittings are connected by a fillet weld, which is not a full penetration weld and cannot be confirmed by nondestructive testing to meet pull-out requirements. The socket weld fitting also contains a void between the pipe and fitting that can be a site for contaminant, corrosion, natural gas, and petroleum distillate to reside, undetected.

3-3.1.3 Branch Connections.

Branch connections must be designed for both pressure and temperature requirements and mechanical strength. Tee fittings should be used for branch connections where practical. Welded branch connection must be designed and constructed to ensure that the strength of the pipeline system is not reduced, taking into account the stresses in the remaining pipe wall due to the opening in the pipe or header, the shear stresses produced by the pressure acting on the area of the branch opening, and any external loadings due to thermal movement, weight, and vibration.

3-3.1.4 Mechanical Fittings.

Mechanical fittings used to make a hot taps must be qualified to withstand the maximum anticipated operating pressure and temperature of the pipeline.

3-3.1.5 Mechanical Compression Joints.

Mechanical compression joints are allowed to connect plastic pipe only in locations where other fitting types are not feasible. When compression joints are utilized, they must be installed in accordance with the requirements of 49 CFR § 192.281(e). Proof of satisfying the design requirements must be provided by a knowledgeable third party such as a representative of the compression joints manufacturer. The manufacturer of the mechanical compression fitting must certify that the fitting is intended for the specific gas service, that the gasket is compatible with the type of plastic specified, and that a rigid tubular internal stiffener, not split tubular, is incorporated in the design. The manufacturer must provide the part number, serial number and year made for each mechanical fitting used on a DoD installation and the contractor must submit this information along with the GIS Location and date of installation for the Government's permanent record.

3-3.2 Valves.

Steel valves installed in natural and manufactured gas distribution pipelines must comply with API SPEC 6D. Although ASME B16.34 is the basis for all valves specified in API SPEC 6D, §192.145 mandates that all steel valves in a natural gas pipelines comply with the requirements of API SPEC 6D, which adds substantial additional features and testing over and above the requirements of ASME B16.34. Metallic valves installed in metallic distribution pipelines conveying LPG must comply with UL 125. Valves installed in polyethylene distribution pipelines that convey natural gas, manufactured gas, or LPG must comply with ASTM D2513 and ASME B16.40. Valves installed in polyamide distribution pipelines that convey natural gas, manufactured gas, or LPG must comply with ASTM F2945 and ASME B16.40.

3-3.2.1 Restricted Valve Materials.

Cast iron, malleable iron, and ductile iron are restricted materials for use in natural or manufactured gas pipelines within 49 CFR 192 and should not be used in valve shell construction on Government DoD installations. Although these materials have been used in the past, and may qualify under certain conditions, these materials should not be used in new natural gas pipelines installed on Government DoD installations. These materials are not qualified for use at compressor stations.

3-3.2.2 Valve Locations.

Valves must be installed in the distribution pipeline in the locations required by 49 CFR §192.181 and as described below:

- Each high-pressure distribution system must have valves spaced so as to reduce the time to shut down a section of main in an emergency. The valve spacing is determined by the operating pressure, the size of the mains, and the local physical conditions.
- An isolation valve must be installed on the inlet piping to each regulator station that controls the flow or pressure of gas in a distribution system. This isolation valve must be installed at a safe distance from the regulator station sufficient to permit the operation of the valve during an emergency that prevents access to the station.
- Service line operating or emergency shut-off valve must be installed upstream of regulator/meter, must be readily accessible, outside of the building, and in a covered valve box if installed below grade.

Valve locations must be compliant with all requirements of the current edition of 49 CFR §192.181.

3-3.3 Control of Gas Pressure and Over Pressure Protection.

Where a gas source that is at higher pressure than the MAOP of a distribution pipeline, and is connected to that distribution pipeline, a pressure regulator is required and a pressure relieving device or pressure limiting device that meets the requirements of

§192.199 and §192.201 is required to protect the distribution pipeline from over pressurization that could result from failure of the upstream pressure control or of failure of some other type.

3-3.3.1 Natural and Manufactured Gas Pressure Regulators and Relief/Limiting Devices.

The pressure of gas delivered from a high-pressure distribution system must be controlled IAW 49 CFR §192.197. This section differentiates pressure regulation and protection requirements for pipelines operating at pressures 60 psig or less from those required for pipelines operated at pressures greater than 60 psig. It is recommended that distribution pipelines installed on DoD installations must apply the “greater than 60 psig” pressure regulation and protection requirements to allow flexibility in future uprating of MAOP.

Four different types of pressure regulators are used in the design of a natural gas or manufactured gas systems, which are as follows:

- Appliance regulator: allowed in the fuel gas piping defined by NFPA 54, but not qualified to operate in a 49 CFR 192 distribution pipeline.
- Line regulator: allowed in the fuel gas piping defined by NFPA 54, but not qualified to operate in a 49 CFR 192 distribution pipeline.
- Main regulators: supplied by a qualified manufacturer of regulators intended for use in a distribution system.
- Service regulator: qualified by AGA ANSI B109.4 to be installed at the end of service line, with an isolation valve.

Each service regulator installed on a service line intended to regulate the pressure of fuel gas supplied to a consumer must comply with §192.197(c)(3). This paragraph requires that a pressure relief device be installed to protect the piping system connected to the low-pressure side of the regulator. This pressure relief device may be built into the service regulator or may be a separate relief valve installed downstream of the service regulator. The relief device must be capable of relieving downstream pressure, at the rated regulator flow, to prevent over pressurization of the consumer’s fuel gas piping. Even though §192.197(a) allows regulators with specified characteristics, but having no pressure relief, to be installed on distribution systems that operate at 60 psig or less, this practice is not recommended for DoD installations because future pressure increases would require major infrastructure rehabilitation.

3-3.3.2 Natural and Manufactured Gas Pressure Relief and Limiting Devices.

Where the distribution pipeline pressure exceeds 60 psig, a pressure relieving or pressure limiting device is required by §192.197(c) to ensure that the MAOP of the downstream pipeline or service line and appurtenances is never exceeded. The devices required are listed below:

- Pressure relief valve, spring loaded or weight loaded.

- Pilot loaded, back-pressure regulator that acts as a relief device to maintain the inlet pressure of the primary regulator to a specified set point. A pilot senses the pressure downstream from the back-pressure regulator (inlet to the primary regulator) and vents to atmosphere to ensure the inlet pressure to the primary regulator never exceeds the specified set point. This vent must discharge in a safe manner to a non-hazardous location.
- An automatic shut off device installed in series with the primary regulator with manual reset.
- A second regulator installed upstream of the primary or service regulator, set to limit the inlet pressure of the downstream regulator to 60 psig or less, and a device set to relieve the pressure between the two regulators in the event that the upstream regulator fails.
- A monitoring regulator installed upstream of a primary or service regulator. In this arrangement, a sensing line is connected downstream of the primary or service regulator to allow the monitoring regulator to sense the pressure downstream of the primary or service regulator. If the downstream regulator fails, then the monitoring regulator takes over the pressure control. The set point of the monitoring regulator is slightly higher than the set point of the working regulator, but never higher than the MAOP of the downstream pipeline. During normal operation, the monitoring regulator is fully open.
- A service regulator with internal pressure relief or separate relief valve installed downstream of the service regulator, as long as the inlet pressure does not exceed 125 psig.

These devices are more clearly described by trade name in ASME B31.8, para 845, which may be used as a reference.

The pressure relieving or limiting device must be designed IAW §192.199. The capacity of the pressure relieving and limiting device must be IAW §192.201. In all cases where natural gas is vented from a pressure relieving or limiting device to the atmosphere, the vent must be constructed to prevent blockage by rain, snow, ice, insects, or vermin and must discharge safely to the environment without undue hazard.

3-3.3.3 LPG Pressure Regulators and Relief Devices.

The pressure of LPG in the vapor phase must be reduced and regulated when leaving the LPG liquid container in accordance with NFPA 58, paragraph 5.10. This pressure regulator must be one of the two stage regulator combinations specified in NFPA 58, paragraph 5.10, and must contain the required pressure relief device or overpressure shutoff device. The regulators used in an LPG distribution pipeline must comply with UL 144. Do not use line pressure regulators per ANSI Z21.80, or appliance regulators per ANSI Z21.18 in an LPG distribution pipeline. Line and appliance regulators belong in the fuel gas piping system as specified in NFPA 54 with specific reference to NFPA 58.

A summary of regulator combinations qualified to be installed in an LPG distribution pipeline are as follows:

- Automatic changeover regulator incorporating an integral two stage regulator, with integral pressure relief to limit second stage outlet pressure to 2 psig when seat disc is removed, and inlet pressure is 15 psig or overpressure shutoff with manual reset on the outlet of the second stage regulator. This regulator is for use on multiple cylinder installation.
- Integral two-stage regulator with means to determine the outlet pressure of the high-pressure regulator, and with integral pressure relief to limit second stage outlet pressure to 2 psig when seat disc is removed, and inlet pressure is 15 psig or overpressure shutoff with manual reset.
- High pressure regulator installed on the LPG container with integral relief valve, and a first stage regulator, with integral pressure relief, installed downstream of the high-pressure regulator to serve multiple second stage regulators. Second stage regulators must have integral pressure relief to limit second stage outlet pressure to 2 psig when seat disc is removed, and inlet pressure is 15 psig or overpressure shutoff with manual reset on the outlet of the second stage regulator.
- First stage regulator, 10 psig maximum outlet pressure, with integral pressure relief, and a second stage regulator with integral pressure relief to limit second stage outlet pressure to 2 psig when seat disc is removed, and inlet pressure is 15 psig or overpressure shutoff with manual reset.
- 2 psig regulator system including a first stage regulator, 10 psig maximum outlet pressure, with integral pressure relief, and a 2 psig regulator, 2.5 psig maximum outlet pressure with integral pressure relief to limit 2 psig regulator outlet pressure to 5 psig when seat disc is remove and inlet pressure is 15 psig or overpressure shutoff with manual reset.
- Or an integral 2 psig service regulator meeting the design intent of the 2 psig regulator system but manufactured into one assembly.

Automatic changeover, integral two stage, high pressure, first stage, and integral 2 psig regulators must be installed in compliance with NFPA 58, paragraph 6.10.1, either on the LPG storage tank vapor service valve or connected to the vapor discharge valve using a flexible metallic connector that is qualified for LPG service. The regulators must be installed so that weather elements do not affect their operation. The relief vent discharge must be located in compliance with NFPA 58 such that the termination point presents little hazard, is a minimum of 3 horizontal feet from any building opening and 5 feet from sources of ignition, mechanical air intake, or direct vented gas appliance.

3-3.4 Customer Meters, Regulators and Service Lines.

Customer meters, service regulators and service lines must comply with the requirements of 49 CFR 192, Subpart H. This subpart addresses the allowed locations for installation, the requirement for protection against damage, and the elimination of stress on the piping system.

DoD installations require, in most cases, adherence to an Advanced Metering Program. Each branch of military service has written its own specific requirements that guide the design of advanced metering systems and their electronic reporting system. Cybersecurity and on-board memory are necessary elements of each program. Please refer to the requirements of the specific DoD installation for guidance on specifying the required metering systems and connectivity.

3-3.4.1 Meters.

§192.359 requires that all new meters be tested by the manufacturer at a shell pressure of not less than 10 psig. Meters may not be operated at a pressure higher than 67% of the manufacturer's shell test pressure. A rebuilt or repaired tinned steel meter may not be operated at more than 50% of the pressure used to test the meter after rebuilding or repairing. Gas meters that comply with AGA ANSI B109 are qualified for natural gas, manufactured gas and LPG in the vapor phase, but the manufacturer must know which gas will be metered. LPG in the vapor phase may or may not require metering when it is supplied from a distribution pipeline to multiple customers on a DoD installation. Please coordinate with the contracting officer of the project to determine the Government's desire for metering of LPG.

3-3.4.2 Regulators.

The service regulator that reduces the natural or manufactured gas pressure to the meter and the customer's fuel gas piping system are described in paragraph 3-2.3 of this UFC. Refer to NFPA 54 for specific usage of line pressure regulators that reduce 2 psig gas supply to appliance regulator inlet pressure and appliance regulators.

The term 'service regulator' does not apply to LPG distribution pipelines. Required regulators are described in paragraph 3-2.3 of this UFC. Refer to NFPA 58 and NFPA 54 for specific usage of line pressure regulators that reduce 2 psig LPG vapor supply to appliance regulator inlet pressure and appliance regulators.

3-3.4.3 Service Lines.

Each steel service line to be operated at less than 100 psig must be constructed of pipe designed for a minimum of 100 psig. Additional requirements are defined in §192.361 through §192.379. Exception to §192.375 is that a plastic service line may not be exposed above grade level on a DoD installation. An anode less riser must be used to bring a plastic service line from below grade to a steel pipe serving the isolation valve, service regulator, and meter.

3-3.5 Excess Flow Valve (EFV).

An EFV must be installed on all new or replaced single and branched service lines that serve single-family residences where the service line operates at 10 psig or greater. EFVs are also required to be installed on multifamily residences, and small commercial entities consuming gas volumes not exceeding 1,000 standard cubic feet per hour (SCFH). The EFV must comply with the requirements of §192.381 and close upon detection of flow in excess of the anticipated maximum flow through the service line.

Sizing an EFV requires knowing the maximum gas demand of all the appliances connected to the service line. The potential for adding future gas burning equipment should also be considered.

3-3.6 Vaults.

Vaults must be structurally sound, designed to minimize entrance of water, and must not be drained to any other underground structure. Vaults serving as access to natural gas distribution pipelines must comply with §192.183 through §192.189. Where plastic pipe passes through a vault must be encased in ASTM A53/A53M minimum schedule 40 steel pipe that is properly protected from corrosion and vented.

CHAPTER 4 CONSTRUCTION OF DISTRIBUTION PIPELINES

4-1 QUALIFICATION OF PROCESSES.

Methods used to install natural gas distribution pipelines must be proven to provide a durable, gas-tight system. All pipe joints made in the system must be made in accordance with qualified written procedures and by personnel qualified by training and testing that have been proven by test or experience to produce strong, gas-tight joints.

The DoD installation must include these qualified written procedures and personnel qualifications in its operations and maintenance manual. It is therefore required that the installing contractor provide a qualified written procedure and personnel qualifications for each joint made in the distribution pipeline.

4-2 WELDING OF STEEL PIPE.

Welding of steel pipelines must comply with the requirements of 49 CFR 192, Subpart E.

4-2.1 Welding Procedures for Steel Pipe.

The installing contractor must submit for Government approval, a written procedure for welding steel pipe and fittings installed in the distribution pipeline. Welding procedures must be qualified under API STD 1104, Section 5, Section 12, or Appendix A or under the ASME/BPVC SEC IX as written in §192.225. The contractor must make sure that welding is performed in accordance with these established written welding procedures that have been qualified and tested to produce quality welds.

4-2.2 Welder Qualifications.

Welders must be qualified IAW API STD 1104, Section 6, Section 12, or Appendix A or under the ASME/BPVC SEC IX as written in §192.227. The contractor must submit to the Government, proof of each welder's current certification of qualification. Welders qualifications must further comply with the limitations specified in §192.229, which include qualification intervals and methods of qualification.

Welders of pipe segments and components intended to serve natural gas compressors must be qualified under the destructive test requirements of the applicable API STD 1104 sections.

4-2.3 Inspection and Testing of Welds.

All welds must be inspected by a person that is qualified by training and experience to ensure welding is performed by certified welders, using a qualified written procedure, and has produced acceptable welds under API STD 1104, Section 9 or Appendix A, which will not be used to accept cracks. In accordance with §192.243, and minimum location class 3 for DoD installations, 100% of welds on pipelines and components operating at a hoop stress of 20% or more of the SMYS must be nondestructively tested.

4-3 HEAT FUSION JOINING OF PLASTIC PIPE.

4-3.1 Written Joining Procedures.

The installing contractor must submit for Government approval, a qualified, written procedure for joining plastic materials obtained from the manufacturer of the plastic pipe and fittings installed in the system. The procedure must have been proven to make strong, gas-tight joints by passing the tests specified in §192.283. Vendors who cannot provide this qualified jointing procedure must be disqualified from supplying materials for the work. The contractor must make sure that each joint is made in accordance with these Government approved procedures. Any contract that purchases plastic pipe for use in the natural gas distribution system must disallow the purchase of plastic pipe from any manufacturer or supplier that does not certify qualified joining procedures for the pipe. It is the DoD installation's responsibility to verify that the contractor follows these written joining procedures for each type of pipe and fitting used.

4-3.2 Joint Maker Qualifications.

The contract documentation must require the contractor to train, test, and qualify each person performing work on the natural gas distribution system located on a DoD installation in accordance with 49 CFR 192, Subpart F. No person may make a plastic pipe joint unless that person has been qualified under the pipe manufacturer's written joining procedure by making a specimen joint that passes inspection and test. The specimen joint used to qualify the joiner must be visually examined during and after joining and found to have the same appearance as a joint or photograph of a joint that is acceptable under the procedure. In the case of heat fusion, the specimen must be cut into at least three longitudinal straps, each of which is:

- Visually examined and found not to contain voids or discontinuities on the cut surfaces of the joint area;
- Deformed by bending, torque, or impact, and if failure occurs, it must not initiate in the joint area.

Each person joining plastic in a distribution pipeline must be re-qualified under the applicable procedure §192.285(c), or after any production joint is found unacceptable by testing under §192.513. A person that is qualified by appropriate training or experience to evaluate the acceptability of the joint must inspect each joint installed in a gas piping system. This inspection may be performed by the person installing the joint if so qualified.

4-4 PIPELINE INSTALLATION AND REPAIR.

All pipelines must be installed IAW 49 CFR 192. Joining of new pipe to existing pipe must be in a manner approved in 49 CFR 192.

Where a distribution pipeline passes under a roadway or a railroad, the pipeline must be encased in steel pipe that protected from corrosion. If the casement is not vented it must be sufficiently strong to contain the operating pressure of the gas without exceeding the stress levels presented in §192.323. Vented casements must be protected from the weather. Distribution pipeline must be installed with sufficient underground clearance from other buried items to allow for proper maintenance and to protect against damage caused by those buried items.

Distribution mains must have minimum cover of 24” or be otherwise protected from external loads and excavation damage. In accordance with §192.361, the part of the service line installed in a public right-of-way must have minimum cover of 18”. This service line is allowed to have a minimum cover of 12” once it has passed onto private property. For DoD installations, it is recommended that the 12” cover apply only to single family dwellings but could be safely expanded to duplexes and quad-plexes. A minimum 18” cover is required for service lines serving any other type of building on a DoD Installation.

4-4.1 Plastic Pipe Installation.

Plastic pipe installed in a distribution pipeline must be installed below grade and must be continuously supported in suitable compacted soil to prevent movement after installation. Ensure that the installation has sufficient slack to prevent pullout due to thermal contraction. Inspect pipe and fittings for damage prior to backfilling. If the pipe has a scratch or cut that exceeds 10% of the wall thickness, it must be replaced.

Plastic pipelines must be installed with sufficient clearance from any item that may increase the temperature of the plastic pipe segment, to prevent degradation of the pipe strength. These items may include, but are not limited to, hot water piping, steam piping, condensate piping, and electrical equipment. Where proximity cannot be avoided, the DoR must design adequate protection to prevent pipe temperature increase. Where temperature increase of the plastic pipe cannot be avoided, the DoR must reduce the design pressure of the plastic pipe by using a Hydrostatic Design Basis value for a temperature that is higher than the actual anticipated temperature.

4-4.2 Steel Pipe Installation.

Aboveground steel pipe must be securely supported and protected from vehicular collisions. Steel pipe must be painted for corrosion protection.

Where steel pipe is required for below grade installations the pipe must be coated with an approved anti corrosion coating and must be cathodically protect IAW 49 CFR 192, Subpart I. The pipe must be continuously supported by properly compacted material.

Where connections are made to existing underground steel pipe, the contractor must inspect the existing pipe for corrosion and take remedial action IAW 49 CFR 192 Subpart I if corrosion is found.

This Page Intentionally Left Blank

CHAPTER 5 CONTROL OF CORROSION

5-1 METALLIC PIPELINES.

Metallic pipelines installed underground must be protected from corrosion IAW 49 CFR 192, Subpart I, which includes both an approved anti corrosion coating per §192.461 and a cathodic protection system in compliance with the requirements of §192.463.

5-2 DISTRIBUTION PIPELINE INTEGRITY MANAGEMENT PLAN.

The distribution pipeline operator is required to maintain a Distribution Pipeline Integrity Management Plan that details, among other items, all aspects of metallic pipeline installed underground, methods used to protect against corrosion, and inspections to determine the efficacy of the corrosion control program. A complete listing of information required to be maintained can be found in Chapter IX "Guidance Manual for Operators of Small Natural Gas Systems", current edition, DOT Pipeline and Hazardous Materials Safety Administration.

The DoR for any project installing or connecting to existing underground metallic pipe must support the distribution pipeline operator's efforts to control corrosion through proper design and requiring the installing contractor to do the following:

- Perform corrosion inspection and report on inspections of any underground metallic natural gas pipe that is uncovered during construction.
- Provide mill coating on steel pipelines installed below grade.
- Properly install and backfill coated pipe without damage to the coating.
- Properly field coat all connection and components.
- Thoroughly inspect and test the coatings for holidays.
- Properly install and test new cathodic protection systems.
- Properly install test stations for new cathodic protection systems.
- Electrically isolate protected pipelines from other, unprotected below grade metal and all above grade pipeline connections.
- Hire a corrosion control expert to help solve known corrosion problems.
- Obtain the operator's acceptance of the installation before backfill.

Where corrosion is found, remedial methods described in §192.487 and §192.489 should be employed.

This Page Intentionally Left Blank

CHAPTER 6 NATURAL GAS COMPRESSORS

6-1 COMPRESSOR STATIONS PER 49 CFR 192.

Compressor Stations are not defined but are only described within 49 CFR 192. 49 CFR 192 and ASME B31.8 provide the following specific requirements for piping that connects to compressor stations:

- Steel pipe from the gas distribution main to the compressor, 49 CFR 192 §192.229 and ASME B31.8, 843.4.
- Cast iron components must not be used in compressor station piping systems, 49 CFR 192 §192.145 (e) and ASME B31.8, 831.1.
- Welders must be qualified based on destructive test requirements of API 1104. 49 CFR 192 §192.229 and ASME B31.8, 823.2.2.
- Butt welds must be 100% tested by non-destructive methods such as radiography, 49 CFR 192 §192.243, ASME B31.8, 826.3.

6-2 FUEL GAS BOOSTER COMPRESSORS.

It is rare that a compressor station as described by 49 CFR 192 is installed in the pipeline that is operated by a DoD installation. It is quite common, however, that a fuel gas booster compressor be installed on a distribution service line in order to boost pressure and gas flow to a local, point-of-use piece of equipment such as a gas turbine. Although the 49 CFR 192 and ASME B31.8 code requirements would not seem to apply to the connection of a point-of-use fuel gas booster compressor, the engineering precautions necessary to ensure safe operation do apply. The booster compressor has the potential to transmit vibration and pressure pulsation to the service line, which can cause the service line to fail. It is recommended that the service line be welded steel pipe, constructed and inspected in accordance with 49 CFR 192. Where alternative methods are used, the Designer of Record must ensure the installation and pipe connections comply with the requirements of the compressor manufacturer, state and local codes. Analysis must also be performed and submitted to the government showing that the vibration and pulsation load and cycle will not cause the pipe to fail. It is recommended that fuel gas piping that connects to the discharge of a booster compressor be welded steel, but this piping is beyond the scope of this UFC as it is downstream from the demarcation between 49 CFR 192 and NFPA 54. There are codes that apply to specific fuel gas using equipment that also place requirements on the fuel gas supply piping. NFPA 37 is an example of code that places requirements on the fuel gas piping system from the discharge of the booster compressor to a gas turbine.

Requirements for construction of natural gas compressors are defined in the following American Petroleum Institute (API) documents:

- API STD 617 Axial and Centrifugal Compressors and Expander Compressors

- API STD 618 Reciprocating Compressors for Petroleum, Chemical, and Gas Industry Services
- API STD 619 Rotary-Type Positive-Displacement Compressors for Petroleum, Petrochemical, and Natural Gas Industries

Recommended practices for installing these compressors can be found in API RP 686 – Recommended Practices for Machinery Installation and Installation Design. This reference requires a vibration analysis, pulsation analysis and a mechanical piping analysis to ensure that pressure limits of the piping system are not exceeded. It further places requirements on pipe arrangement and components, supports and anchors, places restrictions on branch connections, and identifies the need for pulsation and vibration dampeners.

APPENDIX A BEST PRACTICES

Appendix A identifies background information and practices for accomplishing certain design and engineering services. The Designer of Record (DoR) is expected to review and interpret this guidance and apply the information according to the needs of the project. If a Best Practices document has guidelines or requirements that differ from the UFGS or Unified Facilities Criteria, the UFGS and the UFC must prevail. If a Best Practices document has guidelines or requirements that are not discussed in the Unified Facilities Guide specification (UFGS) or UFC, the DoR must submit a list of the guidelines or requirements being used for the project with sufficient documentation to the Government Project Manager for review and approval prior to completing design.

A-1 WHOLE BUILDING DESIGN GUIDE.

The Whole Building Design Guide provides additional information and discussion on practice and facility design, including a holistic approach to integrated design of facilities.

The WBDG provides access to all Construction Criteria Base (CCB) criteria, standards and codes for the DoD Military Departments, National Aeronautics and Space Administration (NASA), and others. These include, Unified Facilities Criteria (UFC), Unified Facilities Guide Specifications (UFGS), Performance Technical Specifications (PTS), design manuals, and specifications. For approved Government employees, it also provides access to non-government standards.

A-2 GUIDANCE.

A-2.1 DOT Manual for Operators of Small Natural Gas Systems.

In absence of installation specific directive instructions and guidance, follow gas pipeline safety regulations defined in the DOT manual as it applies to natural gas systems and operators of natural gas master meter systems. The pipeline safety regulations require operators of natural gas systems to: deliver gas safely and reliably to customers; provide training and written instruction for employees; establish written procedures to minimize the hazards resulting from natural gas pipeline emergencies; and, keep records of inspection and testing.

A-2.2 State Compliance.

Designers and operators should check with the pipeline safety agency in their state to determine:

- Whether a state agency has safety jurisdiction;
- Whether the state agency has pipeline safety requirements that exceed the federal regulations
- The inspection and enforcement procedures of the state agency.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Support Agency (AFCESA) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

CONTENTS

CHAPTER 1

INTRODUCTION

1-1 **PURPOSE AND SCOPE**. This UFC is comprised of two sections. Chapter 1 introduces this UFC and provides a listing of references to other Tri-Service documents closely related to the subject. Appendix A contains the full text copy of the previously released Military Handbook (MIL-HDBK) on this subject. This UFC serves as criteria until such time as the full text UFC is developed from the MIL-HDBK and other sources.

This UFC provides general criteria for the design of steam, high-pressure water, chilled water, natural gas, and compressed air.

Note that this document does not constitute a detailed technical design, maintenance or operations manual, and is issued as a general guide to the considerations associated with design of economical, efficient and environmentally acceptable heating plants.

1-2 **APPLICABILITY**. This UFC applies to all Navy service elements and Navy contractors; all other DoD agencies may use this document unless explicitly directed otherwise.

1-2.1 **GENERAL BUILDING REQUIREMENTS**. All DoD facilities must comply with UFC 1-200-01, *Design: General Building Requirements*. If any conflict occurs between this UFC and UFC 1-200-01, the requirements of UFC 1-200-01 take precedence.

1-2.2 **SAFETY**. All DoD facilities must comply with DODINST 6055.1 and applicable Occupational Safety and Health Administration (OSHA) safety and health standards.

NOTE: All **NAVY** projects, must comply with OPNAVINST 5100.23 (series), *Navy Occupational Safety and Health Program Manual*. The most recent publication in this series can be accessed at the NAVFAC Safety web site: www.navfac.navy.mil/safety/pub.htm. If any conflict occurs between this UFC and OPNAVINST 5100.23, the requirements of OPNAVINST 5100.23 take precedence.

1-2.3 **FIRE PROTECTION**. All DoD facilities must comply with UFC 3-600-01, *Design: Fire Protection Engineering for Facilities*. If any conflict occurs between this UFC and UFC 3-600-01, the requirements of UFC 3-600-01 take precedence.

1-2.4 **ANTITERRORISM/FORCE PROTECTION**. All DoD facilities must comply with UFC 4-010-01, *Design: DoD Minimum Antiterrorism Standards for Buildings*. If any conflict occurs between this UFC and UFC 4-010-01, the requirements of UFC 4-010-01 take precedence.

MILITARY HANDBOOK

EXTERIOR DISTRIBUTION OF STEAM,

HIGH TEMPERATURE WATER, CHILLED WATER,

NATURAL GAS, AND COMPRESSED AIR

NO DELIVERABLE DATA REQUIRED BY THIS DOCUMENT AREA FACR

ABSTRACT

Presented here is basic yet comprehensive design guidance and technical data for exterior distribution piping systems. Services supported by these systems include: steam supply, high-temperature water, chilled water, cooling or condensing water, natural gas, and compressed air to various buildings and other facilities. This handbook also contains data covering return systems for condensate, water, and other spent services. Additional design data includes information on loads and fluid conditions, fluid characteristics, and distribution site locations. Factors governing tests for field permeability, soil resistivity, soil stability, and water conditions, information on distribution pipe sizing, valves and supports, distribution methods, and piping specifications and codes are provided. Material included also covers ownership, operations, and maintenance cost variables associated with permanent or temporary sites.

FOREWORD

This military handbook has been developed from an extensive evaluation of shore establishment facilities, surveys of new materials' availability and construction methods, selections from the best design practices of the Naval Facilities Engineering Command (NAVFACENGCOM), other government agencies and the private sector. MIL-HDBK-1003/8A uses and references design data standards established and validated by national professional societies, associations, and technical institutes. Deviations from these criteria, in planning, engineering, design and construction of naval shore facilities, cannot be made without prior approval of NAVFACENGCOM HQ Code 04.

Design methods and practices cannot remain static any more than the functions they serve or the technologies used. Accordingly, recommendations for improvement are encouraged and should be furnished on the DD Form 1426 provided inside the back cover to Commander, Western Division, Naval Facilities Engineering Command, Code 406, Building 203, San Bruno, CA 94066, telephone (415) 244-3331.

THIS HANDBOOK SHALL NOT BE USED AS A REFERENCE DOCUMENT FOR PROCUREMENT OF FACILITIES CONSTRUCTION. IT IS TO BE USED IN THE PURCHASE OF FACILITIES ENGINEERING STUDIES AND DESIGN (FINAL PLANS, SPECIFICATIONS, AND COST ESTIMATES). DO NOT REFERENCE IT IN MILITARY OR FEDERAL SPECIFICATIONS OR OTHER PROCUREMENT DOCUMENTS.

Section 1: INTRODUCTION

1.1 Scope. Data and criteria in this military handbook apply to design of exterior distribution piping systems for supplying certain central generating plant services to various buildings and facilities and for returning such spent services to the plants.

1.2 Cancellation. This handbook, MIL-HDBK-1003/8A, cancels and supersedes MIL-HDBK-1003/8 of September 1987.

1.3 Related Criteria. All documents referenced in this handbook are listed in the reference section.

Section 2: PLANNING FACTORS

2.1 Types of Exterior Distribution Systems. Types of exterior distribution systems are as follows:

2.1.1 Steam and Condensate. These systems supply heat in the form of steam from central steam generating plants. Several buildings, building groups, or ship berthing facilities may be supplied with steam for domestic hot water and/or for space heating. Heating equipment using steam includes unit heaters, radiators, convectors, heating coils, and other devices. Process equipment using steam includes hot water heaters, laundry machinery, cleaning/plating tanks, kitchen equipment, and other devices. Condensate is returned to the central plant whenever possible.

2.1.2 Hot Water. System circulates hot water which supplies heat from a central heating plant to several buildings for space heating, domestic hot water, and process work, and returns the water to the central plant. High Temperature Water (HTW) systems operate at 260 degrees Fahrenheit (F) (127 degrees Celsius (C)) and higher; Medium Temperature Water (MTW) systems operate between 200 degrees F (93 degrees C) to 259 degrees F (126 degrees C); and Low Temperature Water (LTW) systems operate below 200 degrees F (93 degrees C). Material shall be selected to the same specifications as for High Temperature Water systems, except that Military Specification (Mil. Spec.) MIL-P-28584A, Pipe and Pipe Fittings, Glass Fiber Reinforced Plastic for Condensate Return Lines, plastic piping may be used for LTW distribution systems which have maximum of 125 psig at 250 degrees F (refer to para. 2.2.6).

2.1.3 Compressed Air. System supplies compressed air from a compressor plant to docks, air start systems, shops, hangars, and other structures.

2.1.4 Chilled Water. System circulates chilled water from a central refrigeration plant to several buildings for space cooling and returns the water to the central plant (refer to para. 2.2.7).

2.1.5 Cooling or Condensing Water. System distributes cooling water from a central source (such as a bay, stream, or cooling tower) to several facilities for condensing steam or refrigerants, for cooling water jackets, or stuffing boxes. The water is then returned to the source (cooling tower) or sent to waste in once-through systems.

2.1.6 Natural Gas. System distributes natural gas or propane for gas burning operations.

2.2 Naval Facilities Guide Specifications (NFGS) Related to Distribution Systems. The following NFGSs are for use in the design of the exterior distribution systems discussed in this handbook.

2.2.1 NFGS-02685, Exterior Buried Natural Gas Distribution Systems. NFGS-02685 covers these requirements for maximum system working pressures of 60 psig at 100 degrees F for exterior distribution systems for natural gas. Project drawings shall indicate the design for the entire piping system.

2.2.2 NFGS-02693, Exterior Shallow Trench Heat Distribution System. NFGS-02693 covers the requirements for exterior shallow trench heat distribution systems, including concrete trench, manholes, piping, pipe anchors, pipe supports, interface with each manhole and watershed to aboveground piping. The specification covers system components for working pressure of 150 psig (1034 kiloPascal (kPa)) steam at 366 degrees F (185 degrees C) and 125 psig (862 kPa) condensate at 250 degrees F (121 degrees C) or hot water at 450 degrees F (232 degrees C). Show the design for the entire piping systems and shallow concrete trench systems on the project drawings.

2.2.3 NFGS-02694, Exterior Underground Heat Distribution Systems. NFGS-02694 (formerly NFGS-15705) covers the requirements for Contractor designing and providing exterior buried factory-prefabricated preinsulated or pre-engineered preinsulated steam and condensate piping systems and hot water piping systems for Class A, B, C, and D ground water conditions including concrete pipe anchors exterior of manholes, interface with each manhole, and the watershed to aboveground piping. The specification covers system components for working pressure of 150 psig (1034 kPa) steam at 366 degrees F (185 degrees C) and 125 psig (862 kPa) condensate at 250 degrees F (121 degrees C) or hot water at 450 degrees F (232 degrees C). Show the design for the aboveground piping, the manholes, the piping within manholes, and the piping not in approved conduit systems on the drawings. The Contractor designs and provides buried factory-prefabricated preinsulated piping in a conduit or pre-engineered insulated piping system for which a Federal Agency Approved Brochure has been issued including concrete pipe anchors exterior of manholes, interface with each manhole and building, and the watershed to aboveground piping.

2.2.4 NFGS-02695, Exterior Aboveground Steam Distribution System. NFGS-02695 covers the requirements for exterior aboveground steam and condensate (hot water) piping systems: exposed to the weather exterior of buildings and supported on pedestals or poles; on piers, under piers, and in trenches on piers; and in tunnels, in manholes, and related work. The work also includes providing buried factory-prefabricated preinsulated steam and condensate piping under roads. The specification covers system components for working pressure of 150 psig (1034 kPa) steam at 366 degrees F (185 degrees C) and 125 psig (862 kPa) condensate at 250 degrees F (121 degrees C). Show the design for the aboveground piping, and the piping under roads on project drawings. The design includes manholes, the piping within manholes, (buried factory-prefabricated preinsulated piping in a conduit or pre-engineered insulated piping under roads for which a Federal Agency Approved Brochure has been issued), concrete pipe anchors, interface with each manhole, and the watershed to aboveground piping.

2.2.5 NFGS-02696, Exterior Piping Insulation. NFGS-02696 covers field-applied exterior piping insulation, insulation requirements for exterior steam piping, exterior condensate piping including aboveground piping, piping on piers, piping under piers, piping in trenches on piers, piping in tunnels, and piping in manholes.

2.2.6 NFGS-02697, Exterior Buried Pumped Condensate Return System. NFGS-02697 covers the requirements for exterior buried factory-prefabricated preinsulated pumped condensate (hot water) return piping systems suitable for installation in Class A, B, C, and D ground water conditions, including piping in manholes, plastic piping systems for which a Federal Agency Approved Brochure has been issued, and related work. Use the plastic carrier piping only for sizes 2, 3, 4, 5, 6, 8, and 10 inches. Thus, the connecting system piping should be of equal size or increased to the next size of the plastic carrier piping. NFGS-02697 also covers Contractor's responsibilities which include the following:

a) design,

b) provide exterior buried factory-prefabricated preinsulated pumped condensate (hot water), and

c) provide plastic piping systems for Class A or Class B ground water conditions including concrete pipe anchors exterior of manholes, interface with each manhole, and the watershed to aboveground piping.

Show the design for the aboveground piping, the manholes, the piping within manholes, and the piping not in approved prefabricated conduit or pre-engineered systems on project drawings. The Contractor designs and provides direct buried factory-prefabricated preinsulated piping in a conduit or pre-engineered insulated piping system for which a Federal Agency Approved Brochure has been issued, including concrete piping anchors exterior of manholes, interface with each manhole, and the watershed to aboveground piping.

2.2.7 NFGS-02698, Exterior Buried Preinsulated Water Piping. NFGS-02698 covers the requirements for exterior buried factory-prefabricated preinsulated domestic water piping, including hot domestic water piping, recirculating hot domestic water piping, chilled water piping, chill-hot (dual-temperature) water piping, and hot water piping. Show the design for the entire piping systems on project drawings.

2.2.8 Exterior Compressed Air Piping System. Use NFGS-02682, Exterior Fuel Distribution System, for the requirements of furnishing and installing exterior compressed air piping.

2.3 Loads and Distribution System Locations. For approximate conditions, refer to Table 1.

Table 1
Distribution Loads and Fluid Conditions

FLUID	USE	CAPACITY	FLUID PRESSURE, PSIG VACUUM, IN HG TEMPERATURE, DEGREES F	DEMAND FACTORS 1/	COMMENTS
Steam	Auxiliary power	Determined by heat balance	Boiler steam	1.0	Feedwater and fuel-oil heating
	Heating and snow melting	See criteria in DM-3.03	2 to 10 psig	1.0 2/ for heating radiation, 0.8 2/ for ventilation	- - -
	Waterfront demands	See criteria in MIL-HDBK-1025/2	150 psig maximum	1.0 single berths 0.8 multiple berths	High purity steam for nuclear ships
	Process	Laundry	100 psig	0.65	7 hr/day, 5 days/week, normally
		Kitchen	10 to 40 psig	1.0	2-8 hr/day, 7 days/week, normally
		Bakery	10 psig	1.0	8 hr/day, 5 days/week, normally
		Dry cleaning	70 psig	0.65	- - -
		Hospital	40 to 60 psig	0.65	- - -
		Laundry HW	5 to 45 psig	0.65	7 hr/day, 5 days/week, normally
		Domestic HW: DM-3.01	5 to 45 psig	0.65	- - -
	Refrigeration	Tons x steam rate/ton	Boiler steam pressure 26-28 in. Hg. vacuum	1.0	Turbine-driven centrifugal compressor
		Tons x steam rate/ton	12 in Hg	1.0	Absorption machine
Condensate return	Distribution loss				
	Boiler feed	Losses: Condensate blow-down or blow-off: Determined by amount and analysis of makeup	20 to 60 psig	1.0 for continuous operation of condensate pumps	Check economics of returning condensate
		Process depends on usage. Distribution 10 percent		1.5 to 3 for intermittent operation of condensate pumps	

5

Table 1 (continued)
Distribution Loads and Fluid Conditions

FLUID	USE	CAPACITY	FLUID PRESSURE, PSIG VACUUM, IN HG TEMPERATURE, DEGREES F	DEMAND FACTORS 1/	COMMENTS
Hot Water (supply and return)	Heating and snow melting	Same criteria as for steam	10 to 100 psig	- - -	- - -
	Process	- - -	Same as for steam	Same as for steam	
Chilled water supply and return	Refrigeration	gpm = 12,000 Btu/ton x tons / 500 x (t_s - t_r) 3/	Supply: 42 degrees F to 45 degrees F Return: 52 degrees F to 60 degrees F Pressure depends on friction and static heads	1.0 2/	- - -
Condenser water	Refrigeration	3 gpm/ton	Supply 85 degrees F. Return 105 degrees F	1.0	- - -
	Power system	gpm = steam x 950 lbs/hr Btu/lb / 500 x (t_s - t_r) 3/	Pressure depends on friction and static heads	1.0	
Fuel Gas	Process fuel gas burners	- - -	- - -	- - -	
Compressed air	Low pressure medium pressure high pressure	- - -	- - -	- - -	

1/ Demand factors are to be applied to total connected loads.
2/ Values shown are approximate. Actual Demand Factor is a site-specific determination and is based on actual load diversification.
3/ t_s = Water supply temperature; t_r = water return temperature.

6

2.3.1 Requirements for Individual Facilities. The actual loads and conditions are determined from the design of each building and facility. Refer to P-272, Definitive Designs for Naval Shore Facilities, as guidance for preliminary estimates of requirements. The facility layout, design, and geographic factors will further define requirements.

2.3.2 System Load Demand Factors. For demand factors, refer to Table 1.

2.3.3 Aboveground and Underground Systems. When selecting a system, factors to consider are: permanent versus temporary use, high-water table, corrosiveness of soil for underground systems, cost and degree of hazard. Refer to para. 3.3.6.6.

2.3.4 Distribution Routes. Select the most direct routes, avoiding all obvious obstacles where possible.

2.3.4.1 Aboveground Piping Routes. Aboveground systems are generally lower in life-cycle costs but are less convenient in areas of heavy traffic. Consider blockage of access to areas for future development along with vulnerability to damage and acts of vandalism or sabotage.

Consider aboveground heat distribution systems for use in lieu of underground systems because of generally longer life and lower maintenance and use wherever operations and local conditions permit.

2.3.4.2 Buried Piping Routes. Select routing to allow for proper drainage of the system. Manholes and provision for piping expansion must be considered in space allocation. Consider minimum separation of parallel piping runs where temperatures in the runs vary widely. Consider cover and drainage provisions for manholes.

2.3.5 Economic Studies. Refer to NAVFAC P-442, Economic Analysis Handbook, for procedures in life-cycle cost analyses. Economic studies for all piping system types must include life-cycle (owning, operating, and maintenance) costs. For prefabricated/pre-engineered underground steam or hot water systems, perform the economic analysis, developing costs from heat loss data provided in Part 1 of Appendix A or from heat losses calculated from procedures provided in NFGS-02694. For concrete shallow trench systems of greater than 500-foot (152.5 m) length, use the additional procedures outlined in para. 2.3.6 and modify NFGS-02696 accordingly. Consider first an aboveground system, which, in most cases, will be economically advantageous to the Government. Also consider whether or not the facility is permanent or temporary. Provide a separate economic analysis for the selection of an insulation system among those allowed in NFGS-02696.

2.3.5.1 Annual Owning, Operating, and Maintenance Costs. Consider the following:

a) Base selection of the distribution system and route on the results of life-cycle economic analyses of alternatives. Consider esthetics within the limits of the Station Master Plan.

b) Operation and maintenance costs depend on the type of system design and past experience with various systems.

2.3.5.2 Steam Versus High Temperature Water Distribution. For criteria on steam versus high temperature water distribution, refer to DM-3.6, Central Heating Plants. Some advantages and disadvantages of each system type are summarized on Table 2.

2.3.5.3 High-Pressure (above 50 psig) (344.5 kPa) Steam Versus Low-Pressure (0 to 15 psig) (0 to 103.4 kPa) Steam Distribution. Compare costs of higher pressure pipe, valve, and fitting standards against lower pressure standards plus costs of pressure reducing stations in selecting the most economical system. Low pressure steam may not require full-time boiler operator attendance. If operationally adequate, consider medium-pressure steam systems, 15 to 50 psig (103.4 to 344.5 kPa). End-use temperature requirements of terminal equipment must be met by the system selected.

2.3.6 Insulation for Shallow Trench Systems Which Exceed 500 Feet. If the estimated distribution line length exceeds 500 feet (152.5 m), determine the required insulation thickness as follows and edit NFGS-02693 as required.

2.3.6.1 Heat Loss Formula. For concrete shallow trench systems, perform the economic analysis with heat losses calculated using the following equation:

Equation: $Q = 6.28(T_f - T)/\ln(r_p/r)/K_p + \ln(r_i/r_p)/K_i + 0.5/r_i$

where:

- r = inside radius of pipe, feet (one half of id)
- r_p = outside radius of pipe, feet (one half of od)p
- r_i = radius of insulation, feet (one half of od)
- T_f = temperature of fluid, degrees Ff
- T = temperature of ambient, degrees F (use 75)
- K_p = steel pipe thermal conductivity, Btu-in/(hr)(sq-ft) (degrees F)
- K_i = Insulation thermal conductivity, Btu-in/(hr)(sq-ft)i (degrees F)
- Q = pipe heat loss, Btu/hr (ft of pipe)

Table 2
Advantages and Disadvantages of Steam and
Hot Water Distribution Systems

STEAM SYSTEM ADVANTAGES

1. Smaller return pipe sizes are required.
2. Pumping costs for maintaining circulation are lower. Motor size is a fraction of that required for water, as is operating time in some cases.
3. Maintenance costs are lower. The small difference of pressure under which the system components operate reduces wear and maintenance expense to a minimum.
4. When the condensate is repeatedly recycled through the boiler and system, makeup water requirements and corrosion are negligible, and equipment life is lengthened.

STEAM SYSTEM DISADVANTAGES

1. Larger supply piping sizes are required.
2. Larger expansion loops, joints and swing connections are required.
3. Convectors and radiators must be installed in a pitched position.
4. Additional specialty items such as traps, lifts and in some cases pressure-reducing valves are required.
5. Condensate systems fail frequently, causing significant losses of heat.

Reference:
ASHRAE Handbook –
HVAC Systems and Applications

HOT WATER SYSTEM DISADVANTAGES

1. Fast, uniform response to instantaneous load changes using minimum pipe sizes.
2. Piping may be installed level or at any pitch.
3. Smaller supply pipe sizes are used.
4. Forced circulation provides, in the total water mass, the desirable inertia effect which helps to diversify system load requirements contributing to uniform input at fuel burners.
5. Requires fewer specialty items.
6. Permits practical air elimination to minimize corrosion and maintenance.
7. Resetting of system supply water temperature to meet changing loads permits more efficient energy usage.

HOT WATER SYSTEM DISADVANTAGES

1. Larger motor sizes are required for circulating pumps.
2. Larger return pipe sizes are required.
3. Expansion tanks and air vents are required.
4. More maintenance is required due to increased equipment wear caused by longer operating times.
5. More intricate controls may be required, to compensate for areas with frequent load variations, in order to keep system in balance.

ASHRAE Handbook – Fundamentals

2.3.6.2 Heat Loss and Cost Relationship. To optimize the costs the designer must calculate the total owning and operating cost of different sections of the system, assuming use of one particular type of system configuration with various thicknesses of insulation. Only one type of system configuration needs to be considered because the optimum heat loss rate in a particular set of circumstances is not significantly different for different types of system configurations. As illustrated in Figure 1, the total owning and operating cost of a system is represented by a "U" shaped curve when cost is plotted against heat loss which is a function of insulation thickness. The curve is the sum of three other curves: the owning cost curve, which increases as heat loss increases; the maintenance cost curve, which is constant within limits regardless of heat loss; and the operating cost curve, which is directly proportional to the heat loss. The lowest point of the total cost curve is the minimum total owning and operating cost for the system, and the heat loss for the point is the optimum heat loss for the system. When total cost curves are generated for various types of system configurations for a particular site, the point of optimum heat loss is approximately the same for all the system configurations even though the total cost of owning and operating the different systems is different, as illustrated in Figure 2. Therefore, it is not necessary to calculate the insulation requirements for all types of system configurations.

2.4 Federal Agency Approved System Suppliers. The following list contains all approved system suppliers issued Federal Agency Letters of Acceptability required in NFGS-02694, Exterior Underground Heat Distribution System.

2.4.1 Class A, B, C, and D Ground Water Conditions.

a) Intergy Systems, Brecksville, OH
b) Perma Pipe, Niles, IL
c) Rovanco Pipe, Joliet, IL
d) E. B. Kaiser Company, Glenview, IL
e) Pittcon Preinsulated Pipes, Inc., Syracuse, NY
f) U. S. Polycon Corporation, Panama City, FL
g) Nova Group, Inc., Napa, CA
h) Thermacor Process, Inc., Fort Worth, TX
i) Sigma Piping Company, Inc., Incline Village, NV

2.4.2 Class B, C, and D Ground Water Conditions.

a) Thermal Pipe Systems, Media, PA

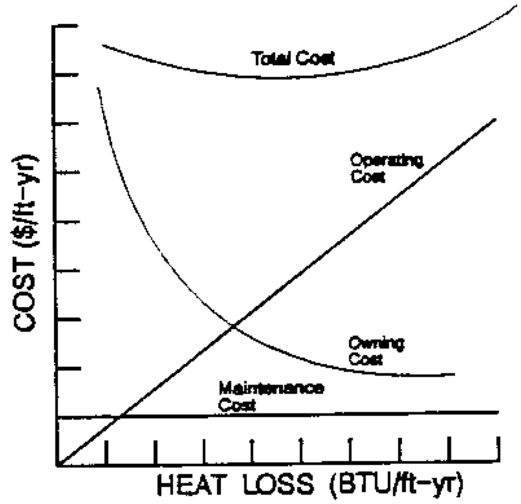

Figure 1
Relation Between Heat Loss and System Costs

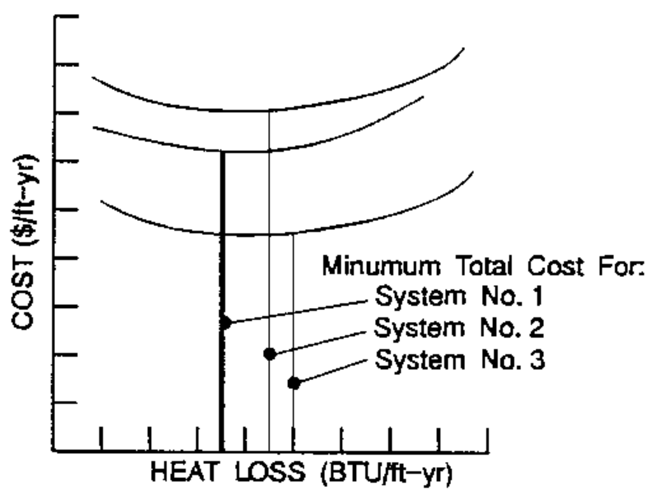

Figure 2
Total Cost of Owning and Operating Three Hypothetical Systems

Step 1. After the general layout of the system has been made and the site and application conditions have been determined, size the system carrier piping assuming a 2 percent heat loss from the supply line at maximum flow.

Step 2. Select one particular type of system configuration which is relatively low in first cost and is approved for use with the site and application conditions identified, to use as a model in making the economic analysis.

Step 3. Determine separately, for each section of the system, the installed cost per foot of the system configuration with each of the applicable combinations of insulation thicknesses shown in Table 3. A section can be considered as any portion of the system in which the conditions that affect heat loss are similar--e.g., pipe size, tunnel shape, cover type. The cost of all components, other than valve vaults called for in the selected system should be included in the cost estimate. If only one pipe is to be installed (i.e., either a supply or return, but not both), use only the appropriate column from the table for that type of pipe.

Step 4. Determine the annual owning cost per foot of each section of the system with each of the different thicknesses of insulation called for in Table 3, using the following equation:

$$\text{Owning Cost (\$/ft-yr)} = \frac{\text{Installed Cost (\$/ft)}}{\text{*Series Present Worth Factor}}$$

*The series present worth factor is the reciprocal of the capital recovery factor.

The series present worth factor can be obtained from any set of interest tables, given the annual interest rate (or rate or return) and the number of years over which the cost is to be amortized (i.e., the economic life of the item). Use an economic life of 25 years and a discount rate as published in National Bureau of Standards (NBS) Handbook 135, entitled Life Cycle Cost Manual for the Federal Energy Management Program.

Step 5. Calculate the heat loss per linear foot separately for each pipe in each section of the selected model system, assuming the various thicknesses of insulation called for in Table 3, using applicable calculation procedures in para. 2.3.6.1.

Table 3
Insulation Thickness (in inches) to be Assessed in Calculations

Thermal Conductivity of Insulation (Btu/hr, square feet, degrees F/in.) Section 3: GENERAL DESIGN FACTORS

3.1 Design Responsibilities for Underground Pre-engineered Heat Distribution Systems. The project designer is responsible for accomplishing the following prior to project bidding:

a) Define site conditions for underground water classification (A, B, C, or D), soil corrosiveness, soil pH if less than 5.0, and potential soil load bearing problems.

b) Determine the general layout and essential characteristics of the system such as system media, maximum operating temperature and pressure, location and design of manholes, and branch runouts. The interface detail of the system at manhole walls shall be provided by the system supplier.

c) Design special elements of the system as required.

d) Calculate the maximum heat loss per lineal foot of the conduit in accordance with the procedures outlined in NFGS-02694.

3.1.1 Design by Project Designer. The project designer shall design on project drawings the exterior steam and condensate piping systems aboveground, the manholes, piping within manholes, and piping not in approved conduit systems. The project designer shall establish the system design parameters of the entire underground piping system, such as site classification, general layout, essential characteristics of the system, and specially designed elements of the system. The project designer is responsible for sizing the pipe, establishing the piping elevations, identifying the piping right-of-way, obstructions and utilities (plan and profile) within 25 feet (7.62 m) of the center line of the right-of-way, and every area within 25 feet of the center line that must be avoided; for example, paved areas and buildings. The project designer is also responsible for the location and sizing of manholes, the design of concrete manholes and the piping and equipment layout of manholes including valves, fittings, traps, expansion joints (when required), and manhole drains.

3.1.2 Design by System Supplier. The construction Contractor shall design and provide buried factory-prefabricated preinsulated piping in a conduit or pre-engineered insulated piping system for which a Federal Agency Approved Brochure has been issued. It is intended that the supplier of a Federal Agency approved system provide the details of design for his system in accordance with his Federal Agency Approved Brochure. The preapproved brochure and the design will address expansion loops, bends, offsets, concrete pipe anchors outside of manholes, interface with each manhole, and the watershed to aboveground piping. When prefabricated steel manholes are indicated, the system supplier is responsible for the structural design of the manhole and the manufacture of the complete manhole, including installation of valves, fittings, and other equipment as specified herein and indicated on the project drawings. The Contractor is responsible for the design, fabrication, and installation of the underground piping system within the system design parameters established by the project designer.

3.2 Distribution Site Location. Fluid distribution site locations should be according to the following:

3.2.1 Location Factors. For location factors for each system, refer to Table 4.

3.2.2 Subsurface Explorations. When a concrete trench or a buried steam or hot water system is specified, make a thorough investigation of ground and water conditions shall be made. Employ a soils engineer familiar with ground water conditions at the site to establish the classification. In the absence of existing definitive information on soil types and ground water conditions, make a detailed site classification survey. Upon completion of the survey, classify each exploration point as A, B, C, or D on the basis of the criteria presented in Tables 5 and 6. The worst ground water condition encountered between adjacent manholes determines the class of the system to be installed between adjacent manholes. Conduct this survey within the guidelines specified in paras. 3.2.2.1 through 3.2.2.12. When concrete shallow trench systems are specified, use the criteria of NFGS-02693 for prefabricated piping systems covered in this handbook.

3.2.2.1 Timing of Survey. Conduct the survey after the general layout of the system has been determined.

3.2.2.2 Time of Year. Make the survey at a time of year when the highest water table is expected to exist, if possible. If this is not possible, correct water table measurements on the basis of professional judgment, to indicate conditions likely to exist at the time of year when the water table is at its highest point. Follow exploration methods indicated in the NAVFAC criteria manual DM-7.01, Soil Mechanics.

3.2.2.3 Exploration Considerations. As a minimum, collect information on ground water conditions, soil types, terrain, and precipitation rates and irrigation practices in the area of the system. Information on terrain and precipitation rates and irrigation practices may be obtained from available records at the installation.

3.2.2.4 Test Explorations. Make test explorations (borings or test pits) at least every 100 feet (30.5 m) along the line of a proposed system. If changes in stratification are noted, decrease the boring spacings so an accurate horizontal soil profile may be obtained.

MIL-HDBK-1003/8A

Table 4
Location Factors for Each Distribution System

ITEM	DETERMINE THE FOLLOWING
Load Centers	Maximum demand load of system. (See criteria in Table 1 and ascertain requirements of all facilities.)
	Distance from generating plant.
	Basements or crawl spaces under buildings available for piping.
	Location of entry of system to load center structure.
	Location or need of meters for billing purposes.
	Future expansion.
Route	Existing piers, tunnels or trenches available for system.
	Aboveground obstructions, such as rivers, lakes, roads, railroads, structures, etc.
	Belowground obstructions, such as tunnels, trenches, piping, rock, storage tanks, etc.
	Location of expansion loops, joints and manholes.
	Master Plan. (Refer to DM-1.01)
Site	For above and underground systems: Ground contours along route.
	For underground systems:
	Borings every 100 feet along route (refer to para 3.1.2) - longer for larger projects.
	Absorption test (refer to para 3.1.2.5)
	Resistivity test (refer to para 3.1.2.7)
	Stability of soil (refer ro para 3.1.2.8)
	Water table survey made at time of highest levels if possible, or modify by judgement based on local data.
	Maximum, normal, and minimum groundwater levels.
	Frost level.
	Location of distribution line drainage and venting.
Coordination	Installation of other related distribution systems and manholes.
	Interference with electric distribution lines and manholes.
	Interference with water supply and fire extinguishing systems.
	Interference with sanitary and storm sewers and manholes.
	Interface with communications systems.
	Interference with ground drainage lines, catch basins, and manholes.
	Interference with fuel distribution piping systems.
	Interface with other gas supplies such as argon, nitrogen and carbon dioxide used in industrial process work.
	Excavation and backfill.
	Landscaping.
Cooperation	Local rules and regulations (permits, tests approvals, etc.).
Hazards	Refer to DM-1.01 for criteria.
Unit costs	Excavation of soil and rock and of landfill.
	Piping material.
	Piping insulation or covering.
	Pipe conduit.
	Construction of manholes.
	Construction of expansion loops and field joints.
Local labor	Availability and costs.
Local material	Availability and costs.

Table 5
Soil Classification

Major division	Subdivision	Fines	Field identification procedures (Excluding particles larger than 3 inches and basing frictions on estimated weights)	Dry strength (crushing characteristics)	Dilatancy (reaction to shaking)	Toughness (consistency near plastic limit)	Group symbols	Typical names	Permeability when compacted
COURSE GRAINED SOILS More than half of material is larger than No. 200 sieve size (The No. 200 sieve size is about the smallest particle visible to the naked eye)	GRAVELS More than half of coarse friction is larger than No. 4 sieve size. (For visual classifications, the 1/4" size may be used as equivalent to the No. 4 sieve size.)	CLEAN GRAVELS (Little or no fines)	Wide range in grain size and substantial amounts of all intermediate particle sizes.				GW	Well graded gravels, gravel-sand mixtures, little or no fines.	Pervious
			Predominantly one size or a range of sizes with some intermediate sizes missing.				GP	Poorly graded gravels, gravel-sand mixtures, little or no fines.	Very Pervious
		GRAVELS WITH FINES (Appreciable amount of fines)	Non-plastic fines (for identification procedures see ML below).				GM	Silty gravels, poorly graded gravel-sand-salt mixtures.	SemiPervious to Impervious
			Plastic fines (for identification procedures see CL below).				GC	Clayey gravels, poorly graded gravel-sand-clay mixtures.	Impervious
	SANDS More than half of coarse friction is smaller than No. 4 sieve size	CLEAN SANDS (Little or no fines)	Wide range in grain sizes and substantial amounts of all intermediate particle sizes.				SW	Wel graded sands, gravelly sands; little or no fines	Pervious
			Predominantly one size or a range of sizes with some intermediate sizes missing.				SP	Poorly graded sands, gravelly sands; little or no fines.	Pervious
		SANDS WITH FINES (Appreciable amount of fines)	Non-plastic fines (for identification procedures see ML below)				SM	Silty sands, poorly graded sand-salt mixtures	Semi-pervious to Impervious
			Plastic fines (for identification procedures see CL below).				SC	Clayey sands, poorly graded sand-clay mixtures	Impervious
FINE GRAINED SOILS More than half of material is smaller than No. 200 sieve size	IDENTIFICATION PROCEDURES ON FRACTION SMALLER THAN No. 40 SIEVE SIZE								
	SILTS AND CLAYS Liquid Limit less than 50			None to slight	Quick to slow	None	ML	Inorganic silts and very fine sands, rock, flour, silty or clayey fine sands with slight plasticity.	Semipervious to Impervious
				Medium to high	None to very slow	Medium	CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays.	Impervious
				Slight to medium	Slow	Slight	OL	Organic silts and organic silts-clays of low plasticity.	Semipervious to Impervious
	SILTS AND CLAYS Liquid limit greater than 50			Slight to medium	Slow to none	Slight to medium	MH	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts.	Semipervious to Impervious
				High to very high	None	High	CH	Inorganic clays of high plasticity, fat clays	Impervious
				Medium to high	None to very slow	Slight to medium	OH	Organic clays of medium to high plasticity.	Impervious
HIGHLY ORGANIC SOILS			Readily identified by color, odor, spongy feel and frequently by fibrous texture.				Pr	Peat and other highly organic soils	

Table 6
Site Classification Criteria

Site Class	General Conditions Required for such Classification	Conditions Found During Site Classification Survey that are Indicative of the Class			
		Relative to Water Table Level	Relative to Surface Water Accumulation		
			Soil Types	Terrain	Precipitation Rates or Irrigation Practices in Area
A–Severe	Water table frequently above bottom of the system	Groundwater within 1 ft of bottom of system	Any	Any	Any
	Water table occasionally above bottom of the system and surface water accumulates and remains for long periods of soil surrounding the system	Groundwater within 1 ft of bottom of system	GC, SC, CL, CH, OH	Any	Any
B--Bad	Water table occasionally above bottom of the system and surface water accumulates and remains either for short periods in soil surrounding the system	Groundwater within 5 ft of bottom of system	GW, GP, SW SP GM, SM, ML, OL, MH	Any	Any
	Water table never above the bottom of the system, but surface water accumulates and remains for long periods in soil surrounding the system	No groundwater encountered	GC, SC, CL CH, OH	Any	Equivalent to 3 in. or more in any one month or 20 in. or more in one year
C--Moderate	Water table never above the bottom of the system, but surface water accumulates and remains for short periods in soil surrounding the system	No ground water encountered	GM, SM, ML, OL, MH	Any	Equivalent to 3 in. or more in any one month or 20 in. or more in one year
			GC, SC, CL, CH, OH	Any except low areas	Equivalent to less than 3 in. in any one month and to less than 20 in. in one year
D--Mild	Water table never above the bottom of the system and surface water does not accumulate and remain in soil surrounding the system	No groundwater encountered	GW, GP, SW, SP	Any	Any
			GM, SM, ML, OL, MH	Any except low areas	Equivalent to less than 3 in. in any one month and to less than 20 in. in one year

3.2.2.5 Depth of Exploration. Extend all explorations 5 ft (1.53 m) below the expected elevation of the concrete trench invert or the depth of the pre-engineered system to determine ground water conditions.

3.2.2.6 Special Ground Considerations. Give particular attention to the following conditions:

a) The possibility that the ground below a backfilled piping system may not be able to absorb runoff that has seeped into it.

b) Areas where ponding may occur, either along a sloping surface or in low flat areas.

c) The permeability of the ground below the system (see below).

3.2.2.7 Permeability Tests. Perform field permeability tests as follows:

a) Space field permeability tests (percolation) along the line of a trench at intervals of approximately 100 feet (30.5 m). When available information indicates uniform subsurface conditions, longer intervals may be allowed for larger projects.

b) Dig holes approximately 1 foot2 (0.093 m2) to a depth of 2 feet (620 mm) below the approximate bottom of a trench.

c) Fill each hole with water to the bottom elevation of the planned trench.

d) After the water has completely seeped away, immediately refill each hole with water to the same depth.

e) If it requires 20 minutes or less for the water to drop 2 inches (51 mm), consider the soil dry; otherwise, consider it as saturated at times.

3.2.2.8 Test Results. Use test results as follows:

a) If the soil is saturated, no further tests are required. Class A underground conduit systems for wet soils must be used.

b) If the soil is dry, as defined above, deepen permeability test holes an additional 3 feet (920 mm) to determine if the water table is within 5 feet (1.53 m) of the trench bottom.

3.2.2.9 Soil Resistivity. Considerations for soil resistivity are as follows:

a) Take soil resistivity readings along the conduit line (in accordance with Table 4).

b) A cathodic protection system is required to protect metallic piping systems and manholes. This applies to all sites where soil resistivity is less than 30,000 ohms per cubic centimeter (ohm-cm), where stray direct currents can be detected underground or where underground corrosion, due to local soil conditions, has been found to be severe.

3.2.2.10 Soil Corrosiveness Classification. Have an experienced corrosion engineer make the classification based on a field survey of the site carried out in accordance with recognized guidelines for conducting such surveys. Classify the soil at the site as corrosive or noncorrosive on the basis of the following criteria:

a) Corrosive: The soil resistivity is less than 30,000 ohms-centimeter (ohm-cm) or stray direct currents can be detected underground.

b) Noncorrosive: The soil resistivity is 30,000 ohm-cm or greater and no stray direct currents can be detected underground.

3.2.2.11 Soil Stability. During the above survey, observe and note the soil stability. Use NAVFAC DM-7.01 for criteria. Note areas of unstable soil on the site plans depicting the distribution route.

3.2.2.12 Soil Load-Bearing Capacity. As a part of the project designer's survey, have an experienced soils engineer investigate the load-bearing qualities of the soil in which the system will be installed. Identify the location and nature of potential soils problems. Depending on the nature of the problem, the designer may choose to reroute the line, use a combination of concrete shallow trench, direct buried, or aboveground low-profile systems, or elect to over-excavate and replace with nonexpensive fill.

3.2.3 Site Classification. Base selection of the conduit system type on the underground water conditions at the project site as defined in Tables 4, 5, and 6 for Class A, B, C, or D application corresponding to underground water conditions ranging from severe to mild, respectively.

3.2.3.1 Class A, Severe. The water table is expected to be frequently above the bottom of the system or the water table is expected to be occasionally above the bottom of the system and surface water is expected to accumulate and remain for long periods in the soil surrounding the system.

3.2.3.2 Class B, Bad. The water table is expected to be occasionally above the bottom of the system and surface water is expected to accumulate and remain for short periods (or not at all) in the soil surrounding the system or the water table is expected never to be above the bottom of the system but surface water is expected to accumulate and remain for long periods in the soil surrounding the system.

3.2.3.3 Class C, Moderate. The water table is expected to never be above the bottom of the system, but surface water is expected to accumulate and remain for short periods in the soil surrounding the system.

3.2.3.4 Class D, Mild. The water table is expected never to be above the bottom of the system and surface water is not expected to accumulate or remain in the soil surrounding the system.

3.2.4 Analyzing Site Classification for Application of Pre-Engineered Underground System. The Federal Agency Committee on Underground Heat Distribution Systems has reviewed and approved systems by suppliers. Each system is defined in the brochure approved by the Committee. No system may be installed without prior approval as given in the brochure. The letter of certification contained in the conduit system brochure stipulates the approved site classification. A system approved for higher classification is acceptable for use in lower classifications. For example, Class A is acceptable for Classes B, C, and D, etc.

3.2.5 Analyzing Site Classification for Application of Shallow Concrete Trench System

3.2.5.1 Soils

a) Fine grained soils (impervious). The highest ground water level evident during the wettest period of the year should be a minimum of 1 foot (305 mm) below the lowest point of water entry into the concrete shallow trench system. The lowest point of entry is defined as the joint between the concrete trench wall and concrete trench bottom. The concrete trench bottom will be continuous with no openings. The above condition will ensure that constructability of the concrete shallow trench is practical and that potential infiltration of water into the shallow trench will be negligible. Open drainage ways, swales, or swampy/boggy areas will preclude use of a concrete shallow trench system because of ground water level guidance in Table 5. The concrete shallow trench system must be rerouted or regraded to bring the concrete trench out of the unsuitable conditions. Have the geotechnical engineer who performed the detailed site classification survey provide regrading instructions. The designer will ensure that the fill will remain stable and will not be subject to future wash-outs. If the specific site conditions are such that these alternatives are not viable, consider aboveground low profile or a direct buried system of the prefabricated or preengineered type in accordance with NFGS-02694 for these areas.

b) Coarse grained soils (semipervious/pervious). The ground water level during the wettest period of the year should be at least 1 foot (305 mm) below the lowest point of water entry into the concrete shallow trench system.

(1) Water table located 1 to 2 feet (305 to 610 mm) below lowest point of water entry. The criteria of para. 3.2.5.1 a) applies.

(2) Water table located 2 or more feet below lowest point of water entry: Concrete shallow trench systems with noncontinuous bottom (tunnel constructed of noncontinuous concrete bottom with openings provided in bottom at intervals of 4 feet (1220 mm) or more to permit drainage into the semipervious/pervious soils) may be used. Special considerations are required when the concrete shallow trench would traverse open drainage ways or swales where the water table would be less than 2 feet (610 mm) below the concrete trench bottom. The designer may elect to reroute the system, place fill to bring the system out of the unsuitable conditions, or provide a continuous bottom trench floor for this area of the site.

c) Swelling Soils (material with high swell potential): If the specific site conditions are such that these alternatives are not viable, consider aboveground low profile or a direct buried system of the prefabricated or preengineered type in accordance with NFGS-02694 for those areas. Design the concrete shallow trench system in materials having high swell potential in accordance with para. 3.2.5.1 a). Soils having a liquid limit (LL) greater than 50 and a plasticity index (PI) greater than 25 require testing (consolidation swell) to determine the swell characteristics. When the results of the swell test indicate high swell potential, special considerations such as over excavation (width and depth) and replacement with nonexpansive fill, under-trench drainage system or other methods of minimizing differential heave will be provided. The design of special features such as described above will be in accordance with instructions provided by the geotechnical engineer who performed the detailed site classification survey. Design of joint spacing and joint details to accommodate movements will also be provided when required.

3.2.5.2 Settlement of Trenches. Generally, settlement of concrete trenches will not be a problem since the unit load of the shallow trench system will be similar to the existing unit overburden load. Backfill adjacent to the concrete trench must be thoroughly compacted to prevent settlement which would create ponding. Positive slopes away from the concrete trench are desirable. Special care of backfill and compaction is required where the system crosses existing streets to preclude settlement and cracking of the roadway adjacent to the trench from repeated traffic loads.

3.2.5.3 Under-Trench Drainage Systems. Use concrete trench subdrain systems as required. When subsurface conditions are of differing soil types, (fine grained and coarse grained) and those differing soil conditions will cause blocked drainage either horizontally or vertically adjacent to the concrete trench, provide subdrains to ensure drainage to prevent ponding or entrapment of water adjacent to the shallow trench system. Base the design of the subdrain system on the instructions provided by the geotechnical engineer who performed the detailed site classification survey and classified each exploration point. Soils of low permeability and high moisture content (lean and fat clays (CL-CH)) shall not require under-drains when the shallow trench system is designed to accommodate all anticipated inflow with systems or equipment such as direct connections to storm sewers or the use of dual sump pumps. Connect drainage system sump pump discharge pipes to storm sewer system where feasible. If not feasible, provide discharge to splash blocks on grade. When discharging to grade install the pump discharge line without a check valve to allow complete drainage of the discharge pipe to prevent freezing. Do not use under-trench drainage to alter ground water level to meet requirements of Table 5.

3.2.6 Reinforced Thermosetting Resin Plastic (RTRP) Pipe. RTRP pipe is normally supplied under Mil Spec. MIL-P-28584, when used for condensate systems. This pipe is suitable for service pressures up to 150 psig (1034 kPa) and temperatures up to 200 degrees F (93 degrees C). Above 200 degrees F (93 degrees C) the pressure rating drops off rapidly. At 250 degrees F (121 degrees C) the pressure rating is 125 psig (861.3 kPa) and drops to 45 psig (310.1 kPa) at 270 degrees F (132 degrees C). These ratings are for hot water. Live steam cannot be tolerated, although RTRP pipe may be used for vented gravity condensate piping as well as for pumped condensate piping. RTRP pipe is acceptable at Class B sites (refer to para. 3.2.3). It is recommended for Class A sites, as permitted in para. 2.1.2, due to its low cost and long service life. Procure and install RTRP condensate piping in accordance with NFGS-02697. Take special care in the design of steam drip connections to protect the RTRP piping from live steam from failed traps. Insulate condensate piping only when a life-cycle cost analysis indicates a payback in energy savings, or where needed for personnel protection (manholes, for example).

3.3 Service and Loads. Determine from Section 2 the services, such as steam, high temperature water, hot water, chilled water, compressed air, fuel gas and others, required for each load center or building, the load demands for each service, and the capacity of a source or central plant for each service. (Refer to Section 2 for fluid conditions inside service lines, for sizing pipes for these conditions, and for the required capacities.)

3.3.1 Alternate Routes. Refer to Master Plan and consider system routing and size to accommodate future construction.

3.3.2 Pressure Drop. From the total allowable pressure drop and ultimate length of a line, determine the pressure drop per 100 feet (30.5 m). Note the maximum flow between each load center and size the different pipeline sections accordingly.

3.3.3 Obstacles. From a field survey, note all obstacles for each route.

3.3.4 Future Loads. Refer to Master Plan and consider system routing to accommodate future construction.

3.3.5 Distribution Circuits. Select a circuit which is economical, easy to operate, balance and control, and is suitable for a particular project terrain. Note that types easiest to balance and control are those where pressure and temperature differences are fairly constant between equipment supply and return branches.

3.3.6 Route Types. Run distribution piping through buildings, aboveground, or underground and below piers.

3.3.6.1 Through Buildings. Select the route considered technically and economically best justified; make full use of building piers, underpiling spaces, basements, crawl spaces, and attics, including connecting corridors between buildings, existing tunnels and concrete trenches. However, high-pressure fuel gas, steam, and HTW piping inside buildings should be routed to comply with federal and local fire and life safety codes. Gas piping shall comply with ANSI B31.8, Gas Transmission and Distribution Piping Systems, and NFPA 54, National Fuel Gas Code. Steam, condensate and compressed air lines shall comply with ANSI B31.1, Power Piping.

3.3.6.2 Exterior Steam Distribution. Use NFGS-02695 for all steam distribution piping exposed to the weather, on building exteriors, aboveground piping supports, piers (pedestals), poles, and for all steam piping on piers and under piers, in tunnels and in manholes. Use NFGS-02693 for piping in trenches. Use NFGS-02694 for buried steam piping .

3.3.6.3 Aboveground Overhead Piping. Locate piping as low as 1 foot (305 mm) or as high as 22 feet (6.7 m) above the ground surface. A 16-foot (4.9 m) clearance is required for automobile and truck traffic, and a 22-foot (6.7 m) clearance for railroad cars.

3.3.6.4 Buried Piping. For buried piping routes, the following criteria apply (refer to NFGS-02694):

a) Compressed Air and Gas Piping. Compressed air and gas piping generally require no insulation, but they should be shop coated, wrapped, tested, and handled in accordance with provisions of NFGS-02685, Exterior Buried Natural Gas Distribution Systems, NFGS-02682, Exterior Fuel Distribution System), and NFGS-09809, Protection of Buried Steel Piping and Steel Bulkhead Tie Rods. Provide for testing of coverings by electrical flow detectors (spark test).

b) Minimum Cover. Protect all buried piping and conduits by laying them under a minimum cover of 24 inches (610 mm). However, protect buried piping under railroads, roads, streets, or highways or due to changes in ground contours against possible external damage due to the superimposed car or truck traffic. Lay pipes below the frost line. Casings may be needed where there is no frost.

c) Other Hazards. When piping must be laid where it will be subjected to hazards such as earthquakes, washouts, floods, unstable soils, landslides, dredging of water bottoms and other categorically similar conditions, protect it by increasing pipe wall thickness, constructing intermediate supports or anchors, erosion prevention, covering pipes with concrete, adding seismic restraints for above-grade piping or other reasonable protection.

d) Manholes. Select manhole locations in accordance with the following. Details of piping and design of manholes are the responsibility of the project designer. Design manholes to provide adequate space for maintenance, proper venting and quick egress. Manholes are required where vertical offsets in steam piping are required to conform to grading requirements. Manholes accommodate the required steam main drip traps and any block valves needed. Manholes are usually provided at all major branch line connections and at drip traps on compressed air lines.

e) Tunnels. Construct tunnels for underground routes with a walkway minimum height of 76 inches (1.93 m) and clear width of 36 inches (920 mm), with piping stacked vertically on one side and enlarged zones for crossovers and takeoffs. Label all pipes and conduit. Provide enough room to reach all flange bolts, to operate tools, and to operate or to replace any component. Run a drainage trench along one wall to a point of disposal such as a storm sewer or a sump pit, with an automatic drainage pump driven by an electric motor or steam jet. Install all electrical systems in rigid metal conduit. Identify and separate by voltage class. Tunnels shall be well lighted and ventilated. Use moisture resistant electrical fixtures. Tunnels may be built of reinforced concrete, brick, or other suitable structural materials, and shall be membrane waterproofed.

3.3.6.5 Condensate Return Cost. Refer to para. 4.1.2 and 4.2.2.3.

3.3.6.6 Choice of Route. Except in congested and vulnerable areas, choose aboveground routes for heat distribution systems. Otherwise, adapt site conditions to comparative advantages of going above or underground as stated below:

Aboveground	Underground
Lower first cost	Less heat loss on hot lines Less vulnerable target
Less maintenance	Less obstruction to aboveground traffic
Easy detection of failure	Less unsightly
Higher continuous operating efficiency	Freeze protected when buried
Longer life	Less heat gain in chilled and condenser water piping

3.3.6.7 Piping Layouts. The project designer is responsible for determining location of expansion bends, loops and joints, anchors, takeoffs, isolation valves, and drip points. The project designer is also responsible for locating all manholes, takeoffs, isolation valves, and drip points. The system designer determines the initial location of anchors, expansion bends, loops and joints; the system supplier determines final location and design of these features to fit actual field conditions. Plan and position piping layouts as follows:

a) Determine what lines between the same points should be parallel to each other (such as supply and return) or be separated (such as steam from chilled water). The minimum clearance between pipe conduits in the same trench shall be 6 inches (150 mm).

b) Determine locations of expansion bends or loops, anchors, takeoffs, and drip points. In non-pre-engineered/prefabricated heat distribution systems, the project designer is responsible for determining location of expansion bends, loops and joints; anchors; takeoffs; isolation valves; and drip points. In pre-engineered/prefabricated heat distribution systems, the project designer is responsible for locating all manholes, takeoffs, isolation valves and drip points. Initial location of anchors, expansion bends, loops and joints shall be by the system designer. The system designer determines the initial location of anchors, expansion bends, loops and joints; the system supplier determines final location and design of these features to fit actual field conditions.

c) Lay out piping on a scaled contour map of the site and on a profile drawing along the route, locating all obstructions and interferences, such as streams, roads, railroads, buried tunnels, concrete trenches, drainage piping, sewers, water piping, electrical conduits, and other service piping, within 25 (7.6 m) feet of the center line of the right-of-way and identify areas within 25 feet of the center line that must be avoided. If sufficient right-of-way to accommodate pipe expansion cannot be identified and expansion joints are required, they must be specified and located with installation details noted on the drawings.

d) Provide a log of soil conditions along the piping right-of-way which gives, as a minimum, soil type, soil resistivity and pH, bearing strength and unstable conditions, and indicate corrective work required.

e) Provide details at building entries on the project drawings to show pipe elevation, floor elevation, building wall construction, and existing equipment.

3.3.6.8 Underground. Use only approved and certified conduit systems for steam, condensate and HTW, and procure and install in accordance with the requirements of NFGS-02694, NFGS-02697, and NFGS-02698, respectively. The Federal Agency Committee for Underground Heat Distribution Systems approves and certifies the various types of conduit systems, i.e., drainable and dryable (pressure testable), sectionalized, prefabricated (non-pressure testable), and poured-in-place granular insulation type conduit systems. Concrete shallow trench systems may be used only if the soil characteristics set forth in NFGS-02693 are met. In this case, design and specify the system in accordance with NFGS-02693.

3.4 Insulation. Evaluate insulation for all piping systems with the potential for significant thermal losses. These include steam, condensate, HTW, MTW, LTW, and CHW piping. Use NFGS-15250, Insulation of Mechanical Systems, for CHW, LTW and special applications requiring insulation of fuel gas and compressed air piping systems. Use NFGS-02696 for above-grade steam, HTW, MTW, LTW, and condensate return piping systems. (Alternately, NFGS-15250 may be used for these above-grade piping systems.) Use aluminum jackets and organic felt as specified in NFGS-15250 and NFGS-02696. Use NFGS-02694 for underground heat distribution piping insulation. Insulation materials shall not contain asbestos.

3.5 Miscellaneous Criteria. Anchor or guy exterior distribution systems to withstand the wind velocity specified for design of structures, refer to MIL-HDBK-1002/2, Loads.

Section 4: SPECIFIC PIPING DESIGN FACTORS

4.1 Fluid Characteristic

4.1.1 Steam. Refer to Keenan and Keyes, Thermodynamic Properties of Steam.

4.1.2 Condensate. For the economics of returning condensate, use the American Society of Heating, Refrigerating, and Air Conditioning Engineers (ASHRAE) 1985 Handbook - Fundamentals and ASHRAE 1987 Handbook - HVAC Systems and Applications.

4.1.3 High Temperature Water (HTW), Medium Temperature Water (MTW), and Low Temperature Hot Water (LTW). Use ASHRAE 1985 Handbook - Fundamentals and ASHRAE 1987 Handbook - HVAC Systems and Applications.

4.1.4 Compressed Air. For data on compressed air, refer to DM-3.5, Compressed Air and Vacuum Systems.

4.1.5 Natural Gas. Refer to NFPA 54.

4.2 Distribution System Piping

4.2.1 Equivalent Lengths of Piping. To the straight lengths of pipe along a pipeline route, add equivalent lengths for valves and fittings as indicated in Table 7.

4.2.2 Sizing of Distribution Piping. Size distribution piping as follows:

4.2.2.1 Minimum Pipe Size. Use minimum of 2-inch (51 mm) pipe which requires extra strong piping for direct buried piping with threaded end connections sized for piping in shallow trench system with all joints welded. Smaller pipe sizes and threaded joints are allowable in valve manholes.

4.2.2.2 Steam Piping. The project designer shall specify the design temperatures and pressures. The approved systems are suitable for temperatures to 450 degrees F (232 degrees C). If higher temperature systems are required, review manufacturers' approved brochures to determine the exceptions to the brochures to be made in the project specification relative to pipe material, pipe expansion, and valve classification. Design considerations are as follows:

Table 7
Representative Equivalent Length in Pipe/Diameter Ratio (L/D) for Various Valves and Fittings 1/

ITEM	DESCRIPTION OF PRODUCT		EQUIVALENT LENGTH IN PIPE LENGTH/DIAMETER
Valves:			
Conventional globe	With no obstruction in flat, bevel or plug type seat.	Fully open	340
	With wing or pin guided disc.	Fully open	450
Y-pattern globe	With stem 60 degrees from run of pipe line.	Fully open	175
	With stem 45 degrees from run of pipe line.	Fully open	145
Conventional angle	With no obstruction in flat, bevel or plug type seat.	Fully open	145
	With wing or pin guided disc.	Fully open	200
Conventional wedge, disc, plug or gate.		Fully open	13
		Three-quarters open	35
		One-half open	160
		One-quarter open	900
Pulp stock gate		Fully open	17
		Three-quarters open	50
		One-half open	260
		One-quarter open	1,200
Conduit pipe line gate		Fully open	3 2/
Butterfly 6-inch and larger		Fully open	20
Conventional swing check		0.5 3/ - Fully open	135
Clearway swing check		0.5 3/ - Fully open	50
Globe lift check or stop-check		2.0 3/ - Fully open	Same as conventional globe
Angle lift check or stop-check		2.0 3/ - Fully open	Same as conventional angle
Foot valves	With strainer and poppet lift-type disc.	0.3 3/ - Fully open	420
	With strainer and leather-hinged disc.	0.4 3/ - Fully open	75
in-line-ball check	2.5 vertical and 0.25 horizontal	3 - fully open	150
Straight-through cocks	Rectangular plug port area equal to 100% of pipe area.	Fully open	18
Three-way cocks	Rectangular plug port area equal to 80% of pipe area (fully open).	Flow straight through	44
		Flow through branch	140
Fittings:			
90 degrees standard elbow			30
45 degrees standard elbow			16
90 degrees long radius elbow			20
90 degrees street elbow			50
45 degrees street elbow			26
Square corner elbow			57
Standard tee	With flow through run.		20
	With flow through branch.		60
Close pattern return bend			50

1/ Legitimate for all flow conditions except in laminar flow range where Reynolds number is less than 1000.
2/ Exact equivalent length is equal to the length between flange faces of welding ends.
3/ Minimum calculated pressure drop in psi across vavle to provide sufficient flow to lift disc fully.
Note: For additional data refer to DM-3.05.

a) Steam Flow Charts. For pressures of 30 psig (206.7 kPa), 50 psig (344.5 kPa), 100 psig (689.4 kPa), and 150 psig (1033.5 kPa), see Figures 3 through 6. These charts show weight-rate pressure drop and velocities of saturated steam in Schedule 40 steel pipe. By selecting all pipe sizes on an optimum pressure drop, the total pressure drop of a pipeline may be estimated from an equivalent length, irrespective of pipe size. The charts are based on the rational flow formula (Darcy) shown below. For higher pressures, refer to Piping Handbook, by Crocker and King.

b) Rational Flow Charts. The simplified rational flow formula (Darcy) is used for compressible fluids for all pressures:

EQUATION: $$P_{100} = W^{2}(0.000336f)\ v/d^{5} = C_{1} \times C_{2} \times v \quad (2)$$

Where:

P_{100} = pressure drop per 100 feet of equivalent length of pipe (psi)

C_{1} = $W^{2}10^{-9}$ (for values, see Figure 7)

C_{2} = $336000f/d^{5}$ (for values, refer to Table 8)

W = rate of flow, pounds per hour (pph) (0.454 Kg/h)
f = friction factor
d = inside diameter of pipe (in)
v = specific volume of fluid (ft^{3} per lb) at average pressure

c) Velocities. (Refer to Table 9.)

EQUATION: $$V = \frac{3.06W}{d^{2}} \quad (3)$$

Where:

V = velocity of flow (fpm)
R = density (pcf)

NOTE: The letters s, x, and xx in the columns of Schedule No. indicate Standard, Extra Strong, and Double Extra Strong pipe respectively.

Table 9
Reasonable Velocities for Flow of Steam in Pipes

CONDITION OF STEAM	PRESSURE (psig)	SERVICE	REASONABLE VELOCITY [1] (fpm)
Saturated	Vacuum	Turbine exhaust	Up to 18,000
	0 to 25	Heating	4,000 to 6,000
	25 and up	Steam distribution	6,000 to 10,000
	125 and up	Underground steam distribution	Up to 20,000
Superheated	200 and up	Boiler and turbine leads	7,000 to 20,000

[1] Velocities should be below those which would produce excessive noise or erosion.

d) Steam Distribution Pressures. Steam pressure is governed by the highest pressure needed by the equipment served at the most remote location as well as by an economic analysis of the feasible systems, including pressure considerations. The advantages of a low-pressure system (under 15 psig) (103.4 kPa) are low distribution loss, lower losses and less trouble from leakage, traps, and venting, simplified pressure reduction at buildings, standard steel fittings, and low maintenance. The advantages of high-pressure distribution, over 50 psig (344.5 kPa), are smaller pipe sizes, availability of steam for purposes other than for heating, and more flexibility in velocities and pressure drops.

e) Selection of Valve Types. Install double-ported, pilot-operated valves for large capacities, especially for inlet pressures above 125 psig (861.3 kPa). Double-ported valves will not shut off completely on no-load demand; therefore, single-seated valves must be used for such services. Do not install reducing valves on the basis of pipe sizes, because oversized valves do not give satisfactory service. Select valves to operate generally fully open, with ratings and reduction ratios as recommended by the manufacturer. Install a strainer and condensate drain ahead of the pressure-reducing valve. Because the volume of steam increases rapidly as the pressure is reduced, a reducing valve with increased outlet or expanding nozzle is required when the reduction ratio is more than 15 to 1. Provide cutout valves to isolate the pressure reducing valve to permit maintenance. Where the resulting superheated steam temperature is objectionable to the process on the low pressure side or the temperature-use limit of the equipment has been exceeded, a desuperheater must be used to lower the steam temperature to that for saturation. Provide a manual bypass for emergency operation when the pressure reducing valve is out of service. Provide a pressure gauge on the low pressure side. Where steam requirements are relatively large, above approximately 3,000 pounds/hour (1364 kg/hr), and subject to seasonal variation, install two reducing valves in parallel, sized to pass 70 percent and 30 percent of maximum flow. During mild spring and fall weather, set the large valve at a slightly reduced pressure so that it will remain closed as long as the smaller valve can supply the demand. During the remainder of the heating season reverse the valve settings to keep the smaller one closed except when the larger one is unable to supply the demand.

f) Safety Valves. Provide one or more relief or safety valves on the low pressure side of each reducing valve in case the piping and/or equipment on the low pressure side do not meet the requirements of the full initial pressure. The combined discharge capacity of the relief valves shall be such that the pressure rating of the lower pressure piping and equipment will not be exceeded. For special conditions refer to ASME B31.1 and ASHRAE Handbooks - Systems and Applications.

g) Takeoffs from Mains. Takeoffs from mains to buildings must be at the top of mains and located at fixed points of the mains, at or near anchor points. When a branch is short, valves at each takeoff are unnecessary. Takeoffs shall have valves when the branch is of considerable length or where several buildings are served. A 45 takeoff is preferred; 90 takeoffs are acceptable. Branch line slope of 1/2 inch (12.6 mm) should be used for lines less than 10 feet (3.05 m) in length and should be 1/2 inch per 10 feet (3.05 m) on branch lines longer than 10 feet.

4.2.2.3 Condensate Returns. Condensate returns are preferred if owning and operating costs of such a system are less than that of using and treating raw water for makeup. Factors favoring condensate return are: high area concentration of steam usage; restriction on condensate disposal; high raw water treatment costs; water treatment space unavailable; high cost of raw water; and high cost of fuel for feedwater heating. Design considerations are as follows:

a) Return Piping. Size condensate trap piping to conform with 30 to 150 psig (206.7 to 1033.5 kPa) steam piping in accordance with Tables 10 and 11 and interpolate these for other pressures.

b) Discharge Piping. Size discharge piping from condensate and heating pumps in accordance with pump capacities, which may be between one to three times the capacity of the steam system branch which they serve, depending on whether continuously or intermittently operated.

Table 10
Return Pipe Capacities for 30 psig (206.7 kPa) Steam Systems (a)
(Capacity Expressed in lbs/hr)

	DROP IN PRESSURE (psi PER 100 ft IN LENGTH)				
PIPE SIZE (in.)	1/8	1/4	1/2	3/4	1
3/4	115	170	245	308	365
1	230	340	490	615	730
1-1/4	485	710	1,025	1,290	1,530
1-1/2	790	1,160	1,670	2,100	2,500
2	1,580	2,360	3,400	4,300	5,050
2-1/2	2,650	3,900	5,600	7,100	8,400
3	4,850	7,100	10,300	12,900	15,300
3-1/2	7,200	10,600	15,300	19,200	22,800
4	10,200	15,000	21,600	27,000	32,300
5	19,000	27,800	40,300	55,500	60,000
6	31,000	45,500	65,500	83,000	98,000

(a) Based on 0-4 psig maximum return pressure.

Table 11
Return Pipe Capacities for 150 psig (1033.5 kPa) Steam Systems (a)
(Capacity Expressed in lbs/hr)

	DROP IN PRESSURE (psi PER 100 ft IN LENGTH)					
PIPE SIZE (in.)	1/8	1/4	1/2	3/4	1	2
3/4	156	232	360	465	560	890
1	313	462	690	910	1,120	1,780
1-1/4	650	960	1,500	1,950	2,330	3,700
1-1/2	1,070	1,580	2,460	3,160	3,800	6,100
2	2,160	3,300	4,950	6,400	7,700	12,300
2-1/2	3,600	5,350	8,200	10,700	12,800	20,400
3	6,500	9,600	15,000	19,500	23,300	37,200
3-1/2	9,600	14,400	22,300	28,700	34,500	55,000
4	13,700	20,500	31,600	40,500	49,200	78,500
5	25,600	38,100	58,500	76,000	91,500	146,000
6	42,000	62,500	96,000	125,000	150,000	238,000

(a) Based on 1-20 psig maximum return pressure.

c) Common Pump Discharge Mains. Size common pump discharge mains to serve the sum of their capacities. Use the Hydraulic Institute (HI) Pipe Friction Manual for steel pump discharge pipe sizing of new clean steel pipe, 6 feet per second (fps) (1.83 m/s) maximum velocity, and a correction factor of 1.85 to provide for increased pressure drops when the pipe becomes dirty and rough with age. Friction plus static heads shall not exceed the pump characteristics of standard pump and receiver units.

4.2.2.4 High Temperature Water (HTW) Piping. High temperature water piping is as follows:

a) Sizing Piping. Use pipe friction charts in ASHRAE 1985 Handbook Fundamentals. These charts are based on the rational flow formula using clean pipe. A reasonable average velocity is approximately 5 fps (1.53 m/s). The minimum allowable velocity is 2 fps (0.61 m/s).

b) Venting and Draining. For methods of venting high points of distribution lines, refer to DM-3.03, Heating, Ventilating, Air Conditioning and Dehumidifying Systems. Piping must have drainage means at low points.

4.2.2.5 Chilled Water Piping. Use the standards of the Hydraulic Institute Pipe Friction Manual for sizing new clean pipe, unless water is renewed annually, in which case a correction factor of 1.41 for pressure drop is also to be used. For recommended velocities, refer to DM-3.03.

4.2.2.6 Condenser Water Piping. Use the standards of the Hydraulic Institute Pipe Friction Manual for pipe sizing, multiplying the pressure drop by a factor of 1.85 to correct for the increase of pipe roughness with age. For recommended velocities, refer to DM-3.03. No correction faction is required for RTRP pipe.

4.2.2.7 Natural Gas Piping. Apply criteria in DM-3.01, Plumbing Systems, for sizing pipe inside buildings. Use Figure 8 for low volume flow rates and Figure 9 for high volume flow rates in sizing distribution piping. Using these figures will simplify design of piping by indicating required diameter, maximum rate of flow, permissible pressure drop, initial pressure, or final pressure when the rest of these values are known. These charts are based on the Weymouth formula for rate of flow in cubic feet of gas per hour. (The chart is based upon the following conditions: gas at 60 degrees F (15.5 degrees C) and specific gravity of 0.60, with air = 1.0.). Exterior distribution piping usually stops 5 feet (1.53 m) outside of buildings.

4.2.2.8 Compressed Air. For criteria on distribution piping, refer to DM-3.5, Compressed Air and Vacuum Systems.

4.2.3 Piping Specifications and Codes. Piping specifications and codes are as follows:

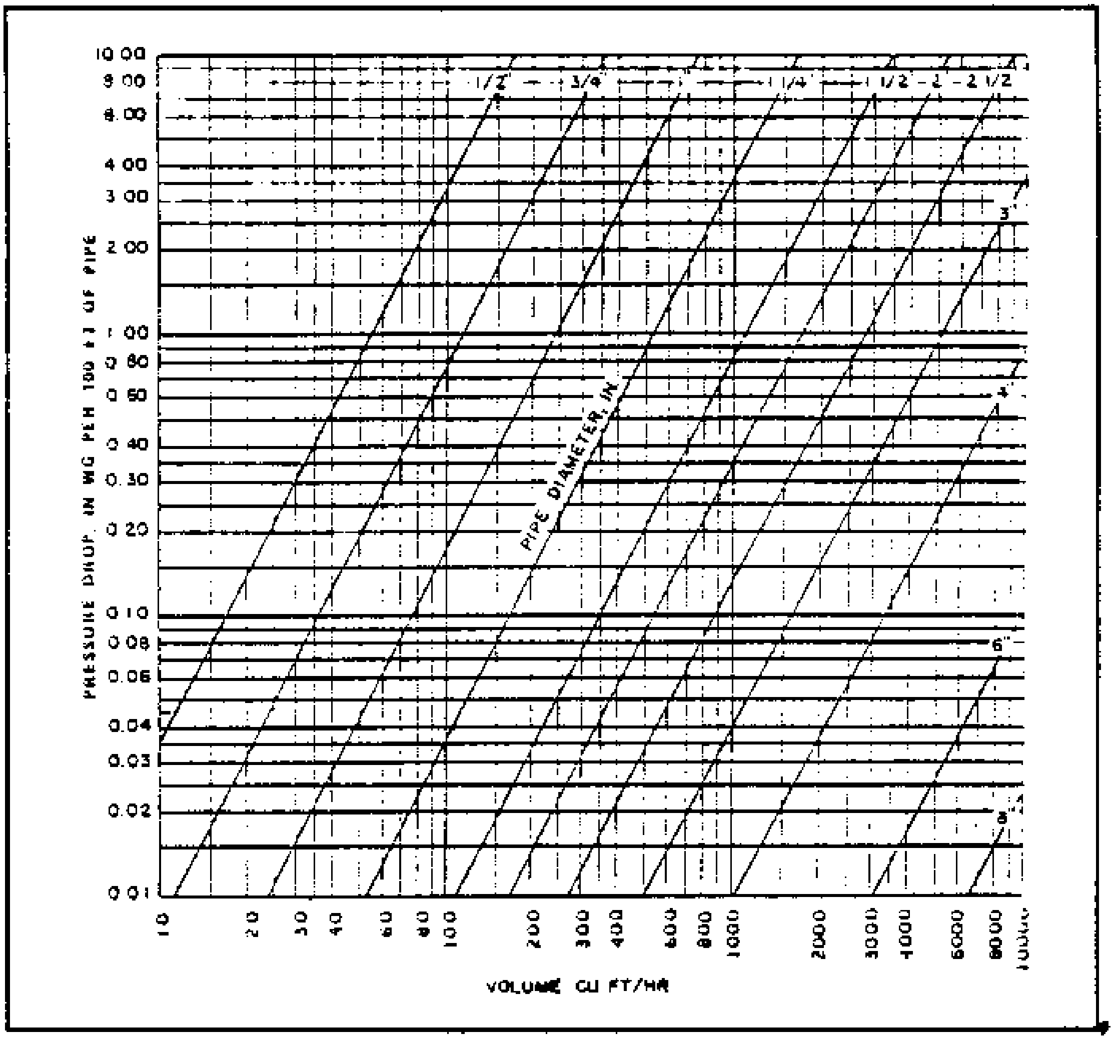

Figure 8
Low Volume Flow Rate Natural Gas Chart (10 to 10,000 ft^3/hr)
(.283 to 283 m^3/hr)

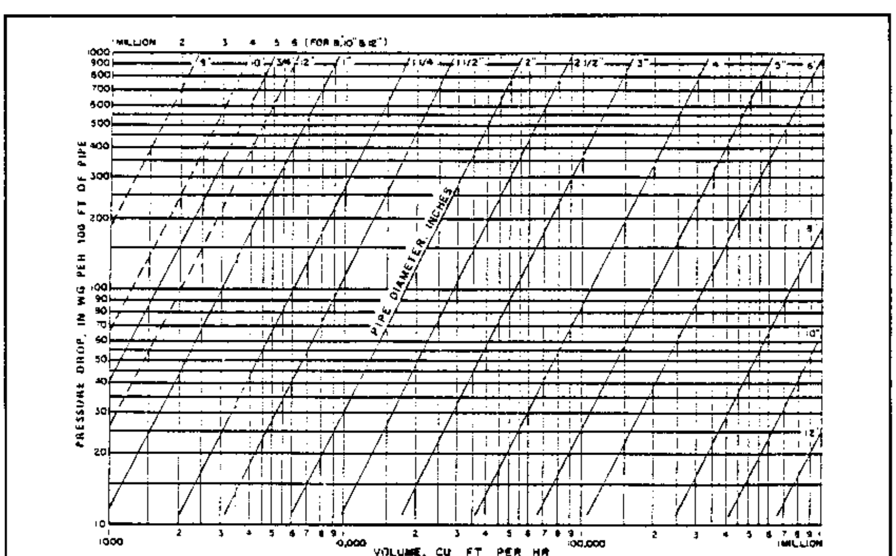

Figure 9
High Volume Flow Rate Natural Gas Chart (1,000 to 1 million ft^3 hr)
(28.3 to 28,300 m^3/hr)

4.2.3.1 Steam Supply and Condensate Return. Piping shall conform to ASME B31.1, except for underground prefabricated or pre-engineered type systems, in which case the entire system shall conform to NFGS-02694.

a) If a separate pump condensate return system is used, it shall conform to NFGS-02697.

b) For condensate provided as a part of an underground prefabricated, pre-engineered system, include Mil. Spec MIL-P-28584 plastic condensate piping in the specification as a Contractor's option for sites classified B, C, or D. Plastic piping is optional but encouraged for sites classified A. The Contracting Officer shall give specific approval for plastic condensate piping in Class A systems. Take particular care that the failure of high pressure steam drip traps shall not discharge high temperatures and pressures into the plastic condensate piping.

4.2.3.2 High Temperature Water, Medium Temperature Water, and Low Temperature Hot Water. Piping specifications and codes are as follows, except for underground prefabricated or pre-engineered types, in which case the entire system shall conform to NFGS-02694.

a) Piping. HTW metallic piping (450 degrees F maximum) (232 degrees C) and medium temperature water metallic piping shall conform to ASME B31.1.

b) Joints. Welded joints are preferred. Threaded joints are not permitted. Hold flanged joints to a minimum and use ferrous alloy gaskets in such joints. Avoid the use of copper and brass pipe.

c) Valves. All valves shall have cast steel bodies with stainless steel trim (no bronze trim). All valves shall be capable of being repacked under operational pressures. Use gate valves only as shutoff or isolation valves.

4.2.3.3 Natural Gas and Compressed Air. Piping shall conform to ASME B31.1 and B31.8 including guidance for abandoning existing gas lines. Note that ASME B31.8 requires that abandoned gas lines be physically disconnected from gas sources and purged prior to sealing. Shutoff valves are not an acceptable means of disconnect. Cathodic protection systems on lines to be abandoned should be evaluated for modifications required to ensure continuity of the systems after abandoned lines are disconnected or removed. Provide excess-flow (earthquake) shutoff valves in gas supply piping outside of each building served in earthquake zones 3 and 4. In addition, provide flexible connections. Gas piping and appurtenances from point of connection with existing system to a point approximately 5 feet (1.53 m) from the building shall conform to NFGS-02685.

4.2.3.4 Chilled and Condenser Water. Use Schedule 40 steel pipe in 10-inch (254 mm) size and smaller, and use 1/2-inch (12.5 mm) wall thickness steel pipe for 12-inch (305 mm) size and larger. RTRP pipe and PVC pipe are also acceptable. RTRP pipe and PVC pipe are available in 2 through 12-inch (51 through 305-mm) pipe sizes.

4.2.4 Thermal Expansion of Steel and Copper Pipe. Pipe expands with temperature increases (such as between installation and operating temperatures) as indicated in Table 12. Make provisions for the control of expansion in any piping system where thermal expansion is a factor. Wherever possible, provide for expansion of pipes by changes in direction of pipe runs.

4.2.4.1 Branch Lines. Where practicable, design branch line piping to provide for expansion inside buildings. Expansion control of branch lines should be designed so as to have no effect on mains.

4.2.4.2 Expansion Bends. Bends are to be factory fabricated except for RTRP pipe.

a) Loop Sections. Loops may be furnished in sections to facilitate delivery and handling.

b) Anchors. A reasonable distance between anchors for expansion loops is 200 feet (61 mm) for 125 psig (861.3 kPa) steam system. Expansion is usually kept at about 6 inches (150 mm) between anchors.

c) Cold Springing. Cold springing may be used in installations but no design stress relief is allowed for it. For credit permitted in thrust and moments, refer to ANSI B31.1.

4.2.4.3 Expansion Joints. Install expansion joints only where space restrictions prevent the use of other means. When necessary to use, expansion joints shall be in an accessible location and shall be one of the following types:

a) Mechanical Slip Joint. An externally guided joint designed for repacking under operating pressures. Hold maximum traverse of piping in expansion joints under 8 inches (203 mm).

b) Bellows Type Joint. Use these joints on steel pipe for thermal expansion with stainless steel bellows, guided and installed according to manufacturer’s instructions. Make bellows or corrugations for absorbing vibrations or mechanical movements at ambient temperatures of copper or other materials suitable for the job conditions. A maximum travel of 4 inches (102 mm) is allowed for this type. RTRP expansion joints may be polytetrafluoroethylene bellows type.

c) Flexible Ball Joints. Install these joints according to manufacturer’s instructions.

4.2.4.4 Flexibility Analysis. Refer to ASME B31.1 for expansion and flexibility criteria and allowable stresses and reactions.

Table 12
Pipe Expansion in Inches Per 100 Feet (30.5 m) of Length
for Temperature Shown

4.2.4.5 Stress Analysis. For methods of analyzing stresses in piping systems, use piping handbooks and publications of pipe and pipe fitting manufactures. These manufacturers also supply calculation forms and charts. Keep calculated pipe stresses under those allowed by ANSI B31.1.

4.2.5 Insulation of Piping Systems. Use NFGS-02694 for insulation design for underground heat distribution piping. Use NFGS-02696 for above grade steam, condensate, HTW, MTW, and LTW. Use applicable sections of NFGS-15250 for other systems.

4.2.5.1 Insulation Thickness. Insulation thicknesses indicated in NFGS-02696 and in NFGS-15250 are suitable for most geographic locations. However, in locations where extreme annual temperatures occur, the project designer should evaluate different thicknesses of insulation. Make final selection based on an economic analysis in accordance with para. 2.3.5.

4.2.5.2 Jackets. Design insulation jackets in waterfront or other locations subject to flooding to drain; they shall not be watertight.

4.2.6 Drainage Provisions. Drainage provisions must conform to requirements listed below.

4.2.6.1 Pitch. The surrounding terrain and piping application both affect the pitch of piping as indicated below.

a) Horizontal Piping. Pitch horizontal steam piping down at a minimum of 2-1/2 inches (64 mm) per 100 feet (30.5 m) of length in the direction of steam flow.

b) Underground Piping. Pitch horizontal piping down towards drain points (unless otherwise noted) a minimum of 2-1/2 inches (64 mm) in 100 feet (30.5 m). Where the ground surface slopes in the opposite direction to steam piping, step up underground piping in vertical risers at drip points in manholes, and pitch them down to the next drip point. Use this method also for all very long horizontal runs, above- or belowground, to keep piping within a reasonable range of elevations with reference to the ground surface.

c) Counter-Flow Conditions. Where counter-flow of condensate within the steam pipe may occur in a portion of a pipeline because the stepped construction cannot be built, or because of steam flow reversal in a loop system, pitch that portion up in the direction of steam flow a minimum of 6 inches (152 mm) per 100 feet (30.5 m) and increase pipe diameter by one standard pipe size.

d) Compressed Air and Natural Gas Lines. Pitch compressed air and gas piping as for steam piping.

e) Pumped Water Pipe. Pitch pumped water pipes (condensate, HTW, MTW, LTW, CHW, or condenser water) up or down in direction of flow at a minimum slope of 2-1/2 inches (64 mm) per 100-foot (30.5 m) length. Place drain valves at all low points and vents at high points.

4.2.6.2 Drips and Vents. Provide drips and vents as follows:

a) Drip Legs. Provide drip legs to collect condensate from steam piping and compressed air piping for removal by automatic moisture traps, or by manual drain valves for compressed air piping when practicable. Locate drip legs at low points, at the bottom of all risers, and at intervals of approximately 200 to 300 feet (61 to 91.5 m) for horizontally pitched pipe where a trap is accessible, and not over 500 feet (152.5 m) for buried underground pipe systems. On gas piping, drip legs are not usually required where dry gas is provided. Where there is moisture in the gas, provide drip legs and sediment traps in accordance with NFPA 54. Automatic traps are not utilized.

b) Water Piping. Vent piping, especially high-temperature water piping, at distribution piping high points.

c) Fuel Gas Piping. Provide capped dirt traps in vertical risers upstream of gas-burning devices.

4.2.6.3 Condensate Systems. Condensate systems are as follows:

a) Furnish a complete system of drip traps and piping to drain all steam piping of condensate from drip legs. Ensure drip piping to traps is the same weight and material as the drained piping.

b) Preferably, run a condensate line from a trap separately to a gravity condensate return main or to a nearby flash tank. (Refer to ASHRAE Handbooks - Systems and Applications for flash tank details and specific trap applications. Additionally, refer to Naval Civil Engineering Laboratory (NCEL) UG-0005, Steam Trap Users Guide.) However, a trap may be discharged through a check valve into the pumped condensate line if pressure in the trap discharge line exceeds the back pressure in the pumped condensate line during standby time of an intermittently operated pump. If the pumped condensate line is RTRP pipe, install a condensate cooling device, similar to that shown in Figure 10, to limit temperature of the condensate entering the line to less than 250 degrees F (121 degrees C).

c) Select traps using a safety load factor no greater than 2. The condensate load should be indicated on design drawings and may be determined for aboveground lines by using Table 13. The condensate load for underground distribution lines is determined from maximum heat loss as indicated by the design. With the tight safety load factor for sizing traps, an alternate method of expelling gasses during warmup is required. To this end, all strainers should have blowdown valves which will also be used for controlled warmup.

Table 13
Condensate Loads from Aboveground Heat Distribution Piping
(Pounds Per Hour Per 100 Linear Feet)

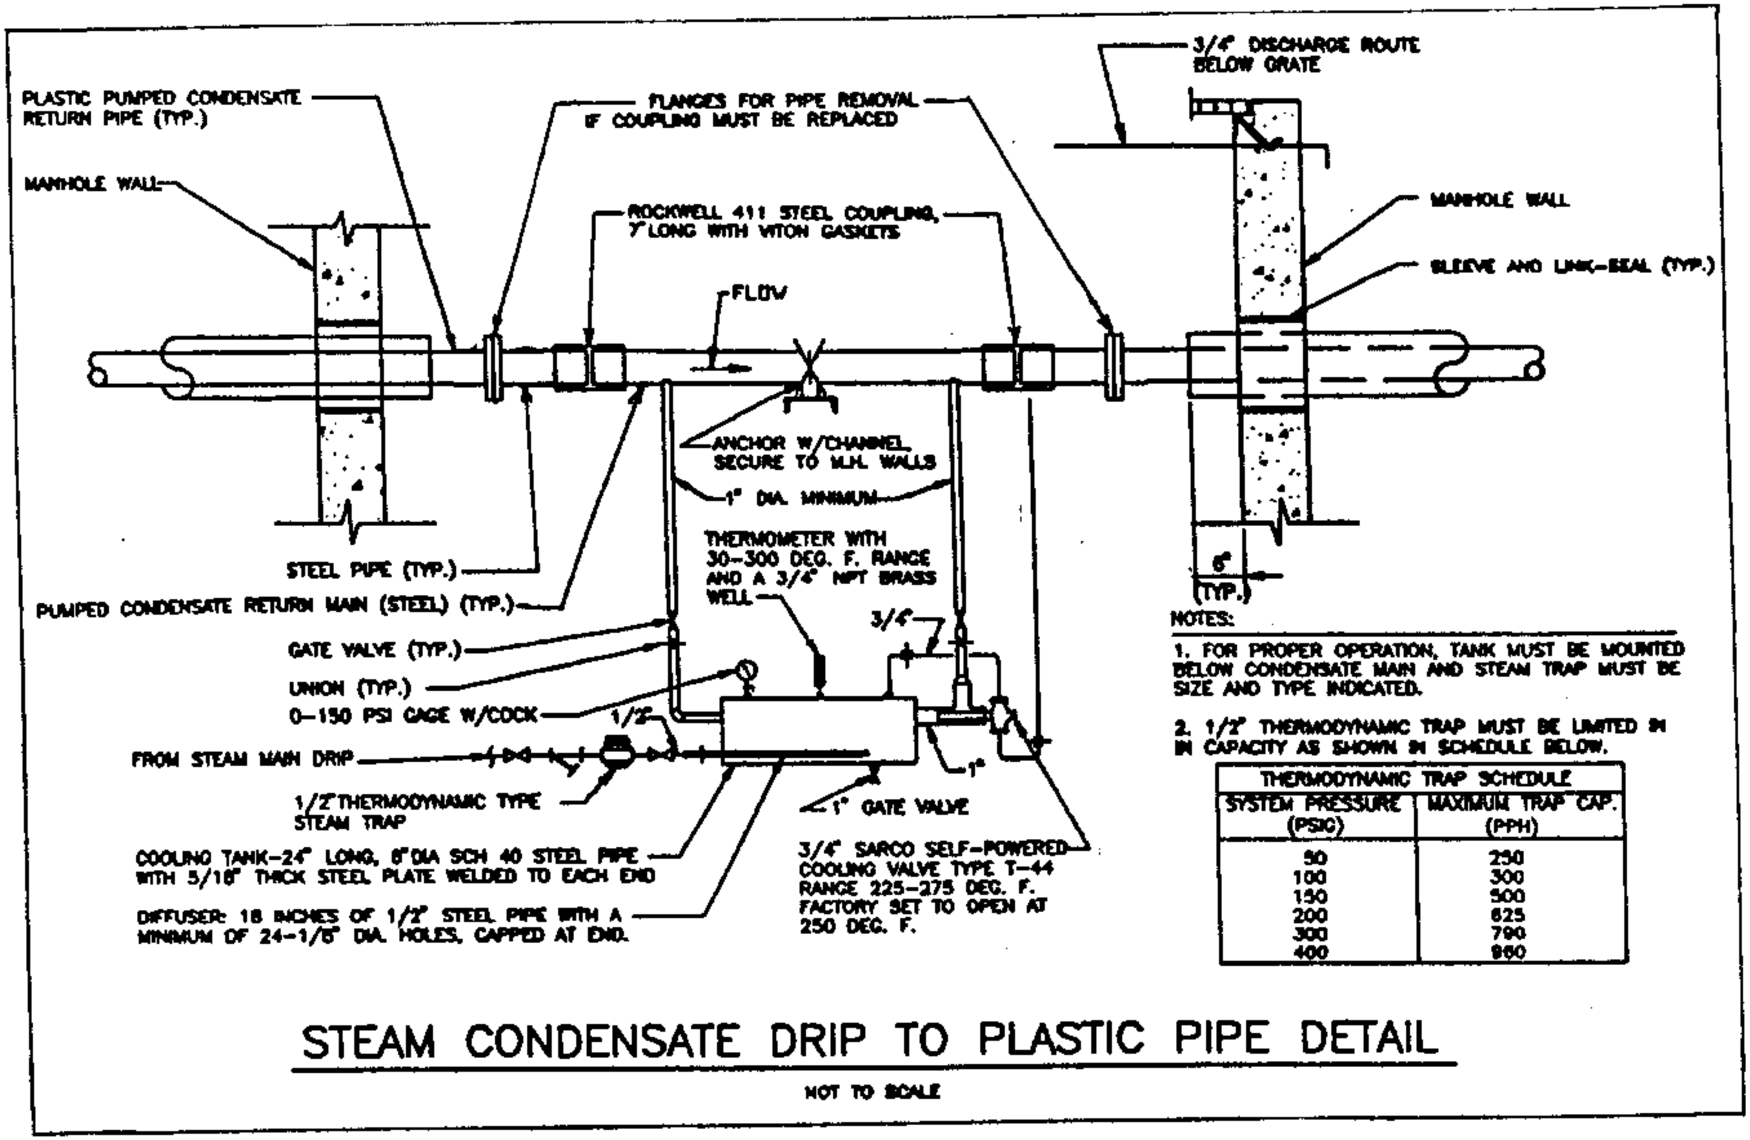
STEAM PRESSURE (psig)	STEAM PIPE SIZE (INCHES, DIAMETER)					
	2	4	6	8	10	12
10	6	12	16	20	24	30
30	10	18	25	32	40	46
60	13	22	32	41	51	58
125	17	30	44	55	68	80
300	25	46	64	83	203	122
600	37	68	95	124	154	182

d) Pitch discharge piping down a minimum of 3 inches (76 mm) per 100 feet (30.5 m) to the collection tank. This applies where a condensate pump set or reliance upon a gravity return is used. An exception to this "rule-of-thumb" exists when there is sufficient pressure in a steam line to overcome its friction and static head, whether the line is level, or pitched up. Trap discharge line shall not be RTRP pipe nor shall the trap discharge connect to an RTRP pipe by direction connection. Install pipe through a condensate cooling device as depicted in Figure 10. This system provides a cooling tank and diffuser, plus a temperature relief valve to limit the temperature of condensate returned to a pumped RTRP condensate line to less than 250 degrees F (121 degrees C).

e) If it is not justifiable to return drips to a condensate system, they may be drained as waste to a sewer. If the temperature exceeds sewer limitations, condensate must be cooled in a sump or by other means. Disposal of condensate from steam systems along the waterfront or under piers warrants special consideration to be determined on a case-by-case basis.

4.2.7 Pipe Anchors. Ensure anchors comply with the following criteria:

4.2.7.1 Location. Locate anchors for non-pre-engineered/prefabricated systems at takeoffs from mains and other necessary points to contain pipeline expansion. If possible, locate anchors in buildings, piers, tunnels, and manholes with suitable access.



NOTES:

1. FOR PROPER OPERATION, TANK MUST BE MOUNTED BELOW CONDENSATE MAIN AND STEAM TRAP MUST BE SIZE AND TYPE INDICATED.

2. 1/2" THERMODYNAMIC TRAP MUST BE LIMITED IN IN CAPACITY AS SHOWN IN SCHEDULE BELOW.

THERMODYNAMIC TRAP SCHEDULE

SYSTEM PRESSURE (PSIG)	MAXIMUM TRAP CAP. (PPH)
50	250
100	300
150	500
200	625
300	790
400	960

STEAM CONDENSATE DRIP TO PLASTIC PIPE DETAIL

NOT TO SCALE

Figure 10
Protective Arrangement for RTRP Pipe

4.2.7.2 Specification. Design and locate anchors in accordance with ASME B31.1.

4.2.7.3 Strength. Design anchors to withstand expansion reactions. With expansion joints, consider the additional end reactions due to internal fluid pressure, and add end reactions due to spring rate of the joint.

4.2.7.4 Guying. Anchors for elevated aboveground systems shall consist of wire rope guys running from embedded concrete deadmen to pipe saddles welded to the pipe and secured to the vertical support(s). Guy in both directions. Guys may be located on the diagonal to serve also as sway bracing.

4.2.7.5 Embedding. In underground concrete tunnels, the ends of structural steel shapes anchoring a pipe may be embedded in the tunnel walls or floors.

4.2.8 Supports. Insure pipe supports conform to ASME B31.1.

4.2.8.1 Low Elevations. For aboveground systems at low elevations (defined as lower than 5 feet (1.53 m) above grade or the working surface), use and space concrete pedestals, steel frames, or treated wood frames as required depending on pipe sizes.

4.2.8.2 High Elevations. At higher elevations above ground, support pipelines on wood, steel pipe, H-section steel, reinforced concrete, prestressed concrete poles with crossarms, or steel frameworks fitted with rollers and insulation saddles. (See Figure 11.) Details of design will vary depending on site conditions.

4.2.8.3 Long Spans. When long spans are necessary, cable-suspension or catenary systems may be used.

4.2.8.4 Underground Conduits. Use approved types of manufacturers' standard designs supports for underground conduits.

4.2.8.5 In Trench. Suspend pipes either from the walls or the tops of the walls. Do not support piping from either the floor of the trench or from the removable top. The pipe hanger design must provide for adequate system expansion and contraction.

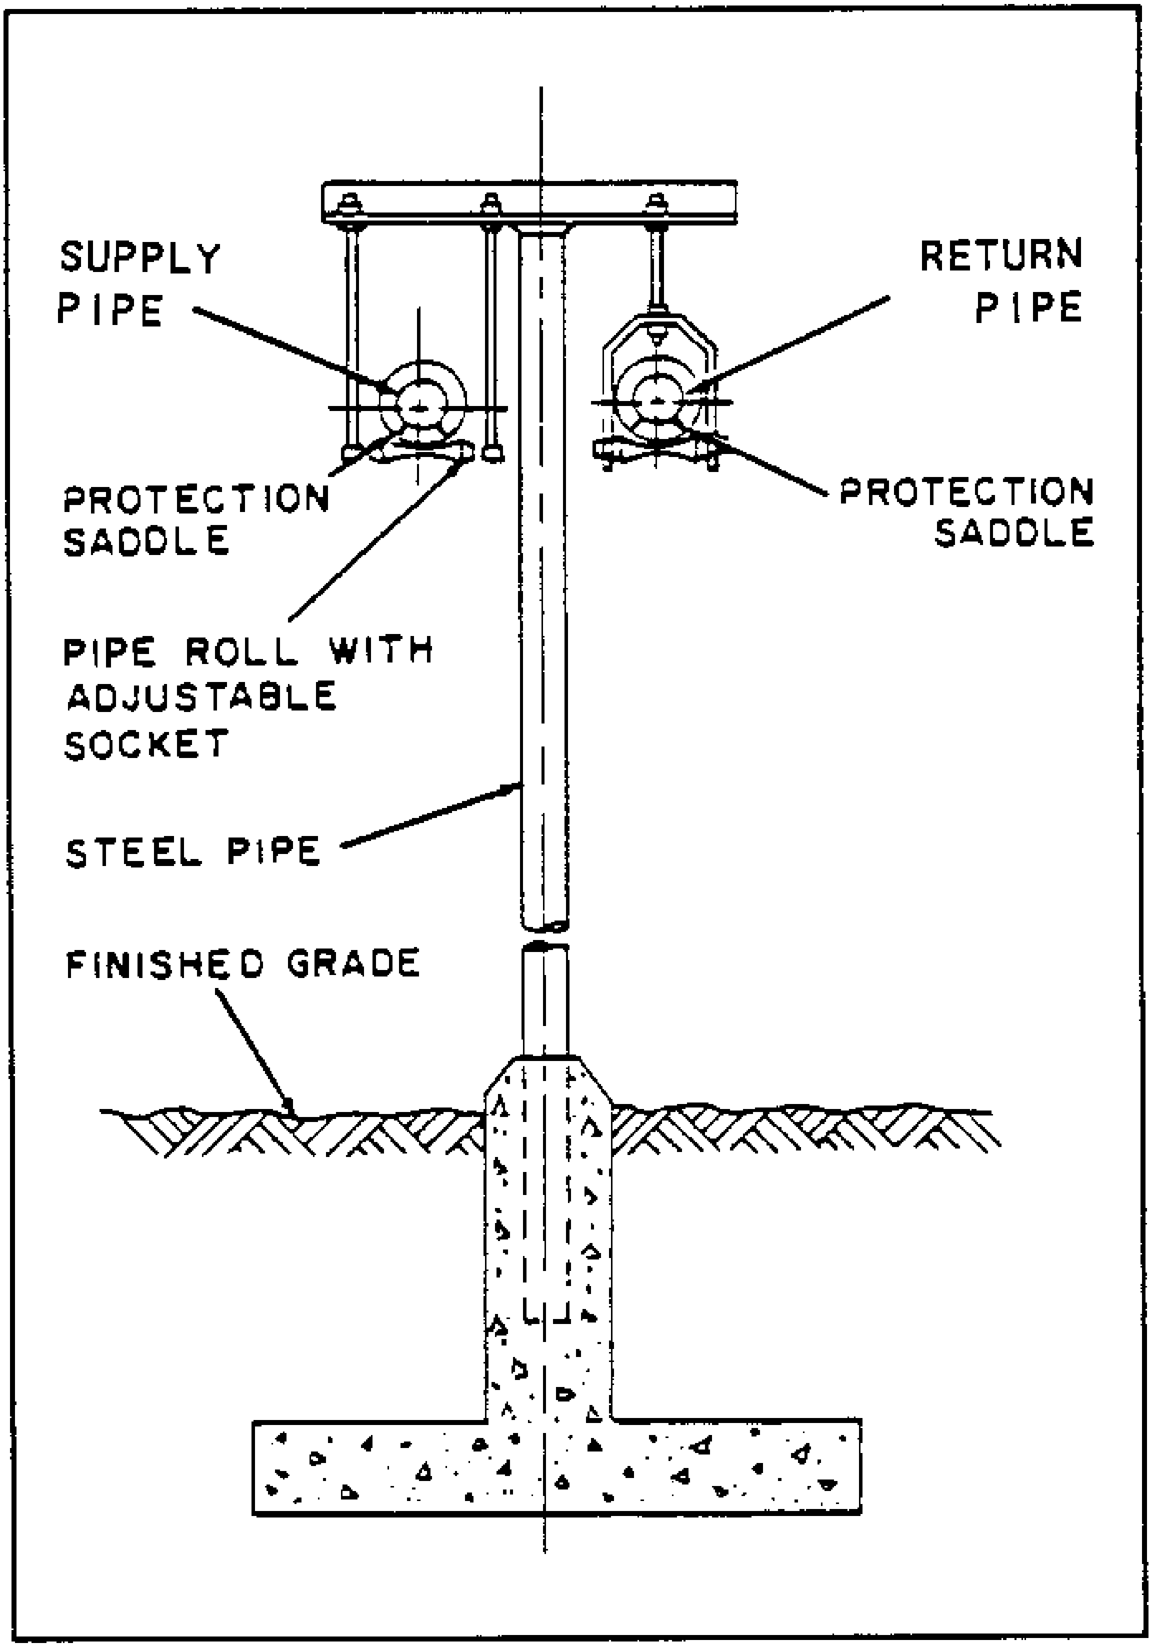


Figure 11
Typical Aboveground Pipe Supports

4.2.9 Finish and Protection. All noninsulated ferrous parts of the piping, piping support system, or equipment will be hot-dipped galvanized or primed with red oxide primer and painted with epoxy paint.

4.3 Concrete Trench Design. The concrete shallow trench will consist of poured concrete sides and floor, with removable tops. Portions of the floor may be omitted at locations outlined previously under course grained soils with water table 2 feet (610 mm) or more below lowest point of water entry.

4.3.1 Depth of Trench. Ensure the depth of the concrete trench is sufficient to provide adequate protection to the piping system and, slope the floor of the trench to provide adequate internal drainage, but in all cases not less than 6 inches (150 mm) from the bottom surface of the suspended pipe insulation to the floor of the trench. Ensure there is a minimum of 3 inches (75 mm) between the surface of the pipe insulation and the adjoining trench walls and a minimum of 4 inches (100 mm) between surfaces of adjacent pipe insulation.

4.3.2 Drainage of Trench. Base the design on sound engineering practices which provide for drainage under all anticipated conditions. Consider the annual rainfall, water table, and other topographic conditions in the basis for the design. For those instances where natural drainage cannot be provided (storm water drainage system at least 2 feet (610 mm) below trench bottom at all times), provide a dual sump pump capability with failure annunciator.

4.3.3 Tops. The tops of the concrete trenches will be removable by use of a portable lifting device such as a forklift or backhoe, and can also be used for sidewalks, if practical. Earth must not cover the tops. Covers will be close tolerance fit with a maximum gap tolerance build up of 0.12 inch from all causes.

4.3.4 Details. Design the Concrete Shallow Trench Heat Distribution System and show on the contract drawings. Use Figures 12 through 23 as appropriate.

Provide the following information on the contract drawings for the concrete Shallow Trench System, as applicable: dimension on all runs of pipe; elevations of the pipe along the systems path; sizes of the pipe; location of all valves; location and details of all expansion loops, Z- and L-bends; location of pipe anchors; how changes in pipe direction are made; thickness of the insulation on the pipe; concrete trench details; final elevations of concrete trench; profile of trench showing all existing utilities; manhole dimensions; manhole cover details; how manhole is drained and vented where required; sump pump piping details; sump pump capacity; condensate pump capacity and details; include specific requirements for modification to existing; steam drip trap locations and capacity; steam pressure reducing valve capacity and details; and other pertinent information and details required to clearly show the intent of the Shallow Trench Heat Distribution System. Also indicate any obstructions in the path of the distribution system that the Contractor may have to work around.

4.3.5 Valve Manholes. Extend valve manholes at least 9 to 12 inches (175 to 305 mm) above finished grade to prevent seasonal runoff from entering except where trench will be a pedestrian walk, in which case the vault cover will be flush with the trench covers.

4.3.6 Inspection Ports. Where required, provide inspection ports at appropriate locations to enable the user to observe drains or expansion at loops or locations requiring frequent (monthly) observation.

4.3.7 Crossings. At all road and railroad type crossings, provide required slab thickness for railroad crossings and H-20 loading for street crossings. Review railroad track removal/replacement with respective authority and coordinate all activities. Road and rail crossing where maintenance of traffic is critical may be accomplished by jacking using an acceptable conduit/tunnel.

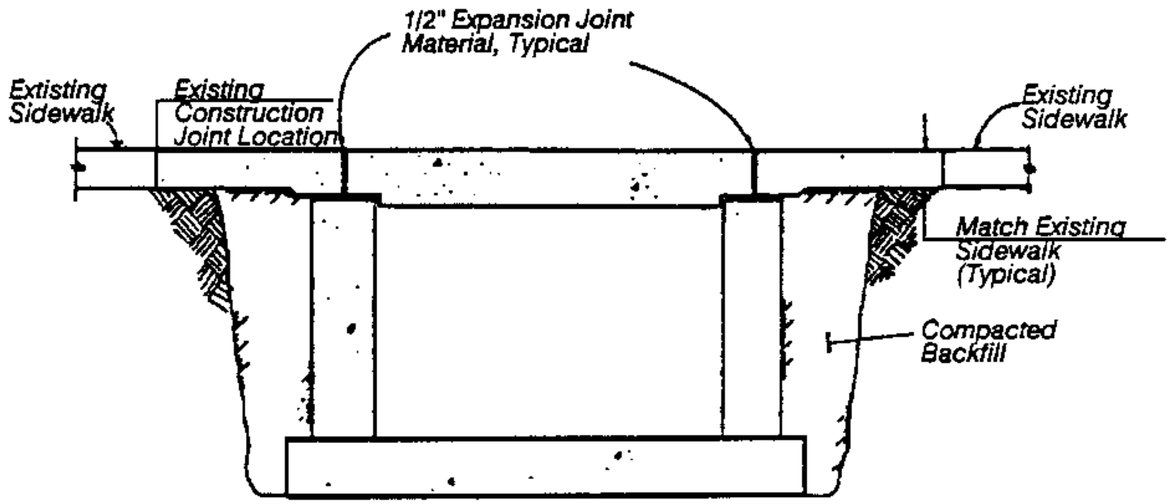
4.3.8 Precast Concrete Shallow Trench Options. In addition to or in combination with a poured-in-place concrete shallow trench system, a precast or prefabricated shallow trench system consisting of precast concrete covers, concrete trench, or supports may be specified. If the designer selects this option, he must include special details and specification requirements of the precast system and the transition between the poured-in-place and precast system.

4.4 Manholes

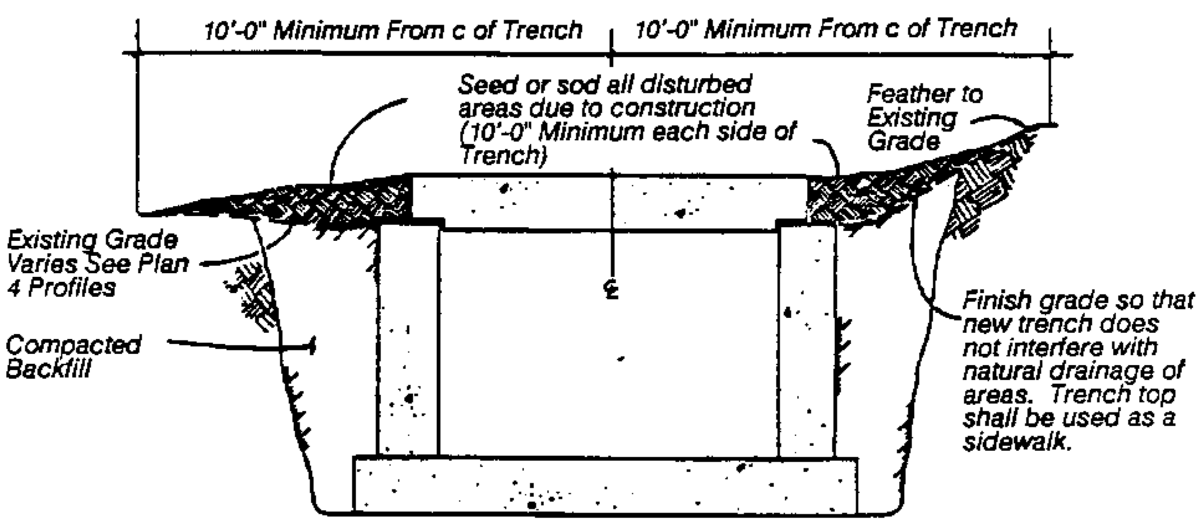
4.4.1 Drainage. Provide sump pumps in manholes. Units should discharge by buried piping to nearest storm sewer if possible. Where not economical to discharge to storm sewer, pumps are to discharge above grade to splashblocks. Plan discharge locations carefully so water will not be placed over tunnel tops, sidewalks, etc. Use sump pumps capable of passing 3/8-inch (12 mm) solid (sphere) minimum. Adjust float switches so the pumps start sequentially, reducing electrical line surge. Coordinate power requirements with electrical designer and provide tell-tale light above ground to indicate that power is available to sump pumps.

4.4.2 Waterproofing. If portions of manholes are installed below the water table, waterproof that portion below the water table.

4.4.3 Pipe Entry. Pipe entry, for buried pre-engineered systems piping, shall be in accordance with Figure 24.



Sidewalk Transverse Cut Detail



Note:
Trench floors must be sloped to provide continuous drainage to sump pumps in manholes. All pockets found in trench floor shall be provided with a floor drain to the nearest manhole sump or the floor shall be sloped to provide gravity drainage.

APPENDIX A

HEAT LOSS CALCULATION DATA

PART 1: EARTH THERMAL CONDUCTIVITY FACTORS

The earth thermal conductivity factors (Ke) in Btu-in/(hr) (sq-ft) (degrees F) to be used in the heat loss calculations are as follows:

	TYPE OF SOIL		
Moisture Content of Soil	Sand	Silt	Clay
Low (less than 4% by weight)	2	1	1
Medium (from 4% to 20% by weight)	13	9	7
High (greater than 20% by weight)	15	15	15

Note: Dry soil is exceedingly rare in most parts of the United States, and a low moisture content should be assumed only if the assumption can be proven valid.

APPENDIX A (continued)

PART 2: ENERGY COST AND MAXIMUM PIPE HEAT LOSS

Maximum heat loss, Btu/hr (ft), for each energy cost (EC) in $/1,000,000 Btu shall be based on the following:

$2. EC and Maximum Pipe Heat Loss, Btu/hr (ft)

Pipe Size	Fluid Temperature (Tf), degrees F							
(Inches)	150	200	250	300	350	400	450	500

APPENDIX A (continued)

PART 3: EARTH TEMPERATURES

The earth tempevatures (Te) to be used in the heat loss calculations are listed below. The list presents the average earth temperature from 0 to 10 feet below the surface for the four seasons of the year and for the whole year for the indicated locale. The temperatures were computed on the basis of the method described in the 1965 ASHRAE technical paper entitled "Earth Temperature and Thermal Diffusivity at Selected Stations in the United States" by T. Kusuda and P. R. Achenback (in ASHRAE Transactions, Volume 71, Part 1, p. 61, 1965) using the monthly average air temperatures published by the U.S. Weather Bureau for the listed localities in the United States. Earth temperatures are expressed in Fahrenheit degrees. AP refers to airport data, CO to city office data, COOP to cooperative weather station data, and OBS to observation station data. When data is not available for exact project location, use nearest location shown in following table.

Location	Winter	Spring	Summer	Autumn	Annual
Alabama					
Anniston AP	55	58	7O	67	63

This UFC supersedes UFC 3-430-11 Boiler Control Systems, dated 02-14-2001.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNITED FACILITIES CRITERIA
REVISION SUMMARY SHEET

Document: UFC 3-430-11, *Boiler Plant Instrumentation and Control Systems*

Superseding: UFC 3-430-11 Boiler Control Systems, 14 February 2001.

Description: This document provides criteria for the design of heating plant instrumentation and control systems for heating and process boiler plants.

Reasons for Document:

- This revision incorporates current industry and technology standards to provide an up-to-date document that will serve as a guide for facility planners/designers.

Impact:

- There are no associated cost impacts.

Unification Issues

There are no unification issues.

TABLE OF CONTENTS

TABLES

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Boiler plant instrumentation and control systems are integral to safe and efficient operation of boiler plants. The Department of Defense adopts American Society of Mechanical Engineers (ASME) and National Fire Protection Association (NFPA) criteria for all boiler applications.

1-2 PURPOSE AND SCOPE.

This Unified Facility Criteria (UFC) provides requirements and guidance for the majority of plants that provide boilers for heating facilities and for process. These boilers are governed by ASME Boiler and Pressure Vessel Code, *Section I, Rules for the Construction of Power Boilers and Section IV, Rules for the Construction of Heating Boilers*. Typically, these are isolated steam plants under 1.0 bar (15 psig), central steam plants over 1.0 bar (15 psig), and isolated and central hot water heating plans.

A heating plant contains one or more boilers. The plant may be an individual boiler serving a single building or a compact group of buildings, or a central plant with several boilers serving many buildings and facilities through an extensive distribution system. The heating plant instrumentation and controls discussed are in general, for a saturated-steam power boiler heating plant. The typical saturated-steam power boiler heating plant discussed will operate at a design steam pressure greater than 1.0 bar (15 psig), with a heating capacity of greater than 422 Megajoule/h (400,000 Btu/h).

Instrumentation is a rapidly changing field. The options available in choosing and designing plant instrumentation are numerous. A boiler plant includes a large number of instrument items, all of which have to be specified in the procurement of a boiler plant. This UFC does not attempt to cover all details. Rather, its purpose is to present general guidelines for selecting and designing instrumentation for boiler plants.

1-3 APPLICABILITY.

This document applies to boiler plant instrumentation and control systems for construction, repair, and maintenance.

The information provided may also be applicable to low, medium, and high temperature hot water heating plants, but does not cover all of the requirements of those plants, such as control of water pressurization and circulation systems. The information may also be applicable to superheated-steam power plants, but does not cover all of the requirements of those plants, such as steam extraction, reheating, steam turbine control, and cooling water controls.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, *Cybersecurity Of Facility-Related Control Systems* and as required by individual Service Implementation Policy.

1-6 GLOSSARY.

APPENDIX A contains acronyms, abbreviations, and terms.

1-7 REFERENCES.

APPENDIX B contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 TYPE OF CONTROLS

2-1 GENERAL.

Control systems may be analog, digital, or a combination of the two. Analog control systems were an industry standard for a short time before quickly being replaced by digital control systems. The present industry standard is for a distributed control system (DCS), a programmable logic controller (PLC), or a direct digital controller (DDC) to provide digital control logic based on information gathered from electronic sensor inputs and responding with electronic control of electric powered valves and dampers. Additional criteria not specific to boiler plants but required for interfacing Facility-Related Control Systems (FRCS) is found in UFC 3-470-01, *Utility Monitoring And Control System (UMCS) Front End And Integration* and UFC 3-410-02, *Direct Digital Control For HVAC And Other Building Control Systems*.

2-2 CONTROL SELECTION.

Choose the type of control that will do the job most economically. This includes total cost over the lifetime of the equipment. Also consider compatibility with controls used in the existing plant, ease of operation and maintenance, and plant personnel familiarity and training. Consider unique situations such as a high EMF (electric magnetic field) where either EMF shielding or fiber optic data transmission are required. Obtaining the latest technology should not be used as the main criteria in the selection of controls.

Use the following as a guideline in selecting the type of control.

- Microprocessor digital type of controls (e.g. PLC, DDC, DCS or combination thereof) should be used for most new designs and in particular where a large number of control loops are involved. Consideration should also be given to using microprocessor digital type controls to replace pneumatic control systems that have exceeded their life expectancy or efficacy.
- Analog logic devices (e.g. electric potentiometer controllers) must not be considered for new designs.
- Consider the environmental conditions (e.g. temperature and humidity) in which the controls will be installed.

2-3 ELECTRICAL CHARACTERISTICS.

2-3.1 Electrical Interface.

The electrical interface between instruments and a digital controller varies depending upon application. Typical analog signal ranges and levels include the following:

- mA direct current (DC) (4-20 mA, 10-50 mA, or 0-100 mA)
- volts DC (0-10 millivolts, 0-100 millivolts, or 0-5 volts)

- temperature (thermocouple in millivolts, or RTD)
- volts alternating current (AC) (120 volts)

Transmitters and control valves commonly use a range of 4-20 mA DC. Switches and solenoid control commonly use a switched level of 120 volts AC. For signal requirements for instrument loops refer to ANSI/ISA-50.00.01, *Compatibility of Analog Signals for Electronic Industrial Process Instruments*.

2-3.2 Communication Data Bus.

Complex boiler control systems may involve multiple digital control systems (e.g. DCS, PLC, or computer controlled smart instruments) linked together by a communication data bus. The communication data bus passes significant data between the digital control systems in a serial format. Refer to UFC 4-010-06, *Cybersecurity of Facility-Related Control Systems* for requirements on incorporating cybersecurity into the design of all FRCS. Only open-protocol standards must be used. Proprietary standards are not permitted per UFC 3-410-02 Direct Digital Control For HVAC And Other Building Control Systems. Typical industry open communication bus standards include:

- DeviceNet: A software protocol that typically uses a Controller Area Network (CAN). DeviceNet is maintained by the Open DeviceNet Vender Association (ODVA) and has been standardized by the International Electrotechnical Commission (IEC).
- Fieldbus: Now technically known as Foundation Fieldbus, is an open hardware and software protocol created by the Fieldbus Foundation, maintained by FieldComm Group and standardized by the International Electrotechnical Commission (IEC) as a part of the Fieldbus family.
- HART: Highway Addressable Remote Transducer protocol is an open hardware and software standard that was originally created and defined by the Rosemount Company, is currently managed by the FieldComm Group, and is standardized by the International Electrotechnical Commission (IEC) as a part of the Fieldbus family. The HART protocol utilizes existing 4-20mA current loop technology by superimposing a low level digital signal on top of the current loop analog signal, which is undetectable by the analog equipment.
- Modbus: An open software protocol that typically uses TIA/EIA-485 and TCP/IP networks. Modbus was originally created and defined by the Modicon Company and is maintained by the Modbus Organization.

2-3.2.2 Communications Between or Among Boilers.

New boiler digital controllers must be of the same manufacturer and product line. Existing boiler plants of different manufacturers with their own proprietary language will need to be translated to a common language through a Gateway or similar device when adding on new boilers.

CHAPTER 3 GENERAL REQUIREMENTS

3-1 GENERAL.

Provide control systems in accordance with applicable codes. Refer to paragraph 3-14 for applicable codes. Design control systems so that the loss of the control medium (e.g. electricity) will leave the controls in a fail-safe position.

3-2 CONTROL LOCATION.

Locate instrument control in the control room as much as practical. Provide local control panels where they are required for equipment start-up.

3-3 TURNDOWN.

Instruments have to cover normal operating as well as upset conditions. Several instruments might have to be provided to cover all of the ranges. It is important that all instruments be reviewed for covering all operating as well as upset conditions during the plant design stage.

3-4 INSTRUMENT RANGES.

Size flow instruments based on a normal operating flow of approximately 70 percent of full scale. For all other instruments set the normal operating point at 50 percent of full scale. Use the following scales:

- Flow: Direct reading
- Pressure: Direct reading
- Temperature: Direct reading
- Level: 0-100% Linear
- Analyzers: Direct reading

Suppressed ranges for temperature and pressure may be used as long as they cover startup and upset conditions.

3-5 ALARMS AND SHUTDOWNS.

Design the plant controls to avoid nuisance shutdowns. These can be caused by excessive complexity, unnecessary items being interlocked into the shutdowns, or lack of provisions in the case of power or instrument air failure. Also design for easy restart in the case of shutdown, especially when caused by non-process type failures such as interruption of power.

3-5.1 Design Criteria.

Use contacts that open on abnormal conditions to alarm or shut down. For all shutdowns provide a pre-alarm that precedes the shutdown. Provide separate devices for alarms and shutdowns. Do not use the same device for an alarm or shutdown as used for control. An electrical power failure must shut off all fuel and require operating personnel attention for a restart.

3-5.2 Testing and Servicing.

Include provisions for the testing and servicing of the shutdown device and related alarms without interfering with plant operation.

3-5.3 Interlock and Safety Requirements.

Safety controls are needed to protect against boiler explosions and implosions. Interlock and other safety requirements for boilers are given in the following American Society of Mechanical Engineers (ASME) and National Fire Protection Association (NFPA) standards.

- ASME CSD-1 Controls and Safety Devices for Automatically Fired Boilers
- NFPA 85 Boiler and Combustion Systems Hazards Code.

3-5.3.2 Safety Interlocks.

Safety interlocks are required but not limited to those listed below.

- Prepurge Interlock – Prevents fuel from being admitted to a furnace until the furnace has been thoroughly air-purged to remove residual combustibles.
- High Steam Pressure Interlock – Fuel is shutoff upon abnormally high boiler steam pressure.
- Low Airflow Interlock – Fuel is shutoff upon loss of airflow from the combustion air fan or blower, the induced draft fan or the forced draft fan.
- Low Fuel Supply Interlock—Fuel is shut off upon loss of fuel supply pressure. The loss of fuel supply pressure would result in unstable flame conditions.
- Loss of Flame Interlock – All fuel is shut off upon loss of flame in the furnace or to an individual burner in the furnace.
- Fan Interlock – Stop forced draft upon loss of induced draft fan.
- Low Water Interlock – Shut off fuel on low water level in boiler drum.
- High Combustibles Interlock (optional) – Shut off fuel on highly combustible content in the flue gases.

- Post Purge Interlock – Continues fan operations to remove residual combustibles from the furnace prior to shutting down the fans.

3-5.3.3 Shutdown Valve Reset.

Safety shutoff valves must be a manual reset type and shall not be operable until all limit controls are in the safe position. Sequence interlocks for start-up and stop must also be provided. Provide annunciator alarms to respond to any safety shutdown.

3-5.3.4 Dedicated Safety System.

The safety shutdown system must be dedicated and independent of the one used for boiler control. For example, if PLC controllers are utilized, the design must contain a PLC for safety shutdown that is separate and independent of the one used for boiler control.

3-5.3.5 Special Considerations.

Special attention should be maintained throughout the boiler design to prevent the following safety hazards.

- Equipment must be designed to protect against electrical shock from exposure to control power.
- Boiler control must assure a sufficient quantity and duration of pre-purge airflow through the boiler prior to ignition to prevent boiler explosions.
- Boiler control must assure a sufficient quantity and duration of post-purge airflow through the boiler during shutdown to prevent boiler explosions.
- Boiler control must assure a sufficient quantity of combustion air and prevent excessive fuel during boiler operation to prevent boiler explosions.
- Boiler control must limit the number of retries when igniting the boiler pilot. The industry standard is to allow three attempts at achieving pilot ignition prior to necessitating a boiler purge cycle.

3-6 HARDWARE.

Hardware standards are defined by NEMA ICS 2, *Industrial Control and Systems Controls, Contactors and Overload Relays Rated 600 Volts.*

3-7 EQUIPMENT RATING AND CLASSIFICATION.

Provide instruments that are rated for the environment. Electrical components must be designed for the anticipated temperature and humidity inside of the enclosure, fungus proofing where required, and vibration. Refer to NEMA ICS 1.1, *Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control* for additional information.

3-7.1 Enclosures.

Enclosures must be certified by the National Electrical Manufacturers Association (NEMA) for the environment where they will be used. NEMA 4 enclosures must be used for outdoor locations. NEMA 4X enclosures must be used in corrosive environments. A space heater is required whenever condensation may occur.

Enclosure ratings are defined by NEMA 250, *Enclosures for Electrical Equipment (1000 Volts Maximum)*, and NEMA ICS 6, *Industrial Control and Systems: Enclosures*.

3-7.2 Hazardous locations

Hazardous locations are defined by NFPA 70, *National Electric Code*. Enclosures must be rated for the location in which they will be installed. Cost savings may be achieved by relocating an enclosure from a hazardous location to a non-hazardous one. A summary of applicability in reference to NFPA hazardous area classifications follows.

3-7.2.1 Class Definition.

Classes I and II are applicable to boiler plants; Class III is not.

3-7.2.2 Division Definition.

Division 1 is usually not applicable to boiler plants except for coal handling and fuel storage areas. Division 2 is often applicable.

3-7.2.3 Group Definition.

Groups A, B, C, E, and G are not applicable to boiler plants. Groups D and F are applicable.

3-7.3 Special Considerations.

When specifying enclosures note the following:

3-7.3.1 Maintenance.

Class I, Group D, Division 2 can be met by either providing an explosion proof enclosure or by providing a non-explosion proof enclosure and purging it with air. The non-explosion proof enclosure is less expensive (initial cost) but requires an air supply and more attention in that a constant air purge must be maintained. This long-term maintenance is expensive. Therefore, to keep maintenance to a minimum, specify the enclosure as explosion proof. Only exceptionally large equipment should be considered for a Class 1, Group D, Division 2 constant air-purge system, where the life cycle cost of the special enclosure will clearly exceed the life cycle cost of maintenance of the air purge and the effort to provide continuous assurance of safe operation.

3-7.3.2 Specification Completeness.

Include all requirements when specifying explosion-proof enclosures. For example, specify the enclosure as Class I, Group D explosion-proof, not just explosion-proof. An explosion proof enclosure is not necessarily dust tight or suited for an outdoor location. Therefore, both the explosion proof requirement and the weather or dust tight requirement must be specified to define the required enclosure.

3-8 POWER SUPPLIES.

Furnish a power supply that provides clean power to the instruments that is free of disturbances and nuisance shutdowns. The manufacturer should be able to provide equipment specifications and recommend safeguards against severe power disturbances. Refer to NEMA ICS 1.1, *Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control* for additional information. Include the following:

- Provide power supplies that enable the controls, including combustion safeguard systems and other control devices, to operate through an electric power interruption of 20 milliseconds without affecting the operation of the plant.
- Provide an uninterruptible power supply (UPS) system to keep the electronic instrumentation on line in case of a power interruption. The required time depends on the plant and instrumentation, but 30 minutes is often specified. The UPS system must provide a safe plant shutdown in case of a longer power outage. Small UPSs located inside of control panels should be equipped with ventilation fans to remove unwanted heat.
- Connect all trip circuits to the UPS system.

UPS system standards are defined by NEMA PE 1, *Uninterruptible Power Systems*.

3-9 WIRING AND CONDUITS.

Wiring must conform to NFPA 70, *National Electric Code*. Run signal, thermocouple, and power wiring in separate conduits. Wiring for alarm, shutdown, and interlock circuits of the same voltage as the power wiring may be run in the same conduit as the power wiring.

Cable and thermocouple wire must conform to NEMA WC57,*Standard for Control, Thermocouple Extension, and Instrumentation Cables*. Provide high point vents and low point drains for all conduits. Recommended practices for control centers are defined by ISA-RP60.8, *Electrical Guide for Control Centers*.

3-10 TUBING AND PIPING.

Do not bring lines containing process fluids such as water and steam into the control room, control panels or control boards.

3-11 IDENTIFICATION.

Identify all instruments and controls with a stainless steel metal tag permanently mounted on the instrument. Include the instrument number and service in the identification.

3-11.1 Nameplates.

Provide nameplates for all panel instruments on both the front and the rear of the panel. Minimum front panel information must include instrument number, service, scale factors, and units. The rear of panel only requires the instrument number. Use recommended practices on panel nameplates as defined by ISA-RP60.6, *Nameplates, Labels and Tags for Control Centers*.

3-11.2 Terminations.

Identify each electrical and tubing terminal with the instrument item number to which it connects. Tag and number all terminals and the ends of all wires. Identify all electrical conduits as to type of wiring (power, thermocouple, DC signals, or other).

3-11.3 Instruments.

Identify all local instruments such as valves and switches with the item number of the instrument with which it operates.

3-12 INSTRUMENT SPECIFICATION FORMS.

Use instrument specification forms when ordering instruments. Forms and specification checklists for a number of instruments are provided in ISA-S20, *Specification Forms for Process Measurement and Control Instruments, Primary Elements and Control Valves*. Obtain complete information on the instrument from the manufacturer before ordering. Sources of information include manufacturer catalogs, data sheets and other literature. Provide all data required for ordering the instrument. Specify all items including optional selections and deviations from the manufacturer’s standard.

3-13 DRAWINGS.

Use standard symbols. For standard symbols, presentation, and terminology refer to the following industry standards.

- ANSI/ISA S5.1, Instrumentation Symbols and Identification
- ISA S5.3, Graphic Symbols for Distributed Control/Shared Display Instrumentation, Logic and Computer Systems
- ISA S5.4, Instrument Loop Diagrams

Provide control schematic diagrams, logic diagrams following UFC 3-410-02 control logic diagram overview which is contained in APPENDIX F, and instrument loop diagrams.

3-14 CODE REQUIREMENTS.

The following codes apply.

- ASME, Boiler and Pressure Vessel Code, Section I, Rules for the Construction of Power Boilers, and Section IV, Rules for the Construction of Heating Boilers
- ASME CSD-1, Controls and Safety Devices for Automatically Fired Boilers
- ASME B16.5, Pipe Flanges and Flanged Fitting
- ASME B31.1, Power Piping
- NFPA-70, National Electric Code
- NFPA 85, Boiler and Combustion Systems Hazards Code

3-15 STANDARDIZATION.

Standardize all instrumentation in the boiler plant. Specify that all like instruments, such as all control valves, be provided from the same manufacturer. Avoid having two control valves in identical service from two different manufacturers or from the same manufacturer but of two different model numbers.

3-15.1 Multiple Manufacturers.

Multiple manufacturers are acceptable for different types of instruments. Instruments of the same type, however, must be standardized. For example, controllers can be obtained from one manufacturer, control valves from a second manufacturer, and pressure gauges from a third manufacturer.

3-15.2 Packaged Equipment.

Packaged equipment, which is often furnished with instrumentation included, does not always lead to standardization. Buying the package manufacturers standard, however, might result in considerable cost savings. Even with packaged equipment, however, the instruments should conform to the open architecture and plant standards whenever practical.

3-15.3 Special Considerations.

Also standardize the following for the boiler plant.

3-15.3.1 Signal Amplitude.

Use standard signals. These are 4-20 mA DC for transmitters and control valves and 120 volts AC for switches.

3-15.3.2 Connections.

Use standard types of connections and connection sizes. Avoid non-standard connections.

3-16 ENVIRONMENTAL CONCERNS.

The Environmental Protection Agency (EPA) regulates the maximum allowed emissions from all external combustion sources including boilers. EPA AP-42, *The Compilation of Air Pollutant Emission Factors* contains information associated with the types and quality of emissions and methods used to control them. Allowable emission limits varies by local and state regulations. Consult the Code of Federal Regulations (CFR), Title 40, *Protection of Environment* for regulated limitations and monitoring requirements.

3-17 SAFETY PLAN AND HAZOP STUDY.

Boiler controls must be included in the Safety Plan and Hazardous Operations (HAZOP) Study submitted by the boiler designer.

CHAPTER 4 PANEL INSTRUMENTS

4-1 GENERAL.

This section covers instruments usually located on panels. Non-panel instruments, such as control valves, are covered in Chapter 5.

4-1.1 Types of Control Panels.

Boiler plant panels include panels for boiler control, combustion safeguards, and the control of special equipment such as electrostatic precipitators.

4-1.2 Panel Location.

Panels may be located either in a control room or locally. Both types of panels are covered in this section and are discussed below.

4-1.2.1 Control Room Panels.

The control room is the preferred location for panels. Locate as much of the plant instrumentation in the control room as practical. The central location of panels will simplify both operation and maintenance. The control room is also usually cleaner, has better temperature and humidity control, and has less vibration than other plant locations. These conditions necessitate less stringent instrument enclosure requirements and the instruments will last longer.

4-1.2.2 Local Panels.

Local panels are located in the vicinity of the equipment that they control. This can be either indoors or outdoors. The atmosphere can vary from clean to dusty or corrosive. Local panels must be minimized since more time and effort is required to access and monitor a large number of local panels than a centrally located one.

Restrict local panels to instrumentation that does not require continuous attention and is used extensively for start-up and shutdown of the local equipment. Locate the panel as close to the equipment as practical. Do not locate local panels in front of any access panels or inspection plates where an operator may interfere with boiler inspections or where an explosion may injure an operator.

Provide a panel designed for the environment. Furnish the panel with a rain hood for outdoor locations. Avoid local wall mounted panels which are mounted flush with the wall. These panels may allow wall condensate to enter. The panel must be a self-supporting box type if it is not mounted integrally with the local equipment.

4-1.3 Layout.

Good panel layout requires experienced personnel in panel design and user drawing review. The layout depends on the type of instrumentation to be placed on the panel and how it will be operated. For best results coordinate instrument panel layout with the end user prior to start of panel fabrication. Once the panel is in fabrication changes are expensive and must be kept to a minimum.

Provide a minimum of 10 percent spare panel space for the future expansion of control room panels. Provide 1.52 to 1.83 meters (5 to 6 feet) access clearance between the panel and the wall behind it when possible. Recommended practices on control room and panel layout are defined by ISA-RP60.2, *Control Center Design Guide and Terminology.*

4-1.4 Construction.

The following applies to both control room and local panels.

4-1.4.1 Electrical Components.

Use solid state logic. Do not use relay logic except where only a few logic steps are involved.

Use items that have a long life and do not have to be frequently replaced. A typical example is the use of LED bulbs instead of incandescent bulbs for indicator lights. The LED bulbs have a longer life.

4-1.4.2 Displays.

Use displays that are readily visible to the operator. This might entail specifying LED instead of LCD, although LCD consumes less power.

4-1.4.3 Lighting.

Provide switched vapor tight light fixtures to illuminate the front of the panel. Provide additional switched lights to illuminate the inside of the panel enclosure.

4-1.4.4 Service Outlets.

Provide ground fault interrupt (GFI) protected 120 VAC duplex outlets within each panel enclosure section. Locate outlets not more than 6 feet apart within each section.

4-1.4.5 Steelwork.

Fabricate enclosure panels from 3.04 millimeter (11 gauge (0.1196-inch)) or 3.18 millimeter (1/8-inch) steel plate, powder-coated where corrosion protection is required. Reinforce the panels as required for stiffness. Use 1.52 millimeter (16 gauge (0.0598-inch)) minimum steel plate for doors. Slightly bevel or round all exposed edges. Larger panels are usually fabricated in 3.05 to 3.66 meter (10 to 12 foot) long sections. Make all joints vertical. Horizontal panel joints are not acceptable. Use angle iron at each end of a section to make up vertical butt joints. Preassemble the complete panel in the shop to check for accurate alignment and surface matching. Panel joints passing through an instrument are not acceptable.

4-1.4.6 Prefabrication.

Construct panels in accordance with UL 508A. Specify panels to be complete with all instruments installed, piped, and wired. The only actions that should be necessary to place the panel in service are to connect power and instrument signals.

4-2 INDIVIDUAL ITEM REQUIREMENTS.

4-2.1 Controllers.

Boilers use two types of controllers. These are digital (e.g. microcontroller based) and analog. Use the following guidelines in selecting the type of controller to be used:

- Use the type of controller that is the most economical and reliable.
- For plants with many control loops use digital type of controllers.
- For the expansion of existing digital or analog electronic controls within a plant use the existing technology. This may be either digital or analog electronic controllers.
- When using digital control avoid depending on a single or a few control devices for the entire plant without having a backup. A redundant controller might not be required if only a single controller controls one loop. However, if a single controller controls a large number of loops then provide redundancy so that if the controller fails another controller will automatically take over.

4-2.1.2 Process Controllers.

Process controllers use one or several of the following control modes:

- On-off
- Proportional
- Integral (also called reset)
- Derivative (also called rate)

Most digital controllers have all of the above control modes included. Integral controllers must include anti-integral windup. Analog controllers often do not include all three control modes or anti-integral windup.

4-2.1.2.2 Control Modes.

In general, use the following control modes for the indicated control loop.

- Flow -- Use proportional plus integral.
- Level -- Use proportional plus integral.

- Pressure and Temperature -- Use proportional plus integral. Use proportional plus integral plus derivative (rate) when the application requires a quick response time.

4-2.1.2.3 Testing.

Recommended practices on tests to be conducted on digital controllers are defined by ISA-RP55.1, *Hardware Testing of Digital Process Computers*.

4-2.1.2.4 Controls.

Provide a separate control station for each control loop when using digital controls. Locate critical controls on the front of the panel. Provide the following minimum controls.

- Automatic/manual selection
- Set point adjustment
- Output signal adjustment when on manual control
- Alarm setting

4-2.1.2.5 Alarms.

Provide the following minimum alarms.

- Controller failure
- High-high alarm
- High alarm
- Low alarm
- Low-low alarm

4-2.1.2.6 Displays.

Provide each control station with the following minimum displays

- Process reading
- Set point
- Output signal
- Input signal
- Automatic/Manual indication
- Controller failure indication
- High-high alarm
- High alarm
- Low alarm

- Low-low alarm

4-2.1.2.7 Features.

Provide the following features as a minimum.

- Proportional, integral and derivative control modes
- Anti-integral windup
- Automatic/manual and manual/automatic bumpless transfer
- Change configuration without shutting down the control loop
- Display configuration data without interfering with the operation of the controller.

4-2.1.2.8 Failure Response.

Provide the following minimum actions on controller failure.

- The controller should switch to manual operation, hold its last output signal, and send out an alarm showing controller failure if a backup controller is not provided.
- The control should automatically switch over to the backup controller and send out an alarm showing controller failure if a backup controller is provided.

4-2.1.2.9 Signal Interface.

Digital controllers do not always have dedicated contacts for alarms and shutdowns. If the contacts are not provided, specify a controller where dedicated contacts for each alarm and shutdown condition can be easily added using hardware obtainable from the controller manufacturer. Provide one set of single pole double throw (SPDT) contacts as a minimum.

4-2.1.3 Programmable Logic Controllers.

Programmable logic controllers (PLCs) are usually programmed in the electrical ladder diagram format. Other formats are also used. When specifying PLCs include the following features.

- Provide a controller that can be programmed in the electrical ladder diagram format when many logic steps are involved.
- Include provisions so that the controller can be programmed and the program read without disturbing its operation.

4-2.1.4 Controller Configuration.

Provide a controller that can be programmed in any of the following ways at the programmer’s option.

- From the front of the controller if a separate controller is provided
- From a manual control station if a separate controller is not provided
- From a configuration device manually
- From a configuration device using stored information from a data storage device

Provide either a non-volatile memory or battery back-up for the controller so that the controller configuration memory is not lost due to a power outage.

4-2.2 Recording.

The preferred method of recording data is on non-volatile data storage. This data can later be viewed on a monitor, printed, or plotted.

4-2.3 Totalizers.

Record the data on non-volatile data storage and use a computer program to add up the totals.

4-2.4 Indicators.

Do not specify a dedicated indicator except for critical items when using digital type control systems. Obtain non-critical information from a control station read out or from a monitor.

4-2.5 Status Lights.

Do not specify a dedicated status light except for critical items. When dedicated status lights are required, use LED lights as much as practical. LED lights have lower power consumption and longer life. Use "Push to Test" indicating/status lights to ensure lights are functioning properly.

Obtain the information from a control station read-out or from a monitor whenever practical instead of using status lights for digital type control systems.

4-2.6 Annunciators.

Annunciator standards are defined by ANSI/ISA-18.1, *Annunciator Sequences and Specifications*. Use common trouble alarms instead of dedicated alarms as much as practical. Provide both visual and audible alarms. Provide a dedicated alarm for critical items.

4-2.6.1 Common Alarms.

Provide a dedicated window to contain the common trouble alarms. When possible, include on this display the specific item within the group that caused the alarm.

4-2.6.2 Dedicated Alarms.

Provide a separate window that includes all dedicated alarms associated with an area. Typical dedicated alarms are summarized in Table 6-2.

4-2.6.3 Annunciator Systems.

Include the following minimum items in an annunciator system.

- Solid-state electronic system with first-out sequence.
- Back-lighted windows.
- Acknowledge, test, and reset pushbuttons. Locate the pushbuttons outside of the annunciator cabinet so that the cabinet door does not have to be opened to depress the pushbuttons. Provide a separate audible signal device and separate pushbuttons for each annunciator system.

4-2.6.4 Alarm Indicators.

- The alarm indication is controlled by the annunciator manufacturer. Typical indications for various fault conditions follow.
- Normal - Light off and audible alarm off
- Abnormal - Light flashing, audible alarm on
- Abnormal First Out - Same as above except flashing pattern is different to distinguish it as a first out.
- Acknowledge - Audible alarm off
- Other than first-out - Light steady
- First-out - Light flashing but pattern is different from prior to acknowledgment
- Return to Normal - Light off and audible alarm off.

4-2.7 Selector Switches.

Provide a minimum of SPDT contacts for selector switches. Clearly label all switch positions. Label unused positions as such. Use back-lighted switches for critical items in areas that are not well lit.

Momentary selector switches may be required to electrically sequence equipment to start on emergency diesel generator power following the loss of normal power. This is necessary so as not to overload the emergency power circuit with equipment that has selector switches maintained in the "Run" mode.

4-2.8 Pushbuttons.

Use SPDT contacts as a minimum. Provide recessed or covered pushbuttons for shutdowns to guard against nuisance trips.

4-2.9 Plant Control Stations.

Plant control stations, like panels, can be located either in a main control room or locally. The main control room is the preferred location. Restrict local plant control stations to equipment that require them for start-up or shutdown. In this case locate the control station as close to the equipment as practical.

A typical control station consists of a computer for processing and storing data, a monitor, a keyboard, and a printer. Each of these items is discussed below.

4-2.9.1 Computers.

Furnish the computer with a power supply that provides power that is free of disturbances. The manufacturer should be able to provide power supply specifications and recommend safeguards against severe power disturbances.

4-2.9.1.1 Control Limits.

Limit the ability of the computer to control the plant to those functions that can be safely controlled from the computer and in compliance with applicable codes. Provide an alarm connected to an annunciator to show computer malfunction.

4-2.9.1.2 Data Overflow Limit.

- Provide computers that are used for logging data with an alarm and pop-up annunciator on the operator screen to show the following.
- Data storage capacity is approaching full.
- Data storage capacity has been exceeded.

Provide sufficient memory to log one year of data in a continuous loop without resulting in an overflow condition. Record data in a continuous format so that old data is over-written by new data. Consult with the end user for sampling frequencies.

4-2.9.1.3 Redundancy.

Provide a means by which to automatically take over the logging of critical data in the event of primary computer malfunction.

4-2.9.2 Monitors.

Provide each workstation with two monitors.

4-2.9.3 Keyboards.

Provide sealed-type keyboards to resist liquid spills. Keyboards can be either a standard type or a non-standard with specialized keys. Standard keyboards must be used as much as practical. Mistakes are more likely to be made using a non-standard keyboard than using a standard keyboard. Keyboard replacement is also more difficult with a non-standard type.

4-2.9.4 Printers and Plotters.

Provide an alarm connected to an annunciator to show printer failure for printers receiving critical on-line data. Also, for critical on-line data, provide a back-up printer to take over if the primary printer malfunctions.

4-2.10 Data Logging.

Provide the following minimum data logging for digital type control systems. Print out this information automatically on a dedicated printer.

- Date, time for all data entries
- Device alarmed or shut down
- Identify first out
- Time alarm acknowledged
- Time for return to normal

Include year, day, hours, minutes, and seconds in the date and time. In first out, show the device to alarm first then the device to first shut down the equipment.

This Page Intentionally Left Blank

CHAPTER 5 LOCAL DEVICES AND INSTRUMENTATION

5-1 GENERAL.

This chapter covers local instruments. Panel instruments are not included. Instruments that are usually located on panels, such as controllers, are covered in chapter 4.

Instruments should be located where they are accessible. Instruments that must be operated during the start-up or shutdown of equipment should be located as close to the equipment as practical. Some instruments must be accessed continuously for operation, others only during startup and shutdown. The designer must consider whether instrumentation may be needed for both normal, continuous operation and startup and shutdown. In such cases, two sets of instrumentation may be required in two different locations. All instruments must be accessible for calibration and maintenance. Locate instruments using the following order of access preference.

- Grade
- Platform
- Stairs
- Ladder
- Portable ladder

5-2 INDIVIDUAL ITEM REQUIREMENTS.

5-2.1 Valves.

This paragraph covers control valves, pressure regulators, and solenoid valves. Each type is discussed below.

5-2.1.1 Control Valves.

Common types of flow characteristics for control valves include quick opening, linear, and equal percentage. Control valves with equal percentage flow characteristics are specified for most applications. Control valves with linear flow characteristics are hard to tune at low flow and should be avoided. Select the flow characteristic to suit the application. Tolerance criteria for control valves are defined by ISA-75.11.01 *Inherent Flow Characteristic and Rangeability of Control Valves*.

5-2.1.1.1 Control Valve Selection.

There are many items to be considered in control valve selection. Checklists are provided in most manufacturer catalogs. Critical items that are sometimes overlooked include type of shutoff, shutoff pressure, line hydrotest pressure and controllability at turndown conditions. Review all pertinent sizing and selection information including accessories when selecting a control valve.

5-2.1.1.2 Construction.

Use carbon steel body with stainless steel trim. Other materials may be specified when required by unique conditions.

5-2.1.1.3 Sizing.

Size control valves to absorb 30 to 50 percent of the total system pressure drop.

5-2.1.1.4 Maintenance

Provide manual block and bypass valves around control valves to allow for control valve removal and servicing while the system is operational.

5-2.1.1.5 Location.

Locate control valves at grade where practical. Install the control valve near the operating equipment that has to be observed while in local manual control.

5-2.1.2 Pressure Regulators.

Use self-actuated regulators only where the operating pressure is below 10.3 bar (150 psig) and where variations from the control point are acceptable. Use pilot-operated pressure regulators where the operating pressure is equal to or above 10.3 bar (150 psig), or where minimal variations from the control setpoint are required.

5-2.1.3 Solenoid Valves.

Common uses for solenoid valves in a boiler plant include the routing of steam to pilot valves.

Verify solenoid valve sizing to ensure that the valve will open or close within the specified amount of time. Port size might have to be increased to ensure the proper actuation time.

Verify that the proper solenoid valve is used for the intended service. An example of a critical service application is a pilot gas shutoff solenoid valve. Most manufacturer catalogs include checklists on items to be specified. Critical items sometimes overlooked include type of fluid, shutoff and opening pressures, and line test pressure.

5-2.2 Actuators.

Use spring-loaded diaphragm type actuators where practical. Springless operators are acceptable only when spring-loaded type actuators cannot provide the desired performance.

Select the actuator so that the valve or damper that it controls will fail safe. Fail safe is defined as lock in position or take a position (either open or closed) that will result in the least upset.

Furnish positioners for all automatically operated dampers. Furnish positioners for all control valves in critical service and where the variable, such as flow, has to be closely controlled. Specify that the positioner be furnished with the control valve or damper instead of separate procurement.

5-2.3 Dampers.

Dampers can be operated either manually or by means of an actuator. This paragraph covers only actuator-operated dampers. Manually operated dampers are not included in this document.

Specify temperature, pressure, pressure drop, type of shutoff, materials, damper bearings, linkages, damper bearing and linkage lubrication, and other applicable data when selecting dampers.

Provide a hand wheel or lever so that the damper can be manually operated in case of damper actuator failure.

5-2.4 Pressure Relief Valves.

Provide pressure relief valves in accordance with the applicable codes. Refer to paragraph 3-14 for applicable codes.

5-2.5 Rupture Disks.

Use reverse buckling type rupture disks at the inlet of the relief valve in corrosive services.

5-2.6 Level Instruments.

Provide level instruments in accordance with applicable codes. In general, provide separate vessel connections for each level instrument. Provide 13 millimeter (½ -inch) minimum vent and drain valves with plugs for all level instruments.

5-2.6.1 Gauge Glasses.

Complete coverage of total liquid range is not always required. Consult the applicable codes for requirements. Also consider all operating conditions and upsets. Provide gauge glasses to cover and overlap a minimum of 5 centimeters (2 inches) beyond the ranges of displacers and switches.

Gauge glasses should only cover the critical range zone such as high, low, and normal levels when the range is also covered by differential pressure type level transmitters.

Provide illuminators for transparent gauge glasses.

5-2.6.2 Displacer.

Displacer type level instruments can be used for level ranges up to 1.5 meters (60 inches) of fluid height. Avoid use of internal displacers except for open tanks and sumps. Provide carbon steel body material with stainless steel trim as a minimum.

5-2.6.3 Differential Pressure.

Use differential pressure type level instruments instead of displacer type level instruments for ranges over 1.5 meters (60 inches) of fluid height. They may also be used for ranges under 1.5 meters (60 inches).

5-2.6.4 Capacitance Level.

Avoid the use of capacitance type level instruments in boiler plants.

5-2.7 Flow Instruments.

The most commonly used flow element in boiler plants is the orifice plate. There are numerous other flow measuring devices that can be used depending on the application. In alphabetical order these include annubar flowmeters, coriolis type mass flowmeters, elbow meters, flow nozzles, magnetic flowmeters, pitot tubes, pitot-venturi tubes, positive displacement meters, rotameters, target meters, thermal-loss meters (also known as heat-loss meters), turbine meters, ultrasonic flowmeters, venturi tubes, vortex flowmeters, and wedge elements.

Use an orifice plate for most flow measurement applications unless a different type of flow element, such as a flow nozzle or a pitot tube, offers specific advantages. Reasons for using flow elements other than orifice plates include higher accuracy, shorter meter run, lower pressure drop and large line size.

5-2.7.1 Meter Runs.

Flow disturbances as much as 100 pipe diameters upstream of the flow measuring element can affect the accuracy of the flow measurement. Meter run requirements, including pressure tap locations, depend on a number of items. These include type of flow element, beta ratio, and flow disturbances upstream and downstream of the flow element. Flow disturbances result from valves, elbows, enlargers, reducers, and other pipe fittings.

5-2.7.1.1 Requirements.

Obtain complete meter run requirements from the flow measuring device manufacturer to insure accurate measurements. This includes pressure tap locations and other details such as pressure tap size.

5-2.7.1.2 Fabrication.

Do not fabricate meter runs in the field. Fabricate them in a shop qualified in that type of work. Include in the shop fabricated meter run at least 10 pipe diameters of upstream piping and 5 pipe diameters of downstream piping. Straight runs of piping required in addition to the above can be fabricated in the field.

5-2.7.2 Orifice Plates.

Orifice plate types include concentric and eccentric, square edge, quadrant edge, segmental and annular. In general, use concentric, square-edge orifice plates except for the following.

- Use quadrant edge for orifice plates with a Reynolds number of less than 10,000 (based on pipe diameter).
- Do not use concentric orifice plates for horizontal runs flowing wet steam or gas, liquids containing solids, or liquids containing gas or vapor. All of the above will result in inaccurate measurements.
- Solids in the liquid can settle out upstream of the orifice plate. As a first solution use a concentric, square-edge orifice plate but locate it in a vertical run with flow in the downward direction. If locating the orifice plate in a horizontal run cannot be avoided then use a segmental or eccentric orifice plate.
- Use a concentric, square-edge orifice plate located in a vertical run with flow in the upward direction for liquids containing gas or vapor. Use a segmental or eccentric orifice plate with the opening at the top if locating the orifice plate in a horizontal run cannot be avoided.

5-2.7.2.2 Design.

Orifice plates must be a minimum diameter of 5 centimeters (2 inches). Do not use an orifice bore diameter of less than 13 millimeters (½ -inch) due to the possibility of plugging. Do not locate orifices where a liquid is subject to flashing.

Select the orifice plate maximum design flow and meter differential to give a scale reading of approximately 70 percent at normal flow. Use a meter differential of 2.5 meters (100 inches) of water unless not practical.

The orifice plate beta ratio must be between 0.25 and 0.70 and preferably between 0.4 and 0.6. The beta ratio must never be less than 0.20. Do not exceed a beta ratio of 0.70 for gases or steam and 0.75 for liquids.

5-2.7.2.3 Mounting.

Mount the transmitter near the orifice flanges. Use flange taps whenever practical. Specify orifice flange and taps in accordance with ASME B16.36, *Orifice Flanges*. Flange taps are well suited for pipe sizes of 5 centimeters (2 inches) and larger. Provide meter taps at the top of the flange for gas service in horizontal lines. Provide meter taps on the sides of the flange for steam, vapor and liquid service in horizontal lines. Mount the meter below the orifice taps for liquid and steam service and above the orifice taps for gas service. Provide a separate three-valve type manifold for each meter. Provide condensate traps for both the high and low pressure sensing lines for steam and condensate service lines.

5-2.7.2.4 Construction.

Use 304SS material as a minimum for the orifice plate. Provide an identification tab projecting beyond the orifice flange. Show the following minimum information on the tab.

- Actual measured orifice bore
- Pipe inside diameter
- Orifice plate material
- Orifice plate orientation to flow
- Type of fluid

5-2.7.3 Positive Displacement Meters.

Furnish a removable strainer installed upstream of the displacement meter.

5-2.7.4 Turbine Meters.

Refer to ISA-RP31.1, *Specification, Installation, and Calibration of Turbine Flowmeters* for additional information on turbine meters.

5-2.8 Temperature Measurements.

Temperature instruments include thermocouples, resistance-temperature detectors (RTDs), filled bulb systems, and bimetallic thermometers.

5-2.8.1 Thermowells.

Thermowells are used to protect the temperature element from the environment and for personnel protection. Thermowell design varies depending on the application. Items affecting design include temperature, pressure, type of fluid and fluid velocity. In general, thermowells can be classified into two types. These are pressure service and non-pressure service. Thermowells used in non-pressure service are commonly referred to as protective tubes.

Provide thermowells for all temperature elements in pressure service. Use 304 SS material as a minimum. Use the material best suited for the application of protective tubes.

5-2.8.2 Thermocouples.

In general, use the following thermocouples for the different temperature ranges:

- Type T, Copper constantan -- Below –17.8 to 371 degrees C (0 to 700 degrees F)

- Type J, Iron constantan ---17.78 to 593 degrees C (0 to1,100 degrees F)
- Type K, Chromel alumel -- 315 to 1093 degrees C (600 to 2,000 degrees F)

Thermocouple assemblies can be single (one thermocouple) or duplex (two thermocouples). Provide duplex thermocouples for all temperature control loops. Use one thermocouple for control and the other for indication. Thermocouple and thermocouple extension wire specifications are defined in NEMA WC 57, *Standard for Control, Thermocouple Extension, and Instrumentation Cables*.

5-2.8.3 Resistance-Temperature Detectors.

Resistance-temperature detectors (RTDs) are used where accurate temperature or temperature difference measurements are required.

5-2.8.4 Filled Bulb Systems.

Filled bulb systems are used for local temperature indicators and controllers in services where the fluid temperature is below 427 degrees C (800 degrees F). Mercury filled bulb systems are not allowed. Provide armored capillary tubing for all filled bulb systems. Limit capillary length to 15 meters (50 feet) maximum. In all cases provide a thermowell where the filled bulb system is used in pressure service.

5-2.8.5 Bimetallic Thermometers.

Bimetallic thermometers are mostly dial type thermometers used for local temperature indication. In all cases provide a thermowell where the bimetallic thermometer is used in pressure service.

5-2.9 Pressure Measurements.

Pressure instruments include gauges, switches, and transmitters. In general pressure gauges use bourdon tubes to measure pressure greater than 1.0 bar (15 psig), and bellows to measure pressure less than 1.0 bar (15 psig) or differential pressure. Transmitters and switches use diaphragms to measure pressure. Use pulsation dampeners where required.

5-2.9.1 Gauges.

Provide blowout discs for pressure gauges in services with pressures greater than 1.0 bar (15 psig). Provide a safety wall between the dial and the bourdon for service pressures above 68.9 bar (1000 psig). Provide pigtail siphons for all gauges in steam service. Pigtail siphons should be installed perpendicular to the gauge. Provide pulsation dampers and diaphragm seals where required by service conditions and for all gauges in steam and condensate service. Provide a gauge isolation valve for each gauge.

Pressure gauges are usually direct connected and field mounted. The size and range is specified by the user. Locate local gauges so that they are visible from the operating area and are readable from grade or a platform. Local mounted gauges give a “backup” reading and also help operators in determining if equipment or pressure systems are working satisfactorily. Pressure gauges should conform to ASME B40.100, *Pressure Gauges and Gauge Attachments*.

5-2.9.2 Switches.

Pressure switches are used for monitoring alarm conditions and providing safety shutdowns. They are typically mounted directly to the process pipe.

5-2.9.3 Transmitters.

Pressure transmitters convert the measured pressure to an analog or digital signal that is monitored by the control system (e.g. PLC). Provide a three-valve manifold to accomplish block, drain, and test functions for all pressure transmitters. Provide a five-valve manifold to accomplish block, equalize, drain, and test functions for all differential-pressure transmitters. Refer to paragraph 5-2.10 for additional transmitter requirements.

5-2.9.4 Draft.

Pressure instruments for the measurement of draft in furnaces require careful attention as to range and sizing. Note that the draft in a balanced draft boiler furnace is slightly negative, around -2.54 millimeter (-0.1 inch) WC, at the top of the furnace. Too wide an instrument range will result in the loss of accuracy. Too narrow a range will not cover all operating conditions.

Verify that the connections and sensing lines are adequately sized for the low negative pressures. Use larger sizes than for lines sensing positive and high pressures.

5-2.10 Electronic Transmitters.

Electronic transmitters are used to transmit an electronic signal from a local measuring device to a remotely located device such as a panel mounted controller. Typical transmitters include flow, level, pressure and flue gas oxygen. A typical electronic signal is 4-20 mA DC.

Use stainless steel material for all transmitter components in contact with the stream. Provide local indicators for all electronic transmitters. Locate the local indicator at the transmitter for non-controlling loops such as a signal to an indicator. Locate the local indicator at the controlling device for controlling loops such as diaphragm-operated valves. Provide an integrally mounted junction box with a metal cover and a terminal block for blind electronic transmitters to allow for the connection of a plug-in ammeter.

Electronic transmitters with internal microprocessors are known as “smart transmitters”. These transmitters provide on-board sensor linearization, data correction coefficients, measurement ranging, system diagnostics, and instrument configuration. These transmitters communicate to the control system via a communication bus (e.g. HART or Fieldbus).

5-2.11 Electrical Instrument Switches.

Typical applications for electrical instrument switches are alarms and shutdowns. Contacts must open to alarm or shut down for fail safe operation. Provide switches that are suited for the environment. Provide switches that are dust tight and vibration proof for all locations. Provide NEMA 4 rated switches for outdoor locations with non-corrosive atmospheres and NEMA 4X rated switches for corrosive atmospheres. Provide SPDT contacts as a minimum.

5-2.12 Analyzers.

Include all analyzers necessary to meet federal, state, and local environmental monitoring requirements. Analyzers used in a boiler plant include the following:

- In-line
- Sample diverted from the stream to the analyzer and then returned to the stream
- Sample diverted from the stream to the analyzer and then discharged to the atmosphere or a drain.

5-2.12.1 General Guidelines.

Use in-line analyzers where practical. As a second choice use an analyzer where the sample is diverted to the analyzer and then returned to the stream. Use an analyzer where the sample is discharged to the atmosphere or drain as a last choice. Provide a relatively constant differential pressure device, such as a pump, as a bypass to divert a sample that is to be returned to the stream. Do not bypass around a control valve.

5-2.12.1.1 Calibration.

Where practical use a self-calibrating analyzer that provides zero and full span in the range in which the analyzer will be operating. Provide automatic calibration at power-up, at manual command, and at preprogrammed intervals.

5-2.12.1.2 Application.

When to use analyzers and what type of analyzer to use depends upon environmental and value engineering concerns for a given boiler size. These issues are discussed in paragraph 6-4. Analyzers should be used for trim or alarms. Avoid using analyzers as a sole means of control or shutdown.

5-2.12.1.3 Packaging.

It is possible to obtain multiple analyzers packaged in one system. For example, flue gas analyzers are available that combine oxygen, combustibles and methane measurement in one package. This packaging concept would reduce installation complexity and may provide cost savings.

When practical obtain the analyzer from the manufacturer completely packaged in a housing, wired, piped and with the sample system installed. Specify the analyzer to be free standing unless it is mounted on the equipment.

5-2.12.2 Oxygen Analyzer.

Oxygen analyzers in a boiler plant are used for oxygen measurement to provide an indication of excess air in the flue gas. Use the analyzer for alarms and trim. Do not use it as the sole instrument for the control of combustion air.

Probe location is not critical for forced draft type or pressurized boilers since leakage is flue gas out of the boiler. Probe location is critical, however, for balanced draft boilers (which have induced draft fans), since leakage is typically tramp air into the boiler from flue ductwork. Locate the oxygen probe so as to keep the effect of tramp air on the oxygen reading at a minimum. This usually entails locating the probe as close to the furnace as practical.

5-2.12.3 Combustibles Analyzer.

Combustibles analyzers in a boiler plant are used for carbon monoxide measurement, hydrogen measurement or both to provide an indication of incomplete combustion in the flue gas. Use the analyzer for alarms and trim. Do not use it as the sole instrument for the control of combustion air.

5-2.12.3.1 Carbon Monoxide Analyzer.

Carbon monoxide (CO) analyzers used in a boiler plant may utilize a catalytic element, wet electrochemical cell, or non-dispersive infrared absorption.

Install the CO analyzer in a clean gas stream that is downstream of the particulate removal system.

A CO analyzer permits firing at lower oxygen levels than without it. A minimum air requirement is established by decreasing oxygen in the stack gas until a large increase in the CO reading occurs. A CO analyzer is also useful in boiler start-up. During start-up monitor the CO analyzer closely for unsafe firing conditions. High CO readings indicate incomplete combustion, which implies potentially unsafe conditions in the furnace.

5-2.12.3.2 Hydrogen Analyzer.

Hydrogen (H_2) analyzers used in a boiler plant are on line monitors that employ a catalytic element.

Like the CO analyzer, a H_2 analyzer permits firing at lower oxygen levels than without it. A minimum air requirement is established by decreasing oxygen in the stack gas until a large increase in the H_2 reading occurs. A H_2 analyzer is also useful in boiler start-up. During start-up monitor the H_2 analyzer closely for unsafe firing conditions. High H_2 readings indicate incomplete combustion, which implies potentially unsafe conditions in the furnace.

5-2.12.4 Stack Opacity Analyzer.

Stack opacity analyzers are used in a boiler plant to monitor particulate emissions. Their main use is in coal and heavy oil fired boilers. Stack opacity monitors are generally not required for gas fired boilers; however, state and federal regulations should be consulted. Also, most large boilers are dual fuel which may be a combination of gas and oil.

5-2.12.5 Conductivity Analyzer.

Conductivity analyzers are used in boiler plants to monitor dissolved solids in the boiler drum. Use a conductivity analyzer for adjusting boiler blowdown. Do not use it as the sole device for boiler blowdown control.

5-2.12.6 Methane Analyzer.

Methane analyzers in a boiler plant are used for methane measurement to provide an indication of a completed purge cycle prior to boiler ignition or during boiler shutdown. Note that this analyzer must be used in conjunction with and not as a substitute for the minimum purge time requirements stated in the applicable codes.

5-2.13 Flame Detectors.

Provide the flame detector best suited for the fuel and flame. For gas fired boilers always use an ultraviolet (UV) self-checking flame scanner.

Do not use a flame detector that is activated by hot refractory.

Provide a separate flame detector for each burner. Locate the flame detector so that it will be activated only by its own burner and not by an adjacent burner or hot refractory.

5-2.14 Continuous Emission Monitoring (CEM).

Provide all necessary equipment to meet federal, state, and local environmental analysis and documentation requirements.

CHAPTER 6 RECOMMENDED BOILER INSTRUMENTATION

6-1 BOILER CONTROL PANEL INDICATORS AND TOTALIZERS.

The instrumentation in Table 6-1 represents the minimum recommended requirements for a boiler plant. This instrumentation selection is based primarily on boiler operation safety concerns. Refer to NFPA 85 *Boilers and Combustion Systems Hazards Code* for further instrumentation concerns for boiler plants in the 13.18 gigajoule/h (12,500,000 Btu/h) or above range and ASME CSD-1, *Controls and Safety Devices for Automatically Fired Boilers* for boiler plants below 13.18 gigajoule/h (12,500,000 Btu/h). The indicators can be either dedicated or shared devices. Totalizers must be dedicated devices. Shared device selection may be either by means of pushbuttons, a selector switch, or by entering commands on a keyboard. Provide the following in the display of information associated with a shared device:

- Name of process variable
- Instrument number
- Units
- Process variable value

Store the process data in a storage device such as a computer disk or non-volatile memory. Label the data storage as to process variable, instrument number, date, time, and units. The time label must include hours, minutes, and seconds. Store the data so that it can be retrieved selectively. In selective retrieval as a minimum include the name of process variable, instrument number, date and desired time interval. Include maximum and minimum points and alarms with the data to be recorded. Provide a dedicated printer or printer/plotter on which the recorded and totalized data can be presented on paper on demand. Data storage, retrieval, and printing must meet federal, state, and local environmental documentation requirements.

6-2 BOILER CONTROL PANEL ALARMS AND SHUTDOWNS.

The alarms and shutdowns in Table 6-2 represents the minimum recommended requirements for a boiler plant. These were selected based primarily on boiler operation safety concerns. Refer to NFPA 85 *Boiler and Combustion Systems Hazards Code* for further information for boiler plants in the 13.18 gigajoule/h (12,500,000 Btu/h) or above range and ASME CSD-1, *Controls and Safety Devices for Automatically Fired Boilers* for boiler plants below 13.18 gigajoule/h (12,500,000 Btu/h). Provide a separate window in an annunciator system for each dedicated alarm. Provide a dedicated common trouble alarm window to which the non-dedicated alarms are wired. Include a first-out listing to show which device connected to the common trouble alarm tripped first. Provide instrumentation to show which device shut the equipment down first during a system shutdown. Refer also to paragraphs 3-5 and 4-2.6.

6-3 BOILER CONTROL PANEL CONTROLLERS.

Provide controllers as required for the proper operation of the boiler plant. Controllers required for a typical boiler plant include steam header pressure (plant master and boiler master), boiler drum water level (feedwater flow), fuel flow, and combustion air flow and boiler furnace draft.

6-4 VALUE ENGINEERING.

There are many cost tradeoffs associated with the design of a boiler. The use of an oxygen trim system is one example. The installation of an oxygen trim system in a boiler design will provide fuel savings. The analyzer that provides this function, however, is costly to buy and maintain. Therefore, oxygen trim systems should only be used on large boilers where the cost of fuel savings outweighs the cost of the analyzer.

CHAPTER 7 CONTROL SCHEMES

7-1 GENERAL.

Provide controls in accordance with applicable codes. Refer to paragraph 3-14 for applicable codes. The codes take precedence over the control requirements shown in this UFC.

7-2 CONTROL LOOPS.

A control loop consists of all components necessary to control a process variable to maintain its setpoint. Typical process variables for boilers are pressure, temperature, flow, and liquid level.

Control loops have three main components which are a sensor(s), a controller, and a final control element. The sensor is made up of a sensing element and transmitter. The controller monitors the sensor transmissions and transmits a control signal based on the sensor values and setpoint. The final control element receives the control signal and modulates a process value.

7-2.1 Pressure.

Pressure control loops may be used for the control of boiler drum pressure or fuel oil pressure. For the control of boiler pressure, the final control element regulates fuel flow to the boiler in response to boiler steam pressure. For the control of fuel oil pressure, the final control element is usually a pressure reducing control valve that regulates in response to downstream pressure. A typical pressure control loop is shown in Figure 7-1.

7-2.2 Temperature.

Temperature control loops may be used for the control of steam temperature from boilers or fuel oil temperature from fuel oil heaters. A typical temperature control loop is shown in Figure 7-2.

7-2.3 Liquid Level.

Liquid level control loops may be used for the control of boiler drum water level. A typical liquid level control loop is shown in Figure 7-3.

7-2.4 Flow.

Flow control loops may be used for the control of fuel flow into the boiler burners, burner draft airflow, feed water into a boiler, or steam flow out of a boiler. A typical flow control loop is shown in Figure 7-4.

7-3 AIR TO FUEL RATIO.

Furnish controls to automatically provide the proper fuel to air ratio over the entire boiler operating range from maximum turndown to Maximum Continuous Rating (MCR). Provide cross-limited (lead-lag) controls between air and fuel to increase airflow before increasing fuel flow and to decrease fuel flow before decreasing airflow.

7-3.1 Control Type.

Consider full metering controls, which measure directly both airflow and fuel flow, for all boilers with capacities greater than 5.28 gigajoule/h (5,000,000 Btu/h). Consider an oxygen analyzer, for trim only, for all boilers with capacities greater than 25.3 gigajoule/h (24,000,000 Btu/h). Consider CO trim for all boilers with capacities greater than 52.8 gigajoule/h (50,000,000 Btu/h), especially coal fired boilers. Evaluate the energy savings of these measures and provide all those that are life cycle cost effective per UFC 3-401-01, Mechanical Engineering. A typical cross-limited (lead-lag) boiler control system with oxygen trim for a single fuel is shown in Figure 7-5.

7-3.2 Control Configuration.

Configure the controls so that the air to fuel ratio does not have to be manually reset or reprogrammed when switching from one fuel to another or from one combination of fuels to another. Provide an 8-point minimum fuel to air characterization curve for each fuel or combination of fuels. Provide controls so that the air to fuel ratio is automatically adjusted to the proper proportions for all of the following:

- Load change (between minimum firing and MCR)
- Fuel change (either change in fuels or same fuel but different specifications)
- Fuel ratio change (more than one fuel firing)

7-3.3 Fuel Changeover.

Accomplish the switch over from one fuel to another without shutting down the boiler. Configure the controls so that the changeover from one fuel to another can be made by either a selector switch, pushbuttons, or by entering commands on a keyboard.

7-3.4 Simultaneous Fuel Firing.

Provide automatic controls for maintaining the proper fuel ratio and fuel to air ratio to compensate for load changes when firing several fuels at the same time. Do not allow multiple attempts to switch fuels without a full post-purge and pre-purge after each unsuccessful fuel switch attempt.

7-3.5 Alarms.

Furnish alarms to announce the approach of unsafe conditions. Provide shutdowns to shut the equipment down under unsafe conditions.

7-4 BOILER DRUM LEVEL.

Provide controls to always maintain the boiler drum level within the boiler manufacturer's specifications under all operating conditions. Two typical types of control systems used in boiler plants are single element control and three element control based. Two element control based systems are available but are not permitted. Two element control is not needed for steady loads and they are not adequate enough for most variable loads.

7-4.1 Single Element Control.

A single element control system, Figure 7-6, utilizes just a level transmitter to maintain control of the boiler drum water level. Use a single element control system only for boilers operating at steady loads.

7-4.2 Two Element Control (Not Permitted).

Two Element Control is not permitted. A two element control system, Figure 7-7, utilizes a level transmitter and the amount of steam flow from the boiler to maintain control of the boiler drum water level. A two element control system provides some compensation for variable loads. It does not adequately correct for the expansion of water within a boiler due to the decreased boiler pressure that occurs when a large amount of steam is required or the contraction of heated water in a boiler due to the addition of cold feedwater.

7-4.3 Three Element Control.

A three element control system, Figure 7-8, utilizes a level transmitter, the amount of steam flow from the boiler and the amount of water into the boiler to maintain control of the boiler drum water level. Note that although not shown, the steam flow from the boiler is usually compensated for pressure and temperature. A three element control system corrects the problems associated with a two element control system and provides the best method of compensating for variable loads.

7-5 MULTIPLE BOILERS.

The output of multiple boilers is accomplished by routing the steam from each individual boiler into a common plant output header. The pressure measured at this plant output header will be fed back into each individual boiler control loop. Control is maintained by the plant master cascading the output of the boiler masters to achieve the desired steam output. A typical multiple boiler control loop is shown in Figure 7-9. Dual Pressure Indicating Transmitters (PIT) are shown feeding their output signals into a High Signal Selector. This redundancy may be provided for plants with three or more boilers to allow continued plant operations during maintenance or failure of one PIT.

A-2 DEFINITION OF TERMS

Bumpless Transfer: A transfer from Automatic Mode to Manual Mode or from Manual mode to Automatic Mode that does not interrupt the control loop and controlled process.

Heating Boiler: A boiler rated in accordance with ASME BPVC, Section IV. This is typically a steam boiler for operation at pressures not exceeding 1.0 bar (15 psig) or a hot water boiler for operation at pressures and temperatures, not exceeding 11.0 bar (160 psig) and 120°C (250°F), respectively.

Non-Volatile Data Storage: Storage that does not require power to retain data.

Power Boiler: A boiler rated in accordance with ASME BPVC, Section I. This is typically a steam boiler for operation at pressures exceeding 1.0 bar (15 psig) or a hot water boiler for operation at pressures and/or temperatures, exceeding 11.0 bar (160 psig) and 120°C (250°F), respectively.

Change No.	**Date**	**Location**

This UFC supersedes UFC 3-440-01, dated 14 June 2002 and UFC 3-440-04N, dated 16 January 2004.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

(Energy, Installations and Environment)

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 3-440-01, *Facility-Scale Renewable Energy Systems*

Superseding: UFC 3-440-01, *Active Solar Preheat Systems* and UFC 3-440-04N, *Solar Heating of Buildings and Domestic Hot Water*

Description: This new UFC 3-440-01 consolidates into one Tri-Service document the renewable energy criteria applicable to solar thermal energy that was in the superseded documents, and new solar photovoltaic electrical energy generation. This UFC applies to facility-scale renewable energy systems and is not intended for utility-scale energy generation.

Reasons for Document:

- To provide unified Department of Defense renewable energy power generation criteria and create more consistency in DoD designs.

Impact:

This uniform effort will result in the more effective use of DoD funds in the following ways:

- Standardized guidance of facility-scaled renewable energy power production planning, design, construction, and operations and maintenance among the Services.
- The consolidation of the UFC 3-440-01 will positively impact the project costs incurred, as a result of the following direct benefits:
    - Reduction in ambiguity and the need for interpretation reduces the potential for design and construction conflicts.
    - The reduction in the number of documents and the use of industry standards improves the ease of updating the revising this reference document as better information becomes available.

Unification Issues:

The Air Force does not allow paralleling facility-level renewable energy systems with any standby power regardless of whether it is for emergency, Critical Operations Power Systems (COPS), or other purposes.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE

This UFC is issued to provide guidance for designing and installing facility-scale renewable energy systems. The criteria contained herein are intended to ensure durable, efficient, and reliable systems and installations. Guidelines apply to facility-scale applications. A facility-scale project has the interconnection point at the facility's service entrance equipment and generally provides electricity for the facility. A utility-scale project has the interconnection point directly to the utility distribution grid. Facility-scale projects are typically less than 1 megawatt, and utility-scale projects are usually greater than 1 megawatt. For renewable energy systems designed to generate power on a utility-scale, and privately-financed projects, see UFC 3-540-08 (Draft).

Future revisions of this UFC will address additional renewable energy system technologies and components that can be applied on a facility-scale level, such as geothermal energy, wind energy, and on-site energy storage (batteries). Whenever unique conditions and problems are not specifically covered by this UFC, use the applicable referenced industry standards and other documents for design guidance.

Note that this document does not constitute a detailed technical design, maintenance or operations manual, and is issued as a general guide to the considerations associated with design of economical, efficient and environmentally acceptable facility-scale renewable energy systems.

1-2 ORGANIZATION

This UFC is comprised of three sections. Chapter 1 provides an introduction and a general reference to other documents closely related to the subject. Chapter 2 provides general criteria for the design of solar thermal systems. Chapter 3 provides general criteria for the design of solar photovoltaic power generation systems.

1-3 APPLICABLITY

This UFC applies to all planning, design and construction, renovation, repair, maintenance and operation, and equipment installation in new and existing facilities and installations, regardless of funding source that result in DoD real property assets. The designs developed in this document are targeted for new construction, although most are also appropriate for renovation applications.

1-4 GENERAL BUILDING REQUIREMENTS

Comply with UFC 1-200-01, *General Building Requirements*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

Comply with UFC 3-560-01, *Electrical Safety, O&M*, for electrical safety requirements applicable to the installation and operation of electrical systems.

1-5 LIFE-CYCLE COST ANALYSIS (LCCA)

Provide a Life Cycle Cost Analysis in accordance with UFC 1-200-02, paragraph entitled " LIFE CYCLE COST ANALYSIS (LCCA)".

1-6 AIRSPACE COORDINATION

Comply with UFC 3-260-01 when evaluating renewable power generation systems and equipment to be sited near an airfield or related facilities and equipment used to sustain flight operations. Submit plans to site renewable power generation systems and equipment near an airfield to the airfield manager and safety officer (among other stakeholders) for approval.

1-6.1 Military Training Route and DoD Siting Clearinghouse

The Military Training Route (MTR) program is a joint venture by the Federal Aviation Administration (FAA) and the DoD to develop routes for the purpose of conducting low-altitude, high-speed testing and training activities. Improper site planning can negatively affect the MTR program. Contact the DoD Siting Clearinghouse (http://www.acq.osd.mil/dodsc/) during initial planning, and prior to applying for permits on any federal or non-federal lands, for project site vetting. Provide applicable data items required for the DoD Siting coordination.

1-6.2 FAA Requirements

FAA requires early planning coordination for structures and assessment of glare from solar panels. For structure assessment, complete FAA Form 7460. Glare assessments are covered under FAA interim policy, FAA Review of Solar Energy System Projects on Federally Obligated Airports. This interim policy requires use of the Solar Glare Hazard Analysis Tool (SGHAT). Provide both FAA Form 7460 and SGHAT report to the DoD Siting Clearinghouse.

1-7 CYBERSECURITY

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with DoD Instruction 8500.01, DoD Instruction 8510.01, and as required by individual Service Implementation Policy.

1-8 REFERENCES

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-9 BEST PRACTICES

Appendix B contains background information and best practices for accomplishing certain renewable energy design and engineering services.

1-10 GLOSSARY

Appendix C contains acronyms, abbreviations, and terms.

1-11 ADDITIONAL RESOURCES

For additional resources on renewable energy applications and systems, refer to the Whole Building Design Guide (WBDG) Internet site: http://www.wbdg.org/resources/.

This Page Intentionally Left Blank

CHAPTER 2 SOLAR THERMAL TECHNICAL REQUIREMENTS

2-1 GENERAL REQUIREMENTS

2-1.1 Economic Feasibility Study

As required in UFC 1-200-02, Section 523 of the Energy Independence and Security Act (EISA) 2007 requires that at least 30% of the domestic hot water demand for each new federal building (or major renovations to existing federal buildings) be met through the use of solar water heating, if life cycle cost-effective.

Perform a life-cycle cost analysis for all new military construction to determine whether the use of renewable forms of energy will result in a net monetary savings to the government. The methodologies and parameters required for Federal energy project feasibility studies are mandated by Federal law (10 CFR 436). Provide a solar thermal energy system when life-cycle cost effective.

2-1.2 Screening Procedures

Perform the initial evaluation for solar hot water system viability. Generate a final report containing at least the solar hot water system size, system cost, annual energy savings, annual cost savings, savings-to-investment ratio (SIR), simple payback, solar fraction, and annual greenhouse gas reduction. See Appendix B for recommended tools.

2-1.3 Detailed Analysis and Study

If the results of the screening procedure indicate that a solar hot water system is a viable consideration, then perform a detailed life-cycle cost analysis (LCCA) to determine the most effective design alternative to develop. Perform LCCA calculations and reports. See Appendix B for recommended tools. Budget constraints, maintenance capabilities of customer, system complexities, and other factors in addition to the LCCA influence the final selected system design.

2-1.4 System Applications

2-1.4.1 Domestic Hot Water

For domestic hot water systems (DHW) without combined space heating, provide lined, insulated, pressurized tanks similar to the conventional water heater. Provide appropriate temperature and pressure relief valves. Provide a tempering or mixing valve. To size the collectors and storage tank it is necessary to estimate or measure the hot water consumption of the facility or building. See Appendix B for recommended estimating tools.

2-1.4.2 Hydronic Space Heating Combined with Domestic Hot Water

Size the collectors and storage tank to provide the greater loads of space heating plus domestic hot water. A heat delivery system is added to the domestic hot water system. Provide an auxiliary heating source to supply heat when the solar system cannot supply sufficient heat. Provide corrosion and freeze protection through the use of a closed collector loop and heat exchanger.

2-1.5 Solar Thermal Basis of Design

At a preliminary design stage equivalent to 35% design, the designer of record must provide a basis of design which covers the general facility design requirements in accordance with UFC 1-200-01 and its referenced documents. In addition to the UFC 3-401-01 requirements for preliminary basis of design and follow-on submittals, provide the following general system specific analysis information:

- Narrative
  - FY Year, Project Number, and project location.
  - Briefly state scope, project description, references, and calculation method used.
  - Geographic and operating environment, including coastal locations/corrosive conditions, humidity, altitude, seismic zones, and ambient temperature extremes.
  - Type of solar energy system (domestic hot water, space heating).
- Life Cycle Cost Effectiveness
  - Life Cycle Cost Analysis results.
  - Solar energy system design cost (study and design costs itemized).
  - Average annual energy savings and fuel used.
  - Fuel costs provided in the study.
  - Percent energy contribution from solar energy system.
  - Savings to investment ratios (SIR).
  - Estimate of solar energy system installed costs [exclusive of supervision, inspection and overhead (SIOH) and contingency].
  - Initial year O&M costs and requirements.
- Design Feasibility
  - Schematic of system layout.
  - Structural design considerations (roof mounting discussion, life span of roof, structural adequacy).
  - Type and area of collectors.
  - Description of freeze and high temperatures and pressure protection.

- o Description of control sequence.
- o Description of operating sequence.
  - Startup procedures.
  - Shut off procedures.
  - Normal positions of valves, controls.
  - Typical temperatures at key locations.
- o Calculations used: input data, analysis, method used.

2-2 SYSTEM SELECTION

2-2.1 Standard System Types

2-2.1.1 Closed-Loop (Indirect) System

Closed-loop circulation systems circulate a heat transfer fluid through the solar collectors and implement a heat exchanger to heat potable water. While the closed loop solar energy system can provide reliable service in any climate, take certain design precautions:

- Closed-loop circulation systems must be pressurized. Drainback systems are prohibited.
- Provide a check valve in the collector loop to prevent reverse thermosiphoning. Locate check valves so that the fluid in the collector loop can be drained if necessary.
- Use non-ferrous piping and components. Size the expansion tank and pressure relief valves to prevent loss of solution and opening of the collector loop in the event of high pressure stagnation. See Expansion Tank Paragraph for expansion tank design. Provide for the collection and recovery of freeze protection solution in the event of pressure relief.
- Do not use the cold-water leg between the mixing valve and the cold water supply to the solar storage tank for connection to any other fixture.

2-2.1.2 Open-Loop (Direct) Circulation System

Direct circulation systems circulate potable water through the solar collectors and do not implement a separate heat exchanger. Direct circulation systems must be active. Drain-down systems are prohibited. Limit use of direct circulation systems to locations where there are no freezing days, and where the water supply is of sufficiently high quality, between 0-0.015 oz/gallon (0-120 mg/L) calcium carbonate. Obtain water supply quality information from the local water authority. Where the water supply is of poor quality, it is necessary to treat the incoming water supply so that it is within quality limits using a mechanical water softener, water conditioner, or ion-exchange device.

2-2.1.3 Thermosiphon and Integral Storage Collector Systems

Mount the bottom of the thermosiphon system tank approximately 2 feet (0.6 meters) higher than the highest point of the collector. Test integral storage collector (ISC) units as whole systems and using the method given in ASHRAE Standard 95. Only install ISC systems in areas where temperatures rarely fall below freezing. The results of system tests on these models are reported in the Directory of SRCC Ratings: http://www.solar-rating.org.

2-2.2 Mount Types

2-2.2.1 Roof Mounting

Comply with UFC 3-301-01 for requirements related to wind and seismic loads on rooftop solar thermal arrays. Use rooftop mounting systems of the same manufacturer for the entire project array.

2-2.2.2 Ground Mounting

Comply with UFC 3-301-01 for requirements related to the foundation, soil stability, and seismic analysis. Use ground mounting systems of the same manufacturer for the entire project array. The system must withstand the expected wind loads for the location. Complete an environmental impact assessment for the site. Foundation must be either concrete, concrete pad ballast, driven pile, or helical pile.

2-2.3 Collector Types

Solar thermal system collectors are either flat plate or evacuated tube. Use flat plate collectors in ASHRAE Climate Zones 1-3. Use evacuated tube collectors in ASHRAE Climate Zones 4 and above or within zones 1-3 when water heating above 140 degrees F (60 degrees C) is required.

2-2.3.1 Flat Plate Selective Surfaces

Use Collector surface of highly selective black absorber coating, which absorbs the high frequency incoming solar radiation and emits low frequency infrared radiation poorly, with a minimum absorptivity of 0.85.

2-2.3.2 Flat Plate Collector Insulation

Use Collector insulation that is not flammable, has a low thermal expansion coefficient, will not melt or outgas at collector stagnation temperatures 300 degrees F – 400 degrees F (149 degrees C – 204 degrees C), and contains reflective foil to reflect thermal radiation back to the absorber.

2-2.3.3 Flat Plate Collector Housings

Construct housing of powder-coated aluminum. Do not use wood as a structural member, spacer, or anchor for panels due to its susceptibility to deterioration and flammability. Provide adequate room for expansion of the internal manifold and absorber plate assembly within the collector housing.

2-2.3.4 Evacuated Tubes

The evacuated tube collector's individual tubes must be easily replaceable, and made of low emissivity borosilicate glass with a highly selective coating.

2-2.3.5 Collector Gaskets & Sealants

Provide gaskets and seals that:

- Withstand significant expansion and contraction without destruction.
- Adhere effectively to all surfaces.
- Resist ultraviolet degradation.
- Resist outdoor weathering.
- Do not harden or become brittle.
- Withstand temperature cycling from -30 degrees F to 400 degrees F (-34 degrees C to 204 degrees C).
- Do not outgas at high temperatures.

2-2.3.6 Fill Ports and Drains

Provide fill ports and drains that are tamper-resistant.

2-2.4 Fluid Types

Provide heat transfer fluid that is nonionic, high dielectric, nonreactive, noncorrosive, and stable with temperature and time. If system design requirement mandates the use of toxic fluid, receive approval from the installation. The closed-cup flashpoint must be provided by the heat transfer fluid manufacturer and determined using the methods described in NFPA 30. To reduce the risk of fire, the closed-cup flashpoint of the liquid heat transfer fluid must equal or exceed the highest temperature determined from below:

- A temperature of 50 degrees F (28 degrees C) above the design maximum flow temperature of the fluid in the solar system; or
- A temperature of 50 degrees F (28 degrees C) above the maximum no-flow temperature to be reached by the fluid in the collector.
- 100 degrees F (56 degrees C) greater than the maximum expected collector temperature.

To minimize the probability of contamination of potable water systems, address the following items:

- Use tags, color coding, and different pipe connections to preclude the possibility of cross connection of potable water piping with heat transfer fluid piping is required. Use of double-wall separation is required.
- Hydrostatic testing of system to find leaks.
- Color indicators in heat transfer fluid to find leaks.
- Safe designs for heat exchangers.
- Determine toxicity classification of heat transfer fluids.

2-2.4.2 Hydrocarbon Oils

Hydrocarbon oil must have a closed-cup flashpoint 100 degrees F (38 degrees C) higher than maximum expected collector temperature. Provide synthetic hydrocarbon oils.

2-2.4.3 Glycol/Water Mixture

Mixtures must be either a 50/50 or 60/40 glycol-to-water ratio. Circulate glycol/water liquids in a closed loop with a double wall heat exchanger between the collector loop and the storage tank. Maintain the pH between 6.5 and 8.0. Replacement of the glycol/water solution may be as often as every 12-24 months or even sooner in high temperature systems. The glycol manufacturer specifies the expected life of the solution and the amount of monitoring required. Consider the cost of periodic fluid replacement and monitoring in the economic analysis.

2-3 SYSTEM DESIGN

For potable water systems, all components must meet potable water requirements of UFC 3-420-01.

2-3.1 Checklist

2-3.1.1 Schematic

Appendix D provides a checklist of items to consider as part of system planning and design.

2-3.1.2 Component Connections

Provide isolation valves on all major system components, such as the collector banks, storage tank, heat exchanger, and circulation pumps, for removal, cleaning, repair, or replacement.

2-3.1.3 Roof Penetrations

Design roof penetrations for the array supply and return piping and sensor wiring conduit to prevent leaking and to account for movement due to thermal expansion.

2-3.2 Collector Sub-System

2-3.2.1 Array Tilt Angle

For annual loads, tilt collectors to the value of the local latitude. To accommodate for seasonal load variation, tilt the array to the latitude minus an offset up to 10 degrees (to favor summer energy output) or to the latitude plus an offset up to 10 degrees (to favor winter energy output). It should be noted that as the tilt angle increases, the minimum spacing between rows due to shading must be increased due to shading, requiring a larger area.

Anticipate any future structures or vegetation (trees) that could block future solar access, and generally keep the collectors out of the shade between 9 a.m. and 3 p.m., when the bulk of the energy collection occurs.

2-3.2.2 Array Azimuth Angle

Consider the orientation of a collector (i.e. the direction the collector faces). For optimum performance, orient the collector true south, however slightly west of south (azimuth angle of true south plus 10 degrees) may be preferable in some locations if an early morning haze or fog is a regular occurrence. Design the array’s azimuth angle within plus or minus 20 degrees from due south.

2-3.2.3 Pressure Drop

2-3.2.3.1 The 30 Percent Rule

To ensure uniform flow through the piped collector bank array, the ratio of a manifold's pressure drop to its riser pressure drop should be designed to be around 10 percent, and under no circumstances exceed 30 percent (for a pressure drop ratio of 30 percent, the flow in any riser should not deviate from the average riser flow rate by more than plus or minus 5 percent).

2-3.2.3.2 Pressure Drop Across Banks and Rows

Determine the pressure drop across a bank of collectors in order to calculate the pipe sizes necessary to achieve balanced flow in the array. Once the array layout is determined and assuming that the pressure drop across each collector unit at the recommended flow rate is known, the pressure drop associated with each branch extending from a manifold can be determined.

2-3.2.4 Collector Grouping

Group internal-manifold collectors into banks ranging from four to seven collectors, with each bank containing the same number of collectors to maintain uniform flow throughout the array and minimize thermal expansion.

2-3.2.5 Minimum Array Row Spacing

Calculate the minimum row spacing for multi-row arrays. Base north-south spacing of collector banks on no shading of the array on the “worst” solar day of the year (21

December, when the sun is lowest in the sky in the northern hemisphere) for the designated time period of 10 a.m. to 2 p.m. solar time.

2-3.2.5.1 Roof Pitch

If the roof pitch does not allow flush mounting of the collectors, or if the tilt angle must be fixed, coordinate the array design with the roof pitch so that the collectors are raised at one end to give a tilt per paragraph entitled “Array Azimuth Angle.”

2-3.2.5.2 Array Layout

Determine the array layout keeping the piping length minimized while geometric symmetry is maintained, so that banks contain as many collectors as possible, and the array layout is rectangular in area with an even number of banks installed in multiple rows.

2-3.2.5.3 Array Support Structure

Meet all code requirements and coordinate design with, or review by, a licensed professional structural engineer. Design stepped arrays with elevated walkways for maintenance personnel. Coordinate with roof design and coordinate with support structure manufacturer to identify materials options. Use galvanic barrier when design uses incompatible metals. Comply with UFC 3-575-01 for utilizing lightning protection requirements.

2-3.2.5.4 Lightning Protection Requirements

Comply with UFC 3-501-01 for requirements related to providing a lightning risk assessment.

If lightning protection is a design requirement, provide UL listed lightning arrestor and comply with UFC 3-575-01 for requirements related to providing a lightning protection system. Provide side flash calculations as required by NFPA 780.

2-3.2.6 Collector Selection

Provide a collector with a minimum Clear C of 0.98 kBtu/(ft^2·day) (11 MJ/(m^2·day)) as reported by the Solar Rating and Certification Corporation (SRCC): http://www.solar-rating.org/. To validate that the array size and layout is a viable option, information required by the designer and to be submitted by the manufacturer on the shop drawings includes the net aperture area; ranges of overall dimensions of length or height and width; the manufacturer's recommended collector flow rates and the pressure drop across the collector at that flow rate; the internal manifold tube diameter; and the collector weight when filled. Note on the drawings the number of collectors per bank and whether the manufacturer recommends a maximum number of collectors per bank less than seven.

2-3.2.7 Collector Sub-System Piping

2-3.2.7.1 Manifolds

Each collector must have internal manifolds. External manifolds are not permitted.

2-3.2.7.2 Flow Balancing

Design the array plumbing for passive flow balancing, so that uniform flow will occur as naturally as possible in the array. Provide flow control balancing valves on the outlet of each bank to adjust for any flow imbalances after construction.

2-3.2.7.3 Reverse-Return Piping Layout – Diagonal Attachment Rule

The reverse-return strategy of providing approximately equal length flow paths for supply and return pipes attached to the array at any two opposite diagonal corners of the array must be used for all projects.

2-3.2.7.4 Reverse-Return Piping Design

Use the corner closest to the pipe roof penetrations as the return point since this will result in the shortest pipe length for the heated fluid. If the pipe roof penetrations are near the centerline of a multiple row, multiple column array with an even number of columns, save pipe length by feeding the array on the outside and returning the heated fluid from the center of the array.

2-3.2.7.5 Stepped Collector Rows

Although a true reverse-return design is not possible for stepped collector rows, use the same diagonal attachment strategy and the pipe length for each elevation must be accounted for in the pressure drop/pump sizing calculation.

2-3.2.7.6 Array Layout and Piping Schematic

Note the array layout and piping schematic in the construction drawings to pipe the array exactly as that shown to ensure flow balance.

2-3.2.8 Pipe Sizing

Flow throughout the array must be in balance at the proper flow rates, while maintaining a maximum velocity limit of 5 ft/s (1.5 m/s).

2-3.2.9 Volumetric Flow Rates

Use the manufacturer's recommended collector flow rate and the piping schematic to determine the design flow rates throughout the collector sub-system. The total array flow rate is determined by multiplying the collector flow rate by the actual number of collectors. Bank flow rates and row or other branch flow rates are determined by multiplying the collector flow rate by the number of collectors per bank or per row.

2-3.2.10 Pressure Drop Models and the Fluid Velocity Constraints

The design operating temperature of the collector loop inlet (return, entering the collector) should be between 60 and 90 degrees F (15 and 32 degrees C), with the 60 degrees F (15 degrees C) value preferred because it is the lowest temperature (thus highest viscosity and pressure drop) that steady-state operation could be expected. If a higher temperature is to be used, the designer should apply the standard temperature corrections for water before correcting for the use of propylene glycol.

2-3.2.11 Collector Sub-System Plumbing Details

The collector banks must be able to be valved off for maintenance, repair, or replacement. Use ball valves for collector bank isolation. Manually operated, calibrated balancing valves must be located at the outlet to each collector bank to adjust for any flow imbalances present after construction. Drain valves must be located at all low points in the collector sub-system to allow the collectors to be drained if necessary. Pressure relief valves must be located on each collector bank. Manual air vents must be located at the high points of the collector loop to allow air to escape during the filling process. The differential expansion between the system flow paths and the system and the support structure must be considered in the design.

2-3.2.12 Thermal Expansion

When long pipe runs are required, ensure that the resulting expansion or contraction will not harm system components or cause undue stress on the system or the building. Provide pipe anchors, supports, guides, and expansion loops to allow freedom of movement in the direction of motion.

2-3.3 Storage Sub-System

2-3.3.1 Supplementary Heat

Supplementary heat sources are required and shall supply 100% of the system required loads. Operate the auxiliary heater automatically as needed, use the most economical fuel, and share a common heat delivery system with the solar system.

2-3.3.2 Location

Design the equipment room to house the solar storage tank, pumps, heat exchangers, controls, and all system components except the solar collectors.

2-3.3.3 Legionella or Legionnaire's Disease

For domestic use, heat the water in the storage tank to a minimum of 140 degrees F (60 degrees C) in order to avoid any potential source of Legionnaire's disease. For additional information on Legionnaire's disease refer to: http://www.wbdg.org/pdfs/legionella.pdf.

2-3.3.4 Tank Support and Floor Loads

Provide reinforced concrete pads and footings to ensure that the weight of the tank does not endanger the structural integrity of the building. The design load calculation must take into account the estimated weight of the empty tank, the water to be stored in the tank, the insulation, and the tank support structure.

2-3.3.5 Storage Tank Construction

Insulate solar storage tanks to a minimum value of R-30. The storage tank must be equipped with a minimum of four pipe connections, two located near the top of the tank and two located near the bottom. To take advantage of storage tank stratification, pipes supplying the collector array and the cold-water inlet must be connected to the bottom penetrations, and the pipes returning to the tank from the collector array and hot water supplied to the load must be connected to the penetrations near the top. Instrumentation openings will be required as well as openings for relief valves, and drains. Since copper is to be used for all system plumbing, a dielectric coupling must be included in the design of any necessary penetrations of the storage tank**.**

2-3.3.6 Storage Tank Sizing

Specify the solar storage tank based on the sizing criteria that the volume is between 1.5 to 2 gals per square foot (61 to 82 L per square meter) of total array collector area.

2-3.3.7 Storage Sub-System Flow Rate

To ensure that the storage loop can accept the energy available, the thermal capacity on the storage side of the heat exchanger (the product of the mass flow rate and constant pressure specific heat) must be greater than or equal to the thermal capacity on the collector side of the heat exchanger. The storage sub-system volumetric flow rate must be at least 0.9 times that of the total array volumetric flow rate.

2-3.4 Heat Exchanger

2-3.4.1 Sizing

Size the heat exchanger to a minimum effectiveness of 0.5.

2-3.4.2 Specification

The heat exchanger area and pressure drop must be indicated on the drawings and provided by the designer. All materials used in the heat exchanger must be compatible with the fluids used.

2-3.5 Piping

Design piping for low pressure drop. All exposed piping must be well-insulated with approved weather-resistant insulation. Use dielectric unions at connections between dissimilar metals. Provide thermal expansion for all piping.

2-3.5.1 Materials

Piping materials must be copper or steel. Only tin-antimony (Sn-Sb) solders are allowed (Sb5, Sn94, Sn95, and Sn96). Lead solders are forbidden in any part of the potable water system.

2-3.5.2 Insulation

Coordinate insulation requirements with specification UFGS 23 07 00. Insulation must withstand temperatures up to 400 degrees F (204 degrees C) within 1.5 ft. (457 mm) of the collector absorber surface, and 250 degrees F (121 degrees C) at all other locations. Insulation exposed to the outside environment must be weatherproof and protected against ultraviolet degradation. A minimum of R-4 insulation must be specified on all piping.

2-3.6 Expansion Tank

2-3.6.1 Location

Locate the expansion tank in the equipment room or existing mechanical room on the suction side of the pump.

2-3.6.2 Determination of Acceptance Volume

Size the expansion tank to account for the displacement of all the fluid contained in the collector array that is subject to vaporization. During stagnation conditions, only the volume of fluid located in the collector array and associated piping above the lowest point of the collectors is subject to vaporization. The required acceptance volume is determined by adding the total volume of all collectors plus the volume of any piping at or above the elevation of the collector inlets.

2-3.6.3 Determination of Design Pressures

The air-side of closed expansion tanks must be precharged by the manufacturer. This initial or precharged pressure (P_i) must be determined, along with the collector loop fill pressure (P_f) and the maximum relief pressure allowed in the system (P_r). The maximum pressure in the collector loop should be 125 psi (862 kPa). The system-fill pressure should result in a +10 to +15 psi (+69 to +103 kPa) pressure at the highest point of the system. The expansion tank precharge pressure should be equal to the fill pressure at the expansion tank inlet, minus 5 to 10 psi (35 to 69 kPa). This initial condition allows fluid to be contained within the expansion tank at the time of filling and will provide positive pressure in the event of the system operating at temperatures below that occurring when the system is filled.

2-3.6.4 Sizing and Specification

The designer must specify operating modes and freeze/over-temperature protection methods.

2-3.7 Fittings

Valves, other than seasonal or emergency shut-off valves, should be electrically operated and located out of the weather or well-protected. A vent must be provided at the high point in liquid systems to eliminate entrapped air and it should also serve as a vacuum breaker to allow draining of the system. To avoid multiple venting, systems should be piped to avoid having more than one high point. Pressure relief must be provided in each flow circuit. Add check valves to prevent thermally induced gravity circulation. A flow-check valve (used in the hydronic heating industry) will also accomplish the same purpose. Mixing valves should be used to protect DHW systems from delivering water hotter than specified [usually 120–140 degrees F (49–60 degrees C)].

2-3.7.1 Isolation Valves

Use gate valves only in locations where only on/off operation is required. Ball valves must be used at locations where partial flow may be required, such as on the outlet side of the collector banks. These valves are manually operated and must have a key or special tool to prevent unauthorized tampering. Isolation valve locations must ensure that system pressure relief cannot be valved off accidentally. Globe-type valves must not be used.

2-3.7.2 Thumb Valves

Thumb valves also function as on/off valves and only for smaller sized tubing [1/4 inch (6 mm) or less], used to manually open pressure gauges or flow indicators to local flow and are not meant for constant use.

2-3.7.3 Drain Valves

Drain valves are required at all system low points. Specifically, these locations include the low points of the collector banks, the bottom of the storage tank, and two at the bottom of the collector loop between the expansion tank and the pump. The latter two drain valves are used for filling and draining and must be separated by a gate valve.

2-3.7.4 Check Valves

Locate a spring-type check valve in the system between the pump and the collector array, on the supply side.

2-3.7.5 Pressure Relief Valves

A pressure relief valve is required in any line containing a heat source that can be isolated (such as a collector row) and also must be provided between the heat exchanger and the suction side of the collector loop pump. Pressure relief for solar systems must be set at 125 psi (862 kPa) (maximum system design pressure). The discharge from pressure relief valves must be either routed to an appropriate floor drain or captured as required by either local or state regulatory requirements. The discharge must be piped to avoid personnel injury from the hot fluid.

2-3.7.6 Temperature-Pressure Relief Valves

Install temperature-pressure relief valves on the solar storage tank and set for 125 psi (862 kPa) or 210 degrees F (99 degrees C).

2-3.7.7 Balancing Valve

Provide balancing valve with taps to read flow across outlet of each collector bank.

2-3.7.8 Manual Air Vents

Locate manual air vents at the high point(s) of the system where air will accumulate.

2-3.7.9 Strainers

Locate a strainer before the pump to test for system flush.

2-3.8 Pumps

2-3.8.1 Operation

Circulation pumps in both the collector and storage loops must be activated simultaneously by the control sub-system when it has been determined that net energy collection can occur.

2-3.8.2 Pump Sizing and Specification

Select the pump using the manufacturer's standard tables and graphs. After the selected pump is installed and the system is started, balance the system. Provide ECM pump. Comply with UFC 3-420-01 for requirements related to potable water systems.

2-3.9 Control Sub-System

The differential temperature controller (DTC) and all solar thermal system control components must be compatible with the building automation system (BAS) controls specified in the project.

2-3.9.1 Control Strategy

Specify operating modes and freeze/over-temperature protection methods. Connect the control sub-system to the BAS to access at a minimum the following:

- BTU meter in storage loop to measure and record thermal energy sent to storage tank.
- Indicate and record elapsed time of activated pumps.
- Activation of conventional system in event of solar thermal system failure.

Specify at a minimum the following control sequences:

- DTC--activates solar loop pump at preset temperature delta between collector and storage.

- Simultaneous activation of storage loop pump and collector loop pump after input from DTC.

Specify at a minimum the following control points:

- Collector temperature sensor (located at manufacturer's recommendation).
- Storage temperature tank sensor (located in coolest section of tank).
- Heat exchanger temperature sensors at inlet and outlet.
- Pressure indicators at supply and discharge sides of storage loop pump and collector loop pump.
- Pressure indicators at inlet and outlet of heat exchanger.
- Pressure indicator at storage tank.
- Flow indicator in collector loop.
- Flow indicator in storage loop.

2-3.9.2 Location of Controls

Panel-mount electronic displays and visual pressure and temperature gauges together in the mechanical room.

2-3.9.3 Differential Temperature Control Unit (DTC)

The DTC must include a solid-state design with an integral transformer. The DTC must allow the on and off set-points to be variable, and must allow the instantaneous temperatures of the collector and storage tank to be displayed by the system operator or maintenance personnel. The DTC must be able to diagnose and flag open or short circuits.

Using the DTC, the collector and storage loop pumps must be energized whenever the difference between the absorber plate and storage tank temperatures is greater than the high setpoint differential temperature, typically 15 to 25 degrees F (8 to 14 degrees C). The pumps must stay on until that temperature difference is less than the low setpoint differential temperature, usually 5 to 8 degrees F (3 to 4 degrees C).

2-3.9.4 Temperature Sensors and Locations

Provide sensors that are platinum resistance temperature detectors (RTDs) or 10 K-ohm thermistors. Sensors must be easily accessible for calibration and servicing.

2-3.9.4.1 Collector Temperature Sensor

To determine when sufficient energy is available for collection, locate one sensor on the collector array, either in the fluid stream (on a nearby collector bank and in the top internal manifold piping between two collectors) or fastened directly to the absorber plate (only if the collector manufacturer provides this service at the factory). Do not use threaded wells that consist of ferrous materials due to material compatibility with glycol heat transfer fluid. Cover the sensor assembly with a weatherproof junction box.

2-3.9.4.2 Storage Tank Sensor

Locate the storage tank sensor within a well protruding into the storage tank near the outlet to the heat exchanger.

2-3.9.4.3 Sensor Wiring

Locate wiring from the controller to the collector and storage sensors within metal conduit. Keep color-coding consistent from the controller to the sensor, and do not locate junctions or pull boxes in concealed areas.

2-3.9.5 Monitoring Equipment

2-3.9.5.1 Pressure Indicators

Install pressure gauges on the supply and discharge sides of both pumps, on all inlets and outlets of the heat exchanger, and on the storage tank. Duplex gauges can be used or single pressure gauges can be connected to supply and discharge pipe with small plug valves installed in the gage lines. Pressure gauges must be rated for 150 psi (1,034 kPa) and 210 degrees F (99 degrees C) operation.

2-3.9.5.2 Temperature Indicators

Provide thermometers at the heat exchanger inlets and outlets and at the top and bottom of the solar storage tank.

2-3.9.5.3 Flow Indicators

Specify a flow indicator in the collector loop and in the storage loop, after the pump(s). Use venturi-type flow meters to quantify flow measurement with flow indicator components made of brass, bronze, or other compatible non-ferrous material. Install flow devices at least five pipe diameters downstream of any other fittings. Connect flow indicators to the building automation system.

2-3.9.5.4 Elapsed Time Monitor

Record operating time of each circulation pump with an elapsed time monitor.

2-3.9.5.5 BTU Meter

When the solar energy system performance is monitored, specify a BTU meter, and install according to the manufacturer’s recommendation.

2-3.10 Design Precautions

2-3.10.1 Collector Loop Check Valve

Locate check valves so that the fluid in the collector loop can be completely drained.

2-3.10.2 Mixing Valves

Ensure that the cold water leg between the mixing valve and the cold water supply to the solar storage tank is not used for connection to any other fixture.

2-3.11 Safety Features

2-3.11.1 Fall Protection

Design equipment to minimize work at heights and minimize fall hazards during maintenance, repair, and inspection or cleaning. Design must include prevention systems, such as guardrails, catwalks, and platforms, and anchor points compatible with the job tasks and work environment.

2-3.11.2 Equipment Lockout and Disconnect

Machinery and equipment layout must ensure safe access to lockout devices and provide equipment with independent disconnects. All equipment and utilities must have lockout capability and any replacement, major repair, renovation, or modification of equipment must still accept lockout devices. Emergency and non-emergency shutoff controls must be located in the equipment room and have easy access and usability.

2-3.12 Coordination

The system designer is responsible for ensuring the requirements below are coordinated appropriately between the architect and structural engineer.

2-3.12.1 Roof Requirements

Provide a minimum space of 4 inches (100 mm) between the collector and the roof. Provide a roof design with penetrations near the array for collector supply and return lines. Other architectural requirements for roof design include designing the array support structure and provide calculations assuring that the roof structure is adequate to support the added loading and point loading from the new system; allowing adequate access to the array for maintenance; including access to the roof for personnel path (and equipment); including fire path access; and including walkways around the array and between adjacent arrays. Coordinate with paragraph entitled “Fire Safety Design” Requirements herein.

2-3.12.2 Equipment Room

There must be an equipment room for the solar energy system hardware in one location, and it must contain the storage tank, heat exchanger, expansion tank, pumps, control system, and related plumbing. The equipment room must be configured and sized to allow personnel easy access to maintain and replace equipment. A floor drain must be provided near the storage tank relief valve. Control panels must be installed in an accessible area within line of sight of the equipment room door.

2-3.12.3 Maintenance and Accessibility

Do not use protective mesh screens to cover collectors. Collectors and mounts must withstand expected wind and snow loads. Collector design must allow for rapid replacement of glass covers. Pumps, pipes, and controls must be accessible to allow for repair or replacement. Water pumps must be located so that leakage does not cause serious damage. The operations and maintenance (O&M) manual must be developed by the contractor for the specific design of the solar system.

CHAPTER 3 SOLAR PHOTOVOLTAIC TECHNICAL REQUIREMENTS

3-1 GENERAL REQUIREMENTS

3-1.1 Economic Feasibility Study

As required in UFC 1-200-02, provide on-site renewable energy systems in accordance with ASHRAE 189.1 Section 7.4.1.1 (On-Site Renewable Energy Systems), if life cycle cost-effective. ASHRAE 189.1 requires a minimum annual renewable energy production requirement based on the size of the total roof area. This result refers to the rated DC nameplate capacity of the system.

Perform a life-cycle cost analysis for all new military construction to determine whether the use of renewable forms of energy will result in a net monetary savings to the government. The methodologies and parameters required for Federal energy project feasibility studies are mandated by Federal law (10 CFR 436). Provide a solar photovoltaic energy system when life-cycle cost effective.

3-1.2 Screening Procedures

Perform the initial evaluation for solar photovoltaic system viability. Generate a final report containing at least the solar photovoltaic system size, system cost, annual energy savings, annual cost savings, savings-to-investment ratio (SIR), simple payback, solar fraction, and annual greenhouse gas reduction. The utility rate used for calculating savings must be the burdened rate. See Appendix B for recommended tools.

3-1.3 Detailed Analysis and Study

If the results of the screening procedure indicate that a solar photovoltaic system is a viable consideration, then the next step will be to perform a detailed life-cycle cost analysis (LCCA) to determine the most effective design alternative to develop. Perform LCCA calculations and reports. Include evaluation of tracking array. See Appendix B for recommended tools.

3-1.4 Energy Security Risk Mitigation

On-site renewable energy system designs must include the following requirements in accordance with UFC 3-501-01 in order to limit the risk to energy security:

a. Direct interconnection of system to installation-wide electrical system (grid):

  - o For renewable energy systems that include a tie-in by a direct connection to the primary distribution system, provide a cumulative renewable energy load analysis of both the direct connection and building renewable power systems.
  - o Evaluate the proposed systems and verify there are no adverse effects on the installation-wide electrical system frequency control, voltage

regulation, and power quality. See Appendix B for issues that should be considered.

b. Direct interconnection of system to buildings that utilize engine generators that may operate in parallel with the renewable energy generation[1]:

  - Evaluate the proposed systems and verify there are no adverse effects on the generator's ability to maintain frequency control, voltage regulation, and power quality. See Appendix B for issues that should be considered.
  - If the stability of the combined systems cannot be confirmed, then design system to automatically disconnect renewable power generation when the backup generator is in operation.

c. Direct interconnection of system to buildings that either do not utilize engine generators or have backup power systems that would never operate in parallel with the renewable energy generation, such as a backup generator supplying power via an automatic transfer switch:

  - Provide analysis validating that the electrical system design addresses the electrical characteristics (real and reactive power output) of the renewable energy system.

3-1.5 Solar Photovoltaic Basis of Design

At a preliminary design stage equivalent to 35% design unless stated otherwise, the designer of record must provide a basis of design which covers the general facility design requirements in accordance with UFC 1-200-01 and its referenced documents. In addition to the UFC 3-501-01 requirements for preliminary basis of design and follow-on submittals, provide the following general system specific analysis information:

- Narrative
  - FY Year, Project Number, and project location.
  - Project acquisition: Design-Bid-Build or Design-Build.
  - Briefly state scope, project description, references, and calculation method used.
  - Geographic and operating environment, including coastal locations/corrosive conditions, humidity, altitude, seismic zones, and ambient temperature extremes.
  - Type of solar PV system (BIPV, ground mount, roof mount, tracking).
- Life Cycle Cost Effectiveness
  - Life Cycle Cost Analysis results.
  - Solar PV system design cost (study and design costs itemized).

[1] The Air Force does not allow paralleling facility-scale renewable energy systems with any standby power regardless if it is emergency, Critical Operations Power Systems (COPS), or other.

- Average annual energy savings and fuel used.
- Fuel costs provided in the study.
- Percent energy contribution from solar PV system.
- Savings to investment ratios (SIR).
- Estimate of solar PV system installed costs [exclusive of supervision, inspection and overhead (SIOH) and contingency].
- Initial year O&M costs and requirements.

- Design Feasibility
  - Consideration must be taken to avoid shadowing from nearby structures and vegetation.
  - Schematic of system layout.
  - Structural design considerations (roof mounting discussion, life span of roof, structural adequacy).
  - Type and area of solar PV modules.
  - Tracking or fixed solar PV array.
  - Azimuth angle of solar PV modules.
  - Tilt angle of solar PV modules.
  - Calculations used: input data, analysis, method used.
- Connection to Facility (50% Design) in accordance with NFPA 70
  - Ground fault protection.
  - Overcurrent protection.
  - Arc-fault circuit protection.
  - Disconnecting means.
  - System grounding.
  - Grounding electrode system.
  - Rating of AC interconnection panel/switchboard and potential for source to exceed busbar rating. Where the busbar rating would be exceeded, provide design alternative for grid interconnection.
  - Calculations used: input data, analysis, method used.
- Solar PV system schedule (50% Design).
  - Solar PV module technology (crystalline-silicon, thin film).
  - Solar PV module wattage.
  - Solar PV source circuits voltage, current, wattage.
  - Solar PV combiner box output circuit voltage, current, wattage.
  - Inverter input and output voltage, current, wattage.

- Description of operating sequence (90% Design).
  - Startup procedures.
  - Shut off procedures (rapid shutdown of PV systems on buildings).

3-2 SYSTEM SELECTION

3-2.1 Photovoltaic Modules

Solar photovoltaic (PV) modules generate direct current (DC) electrical power from semiconductors when they are excited by sunlight. There are a number of solar PV technologies commercially available and can be categorized into crystalline silicon, ribbon sheet, and thin film. See Appendix E for a discussion on each solar PV technology. Select one commercially-available PV module type based on LCCA, required energy production, site location environmental conditions, and maintainability.

3-2.2 Inverter Types

A micro-inverter converts the DC power to AC at each individual solar module. A string inverter converts the DC power to AC for a series of solar modules. Use either micro-inverters mounted on each individual solar PV module, micro-inverters mounted on racking, or string inverters that serve a series of solar PV modules.

NOTE: Utility-size systems in UFC 3-540-08 (Draft) require reactive power; however this is not necessary for facility-size systems. As regulations are enacted and standards evolve, more inverters will feature reactive power adjustment, but currently very few do.

3-2.3 Mount Types

3-2.3.1 Roof Mounting

Comply with UFC 3-110-03 for requirements related to rack-mounted photovoltaic systems. Design mounting systems in accordance with UFC 3-301-01. For racking requirements dependent upon the roof type, comply with NRCA Guidelines for Roof Systems with Rooftop Photovoltaic Components. Use rooftop mounting systems of the same manufacturer for the entire project array.

3-2.3.1.1 Asphalt Shingle Roof Systems

Comply with CEIR PV Racking and Attachment Criteria for Effective Asphalt Shingle Roof System Integration for requirements related to attaching the mounting system to an asphalt shingle roof system.

3-2.3.1.2 Low-Slope Roof Systems

Comply with CEIR PV Racking and Attachment Criteria for Effective Low-Slope Roof System Integration for requirements related to attaching the mounting system to a low-slope roof system.

3-2.3.1.3 Metal Panel Roof Systems

Comply with CEIR PV Racking and Attachment Criteria for Effective Low-Slope Metal Panel Roof System Integration for requirements related to attaching the mounting system to a low-slope metal panel roof system.

3-2.3.2 Ground Mounting

Design mounting systems in accordance with UFC 3-301-01. Foundation must be either concrete, driven pile, or helical pile. Complete an environmental impact assessment for the site.

3-2.3.3 Tracking Array System

Design for solar PV tracking system in accordance with IEC 62727. See Appendix E for tracking system pros and cons.

3-2.4 DC Input Voltage

Maximum DC string input voltage must not exceed 1,000 VDC.

3-2.5 System Warranty

Provide a warranty in the event of component failure due to workmanship, defective components or assemblies for the entire solar PV system at a minimum one year parts and labor. Coordinate all warranty requirements with the LCCA.

3-2.5.1 PV Module Warranty

Provide PV module warranty of minimum 10 years for workmanship material and manufacturing defects from the date of manufacture. Concerning performance, PV module warranty must include manufacturer written guarantee for minimum continuous, linear power output of 80 percent for 25 years.

3-2.5.2 Inverter Warranty

Provide inverter warranty of minimum 15 years.

3-2.5.3 Mounting System Warranty

Provide PV mounting system warranty of minimum 15 years.

3-2.6 Standard Test Conditions

All compliance testing must be completed under Standard Test Conditions (STC) which are defined as 92.9 W/ft^2 (1,000 W/m^2) insolation, 68 degrees F (25 degrees C) cell temperature, and 2.2 mph (1 m/s) average wind velocity. Modules must be supplied with original current/voltage maximum power measurement data.

3-3 SYSTEM DESIGN

Installation must meet requirement based on roof area although it does not have to be installed on the roof (it can be ground-mounted).

3-3.1 Array Tilt Angle

Tilt the array to the latitude plus or minus 10 degrees. It should be noted that as the tilt angle increases, the minimum spacing between rows must be increased due to shading, requiring a larger roof area. Do not allow inter-row shading between 9 a.m. and 3 p.m., when the bulk of the energy collection occurs.

3-3.2 Array Azimuth Angle

For optimum performance, orient the module true south, however slightly west of south (azimuth angle of true south plus 10 degrees) may be preferable in some locations if an early morning haze or fog is a regular occurrence. Design the array's azimuth angle off of due south as coordinated with the Basis of Design.

3-3.3 PV Module Design

The solar photovoltaic module must comply with UL 1703. The backsheet and encapsulent must be specified in accordance with UFGS 26 31 00 with a guarantee of their construction submitted by the manufacturer.

3-3.3.1 Insulation

All module circuitry must be insulated from external surfaces and withstand open-circuit system voltage of 1,000 VDC.

3-3.4 Inverter and Array Design

3-3.4.1 Network Communication

Provide inverter capable of network communication to allow for PV array performance monitoring.

3-3.4.2 Inverter Location

Locate the string inverter(s) in the electrical equipment room or outdoors with appropriate personnel safety to prevent unauthorized access. If a ventilated enclosure is not available, provide enclosure in accordance with UFC 3-501-01, paragraph entitled "Corrosive and High Humidity Areas."

3-3.4.3 Micro-Inverter Systems

For micro-inverter systems, coordinate the maximum number of micro-inverters per branch circuit and overcurrent protection size with the inverter manufacturer. The maximum number will be dependent on the AC system voltage, AC output power, and conductor size of the interconnection cable. Design the array to the best power output using best practices in Appendix B.

3-3.5 Metering and Monitoring

Coordinate revenue metering requirements with the utility provider and DoD installation regarding interconnection-specific data and guidelines, utilizing metering specifications UFGS 26 27 13.10 30 (Air Force only) and UFGS 26 27 14.00 20 (Navy only). Coordinate with Activity for requirements and plan of action to manage excess energy, including the utilization of net metering.

Provide communication and annunciator panel. Monitoring must be module-based if micro-inverters are implemented, otherwise monitoring must be string-inverter based. Provide monitoring based on inverter type utilized (i.e. string inverter or micro-inverter).

3-3.6 Wiring

Provide UL 4703 listed PV wiring. Provide grounding in accordance with NFPA 70.

3-3.7 Sensors and Locations

Provide sensors that are easily accessible for calibration and servicing, and relevant to affecting PV output.

3-3.7.1 Ambient Temperature Sensor

The ambient temperature sensor must be located near the array but not on it, such that it will not cast a shadow on the array, is at the same mean height as the array, and is exposed to the same hours of sunlight as the majority of the array panels.

3-3.7.2 Panel Temperature Sensor

The panel temperature sensor must be located on the array, fastened directly to the center of the back side of a solar panel. Sensors must be either thermocouple platinum or digital, and fully encapsulated including a minimum 3/8 inch (10 mm) thick insulation block.

3-3.7.3 Insolation Sensor

The solar insolation sensor must be located in the plane of the array, fastened directly to the front side of a solar panel frame but must not cast a shadow on the panel cells, and constructed of UV-resistant material.

3-3.7.4 Wind Speed Sensor

Locate the wind speed sensor near the array but not on it, such that it will not cast a shadow on the array, and away from tall obstructions. Wind speed sensor is necessary for solar tracking PV systems to prevent damage.

3-3.7.5 Sensor Wiring

Comply with NFPA 70 for requirements related to sensor wiring.

3-3.8 Lightning and Surge Protection

3-3.8.1 Lightning Protection

Comply with UFC 3-501-01 for requirements related to providing a lightning risk assessment.

If lightning protection is a design requirement, comply with UFC 3-575-01 for requirements related to providing a lightning protection system. Provide side flash calculations as required by NFPA 780.

3-3.8.2 Overcurrent Protection

Provide overcurrent protection in accordance with NFPA 70. Show locations of overcurrent protective device on drawings.

3-3.8.3 Surge Protection

Provide surge protection in accordance with NFPA 780. Comply with UFC 3-520-01 for requirements related to providing surge protection. Show locations of surge protective device on drawings.

3-3.9 System Grounding

Comply with NFPA 70 for requirements related to general system grounding.

3-3.10 Utility Interconnection

Coordinate with local transmission and interconnection services provider for specific procedures in accordance with the provider’s pro forma Open Access Transmission Tariff (OATT). Where the busbar rating would be exceeded, provide design alternatives for interconnection to the grid. Comply with all IEEE 1547 requirements regarding the interconnection technical and testing requirements necessary for electrical systems to operate under normal conditions without degradation. Prior to interconnect, provide proper documentation and certifications for all generation equipment, installation, operation, and maintenance to show that the system is in compliance with IEEE 1547.

3-3.11 Safety Features

3-3.11.1 Emergency Shutdown

Provide system rapid shutdown equipment in accordance with NFPA 70.

3-3.11.2 Fall Protection

Comply with UFC 3-110-03 for requirements related to elimination, prevention, or control of fall hazards. Design equipment to minimize work at heights and minimize fall hazards during maintenance, repair, and inspection or cleaning. Design must include prevention systems, such as guardrails, catwalks, and platforms, and anchor points compatible with the job tasks and work environment.

3-3.12 Fire Safety Design Requirements

Comply with UFC 3-600-01 and all requirements in NFPA 1 related to "Photovoltaic Systems" with the following modifications.

3-3.12.1 Buildings Other Than One- and Two-Family Dwellings and Townhouses.

3-3.12.1.1 Access

Provide a minimum 6 ft (1.8 m) wide clear perimeter around the edges of the roof for all buildings.

3-3.12.1.2 Single Story Smoke Ventilation

Ventilation options shall be provided as required by NFPA 1. It is preferable to provide skylights (that can be manually opened) or manually operated smoke vents in lieu of the "venting cutout options".

3-3.12.1.3 Multistory Smoke Ventilation

Increased pathway width or venting cutout options are not required. The minimum width of any pathway must be 4 ft (1.2 m).

Provide a roof access hatch or skylight above every enclosed stairway. The hatch or skylight must not be less than 16 square ft (1.5 square m) in area and having a minimum dimension of 2 ft (6.1 m).

3-4 COORDINATION

3-4.1.1 Roof Requirements

Architectural requirements for roof design include providing roof penetrations near the array for conduit; designing the array support structure; allowing adequate access to the array for maintenance; including access to the roof for personnel (and equipment); and including walkways around the array.

3-4.1.2 Equipment Locations

Coordinate equipment locations with the system design, and consider the best practices in Appendix B. Design to minimize conductor cable distances. Provide panels in easily accessible areas and clearly visible.

Accommodate the inverters, meters, and subpanels in the electrical equipment room or other designated equipment area. Size area to allow personnel to move about freely and have easy access to replace equipment as necessary in accordance with NFPA 70.

APPENDIX B BEST PRACTICES

This appendix identifies background information and practices for accomplishing certain renewable energy design and engineering services. The Designer of Record (DoR) is expected to review and interpret this guidance and apply the information according to the needs of the project. If a Best Practices document has guidelines or requirements that differ from the UFGS or UFC, the UFGS and the UFC must prevail. If a Best Practices document has guidelines or requirements that are not discussed in the UFGS or UFC, the DoR must submit a list of the guidelines or requirements being used for the project with sufficient documentation to the Government Engineer for review and approval prior to completing design.

B-1 WHOLE BUILDING DESIGN GUIDE.

The Whole Building Design Guide (www.wbdg.org) provides additional information and discussion on practice and facility design, including a holistic approach to integrated design of facilities.

The WBDG provides access to Construction Criteria Base (CCB) criteria, standards and codes for the DoD Military Departments, National Aeronautics and Space Administration (NASA), and others. These include, UFC, UFGS, Performance Technical Specifications (PTS), design manuals, and specifications.

B-2 RENEWABLE ENERGY SYSTEMS AND ENERGY SECURITY.

Designs should address the following issues concerning the utilization of renewable energy (RE) systems:

B-2.1 Low Energy Security Risk RE Systems.

Waste-to-energy, geothermal, or biomass, are low energy security risk RE systems and are highly desirable.

- No power quality issues.
- Stable, reliable, easily controllable.
- Easily integrated into microgrid topology.
- Straightforward, easily implemented IEEE 1547 standard.

B-2.2 High Energy Security Risk RE Systems.

Photovoltaic and wind renewable energy (RE) systems are high energy security risk due to their possible adverse effect on electric grid frequency control, voltage regulation, and power quality.

B-2.2.1 Wind Energy Generators Systems.

- Consume reactive power – cannot provide reactive power to meet needs of base.

- Lower utility power factor (PF) during operation – creates risk of utility power factor penalty charges or power outages.
- Electromagnetic interference.
- Implementation of IEEE 1547 standard is more complex.

B-2.2.2 Solar PV Energy Systems.

- Provide near unity PF – little to no reactive power.
- Lower utility PF during operation.
- Unstable effect on system frequency control.
- Additional stress on emergency generators supporting critical facilities if operated in parallel.
- Implementation of IEEE 1547 standard is more complex.

B-3 SOLAR THERMAL BEST PRACTICES.

B-3.1 Tools.

B-3.1.1 Screening Tools.

B-3.1.1.1 Solar Hot Water System Calculator.

Use the Solar Hot Water System Calculator developed by the Federal Energy Management Program (FEMP) for the initial evaluation for solar hot water system viability: http://apps1.eere.energy.gov/femp/solar_hotwater_system/.

B-3.1.1.2 System Advisor Model (SAM).

Use the System Advisor Model, a performance and financial model designed to facilitate decision-making for those involved in the renewable energy industry: https://sam.nrel.gov/.

B-3.1.2 Shading Analysis Tools.

B-3.1.2.1 Solar Pathfinder.

Use the Solar Pathfinder tool to determine the most economical and efficient solar thermal array location and position: http://www.solarpathfinder.com/.

B-3.1.2.2 Solmetric SunEye.

Use the Solmetric SunEye tool to determine the most economical and efficient solar thermal array location and position: http://www.solmetric.com/.

B-3.1.2.3 Manual Calculation.

Manual calculations may be an acceptable approach for more experienced designers. Perform calculations justifying the basis of shadowing exclusion areas.

B-3.1.3 LCCA Tools.

B-3.1.3.1 Economic Analysis Package (ECONPACK).

Perform LCCA calculations and reports by utilizing a service's economic analysis program, such as the Economic Analysis Package (ECONPACK): http://www.wbdg.org/tools/econpack.php.

B-3.1.3.2 Building Life-Cycle Cost (BLCC).

Perform LCCA calculations and reports by utilizing a service's economic analysis program, such as the Building Life-Cycle Cost (BLCC) Program: http://www1.eere.energy.gov/femp/information/download_blcc.html.

B-3.1.4 Domestic Hot Water.

The FEMP Solar Hot Water System Calculator (http://apps1.eere.energy.gov/femp/solar_hotwater_system/) incorporates hot water demand estimates for several types of buildings: barracks, dormitory, food service, hospital, motel, office, residence, and school. Other required inputs are: number of persons, cold water temperature, and hot water temperature. The outputs are the total calculated load and estimated system size.

B-3.2 Solar Thermal Heat Transfer Fluids.

Observe the cautions regarding toxic heat transfer fluids as given here: http://www.energysavers.gov/your_home/water_heating/index.cfm/mytopic=12930.

B-3.2.1 Hydrocarbon Oils

Hydrocarbon oils are for systems susceptible to regular freezing or stagnation temperatures, usually in ASHRAE Climate Zones 6 and above. Hydrocarbon must have a minimum closed-cup flashpoint 100 degrees F (38.7 degrees F) higher than the maximum expected collector temperature. Use oxygen scavenger additives when unsaturated hydrocarbons are used as heat transfer fluids. Some non-synthetic hydrocarbons thicken at low temperatures and the resultant higher viscosity can cause pumping problems. Synthetic hydrocarbon oils retain low viscosity at low temperatures, and therefore are required.

B-3.2.2 Distilled Water

Due to distilled water being subject to freezing and boiling, add an anti-freeze/anti-boil agent such as glycol.

B-3.3 Hydronic Heating Combined with Domestic Hot Water

Water-to-air heat exchangers may be placed in existing ductwork, in which case, an unpressurized, unlined tank may be used and represents a minimum heating system. The following is guidance for baseboard heaters:

- Most baseboard heaters have comparatively small surface areas, so they require higher temperatures, typically about 180 degrees F (82.2 degrees C). If larger heat transfer areas are available as in older or modified hot water systems, temperatures of 120 degrees F (48.9 degrees C) may be sufficient. Temperatures of 100 degrees F (37.8 degrees C) are adequate for the system which uses entire floors, walls, and ceilings as radiator surfaces.
- During the winter, typical liquid-type solar systems are seldom operated at delivery temperatures above 150 degrees F (65.6 degrees C). The use of solar heated water in standard baseboard heaters is impractical. Only modified baseboard heaters of adequate size or radiant panels shall be used in hydronic systems which use solar heated water.

B-3.4 Solar Thermal Collector Sub-System Array Design.

Select a specific collector for the detailed design before the actual array size is determined.

B-3.5 Reverse-Return Piping Layout – Diagonal Attachment Rule.

The reverse-return strategy of providing approximately equal length flow paths for supply and return pipes attached to the array at any two opposite diagonal corners of the array must be used for all projects.

B-3.6 Solar Thermal Pressure Drop Across Banks and Rows.

When internal-manifold collectors are banked together in groups of seven or less, it can be assumed that the pressure drop across the entire bank is equal to the pressure drop across a single collector.

B-3.7 Draindown and Drainback Systems.

Draindown (closed-loop) and drainback (open-loop) systems are prohibited due to additional maintenance required over the approved systems.

B-3.8 Over-Temperature Protection.

Over-temperature protection of the collector loop in the event of stagnation is provided through expansion tank sizing, and therefore there are no additional control requirements. The pressure-temperature relief valve located on the storage tank supplies over-temperature protection of the storage loop. If a direct circulating system is supplying water for domestic use, protection is provided through relief and mixing valves.

B-3.9 Heat Exchanger.

Effectiveness is a relatively complex term to calculate. Two methods of heat exchanger analysis are used in design: the log mean temperature difference (LMTD) method and the effectiveness-number of transfer units (e-NTU) method. The LMTD method is used most often for conventional HVAC systems and requires knowledge of three of the four inlet and outlet temperatures. This method cannot be applied directly to solar systems because the inlet temperatures to the heat exchangers from both the collectors and storage are not constant. Since the goal of the solar system heat exchanger is to transfer as much energy as possible, regardless of inlet and outlet temperatures, the e-NTU method should be used. However, a complete e-NTU analysis can be avoided by considering the impact of the heat exchanger on the overall system performance. The annual system solar fraction is decreased by less than 10 percent as heat exchanger effectiveness is decreased from 1.0 to 0.3. By setting a minimum acceptable effectiveness of 0.5, the e-NTU method can be used to generate the temperatures required by the LMTD method. These temperatures and the corresponding flow rates can then be used to size the heat exchanger according to the LMTD method, with the resulting heat exchanger satisfying the minimum effectiveness of 0.5.

Consult manufacturer’s representatives and catalogued data to size heat exchangers. A 120 degrees F (49 degrees C) solar loop exit temperature yields an effectiveness of 0.5, and increasing the exit temperature decreases effectiveness. To ensure an effectiveness greater than 0.5 is achieved, the designer provides the following recommended temperatures and flow rates:

- Solar loop inlet temperature = 140 degrees F (60 degrees C)
- Solar loop exit temperature = 120 degrees F (49 degrees C) or less
- Storage side inlet temperature = 100 degrees F (38 degrees C)
- Solar loop flow rate = Average flow rate (AFR)
- Storage loop flow rate = 1.25 × AFR.

B-4 SOLAR PHOTOVOLTAIC (PV) BEST PRACTICES.

B-4.1 Tools.

B-4.1.1 Screening Tools.

B-4.1.1.1 Solar Insolation Map.

Determined with a solar insolation map, sites with an average solar radiation rate above 5.0 kWh/m^2 per day must be carefully considered for solar photovoltaic energy.

B-4.1.1.2 PVsyst.

Consider using the PVsyst software package for preliminary design, project management, and data simulation: http://www.pvsyst.com.

B-4.1.1.3 PVWatts.

Consider using the PVWatts web application, developed to estimate the electricity production of a grid-connected roof- or ground-mounted photovoltaic system based on a few simple inputs: http://www.nrel.gov/rredc/pvwatts/.

B-4.1.1.4 Solar Prospector.

Use the Solar Prospector tool for mapping direct normal irradiance (DNI), developed by the National Renewable Energy Laboratory (NREL) for the initial evaluation for solar photovoltaic system viability: http://maps.nrel.gov/node/10/.

B-4.1.1.5 System Advisor Model (SAM).

Use the System Advisor Model, a performance and financial model designed to facilitate decision-making for those involved in the renewable energy industry: https://sam.nrel.gov/.

B-4.1.2 Shading Analysis Tools.

B-4.1.2.1 Solar Pathfinder.

Consider using the Solar Pathfinder tool to determine the most economical and efficient solar thermal array location and position: http://www.solarpathfinder.com/.

B-4.1.2.2 Solmetric SunEye.

Consider using the Solmetric SunEye tool to determine the most economical and efficient solar thermal array location and position: http://www.solmetric.com/.

B-4.1.2.3 Manual Calculation.

Experienced designers who may be more comfortable with using manual tools such as a tape measure is also an acceptable approach. Provide calculations justifying the basis of shadowing exclusion areas.

B-4.1.3 LCCA Tools.

B-4.1.3.1 Economic Analysis Package (ECONPACK).

Perform LCCA calculations and reports by utilizing a service's economic analysis program, such as the Economic Analysis Package (ECONPACK): http://www.wbdg.org/tools/econpack.php.

B-4.1.3.2 Building Life-Cycle Cost (BLCC).

Perform LCCA calculations and reports by utilizing a service's economic analysis program, such as the Building Life-Cycle Cost (BLCC) Program: http://www1.eere.energy.gov/femp/information/download_blcc.html.

B-4.2 Warranty.

Note that specific system components can have warranties that vary with each manufacturer. Typically, PV module warranty ranges from 5-10 years. Concerning performance, PV module warranty includes manufacturer written guarantee for minimum continuous power output of 80 percent for 20 years. Warranties for inverters have a typical range of 10-25 years depending on the manufacturer and technology. In addition, the PV mounting system warranty typically varies between 5-10 years.

B-4.3 Array Tilt Angle.

Anticipate any future structures or vegetation (trees) that could block future solar access, and keep the modules out of the shade between 9 a.m. and 3 p.m. when the bulk of the energy collection occurs.

B-4.4 Inverter and Array Design.

For string-inverter and micro-inverter systems, because the inverter must be sized for a system to last 20 years, the PV-to-inverter (DC-to-AC) size ratio must be between 1.1 and 1.4, or according to the microinverter manufacturer if microinverters are used. The ideal ratio must be determined by the designer using simulation software. Consider designing the system using smaller inverters so that less power is lost in the event one fails.

B-4.4.1 Maximum Panels for Inverter.

The temperature-corrected open-circuit voltage calculation used in determining the maximum number of panels for the inverter must not use the location record low temperature but rather refer to the Extreme Annual Mean Minimum Design Dry Bulb Temperature data published in ASHRAE Handbook – Fundamentals. The recommended method is to calculate the temperature-corrected, minimum expected module maximum power voltage, Vminmp = Vmp + ((T_rise + T_max – T_stc) X TCVmp), where,

- Vminmp = Minimum expected module maximum power voltage
  - Vmp = Module maximum power voltage
- T_rise = Temperature rise resulting from mounting conditions
- T_max = Average high ambient temperature
- T_stc = Temperature at Standard Test Conditions
- TCVmp = Temperature coefficient at maximum power voltage.

B-4.4.2 Minimum Panels for Inverter.

To determine the minimum number of panels in the string for the inverter, use the equation Nmin = Vmininv / Vmin, where:

- Nmin = Minimum number of panels per inverter string

- Vmininv = Minimum inverter voltage
- Vminmp = Minimum expected module maximum power voltage.

B-4.5 PV Array Zone Labeling.

On the as-built plans, label PV arrays into zones to match with corresponding inverters and combiner boxes. Labeling will help in identifying locations for troubleshooting and repair.

B-4.6 PV Modules and Hot Roofs.

Design for an air gap between continuous rows of PV modules for ventilation.

B-4.7 Equipment Locations.

Depending on the system design, equipment may be located indoors or outdoors. Equipment indoors adds generated heat to the building, but also adds longevity. Equipment outdoors may be subjected to a harsh environment. If equipment is in a desert environment, in addition to the proper NEMA enclosure, it must also be provided with a shading structure.

APPENDIX C GLOSSARY

C-1 ACRONYMS.

AC	Alternating Current
AFR	Average Flow Rate
BAS	Building Automation System
BIA	Bilateral Infrastructure Agreement
BTU	British Thermal Unit
CCB	Construction Criteria Base
CIS/CIGS	Copper Indium [Gallium] (di)Selenide
DC	Direct Current
DoR	Designer of Record
DHW	Domestic Hot Water
DTC	Differential Temperature Controller
ECM	Electronically Commutated Motor
EISA	Energy Independence and Security Act
FEMP	Federal Energy Management Program
HNFA	Host Nation Funded Construction Agreements
ISC	Integral Storage Collector
kW	Kilowatt
kWh	Kilowatt-Hour
LCCA	Life Cycle Cost Analysis
MTR	Military Training Route
NFPA	National Fire Protection Association
NREL	National Renewable Energy Laboratory
O&M	Operation & Maintenance
PV	Photovoltaic

SIR Savings-to-Investment Ratio

SRCC Solar Rating and Certification Corporation

WBDG Whole Building Design Guide

C-2 DEFINITION OF TERMS.

Albedo: The fraction of solar radiation that is reflected from the ground, ground cover, and bodies of water on the surface of the earth.

Anemometer: An instrument that measures wind speed.

Azimuth Angle: The angle between the horizontal direction (of the sun, for example) and a reference direction (usually North).

Dry-Bulb Temperature: Air temperature measured with a thermometer, similar to ambient temperature.

Fixed-Tilt Array: An array of solar power collectors that do not pivot to follow the track of the Sun in the sky. In the Northern Hemisphere, they are usually mounted with a southern tilt that will maximize the amount of energy that they can receive.

Flat-Plate Collector: A solar power collector that absorbs the Sun's energy on a flat surface without concentrating or refocusing it.

Insolation: The amount of solar energy that arrives, at a specific area of a surface during a specific time interval. A typical unit is W/m^2.

Nadir: Straight down (toward the center of the Earth)

Net Metering: A service to an electric consumer under which electric energy generated by that electric consumer from an eligible on-site generating facility and delivered to the local distribution facilities may be used to offset electric energy provided by the electric utility to the electric consumer during the applicable billing period.

Orientation: The direction that a solar energy collector faces. The two components of orientation are tilt angle (the angle the collector makes from the horizontal) and the aspect angle (the angle the collector makes from North)

Parabolic Collector Trough: A system that tracks the path of the sun by pivoting on one axis (typically East-West or North-South), using shiny parabolic troughs to heat the collector fluid that passes through a tube at the focus

Photovoltaic: Technology for converting sunlight directly into electricity, usually with photovoltaic cells

Solar Absorber: A sheet of metal, usually copper, aluminum, or steel, which forms the surface of a solar collector. It collects and retains solar radiation, which is passed to a heat transfer medium

Tracking Collector/Module: Any collector that changes its orientation throughout the day in order to follow the path of the sun in the sky. Two-axis trackers continually face the sun, while one-axis trackers rotate on one axis so that collectors receive the maximum amount of circumsolar radiation that strikes the axis.

APPENDIX D EXAMPLE SOLAR THERMAL DRAWINGS AND SCHEDULE CHECKLIST

D-1 PURPOSE.

The drawings and schedule checklist provides the solar thermal system designer, project manager, and quality assurance personnel with a list of those items that are called out by the guide specification to appear on the drawings, or are strongly suggested based on experience with solar thermal system design problems. The designer is encouraged to annotate the drawings to ensure that design changes are properly accounted for, to provide a record of system settings and performance criteria, and to ensure that important details are not overlooked during construction. The following items should be included as part of the system drawings and schedule.

D-2 SUGGESTED DRAWINGS AND SCHEDULE.

D-2.1 Collector Array Layout (No Scale).

The collector array layout will be in accordance with the guidance defined in Chapter 2. As a minimum define the layout, number of collectors, bank sizes, rows (if applicable), and required fittings.

D-2.2 System Schedule.

The job specific system schedule includes the following:

- Note the collector parameters around which the system was designed:
    - Collector net aperture area.
    - Collector fluid volume.
    - Collector gross dimensions (length, width, and thickness).
    - Collector design flow rate (CFR, recommended by manufacturer).
    - Pressure drop at design flow rate.
    - Internal manifold diameter.
- Note the following system parameters:
    - System calculated net aperture area.
    - System (collector loop) flow rate required (AFR = CFR × Number of collectors).
    - Storage loop flow rate = 1.25 × AFR.
    - Propylene glycol concentration required in collector loop.
    - Minimum pressure drop throughout piping loop, corrected for propylene glycol solution, if necessary.
- Note the following information about the heat transfer fluid:

- Recommend only food-grade propylene glycol/distilled water solutions as the heat transfer fluid.
- Percent concentration required (30 percent or 50 percent).
- Tamper-resistant resistant seals are required at all fill ports or drains.

- Note the heat exchanger recommended minimum performance requirements to achieve an effectiveness of 0.5, although this may vary due to the system design and environment:
  - Solar loop (hot) inlet = 140 degrees F (60 degrees C).
  - Storage loop (cold) inlet = 100 degrees F (38 degrees C).
  - Solar loop (hot) outlet = 120 degrees F (49 degrees C), or less.
  - Solar loop (hot) flow rate = AFR.
  - Storage loop (cold) flow rate = 1.25 × AFR.
  - Solar (hot) fluid: 30 percent or 50 percent propylene glycol/water solution.
  - Storage (cold) fluid: water.
  - Note required pipe diameters.
  - Locate expansion tanks near pump inlets.
  - Require expansion tank bladders to be compatible with propylene glycol/water solutions.
  - Require a check valve in the collector loop in order to prevent reverse thermosiphoning.
  - Require isolation valves around the collector banks and all major components.
  - Require pressure relief shown on all banks.
  - Require calibrated balancing valves at all bank outlets.
  - Require drain valves at low points of each collector bank or row.
  - Require thumb valves (if required) to manually open and close pressure gauges and flow indicators not meant for constant use.
  - Require two drain valves, with gate in between, at all low points in the system to allow for filling.
  - Require 125 psi/210 degrees F (862 kPa/99 degrees C), pressure/temperature relief valve on the storage tank.
  - Require manual air vents at all high points of the system plumbing.
  - Locate collector temperature sensor on a nearby collector bank and in the top internal manifold piping between two collectors; or on the collector absorber plate, only if installed by manufacturer.

- o Locate a storage sensor in the thermal well at the bottom of the storage tank.
- o Require sensor wiring be installed in a conduit.
- o Require pressure gauges, rated for 125 psi (862 kPa), on both sides of pump(s), on all ports of the heat exchanger, and on the storage tank.
- o Require thermometers on all ports of the heat exchanger and at the top and bottom of the storage tank.
- o Require flow indicators or meters in each loop to allow either visual or quantified flow measurements to be observed.
- o Require an elapsed time meter be installed on circulation pump(s).
- o Require BTU meter be located across the heat exchanger on the storage side (if needed).

D-2.3 Roof Plan (To Scale Unless Noted).

- For Navy projects, coordinate with FC 1-300-09N.
- Collector groupings in banks and rows as designed.
- Minimum row spacing shown and noted.
- Orientation with respect to due south shown and noted.
- Rooftop mounted equipment, vents, and system penetrations shown and noted.
- Reverse-return piping shown and noted (not to scale).
- Expansion loops (if required) shown and noted.
- Manual air vents, pressure relief, valves and drains shown.
- Walkway, catwalk, or other array access shown and noted.

D-2.4 System Elevation.

- Pipe pitches for positive draining shown and noted.
- Piping elevations from equipment room to system and throughout array shown and system elevation head noted.
- Required collector tilt angle shown and noted.
- Mechanical chase shown between equipment room and roof.
- Array support structure shown.
- Walkway, catwalk, or other array access shown and noted.

D-2.5 Equipment Room Layout.

- Storage tank, pump(s), piping, control panel, heat exchanger, expansion tank, and drain shown.

- Backup water heating unit shown.
- Access is available to all equipment by maintenance personnel for repair, replacement, or monitoring.

D-2.6 Additional Schedules and Instructions.

- Schedule of operation. The operating characteristics (including the on/off temperature differential) of the system should be indicated.
- Installation instructions. Instructions should be provided regarding important installation details. These details include the use of Sb5, Sn94, or Sn96 solder for copper piping and on-site insulating instructions for equipment and piping.
- Design information schedule. Include the system design parameters into a drawing schedule(s).
- System filling and start-up instructions. Instructions on mixing the propylene glycol solution and filing the system will be provided. System fill pressure will be stated.
- Equipment schedule (standard).

D-2.7 Details.

- Storage tank.
  - Minimum of two tank penetrations each shown at both top and bottom of tank shown and noted.
  - Minimum insulation value of R-30 (factory or on-site application) shown and noted.
  - Storage sensor located in thermal well bottom of storage tank shown and noted.
  - Show and note that incoming water supply and outlet to solar system are connected to bottom of storage tank; inlet from solar thermal system and outlet to backup heating unit are connected to top of tank.
  - Dielectric couplings will be used on all piping connections.
  - Note that tank is to be lined with epoxy, glass, or cement.
  - If outdoors, weather protection and added insulation should be shown and noted.
  - Storage tank weight when filled should be noted.
  - Proper foundation for storage tank should be shown and noted.
- Heat exchanger (optional): For shell-in-tube heat exchangers, indicate the access areas allotted for tube bundle removal (to allow cleaning). Indicate that materials in the heat exchanger must be compatible with propylene glycol.
- Array support structure (typical).

- Collector mounting to support detail at proper tilt (within 10 degrees of site latitude) shown.
- Support mounting to roof detail shown.
- Aluminum structure with stainless steel hardware noted.
- Design loads noted.

- Collector temperature sensor mounting details. Detail showing mounting of the collector array temperature sensor should be provided. The sensor should show either mounting in the upper manifold piping between two collectors or should show mounting by the manufacturer directly to the absorber plate.
- Building piping penetrations. Design of piping penetration is weather tight and will withstand temperature expansion variations from 350 degrees F (177 degrees C) to the design low temperature of the project location.
- Pipe support. Pipe support design allows for temperature expansion variations from 350 degrees F (177 degrees C) to the design low temperature of the project location.

This Page Intentionally Left Blank

APPENDIX E SOLAR PHOTOVOLTAIC TECHNOLOGIES

E-1 TECHNOLOGY.

This appendix identifies various solar PV technology alternatives and their main differences, to help the designer select the technology most appropriate for the project.

E-2 CRYSTALLINE SILICON.

Crystalline silicon PV is the most widely used to date with an approximate market share of 85%. There are two types of crystalline silicon: mono-crystalline and poly-crystalline.

E-2.1 Mono-Crystalline Silicon.

Most PV cells are mono-crystalline type. Silicon is purified, melted, and crystallized into ingots, which are then sliced into thin wafers or individual cells. The cells have a uniform color, usually blue or black and all cells in a module are cut from the same silicon ingot. Mono-crystalline possesses the highest conversion efficiency of approximately 18% and are more expensive than poly-crystalline silicon.

E-2.2 Poly-Crystalline Silicon.

Poly-crystalline silicon PV cells are manufactured and operated similar to the mono-crystalline type. The main difference is the usage of silicon that is of lower cost and quality, which results in a conversion efficiency lower than mono-crystalline, of approximately 14%. The surface of poly-crystalline cells has random patterns of crystal borders due to cells in the module cut from different ingots.

E-3 RIBBON SHEET SILICON.

Ribbon sheet cells are produced by growing a ribbon from molten silicon. These cells operate the same manner as mono- and poly-crystalline cells. The surface of these cells is coated with an anti-reflective material giving off a prismatic rainbow appearance.

E-4 THIN FILM.

Thin film technology emerged through successful efforts to reduce the amount of silicon per watt of PV energy generation and to improve the efficiency of cells manufactured when compared to crystalline silicon. Thin film technology is generally classified into three major categories: Amorphous silicon (a-Si), Cadmium Telluride (CdTe), and Copper Indium (Gallium) (di)Selenide (CIS/CIGS).

E-4.1 Amorphous Silicon Film.

Amorphous silicon cells have no particular shape and are deposited on a variety of substrates. Despite having a low conversion efficiency of 6-8%, the cells possess a reliable output in low-light conditions.

E-4.2 Cadmium Telluride Film.

Cadmium Telluride cells are formed from depositing four layers of material onto transparent glass as a substrate. This technology is manufactured at a relatively low cost with a production of 9-10% conversion efficiency.

E-4.3 Copper Indium (Gallium) (di) Selenide Film.

Copper Indium (Gallium) (di) Selenide (CIGS) film has the highest efficiency among thin film technologies. CIGS cells utilize either a rigid or flexible substrate coated with multiple layers of materials with an antireflective coating. Typical conversion efficiency is approximately 10-12%.

E-5 PROS-CONS: PV TECHNOLOGIES AND APPLICATIONS.

Refer to the Table E-1 for guidance on how to select the most appropriate PV technology.

Table E-1 PV Technologies Pros and Cons

Technology/Application	Pros	Cons
Mono-Crystalline Silicon	Crystalline silicon is more widely-used, proven technology. Highest conversion efficiency. Non-toxic to the environment.	Considerably more expensive than poly-crystalline at only marginally higher conversion efficiency.
Poly-Crystalline Silicon	Crystalline silicon is more widely-used, proven technology. More affordable than mono-crystalline. Non-toxic to the environment.	Lower conversion efficiency than mono-crystalline due to overall lower-quality silicon.
Ribbon Sheet Silicon	Manufacturing process yields less waste, more environmentally-friendly. Conversion efficiency similar to poly-crystalline.	Few vendors. Manufacturing method yields inconsistent thickness, yields conversion efficiency similar or worse than poly-crystalline.
Thin Film	Lower weight than crystalline silicon. Better wind resistance. Durable to foot traffic. Versatile. Affordable modules. Withstands high heat. Can use indirect light.	Much worse conversion efficiency and quicker performance degradation than crystalline silicon. Contains toxic materials.

Amorphous Silicon Film	Affordable modules. Flexible. Withstands high heat and partial shading.	Much worse conversion efficiency and quicker performance degradation than crystalline silicon.
Cadmium Telluride Film	Layered design allows module to capture more of the sunlight spectrum for more energy generation.	Cadmium is an exotic metal and toxic substance that may pose problems at the end of the life-cycle for disposal. Few vendors. Less efficient and more expensive than crystalline-silicon.
Copper Indium (Gallium) (di)Selenide Film	Layered design allows module to capture more of the sunlight spectrum for more energy generation.	Cadmium is an exotic metal and toxic substance that may pose problems at the end of the life-cycle for disposal. More difficult to manufacture than Cadmium Telluride. Few vendors. Less efficient and more expensive than crystalline-silicon.
BIPV [roof (i.e. solar shingles), façade]	Architecturally blends into structure, more aesthetically pleasing. Covers maximum surface area for more energy generation. Building itself is support structure.	Much worse conversion efficiency and quicker performance degradation than crystalline silicon. Difficult to repair and replace due to components beneath roof membrane.
BAPV	Architecturally blends into structure, more aesthetically pleasing. Covers more surface area for more energy generation. Building itself is support structure.	Much worse conversion efficiency and quicker performance degradation than crystalline silicon. Difficult to repair and replace.

E-6 PROS-CONS: PV TRACKING ARRAYS

E-6.1 PV Tracking Array Pros:

- Captures more solar irradiance energy than fixed-tilt arrays, increasing system output by up to 50% in the summer and 20% in the winter.

- Passive designs do not consume additional energy.

E-6.2 PV Tracking Array Cons:

- More expensive upfront than fixed-tilt arrays by up to 25%.
- Motorized designs consume energy for tracking mechanism to operate.
- Moving parts and more complicated design than fixed-tilt arrays.
- Heavier than fixed-tilt arrays.
- Higher maintenance costs than fixed-tilt arrays.
- A failed tracking mechanism can leave the array at an angle where it collects almost no sun.

APPENDIX F EXAMPLE SOLAR PV DRAWINGS AND SCHEDULE CHECKLIST

F-1 PURPOSE.

The drawings and schedule checklist provides the solar PV system designer, project manager, and quality assurance personnel with a list of those items that are called out by the guide specification to appear on the drawings, or are strongly suggested based on experience with solar PV system design problems. The designer is encouraged to annotate the drawings to ensure that design changes are properly accounted for, to provide a record of system settings and performance criteria, and to ensure that important details are not overlooked during construction. The following items should be included as part of the system drawings and schedule.

F-2 SUGGESTED DRAWINGS AND SCHEDULE.

F-2.1 PV Array Layout (No Scale).

The PV array layout will be in accordance with the guidance defined in Chapter 3. As a minimum define the layout, number of modules, string sizes, rows (if applicable), and required balance of system components. Coordinate with site plan to anticipate any future structures or vegetation (trees) that could block future solar access.

F-2.2 System Schedule.

The job specific system schedule includes the following:

- Note the module parameters around which the system was designed:
  - Module technology.
  - Module tilt and azimuth angle.
  - Racking type.
- Note the following system parameters:
  - System wattage and voltage.

F-2.3 Roof Plan (To Scale).

- Module groupings in strings and rows as designed.
- Minimum row spacing shown and noted.
- Orientation with respect to due south shown and noted.
- Tilt angle.
- Combiner boxes shown and noted.
- Rooftop mounted equipment, vents, and system penetrations shown and noted.
- Rooftop conduit shown and noted.
- Walkway, catwalk, or other array access shown and noted.

F-2.4 System Elevation.

- Required module tilt angle shown and noted.
- Conduit run shown between equipment room and roof.
- Array support structure shown.
    - Collector mounting to support detail at tilt shown.
    - Support mounting to roof detail shown.
    - Structure with hardware noted.
    - Design loads noted.
- Walkway, catwalk, or other array access shown and noted.

F-2.5 Equipment Area Layout.

- Inverters, disconnects, conduits, meters, main panel, and any subpanels shown.
- Access is available to all equipment by maintenance personnel for repair, replacement, or monitoring.
- Adequate working and personnel safety clearance distances must be indicated on the plans.

F-2.6 Additional Schedules and Instructions.

- Schedule of operation. The operating characteristics of the system should be indicated.
- Schedule of labels.

This Page Intentionally Left Blank

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Mil Standard 3007G and UFC 1-300-01 requires the Tri-service community to achieve conformance to the Defense Standardization Program format and provide guidance consistent with current industry standards and incorporate best practices where applicable.

Noise and Vibration is a critical engineering feature to address in the design and construction of Tri-Service projects. UFC 3-450-01 (2003) is a unified document that includes ARMY TM 5-805-4/AFJAM 32-1090 (26 May 1995) Noise and Vibration Control. As written, ARMY TM 5-805-4/AFJAM 32-1090 is principally a technical "How To" manual to address Noise and Vibration control on projects.

1-2 REISSUES AND CANCELS.

This UFC updates and supersedes UFC 3-450-01 (May 2003).

1-3 INCORPORATES AND CANCELS.

This UFC incorporates salient features of and cancels ARMY TM 5-805-4/AFJAM 32-1090 (26 May 1995) Noise and Vibration Control.

1-4 PURPOSE.

This UFC provides qualified designers the criteria required for design and construction of those features related to noise and vibration control of electro-mechanical, mechanical, ductwork, and plumbing systems most commonly encountered in government facilities.

1-5 SCOPE.

This UFC applies to all new construction and to major alteration of existing structures. US government facilities that require higher standards because of special functions or missions are not covered in this document; criteria for these and other exceptions are normally contained in a design directive. If standards given in this UFC and its referenced documents do not provide all the needs of a project, recognized construction practices and design standards must be used.

1-6 DUCT LINING ATTENUATION.

Internal duct lining is prohibited. Prior to any design or construction, any consideration for its use must first be approved by exemption.

1-7 NOISE ESTIMATES.

Noise level estimates have been derived for various types of mechanical equipment, and in some cases graded for power or speed variations of the noise-producing machines. Noise data in the form of sound power levels per octave band must be obtained from the manufacturer to have the most acoustical accuracy, but these noise estimates can be used as a reference for typical expected noise levels across the frequency range. Data and recommendations are given for mechanical equipment installations on-grade and in upper-floor locations of steel and concrete buildings. Data and recommendations are also given for the analysis of noise in the surrounding neighborhood caused by mechanical equipment, such as cooling towers. On-site power plants driven by reciprocating and gas turbine engines have specific sound and vibration problems, which are considered separately, and their requirements are exclusive of this UFC.

1-8 SAFETY.

In addition to the subjective or perceived effects of noise, the requirements and information outlined in this document also consider the well-being of occupants in the facilities as pertaining to noise exposure. This accounts for avoiding long-term hearing damage or injury from loud noises to the occupants. The Occupational Safety and Health Administration (OSHA) Standard 29 CFR 1910.95 covers the requirements for occupational noise exposure limits within a building or facility. The requirements listed within this document are established as not to exceed limits from the OSHA standard(s).

1-9 ENGLISH METRIC UNITS.

English units are used throughout this manual. Where applicable, metric units are listed in parentheses alongside the corresponding English units. Metric units are used in special applications where the United States has joined with the International Standards Organization (ISO) in defining certain acoustic standards, such as 20 microPascal (µPa) as the reference base for sound pressure level.

1-10 GLOSSARY.

APPENDIX B contains acronyms and terms.

1-11 REFERENCES.

APPENDIX E contains a list of references used in this document.

CHAPTER 2 PROJECT REQUIREMENTS AND DOCUMENTATION

2-1 GENERAL.

This chapter outlines the expected applications and minimum expectations of an acoustical review for a facility in-design or an existing facility. In addition, guidance is given for expected documents/deliverables that will display the results and recommendations needed for the acoustical review. This chapter must be followed by the engineer/consultant carrying out the analysis.

2-2 APPLICABILITY.

This UFC is applicable to all service elements and contractors involved in the planning, design, and construction of DoD facilities worldwide. Where conflicts in requirements appear between sections of any UFC or applicable codes, the AHJ is the responsible party for determining the most restrictive requirement.

Refer to UFC 1-200-01 applicability paragraph for additional applicability guidance.

2-3 REQUIREMENTS FOR ACOUSTICAL REVIEWS.

When carrying out an acoustical review of a facility, there are several primary fields to analyze and report. These include, but are not limited to, HVAC noise & vibration control, interior sound isolation, and reverberant noise control. Criteria must be established for these fields. It is important to note that the fields included in an acoustical review are dependent on scoping for each individual facility project.

Calculations must be made for each of these fields to test for criteria compliance. The methods for completing these calculations must be determined by the engineer/consultant (computer software calculations, handwritten calculations, or similar). There are sample calculations and best practice techniques listed in Appendix A through Appendix C of this document.

2-4 DELIVERABLES FOR ACOUSTICAL DESIGN REVIEWS.

Documents that list the analysis results must be created by the engineer/consultant to report the acoustical review. At minimum, the deliverable must report the following for each acoustical field that is being reviewed:

1. Establish and list the acoustical design criteria. The standards used must be cited in the deliverable.
2. Supporting calculations and results of the analysis must also be included in the deliverable.
3. Provide recommendations for any fields that do not meet the established criteria. This is not needed if the facility has full criteria compliance.

The specific number of reports needed throughout the design process is dependent on the scope for each facility. For guidance in preparing an acoustical analysis report, please refer to the Sample Acoustical Analysis Report which can be found on the Whole Building Design Guide (https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-450-01).

2-5 DELIVERABLES FOR ACOUSTICAL MEASUREMENTS.

If on-site acoustical measurements are required at a facility, provide a report that outlines the corresponding measurement findings. The scope of the measurements is dependent on each individual facility. At minimum, the deliverable must report the following for each acoustical field that was measured:

1. Establish the methods used for the measurements. This must include the equipment used, measurement locations, and compliance with the measurements criteria listed in Chapter 8 of this document.
2. Report the existing conditions and list the acoustical design criteria for the fields that were analyzed. The standards used must be cited in the deliverable.
3. Report the measurement results for each analyzed field and compare to the existing conditions. These can be listed in tables, charts, or similar.
4. Provide recommendations for any fields that do not meet the established criteria. This is not needed if there were no deficiencies indicated in the measurement results.

The specific number of measurement reports required is dependent on the scope for each facility.

CHAPTER 3 NOISE CRITERIA

3-1 GENERAL.

This chapter includes data and discussions on generally acceptable indoor noise criteria for acceptable living and working environments. This criterion can be used to evaluate the suitability of existing indoor spaces and spaces under design.

3-2 NOISE CRITERIA IN BUILDINGS.

3-2.1 Evaluation Criteria.

Noise Criteria (NC) and Room Criterion (RC) are two widely recognized criteria used in the evaluation of the suitability of intrusive mechanical equipment noise into indoor occupied spaces. The Speech Interference Level (SIL) is used to evaluate the adverse effects of noise on speech communication.

3-2.2 NC Criteria.

For typical facility spaces (refer to Table 2-1 and Table 2-2 of UFC 3-101-01). Table 3-1 in this document must be used for spaces not covered under the referenced UFC 3-101-01 tables.

3-2.3 Strict Interpretation.

The sound levels of the mechanical equipment or ventilation system under design must be equal to or be lower than the selected NC target curve in all octave bands to meet the design goal. An estimation of the NC Level within a given space can be made using the following procedure:

1. Use Fig 3-1 to plot the sound pressure levels (dB) at each octave band frequency. The levels used can either be measured or calculated data. Methods for calculating sound pressure levels from known sound power levels are discussed in Appendix C.
2. Follow paragraph 3-2.2 Tangent Rating Procedure to determine the NC level curve for the space.

Refer to ASHRAE Applications (2019) Chapter 49 for further analysis and procedures. Additionally, Chapter 49 provides a Balanced Noise Criteria Method (NCB) used to specify or evaluate room noise.

Table 3-1 Design Guidelines for HVAC-related Background Sound in Rooms

Space Types		NC Design Goal	Approximate Overall dBA	Sound Pressure Level dBC
Rooms with Outdoor Noise Intrusion	Traffic Noise	N/A	45	70
	Aircraft Flyovers	N/A	45	70
Office Buildings	Executive & Private Offices	30	35	60
	Conference Rooms	30	35	60
	Teleconference Rooms	25	30	55
	Open-plan Offices	40	45	65
	Corridors & Lobbies	40	45	65
Courtrooms	Unamplified Speech	30	35	60
	Amplified Speech	35	40	60
Performing Arts Spaces	Concert & Recital Halls	20	25	50
	Music Teaching Studios	25	30	55
	Music Practice Rooms	30	35	60
Hospitals & Clinics	Patient Rooms	30	35	60
	Wards	35	40	60
	Operating & Procedure Rooms	35	40	60
	Corridors & Lobbies	40	45	65
Laboratories	Testing/Research w/ minimal speech	50	55	75
	Extensive speech & phone use	45	50	70
	Group Teaching	35	40	60
Places of Worship	General assembly w/ critical music program	25	30	55

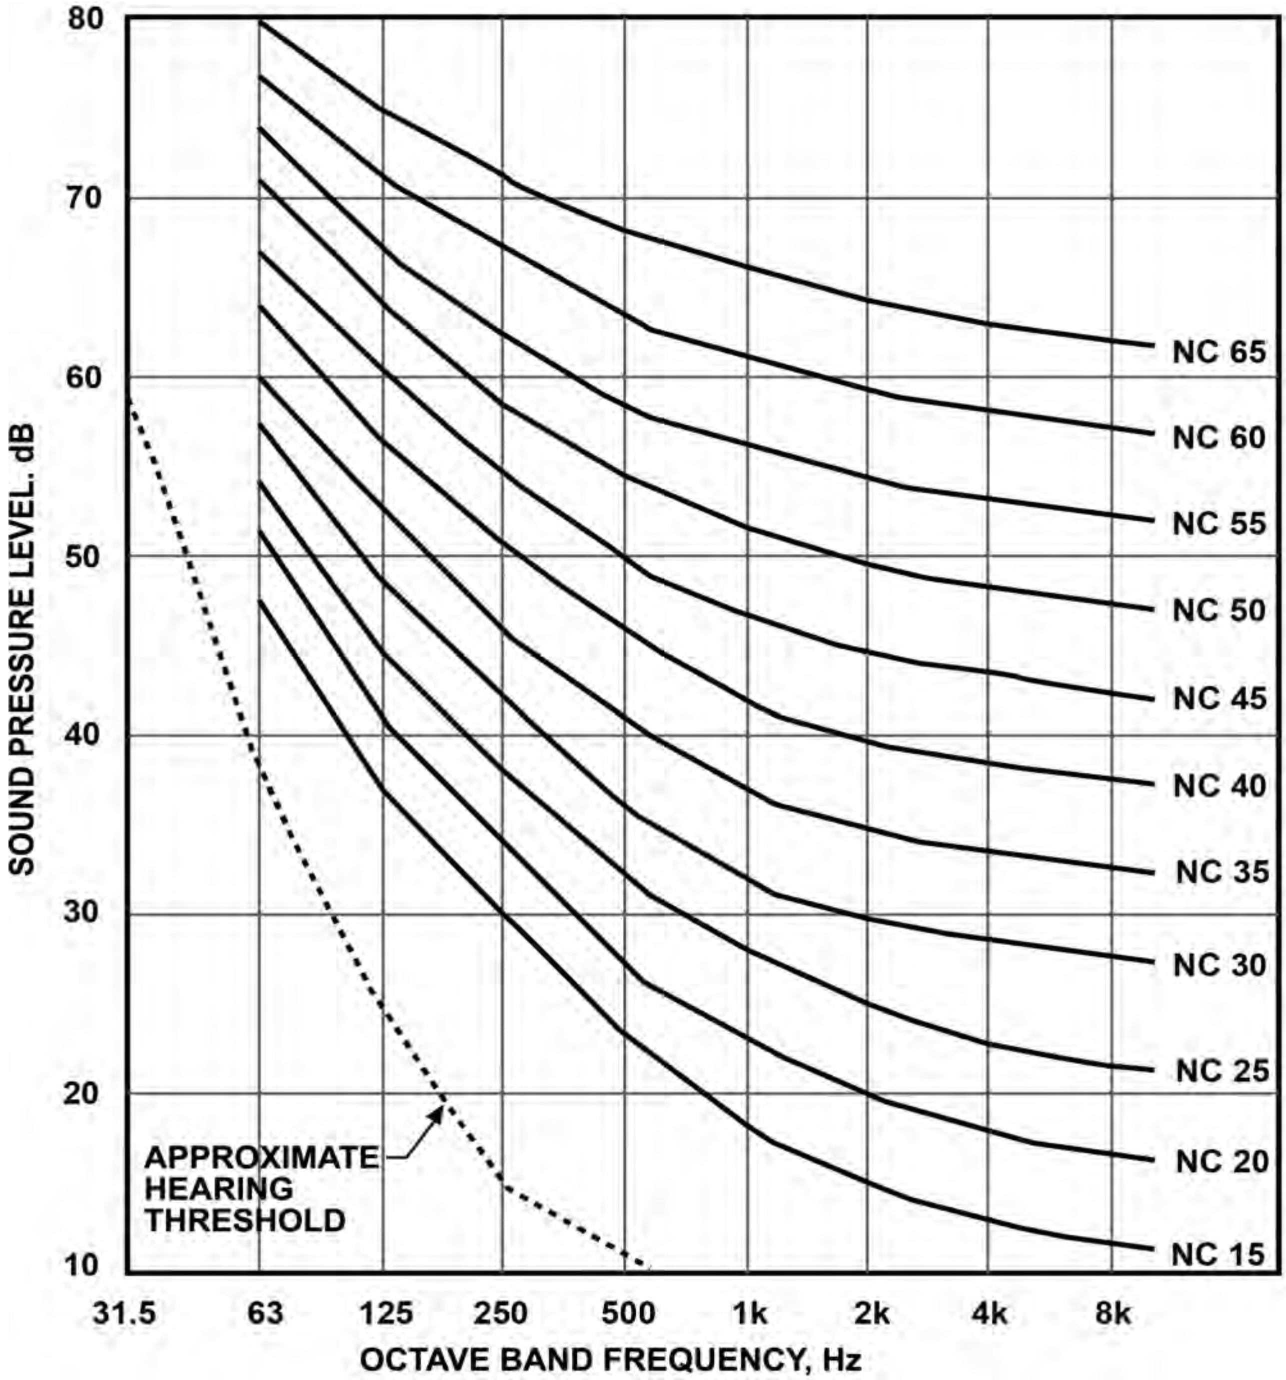
	Large Lecture Hall w/ speech amplification	30	35	60
	Large Lecture Hall w/o speech amplification	25	30	55
	Libraries	30	35	60
Indoor Stadiums/ Gymnasiums	Gymnasiums and Natatoriums	45	50	70
	Large-seating-capacity Spaces w/ speech amplification	50	55	75

3-2.4 Noise-Criterion (NC) Curves.

Figure 3-1 presents the NC curves. NC curves have been used to set or evaluate suitable indoor sound levels resulting from the operation of building mechanical equipment. These curves give sound pressure levels (SPLs) as a function of the octave frequency bands. The curves within this total range may be used to set desired noise level goals for almost all normal indoor functional areas.

Figure 3-1 Noise Criterion (NC) Curves.



Reprinted with permission from the 2019 ASHRAE Handbook, HVAC Applications

3-2.5 TANGENT Rating Procedure.

NC: Noise Criteria Method. The NC method for rating noise (described in Chapter 8 of the 2017 ASHRAE Handbook-Fundamentals) has been used for more than 50 years. It is a single-number rating that is somewhat sensitive to the relative loudness and speech interference properties of a given noise spectrum. The method consists of a family of criterion curves, shown in Figure 3-2, extending from 63 to 8000 Hz, and a tangency rating procedure. The criterion curves define the limits of octave band spectra that must not be exceeded to meet occupant acceptance in certain spaces. The rating is expressed as NC followed by a number (in example, NC 40). The octave mid-band frequency of the point at which the spectrum is tangent to the highest NC curve must also be reported (in example NC 43 [4k Hz]). The NC values are formally defined only in 5 dB increments, with intermediate values determined by discretionary interpolation. Widely used and understood, the NC method is sensitive to level but has the disadvantage that the tangency method used to determine the rating does not require that the noise spectrum precisely follow the balanced shape of the NC curves. Thus, sounds with different frequency content can have the same numeric rating, but rank differently based on sound quality. With the advent of VAV systems, low-frequency content (in other words, below the 63 Hz octave band) is prevalent, and the NC rating method fails to properly address this issue (Ebbing and Blazier 1992). Consequently, if the NC method is chosen, sound levels at frequencies below 63 Hz must be evaluated by other means.

In HVAC systems that do not produce excessive low-frequency noise and strong discernible pure tones, the NC rating correlates relatively well with occupant satisfaction if sound quality is not a significant concern. NC rating is often used because of its simplicity.

Figure 3-2 Noise Criterion (NC) Curves Tangent Plot.

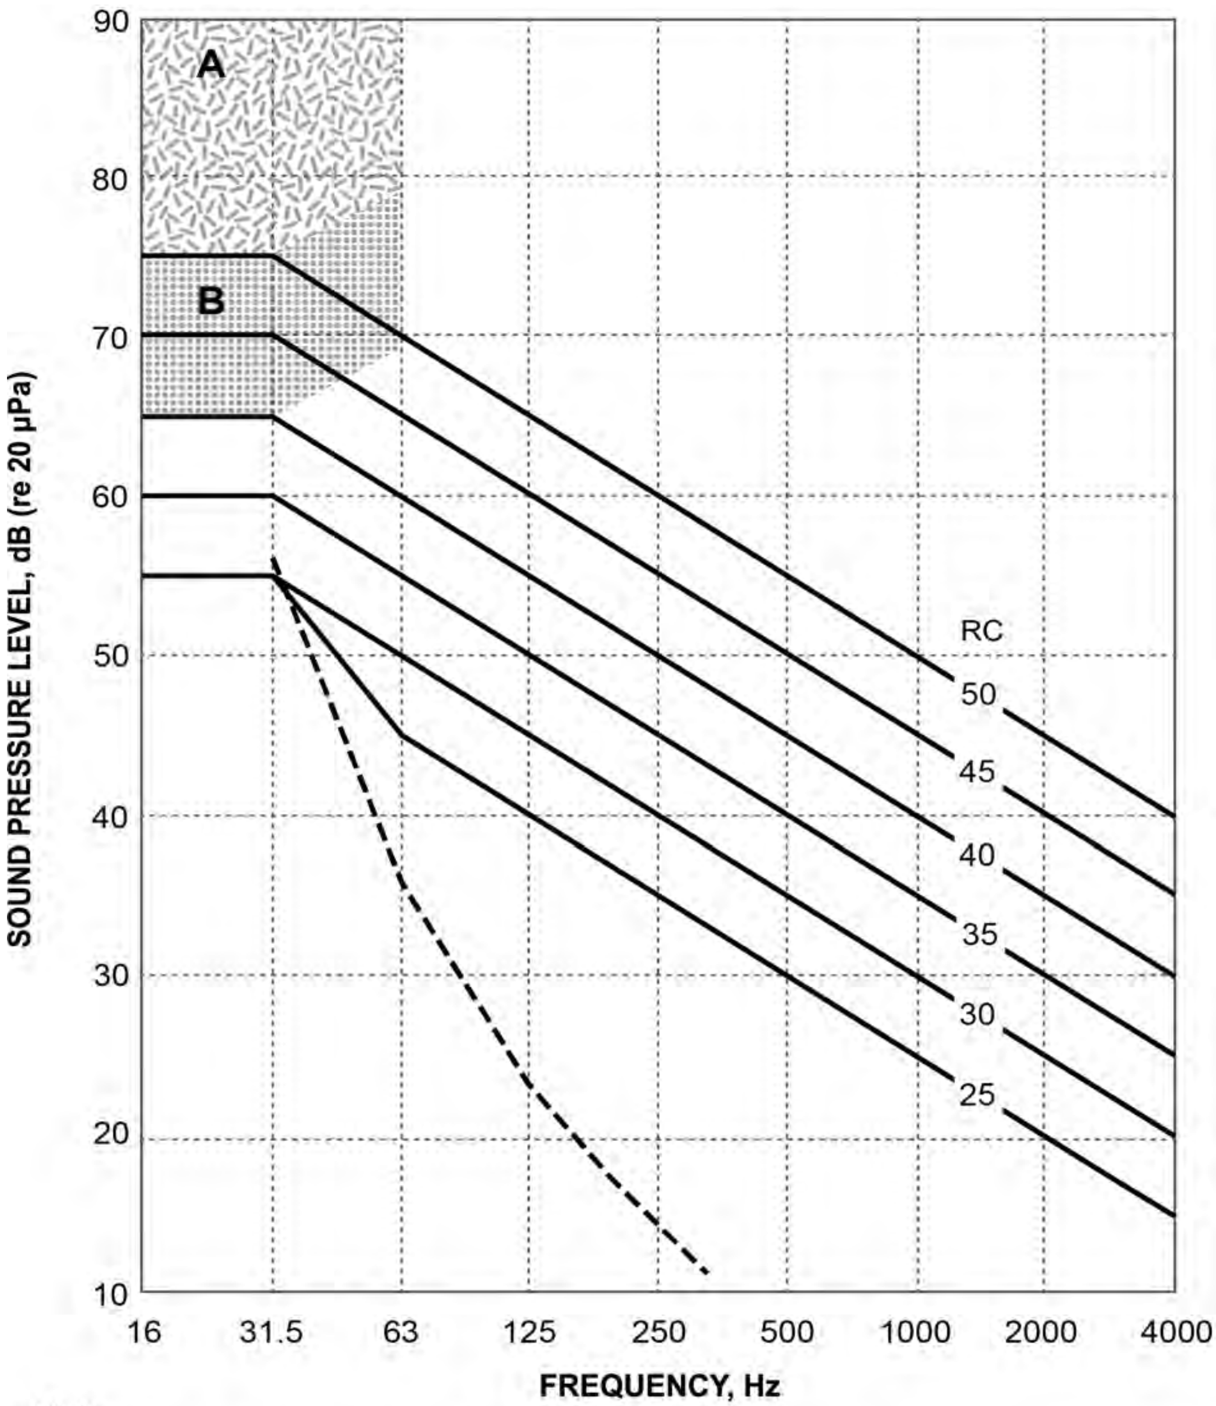
Hz	31.5	63	125	250	500	1000	2000	4000	8000
dB	64	60	49	42	45	45	42	43	37

Figure 3-3 Fig 3-3 Room Criterion (RC) Curves, Mark II



Note:

- Noise levels for lightweight wall and ceiling constructions:
  - In shaded region B are likely to generate vibration that may be perceptible. There is a slight possibility of rattles in light fixtures, doors, windows, etc.
  - In shaded region A have a high probability of generating easily perceptible noise-induced vibration. Audible rattling in light fixtures, doors, windows, etc. may be anticipated.

Reprinted with permission from the 2019 ASHRAE Handbook, HVAC Applications

3-3 ROOM CRITERION (RC) CURVES.

3-3.1 Evaluation.

Figure 3-3 presents the Room Criterion (RC) curves. RC curves, like NC curves, are currently being used to set or evaluate indoor sound levels resulting from the operation of mechanical equipment.

The evaluation of the RC curves is different than that for the NC curves. ASHRAE HVAC Applications (2019), Chapter 49 provides the RC Mark II method for RC analysis. The RC Mark II method has three parts:

1. A family of criterion curves (Figure 3-2)
2. A procedure for determining the RC numerical rating and the noise spectral balance (quality)
3. A procedure for estimating occupant satisfaction when the spectrum does not have the shape of an RC curve (quality assessment index)

Refer to Appendix C-14 for a detailed example of the RC Mark II rating procedure.

3-3.2 Rating.

The rating is expressed as RC followed by a number and a letter (in example, RC 35[N]). The number is the arithmetic average rounded to the nearest integer of sound pressure levels in the 500, 1000, and 2000 Hz octave bands (the main speech frequency region) and is known as the preferred speech interference level (PSIL). The letter is a qualitative descriptor that identifies the sound's perceived character: (N) for neutral, (LF) for low-frequency rumble, (MF) for midfrequency roar, and (HF) for high-frequency hiss. There are also two subcategories of the low-frequency descriptor: (LFB), denoting a moderate but perceptible degree of sound-induced ceiling/wall vibration, and (LFA), denoting a noticeable degree of sound-induced vibration.

Also indicated on the RC curves (Fig 3-3) are two regions where low frequency sound, with the octave band levels indicated, can induce feelable vibration or audible rattling in light weight structures. *Refer to ASHRAE Applications (2019) Chapter 49 for procedure in determining the RC Mark II rating for a system.*

3-4 SPEECH INTERFERENCE LEVELS.

The speech interference level (SIL) of a noise is the arithmetic average of the SPLs of the noise in the 500-, 1000-, 2000- and 4000-Hz octave bands. The approximate conditions of speech communication between a speaker and listener can be estimated from Table 3-2 when the SIL of the interfering noise is known. Table 3-2 provides “barely acceptable” speech intelligibility, which implies that a few words or syllables will not be understood but that the general sense of the discussion will be conveyed or that the listener will ask for a repetition of portions missed.

Table 3-2 Speech Interference Levels (SIL) That Permit Barely Acceptable Speech Intelligibility at the Distances and Voice Levels Shown

Distance (ft.)	Voice Level			
	Normal	Raised	Very Loud	Shouting
1/2	74	80	86	92
1	68	74	80	86
2	62	68	74	80
4	56	62	68	74
6	53	59	65	71
8	50	56	62	68
10	48	54	60	66
12	46	52	58	64
16	44	50	56	62

SIL is arithmetic average of noise levels in the 500-, 1000-, 2000-and 4000-Hz octave frequency bands. SIL values apply for average male voices (reduce values 5 dB for female voice), with speaker and listener facing each other, using unexpected work material. SIL values may be increased 5 dB when familiar material is spoken. Distances assume no nearby reflecting surface to aid the speech sounds.

The quality of telephone usage is related to SIL approximately as follows:

SIL Range (dB) for Telephone Usage

- 30-45 Satisfactory
- 45-60 Slightly difficult
- 60-75 Difficult
- Above 75 Unsatisfactory

3-5 LIMITATIONS.

The indoor noise criteria considered above assume that the noise is almost continuous and of a steady nature (not enough modulating or fluctuating up and down in level or frequency to attract attention), and there are no raucous, unpleasant sounds or strong tonal sounds. If any of these assumptions are not met, the sound level criteria must be even lower than the criteria normally considered applicable. The criteria given above is intended to be illustrative; any occupied or habitable area not identified in the list can be assigned to one of these categories based on similarity to the types of areas already listed. Generally, where a range of criteria is given, the lower values must be used for the more critical spaces in the category and for non-government areas outside the control of the facility; the higher of the range of criteria may be used for the less critical spaces in the category. Some short-term infrequent sounds (such as the weekly testing of a fire pump or an emergency power generator) may be allowed to exceed normal criteria in relatively noncritical areas if the normal functions of these areas are not seriously restricted by the increase in noise.

.

CHAPTER 4 VIBRATION CONTROL

4-1 GENERAL.

This chapter includes data and requirements of indoor vibration criteria for acceptable living and working environments. This criterion can be used to evaluate the suitability of existing indoor spaces and spaces under design.

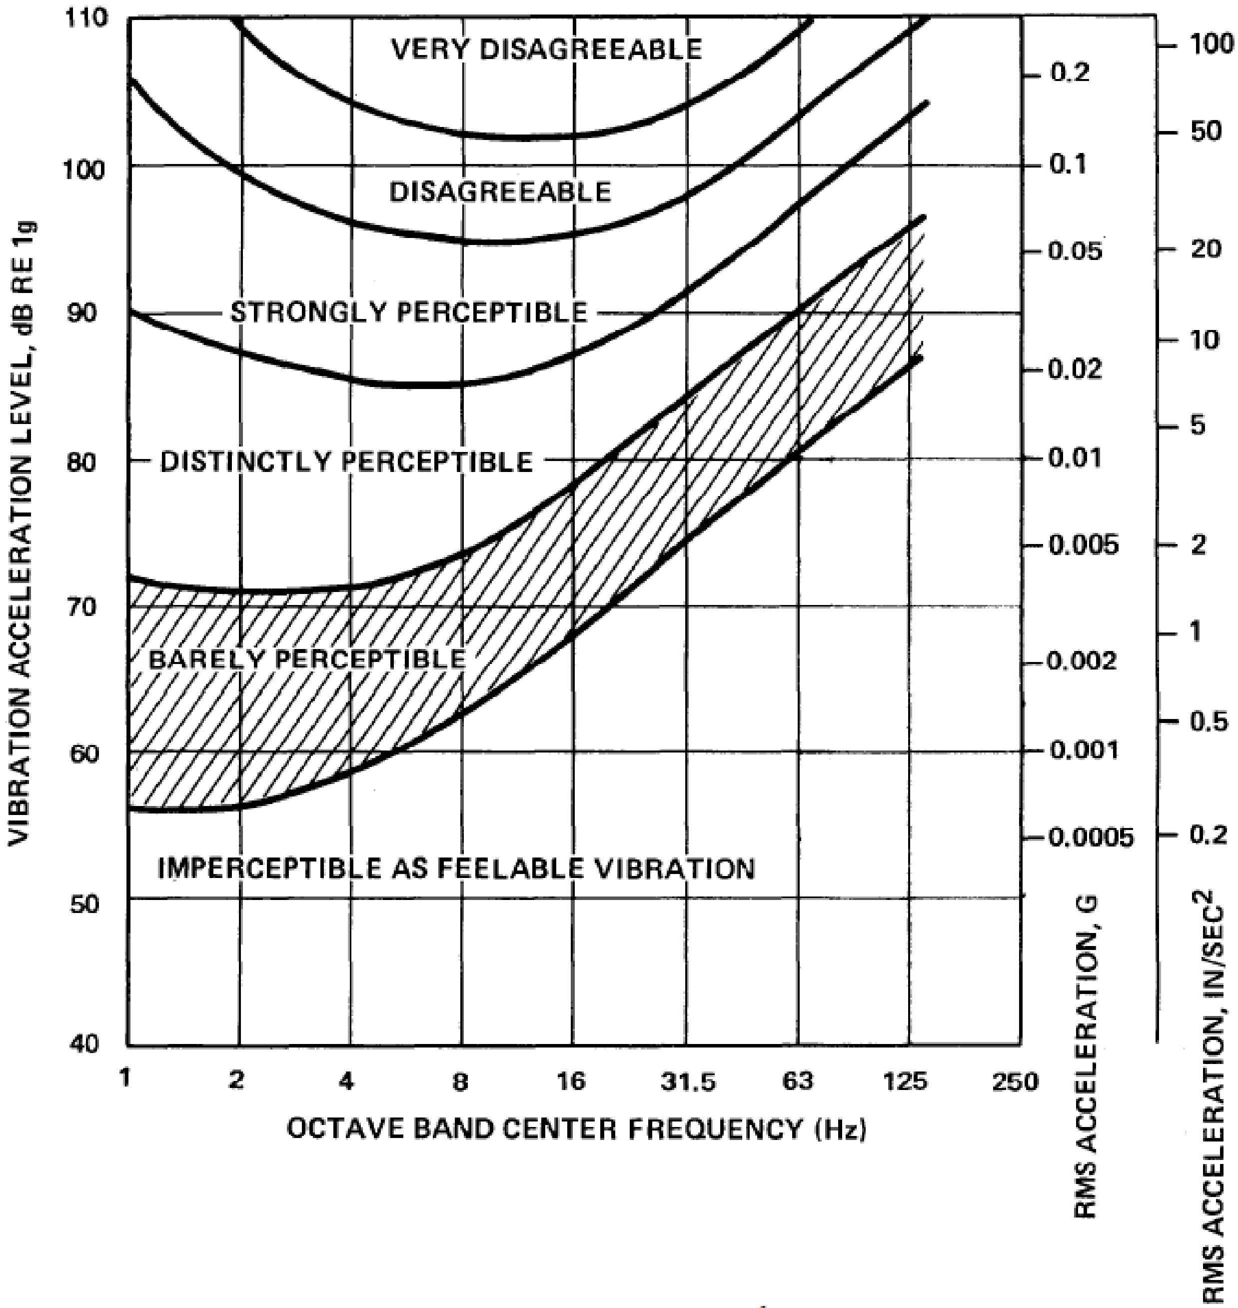
4-2 VIBRATION CRITERIA IN BUILDINGS.

Structural vibration in buildings, which results in feelable vibration, produces structural or superficial damage of building components, or interferes with equipment operation is unacceptable. In addition. large building components that vibrate can produce unacceptable sound levels.

4-3 VIBRATION CRITERIA FOR OCCUPANTS.

Figure 4-1 shows the approximate occupant response to building vibration levels. An approximation of the “threshold of sensitivity” of individuals to feelable vibration is shown by the shaded area of Figure 4-1, labeled “barely perceptible.” Other typical responses of people to vibration are indicated by the other zones in Figure 4-1. These reactions or interpretations may vary over a relatively wide range for different individuals and for different ways in which a person might be subjected to vibration (standing, seated, through the fingertips). The choice of a vibration criteria, for annoyance due to feelable vibration, will be determined by the usage of the space and the perceived sensitivity of the occupants. There will likely not be a problem with perceptible vibration when levels are 6 to 8 dB are below the “barely perceptible” range of Figure 4-1.

Figure 4-1 Approximate Sensitivity - Response of People to Feelable Vibration

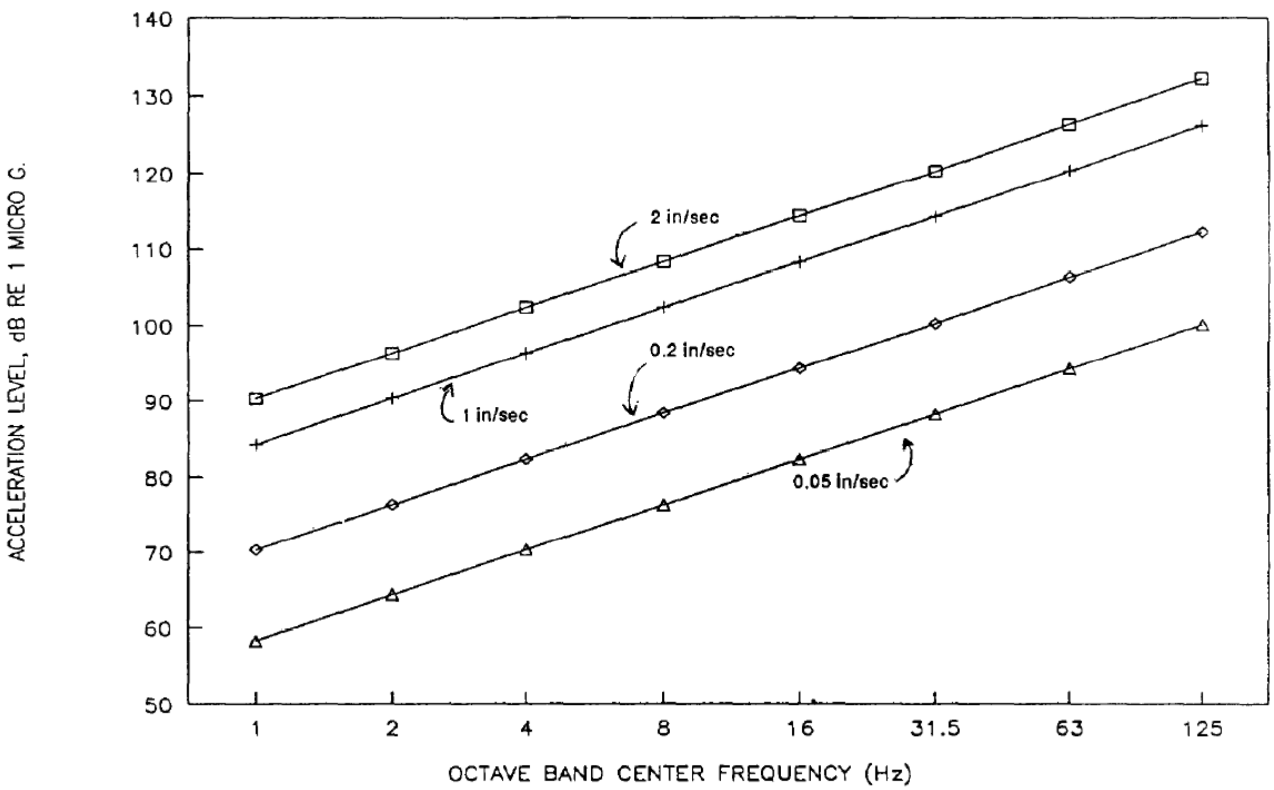


4-4 VIBRATION CRITERIA FOR BUILDING STRUCTURES.

A structural vibration velocity of 2.0 in/sec (0.0508 m/sec) has commonly been used as an upper safe limit for building structures, and vibrations above this value will have adverse environmental impact. A vibration velocity of 1.0 in/sec (0.0254 m/sec) must be used as a normally safe vibration upper limit with respect to structural damage. Vibrations with a velocity level greater than 1.0 in/sec must be avoided and measures must be implemented to reduce vibrations to 1.0 in/sec or less. Even with a vibration level of 1.0 in/sec (0.0254 m/sec) superficial damage may occur in isolated instances.

Superficial damage can consist of small cracking in brittle facades such as plaster. To ensure that the possibility of superficial damage is minimized a vibration criterion of 0.2 in/sec (0.00508 m/sec) has been recommended. And finally, for very old structures an even lower level of 0.05 in/sec (0.00127 m/sec) is recommended. The way the level is to be determined is a function of the type of vibration expected or experienced. For continuous vibration the RMS level must be used. For impulsive vibration the Peak value is to be used. See Appendix B for a discussion of Peak and RMS vibration. On Figure 4-2 the vibration limits mentioned above have been plotted in terms of acceleration level in dB re 1 micro-G.

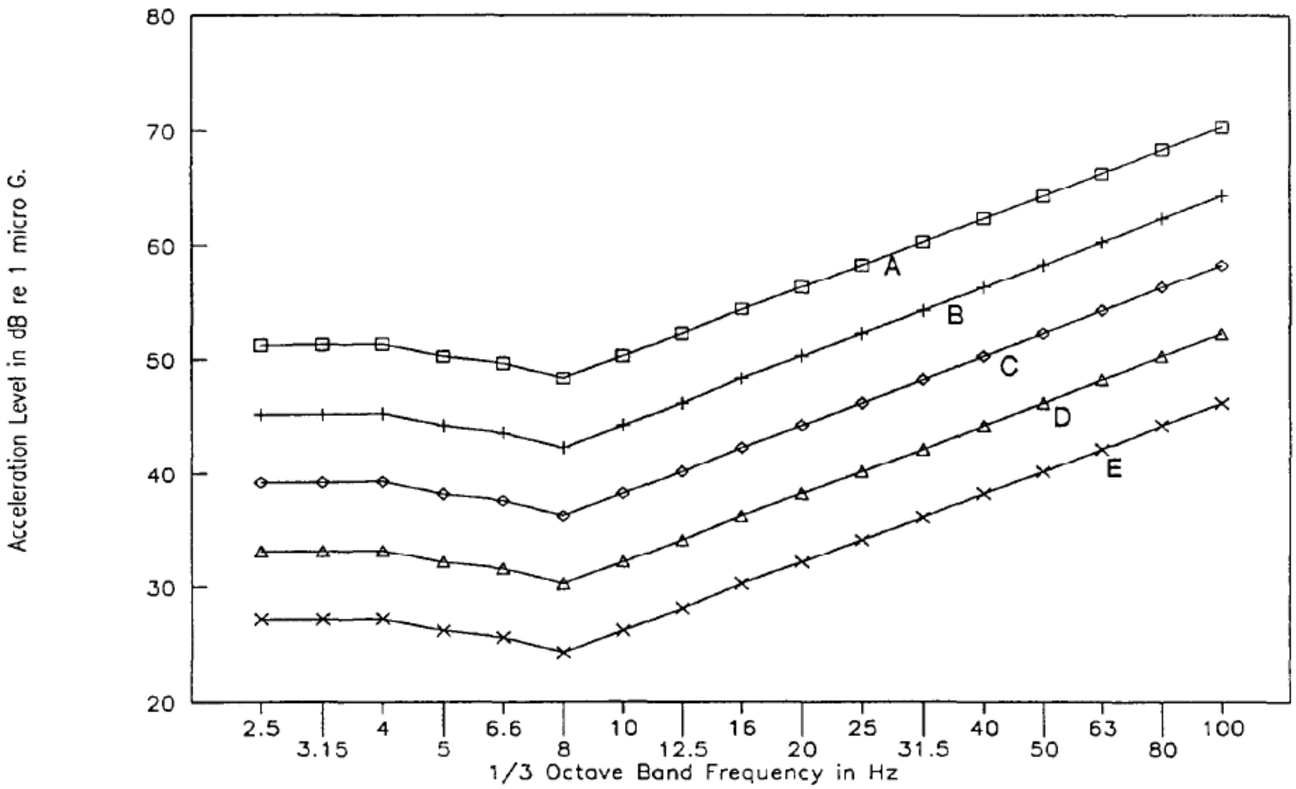
Figure 4-2 Vibration Criteria for Damage Risk to Buildings.



4-5 VIBRATION CRITERIA FOR SENSITIVE EQUIPMENT.

Building vibration may be disturbing to the use or proper operation of vibration-sensitive equipment, such as electron microscopes and other special chemical, medical, or industrial instruments or processes. Figure 4-3 shows vibration criteria for some sensitive equipment types. To achieve these low-level vibration levels special building construction, mechanical equipment selection and isolation, and vibration isolation for the sensitive equipment are required.

Figure 4-3 Vibration Criteria for Sensitive Equipment in Buildings.

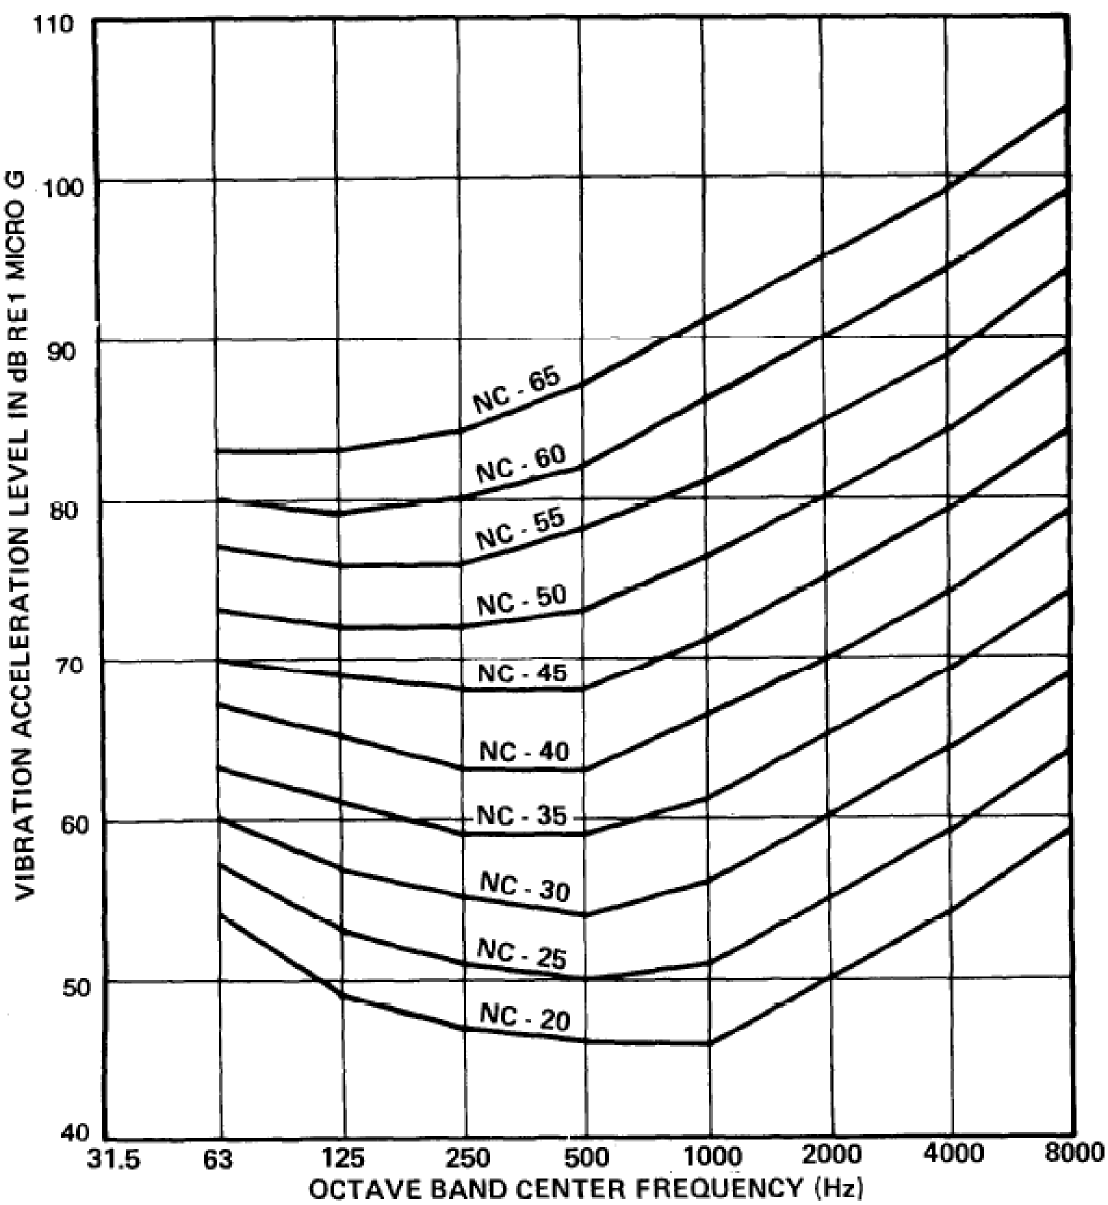


Note:
a. 100 X Microscopes.
b. 500 X Microscopes.
c. 1,000 X Microscopes.
d. Electron Beam Microscopes to 0.3 micrometer geometries.
e. Anticipated Adequate for future low submicron geometries.

4-6 VIBRATION CRITERIA FOR SOUND CONTROL.

Vibrating building components will produce sound radiation which may be unacceptable. Figure 4-4 shows “NC-equivalent” sound level curves as a function of acceleration level of a large surface. These NC-equivalent curves show the vibration acceleration levels of a large vibrating surface (such as a wall, floor, or ceiling of a room) that will produce radiated sound having approximately the octave band sound pressure levels of the NC curves (shown earlier in Figure 3-1).

Figure 4-4 Vibration Acceleration Levels of a Large Vibrating Surface that Will Produce Radiated Sound Levels into a Room Approximating the Sound Levels of the NC Curves



This Page Intentionally Left Blank

CHAPTER 5 SOUND ISOLATION BETWEEN ROOMS

5-1 OBJECTIVE.

This chapter provides data and procedures for estimating the changes in sound levels as one follows the "energy flow" path from a sound source to a receiver, through building components, such as walls, floors, doors and similar items. First, the sound pressure levels in the room containing the source drop off as one moves away from the source. Then, at the walls of the room, some sound is absorbed, some is reflected back into the room, and some is transmitted by the walls into the adjoining rooms (this also occurs at the floor and ceiling surfaces). The combined effects of this absorption, reflection, and transmission are the subject of this chapter.

5-2 SOUND TRANSMISSION LOSS (TL) AND SOUND TRANSMISSION CLASS (STC).

With the knowledge of the acoustical isolation provided by walls and floors, it is possible to select materials and designs to limit noise intrusion from adjacent mechanical equipment rooms to acceptable levels. The degree of sound that is transmitted is influenced by the noise isolation properties of the demising construction, the area of the demising wall, floor or ceiling and the acoustical properties in the quiet room. Definitions for Transmission Loss (TL) and Sound Transmission Class (STC) are listed below. See Appendix C for additional information on sound transmission.

- Transmission Loss (TL): The TL of a wall is the ratio, expressed in decibels, of the sound intensity transmitted through the wall to the airborne sound intensity incident upon the wall.
- Sound Transmission Class (STC): A one-number weighting of transmission losses at various frequencies used to rate partitions, doors, windows, and other acoustic dividers in terms of their relative ability to provide privacy against intrusion of speech or noise.

5-3 SOUND TRANSMISSION LOSS CRITERIA FOR INTERIOR PARTITIONS.

Refer to UFC 3-101-01 (Table 2-1 and Table 2-2) for sound transmission criteria of partitions and doors at typical spaces that must be followed. In the case where criterion is dependent on the privacy requirements of the occupants, Table 5-1 in this document must be used to determine the appropriate STC design criteria for rooms of varied privacy levels. When rooms of differing privacy levels are adjacent to each other, the higher of the two STC requirements must be used at the dividing partition.

Table 5-1 STC Requirements based on Room Privacy Level

Room Privacy Level	Typical Adjacency	Sound Isolation Requirement
Private	Occupied Space	STC 45 - 50
	Corridor	STC 40 - 45
	Stairwell	STC 45 - 50
Confidential	Occupied Space	STC 50 - 55
	Corridor	STC 45 - 50
	Stairwell	STC 50 - 55
Classified	Occupied Space	STC 50 - 55
	Corridor	STC 50 - 55
	Stairwell	STC 50 - 55
Collaborative/Multi-use	Occupied Space	STC 35 - 40
	Corridor	STC 35 - 40
	Stairwell	STC 35 - 40
Mechanical Room	Occupied Space	STC 60 - 65
Restroom	Occupied Space	STC 50 - 55

5-4 DEFINITIONS OF ROOM PRIVACY LEVEL CATEGORIES.

The following lists defines each of the Room Privacy Levels listed in Table 5-1 and includes examples of typical spaces in each category.

1. Private: this covers rooms where moderate speech privacy is required. Speech intelligibility and concentration are preferred, but not critical for these rooms. Typical "Private" spaces such as private offices, exam rooms, group study rooms, and similar.
2. Confidential: this covers rooms where critical speech privacy is required. Speech intelligibility and concentration are of high priority in these rooms

and are essential for the occupants. Typical "Confidential" spaces can include conference rooms, classrooms, consultation rooms, and similar.

3. Classified: this covers rooms where critical speech privacy is required. Speech intelligibility and concentration are of critical priority in these rooms and are essential for the occupants. Typical "Classified" spaces can include conference rooms, classrooms, consultation rooms, and similar. with teleconferencing capabilities.

4. Collaborative/Multi-use: these are occupiable spaces where speech privacy is not critical. These rooms are generally occupied by multiple occupants. Typical "Collaborative/Multi-use" spaces include open offices, research laboratories, and similar.

5. Mechanical Room: any room designated for mechanical equipment servicing the HVAC systems of the building. The requirements must be followed for any room, housing air handler units, chillers, or other equipment with significant noise generation.

6. Restroom: any single or multi-occupant restrooms where plumbing noise is expected.

This Page Intentionally Left Blank

CHAPTER 6 AIRBORNE SOUND CONTROL

6-1 INTRODUCTION.

This chapter draws together much of the factual content of the earlier chapters and presents a systematic approach for evaluating noise data and arriving at design decisions for controlling reverberation within noise-critical rooms, as well as the noise of electrical and mechanical equipment transmitted between room within a building and to other nearby structures. The chapter concludes with discussions of the various noise control treatments that are practical and available for solution of equipment noise problems. Almost all sound analysis problems can be divided into considerations of the; 1) Source; 2) Path and 3) Receiver Noise and vibration for specific problems may be reduced by using the following system approach:

1. Reduce noise and vibration at the source by using quieter equipment or noise-reducing modifications.
2. Prevent noise transmission by using barriers and prevent vibration transmission by using vibration isolators.
3. Relocate the receiver.

Sources of mechanical equipment sound are provided in Appendix B. Criteria for acceptable sound is given in Chapter 3. Chapter 7 provides a similar discussion for sound transmitted via air distribution systems in buildings. Considerations for vibration control of mechanical equipment are given in Chapter 8.

6-2 REVERBERENT NOISE CONTROL.

The interior acoustics of a room often refers to the overall noise within the space and the effects it has on the occupants. One driving factor of the “acoustical quality” within a space in the reverberant noise levels. When sound travels within a room, the energy can either be redirected by a reflective surface or distributed by diffusive/absorptive materials. When a room has little to no absorptive or diffusive surface materials, reverberant noise buildup can occur. This will lead to lower speech intelligibility within the room. To counteract this, a noise-critical room must be strategically designed with finishes and treatments to prevent excessive reverberant noise buildup.

Reverberation time (RT_{60}) is a metric used to quantify the reverberant noise within a room, measured in seconds. RT_{60} is the amount of time (in seconds) it takes for a given noise source to dissipate 60 dB across each frequency band. It is important to note that sound from the given source can take longer to dissipate at different frequencies. An overall RT_{60} can be determined from a weighted average of the RT_{60} at each band.

6-2.1 Reverberation Time (RT_{60}) Design Criteria.

The RT_{60} requirements for noise-critical spaces are a factor of the volume of the room and the intended application. If speech intelligibility is critical for a given space (in other words, classrooms, teleconferencing rooms, and similar.), the space must be designed to meet a specific overall RT_{60} criteria. Refer to UFC 3-101-01 (Table 2-1 and Table 2-2) for reverberation time criteria of typical facility spaces which must be followed.

6-3 INDOOR SOUND ANALYSIS.

6-3.1 Suggested Approach.

Essentially a flow diagram of sound from source to receiver, following certain prescribed steps.

1. The SPL or PWL values are obtained for each noise source (from Appendix B or other available source date).
2. The acoustic conditions inside the MER source room and in the receiving rooms are calculated.
3. The SPL values of all equipment sources are extrapolated to the interior MER walls and surfaces of interest (Appendix C).
4. Noise criteria are selected for all the receiving rooms of interest (Chapter 2).
5. Wall and floor designs are selected to permit acceptable amounts of equipment noise into the adjoining spaces (refer to Chapter 5 and APPENDIX C for additional guidance.)
6. Additional material in paragraph C-10.2.4 is considered if special noise control treatments are required. The procedures offered here are simple and relatively easy to follow, while designs are still on paper. Remedial treatments are difficult, expensive, time-consuming, and frequently less effective after the completed designs are fixed in steel and concrete. In some cases, it is found that the normally used walls or floors are not adequate, and improved versions must be substituted. Three additional factors must be considered in an overall acoustic design; these factors are aimed at finding the best mixture of practicality and total economy. One involves the possibility of using noise specifications to limit the amount of noise produced by noise-dominating equipment, the second involves use of noise control treatments on particularly noisy equipment, and the third involves building layout and equipment arrangement.

6-3.2 Use of Noise Specifications.

The use of noise specifications is presented in Chapter 7. It must be kept in mind that the noise levels quoted represent the 80- to 90-percentile range of the data studied and it can reasonably be expected that many suppliers of equipment can furnish products that are a few decibels quieter without burdening the job with excessive costs. Therefore, when it becomes apparent that one or two pieces of equipment stand out above all others in noise levels and dictate the need for unusually heavy walls or floors, it is good engineering to prepare noise-level specifications on those pieces of equipment and require that they be brought under reasonable noise limits. When this approach is used successfully, reduced noise can be achieved, and less expensive building designs can be used. It would be reasonable, first, to specify sound levels that range about 3 dB below the levels quoted in the manual. Such specifications would not seriously limit the availability of equipment, but they would weed out the noisiest equipment.

6-3.3 Use of Noise Control Treatments.

This subject is discussed in paragraph C-10.2.4. For some types of equipment, a noise control treatment may be more practical and less expensive than the problems of accommodating the untreated noisy equipment with strengthened building structures.

6-3.4 Building Layout Alternatives.

Many noise problems can be reduced during the design stage. In the building layout, critical spaces must be moved away from the mechanical rooms and, where possible, “buffer zones” be placed between the noisy and the quiet rooms. In the mechanical equipment rooms (MER), the noisiest equipment must be placed away from the common walls that join the critical rooms; and when reverberant sound levels pervade the entire MER and control the design, sound absorption may be applied to reduce those reverberant levels.

6-4 OUTDOOR SOUND PROBLEM AND ANALYSIS.

The basic procedure here, also, is to follow the sound path from the source to the receiver, applying certain adjustments and calculations along the way.

1. The SPL or PWL values must be determined for each source that can radiate noise outdoors.
2. The outdoor sound propagation factors of distance, air absorption, and anomalous excess attenuation must be applied for the prevailing temperature and humidity conditions.
3. Proper adjustments must be made for terrain, vegetation, and barrier effects encountered by the sound.
4. All the pertinent data are collected and summarized, and the outdoor and indoor SPLs are estimated for the various neighbors of interest.
5. The expected neighbor reaction to the outdoor noise is estimated and the expected indoor SPLs are compared against the indoor noise criterion applicable to the neighbor’s building.
6. Available noise control treatments and operational changes are considered if noise reduction is required to achieve satisfactory response of the neighbors to the outside noise.

This Page Intentionally Left Blank

CHAPTER 7 MECHANICAL NOISE SPECIFICATIONS

7-1 OBJECTIVE.

Once noise and vibration control has been determined it is then necessary to specify the performance and materials for the noise control treatments. This chapter covers specifications for specialized acoustical products commonly used in building mechanical systems. Manufacturers can also provide guidance for acoustical products. Commonly used noise control products include attenuators in ducting systems and vibration isolation products. In addition, a noise level limit may be imposed on the equipment to be used, in which case it is the responsibility of the manufacturer to provide suitable noise or vibration control which will meet the criteria.

7-2 GENERAL CONSIDERATION.

All noise control specifications must include some common information. This includes:

- A statement as to the purpose for the noise control treatment. Although it may not be the responsibility of the supplier to meet the overall objective, if they know the overall objective, they may be able to provide guidance on the application of their product to aid in achieving the overall objective.
- Materials of construction that will be acceptable. This can be stated specifically, or it can be given in general terms.
- Conditions under which the material or items will be used. This mainly pertains to the environmental conditions (such as temperature, flow velocity, pressure, and similar).
- Acoustical performance that is expected. This can be the specific performance of a noise control item, or it can be the overall performance.
- How the acoustical performance is to be evaluated. This is the most important and difficult portion of any specification. This may take the form of a laboratory test or a test in the field under actual operating conditions. The references provide ASTM, ARI and ASHRAE standards commonly used to evaluate acoustical performance in the laboratory and in the field.
- What action is expected if the specified performance is not met.

7-3 PARTITIONS AND ENCLOSURES.

The performance specification of partitions and enclosures usually includes the sound isolation properties. The most common method is to specify the sound transmission loss (TL) required. The laboratory procedure is given in ASTM E90. ASTM standards E336 and E966 provide procedures for on-site evaluations of building partitions and building facades, respectively. For machinery enclosures the interior sound absorptive properties also need to be specified. ASTM standard C423 and E795 provides methods for mounting and measuring sound absorptive properties in the laboratory. ASTM standard E596 provides a laboratory method of rating the noise reduction of sound isolating enclosures. In addition, there are standards for the installation of partitions which are intended to provide sound isolation, such as ASTM E497.

7-4 ATTENUATORS AND DUCT LINING FOR DUCTED VENTILATION SYSTEMS.

Internal duct lining is prohibited. Prior to any design or construction, any consideration for its use must first be approved by exemption.

The acoustical performance for duct lining and attenuators is typically specified to be made in accordance with ASTM Standard E477. Note: this is a laboratory standard and includes insertion loss and regenerated noise (for attenuators). All suppliers of prefabricated duct attenuators are required to submit attenuator performance in accordance with this standard. In addition, many suppliers of duct attenuators will also provide guidance on how actual field installation may modify the laboratory performance.

CHAPTER 8 NOISE AND VIBRATION MEASUREMENTS

8-1 OBJECTIVE.

In the event that demonstration of compliance with noise or vibration criteria is required, sound or vibration measurements will be required. Within the scope of this manual, sound and vibration measurements and instrumentation might be involved in two types of situations: noise and vibration in buildings, and community noise or measurements. This chapter discusses these subjects.

8-2 SOUND AND VIBRATION INSTRUMENTATION.

8-2.1 Instrumentation.

Measuring sound and vibration vary widely in complexity and capability. However most sound and vibration level measurements for building mechanical equipment systems can be obtained with hand-held, battery operated meters. A basic sound level meter consists of a microphone, electronic circuits, and a display. Vibration measurements can be made with a sound level meter if the microphone is replaced with a vibration transducer. The most common vibration transducer is an accelerometer. With the use of an accelerometer the meter will display acceleration level in dB. Many sound level meters are equipped with “internal calibration” capabilities. While this is adequate for checking the internal electric circuits and display, the internal calibration does not check the operation of the microphone or accelerometer. Therefore, it is highly recommended that all sound level meter systems be equipped with a separate calibrator. Sound level calibrators generate a known sound level and vibration calibrators generate a known vibration signal. As a minimum, the sound level meter must be equipped with internal filters providing the capability octave band levels from 16 to 8,000 Hz. Many sound level meters have the capability to “A-weight” the octave band levels. The use of A-weighting is not appropriate for evaluating building mechanical systems.

8-2.2 Sound Level Meters.

The American National Standards Institute (ANSI) provides specifications for the acoustical and electrical response of sound level meters. ANSI Standard S1.4 specifies four types of sound level meters:

- Type 1 Precision (recommended for detailed analysis)
- Type 2 General Purpose
- Type 3 Survey
- Type S Special Purpose

The Type 1 Sound Level Meter has the capability to perform at least 1/1 octave and 1/3 octave frequency bands analysis, the tightest specification on frequency response, precision and stability. This meter is fitted with a microphone; it has a stable amplifier, controllable attenuators, and a meter that permits reading of sound levels over a wide range of values, such as from 30 decibels to 130 decibels sound pressure level (SPL) or more. The accuracy of the reading may be expected to be within 1 to 1.5 dB of the true SPL. This instrument also has the A-, C-, and Z- weighted filters that are held to within specified tolerances, and the meter has a “slow” and a “fast” response. At the “slow” setting, the meter in effect integrates the sound pressure level fluctuations of the last half second (approximately) and shows the “average” of that fluctuating signal. The “slow” setting is used for readings of “continuous” noise, in other words, noise that is produced by a continuing sound source without any noticeable periodic change (a fan would be considered a “continuous” source of noise, a pile drive would not). The “fast” response integrates the fluctuations of the last 1/8 second (approximately); thus, the needle jumps back and forth over a wider range of the meter face as it attempts to follow all short-term instantaneous changes. The Type 2 Sound Level Meter has slightly less stringent specifications than apply to the Type 1 meter. The A-, C-, and Z-weighted networks and the directionality limits of the microphone are slightly relaxed. The Type 3 Sound Level Meter is for general survey applications, where still less accuracy is acceptable. The Type 3 instrument is not acceptable for OSHA use, nor for any noise level application involving compliance with noise codes, ordinances, or standards. The Type S Sound Level Meter may be a simplified version of any of the Type 1, 2, or 3 instruments. It is a special purpose meter that may have, for example, Type 1 accuracy and only an A-weighted filter. In this case, it would be described as Type S1A (“S” indicates Special, “1” indicates Type 1 accuracy, and “A” indicates A-weighted filter). The Type S meter must carry a designation that describes its function (such as Type S1A or Type S2C, and similar), and must be constructed to meet the appropriate specification applicable to that special combination.

8-2.3 Octave Band Filters.

ANSI standards also exist on the frequency limits and tolerances of octave band and one-third octave band sound and vibration analyzers (ANSI S1.11). These filters are given a Class 1, 2 or 3 designations. Class 3 filters have the highest frequency discrimination and Class 1 have the lowest. It is recommended that all octave band filter sets used for the evaluation of noise in buildings, with respect to compliance with noise or vibration specifications, have a Class 2 or higher designation. For cursory evaluation a Class 1 will be sufficient.

8-2.4 Microphones.

Microphones are categorized by their frequency response, level sensitivity and directionality. Most provided microphones will provide suitable frequency response (10 to 10,000 Hz) and level sensitivity (30 to 130 dB) for the evaluation of mechanical equipment in buildings. The microphone directionality is important, however. Measurement microphones directionality is typically given as “free-field” or “random incidence”. Free field microphones are intended for use outdoors and the microphone must be aimed at the sound source under investigation. Random incidence microphones are used indoors where the reverberant sound is significant. There are adapters that can be applied to a free field microphone when used indoors.

8-2.5 Accelerometers.

Due to their small size, durability and extended frequency response, accelerometers are the most common vibration transducers. As a rule, the sensitivity of an accelerometer is directly proportional to the physical size (as such, larger accelerometers usually can measure lower vibration levels). The frequency response is inversely proportional to the sensitivity (as such, accelerometers with an extended frequency response may be limited in measuring low vibration levels.) In general, use a low-sensitivity accelerometer to measure high amplitude signals and a high-sensitivity accelerometer to measure low amplitude signals. Some accelerometers require an external power supply to operate a pre-amp that is incorporated into the accelerometer casing. There exists a large variety of accelerometers which to choose. Once the intended purpose is ascertained, a vendor/manufacturer can provide guidance on the most appropriate type and model of accelerometer to select.

8-3 MEASUREMENT OF NOISE AND VIBRATION IN BUILDINGS.

Noise measurements in buildings are commonly made either to determine if RC or NC curves have been met or to search for the cause of their not having been met. Conducting measurements after the equipment has been turned off is extremely helpful. A comparison of the measurement with and without the equipment in operation will indicate if the measurements are indicative of the equipment or another extraneous source. If the level decreases after the equipment have been turned off, then the measurements are indicative of the equipment under evaluation. If the sound level does not decrease after the equipment is turned off, then the measured level is not indicative of the equipment under evaluation. If the decrease is more than 2 dB but less than 10 dB, the measured levels after the equipment has been shut down can be subtracted from the levels with the equipment (see Appendix C). For the most accurate results, conduct these measurements at night or when the building is not in use. At these times it is easier to turn on and off equipment and extraneous sources are at a minimum.

8-3.1 Procedures.

For various indoor measurement types, the following procedures must be followed if these indoor measurement types are required for on-site testing:

- For background noise measurements, follow the guidelines from ASTM E1574
- For sound isolation measurements, follow the guidelines from ASTM E336
- For reverberant noise measurements, follow the guidelines from ASTM C423 (4.1 and 5.5)

8-4 MEASUREMENT OF NOISE AND VIBRATION OUTDOORS.

The consideration for measuring noise and vibration outdoors is identical to that for indoor measurements. The most significant factor is the environmental influence on the transmission of the sound. Environmental factors, such as wind, humidity and temperature gradients can produce significant (such as 5, 10 dB or greater) variations in the measured sound level. Therefore, it is important to document the environmental conditions at the time of the measurements. Ideally, take measurements under neutral conditions (such as no wind, cloudy overcast day).

8-4.1 Procedures.

For various outdoor measurement types, the following procedures must be followed if these outdoor measurement types are required for on-site testing.

- For outdoor noise measurements, follow the guidelines from ASTM E1014.
- For outdoor-to-indoor noise measurements, follow the guidelines from ASTM E966.

APPENDIX A BASICS OF ACOUSTICS

A-1 INTRODUCTION.

This Appendix presents the basic quantities used to describe acoustical properties. For the purposes of the material contained in this document perceptible acoustical sensations can be generally classified into two broad categories, these are:

A-1.1 Sound.

A disturbance in an elastic medium resulting in an audible sensation. Noise is by definition “unwanted sound”.

A-1.2 Vibration.

A disturbance in a solid elastic medium which may produce a detectable motion. Although this differentiation is useful in presenting acoustical concepts, sound and vibration are often interrelated. That is, sound is often the result of acoustical energy radiation from vibrating structures and, sound can force structures to vibrate. Acoustical energy can be completely characterized by the simultaneous determination of three qualities. These are:

A-1.2.1 Level or Magnitude.

This is a measure of the intensity of the acoustical energy.

A-1.2.2 Frequency or Spectral Content.

This is a description of an acoustical energy with respect to frequency composition.

A-1.2.3 Time or Temporal Variations.

This is a description of how the acoustical energy varies with respect to time. The subsequent material in this chapter defines the measurement parameters for each of these qualities that are used to evaluate sound and vibration.

A-2 DECIBELS.

The basic unit of level in acoustics is the “decibel” (abbreviated dB). In acoustics, the term “level” is used to designated that the quantity is referred to some reference value, which is either stated or implied.

A-2.1 Definition and Use.

The decibel (dB), as used in acoustics, is a unit expressing the ratio of two quantities that are proportional to power. The decibel level is equal to 10 times the common logarithm of the power ratio; or

Equation A-1. Decibel Level

$$\mathbf{dB = 10\log\frac{P_1}{P_2}}$$

Where:
dB = decibel
P_1 = absolute value of the power under evaluation (units vary)
P_2 = absolute value of a power reference quantity (same units as P_2)

In this equation P_1 is the absolute value of the power under evaluation and P_2 is an absolute value of a power reference quantity with the same units. If the power P_2 is the accepted standard reference value, the decibels are standardized to that reference value. In acoustics, the decibel is used to quantify sound pressure levels that people hear, sound power levels radiated by sound sources, the sound transmission loss through a wall, and in other uses, such as simply “a noise reduction of 15 dB” (a reduction relative to the original sound level condition). Decibels are always related to logarithms to the base 10, so the notation 10 is usually omitted. It is important to realize that the decibel is in reality a dimensionless quantity (somewhat analogous to “percent”). Therefore, when using decibel levels, reference needs to be made to the quantity under evaluation and the reference level. It is also instructive to note that the decibel level is primarily determined by the magnitude of the absolute value of the power level. That is, if the magnitude of two different power levels differs by a factor of 100 then the decibel levels differ by 20 dB.

A-2.2 Decibel Addition.

A-2.2.1 Example.

In many cases cumulative effects of multiple acoustical sources have to be evaluated. In this case the sum the individual sound levels. Decibel levels are added logarithmically and not algebraically. For example, 70 dB plus 70 dB does not equal 140 dB, but only 73 dB. A very simple, but usually adequate, schedule for obtaining the sum of two decibel values is:

When two decibel values differ by	Add the following amount to the higher value
0 or 1 dB	3 dB
2 or 3 dB	2 dB
4 to 9 dB	1 dB
10 dB or more	0 dB

Use Equation A-2 when several decibel values are to be added.

Equation A-2. Decibel Addition

$$\mathbf{L_{sum}} = \mathbf{log}\left[\mathbf{10^{\frac{L_{p1}}{10}}} + \mathbf{10^{\frac{L_{p2}}{10}}} + \cdots + \frac{\mathbf{10^{L_{pn}}}}{\mathbf{10}}\right]$$

Where:
L_{sum} = cumulative decibel level
L_p = decibel level (each level to be added is notated by 1, 2,… n)

A-2.2.2 Special Case.

In the special case where decibel levels of equal magnitudes are to be added, the cumulative level can be determined with Equation A-3.

Equation A-3. Addition of Decibels with Equal Magnitudes

$$\mathbf{L_{sum}} = \mathbf{L_p} + \mathbf{10\ log(n)}$$

Where:
L_{sum} = cumulative decibel level
L_p = common decibel level
n = number of levels with equal magnitude

where n is the number of sources, all with magnitude L_p.

A-2.3 Decibel Subtraction.

In some case it is necessary to subtract decibel levels. For example, if the cumulative level of several sources is known, what would the cumulative level be if one of the sources were reduce? Decibel subtraction is given by Equation A-4.

Equation A-4. Decibel Subtraction

$$\mathbf{L_{diff}} = \mathbf{10\ log}[\mathbf{10^{\frac{L_{p1}}{10}}} - \mathbf{10^{\frac{L_{p2}}{10}}}]$$

Where:
Ldiff = cumulative decibel level
Lp1 = first decibel level
Lp2 = second decibel level

A-2.4 Decibel Averaging.

Strictly speaking decibels, average logarithmically not arithmetically. Use Equation A-5 for decibel averaging.

Equation A-5. Decibel Averaging

$$L_{avg} = 10\log\left[\frac{10^{\frac{L_{p1}}{10}} + 10^{\frac{L_{p2}}{10}} + \cdots + 10^{\frac{L_{pn}}{10}}}{n}\right]$$

Where:
Lavg = average decibel level
Lp = decibel level (each level to be added is notated by 1, 2,… n)

A-3 SOUND PRESSURE LEVEL (LP OR SPL).

The ear responds to sound pressure. Sound waves represent tiny oscillations of pressure just above and below atmospheric pressure. These pressure oscillations impinge on the ear, and sound is heard. A sound level meter is also sensitive to sound pressure.

A-3.1 Definition, sound pressure level.

The sound pressure level (in decibels) is defined by:

Equation A-6. Sound Pressure Level Format 1

$$L_p = 10\log[(\frac{p}{Pref})^2]$$

Where:
L_p = sound pressure level (in dB)
P = sound pressure (Pa)
Pref = reference sound pressure (20 µPa)

Where p is the absolute level of the sound pressure and Pref is the reference pressure. Unless otherwise stated the pressure, p, is the effective root mean square (rms) sound pressure. This equation is also written as:

Equation A-7. Sound Pressure Level Format 2

$$L_p = 20\log\left[\left(\frac{p}{Pref}\right)\right]$$

Where:
L_p = sound pressure level (in dB)
P = sound pressure (Pa)
Pref = reference sound pressure (20 µPa) (microPascal)

Although both formulas are correct, it is instructive to consider sound pressure level as the log of the pressure squared (Equation A-6). This is because when combining sound pressure levels, in almost all cases, it is the square of the pressure ratios (in other words, $\{p/P_{ref})^2\}$'s) that must be summed not the pressure ratios (in other words, not the {p/Pref}'s). This is also true for sound pressure level subtraction and averaging.

A-3.2 Definition, Reference Pressure.

Sound pressure level, expressed in decibels, is the logarithmic ratio of pressures where the reference pressure is 20 microPascal or 20 µPa (Pascal, the unit of pressure, equals 1 Newton/m2). This reference pressure represents approximately the faintest sound that can be heard by a young, sensitive, undamaged human ear when the sound occurs in the frequency region of maximum hearing sensitivity, about 1000 Hertz (Hz). A 20 µPa pressure is 0 dB on the sound pressure level scale. In the strictest sense, a sound pressure level must be stated completely, including the reference pressure base, such as "85 decibels relative to 20 µPa." However, in normal practice and in this document the reference pressure is omitted, but it is nevertheless implied.

A-3.3 Abbreviations.

The abbreviation SPL is often used to represent sound pressure level, and the notation Lp is normally used in equations, both in this document and in the general acoustics - literature.

A-3.4 Limitations on the Use of Sound Pressure Levels.

Sound pressure levels can be used for evaluating the effects of sound with respect to sound level criteria. Sound pressure level data taken under certain installation conditions cannot be used to predict sound pressure levels under other installation conditions unless modifications are applied. Implicit in these modifications is a sound power level calculation.

A-4 SOUND POWER LEVEL (LW OR PWL).

Sound power level is an absolute measure of the quantity of acoustical energy produced by a sound source. Sound power is not audible like sound pressure. However, they are related (see Section A-5). It is the way the sound power is radiated and distributed that determines the sound pressure level at a specified location. The sound power level, when correctly determined, is an indication of the sound radiated by the source and is independent of the room containing the source. The sound power level data can be used to compare sound data submittals more accurately and to estimate sound pressure levels for a variety of room conditions. Thus, there is technical need for the generally higher quality sound power level data.

A-4.1 Definition, sound power level.

The sound power level (in decibels) is defined by:

Equation A-8. Sound Power Level

$$L_w = 10 \log \frac{P}{Pref}$$

Where:
L_W = sound power level (in dB)
P = sound power (W)
Pref = reference sound power (10^{-12} W)

Where P is the absolute level of the sound power and Pref is the reference power. Unless otherwise stated the power, P, is the effective root mean square (rms) sound power.

A-4.2 Definition, Reference Power.

Sound power level, expressed in decibels, is the logarithmic ratio of the sound power of a source in watts (W) relative to the sound power reference base of 10-12 W. Before the US joined the IS0 in acoustics terminology, the reference power in this country was 10-13 W, so it is important in using old data (earlier than about 1963) to ascertain the power level base that was used. If the sound power level value is expressed in dB relative to 10-13 W, it can be converted to dB relative to 10-12 W, by subtracting 10 dB from the value. Special care must be used not to confuse decibels of sound pressure with decibels of sound power. It is often recommended that power level values always be followed by the notation "dB re 10-12 W." However, in this document this notation is omitted, although it will always be made clear when sound power levels are used.

A-4.3 Abbreviations.

The abbreviation PWL is often used to represent sound power level, and the notation L_W normally used in equations involving power level. This custom is followed in the document.

A-4.4 Limitations of Sound Power Level Data.

There are two notable limitations regarding sound power level data: Sound power cannot be measured directly but are calculated from sound pressure level data, and the directivity characteristics of a source are not necessarily determined when the sound power level data are obtained.

A-4.4.1 PWL Calculated, Not Measured.

Under the first of these limitations, accurate measurements and calculations are possible, but nevertheless there is no simple measuring instrument that reads directly the sound power level value. The procedures involve either comparative sound pressure level measurements between a so-called standard sound source and the source under test (in example, the "substitution method"), or very careful acoustic qualifications of the test room in which the sound pressure levels of the source are measured. Either of these procedures can be involved and requires quality equipment and knowledgeable personnel. However, when the measurements are carried out properly, the resulting sound power level data generally are more reliable than most ordinary sound pressure level data.

A-4.4.2 Loss of Directionality Characteristics.

Technically, the measurement of sound power level considers the fact that different amounts of sound radiate in different directions from the source, but when the measurements are made in a reverberant or semi-reverberant room, the actual directionality pattern of the radiated sound is not obtained. If directivity data are desired, measurements must be made either outdoors, in a totally anechoic test room where reflected sound cannot distort the sound radiation pattern, or in some instances by using sound intensity measurement techniques. This restriction applies equally to both sound pressure and sound power measurements.

A-5 SOUND INTENSITY LEVEL (LI).

Sound intensity is sound power per unit area. Sound intensity, like sound power, is not audible. It is the sound intensity that directly relates sound power to sound pressure. Strictly speaking, sound intensity is the average flow of sound energy through a unit area in a sound field. Sound intensity is also a vector quantity, that is, it has both a magnitude and direction. Like sound power, sound intensity is not directly measurable, but sound intensity can be obtained from sound pressure measurements.

A-5.1 Definition, Sound Intensity Level.

The sound intensity level (in decibels) is defined by:

Equation A-9. Sound Intensity Level

$$\mathbf{L_i = 10\log\frac{I}{I_{ref}}}$$

Where:
L_i = sound intensity level (in dB)
I = sound intensity (W/m^2)
I_{ref} = sound intensity reference (10^{-12} W/m^2)

Where I is the absolute level of the sound intensity and I_{ref} is the reference intensity. Unless otherwise stated the intensity, I, is the effective root mean square (rms) sound intensity.

A-5.2 Definition, Reference Intensity.

Sound intensity level, expressed in decibels, is the logarithmic ratio of the sound intensity of at a location, in watts/square meter (W/m^2) relative to the sound power reference base of 10^{-12} W/m^2.

A-5.3 Notation.

The abbreviation Li is often used to represent sound intensity level. The use of IL as an abbreviation is not recommended since this is often the same abbreviation for "Insertion Loss" and can lead to confusion.

A-5.4 Computation of Sound Power Level from Intensity Level.

The conversion between sound intensity level (in dB) and sound power level (in dB) is as follows:

Equation A-10. Sound Power Level from Intensity Level Format 1

$$\mathbf{L_w = 10\log\left[A\left(\frac{I}{I_{ref}}\right)\right]}$$

Where:
L_W = sound power level (in dB)
A = area of average intensity (m^2)
I = sound intensity (W/m^2)
I_{ref} = sound intensity reference (10^{-12} W/m^2)

where A is the area over which the average intensity is determined in square meters (m^2). Note this can also be written as:

Equation A-11. Sound Power Level from Intensity Level Format 2

$$\mathbf{L_w = L_i + 10\log\{A\}}$$

Where:
L_W = sound power level (in dB)
L_i = sound intensity level (in dB)
A = area of average intensity (m^2)

if A is in English units (sq. ft.) then Equation A-11 can be written as:

Equation A-12. Sound Power Level from Intensity Level (English Units)

$$\mathbf{L_w = L_i + 10\log\{A\} - 10}$$

Where:
L_W = sound power level (in dB)
L_i = sound intensity level (in dB)
A = area of average intensity (ft^2)

Note, when the area A completely closes the sound source, these equations can provide the total sound power level of the source. However, care must be taken to ensure that the intensity used is representative of the total area. This can be done by using an area weighted intensity or by logarithmically combining individual Lw's.

A-5.5 Determination of Sound Intensity.

Although sound intensity cannot be measured directly, a reasonable approximation can be made if the direction of the energy flow can be determined. Under free field conditions where the energy flow direction is predictable (outdoors for example) the magnitude of the sound pressure level (L_p) is equivalent to the magnitude of the intensity level (L_i). This result because, under these conditions, the intensity (I) is directly proportional to the square of the sound pressure (p^2). This is the key to the relationship between sound pressure level and sound power level. This is also the reason that when two sounds combine the resulting sound level is proportional to the log of the sum of the squared pressures (in example, the sum of the p^2's) not the sum of the pressures (in example, not the sum of the p's). That is, when two sounds combine it is the intensities that add, not the pressures. Recent advances in measurement and computational techniques have resulted in equipment that determine sound intensity directly, both magnitude and direction. Using this instrumentation sound intensity measurements can be conducted in more complicated environments, where fee field conditions do not exist and the relationship between intensity and pressure is not as direct.

A-6 VIBRATION LEVELS.

Vibration levels are analogous to sound pressure levels.

A-6.1 Definition, Vibration Level.

The vibration level (in decibels) is defined by:

Equation A-13. Vibration Level

$$L_a = \log\left[\left(\frac{a}{a_{ref}}\right)^2\right]$$

Where:
L_a = vibration level (in dB)
a = acceleration level (micro-G)
a_{ref} = acceleration level reference (1 micro-G)

Where a is the absolute level of the vibration and a_{ref} is the reference vibration. In the past different measures of the vibration amplitude have been utilized, these include, peak-to-peak (p-p), peak (p), average and root mean square (rms) amplitude. Unless otherwise stated the vibration amplitude, a, is the root mean square (rms). For simple harmonic motion these amplitudes can be related by:

rms value	=	0.707 x peak
average value	=	0.637 x peak
rms value	=	1.11 x average
peak-to peak	=	2 x peak

In addition, vibration can be measured with three different quantities, these are, acceleration, velocity and displacement. Unless otherwise stated the vibration levels used in this document are in terms of acceleration and are called "acceleration levels". For simple harmonic vibration at a single frequency the velocity and displacement can be related to acceleration by:

$$\text{velocity} = \text{acceleration}/(2\pi f)$$

$$\text{displacement} = \text{acceleration}/\ (2\pi f)^2$$

Where f is the frequency of the vibration in hertz (cycles per second). For narrow bands and octave bands, the same relationship is approximately true where f is the band center frequency in hertz.

A-6.2 Definition, Reference Vibration.

In this document, the acceleration level, expressed in decibels, is the logarithmic ratio of acceleration magnitudes where the reference acceleration is 1 micro-G (10-6), where G is the acceleration of gravity (32.174 ft/sec^2 or 9.81 m/s^2). Note: other reference acceleration levels are in common use, these include, 1 micro m/s^2,10 micro m/s^2 (approximately equal to 1 micro-G) and 1 G. Therefore, when stating an acceleration level, it is customary to state the reference level, such as "60 dB relative to 1 micro G."

A-6.3 Abbreviations.

The abbreviation VAL is sometimes used to represent vibration acceleration level, and the notation La is normally used in equations, both in this document and in the general acoustics literature.

A-7 FREQUENCY.

Frequency is analogous to "pitch." The normal frequency range of hearing for most people extends from a low frequency of about 20 to 50 Hz (a "rumbling" sound) up to a high frequency of about 10,000 to 15,000 Hz (a "hissy" sound) or even higher for some people. Frequency characteristics are important for the following four reasons: People have different hearing sensitivity to different frequencies of sound (generally, people hear better in the upper frequency region of about 500-5000 Hz and are therefore more annoyed by loud sounds in this frequency region); high-frequency sounds of high intensity and long duration contribute to hearing loss; different pieces of electrical and mechanical equipment produce different amounts of low-, middle-, and high-frequency noise; and noise control materials and treatments vary in their effectiveness as a function of frequency (usually, low frequency noise is more difficult to control; most treatments perform better at high frequency).

A-7.1 Frequency Unit, Hertz, Hz.

When a piano string vibrates 400 times per second, its frequency is 400 vibrations per second or 400 Hz. Before the US joined the IS0 in standardization of many technical terms (about 1963), this unit was known as "cycles per second."

A-7.2 Discrete Frequencies, Tonal Components.

When an electrical or mechanical device operates at a constant speed and has some repetitive mechanism that produces a strong sound, that sound may be concentrated at the principal frequency of operation of the device. Examples are the blade passage frequency of a fan or propeller, the gear-tooth contact frequency of a gear or timing belt, the whining frequencies of a motor, the firing rate of an internal combustion engine, the impeller blade frequency of a pump or compressor, and the hum of a transformer. These frequencies are designated "discrete frequencies" or "pure tones" when the sounds are clearly tonal in character, and their frequency is usually calculable. The principal frequency is known as the "fundamental," and most such sounds also contain many "harmonics" of the fundamental. The harmonics are multiple of the fundamental frequency, in other words, 2, 3, 4, 5, and the other times the fundamental. For example, in a gear train, where gear tooth contacts occur at the rate of 200 per second, the fundamental frequency would be 200 Hz, and it is very probable that the gear would also generate sounds at 400, 600, 800, 1000, 1200 Hz and so on for possible 10 to 15 harmonics. Considerable sound energy is often concentrated at these discrete frequencies, and these sounds are more noticeable and sometimes more annoying because of their presence. Discrete frequencies can be located and identified within a general background of broadband noise (noise that has all frequencies present, such as the roar of a jet aircraft or the water noise in a cooling tower or waterfall) with the use of narrowband filters that can be swept through the full frequency range of interest.

A-7.3 Octave Frequency Bands.

Typically, a piece of mechanical equipment, such as a diesel engine, a fan, or a cooling tower, generates and radiates some noise over the entire audible range of hearing. The amount and frequency distribution of the total noise is determined by measuring it with an octave band analyzer, which is a set of contiguous filters covering essentially the full frequency range of human hearing. Each filter has a bandwidth of one octave, and nine such filters cover the range of interest for most noise problems. The standard octave frequencies are given in Table A-1. An octave represents a frequency interval of a factor of two. The first column of Table A-1 gives the band width frequencies, and the second column gives the geometric mean frequencies of the bands. The latter values are the frequencies that are used to label the various octave bands. For example, the 1000-Hz octave band contains all the noise falling between 707 Hz (1000/square root of 2) and 1414 Hz (1000 x square root of 2). The frequency characteristics of these filters have been standardized by agreement (ANSI S1.11 and ANSI S1.6). In some instances, reference is made to "low", "mid" and "high" frequency sound. This distinction is somewhat arbitrary, but for the purposes of this document low frequency sound includes the 31 through 125 Hz octave bands, mid frequency sound includes the 250 through 1,000 Hz octave bands, and high frequency sound includes the 2,000 through 8,000 Hz octave band sound levels. For finer resolution of data, narrower bandwidth filters are sometimes used; for example, finer constant percentage bandwidth filters (such as half-octave, third octave, and tenth-octave filters), and constant width filters (such as 1 Hz, 10 Hz, and similar). The spectral information presented in this document in terms of full octave bands. This has been found to be a sufficient resolution for most engineering considerations. Most laboratory test data is obtained and presented in terms of 1/3 octave bands. A reasonably approximate conversion from 1/3 to full octave bands can be made (see d. below). In certain cases, the octave band is referred to as a “full octave” or "1/1 octave” to differentiate it from partial octaves such as the 1/3 or 1/2 octave bands. The term “overall” is used to designate the total noise without any filtering.

Table A-1 Bandwidth and Geometric Mean Frequency of Standard Octave and 1/3 Octave Bands.

Frequency, Hz					
Octave			One-third octave		
Lower band limit	Center	Upper band limit	Lower band limit	Center	Upper band limit
11	16	22	14.1	16	17.8
			17.8	20	22.4

			8,913	10,000	11,220
			11,220	12,500	14,130
11,360	16,000	22,720	14,130	16,000	17,780
			17,780	20,000	22,390

Where TLob is the resulting octave band transmission loss and TL1, TL2 & TL3 are the 1/3 octave band transmission losses.

A-7.4 Octave Band Levels (1/3).

Each octave band can be further divided into three 1/3 octave bands. Laboratory data for sound pressure, sound power and sound intensity levels may be given in terms of 1/3 octave band levels. The corresponding octave band level can be determined by adding the levels of the three 1/3 octave bands using (lower, middle, and upper) Equation A-2. There is no method of determining the 1/3 octave band levels from octave band data. However, as an estimate one can assume that the 1/3 octave levels are approximately 4.8 dB less than the octave band level. Laboratory data for sound transmission loss is commonly given in terms of 1/3 octave band transmission losses. To convert from 1/3 octave band transmission losses to octave band transmission losses use Equation A-14.

Equation A-14. 1/3 Octave Bands to Octave Band Conversion

$$\mathbf{TL_{ab} = 4.77 - 10\log\left[10^{\frac{-TL_{lower}}{10}} + 10^{\frac{-TL_{middle}}{10}} + 10^{\frac{-TL_{upper}}{10}}\right]}$$

Where:

TL_{ab} = octave band transmission loss (in dB)
TL_{lower} = lower 1/3 octave band transmission loss (in dB)
TL_{middle} = middle 1/3 octave band transmission loss (in dB)
TL_{upper} = upper 1/3 octave band transmission loss (in dB)

A-7.5 A-, C-, & Z-Weighted Sound Levels.

Sound level meters are usually equipped with "weighting circuits" that tend to represent the frequency characteristics of the average human ear for various sound intensities. The frequency characteristics of the A-, C-, and Z-weighting networks are shown in Figure A-1. Table A-2 lists the uncompensated electrical frequency responses for A-, C-, and Z- weightings. The relative frequency response of the average ear approximates the A curve when sound pressure levels of about 20 to 30 dB are heard. For such quiet sounds, the ear has fairly poor sensitivity in the low-frequency region, the C curve shows the almost flat frequency response of the ear for loud sounds in the range of about 90 to 100 dB, and the Z-curve indicates unweighted or "linear" frequency responses. Annoyance usually occurs when an unwanted noise intrudes into an otherwise generally quiet environment. At such times, the ear is listening with a sensitivity resembling the A curve. Thus, judgment tests are often carried out on the loudness, noisiness, annoyance, or intrusiveness of a sound or noise related to the A-weighted sound level of that sound. The correlation is generally quite good, and it is a generally accepted fact that the high-frequency noise determined from the A- weighted sound level is a good indicator of the annoyance capability of a noise. Thus, noise codes and community noise ordinances are often written around A-weighted sound levels. For example: "The sound level at the property line between a manufacturing or industrial plant and a residential community must not exceed 65 dB(A) during daytime or 55 dB(A) during nighttime." Of course, other sound levels and other details might appear in a more complete noise code. Sound levels taken on the A-, C-, and Z-weighted networks have usually been designated by dB(A), dB(C), and dB(Z), respectively. The parentheses are sometimes omitted, as in dBA. The weighting networks, in effect, discard some of the sound, so it is conventional not to refer to their values as sound pressure levels, but only as sound levels-as in “an A-weighted sound level of 76 dB(A).” High-intensity, high-frequency sound is known to contribute to hearing loss, so the A-weighted sound level is also used as a means of monitoring factory noise for the hearing damage potential. It is very important, when reading or reporting sound levels, to identify positively the weighting network used, as the sound levels can be quite different depending on the frequency content of the noise measured. In some cases, if no weighting is specified, A-weighting will be assumed. This is very poor practice and is discouraged.

Figure A-1 Approximate Electrical Frequency Response of the A-, C-, and Z-weighted Networks of Sound Level Meters.

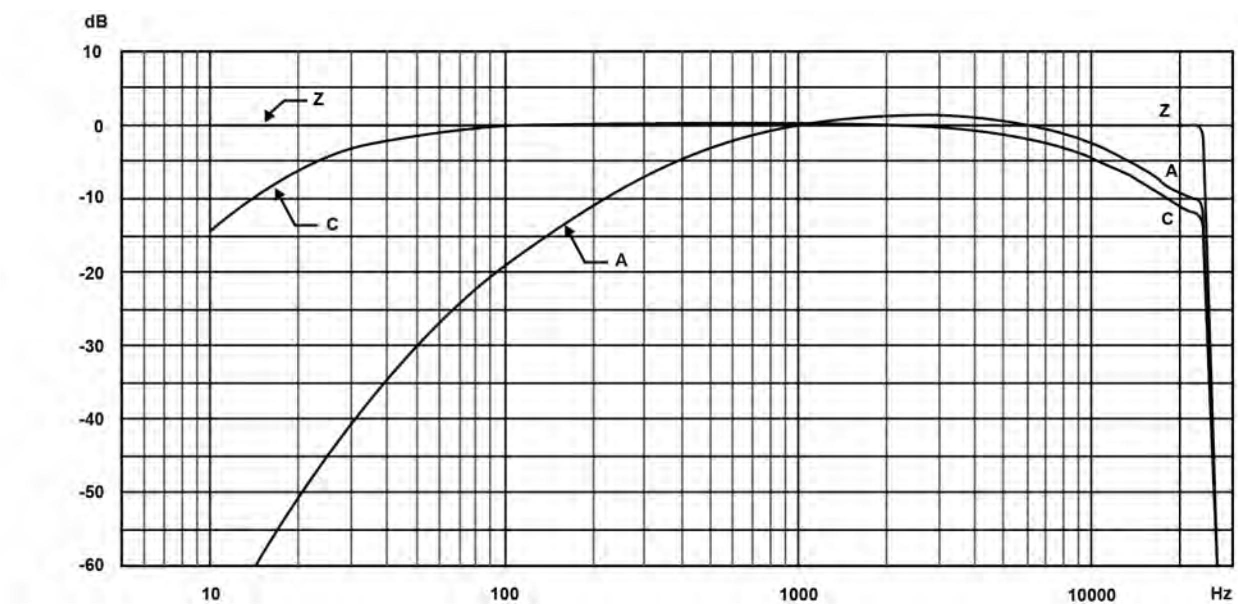

Table A-2 Uncompensated Electrical Frequency Responses for A-, C-, and Z-Weightings

A-7.6 Calculation of A-Weighted Sound Level.

For analytical or diagnostic purposes, octave band analyses of noise data are much more useful than sound levels from only the weighting networks. It is always possible to calculate, with a reasonable degree of accuracy, an A-weighted sound level from octave band levels. This is done by subtracting the decibel weighting from the octave band levels and then summing the levels logarithmically using Equation A-2. But it is not possible to determine accurately the detailed frequency content of a noise from only the weighted sound levels. In some instances, it is considered advantageous to measure or report A-weighted octave band levels. When this is done the octave band levels must not be presented as “sound levels in dB(A)“but must be labeled as “octave band sound levels with A-weighting”, otherwise confusion will result.

A-8 TEMPORAL VARIATIONS.

Both the acoustical level and spectral content can vary with respect to time. This can be accounted for in several ways. Sounds with short term variations can be measured using the meter averaging characteristics of the standard sound level meter as defined by ANSI S1.4. Typically, two-meter averaging characteristics are provided, these are termed “Slow” with a time constant of approximately 1 second and “Fast” with a time constant of approximately 1/8 second. The slow response is useful in estimating the average value of most mechanical equipment noise. The fast response if useful in evaluating the maximum level of sounds which vary widely.

A-9 SPEED OF SOUND AND WAVELENGTH.

The speed of sound in air is given by Equation A-15 (Imperial units) and Equation A-16 (S.I. units):

Equation A-15. Speed of Sound (ft/s)

$$\mathbf{c = 49.03\ x\ (460 + t_F)^{1/2}}$$

Where:

c = speed of sound (ft/s)
*c = SQRT(k*gc*R*T/MW) ft/sec*
c = 49.02 x SQRT(T°R) ft/sec (air only)
k is specific heat ratio (dimensionless) for air k = 1.4
gc is gravitational conversion constant = 32.174 lbm.ft/(lbf.sec^2)
R is universal gas constant = 1545.4 ft.lbf/(lbm.°R) or 8314 J/(kmol.°K)
MW is Molecular Weight lbm/lbmol, MW for air is 28.965 lbm/lbmol or 28.965 kg/kmol
t_F = air temperature (degrees F)

Equation A-16. Speed of Sound (m/s)

$$\mathbf{c = 20.05 \ x \ (273 + t_C)^{1/2}}$$

Where:

c = speed of sound (m/s)
*c = SQRT(k*R*T/MW) m/sec*
t_F = air temperature (degrees C)

A-9.1 Temperature Effect.

For most normal conditions, the speed of sound in air can be taken as approximately 1120 ft./sec. (341.38 m/sec.). For an elevated temperature of about 1000 deg. F (537.78 deg. C), as in the hot exhaust of a gas turbine engine, the speed of sound will be approximately 1870 ft./sec. (569.98 m/sec.). This higher speed becomes significant for engine muffler designs, as will be noted in the following paragraph.

A-9.2 Wavelength.

The wavelength of sound in air is given by Equation A-17.

Equation A-17. Wavelength

$$\boldsymbol{\gamma = c/f}$$

Where:

γ = wavelength (ft)
c = speed of sound (ft/s)
f = frequency (Hz)

where γ is the wavelength in ft., c is the speed of sound in air in ft./sec, and f is the frequency of the sound in Hz. Over the frequency range of 50 Hz to 12,000 Hz, the wavelength of sound in air at normal temperature varies from 22 feet (6.71 meters) to 1.1 inches (0.02794 meters), a relatively large spread. The significance of this spread is that many acoustical materials perform well when their dimensions are comparable to or larger than the wavelength of sound. Thus, a l-inch thickness of acoustical ceiling tile applied directly to a wall is quite effective in absorbing high-frequency sound but is of little value in absorbing low-frequency sound. At room temperature, a 10-feet-long (3.05 meters) dissipative attenuator is about 9 wavelengths long for sound at 1000 Hz and is therefore quite effective but is only about 0.4 wavelength long at 50 Hz and is therefore not very effective. At an elevated exhaust temperature of 1000 deg. F (537.78 deg. C), the wavelength of sound is about 2/3 greater than at room temperature, so the length of a corresponding attenuator must be about 2/3 longer in order to be as effective as one at room temperature. In the design of noise control treatments and the selection of noise control materials, the acoustical performance will frequently be found to relate to the dimensions of the treatment compared to the wavelengths of sound. This is the basic reason why it is generally easier and less expensive to achieve high-frequency noise control (short wavelengths) and more difficult and expensive to achieve low-frequency noise control (long wavelengths).

A-10 LOUDNESS.

The ear has a wide dynamic range. At the low end of the range, one can hear very faint sounds of about 0 to 10 dB sound pressure level. At the upper end of the range, one can hear with clarity and discrimination loud sounds of 100-dB sound pressure level, whose actual sound pressures are 100,000 times greater than those of the faintest sounds. People may hear even louder sounds, but in the interest of hearing conservation, exposure to very loud sounds for significant periods of time must be avoided. It is largely because of this very wide dynamic range that the logarithmic decibel system is useful; it permits compression of large spreads in sound power and pressure into a more practical and manageable numerical system. For example, a commercial jet airliner produced 100,000,000,000 times the sound power of a cricket. In the decibel system, the sound power of the jet is 110 dB greater than that of the cricket (110 = 10 log 1011). Humans judge subjective loudness on a still more compressed scale.

A-10.1 Loudness Judgments.

Under controlled listening tests, humans judge that a 10 dB change in sound pressure level, on the average, represents approximately a halving or a doubling of the loudness of a sound. Yet a 10-dB reduction in a sound source means that 90 percent of the radiated sound energy has been eliminated. Table A-3 shows the approximate relationship between sound level changes, the resulting loss in acoustic power, and the judgment of relative loudness of the changes. Toward the bottom of the table, it becomes clear that tremendous portions of the sound power must be eliminated to achieve impressive amounts of noise reduction in terms of perceived loudness.

Table A-3 Relationship Between Changes in Sound Level, Acoustic Energy Loss, and Approximate Relative Loudness of a Sound

Sound Level Change	Acoustic Energy Loss	Relative Loudness
0 dB	0%	Reference
-3 dB	50%	Perceptible Change
-10 dB	90%	Half as loud
-20 dB	99%	1/4 as loud
-30 dB	99.9%	1/8 as loud
-40 dB	99.99%	1/16 as loud

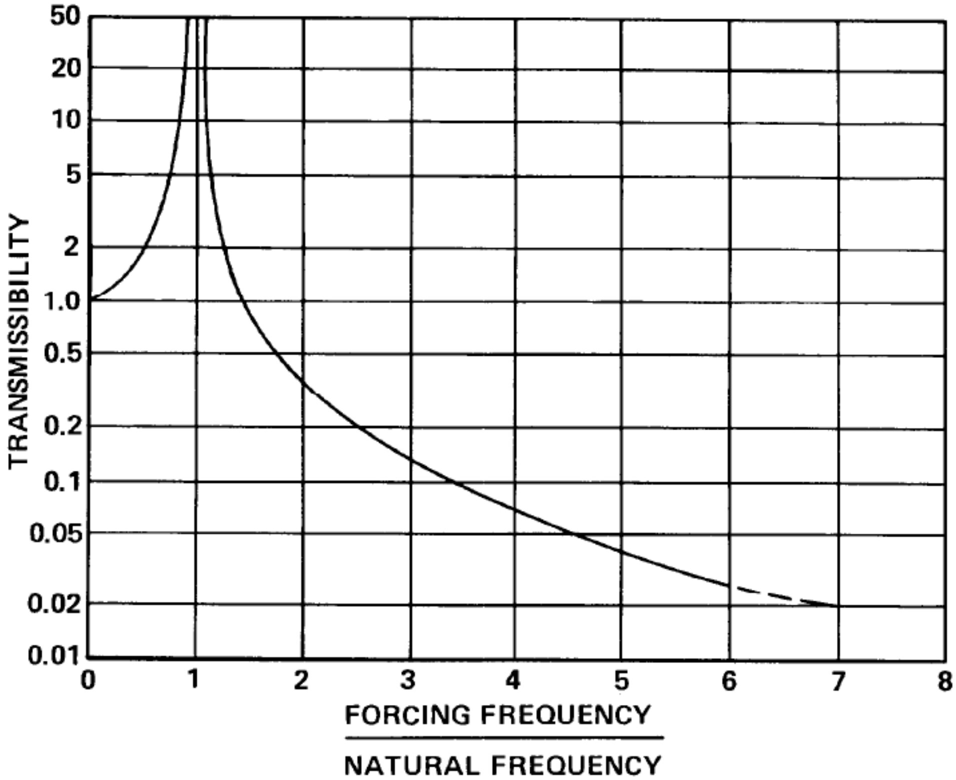
A-10.2 Sones and Phons.

Sones and phons are units used in calculating the relative loudness of sounds. Sones are calculated from nomograms that interrelate sound pressure levels and frequency, and phons are the summation of the sones by a special addition procedure. The results are used in judging the relative loudness of sounds, as in “a 50-phon motorcycle would be judged louder than a 40-phon motorcycle.” When the values are reduced to phon ratings, the frequency characteristics and the sound pressure level data have become detached, and the noise control analyst or engineer has no concrete data for designing noise control treatments. Sones and phons are not used in this document, and their use for noise control purposes is of little value. When offered data in sones and phons, the noise control engineer must request the original octave or 1/3 octave band sound pressure level data, from which the sones and phons were calculated.

A-11 VIBRATION TRANSMISSIBILITY.

A transmissibility curve is often used to indicate the general behavior of a vibration-isolated system. Transmissibility is roughly defined as the ratio of the force transmitted through the isolated system to the supporting structure to the driving force exerted by the piece of vibrating equipment. Figure A-2 is the transmissibility curve of a simple undamped single-degree-of-freedom system. The forcing frequency is usually the lowest driving frequency of the vibrating system. For an 1800-rpm pump, for example, the lowest driving frequency is 1800/60 = 30 Hz. The natural frequency, in Figure A-2, is the natural frequency of the isolator mount when loaded. An isolator mount might be an array of steel springs, neoprene-in-shear mounts, or pads of compressed glass fiber or layers of ribbed or waffle-pattern neoprene pads. When the ratio of the driving frequency to the natural frequency is less than about 1.4, the transmissibility goes above 1, which is the same as not having any vibration isolator. When the ratio of frequencies equals 1, that is, when the natural frequency of the mount coincides with the driving frequency of the equipment, the system may go into violent oscillation, to the point of damage or danger, unless the system is restrained by a damping or snubbing mechanism. Usually, the driver (the operating equipment) moves so quickly through this unique speed condition that there is no danger, but for large, heavy equipment that builds up speed slowly or runs downs slowly, this is a special problem that must be handled. At higher driving speeds, the ratio of frequencies exceeds 1.4 and the mounting system begins to provide vibration isolation, that is, to reduce the force reduce the force transmitted into the floor or other supported structure. The larger the ratio of frequencies, the more effective the isolation mount.

Figure A-2 Transmissibility of a Simple Undamped Single Degree-of-Freedom System.



A-11.1 Isolation Efficiency.

An isolation mounting system that has a calculated transmissibility, say, of 0.05 on Figure A-2 is often described as having an "isolation efficiency" of 95 percent. A transmissibility of 0.02 corresponds to 98 percent isolation efficiency, and so on. Strict interpretation of transmissibility data and isolation efficiencies, however, must be adjusted for real-life situations.

A-11.2 Transmissibility Limitations.

The transmissibility curve implies that the mounted equipment (in example, equipment plus the isolators) are supported by a structure that is infinitely massive and infinitely rigid. In most situations, this condition is not met. For example, the deflection of a concrete floor slab under static load may fall in the range of 1/4 inch to 1/2 inch (0.635 cm to 1.27 cm). This does not qualify as being infinitely rigid. The isolation efficiency is reduced as the static floor deflection increases. Therefore, the transmissibility values of Figure A-2 must not be expected for any specific ratio of driving frequency to natural frequency.

A-11.2.1 Adjustment for Floor Deflection.

In effect, the natural frequency of the isolation system must be made lower or the ratio of the two frequencies made higher to compensate for the resilience of the floor. This fact is especially true for upper floors of a building and is even applicable to floor slabs poured on grade (where the earth under the slab acts as a spring). Only when equipment bases are supported on large extensive portions of bedrock can the transmissibility curve be applied directly.

A-11.2.2 Adjustment for Floor Span.

This interpretation of the transmissibility curve is also applied to floor structures having different column spacings. Usually, floors that have large column spacing, such as 50 to 60 feet (15.24 to 18.29 meters), will have larger deflections that floors of shorter column-spacing, such as 20 to30 feet (6.1 to 9.14 meters). To compensate, the natural frequency of the mounting system is usually made lower as the floor span increases. All of these factors are incorporated into the vibration isolation recommendations in this chapter.

A-11.2.3 Difficulty of Field Measurement.

In field situations, the transmissibility of a mounting system is not easy to measure and check against a specification. Yet the concept of transmissibility is at the heart of vibration isolation and must not be discarded because of the above weakness. The material that follows is based on the valuable features of the transmissibility concept but added to it are some practical suggestions.

A-12 VIBRATION ISOLATION EFFECTIVENESS.

With the transmissibility curve as a guide, three steps are added to arrive at a fairly practical approach toward estimating the expected effectiveness of an isolation mount.

A-12.1 Static Deflection of a Mounting System.

The static deflection of a mount is simply the difference between the free-standing height of the uncompressed, unloaded isolator and the height of the compressed isolator under its static load. This difference is easily measured in the field or estimated from the manufacturer’s catalog data. An uncompressed 6-inch-high (15.24 cm) steel spring that has a compressed height of only 4 inches (10.2 cm) when installed under a fan or pump is said to have a static deflection of 2 inches (5.08 cm). Static deflection data are usually given in the catalogs of the isolator manufacturers or distributors. The data may be given in the form of “stiffness” values. For example, a stiffness of 400 lb/in (71.65 kg/cm) means that a 400 lb (181.44 kg) load will produce a 1-inch (2.54 cm) static deflection, or that an 800 lb (362.87 kg) load will produce a 2-inch (5.08 cm) deflection, if the mount has freedom to deflect a full 2 inches (5.08 cm).

A-12.2 Natural Frequency of a Mount.

The natural frequency of steel springs and most other vibration isolation materials can be calculated approximately from the formula in Equation A-18 (Imperial units) and Equation A-19 (S.I. units).

Equation A-18. Natural Frequency of Vibration Isolation Materials (Imperial)

$$\mathbf{f_n = 3.13\ x\ \sqrt{\frac{1}{SD}}}$$

Where:
f_n = natural frequency (Hz)
SD = static deflection (in)

Equation A-19. Natural Frequency of Vibration Isolation Materials (S.I.)

$$\mathbf{f_n = 0.5\ x\ \sqrt{\frac{1}{SD}}}$$

Where:
f_n = natural frequency (Hz)
SD = static deflection (m)

A-12.2.1 Example, Steel Spring.

Suppose each steel springs has a static deflection of 1- inch (0.0254 meters) when placed under each corner of a motor-pump base. The natural frequency of the mount is approximately:

Equation A-20. Example Natural Frequency of a Steel Spring Mount (Imperial)

$$\mathbf{f_n = 3.13\ x\ \sqrt{\frac{1}{1}} = 3.13\ Hz}$$

Where:
f_n = natural frequency (Hz)

A-12.2.2 Example, Rubber Pad.

Suppose a layer of 3/8-inch-thick (0.953 cm) ribbed neoprene is used to vibration isolate high-frequency structure borne noise or vibration. Under load, the pad is compressed enough to have a 1/16-inch (0.159 cm) static deflection. The natural frequency of the mount is approximately:

Equation A-21. Example Natural Frequency of a Neoprene Pad (Imperial)

$$f_n = 3.13 \text{ x } \sqrt{\frac{1}{\frac{1}{16}}}$$

$$= 3.13 \text{ x } \sqrt{16}$$

$$= 3.13 \text{ x } 4 = 12 \text{ Hz}$$

Where:
f_n = natural frequency (Hz)

This formula usually has an accuracy to within about plus or minus 20 percent for material such as neoprene-in-shear, ribbed or waffle-pattern neoprene pads, blocks of compressed glass fiber, and even pads of cork and felt when operating in their proper load range.

A-12.3 Application Suggestions.

Table A-4 provides a suggested schedule for achieving various degrees of vibration isolation in normal construction. The table is based on the transmissibility curve but suggests operating ranges of the ratio of driving frequency to natural frequency. The terms “low,” “fair,” and “high” are merely word descriptors, but they are more meaningful than such terms as 95 or 98 percent isolation efficiency which are clearly erroneous when they do not consider the mass and stiffness of the floor slab. Vibration control recommendations given in this chapter are based on the application of this table.

Table A-4 Suggested Schedule for Estimating Relative Vibration Isolation Effectiveness of a Mounting System

Ratio of Driving Frequency of Source to Natural Frequency of Mount	Degree of Vibration Isolation
Below 1.4	Amplification
1.4 - 3	Negligible
3 - 6	Low
6 - 10	Fair
Above 10	High

A-12.3.1 Example.

Suppose an 1800-rpm motor-pump unit is mounted on steel springs having 1-inch (2.54 cm) static deflection (as in the example above). The driving frequency of the system is the shaft speed, 1800 rpm or 30 Hz. The natural frequency of the mount is 3 Hz, and the ratio of driving frequency to natural frequency is about 10. Table A-4 shows that this would provide a “fair” to “high” degree of vibration isolation of the motor pump at 30 Hz. If the pump impeller has 10 blades, for example, this driving frequency would be 300 Hz, and the ratio of driving to natural frequencies would be about 100; the isolator would clearly give a “high” degree of vibration isolation for impeller blade frequency.

A-12.3.2 Caution.

The suggestion on vibration isolation offered in the document are based on experiences with satisfactory installations of conventional electrical and mechanical HVAC equipment in buildings. The concepts and recommendations described here may not be suitable for complex machinery, with unusual vibration modes, mounted on complex isolation systems. For such problems, assistance must be sought from a vibration specialist.

APPENDIX B SOUND LEVEL DATA FOR MECHANICAL AND ELECTRICAL EQUIPMENT

B-1 INTRODUCTION.

This appendix contains sound pressure and sound power data for mechanical equipment commonly found in many commercial buildings. Where possible, the noise data have been correlated with some of the more obvious noise influencing parameters, such as type, speed, power rating, and flow conditions. The noise levels quoted in the UFC are suggested for design uses; these noise levels represent approximately the 80 to 90 percentile values. That is, based on these sample sizes, it would be expected that the noise levels of about 80 to 90 percent of a random selection of equipment would be equal to or less than the design values quoted in the document, or only about 10 to 20 percent of a random selection would exceed these values. This is judged to be a reasonable choice of design values for typical uses. Higher percentile coverage, such as 95 percent, would give increased protection in the acoustic design, but at greater cost in weight and thickness of walls, floors, columns, and beams. On-site power plants driven by reciprocating and gas turbine engines have specific sound and vibration problems, which are considered separately in the inactive UFC 3-450-02 Power Plant Acoustics.

B-2 SOUND PRESSURE AND SOUND POWER LEVEL DATA.

In the collection of data, most noise levels were measured at relatively close-in distances to minimize the influence of the acoustic conditions of the room and the noise interference of other equipment operating in the same area.

B-2.1 Normalized Conditions for SPL Data.

Note: All measurements were normalized to a common MER condition by selecting a distance of 3 feet (0.914 meters) and a Room Constant of 800 ft^2 (74.32 m^2) as representative. SPL data measured at other distances and Room Constants were brought to these normalized conditions by using the procedures of Chapters 3 and 6.

B-2.2 Sound Power Level Data.

For equipment normally located and used outdoors, outdoor measurements were made, and sound power level data are given. To use these data, one may procedures of Chapter 3 and 6. Usually, more measurements and a more detailed estimate of the measurement conditions were involved in deriving the PWL data, so they are believed to have a slightly higher confidence level than the normalized SPL data.

B-2.3 A-Weighted Sound Levels.

In the tables and figures that follow, A-weighted sound levels are also given. Where sound pressure levels are given, the A-weighted sound level is in pressure; where sound power levels are given, the A-weighted value is in sound power. A-weighted sound levels are useful for simply comparing the noise output of competitive equipment. For complete analysis of an indoor or outdoor noise problem, however, octave band levels must be used.

B-2.4 Manufacturers' Noise Data.

Whenever possible, and especially for new types of equipment, the manufacturer must be asked to provide sound level data on their equipment. If the data show remarkably lower noise output than competitive models or are significantly lower than the data quoted in the document, the manufacturer must be asked to give guarantees of the noise data and to specify the conditions under which the data were measured and/or computed.

B-3 PACKAGED CHILLERS WITH RECIPROCATING COMPRESSORS.

These units' range in size from 15-ton to 200-ton (8.8 kW to 703.4 kW) cooling capacity. The noise levels have been reduced to the normalized 3-foot (.914 m) distance from the acoustic center of the assembly. In terms of noise production, the measured compressors are divided into two groups: up to 50 tons (175.8 kW) and over 50 tons (175.8 kW). The suggested 80- to 90-percentile noise level estimates are given in Figure B-1 and in Table B-1 for the two size ranges selected. Although major interest is concentrated here on the compressor component of a refrigeration machine, an electric motor is usually the drive unit for the compressor. The noise levels attributed here to the compressor will encompass the drive motor most of the time, so these values are taken to be applicable to either a reciprocating compressor alone or a motor-driven packaged chiller containing a reciprocating compressor.

Figure B-1 Sound Pressure Levels Reciprocating Compressors at 3-ft (.914 m) Distance

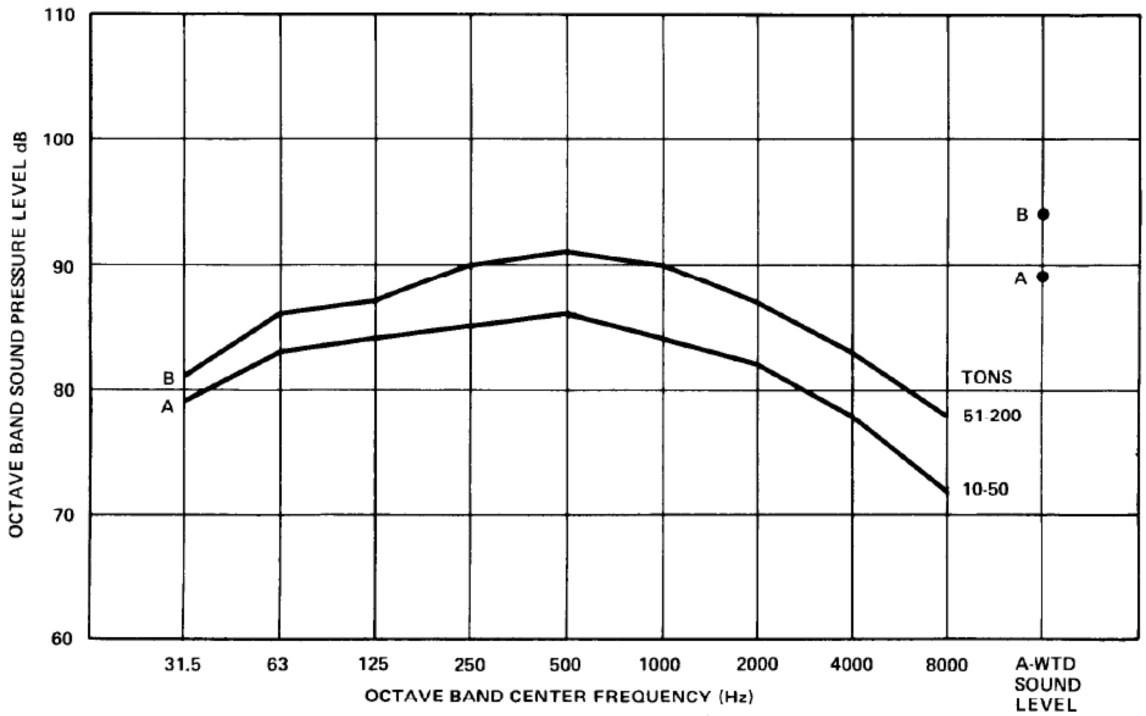


Table B-1 Sound Pressure Levels (in dB at 3-ft (.914 m) distance) for Packaged Chillers With Reciprocating Compressors

Octave Frequency Band (Hz)	Sound Pressure Level, dB	
	10-50 Tons Cooling Capacity	51-200 Tons Cooling Capacity
31	79	81
63	83	86
125	84	87

1000	84	90
2000	82	87
4000	78	83
8000	72	78
A-weighted, dB(A)	89	94

B-4 PACKAGED CHILLERS WITH ROTARY-SCREW COMPRESSORS.

The octave band sound pressure levels (at 3-foot (0.914 m) distance) believed to represent near-maximum noise levels for rotary-screw compressors are listed in Table B-2. The data applies for the size range of 100- to 300-ton cooling capacity, operating at or near 3600 RPM

Table B-2 Sound Pressure Levels (in dB at 3-ft. (0.914 m) Distance) for Packaged Chillers With Rotary Screw Compressors

2000	80
4000	75
8000	73
A-weighted, dB(A)	90

B-5 PACKAGED CHILLERS WITH CENTRIFUGAL COMPRESSORS.

These compressors range in size from 100 tons to 4000 tons (351.8 kW to 14067.4 kW) and represent the leading manufacturers. The noise levels may be influenced by the motors, gears, or turbines, but the measurement positions are generally selected to emphasize the compressor noise. The noise levels given in Figure B-2 and Table B-3 represent the 80- to 90- percentile values found when the units were divided into the two size groups: under 500 tons (1758.4 kW) and 500 or more tons (1758.4 kW). The low-frequency noise levels reflect the increased noise found for off-peak loads for most centrifugal machines. This data may be used for packaged chillers, including their drive units. For built-up assemblies, this data must be used for the centrifugal compressor only and the suggestions of paragraph B-5 followed for combining the noise of other components.

Figure B-2 Sound Pressure Levels, Centrifugal Compressors at 3-ft.(0.914 m)Distance

B-6 BUILT-UP REFRIGERATION MACHINES.

The noise of packaged chillers, as presented in the preceding paragraphs, includes the noise of both the compressor and the drive unit. If a refrigeration system is built up of separate pieces, then the noise level estimate must include the noise of each component making up the assembly. Compressor noise levels must be taken from the packaged chiller data. Sound level data for the drive units (motors, gears, steam turbines) must be taken from the appropriate tables in the document or obtained from the manufacturers. Use decibel addition to determine each octave band sum from the octave band levels of the various components. Assume the acoustic center to be at the approximate geometric center of the assembly, and distances must be extrapolated from that point. For very close distances (such as 2 to 3 feet or 0.61 to 0.914 meters) to each component, assume the total sound levels apply all around the equipment at distances of 3 feet (0.914 meters) from the approximate geometric centers of each component, although this assumption will not provide exact close-in sound levels.

B-7 ABSORPTION MACHINES.

These units are normally masked by other noise in a mechanical equipment room. The machine usually includes one or two small pumps; steam flow noise or steam valve noise may also be present. The 3-foot (0.914 meters) distance SPLs for most absorption machines used in refrigeration systems for buildings are given in Table B-4.

Table B-4 Sound Pressure Levels (dB at 3-ft (.914 m) Distance) for Absorption Machines

Octave Frequency Band (Hz)	Sound Pressure Level, dB All Sizes
31	80
63	82

A-weighted, dB(A)	86

B-8 BOILERS.

B-8.1 Noise Data.

The estimated noise levels given in Table B-5 are believed applicable for all boilers, although some units will exceed these values and, certainly, many units will be much lower than these values. These 3-foot (0.914 meters) noise levels apply to the front of the boiler, so when other distances are of concern, the distance must always be taken from the front surface of the boiler. Noise levels are much lower off the side and rear of the typical boiler. The wise variety of blower assemblies, air and fuel inlet arrangements, burners, and combustion chambers provides such variability in the noise data that it is impossible simply to correlate noise with heating capacity.

Table B-5 Sound Pressure Levels (dB at 3-ft (.914 m) Distance from the Front of Boilers

500	84
1000	82
2000	80
4000	76
8000	70
A-weighted, dB(A)	88

B-8.2 Boiler Rating.

Heating capacity of boilers may be expressed in different ways: sq. ft.(m^{2}) of heating surface, BTU/hour (kW), Lb (kG) of steam/hour, or bhp boiler horsepower (kW)). To a first approximation, some of these terms are interrelated as follows:

33,500 BTU/hour = 1 bhp   33 lb of steam/hour = 1 bhp.   1 bhp = 0.745 kW

All ratings have been reduced to equivalent bhp.

B-9 STEAM VALVES.

Estimated noise levels are given in Table B-6 for a typical thermally insulated steam pipe and valve. Even though the noise is generated near the orifice of the valve, the pipes on either side of the valve radiate a large part of the total noise energy that is radiated. Hence, the pipe is considered, along with the valve, as a part of the noise source. Valve noise is largely determined by valve type and design, pressure and flow conditions, and pipe wall thickness. Some valve manufacturers can provide valve noise estimated for their products.

Table B-6 Sound Pressure Levels (dB at 3-ft (.914 m) Distance) for High-Pressure Thermally Insulated Steam Valves and Nearby Piping

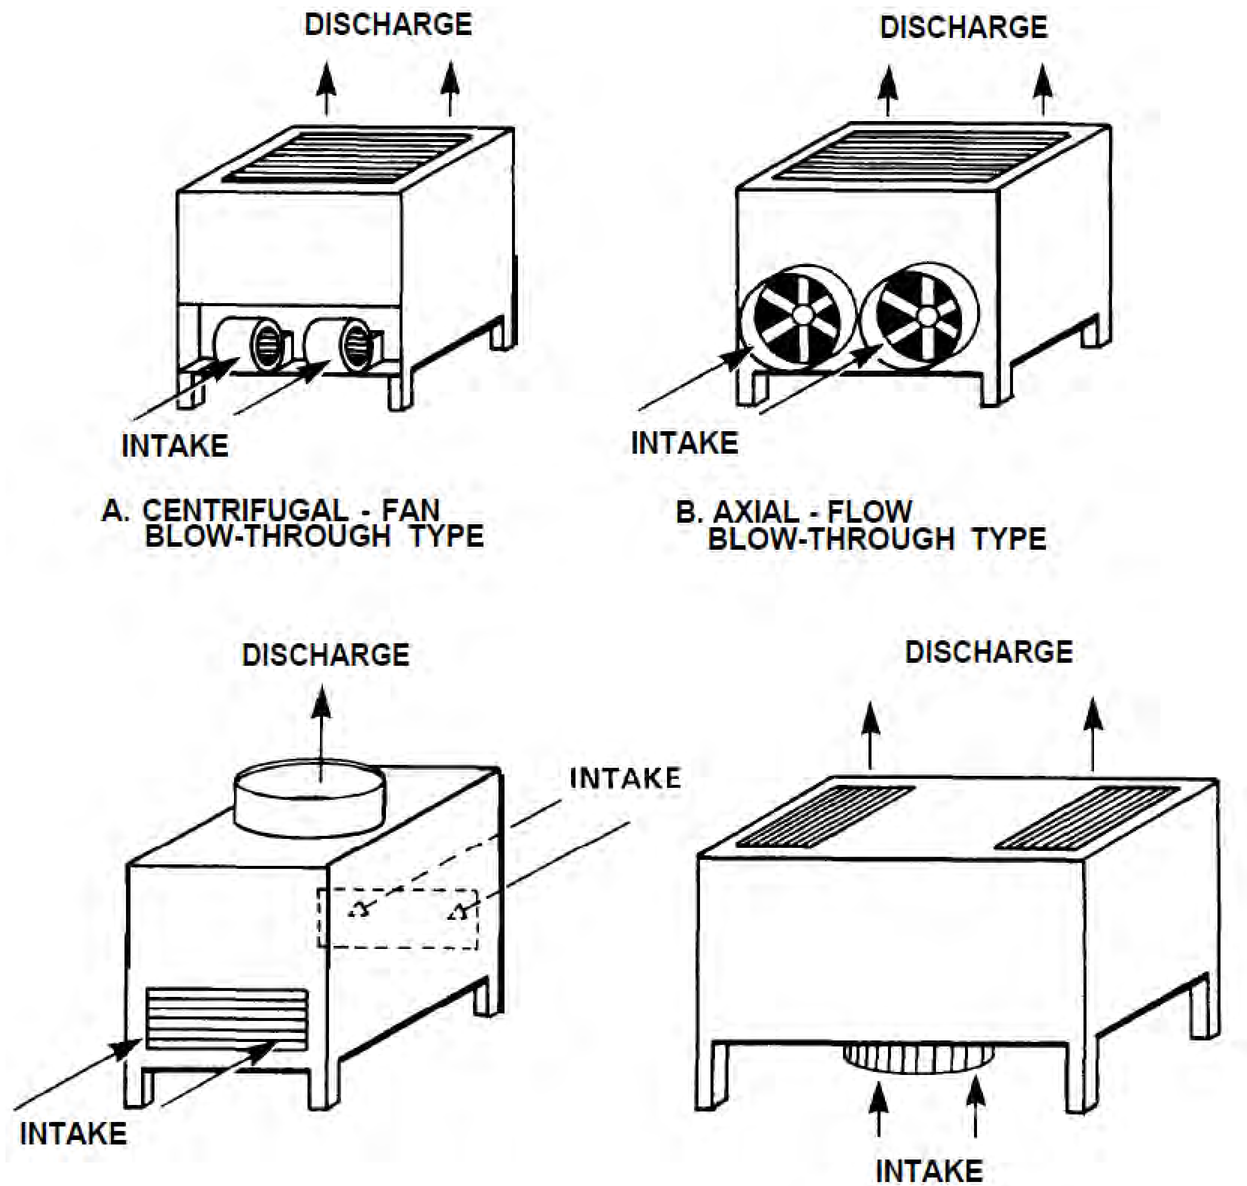
B-10 COOLING TOWERS AND EVAPORATIVE CONDENSERS.

The generalizations drawn here may not apply exactly to all cooling towers and condensers, but the data are useful for laying out cooling towers and their possible noise control treatments. It is desirable to obtain from the manufacturer actual measured noise levels for all directions of interest, but if these data are not forthcoming, it is essential to be able to approximate the directional pattern of the cooling tower noise. For aid in identification, four general types of cooling towers are sketched in Figure B-3: A.) The centrifugal-fan blow-through type; B.) The axial-flow blow-through type (with the fan or fans located on a side wall); C.) The induced-draft propeller type; and D.) The “underflow” forced draft propeller type (with the fan located under the assembly).

Figure B-3 Principal Types of Cooling Towers.



B-10.1 Sound Power Level Data.

Sound power level data are given for both propeller-type and centrifugal-fan cooling towers.

B-10.1.1 Propeller-type Cooling Tower.

The approximate overall and A-weighted sound power levels of propeller-type cooling towers are given by Equations B-1 and B-2, respectively: for overall PWL (propeller-type),

Equation B-1. Sound Power Levels of Propeller-Type Cooling Towers

$$\mathbf{Lw} = \mathbf{95 + 10\log(fan\ hp)}$$

Where:
Lw = sound power level (in dB)
fan hp = horsepower of cooling tower fan motor

and for A-weighted PWL,

Equation B-2. A-Weighted Sound Power Levels of Propeller-Type Cooling Towers

$$\mathbf{Lw_a} = \mathbf{86 + 10\log(fan\ hp)}$$

Where:
Lw_a = sound power level (in dBA)
fan hp = horsepower of cooling tower fan motor

where “fan hp” is the nameplate horsepower rating of the motor that drives the fan. Octave band PWLs can be obtained by subtracting the values of Table B-7 from the overall PWL.

Table B-7 Frequency Adjustments (in dB) for Propeller-Type Cooling Towers

Octave Frequency Band (Hz)	Value to be Subtracted From Overall PWL (dB)
31	8
63	5
125	5
250	8
500	11
1000	15
2000	18
4000	21
8000	29
A-weighted, dB(A)	9

B-10.1.2 Centrifugal Fan Cooling Tower.

The approximate overall and A-weighted sound power levels of centrifugal-fan cooling towers are given by Equations B-3 and B-4, respectively: for overall PWL (centrifugal-fan),

Equation B-3. Sound Power Levels of Centrifugal-Fan Cooling Towers

$$\mathbf{Lw = 85 + 10\log(fan\ hp)}$$

Where:
L_W = sound power level (in dB)
fan hp = horsepower of cooling tower fan motor

For A-weighted PWL,

Equation B-4. A-Weighted Sound Power Levels of Centrifugal-Fan Cooling Towers

$$\mathbf{L_a = 78 + 10\log(fan\ hp)}$$

Where:
L_a = sound power level (in dBA)
fan hp = horsepower of cooling tower fan motor

When more than one fan or cooling tower is used, "fan hp" is the total motor-drive hp of all fans or towers. Octave band PWLs can be obtained by subtracting the values of Table B-8 from the overall PWL.

Table B-8 Frequency Adjustments (in dB) for Centrifugal-Fan Cooling Towers

Octave Frequency Band (Hz)	Value to be Subtracted From Overall PWL (dB)
31	6
63	6
125	8
250	10
500	11
1000	13
2000	12
4000	18
8000	25
A-weighted, dB(A)	7

B-10.2 SPLs at a Distance.

To obtain the average outdoor SPL at any distance, use equation C-11 and obtain the value of the "distance term" from Tables C-24 or C-25 in Appendix C. Cooling towers usually radiate different amounts of sound in different directions, and the directional corrections of Table B-9 must be made to the average SPL. These corrections apply to the five principal directions from a cooling tower, in other words, in a direction perpendicular to each of the four sides and to the top of the tower. If it is necessary to estimate the SPL at some direction other than the principal directions, it is common practice to interpolate between the values given for the principal directions.

Table B-9 Correction to Average SPLs for Directional Effects of Cooling Towers

Octave Band (Hz)	31	63	125	250	500	1000	2000	4000	8000
CENTRIFUGAL-FAN BLOW-THROUGH TYPE

Top	+2	+2	+2	+3	+3	+4	+4	+5	+5

B-10.3 Close-in SPLs.

Sound power level data usually will not give accurate calculated SPLs at very close distances to large-size sources, such as cooling towers. The data of Table B-10 may be used where it is required to estimate close-in SPLs at nearby walls, floors, or in closely confined spaces (at 3 to 5-foot or 0.914 meter to 1.524-meter distances from inlet and discharge openings).

Table B-10 Approximate Close-In SPLs (in dB) Near the Intake and Discharge Openings of Various Cooling Towers (3- to 5ft. distance (0.914 to 1.524 m))

Octave Band (Hz)	31	63	125	250	500	1000	2000	4000	8000
CENTRIFUGAL-FAN BLOW-THROUGH TYPE									
Intake	85	85	85	83	81	79	76	73	68
Discharged	80	80	80	79	78	77	76	75	74
AXIAL-FLOW BLOW-THROUGH TYPE (INCLUDING "UNDERFLOW" TYPE)									
Intake	97	100	98	95	91	86	81	76	71
Discharged	88	88	88	86	84	82	80	78	76
PROPELLER-FAN INDUCED-DRAFT TYPE									
Intake	94	96	94	92	88	83	78	72	65
Discharged	99	103	99	95	90	85	81	76	70

B-10.4 Half-speed Operation.

When it is practical to do so, the cooling tower fan can be reduced to half speed in order to reduce noise; such a reduction also reduces cooling capacity. Half-speed produces approximately two-thirds cooling capacity and approximately 8- to 10-dB noise reduction in the octave bands that contain most of the fan-induced noise. For half-speed operation, the octave band SPLs or PWLs of full-speed cooling tower noise may be reduced by the following amounts, where fB is the blade passage frequency and is calculated from the relation fB = No. of fan blades x shaft RPM/GO.

Octave band that contains:	Noise reduction due to half-speed:
1/8 fB	3 dB
1/4 fB	6 dB
1/2 fB	9 dB
fB	9 dB
2 fB	9 dB
4 fB	6 dB
8 fB	3 dB

If the blade passage frequency is not known, it may be assumed to fall in the 63-Hz band for propeller type cooling towers and in the 250-Hz band for centrifugal cooling towers. Waterfall noise usually dominates in the upper octave bands, and it would not change significantly with reduced fan speed.

B-10.5 Limitations.

B-10.5.1 Design Variations.

The data given here represent a reasonable summary of cooling tower noise, but it must still be expected that noise levels may vary from manufacturer to manufacturer, and from model to model as specific design changes take place. Whenever possible, request the manufacturer to supply the specific noise levels for the specific needs.

B-10.5.2 Enclosed Locations.

Most of the preceding discussion assumes that cooling towers will be used in outdoor locations. If they are located inside enclosed mechanical equipment rooms or within courts formed by several solid walls, the sound patterns will be distorted. In such instances, the PWL of the tower (or appropriate portions of the total PWL) can be placed in that setting, and the enclosed or partially enclosed space can be likened to a room having certain estimated amounts of reflecting and absorbing surfaces. Because of the limitless number of possible arrangements, this is not handled in a general way, so the problem of partially enclosed cooling towers is not treated here. In the absence of a detailed analysis of cooling tower noise levels inside enclosed spaces, it is suggested that the close-in noise levels of Table B-10 be used as approximations.

B-10.5.3 Evaporative Condensers.

Evaporative condensers are somewhat like cooling towers in terms of noise generation. A few evaporative condensers have been included with the cooling towers, but not enough units have been measured to justify a separate study of evaporative condensers alone. In the absence of noise data on specific evaporative condensers, it is suggested that noise data be used for the most nearly similar type and size of cooling tower.

B-10.6 Air-cooled Condensers.

For some installations, an outdoor air-cooled condenser may serve as a substitute for a cooling tower or evaporative condenser. The noise of an air-cooled condenser is made up almost entirely of fan noise and possibly air-flow noise through the condenser coil decks. In general, the low-frequency fan noise dominates. Since most of the low-frequency noise of a typical cooling tower is due to the fan system, in the absence of specific data on air-cooled condensers, it is suggested that noise data be used for the most nearly similar type and size of cooling tower.

B-10.7 Ejector-type Cooling Tower.

This is a fan less-type cooling tower that induces air flow using nozzles of high-pressure water spray. Noise levels are generally lower for the ejector cooling tower than for cooling towers using fans to produce air flow. Adequate vibration isolation of the drive pump, piping, and tower are necessary, although the elimination of the fan reduces the severity of tower vibration.

B-11 PUMPS.

The overall and A-weighted 3-foot SPLs given in Table B-11. The pump power rating is taken as the nameplate power of the drive motor. This is easily determined in field measurements, whereas actual hydraulic power would be unknown in a field situation. For pump ratings under 100 hp (74.6 kW), the radiated noise increases with the function (10 log hp), but about 100 hp the noise changes more slowly with increasing power, hence, the function (3 log hp). Octave band SPLs are obtained by subtracting the values of Table B-12 from the overall SPLs of Table B-11. Pumps intended for high-pressure operation have smaller clearances between the blade tips and the cutoff edge and, as a result, may have higher noise peaks than shown in Tables B-11 and B-12 (by 5 dB, sometimes 10 dB) in the octave bands containing the impeller blade passage frequency and its first harmonic. These would usually fall in the 1,000 and 2,000 Hz octave bands. The data of Tables B-11 and B-12 are summarized in Figure B-4.

Table B-11 Overall and A-Weighted Sound Pressure Levels (dB and dB(A) at 3-ft (0.914 m) Distance) for Pumps

Speed Range rpm	Drive Motor Nameplate Power Under 100 hp	Above 100 hp
Overall sound messure level, dB:		
3000-3600	71+10 log hp	85+3 log hp
1600-1800	74+10 log hp	88+3 log hp
1000-1500	69+10 log hp	83+3 log hp
450- 900	67+10 log hp	81+3 log hp
A-weighted sound level, dB(A):		
3000-3600	69+10 log hp	82+3 log hp
1600-1800	72+10 log hp	86+3 log hp
1000-1500	67+10 log hp	81+3 log hp
450- 900	65+10 log hp	79+3 log hp

B-12 FANS.

B-12.1 In-duct Noise.

Recent issues of ASHRAE publications provide updated methods for estimating the in-duct noise of ventilating fans. Manufacturers also furnish in-duct PWL data of their fans on request. A current ASHRAE estimation is given by Equation B-5:

Equation B-5. In-Duct Sound Power Level

$$\mathbf{Lw = Kw + 10\log Q + 20\ \log P + BFI + C}$$

Where:
Lw = sound power level (in dB)
Kw = sound power level of specific fan design (dB)
Q = volumetric flow rate (cfm)
P = static pressure of the fan (inches of water)
BFI =blade frequency increment (dB)
where Lw the in-duct sound power level of the fan at either the inlet or discharge end of the fan, Kw the specific sound power level for the particular fan design, Q is the volume flow rate in cfm (ft^3/min.) (lps), and P is the static pressure produced by the fan (inches (cm) of water gage). Values of Kw for the octave bands and for various basic fan blade designs are given in part A of Table B-13. The blade passage frequency of the fan is obtained from

$$\mathbf{fan\ \ RPM\,x\ no.of\ blades/60}$$

and the “blade frequency increment” BFI (in dB) is added to the octave band sound power level in the octave in which the blade passage frequency occurs. It is best to obtain the number of blades and the fan rotational speed from the manufacturer to calculate the blade passage frequency. In the event this information is not available, part B of Table B-13 provides the usual blade passage frequency. The estimates given by this method assume ideal inlet and outlet flow conditions and operation of the fan at its design condition. The noise is quite critical to these conditions and increases significantly for deviations from ideal.

Part C of Table B-13 provides a correction factor for off-peak fan operation.

Table B-13 Specific Sound Power Levels Kw (in dB), Blade Frequency Increments (in dB) and Off-Peak Correction for Fans of Various Types, for Use in Equation B-5.

(for table below: for metric convert inches to cm: multiply by 2.54)

Fan & Blade Type	Size & Operation	Octave Band Center Frequency - Hz								
		63	125	250	500	1000	2000	4000	8000	BFI
CENTRIFUGAL- Airfoil, Backward Curved and Inclined	Over 30 in . dia.	37	37	36	31	27	20	16	14	3
	Under 30 in. dia.	42	42	40	36	31	25	21	16	3

PROPELLER	All sizes	45	48	55	53	52	46	43	39	5

Note – Kw for inlet or outlet level, add 3dB for total level.

Part B. Octave band in which blade frequency increment (BFI) occurs.

Fan Type	Octave Band in Which BFI occurs
Centrifugal	
Airfoil, backward curved & backward inclined	250 Hz
Forward curved	500 Hz
Radial blade	125 Hz
Vane axial	125 Hz
Tube axial	63 Hz
Propeller	63 Hz

Note – Use for estimating purposes only. Use manufacturer's data when available.

Part C. Correction factor, C, for Off-peak Operation.

Static Efficiency % of Peak	Correction Factor dB
90 to 100	0
85 to 89	3
75 to 84	6
65 to 74	9
55 to 64	12
50 to 54	15

B-12.2 Noise Reduction from Fan Housing.

The fan housing and its nearby connected ductwork radiate fan noise into the fan room. The amount of noise is dependent on both internal and external dimensions of the housing and ductwork, the TL of the sheet metal, and the amount of sound absorption material inside the ductwork. Because of so many variables, there is no simple analysis procedure for estimating the PWL of the noise radiated by the housing and ductwork. However, Table B-14 offers a rough estimate of this type of noise. These are simply deductions, in dB, from the induct fan noise. At low frequency, the housing appears acoustically transparent to the fan noise, but as frequency increases, the TL of the sheet metal becomes increasingly effective.

Table B-14 Approximate Octave-Band Adjustments for Estimating the PWL of Noise Radiated by a Fan Housing and its Nearby Connected Duct Work.

Octave Frequency Band (Hz)	Value to be Subtracted From In-Duct Fan Noise (dB)

B-13 AIR COMPRESSORS.

Two types of air compressors are frequently found in buildings: one is a relatively small compressor (usually under 5 hp (3.73 kW)) used to provide a high-pressure air supply for operating the controls of the ventilation system, and the other is a medium-size compressor (possibly up to 100 hp (746 kW)) used to provide “shop air” to maintenance shops, machine shops, and laboratory spaces, or to provide ventilation system control pressure for large buildings. Larger compressors are used for special industrial processes or special facilities, but these are not considered within the scope of the document. The 3-foot (.914 m) SPLs are given in Figure B-5 and Table B-15.

Figure B-5 Sound Pressure Levels of Air Compressors at 3-ft (.914 m) Distance.
(Multiply hp values by 7.46 for metric equivalent of kW)

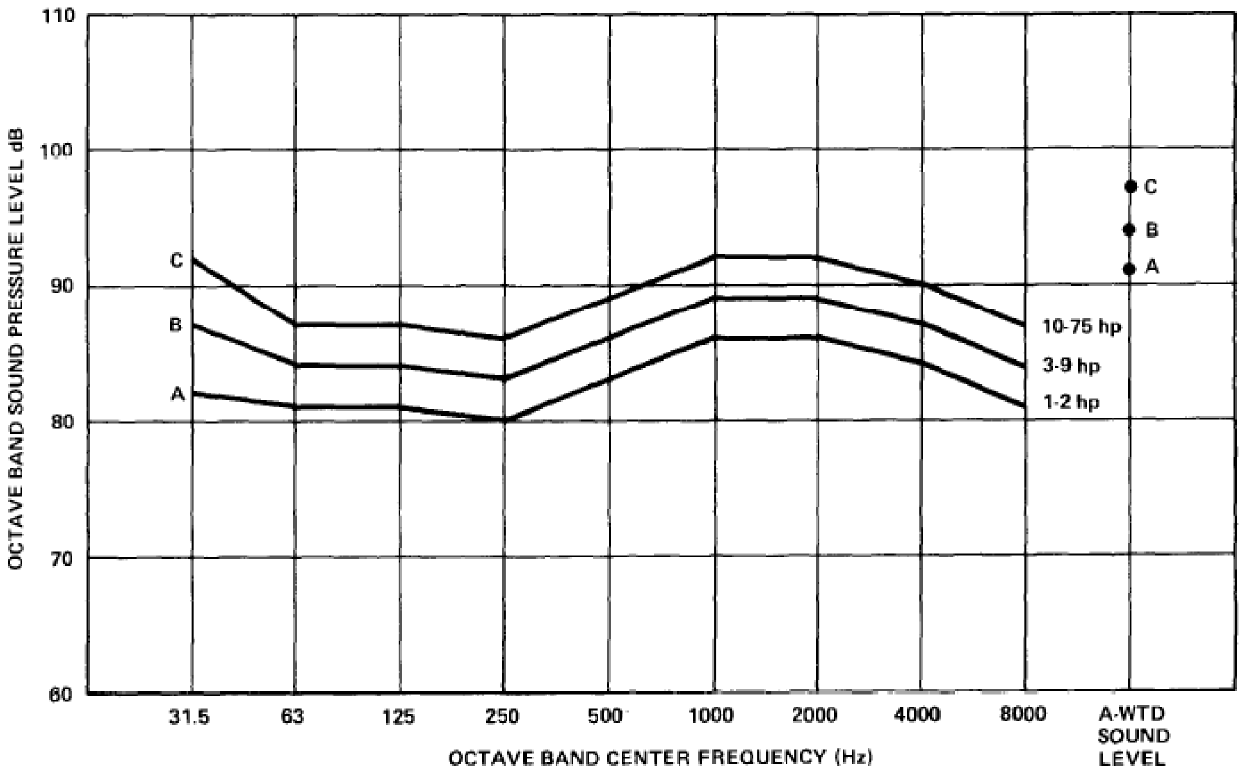

Table B-15 Sound Pressure Levels (dB at 3-ft (.914 m) Distance) for Air Compressors.

Octave Frequency Band (Hz)	Air Compressor Power Range		
	1-2 hp (dB)	3-9 hp (dB)	10-75 hp (bB)

B-14 RECIPROCATING ENGINES.

In a separate project for the Department of the Army, a comprehensive study has been made of the noise characteristics of reciprocating and turbine engines fueled by natural gas and liquid fuel. In the inactive UFC 3-450-02 Power Plant Acoustics, details are given for handling these data and for designing noise control treatments for small power plants at military bases. The noise levels of the engines as sound sources are summarized here because these engines may be used as power sources in buildings, and their noise must be considered. Typically, each engine type has three sound sources of interest: the engine casing, the air inlet into the engine, and the exhaust from the engine.

B-14.1 Engine Casing.

The PWL of the noise radiated by the casing of a natural-gas or diesel reciprocating engine is given by Equation B-6:

Equation B-6. Sound Power Level of Natural-Gas or Diesel Reciprocating Engine Casing

$$\mathbf{Lw} = \mathbf{93} + \mathbf{10}\,\mathbf{log}(\mathbf{rated\ hp}) + \mathbf{A} + \mathbf{B} + \mathbf{C} + \mathbf{D},$$

Where:
Lw = sound power level (dB)
rated hp = manufacturer’s engine horsepower rating
A, B, C, D = correction items from Table B-16 (in dB)

where Lw is the overall sound power level (in dB), “rated hp” is the engine manufacturer’s continuous full-load rating for the engine (in horsepower), and A, B, C, and D are correction terms (in dB), given in Table B-16. Octave band PWLs can be obtained by subtracting the Table B-17 values from the overall PWL given by Equation B-6. The octave band corrections are different for the different engine speed groups. For small engines (under about 450 hp), the air intake noise is usually radiated close to the engine casing, so it is not easy or necessary to separate these two sources; and the engine casing noise may be considered as including air intake noise (from both naturally aspirated and turbocharged engines).

Table B-16 Correction Terms (in dB) to be Applied to Equation B-6 for Estimating the Overall PWL of the Casing Noise of a Reciprocating Engine.

Speed correction term "A"	dB
Under 600 rpm	-5
600-1500 rpm	-2
Above 1500 rpm	0
Fuel correction term "B"	**dB**
Diesel fuel only	0
Diesel and/or natural gas	0
Natural gas only (May have small amount of "pilot oil")	-3
Cylinder arrangement term "C"	**dB**
In-line	0
V-type	-1
Radial	-1
Air intake correction term "D"	**dB**
Unducted air inlet to unmuffled Roots Blower	+3
Ducted air from outside the room or into muffled Roots Blower	0
All other inlets to engine (with or without turbochargers)	0

Table B-17 Frequency Adjustments (in dB) for Casing Noise of Reciprocating Engines.

Octave Frequency Band (Hz)	Value to be Subtracted from Overall PWL, in dB			
	Engine Speed Under 600 rpm	Engine Speed 600-1500 rpm		Engine Speed Over 1500 rpm
		Without Roots Blower	With Roots Blower	
31	12	14	22	22
63	12	9	16	14
125	6	7	18	7

500	7	7	3	8
1000	9	7	4	6
2000	12	9	10	7
4000	18	13	15	13
8000	28	19	26	20
A-weighted, dB(A)	4	3	1	2

B-14.2 Turbocharged Air Inlet.

Most large engines have turbochargers at their inlet to provide pressurized air into the engine for increased performance. The turbocharger is a turbine driven by the released exhaust gas of the engine. The turbine is a high-frequency sound source. Turbine configuration and noise output can vary appreciably, but an approximation of the PWL, of the turbocharger noise is given by Equation B-7:

Equation B-7. Sound Power Level of Turbocharger Air Inlet

$$\mathbf{Lw = 94 + 5\log(rated\ hp) - L/6}$$

Where:
Lw = sound power level (in dB)
rated hp = manufacturer's engine horsepower rating
L = length of ducted inlet to the turbocharger (ft) (m)

where Lw and "rated hp" are already defined and L is the length, in ft (cm m)., of a ducted inlet to the turbocharger. For many large engines, the air inlet may be ducted to the engine from a fresh air supply or a location outside the room or building. The term L/6, in dB, suggests that each 6 ft. (1.83 m) of inlet ductwork, whether lined with sound absorption material, will provide about 1 dB of reduction of the turbocharger noise radiated from the open end of the duct. This is not an accurate figure for ductwork in general; it merely represents a simple token value for this estimate. The octave band values given in Table B-18 are subtracted from the overall PWL of Equation B-7 to obtain the octave band PWLs of turbocharged inlet noise.

Table B-18 Frequency Adjustments fin dB) for Turbocharger Air Inlet Noise.

Octave Frequency Band (Hz)	Value to be Subtracted From Overall PWL (dB)
31	4
63	11
125	13
250	13
500	12
1000	9
2000	8
4000	9
8000	17
A-weighted, dB(A)	3

B-14.3 Engine Exhaust.

The PWL of the noise radiated from the unmuffled exhaust of an engine is given by Equation B-8:

Equation B-8. Sound Power Level of Unmuffled Natural-Gas or Diesel Reciprocating Engine Exhaust

$$\mathbf{Lw = 119 + 10\,log(rated\ hp) - T - L/4}$$

Where:
Lw = sound power level (in dB)
rated hp = manufacturer's engine horsepower rating
T = correction term (in dB)
L = length of exhaust pipe (ft)(m)

where T is the turbocharger correction term (T = 0 dB for an engine without a turbocharger and T = 6 dB for an engine with a turbocharger) and L is the length, in ft (cm m)., of the exhaust pipe. A turbocharger takes energy out of the discharge gases and results in an approximately 6-dB reduction in noise. The octave band PWLs of unmuffled exhaust noise are obtained by subtracting the values of Table B-19 from the overall PWL derived from Equation B-8. If the engine is equipped with an exhaust muffler, the final noise radiated from the end of the tailpipe is the PWL of the unmuffled exhaust minus the insertion loss, in octave bands, of the muffler.

Table B-19 Frequency Adjustments (in dB) for Unmuffled Engine Exhaust Noise.

Octave Frequency Band (Hz)	Value to be Subtracted From Overall PWL (dB)

B-15 GAS TURBINE ENGINES.

B-15.1 PWL of Three Sources.

As with reciprocating engines, the three principal sound sources of turbine engines are: the engine casing, the air inlet, and the exhaust. Most gas turbine manufactures will provide sound power estimates of these sources. However, when these are unavailable the overall PWLs of these three sources, with no noise reduction treatments, are given in the following equations:

for engine casing noise:

Equation B-9. Sound Power Level of Gas Turbine Engine Casing

$$\mathbf{Lw = 120 + 5\ \log(rated\ MW);}$$

Where:
Lw = sound power level (in dB)
rated MW = manufacturer's engine megawatts rating

for air inlet noise:

Equation B-10. Sound Power Level of Gas Turbine Engine Air Inlet

$$\mathbf{Lw = 127 + 15\ \log(rated\ MW);}$$

Where:
Lw = sound power level (dB)
rated MW = manufacturer's engine megawatts rating

for exhaust noise:

Equation B-11. Sound Power Level of Gas Turbine Engine Exhaust

$$\mathbf{Lw = 133 + 10\log(rated\ MW)};$$

Where:
Lw = sound power level (dB)
rated MW = manufacturer's engine megawatts rating

where "rated MW" is the maximum continuous full-load rating of the engine in megawatts. If the manufacturer lists the rating in "effective shaft horsepower" (EShp), the MW rating may be approximated by

Equation B-12. Megawatts Rating by Effective Shaft Horsepower

$$\mathrm{MW} = \mathrm{eshp}/1400.$$

Where:
MW = engine megawatts rating
EShp = effective shaft horsepower

Overall PWLs, obtained from Equations B-9 through B-11, are tabulated in Table B-20 for a useful range of MW ratings.

Table B-20 Overall PWLs of the Principal Noise Components of Gas Turbine Engines Having No Noise Control Treatments

Rated MW	Casing PWL dB	Inlet PWL dB	Exhaust PWL dB
0.10	115	112	123
0.13	116	114	124

80	130	156	152

B-15.1.1 Tonal Components.

For casing and inlet noise, particularly strong high-frequency sounds may occur at several of the upper octave bands. However which bands contain the tones will depend on the specific design of the turbine and, as such, will differ between models and manufacturers. Therefore, the octave band adjustments of Table B-21 allow for these peaks in several different bands, even though they probably will not occur in all bands. Because of this randomness of peak frequencies, the A-weighted levels may also vary from the values quoted.

Table B-21 Frequency Adjustments (dB) for Gas Turbine Engine Noise Sources

Octave Frequency Band (Hz)	Value To Be Subtracted From Overall PWL, in dB		
	Casing	Inlet	Exhaust
31	10	19	12
63	7	18	8
125	5	17	6
250	4	17	6
500	4	14	7
1000	4	8	9
2000	4	3	11
4000	4	3	15
8000	4	6	21
A-weighted, dB(A)	2	0	4

B-15.1.2 Engine covers.

The engine manufacturer sometimes provides the engine casing with a protective thermal wrapping or an enclosing cabinet, either of which can give some noise reduction. Table B-22 suggests the approximate noise reduction for casing noise that can be assigned to different types of engine enclosures. Refer to the notes of the table for a broad description of the enclosures. The values of Table B-22 may be subtracted from the octave band PWLs of casing noise to obtain the adjusted PWLs of the covered or enclosed casing. An enclosure specifically designed to control casing noise can give larger noise reduction values than those in the table. Note: the performance of enclosures that are supported on the same structure as the gas turbine, will be limited by structure borne sound. For this reason, care must be used in applying laboratory data of enclosure performance to the estimation of sound reduction of gas turbine enclosures.

Table B-22 Approximate Noise Reduction Gas Turbine Engine Casing Enclosures

Octave Frequency Band (Hz)	Noise Reduction, dB				
	Type 1	Type 2	Type 3	Type 4	Type 5
31	2	4	1	3	6
63	2	5	1	4	7
125	2	5	1	4	8
250	3	6	2	5	9
500	3	6	2	6	10
1000	3	7	2	7	11
2000	4	8	2	8	12
4000	5	9	3	8	13
8000	6	10	3	8	14

Notes:

- **Type 1.** Glass fiber or mineral wool thermal insulation with lightweight foil cover over the insulation.
- **Type 2.** Glass fiber or mineral wool thermal insulation with minimum
- 20 gage aluminum or 24 gage steel or 1/2-in. (1.27 cm) thick plaster cover over the insulation.
- **Type 3.** Enclosing metal cabinet for the entire packaged assembly, with open ventilation holes and with no acoustic absorption lining inside the cabinet.
- **Type 4.** Enclosing metal cabinet for the entire packaged assembly, with open ventilation holes and with acoustic absorption lining inside the cabinet.
- **Type 5.** Enclosing metal cabinet for the entire packaged assembly, with all ventilation holes into the cabinet muffled and with acoustic absorption lining inside the cabinet.

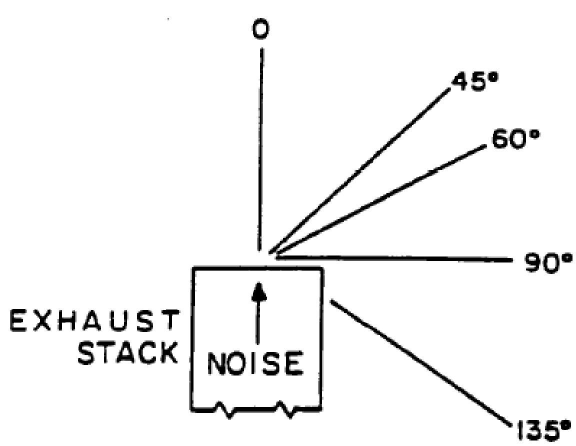
B-15.2 Exhaust and Intake Stack Directivity.

Frequently, the exhaust of a gas turbine engine is directed upward. The directivity of the stack provides a degree of noise control in the horizontal direction. Or, in some installations, it may be beneficial to point the intake or exhaust opening horizontally in a direction away from a sensitive receiver area. In either event, the directivity is a factor in noise radiation. Table B-23 gives the approximate directivity effect of a large exhaust opening. This can be used for either a horizontal or vertical stack exhausting hot gases. Table B-23 shows that from approximately 0 to 60 degrees from the axis of the stack, the stack will yield higher sound levels than if there was no stack and the sound were emitted by a nondirectional point source. From about 60 to 135 degrees from the axis, there is less sound level than if there were no stack. In other words, directly ahead of the opening there is an increase in noise, and off to the side of the opening there is a decrease in noise. The Table B-23 values also apply for a large-area intake opening into a gas turbine for the 0 to 60-degree range; for the 90 to 135 degree range, subtract an addition 3 dB from the already negative-valued quantities. For horizontal stacks, sound-reflecting obstacles out in front of the stack opening can alter the directivity pattern. Even irregularities on the ground surface can cause some backscattering of sound into the 90 to 180-degree regions, for horizontal stacks serving either as intake or exhaust openings. For small openings in a wall, such as for ducted connections to a fan intake or discharge, use approximately one-half the directivity effect of Table B-23 (as applied to intake openings) for the 0 to 90-degree region. For angles beyond 90 degrees, estimate the effect of the wall as a barrier.

Table B-23 Approximate Directivity Effect (in dB) of a Large Exhaust Stack Compared to a Nondirectional Source of the Same Power

Octave Frequency Band (Hz)	Relative Sound Level for Indicated Angle From Axis				
	0°	45°	60°	90°[a]	135° and larger[a]
31	8	5	2	-2	-3
63	8	5	2	-3	-4
125	8	5	2	-4	-6
250	8	6	2	-6	-8
500	9	6	2	-8	-10
1000	9	6	1	-10	-13
2000	10	7	0	-12	-16
4000	10	7	-1	-14	-18
8000	10	7	-2	-16	-20

[a] For air intake openings subtract 3 dB from the values in the 90º and 135° columns, in other words, -2 -3 = -5 dB for 31 cps at 90°.The diagram below represents the exhaust stack described in Table B-23.



B-16 ELECTRIC MOTORS.

Motors cover a range of 1 to 4000 hp (7.46 kW to 29.8 MW) and 450 to 3600 RPM. The data include both “drip-proof’ (DRPR) (splash-proof or weather-protected) and “totally enclosed fan-cooled” (TEFC) motors. Noise levels increase with power and speed.

Metric Conversion: Multiply motor hp by 7.46 for equivalent kW)

B-16.1 TEFC Motors.

The overall SPLs of TEFC motors, at the normalized 3-foot (.914 m) condition, follow approximately the relationships of Equations B-13 and B-14.

for power ratings under 50 hp,

Equation B-13. Sound Pressure Level of TEFC Motor Under 50 hp

$$\mathbf{Lp = 15 + 17\log hp + 15\ \log RPM}$$

Where:
Lp = sound pressure level (in dB)
hp = manufacturer’s horsepower rating
RPM = motor shaft speed in revolutions per minute

for power ratings above 50 hp,

Equation B-14. Sound Pressure Level of TEFC Motor Above 50 hp

$$\mathbf{Lp = 27 + 10\ \log hp + 15\ \log RPM}$$

Where:
Lp = sound pressure level (in dB)
hp = manufacturer’s horsepower rating
RPM = motor shaft speed in revolutions per minute

where “hp” is the nameplate motor rating in horsepower and “RPM” is the motor shaft speed. For motors above 400 hp, use the calculated noise value for a 400-hp motor. These data are not applicable to large commercial motors in the power range of 1000 to 5000 hp. The octave band corrections for TEFC motors are given in Table B-24. The data of Equations B-12 and B-13 and Table B-24 are summarized in Figure B-6, which gives the SPLs at 3-foot (0.914 m) distance for TEFC motors for a working range of speeds and powers. Some motors produce strong tonal sounds in the 500, 1,000, or 2,000 Hz octave bands because of the cooling fan blade frequency. Table B-24 and Figure B-6 allow for a moderate amount of these tones, but a small percentage of motors may still exceed these calculated levels by as much as 5 to 8 dB. When specified, motors that are quieter than these calculated values by 5 to 10 dB can be purchased.

B-16.2 DRPR Motors.

The overall SPLs of DRPR motors, at the normalized 3-foot condition, follow approximately the relationships of Equations B-15 and B-16.

for power ratings under 50 hp:

Equation B-15. Sound Pressure Level of DRPR Motor Under 50 hp

$$\mathbf{Lp = 10 + 17\ log\,hp + 15\ log\,RPM}$$

Where:
Lp = sound pressure level (in dB)
hp = manufacturer's horsepower rating
RPM = motor shaft speed in revolutions per minute

for power ratings above 50 hp:

Equation B-16. Sound Pressure Level of DRPR Motor Above 50 hp

$$\mathbf{Lp = 22 + 10\ log\,hp + 15\ log\,RPM}$$

Where:
Lp = sound pressure level (in dB)
hp = manufacturer's horsepower rating
RPM = motor shaft speed in revolutions per minute

For motors above 400 hp, use the calculated noise value for a 400 hp motor. The octave band corrections for DRPR motors are given in Table B-25. The data of Equations B-15 and B-16 and Table B-25 are summarized in Figure B-7, which gives the SPLs at 3-foot distance for DRPR motors over a range of speeds and powers.

B-17 STEAM TURBINES.

Noise levels are found generally to increase with increasing power rating, but it has not been possible to attribute any specific noise characteristics with speed or turbine blade passage frequency (because these were not known on the units measured). The suggested normalized SPLs at 3-foot (0.914 m) distance are given in Figure B-8 and Table B-26.

Figure B-8 Sound Pressure Levels of Steam Turbines at 3 ft (0.914 m) Distance

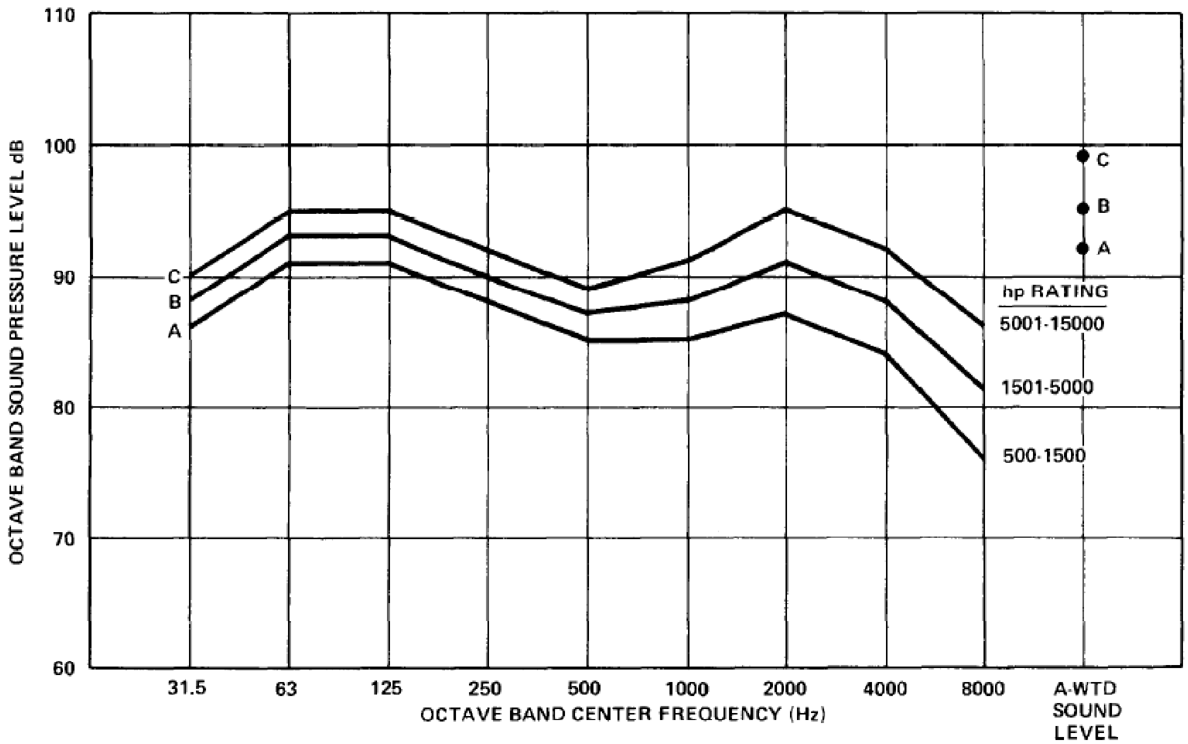

Table B-26 Sound Pressure Levels (dB at 3 feet (0.914 m) distance) for steam turbines

Octave Frequency Band (Hz)	Steam Turbine Power Ranger		
	500-1500 hp (dB)	1501-5000 hp (dB)	5001-15000 hp (dB)

Metric Conversion: Multiply motor hp by 7.46 for equivalent kW)

B-18 GEARS.

It is generally true that the noise output increases with increasing speed and power, but it is not possible to predict in which frequency band the gear tooth contact rate or the “ringing frequencies” will occur for any unknown gear. The possibility that these frequency components may occur in any of the upper octave bands is covered by, Equation B-17, which gives the octave band SPL estimate (at the 3 feet normalized condition) for all bands at and above 125 Hz:

Equation B-17. Sound Pressure Level of Gear Noise

$$\mathbf{Lp} = \mathbf{78} + \mathbf{3}\,\mathbf{log}(\mathbf{RPM}) + \mathbf{4}\,\mathbf{log}(\mathbf{hp})$$

Where:
Lp = sound pressure level (in dB)
RPM = speed of the slower gear shaft in revolutions per minute
hp = horsepower rating of the gear

where “RPM" is the speed of the slower gear shaft and “hp” is the horsepower rating of the gear or the power transmitted through the gear. For the 63 Hz band, 3 dB is deducted; and for the 31 Hz band, 6 dB is deducted from the Equation B-17 value. This estimate may not be highly accurate, but it will provide a reasonable engineering evaluation of the gear noise. Table B-27 gives the estimated SPL in the 125 through 8,000 Hz bands for a variety of speeds and powers, based on Equation B-17.

Table B-27 Approximate Sound Pressure Levels (dB at 3-ft (0.914 m). Distance) for Gears, in the 125-through 8000-Hz Octave Bands, from Equation B-17

Speed of Slower Gear Shaft (rpm)	Power Rating of Gear					
	50 hp (dB)	100 hp (dB)	200 hp (dB)	500 hp (dB)	1000 hp (dB)	2000 hp (dB)

B-19 GENERATORS.

The noise of generators, in general, can be quite variable, depending on speed, the presence or absence of air-cooling vanes, clearances of various rotor parts, and similar, but, most of all, on the driver mechanism. When driven by gas or diesel reciprocating engines, the generator is usually so much quieter than the engine that it can hardly be measured, much less heard. For gas turbine engines, the high-speed generator may be coupled to the engine through a large gear, and the gear and the generator may together produce somewhat indistinguishable noise in their compartment, which frequently is separated by a bulkhead from the engine compartment. Table B-28 gives an approximation of the overall PWL of several generators. It is not claimed that this is an accurate estimate, but it will give reasonable working values of PWL. It is to be noted that the PWL of the generator is usually less than that of the drive gear and less than that of the untreated engine casing. Octave band corrections to the overall PWL are given in Table B-29.

Table B-28 Approximate Overall PWL (in dB) of Generators, Excluding the Noise of the Driver Unit

Generator Speed, (rpm)	Electrical Power Rating of Generator							
	0.2 MW (dB)	0.5 MW (dB)	1 MW (dB)	2 MW (dB)	5 MW (dB)	10 MW (dB)	20 MW (dB)	50 MW (dB)

B-20 TRANSFORMERS.

The National Electrical Manufacturers Association (NEMA) provides a means of rating the noise output of transformers. The NEMA "audible sound level," as it is called in the standard, is the average of several A-weighted sound levels measured at certain specified positions. The NEMA sound level for a transformer can be provided by the manufacturer. Based on field studies of many transformer installations, the PWL in octave bands has been related to the NEMA rating and the area of the four side walls of the unit. This relationship is expressed by Equation B-18:

Equation B-18. Sound Power Level of a Transformer

$$\mathbf{Lw = NEMA\ rating + 10\log A + C}$$

Where:
Lw = sound power level (in dBA)
NEMA rating = NEMA-compliant A-weighted transformer sound level
A = total surface area of transformer side walls (ft^2)
C = octave band correction (in dBA)

where “NEMA rating” is the A-weighted sound level of the transformer provided by the manufacturer, obtained in accordance with current NEMA Standards, A is the total surface area of the four side walls of the transformer in ft.^{2}, and C is an octave band correction that has different values for different uses, as shown in Table B-30. If the exact dimensions of the transformer are not known, an approximation will suffice. When in doubt, estimate the area on the high side. An error of 25 percent in area will produce a change of 1 dB in the PWL. Use the most nearly applicable C value from Table B-30. The Cl value assumes normal radiation of sound. Use the C_2 value in regular-shaped confined spaces where standing waves will very likely occur, which typically may produce 6 dB higher sound levels at the transformer harmonic frequencies of 120, 240, 360, 480, and 600 Hz (for 60-Hz line frequency; or other sound frequencies for other line frequencies). The sound power level of the transformer does not increase in this location, but the sound analysis procedure is more readily handled by presuming that the sound power is increased. The C_3 value approximates the noise of a transformer that has grown noisier (by about 10 dB) during its lifetime. This happens occasionally when the laminations or tie-bolts become loose, and the transformer begins to buzz or rattle. In a highly critical location, it would be wise to use this value. All the Table B-30 values assume that the transformer initially meets it quoted NEMA sound level rating. Field measurements have shown that transformers may have A-weighted sound levels that range from a few decibels (2 or 3 dB) above to as much as 5 or 6 dB below the quoted NEMA value. Quieted transformers that contain various forms of noise control treatments can be purchased at as much as 15 to 20 dB below normal NEMA ratings. When a quieter transformer is purchased and used, use the lowered sound level rating in place of the regular NEMA rating in Equation B-18, and the appropriate corrections from Table B-30 selected.

Table B-30 Octave-Band Corrections (in dB) to be Used in Equation B-18 for Obtaining PWL of Transformers in Different Installation Conditions

Octave Frequency Band (Hz)	Octave Band Corrections, in dB		
	C_1, see Note 1	C_2, see Note 2	C_3, see Note 3
31	-1	-1	-1
63	+5	+8	+8
125	+7	+13	+13
250	+2	+8	+12
500	+2	+8	+12
1000	-4	-1	+6
2000	-9	-9	+1
4000	-14	-14	-4
8000	-21	-21	-11

Notes:
Note 1. Use C1 for outdoor location or for indoor location in a large mechanical equipment room (over about 5000 $ft.^3$ or 141.58 m^3) containing many other pieces of mechanical equipment that serve as obstacles to diffuse sound and breakup standing waves.

Note 2. Use C2 for indoor locations in transformer vaults or small rooms (under about 5000 ft.3 or 141.58 m^3) with parallel walls and relatively few other large-size obstacles that can diffuse sound and breakup standing waves.

Note 3. Use C3 for any location where a serious noise problem would result when the transformer becomes noisy above its NEMA rating, following its installation and initial period of use.

B-21 OPENING IN A WALL.

An opening, such as a door, window, or louvered vent, in an exterior wall of a noisy room will allow noise to escape from that room and perhaps be disturbing to neighbors. The PWL of the sound that passes through the opening can be estimated from Equation B-19:

Equation B-19. Sound Power Level at Wall Opening

$$\mathbf{Lw = Lp + 10\ \log A - 10}$$

Where:
Lw = sound power level (in dB)
Lp = sound pressure level (in dB)
A = area of the opening (ft^2)(m^2)

where Lp is the SPL in the room at the location of the opening and A is the area, in $ft.^2$, of the opening. (Note, the factor of - 10 is due to the use of ft^2 for A, if m^2 had been used then this factor would be 0). For normal openings (windows or vents) without ducted connections to the noise source, it may be assumed that the sound radiates freely in all directions in front of the opening, but to the rear of the wall containing the opening, the barrier effect of the wall must be considered. For ducted connections from a sound source to an opening in the wall, the sound is somewhat “beamed” out of the opening and may be assumed to have a directivity effect of above one-half the amount given in Table B-23 for air intake openings of large stacks.

APPENDIX C INFORMATIVE REFERENCE

C-1 GENERAL.

This reference is not part of this UFC. It is intended to be informative and does not contain any requirements necessary for conformance to this document. Additional information can be found in a wide variety of other non-government technical publications related to noise and vibration control.

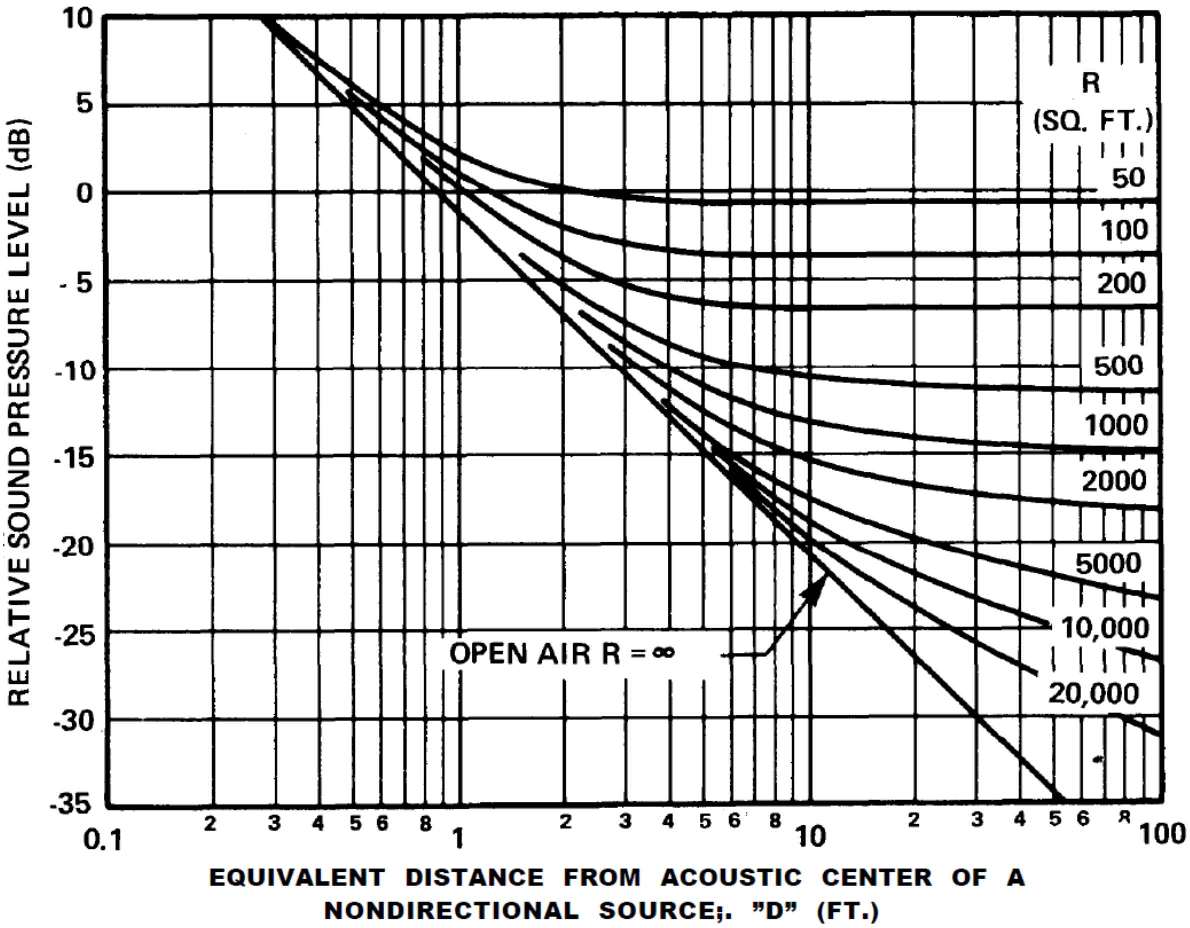
C-2 SOUND PRESSURE LEVEL IN A ROOM.

The sound pressure levels at a given distance or the sound power levels for individual equipment items can often be obtained from equipment suppliers. Appendix B also provides sound level and power level estimates for general classes of mechanical equipment. Once the characteristics of the sound source has been determined, then the sound level at any location within an enclosed space can be estimated. In an outdoor "free field" (no reflecting surfaces except the ground), the sound pressure level (SPL) decreases at a rate of 6 dB for each doubling of distance from the source. In an indoor situation, however, all the enclosing surfaces of a room confine the sound energy so that they cannot spread out indefinitely and become dissipated with distance. As sound waves bounce around within the room, there is a build-up of sound level because the sound energy is "trapped" inside the room and escapes slowly.

C-2.1 Effect of Distance and Absorption.

The reduction of sound pressure level indoors, as one moves across the room away from the sound source, is dependent on the surface areas of the room, the amount of sound absorption material on those areas, the distances to those areas, and the distance from the source. All of this is expressed quantitatively by the curves of Figure C-1. Figure C-1 offers a means of estimating the amount of SPL reduction for a piece of mechanical equipment (or any other type of sound source) in a room, as one moves away from some relatively close-in distance to any other distance in the room, provided the sound absorptive properties of the room (Room Constant) is known. Conversely Figure C-1 also provides a means of estimating the sound reduction in a room, from a given source, if the distance is constant and the amount of absorptive treatment is increased.

Figure C-1 Approximate Relationship Between "Relative Sound Pressure Level" (REL SPL) and Distance to a Sound Source for Various "Room Constant" Values



Note: This figure has been adjusted to consider large obstacles or large pieces of equipment distributed about the room. Therefore, the curves for large values of R do not agree with similar textbook curves that tend to ignore such obstacles. For metric where Ft is identified convert to m (meters)

C-2.2 General Application of Figure C-1.

Figure C-1 may be used for estimating SPL change from any given condition of Room Constant and distance to any other wanted condition of Room Constant and distance. This can be expressed by Equation C-1:

Equation C-1. Change in Room SPL between Room Constant and Distance Conditions

$$\mathbf{L_{pD2R2} = L_{pD1R1} - (REL\ SPL_{D1R1} - REL\ SPL_{\ D2R2})}$$

Where:
L_{pD2R2} = Change in SPL (in dBA) based on new conditions D2 (ft) and R2 (ft^2)
L_{pD1R1} = Known SPL (in dBA) based on measured conditions D1 (ft) and R1 (ft^2)
REL SPL_{D1R1} = Relative SPL based on new conditions (in dB)
REL SPL_{D2R2} = Relative SPL based on measured conditions (in dB)

where D1 and R1 are the distance (in feet or m) and Room Constant (in ft.^{2} or m^2) values for the measured or known sound pressure level L_{pD1Rl}; D_2 and R_2 are the distance and Room Constant values for the new set of conditions for which the new sound pressure level L_{pD2R2} is wanted; and REL SPL $_{D1R1}$ and REL SPL_{D2R2} (in dB) are read from the ordinate (vertical axis) of Figure C-1 for the specific combinations of D_1, R_1 and D_2, R_2. For estimating SPL change when only the Room Constant is changed and there is no change of distance (in other words, the equipment distance remains constant), the same distance value for D_1 and D_2 is used, and the equation is solved. For estimating SPL change when only the distance is changed and there is no change in Room Constant (in other words, the equipment remains in the same room, with no change in absorption), the same value of Room Constant for R_1 and R_2 is used, and the equation is solved. For a complete analysis, the calculations must be carried out for each octave frequency band.

C-2.3 Simplified Table for SPL Correction for Distance and Room Constant.

Table C-1 represents a simplification of Figure C-1 for a special condition of distance and room constant. Much of the collection of equipment sound data in Appendix B is given in terms of SPL at a normalized distance of 3 feet (0.914 m) and a normalized room constant of approximately 800 ft.^{2} (74.32 m^2). Table C-1 must not be used in converting sound power level (PWL) data to sound pressure level (see Equation C-2 and Table C-2). Table C-3 permits extrapolation from those normalized 3-foot (0.914 m) SPLs to some greater distance for a variety of different Room Constants.

Table C-1 Reduction of SPL in (dB) in Going from Normalized 3-foot (0.914 m) Distance and 800-ft.2 (74.32 m²) Room Constant to Any Other Distance and Room Constant

Room Constant "R" ($ft.^2$)	Distance "D" (in ft.) from Equipment								
	3	5	10	15	20	30	40	60	80
100	-5	-4	-4	-4	-4	-4	-4	-4	-4

500	1	1.1	1.1	1.2	1.2	1.3	1.5	1.6

Area in Table C-3 is shown as Ft², convert to M² as applicable.

C-2.4 SPL in a Room when PWL is Known.

The second major use of Figure C-1 is in determining the SPL in a room when the sound power level of the source is known. Equation C-2 provides this.

Equation C-2. Room SPL with Known PWL

$$\mathbf{L_{pD,R} = Lw + REL\ SPL_{D,R}}$$

Where:
$L_{pD,R}$ = sound pressure level (in dB) based on conditions D (ft) and R (ft^2)
Lw = known sound power level (in dB)
REL $SPL_{D,R}$ = relative sound pressure level (in dB)

where $L_{pD,R}$ is the SPL to be determined at distance D in the room of Room Constant R, Lw the sound power level of the source (in dB re 10^{12}W) and REL $SPL_{D,R}$ is read from the ordinate of Figure C-1 for the point of intersection of the D and R values specified. In most uses, the value of REL $SPL_{D,R}$ will be negative, so this amounts to a subtraction function. Hence, the signs must be followed carefully. The calculation is repeated for each octave band.

C-3 ROOM CONSTANT.

C-3.1 Calculation of a Room Constant.

The room constant is a measure of the amount of sound absorption that exists within a room. Most current acoustic textbooks give details of a conventional calculation of the Room Constant for any specific room, when the following facts are known: (1) all the room dimensions, (2) the wall, floor, and ceiling materials, (3) the amount and type of acoustic absorption materials, and (4) the sound absorption coefficients of the acoustic-materials at various specified frequencies. The calculation is summarized in Equation C-3:

Equation C-3. Room Constant Calculation

$$\mathbf{R} = \mathbf{S_1} \propto_1 + \mathbf{S_2} \propto_2 + \mathbf{S_3} \propto_3 + \ldots + \mathbf{S_n} \propto_n$$

Where:
R = room constant (ft²) (m²)
S_1 = surface area (each surface area in ft² (m²) notated by 1, 2,… n)
$\propto_1$ = sound absorption coefficient (each material coefficient notated by 1, 2,… n)

where R is the Room Constant (or "room absorption" as it is often called), S_1 is the total area of all the room surfaces having "sound absorption coefficients" $\propto_1$; S_2 is the total area of all the room surfaces having sound absorption coefficient $\propto_{12}$; and similar. The areas S_1…..S_n are expressed in ft² (m²), and the sound absorption coefficients ($\propto$'s) are dimensionless. The resulting Room Constant R is also expressed in ft² (m²). The term "Sabin" is used in the literature as a unit of room absorption or Room Constant, where one Sabin is the absorption provided by 1 ft² (0.093 m²) of material having perfect absorption, in other words, having a value of 1.0. In the manual, 1 ft² (0.093 m²) of absorption and 1 Sabin are used synonymously.

C-3.2 Sound Absorption Coefficients.

For most surfaces and materials, the sound absorption coefficients vary with frequency; hence the Room Constant must be calculated for all frequencies of interest. Even room surfaces that are not normally considered absorptive have small amounts of absorption. Table C-4 gives the published sound absorption coefficients of typical building materials. Usually, sound absorption coefficients are not measured in the 31, 63 and 8,000 Hz frequencies. Where the data at these frequencies are not available use 40% of the value of the 125 Hz for the 31 Hz band, 70% of the 125 Hz value for the 63 Hz band and 80% of the 4,000 values for the 8,000 Hz octave band. Values of sound absorption coefficients for specialized acoustical materials must be obtained from the manufacturer.

Table C-4 Sound Absorption Coefficients of General Building Materials and Furnishings (material in table is imperial, convert to metric as applicable)

Materials Part A	Coefficients					
	125 Hz	250 hz	500 hz	1000 hz	2000 hz	4000 hz
Brick, unglazed	.03	.03	.03	.04	.05	.07
Brick, unglazed, painted	.01	.01	.02	.02	.02	.03
Carpet, heavy, on concrete	.02	.06	.14	.37	.60	.65

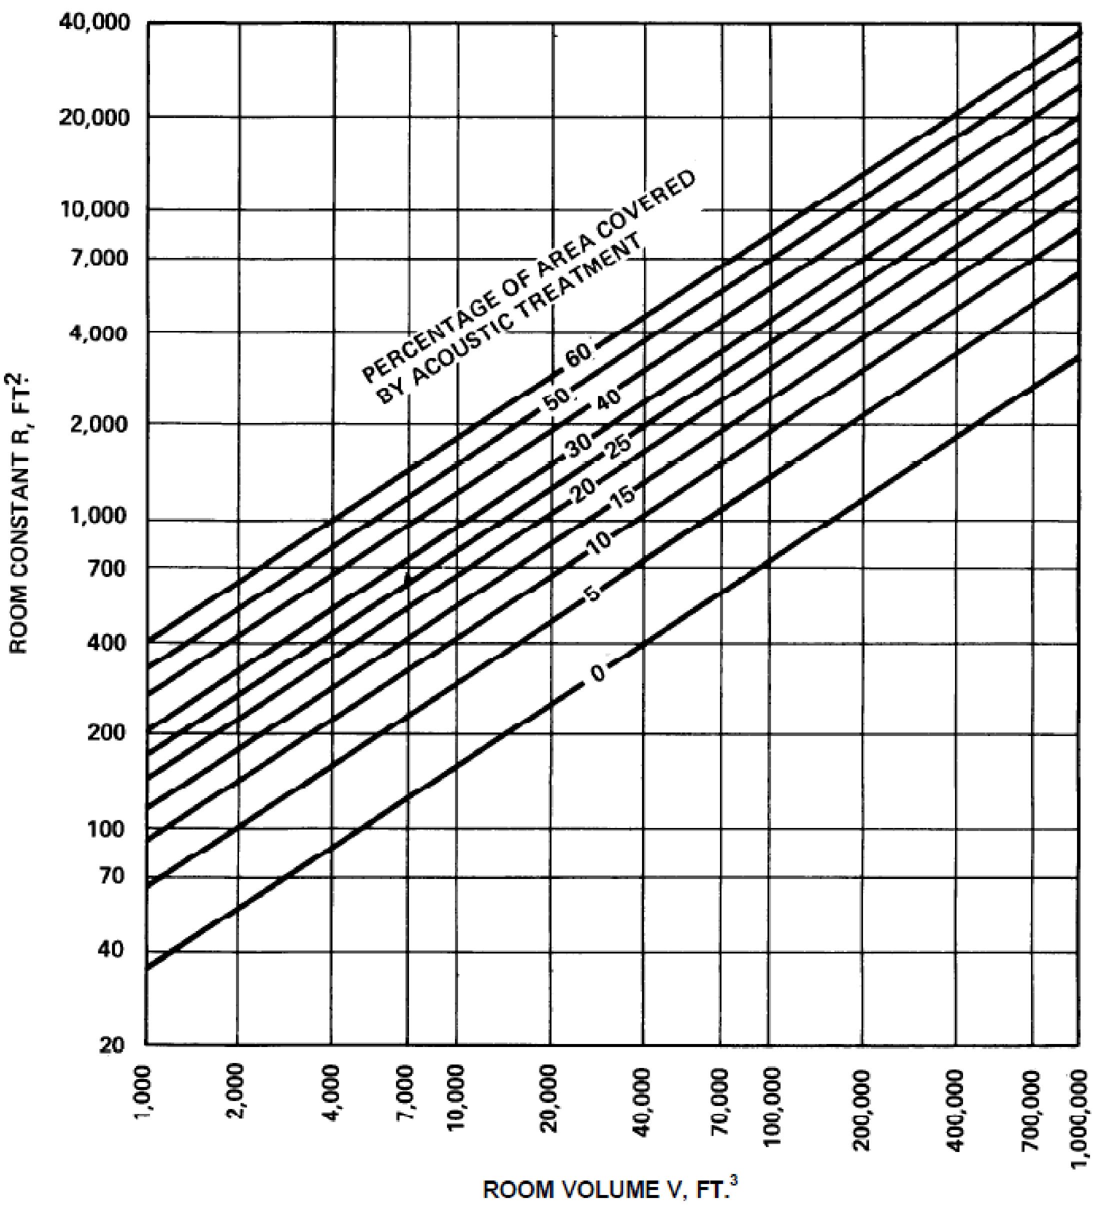
C-3.3 Estimation of Room Constant.

In the early stages of a design, some of the details of a room may not be finally determined, yet it may be necessary to proceed with certain portions of the design. An approximation of the Room Constant can be made using Table C-3 and Table C-4. The basic room dimensions are required but it is not necessary to have made all the decisions on side wall, floor, and ceiling materials. This simplification yields a less accurate estimate than does the more detailed procedure, but it permits rapid estimates of the Room Constant with gross, but nonspecific, changes in room materials and sound absorption applications. Then, when a favored condition is found, detailed calculations can be made with Equation C-1.

C-3.4 Use of Figure C-2.

Figure C-2 gives a broad relationship between the volume of a typically shaped room and the Room Constant as a function of the percentage of room area that is covered by sound absorption material. Room area means the total interior surface area of floor, ceiling, and all side walls. The Room Constant values obtained from this chart strictly apply at 1000 Hz, but in this simplified procedure are considered applicable for the 2000- through 8000-Hz bands as well.

Figure C-2 Room Constant Estimate



From Bolt Beranek and Newman Inc. Used with permission.
(Convert room constant (ft²) and room vol (ft³) to metric as applicable).

C-3.5 Use of Table C-4, part A.

Sound absorption materials are less effective at low frequency (at and below 500 Hz) than at high frequency (at and above 1000 Hz). Therefore, the high-frequency Room Constant obtained from Figure C-2 must be reduced to apply to the lower frequencies. Part A of Table C-4 gives a multiplier for doing this. This multiplier is a function of frequency, Noise Reduction Coefficient (NRC) range of any special sound absorption material, and the mounting type for installing the absorption material. The Noise Reduction Coefficient is the arithmetic average of the sound absorption coefficient at 250, 500, 1,000 and 2,000 Hz. Mounting type A consists of application sound absorptive material applied directly onto a hard backing such as a wall or ceiling. Mounting type B consists of sound absorptive material mechanically supported with a large air space behind the material, such as a typical suspended ceiling.

C-3.6 Use of Table C-4, part B.

Relatively thin wall materials (such as gypsum board, plaster, plywood, and glass), even though not normally considered as soft, porous, and absorptive, have relatively large values of sound absorption coefficient at low frequency. This is because these thin surfaces are lightweight and are easily driven by airborne sound waves. For this reason, they appear as effective sound absorbers at low frequency, and this characteristic must be considered in the calculation or estimation of Room Constant. Part B of Table C-4 gives a multiplier for doing this.

C-4 SAMPLE CALCULATIONS FOR INDOOR SOUND DISTRIBUTION.

Two sample calculations are provided, one in which the sound pressure level (SPL) for the equipment is provided and one where the sound power level (PWL) is provided.

C-4.1 Sound Pressure Level Provided.

To illustrate use of Equation C-2, a piece of equipment is measured by a manufacturer under one set of conditions and is to be used by the customer under an entirely different set of conditions. The data and calculations are summarized in Table C-5. The manufacturer's measurements, shown in column 2, are made at a 6-foot (1.83 m) distance from the equipment (here assumed nondirectional, that is, equal sound output in all directions) in a room whose Room Constants as a function of frequency are shown in column 3 of Table C-5. The customer is interested in the sound pressure levels at a 20-foot distance in a mechanical equipment room having the Room Constant values shown in column 5. In applying equation 3-2, D_1 = 6 ft (1.83 m)., D_2 = 20 ft (6.1 m)., R_1 is given by the column 3 data, R_2 is given in column 5, and the measured levels are listed in column 2. First, Figure C-1 is used to estimate the REL SPL_{D1R1} values for the 6-ft. distance and all the column 3 values of R1. These REL SPL values are given in column 4. Next, the REL SPLD2R2 values are estimated for the 20-foot (6.1 m) distance and all the column 5 values of R2. These REL SPL values are given in column 6. Column 7 shows the value of the difference (REL $SPLD_{1RI}$ - REL SPL_{D2R2}); it is necessary here to be extremely careful to preserve the correct signs. Finally, column 8 gives the value of SPL at D_2, R_2, which is equal to the column 2 value minus the column

7 value, again, being careful with the signs. To check the calculations, go back to Figure C-1 and follow one specific conversion, such as the 1000-Hz change of conditions. A pencil mark is placed at the junction of D_1 = 6 ft (1.83 m). and R_1 = 500 ft.^{2} (46.45 m^2), and it is noted that the measured SPL was 91 dB for that condition. Now, as one moves out to the junction of D_2 = 20 ft (6.1m). and R_2 = 1200 ft.^{2} (111.48 m^2), it is observed that there is a movement down the graph by 5 dB. This means there is a reduction of 5 dB from the initial condition of 91 dB. Therefore, the end condition is 91 - 5 = 86 dB, which is confirmed in the column 8 of Table C-5 for the 1000-Hz octave band. Hint: When the net movement is down on Figure C-1, there is a reduction from "starting SPL" to "ending SPL"; when the net movement is up on Figure C-1, there is an increase from "starting SPL to ending SPL." Note: this equation is to be used when SPL is given for one set of conditions and SPL is wanted for another set of conditions.

C-4.2 Sound Power Level Given.

Suppose a manufacturer submits the PWL data given in column 2 of Table C-6 for a particular centrifugal compressor. An engineer intends to install this compressor in a room having the R values shown in column 3 and needs to know the SPL at a 20-foot (6.1 m) distance. Column 4 shows the REL SPL values from Figure C-1 for the 20-foot (6.1 m) distances and the various Room Constants. Column 5 then gives the calculated SPL values.

C-5 ADDITIONAL INFORMATION ON SOUND TRANSMISSION LOSS (TL), NOISE REDUCTION (NR) AND SOUND TRANSMISSION CLASS (STC).

(Convert room constant (ft^2) to metric as applicable)

C-5.1 Transmission Loss (TL) of Walls.

The TL of a wall is the ratio, expressed in decibels, of the sound intensity transmitted through the wall to the airborne sound intensity incident upon the wall. Thus, the TL of a wall is a performance characteristic that is entirely a function of the wall weight, material and construction, and its numerical value is not influenced by the acoustic environment on either side of the wall or the area of the wall. Procedures for determining transmission loss in the laboratory are given in ASTM E 90. This is the data usually given in most manufacturers' literature and in acoustic handbooks. Laboratory ratings are rarely achieved in field installations. Transmission loss values in the laboratory are usually greater, by 4 to 5 dB, than that which can be realized in the field even when good construction practices are observed. ASTM E336 is a corresponding standard method for determination of sound isolation in buildings (in situ). The approximate transmission loss or "TL" values, expressed in dB, of a number of typical wall construction materials are given in the tables of paragraph C-6. There are many other references that provide transmission loss performance for building materials. In addition, many manufactures also provide transmission loss for their products.

C-5.1.1 "Suggested" vs "Ideal" TL Values.

In several of the tables of paragraphs C-6 and C-7, two sets of TL data are given. The first is labeled "suggested design values," and the second is headed "ideal values." With good design and workmanship, the "suggested design values" can be expected. The "ideal values" are perhaps the highest values that can be achieved if every effort, in both design and execution, is made to assure a good installation, including control of all possible flanking paths of sound and vibration. The "suggested design values" are 1 to 3 dB low the "ideal values" in the low-frequency region and as much as 10 to 15 dB lower in the high-frequency region. When walls have ideal TL values as high as 60 to 70 dB, even the slightest leakage or flanking can seriously reduce the TL in the high-frequency region.

C-5.1.2 TL of Other Materials and Fabricated Partitions.

Because of the increasing need for good sound isolation in building design, many manufacturers are producing modular wall panels, movable partitions, folding curtains, and other forms of acoustic separators. When inquiring about these products, it is desirable to request their transmission loss data and to determine the testing facility where the product was evaluated (in example, laboratory vs field, and the standard employed).

C-5.1.3 Estimated TL of Untested Partitions.

For estimations of the TL of an untested partition, its average surface weight in (lb./ft.^{2}) (kg/m^2) and its basic structural form must be determined. Then, the range of approximate TL values for partitions of similar weight and structure can be obtained.

C-5.2 Noise Reduction (NR) of a Wall.

When sound is transmitted from one room (the "source room") to an adjoining room (the "receiving room"), it is the transmitted sound power that is of interest. The transmission loss of a wall is a performance characteristic of the wall structure, but the total sound power transmitted by the wall is also a function of its area (such as the larger the area, the more the transmitted sound power). The Room Constant of the receiving room also influences the SPL in the receiving room. A large Room Constant reduces the reverberant sound level in the room at an appropriate distance from the wall. Thus, three factors influence the SPL in a receiving room: the TL of the wall, the area S_W of the common wall between the source and receiving rooms, and the Room Constant R2 of the receiving room. These three factors are combined in Equation C-4:

Equation C-4. Sound Pressure Level of Receiving Room

$$\mathbf{L_{p2} = L_{p1} - TL + 10\log\left(\frac{1}{4} + \frac{S_W}{R_2}\right)}$$

Where:
L_{p2} = sound pressure level in the receiving room (in dB)
L_{p1} = sound pressure level in the source room (in dB)
TL = transmission loss of the wall (in dB)
S_w = common wall area (ft^2)(m^2)
R_2 = room constant of receiving room (ft^2)(m^2)

where L_{p1} is the SPL near the wall in the source room, and L_{p2} is the estimated SPL in the receiving room at a distance from the wall approximately equal to 75 percent of the smaller dimension (length or height) of the wall. The “noise reduction” (NR) of a wall is the difference between L_{p1} and L_{p2}; therefore,

Equation C-5. Transmission Loss with Wall Correction Term

$$\mathbf{NR + TL - 10\log\left(\frac{1}{4} + \frac{S_W}{R_2}\right) = T\,L + C}$$

Where:
NR = noise reduction (in dB)
TL = transmission loss (in dB)
S_w = common wall area (ft^2)(m^2)
R_2 = room constant of receiving room (ft^2)(m^2)
C = wall correction term (in dB)

And

Equation C-6. Wall Correction Term

$$\mathbf{C = -\,10\log\left(\frac{1}{4} + \frac{S_W}{R_2}\right)}$$

Where:
C = wall correction term (in dB)
S_w = common wall area (ft^2)(m^2)
R_2 = room constant of receiving room (ft^2)(m^2)

In the document, C is called the “wall correction term” and its value is given in Table C-7 for a range of values of the ratio S_W/R_2. Both S_W and R_2 are expressed in ft (m), so the ratio is dimensionless. When NR is known for the wall and room geometry, Equation C-7 becomes:

Equation C-7. Wall Correction Term with Known NR

$$\mathbf{L_{p2} + L_{p1} - NR}$$

Where:
C = wall correction
L_{p2} = sound pressure level in the receiving room (in dB)
L_{p1} = sound pressure level in the source room (in dB)
NR = noise reduction (in dB)

Table C-7 Wall or Floor Correction Term "C" for Use in the Equation NR = TL + "C"

Ratio S_W/R_2	"C" (dB)	Ratio S_W/R_2	"C" (dB)	Ratio S_W/R_2	"C" (dB)
0.00	+6	1.7	-3	15	-12
0.07	+5	2.2	-4	20	-13
0.15	+4	2.9	-5	25	-14
0.25	+3	3.7	-6	31	-15
0.38	+2	4.7	-7	40	-16
0.54	+1	6.1	-8	50	-17
0.75	0	7.7	-9	63	-18
1.0	-1	9.7	-10	80	-19
1.3	-2	12.0	-11	100	-29

(Select nearest integral value of C)

The SPL at any distance from the wall of the receiving room can be determined by using Figure C-1 and extrapolating from the "starting distance" (75 percent of the smaller dimension of the wall) to any other desired distance for the particular R2 value.

C-5.3 *TL_c* of Composite Structures.

When a wall is made up of two or more different constructions, each with its own set of TL values, the effective transmission loss of the composite wall (*TL_c*) can be calculated. The transmission coefficient "t", of each construction, is the ratio of the transmitted acoustic power to the incident acoustic power and is related to TL by Equations C-8.

Equation C-8. Transmission Coefficient

$$\mathbf{t} = \frac{\mathbf{1}}{\mathbf{10^{(0.1\,x\,TL)}}}$$

Where:
t = transmission coefficient
TL = transmission loss (in dB)

Once the transmission coefficient of each of the individual constructions has been determined then the composite transmission loss can be determined by Equation C-9.

Equation C-9. Composite Transmission Loss

$$\boldsymbol{TL_c} = \mathbf{10\,log}[(\boldsymbol{S_1} + \boldsymbol{S_2} + \boldsymbol{S_3} + \ldots)/(\boldsymbol{S_1}\,\boldsymbol{t_1} + \boldsymbol{S_2}\,\boldsymbol{t_2} + \boldsymbol{S_3}\,\boldsymbol{t_3}\ldots)]$$

Where:
TL_c = composite transmission loss (in dB)
S = surface area (in ft^2 (m^2)where each wall is notated by 1, 2,… n)
t = transmission coefficient (where each coefficient is notated by 1, 2,… n)

Where S_1 is the surface area of the basic wall having transmission loss TL_1, S_2 is the surface area of a second section (such as a door) having TL_2, S_3 is the surface area of a third section (such as a window) having TL3, and so on. Since the transmission loss is different depending on the frequency, this calculation must be repeated for each octave band of interest.

C-5.4 Sound Transmission Class (STC).

Current architectural acoustics literature refers to the term “Sound Transmission Class” (STC). This is a one-number weighting of transmission losses at many frequencies. The STC rating is used to rate partitions, doors, windows, and other acoustic dividers in terms of their relative ability to provide privacy against intrusion of speech or similar type sounds. This one-number rating system is heavily weighted in the 500- to 2000-Hz frequency region. Its use is not recommended for mechanical equipment noise, whose principal intruding frequencies are lower than the 500- to 2000 Hz region. However, manufacturers who quote STC ratings must have the 1/3 octave band TL data from which the STC values were derived, so it is possible to request the TL data when these types of partitions are being considered for isolation of mechanical equipment noise. The procedure for determining an STC rating is given in ASTM standard E 413.

C-5.5 TL of double walls.

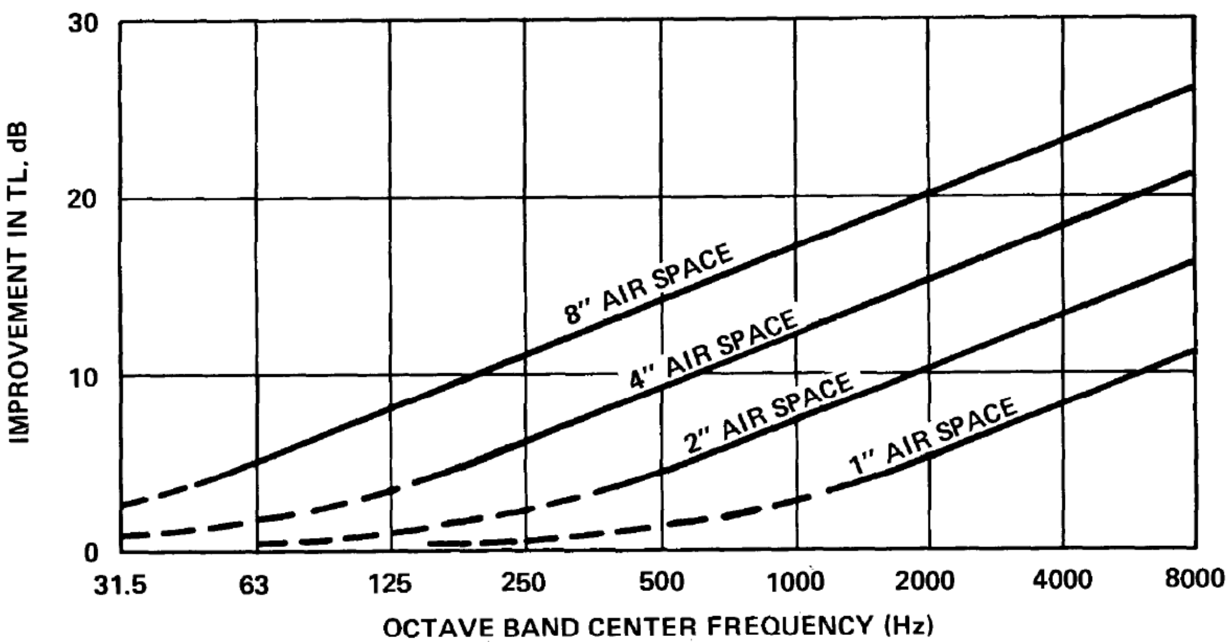
If mechanical equipment rooms are bordered by workspaces where a moderate amount of noise is acceptable, the equipment noise usually can be adequately contained by a single wall. Double walls of masonry, or two separate drywall systems, can be used to achieve even greater values of TL. Various intentional and unintentional structural connections between double walls have highly varying effects on the TL of double walls.

The improvement will be greatest at high frequency. The air space between the walls must be as large as reasonably possible to enhance the low-frequency improvement.

C-5.5.1 Influence of Air Space.

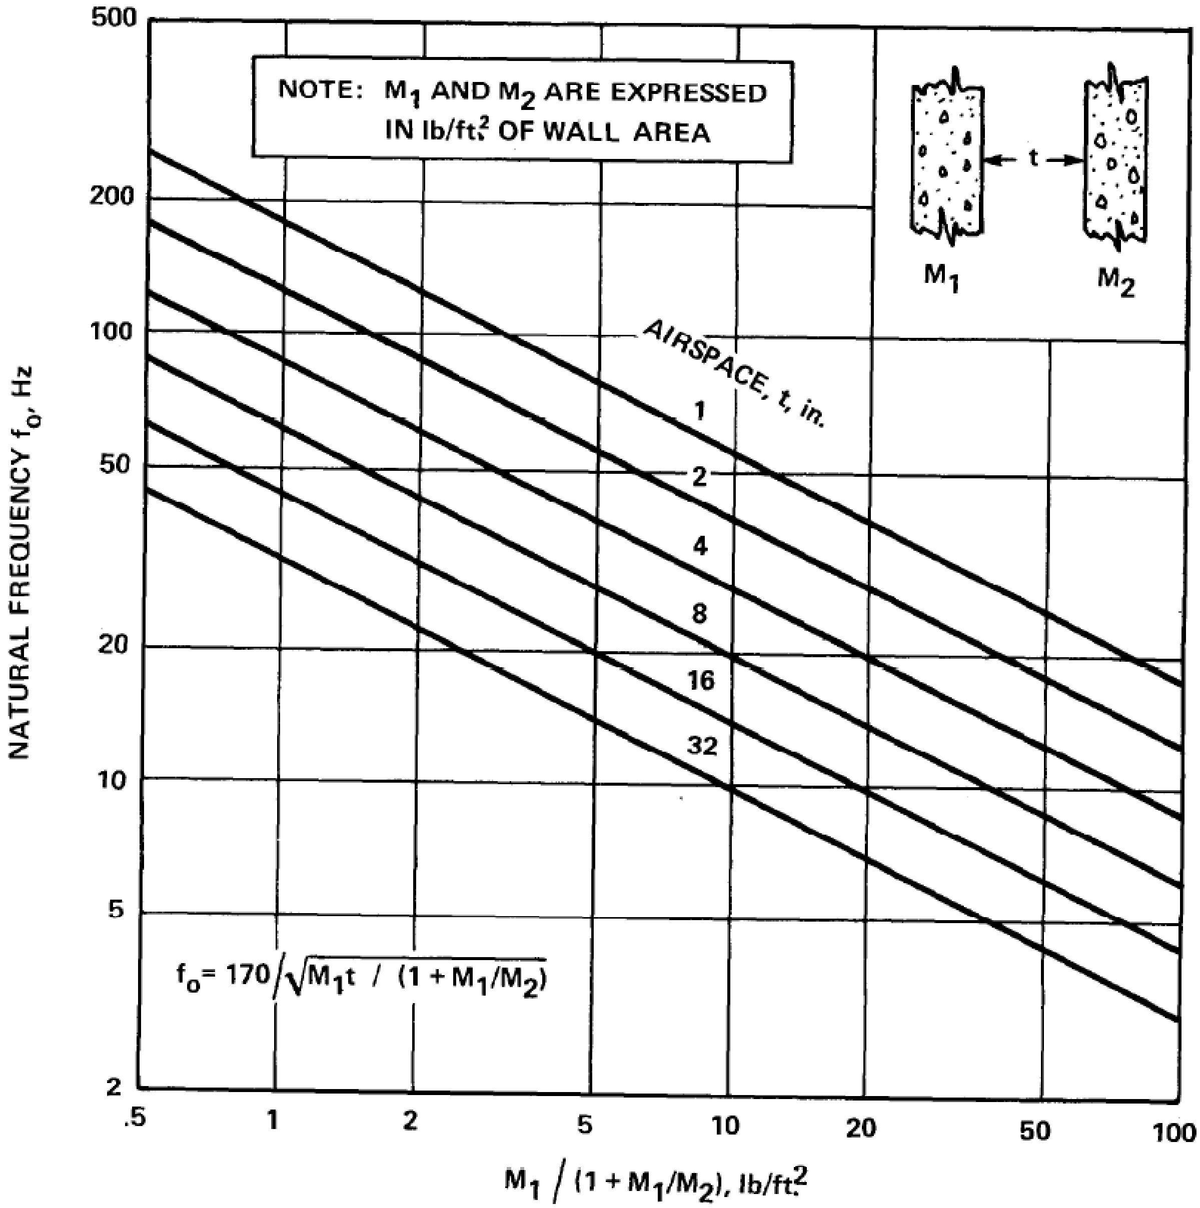
Figure C-3 shows the influence of the air space in double wall construction, assuming no structural connections between the two walls. Even though there may exist no structural connection between the walls, the walls are coupled by the intervening air space at low frequencies. The air space in a double-wall cavity acts somewhat as a spring (air is an "elastic medium"), and the mass of the walls and the air in the cavity have natural frequencies, as seen in Figure C-4. The total effect of a double wall, then, is to gain the improvement of Figure C-3 but to lose some of that gain in the vicinity of the natural frequency determined in Figure C-4. It is suggested that a loss of 5 dB be assigned to the octave band containing the natural frequency and a loss of 2 dB be assigned to the octave band on each side of the band containing the natural frequency.

Figure C-3 Improvement in Transmission Loss Caused by Air Space Between Double Walls Compared to Single Wall of Equal Total Weight, Assuming no Rigid Ties Between Walls



(for metric: air space in inches(") convert to centimeters (cm)

Figure C-4 Natural Frequency of a Double Wall With an Air Space

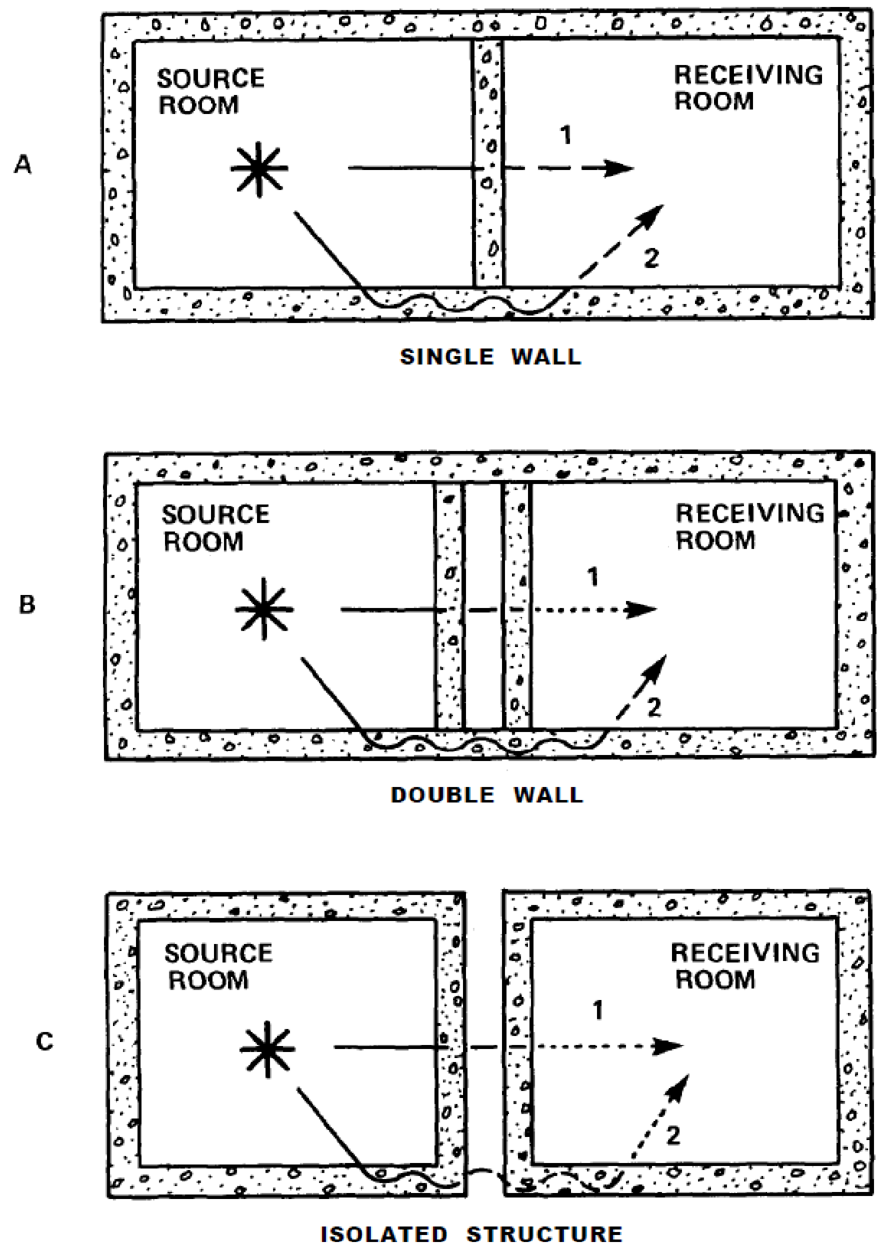


For metric: convert inches to centimeters and lb/ft^2 to kg/m^2)

C-5.5.2 Flanking Paths.

An obvious extension of the double wall concept is a wide corridor used to separate a noisy mechanical equipment room and rooms requiring NC 15 to NC 30 (Table 2-2). Although the airborne sound path through the double wall may appear to be under control, “flanking paths” may limit the actual achievable noise reduction into the quiet room. Figure C-5 illustrates flanking paths. When a structure, such as a wall or floor slab, is set into vibration by airborne sound excitation, that vibration is transmitted throughout all nearby connecting structures with very little decay as a function of distance. In a very quiet room, that vibration can radiate as audible sound. For most single walls between noisy and quiet spaces (part A of Figure C-5), the sound levels in the quiet room are limited by the TL of the single wall (path 1), and the sound by the flanking path (path 2) is too low to be of concern. However, the higher TL of the double wall (part B of Figure C-5) reduces the airborne sound (path 1) so much that the flanking path (path 2) becomes significant and limits the amount of noise reduction that can be achieved. Therefore, structural separation (part C of Figure C-5) is required in order to intercept the flanking path (path 2) and achieve the potential of the double wall.

Figure C-5 Schematic Illustration of Flanking Paths of Sound



C-5.5.3 Resilient Wall Mountings.

It is sometimes possible to enhance the TL of a simple concrete block wall or a study-type partition by resiliently attaching to that wall or partition additional layers of dry wall (gyp. bd.), possibly mounted on spring clips that are installed off 1-inch or 2-inch-thick furring strips, with the resulting air space tilled with sound absorption material. These constructions can provide an improvement in TL of 5 to 10 dB in the middle frequency region and 10 to 15 dB in the high frequency region, when properly executed.

C-6 TRANSMISSION LOSS - WALLS, DOORS, WINDOWS.

Generally, a partition will have better noise reduction with increasing frequency. It is therefore important to check the noise reduction at certain frequencies when dealing with low frequency, rumble type noise. Note that partitions can consist of a combination of walls, glass and doors. Walls can generally be classified as fixed walls of drywall or masonry, or as operable walls. These walls consist of drywall, studs and, sometimes, fibrous blankets within the stud cavity.

C-6.1 Framed Walls.

C-6.1.1 Drywall.

Drywall is a lightweight, low-cost material, and can provide a very high STC when used correctly. The use of Type X, or fire-rated drywall of the same nonrated drywall thickness, will have a negligible effect on acoustical ratings. Drywall is generally poor at low frequency noise reduction and is also very susceptible to poor installation. Drywall partitions must be thoroughly caulked with a nonhardening acoustical caulk at the edges. Tape and spackle is an acceptable seal at the ceiling and side walls. Electrical boxes, phone boxes, and other penetrations must not be back-to-back, but be staggered at least 2 feet (0.61 meters), covered with a fibrous blanket, and caulked. Multiple layers of drywall must be staggered. Wood stud construction has poor noise reduction characteristics because the wood stud conducts vibration from one side to the other. This can be easily remedied by using a metal resilient channel which is inserted between the wood stud and drywall on one side. Non-load bearing metal studs are sufficiently resilient and do not improve with a resilient channel. Load-bearing metal studs are stiff and can be improved with resilient channels installed on one side.

C-6.1.2 Fibrous Blankets.

Fibrous blankets in the stud cavity can substantially improve a wall's performance by as much as 10 dB in the mid and high frequency range where non-load bearing metal studs, or studs with resilient channels, are used. Use a minimum 2-inch-thick (5.1 cm), 3/4 lb/ft^3 (12.2 kg/m^3) fibrous blanket. Blankets up to 6 inches (15.24 cm) thick provide a modest additional improvement.

C-6.1.3 Double or Staggered Stud Walls.

When a high degree of noise reduction is needed, such as between a conference room and mechanical room, use double or staggered stud wall construction with two rows of metal or wood studs without bracing them together, two layers of drywall on both sides, and a 6 inch (15.24 cm) thick fibrous blanket.

C-6.2 Masonry Walls.

Masonry construction is heavy, durable, and can provide particularly good low frequency noise reduction. Concrete masonry units (CMU) made of shale or cinder have good noise reduction properties when they are approximately 50 percent hollow and not less than medium weight aggregate. Parging or furring with drywall on at least one side substantially improves the noise reduction at higher frequencies. The thicker the block, the better the noise reduction. An 8-inch-thick (20.32 cm), semi-hollow medium aggregate block wall with furring and drywall on one side is excellent around machine rooms, trash chutes, and elevator shafts.

C-6.3 Doors.

The sound transmission loss of both hollow and solid core doors will substantially increase when properly gasketed. Regular thermal type tape-on gaskets may not seal well because of door warpage and can also cause difficulty in closing the door. Tube type seals fitted into an aluminum extrusion can be installed on the door stop and fitted to the door shape. Screw type adjustable tube seals are available for critical installations. Sills with a half-moon seal at the bottom of the door are recommended in place of drop seals, which generally do not seal well. Two gasketed doors with a vestibule are recommended for high noise isolation. Special acoustical doors with their own jambs and door seals are available when a vestibule is not practical or very high noise isolation is required.

C-6.4 Windows.

Fixed windows will be close to their laboratory TL rating. Operable sash windows can be 10 dB less than the lab rating due to sound leaks at the window frame. Gaskets are necessary for a proper seal. Some window units will have unit TL ratings which would be a rating of both the gasketing and glass type. Double-glazed units are no better than single-glazed if the air space is 1/2 inch (1.3 cm) or thinner. A 2-inch (5.1 cm) airspace between glass panes will provide better noise reduction. Laminated glass has superior noise reduction capabilities. Installing glass in a neoprene “U” channel and installing sound absorbing material on the jamb between the panes will also improve noise reduction. Special acoustical window units are available for critical installations.

C-6.5 Transmission loss values for building partitions.

Tables C-8 through C-17 provide octave band transmission losses for various constructions, comments or details on each structure are given in the footnotes of the tables. STC ratings are useful for cursory analysis when speech transmission is of concern. Use the octave band transmission losses for a more thorough analysis, particularly when the concern is for mechanical equipment.

Table Construction Material No.

- Dense poured concrete or solid-core concrete block or masonry.
- Hollow-core dense concrete block.
- “Cinder block” or other lightweight porous block with sealed skin.
- Dense plaster.
- Stud-type partitions.
- Plywood, lumber and simple wood doors.
- Glass walls or windows.
- Double-glass windows.
- Filled metal panel partition and acoustic doors.
- Sheet aluminum, steel, lead, and lead-vinyl curtain.

Table C-8 Transmission Loss (in dB) of Dense Poured Concrete or Solid-Core Concrete Block or Masonry[a]

Octave Frequency Band (Hz)	Suggested Design Values						“Ideal Values”		
	Thickness of Concrete or Masonry (in.)						Thickness (in.)		
	4	6	8	10	12	16	4	8	16
	Approximate Surface Weight (lb/ft.^{2})						Surface Wt. (lb/ft.^{2})		
	48	72	96	120	144	192	48	96	192
31	29	32	34	36	36	36	30	36	38
63	35	36	36	36	36	37	36	38	38
125	36	36	37	37	38	41	38	38	44
250	36	38	41	43	44	46	38	44	52
500	41	44	45	47	48	49	43	52	58
1000	45	48	49	50	51	53	51	58	64
2000	50	52	53	54	55	57	57	64	70

8000	58	60	61	62	63	65	69	76	82
STC	45	48	49	51	52	53	49	55	62

Notes:

a. Apply appropriate conversion in table when calculations are metric.
b. "Dense" concrete and masonry assumes 140-150 lb/ft^2 density.
c. For lower values of density, estimate the actual surface weight (in lb/ft^2 of wall area) and use the TL from the column in the table that is closest to that surface weight.
d. If desired, install hollow-core block and fill voids completely (a course at a time) with concrete or mortar of the required density.

Table C-9 Transmission Loss (in dB) of Hollow-Core Dense Concrete Block or Masonry[a]

Octave Frequency Band (Hz)	Suggested Design Values						"Ideal Values"		
	Thickness of Concrete or Masonry (in.)						Thickness (in.)		
	4	6	8	10	12	16	4	8	16
	Approximate Surface Weight (lb/ft.^{2})						Surface Wt. (lb/ft.^{2})		
	28	36	44	52	60	76	28	44	76
31	26	28	29	31	32	33	26	30	34
63	31	33	35	36	36	36	32	36	38
125	35	36	36	36	36	36	37	38	38
250	36	36	36	37	37	38	38	38	39
500	37	38	41	42	43	44	38	42	48
1000	42	44	45	46	47	48	45	50	54

4000	50	52	53	54	55	56	59	62	66
8000	54	56	57	58	59	60	65	68	72
STC	42	43	45	46	47	48	45	48	52

Notes:

a. Apply appropriate conversion in table when calculations are metric.
b. "Dense" concrete and masonry assumes 140-150 lb/ft^3 density, if solid.
c. For lower density concrete, estimate the actual surface weight and use the TL for that value.

Table C-10 Transmission Loss (in DB) of "Cinder Block" or Other Lightweight Porous Block Material with Impervious Skin on Both Sides to Seal Pores[a]

Octave Frequency Band (Hz)	Suggested Design Values				"Ideal Values"	
	Thickness of Cinder Block (in.)				Thickness (in.)	
	4	6	8	10	4	10
	Approximate Surface Weight (lb/ft.^{2})				Surface Wt. (lb/ft.^{2})	
	24	36	48	60	24	60
31	22	26	27	28	24	30
63	27	28	28	28	29	30
125	28	28	28	28	30	30
250	28	29	30	33	30	35
500	30	34	36	37	32	42
1000	36	38	40	41	41	48
2000	40	42	43	44	47	54
4000	43	45	46	47	53	60
8000	46	48	49	50	59	66
STC	36	38	39	41	39	46

Notes:
a. Apply appropriate conversion in table when calculations are metric.
b. Lightweight block material assumes 65-75 lb/ft.^{3} density.
c. If hollow-core block or block of other density is used, select TL value for equivalent surface weight; interpolate or extrapolate if necessary.
d. Both sides of wall surfaces must be sealed with a plaster skim coat or two coats of heavy paint to achieve these values.

Table C-11 Transmission Loss (in dB) of Dense Plaster[a]

Octave Frequency Band (Hz)	Suggested Design Values					"Ideal Values"	
	Thickness of Plaster (in.)					Thickness (in.)	
	1/2	3/4	1	1-1/2	2	1/2	2
	Approximate Surface Weight (lb/ft.^{2})					Surface Wt. (lb/ft.^{2})	
	4-1/2	7	9	13	18	4-1/2	18
31	8	12	14	17	20	10	22
63	14	18	20	24	26	16	28
125	20	24	26	27	28	22	30
250	26	28	28	28	28	28	30
500	28	28	28	28	29	30	30
1000	28	28	29	32	34	30	38
2000	29	32	34	36	38	30	44
4000	35	37	38	40	41	38	50
8000	38	41	42	43	44	44	56
STC	29	30	31	33	34	31	37

Notes:

a. Apply appropriate conversion in table when calculations are in metric.
b. “Dense” plaster assumes approximately 9 lb/ft^2 surface weight per 1 in. thickness.
c. If lightweight nonporous plaster is used, these TL values may be used for equivalent surface weight. These data must not be used for porous or "Acoustic plaster."
d. If plaster is to be used on typical stud wall construction, estimate the surface weight of the-plaster and use the TL values given here for that amount, but increase the TL values where appropriate.

Table C-12 Transmission Loss (in dB) of Stud-Type Partitions

Octave Frequency Band (Hz)	Type 1	Type 2	Type 3	Improvements A	Improvements B
31	4	9	6	2	2
63	10	16	12	2	2
125	17	24	20	3	2
250	26	34	30	3	3
500	34	42	39	4	4
1000	40	48	46	4	4
2000	46	46	52	3	5
4000	44	48	50	3	6
8000	48	52	54	3	5
STC	37	44	41	3	3

Notes:

Type 1: One layer 1/2-in (1.27 cm). thick gypsum wallboard on each side of 2x4-in (5.1x10.2 cm). wood studs on 16-in (40.1 cm). centers. Fill and tape joints and edges, finish as desired. For equal width metal studs, add 2 dB in all bands and to STC.

Type 2: Two layers 5/8-in (1.6 cm). thick gypsum wallboard on each side of 2x4-in. (5.1x10.2 cm) wood studs on 16-in. (40.1 cm) centers. Fill and tape Joints and edges, finish as desired. For equal width metal studs, add 3 dB in all bands and to STC.

Type 3: One layer 5/8-in (1.6 cm). thick gypsum wallboard on outer edges of staggered studs, alternate studs supporting separate walls.2x4 in. (5.1x10.2 cm) wood studs on 16-in. (40.1 cm) centers for each wall. Fill and tape joints and edges, finish as desired. For equal width metal studs, add 1 dB in all bands and to STC.

Improvement A.
1. These values may be added to TL of Type 1 or Type 3 partition if l/2-in (1.27 cm) thick fibrous "sound-deadening board" is installed between studs and each layer of gypsum board.
2. These values may be added to TL of each type of partition if resilient spring clips or resilient metal channels are used to support one layer of gypsum board on one side of the set of studs. (For Type 2, delete the second layer of gypsum board on this side; keep two layers on opposite side.) No significant additional benefit will result from combining resilient supports and sound-deadening board under the same layer of gypsum board.

Improvement B.
1. If full area 3-in (7.62 cm). thick glass fiber or mineral wool is loosely supported inside the air cavity between walls, add these values to TL of Type 1 or Type 2 partition. Acoustic absorption material must not contact both interior surfaces of gypsum board (in other words, must not serve as partial "sound bridge" between walls).
2. If minimum 1-1/2-in. (3.8 cm) thick glass fiber or mineral wool is loosely supported inside the air cavity, add these values to TL of Type 3 partition or add one half these values to TL of Type 1 or 2 partition. Follow precautions of Step B.1 above.

Notes (continued)
Regarding both Improvements A and B.
The combined TL benefits of one type A improvement and one type B improvement can be applied to each of the partition types shown. More than two of these improvements to one partition will result in no significant additional TL benefit.

Table C-13 Transmission Loss (in dB) of Plywood, Lumber, and Simple Wood Doors.

Octave Frequency Band (Bz)	Thickness of Plywood or Lumber (In.)				
	1/4	1/2	1	2	4
	Approximate Surface Weight (lb/ft²)				
	1	2	4	8	16
31	0	2	7	12	17
63	2	7	12	17	18
125	7	12	17	18	19
250	12	17	18	19	22
500	17	18	19	22	30
1000	18	19	22	30	35
2000	19	22	30	35	39
4000	22	30	35	39	43
8000	30	35	39	43	47
STC	18	21	24	28	33

1. Apply metric conversion to material dimension when calculations are metric.
2. Surface weight based on 48 lb/ft^3 density, or 4 lb/ft^2 per in. thickness.
3. Lumber construction requires tongue-and-groove Joints, overlapping joints or sealing of joints against air leakage. For intermediate thicknesses, interpolate between thicknesses given in table.
4. For ungasketed hollow-core flush-mounted wood doors, use TL for 1/2-in. thick plywood.
5. For solid-core wood doors or approximately 2-in. thickness, well gasketed all around, use TL for 2-in. thick plywood.
6. For small-area doors or boxes, framing around Cage of panel adds effective mass and stiffness and will probably give higher TL values than shown.

Table C-14 Transmission LOSS (in dB) of Glass Walls or Windows

Octave Frequency Band (Hz)	Thickness of Glass (in.) 1/8	1/4	1/2	3/4
	Approximate Surface Weight (lb/ft^2) 1-1/2	3	6-1/2	10
31	2	7	13	17
63	8	14	19	22
125	13	20	24	26
250	19	25	27	28
500	23	27	29	29
1000	27	28	29	30
2000	27	28	31	32
4000	27	31	36	38
8000	31	34	40	43
STC	26	28	30	31

Notes:

1. Apply metric conversion to material dimensions when calculations are metric.
2. Variations in surface area and edge-clamping conditions can alter the TL values considerably.
3. There is not much consistency among published data.
4. TL tests usually are not carried out at 31-63 Hz; values given are estimates only.
5. In typical operable windows, poor seals can reduce these values.
6. Special laminated safety glass containing one or more viscoelastic layers sandwiched between glass panels will yield 5-10 dB higher values than given here for single thicknesses of glass; available in approximately 1/4- to 3/4-in. (0.64- to 1.9-cm) thicknesses.

Table C-15 Transmission Loss (in dB) of Typical Double-Glass Windows, Using 1/4-in (0.64 cm).-Thick Glass Panels with Different Air Space Widths

Octave Frequency Band (Hz)	Width of Air Space (in.)		
	1/4	1-1/2	6
31	13	14	15
63	18	19	22
125	23	26	30
250	26	30	35

8000	52	--	--	60	--	95
STC	41	40	45	58	64	71

Notes:

a. Apply metric conversion to material dimensions when calculations are metric.
b. Constructed of two 18 ga. steel panels filled with 3 in. of 6-8 lb/ft^3 glass fiber or mineral wool; Joints and edges sealed airtight.
c. Average of 4 doors, 1-3/4-in. to 2-5/8-in. thick, gasketed.
d. Average of 2 doors, all 4-in. thick, gasketed around all edges, range of weight 12-23 lb/ft.
e. Average of 4 doors, 6-in to 7-in. thick, gasketed, installed by manufacturer, range of weight 23-70 lb/ft^2.
f. Average of 2 doors, each 10-in. thick, gasketed, installed by manufacturer, range of weight 35-38 lb/ft^2.
g. Estimated performance, in isolated 12-in. thick concrete walls, no leakage, no flanking paths.

Table C-17 Approximate Transmission Loss (in dB) of Aluminum, Steel and Lead

	Aluminum			**Steel**				**Lead**			
	Thickness (in.)			Thickness (in.)				Thickness (in.)			
Octave Frequency Band (Hz)	1/16	1/8	1/4	1/16	1/8	1/4	1/2	1/32	1/16	1/8	Lead/Vinyl Curtain
	Surface Weight (lb/ ft²)			Surface Weight (lb/ ft²)				Surface Weight (lb/ ft²)			Surface Weight (lb/ ft²)
	1	2	3 ½	2 ½	5	10	20	2	4	7 ½	1
31	0	3	9	5	11	17	23	2	6	14	--
63	3	9	15	11	17	23	29	8	14	20	--
125	9	15	21	17	23	29	35	14	20	26	13
250	15	21	27	23	29	35	40	20	26	32	17
500	21	27	29	29	35	40	40	26	32	38	20
1000	21	29	29	35	40	40	40	32	38	44	28
2000	29	29	29	40	40	40	41	38	44	50	34
4000	29	29	30	40	40	41	48	44	50	56	38
8000	29	30	40	40	41	48	54	50	56	56	–
STC	25	28	29	33	38	40	41	30	36	42	26

Notes:

a. Apply metric conversion to material dimensions when calculations are metric.
b. Surface weight of aluminum based on 170 lb/ft^3 density or 14 lb/ft^2 per in. thickness.
c. Surface weight of steel based on 480 lb/ft^3 density or 40 lb/ft^3 per-in. thickness.
d. Surface weight of lead based on 700 lb/ft^3 density or 59 lb/ft^3 per In. thickness.
e. Variations in surface area and edge clamping conditions can alter the TL values or aluminum and steel. Lead assumed "limp." Application of vibration damping material to one surface of steel or aluminum will reduce resonances and help increase TL values in resonance regions.
f. TL tests usually are not conducted at 31-63 Hz; values given are estimates only.

C-7 TRANSMISSION LOSS OF FLOOR-CEILING COMBINATIONS.

Many mechanical equipment areas are located immediately above or below occupied floors of buildings. Airborne noise and structure borne vibration radiated as noise may intrude into these occupied floors if adequate controls are not included in the building design. The approximate octave band “TL” and “NR” are given here for five floor-ceiling combinations frequently used to control airborne machinery noise to spaces above and below the mechanical equipment room. To achieve high airborne sound isolation and provide a massive base for the equipment, one must specify heavy concrete floors. All floor slabs are assumed to be of dense concrete (140 to 150 lb/ft.^{3} density). For low density concrete, the thickness must be increased to have the equivalent surface weight for the desired TL. The weight of a housekeeping pad under the equipment must not be counted in the floor weight, although it does aid in the support of heavy equipment. The five suggested floor-ceiling combinations are based on flat concrete slab construction, but comments are given later for the use of other forms and shapes of concrete floors. **Many of the following tables and figures will need conversion of material dimensions when calculations are performed in metric units.**

C-7.1 Type 1 Floor-ceiling.

This is the simplest type and consists only of a flat concrete floor slab. The TL is given in Table C-18 for several thicknesses. Acoustic tiles or panels mounted directly to the underside of the slab add nothing to the TL, but they contribute to the Room Constant in the room in which they are located and therefore aid in reducing reverberant levels of noise. The TL table starts with a 4-inch-thick (10.2 cm) slab, but this thickness is not recommended for large heavy rotary equipment at shaft speeds under about 1200 rpm or for any reciprocating equipment over about 25 hp. It is essential that there be no open holes through the floors to weaken the TL values.

Table C-18 Transmission Loss (in dB) of Type 1 Floor-Ceiling Combinations

Octave Frequency Band (Hz)	Thickness of Dense Concrete Slab (In.) 4	6	8	10	12
	Approximate Surface Weight ($lb/ft.^2$) 48	72	96	120	144
31	29	32	34	36	36
63	35	36	36	36	37
125	36	36	37	37	38
250	36	38	41	43	44
500	41	44	45	47	48
1000	45	48	49	50	51
2000	50	52	53	54	55
4000	54	56	57	58	59
8000	58	60	61	62	63
STC	45	48	49	51	52

C-7.2 Type 2 Floor-ceiling.

This floor-ceiling combination consists of a concrete floor slab below which is suspended a typical low-density acoustic tile ceiling in a mechanical support system. To qualify for the Type 2 combination, the acoustic tile must not be less than 3/4 in. (1.9 cm) thick, and it must have a noise reduction coefficient (NRC) of at least 0.65 when mounted. The air space between the suspended ceiling and the concrete slab above must be at least 12 inches (30.5 cm), but the TL improves when the space is larger. The estimate TL of a Type 2 floor-ceiling is given in Table C-19 for a few typical dimensions of concrete floor slab thickness and air space. Interpolate or extrapolate for dimensions not given in the table. Increased mass is most beneficial at low frequency and increased air space is helpful across all frequency bands.

Table C-19 Transmission Loss (in dB) of Type 2 Floor-Ceiling Combinations

Octave Frequency Band (Hz)	Thickness of Dense Concrete Slab (in.) 4	6	8	10	12
	Air Space Between Slab and Suspended Acoustic Ceiling (in.) 12	15	18	24	24
31	29	33	35	37	38
63	35	37	38	39	40
125	37	38	40	41	42

500	43	47	49	51	53
1000	48	53	54	56	57
2000	53	57	59	61	62
4000	57	61	63	64	65
8000	61	64	67	68	69
STC	48	51	52	55	57

C-7.3 Type 3 Floor-ceiling.

This floor-ceiling combination is very similar to the Type 2 combination except that the acoustic tile material is of the “high TL” variety. This means that the material is of high density and usually has a foil backing to decrease the porosity of the back surface of the material. Most acoustical ceiling materials manufacturers produce “high TL” products within their lines. An alternate version of the Type 3 combination includes a suspended ceiling system of light-weight metal panel sandwich construction, consisting of a perforated panel on the lower surface and a solid panel on the upper surface, with acoustic absorption material between. The minimum NRC for the Type 3 acoustical material must be 0.65. The estimated TL of a Type 3 floor-ceiling is given in Table C-20 for a few typical dimensions of concrete floor slab thickness and air space.

Table C-20 Transmission Loss (in dB) of Type 3 Floor-Ceiling Combinations

Octave Frequency Band (Hz)	Thickness of Dense Concrete Slab (in.)				
	4	6	8	10	12
	Air Space Between Slab and Suspended "High TL" Acoustic Ceiling (in.)				
	12	15	18	24	24
31	31	35	38	40	42
63	37	39	41	42	44

2000	57	62	64	66	68
4000	62	67	69	70	71
8000	66	71	74	75	76
STC	51	55	58	60	62

C-7.4 Type 4 Floor-ceiling.

This floor-ceiling combination consists of a concrete floor slab, an air space, and a resiliently supported plaster or gyp. bd. ceiling. This combination is for use in critical situations where a high TL is required. The ceiling must have a minimum 12 lb/ft.^{2} (703.1 kg/m^2) surface weight and the plenum space must be at least 18 inches (4.6 cm) high. The estimated TL of the Type 4 floor-ceiling combination is given in Table C-21 for a few typical dimensions of floor slab, air space, and ceiling thicknesses.

Table C-21 Transmission Loss (in dB) of Type 4 Floor-Ceiling Combinations

Octave Frequency Band (Hz)	Thickness of Dense Concrete Slab (in.)				
	4	6	8	10	12
	Air Space Between Slab and Resiliently Suspended Plaster Ceiling (in.)				
	15	18	24	30	30
	Thickness of Dense Plaster Ceiling (in.)				
	1	1	1	14	2
31	33	38	41	44	16
63	39	42	44	46	48
125	41	43	46	48	51
250	44	48	51	54	58
500	50	54	57	60	64
1000	56	61	64	66	69
2000	61	66	70	72	74
4000	67	72	75	76	77
8000	70	75	78	81	83
STC	55	59	61	64	68

C-7.4.1 Resiliently Supported Ceiling.

The ceiling must be supported on resilient ceiling hangers that provide at least 1/10 inch (0.25 cm) static deflection under load. Neoprene-in-shear or compressed glass fiber hangers can be used, or steel springs can be used if they include a pad or disc of neoprene or glass fiber in the mount. A thick felt pad hanger arrangement can be used if it meets the static deflection requirement. The hanger system must not have metal-to-metal short-circuit paths around the isolation material of the hanger. Where the ceiling meets the vertical wall surface, the perimeter edge of the ceiling must not make rigid contact with the wall member. Provide a 1/4-inch (0.64 cm) open joint at this edge, which is tilled with a nonhardening caulking or mastic or fibrous packing after the ceiling plaster is set.

C-7.4.2 Critical Locations.

Critical locations require special care, Caution: This combination must be used only in critical situations, and special care must be exercised to achieve the desired TL values: full vague floor weight and thickness, no holes through the floor, and completely resiliently supported nonporous dense ceiling. When the plaster of gyp. bd. ceiling is not supported resiliently, the TL value will fall about midway between the Type 3 and Type 4 values for the corresponding dimensions and floor slab weights.

C-7.5 Type 5 floor-ceiling.

The "floating concrete floor," as shown on Figure C-6, is a variation that can be added to any one of the Type 1 through 4 combinations. This becomes necessary when all other floor systems clearly fail to meet the required TL values. The values given in Table C-22 are improvements in TL that can be added to the values of Tables C-18 through C-21 if a well-designed and well-constructed floating floor is used. Careful designs have included prevention of flanking paths of sound or vibration, the Table C-22 values have been achieved and even exceeded. However, if flanking paths are not prevented by intentional design considerations, only one-half of these improvements may be reached.

Figure C-6 Typical Floating Floor Construction

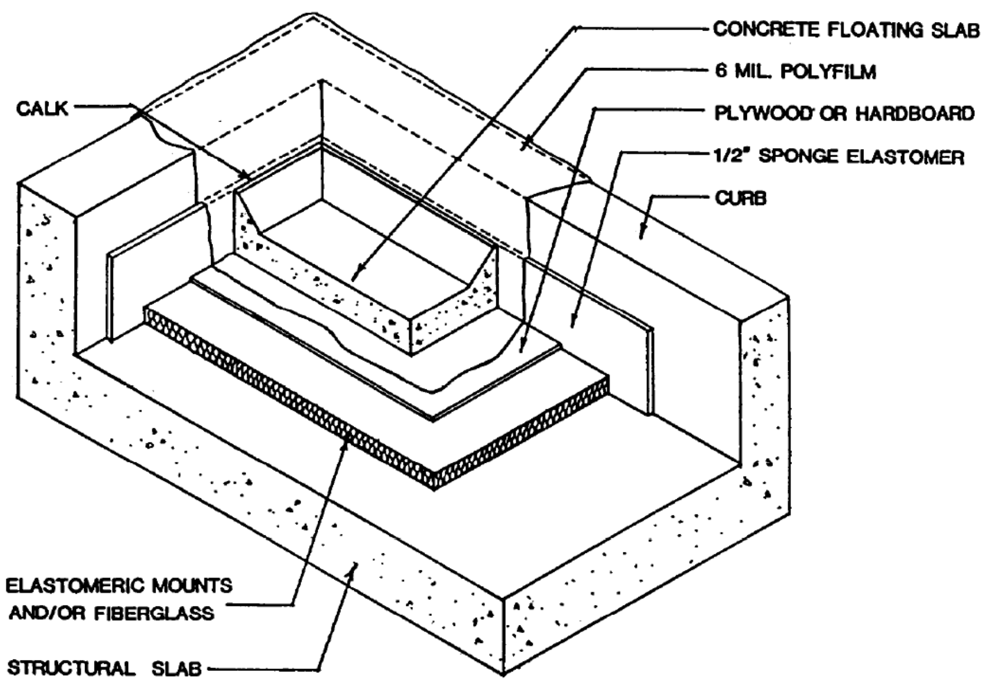

Table C-22 Approximate Improvement in Transmission Loss (in dB) When Type 5 Floating Floor is Added to Types 1 through 4 Floor-Ceiling Combinations

Octave Frequency Band (Hz)	Thickness of Floating Floor Slab (tn.)		
	3	4	5
	Air Space Between Structural Slab and Floating Slab (in.)		
	2	2	2
	Add Following Values (in dB) to Type 1-Type 4 TL Values		
31	5	7	9
63	7	9	11
125	8	10	12
250	9	11	13
500	10	12	14
1000	11	13	15
2000	12	14	16
4000	12	11	16
8000	12	14	16
STC	10	12	14

Note:

1. To achieve these values in practice, flanking paths of noise and vibration must be eliminated. Use only one half of the values if flanking paths are not clearly reduced by intentional design measures.

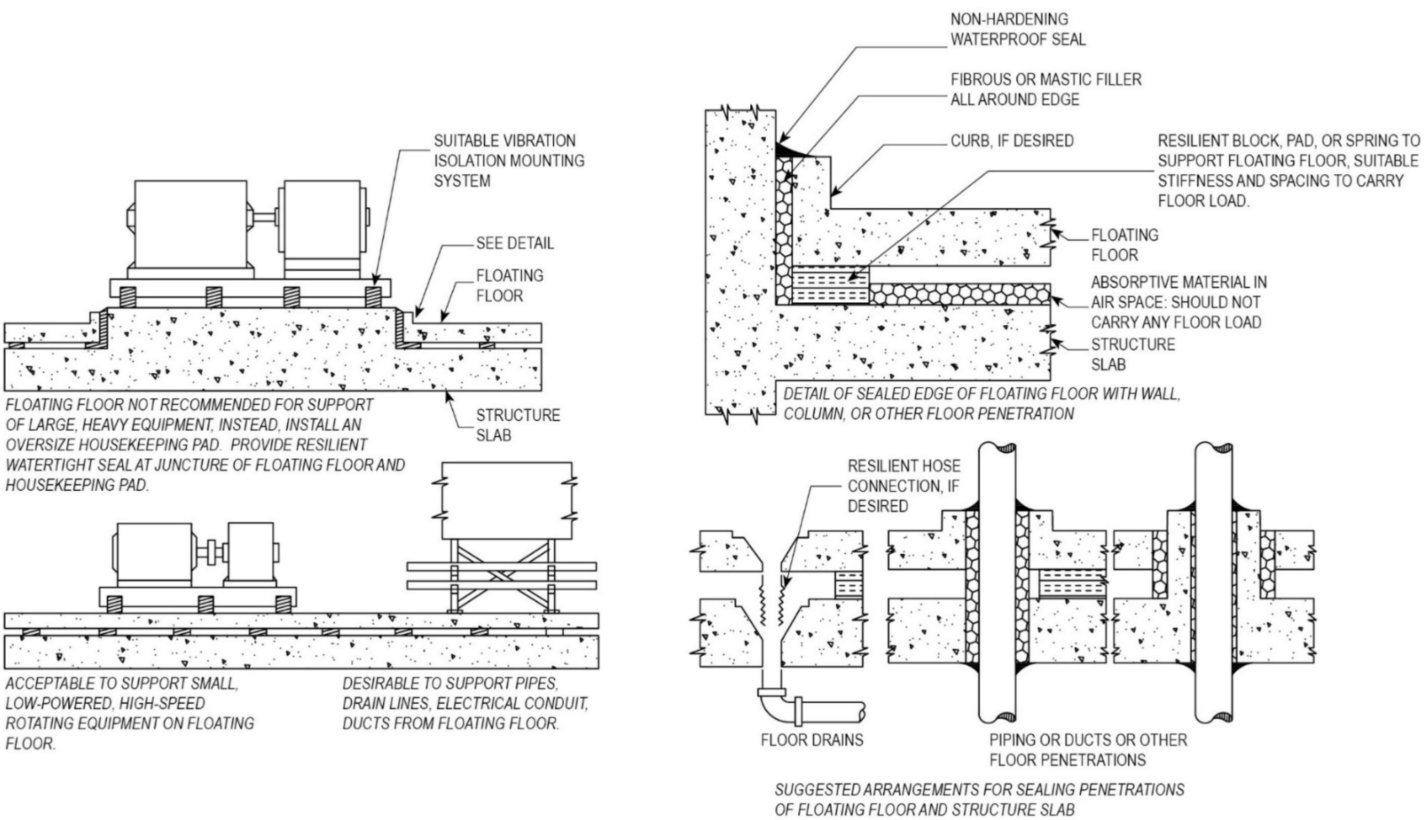
C-7.5.1 Support of Floating Floor.

The floating concrete floor must be supported off the structure floor at a height of at least 2 inches (5.1 cm) with properly spaced blocks of compressed glass fiber or multiple layers of ribbed or waffle-pattern neoprene pads or steel springs in series with two layers of ribbed or waffle-pattern neoprene pads. The density and loading of the compressed glass fiber or neoprene pads must follow the manufacturers' recommendations. When steel springs are used, their static deflection must not be less than 1/4 inch (0.64 cm). In some systems the 2-inch (5.1 cm) space between the floating slab and the structure slab is partially filled with a 1-inch (2.54 cm) thickness of low-cost glass fiber or mineral wool blanket of 3- to 4-lb/ft^3 density. Around all the perimeter edges of the floating floor (at the walls and around all concrete inertia bases within the floating floor area), there must be l-inch gaps and packed with mastic or fibrous filling and then sealed with a waterproof nonhardening caulking or sealing material. A curb must be provided around the perimeter of the floated slab to prevent water leakage into the sealed perimeter joints, and several floor drains must be set in the structure slab under the floating slab to provide run-off of any water leakage into this cavity space.

C-7.5.2 Area of Floating Slab.

The floating slab must extend over the full area that needs the added protection between the noisy and the quiet spaces. The floating floor must not support any large, heavy operating equipment. Instead, such equipment must be based on extra-height house-keeping pads that protrude above the floating floor. The floating floor is beneficial, however, in reducing transmitted noise from lightweight equipment and pipe and duct supports. Figure C-7 offers suggestions on applications and details of floating floors.

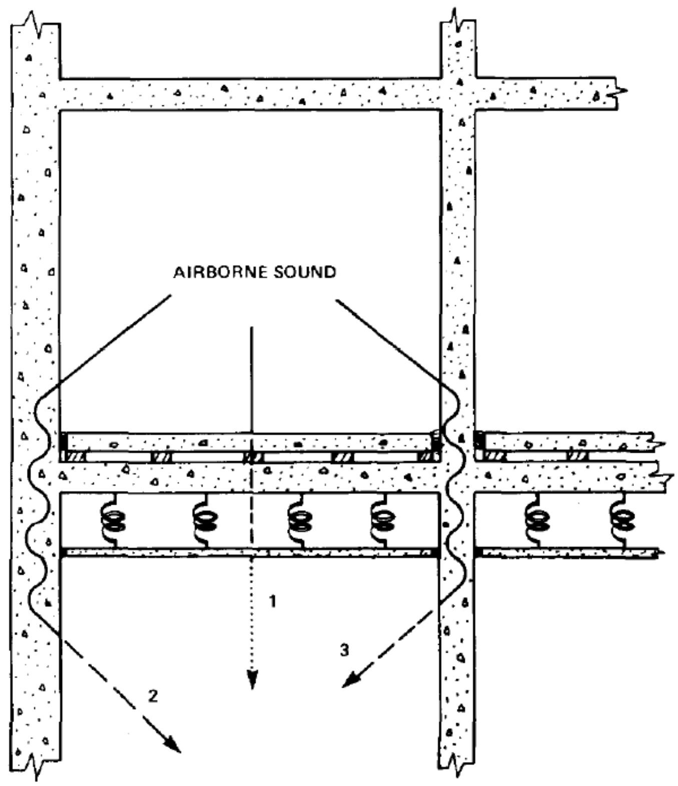
Figure C-7 Suggested Applications and Details of Floating Floors for Improvement of Airborne Sound Transmission Loss



C-7.5.3 Prevention of Flanking Paths.

Figure C-8 illustrates possible flanking paths (paths 2 and 3) of noise and vibration caused by airborne excitation of walls and columns in the mechanical equipment room. These paths make it impossible to achieve the low noise levels that the floating floor and resilient ceiling would permit (via path 1). Airborne excitation of structural surfaces in the mechanical equipment room must be prevented by protecting all walls and columns with isolated second walls or encasements. As an alternative, the radiating walls and columns in the quiet receiving room can be covered with isolated second walls or encasements.

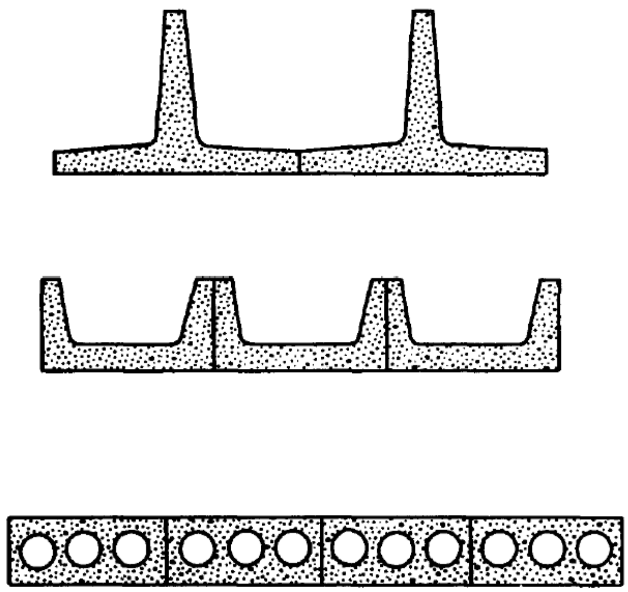
Figure C-8 Structure-borne Flanking Paths of Noise (Paths 2 and 3) Limit the Low Sound Levels Otherwise Achievable with High-TL Floating Floor Construction (Path 1)



C-7.6 Non-flat Floor Slabs.

The above five types of floors are assumed to be of flat slab construction. Other popular forms are of a beam-slab type that provides stiffening beams combined with thin sections of concrete, such as prestressed cored slabs, T-shaped beams, and coffered pan construction (Figure C-9). Since the thin section usually accounts for about 60 to 80 percent of the total floor area, the TL is largely influenced by the thickness and area of the thinnest section. The thick web of the beam component gives mass and stiffness, and this may improve the low-frequency TL. There is no collection of measured data on these types of floors, so only a rough estimating procedure is suggested. First, it is necessary to estimate the surface weight in (lb/ft^2 or kg/m^2) of the thinnest section of concrete and to estimate the average surface weight of the total floor. Second, the arithmetic average of these two surface weights is obtained, and this average is used to enter Tables C-18 through C-21 for the TL of the equivalent weight of a flat concrete slab. If the resulting average corresponds to a surface weight of less than 6-inch (15.24 cm)- thick solid concrete, the floor is not recommended for the support of large mechanical equipment directly above spaces requiring NC 20 to NC 35 (Table 3-1). All floor slab recommendations are based on acoustical considerations and must not be construed as referring to the structural adequacy of the slabs.

Figure C-9 Non-flat Concrete Floors



C-7.7 Noise Reduction (NR) of Floor-ceilings.

The procedure for determining the noise reduction of floor-ceiling construction is identical to that given in Section C-5.2 for walls. The area SW now becomes the floor area common to the source and receiving rooms, and the correction term C is now called the “floor correction term,” but it is still obtained from Table C-1.

C-8 OUTDOOR NOISE.

Mechanical equipment such as cooling towers, rooftop units and exhaust fans are commonly located outdoors. In addition, there is an increasing trend to placing additional mechanical equipment outdoors. Unacceptable noise from electrical or mechanical equipment, whether located indoors or outdoors, may be strong enough to be transmitted to neighbor locations. The sound transmission paths are influenced by three broad types of natural effects: distance effects, atmospheric effects, and terrain and vegetation effects. In addition, structures such as barriers and buildings influence the transmission of sound to the neighbor positions. The quantitative values of these natural effects and structural interferences in outdoor sound propagation are given in this section.

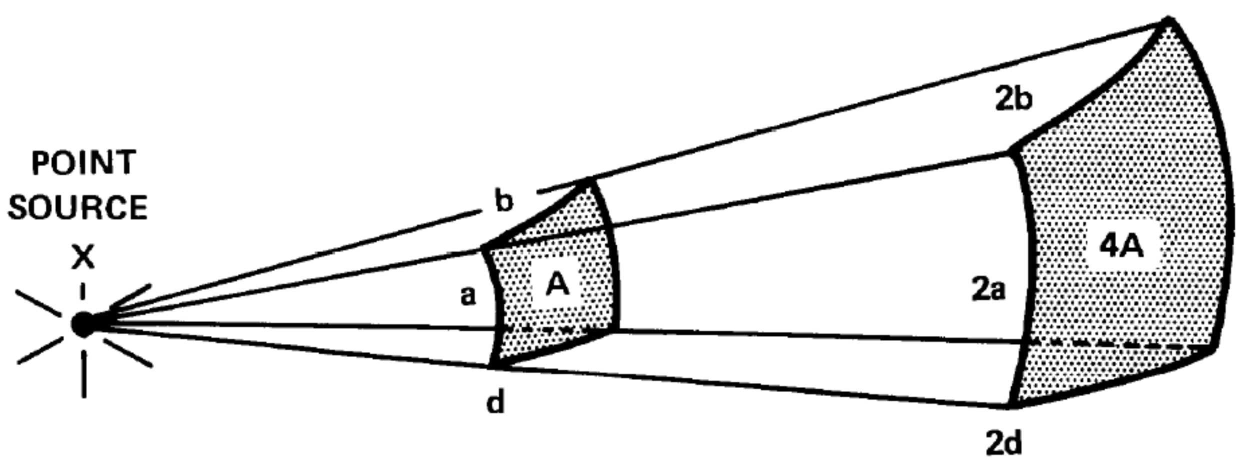
C-8.1 Distance Effects.

Acoustical energy from a source spread out as it travels away from the source, and the sound pressure level drops off with distance according to the “inverse square law.” This effect is common to all types of energy propagation originating from an essentially point source and free of any special focusing. In addition, the air absorbs a certain amount of sound energy by “molecular absorption,” and small amounts of ever-present air movement and inhomogeneities give rise to “anomalous excess attenuation.” These three distance effects are summarized in the following paragraphs.

C-8.1.1 Effect of Distance.

Figure C-10 illustrates the “inverse square law” for drop-off of SPL with distance. A point source of sound is shown at point “X”, and the rays show the path of an element of sound energy traveling away from the source. At the distance “d” from the source, the sound energy is assumed uniformly spread over the small area “A” (which is the product of the two lengths “a” and “b”). At twice the distance, 2d, the lengths a and b are expanded to 2a and 2b, and the resulting area over which the sound is now spread has become 4A, 4 times the area back at distance d. Sound pressure level is related to the “energy per unit area” in the sound wave; so, in traveling twice the original distance from the source, the energy per unit area has decreased by a factor of 4 which corresponds to a reduction of 6 dB in the sound pressure level. Simply illustrated, this is the “inverse square law”; that is, the SPL decreases at the rate of 6 dB for each doubling of distance from the source. An equation and a table incorporating this effect are given in paragraph C-8.1.4.

Figure C-10 Inverse Square Law of Sound Propagation



C-8.1.2 Molecular Absorption.

In addition to the reduction due to the inverse square law, air absorbs sound energy, and that the amount of absorption is dependent on the temperature and humidity of the air and the frequency of the sound. Table C-23 gives the molecular absorption coefficients in dB per 1000-foot (305 meter) distance of sound travel for a useful range of temperature and relative humidity of the octave frequency bands. A “standard day” is frequently defined as having a temperature of 59 deg. F (15 deg. C) and a relative humidity of 70 percent. For long-time average sound propagation conditions, use the molecular absorption coefficients for standard day conditions. For any specific application of measured or estimated SPL for known temperature and humidity conditions, use the Table C-23 values.

Table C-23 Molecular Absorption Coefficients, dB per 1000 ft (305 m), as a Function of Temperature and Relative Humidity

C-8.1.3 Anomalous Excess Attenuation.

Large-scale effects of wind speed, wind direction, and thermal gradients in the air can cause large differences in sound transmission over large distances. These are discussed briefly under "atmospheric effects" in section C-8.2. Almost all the time, however, there are small-scale influences of these atmospheric factors. Even under stable conditions for sound propagation through the air, small amounts of diffraction, refraction (bending), and sound interference occur over large distances because of small wind, temperature, and humidity differences in the air. These are combined into "anomalous excess attenuation" which is applied to long-term sound level estimates for average-to-good sound propagation conditions. Table C-24 gives the values of anomalous excess attenuation, in dB per 1000-foot (305 meter) distance. These are conservative average values; higher values than these have been measured in long-time studies of sound travel over a variety of field conditions. Anomalous excess attenuation helps explain the fact that measure SPLs at large distances are frequently lower than estimated SPLs even when sound propagation conditions seem quite good.

Table C-24 Values of Anomalous Excess Attenuation per 1000 ft (305 m)

Frequency Band, HZ	Anomalous Excess Attenuation, dB/1000 ft.

8000	4.0

C-8.1.4 Estimating Outdoor Sound Levels.

The sound level, at a distance, can most readily be calculated if the sound power level (Lw) is known. In some cases, the sound power is not known, however the sound pressure level (Lp) at a given distance is known. In this case the sound pressure level at different distance can be derived from the known sound pressure level. Consideration for each of these cases is given below.

C-8.1.4.1 SPL from Known Lw.

Equation C-10 combines the effects of distance, atmospheric attenuation, and anomalous attenuation for the calculation of sound pressure level when the sound power level of the source is known.

Equation C-10. SPL Using Known Outdoor Conditions

$$\mathbf{Lp = Lw - 10\log(2\pi d^2)1 + d(\propto_m + \propto_a)/1000\ -\ 10}$$

Where:
Lp = sound pressure level (in dB)
Lw = sound power level (in dB)
d = distance from source (ft)(m)
$\propto_{\mathbf{m}}$ = *molecular absorption coefficient*
$\propto_{\mathbf{a}}$ = *anomalous excess attenuation*

Where Lp is the SPL at distance d (in ft.) from a sound source whose PWL is Lw, is the molecular absorption coefficient (in dB/1000 ft (305 m).) from Table C-23 and is the anomalous excess attenuation (in dB/1000 ft (305 m).) from Table C-24. Equation C-10 is simplified to Equation C-11:

Equation C-11. SPL Using Known Distance Term

$$\mathbf{Lp = Lw - DT}$$

Where:
Lp = sound pressure level (in dB)
Lw = sound power level (in dB)
DT = distance term (in dB)

where DT, in decibels, is called the “distance term” and is defined by equation C-12:

Equation C-12. Distance Term

$$\mathbf{DT = 10(\log 2\pi d^2) + d(\propto_m + \propto_a)/1000 - 10}$$

Where:
DT = distance term (in dB)
d = distance from source (ft)(m)
$\propto_{\mathbf{m}}$ = *molecular absorption coefficient*
$\propto_{\mathbf{a}}$ = *anomalous excess attenuation*

Table C-25 gives tabulated data for the distance term out to a distance of 80 feet (25.4 meters). For such short distances, the molecular absorption and anomalous excess attenuation are usually negligible and are ignored in this simplifying table. The Table C-25 values can be applied to all octave bands for most close-in situations. However, at larger distances the absorption and attenuation effects become significant, and Table C-26 gives the distance terms as a function of the octave bands for distances from 80 feet (25.4 meters) out to 8000 feet (2439 meters).

Table C-25 Distance Term (DT), in dB, to a Distance of 80 ft (25.4 m)

C-8.1.4.2 SPL at Another Distance from Known SPL.

Equation C-13 can be used to calculate the sound pressure level at any distance if the sound pressure level at one distance is given.

Equation C-13. Calculated Sound Pressure Level Using Known SPL and DT

$$\mathbf{L_{p2} = L_{p1} - DT_2 + DT_1}$$

Where:
L_{p2} = calculated sound pressure level (in dB)
L_{p1} = known sound pressure level (in dB)
DT_2 = known distance term for calculated SPL (in dB)
DT_1 = known distance term for known SPL (in dB)

where Lp1 is the known SPL at distance d, and L_{p2} is the wanted SPL distance d_2. The distance terms DT_1 and DT_2 are evaluated in Equation C-12 or obtained from Tables C-25 and C-26. This equation applies when d_1 is greater than the physical dimension of the sound source.

C-8.2 Atmospheric Effects.

Wind and temperature variations can cause bending of sound waves and can influence changes in sound levels at large distances. These are normally short-term effects and do not provide reliable noise control. However, they help explain the variations that occur in outdoor sound propagation and measurements.

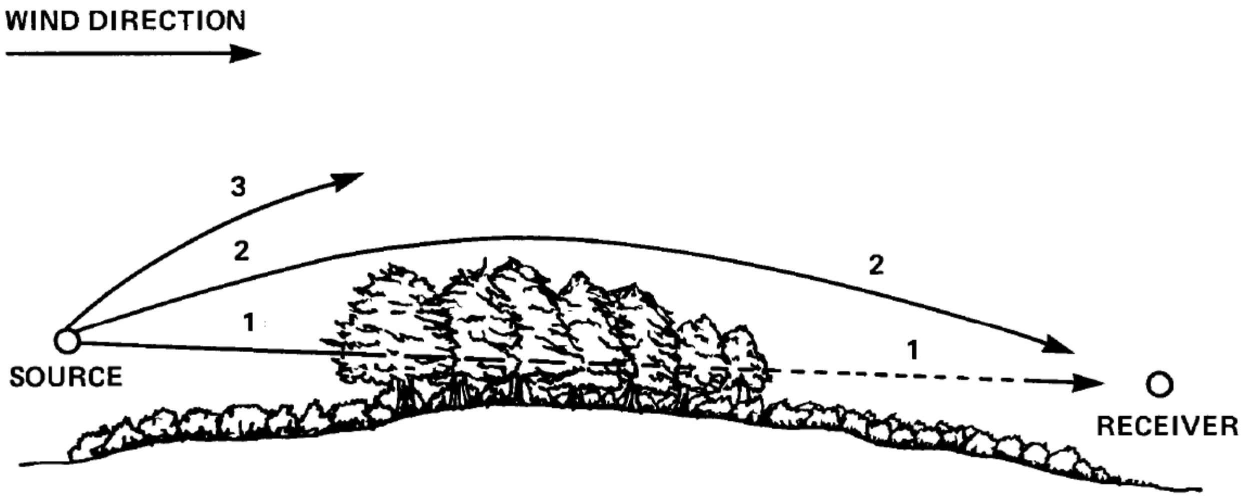
C-8.2.1 Wind Effect.

A steady, smooth flow of wind, equal at all altitudes, would have no noticeable effect on sound transmission. In practice, however, wind speeds are slightly higher above the ground than at the ground, and the resulting wind speed gradients tend to “bend” sound waves over large distances. Sound traveling with the wind is bent down to earth, while sound traveling against the wind is bent upwards above the ground. The downwind and upwind effects are summarized in the next two paragraphs. Irregular, turbulent, or gusty wind provides fluctuations in sound transmission over large distances (possibly because of partial wavelength interference of various paths taken by various sound rays of the total beam). The net effect of these fluctuations may be an average reduction of a few decibels per 100 yards (91.44 meters) for gusty wind with speeds of 15 to 30 mph (24.1 to 48.3 km/hr). However, gusty wind or wind direction cannot be counted on for noise control over the lifetime of an installation.

C-8.2.2 Downwind Effect.

Figure C-11 illustrates the principal influence of downwind on sound propagation. When there is no wind, the principal sound arrives at the receiver by path 1. Along this path, the ground, vegetation, and trees can absorb some of the sound. During downwind conditions, however, the path 2 sound (that normally travels upward into the sky and does not return to earth) is bent down and returns to the earth, sometimes passing above the attenuating ground surfaces and the vegetation, thus yielding higher sound levels to the receiver. This can occur only for relatively large distances between source and receiver (say, 1000 feet (305 m) or more). In summary, downwind can reduce or eliminate some of the attenuating effects of terrain and vegetation or of solid barriers that otherwise intercept sound paths.

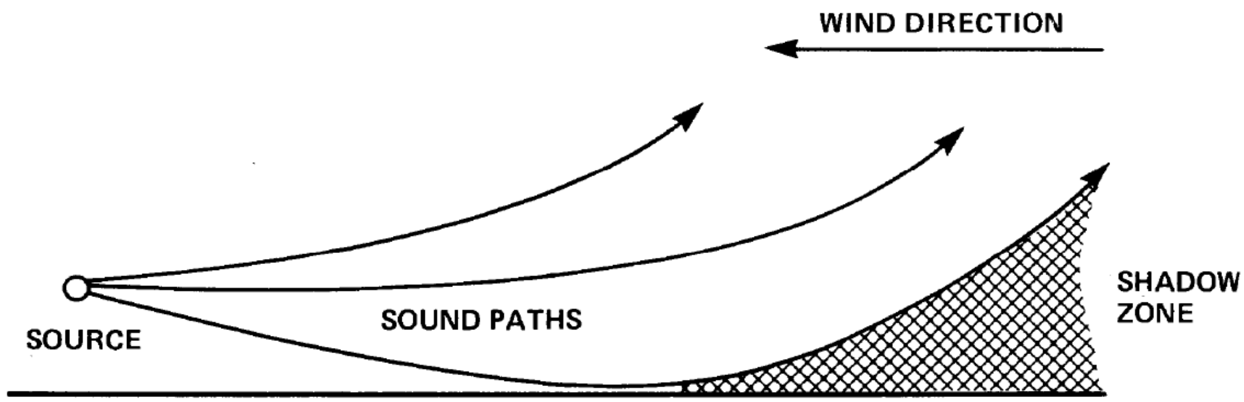
Figure C-11 Downwind Sound Diffraction.



C-8.2.3 Upwind effect.

A strong persistent upwind condition can cast a shadow zone, as shown schematically in Figure C-12. When wind speed profiles are known, the distance to the shadow zone can be estimated, but this is an impractical field evaluation. It is sufficient to realize that the shadow zone can account for up to about 25-dB sound level reduction and that this can occur at distances greater than about 1000 feet (305 meters) for wind speeds above about 10 to 15 mph (24.1 to 48.3 km/hr).

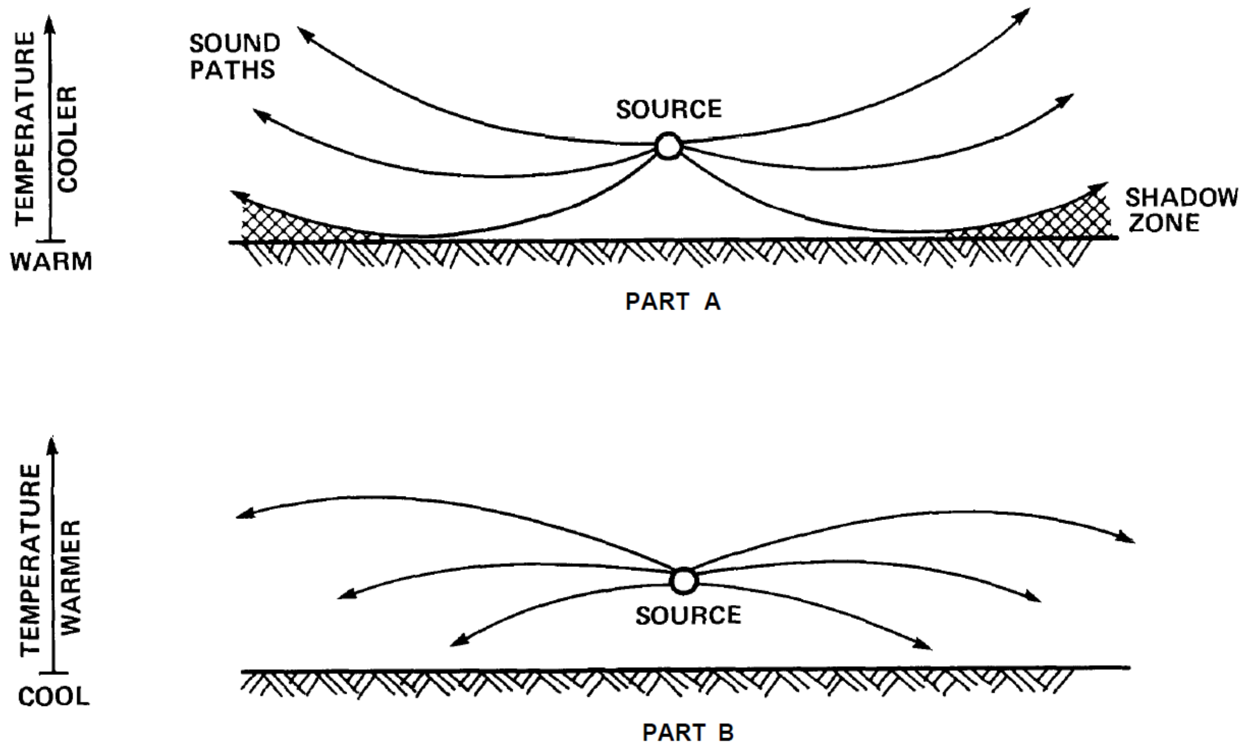
Figure C-12 Upwind Sound Diffraction



C-8.2.4 Temperature effect.

Constant temperature with altitude produces no effect on sound transmission, but temperature gradients can produce bending in much the same way as wind gradients do. Air temperature above the ground is normally cooler than at the ground, and the denser air above tends to bend sound waves upward, as in part A of Figure C-13. With “temperature inversions,” the warm air above the surface bends the sound waves down to earth. These effects are negligible at short distances, but they may amount to several dB at very large distances (say, over a half mile). Again, little or no increase is caused by thermal gradients (compared to homogeneous air), but there may be a decrease in sound levels.

Figure C-13 Effects of Temperature Gradients on Sound Propagation



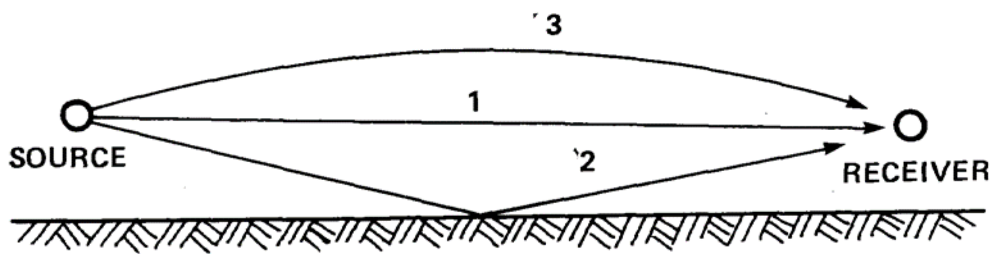
C-8.2.5 Precipitation.

Rain, mist, fog, hail, sleet, and snow are the various forms of precipitation to consider. These have not been studied extensively in their natural state, so there are no representative values of excess attenuation to be assigned to them. Rain, hail, and sleet may change the background noise levels, and a thick blanket of snow provides an absorbent ground cover for sound traveling near the ground. Precipitation or a blanket of snow are intermittent, temporary, and of relatively short total duration, and they must not be counted on for steady-state sound control, even though they offer noticeable attenuation.

C-8.3 Terrain and vegetation.

Sound transmission near the earth's surface involves essentially three components of sound paths, shown schematically by Figure C-14. The ground-reflected sound (path 2) may arrive at the receiver either in phase or out of phase with the direct sound (path 1) and can either increase or decrease the received sound level. The ground surface may be hard or soft (reflective or absorbent), and this also affects the phase and magnitude of the reflected path. Paths 1 and 2 usually determine the sound levels at the receiver, but a solid barrier or dense woods can practically eliminate these paths. In such situations, path 3 may become significant. Path 3 is made up of relatively low-level sound that is refracted (bent) or scattered back to earth by numerous small patches of inhomogeneous air of varying temperature, speed, direction, density, and similar. Field studies show that when paths 1 and 2 are virtually eliminated, there remain sound levels that are about 20 to 25 dB below the path 1 and 2 sound levels. These are the sound levels arriving by way of the numerous paths that together make up path 3, as visualized in Figure C-14.

Figure C-14 Outdoor Sound Propagation Near the Ground



C-8.3.1 Attenuation of Woods and Vegetation.

Table C-27 presents the approximate insertion loss of a 100-foot-deep growth of medium-dense woods made up of a mixture of deciduous and coniferous trees having a height in the range of 20 to 40 feet (6.1 to 12.2 m). For this density, the visibility penetration is about 70 to 100 feet (21 to 30 m).

Table C-27 Insertion Loss for Sound Transmission Through a Growth of Medium-Dense Woods

Octave Frequency Band, HZ	Insertion Loss, dB per 100 ft. of Woods
31	0
63	1/2
125	1
250	1 1/2
500	2
1000	3
2000	4
4000	4 1/2
8000	5

C-8.4 Barriers.

A barrier is a solid structure that intercepts the direct sound path from a source to a receiver. It provides a reduction in sound pressure level within its “shadow zone.” A wall, a building, a large mound of earth, an earth berm, a hill, or some other form of solid structure can serve as a barrier. The approximate insertion loss of an outdoor barrier can be estimated.

C-8.4.1 Barrier Parameters.

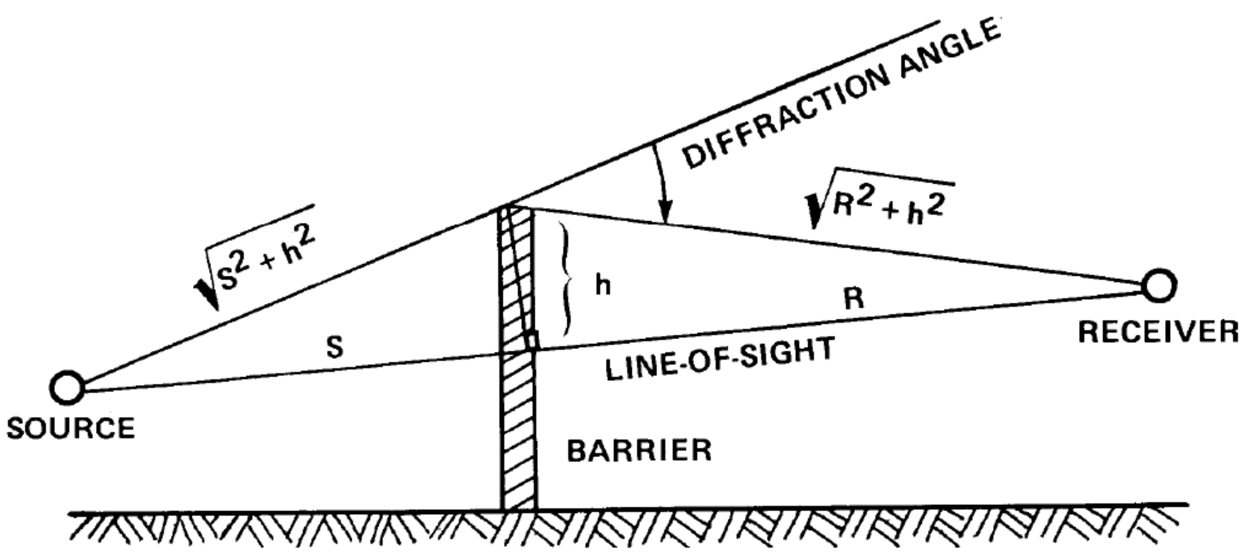
Figure C-15 illustrates the geometrical aspects of an outdoor barrier where no extraneous surfaces reflect sound into the protected area. The insertion loss provided by the barrier to the receiver position is a function of the path length difference between the actual path traveled and the line-of-sight direct path. Large values of barrier height “h” above the line-of-sight path produce large values of the diffraction angle and large values of path length difference, which in turn provide strong shadow zones and large values of insertion loss. The direct line-of-sight path length is S+R, and the actual distance traveled is $\left(\sqrt{\{S^2 + h^2\}} + \sqrt{\{R^2 + h^2\}}\right)$. Then the path length difference is given in Equation C-14.

Equation C-14. Path Length Difference

$$\boldsymbol{\delta = \sqrt{\{S^2 + h^2\}} - S + (\sqrt{\{R^2 + h^2\}} - R}$$

Where:
δ = path length difference
S = distance from source to barrier along line-of-sight to the receiver (ft)(m)
h = barrier height (ft)(m)
R = distance from receiver to barrier along line-of-sight to the source (ft)(m)

Figure C-15 Parameters and Geometry of Outdoor Sound Barrier



C-8.4.1.1 Insertion Loss Values.

Table C-28 gives the insertion loss of an outdoor barrier wall as a function of the path length difference and the octave band frequency. The following restrictions apply.

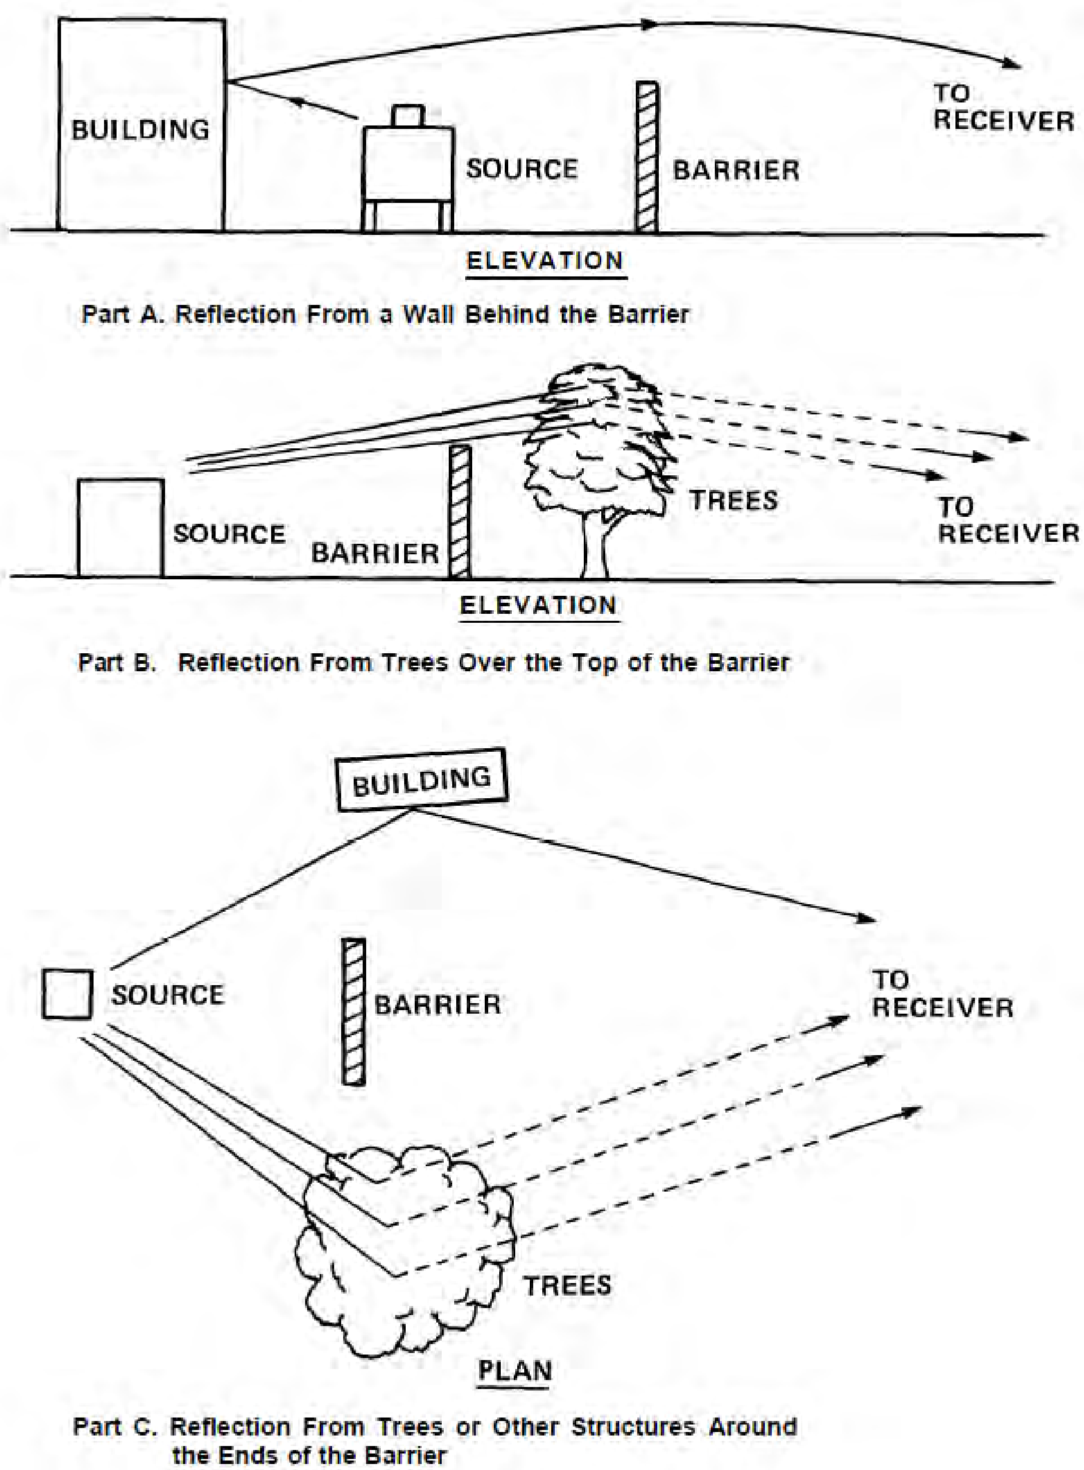
Table C-28 Insertion Loss of an Ideal Solid Outdoor Barrier

Path-Length Difference, ft.	Insertion Loss, dB Octave Band Center Frequency, Hz								
	31	63	125	250	500	1000	2000	4000	8000
.01	5	5	5	5	5	6	7	8	9
.02	5	5	5	5	5	6	8	9	10
.05	5	5	5	5	6	7	9	10	12
.1	5	5	5	6	7	9	11	13	16
.2	5	5	6	8	9	11	13	16	19
.5	6	7	9	10	12	15	18	20	22
1	7	8	10	12	14	17	20	22	23
2	8	10	12	14	17	20	22	23	24
5	10	12	14	17	20	22	23	24	24
10	12	15	17	20	22	23	24	24	24
20	15	18	20	22	23	24	24	24	24
50	18	20	23	24	24	24	24	24	24

C-8.4.1.2 Other Reflecting Surfaces.

There must be no other surfaces that can reflect sound around the ends or over the top of the barrier into the protected region (the shadow zone). Figure C-16 shows examples of reflecting surfaces that can reduce the effectiveness of a barrier wall. These situations must be avoided.

Figure C-16 Examples of Surfaces That Can Reflect Sound Around or Over a Barrier Wall



C-8.4.1.3 TL of Barrier.

The barrier wall or structure must be solid (no penetrating holes) and must be constructed of a material having sound transmission loss (TL) that is at least 10 dB greater than the calculated insertion loss of the barrier in all octave bands.

C-8.4.1.4 Width of Barrier.

Each end of the barrier must extend horizontally beyond the line of sight from the outer edge of the source to the outer edge of the receiver building by a distance that is at least 3 times the value of h used in the calculation.

C-8.4.1.5 Large Distances.

For large distances, sound scattered and bent over the barrier (the path 3 concept in Figure C-14) reduces its effectiveness. It is suggested that the calculated insertion loss be reduced by about 10 percent for each 1000-foot (305 meter) distance between source and receiver.

C-8.4.1.6 Atmospheric Effects.

For wind speeds above about 10 to 15 mph (24.1 to 48.3 km/hr).along the direction of the sound path from source to receiver and for distances over about 1000 feet (305 meters) between source and receiver, the wind bends the sound waves down over the top of the barrier. Under these conditions, the barrier will appear to be very ineffective.

C-8.4.1.7 Terrain-vegetation Effects.

When both a barrier and the terrain-vegetation effects of paragraph C-8.3 occur simultaneously, only the larger values of attenuation calculated for these two effects must be used. The sum of both effects should not be used.

C-8.4.1.8 Another building as a Barrier.

If the barrier is another building, there must be no large openings entirely through the building that would destroy its effectiveness as a barrier. A few small open windows in the near and far walls would probably be acceptable, provided the interior rooms are large. The building may qualify as a compound barrier.

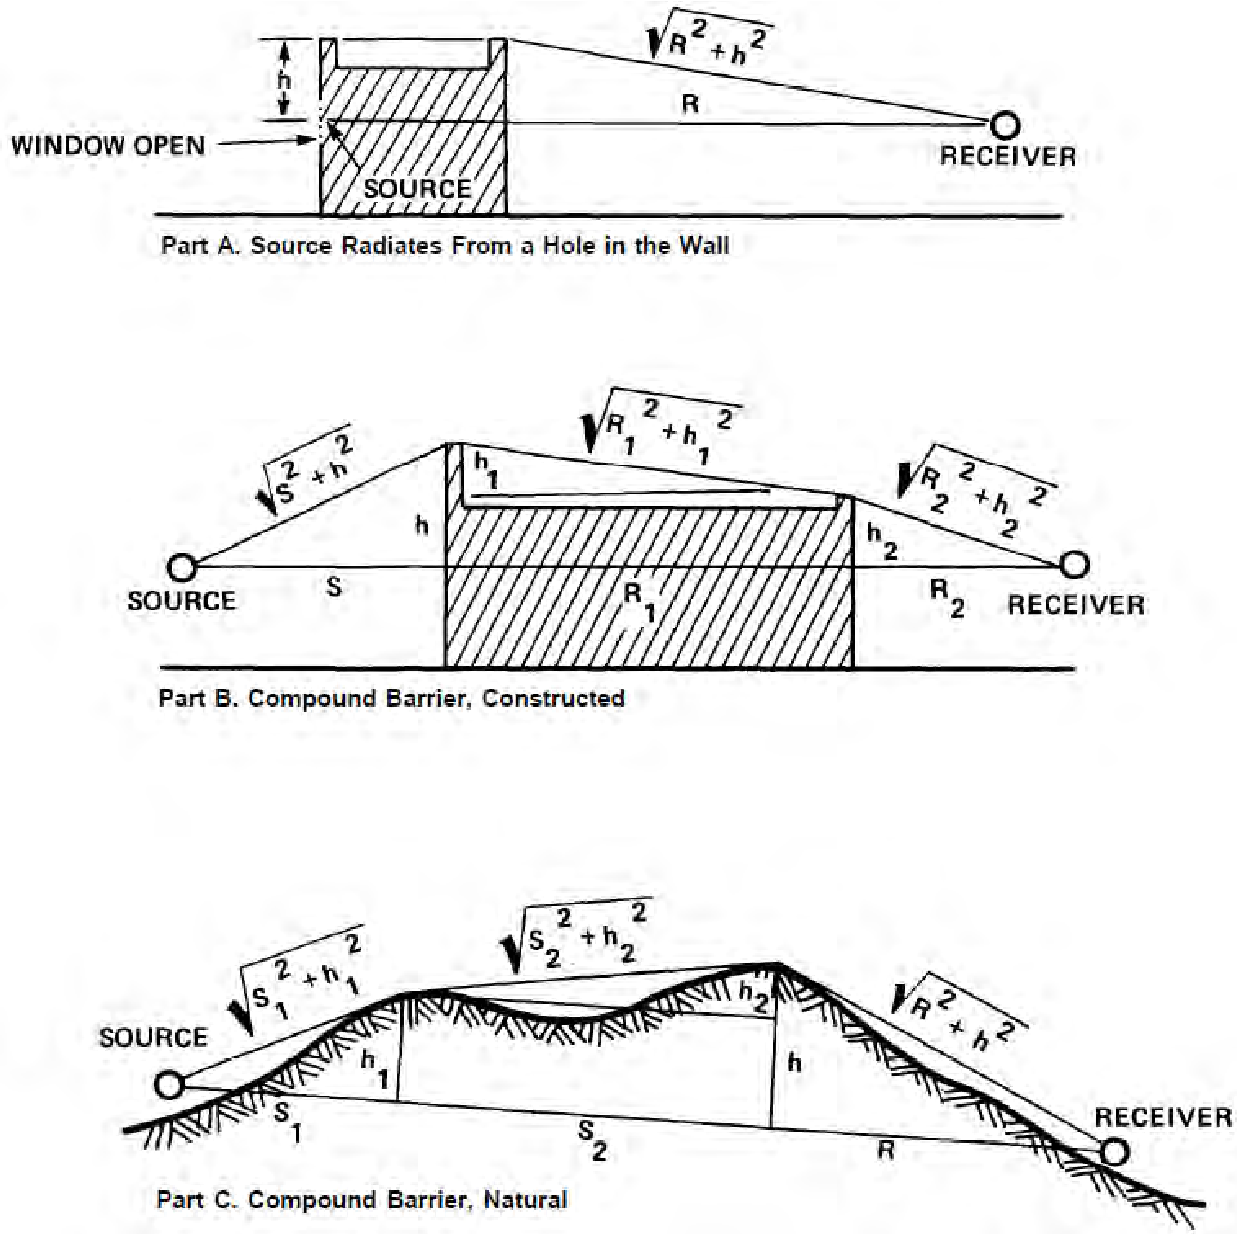
C-8.4.1.9 Caution.

A large flat reflecting surface, such as the barrier wall, may reflect more sound in the opposite direction than there would have been with no wall at all present. If there is no special focusing effect, the wall may produce at most only about 2 or 3 dB higher levels in the direction of the reflected sound.

C-8.4.2 Unusual Barrier Geometries.

Figure C-17 illustrates three common situations that do not fall into the simple geometry of Figure C-15. The procedure suggested here is to estimate the path length difference and use Table C-28 to obtain the insertion loss, even though this simplified approach has not been proven in field or model studies.

Figure C-17 Compound Barriers



C-8.4.3 In-wall Sound Source.

In part A of Figure C-17, the source could be a wall-mounted exhaust fan, an inlet to a ventilating fan, or a louvered opening permitting air into (and noise out of) a mechanical equipment room. The conventional source distance S is zero and the slant distance becomes h. Thus, the total path length difference is $\left(h + \sqrt{\{R^2 + h^2\}} - R\right)$.

C-8.4.4 Compound Barrier.

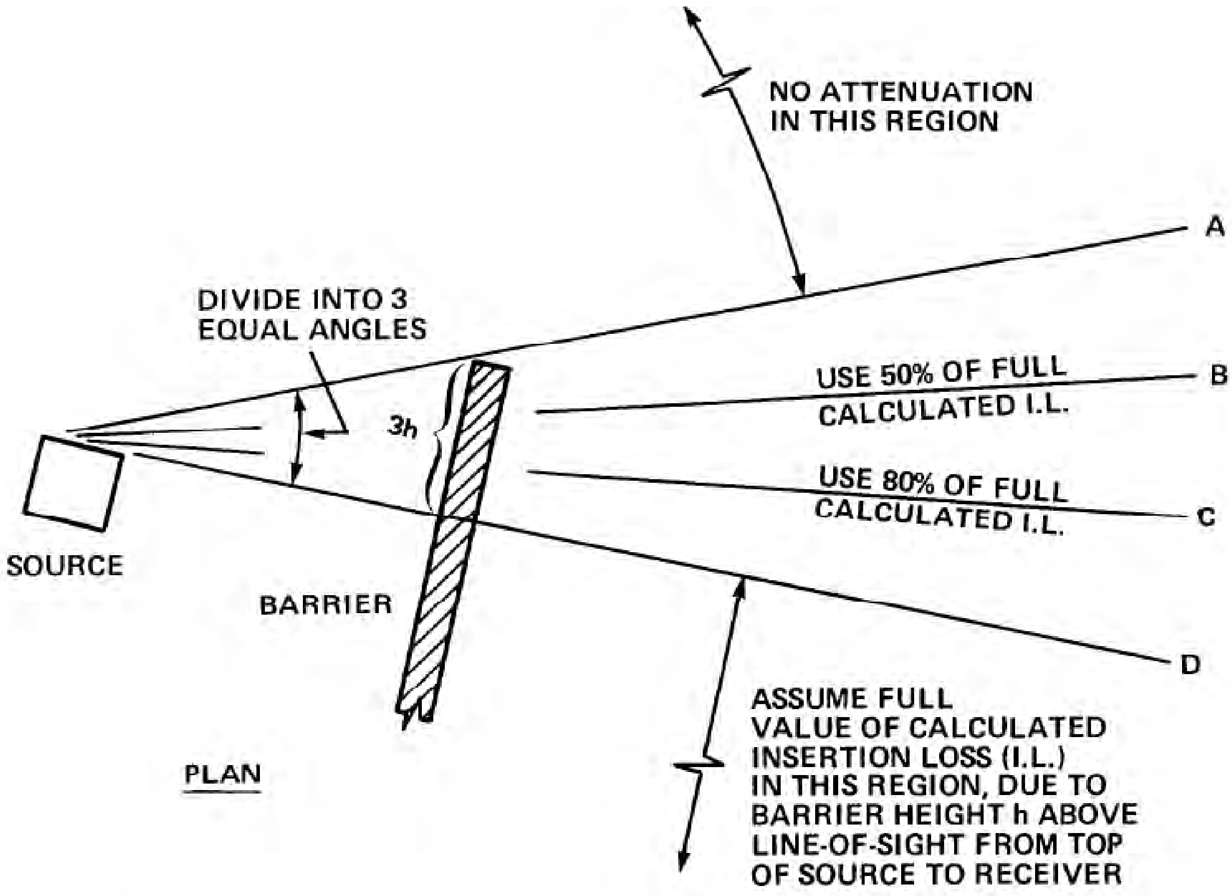
In part B of Figure C-17, the path length difference is calculated from three triangles, as follows: $\delta = \left[\left(\sqrt{\{S^2 + h^2\}} - S\right) + \left(\sqrt{\{{R_1}^2 + {h_1}^2\}} - R1\right) + \left(\sqrt{\{{R_2}^2 + {h_2}^2\}} - R2\right)\right]$

Part C of Figure C-17 is another form of compound barrier and also requires the three-triangle calculation.

C-8.4.5 Edge Effect of Barriers.

Figure C-18 represents a plan view of a source and one end of a barrier wall. Near the end of the wall, the barrier effectiveness is reduced because some sound is refracted over the top of the wall, some sound is refracted around the end of the wall, and some sound is reflected and scattered from various non-flat surfaces along the ground near the end of the barrier. For critical problems, this degradation of the barrier near its end must be considered. Figure C-18 suggests a simplified procedure that gives approximately the insertion loss (IL.) near the end of the barrier.

Figure C-18 Edge Effects at End of Barrier



PROCEDURE

GIVEN: h IS HEIGHT OF BARRIER USED IN CALCULATION OF I.L.

STEPS:
1. MARK OFF HORIZONTAL DISTANCE 3h FROM EACH END OF BARRIER (ONLY ONE END SHOWN IN ABOVE SKETCH)
2. DRAW LINES A AND D
3. DIVIDE ANGLE INTO 3 EQUAL PARTS
4. DRAW LINES B AND C
5. ASSIGN I.L. VALUES AS SHOWN; INTERPOLATE BETWEEN

C-8.5 Reception of Outdoor Noise Indoors.

An intruding noise coming from an outdoor noise source or by an outdoor noise path may be heard by neighbors who are indoors.

C-8.5.1 Noise Reduction (NR) of Exterior Constructions.

When outdoor noise enters a building, it is reduced, even if the building has open windows. The actual amount of noise reduction depends on many factors: building construction, orientation, wall area, window area, open window area, and interior acoustic absorption. For practical purposes, however, the approximate noise reduction values provided by a few typical building constructions are given in Table C-29. For convenience and identification, the listed wall constructions are labeled with letters A through G and are described in the notes under the table. If the exact wall construction of a building is known, a more accurate estimate of the noise reduction can use the procedures of paragraph C-5.

Table C-29 Approximate Noise Reduction of Typical Exterior Wall Constructions

Octave Frequency Band (Hz)	Wall Type						
	A	B	C	D	E	F	G
31	0	8	12	17	10	22	28
63	0	9	13	19	14	24	32
125	0	10	14	20	20	25	34
250	0	11	15	22	26	27	36
500	0	12	16	24	28	30	38
1000	0	13	17	26	29	33	42
2000	0	14	18	28	30	38	48
4000	0	15	19	30	31	43	53
8000	0	16	20	30	33	48	58

Notes:

A. No wall; outside conditions.

B. Any exterior wall construction, with open windows covering about 5% of exterior wall area.

C. Any typical wall construction, with small open-air vents of about 1% of exterior wall area; all windows closed.

D. Any typical wall construction, with closed but operable windows covering about 10-20% of exterior wall area.

E. Sealed glass wall construction, 1/4 in. glass thickness over approximately 50% of exterior wall area.

F. Approximately 20 lb/ft.^{2} solid wall construction with no windows and no cracks or openings.

G. Approximately 50 lb/ft.^{2} solid wall construction with no windows and no cracks or openings.

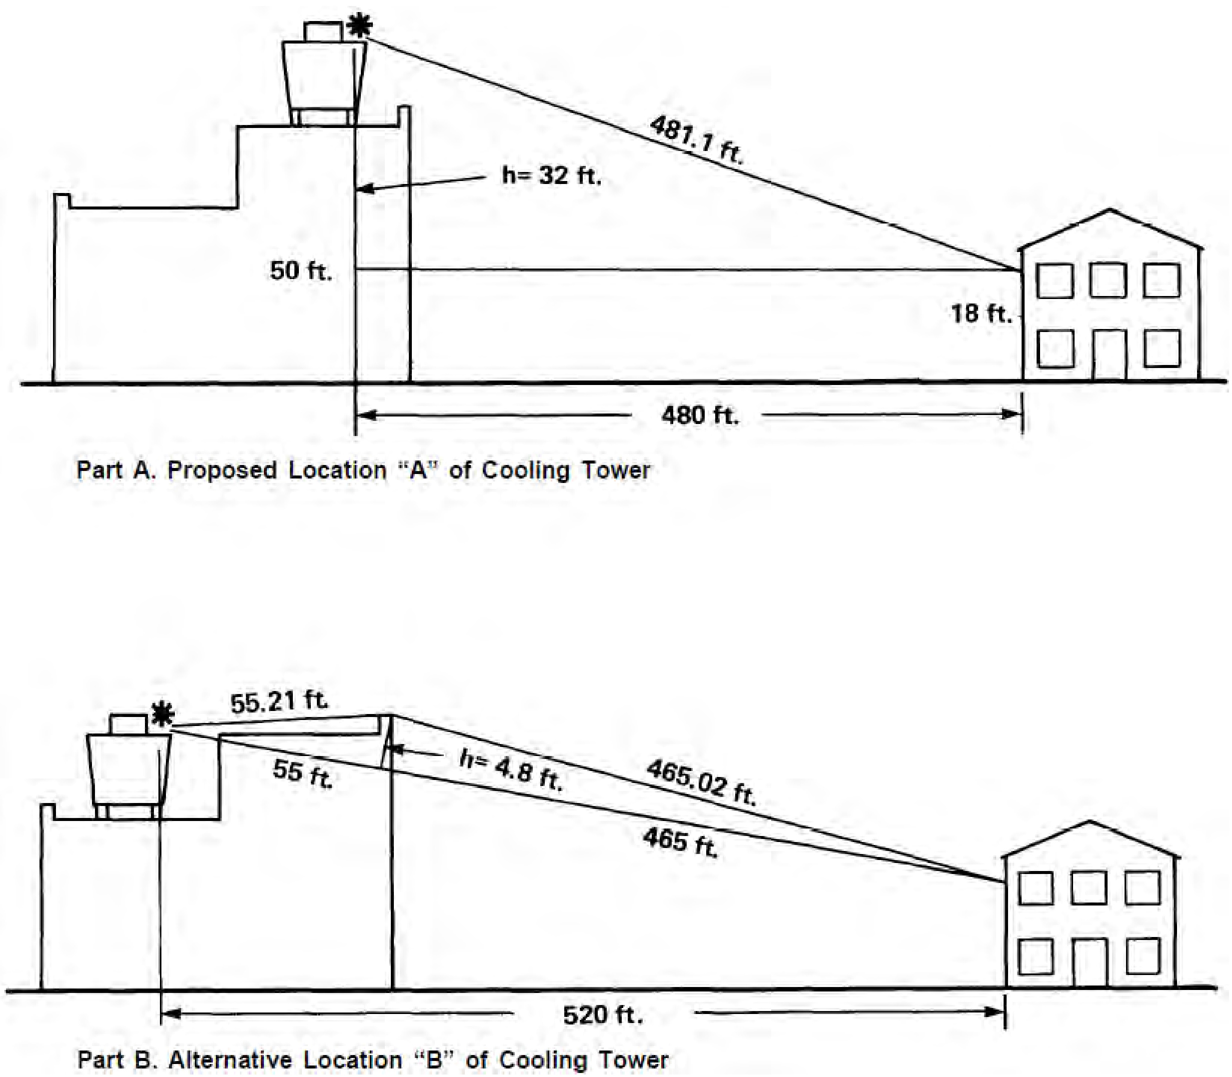
C-8.5.2 Indoor Sound Pressure Levels.

Indoor octave band SPLs are calculated by subtracting the Table C-29 NR values from the outdoor SPLs measured or estimated at the outdoor receiver position.

C-8.6 Combined Effects, Sample Calculation.

A sample calculation shows the steps for combining the material of this chapter. The calculations are completed in all octave bands and illustrate some portion of each item covered. Figure C-19 shows an elevation view of a refrigerated warehouse and a nearby residence. Part A of the figure shows the proposed location of a cooling tower on top of a penthouse mechanical equipment room that has a direct line-of-sight path to the second-floor windows of the dwelling. The sound power level of the cooling tower is known. The residence is of brick construction with open windows covering about 5 percent of the exterior wall area. It is desired to calculate the SPL for the cooling tower noise received inside the upper floor of the residence. Assume the entire PWL radiates from the position near the top of the cooling tower.

Figure C-19 Elevation Profile of Cooling Tower Used in Example.



C-8.6.1 Location "A."

Table C-30 summarizes the data for this part of the analysis. Column 2 of the table gives the sound power level of the cooling tower; Column 3 gives the distance term for the 480-foot distance (from Table C-26) and Column 4 gives the calculated average SPL outside the upper windows of the residence (Col 4 = Col 2 - Col 3). Column 5 gives the noise reduction for the type E wall (from Table C-29), Column 6 gives the indoor SPL, and Column 7 shows the indoor SPL values that correspond to an NC-25 curve, suggested here for sleeping. Comparison of the estimated SPL values with the NC-25 values shows excess noise of 8 to 12 dB in the 250- to 2000-Hz bands (Co1 8).

Table C-30 Location "A" Cooling Tower Problem

Col. 1 Octave Band Center Frequency (Hz)	Col. 2 Sound Power Level of Source (dB)	Col. 3 Distance Term for 480 ft Distance (dB)	Col. 4 Average Outdoor SPL at Residence (dB)	Col. 5 NR Wall Type B (dB)	Col. 6 Indoor SPL (dB)	Col. 7 SPL of NC-25 Curve (dB)	Col. 8 Noise Excess (dB)
31	108	52	56	8	48	--	--
63	109	52	57	9	48	54	--
125	112	52	60	10	50	44	6
250	110	53	57	11	46	37	9
500	108	53	55	12	43	31	12
1000	105	53	52	13	39	27	12
2000	100	54	46	14	32	24	8
4000	95	57	38	15	23	22	1
8000	91	60	31	16	15	21	--

C-8.6.2 Location "B."

Table C-31 summarizes the data for this alternate location of the cooling tower where it receives the benefit of the barrier effect of the penthouse mechanical room. The geometry for this barrier produces a path length difference of 0.23 feet. The insertion loss for the barrier is given in column 4 of Table C-31. Column 5 gives the average outdoor SPL at the residence because of the barrier and the slightly increased distance to the new location (Col 5 = Col 2 - Col 3 - Col 4). Column 7 gives the new indoor SPLs which are compared with the column 8 values of the NC-25 curve. A noise excess of only 3 dB occurs in one octave band. This would be considered a more nearly acceptable solution to the cooling tower noise problem.

Table C-31 Location "B" Cooling Tower Problem

Col. 1 Octave Band Center Frequency (Hz)	Col. 2 Sound Power Level of Source (dB)	Col. 3 Distance Term for 520 ft. Distance (dB)	Col. 4 Barrier Insertion Loss for δ = .23 ft. C-8.7 Source Directivity.

The analysis procedures of this chapter assume that the sound source radiates sound equally in all directions. In some cases, this is not the case, that is more sound energy will be transmitted in one direction when compared to other directions. This is referred to as the "Directivity" of the sound source, which can be an inherent result of the design or the result of the equipment installation very close to reflecting surfaces. In the example given above the cooling tower directivity was not considered. In Location A, the SPLs at the residence would have been a few dB higher if the louvered surface of the cooling tower faced the residence or a few dB lower of the end surface of the cooling tower faced the residence. In Location B, the orientation of the cooling tower would have been less critical, because the barrier and other reflecting surfaces on the roof would tend to average out the cooling tower directivity characteristics. Typically, source directivity is difficult to obtain. Source directivity for certain sources is included under Appendix B. If source directivity information is unavailable assume that the sound source radiates uniformly in all directions.

C-9 AIRBORNE SOUND.

C-9.1 Quality of Analysis Procedure.

C-9.1.1 Variations and Uncertainties in the Individual Data.

It is necessary to realize that small errors or discrepancies or uncertainties exist with each bit of quoted data, and it is not realistic to rely on the analysis method to the nearest one or two decibels. It is largely for that reason that labels such as "preferred", "acceptable" and "marginal" are used. These labels offer some gradations in degree of reliability of the final values. It is even possible that, if the noise levels of certain specific pieces of mechanical equipment are much lower than the design estimates used in the manual, a design calculated to be "unacceptable" could actually turn out to be "acceptable." This result must not be counted on, however, as a means of avoiding a difficult problem. Of course, there is also the possibility that in a particular installation many of the statistical factors will work together to produce a "marginal" condition where the analysis showed "preferred" or "acceptable" condition.

C-9.1.2 System Reliability.

In most cases, the procedure will produce a workable design. The methods and techniques described here are based on many experiences with noise control problems, and these methods have helped produce many satisfactory or improved installations. (Sometimes the economics of a situation may not justify an entirely satisfactory solution for all concerned, but proper use of the analysis can bring a desired and predictable improvement.) The manual will have served a sufficiently useful purpose if it reveals only that a problem is so serious that the manual alone cannot solve the problem and that special assistance or special designs may be required.

C-9.1.3 Aids in Decision-making.

A certain amount of judgment may enter some design decisions. A suggestion is offered here for helping guide the decision for three types of situations.

1. When a particular design involves a crucial area, a conservative approach must be followed. The design must not be weakened to try "to get by" with something simpler.
2. When a particular design involves a distinct threat to someone's safety or well-being, a conservative approach must be used. Examples could be an employee who might suffer hearing loss in an MER because a separate control room was not provided, or a tenant who would not pay rent because of noise coming from an overhead MER, or a neighbor who might go to court because of disturbing noise. On the other hand, noise in a corridor or a lobby is of much less concern to someone's well-being.
3. If a particular design involves a permanent structural member that is not easily modified or corrected later (in the event it may prove unsatisfactory), a conservative approach must be used. A poured concrete floor slab is not easily replaced by a new and heavier floor slab. On the other hand, a lightweight movable partition can be changed later if necessary. An attenuator can be added later or enlarged later if necessary. Compromises may be justified if the compromised member can be corrected later at relatively small extra cost. Compromises must not be made when the later corrective measure is impossible or inordinately expensive.

C-9.2 Noise Control Treatments.

C-9.2.1 General Applications.

A primary advantage of the manual and of the various noise-analysis procedures offered in this document is that it elevates the awareness of the architect and engineer to problems of noise and vibration. This is an important first step to noise control. Without awareness, the noise problem is ignored in the design, and later problems in remedial steps are compounded. In most building situations, noise control is provided by application of the basic contents of the manual:

- Adequate wall and floor-ceiling constructions must be designed to contain the noise and limit its transmission into adjoining areas.
- Acoustic absorption material must be used in either or both the sound transmitting room and the sound receiving room to absorb some of the sound energy that “bounces” around the room. Quantitative data and procedures for incorporating sound absorption materials are included in the tables and data forms.
- Transmission loss data must be used to select various types of construction materials for the design of noise enclosures.
- Building layouts must be modified to redistribute noise sources in a more favorable arrangement, bring together noisy areas in one part of a building and quiet areas in a different part of the building (to minimize their reaction on one another), and use less critical “buffer zones” to separate noisy and quiet areas.
- Vibration isolation mounts must be used for the support of mechanical or vibrating equipment. Details of such mounts are given in chapter 9.
- Attenuators must be used to control noise transmission through air passageways.
- Duct lining treatments (when allowed) may be used to control noise transmission through ducted connections.
- Specifications must be used to limit the noise output of purchased equipment for use in the building.
- The basic elements of acoustics must be understood and used in order to work intelligently with SPL and PWL data for many types of electrical and mechanical noise sources, know the effects of distance (both indoors and outdoors), appreciate the significance of noise criteria, and be able to manipulate acoustic data in a meaningful and rational way. A few of these items are discussed below.

C-9.2.2 Absorbers.

Acoustical ceiling and wall panels are the most common sound absorbers. Absorbers are rated by the ratio of noise absorbed to noise impacted on the absorber’s surface. A coefficient of 1.0 indicates 100 percent absorption; a coefficient of zero indicates 0 percent absorption. Noise Reduction Coefficient (NRC) is the average coefficient of sound absorption measured at 250 Hz, 500 Hz, 1 kHz, and 2 kHz. Sound absorption must be designed to absorb the frequencies of the sound striking it. For example, a transformer enclosure must have an absorption coefficient of at least .75 in the 125 Hz band (the sound of electrical hum is twice the 60-cycle powerline frequency). Auditoriums must have even absorption over a wide frequency range for a balanced reverberant sound.

C-9.2.3 Test Methods.

There are three basic mountings for sound absorption tests used by ASTM (ASTM E 795-83): 1) Type A.-hard against a concrete surface (formally designated as No. 1), 2) Type D.-with a 3/4-inch (1.9 cm) airspace behind the test material, such as a wood furring strip (formally designated as No. 2), and 3) Type E.-with a 16-inch (40.1 cm) airspace behind the test material, such as an acoustical ceiling (formally designated as No. 7). See Table C-3 for absorption coefficients of some typical building materials.

C-9.2.4 Core Material.

Absorbers consist of a core material, usually fibrous or porous, with a facing as a cover. Fibrous cores are typically 1 inch (2.54 cm) thick for general noise control, and 2 inches (5.1 cm) thick for auditoriums, music, or low frequency absorption. If a minimum 2-inch (5.1 cm) airspace is provided behind a 1-inch (2.54 cm) core, the effect is approximately equivalent to a 2-inch (5.1 cm) thick core. 1-inch (2.54 cm) thick fibrous cores have an NRC of .75, and 2 inch (5.1 cm) thick fibrous cores have a NRC of .95 with a Type D mounting.

C-9.2.5 Facings.

Facings over the acoustical core material serve as both a visual and a protective screen. They are typically cloth, perforated vinyl, wood screens, or expanded metal. Expanded metal, such as plasterer's metal lath, is relatively vandal-proof. Expanded or perforated metal facings must be at least 23 percent open; 33 percent is preferable.

C-9.2.6 Ceilings.

Acoustical ceilings are of two basic types: mineral fiber and fiberglass. Mineral ceiling tiles with a fissured pattern have an NRC of .55 to .65 with a Type E (or No. 7) mounting. Fiberglass ceiling tiles have an NRC of .95 and are normally used in open office design. Fiberglass ceiling tiles, however, have no resistance to sound traveling through them, whereas 5/8-inch standard mineral tiles have a 35 to 40 STC rating for sound transmission from one office to another where the dividing wall stops just above the dropped ceiling line. Lab ratings for such walls can be achieved by installing a baffle over the wall in the ceiling plenum, or by extending the walls up to the underside of the next floor.

C-9.2.7 Enclosures.

From the material given in the manual, it is possible to estimate the noise levels inside a solid-wall enclosure that contains a piece of noisy equipment and to estimate the noise levels that will be transmitted from that enclosure into the surrounding spaces.

- In acoustic terms, an enclosure is an almost air-tight chamber containing the noise source. Small cracks around doors are known noise leaks and cannot be tolerated if a high degree of sound isolation is required. The walls of the enclosure must be solid and well-sealed. If air can escape through the enclosure, sound can escape through the enclosure. A favorite analogy in acoustics is that the same amount of sound power can pass through a 1-in.^{2} (0.093 m^2) hole as through a 100-ft.^{2} (9.3 m^2), 6-inch, 15 cm) thick solid concrete wall. A seemingly negligible crack around a door or at the ceiling joint of a wall can have much more than 1 in.^{2} (6.5 cm^2) of area.
- Where openings in an enclosure are required, they must be given adequate acoustic treatment in order not to weaken seriously the effectiveness of the enclosure. Ventilation ducts may be muffled, clearance holes around pipes, ducts, and conduit must be sealed off airtight, and passageways for material flow must be protected with “sound traps” (attenuators).

C-9.2.8 Barriers, Partial-height Partitions.

Many offices, shops, and tool rooms contain barriers or partial-height partitions that serve to separate areas or people or functions. When used with nearby acoustically absorbent ceilings, these partitions can provide a small amount of acoustic separation-possibly 3 to 5 dB of noise reduction in the low-frequency region and 5 to 10 dB in the high-frequency region, depending on the geometry and the absorption in the area. Where noise reduction values of 20 to 30 dB are desired, partial-height partitions would be useless. A caution is offered here against use of partial-height partitions as control room separators or as small office enclosures out in the middle of an engine room or as a telephone booth enclosure during MER noise.

C-9.2.9 Damping Materials.

Damping is the resistive force to vibratory motion. Sheet metal has low damping properties and will ring when impacted. Loaded vinyl and lead both have high mass and high damping and will thud when impacted. Loaded vinyl has replaced lead in general usage because of lower cost, and because loaded vinyl is available in sheets with an adhesive backing. The loaded vinyl may be cut with scissors and directly applied to noisy ducts or sheet metal at a low cost, usually with good results.

C-9.2.10 Combination.

Combination foam absorbers and loaded vinyl barriers in sandwich type construction are available with adhesive backs and are often used to reduce noise in vehicle cabs or on vibrating equipment covers. Lagging is the process of applying a fibrous or porous material, such as 3-pound density fiberglass, over a noisy duct or pipe, and then covering the fiberglass with sheet metal or loaded vinyl. This method is useful on steam piping, valves, ducting, and fans. Lagging may not be used where it could cause excessive heat buildup, such as on compressors. Enclosures, made of plywood or sheet metal with fiberglass used as an absorber on the inside, can be effective in reducing machinery noise. Enclosures of clear plastic panels can be used where visibility is required. Ventilation may be provided on compressors or computer enclosures by installing foam or fiberglass lined duct (when allowed) at the bottom for cool inlet air, and at the top for hot exhaust air. Enclosures must be carefully fitted together with no gaps which could leak noise. Convenient access panels must be designed into all noise control enclosures.

C-9.2.11 Attenuators.

Attenuators are characterized as either “reactive attenuator” or “dissipative attenuators.” Reactive attenuators usually consist of large-volume chambers containing an internal labyrinth-like arrangement of baffles, compartments, and perforated tubes. Reactive attenuators smooth out the flow of impulsive-type exhaust discharge and, by the arrangement of the internal components, attempt to reflect sound energy back toward the source. There is usually no acoustic absorption material inside a reactive attenuator. Dissipative attenuators are almost entirely made up of various arrangements of acoustic absorption material that dissipates or absorbs the acoustic energy.

C-9.2.12 Reactive Attenuators.

Reactive attenuators are used almost entirely for gas and diesel reciprocating engine exhausts. Somewhat more detailed information on the performance and use of reactive attenuators is included in the **Inactive** UFC 3-450-02 Power Plant Acoustics.

C-9.2.13 Dissipative Attenuators.

As the name implies, these attenuators are made up of various arrangements of acoustically absorbent material that absorbs sound energy out of the moving air or exhaust stream. The most popular configuration is an array of “parallel baffles” placed in the air stream. The baffles may range from 2 inches to 16 inches (5.1 cm to 40.1 cm) thick and are filled with glass fiber or mineral wool. Under severe uses, the attenuator material must be able to withstand the operating temperature of the air or gas flow, and it must have adequate internal construction and surface protection to resist the destruction and erosion of high-speed turbulent flow. These attenuators must be obtained from an experienced, reputable manufacturer to ensure proper quality of materials, design, workmanship, and ultimately, long life and durability of the installation.

C-9.2.14 Packaged Duct Attenuator.

For ducted air handling or air-conditioning systems, packaged duct attenuators can be purchased directly from reputable acoustical products suppliers. Their catalogs show the available dimensions and insertion losses provided in their standard rectangular and circular cross-section attenuators. These packaged duct attenuators are sold by most manufacturers in 3-foot (0.91 meters), 5-foot (1.52 meters), and 7-foot (2.13 meters) lengths. They are also usually available in two or three "classes," depending on attenuation. The mufflers of the higher attenuation class typically have only about 25 to 35 percent open area, with the remainder of the area tilled with absorption material. The lower attenuation classes have about 50 percent open area. The attenuators with the larger open area have less pressure drop and are known as "low pressure-drop units." The attenuators with the smaller open area are known as "high pressure-drop units." In critical situations, attenuator "self-noise" may also be a problem with these duct attenuators. If high-speed air is required, the manufacturer can usually provide self-noise data. When ordering special-purpose attenuators, specify the flow speed and the temperature of the air or gas flow, as these may require special surface protection and special acoustic filler materials.

C-9.2.15 Duct Lining.

Internal duct lining is prohibited. Prior to any design or construction, any consideration for its use must first be approved by exemption.

Only when approved for use: Duct lining is used to absorb duct-transmitted noise. Typically, duct lining is 1 inch (2.54 cm) thick. Long lengths of duct lining can be very effective in absorbing high-frequency sound, but the thin thickness is not very effective for low frequency absorption. The ASHRAE Guide can be used to estimate the attenuation of duct lining. Lined 90-degree turns are very effective in reducing high-frequency noise. For other than acoustical purposes (in example thermal), review other criteria for the use of duct lining and the potential of its prohibition.

C-10 AIR DISTRIBUTION FOR HEATING, VENTILATING, AND AIR CONDITIONING SYSTEMS.

In this section, consideration is given to the sound levels resulting from the operation of Heating, Ventilation and Air Conditioning (HVAC) systems in buildings. Information is provided on the most common HVAC equipment found in many commercial office buildings, how sound is propagated within ducted ventilation systems and the procedure for calculating sound levels in rooms from ventilation systems.

C-10.1 General Spectrum Characteristics of Noise Sources.

The most frequently encountered noise sources in a ducted air distribution system designed to deliver a constant volume of air are fans, control dampers, and air outlets such as diffusers, grilles, and registers (return air grilles with dampers). In a variable volume system terminal unit, such as variable air valves (VAVs), fan powered air valves, and mixing boxes, are an additional frequently encountered noise source. Operation of any of these identified noise sources can result in noise generated over most of the audio frequency spectrum. Typically, however, centrifugal fans generate their highest noise levels in the low frequency range in or below the octave centered at 250 Hz. Diffusers, and grilles, however, typically generate the highest noise levels in the octaves centered at 1000 Hz, or above. In between these low and high frequency sources, terminal units produce their highest noise levels in the mid-frequency range in the octaves centered at 250, 500, and 1000 Hz bands. In addition to these frequency characteristics, the normal sound propagation path between the various system sources and an occupant of the space served influences the typically observed spectra. Thus, the fans in a system are typically somewhat remote to an observer, and the fan sound is attenuated by the properties of the path including noise control measures. However, this path attenuation is greatest in the mid-, and high frequency range, and thus the noise reaching the receiver will primarily be in the low frequency range because of both the source and path characteristics. With diffusers and grilles, however, there is little or no opportunity to provide attenuation between the source and the receiver, and thus the high frequency noise of the source alone determines the spectrum content. With air terminal units the most direct path is often sound radiating from the case of the unit and traveling through a ceiling, usually acoustical, direct to the observer in the space being served. The attenuation of a typical ceiling increases slightly with frequency, and thus the typical noise of an air terminal unit in an occupied space will tend to shift downward by an octave to have its highest sound pressure levels in the octaves with center frequencies at 125, 250, and 500 Hz. Thus, in summary, when a system is designed to achieve good acoustical balance among the various sources, fan noise will control the noise level in the low frequency range, air terminal units will control in the mid-frequency range, and air outlets will control in the high frequency range.

C-10.2 Specific Characteristics of Noise Sources.

C-10.2.1 Fans.

To determine the requirements for noise control for a ducted air distribution system one of the primary requirements is to determine the octave band sound power level of the fan noise at the discharge and intake duct connections to a fan. These sound power levels can be determined by a methodology described in Appendix B or obtained from a fan manufacturer for the specific application and this is generally the preferable method. Note: the method given in Appendix B yields the sound power level for a fan selected to operate at its maximum efficiency, however the ASHRAE method suggests a correction factor, “C” on Table B-13, for off-peak operation at various fan efficiencies. With a system designed to deliver a constant volume to a space it is usually possible to operate a properly selected fan at or near its maximum efficiency. However, for a variable volume system, with a fan operating at a constant speed, the static efficiency will generally be significantly below its maximum static efficiency. Thus, for variable volume systems the adjustment to the power level for operating efficiency is very important. Variable speed drives allow the fan to operate at or near the peak efficiency for different air quantities and static pressures. In this instance the fan efficiency can be maintained near its maximum, and the sound power levels are reduced as the air quantity delivered and the static pressure are reduced in accordance with Equation B-5.

In order to use Equation B-5 and Table B-13 it is necessary to determine the static efficiency of the fan, and to compare it with the maximum static efficiency of the type of fan being utilized. The operating static efficiency of a fan may be obtained from the following:

Equation C-15. Static Efficiency

$$\textbf{Static Efficiency} = (\mathbf{Q} * \mathbf{P})/(\mathbf{6356} * \mathbf{BHP})$$

Where :
Q = air quantity (cfm)(m³/s)
P = static pressure (in)(cm)
BHP = brake horsepower

This calculated static efficiency is then compared with the maximum efficiency for the fan, which may be taken as 80% for a centrifugal fan with airfoil blades; 75% for centrifugal fans with backwardly inclined, single thickness blades; 70% for a vane axial fan; and 65% for a centrifugal forward curved fan. The ratio of the calculated static efficiency to the maximum static efficiency is then used to determine the correction for off-peak efficiency as shown on part C of Table B-13. For example, if the calculated static efficiency for a forward curved fan is 62%, then the ratio of the calculated static efficiency to the maximum static efficiency is 62% divided by 80%, or approximately 82%. In other words, the actual static efficiency is approximately 82% of the maximum static efficiency and the off-peak correction from part C of Table B-13 is 6 dB.

C-10.2.2 Air Terminal Units.

Air terminal units are components used in ducted air distribution systems to maintain the desired temperature in a space served by varying the volume of air. Basically, these units consist of a sheet metal box containing a damper, controls, and a sensor, and they are usually connected to a supply header via a flexible circular duct. They usually discharge air to one or more diffusers via rectangular sheet metal ducts. In their simplest form these units are designated as variable air valves (VAVs). However, units are also available with an auxiliary fan in the box to supplement the air delivered by mixing induced air from the ceiling plenum with the primary air from the supply header. Units with these auxiliary fans are termed fan powered terminals (FPTs), and they are available in two forms. In one form the fan only operates when it is necessary to mix warm air from the ceiling plenum with the primary air, and this type of unit is designated as a “parallel” FPT. The intermittent operation of the fan in this type of unit leads to some increased awareness of the noise generated. In a second form the fan operates continuously and handles both the primary air and the return air from the ceiling plenum. Both the primary air and return is mixed in varying quantities to maintain a constant volume delivered to the space served. This type of unit is designated as a “series” FPT. The noise of any air terminal unit can propagate to the space served via a number of paths, but the two prominent paths are (1) via the unit’s discharge ductwork to the connected outlet(s), or (2) by direct sound radiated from the casing of the unit into a ceiling plenum and then through a ceiling (usually acoustical) into the space served. Manufacturers publish data giving the octave band sound power level for the unit discharge sound, and the casing sound. These data are usually measured in accordance with Air-Conditioning, Heating, and Refrigeration Institute (AHRI) Standard 880-2008. With a VAV terminal unit the measurements for the casing sound measure only the casing sound. For a fan powered box (FPT) the casing sound data includes both the sound radiated by the casing, and the fan sound radiated from the air intake opening to the unit casing.

C-10.2.3 Noise Level Prediction.

C-10.2.3.1 Sound Level.

To predict the sound level in an occupied space produced by a terminal unit serving a space, procedures suggested in AHRI Standard 885-2008 may be used. For the duct borne sound, radiated by the air outlets, the estimation procedure involves two steps:

1. Reducing the sound power of the discharge, by the insertion loss (IL) of the duct system between the unit outlet and the space outlets, to obtain the unit sound power emitted into the room from the air outlets.
2. Applying the octave band “Rel SPLs” to obtain the octave band sound pressure levels in the room.

C-10.2.3.2 Radiated Sound.

For the casing radiated sound again two steps are required to estimate the sound pressure levels in a room with a unit located in the ceiling plenum, these are:

1. a plenum/ceiling transfer factor which combines the insertion loss (IL) of the ceiling and the absorption of the plenum is subtracted from the published power level for each octave band, and
2. the room factor for the space is subtracted from the power levels transmitted through the ceiling.

C-10.2.3.3 Transfer Values.

Values for the Plenum/Ceiling Transfer for typical acoustical ceilings are given in Table C-32. These values are applicable to typical ceiling construction, with some openings for lights and return air. These values do not apply when the terminal unit is located directly above a return air opening.

Table C-32 Plenum/Ceiling Transfer Factor.

	Octave Band Center Frequency (Hz)						
	63	125	250	500	1000	2000	4000
Type 1 Fiberglass Tile 1/2" - 6 lb/cu.ft	4	8	8	8	10	10	14
Type 2 Mineral Fiber Tile 5/8" - 35 lb/cu.ft	5	9	10	12	14	15	15
Type 3 Sheet Rock 5/8" - 22 lb/sq.ft	10	15	21	25	27	26	27

Note: Values for ceilings with typical penetrations and light fixtures.

C-10.2.4 Noise Control.

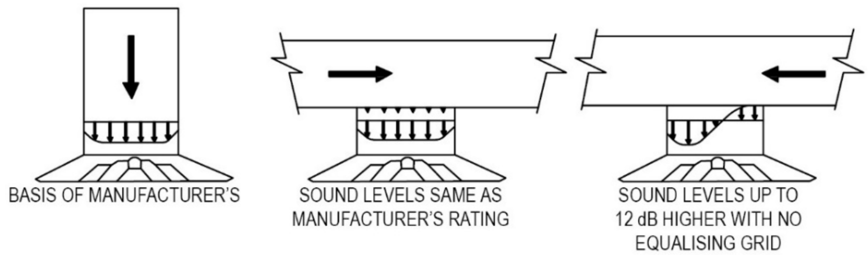
Typical noise control measures for air terminals, including VAVs, fan powered units, and mixing boxes are:

- Locating units above spaces such as corridors, work rooms, or open plan office areas. Do not locate VAV units over spaces where the noise exceeds an NC or RC 35. Do not locate fan powered terminal units (FPT), which are sized for 1,500 CFM, over spaces where the noise exceeds an NC or RC 40.
- Locating the units at least 5 ft. (1.52 meters) away from an open return air grille located in the ceiling,
- Installing sound attenuators, provided as options by some manufacturers, or acoustically lined sheet metal elbows, at the induced (return) air openings in the casings of fan powered units, or
- Installing acoustically lined elbows above ceiling return air openings when they must be near, or directly below a terminal unit.

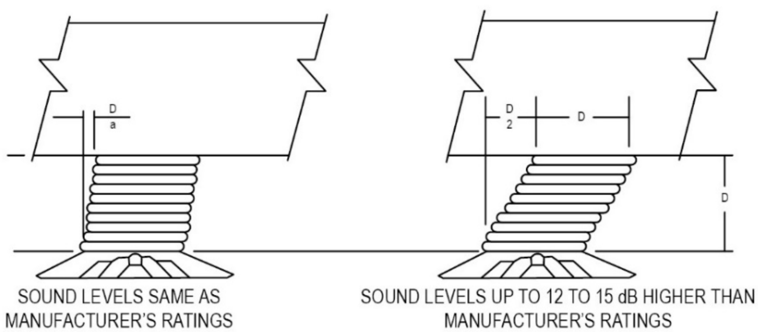
C-10.2.4.1 Diffusers, Grilles, and Control Dampers.

Diffusers and grilles are devices used to deliver to, or return air from, a building space. They are available in rectangular and circular forms, and in a linear or strip form. Generally, these devices include vanes, bars, tins, and perforated plates to control the distribution of air into the space. All these elements which make up a diffuser or grille act as spoilers in the air stream. When the air flows across the spoilers, noise is generated that, for a particular diffuser or grille design, varies by the 5th to the 6th power of the velocity. Because of the wide variety in diffuser design, and the sizes available, manufacturers publish sound level data in their catalogs. Most manufacturers only provide the NC level that the diffuser noise will reach with different quantities of air flow in a room where the “Rel SPL” is 10 dB. Thus, for a room with different acoustical properties an adjustment must be made to the quoted NC value. Some manufactures also publish the sound power level of the diffusers or grilles in octave bands. As this form of information is more useful for design than the NC values, request octave band data for any facility where sound level is considered critical. In using the manufacturer’s data care must be taken to note the data usually applies only to diffusers in an ideal installation. For example, placing a damper, even in an open position, behind a diffuser or grill may increase the noise generated by up to 15 dB. In general, where sound level is critical dampers must not be placed directly behind diffusers but preferably be located where the diffuser duct branches off the header, or main duct. In this location any damper generated sound can be attenuated by acoustic lining in the diffuser drop, and any resulting non-uniformity in the air flow delivered to the diffuser will be much less than if a damper is placed directly behind the diffuser. Also, the position of deflection bars in grilles, and vanes in diffuser can change the level of the noise generated. Thus, these factors need to be noted when using the data to predict diffuser sound levels in a space. Finally, regarding published data, Note: that the data is taken with uniform air delivery to or from the device. In application, this condition may not be met as shown in Figure C-20 showing that with non-uniform flow caused by short duct connections to a header duct, or by badly misaligned flexible duct the sound levels may be quickly increased by 5, 10, or 15 dB.

Figure C-20 Good and Poor Air Delivery Conditions to Air Outlets



A. Proper and Improper Airflow Conditions to an Outlet



B. Effect of Proper and Improper Alignment of Flexible Duct Connector

C-10.2.4.2 Control of Fan Noise in a Duct Distribution System.

Fan noise propagating along a duct system may be reduced by (1) propagation along the duct, (2) by duct branching, (3) by elbows, and (4) by end reflection.

C-10.2.4.3 Propagation in the Duct Distribution System.

Noise attenuation with propagation in a duct system result from; 1) natural energy losses as sound is transmitted through sheet metal duct walls to the space through which the duct passes; and 2) by absorption of energy in the internal glass fiber lining of the sheet metal duct.

C-10.2.4.4 Unlined Duct.

Table C-33 lists the natural attenuation, in dB/ft (m) for unlined rectangular sheet metal ducts without external thermal insulation. This attenuation, attributed to sound transmission through the duct walls, can be significant, in the low frequency range, for long lengths of duct. The attenuation values are given as a function of the ratio of the duct perimeter P and the duct cross sectional area A. This data is applicable only to normal sheet metal rectangular ducts typically used in the air conditioning industry. This data must not be used for ducts using metal heavier than 16 ga.; for circular ducts (which is relatively stiff) or for ducts made of glass fiber board.

Table C-33 Approximate Natural Attenuation in Unlined Sheet-Metal Ducts

P/A ratio in/sq. in.	Octave Band Center Frequency (Hz)		
	63	125	250 and over
Over 0.31	0	0.3	0.1
0.31 to 0.13	0.3	0.1	0.1
Under 0.13	0.1	0.1	0.1
Note: Double these values for Sheetmetal duct with external glass fiber insulation			

C-10.2.4.5 Duct Lining Attenuation.

Internal duct lining is prohibited. Prior to any design or construction, any consideration for its use must first be approved by exemption.

Only when approved for use: The octave band attenuation, in dB/ft (m), that is expected due to absorption of sound by 1 inch thick internally duct lining, is given in Table C-34. As noted on the table, the data can be used for any length of duct in the unshaded portion, but in the shaded portion the attenuation must not be applied for more than 10 ft. in any straight duct run between elbows or turns. Note, these attenuation factors are for the effects of the internal lining only and do not include the effects of natural attenuation as given on Table C-33.

Table C-34 Attenuation in Lined Ducts

Internal Cross-Sectional Dimensions (Inches)			Perimeter / Area Ratio (in/in^2)	Octave Band Center Frequency (Hz)						
				63	125	250	500	1000	2000	4000

Notes:
a) Apply appropriate conversion when calculations are performed in metric units.
b) Based on measurements of surface-coated duct liners of 1.5 lb./cu feet density representative for all liners with density of 1.5 to 3.0lb./cu ft.
c) dark line represents division between high and low frequency high frequency attenuation are applicable to a maximum of 10-ft.
d) attenuations apply to, airflow less than 2,000 1pm.
e) for attenuation due to sheet metal only SN Table 12 - 5
f) for critical applications, reduce attenuations by 10% to account for differences between manufacturers.

For the bands centered at 63, and 125 Hz the total attenuation for a lined duct is a sum of the natural (Table C-33) and lined duct (Table C-34) attenuations. For example, in a 24 x 24-inch (61 x 61 cm) (duct the attenuation in the 63 Hz octave is 0.05 dB/ft due to internal lining (Table C-34), plus 0.3 dB for the loss associated with sound transmission through the duct wall (Table C-33 with a P/A ration of 0.17). Review other criteria for prohibition of duct lining.

C-10.2.5 Sound Transmission Loss at Duct Branches.

When one duct branches off from a main, or header, duct the sound power propagating in the main duct up to the branch point is assumed to divide into the branch ducts in accordance with the ratio of the cross-sectional area of each branch, to the total cross-sectional area of all the ducts leaving the branch point. Thus, following any branch point the energy transmitted into any one duct is less than the initial sound power in the main duct before the branch point, and this loss, in dB, for each branch duct is given as:

Equation C-16. Duct Branch Sound Transmission Loss

Duct Branch Division Loss in $\mathbf{dB = 10\,log(B/T)}$

Where:
B = use Table 35 for branch area ratios
T = use Table 35 for branch area ratios

Table C-35 Lists the energy loss in dB for a range of branch area ratios. This power division is applied equally to each octave band.

Table C-35 Power Level Loss at Branches

B/T	Division (dB)	B/T	Division (dB)
1.00	0	0.10	10
0.00	1	0.08	11
0.63	2	0.063	12
0.50	3	0.05	13
0.40	4	0.04	14
0.32	5	0.032	15
0.25	6	0.025	16
0.20	7	0.02	17
0.16	8	0.016	18
0.12	9	0.012	19

C-10.2.6 End Reflection.

When a duct, in which sound is propagating, opens abruptly into a large space, or room, sound reflection occurs at the end or opening of the duct. The reflected sound is transmitted back into the duct and is attenuated. The loss in dB associated with this reflection is significant at low frequencies and is given in Table C-36 for a range of duct diameters. These values apply to a duct outlet flush mounted in a structure, but may also be applied, conservatively, to duct outlets flush mounted in a suspended acoustical ceiling. This data must not be applied when the duct branch dropping from a header duct to a diffuser or grill is less than 3 to 5 duct diameters, or where flexible ducts are used to connect a diffuser to a main branch. When the duct distribution system connects to a strip or linear diffuser, the end reflection must be taken as one-half the loss in dB given in Table C-36 for the diameter of the duct serving the linear diffuser section.

Table C-36 End Reflection Loss

A. Terminated at Acoustic Tile Ceiling or in Free Space.

Circular Duct Mean Duct Width (Inches)	Octave-Band Center Frequency (Hz) 63	125	250	500	1K
6	20	14	9	5	2
8	18	12	7	3	1
10	16	10	6	2	1
12	14	9	5	2	1
16	12	7	3	1	0
20	10	6	2	1	0
24	9	5	2	1	0
28	8	4	1	0	0
32	7	3	1	0	0

28	7	3	1	0	0
32	6	2	1	0	0
36	5	2	1	0	0
48	4	1	0	0	0
72	2	1	0	0	0

C-10.2.7 Losses at Elbows.

Sound is reflected or attenuated at 90-degree elbows occurring in duct systems. Table C-37 lists representative losses in dB for unlined rectangular elbows with turning vanes, or circular elbows for any size, and for a range of sizes for elbows with one-inch-thick lining in the elbow and associated upstream and downstream ductwork.

Table C-37 Losses Caused by Duct Elbows

	Duct Diameter (inches)	Octave Band Frequency (Hz) 63	125	250	500	1000	2000	4000	8000
Lined elbows	5 to 10	0	0	1	2	3	4	6	8
	11 to 20	0	1	2	3	4	6	8	10
	21 to 40	1	2	3	4	5	6	8	10
	41 to 80	2	3	4	5	6	8	10	12
Unlined elbows	All sizes	1	2	3	3	3	3	3	3

C-10.2.8 Sound Attenuators (Prepackaged Attenuators).

Sound attenuators, sometimes termed duct silencers, or mufflers are manufactured specifically for ventilation, and air conditioning systems by several manufacturers. These are used in air distribution systems as a means of providing increased sound attenuation where normal duct attenuation is insufficient. Attenuators are available in modular form to fit a range of cross-sections for rectangular ducts, and are usually readily available in lengths of 3, 5, 7, and 10 ft. (0.91, 1.52, 2.13, and 3.01 meters). They are also available for circular ducts in a range of diameters, and the length is a function of diameter, being 2 to 3 times the diameter. For the various lengths, and for both rectangular and circular ducts the attenuators are available with low, medium, or high pressure drop for a given velocity, usually expressed in terms of the air velocity in the duct at the attenuator entrance (in other words, “face velocity”). For example, low pressure drop attenuators will have a pressure drop of less than 0.1 in. of water with a face velocity of 1000 ft/min (5.08 m/s), but high pressure drop units will have a drop of close to 0.5 inch (1.27 cm) of water at the same velocity. Attenuators with a higher-pressure drop will most often provide greater sound attenuation. The actual installed pressure drop will also be a function of both the unit location in an air distribution system, and the uniformity and turbulence of the entering air flow. Manufacturers provide guidelines for estimating the installed operating pressure drop for different conditions. The manufacturers of duct attenuators also publish information on the sound power generated by flow in the air passages of the attenuator. However, this flow noise, or self-noise, is seldom a problem unless the flow velocities in the duct are high (in example greater than 3,000 FPM, (4560 mps), or the sound level criteria for the space served calls for very low levels, such as for a concert hall). Typical dynamic sound insertion loss values for normal rectangular sound attenuators, with glass fiber packed linings, for both low and high pressure drop attenuators are tabulated in Table C-38. These values are applicable when the flow and the sound are in the same direction and the flow velocity is moderate (approximately 1,000 FPM, 4560 mps). Manufactures provide dynamic sound insertion losses for various flow velocities when the air flow and sound are in the same direction (supply) and when the air flow and sound are in opposite directions (return).

Table C-38 Representative IL Values for Sound Attenuators

Type	Length in Ft.	Octave Band Center Frequency (Hz) 63	125	250	500	1000	2000	4000	8000
Low Pressure Drop	3	2	4	8	14	21	22	14	11
	5	3	5	11	23	31	34	19	13
	7	5	9	16	32	41	43	24	16
	10	6	15	22	37	52	53	35	23
Standard Pressure Drop	3	3	6	13	23	33	33	23	14
	5	4	11	20	37	44	44	36	22
	7	6	13	28	42	47	47	45	30
	10	8	15	35	50	56	57	57	40

The manufacturers of these attenuators can also provide polymer sheeting to enclose the sound absorptive glass fiber packing for cleanliness and resistance to certain chemicals. Certain manufactures also make attenuators without any sound absorptive packing (in other words, “pack-less”) for systems serving spaces that must maintain very clean environments. The insertion losses for these units are typically somewhat less than for the normal attenuators, and the manufacturers must be consulted regarding their specific acoustic performance.

C-10.2.9 Attenuators Using Active Cancellation.

Active sound attenuation as a means of noise control has in recent years moved from the laboratory to a growing number of applications including the control of fan noise in ducted systems. Active sound attenuation involves the use of an auxiliary sound source to generate a sound wave that interferes and cancels an unwanted sound wave. This system of cancellation is limited to plane wave conditions, which means that the wavelength of the sound to be cancelled must generally be greater than the largest dimension of the duct. While this is not a problem for most air distribution systems, it does generally limit the frequency range for application to below about 500 Hz. Recently, with the development of adaptive, digital signal processing, the application of this method has been extended to cancelling broad band noise and thus is not now limited to cancelling only tonal sounds. Finally, in some applications it has been proposed to combine in one attenuator both active cancellation and passive dissipative elements to attenuate the low and high frequencies respectively. Thus, active cancellation may find application in the future in the HVAC industry, but its cost and operation will probably limit its application to situations where the space for the use of conventional dissipative lining or attenuators is not available.

C-11 PROCEDURE FOR CALCULATING NOISE CONTROL REQUIREMENTS FOR AN AIR DISTRIBUTION SYSTEM.

C-11.1 Procedure for Calculating Noise Control Requirements for an Air Distribution System.

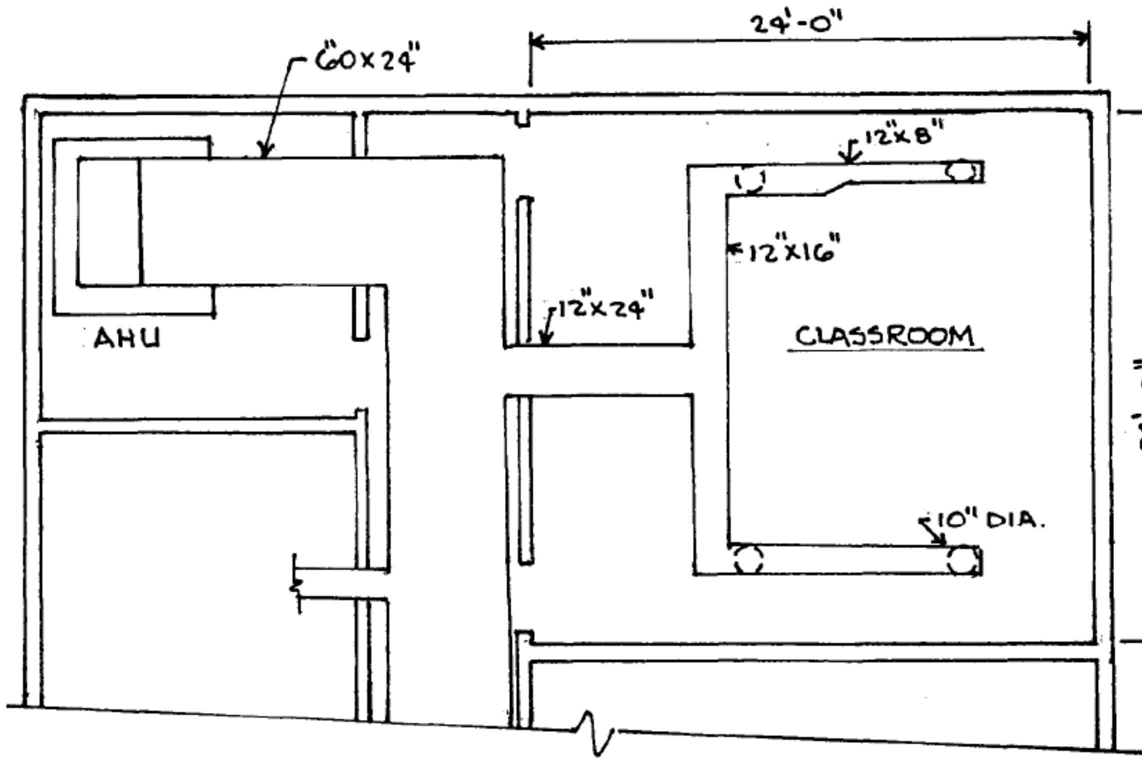
1. The procedure for calculating the noise control requirements for an air distribution system involves six steps:
   a. Selection of noise criteria or goal for the space(s) served.
   b. Estimating sound power level of sources.
   c. Estimating the insertion loss of the duct distribution system applicable to each source to arrive at the sound power at the air outlet(s) in the space(s) served.
   d. Determine the total sound power within the room from all the sources.
   e. Determining the “Rel SPL” for the space served and subtracting that from the sound power levels, from previous step, to obtain the sound pressure levels in the space.
   f. Compare calculated sound pressure levels in each octave band with the criteria to determine noise control requirements in dB.
2. To carry out step (a) it is necessary to know the function of the space served, and for that function such as a conference room select the appropriate RC or NC criteria, to serve as the noise control. To carry out step (b) for a constant volume system essentially means determining the sound power level, in each octave band, for the fan, and for a diffuser, or grille. These data can normally be obtained from a manufacturer, but if the equipment is not selected the fan power levels can be determined from the method given in Appendix B. The diffuser or grille sound power levels can be determined approximately from a manufacturer’s catalog for an identical or similar type of outlet. Similarly, with a variable volume system the sound power level for the air discharge of an air terminal unit, such as a VAV, or FPT, can be obtained from a manufacturer’s catalog for a given operating condition. For step (c) the attenuation provided by unlined and lined ducts, by sound attenuators, elbows, branches, and end reflection are added together to find the total insertion loss (IL) applicable to the control of the fan sound power as it propagates along the duct path between the fan and the air outlet. Similarly, for the prediction of the noise level in the space served caused by duct transmitted air discharge noise from an air terminal unit it is necessary to determine the insertion loss of the duct distribution system between the terminal unit and the room air outlet. This IL will consist of the attenuation of any unlined or lined ductwork, elbows, duct branches, or splits, and end reflection although this latter will not be significant for air terminal unit noise. In step (d) the sound power level of all sources contributing to the sound power at the air outlet are determined and combined to find the total sound power level, in

octave bands, at the air outlet. For step (e) it is necessary to determine the Room Factors and the “Rel SPLs” (see Chapter 3) for the space served and apply the “Rel SPL” to the sound power levels at the air outlet for each source to obtain the sound pressure level produced by that outlet at any location in the space served. For step (f) the resulting sound pressure levels are compared to the selected criteria to determine if additional sound attenuation is necessary.

C-11.2 Calculation Example.

In this example the noise control requirements for an air distribution system serving a classroom as shown in Figure C-21 are calculated. A fan with forward curved blades delivers 20,000 cubic feet per minute (cfm) to several classrooms and offices against a static pressure of 2.5 in. of water with 12 brake horsepower. The main supply duct has dimensions of 60 x 24 inches resulting in an air velocity of 2000 ft/min. The closest classroom, which has dimensions of 24 x 24 x 10 ft, is supplied by a duct branching off from the main header duct. The classroom air is delivered from four diffusers, 10 inch in diameter each, mounted in the ceiling, each delivering 500 cfm. Thus, the total air supplied by the branch duct is 2000 cfm, with an air velocity of 1000 ft/min. in the 12 x 24 in. duct. The only acoustical material applied to the room surfaces is a suspended acoustical ceiling representing approximately 25% of the room surfaces. In this example it is assumed that the entire duct system is internally lined with one-inch-thick sound absorptive insulation, and the duct cross-sectional flow area is given by the dimensions stated in the schematic figure.

Figure C-21 Plan View of Supply Duct for Example



The tabulated results for this example are as follows:

C-11.2.1 Step (1).

In this step an NC 30 is selected as the sound pressure level design criteria.

C-11.2.2 Step (2).

In this step the sound power level (Lw), in dB re 10-12 watts of the supply fan and the diffusers are determined.

C-11.2.2.1 Fan Lw.

From Equation B-5 and Table B-13 Octave Band Center Frequencies

Octave Band Center Frequencies

	63	*125*	*250*	*500*	*1k*	*2k*	*4k*
Fan Kw	47	43	39	36	34	32	28
10log(cfm)	43	43	43	43	43	43	43
BFI.				2			
20log(p)	8	8	8	8	8	8	8
Eff. Corr.	6	6	6	6	6	6	6
Total Lw of Fan	104	100	96	95	91	89	85

C-11.2.2.2 Diffuser Lw, w/o Damper.

From suppliers' catalog.

Octave Band Center Frequencies

	63	125	250	500	1k	2k	4k
Lw of One Diffuser	N/A	43	37	35	40	40	23

C-11.2.3 Step (3).

In this step, the total attenuation for fan noise provided by the duct system (including the lined ductwork If applicable), the duct branches, the elbows, and the end reflection loss are determined. This consists of determining the insertion loss (IL) for each element and then summing all the insertion losses.

C-11.2.3.1 (1) Lined Ductwork (where applicable) IL in dB.

The insertion losses from each rectangular duct element are determined from Tables C-33 and C-34. The result of each element is summed by octave bands to provide the total duct attenuation in dB in each octave band.

Octave Band Center Frequencies

	63	125	250	500	lk	2k	4k
20' of 24x60	3	4	7	18	32	30	30
9' of 12x24	3	2	5	12	31	27	19
10' of 12x16	4	3	7	16	41	41	28
3' of 10"	0	1	2	5	6	6	5
Total	10	10	21	>50	>50	>50	>50

Note: Table C-34 does not contain entries for the 24x60 and 12x16 ducts. The attenuation values for these ducts are obtained by interpolation. For example, the attenuation for the 24x60 duct is the average value of the 24x48 and 24x72 ducts. For the 24x60 duct the full 20 feet of length is used since the elbow breaks the length into two lengths less than 10 feet each. Note: that the total attenuation is the sum of the attenuation due to the internal lining (Table C-34) and the natural attenuation (Table C-33). The attenuation for the 10" round duct was obtained from a supplier's catalog. The total attenuation for all the duct elements is limited to approximately 50 dB because this is usually the maximum that can be obtained in a connected system due to structural flanking down the duct wall.

C-11.2.3.2 (2) Branches (to one diffuser).

The branch attenuation is determined by Equation C-16 or Table C-35. With a branch area of 2 sq. ft. (for example: 24x24) and the area after the branch of 10 sq. ft. (for example: 24x60) the area ratio of the branch is 2/(10+2) or 0.167. The sound power loss at the take-off in the corridor is approximately 8 dB in accordance with Equation C-16. The power division in the "T" and diffuser take-off are determined in a similar fashion and are approximately 3 dB each (in other words, 50% each way). Therefore, the total attenuation due to all the branching is approximately 14 dB in all the octave bands.

Octave Band Center frequencies

	63	125	250	500	1k	2k	4k
Branch att. in corridor	8	8	8	8	8	8	
"T" in room	3	3	3	3	3	3	3
Diffuser Take-off	3	3	3	3	3	3	3
Total (dB)	14	14	14	14	14	14	14

C-11.2.3.3 (3) Four elbows.

There are four elbows between the fan and the classroom. The attenuation of each of these can be found from Table C-37. The first elbow is the 24x60 inch elbow that goes from the vertical to the horizontal at the fan outlet. For this elbow the duct diameter used is 24 inches since this is the dimension in the plane of the turn. The second elbow is a 60x24, for this elbow the dimension is 60 inches. The third elbow is the "T" from 12x24 to 12x16 over the classroom. In (2) above a power division was taken for this "T" fitting, however since some energy is also reflected from the "T" it also acts like an elbow. For the "T" the characteristic dimension is 24". And the final elbow is the 12x16 over the classroom. For this elbow the characteristic dimension is 16". The attenuations for each elbow and the total attenuations for all of the elbows is given below.

Octave Band Center Frequencies

	63	125	250	500	1k	2k	4k
24x60	1	2	3	4	5	6	8
60x24	2	3	4	5	6	8	10
24x12	1	2	3	4	5	6	8
16x12	0	1	2	3	4	6	8
Total IL	4	8	12	16	20	26	34

C-11.2.3.4 (4) End loss.

The end reflection loss is taken from Table C-36 part A, where the diameter is 10 inches. Part A was used since the diffuser was mounted in an acoustical tile ceiling. If the ceiling was hard (gyp. bd., plaster, concrete, and the rest.) then part B would have been used.

Octave Band Center Frequencies

	63	125	250	500	1k	2k	4k
End Reflection	16	10	6	2	1	0	0

C-11.2.3.5 Total IL.

The total insertion loss of the ducted air supply system is the arithmetical sum, in each octave band, of the insertion losses of (1) through (4) above.

Octave Band Center Frequencies

	63	125	250	500	1k	2k	4k
Total line ducts	10	10	21	>50	>50	>50	>50
Total branches	14	14	14	14	14	14	14
Total elbows	4	8	12	16	20	26	34
End Reflection	16	10	6	2	1	0	0
Total IL (all duct elements)	44	42	53	>50	>50	>50	>50

Note again, the insertion loss is limited to approximately 50 dB. This is because flanking sound traveling within the duct walls can become a significant source of sound when the sound levels within the air stream have been attenuated a great deal. If attenuations greater than 50 dB are required, additional vibration breaks within the duct would have to be evaluated.

C-11.2.4 Step (4).

In this step the total sound power at each of the two diffusers closest to the fan is determined. First the sound power transmitted to the room from the fan via the supply duct, is determined by subtracting the total attenuations (c. (5) above) from the total sound power of the fan (b. (1) above) by octave bands. These steps are shown below.

	Octave Band Center Frequencies						
	63	125	250	500	1k	2k	4k
Total Fan Lw (b.(1) above)	104	100	96	95	91	89	85
Total Duct IL (c.(5) above)	44	42	53	>50	>50	>50	>50
Resulting Fan Lw in Classroom	60	58	43				

Then the sound power of the diffuser is added, logarithmically, to the sound power transmitted by the fan, as shown below.

	Octave Band Center Frequencies						
	63	125	250	500	1k	2k	4k
Fan Lw in Classroom	60	58	43				
Diffuser Lw		43	37	35	40	40	23
Total	60	58	44	35	40	40	23

This analysis provides the total sound power into the room from the operation of one diffuser. It also indicates the frequency range of the significant sources of sound. For example, the 63, 125 and 250 Hz octave bands are dominated by the sound of the fan, whereas the level of the other octave bands are determined by the operation of the ceiling diffuser. This distinction is important since sound control for each of these two items are different, as discussed in the section below.

C-11.2.5 Step (5).

In this step the Room Factor is determined to obtain the “Rel SPL” as described in paragraph C-2. The sound pressure levels in octave bands (Lp) in the room, from one diffuser, is then the total sound power from the diffuser plus the “Rel Spl” as given in equation C-13. The room volume is 5760 cu. ft., and the acoustic ceiling is 25% of the room surface area. Thin wall surfaces are used on 30% of the room surface area. The term “REL SPL” is determined for a distance of 8 ft. from one diffuser.

	Octave Band Center Frequencies						
	63	125	250	500	1k	2k	4k
Room Factor (sq/ft.)	450	600	450	500	600	600	600
"Rel SPL"	-9	-11	-9	-10	-11	-11	-11
Total Lw (d. above)	60	58	44	35	40	40	23
Lp-Octave band Sound level	51	47	35	25	29	29	12

C-11.2.6 Step (6).

In this step the Lp from e. above is compared with the NC 30 criteria.

	Octave Band Center Frequencies						
	63	125	250	500	1k	2k	4k
Lp (one diffuser)	51	47	35	25	29	29	12
NC 30 criteria	57	48	41	35	31	29	28
Required Reduction	0	0	0	0	0	0	0

This analysis shows that the sound due to the operation of the fan just meets the selected goal in the 125 Hz octave band. In addition, the diffuser sound, from one diffuser, would just meet the criteria in the octave band centered at 2000 Hz. However, for this classroom, consider the total sound from all four diffusers. As the two diffusers closest to the fan are at identical duct distances from the fan the sound of each diffuser can be assumed to be identical. Also, the added duct length to the next two diffusers is not sufficient to lower the fan noise significantly. Therefore, the diffuser noise must be equal for all four outlets. Thus, in the center of the room it is found that the required IL must be increased by the factor of 10 log (4), or 6 dB. In this case the sound pressure level in the room for all four diffusers would be:

	Octave Band Center Frequencies						
	63	125	250	500	1k	2k	4k
Lp (4 diffusers)	57	53	41	31	35	35	18
NC 30 criteria	57	48	41	35	31	29	28
Required Reduction (Considering Four Outlets)	0	5	0	0	4	6	0

To provide the additional IL required for the fan noise in the 125 Hz octave band a 5 ft. long standard pressure drop attenuator could be installed in the 60x24 duct in the fan room, or in the 12x24 duct leading to the classroom. The location of choice would depend on the need for sound attenuation in other portions of the duct system. The sound in the 1,000 and 2,000 Hz octave bands are due to the diffusers. Attenuators in the duct will not attenuate this sound. For the diffuser noise one solution would be to increase the diffuser size, and this would require changing the diameter of the diffuser drop from a 10 in. to 12 in. diameter yielding lower sound power levels by the order of 8 to 10 dB.

C-12 VIBRATION CONTROL INFORMATION.

This section provides the details of vibration isolation mountings so that the desired vibration conditions discussed in Chapter 4 can be met for most electrical and mechanical equipment. In addition, typical forms of vibration isolators are given, five general types of mounting systems are described, and summary tables offer suggested applications of five mounting systems for the mechanical equipment commonly found in buildings. A discussion of the general consideration for effective vibration isolation is presented in Appendix A.

C-12.1 Vibration Isolation Elements.

Table C-39 lists the principal types of vibration isolators and their general range of applications. This table may be used as a general guide for comparing isolators and their range of static deflections and natural frequencies as applied to two equipment categories (rotary and reciprocating) and two equipment locations (noncritical and critical). Additional details are required for actual selections of mounts. Vibration isolator types are discussed in this paragraph, and equipment installations are discussed in the remaining paragraphs of this chapter.

Table C-39 General Types and Applications of Vibration Isolators

Isolator Type	Typical Range of Static Deflection (in.)	Corresponding Approximate Range of Natural Frequency (Hz)	Vibration Isolation Applications – Non-specific			
			Noncritical Locations[c]		Critical Locations[c]	
			Rotary Equipment	Reciprocating Equipment	Rotary Equipment	Reciprocating Equipment
Steel Spring[a]	.25 to 10	6 to 1	Yes	Yes	Yes	Special[d]
Neoprene-in-shear, double deflection	.25 to .5	6 to 4	Yes	Yes	Yes	No[e]
Neoprene-in-shear, single deflection	.1 to .25	10 to 6	Yes	Yes	Yes	No[e]
Compressed block of glass fiber, 2-in thick[b]	.02 to .15	20 to 8	Yes	No	Yes	No
Neoprene pad, ribbed or waffle-pattern, 1 to 4 layers[b]	.02 to .25	20 to 6	Yes	No	Yes	No
Felt or cork pads or strips	.01 to .1	30 to 10	See text for application and limitations			
Air Spring	---	10 to 1	See text for application and limitations			

Note:
a. Apply appropriate conversion to material dimension when using metric calculations.
b. Always use pad-type isolator in series with spring to control high-frequency structure borne noise in critical locations.
c. May be used alone for relatively high-speed rotary equipment or in series with steel springs in critical locations for reduction of high-frequency structure borne noise. Not normally used alone for vibration isolation of reciprocating equipment.
d. Refer to paragraph 4-2d for definition of noncritical and critical locations.
e. Special design required for reciprocating equipment at critical locations, especially for low speeds.
f. Not normally recommended for this application but can be adapted as special design.

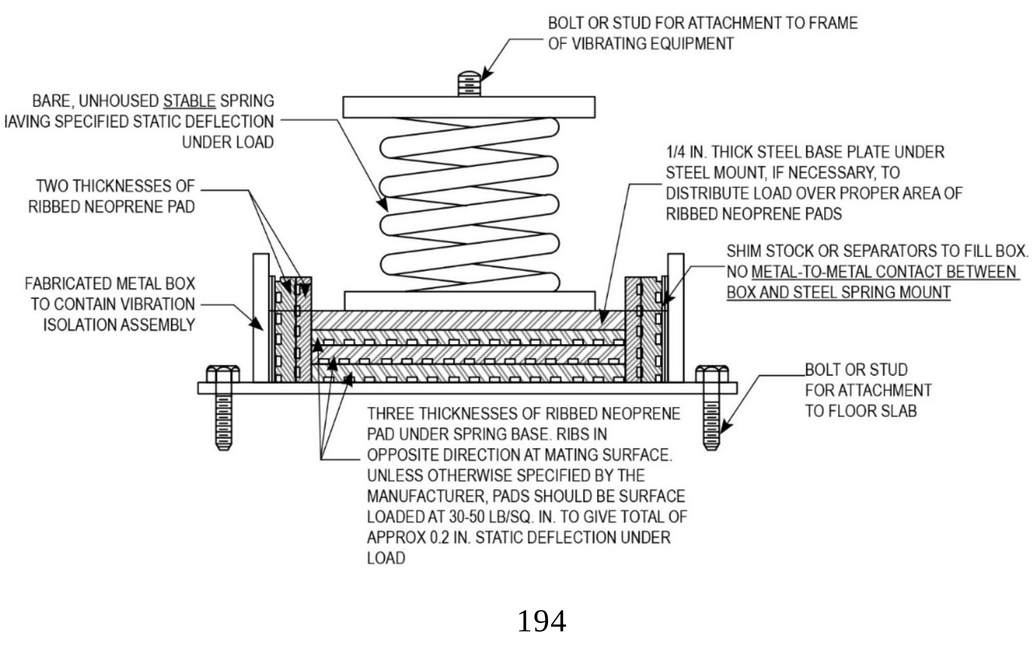
C-12.1.1 Steel Spring Isolators.

Steel springs are used to support heavy equipment and to provide isolation for the typical low-frequency range of about 3 to 60 Hz (180- to 3600-rpm shaft speed). Steel springs have natural frequencies that fall in the range of about 1 Hz (for approximately 10-inch static deflection) to about 6 Hz (for approximately 1/4-inch or 0.64-cm) static deflection). Springs transmit high-frequency structure borne noise, so they must be supplemented with a high-frequency pad-type isolator when used to support equipment directly over critical locations in a building. Unhoused "stable" steel springs are preferred over housed unstable or stable springs. Unstable springs tend to tilt over when they are loaded and to become short-circuited when they bind against the inside walls of the spring housing. Stable steel springs have a diameter that is about 0.8 to 1.2 times their compressed height. They have a horizontal stiffness that is approximately equal to their vertical stiffness; therefore, they do not tend to tilt sideways when a vertical load is applied. The free-standing unhoused spring can easily be inspected to determine if the spring is compressed correctly, is not overloaded to the point that adjacent coils are solid against one another, and is not binding against its mounting bracket, and to ensure that all springs of a total installation are uniformly compressed, and that the equipment is not tilting on its base. For reasons of safety, steel springs are always used in compression, not in tension.

C-12.1.2 Neoprene-In-shear Isolators.

Neoprene is a long-lasting material which, when properly shaped, can provide good vibration isolation for the conditions shown in Figure C-22. Typically, neoprene-in-shear mounts have the appearance of a truncated cone of neoprene bonded to bottom and top metal plates for bolting to the floor and to the supported equipment. The mount usually has an interior hollow space that is conically shaped. The total effect of the shaping is that for almost any direction of applied load, there is a shearing action on the cross section of neoprene. In this shearing configuration, neoprene serves as a vibration isolator; hence, the term "neoprene-in-shear." A solid block of neoprene in compression is not as effective as an isolator. Manufacturers' catalogs will show the upper limit of load-handling capability of large neoprene-in-shear mounts. Two neoprene-in-shear mounts are sometimes constructed in series in the same supporting bracket to provide additional static deflection. This gives the double deflection mount referred to in Table C-39.

Figure C-22 Suggested Arrangement of Ribbed Neoprene Pads for Providing Resilient Lateral Restraint to a Spring Mount



C-12.1.3 Compressed Glass Fiber.

Blocks of compressed glass fiber serve as vibration isolators when properly loaded. The manufacturers have several different densities available for a range of loading conditions. Typically, a block is about 2-inches (0.051 meters) thick and has an area of about 10 to 20 in.^{2} (65 to 129 cm^2). but other dimensions are available. These blocks are frequently used in series with steel springs to remove high-frequency structure borne noise, and they are often used alone, at various spacings, to support floating concrete floor slabs. The manufacturer's data must be used to determine the density and area of a block required to achieve the desired static deflection. Unless otherwise indicated, a static deflection of about 5 to 10 percent of the uncompressed height is normal. With long-time use, the material might compress an additional 5 to 10 percent of its height. This gradual change in height must be kept in mind during the designing of floating floors to meet floor lines of structural slabs.

C-12.1.4 Ribbed Neoprene Pads.

Neoprene pads with ribbed or waffle-pattern surfaces are effective as high frequency isolators in series with steel springs. In stacks of 2 to 4 inch (0.051 to 0.1 meters) thicknesses, they are also used for vibration isolation of flow power rotary equipment. The pads are usually about 1/4 to 3/8 inches (0.64 to 0.95 cm) thick, and they compress by about 20 percent of their height when loaded at about 30 to 50 lb/in^2 (2.11 to 3.52 kg/cm^2). Higher durometer pads may be loaded up to about 100 lb/in^2 (7.04 kg/cm^2). The pads are effective as isolators because the ribs provide some shearing action, and the spaces between the ribs allow lateral expansion as an axial load is applied. The manufacturer's literature must be used for proper selection of the material (load-deflection curves, durometer, surface area, height, and similar).

C-12.1.5 Felt Pads.

Felt strips or pads are effective for reducing structure borne sound transmission in the mounting of piping and vibrating conduit. One or more layers of 1/8 or 1/4-inch (0.32 or 0.64 cm) thick strips must be wrapped around the pipe under the pipe clamps that attach the piping to building structures. Felt pads will compress under long time and high load application and must not be used alone to vibration isolate heavy equipment.

C-12.1.6 Cork Pads.

Cork pads, strips, or blocks may be used to isolate high frequency structure borne noise, but they are not recommended for high load bearing applications because cork gradually compresses under load and loses its resilience. High density construction cork is sometimes used to support one wall of a double wall. In this application, the cork will compress slightly with time, and it will continue to serve as a high frequency isolator (say, for structure borne noise above about 100 to 200 Hz), but it will not provide good low frequency isolation at equipment driving frequencies of about 10 to 60 Hz. Years ago, before other resilient materials came into widespread use, cork was often misused under heavy vibrating equipment mounts: full area cork pads were frequently loaded at rates of 1 to 5 lb/in^2 (0.071 to 0.352 kg/cm^2). This is such a low loading rate that the cork appears stiff and does not provide the desired resilience. If cork is to be used for vibration isolation, a load deflection curve must be obtained from the supplier, and the cork must be used in the central linear region of the curve (possibly loaded at about 10 to 20 lb/in^2 or 0.7 to 14.1 kg/cm^2). With this loading, the compressed material will have an initial deflection of about 5% and will continue to compress gradually with age.

C-12.1.7 Air Springs.

Air springs are the only practical vibration isolators for very low frequencies, down to about 1 Hz or even lower for special problems. An air mount consists of pressurized air enclosed in a resilient reinforced neoprene chamber. The air is pumped up to the necessary pressure to carry its load. Since the chamber is subject to very slow leakage, a system of air mounts usually includes a pressure sensing monitor and an air supply (either a pump or a pressurized air tank). A group of air mounts can be arranged to maintain very precise leveling of a base by automatic adjustment of the pressure in the various mounts. If air mounts are used in a design, an active air supply is required. Operational data must be obtained from the manufacturer.

C-12.2 Mounting Assembly Types.

In this paragraph, five basic mounting systems are described for the vibration isolation of equipment. Certain general conditions relating to all the systems are first mentioned.

C-12.2.1 General Conditions.

C-12.2.1.1 Building Uses.

Isolation recommendations are given for three general equipment locations: on grade slabs, on upper floors above noncritical areas, and on upper floors above critical areas. It is assumed that the building under consideration is an occupied building involving many spaces that would require or deserve the low noise and vibration environments of such buildings as hotels, hospitals, office buildings, and the like. Hence, the recommendations are aimed at providing low vibration levels throughout the building. If a building is intended to serve entirely such uses lobbies, kitchens, and machinery spaces, the recommendations given here are too severe and can be simplified at the user’s discretion. An on-grade slab usually represents a more rigid base than is provided by a framed upper floor, so the vibration isolation recommendations can be relaxed for on-grade installations. Of course, vibration isolation treatments must be the very best when a high-quality occupied area is located immediately under the MER, as compared with the case where a “buffer zone” or noncritical area is located between the MER and the critical area.

C-12.2.1.2 Structural Ties, Rigid Connections.

Each piece of isolated equipment must be free of any structural ties or rigid connections that can short-circuit the isolation joint.

- Flexible electrical conduit whip must be long and "floppy" so that it does not offer any resistance or constraint to the free movement of the equipment. Piping must be resiliently supported. Limit stops, shipping bolts, and leveling bolts on spring isolators must be set and inspected to ensure that they are not inadvertently short-circuiting the spring mounts.
- All building trash must be removed from under the isolated base of the equipment. Loose pieces of grout, 2x4s, nuts, bolts, soft drink bottles, beer cans, welding rods, pipes, and pipe couplings left under an equipment base can short-circuit the isolation mounts. It is recommended that 2-inch (5.1 cm) to 4-inch (10.2 cm) clearances be provided under all isolated equipment in order to facilitate inspection and removal of trash from under the base.
- For many equipment installations, there is no need to bolt down the isolation mounts to the floor because the smooth operation of the machine and the weight of the complete assembly keep the system from moving. For some systems, however, it may be necessary to restrain the equipment from "creeping" across the floor. In these situations, it is imperative that the hold-down bolts not short circuit the pads. A suggested restraining arrangement is illustrated in Figure C-22. Simpler versions can be devised.
- For buildings located in earthquake-prone areas, the isolation mounts must contain snubbers or motion-limiting devices that restrain the equipment against unusual amounts of movement. These snubbers must be set to provide adequate free movement for normal equipment operation. These devices are available from most suppliers of isolator equipment.

C-12.2.2 Type I Mounting Assembly.

The specified equipment must be mounted rigidly on a large integral concrete inertia block. (Unless specified otherwise, all concrete referred to in this manual must have a density of at least 140 to 150 lb/ft.^{3} or 2270 to 2432 kg/m^3)

- The length and the width of the inertia block must be at least 30 percent greater than the length and width of the supported equipment.
- Mounting brackets for stable steel springs must be located off the sides of the inertia block at or near the height of the vertical center-of-gravity of the combined completely assembled equipment and concrete block. If necessary, curbs or pedestals must be used under the base of the steel springs in order to bring the top of the loaded springs up to the center-of-gravity position. As an alternative, the lower portion of the concrete inertia block can be lowered into a pit or cavity in the floor so that the steel springs will not have to be mounted on curbs or pedestals. In any event, the clearance between the floor (or all the surfaces of the pit) and the concrete inertia block must be at least 4 inches, and provision must be allowed to check this clearance at all points under the block.

- Floor slab thickness. It is assumed that MER upper floor slabs will be constructed of dense concrete of 140-150 lb/ft3 (2270 to 2432 kg/m^{3}) density, or, if lighter concrete is used, the thickness will be increased to provide the equivalent total mass of the specified floor. For large MERs containing arrays of large and heavy equipment, it is assumed that the floor slab thickness will be in the range of 8 to 12 inches (20 to 31 cm), with the greater thicknesses required by the greater floor loads. For smaller MERs containing smaller collections of lighter weight but typical equipment, floor slab thicknesses of 6 to 10 inches (15 to 25 cm) are assumed. For occasional locations of one or a very few pieces of small high-speed equipment (say 1800 rpm or higher) having no reciprocating action, floor slabs of 4 to 6 inches (10 to 15 cm) may be used with reasonable expectation of satisfactory results. However, for reciprocating-action machines operating at the lower speeds (say, under 1200 rpm), any floor slab thicknesses reduced from those listed above begin to invite problems. There is no clear crossover from “acceptable” to “unacceptable” in terms of floor slab thickness, but each reduction in thickness increases the probability of later difficulties due to vibration. The thicknesses mentioned here are based on experience with the “acoustics” of equipment installations. These statements on thicknesses are in no way intended to represent structural specifications for a building. “House-keeping pads” under the equipment are assumed, but the height of these pads is not to be used in calculating the thickness of the floor slab.
- The ratio of the weight of the concrete block to the total weight of all the supported equipment (including the weight of any attached filled piping up to the point of the first pipe hanger) must be in accordance with the recommendations given in the paragraph and table for the equipment requiring this mounting assembly. The inertia block adds stability to the system and reduces motion of the system in the vicinity of the driving frequency. For reciprocating machines or for units involving large starting torques, the inertia block provides much-needed stability.
- The static deflection of the free-standing stable steel springs must be in accordance with the recommendations given in the paragraph and table for the equipment. There must be adequate clearance all around the springs to assure no contact between any spring and any part of the mounted assembly for any possible alignment or position of the installed inertia block.

C-12.2.3 Type II Mounting Assembly.

This mount is the same as the Type I mount in all respects except that the mounting brackets and the top of the steel springs must be located as high as practical on the concrete inertia block but not necessarily as high as the vertical center-of-gravity position of the assembly, and the clearance between the floor and the concrete block must be at least 2 inches (5.1 cm).

- If necessary, the steel springs can be recessed into pockets in the concrete block, but clearances around the springs must be large enough to assure no contact between any spring and any part of the mounted assembly for any possible alignment or position of the installed inertia block. Provision must be made to allow positive visual inspection of the spring clearance in its recessed mounting.
- When this type of mounting is used for a pump, the concrete inertia block can be given a T-shape plan, and the pipes to and from the pump can be supported rigidly with the pump onto the wings of the T. In this way, the pipe elbows will not be placed under undue stress.
- The weight of the inertia block and the static deflection of the mounts must be in accordance with the recommendations given in the table for the equipment.

C-12.2.4 Type III Mounting Assembly.

The equipment or the assembly of equipment must be mounted on a steel frame that is stiff enough to allow the entire assembly to be supported on flexible point supports without fear of distortion of the frame or misalignment of the equipment. Mount the frame on resilient mounts-steel springs or neoprene-in-shear mounts or isolation pads, as the static deflection would require. If the equipment frame itself already has adequate stiffness, no additional framing is required, and the isolation mounts may be applied directly to the base of the equipment.

- The vibration-isolation assembly must have enough clearance under and all around the equipment to prohibit contact with any structural part of the building during operation.
- If the equipment has large starting and stopping torques and the isolation mounts have large static deflections, give consideration to providing limit stops on the mounts. Limit stops might also be desired for large deflection isolators if the filled and unfilled weights of the equipment are very different.

C-12.2.5 Type IV Mounting Assembly.

The equipment must be mounted on an array of “pad mounts”. The pads may be of compressed glass fiber or of multiple layers of ribbed neoprene or waffle-pattern neoprene of sufficient height and of proper stiffness to support the load while meeting the static deflection recommended in the applicable accompanying tables. Cork, cork-neoprene, or felt pad materials may be used if their stiffness characteristics are known and if they can be replaced periodically whenever they have become so compacted that they no longer provide adequate isolation.

- The floor must be grouted or shimmed to assure a level base for the equipment and therefore a predictable uniform loading on the isolation pads.

- The pads must be loaded in accordance with the loading rates recommended by the pad manufacturer for the densities or durometers involved. In general, most of these pads are intended for load rates of 30 to 60 psi (2.1 to 4.2 kg/cm^2), and if they are underloaded (for example, at less than about 10 psi (0.7 kg.cm^2)), they will not be performing at their maximum effectiveness.

C-12.2.6 Type V Mounting Assembly (for Propeller-type Cooling Towers).

Large, low-speed propeller-type cooling towers located on roof decks of large buildings may produce serious vibration in their buildings if adequate vibration isolation is not provided. In extreme cases, the vibration may be evident two or three floors below the cooling towers.

- It is recommended that the motor, drive shaft, gear reducer, and propeller be mounted as rigidly as possible on a “unitized” structural support and that this entire assembly be isolated from the remainder of the tower with stable steel springs in accordance with paragraph C-12.3. Adequate clearance between the propeller tips and the cooling tower shroud must be provided to allow for starting and stopping vibrations of the propeller assembly. Several of the cooling tower manufacturers provide isolated assemblies as described here. This type of mounting arrangement is shown schematically in Figure C-23.
- In addition, where the cooling tower is located on a roof deck directly over an acoustically critical area, the structure-borne waterfall noise may be objectionable; it can be reduced by locating three layers of ribbed or waffle-pattern neoprene between the base of the cooling tower and the supporting structure of the building. This treatment is usually not necessary if there is a noncritical area immediately under the cooling tower.
- A single-treatment alternate to the combined two treatments of (1) and (2) above is the isolation of the entire cooling tower assembly on stable steel springs, also in accordance with paragraph C-12.3. The springs must be in series with at least two layers of ribbed or waffle-pattern neoprene if there is an acoustically critical area immediately below the cooling tower (or within about 25 feet (7.6 m) horizontally on the floor immediately under the tower). It is necessary to provide limit stops on these springs to limit movement of the tower when it is emptied and to provide limited movement under wind load.
- Pad materials, when used, must not be short-circuited by bolts or rigid connections. A schematic of an acceptable clamping arrangement for pad mounts is shown in Figure C-24. Cooling tower piping must be vibration-isolated in accordance with suggestions given for piping.

Figure C-23 Schematic of Vibration Isolation Mounting for Fan and Drive-Assembly of Propeller-Type Cooling Tower

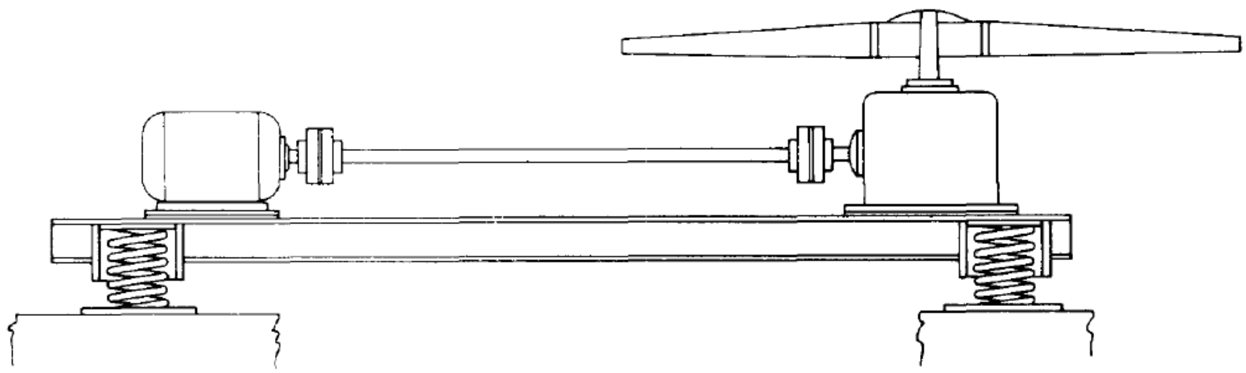


Figure C-24 Schematic of a Resilient Clamping Arrangement With Ribbed Neoprene Pads

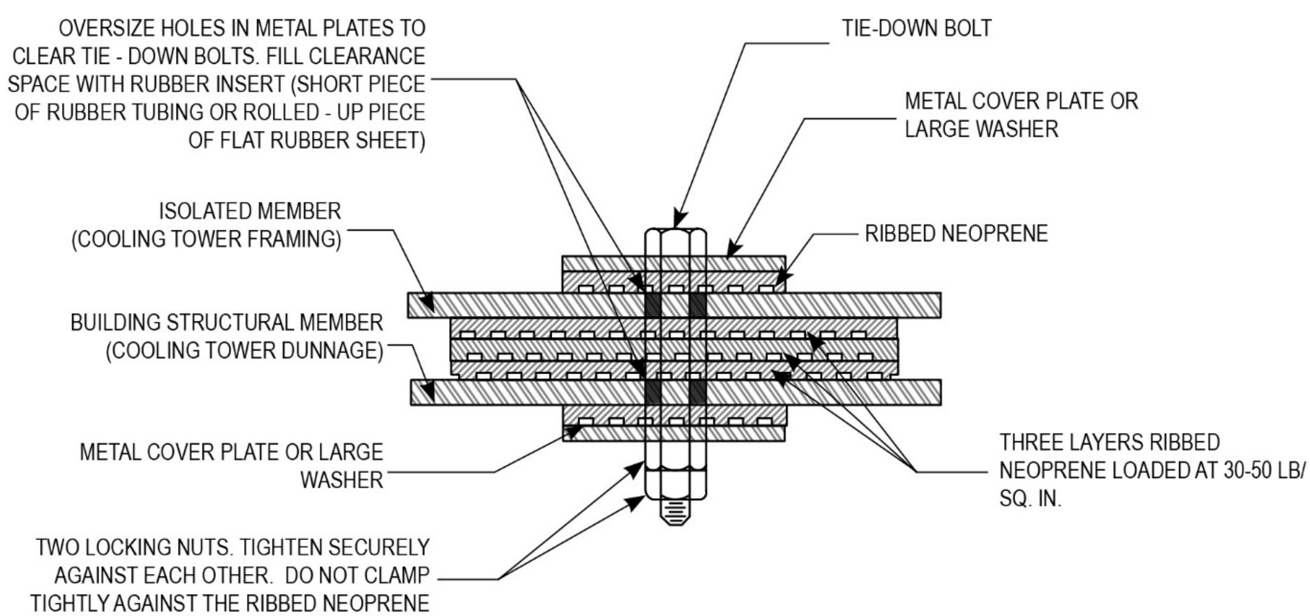

C-12.3 Tables of Recommended Vibration Isolation Details.

C-12.3.1 Table Format.

A common format is used for all the tables that summarize the recommended vibration isolation details for the various types of equipment. A brief description of the format is given here.

C-12.3.1.1 Equipment Conditions.

The three columns on the left of the table define the equipment conditions covered by the recommendations: location, rating, and speed of the equipment. The rating is given by a power range for some equipment, cooling capacity for some, and heating capacity for some. The rating and speed ranges generally cover the range of equipment that might be encountered in a typical building. Subdivisions in rating and speed are made to accommodate variations in the isolation. If vibrating equipment is supported or hung from an overhead floor slab, immediately beneath an acoustically critical area, the same degree of vibration isolation must be provided as is recommended for the location designated as "on upper floor above critical area". Similarly, if the vibrating equipment is hung from an overhead floor slab beneath a noncritical area, the same vibration isolation should be provided as is recommended for the location designated as "on upper floor above noncritical area."

C-12.3.1.2 Mounting Recommendations.

In the following tables, the three columns on the right of the table summarize three basic groups of recommendations: Column 1, the type of mounting; Column 2, the suggested minimum ratio of the weight of the inertia block (when required) to the total weight of all the equipment mounted on the inertia block; and Column 3, the suggested minimum static deflection of the isolator to be used.

- When the weight of the inertia block is being considered, the larger weight of the range given must be applied where the nearby critical area is very critical, or where the speed of the equipment is near the lower limit of the speed range given or the rating of the equipment is near the upper limit of the rating range. Conversely, the lower end of the weight range may be applied where the nearby critical area is less critical, or where the speed is near the upper limit of the speed range, or the rating is near the lower limit of the rating range.
- When the static deflection of the isolators is being considered, these minimum values are keyed to the approximate span of the floor beams; that is, as the floor span increases, the floor deflection increases, and therefore the isolator deflection must increase. The specific minimum deflection in effect specifies the type of isolator that can be used; refer to Table C-39 for the normal range of static deflection for most isolators. Specific selections must be made from manufacturers' catalog data.
- The recommendations given here assume that a moderate amount of large equipment (say, more than five or six pieces, totaling more than about 300 to 600 hp) is located on the MER floor. For a smaller array of equipment or for a single piece of equipment remote from other equipment, the recommendations can be relaxed, either by decreasing the static deflection of the mount or by decreasing the weight of the inertia block or even by eliminating the inertia block where a critical area is not involved.
- Resilient support of all piping connected to vibrating equipment must be in accordance with paragraph C-12.4.1. This recommendation applies to the mounting of each piece of vibrating equipment, even though it is not repeated below for each piece of equipment.

C-12.3.2 Centrifugal and Axial-flow Fans.

The recommended vibration isolation mounting for fans are given in Table C-40. Ducts must contain flexible connections at both the inlet and discharge of the fans, and all connections to the fan assembly must be clearly flexible. The entire assembly can bounce with little restraint when one jumps up and down on the unit. Where supply fan assemblies are located over critical areas, it is desirable to install the entire inlet casing and all auxiliary equipment (coil decks and filter sections) on floated concrete slabs. The floated slab may also serve to reduce airborne noise from the fan inlet area into the floor area below. Large ducts (cross-section area over 15 sq feet) that are located within about 30 feet of the inlet or discharge of a large fan (over 20 hp) must be supported from the floor or ceiling with resilient mounts having a static deflection of at least 1/4 inch (0.64 cm).

Table C-40 Vibration Isolation Mounting for Centrifugal and Axial-flow Fans

Equipment Conditions			Mounting recommendations				
Equipment Location	Power Range (HP)	Speed Range (rpm)	Column 1	Column 2	Column 3		
					30 ft.	40 ft.	50 ft.
On Grade Slab	Under 3	Under 600 600-1200 Over 1200		No Isolation Required			
	3-25	Under 600 600-1200 Over 1200	III	–	1 in. ½ ½		
	26-200	Under 600 600-1200 Over 1200	III	–	1 ½ in. 1 ½		
On Upper Floor Above Non-Critical Area	Under 3	Under 600 600-1200 Over 1200	III III III	– – –	1 in. ½ ½	1 ½ in. ¾ ½	2 in. 1 ¾
	3-25	Under 600 600-1200 Over 1200	II III III	2 in. – –	1 in. 1 ½ 1	1 ½ in. 2 1 ½	2 in. 3 2
	26-200	Under 600 600-1200 Over 1200	II II II	2 in. 2 2	2 in. 1 ½ 1	3 in. 2 1 ½	4 in. 3 2
On Upper Floor Above Critical Area	Under 3	Under 600 600-1200 Over 1200	II III III	2 in. – –	1 ½ in. 1 ½ 1	2 in. 2 1 ½	3 in. 3 2
	3-25	Under 600 600-1200 Over 1200	II II II	3 in. 2 2	2 in. 1 ½ 1	3 in. 2 1 ½	4 in. 3 2
	26-200	Under 600 600-1200 Over 1200	II II II	3 in. 2 2	3 in. 2 1	4 in. 2 ½ 1 ½	5 in. 3 2

C-12.3.3 Reciprocating Compressor Refrigeration Equipment.

The recommended vibration isolation for this equipment is given in Table C-41. These recommendations apply also to the drive unit used with the reciprocating compressor. Pipe connections from this assembly to other equipment must contain flexible connections.

Table C-41 Vibration Isolation Mounting for Reciprocating Compressor Refrigeration Equipment Assembly

Col. 2: Minimum ratio of weight of inertia block to total weight of supported load.
Col. 3: Minimum static deflection or isolators in inches for indicated floor span in feet.

C-12.3.7 Boilers.

The recommended vibration isolation for boilers is given in Table C-45. These apply for boilers with integrally attached blowers. Follow Table C-40 for the support of blowers that are not directly mounted on the boiler. A flexible connection or a thermal expansion joint must be installed in the exhaust breaching between the boiler and the exhaust stack.

Table C-45 Vibration Isolation Mounting for Boilers

Mounting recommendations						
Equipment Location	Heating Capacity (bhp)	Column 1	Column 2	Column 3		
				30 ft.	40 ft.	50 ft.
On Grade Slab	Under 200 200 - 1000 Over 1000	–		Not required		
On Upper Floor Above Non-Critical Area	Under 200	III		1/8 in.	½ in.	½ in.
	200-1000	III		½	½	1
	Over 1000	III		½	½	1
On Upper Floor Above Critical Area	Under 200	III		½	1	1 ½
	200-1000	III		1	1 ½	2
	Over 1000	III		1	1 ½	2

C-12.3.8 Steam Valves.

Steam valves are usually supported entirely on their pipes; paragraph C-12.4.1 must be applied to the resilient support of steam piping, including steam valves.

C-12.3.9 Cooling Towers.

The recommended vibration isolation for propeller-type cooling towers is given in Table C-46. Additional for the installation are given in paragraph C-12.2.6, which describes the Type V mounting assembly. The recommended vibration isolation for centrifugal-fan cooling towers is given in Table C-47.

Table C-46 Vibration Isolation Mounting for Propeller-Type Cooling Towers

Equipment Conditions			Mounting recommendations			
Equipment Location	Power Range (hp)	Speed Range (rpm)	Column 1	Column 2	Column 3	
On Grade Slab	Vibration isolation usually not required					
On Upper Floor Above Non-Critical Area	Under 25	150-300 301-600 Over 600	V	Install On	5 in. 3 3	SPRINGS MAY BE LOCATED
	25-150	150-300 301-600 Over 600	V	Dunnage Attached To	6 in. 4 3	UNDER DRIVE ASSEMBLY
	Over 150	150-300 301-600 Over 600	V	Building Columns Only	6 in. 5 4	OR UNDER TOWER BASE
On Upper Floor Above Critical Area	Same as for location above noncritical area, except install ribbed or waffle pattern neoprene between tower and building.					
Apply conversion to material dimensions and distances when metric calculations are performed. Col. l: Mounting type (see text). Col. 2: Minimum ratio of weight of inertia block to total weight or supported load (not applicable here). Col. 3: Minimum static deflection of stable steel springs in inches.						

Table C-47 Vibration Isolation Mounting for Centrifugal-Type Cooling Towers

Equipment Conditions			Mounting recommendations				
Equipment Location	Power Range (HP)	Speed Range (rpm)	Column 1	Column 2	Column 3		
					30 ft.	40 ft.	50 ft.
On Grade Slab	Vibration isolation usually not required						
On Upper Floor Above Non-Critical Area	Under 25	450-900 901-1800 Over 1800	III		1 in. ¾ ¾	1 ½ in. 1 1	2 in. 1 ½ 1 ½
	25-150	450-900 901-1800 Over 1800	III		1 ½ in. 1 ¾	2 in. 1 ½ 1	3 in. 2 1 ½
	Over 150	450-900 901-1800 Over 1800	III		2 in. 1 ½ 1	3 in. 2 1 ½	4 in. 3 2
On Upper Floor Above Critical Area	Under 25	450-900 901-1800 Over 1800	III	Include ribbed or waffle-pattern neoprene between tower and building.	1 ½ in. 1 ¾	2 in. 1 ½ 1	3 2 1 ½
	25-150	450-900 901-1800 Over 1800	III		2 in. 1 ½ 1	3 in. 2 1 ½	4 in. 3 2
	Over 150	450-900 901-1800 Over 1800	III		3 in. 1 ½ 1	4 in. 2 1 ½	6 in. 3 2

Apply conversion to material dimensions and distances when metric calculations are performed.

Col. 2: Minimum ratio or weight or inertia block to total weight of supported load.
Col. 3: Minimum static deflection of stable steel springs in inches for indicated floor span in feet.

C-12.3.10 Motor- Pump Assemblies.

Recommended vibration isolation for motor-pump units is given in Table C-48. Make electrical connections to the motors with long “floppy” lengths of flexible armored cable, and piping must be resiliently supported. For most situations, a good isolation mounting of the piping will overcome the need for flexible connections in the pipe. An important function of the concrete inertia block (Type II mounting) is its stabilizing effect against undue bouncing of the pump assembly at the instant of starting. This gives better long-time protection to the associated piping. These same recommendations may be applied to other motor-driven rotary devices such as centrifugal-type air compressors and motor-generator sets in the power range up to a few hundred horsepower.

Table C-48 Vibration Isolation Mounting for Motor-Pump Assemblies

Equipment Conditions			Mounting Recommendations				
Equipment Location	Power Range (hp)	Speed Range (rpm)	Column 1	Column 2	Column 3		
					30 ft.	40 ft.	50 ft.

C-12.3.11 Steam Turbines.

Table C-49 provides a set of general isolation recommendations for steam-turbine-driven rotary equipment, such as gears, generators, or centrifugal-type gas compressors. The material given in Table C-43 applies when a steam turbine is used to drive centrifugal-compressor refrigeration equipment. The recommendations given in Table C-41 apply when a steam turbine is used to drive reciprocating-compressor refrigeration equipment or reciprocating-type gas compressors.

Table C-49 Vibration Isolation Mounting for Steam-Turbine Driven Rotary Equipment

Equipment Conditions			Mounting recommendations				
Equipment Location	Power Range (hp)	Speed Range (rpm)	Column 1	Column 2	Column 3		
					30 ft.	40 ft.	50 ft.
On Grade Slab	500-1500	Over 3000	III		½ in.		
	1501-5000	Over 3000	III		¾		
	5001-150000	Over 3000	III		1

Col. 1: Mounting type (see text). Col. 2: Minimum ratio of weight of inertia block to total weight of supported load. Col. 3: Minimum static deflection of stable steel springs in inches for indicated floor span in feet.							

C-12.3.12 Gears.

When a gear is involved in a drive system, vibration isolation must be provided in accordance with recommendations given for either the main power drive unit or the driven unit, whichever imposes the more stringent isolation conditions.

C-12.3.13 Transformers.

Recommended vibration isolation for indoor transformers is given in Table C-50. In addition, power leads to and from the transformers must be as flexible as possible. In outdoor locations, earth-borne vibration to nearby neighbors is usually not a problem, so no vibration isolation is suggested. When vibration becomes a problem, the transformer could be installed on neoprene or compressed glass fiber pads having 1/4-inch (.64cm) static deflection.

Table C-50 Vibration Isolation Mounting for Transformers

Equipment Conditions			Mounting recommendations				
Equipment Location	Power Range (kva)	Speed Range (rpm)	Column 1	Column 2	Column 3		
					30 ft.	40 ft.	50 ft.
On Grade Slab	Under 10		IV		1/8 in.		
	10-100		IV		1/8 in.

Col. 3: Minimum static deflection of isolators in inches for indicated floor span in feet.

C-12.3.14 Air Compressors.

Recommended mounting for centrifugal type air compressors of less than 10 hp are the same as those given for motor-pump units in Table C-48. The same recommendations would apply for small (under 10 hp) reciprocating type air compressors. For reciprocating type air compressors (with more than two cylinders) in the 10 to 50 hp range, the recommendations given in Table C-41 apply for the conditions. For 10 to 100 hp, one-or two-cylinder, reciprocating type air compressors, the recommendations of Table C-51 apply. This equipment is a potential serious source of low frequency vibration in a building when it is not isolated. In fact, the compressor must not be in certain parts of the building, even if it is vibration isolated. The locations to avoid are indicated in Table C-51. When these compressors are used, all piping should contain flexible connections (paragraph C-14.4.2), and the electrical connections must be made with flexible armored cable.

Table C-51 Vibration Isolation Mounting for One or Two-Cylinder Reciprocating-Type Air Compressors in the 10-to l00-hp Size Range

Equipment Conditions			Mounting Recommendations

a. 'NO" indicates "NOT RECOMMENDED" for this combination of conditions.

C-12.3.15 Natural-gas and Liquid-fuel Engines, Reciprocating and Turbine.

Vibration isolation of these engines is discussed in detail in the **Inactive** UFC 3-450-02 Power Plant Acoustics.

C-12.4 Vibration isolation - Miscellaneous.

C-12.4.1 Resilient Pipe Supports.

All piping in the MER that is connected to vibrating equipment must be supported from resilient ceiling hangers or from floor-mounted resilient supports.

- As a rule, the first three pipe supports nearest the vibrating equipment must have a static deflection of at least one-half the static deflection of the mounting system used with that equipment. Beyond the third pipe support, the static deflection can be reduced to 1/4 inch (0.64 cm) or 1/2 inch (1.3 cm) for the remainder of the pipe run in the MER.
- When a pipe passes through the MER wall, a minimum 1-inch (2.54 cm) clearance must be provided between the pipe and the hole in the wall. The pipe must be supported on either side of the hole, so that the pipe does not rest on the wall. The clearance space must then be stuffed with fibrous filler material and sealed with a nonhardening caulking compound at both wall surfaces.
- Vertical pipe chases through a building must not be located beside acoustically critical areas. When they are located beside critical areas, pipes must be resiliently mounted from the walls of the pipe chase for a distance of at least 10 feet (3.05 meters) beyond each such area, using both low-frequency and high-frequency isolation materials.
- Pipes to and from the cooling tower must be resiliently supported for their full length between the cooling tower and the associated MER. Steam pipes must be resiliently supported for their entire length of run inside the building. Resilient mounts must have a static deflection of at least 1/2 inch (1.3 cm).
- In highly critical areas, domestic water pipes and waste lines can be isolated with the use of 1/4-inch (0.64 cm) to 1/2-inch (1.3 cm) thick wrappings of felt pads under the pipe strap or pipe clamp.
- Whenever a steel spring isolator is used, it must be in series with a neoprene isolator. For ceiling hangers, a neoprene washer or grommet must always be included; and if the pipe hangers are near very critical areas, the hanger must be a combination hanger that contains both a steel spring and a neoprene-in-shear mount.
- During inspection, the hanger rods must be checked to ensure they are not touching the sides of the isolator housing and thereby shorting-out the spring.

C-12.4.2 Flexible pipe connections.

To be effective, a flexible pipe connection must have a length that is approximately 6 to 10 times its diameter. Tie rods must not be used to bolt the two end flanges of a flexible connection together. Flexible connections are either of the bellows type or are made up of wire-reinforced neoprene piping, sometimes fitted with an exterior braided jacket to confine the neoprene. These connections are useful when the equipment is subject to high-amplitude vibration, such as for reciprocating-type compressors. Flexible connections generally are not necessary when the piping and its equipment are given thorough and compatible vibration isolation. For serious pipe vibration problems, two flexible connections can be used, mounted 90 degrees to each other. Inertial masses may be attached to the piping to add stability and help maintain pipe alignment.

C-12.4.3 Non-vibrating Equipment.

When an MER is located directly over or near a critical area, it is usually desirable to isolate most of the nonvibrating equipment with a simple mount made up of one or two pads of neoprene or a 1-inch (2.54 cm) or 2 inch (5.1cm) layer of compressed glass fiber. Heat exchangers, hot water heaters, water storage tanks, large ducts, and some large pipe stands may not themselves be noise sources, yet their pipes or their connections to vibrating sources transmit small amounts of vibrational energy that they then may transmit into the floor. A simple minimum isolation pad will usually prevent this noise transfer.

C-12.4.4 Summary.

In this section, complete vibration isolation mounting is laid out for most of the equipment included in an MER. Most of these have been developed and proven over many years of use. Although all the entries of the accompanying tables have not been tested in actual equipment installations, the schedules are self-consistent in terms of various locations and degrees of required isolation. Hence, the mounting is considered realistic and reliable. They are not extravagant when considered in the light of the extremely low vibration levels required to achieve near inaudibility. The noise and vibration control methods given here are designed to be simple to follow and to put into use. If these methods and recommendations are carried out, with appropriate attention to detail, most equipment installations will be tailored to the specific needs of the building and will give very satisfactory results acoustically.

C-13 SOUND LEVELS FOR EQUIPMENT.

Due to the variety of equipment installed in buildings and the multiplicity of uses for each equipment item, there are several standards for measurement of sound from mechanical equipment. There are many ANSI standards that describe general procedures for the measurement of sound power levels and sound levels of equipment, both in the laboratory and in field. AHRI has produced several standards for the measurement of air-conditioning equipment. The noise level estimates given in this manual will probably equal or exceed the actual noise levels of approximately 80 to 90 percent of all those types of machinery that will be encountered in typical building use. In many cases, actual noise levels may fall 3 to 6 dB below the estimates, and for some types of equipment some noise levels may fall as much as 10 to 15 dB below the estimates. Thus, there appears to be no shortage of available equipment that will fall at or below the estimated noise levels given in the manual, and it would not be discriminatory or unreasonable to specify that any purchased equipment for a particular building be required not to exceed the estimated values given here for that equipment. This is especially true if the actual acoustic design of a wall or floor or room treatment is dependent upon one or two particularly noisy pieces of equipment. A noise specification would not be necessary for relatively quiet equipment that does not dictate noise control design for the MER or the building.

C-13.1 Exemptions and Waiver.

If a noise level specification is required to be met for a particular piece of equipment, and this becomes a “hardship” on the manufacturer or the owner in terms of cost or availability, depending on the response of all the bidders, utilize the exemption and waiver process and the noise specification may possibly be exempted or waived. If some bidders agree to meet the specification while others do not, this could be a valid basis for selecting the quieter equipment.

If no bidders can meet the specification, it may be necessary to reevaluate the noise control requirements of the MER. If the equipment is so noisy that it is responsible for the noise design in the first place the specification can be exempted or waived via the exemption and waiver process. It is the primary purpose of this UFC to prevent such situations. Too many waivers would negate the value of the noise evaluation as a part of the design phase of the building. When the equipment measured for this study represents a fair sampling, it is likely that most of the equipment would meet a noise specification.

C-13.2 Sample Specifications.

The sample noise level specifications given below offer a broad set of procedures and suggestions for specifying noise data (SPL or PWL) on any desired piece of equipment. This is not offered as a “standard” for noise measurements, however. Any acceptable and applicable measurement and specification procedure recommended by an appropriate standards group (such as ANSI, ISO, ASTM, IEEE, ASHRAE, or others) may be used as a basis for setting up an equipment noise specification.

C-13.2.1 Sample SPL Specifications.

Table C-52 is an example form of a SPL specification. The type of equipment and the desired maximum sound pressure levels are inserted in the appropriate blanks. The 3-foot (0.914 m) distance is taken from the nearest surface rather than from the acoustic center since the exact location of the acoustic center is not easily defined. A minimum room volume of 4000 ft^3 (113 m^3) is offered, but this could be modified to accept somewhat smaller rooms. Small rooms are more subject to standing wave fluctuations. Even at the 3-foot (0.914 m) distance, SPL values for the same source may vary as much as 5 to 7 dB from an outdoor to an indoor site (or from a large room to a small room). Since it is impractical to specify Room Constant limits for the measurement room, it then becomes necessary to judge or compare various sound level submittals in terms of their ability to meet the design need. A sound source measured in a large-volume room, in a highly absorbent room, or outdoors will produce lower sound levels than when measured in a small or reverberant room. This difference is an important aspect of comparing competitive equipment.

Table C-52 Sample Sound Pressure Level Specification

Octave Band (Hz)	Sound Pressure Level (dB re 20 miropascals)
31	____________
63	____________
125	____________
250	____________
500	____________
1000	____________
2000	____________
4000	____________
8000	____________

(Insert desired values in blanks)

C-13.2.2 Sample PWL Specification.

Table C-53 is an example form of a PWL specification.

1. The maximum sound pressure levels measured at a distance of 3 ft. from the (equipment in question) must not exceed the following decibel values in the nine octave frequency bands:

Table C-53 Sample Sound Power Level Specification

Octave Band (Hz)	Sound Power Level (dB re 10^{-12} watt)
31	______
63	______
125	______
250	______
500	______
1000	______
2000	______
4000	______
8000	______

(Insert desired values in blanks)

2. At least four sets of sound pressure level readings must be submitted with the bid, where each set is taken at a 3-ft (0.914 m). distance from each of the four principal orthogonal surfaces of the equipment. Each octave band reading of each set of readings must be no greater than the specified value of Item 1 above.
3. The test room in which the noise measurements are conducted must have a volume of not less than 4000 ft^3 (113 m^3)and all principal surface areas of the room must be described in sufficient acoustic detail to permit an estimation of the approximate Room Constant or Room Absorption for the space.
4. During the tests, the equipment must be in normal operation at not less than 50% full rated load (or at a specified mutually acceptable load' condition). The tests must be carried out by the equipment manufacturer or by an approved testing agency, having proven capability in noise measurements and using approved measurement equipment and acceptable measurement procedures. Approved "standards" of measurements must apply.
5. In lieu of the tests under Item 4 above, final testing for conformance with the Item 1 noise levels may be made following complete installation of the equipment in the customer's building, provided the equipment manufacturer will remove and replace the equipment at his own expense if it fails to meet the noise tests. To be acceptable, the replacement equipment must meet the noise tests. For the on-site tests, the equipment must be in normal operation at not less than 50% hill rated load (or at a specified mutually acceptable load condition), and the tests must be in accordance with the procedures given in Item 4 above.
6. For all noise tests, the ambient sound levels of the test area must be at least 10 dB below the specified levels of Item 1 above, and the octave

band sound measurement equipment must meet the applicable ANSI standards for that type of equipment.

During the tests, the equipment must be in normal operation at not less than 50% full rated load (or at a specified mutually acceptable load condition). The tests must be carried out by the equipment manufacturer or by an approved testing agency, having proven capability in noise measurements and using approved measurement equipment and acceptable measurement procedures. Approved "standards" of measurements must apply. In lieu of the tests under Item 2 above, final testing for conformance with the Item 1 noise levels may be made following complete installation of the equipment in the customer's building, provided the equipment manufacturer will remove and replace the equipment at his own expense if it fails to meet the noise tests. To be acceptable, the replacement equipment must meet the noise tests. For the on-site tests, the equipment must be in normal operation at not less than 50% full rated load (or at a specified mutually acceptable load condition), and the tests must be in accordance with the procedures given in Item 2 above. For all noise tests, the ambient sound levels of the test area must be at least 10 dB below the equipment sound levels, and the octave band sound measurement equipment must meet the applicable ANSI standards for that type of equipment. Sound pressure level readings (in decibels re 20 microPascals) and all other data (including test room size and acoustic characteristics) used in the determination of the sound power levels must be submitted with the bid.

C-14 SAMPLE RC MARK II RATING.

C-14.1 RC Mark II Rating Method.

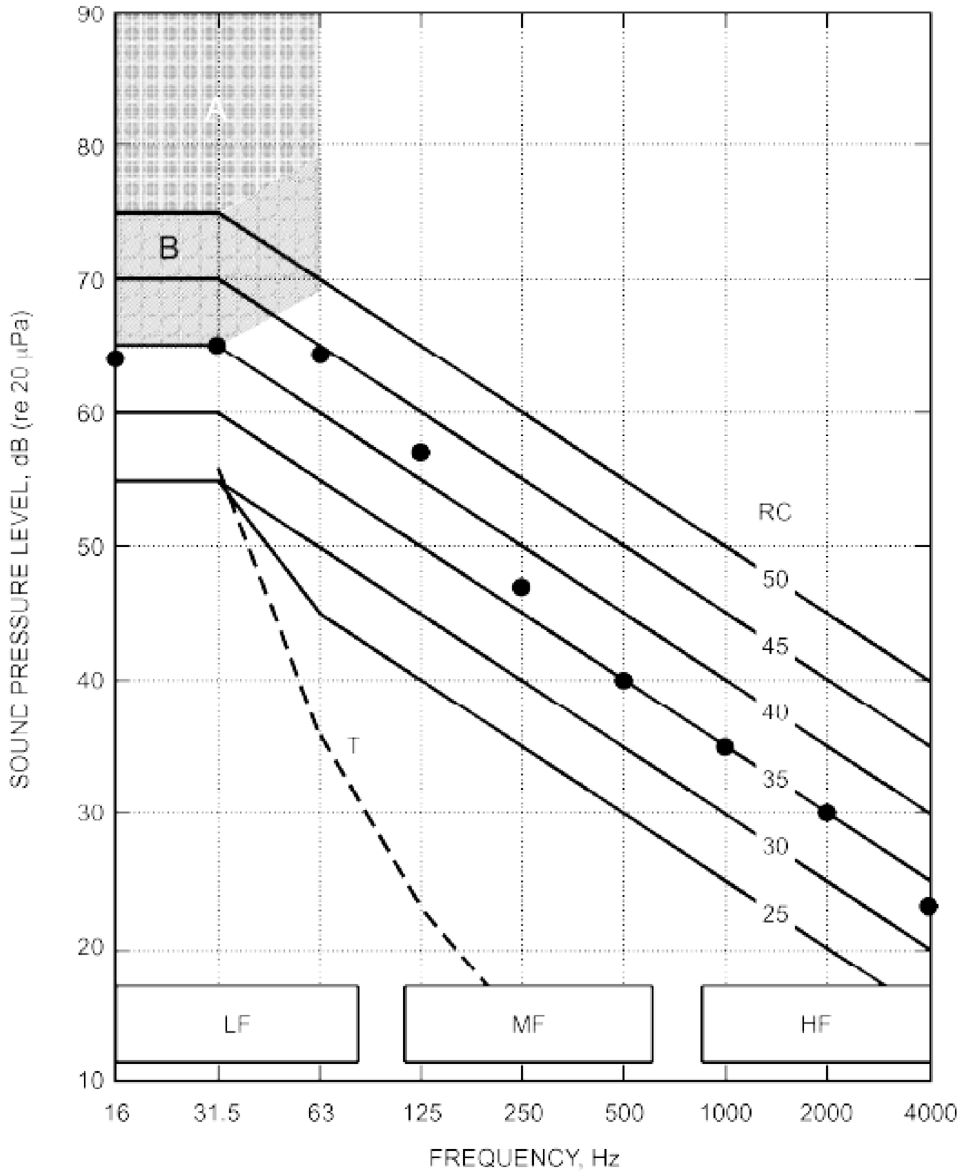
The following shows a sample plot and calculation for RC Mark II rating of known HVAC system noise levels. For additional information on procedures and applications of the RC Mark II method, see 2019 ASHRAE Handbook, Chapter 49 “Noise and Vibration Control. “Quality assessment index (QAI).

The quality assessment index (QAI) is a measurement of the deviation of the noise spectrum under evaluation from the shape of the RC reference curve. The QAI estimates the probable reaction of an occupant when system design does not produce optimum sound quality. The basis for estimating occupant satisfaction is that changes in sound level of less than 5 dB do not cause subjects to change their ranking of sounds of similar spectral content. However, level changes greater than 5 dB do significantly affect subjective judgments. Additional information on QAI is described in the 2019 ASHRAE Handbook, Chapter 49 “Noise and Vibration Control.”

C-14.2 Sample RC Mark II Rating.

Figure C-25 is an example of an RC Mark II rating plotted against RC curves. Table C-54 is a sample calculation of the RC Mark II Rating method using the data from Figure C-25.

Figure C-25 Example Plot of RC Mark II Rating



Note:

- Noise levels for lightweight wall and ceiling constructions:
  - In shaded region B are likely to generate vibration that may be perceptible. There is a slight possibility of rattles in light fixtures, doors, windows, etc.
  - In shaded region A have a high probability of generating easily perceptible noise-induced vibration. Audible rattling in light fixtures, doors, windows, etc. may be anticipated.
- Regions LF, MF, and HF are explained in the text.
- Solid dots are sound pressure levels for the example discussed in the text.

Table C-54 Example Calculation of RC Mark II Rating

	Frequency, Hz								
	16	**31**	**63**	**125**	**250**	**500**	**1000**	**2000**	**4000**
Spectrum Levels	64	65	64	57	47	40	35	30	23
Average of 500 to 2000 Hz levels							35		
RC contour	60	60	55	50	45	40	35	30	25
Levels: RC contour	4	5	9	7	2	0	0	0	-2
		LF			MF			HF	
Special deviations		6.6			4.0			-0.6	
QAI					7.2				
RC Mark II rating					**RC 35 (LF)**				

1000, and 2000 Hz octave bands is 35 dB, so the RC 35 curve is selected as the reference for spectrum quality evaluation.

The spectral deviation factors in the LF, MF, and HF regions are 6.6, 4.0, and -0.6 respectively, giving a QAI of 7.2 The maximum positive deviation factor occurs in the LF region and QAI exceeds 5; therefore, the rating of the spectrum is RC 35 (LF). An average room occupant likely will perceive this spectrum as rumbly in character.

APPENDIX D GLOSSARY

D-1 ACRONYMS.

ANSI	American National Standards Institute
ASHRAE	American Society of Heating, Refrigerating and Air-conditioning Engineers
DRPR	Drip Proof
FGI	Facilities Guidelines Institute

MER	Mechanical Equipment Room
NC	Noise Criterion
NIC	Noise Isolation Class
OSHA	Occupational Safety and Health Administration
PWL	Sound Power Level
RC	Room Constant
SD	Static Deflection
SPL	Sound Pressure Level
STC	Sound Transmission Class
STCc	Composite Sound Transmission Class
TEFC	Totally Enclose Fan-cooled
TL	Transmission Loss
TLc	Composite Transmission Class
UFC	Unified Facilities Criteria
U.S.	United States

D-2 DEFINITION OF TERMS.

Absorption: Conversion of acoustic energy to heat energy or another form of energy within the medium of sound-absorbing materials.

Absorption Coefficient: The ratio of sound energy absorbed by the acoustical material to that absorbed by a perfect absorptive material. It is expressed as a decimal fraction.

Average Sound Level and Average SPL: The arithmetic average of several related sound levels (or SPL in a specified frequency band) measured at different positions or different times, or both.

A-Weighting (dBA): A frequency response characteristic incorporated in sound-level meters and similar instrumentation. The A-weighted scale response de-emphasizes the lower frequencies and is therefore like the human hearing.

Background Noise: The total noise produced by all other sources associated with a given environment in the vicinity of a specific sound source of interest and includes any Residual Noise.

Decibel (dB): A unit for expressing the relative power level difference between acoustical or electrical signals. It is ten times the common logarithm of the ratio of two related quantities that are proportional to power.

Field Sound Transmission Class (FSTC): A single-number rating derived from measured values of field sound transmission loss in accordance with ASTM E-413, “Rating Sound Insulation”, and ASTM E-336, “Measurement of Airborne Sound Insulation in Buildings”. It provides an estimate of the performance of actual partitions in place and considers acoustical room effects.

Field Sound Transmission (FSTL): The sound loss through a partition installed in a building, in a Loss specified frequency band. It is the ratio of the airborne sound power incident on the partition to the sound power transmitted by the partition and radiated on the other side, expressed in decibels.

Frequency (Hz): The number of cycles occurring per second. (Hertz is a unit of frequency, defined as one cycle per second).

Noise: Any unwanted sound that can produce undesirable effects or reactions in humans.

Noise Criteria (NC): Octave band curves used to define acceptable levels of mechanical equipment noise in occupied spaces. Superseded by the Room Criteria (RC).

Noise Isolation Class (NIC): A single-number rating derived from measured values of noise reduction, as though they were values of transmission loss, in accordance with E-413. It provides an estimate of the sound isolation between two enclosed spaces that are acoustically connected by one or more paths.

Octave Band: A range of frequencies whose upper band limit frequency is nominally twice the lower band limit frequency.

Octave-Band Sound Level: The integrated sound pressure level of only those sin-wave Pressure components in a specified octave band, for a noise or sound having a wide spectrum.

Residual Noise: The measured sound level which represents the summation of the sound from all the discrete sources affecting a given site at a given time, exclusive of the Background Noise or the sound from a Specific Sound Source of interest. In acoustics, residual noise often is defined as the sound level exceeding 90% of a noise monitoring period.

Room Criteria (RC): Octave band criteria used to evaluate acceptable levels of mechanical equipment noise in occupied spaces.

Sound Power level (Lw or PWL): Ten times the common logarithm of the ratio of the total acoustic power radiated by a sound source to a reference power. A reference power of a picowatt or 10^{-12} watt is conventionally used.

Sound Pressure Level (Lp or SPL): Ten times the common logarithm to the base 10 of the ratio of the mean square sound pressure to the square of a reference pressure. Therefore, the sound pressure level is equal to 20 times the common logarithm of the ratio of the sound pressure to a reference pressure (20 microPascals or 0.0002 microbar).

Sound Transmission Class (STC): A single-number rating derived from measured values of transmission loss in accordance with ASTM E-413, “Classification for Rating Sound Insulation” and ASTM E-90, “Test Method for Laboratory Measurement of Airborne Sound Transmission Loss of Building Partitions”. It is designed to give an estimate of the sound insulation properties of a partition or a rank ordering of   a series of partitions.

Sound Transmission Loss (TL): A measure of sound insulation provided by a structural configuration. Expressed in decibels, it is ten times the common logarithm of the sound energy transmitted through a partition, to the total energy incident upon the opposite surface.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	1 May 2020	Chapters 2, 3, 4, 5, 7, 8, 10, 12, Appendix D. Main changes include removing AFFF use and clarified the criteria for Canopies.
2	12 January 2022	Chapters 2, 4, 5, 8, 9, 11, 15, and 16. Main change is adding Chapter 16 Austere Fuel Facilities. Other changes include providing distances between tanks and photovoltaic arrays, allowing non-metallic material for external stairways, and allowing the use of positive displacement pumps for product recovery return. Other changes includes updating reference documents.
3	08 Jun 2023	Chapters 2, 4, 6, 8, 9, 10, 12, Appendix E, Restored paragraphs which were inadvertently deleted during Change 2 publication. Other changes includes updating reference documents.

This UFC supersedes UFC 3-460-01, dated 16 July 2019.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)

REVISION SUMMARY SHEET

Document: UFC 3-460-01, Design: Petroleum Fuel Facilities

Superseding: UFC 3-460-01, dated 16 July 2019, Change 2, dated 12 January 2022

Description: Unified Facilities Criteria (UFC) 3-460-01 contains general criteria and standard procedures for the design and construction of military land-based facilities which receive, store, distribute, or dispense liquid petroleum fuels. It is also applicable to liquefied petroleum gases (LPG) and compressed natural gas (CNG) facilities. These criteria are applicable to all branches of the Department of Defense (DoD) and the Defense Logistics Agency (DLA).

Reasons for Document: This update to UFC 3-460-01 incorporates changes to the design requirements for fuel facilities. These changes are based on lessons learned from the previous guidelines, new technologies, updated requirements by the services for fuel handling and quality, new regulations, coordinate with unified facilities guide specifications (UFGS), and other reference documents. Incorporation of these changes will decrease the life-cycle costs by ensuring the integrity of the fueling systems during operations and decreasing maintenance requirements.

Impact: The changes to this UFC will impact the design and cost of fuel facilities. However, the following benefits should be realized.

- Ensure that the fuel quality issued to the DoD aircraft, trucks, ships, and vehicles is such that no damage is realized to DoD assets.
- By ensuring that all fuel facilities will be standardized throughout the tri-services.
- Decrease the amount of maintenance and repair required on the fuel facility system.
- Exceptions for austere locations can be approved by Service Headquarters SME to avoid non-beneficial costs.

Unification Issues:

There are a few items that are either Navy, Air Force or Army specific. The list below summarizes these items, along with the justification for it to be Service Specific:

- The Navy requires the use of a fusible link butterfly valve at the inlet to truck fillstand and on supply and return risers at aircraft direct fueling stations. The Navy's position for fusible link valves is primarily because JP-5, which is primarily used by the Navy, does not have the static dissipater additive (SDA), so it is more likely to spark during transport thru pipelines and equipment than any other fuel. (Refer to paragraph 2-

3.14.3). The fusible link will shut if there is a fire or other high-temperature event. Also, the Navy's aircraft direct fueling stations are designed to hot refuel aircraft, so the fusible link will also protect the aircraft if there is a high-temperature event between the tank and the fusible link.

- The Air Force allows the use of internally coated filter-separators and piping from the filter-separators to the skin of the aircraft. Since it is Air Force policy to always filter the fuel at the skin of the aircraft, any paint and carbon particles in the fuel will be filtered before entering the aircraft. The Navy does not filter at the skin of the aircraft, therefore the filter-separator must be either aluminum or stainless steel, and the piping from the filter-separator to the aircraft is to be stainless steel. In addition, for Navy systems, the return line is also to be stainless steel if there is any possibility for recirculating the fuel without going thru two filtrations.
- This UFC references Service-Specific documents, which the tri-service fuel community does not oversee. Also, each service has its own requirements for fuel quality and operations.

TABLE OF CONTENTS

TABLES

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facilities Criteria, UFC 3-460-01, contains general criteria and standard procedures for the design and construction of military land-based facilities which receive, store, distribute, or dispense liquid fuels. It is also applicable to the handling of liquefied petroleum gases (LPG) and compressed natural gas (CNG). It provides guidance on the rehabilitation, deactivation, or closure of fueling facilities. Support facilities are also included. Facility Plate 001 provides assistance in identifying UFC chapter numbers for specific fueling components.

These criteria, except Chapters 12, 13, and 14 of this UFC, are intended for new construction only and do not apply retroactively to facilities existing at the time this UFC was issued. However, these criteria, including Chapters 12, 13, and 14, are applicable when modernizing or expanding existing facilities if the improvements can be justified in terms of obsolescence, expanded operational requirements, safety, environmental compliance, or excessive maintenance costs.

1-2 APPLICABILITY.

The guidance contained in this UFC is intended for use by facility planners, engineers, and architects for individual project planning and for preparing engineering and construction documentation for all real property facilities used for storing, distributing, and dispensing fuels for reciprocating and jet engine aircraft, automotive fuels, lubricating oils, and alternate fuels. In addition, it is intended for use by operations and maintenance personnel as a guidance document for facility design, modifications, and improvements.

1-3 DEPARTMENT OF DEFENSE (DOD) FUELS DISCIPLINE WORKING GROUP (FDWG).

This UFC was updated by the DoD Fuels Discipline Working Group (FDWG). The DoD FDWG consists of recognized POL experts, primarily from the engineering community, to establish the criteria for the DoD community on ways to provide safe, operationally effective, and economic DoD fuel facilities systems to meet the mission requirements. The FDWG will examine, develop, recommend, and provide design features for the standardization of facilities, system components, and equipment, and procedures used in fuel handling systems for storage, distribution, maintenance and dispensing of aircraft, marine, and ground fuels. The FDWG will evaluate facility component parts on DoD installations and will serve as a pool of expertise to assist in resolving systemic fuel handling facility problems. FDWG meetings will also serve as a forum to update members on new system components, and equipment, DoD or service-specific programs, and changes affecting the fuels maintenance, repair and construction community. Refer to Appendix B, Charter for DoD Fuels Discipline Working Group for more information.

1-4 SERVICE HEADQUARTERS SUBJECT MATTER EXPERTS (SME).

It is recognized that the policies, obligations, and responsibilities of the military branches may vary on some minor points. Therefore, consult the Subject Matter Expert at the appropriate Service Headquarters for interpretation. For the purposes of interpretation of this UFC, the Subject Matter Expert at the appropriate Service Headquarters is defined as follows:

a. Army – Headquarters, U.S. Army Corps of Engineers, POL Facilities Proponent (CECW-EC)

b. Air Force – The Air Force Fuels Facilities Subject Matter Expert (AFCEC/COSM) or officially designated alternate

c. Navy/Marine Corps – NAVFAC POL Facility Subject Matter Expert (NAVFAC EXWC, SH25)

1-4.1 Service Provider Subject Matter Expert (SME).

DLA Installation Support for Energy (DLA DS-FEI) is the Executive Agent as defined in DOD 4140.25M.

1-4.2 Service Control Point (SCP).

For the purposes of interpretation of this UFC, the Service Control Point is defined as follows:

a. Army – Army Petroleum Center

b. Air Force – Air Force Petroleum Office

c. Navy/Marine Corps – Naval Supply Systems Command - Energy

1-5 WAIVERS AND EXEMPTIONS.

For specific interpretations, waivers or exemption, contact the appropriate Service Headquarters Subject Matter Experts (SME) and refer to MIL-STD-3007 for the waiver process.

Recommended UFC language generated from recurring waivers and exemptions will be considered by the DoD Fuel Facilities Engineering Panel with supporting rationale for inclusion on FDWG voting agendas. Recommended changes to this UFC are then reviewed/approved by the voting members of the DoD Fuels Facilities Discipline Working Group, preferably in a normal recurring meeting.

1-6 POLICY.

Design petroleum fuel facilities to meet the operational and management requirements of the Command in which the facility is located, as well as to meet all applicable federal, state, and local regulations concerning environmental, health, safety, and fire protection issues.

1-7 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, DoD Building Code (General Building Requirements). UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFC and government criteria referenced therein.

1-8 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-9 REFERENCED STANDARDS.

The execution agency issuing a contract for design and/or construction services will direct the use of standard designs, guide specifications, and/or definitive drawings. In other situations, where these standards are not readily available, contact appropriate Service Headquarters for assistance in obtaining these documents.

1-10 GLOSSARY.

Appendix D contains acronyms, abbreviations, and definition of terms.

1-11 REFERENCES.

Appendix E contains a list of other criteria and references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

1-12 PROJECTS OUTSIDE OF THE UNITED STATES AND ITS TERRITORIES.

1-12.1 NATO Standards.

For fueling projects located outside of the United States and its territories, and in a NATO (North Atlantic Treaty Organization) country, review and comply with all appropriate host-nation regulations, NATO documents such as STANAG 3784, and this UFC.

1-12.2 Non-NATO Projects.

For fueling projects located outside of the United States and its territories, and not in a NATO country, use host-nation standards (if more stringent), this UFC, and applicable Service policy.

1-13 DOCUMENT HIERARCHY.

For the design of all DoD fueling projects, modify the UFGS and standard design drawings to meet the specific needs of the project. The document hierarchy in order of decreasing precedence is as follows:

a. Unified Facility Criteria (UFC)

b. Unified Facilities Guide Specification (UFGS)

c. DoD Standards

The UFCs, UFGSs, and DoD Standards must be site-adapted for each specific fueling facility.

CHAPTER 2 GENERAL DESIGN REQUIRMENTS

2-1 OPERATIONAL CAPABILITIES.

Design fuel facilities for continued operation using emergency or temporary expedients despite the loss of one or more components of the fuel receiving and/or dispensing system by enemy action or other factors. For tactical or mission-related fuel facilities, provide an alternative source of fuel supply to the fuel facility to ensure emergency operation under the most adverse conditions, including back up power (emergency generators). Maintain consistency with prescribed criteria in appropriate directives, instructions, and standard designs (including NATO Standards).

2-2 FUEL SPECIFICATIONS.

The following specifications apply to the various petroleum fuels that may be addressed:

a. MIL-DTL-5624, Turbine Fuel, Aviation, Grades JP-4 and JP-5.

b. MIL-DTL-38219, Turbine Fuel, Low Volatility, JP-7.

c. MIL-DTL-83133, Turbine Fuel, Aviation, Kerosene Type, JP-8 (NATO F-34 and NATO F-35).

d. AFLP-3747 Guide Specifications (Minimum Quality Standards) for Aviation Turbine Fuels (F-24, F-27, F-34, F-35, F-37, F-40 and F-44).

e. MIL-DTL-25524, Turbine Fuel, Aviation, Thermally Stable (JPTS).

f. ASTM D1655, Standard Specification for Aviation Turbine Fuels.

g. CID A-A-52557, Fuel Oil, Diesel; for Posts, Camps and Stations.

h. CID A-A-59693, Diesel Fuel, Biodiesel Blend (B20).

i. MIL-DTL-16884, Fuel, Naval Distillate.

j. ASTM D3699, Standard Specification for Kerosene.

k. ASTM D4814, Standard Specification for Automotive Spark-Ignition Engine Fuel.

l. ASTM D910, Standard Specification for Aviation Gasoline (Avgas).

m. ASTM D975, Standard Specification for Diesel Fuel Oils.

n. MIL-DTL-87107, Propellant, High Density Synthetic Hydrocarbon Type, Grade JP-10.

o. ASTM D5798, Standard Specification for Fuel Ethanol (Ed75-Ed85) for Automotive Spark-Ignition Engines.

p. ASTM D6751, Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels.

q. ASTM D7467, Standard Specification for Diesel Fuel Oil, Biodiesel Blend (B6 to B20).

r. ASTM D396, Standard Specification for Fuel Oils.

s. MIL-PRF-26536 Propellant, Hydrazine.

t. MIL-PRF-9000 Lubricating Oil, Shipboard Internal Combustion Engine, High-Output Diesel.

u. MIL-PRF-17331 Lubricating Oil, Steam Turbine & Gear, Moderate Service.

v. ASTM D1835, Standard Specification for Liquefied Petroleum (LP) Gases.

w. SAE J1616, Standard for Natural Gas Vehicle Fuel.

2-3 FUEL PROPERTIES AND ADDITIVES.

In addition to the fuel specifications, refer to Coordinating Research Council, Inc., CRC Report No. 635, Handbook of Aviation Fuel Properties, for additional fuel properties. The following paragraphs list typical physical properties of various grades of fuel and additives which would affect the design of a petroleum fuel facility. The NATO designation is shown in brackets.

2-3.1 Motor Gasoline (Mogas) [F-46] [ASTM D4814].

2-3.1.1 Physical Properties of Mogas.

a. Specific Gravity 0.70 to 0.78

b. Reid Vapor Pressure 0.58 to 15 psia (at 100 degrees F (38 degrees C))

c. Flash Point -31 degrees F (-35 degrees C) to -45 degrees F (-43 degrees C)

d. Viscosity <1 cSt (at 104 degrees F (40 degrees C))

2-3.1.2 Special Precautions for Mogas.

Because of its high volatility, gasoline produces large amounts of vapor at ordinary temperatures. When confined in a tank or container at liquid temperatures above 20 degrees F (-7 degrees C), the vapor space is normally too rich to be explosive. At temperatures 20 degrees F (-7 degrees C) or less, vapor spaces above gasoline may be in the explosive range. One gallon (3.785 L) of liquid gasoline when vaporized will occupy about 25 cubic feet (700 L) of space, and if permitted to escape and become diluted with air, it is highly flammable. Provide a design that precludes disposing of mogas into storm or sanitary sewers.

2-3.2 Aviation Gasoline (Avgas) [F-18] [ASTM D910].

2-3.2.1 Descriptions of Aviation Gasoline.

Aviation gasoline is a high-octane aviation fuel used for piston or Wankel engine powered aircraft. It is distinguished from motor gasoline, which is the everyday gasoline used in ground vehicles. In military service, avgas is seldom used in manned aircraft but is commonly used in Unmanned Aerial Vehicles (UAVs).

The Air Force has a standard design for small avgas fuel systems. Contact the Air Force Fuels Service Headquarters Subject Matter Expert (SME) for more information.

2-3.2.2 Avgas Grades.

100LL, spoken as "100 low lead", is the most common grade used in military applications. It is dyed blue and contains a maximum of 2 grams of lead per US gallon (0.56 grams/liter) and is the most commonly available and used aviation gasoline. Other grades that are theoretically available include Grade 80, Grade 91, Grade 100, and Grade 82UL. The differences between all 80, 91, 100, and 100LL are lead content and color. Grade 82UL is unleaded.

2-3.2.3 Physical Properties of Avgas (100 LL).

a. Specific Gravity 0.68 to 0.74

b. Reid Vapor Pressure 5.5 to 7.0 psia (at 100 degrees F (38 degrees C))

c. Flash Point < -35 degrees F (-37 degrees C)

d. Melting/Freezing Point < -72 degrees F (-58 degrees C)

2-3.2.4 Special Precautions for Avgas.

Using the wrong grade of gasoline will cause engine problems. Virtually all grades of avgas available contain tetra-ethyl lead (TEL) as a lead based anti-knock compound. See mogas for flammability issues.

2-3.3 Aviation Turbine Fuels.

2-3.3.1 Physical Properties of Aviation Turbine Fuels.

Table 2-1. Properties of Aviation Fuels

	Property					
Grade Number [NATO Code]	Relative Density	Specific Gravity	Reid Vapor Pressure at 100°F(38°C) psia (kPa)	Minimum Flash Point, °F (°C)	Average (kin.) Viscosity at 100°F (38°C), $ft^2/s \times 10^{-5}$ (cSt)	Freezing Point, °F (°C)
JP-4 [F-40]	57° to 45° API	0.751 to 0.802	2 to 3 (13.8 to 20.7)	-20 (-29)	0.9×10^{-5} (0.8)	-72 (-58)
JP-5 [F-44]	48° to 36° API	0.788 to 0.845	0.04 (0.3)	140 (60)	1.6×10^{-5} (1.5)	-61 (-52)
JP-8 [F-34]	51° to 37° API	0.775 to 0.840	0.05 (0.3)	100 (38)	1.9×10^{-5} (1.8)	-53 (-47)

	Property					
Grade Number [NATO Code]	Relative Density	Specific Gravity	Reid Vapor Pressure at 100°F(38°C) psia (kPa)	Minimum Flash Point, °F (°C)	Average (kin.) Viscosity at 100°F (38°C), $ft^2/s \times 10^{-5}$ (cSt)	Freezing Point, °F (°C)
JP-10	20° to 18.5° API	0.935 to 0.943	0.11 (0.8)	67 (19)	3.4×10^{-5} (3.2)	-110 (-79)
JPTS	53° to 46° API	0.767 to 0.797	0.11 (0.8)	110 (43)	1.3×10^{-5} (1.2)	-64 (-53)

Hydrazine	9° API	1.007	NA	126 (52)	NA	NA

2-3.3.2 Special Precautions for Aviation Turbine Fuels.

Because of the serious consequences of a turbine engine failure and the nature of the fuel systems in turbine engines, provide designs which include means to prevent contamination of aviation turbine fuels by dirt, water, or other types of fuels. Solid contaminants are generally those which are insoluble in fuel. Most common are iron rust, scale, sand, and dirt. Iron rust contaminates aviation turbine fuel. Special filtration is required for receiving aviation turbine fuel into bulk storage and operating storage to remove contaminants before the fuel is delivered to aircraft. To preserve fuel quality, limit materials in contact with the fuel to stainless steel, non-ferrous, or coated carbon steel for aircraft fueling systems. Do not use zinc, copper, and zinc- or copper-bearing alloys in contact with aviation turbine fuels, including pipe, valves, system components, and accessories. The maximum allowable aircraft servicing use limits of solids and free water are provided in MIL-STD-3004. Provide a design that precludes disposing of aviation turbine fuels into storm or sanitary sewers.

2-3.4 Kerosene [ASTM D3699].

2-3.4.1 Physical Properties of Kerosene.

a. Relative density

b. API Gravity 51 degrees to 37 degrees API

c. Specific Gravity 0.775 to 0.840

d. Reid Vapor Pressure 0.5 psia (3.5 kPa) (maximum at 100 degrees F (38 degrees C))

e. Flash Point (minimum) 100 degrees F (38 degrees C)

f. Viscosity at 104 degrees F (40 degrees C) 1 to 2 x 10-5 ft2/s (0.9 to 1.9 cSt.)

g. Freezing Point -22 degrees F (-30 degrees C) (maximum)

2-3.4.2 Special Precautions for Kerosene.

Design separate systems for kerosene to avoid discoloration caused by contamination. Provide a design that precludes disposing of kerosene into storm or sanitary sewers.

2-3.5 Diesel Fuels.

2-3.5.1 Sulfur Content of Diesel Fuels.

Diesel fuel that is available for motive fuel in the United States is Low Sulfur Diesel (LSD) which has a maximum sulfur content of 500 ppm and Ultra Low Sulfur Diesel (ULSD) which has a maximum sulfur content of 15 ppm, both meeting ASTM D975. Since ULSD has a sulfur content much less than LSD, very small concentrations of LSD will contaminate ULSD and mandate downgrading it to LSD. Take precautions when designing systems to ensure that cross contamination is prevented.

2-3.5.2 Physical Properties of Diesel Fuels.

Table 2-2. Physical Properties of Diesel Fuels

	Automotive DF-2 [F-54]	Diesel Fuel Marine [F-76]	Ultra Low Sulfur Diesel [ASTM D975]
(a) Relative Density API Gravity, °API (Specific Gravity)	40 to 34 (0.825 to 0.855)	39 to 33 (0.830 to 0.860)	30 (0.876)
(b) Reid Vapor Pressure at 100 °F (38 °C), psia (kPa)	0 (0)	0 (0)	0 (0)
(c) Flash Point, °F (°C)	131 (55)	140 (60)	150 (66)
(d) Viscosity at 104°F (40°C) ft^2/s (cSt)	2.0 to 4.4 x 10-5 (1.9 to 4.1)	1.8 to 4.6 x 10-5 (1.7 to 4.3)	2.7 x 10-5 (2.5)
(e) Pour Point, °F (°C)	10 (-12)	20 (-7)	0 (-18)

Notes: (1) JP-8 is currently used as arctic grade diesel fuel (DFA) in the Arctic and Antarctic for heating fuel. The gross heating value of JP-8 is 18,400 Btu/lb (42 800 kJ/kg).

(2) DF-1, winter grade diesel fuel, has a flash point of 100 degrees F (38 degrees C) and a viscosity of 1.4 to 2.6 x 10^{-5} ft^2/s (1.3 to 2.4 cSt) at 104 degrees F (40 degrees C).

2-3.5.3 Special Precautions for Low Sulfur Diesel Fuels.

While not as critical as with aviation turbine fuels, diesel fuel systems are subject to damage by dirt and water in the fuel. Avoid contamination by dirt and water or dilution by lighter fuels. In cold climates, provide designs that will prevent "gelling." Provide a design that precludes disposing of diesel fuels into storm or sanitary sewers.

2-3.5.4 Special Precautions for Ultra Low Sulfur Diesel.

With the reduction in sulfur content comes a reduction in overall lubricity and conductivity of the fuel. A lower lubricity level can cause premature wear and damage to metal parts in typical compression ignition engines. Lubricity additives are added in accordance with ASTM D975 . Lower conductivity can cause a potential for an increased risk in fire or explosion caused by static electricity. Even though a conductivity additive is added it is recommended that flow rates are limited and bonding and grounding of system components be utilized to minimize static electricity during loading operations.

2-3.6 Burner Fuel Oils.

2-3.6.1 Physical Properties of Burner Fuel Oils.

Table 2-3. Physical Properties of Burner Fuel Oils

	Grade Number					
	1	2	4	5 Light	5 Heavy	6
Relative Density °API	48 to 36	40 to 28	30 to 15	22 to 14	23 to 8	22 to 7
Specific Gravity	0.786 to 0.843	0.825 to 0.877	0.876 to 0.966	0.922 to 0.972	0.913 to 1.017	0.922 to 1.022
Reid Vapor Pressure at 100°F (38°C), psia (kPa)	< 0.1 (< 0.7)	< 0.1 (< 0.7)	< 0.1 (< 0.7)	< 0.1 (< 0.7)	< 0.1 (< 0.7)	< 0.1 (< 0.7)
Minimum Flash Point, °F (°C)	100 (38)	100 (38)	130 (54)	130 (54)	130 (54)	150 (66)
Average viscosity at 100°F (38°C), $ft^2/s \times 10^{-5}$(cSt)	1.5 to 2.4 (1.4 to 2.2)	2 to 3.3 (1.9 to 3.1)	11.3 to 70 (10.5 to 65)	70 to 215 (65 to 200)	323 to 969 (300 to 900)	208 to 807 (193 to 750)
Pour Point, °F (°C)	-10 (-23)	-5 (-21)	21 (-6)	20 to 30 (-7 to -1)	20 to 30 (-7 to -1)	30 to 70 (-1 to 21)
Gross Heat Value, Btu/lb (kJ/kg)	19,765 (45 973)	19,460 (45 264)	18,840 (43 820)	18,560 (43 171)	18,825 (43 787)	18,200 (42 333)

2-3.6.2 Special Precautions for Burner Fuel Oils.

When the ambient temperature of the burner fuel oil is less than 20 degrees F (11 degrees C) above the pour point temperature, the burner fuel oil needs to be heated. At the burner fuel oil's pour point temperature, the fuel oil has reached a gel-like state and would be difficult to pump. In nearly all cases, No. 6 fuel oil requires heating to be pumped. In some cases, No. 4 and No. 5 burner fuel oils will require heating. Provide a design that precludes disposing of burner fuel oils into storm or sanitary sewers.

2-3.7 Alternative Fuel (E85) [[ASTM D5798].

2-3.7.1 Physical Properties of E85.

a. Specific Gravity 0.760 to 0.780

b. Reid Vapor Pressure 6-12 psia (42 to 83 kPa)

c. Flash Point (minimum) -20 degrees F (-30 degrees C)

d. Viscosity is 6.1x10-6 to 3.4x10-5 ft2/s (0.57 to 3.19 cSt)

e. Pour Point -212 degrees F (-100 degrees C)

2-3.7.2 Special Precautions for E85.

Due to the corrosiveness of E85, many common materials used with gasoline systems are not compatible with the handling and storage of alcohols (E85, or ethanol, is 85 percent ethyl alcohol). Zinc, brass, lead, aluminum, and lead based solder are several metals that become degraded by ethanol exposure. Other metals, including unplated carbon steel, stainless steel, black iron and bronze seem to have acceptable resistance to ethanol corrosion. Certain nonmetallic materials that have been successfully used with ethanol include: Buna-N, Neoprene rubber, polyethylene, nylon, polypropylene, nitrile, Viton, and Teflon. Common nonmetallic materials degraded by ethanol are natural rubber, polyurethane, cork gasket material, leather, polyester-bonded fiberglass laminate, polyvinyl chloride (PVC), polyamides, and methyl-methacrylate plastics. Proper cleaning of existing tanks that are being converted for E85 storage is required, because E85's solvent properties loosen tank deposits. In ethanol dispensing a one-micron in-line filter is recommended for impurity/particle removal. The shelf life of E85 is approximately 60-90 days in some cases. At normal temperatures E85 is less explosive than gasoline, but E85 is more explosive at lower temperatures. Ethanol vapors have similar behavior to gasoline, but a lower vapor pressure. E85 is an electrical conductor and is potentially carcinogenic. Provide a design that precludes disposing of E85 into storm or sanitary sewers.

2-3.8 Alternative Fuel Bio-Diesel (B20).

2-3.8.1 Physical Properties of Bio-Diesel.

Biodiesel fuel B20 is a blend of petroleum diesel fuel meeting ASTM D975 and 100 percent (neat) biodiesel fuel meeting either ASTM D6751 or EN 14214, where the biodiesel content of the blended fuel is no more than 20 percent biodiesel by volume (B20). Biodiesel has physical properties very similar to conventional diesel.

a. Specific Gravity 0.870 to 0.890

b. Reid Vapor Pressure 0.0 psia (0.0 kPa) (maximum at 100 degrees F (38 degrees C))

c. Flash Point (minimum) 100 degrees F (38 degrees C) for D1, 126 degrees F (52 degrees C)

d. Viscosity at 104 degrees F (40 degrees C) 1.2 to 4.4 x 10-5 ft2/s (1.3 to 4.1 cSt.)

e. Pour Point 10 degrees F (-12 degrees C)

2-3.8.2 Special Precautions for Bio-Diesel.

In dispensing Bio-Diesel, it is recommended that a 30-micron and a 10-micron in-line filter be used, in succession, as a primary and secondary means for impurity/particle removal. Bio-Diesel (B100) has good solvent qualities and will remove deposits from fuel systems. As a result, it may require more filter changes initially. One of the most commonly used blends of Bio-Diesel is B20. B20 has not been approved for use in combat or tactical vehicles or equipment. The usage of bio-diesel in other engines/vehicles has been reviewed by vehicle manufacturers and copies can be obtained at http://www.biodiesel.org/. B20 should be used within six months of manufacturer, because of the fuels shelf life. Users should be aware that a B20 blend will have increased viscosity requirements. Provide a design that precludes disposing of bio-diesel fuels into storm or sanitary sewers.

2-3.9 Liquefied Petroleum Gas (LPG).

2-3.9.1 Physical Properties of LPG.

LPG is composed predominantly of propane and propylene with minor amounts of butane, isobutane, and butylene. It is odorless, colorless, and non-toxic. To reduce the danger of an explosion from undetected leaks, commercial LPG usually contains an odorizing agent which gives it a distinctive pungent odor. LPG is a vapor at atmospheric conditions. It is normally stored as a liquid at a storage pressure of 200 psia (1400 kPa). LPG has the following properties:

a. Freezing Point, degrees F (degrees C) -305 (-187)

b. Relative Density (Specific Gravity) 147 degrees API (0.588)

c. Vapor Pressure at 100 degrees F (38 degrees C), 175.8 (1212) psi (kPa)

d. Heat Content, Btu/lb (kJ/kg) 21,591 (50 221)

2-3.9.2 Special Precautions for LPG.

a. Store LPG under pressure in appropriate pressure-rated tanks.

b. The potential for fire and explosion presents extreme hazards to life and property. Provide adequate relief venting and additional fire protection in accordance with NFPA 58.

c. Provide tank spacing in accordance with the requirements of Chapter 10 of this UFC.

2-3.10 Compressed Natural Gas (CNG).

2-3.10.1 Physical Properties of CNG.

Appendix A to NFPA 52, Compressed Natural Gas (CNG) Vehicular Fuel Systems, defines certain CNG properties. Natural gas is a flammable gas. It is colorless, tasteless, and non-toxic. It is a light gas, weighing about two thirds as much as air. It tends to rise and diffuse rapidly in air when it escapes from the system. Natural gas burns in air with a luminous flame. At atmospheric pressure, the ignition temperature of natural gas mixtures has been reported to be as low as 900 degrees F (482 degrees C). The flammable limits of natural gas-air mixtures at atmospheric pressure are about 5 percent to 15 percent by volume of natural gas. While natural gas consists principally of methane, it also contains ethane, small amounts of propane, butane, and higher Hydrocarbons and may contain small amounts of nitrogen, carbon dioxide, hydrogen sulfide, and helium which will vary from zero to a few percent depending upon the source and seasonal effects. As distributed in the United States and Canada, natural gas also contains water vapor. This “pipeline quality” gas can contain 7 pounds or more of water per million cubic feet of gas (112 kg/106 m^3). Some constituents of natural gas, especially carbon dioxide and hydrogen sulfide in the presence of liquid water, can be corrosive to carbon steel, and the corrosive effect is increased by pressure. The pressures used in CNG systems covered by NFPA 52 are substantial and well above those used in transmission and distribution piping and in other natural gas consuming equipment. As excessive corrosion can lead to sudden explosive rupture of a container, this hazard must be controlled. Pressures in CNG fueling stations are typically less than 5,000 psi (35 000 kPa).

2-3.10.2 Special Precautions for CNG.

a. Provide venting for safety relief in areas where CNG is to be stored.

   1. CNG is a highly flammable substance. Therefore, in design of facilities, use the following precautions to prevent fires from becoming uncontrollable:
   2. Do not directly extinguish fires with water.
   3. Do not extinguish large fires.
   4. Allow large fires to burn while cooling adjacent equipment with water spray.
   5. Shut-off CNG source, if possible.
   6. Extinguish small fires with dry chemicals.

b. CNG is non-toxic but can cause anoxia (asphyxiation) when it displaces the normal 21 percent oxygen in a confined area without adequate ventilation.

c. Because of corrosion problems, water in Department of Transportation (DOT) certified tanks is limited to 0.5 pounds per million cubic feet (8 kg/10 6 m3).

2-3.11 OTTO Fuels.

Information on OTTO fuels is contained in NAVSEA S6340-AA-MMA-010, Technical Manual for OTTO Fuel II Safety, Storage, and Handling Instructions, published by direction of Commander, Naval Sea Systems Command. Distribution of this document is restricted and Naval Sea Systems Command handles requests for information.

2-3.12 Lubricating Oils.

2-3.12.1 Steam Turbine Oils [0-250] [MIL-PRF-17331].

a. For use in main turbines and gears, auxiliary turbine installations, certain hydraulic equipment, general mechanical lubrication, and air compressors.

b. Physical Properties:

1. Flash Point: 400 degrees F (204 degrees C) minimum.
2. Pour Point: 20 degrees F (-6 degrees C) maximum.
3. Viscosity at 104 degrees F (40 degrees C), 80 to 104 x 10-5 ft2/s (74 to 97 x 10-6 m2/s).

2-3.12.2 Lubricating Oils [0-278], [MIL-PRF-9000].

For use in advanced design high-output shipboard main propulsion and auxiliary diesel engines using fuel conforming to MIL-DTL-16884.

2-3.12.3 Special Precautions for Lubricating Oils.

To pump the oil when the ambient temperature of the lubricating oil is less than 20 degrees F (11 degrees C) above the pour point temperature, heat the lubricating oil. At the pour point temperature, the oil becomes gel-like and is difficult to pump. Ensure the design does not allow the discharge of lubricating oil into storm or sanitary sewers.

2-3.13 Hydrazine - Water (H-70) [MIL-PRF-26536].

2-3.13.1 Physical Properties of H-70.

This fuel is a mixture of 70 percent hydrazine and 30 percent water. It is a clear, oily, water-like liquid with a fishy, ammonia-like odor. It is stable under extremes of heat and cold; however, it will react with carbon dioxide and oxygen in the air. It may ignite spontaneously when in contact with metallic oxides such as rust.

2-3.13.2 Special Precautions for H-70.

Keep working and storage areas clean and free of materials that may react with hydrazine. Provide only stainless steel in areas where extended contact is possible. Areas where incidental contact is possible should be kept free of rust. Ensure the design does not allow the discharge of H-70 into storm or sanitary sewers.

2-3.14 Fuel Additives.

Contact Service Control Point for fuel additization requirements.

2-3.14.1 Fuel System Icing Inhibitor (FSII), High Flash, [MIL-DTL-85470] (diethylene glycol monomethyl ether (DIEGME)).

a. Used in aviation turbine fuels to prevent the formation of ice crystals from entrapped water in the fuel at freezing temperatures. In addition, it has good biocidal properties, preventing growth of microorganisms in the fuel.

b. Avoid water entry/bottoms in storage tanks because the additive will dissolve in the water, reducing the concentration of additives left in the fuel.

c. Refer to fuel specification for more information.

d. Consult federal, state, and local regulations for appropriate disposal methods.

2-3.14.2 Corrosion Inhibitor/Lubricity Improver (CI), [MIL-PRF-25017].

A combination lubricity improver and corrosion inhibitor additive, procured under MIL-PRF-25017, is injected in all military aviation turbine fuels at the refinery in order to improve the lubricating characteristics of the fuel.

2-3.14.3 Static Dissipater Additive.

Static dissipater additive (SDA) enhances safety during handling and flight by reducing static discharge potential in the vapor space above the fuel. SDA increases the conductivity of the fuel, thus decreasing the electrostatic charge relaxation time (the rate of which a charge dissipates or travels through the fuel) which decreases the potential for ignition from static charges. The actual proportion is in accordance with the specific fuel military specification. For fuel system design purposes, assume a lower limit of 50 picosiemens per meter in the determination of relaxation requirements. SDA is added to all JP-8 (F-34; F-35). SDA is not added to JP-5 and F-76 or to Jet A/A-1 that is stored at military installations

2-4 PRODUCT SEGREGATION.

2-4.1 Product Grades.

Except as otherwise approved by Service Headquarters, provide separate receiving, storage, and distribution systems for each product. Except as otherwise approved by Service Headquarters, prevent misfueling (transferring a type of fuel other than the type intended) by using different size piping, valves, adaptors, nozzles, etc. The products to be segregated include:

a. Mogas.

b. Avgas.

c. Diesel fuel, including low sulfur diesel and ultra-low sulfur diesel and distillate type burner fuels (No. 1, No. 2, and kerosene).

d. Aviation turbine fuel, separate systems for each grade.

e. Residual type burner fuels (No. 4, No. 5, and No. 6).

f. Lubricating oils.

g. LPG.

h. CNG.

i. OTTO fuels.

j. E85.

k. Bio-diesel.

l. Hydrazine.

2-4.2 Exceptions.

Designs for different products using the same piping may be approved for long receiving lines such as from a tanker or barge pier or a cross-country pipeline to a storage facility. Where such common use occurs, make provisions for receiving and segregating the interface between two products. Consider the use of pigs or break-out tanks to separate batches. Exceptions will not be approved for common systems to carry both clean and residual type fuels.

2-5 TRANSFER FLOW RATES.

Table 2-4 shows the recommended range of design flow rates. In some cases, greater rates may be needed to meet the operational requirements of a particular facility.

Table 2-4. Design Flow Rates

Service[1]	Aviation Turbine Fuel	Diesel Fuel	Burner Fuel Oils	Mogas
Between storage tanks, gpm (m^3/hr)	600 to 1,200 (136 to 272)	600 to 1,200 (136 to 272)	600 to 1,200 (136 to 272)	600 to 1,200 (136 to 272)
Tank car unloading to storage (per car), gpm (m^3/hr)	300 to 600 (68 to 136)	300 to 600 (68 to 136)	300 to 600 (68 to 136)	300 (68)
Tank truck unloading to storage (per truck), gpm (m^3/hr)	300 to 600 (68 to 136)	300 to 600 (68 to 136)	300 to 600 (68 to 136)	300 to 600 (68 to 136)
Gravity receipt tank to storage gpm (m^3/hr)	600 (136)	600 (136)	600 (136)	600 (136)
Storage to tank truck/refueler loading (per truck), gpm (m^3/hr)[2]	300 or 600 (68 or 136)	300 or 600 (68 or 136)	300 or 600 (68 or 136)	300 or 600 (68 or 136)
Delivery from direct fueling stations to aircraft, gpm (m^3/hr)	Varies[3]	N/A	N/A	N/A
Delivery from direct fueling stations to helicopters, gpm (m^3/hr)	Varies[3]	N/A	N/A	N/A
Between super tanker and storage, gpm (m^3/hr)	16,800 (3815)	16,800 (3815)	16,800 (3815)	16,800 (3815)
Between regular tanker and storage, gpm (m^3/hr)	7,000 (1590)	7,000 (1590)	7,000 (1590)	7,000 (1590)
Between barge and storage, gpm (m^3/hr)	2,800 (636)	2,800 (636)	2,800 (636)	2,800 (636)
To fleet oilers, gpm (m^3/hr)	3,500 (795)	3,500 (795)	N/A	N/A
To AOEs, gpm (m^3/hr)	7,000 (1590)	7,000 (1590)	N/A	N/A
To carriers, gpm (m^3/hr)	2,450 (556)	2,450 (556)	N/A	N/A
To average cruisers, gpm (m^3/hr)	700 (159)	1,400 (318)	N/A	N/A
To average destroyers, gpm (m^3/hr)	700 (159)	1,400 (318)	N/A	N/A
Storage to tank car loading (per car), gpm (m^3/hr)	300 or 600 (68 or 136)	300 or 600 (68 or 136)	300 or 600 (68 or 136)	300 or 600 (68 or 136)

Notes: (1) At dockside, deliveries from tankers should be assumed to be at a pressure of 80 to 100 psig (600 to 700 kPa), and deliveries to tankers to be at 60 psig (400 kPa). Rates to other ships are maximums based on fueling at sea capacities. Lesser rates for fueling at piers can be used if more practical. Loading rates are based on 40 psig (300 kPa) maximum per hose at ship connections.
(2) For truck fillstands, system must be designed to deliver a refueling nozzle pressure of 35 psig with a flow range of 50 to 560 gpm.
(3) Refer to Chapter 4 of this UFC for guidance on fueling rates for aircraft. Contact appropriate Service Headquarters for actual fueling rates for aircraft for which design applies.

2-6 PHYSICAL SECURITY.

Plan and design fuel facilities with the goal of protecting the fuels, storage, and transfer capability from enemy attack, terrorists, sabotage, fire, seismic activity, and other damaging influences. In high threat areas, more extensive protection may be required. Consult appropriate Service Headquarters for guidance. NATO projects have their own specific criteria which govern protection level requirements.

2-6.1 Antiterrorism and Physical Security.

2-6.1.1 Physical Security Program.

Per DoD 5200.08-R, *Physical Security Program*, at a minimum, fuel support points, pipeline, pumping stations, and piers must be designated and posted as Controlled Areas. Areas containing critical assets may be designated as a restricted area. Coordinate with installation or activity Security and Antiterrorism Officer (ATO) to determine area designation (controlled or restricted), threat environment, Design Basis Threat (DBT), level of protection and access control requirements.

Controlled and restricted areas are defined areas in which there are special restrictive measures employed to prevent unauthorized entry. Restricted areas may be of different types depending on the nature and varying degree of importance of the protected asset. Restricted areas must be authorized by the installation Commander, properly posted, and must employ physical security measures.

2-6.1.2 DoD Security Engineering Facilities Planning Manual.

UFC 4-020-01, *DoD Security Engineering Facilities Planning Manual*, supports the planning of DoD facilities that include requirements for security and antiterrorism. Use in conjunction with UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*, to establish the security and antiterrorism design criteria that will be the basis for DoD facility designs.

2-6.2 Security Fencing.

Unless otherwise directed by Service Headquarters, provide security fencing around all petroleum facilities to ensure safety and inhibit sabotage, theft, vandalism, or entry by unauthorized persons. Install a 7-foot (2.1 m) fabric height fence of chain-link type with three-strand barbed wire outriggers on top or its equivalent. Ensure fencing, gates, and associated clearance requirements are in accordance with UFC 4-022-03. Contact the Installation Security Organization for additional requirements.

2-7 MAINTAINABILITY CAPABILITIES.

Provide adequate maintenance space around all system components including:

a. Filter-separator and other filtration device maintenance access, particularly element removal. For vertical filtration devices provide stair and platform access to at least one side of each unit.

b. Manual valves, especially replacement of slips in double block and bleed tapered lift plug valves.

c. Adequate room and locations for the use of an intelligent pig launcher/receiver in all section of piping.

d. Meter reading and maintenance.

e. Control valves.

f. Pumps, including removal.

g. Instruments, especially those mounted on tank shells.

2-8 VOICE COMMUNICATIONS.

Provide voice communications (direct line for Air Force projects only) between separated areas such as receiving, dispensing, pump stations, and fuel storage areas to coordinate operations involved in fuel transfer. Refer to UFC 3-501-01 and UFC 3-550-01.

2-9 OTHER COMMUNICATIONS.

2-9.1 Data Communications.

Data communications systems must be designed and accredited by designated accrediting authority or authorizing official in accordance with the applicable Telecommunications Industry Association (TIA) and Electronic Industries Association (EIA) documents. Coordinate with local Base Communications squadron where applicable. For Army, Navy, and Air Force communication systems design criteria see UFC 3-580-01.

2-9.2 Fire Alarm Communication.

Fire alarm communications systems must be coordinated with the Base Fire Department. For fire alarm communication system requirements see the relevant UFGS.

2-10 WORKER SAFETY.

Design facilities to comply with the most stringent of the Occupational Safety and Health Administration (OSHA) or the host nation standards. Also, ensure that design complies with service-specific occupational safety and health criteria. For Navy, OPNAVINST 5100.23 Series applies. For Air Force,**\2** AFMAN 91-203 ***/2/*** applies. Incorporate design standards to ensure proper storage for all hazardous chemicals in accordance with 29 CFR 1910.1200, Hazard Communication.

2-10.1 Emergency Showers and Eyewash Stations.

Fixed emergency showers and eyewash stations are required in workshops, **\2\ /2/** hydrazine storage facilities, hydrazine servicing facilities, additive injection facilities, pumphouses, fuel piers and other similar facilities. Fixed emergency showers and eyewash stations, or portable eyewash units, must be installed at other locations where fuel is transferred to/from **\1\ /1/** aircraft. Table 2-5 below provides minimum requirements for fixed emergency shower and eyewash stations and portable eyewash stations for DoD installations. **\2** Refer to UFC 4-310-03 for requirements for Emergency Showers and Eyewash Stations for fuel laboratories. **/2/** Refer to Appendix D of UFC 3-420-01 for additional requirements associated with Emergency Shower and Eyewash Stations.

Table 2-5. Emergency Shower and Eyewash Station Locations[1]

2-11 ELECTRICAL DESIGN.

2-11.1 Area Classifications.

Classify all fuel facilities, except as modified by this UFC, in accordance with API RP 500, NFPA 30, NFPA 70, and IEEE C2. These practices may be modified where unusual conditions occur, where locations contain hazardous atmospheres classified other than Group D (as defined by NFPA 70), or where a system component malfunction may cause hazardous situations. Use sound judgment in applying these requirements. Specify a higher classification wherever necessary to maintain safety and continuity of service. Treat combustible liquids under pressure as flammable liquids. All piping and system components including those connected to an atmospheric storage tank must be considered pressurized. Ensure design is in accordance with the requirements designated in NFPA 70 for the specific division and class. Ensure temperature class or operating temperature of the system components are in accordance with NFPA 70. Ensure that project drawings include hazardous area plans indicating extent and classification of areas. Drawings should provide dimensions indicating extent of classified areas and should include sections/elevations when required to fully convey the extent of the areas.

2-11.1.1 Class I, Division 1.

Class I, Division 1 locations include:

a. Outdoor locations and those indoor locations having positive mechanical ventilation that is within 3 feet (0.9 m) of the fill openings or vents on individual containers to which flammable liquids are being transferred. Provide alarm devices on all ventilation systems.

b. Outdoor locations within 5 feet (1.5 m) of open end of vents and openings on liquid fuel storage tanks extending in all directions.

c. Entire pit, sump, open trench, or other depression, any part of which is within a Division 1 or 2 location and is without mechanical ventilation.

d. Locations within and on exterior walls of open top spill containment structures including oil/water separators and spill containment boxes.

e. Locations at fuel dispensers.

f. Locations within 3 feet (0.9 m) of vent, extending in all directions, when loading a truck through the bottom connection.

g. All pump/filter houses handling liquid fuels.

h. Any area containing electrical system components that are or may be exposed to atomized fuel and where the ambient temperature can at any time be above the flash point of the fuel.

2-11.1.2 Class I, Division 2.

Class I, Division 2 locations include:

a. Outdoor locations between 5 feet (1.5 m) and 10 feet (3 m) of the Division 1 zones at vents and openings, on liquid fuel storage tanks extending in all directions.

b. Entire pit, sump, open trench, or other depression, any part of which is within a Division 1 or 2 location and is provided with mechanical ventilation.

c. Outdoor locations within 3 feet (0.9 m) of the exterior surface of pumps, air relief valves, withdrawal fittings, meters, and similar devices that are located in pipelines handling liquid fuels under pressure. Class I, Division 2 locations extend upward 18 inches (450 mm) above grade level and within 10 feet (3 m) horizontally from any surface of the device.

d. Locations within and extending upward to the top of the dikes that surround aboveground tanks containing liquid fuels and within 10 feet (3 m), extending in all directions of the tank shell, ends, or roof.

e. Locations extending upward 18 inches (450 mm) above grade level within 15 feet (4.6 m) horizontally from any surface of open top spill containment structures including oil/water separators and spill containment boxes, whether installed indoors or outdoors.

f. Locations 25 feet (7.6 m) horizontally in all directions on pier side from portion of hull containing cargo and from water level to 25 feet (7.6 m) above cargo tank at highest point.

g. Area between 3 feet (0.9 m) and 10 feet (3 m) extending in all directions from vent when loading a truck. Also upward 18 inches (450 mm) above grade and within 10 feet (3 m) horizontally from the truck load connection

2-11.1.3 Non-Classified Locations.

Non-classified locations include:

a. Outdoor locations having closed piping systems handling flammable or combustible liquids that have no pumps, air relief valves, withdrawal fittings, valves, screwed fittings, flanges, meters, or similar devices which create joints in piping.

b. Office buildings, boiler rooms, control rooms, and similar locations that are outside the limits of hazardous locations, as defined above, and are not used for transferring flammable or combustible liquids or containers for such liquids.

c. Areas in which flammable and combustible liquids are stored in accordance with NFPA 30, outside the limits of a classified location, and the liquids are not transferred.

2-11.2 Illumination.

Illuminate all working areas for night operations to the minimum intensity recommended in Table 4 of API RP 540 and Petroleum, Chemical and Petrochemical Plants in Table 30.2 of IESNA Lighting Handbook 10th Edition. Lighting design should also provide for road access on tall light posts to allow for lamp replacement. For facilities within the jurisdiction of the U.S. Coast Guard under 33 CFR Part 154, illuminate to the minimum intensity required by that regulation. Provide security lighting in accordance with UFC 3-530-01. If local or state regulations exist, follow the most stringent requirements.

2-11.3 Grounding and Bonding***.

The following references apply to grounding and bonding systems:

a. IEEE 142

b. NFPA 70

c. NFPA 77

d. NFPA 780

e. API RP 540

f. API RP 2003

g. IEEE 1100

h. NFPA 407

i. UFC 3-575-01

2-11.3.1 Grounding Requirements.

Ground the following items in accordance with Article 250 of NFPA 70:

a. Motor, generator, and transformer frames.

b. Non-current-carrying metallic parts of electrical system components and installations, such as enclosures for IESNA boards, switchgear, and motor control centers.

c. Metallic messengers of self-supporting cables.

d. Exposed conductive materials enclosing electrical conductors, such as metallic conduit, metallic tubing, metallic armoring, sheaths and shields, cable troughs, trays and racks, wireways, and busways.

e. Filter-separators and other filtration system components.

2-11.3.2 Current and Lighting Protection.

Provide lightning protection in accordance with **\2** UFC 3-575-01 and NFPA 780 ***/2/*** and local installation requirements. For fault current protection and lightning protection, ground the following items through ground rods or beds or bond to a grounded network. Provide ground for these items as required by the above references.

a. **\2\ /2/**

b. Lightning arrestors and lightning shield conductors.

c. Operating mechanisms of overhead airbreak switches.

d. Canopies.

e. Aboveground storage tanks.

2-11.3.3 Static Electricity Prevention.

To prevent the buildup static electricity, ground the following items directly through ground rods or beds or bond to a grounded network. Do not exceed 10,000 ohms of resistance to ground, unless otherwise stated. Do not bond dissimilar metals together.

a. Aboveground tanks, vessels, stacks, heat exchangers, and similar system components not directly supported or bolted to a grounded supporting network.

b. Pipe and pipe support columns in accordance with the more stringent of NFPA 77 or below.

   1. Provide (minimum) 1 ground rod on pipe runs 100 feet (30 m) long or less unless the pipe is connected to a grounded source within the 100 feet (30 m).

   2. Provide (minimum) 2 ground rods on runs of pipe that exceed 100 feet (30 m), but are less than 300 feet (90 m) in length.

   3. Provide (minimum) 1 ground rod at intervals not exceeding 300 feet (90 m) on runs of pipe that are greater than 300 feet (90 m) in length.

   4. Parallel pipes may be bonded and common ground rods used, spaced in accordance with (1) through (3) above.

c. Aircraft direct fueling stations.

d. Hydrant pits.

e. Internal floating pans bonded to the storage tank shell.

f. Aboveground portions of electrically isolated piping at truck, rail, and marine loading and unloading stations.

2-11.3.4 Installation.

Isolate grounding systems for instrumentation, instrument control boards, and electronic system components from all other ground systems. Additional grounding is not required for overhead electrical system components bolted directly to grounded metallic structures. Where feasible, separate the conductor connecting a lightning rod to the grounding electrode from other grounding conductors. Route with a minimum of sharp bends and in the most direct manner to the grounding electrode. Do not use this electrode in lieu of grounding electrodes which may be required for other systems. This provision does not prohibit the required bonding together for grounding electrodes of different systems.

2-12 CATHODIC PROTECTION.

Obtain the services of a National Association of Corrosion Engineers (NACE)-certified Corrosion Specialist or Cathodic Protection Specialist or a registered professional

Corrosion Engineer to perform all cathodic protection design and testing. **\2** All designs will comply with UFC 3-570-01. ***/2/***

2-12.1 Tanks.

For all underground steel tanks and tank bottoms of aboveground vertical tanks, provide cathodic protection in accordance with UFC 3-570-01, API RP 651, 40 CFR Part 280, UL 1746, and UFC 3-460-03. For additional information on cathodic protection, refer to UFC 3-460-03 and **\2\ for Air Force follow** AFI32-1001 ***/2/***. Current tank design configuration electrically isolates the tank bottom from surrounding earth. Therefore, install cathodic protection between the liner and the tank bottom.

2-12.2 Piping.

For all carbon steel and stainless steel underground and underwater piping, provide cathodic protection in accordance with UFC 3-570-01 and 40 CFR Part 280. For additional information on cathodic protection, refer to UFC 3-460-03, NACE SP0169, and 49 CFR Part 195. Buried stainless steel corrodes and, therefore, must be cathodically protected.

2-12.2.1 Over-Voltage Protection (OVP) Devices.

Provide OVP devices across all aboveground flanges with insulating flange kits connected to underground and underwater cathodically protected piping. Require OVP devices to be designed for use with insulating flange kits and for use in Class I, Division 1 areas. Provide covers over flanges to preclude dirt from degrading insulating flange gaskets; refer to DoD Standard Design AW 078-24-28.

2-12.3 Structures.

Obtain the services of a (NACE)-certified Corrosion Specialist or Cathodic Protection Specialist or a registered professional Corrosion Engineer to evaluate the need for cathodic protection on carbon steel portions of fueling support facilities. Comply with UFC 3-570-01.

2-12.4 Test Stations.

Installation of cathodic protection test stations within Class I, Division 1 locations is prohibited and within Class I, Division 2 locations must be avoided, if practical. If the installation of cathodic protection test stations within Class I, Division 2 locations is unavoidable, these test stations must be considered nonincendive and therefore will not require explosion proof enclosures.

2-13 ENVIRONMENTAL PROTECTION.

2-13.1 General Policy.

It is the firm policy of the Department of Defense to design and construct fueling facilities in a manner that will prevent damage to the environment by accidental discharge of fuels, their vapors or residues. Designs must comply with foreign government, national, state, and local environmental protection regulations that are in effect at a particular facility.

2-13.2 Regulations and Guidelines.

2-13.2.1 Within U.S.A.

Within the jurisdiction of the United States, adhere to the following environmental protection guidelines:

a. National Environmental Policy Act (NEPA), 42 USC 4321.

b. Facilities Transferring Oil or Hazardous Material in Bulk, U.S. Coast Guard Regulations, 33 CFR Part 154.

c. Standards of Performance for New Stationary Sources, Environmental Protection Agency Regulations, 40 CFR Part 60.

d. National Emission Standards for Hazardous Air Pollutants for Source Categories, Environmental Protection Agency Regulations, 40 CFR Part 63.

e. Oil Pollution Prevention, Environmental Protection Agency Regulations, 40 CFR Part 112.

f. EPA Administered Permit Programs: The National Pollutant Discharge Elimination System (NPDES), Environmental Protection Agency Regulations, 40 CFR Part 122.

g. Technical Standards and Corrective Action Requirements for Owners and Operators of Underground Storage Tanks (UST), Environmental Protection Agency Regulations, 40 CFR Part 280.

h. Approval of State Underground Storage Tank Programs, Environmental Protection Agency Regulations, 40 CFR Part 281.

i. Transportation of Hazardous Liquids by Pipeline, Department of Transportation Regulations, 49 CFR Part 195.

j. Low Impact Development, UFC 3-210-10.

k. Obtain additional data on anti-pollution regulations for specific locations from Service Headquarters Environmental Support Office.

2-13.2.2 Outside U.S.A.

At facilities in other countries, consult appropriate service environmental directives, DODD Overseas Environmental Baseline Guidance Document and for Navy, OPNAVINST 5090.1. It may be appropriate to address the DoD Overseas Environmental Baseline Guidance Document and appropriate Final Governing

Standards for the region/country. If tank is to be installed in a locale or state with more stringent criteria, use the more stringent criteria. If tank is to be installed in a NATO country other than the CONUS, follow the most stringent of local regulations or NATO Airfield Standard Design - Jet Fuel Storage and Dispensing Systems, STD 121-122-01.

2-13.3 Transfer of Fuel at Ports.

2-13.3.1 Bulk Transfer.

Compliance with 33 CFR Part 154 is required for each fixed facility capable of transferring fuel in bulk to or from a vessel with a capacity of 10,500 gallons (39,700 L) or more. These facilities are required to have an operations manual approved by the Captain of the Port. In the operations manual, include the requirement for the following systems:

a. Hose assemblies
b. Loading arms
c. Closure devices
d. Monitoring devices
e. Small discharge containment
f. Discharge removal
g. Discharge containment system components
h. Emergency shutdown
i. Communications
j. Lighting

2-13.3.2 Vapor Collections.

For facilities that collect vapor from vessel cargo tanks, ensure that the requirements of 40 CFR Part 60 for the following items are met:

a. Vapor line connections
b. Vessel liquid overfill protection
c. Vessel vapor overpressure and vacuum protection
d. Fire, explosion, and detonation protection
e. Detonation arrestors, flame arrestors, and flame screens
f. Inerting, enriching, and diluting systems
g. Vapor compressors and blowers
h. Vapor recovery and vapor destruction units

2-13.4 Air Quality Control.

2-13.4.1 Design Requirements.

Regulatory requirements pertaining to air quality control will vary according to locality and to type and size of the petroleum vapor source. Petroleum storage and dispensing facilities are common sources of air pollution. Provide vapor recovery where required by federal (40 CFR Part 60 Subpart Kb), state, and local regulations and other chapters of this UFC. If gasoline is being handled, refer to 40 CFR Part 60 Subpart XX, 40 CFR Part 63 Subpart R, 40 CFR Part 63 Subpart BBBBBB, and 40 CFR Part 63 Subpart CCCCCC for design, installation, and testing requirements.

2-13.4.2 Aboveground Storage Tanks.

Federal regulation 40 CFR Part 60 Subpart Kb requires that tanks used for the storage of fuel with a design capacity greater than 19,000 gallons (72,000 L) having a true vapor pressure greater than 0.75 psia (5. kPa) at operating temperature must be equipped with either: 1) a fixed roof in combination with an internal floating pan; 2) an external floating roof equipped with a dual seal closure device between the wall of the tank and the roof edge; or 3) a closed vent system designed to collect all volatile organic compound (VOC) vapors and gases discharged from the tank and a control device designed to reduce VOC emissions by 95 percent or greater. It is the design intent that most vertical aboveground tanks will have internal floating pans and that vapor recovery will be used only if required by federal, state, or local regulations for the type of fuel and type of tank proposed, except as specifically required by another chapter of this UFC. Refer to Chapter 8 of this UFC for specific requirements for floating pans.

2-13.4.3 Truck and Rail Loading Facilities.

Tank truck and tank car loading facilities constructed or modified after December 17, 1980 which load an annual average of more than 20,000 gallons (76,000 L) per day of fuel having a true vapor pressure (TVP) of 0.75 psia (5 kPa) or greater must discharge the vapors resulting from such operations into a closed system. Ensure this system leads to a vapor recovery or disposal system which is capable of removing 95 percent of the petroleum vapor before final discharge into the atmosphere. Equip bulk gasoline terminals (handling fuels with TVP > 4.003 psia or 27.60 kPa) with a vapor collection system designed to collect total organic carbon (TOC) vapors displaced from tank trucks during loading. Emissions from the vapor control system due to loading must not exceed 35 mg of TOC per liter of gasoline loaded. For facilities with an existing vapor processing system, the TOC emissions must not exceed 80 mg of TOC per liter of gasoline loaded (40 CFR Part 60 Subpart XX).

2-13.4.4 Permit Requirements.

Air quality permits are typically required for the construction of petroleum storage and dispensing facilities. It is essential for designers to review regulatory requirements to ensure incorporation of proper environmental controls. State and local regulations are primary sources for air quality requirements, but for particularly large facilities, it is also beneficial to confer with the EPA regional office. The permit review and air quality controls will further depend on whether the construction site is located in an attainment or non-attainment area for ozone. Different permit programs apply in these areas, but they can both yield strict control requirements depending on the air quality of the area. An emissions offset analysis may be necessary before any construction permit can be granted. This analysis will require and demonstrate a reduction in VOC emissions from other sources in the locality where the new source construction is to take place. The offset can be obtained by providing new or better controls or otherwise decreasing emissions from an existing source.

2-13.5 Water Quality Control.

2-13.5.1 Design Requirements.

Protection of the natural waters against pollution from discharge of petroleum is achieved by complying with federal, state, and local regulations.

2-13.5.2 Stormwater Discharge.

A National Pollutant Discharge Elimination System (NPDES) Permit, 40 CFR Part 122, may be required for the discharge of stormwater. A review of federal, state, and local stormwater regulations is required prior to design and construction. Discharge of stormwater includes:

a. Controlled drainage from storage tank areas with impermeable diked enclosures or drainage systems leading to impoundments.

b. Drainage from treatment systems.

c. Drainage from facility transfer operations, pumping, and tank car and tank truck loading/off-loading areas.

d. Drainage from equipment/vehicle maintenance areas.

2-13.5.3 Spill Prevention Control and Countermeasures (SPCC) Plan.

The minimum requirements for spill prevention in the United States are contained in 40 CFR Part 112. It requires the preparation of a SPCC Plan for facilities that may discharge fuel into navigable waters of the United States. Specific design features are necessary to meet the SPCC objectives at all facilities. The SPCC plan must demonstrate that the fuel facility will be designed and constructed in a manner that will prevent spillage, and should such a spillage occur, prevent the spill from leaving the property and entering a waterway. Review API Bulletin D16 to assist with conformance to regulations. Refer to 33 CFR Part 154 for small discharge containment. Verify the requirements of the SPCC Plan with Base Environmental prior to introducing fuel into a new system. Revisions to the SPCC Plan and registration of tank may be required. Refer to EPA 550-B-13-002 to assist with guidance on SPCC plans.

2-13.5.4 Meeting SPCC Plan Objectives.

40 CFR Part 112 allows SPCC Plan objectives to be met by either spill containment or spill treatment. For facilities covered by this UFC only spill containment systems are acceptable. Spill treatment systems must not be allowed to meet SPCC requirements unless required by regulations. Provide treatment systems (oil/water separators) to treat the discharge from spill containment systems only when required by federal, state, or local regulations, or by Service Headquarters. Typical facilities requiring a spill containment system are fuel storage tanks, tank truck loading/off-loading/parking areas, and tank car loading/off-loading areas.

2-13.5.5 Spill Containment Systems.

The SPCC Plan objectives expressed in 40 CFR Part 112 must be met with impermeable spill containment system designed to prevent a spill from leaving the property unless a spill treatment system is required by federal, state, or local regulations, or by Service Headquarters. See the individual chapters of this UFC for requirements.

2-13.5.6 Spill Treatment Systems (Oil/Water Separators).

Treatment systems (oil/water separators) may not be used to meet the requirements of 40 CFR Part 112 unless required by federal, state, or local regulations, or as determined by the appropriate Service Headquarters. Do not provide oil/water separator to treat the discharge from spill containment systems (e.g. secondary containment dikes, tank truck parking areas, loading/off-loading facilities), unless specifically required by regulations. Select either a conventional rectangular API type gravity oil/water separator or one with inclined parallel plates. Where possible, design the separator as a rectangular vessel with a fully open top with lid for ease of inspection and cleaning.

a. Design and construct the separator in accordance with the following:

   1. UFC 1-200-01, UFC 3-301-01, and UFC 3-240-01.
   2. UFGS 46 25 14.
   3. Army Corps of Engineers ETL 1110-3-466.
   4. ACI 350.4R-04, Design Considerations for Environmental Engineering Concrete Structures.

b. Consider the following items in sizing the oil/water separator:

   1. Anticipated inlet flow rate of a 5-year, 1-hour duration storm event.
   2. Type of fuel.
   3. Specific Gravity and Viscosity of fuel.
   4. Specific ambient and product temperature ranges.
   5. Product storage capacity required.

6. Possible contaminants present.

7. Operating parameters are intermittent or continuous.

c. Require parallel plates to be constructed from non-oleophilic materials such as fiberglass. Arrange the plates in either a downflow or crossflow mode so that the oil collects in the high point of the corrugations and rises to the top without clogging from settleable solids.

d. Consider installing a retention basin upstream of the oil/water separator. This would allow solids to settle prior to reaching the oil/water separator and allow the option of either releasing the stormwater to the oil/water separator or to an appropriate stormwater collection system.

2-13.5.7 Leak Detection.

As required by federal, state, and local regulations install leak detection on aboveground tank bottoms, underground storage tanks, and underground piping. Comply with the latest edition of 40 CFR Part 280.

2-13.5.8 Wastewater Disposal.

Provide a holding tank for wastewater. Wastewater is any water which has been in contact with significant quantities of fuel such as water collected from tank sumps, system component drains, and system component sumps. Ensure that tank construction conforms to federal, state, and local environmental requirements. Provide a means to remove wastewater for off-site disposal.

2-13.5.9 Dewatering.

Where dewatering for construction purposes is necessary and contamination is suspected, test the groundwater prior to construction to determine the extent of contamination. If the groundwater is, or has the potential to be, contaminated with petroleum products, review federal, state, and local regulations for acceptable treatment methods. Permits may be required for treatment and/or disposal of the water. Contact facility Environmental Department for guidance.

2-13.6 Aboveground Storage Tanks.

2-13.6.1 Design Requirements.

Aboveground storage tanks may be single wall, double wall, horizontal, vertical, protected, or fire resistant as discussed in Chapter 8. There is not a single federal regulation that specifically addresses aboveground storage tanks similar to 40 CFR Part 280 that solely governs underground storage tanks. The majority of the federal environmental design requirements come from either 40 CFR Part 112 or 29 CFR Part 1910.106. These regulations include environmental related requirements for:

a. Diking and drainage.

b. Flooding.

c. Corrosion Protection.

d. Inspections, Tests, and Records.

e. Brittle Fracture Analysis.

The designer must consult the latest version of these regulations and comply with all federal, state, and local regulations.

2-13.6.2 Other Requirements.

If a tank is to be installed in a locale or state with more stringent criteria, use the more stringent criteria. If tank is to be installed in a NATO country other than the CONUS, follow the most stringent of local regulations or NATO Airfield Standard Design - Jet Fuel Storage and Dispensing Systems, STD 121-122-01.

2-13.7 Underground Storage Tanks.

2-13.7.1 Design Requirements.

All underground and cut and cover storage tanks are to be double wall type. Single wall underground storage tanks are not allowed. For underground storage tanks larger than 110 gallons (416 L), the following are required by 40 CFR Part 280:

a. Corrosion protection for tanks and associated underground piping.

b. High level alarm.

c. Spill and overfill protection.

d. Release detection.

2-13.7.2 Other Requirements.

If a tank is to be installed in a locale or state with more stringent criteria, use the more stringent criteria. If tank is to be installed in a NATO country other than the CONUS, follow the most stringent of local regulations or NATO Airfield Standard Design - Jet Fuel Storage and Dispensing Systems, STD 121-122-01.

2-14 FIRE PROTECTION.

2-14.1 General Requirements.

Design all petroleum fuel storage, handling, transportation, and distribution facilities with full consideration of the hazardous nature of the fuels to be handled and their vapors. Ensure compliance with UFC 3-600-01.

2-14.2 Fire Protection of Aboveground Storage Tanks.

2-14.2.1 Tank Exterior Fire Protection Water Systems.

Provide fire protection water mains, hydrants, valves, pumps, and application devices to permit control of brush and grass fires and cooling of storage tanks in the event of a fire exposure. Provide a minimum of two hydrants. Locate hydrants and valves outside of diked areas and accessible to fire department pumper vehicles. Locate hydrants so that protected exposures can be reached through hose runs not exceeding 300 feet (90 m). Comply with all requirements of Table 2-6 and Table 2-7 in the "Fire Protection Water Systems" paragraph of this chapter for water supply.

2-14.2.2 Tank Interior Fire Protection Systems.

Tanks containing Class I flammable fuels or mission-critical Class II combustible fuels, such as JP-8, must be equipped with a full contact, aluminum honeycomb floating pan. Other Class II fuels require a full contact, aluminum honeycomb floating pan if the tank does not comply with the spacing and diking requirements of this UFC. Tanks storing mission-critical Class III fuels, such as JP-5 and diesel fuel marine (F-76), if located in hot (desert-like) climate, also require a floating pan to eliminate the fuel/air interface. A single slotted stilling well, that penetrates the floating pan, has a maximum diameter of 8 inches (200 mm) and is used for the automatic tank gauge system, is allowed to be provided without a vapor sleeve (bellow). A single slotted stilling well, that penetrates the floating pan, has a maximum diameter of 6 inches (150 mm) and is used for the water probe, is allowed to be provided without a vapor sleeve (bellow). The slotted well used for manual measurements must be equipped with a floating plug. The 8-inch (200 mm) slotted stilling well for the automatic tank gauge system level sensing device and the 6-inch (150 mm) minimum nominal size slotted stilling well for the automatic tank gauge system water probe are allowed to be provided without floating plugs.

\1

a. Aboveground Atmospheric POL Tanks. Table 2-6 provides fire flow rates for non-pressurized POL tanks.

b. Aboveground Pressurized POL Tanks. Table 2-7 provides fire flow rates for pressurized POL tanks.

c. Underground Atmospheric Tanks. 500 gpm (1900 L/min) for 240 minutes.

d. Underground Pressurized Tanks. 250 gpm (950 L/min) for 240 minutes.

Table 2-6. Atmospheric POL Tank Cooling Water

Tank Diameter		Fire Flow Rate	
(feet)	(meters)	(gpm)	(l/min)
0 – 64	0 – 19	500	1,900
65 – 119	20 – 35	750	2,840
120 – 154	36 – 46	1,000	3,785
155 – 199	47 – 61	1,250	4,740
200 or greater	61 or greater	1,500	5,680
Minimum duration: 240 minutes			

Note: Provide an additional 500 gpm (1,900 L/min) for each exposed tank, pressure vessel or handling facility within 50 ft (15.3 m) or one tank diameter, whichever is greater, of the largest tank under consideration. The maximum water supply for storage tanks must not exceed 2,500 gpm (9,465 L/m).

Table 2-7. Pressurized POL Tank Cooling Water

Tank Group Size	Fire Flow Rate gpm (l/min)
Single tank less than 30,000 gallon (113,550 L) capacity.	250 (950)
Single tank more than 30,000 gallon (113,500 L) capacity.	500 (1900)
2 to 6 tanks, one or more tanks greater than 30,000 gallon (113,550 L) capacity.	500 (1900)
2 to 6 tanks, each greater than 30,000 gallon (113,500 L) capacity.	1,000 (3785)
7 or more tanks, each tank less than 30,000 gallon (113,500 L) capacity.	1,000 (3785)
7 or more tanks, one or more tanks greater than 30,000 gallon (113,550 L) capacity.	1,500 (5680)
Minimum duration: 240 minutes	

/1/

2-14.3 Fire Protection of Underground Vertical Storage Tanks.

\1\ /1/In accordance with the Installation Fire Protection Plan, provide fire protection water mains, hydrants, valves, pumps, and application devices to permit control of brush and grass fires and for cooling of the aboveground piping and system components associated with underground vertical storage tanks in the event of a fire exposure. Provide a minimum of two hydrants. Locate hydrants so that protected exposures can be reached through hose runs not exceeding 300 feet (90 m). The minimum fire flow rate and minimum duration per hydrant must be calculated using the smallest diameter of aboveground POL tank. **\1\ /1/**

2-14.4 Fire Protection of Pumping Facilities.

2-14.4.1 Fire Department Access.

Provide adequate fire department access for all pumping facilities. Provide fire department access to all open sides of a pumphouse or pump shelter. Provide fire department access to at least two sides of a pump pad.

2-14.4.2 Pump Pad and Pump Shelter Sprinkler Requirements.

Pump pads and pump shelters do not need fire suppression systems.

2-14.4.3 Fuel Issue Pumphouse Sprinkler Requirements.

All of the following criteria must be met for a fuel issue pumphouse (typically a fuel hydrant system or independent fillstand system) to require protection with an automatic fire suppression system, foam water fire suppression system, etc.

a. Pumphouse must directly supply a mission critical asset or supply a refueler (e.g. R-11) which in turn supplies a mission critical asset. Fillstands attached to hydrant systems are counted as a part of the hydrant system.

b. Pumphouse must be in one (enclosed) fire area.

c. Pumphouse must supply over 50% of the fueling capability of a mission critical asset. For fillstands, pump capability and available trucks need to be taken into account.

2-14.4.4 Transfer Pumphouse Sprinkler Requirements.

All of the following criteria must be met for a fuel transfer pumphouse to require protection with an automatic fire suppression system, foam water fire suppression system, etc.

a. Pumphouse must supply a mission critical asset.

b. Pumphouse must be in one (enclosed) fire area.

c. Pumphouse must supply over 50% of the pumping capacity to the mission critical asset.

2-14.4.5 Mobile Fuel Pumping Equipment Sprinkler Requirements.

Readily available mobile fuel pumping equipment with 50% of the total fuel pumping capacities can be used to eliminate need for a fire suppression system. Mobile equipment that may be deployed may not be considered. This option must be approved by the Service Headquarters Subject Matter Expert. Where mobile pumping option is selected, provide connection points in the fuel system for temporary mobile pumps in the event that a pump facility is lost.

2-14.5 Fire Protection of Filtration Facilities.

Provide adequate fire department access for all filtration facilities. Provide fire department access to all open sides of a filtration building. Provide fire department access to at least two sides of a filtration pad.

2-14.5.1 Filtration Pad Sprinkler Requirements.

Filtration pads do not need fire suppression systems.

2-14.5.2 Filtration Building Sprinkler Requirements.

All of the following criteria must be met for a filtration building (typically associated with cut and cover hydrant systems) to require protection with an automatic fire suppression system, foam water fire suppression system, etc.

a. Filtration building associated with a fuel system that directly supplies a mission critical asset or supplies a refueler (e.g. R-11) which in turn supplies a mission critical asset.

b. Filtration building must be in one (enclosed) fire area.

c. Filtration building associated with a fuel system that supplies over 50% of the fueling capability of a mission critical asset.

2-14.6 Fire Protection of Tank Truck and Tank Car Facilities.

For facilities (such as loading stands) used for the transfer of flammable or combustible liquids to or from tank truck, refuelers, tank cars, drums, or other portable containers, provide portable dry chemical extinguishers of appropriate size, number, and location for the exposure.

2-14.7 Fire Protection of Aircraft Parking and Fueling Facilities.

Provide firefighting system components in accordance with service requirements. A minimum fire flow rate of 1,000 gpm (3,785 L/min) for a 2-hour duration is to be provided for all such facilities. Refer to USAF TO 00-25-172, NAVAIR 00-80R-14, NAVAIR 00-80T-109, AR 420-90 and NFPA 407.

2-14.8 Fire Protection of Refueler Vehicle Facilities.

Facilities that are covered and enclosed on at least three sides and that are used for the parking, storage, maintenance, and repair of aircraft refueler vehicles must be protected by an automatic sprinkler system or a closed-head foam-water **\1\ /1/** sprinkler system and utilize Class I Division 2 electrical system components and wiring as defined by NFPA 70

2-14.9 Fire Protection of Fuel Testing Laboratory.

\2 Comply with UFC 4-310-03 for fire protection of Fuel Testing Laboratories. ***/2/***

2-14.10 Fire Protection of Support Facilities.

Comply with UFC 3-600-01 for fire protection of support facilities.

2-14.11 Fire Protection of Fuel Piers.

Provide protection for piers with fixed piping systems used for the transfer of flammable or combustible liquids in accordance with the following:

a. UFC 3-600-01

b. UFC 4-152-01, UFC 4-150-02, and UFC 4-150-06

c. NFPA 30

d. NFPA 30A

e. NFPA 307 (If liquids are handled in bulk quantities across general purpose piers and wharves.)

f. "Guide on Marine Terminal Fire Protection and Emergency Evacuation," Oil Companies International Marine Forum.

2-14.11.1 Fire Protection Water Systems.

Use fire water systems with hydrants located so that vessels alongside can be reached through hose lines not longer than 300 feet (90 m). Consult UFC 3-600-01 to determine total water demands for piers based on an extra hazard occupancy classification.

2-15 EMERGENCY SHUT-DOWN.

Emergency fuel shutoff (EFSO) pushbuttons are required wherever there is a potential for an accidental release. EFSO pushbutton stations are required near tanks (outside of berm area), tank car and tank truck loading and off-loading, refueler truck fillstands, aircraft direct fueling stations, pumps, fuel piers, etc. All pumps must shut down and all motor operated valves must close when an EFSO pushbutton is pressed. An alarm must be annunciated at the master alarm panel. Operation of all pumps and valves must be discontinued until all EFSO pushbuttons are cleared and the alarm acknowledged. Off-base pipeline receipt and tanker receipt may be exceptions; contact Service Headquarters for direction.

2-16 ELECTROMAGNETIC RADIATION HAZARDS.

Potential ignition hazards to petroleum storage, dispensing, or handling facilities may be created by emissions from electromagnetic devices such as radio and radar. Beam/signal strength has been known to cause ignition of flammable vapor-air mixtures from inductive electrical heating of solid materials or from electrical arcs or sparks from chance resonant connections. For additional information, refer to NAVSEA OP 3565/NAVAIR 16-1-529, MIL-STD-461 and NFPA 407. Contact the installation for radio tower locations and confirm with authority having jurisdiction. Incorporate the following specific precautions and restrictions in the design of petroleum fuel facilities:

a. Locate the radio transmitting antennas as far as practically possible from fuel storage or transfer areas.

b. Do not locate the fuel storage or transfer facilities closer than 300 feet (90 m) from aircraft warning radar antennas.

c. Do not locate fuel storage or transfer facilities closer than 500 feet (150 m) from airport ground approach and control system components.

d. Do not locate fuel storage or transfer facilities closer than 300 feet (90 m) from areas where airborne surveillance radar may be operated.

e. Do not locate fuel storage and transfer facilities closer than 100 feet (30 m) from airport surface detection radar system components.

2-17 IDENTIFICATION.

Identify all pipelines and tanks as to product service by color coding, banding, product names, NATO designation, and directions of flow in accordance with MIL-STD-161.

a. Mark valves, pumps, meters, and other system components with easily discernible painted numbers or numbered corrosion-resistant metal or plastic tags attached with a suitable fastener. Ensure numbers correspond to those on the schematic flow diagrams and other drawings for the installation.

b. Mark tanks with easily discernible painted numbers and letters indicating the following in addition to the requirements stated in MIL-STD-161: Tank number, Facility number, “No Smoking” on class 1 tanks, and “Confined Space” on Roof Manhole/Ladder Hatch

c. Mark tanks in accordance with NFPA 704.**\2**

d. Mark underground storage tanks as stated above. The markings must be sized appropriately as to be clearly visible form operating and emergency response positions. The markings must be positioned near the main vehicular or pedestrian access to the tank. The markings are not required to be the same sizing as required in MIL-STD-161. ***/2/***

2-18 ANTISTATIC DESIGN.

Consider static build-up in the design. Refer to CRC Report No. 346 and No. 355, API RP 2003; and UFC 3-460-03. Because of the many variables involved, such as properties of fuels and geometry of system component layouts, no specific limits are established for design factors such as flow velocities.

2-18.1 Piping Inlet Connections.

Design connections to tanks for reduced velocity and to prevent splashing by use of diffusers. Fuel products are not permitted to free fall under any circumstances. Position inlet as close to the tank floor as possible to limit free fall.

2-18.2 Enclosed Vapor Spaces.

Spaces above flammable or combustible Hydrocarbons in tanks or other liquid containers must not have any pointed projection or probes which could be focal points for static electricity discharges.

2-18.3 Filter-Separators.

The heaviest electrostatic charges are usually developed in filtering elements of this system component. The design should attempt to reduce such charges before fuel is transferred into storage tanks, vehicle tanks, or any system component containing vapor spaces.

a. By means of residence time in piping or in a relaxation tank, provide a minimum of 30 seconds relaxation time between this system component and discharging into a tank or vehicle. The only aviation turbine fuel currently in the inventory that requires this minimum relaxation time are JP-5, JPTS and other aviation turbine fuels that do not contain SDA.

b. Relaxation time is not required for projects handling only fuels containing a static dissipater additive (SDA) that provides a conductivity level greater than 50 conductivity units (50 picosiemens per meter) at the fuel temperature of the operations. Examples of this are JP-4 and JP-8.

c. **\2** Provide a means for slow filling through the sump, to prevent static discharge when first filling empty filter-separator vessels. Slow filling through the sump may be bypassed, depending on the type of system, fuel type, and Service Headquarters requirements. ***/2/***

2-18.4 Aircraft Direct Fueling Stations.

Fuel that has not been additized with SDA upon filtration (i.e. JP-5, JPTS, Jet-A, etc.) requires a 30-second residence time in the piping or in a relaxation tank after flowing through filtration and before being discharged into the aircraft to allow separate charges generated by the filtering elements to recombine and neutralize themselves. Where possible, design the piping layout to provide the required 30-second relaxation time without use of a relaxation tank.

2-18.5 Truck Bottom Loading.

Provide facilities only capable of bottom loading of trucks. Army facilities that routinely handle trucks that are not capable of bottom loading must obtain approval for the addition of top loading capability from the Army Service Headquarters. Refer to NFPA 77 and API RP 2003 for additional information and requirements.

2-19 OPERATION AND MAINTENANCE DOCUMENTATION.

2-19.1 Operation and Maintenance Documentation for Systems Components.

\3 In all construction and procurement contracts, require operation and maintenance data for pieces of system components which require maintenance and/or which require setting, adjusting, starting, stopping, calibrating, and similar operational activities. **/3/**

2-19.2 Operation and Maintenance Support Information (OMSI).

An OMSI for all new facilities is required. The determination to include a requirement for a complete OMSI for new facilities or a major rehabilitation will be made by the appropriate Service Headquarters.

2-20 PROTECTION AGAINST SEISMIC ACTIVITY.

Design fuel facility buildings and structures for seismic requirements in accordance with UFC 1-200-01. Design aboveground vertical storage tanks in accordance with Appendix E of API Std 650. Analyze flexible aboveground pipelines using techniques to account for harmonic response.

2-21 STRUCTURAL DESIGN.

Design all buildings and structures in accordance with UFC 1-200-01. General risk categories for fuel facilities are to be in accordance with UFC 3-301-01. The risk categories are:

a. II for operations buildings, canopies, truck load/off-load facilities and similar structures.

b. III for storage tanks**\1**, pumphouses, filter buildings, and control rooms.**/1/**

2-22 CANOPIES.

2-22.1 Canopies to Protect Fixed Assets from Extreme Weather Conditions.

Unless otherwise directed by Service Headquarters, provide a canopy to protect fixed facility assets, operators, and system components from extreme weather conditions. Fixed facilities and system components include but are not limited to: pump pads, filtration pads, meter pads, isolation valve pads, tank truck and tank-car off-loading and loading system component pads, control panels, electrical panels, and motor control centers (MCCs). Ensure structural design is in accordance with UFC 1-200-01 and UFC 3-301-01.

2-22.2 Extreme Weather Condition for Canopies.

The following table provides a guide for determining extreme weather locations where fixed assets, operators and system components should be protected. UFC 3-400-02 provides information on Design Engineering Weather Data. Table 2-8 provides the lower condition limit for each of the Design Engineering Weather Data provided by UFC 3-400-02. A canopy should be considered if the Design Weather Data at the facility meets at least one of the weather data criteria limit.

Table 2-8. Design Engineering Weather Data for Canopies

Weather Data	Criteria	Limit	Limit
Dry Bulb High Temperature	2.0% occurrence	89 °F	32 °C
Mean Daily Range		18 °F	-8 °C
Rain Rate	100 year occurrence	3.6 in/hr	91 mm/hr
Ground Snow	50 year occurrence	25 lb/ft^2	122 kg/m^2

2-22.3 Canopies to Reduce Stormwater.

Do not provide a canopy to preclude rain from reaching the containment area unless it is required by federal, state, or local regulations or if directed by Service Headquarters.

2-22.4 Canopies to Reduce Temperature.

If canopy is intended to protect against direct sunlight, then a solar angle analysis should be performed and the overhang increased if warranted by such analysis. The solar angle analysis should consider the angle of the sun at different times of the day in relationship to the asset being protected during the months when the temperature exceeds the value provided in Table 2-8.

2-22.5 General Canopy Construction.

Canopy edges should overhand the edge of the equipment, facility, or personnel to be protected. To provide adequate protection from precipitation, such overhang should extend at least 4 feet (1.2 m) horizontally for every 10 feet (3 m) of canopy height. At a canopy over a tank truck or tank car loading and off-loading containment area, ensure that the underside of the canopy is high enough to provide headroom for personnel when access is required on top of the truck or car. Ensure structural design is in accordance with UFC 1-200-01 and UFC 3-301-01.

For personnel safety, access to the top of tank trucks or tank cars should not be allowed for loading and off-loading operations. If local circumstances dictate that personnel must routinely gain access to the top of tank trucks or tank cars, at loading and/or off-loading facilities or other locations with canopies, a fall protection system must be provided that is designed to meet all OSHA standards./1/

2-23 CONCRETE.

Concrete where used in this UFC refers to cast-in-place, Portland Cement Concrete (PCC), reinforced as required, finished, and cured. The use of coated or uncoated bituminous asphalt concrete (asphalt), “shotcrete”, or autoclaved cellular concrete (ACC) in its place is prohibited.

2-24 AIRFIELD/AIRSPACE REQUIREMENTS.

Incorporate requirements for airfield and airspace clearances into all construction documents for work near an airfield. Verify compliance with UFC 3-260-01.

2-25 PERMITS.

The planner, programmer, and designer should give consideration to required permits (dredging, air emissions, water discharges, etc.). For all locations, consideration should also be given to storage tank system registration and fuel system operational permit/plan requirements. Considerations are cost of permit, cost impact of project to meet permit requirements, schedule impact of permit, who is to obtain permit, and at what time in the project schedule should application be made.**\2**

2-26 COMMISSIONING AND START-UP.

The designer must include the requirement and the capability for commissioning, equipment performance testing, and start-up of the entire fueling system following the construction. **/2/**

This Page Intentionally Left Blank

CHAPTER 3 BULK FUEL STORAGE FACILITIES

3-1 INTRODUCTION.

This chapter provides guidance for the design of bulk fuel storage facilities, including bulk storage tanks and those components normally located within a typical bulk storage compound. These components include pipeline receiving facilities, tank truck and tank car receiving facilities, pipeline dispensing (pumping) facilities, tank truck and tank car loading facilities, and all related piping and system components. Fuel storage tanks are discussed in Chapter 8 and piping systems in Chapter 9 of this UFC. Support facilities, which are discussed in Chapter 11 of this UFC, are often collocated within bulk facilities. Systems used to receive and dispense aviation turbine fuels are discussed in Chapter 4 of this UFC. Systems used to receive and dispense fuel from barges and ships are discussed in Chapter 5 of this UFC. Installation pipelines connecting bulk facilities with marine receiving and dispensing facilities, aircraft fueling facilities, and ground vehicle fueling facilities, as well as interterminal pipelines are discussed in Chapter 6 of this UFC. Refer to Facility Plate 001 for the entire chapter identification plan pertaining to this UFC.

Note: If aviation fuel can be pumped directly from a tank into an aircraft, aircraft direct fueling system or a refueler, treat the tank as an operating storage tank regardless of size and location and must meet the applicable requirements for aviation turbine fuel operating tanks. The exception is bulk storage tanks that are configured to fill refuelers on an emergency basis only.

3-2 GENERAL REQUIREMENTS.

Chapter 2, General Design Information, contains important information on fueling facilities. Do not begin the design of any fueling system without first becoming completely familiar with Chapter 2 and Chapter 9 of this UFC.

3-2.1 Custody Transfer.

Custody transfer generally takes place at the following locations:

a. Every pipeline receipt station.

b. Every tank truck and tank car loading and offloading position.

c. Every marine loading and offloading system.

3-3 RECEIVING FACILITIES.

Fuel is normally received at bulk fuel storage facilities by pipeline, tank truck, tank car, barge, or ship. In many cases, the fuel is pumped by pipeline from the marine receiving facility to the bulk storage facility. Marine receiving facilities are addressed in Chapter 5 of this UFC. Service Headquarters, with concurrence from the DLA-Energy, will determine the appropriate type of delivery method based on mission requirements and an economic analysis. A secondary method of delivery is normally required for aviation activities.

3-3.1 Pipeline Receiving Facilities.

3-3.1.1 General Criteria.

Petroleum fuels may be supplied to bulk fuel storage tanks by interterminal pipelines which may be dedicated to serving the particular facility or may be commercial pipelines handling a number of types or grades of fuel for more than one user. In some cases, the pipeline will be an installation pipeline. If different fuel types are used, separate each type within the receiving facility. Exercise extreme care to avoid designing a system that could create damaging surges in the pipeline created by quick closing valves.

3-3.1.2 Required System Components.

a. Provide pressure-regulating diaphragm control valves to reduce pipeline pressures to the design pressure of the facility's piping and system components. Provide a manual isolation valve at both the upstream and downstream side of each diaphragm control valve. Prior to designing any features into the system which might affect the flow from a pipeline, contact the operator of the pipeline to ascertain the current operating conditions, evaluate the use of diaphragm control valves, conduct a surge analysis of the pipeline, and determine whether the use of diaphragm control valves is appropriate.

b. Provide a meter at the receiving end of the line to measure quantities of fuel received. Turbine-type meters are commonly used for pipeline receipt above 1200 gpm because of the cost of large positive displacement meters. However, positive displacement meters are acceptable if available at the required flow rate. Compensate for fuel temperature at the point of custody transfer. Provide a basket strainer immediately upstream of the meter and connections for proving the meter with a portable prover. A meter prover connection consists of a manual isolation valve in the main pipeline with a tee on both the upstream and downstream sides of the valve. The branch of each of the tees has a manual isolation valve and a hose connection. The master meter can be attached to the hose connections.

c. Provide a means for sampling each pipeline product at a breakout manifold.

d. Provide provisions for maintenance and ILI pigging on interterminal pipeline receipt location. Consult Service Headquarters for arrangements required to meet commercial pipeline agreements. Provide ILI launcher and receiver on government owned interterminal pipelines. Arrange pig receiving connections to avoid introducing pipeline sludge and sediment into the tanks. Pig launching and receiving provisions are required for interterminal (cross-country) and installation (as described in Chapter 6 of this UFC) underground pipelines.

e. Provide an interface tank to receive mixed fuels at the beginning and ending of a shipment unless the commercial pipeline company can provide this service satisfactorily.

f. Provide a breakout tank only if pipeline flow cannot be stopped due to pipeline operational requirements. Provide valves to divert the flow of fuel from the pipeline to the breakout tank in the event fuel transfer is blocked by a manual or automatic valve within the fuel facility system such that the fuel facility system would be over pressurized from transient surge or high pressure from deadheading a pipeline supply pump. Provide appropriate breakout tank overfill alarms and alarm breakout operation so fuel facility operators can take necessary steps to stop pipeline flow. Provide means of transferring fuel out of breakout tank back to fuel systems after a breakout event. Conduct a thorough review with the pipeline operator and perform a transient surge analysis to determine if surge pressure reduction methods are required to avoid damage to the pipeline. Consider multiple factors when determining size of breakout tank. Factors shall include ability of receiving facility to recognize excursion (over pressure event), ability to notify source of transfer to shutdown pipeline pumps, impact of deadheading pipeline pump, and factor of safety. Increased confidence of ability to shutdown pumps, via receipt pressure sensors with rate of rise PLC assessment, communication to transfer source via fiber optics communication, and automatic transfer pump shutdown will lead to smaller sized breakout tanks. Whereas reliance on receipt staff to respond to alarm and notify source pumpstation via telephone will lead to larger sized breakout tank. Consideration shall also be given to type of surge breakout system, such as side stream pressure relief versus rapid full opening surge dump valve. As a minimum, the surge breakout tank must be sized such that its ullage volume, above a minimum heal level, can safely store not less than two times the volume of fuel resulting from a release event, but not less than two times the receipt volume for a 10-minute flow at normal pipeline flow. When sizing breakout tanks also consider using aboveground shop fabricated UL listed tanks, and that increasing the tank size (and thus safety factor of release) very often is a small cost, compared to the cost of release cleanup. Contact Service Headquarters for design considerations and approval of surge breakout tank system approval.

g. Provide means of inbound filtration for all products. The selection of filtration depends on anticipated impurities, the source of fuel, and the shipping methods. Consider the use of filter-separators, micronic filters, and Haypack coalescers as possible filtration devices. Avoid the use of water slug shutoff diaphragm control valves or other rapid-closing valves on pipeline receipt facilities. For inbound filtration of aviation turbine fuels, refer to "Special In-Bound Filtration" paragraph of Chapter 4 of this UFC.

When a water slug shutoff is not provided, provide sump water detector and alarm panel.

h. Provide manual isolation valves to isolate system components for service.

i. Provide basket strainers immediately upstream of pumps, meters and receipt filtration. On piggable pipeline receipt, provide two parallel strainers with isolation valves so pigging can continue while cleaning one strainer.

j. Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

k. Provide a concrete housekeeping pad **\1** , and a canopy for protection from the elements of fixed facility assets and system components in accordance with paragraph 2-22. **/1/**

3-3.2 Tank Truck and Tank Car Off-loading Facilities.

3-3.2.1 General Criteria.

Bulk fuel storage tanks may be supplied with fuel by tank truck or tank car or both. At facilities with pipeline or water transport as their principal supply source, provide tank truck or tank car deliveries as a secondary supply source. Tank truck deliveries are the most common method. However, special transportation considerations or changing circumstances may make the use of rail facilities desirable. Therefore, at an activity with railroad service, arrange a tank truck receiving facility so that the system can be easily and economically extended to the existing rail spur. See Facility Plate 002.

a. The preferred off-loading method is into a drop tank off-loading system. See Facility Plate 003.

b. Provide a packaged off-loading system when a drop tank type off-loading system is not practical for off-loading tank trucks or tank cars due to environmental concerns, site limitations, or cost considerations, and/or when directed by Service Headquarters. See Facility Plate 004.

c. Provide a direct off-loading system when only an occasional tank truck requires off-loading and when directed by Service Headquarters. See Facility Plate 005.

d. Do not locate tank truck or tank car receiving facilities closer than 50 feet (15 m) from buildings, roads, overhead power lines, pad-mounted transformers, and installation property lines, and 25 feet (7.6 m) from the installation interior fence surrounding the fuel farm. See Chapter 8 of this UFC for clearance requirements from tanks.

e. Provide an adequate number (minimum two) of positions to off-load the daily fuel requirements of the facility in an 8-hour period without causing detention or demurrage of delivery conveyances.

f. Provide separate off-loading connections for each type of fuel to be handled. To facilitate the use of tank trucks with multiple independent compartments, provide a hose manifold with a minimum of two connections per tank truck. A manifold with hose connections equal to the number of truck compartments is recommended for quick turnaround. If less than five connections are provided, provide a blind flange on the end of the manifold to accommodate additional connections.

g. Provide a containment area at each truck off-loading position consisting of an impermeable retention and controlled drainage system leading to a concrete remote spill containment system. Pave the containment area consisting of the islands, the spaces between islands and on each side of the outer islands, with concrete pitched a minimum of one percent toward catch basins or trench drains. Design the containment area in accordance with UFC 1-200-01, federal, state, and local regulations. Do not use asphalt within a spill containment area. The maximum slope of any paving within a truck movement or parking area must not exceed 2 percent excepting ramps. If a ramp is provided, the sum of the vertical entrance and exit grades must not exceed 8 percent and the ramp must be aligned perpendicular with direction of truck movement. The designer must assure that adequate ground clearance is achieved for all vehicles utilizing the containment areas.

h. Provide spill containment at each rail tank car off-loading position consisting of an impermeable containment system surrounding the rail car with drainage leading to a concrete remote spill containment basin. Pave the offload equipment area and space between the offload equipment and rail car containment system with concrete sloped a minimum of one percent toward a drainage collection system that leads to the concrete remote spill containment basin.

i. Provide a concrete remote spill containment system for each containment area. Design the remote spill containment system in accordance with UFC 1-200-01, federal, state, and local regulations. Provide the remote spill containment system with capacity greater than the volume of the largest tank truck or tank car compartment to be off-loaded. The top elevation of the remote spill containment basin must not be set less than 6-inches above the top of the refueler truck parking area's maximum ponding elevation. This will prevent overflow of the remote spill containment basin during a heavy rain event. A curbed truck position may be provided in addition to a remote system. Twenty-five percent or more of the total required containment volume must be directed to, and stored at, the remote system before any of the shared containment volume will pond at the truck stand area. Provide a lockable eccentric plug valve with indicator post located outside the containment area at a location that will be safely accessible during a fire. The valve must be lockable and normally closed to allow for containment during fueling operations and which can be opened to drain the area when necessary. Tank trucks can be as large as 10,000 gallons (38,000 L) in capacity and tanks cars as large as 40,000 gallons (150,000 L). Consider combining the remote spill containment system with other spill containment systems on-site, except with tank containment systems. However, take the level of contamination in each containment area into consideration.

j. Construct the drain piping between the containment area and the remote spill containment system, and between the remote spill containment system and lockable plug valve of petroleum-resistant, impermeable materials with water-tight joints such as ductile iron or HDPE pipe with fusion welded joints. Do not use clay, concrete, or fiberglass piping materials.

k. For off-loading tank trucks, arrange the flow of traffic to permit continuous forward movement of tank trucks at all times. Commercial tank trucks off-load on the passenger side.

l. Tank truck configurations vary. Key variables are: the number of compartments per tank, single or multiple trailers, location of connections on each trailers, height of trailer connections, etc. Designer must coordinate with the installation and Service Control Point regarding the type of delivery trucks used at the installation.

m. To determine the number of connections needed for off-loading tank cars, consult with Service Headquarters and consider minimizing tank car movements, tank car shipping schedules, conveyance turn-around times, local rail switching capabilities, and quantity of fuel needed for one day's fuel supply.

n. Provide an electrical design that meets the minimum requirements of NFPA 70, NFPA 77, and NFPA 780. Treat combustible liquids under pressure as a flammable liquid.

o. Provide a canopy for protection from the elements of fixed facility assets and system components **\1** in accordance with paragraph 2-22. **/1/**

p. Provide a canopy to preclude rain from the containment area **\1** in accordance with paragraph 2-22. **/1/**

q. Provide for egress and entrance of emergency response vehicles. The egress and entrance routes need to be large enough to allow both, trucks and emergency vehicles, leaving and entering the facility.

r. When directed by Service Headquarters, provide means of inbound filtration for all products. The selection of filtration depends on anticipated impurities, the source of fuel, and the shipping methods. Consider the use of filter-separators, micronic filters, and Haypack coalescers as possible filtration devices. For inbound filtration of aviation turbine fuels, refer to Chapter 4 of this UFC.

3-3.2.2 Tank Truck and Tank Car Drop Tank Off-Loading System.

The introduction of air into a fuel receiving system poses extreme hazards which can result in fire and/or explosion. Hazards are compounded when an air/fuel mixture is passed through receipt filter-separators where static electricity is generated and ignition can occur. Design off-loading facilities so air is not introduced into the system. For facilities with the capability to off-load several tank trucks at once or where newer tank trucks with multiple hoses are connected to multiple isolated compartments, consider providing an underground, gravity-type, receiving tank with submersible transfer pumps and level controls. For smaller systems of one or two tank trucks, consider a low profile, aboveground, receiving tank with a centrifugal transfer pump. For either case, provide level sensors to control the transfer flow rate. Provide a temperature compensated meter on the receipt line to the tank at points of custody transfer and when directed by Service Headquarters. For materials of construction for off-loading drop tanks, refer to Chapter 8. See Facility Plate 003.

3-3.2.3 Tank Truck and Tank Car Packaged Off-Loading System.

For tank truck or tank car off-loading, an off-loading drop tank may not be practical due to environmental concerns, site limitations, or cost considerations. In these instances, provide a 600 gpm (38 L/s) packaged off-loading system. Provide one packaged system, including vertical inline centrifugal pump, diaphragm control valves to control flow, meter, and multiple hose connections (one for each tank truck compartment), for each tank truck or tank car receiving station. Provide an air eliminator tank to remove air from the system, reducing the risk of an air/fuel mixture passing through receipt filter-separators and preventing the metering of air. Level sensors in the air eliminator tank control the pump discharge diaphragm control valves, modulating the flow rate based on the level in the air eliminator tank. Refer to DoD Standard Design AW 078-24-28 and Facility Plate 004.

3-3.2.4 Tank Truck and Tank Car Direct Off-Loading System.

Use when only an occasional tank truck requires off-loading and when directed by Service Headquarters. Refer to Facility Plate 005

3-3.2.5 Required System Components.

a. When tank trucks or tank cars are off-loaded with a drop tank off-loading system, do not provide an off-loading pump. Provide at least two pumps in the drop tank to transfer fuel to the storage tank.

b. When tank trucks or tank cars are off-loaded with packaged off-loading systems, provide one system for each tank truck or tank car that is to be off-loaded simultaneously, at an average capacity of 600 gpm (38 L/s) each. The number of systems will be determined by Service Headquarters but must be a minimum of two. The capacity of the systems may be reduced to 300 gpm (19 L/s) each only when directed by Service Headquarters.

c. When tank trucks or tank cars are off-loaded with direct off-loading systems, provide centrifugal pumps configured to provide automatic air elimination as shown on Facility Plate 005. Provide at least two pumps to allow continued operation if one is out of service. The capacity of the pumps may be increased to 600 gpm (38 L/s) each only when directed by Service Headquarters. The centerline height of suction line from manifold to pump generally should not exceed 23.25 inches (591 mm) above truck unloading, parked position. Confirm this with the activity; in western CONUS, trucks tend to have lower connections. Locate the pump as close as possible to the off-load point to prevent suction problems.

d. Provide lightweight reinforced vacuum rated off-loading hoses and covered hose storage racks for each hose connection at each off-loading position. Eliminate covered hose storage rack if off-load rack is to be covered by a canopy. Ensure that all swivels are non-lubricated aluminum or stainless steel in-line repairable type. Consult with activity to verify the need for hoses, since at some locations, the fuel hauling contractor provides the hoses.

e. Equip each tank truck off-loading position with an electronic, intrinsically safe, automatic, self-monitoring ground verification unit with a lockable bypass. If grounding is not verified and there is an off-loading pump dedicated to that position, ensure the unit prevents the pump from starting. If the pump is not dedicated, ensure an alarm sounds if the off-loading valve is opened prior to grounding verification. Include a separate grounding reel to accommodate vehicles without grounding system components.

f. Provide emergency fuel shutoff (EFSO) pushbutton stations. For truck off-loading stations with multiple positions, an EFSO pushbutton station is required for each position and along routes of personnel ingress and egress between 100 and 200 feet (30 m and 60 m) from the off-loading position. Design in such a manner that activation of the emergency stop will shut off all fueling in the off-loading area and/or the associated pumphouse or pump pad.

g. Provide fuel sampling connections at each position for each product line for collecting test samples.

h. Provide pressure gauges on both sides of each strainer or a differential type gauge across each strainer. Where a strainer is upstream of a pump, the pump suction gauge may function as the strainer downstream gauge.

i. Provide a compound (pressure/vacuum) gauge on the inlet side of pumps and a pressure gauge on the outlet side of pumps.

j. If the system is for JP-5 or other fuel that does not have a static dissipater additive (SDA) which provides a conductivity level greater than 50 conductivity units (50 picosiemens per meter), and a 30-second retention time is not provided between filter-separator and receiving tank, provide a relaxation tank downstream of the filter-separator or design the piping layout to provide the required 30-second relaxation time downstream of filter-separator.

k. Provide basket strainers immediately upstream of pumps, meters, and receipt filtration. Provide duplex straining (two individual basket strainers and isolation valves) on pipeline receipts, including interterminal and installation pipelines upstream of receipt filtration.

l. Provide a combination flow control and non-surge check diaphragm control valve on all off-loading pumps except positive displacement types. If a bulk air eliminator with automatic air release head is included, provide a means of closing the diaphragm control valve with a solenoid pilot.

m. Provide a positive displacement or turbine meter. Provide meter with temperature compensation capability and meter proving connections at each offload position (custody transfer location). Provide a basket strainer immediately upstream of the meter.

n. On each off-loading connection or on the off-loading riser, install a visual fuel flow indicator (maximum pressure 275 psi (1900 kPa) at 100 degrees F (38 degrees C), with Viton Seals with a maximum temperature rating of 350 degrees F (177 degrees C)). This will allow visual quality assurance and provide the operator with a backup system to shut off the pumps when off-loading is complete to prevent air build-up in the receipt lines.

o. Provide manual isolation valves to isolate system components for service.

p. Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

q. Where tank trucks or tank cars are off-loaded into drop tanks, provide meters on the downstream side of the drop tank pumps.

r. When directed by Service Headquarters, provide means of inbound filtration for all products. The selection of filtration depends on anticipated impurities, the source of fuel, and the shipping methods. Consider the use of filter-separators, micronic filters, and Haypack coalescers as possible filtration devices. For inbound filtration of aviation turbine fuels, refer to Chapter 4 of this UFC.

3-3.3 Marine Off-Loading Facilities.

See Chapter 5 of this UFC.

3-4 DISPENSING FACILITIES.

Fuel is normally dispensed from a bulk facility via an installation pipeline, interterminal pipeline, tank truck, or tank car.

3-4.1 Pipeline Pumping Facilities.

3-4.1.1 General Criteria.

As discussed in Chapter 6 of this UFC, pipelines are either interterminal pipelines or installation pipelines. Installation pipelines are commonly used to transfer fuel to an aircraft fueling facility or a marine dispensing facility. Interterminal pipelines are cross-country between installations. However, since pipeline pumping facilities are typically at a bulk fuel storage facility, they are covered in this chapter.

3-4.1.2 Required System Components.

a. Centrifugal pumps complying with API Std 610 with adequate head and capacity. Always provide one additional pump as back up.

b. Turbine or positive displacement meter with proving connections. Compensate for fuel temperature at custody transfer point.

c. Provide fuel sampling connections for collecting test sample.

d. Pig launching and receiving capability for interterminal and installation pipelines.

e. Strainer immediately upstream of meters and pumps.

f. Manual double block and bleed isolation valves where total isolation is required.

g. Pressure gauges on both sides of the strainer or a differential pressure type gauge across the strainer.

h. Compound (pressure/vacuum) gauges on the inlet side of pumps and pressure gauges on the outlet side of pumps.

i. Provide a combination flow control and non-surge check diaphragm control valve on all pumps except positive displacement types. If a bulk air eliminator with automatic air release head is included, provide a means of closing the diaphragm control valve with a solenoid pilot.

j. Provide manual isolation valves to isolate system components for service.

k. Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

l. Provide a concrete housekeeping pad **\1** , and a canopy for protection from the elements of fixed facility assets and system components in accordance with paragraph 2-22. **/1/**

m. When directed by Service Headquarters, provide means of filtration for all products. The selection of filtration depends on anticipated impurities, the source of fuel, and the shipping methods. Consider the use of filter-separators, micronic filters, and Haypack coalescers as possible filtration devices. For filtration of aviation turbine fuels, refer to Chapter 4 of this UFC.

3-4.2 Tank Truck and Tank Car Loading Facilities.

3-4.2.1 General Criteria.

This chapter applies to facilities required for loading over-the-road tank truck transports or rail tank cars used for the bulk transfer of fuel. A typical application is the transfer by tank truck from a storage terminal to secondary storage, such as a filling station or a heating plant. In many cases, the receiving and loading facilities are combined. In these cases, both receiving and loading facility requirements must be addressed. This chapter does not include facilities for loading aviation refuelers for direct issue to aircraft. This process requires special design considerations as discussed in Chapter 4 of this UFC. See Facility Plates 002, 003 and 005.

a. Determine the volume of fuel and number of tank trucks or tank cars to be handled by an operational analysis with assistance from Service Headquarters.

b. Do not locate tank truck or tank car loading facilities closer than a minimum of 50 feet (15 m) from buildings, roads, overhead power lines, pad-mounted transformers, and installation property lines, and 25 feet (7.6 m) from the installation interior fence surrounding the fuel farm. Do not locate a tank truck loading facility closer than 100 feet (30 m) from a railroad track (or spur) or rail siding for loading/offloading. See Chapter 8 of this UFC for clearance requirements from tanks.

c. Bottom loading is the only acceptable method of loading tank trucks. Bottom loading results in increased safety, manpower savings, quality control of product, and area cleanliness. At non-U.S. locations where only contracted top loading tank trucks are available, install a top loading rack with an elevated steel platform with approval of Service Headquarters. In this event, provide future bottom loading capabilities.

d. Provide a containment area at each truck loading position consisting of an impermeable retention and controlled drainage system leading to a concrete remote spill containment system. Pave the containment area consisting of the islands, the spaces between islands and on each side of the outer islands, with concrete pitched a minimum of one percent toward catch basins or trench drains. Design the containment area in accordance with UFC 1-200-01, federal, state, and local regulations. Do not use asphalt within a spill containment area. The maximum slope of any paving within a truck movement or parking area must not exceed 2 percent excepting ramps. If a ramp is provided, the sum of the vertical entrance and exit grades must not exceed 8 percent and the ramp must be aligned perpendicular with direction of truck movement. The designer must assure that adequate ground clearance is achieved for all vehicles utilizing the containment areas.

e. Provide spill containment at each rail tank car loading position consisting of an impermeable containment system surrounding the rail car with drainage leading to a concrete remote spill containment basin. Pave the offload equipment area and space between the offload equipment and rail car containment system with concrete sloped a minimum of one percent toward a drainage collection system that leads to the concrete remote spill containment basin.

f. Provide a concrete remote spill containment system for each containment area. Design the remote spill containment system in accordance with UFC 1-200-01, federal, state, and local regulations. Provide the remote spill containment system with capacity greater than the volume of the largest tank truck or tank car compartment to be off-loaded. The top elevation of the remote spill containment basin must not be set less than 6-inches above the top of the refueler truck parking area's maximum ponding elevation. This will prevent overflow of the remote spill containment basin during a heavy rain event. A curbed truck position may be provided in addition to a remote system. Twenty-five percent or more of the total required containment volume must be directed to, and stored at, the remote system before any of the shared containment volume will pond at the truck stand area. Provide a lockable eccentric plug valve with indicator post located outside the containment area at a location that will be safely accessible during a fire. The valve must be lockable and normally closed to allow for containment during fueling operations and which can be opened to drain the area when necessary. Tank trucks can be as large as 10,000 gallons (38,000 L) in capacity and tanks cars as large as 40,000 gallons (150,000 L). Consider combining the remote spill containment system with other spill containment systems on-site, except with tank containment systems. However, take the level of contamination in each containment area into consideration.

g. Construct the drain piping between the containment area and the concrete remote spill containment system, and between the remote spill containment system and lockable eccentric plug valve of petroleum-resistant, impermeable materials with water-tight joints such as ductile iron or HDPE pipe with fusion welded joints. Do not use clay, concrete, or fiberglass piping materials.

h. Provide a canopy for protection from the elements of fixed facility assets and system components **\1** in accordance with paragraph 2-22. **/1/**

i. Provide a canopy to preclude rain from the containment area **\1** in accordance with paragraph 2-22**. /1/**

j. Provide separate piping, pumps, loading connections, and controls for each different type and grade of fuel.

k. Provide electrical systems and apparatus that are properly rated for the environment in which they are installed. Hazardous areas are established in Chapter 2 of this UFC. Installation shall be as required by NEC.

l. Arrange loading rack with a row of islands with sufficient clearance between to allow easy access to all parts of the tank trucks when parked. Arrange islands and approaches in a manner that allows forward motion for all tank trucks at all times with ample room for turning. Space and arrange bottom loading islands to accommodate one tank truck only on the side adjacent to the tank truck's liquid connections, usually the passenger side of the tank truck.

m. Provide for entrance and egress of emergency vehicles. The egress and entrance routes need to be large enough to allow both trucks and emergency vehicles to leave and enter the facility.

n. If top loading is required for tank cars (normally only when commercial contract leaves no other choice) and approved by Service Headquarters, provide a typical tank car loading rack with an elevated steel platform, consisting of a walkway, 4 feet (1.2 m) wide, 10.5 feet (3.2 m) above the top of the rails, and the full length of six tank cars. Ensure that the centerline of the structure is 10.5 feet (3.2 m) above the centerline of the tracks. Equip the platform with a counterweighted or spring-loaded tilting bridge to connect to the tank car dome at each loading station. Design so that when released from the horizontal position, the bridge will automatically move and lock in an upright position away from any part of the tank car under all weather conditions. Ensure conformance with UFC 1-200-01 requirements.

3-4.2.2 Required System Components for Tank Truck Fillstand.

a. Provide a positive displacement or turbine meter for each tank truck fill connection. Protect each meter with a basket strainer located immediately upstream of the meter. Include temperature compensation if rack is to be point of custody transfer. At DFSPs, consider providing meter with preset functions that will shut down the flow by closing the truck loading control valve upon issue of a preset quantity of fuel. To ensure proper operation, meter and control valve must be supplied as a packaged system and installed by a single system supplier.

b. Provide a sample outlet with probe, ball valve, and quick disconnect at each position for each product line.

c. Provide pressure gauges on both sides of the strainer or a differential pressure type across the strainer.

d. Self-closing emergency valve with 165 degrees F (74 degrees C) fusible link. (These valves are neither required nor permitted on Air Force projects).

e. Make provisions to start and stop the pumps with start and stop pump control stations at each position. Include pump status indicator light on control box.

f. Provide a solenoid operated truck loading diaphragm control valve with opening/closing speed control, pressure regulating, check and solenoid shut-off features. Interlock the solenoid with the electronic high-level shutoff, and electronic ground verification control system.

g. Provide each fill position with an electronic high-level shutoff, electronic ground verification, and electronic or hydraulic deadman control system. The system must be intrinsically safe and self-checking. Interlock the system with either the solenoid operated truck loading diaphragm control valve or the pump such that the valve cannot remain open or the pump cannot operate if the tank truck compartment is full, the tank truck is not bonded to the fueling system components, or the deadman is released. Ensure the system is compatible with both electronic and fiber optic sensors with manual-keyed bypass. (May require a parallel effort beyond the project scope to ensure that all trucks using the facility have compatible connections. If facility has trucks that do not have fixed probes, use cane probes instead.) (This unit is optional on Army projects with only tactical refuelers. Contact the Service Headquarters for guidance.)

h. Provide emergency fuel shutoff (EFSO) pushbutton stations. For fillstands with multiple positions, an EFSO pushbutton station is required for each position and along routes of personnel ingress and egress between 100 and 200 feet (30 m and 60 m) from the fillstand. Design in such a manner that activation of the emergency stop will shut off all fueling at that pump house or pump pad.

i. Equip liquid connections to tank trucks for bottom loading with drybreak couplers in accordance with API RP 1004.

j. Refer to Chapter 2 of this UFC for guidelines on vapor collection and recovery or disposal systems.

k. Provide heaters and insulated, heated pipelines, as required, where viscous fuels are to be loaded to maintain the temperature of the fuel at its minimum pumping temperature.

l. Provide stainless steel loading arms (pantograph, without hoses) equipped with non-lubricated swivels may be used instead of hoses, if approved by Service Headquarters. Ensure all swivels are non-lubricated, stainless steel in-line repairable type.

m. Provide meter proving connections as described in the paragraph titled “Pipeline Receiving Facilities”, unless local procedure provides an alternative.

n. Provide relaxation tank or piping configuration with sufficient capacity to retain the maximum flow of the loading station for 30 seconds from the time the fuel leaves the last piece of filtration system component to the fuel reaching the loading nozzle. Applies only to JP-5, Jet A and other fuels which do not have a static dissipation additive that provides a conductivity level greater than 50 picosiemens.

o. Provide basket strainer immediately upstream of meters and pumps.

p. Provide manual isolation valves to isolate system components for service.

q. Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

r. Grounding/bonding reel (provided as an integral part of the high level shutoff system).

s. Provide hydraulic shock surge suppressors (if required).

t. When directed by Service Headquarters, provide means of filtration for all products. The selection of filtration depends on anticipated impurities, the source of fuel, and the shipping methods. Consider the use of filter-separators, micronic filters, and Haypack coalescers as possible filtration devices. For filtration of aviation turbine fuels, refer to Chapter 4 of this UFC.

3-4.2.3 Required System Components for Tank Car Loading Station.

a. Provide a positive displacement or turbine meter for each tank car fill connection. Protect each meter with a basket strainer located immediately upstream of the meter. Include temperature compensation if rack is to be point of custody transfer.

b. Provide meter proving connections as described in the paragraph titled “Pipeline Receiving Facilities”, unless local procedure provides an alternative.

c. Provide a sample outlet with probe, ball valve, and quick disconnect at each position for each product line.

d. Provide pressure gauges on both sides of the strainer or a differential pressure type across the strainer.

e. Provide fusible link butterfly isolation valves as the first piece of system component (in the direction of the flow) on the loading position. (These valves are neither required nor permitted on Air Force projects).

f. Provide loading connections, controls, valves, etc., on one or both sides of the loading platform as specified by Service Headquarters. Load tank cars from the bottom using counterbalanced, articulated tank car loading assemblies.

g. Provide an electronic, intrinsically safe, portable liquid high level sensor with adjustable height at each loading rack. To prevent an overfill, interlock the sensor with the electronic high-level shutoff and electronic ground verification control system.

h. Provide each fill position with an electronic high-level shutoff, electronic ground verification, and electronic or hydraulic deadman control systems. The system must be intrinsically safe and self-checking. Interlock the system with either the solenoid operated tank car loading diaphragm control valve or the pump such that the valve cannot remain open or the pump cannot operate if: the tank car is full, the tank car is not bounded to the fueling system component, or the deadman is released. Provide the capability to connect the ground verification rack to the rail tank car frame.

i. Provide emergency fuel shutoff (EFSO) pushbutton stations. For tank car loading stations with multiple positions, an EFSO pushbutton station is required for each position and along routes of personnel ingress and egress between 100 and 200 feet (30 m and 60 m) from the tank car loading station. Design in such a manner that activation of the emergency stop will shut off all fueling at that pump house or pump pad.

j. Provide solenoid operated tank car loading diaphragm control valve with opening/closing speed control, pressure regulating, check, and solenoid shut-off features. Interlock the solenoid with the electronic high-level shutoff, and electronic ground verification control system.

k. Provide a basket strainer immediately upstream of meters and pumps.

l. Provide manual isolation valves to isolate system components for service.

m. Provide thermal relief valves around isolation and check valves to relieve excessive pressures caused by thermal expansion of liquid trapped between shutoff points. See Facility Plates 020, 021, 022 and 023.

n. Provide relaxation tank or piping configuration with sufficient capacity to retain the maximum flow of the loading station for 30 seconds from the time the fuel leaves the last piece of filtration system component to the fuel reaching the loading nozzle. Applies only to JP-5, Jet A and other fuels which do not have a static dissipation additive that provides a conductivity level greater than 50 picosiemens.

o. Provide hydraulic shock surge suppressors (if required).

p. When directed by Service Headquarters, provide means of filtration for all products. The selection of filtration depends on anticipated impurities, the source of fuel, and the shipping methods. Consider the use of filter-separators, micronic filters, and Haypack coalescers as possible filtration devices. For filtration of aviation turbine fuels, refer to Chapter 4 of this UFC.

3-4.3 Marine Loading Facilities.

See Chapter 5 of this UFC.

3-5 PIPING SYSTEMS.

Refer to Chapter 9 of this UFC for more information regarding piping systems.

3-5.1 Product Segregation.

Except as otherwise approved by Service Headquarters provide separate receiving, storage, and distribution systems for each product. Except as otherwise approved by Service Headquarters, prevent misfueling (transferring a type of fuel other than the type intended) by using different size piping, valves, adaptors, nozzles, etc.

3-6 DESCRIPTION OF SYSTEMS COMPONENTS.

The appropriate guide specification and/or standard design provides specific information for selection of system components. Make provisions to drain system components for maintenance. Provide hardpiped drains when a system component holds more than 5 gallons (19 L) of fuel or when a pipe which drains to the product recovery tank is within 12 ft (3.7 m) of a system component. Unless otherwise indicated below, refer to Chapter 15 for description of system components. The following system components are typically used in bulk storage facilities:

a. Bulk Air Eliminators

b. Meters – Positive Displacement, Turbine, and Orifice

c. Pressure Gauges

d. Strainers

e. Surge Suppressors

f. Filtration – Filter-Separators, Micronic Filters, and Haypack Coalescers

g. Pumps – Centrifugal, Vertical Turbine, Jockey, and Rotary

h. Manual Valves – Isolation Valves

i. Manual Valves – Isolation Valve Locations

Provide isolation valves in piping systems to control flow and to permit isolation of system components for maintenance or repair. Provide additional valves at locations necessary to conduct a valid hydrostatic test. Require manually operated valves, except where motor operators are specifically authorized by applicable standard drawings or technical specifications. Use double block and bleed type isolation valves for separation of product services, on tank shell connections (ASTs over 12,000 gallons (45 800 L) only), when piping goes aboveground or underground, between pier and tank storage, and other locations critical to periodic pressure-testing of piping. Quick opening/frequent opening type isolation valves may be used for less critical applications where double block and bleed shutoff is not required. As a minimum requirement, provide isolation valves at the following locations:

1. Where piping goes underground or comes aboveground and requires periodic pressure testing.

2. At all subsurface and aboveground piping connections to storage tanks.

3. On each branch line at the point of connection to the main product pipeline or header.

4. On the product pipeline or header just before the line leaves a pumping station.

5. On the suction side and discharge side of each pumping unit, except the suction side of vertical centrifugal pumps installed in underground tanks.

6. On the upstream and downstream side of each line blind at connections to cross country pipelines.

7. On the inlet and outlet connection of each line strainer, filter-separator, meter, diaphragm control valve, and other system components that requires periodic servicing. One inlet valve and one outlet valve may be used to isolate more than one piece of adjacent system components which are connected in series.
